This function sets the PHY preferences for the connection. The result of this API call is notified in BLE\_GAP\_EVENT\_PHY\_SET\_COMP event. When the PHY has been updated, BLE\_GAP\_EVENT\_PHY\_UPD event is notified to the application layer.

After PHY update, the PHY accept configuration of local device is the same as the values in BLE\_GAP\_EVENT\_PHY\_UPD event.

For example, after calling R\_BLE\_GAP\_SetPhy(), if tx\_phy, rx\_phy by BLE\_GAP\_EVENT\_PHY\_UPD event are updated to 2M PHY, the PHY accept configuration is 2M PHY only.

Therefore after receiving BLE\_GAP\_EVENT\_PHY\_UPD event, if local device wants to accept the other PHY configuration, it needs to call R\_BLE\_GAP\_SetPhy() with the desired PHY accept configuration.

Because the maximum transmission packet size or the maximum transmission time might be updated by PHY update, if the same packet size or transmission time as the previous one is desired, change the maximum transmission packet size or the maximum transmission time by R\_BLE\_GAP\_SetDataLen().

Set advertising data/scan response data/periodic advertising data, after allocating the memory for the data. The following shall be applied regarding the adv\_prop\_type field and the data\_type field in st\_ble\_gap\_adv\_param\_t parameter specified in [R\\_BLE\\_GAP\\_SetAdvParam\(\)](#).

The following shall be applied regarding the adv\_prop\_type field and the data\_type field in st\_ble\_gap\_adv\_param\_t parameter specified in [R\\_BLE\\_GAP\\_SetAdvParam\(\)](#).

- When `adv_prop_type` is Legacy Advertising PDU type,
  - it's possible to set advertising data/scan response data up to 31 bytes.
  - advertising data/scan response data can be updated by this function in advertising.
- When `adv_prop_type` is Extended Advertising PDU type,
  - it's possible to set at most 1650 bytes of data as advertising data/scan response data per 1 advertising set.
  - the total buffer size in Controller for advertising data/scan response data is 4250 bytes. Therefore please note that more than 4250 bytes of advertising data/scan response data can not be set to all the advertising sets. Please refer to Figure 1.1 and Figure 1.2 about examples of setting advertising data/scan response data.
  - it's possible to update advertising data/scan response data in advertising, if the `data_length` field in `st_ble_gap_adv_data_t` parameter is up to 251 bytes.

Figure 237: Figure 1.1

Figure 238: Figure 1.2

◆ **R\_BLE\_GATTC\_ReliableWrites()**

```
ble_status_t R_BLE_GATTC_ReliableWrites ( uint16_t conn_hdl,
st_ble_gattc_reliable_writes_char_pair_t* p_char_pair, uint8_t pair_num, uint8_t auto_flag )
```

This function performs the Reliable Writes procedure described in GATT Specification.

When the data written to the Characteristic has been transmitted, BLE\_GATTC\_EVENT\_CHAR\_PART\_WRITE\_RSP event is notified to the application layer. If the data included in the event is different from the data that GATT Client has sent, host stack automatically cancels the Reliable Writes.

After all of the contents has been sent to the GATT Server, if the auto\_flag parameter has been set to BLE\_GATTC\_EXEC\_AUTO, the GATT Server automatically writes the data to the Characteristic. If the auto\_flag parameter has been set to BLE\_GATTC\_EXEC\_NOT\_AUTO, BLE\_GATTC\_EVENT\_RELIABLE\_WRITES\_TX\_COMP event notifies the application layer in GATT Client that all of the contents has been sent to the GATT Server. Then GATT Client requests for writing the data to the Characteristic to the GATT Server with R\_BLE\_GATTC\_ExecWrite(). When the write has been done, BLE\_GATTC\_EVENT\_RELIABLE\_WRITES\_COMP event is notified to the application layer.

**Parameters**

[in]	conn_hdl	Connection handle identifying the GATT Server to be written.						
[in]	p_char_pair	Pair of Characteristic Value and Characteristic Value Handle identifying the Characteristic to be written by Reliable Writes.						
[in]	pair_num	The number of the pairs specified by the p_char_pair parameter. Valid range is 0 < pair_num ≤ BLE_GATTC_RELIABLE_WRITES_MAX_CHAR_PAIR.						
[in]	auto_flag	The flag that indicates whether auto execution or not. <table border="1"> <thead> <tr> <th>macro</th> <th>description</th> </tr> </thead> <tbody> <tr> <td>BLE_GATTC_EXEC_AUTO(0x01)</td> <td>Auto execution.</td> </tr> <tr> <td>BLE_GATTC_EXEC_NOT_AUTO (0x02)</td> <td>Not auto execution.</td> </tr> </tbody> </table>	macro	description	BLE_GATTC_EXEC_AUTO(0x01)	Auto execution. ◆ **R\_BLE\_GATTC\_ExecWrite()**

```
ble_status_t R_BLE_GATTC_ExecWrite ( uint16_t conn_hdl, uint8_t exe_flag )
```

If the auto execute of Reliable Writes is not specified by [R\\_BLE\\_GATTC\\_ReliableWrites\(\)](#), this function is used to execute a write to Characteristic.

When all of the contents has been sent to the GATT Server, BLE\_GATTC\_EVENT\_RELIABLE\_WRITES\_TX\_COMP event notifies the application layer. After this event has been received, execute the write by this function. The result of the write is notified by BLE\_GATTC\_EVENT\_RELIABLE\_WRITES\_COMP event.

**Parameters**

[in]	conn_hdl	Connection handle identifying the target GATT Server.

◆ **R\_BLE\_L2CAP\_RegisterCfPsm()**

```
ble_status_t R_BLE_L2CAP_RegisterCfPsm ( ble_l2cap_cf_app_cb_t cb, uint16_t psm, uint16_t lwm )
```

This function registers PSM that uses L2CAP CBFC Channel and a callback for L2CAP event.

Only one callback is available per PSM. Configure in each PSM the Low Water Mark of the LE-Frames that the local device can receive.

When the number of the credit reaches the Low Water Mark, BLE\_L2CAP\_EVENT\_CF\_LOW\_RX\_CRD\_IND event is notified to the application layer.

The number of PSM is defined as BLE\_L2CAP\_MAX\_CBFC\_PSM.

The result of this API call is returned by a return value.

**Parameters**

[in]	cb	Callback function for L2CAP event.									
[in]	psm	Identifier indicating the protocol/profile that uses L2CAP CBFC Channel. <table border="1"> <thead> <tr> <th>type</th> <th>range</th> <th>description</th> </tr> </thead> <tbody> <tr> <td>Fixed, SIG assigned</td> <td>0x0001 - 0x007F</td> <td>PSM defined by SIG. 			y allocated PSM by GATT Service.
[in]	lwm		Low Water Mark that indicates the LE-Frame numbers that the local device can receive.

**Return values**

BLE_SUCCESS(0x0000)	Success

**◆ R\_BLE\_L2CAP\_DeregisterCfPsm()**

```
ble_status_t R_BLE_L2CAP_DeregisterCfPsm ( uint16_t psm)
```

This function stops the use of the L2CAP CBFC Channel specified by the psm parameter and deregisters the callback function for L2CAP event.

The result of this API call is returned by a return value.

**Parameters**

```
ble_status_t R_BLE_L2CAP_ReqCfConn ( uint16_t conn_hdl, st_ble_l2cap_conn_req_param_t *

```

This function sends a connection request for L2CAP CBFC Channel.

The connection response is notified by BLE\_L2CAP\_EVENT\_CF\_CONN\_CNF event.

Vendor Specific API supports the flow control function(TxFlow) for the transmission on L2CAP fixed channel in Basic Mode such as GATT.

Host stack has 10 transmission packet buffers for the transmission.

When the number of the available transmission packet buffers has been less than Low Water Mark, the state of TxFlow transmits into the TxFlow OFF state from the TxFlow ON state that is the initial state and host stack notifies the application layer of timing to stop packet transmission.

When host stack has sent the transmission packets to Controller and the number of the available transmission packet buffers has been more than High Water Mark, the state of TxFlow transmits into the TxFlow ON state from the TxFlow OFF state and host stack notifies the application layer of

timing to restart packet transmission.

It is possible to perform flow control on a fixed channel by using the event notification.

### Parameters

[in]	tx_queue_lwm	Low Water Mark. Set 0-9 less than tx_queue_hwm to the parameter. When the number of the available transmission packet buffers has been less than the value specified by the tx_queue_lwm parameter, host stack notifies the application layer of the timing to stop packet transmission.
[in]	tx_queue_hwm	High Water Mark. Set 1-10 more than tx_queue_lwm to the parameter. When the number of the available transmission packet buffers has been more than the value specified by the tx_queue_hwm parameter, host stack notifies the application layer of the timing to restart packet transmission.

### Return values

**4.3.23 CGC Interface**

## Interfaces

### Detailed Description

---

Interface for clock generation.

## Summary

The CGC interface provides the ability to configure and use all of the CGC module's capabilities. Among the capabilities is the selection of several clock sources to use as the system clock source. Additionally, the system clocks can be divided down to provide a wide range of frequencies for various system and peripheral needs.

Clock stability can be checked and clocks may also be stopped to save power when not needed. The API has a function to return the frequency of the system and system peripheral clocks at run time. There is also a feature to detect when the main oscillator has stopped, with the option of calling a user provided callback function.

The CGC interface is implemented by:

#### Implemented as

- R\_JPEG\_InputBufferSet()

#### Precondition

*The buffer starting address must be 8-byte aligned.*

#### Parameters

[in]	p_ctrl	Control block set in <a href="#">jpeg_api_t::open</a> call.
[in]	p_buffer	Pointer to the input buffer space

#### Implemented as

- R\_JPEG\_OutputBufferSet()

#### Precondition

The JPEG codec module must have been opened properly.

#### Note

*The buffer starting address must be 8-byte aligned. For the decoding process, the HLD driver automatically computes the number of lines of the image to decoded so the output data fits into the given space. If the supplied output buffer is not able to hold the entire frame, the application should call the Output Full Callback function so it can be notified when additional buffer space is needed.*

**4.3.47 Key Matrix Interface****Interfaces****Detailed Description**

Interface for key matrix functions.

**Summary**

The KEYMATRIX interface provides standard Key Matrix functionality including event generation on a rising or falling edge for one or more channels at the same time. The generated event indicates all channels that are active in that instant via a bit mask. This allows the interface to be used with a matrix configuration or a one-to-one hardware implementation that is triggered on either a rising or a falling edge.

## 4.3.71 Timer Interface

### Interfaces

## Detailed Description

---

Interface for timer functions.

## Summary

The general timer interface provides standard timer functionality including periodic mode, one-shot mode, PWM output, and free-running timer mode. After each timer cycle (overflow or underflow), an interrupt can be triggered.

If an instance supports output compare mode, it is provided in the extension configuration `timer_on_<instance>_cfg_t` defined in `r_<instance>.h`.

Implemented by:

- Timer, General PWM (`r_gpt`)
- Timer, Low-Power (`r_agt`)

**Enumeration Type Documentation**

---

◆ **transfer\_mode\_t**

enum <code>transfer_mode_t</code>	
Transfer mode describes what will happen when a transfer request occurs.	
Enumerator	
<code>TRANSFER_MODE_NORMAL</code>	In normal mode, each transfer request causes a transfer of <code>transfer_size_t</code> from the source pointer to the destination pointer. The transfer length is decremented and the source and address pointers are updated according to <code>transfer_addr_mode_t</code> . After the transfer length reaches 0, transfer requests will not cause any further transfers.
<code>TRANSFER_MODE_REPEAT</code>	Repeat mode is like normal mode, except that when the transfer length reaches 0, the pointer to the repeat area and the transfer length will be reset to their initial values. If DMAC is used, the transfer repeats only <code>transfer_info_t::num_blocks</code> times. After the transfer repeats <code>transfer_info_t::num_blocks</code> times, transfer requests will not cause any further transfers. If DTC is used, the transfer repeats continuously (no limit to the number of repeat transfers).
<code>TRANSFER_MODE_BLOCK</code>	In block mode, each transfer request causes <code>transfer_info_t::length</code> transfers of <code>transfer_size_t</code> . After each individual transfer, the source and destination pointers are updated according to <code>transfer_addr_mode_t</code> . After the block transfer is complete, <code>transfer_info_t::num_blocks</code> is decremented. After the <code>transfer_info_t::num_blocks</code> reaches 0, transfer requests will not cause any further transfers.
<code>TRANSFER_MODE_REPEAT_BLOCK</code>	In addition to block mode features, repeat-block mode supports a ring buffer of blocks and offsets within a block (to split blocks into arrays of their first data, second data, etc.)

◆ **transfer\_size\_t**

enum <a href="#">transfer_size_t</a>	
Transfer size specifies the size of each individual transfer. Total transfer length = <code>transfer_size_t * transfer_length_t</code>	
Enumerator	
TRANSFER_SIZE_1_BYTE	Each transfer transfers a 8-bit value.
TRANSFER_SIZE_2_BYTE	Each transfer transfers a 16-bit value.
TRANSFER_SIZE_4_BYTE	Each transfer transfers a 32-bit value.

◆ **transfer\_addr\_mode\_t**

enum <a href="#">transfer_addr_mode_t</a>	
Address mode specifies whether to modify (increment or decrement) pointer after each transfer.	
Enumerator	
TRANSFER_ADDR_MODE_FIXED	Address pointer remains fixed after each transfer.
TRANSFER_ADDR_MODE_OFFSET	Offset is added to the address pointer after each transfer.
TRANSFER_ADDR_MODE_INCREMENTED	Address pointer is incremented by associated <a href="#">transfer_size_t</a> after each transfer.
TRANSFER_ADDR_MODE_DECREMENTED	Address pointer is decremented by associated <a href="#">transfer_size_t</a> after each transfer.

◆ **transfer\_repeat\_area\_t**

enum <a href="#">transfer_repeat_area_t</a>	
Repeat area options (source or destination). In <a href="#">TRANSFER_MODE_REPEAT</a> , the selected pointer returns to its original value after <a href="#">transfer_info_t::length</a> transfers. In <a href="#">TRANSFER_MODE_BLOCK</a> and <a href="#">TRANSFER_MODE_REPEAT_BLOCK</a> , the selected pointer returns to its original value after each transfer.	
Enumerator	
<a href="#">TRANSFER_REPEAT_AREA_DESTINATION</a>	Destination area repeated in <a href="#">TRANSFER_MODE_REPEAT</a> or <a href="#">TRANSFER_MODE_BLOCK</a> or <a href="#">TRANSFER_MODE_REPEAT_BLOCK</a> .
<a href="#">TRANSFER_REPEAT_AREA_SOURCE</a>	Source area repeated in <a href="#">TRANSFER_MODE_REPEAT</a> or <a href="#">TRANSFER_MODE_BLOCK</a> or <a href="#">TRANSFER_MODE_REPEAT_BLOCK</a> .

◆ **transfer\_chain\_mode\_t**

enum <a href="#">transfer_chain_mode_t</a>	
Chain transfer mode options.	
<i>Note</i> <i>Only applies for DTC.</i>	
Enumerator	
<a href="#">TRANSFER_CHAIN_MODE_DISABLED</a>	Chain mode not used.
<a href="#">TRANSFER_CHAIN_MODE_EACH</a>	Switch to next transfer after a single transfer from this <a href="#">transfer_info_t</a> .
<a href="#">TRANSFER_CHAIN_MODE_END</a>	Complete the entire transfer defined in this <a href="#">transfer_info_t</a> before chaining to next transfer.

◆ **transfer\_irq\_t**

enum <code>transfer_irq_t</code>	
Interrupt options.	
Enumerator	
TRANSFER_IRQ_END	<p>Interrupt occurs only after last transfer. If this transfer is chained to a subsequent transfer, the interrupt will occur only after subsequent chained transfer(s) are complete.</p> <p><b>Warning</b> DTC triggers the interrupt of the activation source. Choosing TRANSFER_IRQ_END with DTC will prevent activation source interrupts until the transfer is complete.</p>
TRANSFER_IRQ_EACH	<p>Interrupt occurs after each transfer.</p> <p><i>Note</i> <i>Not available in all HAL drivers. See HAL driver for details.</i></p>

◆ **transfer\_start\_mode\_t**

enum <code>transfer_start_mode_t</code>	
Select whether to start single or repeated transfer with software start.	
Enumerator	
TRANSFER_START_MODE_SINGLE	Software start triggers single transfer.
TRANSFER_START_MODE_REPEAT	Software start transfer continues until transfer is complete.

## Field Documentation

### ◆ open

`fsp_err_t(* uart_api_t::open) (uart_ctrl_t *const p_ctrl, uart_cfg_t const *const p_cfg)`

Open UART device.

#### Implemented as

- `R_SCI_UART_Open()`

## ◆ write

```
fsp_err_t(* uart_api_t::write) (uart_ctrl_t *const p_ctrl, uint8_t const *const p_src, uint32_t const bytes)
```

Write to UART device. The write buffer is used until write is complete. Do not overwrite write buffer contents until the write is finished. When the write is complete (all bytes are fully transmitted on the wire), the callback called with event `UART_EVENT_TX_COMPLETE`. The maximum transfer size is reported by `infoGet()`.
