When setting the RECREQ bit to 1, do not set the TRMREQ bit to 1. To change the configuration of a mailbox from transmission to reception, first abort the transmission and then set flags SENTDATA and TRMABT to 0 before changing to reception.

**TRMREQ Bit (Transmit Mailbox Request)**

The TRMREQ bit selects transmit modes listed in Table 34.10.

When the TRMREQ bit is set to 1, the corresponding mailbox is configured for transmission of a data frame or a remote frame.

When the TRMREQ bit is set to 0, the corresponding mailbox is not configured for transmission of a data frame or a remote frame.

If the TRMREQ bit is changed from 1 to 0 to cancel the corresponding transmission request, either the TRMABT or SENTDATA flag is set to 1. When setting the TRMREQ bit to 1, do not set the RECREQ bit to 1. To change the configuration of a mailbox from reception to transmission, first abort the reception and then set flags NEWDATA and MSGLOST to 0 before changing to transmission.

### 34.2.9 Receive FIFO Control Register (RFCR)

Address(es): CAN0.RFCR 0009 0848h

Write to RFCR in CAN operation mode or CAN halt mode.

#### RFE Bit (Receive FIFO Enable)

When the RFE bit is set to 1, the receive FIFO is enabled.

When the RFE bit is set to 0, the receive FIFO is disabled for reception and becomes empty (RFEST flag = 1). Write 0 to the RFE bit simultaneously with setting the RFMLF flag.

Do not set this bit to 1 in normal mailbox mode (MBM bit in CTLR = 0). Due to hardware protection, the RFE bit is not set to 0 by writing 0 by a program during the following period.

- Hardware protection is started
  - From the acceptance filter processing (the beginning of CRC field)
- Hardware protection is released
  - If the receive FIFO is specified to receive the incoming message, after the received data is stored into the receive FIFO or a CAN bus error occurs (i.e. maximum period of hardware protection is from the beginning of CRC field to the end of 7th bit of EOF)
  - If the receive FIFO is not specified to receive the message, after the acceptance filter processing

#### RFUST[2:0] Flags (Receive FIFO Unread Message Number Status Flag)

The RFUST[2:0] flags indicate the number of unread messages in the receive FIFO.

The value of the RFUST[2:0] flags is initialized to 000b when the RFE bit is set to 0.

**RFMLF Flag (Receive FIFO Message Lost Flag)**

The RFMLF flag is set to 1 (receive FIFO message lost has occurred) when the receive FIFO receives a new message and the receive FIFO is full. The timing for setting this bit to 1 is at the end of the 6th bit of EOF.

The RFMLF flag is set to 0 by writing 0 by a program (writing 1 has no effect). In both overwrite and overrun modes, the RFMLF flag cannot be set to 0 (receive FIFO message lost has not occurred) by writing 0 by a program due to hardware protection during five peripheral module clock (PCLKB) cycles following the sixth bit of EOF, if the receive FIFO is full and determined to receive a message.

**RFFST Flag (Receive FIFO Full Status Flag)**

The RFFST flag is set to 1 (receive FIFO is full) when the number of unread messages in the receive FIFO is 4. The RFFST flag is 0 (receive FIFO is not full) when the number of unread messages in the receive FIFO is less than 4. The RFFST flag is set to 0 when the RFE bit is 0.

**RFWST Flag (Receive FIFO Buffer Warning Status Flag)**

The RFWST flag is set to 1 (receive FIFO is buffer warning) when the number of unread messages in the receive FIFO is 3. The RFWST flag is 0 (receive FIFO is not buffer warning) when the number of unread messages in the receive FIFO is less than 3 or equal to 4. The RFWST flag is set to 0 when the RFE bit is 0.

**RFEST Flag (Receive FIFO Empty Status Flag)**

The RFEST flag is set to 1 (no unread message in receive FIFO) when the number of unread messages in the receive FIFO is 0. The RFEST flag is set to 1 when the RFE bit is set to 0. The RFEST flag is set to 0 (unread message in receive FIFO) when the number of unread messages in the receive FIFO is one or more.

Figure 34.2 shows the receive FIFO mailbox operation.

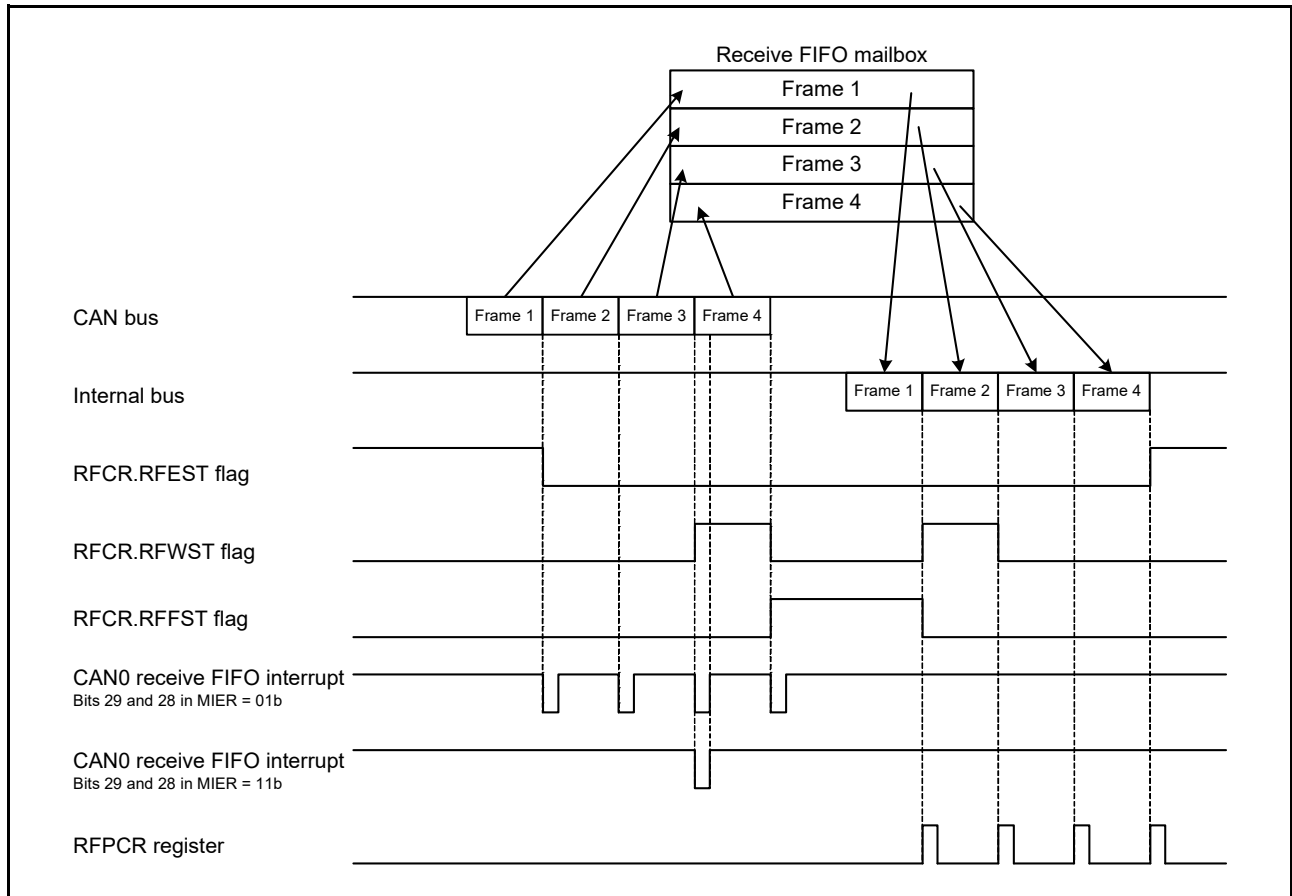

Figure 34.2 Receive FIFO Mailbox Operation (Bits 29 and 28 in MIER = 01b or 11b)

### 34.2.10 Receive FIFO Pointer Control Register (RFPCR)

Address(es): CAN0.RFPCR 0009 0849h

| Bit      | Description                                                                       | R/W |
|----------|-----------------------------------------------------------------------------------|-----|
| b7 to b0 | The CPU-side pointer for the receive FIFO is incremented by writing FFh to RFPCR. | W   |

When the receive FIFO is not empty, write FFh to RFPCR by a program to increment the CPU-side pointer for the receive FIFO to the next mailbox location.

Do not write to RFPCR when the RFE bit in RFCR is 0 (receive FIFO disabled).

Both the CAN-side pointer and the CPU-side pointer are incremented when a new message is received and the RFFST flag is 1 (receive FIFO is full) in overwrite mode. When the RFMLF flag is 1 in this condition, the CPU-side pointer cannot be incremented by writing to RFPCR by a program.

### 34.2.11 Transmit FIFO Control Register (TFCR)

Address(es): CAN0.TFCR 0009 084Ah

Write to TFCR in CAN operation mode or CAN halt mode.

**TFE Bit (Transmit FIFO Enable)**

When the TFE bit is set to 1, the transmit FIFO is enabled.

When the TFE bit is set to 0, the transmit FIFO becomes empty (TFEST flag = 1) and then unsend messages from the transmit FIFO are lost as described below:

- Immediately if a message from the transmit FIFO is not scheduled for the next transmission or during transmission
- Following the completion of transmission, a CAN bus error, CAN bus arbitration-lost, or entry to CAN halt mode if a message from the transmit FIFO is scheduled for the next transmission or already during transmission

Before setting the TFE bit to 1 again, ensure that the TFEST flag has been set to 1. After setting the TFE bit to 1, write transmit data into MB24.

Do not set the TFE bit to 1 in normal mailbox mode (MBM bit in CTRLR = 0).

**TFUST[2:0] Flags (Transmit FIFO Unsent Message Number Status Flag)**

The TFUST[2:0] flags indicate the number of unsend messages in the transmit FIFO.

The TFUST[2:0] flags are set to 000b after TFE bit is cleared to 0 and transmission is aborted or completed.

**TFFST Flag (Transmit FIFO Full Status Flag)**

The TFFST flag is set to 1 (transmit FIFO is full) when the number of unsend messages in the transmit FIFO is 4. The

TFFST flag is set to 0 (transmit FIFO is not full) when the number of unsend messages in the transmit FIFO is less than 4.

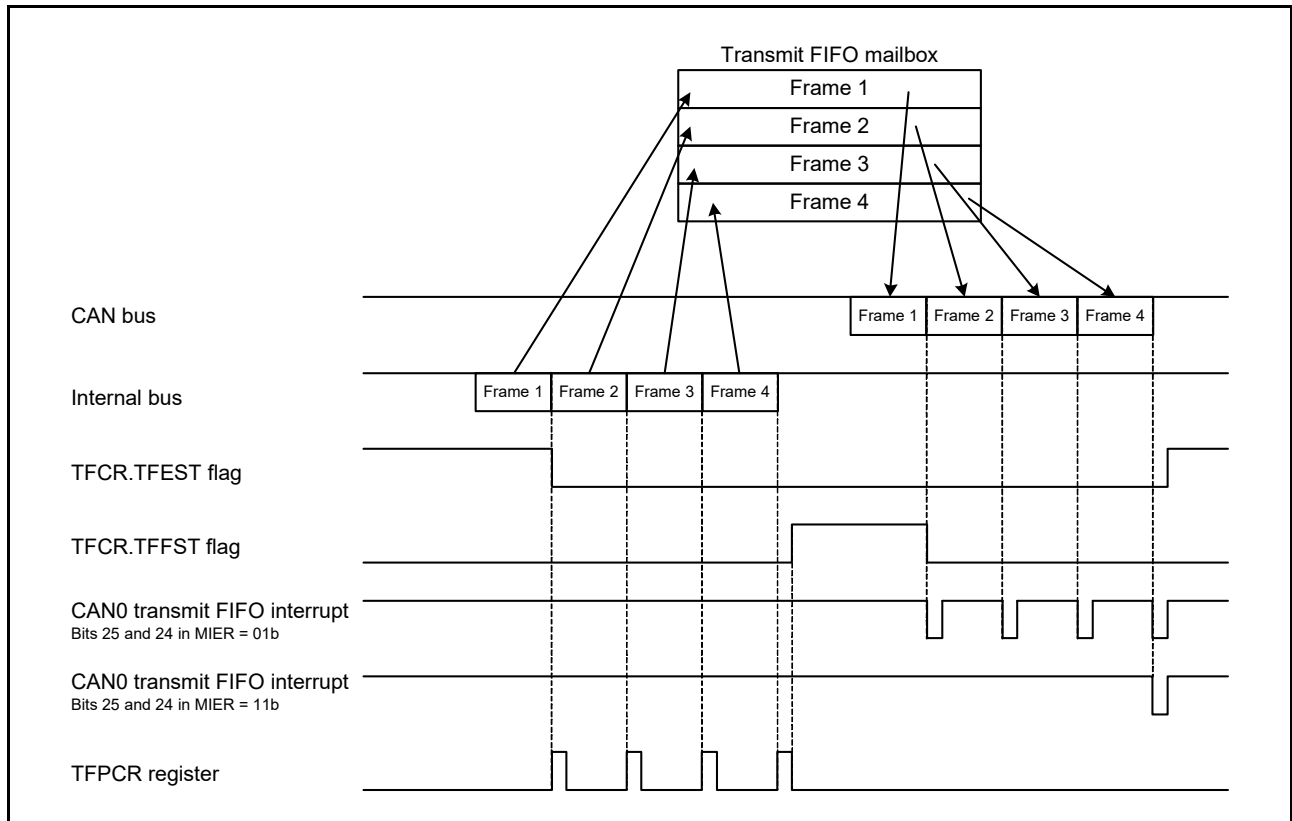

The TFFST flag is set to 0 when transmission from the transmit FIFO has been aborted.

**TFEST Flag (Transmit FIFO Empty Status Flag)**

The TFEST flag is set to 1 (no message in transmit FIFO) when the number of unsend messages in the transmit FIFO is 0.

The TFEST flag is set to 1 when transmission from the transmit FIFO has been aborted. The TFEST flag is set to 0 (message in transmit FIFO) when the number of unsend messages in the transmit FIFO is not 0.

Figure 34.3 shows the transmit FIFO mailbox operation.

**Figure 34.3** Transmit FIFO Mailbox Operation (Bits 25 and 24 in MIER = 01b or 11b)

### 34.2.12 Transmit FIFO Pointer Control Register (TFPCR)

Address(es): CAN0.TFPCR 0009 084Bh

Value after reset: x x x x x x x x

x: Undefined

| Bit      | Description                                                                        | R/W |
|----------|------------------------------------------------------------------------------------|-----|
| b7 to b0 | The CPU-side pointer for the transmit FIFO is incremented by writing FFh to TFPCR. | W   |

When the transmit FIFO is not full, write FFh to TFPCR by a program to increment the CPU-side pointer for the transmit FIFO to the next mailbox location.

Do not write to TFPCR when the TFE bit in TFCR is 0 (transmit FIFO disabled).

### 34.2.13 Status Register (STR)

Address(es): CAN0.STR 0009 0842h

| b13 | TRMST  | Transmit Status Flag (transmitter)      | 0: Bus idle or reception in progress<br>1: Transmission in progress or in bus-off state | R   |
| b14 | RECST  | Receive Status Flag (receiver)          | 0: Bus idle or transmission in progress<br>1: Reception in progress                     | R   |
| b15 | —      | Reserved                                | The read value is 0.                                                                    | R   |

#### NDST Flag (NEWDATA Status Flag)

The NDST flag is set to 1 when at least one NEWDATA flag in MCTLj (j = 0 to 31) is 1 regardless of the value of MIER. The NDST flag is set to 0 when all NEWDATA flags are 0.

#### SDST Flag (SENTDATA Status Flag)

The SDST flag is set to 1 when at least one SENTDATA flag in MCTLj (j = 0 to 31) is 1 regardless of the value of MIER. The SDST flag is set to 0 when all SENTDATA flags are 0.

**RFST Flag (Receive FIFO Status Flag)**

The RFST flag is set to 1 when the receive FIFO is not empty. The RFST flag is set to 0 when the receive FIFO is empty or normal mailbox mode is selected.

**TFST Flag (Transmit FIFO Status Flag)**

The TFST flag is set to 1 when the transmit FIFO is not full. The TFST flag is set to 0 when the transmit FIFO is full or normal mailbox mode is selected.

**NMLST Flag (Normal Mailbox Message Lost Status Flag)**

The NMLST flag is set to 1 when at least one MSGLOST flag in MCTLj ( $j = 0$  to 31) is 1 regardless of the value of MIER. The NMLST flag is set to 0 when all MSGLOST flags are 0.

**FMLST Flag (FIFO Mailbox Message Lost Status Flag)**

The FMLST flag is set to 1 when the RFMLF flag in RFCR is 1 regardless of the value of MIER. The FMLST flag is set to 0 when the RFMLF flag is 0.

**TABST Flag (Transmission Abort Status Flag)**

The TABST flag is set to 1 when at least one TRMABT flag in MCTLj ( $j = 0$  to 31) is 1 regardless of the value of MIER. The TABST flag is set to 0 when all TRMABT flags are 0.

**EST Flag (Error Status Flag)**

The EST flag is set to 1 when at least one error is detected by EIFR regardless of the value of EIER. The EST flag is set to 0 when no error is detected by EIFR.

**RSTST Flag (CAN Reset Status Flag)**

The RSTST flag is set to 1 when the CAN module is in CAN reset mode. The RSTST flag is 0 when the CAN module is not in CAN reset mode. Even when the state is changed from CAN reset mode to CAN sleep mode, the RSTST flag remains 1.

**HLTST Flag (CAN Halt Status Flag)**

The HLTST flag is set to 1 when the CAN module is in CAN halt mode. The HLTST flag is set to 0 when the CAN module is not in CAN halt mode. Even when the state is changed from CAN halt mode to CAN sleep mode, the HLTST flag remains 1.

**SLPST Flag (CAN Sleep Status Flag)**

The SLPST flag is set to 1 when the CAN module is in CAN sleep mode. The SLPST flag is set to 0 when the CAN module is not in CAN sleep mode.

**EPST Flag (Error-Passive Status Flag)**

The EPST flag is set to 1 when the value of TECR or RECR exceeds 127 and the CAN module is in the error-passive state ( $128 \leq \text{TEC} < 256$  or  $128 \leq \text{REC} < 256$ ). The EPST flag is set to 0 when the CAN module is not in the error-passive state.

**BOST Flag (Bus-Off Status Flag)**

The BOST flag is set to 1 when the value of TECR exceeds 255 and the CAN module is in the bus-off state ( $\text{TEC} \geq 256$ ). The BOST flag is set to 0 when the CAN module is not in the bus-off state.

**TRMST Flag (Transmit Status Flag (transmitter))**

The TRMST flag is set to 1 when the CAN module performs as a transmitter node or is in the bus-off state. The TRMST flag is set to 0 when the CAN module performs as a receiver node or is in the bus-idle state.

**RECST Flag (Receive Status Flag (receiver))**

The RECST flag is set to 1 when the CAN module performs as a receiver node. The RECST flag is set to 0 when the CAN module performs as a transmitter node or is in the bus-idle state.

**34.2.14 Mailbox Search Mode Register (MSMR)**

Address(es): CAN0.MSMR 0009 0853h

| Bit      | Symbol    | Bit Name                   | Description                                                                                                                                 | R/W |
|----------|-----------|----------------------------|---------------------------------------------------------------------------------------------------------------------------------------------|-----|
| b1, b0   | MBSM[1:0] | Mailbox Search Mode Select | b1 b0<br>0 0: Receive mailbox search mode<br>0 1: Transmit mailbox search mode<br>1 0: Message lost search mode<br>1 1: Channel search mode | R/W |
| b7 to b2 | —         | Reserved                   | These bits are read as 0. The write value should be 0.                                                                                      | R/W |

Write to MSMR in CAN operation mode or CAN halt mode.

**MBSM[1:0] Bits (Mailbox Search Mode Select)**

The MBSM[1:0] bits select the search mode for the mailbox search function.

When the MBSM[1:0] bits are 00b, receive mailbox search mode is selected. In this mode, the search targets are the NEWDATA flag in MCTLj (j = 0 to 31) for the normal mailbox and the RFEST flag in RFCR.

When the MBSM[1:0] bits are 01b, transmit mailbox search mode is selected. In this mode, the search target is the SENTDATA flag in MCTLj.

When the MBSM[1:0] bits are 10b, message lost search mode is selected. In this mode, the search targets are the MSGLOST flag in MCTLj for the normal mailbox and the RFMLF flag in RFCR.

When the MBSM[1:0] bits are 11b, channel search mode is selected. In this mode, the search target is CSSR. Refer to section 34.2.16, Channel Search Support Register (CSSR).

### 34.2.15 Mailbox Search Status Register (MSSR)

Address(es): CAN0.MSSR 0009 0852h

| Bit      | Symbol     | Bit Name                                 | Description                                                                          | R/W |
|----------|------------|------------------------------------------|--------------------------------------------------------------------------------------|-----|
| b4 to b0 | MBNST[4:0] | Search Result Mailbox Number Status Flag | These bits output the smallest mailbox number that is searched in each mode of MSMR. | R   |
| b6, b5   | —          | Reserved                                 | These bits are read as 0. The write value should be 0.                               | R/W |
| b7       | SEST       | Search Result Status Flag                | 0: Search result found<br>1: No search result                                        | R   |

#### MBNST[4:0] Flags (Search Result Mailbox Number Status Flag)

The MBNST[4:0] flags output the smallest mailbox number that is searched in each mode of MSMR. In receive mailbox search mode, transmit mailbox search mode, and message lost search mode, the value of the mailbox i.e., the search result to be output, is updated as described below:

- When the NEWDATA, SENTDATA or MSGLOST flag for the output mailbox is set to 0
- When the NEWDATA, SENTDATA or MSGLOST flag for a higher-priority mailbox is set to 1

If the MBSM[1:0] bits are set to 00b (receive mailbox search mode) or 10b (message lost search mode), the receive FIFO (mailbox [28]) is output when the receive FIFO is not empty and there are no unread received messages or no lost messages in any of the normal mailboxes (mailboxes [0] to [23]). If the MBSM[1:0] bits are set to 01b (transmit mailbox search mode), the transmit FIFO (mailbox [24]) is not output. Table 34.6 lists the behavior of the MBNST[4:0] flags in FIFO mailbox mode.

In channel search mode, the MBNST[4:0] flags output the corresponding channel number. After MSSR is read by a program, the next target channel number is output.

#### SEST Flag (Search Result Status Flag)

The SEST flag is set to 1 (no search result) when no corresponding mailbox is found after searching all mailboxes. For example, in transmit mailbox search mode, the SEST flag is set to 1 when no SENTDATA flag for mailboxes is 1. The SEST flag is set to 0 when at least one SENTDATA flag is 1. When the SEST flag is 1, the value of the MBNST[4:0] flags is undefined.

**Table 34.6 Behavior of MBNST[4:0] Flags in FIFO Mailbox Mode**

| MBSM[1:0] Bits | Mailbox [24] (Transmit FIFO) | Mailbox [28] (Receive FIFO)                                                                                                                                                                                                 |
|----------------|------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 00b            | Mailbox [24] is not output.  | Mailbox [28] is output when no MCTLj.NEWDATA flag for the normal mailboxes is set to 1 (new message is being stored or has been stored to the mailbox) and the receive FIFO is not empty.                                   |
| 01b            |                              | Mailbox [28] is not output.                                                                                                                                                                                                 |
| 10b            |                              | Mailbox [28] is output when no MCTLj.MSGLOST flag for the normal mailboxes is set to 1 (message is overwritten or overrun) and the RFCR.RFMLF bit is set to 1 (receive FIFO message lost has occurred) in the receive FIFO. |
| 11b            |                              | Mailbox [28] is not output.                                                                                                                                                                                                 |

### 34.2.16 Channel Search Support Register (CSSR)

Address(es): CAN0.CSSR 0009 0851h

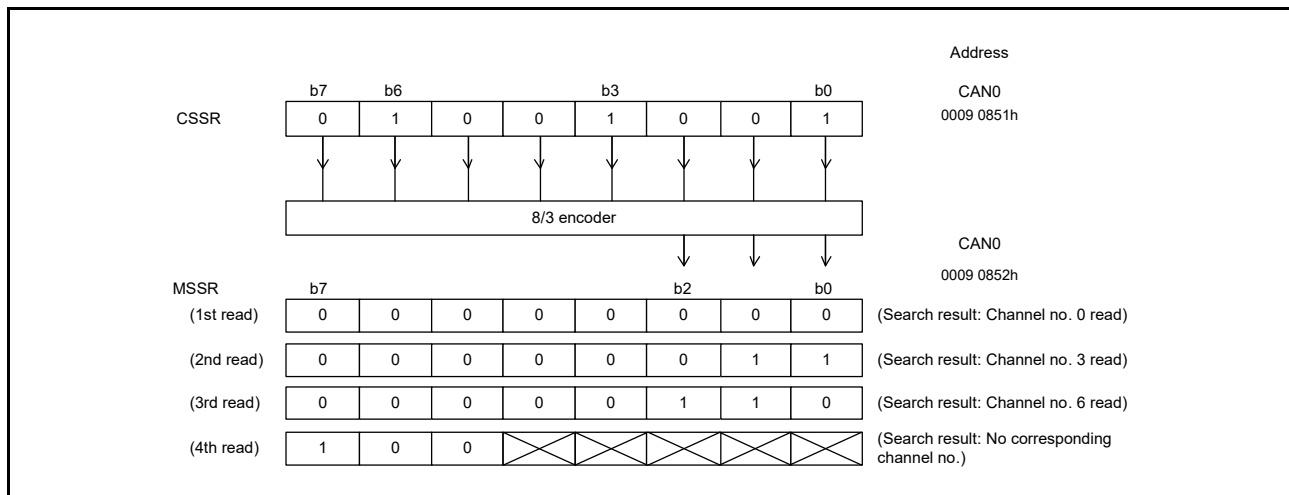

| Bit      | Description                                                                           | R/W |
|----------|---------------------------------------------------------------------------------------|-----|
| b7 to b0 | When the value for the channel search is input, the channel number is output to MSSR. | R/W |

The bits in CSSR, which are set to 1, are encoded by an 8/3 encoder (the LSB position has the higher priority) and output to the MBNST[4:0] flags in MSSR.

MSSR outputs the updated value whenever MSSR is read by a program.

Write to CSSR only when the MSMR.MBSM[1:0] bits are 11b (channel search mode). Write to CSSR in CAN operation mode or CAN halt mode.

Figure 34.4 shows the write and read of CSSR and MSSR.

**Figure 34.4 Write and Read of CSSR and MSSR**

The value of CSSR is also updated whenever MSSR is read. When read, the value prior to conversion by the 8/3 encoder can be read.

### 34.2.17 Acceptance Filter Support Register (AFSR)

Address(es): CAN0.AFSR 0009 0856h

| Bit       | Description                                                                                                    | R/W |
|-----------|----------------------------------------------------------------------------------------------------------------|-----|
| b15 to b0 | After the standard ID of a received message is written, the value converted for data table search can be read. | R/W |

Note: Write to AFSR in CAN operation mode or CAN halt mode.

The acceptance filter support unit (ASU) can be used for data table (8 bits × 256) search. In the data table, all standard IDs created by the user are set to be valid/invalid in bit units. When AFSR is written with data in 16-bit units including the SID[10:0] bit in MBj (j = 0 to 31), in which a received standard ID is stored, a decoded row (byte offset) position and column (bit) position for data table search can be read. The ASU can be used for standard (11-bit) IDs only.

The ASU is enabled in the following cases:

- When the ID to receive cannot be masked by the acceptance filter  
(Example) IDs to receive: 078h, 087h, and 111h
- When there are too many IDs to receive and software filtering time is expected to be shortened  
It should be noted that AFSR cannot be set in CAN reset mode.

Figure 34.5 shows the write and read of AFSR.

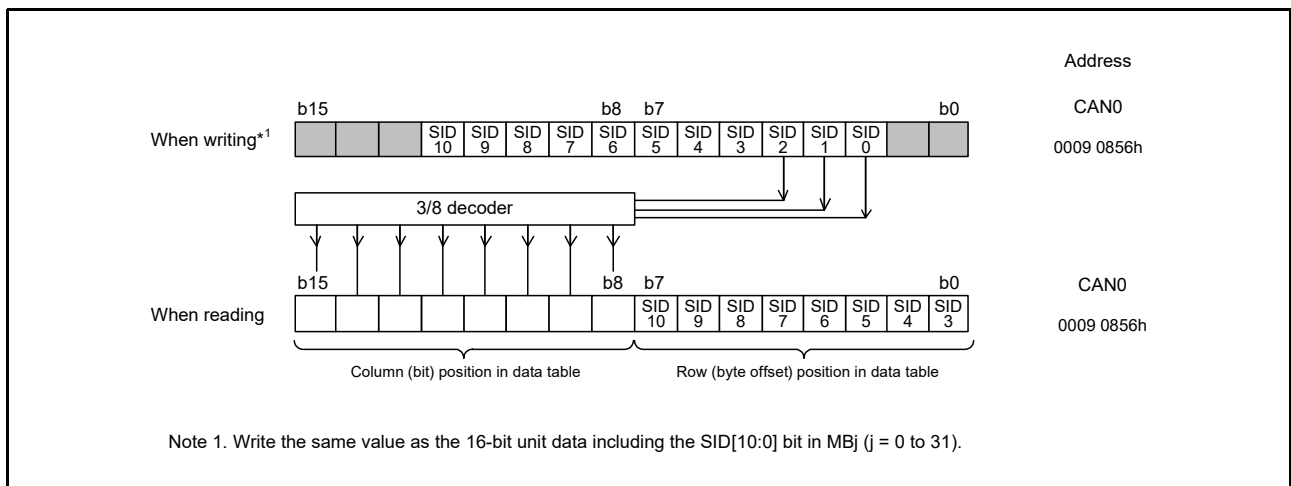

Figure 34.5 Write and Read of AFSR

### 34.2.18 Error Interrupt Enable Register (EIER)

Address(es): CAN0.EIER 0009 084Ch

|                    | b7   | b6   | b5   | b4    | b3    | b2   | b1   | b0   |
|--------------------|------|------|------|-------|-------|------|------|------|
|                    | BLIE | OLIE | ORIE | BORIE | BOEIE | EPIE | EWIE | BEIE |
| Value after reset: | 0    | 0    | 0    | 0     | 0     | 0    | 0    | 0    |

| Bit | Symbol | Bit Name                                 | Description                                                                                   | R/W |
|-----|--------|------------------------------------------|-----------------------------------------------------------------------------------------------|-----|
| b0  | BEIE   | Bus Error Interrupt Enable               | 0: Bus error interrupt disabled<br>1: Bus error interrupt enabled                             | R/W |
| b1  | EWIE   | Error-Warning Interrupt Enable           | 0: Error-warning interrupt disabled<br>1: Error-warning interrupt enabled                     | R/W |
| b2  | EPIE   | Error-Passive Interrupt Enable           | 0: Error-passive interrupt disabled<br>1: Error-passive interrupt enabled                     | R/W |
| b3  | BOEIE  | Bus-Off Entry Interrupt Enable           | 0: Bus-off entry interrupt disabled<br>1: Bus-off entry interrupt enabled                     | R/W |
| b4  | BORIE  | Bus-Off Recovery Interrupt Enable        | 0: Bus-off recovery interrupt disabled<br>1: Bus-off recovery interrupt enabled               | R/W |
| b5  | ORIE   | Overrun Interrupt Enable                 | 0: Receive overrun interrupt disabled<br>1: Receive overrun interrupt enabled                 | R/W |
| b6  | OLIE   | Overload Frame Transmit Interrupt Enable | 0: Overload frame transmit interrupt disabled<br>1: Overload frame transmit interrupt enabled | R/W |
| b7  | BLIE   | Bus Lock Interrupt Enable                | 0: Bus lock interrupt disabled<br>1: Bus lock interrupt enabled                               | R/W |

EIER is used to enable or disable the error interrupt individually for each error interrupt source in EIFR. Write to EIER in CAN reset mode.

#### BEIE Bit (Bus Error Interrupt Enable)

When the BEIE bit is 0, no error interrupt request is generated even if the BEIF flag in EIFR is set to 1. When the BEIE bit is 1, an error interrupt request is generated if the BEIF flag is set to 1.

#### EWIE Bit (Error-Warning Interrupt Enable)

When the EWIE bit is 0, no error interrupt request is generated even if the EWIF flag in EIFR is set to 1. When the EWIE bit is 1, an error interrupt request is generated if the EWIF flag is set to 1.

#### EPIE Bit (Error-Passive Interrupt Enable)

When the EPIE bit is 0, no error interrupt request is generated even if the EPIF flag in EIFR is set to 1. When the EPIE bit is 1, an error interrupt request is generated if the EPIF flag is set to 1.

#### BOEIE Bit (Bus-Off Entry Interrupt Enable)

When the BOEIE bit is 0, no error interrupt request is generated even if the BOEIF flag in EIFR is set to 1. When the BOEIE bit is 1, an error interrupt request is generated if the BOEIF flag is set to 1.

#### BORIE Bit (Bus-Off Recovery Interrupt Enable)

When the BORIE bit is 0, an error interrupt request is not generated even if the BORIF flag in EIFR is set to 1. When the BORIE bit is set to 1, an error interrupt request is generated if the BORIF flag is set to 1.

**ORIE Bit (Overrun Interrupt Enable)**

When the ORIE bit is 0, an error interrupt request is not generated even if the ORIF flag in EIFR is set to 1. When the ORIE bit is 1, an error interrupt request is generated if the ORIF flag is set to 1.

**OLIE Bit (Overload Frame Transmit Interrupt Enable)**

When the OLIE bit is 0, no error interrupt request is generated even if the OLIF flag in EIFR is set to 1. When the OLIE bit is 1, an error interrupt request is generated if the OLIF flag is set to 1.

**BLIE Bit (Bus Lock Interrupt Enable)**

When the BLIE bit is 0, no error interrupt request is generated even if the BLIF flag in EIFR is set to 1. When the BLIE bit is 1, an error interrupt request is generated if the BLIF flag is set to 1.

**34.2.19 Error Interrupt Factor Judge Register (EIFR)**

Address(es): CAN0.EIFR 0009 084Dh

| b7   | b6   | b5   | b4    | b3    | b2   | b1   | b0   |

| b5  | ORIF   | Receive Overrun Detect Flag             | 0: No receive overrun detected<br>1: Receive overrun detected                         | R/W |
| b6  | OLIF   | Overload Frame Transmission Detect Flag | 0: No overload frame transmission detected<br>1: Overload frame transmission detected | R/W |
| b7  | BLIF   | Bus Lock Detect Flag                    | 0: No bus lock detected<br>1: Bus lock detected                                       | R/W |

If an event corresponding to each bit occurs, the corresponding bit in EIFR is set to 1 regardless of the setting of EIER. To set each bit to 0, write 0 by a program. If the set timing occurs simultaneously with the clear timing by the program, the bit becomes 1.

When a single bit is set to 0 by a program, do not use the logic operation instruction (AND) – use the transfer instruction (MOV) to ensure that only the specified bit is set to 0 and the other bits are set to 1. Writing 1 has no effect to these bit values.

**BEIF Flag (Bus Error Detect Flag)**

The BEIF flag is set to 1 when a bus error is detected.

**EWIF Flag (Error-Warning Detect Flag)**

The EWIF flag is set to 1 when the value of the receive error counter (REC) or transmit error counter (TEC) exceeds 95. The EWIF flag is set to 1 only when the REC or TEC initially exceeds 95. Thus, if 0 is written to the EWIF flag by a program while the REC or TEC remains greater than 95, the EWIF flag is not set to 1 until the REC and TEC go below 95 and then REC or TEC exceeds 95 again.

**EPIF Flag (Error-Passive Detect Flag)**

The EPIF flag is set to 1 when the CAN error state becomes error-passive (the REC (receive error counter) or TEC (transmit error counter) value exceeds 127).

The EPIF flag is set to 1 only when the REC or TEC initially exceeds 127. Thus, if 0 is written by a program while the REC or TEC remains greater than 127, the EPIF flag is not set to 1 until the REC and TEC go below 127 and then REC or TEC exceeds 127 again.

**BOEIF Flag (Bus-Off Entry Detect Flag)**

The BOEIF flag is set to 1 when the CAN error state becomes bus-off (the TEC (transmit error counter) value exceeds 255). The BOEIF flag is also set to 1 when the BOM[1:0] bits in CTRLR are 01b (entry to CAN halt mode automatically at bus-off entry) and the CAN module becomes the bus-off state.

**BORIF Flag (Bus-Off Recovery Detect Flag)**

The BORIF flag is set to 1 when the CAN module recovers from the bus-off state normally by detecting 11 consecutive bits 128 times in the following conditions:

- When the BOM[1:0] bits in CTRLR are 00b
- When the BOM[1:0] bits in CTRLR are 10b
- When the BOM[1:0] bits in CTRLR are 11b

However, the BORIF flag is not set to 1 if the CAN module recovers from the bus-off state in the following conditions:

- When the CANM[1:0] bits in CTRLR are set to 01b or 11b (CAN reset mode)
- When the RBOC bit in CTRLR is set to 1 (forcible return from bus-off)
- When the BOM[1:0] bits in CTRLR are set to 01b
- When the BOM[1:0] bits in CTRLR are set to 11b and the CANM[1:0] bits in CTRLR are set to 10b (CAN halt mode) before normal recovery occurs

Table 34.7 lists the behavior of BOEIF and BORIF flags according to the CTRLR.BOM[1:0] bit setting.

**Table 34.7 Behavior of BOEIF and BORIF Flags according to CTRLR.BOM[1:0] Bit Setting**

| BOM[1:0] Bits | BOEIF Flag                              | BORIF Flag                                                                                           |
|---------------|-----------------------------------------|------------------------------------------------------------------------------------------------------|
| 00b           | Set to 1 on entry to the bus-off state. | Set to 1 on exit from the bus-off state.                                                             |
| 01b           |                                         | Do not set to 1.                                                                                     |
| 10b           |                                         | Set to 1 on exit from the bus-off state.                                                             |
| 11b           |                                         | Set to 1 if normal bus-off recovery occurs before the CANM[1:0] bits are set to 10b (CAN halt mode). |

**ORIF Flag (Receive Overrun Detect Flag)**

The ORIF flag is set to 1 when a receive overrun occurs. This flag is not to set to 1 in overwrite mode.

In overwrite mode, a reception complete interrupt request is generated if an overwrite condition occurs and the ORIF flag is not set to 1.

In normal mailbox mode, if an overrun occurs in any of mailboxes [0] to [31] in overrun mode, this flag is set to 1. In

FIFO mailbox mode, if an overrun occurs in any of mailboxes [0] to [23] or the receive FIFO in overrun mode, this flag is set to 1.

#### OLIF Flag (Overload Frame Transmission Detect Flag)

The OLIF flag is set to 1 if the transmitting condition of an overload frame is detected when the CAN module performs transmission or reception.

#### BLIF Flag (Bus Lock Detect Flag)

The BLIF flag is set to 1 if 32 consecutive dominant bits are detected on the CAN bus while the CAN module is in CAN operation mode.

After the BLIF flag is set to 1, a bus lock is detected again under either of the following conditions:

- After this flag is set to 0 from 1, recessive bits are detected
- After this flag is set to 0 from 1, the CAN module enters CAN reset mode or CAN halt mode and then enters CAN operation mode again (internal reset).

### 34.2.20 Receive Error Count Register (RECR)

Address(es): CAN0.RECR 0009 084Eh

| Bit      | Description                                                                                                                                       | R/W |
|----------|---------------------------------------------------------------------------------------------------------------------------------------------------|-----|
| b7 to b0 | Receive error count function<br>RECR increments or decrements the counter value according to the error status of the CAN module during reception. | R   |

RECR indicates the value of the receive error counter.

Refer to the ISO 11898-1 Standards about the increment/decrement conditions of the receive error counter.

The value of RECR in the bus-off state is undefined.

### 34.2.21 Transmit Error Count Register (TECR)

Address(es): CAN0.TECR 0009 084Fh

| Bit      | Description                                                                                                                                           | R/W |
|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------|-----|
| b7 to b0 | Transmit error count function<br>TECR increments or decrements the counter value according to the error status of the CAN module during transmission. | R   |

TECR indicates the value of the transmit error counter.

Refer to the ISO 11898-1 Standards about the increment/decrement conditions of the transmit error counter.

The value of TECR in the bus-off state is undefined.

### 34.2.22 Error Code Store Register (ECSR)

Address(es): CAN0.ECSR 0009 0850h

| Bit | Symbol | Bit Name                         | Description                                                                   | R/W |
|-----|--------|----------------------------------|-------------------------------------------------------------------------------|-----|
| b0  | SEF    | Stuff Error Flag*1, *2           | 0: No stuff error detected<br>1: Stuff error detected                         | R/W |
| b1  | FEF    | Form Error Flag*1, *2            | 0: No form error detected<br>1: Form error detected                           | R/W |
| b2  | AEF    | ACK Error Flag*1, *2             | 0: No ACK error detected<br>1: ACK error detected                             | R/W |
| b3  | CEF    | CRC Error Flag*1, *2             | 0: No CRC error detected<br>1: CRC error detected                             | R/W |
| b4  | BE1F   | Bit Error (recessive) Flag*1, *2 | 0: No bit error (recessive) detected<br>1: Bit error (recessive) detected     | R/W |
| b5  | BE0F   | Bit Error (dominant) Flag*1, *2  | 0: No bit error (dominant) detected<br>1: Bit error (dominant) detected       | R/W |
| b6  | ADEF   | ACK Delimiter Error Flag*1, *2   | 0: No ACK delimiter error detected<br>1: ACK delimiter error detected         | R/W |
| b7  | EDPM   | Error Display Mode Select*3, *4  | 0: Output of first detected error code<br>1: Output of accumulated error code | R/W |

Note 1. Writing 1 has no effect to these flag values.

Note 2. To write 0 to SEF, FEF, AEF, CEF, BE1F, BE0F, and ADEF flags, do not use the logic operation instruction (AND). Use the transfer (MOV) instruction to ensure that only the specified flag is set to 0 and the other flags are set to 1.

Note 3. Write to the EDPM bit in CAN reset mode or CAN halt mode.

Note 4. If more than one error condition is detected simultaneously, all related flags are set to 1.

ECSR can be used to monitor whether an error has occurred on the CAN bus.

Refer to the ISO 11898-1 Standards to check the generation conditions of each error.

To set each flag except for the EDPM bit to 0, write 0 by a program. If the timing at which each flag is set to 1 and the timing at which 0 is written by a program are the same, the relevant flag is set to 1.

#### SEF Flag (Stuff Error Flag)

The SEF flag is set to 1 when a stuff error is detected.

#### FEF Flag (Form Error Flag)

The FEF flag is set to 1 when a form error is detected.

#### AEF Flag (ACK Error Flag)

The AEF flag is set to 1 when an ACK error is detected.

#### CEF Flag (CRC Error Flag)

The CEF flag is set to 1 when a CRC error is detected.

#### BE1F Flag (Bit Error (recessive) Flag)

The BE1F flag is set to 1 when a recessive bit error is detected.

#### BE0F Flag (Bit Error (dominant) Flag)

The BE0F flag is set to 1 when a dominant bit error is detected.

#### ADEF Flag (ACK Delimiter Error Flag)

The ADEF flag is set to 1 when a form error is detected with the ACK delimiter during transmission.

#### EDPM Bit (Error Display Mode Select)

The EDPM bit selects the output mode of ECSR. When the EDPM bit is set to 0, ECSR outputs the first error code. When the EDPM bit is set to 1, ECSR outputs the accumulated error code.

### 34.2.23 Time Stamp Register (TSR)

Address(es): CAN0.TSR 0009 0854h

| Bit       | Description                                            | R/W |
|-----------|--------------------------------------------------------|-----|
| b15 to b0 | Free-running counter value for the time stamp function | R   |

Note: Read TSR in 16-bit units.

When TSR is read, the value of the time stamp counter (16-bit free-running counter) at that moment is read. The value of the time stamp counter reference clock is a multiple of 1 bit time, as configured by the TSPS[1:0] bits in CTLR.

The time stamp counter stops in CAN sleep mode and CAN halt mode, and is initialized in CAN reset mode.

The time stamp counter value is stored to bits TSL[7:0] and TSH[7:0] in MBj when a received message is stored in a receive mailbox.

### 34.2.24 Test Control Register (TCR)

Address(es): CAN0.TCR 0009 0858h

| Bit      | Symbol    | Bit Name             | Description                                                                                                                                               | R/W |
|----------|-----------|----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------|-----|
| b0       | TSTE      | CAN Test Mode Enable | 0: CAN test mode disabled<br>1: CAN test mode enabled                                                                                                     | R/W |
| b2, b1   | TSTM[1:0] | CAN Test Mode Select | b2 b1<br>0 0: Other than CAN test mode<br>0 1: Listen-only mode<br>1 0: Self-test mode 0 (external loopback)<br>1 1: Self-test mode 1 (internal loopback) | R/W |
| b7 to b3 | —         | Reserved             | These bits are read as 0. The write value should be 0.                                                                                                    | R/W |

TCR controls the CAN test mode. Write to TCR in CAN halt mode only.

#### (1) Listen-Only Mode

The ISO 11898-1 Standards recommend an optional bus monitoring mode. In listen-only mode, valid data frames and valid remote frames can be received. However, only recessive bits can be sent on the CAN bus, and the ACK bit, overload flag, and active error flag cannot be sent.

Listen-only mode can be used for baud rate detection.

Do not request transmission from any mailboxes in listen-only mode.

Figure 34.6 shows the connection when listen-only mode is selected.

Figure 34.6 Connection when Listen-Only Mode is Selected

### (2) Self-Test Mode 0 (External Loopback))

Self-test mode 0 is provided for CAN transceiver tests.

In self-test mode 0, the protocol controller treats its own transmitted messages as messages received via the CAN transceiver and stores them into the receive mailbox. To be independent from external stimulation, the protocol controller generates the ACK bit.

Connect the CTX0 and CRX0 pins to the transceiver.

Figure 34.7 shows the connection when self-test mode 0 is selected.

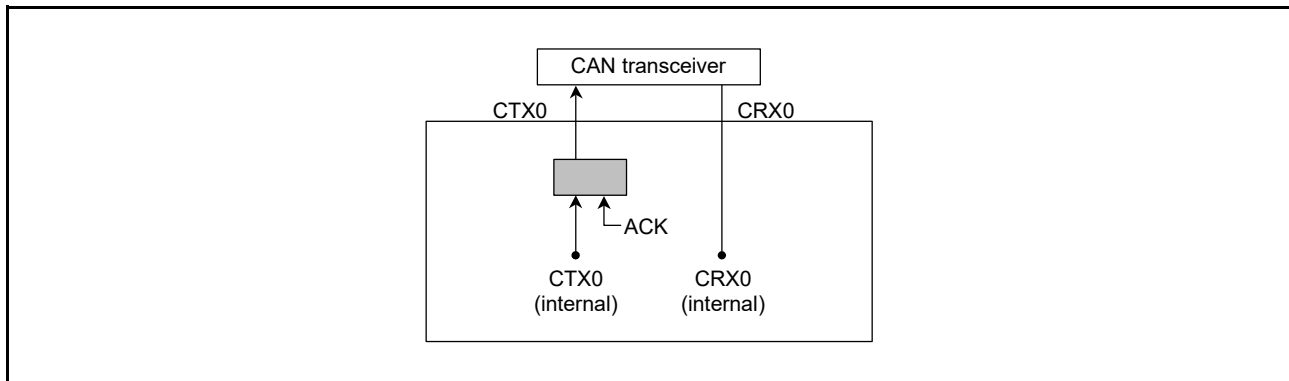

Figure 34.7 Connection when Self-Test Mode 0 is Selected

### (3) Self-Test Mode 1 (Internal Loopback)

Self-test mode 1 is provided for self-test functions.

In self-test mode 1, the protocol controller treats its transmitted messages as received messages and stores them into the receive mailbox. To be independent from external stimulation, the protocol controller generates the ACK bit.

In self-test mode 1, the protocol controller performs an internal feedback from the internal CTX0 pin to the internal CRX0 pin. The input value of the external CRX0 pin is ignored. The external CTX0 pin outputs only recessive bits. The CTX0 and CRX0 pins do not need to be connected to the CAN bus or any external device.

Figure 34.8 shows the connection when self-test mode 1 is selected.

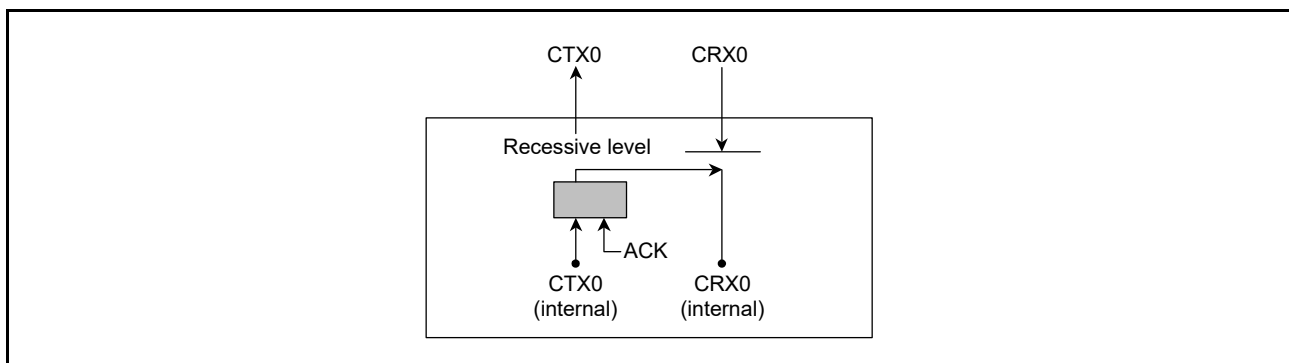

Figure 34.8 Connection when Self-Test Mode 1 is Selected

### 34.3 Operating Mode

The CAN module has the following four operating modes.

- CAN reset mode
- CAN halt mode
- CAN operation mode
- CAN sleep mode

Figure 34.9 shows the transition between CAN operating modes.

**Figure 34.9 Transition between CAN Operating Modes**

### 34.3.1 CAN Reset Mode

CAN reset mode is provided for CAN communication configuration.

When the CTLR.CANM[1:0] bits are set to 01b or 11b, the CAN module enters CAN reset mode. Then, the STR.RSTST flag is set to 1. Do not change the CTLR.CANM[1:0] bits until the RSTST flag is set to 1. Set BCR before exiting CAN reset mode to any other modes.

The following registers are initialized to their reset values after entering CAN reset mode, and their initial values are retained during CAN reset mode:

- MCTLj
- STR (except for the SLPST and TFST flags)
- EIFR
- RECR
- TECR
- TSR
- MSSR
- MSMR
- RFCR
- TFCR
- TCR
- ECSR (except for the EDPM bit)

The following registers retain their previous values even after entering CAN reset mode.

- CTLR
- STR (only the SLPST and TFST flags)
- MIER
- EIER
- BCR
- CSSR
- ECSR (only the EDPM bit)
- MBj
- MKR0 to MKR7
- FIDCR0 and FIDCR1
- MKIVLR
- AFSR
- RFPCR
- TFPCR

### 34.3.2 CAN Halt Mode

CAN halt mode is used for mailbox configuration and test mode setting.

When the CTLR.CANM[1:0] bits are set to 10b, CAN halt mode is selected. Then the STR.HLTST flag is set to 1. Do not change the CTLR.CANM[1:0] bits until the HLTST flag is set to 1.

See Table 34.8 for the state transition conditions when transmitting or receiving.

All registers except for RSTST, HLTST, and SLPST flags in STR remain unchanged when the CAN enters CAN halt mode.

Do not change CTLR (except for bits CANM[1:0] and SLPM) and EIER in CAN halt mode. BCR can be changed in CAN halt mode only when listen-only mode is selected for automatic baud rate detection.

**Table 34.8 Operation in CAN Reset Mode and CAN Halt Mode**

| Mode                                                    | Receiver                                                                              | Transmitter                                                                                  | Bus-Off                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|---------------------------------------------------------|---------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

CANM[1:0], BOM[1:0]: Bits in CTLR

- Note 1. If several messages are requested to be transmitted, mode transition occurs after the completion of the first message transmission. In a case that the CAN reset mode is being requested during suspend transmission, mode transition occurs when the bus is idle, the next transmission ends, or the CAN module becomes a receiver.
- Note 2. If the CAN bus is locked at the dominant level, the program can detect this state by monitoring the EIFR.BLIF flag. While the CAN bus is locked at the dominant level, the CAN module does not enter CAN halt mode. In that case, enter CAN reset mode.
- Note 3. If a CAN bus error occurs during reception after CAN halt mode is requested, the CAN module transits to CAN halt mode. However, while the CAN bus is locked at the dominant level, the CAN module does not enter CAN halt mode.
- Note 4. If a CAN bus error or arbitration-lost occurs during transmission after CAN reset mode or CAN halt mode is requested, the CAN module transits to the requested operating mode. However, while the CAN bus is locked at the dominant level, the CAN module does not enter CAN halt mode.

### 34.3.3 CAN Sleep Mode

CAN sleep mode is used for reducing current consumption by stopping the clock supply to the CAN module. After a reset from an MCU pin or software reset, the CAN module starts from CAN sleep mode.

When the SLPM bit in CTRL is set to 1, the CAN module enters CAN sleep mode. Then, the SLPST flag in STR is set to 1. Do not change the value of the SLPM bit until the SLPST flag is set to 1. The other registers remain unchanged when the CAN module enters CAN sleep mode.

Write to the SLPM bit in CAN reset mode and CAN halt mode. Do not change any registers (except for the SLPM bit) during CAN sleep mode. Read operation is still allowed.

When the SLPM bit is set to 0, the CAN module is released from CAN sleep mode. When the CAN module exits CAN sleep mode, the other registers remain unchanged.

### 34.3.4 CAN Operation Mode (Excluding Bus-Off State)

CAN operation mode is used for CAN communication.

When the CANM[1:0] bits in CTRL are set to 00b, the CAN module enters CAN operation mode.

Then RSTST and HLTST flags in STR are set to 0. Do not change the value of the CANM[1:0] until bits RSTST and HLTST flags are set to 0.

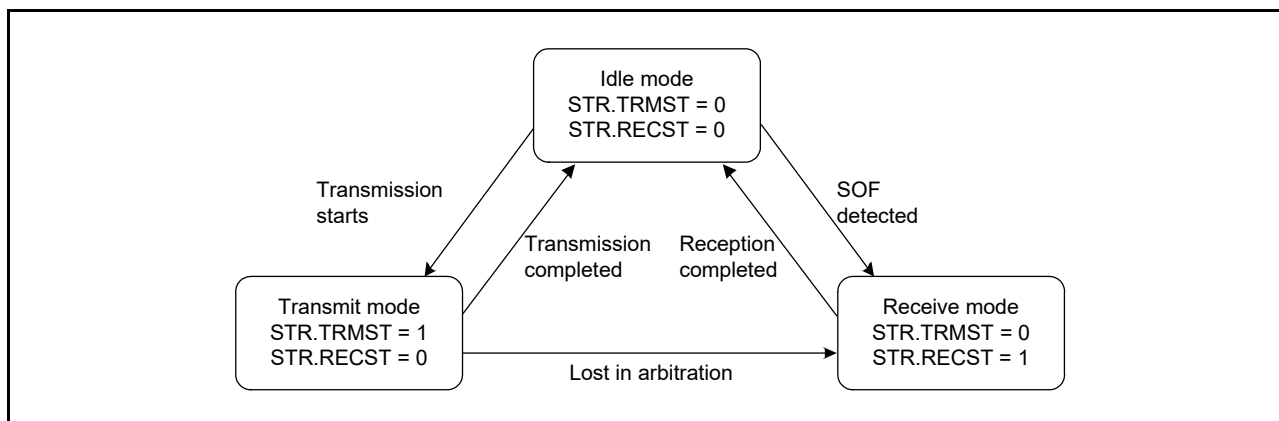

If 11 consecutive recessive bits are detected after entering CAN operation mode, the CAN module is in the following states:

- The CAN module becomes an active node on the network, thus enabling transmission and reception of CAN messages.
- Error monitoring of the CAN bus, such as receive and transmit error counters, is performed.

During CAN operation mode, the CAN module may be in one of the following three sub-modes, depending on the status of the CAN bus.

- Idle mode: Transmission or reception is not being performed.
- Receive mode: A CAN message sent by another node is being received.
- Transmit mode: A CAN message is being transmitted. The CAN module receives a message transmitted by the local node simultaneously when self-test mode 0 (TSTM[1:0] bits in TCR = 10b) or self-test mode 1 (TSTM[1:0] bits = 11b) is selected.

Figure 34.10 shows the sub-modes of CAN operation mode.

**Figure 34.10 Sub-Modes of CAN Operation Mode**

### 34.3.5 CAN Operation Mode (Bus-Off State)

The CAN module enters the bus-off state according to the increment/decrement rules for the transmit/error counters in the CAN Specifications.

The following cases apply when the CAN module is recovering from the bus-off state. When the CAN module is in the bus-off state, the values of the CAN-related registers, except for STR, EIFR, RECR, TECR and TSR, remain unchanged.

(1) When bits BOM[1:0] in CTLR are 00b (normal mode)

The CAN module enters the error-active state after it has completed the recovery from the bus-off state and CAN communication is enabled. The BORIF flag in EIFR is set to 1 (bus-off recovery detected) at this time.

(2) When bit RBOC in CTLR is set to 1 (forcible return from bus-off)

The CAN module enters the error-active state when it is in the bus-off state and the RBOC bit is set to 1. CAN communication is enabled again after 11b consecutive recessive bits are detected. The BORIF flag is not set to 1 at this time.

(3) When bits BOM[1:0] are 01b (automatic transition to CAN halt mode at bus-off entry)

The CAN module enters CAN halt mode when it reaches the bus-off state. The BORIF flag is not set to 1 at this time.

(4) When bits BOM[1:0] are 10b (automatic transition to CAN halt mode at bus-off end)

The CAN module enters CAN halt mode when it has completed the recovery from bus-off. The BORIF flag is set to 1 at this time.

(5) When bits BOM[1:0] are 11b (automatic transition to CAN halt mode by a program) and bits CANM[1:0] in CTLR are set to 10b (CAN halt mode) during bus-off state

The CAN module enters CAN halt mode when it is in the bus-off state and the CANM[1:0] bits are set to 10b (CAN halt mode). The BORIF flag is not set to 1 at this time.

If the CANM[1:0] bits are not set to 10b during bus-off, the same behavior as (1) applies.

### 34.4 CAN Communication Speed Setting

The following description explains about CAN communication speed setting.

#### 34.4.1 CAN Clock Setting

The CAN module has a CAN clock selector.

The CAN clock can be set by the CCLKS bit and the BRP[9:0] bits in BCR.

Figure 34.11 shows a block diagram of the CAN clock generator.

**Figure 34.11 Block Diagram of CAN Clock Generator**

#### 34.4.2 Bit Timing Setting

The bit time consists of the following three segments.

Figure 34.12 shows the bit timing.

**Figure 34.12 Bit Timing**

### 34.4.3 Bit Rate

The bit rate depends on the division value of fCAN (CAN clock), the division value of the baud rate prescaler, and the number of Tq of 1 bit time.

$$\text{Bit rate [bps]} = \frac{\text{fCAN}}{\text{Baud rate prescaler division value}^*1 \times \text{number of Tq of 1 bit time}} = \frac{\text{fCANCLK}}{\text{Number of Tq of 1 bit time}}$$

Note 1. Division value of baud rate prescaler = P + 1 (P: 0 to 1023)

P: Setting of the BRP[9:0] bits in BCR

Table 34.9 lists bit rate examples.

**Table 34.9 Bit Rate Examples**

| fCAN      | 50 MHz       |       | 48 MHz       |       | 40 MHz       |       | 32 MHz       |       |
|-----------|--------------|-------|--------------|-------|--------------|-------|--------------|-------|
|           | Number of Tq | P + 1 | Number of Tq | P + 1 | Number of Tq | P + 1 | Number of Tq | P + 1 |
| 1 Mbps    | 10Tq         | 5     | 8Tq          | 6     | 10Tq         | 4     | 8Tq          | 4     |

### 34.5 Mailbox and Mask Register Structure

Figure 34.13 shows the structure of MB<sub>j</sub>.

There are 32 mailboxes with the same structure.

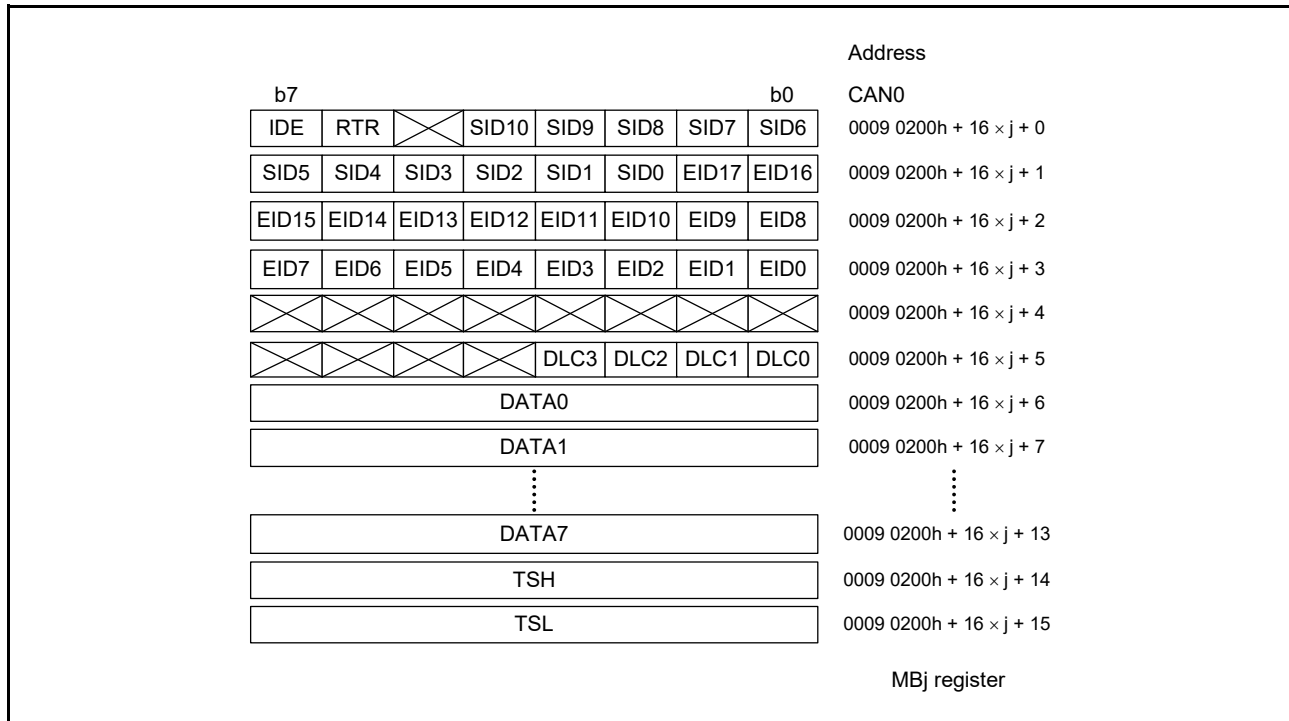

Figure 34.13 Structure of MB<sub>j</sub> (j = 0 to 31)

Figure 34.14 shows the structure of MKR<sub>k</sub>.

There are eight mask registers with the same structure.

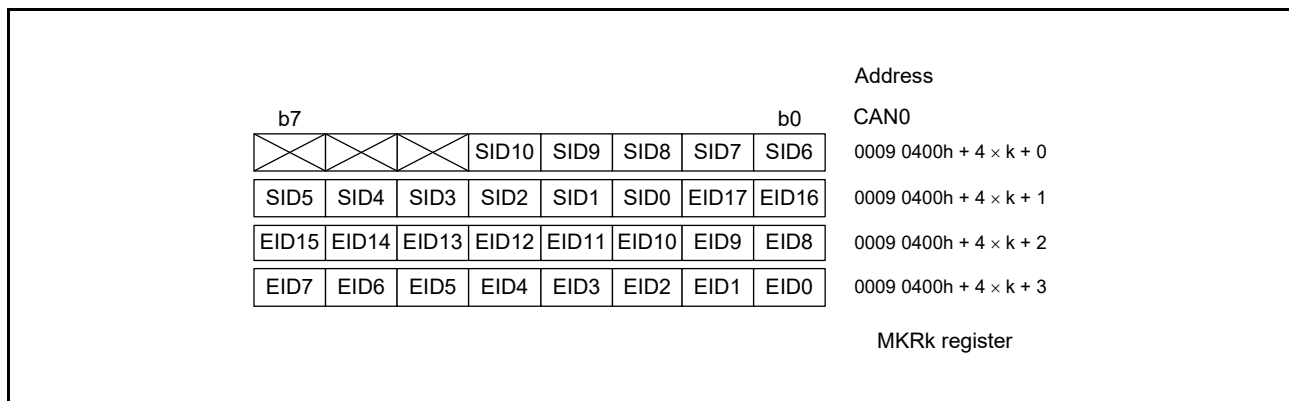

Figure 34.14 Structure of MKR<sub>k</sub> (k = 0 to 7)

Figure 34.15 shows the structure of FIDCR0 and FIDCR1. There are two FIFO received ID compare registers with the same structure.

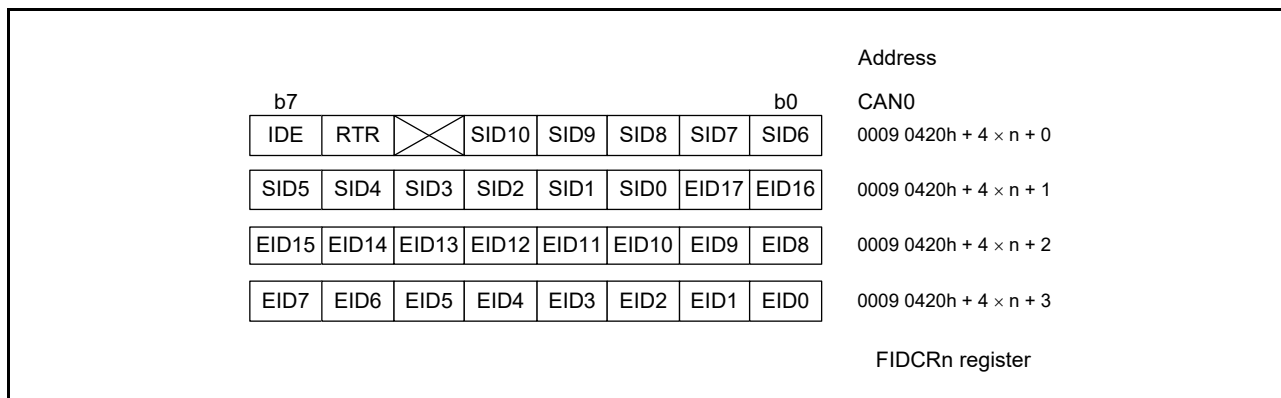

Figure 34.15 Structure of FIDCRn (n = 0, 1)

### 34.6 Acceptance Filtering and Masking Functions

The acceptance filtering function and masking function allows the user to select and receive messages with a specified range of multiple IDs for mailboxes.

Registers MKR0 to MKR7 can perform masking of the standard ID and the extended ID of 29 bits.

- MKR0 corresponds to mailboxes [0] to [3]
- MKR1 corresponds to mailboxes [4] to [7]
- MKR2 corresponds to mailboxes [8] to [11]
- MKR3 corresponds to mailboxes [12] to [15]
- MKR4 corresponds to mailboxes [16] to [19]
- MKR5 corresponds to mailboxes [20] to [23]
- MKR6 corresponds to mailboxes [24] to [27] in normal mailbox mode and the receive FIFO mailboxes [28] to [31] in FIFO mailbox mode.
- MKR7 corresponds to mailboxes [28] to [31] in normal mailbox mode and the receive FIFO mailboxes [28] to [31] in FIFO mailbox mode.

MKIVLR disables acceptance filtering individually for each mailbox.

The IDE bit in MBj is valid when the IDFM[1:0] bits in CTLR are 10b (mixed ID mode).

The RTR bit in MBj selects a data frame or a remote frame.

In FIFO mailbox mode, normal mailboxes (mailboxes [0] to [23]) use the single corresponding register among MKR0 to MKR5 for acceptance filtering. Receive FIFO mailboxes (mailboxes [28] to [31]) use two registers MKR6 and MKR7 for acceptance filtering.

Also, the receive FIFO uses two registers FIDCR0 and FIDCR1 for ID comparison. Bits EID[17:0], SID[10:0], RTR, and IDE in MB28 to MB31 for the receive FIFO are disabled. As acceptance filtering depends on the result of two logic AND operations, two ranges of IDs can be received into the receive FIFO.

MKIVLR is disabled for the receive FIFO.

If both the standard ID and extended ID are set in the IDE bits in FIDCR0 and FIDCR1 individually, both ID formats are received.

If both the data frame and remote frame are set in the RTR bits in FIDCR0 and FIDCR1 individually, both data and remote frames are received.

When combination with two ranges of IDs is not necessary, set the same mask value and the same ID into both the FIFO ID and mask register.

Figure 34.16 shows the correspondence between mask registers and mailboxes. Figure 34.17 shows acceptance filtering.

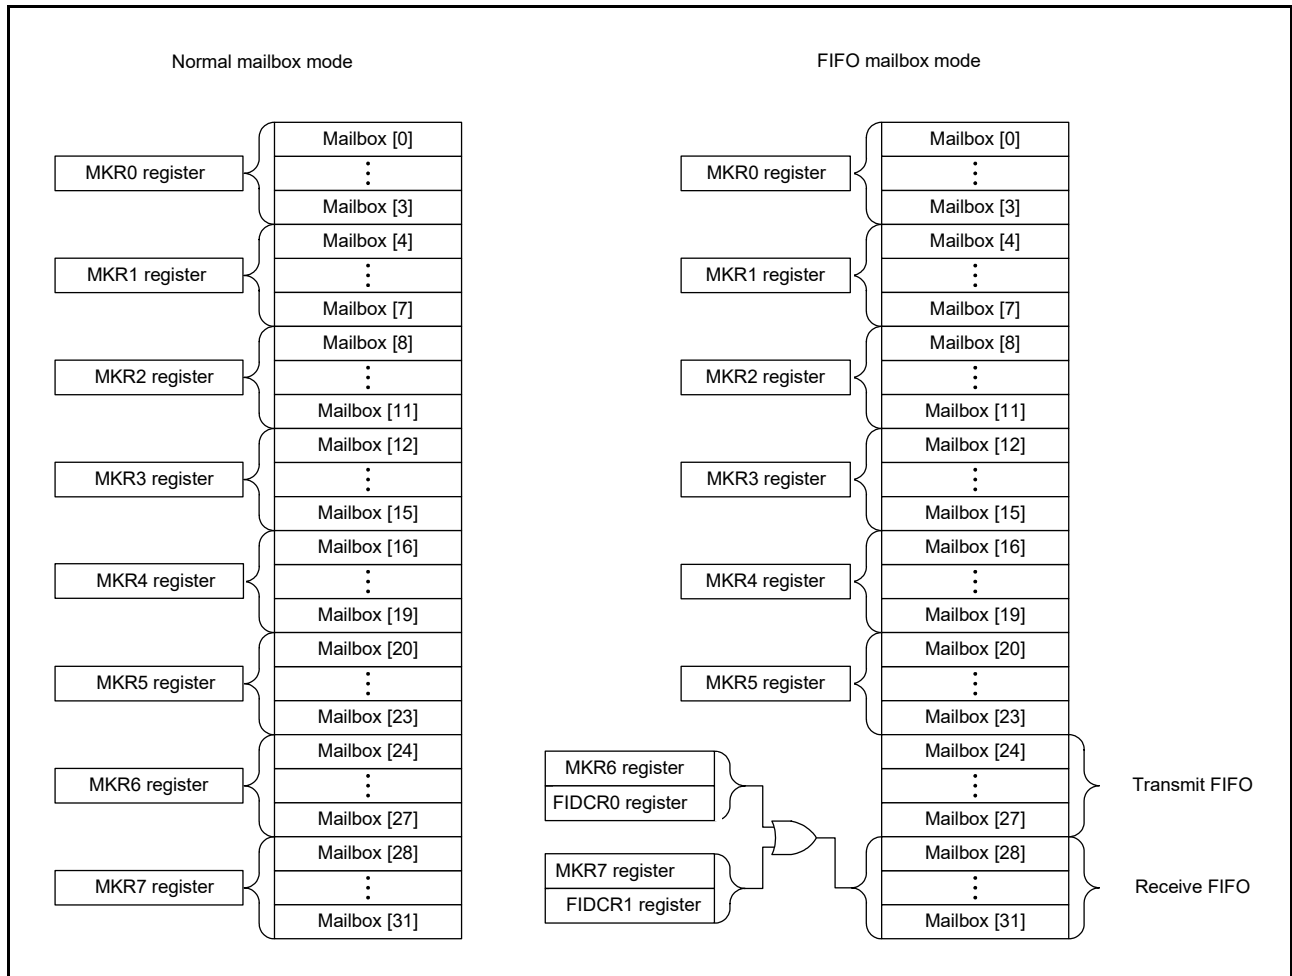

Figure 34.16 Correspondence between Mask Registers and Mailboxes

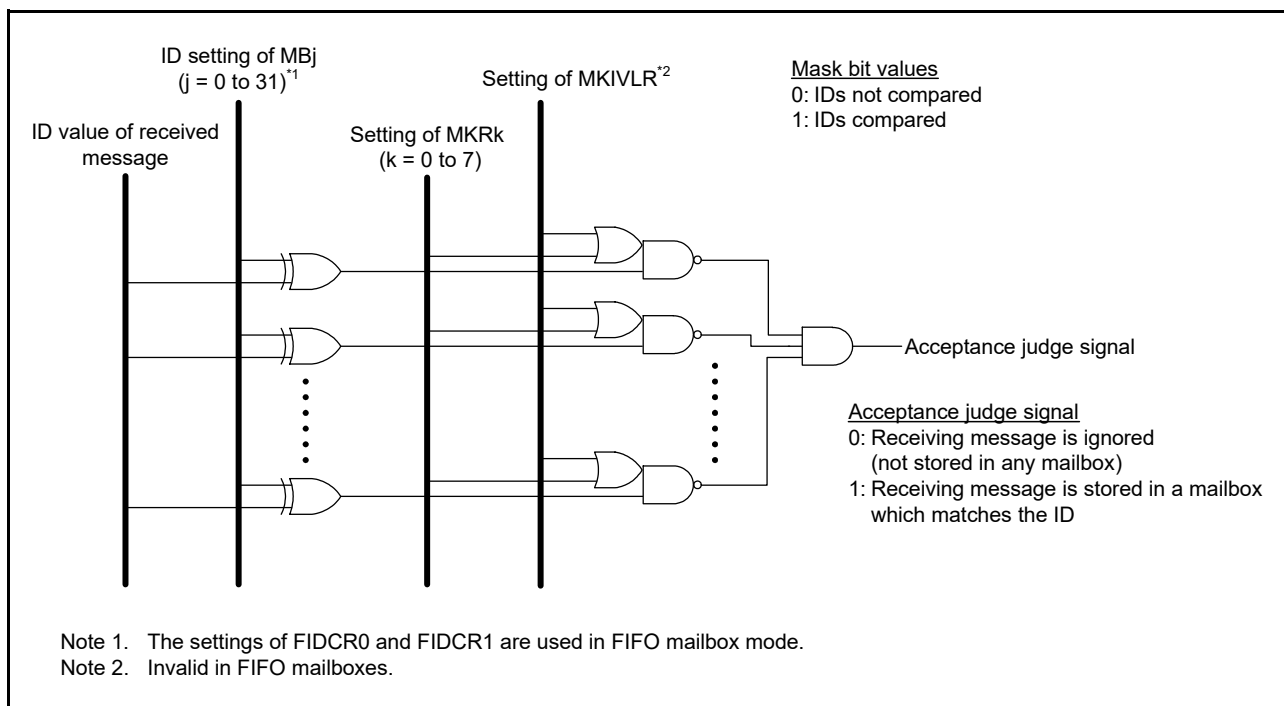

Figure 34.17 Acceptance Filtering

## 34.7 Reception and Transmission

Table 34.10 lists how to make the CAN communication mode settings.

**Table 34.10 Setting of CAN Receive Mode and CAN Transmit Mode**

| MCTLj.<br>TRMREQ | MCTLj.<br>RECREQ | MCTLj.<br>ONESHOT | Communication Mode of Mailbox                                                                                |
|------------------|------------------|-------------------|--------------------------------------------------------------------------------------------------------------|
| 0                | 0                | 0                 | Mailbox disabled or transmission being aborted.                                                              |
| 0                | 0                | 1                 | Can be configured only when transmission or reception from a mailbox programmed in one-shot mode is aborted. |
| 0                | 1                | 0                 | Configured as a receive mailbox for a data frame or a remote frame.                                          |
| 0                | 1                | 1                 | Configured as a one-shot receive mailbox for a data frame or a remote frame.                                 |
| 1                | 0                | 0                 | Configured as a transmit mailbox for a data frame or a remote frame.                                         |
| 1                | 0                | 1                 | Configured as a one-shot transmit mailbox for a data frame or a remote frame.                                |
| 1                | 1                | 0                 | Do not set.                                                                                                  |
| 1                | 1                | 1                 | Do not set.                                                                                                  |

j = 0 to 31

When a mailbox is configured as a receive mailbox or a one-shot receive mailbox, note the following:

1. Before a mailbox is configured as a receive mailbox or a one-shot receive mailbox, set MCTLj to 00h.
2. A received message is stored into the first mailbox that matches the condition according to the result of receive mode setting and acceptance filtering. Upon deciding the mailbox to store the received message, the mailbox with the smaller number has higher priority.
3. In CAN operation mode, when the CAN module transmits a message whose ID matches with the ID/mask set of a mailbox configured to receive messages, the CAN module never receives the transmitted data. In self-test mode, however, the CAN module will receive its transmitted data. In this case, the CAN module returns ACK.

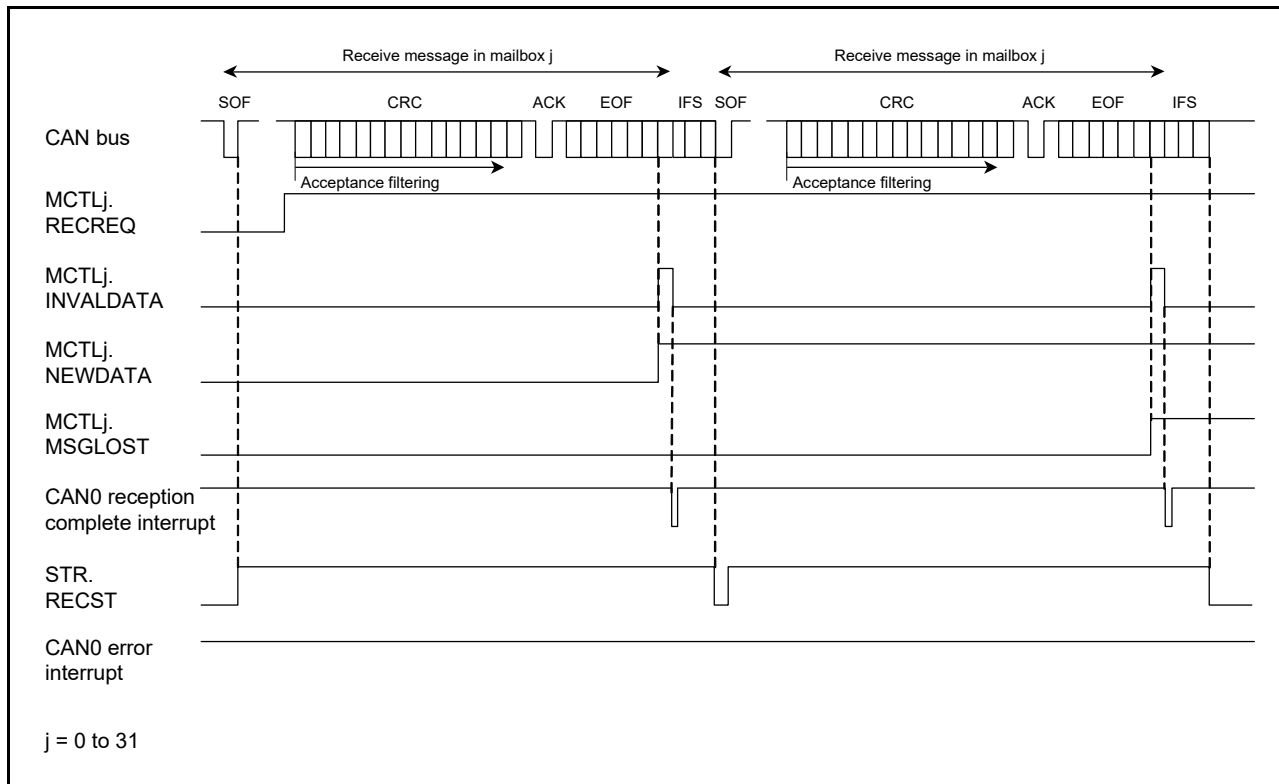

When configuring a mailbox as a transmit mailbox or a one-shot transmit mailbox, note the following:

4. Before a mailbox is configured as a transmit mailbox or a one-shot transmit mailbox, ensure that MCTLj is 00h and that there is no pending abort process.

### 34.7.1 Reception

Figure 34.18 shows an operation example of data frame reception in overwrite mode.

This example shows the operation of overwriting the first message when the CAN module receives two consecutive CAN messages which match the receiving conditions of MCTLj ( $j = 0$  to 31).

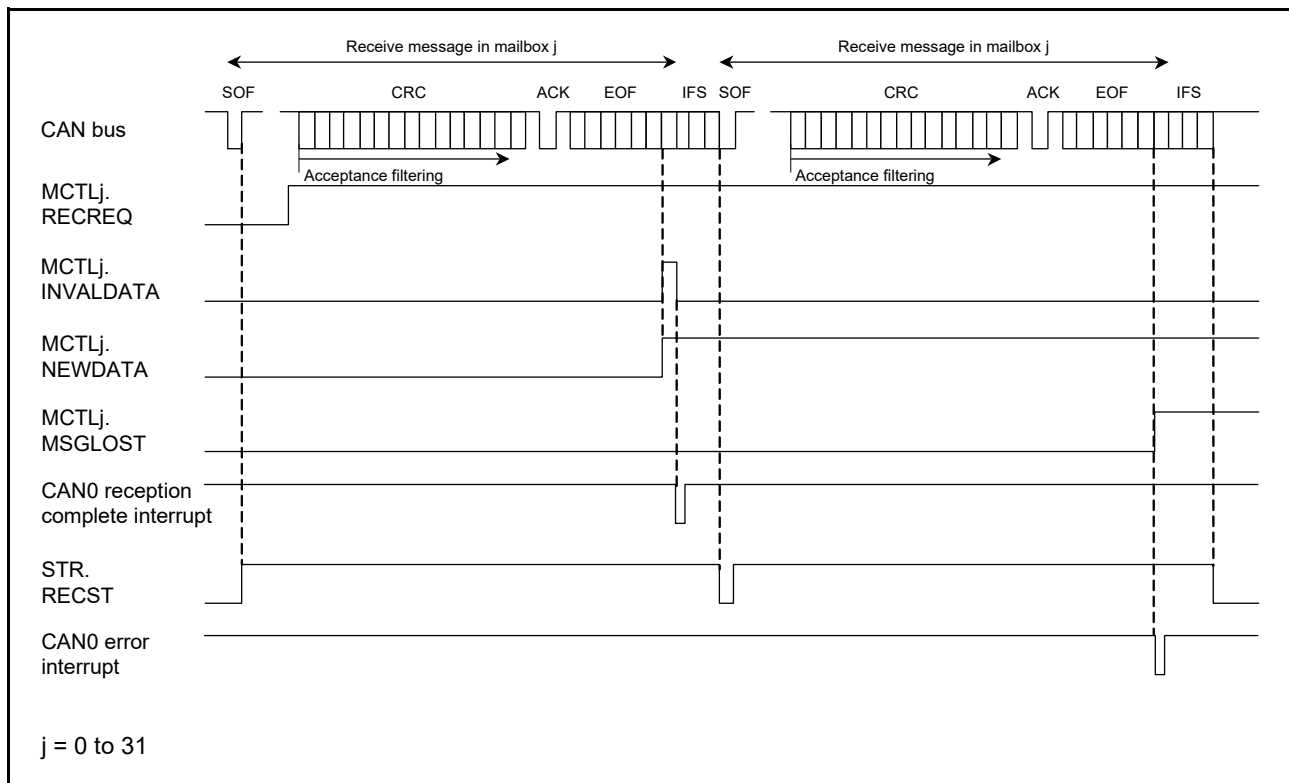

**Figure 34.18 Operation Example of Data Frame Reception in Overwrite Mode**

1. When an SOF is detected on the CAN bus, the RECST flag in STR is set to 1 (reception in progress) if the CAN module has no message ready to start transmission.
2. The acceptance filter processing starts at the beginning of the CRC field to select the receive mailbox.
3. After a message has been received, the NEWDATA flag in MCTLj for the receive mailbox is set to 1 (new message is being stored or has been stored to the mailbox). The INVALIDATA flag in MCTLj is set to 1 (message is being updated) at the same time, and then the INVALIDATA flag is set to 0 (message valid) again after the complete message is transferred to the mailbox.
4. When the interrupt enable bit in MIER for the receive mailbox is 1 (interrupt enabled), the CAN0 reception complete interrupt request is generated. This interrupt (CAN0 reception complete interrupt) is generated when the INVALIDATA flag is set to 0.
5. After reading the message from the mailbox, the NEWDATA flag needs to be set to 0 by a program.
6. In overwrite mode, if the next CAN message has been received into a mailbox whose NEWDATA flag is still set to 1, the MSGLOST flag in MCTLj is set to 1 (message has been overwritten). The new received message is transferred to the mailbox. The CAN0 reception complete interrupt request is generated the same as in 4.

Figure 34.19 shows the operation example of data frame reception in overrun mode.

This example shows the operation of overrunning the second message when the CAN module receives two consecutive CAN messages which match the receiving conditions of MCTLj (j = 0 to 31).

**Figure 34.19 Operation Example of Data Frame Reception in Overrun Mode**

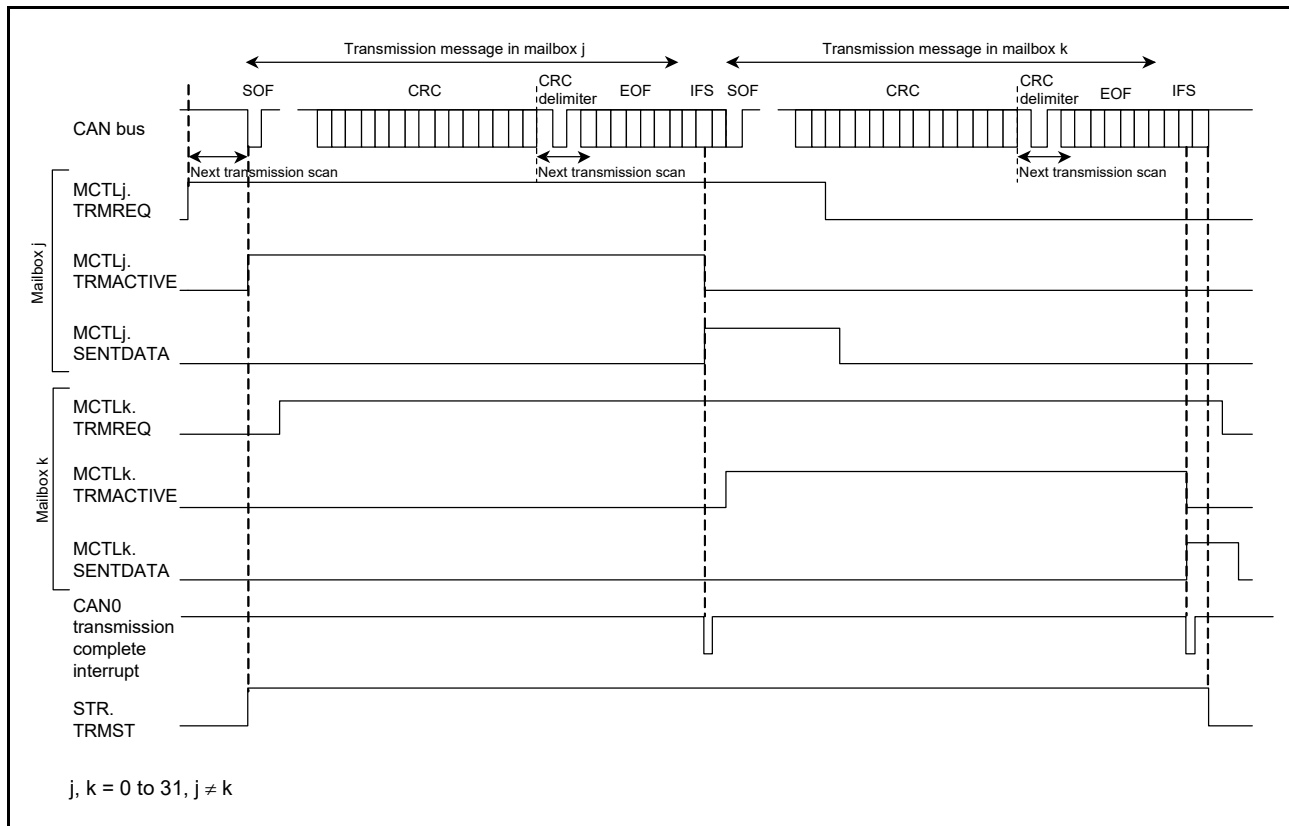

1. to 5. are the same as in overwrite mode.

6. In overrun mode, if the next CAN message has been received before the NEWDATA flag in MCTLj is set to 0, the MSGLOST flag in MCTLj is set to 1 (message has been overrun). The new received message is discarded and a CAN0 error interrupt request is generated if the corresponding interrupt enable bit in EIER is set to 1 (interrupt enabled).

### 34.7.2 Transmission

Figure 34.20 shows an operation example of data frame transmission.

**Figure 34.20 Operation Example of Data Frame Transmission**

1. When a TRMREQ bit in MCTLj ( $j = 0$  to  $31$ ) is set to 1 (transmit mailbox) in the bus-idle state, the mailbox scan processing starts to decide the highest-priority mailbox for transmission. Once the transmit mailbox is decided, the TRMACTIVE flag in MCTLj is set to 1 (from acceptance of transmission request to completion of transmission, or error/arbitration-lost), the TRMST flag in STR is set to 1 (transmission in progress), and the CAN module starts transmission.\*1
2. If other TRMREQ bits are set, the transmission scan processing starts with the CRC delimiter for the next transmission.
3. If transmission is completed without losing arbitration, the SENTDATA flag in MCTLj is set to 1 (transmission completed) and the TRMACTIVE flag is set to 0 (transmission is pending or transmission is not requested). If the interrupt enable bit in MIER is 1 (interrupt enabled), the CAN0 transmission complete interrupt request is generated.
4. When requesting the next transmission from the same mailbox, set SENTDATA flag and TRMREQ bit to 0, then set the TRMREQ bit to 1 after checking that SENTDATA flag and TRMREQ bit have been set to 0.

Note 1. If arbitration is lost after the CAN module starts transmission, the TRMACTIVE flag is set to 0. The transmission scan processing is performed again to search for the highest-priority transmit mailbox from the beginning of the CRC delimiter. If an error occurs either during transmission or following the arbitration-lost, the transmission scan processing is performed again to search for the highest-priority transmit mailbox from the start of the error delimiter.

## 34.8 CAN Interrupt

The CAN module provides the following CAN interrupts for each channel. Table 34.11 lists CAN interrupts.

- CAN0 reception complete interrupt (mailboxes 0 to 31) [RXM0]
- CAN0 transmission complete interrupt (mailboxes 0 to 31) [TXM0]
- CAN0 receive FIFO interrupt [RXF0]
- CAN0 transmit FIFO interrupt [TXF0]
- CAN0 error interrupt [ERS0]

There are eight types of interrupt sources for the CAN0 error interrupts. These sources can be determined by checking EIFR.

- Bus error
- Error-warning
- Error-passive
- Bus-off entry
- Bus-off recovery
- Receive overrun
- Overload frame transmission
- Bus lock

**Table 34.11 CAN Interrupts**

| Module | Interrupt Symbol | Interrupt Source                                            | Source Flag                       |
|--------|------------------|-------------------------------------------------------------|-----------------------------------|
| CAN0   | ERS0             | Bus lock detected                                           | EIFR.BLIF                         |
|        |                  | Overload frame transmission detected                        | EIFR.OLIF                         |
|        |                  | Overrun detected                                            | EIFR.ORIF                         |
|        |                  | Bus-off recovery detected                                   | EIFR.BORIF                        |
|        |                  | Bus-off entry detected                                      | EIFR.BOEIF                        |
|        |                  | Error-passive detected                                      | EIFR.EPIF                         |
|        |                  | Error-warning detected                                      | EIFR.EWIF                         |
|        |                  | Bus error detected                                          | EIFR.BEIF                         |
| RXF0   | RXF0             | Receive FIFO message received (MIER[29] = 0)                | RFCR.RFUST[2:0]                   |
|        |                  | Receive FIFO warning (MIER[29] = 1)                         |                                   |
| TXF0   | TXF0             | Transmit FIFO message transmission completed (MIER[25] = 0) | TFCR.TFUST[2:0]                   |
|        |                  | FIFO last message transmission completed (MIER[25] = 1)     |                                   |
| RXM0   | RXM0             | Mailbox 0 to 31 message received                            | MCTL0.NEWDATA to MCTL31.NEWDATA   |
| TXM0   | TXM0             | Mailbox 0 to 31 message transmission completed              | MCTL0.SENTDATA to MCTL31.SENTDATA |

## 34.9 Usage Notes

### 34.9.1 Setting for the Module-Stop State

Module stop control register B (MSTPCRB) can be used to enable or disable operation of the CAN module. The CAN module is stopped after a reset. The registers become accessible on release from the module-stop state. For details, refer to section 11, Low Power Consumption.

## 35. Serial Peripheral Interface (RSPIC)

In this section, “PCLK” is used to refer to PCLKA.

### 35.1 Overview

This MCU includes one channel of Serial Peripheral Interface (RSPIC).

The RSPIC channels are capable of high-speed, full-duplex or simplex (transmit-only) synchronous serial communications with multiple processors and peripheral devices.

Table 35.1 lists the specifications of the RSPIC, and Figure 35.1 shows a block diagram of the RSPIC.

In this section, m as used with the RSPIC command registers (SPCMDm) indicates 0 to 7.

**Table 35.1 RSPIC Specifications (1/2)**

| Item                       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

| Low power consumption function | Module stop state can be set.                                                                                                                                                                                                                                                                                                                                                    |

Note 1. In master reception and when the RSPCK auto-stop function is enabled, an overrun error does not occur because the transfer clock is stopped at the timing of overrun error detection.

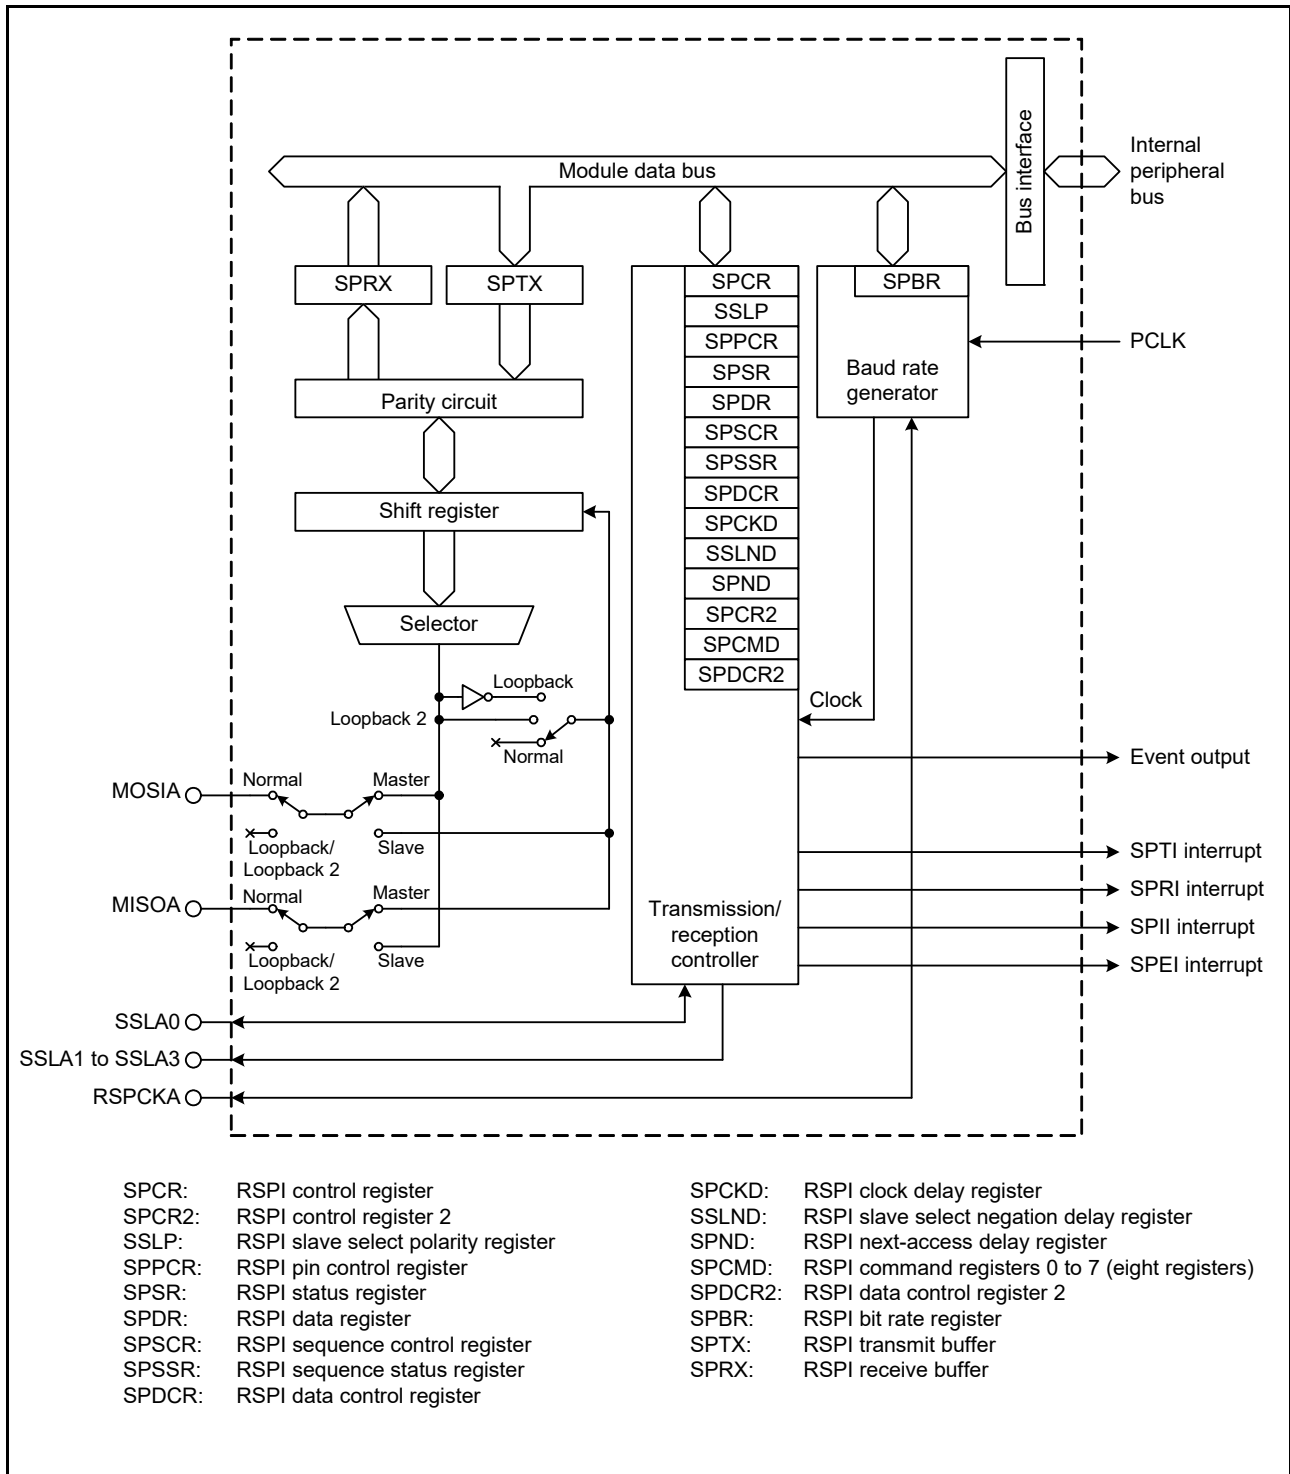

Figure 35.1 RSPI Block Diagram

Table 35.2 lists the I/O pins used in the RSPI.

The RSPI automatically switches the I/O direction of the SSLA0 pin. SSLA0 is set as an output when the RSPI is a single master and as an input when the RSPI is a multi-master or a slave. Pins RSPCKA, MOSIA, and MISOA are automatically set as inputs or outputs according to the setting of master or slave and the level input on the SSLA0 pin. Refer to section 35.3.2, Controlling RSPI Pins for details.

**Table 35.2 RSPI Pin Configuration**

| Channel | Pin Name | I/O    | Function                 |
|---------|----------|--------|--------------------------|
| RSPI0   | RSPCKA   | I/O    | Clock I/O                |
|         | MOSIA    | I/O    | Master transmit data I/O |
|         | MISOA    | I/O    | Slave transmit data I/O  |
|         | SSLA0    | I/O    | Slave selection I/O      |
|         | SSLA1    | Output | Slave selection output   |
|         | SSLA2    | Output | Slave selection output   |
|         | SSLA3    | Output | Slave selection output   |

## 35.2 Register Descriptions

| b5  | SPTIE  | Transmit Buffer Empty Interrupt Enable | 0: Disables the generation of transmit buffer empty interrupt requests<br>1: Enables the generation of transmit buffer empty interrupt requests | R/W |
| b6  | SPE    | RSPI Function Enable                   | 0: Disables the RSPI function<br>1: Enables the RSPI function                                                                                   | R/W |
| b7  | SPRIE  | Receive Buffer Full Interrupt Enable   | 0: Disables the generation of receive buffer full interrupt requests<br>1: Enables the generation of receive buffer full interrupt requests     | R/W |

Note 1. Do not change the values of the MSTR, MODFEN, TXMD, and SPMS bits while the SPE bit is 1.

#### SPMS Bit (RSPI Mode Select)

The SPMS bit selects SPI operation (4-wire method) or clock synchronous operation (3-wire method).

The SSLA0 to SSLA3 pins are not used in clock synchronous operation. The RSPCKA, MOSIA, and MISOA pins handle communications. If clock synchronous operation is to proceed in master mode (SPCR.MSTR = 1), the SPCMDm.CPHA bit can be set to either 0 or 1. Set the CPHA bit to 1 if clock synchronous operation is to proceed in slave mode (SPCR.MSTR = 0). Do not set the CPHA bit to 0 when clock synchronous operation is to proceed in slave mode (SPCR.MSTR = 0).

#### TXMD Bit (Communications Operating Mode Select)

The TXMD bit selects full-duplex communications or transmit-only simplex communications.

When performing communications with the TXMD bit set to 1, the RSPI performs only transmit operations and not receive operations (refer to section 35.3.6, Communications Operating Mode).

When the TXMD bit is set to 1, receive buffer full interrupt requests cannot be used.

**MODFEN Bit (Mode Fault Error Detection Enable)**

The MODFEN bit enables or disables the detection of mode fault error (refer to section 35.3.9, Error Detection). In addition, the RSPI determines the I/O direction of the SSLA0 to SSLA3 pins based on combinations of the MODFEN and MSTR bits (refer to section 35.3.2, Controlling RSPI Pins).

**MSTR Bit (RSPI Master/Slave Mode Select)**

The MSTR bit selects master/slave mode of the RSPI. According to MSTR bit settings, the RSPI determines the direction of pins RSPCKA, MOSIA, MISOA, and SSLA0 to SSLA3.

**SPEIE Bit (Error Interrupt Enable)**

The SPEIE bit enables or disables the generation of error interrupt requests when the RSPI detects a mode fault error or underrun error and sets the SPSR.MODF flag to 1, when the RSPI detects an overrun error and sets the SPSR.OVRF flag to 1, or when the RSPI detects a parity error and sets the SPSR.PERF flag to 1 (refer to section 35.3.9, Error Detection).

**SPTIE Bit (Transmit Buffer Empty Interrupt Enable)**

The SPTIE bit enables or disables the generation of transmit buffer empty interrupt requests when the RSPI detects when the transmit buffer is empty.

A transmit buffer empty interrupt request when transmission starts is generated by setting the SPE and SPTIE bits to 1 at the same time or by setting the SPE bit to 1 after setting the SPTIE bit to 1.

Note that a transmit buffer interrupt is generated when the SPTIE bit is 1 even if the RSPI function is disabled (the SPTIE bit is changed to 0).

**SPE Bit (RSPI Function Enable)**

The SPE bit enables or disables the RSPI function.

When the SPSR.MODF flag is 1, the SPE bit cannot be set to 1. For details, refer to section 35.3.9, Error Detection.

Setting the SPE bit to 0 disables the RSPI function, and initializes a part of the module function. For details, refer to section 35.3.10, Initializing RSPI. Furthermore, a transmit buffer empty interrupt request is generated by the state of the SPE bit changing from 0 to 1 or from 1 to 0.

**SPRIE Bit (Receive Buffer Full Interrupt Enable)**

If the RSPI has detected a receive buffer full write after completion of a serial transfer, the SPRIE bit enables or disables the generation of a receive buffer full interrupt request.

### 35.2.2 RSPI Slave Select Polarity Register (SSLP)

Address(es): RSPI0.SSLP 000D 0101h

| b1     | SPLP2  | RSPI Loopback 2               | 0: Normal mode<br>1: Loopback mode (data is not inverted for transmission)                                                                                | R/W |
| b3, b2 | —      | Reserved                      | These bits are read as 0. The write value should be 0.                                                                                                    | R/W |
| b4     | MOIFV  | MOSI Idle Fixed Value         | 0: The level output on the MOSIA pin during MOSI idling corresponds to low<br>1: The level output on the MOSIA pin during MOSI idling corresponds to high | R/W |
| b5     | MOIFE  | MOSI Idle Value Fixing Enable | 0: MOSI output value equals final data from previous transfer<br>1: MOSI output value equals the value set in the MOIFV bit                               | R/W |
| b7, b6 | —      | Reserved                      | These bits are read as 0. The write value should be 0.                                                                                                    | R/W |

Note: Do not change the SPPCR register while the SPCR.SPE bit is 1.

#### SPLP Bit (RSPI Loopback)

The SPLP bit selects the mode of the RSPI pins.

When the SPLP bit is set to 1, the RSPI shuts off the path between the MISOA pin and the shift register if the SPCR.MSTR bit is 1, and between the MOSIA pin and the shift register if the SPCR.MSTR bit is 0, and connects (inverts) the input path and output path for the shift register (loopback mode).

#### SPLP2 Bit (RSPI Loopback 2)

The SPLP2 bit selects the mode of the RSPI pins.

When the SPLP2 bit is set to 1, the RSPI shuts off the path between the MISOA pin and the shift register if the SPCR.MSTR bit is 1, and between the MOSIA pin and the shift register if the SPCR.MSTR bit is 0, and connects the input path and output path for the shift register (loopback mode).

#### MOIFV Bit (MOSI Idle Fixed Value)

If the MOIFE bit is 1 in master mode, the MOIFV bit determines the MOSIA pin output value during the SSL negation period (including the SSL retention period during a burst transfer).

#### MOIFE Bit (MOSI Idle Value Fixing Enable)

The MOIFE bit fixes the MOSIA output value when the RSPI in master mode is in an SSL negation period (including the SSL retention period during a burst transfer). When the MOIFE bit is 0, the RSPI outputs the last data from the previous serial transfer during the SSL negation period to the MOSIA pin. When the MOIFE bit is 1, the RSPI outputs the fixed value set in the MOIFV bit to the MOSIA pin.

### 35.2.4 RSPIC Status Register (SPSR)

Address(es): RSPIC0.SPSR 000D 0103h

|                    | b7   | b6 | b5    | b4   | b3   | b2   | b1    | b0   |

| b6  | —      | Reserved                   | This bit is read as 0. The write value should be 0.                                                                                                                                                                                                    | R/W             |
| b7  | SPRF   | Receive Buffer Full Flag   | 0: Receive buffer has no valid data<br>1: Receive buffer has valid data                                                                                                                                                                                | R*3             |

Note 1. Only 0 can be written to clear the flag after reading 1.

Note 2. Clear the MODF and UDRF flags at the same time.

Note 3. The write value should be 1.

#### OVRF Flag (Overrun Error Flag)

The OVRF flag indicates the occurrence of an overrun error. In master mode (when the SPCR.MSTR bit is 1) and when the RSPCK clock auto-stop function is enabled (the SPCR2.SCKASE bit is 1), an overrun error does not occur; accordingly this flag does not become 1. For details, refer to section 35.3.9.1, Overrun Error.

[Setting condition]

- When the next data reception ends while the SPCR.TXMD bit is 0 and the receive buffer is full.

[Clearing condition]

- When the SPSR register is read while the OVRF flag is 1, and then 0 is written to the OVRF flag.

**IDLNF Flag (Idle Flag)**

The IDLNF flag indicates the transfer status of the RSPI.

[Setting condition]

Master mode

- When both of the conditions in master mode under the [Clearing condition] below are not satisfied.

Slave mode

- When the SPCR.SPE bit is set to 1 (enables the RSPI function).

[Clearing condition]

Master mode

- When the SPCR.SPE bit is set to 0 (disables the RSPI function)
- When all of the following conditions are satisfied.
  1. The transmit buffer is empty (the SPTEF flag is 1)
  2. The SPSSR.SPCP[2:0] bits are 000b
  3. The transmission of the last bit has been completed and the time specified by the SSLND.SLNDL[2:0] and SPND.SPNDL[2:0] bits has elapsed

Slave mode

- When the SPCR.SPE bit is set to 0 (disables the RSPI function).

**MODF Flag (Mode Fault Error Flag)**

Indicates the occurrence of a mode fault error or an underrun error. The UDRF flag indicates whether the error is a mode fault error or an underrun error.

[Setting condition]

Multi-master mode

- When the input level of the SSLAi pin changes to the active level while the SPCR.MSTR bit is 1 (master mode) and the SPCR.MODFEN bit is 1 (mode fault error detection is enabled), the RSPI detects a mode fault error.

Slave mode

- When the SSLAi pin is negated before the RSPCK cycle necessary for data transfer ends while the SPCR.MSTR bit is 0 (slave mode) and the SPCR.MODFEN bit is 1 (mode fault error detection is enabled), the RSPI detects a mode fault error.
- When the serial transfer starts while the SPCR.SPE bit is 1 (enables the RSPI function) and the transmit data are not ready for output, the RSPI detects an underrun error.

The active level of the SSLAi signal is determined by the SSLP.SSLiP bit (SSLi signal polarity setting bit).

[Clearing condition]

- When the SPSR register is read while the MODF flag is 1, and then 0 is written to the MODF flag.

**PERF Flag (Parity Error Flag)**

Indicates the occurrence of a parity error.

[Setting condition]

- When a data reception ends while the SPCR.TXMD bit is 0 and the SPCR2.SPPE bit is 1, the RSPI detects a parity error.

[Clearing condition]

- When the SPSR register is read while the PERF flag is 1, and then 0 is written to the PERF flag.

**UDRF Flag (Underrun Error Flag)**

Indicates the occurrence of an underrun error. When this flag becomes 1, the MODF flag becomes 1 too. When the MODF flag is 1 and this flag is 0, the error is a mode fault error.

[Setting condition]

- When the serial transfer starts while the SPCR.MSTR bit is 0 (slave mode), the SPCR.SPE bit is 1 (enables the RSPI function), and the transmit data are not ready for output, the RSPI detects an underrun error

[Clearing condition]

- When 0 is written to the UDRF flag after reading the SPSR register while the UDRF flag is 1

**SPTEF Flag (Transmit Buffer Empty Flag)**

Indicates whether the transmit buffer (SPTX) in the RSPI data register has valid data.

[Setting condition]

- When the SPCR.SPE bit is set to 0 (disables the RSPI function).
- When the number of frames of transmit data specified by the SPDCR.SPFC[1:0] bits have been transferred from the transmit buffer to the shift register.

[Clearing condition]

- When the number of frames of transmit data specified by the SPDCR.SPFC[1:0] bits is written to the SPDR register.

The SPDR register can be set only when the SPTEF flag is 1. The data in the transmit buffer is not updated when the SPDR register is set while the SPTEF flag is 0.

**SPRF Flag (Receive Buffer Full Flag)**

Indicates whether the receive buffer (SPRX) in the RSPI data register has valid data.

[Setting condition]

- When the number of frames of receive data specified by the SPDCR.SPFC[1:0] bits is transferred from shift register to the receive buffer (SPRX) while the SPCR.TXMD bit is 0 (full duplex) and the SPRF flag is 0.  
Note that the SPRF flag does not become 1 when the OVRF flag is 1.

[Clearing condition]

- When all of the received data are read from the SPDR register.

### 35.2.5 RSPI Data Register (SPDR)

- When accessing in longword size

Address(es): RSPI0.SPDR 000D 0104h

- When accessing in word size

Address(es): RSPI0.SPDR.H 000D 0104h

- When accessing in byte size

Address(es): RSPI0.SPDR.HH 000D 0104h

The SPDR register is the interface with the buffers that hold data for transmission and reception by the RSPI. When accessing in longwords (the SPLW bit is 1 and the SPBYT bit is 0), access the SPDR register in 32-bit units. When accessing in words (the SPLW bit is 0 and the SPBYT bit is 0), access the SPDR.H register in 16-bit units. When accessing in bytes (the SPBYT bit is 1), access the SPDR.HH register in 8-bit units. The transmit buffer (SPTX) and receive buffer (SPRX) are independent but are both mapped to the SPDR register. Figure 35.2 shows the Configuration of the SPDR Register.

**Figure 35.2 Configuration of the SPDR Register**

The transmit and receive buffers each have four stages. The number of stages to be used is selectable by the number of frames specification bits in the RSPI data control register (SPDCR.SPFC[1:0]). The eight stages of the buffer are all mapped to the single address of the SPDR register.

Data written to the SPDR register are written to a transmit-buffer stage (SPTX $n$ ) ( $n = 0$  to 3) and then transmitted from the buffer. The receive buffer holds received data on completion of reception. The receive buffer is not updated if an overrun is generated.

Furthermore, if the data length is other than 32 bits, bits not referred to in SPTX $n$  ( $n = 0$  to 3) are stored in the corresponding bits in SPRX $n$ . For example, if the data length is 9 bits, received data are stored in the SPRX $n$ [8:0] bits and the SPTX $n$ [31:9] bits are stored in the SPRX $n$ [31:9] bits.

## (1) Bus Interface

The SPDR register is the interface with 32-bit wide transmit and receive buffers, each of which has four stages, for a total of 32 bytes. In other words, the 32 bytes are mapped to the 4-byte address space for the SPDR register. Furthermore, the unit of access for the SPDR register is selected by the SPDCR.SPLOW bit and the SPDCR.SPBYT bit.

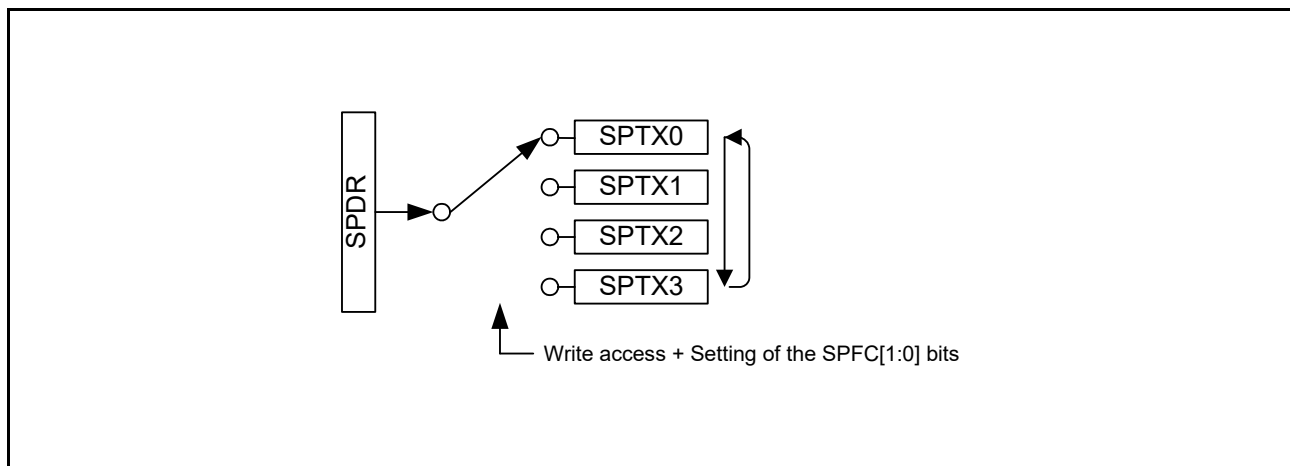

Data for transmission should be flush with the LSB end of the register. Received data are stored flush with the LSB end. Operations involved in writing to and reading from the SPDR register are described below.

### (a) Writing

Data written to the SPDR register are written to a transmit buffer (SPTX<sub>n</sub>). This is not influenced by the value of the SPDCR.SPRDTD bit unlike when reading from the SPDR register.

The transmit buffer includes a transmit buffer write pointer which is automatically updated to indicate the next stage each time data are written to the SPDR register.

Figure 35.3 shows the configuration of the bus interface with the transmit buffer in the case of writing to the SPDR register.

**Figure 35.3 Configuration of the SPDR Register (Writing)**

The sequence for switching the transmit buffer write pointer differs with the setting of the number of frames specification bits in the RSPI data control register (SPDCR.SPFC[1:0]).

- Settings of the SPFC[1:0] bits and sequence of switching the pointer among SPTX0 to SPTX3.
  - When the SPFC[1:0] bits are 00b: SPTX0 → SPTX0 → SPTX0 → ...
  - When the SPFC[1:0] bits are 01b: SPTX0 → SPTX1 → SPTX0 → SPTX1 → ...
  - When the SPFC[1:0] bits are 10b: SPTX0 → SPTX1 → SPTX2 → SPTX0 → SPTX1 → ...
  - When the SPFC[1:0] bits are 11b: SPTX0 → SPTX1 → SPTX2 → SPTX3 → SPTX0 → SPTX1 → ...

When 1 is written to the RSPI function enable bit in the RSPI control register (SPCR.SPE) while the bit's current value is 0, SPTX0 will be the destination the next time writing proceeds.

When writing to the transmit buffer (SPTX<sub>n</sub>) after generation of the transmit buffer empty interrupt (after the SPSR.SPTEF flag becomes 1), write the number of frames set by the number of frames specification bits (SPFC[1:0]) in the RSPI data control register (SPDCR). Even if the number of frames is written to the transmit buffer (SPTX<sub>n</sub>), the value of the buffer is not updated after completion of the writing and before generation of the next transmit buffer empty interrupt (while the SPSR.SPTEF flag is 0).

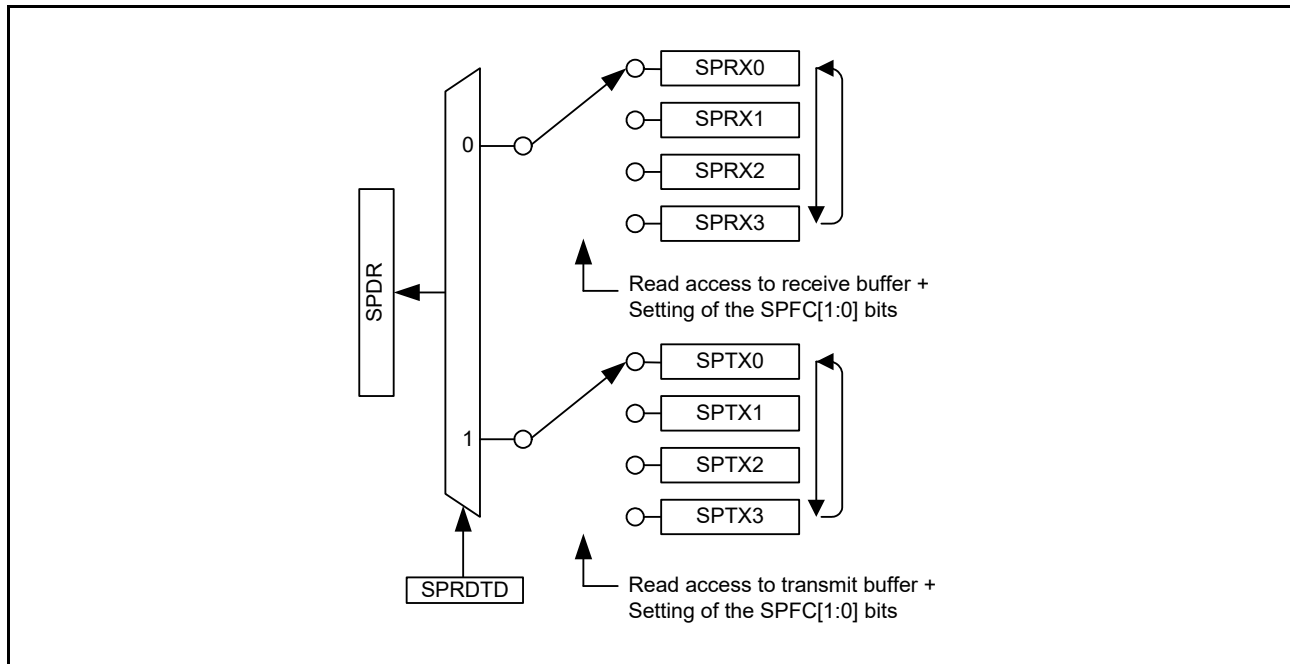

## (b) Reading

The SPDR register can be read to read the value of a receive buffer (SPRXn) or a transmit buffer (SPTXn). The setting of the RSPI receive/transmit data select bit in the RSPI data control register (SPDCR.SPRDTD) selects whether reading is of the receive or transmit buffer.

The sequence of reading the SPDR register is controlled by independent pointers, receive buffer read pointer and transmit buffer read pointer.

Figure 35.4 shows the configuration of the bus interface with the receive and transmit buffers in the case of reading from the SPDR register.

**Figure 35.4 Configuration of the SPDR Register (Reading)**

Reading the receive buffer switches the receive buffer read pointer to the next buffer automatically.

The sequence of switching the receive buffer read pointer is the same as that for the transmit buffer write pointer.

However, when 1 is written to the RSPI function enable bit in the RSPI control register (SPCR.SPE) while the bit's current value is 0, SPRX0 will be indicated by the buffer read pointer the next time reading proceeds.

The transmit buffer read pointer is updated when writing to the SPDR register, and not updated when reading from the transmit buffer. When reading from the transmit buffer, the value most recently written to the SPDR register is read.

However, after generation of the transmit buffer empty interrupt, the values read from the transmit buffer are all 0 in the interval after completion of writing the number of frames of data specified in the number of frames specification bits (SPDCR.SPFC[1:0]) and before generation of the next buffer empty interrupt (while the SPSR.SPTEF flag is 0).

### 35.2.6 RSPI Sequence Control Register (SPSCR)

Address(es): RSPI0.SPSCR 000D 0108h

| Bit      | Symbol     | Bit Name                           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | R/W |    |                 |                                             |        |   |  |         |        |   |  |           |        |   |  |             |        |   |  |               |        |   |  |                 |        |   |  |                   |        |   |  |                     |        |   |  |                       |     |

| b2 to b0 | SPSLN[2:0] | RSPI Sequence Length Specification | <table border="0"> <tr> <td>b2</td> <td>b0</td> <td>Sequence Length</td> <td>Referenced SPCMD0 to SPCMD7 registers (No.)</td> </tr> <tr> <td>0 0 0:</td> <td>1</td> <td></td> <td>0→0→...</td> </tr> <tr> <td>0 0 1:</td> <td>2</td> <td></td> <td>0→1→0→...</td> </tr> <tr> <td>0 1 0:</td> <td>3</td> <td></td> <td>0→1→2→0→...</td> </tr> <tr> <td>0 1 1:</td> <td>4</td> <td></td> <td>0→1→2→3→0→...</td> </tr> <tr> <td>1 0 0:</td> <td>5</td> <td></td> <td>0→1→2→3→4→0→...</td> </tr> <tr> <td>1 0 1:</td> <td>6</td> <td></td> <td>0→1→2→3→4→5→0→...</td> </tr> <tr> <td>1 1 0:</td> <td>7</td> <td></td> <td>0→1→2→3→4→5→6→0→...</td> </tr> <tr> <td>1 1 1:</td> <td>8</td> <td></td> <td>0→1→2→3→4→5→6→7→0→...</td> </tr> </table> <p>The order in which the SPCMD0 to SPCMD7 registers are to be referenced is changed according to the sequence length that is set in these bits. The relationship among the setting of these bits, sequence length, and the SPCMD0 to SPCMD7 registers referenced by the RSPI is shown above. However, the RSPI in slave mode references the SPCMD0 register.</p> | b2  | b0 | Sequence Length | Referenced SPCMD0 to SPCMD7 registers (No.) | 0 0 0: | 1 |  | 0→0→... | 0 0 1: | 2 |  | 0→1→0→... | 0 1 0: | 3 |  | 0→1→2→0→... | 0 1 1: | 4 |  | 0→1→2→3→0→... | 1 0 0: | 5 |  | 0→1→2→3→4→0→... | 1 0 1: | 6 |  | 0→1→2→3→4→5→0→... | 1 1 0: | 7 |  | 0→1→2→3→4→5→6→0→... | 1 1 1: | 8 |  | 0→1→2→3→4→5→6→7→0→... | R/W |

The write value should be 0.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         | R/W |    |                 |                                             |        |   |  |         |        |   |  |           |        |   |  |             |        |   |  |               |        |   |  |                 |        |   |  |                   |        |   |  |                     |        |   |  |                       |     |

The SPSCR register sets the sequence length when the RSPI operates in master mode. When changing the SPSCR.SPSSLN[2:0] bits while both the SPCR.MSTR and SPCR.SPE bits are 1, the bits should be changed while the SPSR.IDLNF flag is 0.

#### SPSLN[2:0] Bits (RSPI Sequence Length Specification)

The SPSLN[2:0] bits specify a sequence length when the RSPI in master mode performs sequential operations. The RSPI in master mode changes the SPCMD0 to SPCMD7 registers to be referenced and the order in which they are referenced according to the sequence length that is set in the SPSLN[2:0] bits.

In slave mode, the SPCMD0 register is referred.

### 35.2.7 RSPI Sequence Status Register (SPSSR)

Address(es): RSPI0.SPSSR 000D 0109h

| b7       | —          | Reserved             | This bit is read as 0.                                                                                                                        | R   |

The SPSSR register indicates the sequence control status when the RSPI operates in master mode. Any writing to the SPSSR register is ignored.

#### SPCP[2:0] Bits (RSPI Command Pointer)

The SPCP[2:0] bits indicate the SPCMD<sub>m</sub> register that is currently pointed to by the pointer during sequence control by the RSPI.

For the RSPI's sequence control, refer to section 35.3.11.1, Master Mode Operation.

#### SPECM[2:0] Bits (RSPI Error Command)

The SPECM[2:0] bits indicate the SPCMD<sub>m</sub> register that is specified by the SPCP[2:0] bits when an error is detected during sequence control by the RSPI. The RSPI updates the SPECM[2:0] bits only when an error is detected. If both the SPSR.OVRF and SPSR.MODF flags are 0 and there is no error, the values of the SPECM[2:0] bits have no meaning.

For the RSPI's error detection function, refer to section 35.3.9, Error Detection. For the RSPI's sequence control, refer to section 35.3.11.1, Master Mode Operation.

### 35.2.8 RSPI Bit Rate Register (SPBR)

Address(es): RSPI0.SPBR 000D 010Ah

The SPBR register sets the bit rate in master mode. Do not change the SPBR register while both the SPCR.MSTR and SPCR.SPE bits are 1.

When the RSPI is used in slave mode, the bit rate depends on the bit rate of the input clock (bit rate satisfying the electrical characteristics should be used) regardless of the settings of the SPBR register and the SPCMDm.BRDV[1:0] bits (bit rate division setting bits).

The bit rate is determined by combinations of the SPBR register setting and the SPCMDm.BRDV[1:0] bit setting. The equation for calculating the bit rate is given below. In the equation, n denotes the SPBR register setting (0, 1, 2, ..., 255), and N denotes the BRDV[1:0] bit setting (0, 1, 2, 3).

$$\text{Bit rate} = \frac{f(\text{PCLK})}{2 \times (n + 1) \times 2^N}$$

Table 35.3 lists examples of the relationship among the SPBR register settings, the BRDV[1:0] bit settings, and bit rates.

Use the bit rate that meets electrical characteristics based on the AC specifications of the target device.

**Table 35.3 Relationship among SPBR Settings, BRDV[1:0] Settings, and Bit Rates**

| SPBR (n) | BRDV[1:0] Bits (N) | Division Ratio | Bit Rate      |               |               |               |               |               |                |                |
|----------|--------------------|----------------|---------------|---------------|---------------|---------------|---------------|---------------|----------------|----------------|
|          |                    |                | PCLK = 32 MHz | PCLK = 36 MHz | PCLK = 40 MHz | PCLK = 50 MHz | PCLK = 60 MHz | PCLK = 80 MHz | PCLK = 100 MHz | PCLK = 120 MHz |

| b6     | SPBYT     | RSPI Byte Access Specification                   | 0: The SPDR register is accessed in words or longwords (the SPLW bit is enabled)<br>1: The SPDR register is accessed in bytes (the SPLW bit is disabled) | R/W |
| b7     | —         | Reserved                                         | This bit is read as 0. The write value should be 0.                                                                                                      | R/W |

Note 1. Set the SPBYT bit to 0, when accessing the SPDR register in words or longwords.

Up to four frames can be transmitted or received in one round of transmission or reception activation. The amount of data in each transfer is controlled by the combination of the SPCMDm.SPB[3:0] bits, the SPSCR.SPSSLN[2:0] bits, and the SPDCR.SPFC[1:0] bits.

When changing the SPDCR.SPFC[1:0] bits while the SPCR.SPE bit is 1, the bits should be changed while the SPSR.IDLNF flag is 0.

#### SPFC[1:0] Bits (Number of Frames Specification)

The SPFC[1:0] bits specify the number of frames that can be stored in the SPDR register (per transfer activation). Up to four frames can be transmitted or received in one round of transmission or reception, and the amount of data is determined by the combination of the SPSCR.SPSSLN[2:0] bits, and the SPDCR.SPFC[1:0] bits. Furthermore, the setting of the SPFC[1:0] bits adjusts the number of frames for generation of receive buffer full interrupt, and start of transmission or generation of transmit buffer empty interrupts.

When the number of frames of transmit data specified by SPFC[1:0] bits is written to the SPDR register, the SPSR.SPTEF flag becomes 0 and transmission starts. Then, when the specified number of frames of transmit data has been transferred to the shift register, the SPTEF flag becomes 1 and the RSPI transmit buffer empty interrupt is generated.

When the number of frames specified by the SPFC[1:0] bits are received, the SPSR.SPRF flag becomes 1 and the receive buffer full interrupt is generated.

Table 35.4 lists the frame configurations that can be stored in the SPDR register and examples of combinations of settings for transmission and reception. Do not select the combinations of settings other than those shown in the examples.

**Table 35.4** Settable Combinations of SPSLN[2:0] Bits and SPFC[1:0] Bits

| Setting | SPSLN[2:0] | SPFC[1:0] | Number of Frames in a Single Sequence | Number of Frames at which Transmit Buffer or Receive Buffer Status Becomes “Has Valid Data” |
|---------|------------|-----------|---------------------------------------|---------------------------------------------------------------------------------------------|
| 1-1     | 000b       | 00b       | 1                                     | 1                                                                                           |
| 1-2     | 000b       | 01b       | 2                                     | 2                                                                                           |
| 1-3     | 000b       | 10b       | 3                                     | 3                                                                                           |
| 1-4     | 000b       | 11b       | 4                                     | 4                                                                                           |
| 2-1     | 001b       | 01b       | 2                                     | 2                                                                                           |
| 2-2     | 001b       | 11b       | 4                                     | 4                                                                                           |
| 3       | 010b       | 10b       | 3                                     | 3                                                                                           |
| 4       | 011b       | 11b       | 4                                     | 4                                                                                           |
| 5       | 100b       | 00b       | 5                                     | 1                                                                                           |
| 6       | 101b       | 00b       | 6                                     | 1                                                                                           |
| 7       | 110b       | 00b       | 7                                     | 1                                                                                           |
| 8       | 111b       | 00b       | 8                                     | 1                                                                                           |

**SPRDTD Bit (RSPI Receive/Transmit Data Select)**

The SPRDTD bit selects whether the SPDR register reads values from the receive buffer or from the transmit buffer. If reading is from the transmit buffer, the value written to the SPDR register immediately beforehand is read.

When reading the transmit buffer, do so before writing of the number of frames set in the SPFC[1:0] bits is finished and after generation of the transmit buffer empty interrupt (While the SPSR.SPTEF flag is 1).

For details, refer to section 35.2.5, RSPI Data Register (SPDR).

**SPLW Bit (RSPI Longword Access/Word Access Specification)**

The SPLW bit specifies the access width for the SPDR register. This bit setting is enabled when the SPBYT bit is 0. Access to the SPDR register in words when the SPLW bit is 0 and in longwords when the SPLW bit is 1.

Also, when the SPLW bit is 0, set the SPCMDm.SPB[3:0] bits (RSPI data length setting bits) to 8 to 16 bits. Do not select 20, 24, or 32 bits.

**SPBYT Bit (RSPI Byte Access Specification)**

The SPBYT bit specifies the access width for the SPDR register. Access to the SPDR register according to the SPLW bit setting when the SPBYT bit is 0. Access to the SPDR register in bytes when the SPBYT bit is 1.

When the SPBYT bit is 1, set the SPCMDm.SPB[3:0] bits (RSPI data length setting bits) to 8 bits. Do not select 9 to 16, 20, 24, or 32 bits.

### 35.2.10 RSPI Clock Delay Register (SPCKD)

Address(es): RSPIC.SPCKD 000D 010Ch

| Bit      | Symbol     | Bit Name            | Description                                                                                                                                           | R/W |
|----------|------------|---------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------|-----|
| b2 to b0 | SCKDL[2:0] | RSPCK Delay Setting | b2 b0<br>0 0 0: 1 RSPCK<br>0 0 1: 2 RSPCK<br>0 1 0: 3 RSPCK<br>0 1 1: 4 RSPCK<br>1 0 0: 5 RSPCK<br>1 0 1: 6 RSPCK<br>1 1 0: 7 RSPCK<br>1 1 1: 8 RSPCK | R/W |
| b7 to b3 | —          | Reserved            | These bits are read as 0. The write value should be 0.                                                                                                | R/W |

The SPCKD register sets a period from the beginning of SSLAi signal assertion to RSPCK oscillation (RSPCK delay) when the SPCMDm.SCKDEN bit is 1. Do not change the SPCKD register while both the SPCR.MSTR and SPCR.SPE bits are 1.

#### SCKDL[2:0] Bits (RSPCK Delay Setting)

The SCKDL[2:0] bits set an RSPCK delay value when the SPCMDm.SCKDEN bit is 1.

When using the RSPIC in slave mode, set the SCKDL[2:0] bits to 000b.

### 35.2.11 RSPI Slave Select Negation Delay Register (SSLND)

Address(es): RSPI0.SSLND 000D 010Dh

| Bit      | Symbol     | Bit Name                   | Description                                                                                                                                           | R/W |
|----------|------------|----------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------|-----|
| b2 to b0 | SLNDL[2:0] | SSL Negation Delay Setting | b2 b0<br>0 0 0: 1 RSPCK<br>0 0 1: 2 RSPCK<br>0 1 0: 3 RSPCK<br>0 1 1: 4 RSPCK<br>1 0 0: 5 RSPCK<br>1 0 1: 6 RSPCK<br>1 1 0: 7 RSPCK<br>1 1 1: 8 RSPCK | R/W |
| b7 to b3 | —          | Reserved                   | These bits are read as 0. The write value should be 0.                                                                                                | R/W |

The SSLND register sets a period (SSL negation delay) from the transmission of a final RSPCK edge to the negation of the SSLAi signal during a serial transfer by the RSPI in master mode. Do not change the SSLND register while both the SPCR.MSTR and SPCR.SPE bits are 1.

#### SLNDL[2:0] Bits (SSL Negation Delay Setting)

The SLNDL[2:0] bits set an SSL negation delay value when the SPCMDm.SLNDEN bit is 1.

When using the RSPI in slave mode, set the SLNDL[2:0] bits to 000b.

### 35.2.12 RSPI Next-Access Delay Register (SPND)

Address(es): RSPIO.SPND 000D 010Eh

| Bit      | Symbol     | Bit Name                       | Description                                                                                                                                                                                                                   | R/W |
|----------|------------|--------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----|
| b2 to b0 | SPNDL[2:0] | RSPI Next-Access Delay Setting | b2 b0<br>0 0 0: 1 RSPCK + 2 PCLK<br>0 0 1: 2 RSPCK + 2 PCLK<br>0 1 0: 3 RSPCK + 2 PCLK<br>0 1 1: 4 RSPCK + 2 PCLK<br>1 0 0: 5 RSPCK + 2 PCLK<br>1 0 1: 6 RSPCK + 2 PCLK<br>1 1 0: 7 RSPCK + 2 PCLK<br>1 1 1: 8 RSPCK + 2 PCLK | R/W |
| b7 to b3 | —          | Reserved                       | These bits are read as 0. The write value should be 0.                                                                                                                                                                        | R/W |

SPND sets a non-active period (next-access delay) of the SSLAi signal after termination of a serial transfer when the SPCMDm.SPNDEN bit is 1. Do not change the SPND register while both the SPCR.MSTR and SPCR.SPE bits are 1.

#### SPNDL[2:0] Bits (RSPI Next-Access Delay Setting)

The SPNDL[2:0] bits set a next-access delay when the SPCMDm.SPNDEN bit is 1. When using the RSPI in slave mode, set the SPNDL[2:0] bits to 000b.

### 35.2.13 RSPI Control Register 2 (SPCR2)

Address(es): RSPI0.SPCR2 000D 010Fh

| Bit      | Symbol | Bit Name                          | Description                                                                                                                                                                            | R/W |
|----------|--------|-----------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----|
| b0       | SPPE   | Parity Enable*1                   | 0: Does not add the parity bit to transmit data and does not check the parity bit of receive data<br>1: Adds the parity bit to transmit data and checks the parity bit of receive data | R/W |
| b1       | SPOE   | Parity Mode*1                     | 0: Selects even parity for use in transmission and reception<br>1: Selects odd parity for use in transmission and reception                                                            | R/W |
| b2       | SPIIE  | Idle Interrupt Enable             | 0: Disables the generation of idle interrupt requests<br>1: Enables the generation of idle interrupt requests                                                                          | R/W |
| b3       | PTE    | Parity Self-Diagnosis             | 0: Disables the self-diagnosis function of the parity circuit<br>1: Enables the self-diagnosis function of the parity circuit                                                          | R/W |
| b4       | SCKASE | RSPCK Auto-Stop Function Enable*1 | 0: Disables the RSPCK auto-stop function<br>1: Enables the RSPCK auto-stop function                                                                                                    | R/W |
| b7 to b5 | —      | Reserved                          | These bits are read as 0. The write value should be 0.                                                                                                                                 | R/W |

Note 1. Do not change the SPPE, SPOE, and SCKASE bits while the SPCR.SPE bit is 1.

#### SPPE Bit (Parity Enable)

The SPPE bit enables or disables the parity function.

#### SPOE Bit (Parity Mode)

The SPOE bit specifies odd or even parity.

When even parity is set, parity bit addition is performed so that the total number of 1-bits in the transmit/receive character plus the parity bit is even. Similarly, when odd parity is set, parity bit addition is performed so that the total number of 1-bits in the transmit/receive character plus the parity bit is odd.

The SPOE bit is valid only when the SPPE bit is 1.

#### SPIIE Bit (Idle Interrupt Enable)

The SPIIE bit enables or disables the generation of idle interrupt requests when the RSPI being in the idle state is detected and the SPSR.IDLNF flag is set to 0.

#### PTE Bit (Parity Self-Diagnosis)

The PTE bit enables the self-diagnosis function of the parity circuit in order to check whether the parity function is operating correctly.

#### SCKASE Bit (RSPCK Auto-Stop Function Enable)

The SCKASE bit enables or disables the RSPCK auto-stop function. When this function is enabled, the RSPCK clock is stopped before an overrun error occurs when data is received in master mode. For details, refer to section 35.3.9.1, Overrun Error.

## 35.2.14 RSPI Command Register m (SPCMDm) (m = 0 to 7)

| b14       | SLNDEN    | SSL Negation Delay Setting Enable | 0: An SSL negation delay of 1 RSPCK<br>1: An SSL negation delay is equal to the setting of the RSPI slave select negation delay register (SSLND)                                                                                                             | R/W |
| b15       | SCKDEN    | RSPCK Delay Setting Enable        | 0: An RSPCK delay of 1 RSPCK<br>1: An RSPCK delay is equal to the setting of the RSPI clock delay register (SPCKD)                                                                                                                                           | R/W |

x: Don't care

The SPCMDm register is used to set a transfer format for the RSPI in master mode. Each channel has eight RSPI command registers (SPCMD0 to SPCMD7). Some of the bits in the SPCMD0 register is used to set a transfer mode for the RSPI in slave mode. The RSPI in master mode sequentially references the SPCMDm register according to the settings in the SPSCR.SPSSLN[2:0] bits, and executes the serial transfer that is set in the referenced SPCMDm register. SPCMDm register should be set while the transmit buffer is empty (data for the next transfer is not set) and before setting of the data that is to be transmitted when that SPCMDm register is referenced.

An SPCMDm register that is referenced by the RSPI in master mode can be checked by means of the SPSSR.SPCP[2:0] bits. Do not change the SPCMDm register while the SPCR.MSTR bit is 0 and the SPCR.SPE bit is 1.

#### **CPHA Bit (RSPCK Phase Setting)**

The CPHA bit sets an RSPCK phase of the RSPI in master mode or slave mode. Data communications between RSPI modules require the same RSPCK phase setting between the modules.

#### **CPOL Bit (RSPCK Polarity Setting)**

The CPOL bit sets an RSPCK polarity of the RSPI in master mode or slave mode. Data communications between RSPI modules require the same RSPCK polarity setting between the modules.

#### **BRDV[1:0] Bits (Bit Rate Division Setting)**

The BRDV[1:0] bits are used to determine the bit rate. A bit rate is determined by combinations of the settings in the BRDV[1:0] bits and the SPBR register (refer to section 35.2.8, RSPI Bit Rate Register (SPBR)). The settings in the SPBR register determine the base bit rate. The settings in the BRDV[1:0] bits are used to select a bit rate which is obtained by dividing the base bit rate by 1, 2, 4, or 8. In the SPCMDm register, different BRDV[1:0] bit settings can be specified. This enables execution of serial transfers at a different bit rate for each command.

#### **SSLA[2:0] Bits (SSL Signal Assertion Setting)**

The SSLA[2:0] bits control the SSLAi signal assertion when the RSPI performs serial transfers in master mode.

Setting the SSLA[2:0] bits controls the assertion for the SSLAi signal. When an SSLAi signal is asserted, its polarity is determined by the set value in the corresponding SSLP. When the SSLA[2:0] bits are set to 000b in multi-master mode, serial transfers are performed with all the SSL signals in the negated state (as the SSLA0 pin acts as input).

When using the RSPI in slave mode, set the SSLA[2:0] bits to 000b.

#### **SSLKP Bit (SSL Signal Level Keeping)**

When the RSPI in master mode performs a serial transfer, the SSLKP bit specifies whether the SSLAi signal level for the current command is to be kept or negated between the SSL negation timing associated with the current command and the SSL assertion timing associated with the next command.

Setting the SSLKP bit to 1 enables a burst transfer. For details, refer to section 35.3.11.1, Master Mode Operation (4) Burst Transfer.

When using the RSPI in slave mode, the SSLKP bit should be set to 0.

#### **SPB[3:0] Bits (RSPI Data Length Setting)**

The SPB[3:0] bits set a transfer data length for the RSPI in master mode or slave mode. When the SPDCR.SPBYT is 1, set the SPB[3:0] bits to 0100b (8 bits). When the SPBYT bit is 0 and the SPDCR.SPLW bit is 0, set the SPB[3:0] bits to 0100b (8 bits) to 1111b (16 bits).

#### **LSBF Bit (RSPI LSB First)**

The LSBF bit sets the data format of the RSPI in master mode or slave mode to MSB first or LSB first.

**SPNDEN Bit (RSPI Next-Access Delay Enable)**

The SPNDEN bit sets the period from the time the RSPI in master mode terminates a serial transfer and sets the SSLAi signal inactive until the RSPI enables the SSLAi signal assertion for the next access (next-access delay). If the SPNDEN bit is 0, the RSPI sets the next-access delay to 1 RSPCK + 2 PCLK. If the SPNDEN bit is 1, the RSPI inserts a next-access delay in compliance with the SPND setting.

When using the RSPI in slave mode, the SPNDEN bit should be set to 0.

**SLNDEN Bit (SSL Negation Delay Setting Enable)**

The SLNDEN bit sets the period from the time the RSPI in master mode stops RSPCK oscillation until the RSPI sets the SSLAi signal inactive (SSL negation delay). If the SLNDEN bit is 0, the RSPI sets the SSL negation delay to 1 RSPCK. If the SLNDEN bit is 1, the RSPI negates the SSL signal at an SSL negation delay in compliance with the SSLND setting.

When using the RSPI in slave mode, the SLNDEN bit should be set to 0.

**SCKDEN Bit (RSPCK Delay Setting Enable)**

The SCKDEN bit sets the period from the point when the RSPI in master mode activates the SSLAi signal until the RSPCK starts oscillation (RSPI clock delay). If the SCKDEN bit is 0, the RSPI sets the RSPCK delay to 1 RSPCK. If the SCKDEN bit is 1, the RSPI starts the oscillation of RSPCK at an RSPCK delay in compliance with the SPCKD setting.

When using the RSPI in slave mode, the SCKDEN bit should be set to 0.

### 35.2.15 RSPIC Data Control Register 2 (SPDCR2)

Address(es): RSPIC0.SPDCR2 000D 0120h

| Bit      | Symbol | Bit Name  | Description                                                                     | R/W |
|----------|--------|-----------|---------------------------------------------------------------------------------|-----|
| b0       | BYSW   | Byte Swap | 0: Byte swapping of SPDR data disabled<br>1: Byte swapping of SPDR data enabled | R/W |
| b7 to b1 | —      | Reserved  | These bits are read as 0. The write value should be 0.                          | R/W |

This register is used to enable or disable byte swapping of transmit and receive data. The SPCR.SPE bit should be 0 when rewriting this register.

#### BYSW Bit (Byte Swap)

On transmit, this bit specifies that data bytes written in the SPDR register will be swapped before being transmitted. On receive, this bit specifies that received bytes will be swapped before the data is transferred to the SPDR register. This bit setting is enabled when the SPDCR.SPBYT bit is 0.

When using byte swap, set the SPCMD.SPB[3:0] bits to 1111b (16 bits), 0010b (32 bits), or 0011b (32 bits). Also, set the SPCR2.SPPE bit to 0 (parity bit not added). For details, refer to sections 35.3.4.3 Byte Swap Transmission and 35.3.4.4 Byte Swap Reception.

### 35.3 Operation

In this section, the serial transfer period means a period from the beginning of driving valid data to the fetching of the final valid data.

#### 35.3.1 Overview of RSPI Operations

The RSPI is capable of synchronous serial transfers in slave mode (SPI operation), single-master mode (SPI operation), multi-master mode (SPI operation), slave mode (clock synchronous operation), and master mode (clock synchronous operation). A particular mode of the RSPI can be selected by using the MSTR, MODFEN, and SPMS bits in SPCR.

Table 35.5 lists the relationship between RSPI modes and SPCR settings, and a description of each mode.

**Table 35.5 Relationship between RSPI Modes and SPCR Settings and Description of Each Mode**

| Mode                            | SPI Operation                         |                                                                                                                  |                                                                                                                  | Clock Synchronous Operation |                                                                                                                  |

Note 1. When SSLA0 is asserted by another master device, the pin becomes Hi-Z.

Note 2. When SSLA0 is negated or the SPCR.SPE bit is 0, the pin becomes Hi-Z.

Note 3. This function is not supported in this mode.

Note 4. When the SPCR.TXMD bit is 1, the detections of receiver buffer full, overrun error, and parity error are not performed.

Note 5. When the SPCR2.SPPE bit is 0, the detection of parity error is not performed.

Note 6. When the SPCR2.SCKASE bit is 1, the detection of overrun error is not performed.

### 35.3.2 Controlling RSPI Pins

The RSPI in single-master mode (SPI operation) or multi-master mode (SPI operation) determines MOSI signal values during the SSL negation period (including the SSL retention period during a burst transfer) according to MOIFE and MOIFV bit settings in SPPCR, as listed in Table 35.6.

**Table 35.6 MOSI Signal Value Determination during SSL Negation Period**

| MOIFE Bit | MOIFV Bit | MOSIA Signal Value during SSL Negation Period |
|-----------|-----------|-----------------------------------------------|
| 0         | 0, 1      | Final data from previous transfer             |
| 1         | 0         | Low                                           |
| 1         | 1         | High                                          |

### 35.3.3 RSPIC System Configuration Examples

#### 35.3.3.1 Single Master/Single Slave (with This MCU Acting as Master)

Figure 35.5 shows a single-master/single-slave RSPIC system configuration example when this MCU is used as a master. In the single-master/single-slave configuration, the SSLA0 to SSLA3 output of this MCU (master) are not used. The SSL input of the SPI slave is fixed to the low level, and the SPI slave is maintained in a select state.\*1

This MCU (master) drives the RSPCKA and MOSIA. The SPI slave drives the MISO.

Note 1. In the transfer format corresponding to the case where the SPCMDm.CPHA bit is 0, there are slave devices for which the SSL signal cannot be fixed to the active level. In situations where the SSL signal cannot be fixed, the SSLAi output of this MCU should be connected to the SSL input of the slave device.

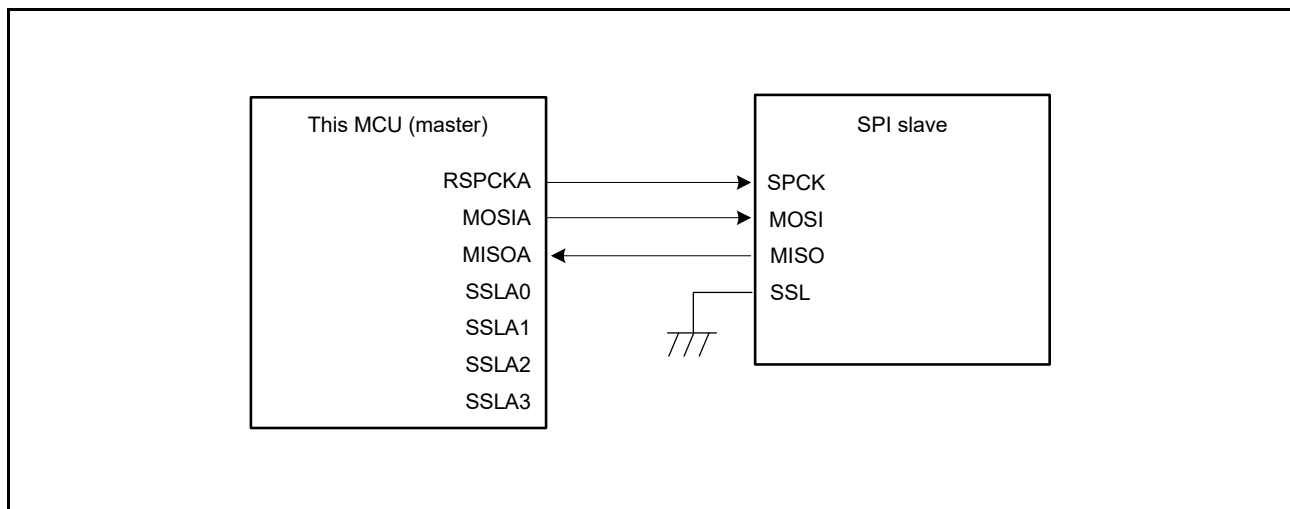

Figure 35.5 Single-Master/Single-Slave Configuration Example (This MCU = Master)

### 35.3.3.2 Single Master/Single Slave (with This MCU Acting as Slave)

Figure 35.6 shows a single-master/single-slave RSPIC system configuration example when this MCU is used as a slave. When this MCU is to operate as a slave, the SSLA0 pin is used as SSL input. The SPI master drives the RSPCK and MOSI. This MCU (slave) drives the MISOA.\*1

In the single-slave configuration in which the SPCMDm.CPHA bit is set to 1, the SSLA0 input of this MCU (slave) is fixed to the low level, this MCU (slave) is maintained in a select state, and in this manner it is possible to execute serial transfer (Figure 35.7).

Note 1. When SSLA0 is at the non-active level, the pin state is Hi-Z.

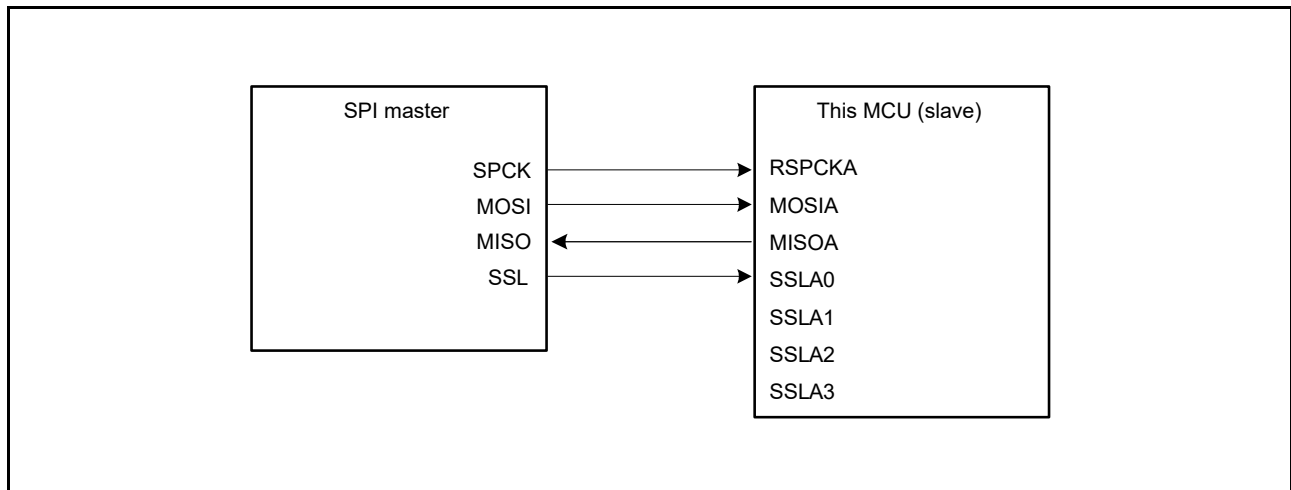

Figure 35.6 Single-Master/Single-Slave Configuration Example (This MCU = Slave, CPHA = 0)

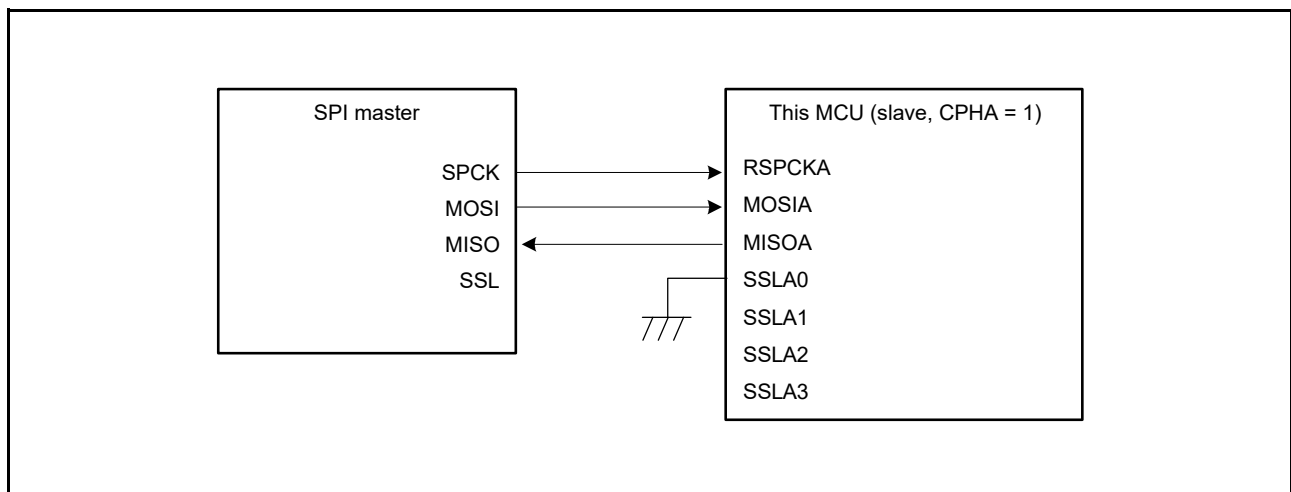

Figure 35.7 Single-Master/Single-Slave Configuration Example (This MCU = Slave, CPHA = 1)

### 35.3.3.3 Single Master/Multi-Slave (with This MCU Acting as Master)

Figure 35.8 shows a single-master/multi-slave RSPI system configuration example when this MCU is used as a master. In the example of Figure 35.8, the RSPI system is comprised of this MCU (master) and four slaves (SPI slave 0 to SPI slave 3).

The RSPCKA and MOSIA outputs of this MCU (master) are connected to the RSPCK and MOSI inputs of SPI slave 0 to SPI slave 3. The MISO outputs of SPI slave 0 to SPI slave 3 are all connected to the MISOA input of this MCU (master). SSLA0 to SSLA3 outputs of this MCU (master) are connected to the SSL inputs of SPI slave 0 to SPI slave 3, respectively.

This MCU (master) drives RSPCKA, MOSIA, and SSLA0 to SSLA3. Of the SPI slave 0 to SPI slave 3, the slave that receives low-level input into the SSL input drives MISO.

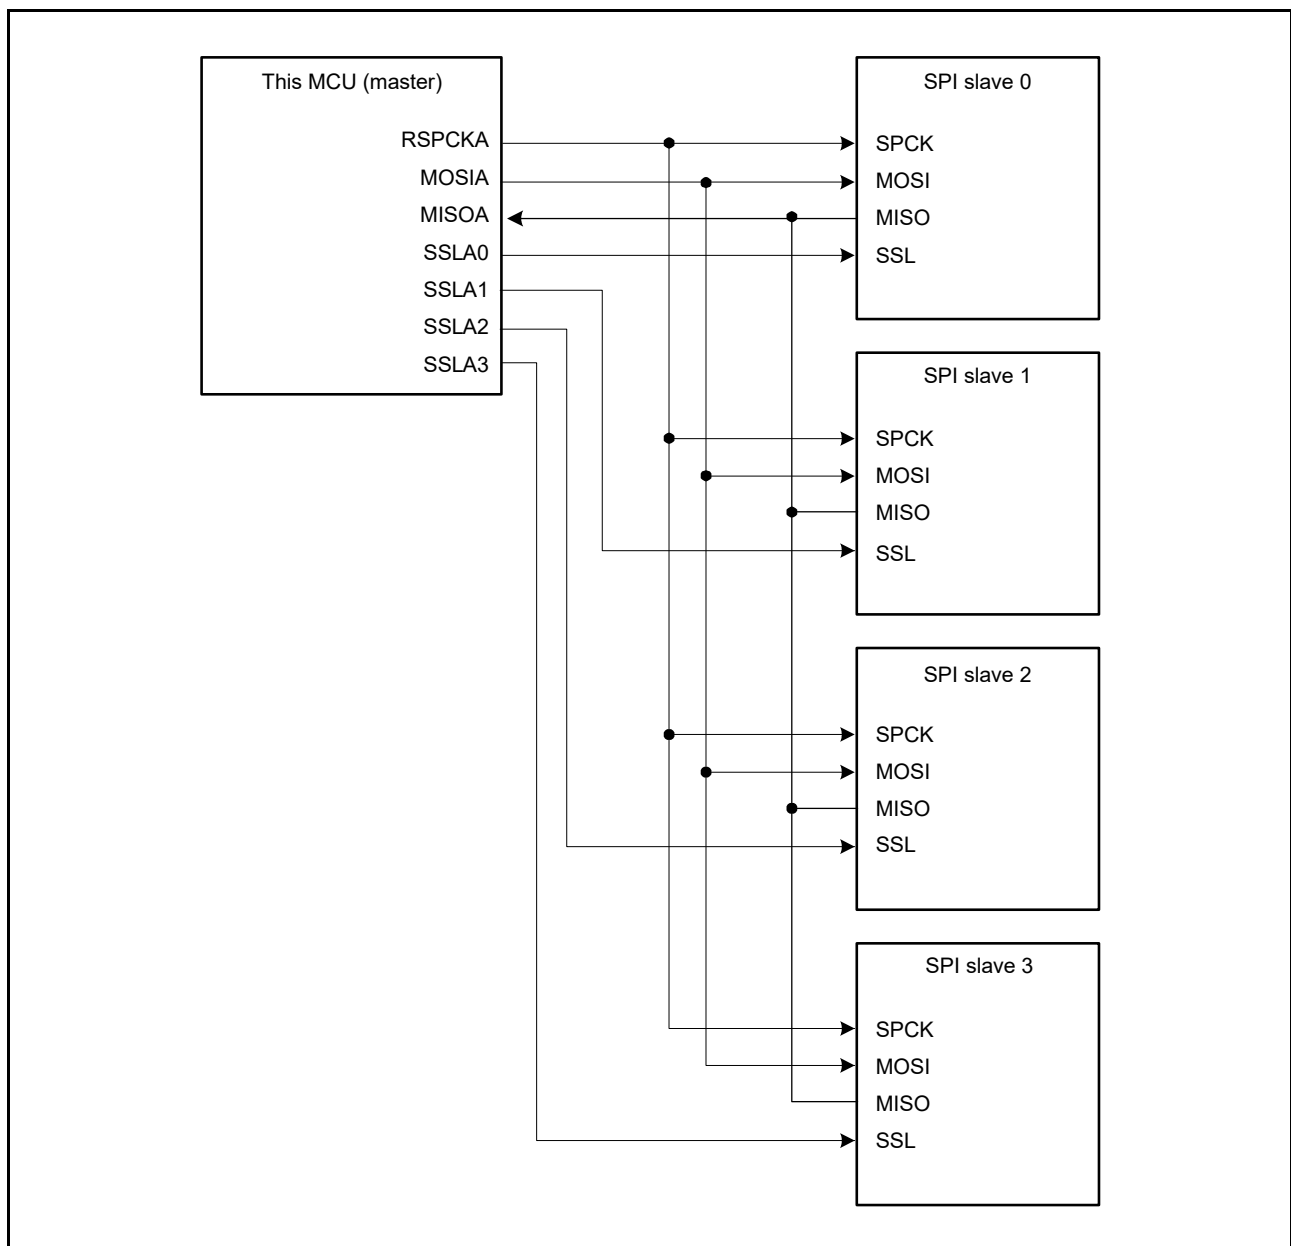

Figure 35.8 Single-Master/Multi-Slave Configuration Example (This MCU = Master)

### 35.3.3.4 Single Master/Multi-Slave (with This MCU Acting as Slave)

Figure 35.9 shows a single-master/multi-slave RSPI system configuration example when this MCU is used as a slave. In the example of Figure 35.9, the RSPI system is comprised of an SPI master and two MCUs (slave X and slave Y).

The SPCK and MOSI outputs of the SPI master are connected to the RSPCKA and MOSIA inputs of the MCUs (slave X and slave Y). The MISOA outputs of the MCUs (slave X and slave Y) are all connected to the MISO input of the SPI master. SSLX and SSLY outputs of the SPI master are connected to the SSLA0 inputs of the MCUs (slave X and slave Y), respectively.

The SPI master drives SPCK, MOSI, SSLX, and SSLY. Of the MCUs (slave X and slave Y), the slave that receives low-level input into the SSLA0 input drives MISOA.

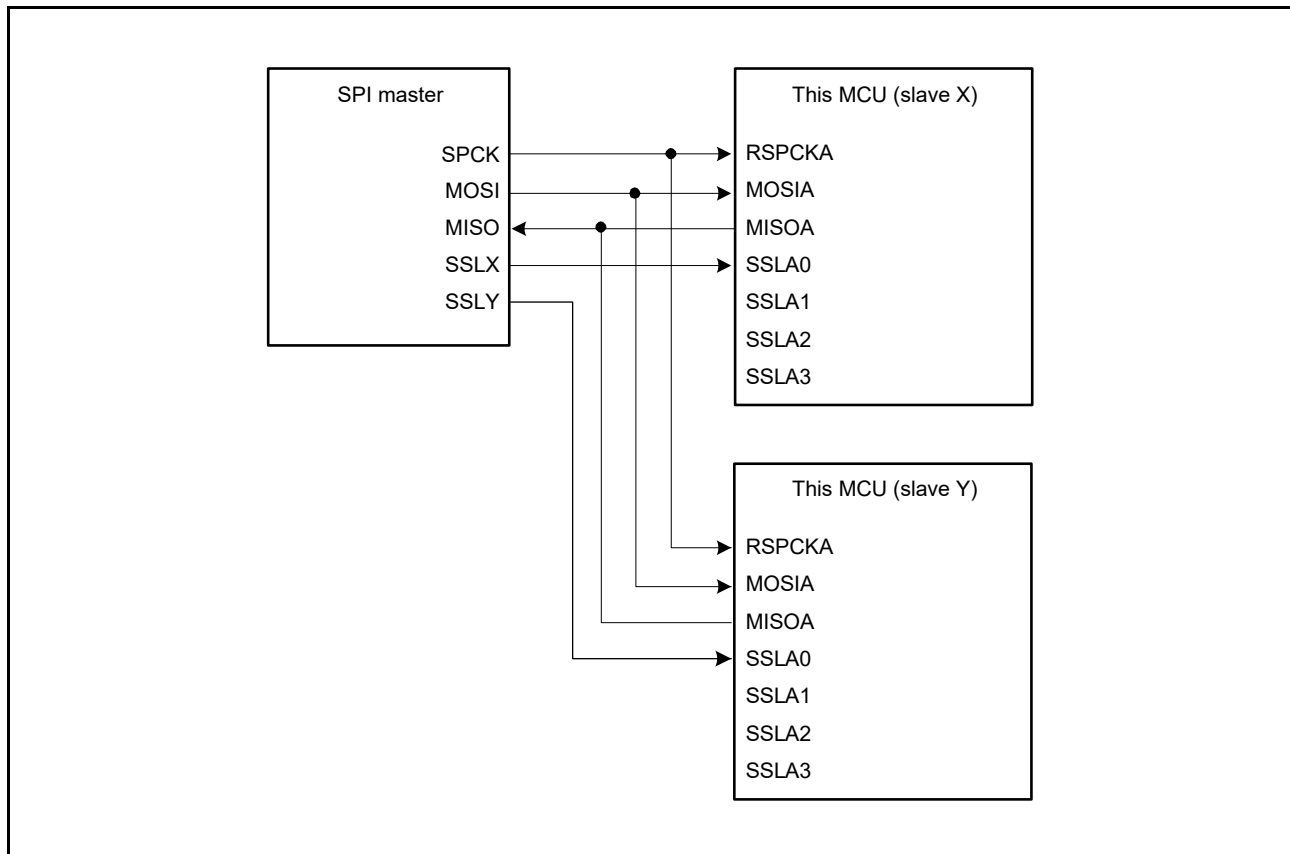

Figure 35.9 Single-Master/Multi-Slave Configuration Example (This MCU = Slave)

### 35.3.3.5 Multi-Master/Multi-Slave (with This MCU Acting as Master)

Figure 35.10 shows a multi-master/multi-slave RSPIC system configuration example when this MCU is used as a master. In the example of Figure 35.10, the RSPIC system is comprised of two MCUs (master X and master Y) and two SPI slaves (SPI slave 1 and SPI slave 2).

The RSPCKA and MOSIA outputs of the MCUs (master X and master Y) are connected to the RSPCK and MOSI inputs of SPI slaves 1 and 2. The MISO outputs of SPI slaves 1 and 2 are connected to the MISOA inputs of the MCUs (master X and master Y). Any generic port Y output from this MCU (master X) is connected to the SSLA0 input of this MCU (master Y). Any generic port X output of this MCU (master Y) is connected to the SSLA0 input of this MCU (master X). The SSLA1 and SSLA2 outputs of the MCUs (master X and master Y) are connected to the SSL inputs of the SPI slaves 1 and 2. In this configuration example, since the system can be comprised solely of SSLA0 input, and SSLA1 and SSLA2 outputs for slave connections, the SSLA3 output of this MCU is not required.

This MCU drives RSPCKA, MOSIA, SSLA1, and SSLA2 when the SSLA0 input level is high. When the SSLA0 input level is low, this MCU detects a mode fault error, sets RSPCKA, MOSIA, SSLA1, and SSLA2 to Hi-Z, and releases the RSPIC bus right to the other master. Of the SPI slaves 1 and 2, the slave that receives low-level input into the SSL input drives MISO.

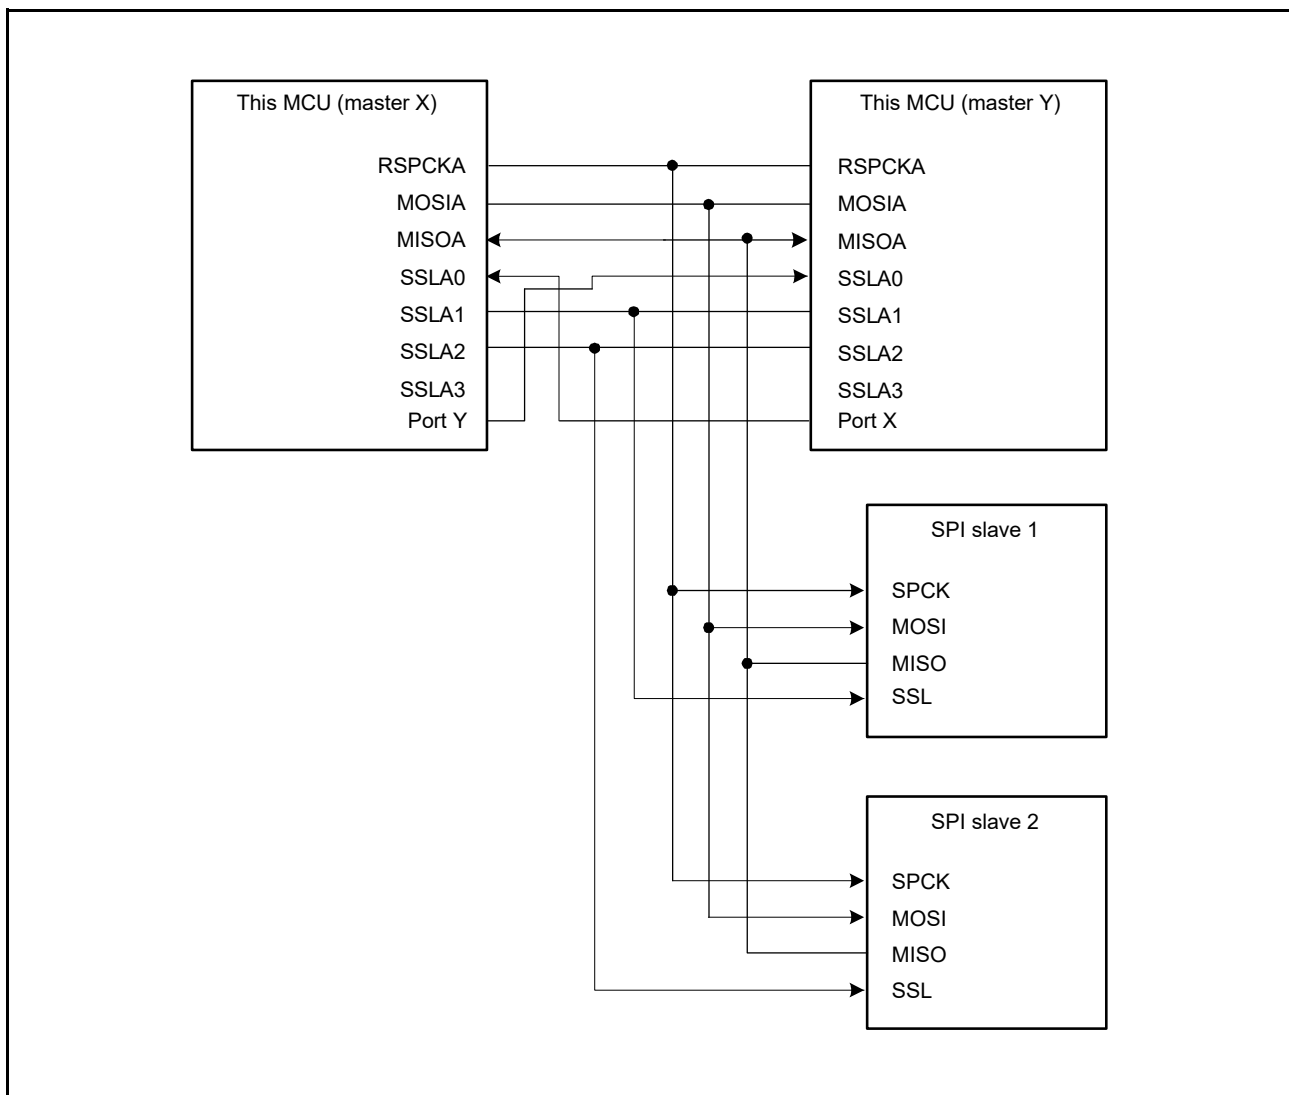

Figure 35.10 Multi-Master/Multi-Slave Configuration Example (This MCU = Master)

### 35.3.3.6 Master (Clock Synchronous Operation)/Slave (Clock Synchronous Operation) (with This MCU Acting as Master)

Figure 35.11 shows a master (clock synchronous operation)/slave (clock synchronous operation) RSPI system configuration example when this MCU is used as a master. In the master (clock synchronous operation)/slave (clock synchronous operation) configuration, SSLA0 to SSLA3 of this MCU (master) are not used.

This MCU (master) drives the RSPCKA and MOSIA. The SPI slave drives the MISO.

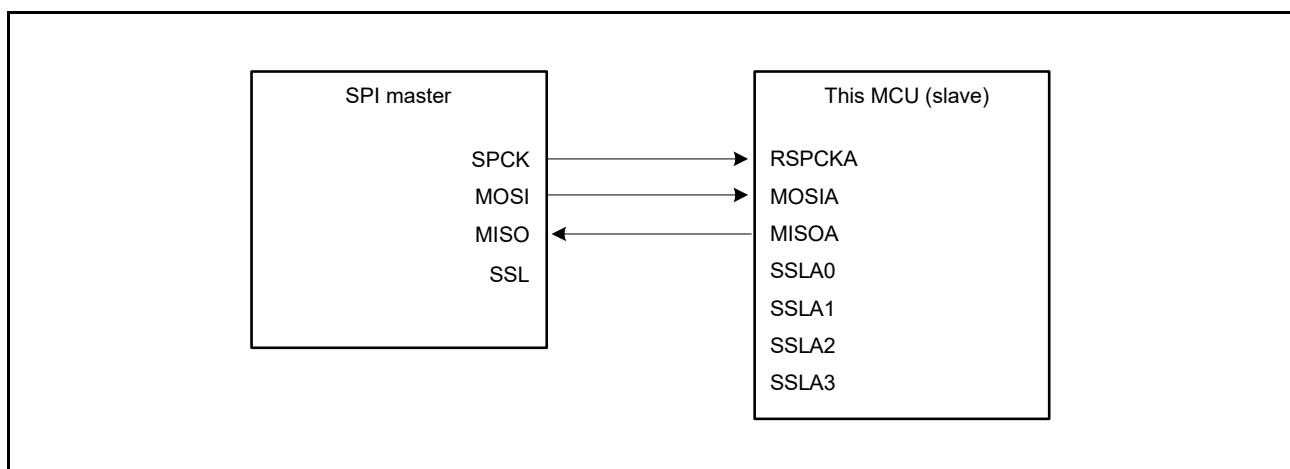

**Figure 35.11 Master (Clock Synchronous Operation)/Slave (Clock Synchronous Operation) Configuration Example (This MCU = Master)**

### 35.3.3.7 Master (Clock Synchronous Operation)/Slave (Clock Synchronous Operation) (with This MCU Acting as Slave)

Figure 35.12 shows a master (clock synchronous operation)/slave (clock synchronous operation) RSPI system configuration example when this MCU is used as a slave. When this MCU is to operate as a slave (clock synchronous operation), this MCU (slave) drives the MISOA and the SPI master drives the SPCK and MOSI. In addition, SSLA0 to SSLA3 of this MCU (slave) are not used.

Only in the single-slave configuration in which the SPCMDm.CPHA bit is set to 1, this MCU (slave) can execute serial transfer.

**Figure 35.12 Master (Clock Synchronous Operation)/Slave (Clock Synchronous Operation) Configuration Example (This MCU = Slave, CPHA = 1)**

### 35.3.4 Data Format

The RSPI's data format depends on the settings in RSPI command register  $m$  (SPCMD $m$ ) ( $m = 0$  to  $7$ ) and the parity enable bit in RSPI control register 2 (SPCR2.SPPE) and RSPI data control register 2 (SPDCR2). Regardless of whether the MSB or LSB is first, the RSPI treats the range from the LSB bit in the RSPI data register (SPDR) to the selected data length as transfer data.

The format of one frame of data before or after transfer is shown below.

#### (a) With Parity Disabled

When parity is disabled, transmission or reception of data proceeds with the length in bits selected in the RSPI data length setting bits in RSPI command register  $m$  (SPCMD $m$ .SPB[3:0]).

#### (b) With Parity Enabled

When parity is enabled, transmission or reception of data proceeds with the length in bits selected in the RSPI data length setting bits in RSPI command register  $m$  (SPCMD $m$ .SPB[3:0]). In this case, however, the last bit is a parity bit.

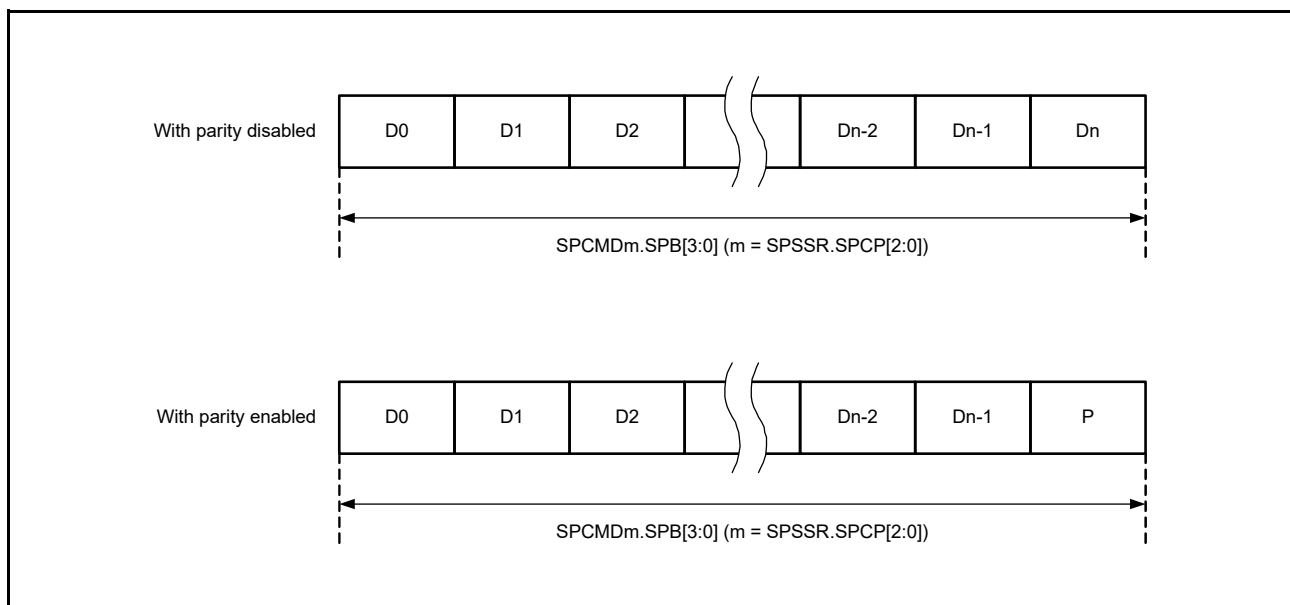

Figure 35.13 Outline of the Data Format (with Parity Disabled/Enabled)

### 35.3.4.1 When Parity is Disabled (SPCR2.SPPE = 0)

When parity is disabled, data for transmission are copied to the shift register with no prior processing. A description of the connection between the RSPI data register (SPDR) and the shift register in terms of the combination of MSB or LSB first and data length is given below.

#### (1) MSB First Transfer (32-Bit Data)

Figure 35.14 shows details of operations by the RSPI data register (SPDR) and the shift register in transfer with parity disabled, an RSPI data length of 32 bits, and MSB first selected.

In transmission, bits T31 to T00 from the current stage of the transmit buffer are copied to the shift register. Data for transmission are shifted out from the shift register in order from T31, through T30, and so on to T00.

In reception, received data are shifted in bit by bit through bit 0 of the shift register. When bits R31 to R00 have been collected after input of the required number of cycles of RSPCK, the value in the shift register is copied to the receive buffer.

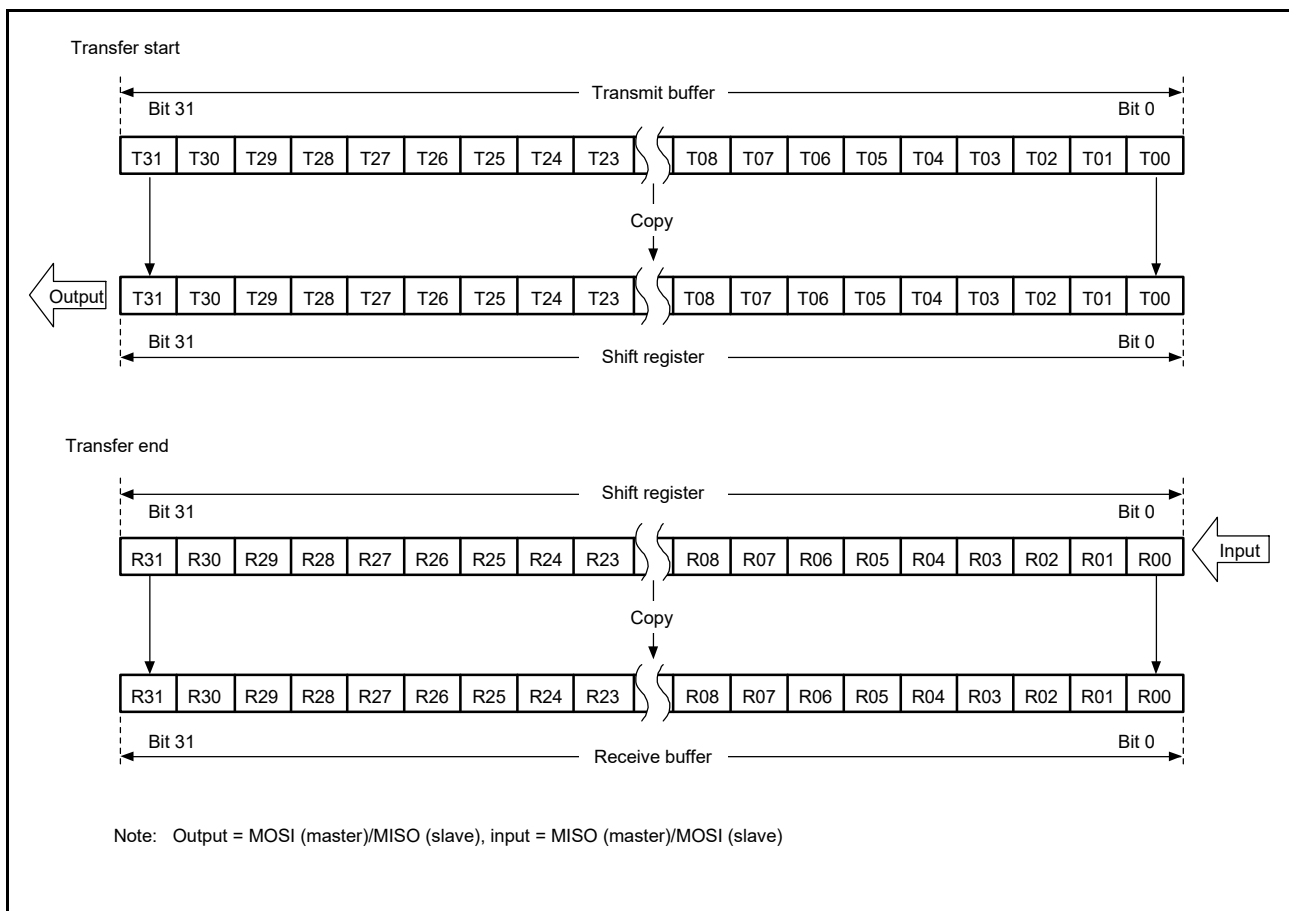

Figure 35.14 MSB First Transfer (32-Bit Data, Parity Disabled)

(2) MSB First Transfer (24-Bit Data)

Figure 35.15 shows details of operations by the RSPI data register (SPDR) and the shift register in transfer with parity disabled, 24 bits as the RSPI data length for an example that is not 32 bits, and MSB first selected.

In transmission, the lower 24 bits (T23 to T00) from the current stage of the transmit buffer are copied to the shift register. Data for transmission are shifted out from the shift register in order from T23, through T22, and so on to T00. In reception, received data are shifted in bit by bit through bit 0 of the shift register. When bits R23 to R00 have been collected after input of the required number of cycles of RSPCK, the value in the shift register is copied to the receive buffer. At this time, the upper 8 bits of the transmit buffer are stored in the upper 8 bits of the receive buffer. Writing 0 to bits T31 to T24 at the time of transmission leads to 0 being set in the upper 8 bits of the receive buffer.

Figure 35.15 MSB First Transfer (24-Bit Data, Parity Disabled)

(3) LSB First Transfer (32-Bit Data)

Figure 35.16 shows details of operations by the RSPIC data register (SPDR) and the shift register in transfer with parity disabled, an RSPIC data length of 32 bits, and LSB first selected.

In transmission, bits T31 to T00 from the current stage of the transmit buffer are reordered bit by bit to obtain the order T00 to T31 for copying to the shift register. Data for transmission are shifted out from the shift register in order from T00, through T01, and so on to T31.

In reception, received data are shifted in bit by bit through bit 0 of the shift register. When bits R00 to R31 have been collected after input of the required number of cycles of RSPCK, the value in the shift register is copied to the receive buffer.

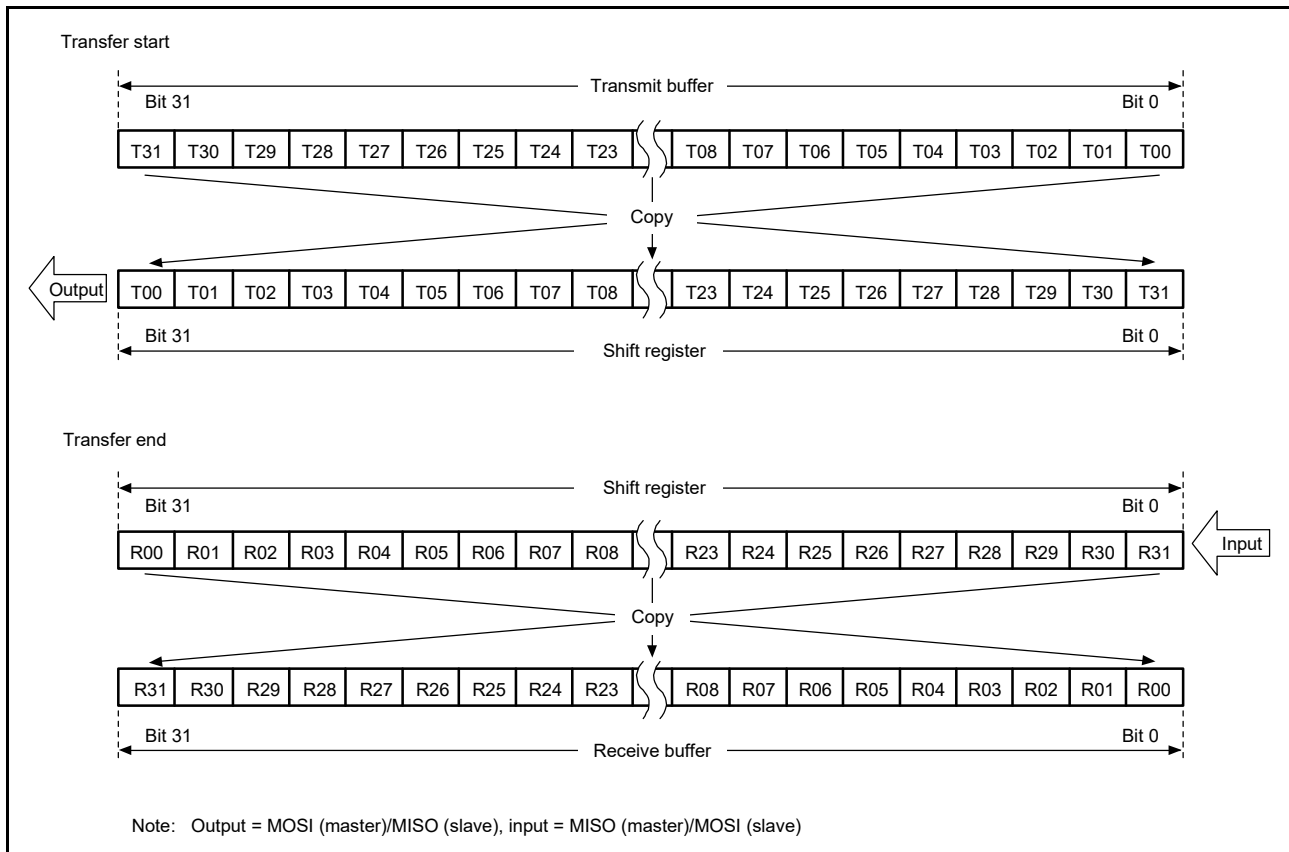

Figure 35.16 LSB First Transfer (32-Bit Data, Parity Disabled)

(4) LSB First Transfer (24-Bit Data)

Figure 35.17 shows details of operations by the RSPI data register (SPDR) and the shift register in transfer with parity disabled, 24 bits as the RSPI data length for an example that is not 32 bits, and LSB first selected.

In transmission, the lower 24 bits (T23 to T00) from the current stage of the transmit buffer are reordered bit by bit to obtain the order T00 to T23 for copying to the shift register. Data for transmission are shifted out from the shift register in order from T00, through T01, and so on to T23.

In reception, received data are shifted in bit by bit through bit 8 of the shift register. When bits R00 to R23 have been collected after input of the required number of cycles of RSPCK, the value in the shift register is copied to the receive buffer. At this time, the upper 8 bits of the transmit buffer are stored in the upper 8 bits of the receive buffer. Writing 0 to bits T31 to T24 at the time of transmission leads to 0 being set in the upper 8 bits of the receive buffer.

Figure 35.17 LSB First Transfer (24-Bit Data, Parity Disabled)

### 35.3.4.2 When Parity is Enabled (SPCR2.SPPE = 1)

When parity is enabled, the lowest-order bit of the data for transmission becomes a parity bit. Hardware calculates the value of the parity bit.

#### (1) MSB First Transfer (32-Bit Data)

Figure 35.18 shows details of operations by the RSPI data register (SPDR) and the shift register in transfer with parity enabled, an RSPI data length of 32 bits, and MSB first selected.

In transmission, the value of the parity bit (P) is calculated from bits T31 to T01. This replaces the final bit, T00, and the whole is copied to the shift register. Data are transmitted in the order T31, T30, ..., T01, and P.

In reception, received data are shifted in bit by bit through bit 0 of the shift register. When bits R31 to P have been collected after input of the required number of cycles of RSPCK, the value in the shift register is copied to the receive buffer. On copying of data to the shift register, the data from R31 to P are checked by judging the parity.

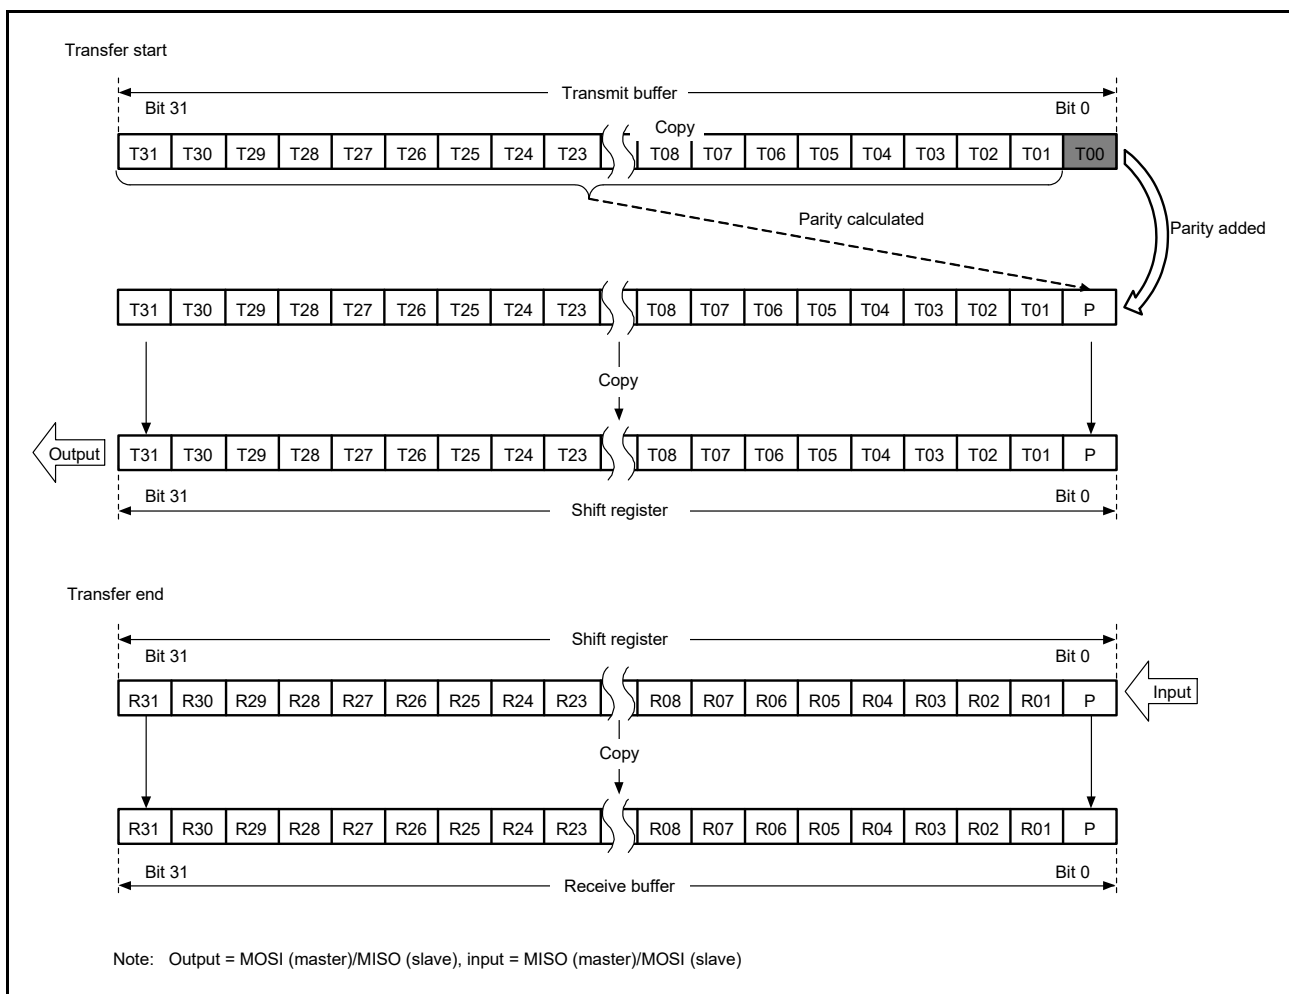

Figure 35.18 MSB First Transfer (32-Bit Data, Parity Enabled)

(2) MSB First Transfer (24-Bit Data)

Figure 35.19 shows details of operations by the RSPIC data register (SPDR) and the shift register in transfer with parity enabled, 24 bits as the RSPIC data length for an example that is not 32 bits, and MSB first selected.

In transmission, the value of the parity bit (P) is calculated from bits T23 to T01. This replaces the final bit, T00, and the whole is copied to the shift register. Data are transmitted in the order T23, T22, ..., T01, and P.

In reception, received data are shifted in bit by bit through bit 0 of the shift register. When bits R23 to P have been collected after input of the required number of cycles of RSPCK, the value in the shift register is copied to the receive buffer. On copying of data to the shift register, the data from R23 to P are checked by judging the parity. At this time, the upper 8 bits of the transmit buffer are stored in the upper 8 bits of the receive buffer. Writing 0 to bits T31 to T24 at the time of transmission leads to 0 being set in the upper 8 bits of the receive buffer.

Figure 35.19 MSB First Transfer (24-Bit Data, Parity Enabled)

(3) LSB First Transfer (32-Bit Data)

Figure 35.20 shows details of operations by the RSPIC data register (SPDR) and the shift register in transfer with parity enabled, an RSPIC data length of 32 bits, and LSB first selected.

In transmission, the value of the parity bit (P) is calculated from bits T30 to T00. This replaces the final bit, T31, and the whole is copied to the shift register. Data are transmitted in the order T00, T01, ..., T30, and P.

In reception, received data are shifted in bit by bit through bit 0 of the shift register. When bits R00 to P have been collected after input of the required number of cycles of RSPCK, the value in the shift register is copied to the receive buffer. On copying of data to the shift register, the data from R00 to P are checked by judging the parity.

Figure 35.20 LSB First Transfer (32-Bit Data, Parity Enabled)

(4) LSB First Transfer (24-Bit Data)

Figure 35.21 shows details of operations by the RSPIC data register (SPDR) and the shift register in transfer with parity enabled, 24 bits as the RSPIC data length for an example that is not 32 bits, and LSB first selected.

In transmission, the value of the parity bit (P) is calculated from bits T22 to T00. This replaces the final bit, T23, and the whole is copied to the shift register. Data are transmitted in the order T00, T01, ..., T22, and P.

In reception, received data are shifted in bit by bit through bit 8 of the shift register. When bits R00 to P have been collected after input of the required number of cycles of RSPCK, the value in the shift register is copied to the receive buffer. On copying of data to the shift register, the data from R00 to P are checked by judging the parity. At this time, the upper 8 bits of the transmit buffer are stored in the upper 8 bits of the receive buffer. Writing 0 to bits T31 to T24 at the time of transmission leads to 0 being set in the upper 8 bits of the receive buffer.

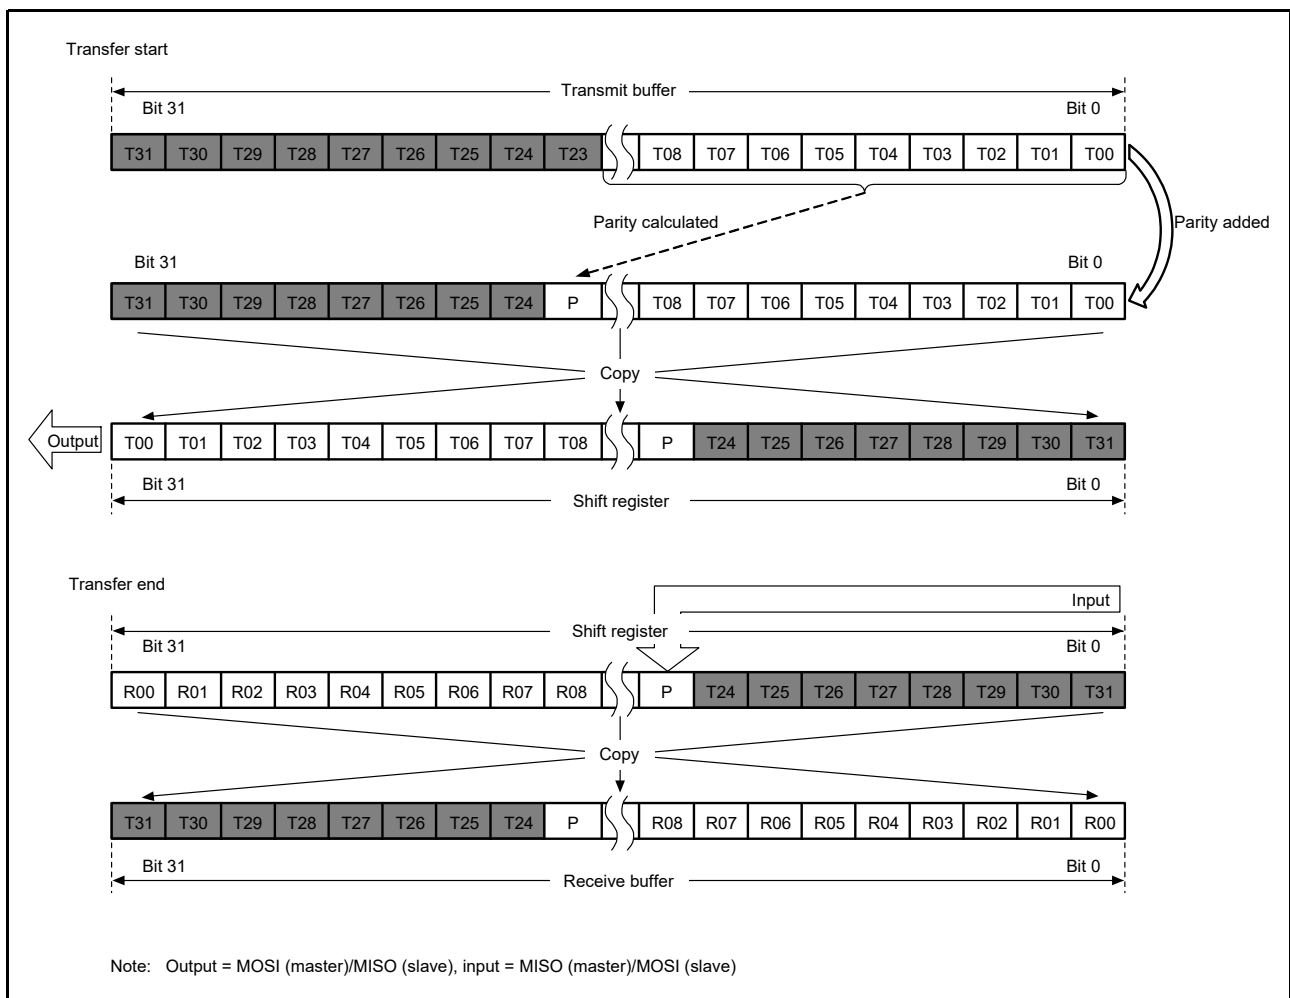

Figure 35.21 LSB First Transfer (24-Bit Data, Parity Enabled)

### 35.3.4.3 Byte Swap Transmission

When the SPDCR2.BYSW bit is 1 (byte swapping of SPDR data enabled), data bytes written in the transmit buffer (SPDR) will be swapped (in 8 bit units) when the data is transferred to the shift register. Figure 35.22 shows data transfer between the SPDR register and the shift register when data length is 32 bits.

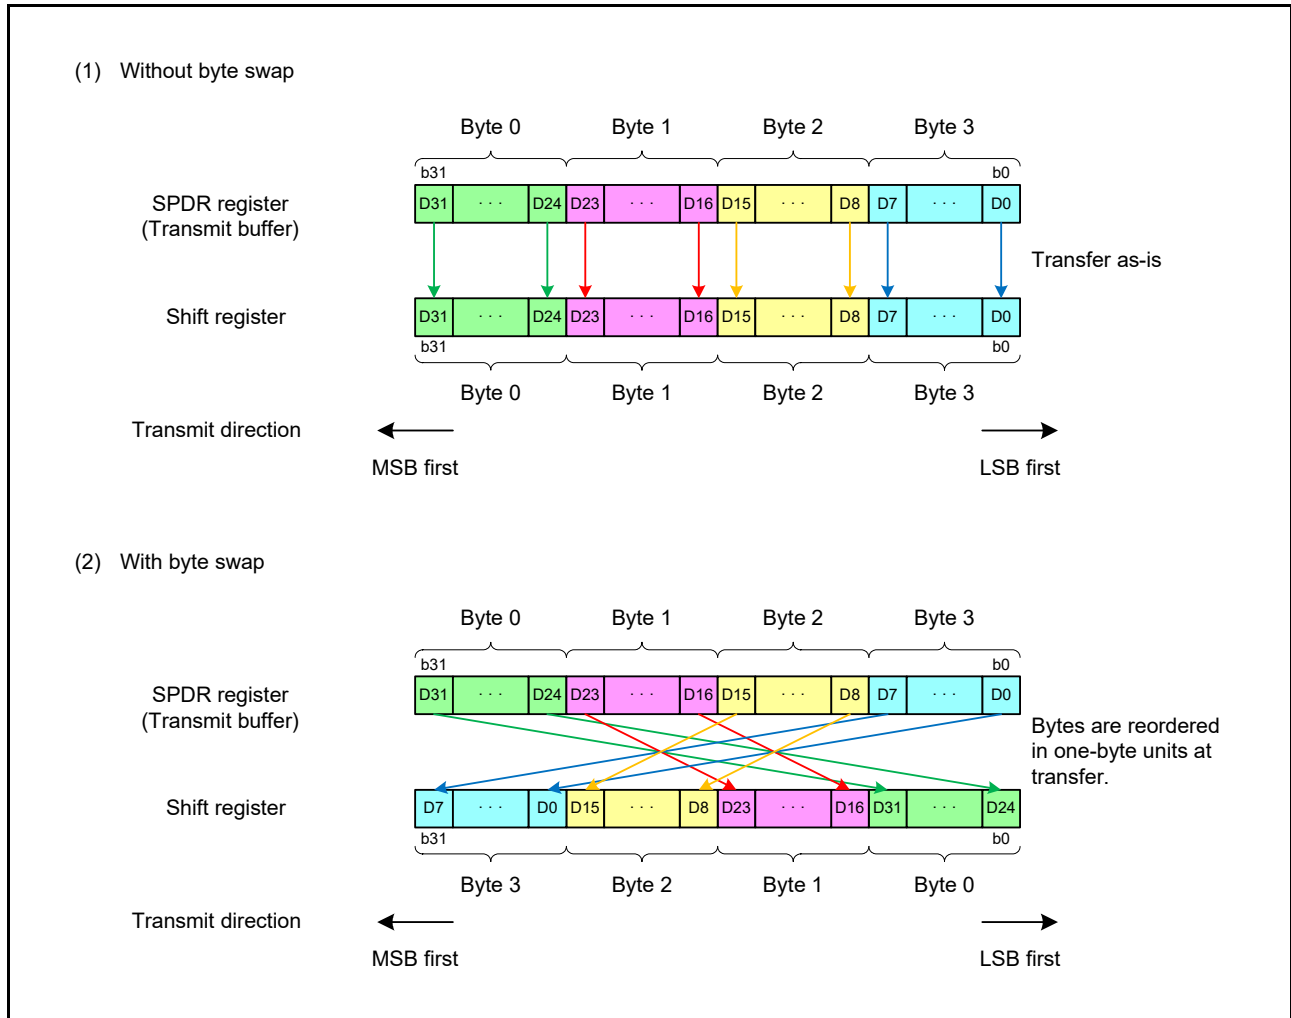

Figure 35.22 Transmit Data Handling in MSB/LSB First with Byte Swapping Enabled/Disabled

### 35.3.4.4 Byte Swap Reception

When the SPDCR2.BYSW bit is 1 (byte swapping of SPDR data enabled), data bytes in the shift register will be swapped (in 8 bit units) when the data is transferred to the receive buffer (SPDR). Figure 35.23 shows data transfer between the shift register and the SPDR register when data length is 32 bits.

Figure 35.23 Receive Data Handling in MSB/LSB First with Byte Swapping Enabled/Disabled

### 35.3.5 Transfer Format

#### 35.3.5.1 CPHA = 0

Figure 35.24 shows a sample transfer format for the serial transfer of 8-bit data when the SPCMDm.CPHA bit is 0. Note that clock synchronous operation (the SPCR.SPMS bit is 1) should not be performed when the RSPI operates in slave mode (SPCR.MSTR = 0) and the CPHA bit is 0. In Figure 35.24, RSPCKA (CPOL = 0) indicates the RSPCKA signal waveform when the SPCMDm.CPOL bit is 0; RSPCKA (CPOL = 1) indicates the RSPCKA signal waveform when the CPOL bit is 1. The sampling timing represents the timing at which the RSPI fetches serial transfer data into the shift register. The I/O directions of the signals depend on the RSPI settings. For details, refer to section 35.3.2, Controlling RSPI Pins.

When the SPCMDm.CPHA bit is 0, the driving of valid data to the MOSIA and MISOA signals commences at an SSLAi signal assertion timing. The first RSPCKA signal change timing that occurs after the SSLAi signal assertion becomes the first transfer data fetch timing. After this timing, data is sampled at every 1 RSPCK cycle. The change timing for MOSIA and MISOA signals is 1/2 RSPCK cycles after the transfer data fetch timing. The CPOL bit setting does not affect the RSPCKA signal operation timing; it only affects the signal polarity.

t1 denotes a period from an SSLAi signal assertion to RSPCKA oscillation (RSPCK delay). t2 denotes a period from the termination of RSPCKA oscillation to an SSLAi signal negation (SSL negation delay). t3 denotes a period in which SSLAi signal assertion is suppressed for the next transfer after the end of serial transfer (next-access delay). t1, t2, and t3 are controlled by a master device running on the RSPI system. For a description of t1, t2, and t3 when the RSPI of this MCU is in master mode, refer to section 35.3.11.1, Master Mode Operation.

Figure 35.24 RSPI Transfer Format (CPHA = 0)

### 35.3.5.2 CPHA = 1

Figure 35.25 shows a sample transfer format for the serial transfer of 8-bit data when the SPCMDm.CPHA bit is 1. However, when the SPCR.SPMS bit is 1, the SSLAi signals are not used, and only the three signals RSPCKA, MOSIA, and MISOA handle communications. In Figure 35.25, RSPCK (CPOL = 0) indicates the RSPCKA signal waveform when the SPCMDm.CPOL bit is 0; RSPCKA (CPOL = 1) indicates the RSPCKA signal waveform when the CPOL bit is 1. The sampling timing represents the timing at which the RSPI fetches serial transfer data into the shift register. The I/O directions of the signals depend on the RSPI mode (master or slave). For details, refer to section 35.3.2, Controlling RSPI Pins.

When the SPCMDm.CPHA bit is 1, the driving of invalid data to the MISOA signal commences at an SSLAi signal assertion timing. The output of valid data to the MOSIA and MISOA signals commences at the first RSPCKA signal change timing that occurs after the SSLAi signal assertion. After this timing, data is updated at every 1 RSPCK cycle. The transfer data fetch timing is 1/2 RSPCK cycles after the data update timing. The SPCMDm.CPOL bit setting does not affect the RSPCKA signal operation timing; it only affects the signal polarity.

t1, t2, and t3 are the same as those in the case of CPHA = 0. For a description of t1, t2, and t3 when the RSPI of this MCU is in master mode, refer to section 35.3.11.1, Master Mode Operation.

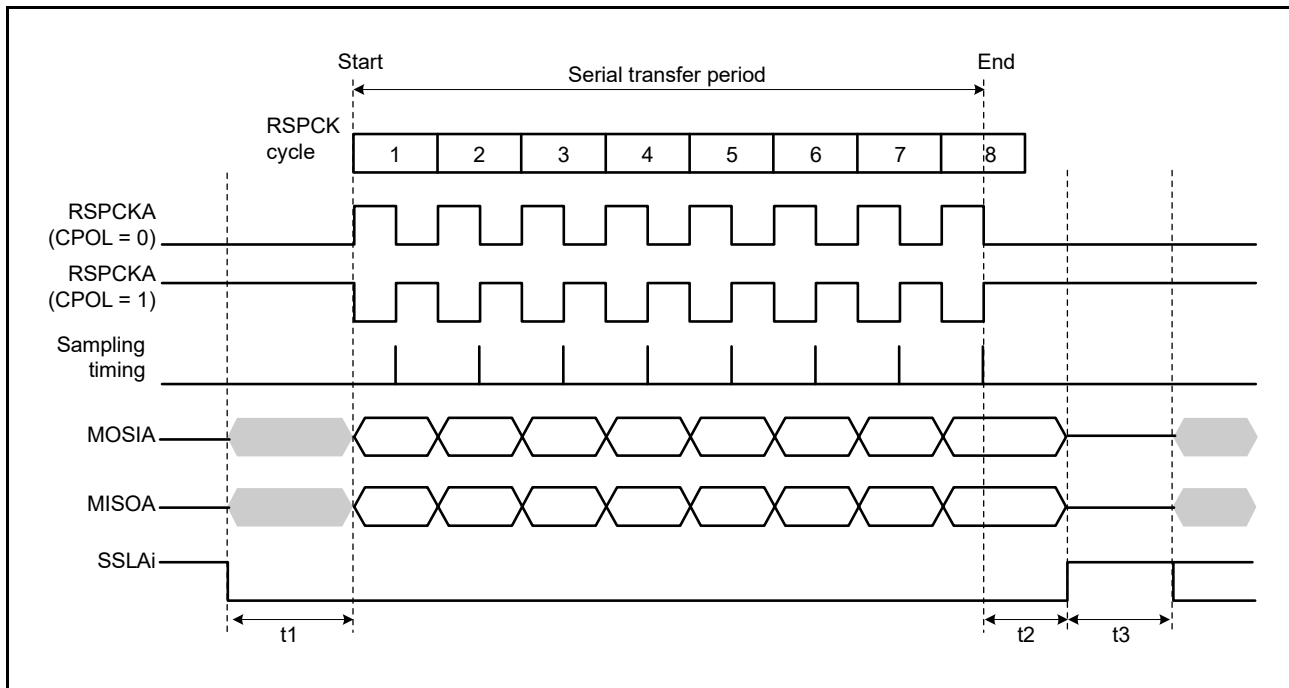

Figure 35.25 RSPI Transfer Format (CPHA = 1)

### 35.3.6 Communications Operating Mode

Full-duplex communications or transmit-only simplex communications can be selected by the SPCR.TXMD bit. 'SPDR access' shown in Figure 35.26 and Figure 35.27 indicate the condition of access to the SPDR register, where 'W' denotes a write cycle.

#### 35.3.6.1 Full-Duplex Communications (SPCR.TXMD = 0)

Figure 35.26 shows an example of operation when the SPCR.TXMD bit is set to 0. In the example in Figure 35.26, the RSPICR.SPFC[1:0] bits are 00b, the SPCMDm.CPHA bit is 1, and the SPCMDm.CPOL bit is 0. The numbers given under the RSPCKA waveform represent the number of RSPCK cycles (i.e., the number of transferred bits).

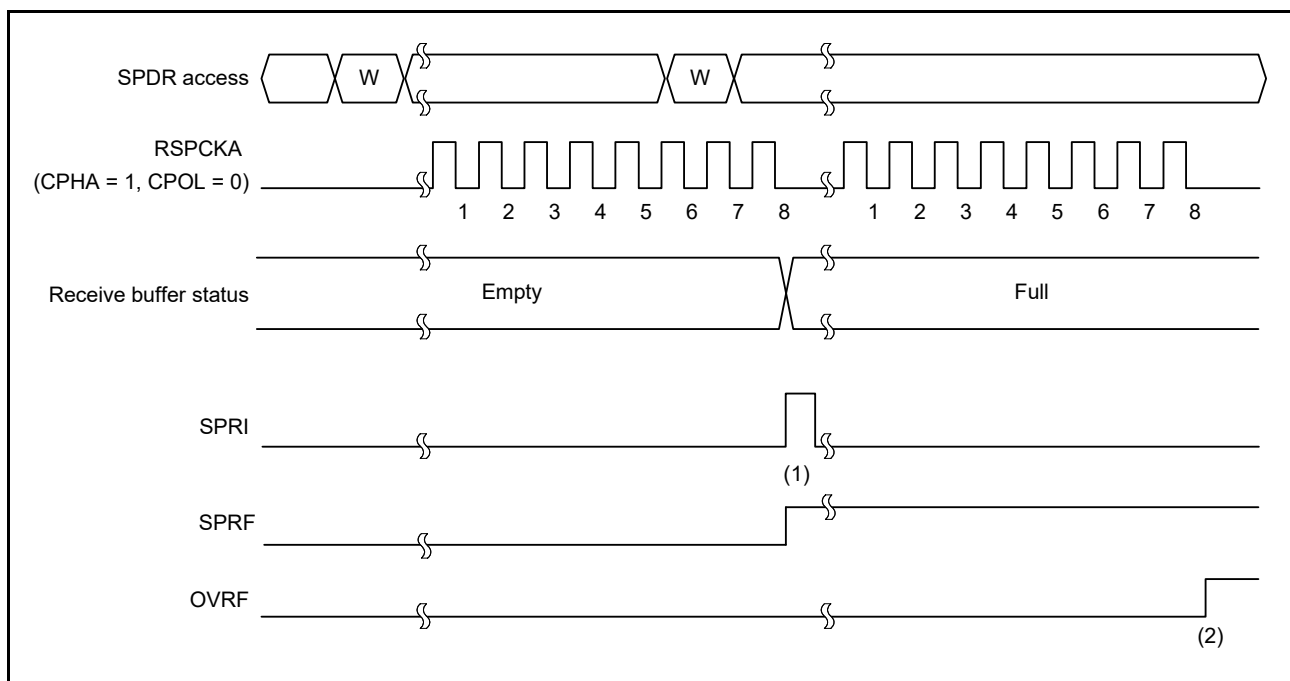

Figure 35.26 Operation Example of SPCR.TXMD = 0

The operation of the flags at timings shown in steps (1) and (2) in the figure is described below.

- (1) When a serial transfer ends with the receive buffer of the SPDR register empty, the RSPI generates a receive buffer full interrupt request (SPRI) (sets the SPSR.SPRF flag to 1) and copies the received data in the shift register to the receive buffer.
- (2) When a serial transfer ends with the receive buffer of the SPDR register holding data that was received in the previous serial transfer, the RSPI sets the SPSR.OVRF flag to 1 and discards the received data in the shift register.

When full-duplex communications (SPCR.TXMD = 0) is selected, reception occurs simultaneously with transmit operations. As such, the SPRF and OVRF flags in the SPSR register become 1 at the timing described in (1) and (2), respectively, according to the state of the receive buffer.

### 35.3.6.2 Transmit-only Simplex Communications (SPCR.TXMD = 1)

Figure 35.27 shows an example of operation when the SPCR.TXMD bit is set to 1. In the example in Figure 35.27, the SPDCR.SPFC[1:0] bits are 00b, the SPCMDm.CPHA bit is 1, and the SPCMDm.CPOL bit is 0. The numbers given under the RSPCKA waveform represent the number of RSPCK cycles (i.e., the number of transferred bits).

**Figure 35.27** Operation Example of SPCR.TXMD = 1

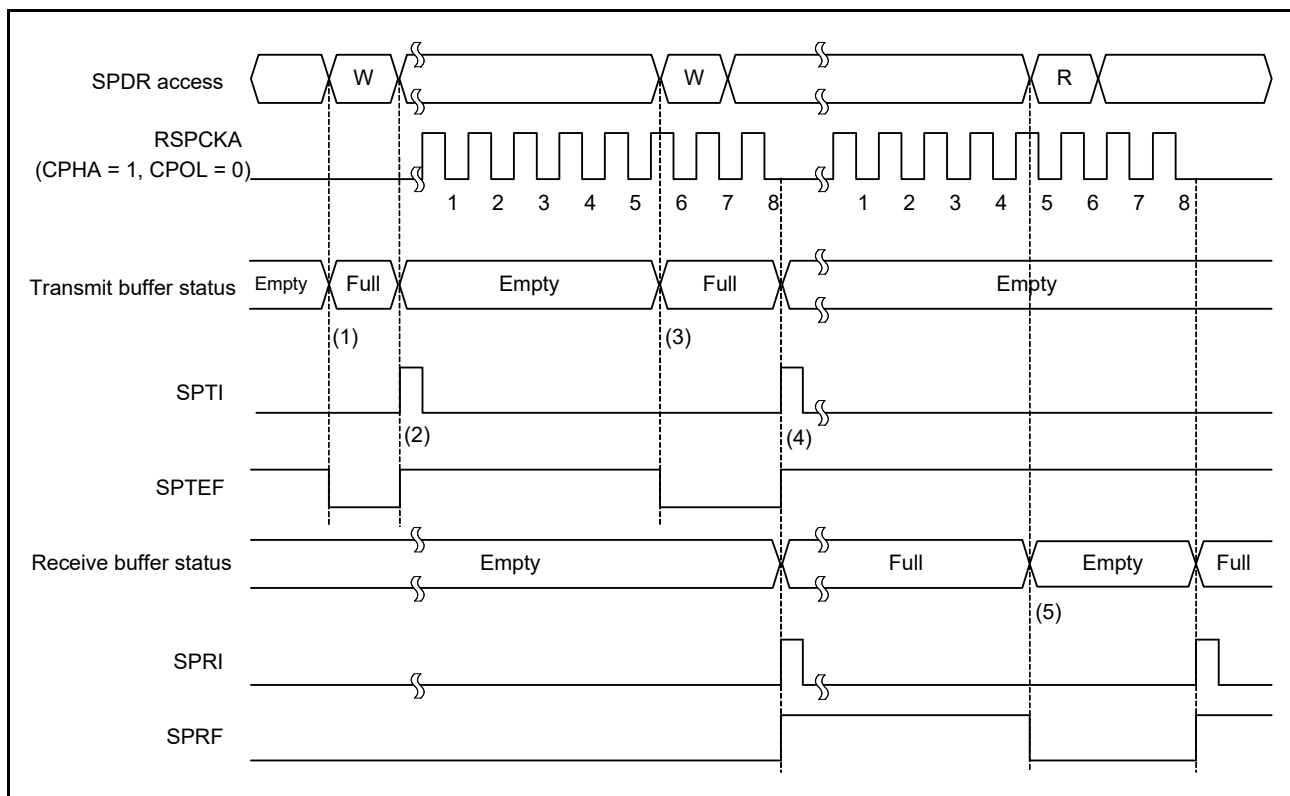

The operation of the flags at timings shown in steps (1) to (3) in the figure is described below.

- (1) Make sure there is no data left in the receive buffer and the SPSR.SPRF, OVRF flags are 0 before entering the mode of transmit-only simplex communications (SPCR.TXMD = 1).
- (2) When a serial transfer ends with the receive buffer of the SPDR register empty, if the mode of transmit-only simplex communications is selected (SPCR.TXMD = 1), the SPRF flag remains 0 and the RSPI does not copy the data from the shift register to the receive buffer.
- (3) Since the receive buffer of the SPDR register does not hold data that was received in the previous serial transfer, even when a serial transfer ends, the SPSR.OVRF flag retains the value of 0, and the data in the shift register is not copied to the receive buffer.

When performing transmit-only simplex communications (SPCR.TXMD = 1), the RSPI transmits data but does not receive data. Therefore, the SPSR.SPRF, OVRF flags remain 0 at the timings of (1) to (3).

### 35.3.7 Transmit Buffer Empty/Receive Buffer Full Interrupts

Figure 35.28 shows an example of operation of the transmit buffer empty interrupt (SPTI) and the receive buffer full interrupt (SPRI). ‘SPDR access’ shown in Figure 35.28 indicates the condition of access to the SPDR register, where ‘W’ denotes a write cycle, and ‘R’ a read cycle. In the example in Figure 35.28, the RSPI performs an 8-bit serial transfer in which the SPCR.TXMD bit is 0, the SPDCR.SPFC[1:0] bits are 00b, the SPCMDm.CPHA bit is 1, and the SPCMDm.CPOL bit is 0. The numbers given under the RSPCKA waveform represent the number of RSPCK cycles (i.e., the number of transferred bits).

**Figure 35.28** Operation Example of SPTI and SPRI Interrupts

The operation of the interrupts at timings shown in steps (1) to (5) in the figure is described below.

- (1) When transmit data is written to the SPDR register when the transmit buffer of the SPDR register is empty (data for the next transfer is not set), the RSPI writes data to the transmit buffer and sets the SPSR.SPTEF flag to 0.
- (2) If the shift register is empty, the RSPI copies the data from the transmit buffer to the shift register and generates a transmit buffer empty interrupt request (SPTI) and sets the SPSR.SPTEF flag to 1. How a serial transfer is started depends on the mode of the RSPI. For details, refer to section 35.3.11, SPI Operation, and section 35.3.12, Clock Synchronous Operation.
- (3) When transmit data is written to the SPDR register in the transmit buffer empty interrupt routine or in the transmit buffer empty detecting process by polling the SPTEF flag, the data is transferred to the transmit buffer and the SPSR.SPTEF flag becomes 0. Because the data being transmitted is stored in the shift register, the RSPI does not copy the data from the transmit buffer to the shift register.
- (4) When the serial transfer ends with the receive buffer of the SPDR register being empty, the RSPI copies the receive data from the shift register to the receive buffer, generates a receive buffer full interrupt request (SPRI), and sets the SPSR.SPRF flag to 1. Since the shift register becomes empty upon completion of serial transfer, when the transmit buffer had been full before the serial transfer ended, the RSPI sets the SPSR.SPTEF flag to 1 and copies the data from the transmit buffer to the shift register. Even when received data is not copied from the shift register to the receive buffer in an overrun error status, upon completion of the serial transfer, the RSPI determines that the shift register is empty, thus data transfer from the transmit buffer to the shift register is enabled.

- (5) When the SPDR register is read in the receive buffer full interrupt routine or in the receive buffer full detecting process by polling the SPRF flag, the receive data can be read. When the receive data is read, the SPRF flag becomes 0.

If transmit data is written to the SPDR register while the transmit buffer holds data that has not yet been transmitted (the SPTEF flag is 0), the RSPI does not update the data in the transmit buffer. Transmit data should be written to the SPDR register in the transmit buffer empty interrupt request routine or in the transmit buffer empty detecting process by polling the SPTEF flag. To use a transmit buffer empty interrupt, set the SPTIE bit in SPCR to 1.

When setting the SPCR.SPE bit to 0 (RSPI disabled), the SPCR.SPTIE bit should also be set to 0. Otherwise (if the SPCR.SPE bit is 0 and the SPCR.SPTIE is 1), a transmit buffer empty interrupt request will occur.

When serial transfer ends with the receive buffer being full (the SPRF flag is 1), the RSPI does not copy data from the shift register to the receive buffer, and detects an overrun error (refer to section 35.3.9, Error Detection). To prevent a receive data overrun error, read the received data using a receive buffer full interrupt request before the next serial transfer ends. To use an receive buffer full interrupt, set the SPCR.SPRIE bit to 1.

Transmit and receive interrupts or the corresponding IRn.IR flags (where n is the interrupt vector number) in the ICU can be used to confirm the states of the transmit and receive buffers. Refer to section 14, Interrupt Controller (ICUC), for the interrupt vector numbers. The status of the transmit and receive buffers can be also confirmed by the SPTEF and SPRF flags.

### 35.3.8 Idle Interrupt

When the SPSR.IDLNF flag becomes 0 while the SPCR2.SPIIE bit is 1, an idle interrupt request (SPII) is generated.

In master mode, the IDLNF flag is 0 before transmission. Therefore, write data in the transmit buffer and set the SPIIE bit to 1 after the IDLNF flag becomes 1 so that an idle interrupt is not generated at this time. When the SSLA0 signal is negated after the transmission is completed and the next data is not supplied until next-access delay time (t3) elapses, the IDLNF flag becomes 0.

### 35.3.9 Error Detection

In the normal RSPI serial transfer, the data written to the transmit buffer of the SPDR register is transmitted, and the received data can be read from the receive buffer of the SPDR register. If access is made to the SPDR register, depending on the status of the transmit/receive buffer or the status of the RSPI at the beginning or end of serial transfer, in some cases non-normal transfers can be executed.

If a non-normal transfer operation occurs, the RSPI detects the event as an underrun error, overrun error, parity error, or mode fault error. Table 35.7 lists the relationship between non-normal transfer operations and the RSPI's error detection function.

**Table 35.7 Relationship between Non-Normal Transfer Operations and RSPI Error Detection Function**

|   | Occurrence Condition                                                                                                          | RSPI Operation                                                                                                                                                                                                                               | Error Detection  |
|---|-------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------|
| 1 | The SPDR register is written when the transmit buffer is full.                                                                | <ul style="list-style-type: none"> <li>The contents of the transmit buffer are kept.</li> <li>Missing write data.</li> </ul>                                                                                                                 | None             |
| 2 | The SPDR register is read when the receive buffer is empty.                                                                   | If reception has completed, then the received data is output to the bus. Otherwise, data received previously is output instead.                                                                                                              | None             |
| 3 | Serial transfer is started when transmit data is still not loaded on the shift register while the RSPI is used in slave mode. | <ul style="list-style-type: none"> <li>Serial transfer is suspended</li> <li>Transmit/receive data is missing</li> <li>The MISO signal output is disabled</li> <li>RSPI function is disabled</li> </ul>                                      | Underrun error   |
| 4 | Serial transfer terminates when the receive buffer is full.                                                                   | <ul style="list-style-type: none"> <li>The contents of the receive buffer are kept.</li> <li>Missing receive data.</li> </ul>                                                                                                                | Overrun error    |
| 5 | An incorrect parity bit is received when performing full-duplex communications with the parity function enabled.              | The parity error flag is set.                                                                                                                                                                                                                | Parity error     |
| 6 | The SSLA0 input signal is asserted when the serial transfer is idle in multi-master mode.                                     | <ul style="list-style-type: none"> <li>Driving of the RSPCKA, MOSIA, SSLA1 to SSLA3 output signals is stopped.</li> <li>RSPI function is disabled.</li> </ul>                                                                                | Mode fault error |
| 7 | The SSLA0 input signal is asserted during serial transfer in multi-master mode.                                               | <ul style="list-style-type: none"> <li>Serial transfer is suspended.</li> <li>Missing transmit/receive data.</li> <li>Driving of the RSPCKA, MOSIA, SSLA1 to SSLA3 output signals is stopped.</li> <li>RSPI function is disabled.</li> </ul> | Mode fault error |
| 8 | The SSLA0 input signal is negated during serial transfer in slave mode.                                                       | <ul style="list-style-type: none"> <li>Serial transfer is suspended.</li> <li>Missing transmit/receive data.</li> <li>Driving of the MISOA output signal is stopped.</li> <li>RSPI function is disabled.</li> </ul>                          | Mode fault error |

On operation 1 described in Table 35.7, the RSPI does not detect an error. To prevent data omission during the writing to the SPDR register, the SPDR register should be written when a transmit buffer empty interrupt request occurs or while the SPSR.SPTEF flag is 1.

Likewise, the RSPI does not detect an error on operation 2. To prevent extraneous data from being read, the SPDR register should be read when a receive buffer full interrupt request occurs or while the SPSR.SPRF flag is 1.

An underrun error shown in 3 is described in section 35.3.9.4, Underrun Error. An overrun error shown in 4 is described in section 35.3.9.1, Overrun Error. A parity error shown in 5 is described in section 35.3.9.2, Parity Error. A mode fault error shown in 6 to 8 is described in section 35.3.9.3, Mode Fault Error.

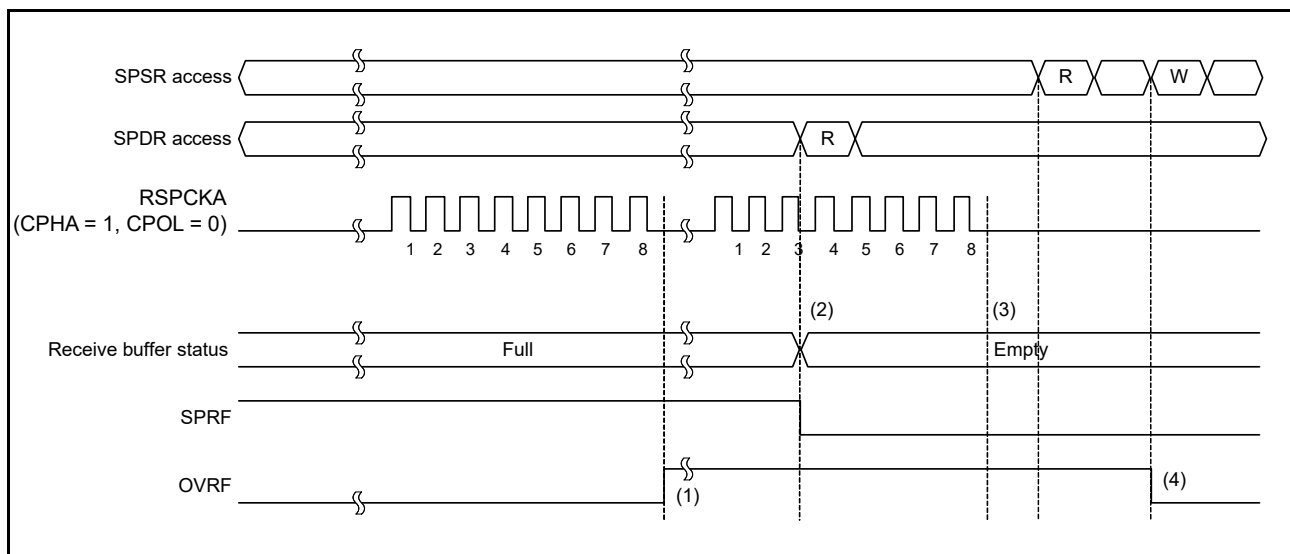

For the transmit and receive interrupts, refer to section 35.3.7, Transmit Buffer Empty/Receive Buffer Full Interrupts.

### 35.3.9.1 Overrun Error

If a serial transfer ends when the receive buffer of the SPDR register is full, the RSPI detects an overrun error, and sets the SPSR.OVRF flag to 1. When the OVRF flag is 1, the RSPI does not copy data from the shift register to the receive buffer so that the data prior to the occurrence of the error is retained in the receive buffer. To set the OVRF flag to 0, write 0 to the OVRF flag after the CPU has read the SPSR register with the OVRF flag set to 1.

Figure 35.29 shows an example of operations of the SPRF and OVRF flags. ‘SPSR access’ and ‘SPDR access’ shown in Figure 35.29 indicate the condition of accesses to the SPSR and SPDR registers, respectively, where ‘W’ denotes a write cycle, and ‘R’ a read cycle. In the example in Figure 35.29, the RSPI performs an 8-bit serial transfer in which the SPCMDm.CPHA bit is 1 and the SPCMDm.CPOL bit is 0. The numbers given under the RSPCKA waveform represent the number of RSPCK cycles (i.e., the number of transferred bits).

**Figure 35.29 Operation Example of the SPRF and OVRF Flags**

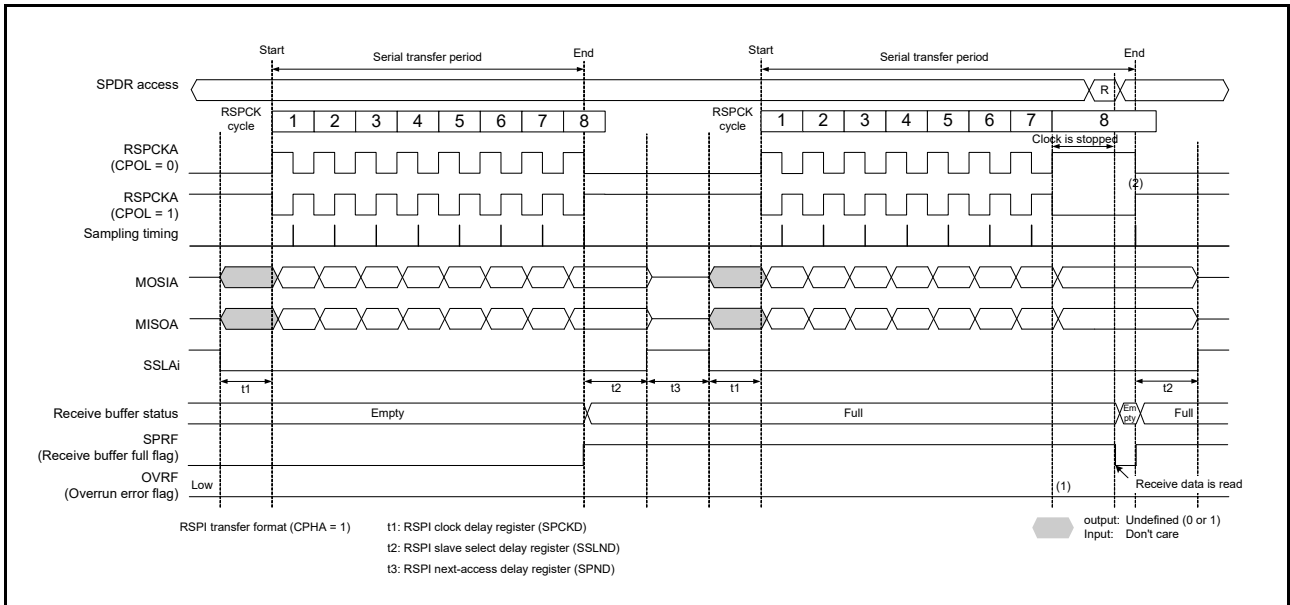

The operation of the flags at the timing shown in steps (1) to (4) in the figure is described below.

- (1) If a serial transfer terminates with the receive buffer full (the SPRF flag is 1), the RSPI detects an overrun error, and sets the OVRF flag to 1. The RSPI does not copy the data in the shift register to the receive buffer. Even if the SPPE bit is 1, parity errors are not detected. In master mode, the RSPI copies the pointer value to the SPCMDm register to the SPSSR.SPECM[2:0] bits.
- (2) When the SPDR register is read, the RSPI outputs the data in the receive buffer. At this time the SPRF flag becomes 0. Even if the receive buffer becomes empty, the OVRF flag does not become 0.
- (3) If the serial transfer ends with the OVRF flag being 1 (an overrun error occurs), the RSPI does not copy the data in the shift register to the receive buffer (the SPRF flag remains 0). A receive buffer full interrupt is not generated. Even if the SPPE bit is 1, parity errors are not detected. When in master mode, the RSPI does not update the SPSSR.SPECM[2:0] bits. When in an overrun error state and the RSPI does not copy the received data from the shift register to the receive buffer, upon termination of the serial transfer, the RSPI determines that the shift register is empty; in this manner, data transfer from the transmit buffer to the shift register is enabled.
- (4) If 0 is written to the OVRF flag after the SPSR register is read when the OVRF flag is 1, the OVRF flag is set to 0.

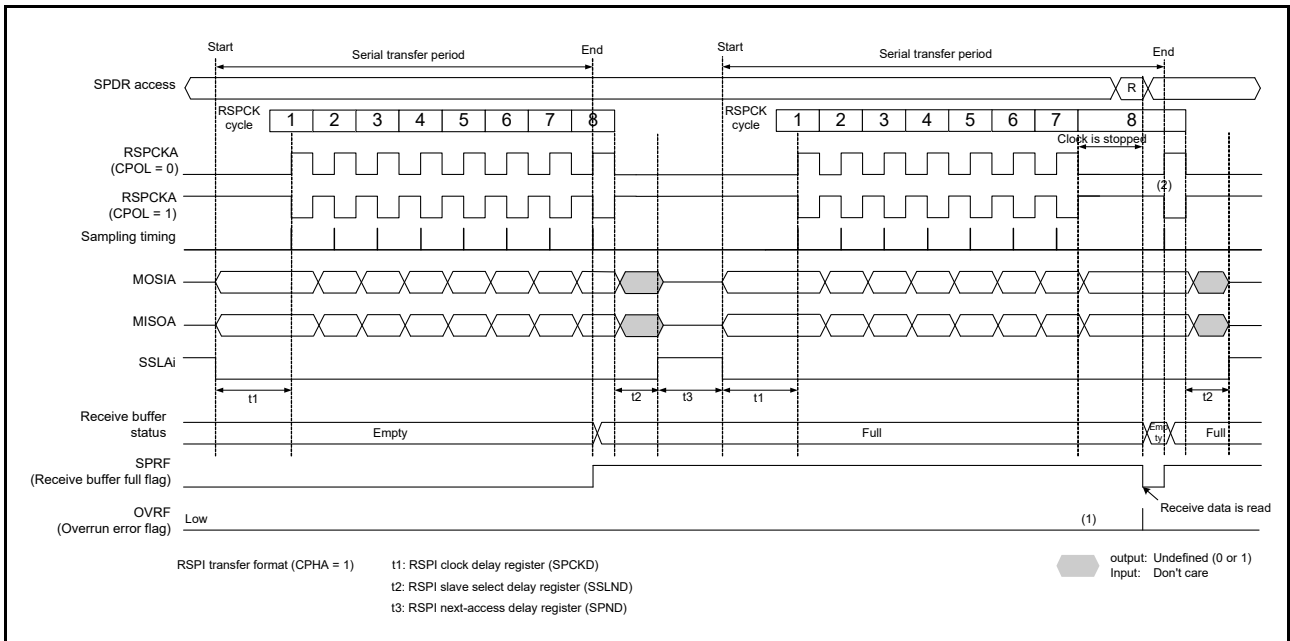

The occurrence of an overrun can be checked either by reading the SPSR register or by using an error interrupt and reading the SPSR register. When executing a serial transfer, measures should be taken to ensure the early detection of overrun errors, such as reading the SPSR register immediately after the SPDR register is read. When the RSPI is used in master mode, the pointer value to the SPCMDm register at the occurrence of the error can be checked by reading the SPSSR.SPECM[2:0] bits.

If an overrun error occurs and the OVRF flag is set to 1, normal reception operations cannot be performed until the OVRF flag is set to 0.

When the RSPCK auto-stop function is enabled in master mode, an overrun error does not occur. Figure 35.30 and Figure 35.31 show the clock stop waveform when a serial transfer continues while the receive buffer is full in master mode.

**Figure 35.30** Clock Stop Waveform When a Serial Transfer Continues While the Receive Buffer is Full in Master Mode (CPHA = 1)

**Figure 35.31** Clock Stop Waveform When a Serial Transfer Continues While the Receive Buffer is Full in Master Mode (CPHA = 0)

The operation of the flags at the timings shown in steps (1) and (2) in the figure is described below.

- (1) When the receive buffer is full, an overrun error does not occur because the RSPCK clock is stopped.
- (2) If the SPDR register is read while the clock is stopped, data in the receive buffer can be read. The RSPCK clock restarts after reading the receive buffer (after the SPRF flag becomes 0).

### 35.3.9.2 Parity Error

If full-duplex communication is performed with the SPCR.TXMD bit set to 0 and the SPCR2.SPPE bit set to 1, when serial transfer ends, the RSPI checks whether there are parity errors. Upon detecting a parity error in the received data, the RSPI sets the SPSR.PERF flag to 1. Since the RSPI does not copy the data in the shift register to the receive buffer when the SPSR.OVRF flag is set to 1, parity error detection is not performed for the received data. To set the PERF flag to 0, write 0 to the PERF flag after the SPSR register is read with the PERF flag set to 1.

Figure 35.32 shows an example of operation of the OVRF and PERF flags. 'SPSR access' shown in Figure 35.32 indicates the condition of access to the SPSR register, where 'W' denotes a write cycle, and 'R' a read cycle. In the example of Figure 35.32, full-duplex communication is performed while the SPCR.TXMD bit is 0 and the SPCR2.SPPE bit is 1. The RSPI performs an 8-bit serial transfer in which the SPCMDm.CPHA bit is 1 and the SPCMDm.CPOL bit is 0. The numbers given under the RSPCKA waveform represent the number of RSPCK cycles (i.e., the number of transferred bits).

**Figure 35.32 Operation Example of PERF Flag**

The operation of the flags at the timing shown in steps (1) to (3) in the figure is described below.

- (1) If a serial transfer terminates with the RSPI not detecting an overrun error, the RSPI copies the data in the shift register to the receive buffer. The RSPI judges the received data at this timing, and sets the PERF flag to 1 if a parity error is detected. In master mode, the RSPI copies the pointer value to the SPCMDm register to the SPSSR.SPECM[2:0] bits.
- (2) If 0 is written to the PERF flag after the SPSR register is read when the PERF flag is 1, the PERF flag is set to 0.
- (3) When the RSPI detects an overrun error and serial transfer is terminated, the data in the shift register is not copied to the receive buffer. The RSPI does not perform parity error detection at this timing.

The occurrence of a parity error can be checked either by reading the SPSR register or by using an error interrupt and reading the SPSR register. When executing a serial transfer, measures should be taken to ensure the early detection of parity errors, such as reading the SPSR register. When the RSPI is used in master mode, the pointer value to the SPCMDm register at the occurrence of the error can be checked by reading the SPSSR.SPECM[2:0] bits.

### 35.3.9.3 Mode Fault Error

The RSPI operates in multi-master mode when the SPCR.MSTR bit is 1, the SPCR.SPMS bit is 0, and the SPCR.MODFEN bit is 1. If the active level is input with respect to the SSLA0 input signal of the RSPI in multi-master mode, the RSPI detects a mode fault error irrespective of the status of the serial transfer, and sets the SPSR.MODF flag to 1. Upon detecting the mode fault error, the RSPI copies the value of the pointer to the SPCMDm register to the SPSSR.SPECM[2:0] bits. The active level of the SSLA0 signal is determined by the SSLP.SSL0P bit.

When the MSTR bit is 0, the RSPI operates in slave mode. The RSPI detects a mode fault error if the MODFEN bit of the RSPI in slave mode is 1, and the SPMS bit is 0, and if the SSLA0 input signal is negated during the serial transfer period (from the time the driving of valid data is started to the time the final valid data is fetched).

Upon detecting a mode fault error, the RSPI stops driving of the output signals and clears the SPCR.SPE bit to 0 (refer to section 35.3.10, Initializing RSPI). In the case of multi-master configuration, detection of a mode fault error is used to stop driving of the output signals and the RSPI function, which allows the master right to be released.

The occurrence of a mode fault error can be checked either by reading the SPSR register or by using an error interrupt and reading the SPSR register. Detecting mode fault errors without utilizing the error interrupt requires polling of the SPSR register. When using the RSPI in master mode, the pointer value to the SPCMDm register at the occurrence of the error can be checked by reading the SPSSR.SPECM[2:0] bits.

When the MODF flag is 1, writing of the value 1 to the SPE bit is ignored by the RSPI. To enable the RSPI function after the detection of a mode fault error, set the MODF flag to 0. When setting the MODF flag to 0, the SPE bit becomes 1.

### 35.3.9.4 Underrun Error

If a serial transfer is started when the SPCR.SPE bit is 1 (RSPI function is enabled) and transmit data is still not loaded on the shift register while RSPI operates in slave mode (the SPCR.MSTR bit is 0), the RSPI detects an underrun error, and sets the SPSR.MODF and SPSR.UDRF flags to 1. Upon detecting an underrun error, the RSPI stops driving of the output signals and clears the SPCR.SPE bit to 0. Clearing of the SPE bit disables the RSPI function. (Refer to section 35.3.10, Initializing RSPI). The occurrence of an underrun error can be checked either by reading the SPSR register or by using an error interrupt and reading the SPSR register. Detecting underrun errors without utilizing the error interrupt requires polling of the SPSR register. When the MODF flag is 1, writing of the value 1 to the SPE bit is ignored by the RSPI. To enable the RSPI function after the detection of an underrun error, set the MODF flag to 0. When setting the MODF flag to 0, the SPE bit becomes 1.

### 35.3.10 Initializing RSPI

If 0 is written to the SPCR.SPE bit or the RSPI sets the SPE bit to 0 because of the detection of a mode fault error or an underrun error, the RSPI disables the RSPI function, and initializes some of the module functions. When a system reset is generated, the RSPI initializes all of the module functions. The following describes initialization by the clearing of the SPCR.SPE bit and initialization by a system reset.

#### 35.3.10.1 Initialization by Clearing the SPE Bit

When the SPCR.SPE bit is set to 0, the RSPI performs the following initialization:

- Aborting the transmission and reception that is being executed
- Stopping the driving of output signals (Hi-Z) in slave mode
- Initializing the internal state of the RSPI
- Initializing the transmit buffer of the RSPI (Set the SPTEF flag to 1)

Initialization by the clearing of the SPE bit does not initialize the control bits of the RSPI. For this reason, the RSPI can be started in the same transfer mode as prior to the initialization if the SPE bit is set to 1 again.

The SPSR.SPRF, UDRF, PERF, MODF, and OVRF flags are not initialized, nor is the value of the RSPI sequence status register (SPSSR) initialized. For this reason, even after the RSPI is initialized, data from the receive buffer can be read and the status of error occurrence during the RSPI transfer can be checked.

The transmit buffer is initialized to an empty state (the SPTEF flag is 1). Therefore, if the SPCR.SPTIE bit is set to 1 after RSPI initialization, a transmit buffer empty interrupt is generated. When the RSPI is initialized, in order to disable any transmit buffer empty interrupt, 0 should be written to the SPTIE bit simultaneously with the writing of 0 to the SPE bit.

#### 35.3.10.2 System Reset

The initialization by a system reset completely initializes the RSPI through the initialization of all bits for controlling the RSPI, initialization of the status bits, and initialization of data registers, in addition to the requirements described in section 35.3.10.1, Initialization by Clearing the SPE Bit.

## 35.3.11 SPI Operation

### 35.3.11.1 Master Mode Operation

The only difference between single-master mode operation and multi-master mode operation lies in mode fault error detection (refer to section 35.3.9, Error Detection). When operating in single-master mode, the RSPI does not detect mode fault errors whereas the RSPI running in multi-master mode does detect mode fault errors. This section explains operations that are common to single-master mode and multi-master mode.

#### (1) Starting a Serial Transfer

The RSPI updates the data in the transmit buffer (SPTX) when data is written to the RSPI data register (SPDR) with the RSPI transmit buffer being empty (the SPTEF flag is 1 and data for the next transfer is not set). When the shift register is empty after the number of frames set in the SPDCR.SPFC[1:0] bits are written to the SPDR register, the RSPI copies data from the transmit buffer to the shift register and starts serial transfer. Upon copying transmit data to the shift register, the RSPI changes the status of the shift register to “full”, and upon termination of serial transfer, it changes the status of the shift register to “empty”. The status of the shift register cannot be referenced.

For details on the RSPI transfer format, refer to section 35.3.5, Transfer Format. The polarity of the SSLAi output pins depends on the SSLP register settings.

#### (2) Terminating a Serial Transfer

Irrespective of the SPCMDm.CPHA bit, the RSPI terminates the serial transfer after transmitting an RSPCKA edge corresponding to the final sampling timing. If free space is available in the receive buffer (SPRX) (the SPRF flag is 0), upon termination of serial transfer, the RSPI copies data from the shift register to the receive buffer of the SPDR register. It should be noted that the final sampling timing varies depending on the bit length of transfer data. In master mode, the RSPI data length depends on the SPCMDm.SPB[3:0] bit setting. The polarity of the SSLAi output pin depends on the SSLP register settings.

For details on the RSPI transfer format, refer to section 35.3.5, Transfer Format.

### (3) Sequence Control

The transfer format that is employed in master mode is determined by the SPSCR, SPCMDm, SPBR, SPCKD, SSLND, and SPND registers.

The SPSCR register is a register used to determine the sequence configuration for serial transfers that are executed by the RSPI in master mode. The following items are set in the SPCMDm register: SSLAi pin output signal value, MSB/LSB first, data length, some of the bit rate settings, RSPCK polarity/phase, whether the SPCKD register is to be referenced, whether the SSLND register is to be referenced, and whether the SPND register is to be referenced. The SPBR register holds some of the bit rate settings; the SPCKD register, an RSPI clock delay value; the SSLND register, an SSL negation delay; and the SPND register, a next-access delay value.

According to the sequence length that is assigned to the SPSCR register, the RSPI makes up a sequence comprised of a part or all of the SPCMDm register. The RSPI contains a pointer to the SPCMDm register that makes up the sequence. The value of this pointer can be checked by reading the SPSSR.SPCP[2:0] bits. When the SPCR.SPE bit is set to 1 and the RSPI function is enabled, the RSPI loads the pointer to the commands in the SPCMD0 register, and incorporates the SPCMD0 settings into the transfer format at the beginning of serial transfer. The RSPI increments the pointer each time the next-access delay period for a data transfer ends. Upon completion of the serial transfer that corresponds to the final command comprising the sequence, the RSPI sets the pointer in the SPCMD0 register, and in this manner the sequence is executed repeatedly.

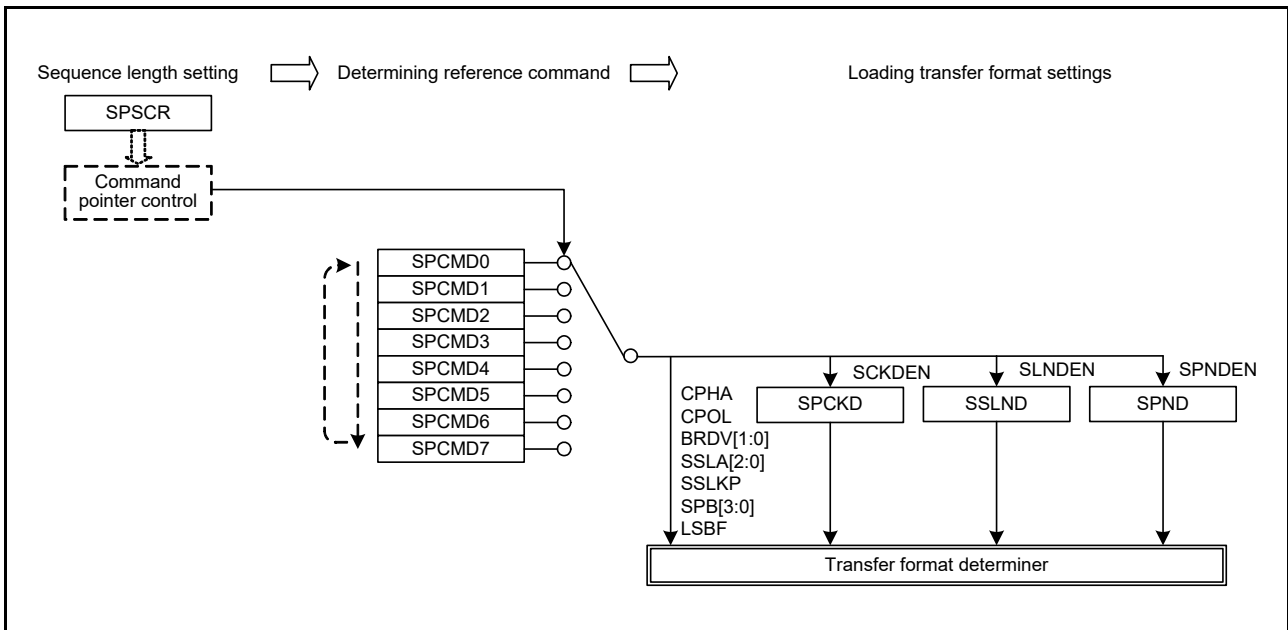

Figure 35.33 Procedure for Determining the Form of Serial Transfer in Master Mode

In this section, a frame is the combination of the data (SPDR) and the settings (SPCMDm).

Figure 35.34 Concept of a Frame

Figure 35.35 shows the relationship between the command and the transmit and receive buffers in the sequence of operations specified by the settings in Table 35.4.

Figure 35.35 Correspondence between the RSPI Command Register and Transmit/Receive Buffers in Sequence Operations

#### (4) Burst Transfer

If the SPCMDm.SSLKP bit that the RSPI references during the current serial transfer is 1, the RSPI keeps the SSLAi signal level during the serial transfer until the beginning of the SSLAi signal assertion for the next serial transfer. If the SSLAi signal level for the next serial transfer is the same as the SSLAi signal level for the current serial transfer, the RSPI can execute continuous serial transfers while keeping the SSLAi signal assertion status (burst transfer).

Figure 35.36 shows an example of an SSLAi signal operation for the case where a burst transfer is implemented using SPCMD0 and SPCMD1 register settings. The text below explains the RSPI operations (1) to (7) as shown in Figure 35.36. It should be noted that the polarity of the SSLAi output signal depends on the SSLP register settings.

**Figure 35.36 Example of Burst Transfer Operation Using SSLKP Bit (CPHA = 1, CPOL = 0)**

- (1) Based on the SPCMD0 register, the RSPI asserts the SSLAi signal and inserts RSPCK delays.
- (2) The RSPI executes serial transfers according to the SPCMD0 register.
- (3) The RSPI inserts SSL negation delays.
- (4) Since the SPCMD0.SSLKP bit is 1, the RSPI keeps the SSLAi signal value on the SPCMD0 register. This period is sustained, at the shortest, for a period equal to the next-access delay of the SPCMD0 register. If the shift register is empty after the passage of a minimum period, this period is sustained until the transmit data is stored in the shift register for the next transfer.
- (5) Based on the SPCMD1 register, the RSPI inserts RSPCK delays.
- (6) The RSPI executes serial transfers according to the SPCMD1 register.
- (7) The RSPI inserts SSL negation delays.
- (8) Because the SPCMD1.SSLKP bit is 0, the RSPI negates the SSLAi signal. In addition, a next-access delay is inserted according to the SPCMD1 register.

If the SSLAi signal output settings in the SPCMDm register in which 1 is assigned to the SSLKP bit are different from the SSLAi signal output settings in the SPCMDm register to be used in the next transfer, the RSPI switches the SSLAi signal status to SSLAi signal assertion ((5) in Figure 35.36) corresponding to the command for the next transfer. Note that if such an SSLAi signal switching occurs, the slaves that drive the MISOA signal compete, and collision of signal levels may occur.

The RSPI in master mode references the SSLAi signal operation within the module for the case where the SSLKP bit is not used. Even when the SPCMDm.CPHA bit is 0, the RSPI can accurately start serial transfers by using the SSLAi signal assertion for the next transfer that is detected internally.

**(5) RSPCK Delay (t1)**

The RSPCK delay value in master mode depends on the SPCMDm.SCKDEN bit setting and the SPCKD register setting. The RSPI determines the SPCMDm register to be referenced during serial transfer by pointer control, and determines an RSPCK delay value during serial transfer by using the SPCMDm.SCKDEN bit and the SPCKD register, as listed in Table 35.8. For a definition of RSPCK delay, refer to section 35.3.5, Transfer Format.

**Table 35.8 Relationship among SCKDEN Bit, SPCKD, and RSPCK Delay Value**

| SPCMDm.SCKDEN Bit | SPCKD.SCKDL[2:0] Bits | RSPCK Delay Value |
|-------------------|-----------------------|-------------------|
| 0                 | 000b to 111b          | 1 RSPCK           |
| 1                 | 000b                  | 1 RSPCK           |
|                   | 001b                  | 2 RSPCK           |
|                   | 010b                  | 3 RSPCK           |
|                   | 011b                  | 4 RSPCK           |
|                   | 100b                  | 5 RSPCK           |
|                   | 101b                  | 6 RSPCK           |
|                   | 110b                  | 7 RSPCK           |
|                   | 111b                  | 8 RSPCK           |

**(6) SSL Negation Delay (t2)**

The SSL negation delay value in master mode depends on the SPCMDm.SLNDEN bit setting and the SSLND register setting. The RSPI determines the SPCMDm register to be referenced during serial transfer by pointer control, and determines an SSL negation delay value during serial transfer by using the SPCMDm.SLNDEN bit and the SSLND register, as listed in Table 35.9. For a definition of SSL negation delay, refer to section 35.3.5, Transfer Format.

**Table 35.9 Relationship among SLNDEN Bit, SSLND, and SSL Negation Delay Value**

| SPCMDm.SLNDEN Bit | SSLND.SLNDL[2:0] Bits | SSL Negation Delay Value |
|-------------------|-----------------------|--------------------------|
| 0                 | 000b to 111b          | 1 RSPCK                  |
| 1                 | 000b                  | 1 RSPCK                  |
|                   | 001b                  | 2 RSPCK                  |
|                   | 010b                  | 3 RSPCK                  |
|                   | 011b                  | 4 RSPCK                  |
|                   | 100b                  | 5 RSPCK                  |
|                   | 101b                  | 6 RSPCK                  |
|                   | 110b                  | 7 RSPCK                  |
|                   | 111b                  | 8 RSPCK                  |

**(7) Next-Access Delay (t3)**

The next-access delay value in master mode depends on the SPCMDm.SPNDEN bit setting and the SPND setting. The RSPIC determines the SPCMDm register to be referenced during serial transfer by pointer control, and determines a next-access delay value during serial transfer by using the SPCMDm.SPNDEN bit and SPND, as listed in Table 35.10. For a definition of next-access delay, refer to section 35.3.5, Transfer Format.

**Table 35.10 Relationship among SPNDEN Bit, SPND, and Next-Access Delay Value**

| SPCMDm.SPNDEN Bit | SPND.SPNDL[2:0] Bits | Next-Access Delay Value |
|-------------------|----------------------|-------------------------|
| 0                 | 000b to 111b         | 1 RSPCK + 2 PCLK        |
| 1                 | 000b                 | 1 RSPCK + 2 PCLK        |
|                   | 001b                 | 2 RSPCK + 2 PCLK        |
|                   | 010b                 | 3 RSPCK + 2 PCLK        |
|                   | 011b                 | 4 RSPCK + 2 PCLK        |
|                   | 100b                 | 5 RSPCK + 2 PCLK        |
|                   | 101b                 | 6 RSPCK + 2 PCLK        |
|                   | 110b                 | 7 RSPCK + 2 PCLK        |
|                   | 111b                 | 8 RSPCK + 2 PCLK        |

(8) Initialization Flowchart

Figure 35.37 is a flowchart illustrating an example of initialization in SPI operation when the RSPIC is used in master mode. For a description of how to set up the interrupt controller, DMAC, and I/O ports, refer to the descriptions given in the individual blocks.

Figure 35.37 Example of Initialization Flowchart in Master Mode (SPI Operation)

(9) Software Processing Flow

Figure 35.38 to Figure 35.40 show examples of the flow of software processing.

(a) Transmit Processing Flow

When transmitting data, the CPU will be notified of the completion of data transmission by enabling the SPII interrupt after the last writing of data for transmission.

The completion of data transmission can also be checked by polling to see if the SPSR.IDLNF flag has become 0, instead of using the SPII interrupt. However, one cycle of PCLK is required for the time from when data for transmission is written in the SPDR register to when the IDLNF flag becomes 1. After the last data is written in the SPDR register, discard the value of the SPSR register once not to judge the condition with the IDLNF flag which has not yet become 1, and read and use the value of the IDLNF flag to confirm the completion of data transmission.

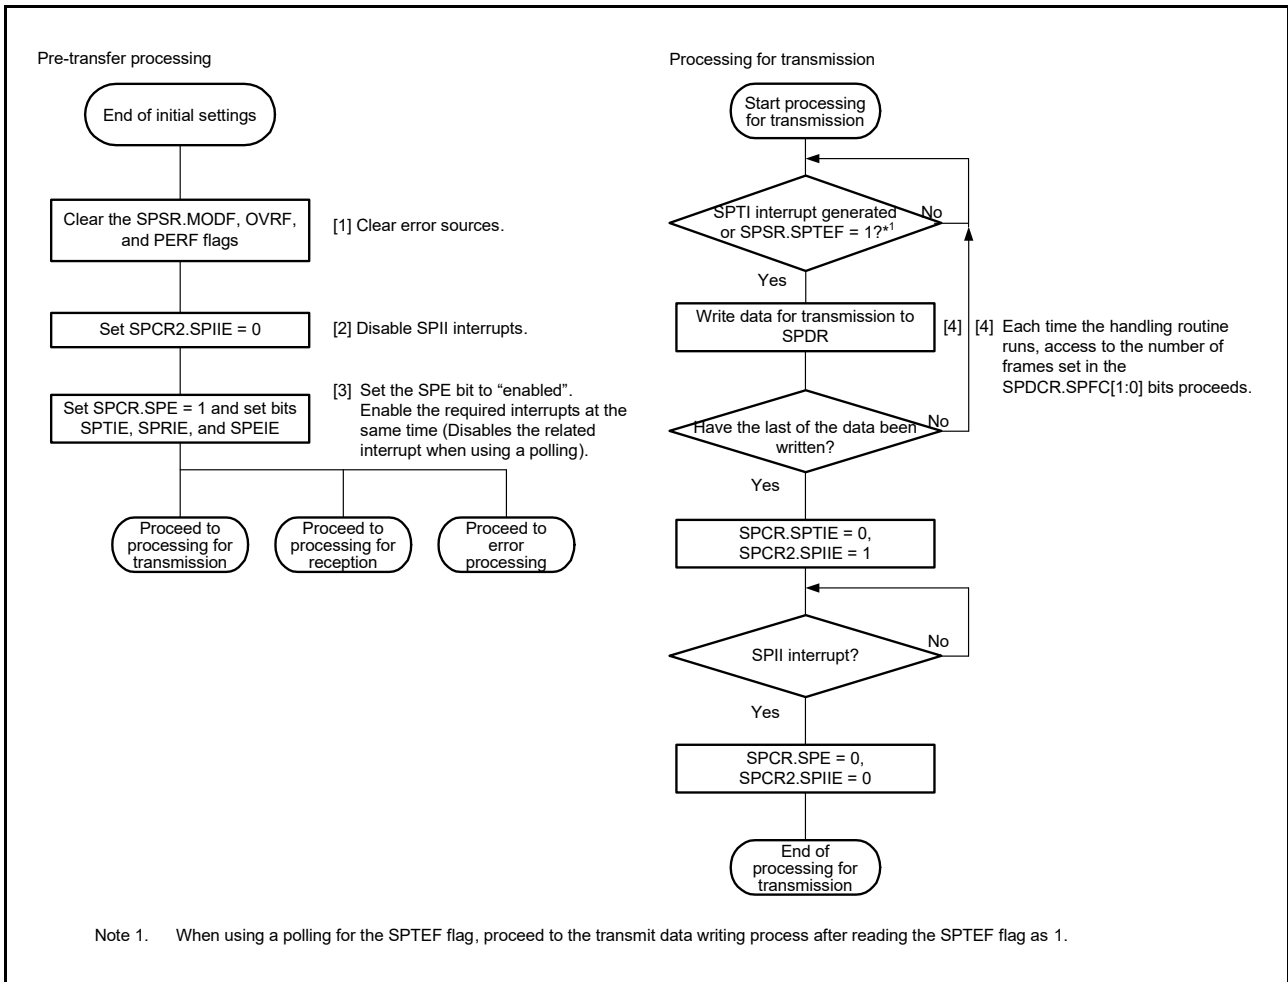

Figure 35.38 Flowchart in Master Mode (Transmission)

(b) Receive Processing Flow

The RSPI does not support receive-only simplex communications, so processing for transmission is required.

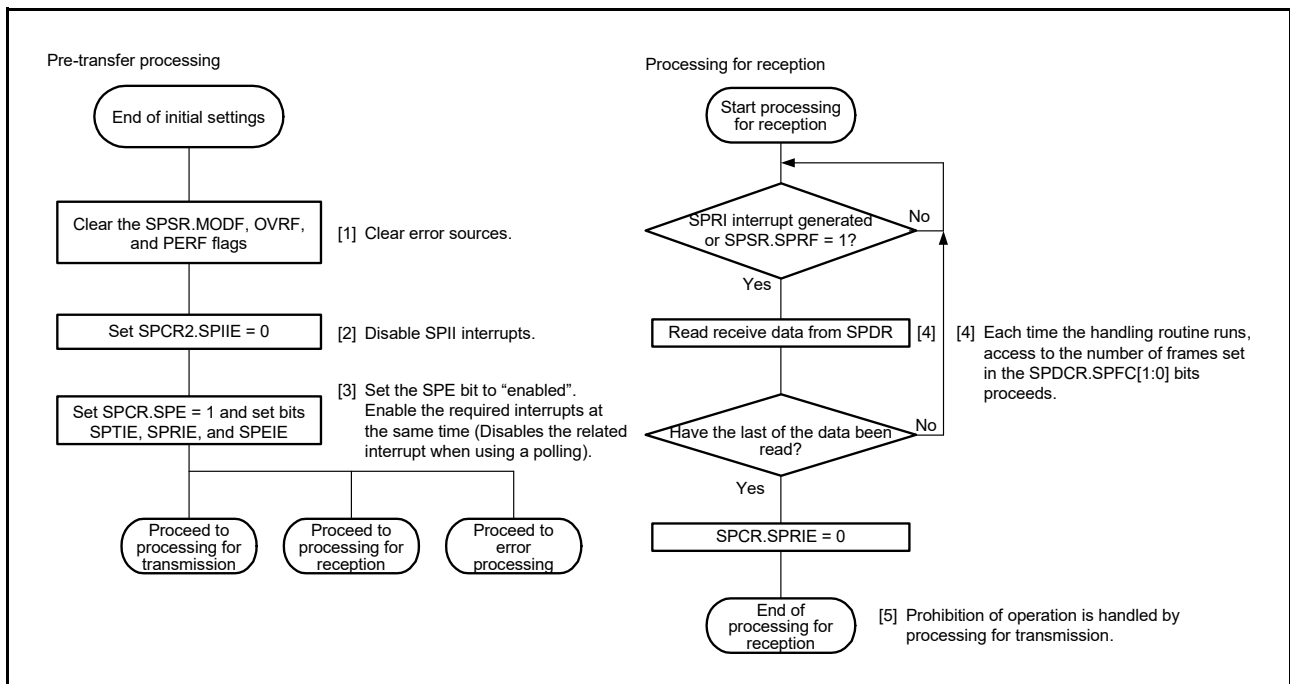

Figure 35.39 Flowchart in Master Mode (Reception)

(c) Flow of Error Processing

When a mode fault error is generated, the SPCR.SPE bit is automatically cleared, stopping operations for transmission and reception. For errors from other sources, however, the SPCR.SPE bit is not cleared and operations for transmission and reception continue; accordingly, we recommend clearing of the SPCR.SPE bit to stop operations in the case of errors other than mode fault errors. Not doing so will lead to updating of the SPSSR.SPECM[2:0] bits.

When interrupts are used and an error occurs, if the ICU.IRn.IR flag for the SPTI or SPRI interrupt request is set to 1, clear the ICU.IRn.IR flag in the error processing routine. If the SPRI interrupt request is indicated, read the receive buffer and initialize the sequencer in the RSPI.

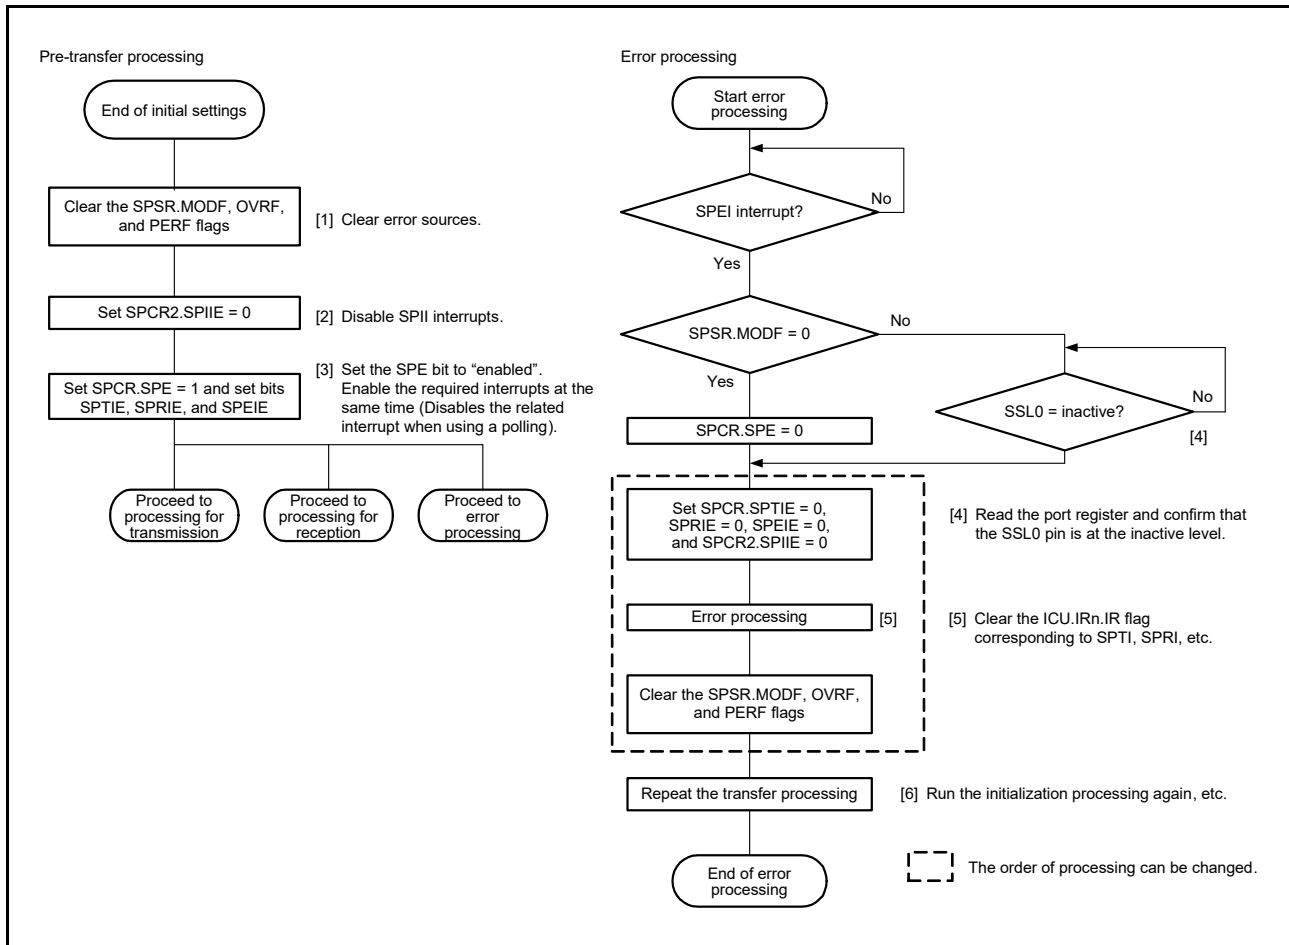

Figure 35.40 Flowchart for Master Mode (Error Processing)

### 35.3.11.2 Slave Mode Operation

#### (1) Starting a Serial Transfer

If the SPCMD0.CPHA bit is 0, when detecting an SSLA0 input signal assertion, the RSPI needs to start driving valid data to the MISOA output signal. For this reason, when the CPHA bit is 0, the assertion of the SSLA0 input signal triggers the start of a serial transfer.

If the CPHA bit is 1, when detecting the first RSPCKA edge in an SSLA0 signal asserted condition, the RSPI needs to start driving valid data to the MISOA output signal. For this reason, when the CPHA bit is 1, the first RSPCKA edge in an SSLA0 signal asserted condition triggers the start of a serial transfer.

Irrespective of the CPHA bit setting, the timing at which the RSPI starts driving of the MISOA output signal is the SSLA0 signal assertion timing. The data which is output by the RSPI is either valid or invalid, depending on the CPHA bit setting.

For details on the RSPI transfer format, refer to [section 35.3.5, Transfer Format](#). The polarity of the SSLA0 input signal depends on the setting of the SSLP.SSL0P bit.

#### (2) Terminating a Serial Transfer

Irrespective of the SPCMD0.CPHA bit, the RSPI terminates the serial transfer after detecting an RSPCKA edge corresponding to the final sampling timing. When free space is available in the receive buffer (the SPRF flag is 0), upon termination of serial transfer the RSPI copies received data from the shift register to the receive buffer of the SPDR register. Upon termination of a serial transfer the RSPI changes the status of the shift register to “empty”, regardless of the receive buffer state. A mode fault error occurs if the RSPI detects an SSLA0 input signal negation from the beginning of serial transfer to the end of serial transfer (refer to [section 35.3.9, Error Detection](#)).

The final sampling timing changes depending on the bit length of transfer data. In slave mode, the RSPI data length depends on the SPCMD0.SPB[3:0] bit setting. The polarity of the SSLA0 input signal depends on the SSLP.SSL0P bit setting.

For details on the RSPI transfer format, refer to [section 35.3.5, Transfer Format](#).

#### (3) Notes on Single-Slave Operations

If the SPCMD0.CPHA bit is 0, the RSPI starts serial transfers when it detects the assertion edge for an SSLA0 input signal. In the type of configuration shown in [Figure 35.7](#) as an example, if the RSPI is used in single-slave mode, the SSLA0 signal is fixed at the active state. Therefore, when the CPHA bit is set to 0, the RSPI cannot correctly start a serial transfer. To correctly execute transmit/receive operations by the RSPI in slave mode in a configuration in which the SSLA0 input signal is fixed at the active state, the CPHA bit should be set to 1. If there is a need for setting the CPHA bit to 0, the SSLA0 input signal should not be fixed.

#### (4) Burst Transfer

If the SPCMD0.CPHA bit is 1, continuous serial transfer (burst transfer) can be executed while retaining the assertion state for the SSLA0 input signal. If the CPHA bit is 1, the period from the first RSPCKA edge to the sampling timing for the reception of the final bit in an SSLA0 signal active state corresponds to a serial transfer period. Even when the SSLA0 input signal remains at the active level, the RSPI can accommodate burst transfers because it can detect the start of an access.

If the CPHA bit is 0, the second and subsequent serial transfers during burst transfer cannot be executed correctly.

#### (5) Initialization Flowchart

Figure 35.41 is a flowchart illustrating an example of initialization in SPI operation when the RSPI is used in slave mode. For a description of how to set up the interrupt controller, DMAC, and I/O ports, refer to the descriptions given in the individual blocks.

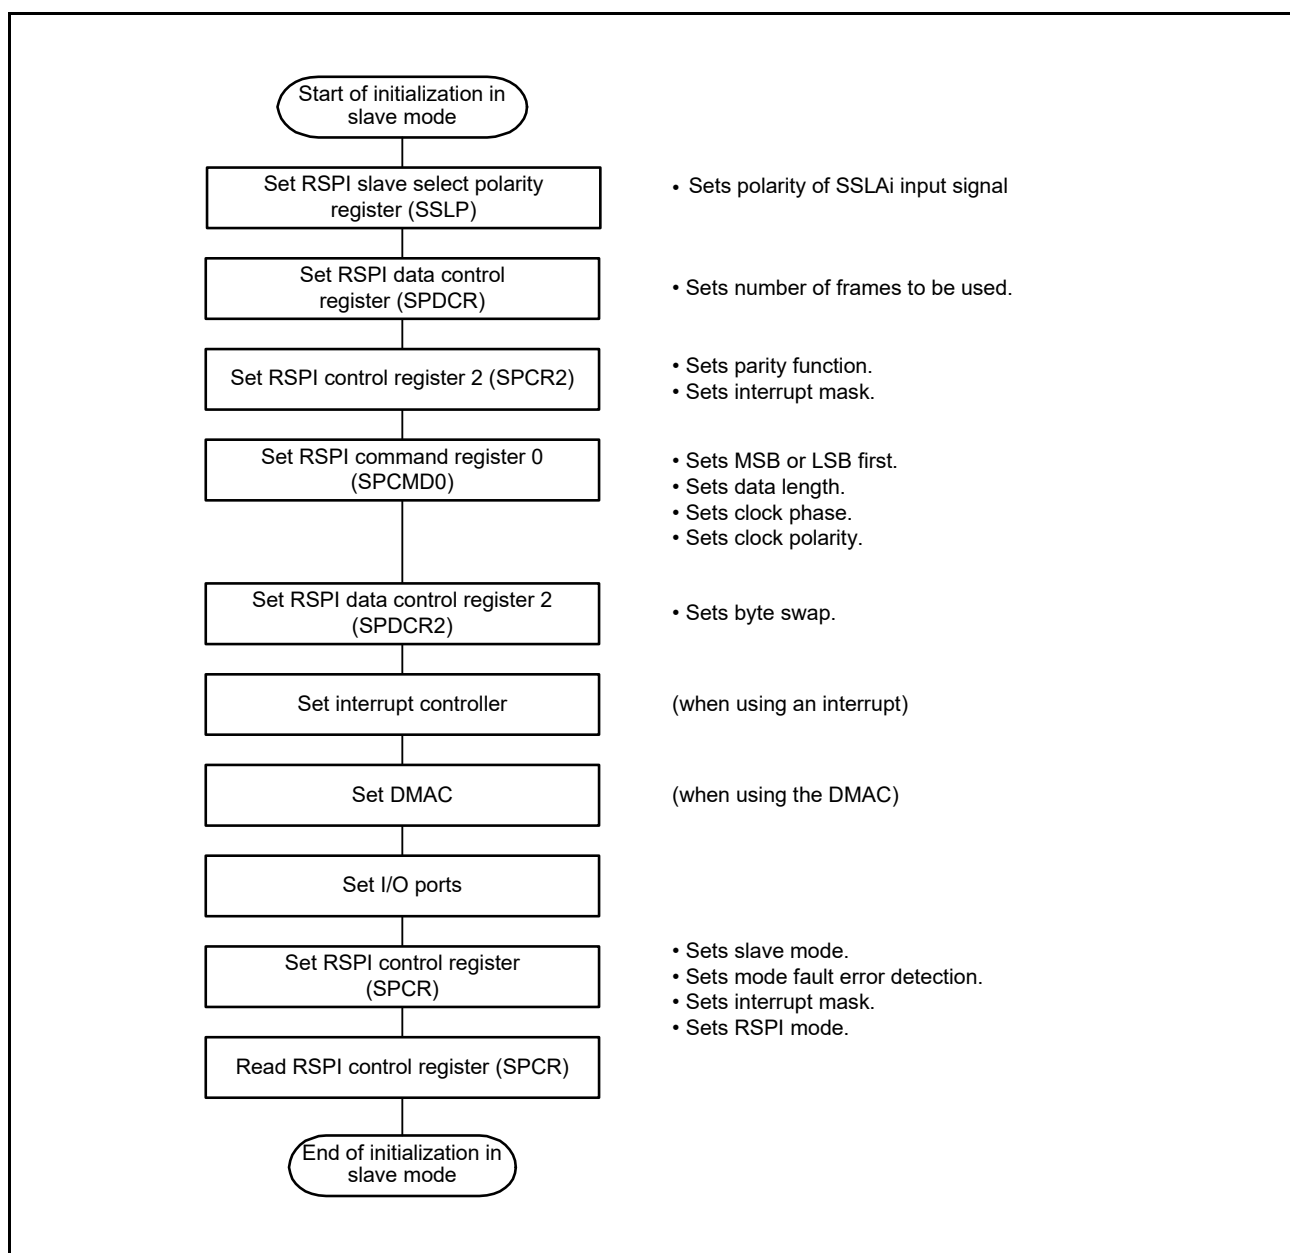

Figure 35.41 Example of Initialization Flowchart in Slave Mode (SPI Operation)

(6) Software Processing Flow

Figure 35.42 to Figure 35.44 show examples of the flow of software processing.

(a) Transmit Processing Flow

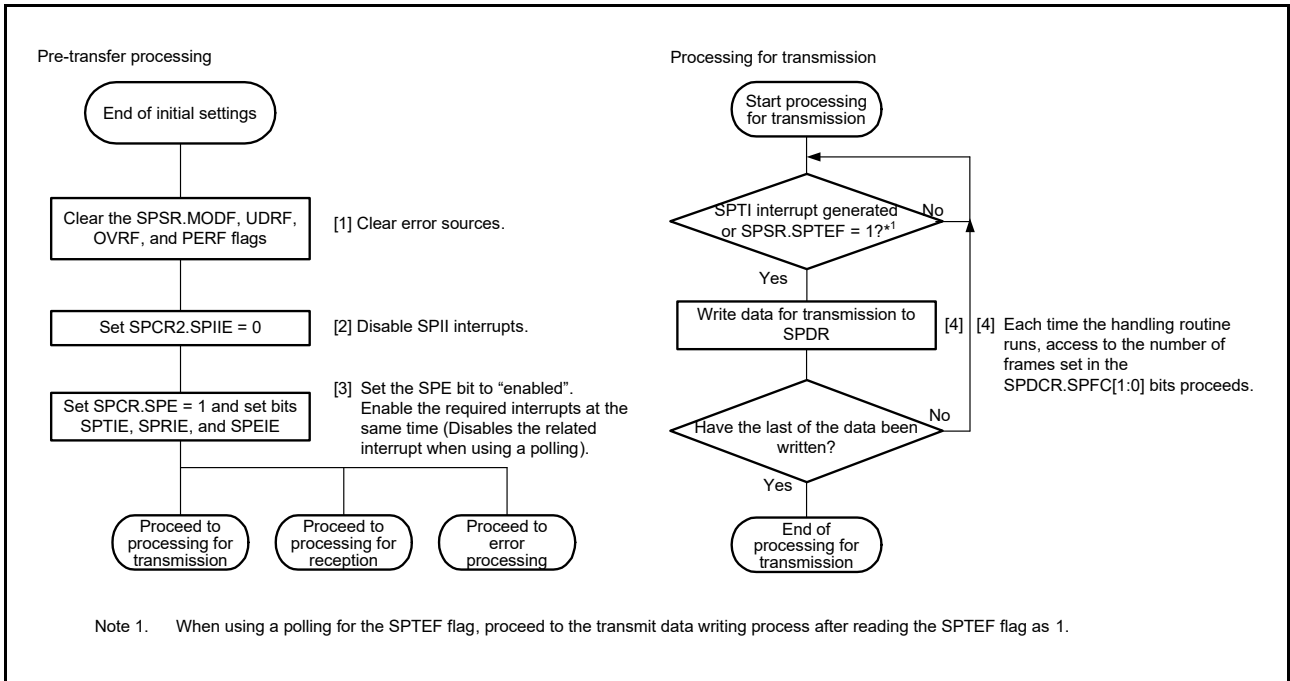

Figure 35.42 Flowchart in Slave Mode (Transmission)

(b) Receive Processing Flow

The RSPI does not support receive-only simplex communications, so processing for transmission is required.

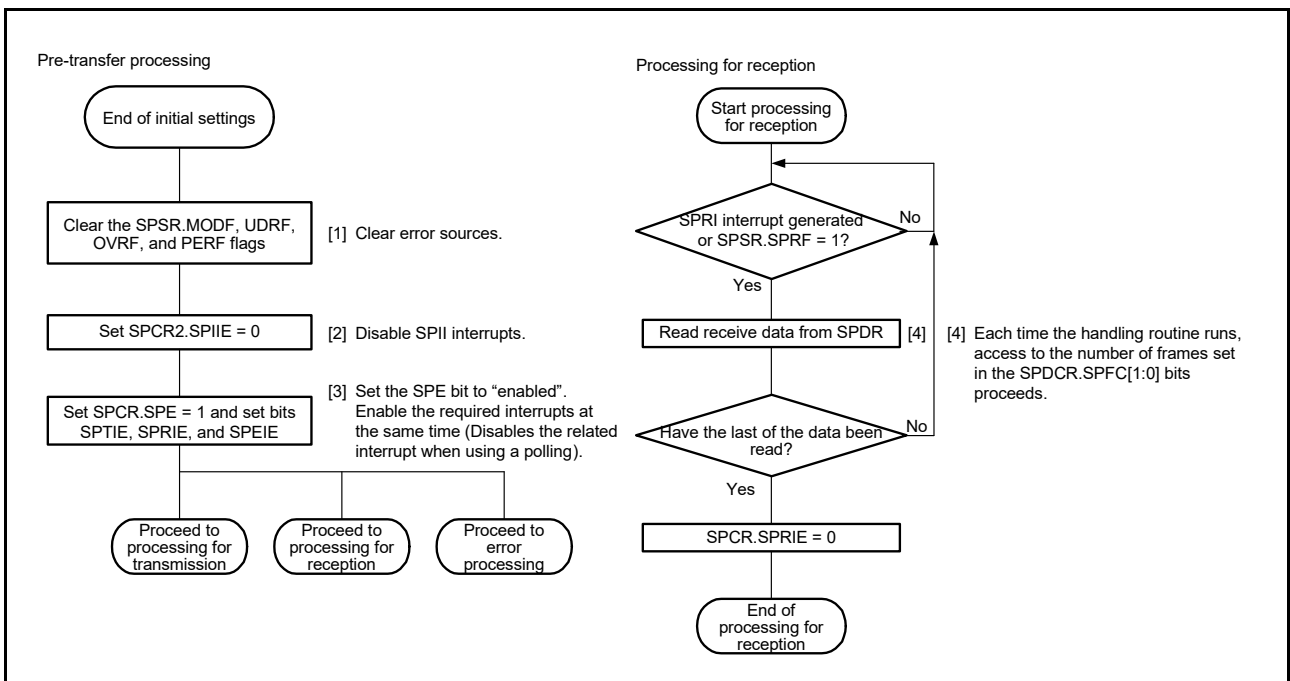

Figure 35.43 Flowchart in Slave Mode (Reception)

(c) Flow of Error Processing

In slave mode, even when a mode fault error is generated, the SPSR.MODF flag can be cleared regardless of the status of the SSLA0 pin.

When interrupts are used and an error occurs, if the ICU.IRn.IR flag for the SPTI or SPRI interrupt request is set to 1, clear the ICU.IRn.IR flag in the error processing routine. If the SPRI interrupt request is indicated, read the receive buffer and initialize the sequencer in the RSPI.

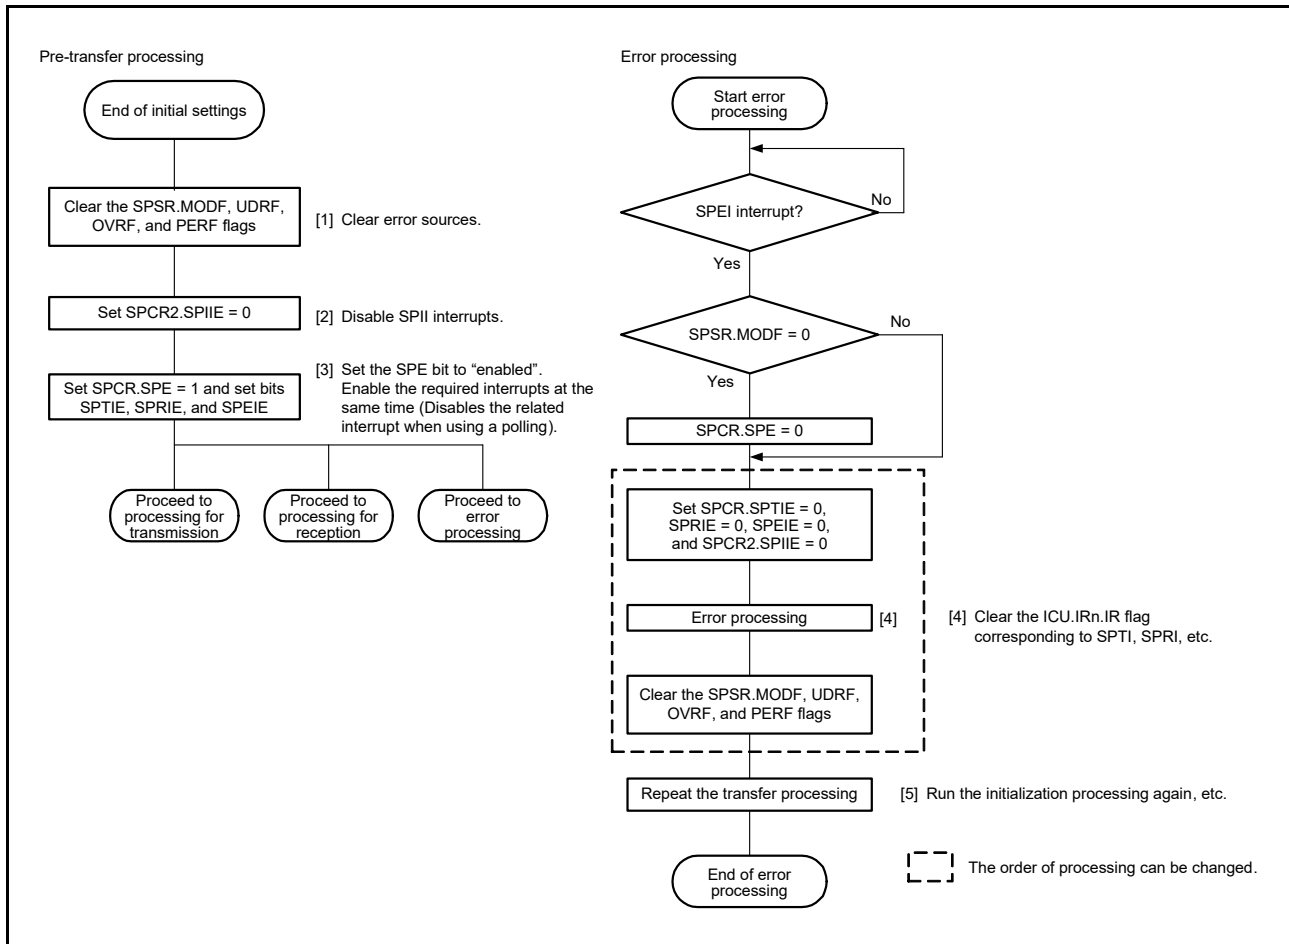

Figure 35.44 Flowchart for Slave Mode (Error Processing)

### 35.3.12 Clock Synchronous Operation

Setting the SPCR.SPMS bit to 1 selects clock synchronous operation of the RSPI. In clock synchronous operation, the SSLAi pin is not used, and the three pins of RSPCKA, MOSIA, and MISOA handle communications. The SSLAi pin is available as I/O port pins.

Although clock synchronous operation does not require use of the SSLAi pin, operation of the module is the same as in SPI operation. That is, in both master and slave mode operations, communications can be performed with the same flow as in SPI operation. However, mode fault errors are not detected because the SSLAi pin is not used.

Furthermore, do not set the SPCMDm.CPHA bit to 0 if clock synchronous operation is to proceed in slave mode (SPCR.MSTR = 0).

#### 35.3.12.1 Master Mode Operation

##### (1) Starting a Serial Transfer

The RSPI updates the data in the transmit buffer (SPTX) of the SPDR register when data is written to the SPDR register with the transmit buffer being empty (the SPTEF flag is 1 and data for the next transfer is not set). When the shift register is empty after the number of frames set in the SPDCR.SPFC[1:0] bits are written to the SPDR register, the RSPI copies data from the transmit buffer to the shift register and starts serial transmission. Upon copying transmit data to the shift register, the RSPI changes the status of the shift register to “full”, and upon termination of serial transfer, it changes the status of the shift register to “empty”. The status of the shift register cannot be referenced.

For details on the RSPI transfer format, refer to [section 35.3.5, Transfer Format](#).

However, transfer in clock synchronous operation is conducted without the SSLA0 output signal.

##### (2) Terminating a Serial Transfer

The RSPI terminates the serial transfer after transmitting an RSPCKA edge corresponding to the sampling timing. If free space is available in the receive buffer (SPRX) (the SPRF flag is 0), upon termination of serial transfer, the RSPI copies data from the shift register to the receive buffer of the RSPI data register (SPDR).

It should be noted that the final sampling timing varies depending on the bit length of transfer data. In master mode, the RSPI data length depends on the SPCMDm.SPB[3:0] bit setting.

For details on the RSPI transfer format, refer to [section 35.3.5, Transfer Format](#).

However, transfer in clock synchronous operation is conducted without the SSLA0 output signal.

##### (3) Sequence Control

The transfer format employed in master mode is determined by SPSCR, SPCMDm, SPBR, SPCKD, SSLND, and SPND registers. Although the SSLAi signals are not output in clock synchronous operation, these settings are valid.

The SPSCR register is a register used to determine the sequence configuration for serial transfers that are executed by the RSPI in master mode. The following items are set in the SPCMDm register: SSLAi output signal value, MSB/LSB first, data length, some of the bit rate settings, RSPCKA polarity/phase, whether the SPCKD register is to be referenced, whether the SSLND register is to be referenced, and whether the SPND register is to be referenced. The SPBR register holds some of the bit rate settings; the SPCKD register, an RSPI clock delay value; the SSLND register, an SSL negation delay; and the SPND register, a next-access delay value.

According to the sequence length that is assigned to the SPSCR register, the RSPI makes up a sequence comprised of a part or all of the SPCMDm register. The RSPI contains a pointer to the SPCMDm register that makes up the sequence. The value of this pointer can be checked by reading the SPSSR.SPCP[2:0] bits. When the SPCR.SPE bit is set to 1 and the RSPI function is enabled, the RSPI loads the pointer to the commands in the SPCMD0 register, and incorporates the SPCMD0 register setting into the transfer format at the beginning of serial transfer. The RSPI increments the pointer each time the next-access delay period for a data transfer ends. Upon completion of the serial transfer that corresponds to the final command comprising the sequence, the RSPI sets the pointer in the SPCMD0 register, and in this manner the sequence is executed repeatedly.

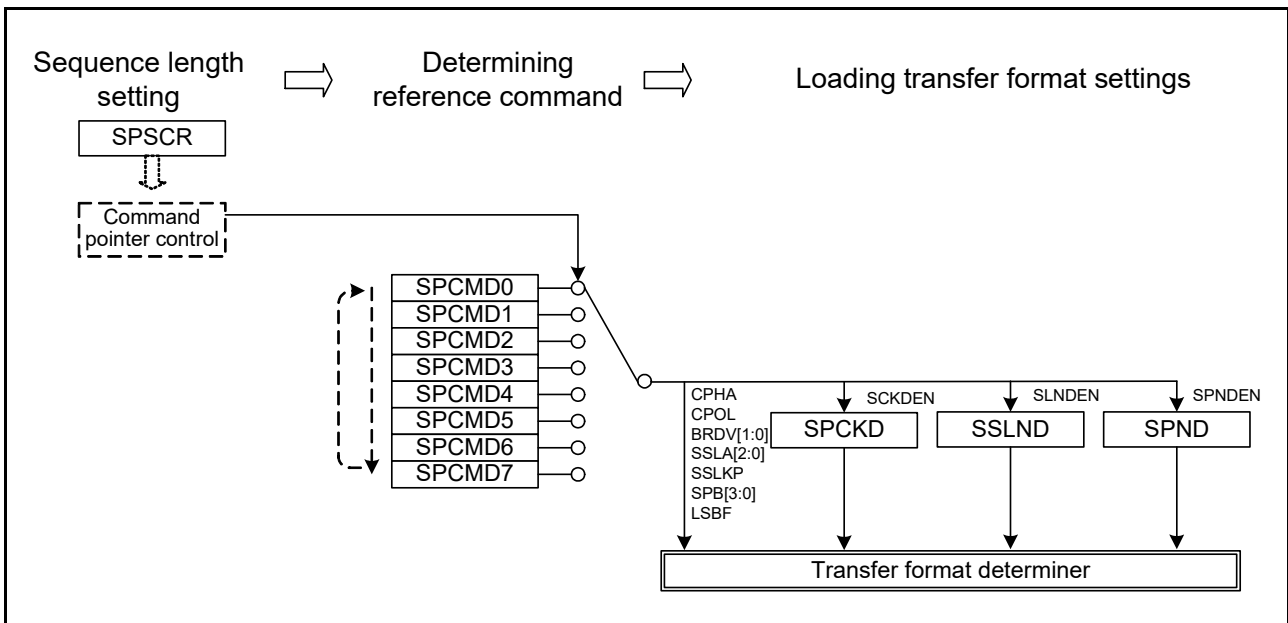

Figure 35.45 Procedure for Determining the Form of Serial Transmission in Master Mode

In this section, a frame is the combination of the data (SPDR) and the settings (SPCMDm).

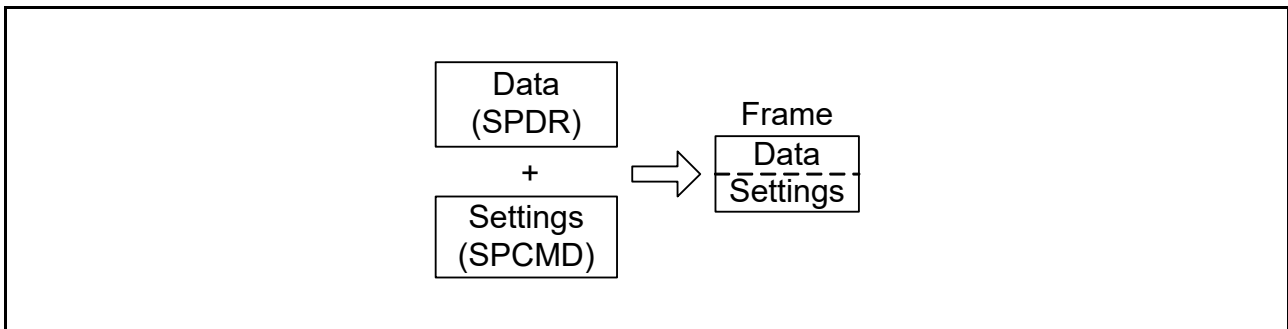

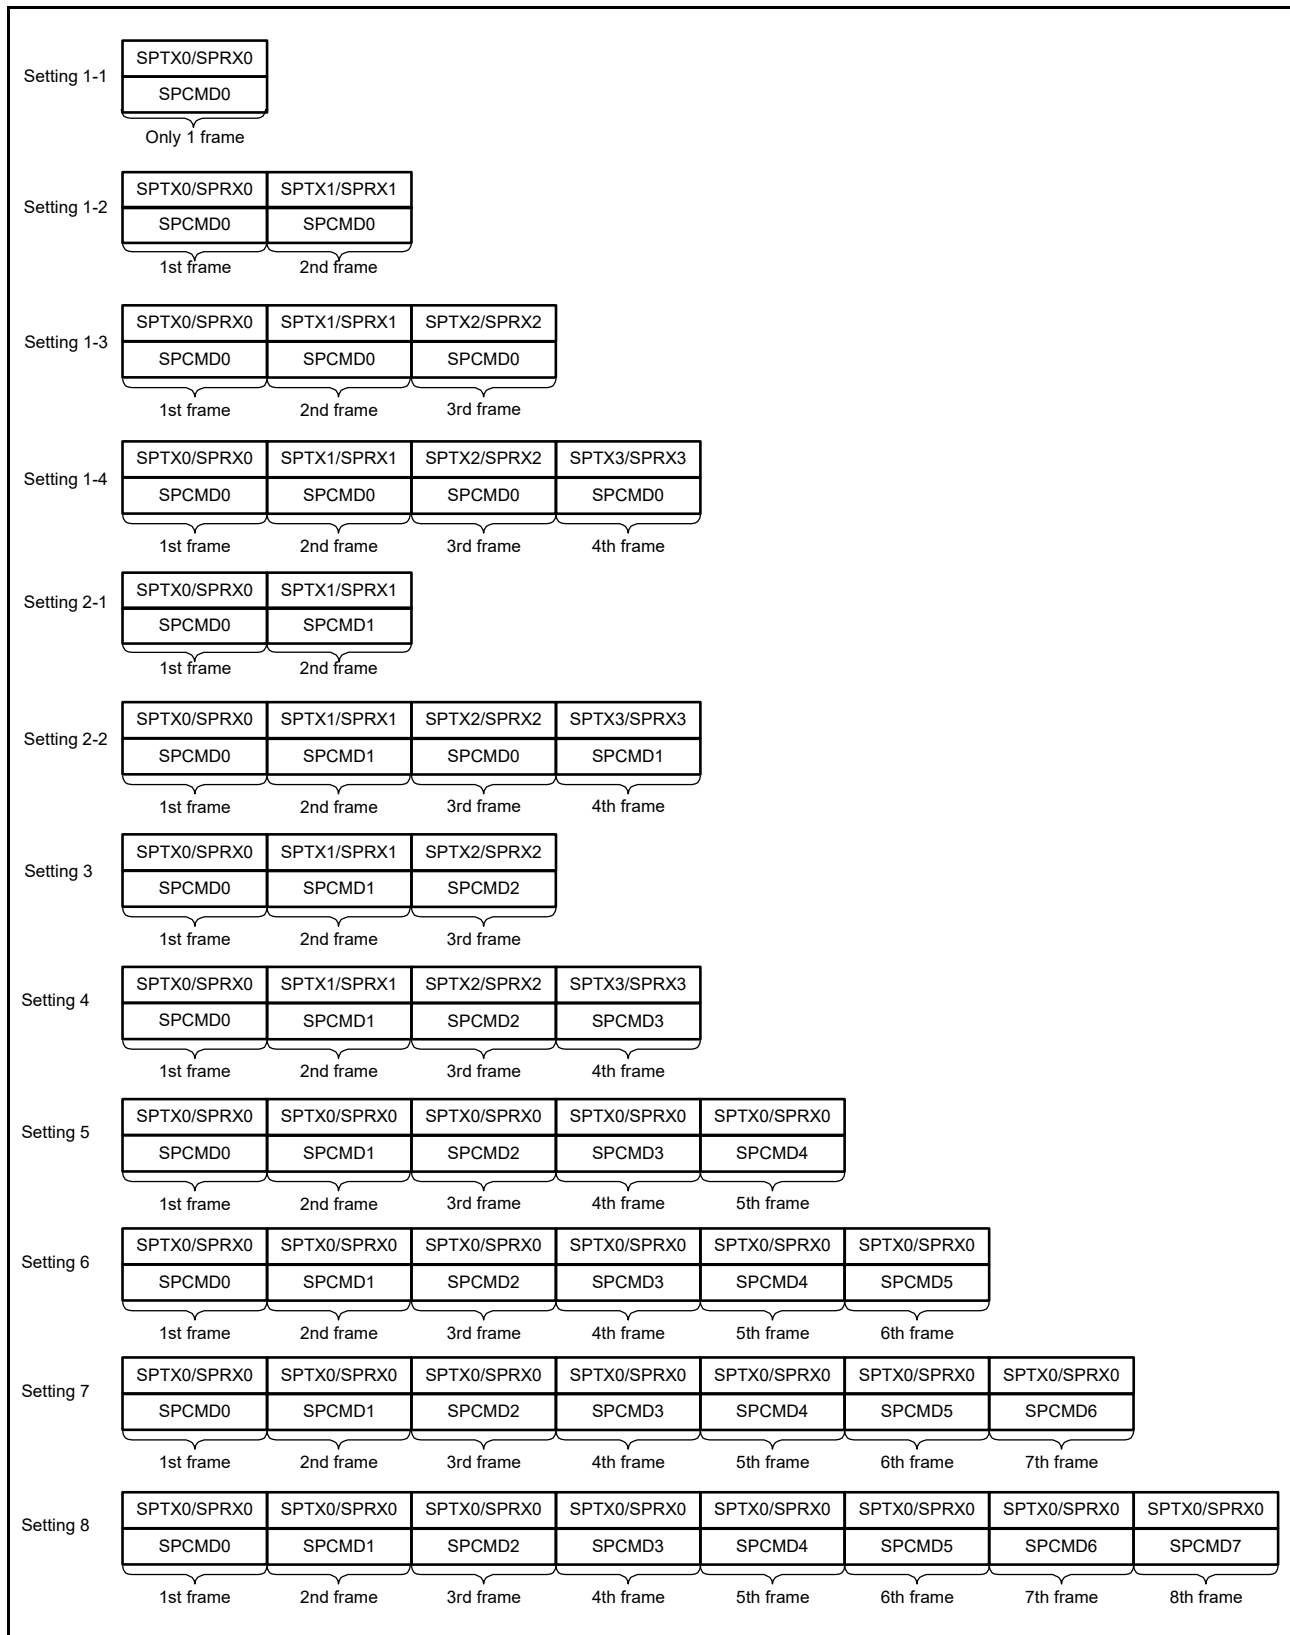

Figure 35.46 Concept of a Frame

Figure 35.47 shows the relationship between the command and the transmit and receive buffers in the sequence of operations specified by the settings in Table 35.4.

**Figure 35.47 Correspondence between the RSPI Command Register and Transmit/Receive Buffers in Sequence Operations**

(4) Initialization Flowchart

Figure 35.48 is a flowchart illustrating an example of initialization in clock synchronous operation when the RSPIC is used in master mode. For a description of how to set up the interrupt controller, DMAC, and I/O ports, refer to the descriptions given in the individual blocks.

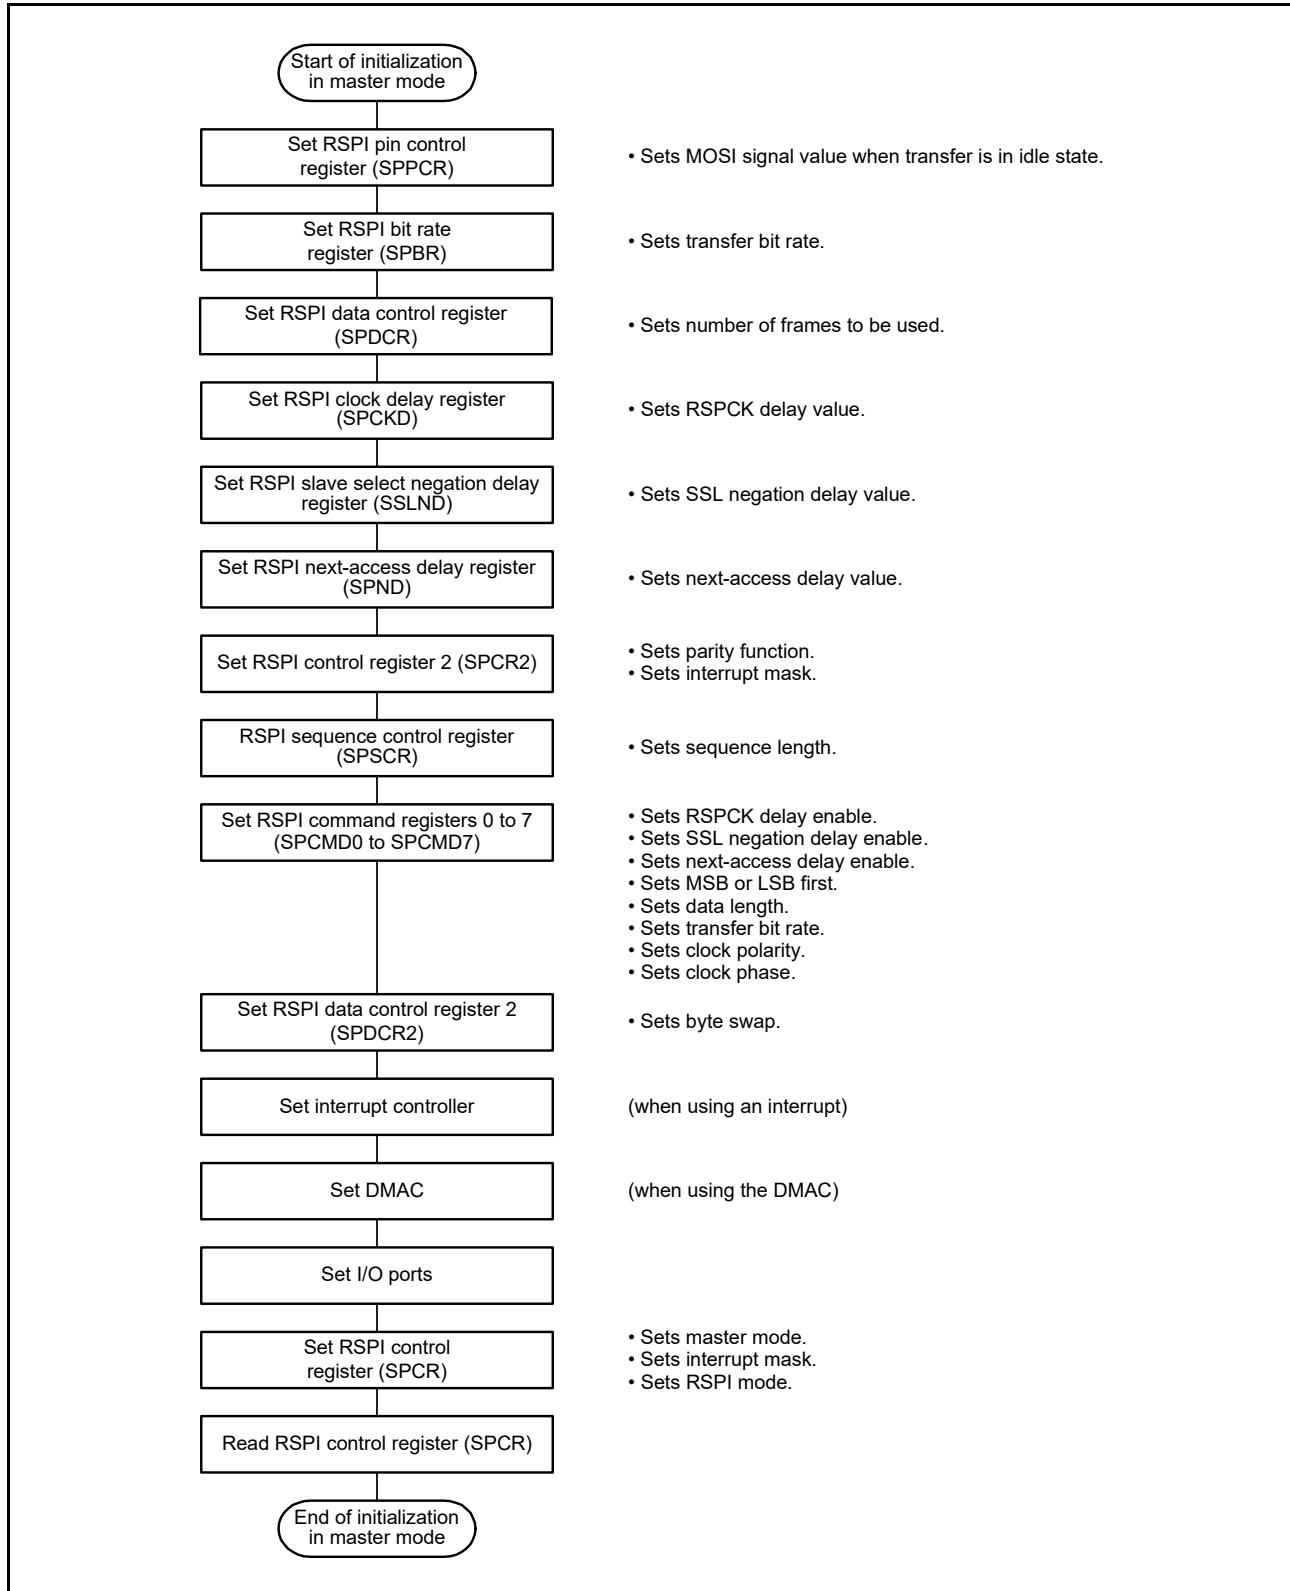

Figure 35.48 Example of Initialization Flowchart in Master Mode (Clock Synchronous Operation)

### (5) Flow of Software Processing

Software processing during clock-synchronous operation when the RSPI is used in master mode is the same as that for SPI master mode operation. For details, refer to section 35.3.11.1, (9) Software Processing Flow. Note that mode fault errors will not occur.

## 35.3.12.2 Slave Mode Operation

### (1) Starting a Serial Transfer

When the SPCR.SPMS bit is 1, the first RSPCKA edge triggers the start of a serial transfer in the RSPI.

When the SPMS bit is 1, the RSPI drives the MISOA output signal.

For details on the RSPI transfer format, refer to section 35.3.5, Transfer Format.

It should be noted that the SSLA0 input signal is not used in clock synchronous operation.

### (2) Terminating a Serial Transfer

The RSPI terminates the serial transfer after detecting an RSPCKA edge corresponding to the final sampling timing.

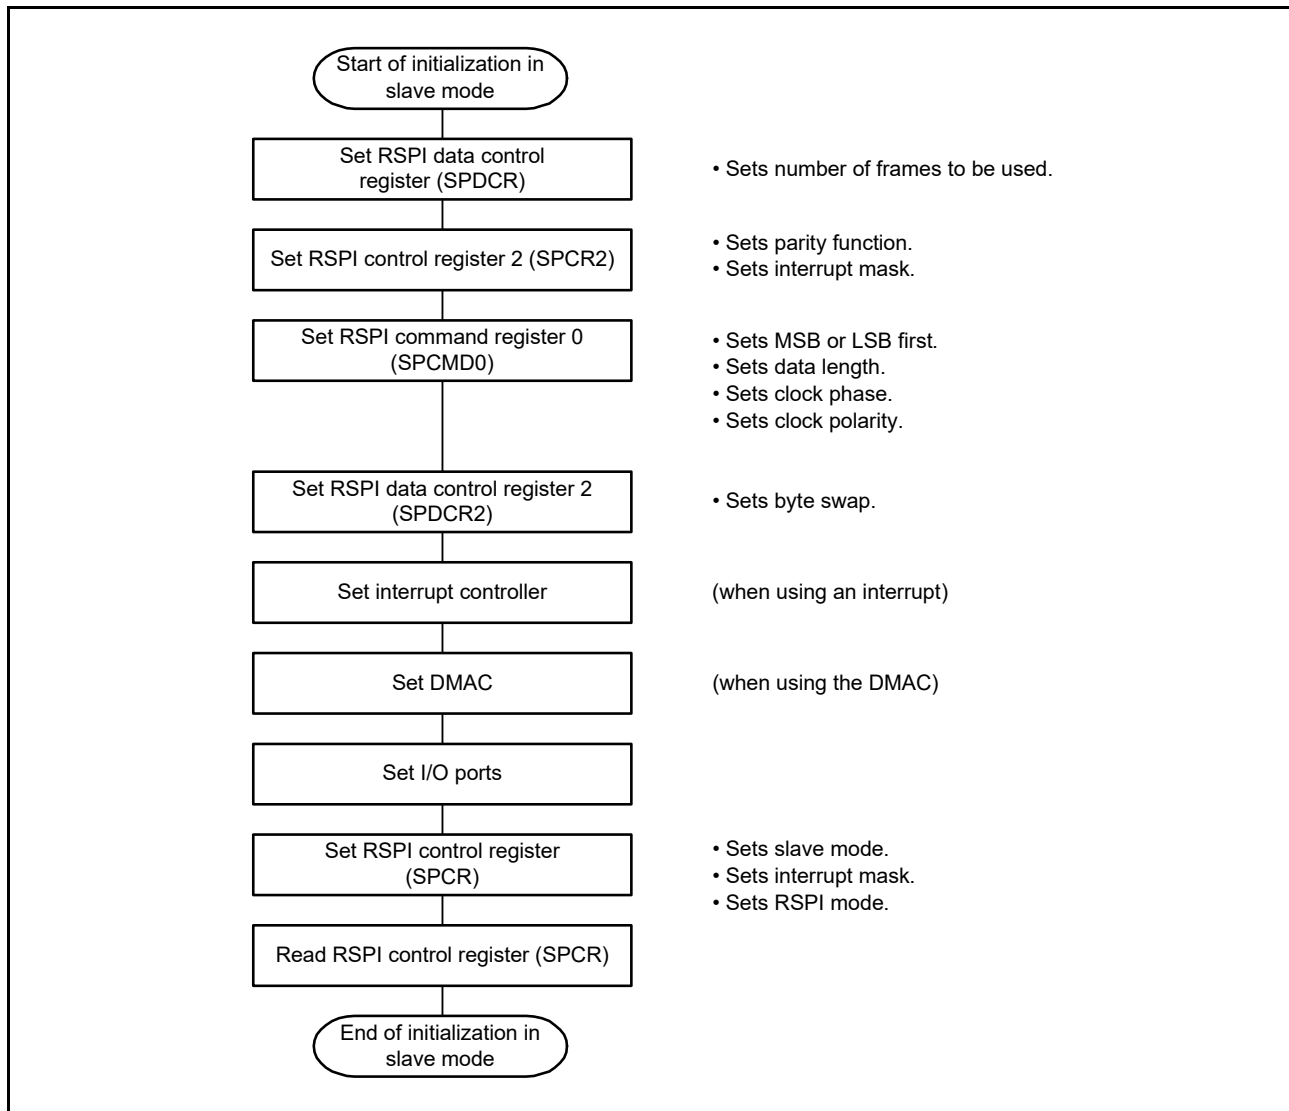

When free space is available in the receive buffer (the SPRF flag is 0), upon termination of serial transfer the RSPI copies received data from the shift register to the receive buffer of the SPDR register. Upon termination of a serial transfer the RSPI changes the status of the shift register to “empty” regardless of the receive buffer status. The final sampling timing changes depending on the bit length of transfer data. In slave mode, the RSPI data length depends on the SPCMD0.SPB[3:0] bit setting.

For details on the RSPI transfer format, refer to section 35.3.5, Transfer Format.

### (3) Initialization Flowchart

Figure 35.49 is a flowchart illustrating an example of initialization in clock synchronous operation when the RSPI is used in slave mode. For a description of how to set up the interrupt controller, DMAC, and I/O ports, refer to the descriptions given in the individual blocks.

**Figure 35.49 Example of Initialization Flowchart in Slave Mode (Clock Synchronous Operation)**

### (4) Flow of Software Processing

Software processing during clock-synchronous operation when the RSPI is used in slave mode is the same as that for SPI slave mode operation. For details, refer to section 35.3.11.2, (6) Software Processing Flow. Note that mode fault errors will not occur.

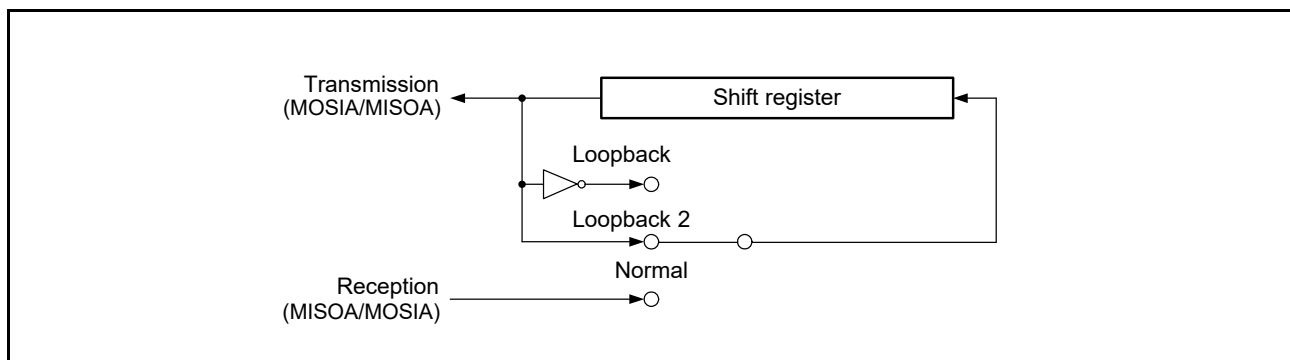

### 35.3.13 Loopback Mode

When 1 is written to the SPPCR.SPLP2 bit or SPPCR.SPLP bit, the RSPI shuts off the path between the MISOA pin and the shift register if the SPCR.MSTR bit is 1, and between the MOSIA pin and the shift register if the SPCR.MSTR bit is 0, and connects the input path and output path of the shift register. The RSPI does not shut off the path between the MOSIA pin and the shift register if the SPCR.MSTR bit is 1, and between the MISOA pin and the shift register if the SPCR.MSTR bit is 0. This is called loopback mode. When a serial transfer is executed in loopback mode, the transmit data for the RSPI or the reversed transmit data becomes the received data for the RSPI.

Table 35.11 lists the relationship among the SPLP2 and SPLP bits and the received data. Figure 35.50 shows the configuration of the shift register I/O paths for the case where the RSPI in master mode is set in loopback mode (SPPCR.SPLP2 = 0, SPPCR.SPLP = 1).

**Table 35.11 SPLP2 and SPLP Bit Settings and Received Data**

| SPPCR.SPLP2 Bit | SPPCR.SPLP Bit | Received Data                              |
|-----------------|----------------|--------------------------------------------|
| 0               | 0              | Input data from the MOSIA pin or MISOA pin |
| 0               | 1              | Inverted transmit data                     |
| 1               | 0              | Transmit data                              |
| 1               | 1              | Transmit data                              |

**Figure 35.50 Configuration of Shift Register I/O Paths in Loopback Mode (Master Mode)**

### 35.3.14 Self-Diagnosis of Parity Bit Function

The parity circuit consists of a parity bit adding unit used for transmit data and an error detecting unit used for received data. In order to detect defects in the parity bit adding unit and error detecting unit of the parity circuit, self-diagnosis is executed for the parity circuit following the flowchart shown in Figure 35.51.

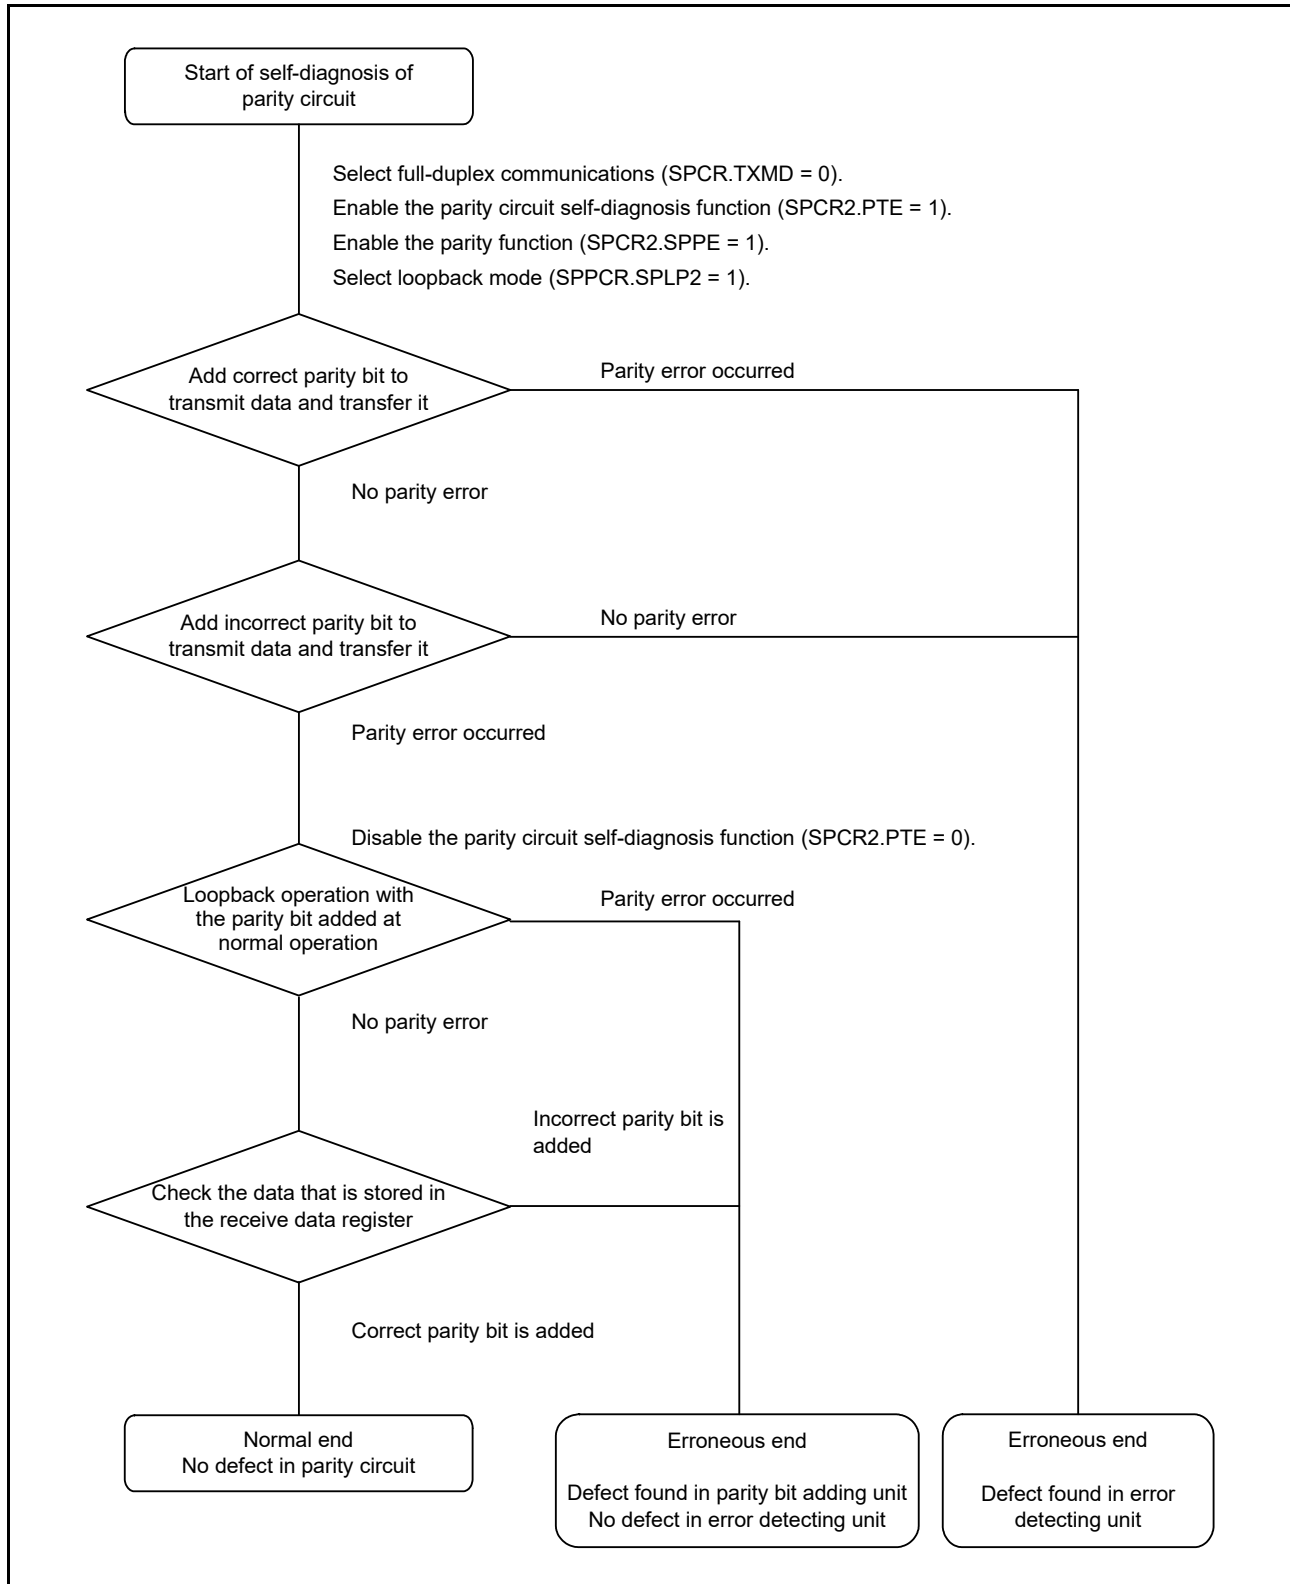

Figure 35.51 Flowchart for Self-Diagnosis of Parity Circuit

### 35.3.15 Interrupt Sources

The RSPI has interrupt sources of receive buffer full, transmit buffer empty, error (mode fault, underrun, overrun, and parity error), and idle. In addition, the DTC or DMAC can be activated by the receive buffer full or transmit buffer empty interrupt to perform data transfer.

Since the vector address for SPEI is allocated to interrupt requests due to mode fault, underrun, overrun, and parity errors, the actual interrupt source must be determined from the flags. Interrupt sources for the RSPI are listed in Table 35.12. An interrupt is generated on satisfaction of an interrupt condition in Table 35.12. Clear the receive buffer full and transmit buffer empty sources through data transfer.

When using the DTC or DMAC to perform data transmission/reception, the DTC or DMAC must be set up first to be in a status in which transfer is enabled before making the RSPI settings. For the method for setting the DTC or DMAC, refer to section 17, DMA Controller (DMACa), or section 18, Data Transfer Controller (DTCa).

If the conditions for generating a transmit buffer empty or receive buffer full interrupt are generated while the ICU.IRn.IR flag is 1, the interrupt is not output as a request for ICU but is retained internally (the capacity for retention is one request per source). A retained interrupt request is output when the ICU.IRn.IR flag becomes 0. A retained interrupt request is automatically discarded once it is output as an actual interrupt request. The interrupt enable bit (the SPCR.SPTIE or SPCR.SPRIE bit) for an internally retained interrupt request can also be cleared to 0.

**Table 35.12 Interrupt Sources of RSPI**

| Interrupt Source                                         | Symbol | Interrupt Condition                                                                         | DMAC/DTC Activation |
|----------------------------------------------------------|--------|---------------------------------------------------------------------------------------------|---------------------|
| Receive buffer full                                      | SPRI   | The receive buffer becomes full (the SPRF flag becomes 1) while the SPCR.SPRIE bit is 1.    | Possible            |
| Transmit buffer empty                                    | SPTI   | The transmit buffer becomes empty (the SPTEF flag becomes 1) while the SPCR.SPTIE bit is 1. | Possible            |
| Errors (mode fault, underrun, overrun, and parity error) | SPEI   | The SPSR.MODF, UDRF, OVRF, or PERF flag is set to 1 while the SPCR.SPEIE bit is 1.          | Impossible          |
| Idle                                                     | SPII   | The SPSR.IDLNF flag is set to 0 while the SPCR2.SPIIE bit is 1.                             | Impossible          |

## 35.4 Link Operation by Event Linking

The RSPI0 supports the following event output for the event link controller (ELC). The event link output signal is output regardless of the interrupt enable bit setting.

### 35.4.1 Receive Buffer Full Event Output

This event signal is output when received data have been transferred from the shift register to the SPDR register on completion of serial transfer.

### 35.4.2 Transmit Buffer Empty Event Output

This event signal is output when data for transmission have been transferred from the transmit buffer to the shift register and when the value of the SPE bit has changed from 0 to 1.

### 35.4.3 Mode Fault, Underrun, Overrun, or Parity Error Event Output

#### (1) Mode Fault

Table 35.13 lists the occurrence conditions of a mode fault event.

**Table 35.13 Occurrence Conditions of Mode Fault Event**

|                               | SPCR.MODFEN Bit | SSLA0 Pin  | Remarks                                                                                                                                                                                                                  |
|-------------------------------|-----------------|------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Master<br>(SPCR.MSTR bit = 1) | 1               | Active     | Under the condition (the SPCR.MSTR bit is 1 and the MODFEN bit is 1), if the SPCR.SPMS bit is 0, mode fault error, overrun error, and parity error event output cannot be used.<br>Do not set the ELSRn register to 52h. |
| Slave<br>(SPCR.MSTR bit = 0)  | 1               | Not active | Event is output only when the pin is deactivated during transmission.                                                                                                                                                    |

#### (2) Underrun

The condition for this event signal being output in response to an underrun is the start of serial transfer with the transmit buffer containing no transmit data while the value of the SPCR.MSTR bit is 0 and the value of the SPCR.SPE bit is 1, in which case the UDRF and MODF flags are set to 1.

#### (3) Overrun

The condition for this event signal being output in response to an overrun is completion of serial transfer while the receive buffer contains data that have not been read and the value of the SPCR.TXMD bit is 0, in which case the OVRF flag is set to 1.

#### (4) Parity Error

The condition for this event signal being output in response to a parity error is detection of a parity error on completion of serial transfer while the value of the TXMD bit in SPCR is 0 and the value of the SPPE bit in SPCR2 is 1.

### 35.4.4 Idle Event Output

#### (1) In Master Mode

In master mode, an event is output when the condition for setting the IDLNF flag (idle flag) to 0 is satisfied.

#### (2) In Slave Mode

In slave mode, an event is output when the SPCR.SPE bit is set to 0 (RSPI is initialized).

### 35.4.5 Transmit End Event Output

During both SPI operation and clock synchronous operation in master mode, an event is output under the condition for setting the IDLNF flag (idle flag) from 1 to 0. In slave mode, an event is output under the conditions listed in Table 35.14.

**Table 35.14 Generating Conditions of Transmit End Event (Slave mode)**

| RSPI Mode                              | Transmit Buffer State | Shift Register State | Others                                                   |
|----------------------------------------|-----------------------|----------------------|----------------------------------------------------------|
| SPI operation (SPMS = 0)               | Empty                 | Empty                | Negation of the SSLA0 input                              |
| Clock synchronous operation (SPMS = 1) | Empty                 | Empty                | Even edge detection of the last RSPCKA for the last data |

Whether the operation is in master mode or slave mode, an event is not output if 0 is written to the SPCR.SPE bit during transmission or the SPCR.SPE bit is cleared by the mode fault error.

## 35.5 Usage Notes

### 35.5.1 Setting Module Stop Function

Module stop control register B (MSTPCRB) can be used to enable or disable the RSPI. Immediately after a reset, operation of the RSPI is disabled. Register access is enabled by releasing the module stop state. For details, refer to section 11, Low Power Consumption.

### 35.5.2 Note on Low Power Consumption Functions

When using the module stop function and entering a low power consumption mode other than sleep mode, set the SPCR.SPE bit to 0 before completing communication.

### 35.5.3 Notes on Starting Transfer

If the ICU.IRn.IR flag is 1 at the time transfer is to be started, an interrupt request is internally retained after transfer starts, and this can lead to unanticipated behavior of the ICU.IRn.IR flag.

When the ICU.IRn.IR flag is 1 at the time transfer is to start, follow the procedure below to clear interrupt requests before enabling operations (by setting the SPCR.SPE bit to 1).

1. Confirm that transfer has stopped (i.e. that the SPCR.SPE bit is 0).
2. Set the relevant interrupt enable bit (the SPCR.SPTIE or SPCR.SPRIE bit) to 0.
3. Read the relevant interrupt enable bit (the SPCR.SPTIE or SPCR.SPRIE bit) and confirm that its value is 0.
4. Set the ICU.IRn.IR flag to 0.

### 35.5.4 Notes on the SPRF and SPTEF flags

When polling the SPSR.SPRF flag and/or SPSR.SPTEF flag, set the SPCR.SPRIE bit and/or SPCR.SPTIE bit to 0.

## 36. CRC Calculator (CRCA)

The CRC (Cyclic Redundancy Check) calculator generates CRC codes.

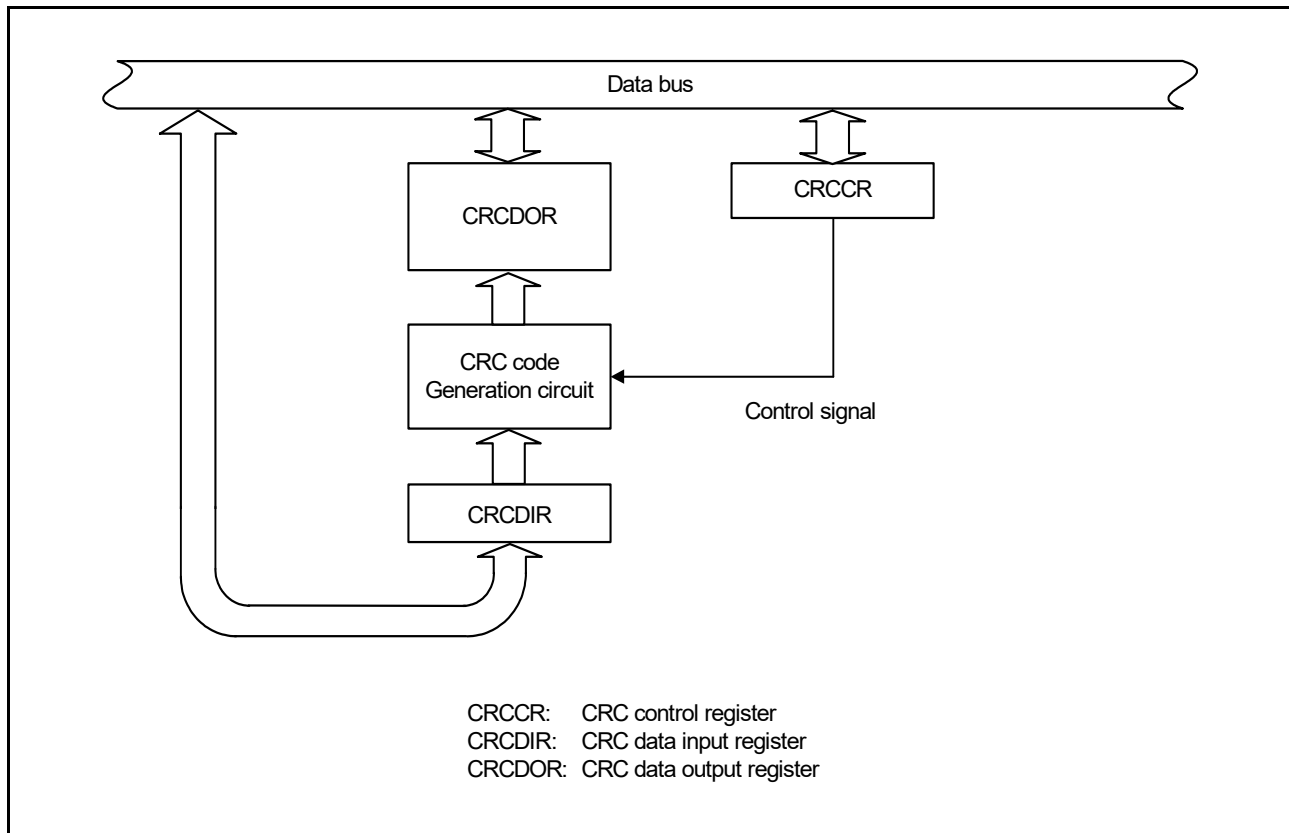

### 36.1 Overview

Table 36.1 lists the specifications of the CRC calculator, and Figure 36.1 shows a block diagram of the CRC calculator.

**Table 36.1 CRC Specifications**

| Item                       | Description                                                                                                                                                                                                                                                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|----------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Data size                  | 8 bits                                                                                                                                                                                                                                                         | 32 bits                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| Data for CRC calculation*1 | CRC codes are generated for any desired data in 8n-bit units (where n is a whole number)                                                                                                                                                                       | CRC codes are generated for any desired data in 32n-bit units (where n is a whole number)                                                                                                                                                                                                                                                                                                                                                             |
| CRC processor unit         | 8-bit parallel processing                                                                                                                                                                                                                                      | 32-bit parallel processing                                                                                                                                                                                                                                                                                                                                                                                                                            |

Note 1. Only 1 can be written.

#### LMS Bit (CRC Calculation Switching)

The setting this bit selects the order of the bits of generated CRC codes. The bit selects transmission of the lower-order byte of the CRC code first for LSB first communication, or the higher-order byte first for MSB first communication. For details on the transmission and reception of CRC codes, refer to section 36.3, Operation.

#### DORCLR Bit (CRCDOR Register Clear)

Write 1 to this bit so that the CRCDOR register is set to 0000 0000h.

This bit is read as 0. Writing 0 to this bit has no effect.

### 36.2.2 CRC Data Input Register (CRCDIR)

- When 32-bit CRC is selected

Address(es): CRC.CRCDIR 0008 8284h

- When 16-bit or 8-bit CRC is selected

Address(es): CRC.CRCDIR 0008 8284h

The CRCDIR register is a readable and writable register. Write data for CRC calculation to this register.

When generating a 32-bit CRC, the CRCDIR register should be accessed in longword units. When generating a 8-bit or 16-bit CRC, the CRCDIR register should be accessed in byte units.

### 36.2.3 CRC Data Output Register (CRCDOR)

- When 32-bit CRC is selected

Address(es): CRC.CRCDOR 0008 8288h

- When 16-bit CRC is selected

Address(es): CRC.CRCDOR 0008 8288h

- When 8-bit CRC is selected

Address(es): CRC.CRCDOR 0008 8288h

The CRCDOR register is a readable and writable register.

The value after a reset is 0000 0000h. When calculating with the initial value set to a value other than 0000 0000h, rewrite the CRCDOR register.

Writing data to the CRCDIR register stores result of calculation in the CRCDOR register. In addition, following communication data, when a CRC code is written to the CRCDIR register and if the calculation result is 0000 0000h, there is no error in the communication data.

When a 32-bit CRC is selected, the CRCDOR register should be accessed in longword units. When a 16-bit CRC is selected, the CRCDOR register should be accessed in word units. When an 8-bit CRC is selected, the CRCDOR register should be accessed in byte units.

### 36.3 Operation

The CRC calculator generates CRC codes for use in LSB first or MSB first communication.

The following shows examples of generating the CRC code for input data (F0h) using the 16-bit CRC generating polynomial ( $X^{16} + X^{12} + X^5 + 1$ ). In these examples, the value of the CRC data output register (CRCDOR) is cleared by setting the DORCLR bit to 1 to set the initial value for CRC calculation to 0000 0000h.

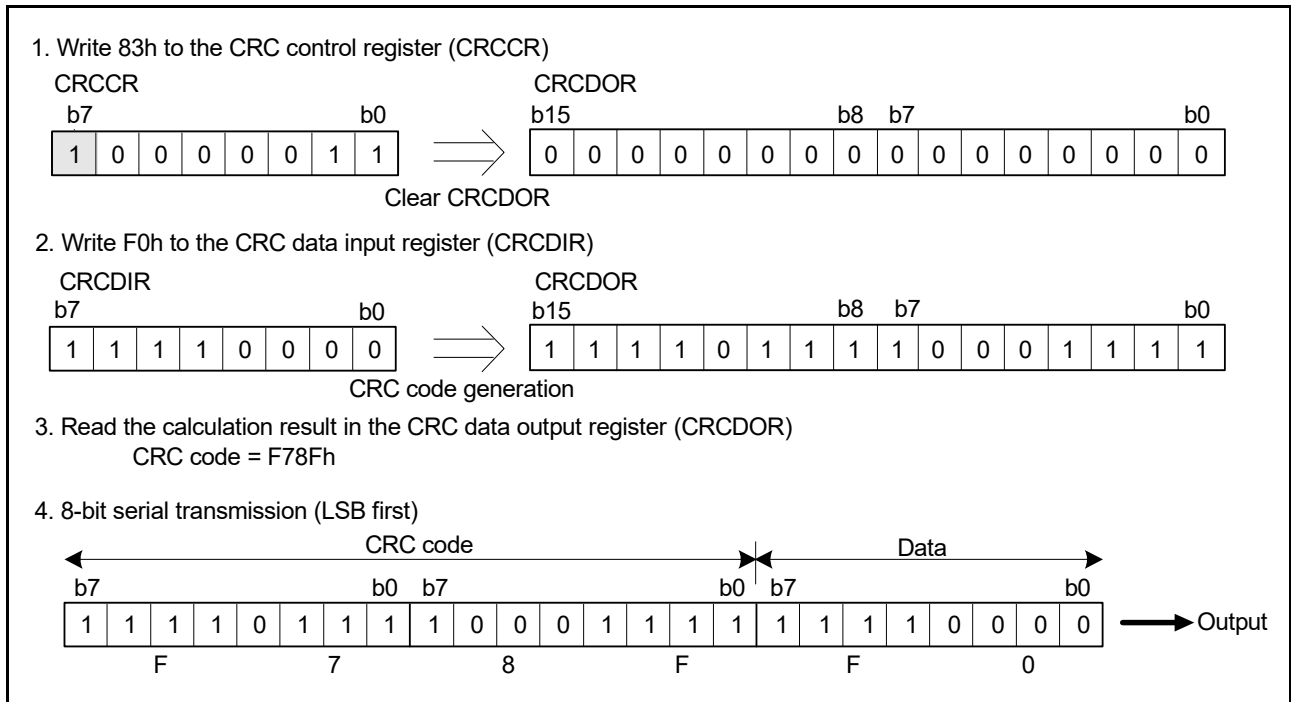

Figure 36.2 LSB First Data Transmission

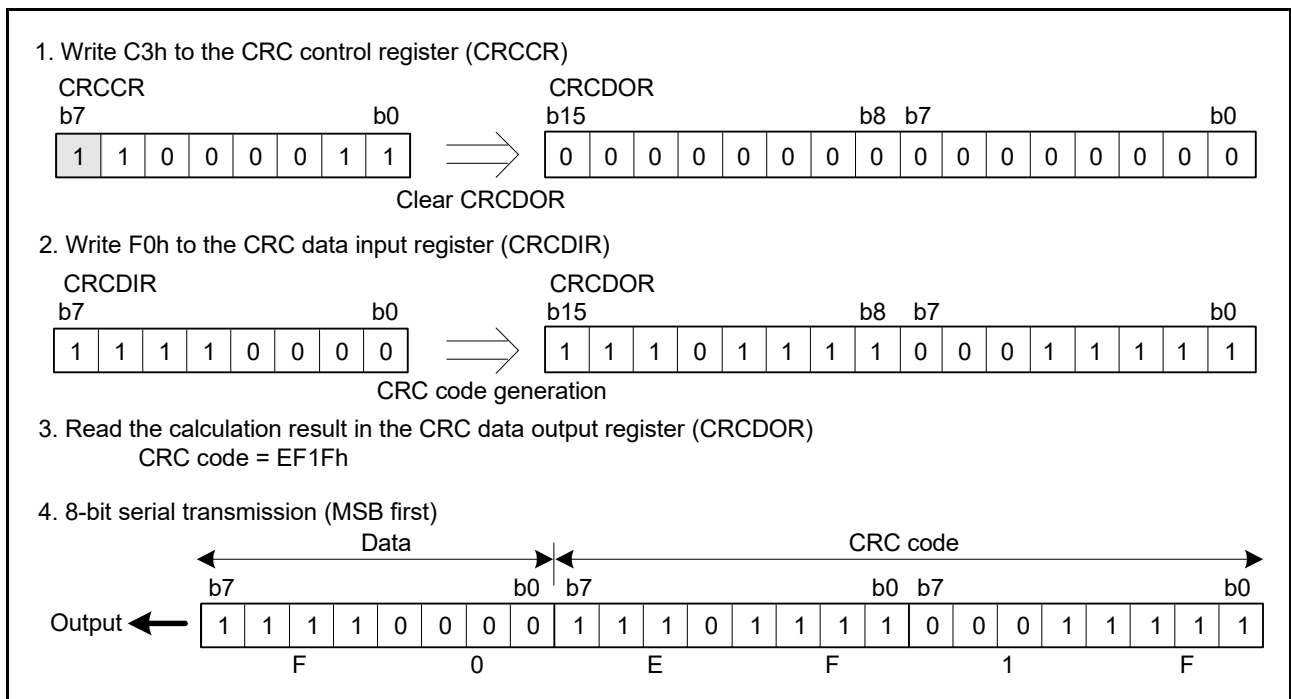

Figure 36.3 MSB First Data Transmission

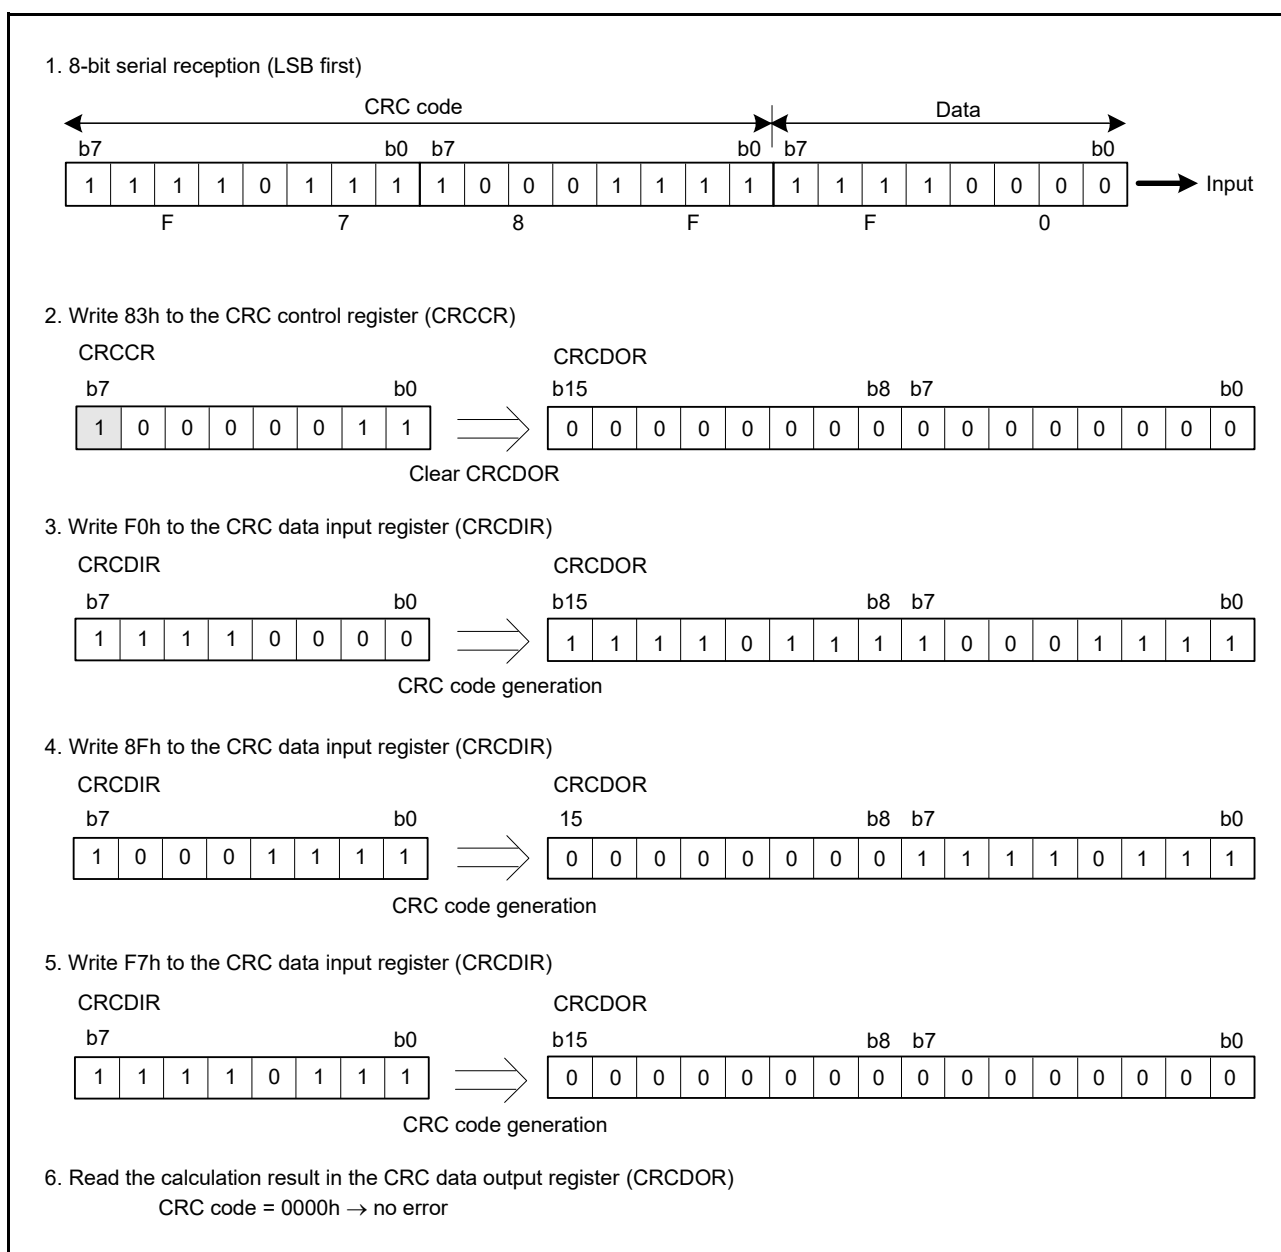

Figure 36.4 LSB First Data Reception

Figure 36.5 MSB First Data Reception

### 36.4 Usage Notes

#### 36.4.1 Module Stop Function Setting

Operation of the CRC calculator can be disabled or enabled using the module stop control register B (MSTPCRB). After a reset, the CRC is in the module stop state. Register access is enabled by releasing the module stop state. For details, refer to section 11, Low Power Consumption.

#### 36.4.2 Note on Transmission

Note that the sequence of transmission for the CRC code differs according to whether transmission is LSB first or MSB first.

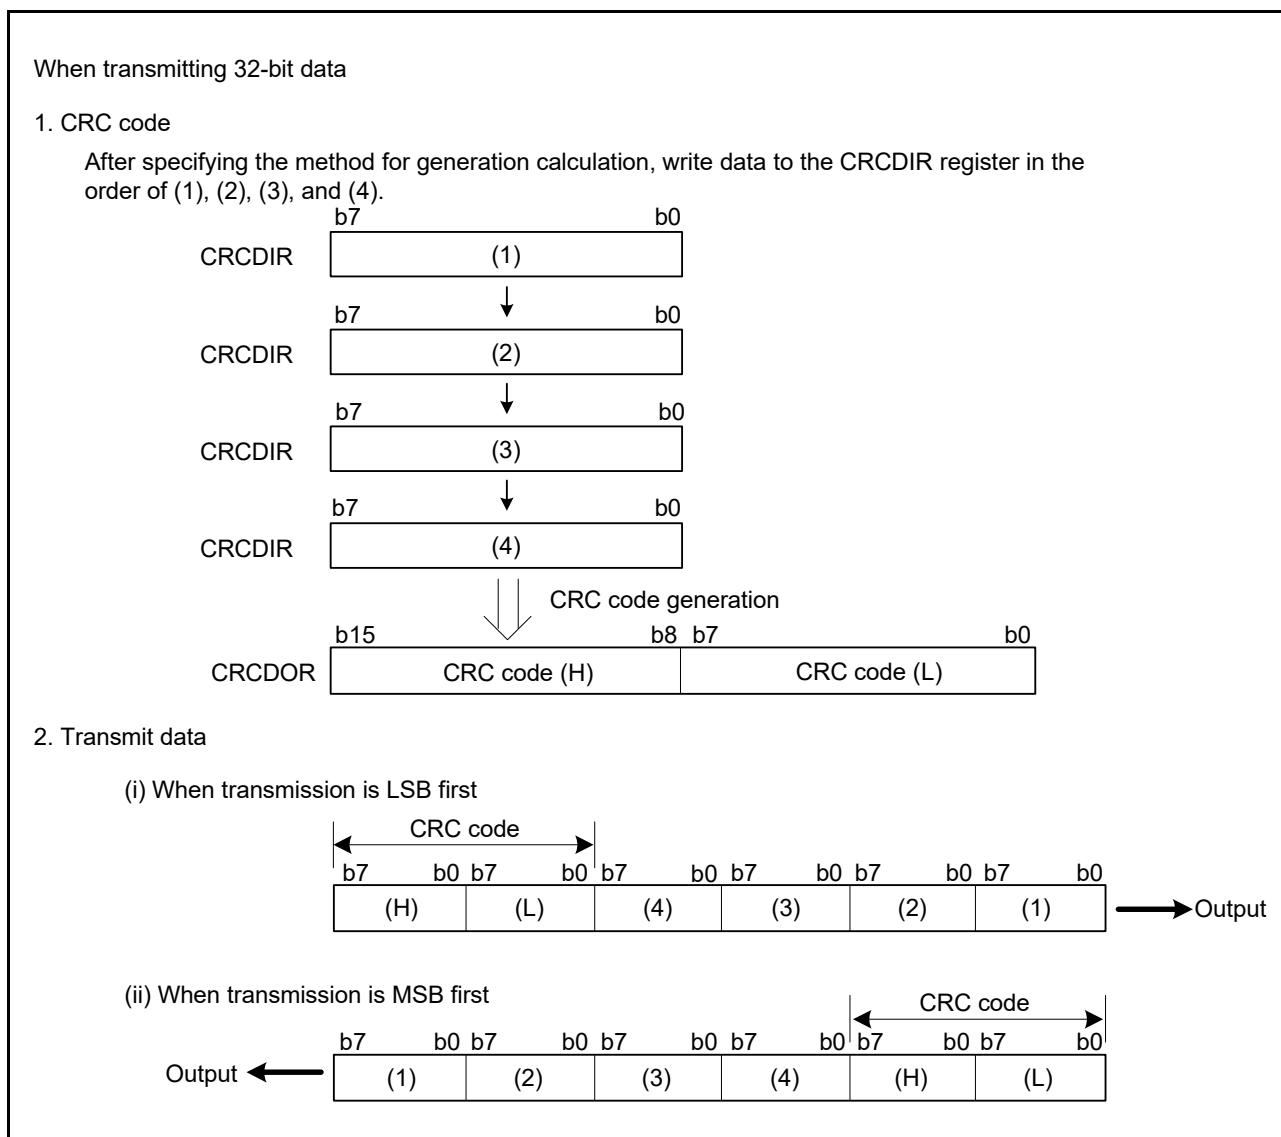

Figure 36.6 LSB First and MSB First Data Transmission

## 37. Trusted Secure IP (TSIP-Lite)

This MCU incorporates a Trusted Secure IP Lite (TSIP-Lite) module to provide security functions. The module consists of an access management circuit, encryption engine, and random number generator. In combination with the TSIP-Lite library, the TSIP-Lite can prevent eavesdropping (confidentiality), falsification of information (integrity), and impersonation (authenticity).

Key information to be used in encrypting and decrypting data is only stored within the TSIP-Lite, and any external access can be shut out to obtain a system with strong security.

### 37.1 Overview

Table 37.1 summarizes the specifications of the TSIP-Lite. Figure 37.1 shows a block diagram of the TSIP-Lite.

**Table 37.1 Specifications of TSIP-Lite**

| Item                                   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

## 37.2 Operation

### 37.2.1 Operating Modes and State Transitions

Figure 37.2 shows the state transitions of the TSIP-Lite.

Use of the TSIP-Lite security functions is only possible through use of the TSIP-Lite library provided by Renesas Electronics, in accordance with the state transitions as shown in the figure below.

When irregular access to the TSIP-Lite (access that violates the defined procedure) due to a falsified program or a program entering runaway execution, etc. is attempted, the access management circuit does not accept any subsequent access and stops the output of any data from the TSIP-Lite.

**Figure 37.2** TSIP-Lite Operating Modes and State Transitions

Many of the security functions that the TSIP-Lite offers are applicable only in the encryption engine active mode. The operations that can be performed in this mode are given below.

- (1) Key Installation
- (2) Encryption and decryption
- (3) Key generation
- (4) Random number generation

### 37.2.2 Encryption Engine

Figure 37.3 shows processes of the encryption engine integrated in the TSIP-Lite.

The encryption engine, using the key generation information, performs plaintext to ciphertext encryption and ciphertext to plaintext decryption by hardware.

In no part of the encryption or decryption process, is key data or intermediate data ever exposed outside of the TSIP-Lite.

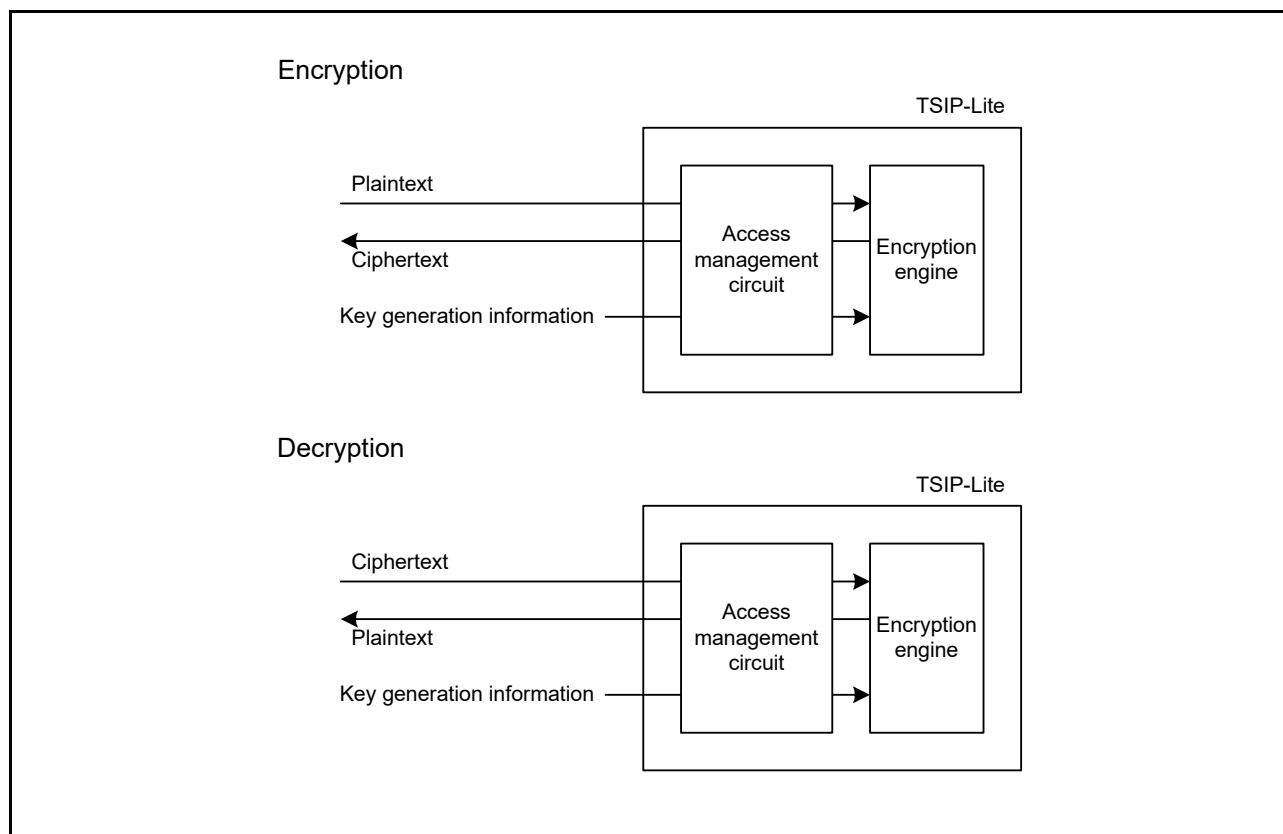

Figure 37.3 Encryption and Decryption processes by Encryption Engine

### 37.2.3 Key Installation

The key installation is the operation that safely converts the user key to the key generation information and stores it in flash memory. The procedure for installing the key data are given below.

- (1) The user uses the key (Key-2) used for encrypting the user key to encrypt the user key (Key-1) producing eKey-1.
- (2) The user sends the encrypted user key (eKey-1) to the TSIP-Lite over the serial interface.
- (3) The key generation information of the Key-2 (Index-2) contained in the TSIP-Lite library is used to recover the Key-2, which is then used to decrypt the user key.
- (4) The user key is converted to user key generation information (Index-1) using the unique ID and a random number, and stored in flash memory.

The installation process and flow chart are given in Figure 37.4 and Figure 37.5, respectively.

Once the key data is installed, the user key generation information (Index-1) can then be used to perform encryption or decryption.

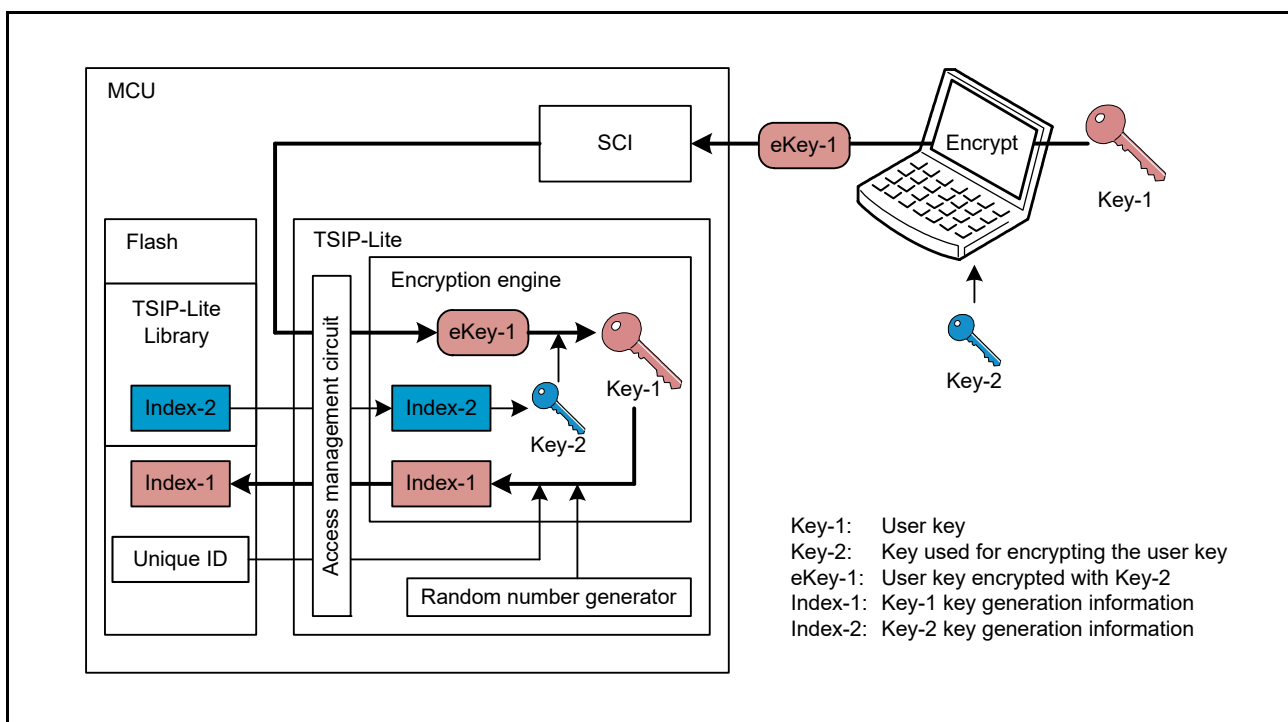

Figure 37.4 Key Installation Process

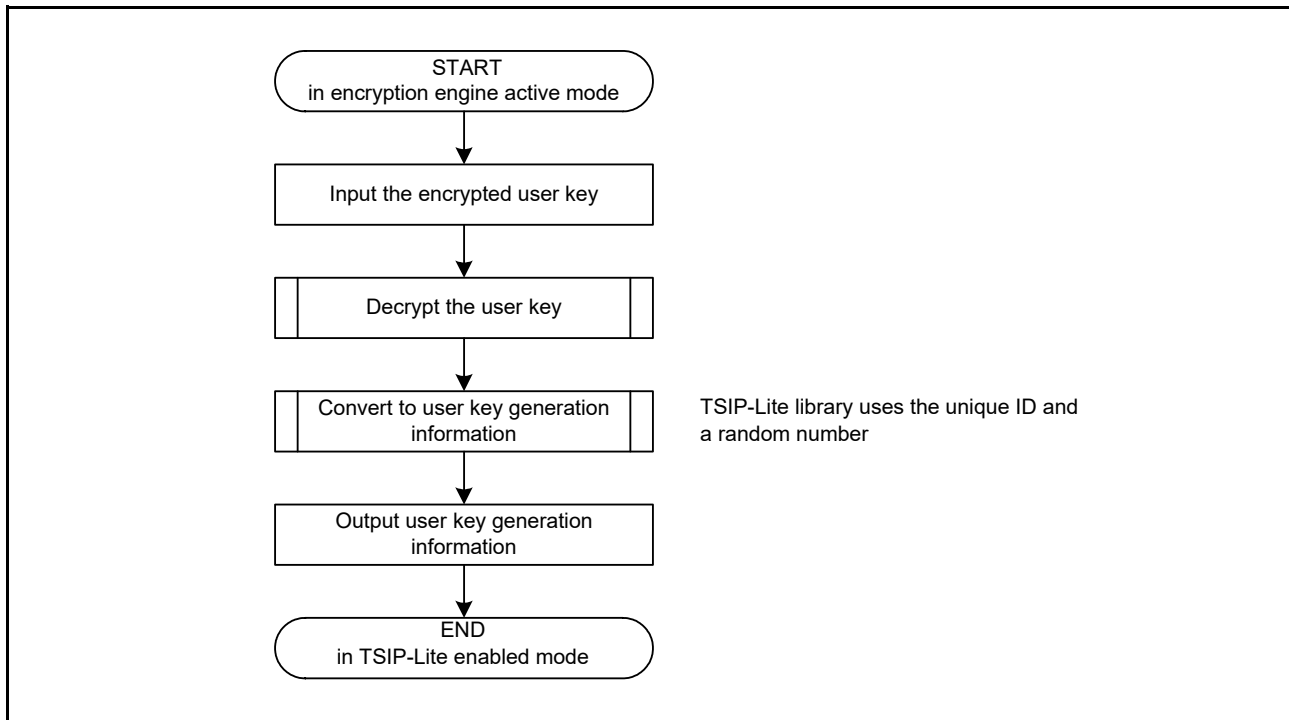

Figure 37.5 Key Installation Flow Chart

### 37.2.4 Encryption and Decryption

The procedures for encrypting and decrypting data are given below.

- (1) Input the key generation information into the TSIP-Lite, and recover the key data.
- (2) Input the data to encrypt or decrypt into the TSIP-Lite. This converts plaintext into ciphertext, and ciphertext into plaintext.
- (3) Read the converted data.

The encryption engine has an input buffer and an output buffer, enabling encryption/decryption to proceed in parallel with data input/output.

Figure 37.6, Figure 37.7, and Figure 37.8 show the timing diagram, encryption flow, and decryption flow, respectively.

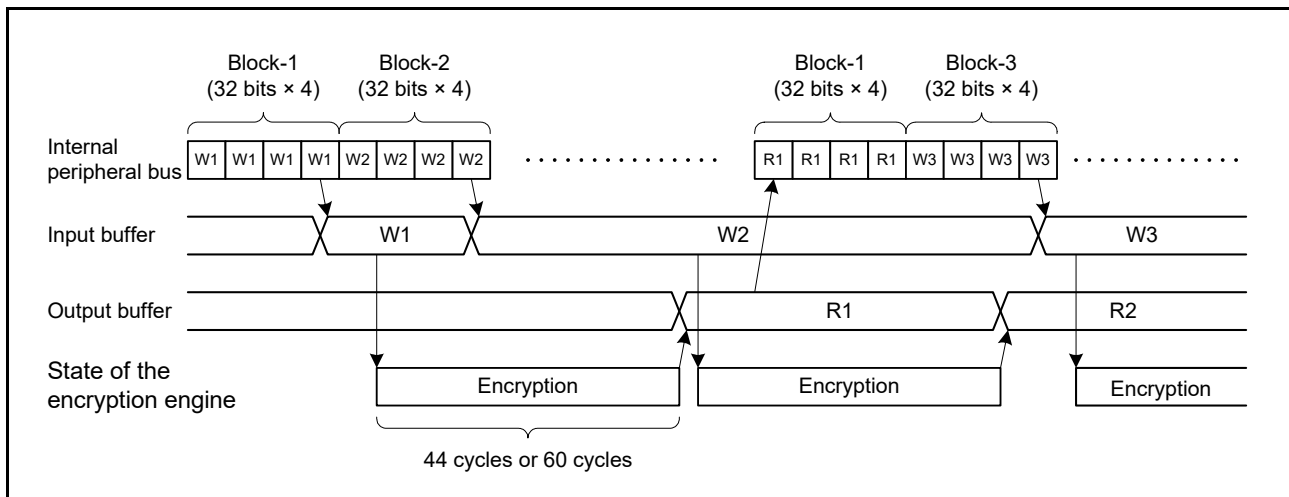

Figure 37.6 Encryption and Decryption Timing Diagram

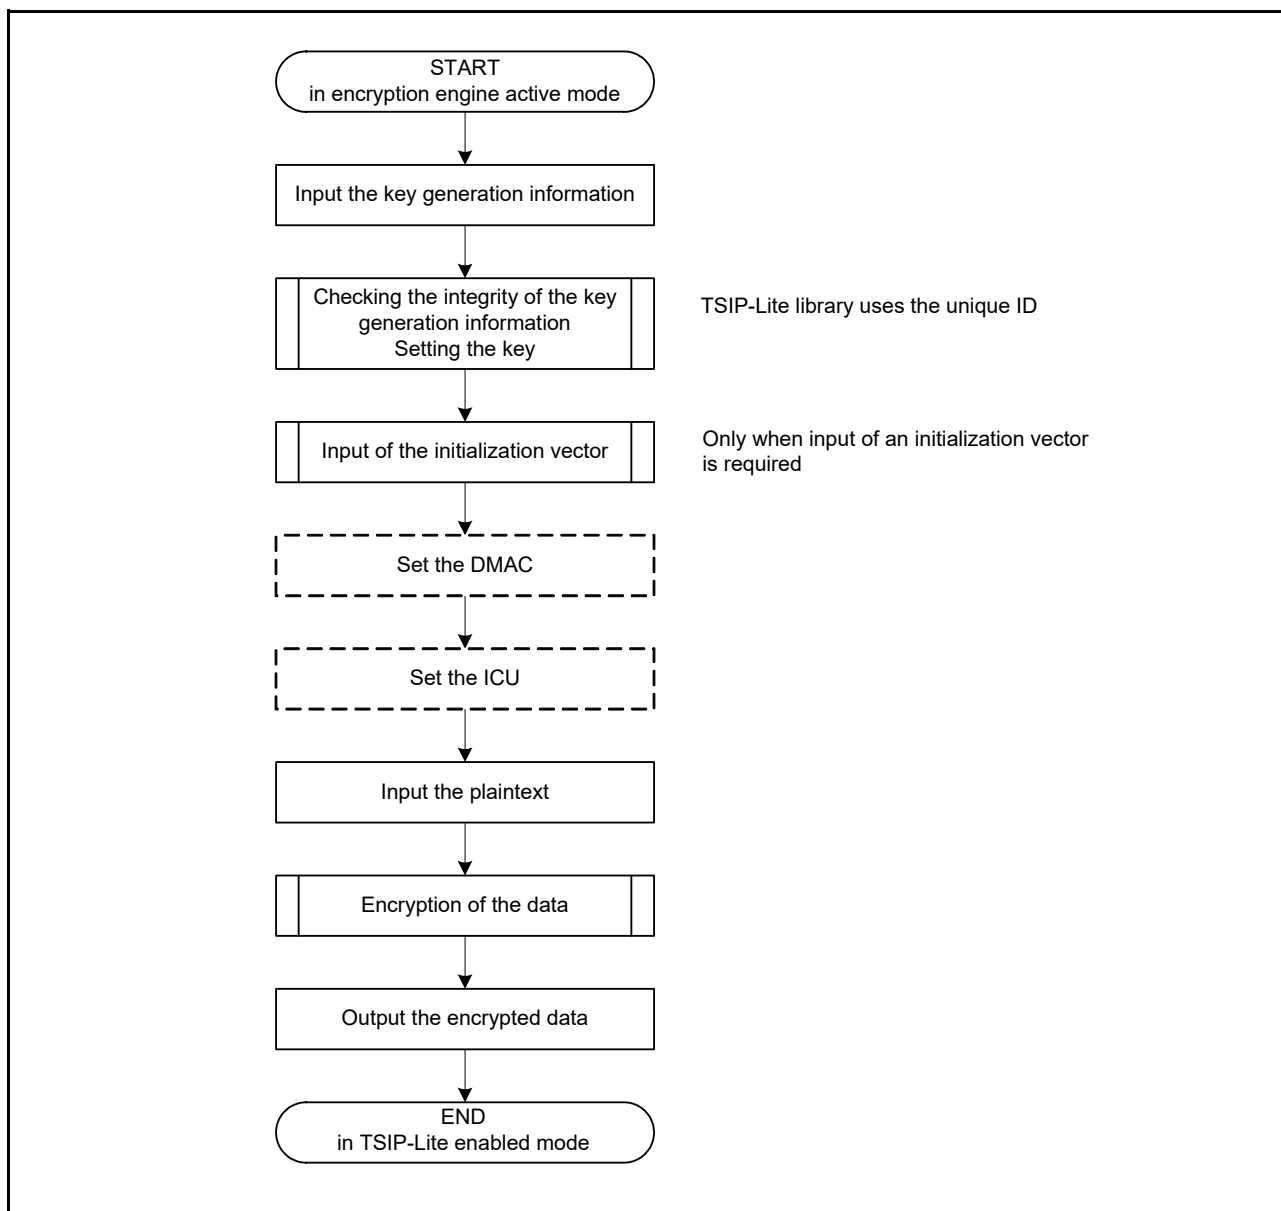

Figure 37.7 Encryption Flow Chart

Figure 37.8 Decryption Flow Chart

### 37.2.5 Generating Key Generation Information (by Using Random Numbers)

Figure 37.9 shows the generating flow for the key generation information by using random numbers.

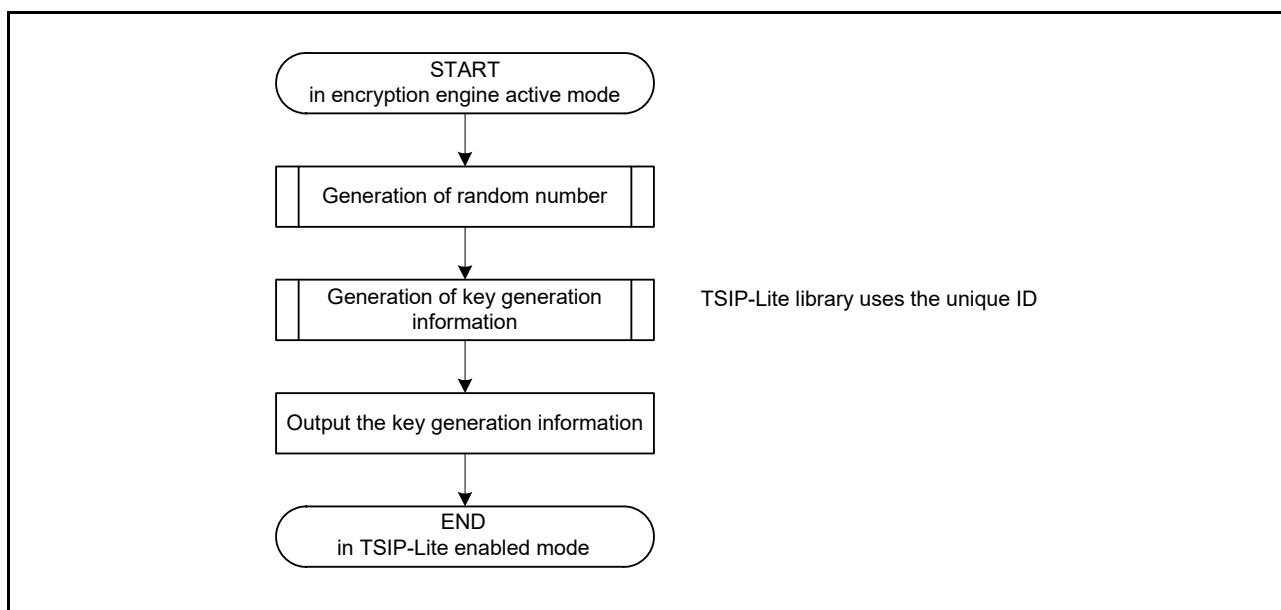

Figure 37.9 Key Generation Information Generating Flow Chart (Using Random Numbers)

### 37.2.6 Random Number Generation

Figure 37.10 shows the random number generation flow.

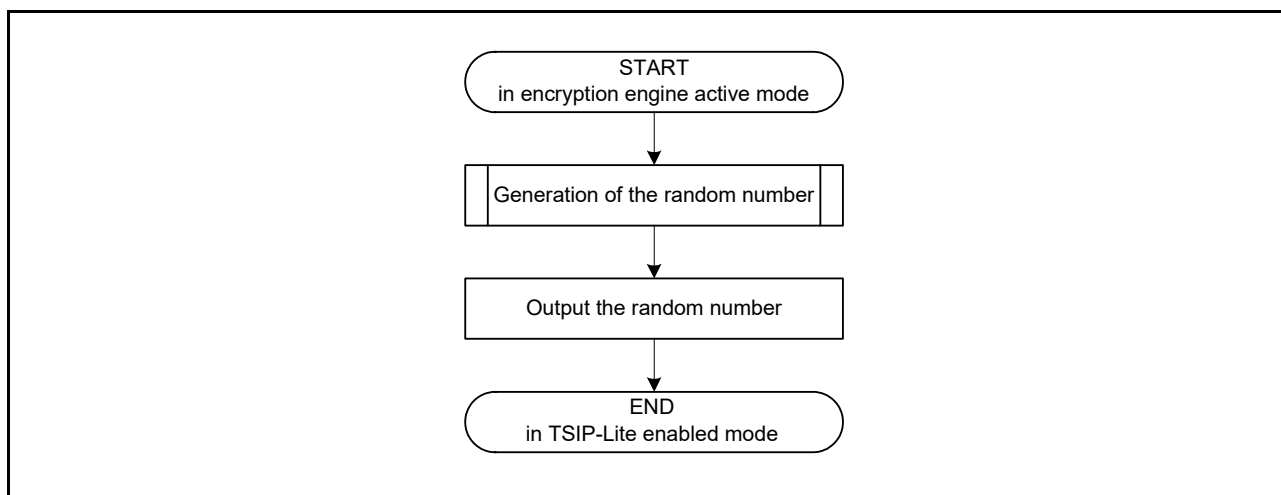

Figure 37.10 Random Number Generation Flow Chart

### 37.3 Interrupt

Table 37.2 lists the interrupt sources.

TSIP-Lite library uses interrupts caused by these interrupt sources. Do not set the ICU.IERm.IENj bits corresponding to these interrupt sources to 0.

**Table 37.2 TSIP-Lite Interrupt Sources**

| Name  | Interrupt Source        | DTC Triggerable | DMAC Triggerable |
|-------|-------------------------|-----------------|------------------|
| RD    | Data read ready         | Yes             | Yes              |
| WR    | Data write ready        | Yes             | Yes              |
| Error | Illegal access detected | No              | No               |

### 37.4 Usage Notes

#### 37.4.1 Standby Mode

When standby mode is entered while the encryption engine is in processing, proper processing cannot be resumed after standby mode is exited. Standby mode should therefore be entered only after first entering TSIP-Lite disabled mode or TSIP-Lite enabled mode.

#### 37.4.2 Setting the Module Stop Function

The module stop control register D (MSTPCRD) enables or disables operation of the TSIP-Lite. After a reset, the TSIP-Lite is stopped. After exiting the module stop state, the TSIP-Lite can be accessed. Refer to section 11, Low Power Consumption for details.

#### 37.4.3 TSIP-Lite Library

Use of the TSIP-Lite requires the TSIP-Lite library provided by Renesas Electronics. Please contact our sales office for information regarding the TSIP-Lite library.

## 38. 12-Bit A/D Converter (S12ADH)

### 38.1 Overview

This MCU has three units of 12-bit successive approximation A/D converters (S12AD, S12AD1, S12AD2).

The 12-bit A/D converter converts analog input of the selected channels, temperature sensor output, or internal reference voltage into a 12-bit digital value through successive approximation.

The A/D converter has three operating modes: single scan mode in which the arbitrarily selected analog inputs are converted in ascending channel order; continuous scan mode in which the arbitrarily selected analog inputs are continuously converted in ascending channel order; and group scan mode in which the arbitrarily selected analog inputs are arbitrarily divided into two groups (groups A and B) or three groups (groups A, B, and C) and converted in ascending channel order in each group.

In group scan mode, either two groups (groups A and B) or three groups (groups A, B, and C) is selected.

The conditions for scanning start of each group (A, B, and C) (synchronous trigger) can be independently selected, thus allowing A/D conversion of each group to be started independently.

During group priority operation, in addition to the above-mentioned operation, a trigger to start scanning for the priority group is accepted during scan for the low-priority group, and scan for the priority group is started after scan for the low-priority group was interrupted. The priority order is group A > group B > group C. Accordingly, as priority operation, when a trigger to start scanning for group B is accepted during scan for group C, group C scan is interrupted, and scan for group B is started. Likewise, when a trigger to start scanning for group A is accepted during scan for group C, group C scan is interrupted and scan for group A is started. In the same way, when a trigger to start scanning for group A is accepted during scan for group B, group B scan is interrupted and scan for group A is started.

The interrupted scan operation can be restarted after the scanning of the priority group is completed.

In double trigger mode, one analog input channel arbitrarily selected is converted in single scan mode or group scan mode (group A), and the resulting data of A/D conversion started by the first and second synchronous triggers are stored into different registers (duplication of A/D conversion data).

Self-diagnosis is executed once at the beginning of each scan, and one of the three voltages internally generated in the 12-bit A/D converter is converted.

The temperature sensor output or internal reference voltage can be selected in single scan mode and group scan mode.

A/D conversion is performed on the temperature sensor output prior to internal reference voltage when both the temperature sensor output and internal reference voltage are selected.

The temperature sensor output or internal reference voltage cannot be selected in continuous scan mode.

The MCU incorporates the comparison function (with windows A and B). In addition, the value of A/D conversion and the reference value of the low side can be compared by a comparator.

Table 38.1 lists the specifications of the 12-bit A/D converter and Table 38.2 lists the functions of the 12-bit A/D converter. Figure 38.1 to Figure 38.5 show block diagrams of the 12-bit A/D converter.

**Table 38.1 Specifications of 12-Bit A/D Converter (1/2)**

| Item                                | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

Note 1. The peripheral module clock PCLKB frequency is set according to the setting of the SCKCR.PCKB[3:0] bits and the A/D conversion clock ADCLK frequency is set according to the setting of the SCKCR.PCKD[3:0] bits.

Note 2. The number of extended bits during addition differs depending on the addition count.  
 2-bit extension: 1-time to 4-time conversion (add zero to three times)  
 4-bit extension: 16-time conversion (add 15 times)

Note 3. Pseudo-differential amplification with common pins (PGAVSS0 and PGAVSS1) for three-shunt current sensing is possible.

Note 4. Refer to section 11, Low Power Consumption for details.

Note 5. Wait for 1 μs or longer to start A/D conversion after release from the module stop state.

Note: When setting an A/D conversion start trigger to ADTRG0#, ADTRG1#, or ADTRG2#, set the pin mode control bit in the port mode register for the corresponding pin to 1 (peripheral functions), and set the pin function select bit in the pin function control register to ADTRG0#, ADTRG1#, or ADTRG2#. Refer to section 20, I/O Ports and section 21, Multi-Function Pin Controller (MPC) for details.

Note 1. Refer to section 11, Low Power Consumption for details.

Note 2. Wait for 1  $\mu$ s or longer to start A/D conversion after release from the module stop state.

**Figure 38.1** Block Diagram of 12-Bit A/D Converter  
(Product Without Pseudo-Differential Input to PGAs, Unit 0)

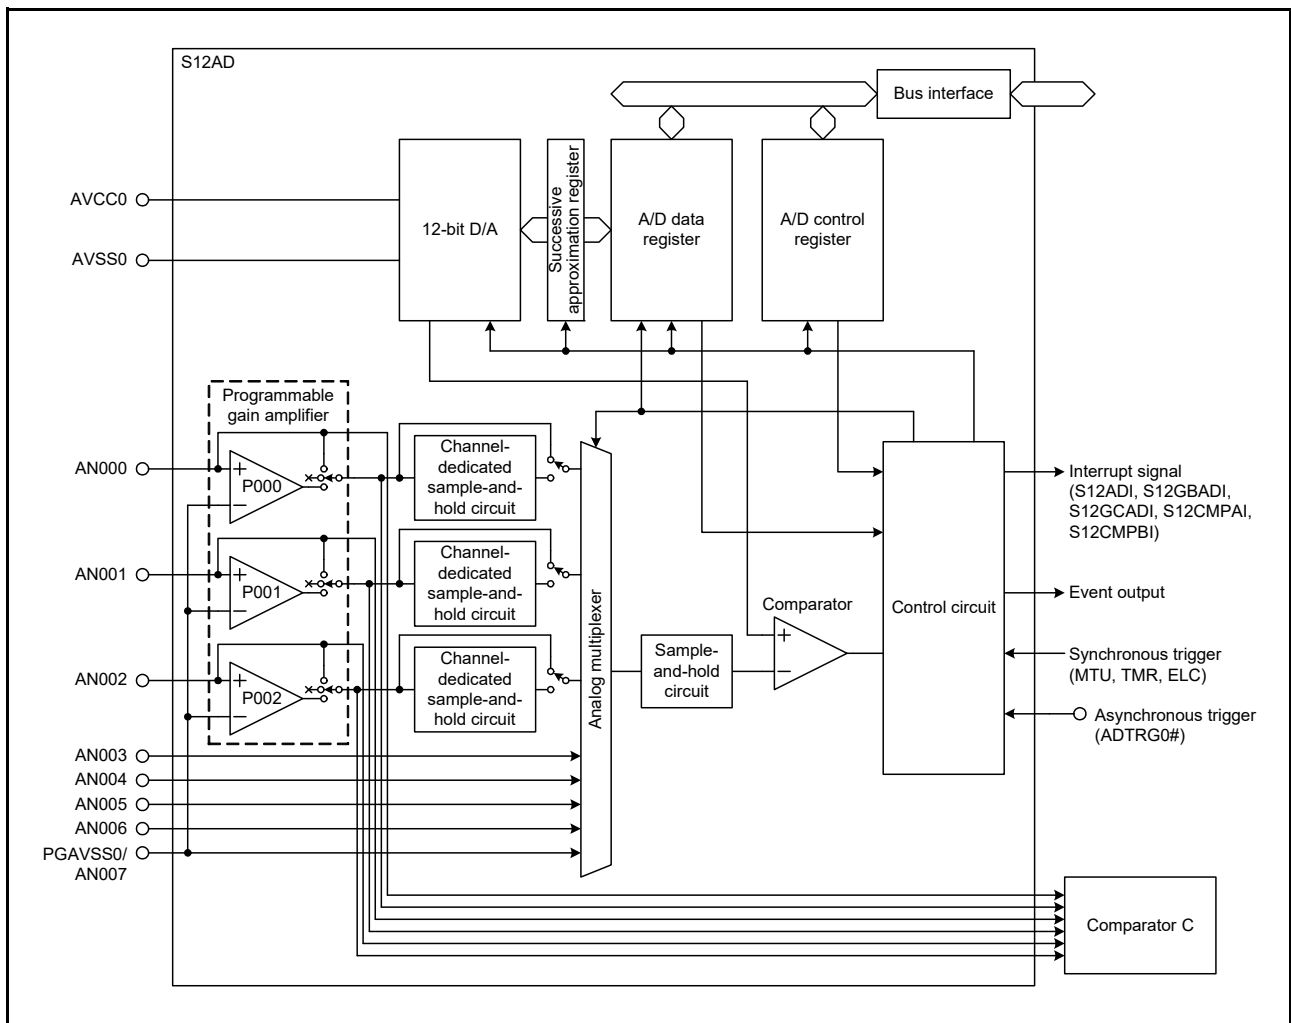

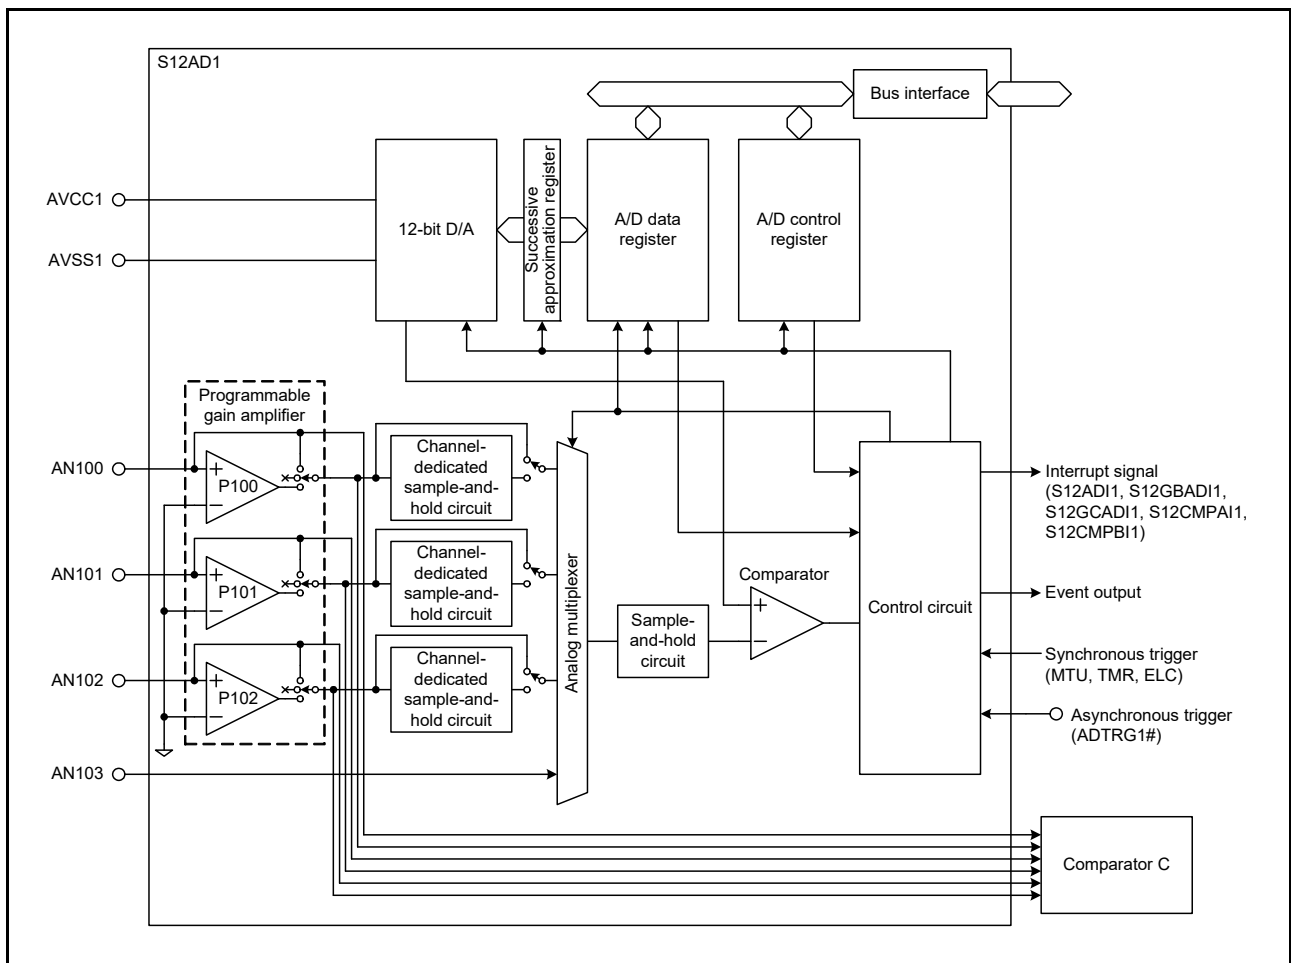

Figure 38.2 Block Diagram of 12-Bit A/D Converter (Product With Pseudo-Differential Input to PGAs, Unit 0)

**Figure 38.5** Block Diagram of 12-Bit A/D Converter (Unit 2)

Table 38.3 lists the input/output pins of the 12-bit A/D converter.

There are three 12-bit A/D converter units, unit 0 (S12AD), unit 1 (S12AD1), and unit 2 (S12AD2), with operation independent of each other. The input channels of S12AD, S12AD1, and S12AD2 can be divided into three groups for operation.

**Table 38.3 Input/Output Pins of 12-Bit A/D Converter**

| Unit               | Pin Name                        | I/O    | Function                                               |
|--------------------|---------------------------------|--------|--------------------------------------------------------|

## 38.2 Register Descriptions

### 38.2.1 A/D Data Registers y (ADDRy) (y = 0 to 11, 16, 17), A/D Data Duplication Register (ADDBLDR), A/D Data Duplication Register A (ADDBLDRA), A/D Data Duplication Register B (ADDBLDRB), A/D Temperature Sensor Data Register (ADTSDR), A/D Internal Reference Voltage Data Register (ADOCDR)

Address(es): S12AD.ADDR0 0008 9020h, S12AD.ADDR1 0008 9022h, S12AD.ADDR2 0008 9024h, S12AD.ADDR3 0008 9026h, S12AD.ADDR4 0008 9028h, S12AD.ADDR5 0008 902Ah, S12AD.ADDR6 0008 902Ch, S12AD.ADDR7 0008 902Eh, S12AD.ADDBLDR 0008 9018h, S12AD.ADDBLDRA 0008 9084h, S12AD.ADDBLDRB 0008 9086h, S12AD1.ADDR0 0008 9220h, S12AD1.ADDR1 0008 9222h, S12AD1.ADDR2 0008 9224h, S12AD1.ADDR3 0008 9226h, S12AD1.ADDR4 0008 9228h, S12AD1.ADDR5 0008 922Ah, S12AD1.ADDR6 0008 922Ch, S12AD1.ADDR7 0008 922Eh, S12AD1.ADDBLDR 0008 9218h, S12AD1.ADDBLDRA 0008 9284h, S12AD1.ADDBLDRB 0008 9286h, S12AD2.ADDR0 0008 9420h, S12AD2.ADDR1 0008 9422h, S12AD2.ADDR2 0008 9424h, S12AD2.ADDR3 0008 9426h, S12AD2.ADDR4 0008 9428h, S12AD2.ADDR5 0008 942Ah, S12AD2.ADDR6 0008 942Ch, S12AD2.ADDR7 0008 942Eh, S12AD2.ADDR8 0008 9430h, S12AD2.ADDR9 0008 9432h, S12AD2.ADDR10 0008 9434h, S12AD2.ADDR11 0008 9436h, S12AD2.ADDR16 0008 9440h, S12AD2.ADDR17 0008 9442h, S12AD2.ADDBLDR 0008 9418h, S12AD2.ADDBLDRA 0008 9484h, S12AD2.ADDBLDRB 0008 9486h, S12AD2.ADTSDR 0008 941Ah, S12AD2.ADOCDR 0008 941Ch

The ADDRy registers (y = 0 to 7: S12AD, y = 0 to 7: S12AD1, y = 0 to 11, 16, 17: S12AD2) are 16-bit read-only registers which store the A/D conversion results.

The ADDBLDR register is a 16-bit read-only register used in double trigger mode. The ADDBLDR register stores the results of A/D conversion when the conversion is started by the second trigger.

The ADDBLDRA and ADDBLDRB registers are 16-bit read-only registers that store the A/D conversion results in response to the respective triggers during extended operation in double trigger mode.

The ADTSDR register is a 16-bit read-only register that stores the A/D-converted value of the temperature sensor output.

The ADOCDR register is a 16-bit read-only register that stores the A/D conversion results of the internal reference voltage.

The format of each register differs depending on the conditions below.

- Settings of the A/D data register format select bit (ADDCER.ADRFMT) (right-justified or left-justified)
- Settings of the addition count select bits (ADADC.ADC[2:0]) (2-, 3-, 4-, or 16-time conversion)
- Settings of the average mode enable bit (ADADC.AVEE) (add or average)

The data formats for each given condition are shown below.

(1) When A/D-Converted Value Addition/Average Mode is Disabled

- Right-justified format  
The A/D-converted value is stored in bits 11 to 0. Bits 15 to 12 are read as 0.
- Left-justified format  
The A/D-converted value is stored in bits 15 to 4. Bits 3 to 0 are read as 0.

(2) When A/D-Converted Average Mode is Selected

A/D-converted value average mode can be set only when 2- or 4-time conversion is selected in A/D-converted value addition mode.

- Right-justified format  
The mean value of the A/D-converted results of the same channel is stored in bits 11 to 0.  
Bits 15 to 12 are read as 0.
- Left-justified format

The mean value of the A/D-converted results of the same channel is stored in bits 15 to 4.  
Bits 3 to 0 are read as 0.

(3) When A/D-Converted Value Addition Mode is Selected

When A/D-converted addition mode is selected, the value added by the A/D-converted value of the same channel is indicated. The number of A/D conversions can be set to 1, 2, 3, 4, or 16 times. If A/D-converted addition mode is selected, when the conversion count is set to 1 to 4 times, the value added by the A/D conversion result is retained in the A/D data register as 2-bit extended data of the conversion accuracy bits; when the conversion count is set to 16 times, the value added by the A/D conversion result is retained in the A/D data register as 4-bit extended data of the conversion accuracy bits. Even if A/D-converted value addition mode is selected, the value is stored in the A/D data register according to the settings of the A/D data register format select bits.

- Right-justified format (in A/D-converted value addition mode and when number of conversions is selected for 1 to 4 times)  
The value added by the A/D-converted value of the same channel is stored in bits 13 to 0.  
Bits 15 and 14 are read as 0.
- Right-justified format (in A/D-converted value addition mode and when number of conversions is selected for 16 times)  
The value added by the A/D-converted value of the same channel is stored in bits 15 to 0.
- Left-justified format (in A/D-converted value addition mode and when number of conversions is selected for 1 to 4 times)  
The value added by the A/D-converted value of the same channel is stored in bits 15 to 2.  
Bits 1 and 0 are read as 0.
- Left-justified format (in A/D-converted value addition mode and when number of conversions is selected for 16 times)  
The value added by the A/D-converted value of the same channel is stored in bits 15 to 0.

### 38.2.2 A/D Self-Diagnosis Data Register (ADRD)

Address(es): S12AD.ADRD 0008 901Eh, S12AD1.ADRD 0008 921Eh, S12AD2.ADRD 0008 941Eh

The ADRD register is a 16-bit read-only register that stores the A/D conversion results based on the 12-bit A/D converter's self-diagnosis. In addition to the A/D-converted value, the self-diagnosis status is included in. In the ADRD register, the different formats are used depending on the conditions below.

- Settings of the A/D data register format select bit (ADCER.ADRFMT) (right-justified or left-justified)

The A/D-converted value addition mode and A/D-converted value average mode cannot be applied to the A/D self-diagnosis function. If temperature sensor output or internal reference voltage is selected, self-diagnosis function cannot be selected. For details of self-diagnosis, refer to section 38.2.14, A/D Control Extended Register (ADCER).

The data formats for each given condition are shown below.

- Right-justified format  
The A/D-converted value is stored in bits 11 to 0. The self-diagnosis status is stored in bits 15 and 14. Bits 13 and 12 are read as 0.
- Left-justified format  
The A/D-converted value is stored in bits 15 to 4. The self-diagnosis status is stored in bits 1 and 0. Bits 3 and 2 are read as 0.

**Table 38.4 Self-Diagnosis Status Description**

| Bits 15 and 14 for Right-Justified Format Setting<br>Bits 1 and 0 for Left-Justified Format Setting | Self-Diagnosis Status                                                    |
|-----------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------|
| 00b                                                                                                 | Self-diagnosis has never been executed since power-on.                   |
| 01b                                                                                                 | Self-diagnosis using the voltage of 0 V has been executed.               |
| 10b                                                                                                 | Self-diagnosis using the voltage of $1/2 \times AVCC$ has been executed. |
| 11b                                                                                                 | Self-diagnosis using the voltage of AVCC has been executed.              |

Note: For details of self-diagnosis, refer to section 38.2.14, A/D Control Extended Register (ADCER).

### 38.2.3 A/D Control Register (ADCSR)

Address(es): S12AD.ADCSR 0008 9000h, S12AD1.ADCSR 0008 9200h, S12AD2.ADCSR 0008 9400h

Note 1. To select AN000 to AN002, AN007, AN100 to AN102, and AN107, refer to section 38.3.2, Setting the Input Paths of AN000 to AN002, AN007, AN100 to AN102, and AN107.

The ADCSR register sets double trigger mode, A/D conversion start trigger; enables/disables scan end interrupt; selects the scan mode; and starts or stops A/D conversion.

#### DBLANS[4:0] Bits (Double Trigger Channel Select)

The DBLANS[4:0] bits select one of the channels for A/D conversion data duplication in double trigger mode. The A/D conversion results of the analog input of the channel selected by the DBLANS[4:0] bits are stored into the A/D data register y when conversion is started by the first trigger, and into the A/D data duplication register when started by the second trigger. Table 38.5 shows selection of the channel for double triggered operation.

When double trigger mode is selected, the channels selected by the ADANSA0 and ADANSA1 registers are invalid, and the channel selected by the DBLANS[4:0] bits is subjected to A/D conversion instead.

When double trigger mode is selected in group scan mode, double trigger mode operation is performed for group A only and not performed for group B or C. Also, in double trigger mode, the analog inputs of multiple channels, temperature sensor outputs, or internal reference voltage cannot be selected for group A, but can be selected for groups B and C.

The DBLANS[4:0] bits should be set while the ADST bit is 0. They should not be set simultaneously when 1 is written to the ADST bit.

**Table 38.5 Relationship Between DBLANS[4:0] Bits Settings and Double Trigger Enabled Channels**

| DBLANS[4:0] | Duplication Channel |                 |                 |
|-------------|---------------------|-----------------|-----------------|
|             | S12AD (Unit 0)      | S12AD1 (Unit 1) | S12AD2 (Unit 2) |

| 10001b      | —                   | —               | AN217           |

—: Do not specify this value.

Note: Duplication cannot be selected for the A/D conversion data of self-diagnosis, temperature sensor output, and internal reference voltage.

### GBADIE Bit (Group B Scan End Interrupt Enable)

The GBADIE bit enables or disables group B scan end interrupt in group scan mode.

A group B scan end interrupt is provided individually for each unit. Table 38.6 shows the relationship between each unit and the scan end interrupt for group B.

**Table 38.6 Relationship Between Each Unit and Group B Scan End Interrupt**

| Unit   | Group B Scan End Interrupt |
|--------|----------------------------|
| S12AD  | S12GBADI                   |
| S12AD1 | S12GBADI1                  |
| S12AD2 | S12GBADI2                  |

### DBLE Bit (Double Trigger Mode Select)

Double trigger mode has a function to store the resulting data of A/D conversion started by the first and second synchronous triggers into separate registers.

When double trigger mode is selected, the channels specified in the ADANSA0 and ADANSA1 registers are invalid and the channel selected by the DBLANS[4:0] bits is effective instead. Double trigger mode can be only operated by the synchronous trigger selected by the ADSTRGR.TRSA[5:0] bits. Do not generate an asynchronous or software trigger. The A/D conversion results started by the first trigger are stored into the A/D data register y and those started by the second trigger are stored into the A/D data duplication register. In this case, when the ADIE bit is set to 1, the interrupt request is generated upon completion of the second conversion instead of upon completion of the first conversion. In continuous scan mode, double trigger mode should not be selected. In addition, double trigger mode should not be used for self-diagnosis, or conversion of the temperature sensor output and internal reference voltage. When using double trigger mode in group scan mode, A/D conversion of the temperature sensor output or internal reference voltage should not be selected for group A.

The DBLE bit should be set after the ADST bit has been set to 0.

**EXTRG Bit (Trigger Select)**

The EXTRG bit selects the synchronous trigger or the asynchronous trigger as the trigger for starting A/D conversion. To use an external pin (asynchronous trigger) to start A/D conversion, set the ADCSR.TRGE and ADCSR.EXTRG bits to 1 while the external trigger pin (ADTRG0#, ADTRG1#, or ADTRG2#) is being driven high. Then, if the ADTRG0#, ADTRG1#, or ADTRG2# signal is changed to low, the falling edge is detected and the scan process is started. In this case, the pulse width of the low-level input must be at least 1.5 clock cycles of PCLKB. Table 38.7 lists the units and the corresponding external pins (asynchronous triggers).

**Table 38.7 Relationship Between Each Unit and External Pin (Asynchronous Trigger)**

| Unit   | External Pin (Asynchronous Trigger) |
|--------|-------------------------------------|
| S12AD  | ADTRG0#                             |
| S12AD1 | ADTRG1#                             |
| S12AD2 | ADTRG2#                             |

**TRGE Bit (Trigger Start Enable)**

The TRGE bit enables or disables A/D conversion by the synchronous trigger and the asynchronous trigger. This bit should be set to 1 in group scan mode.

**ADIE Bit (Scan End Interrupt Enable)**

The ADIE bit enables or disables the A/D scan end interrupt in scans except for groups B and C scan in group scan mode. With double trigger mode deselected, the A/D scan conversion end interrupt is generated after the first scan is completed if the ADIE bit is set to 1.

With double trigger mode selected, the A/D scan conversion end interrupt is generated after the second scan is completed if the ADIE bit is set to 1 as long as the scan is started by the synchronous trigger selected by the ADSTRGR.TRSA[5:0] bits.

When scan is started by a software trigger, even with double trigger mode selected, the A/D scan conversion end interrupt is generated if the ADIE bit is set to 1 when the scan is completed. The A/D scan conversion end interrupt is provided individually for each unit. Table 38.8 shows the relationship between each unit and the A/D scan conversion end interrupt.

**Table 38.8 Relationship Between Each Unit and A/D Scan Conversion End Interrupt**

| Unit   | A/D Scan Conversion End Interrupt |
|--------|-----------------------------------|
| S12AD  | S12ADI                            |
| S12AD1 | S12ADI1                           |
| S12AD2 | S12ADI2                           |

**ADCS[1:0] Bits (Scan Mode Select)**

The ADCS[1:0] bits selects the scan mode.

In single scan mode, A/D conversion is performed for the analog inputs for up to eight channels for A/D converter unit 0, eight channels for unit 1, and 14 channels for unit 2 selected with the ADANSA0 and ADANSA1 registers in the ascending order of arbitrary channel number, and the A/D conversion is stopped when one cycle of the A/D scan conversion is completed for all the selected channels.

The temperature sensor output or internal reference voltage can be selected; however, it cannot be selected with a channel input. Conversion of the temperature sensor output takes priority over that of internal reference voltage when both the temperature sensor output and internal reference voltage are selected.

In continuous scan mode, A/D conversion is performed for the analog inputs for up to eight channels for A/D converter unit 0, eight channels for unit 1, and 14 channels for unit 2 selected with the ADANSA0 and ADANSA1 registers in the ascending order of arbitrary channel number, and the A/D conversion is repeated from the first channel when one cycle

of the A/D scan conversion is completed for all the selected channels.

In continuous scan mode, selecting the temperature sensor output and internal reference voltage is prohibited.

In group scan mode, A/D conversion is performed for the analog inputs (group A) for up to eight channels for A/D converter unit 0, eight channels for unit 1, and 14 channels for unit 2 selected with the ADANSA0 and ADANSA1 registers in the ascending order of arbitrary channel number after scanning is started by the synchronous trigger selected by the ADSTRGR.TRSA[5:0] bits, and the A/D conversion is stopped when one cycle of the A/D scan conversion is completed for all the selected channels.

A/D conversion is also performed for the analog inputs (group B or C) for up to eight channels for A/D converter unit 0, eight channels for unit 1, and 14 channels for unit 2 selected with the ADANSB0 and ADANSB1 registers and the ADANSC0 and ADANSC1 registers in the ascending order of arbitrary channel number after A/D conversion is started by the synchronous trigger selected by the ADSTRGR.TRSA[5:0] bits and the ADGCTRGR.TRSC[5:0] bits, and when A/D conversion is completed for all the selected channels, A/D conversion is stopped.

The temperature sensor output or internal reference voltage can be selected; however, it cannot be selected with a channel input in the same group. Conversion of the temperature sensor output takes priority over that of internal reference voltage when both the temperature sensor output and internal reference voltage are selected.

When selecting group scan mode, different channels and triggers should be selected for groups A, B, and C.

When using two groups while group scan mode is set, use groups A and B (ADGCTRGR.GRCE bit = 0). When using three groups, use groups A, B, and C (ADGCTRGR.GRCE bit = 1).

The ADCS[1:0] bits should be set while the ADST bit is 0. They should not be set simultaneously when 1 is written to the ADST bit.

**Table 38.9 Selection of Scan Mode, Double Trigger Mode, and Targets for A/D Conversion**

| Scan Mode Setup | Double Trigger Mode Setting | Targets for A/D Conversion |                                  |                                    |                            |                            |
|-----------------|-----------------------------|----------------------------|----------------------------------|------------------------------------|----------------------------|----------------------------|

### ADST Bit (A/D Conversion Start)

The ADST bit starts or stops A/D conversion process.

Before the ADST bit is set to 1, set the A/D conversion clock, the conversion mode, and conversion target analog input.

[Setting conditions]

- 1 is written by software.
- The synchronous trigger selected by the ADSTRGR.TRSA[5:0] bits is detected with the ADCSR.EXTRG and ADCSR.TRGE bits being set to 0 and 1, respectively.
- The synchronous trigger selected by the ADSTRGR.TRSA[5:0] bits is detected with the ADCSR.TRGE bit being set to 1 in group scan mode.
- The asynchronous trigger is detected with the ADCSR.TRGE and ADCSR.EXTRG bits being set to 1 and the ADSTRGR.TRSA[5:0] bits being set to 000000b.
- With group priority control operation mode enabled (ADCSR.ADCS[1:0] bits = 01b and ADGSPCR.PGS bit = 1), a group B or C trigger is detected and A/D conversion of group B or C is started.

- With group priority control operation mode enabled (ADCSR.ADCS[1:0] bits = 01b and ADGSPCR.PGS bit = 1), the ADGSPCR.GBRP bit is set to 1 and A/D conversion of the lowest-priority group is started.

[Clearing conditions]

- 0 is written by software.
- The A/D conversion of all the selected channels, temperature sensor output, or the internal reference voltage (for unit 2 only) is completed in single scan mode.
- Group A scan is completed in group scan mode.
- Group B scan is completed in group scan mode.
- Group C scan is completed in group scan mode.
- With group priority control operation mode enabled (ADCSR.ADCS[1:0] bits = 01b and ADGSPCR.PGS bit = 1), the ADGSPCR.GBRSCN bit is set to 1 and the scanning of the low-priority group started by a trigger is stopped.

Note: When group priority control operation mode has been enabled (ADCSR.ADCS[1:0] bits = 01b and ADGSPCR.PGS bit = 1), do not set the ADST bit to 1.

Note: When group priority control operation mode has been enabled (ADCSR.ADCS[1:0] bits = 01b and ADGSPCR.PGS bit = 1) and the ADGSPCR.GBRP bit = 1, do not set the ADST bit to 0. When forcibly terminating A/D conversion, follow the procedure for clearing the ADST bit.

Note: When the single-scan continuous function is used (ADGSPCR.GBRP bit = 1) with group priority control operation mode enabled (ADCSR.ADCS[1:0] bits = 01b and ADGSPCR.PGS bit = 1), the ADST bit remains as 1.

| b5        | ANSA005 |                               |                                                                             | R/W |
| b6        | ANSA006 |                               |                                                                             | R/W |
| b7        | ANSA007 |                               |                                                                             | R/W |
| b15 to b8 | —       | Reserved                      | These bits are read as 0. The write value should be 0.                      | R/W |

Note 1. To select AN000 to AN002, and AN007, refer to section 38.3.2, Setting the Input Paths of AN000 to AN002, AN007, AN100 to AN102, and AN107.

The S12AD.ADANSA0 register selects analog input channels for A/D conversion from among AN000 to AN007. In group scan mode, this register selects group A channels.

#### ANSA0n Bit (A/D Conversion Channel Select) (n = 00 to 07)

The ANSA0n bit selects analog input channels for A/D conversion from among AN000 to AN007. The channels to be selected and the number of channels can be arbitrarily set. The ANSA000 bit corresponds to AN000 and the ANSA007 bit corresponds to AN007.

When double trigger mode is selected, the channel selected by the S12AD.ADCSR.DBLANS[4:0] bits is selected in group A, and the ANSA0n bit setting is invalid.

The ANSA0n bit should be set while the S12AD.ADCSR.ADST bit is 0.

| b11        | ANSA011 |                               |                                                                           | R/W |
| b15 to b12 | —       | Reserved                      | These bits are read as 0. The write value should be 0.                    | R/W |

The S12AD2.ADANSA0 register selects analog input channels for A/D conversion from among AN200 to AN211. In group scan mode, this register selects group A channels.

**ANSA0n Bit (A/D Conversion Channel Select) (n = 00 to 11)**

The ANSA0n bit selects analog input channels for A/D conversion from among AN200 to AN211. The channels to be selected and the number of channels can be arbitrarily set. The ANSA000 bit corresponds to AN200 and the ANSA011 bit corresponds to AN211.

When performing A/D conversion of the temperature sensor output or internal reference voltage in single scan mode or for group A in group scan mode, do not select analog input channels (set this register to 0000h).

When double trigger mode is selected, the channel selected by the S12AD2.ADCSR.DBLANS[4:0] bits is selected in group A, and the ANSA0n bit setting is invalid.

The ANSA0n bit should be set while the S12AD2.ADCSR.ADST bit is 0.

| b15 to b2 | —       | Reserved                      | These bits are read as 0. The write value should be 0.                                                                                    | R/W |

The S12AD2.ADANSA1 register selects analog input channels for A/D conversion from among AN216 to AN217. In group scan mode, this register selects group A channels.

#### ANSA1n Bit (A/D Conversion Channel Select) (n = 00, 01)

The ANSA1n bit selects analog input channels for A/D conversion from among AN216 to AN217. The channels to be selected and the number of channels can be arbitrarily set. The ANSA100 bit corresponds to AN216 and the ANSA101 bit corresponds to AN217.

When performing A/D conversion of the temperature sensor output or internal reference voltage in single scan mode or for group A in group scan mode, do not select analog input channels (set this register to 0000h).

When double trigger mode is selected, the channel selected by the S12AD2.ADCSR.DBLANS[4:0] bits is selected in group A, and the ANSA1n bit setting is invalid.

The ANSA1n bit should be set while the S12AD2.ADCSR.ADST bit is 0.

| b5        | ANSB005 |                               |                                                                             | R/W |
| b6        | ANSB006 |                               |                                                                             | R/W |
| b7        | ANSB007 |                               |                                                                             | R/W |
| b15 to b8 | —       | Reserved                      | These bits are read as 0. The write value should be 0.                      | R/W |

Note 1. To select AN000 to AN002, and AN007, refer to section 38.3.2, Setting the Input Paths of AN000 to AN002, AN007, AN100 to AN102, and AN107.

The S12AD.ADANSB0 register selects analog input channels for A/D conversion from among AN000 to AN007 in group B when group scan mode is selected. The S12AD.ADANSB0 register is not used in any scan mode other than group scan mode.

#### ANSB0n Bit (A/D Conversion Channel Select) (n = 00 to 07)

The ANSB0n bit selects analog input channels for A/D conversion from among AN000 to AN007 in group B when group scan mode is selected. The S12AD.ADANSB0 register is used for group scan mode only; not used for any other modes. The channels specified in group A (the S12AD.ADANSA0 register), the channels specified in group C (the S12AD.ADANSC0 register), and the channels corresponding to group A, selected with the S12AD.ADCSR.DBLANS[4:0] bits in double trigger mode should be excluded as the channels to be selected and the number of channels to be set.

The ANSB000 bit corresponds to AN000 and the ANSB007 bit corresponds to AN007.

The ANSB0n bit should be set while the S12AD.ADCSR.ADST bit is 0.

| b7        | ANSB007 |                               |                                                                             | R/W |
| b15 to b8 | —       | Reserved                      | These bits are read as 0. The write value should be 0.                      | R/W |

Note 1. To select AN100 to AN102, and AN107, refer to section 38.3.2, Setting the Input Paths of AN000 to AN002, AN007, AN100 to AN102, and AN107.

The S12AD1.ADANSB0 register selects analog input channels for A/D conversion from among AN100 to AN107 in group B when group scan mode is selected. The S12AD1.ADANSB0 register is not used in any scan mode other than group scan mode.

**ANSB0n Bit (A/D Conversion Channel Select) (n = 00 to 07)**

The ANSB0n bit selects analog input channels for A/D conversion from among AN100 to AN107 in group B when group scan mode is selected. The S12AD1.ADANSB0 register is used for group scan mode only; not used for any other modes. The channels specified in group A (the S12AD1.ADANSA0 register), the channels specified in group C (the S12AD1.ADANSC0 register), and the channels corresponding to group A, selected with the S12AD1.ADCSR.DBLANS[4:0] bits in double trigger mode should be excluded as the channels to be selected and the number of channels to be set.

The ANSB000 bit corresponds to AN100 and the ANSB007 bit corresponds to AN107.

The ANSB0n bit should be set while the S12AD1.ADCSR.ADST bit is 0.

| b9         | ANSB009 |                               |                                                                           | R/W |
| b10        | ANSB010 |                               |                                                                           | R/W |
| b11        | ANSB011 |                               |                                                                           | R/W |
| b15 to b12 | —       | Reserved                      | These bits are read as 0. The write value should be 0.                    | R/W |

The S12AD2.ADANSB0 register selects analog input channels for A/D conversion from among AN200 to AN211 in group B when group scan mode is selected. The S12AD2.ADANSB0 register is not used in any scan mode other than group scan mode.

**ANSB0n Bit (A/D Conversion Channel Select) (n = 00 to 11)**

The ANSB0n bit selects analog input channels for A/D conversion from among AN200 to AN211 in group B when group scan mode is selected. The S12AD2.ADANSB0 register is used for group scan mode only; not used for any other modes. The channels specified in group A (the S12AD2.ADANSA0 and S12AD2.ADANSA1 registers), the channels specified in group C (the S12AD2.ADANSC0 and S12AD2.ADANSC1 registers), and the channels corresponding to group A, selected with the S12AD2.ADCSR.DBLANS[4:0] bits in double trigger mode should be excluded as the channels to be selected and the number of channels to be set.

When performing A/D conversion of the temperature sensor output or internal reference voltage for group B in group scan mode, do not select analog input channels (set this register to 0000h).

The ANSB000 bit corresponds to AN200 and the ANSB011 bit corresponds to AN211.

The ANSB0n bit should be set while the S12AD2.ADCSR.ADST bit is 0.

|-----------|---------|-------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------|-----|
| b0        | ANSB100 | A/D Conversion Channel Select | Select whether the voltages on AN216 to AN217 are to be converted or not.<br>0: Not selected for conversion<br>1: Selected for conversion | R/W |
| b1        | ANSB101 |                               |                                                                                                                                           | R/W |
| b15 to b2 | —       | Reserved                      | These bits are read as 0. The write value should be 0.                                                                                    | R/W |

The S12AD2.ADANSB1 register selects analog input channels for A/D conversion from among AN216 to AN217 in group B when group scan mode is selected. The S12AD2.ADANSB1 register is not used in any scan mode other than group scan mode.

#### ANSB1n Bit (A/D Conversion Channel Select) (n = 00, 01)

The ANSB1n bit selects analog input channels for A/D conversion from among AN216 to AN217 in group B when group scan mode is selected. The S12AD2.ADANSB1 register is used for group scan mode only; not used for any other modes. The channels specified in group A (the S12AD2.ADANSA0 and S12AD2.ADANSA1 registers), the channels specified in group C (the S12AD2.ADANSC0 and S12AD2.ADANSC1 registers), and the channels corresponding to group A, selected with the S12AD2.ADCSR.DBLANS[4:0] bits in double trigger mode should be excluded as the channels to be selected and the number of channels to be set.

When performing A/D conversion of the temperature sensor output or internal reference voltage for group B in group scan mode, do not select analog input channels (set this register to 0000h).

The ANSB100 bit corresponds to AN216 and the ANSB101 bit corresponds to AN217.

The ANSB1n bit should be set while the S12AD2.ADCSR.ADST bit is 0.

| b6        | ANSC006 |                               |                                                                             | R/W |
| b7        | ANSC007 |                               |                                                                             | R/W |
| b15 to b8 | —       | Reserved                      | These bits are read as 0. The write value should be 0.                      | R/W |

Note 1. To select AN000 to AN002, and AN007, refer to section 38.3.2, Setting the Input Paths of AN000 to AN002, AN007, AN100 to AN102, and AN107.

The S12AD.ADANSC0 register selects analog input channels for A/D conversion from among AN000 to AN007 in group C when group scan mode is selected. The S12AD.ADANSC0 register is not used in any scan mode other than group scan mode.

#### ANSC0n Bit (A/D Conversion Channel Select) (n = 00 to 07)

The ANSC0n bit selects analog input channels for A/D conversion from among AN000 to AN007 in group C when group scan mode is selected. The S12AD.ADANSC0 register is used for group scan mode only; not used for any other modes. The channels specified in group A (the S12AD.ADANSA0 register), the channels specified in group B (the S12AD.ADANSB0 register), and the channels corresponding to group A, selected with the S12AD.ADCSR.DBLANS[4:0] bits in double trigger mode should be excluded as the channels to be selected and the number of channels to be set.

The ANSC000 bit corresponds to AN000 and the ANSC007 bit corresponds to AN007.

The ANSC0n bit should be set while the S12AD.ADCSR.ADST bit is 0.

| b6        | ANSC006 |                               |                                                                             | R/W |
| b7        | ANSC007 |                               |                                                                             | R/W |
| b15 to b8 | —       | Reserved                      | These bits are read as 0. The write value should be 0.                      | R/W |

Note 1. To select AN100 to AN102, and AN107, refer to section 38.3.2, Setting the Input Paths of AN000 to AN002, AN007, AN100 to AN102, and AN107.

The S12AD1.ADANSC0 register selects analog input channels for A/D conversion from among AN100 to AN107 in group C when group scan mode is selected. The S12AD1.ADANSC0 register is not used in any scan mode other than group scan mode.

**ANSC0n Bit (A/D Conversion Channel Select) (n = 00 to 07)**

The ANSC0n bit selects analog input channels for A/D conversion from among AN100 to AN107 in group C when group scan mode is selected. The S12AD1.ADANSC0 register is used for group scan mode only; not used for any other modes. The channels specified in group A (the S12AD1.ADANSA0 register), the channels specified in group B (the S12AD1.ADANSB0 register), and the channels corresponding to group A, selected with the S12AD1.ADCSR.DBLANS[4:0] bits in double trigger mode should be excluded as the channels to be selected and the number of channels to be set.

The ANSC000 bit corresponds to AN100 and the ANSC007 bit corresponds to AN107.

The ANSC0n bit should be set while the S12AD1.ADCSR.ADST bit is 0.

| b9         | ANSC009 |                               |                                                                           | R/W |
| b10        | ANSC010 |                               |                                                                           | R/W |
| b11        | ANSC011 |                               |                                                                           | R/W |
| b15 to b12 | —       | Reserved                      | These bits are read as 0. The write value should be 0.                    | R/W |

The S12AD2.ADANSC0 register selects analog input channels for A/D conversion from among AN200 to AN211 in group C when group scan mode is selected. The S12AD2.ADANSC0 register is not used in any scan mode other than group scan mode.

**ANSC0n Bit (A/D Conversion Channel Select) (n = 00 to 11)**

The ANSC0n bit selects analog input channels for A/D conversion from among AN200 to AN211 in group C when group scan mode is selected. The S12AD2.ADANSC0 register is used for group scan mode only; not used for any other modes. The channels specified in group A (the S12AD2.ADANSA0 and S12AD2.ADANSA1 registers), the channels specified in group B (the S12AD2.ADANSB0 and S12AD2.ADANSB1 registers), and the channels corresponding to group A, selected with the S12AD2.ADCSR.DBLANS[4:0] bits in double trigger mode should be excluded as the channels to be selected and the number of channels to be set.

When performing A/D conversion of the temperature sensor output or internal reference voltage or for group C in group scan mode, do not select analog input channels (set this register to 0000h).

The ANSC000 bit corresponds to AN200 and the ANSC011 bit corresponds to AN211.

The ANSC0n bit should be set while the S12AD2.ADCSR.ADST bit is 0.

| b1        | ANSC101 |                               |                                                                                                                                           | R/W |
| b15 to b2 | —       | Reserved                      | These bits are read as 0. The write value should be 0.                                                                                    | R/W |

The S12AD2.ADANSC1 register selects analog input channels for A/D conversion from among AN216 to AN217 in group C when group scan mode is selected. The S12AD2.ADANSC1 register is not used in any scan mode other than group scan mode.

#### ANSC1n Bit (A/D Conversion Channel Select) (n = 00, 01)

The ANSC1n bit selects analog input channels for A/D conversion from among AN216 to AN217 in group C when group scan mode is selected. The S12AD2.ADANSC1 register is used for group scan mode only; not used for any other modes. The channels specified in group A (the S12AD2.ADANSA0 and S12AD2.ADANSA1 registers), the channels specified in group B (the S12AD2.ADANSB0 and S12AD2.ADANSB1 registers), and the channels corresponding to group A, selected with the S12AD2.ADCSR.DBLANS[4:0] bits in double trigger mode should be excluded as the channels to be selected and the number of channels to be set.

When performing A/D conversion of the temperature sensor output or internal reference voltage or for group C in group scan mode, do not select analog input channels (set this register to 0000h).

The ANSC100 bit corresponds to AN216 and the ANSC101 bit corresponds to AN217.

The ANSC1n bit should be set while the S12AD2.ADCSR.ADST bit is 0.

### 38.2.10 A/D Channel Conversion Order Setting Register n (ADSCSn) (n = 0 to 13)

#### (1) S12AD.ADSCSn (n = 0 to 7)

Address(es): S12AD.ADSCS0 0008 91C0h, S12AD.ADSCS1 0008 91C1h, S12AD.ADSCS2 0008 91C2h, S12AD.ADSCS3 0008 91C3h, S12AD.ADSCS4 0008 91C4h, S12AD.ADSCS5 0008 91C5h, S12AD.ADSCS6 0008 91C6h, S12AD.ADSCS7 0008 91C7h

Value after reset: (Refer to Table 38.10)

| Bit      | Symbol | Bit Name | Description                                                                                                                                                                            | R/W |
|----------|--------|----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----|
| b7 to b0 | —      | —        | Specify the order of channels for conversion by the 12-bit A/D converter. The channel with the number set in an ADSCSn register is the (n+1)th to be converted (refer to Table 38.10). | R/W |

The ADSCSn register specifies the order of channels for conversion by the 12-bit A/D converter unit 0.

The order of conversion is set in the order AN000, AN001, ..., AN007 after a reset.

To change the order, change the values in the ADSCSn registers.

To use the channel-dedicated sample-and-hold circuit for AN000 to AN002, set the corresponding channel in any of the ADSCS0, ADSCS1, or ADSCS2 register. When setting them to the ADSCS3 to ADSCS7 registers, the results of conversion for the channels are not guaranteed.

If a specified channel is not selected for conversion in the channel selection registers (ADANSA0, ADANSB0, and ADANSC0), A/D conversion of the corresponding channel does not proceed. Set the channels for conversion in order starting from the ADSCS0 register, and set all the channels other than those above in the rest of the registers. Do not set the same value to plural registers.

**Table 38.10 Relationship Between the Value After Reset of the A/D Channel Conversion Order Setting Register n (ADSCSn) and Conversion Order**

| Register Symbol | Order of Conversion | Value After Reset | Channel Numbers that Can be Set: |
|-----------------|---------------------|-------------------|----------------------------------|
| ADSCS0          | First               | 00h               | 00h to 07h (for AN000 to AN007)  |
| ADSCS1          | Second              | 01h               |                                  |
| ADSCS2          | Third               | 02h               |                                  |
| ADSCS3          | Fourth              | 03h               |                                  |
| ADSCS4          | Fifth               | 04h               |                                  |
| ADSCS5          | Sixth               | 05h               |                                  |
| ADSCS6          | Seventh             | 06h               |                                  |
| ADSCS7          | Eighth              | 07h               |                                  |

(2) S12AD1.ADSCSn (n = 0 to 7)

Address(es): S12AD1.ADSCS0 0008 93C0h, S12AD1.ADSCS1 0008 93C1h, S12AD1.ADSCS2 0008 93C2h, S12AD1.ADSCS3 0008 93C3h, S12AD1.ADSCS4 0008 93C4h, S12AD1.ADSCS5 0008 93C5h, S12AD1.ADSCS6 0008 93C6h, S12AD1.ADSCS7 0008 93C7h

Value after reset: (Refer to Table 38.11)

| Bit      | Symbol | Bit Name | Description                                                                                                                                                                            | R/W |
|----------|--------|----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----|
| b7 to b0 | —      | —        | Specify the order of channels for conversion by the 12-bit A/D converter. The channel with the number set in an ADSCSn register is the (n+1)th to be converted (refer to Table 38.11). | R/W |

The ADSCSn register specifies the order of channels for conversion by the 12-bit A/D converter unit 1.

The order of conversion is set in the order AN100, AN101, ..., AN107 after a reset.

To change the order, change the values in the ADSCSn registers.

To use the channel-dedicated sample-and-hold circuit for AN100 to AN102, set the corresponding channel in any of the ADSCS0, ADSCS1, or ADSCS2 register. When setting them to the ADSCS3 to ADSCS7 registers, the results of conversion for the channels are not guaranteed.

If a specified channel is not selected for conversion in the channel selection registers (ADANSA0, ADANSB0, and ADANSC0), A/D conversion of the corresponding channel does not proceed. Set the channels for conversion in order starting from the ADSCS0 register, and set all the channels other than those above in the rest of the registers. Do not set the same value to plural registers.

**Table 38.11 Relationship Between the Value After Reset of the A/D Channel Conversion Order Setting Register n (ADSCSn) and Conversion Order**

| Register Symbol | Order of Conversion | Value After Reset | Channel Numbers that Can be Set: |
|-----------------|---------------------|-------------------|----------------------------------|
| ADSCS0          | First               | 00h               | 00h to 07h (for AN100 to AN107)  |
| ADSCS1          | Second              | 01h               |                                  |
| ADSCS2          | Third               | 02h               |                                  |
| ADSCS3          | Fourth              | 03h               |                                  |
| ADSCS4          | Fifth               | 04h               |                                  |
| ADSCS5          | Sixth               | 05h               |                                  |
| ADSCS6          | Seventh             | 06h               |                                  |
| ADSCS7          | Eighth              | 07h               |                                  |

(3) S12AD2.ADSCSn (n = 0 to 13)

Address(es): S12AD2.ADSCS0 0008 95C0h, S12AD2.ADSCS1 0008 95C1h, S12AD2.ADSCS2 0008 95C2h, S12AD2.ADSCS3 0008 95C3h, S12AD2.ADSCS4 0008 95C4h, S12AD2.ADSCS5 0008 95C5h, S12AD2.ADSCS6 0008 95C6h, S12AD2.ADSCS7 0008 95C7h, S12AD2.ADSCS8 0008 95C8h, S12AD2.ADSCS9 0008 95C9h, S12AD2.ADSCS10 0008 95CAh, S12AD2.ADSCS11 0008 95CBh, S12AD2.ADSCS12 0008 95D0h, S12AD2.ADSCS13 0008 95D1h

Value after reset: (Refer to Table 38.12)

| Bit      | Symbol | Bit Name | Description                                                                                                                                                                            | R/W |
|----------|--------|----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----|
| b7 to b0 | —      | —        | Specify the order of channels for conversion by the 12-bit A/D converter. The channel with the number set in an ADSCSn register is the (n+1)th to be converted (refer to Table 38.12). | R/W |

The ADSCSn register specifies the order of channels for conversion by the 12-bit A/D converter unit 2.

The order of conversion is set in the order AN200, AN201, ..., AN211, AN216, and AN217 after a reset.

To change the order, change the values in the ADSCSn registers.

If a specified channel is not selected for conversion in the channel selection registers (ADANSA0/1, ADANSB0/1, and ADANSC0/1), A/D conversion of the corresponding channel does not proceed. Set the channels for conversion in order starting from the ADSCS0 register, and set all the channels other than those above in the rest of the registers. Do not set the same value to plural registers.

Furthermore, the places of the temperature sensor output and internal reference voltage in the order of conversion are fixed.

**Table 38.12 Relationship Between the Value After Reset of the A/D Channel Conversion Order Setting Register n (ADSCSn) and Conversion Order**

| Register Symbol | Order of Conversion | Value After Reset | Channel Numbers that Can be Set:                            |
|-----------------|---------------------|-------------------|-------------------------------------------------------------|
| ADSCS0          | First               | 00h               | 00h to 0Bh, 10h, and 11h (for AN200 to AN211, AN216, AN217) |
| ADSCS1          | Second              | 01h               |                                                             |

| b5        | ADS005 |                                                     |                                                                      | R/W |
| b6        | ADS006 |                                                     |                                                                      | R/W |
| b7        | ADS007 |                                                     |                                                                      | R/W |
| b15 to b8 | —      | Reserved                                            | These bits are read as 0. The write value should be 0.               | R/W |

The S12AD.ADADS0 register selects channels AN000 to AN007 on which A/D conversion is performed successively 2, 3, 4, or 16 times and then converted values are added (integrated) or averaged.

#### ADS0n Bit (A/D-Converted Value Addition/Average Channel Select) (n = 00 to 07)

When the ADS0n bit of the number that is the same as that of A/D-converted channel selected by the S12AD.ADANSA0.ANSA0n bit or the S12AD.ADCSR.DBLANS[4:0] bits and the S12AD.ADANSB0.ANSB0n bit and the S12AD.ADANSC0.ANSC0n bit is set to 1, A/D conversion of analog input of the selected channels is performed successively 2, 3, 4, or 16 times that is set with the S12AD.ADADC.ADC[2:0] bits.

When the S12AD.ADADC.AVEE bit is 0, the value obtained by addition (integration) is stored in the A/D data register. When the S12AD.ADADC.AVEE bit is 1, the mean value of the results obtained by addition (integration) is stored in the A/D data register.

An A/D conversion channel with addition/average mode disabled executes a regular one-time conversion and stores the value in the A/D data register.

The ADS0n bit should be set while the S12AD.ADCSR.ADST bit is 0.

## (2) S12AD1.ADADS0

| b7        | ADS007 |                                 |                                                                                                                     | R/W |
| b15 to b8 | —      | Reserved                        | These bits are read as 0. The write value should be 0.                                                              | R/W |

The S12AD1.ADADS0 register selects channels AN100 to AN107 on which A/D conversion is performed successively 2, 3, 4, or 16 times and then converted values are added (integrated) or averaged.

**ADS0n Bit (A/D-Converted Value Addition/Average Channel Select) (n = 00 to 07)**

When the ADS0n bit of the number that is the same as that of A/D-converted channel selected by the S12AD1.ADANSA0.ANSA0n bit or the S12AD1.ADCSR.DBLANS[4:0] bits and the S12AD1.ADANSB0.ANSB0n bit and the S12AD1.ADANSC0.ANSC0n bit is set to 1, A/D conversion of analog input of the selected channels is performed successively 2, 3, 4, or 16 times that is set with the S12AD1.ADADC.ADC[2:0] bits.

When the S12AD1.ADADC.AVEE bit is 0, the value obtained by addition (integration) is stored in the A/D data register. When the S12AD1.ADADC.AVEE bit is 1, the mean value of the results obtained by addition (integration) is stored in the A/D data register.

An A/D conversion channel with addition/average mode disabled executes a regular one-time conversion and stores the value in the A/D data register.

The ADS0n bit should be set while the S12AD1.ADCSR.ADST bit is 0.

| b10        | ADS010 |                                 |                                                                                                                                                                                             | R/W |
| b11        | ADS011 |                                 |                                                                                                                                                                                             | R/W |
| b15 to b12 | —      | Reserved                        | These bits are read as 0. The write value should be 0.                                                                                                                                      | R/W |

The S12AD2.ADADS0 register selects channels AN200 to AN211 on which A/D conversion is performed successively 2, 3, 4, or 16 times and then converted values are added (integrated) or averaged.

**ADS0n Bit (A/D-Converted Value Addition/Average Channel Select) (n = 00 to 11)**

When the ADS0n bit of the number that is the same as that of A/D-converted channel selected by the S12AD2.ADANSA0.ANSA0n bit or the S12AD2.ADCSR.DBLANS[4:0] bits and the S12AD2.ADANSB0.ANSB0n bit and the S12AD2.ADANSC0.ANSC0n bit is set to 1, A/D conversion of analog input of the selected channels is performed successively 2, 3, 4, or 16 times that is set with the S12AD2.ADADC.ADC[2:0] bits.

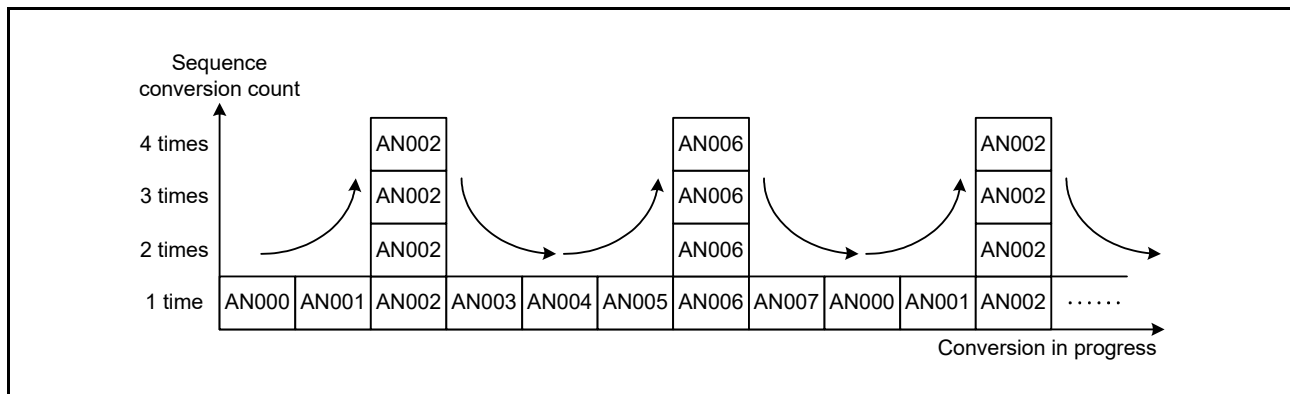

When the S12AD2.ADADC.AVEE bit is 0, the value obtained by addition (integration) is stored in the A/D data register. When the S12AD2.ADADC.AVEE bit is 1, the mean value of the results obtained by addition (integration) is stored in the A/D data register.

An A/D conversion channel with addition/average mode disabled executes a regular one-time conversion and stores the value in the A/D data register.

The ADS0n bit should be set while the S12AD2.ADCSR.ADST bit is 0.

Figure 38.6 shows a scanning operation sequence in which both the S12AD.ADADS0.ADS002 and S12AD.ADADS0.ADS006 bits are set to 1.

It is assumed that addition mode is selected (S12AD.ADADC.AVEE bit = 0) in continuous scan mode (S12AD.ADCSR.ADCS[1:0] bits = 10b), the addition count is set to three times (S12AD.ADADC.ADC[2:0] bits = 011b), and channels AN000 to AN007 are selected (S12AD.ADANSA0 register = 00FFh). The conversion process begins with AN000. The AN002 conversion is performed successively four times (add three times), and the added (integrated) value is stored in A/D data register 2. After that the AN003 conversion is started. The AN006 conversion is performed successively four times and the added (integrated) value is stored in A/D data register 6. After conversion of AN007, the conversion operation is once again performed in the same sequence from AN000.

**Figure 38.6** Scan Conversion Sequence with S12AD.ADADC.ADC[2:0] = 011b, S12AD.ADADC.AVEE = 0, S12AD.ADADS0.ADS002 = 1, and S12AD.ADADS0.ADS006 = 1

| b15 to b2 | —      | Reserved                                            | These bits are read as 0. The write value should be 0.                                                              | R/W |

The S12AD2.ADADS1 register selects channels AN216 to AN217 on which A/D conversion is performed successively 2, 3, 4, or 16 times and then converted values are added (integrated) or averaged.

#### ADS1n Bit (A/D-Converted Value Addition/Average Channel Select) (n = 00, 01)

When the ADS1n bit of the number that is the same as that of A/D-converted channel selected by the S12AD2.ADANSA1.ANSA1n bit or the S12AD2.ADCSR.DBLANS[4:0] bits, the S12AD2.ADANSB1.ANSB1n bit, and the S12AD2.ADANSC1.ANSC1n bit is set to 1, A/D conversion of analog input of the selected channels is performed successively 2, 3, 4, or 16 times that is set with the S12AD2.ADADC.ADC[2:0] bits. When the S12AD2.ADADC.AVEE bit is 0, the value obtained by addition (integration) is stored in the A/D data register. When the S12AD2.ADADC.AVEE bit is 1, the mean value of the results obtained by addition (integration) is stored in the A/D data register.

An A/D conversion channel with addition/average mode disabled executes a regular one-time conversion and stores the value in the A/D data register.

The ADS1n bit should be set while the S12AD2.ADCSR.ADST bit is 0.

### 38.2.13 A/D-Converted Value Addition/Average Count Select Register (ADADC)

Address(es): S12AD.ADADC 0008 900Ch, S12AD1.ADADC 0008 920Ch, S12AD2.ADADC 0008 940Ch

| Bit      | Symbol   | Bit Name              | Description                                                                                                                                                                                                                                                                                                              | R/W |
|----------|----------|-----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----|
| b2 to b0 | ADC[2:0] | Addition Count Select | b2 b0<br>0 0 0: 1-time conversion (no addition; same as normal conversion)<br>0 0 1: 2-time conversion (addition once)<br>0 1 0: 3-time conversion (addition twice)*1<br>0 1 1: 4-time conversion (addition three times)<br>1 0 1: 16-time conversion (addition 15 times)*1<br>Settings other than above are prohibited. | R/W |
| b6 to b3 | —        | Reserved              | These bits are read as 0. The write value should be 0.                                                                                                                                                                                                                                                                   | R/W |
| b7       | AVEE     | Average Mode Enable   | 0: Addition mode is selected.<br>1: Average mode is selected.                                                                                                                                                                                                                                                            | R/W |

Note 1. The AVEE bit is enabled only when 2-time or 4-time conversion is selected. When average mode is selected (ADADC.AVEE bit = 1), do not set 3-time conversion (ADADC.ADC[2:0] bits = 010b) nor 16-time conversion (ADADC.ADC[2:0] bits = 101b).

When the A/D-converted value addition/average modes are enabled for A/D conversion of the channels, temperature sensor output, or internal reference voltage, the number of addition and whether they are to be added or averaged is specified in the ADADC register.

#### ADC[2:0] Bits (Addition Count Select)

The number of addition from channels including those channels selected in double-trigger mode (by the ADCSR.DBLANS[4:0] bits), temperature sensor output, or internal reference voltage for which A/D conversion and addition or averaging is enabled, is selected by the setting of the ADC[2:0] bits.

The ADC[2:0] bits should be set while the ADCSR.ADST bit is 0.

#### AVEE Bit (Average Mode Enable)

The AVEE bit selects whether the results of A/D conversion from channels, including those selected in double-trigger mode (by the DBLANS[4:0] bits), temperature sensor output, or internal reference voltage are to be averaged or added when A/D conversion and addition/average modes are enabled.

When average mode is selected by setting the AVEE bit to 1, do not set the addition count to one time (ADC[2:0] bits = 000b), three times (ADC[2:0] bits = 010b), or 16 times (ADC[2:0] bits = 101b). The mean value of 1-time, 3-time, and 16-time conversion cannot be obtained.

The AVEE bit should be set while the ADCSR.ADST bit is 0.

### 38.2.14 A/D Control Extended Register (ADCER)

Address(es): S12AD.ADCER 0008 900Eh, S12AD1.ADCER 0008 920Eh, S12AD2.ADCER 0008 940Eh

| b14 to b12 | —            | Reserved                                    | These bits are read as 0. The write value should be 0.                                                                                                                                                                                           | R/W |
| b15        | ADRFMT       | A/D Data Register Format Select             | 0: Right-justified is selected for the A/D data register format.<br>1: Left-justified is selected for the A/D data register format.                                                                                                              | R/W |

The ADCER register sets self-diagnosis mode, format of A/D data registers y (ADDRy), and automatic clearing of A/D data registers.

#### ACE Bit (A/D Data Register Automatic Clearing Enable)

The ACE bit enables or disables automatic clearing (all 0) of the ADDRy, ADDR, ADDBLDR, ADDBLDRA, ADDBLDRB, ADTSDR, or ADOCDR register after any of these registers have been read by the CPU, DTC, or DMAC. Automatic clearing of the A/D data register is enabled to detect a failure which has not been updated in the A/D data register.

#### DIAGVAL[1:0] Bits (Self-Diagnosis Conversion Voltage Select)

The DIAGVAL[1:0] bits select the voltage value used in self-diagnosis voltage fixed mode. For details, refer to the descriptions of the DIAGLD bit.

Self-diagnosis should not be executed by setting the DIAGLD bit to 1 when the DIAGVAL[1:0] bits are set to 00b.

#### DIAGLD Bit (Self-Diagnosis Mode Select)

The DIAGLD bit selects whether the three voltage values are rotated or the fixed voltage is used in self-diagnosis. Setting this bit (DIAGLD) to 0 allows conversion of the voltages in rotation mode where 0 V,  $1/2 \times AVCC$ , and AVCC are converted in that order. When self-diagnosis rotation mode is selected after a reset, self-diagnosis is performed from 0 V. When self-diagnosis voltage fixed mode is selected, the fixed voltage specified by the DIAGVAL[1:0] bits is converted. In self-diagnosis voltage rotation mode, the self-diagnosis voltage value does not return to 0 when scan conversion is completed. When scan conversion is restarted, therefore, rotation starts at the voltage value following the previous value. If fixed mode is switched to rotation mode, rotation starts at the fixed voltage value.

The DIAGLD bit should be set while the ADCSR.ADST bit is 0.

**DIAGM Bit (Self-Diagnosis Enable)**

The DIAGM bit enables or disables self-diagnosis.

Self-diagnosis is used to detect a failure of the 12-bit A/D converter. Specifically, one from among the internally generated voltages 0,  $1/2 \times AVCC$ , or  $AVCC$  is selected for conversion. When conversion is completed, information on the converted voltage and the conversion result is stored into the self-diagnosis data register (ADRD). The ADRD register can then be read out by software to determine whether the conversion result falls within the normal range (normal) or not (abnormal). Self-diagnosis is executed once at the beginning of each scan, and one of the three voltages is converted. When self-diagnosis is selected in group scan mode, self-diagnosis is separately executed in groups A, B, and C.

The DIAGM bit should be set while the ADCSR.ADST bit is 0.

When performing the self-diagnosis, A/D conversion of the temperature sensor output and internal reference voltage is prohibited regardless of scanning groups.

**ADRFMT Bit (A/D Data Register Format Select)**

The ADRFMT bit specifies right-justified or left-justified for the data to be stored in the ADDR<sub>y</sub>, ADDBLDR, ADDBLDRA, ADDBLDRB, ADTSDR, ADOCDR, ADRD, ADCMPDR0, ADCMPDR1, ADWINLLB, or ADWINULB register.

The ADRFMT bit should be set while the ADCSR.ADST bit is 0.

For details on the format of each data register, refer to section 38.2.1, A/D Data Registers y (ADDR<sub>y</sub>) (y = 0 to 11, 16, 17), A/D Data Duplication Register (ADDBLDR), A/D Data Duplication Register A (ADDBLDRA), A/D Data Duplication Register B (ADDBLDRB), A/D Temperature Sensor Data Register (ADTSDR), A/D Internal Reference Voltage Data Register (ADOCDR), section 38.2.2, A/D Self-Diagnosis Data Register (ADRD), section 38.2.32, A/D Comparison Function Window A Lower Level Setting Register (ADCMPDR0), section 38.2.33, A/D Comparison Function Window A Upper Level Setting Register (ADCMPDR1), section 38.2.39, A/D Comparison Function Window B Lower Level Setting Register (ADWINLLB), and section 38.2.40, A/D Comparison Function Window B Upper Level Setting Register (ADWINULB).

### 38.2.15 A/D Conversion Start Trigger Select Register (ADSTRGR)

Address(es): S12AD.ADSTRGR 0008 9010h, S12AD1.ADSTRGR 0008 9210h, S12AD2.ADSTRGR 0008 9410h

| Bit       | Symbol    | Bit Name                                    | Description                                                                                                                                                    | R/W |
|-----------|-----------|---------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------|-----|
| b5 to b0  | TRSB[5:0] | Group B A/D Conversion Start Trigger Select | Select the A/D conversion start trigger for group B in group scan mode.                                                                                        | R/W |
| b7, b6    | —         | Reserved                                    | These bits are read as 0. The write value should be 0.                                                                                                         | R/W |
| b13 to b8 | TRSA[5:0] | A/D Conversion Start Trigger Select         | Select the A/D conversion start trigger in single scan mode and continuous mode. In group scan mode, the A/D conversion start trigger for group A is selected. | R/W |
| b15, b14  | —         | Reserved                                    | These bits are read as 0. The write value should be 0.                                                                                                         | R/W |

The ADSTRGR register selects the A/D conversion start trigger.

#### TRSB[5:0] Bits (Group B A/D Conversion Start Trigger Select)

The TRSB[5:0] bits select the trigger to start scanning of the analog input selected in group B. The TRSB[5:0] bits require to be set only in group scan mode and are not used in any other scan mode. For the scan conversion start trigger for group B, setting a software trigger or an asynchronous trigger is prohibited. Therefore, the TRSB[5:0] bits should be set to the value other than 00h and the ADCSR.TRGE bit should be set to 1 in group scan mode.

When two groups are selected (ADGCTRGR.GRCE bit = 0) during group priority operation in group scan mode, setting the ADGSPCR.GBRP bit to 1 allows group B to continuously operate in single scan mode. When setting the GBRP bit to 1, set the TRSB[5:0] bits to 3Fh. Note that the issuance period of trigger for A/D conversion must be more than or equal to the actual scan conversion time ( $t_{SCAN}$ ). If the issuance period is less than  $t_{SCAN}$ , A/D conversion by the trigger may have no effect.

When selecting a trigger from the MTU operated on a PCLKC cycle as an A/D conversion start trigger, a delay of the period for synchronization processing occurs. Refer to section 38.3.8, Analog Input Sampling Time and Scan Conversion Time for details.

Table 38.13 lists the A/D conversion startup sources selected by the TRSB[5:0] bits.

#### TRSA[5:0] Bits (A/D Conversion Start Trigger Select)

The TRSA[5:0] bits select the trigger to start A/D conversion in single scan mode and continuous scan mode. In group scan mode, the trigger to start scanning of the analog input selected in group A is selected. When performing scanning in group scan mode or double trigger mode, set the ADCSR.TRGE bit to 1 and set the ADCSR.EXTRG bit to 0.

- When using the A/D conversion startup source of a synchronous trigger, set the ADCSR.TRGE bit to 1 and set the ADCSR.EXTRG bit to 0.
- When using the asynchronous trigger, set the ADCSR.TRGE bit to 1 and set the ADCSR.EXTRG bit to 1.
- Software trigger (ADCSR.ADST) is enabled regardless of the settings of the ADCSR.TRGE bit, the ADCSR.EXTRG bit, and the TRSA[5:0] bits.

Note that the issuance period of trigger for A/D conversion must be more than or equal to the actual scan conversion time ( $t_{SCAN}$ ). If the issuance period is less than  $t_{SCAN}$ , A/D conversion by a trigger may have no effect. When selecting a trigger from the MTU operated on a PCLKC cycle as an A/D conversion start trigger, a delay of the period for synchronization processing occurs. Refer to section 38.3.8, Analog Input Sampling Time and Scan Conversion

Time for details.

Table 38.14 lists the selection of A/D conversion start sources selected by the TRSA[5:0] bits.

**Table 38.13 Selection of A/D Trigger Sources by the TRSB[5:0] Bits (1/2)**

| Module                           | Source           | Remarks                                                                                                                                             | TRS<br>B[5] | TRS<br>B[4] | TRS<br>B[3] | TRS<br>B[2] | TRS<br>B[1] | TRS<br>B[0] |

| b15 to b12 | —      | Reserved                                                                    | These bits are read as 0. The write value should be 0.                                                                                                                      | R/W |

The ADEXICR register specifies the settings of A/D conversion of the temperature sensor output, internal reference voltage.

#### TSSAD Bit (Temperature Sensor Output A/D-Converted Value Addition/Average Mode Select)

When A/D conversion of the temperature sensor output is selected and the TSSAD bit is set to 1, A/D conversion of the temperature sensor output is performed in sequence for the count set in the ADADC.ADC[2:0] bits (2, 3, 4, or 16 times). The added (accumulated) total value is returned to the A/D temperature sensor data register (ADTSDR) when the ADADC.AVEE bit is 0 and the average is returned to the ADTSDR register when the ADADC.AVEE bit is 1. The TSSAD bit should be set while the ADCSR.ADST bit is 0.

#### OCSAD Bit (Internal Reference Voltage A/D-Converted Value Addition/Average Mode Select)

When A/D conversion of the internal reference voltage is selected and the OCSAD bit is set to 1, A/D conversion of the internal reference voltage is performed in sequence for the count set in the ADADC.ADC[2:0] bits (2, 3, 4, or 16 times). When the ADADC.AVEE bit is 0, the value obtained by addition (integration) is stored in the A/D internal reference voltage data register (ADOCADR). When the ADADC.AVEE bit is 1, the mean value is stored in the ADOCADR register. The OCSAD bit should be set while the ADCSR.ADST bit is 0.

#### TSSA Bit (Temperature Sensor Output A/D Conversion Select)

The TSSA bit selects A/D conversion of the temperature sensor output for group A in single scan mode or group scan mode. When A/D conversion of the temperature sensor output is performed, set the ADCSR.DBLE bit to 0. The TSSA bit should be set while the ADCSR.ADST bit is 0. When setting the TSSB or ADGCXCR.TSSC bit to 1, set this bit to 0.

The temperature sensor output can be selected in single scan mode and group scan mode. Set the sampling time to at least 4  $\mu$ s when A/D-converting the temperature sensor output. When setting the TSSA bit to 1, the temperature sensor is automatically activated. After activation, only start A/D conversion after waiting 200  $\mu$ s for the sensor output to become stable. When A/D conversion is started, auto-discharging for 15 cycles of ADCLK proceeds before sampling. A/D conversion of the temperature sensor outputs in groups B and C should be handled in the same way.

#### **OCSA Bit (Internal Reference Voltage A/D Conversion Select)**

The OCSA bit selects A/D conversion of the internal reference voltage for group A in single scan mode or group scan mode. When A/D conversion of the internal reference voltage is performed, set the ADCSR.DBLE bit to 0.

The OCSA bit should be set while the ADCSR.ADST bit is 0. When setting the OCSB or ADGCEXCR.OCSC bit to 1, set this bit to 0.

To perform A/D conversion of the internal reference voltage, set the OCSA bit to 1, wait for at least 400 ns, and then start A/D conversion. When A/D conversion is started, auto-discharging for 15 cycles of ADCLK proceeds before sampling.

When the disconnection detection assist function is also in use, the setting of the ADNDIS[4:0] bits is ignored.

A/D conversion of the internal reference voltages in groups B and C should be handled in the same way.

#### **TSSB Bit (Group B Temperature Sensor Output A/D Conversion Select)**

The TSSB bit selects A/D conversion of the temperature sensor output for group B in group scan mode.

This bit should be set while the ADCSR.ADST bit is 0. When setting the TSSA or ADGCEXCR.TSSC bit to 1, set this bit to 0.

Refer to description of the TSSA bit for A/D-converting the temperature sensor output.

#### **OCSB Bit (Group B Internal Reference Voltage A/D Conversion Select)**

The OCSB bit selects A/D conversion of the internal reference voltage for group B in group scan mode.

This bit should be set while the ADCSR.ADST bit is 0. When setting the OCSA or ADGCEXCR.OCSC bit to 1, set this bit to 0.

Refer to description of the OCSA bit for A/D-converting the internal reference voltage.

### 38.2.17 A/D Group C Extended Input Control Register (ADGCEXCR)

Address(es): S12AD2.ADGCEXCR 0008 94D8h

|                    |    |    |    |    |    |    |      |      |

|----------|--------|----------------------------------------------------------|------------------------------------------------------------------------------------------------------|-----|
| b0       | TSSC   | Group C Temperature Sensor Output A/D Conversion Select  | 0: Temperature sensor output is not A/D-converted<br>1: Temperature sensor output is A/D-converted   | R/W |
| b1       | OCSC   | Group C Internal Reference Voltage A/D Conversion Select | 0: Internal reference voltage is not A/D-converted<br>1: Internal reference voltage is A/D-converted | R/W |
| b7 to b2 | —      | Reserved                                                 | These bits are read as 0. The write value should be 0.                                               | R/W |

The ADGCEXCR register specifies extended input for group C.

#### TSSC Bit (Group C Temperature Sensor Output A/D Conversion Select)

The TSSC bit selects A/D conversion of the temperature sensor output for group C in group scan mode.

The TSSC bit should be set while the ADCSR.ADST bit is 0. When setting the ADEXICR.TSSA or ADEXICR.TSSB bit to 1, set this bit to 0.

Refer to description of the ADEXICR.TSSA bit for A/D-converting the temperature sensor output.

#### OCSC Bit (Group C Internal Reference Voltage A/D Conversion Select)

The OCSC bit selects A/D conversion of the internal reference voltage for group C in group scan mode.

The OCSC bit should be set while the ADCSR.ADST bit is 0. When setting the ADEXICR.OCSA or ADEXICR.OCSB bit to 1, set this bit to 0.

Refer to description of the ADEXICR.OCSA bit for A/D-converting the internal reference voltage.

### 38.2.18 A/D Group C Trigger Select Register (ADGCTRGR)

Address(es): S12AD.ADGCTRGR 0008 90D9h, S12AD1.ADGCTRGR 0008 92D9h, S12AD2.ADGCTRGR 0008 94D9h

| Bit      | Symbol    | Bit Name                                    | Description                                                                                   | R/W |
|----------|-----------|---------------------------------------------|-----------------------------------------------------------------------------------------------|-----|
| b5 to b0 | TRSC[5:0] | Group C A/D Conversion Start Trigger Select | Select the A/D conversion start trigger for group C in group scan mode.                       | R/W |
| b6       | GCADIE    | Group C Scan End Interrupt Enable           | 0: Group C scan end interrupt is disabled.<br>1: Group C scan end interrupt is enabled.       | R/W |
| b7       | GRCE      | Group C A/D Conversion Operation Enable     | Enables A/D conversion operation for group C.<br>0: Group C is not used<br>1: Group C is used | R/W |

The ADGCTRGR register enables operation for group C and selects the A/D conversion start trigger. For details on group priority operation, refer to Table 38.23 and Table 38.24.

#### TRSC[5:0] Bits (Group C A/D Conversion Start Trigger Select)

The TRSC[5:0] bits select the trigger to start scanning of the analog input selected in group C. These bits are used for group scan mode only; not used for any other modes. Software trigger or asynchronous trigger cannot be set as the scan conversion trigger for group C. When using group C in group scan mode, set the TRSC[5:0] bits to a value other than 00h, set the ADCSR.TRGE bit to 1, and set the GRCE bit to 1.

When group C is used during group priority control in group scan mode and the ADGSPCR.GBRP bit is set to 1, group C can be continuously operated in single scan mode. When continuously operating group C in single scan mode, set the TRSC[5:0] bits to 3Fh to disable trigger selection.

Note that the issuance period of trigger for A/D conversion must be more than or equal to the actual scan conversion time ( $t_{SCAN}$ ). If the issuance period is less than  $t_{SCAN}$ , A/D conversion by a trigger may have no effect.

When selecting a trigger from the MTU operated on a PCLKC cycle as an A/D conversion start trigger, a delay of the period for synchronization processing occurs. Refer to section 38.3.8, Analog Input Sampling Time and Scan Conversion Time for details.

Table 38.15 lists the selection of A/D conversion start sources selected by the TRSC[5:0] bits for group C.

**Table 38.15 Selection of A/D Trigger Sources by the TRSC[5:0] Bits (Group C) (1/2)**

Note 1. Unit 0

Note 2. Unit 1

Note 3. Unit 2

**GCADIE Bit (Group C Scan End Interrupt Enable)**

The GCADIE bit enables or disables scan end interrupt generation for group C. A scan end interrupt for group C is provided individually for each unit. Table 38.16 shows the relationship between each unit and the scan end interrupt for group C.

**Table 38.16 Relationship Between Each Unit and Group C Scan End Interrupt**

| Unit   | Group C Scan End Interrupt |
|--------|----------------------------|
| S12AD  | S12GCADI                   |
| S12AD1 | S12GCADI1                  |
| S12AD2 | S12GCADI2                  |

**GRCE Bit (Group C A/D Conversion Operation Enable)**

When using group C in group scan mode, set the GRCE bit to 1.

When the GRCE bit is 0, trigger input for group C is disabled.

During group priority operation (the ADGSPCR.PGS bit is 1) with group C used, when the ADGSPCR.GBRP bit is set to 1, single scan for group C is continuously operated. When the GRCE bit is set to 1, single scan for group B is not continuously operated.

The GRCE bit should be set while the ADCSR.ADST bit is 0.

### 38.2.19 A/D Sampling State Register n (ADSSTRn) (n = 0 to 11, L, T, O)

Address(es): S12AD.ADSSTR0 0008 90E0h, S12AD.ADSSTR1 0008 90E1h, S12AD.ADSSTR2 0008 90E2h, S12AD.ADSSTR3 0008 90E3h, S12AD.ADSSTR4 0008 90E4h, S12AD.ADSSTR5 0008 90E5h, S12AD.ADSSTR6 0008 90E6h, S12AD.ADSSTR7 0008 90E7h, S12AD1.ADSSTR0 0008 92E0h, S12AD1.ADSSTR1 0008 92E1h, S12AD1.ADSSTR2 0008 92E2h, S12AD1.ADSSTR3 0008 92E3h, S12AD1.ADSSTR4 0008 92E4h, S12AD1.ADSSTR5 0008 92E5h, S12AD1.ADSSTR6 0008 92E6h, S12AD1.ADSSTR7 0008 92E7h, S12AD2.ADSSTR0 0008 94E0h, S12AD2.ADSSTR1 0008 94E1h, S12AD2.ADSSTR2 0008 94E2h, S12AD2.ADSSTR3 0008 94E3h, S12AD2.ADSSTR4 0008 94E4h, S12AD2.ADSSTR5 0008 94E5h, S12AD2.ADSSTR6 0008 94E6h, S12AD2.ADSSTR7 0008 94E7h, S12AD2.ADSSTR8 0008 94E8h, S12AD2.ADSSTR9 0008 94E9h, S12AD2.ADSSTR10 0008 94EAh, S12AD2.ADSSTR11 0008 94EBh, S12AD2.ADSSTR12 0008 94EDh, S12AD2.ADSSTR13 0008 94EEh, S12AD2.ADSSTR14 0008 94EFh, S12AD2.ADSSTR15 0008 94F0h, S12AD2.ADSSTR16 0008 94F1h, S12AD2.ADSSTR17 0008 94F2h, S12AD2.ADSSTR18 0008 94F3h, S12AD2.ADSSTR19 0008 94F4h, S12AD2.ADSSTR20 0008 94F5h, S12AD2.ADSSTR21 0008 94F6h, S12AD2.ADSSTR22 0008 94F7h, S12AD2.ADSSTR23 0008 94F8h, S12AD2.ADSSTR24 0008 94F9h, S12AD2.ADSSTR25 0008 94FAh, S12AD2.ADSSTR26 0008 94FBh, S12AD2.ADSSTR27 0008 94FCh, S12AD2.ADSSTR28 0008 94FDh, S12AD2.ADSSTR29 0008 94FEh, S12AD2.ADSSTR30 0008 94FFh, S12AD2.ADSSTR31 0008 9500h

The ADSSTRn register sets the sampling time for analog input.

Set the sampling time based on the number of clock cycles for ADCLK (A/D conversion clock). The initial value is 27 clock cycles. If the impedance of analog input signal source is too high to secure sufficient sampling time or if the ADCLK is slow, the sampling time can be adjusted. The ADSSTRn register should be set while the ADCSR.ADST bit is 0.

Specify the value for the register as a multiples of 3 in the range from 12 to 252 (clock cycles).

A sampling time can be determined by the following formula:

$$\text{Sampling time} = \text{ADSSTR} \times t_C(\text{ADCLK})$$

Table 38.17 shows the relationship between the A/D sampling state register and the relevant channels.

For details, refer to section 38.3.8, Analog Input Sampling Time and Scan Conversion Time.

**Table 38.17 Relationship Between A/D Sampling State Register and Relevant Channels**

| Unit              | Register Name                | Relevant Channels           |
|-------------------|------------------------------|-----------------------------|
| S12AD             | ADSSTR0 register             | AN000, Self-Diagnosis       |
|                   | ADSSTR1 register             | AN001                       |
|                   | ADSSTR2 register             | AN002                       |
|                   | ADSSTR3 register             | AN003                       |
|                   | ADSSTR4 register             | AN004                       |
|                   | ADSSTR5 register             | AN005                       |
|                   | ADSSTR6 register             | AN006                       |
|                   | ADSSTR7 register             | AN007                       |
| S12AD1            | ADSSTR0 register             | AN100, Self-Diagnosis       |
|                   | ADSSTR1 register             | AN101                       |
|                   | ADSSTR2 register             | AN102                       |
|                   | ADSSTR3 register             | AN103                       |
|                   | ADSSTR4 register             | AN104                       |
|                   | ADSSTR5 register             | AN105                       |
|                   | ADSSTR6 register             | AN106                       |
|                   | ADSSTR7 register             | AN107                       |
| S12AD2            | ADSSTR0 register             | AN200, Self-Diagnosis       |
|                   | ADSSTR1 register             | AN201                       |
|                   | ADSSTR2 register             | AN202                       |
|                   | ADSSTR3 register             | AN203                       |
|                   | ADSSTR4 register             | AN204                       |
|                   | ADSSTR5 register             | AN205                       |
|                   | ADSSTR6 register             | AN206                       |
|                   | ADSSTR7 register             | AN207                       |
|                   | ADSSTR8 register             | AN208                       |
|                   | ADSSTR9 register             | AN209                       |
|                   | ADSSTR10 register            | AN210                       |
|                   | ADSSTR11 register            | AN211                       |
|                   | ADSSTR12 register            | AN216, AN217                |
|                   | ADSSTR13 register            | Temperature sensor output*1 |
| ADSSTR14 register | Internal reference voltage*2 |                             |

Note 1. When performing A/D conversion of the temperature sensor output, it is necessary to set the sampling time that meets the specification described in section 45, Electrical Characteristics.

Note 2. When performing A/D conversion of the internal reference voltage, the sampling time should be 4  $\mu$ s or longer.

### 38.2.20 A/D Sample-and-Hold Circuit Control Register (ADSHCR)

Address(es): S12AD.ADSHCR 0008 9066h, S12AD1.ADSHCR 0008 9266h

| Bit        | Symbol     | Bit Name                                                        | Description                                                                                                                                                                                                                                  | R/W |
|------------|------------|-----------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----|

| b9         | SHANS[1]   |                                                                 | Select whether to use or not use (bypass) the channel-dedicated sample-and-hold circuits either for AN001 or AN101.<br>0: Channel-dedicated sample-and-hold circuit is disabled.<br>1: Channel-dedicated sample-and-hold circuit is enabled. | R/W |
| b10        | SHANS[2]   |                                                                 | Select whether to use or not use (bypass) the channel-dedicated sample-and-hold circuits either for AN002 or AN102.<br>0: Channel-dedicated sample-and-hold circuit is disabled.<br>1: Channel-dedicated sample-and-hold circuit is enabled. | R/W |
| b15 to b11 | —          | Reserved                                                        | These bits are read as 0. The write value should be 0.                                                                                                                                                                                       | R/W |

The ADSHCR register sets the parameters related to channel-dedicated sample-and-hold circuits.

#### SSTSH[7:0] Bits (Channel-Dedicated Sample-and-Hold Circuit Sampling Time Setting)

The SSTSH[7:0] bits set the sampling time for the channel-dedicated sample-and-hold circuits when the ADHMSR.SHMD bit is 0. Set the sampling time in clock cycles of ADCLK (A/D conversion clock). The initial value is 27 clock cycles. If the impedance of analog input signal source is too high to secure sufficient sampling time or if ADCLK is slow, the sampling time can be adjusted. Set the SSTSH[7:0] bits while the ADCSR.ADST bit is 0. Set a value between 12 and 252 clock cycles as the setting for sampling time.

Also, set a value such that the sampling time will be no less than 0.4  $\mu$ s.

#### SHANS[2:0] Bits (Channel-Dedicated Sample-and-Hold Circuit Bypass Select)

The SHANS[2:0] bits select whether to use or bypass the channel-dedicated sample-and-hold circuits of AN000 to AN002 of unit 0 or AN100 to AN102 of unit 1. Set the SHANS[2:0] bits while both the ADCSR.ADST and ADHMSR.SHMD bits are 0. If any of channels AN000 to AN002 of unit 0 or AN100 to AN102 of unit 1 is selected for group B or group C while operation is under group A priority control in group scan mode, the channel-dedicated sample-and-hold circuit should be disabled.

No channels of unit 2 have channel-dedicated sample-and-hold circuits.

### 38.2.21 A/D Sample-and-Hold Operating Mode Select Register (ADSHMSR)

Address(es): S12AD.ADSHMSR 0008 907Ch, S12AD1.ADSHMSR 0008 927Ch

| Bit      | Symbol | Bit Name                                                         | Description                                                                                                                                                               | R/W |
|----------|--------|------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----|
| b0       | SHMD   | Channel-Dedicated Sample-and-Hold Circuit Operating Mode Setting | 0: Constant sampling of the channel-dedicated sample-and-hold circuits is disabled.<br>1: Constant sampling of the channel-dedicated sample-and-hold circuits is enabled. | R/W |
| b7 to b1 | —      | Reserved                                                         | These bits are read as 0. The write value should be 0.                                                                                                                    | R/W |

The ADSHMSR register enables or disables constant sampling of the sample-and-hold circuit dedicated for channels.

#### SHMD Bit (Channel-Dedicated Sample-and-Hold Circuit Operating Mode Setting)

When the SHMD bit is set to 1, constant sampling of the sample-and-hold circuit for the channels selected by the ADSHCR.SHANS[2:0] bits is enabled. The SHMD bit should be set while the ADCSR.ADST bit is 0.

When the constant sampling function is enabled, constant sampling is performed while the 12-bit A/D converter is in the wait state and holding is performed when the A/D conversion is in progress.

Enable use of the channel-dedicated sample-and-hold circuit (ADSHCR.SHANS[2:0] ≠ 000b), enable normal sampling by the channel-dedicated sample-and-hold circuit (ADSHMSR.SHMD = 1), and wait for 6 cycles of ADCLK to pass before input of a trigger signal.

### 38.2.22 A/D Disconnection Detection Control Register (ADDISCR)

Address(es): S12AD.ADDISCR 0008 907Ah, S12AD1.ADDISCR 0008 927Ah, S12AD2.ADDISCR 0008 947Ah

| Bit      | Symbol      | Bit Name                                   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                       | R/W |
|----------|-------------|--------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----|
| b3 to b0 | ADNDIS[3:0] | A/D Disconnection Detection Assist Setting | Specify the period for discharging or precharging as a number of ADCLK cycles.<br><sup>b3</sup> <sup>b0</sup><br>0 0 0 0: No charging (disconnection detection assist function is disabled.)<br>0 0 1 1: Charging period of 3 clock cycles<br>0 1 1 0: Charging period of 6 clock cycles<br>1 0 0 1: Charging period of 9 clock cycles<br>1 1 0 0: Charging period of 12 clock cycles<br>1 1 1 1: Charging period of 15 clock cycles<br>Settings other than above are prohibited. | R/W |
| b4       | ADNDIS[4]   |                                            | 0: Discharge<br>1: Precharge                                                                                                                                                                                                                                                                                                                                                                                                                                                      | R/W |
| b7 to b5 | —           | Reserved                                   | These bits are read as 0. The write value should be 0.                                                                                                                                                                                                                                                                                                                                                                                                                            | R/W |

The ADDISCR register sets the disconnection detection assist function.

#### ADNDIS[4:0] Bits (A/D Disconnection Detection Assist Setting)

The ADNDIS[4:0] bits select either precharge or discharge and the period of precharge/discharge for the A/D disconnection detection assist function. Setting the ADNDIS[4] bit = 1 allows to select precharge and setting the ADNDIS[4] bit = 0 allows to select discharge. The period of precharge/discharge can be set with the ADNDIS[3:0] bits. When ADNDIS[3:0] bits = 0000b, the disconnection detection assist function is disabled. Set the ADNDIS[3:0] bits to 0000b or a multiple of 3. A value other than those above cannot be set. The value set in the ADNDIS[3:0] bits is used to set the number of clock cycles that determines the precharging or discharging period.

The ADNDIS[4:0] bits should be set when the ADCSR.ADST bit is 0.

The disconnection detection assist function cannot be used when the PGA output, temperature sensor output, or internal reference voltage is converted, or when the self-diagnosis function is used. Set the ADNDIS[3:0] bits to 0000b.

When A/D conversion of a temperature sensor output or internal reference voltage proceeds, auto-discharging is also executed beforehand. Therefore, the ADNDIS[4:0] bits are automatically fixed to 0Fh during conversion for a scan group that includes a temperature sensor output or internal reference voltage, and the corresponding analog input paths in the A/D converter are discharged. Sampling starts after discharging is completed.

After the A/D conversion of a temperature sensor output or internal reference voltage is finished, the ADNDIS[4:0] bits automatically return to the setting before the conversion.

### 38.2.23 A/D Event Link Control Register (ADELCCR)

Address(es): S12AD.ADELCCR 0008 907Dh, S12AD1.ADELCCR 0008 927Dh, S12AD2.ADELCCR 0008 947Dh

| Bit      | Symbol    | Bit Name           | Description                                                                                                                                                                                                                                                                                                                                                                                         | R/W |

| b14       | LGRRS  | Restart Channel Select               | (Enabled when PGS = 1 and GBRSCN = 1. Reserved when PGS = 0 or GBRSCN = 0.)<br>0: Scanning is restarted from the scan start channel.<br>1: Scanning is restarted from the channel on which A/D conversion is not completed.                                           | R/W |
| b15       | GBRP   | Single Scan Continuous Start<br>*2   | (Enabled only when PGS = 1. Reserved when PGS = 0.)<br>0: Single scan is not continuously started.<br>1: Single scan for the lowest-priority group is continuously started.                                                                                           | R/W |

Note 1. When the PGS bit is to be set to 1, the ADCSR.ADCS[1:0] bits must be set to 01b (group scan mode). If the bits are set to any other values, proper operation is not guaranteed.

Note 2. When the GBRP bit has been set to 1, single scan is performed continuously for the lowest-priority group regardless of the setting of the GBRSCN bit.

The ADGSPCR register is used to interrupted scanning of the low-priority group and make settings for priority control of scanning for the priority group in group scan mode.

For the settings on group priority operation, refer to Table 38.23 and Table 38.24.

#### PGS Bit (Group Priority Control Setting)

The PGS bit sets the priority of operation in group scan mode. Set this bit to 1 when giving priority to operation on the group.

When the PGS bit is to be set to 1, the ADCSR.ADCS[1:0] bits must be set to 01b (group scan mode).

During group priority operation, a trigger to start scanning for the priority group is accepted during scan for the low-priority group, and scan for the priority group is started after scan for the low-priority group was interrupted. The priority order is group A > group B > group C.

When a trigger to start scanning for group B is accepted during scan for group C, group C scan is interrupted, and scan for group B is started. When a trigger to start scanning for group A is accepted during scan for group C, group C scan is interrupted, and scan for group A is started.

Likewise, when a trigger to start scanning for group A is accepted during scan for group B, group B scan is interrupted and scan for group A is started.

When setting the PGS bit to 0, clearing should be performed by software according to section 38.6.2, Notes on Stopping A/D Conversion. When setting the PGS bit to 1, follow the procedure described in section 38.3.6.3, Operation under Group Priority Control.

**GBRSCN Bit (Low-Priority Group Restart Setting)**

The GBRSCN bit controls the restarting of scan operation during group priority control.

If a scan operation on the low-priority group has been stopped by a priority group trigger input with the GBRSCN bit set to 1, the scan operation is restarted after the scanning of the priority group is completed. Also, if a low-priority trigger is input during scan for the priority group, the scan operation on the low-priority group is restarted after the scan for the priority group is completed.

If the GBRSCN bit has been set to 0, triggers that are input during A/D conversion are ignored. Also, the ADCSR.ADST bit must be 0 when the GBRSCN bit is to be set.

The setting of the GBRSCN bit is enabled when the PGS bit is set to 1.

**LGRRS Bit (Restart Channel Select)**

The LGRRS bit sets the channel on which scan is restarted during group priority control. The setting of the LGRRS bit is enabled when the PGS and GBRSCN bits are set to 1.

If a scan operation on the low-priority group has been stopped due to group priority operation with the LGRRS bit set to 0, the scan operation is restarted from the start channel after the scan for the priority group is completed.

If a scan operation on the low-priority group has been stopped due to group priority operation with the LGRRS bit set to 1, the scan operation is restarted\*1 on the channel on which A/D conversion is not completed after the scan for the priority group is completed.

The LGRRS bit should be set while the ADCSR.ADST bit is 0.

Note 1. If A/D conversion on the addition set channel is not completed for the set number of times when scanning is stopped, A/D conversion on the channel is restarted for the set number of times when scanning is restarted.

**GBRP Bit (Single Scan Continuous Start)**

The GBRP bit is set when the lowest-priority group is continuously operated in single scan mode while group priority operation is set. The lowest-priority group is group C when groups A, B, and C are used; group B when groups A and B are used.

Setting the GBRP bit to 1 starts a single scan on the lowest-priority group. On completion of the scan, another single scan on the lowest-priority group is automatically started.

If scanning has been stopped due to group priority operation, single scan on the lowest-priority group is automatically restarted on completion of the A/D conversion on the priority group.

Disable the trigger input for the lowest-priority group before setting the GBRP bit to 1. When the GBRP bit is set to 1, only the lowest-priority group is scanned again even if the GBRSCN bit is 0.

The ADCSR.ADST bit must be 0 when the GBRP bit is to be set.

The setting of the GBRP bit is enabled when the PGS bit is 1.

### 38.2.25 A/D Comparison Function Control Register (ADCMPCR)

Address(es): S12AD.ADCMPCR 0008 9090h, S12AD1.ADCMPCR 0008 9290h, S12AD2.ADCMPCR 0008 9490h

The ADCMPCR register is used to set the settings for the comparison window function (windows A and B).

#### CMPAB[1:0] Bits (Window A/B Complex Conditions Setting)

The CMPAB[1:0] bits are enabled when single scan mode and window A/B are both enabled (CMPAE bit = 1 and CMPBE bit = 1). These bits specify the monitor conditions of the ADWINMON.MONCOMB flag. The CMPAB[1:0] bits should be set when the ADCSR.ADST bit is 0.

#### CMPBE Bit (Comparison Window B Enable)

The CMPBE bit is used to disable or enable comparison window B. The CMPBE bit should be set when the ADCSR.ADST bit is 0.

To set the following registers, set this bit to 0.

- A/D channel select registers A0/A1/B0/B1/C0/C1 (ADANSA0, ADANSA1, ADANSB0, ADANSB1, ADANSC0, and ADANSC1)
- Bits OCSB, TSSB, OCSA, and TSSA in the A/D conversion extended input control register (ADEXICR.OCSB,

TSSB, OCSA, and TSSA)

- Bits OCSC and TSSC in the A/D group C extended input control register (ADGCEXCR.OCSC and TSSC)
- The CMPCHB[5:0] bits in the window B channel select register (ADCMPBNSR.CMPCHB[5:0])

#### **CMPAE Bit (Comparison Window A Enable)**

The CMPAE bit is used to disable or enable comparison window A. The CMPAE bit should be set when the ADCSR.ADST bit is 0.

To set the following registers, set this bit to 0.

- A/D channel select registers A0/A1/B0/B1/C0/C1 (ADANSA0, ADANSA1, ADANSB0, ADANSB1, ADANSC0, and ADANSC1)
- Bits OCSB, TSSB, OCSA, and TSSA in the A/D conversion extended input control register (ADEXICR.OCSB, TSSB, OCSA, and TSSA)
- Bits OCSC and TSSC in the A/D group C extended input control register (ADGCEXCR.OCSC and TSSC)
- Window A channel select registers 0 and 1 (ADCMPANSR0 and ADCMPANSR1)
- Window A extended input select register (ADCMPANSER)

#### **CMPBIE Bit (Comparison B Interrupt Enable)**

Enables or disables comparison interrupts by a window B comparison condition match. A single comparison interrupt exists for each unit. Table 38.18 lists the relationship between each unit and its comparison interrupt.

#### **WCMPE Bit (Window Function Setting)**

The WCMPE bit is used to disable or enable the window function. The WCMPE bit should be set when the ADCSR.ADST bit is 0.

#### **CMPAIE Bit (Comparison A Interrupt Enable)**

Enables or disables comparison interrupts by a window A comparison condition match. A single comparison interrupt exists for each unit. Table 38.18 lists the relationship between each unit and its comparison interrupt.

**Table 38.18 Relationship Between Each Unit and Its Comparison Interrupt Unit**

| Unit   | Comparison Interrupt                      |                                           |
|--------|-------------------------------------------|-------------------------------------------|
|        | When Window A Comparison Condition is Met | When Window B Comparison Condition is Met |
| S12AD  | S12CMPAI                                  | S12CMPBI                                  |
| S12AD1 | S12CMPAI1                                 | S12CMPBI1                                 |

| b15 to b8 | —         | Reserved                              | These bits are read as 0. The write value should be 0.                                                                                                                                                            | R/W |

The S12AD.ADCMPANSR0 register selects analog inputs AN000 to AN007 of the channels that perform comparison with the conditions of comparison window A.

#### **CMPCHA0n Bit (Comparison Window A Channel Select) (n = 00 to 07)**

The comparison function is enabled when the CMPCHA0n bit with the same index number as the A/D conversion channel selected by the ADANSA0.ANSA0n bit, the ADANSB0.ANSB0n bit, and the ADANSC0.ANSC0n bit is set to 1.

The CMPCHA0n bit should be set while the ADCSR.ADST bit is 0.

| b15 to b8 | —         | Reserved                              | These bits are read as 0. The write value should be 0.                                                                                                                                                               | R/W |

The S12AD1.ADCMPANSR0 register selects analog inputs AN100 to AN107 of the channels that perform comparison with the conditions of comparison window A.

**CMPCHA0n Bit (Comparison Window A Channel Select) (n = 00 to 07)**

The comparison function is enabled when the CMPCHA0n bit with the same index number as the A/D conversion channel selected by the ADANSA0.ANSA0n bit, the ADANSB0.ANSB0n bit, and the ADANSC0.ANSC0n bit is set to 1.

The CMPCHA0n bit should be set while the ADCSR.ADST bit is 0.

| b15 to b12 | —         | Reserved                              | These bits are read as 0. The write value should be 0.                                                                                                                                                               | R/W |

The S12AD2.ADCMPANSR0 register selects analog inputs AN200 to AN211 of the channels that perform comparison with the conditions of comparison window A.

**CMPCHA0n Bit (Comparison Window A Channel Select) (n = 00 to 11)**

The comparison function is enabled when the CMPCHA0n bit with the same index number as the A/D conversion channel selected by the ADANSA0.ANSA0n bit, the ADANSB0.ANSB0n bit, and the ADANSC0.ANSC0n bit is set to 1.

The CMPCHA0n bit should be set while the ADCSR.ADST bit is 0.

### 38.2.27 A/D Comparison Function Window A Channel Select Register 1 (ADCMPANSR1)

| b15 to b2 | —         | Reserved                              | These bits are read as 0. The write value should be 0.                                                                                                                                                            | R/W |

The ADCMPANSR1 register selects analog inputs AN216 to AN217 of the channels that perform comparison with the conditions of comparison window A.

#### CMPCHA1n Bit (Comparison Window A Channel Select) (n = 00, 01)

The comparison function is enabled when the CMPCHA1n bit with the same index number as the A/D conversion channel selected by the ADANSA1.ANSA1n bit, the ADANSB1.ANSB1n bit, and the ADANSC1.ANSC1n bit is set to 1.

The CMPCHA1n bit should be set while the ADCSR.ADST bit is 0.

| b7 to b2 | —      | Reserved                                    | These bits are read as 0. The write value should be 0.                                                                                                                 | R/W |

The ADCMPANSER register selects whether the temperature sensor output or internal reference voltage is compared under the conditions of comparison window A.

#### CMPSTS Bit (Temperature Sensor Output Comparison Select)

The comparison window A is enabled when the CMPSTS bit is set to 1 while the ADEXICR.TSSA, ADEXICR.TSSB, or the ADGCEXCR.TSSC bit is 1. The CMPSTS bit should be set while the ADCSR.ADST bit is 0.

#### CMPSOC Bit (Internal Reference Voltage Compare Select)

The comparison window A is enabled when the CMPSOC bit is set to 1 while the ADEXICR.OCSA, ADEXICR.OCSB, or ADGCEXCR.OCSC bit is 1. The CMPSOC bit should be set while the ADCSR.ADST bit is 0.

| b7        | CMPLCHA007 |                                                                  |                                                                                                      | R/W |
| b15 to b8 | —          | Reserved                                                         | These bits are read as 0. The write value should be 0.                                               | R/W |

The S12AD.ADCMPLR0 register specifies the conditions for comparison of the values in the S12AD.ADCMPDR0/ADCMPDR1 register and the value of A/D conversion. The S12AD.ADCMPLR0 register should be set while the S12AD.ADCSR.ADST bit is 0.

#### CMPLCHA0n Bit (Comparison Window A Comparison Condition Select) (n = 00 to 07)

The CMPLCHA0n bit specifies the comparison conditions of the channels (AN000 to AN007) targeted for the window A comparison conditions. The condition can be specified for each analog input for comparison. The CMPLCHA000 bit corresponds to AN000 and the CMPLCHA007 bit corresponds to AN007.

The S12AD1.ADCMPLR0 register specifies the conditions for comparison of the values in the S12AD1.ADCMPDR0/ADCMPDR1 register and the value of A/D conversion. The S12AD1.ADCMPLR0 register should be set while the S12AD1.ADCSR.ADST bit is 0.

**CMPLCHA0n Bit (Comparison Window A Comparison Condition Select) (n = 00 to 07)**

The CMPLCHA0n bit specifies the comparison conditions of the channels (AN100 to AN107) targeted for the window A comparison conditions. The condition can be specified for each analog input for comparison. The CMPLCHA000 bit corresponds to AN100 and the CMPLCHA007 bit corresponds to AN107.

| b10        | CMPLCHA010 |                      |                                                         | R/W |
| b11        | CMPLCHA011 |                      |                                                         | R/W |
| b15 to b12 | —          | Reserved             | These bits are read as 0. The write value should be 0.  | R/W |

The S12AD2.ADCMPLR0 register specifies the conditions for comparison of the values in the S12AD2.ADCMPDR0/ADCMPDR1 register and the value of A/D conversion. The S12AD2.ADCMPLR0 register should be set while the S12AD2.ADCSR.ADST bit is 0.

**CMPLCHA0n Bit (Comparison Window A Comparison Condition Select) (n = 00 to 11)**

The CMPLCHA0n bit specifies the comparison conditions of the channels (AN200 to AN211) targeted for the window A comparison conditions. The condition can be specified for each analog input for comparison. The CMPLCHA000 bit corresponds to AN200 and the CMPLCHA011 bit corresponds to AN211.

When the result of comparison of each analog input matches with the pre-set condition, the ADCMPDR0.CMPSTCHA0n flag (n = 00 to 11) becomes 1 and a comparison interrupt (S12CMPAI, S12CMPAI1, S12CMPAI2) is generated. The conditions for comparison are shown in Figure 38.7.

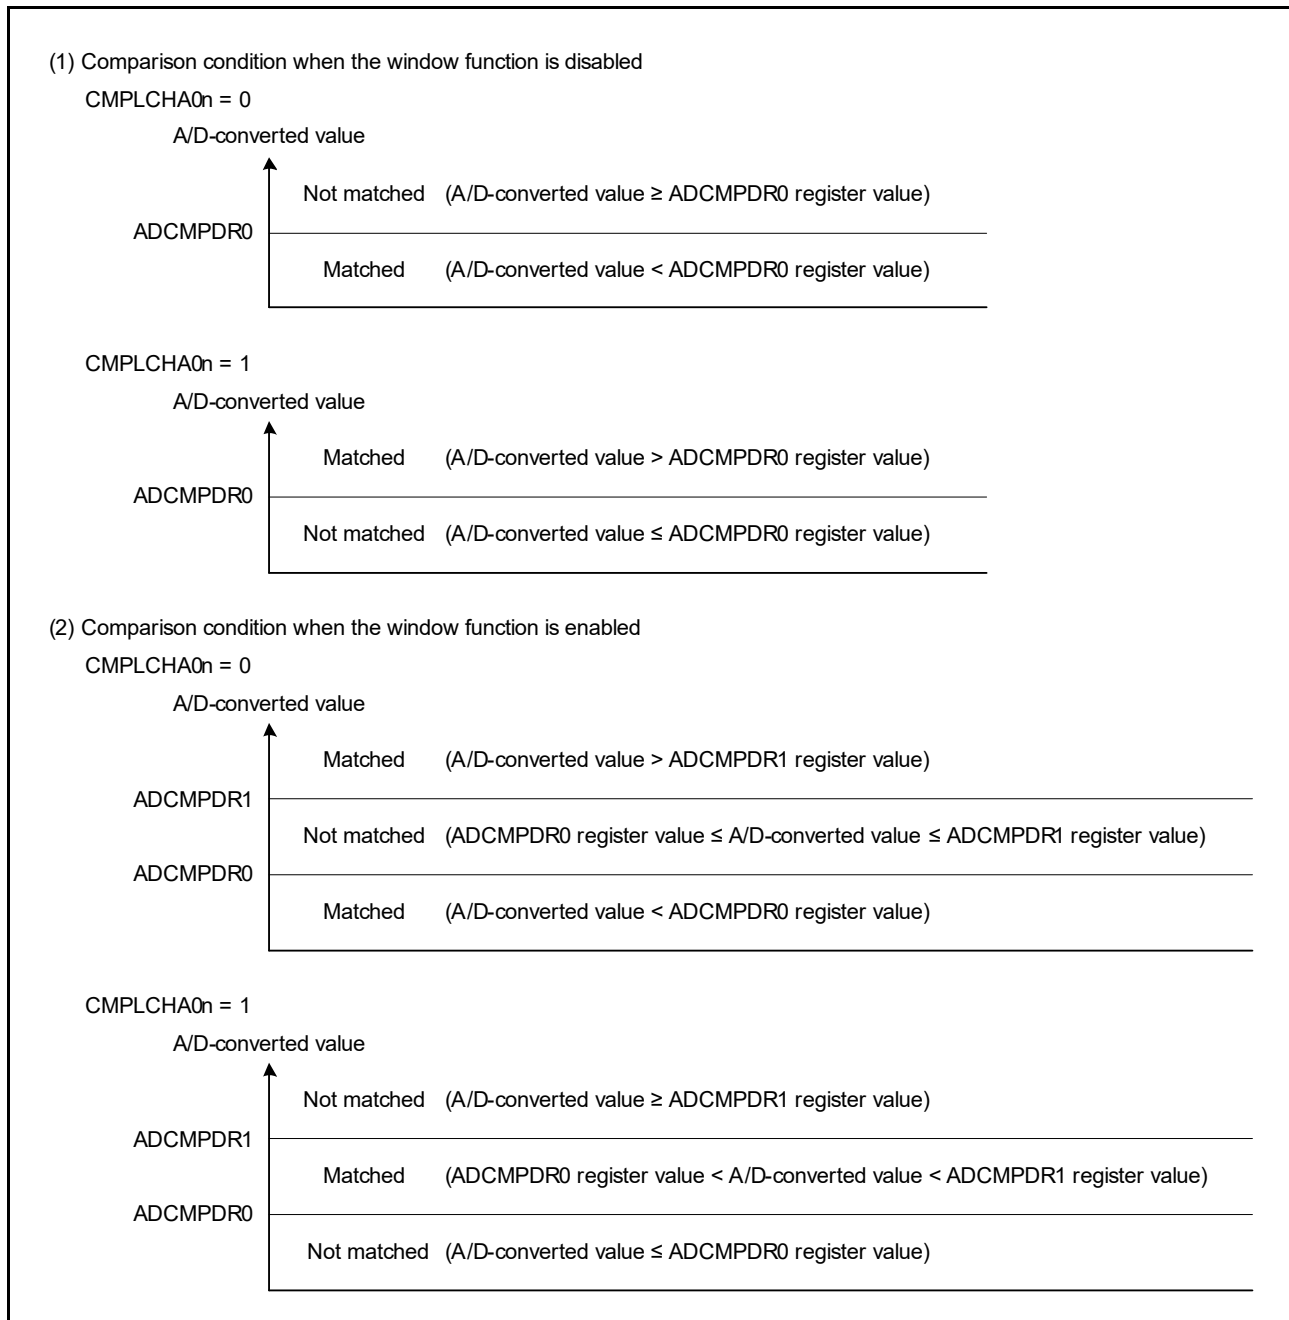

Figure 38.7 Details of Comparison Condition: Comparison Function Window A

### 38.2.30 A/D Comparison Function Window A Comparison Condition Setting Register 1 (ADCMPLR1)

Address(es): S12AD2.ADCMPLR1 0008 949Ah

| b15 to b2 | —          | Reserved                                        | These bits are read as 0. The write value should be 0.                                                                                                                                                                                              | R/W |

The ADCMPLR1 register specifies the conditions for comparison of the values in the ADCMPDR0/ADCMPDR1 register and the value of A/D conversion. The ADCMPLR1 register should be set while the ADCSR.ADST bit is 0.

#### CMPLCHA1n Bit (Comparison Window A Comparison Condition Select) (n = 00, 01)

The CMPLCHA1n bit specifies the comparison conditions of the channels (AN216 to AN217) targeted for the window A comparison conditions. The condition can be specified for each analog input for comparison. The CMPLCHA100 bit corresponds to AN216 and the CMPLCHA101 bit corresponds to AN217.

When the result of comparison of each analog input matches with the pre-set condition, the S12AD2.ADCMPSR1.CMPSTCHA1n flag becomes 1 and a comparison interrupt (S12CMPAI2) is generated. The conditions for comparison are shown in Figure 38.7.

The write value should be 0.                                                                                                                                                                                                                                                                                                                                                                                                                        | R/W |

The ADCMPLER register specifies the conditions for comparison of the values in the ADCMPDR0/ADCMPDR1 register and the value of A/D conversion. The ADCMPLER register should be set while the ADCSR.ADST bit is 0.

#### CMPLTS Bit (Comparison Window A Temperature Sensor Output Comparison Condition Select)

The CMPLTS bit selects the comparison conditions of temperature sensor output targeted for window A.

When the result of comparison of temperature sensor output matches with the pre-set condition, the ADCMPSER.CMPFTS flag becomes 1. A comparison interrupt (S12CMPAI2) is generated.

Figure 38.7 shows the conditions for comparison.

#### CMPLOC Bit (Comparison Window A Internal Reference Voltage Comparison Condition Select)

The CMPLOC bit selects the comparison conditions of the internal reference voltage targeted for window A.

When the result of comparison of the internal reference voltage matches with the pre-set condition, the ADCMPSER.CMPFOC flag becomes 1. A comparison interrupt (S12CMPAI2) is generated.

Figure 38.7 shows the conditions for comparison.

### 38.2.32 A/D Comparison Function Window A Lower Level Setting Register (ADCMPDR0)

Address(es): S12AD.ADCMPDR0 0008 909Ch, S12AD1.ADCMPDR0 0008 929Ch, S12AD2.ADCMPDR0 0008 949Ch

The ADCMPDR0 register is a readable and writable register that specifies the reference data when the comparison window A function is used. The ADCMPDR0 register specifies the lower level of window A.

Writing to the ADCMPDR0 register is enabled even when A/D conversion is in progress. Rewriting the register value during the A/D conversion dynamically changes the reference data.

Satisfy the condition of [Upper limit level  $\geq$  Lower limit level (ADCMPDR1 setting value  $\geq$  ADCMPDR0 setting value)] when setting.

The data formats of the register for each given condition are shown below.

- Setting of the A/D data register format select bit (right-justified or left-justified format)
- Setting of the A/D-converted value addition/averaging function channel select register (A/D-converted value addition/averaging mode is enabled or disabled)
- Setting of the A/D-converted value addition/average count select register (addition/averaging mode is selected and addition count is selected)

Note: When the comparison values are set in a different format from that of the A/D data register y (ADDRy), correct result of comparison cannot be obtained.

(1) When A/D-Converted Value Addition/Average Mode is Disabled

- Right-justified format  
The comparison level (lower) to be compared is set in bits 11 to 0. Write 0 to bits 15 to 12.
- Left-justified format  
The comparison level (lower) to be compared is set in bits 15 to 4. Write 0 to bits 3 to 0.

(2) When A/D-Converted Average Mode is Selected

A/D-converted value average mode can be set only when 2- or 4-time conversion is selected in A/D-converted value addition mode.

- Right-justified format  
The comparison level (lower) to be compared with the value of A/D conversion of the same channel is set in bits 11 to 0. Write 0 to bits 15 to 12.
- Left-justified format  
The comparison level (lower) to be compared with the value of A/D conversion of the same channel is set in bits 15 to 4. Write 0 to bits 3 to 0.

(3) When A/D-Converted Value Addition Mode is Selected

When A/D-converted value addition mode is selected, the value for comparison with the result of cumulative A/D-converted value of the same channel is specified. Conversion 1, 2, 3, 4, or 16 times is selectable. When A/D-converted value addition mode is selected and if conversion 1 to 4 is selected, the resolution of the results of conversion will be extended by 2 bits and so set a value for comparison with the results in the ADCMPDR0 register. When conversion 16 times is selected, the resolution of the results of conversion will be extended by 4 bits and so set a value for

comparison with the results in the ADCMPDR0 register.

Even when A/D-converted value addition mode is selected, set the value for reference based on the setting of the A/D data register format select bit.

- Right-justified format (in A/D-converted value addition mode and when number of conversions is selected for 1 to 4 times)  
The comparison level (lower) to be compared with the value of A/D conversion of the same channel is set in bits 13 to 0. Write 0 to bits 15 and 14.
- Right-justified format (in A/D-converted value addition mode and when number of conversions is selected for 16 times)  
The comparison level (lower) to be compared with the value of A/D conversion of the same channel is set in bits 15 to 0.
- Left-justified format (in A/D-converted value addition mode and when number of conversions is selected for 1 to 4 times)  
The comparison level (lower) to be compared with the A/D-converted value of the same channel is set in bits 15 to 2. Write 0 to bits 1 and 0.
- Left-justified format (in A/D-converted value addition mode and when number of conversions is selected for 16 times)  
The comparison level (lower) to be compared with the value of A/D conversion of the same channel is set in bits 15 to 0.

### 38.2.33 A/D Comparison Function Window A Upper Level Setting Register (ADCMPDR1)

Address(es): S12AD.ADCMPDR1 0008 909Eh, S12AD1.ADCMPDR1 0008 929Eh, S12AD2.ADCMPDR1 0008 949Eh

The ADCMPDR1 register is a readable and writable register that specifies the data for reference when the comparison window A function is used. The register specifies the upper level of window A.

A write operation to the ADCMPDR1 register is enabled even during A/D conversion. Rewriting the value of the register during A/D conversion dynamically changes the reference data.

Satisfy the condition of [upper limit level  $\geq$  lower limit level (ADCMPDR1 setting value  $\geq$  ADCMPDR0 setting value)] when setting.

The ADCMPDR1 register is not used when the window function is disabled.

The data formats of the register for each given condition are shown below.

- Setting of the A/D data register format select bit (right-justified or left-justified format)
- Setting of the A/D-converted value addition/averaging function channel select register (A/D-converted value addition/averaging mode is enabled or disabled)
- Setting of the A/D-converted value addition/averaging time select register (addition/averaging mode is selected and addition count is selected)

Note: When the comparison values are set in a different format from that of the A/D data register y (ADDRy), correct result of comparison cannot be obtained.

(1) When A/D-Converted Value Addition/Average Mode is Disabled

- Right-justified format  
The comparison level (upper) is set in bits 11 to 0. Write 0 to bits 15 to 12.
- Left-justified format  
The comparison level (upper) is set in bits 15 to 4. Write 0 to bits 3 to 0.

(2) When A/D-Converted Average Mode is Selected

A/D-converted value average mode can be set only when 2- or 4-time conversion is selected in A/D-converted value addition mode.

- Right-justified format  
The comparison level (upper) to be compared with the A/D-converted results of the same channel is set in bits 11 to 0. Write 0 to bits 15 to 12.
- Left-justified format  
The comparison level (upper) to be compared with the A/D-converted results of the same channel is set in bits 15 to 4. Write 0 to bits 3 to 0.

(3) When A/D-Converted Value Addition Mode is Selected

When A/D-converted value addition mode is selected, the value for comparison with the result of cumulative A/D-converted value of the same channel is specified. Conversion 1, 2, 3, 4, or 16 times is selectable. When A/D-converted value addition mode is selected and if conversion 1 to 4 is selected, the resolution of the results of conversion will be extended by 2 bits and so set a value for comparison with the results in the ADCMPDR1 register. When conversion 16

times is selected, the resolution of the results of conversion will be extended by 4 bits and so set a value for comparison with the results in the ADCMPDR1 register.

Even when A/D-converted value addition mode is selected, set the value for reference based on the setting of the A/D data register format select bit.

- Right-justified format (in A/D-converted value addition mode and when number of conversions is selected for 1 to 4 times)  
The comparison level (upper) to be compared with the A/D-converted value of the same channel is set bits 13 to 0. Write 0 to bits 15 and 14.
- Right-justified format (in A/D-converted value addition mode and when number of conversions is selected for 16 times)  
The comparison level (upper) to be compared with the A/D-converted value of the same channel is set bits 15 to 0.
- Left-justified format (in A/D-converted value addition mode and when number of conversions is selected for 1 to 4 times)  
The comparison level (upper) to be compared with the A/D-converted value of the same channel is set in bits 15 to 2. Write 0 to bits 1 and 0.
- Left-justified format (in A/D-converted value addition mode and when number of conversions is selected for 16 times)  
The comparison level (upper) to be compared with the A/D-converted value of the same channel is set bits 15 to 0.

## 38.2.34 A/D Comparison Function Window A Channel Status Register 0 (ADCMPSR0)

| b15 to b8 | —           | Reserved                 | These bits are read as 0. The write value should be 0.                                                           | R/W         |

Note 1. Only 0 can be written to clear the flag after reading 1.

The S12AD.ADCMPSR0 register is a register that stores the result of comparison by the comparison window A function.

**CMPSTCHA0n Flag (Comparison Window A Flag) (n = 00 to 07)**

The CMPSTCHA0n flag is a status flag that indicate the result of comparison of the channels (AN000 to AN007) of the comparison condition for window A. When the conversion result matches with the comparison condition specified in the ADCMPLR0.CMPLCHA0n bit on completion of A/D conversion, this flag becomes 1.

When the ADCMPCR.CMPAIE bit is 1, a comparison interrupt request (S12CMPAI) is generated at the setting of the flag. The CMPSTCHA000 flag corresponds to AN000 and the CMPSTCHA007 flag corresponds to AN007.

1 cannot be written to the CMPSTCHA0n flag.

[Setting condition]

- When ADCMPCR.CMPAE bit = 1 and the condition set in the ADCMPLR0.CMPLCHA0n bit is satisfied.

[Clearing condition]

- When 0 is written after reading the state of 1.

## (2) S12AD1.ADCMPSTR0

| b7        | CMPSTCHA007 |                          |                                                                                                                  | R/(W)<br>*1 |
| b15 to b8 | —           | Reserved                 | These bits are read as 0. The write value should be 0.                                                           | R/W         |

Note 1. Only 0 can be written to clear the flag after reading 1.

The S12AD1.ADCMPSTR0 register is a register that stores the result of comparison by the comparison window A function.

**CMPSTCHA0n Flag (Comparison Window A Flag) (n = 00 to 07)**

The CMPSTCHA0n flag is a status flag that indicate the result of comparison of the channels (AN100 to AN107) of the comparison condition for window A. When the conversion result matches with the comparison condition specified in the ADCMPSTR0.CMPLCHA0n bit on completion of A/D conversion, this flag becomes 1.

When the ADCMPSTR0.CMPAIE bit is 1, a comparison interrupt request (S12CMPAI1) is generated at the setting of the flag. The CMPSTCHA000 flag corresponds to AN100 and the CMPSTCHA007 flag corresponds to AN107.

1 cannot be written to the CMPSTCHA0n flag.

[Setting condition]

- When ADCMPSTR0.CMPAE bit = 1 and the condition set in the ADCMPSTR0.CMPLCHA0n bit is satisfied.

[Clearing condition]

- When 0 is written after reading the state of 1.

| b15 to b12 | —           | Reserved                 | These bits are read as 0. The write value should be 0.                                                 | R/W         |

Note 1. Only 0 can be written to clear the flag after reading 1.

The S12AD2.ADCMPSTR0 register is a register that stores the result of comparison by the comparison window A function.

**CMPSTCHA0n Flag (Comparison Window A Flag) (n = 00 to 11)**

The CMPSTCHA0n flag is a status flag that indicate the result of comparison of the channels (AN200 to AN211) of the comparison condition for window A. When the conversion result matches with the comparison condition specified in the ADCMPSTR0.CMPLCHA0n bit on completion of A/D conversion, this flag becomes 1.

When the ADCMPSTR.CMPAIE bit is 1, a comparison interrupt request (S12CMPAI2) is generated at the setting of the flag. The CMPSTCHA000 flag corresponds to AN200 and the CMPSTCHA011 flag corresponds to AN211.

1 cannot be written to the CMPSTCHA0n flag.

[Setting condition]

- When ADCMPSTR.CMPAE bit = 1 and the condition set in the ADCMPSTR0.CMPLCHA0n bit is satisfied.

[Clearing condition]

- When 0 is written after reading the state of 1.

| b15 to b2 | —           | Reserved                 | These bits are read as 0. The write value should be 0.                                                                                                                      | R/W         |

Note 1. Only 0 can be written to clear the flag after reading 1.

The ADCMPSTR1 register is a register that stores the result of comparison by the comparison window A function.

#### CMPSTCHA1n Flag (Comparison Window A Flag) (n = 00, 01)

The CMPSTCHA1n flag is a status flag that indicates the result of comparison of the channels (AN216 to AN217) of the comparison condition for window A. When the conversion result matches with the comparison condition specified in the ADCMPSTR1.CMPLCHA1n bit on completion of A/D conversion, this flag becomes 1. When the ADCMPSTR.CMPAIE bit is 1, a comparison interrupt request (S12CMPAIE2) is generated upon the setting of the flag. The CMPSTCHA100 flag corresponds to AN216 and the CMPSTCHA101 flag corresponds to AN217.

1 cannot be written to the CMPSTCHA1n flag.

[Setting condition]

- When ADCMPSTR.CMPAE bit = 1 and the condition set in the ADCMPSTR1.CMPLCHA1n bit is satisfied.

[Clearing condition]

- When 0 is written after reading the state of 1.

| b7 to b2 | —      | Reserved                                                       | These bits are read as 0. The write value should be 0.                                                                                                                                                                           | R/W         |

Note 1. Only 0 can be written to clear the flag after reading 1.

The ADCMPSER register is a register that stores the result of comparison by the comparison window A function.

#### CMPFTS Flag (Comparison Window A Temperature Sensor Output Comparison Flag)

The CMPFTS flag is a status flag that indicates the result of comparison of the temperature sensor output. When the conversion result matches with the comparison condition specified in the ADCMPPLER.CMPLTS bit upon completion of A/D conversion, this flag becomes 1. When the ADCMPPCR.CMPAIE bit is 1, a comparison interrupt request (S12CMPAI2) is generated upon the setting of the flag.

1 cannot be written to the CMPFTS flag.

[Setting condition]

- When ADCMPPCR.CMPAE bit = 1 and the condition set in the ADCMPPLER.CMPLTS bit is satisfied.

[Clearing condition]

- When 0 is written after reading the state of 1.

#### CMPFOC Flag (Comparison Window A Internal Reference Voltage Comparison Flag)

The CMPFOC flag is a status flag that indicates the result of comparison of the internal reference voltage. When the conversion result matches with the comparison condition specified in the ADCMPPLER.CMPLOC bit upon completion of A/D conversion, this flag becomes 1. When the ADCMPPCR.CMPAIE bit is 1, a comparison interrupt request (S12CMPAI2) is generated upon the setting of the flag.

1 cannot be written to the CMPFOC flag.

[Setting condition]

- When ADCMPPCR.CMPAE bit = 1 and the condition set in the ADCMPPLER.CMPLOC bit is satisfied.

[Clearing condition]

- When 0 is written after reading the state of 1.

### 38.2.37 A/D Comparison Function Window A/B Status Monitoring Register (ADWINMON)

| b7, b6   | —       | Reserved                           | These bits are read as 0.                                                                                                                                                                                                                                | R   |

The ADWINMON register can monitor the results of comparison and the combined result.

#### MONCOMB Flag (Combination Result Monitoring Flag)

The MONCOMB bit is a dedicated bit for reading the combined result of comparison condition A and B that were set in the ADCMPCR.CMPAB[1:0] bits as a combined condition.

[Setting condition]

- When ADCMPCR.CMPAE bit = 1 and ADCMPCR.CMPBE bit = 1, the condition set in the ADCMPCR.CMPAB[1:0] bits is satisfied.

[Clearing condition]

- No match with the combined condition set in the ADCMPCR.CMPAB[1:0] bits
- When ADCMPCR.CMPAE bit = 0 or ADCMPCR.CMPBE bit = 0

#### MONCMPA Flag (Comparison Result Monitor A Flag)

The MONCMPA bit is a dedicated bit for reading 1 when the condition set in the ADCMPLR0, ADCMPLR1, or ADCMPLER register matches with the A/D-converted value of the channel targeted for window A and for reading 0 when such condition is not satisfied.

[Setting condition]

- When ADCMPCR.CMPAE bit = 1, the condition set in the ADCMPLR0.CMPLCHA0n bit is satisfied.

[Clearing condition]

- When ADCMPCR.CMPAE bit = 1, the condition set in the ADCMPLR0.CMPLCHA0n bit is not satisfied.
- When ADCMPCR.CMPAE bit = 0 (the ADCMPCR.CMPAE bit is automatically cleared to 0).

#### MONCMPB Flag (Comparison Result Monitor B Flag)

The MONCMPB bit is a dedicated bit for reading 1 when the condition set in the ADCMPBNSR.CMPLB bit matches with the A/D-converted value of the channel targeted for window B and for reading 0 when such condition is not satisfied.

[Setting condition]

- When ADCMPCR.CMPBE bit = 1, the condition set in the ADCMPBNSR.CMPLB bit is satisfied.
- [Clearing condition]
- When ADCMPCR.CMPBE bit = 1, the condition set in the ADCMPBNSR.CMPLB bit is not satisfied.
  - When ADCMPCR.CMPBE bit = 0 (the ADCMPCR.CMPBE bit is automatically cleared to 0).

### 38.2.38 A/D Comparison Function Window B Channel Select Register (ADCMPBNSR)

#### (1) S12AD.ADCMPBNSR

Address(es): S12AD.ADCMPBNSR 0008 90A6h

| Bit      | Symbol      | Bit Name                                         | Description                                                                                                                                                                                                                                                                                                                                                                                                                          | R/W |

| b6       | —           | Reserved                                         | This bit is read as 0. The write value should be 0.                                                                                                                                                                                                                                                                                                                                                                                  | R/W |
| b7       | CMPLB       | Comparison Window B Comparison Condition Setting | When the window function is disabled (the ADCMPCR.WCMPE bit is 0)<br>0: ADWINLLB register value > A/D-converted value<br>1: ADWINLLB register value < A/D-converted value<br><br>When the window function is enabled (the ADCMPCR.WCMPE bit is 1)<br>0: A/D-converted value < ADWINLLB register value or ADWINULB register value < A/D-converted value<br>1: ADWINLLB register value < A/D-converted value < ADWINULB register value | R/W |

The S12AD.ADCMPBNSR register is used to specify the comparison window B function.

#### **CMPCHB[5:0] Bits (Comparison Window B Channel Select)**

The CMPCHB[5:0] bits select the channel to be compared with the comparison window B from AN000 to AN007. When the number of the A/D conversion channel selected in the ADANS<sub>Ay</sub>.ANS<sub>Ayn</sub> bit ( $y = 0$  to 1,  $n = 00$  to 07) and the ADANS<sub>By</sub>.ANS<sub>Byn</sub> bit is specified, the comparison window B function is enabled. The CMPCHB[5:0] bits should be set while the ADCSR.ADST bit is 0.

#### **CMPLB Bit (Comparison Window B Comparison Condition Setting)**

The CMPLB bit specifies the condition for comparison of the channels for window B. When the result of comparison of each analog input matches with the pre-set condition, the ADCMPBNSR.CMPSTB flag becomes 1 and a comparison interrupt (S12CMPBI) is generated. The conditions for comparison are shown in Figure 38.8.

## (2) S12AD1.ADCMPBNSR

Address(es): S12AD1.ADCMPBNSR 0008 92A6h

The write value should be 0.                                                                                                                                                                                                                                                                                                                                                                                  | R/W |
| b7       | CMPLB       | Comparison Window B Comparison Condition Setting | When the window function is disabled (the ADCMPCR.WCMPE bit is 0)<br>0: ADWINLLB register value > A/D-converted value<br>1: ADWINLLB register value < A/D-converted value<br><br>When the window function is enabled (the ADCMPCR.WCMPE bit is 1)<br>0: A/D-converted value < ADWINLLB register value or ADWINULB register value < A/D-converted value<br>1: ADWINLLB register value < A/D-converted value < ADWINULB register value | R/W |

The S12AD1.ADCMPBNSR register is used to specify the comparison window B function.

**CMPCHB[5:0] Bits (Comparison Window B Channel Select)**

The CMPCHB[5:0] bits select the channel to be compared with the comparison window B from AN100 to AN107. When the number of the A/D conversion channel selected in the ADANS<sub>Ay</sub>.ANS<sub>Ayn</sub> bit ( $y = 0$  to 1,  $n = 00$  to 07) and the ADANS<sub>By</sub>.ANS<sub>Byn</sub> bit is specified, the comparison window B function is enabled. The CMPCHB[5:0] bits should be set while the ADCSR.ADST bit is 0.

**CMPLB Bit (Comparison Window B Comparison Condition Setting)**

The CMPLB bit specifies the condition for comparison of the channels for window B. When the result of comparison of each analog input matches with the pre-set condition, the ADCMPBSR.CMPSTB flag becomes 1 and a comparison interrupt (S12CMPBI1) is generated. The conditions for comparison are shown in Figure 38.8.

## (3) S12AD2.ADCMPBNSR

Address(es): S12AD2.ADCMPBNSR 0008 94A6h

| b7       | CMPLB       | Comparison Window B Comparison Condition Setting | When the window function is disabled (the ADCMPCR.WCMPE bit is 0)<br>0: ADWINLLB register value > A/D-converted value<br>1: ADWINLLB register value < A/D-converted value<br><br>When the window function is enabled (the ADCMPCR.WCMPE bit is 1)<br>0: A/D-converted value < ADWINLLB register value or ADWINULB register value < A/D-converted value<br>1: ADWINLLB register value < A/D-converted value < ADWINULB register value    | R/W |

The S12AD2.ADCMPBNSR register is used to specify the comparison window B function.

**CMPCHB[5:0] Bits (Comparison Window B Channel Select)**

The CMPCHB[5:0] bits select the channel to be compared under the comparison window B condition from AN200 to AN211, AN216, AN217, temperature sensor, and internal reference voltage.

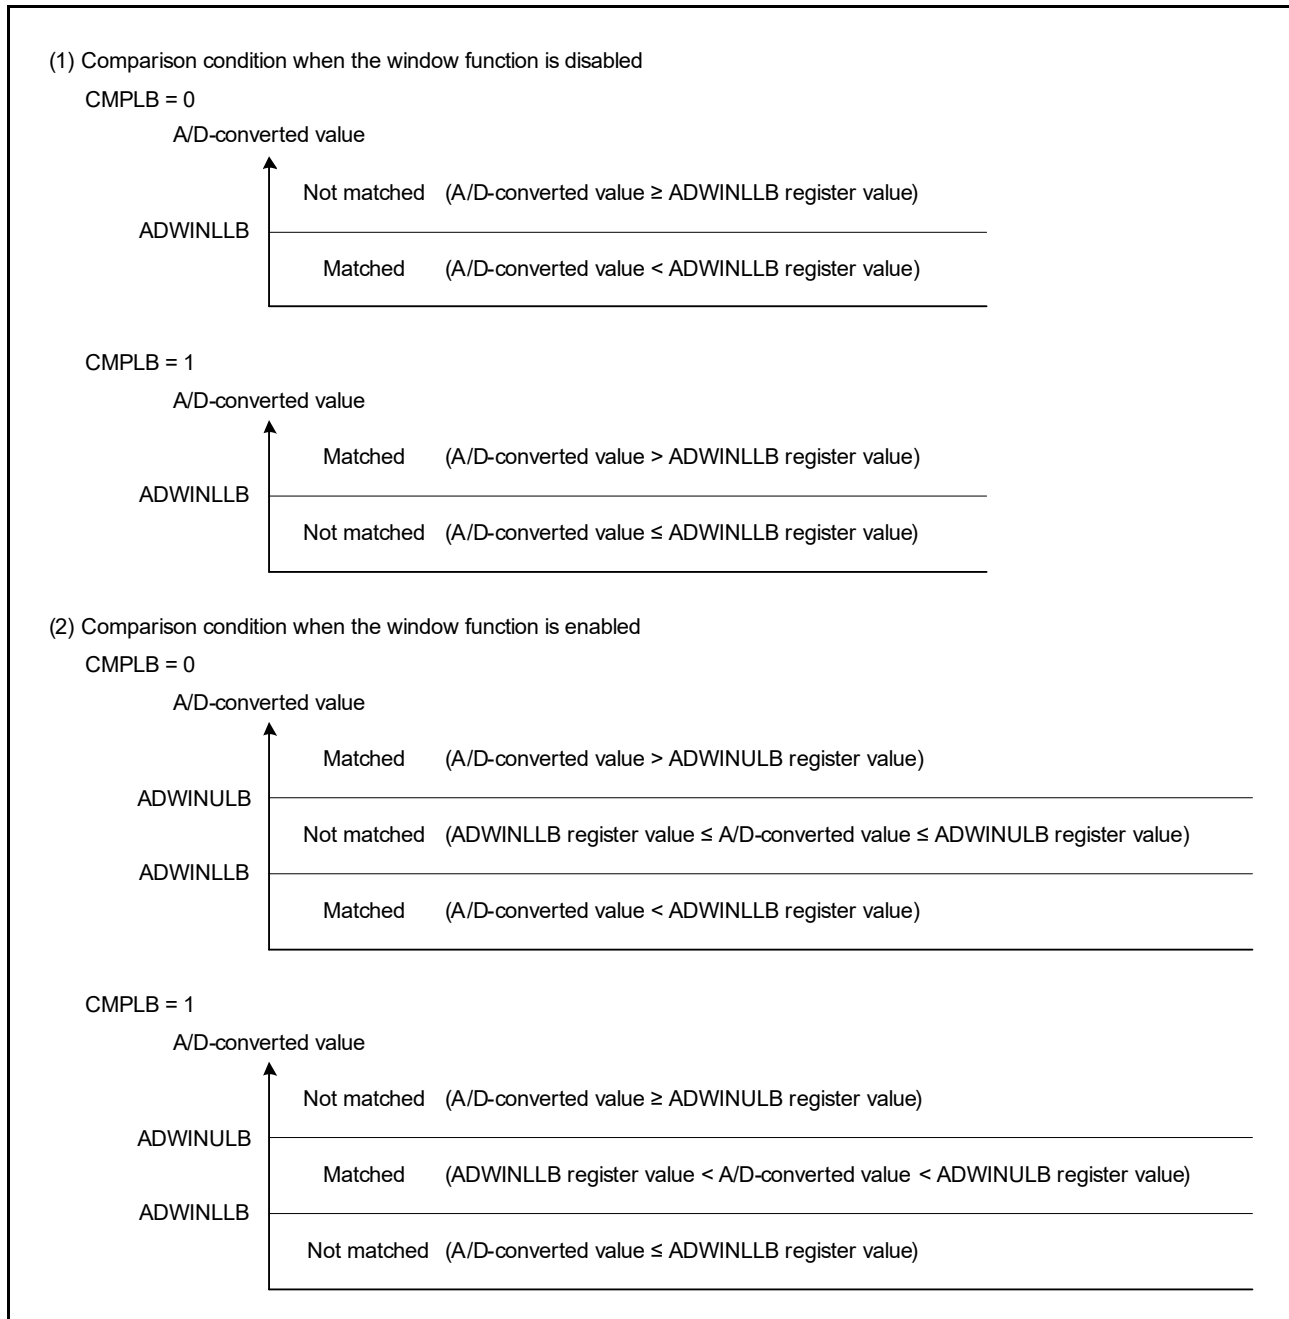

When the number of the A/D conversion channel selected in the ADANS<sub>Ay</sub>.ANS<sub>Ayn</sub> bit (y = 0, 1, n = 00 to 11) and the ADANS<sub>By</sub>.ANS<sub>Byn</sub> bit is specified, the comparison window B function is enabled.

The CMPCHB[5:0] bits should be set while the ADCSR.ADST bit is 0.

**CMPLB Bit (Comparison Window B Comparison Condition Setting)**

The CMPLB bit specifies the condition for comparison of the channels for window B. When the result of comparison of each analog input matches with the pre-set condition, the ADCMPBSR.CMPSTB flag becomes 1 and a comparison interrupt (S12CMPBI2) is generated. The conditions for comparison are shown in Figure 38.8.

**Figure 38.8** Details of Comparison Condition: Comparison Function Window B

### 38.2.39 A/D Comparison Function Window B Lower Level Setting Register (ADWINLLB)

Address(es): S12AD.ADWINLLB 0008 90A8h, S12AD1.ADWINLLB 0008 92A8h, S12AD2.ADWINLLB 0008 94A8h

The ADWINLLB register is a readable and writable register that specifies reference data when comparison window B is in use. The register specifies the lower level of window B.

A write operation to the ADWINLLB register is enabled even during A/D conversion. Rewriting the value of the register during A/D conversion dynamically changes the reference data.

Satisfy the condition of [upper limit level  $\geq$  lower limit level (ADWINULB register setting value  $\geq$  ADWINLLB register setting value)] when setting.

The data formats of the register for each given condition are shown below.

- Setting of the A/D data register format select bit (right-justified or left-justified format)
- Setting of the A/D-converted value addition/averaging function channel select register (A/D-converted value addition/averaging mode is enabled or disabled)
- Setting of the A/D-converted value addition/averaging count select register (addition/averaging mode is selected and addition count is selected)

**Note:** When the comparison values are set in a different format from that of the A/D data register  $y$  (ADDR $y$ ), correct result of comparison cannot be obtained.

(1) When A/D-Converted Value Addition/Average Mode is Disabled

- Right-justified format  
The comparison level (lower) to be compared is set in bits 11 to 0. Write 0 to bits 15 to 12.
- Left-justified format  
The comparison level (lower) to be compared is set in bits 15 to 4. Write 0 to bits 3 to 0.

(2) When A/D-Converted Average Mode is Selected

A/D-converted value average mode can be set only when 2- or 4-time conversion is selected in A/D-converted value addition mode.

- Right-justified format  
The comparison level (lower) to be compared with the value of A/D conversion of the same channel is set in bits 11 to 0. Write 0 to bits 15 to 12.
- Left-justified format  
The comparison level (lower) to be compared with the value of A/D conversion of the same channel is set in bits 15 to 4. Write 0 to bits 3 to 0.

(3) When A/D-Converted Value Addition Mode is Selected

When A/D-converted value addition mode is selected, the value for comparison with the result of cumulative A/D-converted value of the same channel is specified. Conversion 1, 2, 3, 4, or 16 times is selectable. When A/D-converted value addition mode is selected and if conversion 1 to 4 is selected, the resolution of the results of conversion will be extended by 2 bits and so set a value for comparison with the results in the ADWINLLB register. When conversion 16 times is selected, the resolution of the results of conversion will be extended by 4 bits and so set a value for comparison with the results in the ADWINLLB register.

Even when A/D-converted value addition mode is selected, set the value for reference based on the setting of the A/D data register format select bit.

- Right-justified format (in A/D-converted value addition mode and when number of conversions is selected for 1 to 4 times)  
The comparison level (lower) to be compared with the value of A/D conversion of the same channel is set in bits 13 to 0. Write 0 to bits 15 and 14.
- Right-justified format (in A/D-converted value addition mode and when number of conversions is selected for 16 times)  
The comparison level (lower) to be compared with the value of A/D conversion of the same channel is set in bits 15 to 0.
- Left-justified format (in A/D-converted value addition mode and when number of conversions is selected for 1 to 4 times)  
The comparison level (lower) to be compared with the A/D-converted value of the same channel is set in bits 15 to 2. Write 0 to bits 1 and 0.
- Left-justified format (in A/D-converted value addition mode and when number of conversions is selected for 16 times)  
The comparison level (lower) to be compared with the value of A/D conversion of the same channel is set in bits 15 to 0.

### 38.2.40 A/D Comparison Function Window B Upper Level Setting Register (ADWINULB)

Address(es): S12AD.ADWINULB 0008 90AAh, S12AD1.ADWINULB 0008 92AAh, S12AD2.ADWINULB 0008 94AAh

The ADWINULB register is a readable and writable register that specifies the data for reference when the comparison window B function is used. The register specifies the upper level of window B.

A write operation to the register is enabled even during A/D conversion. Rewriting the value of the register during A/D conversion dynamically changes the reference data.

Satisfy the condition of [upper limit level  $\geq$  lower limit level (ADWINULB register setting value  $\geq$  ADWINLLB register setting value)] when setting.

The register is not used when the window function is disabled.

The data formats of the register for each given condition are shown below.

- Setting of the A/D data register format select bit (right-justified or left-justified format)
- Setting of the A/D-converted value addition/averaging function channel select register (A/D-converted value addition/averaging mode is enabled or disabled)
- Setting of the A/D-converted value addition/averaging count select register (addition/averaging mode is selected and addition count is selected)

**Note:** When the comparison values are set in a different format from that of the A/D data register y (ADDRy), correct result of comparison cannot be obtained.

(1) When A/D-Converted Value Addition/Average Mode is Disabled

- Right-justified format  
The comparison level (upper) is set in bits 11 to 0. Write 0 to bits 15 to 12.
- Left-justified format  
The comparison level (upper) is set in bits 15 to 4. Write 0 to bits 3 to 0.

(2) When A/D-Converted Average Mode is Selected

A/D-converted value average mode can be set only when 2- or 4-time conversion is selected in A/D-converted value addition mode.

- Right-justified format  
The comparison level (upper) to be compared with the A/D-converted results of the same channel is set in bits 11 to 0. Write 0 to bits 15 to 12.
- Left-justified format  
The comparison level (upper) to be compared with the A/D-converted results of the same channel is set in bits 15 to 4. Write 0 to bits 3 to 0.

(3) When A/D-Converted Value Addition Mode is Selected

When A/D-converted value addition mode is selected, the value for comparison with the result of cumulative A/D-converted value of the same channel is specified. Conversion 1, 2, 3, 4, or 16 times is selectable. When A/D-converted value addition mode is selected and if conversion 1 to 4 is selected, the resolution of the results of conversion will be extended by 2 bits and so set a value for comparison with the results in the ADWINULB register. When conversion 16

times is selected, the resolution of the results of conversion will be extended by 4 bits and so set a value for comparison with the results in the ADWINULB register.

Even when A/D-converted value addition mode is selected, set the value for reference based on the setting of the A/D data register format select bit.

- Right-justified format (in A/D-converted value addition mode and when number of conversions is selected for 1 to 4 times)  
The comparison level (upper) to be compared with the A/D-converted value of the same channel is set bits 13 to 0. Write 0 to bits 15 and 14.
- Right-justified format (in A/D-converted value addition mode and when number of conversions is selected for 16 times)  
The comparison level (upper) to be compared with the A/D-converted value of the same channel is set bits 15 to 0.
- Left-justified format (in A/D-converted value addition mode and when number of conversions is selected for 1 to 4 times)  
The comparison level (upper) to be compared with the A/D-converted value of the same channel is set in bits 15 to 2. Write 0 to bits 1 and 0.
- Left-justified format (in A/D-converted value addition mode and when number of conversions is selected for 16 times)  
The comparison level (upper) to be compared with the A/D-converted value of the same channel is set bits 15 to 0.

### 38.2.41 A/D Comparison Function Window B Channel Status Register (ADCMPBSR)

#### (1) S12AD.ADCMPBSR

Address(es): S12AD.ADCMPBSR 0008 90ACh

| Bit      | Symbol | Bit Name                 | Description                                                                                | R/W         |
|----------|--------|--------------------------|--------------------------------------------------------------------------------------------|-------------|
| b0       | CMPSTB | Comparison Window B Flag | 0: The comparison condition is not satisfied.<br>1: The comparison condition is satisfied. | R/(W)<br>*1 |
| b7 to b1 | —      | Reserved                 | These bits are read as 0. The write value should be 0.                                     | R/W         |

Note 1. Only 0 can be written to clear the flag after reading 1.

The S12AD.ADCMPBSR register is used to store results of comparison of the comparison window B function.

#### **CMPSTB Flag (Comparison Window B Flag)**

The CMPSTB flag is a status flag that indicates the result of comparison of the channels for window B comparison conditions (AN000 to AN007).

When the conversion result matches with the comparison condition that is set in the ADCMPBSR.CMPLB bit upon completion of A/D conversion, this flag becomes 1. When the ADCMPBSR.CMPBIE bit is 1, a comparison interrupt request (S12CMPBI) is generated upon the setting of the flag.

1 cannot be written to the CMPSTB flag.

[Setting condition]

- When ADCMPBSR.CMPBIE bit = 1 and the condition set in the ADCMPBSR.CMPLB bit is satisfied.

[Clearing condition]

- When 0 is written after reading the state of 1.

## (2) S12AD1.ADCMPBSR

Address(es): S12AD1.ADCMPBSR 0008 92ACh

| Bit      | Symbol | Bit Name                 | Description                                                                                | R/W         |
|----------|--------|--------------------------|--------------------------------------------------------------------------------------------|-------------|
| b0       | CMPSTB | Comparison Window B Flag | 0: The comparison condition is not satisfied.<br>1: The comparison condition is satisfied. | R/(W)<br>*1 |
| b7 to b1 | —      | Reserved                 | These bits are read as 0. The write value should be 0.                                     | R/W         |

Note 1. Only 0 can be written to clear the flag after reading 1.

The S12AD1.ADCMPBSR register is used to store results of comparison of the comparison window B function.

**CMPSTB Flag (Comparison Window B Flag)**

The CMPSTB flag is a status flag that indicates the result of comparison of the channels for window B comparison conditions (AN100 to AN107).

When the conversion result matches with the comparison condition that is set in the ADCMPBNSR.CMPLB bit upon completion of A/D conversion, this flag becomes 1. When the ADCMPPCR.CMPBIE bit is 1, a comparison interrupt request (S12CMPBI1) is generated upon the setting of the flag.

1 cannot be written to the CMPSTB flag.

[Setting condition]

- When ADCMPPCR.CMPBE bit = 1 and the condition set in the ADCMPBNSR.CMPLB bit is satisfied.

[Clearing condition]

- When 0 is written after reading the state of 1.

## (3) S12AD2.ADCMPBSR

Address(es): S12AD2.ADCMPBSR 0008 94ACh

| Bit      | Symbol | Bit Name                 | Description                                                                                | R/W         |
|----------|--------|--------------------------|--------------------------------------------------------------------------------------------|-------------|
| b0       | CMPSTB | Comparison Window B Flag | 0: The comparison condition is not satisfied.<br>1: The comparison condition is satisfied. | R/(W)<br>*1 |
| b7 to b1 | —      | Reserved                 | These bits are read as 0. The write value should be 0.                                     | R/W         |

Note 1. Only 0 can be written to clear the flag after reading 1.

The S12AD2.ADCMPBSR register is used to store results of comparison of the comparison window B function.

**CMPSTB Flag (Comparison Window B Flag)**

The CMPSTB flag is a status flag that indicates the result of comparison of the channels for window B comparison conditions (AN200 to AN211, AN216, AN217, temperature sensor, internal reference voltage).

When the conversion result matches with the comparison condition that is set in the ADCMPBNSR.CMPLB bit upon completion of A/D conversion, this flag becomes 1. When the ADCMPPCR.CMPBIE bit is 1, a comparison interrupt request (S12CMPBI2) is generated upon the setting of the flag.

1 cannot be written to the CMPSTB flag.

[Setting condition]

- When ADCMPPCR.CMPBE bit = 1 and the condition set in the ADCMPBNSR.CMPLB bit is satisfied.

[Clearing condition]

- When 0 is written after reading the state of 1.

## 38.2.42 A/D Programmable Gain Amplifier Control Register (ADPGACR)

### (1) S12AD.ADPGACR

Address(es): S12AD.ADPGACR 0008 91A0h

| Bit        | Symbol      | Bit Name               | Description                                                                                                                                                | R/W |
|------------|-------------|------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------|-----|
| b3 to b0   | P000CR[3:0] | P000 Amplifier Control | These bits control the PGA (P000) that is connected to AN000 and the destinations of the analog signal. For details of the settings, refer to Table 38.19. | R/W |
| b7 to b4   | P001CR[3:0] | P001 Amplifier Control | These bits control the PGA (P001) that is connected to AN001 and the destinations of the analog signal. For details of the settings, refer to Table 38.19. | R/W |
| b11 to b8  | P002CR[3:0] | P002 Amplifier Control | These bits control the PGA (P002) that is connected to AN002 and the destinations of the analog signal. For details of the settings, refer to Table 38.19. | R/W |
| b15 to b12 | —           | Reserved               | These bits are read as 0. The write value should be 0.                                                                                                     | R/W |

### (2) S12AD1.ADPGACR

Address(es): S12AD1.ADPGACR 0008 93A0h

| Bit        | Symbol      | Bit Name               | Description                                                                                                                                                | R/W |
|------------|-------------|------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------|-----|
| b3 to b0   | P100CR[3:0] | P100 Amplifier Control | These bits control the PGA (P100) that is connected to AN100 and the destinations of the analog signal. For details of the settings, refer to Table 38.19. | R/W |
| b7 to b4   | P101CR[3:0] | P101 Amplifier Control | These bits control the PGA (P101) that is connected to AN101 and the destinations of the analog signal. For details of the settings, refer to Table 38.19. | R/W |
| b11 to b8  | P102CR[3:0] | P102 Amplifier Control | These bits control the PGA (P102) that is connected to AN102 and the destinations of the analog signal. For details of the settings, refer to Table 38.19. | R/W |
| b15 to b12 | —           | Reserved               | These bits are read as 0. The write value should be 0.                                                                                                     | R/W |

#### PxCR[3:0] Bits (Px Amplifier Control) (x = 000 to 002, 100 to 102)

These bits set the paths for analog signals which were input to pins AN000 to AN002, and pins AN100 to AN102. Refer to Table 38.19 for the relationships among the settings, input signals to the A/D converter, and input signals to comparator C.

As for the relationships with bits in other registers, refer to section 38.3.16, Programmable Gain Amplifier.

**Table 38.19** Settings of the PxCR[3:0] bits and paths for analog signals (x = 000 to 002, 100 to 102; m = 0 to 5)

| PxCR[3:0] Bits        | PGA      | Input to the A/D converter | Input to comparator C |           |
|-----------------------|----------|----------------------------|-----------------------|-----------|
|                       |          |                            | CMPCm0                | CMPCm1    |
| 0000b (initial value) | Disabled | —                          | —                     | —         |
| 0001b*1               | Disabled | ANx                        | —                     | —         |
| 1000b*1               | Disabled | —                          | ANx                   | —         |
| 1001b*1               | Disabled | ANx                        | ANx                   | —         |
| 1100b                 | Enabled  | —                          | ANx*2                 | Px output |
| 1101b                 | Enabled  | ANx*3                      | ANx*2                 | Px output |
| 1110b                 | Enabled  | Px output                  | ANx*2                 | Px output |

Note: Settings other than those listed above are prohibited.

Note 1. Set the ADPGADC0.PxDEN bit to 0 (single-ended input).

Note 2. ANx is only enabled when the ADPGADC0.PxDEN bit is 0 (single-ended input).

Note 3. Do not input a negative voltage on an ANx pin.

### 38.2.43 A/D Programmable Gain Amplifier Gain Setting Register 0 (ADPGAGS0)

#### (1) S12AD.ADPGAGS0

Address(es): S12AD.ADPGAGS0 0008 91A2h

| Bit        | Symbol        | Bit Name                    | Description                                                                                                                                                                                                                                                                                                                                                                | R/W |

Note: For details of bit setting, refer to section 38.3.16, Programmable Gain Amplifier.

**PxGAIN[3:0] Bits (Px Amplifier Gain Setting) (x = 000 to 002, 100 to 102)**

The PxGAIN[3:0] bits are used to specify the gain of each programmable gain amplifier Px. When using pseudo-differential input (ADPGADC0.PxDEN bit = 1 and ADPGACR.PxCR[2] bit = 1), set the value such that the same gain is obtained as with the ADPGADC0.PxDG[1:0] bits.

| b14 to b12 | —           | Reserved                                   | These bits are read as 0. The write value should be 0.                                             | R/W |
| b15        | —           | Reserved                                   | This bit is read as 1. The write value should be 1.                                                | R/W |

Note: For details of bit setting, refer to section 38.3.16, Programmable Gain Amplifier.

Note 1. This bit is enabled when PxDEN bit = 1 and ADPGACR.PxCR[2] bit = 1 (x = 100 to 102).

Note 2. When a negative voltage is to be input to the PGAVSS1 pin, set each of the P100DEN, P101DEN, and P102DEN bits to 1.

**PxDG[1:0] Bits (Px Amplifier Differential Gain Setting) (x = 000 to 002, 100 to 102)**

The PxDG[1:0] bits specify the gain of each programmable amplifier Px with a pseudo-differential input is enabled. It is effective only when both the PxDEN and ADPGACR.PxCR[2] bits are set to 1.

In these bits, set the value such that the same gain is obtained as with the ADPGAGS0.PxGAIN[3:0] bits.

Example: To set the gain of P000 as × 1.500

ADPGAGS0.P000GAIN[3:0] bits = 0001b

ADPGADCR0.P000DG[1:0] bits = 00b

**PxDEN Bit (Px Amplifier Pseudo-Differential Input Enable) (x = 000 to 002, 100 to 102)**

The PxDEN bit enables or disables the pseudo-differential input of each programmable amplifier Px.

To use a PGA with single-ended input, set the bit to 0. Also, connect the corresponding PGAVSS0 or PGAVSS1 pin to the AVSS0 or AVSS1 pins, respectively.

### 38.2.45 A/D Internal Reference Voltage Monitoring Circuit Enable Register (ADVMONCR)

Address(es): S12AD2.ADVMONCR 0008 95E2h

Value after reset: 0 0 0 0 0 0 0 0

| Bit      | Symbol | Bit Name                                         | Description                                                                                                                                                 | R/W |
|----------|--------|--------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------|-----|
| b0       | VDO    | Voltage Monitoring Circuit Voltage Output Enable | 0: Disables voltage output of internal reference voltage monitoring circuit.<br>1: Enables voltage output of internal reference voltage monitoring circuit. | R/W |
| b7 to b1 | —      | Reserved                                         | These bits are read as 0. The write value should be 0.                                                                                                      | R/W |

The ADVMONO register is used to enable the voltage output of the voltage monitoring circuit for the internal reference voltage.

Set the register while the ADCSR.ADST bit is 0.

### 38.3 Operation

#### 38.3.1 A/D Converter Initialization Flowchart

Initialize the A/D converter following the example of flowchart shown in Figure 38.9.

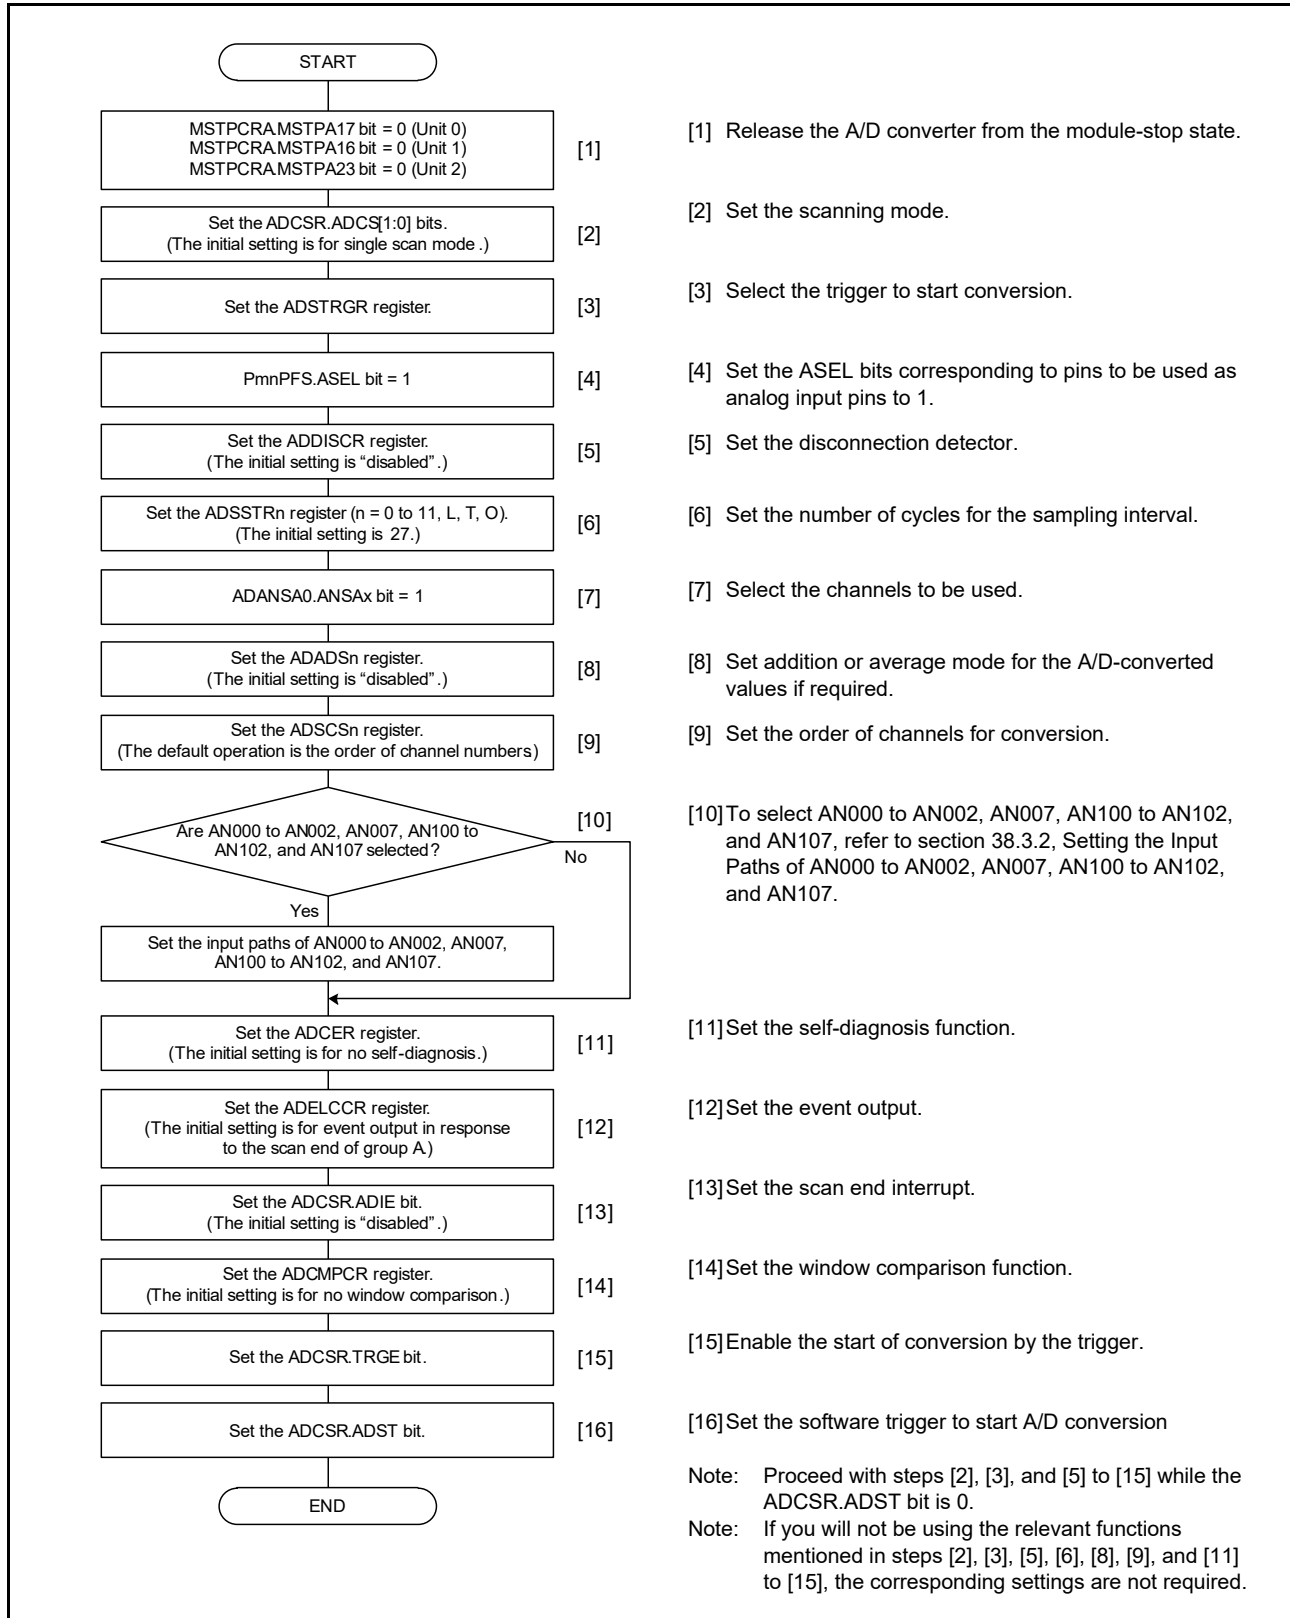

Figure 38.9 A/D Converter Initialization Flowchart

### 38.3.2 Setting the Input Paths of AN000 to AN002, AN007, AN100 to AN102, and AN107

Paths from input pins to the A/D converters or to comparators C are as shown in Figure 38.10. It only shows the path for P000 as an example. The paths for the other channels are the same as this.

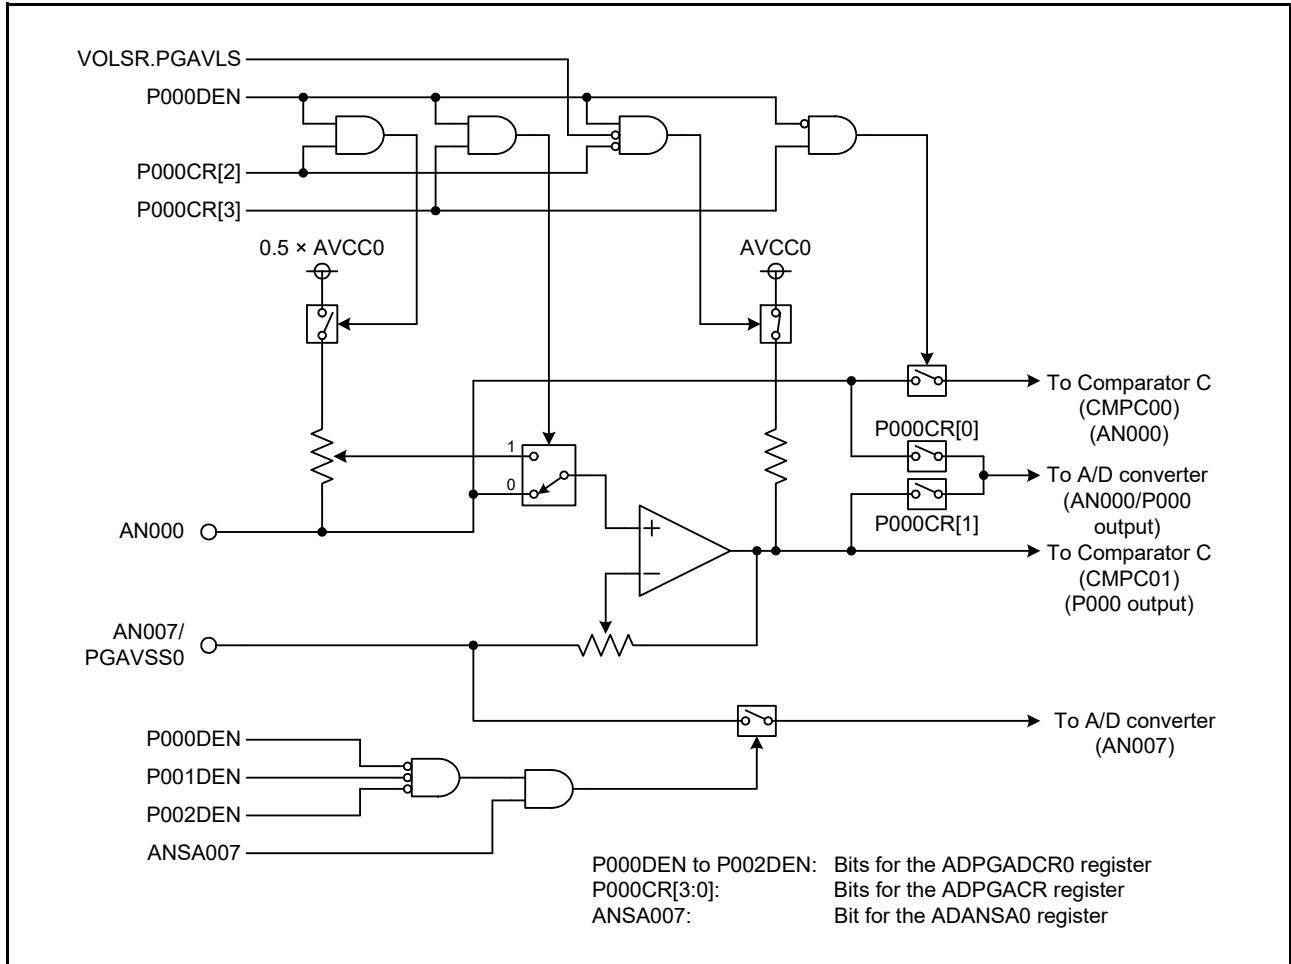

Figure 38.10 Internal Block Chart of PGA (P000)

Set the registers in accordance with Table 38.20 and Table 38.21 depending on the use of pins AN000 to AN002 and AN100 to AN102, the product in use, and the analog power supply voltage. Refer to Figure 38.11 for the setting procedures for AN000 to AN002, AN007, AN100 to AN102, and AN107. The VOLSR.PGAVLS bit controls all channels of PGA. Refer to section 3, Operating Modes for details of the VOLSR.PGAVLS bit.

To use the AN007 or AN107 pin as the pin to be measured, disable all PGAs in the corresponding unit ( $PxCR[2] = 0$ ;  $x = 000$  to  $002$ , or  $100$  to  $102$ ), set them to single-ended input ( $PxDEN = 0$ ), and then set AN007 or AN107 as a target for conversion ( $ANSA007 = 1$ ).

**Table 38.20 Setting for the Function to be Used (Target for Measurement) and PGA-Related Registers (In the Case of a Product Without Pseudo-Differential Input to the PGAs)**  
(x = 000 to 002, 100 to 102; m = 0 to 5)

| Analog input pin               | Pseudo-differential input*2 | —             | —            | Px output | 1         | 1100b     |
| Analog input pin               | Pseudo-differential input*3 | ANx*4         | —            | Px output | 1         | 1101b     |
| Analog input pin               | Pseudo-differential input*2 | Px output     | —            | Px output | 1         | 1110b     |

Note 1. Connect the corresponding PGAVSS0 and PGAVSS1 pins to the AVSS0 and AVSS1 pins.

Note 2. When the AVCC voltage is 4.0 V or higher, and a negative voltage is input to even one of the ANx, PGAVSS0, and PGAVSS1 pins, set the VOLSR.PGAVLS bit to 0.

Note 3. This setting is available when the channel-dedicated sample-and-hold circuit is used. When the AVCC voltage is 4.0 V or higher, and a negative voltage is input to the PGAVSS0 or PGAVSS1 pin, set the VOLSR.PGAVLS bit to 0.

Note 4. Do not input a negative voltage to the ANx pin.

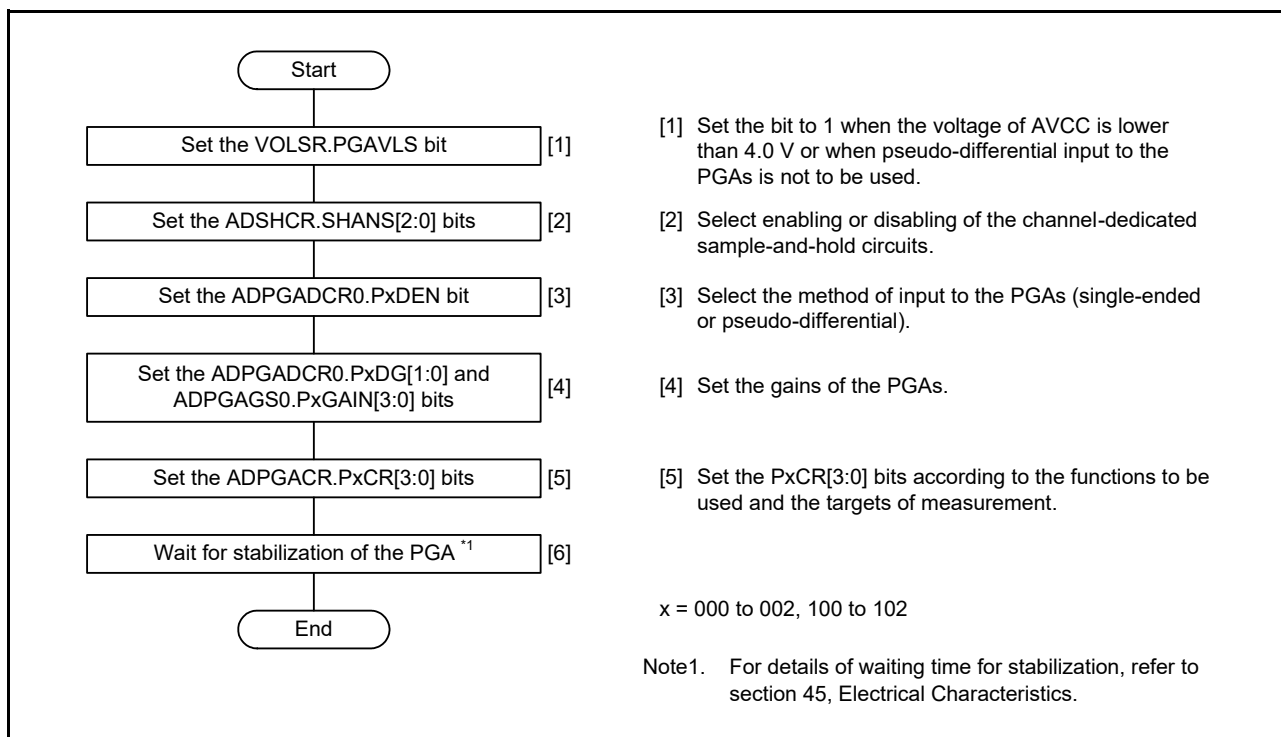

Figure 38.11 Procedure for Settings

### 38.3.3 Scanning Operation

In scanning, A/D conversion is performed sequentially on the analog inputs of the specified channels.

A scan conversion is performed in three operating modes: single scan mode, continuous scan mode, and group scan mode. In single scan mode, one or more specified channels are scanned once. In continuous scan mode, one or more specified channels are scanned repeatedly until the ADCSR.ADST bit is cleared to 0 from 1 by software. In group scan mode, the selected channels of groups A, B, and C are scanned once after starting to be scanned according to the respective synchronous trigger.

In single scan mode and continuous scan mode, A/D conversion is performed for the analog channels selected in the ADANSA0 and ADANSA1 registers according to the order of conversion specified in the ADSCSn register.

In group scan mode, A/D conversion is performed for analog channels of groups A, B, and C selected by the ADANSA0 and ADANSA1 registers, the ADANSB0 and ADANSB1 registers, and the ADANSC0 and ADANSC1 registers, respectively, according to the order of conversion specified in the ADSCSn register.

When self-diagnosis is selected, it is executed once at the beginning of each scan and one of the three voltages internally generated in the 12-bit A/D converter is converted.

The temperature sensor output and the internal reference voltage can be selected; however, they cannot be selected in combination with an analog input of the channels in the same group.

Conversion of the temperature sensor output takes priority when the temperature sensor output and internal reference voltage are selected simultaneously.

When converting the temperature sensor output or the internal reference voltage, an auto-discharging is automatically performed.

Double trigger mode is to be used with single scan mode or group scan mode. With double trigger mode being enabled, A/D conversion data of a channel selected by the ADCSR.DBLANS[4:0] bits is duplicated only if the conversion is started by the synchronous trigger selected by the ADSTRGR.TRSA[5:0] bits. In group scan mode, the double trigger function can be used only for group A.

Extended double trigger mode indicates a state when the following synchronous trigger (two synchronous trigger sources enabled) is selected by the TRSA[5:0] bits in the A/D conversion start trigger select register (ADSTRGR) in double trigger mode.

- TRG4AN or TRG4BN (the ADSTRGR.TRSA[5:0] bits are set to 001011b)
- TRG7AN or TRG7BN (the ADSTRGR.TRSA[5:0] bits are set to 001111b)
- TRGA0N or TRG0N (the ADSTRGR.TRSA[5:0] bits are set to 011001b)
- TRGA9N or TRG9N (the ADSTRGR.TRSA[5:0] bits are set to 011010b)
- TRGA0N or TRGA9N (the ADSTRGR.TRSA[5:0] bits are set to 011011b)
- TRG0N or TRG9N (the ADSTRGR.TRSA[5:0] bits are set to 011100b)
- ELCTRG00N or ELCTRG01N, ELCTRG10N or ELCTRG11N, or ELCTRG20N or ELCTRG21N (the ADSTRGR.TRSA[5:0] bits are set to 111010b)

In extended double trigger mode, in addition to normal operations in double trigger mode, A/D conversion data is stored in A/D data duplication register A (ADDBLDRA) or A/D data duplication register B (ADDBLDRB) depending on the trigger type. If two types of triggers have occurred simultaneously in this mode, A/D conversion data is not sorted by the trigger sources and is stored in data duplication register B (ADDBLDRB).

Note that if a new trigger is input during A/D conversion caused by another trigger, the new trigger is ignored.

When any of AN000 to AN002 or AN100 to AN102 channels is set as a channel-dedicated sample-and-hold circuit by the ADSHCR.SHANS[2:0] bits, the target analog input is sampled and held before the first A/D conversion of each scan.

### 38.3.4 Single Scan Mode

#### 38.3.4.1 Basic Operation (Without Channel-Dedicated Sample-and-Hold Circuits)

In basic operation of single scan mode, A/D conversion is performed once on the analog input of the specified channels as below.

- (1) When the ADCSR.ADST bit is set to 1 (starting A/D conversion) by software, or synchronous or asynchronous trigger input, A/D conversion is performed for the analog channels selected in the ADANSA0 and ADANSA1 registers according to the order of conversion specified in the ADSCSn register. (Specified conversion order in Figure 38.12: AN004 → AN005 → AN006)
- (2) Each time A/D conversion of a single channel is completed, the A/D conversion result is stored into the corresponding A/D data register (ADDRy).
- (3) When A/D conversion of all the selected channels is completed, a scan end interrupt request is generated if the ADCSR.ADIE bit is 1 (scan end interrupt is enabled).
- (4) The ADCSR.ADST bit remains 1 (starting A/D conversion) during A/D conversion, and is automatically cleared to 0 when A/D conversion of all the selected channels is completed. Then the 12-bit A/D converter enters a wait state.

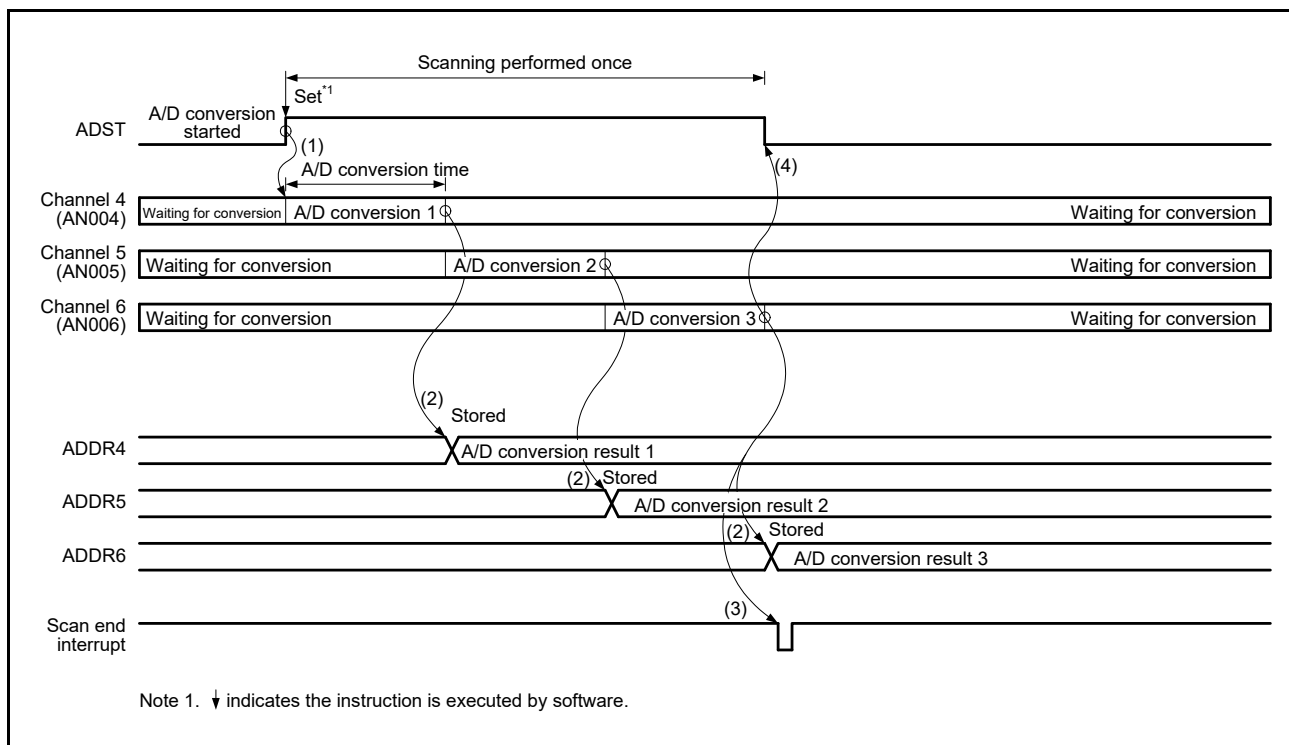

Figure 38.12 Example of Operation in Single Scan Mode (Basic Operation: AN004, AN005, AN006 Selected)

### 38.3.4.2 Basic Operation (with Channel-Dedicated Sample-and-Hold Circuits, with Constant Sampling Disabled)

When a channel-dedicated sample-and-hold circuit is used, sample-and-hold operations are performed first, and this is followed by A/D conversion once of the analog inputs on all selected channels. The ADSHCR.SHANS[2:0] bits are used to select the channels for which the channel-dedicated sample-and-hold circuits are to be used.

- (1) Analog input sampling of all channels for which the channel-dedicated sample-and-hold circuits are to be used is started when the ADCSR.ADST bit is set to 1 (starting A/D conversion) by software, or synchronous or asynchronous trigger input.
- (2) After sample-and-hold operation, A/D conversion is performed for the analog channels selected in the ADANSA0 and ADANSA1 registers according to the order of conversion specified in the ADSCSn register. To use the channel-dedicated sample-and-hold circuit, set the corresponding channel in any of the ADSCS0, ADSCS1, or ADSCS2 register.
- (3) Each time A/D conversion of a single channel is completed, the result of A/D conversion is stored in the corresponding A/D data register (ADDRy).
- (4) When A/D conversion of all the selected channels is completed, a scan end interrupt request is generated if the ADCSR.ADIE bit is 1 (scan end interrupt is enabled).
- (5) The ADCSR.ADST bit remains 1 (starting A/D conversion) during A/D conversion, and is automatically cleared to 0 when A/D conversion of all the selected channels is completed. Then the 12-bit A/D converter enters a wait state.

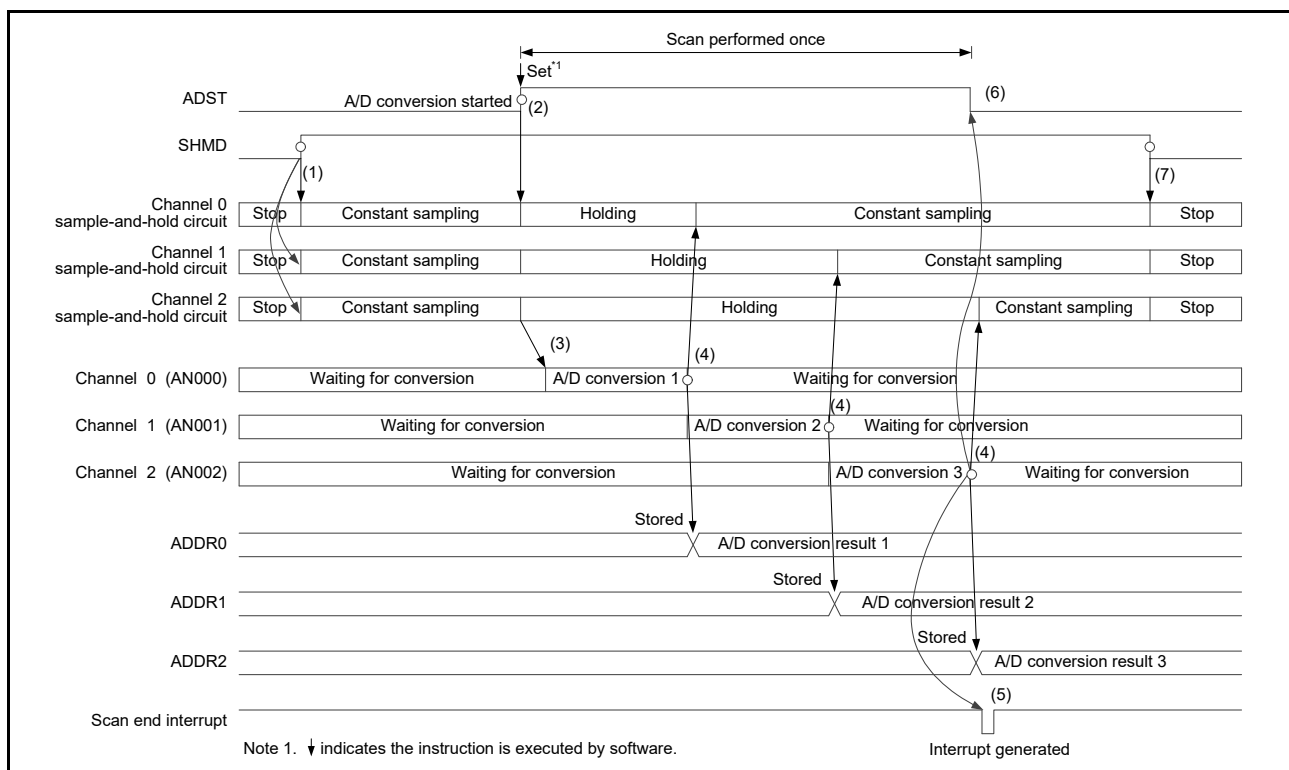

**Figure 38.13 Example of Operation in Single Scan Mode (Channel-Dedicated Sample-and-Hold Circuits Used; AN000, AN001, AN002 Selected, with Constant Sampling Disabled)**

### 38.3.4.3 Basic Operation (with Channel-Dedicated Sample-and-Hold Circuits, with Constant Sampling Enabled)

When constant sampling is enabled and the channel sample-and-hold circuit is used, a single A/D conversion is performed for analog input of all channels selected after sampling and holding is executed.

The channels for channel sample-and-hold circuit can be selected in the ADSHCR.SHANS[2:0] bits.

- (1) When the ADSHMSR.SHMD bit is set to 1, the sample-and-hold circuit selected in the ADSHCR.SHANS[2:0] bits starts constant sampling.
- (2) Analog input sampling of all channels for which the channel-dedicated sample-and-hold circuits are to be used is started when the ADCSR.ADST bit is set to 1 (starting A/D conversion) by software, or synchronous or asynchronous trigger input. After setting the ADSHMSR.SHMD bit to 1 and 750 ns minimum are elapsed, set the ADCSR.ADST bit to 1.
- (3) When the stabilizing time for the sample-and-hold circuit is elapsed, A/D conversion is performed for the analog channels selected in the ADANSA0 and ADANSA1 registers according to the order of conversion specified in the ADSCSn register. To use the channel-dedicated sample-and-hold circuit, set the corresponding channel in any of the ADSCS0, ADSCS1, or ADSCS2 register.
- (4) Each time A/D conversion of a single channels is completed, the A/D-converted value is stored in the corresponding A/D data register (ADDRy), the sample-and-hold circuit resumes constant sampling.
- (5) When A/D conversion of all the selected channels is completed, a scan end interrupt request is generated if the ADCSR.ADIE bit is 1 (scan end interrupt is enabled).
- (6) The ADCSR.ADST bit remains 1 (starting A/D conversion) during A/D conversion, and is automatically cleared to 0 when A/D conversion of all the selected channels is completed. Then the 12-bit A/D converter enters a wait state. When a single scan is performed in sequence, set the time of constant sampling of the sample-and-hold circuit to 400 ns or longer (when allowable impedance of the source of the enabling signal is 1 kΩ).
- (7) When the ADSHMSR.SHMD bit is cleared to 0, the sample-and-hold circuit stops.

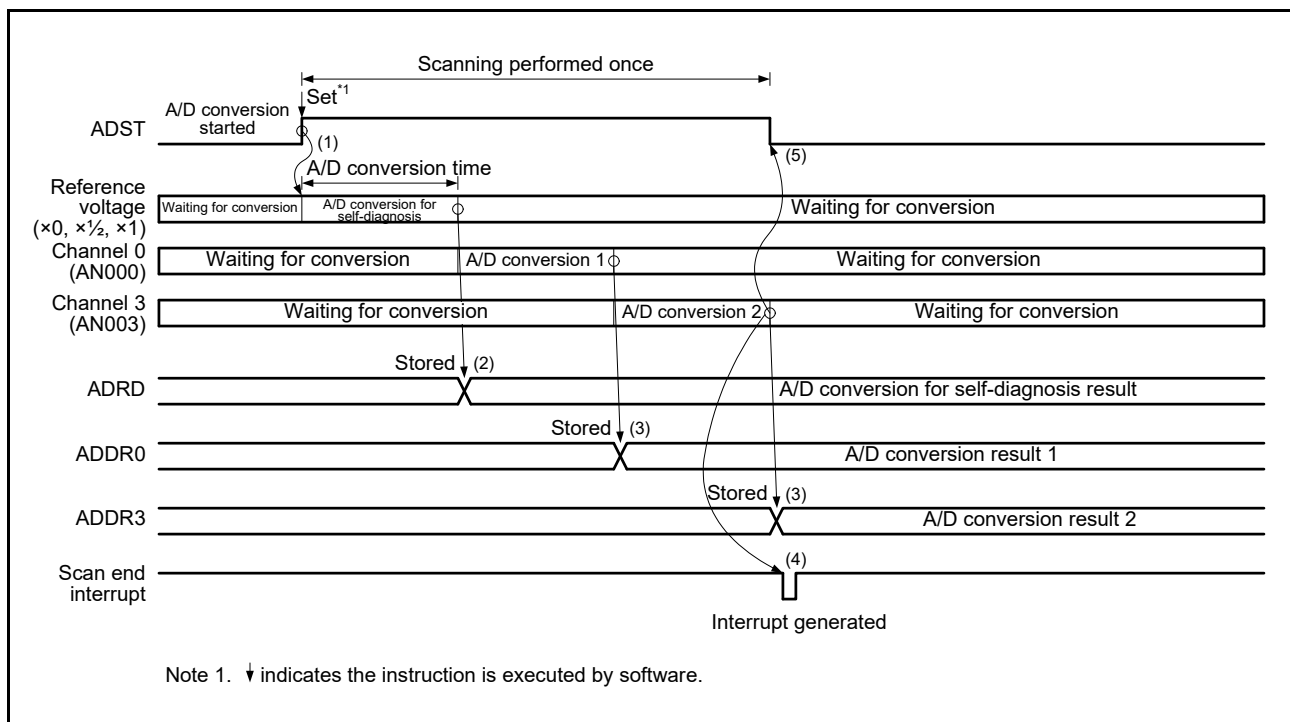

**Figure 38.14 Example of Operation in Single Scan Mode (Channel-Dedicated Sample-and-Hold Circuits Used; AN000 to AN002 Selected, with Constant Sampling Enabled)**

### 38.3.4.4 Channel Selection and Self-Diagnosis (Without Channel-Dedicated Sample-and-Hold Circuits)

When channels and self-diagnosis are selected, A/D conversion is performed once for the reference voltage supplied to the 12-bit A/D converter as below. After that, A/D conversion is performed only once on the analog input of the selected channels.

- (1) A/D conversion for self-diagnosis is started when the ADCSR.ADST bit is set to 1 (starting A/D conversion) by software, or synchronous or asynchronous trigger input.
- (2) When A/D conversion for self-diagnosis is completed, A/D conversion result is stored into the A/D self-diagnosis data register (ADRD), A/D conversion is performed for the analog channels selected in the ADANSA0 and ADANSA1 registers according to the order of conversion specified in the ADSCSn register.
- (3) Each time A/D conversion of a single channel is completed, the A/D conversion result is stored into the corresponding A/D data register (ADDRy).
- (4) When A/D conversion of all the selected channels is completed, a scan end interrupt request is generated if the ADCSR.ADIE bit is 1 (scan end interrupt is enabled).
- (5) The ADST bit remains 1 (starting A/D conversion) during A/D conversion, and is automatically cleared to 0 when A/D conversion of all the selected channels is completed. Then the 12-bit A/D converter enters a wait state.

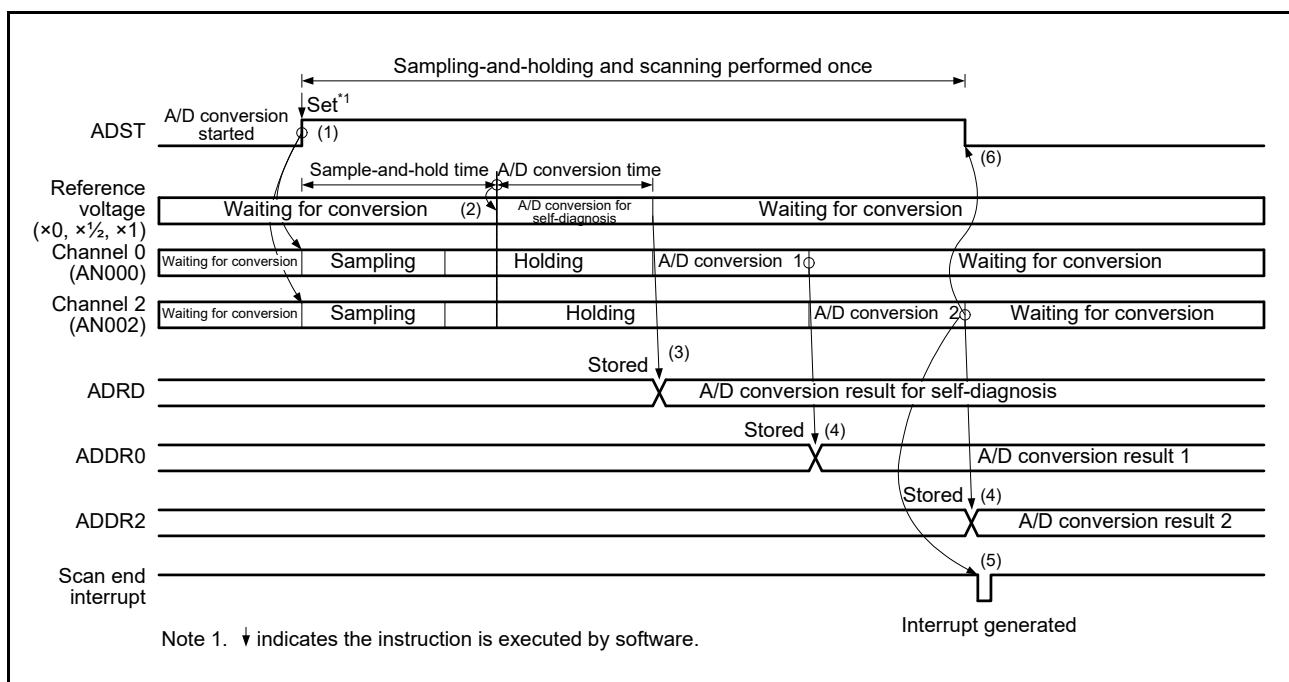

**Figure 38.15 Example of Operation in Single Scan Mode (Basic Operation: AN000, AN003 Selected + Self-Diagnosis)**

### 38.3.4.5 Channel Selection and Self-Diagnosis (with Channel-Dedicated Sample-and-Hold Circuits, with Constant Sampling Disabled)

When channels and self-diagnosis are selected and a channel-dedicated sample-and-hold circuit is used, sample-and-hold operations are performed first, and A/D conversion is performed once for the reference voltage supplied to the 12-bit A/D converter as below. After that, A/D conversion is performed only once on the analog input of the selected channels. The self-diagnosis cannot be used with the temperature sensor output or with the internal reference voltage.

- (1) Analog input sampling of all channels for which the channel-dedicated sample-and-hold circuits are to be used is started when the ADCSR.ADST bit is set to 1 (starting A/D conversion) by software, or synchronous or asynchronous trigger input.
- (2) A/D conversion for self-diagnosis is started after completion of sampling and holding.
- (3) When A/D conversion for self-diagnosis is completed, A/D conversion result is stored into the A/D self-diagnosis data register (ADDRD), A/D conversion is performed for the analog channels selected in the ADANSA0 and ADANSA1 registers according to the order of conversion specified in the ADSCSn register. To use the channel-dedicated sample-and-hold circuit, set the corresponding channel in any of the ADSCS0, ADSCS1, or ADSCS2 register.
- (4) Each time A/D conversion of a single channel is completed, the A/D conversion result is stored into the corresponding A/D data register (ADDRy).
- (5) When A/D conversion of all the selected channels is completed, a scan end interrupt request is generated if the ADCSR.ADIE bit is 1 (scan end interrupt is enabled).
- (6) The ADCSR.ADST bit remains 1 (starting A/D conversion) during A/D conversion, and is automatically cleared to 0 when A/D conversion of all the selected channels is completed. Then the 12-bit A/D converter enters a wait state.

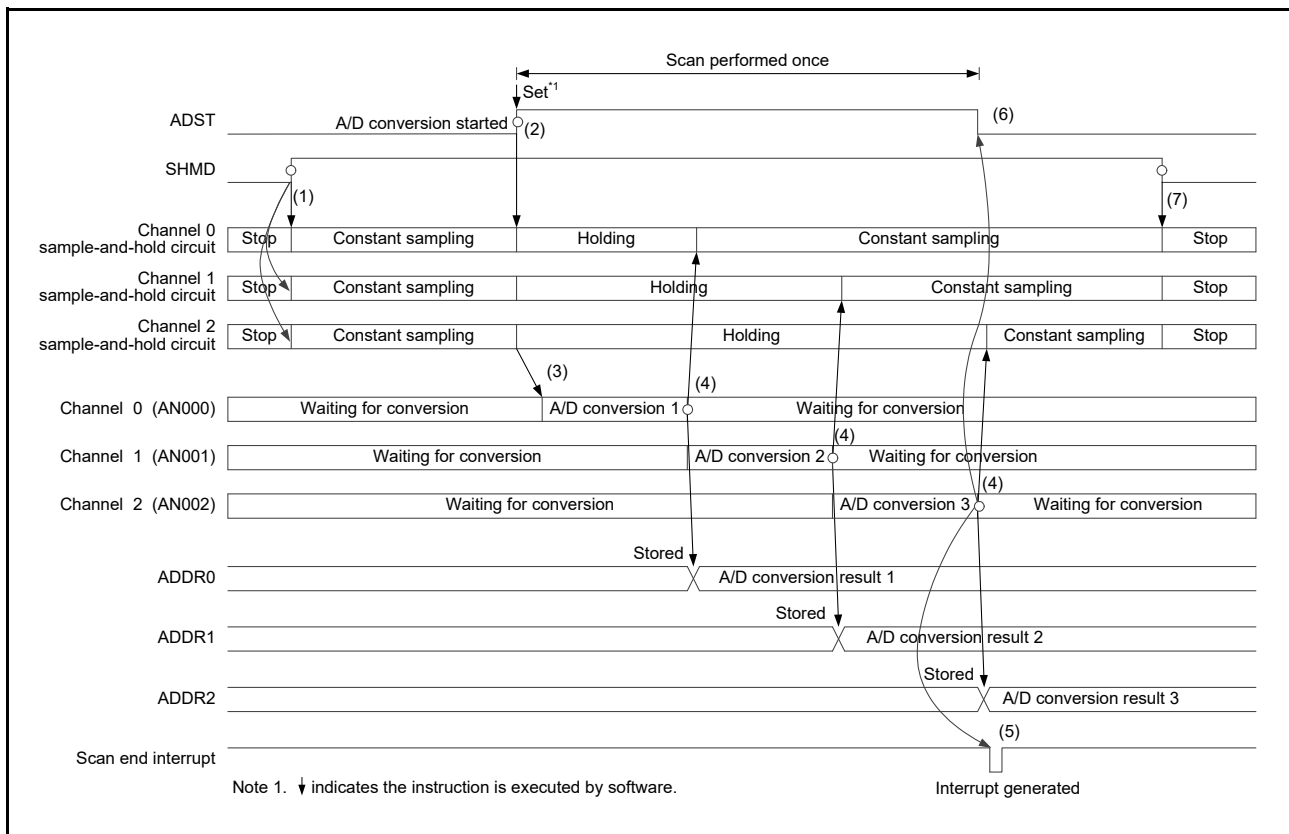

**Figure 38.16 Example of Operation in Single Scan Mode (Channel-Dedicated Sample-and-Hold Circuits Used: AN000, AN002 Selected + Self-Diagnosis, with Constant Sampling Disabled)**

### 38.3.4.6 Channel Selection and Self-Diagnosis (with Channel-Dedicated Sample-and-Hold Circuits, with Constant Sampling Enabled)

When self-diagnosis is selected with channels and a channel-dedicated sample-and-hold circuit is used with constant sampling enabled, sample-and-hold operations are performed first, and A/D conversion is performed on the reference voltage supplied to the 12-bit A/D converter as described below. After that, A/D conversion is performed only once on the analog input of the selected channels. The self-diagnosis cannot be used with the temperature sensor output or with the internal reference voltage.

- (1) When the ADSHMSR.SHMD bit is set to 1, the sample-and-hold circuit selected in the ADSHCR.SHANS[2:0] bits starts constant sampling.
- (2) Analog input sampling of all channels for which the channel-dedicated sample-and-hold circuits are to be used is started when the ADCSR.ADST bit is set to 1 (starting A/D conversion) by software, or synchronous or asynchronous trigger input. After setting the ADSHMSR.SHMD bit to 1 and 750 ns minimum are elapsed, set the ADCSR.ADST bit to 1.
- (3) When the stabilizing time for the sample-and-hold circuit is elapsed, A/D conversion by self-diagnosis is started.
- (4) When A/D conversion for self-diagnosis is completed, A/D conversion result is stored into the A/D self-diagnosis data register (ADRD), A/D conversion is performed for the analog channels selected in the ADANSA0 and ADANSA1 registers according to the order of conversion specified in the ADSCSn register. To use the channel-dedicated sample-and-hold circuit, set the corresponding channel in any of the ADSCS0, ADSCS1, or ADSCS2 register.
- (5) Each time A/D conversion of a single channel is completed, the A/D-converted value is stored in the corresponding A/D data register (ADDRy), the sample-and-hold circuit resumes constant sampling.
- (6) When A/D conversion of all the selected channels is completed, a scan end interrupt request is generated if the ADCSR.ADIE bit is 1 (scan end interrupt is enabled).
- (7) The ADCSR.ADST bit remains 1 (starting A/D conversion) during A/D conversion, and is automatically cleared to 0 when A/D conversion of all the selected channels is completed. Then the 12-bit A/D converter enters a wait state. When a single scan is performed in sequence, set the time of constant sampling of the sample-and-hold circuit to 400 ns or longer (when allowable impedance of the source of the enabling signal is 1 k $\Omega$ ).
- (8) When the ADSHMSR.SHMD bit is cleared to 0, the sample-and-hold circuit stops.

**Figure 38.17 Example of Operation in Single Scan Mode (Channel-Dedicated Sample-and-Hold Circuits Used; AN000, AN002 Selected + Self-Diagnosis, with Constant Sampling Enabled)**

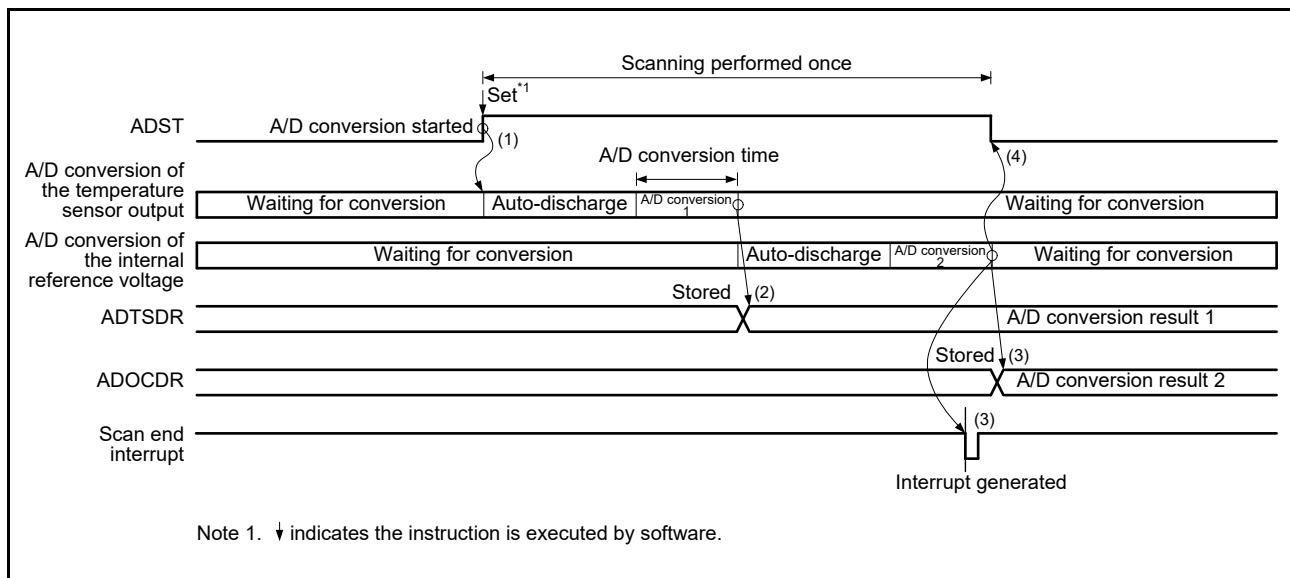

### 38.3.4.7 A/D Conversion with Temperature Sensor Output/Internal Reference Voltage Selected

When temperature sensor output or internal reference voltage is selected with channels, A/D conversion is performed only once for the temperature sensor output or for internal reference voltage as described below.

When the temperature sensor output and internal reference voltage are both selected, A/D conversion is performed for the temperature sensor output first and then for internal reference voltage.

Selecting the temperature sensor output and internal reference voltage simultaneously for analog input is prohibited.

- (1) When the ADCSR.ADST bit becomes 1 (starting A/D conversion) by software, or synchronous or asynchronous trigger input, auto-discharging and A/D conversion is performed in this order for the temperature sensor output.
- (2) When A/D conversion of the temperature sensor output is completed, the A/D-converted value is stored in the corresponding A/D temperature sensor data register (ADTSDR), and then, auto-discharging and A/D conversion is performed in this order for the internal reference voltage.
- (3) After completion of A/D conversion of the internal reference voltage, the A/D-converted value is stored in the corresponding A/D internal reference voltage data register (ADOCDR), a scan end interrupt request is generated if the ADCSR.ADIE bit is 1 (scan end interrupt is enabled).
- (4) The ADCSR.ADST bit remains 1 (starting A/D conversion) during A/D conversion, and is automatically cleared to 0 when A/D conversion of all the selected channels is completed. Then the 12-bit A/D converter enters a wait state.

**Figure 38.18 Example of Operation in Single Scan Mode (Basic Operation: Temperature Sensor Output and Internal Reference Voltage Selected)**

### 38.3.4.8 A/D Conversion in Double Trigger Mode

In single scan mode with double trigger mode, single scan operation started by synchronous trigger is performed twice as below.

Deselect self-diagnosis and set the temperature sensor A/D conversion select bit (ADEXICR.TSSA, ADEXICR.TSSB, ADGCEXCR.TSSC) and internal reference voltage A/D conversion select bit (ADEXICR.OCOSA, ADEXICR.OCOSB, ADGCEXCR.OCOSC) to 0.

Duplication of A/D conversion data is enabled by setting the channel numbers to be duplicated to the ADCSR.DBLANS[4:0] bits and setting the ADCSR.DBLE bit to 1. When the ADCSR.DBLE bit is set to 1, channel selection using the ADANSA0 and ADANSA1 registers is invalid. In double trigger mode, synchronous triggers should be selected using the ADSTRGR.TRSA[5:0] bits, the ADCSR.EXTRG bit should be set to 0, and the ADCSR.TRGE bit should be set to 1. Software trigger should not be used.

- (1) When the ADCSR.ADST bit becomes 1 (starting A/D conversion) by synchronous trigger input, A/D conversion is started on the single channel selected by the ADCSR.DBLANS[4:0] bits.
- (2) When A/D conversion is completed, the A/D conversion result is stored into the corresponding A/D data register (ADDRy).
- (3) The ADCSR.ADST bit is automatically cleared to 0 and the 12-bit A/D converter enters a wait state. Here, a scan end interrupt request is not generated irrespective of the ADCSR.ADIE bit setting (scan end interrupt is enabled).
- (4) When the ADCSR.ADST bit is set to 1 (starting A/D conversion) by the second trigger input, A/D conversion is started on the single channel selected by the ADCSR.DBLANS[4:0] bits.
- (5) When A/D conversion is completed, the A/D conversion result is stored into the A/D data duplication register (ADDBLDR).
- (6) A scan end interrupt request is generated if the ADCSR.ADIE bit is 1 (scan end interrupt is enabled).
- (7) The ADCSR.ADST bit remains 1 (starting A/D conversion) during A/D conversion, and is automatically cleared to 0 when A/D conversion is completed. Then the 12-bit A/D converter enters a wait state.

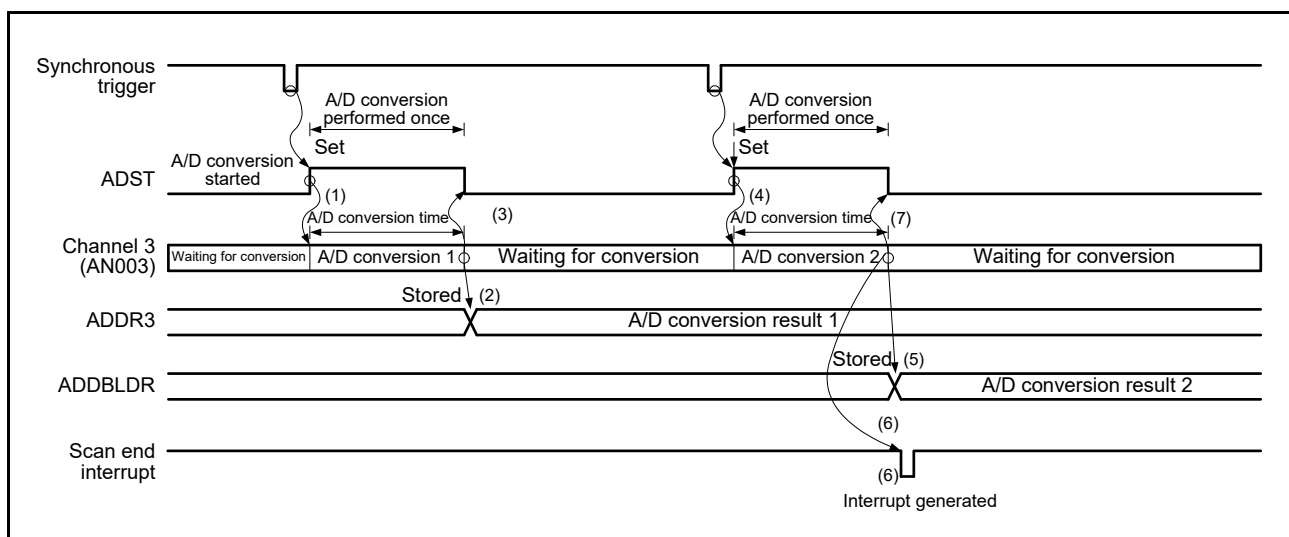

Figure 38.19 Example of Operation in Single Scan Mode (Double Trigger Mode Selected; AN003 Duplicated)

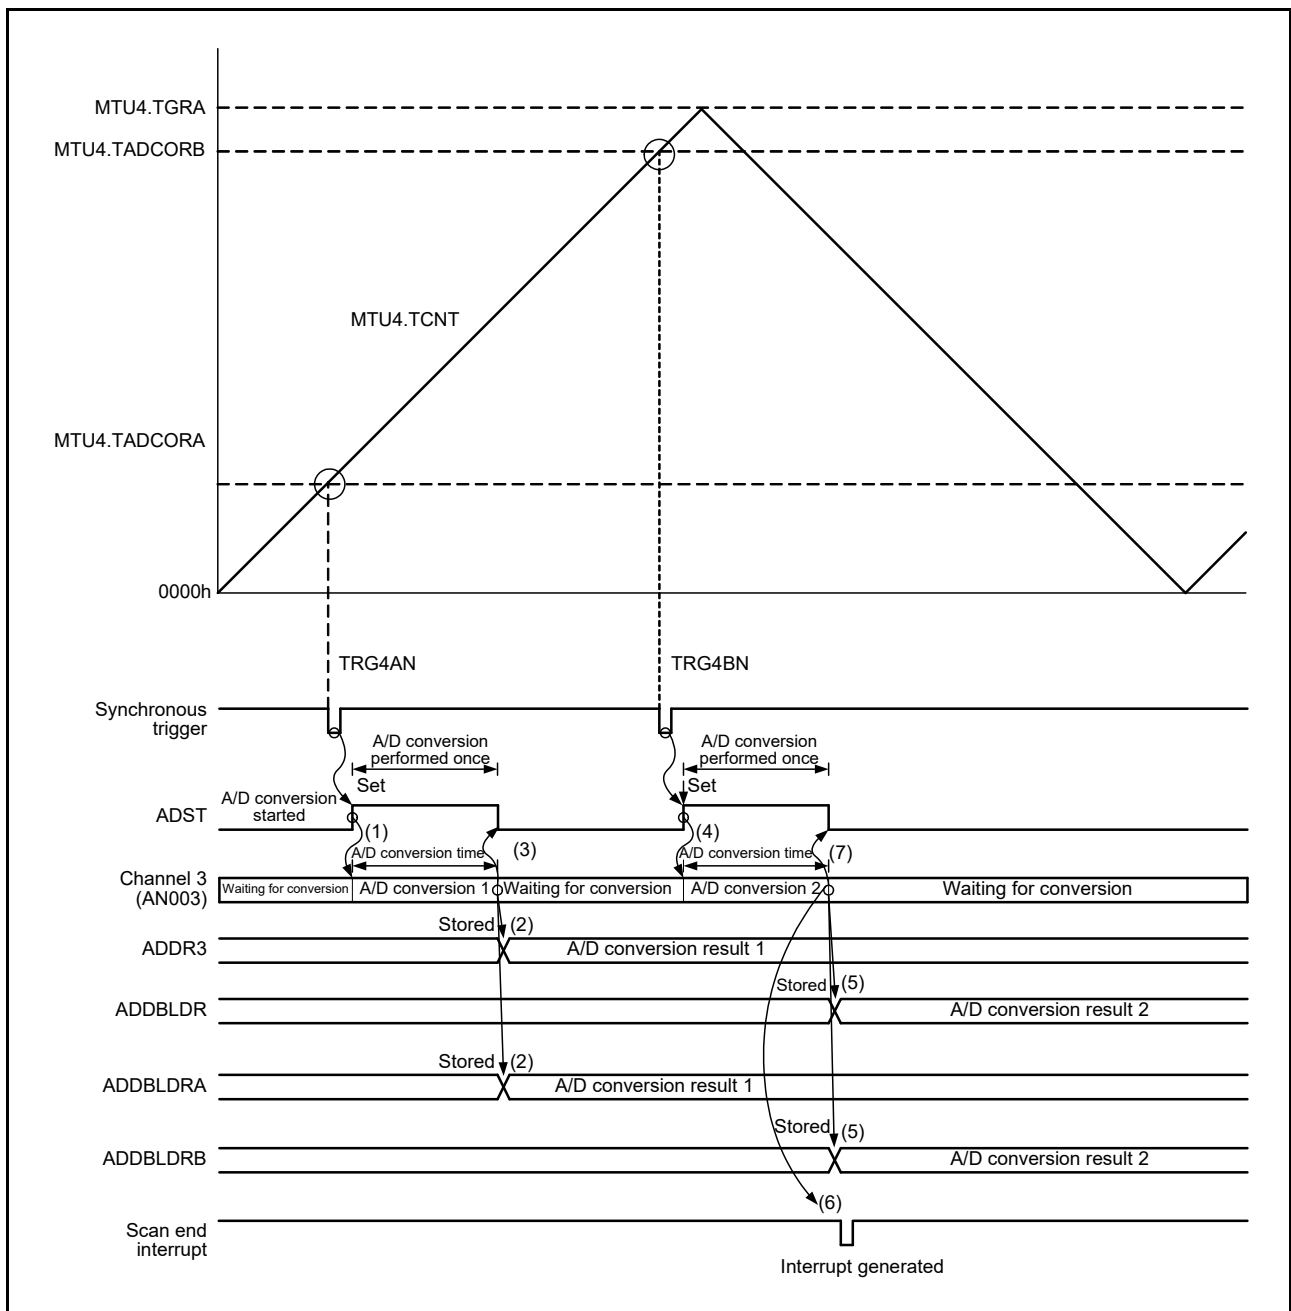

### 38.3.4.9 A/D Conversion in Extended Double Trigger Mode

When selecting the double-trigger mode in single-scanning mode, with TRG4AN or TRG4BN, TRG7AN or TRG7BN, TRGA0N or TRG0N, TRGA9N or TRG9N, TRGA0N or TRGA9N, TRG0N or TRG9N, or ELCTRG00N or ELCTRG01N/ELCTRG10N or ELCTRG11N/ELCTRG20N or ELCTRG21N selected in the TRSA[5:0] bits of the A/D conversion start trigger select register (ADSTRGR), proceed with single scanning mode twice as follows.

Deselect self-diagnosis and set the temperature sensor A/D conversion select bit (ADEXICR.TSSA, ADEXICR.TSSB, ADGCEXCR.TSSC) and internal reference voltage A/D conversion select bit (ADEXICR.OCSA, ADEXICR.OCSB, ADGCEXCR.OCSC) to 0.

Duplication of A/D conversion data is enabled by setting the channel numbers to be duplicated to the ADCSR.DBLANS[4:0] bits and setting the ADCSR.DBLE bit to 1. When the ADCSR.DBLE bit is set to 1, channel selection using the ADANSA0 and ADANSA1 registers is invalid. In extended double trigger mode, the ADCSR.EXTRG bit should be set to 0, and the ADCSR.TRGE bit should be set to 1. Software trigger should not be used.

- (1) When the ADCSR.ADST bit is set to 1 (starting A/D conversion) by TRG4AN input, A/D conversion is started on the single channel selected by the ADCSR.DBLANS[4:0] bits.
- (2) When A/D conversion is completed, the A/D conversion result is stored into the corresponding A/D data register (ADDRy) and A/D data duplication register A (ADDBLDRA).
- (3) The ADCSR.ADST bit is automatically cleared to 0 and the 12-bit A/D converter enters a wait state. Here, a scan end interrupt request is not generated irrespective of the ADCSR.ADIE bit setting (scan end interrupt is enabled).
- (4) When the ADCSR.ADST bit is set to 1 (starting A/D conversion) by TRG4BN input, A/D conversion is started on the single channel selected by the ADCSR.DBLANS[4:0] bits.
- (5) When A/D conversion is completed, the A/D conversion result is stored into A/D data duplication register (ADDBLDR) and A/D data duplication register B (ADDBLDRB).
- (6) A scan end interrupt request is generated if the ADCSR.ADIE bit is 1 (scan end interrupt is enabled).
- (7) The ADCSR.ADST bit remains 1 (starting A/D conversion) during A/D conversion, and is automatically cleared to 0 when A/D conversion is completed. Then the 12-bit A/D converter enters a wait state.

**Figure 38.20 Example of Extended Operation in Double Trigger Mode (1)**  
**(Duplication Selected for AN003, TRG4AN or TRG4BN Selected, First Trigger is TRG4AN)**

### 38.3.5 Continuous Scan Mode

#### 38.3.5.1 Basic Operation (Without Channel-Dedicated Sample and-Hold Circuits)

In basic operation of continuous scan mode, A/D conversion is performed repeatedly on the analog input of the specified channels as below.

In continuous scan mode, specify A/D conversion select bits for the temperature sensor and for the internal reference voltage to deselect respectively.

- (1) When the ADCSR.ADST bit is set to 1 (starting A/D conversion) by software, or synchronous or asynchronous trigger input, A/D conversion is performed for the analog channels selected in the ADANSA0 and ADANSA1 registers according to the order of conversion specified in the ADSCSn register. (Specified conversion order in Figure 38.21: AN000 → AN001 → AN002)
- (2) Each time A/D conversion of a single channel is completed, the A/D conversion result is stored into the corresponding A/D data register (ADDRy).
- (3) When A/D conversion of all the selected channels is completed, a scan end interrupt request is generated if the ADCSR.ADIE bit is 1 (scan end interrupt is enabled).  
The 12-bit A/D converter sequentially starts A/D conversion for the analog channels selected in the ADANSA0 and ADANSA1 registers according to the order of conversion specified in the ADSCSn register.
- (4) The ADCSR.ADST bit is not automatically cleared and steps (2) and (3) are repeated as long as the bit remains 1 (starting A/D conversion). When the ADCSR.ADST bit is set to 0 (stopping A/D conversion), A/D conversion stops and the 12-bit A/D converter enters a wait state.
- (5) When the ADCSR.ADST bit is later set to 1 (starting A/D conversion), A/D conversion starts again for the analog channels selected in the ADANSA0 and ADANSA1 registers according to the order of conversion specified in the ADSCSn register.

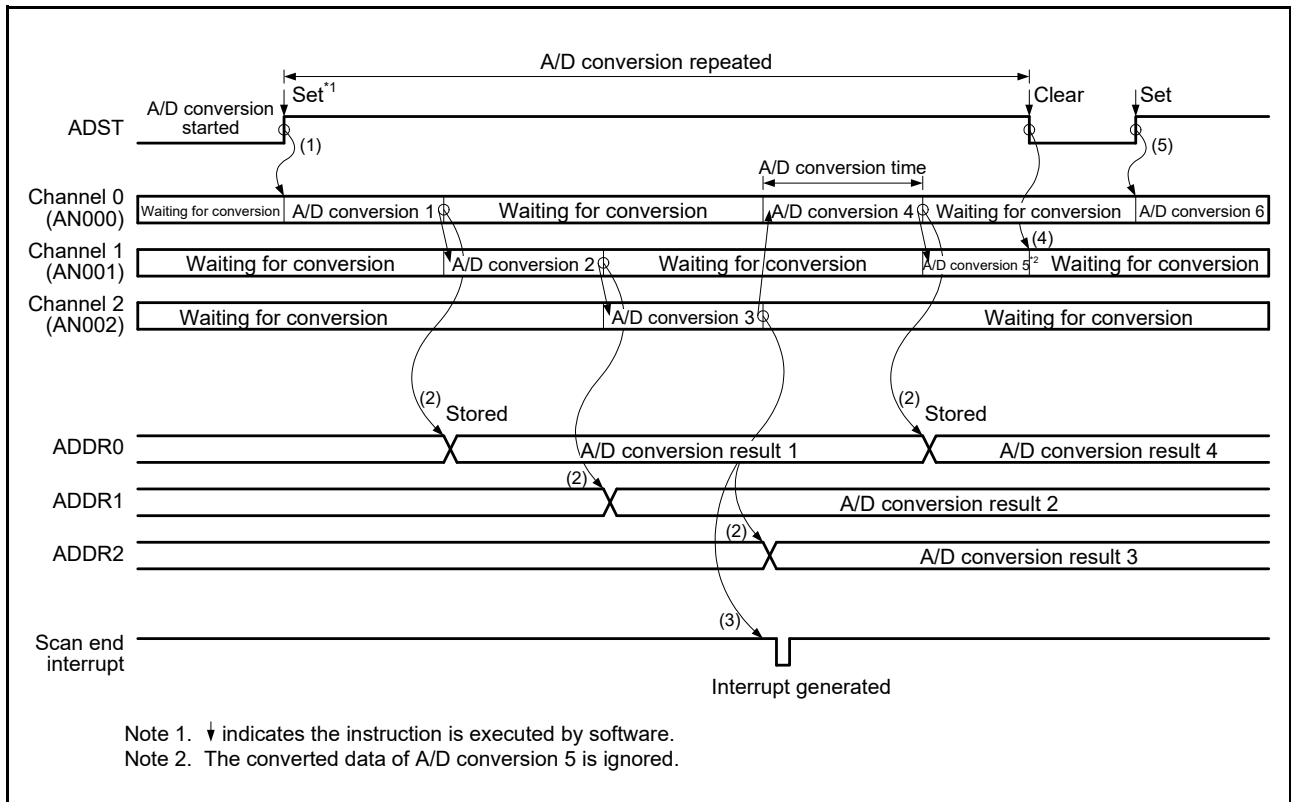

Figure 38.21 Example of Operation in Continuous Scan Mode (Basic Operation: AN000 to AN002 Selected)

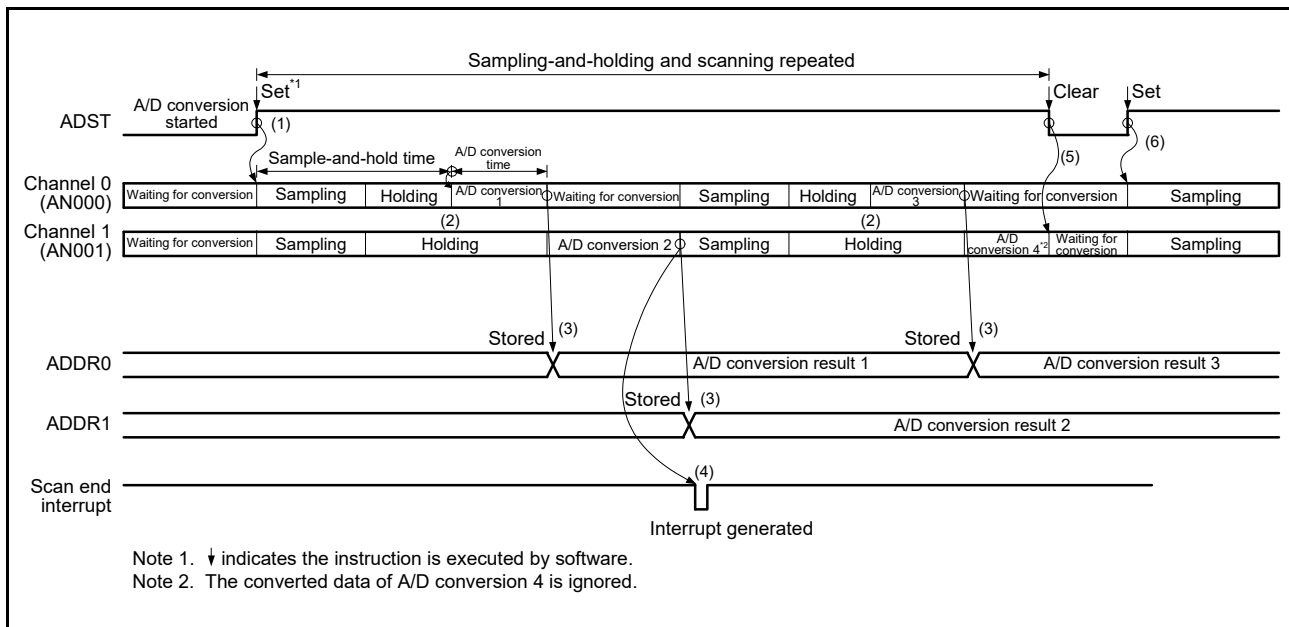

### 38.3.5.2 Basic Operation (with Channel-Dedicated Sample-and-Hold Circuits, with Constant Sampling Disabled)

When a channel-dedicated sample-and-hold circuit is used, sample-and-hold operations are performed first and A/D conversion is repeated for analog input of all selected channels as described below. The ADShCR.SHANS[2:0] bits are used to select the channels for which the channel-dedicated sample-and-hold circuits are to be used.

In continuous scan mode, specify A/D conversion select bits for the temperature sensor and for the internal reference voltage to deselect respectively.

- (1) Analog input sampling of all channels for which the channel-dedicated sample-and-hold circuits are to be used is started when the ADCSR.ADST bit is set to 1 (starting A/D conversion) by software, synchronous trigger input, or asynchronous trigger input.
- (2) After sample-and-hold operation, A/D conversion is performed for the analog channels selected in the ADANSA0 and ADANSA1 registers according to the order of conversion specified in the ADSCSn register. To use the channel-dedicated sample-and-hold circuit, set the corresponding channel in any of the ADSCS0, ADSCS1, or ADSCS2 register.
- (3) Each time A/D conversion of a single channel is completed, the result of A/D conversion is stored in the corresponding A/D data register (ADDRy).
- (4) When A/D conversion of all the selected channels is completed, a scan end interrupt request is generated if the ADCSR.ADIE bit is 1 (scan end interrupt is enabled). At the same time, analog input sampling is started for all the channels for which the channel-dedicated sample-and-hold circuits are to be used.
- (5) The ADCSR.ADST bit is not automatically cleared and steps (2) to (4) are repeated as long as the bit remains 1. When the ADCSR.ADST bit is set to 0 (stopping A/D conversion), A/D conversion stops and the 12-bit A/D converter enters a wait state.
- (6) When the ADCSR.ADST bit is then set to 1 (starting A/D conversion), analog input sampling is started again for all the channels for which the channel-dedicated sample-and-hold circuits are to be used.

**Figure 38.22 Example of Operation in Continuous Scan Mode (Channel-Dedicated Sample-and-Hold Circuits Used, AN000/AN001 Selected, with Constant Sampling Disabled)**

### 38.3.5.3 Basic Operation (with Channel Sample-and-Hold Circuits, with Constant Sampling Enabled)

When constant sampling is enabled and a channel sample-and-hold circuit is used, sample-and-hold operations are performed first and A/D conversion is repeated for analog input of all selected channels as described below.

The ADSHCR.SHANS[2:0] bits are used to select the channels for which the channel-dedicated sample-and-hold circuits are to be used.

In continuous scan mode, specify A/D conversion select bits for the temperature sensor and for the internal reference voltage to deselect respectively.

- (1) When the ADSHMSR.SHMD bit is set to 1, the sample-and-hold circuit selected in the ADSHCR.SHANS[2:0] bits starts constant sampling.
- (2) Analog input sampling of all channels for which the channel-dedicated sample-and-hold circuits are to be used is started when the ADCSR.ADST bit is set to 1 (starting A/D conversion) by software, or synchronous or asynchronous trigger input. After setting the ADSHMSR.SHMD bit to 1 and 750 ns minimum are elapsed, set the ADCSR.ADST bit to 1.
- (3) When the stabilizing time for the sample-and-hold circuit is elapsed, A/D conversion is performed for the analog channels selected in the ADANSA0 and ADANSA1 registers according to the order of conversion specified in the ADSCSn register. To use the channel-dedicated sample-and-hold circuit, set the corresponding channel in any of the ADSCS0, ADSCS1, or ADSCS2 register.
- (4) Each time A/D conversion of a single channels is completed, the A/D-converted value is stored in the corresponding A/D data register (ADDRy), the sample-and-hold circuit resumes constant sampling.
- (5) After completion of A/D conversion of all selected channels, a scan end interrupt request is generated if the ADCSR.ADIE bit is 1 (scan end interrupt is enabled). In addition, all channels that use channel sample-and-hold circuit start holding of analog inputs.
- (6) The ADCSR.ADST bit is not automatically cleared and steps (3) to (5) are repeated as long as the bit remains 1. When the ADCSR.ADST bit is set to 0 (stopping A/D conversion), A/D conversion is stopped and the 12-bit A/D converter enters into a wait state.
- (7) When the ADSHMSR.SHMD bit is cleared to 0, the sample-and-hold circuit stops.
- (8) After that, when the ADSHMSR.SHMD bit is set to 1, the sample-and-hold circuit selected in the ADSHCR.SHANS[2:0] bits starts constant sampling.
- (9) When the ADCSR.ADST bit is set to 1 (starting A/D conversion), all channels that uses sample-and-hold circuit starts holding analog inputs.

**Note:** If only a channel with a channel-dedicated sample-and-hold circuit is selected and continuous scanning is performed, securing a period for normal sampling will not be possible in the second and subsequent rounds of continuous scanning. To proceed with scanning continuously while the sample-and-hold circuit is enabled, select at least one channel from AN003 to AN007 and set the period for constant sampling of the sample-and-hold circuit to at least 400 ns.

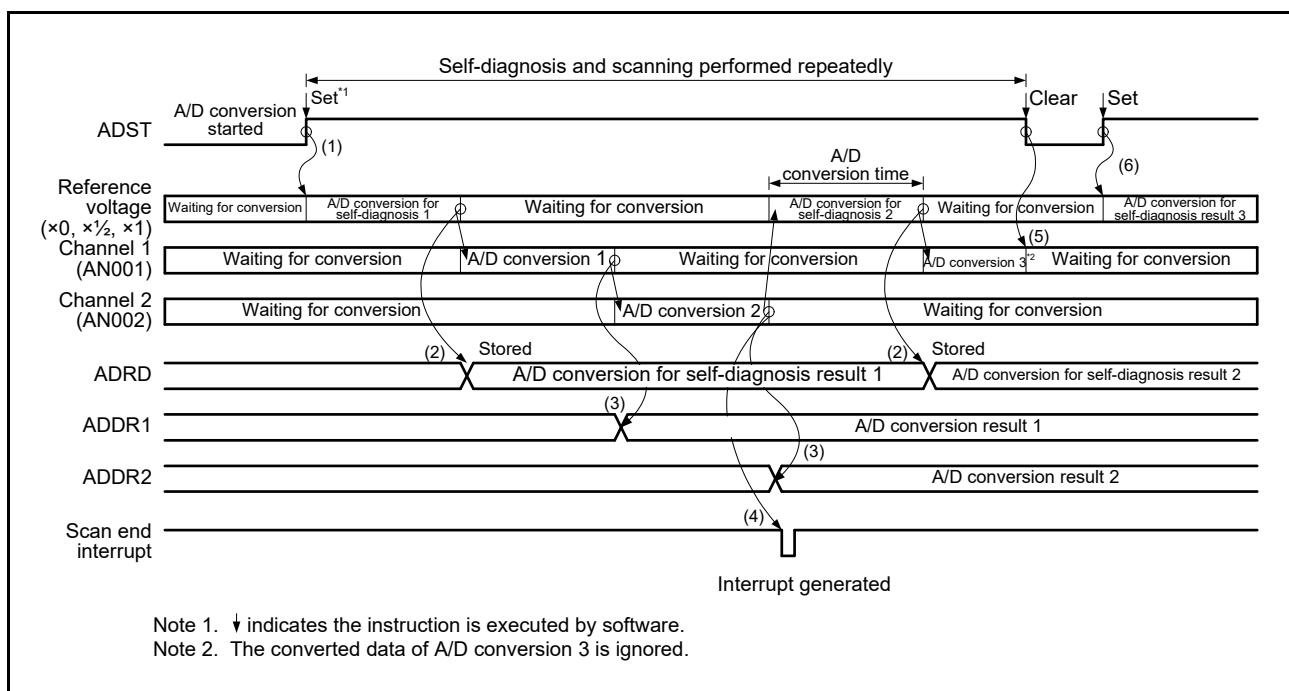

**Figure 38.23 Example of Operation in Continuous Scan Mode (Channel-Dedicated Sample-and-Hold Circuits Used: AN000, AN001, and AN003 Selected, with Constant Sampling Enabled)**

### 38.3.5.4 Channel Selection and Self-Diagnosis (Without Channel-Dedicated Sample-and-Hold Circuits)

When channels and self-diagnosis are selected at the same time, A/D conversion is first performed for the reference voltage supplied to the 12-bit A/D converter, and then A/D conversion is performed on the analog input of the selected channels, which sequence is repeated as below.

- (1) When the ADCSR.ADST bit is set to 1 (starting A/D conversion) by software, or synchronous or asynchronous trigger input, A/D conversion for self-diagnosis is started first.
- (2) When A/D conversion for self-diagnosis is completed, A/D conversion result is stored into the A/D self-diagnosis data register (ADRD), A/D conversion is performed for the analog channels selected in the ADANSA0 and ADANSA1 registers according to the order of conversion specified in the ADSCSn register.
- (3) Each time A/D conversion of a single channel is completed, the A/D conversion result is stored into the corresponding A/D data register (ADDRy).
- (4) When A/D conversion of all the selected channels is completed, a scan end interrupt request is generated if the ADCSR.ADIE bit is 1 (scan end interrupt is enabled). At the same time, the 12-bit A/D converter starts A/D conversion for self-diagnosis, and, upon its completion, starts A/D conversion for the analog channels selected in the ADANSA0 and ADANSA1 registers according to the order of conversion specified in the ADSCSn register.
- (5) The ADCSR.ADST bit is not automatically cleared and steps (2) to (4) are repeated as long as the bit remains 1.
- When the ADST bit is set to 0 (stopping A/D conversion), A/D conversion stops and the 12-bit A/D converter enters a wait state.
- (6) When the ADCSR.ADST bit is later becomes 1 (starting A/D conversion), the A/D conversion for self-diagnosis is started again.

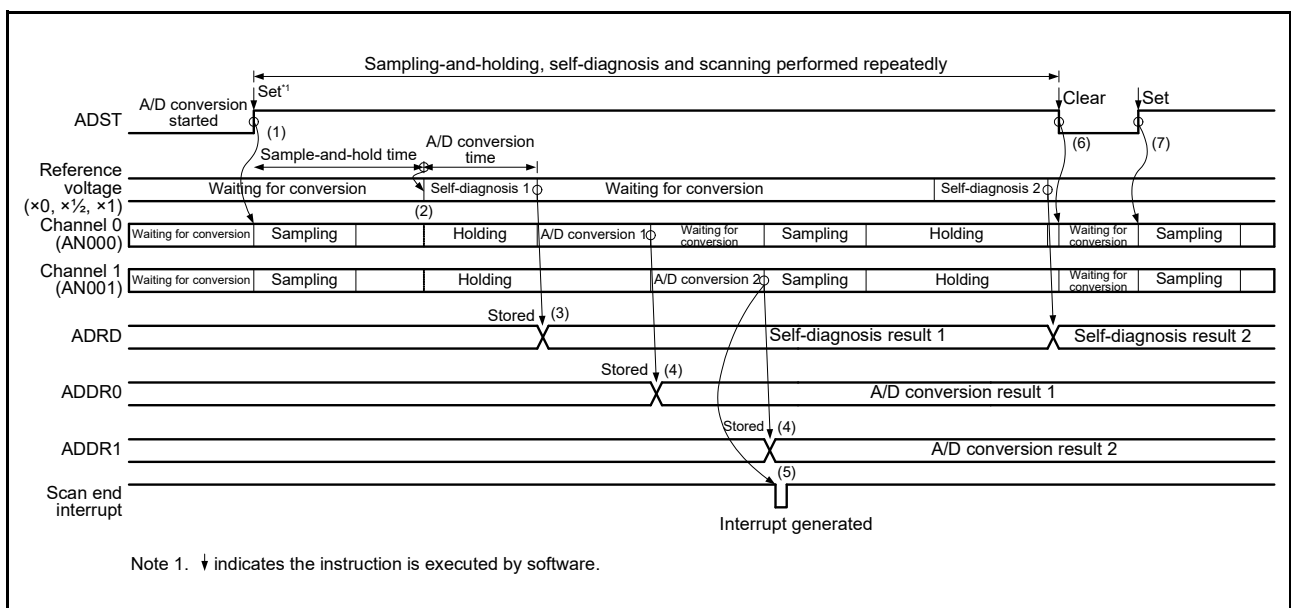

**Figure 38.24 Example of Operation in Continuous Scan Mode (Basic Operation; AN001 and AN002 Selected + Self-Diagnosis)**

### 38.3.5.5 Channel Selection and Self-Diagnosis (with Channel-Dedicated Sample-and-Hold Circuits, with Constant Sampling Disabled)

When channels and self-diagnosis are selected and a channel-dedicated sample-and-hold circuit is used, sample-and-hold operations are performed first, and A/D conversion is performed for the reference voltage supplied to the 12-bit A/D converter as below. After that, A/D conversion is performed repeatedly on the analog input of the selected channels. In continuous scan mode, specify A/D conversion select bits for the temperature sensor and for the internal reference voltage to deselect respectively.

- (1) Analog input sampling of all channels for which the channel-dedicated sample-and-hold circuits are to be used is started when the ADCSR.ADST bit is set to 1 (starting A/D conversion) by software, or synchronous or asynchronous trigger input.
- (2) A/D conversion for self-diagnosis is started after completion of sampling and holding.
- (3) When A/D conversion for self-diagnosis is completed, A/D conversion result is stored into the A/D self-diagnosis data register (ADRD), A/D conversion is performed for the analog channels selected in the ADANSA0 and ADANSA1 registers according to the order of conversion specified in the ADSCSn register. To use the channel-dedicated sample-and-hold circuit, set the corresponding channel in any of the ADSCS0, ADSCS1, or ADSCS2 register.
- (4) Each time A/D conversion of a single channel is completed, the A/D conversion result is stored into the corresponding A/D data register (ADDRy).
- (5) When A/D conversion of all the selected channels is completed, a scan end interrupt request is generated if the ADCSR.ADIE bit is 1 (scan end interrupt is enabled). At the same time, analog input sampling is started for all the channels for which the channel-dedicated sample-and-hold circuits are to be used.
- (6) The ADCSR.ADST bit is not automatically cleared and steps (2) to (5) are repeated as long as the ADCSR.ADST bit as long as the bit remains 1. When the ADCSR.ADST bit is set to 0 (stopping A/D conversion), A/D conversion stops and the 12-bit A/D converter enters a wait state.
- (7) When the ADCSR.ADST bit is later becomes 1 (starting A/D conversion), the A/D conversion for self-diagnosis is started again.

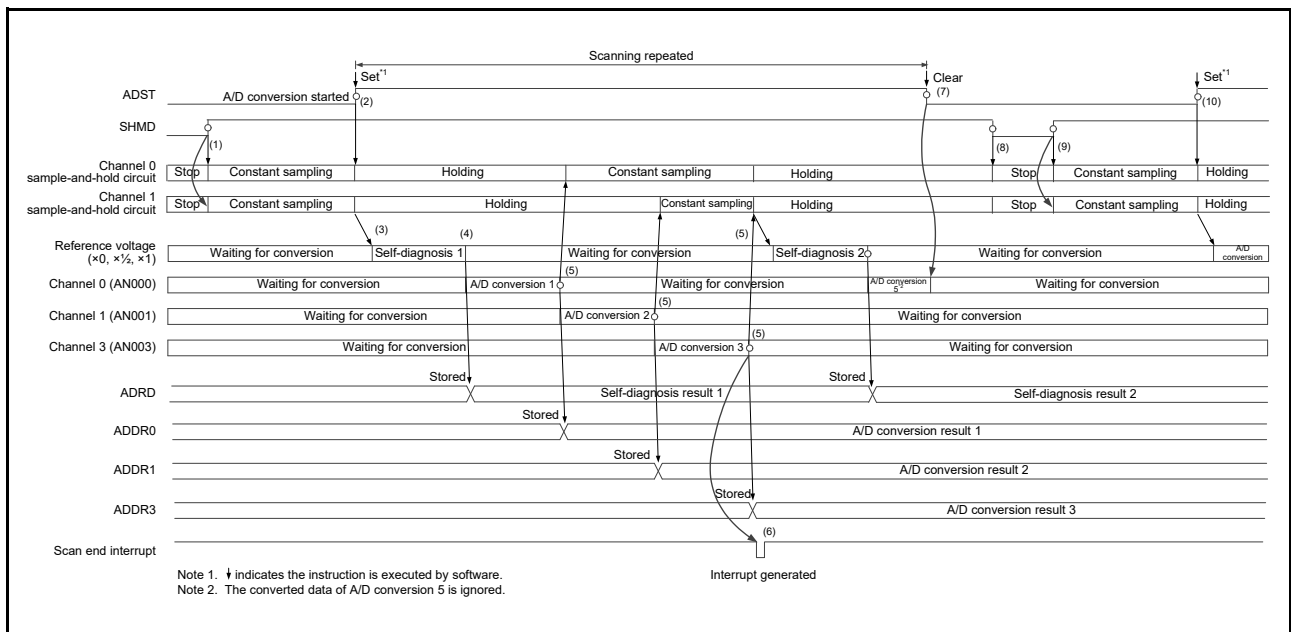

**Figure 38.25 Example of Operation in Continuous Scan Mode (Channel-Dedicated Sample-and-Hold Circuits Used: AN000 and AN001 Selected + Self-Diagnosis)**

### 38.3.5.6 Channel Selection and Self-Diagnosis (with Channel-Dedicated Sample-and-Hold Circuits, with Constant Sampling Enabled)

When self-diagnosis is selected with channels and a channel-dedicated sample-and-hold circuit is used with constant sampling enabled, sample-and-hold operations are performed first and A/D conversion is performed for the reference voltage to be supplied to the 12-bit A/D converter as described below. After that, A/D conversion is performed repeatedly on the analog input of the selected channels.

- (1) When the ADSHMSR.SHMD bit is set to 1, the sample-and-hold circuit selected in the ADSHCR.SHANS[2:0] bits starts constant sampling.
- (2) Analog input sampling of all channels for which the channel-dedicated sample-and-hold circuits are to be used is started when the ADCSR.ADST bit is set to 1 (starting A/D conversion) by software, or synchronous or asynchronous trigger input. After setting the ADSHMSR.SHMD bit to 1 and 750 ns minimum are elapsed, set the ADCSR.ADST bit to 1.
- (3) When the stabilizing time for the sample-and-hold circuit is elapsed, A/D conversion by self-diagnosis is started.
- (4) When A/D conversion for self-diagnosis is completed, A/D conversion result is stored into the A/D self-diagnosis data register (ADDRD), A/D conversion is performed for the analog channels selected in the ADANSA0 and ADANSA1 registers according to the order of conversion specified in the ADSCSn register. To use the channel-dedicated sample-and-hold circuit, set the corresponding channel in any of the ADSCS0, ADSCS1, or ADSCS2 register.
- (5) Each time A/D conversion of a single channels is completed, the A/D-converted value is stored in the corresponding A/D data register (ADDRy), the sample-and-hold circuit resumes constant sampling.
- (6) After completion of A/D conversion of all selected channels, if the ADCSR.ADIE bit is set to 1 (scan end interrupt is enabled), a scan end interrupt request is generated. In addition, all channels that use channel sample-and-hold circuit start holding of analog inputs.
- (7) The ADCSR.ADST bit is not automatically cleared and steps (3) to (6) are repeated as long as the bit remains 1. When the ADCSR.ADST bit is set to 0 (stopping A/D conversion), A/D conversion is stopped and the 12-bit A/D converter enters into a wait state.
- (8) When the ADSHMSR.SHMD bit is cleared to 0, the sample-and-hold circuit stops.
- (9) After that, when the ADSHMSR.SHMD bit is set to 1, the sample-and-hold circuit selected in the ADSHCR.SHANS[2:0] bits starts constant sampling.
- (10) When the ADCSR.ADST bit is set to 1 (starting A/D conversion), all channels that uses sample-and-hold circuit starts holding analog inputs.

**Note:** If only a channel with a channel-dedicated sample-and-hold circuit is selected and continuous scanning is performed, securing a period for normal sampling will not be possible in the second and subsequent rounds of continuous scanning. To proceed with scanning continuously while the sample-and-hold circuit is enabled, select at least one channel from AN003 to AN007 and set the period for constant sampling of the sample-and-hold circuit to at least 400 ns.

**Figure 38.26 Example of Operation in Continuous Scan Mode (Channel-Dedicated Sample-and-Hold Circuits Used: AN000, AN001, and AN003 Selected + Self-Diagnosis, with Constant Sampling Enabled)**

## 38.3.6 Group Scan Mode

### 38.3.6.1 Basic Operation

Either two (groups A and B) or three (groups A, B, and C) can be selected as the number of the groups to be used in group scan mode.

In basic operation of group scan mode, A/D conversion is performed once on the analog inputs of all the specified channels in groups A and B, or groups A, B, and C after scan is started by a synchronous trigger as below. Scan operation of each group is similar to the scan operation in single scan mode.

The synchronous triggers of groups A, B, and C can be selected using the TRSA[5:0] and TRSB[5:0] bits in the ADSTRGR register, and the ADGCTRGR.TRSC[5:0] bits, respectively. Different triggers should be used for each group A, B, and C so that scanning of groups A, B, and C does not occur simultaneously. Software trigger should not be used. The channels to be scanned are selected using registers ADANSA0 and ADANSA1 and bits TSSA and OCSA in register ADEXICR for group A, registers ADANSB0 and ADANSB1 and bits TSSB and OCSB in register ADEXICR for group B, and registers ADANSC0 and ADANSC1 and bits TSSC and OCSC in register ADGCXCR for group C.

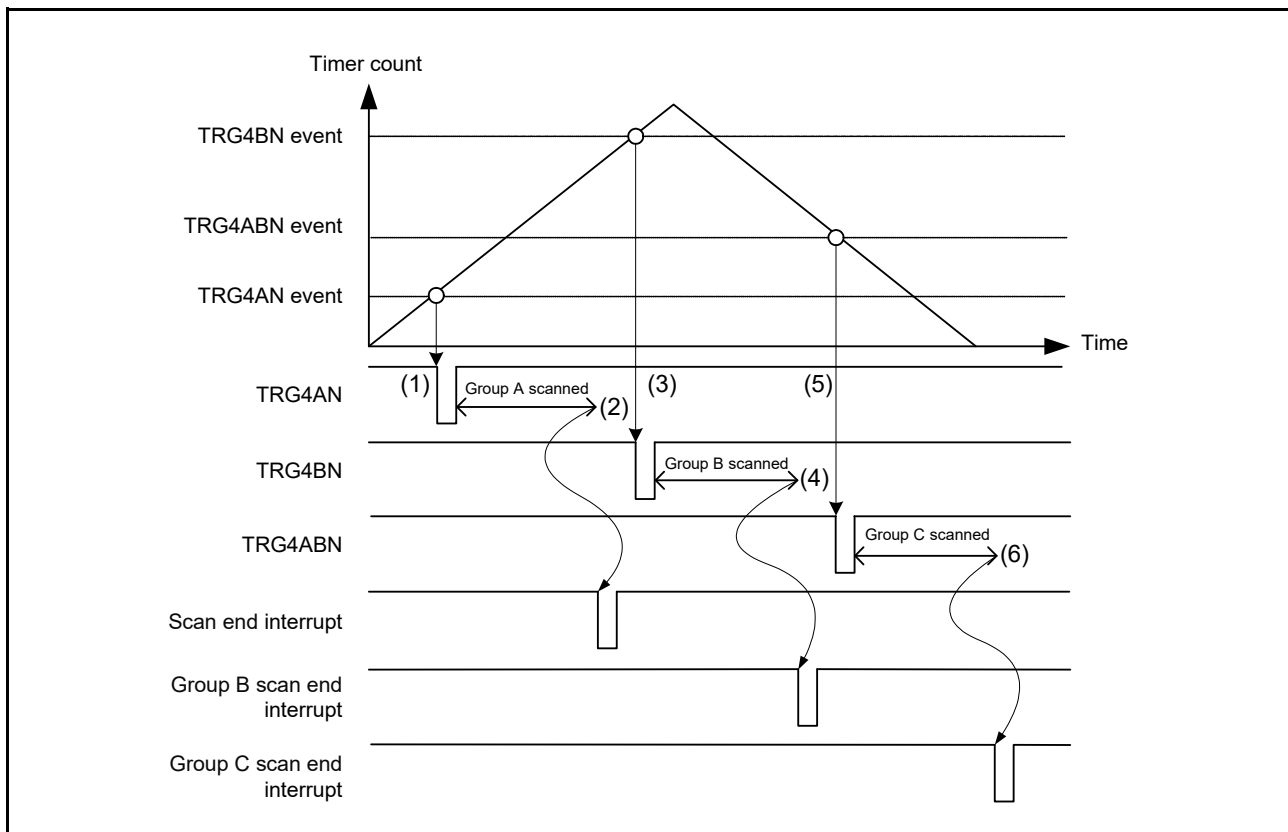

When the temperature sensor output is to be scanned, set only one from among the TSSA, TSSB, and TSSC bits to 1. In the same way, when the internal reference voltage is to be scanned, set only one from among the OCSA, OCSB, and OCSC bits to 1. Discharging for a period of 15 ADCLK is performed for all the conversion channels in a scan group where the temperature sensor output or the internal reference voltage is set.

When self-diagnosis is selected in group scan mode, self-diagnosis is separately executed for groups A and B, or groups A, B, and C.

The following describes operation in group scan mode using a trigger from the MTU. The TRG4AN, TRG4BN, and TRG4ABN triggers from the MTU are assumed to be used to start conversion of groups A, B and C, respectively.

- (1) Scanning of group A is started by the TRG4AN trigger from the MTU.
- (2) When group A scanning is completed, a scan end interrupt is generated if the ADCSR.ADIE bit is 1 (scan end interrupt is enabled).
- (3) Scanning of group B is started by the TRG4BN trigger from the MTU.
- (4) When group B scanning is completed, a group B scan end interrupt is generated if the ADCSR.GBADIE bit is 1 (group B scan end interrupt is enabled).
- (5) Scanning of group C is started by the TRG4ABN trigger from the MTU.
- (6) When group C scanning is completed, a group C scan end interrupt is generated if the ADGCTRGR.GCADIE bit is 1 (group C scan end interrupt is enabled).

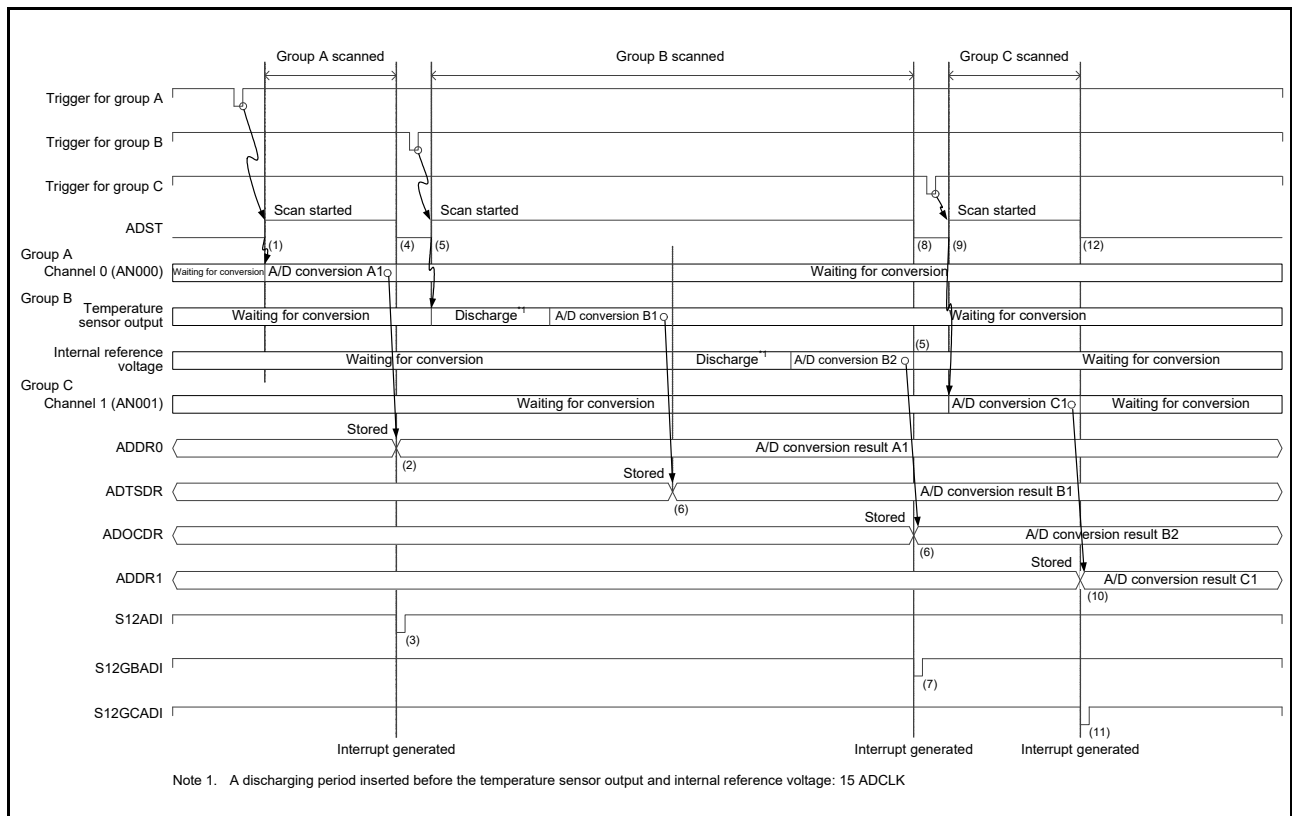

**Figure 38.27 Example of Operation in Group Scan Mode  
(Basic Operation: Synchronous Triggers from MTU Used)**

The following describes operation using the temperature sensor output or the internal reference voltage (in group scan mode and not in group priority operation).

The operation is based on a setting: channel 0 to be A/D-converted for group A, the temperature sensor output and internal reference voltage to be A/D-converted for group B, and channel 1 to be A/D-converted for group C.

- (1) When input of the group A trigger signal sets the ADCSR.ADST bit to 1 (starting A/D conversion), scan for group A starts.
- (2) Start A/D conversion for channel 0, and on its completion, the A/D-converted value is stored in the corresponding A/D data register (ADDR0).
- (3) A scan end interrupt is generated if the ADCSR.ADIE bit is set to 1 (scan end interrupt is enabled).
- (4) The ADCSR.ADST bit is automatically cleared to 0 when scan for group A is completed, and the 12-bit A/D converter enters a wait state.
- (5) When input of the group B trigger signal sets the ADCSR.ADST bit to 1 (starting A/D conversion), scan for group B starts.
- (6) Before A/D-converting the temperature sensor output, 15 ADCLK is inserted as a discharging period. After a completion of the discharging period, A/D conversion for the temperature sensor output starts, and the A/D-converted value is stored in the corresponding A/D data register (ADTSDR) upon completion of A/D conversion. Next, before A/D-converting the internal reference voltage, 15 ADCLK is inserted as a discharging period. After a completion of the discharging period, A/D conversion for the internal reference voltage starts, and the A/D-converted value is stored in the corresponding A/D data register (ADOCDR) upon completion of A/D conversion.
- (7) Group B scan end interrupt is output if the ADCSR.GBADIE bit is set to 1 (group B scan end interrupt is enabled).
- (8) The ADCSR.ADST bit is automatically cleared to 0 when scan for group B is completed, and the 12-bit A/D converter enters a wait state.

- (9) When input of the group C trigger signal sets the ADCSR.ADST bit to 1 (starting A/D conversion), scan for group C starts.
- (10) Start A/D conversion for channel 1, and on its completion, the A/D-converted value is stored in the corresponding A/D data register (ADDR1).
- (11) Group C scan end interrupt is output if the ADGCTRGR.GCADIE bit is set to 1 (group C scan end interrupt is enabled).
- (12) The ADCSR.ADST bit is automatically cleared to 0 when scan for group C is completed, and the 12-bit A/D converter enters a wait state.

**Figure 38.28 Operation When Using the Temperature Sensor Output and the Internal Reference Voltage (in Group Scan Mode and Not in Group Priority Operation)**

### 38.3.6.2 A/D Conversion in Double Trigger Mode

When double trigger mode is selected in group scan mode, two rounds of single scan operation started by a synchronous trigger are performed as a sequence for group A. For groups B and C, single scan operation started by a synchronous trigger is performed once.

In group scan mode, the synchronous triggers of groups A, B, and C can be selected using the TRSA[5:0] and TRSB[5:0] bits in the ADSTRGR register, and the ADGCTRGR.TRSC[5:0] bits, respectively. Different triggers should be used for each group A, B, and C so that scanning of groups A, B, and C does not occur simultaneously. Software trigger and asynchronous trigger should not be used. When TRG4AN or TRG4BN, TRG7AN or TRG7BN, TRGA0N or TRG0N, TRGA9N or TRG9N, TRGA0N or TRGA9N, TRG0N or TRG9N, or ELCTRG00N or ELCTRG01N/ELCTRG10N or ELCTRG11N/ELCTRG20N or ELCTRG21N is selected as the synchronous trigger of group A by the ADSTRGR.TRSA[5:0] bits, operation is performed in extended double trigger mode.

The channels to be scanned are selected using bits ADCSR.DBLANS[4:0] for group A, registers ADANSB0 and ADANSB1 for group B, and registers ADANSC0 and ADANSC1 for group C.

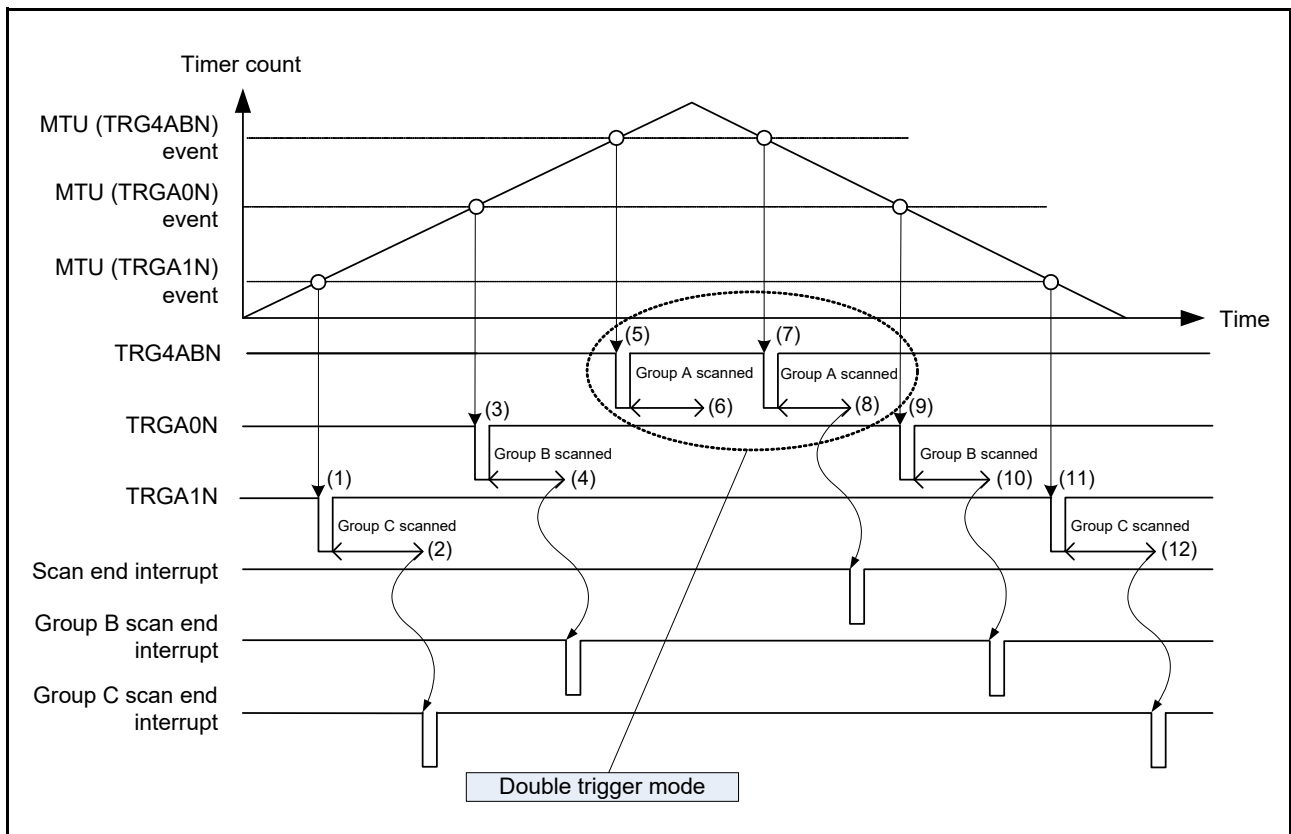

When double trigger mode is selected in group scan mode, the temperature sensor A/D conversion select bit (ADEXICR.TSSA) and internal reference voltage A/D conversion select bit (ADEXICR.OCSA) are set to 0 (not selected).

When double trigger mode is selected in group scan mode, self-diagnosis cannot be selected.

Duplication of A/D conversion data is enabled by setting the channel numbers to be duplicated to the ADCSR.DBLANS[4:0] bits and setting the ADCSR.DBLE bit to 1.

The following describes operation in group scan mode with double trigger mode using a synchronous trigger from the MTU. The TRG4ABN, TRGA0N, and TRGA1N triggers from the MTU are assumed to be used to start conversion of groups A, B, and C, respectively.

- (1) Scanning of group C is started by the TRGA1N trigger from the MTU.
- (2) When group C scanning is completed, a group C scan interrupt is generated if the ADGCTRGR.GCADIE bit is 1 (group C scan end interrupt is enabled).
- (3) Scanning of group B is started by the TRGA0N trigger from the MTU.
- (4) When group B scanning is completed, a group B scan end interrupt is generated if the ADCSR.GBADIE bit is 1 (group B scan end interrupt is enabled).
- (5) The first scanning of group A is started by the first TRG4ABN trigger from the MTU.
- (6) When the first scanning of group A is completed, the conversion result is stored into the corresponding A/D data register (ADDRy); a scan end interrupt request is not generated irrespective of the ADCSR.ADIE bit setting.
- (7) The second scanning of group A is started by the second TRG4ABN trigger from the MTU.
- (8) When the second scanning of group A is completed, the conversion result is stored into the ADDBLDR register a scan end interrupt is generated if the ADCSR.ADIE bit is 1 (scan end interrupt is enabled).
- (9) The second scanning of group B is started by the second TRGA0N trigger from the MTU.
- (10) When the second scanning of group B is completed, a group B scan end interrupt is generated if the ADCSR.GBADIE bit is 1 (group B scan end interrupt is enabled).
- (11) The second scanning of group C is started by the second TRGA1N trigger from the MTU.
- (12) When the second scanning of group C is completed, a group C scan end interrupt is generated if the ADGCTRGR.GCADIE bit is 1 (group C scan end interrupt is enabled).

**Figure 38.29** Example of Operation in Group Scan Mode with Double Trigger Mode  
(Basic Operation: Synchronous Triggers from MTU Used)

### 38.3.6.3 Operation under Group Priority Control

Setting the ADGSPCR.PGS bit to 1 in group scan mode makes operation proceed under group priority control. The group priority order is group A > group B > group C. Either two (groups A and B) or three (groups A, B, and C) can be selected as the number of the groups to be used in group scan mode. When setting the ADGSPCR.PGS bit to 1, follow the procedure described in Figure 38.30. If the procedure is not followed, proper scanning operation and data storage are not guaranteed.

In basic operation of group scan mode, if group A, B, or C is scanning, all other trigger inputs are ignored. Under group priority control, if a priority group trigger is input during A/D conversion for the low-priority group, A/D conversion for the low-priority group is interrupted and A/D conversion for the priority group proceeds.

If the ADGSPCR.GBRSCN bit is 0, the converter enters a wait state for the low-priority group on completion of the A/D conversion for the priority group.

The trigger input for the low-priority group during scanning is ignored.

If the ADGSPCR.GBRSCN bit is 1, the converter automatically restarts scanning for the low-priority group from the head of the group after A/D conversion for the priority group.

Also, the trigger input for the low-priority group generated during scanning for the priority group is enabled, and the converter automatically restarts scanning for the low-priority group after scanning for the priority group.

When the ADGSPCR.LGRRS bit is 0 while the ADGSPCR.GBRSCN bit is 1, the converter restarts scanning for the low-priority group from the head of the group. When the ADGSPCR.LGRRS bit is 1, the converter restarts scanning for the low-priority group from the channel on which scanning is interrupted.

However, when self-diagnosis is used, the converter restarts scanning from the channel on which scanning is interrupted after self-diagnosis is completed.

Table 38.22 summarizes operations in response to the input of a trigger during scanning with the settings of the ADGSPCR.GBRSCN bit.

When the ADGSPCR.GBRP bit is set to 1, scanning operations for the group of the lowest priority are continuously performed in single scan mode.

For the trigger settings in group scan mode, select a synchronous trigger for group A using the ADSTRGR.TRSA[5:0] bits, select a synchronous trigger different from that of group A for group B using the ADSTRGR.TRSB[5:0] bits, and select a synchronous trigger different from those of groups A and B for group C using the ADGCTRGR.TRSC[5:0] bits. Set the ADSTRGR.TRSB[5:0] bits to 3Fh when setting group scan mode for two groups (the ADGCTRGR.GRCE bit to 0) and setting the ADGSPCR.GBRP bit to 1.

Set the ADGCTRGR.TRSC[5:0] bits to 3Fh when setting group scan mode for three groups (the ADGCTRGR.GRCE bit to 1) and setting the ADGSPCR.GBRP bit to 1.

Furthermore, as targets for scanning, select channels for group A by using the ADANSA0 and ADANSA1 registers, and the ADEXICR.TSSA and ADEXICR.OCSA bits; select the group B channels by using the ADANSB0 and ADANSB1 registers, and the ADEXICR.TSSB and ADEXICR.OCSB bits; and select the group C by using the ADANSC0 and ADANSC1 registers, and the ADGCEXCR.TSSC and ADGCEXCR.OCS bits respectively.

Figure 38.30 Flow of Setting the ADGSPCR.PGS Bit

**Table 38.22 Control of Scanning Operations According to the Settings of the ADGSPCR.GBRSCN Bit**

| Scanning Operation                             | Trigger Input                | ADGSPCR.GBRSCN = 0                                                                       | ADGSPCR.GBRSCN = 1                                                                                                                                                                                                               |
|------------------------------------------------|------------------------------|------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| When A/D conversion for group A is in progress | Input of trigger for group A | Trigger input is ineffective.                                                            | Trigger input is ineffective.                                                                                                                                                                                                    |
|                                                | Input of trigger for group B | Trigger input is ineffective.                                                            | A/D conversion is performed on group B after A/D conversion on group A is completed.                                                                                                                                             |
|                                                | Input of trigger for group C | Trigger input is ineffective.                                                            | A/D conversion is performed on group C after A/D conversion on group A is completed.                                                                                                                                             |
| When A/D conversion for group B is in progress | Input of trigger for group A | A/D conversion in progress for group B interrupted and conversion for group A starts.    | <ul style="list-style-type: none"> <li>A/D conversion in progress for group B is interrupted and conversion for group A starts.</li> <li>A/D conversion for group B starts after conversion for group A is completed.</li> </ul> |
|                                                | Input of trigger for group B | Trigger input is ineffective.                                                            | Trigger input is ineffective.                                                                                                                                                                                                    |
|                                                | Input of trigger for group C | Trigger input is ineffective.                                                            | A/D conversion is performed on group C after A/D conversion on group B is completed.                                                                                                                                             |
| When A/D conversion for group C is in progress | Input of trigger for group A | A/D conversion in progress for group C interrupted and conversion for group A starts.    | <ul style="list-style-type: none"> <li>A/D conversion in progress for group C is interrupted and conversion for group A starts.</li> <li>A/D conversion for group C starts after conversion for group A is completed.</li> </ul> |
|                                                | Input of trigger for group B | A/D conversion in progress for group C is interrupted and conversion for group B starts. | <ul style="list-style-type: none"> <li>A/D conversion in progress for group C is interrupted and conversion for group B starts.</li> <li>A/D conversion for group C starts after conversion for group B is completed.</li> </ul> |
|                                                | Input of trigger for group C | Trigger input is ineffective.                                                            | Trigger input is ineffective.                                                                                                                                                                                                    |

When using group priority operation mode, refer to the following tables to select the desirable operating mode and set the registers.

**Table 38.23 Group Priority Operation Setting and Operating Mode for Two Groups (ADGSPCR.PGS = 1, ADGCTRGR.GRCE = 0)**

| ADGSPCR |       |      |                                                                                                                                                                                                                                                                                                                                                                                               |

After group C scan is interrupted, single scan is restarted from the channel on which scan was interrupted*1, among the channels selected with the ADANSC0 and ADANSC1 registers after scan for groups A and B is completed.</li> </ul> |

x = Don't care

Note 1. When self-diagnosis is used (ADCER.DIAGM = 1), A/D conversion of the interrupted channel is started after self-diagnosis.

(1) Group Priority Operation for Two Groups (ADGSPCR.PGS = 1, ADGCTRGR.GRCE = 0)

The following examples 1 to 5 show group priority operation in group scan mode (ADGSPCR.GBRSCN = 1, ADGSPCR.GBRP = 0, ADGSPCR.LGRRS = 0) when channel 0 is selected for group A and channels 1 to 3 are selected for group B.

**Operation example 1: Input of the group A trigger signal during a group B scan, with the rescan setting**

- (1) When input of the group B trigger signal sets the ADCSR.ADST bit to 1 (starting A/D conversion), A/D conversion starts for the analog channels selected in the ADANSB0 and ADANSB1 registers according to the order of conversion specified in the ADSCSn register. (Specified conversion order in Figure 38.31: AN000 → AN001 → AN002 → AN003)
- (2) On completion of A/D conversion on a single channel, the result is stored in the corresponding A/D data register (ADDRy).
- (3) When a group A trigger is input during the group B scanning, the ADCSR.ADST bit retains the value as 1, and the group B scan is interrupted, and the group A scan starts for the analog channels selected in the ADANSA0 and ADANSA1 registers according to the order of conversion specified in the ADSCSn register.
- (4) On completion of A/D conversion on a single channel, the result is stored in the corresponding A/D data register (ADDRy).
- (5) A scan end interrupt request is generated if the ADCSR.ADIE bit is 1 (scan end interrupt is enabled).
- (6) When the ADGSPCR.GBRSCN bit is set to 1 (restarting a group scan which was interrupted due to group priority in scanning), the ADCSR.ADST bit retains the value as 1, and the group B scan for the analog channels selected in the ADANSB0 and ADANSB1 registers according to the order of conversion specified in the ADSCSn register is restarted.
- (7) On completion of A/D conversion on a single channel, the result is stored in the corresponding A/D data register (ADDRy).
- (8) A group B scan end interrupt request is generated if the ADCSR.GBADIE bit is 1 (group B scan end interrupt is enabled).
- (9) The ADCSR.ADST bit is automatically cleared to 0 when scan of all selected channels is completed, and the 12-bit A/D converter enters a wait state.

**Figure 38.31 Example 1 of Group Priority Operation: Input of Group A Trigger Signal During Group B Scan, with the Rescan Setting (ADGSPCR.GBRSCN = 1, ADGSPCR.GBRP = 0, ADGSPCR.LGRRS = 0)**

**Operation example 2: Input of the group A trigger signal during a group B rescan, with the rescan setting**

Figure 38.32 shows an example when a group A trigger is input during rescan operation on group B.

If a group A trigger is input, scan for group A starts even while rescan operation is in progress. Scan for group B starts after scan for group A is completed.

Operations of the ADCSR.ADST bit, storing to the A/D conversion result in the A/D data register (ADDRy), and interrupt requests are the same as example 1.

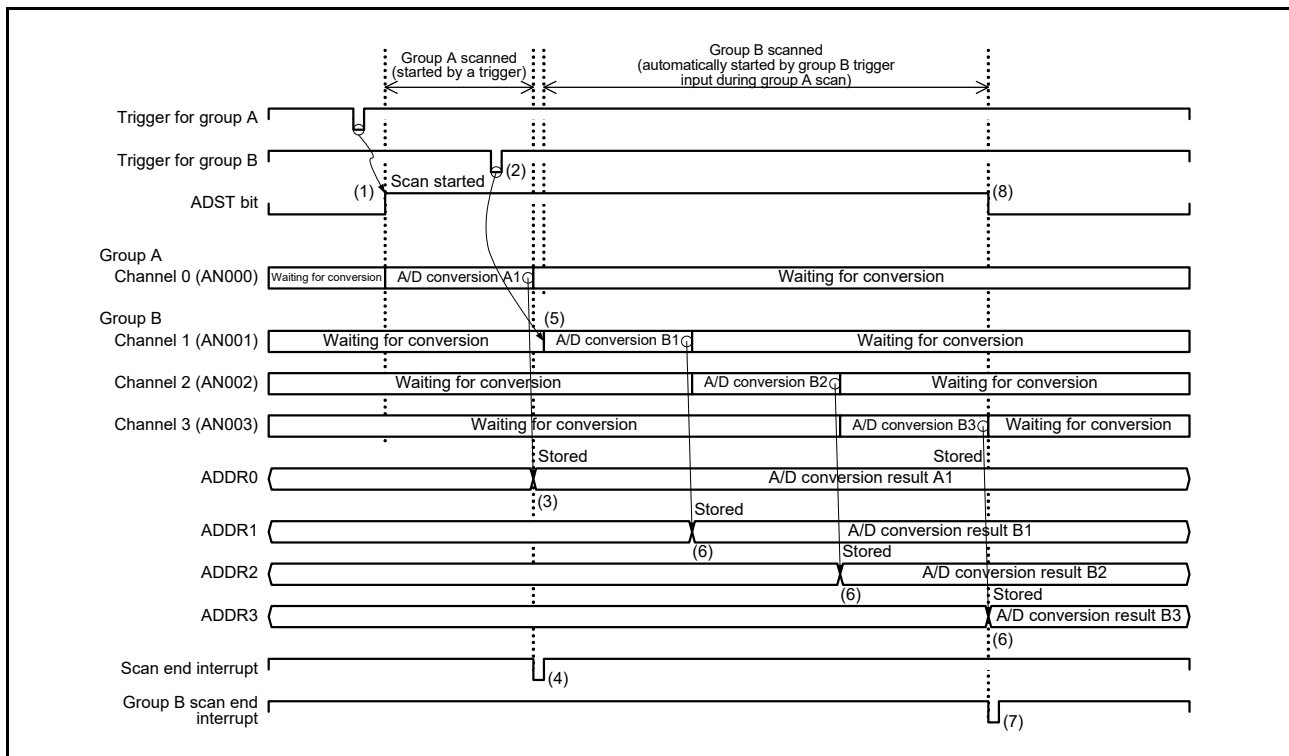

**Figure 38.32 Example 2 of Group Priority Operation: Input of Group A Trigger Signal During Group B Rescan, with the Rescan Setting (ADGSPCR.GBRSCN = 1, ADGSPCR.GBRP = 0, ADGSPCR.LGRRS = 0)**

**Operation example 3: Input of the group B trigger signal during a group A scan, with the rescan setting**

The following describes an example when a group B trigger is input during scan operation on group A when the ADGSPCR.GBRSCN bit is 1 (scan for the group is restarted after having been interrupted due to group priority operation).

If the ADGSPCR.GBRSCN bit is 0, all group B triggers that are input during scan operation on group A are disabled.

- (1) When input of the group A trigger signal sets the ADCSR.ADST bit to 1 (starting A/D conversion), a group A scan starts for the analog channels selected in the ADANSA0 and ADANSA1 registers according to the order of conversion specified in the ADSCSn register.
- (2) When a group B trigger is input during a group A scanning, a group B becomes ready for a scan.
- (3) Each time A/D conversion of a single channel is completed, the A/D conversion result is stored into the corresponding A/D data register (ADDRy).
- (4) After scan for group A is completed, a scan end interrupt request is generated if the ADCSR.ADIE bit is 1 (scan end interrupt is enabled).
- (5) After the group A scan ends, the ADCSR.ADST bit retains the value as 1, and the group B scan is started for the analog channels selected in the ADANSB0 and ADANSB1 registers according to the order of conversion specified in the ADSCSn register.  
(When a group A trigger is input during the group B scanning, the group A scan is started in the same way as in the example 1, and the group B scan is restarted after the group A scan ends.)
- (6) Each time A/D conversion of a single channel is completed, the A/D conversion result is stored into the corresponding A/D data register (ADDRy).
- (7) After scan for group B is completed, a group B scan end interrupt request is generated if the ADCSR.GBADIE bit is 1 (group B scan end interrupt is enabled).
- (8) The ADCSR.ADST bit is automatically cleared to 0 when scan of all selected channels is completed, and the 12-bit A/D converter enters a wait state.

**Figure 38.33 Example 3 of Group Priority Operation: Input of Group B Trigger Signal During Group A Scan, with the Rescan Setting (ADGSPCR.GBRSCN = 1, ADGSPCR.GBRP = 0, ADGSPCR.LGRRS = 0)**

Operation example 4 shows group priority operation in group scan mode (ADGSPCR.GBRSCN = 0, ADGSPCR.GBRP = 0, ADGSPCR.LGRRS = 0) when channel 0 is selected for group A and channels 1 to 3 are selected for group B.

**Operation Example 4 Input of the group A trigger signal during a group B scan, without the rescan setting**

- (1) When input of the group B trigger signal sets the ADCSR.ADST bit to 1 (starting A/D conversion), a group B scan starts for the analog channels selected in the ADANSB0 and ADANSB1 registers according to the order of conversion specified in the ADSCSn register.
- (2) Each time A/D conversion of a single channel is completed, the A/D conversion result is stored into the corresponding A/D data register (ADDRy).
- (3) When a group A trigger is input during the group B scanning, the ADCSR.ADST bit retains the value as 1, and the group B scan is interrupted, and the group A scan starts for the analog channels selected in the ADANSA0 and ADANSA1 registers according to the order of conversion specified in the ADSCSn register.
- (4) Each time A/D conversion of a single channel is completed, the A/D conversion result is stored into the corresponding A/D data register (ADDRy).
- (5) After scan for group A is completed, a scan end interrupt request is generated if the ADCSR.ADIE bit is 1 (scan end interrupt is enabled).
- (6) The ADCSR.ADST bit is automatically cleared to 0 when scan for group A is completed, and the 12-bit A/D converter enters a wait state. Scan for group B is not started until the next group B trigger is input.

**Figure 38.34 Example 4 of Group Priority Operation: Input of Group A Trigger Signal During Group B Scan, Without the Rescan Setting (ADGSPCR.GBRSCN = 0, ADGSPCR.GBRP = 0, ADGSPCR.LGRRS = 0)**

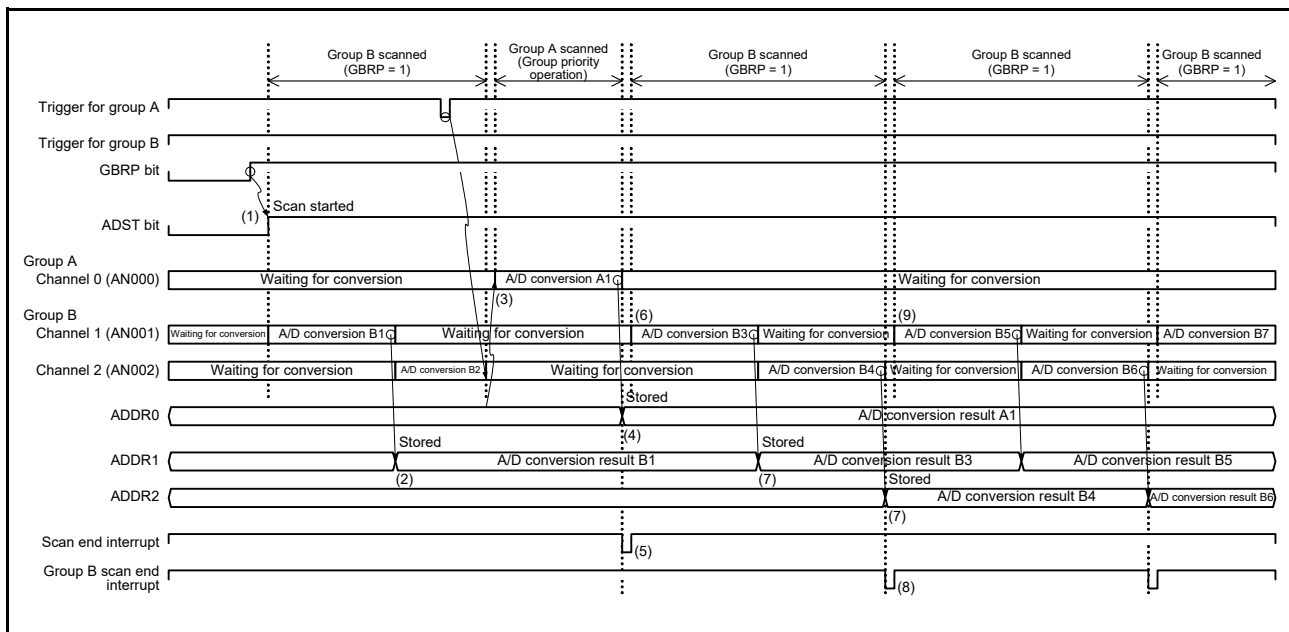

Operation example 5 shows group priority operation in group scan mode (ADGSPCR.GBRSCN = 1, ADGSPCR.GBRP = 1, ADGSPCR.LGRRS = 0) when channel 0 is selected for group A and channels 1 and 2 are selected for group B. When the ADGCTRGR.GRCE bit is set to 1, single scan mode is continuously operated on group C and scan for group B is started by trigger input.

#### Operation example 5: Continuous single scan operation on group B

- (1) When the ADGSPCR.GBRP bit is set to 1, the ADCSR.ADST bit is set to 1 (starting A/D conversion), and a group B scan is started for the analog channels selected in the ADANSB0 and ADANSB1 registers according to the order of conversion specified in the ADSCSn register.
- (2) Each time A/D conversion of a single channel is completed, the A/D conversion result is stored into the corresponding A/D data register (ADDRy).
- (3) When a group A trigger is input during the group B scanning, the ADCSR.ADST bit retains the value as 1, and the group B scan is interrupted, and the group A scan starts for the analog channels selected in the ADANSA0 and ADANSA1 registers according to the order of conversion specified in the ADSCSn register.
- (4) Each time A/D conversion of a single channel is completed, the A/D conversion result is stored into the corresponding A/D data register (ADDRy).
- (5) After scan for group A is completed, a scan end interrupt request is generated if the ADCSR.ADIE bit is 1 (scan end interrupt is enabled).
- (6) When the ADGSPCR.GBRP bit is set to 1 (selecting continuous single scanning), the ADCSR.ADST bit retains the value as 1, and the group B scan for the analog channels selected in the ADANSB0 and ADANSB1 registers according to the order of conversion specified in the ADSCSn register is restarted.
- (7) Each time A/D conversion of a single channel is completed, the A/D conversion result is stored into the corresponding A/D data register (ADDRy).
- (8) A group B scan end interrupt request is generated if the ADCSR.GBADIE bit is 1 (group B scan end interrupt is enabled).
- (9) When the ADGSPCR.GBRP bit is set to 1 (selecting continuous single scanning), the ADCSR.ADST bit retains the value as 1, and the group B scan for the analog channels selected in the ADANSB0 and ADANSB1 registers according to the order of conversion specified in the ADSCSn register is restarted.

To continuously operate single scan for group B, disable trigger input for group B.

Steps (6) to (9) are repeated as long as the ADGSPCR.GBRP bit remains 1. Clearing of the ADCSR.ADST bit to 0 is prohibited while the ADGSPCR.GBRP bit is set to 1. To forcibly stop scanning when ADGSPCR.GBRP = 1, follow the procedures for clear operation by software through the ADCSR.ADST bit shown in section 38.6.2, Notes on Stopping A/D Conversion.

**Figure 38.35 Example 5 for Group Priority Operation: Continuous Single Scan Operation on Group B (ADGSPCR.GBRP = 1, ADGSPCR.LGRRS = 1, ADGCTRGR.GRCE = 0)**

**(2) Group Priority Operation for Three Groups (ADGSPCR.PGS = 1, ADGCTRGR.GRCE = 1)**

The following examples 1 to 5 show group priority operation in group scan mode (ADGSPCR.GBRSCN = 1, ADGSPCR.GBRP = 0, ADGSPCR.LGRRS = 1) when channel 0 is selected for group A, channels 1 and 2 are selected for group B, and channels 3 and 4 are selected for group C.

The priority groups mean groups A and B for group C and group A for group B.

**Operation example 1: Priority group trigger input during low-priority group scan, with the rescan setting**

- (1) When input of the group C trigger signal sets the ADCSR.ADST bit to 1 (starting A/D conversion), the group C scan starts for the analog channels selected in the ADANSC0 and ADANSC1 registers according to the order of conversion specified in the ADSCSn register.
- (2) Each time A/D conversion of a single channel is completed, the A/D conversion result is stored into the corresponding A/D data register (ADDRy).
- (3) When a group B trigger is input during the group C scanning, the ADCSR.ADST bit retains the value as 1, the group C scan is interrupted, and the group B scan starts for the analog channels selected in the ADANSB0 and ADANSB1 registers according to the order of conversion specified in the ADSCSn register. The A/D conversion result is not stored into the corresponding data register (ADDRy) if A/D conversion is not completed when the scan is interrupted.
- (4) Each time A/D conversion of a single channel is completed, the A/D conversion result is stored into the corresponding A/D data register (ADDRy).
- (5) When a group A trigger is input during the group B scanning, the ADCSR.ADST bit retains the value as 1, and the group B scan is interrupted, and the group A scan starts for the analog channels selected in the ADANSA0 and ADANSA1 registers according to the order of conversion specified in the ADSCSn register. The A/D conversion result is not stored into the corresponding data register (ADDRy) if A/D conversion is not completed when the scan is interrupted.
- (6) Each time A/D conversion of a single channel is completed, the A/D conversion result is stored into the corresponding A/D data register (ADDRy).
- (7) A scan end interrupt request is generated if the ADCSR.ADIE bit is 1 (scan end interrupt is enabled).
- (8) When the ADGSPCR.GBRSCN bit is set to 1 (restarting a group scan which was interrupted due to group priority in scanning), the ADCSR.ADST bit retains the value as 1, and the group B scan for the analog channels selected in the ADANSB0 and ADANSB1 registers according to the order of conversion specified in the ADSCSn register is restarted. At this time, the group B scan is restarted from the channel that the A/D conversion was interrupted if the ADGSPCR.LGRRS bit is set to 1.
- (9) Each time A/D conversion of a single channel is completed, the A/D conversion result is stored into the corresponding A/D data register (ADDRy).
- (10) A group B scan end interrupt request is generated if the ADCSR.GBADIE bit is 1 (group B scan end interrupt is enabled).
- (11) When the ADGSPCR.GBRSCN bit is set to 1, the ADCSR.ADST bit retains the value as 1, the group C scan for the analog channels selected in the ADANSC0 and ADANSC1 registers according to the order of conversion specified in the ADSCSn register is restarted. At this time, the group C scan is restarted from the channel that the A/D conversion was interrupted if the ADGSPCR.LGRRS bit is set to 1.
- (12) Each time A/D conversion of a single channel is completed, the A/D conversion result is stored into the corresponding A/D data register (ADDRy).
- (13) A group C scan end interrupt is generated if the ADGCTRGR.GCADIE bit is 1 (group C scan end interrupt is enabled).
- (14) The ADCSR.ADST bit is automatically cleared to 0 when scan of all selected channels is completed, and the 12-bit A/D converter enters a wait state.

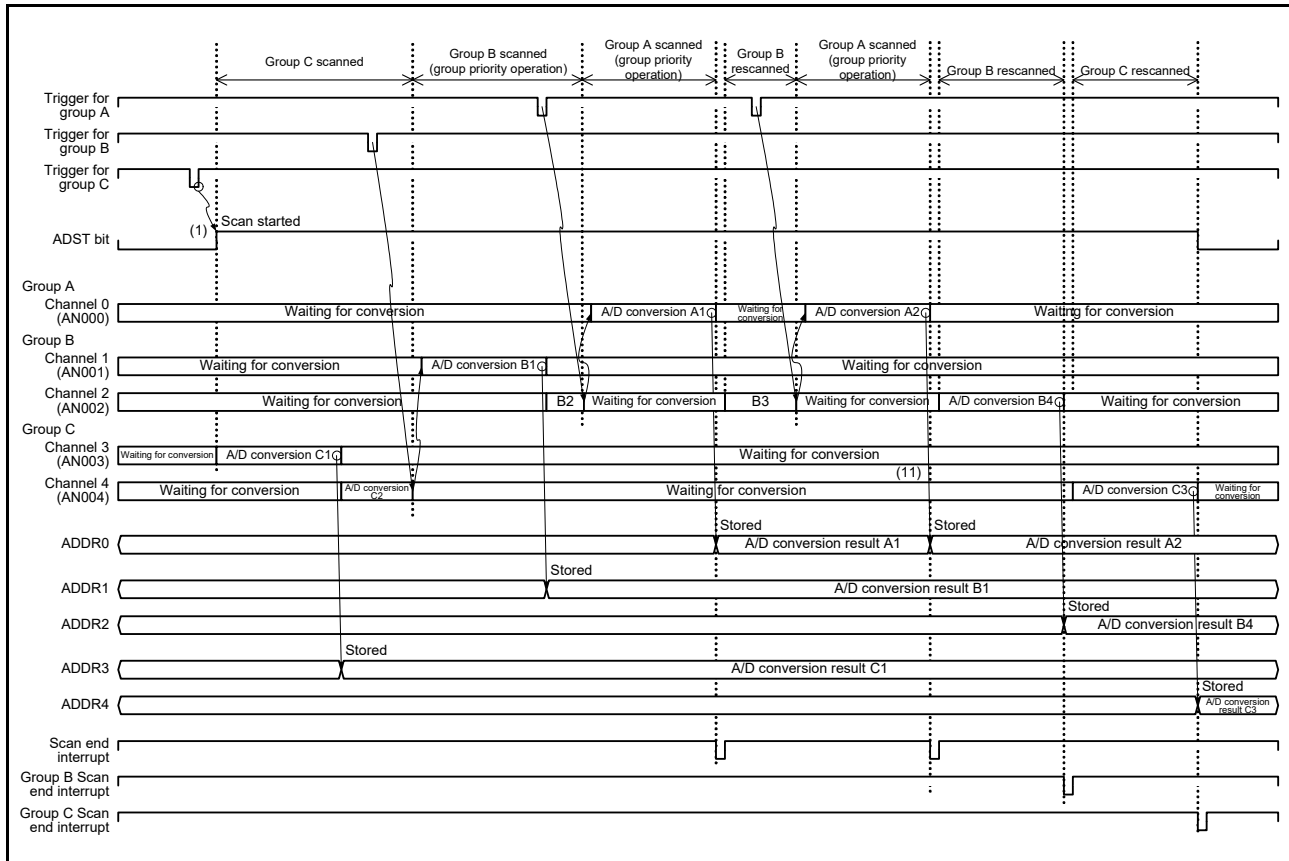

**Figure 38.36** Example 1 of Group Priority Operation: Priority Group Trigger Input During Low-Priority Group Scan, with the Rescan Setting (ADGSPCR.GBRSCN = 1, ADGSPCR.GBRP = 0, ADGSPCR.LGRRS = 1)

**Operation example 2: Priority group trigger input during low-priority group rescan, with the rescan setting**

Figure 38.37 shows an example when a group A trigger is input during rescan operation on group B. If a trigger for the priority groups (groups A and B for group C and group A for group B) is input, scan for the priority group starts even while rescan operation on the low-priority group is in progress. After scan for the priority group is completed, scan for the low-priority group is restarted after having been interrupted. Operations of the ADCSR.ADST bit, storing to the A/D conversion result in the A/D data register (ADDRy), and interrupt requests are the same as example 1.

**Figure 38.37 Example 2 of Group Priority Operation: Priority Group Trigger Input During Low-Priority Group Rescan, with the Rescan Setting (ADGSPCR.GBRSCN = 1, ADGSPCR.GBRP = 0, ADGSPCR.LGRRS = 1)**

### Operation example 3: Low-priority group trigger input during priority group scan, with the rescan setting

The following describes an example when a trigger for the low-priority group is input during scan operation on the priority group when the ADGSPCR.GBRSCN bit is 1 (scan for the group is restarted after having been interrupted due to group priority operation). If the ADGSPCR.GBRSCN bit is 0, all triggers for the low-priority group that are input during scan operation on the priority group are disabled.

- (1) When input of the group A trigger signal sets the ADCSR.ADST bit to 1 (starting A/D conversion), a group A scan starts for the analog channels selected in the ADANSA0 and ADANSA1 registers according to the order of conversion specified in the ADSCSn register.
- (2) If a group B trigger is input during scan for group A, scan for group B can be started.
- (3) Each time A/D conversion of a single channel is completed, the A/D conversion result is stored into the corresponding A/D data register (ADDRy).
- (4) After scan for group A is completed, a scan end interrupt request is generated if the ADCSR.ADIE bit is 1 (scan end interrupt is enabled).
- (5) After the group A scan ends, the ADCSR.ADST bit retains the value as 1, and the group B scan is started for the analog channels selected in the ADANSB0 and ADANSB1 registers according to the order of conversion specified in the ADSCSn register. At this time, the group B scan is restarted from the channel that the A/D conversion was suspended if the ADGSPCR.LGRRS bit is set to 1.  
(When a group A trigger is input during the group B scanning, the group A scan is started in the same way as in the example 1, and the group B scan is restarted after the group A scan ends.)
- (6) If a group C trigger is input during scan for group B, scan for group C can be started.
- (7) Each time A/D conversion of a single channel is completed, the A/D conversion result is stored into the corresponding A/D data register (ADDRy).
- (8) After scan for group B is completed, a group B scan end interrupt request is generated if the ADCSR.GBADIE bit is 1 (group B scan end interrupt is enabled).
- (9) After scan for group B is completed, scan for the ANx channels of group C selected in the ADANSC0 and ADANSC1 registers, starts from the channel with the smallest number x while the ADCSR.ADST bit remains 1. If the ADGSPCR.LGRRS bit is set to 1 at this time, scan for group C starts from the channel on which A/D conversion was interrupted.  
(When a group A or B trigger is input during scan for group C, group A or B scan starts as in example 1, and group C scan starts after group A or B scan is completed.)
- (10) Each time A/D conversion of a single channel is completed, the A/D conversion result is stored into the corresponding A/D data register (ADDRy).
- (11) After scan for group C is completed, a group C scan end interrupt request is generated if the ADGCTRGR.GCADIE bit is 1 (group C scan end interrupt is enabled).
- (12) The ADCSR.ADST bit is automatically cleared to 0 when scan of all selected channels is completed, and the 12-bit A/D converter enters a wait state.

**Figure 38.38 Example 3 of Group Priority Operation: Low-Priority Group Trigger Input During Priority Group Scan, with the Rescan Setting**  
 (ADGSPCR.GBRSCN = 1, ADGSPCR.GBRP = 0, ADGSPCR.LGRRS = 1, ADGCTRGR.GRCE = 1)

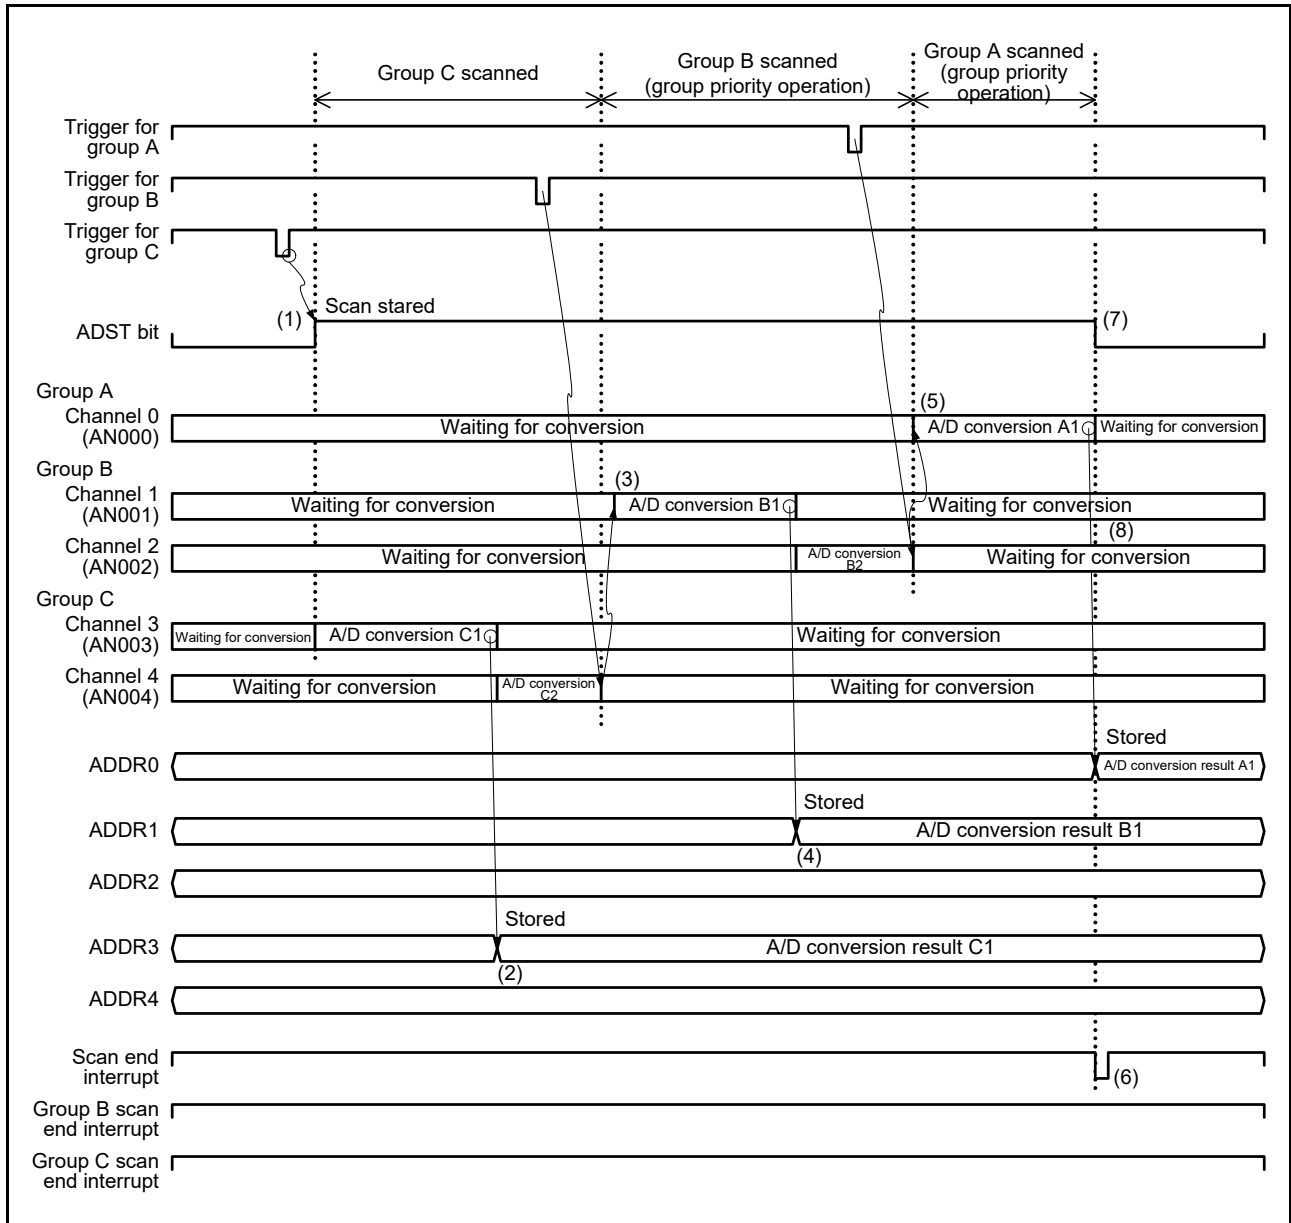

Operation example 4 shows group priority operation in group scan mode (ADGSPCR.GBRSCN = 0, ADGSPCR.GBRP = 0, ADGSPCR.LGRRS = 0) when channel 0 is selected for group A, channels 1 and 2 are selected for group B, and channels 3 and 4 are selected for group C.

#### Operation example 4: Priority group trigger input during low-priority group scan, without the rescan setting

- (1) When input of the group C trigger signal sets the ADCSR.ADST bit to 1 (starting A/D conversion), the group C scan starts for the analog channels selected in the ADANSC0 and ADANSC1 registers according to the order of conversion specified in the ADSCSn register.
- (2) Each time A/D conversion of a single channel is completed, the A/D conversion result is stored into the corresponding A/D data register (ADDRy).
- (3) When a group B trigger is input during the group C scanning, the ADCSR.ADST bit retains the value as 1, the group C scan is interrupted, and the group B scan starts for the analog channels selected in the ADANSB0 and ADANSB1 registers according to the order of conversion specified in the ADSCSn register. The A/D conversion result is not stored into the corresponding data register (ADDRy) if A/D conversion is not completed when the scan is interrupted.
- (4) Each time A/D conversion of a single channel is completed, the A/D conversion result is stored into the corresponding A/D data register (ADDRy).
- (5) When a group A trigger is input during the group B scanning, the ADCSR.ADST bit retains the value as 1, and the group B scan is interrupted, and the group A scan starts for the analog channels selected in the ADANSA0 and ADANSA1 registers according to the order of conversion specified in the ADSCSn register. The A/D conversion

result is not stored into the corresponding data register (ADDRy) if A/D conversion is not completed when the scan is interrupted.

- (6) After scan for group A is completed, a scan end interrupt request is generated if the ADCSR.ADIE bit is 1 (scan end interrupt is enabled).
- (7) The ADCSR.ADST bit is automatically cleared to 0 when scan for group A is completed, and the 12-bit A/D converter enters a wait state. Scan for groups C and B is not started until the next trigger corresponding to the group is input.

**Figure 38.39 Example 4 of Group Priority Operation: Priority Group Trigger Input During Low-Priority Group Scan, Without the Rescan Setting (ADGSPCR.GBRSCN = 0, ADGSPCR.GBRP = 0, ADGSPCR.LGRRS = 1)**

Operation example 5 shows group priority operation in group scan mode (ADGSPCR.GBRSCN = 1, ADGSPCR.GBRP = 1, ADGSPCR.LGRRS = 1) when channel 0 is selected for group A, channel 1 is selected for group B, and channels 2 and 3 are selected for group C.

When the ADGCTRGR.GRCE bit is set to 0, single scan mode is continuously operated on group B and trigger input for group C is disabled.

**Operation example 5: Continuous single scan operation on group C**

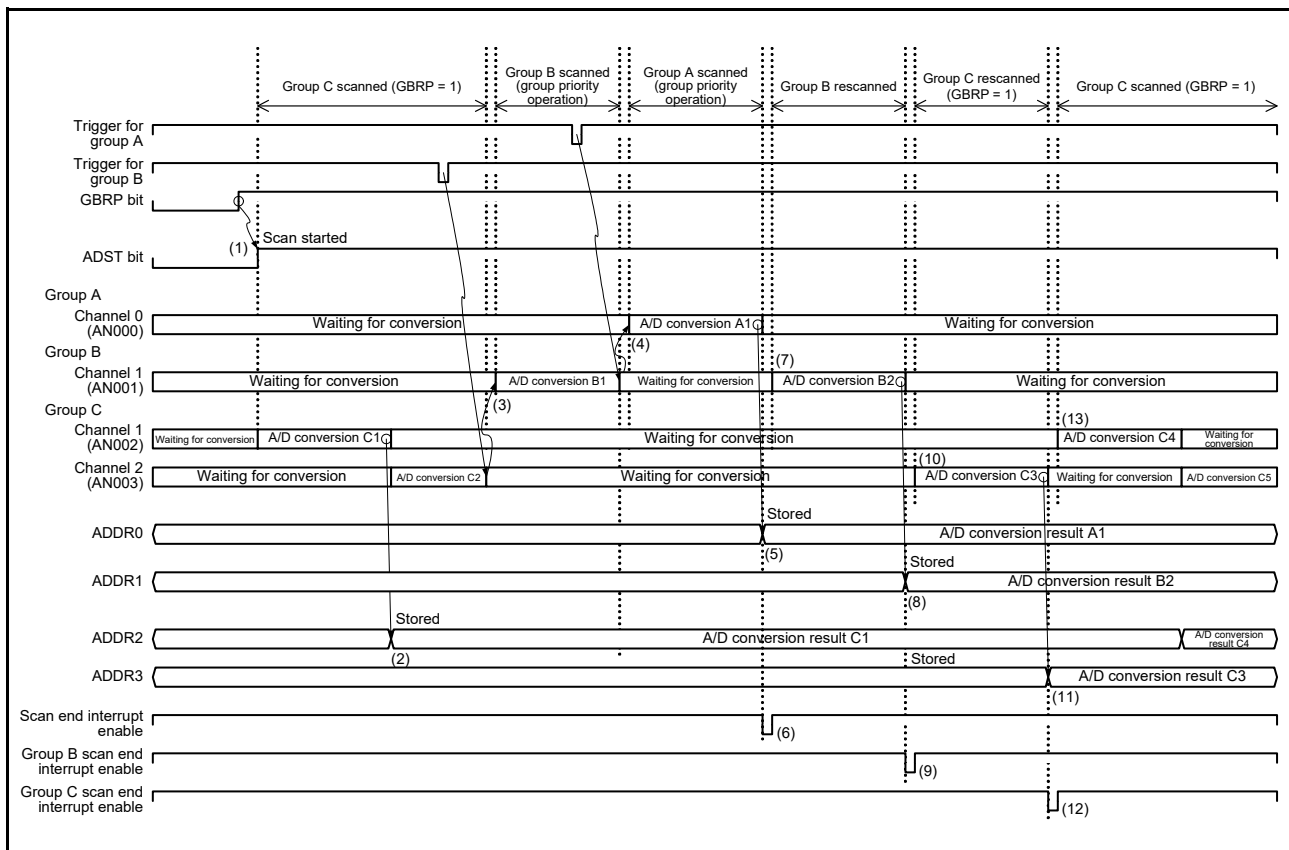

- (1) When the ADGSPCR.GBRP bit is set to 1, the ADCSR.ADST bit is set to 1 (starting A/D conversion), and a group C scan is started for the analog channels selected in the ADANSC0 and ADANSC1 registers according to the order of conversion specified in the ADSCSn register.
- (2) Each time A/D conversion of a single channel is completed, the A/D conversion result is stored into the corresponding A/D data register (ADDRy).
- (3) When a group B trigger is input during the group C scanning, the ADCSR.ADST bit retains the value as 1, the group C scan is interrupted, and the group B scan starts for the analog channels selected in the ADANSB0 and ADANSB1 registers according to the order of conversion specified in the ADSCSn register. The A/D conversion result is not stored into the corresponding data register (ADDRy) if A/D conversion is not completed when the scan is interrupted.
- (4) When a group A trigger is input during the group B scanning, the ADCSR.ADST bit retains the value as 1, and the group B scan is interrupted, and the group A scan starts for the analog channels selected in the ADANSA0 and ADANSA1 registers according to the order of conversion specified in the ADSCSn register. The A/D conversion result is not stored into the corresponding data register (ADDRy) if A/D conversion is not completed when the scan is interrupted.
- (5) Each time A/D conversion of a single channel is completed, the A/D conversion result is stored into the corresponding A/D data register (ADDRy).
- (6) A scan end interrupt request is generated if the ADCSR.ADIE bit is 1 (scan end interrupt is enabled).
- (7) When the ADGSPCR.GBRSCN bit is set to 1 (restarting a group scan which was interrupted due to group priority in scanning), the ADCSR.ADST bit retains the value as 1, and the group B scan for the analog channels selected in the ADANSB0 and ADANSB1 registers according to the order of conversion specified in the ADSCSn register is restarted. At this time, the group B scan is restarted from the channel that the A/D conversion was interrupted if the ADGSPCR.LGRRS bit is set to 1.
- (8) Each time A/D conversion of a single channel is completed, the A/D conversion result is stored into the corresponding A/D data register (ADDRy).
- (9) A group B scan end interrupt request is generated if the ADCSR.GBADIE bit is 1 (group B scan end interrupt is enabled).
- (10) When the ADGSPCR.GBRSCN bit is set to 1 (restarting a group scan which was interrupted due to group priority in scanning), the ADCSR.ADST bit retains the value as 1, and the group C scan for the analog channels selected in the ADANSC0 and ADANSC1 registers according to the order of conversion specified in the ADSCSn register is restarted. At this time, the group C scan is restarted from the channel that the A/D conversion was interrupted if the ADGSPCR.LGRRS bit is set to 1.
- (11) Each time A/D conversion of a single channel is completed, the A/D conversion result is stored into the corresponding A/D data register (ADDRy).
- (12) A group C scan end interrupt is generated if the ADGCTRGR.GCADIE bit is 1 (group C scan end interrupt is enabled).
- (13) When the ADGSPCR.GBRP bit is set to 1 (selecting continuous single scanning), the ADCSR.ADST bit retains the value as 1, and the group C scan for the analog channels selected in the ADANSC0 and ADANSC1 registers according to the order of conversion specified in the ADSCSn register is restarted.

To continuously operate single scan for group C, disable trigger input for group B.

Steps (13), (11), (12), and then (13) are repeated as long as the ADGSPCR.GBRP bit remains 1.

Clearing of the ADCSR.ADST bit to 0 is prohibited while the ADGSPCR.GBRP bit is set to 1.

To forcibly stop scanning when ADGSPCR.GBRP = 1, follow the procedures for clear operation by software through the ADCSR.ADST bit shown in section 38.6.2, Notes on Stopping A/D Conversion.

**Figure 38.40 Example 5 for Group Priority Operation: Continuous Single Scan Operation on Group C (ADGSPCR.GBRP = 1, ADGSPCR.LGRRS = 1)**

### 38.3.7 Comparison Function (Window A and Window B)

#### 38.3.7.1 Comparison Function Windows A/B

The comparison function compares the reference values set in registers ADCMPDR0, ADCMPDR1, ADWINLLB, and ADWINULB with the A/D conversion results. When this function is used, self-diagnosis or double trigger mode cannot be used. A window comparison function can also be used (when ADCMPCR.WCMPE = 1), enabling comparison of two values. Two sets of voltage level ranges can be set in the window comparison function, one for window A and one for window B.

Operation when window comparison is enabled (ADCMPCR.WCMPE = 1) in combination with continuous scan mode is described below.

- (1) When the ADCSR.ADST bit is set to 1 (starting A/D conversion) by software, or synchronous or asynchronous trigger input, A/D conversion is performed for selected channels, temperature sensor output, and internal reference voltage in this order.
- (2) Each time A/D conversion of a single channels is completed, the A/D-converted value is stored in the corresponding A/D data register (ADDRy, ADTSDR, or ADOCDR). When the ADCMPCR.CMPAE bit = 1 and window A is selected in the ADCMPANSRy and ADCMPANSER registers, the A/D-converted value is compared with the setting values of the ADCMPDR0 and ADCMPDR1 registers.  
When the ADCMPCR.CMPBE bit = 1 and window B is selected in the ADCMPBNSR register, the A/D-converted value is compare with the setting values of the ADWINULB and ADWINLLB registers.
- (3) For window A, upon a comparison match with the conditions specified in the ADCMPLR0, ADCMPLR1, and ADCMPLER registers, the flags of comparison window A (ADCMPSR0.CMPSTCHA0n, ADCMPSR1.CMPSTCHA1n, ADCMPSER.CMPFTS, and ADCMPSER.CMPFOC) become 1.  
In this case, if the ADCMPCR.CMPAIE bit is set to 1, an interrupt request S12CMPAI is generated.  
Similarly, for window B, upon a match with the conditions set in the ADCMPBNSR.CMPLB register, the comparison window B flag (ADCMPBSR.CMPSTB) becomes 1. In this case, if the ADCMPCR.CMPBIE bit is set to 1, an interrupt request S12CMPBI is generated.
- (4) When all selected A/D conversion and comparison are completed, scanning is performed again.
- (5) Set the ADCSR.ADST bit to 0 (stopping A/D conversion) and execute the processing for the channels in which the comparison flag is 1.
- (6) After the processing above, clear all comparison flags. When comparison is re-executed, start A/D conversion again.

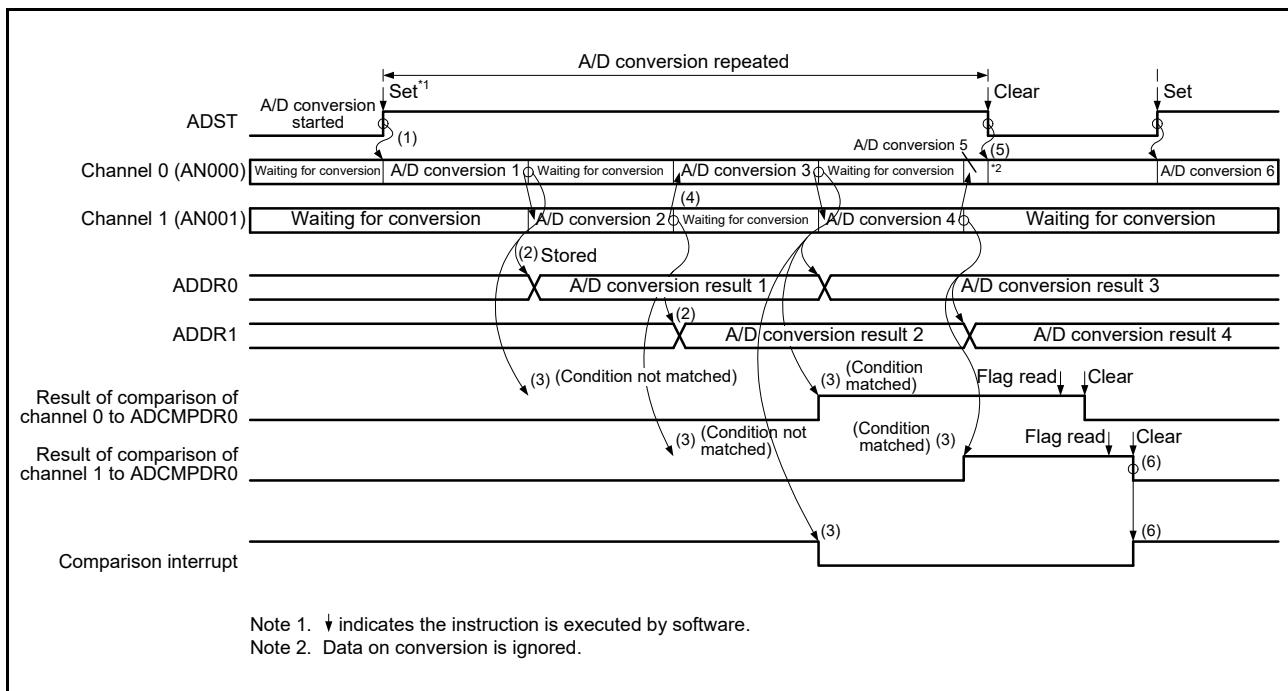

Figure 38.41 Example of Operation of Comparison (AN000 and AN001 for Targets for Comparison)

### 38.3.7.2 Restrictions on Comparison Function

The Comparison function has the following restrictions.

1. Use of self-diagnosis and double trigger mode is prohibited.  
(ADRD, ADDBLDR, ADDBLDRA, and ADDBLDRB are not targeted for the comparison function)
2. When using a matching or unmatching event, set to single scan mode.
3. When temperature sensor or internal reference voltage is selected for window A, operation of window B is prohibited.
4. When temperature sensor or internal reference voltage is selected for window B, operation of window A is prohibited.
5. The same channel cannot be set for window A and window B.
6. Satisfy the condition of [reference value (high side)  $\geq$  reference value (low side)].

### 38.3.8 Analog Input Sampling Time and Scan Conversion Time

Figure 38.42 shows the scan conversion timing in single scan mode, in which scan conversion is started by software or a synchronous trigger. Figure 38.43 shows the scan conversion timing in single scan mode, in which scan conversion is started by an asynchronous trigger. The scan conversion time ( $t_{SCAN}$ ) includes the start-of-scanning-delay time ( $t_D$ ), channel-dedicated sample-and-hold circuit processing time ( $t_{SPLSH}$ )\*1, disconnection detection assistance processing time ( $t_{DIS}$ )\*2, auto-discharging processing time when A/D converting the temperature sensor output and the internal reference voltage ( $t_{ADIS}$ ), self-diagnosis A/D conversion processing time ( $t_{DIAG}$ )\*3, A/D conversion processing time ( $t_{CONV}$ ), channel-dedicated sample-and-hold circuit end time ( $t_{SHED}$ )\*4, and end-of-scanning-delay time ( $t_{ED}$ ).

The A/D conversion processing time ( $t_{CONV}$ ) consists of sampling time ( $t_{SPL}$ ) and time for conversion by successive approximation ( $t_{SAM}$ ). The sampling time ( $t_{SPL}$ ) is used to charge sample-and-hold circuits in the A/D converter. If there is not sufficient sampling time due to the high impedance of an analog input signal source, or if the A/D conversion clock (ADCLK) is slow, sampling time can be adjusted using the ADSSTR register.

The time for conversion by successive approximation ( $t_{SAM}$ ) is at 24 clock cycles of ADCLK. Table 38.25 shows the scan conversion time.

The scan conversion time ( $t_{SCAN}$ ) in single scan mode for which the number of selected channels is  $n$  can be determined as follows:

$$t_{SCAN} = t_D + t_{SPLSH} + (t_{DIS} \times n) + t_{DIAG} + (t_{CONV} \times n)^{*5} + t_{ED}$$

$$t_{SCAN} \text{ (when converting temperature sensor output and internal reference voltage)} = t_D + (t_{ADIS} \times m) + (t_{CONV} \times m) + t_{ED} \text{ }^{*6, *7, *8}$$

The scan conversion time for the first cycle in continuous scan mode is  $t_{SCAN}$  for single scan minus  $t_{ED}$  plus  $t_{SHED}$ .

The scan conversion time for the second and subsequent cycles in continuous scan mode is fixed to  $t_{SPLSH} + (t_{DIS} \times n) + t_{DIAG} + t_{DSD} + (t_{CONV} \times n)^{*5} + t_{SHED}$ .

Note 1. When no channel-dedicated sample-and-hold circuits are used,  $t_{SPLSH} = 0$ .

Note 2. When disconnection detection assistance is not selected,  $t_{DIS} = 0$ . When A/D-converting the temperature sensor output and the internal reference voltage, the value is fixed to 0Fh indicating 15 ADCLK.

Note 3. When the self-diagnosis function is not used,  $t_{DIAG} = 0$ ,  $t_{DSD} = 0$ .

Note 4. When no channel-dedicated sample-and-hold circuits are used,  $t_{SHED} = 0$ . Here, continuous scan mode is assumed. In single scan mode and group scan mode,  $t_{SHED}$  is included in the end-of-scanning-delay time ( $t_{ED}$ ).

Note 5. Although the total  $t_{CONV}$  can be expressed as  $t_{CONV} \times n$  when the sampling times ( $t_{SPL}$ ) of the selected channels are the same, it is basically expressed as the sum of the sampling times ( $t_{SPL}$ ) for each of the channels and times for conversion by successive approximation ( $t_{SAM}$ ) for each of the channels.

Note 6. Set  $m$  to 2 to perform A/D conversion both the temperature sensor output and internal reference voltage, or set  $m$  to 1 to perform A/D conversion either of them.

Note 7. When performing A/D conversion of the temperature sensor output or internal reference voltage, both the  $t_{SPLSH}$  and  $t_{DIAG}$  are 0, since A/D conversion of the self-diagnosis and analog channels cannot be selected in these cases.

Note 8. If the self-diagnosis and analog channels are in one group and the temperature sensor output and internal reference are in another, A/D conversion for all of them can be performed for a group scan.

**Table 38.25 Times for Conversion During Scanning (in Numbers of Cycles of ADCLK and PCLKB)**

| Item                                                                                                                                      | Symbol                                                                                                                               | Type/Conditions                                                                                                                                                              | Type/Conditions                                                                                                                                             |                      |                  | Unit  |

|                                                                                                                                           | Time for conversion by successive approximation                                                                                      | $t_{SAM}$                                                                                                                                                                    | 24 ADCLK                                                                                                                                                    |                      |                  |       |
| Channel-dedicated sample-and-hold end processing time                                                                                     |                                                                                                                                      | $t_{SHED}$                                                                                                                                                                   | 2 ADCLK                                                                                                                                                     |                      |                  |       |
| Scan end processing time*1                                                                                                                |                                                                                                                                      | $t_{ED}$                                                                                                                                                                     | 1 PCLKB + 3 ADCLK (2 PCLKB + 2 ADCLK)*4                                                                                                                     |                      |                  |       |

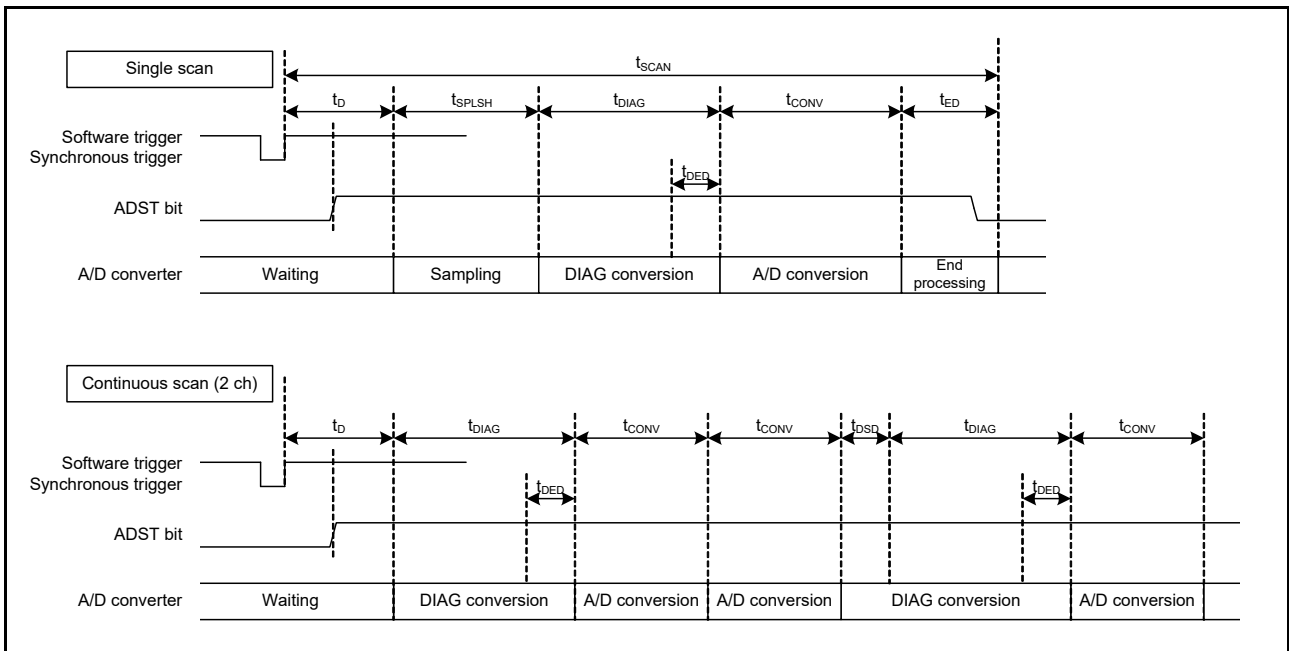

Note 1. For  $t_D$ ,  $t_{SPLSH}$ ,  $t_{DIAG}$ ,  $t_{CONV}$ , and  $t_{ED}$ , refer to Figure 38.42 and Figure 38.43.

Note 2. This is the maximum time required from software writing or trigger input to start A/D conversion.

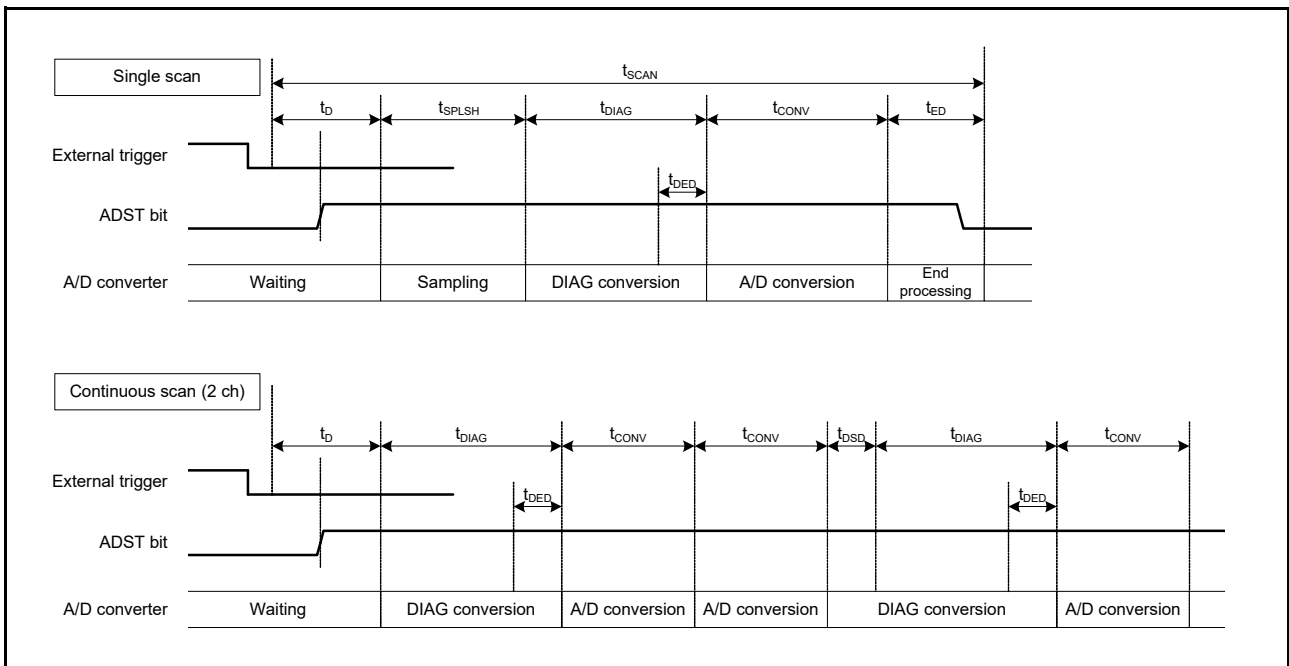

Note 3. Time consumed on the paths from timer output to trigger input is not included.

Note 4. Maximum time for when ADCLK is faster than PCLKB (PCLKB to ADCLK frequency ratio = 1:2)

Note 5. When A/D-converting the temperature sensor output and the internal reference voltage, the value is fixed to 0Fh indicating 15 ADCLK.

**Figure 38.42 Scan Conversion Timing (Started by Software or Synchronous Trigger)**

**Figure 38.43 Scan Conversion Timing (Started by Software or Asynchronous Trigger)**

### 38.3.8.1 Timing of Suspension and Starting of Scanning in Operation under Group Priority Control

The timings for suspension and starting of scanning in operation under group priority control that must be considered are listed below.

1. The timing for suspending a scan of a group with a lower-priority and the timing for starting a scan of a group with a higher-priority.
2. The time at which scanning by the group with a lower-priority is resumed on completion of scanning by the higher-priority group when the trigger for scanning by the lower-priority group is accepted during scanning by the higher-priority group.
3. The timing for performing sequential single scans by a lower-priority group.

Figure 38.44 shows the timing diagram of each of the above cases.

The times at which scanning by group A is completed and scanning by group C resumes or scanning by group B is completed and scanning by group C resumes are the same as those for group A and group B in Figure 38.44.

The timing for consecutive single scans is the same for group B and group C.

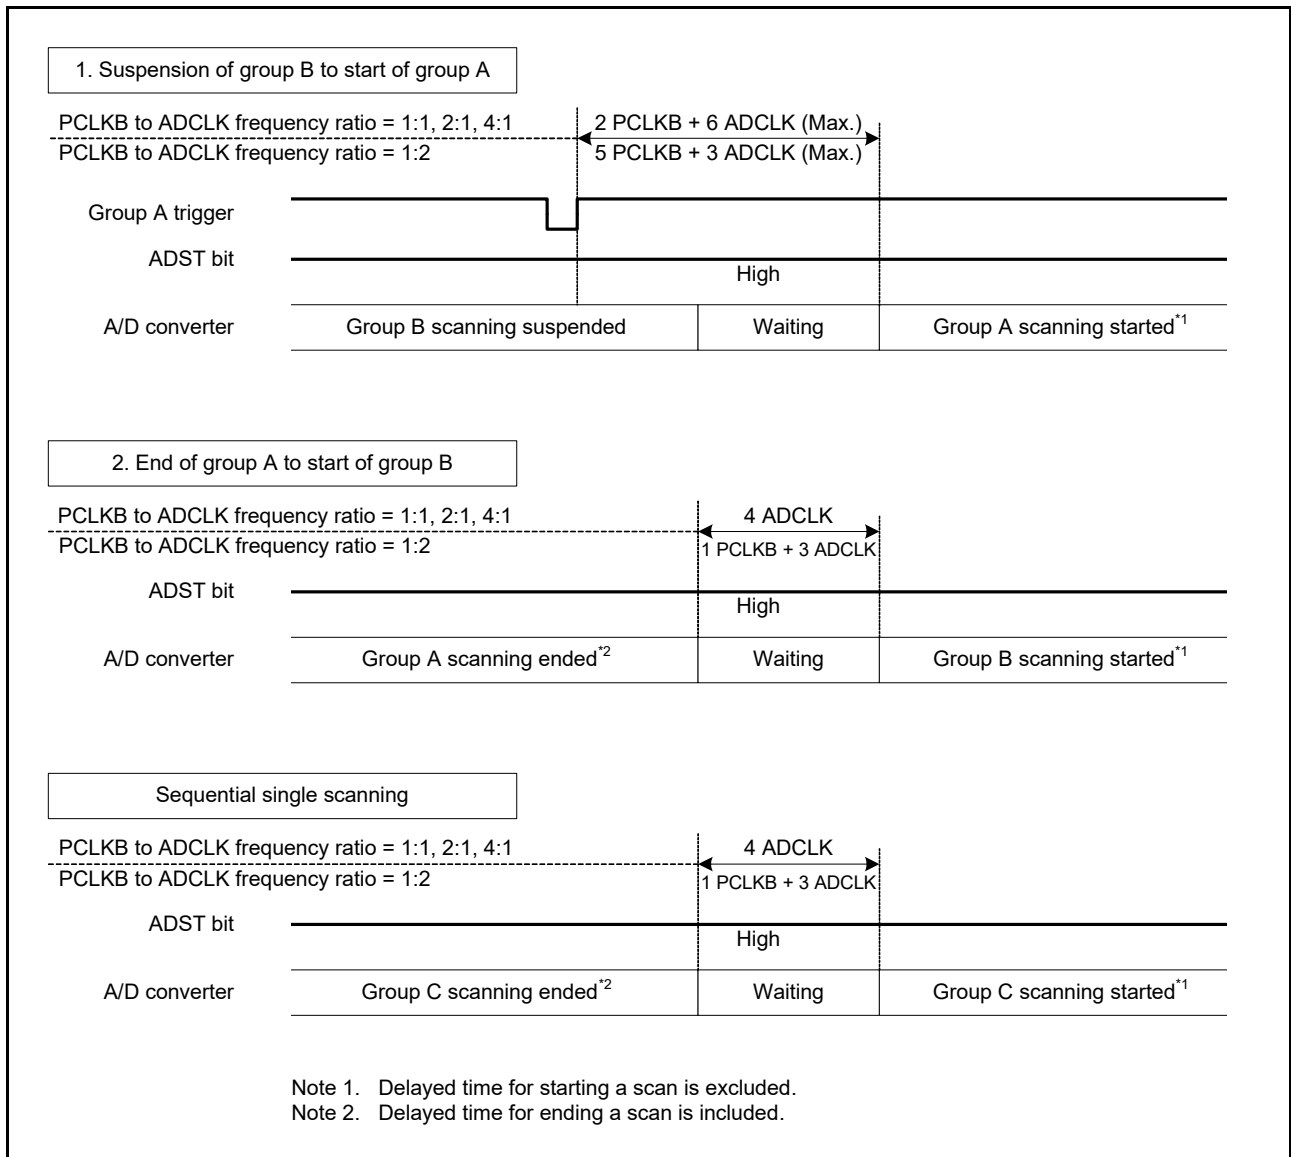

Figure 38.44 Timing of Stop/Start of Scanning in Group Priority Mode

### 38.3.9 Usage Example of A/D Data Register Automatic Clearing Function

Setting the ADCER.ACE bit to 1 automatically clears the A/D data registers (ADDRy, ADRD, ADTSDR, ADOCDR, ADDBLDR, ADDBLDRA, and ADDBLDRB) to 0000h when the A/D data registers (ADDRy, ADRD, ADTSDR, ADOCDR, ADDBLDR, ADDBLDRA, and ADDBLDRB) are read by the CPU, DTC, or DMAC.

This function enables detection of update failures of the A/D data registers (ADDRy, ADRD, ADTSDR, ADOCDR, ADDBLDR, ADDBLDRA, and ADDBLDRB). The following describes the examples in which the function to automatically clear the ADDRy register is enabled and disabled.

In a case where the ADCER.ACE bit is 0 (automatic clearing disabled), if the A/D conversion result (0222h) is not written to the ADDRy register for some reason, the old data (0111h) will be the ADDRy register value. Furthermore, if this ADDRy register value is read into a general register using an A/D scan end interrupt, the old data (0111h) can be saved in the general register. When checking whether there is an update failure, it is necessary to frequently save the old data in the RAM or a general register.

In a case where the ADCER.ACE bit is 1 (automatic clearing enabled), when ADDRy = 0111h is read by the CPU, DTC, or DMAC, the ADDRy register is automatically cleared to 0000h. After that, if the A/D conversion result (0222h) cannot be transferred to the ADDRy register for some reason, the cleared data (0000h) remains as the ADDRy register value. If this ADDRy register value is read into a general register using an A/D scan end interrupt at this point, 0000h will be saved in the general register.

Occurrence of an ADDRy register update failure can be determined by simply checking that the read data value is 0000h.

### 38.3.10 A/D-Converted Value Addition/Average Mode

In A/D-converted value addition mode, the same channel is A/D-converted 2, 3, 4, or 16 consecutive times and the sum of the converted values is stored in the data register. In A/D-converted value average mode, the same channel is A/D-converted two or four consecutive times and the mean of the converted values is stored in the data register. The use of the average of these results can improve the accuracy of A/D conversion, depending on the types of noise components that are present. This function, however, cannot always guarantee an improvement in A/D conversion accuracy.

The A/D-converted value addition/average mode can be used when A/D conversion of the channel select analog input, temperature sensor output (for unit 2 only), or internal reference voltage (for unit 2 only) is selected.

### 38.3.11 Disconnection Detection Assist Function

This converter incorporates the function to fix the charge for sampling capacitance to the specified state before start of A/D conversion. This function enables disconnection detection in wiring of analog inputs.

Figure 38.45 illustrates the A/D conversion operation when the disconnection detection assist function is used. Figure 38.46 shows an example of disconnection detection when precharge is selected. Figure 38.47 shows an example of disconnection detection when discharge is selected.

Figure 38.45 Operation of A/D Conversion When the Disconnection Detection Assist Function is Used

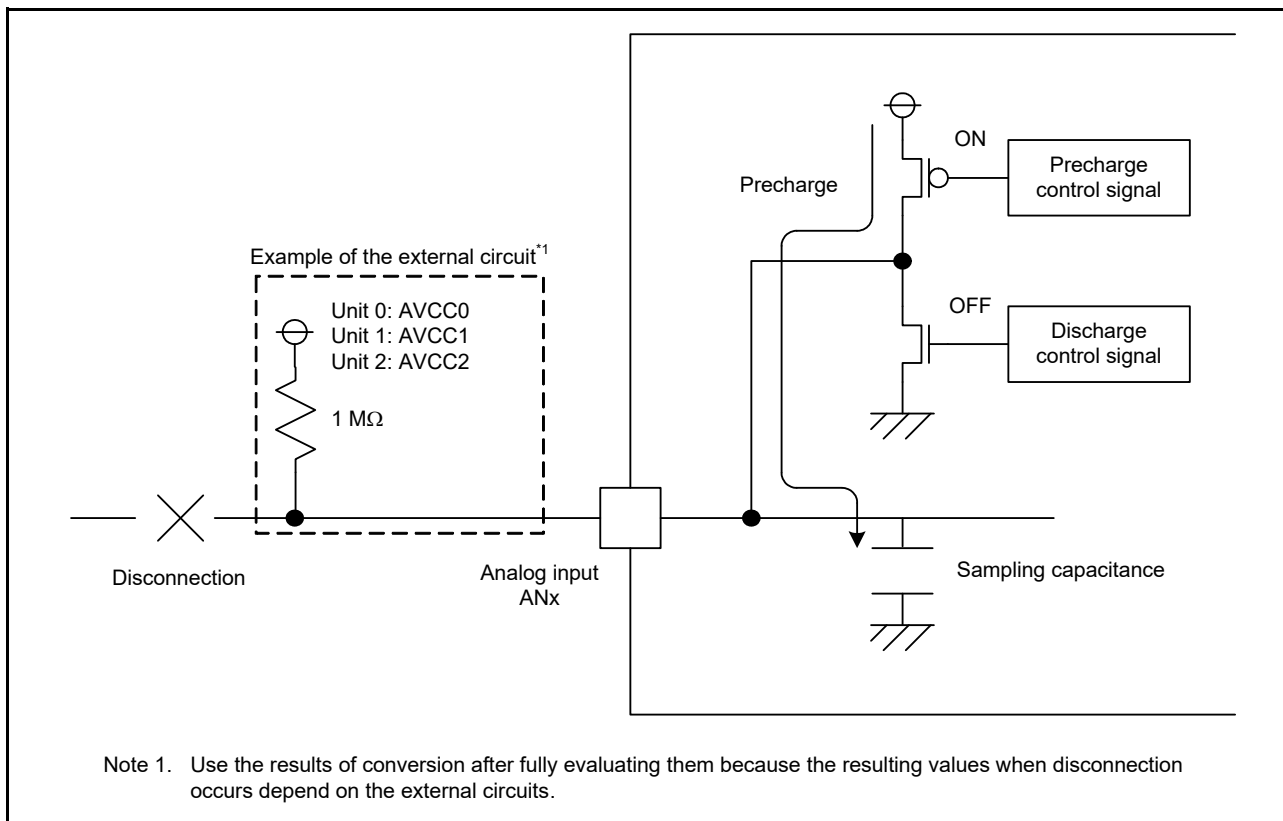

Figure 38.46 Example of Disconnection Detection When Precharge is Selected

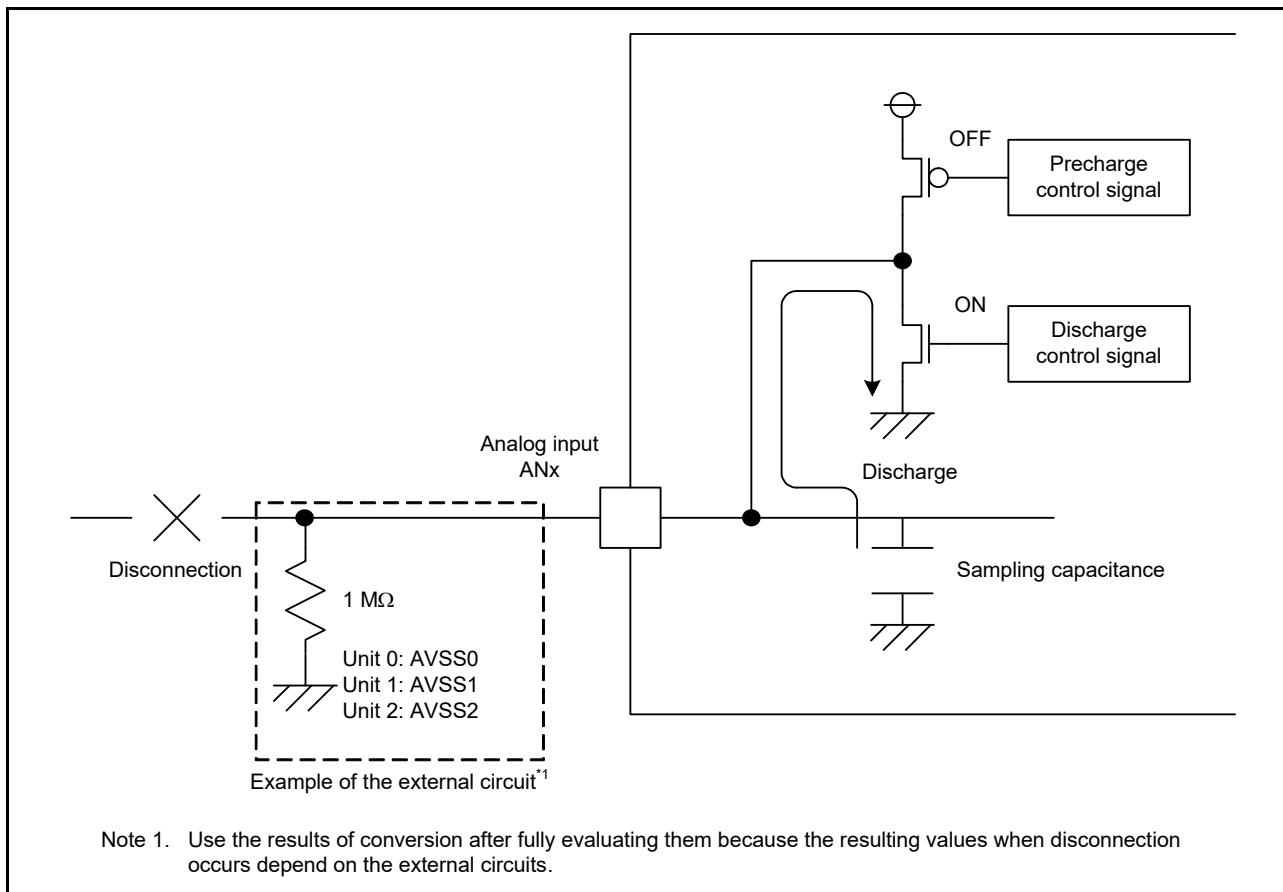

Figure 38.47 Example of Disconnection Detection When Discharge is Selected

### 38.3.12 Starting A/D Conversion with Asynchronous Trigger

The A/D conversion can be started by the input of an asynchronous trigger. To start up the A/D converter by an asynchronous trigger, the A/D conversion start trigger select bits (ADSTRGR.TRSA[5:0]) should be set to 000000b, and a high-level signal should be input to the asynchronous trigger (ADTRG0# pin). Then, the ADCSR.TRGE and ADCSR.EXTRG bits should be set to 1. Figure 38.48 shows a timing of the asynchronous trigger input.

For the time from when the ADST bit is set to 1 until conversion starts, refer to section 38.6.3, A/D Conversion Restarting Timing and Termination Timing. An asynchronous trigger cannot be selected for group B or group C in group scan mode.

Figure 38.48 Timing of the Asynchronous Trigger Input

### 38.3.13 Starting A/D Conversion with Synchronous Trigger from Peripheral Module

The A/D conversion can be started by a synchronous trigger. To start the A/D conversion by a synchronous trigger, the ADCSR.TRGE bit should be set to 1, the ADCSR.EXTRG bit should be cleared to 0, and the relevant sources should be selected by the ADSTRGR.TRSA[5:0] bits, the ADSTRGR.TRSB[5:0] bits, and the ADGCTRGR.TRSC[5:0] bits.

### 38.3.14 Conversion Function in the Order of Arbitrary Channel Number

Conversion function in the order of arbitrary channel number is used to convert analog channels of each unit in the 12-bit A/D converter in the order set by the ADSCSn register.

Setting the same channel in the ADSCSn register is prohibited. Channels whose order can be set with this function are analog channels only.

The conversion order for the self-diagnosis, temperature sensor, and internal reference voltage cannot be changed.

**Table 38.26 Example of Conversion Order When the ADSCSn Register (n = 0 to 4) is Set to the Initial Value in the Scan Group A**

| ADSCSn Setting Value |               | A/D Conversion Order |                  |                  | ADANSA0 Setting Value |
|----------------------|---------------|----------------------|------------------|------------------|-----------------------|
| Symbol               | Initial Value | Physical Channel     | Priority         | Conversion Order | Channel Select Bit    |
| ADSCS0               | 00h           | AN000                | High<br>↓<br>Low | 1                | ANSA0[0] = 1          |
| ADSCS1               | 01h           | AN001                |                  | 2                | ANSA0[1] = 1          |
| ADSCS2               | 02h           | AN002                |                  | 3                | ANSA0[2] = 1          |
| ADSCS3               | 03h           | AN003                |                  | 4                | ANSA0[3] = 1          |
| ADSCS4               | 04h           | AN004                |                  | 5                | ANSA0[4] = 1          |

**Figure 38.49 Example of Conversion Order (Setting Based on Table 38.26)**

**Table 38.27 Example of Conversion Order When a Setting Value of the ADSCSn Register (n = 0 to 4) is Modified in the Scan Group A**

| ADSCSn Setting Value |                   | A/D Conversion Order |                  |                  | ADANSA0 Setting Value |

**Figure 38.51 Example of Conversion Order (Setting Based on Table 38.28)**

### 38.3.15 Internal Reference Voltage Monitoring Function

The internal reference voltage monitoring function is used to output the internal reference voltage to the A/D converter. Set the A/D internal reference voltage monitoring circuit enable register (ADVMONCR) and the A/D internal reference voltage monitoring circuit output enable register (ADVMONO), and enable the internal reference voltage A/D select bit (OCSA/B/C) to perform A/D conversion of the internal reference voltage.

Example of the operation is shown below.

- (1) Set the VDE bit in the A/D internal reference voltage monitoring circuit enable register (ADVMONCR) to 1.
- (2) Set the VDO bit in the A/D internal reference voltage monitoring circuit output enable register (ADVMONO) to 1.
- (3) Select the internal reference voltage either by the internal reference voltage A/D conversion select bit (OCSA) in the A/D conversion extended input control register, the group B internal reference voltage A/D conversion select bit (OCSB), or the group C internal reference voltage A/D conversion select bit (OCSC) in the A/D group C extended input control register (ADGCEXCR).
- (4) After inserting the waiting period of 500 ns, the ADCSR.ADST bit becomes 1 (starting A/D conversion) either by software, synchronous trigger (MTU, TMR, and ELC), or asynchronous trigger, and then, auto-discharging of the internal reference voltage is performed and A/D conversion of the internal reference voltage starts.
- (5) When A/D conversion of the internal reference voltage is completed, A/D conversion result is stored to the corresponding A/D internal reference voltage data register (ADOCDR).
- (6) S12ADI2 interrupt request is generated (pulse output and level output) if the ADCSR.ADST bit is set to 1 (scan end interrupt is enabled).
- (7) The ADCSR.ADST bit is automatically cleared upon completion of A/D conversion, and the 12-bit A/D converter enters a wait state.
- (8) Set the VDO bit in the A/D internal reference voltage monitoring circuit output enable register (ADVMONO) to 0.
- (9) Set the VDE bit in the A/D internal reference voltage monitoring circuit enable register (ADVMONCR) to 0.

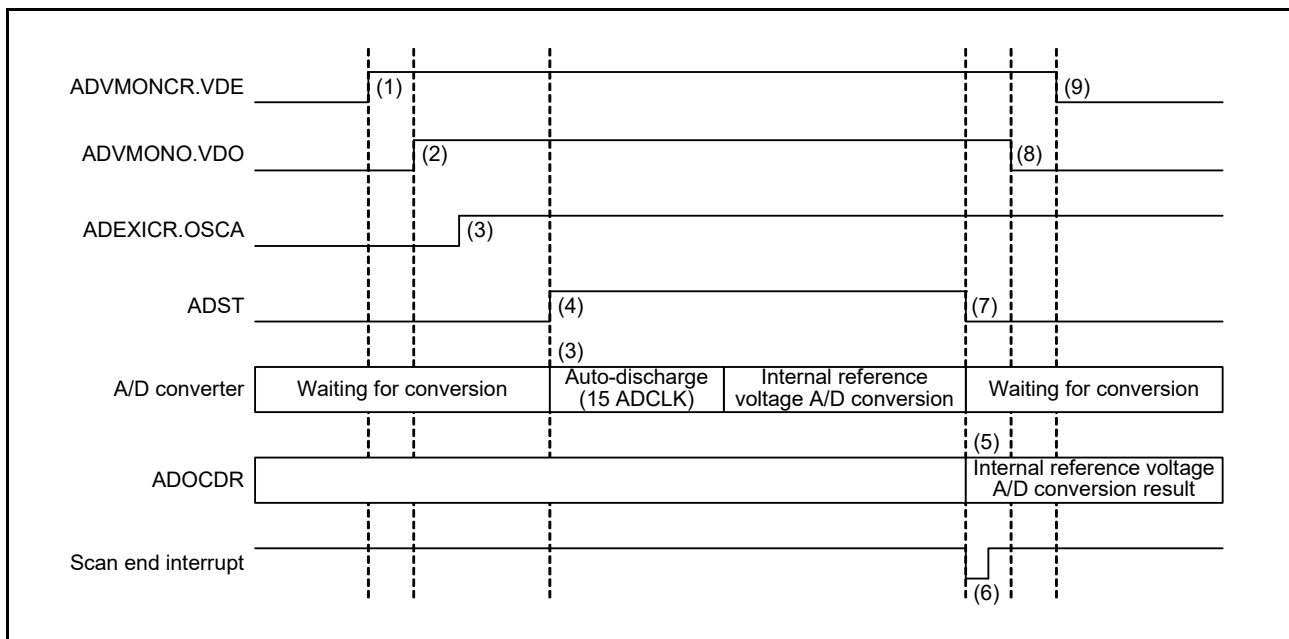

Figure 38.52 Example of Internal Reference Voltage Monitor Output A/D Conversion

### 38.3.16 Programmable Gain Amplifier

Unit 0 and unit 1 of the A/D converter have three programmable gain amplifiers (PGA), respectively.

Either single-ended or pseudo-differential inputs are selectable for the PGAs\*1.

Inverting input pin of a PGA are connected to the same reference ground pin per unit, where the reference ground pin for the AN000 through AN002 pins (in the case of unit 0) is the PGAVSS0 pin and the reference ground pin for the AN100 through AN102 pins (in the case of unit 1) is the PGAVSS1 pin.

Note 1. Only single-ended input is enabled for products without pseudo-differential input to the PGAs. In addition, pins PGAVSS0 and PGAVSS1 are not present. The inverted input pins for the PGAs are internally connected to pins AVSS0 and AVSS1.

Figure 38.53 shows the internal configurations for single-ended and pseudo-differential input.

**Figure 38.53 Internal Configuration of PGA (P000)**

When single-ended input is selected, set the gain of PGA in the ADPGAGS0.PxGAIN[3:0] bits (x = 000 to 002, and 100 to 102). The range of the gain settable by the bits is from times 2.000 to times 20.000. Control the input voltage to ANx pins so that the voltage after amplification does not to exceed the output voltage ranges stipulated in the electrical characteristics. In addition, externally connect the PGAVSS0 and PGAVSS1 pins to AVSS0 and AVSS1 pins.

When pseudo-differential input is selected, set the gains of the PGAs in the ADPGAGS0.PxGAIN[3:0] and ADPGADCR0.PxDG[1:0] bits. The values for gain settable by the bits are times 1.500, times 4.000, times 7.000, and times 12.333. Set the bits so that the same gain is set by both pairs of bits. The range of differential input voltages depends on the gain setting. For details, refer to section 38.3.2, Setting the Input Paths of AN000 to AN002, AN007, AN100 to AN102, and AN107 and section 45, Electrical Characteristics.

## 38.4 Interrupt Sources and DTC/DMA Transfer Requests

### 38.4.1 Interrupt Requests

The 12-bit A/D converter can generate scan end interrupt requests S12ADI/S12ADI1/S12ADI2, S12GBADI/S12GBADI1/S12GBADI2, and S12GCADI/S12GCADI1/S12GCADI2 to the CPU.

The module also can generate the S12CMPAI or S12CMPBI interrupt which is the request of interrupting to the CPU in response to matches with a condition for comparison.

Setting the ADCSR.ADIE bit to 1 and 0 enables and disables an S12ADI/S12ADI1/S12ADI2 interrupt, respectively; similarly, setting the ADCSR.GBADIE bit to 1 and 0 enables and disables a S12GBADI/S12GBADI1/S12GBADI2 interrupt, respectively.

Setting the ADCMPCR.CMPAIE bit to 1 enables an S12CMPAI interrupt and setting the ADCMPCR.CMPAIE bit to 0 disables an S12CMPAI interrupt.

Setting the ADCMPCR.CMPBIE bit to 1 enables an S12CMPBI interrupt and setting the ADCMPCR.CMPBIE bit to 0 disables an S12CMPBI interrupt.

In addition, the DTC/DMA transfer can be triggered when an S12ADI/S12ADI1/S12ADI2, S12GBADI/S12GBADI1/S12GBADI2, or S12GCADI/S12GCADI1/S12GCADI2 interrupt is generated. Using an S12ADI/S12ADI1/S12ADI2, S12GBADI/S12GBADI1/S12GBADI2, or S12GCADI/S12GCADI1/S12GCADI2 interrupt to allow the DTC or DMAC to read the converted data enables sequence conversion without burden on software.

For details on DTC and DMAC settings, refer to section 18, Data Transfer Controller (DTCa) and section 17, DMA Controller (DMACa).

### 38.4.2 Scan Complete Event Output to ELC

The ELC can set up linked operation of a module specified in advance by using the S12ADI, S12ADI1, or S12ADI2 interrupt request signal as an event signal.

The S12GBADI, S12GBADI1, or S12GBADI2 interrupt, S12CMPAI, S12CMPAI1, or S12CMPAI2 interrupt, and S12CMPBI, S12CMPBI1, or S12CMPBI2 interrupt request signals cannot be used as event signals. An event signal is output regardless of the setting of the corresponding interrupt request enable bit. The 12-bit A/D converter outputs the A/D conversion completed signals as event signals.

### 38.5 Allowable Impedance of Signal Source

Figure 38.54 shows an equivalent circuit of an analog input pin and an external sensor.

To perform A/D conversion accurately, the internal capacitor ( $C_s$ ) must be fully charged within the sampling time. If the impedance ( $R_0$ ) of the signal source is high and it takes time to charge  $C_s$ , extend the sampling time with the ADSSTRn register. Conversely, if  $R_0$  is small, the sampling time can be shortened. Refer to the electrical characteristics for the permissible signal source impedance under various operating conditions.

When converting only a single pin input in single scan mode, the influence of  $R_0$  can be ignored because the input load becomes practically only the internal input resistor ( $R_s$ ) by connecting an external high-capacity capacitor ( $C$ ). However, because a low-pass filter is formed by  $R_0$  and  $C$ , it may not possible to follow the analog signal that changes at high speed. Insert a low-impedance buffer when converting high speed analog signals or when converting multiple pins in scan mode.

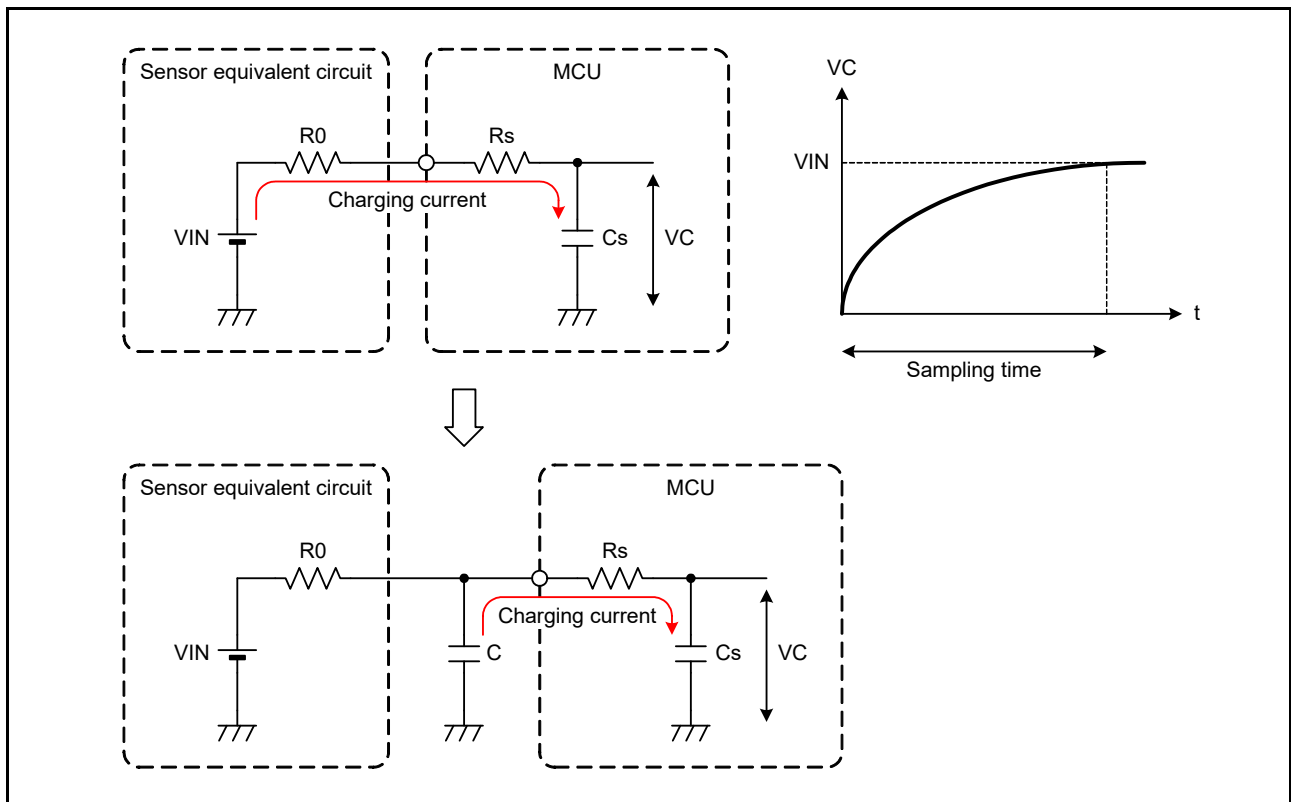

Figure 38.54 Equivalent Circuit of Analog Input Pin and External Sensor

## 38.6 Usage Notes

### 38.6.1 Notes on Reading Data Registers

The A/D data registers, A/D data duplication registers, A/D data duplication register A, A/D data duplication register B, A/D temperature sensor data register, A/D internal reference voltage data register, and A/D self-diagnosis data register should be read in 16-bit units. If a register is read twice in 8-bit units, that is, the higher-order byte and lower-order byte are separately read, the A/D-converted value having been read first may disagree with the A/D-converted value having been read for the second time. To prevent this, the data registers should never be read in 8-bit units.

### 38.6.2 Notes on Stopping A/D Conversion

#### 38.6.2.1 Procedure of Stopping A/D Conversion

To stop A/D conversion when an asynchronous trigger or a synchronous trigger has been selected as the condition for starting A/D conversion, follow the procedure in Figure 38.55.

Figure 38.55 Procedure for Clear Operation by Software Through the ADCSR.ADST Bit

### 38.6.2.2 Notes on Modes and Status Flags

The following values should be initialized or reset as described below: the voltage status used in self-diagnosis, the odd-even determination for the double-trigger mode, the monitor flags for the comparison function.

- Re-set the voltage for use in self-diagnosis by setting the ADCER.DIAGLD bit to 1 and setting the ADCER.DIAGVAL[1:0] bits.
- Make double-trigger mode effective starting from the first scan by changing the ADCSR.DBLE bit from 0 to 1.
- Set the ADCMPCR.CMPAE and ADCMPCR.CMPBE bits to 0, which clears the monitor flags for the comparison function (MONCMPA, MONCMPB, MONCOMB).
- Initialize the constant sampling function (enabled by setting the ADSSHMSR.SHMD bit to 1) by setting the ADSSHMSR.SHMD bit to 0. After this, when using constant sampling function again, wait for at least 1 cycle of ADCLK and then set the ADSSHMSR.SHMD bit to 1.

### 38.6.3 A/D Conversion Restarting Timing and Termination Timing

Starting operation of the analog blocks of the 12-bit A/D converter after setting the ADCSR.ADST bit to 1 takes up to six cycles of ADCLK. Stopping operation of the analog blocks of the 12-bit A/D converter by setting the ADCSR.ADST bit to 0 for a forced stop of the converter takes up to two cycles of ADCLK.

A period from forcible termination to idling of analog blocks takes a maximum of 1 PCLKB + 1 ADCLK cycles when PCLKB to ADCLK frequency ratio is 1:2 (ADCLK is faster).

### 38.6.4 Notes on Scan End Interrupt Handling

When scanning the same analog input twice using any trigger, the first A/D-converted data is overwritten with the second A/D-converted data in the case that the CPU does not complete reading the A/D-converted data by the time the A/D conversion of the first analog input for the second scan ends after the first scan end interrupt is generated.

### 38.6.5 Module Stop Function Setting

Operation of the 12-bit A/D converter can be disabled or enabled by setting module stop control register. The 12-bit A/D converter is stopped after released from the reset state. Register access is enabled by releasing the module stop state.

After the module stop state is released, wait for 1  $\mu$ s to start A/D conversion. To stop the operation of the 12-bit A/D converter using module stop function, set the ADVMONCR.VDE and ADVMONO.VDO bits to 0.

For details, refer to section 11, Low Power Consumption.

### 38.6.6 Notes on Entering Low Power Consumption States

Before entering the module stop state or software standby mode, make sure to stop A/D conversion. Here, set the ADCSR.ADST bit to 0, and secure certain period of time until the analog unit of the 12-bit A/D converter is stopped. Follow the procedure given below to secure this time.

Set the ADCSR.ADST bit to 0 by following the procedure in Figure 38.55 procedure for clear operation by software through the ADCSR.ADST bit. Then wait for two clock cycles of ADCLK before entering the module stop mode or software standby mode.

### 38.6.7 Notes on Canceling Software Standby Mode

After releasing the A/D converter from software standby, wait for the oscillation stabilization flag for the main clock or PLL clock to become 1, wait for at least a further 1  $\mu$ s after that, and then start A/D conversion.

For details, refer to section 11, Low Power Consumption.

### 38.6.8 Notes on Using an External Bus

A/D conversion during access to the external bus may reduce the precision.

In this case, use a software approach, such as performing A/D conversion several times, then obtaining the average after excluding the highest and lowest values.

### 38.6.9 Error in Absolute Accuracy When Disconnection Detection Assistance is in Use

Using disconnection detection assistance leads to an error in absolute accuracy of the A/D converter. This is because an error voltage is input to the analog input pins due to the resistive voltage division between the pull-up or pull-down resistor ( $R_p$ ) and the resistance of the signal source ( $R_s$ ).

This error in absolute accuracy is calculated from the following formula. Only use disconnection detection assistance after thorough evaluation.

$$\text{Maximum error in absolute accuracy (LSB)} = 4095 \times R_s/R_p$$

### 38.6.10 Voltage Range of Analog Power Supply Pins

If this MCU is used with the voltages outside the following ranges, the reliability of the MCU may be affected.

- Analog input voltage range

Set the voltage within the range from AVSS<sub>n</sub> to AVCC<sub>n</sub> (n = 0 to 2) when applying voltages to analog pins AN000 to AN007, AN100 to AN107, AN200 to AN211, AN216, and AN217.

- Relationship between power supply pin pairs (AVCC<sub>n</sub>–AVSS<sub>n</sub>, VCC–VSS)

Supply the voltage from the same power supply to two AVCC2 pins for products without pseudo-differential input to the PGAs and products in LFQFP-144.

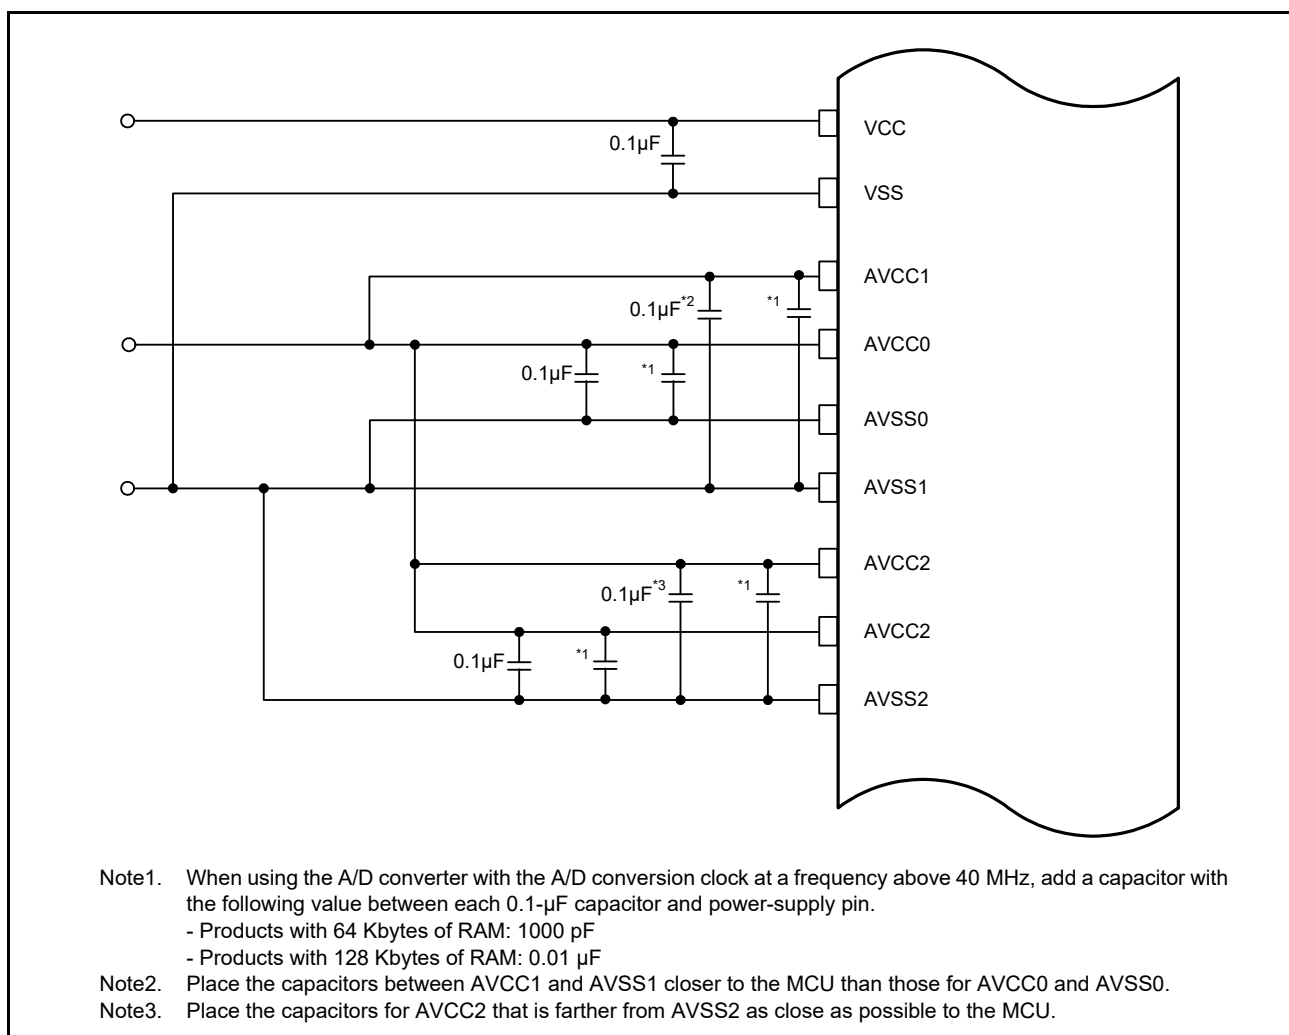

The following condition should be satisfied: AVSS<sub>n</sub> = VSS (n = 0 to 2). When performing A/D conversion of analog input pins AN216 and AN217, the following condition should be satisfied: AVCC<sub>n</sub> = VCC.

A 0.1-μF capacitor should be connected between each pair of power supply pins to create a closed loop with the shortest route possible as shown in Figure 38.56 and Figure 38.57, and connection should be made so that the following condition is satisfied at the supply side: AVSS<sub>n</sub> = VSS

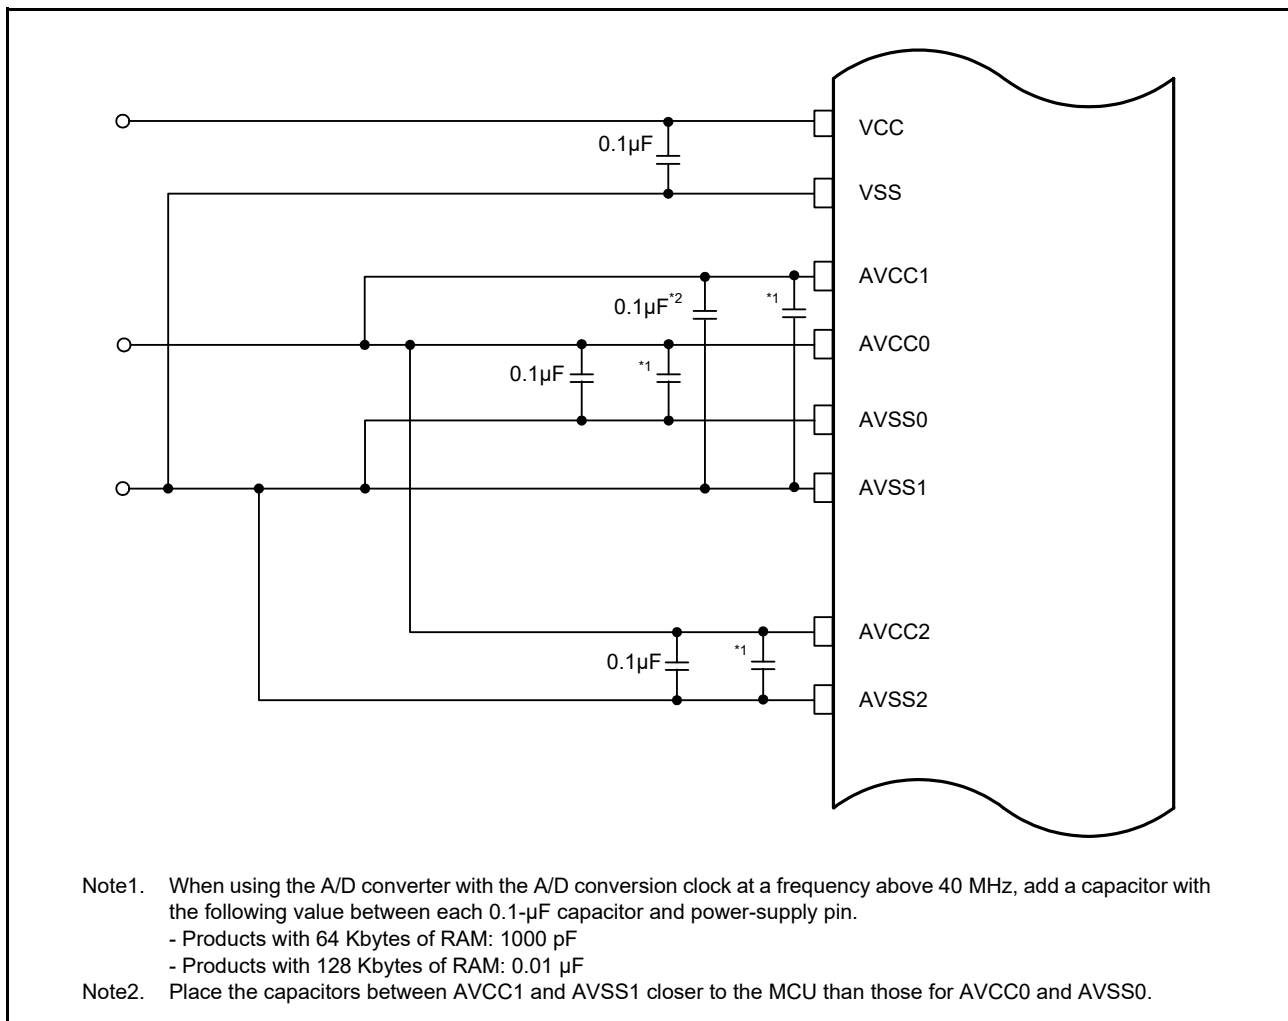

Connect a capacitor to each AVCC2 pin of products without pseudo-differential input to the PGAs and products in LFQFP-144 as shown in Figure 38.56.

When the 12-bit A/D converter is not used, the following conditions should be satisfied:

AVCC<sub>n</sub> = VCC and AVSS<sub>n</sub> = VSS

**Figure 38.56 Example for Connecting Power Supply Pins (for Products Without Pseudo-Differential Input to the PGAs and Products in LFQFP-144)**

**Figure 38.57 Example for Connecting Power Supply Pins (for Products neither Those Without Pseudo-Differential Input to the PGAs nor Those in LFQFP-144)**

### 38.6.11 Notes on Board Design

The board should be designed so that digital circuits and analog circuits are separated from each other as far as possible. In addition, digital circuit signal lines and analog circuit signal lines should not intersect or placed near each other. If these rules are not followed, noise will be produced on analog signals and A/D conversion accuracy will be affected. The analog input pins (AN000 to AN007, AN100 to AN107, AN200 to AN211, AN216, and AN217) and analog power supply (AVCCn) should be separated from digital circuits using the analog ground (AVSSn). The analog ground (AVSSn) should be connected to a stable digital ground (VSS) on the board (single-point ground plane connection).

### 38.6.12 Notes on Noise Prevention

To prevent the analog input pins (AN000 to AN007, AN100 to AN107, AN200 to AN211, AN216, and AN217) from being destroyed by abnormal voltage such as excessive surge, capacitors should be inserted between AVCCn and AVSSn, and protection circuits should be connected to protect the above analog input pins as shown Figure 38.58.

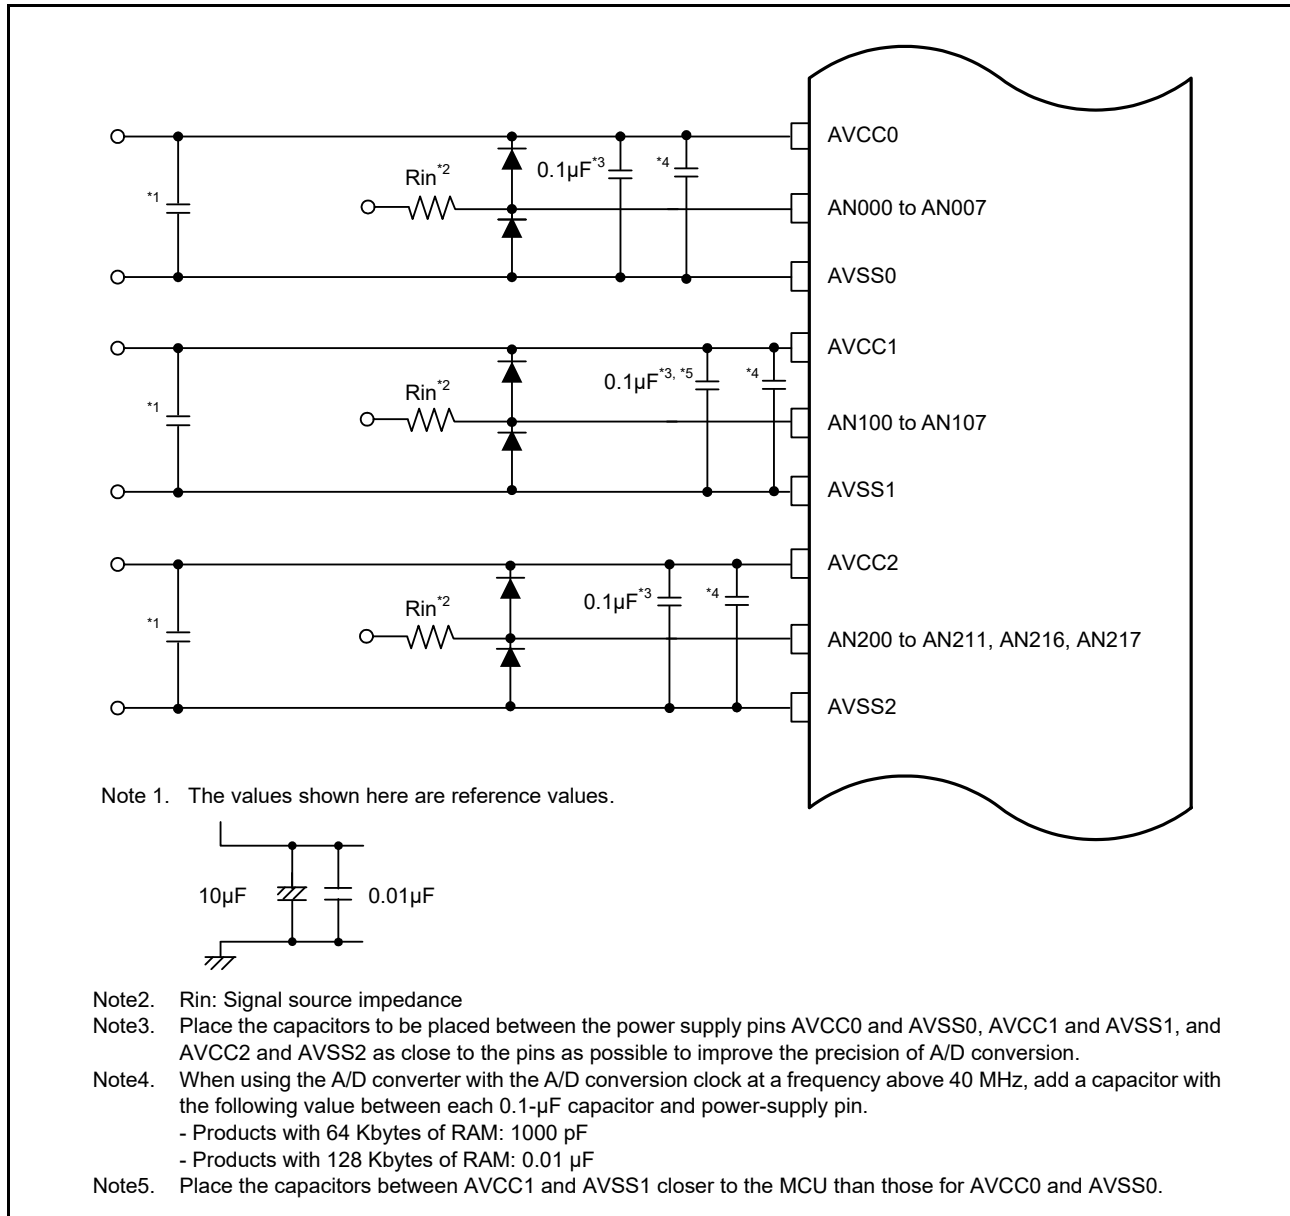

Figure 38.58 Sample Protection Circuit for Analog Inputs

### 38.6.13 Notes on Using Channel-Dedicated Sample-and-Hold Circuit

Enable use of the channel-dedicated sample-and-hold circuit (`ADSHCR.SHANS[2:0] ≠ 000b`), enable normal sampling by the channel-dedicated sample-and-hold circuit (`ADSHMSR.SHMD = 1`), and wait for 6 cycles of `ADCLK` to pass before input of a trigger signal.

To use the channel-dedicated sample-and-hold circuit, set the corresponding channel in any of the `ADSCS0`, `ADSCS1`, or `ADSCS2` register.

### 38.6.14 Notes on Using AN000 to AN002, AN007, AN100 to AN102, and AN107

To select `AN000` to `AN002`, `AN007`, `AN100` to `AN102`, and `AN107`, refer to section 38.3.2, **Setting the Input Paths of AN000 to AN002, AN007, AN100 to AN102, and AN107.**

## 39. 12-Bit D/A Converter (R12DAb)

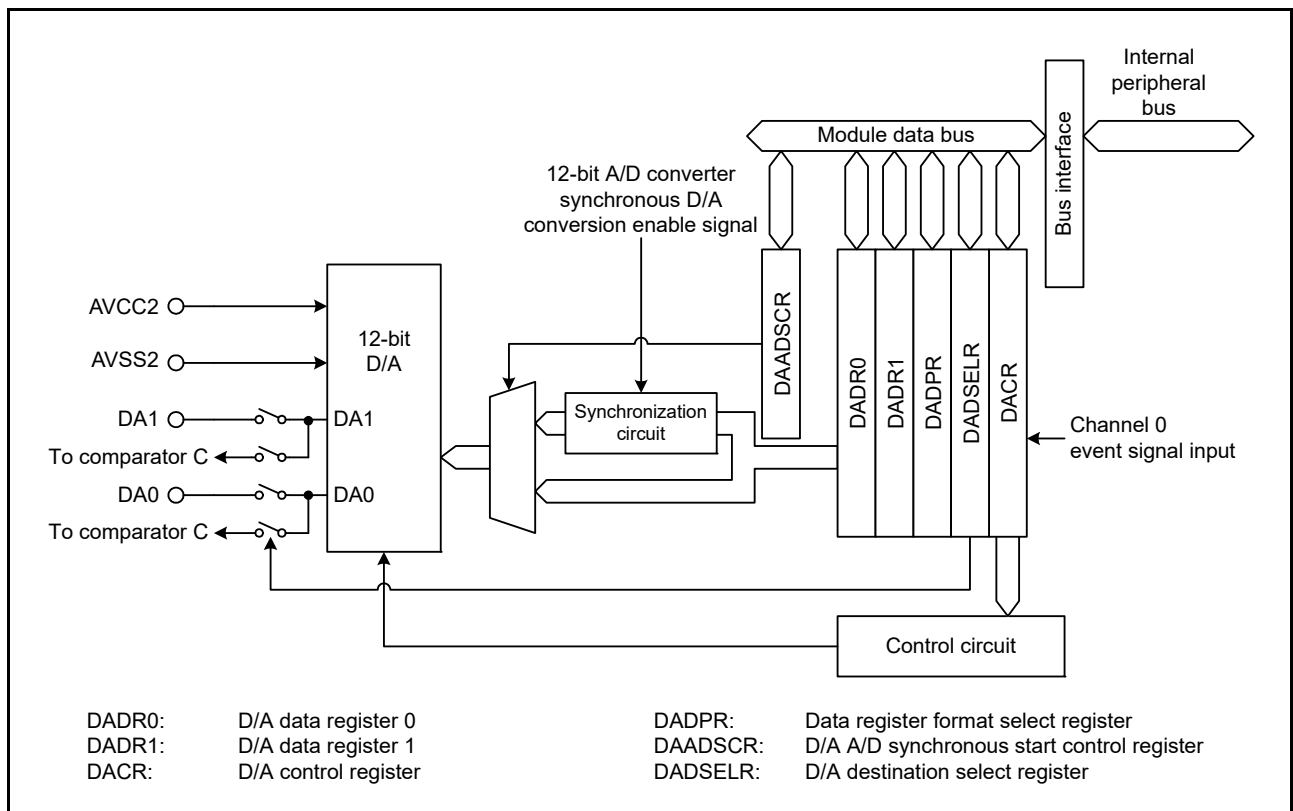

### 39.1 Overview

This MCU includes two channels of 12-bit D/A converter.

Table 39.1 lists the specifications of the 12-bit D/A converter and Figure 39.1 shows a block diagram of the 12-bit D/A converter.

**Table 39.1 Specifications of 12-Bit D/A Converter**

| Item                                                       | Specifications                                                                                                                                                                                                                                                                                                                                                                                                                |
|------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Resolution                                                 | 12 bits                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Output channels                                            | Two channels                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Measure against mutual interference between analog modules | Measure against interference between D/A and A/D conversion<br>D/A converted data update timing is controlled by the 12-bit A/D converter synchronous D/A conversion enable signal from the 12-bit A/D converter (unit 2).<br>Therefore, the degradation of A/D conversion accuracy due to interference is reduced by controlling the timing in which the 12-bit D/A converter inrush current occurs, with the enable signal. |
| Low power consumption function                             | Module stop state can be set.                                                                                                                                                                                                                                                                                                                                                                                                 |
| Event link function (input)                                | DA0 conversion can be started when an event signal is input.                                                                                                                                                                                                                                                                                                                                                                  |
| Destination Selection                                      | Outputs to the external pin and to the comparator C are separately controllable.                                                                                                                                                                                                                                                                                                                                              |

**Figure 39.1 Block Diagram of 12-Bit D/A Converter**

Table 39.2 lists the pin configuration of the 12-bit D/A converter.

**Table 39.2 Pin Configuration of 12-Bit D/A Converter**

| Pin Name | I/O    | Function                    |
|----------|--------|-----------------------------|
| AVCC2    | Input  | Analog power supply pin     |
| AVSS2    | Input  | Analog ground pin           |
| DA0      | Output | Channel 0 analog output pin |
| DA1      | Output | Channel 1 analog output pin |

## 39.2 Register Descriptions

### 39.2.1 D/A Data Register m (DADRm) (m = 0, 1)

Address(es): DA.DADR0 0008 8040h, DA.DADR1 0008 8042h

- DADPR.DPSEL bit = 0 (data is right-justified)

- DADPR.DPSEL bit = 1 (data is left-justified)

The DADRm register is a 16-bit readable/writable register, which stores data to which D/A conversion is to be performed. Whenever an analog output is enabled, the values in DADRm are converted and output from the D/A converter.

12-bit data can be relocated by setting the DADPR.DPSEL bit.

Bits “—” are read as 0. The write value should be 0.

### 39.2.2 D/A Control Register (DACR)

Address(es): DA.DACR 0008 8044h

|                    |       |       |     |    |    |    |    |    |
|--------------------|-------|-------|-----|----|----|----|----|----|
|                    | b7    | b6    | b5  | b4 | b3 | b2 | b1 | b0 |

| 1   | x     | x     | D/A conversion of channels 0 and 1 is enabled.<br>Analog output of channels 0 and 1 (DA0, DA1) is enabled collectively.                                                          |

x: Don't care

Note 1. When analog output is disabled, the analog output signal is placed in the Hi-Z state.

This register should be set when the DAADSCR.DAADST bit is 1 (measure against interference between D/A and A/D conversion is enabled) while the 12-bit A/D converter (unit 2) is halted (the ADCSR.ADST bit is 0). At that time, the software trigger should be selected for the 12-bit A/D converter (unit 2) trigger to securely stop the 12-bit A/D converter (unit 2).

Select the destination for each channel by using the DADSELR register before setting this register.

#### DAE Bit (D/A Enable)

The DAE bit controls D/A conversion and analog output in combination with the DAOEm bit (m = 0, 1).

When the measure against an interference between D/A and A/D conversions is enabled (DAADSCR.DAADST = 1), set the DAE bit while the ADCSR.ADST bit in the 12-bit A/D converter (unit 2) is 0. At that time, the software trigger should be selected for the 12-bit A/D converter (unit 2) trigger to securely stop the 12-bit A/D converter (unit 2).

**DAOEm Bit (D/A Output Enable m) (m = 0, 1)**

The DAOEm bit controls D/A conversion and analog output in combination with the DAE bit.

When both the DAOEm bit and DAE bit are 0, D/A conversion of channel m is not done and no conversion result is output.

When the measure against an interference between D/A and A/D conversions is enabled (DAADSCR.DAADST = 1), set the DAOEi bit while the ADCSR.ADST bit in the 12-bit A/D converter (unit 2) is 0. At that time, the software trigger should be selected for the 12-bit A/D converter (unit 2) trigger to securely stop the 12-bit A/D converter (unit 2).

The event link function can be used to set the DAOE0 bit to 1. The DAOE0 bit becomes 1 when the event specified by setting the ELSR16 register of the ELC occurs, and output of the D/A conversion results starts.

**39.2.3 Data Register Format Select Register (DADPR)**

Address(es): DA.DADPR 0008 8045h

|----------|--------|--------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----|
| b6 to b0 | —      | Reserved                       | These bits are read as 0. The write value should be 0.                                                                                                                                                                                                                                                                                                  | R/W |
| b7       | DAADST | D/A A/D Synchronous Conversion | 0: 12-bit D/A converter operation does not synchronize with 12-bit A/D converter (unit 2) operation. (measure against interference between D/A and A/D conversion is disabled)<br>1: 12-bit D/A converter operation synchronizes with 12-bit A/D converter (unit 2) operation. (measure against interference between D/A and A/D conversion is enabled) | R/W |

As a measure against interference between D/A and A/D conversion, the DAADSCR register selects whether or not the timing for starting 12-bit D/A conversion is synchronized with the 12-bit A/D converter synchronous D/A conversion enable signal from the 12-bit A/D converter (unit 2).

This register should be set while the 12-bit A/D converter (unit 2) is halted (while the ADCSR.ADST bit is 0 after selecting software trigger as the 12-bit A/D converter (unit 2) trigger).

#### DAADST Bit (D/A A/D Synchronous Conversion)

Setting the DAADST bit to 0 allows the DADDR<sub>m</sub> register value ( $m = 0, 1$ ) to be converted into analog data at any time. Setting the DAADST bit to 1 allows synchronous D/A conversion with the 12-bit A/D converter synchronous D/A conversion enable signal from the 12-bit A/D converter (unit 2). Therefore, even if the DADDR<sub>m</sub> register value is modified, D/A conversion does not start until the 12-bit A/D converter (unit 2) completes A/D conversion.

Set this bit while the ADCSR.ADST bit is set to 0. At this time, the software trigger should be selected for the 12-bit A/D converter trigger to securely stop the 12-bit A/D converter (unit 2).

The event link function cannot be used when the DAADST bit is set to 1. Stop the event link function by setting the ELSR16 register of the ELC. The setting of the DAADST bit is common to channels 0 and 1 of the 12-bit D/A converter.

| b7 to b4 | —       | Reserved                          | These bits are read as 0. The write value should be 0.                                                                                                                      | R   |

The DADSELER register is used to set the destinations of the analog voltage generated by the D/A converter. Select such destinations with this register before the output is enabled with the DACR register.

### 39.3 Operation

The 12-bit D/A converter includes D/A conversion circuits for two channels, each of which can operate independently. When the DACR.DA0Em bit ( $m = 0, 1$ ) is set to 1, D/A converter is enabled and the conversion result is output. An operation example of D/A conversion on channel 0 is shown below. Figure 39.2 shows the timing of this operation.

- (1) Set the data for D/A conversion in the DADPR.DPSEL bit and the DADR0 register.
- (2) Select the destination of the D/A converter analog voltage by using the DADSELR register.
- (3) Set the DACR.DA0E0 bit to 1 to start D/A conversion. The DA0 output settles to the voltage corresponding to the setting value after the conversion time  $t_{DCONV}$  has elapsed. The DA0 output voltage is held at this level until the DADR0 register is updated or the DA0E0 bit is set to 0. The output voltage (reference) is expressed by the following formula:

$$\frac{\text{Value of DADRm register}}{4096} \times AVCC2$$

- (4) When the DADR0 register is updated, the conversion starts. The DA0 output settles at the new output voltage after the conversion time  $t_{DCONV}$  has elapsed.

When the DAADSCR.DAADST bit is 1 (measure against interference between D/A and A/D conversion is enabled), it takes a maximum of one A/D conversion time for D/A conversion to start. When ADCLK is faster than the peripheral module clock, it may take longer than one A/D conversion time.

- (5) When the DA0E0 bit is set to 0, analog output is disabled.

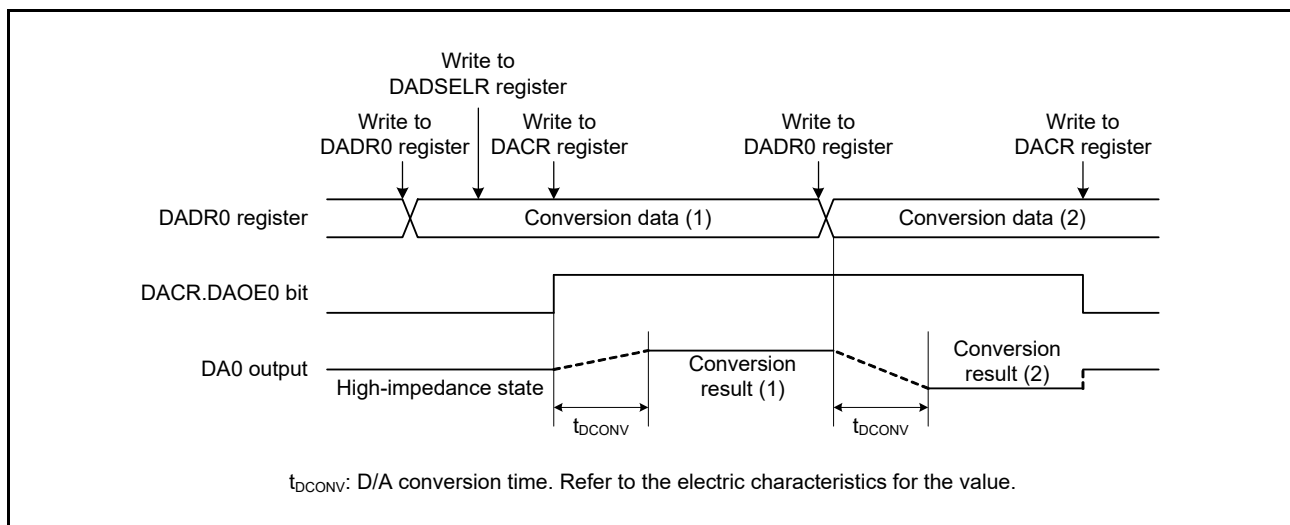

Figure 39.2 Example of 12-Bit D/A Converter Operation

### 39.3.1 Measure against Interference between D/A and A/D Conversion

When D/A conversion starts, an inrush current occurs to the 12-bit D/A converter. Since the same analog power supply is shared by the 12-bit D/A converter and 12-bit A/D converter (unit 2), the inrush current may interfere with the proper operation of the 12-bit A/D converter (unit 2).

With the DAADSCR.DAADST bit being 1, even if the DADR<sub>m</sub> register data (m = 0, 1) is modified during 12-bit A/D converter (unit 2) operation, D/A conversion does not start immediately but starts synchronously with A/D conversion completion. It takes a maximum of one A/D conversion time for the DADR<sub>m</sub> register data update to be reflected as the D/A conversion circuit input. Before reflection, the DADR<sub>m</sub> register value does not correspond to the analog output value.

When this function is enabled, it is impossible to check by any software means whether the DADR<sub>m</sub> register value has been D/A converted or not.

Even with the DAADSCR.DAADST bit being 1, when the DADR<sub>m</sub> register data is modified while the 12-bit A/D converter (unit 2) is halted, D/A conversion starts in one PCLKB cycle.

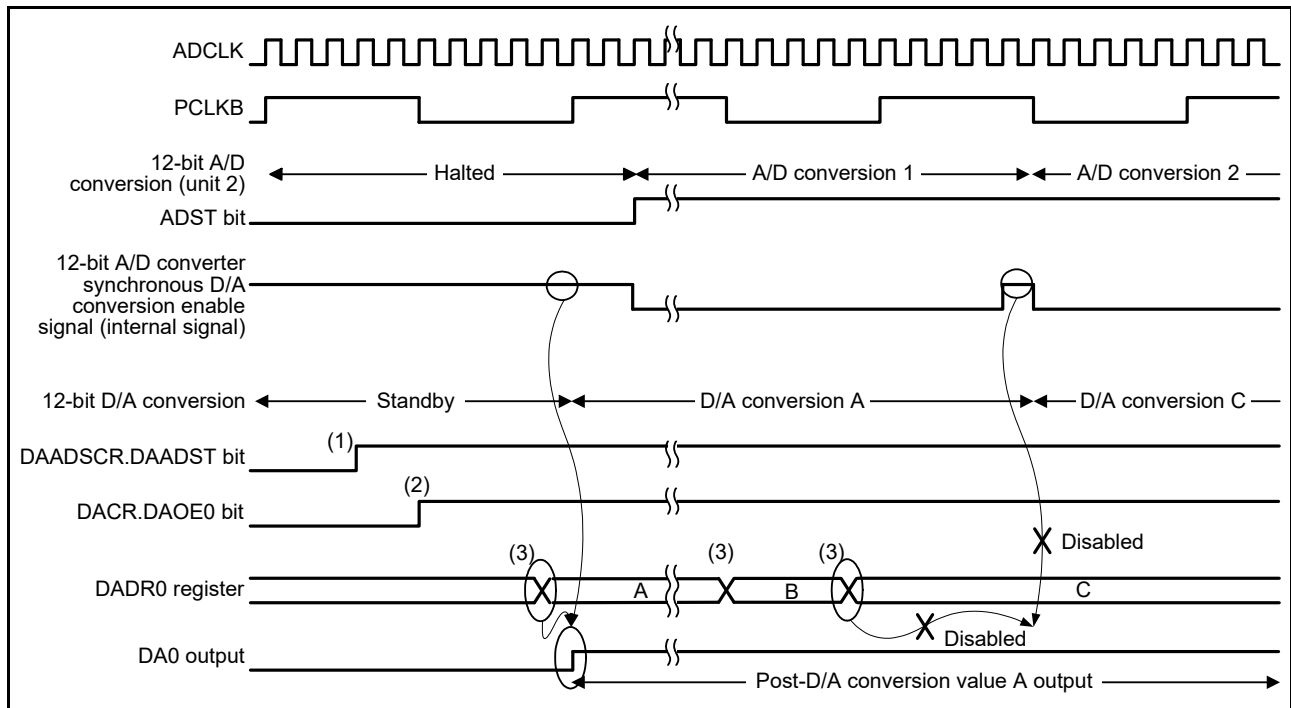

Figure 39.3 shows an example of channel 0 D/A conversion, in which the 12-bit D/A converter operates synchronously with the 12-bit A/D converter (unit 2).

- (1) Confirm that the 12-bit A/D converter (unit 2) is halted. Set the DAADSCR.DAADST bit to 1.
- (2) Confirm that the 12-bit A/D converter (unit 2) is halted. Set the DACR.DAOE0 bit to 1.
- (3) Set the DADR<sub>0</sub> register. When ADCLK is faster than the peripheral module clock, it may take longer than one A/D conversion time.
  - If the 12-bit A/D conversion is halted (ADCSR.ADST bit = 0) when the DADR<sub>0</sub> register is modified, D/A conversion starts in one PCLKB cycle.
  - If the 12-bit A/D conversion is in progress (ADCSR.ADST bit = 1) when the DADR<sub>0</sub> register is modified, D/A conversion starts upon A/D conversion completion. If the DADR<sub>0</sub> register is modified twice during A/D conversion, the first update may not be converted.

**Figure 39.3 Example of Conversion When the 12-Bit D/A Converter is Synchronized with the 12-Bit A/D Converter (Unit 2)**

When ADCLK is faster than PCLKB, the 12-bit D/A converter may not be able to capture a 12-bit A/D converter synchronous D/A conversion enable signal for one ADCLK cycle which is output between A/D conversion 1 and A/D conversion 2. Figure 39.4 shows example when the 12-bit D/A converter cannot capture the 12-bit A/D converter synchronous D/A conversion enable signal. In this case, the DA0 output is held at the level of the post-D/A conversion value A.

**Figure 39.4** Example When the 12-Bit D/A Converter Cannot Capture the 12-Bit A/D Converter Synchronous D/A Conversion Enable Signal

## 39.4 Event Link Operation Setting Procedure

The event link operation procedure is described below.

- (1) Set the DADPR.DPSEL bit and set the data for D/A conversion in the DADR0 register.
- (2) Select the destination of the D/A converter analog voltage by using the DADSELR register.
- (3) Set the bit value of the ELSR16 setting event signal to link the ELSR16 register of the ELC.
- (4) Set the ELCR.ELCON bit to 1. This procedure enables event link operation for all modules with the event link function selected.
- (5) Set the event output source module to activate the event link. After the event is output from the module, the DACR.DAOE0 bit becomes 1, and D/A conversion on channel 0 starts.
- (6) Set the ELSR16.ELS[7:0] bits to 0000 0000b to stop event link operation of 12-bit D/A converter channel 0. All event link operation is stopped when the ELCR.ELCON bit is set to 0.

## 39.5 Usage Notes on Event Link Operation

- (1) When the event link function is used, set the DACR.DAE bit to 0.
- (2) When the event specified by the ELSR16 register is generated while the write cycle is performed to the DACR.DAOE0 bit, the write cycle is stopped, and the setting to 1 by the generated event takes precedence.
- (3) Use of the event link function is prohibited when the DAADSCR.DAADST bit is set to 1 as the measure against an interfere between D/A and A/D conversions.

## 39.6 Usage Notes

### 39.6.1 Module Stop Function Setting

Operation of the 12-bit D/A converter can be disabled or enabled using the module stop control register. The initial setting is for operation of the 12-bit D/A converter to be stopped. Register access is enabled by releasing the module stop state. For details, refer to section 11, Low Power Consumption.

### 39.6.2 Operation of the D/A Converter in Module Stop State

When the MCU enters the module stop state with D/A conversion enabled, the D/A converter outputs are retained, and the analog power supply current is the same as during D/A conversion. If the analog power supply current has to be reduced in the module stop state, disable D/A conversion by setting the DACR.DAOE1, DAOE0, and DAE bits to 0.

### 39.6.3 Operation of the D/A Converter in Software Standby Mode

When the MCU enters software standby mode with D/A conversion enabled, the D/A converter outputs are retained, and the analog power supply current is the same as during D/A conversion. If the analog power supply current has to be reduced in software standby mode, disable D/A conversion by setting the DACR.DAOE1, DAOE0, and DAE bits to 0.

### 39.6.4 Note on Entering Deep Software Standby Mode

When the MCU enters deep software standby mode with D/A conversion enabled, the outputs of the D/A converter are placed in a high impedance state.

### 39.6.5 Note on Usage When Measure against Interference between D/A and A/D Conversion is Enabled

When the DAADSCR.DAADST bit is 1 (measure against interference between D/A and A/D conversion is enabled), do not place the 12-bit A/D converter (unit 2) in the module stop state. It may halt D/A conversion in addition to A/D conversion.

### 39.6.6 Note on Using the D/A Converter Analog Voltage as a Reference Voltage for the Comparator C

When setting the DADSELR.OUTREFn bit (n = 0, 1) to 1, refer to section 41.4.5, Setting the D/A Converter.

### 39.6.7 Note on Enabling the Outputs Both to the DAn pin (n = 0, 1) and Comparator C

When the DADSELR.OUTDAn and OUTREFn bits are set to 1 simultaneously, the characteristics specified in section 45.9, D/A Conversion Characteristics may not be satisfied due to the influence of the load connected to the DAn pin. A full evaluation is recommended before use when both outputs are to be enabled.

## 40. Temperature Sensor (TEMPS)

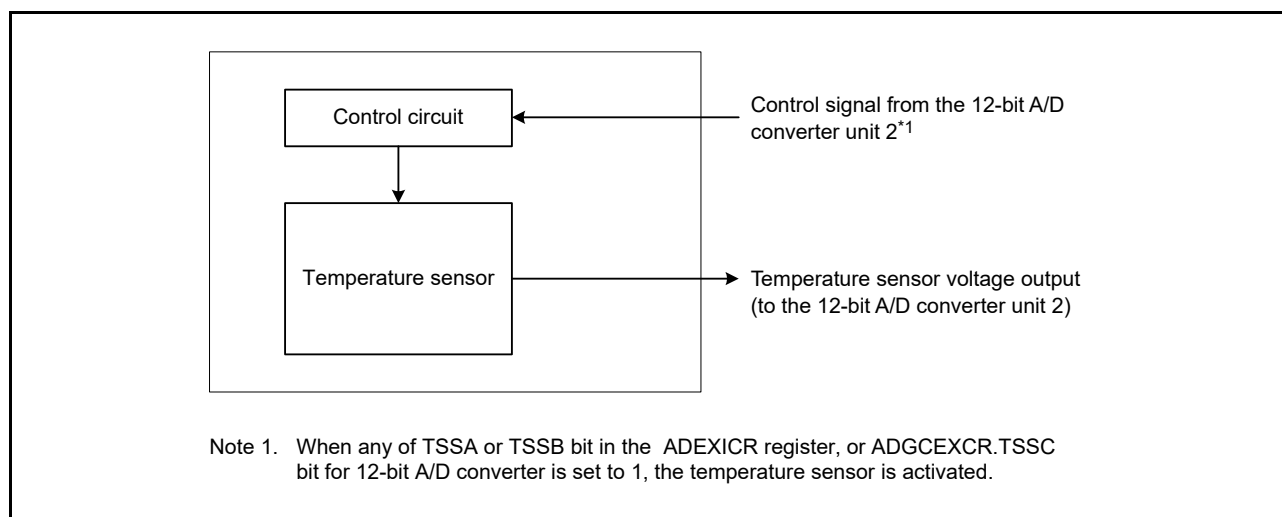

### 40.1 Overview

This MCU has a built-in temperature sensor. The temperature sensor outputs a voltage proportional to temperature. By converting the output voltage of the temperature sensor into a digital value with a 12-bit A/D converter unit 2 and converting it into temperature, the internal temperature of the MCU can be obtained.

Table 40.1 lists the specifications of the temperature sensor, and Figure 40.1 shows a block diagram of the temperature sensor.

**Table 40.1 Specifications of Temperature Sensor**

| Item                                | Description                                                              |
|-------------------------------------|--------------------------------------------------------------------------|
| Temperature sensor voltage output   | Temperature sensor outputs a voltage to the 12-bit A/D converter unit 2. |
| Temperature Sensor Calibration Data | Reference data measured for each chip at factory shipment is stored.     |

**Figure 40.1 Block Diagram of Temperature Sensor**

## 40.2 Register Descriptions

### 40.2.1 Temperature Sensor Calibration Data Register (TSCDR)

Address(es): TEMPS.TSCDR 007F B17Ch

Note: This register is only readable when the SYSCR0.ROME bit is 1 (the on-chip ROM is enabled).

The TSCDR register stores temperature sensor calibration data measured for each chip at factory shipment. The TSCDR register is a 32-bit read-only register and should be read in 32-bit units.

Temperature sensor calibration data is a digital value obtained using the 12-bit A/D converter unit 2 to convert the voltage output by the temperature sensor under the condition of  $T_j = 125^\circ\text{C}$  and  $AVCC2 = 5\text{ V}$ .

The voltage  $V_1$  output by the temperature sensor under the condition of  $T_j = 125^\circ\text{C}$  can be calculated from the value of the TSCDR register according to the formula below.

$$V_1 = 5 \times \text{value of the TSCDR register} / 4096 \text{ [V]}$$

Note that the  $AVCC2$  voltage does not affect voltage  $V_1$ .

### 40.3 Using the Temperature Sensor

The temperature sensor outputs a voltage proportional to temperature. By converting this voltage into a digital value with a 12-bit A/D converter unit 2 and converting it into temperature, the internal temperature of the MCU can be obtained.

#### 40.3.1 Preparation for Using the Temperature Sensor

Perform a calibration of the temperature sensor as shown below. The voltage output by the temperature sensor is proportional to temperature, which can be calculated according to the following formula.

Formula for the temperature characteristic:

$$T = (V_s - V_1)/\text{Slope} + T_1$$

T: Measured temperature (°C)

V<sub>s</sub>: Voltage output by the temperature sensor when the temperature is measured (V)

T<sub>1</sub>: Sample temperature measurement at first point (°C)

V<sub>1</sub>: Voltage output by the temperature sensor when T<sub>1</sub> is measured (V)

T<sub>2</sub>: Sample temperature measurement at second point (°C)

V<sub>2</sub>: Voltage output by the temperature sensor when T<sub>2</sub> is measured (V)

Slope: Temperature slope of the temperature sensor (V/°C); Slope = (V<sub>2</sub> - V<sub>1</sub>)/(T<sub>2</sub> - T<sub>1</sub>)

Since there are individual differences in temperature sensors, it is recommended to prepare a temperature slope by performing trial measurements at two different temperatures as shown below.

Use the 12-bit A/D converter unit 2 to measure the voltage V<sub>1</sub> output by the temperature sensor at temperature T<sub>1</sub>.

Again, using the 12-bit A/D converter unit 2, measure the voltage V<sub>2</sub> output by the temperature sensor at a different temperature T<sub>2</sub>. Obtain the temperature slope (Slope = (V<sub>2</sub> - V<sub>1</sub>)/(T<sub>2</sub> - T<sub>1</sub>)) from these results.

Subsequently, obtain temperatures by substituting the slope into the formula for the temperature characteristic (T = (V<sub>s</sub> - V<sub>1</sub>)/Slope + T<sub>1</sub>).

If you are using the temperature slope given in Table 45.53 of section 45, Electrical Characteristics, use the 12-bit A/D converter unit 2 to measure the voltage V<sub>1</sub> output by the temperature sensor at temperature T<sub>1</sub>, and then calculate the temperature characteristic by using the formula below.

However, this calibration gives less accurate temperatures than two-point calibration.

$$T = (V_s - V_1)/\text{Slope} + T_1$$

T: Measured temperature (°C)

V<sub>s</sub>: Voltage output by the temperature sensor when the temperature is measured (V)

T<sub>1</sub>: Sample temperature measurement at first point (°C)

V<sub>1</sub>: Voltage output by the temperature sensor when T<sub>1</sub> is measured (V)

Slope: Temperature slope given in Table 45.53 ÷ 1000 (V/°C)

In this MCU, the TSCDR register stores the temperature value (CAL<sub>125</sub>) of the temperature sensor measured under the condition of T<sub>j</sub> = 125°C and AVCC2 = 5 V. By using this value as the sample measurement result at the first point, preparation before using the temperature sensor can be omitted.

If V<sub>1</sub> is calculated from CAL<sub>125</sub>,

$$V_1 = 5 \times \text{CAL}_{125}/4096 \text{ [V]}$$

Using this, the measured temperature can be calculated according to the formula below.

$$T = (V_s - V_1) / \text{Slope} + 125 \text{ [}^\circ\text{C]}$$

T: Measured temperature (internal temperature of the MCU) ( $^\circ\text{C}$ )

V<sub>s</sub>: Voltage output by the temperature sensor when the temperature is measured (V)

V<sub>1</sub>: Voltage output by the temperature sensor when T<sub>j</sub> = 125 $^\circ\text{C}$  and AVCC2 = 5 V (V)

Slope: Temperature slope given in Table 45.53  $\div$  1000 (V/ $^\circ\text{C}$ )

Error in the measured temperature (the range of variation is  $3\sigma$ ) is shown in Figure 40.2.

Figure 40.2 Error in the Measured Temperature

### 40.3.2 Setting of 12-Bit A/D Converter Unit 2

For A/D conversion of temperature sensor output voltages, 12-bit A/D converter unit 2 registers should be set as follows.

- **Selecting the Temperature Sensor Voltage as a Source for A/D Conversion**  
Select the temperature sensor voltage as a source for A/D conversion by setting the temperature sensor output A/D conversion select bit in the A/D conversion extended input control register (TSSA or TSSB in the ADEXICR register, or ADGCEXCR.TSSC) to 1.
- **Setting Scan Mode**  
Select scan mode by setting the scan mode select bits in the A/D control register (ADCSR.ADCS[1:0]). Set the bits to the single scan mode or the group scan mode.
- **Setting Addition/Average Mode**  
For A/D conversion of the temperature sensor output, additional or average mode is selectable. To use either additional or average mode, set the temperature sensor output A/D converted value addition mode select bit in the A/D conversion extended input control register (ADEXICR.TSSAD) to 1, and the addition count select bits in the A/D converted value addition count select register (ADADC.ADC[2:0]) to the desired number of addition. Furthermore, clear the AVEE bit in ADADC to 0 to select addition mode; set the AVEE bit in ADADC to 1 to select average mode. In average mode, however, the ADC[2:0] bits in ADADC should not be set to 010b or 101b.
- **Setting the Sampling Time of the 12-bit A/D converter Unit 2**  
The sampling time of the 12-bit A/D converter can be changed at converting the output from the temperature sensor. The initial sampling time is 27 cycles of ADCLK. To change the setting of sampling time from 27 cycles of ADCLK, set the A/D sampling state register T (ADSSTRT) while the ADCSR.ADST bit is 0. Refer to section 38.2.19, A/D Sampling State Register n (ADSSTRn) (n = 0 to 11, L, T, O) for the setting range of the sampling time. Set the sampling time to satisfy the specifications described in section 45, Electrical Characteristics.

Setting the A/D conversion start bit in the A/D control register (ADCSR.ADST) to 1 starts A/D conversion, and the result is stored in the A/D temperature sensor data register (ADTSDR). If you will be using A/D conversion of the output from the temperature sensor, do so in accord with section 40.3.3, Procedure for Using the Temperature Sensor.

### 40.3.3 Procedure for Using the Temperature Sensor

Figure 40.3 shows the procedure for using the temperature sensor.

Figure 40.3 Procedure for Using the Temperature Sensor

### 40.3.4 Timing of A/D Conversion of Temperature Sensor Output

Figure 40.4 shows the timing from the start of temperature-sensor operation until the completion of A/D conversion when only the output from the temperature sensor is to be A/D converted and conversion is in single-scan mode. The times shown in the figure are described in Table 40.2.

When setting the ADST bit to 1 to perform the A/D conversion of the temperature sensor, auto-discharge is performed before sampling. The A/D conversion time of the temperature sensor includes the time for the auto discharge.

**Figure 40.4** Timing from the Start of Temperature-Sensor Operation until Completion of A/D Conversion

**Table 40.2** Time until Completion of A/D Conversion after the Start of Temperature-Sensor Operation

| Item                                              | Symbol | Time                                                                                                                                                                         |
|---------------------------------------------------|--------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Temperature-sensor output stabilization wait time | tOSTBL | 200 μs (min)                                                                                                                                                                 |
| Auto discharge time                               | tADIS  | 15 × tC(ADCLK)                                                                                                                                                               |
| 12-bit A/D converter unit 2 input sampling time   | tSPL   | ADSSTRT setting × tC(ADCLK)                                                                                                                                                  |
| A/D conversion time                               | tCONV  | Refer to Table 38.25, Times for Conversion During Scanning (in Numbers of Cycles of ADCLK and PCLKB) in section 38.3.8, Analog Input Sampling Time and Scan Conversion Time. |
| Scan conversion end delay time                    | tED    | Refer to Table 38.25, Times for Conversion During Scanning (in Numbers of Cycles of ADCLK and PCLKB) in section 38.3.8, Analog Input Sampling Time and Scan Conversion Time. |

## 40.4 Usage Note

### 40.4.1 Activating the Temperature Sensor

The temperature sensor is controlled by the registers in the 12-bit A/D converter unit 2 (S12AD2). To activate the temperature sensor, set any of TSSA or TSSB bit in the ADEXICR register, or ADGCXCR.TSSC bit to 1 after releasing the S12AD2 from the module stop state. For details, refer to section 38, 12-Bit A/D Converter (S12ADH).

## 41. Comparator C (CMPC)

### 41.1 Overview

Comparator C compares a reference input voltage to an analog input voltage.

The comparison result can be read by software and output externally, and an interrupt request can be generated upon any changes to the comparison result.

The reference input voltage of comparator C can be selected from the input from the CVREFC0 or CVREFC1 pin, or the output from the on-chip D/A converter 0 or the on-chip D/A converter 1.

There are four analog inputs, one of which is to be selected.

Table 41.1 lists the specification of comparator C, Figure 41.1 shows a block diagram of comparator C, Table 41.2 shows a comparator C pin configuration, and Table 41.3 shows the analog input pin connections for comparator C.

In this section, “PCLK” is used to refer to PCLKB.

**Table 41.1 Comparator C Specifications**

| Item                           | Specification                                                                                                                                                                                                                                                                                                                                                              |
|--------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Number of channels             | Six (comparator C0 to comparator C5)                                                                                                                                                                                                                                                                                                                                       |
| Analog input voltages          | Input voltage from the CMPCnm pin (n = channel number; m = 0 to 3)                                                                                                                                                                                                                                                                                                         |
| Reference input voltage        | Input voltage from the CVREFC0 or CVREFC1 pin, or output voltage from on-chip D/A converter 0 or on-chip D/A converter 1                                                                                                                                                                                                                                                   |
| Comparison result              | The comparison result can be output externally.                                                                                                                                                                                                                                                                                                                            |
| Digital filter function        | <ul style="list-style-type: none"> <li>• One of three sampling periods can be selected.</li> <li>• The filter function can also be disabled.</li> <li>• A noise-filtered signal can be used to generate the interrupt request output, event output to the ELC, and POE source output*1, and the signal can be used to read the comparison result via registers.</li> </ul> |
| Interrupt request              | <ul style="list-style-type: none"> <li>• An interrupt request is generated upon detecting a valid edge of the comparison result.</li> <li>• A valid edge can be selected from a rising or a falling edge or both edges.</li> </ul>                                                                                                                                         |
| Low power consumption function | Module stop state can be set.                                                                                                                                                                                                                                                                                                                                              |

Note 1. The POE only uses the level detection signal, and the POEG uses the level detection and edge detection signals.

| b2     | —         | Reserved                                   | This bit is read as 0. The write value should be 0.                                                                                                     | R/W |
| b4, b3 | CEG[1:0]  | Comparator Edge Interrupt Detection Select | b4 b3<br>0 0: Interrupt request is not generated.<br>0 1: Rising edge<br>1 0: Falling edge<br>1 1: Both edges                                           | R/W |
| b6, b5 | CDFS[1:0] | Noise Filter Sampling Select*1, *2, *4     | b6 b5<br>0 0: Noise filter not used<br>0 1: Sampling frequency is PCLK/8.<br>1 0: Sampling frequency is PCLK/16.<br>1 1: Sampling frequency is PCLK/32. | R/W |
| b7     | HCMPON    | Comparator Operation Enable*3              | 0: Operation stopped (the output signal is fixed to 0)<br>1: Operation enabled (input to the comparator pins is enabled)                                | R/W |

Note: Set this register before setting registers in the ELC when using event output.

Note: Set this register before setting registers in the POE when using comparator output as a POE source.

Note 1. Rewrite the CDFS[1:0] and CINV bits only after disabling the comparator output (COE bit = 0).

Note 2. If the CDFS[1:0] bits are changed from 00b (noise filter not used) to a value other than 00b (noise filter used), allow four sampling times to elapse until the filter output is updated, and then use the CMPCn interrupt request output, an event output, and a POE source output.

Note 3. The operation stabilization wait time is required after enabling comparator operation (HCMPON bit = 1). As for the value, refer to section 45, Electrical Characteristics.

Note 4. Rewriting the CINV bit or CDFS[1:0] bits may generate a CMPCn interrupt request, event output, and POE source. Before changing these bits, set the registers in the ELC so that the comparator output is not linked and set the registers in the POE/POEG so that comparator output is not used for output disabling control. After changing these bits, also set the corresponding interrupt status flag (IR) in the interrupt request register, the POE comparator channel n output detection flag (n = 0 to 5), and the GPTW or CMPC output stop request detection flag in the POEG to 0.

#### CEG[1:0] Bits (Comparator Edge Interrupt Detection Select)

These bits select which edge of comparator output signal is used to generate an interrupt request.

The valid edge is set for the signal after the comparator polarity is selected by the CINV bit and the filter is selected by CDFS[1:0] bits.

## 41.2.2 Comparator Input Select Register (CMPSEL0)

Address(es): CMPC0.CMPSEL0 000A 0C84h, CMPC1.CMPSEL0 000A 0CA4h, CMPC2.CMPSEL0 000A 0CC4h, CMPC3.CMPSEL0 000A 0CE4h, CMPC4.CMPSEL0 000A 0D04h, CMPC5.CMPSEL0 000A 0D24h

The write value should be 0.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | R/W |    |          |          |          |                 |          |                 |          |                 |          |                 |                                           |  |    |    |          |          |          |                 |          |                 |          |                 |          |                 |                                           |  |    |    |          |          |          |                 |          |                 |          |                 |          |                 |                                           |  |    |    |          |          |          |                 |          |                 |          |                 |          |                 |                                           |  |    |    |          |          |          |                 |          |                 |          |                 |          |                 |                                           |  |    |    |          |          |          |                 |          |                 |          |                 |          |                 |                                           |  |     |

Note 1. Rewrite the CMPSEL[3:0] bits in the following procedure. Writing a value other than 0000b while the value of these bits is not

0000b is invalid. Writing 1 to two or more bits is also invalid. In both cases, the previous value is retained.

- (1) Set the CMPCTL.COE bit to 0.
- (2) Set the CMPSEL[3:0] bits to 0000b.
- (3) Set a new value to the CMPSEL[3:0] bits (with 1 set in only one of the bits).
- (4) Wait for the stabilization time for input selection. As for the value, refer to section 45, Electrical Characteristics.
- (5) Set the CMPCTL.COE bit to 1.
- (6) Set the corresponding interrupt status flag (IR) in the interrupt request register to 0.
- (7) Set the GPTW or CMPC output stop request detection flag (POEGGj.IOCF (j = A to D)) in the corresponding POEG to 0.

Note 2. When using the event output, note that writing to these bits after the corresponding register in the ELC is set may trigger the output of an event signal.

Note 3. If COMPn level detection signal is used as a POE source, note that write access to these bits after the setting of any register in the POE may generate a POE source.

### 41.2.3 Comparator Reference Voltage Select Register (CMPSEL1)

Address(es): CMPC0.CMPSEL1 000A 0C88h, CMPC1.CMPSEL1 000A 0CA8h, CMPC2.CMPSEL1 000A 0CC8h, CMPC3.CMPSEL1 000A 0CE8h, CMPC4.CMPSEL1 000A 0D08h, CMPC5.CMPSEL1 000A 0D28h

| Bit      | Symbol    | Bit Name                                        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          | R/W |
|----------|-----------|-------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----|
| b3 to b0 | CVRS[3:0] | Reference Input Voltage Select*1,<br>*2, *3, *4 | <div style="display: flex; justify-content: space-between; font-size: small;"> <span>b3</span> <span>b0</span> </div> 0 0 0 0: No input<br>0 0 0 1: On-chip D/A converter 1 output voltage selected as reference input voltage<br>0 0 1 0: On-chip D/A converter 0 output voltage selected as reference input voltage<br>0 1 0 0: Input voltage to the CVREFC1 pin selected as reference input voltage<br>1 0 0 0: Input voltage to the CVREFC0 pin selected as reference input voltage<br>Settings other than above are prohibited. | R/W |
| b7 to b4 | —         | Reserved                                        | These bits are read as 0. The write value should be 0.                                                                                                                                                                                                                                                                                                                                                                                                                                                                               | R/W |

Note 1. When the on-chip D/A converter output voltage is used, set the D/A converter for generating comparator C reference voltage before enabling comparator operation (CMPCTL.HCMPON bit = 1). For details on setting the D/A converter, refer to section 39, 12-Bit D/A Converter (R12DAb).

Note 2. Rewrite the CVRS[3:0] bits in the following procedure. Be sure to set the CVRS[3:0] bits to 0000b before changing the set value. Direct rewriting from 0001b to 0010b or 0010b to 0001b, for example, will be ignored even if it is tried.

- (1) Set the CMPCTL.COE bit to 0.
- (2) Set the CVRS[3:0] bits to 0000b.
- (3) Set a new value to the CVRS[3:0] bits (with 1 set in only one of the bits).
- (4) Wait for the stabilization time for input selection. As for the value, refer to section 45, Electrical Characteristics.
- (5) Set the CMPCTL.COE bit to 1.
- (6) Set the corresponding interrupt status flag (IR) in the interrupt request register to 0.
- (7) Set the GPTW or CMPC output stop request detection flag (POEGGj.IOCF (j = A to D)) in the corresponding POEG to 0.

Note 3. When using the event output, note that writing to these bits after the corresponding register in the ELC is set may trigger the output of an event signal.

Note 4. If COMPn level detection signal is used as a POE source, note that write access to these bits after the setting of any register in the POE may generate a POE source.

### 41.2.4 Comparator Output Monitor Register (CMPMON)

Address(es): CMPC0.CMPMON 000A 0C8Ch, CMPC1.CMPMON 000A 0CACH, CMPC2.CMPMON 000A 0CCCh, CMPC3.CMPMON 000A 0CECh, CMPC4.CMPMON 000A 0D0Ch, CMPC5.CMPMON 000A 0D2Ch

Value after reset: 0 0 0 0 0 0 0 0

| Bit      | Symbol  | Bit Name                             | Description                                              | R/W |
|----------|---------|--------------------------------------|----------------------------------------------------------|-----|
| b0       | CMPMON0 | Comparator Output Monitor Flag<br>*1 | 0: Comparator output is 0.<br>1: Comparator output is 1. | R   |
| b7 to b1 | —       | Reserved                             | These bits are read as 0. The write value should be 0.   | R/W |

Note 1. When comparator operation is enabled (CMPCTL.HCMPON and COE bits are 1) while the noise filter is disabled (CMPCTL.CDFS[1:0] bits are 00b), read the CMPMON0 bit twice and use the value only when the results match.

### 41.2.5 Comparator External Output Enable Register (CMPIOC)

Address(es): CMPC0.CMPIOC 000A 0C90h, CMPC1.CMPIOC 000A 0CB0h, CMPC2.CMPIOC 000A 0CD0h, CMPC3.CMPIOC 000A 0CF0h, CMPC4.CMPIOC 000A 0D10h, CMPC5.CMPIOC 000A 0D30h

Value after reset: 0 0 0 0 0 0 0 0

| Bit      | Symbol | Bit Name                   | Description                                                                                                                                                                                                          | R/W |
|----------|--------|----------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----|
| b0       | CPOE   | External Pin Output Enable | Comparison result by the comparator is output to an external pin.<br>0: Output to the comparator external pin is disabled (the output signal is fixed to low)<br>1: Output to the comparator external pin is enabled | R/W |
| b7 to b1 | —      | Reserved                   | These bits are read as 0. The write value should be 0.                                                                                                                                                               | R/W |

### 41.3 Operation

#### 41.3.1 Comparator Operation Example

Figure 41.2 shows an operation example of the comparator. The COMPn level detection signal (n = 0 to 5) becomes high when the analog input voltage is higher than the reference input voltage, and the COMPn level detection signal becomes low when the analog input voltage is lower than the reference input voltage (when the CMPCTL.CINV bit is 0). The COMPn level detection signal can also be used as event output signal. When the CPOE bit in the corresponding CMPIOC register is 1, the signal is output from the COMPn pin. Interrupt request and COMPn edge detection signal are output in response to changes in the comparator output.

Figure 41.2 Comparator Operation Example (n = 0 to 5)

### 41.3.2 Noise Filter

Comparator C contains a noise filter. The sampling clock can be selected by the CMPCTL.CDFS[1:0] bits. The comparator output signal is sampled every sampling clock, and if the same value is sampled three times, that value is determined as the noise filter output at the next sampling clock.

Figure 41.3 shows the configuration of the noise filter and edge detector and Figure 41.4 shows an example of the comparator noise filter and interrupt operation.

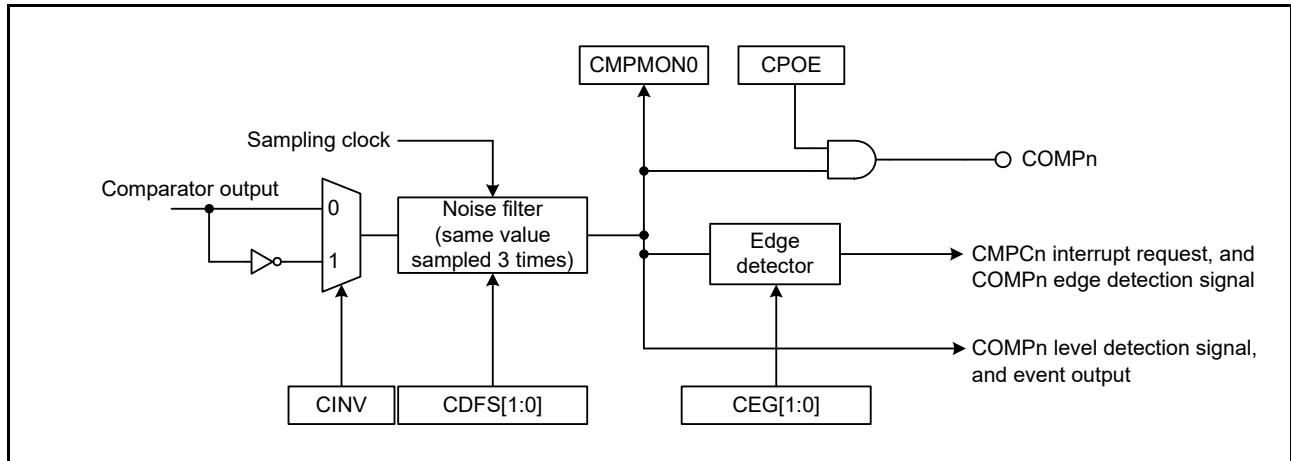

Figure 41.3 Noise Filter and Edge Detector Configuration (n = 0 to 5)

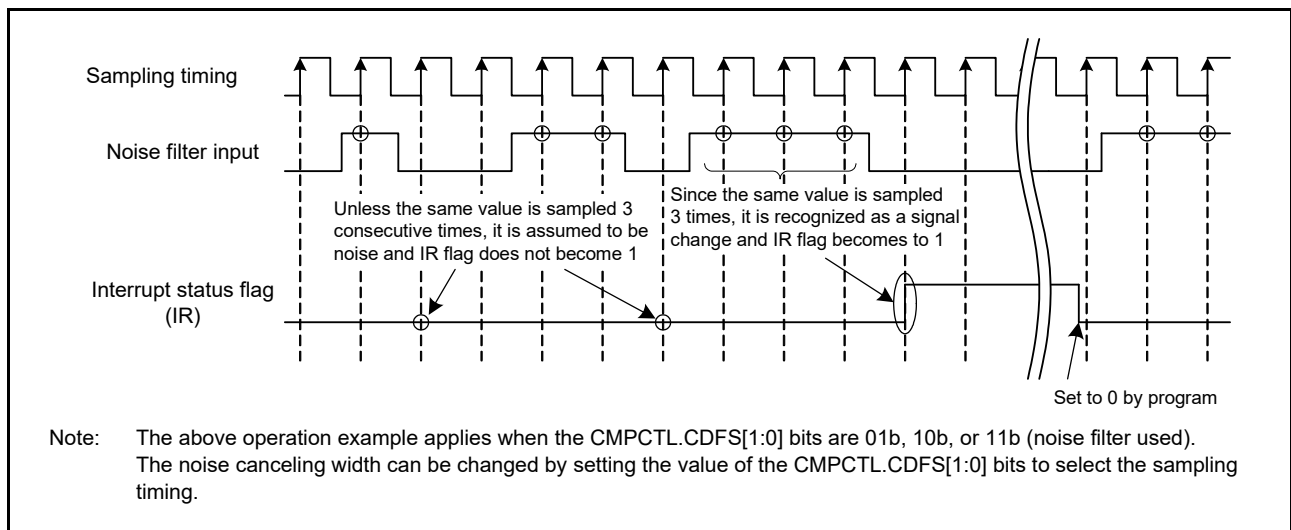

Figure 41.4 Noise Filter and Interrupt Operation Example

Note: The above operation example applies when the CMPCTL.CDFS[1:0] bits are 01b, 10b, or 11b (noise filter used). The noise canceling width can be changed by setting the value of the CMPCTL.CDFS[1:0] bits to select the sampling timing.

### 41.3.3 Interrupts

Comparator C generates an interrupt request upon detecting any changes in the comparison result.

When using the CMPCn interrupt, set at least one of bits CMPCTL.CEG[1:0] to 1 (to a value other than 00b (interrupt request is not generated)).

To use the CMPCn interrupt, use the following setting procedure. Note that steps (1), (2), and (3) can be set in any order.

- (1) When using the on-chip D/A converter output voltage as the reference input voltage, set the D/A converter for generating comparator C reference voltage and enable operation.
- (2) Set the CMPSEL0 or CMPSEL1 register to set the input of the comparator.
- (3) Set the CMPCTL.CINV and CDFS[1:0] bits to select inversion or non-inversion processing and the sampling timing of the noise filter.
- (4) Enable the edge for interrupt detection (set the CMPCTL.CEG[1:0] bits to a value other than 00b).
- (5) Enable input of the comparator (set the CMPCTL.HCMPON bit to 1) and wait for the time until the comparator operation is stabilized. As for the value, refer to [section 45, Electrical Characteristics](#).
- (6) Enable output of the comparator (set the CMPCTL.COE bit to 1).

### 41.3.4 Comparator Pin Output

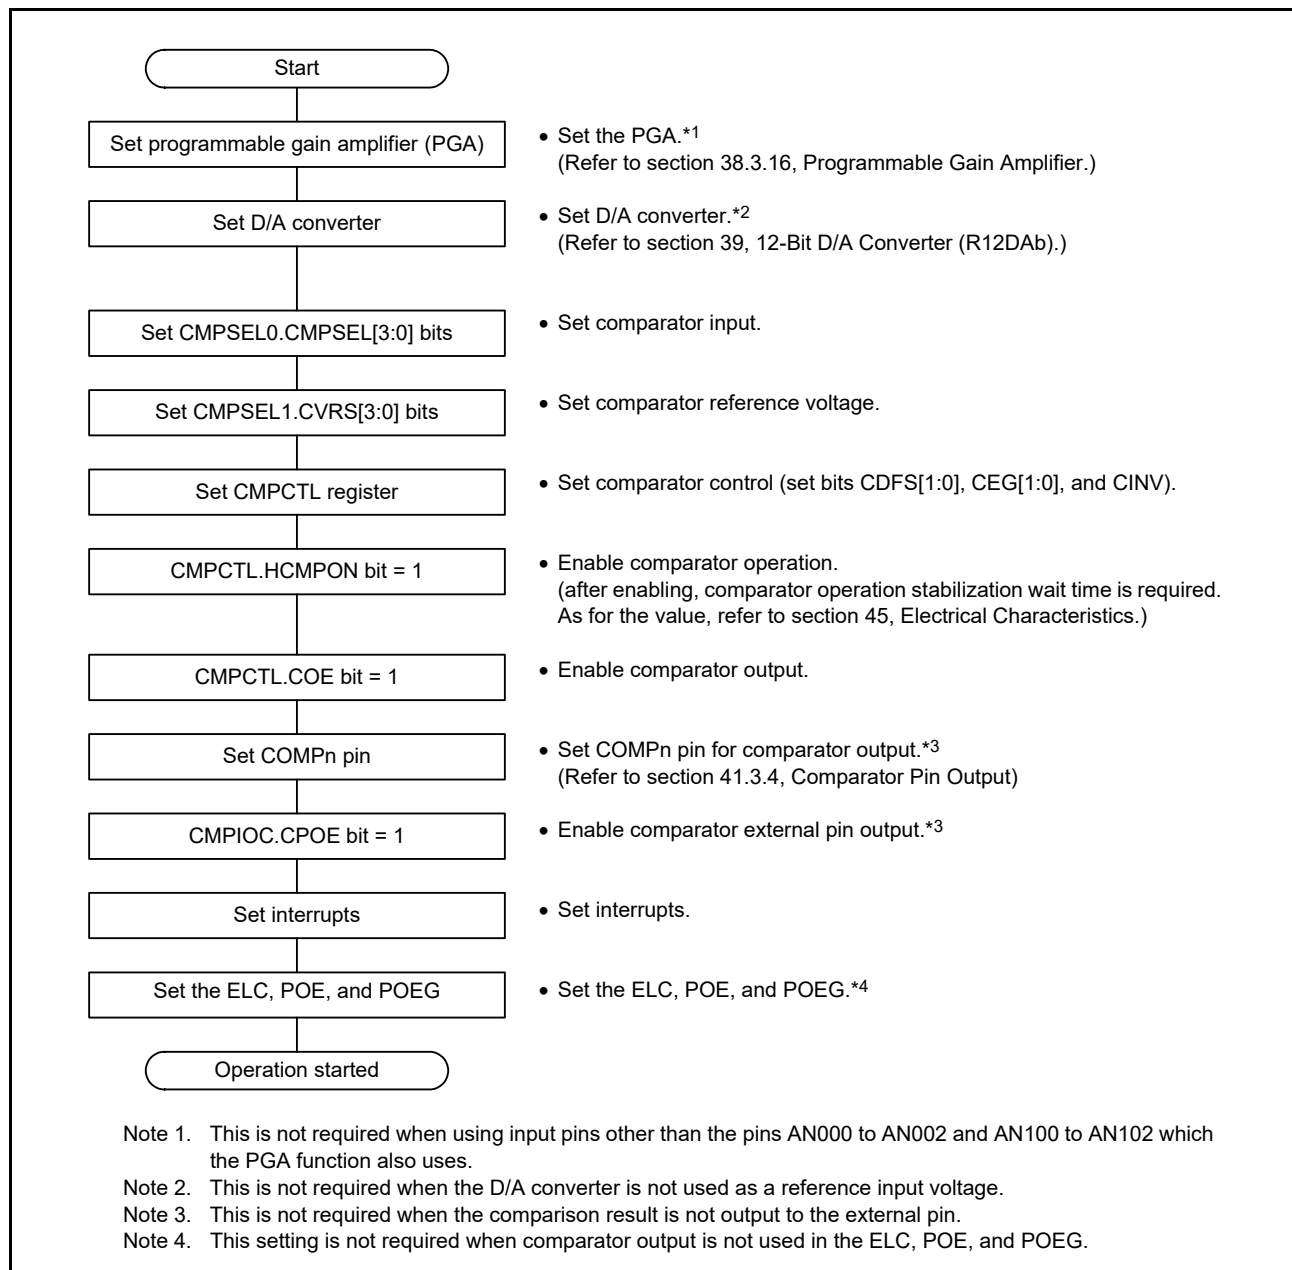

The comparison results can be output to the COMPn pins (n = 0 to 5). The CMPCTL.CINV bit can be used to set the output polarity (non-inverted output or inverted output), and the CMPIOC.CPOE bit can be used to enable or disable the output.

To output the comparison result to the external pin COMPn, use the following setting procedure. Note that the ports are set to input after reset.

- (1) Execute steps (1) to (3) and steps (5) and (6) shown in [section 41.3.3, Interrupts](#).
- (2) Output the comparison result by the comparator to an external pin (set the CMPIOC.CPOE bit to 1).
- (3) Set the port mode register and the pin function control register corresponding to each comparator output pin.

### 41.3.5 Comparator Setting Flowchart

Figure 41.5 shows the flowchart for setting the comparator-related registers.

**Figure 41.5** Comparator Operation Setting Flowchart (n = 0 to 5)

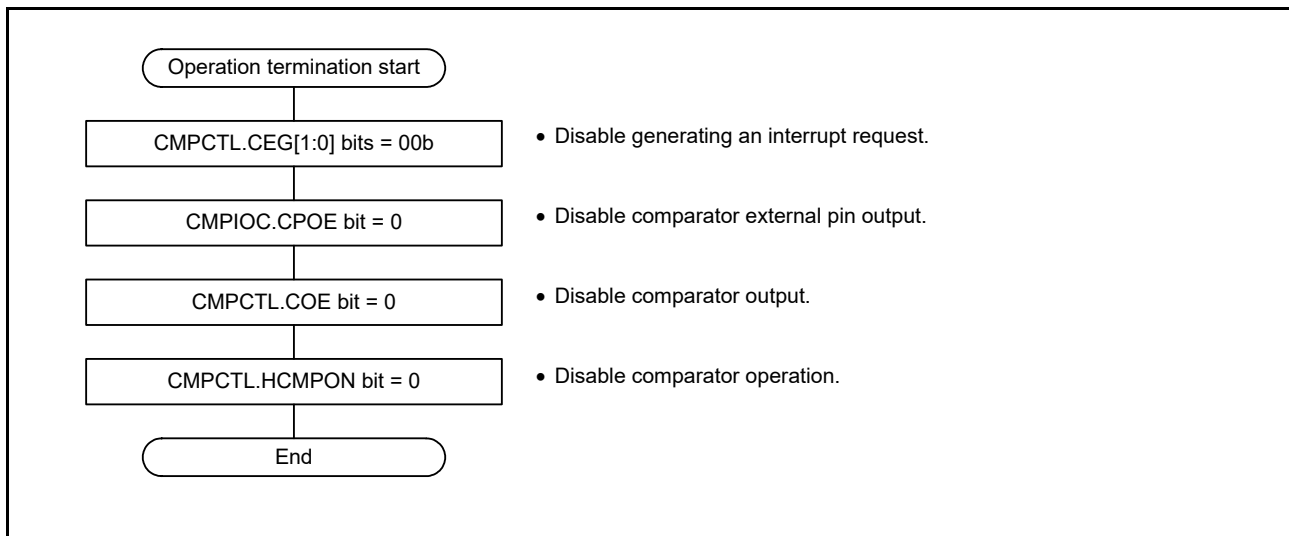

Figure 41.6 Comparator Operation Termination Flowchart

## 41.4 Usage Notes

### 41.4.1 Module Stop Function Setting

Operation of comparator C can be disabled or enabled using module stop control register B (MSTPCRB). After the reset, comparator C is halted. Register access is enabled by releasing the module stop state. For details, refer to section 11, Low Power Consumption.

### 41.4.2 Comparator C Operation in Module Stop State

When the module stop state is entered while comparator C is operating, analog circuits in the comparator C is not stopped and the analog power supply current is the same as that when comparator C is being used. If the analog power supply current needs to be reduced in the module stop state, set the CMPCTL.HCMPON bit to 0 to stop comparator C.

### 41.4.3 Comparator C Operation in Software Standby Mode

When software standby mode is entered while comparator C is operating, analog circuits in the comparator C is not stopped and the analog power supply current is the same as that when comparator C is being used. If the analog power supply current needs to be reduced in software standby mode, set the CMPCTL.HCMPON bit to 0 to stop comparator C.

### 41.4.4 Comparator Operation while the 12-Bit A/D Converter is in the Module-Stop State

The same module stop signal controls the programmable gain amplifiers (PGAs) and the 12-bit A/D converter. The comparison of PGA output for the following pins is not possible while the 12-bit A/D converter is in the module stop state.

- PGA output for AN000 pin
- PGA output for AN001 pin
- PGA output for AN002 pin
- PGA output for AN100 pin
- PGA output for AN101 pin
- PGA output for AN102 pin

The comparison for the following analog input pins is not possible when the 12-bit A/D converter is in the module-stop state.

- AN000 pin
- AN001 pin
- AN002 pin
- AN100 pin
- AN101 pin
- AN102 pin

### 41.4.5 Setting the D/A Converter

Set the D/A converter, set the output to the comparator C using the D/A destination select register (DADSELR), and wait for the D/A converter output settling time. Similarly, before making any changes to the settings of the D/A converter stop the comparator temporarily, and after the changes are made, wait for the D/A converter output settling time before enabling the comparator.

## 42. Data Operation Circuit (DOC)

### 42.1 Overview

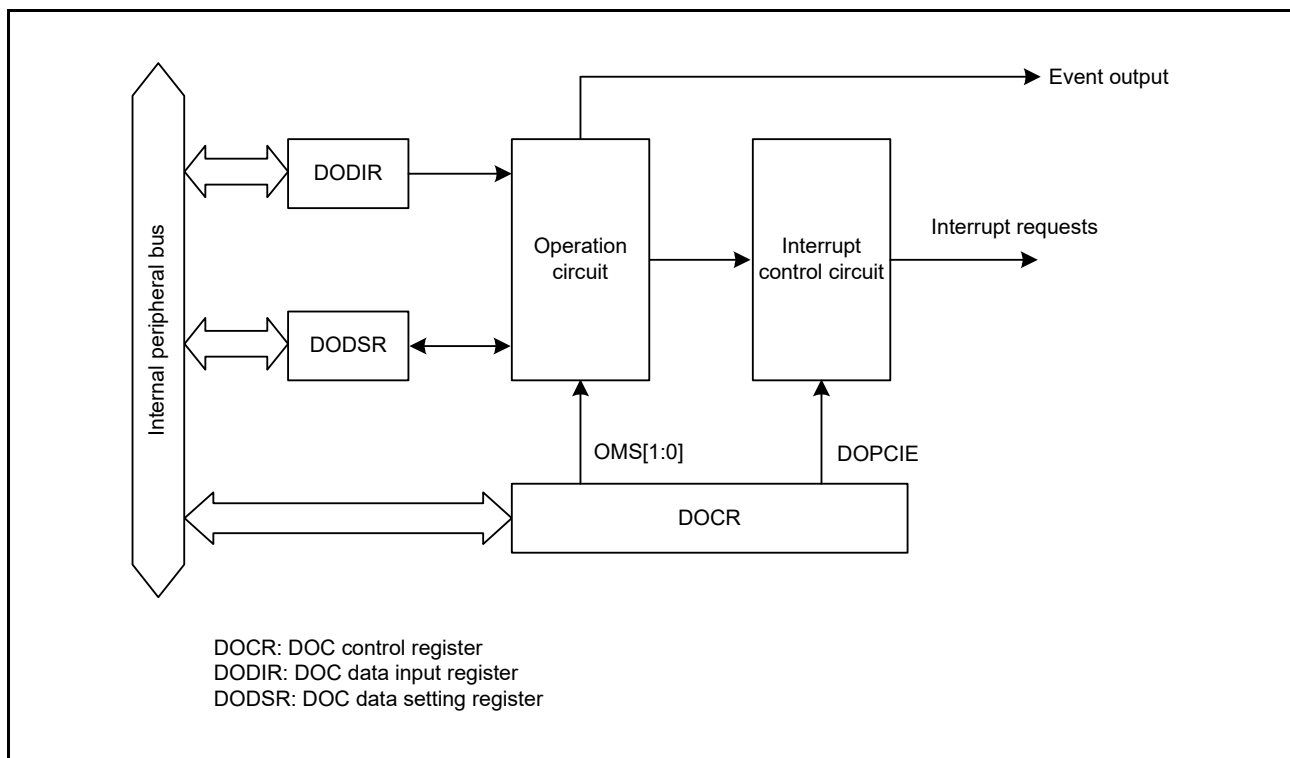

The data operation circuit (DOC) is used to compare, add, or subtract 16-bit values.

Table 42.1 lists the specifications of the DOC and Figure 42.1 is a block diagram of the DOC.

An interrupt can be generated if the result of 16-bit comparison meets one of the set interrupt conditions.

**Table 42.1 DOC Specifications**

| Item                             | Description                                                                                                                                                                                                                                                                         |

**Figure 42.1 DOC Block Diagram**

## 42.2 Register Descriptions

### 42.2.1 DOC Control Register (DOCR)

Address(es): DOC.DOCR 0008 B080h

| Bit    | Symbol   | Bit Name                                | Description                                                                                                            | R/W |
|--------|----------|-----------------------------------------|------------------------------------------------------------------------------------------------------------------------|-----|
| b1, b0 | OMS[1:0] | Operating Mode Select                   | b1 b0<br>0 0: Data comparison mode<br>0 1: Data addition mode<br>1 0: Data subtraction mode<br>1 1: Setting prohibited | R/W |
| b2     | DCSEL    | Detection Condition Select*1            | 0: 'Not equal to' is to be detected.<br>1: 'Equal to' is to be detected.                                               | R/W |
| b3     | —        | Reserved                                | This bit is read as 0. The write value should be 0.                                                                    | R/W |
| b4     | DOPCIE   | Data Operation Circuit Interrupt Enable | 0: Interrupt disabled<br>1: Interrupt enabled                                                                          | R/W |
| b5     | DOPCF    | Data Operation Result Flag              | Indicates the result of an operation.                                                                                  | R   |
| b6     | DOPCFCL  | Data Operation Result Clear             | 0: Retain the value of the DOPCF flag.<br>1: Clears the DOPCF flag.                                                    | R/W |
| b7     | —        | Reserved                                | This bit is read as 0. The write value should be 0.                                                                    | R/W |

Note 1. Valid only when data comparison mode is selected.

The DOCR register specifies the operation of DOC, or enabling or disabling of the interrupt.

#### OMS[1:0] Bits (Operating Mode Select)

These bits select the operating mode of the DOC.

#### DCSEL Bit (Detection Condition Select)

This bit is valid only when data comparison mode is selected.

This bit selects the condition for detection in data comparison mode.

#### DOPCIE Bit (Data Operation Circuit Interrupt Enable)

Setting this bit to 1 enables interrupts from the DOC.

#### DOPCF Flag (Data Operation Result Flag)

[Setting conditions]

- The condition selected by the DCSEL bit is met
- A result of data addition is greater than FFFFh
- A result of data subtraction is less than 0000h

[Clearing condition]

- Writing 1 to the DOPCFCL bit

### DOPCFCL Bit (Data Operation Result Clear)

Writing 1 to this bit clears the DOPCF flag.

This bit is read as 0.

## 42.2.2 DOC Data Input Register (DODIR)

Address(es): DOC.DODIR 0008 B082h

The DODIR register is a readable and writable register that holds values for use in operations.

## 42.2.3 DOC Data Setting Register (DODSR)

Address(es): DOC.DODSR 0008 B084h

The DODSR register is a readable and writable register that holds values for use in comparison or the results of other operations.

In data comparison mode, store the standard value for use in comparison in this register.

In data addition or data subtraction mode, this register holds the results of operations.

## 42.3 Operation

### 42.3.1 Data Comparison Mode

Figure 42.2 shows an example of the steps involved in data comparison mode operation by the DOC.

An example of operation when DCSEL is set to 0 ('not equal to' is to be detected as the result of data comparison) is shown below.

- (1) Writing 00b to the DOCR.OMS[1:0] bits places the DOC in the data comparison mode.
- (2) Specify the standard value for comparison in the DODSR register.
- (3) Write the value for comparison in the DODIR register.
- (4) Write all values for use in comparison to the DODIR register.
- (5) If the value written to the DODIR register is not equal to the value set in the DODSR register, the DOCR.DOPCF flag becomes 1. If the DOCR.DOPCIE bit is 1, a data operation circuit interrupt is also issued.

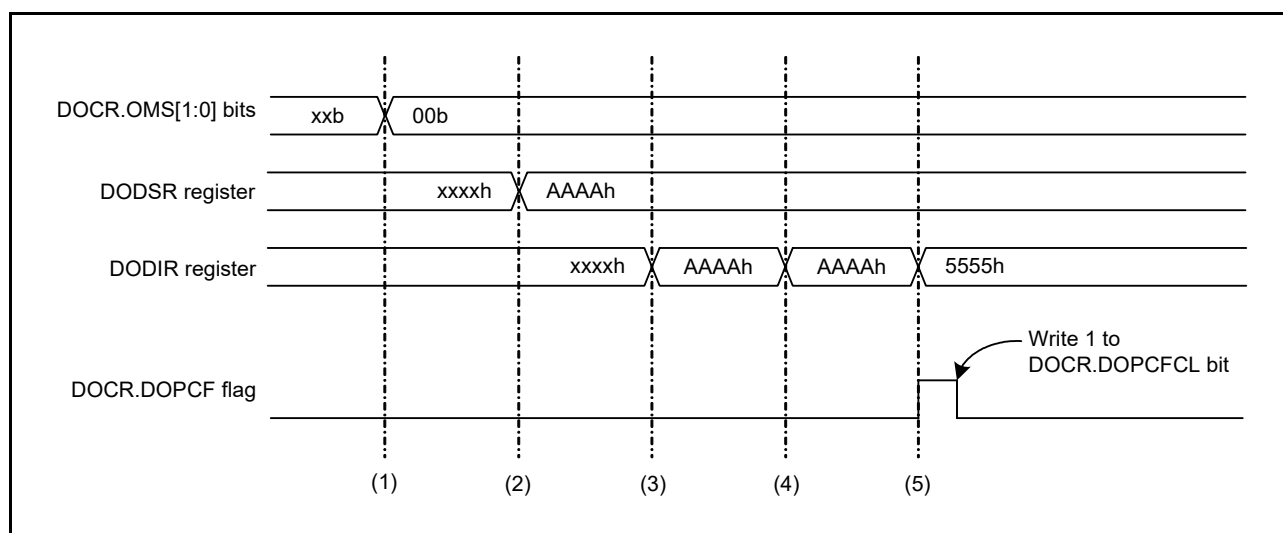

Figure 42.2 Example of Operation in Data Comparison Mode

### 42.3.2 Data Addition Mode

Figure 42.3 shows an example of the steps involved in data addition mode operation by the DOC.

- (1) Writing 01b to the DOCR.OMS[1:0] bits selects data addition mode.
- (2) Set the initial value in the DODSR register.
- (3) Write the value for addition in the DODIR register. The result of the operation is stored in DODSR.
- (4) Write all values for use in addition to the DODIR register.
- (5) If the result of the operation is greater than FFFFh, the DOCR.DOPCF flag becomes 1. If the DOCR.DOPCIE bit is 1, a data operation circuit interrupt is also issued.

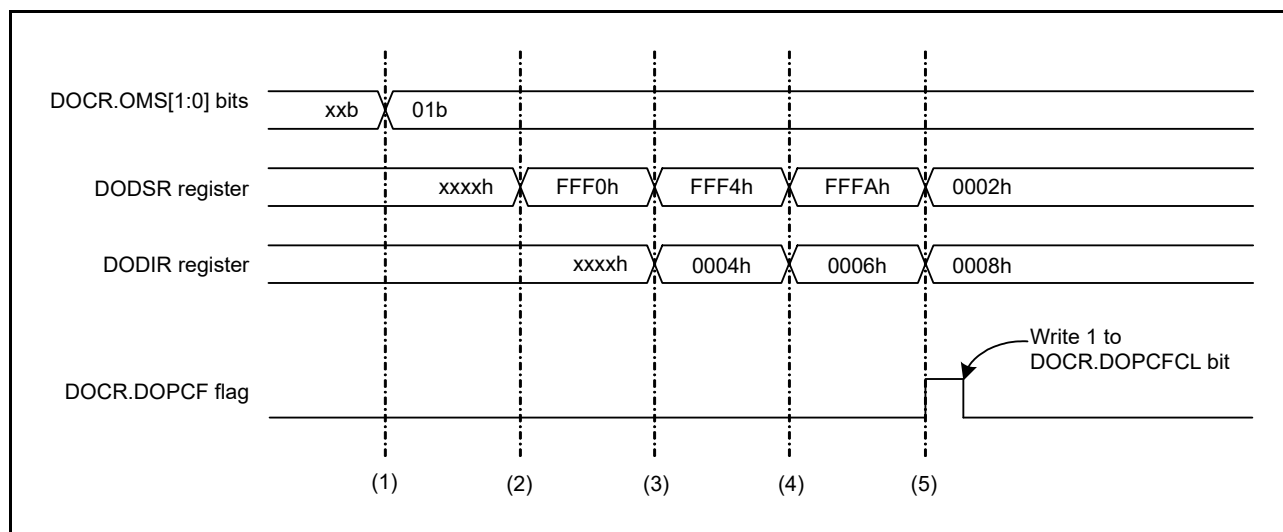

Figure 42.3 Example of Operation in Data Addition Mode

### 42.3.3 Data Subtraction Mode

Figure 42.4 shows an example of the steps involved in data subtraction mode operation by the DOC.

- (1) Writing 10b to the DOCR.OMS[1:0] bits selects data subtraction mode.
- (2) Set the initial value in the DODSR register.
- (3) Write the value for subtraction in the DODIR register. The result of the operation is stored in DODSR.
- (4) Write all values for use in subtraction to the DODIR register.
- (5) If the result of the operation is less than 0000h, the DOCR.DOPCF flag becomes 1. If the DOCR.DOPCIE bit is 1, a data operation circuit interrupt is also issued.

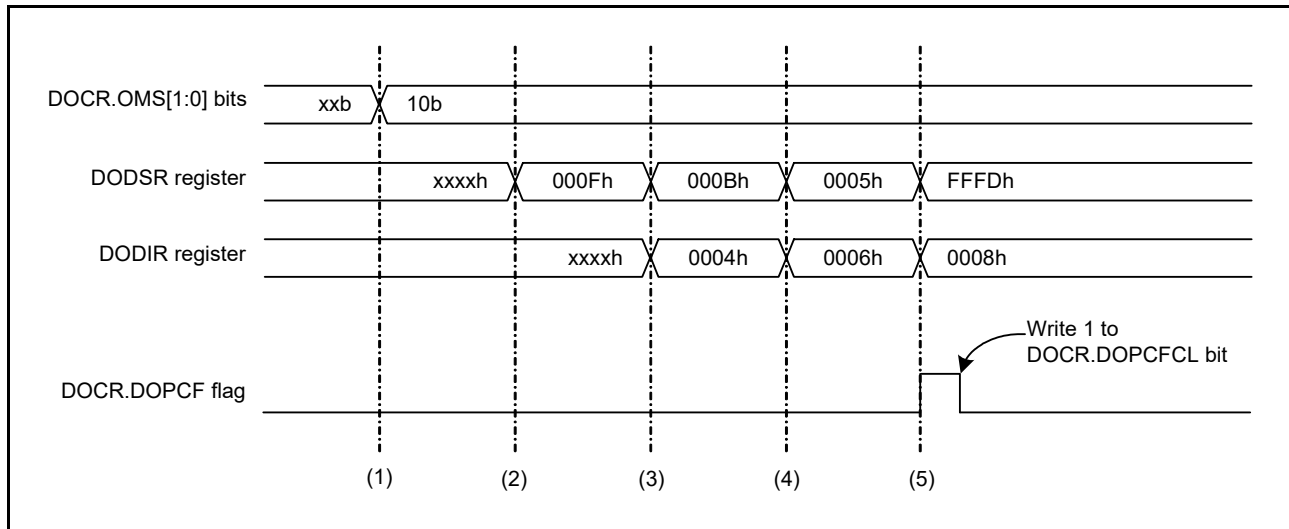

Figure 42.4 Example of Operation in Data Subtraction Mode

## 42.4 Interrupt Requests

The data operation circuit interrupt (DOPCI) is the interrupt request generated by the DOC. The DOCR.DOPCF flag becomes 1 when the interrupt source condition is satisfied.

Table 42.2 lists the details of the interrupt request.

Table 42.2 Interrupt Request from DOC

| Interrupt Request                        | Data Operation Result Flag | Interrupt Generation Timing                                                                                                                                                                                                                  |
|------------------------------------------|----------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Data operation circuit interrupt (DOPCI) | DOPCF                      | <ul style="list-style-type: none"> <li>• The result of data comparison meets the detection condition.</li> <li>• The result of data addition is greater than FFFFh.</li> <li>• The result of data subtraction is less than 0000h.</li> </ul> |

## 42.5 Event Link Output

The DOC outputs event signals for the event link controller (ELC) under the following conditions, and these can be used to initiate operations by other modules selected in advance.

- The result of data comparison meets the detection condition.
- The result of data addition is greater than FFFFh.
- The result of data subtraction is less than 0000h.

### 42.5.1 Interrupt Handling and Event Linking

The DOC has a bit to enable or disable interrupts. When an interrupt source condition is satisfied while the interrupt is enabled, the interrupt request signal is issued to the CPU.

In contrast, an event link output signal is sent to other modules as an event signal via the ELC when an interrupt source is generated, regardless of the setting of the corresponding interrupt enable bit.

## 42.6 Usage Note

### 42.6.1 Module Stop Function Setting

Operation of the DOC can be enabled or disabled by setting the MSTPB6 bit in module stop control register B (MSTPCRB). The DOC is initially disabled after a reset. Register access is enabled by releasing the module stop state. For details, refer to [section 11, Low Power Consumption](#).

## 43. RAM

This MCU has a 128-Kbyte high-speed static RAM (without ECC error correction) and a 16-Kbyte high-speed static RAM with ECC error correction.

### 43.1 Overview

Table 43.1 lists the specifications of the RAM.

**Table 43.1 Specifications of RAM**

| Item                           | Without ECC Error Correction (RAM)                                                                                                                                           | With ECC Error Correction (ECCRAM)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

Note 1. When accessing across the 8-byte boundary, the number of cycles is doubled.

Note 2. Selectable by the RAME bit in SYSCR1. For details on SYSCR1, see section 3.2.4, System Control Register 1 (SYSCR1).

Note 3. Enabling and disabling of the ECCRAM can be selected through the setting of the SYSCR1.ECCRAME bit. For details on SYSCR1, see section 3.2.4, System Control Register 1 (SYSCR1).

Note 4. If the frequency of ICLK is above 120 MHz, the setting of the MEMWAIT register must be changed. For details, see section 9.2.2, Memory Wait Cycle Setting Register (MEMWAIT).

## 43.2 Register Descriptions

### 43.2.1 ECCRAM Operating Mode Control Register (ECCRAMMODE)

Address(es): RAM.ECCRAMMODE 0008 12C0h

| Bit      | Symbol      | Bit Name                  | Description                                                                                                                                                 | R/W |
|----------|-------------|---------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------|-----|
| b1, b0   | RAMMOD[1:0] | RAM Operating Mode Select | b1 b0<br>0 0: ECCs are disabled.<br>0 1: Setting prohibited.<br>1 0: ECCs are enabled without error checking.<br>1 1: ECCs are enabled with error checking. | R/W |
| b7 to b2 | —           | Reserved                  | These bits are read as 0. The write value should be 0.                                                                                                      | R/W |

The ECCRAMMODE register is write-protected by the ECCRAM protection register (ECCRAMPRCR). Before writing to the ECCRAMMODE register, set the corresponding bit in the ECCRAMPRCR register to 1 to enable writing to it. Be sure to read this register immediately after writing to it, and then compare the read and written values. If this operation is not performed, access to the ECCRAM is not guaranteed. Also, do not write to this register while accessing to the ECCRAM.

### 43.2.2 ECCRAM 2-Bit Error Status Register (ECCRAM2STS)

Address(es): RAM.ECCRAM2STS 0008 12C1h

| Bit      | Symbol  | Bit Name                    | Description                                                                  | R/W     |
|----------|---------|-----------------------------|------------------------------------------------------------------------------|---------|
| b0       | ECC2ERR | 2-Bit ECC Error Status Flag | 0: A 2-bit ECC error has not occurred.<br>1: A 2-bit ECC error has occurred. | R/(W)*1 |
| b7 to b1 | —       | Reserved                    | These bits are read as 0. The write value should be 0.                       | R/W     |

Note 1. Only 0 can be written to clear the flag.

When the ECCRAMMODE.RAMMOD[1:0] bits are set to 11b, the ECC2ERR flag is set to 1 if a 2-bit error is found. The RAM error interrupt is also generated at this time. Writing of 0 to the ECC2ERR flag leads to clearing of the RAM error interrupt having the 2-bit ECC error as its source.

### 43.2.3 ECCRAM 1-Bit Error Information Update Enable Register (ECCRAM1STSEN)

Address(es): RAM.ECCRAM1STSEN 0008 12C2h

| Bit      | Symbol        | Bit Name                                     | Description                                                                                                         | R/W |
|----------|---------------|----------------------------------------------|---------------------------------------------------------------------------------------------------------------------|-----|
| b0       | ECC1STS<br>EN | 1-Bit ECC Error Information<br>Update Enable | 0: Disables updating of the 1-bit ECC error information.<br>1: Enables updating of the 1-bit ECC error information. | R/W |
| b7 to b1 | —             | Reserved                                     | These bits are read as 0. The write value should be 0.                                                              | R/W |

The ECCRAM1STSEN register enables or disables updating of the ECCRAM 1-bit error status register (ECCRAM1STS) in response to a 1-bit error in the ECCRAM.

The ECCRAMPRCR register can protect this register against writing. Accordingly, change the effective bit in the ECCRAMPRCR register to the enabled setting before attempting to write to the ECCRAM1STSEN register.

Always be sure to read this register immediately after writing to it, and then compare the read and written values. Do not attempt access to the ECCRAM during this process. Also, do not write to this register while accessing to the ECCRAM.

### 43.2.4 ECCRAM 1-Bit Error Status Register (ECCRAM1STS)

Address(es): RAM.ECCRAM1STS 0008 12C3h

| Bit      | Symbol  | Bit Name               | Description                                                                  | R/W     |
|----------|---------|------------------------|------------------------------------------------------------------------------|---------|
| b0       | ECC1ERR | 1-Bit ECC Error Status | 0: A 1-bit ECC error has not occurred.<br>1: A 1-bit ECC error has occurred. | R/(W)*1 |
| b7 to b1 | —       | Reserved               | These bits are read as 0. The write value should be 0.                       | R/W     |

Note 1. Only 0 can be written to clear the bit.

When ECCs are enabled, error checking is selected, and updating of the 1-bit error information is enabled, the ECC1ERR bit is set to 1 if a 1-bit error is found. The RAM error interrupt is also generated at this time. Writing of 0 to the ECC1ERR bit leads to clearing of the RAM error interrupt having the 1-bit ECC error as its source.

### 43.2.5 ECCRAM Protection Register (ECCRAMPRCR)

Address(es): RAM.ECCRAMPRCR 0008 12C4h

| Bit      | Symbol  | Bit Name                                            | Description                                                                                                                               | R/W |
|----------|---------|-----------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------|-----|
| b0       | PRCR    | ECCRAMMODE and ECCRAM1STSEN Registers Write Control | 0: Disables writing to the ECCRAMMODE and ECCRAM1STSEN registers.<br>1: Enables writing to the ECCRAMMODE and ECCRAM1STSEN registers.     | R/W |
| b7 to b1 | KW[6:0] | Write Key Word                                      | Enables or disables the rewriting of the ECCRAMPRCR register. When rewriting the ECCRAMPRCR register, write 1111000b to the KW[6:0] bits. | R/W |

Writing 1 to the PRCR bit is possible when KW[6:0] = 1111000b.

Otherwise writing to PRCR clears the bit to 0. KW[6:0] is read as 0000000b.

The targets for write protection by the ECCRAMPRCR register are the ECCRAMMODE and ECCRAM1STSEN registers. Once the PRCR bit is set to 1, writing to ECCRAMMODE and ECCRAM1STSEN registers is enabled until the PRCR bit is cleared to 0. Clear the PRCR bit to 0 after writing to ECCRAMMODE and ECCRAM1STSEN registers.

### 43.2.6 ECCRAM 2-Bit Error Address Capture Register (ECCRAM2ECAD)

Address(es): RAM.ECCRAM2ECAD 0008 12C8h

| Bit        | Symbol        | Bit Name                | Description                                            | R/W |
|------------|---------------|-------------------------|--------------------------------------------------------|-----|
| b2 to b0   | —             | Reserved                | These bits are read as 0.                              | R   |
| b14 to b3  | ECC2EAD[11:0] | 2-Bit ECC Error Address | The address where a 2-bit ECC error was found is read. | R   |
| b23 to b15 | —             | Reserved                | These bits are read as 1.                              | R   |
| b31 to b24 | —             | Reserved                | These bits are read as 0.                              | R   |

When the ECCRAMMODE.RAMMOD[1:0] bits are set to 11b, this register will hold the address where a 2-bit ECC error was found. Specifically, the address of the 8-byte boundary below the location where the error was found is written to the ECC2EAD[11:0] bits of this register at the same time as the ECCRAM2STS.ECC2ERR flag is set. The address is not updated whenever the ECC2ERR flag is set to 1 to indicate an error. Its value does not change if ECCs are disabled. The value is initialized by a reset, and this is the only condition that leads to clearing of the register.

### 43.2.7 ECCRAM 1-Bit Error Address Capture Register (ECCRAM1ECAD)

Address(es): RAM.ECCRAM1ECAD 0008 12CCh

| Bit        | Symbol        | Bit Name                | Description                                            | R/W |
|------------|---------------|-------------------------|--------------------------------------------------------|-----|
| b2 to b0   | —             | Reserved                | These bits are read as 0.                              | R   |
| b14 to b3  | ECC1EAD[11:0] | 1-Bit ECC Error Address | The address where a 1-bit ECC error was found is read. | R   |
| b23 to b15 | —             | Reserved                | These bits are read as 1.                              | R   |
| b31 to b24 | —             | Reserved                | These bits are read as 0.                              | R   |

When ECCs are enabled, error checking is selected, and updating of the 1-bit error information is enabled, this register will hold the address where a 1-bit error was found. Specifically, the address of the 8-byte boundary below the location where the error was found is written to the effective bits of this register at the same time as the ECCRAM1STS.ECC1ERR bit is set.

The address is not updated whenever the ECC1ERR bit is set to 1 to indicate an error. Its value does not change if ECCs are disabled. The value is initialized by a reset, and this is the only condition that leads to clearing of the register.

### 43.2.8 ECCRAM Protection Register 2 (ECCRAMPRCR2)

Address(es): RAM.ECCRAMPRCR2 0008 12D0h

| Bit      | Symbol   | Bit Name                          | Description                                                                                                                                  | R/W |
|----------|----------|-----------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------|-----|
| b0       | PRCR2    | ECCRAMETST Register Write Control | 0: Writing to ECCRAMETST is disabled.<br>1: Writing to ECCRAMETST is enabled.                                                                | R/W |
| b7 to b1 | KW2[6:0] | Write Keyword                     | Enables or disables the rewriting of the ECCRAMPRCR2 register. When rewriting the ECCRAMPRCR2 register, write 1111000b to the KW2[6:0] bits. | R/W |

When KW2[6:0] = 1111000b, writing 1 to the PRCR2 bit is enabled.

Otherwise writing to PRCR2 clears the bit to 0. The KW2[6:0] bits are read as 0000000b.

The target for write protection by the PRCR2 bit is the ECCRAM test control register (ECCRAMETST). Once the PRCR2 bit is set to 1, writing to the ECCRAMETST register is enabled until the PRCR2 bit is cleared to 0. After writing to the ECCRAMETST register, clear the PRCR2 bit to 0.

### 43.2.9 ECCRAM Test Control Register (ECCRAMETST)

Address(es): RAM.ECCRAMETST 0008 12D4h

| Bit      | Symbol | Bit Name          | Description                                             | R/W |
|----------|--------|-------------------|---------------------------------------------------------|-----|
| b0       | TSTBYP | ECC Bypass Select | 0: ECC bypass is disabled.<br>1: ECC bypass is enabled. | R/W |
| b7 to b1 | —      | Reserved          | These bits are read as 0. The write value should be 0.  | R/W |

The protection register 2 (ECCRAMPRCR2) protects this register against writing. Accordingly, change the effective bit in the ECCRAMPRCR2 register to the enabled setting before attempting to write to the ECCRAMETST register. Do not write to ECCRAMETST while access to ECCRAM is in progress.

Eight of the 72 bits of data in the ECCRAM are used for the ECC. When the TSTBYP bit is set to 1 to select bypassing of the ECC circuit, the 8 bits for the ECC become directly accessible. Setting the TSTBYP bit for bypassing of the ECC is only possible when the ECC is disabled by setting the ECCRAMMODE.RAMMOD[1:0] bit to 00b.

### 43.2.10 RAM Operating Mode Control Register (RAMMODE)

Address(es): RAM.RAMMODE 0008 1200h

| Bit      | Symbol            | Bit Name                  | Description                                                                                                                 | R/W |
|----------|-------------------|---------------------------|-----------------------------------------------------------------------------------------------------------------------------|-----|
| b1, b0   | RAMMODE<br>E[1:0] | RAM Operating Mode Select | b1 b0<br>0 0: Parity checking is disabled.<br>0 1: Parity checking is enabled.<br>Settings other than above are prohibited. | R/W |
| b7 to b2 | —                 | Reserved                  | These bits are read as 0. The write value should be 0.                                                                      | R   |

The RAMMODE register is write-protected by the RAM protection register (RAMPRCR). Before writing to the RAMMODE register, set the RAMPRCR.RAMPRCR bit to 1 to enable writing to it. Set the RAMMODE register before starting access to the RAM. If this register is modified after accessing to the RAM, RAM operation is not guaranteed.

### 43.2.11 RAM Error Status Register (RAMSTS)

Address(es): RAM.RAMSTS 0008 1201h

| Bit      | Symbol | Bit Name              | Description                                                                        | R/W     |
|----------|--------|-----------------------|------------------------------------------------------------------------------------|---------|
| b0       | RAMERR | RAM Error Status Flag | 0: A parity check error has not occurred.<br>1: A parity check error has occurred. | R/(W)*1 |
| b7 to b1 | —      | Reserved              | These bits are read as 0. The write value should be 0.                             | R       |

Note 1. Only 0 can be written to clear the flag.

When parity checking is enabled, the RAMERR flag is set to 1 if a parity check error is detected. The RAM error interrupt request is also generated at this time.

When parity checking is disabled, the RAMERR flag is not set to 1 because no parity check error is detected. Writing 0 to the RAMERR flag clears the RAM error interrupt request corresponding to the parity check error.

### 43.2.12 RAM Error Address Capture Register (RAMECAD)

Address(es): RAM.RAMECAD 0008 1208h

| Bit        | Symbol | Bit Name      | Description                                  | R/W |
|------------|--------|---------------|----------------------------------------------|-----|
| b2 to b0   | —      | Reserved      | These bits are read as 0.                    | R   |
| b18 to b3  | READ   | Error Address | The address where an error is found is read. | R   |
| b31 to b19 | —      | Reserved      | These bits are read as 0.                    | R   |

When parity checking is enabled, this register will hold the address where a parity check error was found.

The address of the 8-byte boundary below the location where the error was found is stored in this register at the same time the RAMSTS.RAMERR flag is set to 1.

The error address is not updated when the RAMERR flag is 1 (error has occurred). Its value does not change when parity checking is disabled because no parity check error is detected.

The RAMECAD register is initialized only by a reset.

### 43.2.13 RAM Protection Register (RAMPRCR)

Address(es): RAM.RAMPRCR 0008 1204h

| Bit      | Symbol   | Bit Name                       | Description                                                                                                                            | R/W |
|----------|----------|--------------------------------|----------------------------------------------------------------------------------------------------------------------------------------|-----|
| b0       | RAMP RCR | RAMMODE Register Write Control | 0: Disables writing to the RAMMODE register.<br>1: Enables writing to the RAMMODE register.                                            | R/W |
| b7 to b1 | KW[6:0]  | Write Key Word                 | Enables or disables the rewriting of the RAMPRCR register.<br>When rewriting the RAMPRCR register, write 1111000b to the KW[6:0] bits. | R/W |

Writing 1 to the RAMP RCR bit is possible when KW[6:0] = 1111000b. Otherwise writing to RAMP RCR clears the bit to 0. The value of KW[6:0] is read as 0000000b.

The targets for write protection by the RAMP RCR register is the RAM operating mode control register (RAMMODE). Once the RAMP RCR bit is set to 1, writing to RAMMODE register is enabled until the RAMP RCR bit is cleared to 0. Clear the RAMP RCR bit to 0 after writing to RAMMODE register.

## 43.3 Operation

### 43.3.1 Low Power Consumption Function

Power consumption can be reduced by setting module stop control register C (MSTPCRC) to stop supply of the clock signal to RAM and ECCRAM.

When the MSTPC0 bit in MSTPCRC is set to 1, supply of the clock signal to RAM is stopped. When the MSTPC6 bit in MSTPCRC is set to 1, supply of the clock signal to the ECCRAM is stopped.

The RAM and ECCRAM are thus placed in the module-stop state by stopping supply of the clock signals. The RAM and ECCRAM operate after a reset.

RAM and ECCRAM are not accessible if it is in the module-stop state. A transition to the module-stop state should not be made while access to RAM and ECCRAM are in progress.

Access to the RAM and ECCRAM in the module-stop state is prohibited. If access is attempted, correct operation is not guaranteed.

For details on the MSTPCRC register, see section 11, Low Power Consumption.

### 43.3.2 Correction of ECC Errors

Enabling and disabling of ECC error correction can be selected through the register setting. In the initial state, ECC error correction is disabled. The ECC used in this device is SEC-DED (Single-Error Correction and Double-Error Detection Code).

When ECCs are enabled, an 8-bit ECC code is appended to 64-bit data for writing. For reading, 72-bit (data: 64 bits, ECC code: 8 bits) data is read out from the ECCRAM.

When ECCs are enabled and error checking is selected, error correction is done if a 1-bit error occurs and the ECCRAM1STS.ECC1ERR bit is set to 1 if the ECCRAM1STSEN.ECC1STSEN bit is 1. When an error is detected, the address of the 8-byte boundary including the location where the error was found is set to the ECCRAM1ECAD register. If a 2-bit error occurs, error detection is done and the ECCRAM2STS.ECC2ERR flag is set to 1, though error correction is not performed. When an error is detected, the address of the 8-byte boundary including the location where the error was found is set to the ECCRAM2ECAD register. In addition, there is no way to confirm the location where the error was found within the 8-byte boundary. Therefore, when the correct data is written after the occurrence of an error, update all the data in the 8-byte boundary.

When ECCs are enabled but error checking is not selected, error correction is done if a 1-bit error occurs when reading; however, the corrected data is not written back to the ECCRAM, and ECC codes are neither generated nor written back. In writing, write data is replaced and ECC codes are generated then written back.

Since the ECCRAM data is undefined after power on and release from deep software standby mode, accessing the ECCRAM when ECCs are enabled and error checking is selected causes an ECC error to occur. Therefore, when using ECC error correction, initial writing to the area to be used in the ECCRAM should be done beforehand when ECCs are enabled but error checking is not selected. Since the ECC error correction is done in 8-byte units, the initial write must be done for the  $8 \times N$  byte area including the area to be used.

### 43.3.3 Parity Checking

Enabling and disabling of parity checking can be selected through the RAMMODE register setting. In the initial state, parity checking is disabled. Even parity checking is used in this device.

1-bit parity check code is added to each 1-byte data for writing, and the parity is checked for reading.

If a 1-bit error is detected in the 1 byte when the parity is checked for reading, a RAM error interrupt can be generated. If a 2-bit error or more is detected in the 1 byte, errors cannot be correctly detected.

After power-on, parity check code is undefined until data is written. To use parity checking, write the initial value to all areas while parity checking is enabled before accessing to the RAM immediately after a reset.

Operation cannot be guaranteed if access is made to an area where the initial value is not written.

### 43.3.4 RAM Error Interrupt Function

A RAM error interrupt is generated if any of the following bits changes to 1:

When ECCs are enabled and error checking is selected

- ECCRAM2STS.ECC2ERR bit indicating an ECC2 bit error
- ECCRAM1STS.ECC1ERR bit indicating an ECC1 bit error

When parity checking is enabled

- RAMSTS.RAMERR bit indicating a parity check error

Writing 0 to a bit that has been set clears the RAM error interrupt due to the corresponding source.

If the error from the other source is still occurring at this time, the RAM error interrupt will remain generated.

When the ECC 1-bit error interrupt is to be masked, set the ECCRAM1STSEN.ECC1STSEN bit to 0 to disable updating of the ECC1ERR bit. A RAM error interrupt will not be generated while ECCs are disabled and when ECCs are enabled but error checking is not selected.

### 43.3.5 ECC Decoder Testing

In this MCU, the user can test the ECC code control circuit for the ECCRAM.

Figure 43.1 shows the flow for testing of the ECC code control circuit.

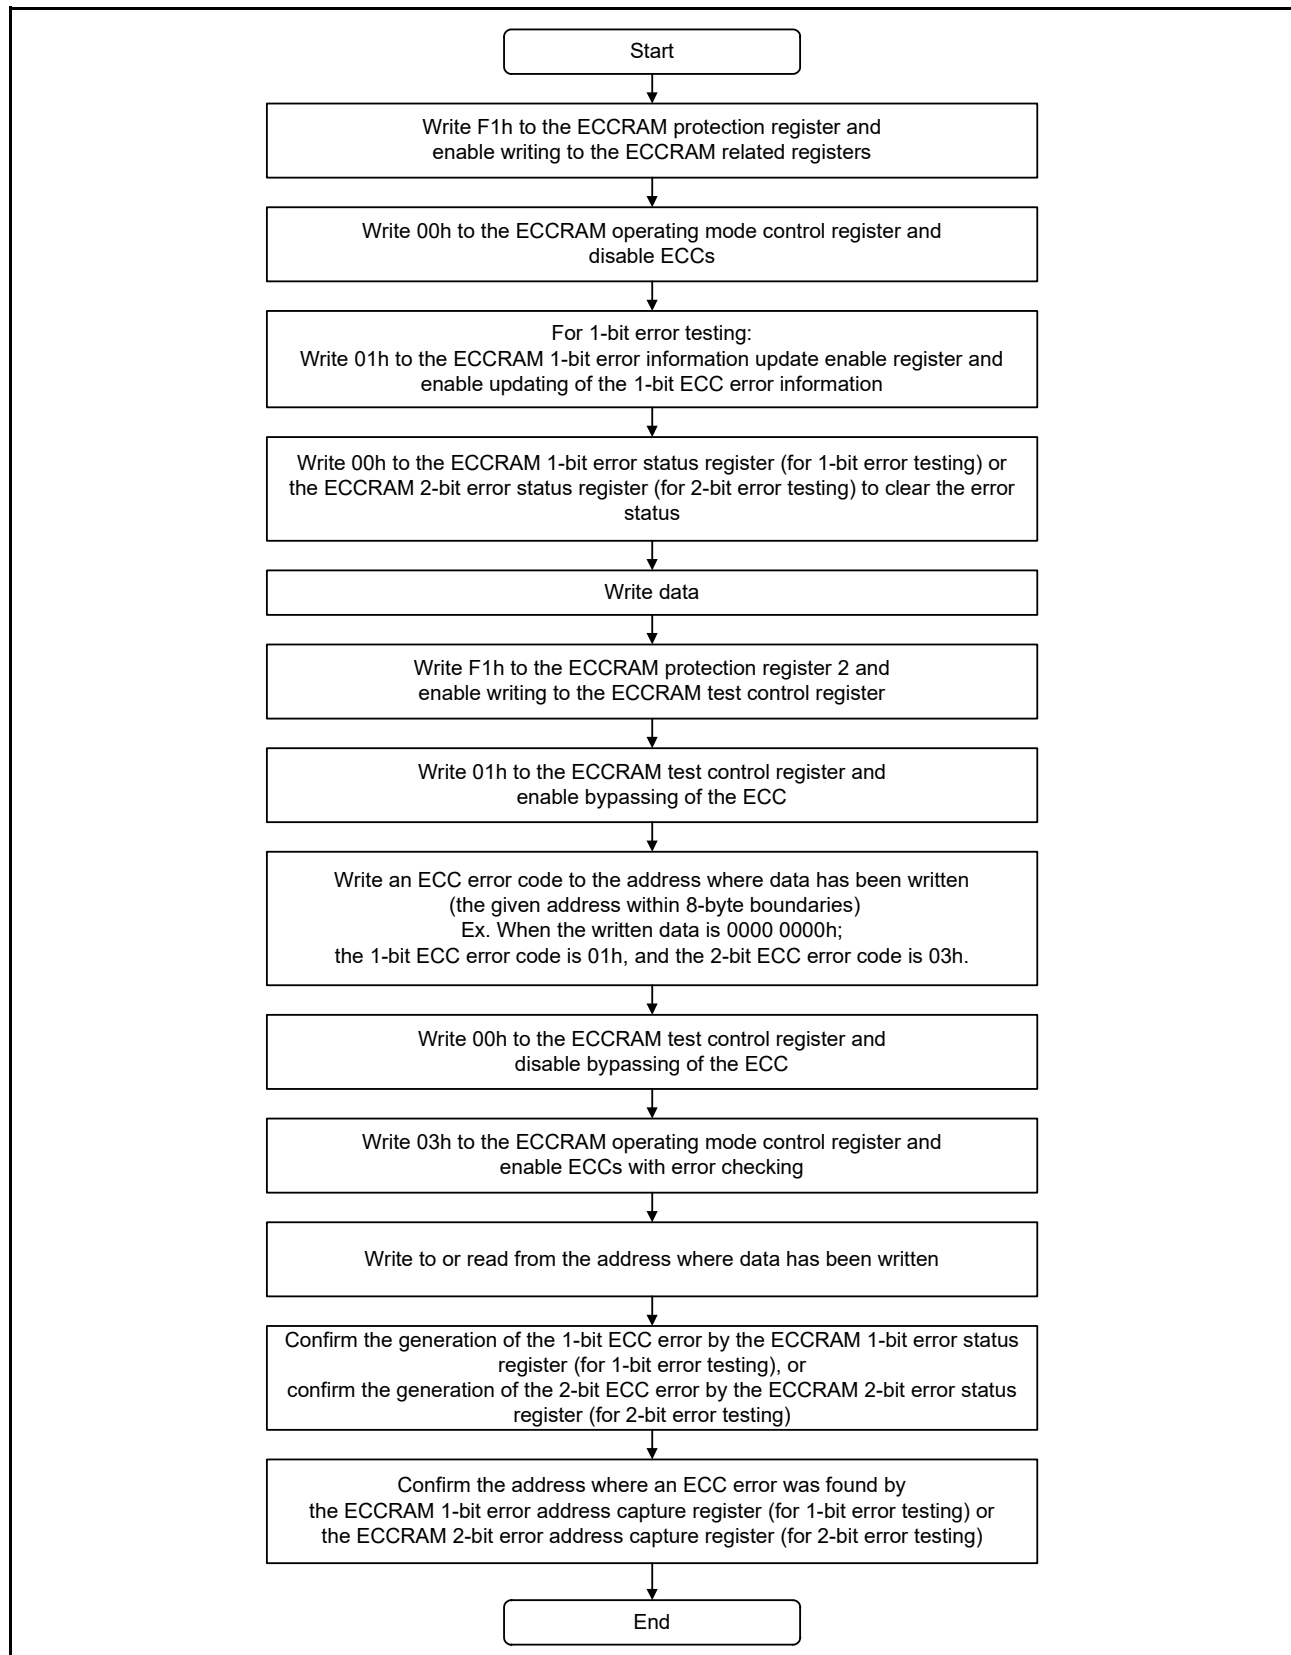

Figure 43.1 Flow for Testing of the ECC Code Control Circuit

### 43.3.6 Interrupt Source

The RAM has two interrupt sources; RAM error interrupt generated from the RAM when a parity check error occurred, or RAM error interrupt generated from the ECCRAM when an ECC error occurred, and can be used as a non-maskable interrupt or interrupt. For details, see section 14, Interrupt Controller (ICUC).

**Table 43.2 RAM Interrupt Source**

| Name   | Interrupt Source                | DTC Activation | DMAC Activation |
|--------|---------------------------------|----------------|-----------------|
| RAMERR | Parity check error or ECC error | Not possible   | Not possible    |

## 43.4 Usage Notes

### 43.4.1 Low Power Consumption Function

Power consumption can be reduced by setting module stop control register C (MSTPCRC) to stop supply of the clock signal to the RAM and ECCRAM.

Setting the MSTPCRC.MSTPC0 bit to 1 stops supply of the clock signal to the RAM. Setting the MSTPCRC.MSTPC6 bit to 1 stops supply of the clock signal to the ECCRAM.

Stopping supply of the clock signal places the RAM and ECCRAM individually in the module stop state.

The RAM and ECCRAM operate after a reset.

The RAM and ECCRAM are not accessible in the module stop state.

Do not allow transitions to the module stop state while accessing to the RAM or ECCRAM.

For details on the MSTPCRC register, refer to section 11, Low Power Consumption.

### 43.4.2 Notes on Using Error Checking of RAM and ECCRAM

Data in RAM and ECCRAM are undefined when the power is turned on. Therefore, parity check errors or ECC errors occur if the data are read before initialization. The RAM and ECCRAM are read in 8-byte (64-bit) units. Initialize them on 8-byte boundaries.

When a program is executed in the RAM or ECCRAM with the parity check or the ECC function enabled, initialize the RAMs in consideration of possible instruction prefetching by the CPU. Instruction prefetching can be performed up to 32 bytes. The initialization must thus cover extra 24 to 31 bytes from the last address of the program.

### 43.4.3 Notes on Self-Diagnosis of the RAM

A write buffer is mounted for the RAM\*1. When the same address is read after a write operation, data in the write buffer, rather than in the memory cell of the RAM may be read. When the RAM is self-diagnosed, confirm that the data have been written by following the procedure below so that data will not be read from the write buffer.

- (1) Write data to the address targeted for diagnosis.
- (2) Write data to an address which is at least 4 addresses away from the that in (1).
- (3) Read the data from the address in (1).

Note 1. This does not apply to the ECCRAM.

## 44. Flash Memory (FLASH)

This MCU incorporates code flash memory, data flash memory, and option-setting memory.

The code flash memory stores instructions and operands, and the data flash memory stores only data. For option-setting memory, refer to section 7, Option-Setting Memory (OSM).

### 44.1 Overview

Table 44.1 lists the specifications of the code flash memory/data flash memory, and Figure 44.1 is a block diagram of the flash memory related modules.

The I/O pins used in boot mode, refer to Table 44.19.

The flash sequencer controls programming and erasure of the flash memory. The FACI (flash application command interface) controls the flash sequencer according to the specified FACI commands.

Regarding the configuration of the code flash memory, refer to Figure 44.2, and for the configuration of the data flash memory, refer to Figure 44.3.

**Table 44.1 Specifications of Code Flash Memory and Data Flash Memory (1/2)**

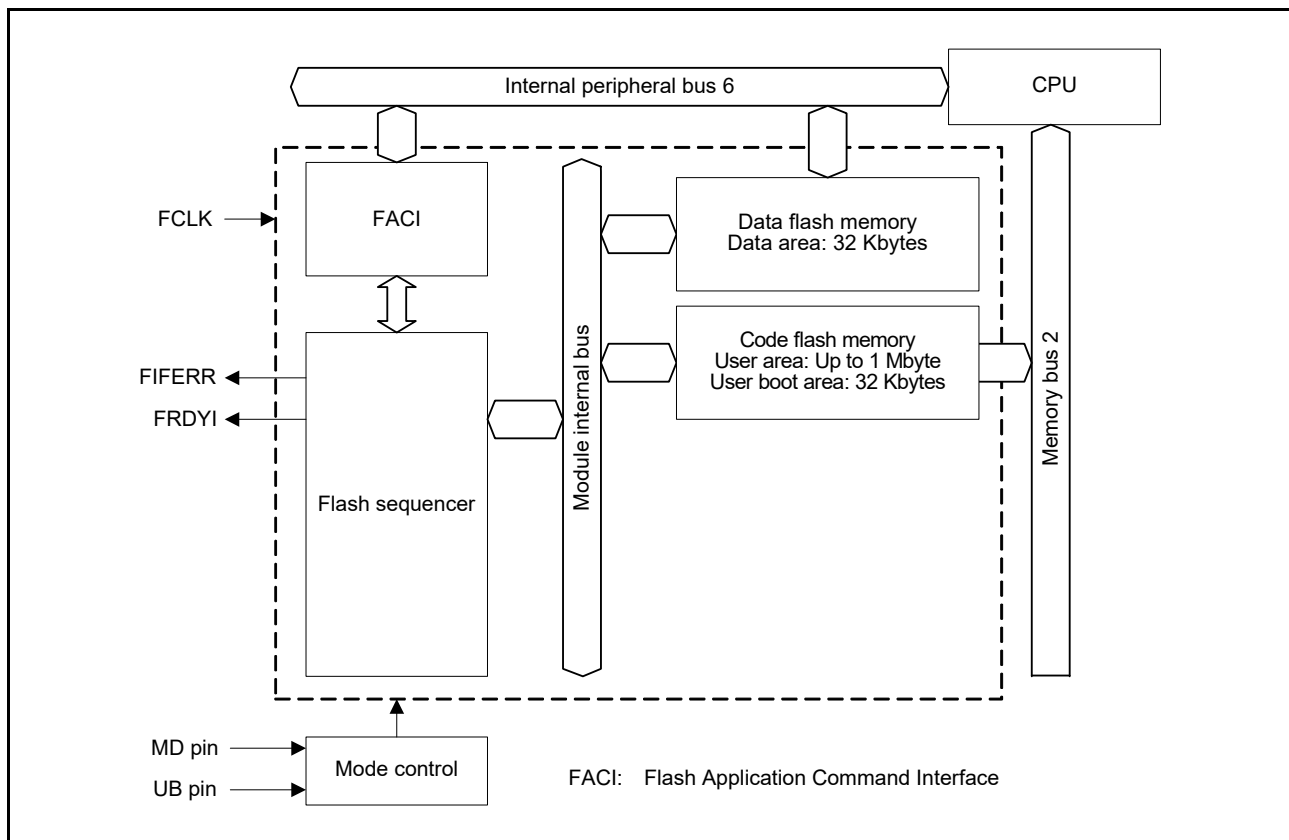

| Item                                     | Code Flash Memory                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | Data Flash Memory                                                                                                                                        |
|------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------|

Note 1. The BGO function cannot be used to rewrite the configuration setting area.

**Figure 44.1 Block Diagram of Flash Memory Related Modules**

## 44.2 Hardware Interface Area

Using the hardware interface with the flash memory requires accessing to the area containing registers of the hardware, that for the issuing of FACI commands. Table 44.2 summarizes information on all of these areas.

**Table 44.2 Information on the Hardware Interface Area**

| Area                                                  | Address                                       | Capacity                                      |
|-------------------------------------------------------|-----------------------------------------------|-----------------------------------------------|
| Area containing the various registers of the hardware | Refer to section 44.4, Register Descriptions. | Refer to section 44.4, Register Descriptions. |
| FACI command-issuing area                             | 007E 0000h                                    | 4 bytes                                       |
| Configuration setting area                            | 0012 0040h to 0012 00FFh                      | 192 bytes                                     |

### 44.3 Structure of Memory

Figure 44.2 illustrates the mapping of the code flash memory. The user area of the code flash memory in this MCU is divided into 8- and 32-Kbyte blocks, which serve as the units of erasure. When the TM function is enabled, blocks 8 and 9 are the TM target areas. A 32-Kbyte user boot area is also incorporated as a single block. The user area and user boot area are available as areas for storing the user program.

Furthermore, a 32-Kbyte user boot area, which is protected against programming by self-programming, is incorporated as a single block. This area is thus available as an area for storing boot programs, etc., for which rewriting while the user program is running has to be prohibited.

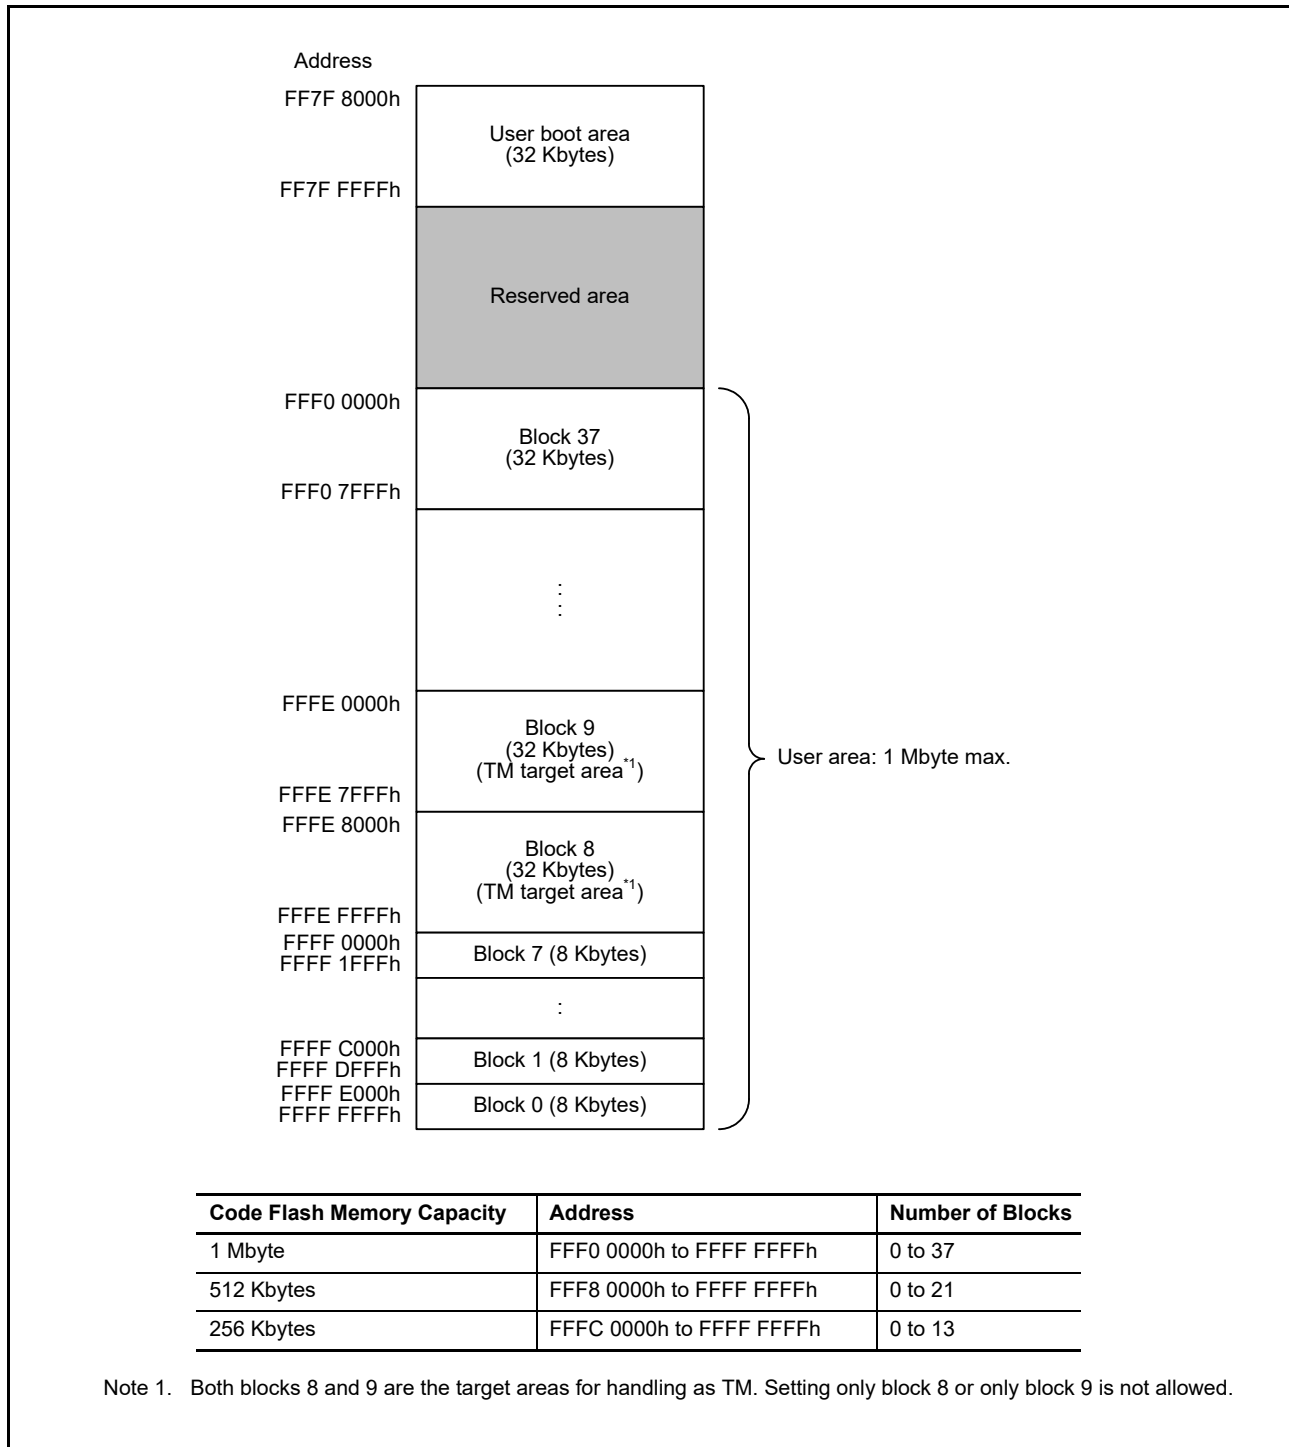

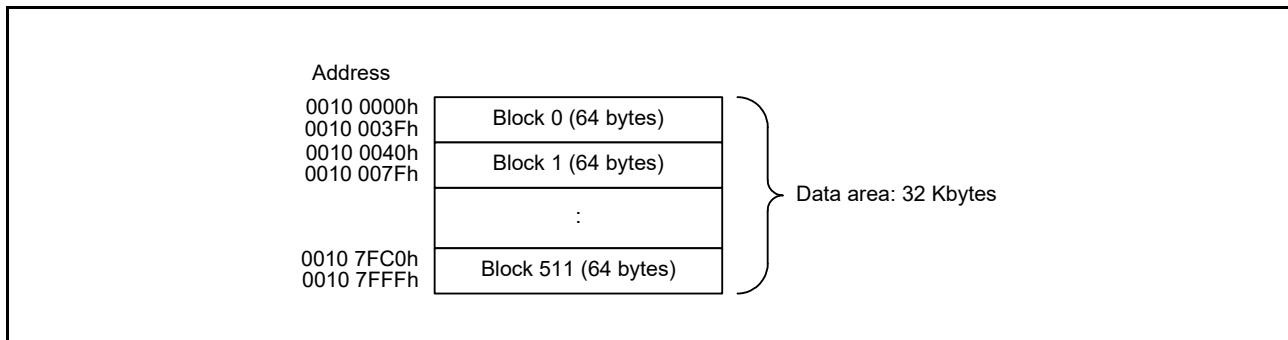

Figure 44.2 Mapping of the Code Flash Memory

The data area of the data flash memory in this MCU is divided into 64-byte blocks, with each being a unit for erasure. Figure 44.3 shows the mapping of the data flash memory.

**Figure 44.3** Mapping of the Data Flash Memory

## 44.4 Register Descriptions

### 44.4.1 ROM Cache Enable Register (ROMCE)

Address(es): FLASH.ROMCE 0008 1000h

|                    |     |     |     |     |     |     |    |    |    |    |    |    |    |    |    |            |
|--------------------|-----|-----|-----|-----|-----|-----|----|----|----|----|----|----|----|----|----|------------|
|                    | b15 | b14 | b13 | b12 | b11 | b10 | b9 | b8 | b7 | b6 | b5 | b4 | b3 | b2 | b1 | b0         |
|                    | —   | —   | —   | —   | —   | —   | —  | —  | —  | —  | —  | —  | —  | —  | —  | ROMC<br>EN |
| Value after reset: | 0   | 0   | 0   | 0   | 0   | 0   | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0          |

| Bit       | Symbol | Bit Name         | Description                                                    | R/W |
|-----------|--------|------------------|----------------------------------------------------------------|-----|
| b0        | ROMCEN | ROM Cache Enable | 0: ROM cache is disabled.<br>1: ROM cache is enabled.          | R/W |
| b15 to b1 | —      | Reserved         | These bits are read as 0. Writing to these bits has no effect. | R   |

#### ROMCEN Bit (ROM Cache Enable)

When setting the ROMCEN bit to 1, the ROM cache starts operation. While ROM cache is enabled, the data is served from the cache when a cache hit occurs.

Set a non-cacheable area while the ROMCEN bit is 0.

### 44.4.2 ROM Cache Invalidate Register (ROMCIV)

Address(es): FLASH.ROMCIV 0008 1004h

|                    |     |     |     |     |     |     |    |    |    |    |    |    |    |    |    |            |
|--------------------|-----|-----|-----|-----|-----|-----|----|----|----|----|----|----|----|----|----|------------|
|                    | b15 | b14 | b13 | b12 | b11 | b10 | b9 | b8 | b7 | b6 | b5 | b4 | b3 | b2 | b1 | b0         |
|                    | —   | —   | —   | —   | —   | —   | —  | —  | —  | —  | —  | —  | —  | —  | —  | ROMCI<br>V |
| Value after reset: | 0   | 0   | 0   | 0   | 0   | 0   | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0          |

| Bit       | Symbol | Bit Name             | Description                                                                                                                                                                                    | R/W |
|-----------|--------|----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----|
| b0        | ROMCIV | ROM Cache Invalidate | When reading<br>0: Invalidation is not started/Invalidation is completed.<br>1: Invalidation is in progress.<br>When writing<br>Writing 1 invalidates the cache line. Writing 0 has no effect. | R/W |
| b15 to b1 | —      | Reserved             | These bits are read as 0. Writing to these bits has no effect.                                                                                                                                 | R   |

#### ROMCIV Bit (ROM Cache Invalidate)

When writing 1 to the ROMCIV bit, the ROM cache invalidation is performed.

### 44.4.3 Non-Cacheable Area n Address Register (NCRGn) (n = 0, 1)

Address(es): FLASH.NCRG0 0008 1040h, FLASH.NCRG1 0008 1048h

The NCRGn register specifies the address where an area in which caching is disabled starts (non-cacheable area).

The higher-order 10 bits (b31 to b22), which are fixed to 1 and the lower-order 4 bits (b3 to b0), which are fixed to 0, are reserved. When writing, write 1 and 0 to the respective sets of bits.

Set the NCRGn register while the ROMCE.ROMCEN bit is 0.

**NC2E Bit (OA Non-Cacheable Area Specification Enable)**

The NC2E bit enables or disables the settings of the non-cacheable area in the cache (OA cache) used for fast operand access (OA) by the CPU.

**NC3E Bit (DM Non-Cacheable Area Specification Enable)**

The NC3E bit enables or disables the settings of the non-cacheable area in the cache (DM cache) used for fast access to data by bus masters other than the CPU.

**NCSZ[16:0] Bit (Non-Cacheable Area Size Specification)**

The NCSZ[16:0] bits specify the size of the non-cacheable area. They are used to mask address bits 4 to 20.

When an address generated by the bus master is compared to the value of the NCRGn register, bits corresponding to NCSZ[16:0] bits with the value 1 are ignored.

**44.4.5 Flash P/E Protect Register (FWEPROR)**

Address(es): FLASH.FWEPROR 0008 C296h

| Bit      | Symbol    | Bit Name                   | Description                                                                                                                                                                                                                                                                                                              | R/W |
|----------|-----------|----------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----|
| b1, b0   | FLWE[1:0] | Flash Program/Erase Enable | b1 b0<br>0 0: Program, block erase, blank check, and lock-bit program are disabled<br>0 1: Program, block erase, blank check, and lock-bit program are enabled<br>1 0: Program, block erase, blank check, and lock-bit program are disabled<br>1 1: Program, block erase, blank check, and lock-bit program are disabled | R/W |
| b7 to b2 | —         | Reserved                   | These bits are read as 0. The write value should be 0.                                                                                                                                                                                                                                                                   | R/W |

This register enables or disables the following four FACI commands for flash memory: program, block erase, blank check, and lock-bit program.

This register is initialized not only by a reset but also by a transition to deep software standby mode or a transition to software standby mode.

### 44.4.6 Flash Access Status Register (FASTAT)

Address(es): FLASH.FASTAT 007F E010h

| b7   | b6 | b5 | b4    | b3   | b2 | b1 | b0 |
|------|----|----|-------|------|----|----|----|
| CFAE | —  | —  | CMDLK | DFAE | —  | —  | —  |
| 0    | 0  | 0  | 0     | 0    | 0  | 0  | 0  |

Value after reset:

| Bit      | Symbol | Bit Name                                | Description                                                                                                          | R/W   |
|----------|--------|-----------------------------------------|----------------------------------------------------------------------------------------------------------------------|-------|
| b2 to b0 | —      | Reserved                                | These bits are read as 0. The write value should be 0.                                                               | R/W   |
| b3       | DFAE   | Data Flash Memory Access Violation Flag | 0: No data flash memory access violation has occurred.<br>1: A data flash memory access violation has occurred.      | R/W*1 |
| b4       | CMDLK  | Command Lock Flag                       | 0: The flash sequencer is not in the command-locked state.<br>1: The flash sequencer is in the command-locked state. | R     |
| b6, b5   | —      | Reserved                                | These bits are read as 0. The write value should be 0.                                                               | R/W   |
| b7       | CFAE   | Code Flash Memory Access Violation Flag | 0: No code flash memory access violation has occurred.<br>1: A code flash memory access violation has occurred.      | R/W*1 |

Note 1. Only 0 can be written to clear the flag after 1 is read.

This register indicates whether a code flash memory or data flash memory access violation has occurred. If either of the CFAE, and DFAE flags is 1, the CMDLK flag is set to 1 and the flash sequencer enters the command-locked state (refer to section 44.5.4.2, Error Protection). To release it from the command-locked state, a status clear command or forced stop command must be issued by the FACI after setting the CFAE and DFAE flags in the FASTAT register to 0.

#### DFAE Flag (Data Flash Memory Access Violation Flag)

This flag indicates whether a data flash memory access violation has occurred. If this flag is set to 1, the FSTATR.ILGLERR flag is set to 1, placing the flash sequencer in the command-locked state.

[Setting Condition]

- Refer to Table 44.11, Error Protection Type

[Clearing Condition]

- When 0 is written after reading of 1

#### CMDLK Flag (Command Lock Flag)

This flag indicates that the flash sequencer is in the command-locked state.

[Setting Condition]

- When the flash sequencer detects any of errors listed in Table 44.11, Error Protection Type and transitions to the command-locked state

[Clearing Condition]

- When the flash sequencer starting to process a status clear or forced stop command while the CFAE or DFAE flag in the FASTAT register is 0

#### CFAE Flag (Code Flash Memory Access Violation Flag)

This flag indicates whether a code flash memory access violation has occurred. If this flag is set to 1, the FSTATR.ILGLERR flag is set to 1, placing the flash sequencer in the command-locked state.

[Setting Conditions]

- Refer to Table 44.11, Error Protection Type

[Clearing Condition]

- When 0 is written after reading of 1

### 44.4.7 Flash Access Error Interrupt Enable Register (FAEINT)

Address(es): FLASH.FAEINT 007F E014h

|                    | b7     | b6 | b5 | b4      | b3     | b2 | b1 | b0 |

| b0     | —       | Reserved                                            | After a reset is released, write 0 to this bit.                                                                                                                                   | R/W |
| b2, b1 | —       | Reserved                                            | These bits are read as 0. The write value should be 0.                                                                                                                            | R/W |
| b3     | DFAEIE  | Data Flash Memory Access Violation Interrupt Enable | 0: Generation of an FIFERR interrupt request is disabled when FASTAT.DFAE is set to 1.<br>1: Generation of an FIFERR interrupt request is enabled when FASTAT.DFAE is set to 1.   | R/W |
| b4     | CMDLKIE | Command Lock Interrupt Enable                       | 0: Generation of an FIFERR interrupt request is disabled when FASTAT.CMDLK is set to 1.<br>1: Generation of an FIFERR interrupt request is enabled when FASTAT.CMDLK is set to 1. | R/W |
| b6, b5 | —       | Reserved                                            | These bits are read as 0. The write value should be 0.                                                                                                                            | R/W |
| b7     | CFAEIE  | Code Flash Memory Access Violation Interrupt Enable | 0: Generation of an FIFERR interrupt request is disabled when FASTAT.CFAE is set to 1.<br>1: Generation of an FIFERR interrupt request is enabled when FASTAT.CFAE is set to 1.   | R/W |

This register enables or disables generation of a flash access error (FIFERR) interrupt request.

#### DFAEIE Bit (Data Flash Memory Access Violation Interrupt Enable)

This bit enables or disables generation of an FIFERR interrupt request when a data flash memory access violation occurs and the FASTAT.DFAE flag is set to 1.

#### CMDLKIE Bit (Command Lock Interrupt Enable)

This bit enables or disables generation of an FIFERR interrupt request when the flash sequencer enters the command-locked state and the FASTAT.CMDLK flag is set to 1.

#### CFAEIE Bit (Code Flash Memory Access Violation Interrupt Enable)

This bit enables or disables generation of an FIFERR interrupt request when a code flash memory access violation occurs and the FASTAT.CFAE flag is set to 1.

### 44.4.8 Flash Ready Interrupt Enable Register (FRDYIE)

Address(es): FLASH.FRDYIE 007F E018h

| Bit      | Symbol | Bit Name                     | Description                                                                                                       | R/W |
|----------|--------|------------------------------|-------------------------------------------------------------------------------------------------------------------|-----|
| b0       | FRDYIE | Flash Ready Interrupt Enable | 0: Generation of an FRDY interrupt request is disabled.<br>1: Generation of an FRDY interrupt request is enabled. | R/W |
| b7 to b1 | —      | Reserved                     | These bits are read as 0. The write value should be 0.                                                            | R/W |

This register enables or disables generation of a flash ready (FRDY) interrupt request.

#### FRDYIE Bit (Flash Ready Interrupt Enable)

This bit is used to enable or disable generation of an FRDY interrupt request when the FASTAT.FRDY flag is changed from 0 to 1 upon completion of processing by the flash sequencer of program, block erase, and blank check command.

### 44.4.9 FACI Command Processing Start Address Register (FSADDR)

Address(es): FLASH.FSADDR 007F E030h

| Bit       | Symbol       | Bit Name                              | Description                               | R/W   |
|-----------|--------------|---------------------------------------|-------------------------------------------|-------|
| b31 to b0 | FSADDR[31:0] | FACI Command Processing Start Address | Start Address for FACI Command Processing | R/W*1 |

Note 1. Writing to these bits is possible only when the FSTATR.FRDY flag is 1. Writing to these bits while the FSTATR.FRDY flag = 0 is ignored. The value of the lower 2 bits (b1 and b0) is fixed to 00b.

This register specifies the address where the target area for command processing starts when the FACI command for program, block erase, blank check, configuration set, lock-bit program, or lock-bit read is issued.

The FSADDR register is initialized when the FSUINITR.SUINIT bit is set to 1. It is also initialized by a reset.

#### FSADDR[31:0] Bits (FACI Command Processing Start Address)

These bits specify the start address for FACI command processing. Bits 31 to 24 are ignored in FACI command processing for the code flash memory. Bits 31 to 19 are ignored in FACI command processing for the data flash memory. Bits that do not reach the address boundaries are also ignored. Table 44.3 shows the address boundary for each command.

**Table 44.3 Address Boundary for Each of the Commands**

| Command                         | Address Boundary    |
|---------------------------------|---------------------|
| Program (code flash memory)     | 256-byte            |
| Program (data flash memory)     | 4-byte              |
| Block erase (code flash memory) | 8-Kbyte or 32-Kbyte |
| Block erase (data flash memory) | 64-byte             |
| Blank check                     | 4-byte              |
| Configuration set               | 16-byte             |
| Lock-bit program                | 8-Kbyte or 32-Kbyte |
| Lock-bit read                   | 8-Kbyte or 32-Kbyte |

Refer to Table 44.18, Address Used by Configuration Set Command for the start address of the configuration setting area.

### 44.4.10 FACI Command Processing End Address Register (FEADDR)

Address(es): FLASH.FEADDR 007F E034h

| Bit       | Symbol       | Bit Name                            | Description                                 | R/W   |
|-----------|--------------|-------------------------------------|---------------------------------------------|-------|
| b31 to b0 | FEADDR[31:0] | FACI Command Processing End Address | The end address for FACI command processing | R/W*1 |

Note 1. Writing to these bits is possible only when the FSTATR.FRDY flag is 1. Writing to these bits while the FSTATR.FRDY flag = 0 is ignored. The value of the lower 2 bits (b1 and b0) is fixed to 00b.

This register is used to specify the end address of the area targeted for the blank checking command handling. When the FBCCNT.BCDIR bit is 0, the setting value of the FSADDR register must be the setting of the FEADDR register or lower. When the FBCCNT.BCDIR bit is 1, the value of the FSADDR register must be at least that of the FEADDR register. If the settings of the FBCCNT.BCDIR bit and the FSADDR and FEADDR registers are inconsistent with the above rules, the flash sequencer enters the command-locked state (refer to section 44.5.4.2, Error Protection). The FEADDR register is initialized when the FSUINTR.SUINIT bit is set to 1. It is also initialized by a reset.

#### FEADDR[31:0] Bits (FACI Command Processing End Address)

These bits are used to specify the end address for handling of the blank checking command. In command processing, bits 31 to 19, 1, and 0 are ignored.

### 44.4.11 Flash Status Register (FSTATR)

Address(es): FLASH.FSTATR 007F E080h

|                    |      |         |        |        |        |        |        |        |     |         |     |     |     |     |     |     |
|--------------------|------|---------|--------|--------|--------|--------|--------|--------|-----|---------|-----|-----|-----|-----|-----|-----|
|                    | b31  | b30     | b29    | b28    | b27    | b26    | b25    | b24    | b23 | b22     | b21 | b20 | b19 | b18 | b17 | b16 |
|                    | —    | —       | —      | —      | —      | —      | —      | —      | —   | —       | —   | —   | —   | —   | —   | —   |
| Value after reset: | 0    | 0       | 0      | 0      | 0      | 0      | 0      | 0      | 0   | 0       | 0   | 0   | 0   | 0   | 0   | 0   |
|                    | b15  | b14     | b13    | b12    | b11    | b10    | b9     | b8     | b7  | b6      | b5  | b4  | b3  | b2  | b1  | b0  |
|                    | FRDY | ILGLERR | ERSERR | PRGERR | SUSRDY | DBFULL | ERSSPD | PRGSPD | —   | FLWEERR | —   | —   | —   | —   | —   | —   |
| Value after reset: | 1    | 0       | 0      | 0      | 0      | 0      | 0      | 0      | 0   | 0       | 0   | 0   | 0   | 0   | 0   | 0   |

| Bit        | Symbol  | Bit Name                        | Description                                                                                                                                                                                                  | R/W |
|------------|---------|---------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----|
| b5 to b0   | —       | Reserved                        | These bits are read as 0. The write value should be 0.                                                                                                                                                       | R/W |
| b6         | FLWEERR | Flash P/E Protection Error Flag | 0: An error has not occurred.<br>1: An error has occurred.                                                                                                                                                   | R   |
| b7         | —       | Reserved                        | This bit is read as 0. The write value should be 0.                                                                                                                                                          | R/W |
| b8         | PRGSPD  | Program Suspend Status Flag     | 0: The flash sequencer is in a state other than those corresponding to the value 1.<br>1: The flash sequencer is in the program suspend processing state or the program-suspended state.                     | R   |
| b9         | ERSSPD  | Erase Suspend Status Flag       | 0: The flash sequencer is in a state other than those corresponding to the value 1.<br>1: The flash sequencer is in the erase suspend processing state or the erase-suspended state.                         | R   |
| b10        | DBFULL  | Data Buffer Full Flag           | 0: The data buffer is empty.<br>1: The data buffer is full.                                                                                                                                                  | R   |
| b11        | SUSRDY  | Suspend Ready Flag              | 0: The flash sequencer cannot receive P/E suspend commands.<br>1: The flash sequencer can receive P/E suspend commands.                                                                                      | R   |
| b12        | PRGERR  | Program Error Flag              | 0: Program operation has been completed successfully.<br>1: An error has occurred during program operation.                                                                                                  | R   |
| b13        | ERSERR  | Erase Error Flag                | 0: Erase operation has been completed successfully.<br>1: An error has occurred during erase operation.                                                                                                      | R   |
| b14        | ILGLERR | Illegal Command Error Flag      | 0: The flash sequencer has not detected an illegal FACI command or illegal flash memory access.<br>1: The flash sequencer has detected an illegal FACI command or illegal flash memory access.               | R   |
| b15        | FRDY    | Flash Ready Flag                | 0: Program, block erase, P/E suspend, P/E resume, forced stop, blank check, configuration set, lock-bit program, or lock-bit read command processing is in progress.<br>1: None of the above is in progress. | R   |
| b31 to b16 | —       | Reserved                        | These bits are read as 0. The write value should be 0.                                                                                                                                                       | R/W |

This register indicates the state of the flash sequencer.

#### FLWEERR Flag (Flash P/E Protection Error Flag)

This flag indicates a violation of the flash memory program/erase protection setting in the FWEPROR register. When this flag is 1, the flash sequencer is in the command-locked state.

[Setting Condition]

- Refer to Table 44.11, Error Protection Type

[Clearing Condition]

- When the flash sequencer starts processing of a forced stop command

#### **PRGSPD Flag (Program Suspend Status Flag)**

This flag indicates that the flash sequencer is in the processing of program suspend or has transitioned to the program-suspended state.

[Setting Condition]

- When the flash sequencer starts processing in response to a program suspend command

[Clearing Conditions]

- When the flash sequencer has received a P/E resume command (after write access to the FACI command-issuing area is completed)
- When the flash sequencer starts processing of a forced stop command

#### **ERSSPD Flag (Erase Suspend Status Flag)**

This flag indicates that the flash sequencer is the processing of erase suspend or has transitioned to the erase-suspended state.

[Setting Condition]

- When the flash sequencer starts processing in response to an erase suspend command

[Clearing Conditions]

- Reception of the P/E resume command by the flash sequencer (after write access to the FACI command-issuing area is completed)
- When the flash sequencer starts processing of a forced stop command

#### **DBFULL Flag (Data Buffer Full Flag)**

This flag indicates the state of the data buffer when a program command is issued. The FACI incorporates a buffer for write data (data buffer). When data for writing to the flash memory are issued to the FACI command-issuing area while the data buffer is full, the FACI inserts a wait cycle in the peripheral bus 6.

[Setting Condition]

- When the data buffer becomes full while a program command is being issued

[Clearing Condition]

- When the data buffer becomes empty

#### **SUSRDY Flag (Suspend Ready Flag)**

This flag indicates whether the flash sequencer can receive a P/E suspend command.

[Setting Condition]

- When the flash sequencer is ready to accept the P/E suspend command after the program or erase sequence has started

[Clearing Conditions]

- When the flash sequencer has accepted the P/E suspend command or forced stop command (after write access to the FACI command-issuing area is completed)
- When the flash sequencer enters the command-locked state during programming or erasure
- When programming or erasure has been completed

#### **PRGERR Flag (Program Error Flag)**

This flag indicates the result of programming the flash memory. If this flag is 1, the flash sequencer is in the command-locked state.

[Setting Condition]

- Refer to Table 44.11, Error Protection Type

[Clearing Condition]

- When the flash sequencer starts processing of a status clear or forced stop command

### **ERSERR Flag (Erase Error Flag)**

This flag indicates the result of erasing the flash memory. If this flag is 1, the flash sequencer is in the command-locked state.

[Setting Condition]

- Refer to Table 44.11, Error Protection Type

[Clearing Condition]

- When the flash sequencer starts processing of a status clear or forced stop command

### **ILGLERR Flag (Illegal Command Error Flag)**

This flag indicates that the flash sequencer has detected an illegal FACI command or flash memory access. When this flag is 1, the flash sequencer is in the command-locked state.

[Setting Condition]

- Refer to Table 44.11, Error Protection Type

[Clearing Condition]

- When the flash sequencer starts processing of a status clear or forced stop command while the DFAE and CFAE flag in the FASTAT register is 0

If the flash sequencer completes processing of a status clear or forced stop command while the CFAE or DFAE flag in the FASTAT register is 1, this flag is set to 1. This flag is temporarily set to 0 during processing of a forced stop command, and is re-set to 1 when the CFAE or DFAE flag is detected as 1 upon completion of command processing.

### **FRDY Flag (Flash Ready Flag)**

This flag indicates the command processing state of the flash sequencer.

[Setting Conditions]

- When the flash sequencer completes command processing
- When the flash sequencer receives a P/E suspend command and suspends program or erase sequence of the flash memory
- When the flash sequencer has received a forced stop command and ended command processing

[Clearing Conditions]

- When the flash sequencer receives the FACI command of the setting of the program and configuration and after the first write access is made to the FACI command-issuing area
- When the flash sequencer receives any FACI command other than of the setting of the program and configuration and after the last write access is made to the FACI command issuing area

### 44.4.12 Flash P/E Mode Entry Register (FENTRYR)

Address(es): FLASH.FENTRYR 007F E084h

| Bit       | Symbol   | Bit Name                         | Description                                                                   | R/W       |
|-----------|----------|----------------------------------|-------------------------------------------------------------------------------|-----------|
| b0        | FENTRYC  | Code Flash Memory P/E Mode Entry | 0: Code flash memory is in read mode.<br>1: Code flash memory is in P/E mode. | R/W*1, *2 |
| b6 to b1  | —        | Reserved                         | These bits are read as 0. The write value should be 0.                        | R/W       |
| b7        | FENTRYD  | Data Flash Memory P/E Mode Entry | 0: Data flash memory is in read mode.<br>1: Data flash memory is in P/E mode. | R/W*1, *2 |
| b15 to b8 | KEY[7:0] | Key Code                         | Key code                                                                      | R/W*3     |

Note 1. Writing to these bits is possible only when the FSTATR.FRDY flag is 1. Writing to these bits while the FSTATR.FRDY flag = 0 is ignored.

Note 2. Writing to this bit is enabled only when this register is written in 16-bit units with the KEY[7:0] bits set to AAh.

Note 3. Written values are not retained by these bits. These bits are read as 0.

This register is used to specify code flash memory P/E mode and data flash memory P/E mode. To specify code flash memory P/E mode or data flash memory P/E mode so that the flash sequencer can receive FACY commands, set either the FENTRYD or FENTRYC bit to 1 to place the flash sequencer in P/E mode.

Note that writing AA81h in this register causes the FSTATR.ILGLERR flag to be set to 1, and the flash sequencer to enter the command-locked state.

The FENTRYR register is initialized when the FSUINTR.SUINIT bit is set to 1. It is also initialized by a reset.

#### FENTRYC Bit (Code Flash Memory P/E Mode Entry)

This bit specifies the P/E mode for code flash memory.

[Setting Condition]

- When AA01h is written to the FENTRYR register while the FSTATR.FRDY flag is 1 and the FENTRYR register is 0000h

[Clearing Conditions]

- When the FENTRYR register is written in 8-bit units while the FSTATR.FRDY flag is 1
- When the FENTRYR register is written in 16-bit units with the KEY[7:0] bits set to a value other than AAh while the FSTATR.FRDY flag is 1
- When AA00h is written to the FENTRYR register while the FSTATR.FRDY flag is 1
- When the FENTRYR register is written while the FSTATR.FRDY flag is 1 and the FENTRYR register is not 0000h

#### FENTRYD Bit (Data Flash Memory P/E Mode Entry)

This bit specifies the P/E mode for data flash memory.

[Setting Condition]

- When AA80h is written to the FENTRYR register while the FSTATR.FRDY flag is 1 and the FENTRYR register is 0000h

[Clearing Conditions]

- When the FENTRYR register is written in 8-bit units while the FSTATR.FRDY flag is 1
- When the FENTRYR register is written in 16-bit units with the KEY[7:0] bits set to a value other than AAh while the FSTATR.FRDY flag is 1

- When AA00h is written to the FENTRYR register while the FSTATR.FRDY flag is 1
- When the FENTRYR register is written while the FSTATR.FRDY flag is 1 and the FENTRYR register is not 0000h

### KEY[7:0] Bits (Key Code)

These bits control permission and prohibition of writing to the FENTRYD and FENTRYC bits.

#### 44.4.13 Flash Protection Register (FPROTR)

Address(es): FLASH.FPROTR 007F E088h

| Bit       | Symbol   | Bit Name                   | Description                                                                         | R/W   |
|-----------|----------|----------------------------|-------------------------------------------------------------------------------------|-------|
| b0        | FPROTCN  | Lock Bit Protection Cancel | 0: Enables protection by the lock bits.<br>1: Disables protection by the lock bits. | R/W*1 |
| b7 to b1  | —        | Reserved                   | These bits are read as 0. The write value should be 0.                              | R/W   |
| b15 to b8 | KEY[7:0] | Key Code                   | Key code                                                                            | R/W*2 |

Note 1. Writing to this bit is possible only when this register is written in 16-bit units with the KEY[7:0] bits set to 55h.

Note 2. Written values are not retained by these bits. These bits are read as 0.

This register enables or disables protection by the lock bits of the code flash memory against programming and erasure. The register is initialized when the FSUINTR.SUINIT bit is set to 1. It is also initialized by a reset.

### FPROTCN Bit (Lock Bit Protection Cancel)

This bit enables or disables protection by the lock bits of the code flash memory against programming and erasure.

[Setting Condition]

- When 5501h is written to the FPROTR register while the FENTRYR register is not 0000h

[Clearing Conditions]

- When the FPROTR register is written in 8-bit units
- When the FPROTR register is written in 16-bit units with the KEY[7:0] bits set to a value other than 55h
- When 5500h is written to the FPROTR register
- When the value of FENTRYR is 0000h

### KEY[7:0] Bits (Key Code)

These bits control permission and prohibition of writing to the FPROTCN bit.

### 44.4.14 Flash Sequencer Set-Up Initialization Register (FSUINTR)

Address(es): FLASH.FSUINTR 007F E08Ch

| Bit       | Symbol   | Bit Name              | Description                                                                                                                                                                                                                          | R/W       |
|-----------|----------|-----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------|
| b0        | SUINIT   | Set-Up Initialization | 0: The FEADDR, FPROTR, FCPSR, FSADDR, FENTRYR, and FBCCNT flash sequencer set-up registers keep their current values.<br>1: The FEADDR, FPROTR, FCPSR, FSADDR, FENTRYR, and FBCCNT flash sequencer set-up registers are initialized. | R/W*1, *2 |
| b7 to b1  | —        | Reserved              | These bits are read as 0. The write value should be 0.                                                                                                                                                                               | R/W       |
| b15 to b8 | KEY[7:0] | Key Code              | Key code                                                                                                                                                                                                                             | R/W*3     |

Note 1. Writing to these bits is possible only when the FSTATR.FRDY flag is 1. Writing to these bits while the FSTATR.FRDY flag = 0 is ignored.

Note 2. Writing to these bits is possible only when this register is written in 16-bit units with the KEY[7:0] bits set to 2Dh.

Note 3. Written values are not retained by these bits. These bits are read as 0.

This register is used for initialization of the flash sequencer set-up.

#### SUINIT Bit (Set-Up Initialization)

This bit initializes the following flash sequencer set-up registers.

- FEADDR
- FPROTR
- FCPSR
- FSADDR
- FENTRYR
- FBCCNT

#### KEY[7:0] Bits (Key Code)

These bits control permission and prohibition of writing to the SUINIT bit.

#### 44.4.15 Lock Bit Status Register (FLKSTAT)

Address(es): FLASH.FLKSTAT 007F E090h

| Bit      | Symbol  | Bit Name             | Description                                            | R/W |
|----------|---------|----------------------|--------------------------------------------------------|-----|
| b0       | FLOCKST | Lock Bit Status Flag | 0: Protected state<br>1: Non-protected state           | R   |
| b7 to b1 | —       | Reserved             | These bits are read as 0. The write value should be 0. | R/W |

##### FLOCKST Flag (Lock Bit Status Flag)

This flag reflects the value of the lock bit as read by executing a lock-bit read command. When the FSTATR.FRDY flag becomes 1 after the lock-bit read command is issued, the value of the target lock bit is stored in the FLOCKST flag. The value of the FLOCKST flag is retained until the next lock-bit command is completed.

### 44.4.16 FACI Command Register (FCMDR)

Address(es): FLASH.FCMDR 007F E0A0h

| Bit       | Symbol     | Bit Name        | Description                                                  | R/W |
|-----------|------------|-----------------|--------------------------------------------------------------|-----|
| b7 to b0  | PCMDR[7:0] | Precommand Flag | The command immediately before the latest command is stored. | R   |
| b15 to b8 | CMDR[7:0]  | Command Flag    | The latest command is stored.                                | R   |

This register records the two most recent commands accepted by the FACI.

#### PCMDR[7:0] Flags (Precommand Flag)

These flags indicate the command received immediately before the last command received by the FACI.

#### CMDR[7:0] Flags (Command Flag)

These flags indicate the latest command received by the FACI.

**Table 44.4 States of FCMDR after Receiving Commands**

| Command           | CMDR | PCMDR            |
|-------------------|------|------------------|
| Program           | E8h  | Previous command |
| Block erase       | D0h  | 20h              |
| P/E suspend       | B0h  | Previous command |
| P/E resume        | D0h  | Previous command |
| Status clear      | 50h  | Previous command |
| Forced stop       | B3h  | Previous command |
| Blank check       | D0h  | 71h              |
| Configuration set | 40h  | Previous command |
| Lock-bit program  | D0h  | 77h              |
| Lock-bit read     | D0h  | 71h              |

### 44.4.17 Flash P/E Status Register (FPESTAT)

Address(es): FLASH.FPESTAT 007F E0C0h

| Bit       | Symbol       | Bit Name              | Description                                                                                                                                                                                                                                                               | R/W |
|-----------|--------------|-----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----|
| b7 to b0  | PEERRST[7:0] | P/E Error Status Flag | 00h: No error<br>01h: Program error due to an area protected by its lock bit<br>02h: Program error for reasons other than lock-bit protection<br>11h: Erase error due to an area protected by its lock bit<br>12h: Erase error for reasons other than lock-bit protection | R   |
| b15 to b8 | —            | Reserved              | These bits are read as 0. The write value should be 0.                                                                                                                                                                                                                    | R/W |

This register indicates the result of programming or erasing the flash memory.

#### PEERRST[7:0] Flags (P/E Error Status Flag)

These flags indicate the source of an error that occurred during processing for the programming or erasure of the code flash memory or data flash memory. The value of these flags is only valid if the ERSERR or PRGERR flag in the FSTATR register is 1 when the FSTATR.FRDY flag becomes 1. When the ERSERR and PRGERR flags are 0, these flags retain their value to indicate the source of the last error to have occurred.

### 44.4.18 Data Flash Blank Check Control Register (FBCCNT)

Address(es): FLASH.FBCCNT 007F E0D0h

| Bit      | Symbol | Bit Name              | Description                                                                                                                                                                              | R/W |
|----------|--------|-----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----|
| b0       | BCDIR  | Blank Check Direction | 0: Blank checking is executed from lower addresses to higher addresses (incremental mode).<br>1: Blank checking is executed from higher addresses to lower addresses (decremental mode). | R/W |
| b7 to b1 | —      | Reserved              | These bits are read as 0. The write value should be 0.                                                                                                                                   | R/W |

This register specifies the addressing mode in processing of a blank check command.

The register is initialized when the FSUINITR.SUINIT bit is set to 1. It is also initialized by a reset.

#### BCDIR Bit (Blank Check Direction)

This bit specifies the addressing mode for blank checking.

#### 44.4.19 Data Flash Blank Check Status Register (FBCSTAT)

Address(es): FLASH.FBCSTAT 007F E0D4h

| Bit      | Symbol | Bit Name                | Description                                                                                                                                                                              | R/W |
|----------|--------|-------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----|
| b0       | BCST   | Blank Check Status Flag | 0: The target area is in the non-programmed state (i.e. is blank; the area has been erased but has not yet been re-programmed).<br>1: The target area has been programmed with 0s or 1s. | R   |
| b7 to b1 | —      | Reserved                | These bits are read as 0. The write value should be 0.                                                                                                                                   | R/W |

This register stores the results of checking in response to a blank check command.

##### BCST Flag (Blank Check Status Flag)

This flag indicates the results of checking in response to a blank check command.

At the point where the FSTATR.FRDY flag is set to 1, the valid data is stored in the BCST flag.

#### 44.4.20 Data Flash Programming Start Address Register (FPSADDR)

Address(es): FLASH.FPSADDR 007F E0D8h

| Bit        | Symbol      | Bit Name                      | Description                                            | R/W |
|------------|-------------|-------------------------------|--------------------------------------------------------|-----|
| b18 to b0  | PSADR[18:0] | Programmed Area Start Address | The address of the first programmed area               | R   |
| b31 to b19 | —           | Reserved                      | These bits are read as 0. The write value should be 0. | R/W |

This register indicates the address of the first programmed area to be found in processing of a blank check command.

##### PSADR[18:0] Bits (Programmed Area Start Address)

These bits indicate the address of the first programmed area to be found in processing of a blank check command. The address is an offset from the address where the data flash memory starts. The setting of these bits is valid only while the FBCSTAT.BCST flag is 1 and when the FSTATR.FRDY flag becomes 1. When the FBCSTAT.BCST flag is 0, the PSADR[18:0] bits holds the address detected by the previous check.

### 44.4.21 Flash Sequencer Processing Switching Register (FCPSR)

Address(es): FLASH.FCPSR 007F E0E0h

|                    |     |     |     |     |     |     |    |    |    |    |    |    |    |    |    |         |
|--------------------|-----|-----|-----|-----|-----|-----|----|----|----|----|----|----|----|----|----|---------|
|                    | b15 | b14 | b13 | b12 | b11 | b10 | b9 | b8 | b7 | b6 | b5 | b4 | b3 | b2 | b1 | b0      |
|                    | —   | —   | —   | —   | —   | —   | —  | —  | —  | —  | —  | —  | —  | —  | —  | ESUSPMD |
| Value after reset: | 0   | 0   | 0   | 0   | 0   | 0   | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0       |

| Bit       | Symbol  | Bit Name           | Description                                            | R/W |
|-----------|---------|--------------------|--------------------------------------------------------|-----|
| b0        | ESUSPMD | Erase Suspend Mode | 0: Suspend priority mode<br>1: Erase priority mode     | R/W |
| b15 to b1 | —       | Reserved           | These bits are read as 0. The write value should be 0. | R/W |

This register is for selecting the erase suspend mode.

The register is initialized when the FSUINTR.SUINIT bit is set to 1. It is also initialized by a reset.

#### ESUSPMD Bit (Erase Suspend Mode)

This bit is for selecting the erase suspend mode when a P/E suspend command is issued while the flash sequencer is executing erase sequence (refer to section 44.6.6.5, P/E Suspend Command). This bit should be set before issuing a block erase command.

## 44.4.22 Flash Sequencer Processing Clock Frequency Notification Register (FPCKAR)

Address(es): FLASH.FPCKAR 007F E0E4h

| Bit       | Symbol    | Bit Name                                                | Description                                                                                                               | R/W       |
|-----------|-----------|---------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------|-----------|
| b7 to b0  | PCKA[7:0] | Flash Sequencer Processing Clock Frequency Notification | These bits are used to set the frequency of the FlashIF clock (FCLK) and notify the flash sequencer of the frequency used | R/W*1, *2 |
| b15 to b8 | KEY[7:0]  | Key Code                                                | Key code                                                                                                                  | R/W*3     |

Note 1. Writing to these bits is possible only when the FSTATR.FRDY flag is 1. Writing to these bits while the FSTATR.FRDY flag = 0 is ignored.

Note 2. Writing to these bits is enabled only when this register is written in 16-bit units with the KEY[7:0] bits set to 1Eh.

Note 3. Written values are not retained by these bits. These bits are read as 0.

This register specifies the frequency of the FlashIF clock (FCLK) generated in the clock generator and notifies the flash sequencer of the frequency used. The flash sequencer determines the FACI command processing time based on the frequency notified by the FPCKAR register. The initial value is set to the maximum operating frequency of the FCLK.

### PCKA[7:0] Bits (Flash Sequencer Processing Clock Frequency Notification)

These bits are used to specify the frequency of the FCLK generated in the clock generator and to notify the flash sequencer of the frequency used. Set the desired frequency in these bits before issuing an FACI command. Specifically, convert the frequency represented in MHz into a binary number and set it in these bits.

Example: When frequency is 35.9 MHz (PCKA[7:0] = 24h)

Round up the first decimal place of 35.9 MHz to a whole number (= 36) and convert it into a binary number.

If the value set in these bits is smaller than the frequency of the FCLK, the rewriting characteristics of the flash memory cannot be guaranteed. Conversely, if the value set in these bits is greater than the frequency of the FCLK, the rewriting characteristics of the flash memory can be guaranteed although the FACI command processing time such as time for rewriting will increase (the FACI command processing time becomes the shortest when the frequency of the FCLK is the same as the value set in the bits).

### KEY[7:0] Bits (Key Code)

These bits control permission and prohibition of writing to the PCKA[7:0] bits.

### 44.4.23 Unique ID Register n (UIDRn) (n = 0 to 2)

Address(es): FLASH.UIDR0 007F B174h, FLASH.UIDR1 007F B1E4h, FLASH.UIDR2 007F B1E8h

Note: These registers are only readable when the SYSCR0.ROME bit is 1 (the on-chip ROM is enabled).

The UIDRn is a read-only register that stores a 12-byte ID code (unique ID) for identifying the individual MCU. The UIDRn register should be read in 32-bit units.

## 44.5 Overview of Functions

### 44.5.1 ROM Cache

This MCU has three types of cache as listed below.

- Instruction fetching cache (IF cache): 8 Kbytes
- Data cache (OA cache): 16 bytes
- Data cache (DM cache): 16 bytes

The IF cache and OA cache are for the CPU, and the DM cache is for bus masters other than the CPU, such as the DMAC and DTC.

After release from a reset, the caches are automatically invalidated following programming and erasure of the flash memory.

The area subject to caching is the 4-Mbyte address range from FFC0 0000h through FFFF FFFFh, in which up to two areas can be set as not within the scope of caching (non-cacheable areas).

#### 44.5.1.1 Setting Non-Cacheable Area

Parts of the flash memory of this MCU that are within the cacheable areas can be set as not in the scope of caching by setting the NCRGn and NCRCn registers ( $n = 0, 1$ ). Figure 44.4 shows the settings of each register and the non-cacheable areas.

Figure 44.4 Specifying a Non-Cacheable Area ( $n = 0, 1$ )

The restrictions shown below in Table 44.5 apply to the settings of the NCRn.NCSZ[16:0] bits and of the NCRGn register.

**Table 44.5 Restrictions Applying to the Settings of the NCRn.NCSZ[16:0] Bits and of the NCRGn Register**

| Settings of the NCRn.NCSZ[16:0] Bits | Restrictions Applying to the Settings of the NCRGn Register |
|--------------------------------------|-------------------------------------------------------------|
| 0 0000 0000 0000 0000: 16 bytes      | No restriction                                              |
| 0 0000 0000 0000 0001: 32 bytes      | Bit 4 in the NCRGn register is ignored.                     |
| 0 0000 0000 0000 0011: 64 bytes      | Bits 5 and 4 in the NCRGn register are ignored.             |
| 0 0000 0000 0000 0111: 128 bytes     | Bits 6 to 4 in the NCRGn register are ignored.              |
| 0 0000 0000 0000 1111: 256 bytes     | Bits 7 to 4 in the NCRGn register are ignored.              |
| 0 0000 0000 0001 1111: 512 bytes     | Bits 8 to 4 in the NCRGn register are ignored.              |
| 0 0000 0000 0011 1111: 1 Kbyte       | Bits 9 to 4 in the NCRGn register are ignored.              |
| 0 0000 0000 0111 1111: 2 Kbytes      | Bits 10 to 4 in the NCRGn register are ignored.             |
| 0 0000 0000 1111 1111: 4 Kbytes      | Bits 11 to 4 in the NCRGn register are ignored.             |
| 0 0000 0001 1111 1111: 8 Kbytes      | Bits 12 to 4 in the NCRGn register are ignored.             |
| 0 0000 0011 1111 1111: 16 Kbytes     | Bits 13 to 4 in the NCRGn register are ignored.             |
| 0 0000 0111 1111 1111: 32 Kbytes     | Bits 14 to 4 in the NCRGn register are ignored.             |
| 0 0000 1111 1111 1111: 64 Kbytes     | Bits 15 to 4 in the NCRGn register are ignored.             |
| 0 0001 1111 1111 1111: 128 Kbytes    | Bits 16 to 4 in the NCRGn register are ignored.             |
| 0 0011 1111 1111 1111: 256 Kbytes    | Bits 17 to 4 in the NCRGn register are ignored.             |
| 0 0111 1111 1111 1111: 512 Kbytes    | Bits 18 to 4 in the NCRGn register are ignored.             |
| 0 1111 1111 1111 1111: 1 Mbyte       | Bits 19 to 4 in the NCRGn register are ignored.             |

### 44.5.2 Methods of Programming and Erasure

By using a flash-memory programmer to program the flash memory of this MCU, the device can be rewritten regardless of whether this is before or after it is mounted on the target system.

Furthermore, security functions to prohibit rewriting or reading of the user program written to the flash memory are incorporated, and this can prevent falsification and illicit reading of the programs by third parties. Blocks 8 and 9 of the code flash memory can also be protected against reading by using the TM function.

Programming by the user program (self-programming) is available to suit applications where the application on the target system may require updating after manufacturing or shipment. Protection features for the safe rewriting of the flash memory are also incorporated. Furthermore, interrupt processing during self-programming is supported, so programming can proceed at the same time as processing for external communications, etc., and this is the case in various situations. Table 44.6 lists the overview of the methods of programming and the corresponding operating modes.

**Table 44.6 Methods of Programming**

| Method of Programming                    | Functional Overview                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          | Operating Mode                                                             |
|------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------|
| Programming by a flash-memory programmer | A serial programmer is capable of on-board programming of the flash memory after the device is mounted on the target system. The TM function can be in enabled or disabled at this time.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     | Boot mode                                                                  |
|                                          | A parallel programmer and dedicated programming adapter board allow off-board programming of the flash memory, i.e. programming of the device before it is mounted on the target system.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |                                                                            |
| Self-programming                         | <p>The execution of the user program that is written to code flash memory in advance by serial programming executing is also capable of programming the flash memory. The TM function can be in the enabled state at this time.</p> <p>The background operation capability makes it possible to fetch instructions or otherwise read data from code flash memory while the data flash memory is being programmed. Therefore, the data flash memory can be rewritten by executing a program for writing contained by the code flash memory.</p> <p>In cases where background operation is not possible, instructions in the code flash memory cannot be fetched and data cannot be accessed while code flash memory is being re-written by self-programming. In such cases, a program for programming must be transferred to the internal RAM or external memory in advance and executed.</p> | Single-chip mode<br>On-chip ROM enabled<br>extended mode<br>User boot mode |

The flash memory area where programming and erasure are permitted and the boot program after a reset are different according to each mode. The differences between modes are listed in Table 44.7.

**Table 44.7 Differences between Modes**

| Item                           | Single-chip Mode or On-chip ROM Enabled Extended Mode                                                                                    | User Boot Mode                                                                                                                           | Boot Mode (SCI, USB or FINE Interface)                                                                                                        |
|--------------------------------|------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------|

| Boot program at a reset        | User area program                                                                                                                        | User boot area program                                                                                                                   | Boot program                                                                                                                                  |

Table 44.8 lists the functions of the flash memory. Serial programmer commands realize each function of serial programming, while reading of the flash memory by an FACI command or the user program realizes each function of self-programming.

For security function settings, refer to section 7.2.1, Serial Programmer Command Control Register (SPCC), in section 7, Option-Setting Memory (OFSM).

**Table 44.8 List of Basic Functions**

| Function                        | Functional Overview                                                                                                                                                                                                                                                                                                                           | Support Status     |                                                                                                      |
|---------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------|------------------------------------------------------------------------------------------------------|
|                                 |                                                                                                                                                                                                                                                                                                                                               | Serial Programming | Self-programming                                                                                     |
| Blank check                     | This is used to check a specified block to ensure that writing to it has not already proceeded. Results of reading from data flash memory to which nothing has been written after erasure are not guaranteed, so use blank checking to confirm that programming to memory has not proceeded after erasure.                                    | Supported          | Supported                                                                                            |
| Block erasure                   | Erases the memory contents in the specified block.                                                                                                                                                                                                                                                                                            | Supported          | Supported                                                                                            |
| Programming                     | Write to the specified address.                                                                                                                                                                                                                                                                                                               | Supported          | Supported                                                                                            |
| Verify/Checksum                 | Compares the data read from flash memory and the data transferred from a flash memory programmer.                                                                                                                                                                                                                                             | Supported          | Not supported<br>(read by user program is possible)                                                  |
| Read                            | Read data programmed to flash memory.                                                                                                                                                                                                                                                                                                         | Supported          | Supported                                                                                            |
| Setting of control or ID codes  | Sets the OSIS register.                                                                                                                                                                                                                                                                                                                       | Supported          | Supported                                                                                            |
| Setting the security functions  | Sets the SPCC register and enables the following functions. <ul style="list-style-type: none"> <li>• Serial programmer ID code protection</li> <li>• Prohibition of serial programmer connection</li> <li>• Prohibition of block erase commands</li> <li>• Prohibition of program commands</li> <li>• Prohibition of read commands</li> </ul> | Supported          | Supported with conditions<br>(Only switching the configuration from disabled to enabled is possible) |
| Setting the protection function | Configures lock bits for each block in code flash memory.                                                                                                                                                                                                                                                                                     | Supported          | Supported                                                                                            |
| Configuration clearing          | Erases the configuration setting area.<br>Disables the TM function.                                                                                                                                                                                                                                                                           | Supported          | Not supported                                                                                        |
| Setting the TM function         | Sets the TM function.                                                                                                                                                                                                                                                                                                                         | Supported          | Supported with conditions<br>(Only switching the configuration from disabled to enabled is possible) |

### 44.5.3 Security Functions

The flash memory supports various security functions.

The security function includes on-chip debugger ID code protection, serial programmer ID code protection, prohibition of serial programmer connection, prohibition of commands (for block erasure, programming, and reading), and ROM code protection.

In serial programming, serial programmer ID code protection, prohibition of serial programmer connection, and prohibition of commands (for block erasure, programming, and reading), can be used. On-chip debugger ID code protection can be used when using the on-chip debugger. In off-board programming, ROM code protection can be used. Table 44.9 lists the security functions supported by the flash memory, and Table 44.10 lists the operations with security settings.

**Table 44.9 Lists of Security Functions**

| Function                                    | Description                                                                                                                                                                                                                                                                                                                         |
|---------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| On-chip debugger ID code protection         | Connection to the on-chip debugger can be controlled by judging the ID code.                                                                                                                                                                                                                                                        |
| Serial programmer ID code protection        | Connection of a serial programmer can be controlled by judging the control code or ID code.                                                                                                                                                                                                                                         |
| Prohibition of serial programmer connection | Connection of a serial programmer for serial programming is prohibited. Since execution of the configuration clear command is also prohibited when the connection of a serial programmer is prohibited, changing a security setting from "disabled" to "enabled" is not possible.                                                   |
| Prohibition of block erase commands         | Block erase commands, area erase command, and configuration clearing command at the time of serial programming are prohibited. Since execution of the configuration clear command is also prohibited when prohibition of block erase commands is enabled, changing a security setting from "disabled" to "enabled" is not possible. |
| Prohibition of program commands             | Program commands are prohibited at the time of serial programming, and a condition applies to the execution of block erase commands and area erase command. Only through execution of the configuration clear command can the prohibition be lifted.                                                                                |
| Prohibition of read commands                | Read commands at the time of serial programming are prohibited. Only through execution of the configuration clear command can the prohibition be lifted.                                                                                                                                                                            |
| ROM code protection                         | This function is to prohibit reading, programming, and erasure of the flash memory when a parallel programmer is in use.                                                                                                                                                                                                            |

Table 44.10 Operations with Security Settings

| Function                                    | Programming/Erasing/Reading with Respective Security Settings                                                                                                                                                                                                         |                                                                                                                                            | Notes for Security Setting                                                                                                                                                                                                                                                                              |                                                                                                                        |
|---------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------|

Note 1. For details, refer to section 44.9.43, Flow for Erasure when Prohibition of Program Commands is Enabled.

## 44.5.4 Protection Function

### 44.5.4.1 Software Protection

Software protection disables programming and erasure of the user area through the settings of control registers and lock bit settings in the user area. If an attempt is made to issue an FACI command against software protection, the flash sequencer enters the command-locked state.

#### (1) Protection through FWEPROR Register

Programming cannot proceed in any mode unless the FWEPROR.FLWE[1:0] bits are set to 01b.

#### (2) Protection through FENTRYR Register

When the FENTRYR register is set to 0000h, the flash sequencer enters read mode. In read mode, FACI commands cannot be accepted. If an attempt is made to issue an FACI command in read mode, the flash sequencer enters the command-locked state.

#### (3) Protection through Lock Bit

Each block in the user area includes a lock bit. When the FPROTR.FPROTCN bit is 0, blocks whose lock bit is set to 0 are disabled from being programmed/erased. To program or erase blocks whose lock bit is set to 0, set the FPROTR.FPROTCN bit to 1. When the lock bit protection is violated and program, block erase or lock-bit program command is issued for the user area, the flash sequencer enters the command-locked state.

### 44.5.4.2 Error Protection

Error protection detects erroneous issuance of FACI commands, unauthorized access, and flash sequencer malfunction. FACI command acceptance is disabled (command-locked state) in response to the detection of these errors. The flash memory cannot be programmed or erased while the flash sequencer is in the command-locked state. For release from the command-locked state, issue a status clear or forced stop command while the CFAE and DFAE flags in the FASTAT register are 0. The status clear command can only be used while the FSTATR.FR DY flag is 1. The forced stop command can be used regardless of the value of the FRDY flag.

Generation of a flash access error (FIFERR) interrupt detects malfunction. An FIFERR interrupt is generated under any of the following conditions.

- When violation in access to the data flash memory occurred (the FASTAT.DFAE flag is 1) while the FAEINT.DFAEIE bit is 1
- When the flash sequencer enters the command lock state (when the FASTAT.CMDLK flag is 1) while the FAEINT.CMDLKIE bit is 1
- When violation in access to the code flash memory occurred (when the FASTAT.CFAE flag is 1) while the FAEINT.CFAEIE bit is 1

When the flash sequencer enters the command-locked state in response to a command other than the P/E suspend command during program or erase processing, the flash sequencer continues the processing for programming or erasure. In this state, the P/E suspend command cannot be used to suspend the processing for programming or erasure. If a command is issued in the command-locked state, the FSTATR.ILGLERR flag becomes 1 and the other flags retain the values set due to previous error detection.

Table 44.11 shows error protection types and status bit values after error detection.

**Table 44.11 Error Protection Type**

| Error Type                         | Description                                                                                                                                                                                                                                                                                                                                                                                                                      | ILGLERR | ERSERR | PRGERR | FLWEERR | CFAE | DFAE |
|------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------|--------|--------|---------|------|------|
| FENTRYR setting error              | AA81h was written to the FENTRYR register.                                                                                                                                                                                                                                                                                                                                                                                       | 1       | 0      | 0      | 0       | 0    | 0    |
|                                    | The FENTRYR register value at suspension disagrees with that at resumption                                                                                                                                                                                                                                                                                                                                                       | 1       | 0      | 0      | 0       | 0    | 0    |
| Illegal command error              | An undefined code was written on the first access of an FACL command.                                                                                                                                                                                                                                                                                                                                                            | 1       | 0      | 0      | 0       | 0    | 0    |
|                                    | A value other than D0h was written on the last access of an FACL command with multiple access cycles.                                                                                                                                                                                                                                                                                                                            | 1       | 0      | 0      | 0       | 0    | 0    |
|                                    | The value "N" (refer to Table 44.17) specified in the second access of the FACL command in the program or configuration set command is wrong.                                                                                                                                                                                                                                                                                    | 1       | 0      | 0      | 0       | 0    | 0    |
|                                    | A blank check command was issued with one of the following settings <ul style="list-style-type: none"> <li>The FBCCNT.BCDIR bit is 0, and the value in the FSADDR register &gt; that in FEADDR register</li> <li>The FBCCNT.BCDIR bit is 1, and the value in the FEADDR register &gt; that in FSADDR register</li> <li>The value of bits b18 to b0 of the FEADDR register is set in the range from 0 8000h to 7 FFFFh</li> </ul> | 1       | 0      | 0      | 0       | 0    | 0    |
|                                    | An FACL command not acceptable in each mode was issued (refer to Table 44.14)                                                                                                                                                                                                                                                                                                                                                    | 1       | 0      | 0      | 0       | 0    | 0    |
|                                    | An FACL command was issued when command acceptance conditions are not satisfied (refer to Table 44.15)                                                                                                                                                                                                                                                                                                                           | 1       | 0/1    | 0/1    | 0/1     | 0/1  | 0/1  |
| Erase error                        | An error occurs during erase operation                                                                                                                                                                                                                                                                                                                                                                                           | 0       | 1      | 0      | 0       | 0    | 0    |
|                                    | A block erase command was issued to an area protected by the lock bit.                                                                                                                                                                                                                                                                                                                                                           | 0       | 1      | 0      | 0       | 0    | 0    |
| Program error                      | An error occurs during program operation                                                                                                                                                                                                                                                                                                                                                                                         | 0       | 0      | 1      | 0       | 0    | 0    |
|                                    | A program or lock-bit program command was issued to an area protected by the lock bit.                                                                                                                                                                                                                                                                                                                                           | 0       | 0      | 1      | 0       | 0    | 0    |

| Flash P/E protection error         | A flash memory program/erase protection error for the setting of the FWEPROR register was detected during command processing by the flash sequencer.                                                                                                                                                                                                                                                                             | 0       | 0/1    | 0/1    | 1       | 0    | 0    |

Note 1. For products with 128 Kbytes of RAM

Note 2. For products with 64 Kbytes of RAM

### 44.5.4.3 Boot Program Protection

#### (1) User Boot Protection

The user boot area can only be written in boot mode (SCI or USB interface). Since this area is usually write-protected in normal operating mode and user boot mode, it can be used for the safe storage of programs such as a boot program.

### 44.5.5 Suspend Function

Reading from the user area/data area without using the BGO function is not possible during programming or erasure. When a P/E suspend command is issued to suspend the programming or erasure of the user area/data area, reading from the user area/data area is enabled. Regarding P/E suspend commands, there are one suspend command mode for programming and two suspend command modes for erasure (suspension priority mode and erasure priority mode). To resume suspended programming or erasure, the P/E resume command is available.

### 44.5.6 Trusted Memory

This MCU has a trusted memory (hereafter called TM) facility to prevent the reading of blocks 8 and 9 in the user area by third party software. When set as trusted memory, these areas are suitable for storing software that handles processing for encryption algorithms, device control software that is associated with proprietary or confidential know-how, purchased middleware, and so on.

Table 44.12 lists the specifications of the TM function, Table 44.13 lists access restrictions within the TM target area when the TM function is enabled, and Figure 44.5 shows the cases where the CPU is able to operate in relation to the TM target area.

**Table 44.12 TM Specifications**

| Item                                                                                                                      | Description                                                                                                                                                                                                                                                                                                                                                                      |
|---------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| TM target area                                                                                                            | Blocks 8 and 9 in the user area (64 Kbytes in total)                                                                                                                                                                                                                                                                                                                             |
| Access restrictions when TM is enabled                                                                                    | Refer to Table 44.13, Restrictions on Access to the TM Target Area while the TM Function is Enabled.                                                                                                                                                                                                                                                                             |
| How to run program code when the TM function is enabled                                                                   | When the TM function is enabled, starting to run program code in an area being handled as TM is only possible with a branch instruction from program code outside the areas being handled as TM.                                                                                                                                                                                 |
| Interrupt processing during the execution of program code in an area being handled as TM while the TM function is enabled | Both the acceptance of requests for interrupt processing and return from interrupt processing are possible.                                                                                                                                                                                                                                                                      |
| Security function                                                                                                         | Enabling the TM function restricts access to program code in the areas for handling as TM to instruction fetching only                                                                                                                                                                                                                                                           |
| Protection functions                                                                                                      | <ul style="list-style-type: none"> <li>Restrictions on data access to the TM target area when the TM function is enabled*1</li> <li>Once enabled, the TM function prevents its own disabling until the areas being handled as TM target area are erased.</li> <li>Once enabled, the TM function prevents further writing to the areas being handled as TM target area</li> </ul> |

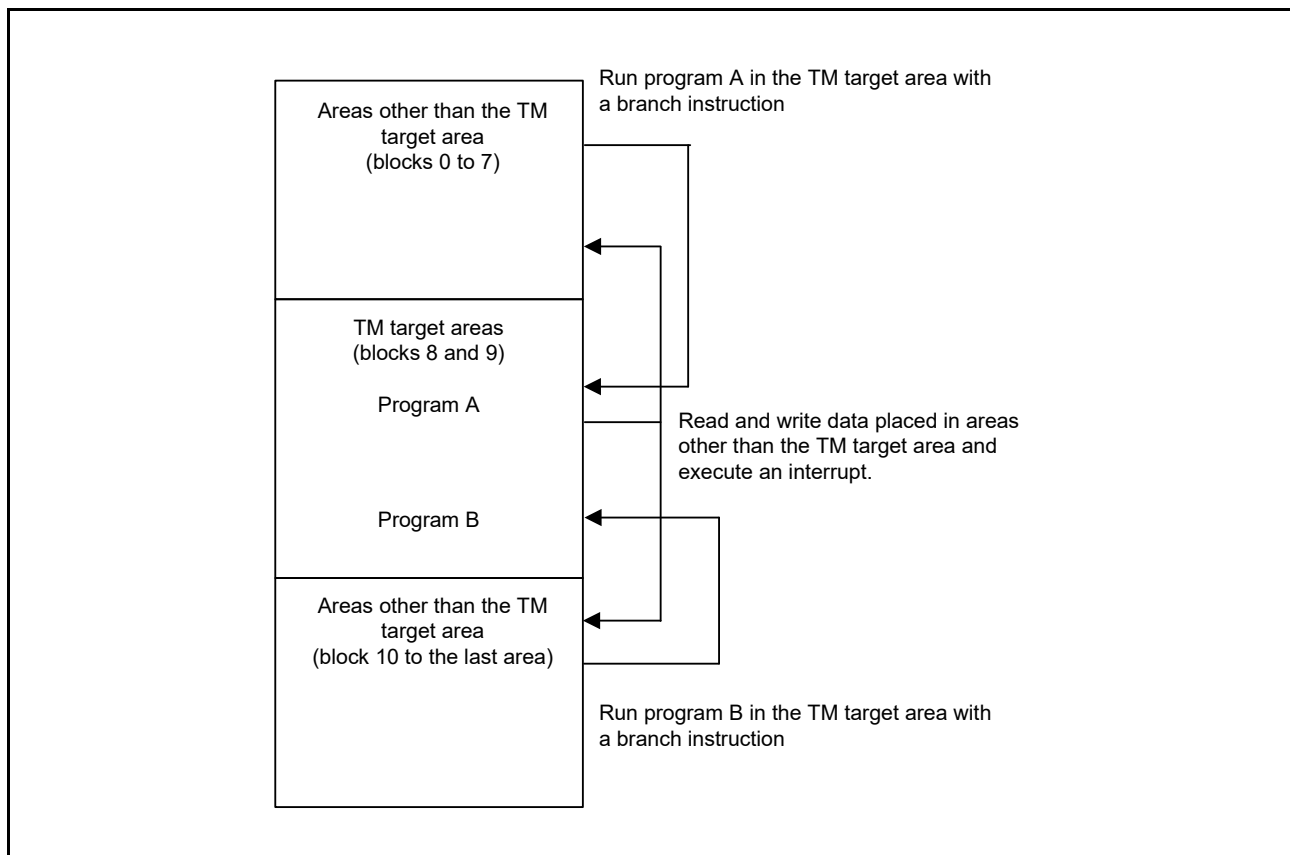

Note 1. Access to data in operations that include the borders of the TM target areas is also not allowed.

**Table 44.13 Restrictions on Access to the TM Target Area while the TM Function is Enabled**

| Type of Access       | CPU | DMAC/DTC |
|----------------------|-----|----------|
| Instruction fetching | Yes | —        |
| Access to data*1     | No  | No       |

Note: When using the on-chip debugger (OCD), the same restrictions apply as for the DMAC in the table above. For the OCD operation to the TM target area, refer to the manual of the emulator to be used.

Note 1. Place data to which access will be required in areas other than the TM target areas.

**Figure 44.5 Cases where CPU is Allowed to Operate in Relation to the TM Target Area when the TM Function is Enabled**

### 44.5.6.1 Allocating Program Code to the TM Target Area

When the TM function is enabled, implement countermeasures in the form of software for the TM target area as required as further measures to prevent the running of programs for access to consecutive addresses in the TM target areas from areas outside the TM target areas.

### 44.5.6.2 How to Enable the TM Function

#### (1) By Self-Programming

After writing to blocks 8 and 9 of the user area, i.e. the target areas for TM, use the configuration setting command of the FACI to enable the TM function.

Figure 44.6 is a flowchart of the procedure for enabling the TM function by self-programming.

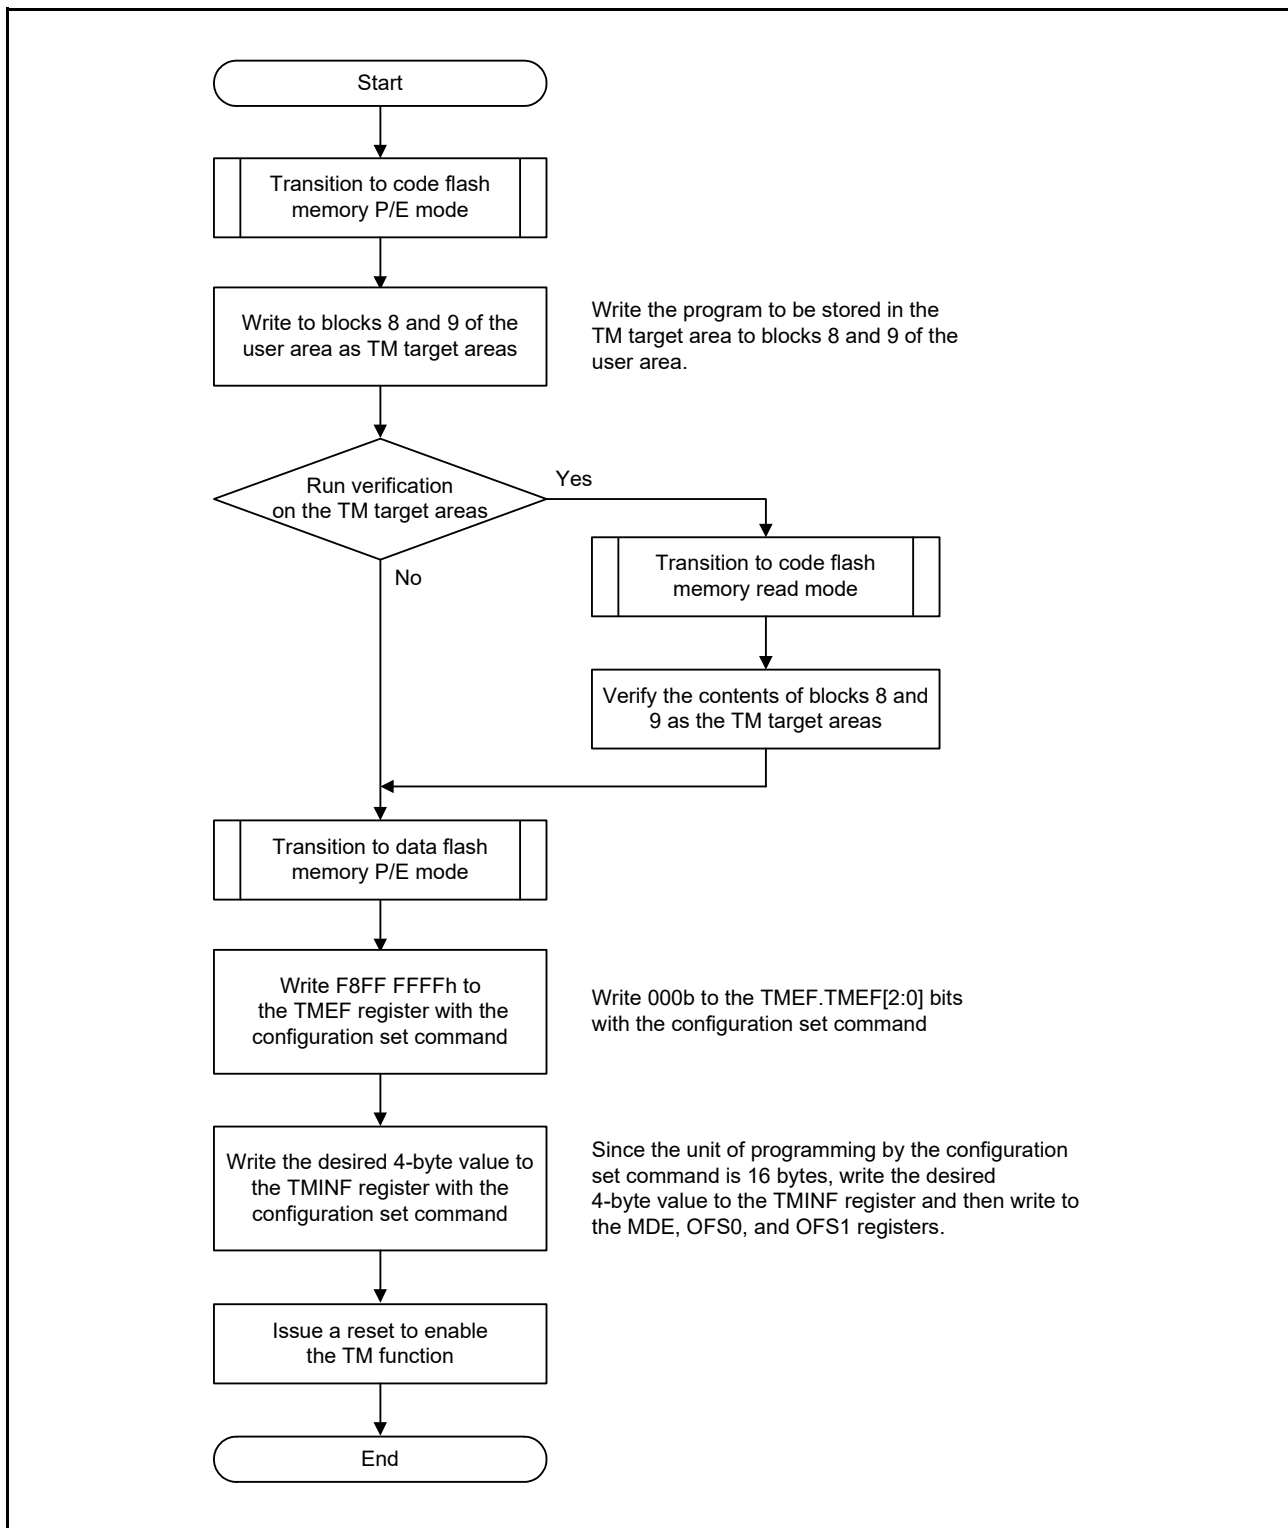

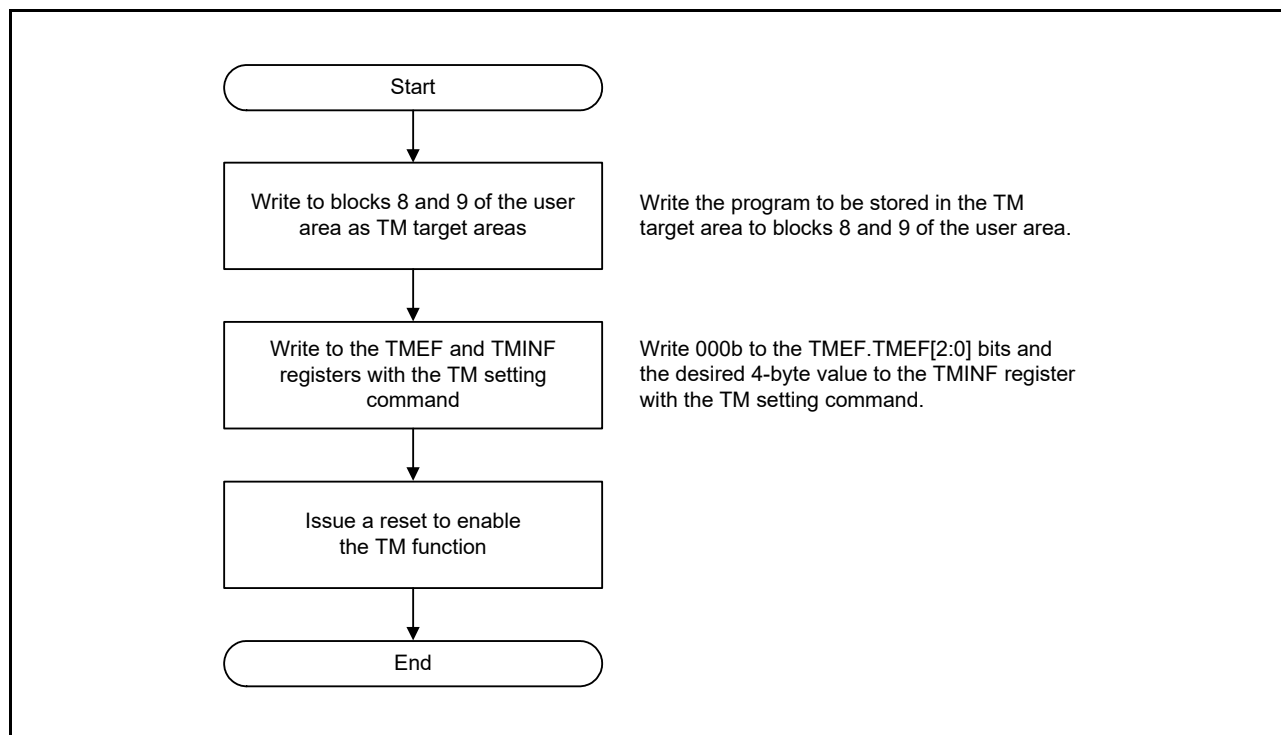

Figure 44.6 Flowchart for Enabling the TM Function by Self-Programming

## (2) By Using Boot Mode

In boot mode, use the TM setting command among the boot commands to enable the TM function after writing to blocks 8 and 9 of the user area.

For the TM setting command among the boot commands, refer to section 44.9.36, TM Setting Command.

Figure 44.7 is a flowchart of enabling the TM function in boot mode.

**Figure 44.7** Flowchart for Enabling the TM Function by Using Boot Mode

### 44.5.6.3 How to Disable the TM Function

The TM function cannot be disabled unless the TM target areas are first erased with the configuration clear command. Do not use the configuration clear command for this purpose unless the TM function is to be disabled.

Figure 44.8 is a flowchart of disabling the TM function in boot mode.

**Figure 44.8** Flowchart for Disabling the TM Function in Boot Mode

#### 44.5.6.4 Notes on Enabling the TM Function

##### (1) Protection against Access to the TM Target Areas

While the TM function is enabled, the only type of access to the TM target areas is instruction fetching by the CPU, so do not allocate data to the TM target areas.

If the CPU, DMAC, DTC, or OCD attempt access to data in the TM target areas while the TM function is enabled, values are always read as 0 instead of the actual values.

##### (2) Further Writing to the TM Target Areas

Further writing to the TM target areas is not allowed as long as the TM function is enabled.

If you need to write further data, follow the procedure described in section 44.5.6.3, How to Disable the TM Function; and follow the procedure described in section 44.5.6.2, How to Enable the TM Function, to program blocks 8 and 9 of the code flash memory and to re-enable the TM function.

To erase the user area, user boot area, and data area, refer to section 44.9.43, Flow for Erasure when Prohibition of Program Commands is Enabled.

##### (3) Executing the Configuration Clear Command

Follow the procedure in section 44.5.6.3, How to Disable the TM Function, before issuing the configuration clear command.

##### (4) When the MPU Setting is for Access to the TM Target Areas

When the TM function is enabled, even if the MPU is set to allow access to the TM target areas, the TM function takes priority.

##### (5) FACI Block Erase Command for the TM Target Areas

There are no special restrictions on block erasure of the TM target areas with the FACI block erase command.

Accordingly, since each area corresponds to an erase block, the areas can be erased by issuing the block erase command.

##### (6) Effect on the Setting for Command Protection

Executing the configuration clear command to disable the TM function also initializes the command protected state at the same time.

##### (7) Conditions for Correct Operation of the TM Function

The TM function operates normally under the conditions prescribed in section 45, Electrical Characteristics.

## 44.6 Flash Sequencer

### 44.6.1 Operating Modes of the Flash Sequencer

The flash sequencer has three operating modes as shown in Figure 44.9. Transitions between modes are initiated by changing the value of the FENTRYR register.

When the value of the FENTRYR register is 0000h, the flash sequencer is in read mode. In this mode, it does not receive FACI commands. The code flash memory and data flash memory are readable.

When the value of the FENTRYR register is 0001h, the flash sequencer is in code flash memory P/E mode where the code flash memory can be programmed or erased by FACI commands. In this mode, the code flash memory and data flash memory is not readable.

When the value of the FENTRYR register is 0080h, the flash sequencer is in data flash memory P/E mode where the data flash memory can be programmed or erased by FACI commands. In this mode, the data flash memory is not readable. However, the code flash memory is readable.

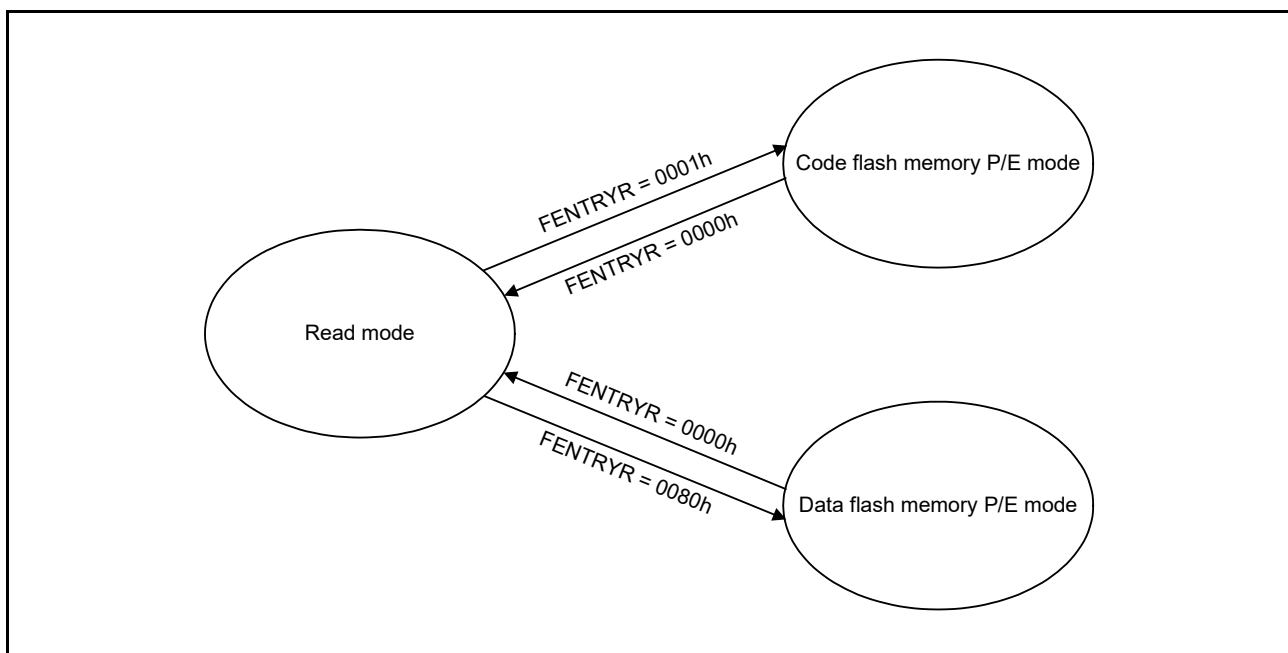

Figure 44.9 Modes of the Flash Sequencer

### 44.6.2 Read Mode

Read mode is for high-speed reading of the code flash memory or data flash memory.

#### (1) Code Flash Memory

Special settings are not required to read code flash memory in single-chip mode, on-chip ROM enabled extended mode, or user boot mode. Data can simply be read out through access to addresses in the code flash memory.

When reading code flash memory that has been erased but not yet been programming again (i.e. that is in the non-programmed state), all bits are read as 1.

#### (2) Data Flash Memory

Special settings are not required to read data flash memory in single-chip mode, on-chip ROM enabled extended mode, or user boot mode. Data can simply be read out through access to addresses in the data flash memory.

Values read from data flash memory that has been erased but not yet been programming again (i.e. that is in the non-programmed state) are undefined. Use blank checking when you need to confirm that an area is in the non-programmed state.

### 44.6.3 P/E Modes

The P/E mode is for programming and erasure of the code flash memory or data flash memory.

#### (1) Code Flash Memory P/E Mode

In this mode, the code flash memory is in P/E mode, and the data flash memory is in read mode. The sequencer enters this mode when setting the FENTRYR.FENTRYD bit to 0 and the FENTRYR.FENTRYC bit to 1.

#### (2) Data Flash Memory P/E Mode

In this mode, the code flash memory is in read mode, and the data flash memory is in P/E mode. The sequencer enters this mode when setting the FENTRYR.FENTRYD bit to 1 and the FENTRYR.FENTRYC bit to 0.

#### 44.6.4 Transitions of Operating Modes

Each FACI command can be accepted in a specific mode or state of the flash sequencer. FACI commands should be issued after the transition of the flash sequencer to the code flash memory P/E mode or data flash memory P/E mode and checking of the state of the flash sequencer. Use the FSTATR and FASTAT registers to check the state of the flash sequencer. The value of the FASTAT.CMDLK flag is the logical OR of values of the ILGLERR, ERSERR, PRGERR, and FLWEERR flags in the FSTATR register, and the CFAE and DFAE flags in the FASTAT register. Therefore, the occurrence of errors can be checked by reading the value of the FASTAT.CMDLK flag.

Table 44.14 lists the available commands in each operating mode.

**Table 44.14 Operating Mode and Available Commands**

| Operating Mode             | FENTRYR Register Value | Available Commands                                                                                                      |
|----------------------------|------------------------|-------------------------------------------------------------------------------------------------------------------------|
| Read mode                  | 0000h                  | None                                                                                                                    |
| Code flash memory P/E mode | 0001h                  | Program<br>Block erase<br>P/E suspend<br>P/E resume<br>Status clear<br>Forced stop<br>Lock-bit program<br>Lock-bit read |
| Data flash memory P/E mode | 0080h                  | Program<br>Block erase<br>P/E suspend<br>P/E resume<br>Status clear<br>Forced stop<br>Blank check<br>Configuration set  |

Table 44.15 shows the state of the flash sequencer and acceptable FACI commands. An appropriate mode is assumed to be set before the commands are executed.

**Table 44.15 Acceptable FACI Commands and the State of the Flash Sequencer**

|                   | Processing of Programming or Erasure*5 | Processing of Configuration Setting | Processing to Suspend Programming or Erasure | Blank checking or lock bit reading | Programming Suspended | Erasure Suspended | Programming while Erasure is Suspended | Command-Locked State (FRDY = 1) | Command-Locked State (FRDY = 0) | Lock-Bit Programming | Processing of Forced Stop Command | Other State |
|-------------------|----------------------------------------|-------------------------------------|----------------------------------------------|------------------------------------|-----------------------|-------------------|----------------------------------------|---------------------------------|---------------------------------|----------------------|-----------------------------------|-------------|
| FRDY flag         | 0                                      | 0                                   | 0                                            | 0                                  | 1                     | 1                 | 0                                      | 1                               | 0                               | 0                    | 0                                 | 1           |

✓: Acceptable

x: Not acceptable (the sequencer in the command-locked state)

—: Ignored

Note 1. Acceptable only in data flash memory P/E mode

Note 2. Acceptable only in code flash memory P/E mode

Note 3. Program command can be issued to a block other than the erase-suspended block.

Note 4. The value read out is undefined when a lock-bit read command is issued for a block where erasure was suspended.

Note 5. Cases that the programming or erasure processing is completed while the P/E suspend command is accepted are also included.

#### 44.6.4.1 Transition to Code Flash Memory P/E Mode

To use the FACL commands for the code flash memory, a transition to code flash memory P/E mode is required. To shift to code flash memory P/E mode, set the FENTRYR.FENTRYC bit to 1.

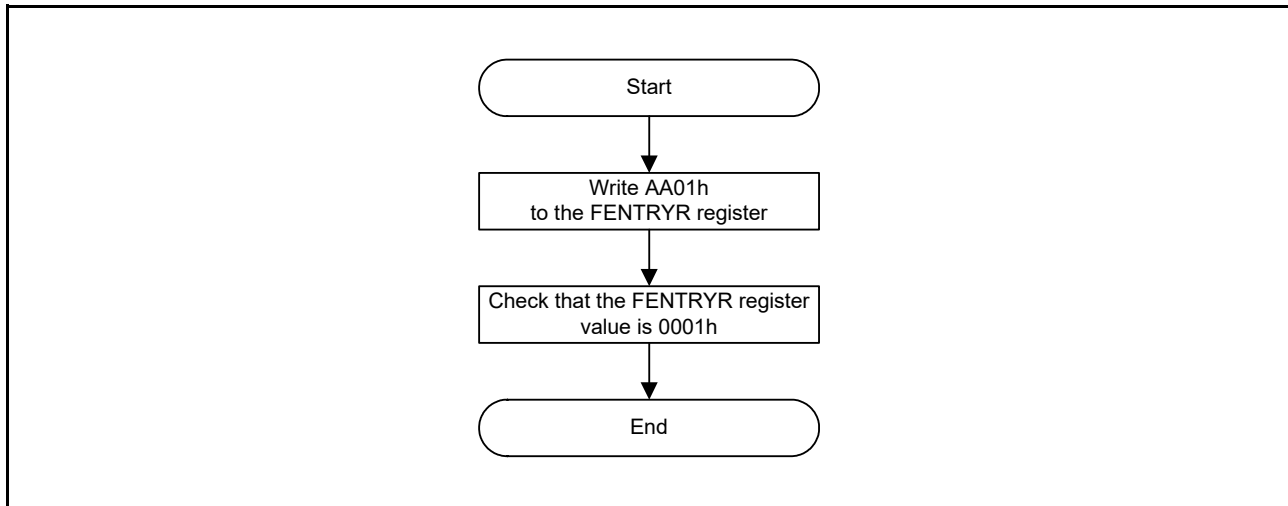

Figure 44.10 Procedure for Transition to Code Flash Memory P/E Mode

#### 44.6.4.2 Transition to Data Flash Memory P/E Mode

To use the FACL commands for the data flash memory, a transition to data flash memory P/E mode is required. To shift to data flash memory P/E mode, set the FENTRYR.FENTRYD bit to 1.

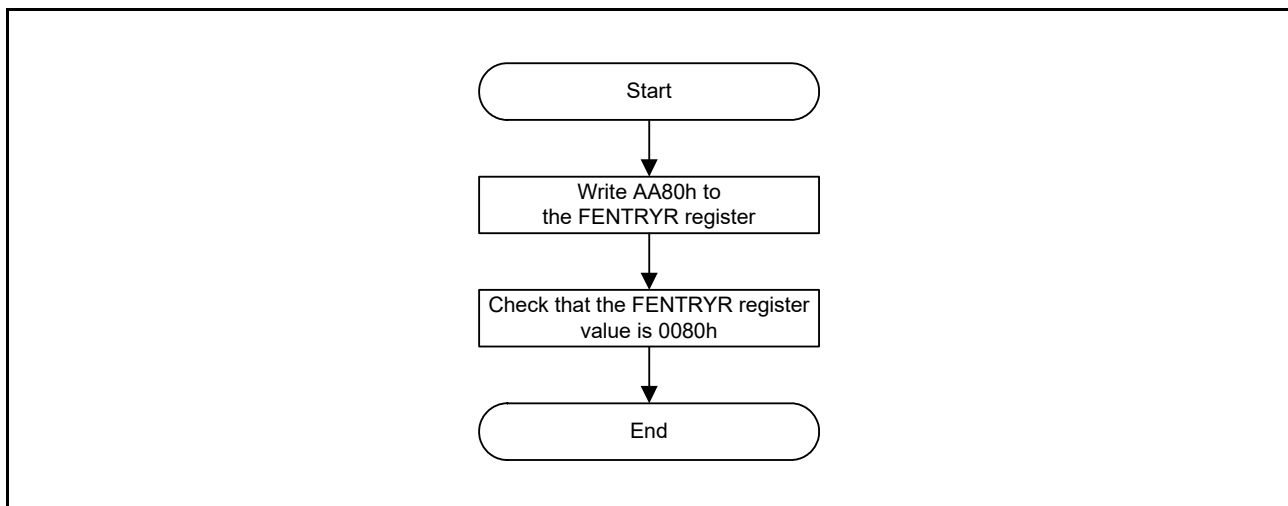

Figure 44.11 Procedure for Transition to Data Flash Memory P/E Mode

### 44.6.4.3 Transition to Read Mode

To read the flash memory without using the BGO function, a transition to read mode is required. To shift to read mode, set the FENTRYR register to 0000h. The transition to read mode should be made after processing by the flash sequencer is completed and while operation is in other than in the command-locked state. In addition, operation is started in read mode after release from the reset state.

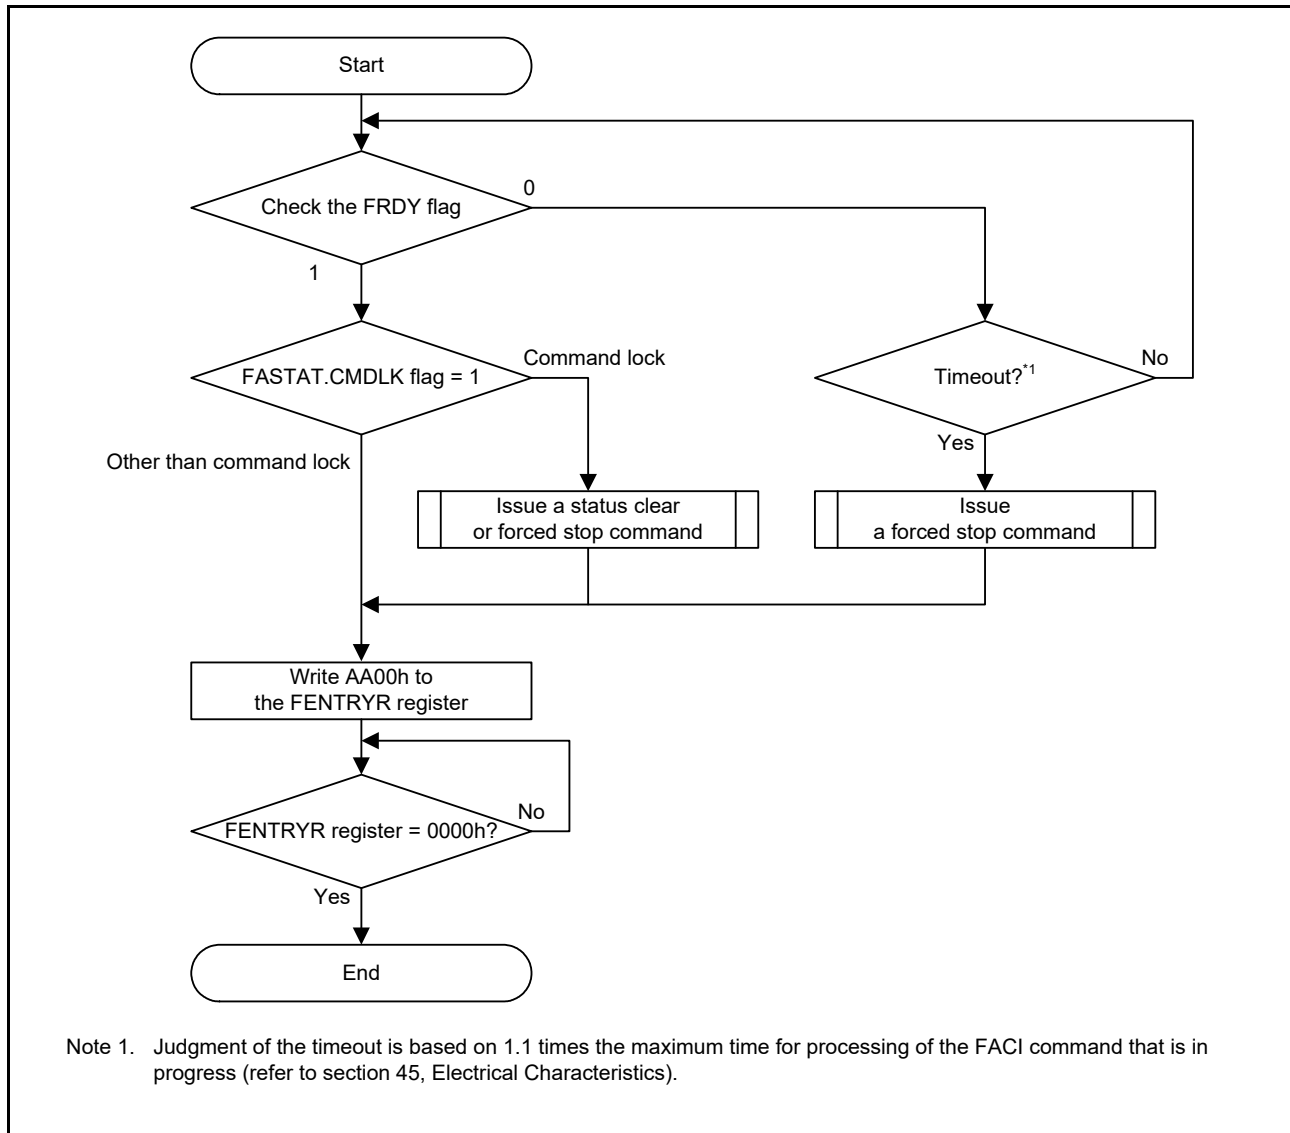

Figure 44.12 Procedure for Transition to Read Mode

## 44.6.5 List of FACI Commands

**Table 44.16 List of FACI Commands**

| FACI Command      | Description                                                                                                                                                                              |
|-------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Program           | This is used to program the user area and data area.<br>Units of programming are 256 bytes for the user area and 4 bytes for the data area.                                              |
| Block erase       | This is used to erase the user area (including the lock bit) and data area.<br>The unit of erasure is one block. (user area: 8 K or 32 Kbytes, data area: 64 bytes)                      |
| P/E suspend       | This suspends programming or erasure processing.                                                                                                                                         |
| P/E resume        | This resumes suspended programming or erasure processing.                                                                                                                                |
| Status clear      | This initializes the ILGLERR, ERSERR, and PRGERR flags in the FSTATR register, and the CMDLK flag in the FASTAT register and releases the flash sequencer from the command-locked state. |
| Forced stop       | This forcibly stops processing of FACI commands and initializes the FSTATR register.                                                                                                     |
| Blank check       | This is used to check if data areas are blank.<br>Units of blank checking: 4 bytes to 32 Kbytes (specified in 4-byte units).                                                             |
| Configuration set | This is used to set the configuration setting area.<br>Units of setting: 16 bytes.                                                                                                       |
| Lock-bit program  | This is used to program the lock bit for a user area.<br>Units of programming: 1 bit (the lock bit for one block)                                                                        |
| Lock-bit read     | The lock bit for a user area is read and the result is stored in the FLKSTAT register.<br>Units of reading: 1 bit (the lock bit for one block)                                           |

The FACI commands are issued by writing to the FACI command-issuing area (refer to Table 44.2). When write access as shown in Table 44.17 proceeds in the specified state, the flash sequencer executes the processing corresponding to the given command (refer to section 44.6.4, Transitions of Operating Modes).

**Table 44.17 FACI Command Formats**

| FACI Commands                                        | Number of Write Access | Data to be Written to the FACI Command-Issuing Area |            |                                      |                |
|------------------------------------------------------|------------------------|-----------------------------------------------------|------------|--------------------------------------|----------------|
|                                                      |                        | 1st Access                                          | 2nd Access | 3rd to (N+2)th Access                | (N+3)th Access |

| Block erase                                          | 2                      | 20h                                                 | D0h        | —                                    | —              |
| P/E suspend                                          | 1                      | B0h                                                 | —          | —                                    | —              |
| P/E resume                                           | 1                      | D0h                                                 | —          | —                                    | —              |
| Status clear                                         | 1                      | 50h                                                 | —          | —                                    | —              |
| Forced stop                                          | 1                      | B3h                                                 | —          | —                                    | —              |
| Blank check                                          | 2                      | 71h                                                 | D0h        | —                                    | —              |
| Configuration set<br>N = 8                           | 11                     | 40h                                                 | 08h (= N)  | WD <sub>1</sub> to WD <sub>8</sub>   | D0h            |
| Lock-bit program                                     | 2                      | 77h                                                 | D0h        | —                                    | —              |
| Lock-bit read                                        | 2                      | 71h                                                 | D0h        | —                                    | —              |

Note: WD<sub>N</sub> (N = 1, 2, ...): Nth 16-bit data to be programmed.

The flash sequencer clears the FSTATR.FRDY flag to 0 at the start of processing of a command other than the status clear command and sets this bit to 1 upon completion of command processing.

When the setting of the FRDYIE.FRDYIE bit is 1 and when the FSTATR.FRDY flag is set to 1, a flash ready (FRDY) interrupt is generated.

## 44.6.6 Usage of FACI Commands

This section gives an overview of the usage of FACI commands.

### 44.6.6.1 Overview Flow when FACI Command is Used

Figure 44.13 shows an overview flow when the FACI command is used.

When using the BGO function, the jump to the internal RAM or external area (other than code flash memory) is not required because an FACI command can be issued for the data flash memory by using the rewriting program in the code flash memory.

When the FCLK is changed, changing the FPCKAR register shortens time for processing the FACI command. For details, refer to section 44.4.22, Flash Sequencer Processing Clock Frequency Notification Register (FPCKAR).

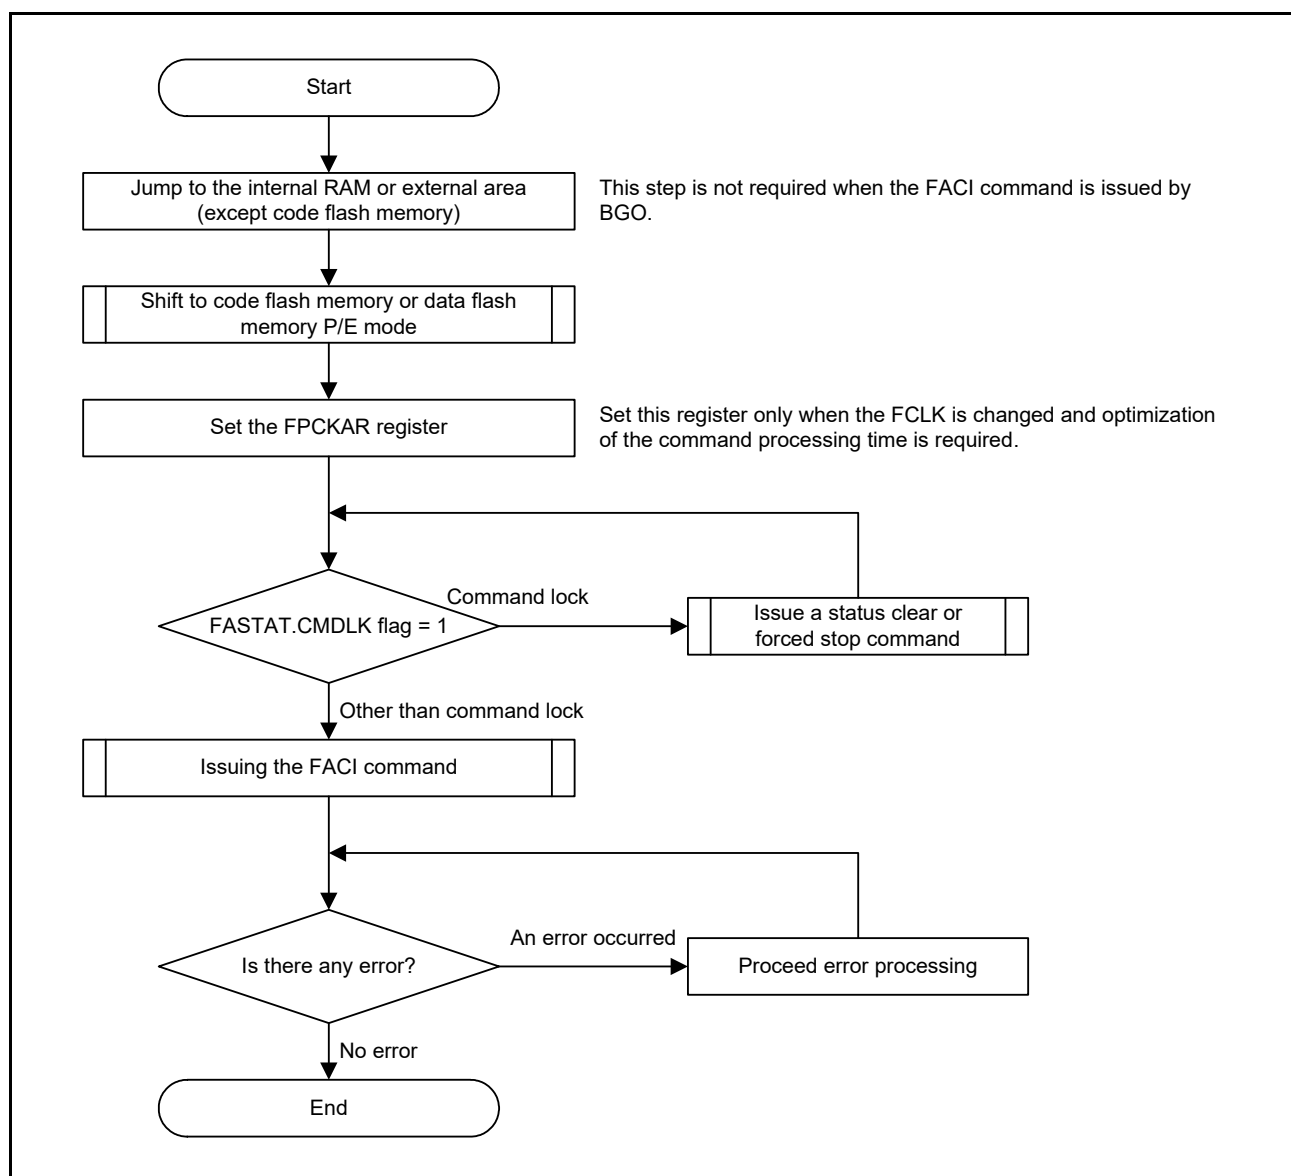

Figure 44.13 Overview Flow when FACI Command is Used

### 44.6.6.2 Recovery from the Command-Locked State

When the flash sequencer enters the command-locked state, FACI commands cannot be accepted. To release the sequencer from the command-locked state, use the status clear command, or forced stop command, or FASTAT register. When the command-locked state is detected by checking for an error before issuing the P/E suspend command, the FSTATR.FRDY flag may hold 0 as the command processing has not been completed. If processing is not completed within the maximum program/erase time specified in section 45, Electrical Characteristics, this can be considered a timeout, and the flash sequencer should be stopped by the forced stop command.

When the FSTATR.ILGLERR flag is 1, check the FASTAT value. If the CFAE or DFAE flag in the FASTAT register is 1, set the CFAE or DFAE flag in the FASTAT register to 0 and then issue the status clear and forced stop commands. The FSTATR.FLWERR flag is not changed from 1 to 0 by the status clear command. When these bits are set to 1, use the forced stop command for release from the command-locked state. The other bits that indicate the command-locked state can be changed from 1 to 0 by the status clear or forced stop command.

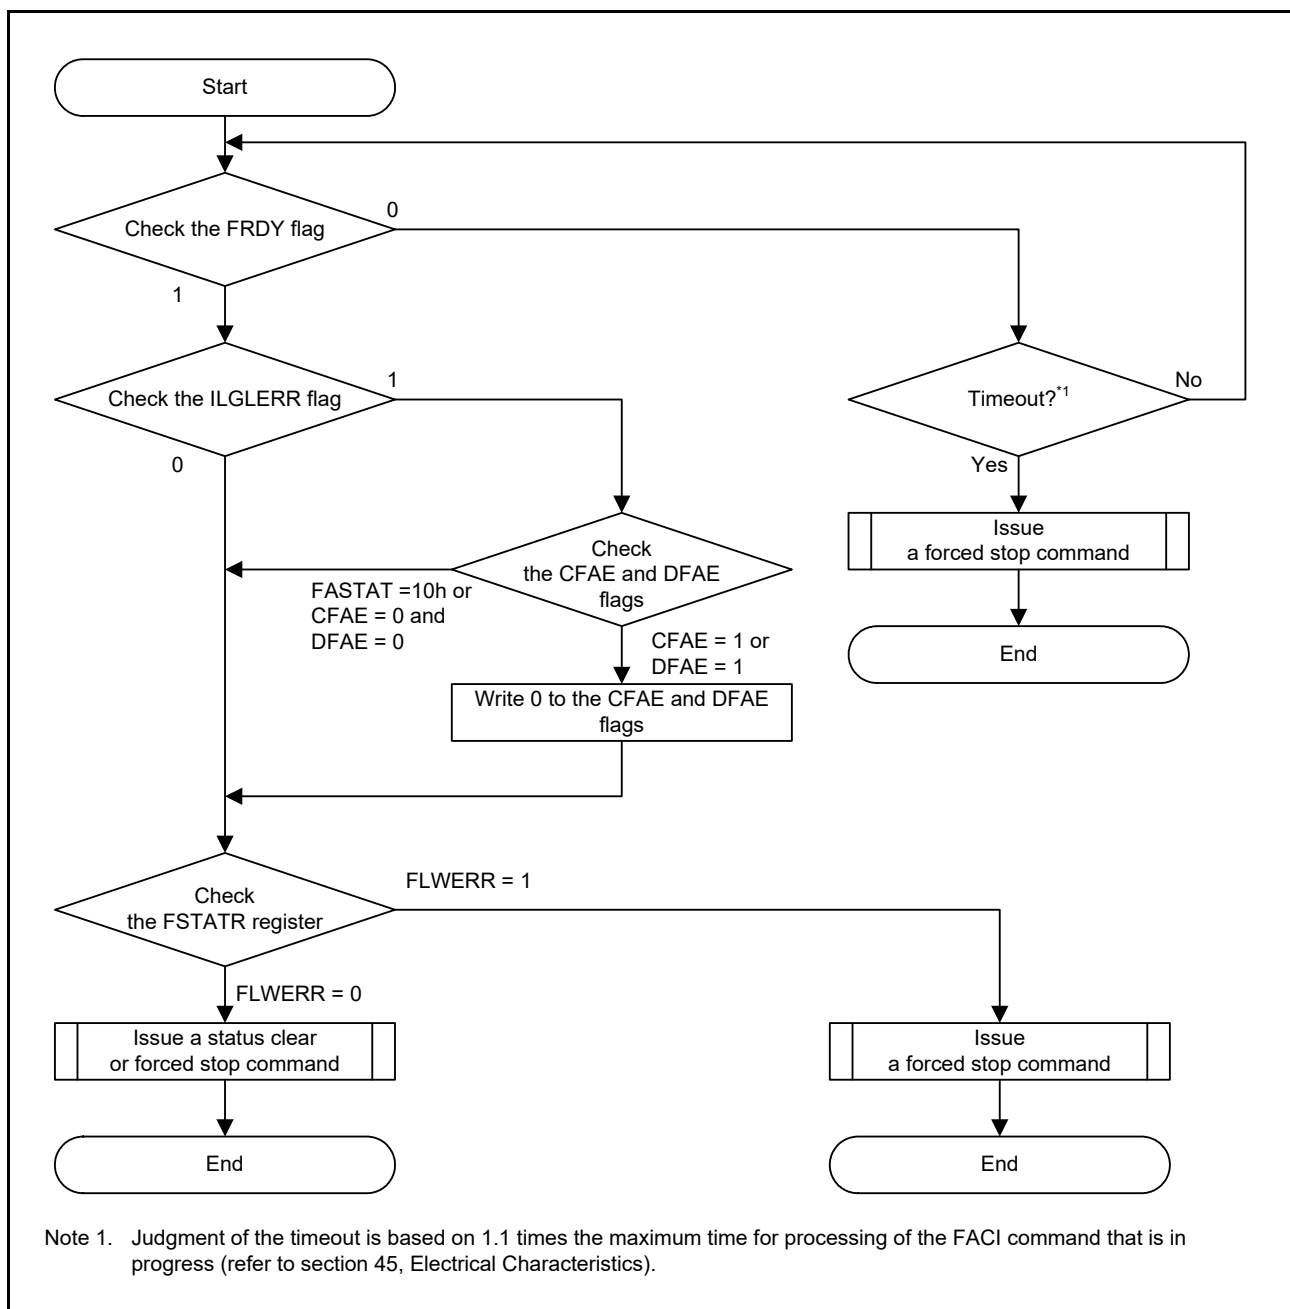

Figure 44.14 Recovery from the Command-Locked State

### 44.6.6.3 Program Command

A program command is used for writing to the user area and data area.

Before issuing a program command, set the first address of the target block in the FSADDR register.

Writing D0h to the FACI command-issuing area at the final access of the FACI command-issuing starts the program command processing. Completion of command processing can be checked by reading the FSTATR.FRDY flag. If the target area of program command processing contains the area not for writing, write FFFh to the corresponding area.

The FPROTR register must be set before issuing a program command. To switch between enabling and disabling of the lock bits, the setting of the FPROTR register must be changed.

Issuing a program command consecutively while the FACI internal data buffer is full leads to a wait on the peripheral bus 6 and this may affect on the bus accesses of the other peripheral IP modules. To avoid the generation of such a wait, issue an FACI command while the FSTATR.DBFULL flag is 0.

Writing to the data area will not lead to the data buffer becoming full.

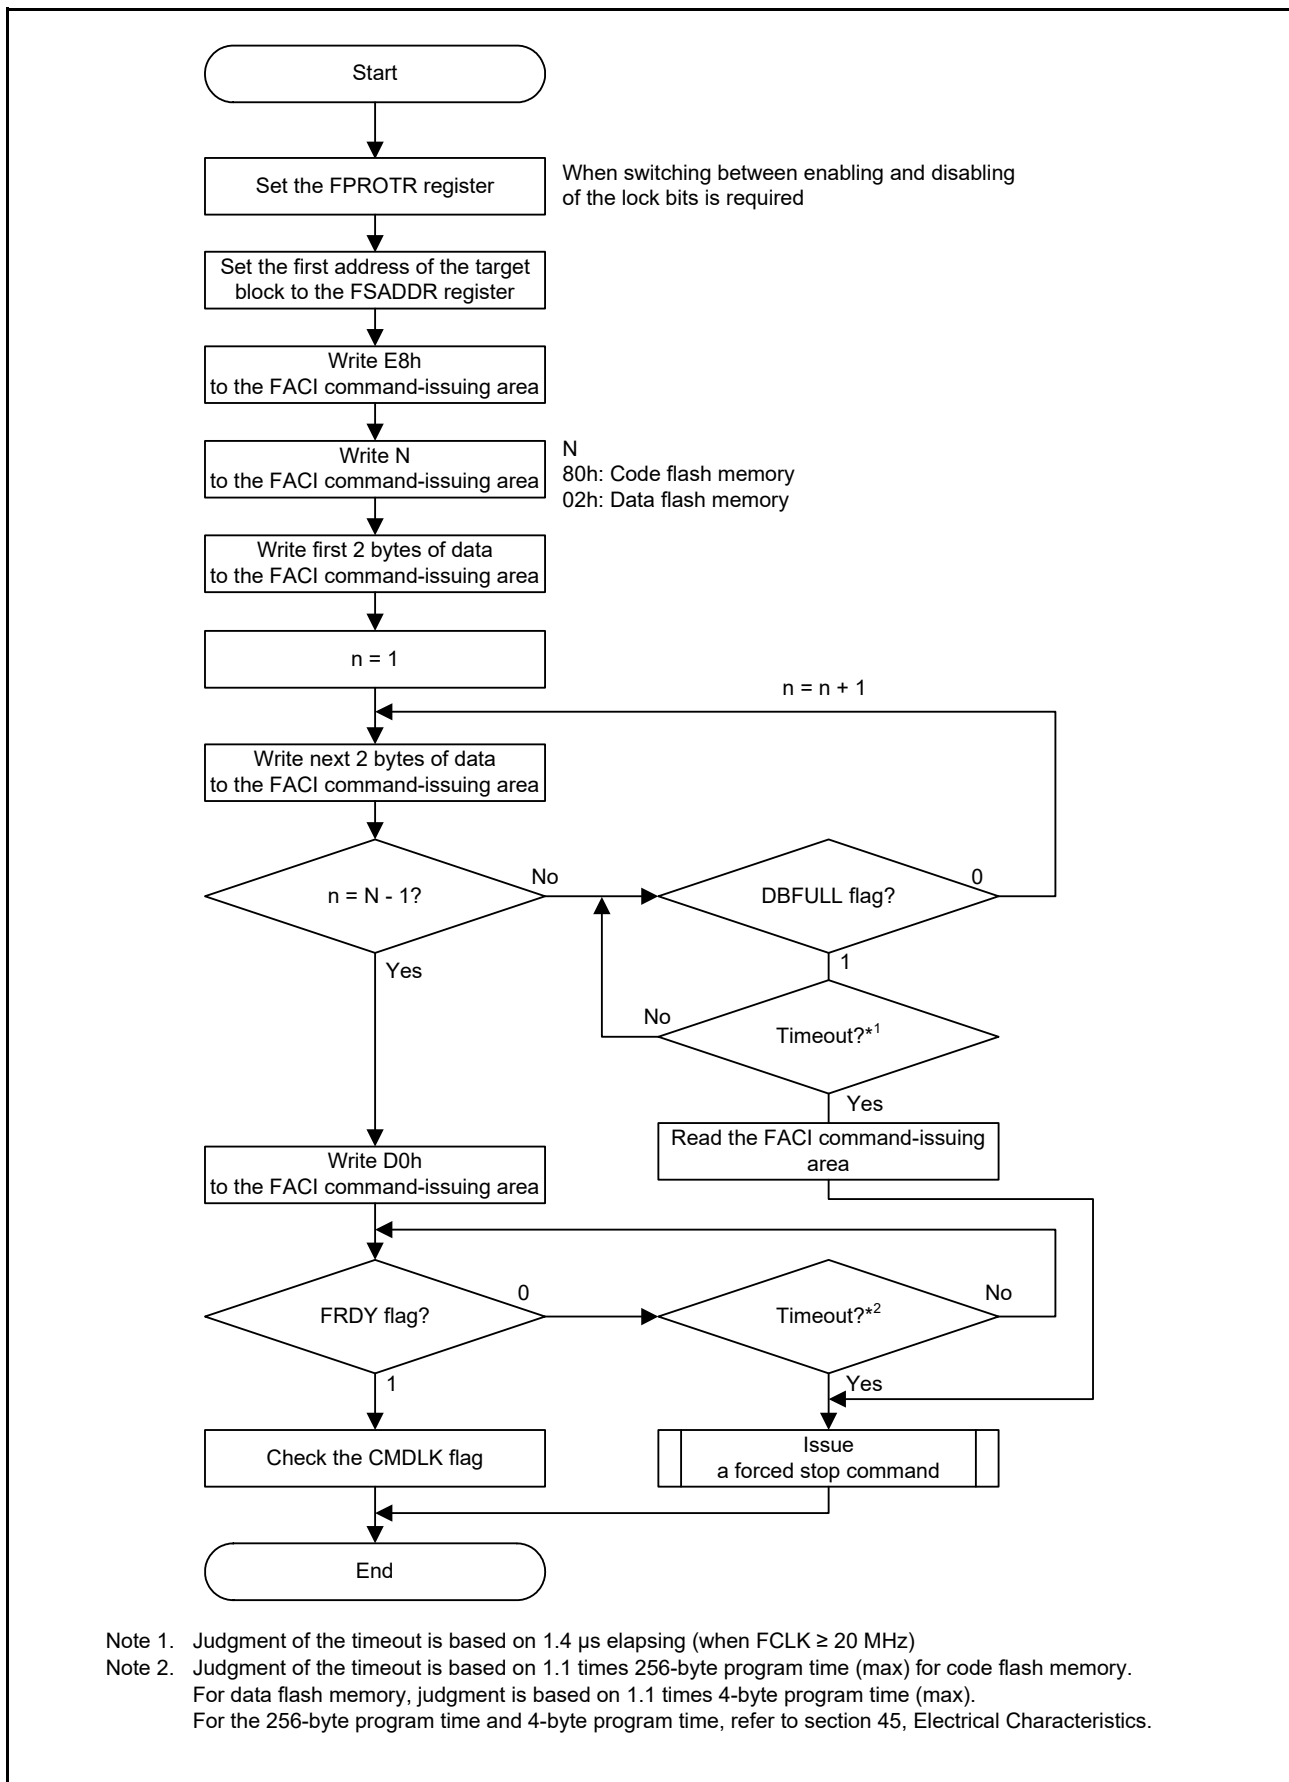

Figure 44.15 Usage of the Program Command

#### 44.6.6.4 Block Erase Command

A block erase command is used to erase the user area, lock bit, and data area in single-block units.

Before issuing a block erase command, set the first address of the target block in the FSADDR register. Writing 20h and D0h to the FACL command-issuing area starts processing of a block erase command. Completion of command processing can be checked by reading the FSTATR.FRDY flag.

The FPROTR and FCPSR registers must be set before issuing the block erase command. To switch between enabling and disabling of the lock bits, the setting of the FPROTR register must be changed. To erase the lock bit, issue a block erase command while the FPROTR.FPROTCN bit is 1. The setting of the FCPSR register must be changed to switch the suspending method (suspend priority mode/erase priority mode) by the P/E suspend command.

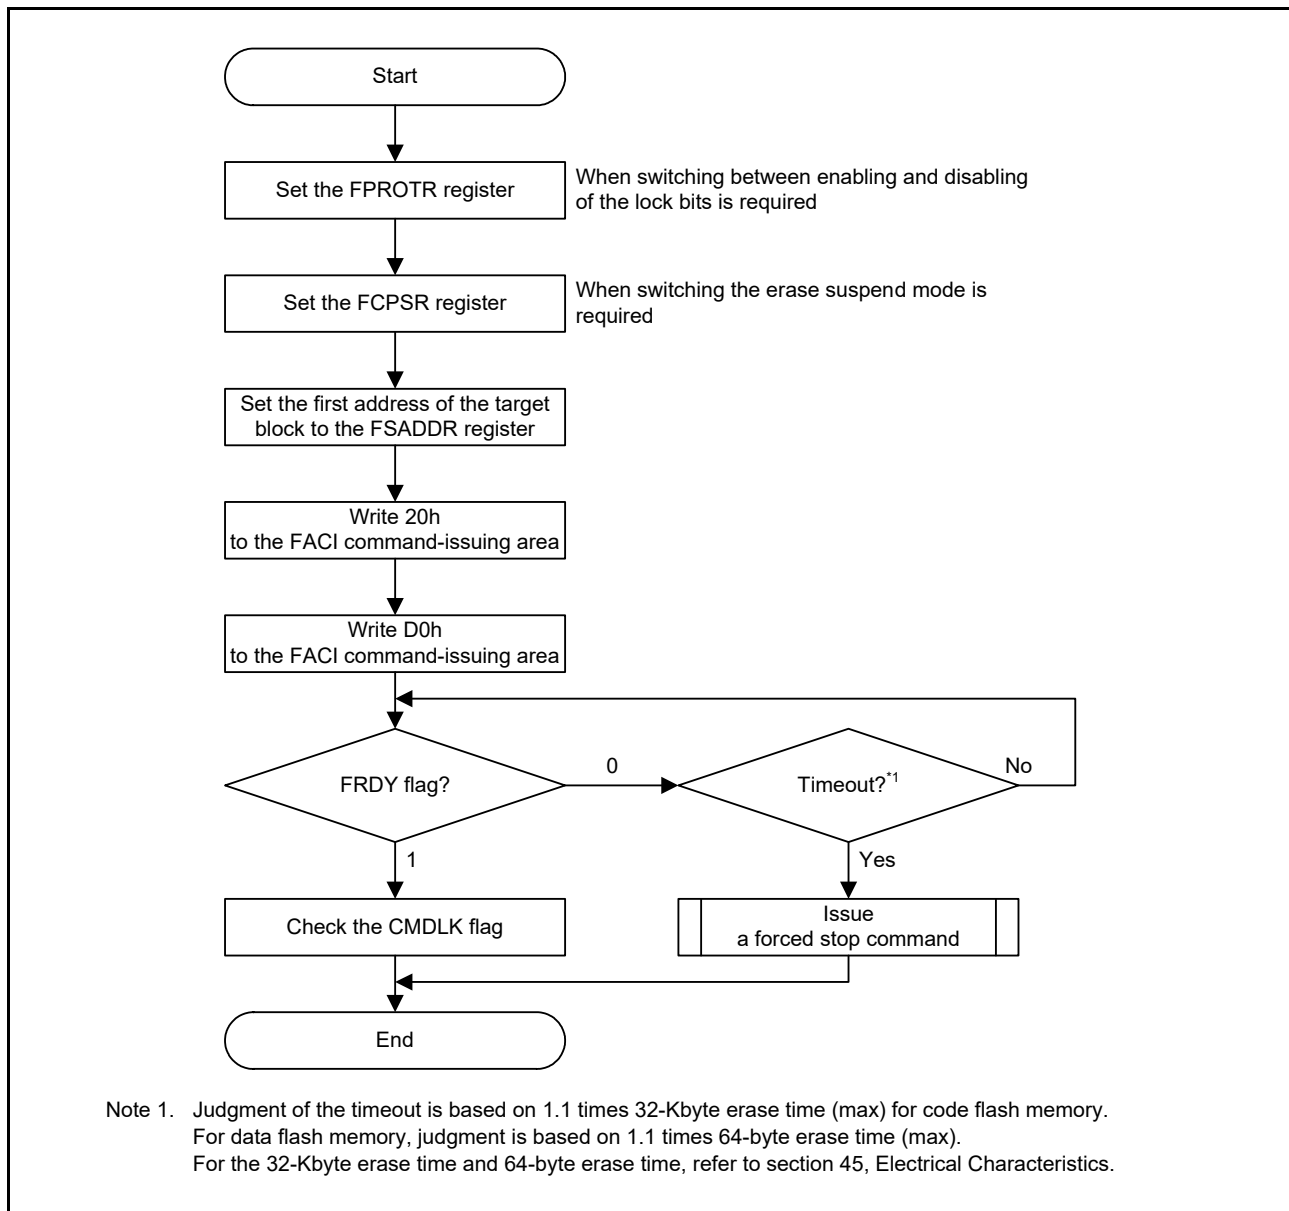

Figure 44.16 Usage of the Block Erase Command

#### 44.6.6.5 P/E Suspend Command

The P/E suspend command is used to suspend programming or erasure. Before issuing a P/E suspend command, check that the FASTAT.CMDLK flag is 0, and the execution of programming/erasure is normally performed. To confirm that the P/E suspend command can be received, also check that the FSTATR.SUSRDY flag is 1. After issuing a P/E suspend command, read the FASTAT.CMDLK flag to confirm that its value is not 1 (the flash sequencer is not in the command-locked state).

If an error occurs during programming or erasure processing, the FASTAT.CMDLK flag is set to 1. When P/E processing is completed between the FSTATR.SUSRDY flag having been confirmed to be 1 and acceptance of the P/E suspension command, the P/E suspension command is ignored and the flash sequencer does not enter the suspended state (the FSTATR.FRDIY flag is 1 and the ERSSPD and PRGSPD flags in the FSTATR register are 0).

When a P/E suspend command is received and then the programming/erasure suspend processing finishes normally, the flash sequencer enters the suspended state, the FSTATR.FRDIY flag is set to 1, and the ERSSPD or PRGSPD flag in the FSTATR register is 1. After issuing a P/E suspend command, check that the ERSSPD or PRGSPD flag in the FSTATR register is 1 and the suspended state is entered, and then decide the subsequent flow. If a P/E resume command is issued in the subsequent flow although the suspended state is not entered, an illegal command error occurs and the flash sequencer shifts to the command-locked state (refer to section 44.5.4.2, Error Protection).

If the erase-suspended state is entered, programming to blocks other than the one currently suspended can be performed. In addition, the program- and erase-suspended states can move to read mode by clearing the FENTRYR register.

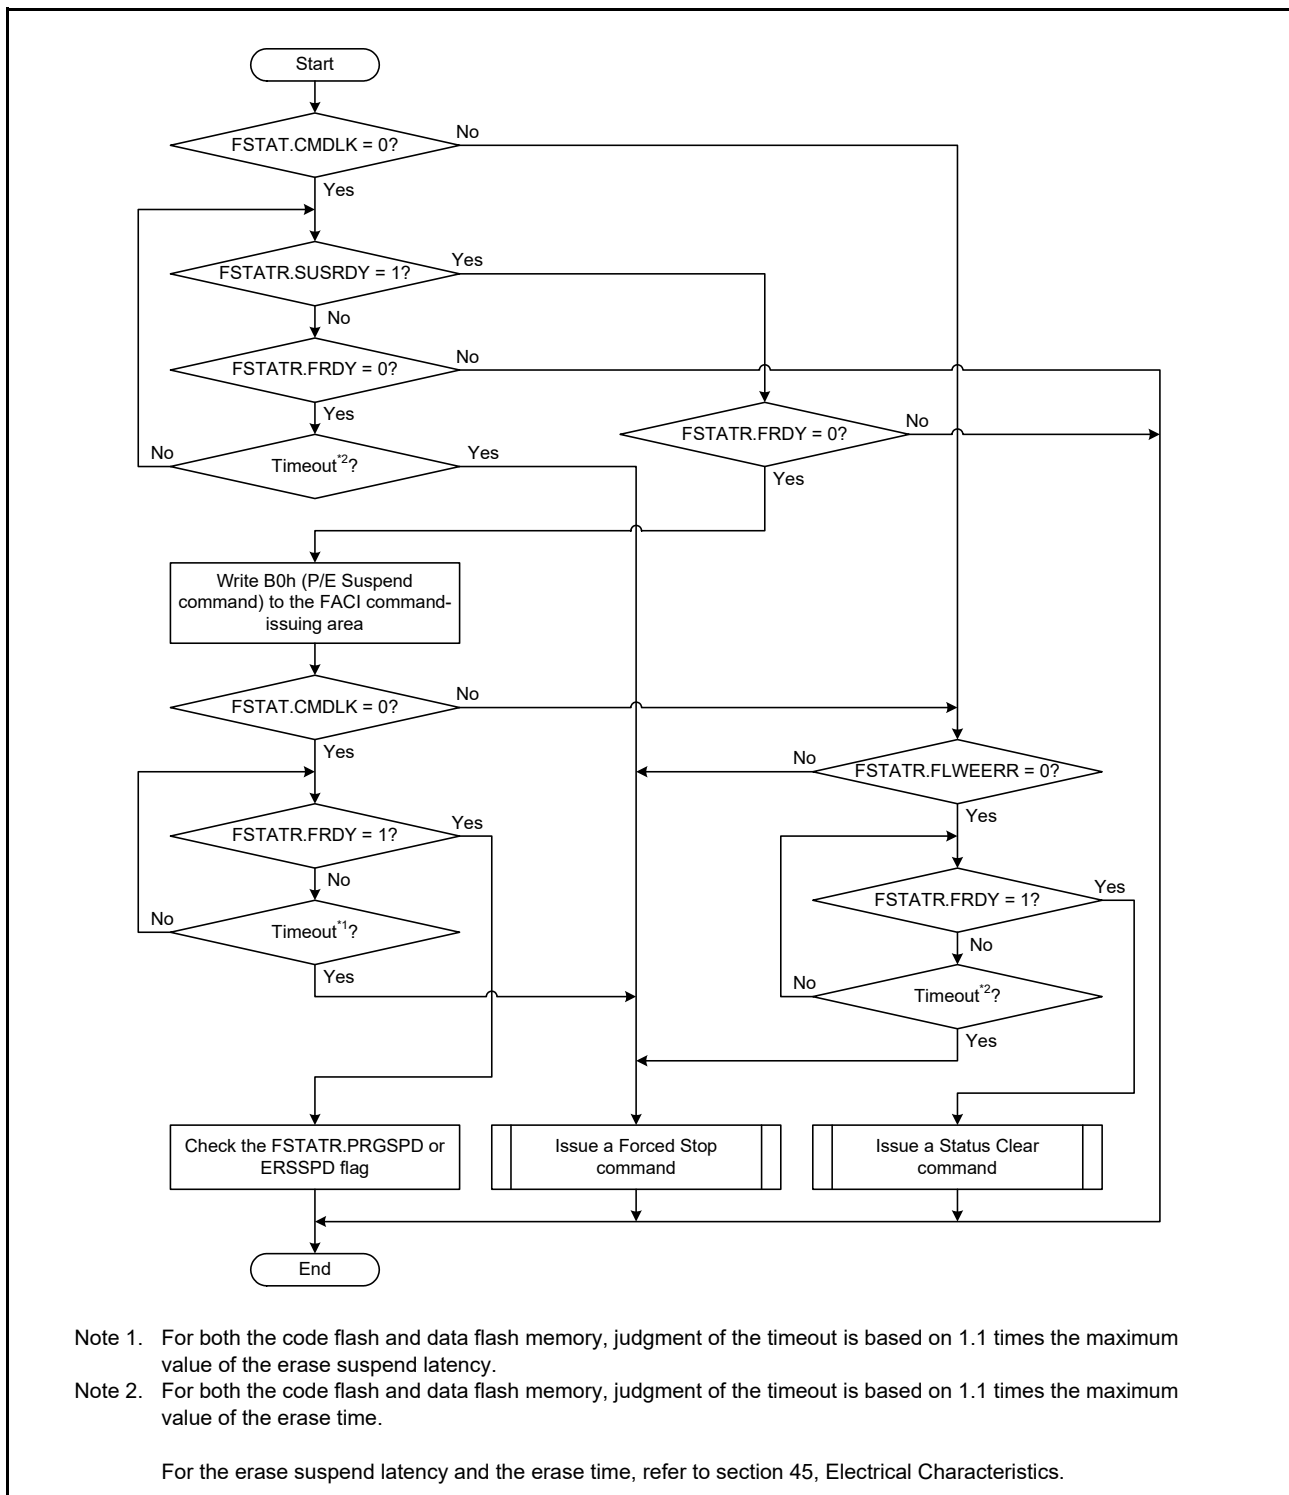

Figure 44.17 Usage of the P/E Suspend Command

(1) Suspension during Programming

When issuing a P/E suspend command during the flash memory programming, the flash sequencer suspends programming processing. Figure 44.18 shows the suspend operation of programming. When receiving a program or P/E resume command, the flash sequencer sets the FSTATR.FRDY flag to 0 to start programming. When the flash sequencer is ready to accept the P/E suspend command after starting programming, it sets the FSTATR.SUSRDY flag to 1. When a P/E suspend command is issued, the flash sequencer receives the command and sets the FSTATR.SUSRDY flag to 0. When the flash sequencer receives a P/E suspend command while a program pulse is being applied, the flash sequencer continues applying the pulse. After the specified pulse application time, the flash sequencer finishes pulse application, and starts the programming suspend processing and sets the FSTATR.PRGSPD flag to 1.

When the suspend processing finishes, the flash sequencer sets the FSTATR.FRDY flag to 1 to enter the program-suspended state. When receiving a P/E resume command in the program-suspended state, the flash sequencer sets the FSTATR.FRDY and FSTATR.PRGSPD flags to 0 and resumes programming.

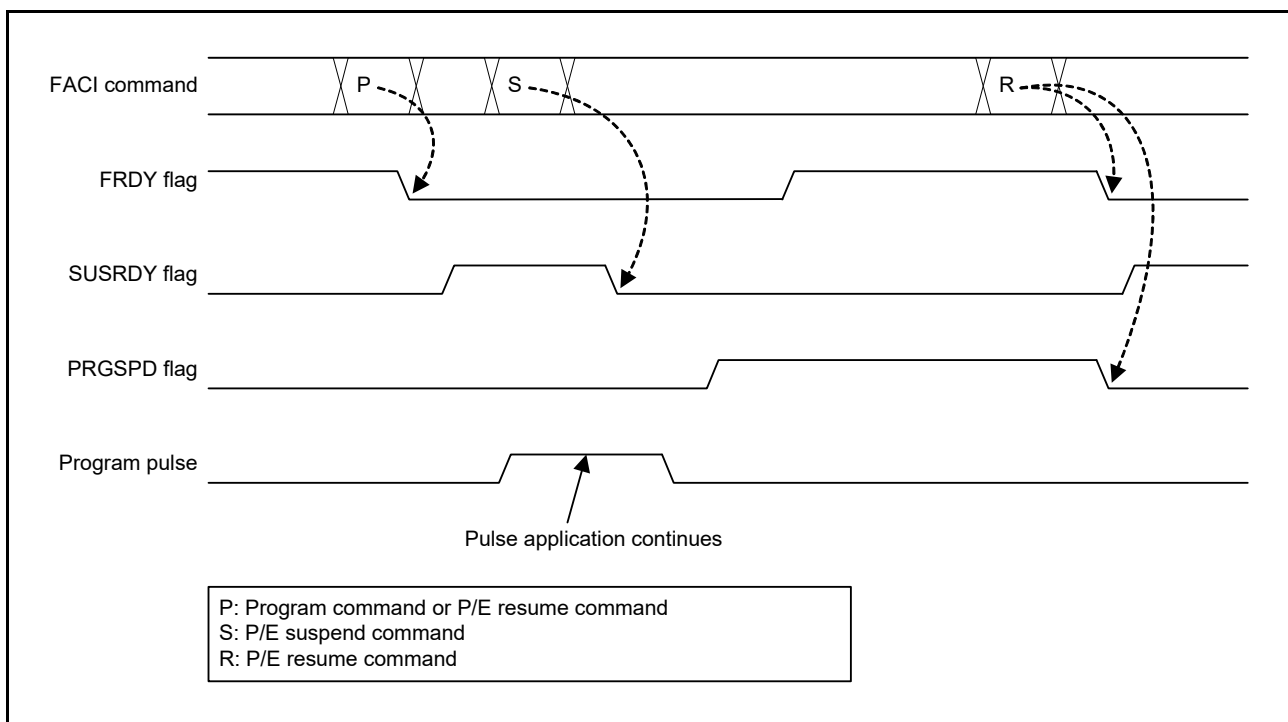

Figure 44.18 Suspension during Programming

(2) Suspension during Erasure (Suspend Priority Mode)

This MCU has a suspend priority mode for the suspension of erasure. Figure 44.19 shows the suspend operation of erasure in suspend priority mode (the FCPSR.ESUSPMD bit is 0).

When receiving a block erase or P/E resume command, the flash sequencer sets the FSTATR.FRDY flag to 0 to start erasure. When the flash sequencer is ready to accept the P/E suspend command after starting erasure, it sets the FSTATR.SUSRDY flag to 1. When a P/E suspend command is issued, the flash sequencer receives the command and sets the FSTATR.SUSRDY flag to 0. When receiving a P/E suspend command during erasure, the flash sequencer starts the suspend processing and sets the FSTATR.ERSSPD flag to 1 even if it is applying an erase pulse. When the suspend processing is completed, the flash sequencer sets the FSTATR.FRDY flag to 1 to enter the erase-suspended state. When receiving a P/E resume command in the erase-suspended state, the flash sequencer sets the FRDY and ERSSPD flags in the FSTATR register to 0 and resumes erasure. Operations of the FRDY, SUSRDY, and ERSSPD flags in the FSTATR register at the suspension and resumption of erasure are the same, regardless of the erase suspend mode.

The setting of the erase suspend mode affects the control method of erase pulses. In suspend priority mode, when receiving a P/E suspend command while erase pulse A that has never been interrupted in the past is being applied, the flash sequencer suspends the application of erase pulse A and enters the erase-suspended state. When receiving a P/E suspend command while reapplying erase pulse A after erasure is resumed by a P/E resume command, the flash sequencer continues applying erase pulse A. After the specified pulse application time, the flash sequencer finishes erase pulse application and enters the erase-suspended state. When the flash sequencer receives a P/E resume command next and erase pulse B starts to be newly applied, and then the flash sequencer receives a P/E suspend command again, the application of erase pulse B is interrupted. In suspend priority mode, delay due to suspension can be minimized because the application of an erase pulse is interrupted once per pulse and priority is given to the suspend processing.

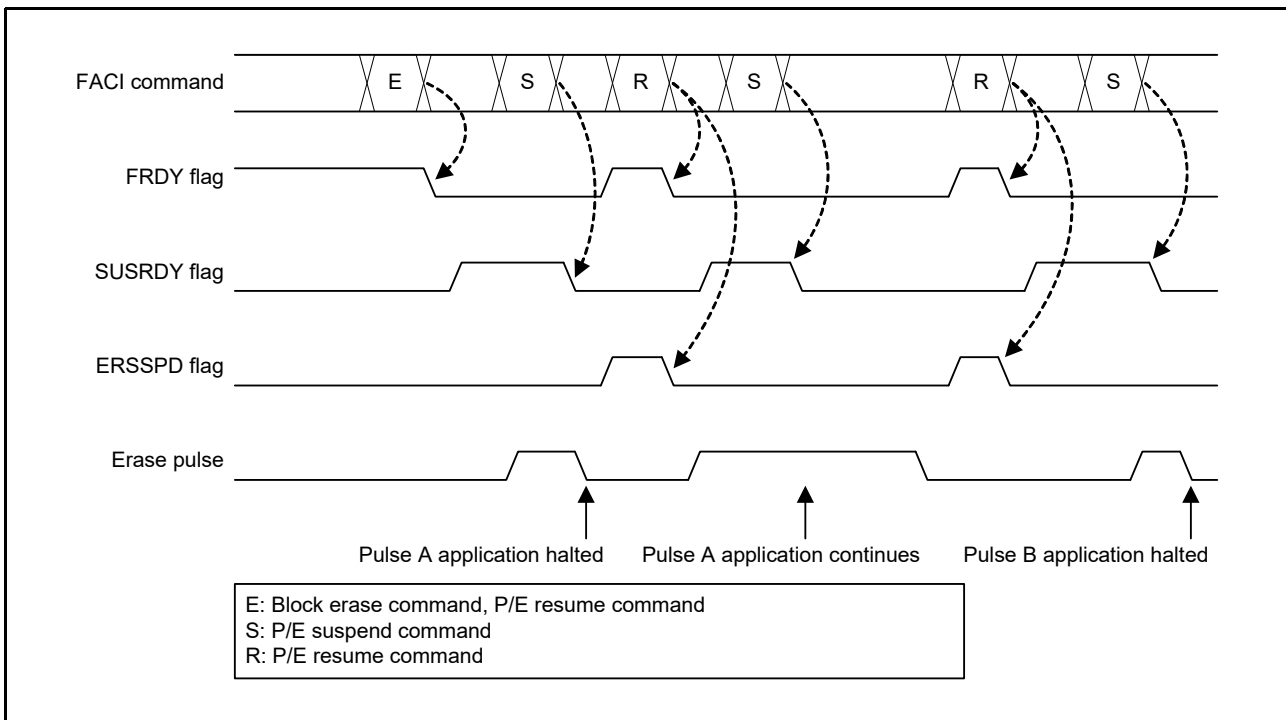

Figure 44.19 Suspension during Erasure (Suspend Priority Mode)

(3) Suspension during Erasure (Erase Priority Mode)

This MCU has an erase priority mode for the suspension of erasure.

Figure 44.20 shows the suspend operation of erasure when the erase suspend mode is set to the erase priority mode (the FCPSR.ESUSPMD bit is 1). The control method of erase pulses in erase priority mode is the same as that of program pulses for the program suspend processing.

When the flash sequencer receives a P/E suspend command while an erase pulse is being applied, the flash sequencer definitely continues applying the pulse. In this mode, the required time for the whole erasure processing can be reduced as compared with the suspend priority mode because the reapplication of erase pulses does not occur when a P/E resume command is issued.

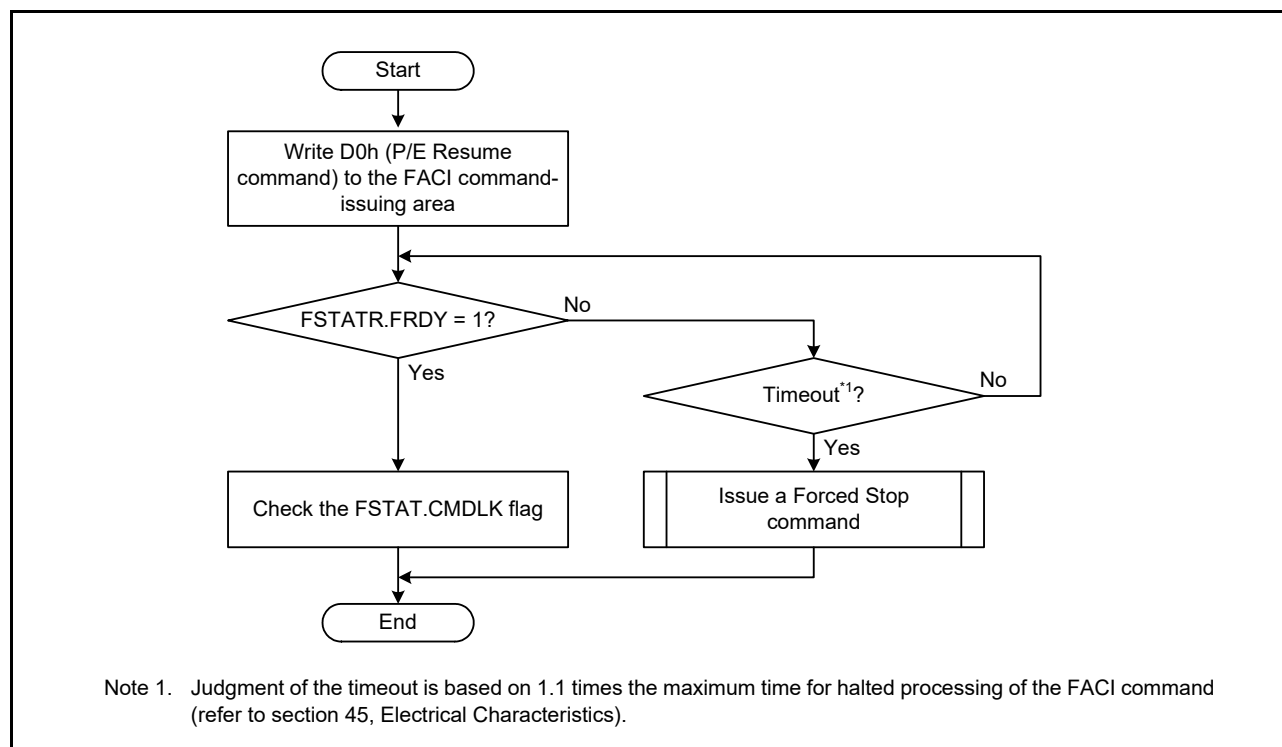

Figure 44.20 Suspension during Erasure (Erase Priority Mode)

### 44.6.6.6 P/E Resume Command

To resume suspended programming or erasure, use the P/E resume command. When the settings of the FENTRYR register are changed during suspended state, reset the setting of the FENTRYR register to the value immediately before the P/E suspend command was issued, and then issue a P/E resume command. Completion of processing of the resumed command can be confirmed by reading the FSTATR.FRDY flag.

**Figure 44.21 Usage of the P/E Resume Command**

#### 44.6.6.7 Status Clear Command

When one of the ILGLERR, ERSERR, PRGERR, and FLWEERR flag bits in the FSTATR register is set to 1, the flash sequencer enters the command-locked state. When one of the CFAE and DFAE flags in the FASTAT register is set to 1, the flash sequencer also enters the command lock state. In the command-locked state, the flash sequencer can accept only status clearing command or forced end command.

The status clear command is used to clear the command-locked state (refer to section 44.6.6.2, Recovery from the Command-Locked State). To clear the CMDLK flags in the FASTAT register, and the ILGLERR, ERSERR, and PRGERR flags in the FSTATR register in the command-locked state, the status clear command is available.

The FSTATR.FLWEERR flag cannot only be cleared by the status clearing command, but can only be cleared by the forced end command.

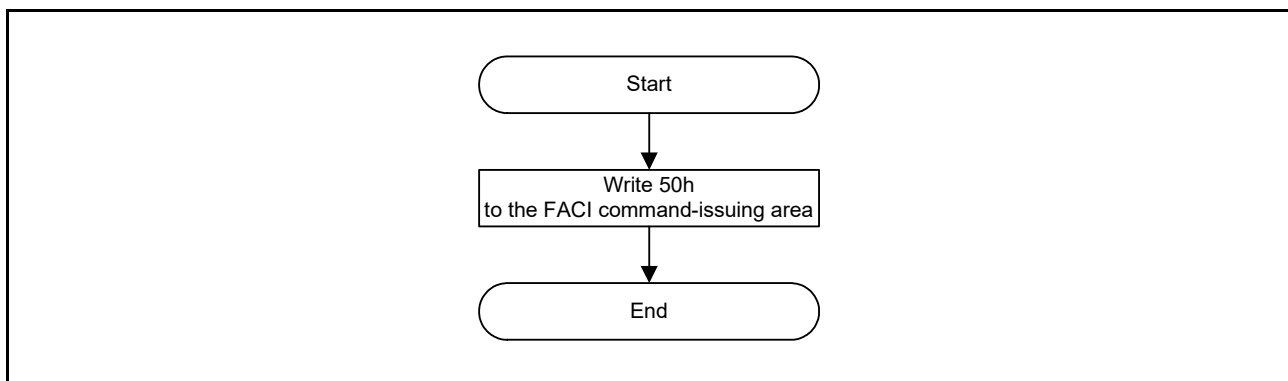

Figure 44.22 Usage of the Status Clear Command

### 44.6.6.8 Forced Stop Command

The forced stop command forcibly terminates command processing by the flash sequencer. Although this command halts command processing faster than the P/E suspend command, values of the area being programmed or erased are not guaranteed. Furthermore, resumption of processing is not possible. A program or erase operation terminated by the forced stop command is also defined as one program/erase cycle.

Executing a forced stop command initializes the entire flash sequencer and part of the FACL. Also, it initializes the FASTAT.CMDLK flag, and the FSTATR register. Accordingly, this command can be used in the procedure for recovery from the command-locked state and in processing in response to a time-out of the flash sequencer (refer to section 44.6.6.2, Recovery from the Command-Locked State).

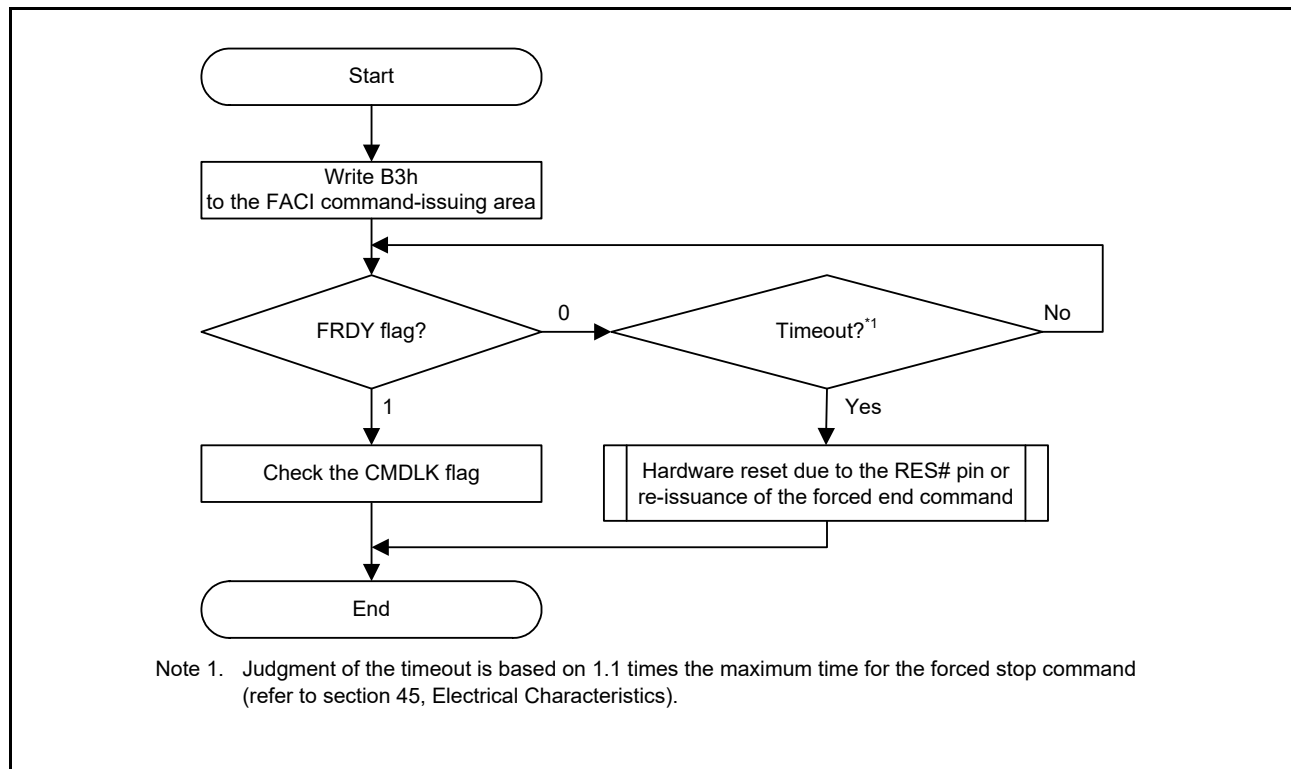

Figure 44.23 Usage of the Forced Stop Command

#### How to Use the Forced Stop Command when a Command is being issued

When processing is terminated by the forced stop command while a timeout is generated based on the DBFULL bit judgment of the program command, writing to the FACL command issuing area may be handled as the data written by the program command. In this case, read the FACL command issuing area and generate a command lock intentionally, then issue the forced stop command according to the method of returning from the command lock state. A command lock can be generated although the access size for reading the FACL command issuing area is in 8-, 16-, or 32-bit units.

#### 44.6.6.9 Blank Check Command

Values read from data flash memory that has been erased but not yet been programming again (i.e. that is in the nonprogrammed state) are undefined. Use the blank check command when you need to confirm that an area is in the nonprogrammed state.

Before issuing a blank check command, set addressing mode, start and end addresses of the target area for blank checking to the FBCCNT, FSADDR, and FEADDR registers.

When the FBCCNT.BCDIR bit is 1, the value specified in the FSADDR register must be set at least the value specified in the FEADDR register.

When the FBCCNT.BCDIR bit is 0, the value specified in the FSADDR register must be the value specified in the FEADDR register or less.

When the settings of the FBCCNT.BCDIR bit, FSADDR register, and FEADDR register are inconsistent, the flash sequencer enters the command-locked state. The size of the target area for blank checking is in the range from 4 bytes to 32 Kbytes and is set in units of 4 bytes.

Write 71h and D0h to the FSCI command-issuing area to start blank checking. Completion of processing can be confirmed by the FSTATR.FRDY flag. At the end of processing, the result of blank checking is stored in the FBCSTAT.BCST flag. If the target area for blank checking includes areas where programming has been completed, the flash sequencer stores the address of the programmed data that it first detected in the FPSADDR register.

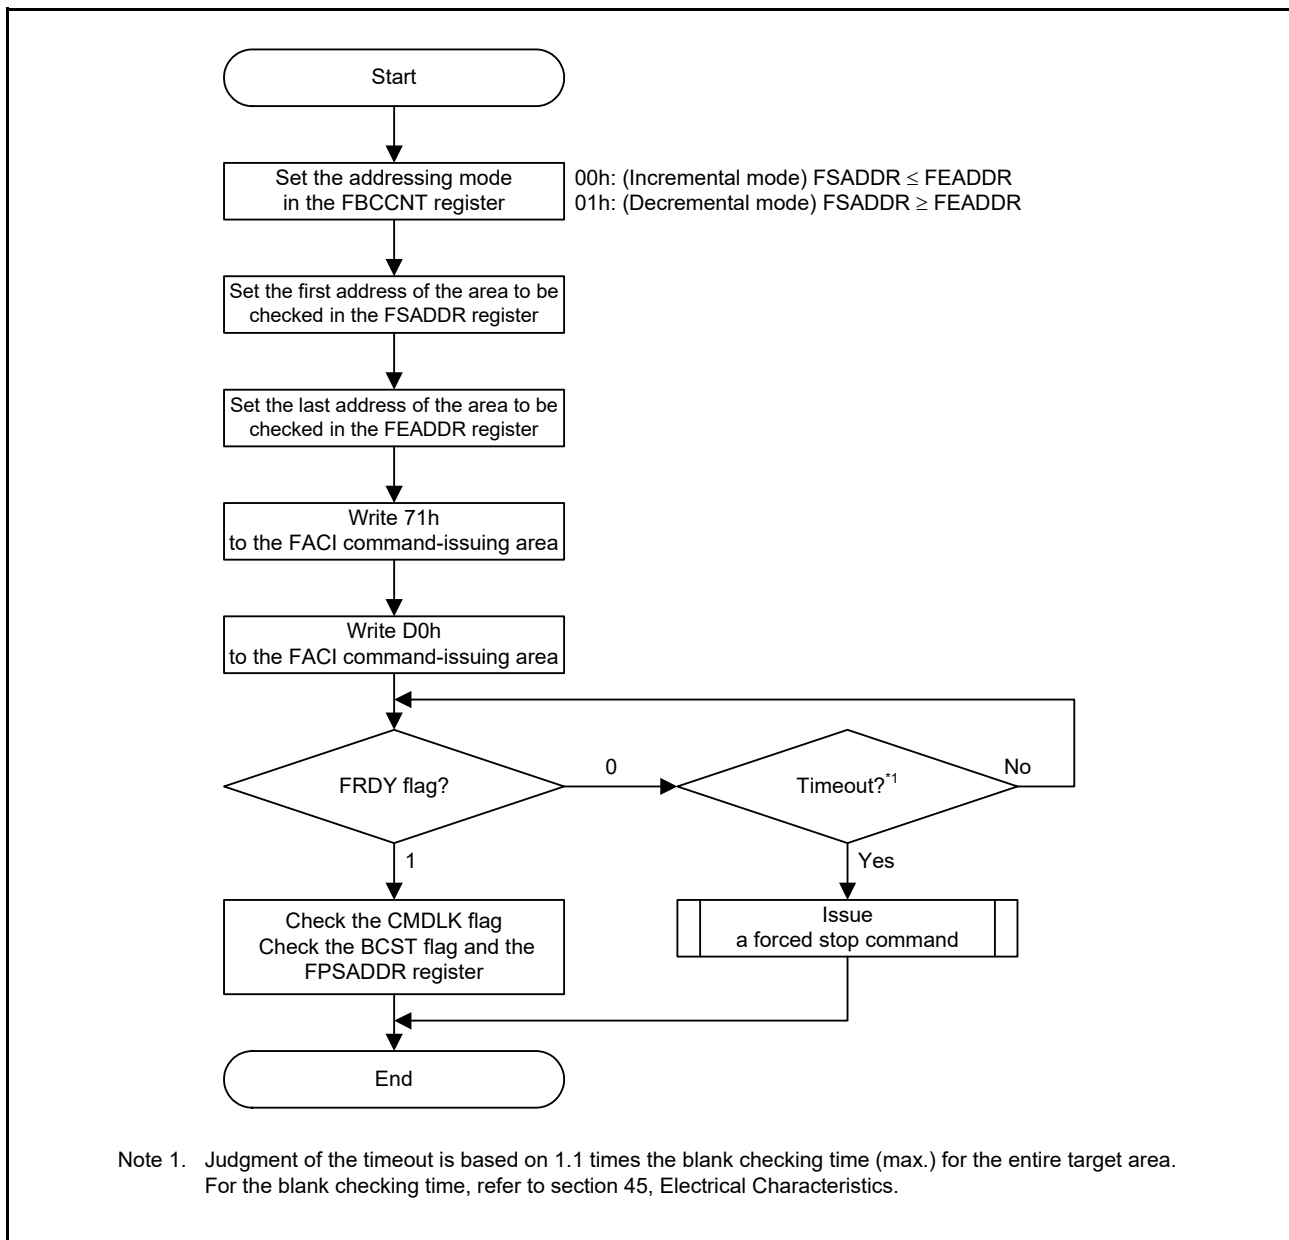

Figure 44.24 Usage of the Blank Check Command

### 44.6.6.10 Configuration Set Command

The configuration set command is used to set the configuration setting area. Before issuing a configuration set command, set the specified address (shown in Table 44.18) in the FSADDR register. Writing D0h to the FACL command-issuing area in the final access for issuing the FACL command starts processing of the configuration set command.

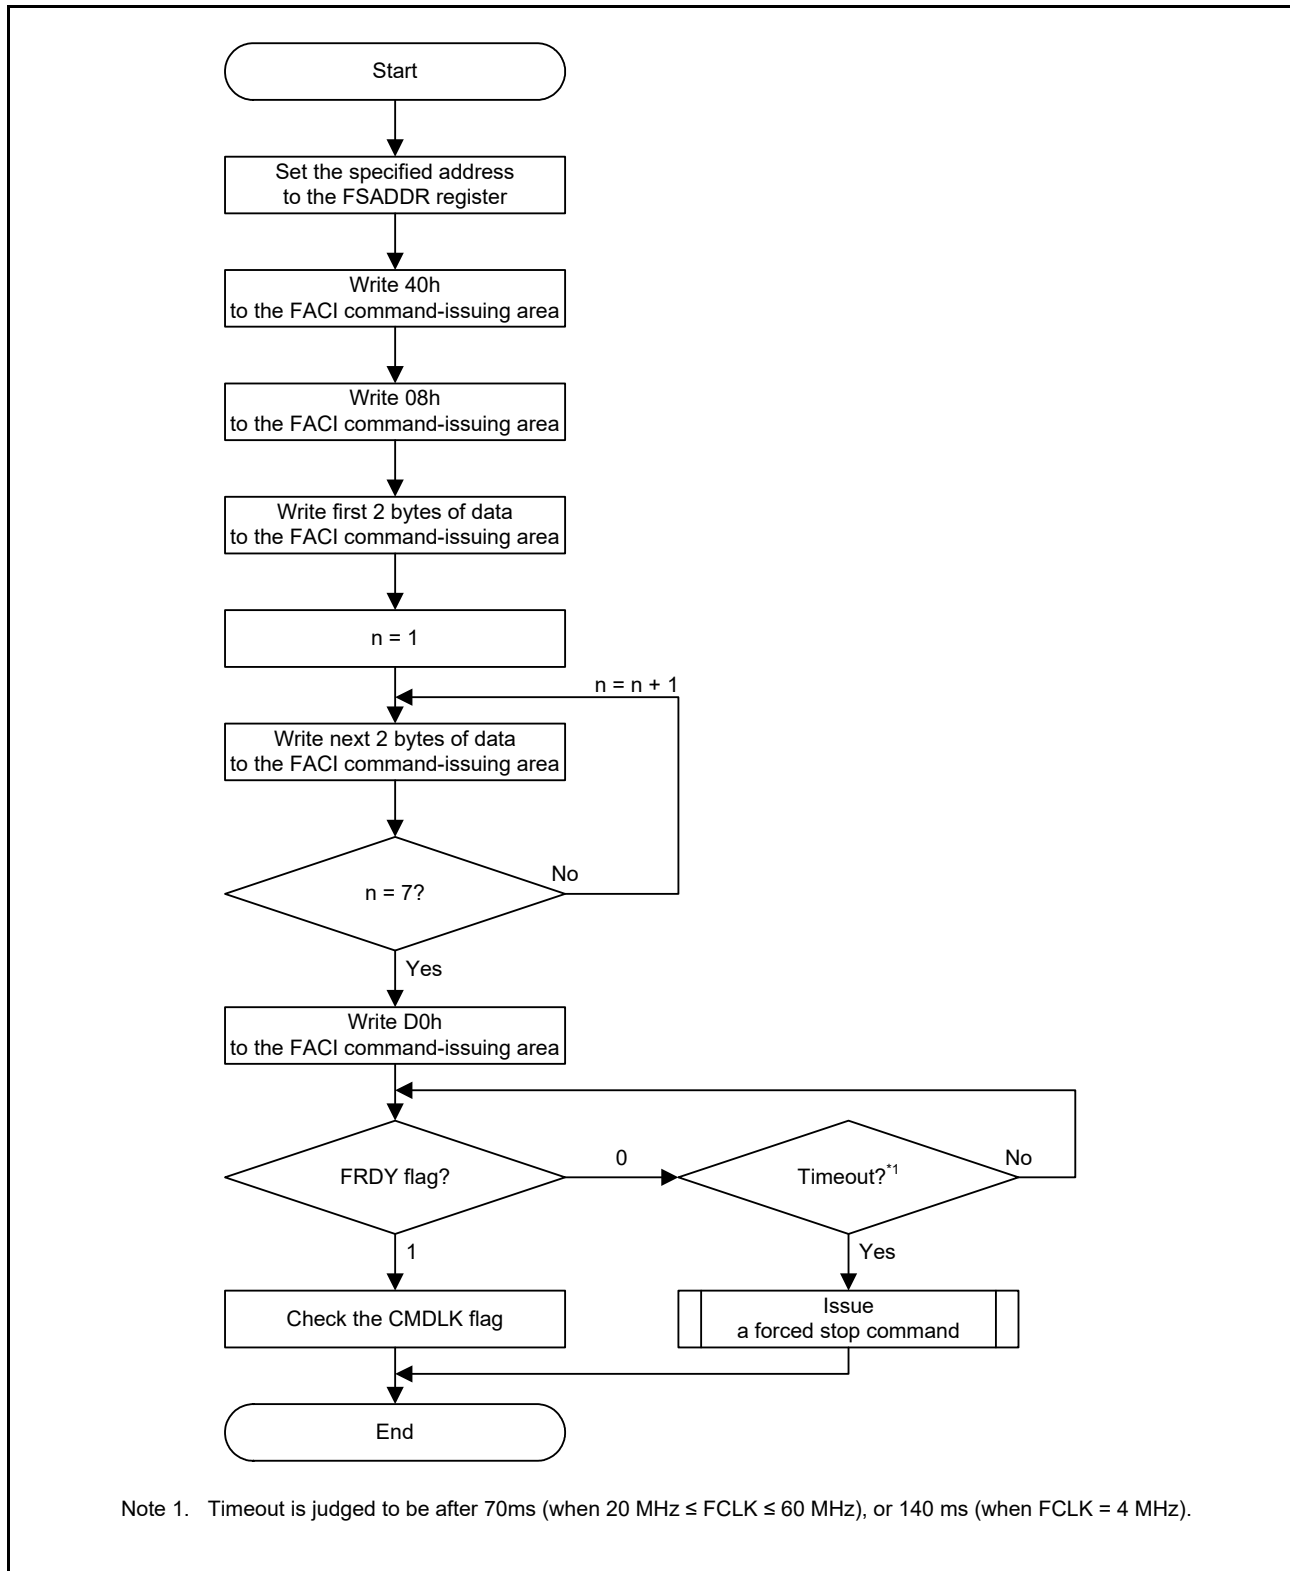

Figure 44.25 Usage of the Configuration Set Command

The correspondence between the possible target data for configuration setting and the address value set in the FSADDR register is shown in Table 44.18.

**Table 44.18 Address Used by Configuration Set Command**

| Address    | FSADDR Register Value | Setting Data                                                                                                                                                                                                                        | Timing when the Setting is Enabled          |
|------------|-----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------|
| 0012 0040h | 0000 0040h            | <ul style="list-style-type: none"> <li>Serial programmer command control register (SPCC)</li> <li>TM enable flag register (TMEF)</li> </ul>                                                                                         | After a reset or when command is executed*1 |
| 0012 0050h | 0000 0050h            | <ul style="list-style-type: none"> <li>OCD/serial programmer ID setting register (OSIS)</li> </ul>                                                                                                                                  | After a reset                               |
| 0012 0060h | 0000 0060h            | <ul style="list-style-type: none"> <li>TM identification data register (TMINF)</li> <li>Endian select register (MDE)</li> <li>Option function select register 0 (OFS0)</li> <li>Option function select register 1 (OFS1)</li> </ul> | After a reset                               |
| 0012 007Ch | 0000 0070h            | <ul style="list-style-type: none"> <li>ROM code protection register (ROMCODE)</li> </ul>                                                                                                                                            | After a reset                               |

Note 1. The setting in the serial programmer command control register (SPCC) is enabled after a reset. The setting of the TM enable flag register (TMEF) is enabled after a reset or when command is executed.

### 44.6.6.11 Lock-Bit Program Command

The lock-bit program command is used to write to a lock bit. The block erase command is used to erase a lock bit (refer to section 44.6.6.4, Block Erase Command).

Before issuing a lock-bit program command, set the first address of the target block in the FSADDR register. Writing 77h and D0h to the FACL command-issuing area starts processing of a lock-bit program command.

The FPROTR register must be set before issuing a lock-bit program command. To switch between enabling and disabling of the lock bits, the setting of the FPROTR register must be changed.

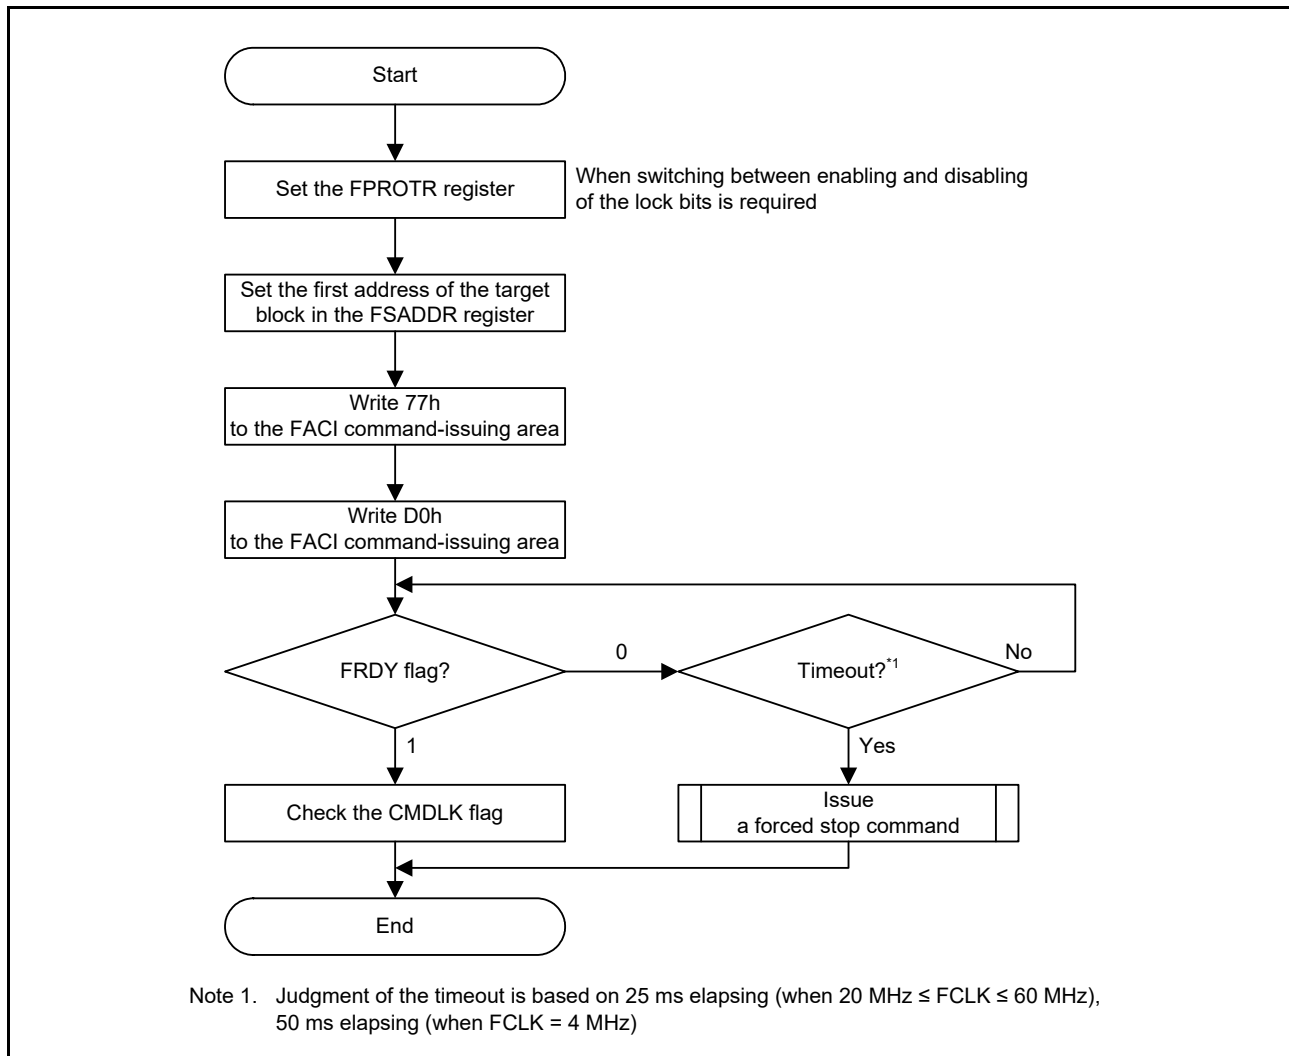

Figure 44.26 Usage of the Lock-Bit Program Command

#### 44.6.6.12 Lock-Bit Read Command

The lock-bit read command is used to read a lock bit.

Before issuing a lock-bit read command, set the first address of the target block in the FSADDR register. Writing 71h and D0h to the FACL command-issuing area starts processing of a lock-bit read command.

Completion of command processing can be confirmed with the FSTATR.FRDY flag. After command processing is completed, the result of reading the lock bit is stored in the FLKSTAT.FLOCKST flag.

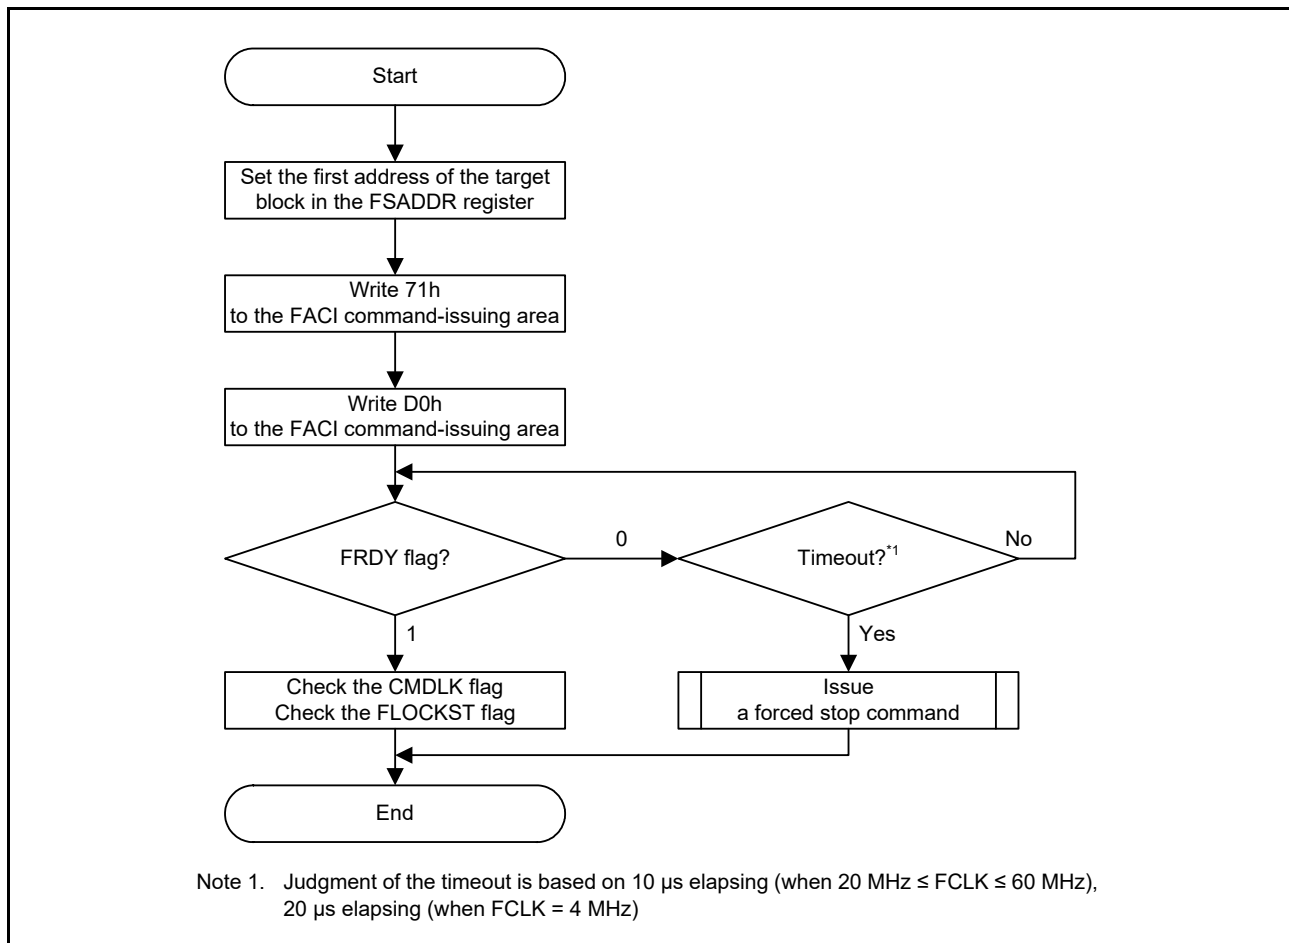

Figure 44.27 Usage of the Lock-Bit Read Command

## 44.7 Boot Mode

There are two serial programming modes; the boot mode (SCI interface) with SCI, the boot mode (USB interface) with USB, and the boot mode (FINE interface) with FINE. Table 44.19 lists the I/O pins used in boot mode.

I/O pins that are not used in boot mode are in the same state as that after a reset.

**Table 44.19 I/O Pins Used in Boot Mode**

| Pin Name         | I/O    | Mode to be Used                             | Use                                                                                      |
|------------------|--------|---------------------------------------------|------------------------------------------------------------------------------------------|
| MD               | Input  | Boot mode (SCI interface)                   | Selection of operating mode                                                              |
| P00/UB           | Input  | User boot mode<br>Boot mode (USB interface) | Selection of boot mode (SCI interface) or user boot mode*1/<br>boot mode (USB interface) |
| PD5/RXD1         | Input  | Boot mode (SCI interface)                   | For host communication (to receive data through SCI)                                     |
| PD3/TXD1         | Output |                                             | For host communication (to transmit data through SCI)                                    |
| USB0_DP, USB0_DM | I/O    | Boot mode (USB interface)                   | Data input/output of USB                                                                 |
| PD2/USB0_VBUS    | Input  |                                             | Detection of connection and disconnection of USB cables                                  |
| PE2/UPSEL        | Input  |                                             | Selection of USB bus-powered mode or self-powered mode                                   |
| MD/FINED         | I/O    | Boot mode (FINE interface)                  | Selection of operating mode, FINE data I/O                                               |

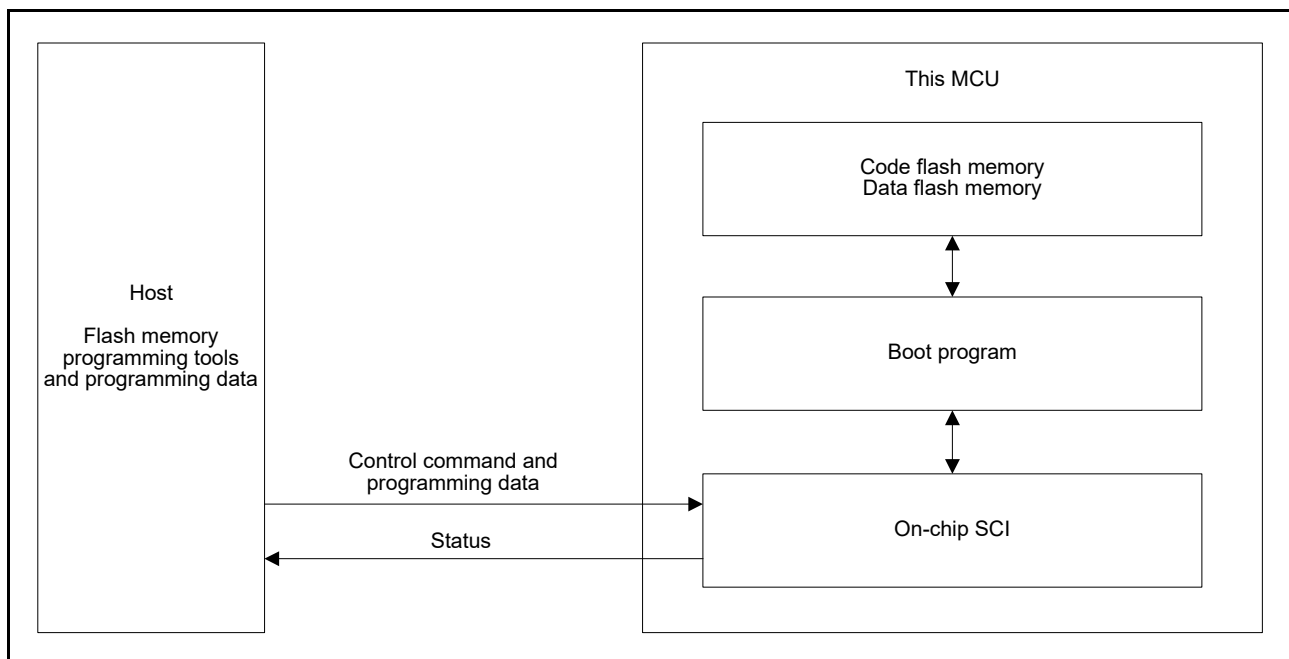

Note 1. To enable user boot mode, the settings for UB code A and UB code B are required.

### 44.7.1 Boot Mode (SCI Interface)

In boot mode (SCI interface), the host sends control commands and data for programming, and the user area or data flash memory, and the user boot area can be programmed or erased. An on-chip SCI handles transfer between the host and this MCU in asynchronous mode. Tools for transmission of control commands and the data for programming must be prepared in the host.

When this MCU is activated in boot mode (SCI interface), the program (boot program) in a dedicated area within the MCU is executed. The boot program automatically adjusts the bit rate of the SCI and controls programming/erasure by receiving control commands from the host.

Figure 44.28 shows the system configuration for operations in boot mode (SCI interface).

**Figure 44.28 System Configuration for Operations in Boot Mode (SCI Interface)**

### 44.7.2 Boot Mode (USB Interface)

In boot mode (USB interface), the host sends control commands and data for programming, and the user area or data flash memory, and the user boot area can be programmed or erased. An on-chip USB handles transfer between the host and this MCU. Tools for transmission of control commands and the data for programming must be prepared in the host. Figure 44.29 shows the configuration of a system for use in boot mode (USB interface).

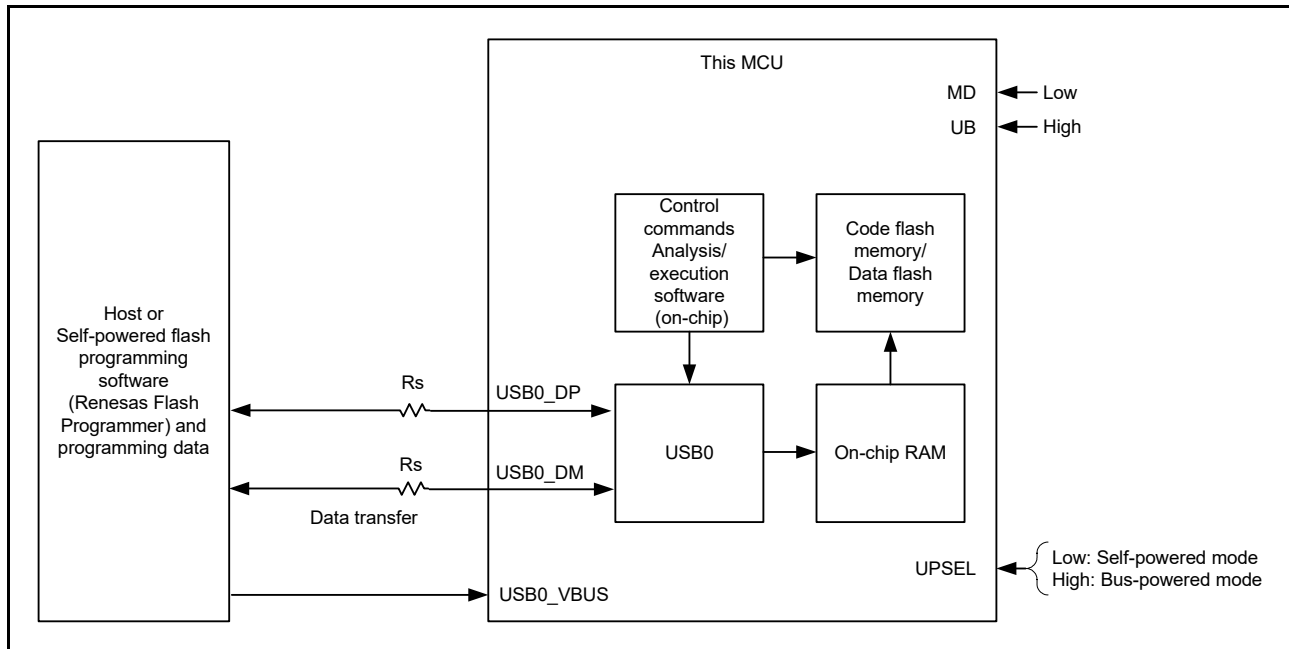

Figure 44.29 System Configuration in Boot Mode (USB Interface)

In boot mode (USB interface), self-powered mode or bus-powered mode is selected for operation. Release from the reset state while the low level is being applied to the MD and UPSEL pins and the high level is being applied to the UB pin selects self-powered mode. Release from the reset state while the low is being applied to the MD pin and the high level is being applied to the UPSEL and UB pins are high selects bus-powered mode.

Table 44.20 shows the enumeration information for each mode.

Table 44.20 Enumeration Information

| USB Specification | Ver.2.0 (Full-Speed)                    |        |
|-------------------|-----------------------------------------|--------|
| Maximum current   | Self-powered mode (PE2/UPSEL pin = Low) | 100 mA |
|                   | Bus-powered mode (PE2/UPSEL pin = High) | 500 mA |

### 44.7.3 Boot Mode (FINE Interface)

The flash memory can be programmed and erased using the FINE in boot mode (FINE interface). The user area or data flash memory, and the user boot area can be rewritten.

#### 44.7.3.1 Operating Conditions in Boot Mode (FINE Interface)

FINE is used to communicate with the serial programmer in boot mode (FINE Interface).

Figure 44.30 shows an Example of Pin Connections in Boot Mode (FINE Interface). Table 44.21 lists Pin Handling in Boot Mode (FINE Interface).

The example of pin connections shown in Figure 44.30 is a simplified circuit. Operations are not guaranteed in all systems.

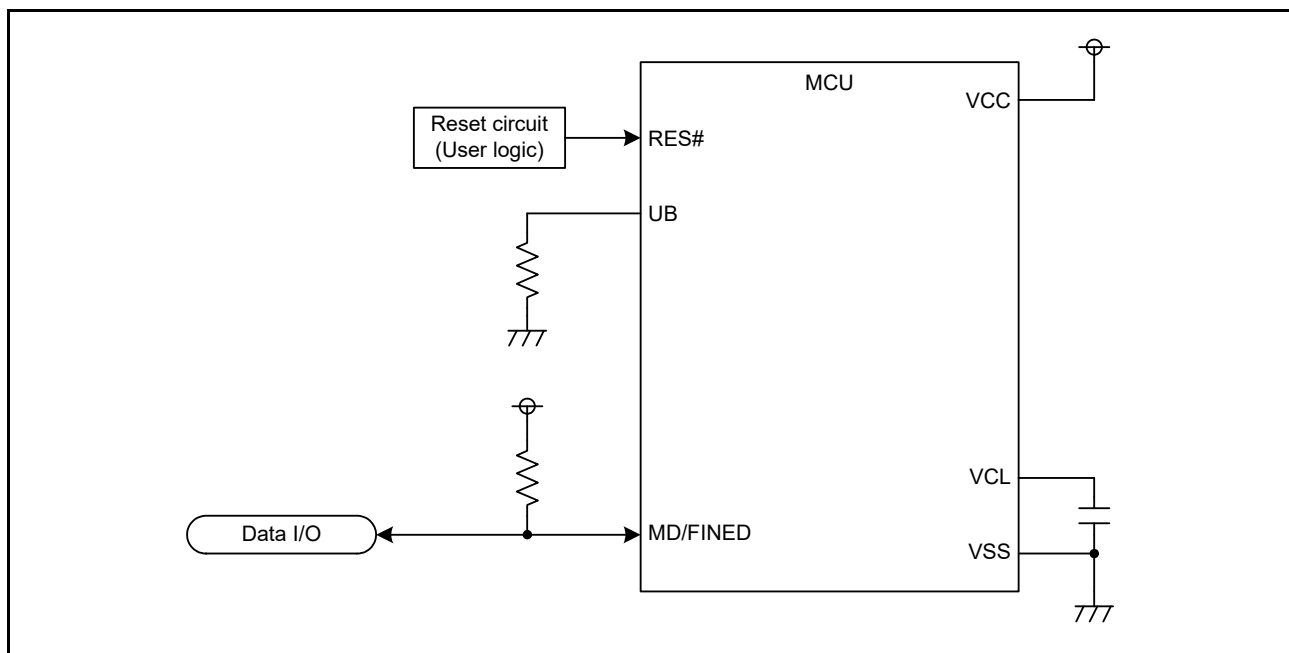

Figure 44.30 Example of Pin Connections in Boot Mode (FINE Interface)

Table 44.21 Pin Handling in Boot Mode (FINE Interface)

| Pin Name | Name                                | I/O   | Function                                                                                                      |
|----------|-------------------------------------|-------|---------------------------------------------------------------------------------------------------------------|
| VCC, VSS | Power supply input                  | Input | Input 2.7 V or higher to the VCC pin.<br>Input 0 V to the VSS pin.                                            |
| VCL      | Decoupling capacitor connect pin    | —     | Connect to the VSS pin via a 0.47- $\mu$ F multilayer ceramic capacitor for stabilizing the internal voltage. |
| MD       | Operating mode control/<br>data I/O | I/O   | Connect the VCC pin via a resistor (pull up).                                                                 |
| UB       | Operating mode control              | Input | Connect the VSS pin via a resistor (pull down).                                                               |
| RES#     | Reset input                         | Input | Reset pin. Connect to the reset circuit.                                                                      |

## 44.8 Flash Memory Protection

Flash memory protection prevents the flash memory from being read or rewritten by the third party.

The on-chip debugger ID code protection is for connecting the on-chip debugger, and the serial programmer ID code protection is for connecting the serial programmer. ROM code protection is for connecting the parallel programmer.

### 44.8.1 ID Code Protection

There are two types of ID code protection: The on-chip debugger ID code protection is for connecting the on-chip debugger and the serial programmer ID code protection for connecting the serial programmer. The same ID codes are used for both functions, but operations differ.

For details, refer to section 7.2.2, OCD/Serial Programmer ID Setting Register (OSIS).

#### 44.8.1.1 On-Chip Debugger ID Code Protection

This function is used to prohibit connection to the on-chip debugger (OCD).

The code sent from the emulator is compared with the ID code in the OCD/serial programmer ID setting register (OSIS) to determine whether they match. If they match, connection to the OCD is allowed. If they do not match, connection to the OCD is prohibited.

#### 44.8.1.2 Serial Programmer ID Code Protection

This function is used to prohibit connection with the serial programmer. When the MCU is connected to a serial programmer, the ID code set in the OCD/serial programmer ID setting register (OSIS) and written in the option-setting memory is used to judge ID code protection on connection of the serial programmer.

The code sent from the serial programmer is compared with the ID code set in the OCD/serial programmer ID setting register (OSIS) to determine whether they match. If they match, connection with the serial programmer is allowed. If they do not match, the serial programmer cannot be connected. If the control code is 45h and the codes do not match three times in a row, all data in the flash memory are erased.

In user boot mode, serial programmer ID code protection function is not available.

### 44.8.2 ROM Code Protection

ROM code protection is a function to prohibit reading, programming, or erasing of the flash memory when the parallel programmer is used during off-board programming.

For details of the ROM code protection register, refer to section 7.2.8, ROM Code Protection Register (ROMCODE).

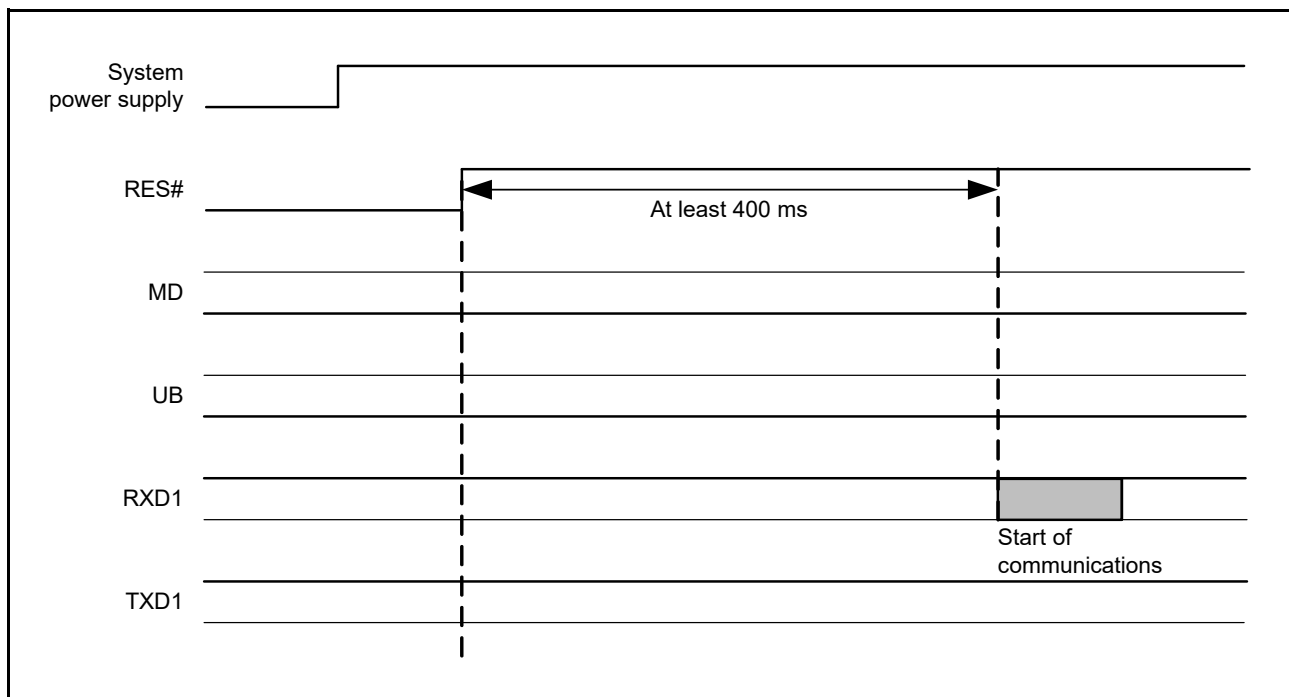

### 44.9 Boot Mode Communications Protocol

This section describes the communications protocol for use in boot mode. When developing a programmer, use this communications protocol to control it.

#### 44.9.1 How to Start the Chip Up in Boot Mode (SCI Interface)

The chip starts up in boot mode (SCI interface) if both the MD and UB pins are at the low level on release from the reset state (i.e. when the level on the RES# pin changes from low to high). A waiting time of at least 400 ms is required while the RES# pin is held at the high level after the chip starts up in boot mode (SCI interface) until communications with the MCU can proceed.

Figure 44.31 shows the states of pins up to communications in boot mode (SCI interface) becoming possible.

**Figure 44.31 States of Pins Up to Communications in Boot Mode (SCI Interface) Becoming Possible**

## 44.9.2 State Transitions in Boot Mode

### 44.9.2.1 State Transitions in Boot Mode (SCI Interface)

Figure 44.32 shows a flowchart for transition to boot mode (SCI interface).

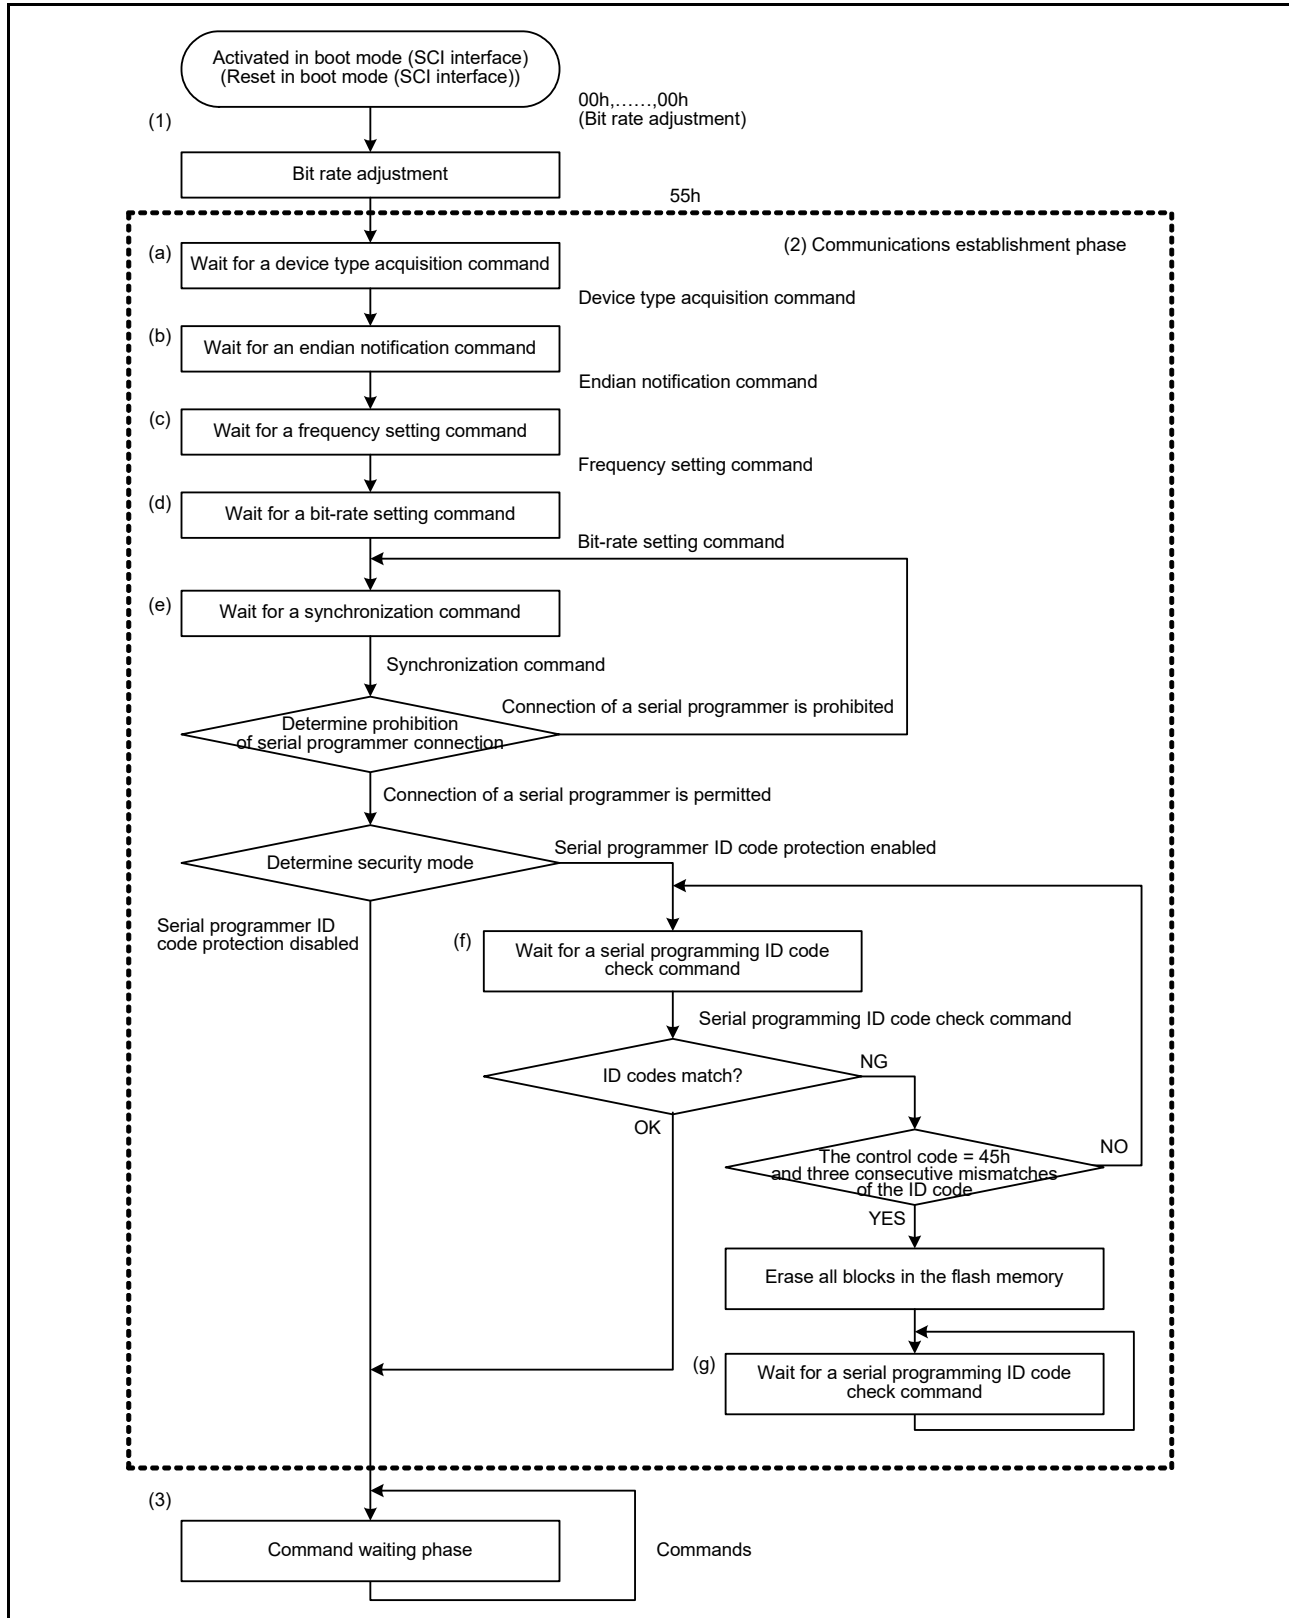

Figure 44.32 Flowchart for Transition to Boot Mode (SCI Interface)

### (1) Matching the bit rates

When this MCU is activated in boot mode, the bit rate of the SCI is automatically adjusted to match that of the host. On completion of this automatic bit rate adjustment, this MCU transmits the value 00h to the host. On subsequent correct reception of the value 55h sent from the host, this MCU enters the communications establishment phase. For details on matching of the bit rates, refer to section 44.9.3, Automatic Adjustment of the Bit Rate.

### (2) Communications establishment phase

The device, endian, frequency, and bit rate are selected in this phase. If serial programmer ID code protection is enabled, ID code authentication is performed. For the commands to use in the communications establishment phase, refer to section 44.9.5, Communications Establishment Phase.

#### (a) Waiting for a device type acquisition command

In this state, the MCU is waiting for a device type acquisition command to be sent from the host. When it receives a device type acquisition command, the state shifts to waiting for an endian notification command. For details of the device type acquisition command, refer to section 44.9.9, Device Type Acquisition Command.

#### (b) Waiting for an endian notification command

In this state, the MCU is waiting for an endian notification command to be sent from the host. When it receives an endian notification command, the state shifts to waiting for a frequency setting command. For details of the endian notification command, refer to section 44.9.10, Endian Notification Command.

#### (c) Waiting for a frequency setting command

In this state, the MCU is waiting for a frequency setting command to be sent from the host. When it receives a frequency setting command, the state shifts to waiting for a bit-rate setting command. For details of the frequency setting command, refer to section 44.9.11, Frequency Setting Command.

#### (d) Waiting for a bit-rate setting command

In this state, the MCU is waiting for a bit-rate setting command to be sent from the host. When it receives a bit-rate setting command, the state shifts to waiting for a synchronization command. For details of the bit-rate setting command, refer to section 44.9.12, Bit-Rate Setting Command.

#### (e) Waiting for a synchronization command

In this state, the MCU is waiting for a synchronization command to be sent from the host. When it receives a synchronization command, it determines whether the serial programmer ID code protection is enabled or disabled. When the ID code protection is disabled, the MCU enters the command waiting phase. When the ID code protection is enabled, it enters the state of waiting for a serial programming ID code check command. If the MCU has been set to prohibit the connection of a serial programmer, this MCU transmits an error code to indicate that connecting a serial programmer is prohibited and remains in the state of waiting for a synchronization command. For details of the synchronization command, refer to section 44.9.13, Synchronization Command.

#### (f) Waiting for a serial programming ID code check command

In this state, the MCU is waiting for a serial programming ID code check command to be sent from the host. The ID code sent is compared with the ID code written in the option-setting memory area, and the command waiting phase is entered if the two match. If they do not match, the next transition is back to the state of waiting for a serial programming ID code check command. If the control code is 45h and the codes do not match three times in a row, all data in the flash memory are erased.

For details of the ID code check command, refer to section 44.9.15, Serial Programming ID Code Check Command.

(g) Waiting for a serial programming ID code check command (after erasure)

After all blocks in the flash memory are erased, reboot the MCU in boot mode.

(3) Phase of waiting for commands

In this state, programming and erasure proceed in accord with commands from the host. For details of the commands that can be issued in the command waiting phase, refer to section 44.9.6, Command Waiting Phase.

### 44.9.2.2 State Transitions in Boot Mode (USB Interface)

Figure 44.33 shows a flowchart for transition to boot mode (USB interface).

Figure 44.33 Flowchart for Transition to Boot Mode (USB Interface)

### (1) Initial Communications

Enumeration starts when this MCU is activated in boot mode (USB interface).

Once the process of enumeration between the host and this MCU is completed, send the value 00h from the host to this MCU three times.

This MCU ignores transmission of the value 00h from the host from the fourth time and onward.

This MCU returns 00h to the host when receiving the value 00h three times. On subsequent correct reception of the value 55h sent from the host, this MCU enters the communications establishment phase.

**Figure 44.34 Initial Communications Between the Host and This MCU**

### (2) Communications establishment phase

The device, endian, frequency, and bit rate are selected in this phase. If serial programmer ID code protection is enabled, ID code authentication is performed. For the commands to use in the communications establishment phase, refer to section 44.9.5, Communications Establishment Phase.

#### (a) Waiting for a device type acquisition command

In this state, the MCU is waiting for a device type acquisition command to be sent from the host. When it receives a device type acquisition command, the state shifts to waiting for an endian notification command. For details of the device type acquisition command, refer to section 44.9.9, Device Type Acquisition Command.

#### (b) Waiting for an endian notification command

In this state, the MCU is waiting for an endian notification command to be sent from the host. When it receives an endian notification command, the state shifts to waiting for a frequency setting command. For details of the endian notification command, refer to section 44.9.10, Endian Notification Command.

#### (c) Waiting for a frequency setting command

In this state, the MCU is waiting for a frequency setting command to be sent from the host. When it receives a frequency setting command, the state shifts to waiting for a bit-rate setting command. For details of the frequency setting command, refer to section 44.9.11, Frequency Setting Command.

#### (d) Waiting for a bit-rate setting command

In this state, the MCU is waiting for a bit-rate setting command to be sent from the host. When it receives a bit-rate setting command, the state shifts to waiting for a synchronization command. For details of the bit-rate setting command, refer to section 44.9.12, Bit-Rate Setting Command.

#### (e) Waiting for a synchronization command

In this state, the MCU is waiting for a synchronization command to be sent from the host. When it receives a synchronization command, it determines whether the serial programmer ID code protection is enabled or disabled. When the ID code protection is disabled, the MCU enters the command waiting phase. When the ID code protection is enabled, it enters the state of waiting for a serial programming ID code check command. If the prohibition of serial programmer connection is enabled, this MCU transmits an error code to indicate that connecting a serial programmer is prohibited and remains in the state of waiting for a synchronization command. For details of the synchronization command, refer to section 44.9.13, Synchronization Command.

#### (f) Waiting for a serial programming ID code check command

In this state, the MCU is waiting for a serial programming ID code check command to be sent from the host. The ID code sent is compared with the ID code written in the option-setting memory area, and the command waiting phase is entered if the two match. If they do not match, the next transition is back to the state of waiting for a serial programming ID code check command.

If the control code is 45h and the codes do not match three times in a row, all data in the flash memory are erased.

For details of the ID code check command, refer to section 44.9.15, Serial Programming ID Code Check Command.

#### (g) Waiting for a serial programming ID code check command (after erasure)

After all blocks in the flash memory are erased, reboot the MCU in boot mode.

### (3) Phase of waiting for commands

In this state, programming and erasure proceed in accord with commands from the host. For details of the commands that can be issued in the command waiting phase, refer to section 44.9.6, Command Waiting Phase.

### 44.9.3 Automatic Adjustment of the Bit Rate

When this MCU is booted up in boot mode (SCI interface), asynchronous transfer by the SCI is used to measure the periods at low level of consecutive bytes with value 00h that are sent from the host. While the period at low level is being measured, set the host's SCI transfer format to 8-bit data, one stop bit, no parity, and a transfer rate of 9,600 bps. This MCU measures the periods at low level in the signal from the host, adjusts the bit rate of its SCI, and then sends the value 00h to the host.

If reception of the value 00h by the host is successful, the host responds by sending the value 55h to this MCU. If successful reception of 00h by the host is not possible, reboot this MCU in boot mode, and then repeat the process of automatically adjusting the bit rate. If reception of the value 55h by this MCU is successful, it responds by sending C1h to the host, and if successful reception of 55h by this MCU is not possible, it responds by sending FFh to the host.

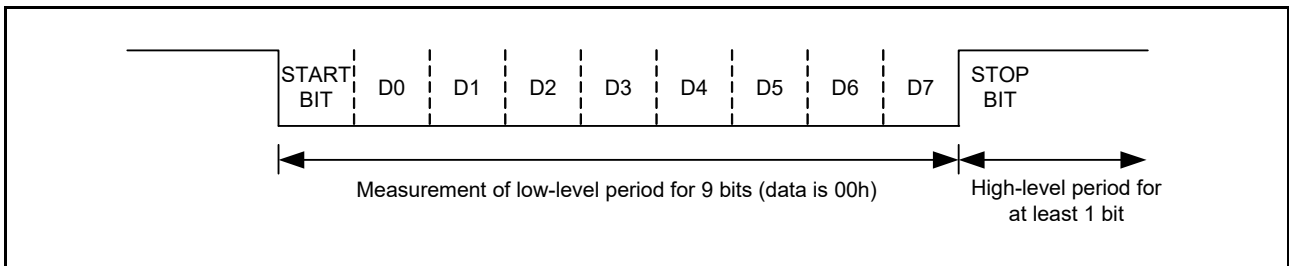

Figure 44.35 Transfer Format Used by SCI in Automatic Adjustment of Bit Rate

Figure 44.36 Sequence of Transfer between Host and This MCU

For the host's SCI bit rate, ensure that SCI communications proceed under the conditions given in Table 44.22.

Table 44.22 Conditions for Automatic Bit-Rate Adjustment

| Bit Rate of SCI in Host |
|-------------------------|
| 9,600 bps               |

#### 44.9.4 Packet Format

##### (1) Command packet

The host sends commands to this MCU in the format below.

|   |   |   |   |                     |   |   |
|---|---|---|---|---------------------|---|---|
| S | L | L | C | Command information | S | E |
| O | N | N | O | (variable length)   | U | T |
| H | H | L | M | (up to 255 bytes)   | M | X |

| Symbol              | Code | Description                                                                                  |
|---------------------|------|----------------------------------------------------------------------------------------------|
| SOH                 | 01h  | Start of a packet (1 byte)                                                                   |
| LNH                 | —    | Packet length (length of COM and the command information) (8 to 15 bits) (1 byte)            |
| LNL                 | —    | Packet length (length of COM and the command information) (0 to 7 bits) (1 byte)             |
| COM                 | —    | Command code (1 byte)                                                                        |
| Command information | —    | Command information (up to 255 bytes)                                                        |
| SUM*1               | —    | Two's complement of the sum of values of LNH, LNL, COM, and the command information (1 byte) |
| ETX                 | 03h  | End of a packet (1 byte)                                                                     |

Note 1. SUM indicates the 1 byte of data that produces 00h as the result of adding LNH, LNL, COM, the command information, and SUM itself.

##### (2) Status packet and data packet

Data transmission proceeds between the host and this MCU in the format below.

|   |   |   |   |                    |   |   |    |   |
|---|---|---|---|--------------------|---|---|----|---|
| S | L | L | R | Data               | S | E | E  |   |
| O | N | N | E | (variable length)  | U | T | or | T |
| D | H | L | S | (up to 1024 bytes) | M | B |    | X |

| Symbol | Code | Description                                                                   |
|--------|------|-------------------------------------------------------------------------------|
| SOD    | 81h  | Start of a packet (1 byte)                                                    |
| LNH    | —    | Packet length (length of RES and the data) (8 to 15 bits) (1 byte)            |
| LNL    | —    | Packet length (length of RES and the data) (0 to 7 bits) (1 byte)             |
| RES    | —    | Response code (1 byte)                                                        |
| Data   | —    | Data (up to 1024 bytes)                                                       |
| SUM*1  | —    | Two's complement of the sum of values of LNH, LNL, RES, and the data (1 byte) |
| ETB    | 17h  | End of a packet (1 byte)                                                      |
| ETX    | 03h  | End of the last packet (1 byte)                                               |

Note 1. SUM indicates the 1 byte of data that produces 00h as the result of adding LNH, LNL, RES, the data, and SUM itself.

### 44.9.5 Communications Establishment Phase

Table 44.23 lists the commands available in the commands establishment phase.

The synchronization command and ID authentication mode acquisition command can also be used in the command waiting phase.

**Table 44.23 Commands Available in the Communications Establishment Phase**

| Command Name                       | Function                                                                                                                                    |
|------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------|
| Device type acquisition            | Transmits the oscillation frequency and CPU operating frequency (in Hz) supported by boot mode to the host.                                 |
| Endian notification                | Indicates whether big-endian or little-endian is to be used.                                                                                |
| Frequency setting                  | Sets the values of the oscillation frequency and CPU operating frequency (in Hz).                                                           |
| Bit-rate setting                   | Changes the bit rate.                                                                                                                       |
| Synchronization                    | This command is used in processing for communications synchronization. It is also used when confirming whether the MCU can accept commands. |
| ID authentication mode acquisition | This command sends the enabled/disabled state of the serial programmer ID code protection to the host.                                      |
| Serial programming ID code check   | Determines whether the control code and ID code written in the option-setting memory matches the control code and ID code sent by the host. |

In the communications establishment phase, send commands from the host in the order of the device type acquisition, endian notification, frequency setting, bit-rate setting, and synchronization commands according to the responses to commands. When serial programmer ID code protection is enabled, send the ID authentication mode acquisition or serial programming ID code check command following the synchronization command.

If commands are issued in an incorrect order or other commands are issued, this MCU returns a response indicating a flow error.

## 44.9.6 Command Waiting Phase

Table 44.24 lists the commands available in the command waiting phase.

The synchronization command and ID authentication mode acquisition command can also be used in the communications establishment phase.

**Table 44.24 Commands Available in the Command Waiting Phase**

| Command Name                             | Function                                                                                                                                                                          |
|------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Synchronization                          | Refer to Table 44.23.                                                                                                                                                             |
| Blank check                              | Check that a selected area is blank.                                                                                                                                              |
| Block erase                              | Erases a selected single block.                                                                                                                                                   |
| Area erase                               | Erases the specified area.                                                                                                                                                        |
| Program                                  | Programs the selected area.                                                                                                                                                       |
| Read                                     | Reads data from a selected area.                                                                                                                                                  |
| Lock-bit setting                         | Sets the lock bits.                                                                                                                                                               |
| Lock-bit acquisition                     | Obtains the settings of lock bits.                                                                                                                                                |
| Lock bit enable                          | Enables the setting of lock bits.                                                                                                                                                 |
| Lock bit disable                         | Disables the setting of lock bits.                                                                                                                                                |
| ID authentication mode acquisition       | Refer to Table 44.23.                                                                                                                                                             |
| Command protection setting               | Enables prohibition of block erase commands, program commands, or read commands.                                                                                                  |
| Command protection acquisition           | Obtains the settings for protection against block erase commands, program commands, and read commands.                                                                            |
| Serial programming ID code setting       | Sets the OSIS register. Also, sets the SPCC register and enables the serial programmer ID code protection.                                                                        |
| ID code setting                          | Sets the OSIS register.                                                                                                                                                           |
| ID code acquisition                      | Obtains the OSIS setting.                                                                                                                                                         |
| Serial programmer connection prohibition | Sets the SPCC.SPE bit and enables the prohibition of serial programmer connection.                                                                                                |
| OFS setting                              | Sets the OFS0 and OFS1 registers.                                                                                                                                                 |
| OFS acquisition                          | Obtains the setting of the OFS0 and OFS1 registers.                                                                                                                               |
| Endian setting                           | Sets the MDE register.                                                                                                                                                            |
| Endian acquisition                       | Obtain the setting of the MDE register.                                                                                                                                           |
| Configuration clear                      | Erases the configuration setting areas and the TM target areas.                                                                                                                   |
| TM setting                               | Sets the TMEF and TMINF registers and enables the TM function.                                                                                                                    |
| TM acquisition                           | Acquires an indicator of whether the TM function is currently enabled or disabled, the contents of the TMINF register, and the addresses where the TM target areas start and end. |
| Simple addition checksum                 | Calculates the sum of values in a selected area.                                                                                                                                  |
| Signature acquisition                    | Obtains information of the flash memory configuration.                                                                                                                            |
| ROM code setting                         | Sets the ROM code protection register.                                                                                                                                            |
| ROM code acquisition                     | Obtains the settings of the ROM code protection register.                                                                                                                         |

If the host has sent an undefined command, this MCU returns a response indicating an error in the form of a non-supported command.

### 44.9.7 Command Transfer Sequence

Though the sequence of transfer differs from command to command, common transfer sequences are used for the commands that only make settings for this MCU and for the commands that obtain information on the settings in this MCU. However, as the contents of the command packet, status packet, and data packet differ for each command, refer to the sections on the individual commands for details.

(1) Common transfer sequence for the commands that only make settings

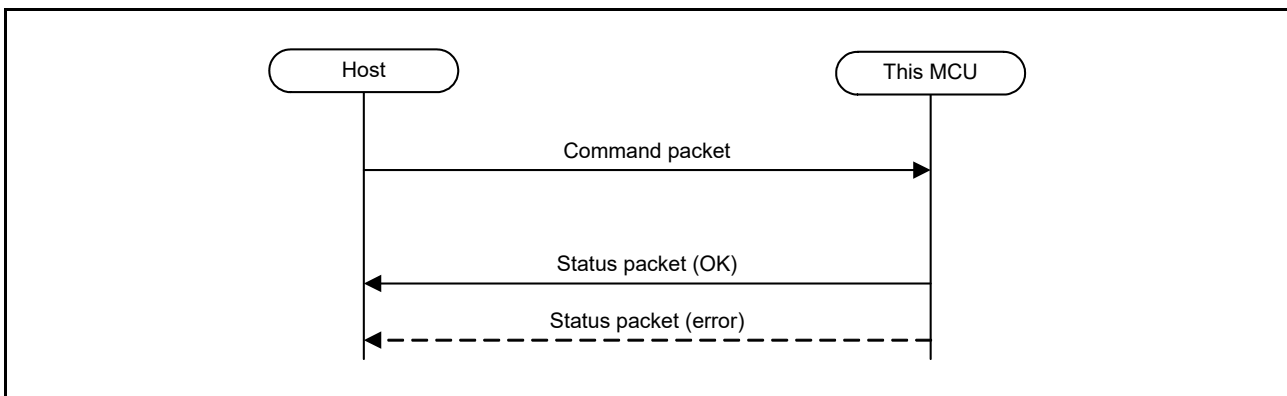

Figure 44.37 Common Transfer Sequence for the Commands that Only Make Settings

(2) Common transfer sequence for the commands that obtain information on settings

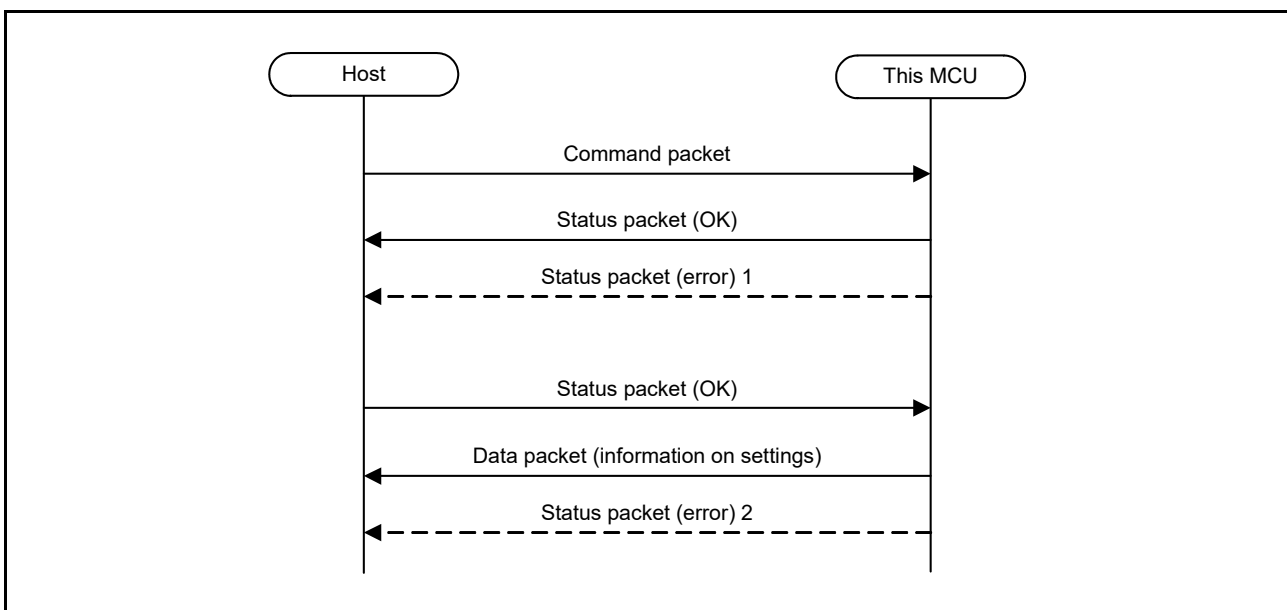

Figure 44.38 Common Transfer Sequence for the Commands that Obtain Information on Settings

**Table 44.25 Common Transfer Sequence**

| Command Name                             | Common Transfer Sequence Type                |
|------------------------------------------|----------------------------------------------|
| Device type acquisition                  | Command that obtains information on settings |
| Endian notification                      | Command that only makes a setting            |
| Frequency setting                        | Command that obtains information on settings |
| Bit rate setting                         | Not in a common transfer sequence            |
| Synchronization                          | Command that only makes a setting            |
| ID authentication mode acquisition       | Command that obtains information on settings |
| Serial programming ID code check         | Command that only makes a setting            |
| Blank check                              | Command that only makes a setting            |
| Block erase                              | Command that only makes a setting            |
| Area erase                               | Command that only makes a setting            |
| Program                                  | Not in a common transfer sequence            |
| Read                                     | Not in a common transfer sequence            |
| Lock-bit setting                         | Command that only makes a setting            |
| Lock-bit acquisition                     | Command that obtains information on settings |
| Lock bit enable                          | Command that only makes a setting            |
| Lock bit disable                         | Command that only makes a setting            |
| Command protection setting               | Command that only makes a setting            |
| Command protection acquisition           | Command that obtains information on settings |
| Serial programming ID code setting       | Command that only makes a setting            |
| ID code setting                          | Command that only makes a setting            |
| ID code acquisition                      | Command that obtains information on settings |
| Serial programmer connection prohibition | Command that only makes a setting            |
| OFS setting                              | Command that only makes a setting            |
| OFS acquisition                          | Command that obtains information on settings |
| Endian setting                           | Command that only makes a setting            |
| Endian acquisition                       | Command that obtains information on settings |
| Configuration clear                      | Command that only makes a setting            |
| TM setting                               | Command that only makes a setting            |
| TM acquisition                           | Command that obtains information on settings |
| Simple addition checksum                 | Command that obtains information on settings |
| Signature acquisition                    | Command that obtains information on settings |
| ROM code setting                         | Command that only makes a setting            |
| ROM code acquisition                     | Command that obtains information on settings |

For the command transfer sequences that are not in a common transfer sequence, refer to the sections on the individual commands.

### 44.9.8 Unsupported Commands

When this MCU receives an undefined command packet, it returns an unsupported error (C0h) and enters the command waiting state.

#### (1) Command packet structure

|   |   |   |   |   |   |
|---|---|---|---|---|---|
| S | L | L | C | S | E |
| O | N | N | O | U | T |
| H | H | L | M | M | X |

SOH: 01h  
 LNH: Packet length (8 to 15 bits)  
 LNL: Packet length (0 to 7 bits)  
 COM: Command code\*1  
 SUM: Sum of values  
 ETX: 03h

Note 1. Command code other than those specified in Table 44.24.

#### (2) Status packet structure

|   |   |   |   |   |   |   |
|---|---|---|---|---|---|---|
| S | L | L | R | E | S | E |
| O | N | N | E | R | U | T |
| D | H | L | S | R | M | X |

SOD: 81h  
 LNH: 00h  
 LNL: 02h  
 RES: 80h | COM (command code)  
 ERR: Error code  
     C0h ("unsupported" error)  
     C1h (packet error)  
     C2h (checksum error)  
     C3h (flow error)  
 SUM: Sum of values  
 ETX: 03h

### 44.9.9 Device Type Acquisition Command

This command is used to make the MCU send the input frequency and system clock frequency (in Hz) supported by boot mode (SCI interface).

This command can only be accepted in the communications establishment phase.

#### (1) Command packet structure

|   |   |   |   |   |   |
|---|---|---|---|---|---|
| S | L | L | C | S | E |
| O | N | N | O | U | T |
| H | H | L | M | M | X |

SOH: 01h  
LNH: 00h  
LNL: 01h  
COM: 38h  
SUM: C7h  
ETX: 03h

#### (2) Data packet structure

|   |   |   |   |   |   |   |   |   |   |   |
|---|---|---|---|---|---|---|---|---|---|---|
| S | L | L | R | T | O | O | C | C | S | E |
| O | N | N | E | Y | S | S | P | P | U | T |
| D | H | L | S | P | A | I | A | I | M | X |

SOD: 81h  
LNH: 00h  
LNL: 19h  
RES: 38h (OK)  
TYP: Type code (8 bytes)\*1  
OSA: Maximum input frequency (4 bytes)  
OSI: Minimum input frequency (4 bytes)  
CPA: Maximum system clock frequency (4 bytes)  
CPI: Minimum system clock frequency (4 bytes)  
SUM: Sum of values  
ETX: 03h

An example of the values sent is given below.

Maximum input frequency = 16,000,000 Hz

OSA (1st byte): 00h  
OSA (2nd byte): F4h  
OSA (3rd byte): 24h  
OSA (4th byte): 00h

Minimum input frequency = 16,000,000 Hz

OSI (1st byte): 00h  
OSI (2nd byte): F4h  
OSI (3rd byte): 24h  
OSI (4th byte): 00h

Maximum system clock (ICLK) = 120,000,000 Hz

CPA (1st byte): 07h  
CPA (2nd byte): 27h  
CPA (3rd byte): 0Eh  
CPA (4th byte): 00h

Minimum system clock: (ICLK) = 120,000,000 Hz

CPI (1st byte): 07h  
CPI (2nd byte): 27h  
CPI (3rd byte): 0Eh  
CPI (4th byte): 00h

Note 1. Reserved data

 ETX: 03h

After the error code is returned, the chip returns to the command waiting state.

### 44.9.10 Endian Notification Command

This command is used to inform the MCU of the endian (big or little).

Specify either endian as the endian information according to the data to be programmed.

This command can only be accepted in the communications establishment phase.

#### (1) Command packet structure

 ETX: 03h

After the error code is returned, the chip returns to the command waiting state.

### 44.9.11 Frequency Setting Command

This command is used to set the values of oscillation frequency and CPU operating frequency (in Hz).

In boot mode (SCI interface) or boot mode (FINE interface), the HOCO runs at 16 MHz and the ICLK runs at 120 MHz, so set the input frequency to 16 MHz and the system clock frequency to 120 MHz. Furthermore, in boot mode (SCI interface) or boot mode (FINE interface), the FCLK and PCLKB run at 60 MHz, so the MCU sends that the frequency of the peripheral module clock is 60 MHz.

In boot mode (USB interface), operation is at the input frequency in use (20 MHz or 24 MHz) and with the ICLK at 120 MHz, so set the input frequency to 20 MHz or 24 MHz and the system clock frequency to 120 MHz. Additionally, in boot mode (USB interface), the FCLK runs at 60 MHz and UCLK at 48 MHz, so the MCU sends that the frequency of the peripheral module clock is 48 MHz.

This command can only be accepted in the communications establishment phase.

#### (1) Command packet structure

|   |   |   |   |   |   |   |   |   |   |   |   |   |   |

After the error code is returned, the chip returns to the command waiting state.

### 44.9.12 Bit-Rate Setting Command

This command is used to change the bit rate after receiving bit rate data (in bps).

If an error occurs, the bit rate is not changed.

This command can only be accepted in the communications establishment phase.

In boot mode (USB interface) or boot mode (FINE interface), switching of the bit rate does not proceed. Set the desired value for the bit rate.

#### (1) Procedure

## 44.9.13 Synchronization Command

This command is used in processing to synchronize communications.

It is also used when checking whether the MCU is ready to accept commands. If a serial programmer connection is prohibited, a serial programmer connection prohibition error is returned.

This command can be accepted in both the communications establishment and command waiting phases.

## (1) Command packet structure

### 44.9.15 Serial Programming ID Code Check Command

This command determines whether the ID code set in the OSIS register matches the ID code sent by the host, and sends the result to the host.

This command can be accepted in the communications establishment phase. When the serial programmer ID code protection is enabled, the MCU does not enter the command waiting phase unless processing in response to this command ends normally.

If the control code is 45h and the codes do not match three times in a row, all data in the flash memory are erased.

After the error code is returned, the chip returns to the command waiting state.

### 44.9.16 Blank Check Command

This command checks whether the specified area is blank.

Specify a range in the user area or user boot area with addresses on 256-byte boundaries or in the data area with addresses on 16-byte boundaries. When the TM function is enabled, an attempt at blank checking of the code flash memory in blocks 8 and 9 leads to an error since they are being handled as TM target area.

This command can only be accepted in the command waiting phase.

#### (1) Command packet structure

After the error code is returned, the chip returns to the command waiting state.

### 44.9.17 Block Erase Command

This command is used to erase a specified single block.

Specify the block for erasure as the first address in the block.

If the lock-bit function is disabled and the lock bit of a block for erasure is set, the lock bit is also erased so the block is released from locking. While the TM function is enabled, blocks 8 and 9 in the user area are handled as TM target areas and so cannot be erased.

To erase areas being handled as TM target, use the configuration clear command described in section 44.9.35, Configuration Clear Command to restore them to normal handling.

If prohibition of program commands is enabled, follow the procedure for erasure prescribed in section 44.9.43, Flow for Erasure when Prohibition of Program Commands is Enabled.

This command cannot be used when prohibition of block erase commands is enabled.

If processing of erasure is forcibly stopped in response to a command due to a reset, the lock bit may be set. In such a case, refer to 44.12.6 Abnormal Termination During Programming/Erase or Blank Checking in section 44.12, Usage Notes.

This command can only be accepted in the command waiting phase.

### 44.9.18 Area Erase Command

The area erase command erases the specified area successively, block by block, in ascending order of addresses.

The target area can be selected from the user area, user boot area, or data area.

When an area for which the lock bit function is disabled and the lock bit has been set is erased, the lock-bit setting is cleared.

When the TM function is enabled, only the blocks other than those in the TM target areas are erased.

If prohibition of program commands is enabled, follow the procedure for erasure prescribed in section 44.9.43, Flow for Erasure when Prohibition of Program Commands is Enabled.

This command cannot be used when prohibition of block erase commands is enabled.

If processing in response to the command is forcibly stopped due to a reset, etc., while erasure is in progress, the lock bit may be set. In such a case, refer to 44.12.6 Abnormal Termination During Programming/Erasure or Blank

Checking in section 44.12, Usage Notes.

This command can only be accepted in the command waiting phase.

After the error code is returned, the chip returns to the command waiting state.

### 44.9.19 Program Command

This command sets up the MCU for data to be programmed to its flash memory and specifies the area where the data are to be programmed.

Specify addresses for a data length that is a multiple of 256 bytes for the user area or user boot area, or a multiple of 16 bytes for the data area. Furthermore, as the address where programming is to start, specify an address on a 256-byte boundary for the user area or user boot area or on a 16-byte boundary for the data area. When the TM function is enabled, blocks 8 and 9 in the user area are handled as TM target areas and so cannot be programmed.

This command cannot be used when prohibition of program commands is enabled.

This command can only be accepted in the command waiting phase.

### 44.9.20 Read Command

This command is used to read data from the specified area in the flash memory and send it to the host.

Specify addresses for a data length that is a multiple of 256 bytes for the user area or user boot area, or a multiple of 16 bytes for the data area. Furthermore, as the address where reading is to start, specify an address on a 256-byte boundary for the user area or user boot area or on a 16-byte boundary for the data area. When the TM function is enabled, reading blocks 8 and 9 in the user area being handled as TM target areas returns 0.

This command cannot be used when prohibition of read commands is enabled.

This command can only be accepted in the command waiting phase.

### 44.9.21 Lock-Bit Setting Command

This command is used to set lock bits for the user area.

When the chip starts up in boot mode, programming or erasure of blocks for which the lock bit has been set is possible since the lock bit function is disabled. To enable the lock bit function during operation in boot mode, use the lock-bit enable command.

This command cannot be used to clear a lock bit that has already been set. Canceling the setting of a lock bit requires erasure of the target block.

This command can only be accepted in the command waiting phase.

After the error code is returned, the chip returns to the command waiting state.

### 44.9.27 Serial Programming ID Code Setting Command

This command is used to set the ID code to the OSIS register. Also, it enables the serial programmer ID code protection with the setting of the SPCC.IDE, SPCC.SEPR, SPCC.WRPR, and SPCC.RDPR bits to 0.

When this command is used, the serial programmer ID code protection is enabled at reconnection.

This command cannot be used if prohibition of block erase commands, prohibition of program commands, or prohibition of read commands is enabled.

Apply a reset after executing this command.

This command can only be accepted in the command waiting phase.

#### (1) Command packet structure

After the error code is returned, the chip returns to the command waiting state.

### 44.9.28 ID Code Setting Command

This command is used to set the ID code to the OSIS register.

Setting the ID code with this command does not enable the serial programmer ID code protection.

This command cannot be used when the serial programmer ID code protection is enabled.

This command cannot be used if prohibition of block erase commands, prohibition of program commands, or prohibition of read commands is enabled.

This command can only be accepted in the command waiting phase.

### 44.9.35 Configuration Clear Command

This command is used to erase the configuration setting areas. When the TM function is enabled, the command can also be used to erase blocks 8 and 9 in the user area being handled as TM target areas.

For the states after execution of this command, refer to (4) Configuration data after clearing.

This command cannot be issued in the following cases: the user area, user boot area, and data area are not blank; the lock bit is set for any block; or prohibition of block erase commands is enabled.

When the serial programmer ID code protection is enabled, a reset is required to disable it.

This command can only be accepted in the command waiting phase.

E2h (program error)  
SUM: Sum error  
ETX: 03h

After the error code is returned, the chip returns to the command waiting state.

#### (4) Configuration data after clearing

| Data                                        | Setting       |
|---------------------------------------------|---------------|
| Prohibition of block erase commands         | Disabled      |
| Prohibition of program commands             | Disabled      |
| Prohibition of read commands                | Disabled      |
| Serial programmer ID code protection        | Disabled      |
| Prohibition of serial programmer connection | Disabled      |
| ID code                                     | All FFh       |
| MDE                                         | Little-endian |
| OFS0 and OFS1                               | All FFh       |
| TM function                                 | Disabled      |
| ROM code protection                         | Disabled      |

### 44.9.36 TM Setting Command

The TM setting command writes 000b to the TMEF.TMEF[2:0] bits and the desired 4-byte value to the TMINF register to enable the TM function. The TMINF register is used to store codes for identification of the programs, etc., in the areas being handled as TM. The TM function is enabled after a reset.

This command can only be accepted in the command waiting phase.

#### (1) Command packet structure

|   |   |   |   |   |   |   |
|---|---|---|---|---|---|---|
| S | L | L | C | T | S | E |

 SUM: Sum of values  
 ETX: 03h

After the error code is returned, the chip returns to the command waiting state.

### 44.9.37 TM Acquisition Command

The TM acquisition command acquires an indicator of whether the TM function is enabled or disabled, the setting of the TMINF register, and the addresses where the areas being handled as TM target start and end, and conveys the results to the host.

This command can only be accepted in the command waiting phase.

### 44.9.38 Simple Addition Checksum Command

This command is used to calculate the sum of values in the specified area and send the result to the host. While the TM function is enabled, however, the values in the TM target areas are not included in the calculation.

The target area of this command can be selected from the user area, user boot area, and data area. Calculation is by simple addition. The initial value is 0 and the sum of values in the specified area is obtained by adding the values of all bytes.

If this command is issued for a data area that includes erased blocks, the result is undefined. When a simple addition checksum is to be executed for the data area, make sure that data have been written throughout the specified area.

This command can only be accepted in the command waiting phase.

#### (1) Command packet structure

## 44.9.42 Usage Example

### (1) Example of the Procedure for Reprogramming

Figure 44.43 shows an example of the procedure for reprogramming.

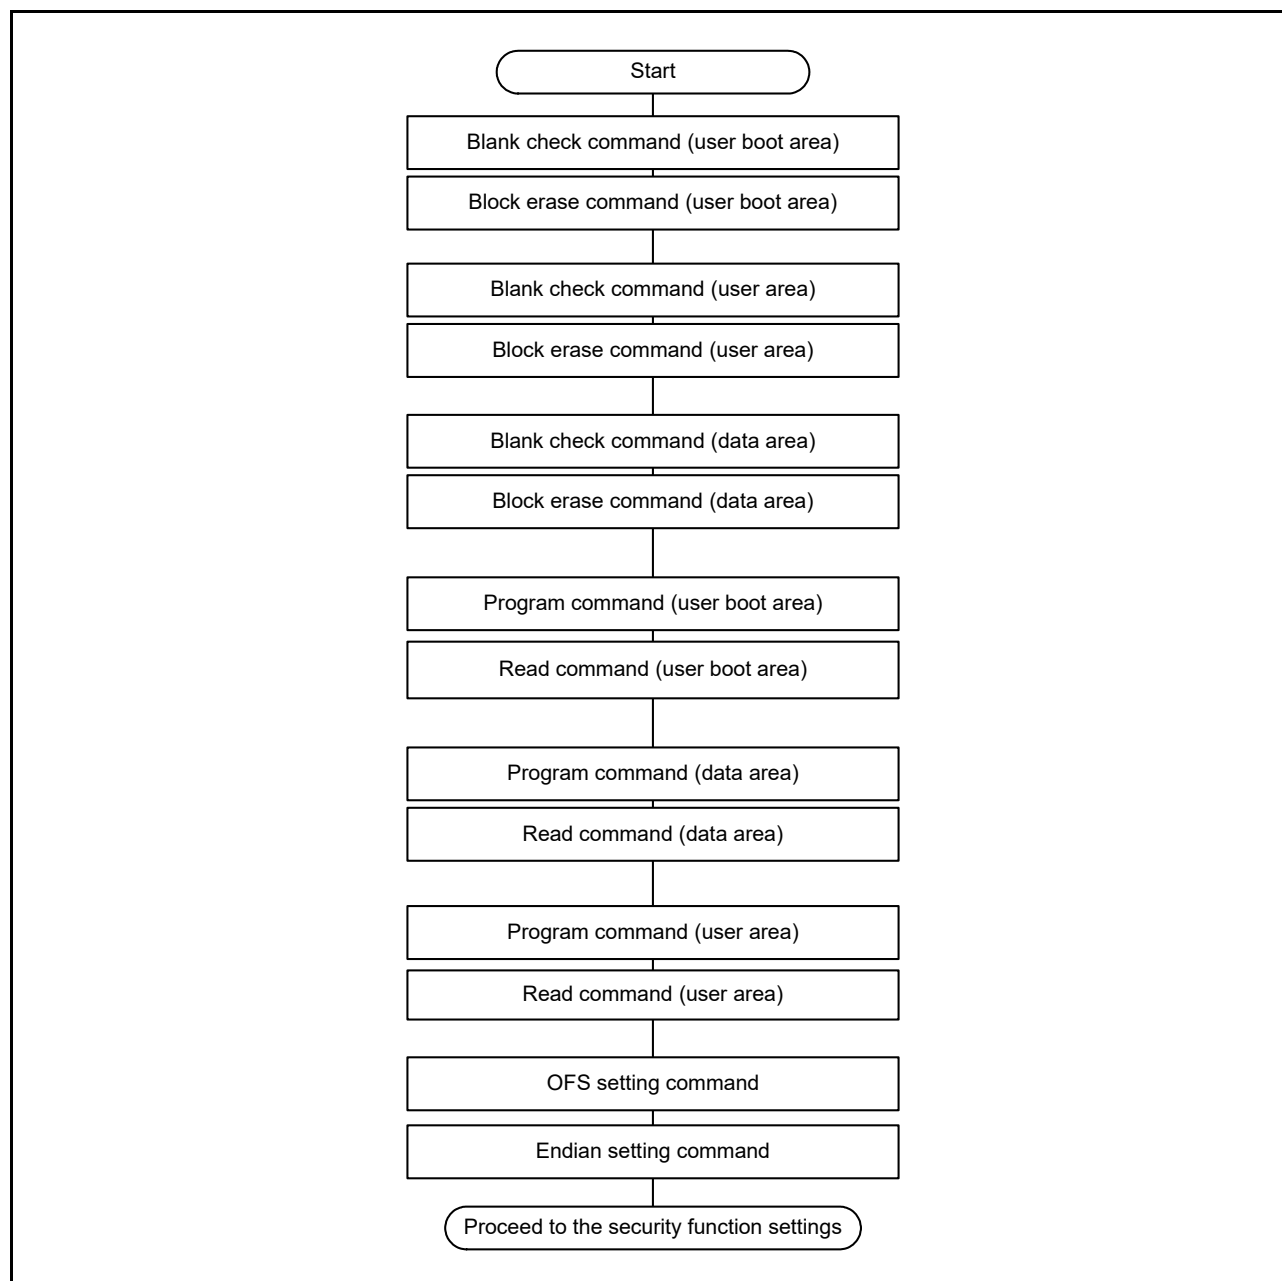

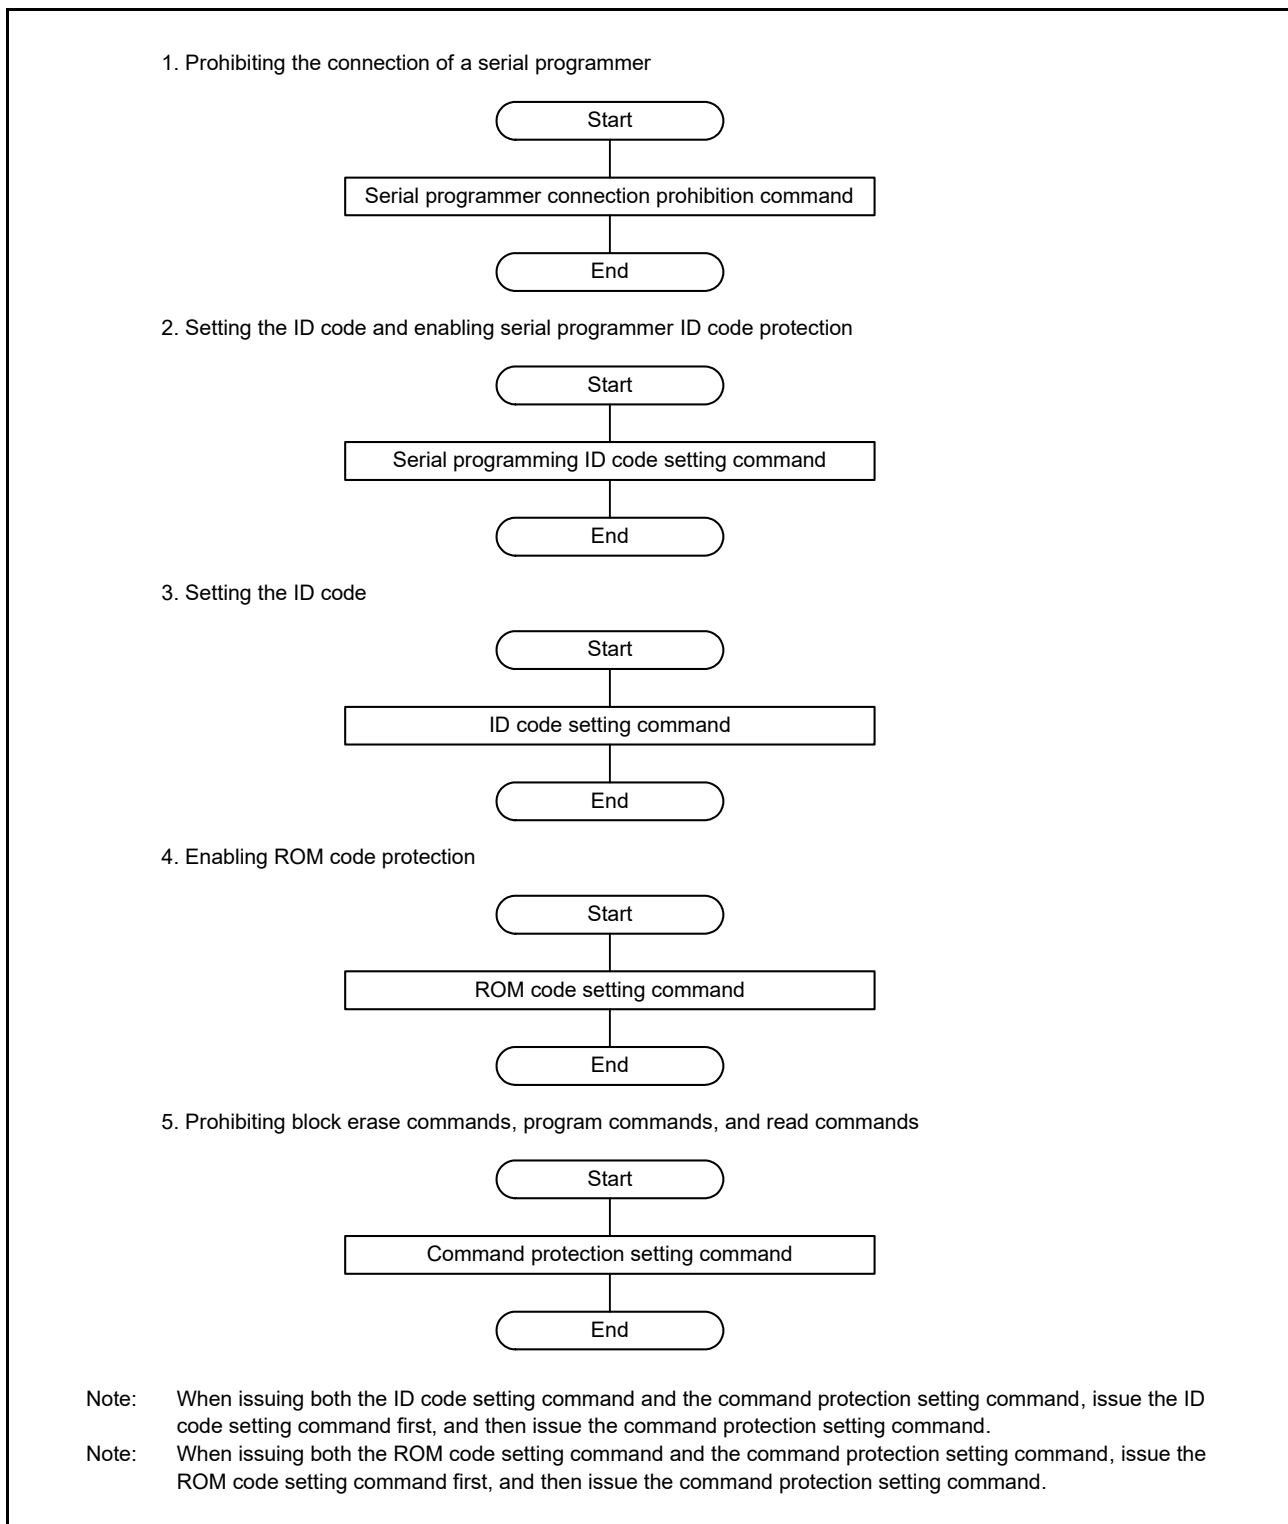

Figure 44.43 Example of Reprogramming Procedure

## (2) Security Function Settings

When the security functions are to be used, follow the procedure below to set the required security functions.

**Figure 44.44 Settings for Use of the Security Functions**

### 44.9.43 Flow for Erasure when Prohibition of Program Commands is Enabled

When prohibition of program commands is enabled, follow the procedure below for erasure.

1. Erase the user boot area.
2. Erase the data area in order from the first block.
3. Erase the user area in order from the last block.

Note that neither a reset nor interrupts, including NMI, should be applied during the steps from erasure of the user boot area to erasure of the user area.

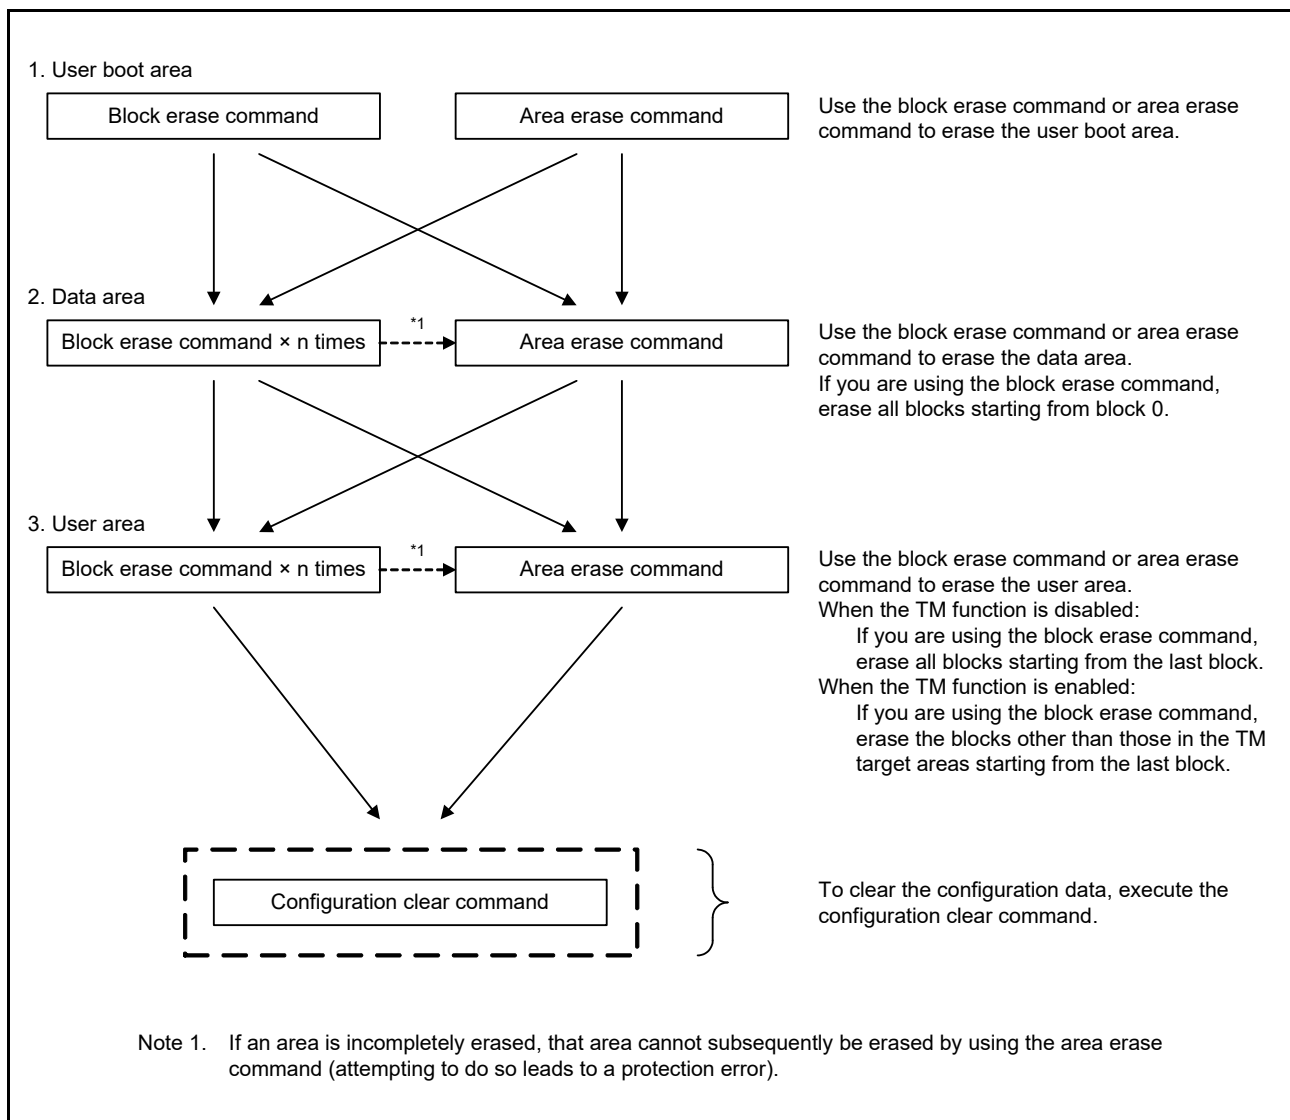

Figure 44.45 Flow for Erasure when Prohibition of Program Commands is Enabled

### 44.10 Using the Serial Programmer for Rewriting

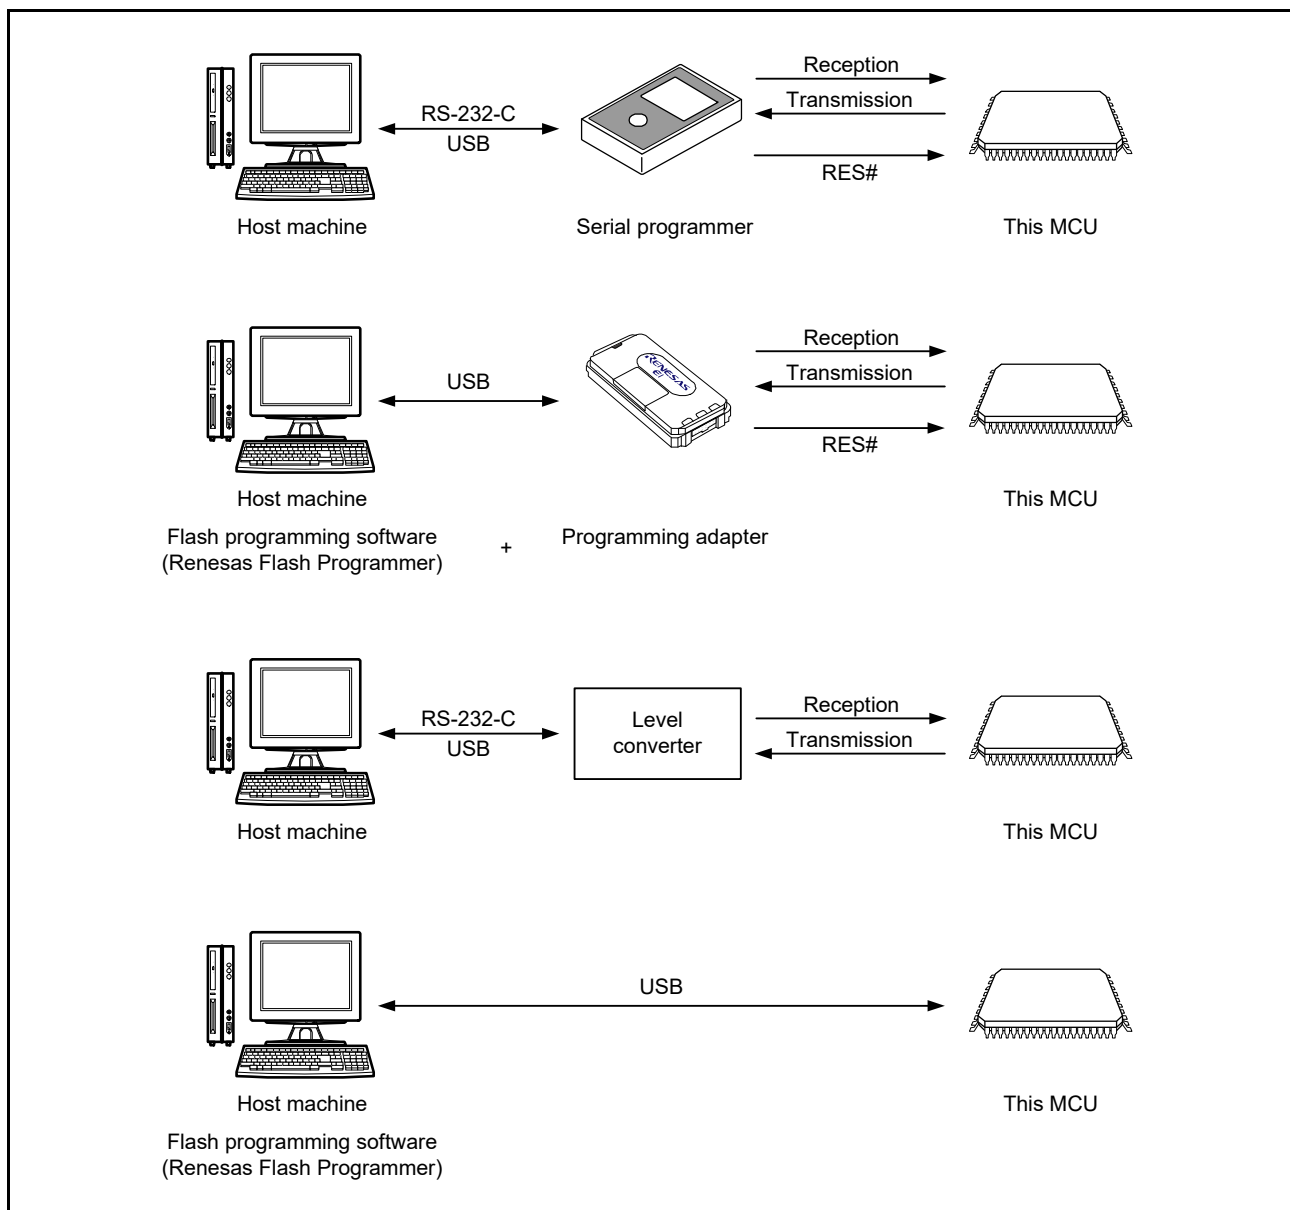

A dedicated serial programmer can be used to rewrite flash memory in boot mode.

#### (1) Serial Programming

By providing a connector on the board, it is possible to program the MCU with a serial programmer while the MCU is mounted on the board.

#### 44.10.1 Environments for Serial Programming

The recommended environments for rewriting the flash memory of the MCU are described below.

**Figure 44.46** Environments for Rewriting the Flash Memory

Note: For details of the serial programmers, refer to the manual of each serial programmer; for details of the Renesas Flash Programmer flash programming software, refer to the Renesas Flash Programmer Flash Programming Software User's Manual.

## 44.11 Programming through Self-Programming

### 44.11.1 Overview

This MCU supports programming of the flash memory by the user program itself. The FACL commands can be used with user programs for writing to the user area and data area. This allows upgrading of user programs and rewriting of constant data fields.

When the data area is programmed, the background operation facility makes it possible to execute a rewriting program from the user area to program the data area. Furthermore, the rewriting program can be copied to internal RAM or external memory in advance of the programming operation, and executed from the given destination to program the data area.

Also, the rewriting program can be copied to internal RAM or external memory in advance of the programming operation, and executed from the given destination to program the user area.

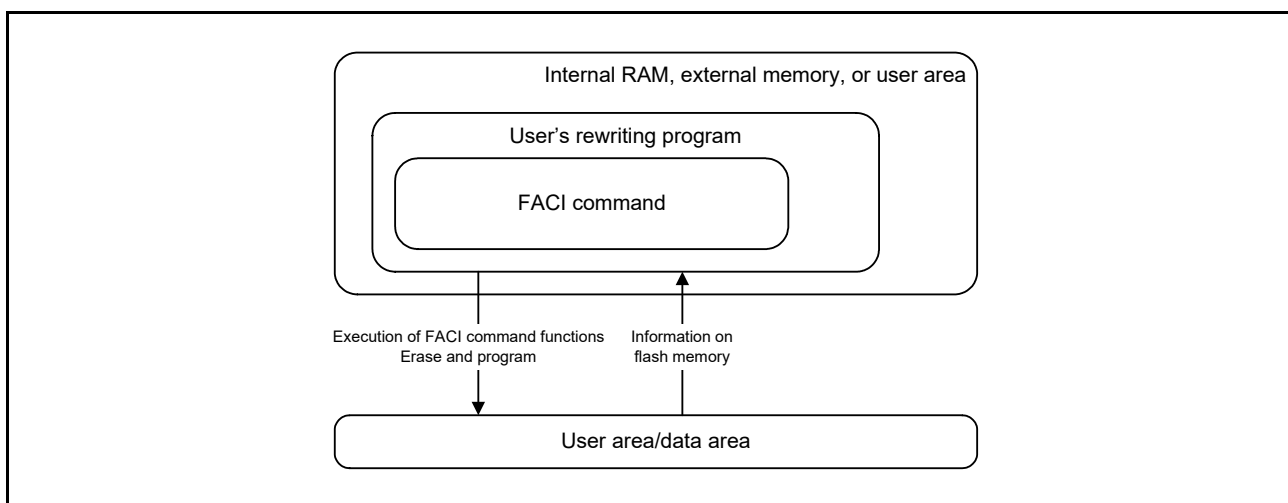

Figure 44.47 Schematic View of Self-Programming

## 44.12 Usage Notes

### 44.12.1 Reading Area Where Program or Erase Operation was Aborted or Suspended

The data stored in the area where program or erase operation has been aborted or suspended are undefined. To avoid malfunctions caused by reading undefined data, take care not to fetch instructions or read data from the area where program or erase operation was aborted or suspended.

### 44.12.2 Suspension During Programming/Erasure

When processing of programming/erasure is interrupted by issuing the P/E suspend command, the programming/erasure processing can be resumed by issuing the P/E resume command. If the flash sequencer enters the command-locked state for any reason and issues the forced stop command after the suspended processing is normally completed and the ERSSPD flag or PRGSPD flag is set to 1, the suspended processing cannot be resumed. In addition, the values in the area where the processing was suspended are not guaranteed. Erase that area.

### 44.12.3 Prohibition of Additional Programming

Programming to the user area, user boot area, or data area twice is not possible. To program user area, user boot area, or data area which has already been programmed, erase the relevant area.

### 44.12.4 Resets During Programming/Erasure or Blank Checking

In the case of a reset due to the signal on the RES# pin during programming/erasure or blank checking, wait for at least  $t_{RESWF}$  (refer to section 45, Electrical Characteristics) of the reset input period once the operating voltage is within the range stipulated in the electrical characteristics after assertion of the reset signal, and then release the device from the reset state.

### 44.12.5 Allocation of Vectors for Interrupts and Other Exceptions During Programming/Erasure

Generation of an interrupt or other exception during programming/erasure may lead to fetching of the vector from the code flash memory. If the conditions for using the background operation (BGO) are not satisfied, set the address for vector to an address that is not in the code flash memory.

### 44.12.6 Abnormal Termination During Programming/Erasure or Blank Checking

Even if programming/erasure ends abnormally due to the generation of a reset by the RES# pin, the programming/erasure state of the flash memory with undefined data cannot be verified or checked. For the area where programming/erasure ends abnormally, the blank check function cannot judge whether the area is erased successfully or not. Erase the area again and confirm that the corresponding area is completely erased before using.

When programming/erasure or blank checking is not completed successfully due to a voltage change that exceeds the operational voltage range, a reset on the RES# pin, the command-locked state in response to error detection, or prohibited actions described in 44.12.7, the lock bit may be enabled.

In this case, erase the target block while the lock bit is disabled to erase the lock bit.

### 44.12.7 Items Prohibited During Programming/Erasure or Blank Checking

High voltage is applied to the flash memory during programming/erasure or blank checking. To prevent damage to the flash memory, do not perform the following operations.

- Have the operating voltage from the power supply go beyond the permitted range.
- Change the FWEPROR.FLWE[1:0] bits.
- Change the SYSCR0.ROME bit.
- Change the SCKCR.FCK[3:0] and PCLKB[3:0] bits.
- Change the SCKCR3.CKSEL[2:0] bits.

- Change the RSTCKCR.RSTCKEN bit.
- Transition to the all module clock stop mode, software standby mode, or deep software standby mode.

#### 44.12.8 Notes on Program Execution in Boot Mode (USB Interface)

- An oscillator is usable in boot mode (USB interface) when its frequency is 20 or 24 MHz and when the setting value of the main clock oscillator driving ability 2 switching bits (MOFCR.MODRV2[1:0]) are 00b in the result of the matching test conducted by the oscillator manufacturer (the recommended setting value).
- To ensure that the power supply is stable during programming/erasure of flash memory, do not connect a cable via a bus-powered HUB.

## 45. Electrical Characteristics

### 45.1 Absolute Maximum Ratings

**Table 45.1 Absolute Maximum Rating**

Conditions:  $V_{SS} = V_{SS\_USB} = AV_{SS0} = AV_{SS1} = AV_{SS2} = 0V$

| Item                          |                                         | Symbol                           | Value        | Unit                              |
|-------------------------------|-----------------------------------------|----------------------------------|--------------|-----------------------------------|
| Power supply voltage*1        |                                         | VCC                              | -0.3 to +6.5 | V                                 |
| USB power supply voltage*1    |                                         | VCC_USB                          | -0.3 to +6.5 |                                   |

|                               | Other than above                        |                                  |              | -0.3 to VCC + 0.3 (up to 6.5)     |
| Junction temperature          | D version                               | $T_j$                            |              | -40 to +105                       |
|                               | G version                               |                                  | -40 to +125  |                                   |
| Storage temperature           |                                         | $T_{stg}$                        | -55 to +125  |                                   |

Caution: Permanent damage to the LSI may result if absolute maximum ratings are exceeded.

Note 1. Insert capacitors with good frequency characteristics between each power supply pin and the ground. Specifically, place capacitors with a value around 0.1  $\mu F$  as close as possible to every power supply pin, and use the shortest and thickest possible traces.

Note 2. This is only available for products with 128 Kbytes of RAM.

Note 3. When VOLS.R.PGAVLS = 0 and ADPGADCR0.PxDEN = 1 (x = 000, 001, 002, 100, 101, 102).

## 45.2 Recommended operating conditions

**Table 45.2 Recommended operating conditions (1)**

| Item                          |                                      | Symbol                        | Min.            | Typ. | Max. | Unit          |  |

|                               | PH0, PH4                             | With negative input enabled*5 |                 | -0.5 | —    | AVCC1 + 0.3   |  |
|                               |                                      | With negative input disabled  |                 | -0.3 | —    |               |  |
|                               | P43, P47, PH1 to PH3, and PH5 to PH7 |                               |                 | -0.3 | —    | AVCC1 + 0.3   |  |
|                               | P50 to P55, and P60 to P65           |                               |                 | -0.3 | —    | AVCC2 + 0.3   |  |
|                               | USB0_DP, USB0_DM                     |                               |                 | -0.3 | —    | VCC_USB + 0.3 |  |
|                               | Other than above                     |                               |                 | -0.3 | —    | VCC + 0.3     |  |
| Operating temperature         | D version                            | T <sub>opr</sub>              | -40             | —    | 85   | °C            |  |
|                               | G version                            |                               | -40             | —    | 105  |               |  |

Note 1. Comply with the following voltage condition:  $VCC\_USB \leq VCC \leq AVCC0 = AVCC1 = AVCC2$

Note 2. When the USB interface is not to be used, connect VCC\_USB to VCC and VSS\_USB to VSS, and set VOLSRS.USBVON=0.

Note 3. When not using any of the 12-bit A/D converter (unit 0 to 2), 12-bit D/A converter, comparator C, or temperature sensor, connect AVCC0, AVCC1, and AVCC2 to VCC, and AVSS0, AVSS1, and AVSS2 to VSS, respectively. For details, refer to section 38.6.10, Voltage Range of Analog Power Supply Pins.

Note 4. This is only available for products with 128 Kbytes of RAM.

Note 5. When VOLSRS.PGAVLS = 0 and ADPGADCR0.PxDEN = 1 (x = 000, 001, 002, 100, 101, 102).

**Table 45.3 Recommended operating conditions (2)**

| Item                                                        | Symbol           | Value           |
|-------------------------------------------------------------|------------------|-----------------|
| Decoupling capacitance for stabilizing the internal voltage | C <sub>VCL</sub> | 0.47 μF ± 30%*1 |

Note 1. Use a multilayer ceramic capacitor with a nominal capacitance of 0.47 μF, for which the sum of the capacitance tolerance and change in the capacitance under the usage conditions will be no greater than ±30%.

## 45.3 DC Characteristics

**Table 45.4 DC Characteristics (1)**

Conditions:  $V_{CC} = 2.7$  to  $5.5$  V,  $V_{CC\_USB} = 2.7$  to  $5.5$  V,  $AV_{CC0} = AV_{CC1} = AV_{CC2} = 3.0$  to  $5.5$  V,  
 $V_{SS} = V_{SS\_USB} = AV_{SS0} = AV_{SS1} = AV_{SS2} = 0$  V,  
 $T_a = T_{opr}$

|                  |               | —                          | 14                                              | 20                                                  | $\mu$ A | VOLSR.PGAVLS = 1 |                                                                                                                                                |     |

Note 1. Supply current values are measured when all output pins are unloaded and all input pull-up resistors are disabled.

Note 2. Peripheral module clocks are supplied. This does not include operations as BGO (background operations).

Note 3.  $I_{CC}$  depends on  $f$  (ICLK) as follows.  
 (when ICLK : PCLKA : PCLKB : PCLKC : PCLKD : BCLK : BCLK pin = 4 : 2 : 1 : 4 : 1 : 1 : 1 and EXTAL = 16 MHz)  
 • D version product

$I_{CC}$  Max. =  $0.375 \times f + 15$  (full operation in normal operating mode)

$I_{CC}$  Typ. =  $0.099 \times f + 5$  (normal operation in normal operating mode)

$I_{CC}$  Max. =  $0.135 \times f + 15$  (sleep mode)

Note 4. This does not include operations as BGO (background operations). Whether the peripheral module clocks are supplied or stopped is controlled only by the bit settings in the module stop control registers A to D.

Note 5. When peripheral module clocks are stopped, each clock frequency is set for division by 64, and the frequencies of FCLK, BCLK, PCLKA, PCLKB, PCLKC, PCLKD, and the BCLK pin are the same.

Note 6. This is an increase caused by program/erase operation to the code flash memory or data flash memory during executing the user program.

|                       | Increase current by operating Trusted Secure IP     |                                            |               | —         | 3.9  | 5.3  |                  |                                                                                                                                                |
|                       | Software standby mode                               |                                            |               | —         | 0.9  | 13.9 |                  |                                                                                                                                                |
|                       | Deep software standby mode                          |                                            |               | —         | 15   | 21   | VOLSR.PGAVLS = 1 |                                                                                                                                                |

Note 1. Supply current values are measured when all output pins are unloaded and all input pull-up resistors are disabled.

Note 2. Peripheral module clocks are supplied. This does not include operations as BGO (background operations).

Note 3.  $I_{CC}$  depends on  $f$  (ICLK) as follows.

(when ICLK : PCLKA : PCLKB : PCLKC : PCLKD : BCLK : BCLK pin = 4 : 2 : 1 : 4 : 1 : 1 : 1 and EXTAL = 16 MHz)

• D version product

$I_{CC}$  Max. =  $0.469 \times f + 21$  (full operation in normal operating mode)

$I_{CC}$  Typ. =  $0.112 \times f + 5$  (normal operation in normal operating mode)

$I_{CC}$  Max. =  $0.15 \times f + 21$  (sleep mode)

Note 4. This does not include operations as BGO (background operations). Whether the peripheral module clocks are supplied or stopped is controlled only by the bit settings in the module stop control registers A to D.

Note 5. When peripheral module clocks are stopped, each clock frequency is set for division by 64, and the frequencies of FCLK, BCLK, PCLKA, PCLKB, PCLKC, PCLKD, and the BCLK pin are the same.

Note 6. This is an increase caused by program/erase operation to the code flash memory or data flash memory during executing the user program.

Caution: To protect the LSI's reliability, the output current values should not exceed the values in this table.

Note 1. This is the value when normal driving ability is set with a pin for which normal driving ability is selectable.

Note 2. This is the value when high driving ability is set with a pin for which normal driving ability is selectable or the value of the pin to which high driving ability is fixed.

Note 3. This is the value when large current output is set with a pin for which large current output ability is selectable.

**Table 45.13 Standard Output Characteristics (1)**

Conditions:  $V_{CC} = AV_{CC0} = AV_{CC1} = AV_{CC2} = 5.0\text{ V}$ ,  $V_{CC\_USB} = 2.7\text{ to }5.5\text{ V}$ ,  
 $V_{SS} = V_{SS\_USB} = AV_{SS0} = AV_{SS1} = AV_{SS2} = 0\text{ V}$ ,  $T_a = 25^\circ\text{C}$

| Main clock oscillator stabilization time (crystal)      | $t_{MAINOSC}$   | —    | —    | —*1  | ms   |                 |
| Main clock oscillator stabilization wait time (crystal) | $t_{MAINOSCWT}$ | —    | —    | —*2  |      |                 |

Note 1. When using a main clock, ask the manufacturer of the oscillator to evaluate its oscillation. Refer to the results of evaluation provided by the manufacturer for the oscillation stabilization time.

Note 2. The number of cycles selected by the value of the MOSCWTCR.MSTS[7:0] bits determines the main clock oscillation stabilization wait time in accord with the formula below.

$$t_{MAINOSCWT} = [(MSTS[7:0] \text{ bits} \times 32) + 7] / f_{LOCO}$$

|                                                             | Low-speed on-chip oscillator operating*4             | t <sub>SBYLO</sub>                                                |                    |      |      | 338                                                    | $100 + 7 / f_{I\text{CLK}} + 2n / f_{\text{LOCO}}$   |      |                 |

Note 1. The time for return after release from software standby is determined by the value obtained by adding the oscillation stabilization waiting time (t<sub>SBYOSCWT</sub>) and the time required for operations by the software standby release sequencer (t<sub>SBYSEQ</sub>).

Note 2. When several oscillators were running before the transition to software standby, the greatest value of the oscillation stabilization waiting time t<sub>SBYOSCWT</sub> is selected.

Note 3. For n, the greatest value is selected from among the internal clock division settings.

Note 4. This condition applies when f<sub>ICLK</sub> : f<sub>FCLK</sub> = 1 : 1, 2 : 1, or 4 : 1.

|                                   | SCL, SDA capacitive load                | C <sub>b</sub>    | —                                       | 400                        | pF   |                      |

Note: t<sub>IICcyc</sub>: RIIC internal reference clock (IICφ) cycle

Note 1. The value within parentheses is applicable when the value of the ICMR3.NF[1:0] bits is 11b while the digital filter is enabled by the setting ICFER.NFE = 1.

Note 2. C<sub>b</sub> is the total capacitance of the bus lines.

Note 3. When VCC ≥ 4.5V, VOLSR.RICVLS = 0  
When VCC < 4.5V, VOLSR.RICVLS = 1

Note: The above specification values apply when there is no access to the external bus during A/D conversion. If access proceeds during A/D conversion, values may not fall within the above ranges.

Note 1. When PCLKD was higher than 40 MHz, capacitors with the following values were placed in parallel with the 0.1- $\mu$ F capacitors between  $AV_{CC0}$  and  $AV_{SS0}$ ,  $AV_{CC1}$  and  $AV_{SS1}$ , and  $AV_{CC2}$  and  $AV_{SS2}$  for measurement of the A/D conversion characteristics.

- Products with 64 Kbytes of RAM: 1000 pF
- Products with 128 Kbytes of RAM: 0.01  $\mu$ F

Note 2. The conversion time is the sum of the sampling time and the comparison time. The numbers of sampling-clock cycles are indicated as the test conditions.

**Table 45.47 12-Bit A/D (Unit 0, 1, 2) Conversion Characteristics (2)**

Conditions:  $V_{CC} = 2.7$  to  $4.5$  V,  $V_{CC\_USB} = 2.7$  to  $4.5$  V,  $3.0$  V  $\leq AV_{CC0} = AV_{CC1} = AV_{CC2} < 4.5$  V,  
 $V_{SS} = V_{SS\_USB} = AV_{SS0} = AV_{SS1} = AV_{SS2} = 0$  V,  $T_a = T_{opr}$ ,  $PCLKB = PCLKD = 8$  to  $40$  MHz,  
 Source impedance =  $1.0$  k $\Omega$

Note: The above specification values apply when there is no access to the external bus during A/D conversion. If access proceeds during A/D conversion, values may not fall within the above ranges.

Note 1. The conversion time is the sum of the sampling time and the comparison time. The numbers of sampling-clock cycles are indicated as the test conditions.

**Table 45.48 A/D Internal Reference Voltage Characteristics**

Conditions:  $VCC = 2.7$  to  $5.5$  V,  $VCC\_USB = 2.7$  to  $5.5$  V,  $AVCC0 = AVCC1 = AVCC2 = 3.0$  to  $5.5$  V,  
 $VSS = VSS\_USB = AVSS0 = AVSS1 = AVSS2 = 0$  V,  $T_a = T_{opr}$ ,  $PCLKB = PCLKD = 8$  to  $60$  MHz

| Item                           | Min. | Typ. | Max. | Unit | Test Conditions |
|--------------------------------|------|------|------|------|-----------------|
| A/D internal reference voltage | 1.20 | 1.25 | 1.30 | V    |                 |

Note: The above specification values apply during normal operations.

## 45.7 Programmable Gain Amplifier Characteristics

**Table 45.49 Programmable Gain Amplifier Characteristics (single-ended input)**

Conditions:  $V_{CC} = 2.7$  to  $5.5$  V,  $V_{CC\_USB} = 2.7$  to  $5.5$  V,  $AVCC0 = AVCC1 = AVCC2 = 3.0$  to  $5.5$  V,  
 $V_{SS} = V_{SS\_USB} = AVSS0 = AVSS1 = AVSS2 = 0$  V,  $T_a = T_{opr}$

Note 1. Definition of program/erase cycle:

The program/erase cycle is the number of erasing for each block. When the number of program/erase cycles is n, each block can be erased n times. For instance, when 256-byte program is performed 32 times for different addresses in 8-Kbyte block and then the block is erased, the program/erase cycle is counted as one. However, the same address cannot be programmed more than once before the next erase cycle (overwriting is prohibited).

Note 2. Characteristics are degraded as the number of program/erase increases. This is the minimum value of program/erase cycles to guarantee all characteristics listed in this table.

Note 3. This shows the characteristic when the flash memory writer or self-programming library from Renesas Electronics is in use, and the number of times programming and erasure proceed does not exceed the specified value.

Note 4. These values are based on the results of reliability testing.

**Table 45.57 Data Flash Memory Characteristics**

Note 1. Definition of program/erase cycle:

The program/erase cycle is the number of erasing for each block. When the number of program/erase cycles is n, each block can be erased n times. For instance, when 4-byte program is performed 512 times for different addresses in 2-Kbyte block and then the block is erased, the program/erase cycle is counted as one. However, the same address cannot be programmed more than once before the next erase cycle (overwriting is prohibited).

Note 2. Characteristics are degraded as the number of program/erase increases. This is the minimum value of program/erase cycles to guarantee all characteristics listed in this table.

Note 3. This shows the characteristic when the flash memory writer or self-programming library from Renesas Electronics is in use, and the number of times programming and erasure proceed does not exceed the specified value.

Note 4. These values are based on the results of reliability testing.

| USB0_DP                                     | All                                                     | Hi-Z  | Keep-O <sup>4</sup>                                                    |         | Hi-Z                                          | Hi-Z                                                                         |            |

H: High-level

L: Low-level

Keep-O: Output pins retain their previous values, and input pins become high-impedance. If the input pull-up resistor control register is enabled, the input pull-up resistor is retained as the enabling state.

Keep: Pin states are retained during periods on software standby.

Hi-Z: High-impedance

Note 1. The I/O port state is retained until the DPSBYCR.IOKEEP bit is cleared to 0.

Note 2. Input is enabled if the pin is specified as the software standby cancelling source while it is used as an external interrupt pin.

Note 3. Input is enabled if the pin is specified as the deep software standby cancelling source.

Note 4. Input is enabled while the pin is used as an input pin.

Note 5. This is only available for products with 128 Kbytes of RAM.

Note 6. Products without pseudo-differential input do not have the corresponding pins.

Note 7. When VOLSR.PGAVLS = 0, the internal pull-up resistors are enabled.

In software standby mode or deep software standby mode, when a voltage higher than 0 V is applied to all pins from P40 to P42, PH0 (only present on products with pseudo-differential input), P44 to P46, and PH4 (only present on products with pseudo-differential input) or they are made open-circuit, the internal pull-up resistors can be disabled by setting VOLSR.PGAVLS = 1.

## Appendix 2. Package Dimensions

Information on the latest version of the package dimensions or mountings has been displayed in “Packages” on Renesas Electronics Corporation website.

Figure A 144-Pin LFQFP (PLQP0144KA-B)

| JEITA Package Code   | RENESAS Code | Previous Code | MASS (Typ) [g] |
|----------------------|--------------|---------------|----------------|
| P-LQFP112-20x20-0.65 | PLQP0112JA-B | —             | 1.2            |

- NOTE)
1. DIMENSIONS "\*\*1" AND "\*\*2" DO NOT INCLUDE MOLD FLASH.
  2. DIMENSION "\*\*3" DOES NOT INCLUDE TRIM OFFSET.
  3. PIN 1 VISUAL INDEX FEATURE MAY VARY, BUT MUST BE LOCATED WITHIN THE HATCHED AREA.
  4. CHAMFERS AT CORNERS ARE OPTIONAL, SIZE MAY VARY.
