User's Manual: Hardware

RENESAS 32-Bit MCU  
RX Family/RX600 Series

All information contained in these materials, including products and product specifications, represents information on the product at the time of publication and is subject to change by Renesas Electronics Corp. without notice. Please review the latest information published by Renesas Electronics Corp. through various means, including the Renesas Electronics Corp. website (<http://www.renesas.com>).

## Notice

1. Descriptions of circuits, software and other related information in this document are provided only to illustrate the operation of semiconductor products and application examples. You are fully responsible for the incorporation or any other use of the circuits, software, and information in the design of your product or system. Renesas Electronics disclaims any and all liability for any losses and damages incurred by you or third parties arising from the use of these circuits, software, or information.
2. Renesas Electronics hereby expressly disclaims any warranties against and liability for infringement or any other claims involving patents, copyrights, or other intellectual property rights of third parties, by or arising from the use of Renesas Electronics products or technical information described in this document, including but not limited to, the product data, drawings, charts, programs, algorithms, and application examples.
3. No license, express, implied or otherwise, is granted hereby under any patents, copyrights or other intellectual property rights of Renesas Electronics or others.
4. You shall be responsible for determining what licenses are required from any third parties, and obtaining such licenses for the lawful import, export, manufacture, sales, utilization, distribution or other disposal of any products incorporating Renesas Electronics products, if required.
5. You shall not alter, modify, copy, or reverse engineer any Renesas Electronics product, whether in whole or in part. Renesas Electronics disclaims any and all liability for any losses or damages incurred by you or third parties arising from such alteration, modification, copying or reverse engineering.
6. Renesas Electronics products are classified according to the following two quality grades: "Standard" and "High Quality". The intended applications for each Renesas Electronics product depends on the product's quality grade, as indicated below.

"Standard": Computers; office equipment; communications equipment; test and measurement equipment; audio and visual equipment; home electronic appliances; machine tools; personal electronic equipment; industrial robots; etc.

"High Quality": Transportation equipment (automobiles, trains, ships, etc.); traffic control (traffic lights); large-scale communication equipment; key financial terminal systems; safety control equipment; etc.

Unless expressly designated as a high reliability product or a product for harsh environments in a Renesas Electronics data sheet or other Renesas Electronics document, Renesas Electronics products are not intended or authorized for use in products or systems that may pose a direct threat to human life or bodily injury (artificial life support devices or systems; surgical implantations; etc.), or may cause serious property damage (space system; undersea repeaters; nuclear power control systems; aircraft control systems; key plant systems; military equipment; etc.). Renesas Electronics disclaims any and all liability for any damages or losses incurred by you or any third parties arising from the use of any Renesas Electronics product that is inconsistent with any Renesas Electronics data sheet, user's manual or other Renesas Electronics document.

7. No semiconductor product is absolutely secure. Notwithstanding any security measures or features that may be implemented in Renesas Electronics hardware or software products, Renesas Electronics shall have absolutely no liability arising out of any vulnerability or security breach, including but not limited to any unauthorized access to or use of a Renesas Electronics product or a system that uses a Renesas Electronics product. RENESAS ELECTRONICS DOES NOT WARRANT OR GUARANTEE THAT RENESAS ELECTRONICS PRODUCTS, OR ANY SYSTEMS CREATED USING RENESAS ELECTRONICS PRODUCTS WILL BE INVULNERABLE OR FREE FROM CORRUPTION, ATTACK, VIRUSES, INTERFERENCE, HACKING, DATA LOSS OR THEFT, OR OTHER SECURITY INTRUSION ("Vulnerability Issues"). RENESAS ELECTRONICS DISCLAIMS ANY AND ALL RESPONSIBILITY OR LIABILITY ARISING FROM OR RELATED TO ANY VULNERABILITY ISSUES. FURTHERMORE, TO THE EXTENT PERMITTED BY APPLICABLE LAW, RENESAS ELECTRONICS DISCLAIMS ANY AND ALL WARRANTIES, EXPRESS OR IMPLIED, WITH RESPECT TO THIS DOCUMENT AND ANY RELATED OR ACCOMPANYING SOFTWARE OR HARDWARE, INCLUDING BUT NOT LIMITED TO THE IMPLIED WARRANTIES OF MERCHANTABILITY, OR FITNESS FOR A PARTICULAR PURPOSE.
8. When using Renesas Electronics products, refer to the latest product information (data sheets, user's manuals, application notes, "General Notes for Handling and Using Semiconductor Devices" in the reliability handbook, etc.), and ensure that usage conditions are within the ranges specified by Renesas Electronics with respect to maximum ratings, operating power supply voltage range, heat dissipation characteristics, installation, etc. Renesas Electronics disclaims any and all liability for any malfunctions, failure or accident arising out of the use of Renesas Electronics products outside of such specified ranges.
9. Although Renesas Electronics endeavors to improve the quality and reliability of Renesas Electronics products, semiconductor products have specific characteristics, such as the occurrence of failure at a certain rate and malfunctions under certain use conditions. Unless designated as a high reliability product or a product for harsh environments in a Renesas Electronics data sheet or other Renesas Electronics document, Renesas Electronics products are not subject to radiation resistance design. You are responsible for implementing safety measures to guard against the possibility of bodily injury, injury or damage caused by fire, and/or danger to the public in the event of a failure or malfunction of Renesas Electronics products, such as safety design for hardware and software, including but not limited to redundancy, fire control and malfunction prevention, appropriate treatment for aging degradation or any other appropriate measures. Because the evaluation of microcomputer software alone is very difficult and impractical, you are responsible for evaluating the safety of the final products or systems manufactured by you.
10. Please contact a Renesas Electronics sales office for details as to environmental matters such as the environmental compatibility of each Renesas Electronics product. You are responsible for carefully and sufficiently investigating applicable laws and regulations that regulate the inclusion or use of controlled substances, including without limitation, the EU RoHS Directive, and using Renesas Electronics products in compliance with all these applicable laws and regulations. Renesas Electronics disclaims any and all liability for damages or losses occurring as a result of your noncompliance with applicable laws and regulations.
11. Renesas Electronics products and technologies shall not be used for or incorporated into any products or systems whose manufacture, use, or sale is prohibited under any applicable domestic or foreign laws or regulations. You shall comply with any applicable export control laws and regulations promulgated and administered by the governments of any countries asserting jurisdiction over the parties or transactions.
12. It is the responsibility of the buyer or distributor of Renesas Electronics products, or any other party who distributes, disposes of, or otherwise sells or transfers the product to a third party, to notify such third party in advance of the contents and conditions set forth in this document.
13. This document shall not be reprinted, reproduced or duplicated in any form, in whole or in part, without prior written consent of Renesas Electronics.
14. Please contact a Renesas Electronics sales office if you have any questions regarding the information contained in this document or Renesas Electronics products.

(Note1) "Renesas Electronics" as used in this document means Renesas Electronics Corporation and also includes its directly or indirectly controlled subsidiaries.

(Note2) "Renesas Electronics product(s)" means any product developed or manufactured by or for Renesas Electronics.

## General Precautions in the Handling of Microprocessing Unit and Microcontroller Unit Products

The following usage notes are applicable to all Microprocessing unit and Microcontroller unit products from Renesas. For detailed usage notes on the products covered by this document, refer to the relevant sections of the document as well as any technical updates that have been issued for the products.

### 1. Precaution against Electrostatic Discharge (ESD)

A strong electrical field, when exposed to a CMOS device, can cause destruction of the gate oxide and ultimately degrade the device operation. Steps must be taken to stop the generation of static electricity as much as possible, and quickly dissipate it when it occurs. Environmental control must be adequate. When it is dry, a humidifier should be used. This is recommended to avoid using insulators that can easily build up static electricity. Semiconductor devices must be stored and transported in an anti-static container, static shielding bag or conductive material. All test and measurement tools including work benches and floors must be grounded. The operator must also be grounded using a wrist strap. Semiconductor devices must not be touched with bare hands. Similar precautions must be taken for printed circuit boards with mounted semiconductor devices.

### 2. Processing at power-on

The state of the product is undefined at the time when power is supplied. The states of internal circuits in the LSI are indeterminate and the states of register settings and pins are undefined at the time when power is supplied. In a finished product where the reset signal is applied to the external reset pin, the states of pins are not guaranteed from the time when power is supplied until the reset process is completed. In a similar way, the states of pins in a product that is reset by an on-chip power-on reset function are not guaranteed from the time when power is supplied until the power reaches the level at which resetting is specified.

### 3. Input of signal during power-off state

Do not input signals or an I/O pull-up power supply while the device is powered off. The current injection that results from input of such a signal or I/O pull-up power supply may cause malfunction and the abnormal current that passes in the device at this time may cause degradation of internal elements. Follow the guideline for input signal during power-off state as described in your product documentation.

### 4. Handling of unused pins

Handle unused pins in accordance with the directions given under handling of unused pins in the manual. The input pins of CMOS products are generally in the high-impedance state. In operation with an unused pin in the open-circuit state, extra electromagnetic noise is induced in the vicinity of the LSI, an associated shoot-through current flows internally, and malfunctions occur due to the false recognition of the pin state as an input signal become possible.

### 5. Clock signals

After applying a reset, only release the reset line after the operating clock signal becomes stable. When switching the clock signal during program execution, wait until the target clock signal is stabilized. When the clock signal is generated with an external resonator or from an external oscillator during a reset, ensure that the reset line is only released after full stabilization of the clock signal. Additionally, when switching to a clock signal produced with an external resonator or by an external oscillator while program execution is in progress, wait until the target clock signal is stable.

### 6. Voltage application waveform at input pin

Waveform distortion due to input noise or a reflected wave may cause malfunction. If the input of the CMOS device stays in the area between  $V_{IL}$  (Max.) and  $V_{IH}$  (Min.) due to noise, for example, the device may malfunction. Take care to prevent chattering noise from entering the device when the input level is fixed, and also in the transition period when the input level passes through the area between  $V_{IL}$  (Max.) and  $V_{IH}$  (Min.).

### 7. Prohibition of access to reserved addresses

Access to reserved addresses is prohibited. The reserved addresses are provided for possible future expansion of functions. Do not access these addresses as the correct operation of the LSI is not guaranteed.

### 8. Differences between products

Before changing from one product to another, for example to a product with a different part number, confirm that the change will not lead to problems. The characteristics of a microprocessing unit or microcontroller unit products in the same group but having a different part number might differ in terms of internal memory capacity, layout pattern, and other factors, which can affect the ranges of electrical characteristics, such as characteristic values, operating margins, immunity to noise, and amount of radiated noise. When changing to a product with a different part number, implement a system-evaluation test for the given product.

# How to Use This Manual

## 1. Purpose and Target Readers

This manual is designed to provide the user with an understanding of the hardware functions and electrical characteristics of the MCU. It is intended for users designing application systems incorporating the MCU. A basic knowledge of electric circuits, logical circuits, and MCUs is necessary in order to use this manual.

The manual comprises an overview of the product, descriptions of the CPU, system control functions, peripheral functions, electrical characteristics, and usage notes.

Particular attention should be paid to the precautionary notes when using the manual. These notes can be found within the body of the text, at the end of each section, and in the Usage Notes section.

The revision history summarizes the locations of revisions and additions. It does not list all revisions. Refer to the text of the manual for details.

The following documents apply to the RX66T Group. Make sure to refer to the latest versions of these documents. The latest versions of the listed documents are available from the Renesas Electronics website.

| Document Type            | Description                                                                                                                                                                                                                                   | Document Title                                                      | Document No.       |

## 2. Notation of Numbers and Symbols

Each register description includes a bit chart, illustrating the arrangement of bits, and a table of bits, describing the meanings of the bit settings. The standard format and notation for bit charts and tables are described below.

### X.X.X ... Register

Address(es): xxxx xxxhh

| Bit      | Symbol   | Bit Name     | Description                                                               | R/W     |
|----------|----------|--------------|---------------------------------------------------------------------------|---------|
| b0       | ...0     | .....        | 0: .....<br>1: Setting prohibited (3)                                     | R/W (1) |
| b3 to b1 | —        | Reserved (2) | These bits are read as 0. The write value should be 0.                    | R/W     |
| b4       | ...4     | .....        | 0: .....<br>1: .....                                                      | R       |
| b6, b5   | ...[1:0] | .....        | 0 0: .....<br>0 1: .....<br>Settings other than above are prohibited. (3) | R/(W)*1 |
| b7       | —        | Reserved     | The read value is undefined. Writing to this bit has no effect.           | R       |

- (1) R/W: The bit or field is readable and writable.  
 R/(W): The bit or field is readable and writable. However, writing to this bit or field has some limitations. For details on the limitations, see the description or notes of respective registers.  
 R: The bit or field is readable. Writing to this bit or field has no effect.
- (2) Reserved.  
 Use the specified value when writing to this bit or field; otherwise, the correct operation is not guaranteed.
- (3) Setting prohibited. The correct operation is not guaranteed if such a setting is performed.

### 3. List of Abbreviations and Acronyms

| Abbreviation | Full Form                                     |
|--------------|-----------------------------------------------|
| ACIA         | Asynchronous Communications Interface Adapter |
| bps          | bits per second                               |
| CRC          | Cyclic Redundancy Check                       |
| DMA          | Direct Memory Access                          |
| DMAC         | Direct Memory Access Controller               |
| GSM          | Global System for Mobile Communications       |
| Hi-Z         | High Impedance                                |
| IEBus        | Inter Equipment Bus                           |
| I/O          | Input / Output                                |
| IrDA         | Infrared Data Association                     |
| LSB          | Least Significant Bit                         |
| MSB          | Most Significant Bit                          |
| NC           | Non-Connect                                   |
| PLL          | Phase Locked Loop                             |
| PWM          | Pulse Width Modulation                        |
| SFR          | Special Function Registers                    |
| SIM          | Subscriber Identity Module                    |
| UART         | Universal Asynchronous Receiver / Transmitter |
| VCO          | Voltage Controlled Oscillator                 |

160-MHz, 32-bit RX MCU, on-chip FPU, 928 CoreMark, Supportive of 5V power supply, up to 1-MB flash memory, up to 128-KB SRAM, 32-KB data flash memory, 16-KB SRAM with ECC, Simultaneous sampling with 3 units of 12-bit A/D converter (up to 7 channels), Single-end/pseudo differential input supportive amplifier (6 channels), Analog comparator (6 channels), 160 MHz PWM (4 channels for 3-phase complementary, 2 channels for 5-phase complementary, 10 channels for single-phase complementary), 4-channel high-resolution PWM with resolution of 195 ps at the minimum, Host/function or OTG controller with full-speed USB 2.0 transfer, CAN, Encryption functions (optional)

## Features

### ■ 32-bit RXv3 CPU core

- Maximum operating frequency: 160 MHz  
Capable of 928 CoreMark in operation at 160 MHz
- JTAG and FINE (one-line) debugging interfaces

### ■ Low-power design and architecture

- Operation from a single 2.7- to 5.5-V supply
- Four low-power modes

### ■ On-chip code flash memory

- Supports versions with 1 Mbytes/512 Kbytes/256 Kbytes
- No wait cycles at up to 120 MHz or when the ROM cache is hit
- User code is programmable by on-board or off-board programming.

### ■ On-chip data flash memory

- 32 Kbytes, reprogrammable up to 100,000 times
- Programming/erasing as background operations (BGOs)

### ■ On-chip SRAM, no wait states

- 128K/64 Kbytes of SRAM (no wait states)
- 16 Kbytes of RAM with ECC (with wait)

### ■ Data transfer

- DMACa: 8 channels
- DTCa: 1 channel

### ■ ELC

- Module operation can be initiated by event signals without using interrupts
- Linked operation between modules is possible when the CPU is in sleep mode

### ■ Reset and supply management

- Power-on reset (POR)
- Low voltage detection (LVDA) with voltage settings

### ■ Clock functions

- Frequency of resonator for main clock oscillator: 8 to 24 MHz (this can be used as the PLL reference clock)
- High-speed on-chip oscillator: 16 MHz/18 MHz/20 MHz (this can be used as the PLL reference clock)
- Low-speed on-chip oscillator: 240 kHz

### ■ Independent watchdog timer

- 120-kHz IWDG-dedicated on-chip oscillator clock operation

### ■ Useful functions for IEC60730 compliance

- Oscillation-stoppage detection, functions for self-diagnosis and detection of disconnection for the A/D converter, clock frequency accuracy measurement circuit, independent watchdog timer, RAM test-assisting function by DOC, and CRCA, etc.
- Register write protection function can protect values in important registers against overwriting.

### ■ External bus

- Bus clock at 40 MHz (max)
- Four CS areas
- 8- or 16-bit bus space is selectable per area

### ■ Various communications interfaces

- Host/function or OTG controller (1 channel) with full-speed USB 2.0 (USBb) transfer
- CAN (compliant with ISO11898-1), incorporating 32 mailboxes (1 channel)
- SCIj and SCII with multiple functionalities (up to 6 channels)  
Choose from among asynchronous mode, clock-synchronous mode, smart-card interface mode, simplified SPI, simplified I<sup>2</sup>C, and extended serial mode.
- SCII with 16-byte transmission and reception FIFOs (1 channel)
- I<sup>2</sup>C bus interface (RIICa) for transfer at up to 400 kbps (fast mode), capable of SMBus operation (1 channel)
- RSPId (1 channel) for transfer at up to 30 Mbps

### ■ Up to 31 extended-function timers

- 32-bit GPTW (10 channels): operation at 160 MHz, input capture, output compare, PWM waveforms: 10 output channels in single-phase complementary PWM mode/3 output channels in 3-phase complementary PWM mode/2 output channels in 5-phase complementary PWM mode, phase-counting mode, linkage with comparator (counting operation, PWM negate control)
- 16-bit MTU3d (9 channels): operation at 160 MHz, input capture, output compare, PWM waveforms: 2 output channels in 3-phase complementary PWM mode, phase-counting mode
- 8-bit TMR (8 channels)
- 16-bit CMT (4 channels)

### ■ High-resolution PWM waveform generation circuit (HRPWM): 4 channels

- Controlling the timing of rising or falling of the PWM output waveform for 32-bit GPTW is realized with minimum of 195 ps resolution (in operation at 160 MHz)

### ■ 12-bit A/D converter (S12ADH): total of 30 channels for three units

- Up to three 12-bit units of sample-and-hold circuit included  
Unit 0 (8 channels for 3 sample-and-hold circuits),  
Unit 1 (8 channels for 3 sample-and-hold circuits),  
Unit 2 (14 channels)
- Programmable gain amplifier with pseudo differential amplification (3 channels × 2)

### ■ Analog Comparator (CMPC): 6 channels

### ■ 12-bit D/A converter: 2 channels

- Usable as a reference voltage for the analog comparator

### ■ Temperature sensor for measuring temperature within the chip

### ■ Encryption functions (Trusted Secure IP Lite)

- 128- or 256-bit key length of AES for ECB, CBC, GCM, others
- True random number generator
- Unauthorized access to the encryption engine is disabled and imposture and falsification of information are prevented
- Safe management of keys

### ■ Up to 110 pins for general I/O ports

- 5-V tolerance, open drain, input pull-up, switchable driving ability

### ■ Recommended operating temp. range (Topr)

- -40°C to +85°C
- -40°C to +105°C

## 1. Overview

### 1.1 Outline of Specifications

Table 1.1 lists the specifications in outline, and Table 1.2 gives a comparison of the functions of products in different packages.

Table 1.1 shows the outline of maximum specifications, and the number of peripheral module channels differs depending on the pin number on the package and the code flash memory capacity. For details, see Table 1.2, Comparison of Functions for Different Packages.

**Table 1.1 Outline of Specifications (1/9)**

| Classification | Module/Function   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

## 1.4 Pin Functions

Table 1.4 lists the pin functions.

**Table 1.4 Pin Functions (1/6)**

| Classifications        | Pin Name         | I/O                                                                    | Description                                                                                                                                                                             |
|------------------------|------------------|------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Digital power supply   | VCC              | —                                                                      | Power supply pin. Connect this pin to the system power supply. Connect the pin to VSS via a 0.1- $\mu$ F multilayer ceramic capacitor. The capacitor should be placed close to the pin. |
|                        | VCL              | —                                                                      | Connect this pin to VSS via a 0.47- $\mu$ F smoothing capacitor used to stabilize the internal power supply. The capacitor should be placed close to the pin.                           |
|                        | VSS              | —                                                                      | Ground pin. Connect it to the system power supply (0 V).                                                                                                                                |
| Clock                  | XTAL             | Output                                                                 | Pins for a crystal resonator. An external clock signal can be input through the EXTAL pin.                                                                                              |
|                        | EXTAL            | Input                                                                  |                                                                                                                                                                                         |
|                        | BCLK             | Output                                                                 | Outputs the external bus clock for external devices.                                                                                                                                    |
| CAC                    | CACREF           | Input                                                                  | Input pin for the clock frequency accuracy measurement circuit.                                                                                                                         |
| Operating mode control | MD               | Input                                                                  | Pins for setting the operating mode. The signal levels on these pins must not be changed during operation.                                                                              |
|                        | UB               | Input                                                                  | Enable pin for boot mode (USB interface) and user boot mode                                                                                                                             |
|                        | UPSEL            | Input                                                                  | Selects the power supply method in boot mode (USB interface). The low level selects self-power mode and the high level selects bus power mode.                                          |
| System control         | RES#             | Input                                                                  | Reset pin. This MCU enters the reset state when this signal goes low.                                                                                                                   |
|                        | EMLE             | Input                                                                  | Input pin for the on-chip emulator enable signal. When the on-chip emulator is used, this pin should be driven high. When not used, it should be driven low.                            |
| On-chip emulator       | FINED            | I/O                                                                    | FINE interface pin.                                                                                                                                                                     |
|                        | TRST#            | Input                                                                  | Pins for the on-chip emulator. When the EMLE pin is driven high, these pins are dedicated for the on-chip emulator.                                                                     |
|                        | TMS              | Input                                                                  |                                                                                                                                                                                         |
|                        | TDI              | Input                                                                  |                                                                                                                                                                                         |
|                        | TCK              | Input                                                                  |                                                                                                                                                                                         |
|                        | TDO              | Output                                                                 |                                                                                                                                                                                         |
|                        | TRCLK            | Output                                                                 | This pin outputs the clock for synchronization with the trace data.                                                                                                                     |
|                        | TRSYNC           | Output                                                                 | This pin indicates that output from the TRDATA0 to TRDATA3 pins is valid.                                                                                                               |
|                        | TRSYNC1          | Output                                                                 | This pin indicates that output from the TRDATA4 to TRDATA7 pins is valid.                                                                                                               |
|                        |                  | TRDATA0, TRDATA1, TRDATA2, TRDATA3, TRDATA4, TRDATA5, TRDATA6, TRDATA7 | Output                                                                                                                                                                                  |
| Address bus            | A0 to A20        | Output                                                                 | Output pins for the address                                                                                                                                                             |
| Data bus               | D0 to D15        | I/O                                                                    | Input and output pins for the bidirectional data bus                                                                                                                                    |
| Multiplexed bus        | A0/D0 to A15/D15 | I/O                                                                    | Address/data multiplexed bus                                                                                                                                                            |
| Bus control            | RD#              | Output                                                                 | Strobe signal which indicates that reading from the external bus interface space is in progress                                                                                         |
|                        | WR#              | Output                                                                 | Strobe signal which indicates that writing to the external bus interface space is in progress, in 1-write strobe mode                                                                   |
|                        | WR0#, WR1#       | Output                                                                 | Strobe signals which indicate that either group of data bus pins (D7 to D0, D15 to D8) is valid in writing to the external bus interface space, in byte strobe mode                     |

**Table 1.4 Pin Functions (2/6)**

| Classifications                   | Pin Name                               | I/O                                                                    | Description                                                                                                                                                           |
|-----------------------------------|----------------------------------------|------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Bus control                       | BC0#, BC1#                             | Output                                                                 | Strobe signals which indicate that either group of data bus pins (D7 to D0, D15 to D8) is valid in access to the external bus interface space, in 1-write strobe mode |
|                                   | ALE                                    | Output                                                                 | Address latch signal when address/data multiplexed bus is selected                                                                                                    |

|                      | CMPCnm                                                                  | Input  | Analog input pin for CMPCnm (n = 0 to 5, m = 0 to 3)                                                                                                                                                                                                                                                                                                                                         |
| Analog power supply  | AVCC0                                                                   | —      | Analog voltage supply pin for 12-bit A/D converter unit 0. Connect the AVCC0 pin to AVCC1 or AVCC2 when 12-bit A/D converter unit 0 is not used.                                                                                                                                                                                                                                             |
|                      | AVSS0                                                                   | —      | Analog ground pin for 12-bit A/D converter unit 0. Connect the AVSS0 pin to AVSS1 or AVSS2 when 12-bit A/D converter unit 0 is not used.                                                                                                                                                                                                                                                     |
|                      | AVCC1                                                                   | —      | Analog voltage supply pin for 12-bit A/D converter unit 1. Connect this pin to AVCC0 when not using the 12-bit A/D converter 1 but using the 12-bit A/D converter 0. Connect this pin to AVCC2 when not using the 12-bit A/D converter 0 and the 12-bit A/D converter 1.                                                                                                                     |
|                      | AVSS1                                                                   | —      | Analog ground pin for 12-bit A/D converter unit 1. Connect this pin to AVSS0 when not using the 12-bit A/D converter 1 but using the 12-bit A/D converter 0. Connect this pin to AVSS2 when not using the 12-bit A/D converter 0 and the 12-bit A/D converter 1.                                                                                                                             |
|                      | AVCC2                                                                   | —      | Analog voltage supply pin for the 12-bit A/D converter unit 2, reference voltage supply pin for the 12-bit D/A converter, analog voltage supply pin for the comparator C, and analog voltage supply pin for the temperature sensor. Connect this pin to either of AVCC0 or AVCC1 when not using the 12-bit A/D converter unit 2, 12-bit D/A converter, comparator C, and temperature sensor. |
|                      | AVSS2                                                                   | —      | Analog ground pin for the 12-bit A/D converter unit 2, reference ground pin for the D/A converter, analog ground pin for the comparator C, and analog ground pin for the temperature sensor. Connect this pin to either of AVSS0 or AVSS1 when not using the 12-bit A/D converter unit 2, 12-bit D/A converter, comparator C, and temperature sensor.                                        |

**Table 1.4 Pin Functions (6/6)**

| Classifications | Pin Name   | I/O | Description                                              |
|-----------------|------------|-----|----------------------------------------------------------|
| I/O ports       | P00, P01   | I/O | 2-bit input/output pins.                                 |
|                 | P10 to P17 | I/O | 8-bit input/output pins.                                 |
|                 | P20 to P27 | I/O | 8-bit input/output pins.                                 |
|                 | P30 to P37 | I/O | 8-bit input/output pins.                                 |
|                 | P40 to P47 | I/O | 8-bit input/output pins (P40 to P42, P44 to P46: input). |
|                 | P50 to P55 | I/O | 6-bit input/output pins.                                 |
|                 | P60 to P65 | I/O | 6-bit input/output pins.                                 |
|                 | P70 to P76 | I/O | 7-bit input/output pins.                                 |
|                 | P80 to P82 | I/O | 3-bit input/output pins.                                 |
|                 | P90 to P96 | I/O | 7-bit input/output pins.                                 |
|                 | PA0 to PA7 | I/O | 8-bit input/output pins.                                 |
|                 | PB0 to PB7 | I/O | 8-bit input/output pins.                                 |
|                 | PC0 to PC6 | I/O | 7-bit input/output pins.                                 |
|                 | PD0 to PD7 | I/O | 8-bit input/output pins.                                 |
|                 | PE0 to PE6 | I/O | 7-bit input/output pins (PE2: input).                    |
|                 | PF0 to PF3 | I/O | 4-bit input/output pins.                                 |
|                 | PG0 to PG2 | I/O | 3-bit input/output pins.                                 |
|                 | PH0 to PH7 | I/O | 8-bit input/output pins (PH0, PH4: input).               |
|                 | PK0 to PK2 | I/O | 3-bit input/output pins.                                 |

Note: When not using any of the A/D converter, D/A converter, comparator C and temperature sensor, connect the AVCC0, AVCC1 and AVCC2 pins to VCC, and connect the AVSS0, AVSS1 and AVSS2 pins to VSS, respectively.

Note: When the pin functions have “-DS” appended to their names, they can also be used as triggers for release from deep software standby.

## 2. CPU

The RXv3 CPU is based on the RXv3 instruction set architecture. Its instruction processing efficiency has been improved relative to that of the RXv2 CPU, so it delivers higher performance.

The RXv3 instruction set architecture (RXv3) provides upward compatibility from the RXv2 instruction set architecture (RXv2) and the RXv1 instruction set architecture (RXv1).

- Adoption of variable-length instruction format  
The CPU has short formats for frequently used instructions, facilitating the development of efficient programs that take up less memory.
- Powerful instruction set  
DSP instructions and floating-point operation instructions realize high-speed arithmetic processing.
- Versatile addressing modes  
The CPU has versatile addressing modes, with register-register operations, register-memory operations, and bitwise operations included. Data transfer between memory locations is also possible.

### 2.1 Features

- Minimum instruction execution rate: One clock cycle
- Address space: 4-Gbyte linear addresses
- Register set of the CPU  
General purpose: Sixteen 32-bit registers  
Control: Ten 32-bit registers  
Accumulator: Two 72-bit registers
- Variable-length instruction format (lengths from one to eight bytes)
- 111 instructions  
Standard provided instructions: 111  
Basic instructions: 77  
Single-precision floating point instructions: 11  
DSP instructions: 23
- Processor modes  
Supervisor mode and user mode
- Vector tables  
Exception vector table and interrupt vector table
- Memory protection unit
- Data arrangement  
Selectable as little endian or big endian

## 2.2 Register Set of the CPU

The CPU has sixteen general-purpose registers, ten control registers, and two accumulator used for DSP instructions.

**Figure 2.1 Register Set of the CPU**

### 2.2.1 General-Purpose Registers (R0 to R15)

This CPU has sixteen 32-bit general-purpose registers (R0 to R15). R0 to R15 can be used as data registers or address registers.

R0, a general-purpose register, also functions as the stack pointer (SP).

The stack pointer is switched to operate as the interrupt stack pointer (ISP) or user stack pointer (USP) by the value of the stack pointer select bit (U) in the processor status word (PSW).

### 2.2.2 Control Registers

This CPU has the following ten control registers.

- Interrupt stack pointer (ISP)
- User stack pointer (USP)
- Exception table register (EXTB)
- Interrupt table register (INTB)
- Program counter (PC)
- Processor status word (PSW)
- Backup PC (BPC)
- Backup PSW (BPSW)
- Fast interrupt vector register (FINTV)
- Single-precision floating-point status word (FPSW)

### 2.2.2.1 Interrupt Stack Pointer (ISP)/User Stack Pointer (USP)

The stack pointer (SP) can be either of two types, the interrupt stack pointer (ISP) or the user stack pointer (USP). Whether the stack pointer operates as the ISP or USP depends on the value of the stack pointer select bit (U) in the processor status word (PSW).

### 2.2.2.2 Exception Table Register (EXTB)

The exception table register (EXTB) specifies the address where the exception vector table starts.

### 2.2.2.3 Interrupt Table Register (INTB)

The interrupt table register (INTB) specifies the address where the interrupt vector table starts.

### 2.2.2.4 Program Counter (PC)

The program counter (PC) indicates the address of the instruction being executed.

## 2.2.2.5 Processor Status Word (PSW)

The write value should be 0.                                                                                                                                                                                                                                                                                                                                                                                                                                                           | R/W |

Note 1. In user mode, writing to the IPL[3:0], PM, U, and I bits by an MVTC or a POPC instruction is ignored. Writing to the IPL[3:0] bits by an MVTIPL instruction generates a privileged instruction exception.

Note 2. In supervisor mode, writing to the PM bit by an MVTC or a POPC instruction is ignored, but writing to the other bits is possible.

Note 3. Switching from supervisor mode to user mode requires execution of an RTE instruction after having set the PSW.PM bit saved on the stack to 1 or executing an RTFI instruction after having set the BPSW.PM bit to 1.

The processor status word (PSW) indicates the results of instruction execution or the state of the CPU.

**C Flag (Carry Flag)**

This flag retains the state of the bit after a carry, borrow, or shift-out has occurred.

**Z Flag (Zero Flag)**

This flag is set to 1 if the result of an operation is 0; otherwise its value is set to 0.

**S Flag (Sign Flag)**

This flag is set to 1 if the result of an operation is negative; otherwise its value is set to 0.

**O Flag (Overflow Flag)**

This flag is set to 1 if the result of an operation overflows; otherwise its value is set to 0.

**I Bit (Interrupt Enable)**

This bit enables interrupt requests. When a WAIT instruction is executed, the value of this bit becomes 1. It becomes 0 when an exception is accepted.

**U Bit (Stack Pointer Select)**

This bit specifies the stack pointer as either the ISP or USP. When an exception request is accepted, this bit is set to 0. When the processor mode is switched from supervisor mode to user mode, this bit is set to 1.

**PM Bit (Processor Mode Select)**

This bit specifies the processor mode. When an exception is accepted, the value of this bit becomes 0.

**IPL[3:0] Bits (Processor Interrupt Priority Level)**

The IPL[3:0] bits specify the processor interrupt priority level as one of sixteen levels from zero to fifteen, wherein priority level zero is the lowest and priority level fifteen the highest. When the priority level of a requested interrupt is higher than the processor interrupt priority level, the interrupt is enabled. Setting the IPL[3:0] bits to level fifteen (Fh) disables all interrupt requests. The IPL[3:0] bits are set to level fifteen (Fh) when a non-maskable interrupt is generated. When interrupts in general are generated, the bits are set to the priority levels of accepted interrupts.

**2.2.2.6 Backup PC (BPC)**

The backup PC (BPC) is provided to speed up response to interrupts.

After a fast interrupt has been generated, the contents of the program counter (PC) are saved in the BPC register.

### 2.2.2.7 Backup PSW (BPSW)

The backup PSW (BPSW) is provided to speed up response to interrupts. After a fast interrupt has been generated, the contents of the processor status word (PSW) are saved in the BPSW. The allocation of bits in the BPSW corresponds to that in the PSW.

### 2.2.2.8 Fast Interrupt Vector Register (FINTV)

The fast interrupt vector register (FINTV) is provided to speed up response to interrupts. The FINTV register specifies a branch destination address when a fast interrupt has been generated.

## 2.2.2.9 Single-Precision Floating-Point Status Word (FPSW)

| b28        | FZ*5    | Division-by-Zero Flag                                 | 0: No division-by-zero has occurred.<br>1: Division-by-zero has occurred.*8                                                                       | R/W         |
| b29        | FU*6    | Underflow Flag                                        | 0: No underflow has occurred.<br>1: Underflow has occurred.*8                                                                                     | R/W         |
| b30        | FX*7    | Inexact Flag                                          | 0: No inexact exception has been generated.<br>1: Inexact exception has been generated.*8                                                         | R/W         |
| b31        | FS      | Single-Precision Floating-Point Error Summary Flag    | This bit reflects the logical OR of the FU, FZ, FO, and FV flags.                                                                                 | R           |

- Note 1. Writing 0 to the bit clears it. Writing 1 to the bit does not affect its value.
- Note 2. Positive denormalized numbers are treated as +0, negative denormalized numbers as -0.
- Note 3. When the EV bit is set to 0, the FV flag is enabled.
- Note 4. When the EO bit is set to 0, the FO flag is enabled.
- Note 5. When the EZ bit is set to 0, the FZ flag is enabled.
- Note 6. When the EU bit is set to 0, the FU flag is enabled.
- Note 7. When the EX bit is set to 0, the FX flag is enabled.
- Note 8. Once the bit has been set to 1, this value is retained until it is set to 0 by software.

The single-precision floating-point status word (FPSW) indicates the results of single-precision floating-point arithmetic operations.

When the corresponding exception handling enable bits ( $E_j$ ) are set to enable processing of the exceptions ( $E_j = 1$ ), the  $C_j$  flags can be used by the exception handling routine to identify the source of that exception. If handling of an exception is masked ( $E_j = 0$ ), the  $F_j$  flag can be used to check for the generation of the exception at the end of a sequence of processing. The  $F_j$  flags operate in an accumulative fashion ( $j = X, U, Z, O, \text{ or } V$ ).

### RM[1:0] Bits (Single-Precision Floating-Point Rounding-Mode Setting)

These bits specify the single-precision floating-point rounding-mode.

#### Explanation of Single-Precision Floating-Point Rounding Modes

- Rounding towards the nearest value (the default behavior): An inexact result is rounded to the available value that is closest to the result of a hypothetical calculation with infinite precision. If two available values are equally close, rounding is to the even alternative.
- Rounding towards 0: An inexact result is rounded to the smallest available absolute value, i.e. in the direction of zero (simple truncation).
- Rounding towards  $+\infty$ : An inexact result is rounded to the nearest available value in the direction of positive infinity.
- Rounding towards  $-\infty$ : An inexact result is rounded to the nearest available value in the direction of negative infinity.

(1) Rounding to the nearest value is specified as the default mode and returns the most accurate value.

(2) Modes such as rounding towards 0, rounding towards  $+\infty$ , and rounding towards  $-\infty$  are used to ensure precision when interval arithmetic is employed.

### CV Flag (Invalid Operation Cause Flag), CO Flag (Overflow Cause Flag), CZ Flag (Division-by-Zero Cause Flag), CU Flag (Underflow Cause Flag), CX Flag (Inexact Cause Flag), and CE Flag (Unimplemented Processing Cause Flag)

Single-precision floating-point exceptions include the five specified in the IEEE754 standard, namely overflow, underflow, inexact, division-by-zero, and invalid operation. For a further single-precision floating-point exception that is generated upon detection of unimplemented processing, the corresponding flag (CE) is set to 1.

- If an exception or processing that is not implemented is not encountered in the execution of a single-precision floating-point arithmetic instruction, the corresponding flags become 0.
- When 0 is written to the bit by the MVTC and POPC instructions, the bit is set to 0; the bit retains the previous value when 1 is written by the instruction.

### DN Bit (0 Flush Bit of Denormalized Number)

When this bit is set to 0, a denormalized number is handled as a denormalized number. When this bit is set to 1, a denormalized number is handled as 0.

### EV Bit (Invalid Operation Exception Enable), EO Bit (Overflow Exception Enable), EZ Bit (Division-by-Zero Exception Enable), EU Bit (Underflow Exception Enable), and EX Bit (Inexact Exception Enable)

When any of five single-precision floating-point exceptions specified in the IEEE754 standard is generated by the single-precision floating-point operation instruction, the bit decides whether the CPU will start handling the exception. When the bit is set to 0, the exception handling is masked; when the bit is set to 1, the exception handling is enabled.

### FV Flag (Invalid Operation Flag), FO Flag (Overflow Flag), FZ Flag (Division-by-Zero Flag), FU Flag (Underflow Flag), and FX Flag (Inexact Flag)

While the exception handling enable bit (Ej) is 0 (exception handling is masked), if any of five single-precision floating-point exceptions specified in the IEEE754 standard is generated, the corresponding bit is set to 1.

- When Ej is 1 (exception handling is enabled), the value of the flag remains.
- When the corresponding flag is set to 1, it remains 1 until it is set to 0 by software (accumulation flag).

### FS Flag (Single-Precision Floating-Point Error Summary Flag)

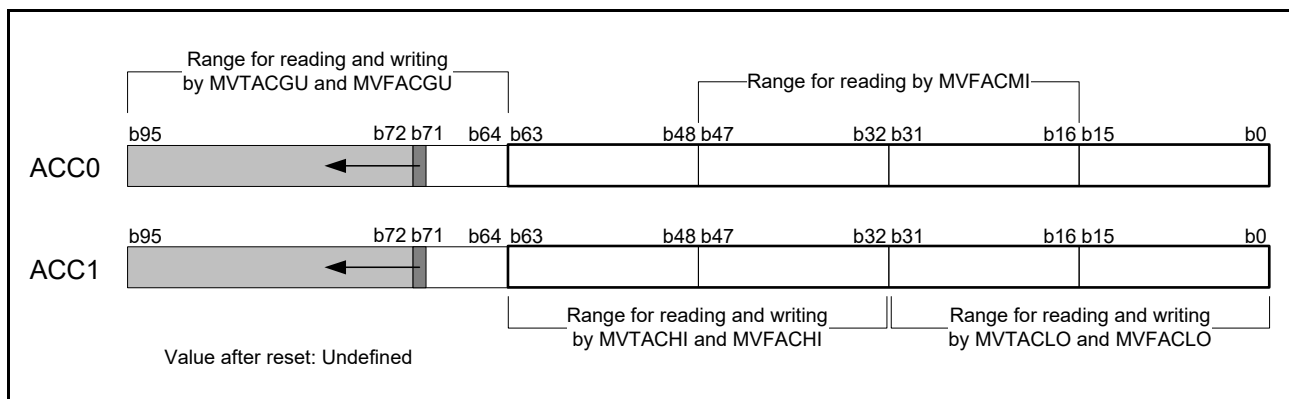

This bit reflects the logical OR of the FU, FZ, FO, and FV flags.

## 2.2.3 Accumulator

The accumulator (ACC0 or ACC1) is a 72-bit register used for DSP instructions. The accumulator is handled as a 96-bit register for reading and writing. At this time, when bits 95 to 72 of the accumulator are read, the value where the value of bit 71 is sign extended is read. Writing to bits 95 to 72 of the accumulator is ignored. ACC0 is also used for the multiply and multiply-and-accumulate instructions; EMUL, EMULU, FMUL, MUL, and RMPA, in which case the prior value in ACC0 is modified by execution of the instruction.

Use the MVTACGU, MVTACHI, and MVTACLO instructions for writing to the accumulator. The MVTACGU, MVTACHI, and MVTACLO instructions write data to bits 95 to 64, the higher-order 32 bits (bits 63 to 32), and the lower-order 32 bits (bits 31 to 0), respectively.

Use the MVFACGU, MVFACHI, MVFACMI, and MVFACLO instructions for reading data from the accumulator. The MVFACGU, MVFACHI, MVFACMI, and MVFACLO instructions read data from the guard bits (bits 95 to 64), higher-order 32 bits (bits 63 to 32), the middle 32 bits (bits 31 to 0), and the lower-order 32 bits (bits 31 to 0), respectively.

Note: The value of bit 71 is sign extended for bits 95 to 72 and the extended value is always read. Writing to this area is ignored.

## 2.3 Processor Mode

The CPU supports two processor modes, supervisor and user. These processor modes and the memory protection function enable the realization of a hierarchical CPU resource protection and memory protection mechanism. Each processor mode imposes a level on rights of access to memory and the instructions that can be executed. Supervisor mode carries greater rights than user mode. The initial state after a reset is supervisor mode.

### 2.3.1 Supervisor Mode

In supervisor mode, all CPU resources are accessible and all instructions are available. However, writing to the processor mode select bit (PM) in the processor status word (PSW) by executing an MVTC or a POPC instruction will be ignored. For details on how to write to the PM bit, refer to section 2.2.2.5, Processor Status Word (PSW).

### 2.3.2 User Mode

In user mode, write access to the CPU resources listed below is restricted. The restriction applies to any instruction capable of write access.

- Some bits (bits IPL[3:0], PM, U, and I) in the processor status word (PSW)
- Interrupt stack pointer (ISP)
- Exception table register (EXTB)
- Interrupt table register (INTB)
- Backup PSW (BPSW)
- Backup PC (BPC)
- Fast interrupt vector register (FINTV)

### 2.3.3 Privileged Instruction

Privileged instructions can only be executed in supervisor mode. Executing a privileged instruction in user mode produces a privileged instruction exception. Privileged instructions include the RTFI, MVTIPL, RTE, and WAIT instructions.

### 2.3.4 Switching Between Processor Modes

Manipulating the processor mode select bit (PM) in the processor status word (PSW) switches the processor mode. However, rewriting to the PM bit by executing an MVTC or a POPC instruction is prohibited. Switch the processor mode by following the procedures described below.

#### (1) Switching from user mode to supervisor mode

After an exception has been generated, the PSW.PM bit is set to 0 and the CPU switches to supervisor mode. The hardware pre-processing is executed in supervisor mode. The state of the processor mode before the exception was generated is retained in the copy of PSW.PM bit is saved on the stack.

#### (2) Switching from supervisor mode to user mode

Executing an RTE instruction when the value of the copy of the PSW.PM bit that has been preserved on the stack is 1 or an RTFI instruction when the value of the copy of the PSW.PM bit that has been preserved in the backup PSW (BPSW) is 1 causes a transition to user mode. In the transition to user mode, the value of the stack pointer designation bit (the U bit in the PSW) becomes 1.

## 2.4 Data Types

The CPU can handle four types of data: integer, single-precision floating-point number, bit, and string.  
 For details, refer to RX Family RXv3 Instruction Set Architecture User’s Manual: Software.

### 2.4.1 Integer

An integer can be signed or unsigned. For signed integers, negative values are represented by two’s complements.

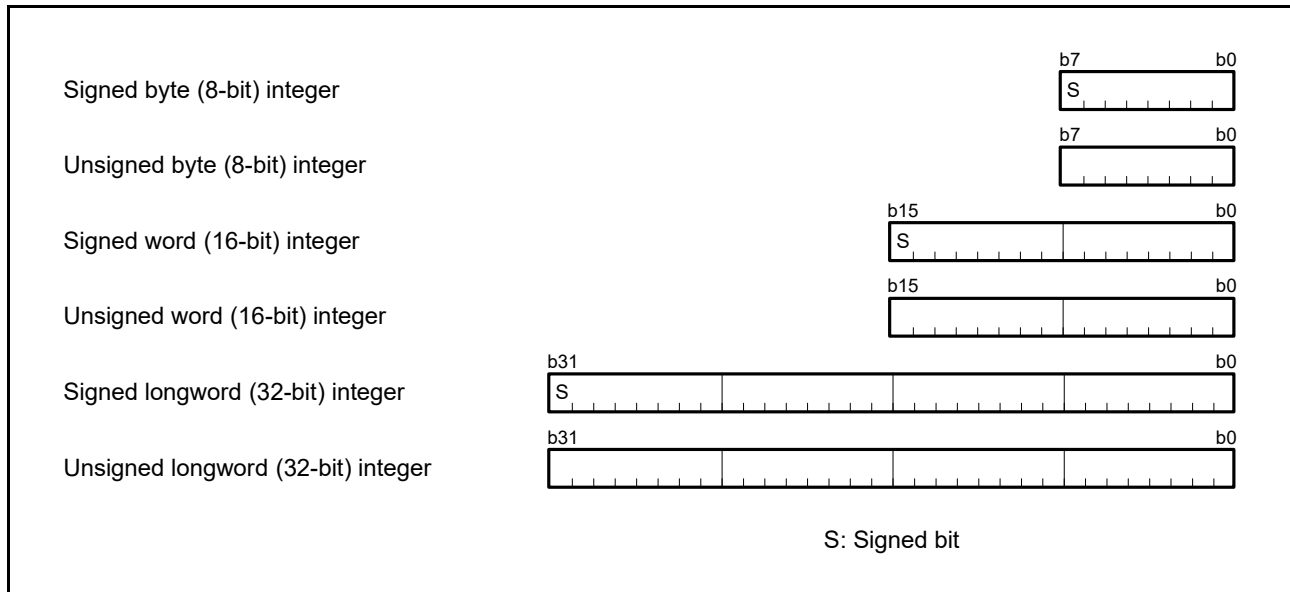

Figure 2.2 Integer

### 2.4.2 Single-Precision Floating-Point Numbers

The single-precision floating-point number is compliant with that specified in the IEEE754 standard; operands of this type can be used in eleven single-precision floating-point operation instructions: FADD, FCMP, FDIV, FMUL, FSQRT, FSUB, FTOI, FTOU, ITOF, ROUND, and UTOF.

**Figure 2.3 Single-Precision Floating-Point Number**

The single-precision floating-point number can represent the values listed below.

- 0 < E < 255 (normal numbers)
- E = 0 and F = 0 (signed zero)
- E = 0 and F > 0 (denormalized numbers)\*1
- E = 255 and F = 0 (infinity)
- E = 255 and F > 0 (NaN: Not-a-Number)

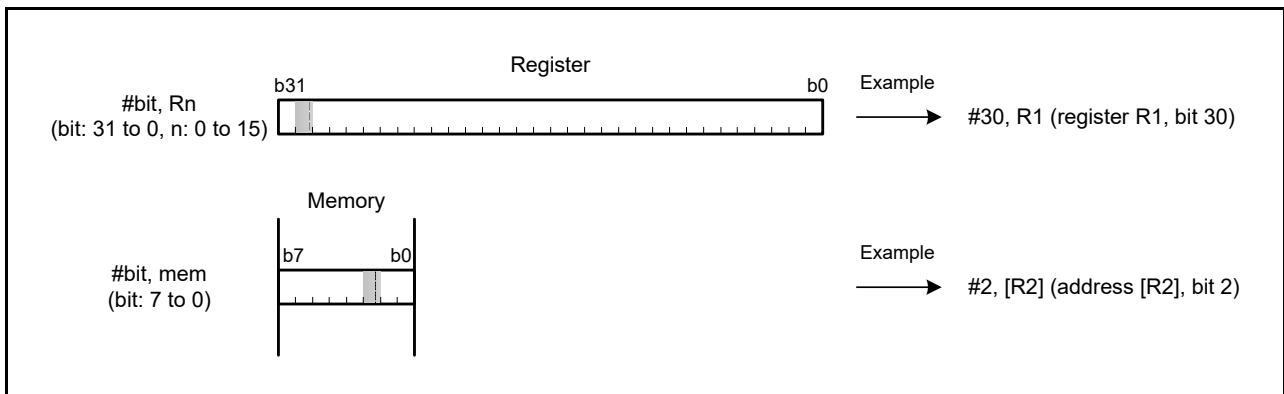

Note 1. The number is treated as 0 when the FPSW.DN bit is 1. When the DN bit is 0, an unimplemented processing exception is generated.

### 2.4.3 Bitwise Operations

Five bit-manipulation instructions are provided for bitwise operations: BCLR, BMCnd, BNOT, BSET, and BTST.

A bit in a register is specified as the destination register and a bit number in the range from 31 to 0.

A bit in memory is specified as the destination address and a bit number from 7 to 0. The addressing modes available to specify addresses are register indirect and register relative.

**Figure 2.4 Bit**

### 2.4.4 Strings

The string data type consists of an arbitrary number of consecutive byte (8-bit), word (16-bit), or longword (32-bit) units. Seven string manipulation instructions are provided for use with strings: SCMPU, SMOVB, SMOVF, SMOVU, SSTR, SUNTIL, and SWHILE.

Figure 2.5 String

## 2.5 Endian

For the CPU, instructions are little endian, but the treatment of data is selectable as little or big endian.

### 2.5.1 Switching the Endian

As arrangements of bytes, this MCU supports both big endian, where the higher-order byte (MSB) is at location 0, and little endian, where the lower-order byte (LSB) is at location 0.

For details on the endian setting, see section 3, Operating Modes.

Operations for access differ according to the endian setting and, depending on the instruction, whether 8-, 16- or 32-bit access has been selected. Operations for access in the various possible cases are described in Table 2.1 to Table 2.12.

In the tables,

- LL indicates bits D7 to D0 of the general-purpose register,
- LH indicates bits D15 to D8 of the general-purpose register,
- HL indicates bits D23 to D16 of the general-purpose register, and
- HH indicates bits D31 to D24 of the general-purpose register.

|                              |                   |                   |                  |                 |
|------------------------------|-------------------|-------------------|------------------|-----------------|

## 2.5.2 Access to I/O Registers

The addresses of I/O registers are fixed, and this is regardless of whether the setting is for little endian or big endian. Accordingly, changes to the endian do not affect access to I/O registers. For the arrangements of I/O registers, refer to the descriptions of registers in the relevant sections.

## 2.5.3 Notes on Access to I/O Registers

Ensure that access to I/O registers is in accord with the following rules.

- With I/O registers for which a bus width of eight bits is indicated, use instructions having operands of the same width (eight bits). That is, access these registers by using instructions with `.B` as the size specifier (`.size`), or with `.B` or `.UB` as the size-extension specifier (`.memex`).
- With I/O registers for which a bus width of 16 bits is indicated, use instructions having operands of the same width (16 bits). That is, access these registers by using instructions with `.W` as the size specifier (`.size`), or with `.W` or `.UW` as the size-extension specifier (`.memex`).
- With I/O registers for which a bus width of 32 bits is indicated, use instructions having operands of the same width (32 bits). That is, access these registers by using instructions with `.L` as the size specifier (`.size`), or with `.L` size-extension specifier (`.memex`).

## 2.5.4 Data Arrangement

### 2.5.4.1 Data Arrangement in Registers

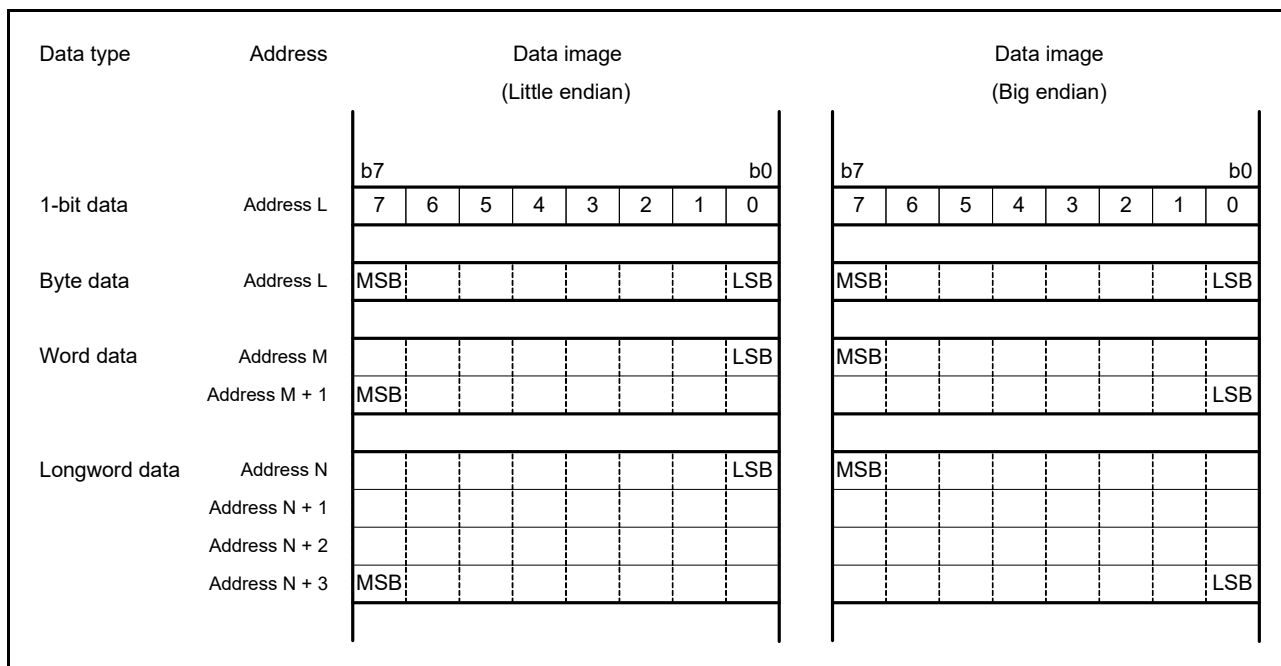

Figure 2.6 shows the relation between the sizes of registers and bit numbers.

**Figure 2.6 Data Arrangement in Registers**

### 2.5.4.2 Data Arrangement in Memory

Data in memory have three sizes: byte (8-bit), word (16-bit), and longword (32-bit). The data arrangement is selectable as little endian or big endian. Figure 2.7 shows the arrangement of data in memory.

**Figure 2.7 Data Arrangement in Memory**

## 2.5.5 Notes on the Allocation of Instruction Codes

The allocation of instruction codes to an external space where the endian differs from that of the chip is prohibited. If the instruction codes are allocated to the external space, they must be allocated to areas where the endian setting is the same as that for the chip.

## 2.6 Vector Table

There are two types of vector table: exception and interrupt. Each vector in the vector table consists of four bytes and specifies the address where the corresponding exception handling routine starts.

### 2.6.1 Exception Vector Table

In the exception vector table, the individual vectors for the privileged instruction exception, access exception, undefined instruction exception, single-precision floating-point exception, and non-maskable interrupt are allocated to the 124-byte area where the value indicated by the exception table register (EXTB) is used as the starting address (ExtBase). The reset vector is always allocated to FFFFFFFCh, regardless of the value of the exception vector table.

Figure 2.8 shows the exception vector table.

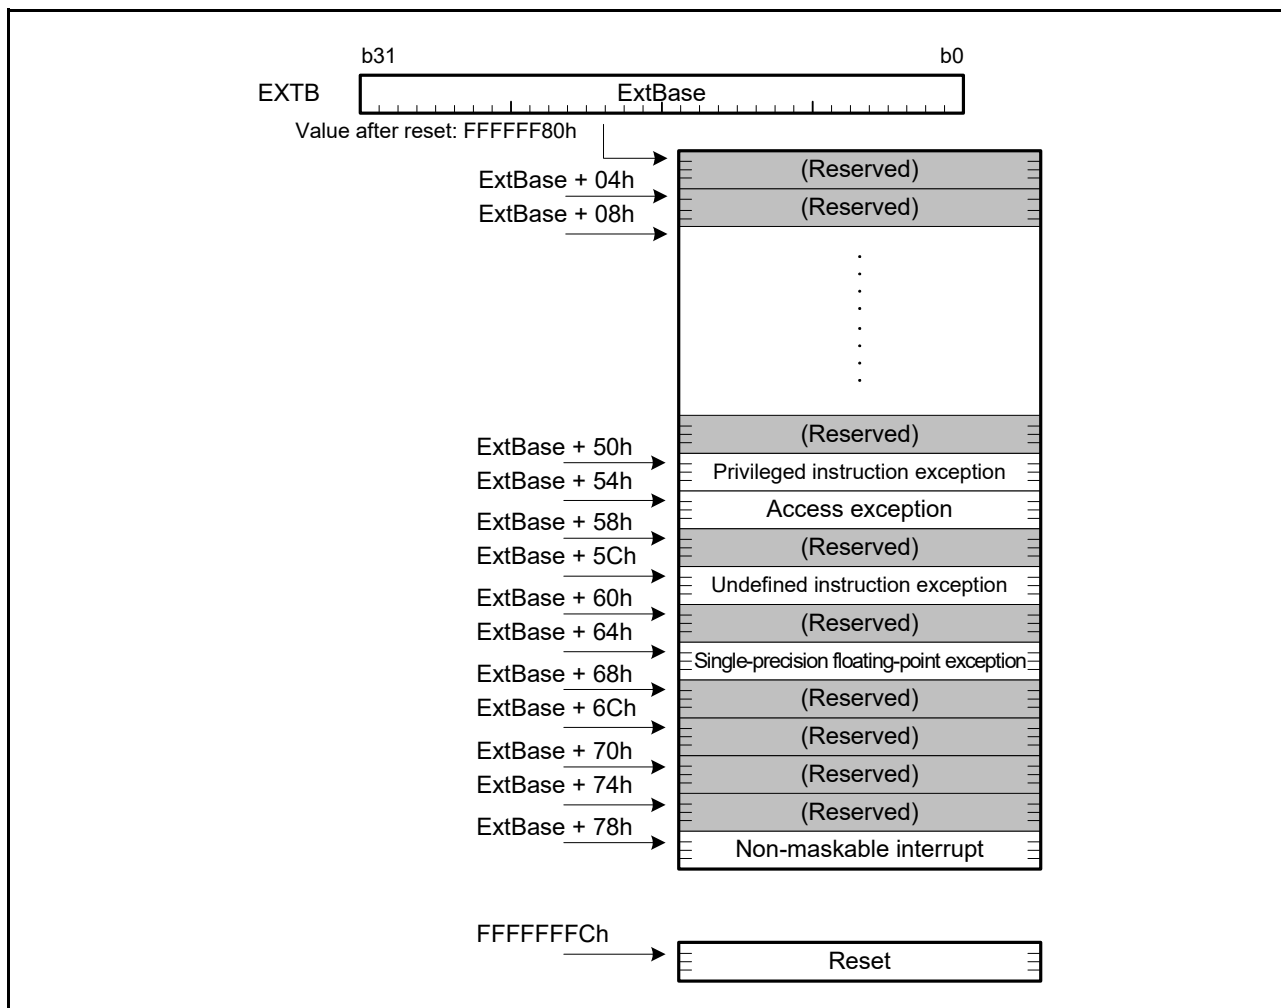

Figure 2.8 Exception Vector Table

### 2.6.2 Interrupt Vector Table

The address where the interrupt vector table is placed can be adjusted. The table is a 1,024-byte region that contains all vectors for unconditional traps and interrupts and starts at the address (IntBase) specified in the interrupt table register (INTB). Figure 2.9 shows the interrupt vector table.

Each vector in the interrupt vector table has a vector number from 0 to 255. Each of the INT instructions, which act as the sources of unconditional traps, is allocated to the vector that has the same number as is specified as the operand of the instruction itself (from 0 to 255). The BRK instruction is allocated to the vector with number 0. Furthermore, vector numbers (from 0 to 255) are allocated to interrupt requests in a fixed way for each product. For more on interrupt vector numbers, see section 14.3.1, Interrupt Vector Table.

Figure 2.9 Interrupt Vector Table

## 2.7 Operation of Instructions

### 2.7.1 Restrictions on RMPA and String-Manipulation Instructions

#### 2.7.1.1 Transfer Size and Data Prefetching

The RMPA instruction and the string-manipulation instructions (SCMPU, SMOVB, SMOVF, SMOVU, SSTR, SUNTIL, and SWHILE instructions) transfer data in longword units to speed up the reading of data from and writing of data to the memory. If the last of the data to be processed is less than a longword, data transfer proceeds with the sizes described below:

- RMPA, SSTR, SUNTIL, and SWHILE instructions: Size specified by the size specifier
- SCMPU, SMOVB, SMOVF, and SMOVU instructions: Byte

Additionally, in the above processing, the RMPA instruction and the string-manipulation instructions other than the SSTR instruction (that is, the SCMPU, SMOVB, SMOVF, SMOVU, SUNTIL, and SWHILE instructions) prefetch data when reading data from the memory. Data is prefetched from the prefetching start position with three bytes as the upper limit. The prefetching start positions of each operation are shown below.

- RMPA instruction: The multiplicand address specified by R1, and the multiplier address specified by R2
- SCMPU instruction: The source address specified by R1 for comparison, and the destination address specified by R2 for comparison
- SUNTIL and SWHILE instructions: The destination address specified by R1 for comparison
- SMOVB, SMOVF, and SMOVU instructions: The source address specified by R2 for transfer

#### 2.7.1.2 Access to the External Space

Although the external space has a per-area ending-switching facility (only for data), the allocation of data to be handled by RMPA or string-manipulation instructions (SCMPU, SMOVB, SMOVF, SMOVU, SSTR, SUNTIL, and SWHILE instructions) to an area where the endian differs from that of the chip is prohibited, and operation is not guaranteed if this restriction is not observed. If data to be handled by RMPA or string-manipulation instructions are allocated to the external space, they must be allocated to areas where the endian setting is the same as that for the chip.

#### 2.7.1.3 Access to I/O Registers

The allocation of data to be handled by RMPA or string-manipulation instructions (SCMPU, SMOVB, SMOVF, SMOVU, SSTR, SUNTIL, and SWHILE instructions) to I/O registers is prohibited, and operation is not guaranteed if this restriction is not observed.

## 2.8 Numbers of Cycles

### 2.8.1 Instruction and Numbers of Cycles

Table 2.13 to Table 2.20 show the numbers of cycles in operation of each instruction. The listed numbers of cycles for access to memory are the numbers of cycles during no-wait access. The operands in the table below indicate the following meanings.

#IMM: Immediate

flag: bit, flag

Rs, Rs2, Rd, Rd2, Ri, Rb: General-purpose register

As, Ad: Accumulator

CR: Control register

dsp: displacement

pcdsp: displacement

**Table 2.13 Numbers of Cycles for Arithmetic/logic Instructions**

| Instruction                                                                  | Mnemonic<br>(indicates the common operation when the size is omitted)                                                                                                                                                                                                                                                                                                                                                                                                   | Numbers of Cycles                                                                                                                                                               |           |

Note 1. The numbers of cycles for the dividing instruction varies according to the divisor and dividend.

Note 2. floor (x): Max. integer that is smaller than x.

**Table 2.14** Numbers of Cycles for Transfer Instructions

Note 1. When the load data is used by the subsequent instruction, the numbers of cycles described as "latency" is counted as the numbers of cycles for the memory load instruction. For the cycles other than the memory load instruction, the numbers of cycles described as "throughput" is counted.

Note 2. The POPM instruction is converted into multiple load operations. The processing is the same as the one for the load operations of the MOV instruction, where the operation is repeated for the number of specified registers.

Note 3. The PUSHM instruction is converted into multiple store operations. The processing is the same as the one for the store operations of the MOV instruction, where the operation is repeated for the number of specified registers.

## 2.8.2 Numbers of Cycles for Response to Interrupts

Table 2.21 lists numbers of cycles taken by processing for response to interrupts.

**Table 2.21 Numbers of Cycles for Response to Interrupts**

| Type of Interrupt Request/Details of Processing                                                                                                                                                                                   | Fast Interrupt                                                                                  | Other Interrupts |
|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------|------------------|
| ICU<br>Judgment of priority order                                                                                                                                                                                                 | 2 cycles                                                                                        |                  |
| CPU<br>Numbers of cycles from notification to acceptance of the interrupt request                                                                                                                                                 | N cycles<br>(varies with the instruction being executed at the time the interrupt was received) |                  |
| CPU Pre-processing by hardware<br>Saving the current PC and PSW values in RAM<br>(or in control registers in the case of the fast interrupt)<br>Reading of the vector<br>Branching to the start of the exception handling routine | 4 cycles                                                                                        | 6 cycles         |

Times calculated from the values in Table 2.21 will be applicable when access to memory from the CPU is processed with no waiting. This MCU has a RAM that allows no-wait access and code flash memory incorporating a ROM Cache. Numbers of cycles for response to interrupts can be minimized by placing program code (and vectors) in code flash memory and the stack in RAM. Furthermore, place the addresses where the exception handling routine start on 8-byte boundaries.

For information on the numbers of cycles from notification to acceptance of the interrupt request, indicated by N in the table above, see Table 2.13 to Table 2.20.

The timing of interrupt acceptance depends on the execution state of the instruction. For more information on this, see section 13.3.1, Acceptance Timing and Saved PC Value.

## 3. Operating Modes

### 3.1 Operating Mode Types and Selection

There are two types of operating-mode selection: one is selected by the level of pins when a reset (RES# pin reset, power-on reset, or LVD0 reset) is released, and the other is selected by software after a reset is released.

Table 3.1 shows the relationship between levels on the mode-setting pins (MD and UB) when a reset is released and the operating mode selected at that time. For details on each of the operating modes, see section 3.3, Details of Operating Modes. Operation starts with the on-chip ROM (code flash memory and data flash memory) enabled and the external bus disabled, regardless of the mode in which operation started. Set the SYSCR0.EXBE bit to 1 (external bus enabled) to enable the external bus.

**Table 3.1 Selection of Operating Modes by the Mode-Setting Pins when the Reset is Released**

| Mode-Setting Pin |      |                            | SYSCR0 Initial State    |                           |
|------------------|------|----------------------------|-------------------------|---------------------------|
| MD*1             | UB*2 | Operating Mode             | ROME                    | EXBE                      |
| High             | —    | Single-chip mode           | 1 (On-chip ROM enabled) | 0 (External bus disabled) |
| Low              | Low  | Boot mode (SCI interface)  |                         |                           |
|                  | High | Boot mode (USB interface)  |                         |                           |
|                  |      | User boot mode             |                         |                           |
| Low → High*3     | Low  | Boot mode (FINE interface) |                         |                           |

Note 1. Do not change the level on the MD pin while the MCU is operating.

Note 2. The P00 pin, which is multiplexed on the same pin as the UB pin function, can also be used as a general purpose I/O port or as an input or output pin for peripheral functions.

Note 3. Place the low level on this pin when the reset is released, and change it to the high level when a period of between 20 and 100 ms has elapsed.

Table 3.2 gives a list of the operating mode settings that can be made with system control register 0 (SYSCR0). For details on each of the operating modes, see section 3.3, Details of Operating Modes.

**Table 3.2 Selection of Operating Modes by Register Setting**

| SYSCR0                     |                           |                                    |
|----------------------------|---------------------------|------------------------------------|
| ROME                       | EXBE                      | Operating Mode                     |
| 0 (On-chip ROM disabled)*1 | 0 (external bus disabled) | Single-chip mode, user boot mode   |
| 1 (On-chip ROM enabled)    | 0 (external bus disabled) |                                    |
| 0 (On-chip ROM disabled)*1 | 1 (external bus enabled)  | On-chip ROM disabled extended mode |
| 1 (On-chip ROM enabled)    | 1 (external bus enabled)  | On-chip ROM enabled extended mode  |

Note 1. Once the ROME bit is set to 0, it cannot be reverted to 1.

The endian is selectable in single-chip mode and user boot mode. Endian is selected by the endian selection bits (MDE[2:0]) in the endian select register (MDE). Table 3.3 lists the correspondence between the setting and endian. For details on selection of endian, see section 7.2.5, Endian Select Register (MDE).

**Table 3.3 Selection of Endian**

| Setting of the MDE[2:0] Bits | Selected Endian |
|------------------------------|-----------------|
| 000b                         | Big endian      |
| 111b                         | Little endian   |

## 3.2 Register Descriptions

### 3.2.1 Mode Monitor Register (MDMONR)

Address(es): 0008 0000h

|                    |     |     |     |     |     |     |    |    |    |    |    |    |    |    |    |       |
|--------------------|-----|-----|-----|-----|-----|-----|----|----|----|----|----|----|----|----|----|-------|
|                    | b15 | b14 | b13 | b12 | b11 | b10 | b9 | b8 | b7 | b6 | b5 | b4 | b3 | b2 | b1 | b0    |
|                    | —   | —   | —   | —   | —   | —   | —  | —  | —  | —  | —  | —  | —  | —  | —  | MD    |
| Value after reset: | 0   | 0   | 0   | 0   | 0   | 0   | 0  | x  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0/1*1 |

| Bit       | Symbol | Bit Name           | Description                                       | R/W |
|-----------|--------|--------------------|---------------------------------------------------|-----|
| b0        | MD     | MD Pin Status Flag | 0: The MD pin was low.<br>1: The MD pin was high. | R   |
| b7 to b1  | —      | Reserved           | These bits are read as 0.                         | R   |
| b8        | —      | Reserved           | The read value is undefined.                      | R   |
| b15 to b9 | —      | Reserved           | These bits are read as 0.                         | R   |

Note 1. This affects the level on the MD pin when the reset is released.

### 3.2.2 Mode Status Register (MDSR)

Address(es): 0008 0002h

|                    |     |     |     |     |     |     |    |    |    |    |       |    |    |    |    |    |
|--------------------|-----|-----|-----|-----|-----|-----|----|----|----|----|-------|----|----|----|----|----|
|                    | b15 | b14 | b13 | b12 | b11 | b10 | b9 | b8 | b7 | b6 | b5    | b4 | b3 | b2 | b1 | b0 |
|                    | —   | —   | —   | —   | —   | —   | —  | —  | —  | —  | UBTS  | —  | —  | —  | —  | —  |
| Value after reset: | 0   | 0   | 0   | 0   | 0   | 0   | 0  | 0  | 0  | 0  | 0/1*1 | 0  | 0  | 0  | 0  | 1  |

| Bit       | Symbol | Bit Name                    | Description                                                          | R/W |
|-----------|--------|-----------------------------|----------------------------------------------------------------------|-----|
| b0        | —      | Reserved                    | This bit is read as 1.                                               | R   |
| b4 to b1  | —      | Reserved                    | These bits are read as 0.                                            | R   |
| b5        | UBTS   | User Boot Mode Startup Flag | 0: Started with single-chip mode.<br>1: Started with user boot mode. | R   |
| b15 to b6 | —      | Reserved                    | These bits are read as 0.                                            | R   |

Note 1. Depends on the operating mode at startup.

### 3.2.3 System Control Register 0 (SYSCR0)

Address(es): 0008 0006h

| Bit       | Symbol   | Bit Name            | Description                                                                                                                | R/W     |
|-----------|----------|---------------------|----------------------------------------------------------------------------------------------------------------------------|---------|
| b0        | ROME     | On-Chip ROM Enable  | 0: The on-chip ROM is disabled.<br>1: The on-chip ROM is enabled.                                                          | R/W     |
| b1        | EXBE     | External Bus Enable | 0: The external bus is disabled.<br>1: The external bus is enabled.                                                        | R/W     |
| b7 to b2  | —        | Reserved            | These bits are read as 0. The write value should be 0.                                                                     | R/W     |
| b15 to b8 | KEY[7:0] | SYSCR0 Key Code     | These bits control permission and prohibition of writing to the SYSCR0 register. To modify the SYSCR0 register, write 5Ah. | R/(W)*1 |

Note 1. Write data is not retained.

The SYSCR0 register controls enabling or disabling of the on-chip ROM and the external bus. Update it as a 16-bit unit. Values written to the lower two bits are only reflected when the value 5Ah is written to the upper eight bits.

#### ROME Bit (On-Chip ROM Enable)

The ROME bit enables or disables the on-chip ROM (code flash memory and data flash memory).

Once set to 0, it cannot be reverted to 1.

Do not set this bit to 0 if a program is being executed from the code flash memory. After writing 0 to this bit, be sure to disable the on-chip ROM by changing the ROME bit to 0 before proceeding with further processing.

#### EXBE Bit (External Bus Enable)

The EXBE bit enables or disables the external bus.

Do not write 0 to this bit while a program is running from an external address space. Write 0 to this bit after access to the external bus is completed. When the external address space is to be included in the transfer range of a bus master other than the CPU (the DMAC or DTC), set this bit after disabling operation of the corresponding bus master or masters.

After writing to the EXBE bit, confirm that its value has actually changed before proceeding with further processing.

When the EXBE bit is set to 1, the related I/O port settings must also be changed as required. For details, see section 21, Multi-Function Pin Controller (MPC).

#### KEY[7:0] Bit (SYSCR0 Key Code)

The KEY[7:0] bits control enabling or disabling of writing to the SYSCR0 register.

To modify the values of the ROME and EXBE bits, write 5Ah to the KEY[7:0] bits. Writing a value other than 5Ah to the KEY[7:0] bits prevents changing the values of the ROME and EXBE bits.

### 3.2.4 System Control Register 1 (SYSCR1)

Address(es): 0008 0008h

|                    |     |     |     |     |     |     |    |    |    |             |    |    |    |    |    |      |
|--------------------|-----|-----|-----|-----|-----|-----|----|----|----|-------------|----|----|----|----|----|------|
|                    | b15 | b14 | b13 | b12 | b11 | b10 | b9 | b8 | b7 | b6          | b5 | b4 | b3 | b2 | b1 | b0   |
|                    | —   | —   | —   | —   | —   | —   | —  | —  | —  | ECCRA<br>ME | —  | —  | —  | —  | —  | RAME |
| Value after reset: | 0   | 0   | 0   | 0   | 0   | 0   | 0  | 0  | 1  | 1           | 1  | 1  | 1  | 1  | 1  | 1    |

| Bit       | Symbol  | Bit Name      | Description                                             | R/W |
|-----------|---------|---------------|---------------------------------------------------------|-----|
| b0        | RAME    | RAM Enable    | 0: The RAM is disabled.<br>1: The RAM is enabled.       | R/W |
| b5 to b1  | —       | Reserved      | These bits are read as 1. The write value should be 1.  | R/W |
| b6        | ECCRAME | ECCRAM Enable | 0: The ECCRAM is disabled.<br>1: The ECCRAM is enabled. | R/W |
| b7        | —       | Reserved      | This bit is read as 1. The write value should be 1.     | R/W |
| b15 to b8 | —       | Reserved      | These bits are read as 0. The write value should be 0.  | R/W |

#### RAME Bit (RAM Enable)

The RAME bit enables or disables the RAM.

A 0 should not be written to this bit during access to the RAM. When accessing the RAM immediately after changing the RAME bit from 0 to 1, make sure that the RAME bit is 1 before the access.

Even when the RAME bit is set to 0, the RAM retains its value. However, the voltage must be maintained at no less than the specified RAM standby voltage (VRAM), which is stipulated in section 45, Electrical Characteristics.

#### ECCRAME Bit (ECCRAM Enable)

The ECCRAME bit enables or disables the ECCRAM.

A 0 should not be written to this bit during access to the ECCRAM. When accessing the ECCRAM immediately after changing the ECCRAME bit from 0 to 1, make sure that the ECCRAME bit is 1 before the access.

Even when the ECCRAME bit is set to 0, the ECCRAM retains its value. However, the voltage must be maintained at no less than the specified RAM standby voltage (VRAM), which is stipulated in section 45, Electrical Characteristics.

### 3.2.5 Voltage Level Setting Register (VOLSR)

Address(es): 0008 C295h

|                    | b7     | b6     | b5 | b4 | b3 | b2     | b1 | b0 |
|--------------------|--------|--------|----|----|----|--------|----|----|
|                    | RICVLS | PGAVLS | —  | —  | —  | USBVON | —  | —  |
| Value after reset: | 0      | 0      | 0  | 0  | 0  | 0      | 0  | 0  |

| Bit      | Symbol | Bit Name                        | Description                                                                                                                                                                                                                                          | R/W |
|----------|--------|---------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----|
| b1, b0   | —      | Reserved                        | These bits are read as 0. The write value should be 0.                                                                                                                                                                                               | R/W |
| b2       | USBVON | USB Power Supply Control        | 0: USB is not used (Deep software standby mode included)<br>1: USB is used                                                                                                                                                                           | R/W |
| b5 to b3 | —      | Reserved                        | These bits are read as 0. The write value should be 0.                                                                                                                                                                                               | R/W |
| b6       | PGAVLS | PGA Operating Condition Setting | 0: The AVCC voltage is at least 4.0 V, and the pseudo-differential inputs of the PGAs are enabled and negative voltages is to be input to the pins.<br>1: The AVCC voltage is lower than 4.0 V or negative voltages are not to be input to the pins. | R/W |
| b7       | RICVLS | RIIC Operating Voltage Setting  | 0: VCC ≥ 4.5 V<br>1: VCC < 4.5 V                                                                                                                                                                                                                     | R/W |

The VOLSR register specifies whether USB is to be used or not, conditions of using the PGAs, and the power-supply voltage when the RIIC is in use.

#### USBVON Bit (USB Power Supply Control)

The USBVON bit is to be set when using the USB. Set this bit to 1 before releasing the USB from the module-stop state. Set this bit to 0 before executing a WAIT instruction when placing the MCU into deep software standby mode. For products without USB, or when the USB is not to be used, retain the bit 0.

#### PGAVLS Bit (PGA Operating Condition Setting)

The PGAVLS bit protects the internal circuits against negative voltages when using the programmable gain amplifiers (PGAs) with pseudo-differential input. When this bit is 0, the internal circuits are protected against negative voltages. Retain the bit 0 when the AVCC voltage is 4.0 V or higher, and when the pseudo-differential inputs of the PGAs are to be enabled, and when negative voltages are to be input to the pins. When the AVCC voltage is below 4.0 V, or when negative voltages are not to be input to the pins, set this bit to 1 in the case of products without PGA pseudo-differential input.

Set this bit before releasing the A/D converter from the module-stop state.

If a transition to software standby or deep software standby mode is made while the value of the bit is left at 0, approximately 0.2 mA of leakage current flows through the analog power supply. To prevent such leakage current, be sure not to input negative voltages to pins P40 to P42, PH0, P44 to P46, and PH4, set this bit to 1, and then, execute the WAIT instruction.

#### RICVLS Bit (RIIC Operating Voltage Setting)

The RICVLS bit controls the slew rate for the RIIC. Set the bit according to the VCC voltage. Set this bit before releasing the RIIC from the module-stop state.

### 3.3 Details of Operating Modes

#### 3.3.1 Single-Chip Mode

In single-chip mode, the external bus is disabled (SYSCR0.EXBE bit = 0) so that all I/O port pins are available for use as input or output port pins, inputs or outputs for peripheral functions, or as interrupt inputs.

If the high level is on the MD pin and the reset is released, the MCU starts in single-chip mode. The on-chip ROM is enabled (SYSCR0.ROME bit = 1) at this time. The on-chip ROM can be disabled by software (by clearing the SYSCR0.ROME bit to 0), but it cannot be re-enabled (by setting the SYSCR0.ROME bit to 1) once this is done. Setting the SYSCR0.EXBE bit to 1 (enabling the external bus) causes a transition to on-chip ROM enabled extended mode or to on-chip ROM disabled extended mode, making the external bus available.

#### 3.3.2 On-Chip ROM Enabled Extended Mode

In this mode, the on-chip ROM is enabled (SYSCR0.ROME bit = 1) and the external bus extension is enabled (SYSCR0.EXBE bit = 1). This mode allows some I/O ports to be used as data bus input/output, address bus output, or bus control signal input/output. For details, see section 21, Multi-Function Pin Controller (MPC).

After the MCU has started up in single-chip mode, setting the SYSCR0.EXBE bit to 1 (external bus enabled) causes it to make the transition to on-chip ROM enabled extended mode.

Writing 0 to the SYSCR0.EXBE bit (external bus disabled) causes a transition to single-chip mode (on-chip ROM enabled).

Writing 0 to the SYSCR0.ROME bit (on-chip ROM disabled) causes a transition to on-chip ROM disabled extended mode.

#### 3.3.3 On-Chip ROM Disabled Extended Mode

In this mode, the on-chip ROM is disabled (SYSCR0.ROME bit = 0) and the external bus extension is enabled (SYSCR0.EXBE bit = 1). This mode allows some I/O ports to be used as data bus input/output, address bus output, or bus control signal input/output. For details, see section 21, Multi-Function Pin Controller (MPC).

After the MCU has started up in single-chip mode, setting the SYSCR0.EXBE bit to 1 (external bus enabled) and setting the SYSCR0.ROME bit to 0 (on-chip ROM disabled) causes it to make the transition to on-chip ROM disabled extended mode.

In this mode, the on-chip ROM cannot be enabled by setting the SYSCR0.ROME bit to 1.

Writing 0 to the SYSCR0.EXBE bit (external bus disabled) causes a transition to single-chip mode (on-chip ROM disabled).

#### 3.3.4 Boot Mode (SCI Interface)

In this mode, the on-chip flash memory writing program (boot program) stored in a dedicated area of the MCU operates. The on-chip ROM (code flash memory and data flash memory) can be modified from outside the MCU by using a universal asynchronous receiver/transmitter (SCI1). For details, see section 44, Flash Memory (FLASH).

The MCU starts up in boot mode if the low level is on both the MD and UB pins, and the reset is released.

#### 3.3.5 Boot Mode (USB Interface)

In this mode, the on-chip flash memory writing program (boot program) stored in a dedicated area of the MCU operates. The on-chip ROM (code flash memory and data flash memory) can be modified from outside the MCU by using the USB. For details, see section 44, Flash Memory (FLASH).

The MCU starts up in boot mode (USB interface) if the low level is on the MD pin and the high level is on the UB pin, and the reset is released while UB code A is FFFF FFFFh, FFFF FFFFh.

### 3.3.6 Boot Mode (FINE Interface)

In this mode, the on-chip flash memory writing program (boot program) stored in a dedicated area of the MCU operates. The on-chip ROM (code flash memory and data flash memory) can be modified from outside the MCU by using the FINE. For details, see [section 44, Flash Memory \(FLASH\)](#).

After the reset is released while the low level is on both the MD and UB pins, if the MD pin is set to High within 20 to 100 msec, the MCU will start up in boot mode (FINE interface).

### 3.3.7 User Boot Mode

In user boot mode, an on-chip flash memory modifying program (user boot program) created by the user operates. After a reset is released, the MCU starts up in a state equivalent to single-chip mode.

After programming the prescribed values for UB code A and the UB code B, the MCU starts up in user boot mode if the low level is on the MD pin and the high level is on the UB pin, then the reset is released. In user boot mode, the reset vector is fetched from address FF7F FFFCh. For UB code A and UB code B, see [section 7, Option-Setting Memory \(OFSM\)](#).

After the MCU has started up in user boot mode, setting the SYSCR0.EXBE bit to 1 (external bus enabled) causes it to make the transition to on-chip ROM enabled extended mode.

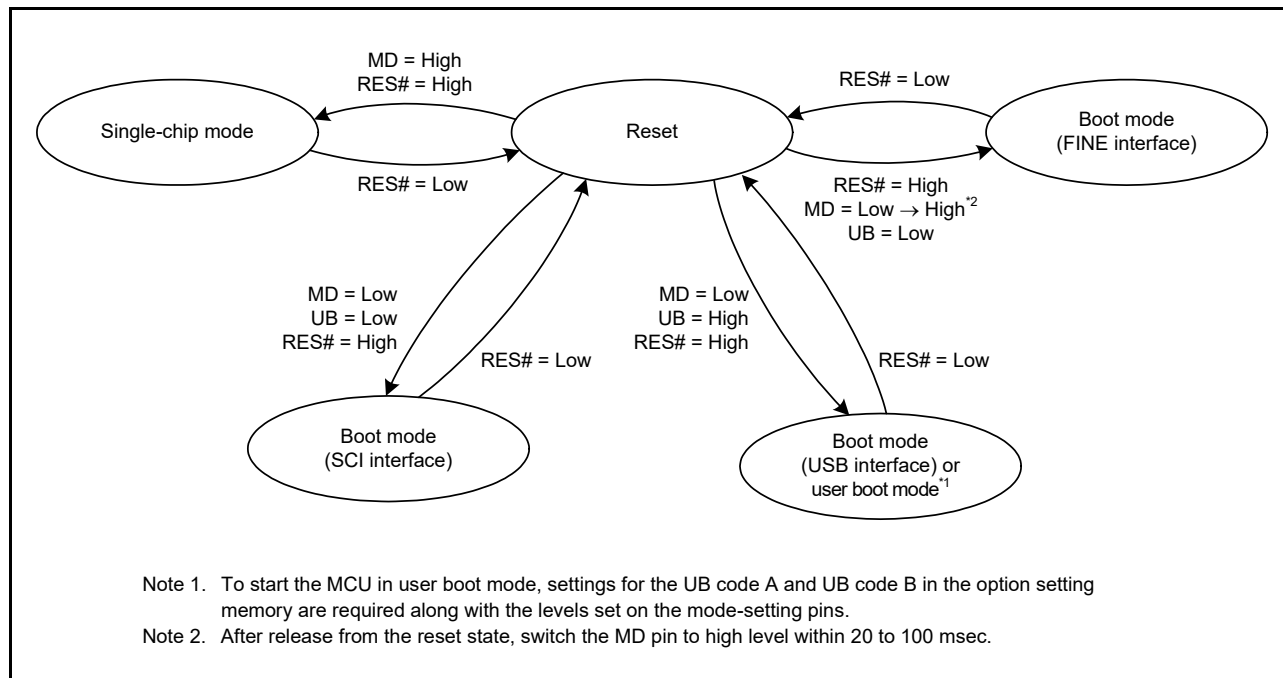

Note: In user boot mode, do not make a transition to software standby mode or deep software standby mode.

Note: The setting in the OFS0/OFS1 registers is ineffective in user boot mode, and the value becomes FFFF FFFFh.

### 3.4 Transitions of Operating Modes

#### 3.4.1 Operating Mode Transitions Determined by the Mode-Setting Pins

Figure 3.1 shows operating mode transitions determined by the settings of the MD pin and the UB pin.

**Figure 3.1 Mode-Setting Pin Level and Operating Mode**

### 3.4.2 Operating Mode Transitions According to Register Setting

Figure 3.2 shows operating mode transitions according to the setting of the ROME and EXBE bits in SYSCR0.

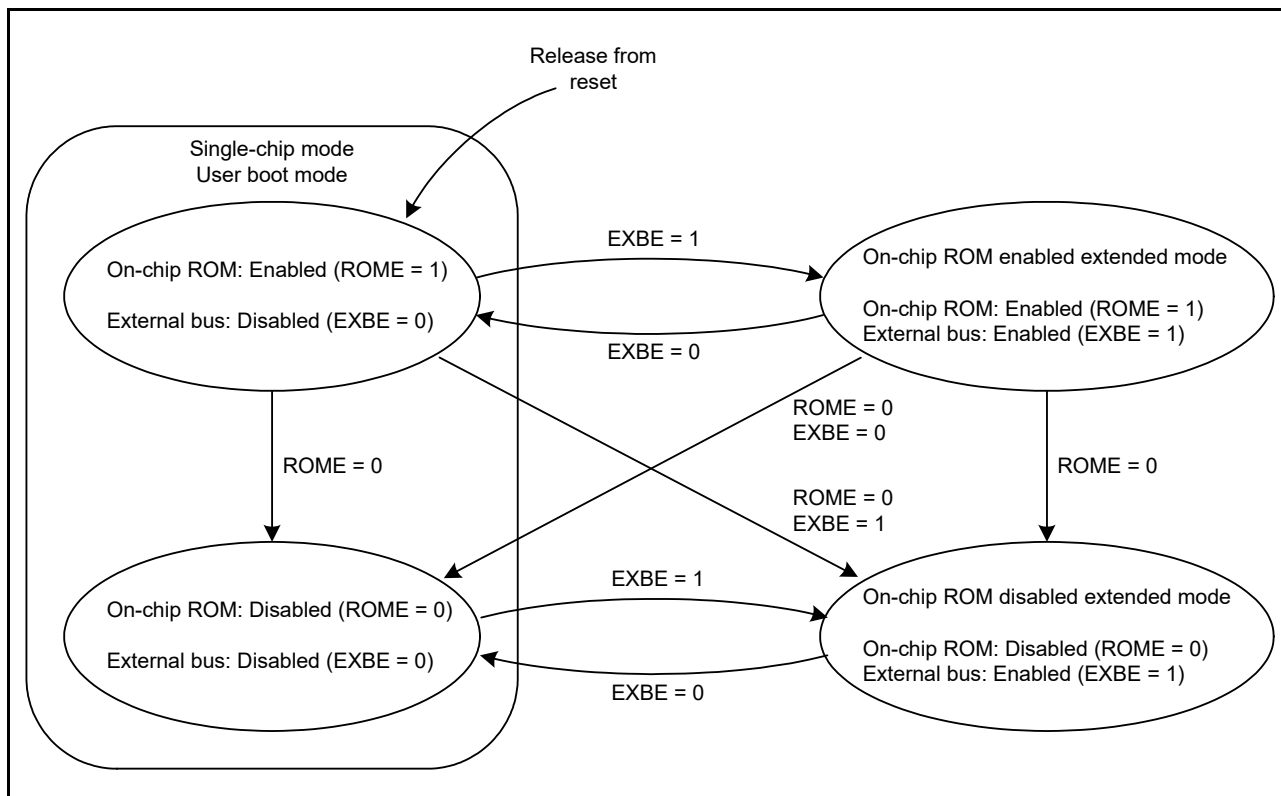

Figure 3.2 Setting of SYSCR0.ROME and EXBE Bits and Operating Modes

## 4. Address Space

### 4.1 Address Space

This MCU has a 4-Gbyte address space, consisting of the range of addresses from 0000 0000h to FFFF FFFFh. Figure 4.1 shows the memory maps in the respective operating modes. Accessible areas will differ according to the operating mode and states of control bits.

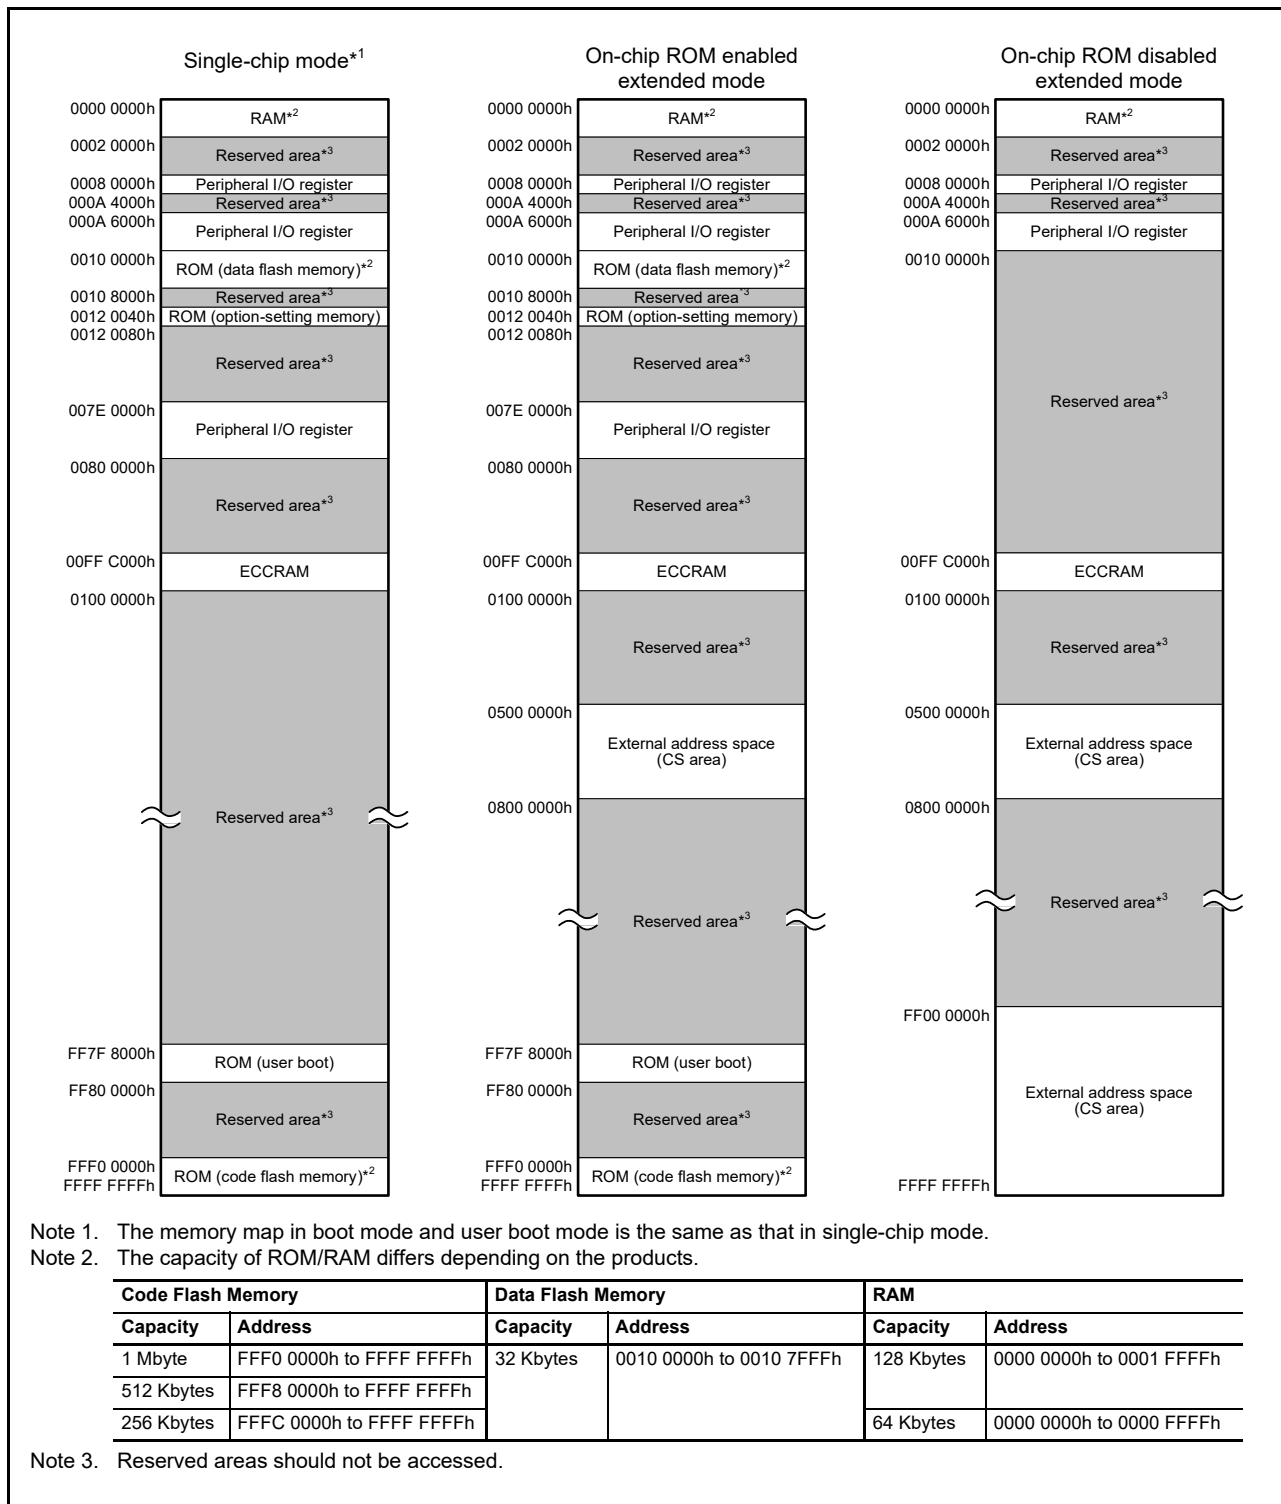

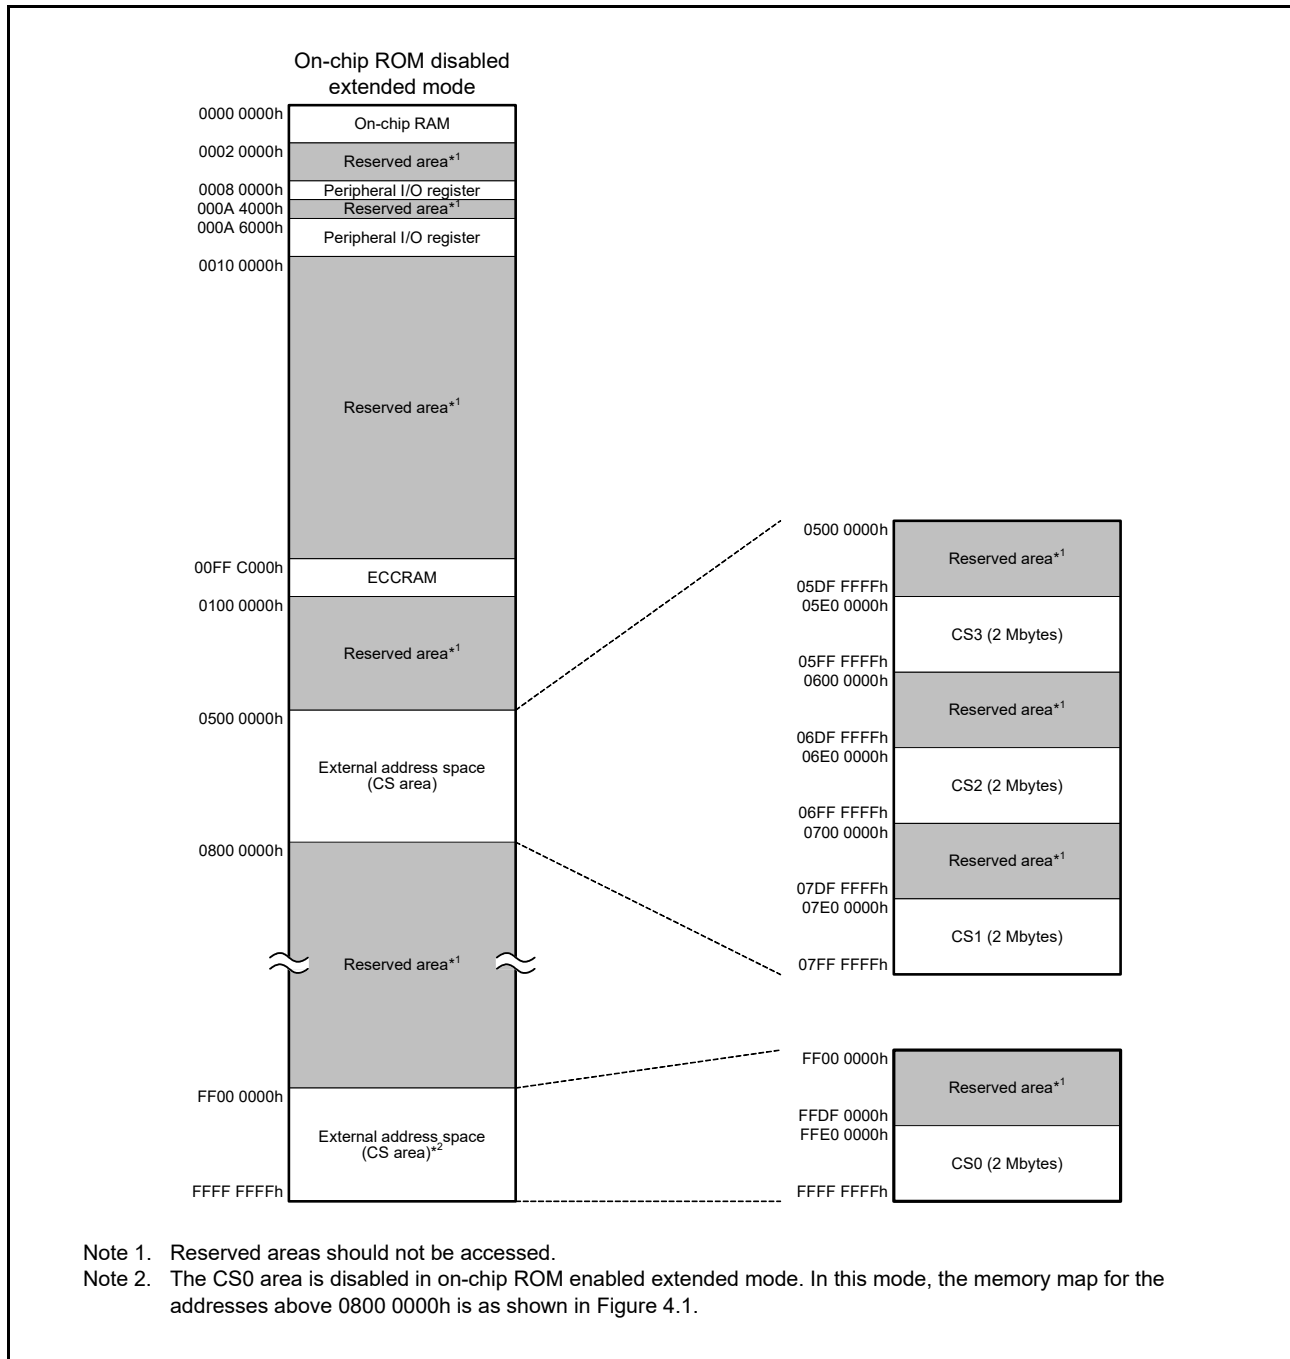

Figure 4.1 Memory Map in Each Operating Mode

## 4.2 External Address Space

The external address space is divided into four CS areas (CS0 to CS3), each corresponding to the CSn# signal output from a CSn# (n = 0 to 3) pin.

Figure 4.2 shows the address ranges corresponding to the individual CS areas (CS0 to CS3) in on-chip ROM disabled extended mode.

**Figure 4.2 Correspondence between External Address Spaces and CS Areas (In On-Chip ROM Disabled Extended Mode)**

## 5. I/O Registers

This section gives information on the on-chip I/O register addresses. The information is given as shown below. Notes on writing to registers are also given at the end.

### (1) I/O register addresses (address order)

- Registers are listed from the lower allocation addresses.
- Registers are classified according to module symbols.
- The number of access cycles indicates the number of cycles based on the specified reference clock.
- Among the internal I/O register area, addresses not listed in the list of registers are reserved. Reserved addresses must not be accessed. Do not access these addresses; otherwise, the operation when accessing these bits and subsequent operations cannot be guaranteed.

### (2) Notes on writing to I/O registers

When writing to an I/O register, the CPU starts executing the subsequent instruction before completing I/O register write. This may cause the subsequent instruction to be executed before the post-update I/O register value is reflected on the operation.

As described in the following examples, special care is required for the cases in which the subsequent instruction must be executed after the post-update I/O register value is actually reflected.

#### [Examples of cases requiring special care]

- The subsequent instruction must be executed while an interrupt request is disabled with the IENj bit in IERn of the ICU (interrupt request enable bit) set to 0.
- A WAIT instruction is executed immediately after the preprocessing for causing a transition to the low power consumption state.

In the above cases, after writing to an I/O register, wait until the write operation is completed using the following procedure and then execute the subsequent instruction.

- Write to an I/O register.
- Read the value from the I/O register to a general register.
- Execute the operation using the value read.
- Execute the subsequent instruction.

#### [Instruction examples]

- Byte-size I/O registers

```
MOV.L #SFR_ADDR, R1
MOV.B #SFR_DATA, [R1]
CMP [R1].UB, R1
;; Next process
```

- Word-size I/O registers

```
MOV.L #SFR_ADDR, R1
MOV.W #SFR_DATA, [R1]
CMP [R1].W, R1
;; Next process
```

- Longword-size I/O registers

```
MOV.L #SFR_ADDR, R1
MOV.L #SFR_DATA, [R1]
CMP [R1].L, R1
;; Next process
```

If multiple registers are written to and a subsequent instruction should be executed after the write operations are entirely completed, only read the I/O register that was last written to and execute the operation using the value; it is not necessary to read or execute operation for all the registers that were written to.

### (3) Number of Access Cycles to I/O Registers

For the number of I/O register access cycles, refer to Table 5.1, List of I/O Registers (Address Order).

The number of access cycles to I/O registers is obtained by following equation.\*1

Number of access cycles to I/O registers = Number of bus cycles for internal main bus 1 +  
 Number of divided clock synchronization cycles +  
 Number of bus cycles for internal peripheral busses 1 to 6

The number of bus cycles of internal peripheral bus 1 to 6 differs according to the register to be accessed. When peripheral functions connected to internal peripheral bus 2 to 6 or registers for the external bus control unit (except for bus error related registers) are accessed, the number of divided clock synchronization cycles is added.

The number of divided clock synchronization cycles differs depending on the frequency ratio between ICLK and PCLK (or FCLK, BCLK) or bus access timing.

In the peripheral function unit, when the frequency ratio of ICLK is equal to or greater than that of PCLK (or FCLK), the sum of the number of bus cycles for internal main bus 1 and the number of the divided clock synchronization cycles will be one cycle of PCLK (or FCLK) at a maximum. Therefore, one PCLK (or FCLK) has been added to the number of access states shown in Table 5.1.

When the frequency ratio of ICLK is lower than that of PCLK (or FCLK), the subsequent bus access is started from the ICLK cycle following the completion of the access to the peripheral functions. Therefore, the access cycles are described on an ICLK basis.

In the external bus control unit, the sum of the number of bus cycles for internal main bus 1 and the number of divided clock synchronization cycles will be one cycle of BCLK at a maximum. Therefore, one BCLK is added to the number of access cycles shown in Table 5.1.

Note 1. This applies to the number of cycles when the access from the CPU does not conflict with the instruction fetching to the external memory or bus access from the different bus master (DMAC or DTC).

### (4) Notes on Sleep Mode and Mode Transitions

During sleep mode or mode transitions, do not write to the registers related to system control (indicated by 'SYSTEM' in the Module Symbol column in Table 5.1, List of I/O Registers (Address Order)).

### (5) Restrictions in Relation to RMPA and String-Manipulation Instructions

The allocation of data to be handled by RMPA or string-manipulation instructions to I/O registers is prohibited, and operation is not guaranteed if this restriction is not observed.

## 5.1 I/O Register Addresses (Address Order)

Table 5.1 List of I/O Registers (Address Order) (1 / 50)

| Address    | Module Symbol | Register Name                                      | Register Symbol | Number of Bits | Access Size | Number of Access Cycles |             | Reference Section |
|------------|---------------|----------------------------------------------------|-----------------|----------------|-------------|-------------------------|-------------|-------------------|
|            |               |                                                    |                 |                |             | ICLK ≥ PCLK             | ICLK < PCLK |                   |

Note 1. When the register is accessed while the USB is operating, a delay may be generated in accessing.

Note 2. The address must end with 0h, 4h, 8h, or Ch when access is made in 32-bit units. The address must end with 0h, 2h, 4h, 6h, 8h, Ah, Ch, or Eh when access is made in 16-bit units.

## 6. Resets

### 6.1 Overview

There are nine types of resets: RES# pin reset, power-on reset, voltage-monitoring 0 reset, voltage-monitoring 1 reset, voltage-monitoring 2 reset, deep software standby reset, independent watchdog timer reset, watchdog timer reset, and software reset.

Table 6.1 lists the reset names and sources.

**Table 6.1 Reset Names and Sources**

| Reset Name                       | Source                                                                |
|----------------------------------|-----------------------------------------------------------------------|
| RES# pin reset                   | Voltage input to the RES# pin is driven low.                          |
| Power-on reset                   | VCC rises (voltage detection: VPOR)*1                                 |
| Voltage-monitoring 0 reset       | VCC falls (voltage detection: Vdet0)*1                                |
| Voltage-monitoring 1 reset       | VCC falls (voltage detection: Vdet1)*1                                |
| Voltage-monitoring 2 reset       | VCC falls (voltage detection: Vdet2)*1                                |
| Deep software standby reset      | Deep software standby mode is canceled by an interrupt.               |
| Independent watchdog timer reset | The independent watchdog timer underflows, or a refresh error occurs. |
| Watchdog timer reset             | The watchdog timer underflows, or a refresh error occurs.             |
| Software reset                   | Register setting                                                      |

Note 1. For details on the voltages to be monitored (VPOR, Vdet0, Vdet1, and Vdet2), see section 8, Voltage Detection Circuit (LVDA) and section 45, Electrical Characteristics.

The internal state and pins are initialized by a reset.

Table 6.2 lists the reset targets to be initialized.

**Table 6.2 Targets to be Initialized by Each Reset Source**

| Targets to be Initialized                                                                                                         | Reset Source   |                |                            |                                  |                      |                            |                            |                             |                |
|-----------------------------------------------------------------------------------------------------------------------------------|----------------|----------------|----------------------------|----------------------------------|----------------------|----------------------------|----------------------------|-----------------------------|----------------|
|                                                                                                                                   | RES# Pin Reset | Power-On Reset | Voltage-Monitoring 0 Reset | Independent Watchdog Timer Reset | Watchdog Timer Reset | Voltage-Monitoring 1 Reset | Voltage-Monitoring 2 Reset | Deep Software Standby Reset | Software Reset |
| Power-on reset detect flag (RSTSR0.PORF)                                                                                          | ✓              | —              | —                          | —                                | —                    | —                          | —                          | —                           | —              |
| Cold start/warm start determination flag (RSTSR1.CWSF)                                                                            | —              | ✓              | —                          | —                                | —                    | —                          | —                          | —                           | —              |

| Operating mode*2                                                                                                                  | ✓              | ✓              | ✓                          | —                                | —                    | —                          | —                          | —                           | —              |
| Registers other than the above, CPU, and internal state                                                                           | ✓              | ✓              | ✓                          | ✓                                | ✓                    | ✓                          | ✓                          | ✓                           | ✓              |

✓: Targets to be initialized, —: No change occurs.

Note 1. Of the registers related to the low-power-consumption function, the DPSBKRY register is not initialized by any reset. For details, see section 11, Low Power Consumption.

Note 2. The operating mode is determined by the level of the mode setting pins when the reset is released. For details, see section 3, Operating Modes.

When a reset is canceled, the reset exception handling starts. For details on the reset exception handling, see section 13, Exception Handling.

Table 6.3 lists the pin related to the reset.

**Table 6.3 Pin Related to Reset**

| Pin Name | I/O   | Function  |
|----------|-------|-----------|
| RES#     | Input | Reset pin |

## 6.2 Register Descriptions

### 6.2.1 Reset Status Register 0 (RSTSR0)

Address(es): 0008 C290h

| Bit      | Symbol  | Bit Name                               | Description                                                                                                                                      | R/W         |
|----------|---------|----------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------|-------------|
| b0       | PORF    | Power-On Reset Detect Flag             | 0: Power-on reset not detected.<br>1: Power-on reset detected.                                                                                   | R/(W)<br>*2 |
| b1       | LVD0RF  | Voltage-Monitoring 0 Reset Detect Flag | 0: Voltage-monitoring 0 reset not detected.<br>1: Voltage-monitoring 0 reset detected.                                                           | R/(W)<br>*2 |
| b2       | LVD1RF  | Voltage-Monitoring 1 Reset Detect Flag | 0: Voltage-monitoring 1 reset not detected.<br>1: Voltage-monitoring 1 reset detected.                                                           | R/(W)<br>*2 |
| b3       | LVD2RF  | Voltage-Monitoring 2 Reset Detect Flag | 0: Voltage-monitoring 2 reset not detected.<br>1: Voltage-monitoring 2 reset detected.                                                           | R/(W)<br>*2 |
| b6 to b4 | —       | Reserved                               | These bits are read as 0. The write value should be 0.                                                                                           | R/W         |
| b7       | DPSRSTF | Deep Software Standby Reset Flag       | 0: Deep software standby mode cancelation not requested by an interrupt.<br>1: Deep software standby mode cancelation requested by an interrupt. | R/(W)<br>*2 |

Note 1. The value after reset depends on the reset source.

Note 2. Only 0 can be written to clear the flag.

#### PORF Flag (Power-On Reset Detect Flag)

The PORF flag indicates that a power-on reset has occurred.

[Setting condition]

- When a power-on reset occurs.

[Clearing conditions]

- When a reset listed in Table 6.2 occurs.
- When PORF is read as 1 and then 0 is written to PORF.

**LVD0RF Flag (Voltage-Monitoring 0 Reset Detect Flag)**

The LVD0RF flag indicates that a voltage-monitoring 0 reset has occurred due to the VCC voltage falling below Vdet0.

[Setting condition]

- When a voltage-monitoring 0 reset occurs.

[Clearing conditions]

- When a reset listed in Table 6.2 occurs.
- When LVD0RF is read as 1 and then 0 is written to LVD0RF.

**LVD1RF Flag (Voltage-Monitoring 1 Reset Detect Flag)**

The LVD1RF flag indicates that a voltage-monitoring 1 reset has occurred due to the VCC voltage falling below Vdet1.

[Setting condition]

- When a voltage-monitoring 1 reset occurs.

[Clearing conditions]

- When a reset listed in Table 6.2 occurs.
- When LVD1RF is read as 1 and then 0 is written to LVD1RF.

**LVD2RF Flag (Voltage-Monitoring 2 Reset Detect Flag)**

The LVD2RF flag indicates that a voltage-monitoring 2 reset has occurred due to the VCC voltage falling below Vdet2.

[Setting condition]

- When a voltage-monitoring 2 reset occurs.

[Clearing conditions]

- When a reset listed in Table 6.2 occurs.
- When LVD2RF is read as 1 and then 0 is written to LVD2RF.

**DPSRSTF Flag (Deep Software Standby Reset Flag)**

The DPSRSTF flag indicates that deep software standby mode has been canceled by an interrupt and that an internal reset (deep software standby reset) occurred.

[Setting condition]

- When deep software standby mode is cancelled by an interrupt.  
For details, see section 11, Low Power Consumption.

[Clearing conditions]

- When a reset listed in Table 6.2 occurs.
- When DPSRSTF is read as 1 and then 0 is written to DPSRSTF.

## 6.2.2 Reset Status Register 1 (RSTSR1)

Address(es): 0008 C291h

Value after reset: 0 0 0 0 0 0 0 0/1\*1

| Bit      | Symbol | Bit Name                           | Description                                            | R/W         |
|----------|--------|------------------------------------|--------------------------------------------------------|-------------|
| b0       | CWSF   | Cold/Warm Start Determination Flag | 0: Cold start<br>1: Warm start                         | R/(W)<br>*2 |
| b7 to b1 | —      | Reserved                           | These bits are read as 0. The write value should be 0. | R/W         |

Note 1. The value after reset depends on the reset source.

Note 2. Only 1 can be written to set the flag.

RSTSR1 determines whether a power-on reset has caused the reset processing (cold start) or a reset signal input during operation has caused the reset processing (warm start).

### CWSF Flag (Cold/Warm Start Determination Flag)

The CWSF flag indicates the type of reset processing: cold start or warm start.

The CWSF flag is initialized by a power-on reset. It is not initialized by a reset signal generated by the RES# pin.

[Setting condition]

- When 1 is written through programming; it is not set to 0 even when 0 is written.

[Clearing condition]

- When a reset listed in Table 6.2 occurs.

### 6.2.3 Reset Status Register 2 (RSTSR2)

Address(es): 0008 00C0h

|                    |    |    |    |    |    |      |           |            |
|--------------------|----|----|----|----|----|------|-----------|------------|
|                    | b7 | b6 | b5 | b4 | b3 | b2   | b1        | b0         |
|                    | —  | —  | —  | —  | —  | SWRF | WDTR<br>F | IWDTR<br>F |
| Value after reset: | 0  | 0  | 0  | 0  | 0  | 0*1  | 0*1       | 0*1        |

| Bit      | Symbol | Bit Name                                     | Description                                                                                        | R/W         |
|----------|--------|----------------------------------------------|----------------------------------------------------------------------------------------------------|-------------|
| b0       | IWDTRF | Independent Watchdog Timer Reset Detect Flag | 0: Independent watchdog timer reset not detected.<br>1: Independent watchdog timer reset detected. | R/(W)<br>*2 |
| b1       | WDTRF  | Watchdog Timer Reset Detect Flag             | 0: Watchdog timer reset not detected.<br>1: Watchdog timer reset detected.                         | R/(W)<br>*2 |
| b2       | SWRF   | Software Reset Detect Flag                   | 0: Software reset not detected.<br>1: Software reset detected.                                     | R/(W)<br>*2 |
| b7 to b3 | —      | Reserved                                     | These bits are read as 0. The write value should be 0.                                             | R/W         |

Note 1. The value after reset depends on the reset source.

Note 2. Only 0 can be written to clear the flag.

#### IWDTRF Flag (Independent Watchdog Timer Reset Detect Flag)

The IWDTRF flag indicates that an independent watchdog timer reset has occurred.

[Setting condition]

- When an independent watchdog timer reset occurs.

[Clearing conditions]

- When a reset listed in Table 6.2 occurs.
- When IWDTRF is read as 1 and then 0 is written to IWDTRF.

#### WDTRF Flag (Watchdog Timer Reset Detect Flag)

The WDTRF flag indicates that a watchdog timer reset has occurred.

[Setting condition]

- When a watchdog timer reset occurs.

[Clearing conditions]

- When a reset listed in Table 6.2 occurs.
- When WDTRF is read as 1 and then 0 is written to WDTRF.

#### SWRF Flag (Software Reset Detect Flag)

The SWRF flag indicates that a software reset has occurred.

[Setting condition]

- When a software reset occurs.

[Clearing conditions]

- When a reset listed in Table 6.2 occurs.
- When SWRF is read as 1 and then 0 is written to SWRF.

## 6.2.4 Software Reset Register (SWRR)

Address(es): 0008 00C2h

| Bit       | Symbol     | Bit Name       | Description                                                 | R/W |
|-----------|------------|----------------|-------------------------------------------------------------|-----|
| b15 to b0 | SWRR[15:0] | Software Reset | Writing A501h resets the LSI. These bits are read as 0000h. | R/W |

## 6.3 Operation

### 6.3.1 RES# Pin Reset

This is a reset generated by the RES# pin.

When the RES# pin is driven low, all the processing in progress is aborted and the LSI enters a reset state.

In order to unfailingly reset the LSI, the RES# pin should be held low for the specified power supply stabilization time at a power-on.

When the RES# pin is driven high from low, the internal reset is canceled after the post-RES# cancelation wait time (tRESWT) has elapsed, and then the CPU starts the reset exception handling.

For details, see section 45, Electrical Characteristics.

### 6.3.2 Power-On Reset and Voltage Monitoring 0 Reset

The power-on reset is an internal reset generated by the power-on reset circuit.

If the RES# pin is in a high level state when power is supplied, a power-on reset is generated. In addition, if the RES# pin is in a high level state when power falls (including the case when VCC falls below VPOR), a power-on reset is generated. After VCC has exceeded VPOR and the specified period (power-on reset time) has elapsed, the internal reset is canceled and the CPU starts the reset exception handling. The power-on reset time is used for the stabilization of the power supply and the LSI circuit.

After a power-on reset has been generated, the PORF flag in the RSTSR0 is set to 1. The PORF flag is initialized by the RES# pin reset.

The voltage monitoring 0 reset is an internal reset generated by the voltage monitoring circuit. If the voltage detection 0 circuit start (LVDAS) bit in the option function select register 1 (OFS1) is 0 (voltage monitoring 0 reset is enabled after a reset) and VCC falls below Vdet0, the RSTSR0.LVD0RF flag becomes 1 and the voltage detection circuit generates voltage monitoring 0 reset. Clear the OFS1.LVDAS bit to 0 if the voltage monitoring 0 reset is to be used.

After VCC has exceeded Vdet0 and the voltage-monitoring 0 reset time (tLVD0) has elapsed, the internal reset is canceled and the CPU starts the reset exception handling. The Vdet0 voltage detection level can be changed by the setting of the VDSEL[1:0] bits in the option function select register 1 (OFS1).

Figure 6.1 shows operations during a power-on reset and voltage monitoring 0 reset.

For details on voltage monitoring 0 reset, refer to section 8, Voltage Detection Circuit (LVDA).

Figure 6.1 Operation Examples During a Power-On Reset and Voltage Monitoring 0 Reset

### 6.3.3 Voltage Monitoring 1 Reset and Voltage Monitoring 2 Reset

The voltage monitoring 1 reset and voltage monitoring 2 reset are internal resets generated by the voltage monitoring circuit.

When the voltage monitoring 1 interrupt/reset enable bit (LVD1RIE) is set to 1 (enabling generation of a reset or interrupt by the voltage detection circuit) and the voltage monitoring 1 circuit mode select bit (LVD1RI) is set to 1 (selecting generation of a reset in response to detection of a low voltage) in the voltage monitoring 1 circuit control register 0 (LVD1CR0), the RSTSR0.LVD1RF flag is set to 1 and the voltage-detection circuit generates a voltage monitoring 1 reset if VCC falls to or below Vdet1.

Likewise, when the voltage monitoring 2 interrupt/reset enable bit (LVD2RIE) is set to 1 (enabling generation of a reset or interrupt by the voltage detection circuit) and the voltage monitoring 2 circuit mode select bit (LVD2RI) is set to 1 (selecting generation of a reset in response to detection of a low voltage) in voltage monitoring 2 circuit control register 0 (LVD2CR0), the RSTSR0.LVD2RF flag is set to 1 and the voltage detection circuit generates a voltage monitoring 2 reset if VCC falls to or below Vdet2.

Timing for release from the voltage monitoring 1 reset state is selectable with the voltage monitoring 1 reset negate select bit (LVD1RN) in the LVD1CR0. When the LVD1CR0.LVD1RN bit is 0 and VCC has fallen to or below Vdet1, the CPU is released from the internal reset state and starts reset exception handling once the voltage-monitoring 1 reset time (tLVD1) has elapsed after VCC has risen above Vdet1. When the LVD1CR0.LVD1RN bit is 1 and VCC has fallen to or below Vdet1, the CPU is released from the internal reset state and starts reset exception handling once the voltage-

monitoring 1 reset time ( $t_{LVD1}$ ) has elapsed.

Likewise, timing for release from the voltage monitoring 2 reset state is selectable by setting the voltage monitoring 2 reset negate select bit (LVD2RN) in LVD2CR0 register.

Detection levels  $V_{det1}$  and  $V_{det2}$  can be changed by settings in the voltage detection select register (LVDLVLR).

Figure 6.2 shows examples of operations during voltage monitoring 1 and 2 resets.

For details on the voltage monitoring 1 reset and voltage monitoring 2 reset, refer to section 8, Voltage Detection Circuit (LVDA).

Figure 6.2 Operation Examples During Voltage Monitoring 1 Reset and Voltage Monitoring 2 Reset

### 6.3.4 Deep Software Standby Reset

This is an internal reset generated when deep software standby mode is canceled by an interrupt.

When a deep software standby mode cancellation source is generated, a deep software standby reset is generated. The deep software standby reset is canceled after tDSBY (recovery time after cancellation of deep software standby mode) has elapsed. At the same time, deep software standby mode is also canceled.

When tDSBYWT (wait time after cancellation of deep software standby mode) has elapsed after deep software standby mode has been canceled, the internal reset is canceled and the CPU starts the reset exception handling.

For details of the deep software standby reset, see section 11, Low Power Consumption.

### 6.3.5 Independent Watchdog Timer Reset

Independent watchdog timer reset is an internal reset generated by the independent watchdog timer.

Output of the independent watchdog timer reset from the independent watchdog timer can be selected by settings in the IWDTR reset control register (IWDTRCR) or option function select register 0 (OFS0).

When output of the independent watchdog timer reset is selected, an independent watchdog timer reset is generated if the independent watchdog timer underflows, or if data is written when refresh operation is disabled. When the internal reset time (tRESW2) has elapsed after the independent watchdog timer reset has been generated, the internal reset is canceled and the CPU starts the reset exception handling.

For details on the independent watchdog timer reset, see section 30, Independent Watchdog Timer (IWDTa).

### 6.3.6 Watchdog Timer Reset

The watchdog-timer reset is an internal reset from the watchdog timer.

Output of the independent watchdog timer reset from the independent watchdog timer can be selected by settings in the IWDTR reset control register (IWDTRCR) or option function select register 0 (OFS0).

When output of the watchdog timer reset is selected, a watchdog timer reset is generated if the watchdog timer underflows, or if data is written when refresh operation is disabled. When the internal reset time (tRESW2) has elapsed after the watchdog timer reset is generated, the internal reset is canceled and the CPU starts the reset exception handling.

For details on the watchdog timer reset, see section 29, Watchdog Timer (WDTA).

### 6.3.7 Software Reset

The software reset is an internal reset generated by the software reset circuit.

When A501h is written to SWRR, a software reset is generated. When the internal reset time (tRESW2) has elapsed after the software reset is generated, the internal reset is canceled and the CPU starts the reset exception handling.

### 6.3.8 Determination of Cold/Warm Start

By reading the CWSF flag in RSTSR1, the type of reset processing caused can be identified; that is, whether a power-on reset has caused the reset processing (cold start) or a reset signal input during operation has caused the reset processing (warm start).

The CWSF flag in RSTSR1 is set to 0 when a power-on reset occurs (cold start); otherwise the flag is not set to 0. The flag is set to 1 when 1 is written to it through programming; it is not set to 0 even when 0 is written.

Figure 6.3 shows an example of cold/warm start determination operation.

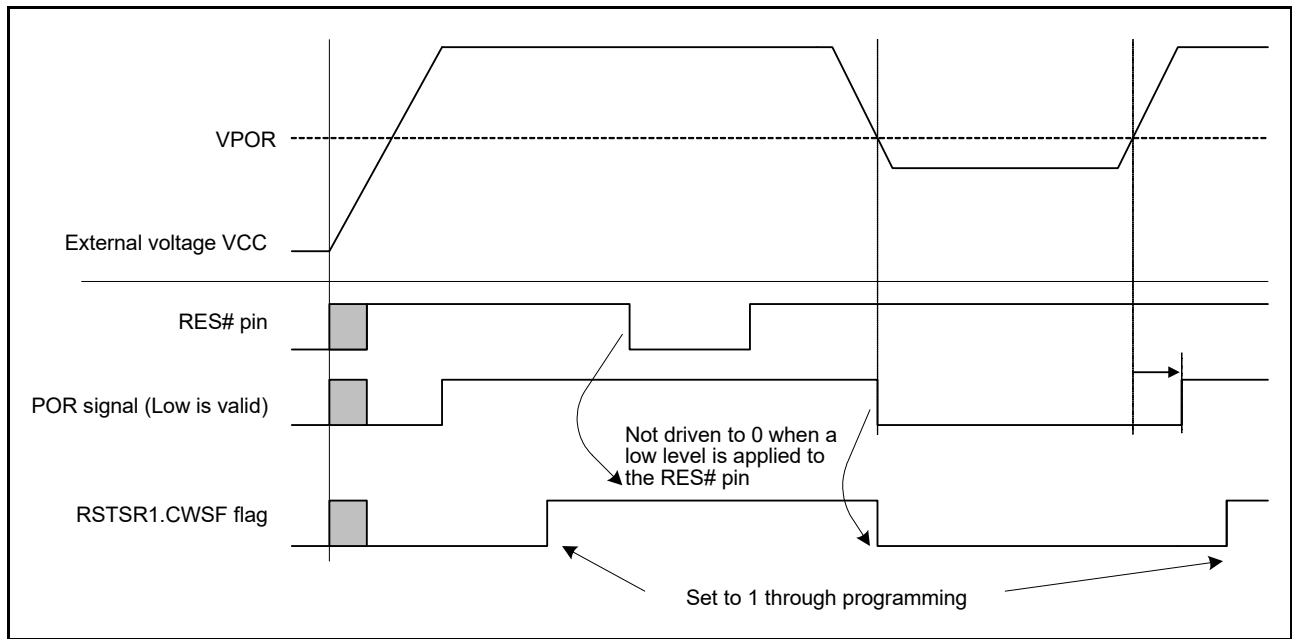

Figure 6.3 Example of Cold/Warm Start Determination Operation

### 6.3.9 Determination of Reset Generation Source

Reading RSTSR0 and RSTSR2 determines which reset was used to execute the reset exception handling. Figure 6.4 shows an example of the flow to identify a reset generation source.

Figure 6.4 Example of Reset Generation Source Determination Flow

## 7. Option-Setting Memory (OFSM)

### 7.1 Overview

The option-setting memory (OFSM) is a collective term for the registers listed below.

- Serial programmer command control register (SPCC)
- OCD/serial programmer ID setting register (OSIS)
- Option function select register 0 (OFS0)
- Option function select register 1 (OFS1)
- Endian select register (MDE)
- TM enable flag register (TMEF)
- TM identification data register (TMINF)
- UB code A
- UB code B
- ROM Code Protection Register (ROMCODE)

The option-setting memory determines the state of this MCU after a reset.

The method of setting the option-setting memory is different from that of the I/O registers. For details, refer to [section 7.6, Setting the Option-Setting Memory](#).

Figure 7.1 shows the option-setting memory area.

Figure 7.1 Option-Setting Memory Area

## 7.2 Register Descriptions

### 7.2.1 Serial Programmer Command Control Register (SPCC)

Address(es): OFSM.SPCC 0012 0040h

Note 1. The value of the blank product is FFFF FFFFh. This register is set to a specified value after setting a value.

Note 2. When the serial programmer ID code protection is enabled, set the RDPR, WRPR, and SEPR bits to 0.

This register is used to enable or disable the serial programmer ID code protection, and to permit or prohibit the connection of a serial programmer, or the execution of block erase commands, program commands, or read commands.

#### IDE Bit (Serial Programmer ID Code Protection Enable)

This bit enables or disables the serial programmer ID code protection.

When setting this bit to 0 (serial programmer ID code protection is enabled), set the RDPR, WRPR, and SEPR bits to 0.

#### SPE Bit (Serial Programmer Connection Enable)

This bit enables or disables the connection of a serial programmer.

Resetting MCU after setting this bit to 0 disables the connection of a serial programmer.

**SEPR Bit (Block Erase Command Protect)**

This bit enables or disables execution of block erase commands by the serial programmer.

When the IDE bit is 1 and this bit is 0, the block erase command cannot be executed. When the IDE bit is 0 and this bit is 0, the block erase command cannot be executed until the ID code matches.

When setting the IDE bit to 0, set this bit to 0.

**WRPR Bit (Program Command Protect)**

This bit enables or disables execution of program commands by the serial programmer.

When the IDE bit is 1 and this bit is 0, the program command cannot be executed. When the IDE bit is 0 and this bit is 0, the program command cannot be executed until the ID code matches.

When setting the IDE bit to 0, set this bit to 0.

**RDPR Bit (Read Command Protect)**

This bit enables or disables execution of read commands by the serial programmer.

When the IDE bit is 1 and this bit is 0, the read command cannot be executed. When the IDE bit is 0 and this bit is 0, the read command cannot be executed until the ID code matches.

When setting the IDE bit to 0, set this bit to 0.

## 7.2.2 OCD/Serial Programmer ID Setting Register (OSIS)

This register is used to store the control code or ID code for the on-chip debugger ID code protection and serial programmer ID code protection.

After the emulator or serial programmer sends a control code or ID code, it is tested for a match with the value stored in this register.

Connection to the emulator/serial programmer can proceed if the codes match and cannot proceed if they do not.

Enabling the serial programmer ID code protection requires setting of the IDE, SPE, RDPR, WRPR, and SEPR bits in the SPCC register, in addition to setting of this register.

For the blank product, the value after a reset for ID code 1/control code to ID code 16 is FFh. These registers are set to the specified values after setting a value.

| Address                  | Bit 31     |            |            | Bit 0                  |
|--------------------------|------------|------------|------------|------------------------|
| 0012 0050h to 0012 0053h | ID Code 4  | ID Code 3  | ID Code 2  | ID Code 1/Control Code |
| 0012 0054h to 0012 0057h | ID Code 8  | ID Code 7  | ID Code 6  | ID Code 5              |
| 0012 0058h to 0012 005Bh | ID Code 12 | ID Code 11 | ID Code 10 | ID Code 9              |
| 0012 005Ch to 0012 005Fh | ID Code 16 | ID Code 15 | ID Code 14 | ID Code 13             |

### ID Code 1/Control Code to ID Code 16

The control code or ID code for the on-chip debugger ID code protection and serial programmer ID code protection is stored in this register.

ID code 1 is used as a control code for connection to a serial programmer and as an ID code for connection to an emulator.

For details of the control code, refer to section 7.5, Settings of the Option-Setting Memory and Read, Program, and Erase Operations.

## 7.2.3 Option Function Select Register 0 (OFS0)

Address(es): OFSM.OFS0 0012 0068h

| b31 to b29 | —            | Reserved                                  | When reading, these bits return the value written by the user. The write value should be 1.                                                                                                                     | R   |

Note 1. The value of the blank product is FFFF FFFFh. This register is set to a specified value after setting a value.

The setting in the OFS0 register is ignored in user boot mode, and this register functions similarly when it is set to FFFF FFFFh.

### IWDTSTRT Bit (IWDT Start Mode Select)

This bit selects the mode in which the IWDT is activated after a reset (stopped state or activated in auto-start mode). When activated in auto-start mode, the OFS0 register setting for the IWDT is effective.

### IWDTTOPS[1:0] Bits (IWDT Timeout Period Select)

These bits select the timeout period, i.e. the time it takes for the down-counter to underflow, as 1024, 4096, 8192, or 16384 cycles of the frequency-divided clock set by the IWDTCKS[3:0] bits. The time (number of clock cycles for the IWDT) it takes to underflow after a refresh operation is determined by the combination of the IWDTCKS[3:0] bits and IWDTTOPS[1:0] bits.

For details, refer to section 30, Independent Watchdog Timer (IWDTa).

### IWDTCKS[3:0] Bits (IWDT-Dedicated Clock Frequency Division Ratio Select)

These bits select, from 1/1, 1/16, 1/32, 1/64, 1/128, and 1/256, the division ratio of the prescaler to divide the frequency of the clock for the IWDT. Using the setting of these bits together with the IWDTTOPS[1:0] bit setting, the IWDT counting period can be set from 1024 to 4194304 clock cycles for the IWDT.

For details, refer to section 30, Independent Watchdog Timer (IWDTa).

### IWDRPES[1:0] Bits (IWDT Window End Position Select)

These bits select the position of the end of the window for the down-counter as 0%, 25%, 50%, or 75% of the value being counted by the counter. The value of the window end position must be smaller than the value of the window start position (window start position > window end position). If the value for the window end position is greater than the value for the window start position, only the value for the window start position is effective.

The counter values corresponding to the settings for the start and end positions of the window in the IWDRPSS[1:0] and IWDRPES[1:0] bits vary with the setting of the IWDTTOPS[1:0] bits.  
For details, refer to section 30, Independent Watchdog Timer (IWDTa).

#### **IWDRPSS[1:0] Bits (IWDT Window Start Position Select)**

These bits select the position where the window for the down-counter starts as 25%, 50%, 75%, or 100% of the value being counted (the point at which counting starts is 100% and the point at which an underflow occurs is 0%). The interval between the positions where the window starts and ends becomes the period in which refreshing is possible, and refreshing is not possible outside this period.

For details, refer to section 30, Independent Watchdog Timer (IWDTa).

#### **IWDRSTIRQS Bit (IWDT Reset Interrupt Request Select)**

The setting of this bit selects the operation on an underflow of the down-counter or generation of a refresh error. An independent watchdog timer reset, a non-maskable interrupt request, or an interrupt request is selectable.

For details, refer to section 30, Independent Watchdog Timer (IWDTa).

#### **IWDTSLCSTP Bit (IWDT Sleep Mode Count Stop Control)**

This bit selects to stop counting when entering sleep, software standby, deep software standby, or all-module clock stop mode.

For details, refer to section 30, Independent Watchdog Timer (IWDTa).

#### **WDTSTRT Bit (WDT Start Mode Select)**

This bit selects the mode in which the WDT is activated after a reset (stopped state or activated in auto-start mode).

When activated in auto-start mode, the OFS0 register setting for the WDT is effective.

#### **WDTTOPS[1:0] Bits (WDT Timeout Period Select)**

These bits select the timeout period, i.e. the time it takes for the down-counter to underflow, as 1024, 4096, 8192, or 16384 cycles of the frequency-divided clock set by the WDTCKS[3:0] bits. The time (number of PCLKB cycles) it takes to underflow after a refresh operation is determined by a combination of the WDTCKS[3:0] bits and WDTTOPS[1:0] bits.

For details, refer to section 29, Watchdog Timer (WDTa).

#### **WDTCKS[3:0] Bits (WDT Clock Frequency Division Ratio Select)**

These bits select, from 1/4, 1/64, 1/128, 1/512, 1/2048, and 1/8192, the division ratio of the prescaler to divide the frequency of PCLKB. Using the setting of these bits together with the WDTTOPS[1:0] bit setting, the WDT counting period can be set from 4096 to 134217728 PCLKB cycles.

For details, refer to section 29, Watchdog Timer (WDTa).

#### **WDRPES[1:0] Bits (WDT Window End Position Select)**

These bits select the position of the end of the window on the down-counter as 0%, 25%, 50%, or 75% of the value being counted by the counter. The value of the window end position must be smaller than the value of the window start position (window start position > window end position). If the value for the window end position is greater than the value for the window start position, only the value for the window start position is effective.

The counter values corresponding to the settings for the start and end positions of the window in the WDRPSS[1:0] and WDRPES[1:0] bits vary with the setting of the WDTTOPS[1:0] bits.

For details, refer to section 29, Watchdog Timer (WDTa).

**WDTRPSS[1:0] Bits (WDT Window Start Position Select)**

These bits select the position where the window for the down-counter starts as 25%, 50%, 75%, or 100% of the value being counted (the point at which counting starts is 100% and the point at which an underflow occurs is 0%). The interval between the positions where the window starts and ends becomes the period in which refreshing is possible, and refreshing is not possible outside this period.

For details, refer to [section 29, Watchdog Timer \(WDTA\)](#).

**WDTRSTIRQS Bit (WDT Reset Interrupt Request Select)**

The setting of this bit selects the operation on an underflow of the down-counter or generation of a refresh error. A watchdog timer reset, a non-maskable interrupt request, or an interrupt request is selectable.

For details, refer to [section 29, Watchdog Timer \(WDTA\)](#).

## 7.2.4 Option Function Select Register 1 (OFS1)

Note 1. The value of the blank product is FFFF FFFFh. This register is set to a specified value after setting a value.

The setting in the OFS1 register is ignored in user boot mode, and this register functions similarly when it is set to FFFF FFFFh.

### VDSEL[1:0] Bits (Voltage Detection 0 Level Select)

These bits select the voltage detection level of the voltage detection 0 circuit.

### LVDAS Bit (Voltage Detection 0 Circuit Start)

This bit selects whether the voltage monitor 0 reset is enabled or disabled after a reset.

### HOCOEN Bit (HOCO Oscillation Enable)

This bit selects whether the HOCO oscillation enable bit is effective or not after a reset.

Setting the HOCOEN bit to 0 allows the HOCO oscillation to be started before the CPU starts operation, and therefore reduces the waiting time for oscillation stabilization.

Note that even if the HOCOEN bit is set to 0, the system clock source is not switched to HOCO. The system clock source is switched to HOCO only by modifying the clock source select bits (SCKCR3.CKSEL[2:0]) from the CPU.

## 7.2.5 Endian Select Register (MDE)

Address(es): OFSM.MDE 0012 0064h

|     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |

| b2 to b0  | MDE[2:0] | Endian Select | b2 b0<br>0 0 0: Big endian<br>1 1 1: Little endian<br>Settings other than above are prohibited. | R   |
| b31 to b3 | —        | Reserved      | When reading, these bits return the value written by the user.<br>The write value should be 1.  | R   |

Note 1. The value of the blank product is FFFF FFFFh. This register is set to a specified value after setting a value.

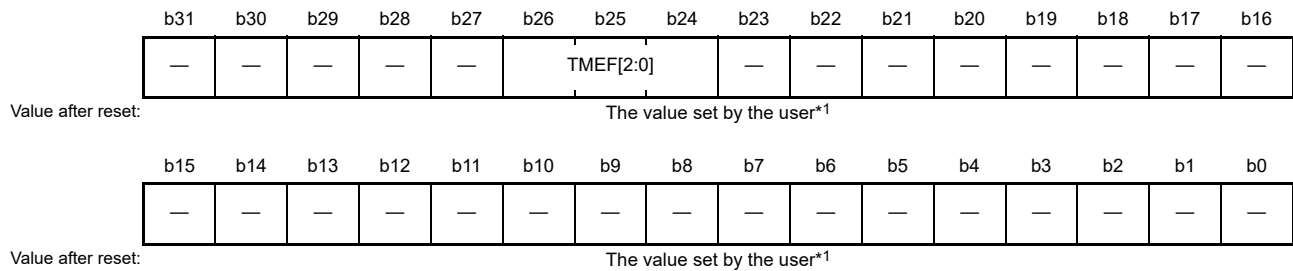

This register selects the endian for the CPU.

### MDE[2:0] Bits (Endian Select)

These bits select little endian or big endian for the CPU.

## 7.2.6 TM Enable Flag Register (TMEF)

Address(es): OFSM.TMEF 0012 0048h

| Bit        | Symbol    | Bit Name  | Description                                                                                                             | R/W |
|------------|-----------|-----------|-------------------------------------------------------------------------------------------------------------------------|-----|
| b23 to b0  | —         | Reserved  | When reading, these bits return the value written by the user.<br>The write value should be 1.                          | R   |
| b26 to b24 | TMEF[2:0] | TM Enable | b26 b24<br>0 0 0: TM function is enabled<br>1 1 1: TM function is disabled<br>Settings other than above are prohibited. | R   |
| b31 to b27 | —         | Reserved  | When reading, these bits return the value written by the user.<br>The write value should be 1.                          | R   |

Note 1. The value of the blank product is FFFF FFFFh. This register is set to a specified value after setting a value.

This register is used to enable the TM function for blocks 8 and 9 in the user area.

To enable the TM function, refer to [section 44.9.36, TM Setting Command](#). When the TMEF[2:0] bits are rewritten with the TM function enabled, rewriting the bits is ignored.

To disable the TM function, refer to [section 44.9.35, Configuration Clear Command](#).

### TMEF[2:0] Bits (TM Enable)

These bits enable or disable the TM function for blocks 8 and 9 in the user area.

## 7.2.7 TM Identification Data Register (TMINF)

Address(es): OFSM.TMINF 0012 0060h

Note 1. The value of the blank product is FFFF FFFFh. This register is set to a specified value after setting a value.

The user can store any desired 32-bit value in this register.

This register is used to store codes that identify the program stored in the TM-target area.

When the TMINF register is rewritten by serial programming while the TM function is enabled, rewriting this register is ignored. To erase the contents of the TMINF register, refer to [section 44.9.35, Configuration Clear Command](#).

## 7.2.8 ROM Code Protection Register (ROMCODE)

Address(es): OFSM.ROMCODE 0012 007Ch

| Bit       | Symbol     | Bit Name | Description                                                                                                                                                                          | R/W |
|-----------|------------|----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----|
| b31 to b0 | CODE[31:0] | ROM Code | 0000 0000h: ROM code protection enabled (ROM code protection 1)<br>0000 0001h: ROM code protection enabled (ROM code protection 2)<br>Other than above: ROM code protection disabled | R   |

Note 1. The value of the blank product is FFFF FFFFh. This register is set to a specified value after setting a value.

This register is used to disable read, program, and erase operations of the flash memory by a parallel programmer being used for off-board programming.

The ROM code in flash memory is a 32-bit code.

Table 7.1 shows the specifications for ROM code protection.

For release from ROM code protection, write FFFF FFFFh (code protection is disabled) to the ROM code by using the configuration setting command of the self-programming, or by using the ROM code setting command of the boot mode, or erase the ROM code by using the configuration clearing command. The user can store any desired 32-bit value in the register.

**Table 7.1 Specifications for ROM Code Protection**

| ROM Code         | State of Protection                                 | Operations at the Time of Connection with the Parallel Programmer         |
|------------------|-----------------------------------------------------|---------------------------------------------------------------------------|
| 0000 0000h       | ROM code protection enabled (ROM code protection 1) | Reading, programming, and erasing of the code flash memory is prohibited. |
| 0000 0001h       | ROM code protection enabled (ROM code protection 2) | Reading from the code flash memory is prohibited.                         |
| Other than above | ROM code protection disabled                        | Reading, programming, and erasing of the code flash memory is permitted.  |

### 7.3 UB Codes

UB codes A and B are required if user boot mode is to be employed. This MCU will start up in user boot mode on release from the reset state if the four conditions below are satisfied.

- UB code A is 5573 6572h and 426F 6F74h.
- UB code B is FFFF FF00h and 0008 C040h.
- The low level is being input on the MD pin.
- The high level is being input on the UB pin.

#### 7.3.1 UB Code A

UB code A consists of two 32-bit words. Set UB code A to 5573 6572h and 426F 6F74h. Do not set any values other than these values in user boot mode. Set UB code A to FFFF FFFFh and FFFF FFFFh in any boot modes other than user boot mode.

Figure 7.2 shows the structure of UB code A in memory. Set UB code A in 32-bit units.

Figure 7.2 UB Code A Structure

#### 7.3.2 UB Code B

UB code B consists of two words, i.e. 32 bits. Set UB code B to FFFF FF00h and 0008 C040h. Do not set any values other than these values in user boot mode. Set UB code B to FFFF FFFFh and FFFF FFFFh in any boot modes other than user boot mode.

Figure 7.3 shows the structure of UB code B in memory. Set UB code B in 32-bit units.

Figure 7.3 UB Code B Structure

## 7.4 Programming and Erasing of the Option-Setting Memory in Individual Operating Modes

Table 7.2 shows programming and erasing of the option-setting memory in the individual operating modes.

**Table 7.2 Programming and Erasing of the Option-Setting Memory in Individual Operating Modes**

| Option-Setting Memory                                                                                       | ROMCODE Setting Value | Boot Mode (SCI Interface, USB Interface, FINE Interface) |       | Self-Programming |       | Parallel Programmer |         |
|-------------------------------------------------------------------------------------------------------------|-----------------------|----------------------------------------------------------|-------|------------------|-------|---------------------|---------|

✓: Possible

x: Not possible

Note 1. The commands for boot mode (SCI, USB, and FINE interfaces) are used for programming or erasing. For details, refer to section 44.7, Boot Mode.

Note 2. The configuration setting command is used for programming. For how to use the configuration setting command, refer to section 44.6.6.10, Configuration Set Command.

Note 3. The ROM code cannot be programmed when the ROM code protection is set.

Note 4. The parallel programmer is used for programming and erasing. For details, refer to the manual of the parallel programmer you are using.

Note 5. It is erasable when the code flash memory is blank.

## 7.5 Settings of the Option-Setting Memory and Read, Program, and Erase Operations

Table 7.3 shows the settings of the option-setting memory and read, program, and erase operations when the MCU is connected to a serial programmer.

Table 7.4 shows the settings of the option-setting memory and judgment on ID codes when the MCU is connected to an OCD.

**Table 7.3 Settings of the Option-Setting Memory and Read, Program, and Erase Operations When the MCU is Connected to a Serial Programmer**

| 11  |           |           |                     |                        | 1          | 1          | 1          | Connection permitted                     | Permitted: read, program, erase                                         |

x: Don't care

Note 1. This determines whether the control code or ID code sent by the serial programmer matches the control code or ID code set in the OSIS register. When the codes match, connection is permitted; if not, connection is not possible.

Note 2. This determines whether the control code or ID code sent by the serial programmer matches the control code or ID code set in the OSIS register. When the codes match, connection is permitted; if not, connection is not possible. However, when results of judgment do not match 3 times in a row, the all data in the flash memory will be erased.

**Table 7.4 Settings of the Option-Setting Memory and Judgment on ID Codes When the MCU is Connected to an OCD**

| No. | SPCC. SPE | SPCC. IDE | OSIS (ID Code 1) | OSIS (ID Code 2 to 16) | SPCC. RDPR | SPCC. WRPR | SPCC. SEPR | Connection to an OCD                                                                                    |

## 7.6 Setting the Option-Setting Memory

### 7.6.1 Allocation of Data in the Option-Setting Memory

Data for programming in the option-setting memory should be allocated to the addresses shown in Figure 7.1. An example of source code for setting the option-setting memory is shown below.

Note: Programming formats vary depending on the compiler. Refer to the compiler manual for details.

Setting 1EFFFFFFh in the serial programmer command control register (SPCC)

```
.ORG 00120040H  
.LWORD 1EFFFFFFH
```

Setting the following ID codes in the OCD/serial programmer ID setting register (OSIS)

```
ID code 1/control code = FFh, ID code 2 = 02h, ID code 3 = 03h, ID code 4 = 04h,  
ID code 5 = 05h, ID code 6 = 06h, ID code 7 = 07h, ID code 8 = 08h,  
ID code 9 = 09h, ID code 10 = 0Ah, ID code 11 = 0Bh, ID code 12 = 0Ch,  
ID code 13 = 0Dh, ID code 14 = 0Eh, ID code 15 = 0Fh, ID code 16 = 10h  
.ORG 00120050H  
.LWORD 040302FFH, 08070605H, 0C0B0A09H, 100F0E0DH
```

Setting EF67BA5Dh in the option function select register 0 (OFS0)

```
.ORG 00120068H  
.LWORD 0EF67BA5DH
```

Setting FFFFFFFFAh in the option function select register 1 (OFS1)

```
.ORG 0012006CH  
.LWORD 0FFFFFFFAH
```

Setting FFFFFFFF8h in the endian select register (MDE)

```
.ORG 00120064H  
.LWORD 0FFFFFFF8H
```

Setting UB codes A and B

```
.ORG 0FF7FFFE8H  
.LWORD 55736572H, 426F6F74H  
.LWORD 0FFFFFFF00H, 0008C040H
```

## 7.7 Usage Note

### 7.7.1 Data for Programming Reserved Areas and Reserved Bits in the Option-Setting Memory

When reserved areas and reserved bits in the option-setting memory are within the scope of programming, write 1 as the value for all bits of reserved areas and all reserved bits. Normal operation cannot be guaranteed if 0 is written to such bits.

## 8. Voltage Detection Circuit (LVDA)

The voltage detection circuit (LVDA) monitors the voltage level input to the VCC pin using a program.

### 8.1 Overview

For voltage detection 0, the detection voltage is selectable from among two different levels and the reset from voltage monitoring 0 can be enabled or disabled after a reset by using the option function select register 1 (OFS1).

For voltage detection 1 and voltage detection 2, the detection voltage is selectable from among five different levels by using the voltage detection level select register (LVDLVLR).

The reset from voltage monitoring 0, reset/interrupt from voltage monitoring 1, and reset/interrupt from voltage monitoring 2 can be used.

Table 8.1 lists the specifications of the voltage detection circuit. Figure 8.1 is a block diagram of the voltage detection circuit. Figure 8.2 is a block diagram of the voltage monitoring 1 interrupt/reset circuit. Figure 8.3 is a block diagram of the voltage monitoring 2 interrupt/reset circuit.

**Table 8.1 Voltage Detection Circuit Specifications**

| Item                           |                          | Voltage Monitoring 0                                                                                      | Voltage Monitoring 1                                                                                                                                             | Voltage Monitoring 2                                                                                                                                             |

## 8.2 Register Descriptions

### 8.2.1 Voltage Monitoring 1 Circuit Control Register 1 (LVD1CR1)

Address(es): 0008 00E0h

| Bit      | Symbol              | Bit Name                                                      | Description                                                                                                                                                       | R/W |
|----------|---------------------|---------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----|
| b1, b0   | LVD1IDTSEL<br>[1:0] | Voltage Monitoring 1 Interrupt<br>Generation Condition Select | b1 b0<br>0 0: When VCC ≥ Vdet1 (rise) is detected<br>0 1: When VCC < Vdet1 (drop) is detected<br>1 0: When drop and rise are detected<br>1 1: Settings prohibited | R/W |
| b2       | LVD1IRQSEL          | Voltage Monitoring 1 Interrupt<br>Type Select                 | 0: Non-maskable interrupt<br>1: Maskable interrupt*1                                                                                                              | R/W |
| b7 to b3 | —                   | Reserved                                                      | These bits are read as 0. The write value should be 0.                                                                                                            | R/W |

Note 1. When enabling maskable interrupts, do not change the value of the NMIER.LVD1EN bit on the ICU side from the reset state.

## 8.2.2 Voltage Monitoring 1 Circuit Status Register (LVD1SR)

Address(es): 0008 00E1h

|                    |    |    |    |    |    |    |         |         |
|--------------------|----|----|----|----|----|----|---------|---------|
|                    | b7 | b6 | b5 | b4 | b3 | b2 | b1      | b0      |
|                    | —  | —  | —  | —  | —  | —  | LVD1MON | LVD1DET |
| Value after reset: | 0  | 0  | 0  | 0  | 0  | 0  | 1       | 0       |

| Bit      | Symbol  | Bit Name                                           | Description                                             | R/W         |
|----------|---------|----------------------------------------------------|---------------------------------------------------------|-------------|
| b0       | LVD1DET | Voltage Monitoring 1 Voltage Change Detection Flag | 0: Not detected<br>1: Vdet1 passage detection           | R/(W)<br>*1 |
| b1       | LVD1MON | Voltage Monitoring 1 Signal Monitor Flag           | 0: VCC < Vdet1<br>1: VCC ≥ Vdet1 or LVD1MON is disabled | R           |
| b7 to b2 | —       | Reserved                                           | These bits are read as 0. The write value should be 0.  | R/W         |

Note 1. Only 0 can be written to this bit. After writing 0 to this bit, it takes 2 system clock cycles for the bit to be read as 0.

### LVD1DET Flag (Voltage Monitoring 1 Voltage Change Detection Flag)

The LVD1DET flag is enabled when the LVCMPCR.LVD1E bit is 1 (voltage detection 1 circuit enabled) and the LVD1CR0.LVD1CMPE bit is 1 (voltage monitoring 1 circuit comparison result output enabled).

The LVD1DET flag should be set to 0 after LVD1CR0.LVD1RIE is set to 0 (disabled). LVD1CR0.LVD1RIE can be set to 1 (enabled) after a period of two or more cycles of PCLKB has elapsed.

Depending on the number of cycles of PCLKB defined for access to read an I/O register, two or more cycles than PCLKB may have to be secured as waiting time.

### LVD1MON Flag (Voltage Monitoring 1 Signal Monitor Flag)

The LVD1MON flag is enabled when the LVCMPCR.LVD1E bit is 1 (voltage detection 1 circuit enabled) and the LVD1CR0.LVD1CMPE bit is 1 (voltage monitoring 1 circuit comparison result output enabled).

## 8.2.3 Voltage Monitoring 2 Circuit Control Register 1 (LVD2CR1)

Address(es): 0008 00E2h

|                    |    |    |    |    |    |            |            |       |

| Bit      | Symbol              | Bit Name                                                   | Description                                                                                                                                                       | R/W |
|----------|---------------------|------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----|
| b1, b0   | LVD2IDTSEL<br>[1:0] | Voltage Monitoring 2 Interrupt Generation Condition Select | b1 b0<br>0 0: When VCC ≥ Vdet2 (rise) is detected<br>0 1: When VCC < Vdet2 (drop) is detected<br>1 0: When drop and rise are detected<br>1 1: Settings prohibited | R/W |
| b2       | LVD2IRQSEL          | Voltage Monitoring 2 Interrupt Type Select                 | 0: Non-maskable interrupt<br>1: Maskable interrupt*1                                                                                                              | R/W |
| b7 to b3 | —                   | Reserved                                                   | These bits are read as 0. The write value should be 0.                                                                                                            | R/W |

Note 1. When enabling maskable interrupts, do not change the value of the NMIER.LVD2EN bit on the ICU side from the reset state.

## 8.2.4 Voltage Monitoring 2 Circuit Status Register (LVD2SR)

Address(es): 0008 00E3h

|                    | b7 | b6 | b5 | b4 | b3 | b2 | b1      | b0      |
|--------------------|----|----|----|----|----|----|---------|---------|
|                    | —  | —  | —  | —  | —  | —  | LVD2MON | LVD2DET |
| Value after reset: | 0  | 0  | 0  | 0  | 0  | 0  | 1       | 0       |

| Bit      | Symbol  | Bit Name                                           | Description                                             | R/W         |
|----------|---------|----------------------------------------------------|---------------------------------------------------------|-------------|
| b0       | LVD2DET | Voltage Monitoring 2 Voltage Change Detection Flag | 0: Not detected<br>1: Vdet2 passage detection           | R/(W)<br>*1 |
| b1       | LVD2MON | Voltage Monitoring 2 Signal Monitor Flag           | 0: VCC < Vdet2<br>1: VCC ≥ Vdet2 or LVD2MON is disabled | R           |
| b7 to b2 | —       | Reserved                                           | These bits are read as 0. The write value should be 0.  | R/W         |

Note 1. Only 0 can be written to this bit. After writing 0 to this bit, it takes 2 system clock cycles for the bit to be read as 0.

### LVD2DET Flag (Voltage Monitoring 2 Voltage Change Detection Flag)

The LVD2DET flag is enabled when the LVCMPCR.LVD2E bit is 1 (voltage detection 2 circuit enabled) and the LVD2CR0.LVD2CMPE bit is 1 (voltage monitoring 2 circuit comparison result output enabled).

The LVD2DET flag should be set to 0 after LVD2CR0.LVD2RIE bit is set to 0 (disabled). LVD2CR0.LVD2RIE bit can be set to 1 (enabled) after a period of two or more cycles of PCLKB has elapsed.

Depending on the number of cycles of PCLKB defined for access to read an I/O register, two or more cycles of PCLKB may have to be secured as waiting time.

### LVD2MON Flag (Voltage Monitoring 2 Signal Monitor Flag)

The LVD2MON flag is enabled when the LVCMPCR.LVD2E bit is 1 (voltage detection 2 circuit enabled) and the LVD2CR0.LVD2CMPE bit is 1 (voltage monitoring 2 circuit comparison result output enabled).

## 8.2.5 Voltage Monitoring Circuit Control Register (LVCMPCR)

Address(es): 0008 C297h

|    |       |       |    |    |    |    |    |
|----|-------|-------|----|----|----|----|----|
| b7 | b6    | b5    | b4 | b3 | b2 | b1 | b0 |
| —  | LVD2E | LVD1E | —  | —  | —  | —  | —  |

Value after reset: 0 0 0 0 0 0 0 0

| Bit      | Symbol | Bit Name                   | Description                                                                       | R/W |
|----------|--------|----------------------------|-----------------------------------------------------------------------------------|-----|
| b4 to b0 | —      | Reserved                   | These bits are read as 0. The write value should be 0.                            | R/W |
| b5       | LVD1E  | Voltage Detection 1 Enable | 0: Voltage detection 1 circuit disabled<br>1: Voltage detection 1 circuit enabled | R/W |
| b6       | LVD2E  | Voltage Detection 2 Enable | 0: Voltage detection 2 circuit disabled<br>1: Voltage detection 2 circuit enabled | R/W |
| b7       | —      | Reserved                   | This bit is read as 0. The write value should be 0.                               | R/W |

### LVD1E Bit (Voltage Detection 1 Enable)

When using voltage detection 1 interrupt/reset or the LVD1SR.LVD1MON bit, set the LVD1E bit to 1. The voltage detection 1 circuit starts once  $t_d(E-A)$  passes after the LVD1E bit value is changed from 0 to 1.

### LVD2E Bit (Voltage Detection 2 Enable)

When using voltage detection 2 interrupt/reset or the LVD2SR.LVD2MON bit, set the LVD2E bit to 1. The voltage detection 2 circuit starts once  $t_d(E-A)$  passes after the LVD2E bit value is changed from 0 to 1.

## 8.2.6 Voltage Detection Level Select Register (LVDLVLR)

Address(es): 0008 C298h

| Bit      | Symbol       | Bit Name                                                                      | Description                                                                                                                                                                                                                                                                                                                                                                                                                                             | R/W |    |  |         |   |                  |         |   |                  |         |   |                  |         |   |                  |         |   |                  |     |

| b7     | LVD1RN             | Voltage Monitoring 1 Reset Negate Select                     | 0: Negation follows a stabilization time (tLVD1) after VCC > Vdet1 is detected.<br>1: Negation follows a stabilization time (tLVD1) after assertion of the LVD1 reset. | R/W |

### LVD1RIE Bit (Voltage Monitoring 1 Interrupt/Reset Enable)

Ensure that neither a voltage monitoring 1 reset nor a voltage monitoring 1 interrupt is generated during programming or erasure of the flash memory.

### LVD1DFDIS Bit (Voltage Monitoring 1 Digital Filter Disable Mode Select)

Set the LOCOCR.LCSTP bit to 0 (the LOCO operates) if the LVD1DFDIS bit is 0 (enabling the digital filter circuit). Set the LVD1DFDIS bit to 1 (digital filter circuit disabled) when using voltage monitoring 1 circuit in software standby mode or deep software standby mode.

### LVD1FSAMP [1:0] Bits (Sampling Clock Select)

The LVD1FSAMP[1:0] bits can be modified only when the LVD1DFDIS bit is 1 (digital filter circuit disabled). The LVD1FSAMP[1:0] bits should not be modified when the LVD1DFDIS bit is 0 (digital filter circuit enabled).

### LVD1RI Bit (Voltage Monitoring 1 Circuit Mode Select)

When the LVD1RI bit is 1 (voltage monitoring 1 reset selected) or when the LVD2CR0.LVD2RI bit is 1 (voltage monitoring 2 reset selected), a transition to deep software standby mode cannot be made, instead a transition to software standby mode is made. To enter deep software standby mode, set the LVD1RI bit to 0 (voltage monitoring 1 interrupt selected) and the LVD2CR0.LVD2RI bit to 0 (voltage monitoring 2 interrupt selected).

**LVD1RN Bit (Voltage Monitoring 1 Reset Negate Select)**

If the LVD1RN bit is to be set to 1 (negation follows a stabilization time after assertion of the LVD1 reset signal), set the LOCOCR.LCSTP bit to 0 (the LOCO operates). Furthermore, if a transition to software standby or deep software standby is to be made, the only possible value for the LVD1RN bit is 0 (negation follows a stabilization time after VCC > Vdet1 is detected). Do not set the LVD1RN bit to 1 (negation follows a stabilization time after assertion of the LVD1 reset signal) when this is the case.

**8.2.8 Voltage Monitoring 2 Circuit Control Register 0 (LVD2CR0)**

| b3     | —              | Reserved                                                     | The read value is undefined. The write value should be 0.                                                                                                              | R/W |
| b5, b4 | LVD2FSAMP[1:0] | Sampling Clock Select                                        | b5 b4<br>0 0: 1/2 LOCO frequency<br>0 1: 1/4 LOCO frequency<br>1 0: 1/8 LOCO frequency<br>1 1: 1/16 LOCO frequency                                                     | R/W |
| b6     | LVD2RI         | Voltage Monitoring 2 Circuit Mode Select                     | 0: Voltage monitoring 2 interrupt during Vdet2 passage<br>1: Voltage monitoring 2 reset enabled when the voltage falls to and below Vdet2                              | R/W |
| b7     | LVD2RN         | Voltage Monitoring 2 Reset Negate Select                     | 0: Negation follows a stabilization time (tLVD2) after VCC > Vdet2 is detected.<br>1: Negation follows a stabilization time (tLVD2) after assertion of the LVD2 reset. | R/W |

**LVD2RIE Bit (Voltage Monitoring 2 Interrupt/Reset Enable)**

Ensure that neither a voltage monitoring 2 reset nor a voltage monitoring 2 interrupt is generated during programming or erasure of the flash memory.

**LVD2DFDIS Bit (Voltage Monitoring 2 Digital Filter Disable Mode Select)**

Set the LOCOCR.LCSTP bit to 0 (the LOCO operates) if the LVD1DFDIS bit is 0 (enabling the digital filter circuit). Set the LVD2DFDIS bit to 1 (digital filter circuit disabled) when using voltage monitoring 2 circuit in software standby mode or deep software standby mode.

**LVD2FSAMP[1:0] Bits (Sampling Clock Select)**

The LVD2FSAMP[1:0] bits can be modified only when the LVD2DFDIS bit is 1 (digital filter circuit disabled). The LVD2FSAMP[1:0] bits should not be modified when the LVD2DFDIS bit is 0 (digital filter circuit enabled).

**LVD2RI Bit (Voltage Monitoring 2 Circuit Mode Select)**

When the LVD2RI bit is 1 (voltage monitoring 2 reset selected) or when the LVD1CR0.LVD1RI bit is 1 (voltage monitoring 1 reset selected), a transition to deep software standby mode cannot be made, instead a transition to software standby mode is made. To enter to deep software standby mode, set the LVD2RI bit to 0 (voltage monitoring 2 interrupt selected) and the LVD1CR0.LVD1RI bit to 0 (voltage monitoring 1 interrupt selected).

**LVD2RN Bit (Voltage Monitoring 2 Reset Negate Select)**

If the LVD2RN bit is to be set to 1 (negation follows a stabilization time after assertion of the LVD2 reset signal), set the LOCOCR.LCSTP bit to 0 (the LOCO operates). Furthermore, if a transition to software standby or deep software standby is to be made, the only possible value for the LVD2RN bit is 0 (negation follows a stabilization time after  $VCC > V_{det2}$  is detected). Do not set the LVD2RN bit to 1 (negation follows a stabilization time after assertion of the LVD2 reset signal) when this is the case.

## 8.3 VCC Input Voltage Monitor

### 8.3.1 Monitoring Vdet0

Monitoring Vdet0 is not possible.

### 8.3.2 Monitoring Vdet1

Table 8.2 lists the procedures for setting up monitoring against Vdet1. After the settings are completed, results of comparison by voltage monitoring 1 can be monitored by using the LVD1SR.LVD1MON flag.

**Table 8.2 Procedures for Setting up Monitoring against Vdet1**

| Step                                    | Monitoring the Results of Comparison by Voltage Monitoring 1 |                                                                                                                                                                |
|-----------------------------------------|--------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Setting the voltage detection 1 circuit | 1                                                            | Select the detection voltage by setting the LVDLVL.R.LVD1LVL[3:0] bits.                                                                                        |
|                                         | 2                                                            | Set LVCMP.R.LVD1E = 1 (enabling the voltage detection 1 circuit).                                                                                              |
|                                         | 3                                                            | Wait for at least $t_d(E-A)$ (LVD operation stabilization time after LVD is enabled). <sup>*1</sup>                                                            |
| Setting the digital filter<br>*2        | 4                                                            | Select the sampling clock for the digital filter by setting the LVD1CR0.LVD1FSAMP[1:0] bits.                                                                   |
|                                         | 5                                                            | Set LVD1CR0.LVD1DFDIS = 0 (enabling the digital filter).                                                                                                       |
|                                         | 6                                                            | Wait for at least $2n + 3$ cycles of the LOCO (where $n = 2, 4, 8, 16$ , and the sampling clock for the digital filter is the LOCO frequency-divided by $n$ ). |
| Enabling output                         | 7                                                            | Set LVD1CR0.LVD1CMPE = 1 (enabling output of the results of comparison by voltage monitoring 1).                                                               |

Note 1. Steps 4 to 6 can be performed during the waiting time of step 3. For details of  $t_d(E-A)$ , see section 45, Electrical Characteristics.

Note 2. Steps 4 to 6 are not required if the digital filter is not in use.

### 8.3.3 Monitoring Vdet2

Table 8.3 lists the procedures for setting up monitoring against Vdet2. After the settings are completed, results of comparison by voltage monitoring 2 can be monitored by using the LVD2SR.LVD2MON flag.

**Table 8.3 Procedures for Setting up Monitoring against Vdet2**

| Step                                    | Monitoring the Results of Comparison by Voltage Monitoring 2 |                                                                                                                                                                |

| Setting the voltage detection 2 circuit | 1                                                            | Select the detection voltage by setting the LVDLVL.R.LVD2LVL[3:0] bits.                                                                                        |
|                                         | 2                                                            | Set LVCMP.R.LVD2E = 1 (enabling the voltage detection 2 circuit).                                                                                              |
|                                         | 3                                                            | Wait for at least $t_d(E-A)$ (LVD operation stabilization time after LVD is enabled). <sup>*1</sup>                                                            |
| Setting the digital filter<br>*2        | 4                                                            | Select the sampling clock for the digital filter by setting the LVD2CR0.LVD2FSAMP[1:0] bits.                                                                   |
|                                         | 5                                                            | Set LVD2CR0.LVD2DFDIS = 0 (enabling the digital filter).                                                                                                       |
|                                         | 6                                                            | Wait for at least $2n + 3$ cycles of the LOCO (where $n = 2, 4, 8, 16$ , and the sampling clock for the digital filter is the LOCO frequency-divided by $n$ ). |
| Enabling output                         | 7                                                            | Set LVD2CR0.LVD2CMPE = 1 (enabling output of the results of comparison by voltage monitoring 2).                                                               |

Note 1. Steps 4 to 6 can be performed during the waiting time of step 3. For details of  $t_d(E-A)$ , see section 45, Electrical Characteristics.

Note 2. Steps 4 to 6 are not required if the digital filter is not in use.

### 8.4 Reset from Voltage Monitor 0

When using the reset from voltage monitor 0, clear the OFS1.LVDAS bit to 0 (enabling the voltage monitor 0 reset after a reset).

Figure 8.4 shows an example of operations for a voltage monitoring 0 reset.

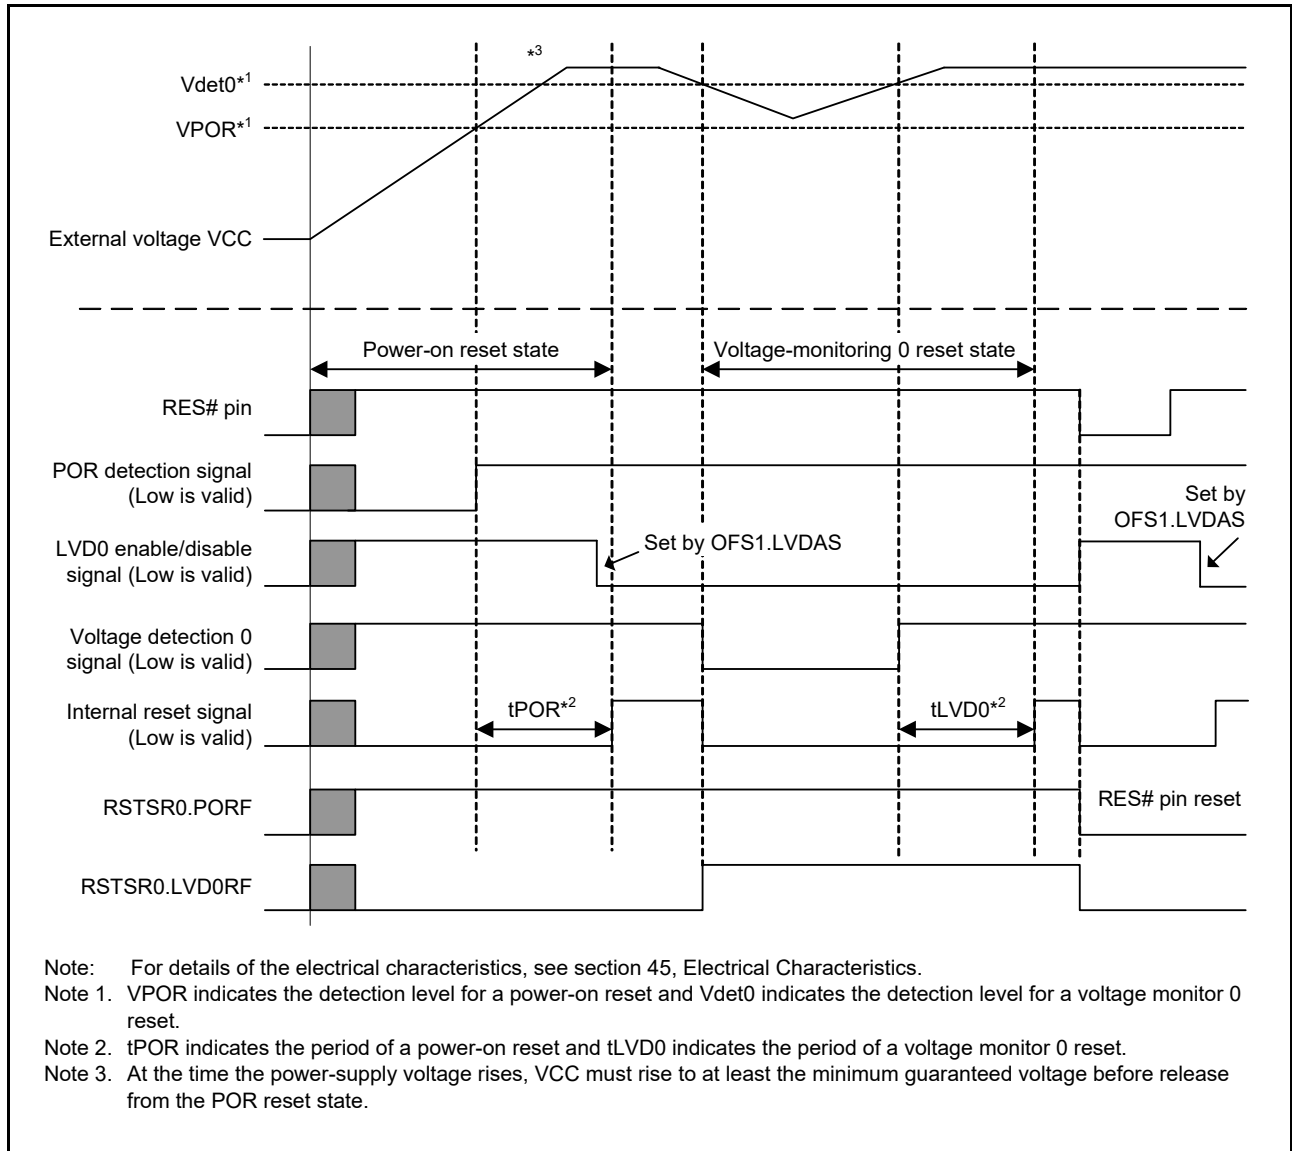

Figure 8.4 Example of Voltage Monitoring 0 Reset Operation

## 8.5 Interrupt and Reset from Voltage Monitor 1

An interrupt or reset can be generated in response to the results of comparison by the voltage detection 1 circuit.

Table 8.4 lists the procedures for setting bits related to the voltage monitor 1 interrupt and voltage monitor 1 reset so that voltage monitoring operates. Table 8.5 shows the procedure for setting bits related to the voltage monitor 1 interrupt and voltage monitor 1 reset so that voltage monitoring stops. Figure 8.5 shows an example of operations for a voltage monitor 1 interrupt. For the operation of the voltage monitor 1 reset, see Figure 6.2 in section 6, Resets.

Furthermore, if you intend to use the voltage monitoring 1 circuit in software standby or deep software standby mode, make settings for the voltage monitoring 1 circuit according to the following procedures.

### (1) Setting in software standby mode

- Disable the digital filter (LVD1DFDIS = 1).
- After  $VCC > V_{det1}$  is detected, negate the voltage monitoring 1 reset signal (LVD1RN = 0) following a stabilization time.

### (2) Settings in deep software standby mode

- Disable the digital filter (LVD1DFDIS = 1).
- Enable voltage monitoring 1 interrupts (LVD1RI = 0). If the voltage monitoring 1 reset is enabled (LVD1RI = 1), a transition to deep software standby mode will not be possible, and the transition will be to software standby mode instead.

**Table 8.4 Procedures for Setting Bits Related to the Voltage Monitoring 1 Interrupt and Voltage Monitoring 1 Reset so that Voltage Monitoring Operates**

| Step                                                | Voltage Monitoring 1 Interrupt<br>(Voltage Monitoring 1 ELC Event Output) | Voltage Monitoring 1 Reset                                                                                                                                                                                                   |

| Setting the voltage monitoring 1 interrupt or reset | 7                                                                         | Set LVD1CR0.LVD1RI = 0 (selecting the voltage monitoring 1 interrupt).<br>• Set LVD1CR0.LVD1RI = 1 (selecting the voltage monitoring 1 reset).<br>• Select the type of the reset negation by setting the LVD1CR0.LVD1RN bit. |
|                                                     | 8                                                                         | • Select the timing of interrupt requests by setting the LVD1CR1.LVD1IDTSEL[1:0] bits.<br>• Select the type of interrupt by setting the LVD1CR1.LVD1IRQSEL bit.                                                              |
| Enabling output                                     | 9                                                                         | Set LVD1SR.LVD1DET = 0.                                                                                                                                                                                                      |
|                                                     | 10                                                                        | Set LVD1CR0.LVD1RIE = 1 (enabling the voltage monitoring 1 interrupt or reset). <sup>*3</sup>                                                                                                                                |
|                                                     | 11                                                                        | Set LVD1CR0.LVD1CMPE = 1 (enabling output of the results of comparison by voltage monitoring 1).                                                                                                                             |

Note 1. Steps 4 to 10 can be performed during the waiting time of step 3. For details of  $t_d(E-A)$ , see section 45, Electrical Characteristics.

Note 2. Steps 4 to 6 are not required if the digital filter is not in use.

Note 3. Step 10 is not required if only the ELC event signal is to be output.

**Table 8.5 Procedures for Setting Bits Related to the Voltage Monitoring 1 Interrupt and Voltage Monitoring 1 Reset so that Voltage Monitoring Stops**

| Step                                     |   | Voltage Monitoring 1 Interrupt (Voltage Monitoring 1 ELC Event Output), Voltage Monitoring 1 Reset                                                                           |
|------------------------------------------|---|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Settings to stop enabling of output      | 1 | Set LVD1CR0.LVD1CMPE = 0 (disabling output of the results of comparison by voltage monitoring 1).                                                                            |
|                                          | 2 | Wait for at least $2n + 3$ cycles of the LOCO (where $n = 2, 4, 8, 16$ , and the sampling clock for the digital filter is the LOCO frequency-divided by $n$ ). <sup>*1</sup> |
|                                          | 3 | Set LVD1CR0.LVD1RIE = 0 (disabling the voltage monitoring 1 interrupt or reset). <sup>*2</sup>                                                                               |
| Stopping the digital filter              | 4 | Set LVD1CR0.LVD1DFDIS = 1 (disabling the digital filter). <sup>*1, *3</sup>                                                                                                  |
| Stopping the voltage detection 1 circuit | 5 | Set LVCMPCR.LVD1E = 0 (disabling the voltage detection 1 circuit).                                                                                                           |

Note 1. Steps 2 and 4 are not required if the digital filter is not in use.

Note 2. Step 3 is not required if only the ELC event signal is to be output.

Note 3. To disable the digital filter from its enabled state and then re-enable it, disable it and wait for at least two cycles of the LOCO before re-enabling it.

If the voltage monitoring 1 interrupt or voltage monitoring 1 reset setting is to be made again after it has been used and stopped once, the following steps in the procedures for stopping and making the setting can be omitted according to the condition.

- Setting or stopping the voltage detection 1 circuit is not required if the setting for the voltage detection 1 circuit is not to be changed.
- Setting or stopping the digital filter is not required if the setting for the digital filter is not to be changed.
- Setting the voltage monitoring 1 interrupt or reset is not required if the setting for the voltage monitoring 1 interrupt or voltage monitoring 1 reset is not to be changed.

Figure 8.5 Example of Voltage Monitoring 1 Interrupt Operation

## 8.6 Interrupt and Reset from Voltage Monitor 2

An interrupt or reset can be generated in response to the results of comparison by the voltage detection 2 circuit.

Table 8.6 shows the procedures for setting bits related to the voltage monitor 2 interrupt and voltage monitor 2 reset so that voltage monitoring operates. Table 8.7 shows the procedure for setting bits related to the voltage monitor 2 interrupt and voltage monitor 2 reset so that voltage monitoring stops. Figure 8.6 shows an example of operations for a voltage monitor 2 interrupt. For the operation of the voltage monitor 2 reset, see Figure 6.2 in section 6, Resets.

Furthermore, if you intend to use the voltage monitoring 2 circuit in software standby or deep software standby mode, make settings for the voltage monitoring 2 circuit according to the following procedures.

### (1) Setting in software standby mode

- Disable the digital filter (LVD2DFDIS = 1).
- After  $VCC > V_{det2}$  is detected, negate the voltage monitoring 2 reset signal (LVD2RN = 0) following a stabilization time.

### (2) Settings in deep software standby mode

- Disable the digital filter (LVD2DFDIS = 1).
- Enable voltage monitoring 2 interrupts (LVD2RI = 0). If the voltage monitoring 2 reset is enabled (LVD2RI = 1), a transition to deep software standby mode will not be possible, and the transition will be to software standby mode instead.

**Table 8.6 Procedures for Setting Bits Related to the Voltage Monitoring 2 Interrupt and Voltage Monitoring 2 Reset so that Voltage Monitoring Operates**

| Step                                                | Voltage Monitoring 2 Interrupt<br>(Voltage Monitoring 2 ELC Event Output) |                                                                                                                                                                                                                         | Voltage Monitoring 2 Reset                                                                                                                                                                                 |
|-----------------------------------------------------|---------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

|                                                     | 10                                                                        | Set LVD2CR0.LVD2RIE = 1 (enabling the voltage monitoring 2 interrupt or reset). <sup>*3</sup>                                                                                                                           |                                                                                                                                                                                                            |
|                                                     | 11                                                                        | Set LVD2CR0.LVD2CMPE = 1 (enabling output of the results of comparison by voltage monitoring 2).                                                                                                                        |                                                                                                                                                                                                            |

Note 1. Steps 4 to 10 can be performed during the waiting time of step 3. For details of  $t_d(E-A)$ , see section 45, Electrical Characteristics.

Note 2. Steps 4 to 6 are not required if the digital filter is not in use.

Note 3. Step 10 is not required if only the ELC event signal is to be output.

**Table 8.7 Procedures for Setting Bits Related to the Voltage Monitoring 2 Interrupt and Voltage Monitoring 2 Reset so that Voltage Monitoring Stops**

| Step                                     |   | Voltage Monitoring 2 Interrupt (Voltage Monitoring 2 ELC Event Output), Voltage Monitoring 2 Reset                                                                           |
|------------------------------------------|---|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Settings to stop enabling of output      | 1 | Set LVD2CR0.LVD2CMPE = 0 (disabling output of the results of comparison by voltage monitoring 2).                                                                            |
|                                          | 2 | Wait for at least $2n + 3$ cycles of the LOCO (where $n = 2, 4, 8, 16$ , and the sampling clock for the digital filter is the LOCO frequency-divided by $n$ ). <sup>*1</sup> |
|                                          | 3 | Set LVD2CR0.LVD2RIE = 0 (disabling the voltage monitoring 2 interrupt or reset). <sup>*2</sup>                                                                               |
| Stopping the digital filter              | 4 | Set LVD2CR0.LVD2DFDIS = 1 (disabling the digital filter). <sup>*1, *3</sup>                                                                                                  |
| Stopping the voltage detection 1 circuit | 5 | Set LVCMPCR.LVD2E = 0 (disabling the voltage detection 2 circuit).                                                                                                           |

Note 1. Steps 2 and 4 are not required if the digital filter is not in use.

Note 2. Step 3 is not required if only the ELC event signal is to be output.

Note 3. To disable the digital filter from its enabled state and then re-enable it, disable it and wait for at least two cycles of the LOCO before re-enabling it.

If the voltage monitoring 2 interrupt or voltage monitoring 2 reset setting is to be made again after it has been used and stopped once, the following steps in the procedures for stopping and making the setting can be omitted according to the condition.

- Setting or stopping the voltage detection 2 circuit is not required if the setting for the voltage detection 2 circuit is not to be changed.
- Setting or stopping the digital filter is not required if the setting for the digital filter is not to be changed.
- Setting the voltage monitoring 2 interrupt or reset is not required if the setting for the voltage monitoring 2 interrupt or voltage monitoring 2 reset is not to be changed.

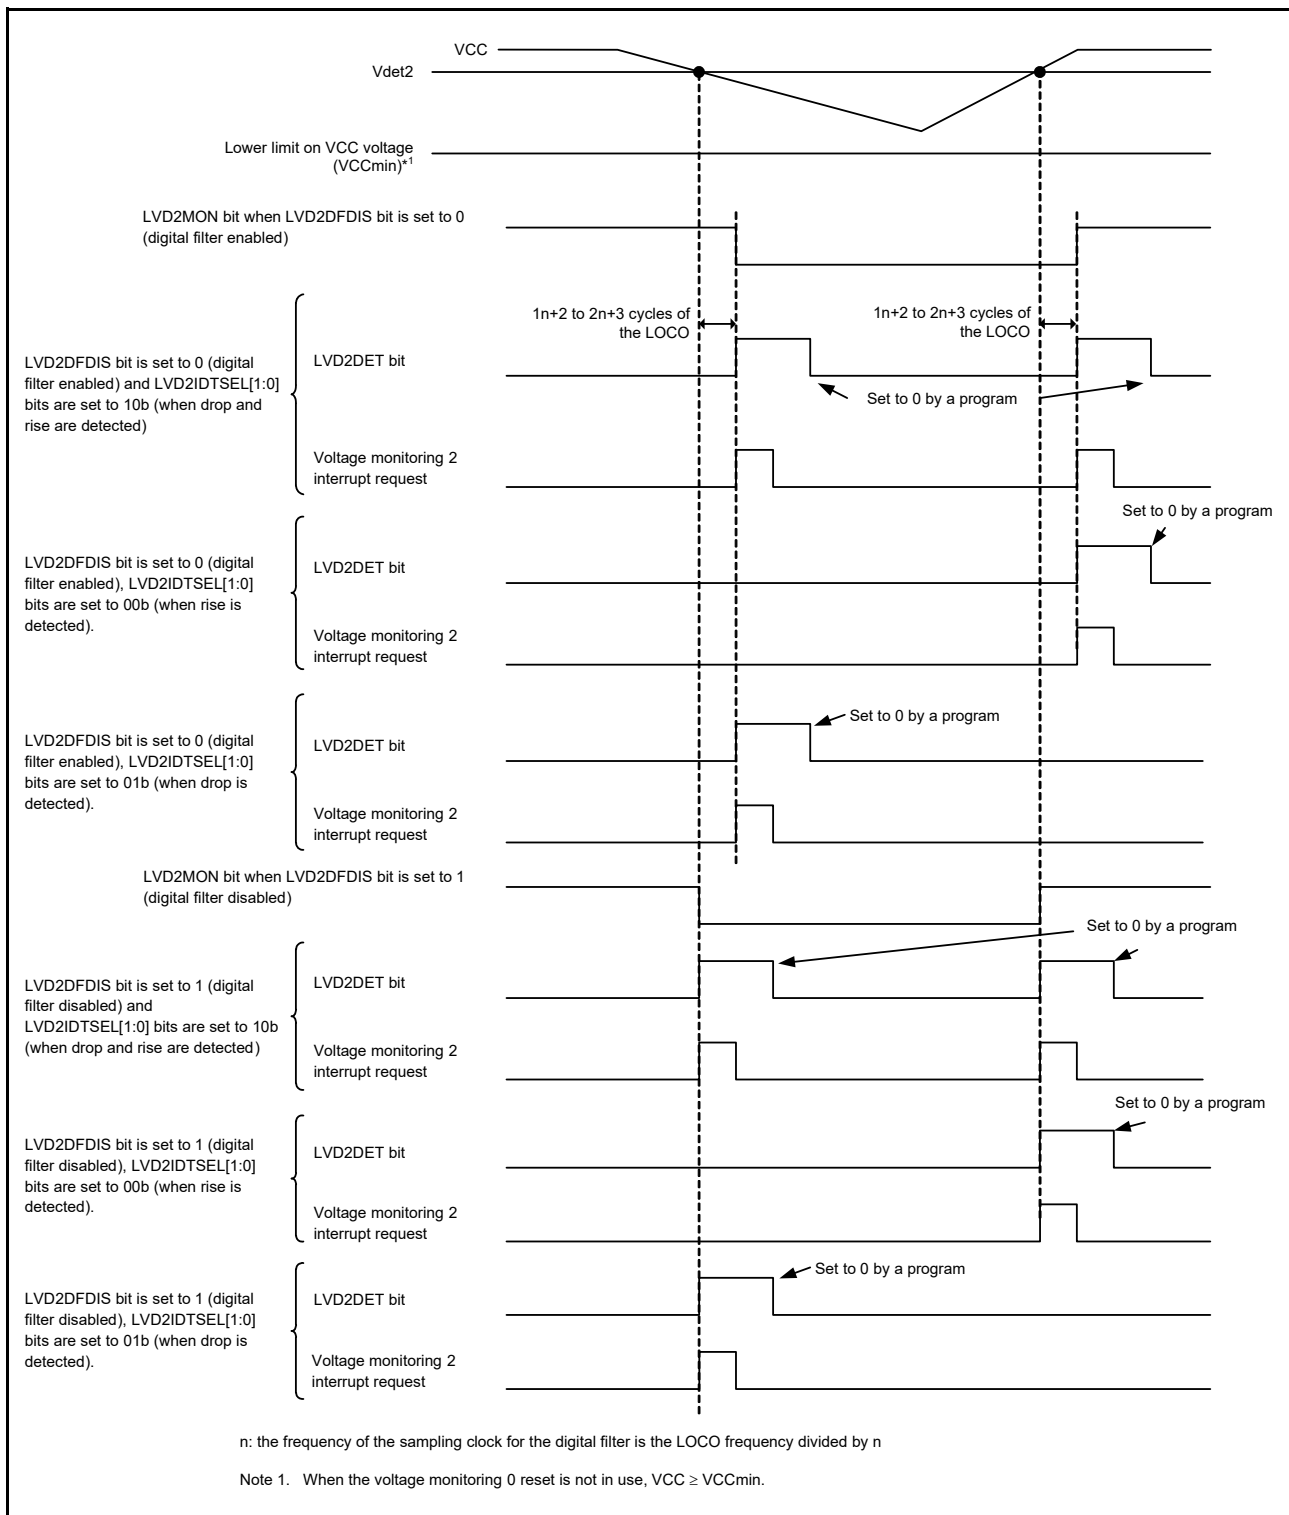

Figure 8.6 Example of Voltage Monitoring 2 Interrupt Operation

## 8.7 Event Link Output

The LVD can output the event signals to the event link controller (ELC).

### (1) Vdet1 passage detection event

The LVD outputs the event signal when it is detected that the voltage has passed the Vdet1 voltage while both the voltage detection 1 circuit and the voltage monitoring 1 circuit comparison result output are enabled.

### (2) Vdet2 passage detection event

The LVD outputs the event signal when it is detected that the voltage has passed the Vdet2 voltage while both the voltage detection 2 circuit and the voltage monitoring 2 circuit comparison result output are enabled.

When enabling the LVD's event link output function, be sure to make settings for enabling the LVD before enabling the LVD event link function of the ELC. To stop the LVD's event link output function, be sure to make settings for stopping the LVD after disabling the LVD event link function of the ELC.

### 8.7.1 Interrupt Handling and Event Linking

The LVD has the bits to separately enable or disable the voltage monitoring 1 and 2 interrupts. When an interrupt source is generated and the interrupt is enabled by the interrupt enable bit, the interrupt signal (LVD1RIE and LVD2RIE) is output to the CPU.

On the contrary, as soon as an interrupt source is generated, the event link signal is output as the event signal to the other module via the ELC regardless of the state of the interrupt enable bit.

It is possible to output voltage monitoring 1 and 2 interrupts in software standby and deep software standby modes. The event signals for the ELC in software standby and deep software standby modes, are output as follows:

- When Vdet1/Vdet2 passage are detected in software standby mode, no event signals are generated for the ELC because no clock is presented in software standby mode. Since Vdet1/Vdet2 passage detection flags are preserved, however, when the supply of the clock is resumed after restoring from software standby mode, the event signals for the ELC are output according to the state of the Vdet1/Vdet2 passage detection flags.
- When Vdet1/Vdet2 passage are detected in deep software standby mode, no event signals are generated for the ELC.

## 9. Clock Generation Circuit

### 9.1 Overview

This MCU incorporates a clock generation circuit.

Table 9.1 lists the specifications of the clock generation circuit. Figure 9.1 shows a block diagram of the clock generation circuit.

**Table 9.1 Specifications of Clock Generation Circuit**

| Item                                 | Specification                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

| Low-speed on-chip oscillator (LOCO)  | Oscillation frequency: 240 kHz                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| IWDTC-dedicated on-chip oscillator   | Oscillation frequency: 120 kHz                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Control of output on the BCLK pin    | <ul style="list-style-type: none"> <li>BCLK clock output or high output is selectable</li> <li>BCLK or BCLK/2 is selectable</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Event linking (output)               | Detection of stopping of the main clock oscillator                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Event linking (input)                | Switching of the clock source to the low-speed on-chip oscillator                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

Note 1. Restrictions on setting clock frequency:  $ICLK \geq BCLK$ ,  $PCLKC \geq PCLKA \geq PCLKB$

Restrictions on clock frequency ratio: (N: integer)  
 ICLK:FCLK = N:1 or 1:N; ICLK:PCLKA = N:1 or 1:N; ICLK:PCLKB = N:1 or 1:N;  
 ICLK:PCLKC = N:1 or 1:N; ICLK:PCLKD = N:1 or 1:N;  
 PCLKA:PCLKC = 1:1 or 1:2, PCLKB:PCLKD = 1:1, 2:1, 4:1 or 1:2

Note 2. When setting the frequency of ICLK to faster than 120 MHz, the value of the MEMWAIT register needs to be changed.

Note 3. When using the HOCO as the input clock source for the PLL, select the multiplication ratio of the PLL so that the HOCO clock oscillation frequency (min./max.) is in the range of 120 to 240 MHz.

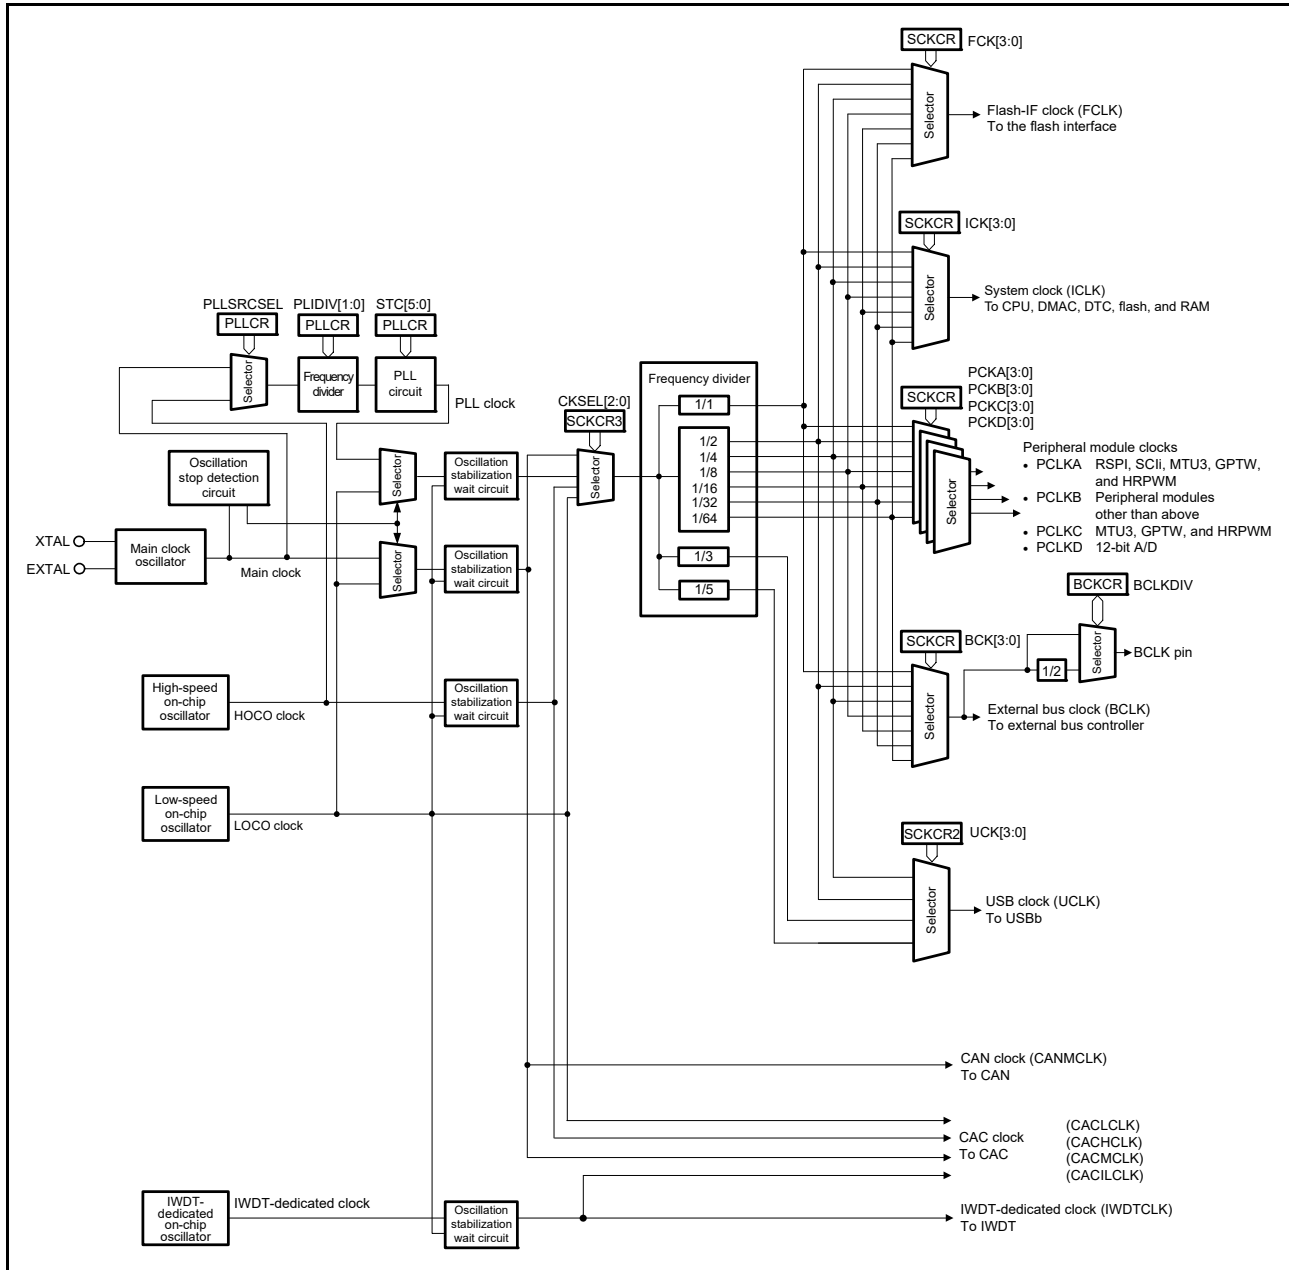

Figure 9.1 Block Diagram of Clock Generation Circuit

Table 9.2 lists the input/output pins of the clock generation circuit.

Table 9.2 Input/Output Pins of Clock Generation Circuit

| Pin Name | I/O    | Description                                                                                                                                                      |
|----------|--------|------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| XTAL     | Output | These pins are used to connect a crystal resonator. The EXTAL pin can also be used to input an external clock. For details, section 9.3.2, External Clock Input. |
| EXTAL    | Input  |                                                                                                                                                                  |
| BCLK     | Output | This pin is used to supply external devices with the external bus clock (BCLK).                                                                                  |

## 9.2 Register Descriptions

### 9.2.1 System Clock Control Register (SCKCR)

Address(es): 0008 0020h

| b27 to b24 | ICK[3:0] | System Clock (ICLK) Select*1 | b27 b24<br>0 0 0 0: ×1/1<br>0 0 0 1: ×1/2<br>0 0 1 0: ×1/4<br>0 0 1 1: ×1/8<br>0 1 0 0: ×1/16<br>0 1 0 1: ×1/32<br>0 1 1 0: ×1/64<br>Settings other than above are prohibited. | R/W |
| b31 to b28 | FCK[3:0] | Flash-IF Clock (FCLK) Select | b31 b28<br>0 0 0 0: ×1/1<br>0 0 0 1: ×1/2<br>0 0 1 0: ×1/4<br>0 0 1 1: ×1/8<br>0 1 0 0: ×1/16<br>0 1 0 1: ×1/32<br>0 1 1 0: ×1/64<br>Settings other than above are prohibited. | R/W |

Note 1. Do not make a setting such that the ICLK runs at a lower frequency than the external bus clock.

Note 2. When operation of the external bus clock is selected, the PE5 I/O port pin function is not available because it is multiplexed on the same pin as the BCLK pin function.

SCKCR should not be modified in the following cases:

- The code flash memory P/E mode entry bit or the data flash memory P/E mode entry bit in the flash P/E mode entry register (FENTRYR.FENTRYC or FENTRYR.FENTRYD) is 1 (P/E mode)
- Time period from WAIT instruction execution for a transition to sleep mode, to return from sleep mode to normal operating mode

## 9.2.2 Memory Wait Cycle Setting Register (MEMWAIT)

Address(es): 0008 101Ch

| Bit      | Symbol  | Bit Name                  | Description                                            | R/W |
|----------|---------|---------------------------|--------------------------------------------------------|-----|
| b0       | MEMWAIT | Memory Wait Cycle Setting | 0: No wait<br>1: One wait cycle                        | R/W |
| b7 to b1 | —       | Reserved                  | These bits are read as 0. The write value should be 0. | R/W |

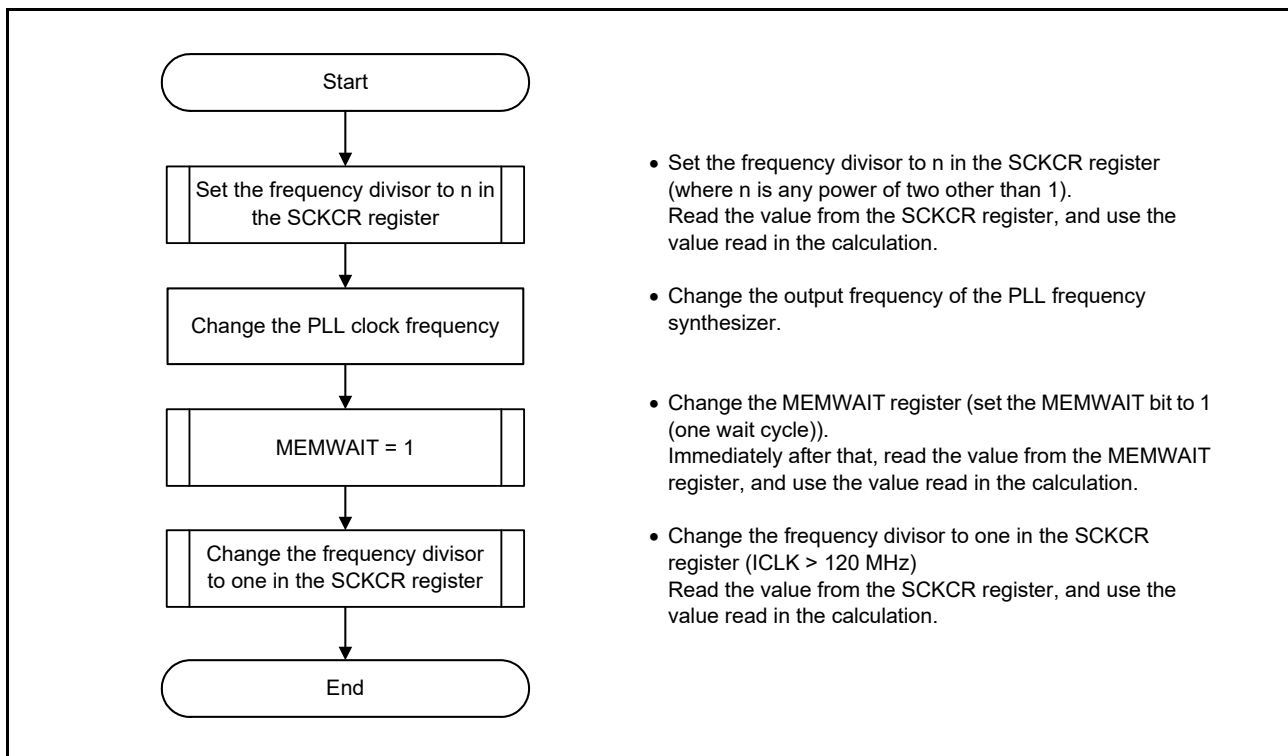

The MEMWAIT register specifies the number of access wait cycles of the code flash memory, ECCRAM and others. For the number of cycles for access to the flash memory, refer to section 44, Flash Memory (FLASH); for the number of cycles for access to the ECCRAM, refer to section 43, RAM. The wait cycle for the RAM is 0 regardless of the MEMWAIT bit value.

Set the MEMWAIT to 1 (one waiting cycle) when the ICLK frequency is to be above 120 MHz. Restrictions on setting of the MEMWAIT register are listed in Table 9.3.

**Table 9.3 Restrictions on Setting of the MEMWAIT register**

| MEMWAIT Bit | ICLK ≤ 120 MHz | ICLK > 120 MHz |
|-------------|----------------|----------------|
| 0           | Possible       | Prohibited     |
| 1           | Possible       | Possible       |

To change the frequency of the ICLK from 120 MHz or less to above 120 MHz, set the MEMWAIT to 1 (one wait cycle) first, and then change the frequency in the SCKCR register. To change the frequency from above 120 MHz to 120 MHz or less, change the frequency to 120 MHz or less in the SCKCR register first, and then set the MEMWAIT to 0 (no wait). Figure 9.3 and Figure 9.2 show the procedures for changing the value of the MEMWAIT bit.

**Figure 9.2 Procedure for Changing the Settings: From ICLK ≤ 120 MHz and MEMWAIT = 0 to ICLK > 120 MHz and MEMWAIT = 1**

**Figure 9.3 Procedure for Changing the Settings: From ICLK > 120 MHz and MEMWAIT = 1 to ICLK ≤ 120 MHz and MEMWAIT = 0**

### 9.2.3 System Clock Control Register 2 (SCKCR2)

Address(es): 0008 0024h

| Bit       | Symbol   | Bit Name                | Description                                                                                                                                                                                                                      | R/W |
|-----------|----------|-------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----|
| b0        | —        | Reserved                | This bit is read as 1. The write value should be 1.                                                                                                                                                                              | R/W |
| b3 to b1  | —        | Reserved                | These bits are read as 0. The write value should be 0.                                                                                                                                                                           | R/W |
| b7 to b4  | UCK[3:0] | USB Clock (UCLK) Select | b7 b4<br>0 0 0 1: ×1/2<br>0 0 1 0: ×1/3<br>0 0 1 1: ×1/4<br>0 1 0 0: ×1/5<br>Settings other than above are prohibited when USB is in use. When USB is not in use, these bits are read as 0001b. The write value should be 0001b. | R/W |
| b15 to b8 | —        | Reserved                | These bits are read as 0. The write value should be 0.                                                                                                                                                                           | R/W |

SCKCR2 should not be modified in the following cases:

- The code flash memory P/E mode entry bit or the data flash memory P/E mode entry bit in the flash P/E mode entry register (FENTRYR.FENTRYC or FENTRYR.FENTRYD) is 1 (P/E mode)
- Time period from WAIT instruction execution for a transition to sleep mode, to return from sleep mode to normal operating mode

#### UCK[3:0] Bits (USB Clock (UCLK) Select)

These bits select the frequency of the USB clock (UCLK).

The duty ratio is 2:1 when × 1/3 is selected while it is 3:2 when × 1/5 is selected.

## 9.2.4 System Clock Control Register 3 (SCKCR3)

Address(es): 0008 0026h

|     |     |     |     |     |            |    |    |    |    |    |    |    |    |    |    |

| —   | —   | —   | —   | —   | CKSEL[2:0] |    | —  | —  | —  | —  | —  | —  | —  | —  | —  |
| 0   | 0   | 0   | 0   | 0   | 0          | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  |

Value after reset:

| Bit        | Symbol     | Bit Name            | Description                                                                                                                             | R/W |
|------------|------------|---------------------|-----------------------------------------------------------------------------------------------------------------------------------------|-----|
| b7 to b0   | —          | Reserved            | These bits are read as 0. The write value should be 0.                                                                                  | R/W |
| b10 to b8  | CKSEL[2:0] | Clock Source Select | b10 b8<br>0 0 0: LOCO<br>0 0 1: HOCO<br>0 1 0: Main clock oscillator<br>1 0 0: PLL circuit<br>Settings other than above are prohibited. | R/W |
| b15 to b11 | —          | Reserved            | These bits are read as 0. The write value should be 0.                                                                                  | R/W |

SCKCR3 should not be modified in the following cases:

- The code flash memory P/E mode entry bit or the data flash memory P/E mode entry bit in the flash P/E mode entry register (FENTRYR.FENTRYC or FENTRYR.FENTRYD) is 1 (P/E mode)
- Time period from WAIT instruction execution for a transition to sleep mode, to return from sleep mode to normal operating mode

### CKSEL[2:0] Bits (Clock Source Select)

These bits select the source of the system clock (ICLK), peripheral module clocks (PCLKA, PCLKB, PCLKC, and PCLKD), flash-IF clock (FCLK), external bus clock (BCLK), and USB clock (UCLK) from low-speed on-chip oscillator (LOCO), high-speed on-chip oscillator (HOCO), the main clock oscillator, and the PLL circuit.

Transitions to clock sources which are not in operation are prohibited.

## 9.2.5 PLL Control Register (PLLCR)

Address(es): 0008 0028h

| Bit         | Symbol      | Bit Name                                  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      | R/W         |         |     |    |     |    |             |         |             |         |             |         |             |         |             |         |             |         |             |         |             |         |             |         |             |         |             |         |             |         |             |         |             |         |             |         |             |         |             |         |             |         |             |         |             |         |             |         |             |         |             |         |             |         |             |         |             |         |             |         |             |         |             |         |             |         |             |         |             |         |             |         |             |         |             |         |             |         |             |         |             |         |             |         |             |         |             |         |  |  |     |

The write value should be 0.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           | R/W         |         |     |    |     |    |             |         |             |         |             |         |             |         |             |         |             |         |             |         |             |         |             |         |             |         |             |         |             |         |             |         |             |         |             |         |             |         |             |         |             |         |             |         |             |         |             |         |             |         |             |         |             |         |             |         |             |         |             |         |             |         |             |         |             |         |             |         |             |         |             |         |             |         |             |         |             |         |             |         |             |         |             |         |             |         |             |         |  |  |     |

Note 1. Set this bit to 0 when using the USB.

Writing to the PLLCR is prohibited when the PLLCR2.PLEN bit is 0 (the PLL operates).

### PLIDIV[1:0] Bits (PLL Input Frequency Division Ratio Select)

These bits select the frequency division ratio of the PLL clock source.

Set these bits so that the frequency of PLL input signal is within the range of 8 MHz to 24 MHz.

### PLLSRCSEL Bit (PLL Clock Source Select)

This bit selects the clock source for the PLL.

### STC[5:0] Bits (Frequency Multiplication Factor Select)

These bits select the frequency multiplication factor of the PLL circuit.

Set these bits so that the output frequency is within the range of the output clock frequency of the PLL circuit (120 MHz to 240 MHz).

## 9.2.6 PLL Control Register 2 (PLLCR2)

Address(es): 0008 002Ah

| Bit      | Symbol | Bit Name         | Description                                            | R/W |
|----------|--------|------------------|--------------------------------------------------------|-----|
| b0       | PLLEN  | PLL Stop Control | 0: PLL is operating.<br>1: PLL is stopped.             | R/W |
| b7 to b1 | —      | Reserved         | These bits are read as 0. The write value should be 0. | R/W |

### PLLEN Bit (PLL Stop Control)

This bit runs or stops the PLL circuit.

The PLL clock source is selectable as the main clock oscillator and HOCO.

Selecting the main clock oscillator as the PLL clock source with the PLLCR.PLLSRCSEL bit requires setting the main clock oscillator wait control register (MOSCWTCR).

After the setting of the PLLEN bit has been changed to make the PLL run, only start using the PLL clock after confirming that the OSCOVFSR.PLOVF flag has been set to 1.

That is, a fixed time for stabilization is required after the setting for PLL operation. A fixed time is also required for oscillation to stop after the setting to stop PLL operation. Accordingly, take note of the following limitations when starting and stopping PLL operation by the PLLEN bit. The following notes apply when selecting the main clock oscillator as the PLL clock source.

- Setting PLL operation with the PLLEN bit is possible regardless of the setting of the OSCOVFSR.PLOVF flag. However, the time until deactivation of the PLL is completed (the time until the PLOVF flag is set to 0 after the setting to stop PLL operation) means that writing to the PLLCR2 register takes longer than the setting to operate the PLL.
- The PLL can be stopped by the PLLEN bit regardless of the setting of the OSCOVFSR.PLOVF flag. However, the wait for oscillation to become stable, i.e. the oscillation settling time (the time until the OSCOVFSR.PLOVF flag is set to 1 after the setting to operate the PLL), means that writing to the PLLCR2 register takes longer than the setting to stop PLL operation.
- Regardless of whether or not the PLL clock is selected as the system clock, confirm that the OSCOVFSR.PLOVF flag has been set to 1 before executing a WAIT instruction to place the chip to software standby or deep software standby after the setting to operate the PLL.
- When a transition to software standby or deep software standby is to follow the setting to stop the PLL, confirm that the OSCOVFSR.PLOVF flag has been set to 0 before executing the WAIT instruction.

Writing of 1 to the PLLEN bit (stopping the PLL) is prohibited while the PLL clock is selected by the clock source select bits in system clock control register 3 (SCKCR3.CKSEL[2:0]).

## 9.2.7 External Bus Clock Control Register (BCKCR)

Address(es): 0008 0030h

| Bit      | Symbol  | Bit Name               | Description                                            | R/W |
|----------|---------|------------------------|--------------------------------------------------------|-----|
| b0       | BCLKDIV | BCLK Pin Output Select | 0: BCLK<br>1: 1/2 BCLK                                 | R/W |
| b7 to b1 | —       | Reserved               | These bits are read as 0. The write value should be 0. | R/W |

BCKCR should not be modified in the following cases:

- The code flash memory P/E mode entry bit or the data flash memory P/E mode entry bit in the flash P/E mode entry register (FENTRYR.FENTRYC or FENTRYR.FENTRYD) is 1 (P/E mode).
- Time period from WAIT instruction execution for a transition to sleep mode, to return from sleep mode to normal operating mode

### BCLKDIV Bit (BCLK Pin Output Select)

This bit selects the clock signal for output from the BCLK pin.

Either the BCLK clock with the frequency selected by the BCK[3:0] bits in SCKCR or the BCLK clock divided by 2 can be selected. To control external bus control signals at the falling edge of the BCLK pin, set this bit to 1.

## 9.2.8 Main Clock Oscillator Control Register (MOSCCR)

Address(es): 0008 0032h

| Bit      | Symbol | Bit Name                   | Description                                                                    | R/W |
|----------|--------|----------------------------|--------------------------------------------------------------------------------|-----|
| b0       | MOSTP  | Main Clock Oscillator Stop | 0: Main clock oscillator is operating.<br>1: Main clock oscillator is stopped. | R/W |
| b7 to b1 | —      | Reserved                   | These bits are read as 0. The write value should be 0.                         | R/W |

### MOSTP Bit (Main Clock Oscillator Stop)

This bit runs or stops the main clock oscillator.

The main clock oscillator is operated or stopped by the MOSTP bit. The main clock oscillator can be started by setting the MOSTP bit to operating.

To make the main clock run, the main clock oscillator wait control register (MOSCWTCR) must be set. In this case, after the setting of the MOSCCR.MOSTP bit has been changed to make the main clock run, only start using the main clock after confirming that the OSCOVFSR.MOOVF flag has been set to 1.

For the main clock oscillator, a fixed time is required for oscillation to become stable after the settings for operation have been made. Furthermore, a fixed time is required for oscillation to actually stop after the settings to stop oscillation have been made. Accordingly, take note of the following limitations when starting and stopping operation.

- Main-clock operation can be selected with the MOSTP bit regardless of the setting of the OSCOVFSR.MOOVF flag. However, the time until deactivation of the main clock is completed (the time until the OSCOVFSR.MOOVF flag is set to 0 after the setting to stop operation) means that writing to the MOSCCR register takes longer than the setting to operate the main clock.
- The main clock can be stopped by the MOSTP bit regardless of the setting of the OSCOVFSR.MOOVF flag. However, the wait for oscillation to become stable, i.e. the oscillation settling time (the time until the OSCOVFSR.MOOVF flag is set to 1 after the setting to operate the main clock), means that writing to the MOSCCR register takes longer than the setting to stop operation.
- Regardless of whether or not it is selected as the system clock, confirm that the OSCOVFSR.MOOVF flag has been set to 1 before executing a WAIT instruction to place the chip to software standby or deep software standby after the setting to operate the main clock oscillator by the MOSTP bit.
- When a transition to software standby or deep software standby is to follow the setting to stop the main clock oscillator, confirm that the OSCOVFSR.MOOVF flag has been set to 0 before executing the WAIT instruction.

Writing of 1 to the MOSTP bit (stopping the main clock oscillator) is prohibited in either of the following cases:

- The main clock oscillator is selected by the clock source select bits in system clock control register 3 (SCKCR3.CKSEL[2:0]).
- 0 (PLL operation) is selected by the PLL stop control bit in PLL control register 2 (PLLCR2.PLEN), and the main clock oscillator is selected by the PLL clock source select bit in the PLL control register (PLLCR.PLLSRCSEL).

### 9.2.9 Low-Speed On-Chip Oscillator Control Register (LOCOCR)

Address(es): 0008 0034h

| b7 to b1 | —      | Reserved  | These bits are read as 0. The write value should be 0. | R/W |

#### LCSTP Bit (LOCO Stop)

This bit runs or stops the LOCO.

After the setting of the LCSTP bit has been changed so that the LOCO operates, only start using the LOCO after the LOCO clock oscillation stabilization time (tLOCOWT) has elapsed.

That is, a fixed time for stabilization of oscillation is required for oscillation to become stable after setting LOCO operation with the LCSTP bit. A fixed time is also required for oscillation to stop after the setting to stop the oscillator. Accordingly, take note of the following limitations when starting and stopping the oscillator.

- When restarting the LOCO after it has been stopped, allow at least five cycles of the LOCO as an interval over which it is still stopped.
- Ensure that oscillation by the LOCO is stable when making the setting to stop the LOCO.
- Regardless of whether or not it is selected as the system clock, ensure that oscillation by the LOCO is stable before executing a WAIT instruction to place the chip on software standby or deep software standby.
- When a transition to software standby or deep software standby is to follow the setting to stop the LOCO, wait for at least three cycles of the LOCO after the setting to stop the LOCO and before executing the WAIT instruction.

Writing of 1 to the LCSTP bit (stopping the LOCO) is prohibited while the LOCO is selected by the clock source select bits in system clock control register 3 (SCKCR3.CKSEL[2:0]).

Writing of 1 to the LCSTP bit (stopping the LOCO) is prohibited if detection of oscillation stopping is enabled by the oscillation stop detection enable bit in the oscillation stop detection control register (OSTDCR.OSTDE).

Since the LOCO clock is used to measure the waiting time for other oscillators, the LOCO clock oscillates while the waiting time for other oscillators is being measured, regardless of the setting of LCSTP bit. Therefore, the LOCO clock may be unintentionally supplied even if the LCSTP bit is set to be stopped.

## 9.2.10 IWDT-Dedicated On-Chip Oscillator Control Register (ILOCOCR)

Address(es): 0008 0035h

|                    |    |    |    |    |    |    |    |        |
|--------------------|----|----|----|----|----|----|----|--------|
|                    | b7 | b6 | b5 | b4 | b3 | b2 | b1 | b0     |
|                    | —  | —  | —  | —  | —  | —  | —  | ILCSTP |
| Value after reset: | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 1      |

| Bit      | Symbol | Bit Name                               | Description                                                                                            | R/W |
|----------|--------|----------------------------------------|--------------------------------------------------------------------------------------------------------|-----|
| b0       | ILCSTP | IWDT-Dedicated On-Chip Oscillator Stop | 0: IWDT-dedicated on-chip oscillator is operating.<br>1: IWDT-dedicated on-chip oscillator is stopped. | R/W |
| b7 to b1 | —      | Reserved                               | These bits are read as 0. The write value should be 0.                                                 | R/W |

When the IWDT start mode select bit in the option function select register 0 (OFS0.IWDTSTRT) is 0 (IWDT operating), the setting of this register is invalid; it is valid only when the OFS0.IWDTSTRT bit is set to 1 (IWDT stopped). The ILCSTP bit cannot be changed from 0 (IWDT-dedicated on-chip oscillator operating) to 1 (IWDT-dedicated on-chip oscillator stopped) while ILOCOCR is valid.

### ILCSTP Bit (IWDT-Dedicated On-Chip Oscillator Stop)

This bit runs or stops the IWDT-dedicated on-chip oscillator.

After the setting of the ILCSTP bit has been changed to make the IWDT-dedicated on-chip oscillator run, confirm that the OSCOVFSR.ILCOVF flag has been set to 1 before starting to use the oscillator.

When a transition to software standby or deep software standby mode is to follow the setting to start the IWDT-dedicated on-chip oscillator, confirm that the OSCOVFSR.ILCOVF flag has been set to 1 before executing the WAIT instruction.

### 9.2.11 High-Speed On-Chip Oscillator Control Register (HOCOOCR)

Address(es): 0008 0036h

| Bit      | Symbol | Bit Name  | Description                                            | R/W |
|----------|--------|-----------|--------------------------------------------------------|-----|
| b0       | HCSTP  | HOCO Stop | 0: HOCO is operating.<br>1: HOCO is stopped.           | R/W |
| b7 to b1 | —      | Reserved  | These bits are read as 0. The write value should be 0. | R/W |

Note 1. The HCSTP bit value after a reset is 0 when the OFS1.HOCOEN bit is 0. It is 1 when the OFS1.HOCOEN bit is 1.

#### HCSTP Bit (HOCO Stop)

This bit runs or stops the HOCO.

After the setting of the HCSTP bit has been changed to make the HOCO run, confirm that the OSCOVFSR.HCOVF flag has been set to 1 before starting to use the oscillator.

A fixed time for stabilization is required for oscillation to become stable after setting HOCO operation with the HCSTP bit. Furthermore, a fixed time is required for oscillation to actually stop after the setting to stop operation. Accordingly, take note of the following when starting and stopping operation with the HCSTP bit.

- Setting HOCO operation with the HCSTP bit is possible regardless of the setting of the OSCOVFSR.HCOVF flag. However, the time until deactivation of the HOCO is completed (the time until the OSCOVFSR.HCOVF flag is set to 0 after the setting to stop HOCO operation) means that writing to the HOCOOCR register takes longer than the setting to operate the HOCO.
- The HOCO can be stopped by the HCSTP bit regardless of the setting of the OSCOVFSR.HCOVF flag. However, the wait for oscillation to become stable, i.e. the oscillation settling time (the time until the OSCOVFSR.HCOVF flag is set to 1 after the setting to operate the HOCO), means that writing to the HOCOOCR register takes longer than the setting to stop HOCO operation.
- Regardless of whether or not it is selected as the system clock, confirm that the OSCOVFSR.HCOVF flag has been set to 1 before executing a WAIT instruction to place the chip on software standby or deep software standby after selecting HOCO operation with the HCSTP bit.
- When a transition to software standby or deep software standby is to follow the setting to stop the HOCO, confirm that the OSCOVFSR.HCOVF flag has been set to 0 after the setting to stop the HOCO and before executing the WAIT instruction.

Writing of 1 to the HCSTP bit (stopping the HOCO) is prohibited while the HOCO is selected by the clock source select bits in system clock control register 3 (SCKCR3.CKSEL[2:0]), or the HOCO is selected as the clock source for the PLL by the PLLCR.PLLSRCSEL bit, and the PLL is selected by the SCKCR3.CKSEL[2:0] bits.

## 9.2.12 High-Speed On-Chip Oscillator Control Register 2 (HOCOCR2)

Address(es): 0008 0037h

| Bit      | Symbol     | Bit Name               | Description                                                                                     | R/W |
|----------|------------|------------------------|-------------------------------------------------------------------------------------------------|-----|
| b1, b0   | HCFRQ[1:0] | HOCO Frequency Setting | b1 b0<br>0 0: 16 MHz<br>0 1: 18 MHz<br>1 0: 20 MHz<br>Settings other than above are prohibited. | R/W |
| b7 to b2 | —          | Reserved               | These bits are read as 0. The write value should be 0.                                          | R/W |

Writing to the HOCOCR2 register is prohibited when the HOCOCR.HCSTP bit is 0 (making the HOCO run).

### 9.2.13 Oscillation Stabilization Flag Register (OSCOVFSR)

Address(es): 0008 003Ch

| b7                 | b6 | b5 | b4         | b3    | b2    | b1 | b0        |

| b4       | ILCOVF*1 | IWDT-Dedicated Clock Oscillation Stabilization Flag | 0: The IWDT-dedicated on-chip oscillator is stopped or oscillation of the IWDT-dedicated on-chip oscillator has not yet become stable.<br>1: Oscillation of the IWDT-dedicated on-chip oscillator is stable so the clock is available for use as the IWDT-dedicated clock. | R   |
| b7 to b5 | —        | Reserved                                            | These bits are read as 0. The write value should be 0.                                                                                                                                                                                                                     | R/W |

Note 1. The ILCOVF flag value after a reset is 1 when the OFS0.IWDTSTRT bit is 0. It is 0 when the OFS0.IWDTSTRT bit is 1.

Note 2. The HCOVF flag value after a reset is 1 when the OFS1.HOCOEN bit is 0. It is 0 when the OFS1.HOCOEN bit is 1.

Note 3. If the value set in the wait control register of the main clock oscillator is not sufficient for the given oscillation stabilization time, the oscillation stabilization flag is set to 1 and supply of the clock signal to the internal circuits starts before oscillation is stable. This may cause malfunction of this MCU, so ensure that the setting of the wait control register is at least the oscillation settling time for the oscillator considering the maximum frequency of the LOCO clock.

OSCOVFSR contains flags to indicate the states of operation of the counters within the oscillation stabilization wait circuits for the individual oscillators.

The counters measure the waiting times until each oscillator output clock is supplied to the internal circuits after oscillation starts, and an overflow of a counter indicates the start of clock supply from the corresponding oscillator to the internal circuits.

#### MOOVF Flag (Main Clock Oscillation Stabilization Flag)

This flag indicates the state of operation of the counter that measures the waiting time for the main clock oscillator.

[Setting condition]

- After the main clock oscillator has stopped and the MOSCCR.MOSTP bit is set to 0, the number of LOCO clock cycles corresponding to the setting of the MOSCWTCR register being counted and supply of the main clock within the MCU starting.

[Clearing condition]

- After the main clock oscillator has started to operate and the MOSCCR.MOSTP bit has been set to 1, deactivation of the main clock oscillator being completed.

**PLOVF Flag (PLL Clock Oscillation Stabilization Flag)**

This flag indicates the state of operation of the counter that measures the waiting time for the PLL.

[Setting condition]

- After the PLL has stopped and the PLLCR2.PLLEN bit is set to 0, 62 cycles of the LOCO clock being counted and supply of the PLL clock within the MCU starting.

If oscillation by the PLL clock source selected by the PLLCR.PLLSRCSEL bit is not stable when the PLLEN bit is set to 0, counting of LOCO clock cycles proceeds after the oscillation of the PLL clock source has been stabilized.

[Clearing condition]

- After the PLL has started to operate and the PLLCR2.PLLEN bit has been set to 1, deactivation of the PLL being completed.

**HCOVF Flag (HOCO Clock Oscillation Stabilization Flag)**

This flag indicates the state of operation of the counter that measures the waiting time for the high-speed on-chip oscillator.

[Setting condition]

- After the high-speed on-chip oscillator has stopped and the HOCOCCR.HCSTP bit is set to 0, 25 cycles of the LOCO clock being counted and supply of the HOCO clock within the MCU starting.

[Clearing condition]

- After the high-speed on-chip oscillator has started to operate and the HOCOCCR.HCSTP bit has been set to 1, deactivation of the high-speed on-chip oscillator being completed.

**ILCOVF Flag (IWDT-Dedicated Clock Oscillation Stabilization Flag)**

This flag indicates the state of operation of the counter that measures the waiting time for the IWDT-dedicated on-chip oscillator.

[Setting condition]

- After the IWDT-dedicated on-chip oscillator has stopped and the ILOCOCCR.ILCSTP bit is set to 0, 34 cycles of the LOCO clock being counted and supply of the IWDT-dedicated clock within the MCU starting.

## 9.2.14 Oscillation Stop Detection Control Register (OSTDCR)

Address(es): 0008 0040h

|                    |       |    |    |    |    |    |    |        |

|----------|--------|---------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----|
| b0       | OSTDIE | Oscillation Stop Detection Interrupt Enable | 0: The oscillation stop detection interrupt is disabled. Oscillation stop detection is not notified to the POE/POEG.<br>1: The oscillation stop detection interrupt is enabled. Oscillation stop detection is notified to the POE/POEG. | R/W |
| b6 to b1 | —      | Reserved                                    | These bits are read as 0. The write value should be 0.                                                                                                                                                                                  | R/W |
| b7       | OSTDE  | Oscillation Stop Detection Function Enable  | 0: Oscillation stop detection function is disabled.<br>1: Oscillation stop detection function is enabled.                                                                                                                               | R/W |

OSTDCR register is used to enable the oscillation stop detection function for the main clock oscillator and conveying of interrupts in response.

### OSTDIE Bit (Oscillation Stop Detection Interrupt Enable)

If the oscillation-stop detection flag in the oscillation-stop detection status register (OSTDSR.OSTDF) requires clearing, do this after clearing the OSTDIE bit to 0. Wait for at least two cycles of PCLKB before again setting the OSTDIE bit to 1. According to the number of cycles for access to read out a given I/O register, waiting time longer than two cycles of PCLKB may have to be secured.

### OSTDE Bit (Oscillation Stop Detection Function Enable)

This bit enables or disables the oscillation stop detection function.

When the OSTDE bit is 1 (oscillation stop detection function enabled), the LOCO stop bit (LOCOCR.LCSTP) is set to 0 and the LOCO operation is started. The LOCO cannot be stopped while the oscillation stop detection function is enabled; writing 1 to the LOCOCR.LCSTP bit (LOCO stopped) is invalid.

When the oscillation stop detection flag in the oscillation stop detection status register (OSTDSR.OSTDF) is 1 (main clock oscillation stop detected), writing 0 to the OSTDE bit is invalid.

When the OSTDE bit is 1, a transition cannot be made to software standby mode or deep software standby mode. To make a transition to software standby mode or deep software standby mode, execute the WAIT instruction with the OSTDE bit being 0.

To check the oscillation stop detection flag in the oscillation stop detection status register (OSTDSR.OSTDF), wait for at least three cycles of ICLK after the OSTDE bit has been set to 1 (oscillation stop detection enabled).

## 9.2.15 Oscillation Stop Detection Status Register (OSTDSR)

Address(es): 0008 0041h

| Bit      | Symbol | Bit Name                        | Description                                                                                                                    | R/W         |
|----------|--------|---------------------------------|--------------------------------------------------------------------------------------------------------------------------------|-------------|
| b0       | OSTDF  | Oscillation Stop Detection Flag | 0: Stopping of the main clock oscillator has not been detected.<br>1: Stopping of the main clock oscillator has been detected. | R/(W)<br>*1 |
| b7 to b1 | —      | Reserved                        | These bits are read as 0 and cannot be modified.                                                                               | R           |

Note 1. This bit can only be set to 0.

The OSTDSR register indicates the detection of stopping of the main clock oscillator.

### OSTDF Flag (Oscillation Stop Detection Flag)

This bit is a flag to indicate the main clock status. When the OSTDF flag is 1, it indicates that the main clock oscillation stop has been detected.

Once the main clock oscillation stop is detected, the OSTDF flag is not set to 0 even though the main clock oscillation is restarted. The OSTDF flag is set to 0 by reading 1 from the bit and then writing 0. At least 3 ICLK cycles of wait time is necessary between writing 0 to OSTDF and reading OSTDF as 0. If the OSTDF flag is set to 0 from 1 while the main clock oscillation is stopped, the OSTDF flag becomes 0 and then returns to 1.

The OSTDF flag cannot be modified to 0 while the main clock oscillator or PLL is selected by the clock source select bits in system clock control register 3 (SCKCR3.CKSEL[2:0]) (010b or 100b). The OSTDF flag should be set to 0 after switching the clock source to other sources than the main clock oscillator and PLL. When a resonator is selected as the source for the main clock oscillator, apply a reset to clear the OSTDF flag.

[Setting condition]

- The main clock oscillation is stopped with the OSTDCR.OSTDE being 1 (oscillation stop detection function enabled).

[Clearing condition]

- 1 is read and then 0 is written when the SCKCR3.CKSEL[2:0] bits are neither 010b nor 100b.

## 9.2.16 Main Clock Oscillator Wait Control Register (MOSCWTCR)

Address(es): 0008 00A2h

MOSCWTCR is used to control the waiting time until output of the signal from the main clock oscillator to the internal circuits starts. The oscillation stabilization wait circuit for the main clock oscillator measures the waiting time by counting the number of LOCO clock cycles corresponding to the setting of the MOSCWTCR register.

The oscillation stabilization wait circuit measures the waiting time and controls the clock supply within the MCU. When the main clock oscillator starts by setting the MOSCCR.MOSTP bit, the oscillation stabilization wait circuit starts counting the waiting time with the LOCO clock. The clock supply within the MCU is disabled over the period until counting of the set number of cycles is completed. After counting is completed, supply of the clock signal within the MCU starts and the OSCOVFSR.MOOVF flag is set to 1.

Counting of LOCO clock cycles by the oscillation stabilization wait circuit proceeds regardless of the setting of the LOCOCR.LCSTP bit. Hardware automatically controls running and stopping of the LOCO clock for measurement of the waiting time.

Values can only be written to MOSCWTCR while the MOSCCR.MOSTP bit is 1 or the OSCOVFSR.MOOVF flag is 1; do not attempt writing to MOSCWTCR if neither is the case.

The waiting time is not required when an external clock signal is input for the main clock oscillator. Set the MSTS[7:0] bits to 00h.

The value of the MSTS[7:0] bits required for correspondence with the waiting time required to secure stable oscillation by the main clock oscillator is obtained by using the maximum frequency for fLOCO in the formula below.

$$\text{MSTS}[7:0] > (\text{tMAINOSC} \times (\text{fLOCO\_max}) + 16)/32$$

(tMAINOSC: main clock oscillation stabilization time; fLOCO\_max: maximum frequency for fLOCO)

If tMAINOSC is 1 ms and fLOCO\_max is 264 kHz (the period is 1/3.78 μs), the formula gives MSTS[7:0] > (1 ms × (264 kHz) + 16)/32 = 8.75, so set the MSTS[7:0] bits to 9.

Waiting time:

When LOCO is at its highest frequency:  $(9 \times 32 - 16) \times (1/264 \text{ kHz} = 3.78 \mu\text{s}) = 1.028 \text{ ms}$

When LOCO is at its normal frequency:  $(9 \times 32 + 3) \times (1/240 \text{ kHz} = 4.18 \mu\text{s}) = 1.216 \text{ ms}$

When LOCO is at its lowest frequency:  $(9 \times 32 + 10) \times (1/216 \text{ kHz} = 4.63 \mu\text{s}) = 1.380 \text{ ms}$

## 9.2.17 Main Clock Oscillator Function Control Register (MOFCR)

Address(es): 0008 C293h

| Bit      | Symbol      | Bit Name                                          | Description                                                                             | R/W |
|----------|-------------|---------------------------------------------------|-----------------------------------------------------------------------------------------|-----|
| b3 to b0 | —           | Reserved                                          | These bits are read as 0. The write value should be 0.                                  | R/W |

| b6       | MOSEL       | Main Clock Oscillator Switching                   | 0: Resonator<br>1: External clock input                                                 | R/W |
| b7       | —           | Reserved                                          | This bit is read as 0. The write value should be 0.                                     | R/W |

MOFCR selects the driving ability of the main clock oscillator, and also selects the oscillator or an external clock signal.

### MODRV2[1:0] Bits (Main Clock Oscillator Driving Ability 2 Switching)

These bits switch the driving ability of the main clock oscillator.

Specify the driving ability according to the frequency of a crystal connected to the main clock oscillator.

The frequency ranges specified in the bit description of the MODRV2[1:0] bits are the reference values of the crystal with capacitive load of 8 pF. A setting value may not fit within the frequency range depending on a crystal. Use values recommended by the resonator manufacturer.

In case of a ceramic resonator, it may be better to select lower frequency range than the frequency of the resonator (for example, specify 10b instead of 01b when a ceramic resonator with the frequency range from 16.1 to 20 MHz is used). Use values recommended by the resonator manufacturer.

### MOSEL Bit (Main Clock Oscillator Switching)

This bit switches the source for the main clock oscillator.

## 9.2.18 High-Speed On-Chip Oscillator Power Supply Control Register (HOCOPCR)

Address(es): 0008 C294h

| Bit      | Symbol   | Bit Name                                           | Description                                                                             | R/W |
|----------|----------|----------------------------------------------------|-----------------------------------------------------------------------------------------|-----|
| b0       | HOCOPCNT | High-Speed On-Chip Oscillator Power Supply Control | 0: Turns the power supply of the HOCO on.<br>1: Turns the power supply of the HOCO off. | R/W |
| b7 to b1 | —        | Reserved                                           | These bits are read as 0. The write value should be 0.                                  | R/W |

### HOCOPCNT Bit (High-Speed On-Chip Oscillator Power Supply Control)

This bit controls the power supply for the HOCO.

When this bit is set to 0, the power supply of the HOCO is turned on, enabling oscillation.

When this bit is set to 1, the power supply of the HOCO is turned off, reducing power consumption.

When setting the HOCOPCNT bit to 1, set the HOCO stop bit in the high-speed on-chip oscillator control register (HOCOOCR.HCSTP) to 1 (HOCO stopped) beforehand.

After the HOCOPCNT bit is changed from 1 to 0, oscillation settling time is required before the HOCOOCR.HCSTP bit is set to 0. For details, see [section 45, Electrical Characteristics](#).

Do not change the value of the HOCOPCNT bit when the HOCO is selected as the clock source by the clock source select bits in system clock control register 3 (SCKCR3.CKSEL[2:0]).

### 9.3 Main Clock Oscillator

There are two ways of supplying the clock signal to the main clock oscillator: connecting an oscillator or the input of an external clock signal.

#### 9.3.1 Connecting a Crystal Resonator

Figure 9.4 shows an example of connecting a crystal.

Connect capacitors referring to the capacitive load of the crystal to be used. In addition, a damping resistor  $R_d$  should be added, if necessary. The values of capacitors and resistor vary depending on the resonator and the oscillator driving ability. Use values recommended by the resonator manufacturer. If use of an external feedback resistor ( $R_f$ ) is directed by the resonator manufacturer, insert an  $R_f$  between EXTAL and XTAL by following the instruction.

When connecting a resonator to supply the clock, the frequency of the crystal must be in the frequency range of the resonator for the main clock oscillator described in Table 9.1.

When a resonator is connected, setting the MOFCR.MODRV2[1:0] bits (Main Clock Oscillator Driving Ability 2 Switching) is required.

The frequency ranges that are specified in the bit description of the MODRV2[1:0] bits are the reference values of the crystal with capacitive load of  $C_L = 8$  pF. The setting value may not fit within the frequency range depending on a crystal. Use values recommended by the resonator manufacturer.

In case of a ceramic resonator, it may be better to select lower frequency range than the frequency of the resonator. (For example, specify 10b instead of 01b when a ceramic resonator with the frequency range of 16.1 to 20 MHz is used). Use values recommended by the resonator manufacturer.

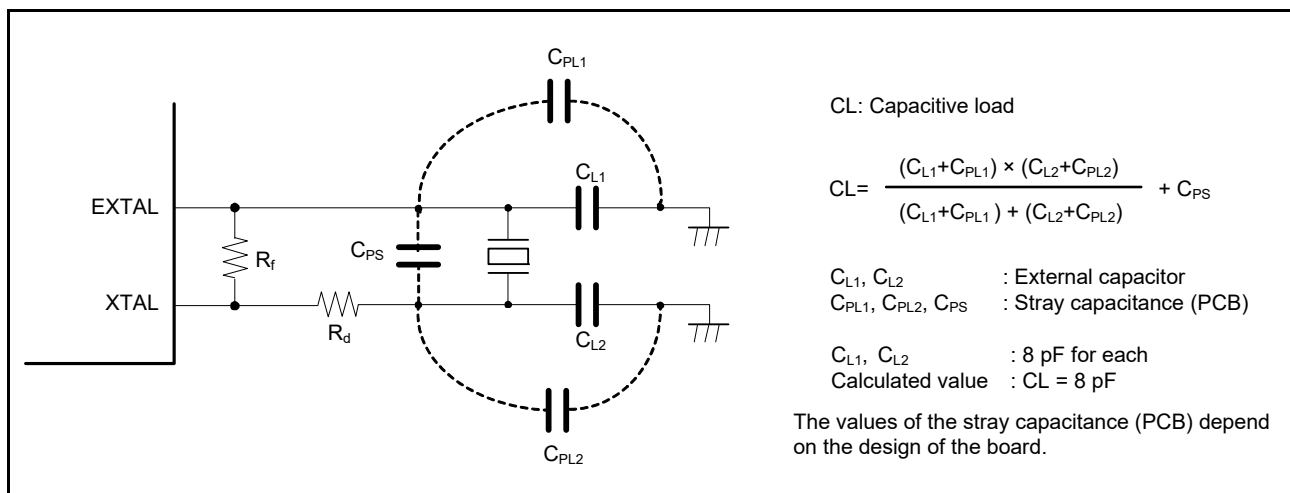

Figure 9.4 Example of Crystal Connection

Table 9.4 Damping Resistance (Reference Values)

| Frequency (MHz)    | 8 | 12 | 16 | 20 | 24 |
|--------------------|---|----|----|----|----|
| $R_d$ ( $\Omega$ ) | 0 | 0  | 0  | 0  | 0  |

Figure 9.5 shows an equivalent circuit of the crystal resonator. Use a crystal resonator that has the characteristics shown in Table 9.5.

Figure 9.5 Equivalent Circuit of Crystal Resonator

Table 9.5 Crystal Characteristics (Reference Values)

| Frequency (MHz)        | 8   | 12  | 16 | 20 | 24 |
|------------------------|-----|-----|----|----|----|
| $R_S$ max ( $\Omega$ ) | 300 | 100 | 80 | 50 | 50 |

### 9.3.2 External Clock Input

Figure 9.6 shows examples of connection of external clock input. Set the MOFCR.MOSEL bit to 1 and open the XTAL pin to operate the oscillator by inputting an external clock signal.

Figure 9.6 Example of Connection of External Clock

### 9.3.3 Notes on the External Clock Input

The frequency of the external clock input can only be changed while the main clock oscillator is stopped. Do not change the frequency of the external clock input while the setting of the main clock oscillator stop bit (MOSCCR.MOSTP) is 0 (making the main clock oscillator run).

## 9.4 Oscillation Stop Detection Function

### 9.4.1 Oscillation Stop Detection and Operation after Detection

The oscillation stop detection function is used to detect the main clock oscillator stop and to supply LOCO clock pulses from the low-speed on-chip oscillator as the system clock source instead of the main clock or PLL clock. When the HOCO is selected as the clock source for the PLL and the PLL clock is selected as the system clock, the system clock is not switched to the LOCO even if stopping of the main clock is detected.

An oscillation stop detection interrupt request can be generated when an oscillation stop is detected. In addition, the MTU3 and GPTW output can be forcedly driven to the high-impedance on the detection. For details, see section 22, Multi-Function Timer Pulse Unit 3 (MTU3d), section 23, Port Output Enable 3 (POE3B), and section 26, GPTW Port Output Enable (POEG).

In the MCU, the input clock remaining at a given level over a certain period due, for example, to a malfunction of the main clock oscillator, is the criterion to detect stopping of the main clock. For details of the detection period, refer to Table 45.55, Oscillation Stop Detection Circuit Characteristics.

When an oscillation stop is detected, the main clock or PLL clock selected by the clock source select bits (SCKCR3.CKSEL[2:0]) is switched to the LOCO clock by the corresponding selectors in the former stage.

Therefore, on detection of oscillation stopping while the PLL clock or system clock is selected as the source of the main clock, the system clock source is switched to the LOCO clock without a change of CKSEL[2:0].

Switching between the main clock and LOCO clock or between the PLL clock and LOCO clock is controlled by the oscillation stop detection flag (OSTDSR.OSTDF). Switching to the LOCO clock is carried out by setting the OSTDF flag.

After a reset is released, activate the main clock oscillator, and then, set the SCKCR3.CKSEL[2:0] bits to the main clock or PLL clock after the specified oscillation settling time has elapsed. If a resonator is selected as the source of the main clock oscillator, apply a reset to clear the OSTDF flag.

When the external clock input is selected as the source for the main clock oscillator, clearing the OSTDF flag by the software switches the clock source back to the main clock or PLL clock.

However, the OSTDF flag cannot be cleared if the main clock oscillator is selected with the SCKCR3.CKSEL [2:0] bits, or if the PLL clock is selected in a state that the main clock oscillator is set for a clock source. After detecting the oscillation stop, in order to set the clock source back to the main clock or the PLL clock, change the setting of the SCKCR3.CKSEL[2:0] bits to the setting other than the main clock oscillator and the PLL clock with the main clock oscillator as the clock source, and then, clear the OSTDF flag by the software. Subsequently, confirm that the OSTDF flag is not set again, and then, set the SCKCR3.CKSEL [2:0] bits to the main clock or PLL clock after the specified oscillation settling time has elapsed.

After a reset is released, the main clock oscillator is stopped and the oscillation stop detection function is disabled. To enable the oscillation stop detection function, activate the main clock oscillator and write 1 to the oscillation stop detection function enable bit (OSTDCR.OSTDE) after confirming that the OSCOVFSR.MOOVF flag or OSCOVFSR.PLOVF flag have been set to 1.

The oscillation stop detection function is provided against the main clock stop by an external cause. Therefore, the oscillation stop detection function should be disabled before the main clock oscillator is stopped by the software or a transition is made to software standby mode or deep software standby mode.

The clocks that are switched to the LOCO clock by the oscillation stop detection are: the main clock, PLL clock, CAC main clock (CACMCLK), and CAN clock (CANMCLK), which are provided as the system clock sources.

Note that the frequencies of the derived clock signals after switching to the LOCO depends on the settings of the system clock control registers (SCKCR, SCKCR2, or SCKCR3).

Figure 9.7 shows an example of a flowchart for initialization of the oscillation stop detection function.

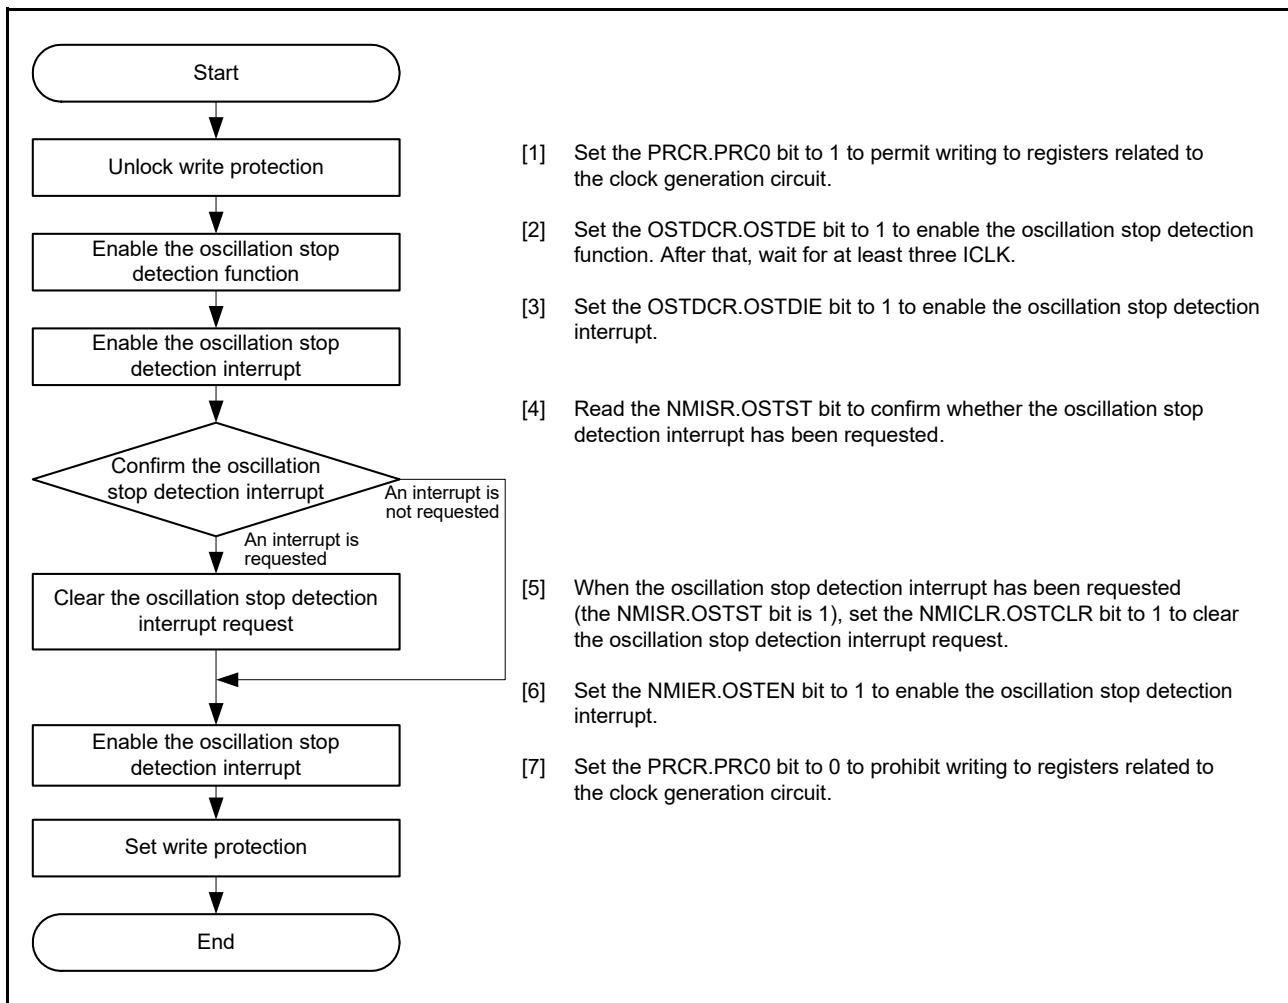

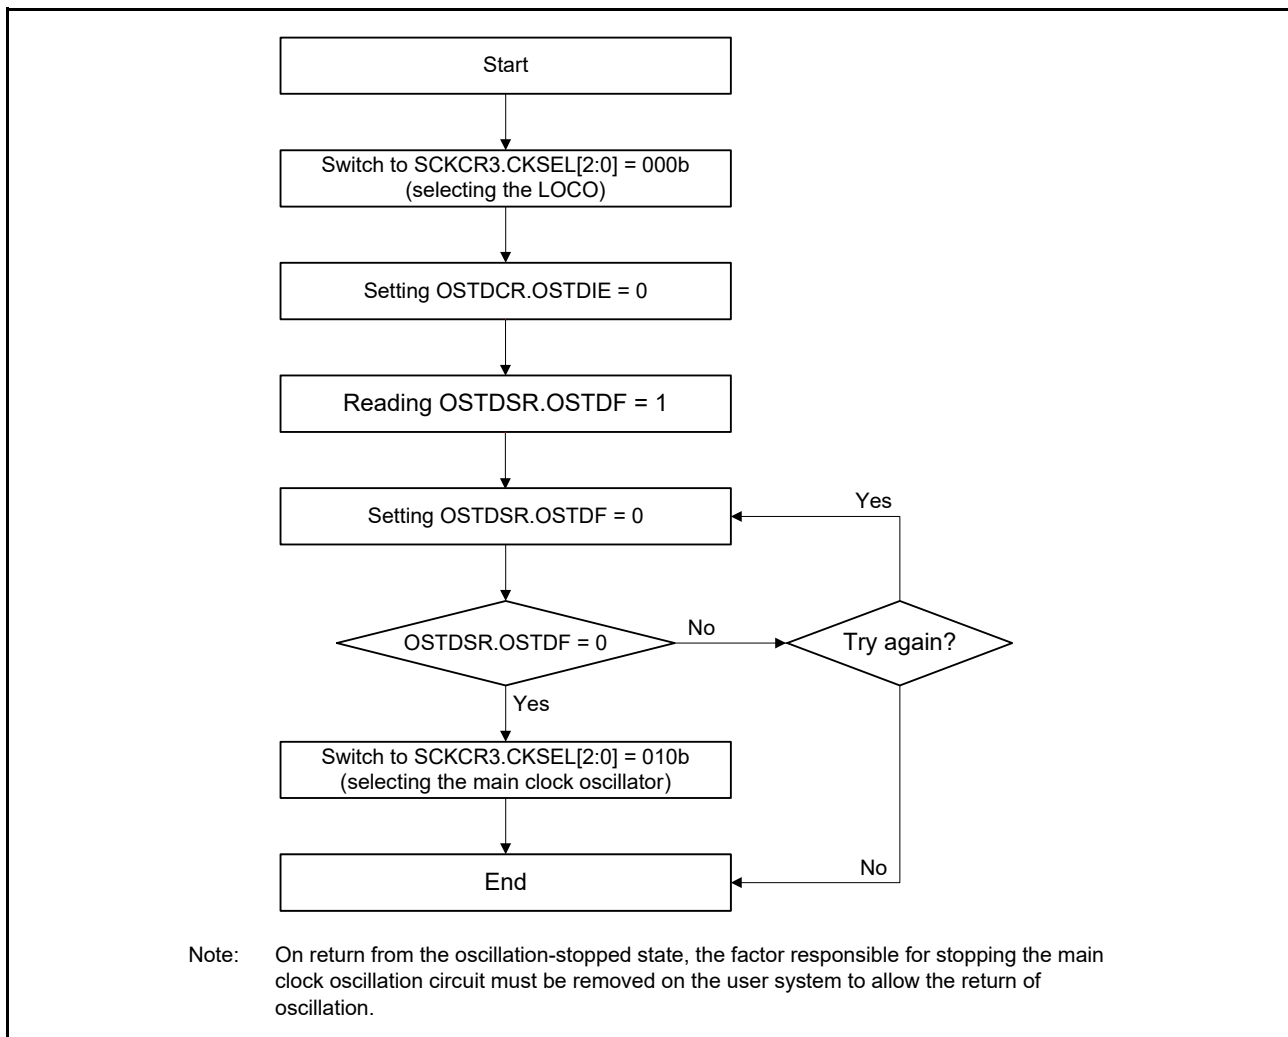

Figure 9.7 Flowchart Example for Initialization of Oscillation Stop Detection Function

**Figure 9.8** Flowchart Example for Recovery from Detection of Oscillator Stop

### 9.4.2 Oscillation Stop Detection Interrupts

An oscillation-stop detection interrupt (OSTDI) will be generated if the oscillation-stop detection flag (OSTDSR.OSTDF) becomes 1 while the oscillation-stop detection interrupt enable bit in the oscillation stop detection control register (OSTDCR.OSTDIE) is 1 (enabling interrupt generation on oscillation stop detection). At this time, the main clock oscillator stop is notified to the port output enable 3 (POE3B) and GPTW port output enable (POEG). On accepting the notification of the oscillation stop, the POE3 sets the OSTST high-impedance flag in input level control/status register 6 (ICSR6.OSTSTF) to 1. After the oscillation stop is detected, wait for at least 10 cycles of PCLKB before writing to this ICSR6.OSTSTF flag. When the OSTDSR.OSTDF flag requires clearing, do so after clearing the oscillation-stop detection interrupt enable bit in the oscillation stop detection control register (OSTDCR.OSTDIE). Wait for at least two cycles of PCLKB clock before again setting the OSTDCR.OSTDIE bit to 1. According to the number of cycles for access to read out a given I/O register, waiting time longer than two cycles of PCLKB may have to be secured. While at the same time, on accepting the notification of the oscillation stop, the POEG sets the oscillation stop detection flag (POEGGn.OSTPF (n = A to D)) in the POEG group n setting register to 1.

If the oscillation stop detection interrupt is to be used as a non-maskable interrupt, since non-maskable interrupts are disabled in the initial state after a reset release, set the corresponding bit in the NMIER register to 1 by software to enable non-maskable interrupts. If it is to be used as a maskable interrupt, do not change the value of the NMIER register from the value after a reset. For details, see section 14, Interrupt Controller (ICUC).

## 9.5 PLL Circuit

The PLL circuit has a function to multiply the frequency from the oscillator.

## 9.6 Internal Clock

Clock sources of internal clock signals are the main clock, HOCO clock, LOCO clock, PLL clock, and dedicated clock for the IWDT. The internal clocks listed in the table below are produced from these sources.

Frequencies of the internal clocks are set by the combination of the divisors selected by the FCK[3:0], ICK[3:0], BCK[3:0], PCKA[3:0], PCKB[3:0], PCKC[3:0], and PCKD[3:0] bits in SCKCR, the BCLKDIV bit in BCKCR, the UCK[3:0] bits in SCKCR2, the clock source selected by the CKSEL[2:0] bits in SCKCR3, the bits that select the frequency of the PLL circuit (STC[5:0] and PLIDIV[1:0] in PLLCR), and the HCFRQ[1:0] bits in HOCO2. If the value of any of these bits is changed, subsequent operation will be at the frequency determined by the new value.

**Table 9.6 Internal Clocks and Supply Destination Modules**

|   | Type of Internal Clock   | Clock Name                         | Supply Destination Module                                                                                                                                |
|---|--------------------------|------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1 | System clock             | ICLK                               | CPU, code flash memory, RAM, ECCRAM, ICU, BSC, DMAC, DTC, MPU                                                                                            |
| 2 | Peripheral module clocks | PCLKA                              | SCli, RSPI, MTU3 (internal peripheral buses), GPTW (internal peripheral buses), and HRPWM (internal peripheral buses)                                    |
|   |                          | PCLKB                              | TMR, CMT, WDT, IWDT, POE3, SClj, SClh, RIIC, CAN, USBb, S12AD, R12DA, CMPC, CRC, DOC, CAC, TSIP-Lite, I/O ports, MPC, ICU, POEG, ELC, temperature sensor |
|   |                          | PCLKC                              | MTU3 (counter reference clock), GPTW (counter reference clock), HRPWM (reference clock)                                                                  |
|   |                          | PCLKD                              | S12AD                                                                                                                                                    |
| 3 | Flash-IF clock           | FCLK                               | Data flash memory, code flash memory (P/E)                                                                                                               |
| 4 | External bus clock       | BCLK                               | BSC, I/O                                                                                                                                                 |
| 5 | USB clock                | UCLK                               | USBb                                                                                                                                                     |
| 6 | CAN clock                | CANMCLK                            | CAN                                                                                                                                                      |
| 7 | CAC clocks               | CACMCLK<br>(Main clock)            | CAC                                                                                                                                                      |
|   |                          | CACHCLK<br>(HOCO clock)            |                                                                                                                                                          |
|   |                          | CACLCLK<br>(LOCO clock)            |                                                                                                                                                          |
|   |                          | CACILCLK<br>(IWDT-dedicated clock) |                                                                                                                                                          |
| 8 | IWDT-dedicated clock     | IWDTCLK                            | IWDT                                                                                                                                                     |

### 9.6.1 System Clock

The system clock (ICLK) is used as the operating clock of the CPU, DMAC, DTC, code flash memory, and RAM. The ICLK frequency is specified by the ICK[3:0] bits in SCKCR, the CKSEL[2:0] bits in SCKCR3, the STC[5:0], and PLIDIV[1:0] bits in PLLCR, and the HCFRQ[1:0] bits in HOCOCR2.

### 9.6.2 Peripheral Module Clock

The peripheral module clocks (PCLKA, PCLKB, PCLKC, and PCLKD) are the operating clocks for use by peripheral modules.

The frequency of the given clock is specified by the PCKA[3:0], PCKB[3:0], PCKC[3:0], and PCKD[3:0] bits in SCKCR, the CKSEL[2:0] bits in SCKCR3, the STC[5:0], and PLIDIV[1:0] bits in PLLCR, and the HCFRQ[1:0] bits in HOCOCR2. The peripheral module clocks can be set to frequencies above that of the system clock.

### 9.6.3 Flash-IF Clock

The flash-interface clock (FCLK) is used as the operating clock for the flash-memory interfaces. That is, FCLK is used for programming and erasure of the code flash memory and data flash memory, and reading from the data flash memory. The FCLK frequency is specified by the FCK[3:0] bits in SCKCR, the CKSEL[2:0] bits in SCKCR3, and the STC[5:0] and PLIDIV[1:0] bits in PLLCR, and the HCFRQ[1:0] bits in HOCOCR2.

### 9.6.4 External Bus Clock

The external bus clock (BCLK) is an operating clock for the external bus controller. It is also output externally from the BCLK pin to the external bus. When the external bus is enabled, PE5 that is function-multiplexed with the BCLK pin cannot be used as an I/O port.

BCLK can be output from the BCLK pin by setting the SCKCR.PSTOP1 bit to 0 and setting the external bus enable bit in the system control register 0 (SYSCR0.EXBE) to 1. Make sure that modification of the SYSCR0.EXBE bit to 1 must always be performed while the PSTOP1 bit in SCKCR is 1.

When the BCKCR.BCLKDIV bit is set to 1, the BCLK clock divided by 2 is output from the BCLK pin.

The BCLK frequency is specified by the BCK[3:0] bits in SCKCR, the CKSEL[2:0] bits in SCKCR3, and the STC[5:0] and PLIDIV[1:0] bits in PLLCR, and the HCFRQ[1:0] bits in HOCOCR2.

A frequency higher than the system clock (ICLK) should not be set for the BCLK. If such a frequency is set, the clock frequency will be the same as the ICLK.

### 9.6.5 USB Clock

The USB clock (UCLK) is used as the operating clock for USBb.

Use the SCKCR2.UCK[3:0], SCKCR3.CKSEL[2:0], PLLCR.STC[5:0], or PLLCR.PLIDIV[1:0] bits to set the UCLK frequency. The UCLK frequency must be set to 48 MHz.

### 9.6.6 CAN Clock

The CAN clock (CANMCLK) is an operating clock for the CAN.

CANMCLK is generated by the main clock oscillator.

### 9.6.7 CAC Clock (CACCLK)

The CAC clock (CACCLK) is an operating clock for the CAC.

CACCLK includes CACMCLK generated by the main clock oscillator, CACHCLK generated by the high-speed on-chip oscillator, CACLCLK generated by the low-speed on-chip oscillator, CACILCLK generated by the IWDT-dedicated on-chip oscillator, and PCLKB supplied to peripheral modules.

### 9.6.8 IWDT-Dedicated Clock

The IWDT-dedicated clock (IWDTCLK) is the operating clock for the IWDT.

IWDTCLK is internally generated by the IWDT-dedicated on-chip oscillator.

## 9.7 Clock Source Switching

In this MCU, the clock signal from the LOCO, which oscillates during release from the reset state, is used to start the fetching of CPU instructions after the internal reset time (tRESWT) has elapsed. After that, set up the clock to which the CPU will be switched while it is still driven by the LOCO, and read the oscillation stabilization flag register to confirm that oscillation of the given clock signal is stable before switching to the selected clock source.

### (1) Example of procedure for settings to switch the system clock source from the LOCO to the PLL (clock source for the PLL: main clock) after release from an internal reset

1. After release from the internal reset state, set the driving ability by writing to the MODRV2[1:0] bits in the MOFCR register.
2. Set the oscillation settling time for the main clock oscillator by writing to the MSTTS[7:0] bits in the MOSCWTCR register.
3. Make the main clock oscillator run by setting the MOSTP bit in the MOSCCR register.
4. When setting the frequency of ICLK to faster than 120 MHz, set the MEMWAIT bit in the MEMWAIT register to 1.
5. Set the frequency multiplication factor in the PLLCR register (the initial setting for the PLL clock source selects the main clock oscillator).
6. Select PLL operation by writing to the PLL stop control bit in the PLLCR2 register.
7. Confirm that the PLL clock has become stable by reading the PLOVF flag in the OSCOVFSR register.
8. Set the division ratios after switching the clock sources by the SCKCR and SCKCR2 registers.
9. Change the clock signal from the LOCO clock to the PLL clock by writing to the CKSEL[2:0] bits in the SCKCR3 register.

### (2) Example of procedure for settings to switch the system clock source from the LOCO to the PLL (clock source for the PLL: HOCO) after release from an internal reset

1. After release from the internal reset state, set the frequency by writing to the HCFRQ[1:0] bits in the HOCOCCR2 register.
2. Make the HOCO clock run by setting the HCSTP bit in the HOCOCCR register (the initial value depends on the value of the OFS1.HOCOEN bit; if the OFS1.HOCOEN bit is 0, an explicit setting to make the HOCO clock run is not required. The oscillation settling time for the HOCO is 25 cycles of the LOCO).
3. When setting the frequency of ICLK to faster than 120 MHz, set the MEMWAIT bit in the MEMWAIT register to 1.
4. Set the frequency multiplication factor and set the HOCO clock as the PLL clock source by writing to the PLLCR register.
5. Select PLL operation by writing to the PLL stop control bit in the PLLCR2 register.
6. Confirm that the PLL clock has become stable by reading the PLOVF flag in the OSCOVFSR register.
7. Set the division ratios after switching the clock sources by the SCKCR and SCKCR2 registers.
8. Change the clock signal from the LOCO clock to the PLL clock by writing to the CKSEL[2:0] bits in the SCKCR3 register.

### (3) Example of procedure for settings to switch the system clock source from the LOCO to the main clock after release from an internal reset

1. After release from the internal reset state, set the driving ability by writing to the MODRV2[1:0] bits in the MOFCR register.
2. Set the oscillation settling time for the main clock oscillator by writing to the MSTTS[7:0] bits in the MOSCWTCR register.
3. Make the main clock oscillator run by setting the MOSTP bit in the MOSCCR register.
4. Confirm that the main clock has become stable by reading the MOOVF flag in the OSCOVFSR register.
5. Set the division ratios after switching the clock sources by the SCKCR and SCKCR2 registers.

6. Change the clock signal from the LOCO clock to the main clock by writing to the CKSEL[2:0] bits in the SCKCR3 register.

(4) Example of procedure for settings to switch the system clock source from the LOCO to the HOCO after release from an internal reset

1. After release from the internal reset state, set the frequency by writing to the HCFRQ[1:0] bits in the HOCOOCR2 register.
2. Make the HOCO clock run by setting the HCSTP bit in the HOCOOCR register (the initial value depends on the value of the OFS1.HOCOEN bit; if the OFS1.HOCOEN bit is 0, an explicit setting to make the HOCO clock run is not required. The oscillation settling time for the HOCO is 25 cycles of the LOCO).
3. Confirm that the HOCO clock has become stable by reading the HCOVF flag in the OSCOVFSR register.
4. Set the division ratios after switching the clock sources by the SCKCR and SCKCR2 registers.
5. Change the clock signal from the LOCO clock to the HOCO clock by writing to the CKSEL[2:0] bits in the SCKCR3 register.

## 9.8 Operations Linked by the ELC

### 9.8.1 Event Signal Output to the ELC

The clock generation circuit is capable of operation linked with another module set in advance when its interrupt request signal is used as an event signal by the event link controller (ELC) on detection of stopping of the main clock oscillation. The clock generation circuit outputs the event signal regardless of the setting of the corresponding oscillation stop detection interrupt enable bit (OSTDCR.OSTDIE). For details, see [section 19, Event Link Controller \(ELC\)](#).

### 9.8.2 Clock Source Switching on Reception of the Event Signal from the ELC

The clock generation circuit is capable of switching the clock source to the low-speed on-chip oscillator in response to the event set in advance when the event specified in the ELSRn register of the ELC occurs.

While this function is in use, clock source switching on return from sleep mode cannot be used. For details, see [section 11.2.6, Sleep Mode Return Clock Source Switching Register \(RSTCKCR\)](#).

## 9.9 Usage Notes

### 9.9.1 Notes on Clock Generation Circuit

- (1) The frequencies of the system clock (ICLK), peripheral module clock (PCLKA to PCLKD), flash-IF clock (FCLK), and external bus clock (BCLK) supplied to each module change according to the settings of SCKCR. Each frequency should meet the following:  
 Select each frequency that is within the operation guaranteed range of clock cycle time (tcyc) specified in AC characteristics of electrical characteristics.  
 The frequencies must not exceed the ranges listed in Table 9.1.  
 The peripheral modules operate on the PCLKA, PCLKB, and PCLKC. Note therefore that the operating speed of modules such as the timer and SCI varies before and after the frequency is changed.
- (2) The following relation is required between the frequencies of the system clock (ICLK) and external bus clock (BCLK).  

$$ICLK \geq BCLK$$
 Also, the following relation is required between the frequencies of the peripheral module clocks.  

$$PCLKC \geq PCLKA \geq PCLKB$$

$$PCLKA:PCLKC = 1:1 \text{ or } 1:2$$

$$PCLKB:PCLKD = 1:1, 2:1, 4:1, \text{ or } 1:2$$
- (3) Do not change the clock frequency during external bus access. Furthermore, when access via the external bus is to start after a change to the clock frequency, only start access via the bus after confirming that the change to the frequencies has been completed.
- (4) If the clock frequency is to be changed by modifying the value of SCKCR, SCKCR2, SCKCR3, or BCKCR register, wait for writing of the value to the register to be complete and the new frequency to be stable before starting subsequent processing. For the procedure to confirm the completion of writing to I/O registers, see (2) Notes on writing to I/O registers, in section 5, I/O Registers.

### 9.9.2 Note on Rewriting the SCKCR3 Register

When the SCKCR3.CKSEL[2:0] bits have been rewritten, the clock output is temporarily stopped to prevent the switch of the clock source from generating a clock pulse of short duration (glitch). The interrupt controller may not detect the following signals that were input during this period.

- (1) An external pin interrupt or NMI pin interrupt with a pulse width shorter than 4 cycles of the PCLKB after the switch while the PCLKB frequency is the 1/1 of the clock source (the SCKCR.PCKB[3:0] bits are 0000b).
- (2) An external pin interrupt or NMI pin interrupt with a pulse width shorter than 2.5 cycles of the PCLKB after the switch while the PCLKB frequency is the 1/2 of the clock source (the SCKCR.PCKB[3:0] bits are 0001b).

When the external pin interrupt or NMI pin interrupt is in use, input the signal with enough pulse width to exceed the time condition described in (1) and (2).

### 9.9.3 Notes on Resonator

Since various resonator characteristics relate closely to the user's board design, adequate evaluation is required on the user side before use, referencing the resonator connection example shown in this section. The circuit constants for the resonator depend on the resonator to be used and the stray capacitance of the mounting circuit. Therefore, the circuit constants should be determined in full consultation with the resonator manufacturer. The voltage to be applied between the resonator pins must be within the absolute maximum rating.

### 9.9.4 Notes on Board Design

When using a crystal resonator, place the resonator and its load capacitors as close to the XTAL and EXTAL pins as possible. Other signal lines should be routed away from the oscillation circuit as shown in Figure 9.9 to prevent electromagnetic induction from interfering with correct oscillation.

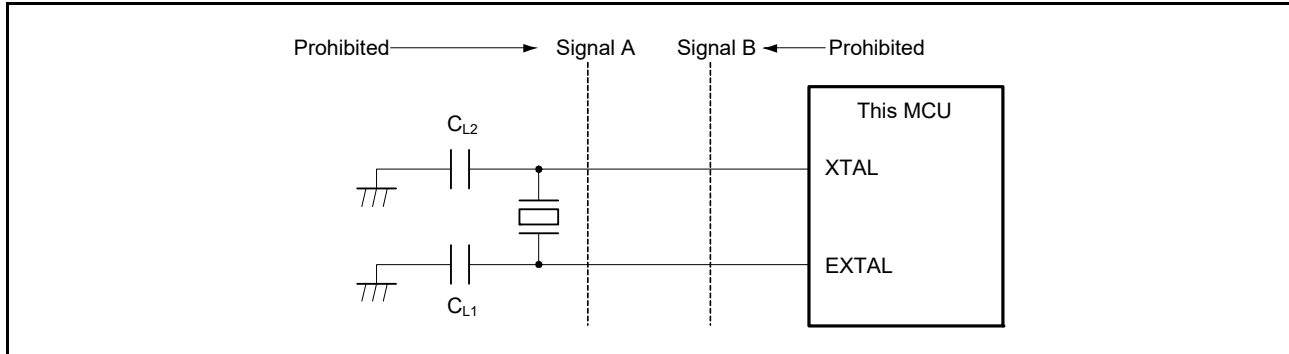

Figure 9.9 Notes on Board Design for Oscillation Circuit

### 9.9.5 Notes on Resonator Connect Pin

When the main clock is not used, the EXTAL and XTAL pins can be used as general ports P36 and P37. When they are used as the general ports, the main clock should be stopped (MOSCCR.MOSTP should be set to 1). However, with the system using the main clock, the EXTAL (P36) and XTAL (P37) pins should not be used as output ports.

For the values of registers related to port settings, refer to Table 21.39, Register Settings.

Furthermore, since the main clock becomes essential if the function indicated below is in use, design the board so that both pins can be used for the main clock signal.

- Programming of flash memory in boot mode (USB interface)\*1

Note 1. For the conditions on the oscillator in the various modes, see section 44.12.8, Notes on Program Execution in Boot Mode (USB Interface).

## 10. Clock Frequency Accuracy Measurement Circuit (CAC)

### 10.1 Overview

The clock frequency accuracy measurement circuit (CAC) counts pulses of the clock to be measured (measurement target clock) within the time generated by the clock to be used as a measurement reference (measurement reference clock), and determines the accuracy depending on whether the number of pulses is within the allowable range.

When measurement is completed or the number of pulses within the time generated by the measurement reference clock is not within the allowable range, an interrupt request is generated.

Table 10.1 lists the specifications of the CAC and Figure 10.1 shows a block diagram of the CAC.

**Table 10.1 CAC Specifications**

| Item                           | Description                                                                                                                                                                                                                                              |
|--------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

| CACREF   | Input | Measurement reference clock input pin |

## 10.2 Register Descriptions

### 10.2.1 CAC Control Register 0 (CACR0)

Address(es): CAC.CACR0 0008 B000h

| Bit      | Symbol | Bit Name                           | Description                                                                               | R/W |
|----------|--------|------------------------------------|-------------------------------------------------------------------------------------------|-----|
| b0       | CFME   | Clock Frequency Measurement Enable | 0: Clock frequency measurement is disabled.<br>1: Clock frequency measurement is enabled. | R/W |
| b7 to b1 | —      | Reserved                           | These bits are read as 0. The write value should be 0.                                    | R/W |

#### CFME Bit (Clock Frequency Measurement Enable)

This bit specifies whether clock frequency measurement is enabled or disabled.

When rewriting this bit, more time is required than other bits for the new value to be reflected in the register. Further write access to this bit are ignored until the current write access is reflected in the register. Read the bit to confirm that the rewrite has been reflected in the register.

## 10.2.2 CAC Control Register 1 (CACR1)

Address(es): CAC.CACR1 0008 B001h

| Bit      | Symbol     | Bit Name                        | Description                                                                                                                                                                                            | R/W |
|----------|------------|---------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----|
| b0       | CACREFE    | CACREF Pin Input Enable         | 0: CACREF pin input is disabled.<br>1: CACREF pin input is enabled.                                                                                                                                    | R/W |
| b3 to b1 | FMCS[2:0]  | Measurement Target Clock Select | b3 b1<br>0 0 0: Main clock<br>0 1 0: HOCO clock<br>0 1 1: LOCO clock<br>1 0 0: IWDT-dedicated clock (IWDTCLK)<br>1 0 1: Peripheral module clock B (PCLKB)<br>Settings other than above are prohibited. | R/W |
| b5, b4   | TCSS[1:0]  | Timer Count Clock Source Select | b5 b4<br>0 0: No division<br>0 1: ×1/4 clock<br>1 0: ×1/8 clock<br>1 1: ×1/32 clock                                                                                                                    | R/W |
| b7, b6   | EDGES[1:0] | Valid Edge Select               | b7 b6<br>0 0: Rising edge<br>0 1: Falling edge<br>1 0: Both rising and falling edges<br>1 1: Setting prohibited                                                                                        | R/W |

Note: Set the CACR1 register when the CACR0.CFME bit is 0.

### CACREFE Bit (CACREF Pin Input Enable)

This bit specifies whether the CACREF pin input is enabled or disabled.

### FMCS[2:0]Bits (Measurement Target Clock Select)

These bits select the measurement target clock whose frequency is to be measured.

### TCSS[1:0] Bits (Timer Count Clock Source Select)

These bits select the count clock source for the clock frequency accuracy measurement circuit.

### EDGES[1:0]Bits (Valid Edge Select)

These bits select the valid edge for the reference signal.

### 10.2.3 CAC Control Register 2 (CACR2)

Address(es): CAC.CACR2 0008 B002h

| Bit      | Symbol    | Bit Name                                                     | Description                                                                                                                                                                                                                                                                                                                      | R/W |
|----------|-----------|--------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----|
| b0       | RPS       | Reference Signal Select                                      | 0: CACREF pin input<br>1: Internal clock (internally generated signal)                                                                                                                                                                                                                                                           | R/W |
| b3 to b1 | RSCS[2:0] | Measurement Reference Clock Select                           | b3 b1<br>0 0 0: Main clock<br>0 1 0: HOCO clock<br>0 1 1: LOCO clock<br>1 0 0: IWDT-dedicated clock (IWDTCLK)<br>1 0 1: Peripheral module clock B (PCLKB)<br>Settings other than above are prohibited.                                                                                                                           | R/W |
| b5, b4   | RCDS[1:0] | Measurement Reference Clock Frequency Division Ration Select | b5 b4<br>0 0: ×1/32 clock<br>0 1: ×1/128 clock<br>1 0: ×1/1024 clock<br>1 1: ×1/8192 clock                                                                                                                                                                                                                                       | R/W |
| b7, b6   | DFS[1:0]  | Digital Filter Select                                        | b7 b6<br>0 0: Digital filtering is disabled.<br>0 1: The sampling clock for the digital filter is the measurement target clock.<br>1 0: The sampling clock for the digital filter is the measurement target clock divided by 4.<br>1 1: The sampling clock for the digital filter is the measurement target clock divided by 16. | R/W |

Note: Set the CACR2 register when the CACR0.CFME bit is 0.

#### RPS Bit (Reference Signal Select)

This bit selects whether to use the CACREF pin input or an internal clock (internally generated signal) as the reference signal.

#### RSCS[2:0]Bits (Measurement Reference Clock Select)

These bits select the clock source for generating the measurement reference clock.

#### RCDS[1:0]Bits (Measurement Reference Clock Frequency Division Ration Select)

These bits select the frequency division ratio of the measurement reference clock.

#### DFS[1:0]Bits (Digital Filter Select)

The setting of these bits enables or disables the digital filter and selects its sampling clock.

## 10.2.4 CAC Interrupt Request Enable Register (CAICR)

Address(es): CAC.CAICR 0008 B003h

|    |            |             |             |    |       |            |            |

### FERRIE Bit (Frequency Error Interrupt Request Enable)

This bit specifies whether the frequency error interrupt request is enabled or disabled.

### MENDIE Bit (Measurement End Interrupt Request Enable)

This bit specifies whether the measurement end interrupt request is enabled or disabled.

### OVFIE Bit (Overflow Interrupt Request Enable)

This bit specifies whether the overflow interrupt request is enabled or disabled.

### FERRFCL Bit (FERRF Clear)

Setting this bit to 1 clears the CASTR.FERRF flag.

### MENDFCL Bit (MENDF Clear)

Setting this bit to 1 clears the CASTR.MENDF flag.

### OVFFCL Bit (OVFF Clear)

Setting this bit to 1 clears the CASTR.OVFF flag.

## 10.2.5 CAC Status Register (CASTR)

Address(es): CAC.CASTR 0008 B004h

Value after reset: 0 0 0 0 0 0 0 0

| Bit      | Symbol | Bit Name             | Description                                                                                                                                                                        | R/W |
|----------|--------|----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----|
| b0       | FERRF  | Frequency Error Flag | 0: The clock frequency is within the range corresponding to the settings.<br>1: The clock frequency has deviated beyond the range corresponding to the settings (frequency error). | R   |
| b1       | MENDF  | Measurement End Flag | 0: Measurement is in progress.<br>1: Measurement has ended.                                                                                                                        | R   |
| b2       | OVFF   | Overflow Flag        | 0: The counter has not overflowed.<br>1: The counter has overflowed.                                                                                                               | R   |
| b7 to b3 | —      | Reserved             | These bits are read as 0. The write value should be 0.                                                                                                                             | R/W |

### FERRF Flag (Frequency Error Flag)

This flag indicates deviation of the clock frequency from the set value (frequency error).

[Setting condition]

- The clock frequency is outside of the setting range.

[Clearing condition]

- 1 is written to the CAICR.FERRFCL bit.

### MENDF Flag (Measurement End Flag)

This flag indicates the end of measurement.

[Setting condition]

- Measurement has finished.

[Clearing condition]

- 1 is written to the CAICR.MENDFCL bit.

### OVFF Flag (Overflow Flag)

This flag indicates that the counter has overflowed.

[Setting condition]

- The counter has overflowed.

[Clearing condition]

- 1 is written to the CAICR.OVFFCL bit.

### 10.2.6 CAC Upper-Limit Value Setting Register (CAULVR)

Address(es): CAC.CAULVR 0008 B006h

The CAULVR register is a 16-bit readable/writable register that specifies the upper-limit value of the counter used for measuring the frequency. When the frequency rises above the value specified in this register, a frequency error is detected.

Write to this register when the CACR0.CFME bit is 0.

The counter value held in the CACNTBR register can vary with the difference between the phases of the digital filter and edge-detection circuit on the one hand and the signal on the CACREF pin on the other, so ensure that this setting allows an adequate margin.

### 10.2.7 CAC Lower-Limit Value Setting Register (CALLVR)

Address(es): CAC.CALLVR 0008 B008h

The CALLVR register is a 16-bit readable/writable register that specifies the lower-limit value of the counter used for measuring the frequency. When the frequency falls below the value specified in this register, a frequency error is detected.

Write to this register when the CACR0.CFME bit is 0.

The counter value held in the CACNTBR register can vary with the difference between the phases of the digital filter and edge-detection circuit on the one hand and the signal on the CACREF pin on the other, so ensure that this setting allows an adequate margin.

### 10.2.8 CAC Counter Buffer Register (CACNTBR)

Address(es): CAC.CACNTBR 0008 B00Ah

The CACNTBR register is a 16-bit read-only register that retains the counter value at the time a valid reference signal edge is input.

### 10.3 Operation

#### 10.3.1 Measuring Clock Frequency

The clock frequency accuracy measurement circuit measures the clock frequency using the CACREF pin input or the internal clock as a reference. Figure 10.2 shows an operating example of the clock frequency accuracy measurement circuit.

The clock frequency accuracy measurement circuit operates as shown below when measuring the clock frequency.

**Figure 10.2 Operating Example of Clock Frequency Accuracy Measurement Circuit**

- (1) When the CACREF pin input is used as a reference (the CACR1.CACREFE bit = 1), clock frequency measurement is enabled by writing 1 to the CACR0.CFME bit while the CACR2.RPS bit is 0 and the CACR1.CACREFE bit is 1. On the other hand, when the internal clock is used as a reference (the CACR1.CACREFE bit = 0), clock frequency measurement is enabled by writing 1 to the CACR0.CFME bit while the CACR2.RPS bit is 1.
- (2) When the CACREF pin input is used as a reference, the timer starts up-counting if the valid edge selected by the CACR1.EDGES[1:0] bits is input from the CACREF pin after 1 is written to the CFME bit. The valid edge is a rising edge (the CACR1.EDGES[1:0] bits = 00b) in Figure 10.2.  
 When the internal clock is used as a reference, the timer starts up-counting if the valid edge selected by the CACR1.EDGES[1:0] bits is input based on the clock source selected by the CACR2.RSCS[2:0] bits after 1 is written to the CFME bit. The valid edge is a rising edge (the CACR1.EDGES[1:0] bits = 00b) in Figure 10.2.
- (3) When the next valid edge is input, the counter value is transferred in the CACNTBR register and compared with the values of the CAULVR and CALLVR registers. If the formula  $CALLVR \leq CACNTBR \leq CAULVR$  is satisfied, only the CASTR.MENDF flag is set to 1 because the clock frequency is correct. If the CAICR.MENDIE bit is 1, a measurement end interrupt is generated.
- (4) When the next valid edge is input, the counter value is transferred in the CACNTBR register and compared with the values of the CAULVR and CALLVR registers. In the case of  $CACNTBR > CAULVR$ , the CASTR.FERRF flag is set to 1 because the clock frequency is erroneous. If the CAICR.FERRIE bit is 1, a frequency error interrupt is

generated. Also, the CASTR.MENDF flag is set to 1. If the CAICR.MENDIE bit is 1, a measurement end interrupt is generated.

- (5) When the next valid edge is input, the counter value is transferred in the CACNTBR register and compared with the values of the CAULVR and CALLVR registers. In the case of  $CACNTBR < CALLVR$ , the CASTR.FERRF flag is set to 1 because the clock frequency is erroneous. If the CAICR.FERRIE bit is 1, a frequency error interrupt is generated. Also, the CASTR.MENDF flag is set to 1. If the CAICR.MENDIE bit is 1, a measurement end interrupt is generated.
- (6) While the CACR0.CFME bit is 1, the counter value is transferred in the CACNTBR register and compared with the values of the CAULVR and CALLVR registers every time a valid edge is input. Writing 0 to the CACR0.CFME bit clears the counter and stops up-counting.

### 10.3.2 Digital Filtering of Signals on the CACREF Pin

The CACREF pin has a digital filter. Levels on the target pin for sampling are conveyed to the internal circuitry after matching three consecutive times at the selected sampling interval and the same level continues to be conveyed internally until the level on the pin again matches three consecutive times.

Enabling and disabling of the digital filter and its sampling clock are selectable.

The counter value transferred in the CACNTBR register may be in error by up to one cycle of the sampling clock due to the difference between the phases of the digital filter and the signal input to the CACREF pin.

When a frequency dividing clock is selected as a count source clock, the counter value error is obtained by the following formula:

$$\text{Counter value error} = (\text{One cycle of the count source clock}) / (\text{One cycle of the sampling clock})$$

## 10.4 Interrupt Requests

The CAC generates three types of interrupt request: frequency error interrupt, measurement end interrupt, and overflow interrupt. When an interrupt source is generated, the corresponding status flag becomes 1. Table 10.3 lists details on the interrupt requests of the clock frequency accuracy measurement circuit.

**Table 10.3 Interrupt Requests of Clock Frequency Accuracy Measurement Circuit**

| Interrupt Request         | Interrupt Enable Bit | Status Flag | Interrupt Source                                                                                                                                                          |
|---------------------------|----------------------|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Frequency error interrupt | CAICR.FERRIE         | CASTR.FERRF | The result of comparing CACNTBR to CAULVR and CALLVR is either $CACNTBR > CAULVR$ or $CACNTBR < CALLVR$ .                                                                 |
| Measurement end interrupt | CAICR.MENDIE         | CASTR.MENDF | A valid edge is input from the CACREF pin.<br>Note however that a measurement end interrupt does not occur at the first valid edge after writing 1 to the CACR0.CFME bit. |
| Overflow interrupt        | CAICR.OVFIE          | CASTR.OVFF  | The counter has overflowed.                                                                                                                                               |

## 10.5 Usage Notes

### 10.5.1 Module Stop Function Setting

CAC operation can be disabled or enabled using module stop control register C (MSTPCRC). The initial setting is for the CAC to be halted. Register access is enabled by releasing the module stop state. For details, refer to **section 11, Low Power Consumption**.

## 11. Low Power Consumption

### 11.1 Overview

This MCU has several functions for reducing power consumption, including switching of clock signals to reduce power consumption, BCLK output control, stopping modules, and transitions to low power consumption states.

Table 11.1 lists the specifications of low power consumption functions, and Table 11.2 lists the conditions to shift to low power consumption modes, states of the CPU and peripheral modules, and the method for release from each mode. After a reset, this MCU enters the normal program execution state, but modules except for the DMAC, DTC, and RAM do not operate.

**Table 11.1 Specifications of Low Power Consumption Functions**

| Item                                                  | Specification                                                                                                                                                                                            |
|-------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Reducing power consumption by switching clock signals | The frequency division ratio is settable independently for the system clock (ICLK), peripheral module clock (PCLKA, PCLKB, PCLKC, PCLKD), external bus clock (BCLK), and flash interface clock (FCLK).*1 |
| BCLK output control function                          | BCLK output or high-level output can be selected.*1                                                                                                                                                      |
| Module-stop function                                  | Functions can be stopped independently for each peripheral module.                                                                                                                                       |
| Function for transition to low power consumption mode | Transition to a low power consumption mode in which the CPU, peripheral modules, or oscillators are stopped is enabled.                                                                                  |

“Operating possible” means that operating or stopped can be controlled by the control register setting.

“Stopped (Retained)” means that internal register values are retained and internal operations are suspended.

“Stopped (Undefined)” means that internal register values are undefined and power is not supplied to the internal circuit.

- Note 1. “Interrupts” here indicates an external pin interrupt (the NMI or IRQ0 to IRQ15) or any of peripheral interrupts (the 8-bit timer, IWDT, USB suspend/resume, voltage monitoring 1, voltage monitoring 2, and main-clock oscillation stop detection).
- Note 2. “Interrupts” here indicates an external pin interrupt (the NMI or IRQ0 to IRQ15) or any of peripheral interrupts (the IWDT, USB suspend/resume, voltage monitoring 1, and voltage monitoring 2 interrupts).
- Note 3. “Interrupts” here indicates a certain external pin interrupt source pin (the NMI or IRQ0-DS to IRQ15-DS) or any of peripheral interrupts (the voltage monitoring 1 and voltage monitoring 2 interrupts). However, these interrupts are enabled only when the corresponding bit in the deep standby interrupt enable registers  $i$  (DPSIER $i$ ) ( $i = 0$  to  $2$ ) is set to 1. When the pin functions have “-DS” appended to their names, they can also be used as triggers for release from deep software standby.
- Note 4. This does not include release initiated by the RES# pin reset, power-on reset, voltage monitoring reset, or independent watchdog-timer reset. The transition is to the reset state when release is initiated by one of these reset sources.
- Note 5. Operation or stopping is selected by the setting of the IWDT sleep mode count stop control bit (IWDTSLCSTP) in the option function select register 0 (OFS0) in IWDT auto start mode. If the OFS0.IWDTSLCSTP bit is 0 (disabling stopping of the counter when a transition to low power consumption mode is made), the transition is to software standby mode rather than deep software standby mode. In any mode other than IWDT auto start mode, operation or stopping is selected by the setting of the sleep mode counter stop control bit (SLCSTP) in the IWDT counter stop control register (IWDTCSTPR). If the IWDTCSTPR.SLCSTP bit is 0 (disabling stopping of the counter when a transition to low power consumption mode is made), the transition is to software standby mode rather than deep software standby mode.
- Note 6. Detection of USB resumption is possible.
- Note 7. When a source condition for POE interrupts is satisfied while POE interrupts are enabled and the chip is in all-module clock stop mode, the flag for the source condition is retained but return from all-module clock stop mode does not proceed. If a different source initiates return from all-module clock stop mode in this situation, the POE interrupt is generated after that.
- Note 8. Stopping or operation is controlled by the module-stop setting bits (MSTPA4 and MSTPA5, respectively) in module-stop control register A (MSTPCRA) for 8-bit timers 0 and 1 (unit 0) and 2 and 3 (unit 1).
- Note 9. If the voltage monitoring 1 circuit mode selection bit in the voltage monitoring 1 circuit control register 0 (LVD1CR0.LVD1RI) or the voltage monitoring 2 circuit mode selection bit in the voltage monitoring 2 circuit control register 0 (LVD2CR0.LVD2RI) is 1, the transition is to software standby mode rather than deep software standby mode.
- Note 10. If pin PE5 is being used for the BCLK signal, operation continues with as-is output of BCLK. While the 8-bit timer is operated, the related pins continue operation.
- Note 11. Retention of levels or placement in the high-impedance state is selectable for the address bus and bus control signals (CS0# to CS3#, RD#, WR0#, WR1#, WR#, BC0#, BC1#, and ALE) by the output port enable bit (OPE) in the standby control register

(SBYCR).

| b15       | SSBY   | Software Standby   | 0: Shifts to sleep mode or all-module clock stop mode after the WAIT instruction is executed<br>1: Shifts to software standby mode after the WAIT instruction is executed                                                                                              | R/W |

#### OPE Bit (Output Port Enable)

The OPE bit specifies whether to retain the output of the address bus and bus control signals (CS0# to CS3#, RD#, WR0#, WR1#, WR#, BC0#, BC1#, and ALE) in software standby mode or deep software standby mode, or to set the output to the high-impedance state.

#### SSBY Bit (Software Standby)

The SSBY bit specifies the transition destination after the WAIT instruction is executed.

When the SSBY bit is set to 1, the MCU enters software standby mode after execution of the WAIT instruction. When the MCU returns to normal operating mode after an interrupt has initiated release from software standby mode, the SSBY bit remains 1. Write 0 to this bit to clear it.

When the oscillation stop detection function enable bit in the oscillation stop detection control register (OSTDCR.OSTDE) is 1, the setting of the SSBY bit is ineffective. Even if the SSBY bit is 1, the MCU will enter sleep mode or all module clock stop mode on execution of the WAIT instruction.

When the code flash memory P/E mode entry bit in the flash P/E mode entry register (FENTRYR.FENTRYC) is 1 or the data flash memory P/E mode entry bit (FENTRYR.FENTRYD) is 1, the setting of this bit is ineffective. Sleep mode is entered on execution of the WAIT instruction even if this bit has been set to 1.

| b31      | ACSE    | All-Module Clock Stop Mode Enable                   | 0: All-module clock stop mode is disabled<br>1: All-module clock stop mode is enabled                                                                     | R/W |

Note 1. The temperature sensor is controlled by a register in the S12AD unit 2.

#### ACSE Bit (All-Module Clock Stop Mode Enable)

The ACSE bit enables or disables a transition to all-module clock stop mode.

With the ACSE bit set to 1, when the CPU executes the WAIT instruction with the SBYCR.SSBY bit, MSTPCRA, MSTPCRB, MSTPCRC, and MSTPCRD satisfying specified conditions, the MCU enters all-module clock stop mode. For details, see section 11.5.2, All-Module Clock Stop Mode.

Whether to stop the 8-bit timers or not can be selected by the MSTPA5 and MSTPA4 bits.

When the MSTPCRA.ACSE bit = 0 while the SBYCR.SSBY = 0, a transition to sleep mode is made after the WAIT instruction is executed.

When the code flash memory P/E mode entry bit in the flash P/E mode entry register (FENTRYR.FENTRYC) is 1 or the data flash memory P/E mode entry bit (FENTRYR.FENTRYD) is 1, the setting of this bit is ineffective. Sleep mode is entered on execution of the WAIT instruction if this bit has been set to 1.

Note 1. The MSTPB0 bit should be rewritten while the oscillation of the clock controlled by the MSTPB0 bit is stabilized. For entering software standby mode after writing a new value to the MSTPB0 bit, wait for two cycles of the CAN clock (CANMCLK) to elapse after writing the new value, and then execute a WAIT instruction.

Note 2. For entering software standby mode after writing a new value to the MSTPB19 bit, wait for two cycles of the USBb clock (UCLK) to elapse after writing the new value, and then execute a WAIT instruction.

| b31 to b28 | —                         | Reserved                                       | These bits are read as 1. The write value should be 1.                                                          | R/W |

Note 1. The MSTPC0 bit should not be set to 1 during access to the RAM. The RAM should not be accessed while the MSTPC0 bit is set to 1.

Note 2. The MSTPC6 bit should not be set to 1 during access to the ECCRAM. The ECCRAM should not be accessed while the MSTPC6 bit is set to 1.

Note 3. The MSTPC19 bit should be rewritten while the oscillation of the clock to be controlled by this bit is stable. For entering software standby mode after writing a new value to this bit, wait for two cycles of the slowest clock among the clocks output by the oscillators actually oscillating, and then execute a WAIT instruction.

## 11.2.5 Module Stop Control Register D (MSTPCRD)

Address(es): 0008 001Ch

| b6 to b3 | —                 | Reserved                                           | These bits are read as 0. The write value should be 0.                                                                                               | R/W |
| b7       | RSTCKEN           | Sleep Mode Return Clock<br>Source Switching Enable | 0: Clock source switching on release from sleep mode is disabled<br>1: Clock source switching on release from sleep mode is enabled                  | R/W |

The RSTCKCR register is used to control clock source switching at the time of release from sleep mode. When operation is restored from sleep mode by setting RSTCKCR, the main clock oscillator stop bit in the main clock oscillator control register (MOSCCR.MOSTP) and HOCO stop bit in the high-speed on-chip oscillator control register (HOCOCCR.HCSTP) corresponding to the clock source to be used on restoration are automatically modified to the operating state. The value of RSTCKSEL[2:0] bits is automatically reloaded to the clock source select bits in the system clock control register 3 (SCKCR3.CKSEL[2:0]).

The sleep mode return clock source switching function and clock source switching function by the ELC cannot be used at the same time. To enable the sleep mode return clock source switching function, write 1 to the RSTCKCR.RSTCKEN bit with the ELC clock source switching function disabled. The ELC clock source switching function should be enabled with the RSTCKCR.RSTCKEN bit being 0.

When the setting of register RSTCKCR is for the HOCO to be used in recovery from sleep mode, the power supply for the HOCO is not automatically switched on. If the HOCO to be used in recovery from sleep mode, the power supply for the HOCO must be on when the transition to sleep mode takes place.

### RSTCKSEL[2:0] Bits (Sleep Mode Return Clock Source Select)

The RSTCKSEL[2:0] bits select the clock source to be used at the time of release from sleep mode. The clock source selected by the RSTCKSEL[2:0] bits is enabled only when the RSTCKEN bit is 1.

### RSTCKEN Bit (Sleep Mode Return Clock Source Switching Enable)

The RSTCKEN bit enables or disables clock source switching at the time of release from sleep mode. On release from sleep mode, the clock source should be switched only when LOCO is selected as a clock for a transition to sleep mode. To make a transition to sleep mode with HOCO, main clock, or PLL selected as the clock source, the RSTCKEN bit should not be set to 1.

| b7       | DPSBY  | Deep Software Standby | SSBY b7<br>0 0: Transition to sleep mode or all-module clock stop mode is made after the WAIT instruction is executed<br>0 1: Transition to sleep mode or all-module clock stop mode is made after the WAIT instruction is executed<br>1 0: Transition to software standby mode is made after the WAIT instruction is executed<br>1 1: Transition to deep software standby mode is made after the WAIT instruction is executed | R/W |

The DPSBYCR register is not initialized by the internal reset signal that is the source for release from deep software standby mode. For details, see Table 6.2, Targets to be Initialized by Each Reset Source.

### IOKEEP Bit (I/O Port Retention)

In deep software standby mode, I/O ports keep retaining the same states from software standby mode. The IOKEEP bit specifies whether to keep retaining the I/O port states from deep software standby mode even after release from deep software standby mode, or to cancel retention of the I/O port states.

### DPSBY Bit (Deep Software Standby)

The DPSBY bit controls transitions to deep software standby mode.

When the WAIT instruction is executed while the SBYCR.SSBY and DPSBY bits are both 1, the MCU enters deep software standby mode through software standby mode.

The DPSBY bit remains 1 when release from deep software standby mode is triggered by certain pins which are sources of external pin interrupts (NMI or IRQ0-DS to IRQ15-DS) or a peripheral interrupt. Write 0 to this bit to clear it.

The setting of the DPSBY bit becomes invalid when the IWDT is in auto-start mode and the OFS0.IWDTSLCSTP is 0 (counting continues) or the IWDT is in register start mode and the SLCSTP bit in IWDCSTPR is 0.

Instead, even when the SBYCR.SSBY bit is 1 and the DPSBY bit 1, the transition after the execution of a WAIT instruction is to software standby mode.

The setting of the DPSBY bit becomes invalid when voltage monitoring 1 reset is enabled by the voltage monitoring 1 circuit mode select bit (LVD1CR0.LVD1RI = 1) or when a voltage monitoring 2 reset is enabled by the voltage monitoring 2 circuit mode bit (LVD2CR0.LVD2RI = 1). In this case, even when the SBYCR.SSBY bit is 1 and the DPSBY bit is 1, the transition after the execution of a WAIT instruction is to software standby mode.

## 11.2.8 Deep Standby Interrupt Enable Register 0 (DPSIER0)

Address(es): 0008 C282h

| b5  | DIRQ5E | IRQ5-DS Pin Enable | 0: Release from deep software standby mode by the IRQ5-DS pin is disabled<br>1: Release from deep software standby mode by the IRQ5-DS pin is enabled | R/W |
| b6  | DIRQ6E | IRQ6-DS Pin Enable | 0: Release from deep software standby mode by the IRQ6-DS pin is disabled<br>1: Release from deep software standby mode by the IRQ6-DS pin is enabled | R/W |
| b7  | DIRQ7E | IRQ7-DS Pin Enable | 0: Release from deep software standby mode by the IRQ7-DS pin is disabled<br>1: Release from deep software standby mode by the IRQ7-DS pin is enabled | R/W |

The DPSIER0 register is not initialized by the internal reset signal used as deep software standby mode releasing source. For details, see Table 6.2, Targets to be Initialized by Each Reset Source.

After the setting of DPSIER0 is modified, an edge may be internally generated depending on the state of the pin, resulting in DPSIFR0 being set to 1. Therefore, DPSIFR0 should be set to 0 before a transition to deep software standby mode.

| b0  | DIRQ8E  | IRQ8-DS Pin Enable  | 0: Release from deep software standby mode by the IRQ8-DS pin is disabled<br>1: Release from deep software standby mode by the IRQ8-DS pin is enabled   | R/W |
| b1  | DIRQ9E  | IRQ9-DS Pin Enable  | 0: Release from deep software standby mode by the IRQ9-DS pin is disabled<br>1: Release from deep software standby mode by the IRQ9-DS pin is enabled   | R/W |
| b2  | DIRQ10E | IRQ10-DS Pin Enable | 0: Release from deep software standby mode by the IRQ10-DS pin is disabled<br>1: Release from deep software standby mode by the IRQ10-DS pin is enabled | R/W |
| b3  | DIRQ11E | IRQ11-DS Pin Enable | 0: Release from deep software standby mode by the IRQ11-DS pin is disabled<br>1: Release from deep software standby mode by the IRQ11-DS pin is enabled | R/W |
| b4  | DIRQ12E | IRQ12-DS Pin Enable | 0: Release from deep software standby mode by the IRQ12-DS pin is disabled<br>1: Release from deep software standby mode by the IRQ12-DS pin is enabled | R/W |
| b5  | DIRQ13E | IRQ13-DS Pin Enable | 0: Release from deep software standby mode by the IRQ13-DS pin is disabled<br>1: Release from deep software standby mode by the IRQ13-DS pin is enabled | R/W |
| b6  | DIRQ14E | IRQ14-DS Pin Enable | 0: Release from deep software standby mode by the IRQ14-DS pin is disabled<br>1: Release from deep software standby mode by the IRQ14-DS pin is enabled | R/W |
| b7  | DIRQ15E | IRQ15-DS Pin Enable | 0: Release from deep software standby mode by the IRQ15-DS pin is disabled<br>1: Release from deep software standby mode by the IRQ15-DS pin is enabled | R/W |

The DPSIER1 register is not initialized by the internal reset signal used as deep software standby mode releasing source. For details, see Table 6.2, Targets to be Initialized by Each Reset Source.

After the setting of DPSIER1 is modified, an edge may be internally generated depending on the state of the pin, resulting in DPSIFR1 being set to 1. Therefore, DPSIFR1 should be set to 0 before a transition to deep software standby mode.

### 11.2.10 Deep Standby Interrupt Enable Register 2 (DPSIER2)

Address(es): 0008 C284h

|    |    |    |       |    |    |         |         |

| b7 | b6 | b5 | b4    | b3 | b2 | b1      | b0      |
| —  | —  | —  | DNMIE | —  | —  | DLVD2IE | DLVD1IE |

Value after reset: 0 0 0 0 0 0 0 0

| Bit      | Symbol  | Bit Name                                | Description                                                                                                                                                                   | R/W   |
|----------|---------|-----------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------|
| b0       | DLVD1IE | LVD1 Deep Standby Release Signal Enable | 0: Disable release from deep software standby mode by the voltage monitoring 1 signal<br>1: Enable release from deep software standby mode by the voltage monitoring 1 signal | R/W   |
| b1       | DLVD2IE | LVD2 Deep Standby Release Signal Enable | 0: Disable release from deep software standby mode by the voltage monitoring 2 signal<br>1: Enable release from deep software standby mode by the voltage monitoring 2 signal | R/W   |
| b3, b2   | —       | Reserved                                | These bits are read as 0. The write value should be 0.                                                                                                                        | R/W   |
| b4       | DNMIE   | NMI Pin Enable                          | 0: Release from deep software standby mode by the NMI pin is disabled<br>1: Release from deep software standby mode by the NMI pin is enabled                                 | R/W*1 |
| b7 to b5 | —       | Reserved                                | These bits are read as 0. The write value should be 0.                                                                                                                        | R/W   |

Note 1. 1 can be written only once. Once 1 is written to this bit, subsequent write accesses are disabled.

The DPSIER2 register is not initialized by the internal reset signal used as deep software standby mode releasing source. For details, see Table 6.2, Targets to be Initialized by Each Reset Source.

After the setting of DPSIER2 is modified, an edge may be internally generated depending on the state of the pin, resulting in DPSIFR2 being set to 1. Therefore, DPSIFR2 should be set to 0 before a transition to deep software standby mode.

### 11.2.11 Deep Standby Interrupt Flag Register 0 (DPSIFR0)

Address(es): 0008 C286h

|                    | b7         | b6         | b5         | b4         | b3         | b2         | b1         | b0         |
|--------------------|------------|------------|------------|------------|------------|------------|------------|------------|
|                    | DIRQ7<br>F | DIRQ6<br>F | DIRQ5<br>F | DIRQ4<br>F | DIRQ3<br>F | DIRQ2<br>F | DIRQ1<br>F | DIRQ0<br>F |

| Bit | Symbol | Bit Name                              | Description                                                                                                                      | R/W      |
|-----|--------|---------------------------------------|----------------------------------------------------------------------------------------------------------------------------------|----------|
| b0  | DIRQ0F | IRQ0-DS Pin Deep Standby Release Flag | 0: Request for release is not being generated on the IRQ0-DS pin<br>1: Request for release is being generated on the IRQ0-DS pin | R(/W) *1 |
| b1  | DIRQ1F | IRQ1-DS Pin Deep Standby Release Flag | 0: Request for release is not being generated on the IRQ1-DS pin<br>1: Request for release is being generated on the IRQ1-DS pin | R(/W) *1 |
| b2  | DIRQ2F | IRQ2-DS Pin Deep Standby Release Flag | 0: Request for release is not being generated on the IRQ2-DS pin<br>1: Request for release is being generated on the IRQ2-DS pin | R(/W) *1 |
| b3  | DIRQ3F | IRQ3-DS Pin Deep Standby Release Flag | 0: Request for release is not being generated on the IRQ3-DS pin<br>1: Request for release is being generated on the IRQ3-DS pin | R(/W) *1 |
| b4  | DIRQ4F | IRQ4-DS Pin Deep Standby Release Flag | 0: Request for release is not being generated on the IRQ4-DS pin<br>1: Request for release is being generated on the IRQ4-DS pin | R(/W) *1 |
| b5  | DIRQ5F | IRQ5-DS Pin Deep Standby Release Flag | 0: Request for release is not being generated on the IRQ5-DS pin<br>1: Request for release is being generated on the IRQ5-DS pin | R(/W) *1 |
| b6  | DIRQ6F | IRQ6-DS Pin Deep Standby Release Flag | 0: Request for release is not being generated on the IRQ6-DS pin<br>1: Request for release is being generated on the IRQ6-DS pin | R(/W) *1 |
| b7  | DIRQ7F | IRQ7-DS Pin Deep Standby Release Flag | 0: Request for release is not being generated on the IRQ7-DS pin<br>1: Request for release is being generated on the IRQ7-DS pin | R(/W) *1 |

Note 1. Only 0 can be written to clear the flag.

Each flag is set to 1 when a request for release specified by the DPSIEGR0 register is generated.

Each flag may be set to 1 when a request for release is generated in any mode (not even deep software standby mode) or when the setting of the DPSIER0 register is modified. Therefore, a transition to deep software standby mode should be made after the DPSIFR0 register is set to 00h.

To set the DPSIFR0 register to 00h after modifying the DPSIER0 register, wait for at least six PCLKB cycles, read the DPSIFR0 register, and then write 0 to the DPSIFR0 register. Six or more PCLKB cycles can be secured, for example, by reading the DPSIER0 register.

The DPSIFR0 register is not initialized by the internal reset signal used as deep software standby mode releasing source. For details, see Table 6.2, Targets to be Initialized by Each Reset Source.

#### DIRQnF Flags (IRQn Deep Standby Release Flag) (n = 0 to 7)

These flags indicate that a request for release has been generated on the IRQn-DS pin.

[Setting condition]

- A request for release is generated on the IRQn-DS pin specified by the DPSIEGR0 register

[Clearing condition]

- Each bit is read as 1 and then written by 0

## 11.2.12 Deep Standby Interrupt Flag Register 1 (DPSIFR1)

Address(es): 0008 C287h

|                    | b7          | b6          | b5          | b4          | b3          | b2          | b1         | b0         |
|--------------------|-------------|-------------|-------------|-------------|-------------|-------------|------------|------------|
|                    | DIRQ1<br>5F | DIRQ1<br>4F | DIRQ1<br>3F | DIRQ1<br>2F | DIRQ11<br>F | DIRQ1<br>0F | DIRQ9<br>F | DIRQ8<br>F |
| Value after reset: | 0           | 0           | 0           | 0           | 0           | 0           | 0          | 0          |

| Bit | Symbol  | Bit Name                               | Description                                                                                                                        | R/W         |
|-----|---------|----------------------------------------|------------------------------------------------------------------------------------------------------------------------------------|-------------|
| b0  | DIRQ8F  | IRQ8-DS Pin Deep Standby Release Flag  | 0: Request for release is not being generated on the IRQ8-DS pin<br>1: Request for release is being generated on the IRQ8-DS pin   | R/(W)<br>*1 |
| b1  | DIRQ9F  | IRQ9-DS Pin Deep Standby Release Flag  | 0: Request for release is not being generated on the IRQ9-DS pin<br>1: Request for release is being generated on the IRQ9-DS pin   | R/(W)<br>*1 |
| b2  | DIRQ10F | IRQ10-DS Pin Deep Standby Release Flag | 0: Request for release is not being generated on the IRQ10-DS pin<br>1: Request for release is being generated on the IRQ10-DS pin | R/(W)<br>*1 |
| b3  | DIRQ11F | IRQ11-DS Pin Deep Standby Release Flag | 0: Request for release is not being generated on the IRQ11-DS pin<br>1: Request for release is being generated on the IRQ11-DS pin | R/(W)<br>*1 |
| b4  | DIRQ12F | IRQ12-DS Pin Deep Standby Release Flag | 0: Request for release is not being generated on the IRQ12-DS pin<br>1: Request for release is being generated on the IRQ12-DS pin | R/(W)<br>*1 |
| b5  | DIRQ13F | IRQ13-DS Pin Deep Standby Release Flag | 0: Request for release is not being generated on the IRQ13-DS pin<br>1: Request for release is being generated on the IRQ13-DS pin | R/(W)<br>*1 |
| b6  | DIRQ14F | IRQ14-DS Pin Deep Standby Release Flag | 0: Request for release is not being generated on the IRQ14-DS pin<br>1: Request for release is being generated on the IRQ14-DS pin | R/(W)<br>*1 |
| b7  | DIRQ15F | IRQ15-DS Pin Deep Standby Release Flag | 0: Request for release is not being generated on the IRQ15-DS pin<br>1: Request for release is being generated on the IRQ15-DS pin | R/(W)<br>*1 |

Note 1. Only 0 can be written to clear the flag.

Each flag is set to 1 when a request for release specified by the DPSIEGR1 register is generated.

Each flag may be set to 1 when a request for release is generated in any mode (not even deep software standby mode) or when the setting of the DPSIER1 register is modified. Therefore, a transition to deep software standby mode should be made after the DPSIFR1 register is set to 00h.

To set the DPSIFR1 register to 00h after modifying the DPSIER1 register, wait for at least six PCLKB cycles, read the DPSIFR1 register, and then write 0 to the DPSIFR1 register. Six or more PCLKB cycles can be secured, for example, by reading the DPSIER1 register.

The DPSIFR1 register is not initialized by the internal reset signal used as deep software standby mode releasing source. For details, see Table 6.2, Targets to be Initialized by Each Reset Source.

### DIRQnF Flags (IRQn Deep Standby Release Flag) (n = 8 to 15)

These flags indicate that a request for release has been generated on the IRQn-DS pin.

[Setting condition]

- A request for release is generated on the IRQn-DS pin specified by the DPSIEGR1 register

[Clearing condition]

- Each bit is read as 1 and then written by 0

### 11.2.13 Deep Standby Interrupt Flag Register 2 (DPSIFR2)

Address(es): 0008 C288h

|                    | b7 | b6 | b5 | b4    | b3 | b2 | b1      | b0      |
|--------------------|----|----|----|-------|----|----|---------|---------|
|                    | —  | —  | —  | DNMIF | —  | —  | DLVD2IF | DLVD1IF |
| Value after reset: | 0  | 0  | 0  | 0     | 0  | 0  | 0       | 0       |

| Bit      | Symbol  | Bit Name                       | Description                                                                                                                                                | R/W         |

| b1       | DLVD2IF | LVD2 Deep Standby Release Flag | 0: Request for release by the voltage monitor 2 signal is not being generated<br>1: Request for release by the voltage monitor 2 signal is being generated | R/(W)<br>*1 |
| b3, b2   | —       | Reserved                       | These bits are read as 0. The write value should be 0.                                                                                                     | R/W         |
| b4       | DNMIF   | NMI Deep Standby Release Flag  | 0: Request for release is not being generated on the NMI pin<br>1: Request for release is being generated on the NMI pin                                   | R/(W)<br>*1 |
| b7 to b5 | —       | Reserved                       | These bits are read as 0. The write value should be 0.                                                                                                     | R/W         |

Note 1. Only 0 can be written to clear the flag.

Each flag is set to 1 when a request for release specified by the DPSIEGR2 register is generated.

Each flag may be set to 1 when a request for release is generated in any mode (not even deep software standby mode) or when the setting of the DPSIER2 register is modified. Therefore, a transition to deep software standby mode should be made after the DPSIFR2 register is set to 00h.

To set the DPSIFR2 register to 00h after modifying the DPSIER2 register, wait for at least six PCLKB cycles, read the DPSIFR2 register, and then write 0 to the DPSIFR2 register. Six or more PCLKB cycles can be secured, for example, by reading the DPSIER2 register.

The DPSIFR2 register is not initialized by the internal reset signal used as deep software standby mode releasing source. For details, see Table 6.2, Targets to be Initialized by Each Reset Source.

#### DLVDmIF Flag (LVDm Deep Standby Release Flag) (m = 1 or 2)

This flag indicates that a request for release by the voltage monitor m signal has been generated.

[Setting condition]

- A request for release is generated by the voltage monitoring m signal that is selected in the DPSIEGR2 register

[Clearing condition]

- This bit is read as 1 and then written by 0

#### DNMIF Flag (NMI Deep Standby Release Flag)

This flag indicates that a request for release has been generated on the NMI pin.

[Setting condition]

- A request for release is generated on the NMI pin specified by DPSIEGR2

[Clearing condition]

- This bit is read as 1 and then written by 0

### 11.2.14 Deep Standby Interrupt Edge Register 0 (DPSIEGR0)

Address(es): 0008 C28Ah

|             |             |             |             |             |             |             |             |
|-------------|-------------|-------------|-------------|-------------|-------------|-------------|-------------|
| b7          | b6          | b5          | b4          | b3          | b2          | b1          | b0          |
| DIRQ7<br>EG | DIRQ6<br>EG | DIRQ5<br>EG | DIRQ4<br>EG | DIRQ3<br>EG | DIRQ2<br>EG | DIRQ1<br>EG | DIRQ0<br>EG |

Value after reset: 0 0 0 0 0 0 0 0

| Bit | Symbol  | Bit Name                | Description                                                                                                       | R/W |
|-----|---------|-------------------------|-------------------------------------------------------------------------------------------------------------------|-----|
| b0  | DIRQ0EG | IRQ0-DS Pin Edge Select | 0: A request for release is generated at a falling edge<br>1: A request for release is generated at a rising edge | R/W |
| b1  | DIRQ1EG | IRQ1-DS Pin Edge Select | 0: A request for release is generated at a falling edge<br>1: A request for release is generated at a rising edge | R/W |
| b2  | DIRQ2EG | IRQ2-DS Pin Edge Select | 0: A request for release is generated at a falling edge<br>1: A request for release is generated at a rising edge | R/W |
| b3  | DIRQ3EG | IRQ3-DS Pin Edge Select | 0: A request for release is generated at a falling edge<br>1: A request for release is generated at a rising edge | R/W |
| b4  | DIRQ4EG | IRQ4-DS Pin Edge Select | 0: A request for release is generated at a falling edge<br>1: A request for release is generated at a rising edge | R/W |
| b5  | DIRQ5EG | IRQ5-DS Pin Edge Select | 0: A request for release is generated at a falling edge<br>1: A request for release is generated at a rising edge | R/W |
| b6  | DIRQ6EG | IRQ6-DS Pin Edge Select | 0: A request for release is generated at a falling edge<br>1: A request for release is generated at a rising edge | R/W |
| b7  | DIRQ7EG | IRQ7-DS Pin Edge Select | 0: A request for release is generated at a falling edge<br>1: A request for release is generated at a rising edge | R/W |

The DPSIEGR0 register is not initialized by the internal reset signal that is the source for release from deep software standby mode. For details, see Table 6.2, Targets to be Initialized by Each Reset Source.

## 11.2.15 Deep Standby Interrupt Edge Register 1 (DPSIEGR1)

Address(es): 0008 C28Bh

|          |          |          |          |          |          |         |         |

| b6  | DIRQ14EG | IRQ14-DS Pin Edge Select | 0: A request for release is generated at a falling edge<br>1: A request for release is generated at a rising edge | R/W |
| b7  | DIRQ15EG | IRQ15-DS Pin Edge Select | 0: A request for release is generated at a falling edge<br>1: A request for release is generated at a rising edge | R/W |

The DPSIEGR1 register is not initialized by the internal reset signal that is the source for release from deep software standby mode. For details, see Table 6.2, Targets to be Initialized by Each Reset Source.

### 11.2.16 Deep Standby Interrupt Edge Register 2 (DPSIEGR2)

Address(es): 0008 C28Ch

| Bit      | Symbol  | Bit Name         | Description                                                                                                                                            | R/W |
|----------|---------|------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------|-----|
| b0       | DLVD1EG | LVD1 Edge Select | 0: A request for release is generated when VCC < Vdet1 (fall) is detected<br>1: A request for release is generated when VCC ≥ Vdet1 (rise) is detected | R/W |
| b1       | DLVD2EG | LVD2 Edge Select | 0: A request for release is generated when VCC < Vdet2 (fall) is detected<br>1: A request for release is generated when VCC ≥ Vdet2 (rise) is detected | R/W |
| b3, b2   | —       | Reserved         | These bits are read as 0. The write value should be 0.                                                                                                 | R/W |
| b4       | DNMIEG  | NMI Edge Select  | 0: A request for release is generated at a falling edge<br>1: A request for release is generated at a rising edge                                      | R/W |
| b7 to b5 | —       | Reserved         | These bits are read as 0. The write value should be 0.                                                                                                 | R/W |

The DPSIEGR2 register is not initialized by the internal reset signal that is the source for release from deep software standby mode. For details, see Table 6.2, Targets to be Initialized by Each Reset Source.

### 11.2.17 Deep Standby Backup Register y (DPSBKRY) (y = 0 to 31)

Address(es): 0008 C2A0h to 0008 C2BFh

x: Undefined

The DPSBKRY register is a 32-byte readable/writable register to store data during deep software standby mode. The value of this register is retained even in deep software standby mode where RAM data is not retained. DPSBKRY is not initialized, and the register value is undefined immediately after power-on.

### 11.3 Reducing Power Consumption by Switching Clock Signals

When the SCKCR.FCK[3:0], ICK[3:0], BCK[3:0], PCKA[3:0], PCKB[3:0], PCKC[3:0], and PCKD[3:0] bits are set, the clock frequency changes. The CPU, DMAC, DTC, code flash memory, and RAM operate on the operating clock specified by the ICK[3:0] bits.

Peripheral modules operate on the operating clock specified by the PCKA[3:0], PCKB[3:0], PCKC[3:0], and PCKD[3:0] bits.

The data flash memory operates on the operating clock specified by the FCK[3:0] bits.

The external bus operates on the operating clock specified by the BCK[3:0] bits. For details, see section 9, Clock Generation Circuit.

### 11.4 Module-Stop Function

The module-stop function can be set for each on-chip peripheral module.

When the MSTP<sub>m</sub>i bit ( $m = A$  to  $D$ ,  $i = 31$  to  $0$ ) in registers MSTPCRA to MSTPCRD is set to 1, the specified module stops operating and enters the module-stop state, but the CPU continues to operate independently. When the corresponding MSTP<sub>m</sub>i bit is set to 0, the module is released from the module-stop state and restarts operating at the end of the bus cycle. The internal states of modules are retained in the module-stop state.

After release from a reset, all modules except for the DMAC, DTC, RAM, and ECCRAM are placed in the module-stop state. Though read/write access cannot be made to the registers of the module that are in the module-stop state, some registers may be written to directly after the setting to the module-stop state. Therefore, care should be paid.

## 11.5 Low Power Consumption Modes

### 11.5.1 Sleep Mode

#### 11.5.1.1 Transition to Sleep Mode

When the WAIT instruction is executed while the SBYCR.SSBY bit is 0, the CPU enters sleep mode. In sleep mode, the CPU stops operating but the contents of its internal registers are retained. Other peripheral functions do not stop.

When the WDT is used, the WDT stops counting when sleep mode is entered.

Counting by the IWDT stops if a transition to sleep mode is made while the IWDT is being used in auto-start mode and the OFS0.IWDTSLCSTP bit is 1 (stopping counting by the IWDT at transitions to low-power-consumption modes). In the same way, counting by the IWDT stops if a transition to sleep mode is made while the IWDT is being used in register start mode and the SLCSTP bit in IWDCSTPR is 1.

Furthermore, counting by the IWDT continues if a transition to sleep mode is made while the IWDT is being used in auto-start mode and the OFS0.IWDTSLCSTP bit is 0 (counting by the IWDT continues through transitions to low-power-consumption modes). In the same way, counting by the IWDT continues if a transition to sleep mode is made while the IWDT is being used in register start mode and the SLCSTP bit in IWDCSTPR is 0.

To use sleep mode, make the following settings and then execute a WAIT instruction.

- (1) Clear the PSW.I bit\*<sup>1</sup> of the CPU to 0.
- (2) Set the interrupt request destination\*<sup>2</sup> to be used for recovery from sleep mode to the CPU.
- (3) Set the priority\*<sup>3</sup> of the interrupt to be used for recovery from sleep mode to a level higher than the setting of the PSW.IPL[3:0] bits\*<sup>1</sup> of the CPU.
- (4) Set the IERm.IENj bit\*<sup>3</sup> for that interrupt to 1.
- (5) For the last I/O register to which writing proceeded, read the register to confirm that the value written has been reflected.
- (6) Execute the WAIT instruction (this automatically sets the I bit\*<sup>1</sup> in the PSW of the CPU to 1).

Note 1. For details, see section 2, CPU.

Note 2. For details, see section 14.7.3, Selecting Interrupt Request Destination.

Note 3. For details, see section 14, Interrupt Controller (ICUC).

#### 11.5.1.2 Release from Sleep Mode

Release from sleep mode is initiated by a non-maskable interrupt, an interrupt, the RES# pin reset, a power-on reset, a voltage monitoring reset, or a reset caused by an IWDT underflow.

- Release triggered by an interrupt signal  
Generation of an interrupt triggers release from sleep mode and the interrupt exception processing starts. If a maskable interrupt has been masked by the CPU (the priority level\*<sup>1</sup> of the interrupt has been set to a value or lower than that of the PSW.IPL[3:0] bits\*<sup>2</sup> of the CPU), release from sleep mode does not proceed.
- Release due to a reset on the RES# pin  
When the RES# pin is driven low, the MCU enters the reset state. When the RES# pin is driven high after the reset signal is input for a predetermined time period, the CPU starts the reset exception processing.
- Release due to a power-on reset  
Release from sleep mode is initiated by a power-on reset.
- Release due to a voltage monitoring reset  
Release from sleep mode is initiated by a voltage monitoring reset from the voltage detection circuit.
- Release due to the independent watchdog timer reset  
Release from sleep mode is initiated by an internal reset generated by an IWDT underflow. However, when such conditions are set that stop IWDT counting in sleep mode (OFS0.IWDTSTRT = 0 and OFS0.IWDTSLCSTP = 1, or OFS0.IWDTSTRT = 1 and IWDCSTPR.SLCSTP = 1), the IWDT is stopped and release from sleep mode is not initiated by the independent watchdog timer reset.

Note 1. For details, see section 14, Interrupt Controller (ICUC).

Note 2. For details, see section 2, CPU.

### 11.5.1.3 Sleep Mode Return Clock Source Switching Function

To switch the clock source used on return from sleep mode, the clock used after return needs to be set by the sleep mode return clock source switching register (RSTCKCR) and the wait control register needs to be set for each clock source. When the return interrupt is generated, after oscillation settling of the oscillator specified as the return clock, the clock source is automatically switched, and then operation returns from sleep mode. At this time, the registers related to clock source switching are automatically rewritten.

For details, see section 11.2.6, Sleep Mode Return Clock Source Switching Register (RSTCKCR). For setting a waiting time for oscillation stabilization, see section 9.2.16, Main Clock Oscillator Wait Control Register (MOSCWTCR).

## 11.5.2 All-Module Clock Stop Mode

### 11.5.2.1 Transition to All-Module Clock Stop Mode

After setting the MSTPCRA.ACSE bit to 1 and placing modules controlled by MSTPCRA, MSTPCRB, MSTPCRC, and MSTPCRD registers in the module-stop state (MSTPCRA = FFFF FF[C-F]Fh, MSTPCRB = FFFF FFFFh, MSTPCRC[31:16] = FFFFh, MSTPCRD = FFFF FFFFh), executing a WAIT instruction while the SBYCR.SSBY bit is 0 stops the bus controller, I/O ports, and all modules except for the 8-bit timers\*<sup>1</sup>, POE3\*<sup>2</sup>, IWDT, power-on reset circuit, voltage detection circuit at the end of the current bus cycle, and the chip enters all-module clock stop mode\*<sup>3</sup>.

When the WDT is used, the WDT stops counting when all-module clock stop mode is entered.

Counting by the IWDT stops if a transition to all-module clock-stop mode is made while the IWDT is being used in auto-start mode and the OFS0.IWDTSLCSTP bit is 1 (stopping counting by the IWDT at transitions to low-power-consumption modes). In the same way, counting by the IWDT stops if a transition to all-module clock-stop mode is made while the IWDT is being used in register start mode and the SLCSTP bit in IWDCSTPR is 1.

Furthermore, counting by the IWDT continues if a transition to all-module clock-stop mode is made while the IWDT is being used in auto-start mode and the OFS0.IWDTSLCSTP bit is 0 (counting by the IWDT continues through transitions to low-power-consumption modes). In the same way, counting by the IWDT continues if a transition to all-module clock-stop mode is made while the IWDT is being used in register start mode and the SLCSTP bit in IWDCSTPR is 0.

To use all-module clock-stop mode, make the following settings and then execute a WAIT instruction.

- (1) Clear the PSW.I bit\*<sup>4</sup> of the CPU to 0.
- (2) Set the interrupt request destination\*<sup>5</sup> to be used for recovery from all-module clock stop mode to the CPU.
- (3) Set the priority\*<sup>6</sup> of the interrupt to be used for recovery from all-module clock stop mode to a level higher than the setting of the PSW.IPL[3:0] bits\*<sup>4</sup> of the CPU.
- (4) Set the IERm.IENj bit\*<sup>6</sup> for the interrupt to be used for recovery from all-module clock stop mode to 1.
- (5) Read the last I/O register to have been written and confirm that its value reflects the value written.
- (6) Execute a WAIT instruction (executing a WAIT instruction causes automatic setting of the PSW.I bit\*<sup>4</sup> of the CPU to 1).

Note 1. The MSTPCRA.MSTPA4 and MSTPA5 bits select operation or stop of these modules.

Note 2. When a POE3 interrupt source condition is satisfied while the setting to enable POE3 interrupts is in place, recovery from all-module clock stop mode does not proceed but the flag to indicate satisfaction of the source condition is retained. If a different source leads to recovery from all-module clock stop mode in this situation, a POE3 interrupt is generated after recovery.

Note 3. Transitions to all-module clock stop mode are not to be made in some states of DTC or DMAC operations. Before setting the MSTPCRA.MSTPA28 bit to 1, clear the DMAST.DMST bit of the DMAC and the DTCST.DTCST bit of the DTC so that the DTC and DMAC are not activated.

Note 4. For details, see section 2, CPU.

Note 5. For details, see section 14.7.3, Selecting Interrupt Request Destination.

Note 6. For details, see section 14, Interrupt Controller (ICUC).

### 11.5.2.2 Release from All-Module Clock Stop Mode

Release from all-module clock-stop mode is initiated by an external pin interrupt (the NMI or IRQ0 to IRQ15), a peripheral interrupt (8-bit timer\*<sup>1</sup>, IWDTC\*<sup>2</sup>, USB suspend/resume, voltage monitoring 1, voltage monitoring 2, or oscillator-stopped detection interrupt), a RES# pin reset, a power-on reset, a voltage monitoring reset, or an independent watchdog timer reset, and the transition to the normal program execution state proceeds via exception processing for the given interrupt or reset.

However, note that in cases where a maskable interrupt has been masked by the CPU (priority level\*<sup>3</sup> of the interrupt has been set to a value or lower than that of the PSW.IPL[3:0] bits\*<sup>4</sup> of the CPU) or a maskable interrupt has been set up as a trigger to start the DTC or DMA transfer, release from all-module clock stop mode will not proceed.

Note 1. The MSTPA4 and MSTPA5 bits of MSTPCRA select operation or stopping of these modules.

Note 2. If a condition for the independent watchdog timer to stop counting applied (OFS0.IWDTSTRT = 0 and OFS0.IWDTSLCSTP = 1, or OFS0.IWDTSTRT = 1 and IWDTCSLTPR.SLCSTP = 1) at the time of a transition to all-module clock-stop mode, using a reset from the independent watchdog timer to release the chip from all-module clock-stop mode is impossible because the independent watchdog timer is stopped.

Note 3. For details, see section 14, Interrupt Controller (ICUC).

Note 4. For details, see section 2, CPU.

### 11.5.3 Software Standby Mode

#### 11.5.3.1 Transition to Software Standby Mode

When a WAIT instruction is executed with the SBYCR.SSBY bit set to 1 and the DPSBYCR.DPSBY bit set to 0, a transition to software standby mode is made. In this mode, the CPU, on-chip peripheral functions, and the oscillator functions stop.\*<sup>1</sup> However, the contents of the CPU internal registers, RAM data, on-chip peripheral functions, and the states of the I/O ports are retained. Whether the address bus and bus control signals are placed in the high-impedance or the output state is retained can be specified by the SBYCR.OPE bit. Software standby mode allows significant reduction in power consumption because the oscillator stops in this mode. For details, see Table 11.2, Entering and Exiting Low Power Consumption Modes and Operating States in Each Mode.

Set the DMAST.DMST bit of the DMAC and the DTCST.DTCST bit of the DTC to 0 before executing the WAIT instruction.

When the WDT is used, the WDT stops counting when software standby mode is entered because the oscillator stops. Counting by the IWDT stops if a transition to software standby mode is made while the IWDT is being used in auto-start mode and the OFS0.IWDTSLCSTP bit is 1 (stopping counting by the IWDT at transitions to low-power-consumption modes). In the same way, counting by the IWDT stops if a transition to software standby mode is made while the IWDT is being used in register start mode and the SLCSTP bit in IWDTCSSTPR is 1.

Furthermore, counting by the IWDT continues if a transition to software standby mode is made while the IWDT is being used in auto-start mode and the OFS0.IWDTSLCSTP bit is 0 (counting by the IWDT continues through transitions to low-power-consumption modes). In the same way, counting by the IWDT continues if a transition to software standby mode is made while the IWDT is being used in register start mode and the SLCSTP bit in IWDTCSSTPR is 0.

When the oscillation stop detection function is enabled (OSTDCR.OSTDE = 1), software standby mode cannot be entered. To make a transition to software standby mode, execute a WAIT instruction after disabling the oscillation stop detection function (OSTDCR.OSTDE = 0).

To use software standby mode, make the following settings and then execute a WAIT instruction.

- (1) Set the PSW.I bit\*<sup>2</sup> of the CPU to 0.
- (2) Set the interrupt request destination\*<sup>3</sup> to be used for recovery from software standby mode to the CPU.
- (3) Set the priority\*<sup>4</sup> of the interrupt to be used for recovery from software standby mode to a level higher than the setting of the PSW.IPL[3:0] bits\*<sup>2</sup> of the CPU.
- (4) Set the IERm.IENj bit\*<sup>4</sup> for the interrupt to be used for recovery from software standby mode to 1.
- (5) For the last I/O register to which writing proceeded, read the register to confirm that the value written has been reflected.
- (6) Execute a WAIT instruction (executing a WAIT instruction causes automatic setting of the PSW.I bit\*<sup>2</sup> of the CPU to 1).

Note 1. When a negative voltage is continuously applied to the PGA input pins even in software standby mode, keep the VOLSR.PGAVLS bit to 0. In this case, 0.2 mA of leakage current will flow at the analog power supply.

To prevent such leakage current, be sure not to input the negative voltage to pins AN000 to AN002, AN100 to AN102, PGAVSS0, and PGAVSS1, and then, set the VOLSR.PGAVLS bit to 1.

Note 2. For details, see section 2, CPU.

Note 3. For details, see section 14.7.3, Selecting Interrupt Request Destination.

Note 4. For details, see section 14, Interrupt Controller (ICUC).

### 11.5.3.2 Release from Software Standby Mode

Release from software standby mode is initiated by an external pin interrupt (the NMI or IRQ0 to IRQ15), peripheral interrupts (the IWDT, USB suspend/resume, voltage monitoring 1, and voltage monitoring 2 interrupts), an RES# pin reset, a power-on reset, a voltage monitoring reset, or an independent watchdog timer reset.

When an interrupt initiates release from software standby, the oscillators which were stopped by the transition to software standby are restarted. After the oscillation of all these oscillators has become stable, operation returns from software standby.

#### (1) Release due to an interrupt

When an interrupt request from the NMI, IRQ0 to IRQ15, IWDT, USB suspend/resume, voltage monitoring 1, or voltage monitoring 2 interrupt is generated, each oscillator which was operating before a transition to software standby mode resumes oscillation. After the time for return from software standby has elapsed, the chip is released from software standby and starts interrupt exception processing.

The time for return after release from software standby is the oscillation stabilization waiting time plus the time required for operations by the software standby release sequencer.

$$t_{SBYi} = t_{SBYOSCWT} + t_{SBYSEQ}$$

$t_{SBYi}$  (i = MC, EX, PC, PE, PH, HO, LO): Time for return after release from software standby

$t_{SBYOSCWT}$ : Oscillation stabilization waiting time

$t_{SBYSEQ}$ : Time required for operations by the software standby release sequencer

For the oscillation stabilization waiting time to be used in calculating the time for return after release from software standby, use the greatest value of the oscillation stabilization waiting time of the oscillators which are to be started. For the oscillation stabilization waiting times of the oscillators, see section 45, Electrical Characteristics.

#### (2) Release due to a reset on the RES# pin

Clock oscillation starts when the low level is applied to the RES# pin. Clock supply for the MCU starts at the same time. Keep the level on the RES# pin low over the time required for oscillation of the clocks to become stable. Reset exception processing starts when the high level is applied to the RES# pin.

#### (3) Release due to a power-on reset

Release from software standby mode proceeds after a fall in the power-supply voltage leads to the generation of a power-on reset.

#### (4) Release due to a voltage monitoring reset

Release from software standby mode proceeds after a fall in the power-supply voltage leads to the generation of a voltage monitoring reset.

#### (5) Release due to an independent watchdog timer reset

An internal reset due to an underflow of the IWDT leads to release from software standby mode.

However, if a condition for the independent watchdog timer to stop counting applied (OFS0.IWDTSTRT = 0 and OFS0.IWDTSLCSTP = 1, or OFS0.IWDTSTRT = 1 and IWDTCSTPR.SLCSTP = 1) at the time of a transition to software standby, using a reset from the independent watchdog timer to release the chip from software standby is impossible because the independent watchdog timer is stopped.

### 11.5.3.3 Example of Software Standby Mode Application

Figure 11.2 shows an example where a transition to software standby mode is made at the falling edge of the IRQn pin, and release from software standby mode is initiated at the rising edge of the IRQn pin.

In this example, an IRQn interrupt is accepted with the IRQCRi.IRQMD[1:0] bits of the ICU set to 01b (falling edge), and then the IRQCRi.IRQMD[1:0] bits are set to 10b (rising edge). After that, the SBYCR.SSBY bit is set to 1 and the WAIT instruction is executed. Thus a transition to software standby mode is made. After that, release from software standby mode is initiated at the rising edge of the IRQn pin.

To return from software standby mode, settings of the interrupt controller (ICU) are also necessary. For details, see section 14, Interrupt Controller (ICUC).

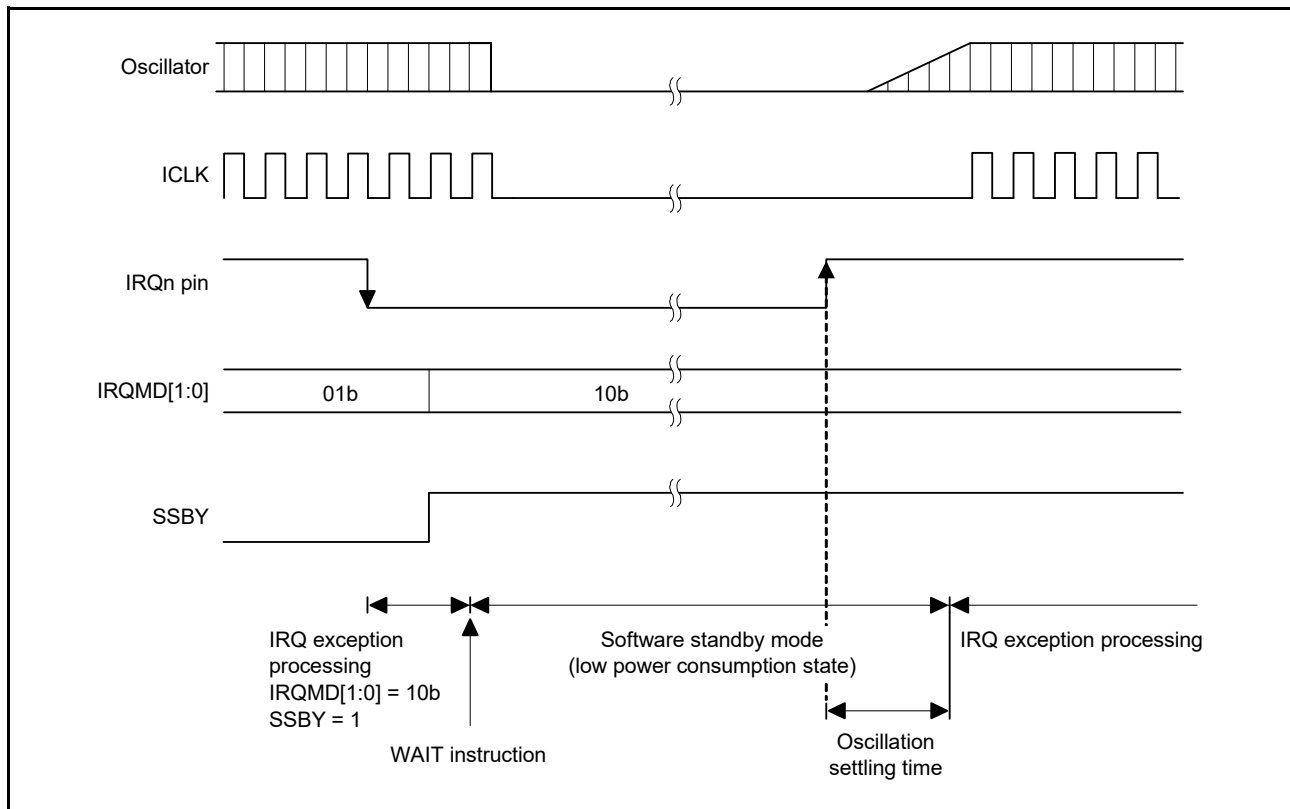

Figure 11.2 Example of Software Standby Mode Application

## 11.5.4 Deep Software Standby Mode

### 11.5.4.1 Transition to Deep Software Standby Mode

Executing a WAIT instruction while the SBYCR.SSBY bit is 1 causes a transition to software standby mode. After that, if the DPSBYCR.DPSBY bit is 1, the transition continues to deep software standby mode.\*1, \*2, \*3

On deep software standby mode, the CPU, internal peripheral modules, RAM, ECC RAM, and functions of the oscillators are stopped; furthermore, since the internal supply of power for these modules is stopped, power consumption is markedly reduced. For details, see Table 11.2, Entering and Exiting Low Power Consumption Modes and Operating States in Each Mode. At this time, the contents of all the registers of the CPU and internal peripheral modules become undefined.

When the WDT is in use, since the oscillators and power supply to the WDT are stopped by the transition to deep software standby mode, counting also stops.

Power supply to the IWDT-dedicated clock and the IWDT is stopped and counting by the IWDT stops if a transition to deep software standby mode is made while the IWDT is being used in auto-start mode and the OFS0.IWDTSLCSTP bit is 1 (stopping counting by the IWDT at transitions to low-power-consumption modes). In the same way, power supply to the IWDT-dedicated clock and the IWDT is stopped and counting by the IWDT stops if a transition to deep software standby mode is made while the IWDT is being used in register start mode and the SLCSTP bit in IWDTCSSTPR is 1. Furthermore, counting by the IWDT continues if a transition to software standby mode is made but not to deep software standby mode while the IWDT is being used in auto-start mode and the OFS0.IWDTSLCSTP bit is 0 (counting by the IWDT continues through transitions to low-power-consumption modes). In the same way, counting by the IWDT continues if a transition to software standby mode is made but not to deep software standby mode while the IWDT is being used in register start mode and the SLCSTP bit in IWDTCSSTPR is 0.

When the voltage monitoring 1 reset function (LVD1CR0.LVD1RI = 1) or voltage monitoring 2 reset function (LVD2CR0.LVD2RI = 1) is selected for the voltage detection circuit, a transition to deep software standby mode cannot be made, but to software standby.

The I/O port states remain unchanged from software standby mode.

Note 1. Conditions on the DTC, DMAC, and IWDT for transition to software standby mode should be satisfied before the WAIT instruction is executed. For details, refer to section 11.5.3, Software Standby Mode.

Note 2. Set the VOLSR.USBVON bit to 0 before executing the WAIT instruction.

Note 3. When a negative voltage (voltage lower than  $-0.3$  V) is continuously applied to the PGA input pins even in deep software standby mode, retain the VOLSR.PGAVLS bit 0. In this case, approximately 0.2 mA of leakage current flows at the analog power supply.

To prevent such leakage current, be sure not to input the negative voltage to pins AN000 to AN002, AN100 to AN102, PGAVSS0, and PGAVSS1, and then, set the VOLSR.PGAVLS bit to 1.

### 11.5.4.2 Release from Deep Software Standby Mode

Release from deep software standby mode is initiated by any of the external pin interrupt source pins (the NMI or IRQ0-DS to IRQ15-DS), peripheral interrupts (the voltage monitoring 1 and voltage monitoring 2 interrupts), an RES# pin reset, a power-on reset, or a voltage monitoring 0 reset.

(1) Release triggered by an external interrupt pin or internal interrupt signal

Release from deep software standby mode is controlled by registers DPSIER<sub>n</sub> (n = 0 to 2) and DPSIFR<sub>n</sub> (n = 0 to 2). When a deep software standby release interrupt is generated, the corresponding flag in DPSIFR<sub>n</sub> is set to 1. At this time, if the releasing source is enabled in DPSIER<sub>n</sub>, release from deep software standby mode proceeds. Rising edge or falling edge can be selected by DPSIEGR<sub>n</sub> (n = 0 to 2) registers. The interrupts for which an edge can be selected are the NMI, IRQ0-DS to IRQ15-DS, voltage monitoring 1, and voltage monitoring 2 interrupts.

When a deep software standby mode releasing source is generated, the internal power supply and LOCO clock oscillation begin, and then a deep software standby reset is generated for the entire MCU.

A stable LOCO clock is then supplied to the entire MCU, which is released from deep software standby reset. This is accompanied by release from deep software standby, and reset exception processing then starts.

When release from deep software standby is triggered by an external interrupt pin or internal interrupt signal, the RSTSR0.DPSRSTF flag is set to 1.

(2) Release due to a reset on the RES# pin

The low level being applied to the RES# pin triggers release from deep software standby.

At this time, the RES# pin should be held low according to the specifications described in section 45, Electrical Characteristics. Reset exception processing starts when the high level is applied to the RES# pin.

(3) Release due to a power-on reset

Release from deep software standby mode proceeds after a fall in the power-supply voltage leads to the generation of a power-on reset.

(4) Release due to a voltage monitoring 0 reset

Release from deep software standby mode proceeds after a fall in the power-supply voltage leads to the generation of a voltage monitoring 0 reset.

### 11.5.4.3 Pin States at the Time of Release from Deep Software Standby Mode

In deep software standby mode, the I/O ports retain the same states from software standby mode. The inside of the MCU is initialized by an internal reset generated on release from deep software standby mode. Upon release from deep software standby mode, the reset exception processing starts. The following shows the states of I/O ports at this time. Whether to initialize the I/O ports or to retain the I/O port states at the time of software standby mode can be selected by the DPSBYCR.IOKEEP bit.

- When the DPSBYCR.IOKEEP bit = 0

I/O ports are initialized by an internal reset generated on release from deep software standby mode.

- When the DPSBYCR.IOKEEP bit = 1

Although the inside of the MCU is initialized by an internal reset generated on release from deep software standby mode, I/O ports retain their states from software standby mode regardless of the MCU internal state. At this time, the I/O port states remain unchanged from software standby mode even if settings of I/O ports or peripheral modules are made. Then, the retained I/O port states are released by clearing the DPSBYCR.IOKEEP bit to 0, and the MCU operates according to the internal state.

The DPSBYCR.IOKEEP bit is not initialized by an internal reset generated on release from deep software standby mode.

#### 11.5.4.4 Example of Deep Software Standby Mode Application

Figure 11.3 shows an example where a transition to deep software standby mode is made at the falling edge of the IRQn-DS pin, and release from deep software standby mode is initiated at the rising edge of the IRQn-DS pin.

In this example, an IRQn interrupt is accepted with the IRQCRi.IRQMD[1:0] bits of the ICU set to 01b (falling edge). Then, after the DPSIEGRy.DIRQnEG (y = 0 or 1, n = 0 to 15) bit is set to 1 (rising edge) and the SBYCR.SSBY bit and DPSBYCR.DPSBY bit are both set to 1, the WAIT instruction is executed. Thus a transition to deep software standby mode is made.

After that, release from deep software standby mode is initiated at the rising edge of the IRQ-DS pin.

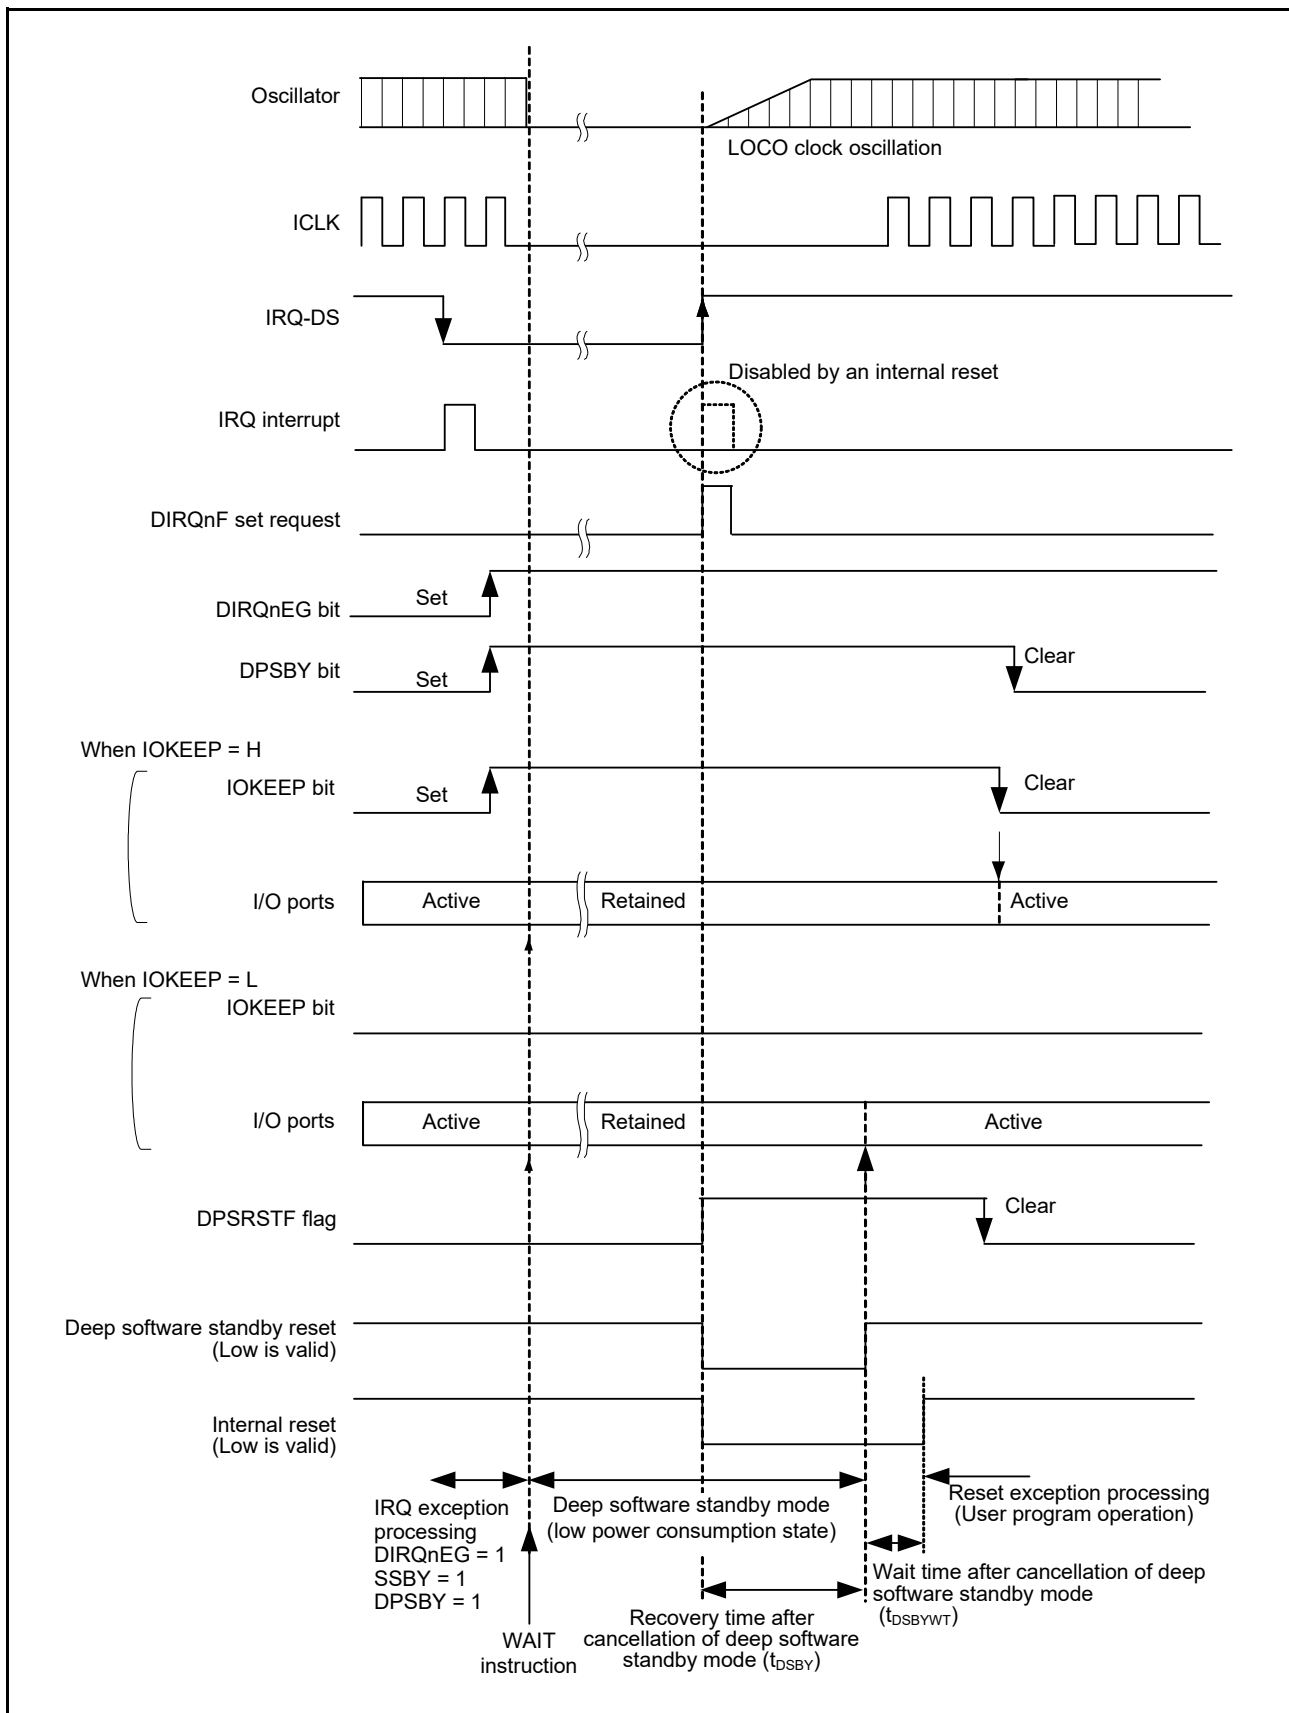

Figure 11.3 Example of Deep Software Standby Mode Application

### 11.5.4.5 Flowchart to Use Deep Software Standby Mode

Figure 11.4 shows an example of a flowchart to use deep software standby mode.

In this example, the RSTSR0.DPSRSTF flag of the reset function is read after the reset exception processing to determine whether a reset was generated by the RES# pin or by release from deep software standby mode.

In the case of a reset by the RES# pin, a transition to deep software standby mode is made after the required register settings have been made.

In the case of a reset by release from deep software standby mode, the DPSBYCR.IOKEEP bit is set to 0 after the I/O port settings have been made.

Figure 11.4 Example of Flowchart to Use Deep Software Standby Mode

## 11.6 Usage Notes

### 11.6.1 I/O Port States

I/O port states are retained in software standby mode and deep software standby mode. When enabling the input pull-up resistor, retain such enable state even during the standby mode as above.

### 11.6.2 Module-Stop State of DMAC and DTC

Before setting the MSTPCRA.MSTPA28 bit to 1, set the DMAST.DMST bit of the DMAC and the DTCST.DTCST bit of the DTC to 0 so that the DMAC and DTC are not activated.

For details, see section 17, DMA Controller (DMACa) and section 18, Data Transfer Controller (DTCa).

### 11.6.3 On-Chip Peripheral Module Interrupts

These interrupts do not operate in the module-stop state. Therefore, if the module-stop state is entered after an interrupt request is generated, a CPU interrupt source or a DMAC or DTC startup source cannot be cleared. For this reason, disable interrupts before entering the module-stop state.

### 11.6.4 Write Access to MSTPCRA, MSTPCRB, MSTPCRC, and MSTPCRD

Write accesses to registers MSTPCRA, MSTPCRB, MSTPCRC and MSTPCRD should be made only by the CPU.

### 11.6.5 Input Buffer Control by DIRQnE Bit (n = 0 to 15)

Setting the DPSIERy.DIRQnE (y = 0 or 1, n = 0 to 15) bit to 1 enables the input buffer of the IRQ0-DS to IRQ15-DS pins. Therefore, note that, although inputs to these pins are sent to the DPSIFRy.DIRQnF (y = 0 or 1, n = 0 to 15) bits, they are not sent to the interrupt controller, peripheral modules, and I/O ports.

### 11.6.6 Timing of WAIT Instruction

A WAIT instruction that follows register writing may be executed before the writing is completed. Accordingly, the WAIT instruction may be executed before the change to the setting of an I/O register is reflected, in which case operation may not be as intended. To avoid this, always execute the WAIT instruction after confirming that the last writing to the register has completed.

### 11.6.7 Rewriting the Register by DMAC and DTC in Sleep Mode

The WDT stops in sleep mode. Do not set up the DMAC and DTC to rewrite any registers related to the WDT while the chip is in sleep mode.

According to the settings of the OFS0.IWDTSLCSTP bit and IWDTCSSTPR.SLCSTP bit, the IWDT may also stop in sleep mode. If that is the case, do not set up the DMAC and DTC to rewrite any registers related to the IWDT in sleep mode.

The RSTCKCR register can be set so that the clock source is switched on recovery from sleep mode. For this reason, rewriting the register while the chip is in sleep mode may lead to unintended operation, so do not allow rewriting of the RSTCKCR register in sleep mode.

## 12. Register Write Protection Function

The register write protection function protects important registers from being overwritten for in case a program runs out of control. The registers to be protected are set with the protect register (PRCR).

Table 12.1 lists the association between the PRCR bits and the registers to be protected.

**Table 12.1 Association between PRCR Bits and Registers to be Protected**

| PRCR Bit | Register to be Protected                                                                                                                                                                                                                                                                                                                                                                                                               |
|----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

## 12.1 Register Descriptions

### 12.1.1 Protect Register (PRCR)

Address(es): 0008 03FEh

| Bit       | Symbol     | Bit Name      | Description                                                                                                                                                                                                                | R/W     |
|-----------|------------|---------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------|
| b0        | PRC0       | Protect Bit 0 | Enables writing to the registers related to the clock generation circuit.<br>0: Write disabled<br>1: Write enabled                                                                                                         | R/W     |
| b1        | PRC1       | Protect Bit 1 | Enables writing to the registers related to operating modes, clock generation circuit, low power consumption, and software reset.<br>0: Write disabled<br>1: Write enabled                                                 | R/W     |
| b2        | —          | Reserved      | This bit is read as 0. The write value should be 0.                                                                                                                                                                        | R/W     |
| b3        | PRC3       | Protect Bit 3 | Enables writing to the registers related to the LVD.<br>0: Write disabled<br>1: Write enabled                                                                                                                              | R/W     |
| b7 to b4  | —          | Reserved      | These bits are read as 0. The write value should be 0.                                                                                                                                                                     | R/W     |
| b15 to b8 | PRKEY[7:0] | PRC Key Code  | These bits control permission and prohibition of writing to the PRCR register. To modify the PRCR register, write A5h to the eight higher-order bits and the desired value to the eight lower-order bits as a 16-bit unit. | R/(W)*1 |

Note 1. Written values are not retained. These bits are read as 00h.

#### PRCi Bits (Protect Bit i) (i = 0, 1, 3)

These bits enable or disable writing to the corresponding registers to be protected.

Setting the PRCi bits to 1 and 0 enables and disables writing to the corresponding registers to be protected, respectively.

## 13. Exception Handling

### 13.1 Exception Events

During execution of a program by the CPU, the occurrence of a certain event may cause execution of that program to be suspended and execution of another program to be started. Such kinds of events are called exception events.

The RXv3 CPU supports eight types of exceptions. The types of exception events are shown in Figure 13.1.

The occurrence of an exception causes the processor mode to shift to supervisor mode.

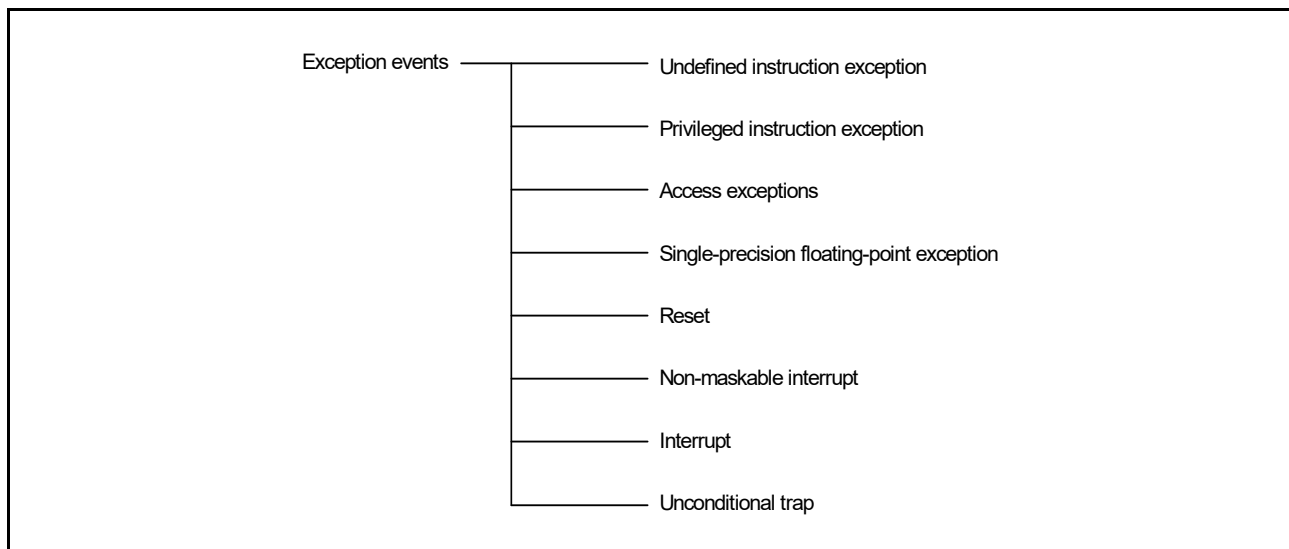

Figure 13.1 Types of Exception Events

### 13.1.1 Undefined Instruction Exception

An undefined instruction exception occurs when execution of an undefined instruction (an instruction not implemented) is detected.

### 13.1.2 Privileged Instruction Exception

A privileged instruction exception occurs when execution of a privileged instruction is detected in user mode. Privileged instructions can be executed only in supervisor mode.

### 13.1.3 Access Exceptions

An access exception occurs when an error is detected in access to memory by the CPU. If the memory-protection unit detects an instruction memory-protection error, an instruction-access exception occurs, and if the unit detects a data memory protection error, an operand-access exception occurs.

### 13.1.4 Single-Precision Floating-Point Exception

Single-precision floating-point exceptions are generated when any of the five exceptions specified in the IEEE 754 standard, namely overflow, underflow, inexact, division-by-zero, or invalid operation, or an attempt to use processing that is not implemented, is detected upon execution of a single-precision floating-point operation instruction. Exception handling by the CPU only proceeds when any among the EX, EU, EZ, EO, or EV bits in the FPSW, which corresponding to the five types of exception, is set to 1.

### 13.1.5 Reset

A reset is generated by input of a reset signal to the CPU. This has the highest priority of any exception and is always accepted.

### 13.1.6 Non-Maskable Interrupt

The non-maskable interrupt is generated by input of a non-maskable interrupt signal to the CPU and is only used when a fatal fault is considered to have occurred in the system. Never use the non-maskable interrupt with an attempt to return to the program that was being executed at the time of interrupt generation after the exception handling routine is ended.

### 13.1.7 Interrupt

Interrupts are generated by the input of interrupt signals to the CPU. A fast interrupt can be selected as the interrupt with the highest priority. In the case of the fast interrupt, hardware pre-processing and hardware post-processing are handled fast. The priority level of the fast interrupt is 15 (the highest). The exception handling of interrupts is masked when the I bit in PSW is 0.

### 13.1.8 Unconditional Trap

An unconditional trap is generated when the INT or BRK instruction is executed.

### 13.2 Exception Handling Procedure

In the exception handling, part of the processing is handled automatically by hardware and part of it is handled by a program (exception handling routine) that has been written by the user. Figure 13.2 shows the processing procedure when an exception other than a reset is accepted.

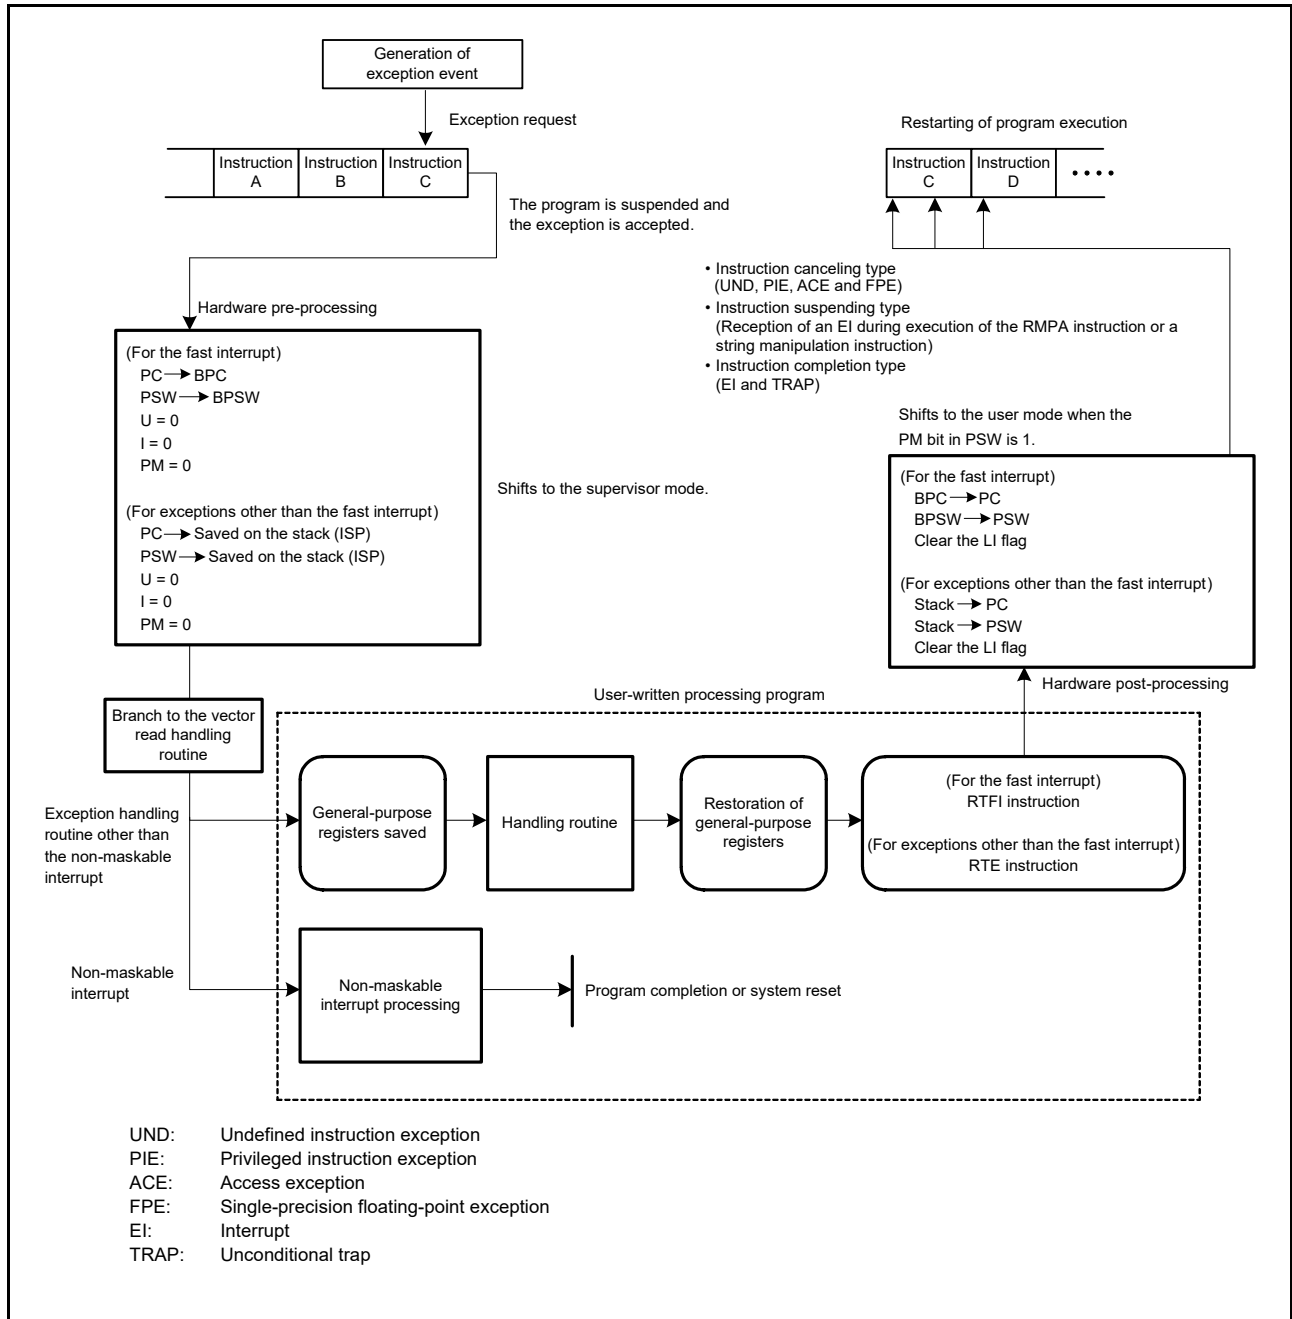

Figure 13.2 Outline of Exception Handling Procedure

When an exception is accepted, hardware processing by the RXv3 CPU is followed by access to the vector to acquire the address of the branch destination. In the vector, a vector address is allocated to each exception, and the branch destination address of the exception handling routine is written to each vector address.

Hardware pre-processing by the RXv3 CPU handles saving of the values of the program counter (PC) and processor status word (PSW). In the case of the fast interrupt, the values of the PC and PSW are saved in the backup PC (BPC) and the backup PSW (BPSW), respectively. In the case of exceptions other than the fast interrupt, the contents are saved on the stack. The values of general purpose registers and control registers other than the PC and PSW that are to be used within an exception handling routine must be saved by the user program at the start of the exception handling routine. On completion of processing by an exception handling routine, saved registers are restored and the RTE instruction is executed to restore execution from the exception handling routine to the original program. For return from a fast interrupt, the RTFI instruction is used instead. In the case of a non-maskable interrupt, however, finish the program or reset the system without returning to the original program.

Hardware post-processing by the RXv3 CPU handles restoration of the contents of the PC and PSW. In the case of the fast interrupt, the values of the BPC and BPSW are restored to the PC and PSW, respectively. In the case of other exceptions, the values are restored from the stack to the PC and PSW.

The stack can be used to save and restore the general-purpose and other registers at the start and end of an exception handling routine. Use the PUSH and POP instructions for saving to and restoring from the stack.

### 13.3 Acceptance of Exception Events

When an exception occurs, the CPU suspends the execution of the program and processing branches to the exception handling routine.

#### 13.3.1 Acceptance Timing and Saved PC Value

Table 13.1 lists the timing of acceptance and the program counter (PC) value to be saved for each exception event.

**Table 13.1 Acceptance Timing and Saved PC Value**

| Exception Event                           | Type of Handling                                                                                | Acceptance Timing                      | Value Saved in BPC or on the Stack                       |                                            |
|-------------------------------------------|-------------------------------------------------------------------------------------------------|----------------------------------------|----------------------------------------------------------|--------------------------------------------|
| Undefined instruction exception           | Instruction canceling type                                                                      | During instruction execution           | PC value of the instruction that generated the exception |                                            |
| Privileged instruction exception          | Instruction canceling type                                                                      | During instruction execution           | PC value of the instruction that generated the exception |                                            |
| Access exception                          | Instruction canceling type                                                                      | During instruction execution           | PC value of the instruction that generated the exception |                                            |
| Single-precision floating-point exception | Instruction canceling type                                                                      | During instruction execution           | PC value of the instruction that generated the exception |                                            |
| Reset                                     | Instruction abandonment type                                                                    | Any machine cycle                      | None                                                     |                                            |
| Non-maskable interrupt                    | During execution of the RMPA, SCMPU, SMOVB, SMOVF, SMOVU, SSTR, SUNTIL, and SWHILE instructions | Instruction suspending type            | During instruction execution                             | PC value of the instruction being executed |
|                                           | Other than above                                                                                | Instruction completion type            | At the next break between instructions                   | PC value of the next instruction           |
| Interrupt                                 | During execution of the RMPA, SCMPU, SMOVB, SMOVF, SMOVU, SSTR, SUNTIL, and SWHILE instructions | Instruction suspending type            | During instruction execution                             | PC value of the instruction being executed |
|                                           | Other than above                                                                                | Instruction completion type            | At the next break between instructions                   | PC value of the next instruction           |
| Unconditional trap                        | Instruction completion type                                                                     | At the next break between instructions | PC value of the next instruction                         |                                            |

### 13.3.2 Vector and Site for Saving the Values in the PC and PSW

The vector for each type of exception and the site for saving the values of the program counter (PC) and processor status word (PSW) are listed in Table 13.2. The addresses where the exception vector table and interrupt vector table start must be set. For details, see section 2.6, Vector Table.

**Table 13.2 Vector and Site for Saving the Values in the PC and PSW**

| Exception                                 |                  | Vector                        | Site for Saving the Values in the PC and PSW |
|-------------------------------------------|------------------|-------------------------------|----------------------------------------------|
| Undefined instruction exception           |                  | Exception vector table (EXTB) | Stack                                        |
| Privileged instruction exception          |                  | Exception vector table (EXTB) | Stack                                        |
| Access exception                          |                  | Exception vector table (EXTB) | Stack                                        |
| Single-precision floating-point exception |                  | Exception vector table (EXTB) | Stack                                        |
| Reset                                     |                  | Exception vector table (EXTB) | Nowhere                                      |
| Non-maskable interrupt                    |                  | Exception vector table (EXTB) | Stack                                        |
| Interrupt                                 | Fast interrupt   | FINTV                         | BPC and BPSW                                 |
|                                           | Other than above | Interrupt vector table (INTB) | Stack                                        |
| Unconditional trap                        |                  | Interrupt vector table (INTB) | Stack                                        |

## 13.4 Hardware Processing for Accepting and Returning from Exceptions

This section describes the hardware processing for accepting and returning from exceptions other than a reset.

### (1) Hardware Pre-Processing for Accepting an Exception

#### (a) Saving PSW

- For a fast interrupt  
PSW → BPSW
- For exceptions other than a fast interrupt  
PSW → Stack

**Note:** The FPSW is not saved by the hardware pre-processing. If single-precision floating-point operation instructions are used within an exception-handling routine, the user must save the FPSW on the stack within the exception-handling routine.

#### (b) Updating PM, U, and I Bits in PSW

I: Set to 0

U: Set to 0

PM: Set to 0

#### (c) Saving PC

- For a fast interrupt  
PC → BPC
- For exceptions other than a fast interrupt  
PC → Stack

#### (d) Setting Branch Destination Address of Exception Handling Routine in PC

Processing is shifted to the exception handling routine by acquiring the vector corresponding to the exception and then branching accordingly.

### (2) Hardware Post-Processing for Execution of RTE and RTFI Instructions

#### (a) Restoring PSW

- For a fast interrupt  
BPSW → PSW
- For exceptions other than a fast interrupt  
Stack → PSW

#### (b) Restoring PC

- For a fast interrupt  
BPC → PC
- For exceptions other than a fast interrupt  
Stack → PC

#### (c) Clearing the LI flag

## 13.5 Hardware Pre-Processing

The hardware pre-processing from reception of each exception request to execution of the associated exception handling routine are explained below.

### 13.5.1 Undefined Instruction Exception

1. The value of the processor status word (PSW) is saved on the stack (ISP).
2. The processor mode select bit (PM), the stack pointer select bit (U), and the interrupt enable bit (I) in PSW are set to 0.
3. The value of the program counter (PC) is saved on the stack (ISP).
4. The vector is fetched from the value of EXTB + address 0000 005Ch.
5. The fetched vector is set to the PC and processing branches to the exception handling routine.

### 13.5.2 Privileged Instruction Exception

1. The value of the processor status word (PSW) is saved on the stack (ISP).
2. The processor mode select bit (PM), the stack pointer select bit (U), and the interrupt enable bit (I) in PSW are set to 0.
3. The value of the program counter (PC) is saved on the stack (ISP).
4. The vector is fetched from the value of EXTB + address 0000 0050h.
5. The fetched vector is set to the PC and processing branches to the exception handling routine.

### 13.5.3 Access Exceptions

1. The value of the processor status word (PSW) is saved on the stack (ISP).
2. The processor mode select bit (PM), the stack pointer select bit (U), and the interrupt enable bit (I) in PSW are set to 0.
3. The value of the program counter (PC) is saved on the stack (ISP).
4. The vector is fetched from the value of EXTB + address 0000 0054h.
5. The fetched vector is set to the PC and processing branches to the exception handling routine.

### 13.5.4 Single-Precision Floating-Point Exception

1. The value of the processor status word (PSW) is saved on the stack (ISP).
2. The processor mode select bit (PM), the stack pointer select bit (U), and the interrupt enable bit (I) in PSW are set to 0.
3. The value of the program counter (PC) is saved on the stack (ISP).
4. The vector is fetched from the value of EXTB + address 0000 0064h.
5. The fetched vector is set to the PC and processing branches to the exception handling routine.

### 13.5.5 Reset

1. The control registers are initialized.
2. The vector is fetched from address FFFF FFFCh.
3. The fetched vector is set to the PC.

### 13.5.6 Non-Maskable Interrupt

1. The value of the processor status word (PSW) is saved on the stack (ISP).
2. The processor mode select bit (PM), the stack pointer select bit (U), and the interrupt enable bit (I) in PSW are set to 0.
3. If the interrupt was generated during the execution of an RMPA, SCMPU, SMOVB, SMOVF, SMOVU, SSTR, SUNTIL, or SWHILE instruction, the value of the program counter (PC) for that instruction is saved on the stack (ISP). For other instructions, the PC value of the next instruction is saved.
4. The processor interrupt priority level bits (IPL[3:0]) in PSW are set to Fh.
5. The vector is fetched from the value of EXTB + address 0000 0078h.
6. The fetched vector is set to the PC and processing branches to the exception handling routine.

### 13.5.7 Interrupt

1. The value of the processor status word (PSW) is saved on the stack (ISP) or, for the fast interrupt, in the backup PSW (BPSW).
2. The processor mode select bit (PM), the stack pointer select bit (U), and the interrupt enable bit (I) in PSW are set to 0.
3. If the interrupt was generated during the execution of an RMPA, SCMPU, SMOVB, SMOVF, SMOVU, SSTR, SUNTIL, or SWHILE instruction, the value of the program counter (PC) for that instruction is saved. For other instructions, the PC value of the next instruction is saved. Saving of the PC is in the backup PC (BPC) for fast interrupts.
4. The processor interrupt priority level bits (IPL[3:0]) in PSW indicate the interrupt priority level of the interrupt.
5. The vector for an interrupt source other than the fast interrupt is fetched from the interrupt vector table. For the fast interrupt, the address is fetched from the fast interrupt vector register (FINTV).
6. The fetched vector is set to the PC and processing branches to the exception handling routine.

### 13.5.8 Unconditional Trap

1. The value of the processor status word (PSW) is saved on the stack (ISP).
2. The processor mode select bit (PM), the stack pointer select bit (U), and the interrupt enable bit (I) in PSW are set to 0.
3. The value of the program counter (PC) for the next instruction is saved on the stack (ISP).
4. For the INT instruction, the value at the vector corresponding to the INT instruction number is fetched from the interrupt vector table.  
For the BRK instruction, the value at the vector from the start address is fetched from the interrupt vector table.
5. The fetched vector is set to the PC and processing branches to the exception handling routine.

## 13.6 Return from Exception Handling Routine

Executing the instruction listed in Table 13.3 at the end of the corresponding exception handling routine leads to restoration of the values of the program counter (PC) and processor status word (PSW) that were saved on the stack or in the control registers (BPC and BPSW) immediately before the exception handling sequence.

**Table 13.3 Return from Exception Handling Routine**

| Exception                                 | Instruction for Return |      |
|-------------------------------------------|------------------------|------|
| Undefined instruction exception           | RTE                    |      |
| Privileged instruction exception          | RTE                    |      |
| Access exception                          | RTE                    |      |
| Single-precision floating-point exception | RTE                    |      |
| Reset                                     | Return is impossible   |      |
| Non-maskable interrupt                    | Prohibited             |      |
| Interrupt                                 | Fast interrupt         | RTFI |
|                                           | Other than above       | RTE  |
| Unconditional trap                        | RTE                    |      |

## 13.7 Priority of Exception Events

The priority of exception events is listed in Table 13.4. When multiple exceptions are generated at the same time, the exception with the highest priority is accepted first.

**Table 13.4 Priority of Exception Events**

| Priority                                                                                           | Exception Event                                                       |
|----------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------|
| High<br><br>Low | 1 Reset                                                               |
|                                                                                                    | 2 Non-maskable interrupt                                              |
|                                                                                                    | 3 Interrupt                                                           |
|                                                                                                    | 4 Instruction access exception                                        |
|                                                                                                    | 5 Undefined instruction exception<br>Privileged instruction exception |
|                                                                                                    | 6 Unconditional trap                                                  |
|                                                                                                    | 7 Operand access exception                                            |
|                                                                                                    | 8 Single-precision floating-point exception                           |

## 14. Interrupt Controller (ICUC)

### 14.1 Overview

The interrupt controller (ICU) controls various interrupt requests from the peripheral modules and the IRQ<sub>i</sub> pin (i = 0 to 15), and generates an interrupt request to the CPU and a transfer request to the DTC and DMAC.

Table 14.1 lists the ICU specifications, and Figure 14.1 shows a block diagram of the interrupt controller.

**Table 14.1 ICU Specifications**

| Item                                     |                                           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|------------------------------------------|-------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

|                                          | Deep software standby mode                | <ul style="list-style-type: none"> <li>Exit deep software standby mode by the NMI pin interrupt, specific external pin interrupt, or peripheral interrupt (voltage monitoring 1, voltage monitoring 2).</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

- Note 1. Groups to which no interrupt source is assigned are reserved. Also, there is no register corresponding to that group.
- Note 2. For the DTC and DMAC triggers, refer to Table 14.4, Interrupt Vector Table.
- Note 3. Once non-maskable interrupts are enabled, they cannot be disabled.
- Note 4. Each source for these non-maskable interrupts can be used for maskable interrupts. When using for maskable interrupts, do not change the NMIER register value from the value after reset. To enable the voltage monitoring 1 interrupt, set the LVD1CR1.LVD1IRQSEL bit to 1, and to enable the voltage monitoring 2 interrupt, set the LVD2CR1.LVD2IRQSEL bit to 1.

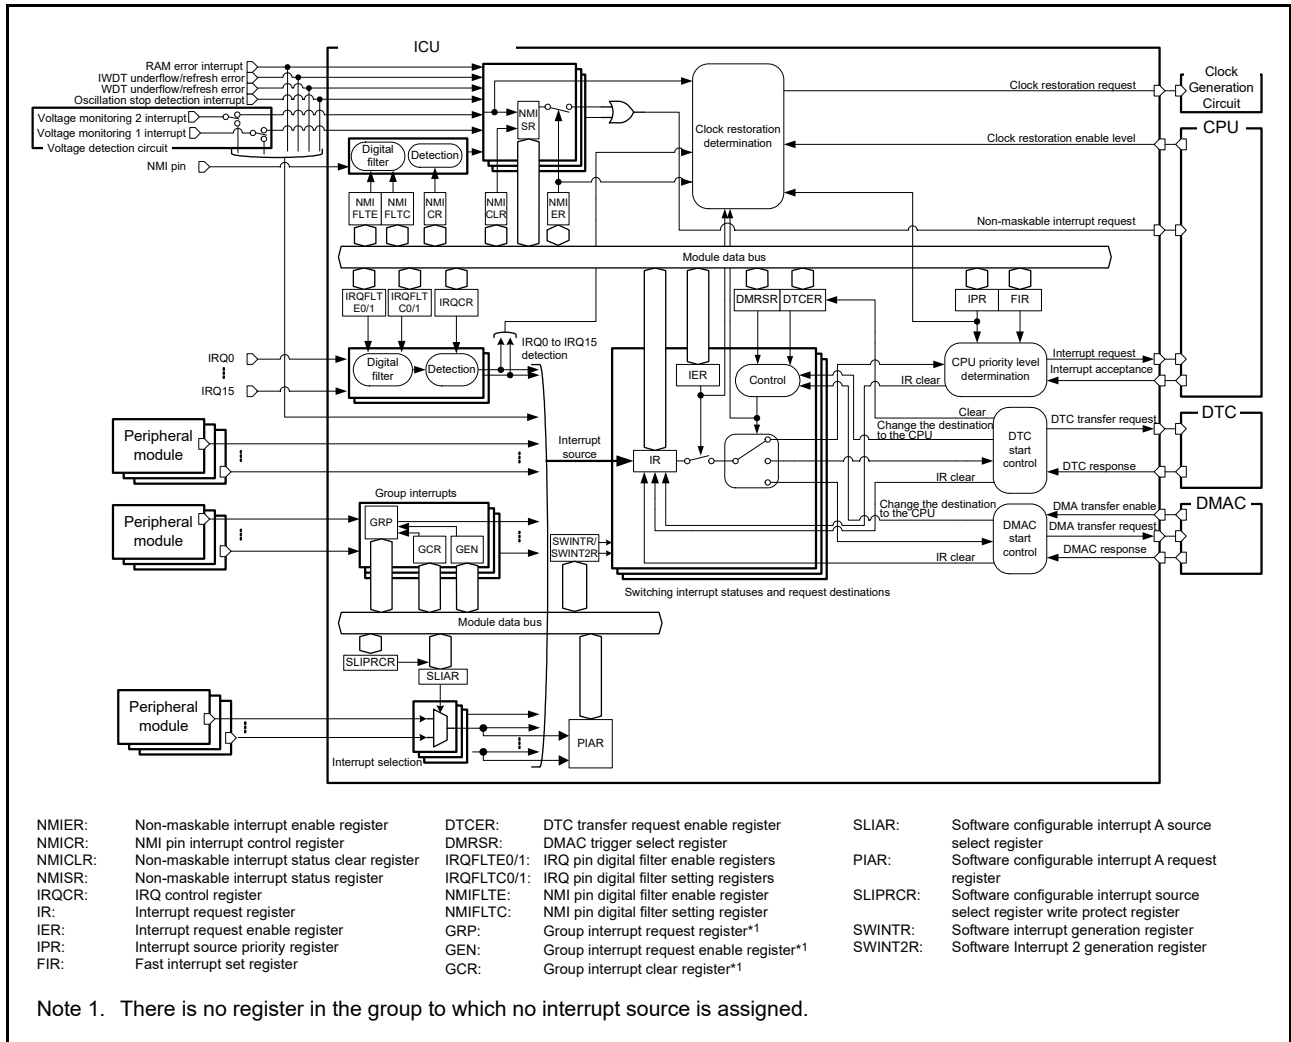

Figure 14.1 Block Diagram of the ICUC

Table 14.2 lists I/O pins used for the ICUC.

Table 14.2 ICUC I/O Pins

| Pin Name      | I/O   | Description                        |
|---------------|-------|------------------------------------|
| NMI           | Input | Non-maskable interrupt request pin |
| IRQ0 to IRQ15 | Input | External interrupt request pins    |

## 14.2 Register Descriptions

### 14.2.1 Interrupt Request Register n (IRn) (n = 016 to 255)

Address(es): ICU.IR016 0008 7010h to ICU.IR255 0008 70FFh

| Bit      | Symbol | Bit Name              | Description                                                                    | R/W         |
|----------|--------|-----------------------|--------------------------------------------------------------------------------|-------------|
| b0       | IR     | Interrupt Status Flag | 0: No interrupt request is generated.<br>1: An interrupt request is generated. | R/(W)<br>*1 |
| b7 to b1 | —      | Reserved              | The read value is 0. The write value should be 0.                              | R/W         |

Note 1. For an edge detection interrupt source, only 0 can be written to this bit; do not write 1.  
For a level detection interrupt source, neither 0 nor 1 can be written.

The IRn register indicates whether an interrupt request has been generated.

This register is provided for each interrupt vector number, and n matches the interrupt vector number.

For the correspondence between interrupt sources and interrupt vector numbers, refer to Table 14.4, Interrupt Vector Table.

#### IR Flag (Interrupt Status Flag)

The IR flag is a status flag indicating whether an interrupt request has been generated. This flag becomes 1 when an interrupt request is generated. To detect an interrupt request, set the interrupt enable bit of the peripheral module to enable output of the interrupt request.

An interrupt request can be detected by edge detection or level detection. For interrupts from peripheral modules, the detection method (edge detection or level detection) is determined depending on the source. Refer to Table 14.4, Interrupt Vector Table for details on the detection method for each source. For interrupts from the IRQi pin (i = 0 to 15), edge detection or level detection can be selected by setting the IRQCRi.IRQMD[1:0] bits.

The interrupt status flag for group interrupts is the ISj flag (j = 0 to 31) in the group interrupt request register (GRPBE0, GRPBL0, GRPBL1, GRPAL0). When any of the ISj flags becomes 1, the IRn.IR flag corresponding to each group interrupt becomes 1. Group interrupts are detected by level detection.

Refer to section 14.4.4, Group Interrupts for details on group interrupts.

### (1) Edge detection

This flag becomes 1 under the following condition:

- The IR flag becomes 1 when an interrupt request for peripheral interrupts or external pin interrupts is generated. For interrupt requests for peripheral modules, refer to the corresponding sections.

This flag becomes 0 under any of the following conditions:

- The IR flag becomes 0 when the interrupt request destination accepts an interrupt request.
- The IR flag becomes 0 by writing 0 to the IR flag. Note that when the interrupt request destination is the DTC or DMAC, do not write 0 to the IR flag.

### (2) Level detection

This flag becomes 1 under any of the following conditions:

- The IR flag is 1 while an interrupt request for peripheral interrupts or external pin interrupts is generated. For interrupt requests for peripheral modules, refer to the corresponding sections.
- For group interrupts, the IR flag becomes 1 when the IS<sub>j</sub> flag in the group interrupt request register (GRPBE0, GRPBL0, GRPBL1, GRPAL0) is 1 (interrupt request is generated) while the EN<sub>j</sub> bit in the group interrupt request enable register (GENBE0, GENBL0, GENBL1, GENAL0) is 1 (enabled) (j = 0 to 31).

This flag becomes 0 under any of the following conditions:

- The IR flag becomes 0 by clearing output of the peripheral module interrupt request. The IR flag does not become 0 when the interrupt request destination accepts the interrupt request. For interrupt requests for peripheral modules, refer to the corresponding sections.
- For group interrupts, the IR flag becomes 0 when the EN<sub>j</sub> bit in the group interrupt request enable register is 0 (disabled) or when the IS<sub>j</sub> flag in the group interrupt request register is 0 (interrupt request is not generated).

When level detection is selected for detecting external pin interrupts, set the input level of the IRQ<sub>i</sub> pin to high (i = 0 to 15) to cancel the external pin interrupt that has occurred. When level detection is selected, do not write to the IR flag.

## 14.2.2 Interrupt Request Enable Register m (IERm) (m = 02h to 1Fh)

Address(es): ICU.IER02 0008 7202h to ICU.IER1F 0008 721Fh

| Bit | Symbol | Bit Name                   | Description                                                           | R/W |
|-----|--------|----------------------------|-----------------------------------------------------------------------|-----|
| b0  | IEN0   | Interrupt Request Enable 0 | 0: Interrupt request is disabled.<br>1: Interrupt request is enabled. | R/W |
| b1  | IEN1   | Interrupt Request Enable 1 |                                                                       | R/W |
| b2  | IEN2   | Interrupt Request Enable 2 |                                                                       | R/W |
| b3  | IEN3   | Interrupt Request Enable 3 |                                                                       | R/W |
| b4  | IEN4   | Interrupt Request Enable 4 |                                                                       | R/W |
| b5  | IEN5   | Interrupt Request Enable 5 |                                                                       | R/W |
| b6  | IEN6   | Interrupt Request Enable 6 |                                                                       | R/W |
| b7  | IEN7   | Interrupt Request Enable 7 |                                                                       | R/W |

Note: When the interrupt source of the interrupt vector number is reserved, set the corresponding bit to 0. The read value is 0.

The IERm register enables or disables output of the interrupt request to the interrupt request destination.

### IENj Bit (Interrupt Request Enable j) (j = 0 to 7)

When the IENj bit is 1, an interrupt request is output to the destination. When the IENj bit is 0, an interrupt request is not output to the destination.

The IRn.IR flag (n = 016 to 255) is not affected by the IENj bit setting. Even when the IENj bit is 0, the IR flag changes according to the conditions described in section 14.2.1, Interrupt Request Register n (IRn) (n = 016 to 255).

The IERm.IENj bit is provided for each interrupt vector number.

Refer to Table 14.4, Interrupt Vector Table for the correspondence between interrupt sources and the IERm.IENj bit.

Note that m and j can be calculated by the following formula:

$m = \text{quotient when } n \text{ divided by } 8$

$j = \text{remainder when } n \text{ divided by } 8$

Refer to section 14.7.3.1, Interrupt Request Destination Setting Procedure for the procedure to set the IERm.IENj bit to select the interrupt request destination.

### 14.2.3 Interrupt Source Priority Register r (IPRr) (r = 000 to 255)

Address(es): ICU.IPR000 0008 7300h to ICU.IPR255 0008 73FFh

| Bit      | Symbol   | Bit Name                        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            | R/W |    |  |       |   |                                 |       |   |         |       |   |         |       |   |         |       |   |         |       |   |         |       |   |         |       |   |         |       |   |         |       |   |         |       |   |          |       |   |          |       |   |          |       |   |          |       |   |          |       |   |                    |     |

| 1 1 0    | 1        | Level 13                        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |     |    |  |       |   |                                 |       |   |         |       |   |         |       |   |         |       |   |         |       |   |         |       |   |         |       |   |         |       |   |         |       |   |         |       |   |          |       |   |          |       |   |          |       |   |          |       |   |          |       |   |                    |     |
| 1 1 1    | 0        | Level 14                        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |     |    |  |       |   |                                 |       |   |         |       |   |         |       |   |         |       |   |         |       |   |         |       |   |         |       |   |         |       |   |         |       |   |         |       |   |          |       |   |          |       |   |          |       |   |          |       |   |          |       |   |                    |     |
| 1 1 1    | 1        | Level 15 (highest)              |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |     |    |  |       |   |                                 |       |   |         |       |   |         |       |   |         |       |   |         |       |   |         |       |   |         |       |   |         |       |   |         |       |   |         |       |   |          |       |   |          |       |   |          |       |   |          |       |   |          |       |   |                    |     |
| b7 to b4 | —        | Reserved                        | The read value is 0. The write value should be 0.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      | R/W |    |  |       |   |                                 |       |   |         |       |   |         |       |   |         |       |   |         |       |   |         |       |   |         |       |   |         |       |   |         |       |   |         |       |   |          |       |   |          |       |   |          |       |   |          |       |   |          |       |   |                    |     |

Note 1. For an interrupt source of a fast interrupt, even when the IPR[3:0] bits are set to level 0, the priority level is level 15.

The IPRr register sets the interrupt priority level of an interrupt source that is assigned to the corresponding interrupt vector number.

#### IPR[3:0] Bits (Interrupt Priority Level Select)

The IPR[3:0] bits select the interrupt priority level of the corresponding interrupt source.

The priority level selected by the IPR[3:0] bits is used for only determining the priority level of interrupt requests to the CPU. It does not affect transfer requests to the DTC and DMAC.

The CPU accepts only interrupt requests that have the higher priority level than the processor interrupt priority level indicated by the PSW.IPL[3:0] bits.

When multiple interrupt requests are concurrently generated, the priority levels selected by the corresponding IPR[3:0] bits are compared. When multiple interrupt requests that have the same priority level are concurrently generated, the interrupt request that has the smallest interrupt vector number has priority.

Write to this register while the corresponding IERm.IENj bit is 0 (interrupt request is disabled) (m = 02h to 1Fh; j = 0 to 7).

Refer to Table 14.4, Interrupt Vector Table for the correspondence between interrupt vectors and the IPRr register.

Note that r matches the vector number when the interrupt vector number is 32 or greater.

## 14.2.4 Fast Interrupt Set Register (FIR)

Address(es): ICU.FIR 0008 72F0h

| Bit       | Symbol    | Bit Name                     | Description                                                                        | R/W |
|-----------|-----------|------------------------------|------------------------------------------------------------------------------------|-----|
| b7 to b0  | FVCT[7:0] | Fast Interrupt Vector Number | Set the vector number of an interrupt source that is assigned to a fast interrupt. | R/W |
| b14 to b8 | —         | Reserved                     | The read value is 0. The write value should be 0.                                  | R/W |
| b15       | FIEN      | Fast Interrupt Enable        | 0: Fast interrupt is disabled<br>1: Fast interrupt is enabled                      | R/W |

The FIR register sets an interrupt source that is handled as the fast interrupt.

The fast interrupt is enabled only when the destination is the CPU. When the destination is the DTC or DMAC, the DTC or DMA transfer request is not affected by setting the interrupt vector number as the fast interrupt.

Write to this register while the corresponding IERm.IENj bit is 0 (m = 02h to 1Fh; j = 0 to 7).

Refer to section 14.9, Fast interrupt for details on the fast interrupt.

### FVCT[7:0] Bits (Fast Interrupt Vector Number)

The FVCT[7:0] bits set the interrupt vector number of an interrupt source for the fast interrupt.

Refer to Table 14.4, Interrupt Vector Table for interrupt vector numbers that can be set in the FVCT[7:0] bits. Do not set an interrupt vector number that is reserved.

### FIEN Bit (Fast Interrupt Enable)

The FIEN bit enables the fast interrupt to be used.

When the FIEN bit is 1, the interrupt source that is assigned to the interrupt vector number set by the FVCT[7:0] bits is handled as the fast interrupt.

When an interrupt request of the interrupt vector number set by the FVCT[7:0] bits is generated to the CPU while the FIEN bit is 1, an interrupt request is output to the CPU as the fast interrupt regardless of the IPRr register setting (r = 000 to 255). Note that the IPRr register setting is required when using the fast interrupt to exit software standby mode. Refer to section 14.10.3, Exiting Software Standby Mode for details.

### 14.2.5 Software Interrupt Generation Register (SWINTR)

Address(es): ICU.SWINTR 0008 72E0h

| Bit      | Symbol | Bit Name                      | Description                                                                                                                      | R/W |
|----------|--------|-------------------------------|----------------------------------------------------------------------------------------------------------------------------------|-----|
| b0       | SWINT  | Software Interrupt Generation | The read value is 0. When writing 1 to this bit, a software interrupt request is generated. Writing 0 to this bit has no effect. | R/W |
| b7 to b1 | —      | Reserved                      | The read value is 0. The write value should be 0.                                                                                | R/W |

The SWINTR register controls generation of a software interrupt request.

#### SWINT Bit (Software Interrupt Generation)

When the SWINT bit is set to 1, a software interrupt request (SWINT) is generated, and the IR027.IR flag becomes 1. A software interrupt request (SWINT) can be set as a DTC trigger, but it cannot be set as a DMAC trigger.

### 14.2.6 Software Interrupt 2 Generation Register (SWINT2R)

Address(es): ICU.SWINT2R 0008 72E1h

| Bit      | Symbol | Bit Name                        | Description                                                                                                                        | R/W |
|----------|--------|---------------------------------|------------------------------------------------------------------------------------------------------------------------------------|-----|
| b0       | SWINT2 | Software Interrupt 2 Generation | The read value is 0. When writing 1 to this bit, a software interrupt request 2 is generated. Writing 0 to this bit has no effect. | R/W |
| b7 to b1 | —      | Reserved                        | The read value is 0. The write value should be 0.                                                                                  | R/W |

The SWINT2R register controls generation of software interrupt request 2.

#### SWINT2 Bit (Software Interrupt 2 Generation)

When the SWINT2 bit is set to 1, software interrupt request 2 (SWINT2) is generated, and the IR026.IR flag becomes 1. Software interrupt request 2 (SWINT2) can be set as the DTC trigger, but it cannot be set as the DMAC trigger.

### 14.2.7 DTC Transfer Request Enable Register n (DTCERn) (n = 026 to 255)

Address(es): ICU.DTCER026 0008 711Ah to ICU.DTCER255 0008 71FFh

| Bit      | Symbol | Bit Name                    | Description                                                                                                                                                                           | R/W |
|----------|--------|-----------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----|
| b0       | DTCE   | DTC Transfer Request Enable | 0: The corresponding interrupt source is selected as an interrupt request to the CPU or as the DMAC trigger.<br>1: The corresponding interrupt source is selected as the DTC trigger. | R/W |
| b7 to b1 | —      | Reserved                    | The read value is 0. The write value should be 0.                                                                                                                                     | R/W |

The DTCERn register selects the interrupt source corresponding to interrupt vector number n as the DTC trigger. Do not set the same interrupt source for both the DTC trigger and DMAC trigger. Refer to [Table 14.4, Interrupt Vector Table](#) for the correspondence between interrupt sources and interrupt vector numbers and interrupt sources that can be used as the DTC trigger.

#### DTCE Bit (DTC Transfer Request Enable)

When the DTCE bit is set to 1, the corresponding interrupt source is selected as the DTC trigger.

This bit becomes 1 under the following condition:

- 1 is written to the DTCE bit

This bit becomes 0 under any of the following conditions:

- The specified number of transfers is completed (for the chain transfer, the number of transfers for the last chain transfer is completed)
- 0 is written to the DTCE bit

### 14.2.8 DMAC Trigger Select Register m (DMRSRm) (m = DMAC channel number)

Address(es): ICU.DMRSR0 0008 7400h, ICU.DMRSR1 0008 7404h, ICU.DMRSR2 0008 7408h, ICU.DMRSR3 0008 740Ch,  
ICU.DMRSR4 0008 7410h, ICU.DMRSR5 0008 7414h, ICU.DMRSR6 0008 7418h, ICU.DMRSR7 0008 741Ch

| Bit      | Symbol | Bit Name | Description                                                                             | R/W |
|----------|--------|----------|-----------------------------------------------------------------------------------------|-----|
| b7 to b0 | —      | —        | These bits set the interrupt vector number of the interrupt source as the DMAC trigger. | R/W |

The DMRSRm register sets an interrupt source as the DMACm trigger.

Do not set the same vector number for multiple DMRSRm registers. Do not set the same interrupt source for both the DTC trigger and DMAC trigger. Otherwise, the operation is not guaranteed.

Set the interrupt vector number of an interrupt source used as the DMAC trigger in the DMRSRm register. Do not set vector numbers of interrupt sources that cannot be used as the DMAC trigger.

Refer to Table 14.4, Interrupt Vector Table for interrupt vector numbers of interrupt sources.

Write the DMRSRm register while the DMACm.DMCNT.DTE bit is 0.

### 14.2.9 IRQ Control Register i (IRQCRi) (i = 0 to 15)

Address(es): ICU.IRQCR0 0008 7500h to ICU.IRQCR15 0008 750Fh

| Bit      | Symbol     | Bit Name             | Description                                                                                       | R/W |
|----------|------------|----------------------|---------------------------------------------------------------------------------------------------|-----|
| b1, b0   | —          | Reserved             | The read value is 0. The write value should be 0.                                                 | R/W |
| b3, b2   | IRQMD[1:0] | IRQ Detection Select | b3 b2<br>0 0: Low level<br>0 1: Falling edge<br>1 0: Rising edge<br>1 1: Rising and falling edges | R/W |
| b7 to b4 | —          | Reserved             | The read value is 0. The write value should be 0.                                                 | R/W |

The IRQCRi register selects the detection method for external pin interrupts.

Write to this register while the corresponding IERm.IENj bit is 0 (m = 02h to 1Fh; j = 0 to 7). After writing to this register, set the IRn.IR flag to 0, and then set the IENj bit to 1 (n = 016 to 255). Note that setting the IR flag to 0 is not required when changing the detection method to level detection.

#### IRQMD[1:0] Bits (IRQ Detection Select)

The IRQMD[1:0] bits set the detection method for the IRQi pin interrupt (i = 0 to 15).

Refer to section 14.7.4, Setting the External Pin Interrupt for the procedure to set the external pin interrupts.

### 14.2.10 IRQ Pin Digital Filter Enable Register 0 (IRQFLTE0)

Address(es): ICU.IRQFLTE0 0008 7520h

|            |            |            |            |            |            |            |            |
|------------|------------|------------|------------|------------|------------|------------|------------|
| b7         | b6         | b5         | b4         | b3         | b2         | b1         | b0         |
| FLTEN<br>7 | FLTEN<br>6 | FLTEN<br>5 | FLTEN<br>4 | FLTEN<br>3 | FLTEN<br>2 | FLTEN<br>1 | FLTEN<br>0 |

Value after reset: 0 0 0 0 0 0 0 0

| Bit | Symbol | Bit Name                   | Description                                                     | R/W |
|-----|--------|----------------------------|-----------------------------------------------------------------|-----|
| b0  | FLTEN0 | IRQ0 Digital Filter Enable | 0: Digital filter is disabled.<br>1: Digital filter is enabled. | R/W |
| b1  | FLTEN1 | IRQ1 Digital Filter Enable |                                                                 | R/W |
| b2  | FLTEN2 | IRQ2 Digital Filter Enable |                                                                 | R/W |
| b3  | FLTEN3 | IRQ3 Digital Filter Enable |                                                                 | R/W |
| b4  | FLTEN4 | IRQ4 Digital Filter Enable |                                                                 | R/W |
| b5  | FLTEN5 | IRQ5 Digital Filter Enable |                                                                 | R/W |
| b6  | FLTEN6 | IRQ6 Digital Filter Enable |                                                                 | R/W |
| b7  | FLTEN7 | IRQ7 Digital Filter Enable |                                                                 | R/W |

The IRQFLTE0 register enables and disables digital filters for pins IRQ0 to IRQ7.

#### FLTENi Bits (IRQi Digital Filter Enable) (i = 0 to 7)

When the FLTENi bit is 1, the digital filter for the IRQi pin is enabled. When the FLTENi bit is 0, the digital filter for the IRQi pin is disabled.

The signal input to the IRQi pin is sampled at the sampling clock set by the IRQFLTC0.FCLKSELi[1:0] bits. When the sampled signal level does not match three times in a row, the input signal is removed.

Refer to section 14.7.6, Digital Filter for details on the digital filter.

### 14.2.11 IRQ Pin Digital Filter Enable Register 1 (IRQFLTE1)

Address(es): ICU.IRQFLTE1 0008 7521h

|             |             |             |             |             |             |            |            |
|-------------|-------------|-------------|-------------|-------------|-------------|------------|------------|
| b7          | b6          | b5          | b4          | b3          | b2          | b1         | b0         |
| FLTEN<br>15 | FLTEN<br>14 | FLTEN<br>13 | FLTEN<br>12 | FLTEN<br>11 | FLTEN<br>10 | FLTEN<br>9 | FLTEN<br>8 |

Value after reset: 0 0 0 0 0 0 0 0

| Bit | Symbol  | Bit Name                    | Description                                                     | R/W |
|-----|---------|-----------------------------|-----------------------------------------------------------------|-----|
| b0  | FLTEN8  | IRQ8 Digital Filter Enable  | 0: Digital filter is disabled.<br>1: Digital filter is enabled. | R/W |
| b1  | FLTEN9  | IRQ9 Digital Filter Enable  |                                                                 | R/W |
| b2  | FLTEN10 | IRQ10 Digital Filter Enable |                                                                 | R/W |
| b3  | FLTEN11 | IRQ11 Digital Filter Enable |                                                                 | R/W |
| b4  | FLTEN12 | IRQ12 Digital Filter Enable |                                                                 | R/W |
| b5  | FLTEN13 | IRQ13 Digital Filter Enable |                                                                 | R/W |
| b6  | FLTEN14 | IRQ14 Digital Filter Enable |                                                                 | R/W |
| b7  | FLTEN15 | IRQ15 Digital Filter Enable |                                                                 | R/W |

The IRQFLTE1 register enables or disables digital filters for pins IRQ8 to IRQ15.

#### FLTEN<sub>i</sub> Bit (IRQ<sub>i</sub> Digital Filter Enable) (i = 8 to 15)

When the FLTEN<sub>i</sub> bit is 1, the digital filter for the IRQ<sub>i</sub> pin is enabled. When the FLTEN<sub>i</sub> bit is 0, the digital filter for the IRQ<sub>i</sub> pin is disabled.

The signal input to the IRQ<sub>i</sub> pin is sampled at the sampling clock set by the IRQFLTC1.FCLKSELi[1:0] bits. When the sampled signal level does not match three times in a row, the input signal is removed.

Refer to section 14.7.6, Digital Filter for details on the digital filter.

### 14.2.12 IRQ Pin Digital Filter Setting Register 0 (IRQFLTC0)

Address(es): ICU.IRQFLTC0 0008 7528h

| Bit      | Symbol        | Bit Name                           | Description                    | R/W |
|----------|---------------|------------------------------------|--------------------------------|-----|
| b1, b0   | FCLKSEL0[1:0] | IRQ0 Digital Filter Sampling Clock | 0 0: PCLKB<br>0 1: PCLKB/8     | R/W |
| b3, b2   | FCLKSEL1[1:0] | IRQ1 Digital Filter Sampling Clock | 1 0: PCLKB/32<br>1 1: PCLKB/64 | R/W |
| b5, b4   | FCLKSEL2[1:0] | IRQ2 Digital Filter Sampling Clock |                                | R/W |
| b7, b6   | FCLKSEL3[1:0] | IRQ3 Digital Filter Sampling Clock |                                | R/W |
| b9, b8   | FCLKSEL4[1:0] | IRQ4 Digital Filter Sampling Clock |                                | R/W |
| b11, b10 | FCLKSEL5[1:0] | IRQ5 Digital Filter Sampling Clock |                                | R/W |
| b13, b12 | FCLKSEL6[1:0] | IRQ6 Digital Filter Sampling Clock |                                | R/W |
| b15, b14 | FCLKSEL7[1:0] | IRQ7 Digital Filter Sampling Clock |                                | R/W |

The IRQFLTC0 register sets the sampling clock of the digital filter for pins IRQ0 to IRQ7.

#### **FCLKSELi[1:0] Bits (IRQi Digital Filter Sampling Clock) (i = 0 to 7)**

The FCLKSELi[1:0] bits set the sampling clock of the digital filter for the IRQi pin.

Refer to section 14.7.6, Digital Filter for details on the digital filter.

### 14.2.13 IRQ Pin Digital Filter Setting Register 1 (IRQFLTC1)

Address(es): ICU.IRQFLTC1 0008 752Ah

| Bit      | Symbol         | Bit Name                            | Description                    | R/W |
|----------|----------------|-------------------------------------|--------------------------------|-----|
| b1, b0   | FCLKSEL8[1:0]  | IRQ8 Digital Filter Sampling Clock  | 0 0: PCLKB<br>0 1: PCLKB/8     | R/W |
| b3, b2   | FCLKSEL9[1:0]  | IRQ9 Digital Filter Sampling Clock  | 1 0: PCLKB/32<br>1 1: PCLKB/64 | R/W |
| b5, b4   | FCLKSEL10[1:0] | IRQ10 Digital Filter Sampling Clock |                                | R/W |
| b7, b6   | FCLKSEL11[1:0] | IRQ11 Digital Filter Sampling Clock |                                | R/W |
| b9, b8   | FCLKSEL12[1:0] | IRQ12 Digital Filter Sampling Clock |                                | R/W |
| b11, b10 | FCLKSEL13[1:0] | IRQ13 Digital Filter Sampling Clock |                                | R/W |
| b13, b12 | FCLKSEL14[1:0] | IRQ14 Digital Filter Sampling Clock |                                | R/W |
| b15, b14 | FCLKSEL15[1:0] | IRQ15 Digital Filter Sampling Clock |                                | R/W |

The IRQFLTC1 register sets the sampling clock of the digital filter for pins IRQ8 to IRQ15.

#### FCLKSELi[1:0] Bits (IRQi Digital Filter Sampling Clock) (i = 8 to 15)

The FCLKSELi[1:0] bits set the sampling clock of the digital filter for the IRQi pin.

Refer to section 14.7.6, Digital Filter for details on the digital filter.

### 14.2.14 Non-Maskable Interrupt Status Register (NMISR)

Address(es): ICU.NMISR 0008 7580h

|                    |    |       |            |            |            |       |       |       |
|--------------------|----|-------|------------|------------|------------|-------|-------|-------|
|                    | b7 | b6    | b5         | b4         | b3         | b2    | b1    | b0    |
|                    | —  | RAMST | LVD2S<br>T | LVD1S<br>T | IWDTS<br>T | WDTST | OSTST | NMIST |
| Value after reset: | 0  | 0     | 0          | 0          | 0          | 0     | 0     | 0     |

| Bit | Symbol | Bit Name                                         | Description                                                                                                            | R/W |
|-----|--------|--------------------------------------------------|------------------------------------------------------------------------------------------------------------------------|-----|
| b0  | NMIST  | NMI Status Flag                                  | 0: NMI pin interrupt is not requested.<br>1: NMI pin interrupt is requested.                                           | R   |
| b1  | OSTST  | Oscillation Stop Detection Interrupt Status Flag | 0: Oscillation stop detection interrupt is not requested.<br>1: Oscillation stop detection interrupt is requested.     | R   |
| b2  | WDTST  | WDT Underflow/Refresh Error Status Flag          | 0: WDT underflow/refresh error interrupt is not requested.<br>1: WDT underflow/refresh error interrupt is requested.   | R   |
| b3  | IWDTS  | IWDT Underflow/Refresh Error Status Flag         | 0: IWDT underflow/refresh error interrupt is not requested.<br>1: IWDT underflow/refresh error interrupt is requested. | R   |
| b4  | LVD1ST | Voltage Monitoring 1 Interrupt Status Flag       | 0: Voltage monitoring 1 interrupt is not requested.<br>1: Voltage monitoring 1 interrupt is requested.                 | R   |
| b5  | LVD2ST | Voltage Monitoring 2 Interrupt Status Flag       | 0: Voltage monitoring 2 interrupt is not requested.<br>1: Voltage monitoring 2 interrupt is requested.                 | R   |
| b6  | RAMST  | RAM Error Interrupt Status Flag                  | 0: RAM error interrupt is not requested.<br>1: RAM error interrupt is requested.                                       | R   |
| b7  | —      | Reserved                                         | This bit is read as 0 and cannot be modified.                                                                          | R   |

The NMISR register indicates whether a non-maskable interrupt request has occurred.

Each flag in the NMISR register is not affected by the setting of the corresponding bit in the NMICR register.

In the non-maskable interrupt handler, read the NMISR register to check if the other non-maskable interrupt has occurred. Confirm that all the status flags are 0 before exiting the interrupt handler.

#### NMIST Flag (NMI Status Flag)

The NMIST flag indicates whether an NMI pin interrupt request has been generated.

This flag is read-only. To set the NMIST flag to 0, set the NMICLR.NMICLR bit to 1.

This flag becomes 1 under the following condition:

- An edge set in the NMICR.NMIMD bit is input to the NMI pin

This flag becomes 0 under the following condition:

- 1 is written to the NMICLR.NMICLR bit

#### OSTST Flag (Oscillation Stop Detection Interrupt Status Flag)

The OSTST flag indicates whether an oscillation stop detection interrupt request has been generated.

The OSTST flag is read-only. To set the OSTST flag to 0, set the NMICLR.OSTCLR bit to 1.

This flag becomes 1 under the following condition:

- An oscillation stop detection interrupt occurs

This flag becomes 0 under the following condition:

- 1 is written to the NMICLR.OSTCLR bit

**WDTST Flag (WDT Underflow/Refresh Error Status Flag)**

The WDTST flag indicates whether a WDT underflow/refresh error interrupt request is generated.

The WDTST flag is read-only. To set the WDTST flag to 0, set the NMICLR.WDTCLR bit to 1.

This flag becomes 1 under the following condition:

- A WDT underflow/refresh error interrupt occurs while the WDTRCR.RSTIRQS bit is 0

This flag becomes 0 under the following condition:

- 1 is written to the NMICLR.WDTCLR bit

**IWDTST Flag (IWDT Underflow/Refresh Error Status Flag)**

The IWDTST flag indicates whether an IWDT underflow/refresh error interrupt request is generated.

The IWDTST flag is read-only. To set the IWDTST flag to 0, set the NMICLR.IWDTCLR bit to 1.

This flag becomes 1 under the following condition:

- An IWDT underflow/refresh error interrupt occurs while the IWDTRCR.RSTIRQS bit is 0

This flag becomes 0 under the following condition:

- 1 is written to the NMICLR.IWDTCLR bit

**LVD1ST Flag (Voltage Monitoring 1 Interrupt Status Flag)**

The LVD1ST flag indicates whether a voltage monitoring 1 interrupt request is generated.

The LVD1ST flag is read-only. To set the LVD1ST flag to 0, set the NMICLR.LVD1CLR bit to 1.

This flag becomes 1 under the following condition:

- A voltage monitoring 1 interrupt occurs while the LVD1CR1.LVD1IRQSEL bit is 0

This flag becomes 0 under the following condition:

- 1 is written to the NMICLR.LVD1CLR bit

**LVD2ST Flag (Voltage Monitoring 2 Interrupt Status Flag)**

The LVD2ST flag indicates whether a voltage monitoring 2 interrupt request is generated.

The LVD2ST flag is read-only. To set the LVD2ST flag to 0, set the NMICLR.LVD2CLR bit to 1.

This flag becomes 1 under the following condition:

- A voltage monitoring 2 interrupt occurs while the LVD2CR1.LVD2IRQSEL bit is 0

This flag becomes 0 under the following condition:

- 1 is written to the NMICLR.LVD2CLR bit

**RAMST Flag (RAM Error Interrupt Status Flag)**

The RAMST flag indicates whether a RAM error interrupt request is generated from the RAM (including the ECCRAM).

The RAMST flag is read-only. To set the RAMST flag to 0, clear all error status flags of the RAM. Refer to section 43.3.4, RAM Error Interrupt Function for details.

This flag becomes 1 under the following condition:

- A parity check error interrupt occurs (When the RAM.RAMSTS.RAMERR flag becomes 1)
- An ECC error interrupt occurs (When the RAM.ECCRAM1STS.ECC1ERR or RAM.ECCRAM2STS.ECC2ERR flag becomes 1)

This flag becomes 0 under the following condition:

- When all sources which set the RAMST flag to 1 are cleared.

## 14.2.15 Non-Maskable Interrupt Enable Register (NMIER)

Address(es): ICU.NMIER 0008 7581h

|                    | b7 | b6    | b5     | b4     | b3     | b2    | b1    | b0    |

| b6  | RAMEN  | RAM Error Interrupt Enable                  | 0: RAM error interrupt is disabled.<br>1: RAM error interrupt is enabled.                                       | R/(W)<br>*1 |
| b7  | —      | Reserved                                    | This bit is read as 0. The write value should be 0.                                                             | R/W         |

Note 1. Once this bit is set to 1, it cannot be set to 0 by software.

The NMIER register enables and disables generation of non-maskable interrupt requests. When each bit is 1, the corresponding interrupt source is used as a non-maskable interrupt.

### NMIEN Bit (NMI Pin Interrupt Enable)

The NMIEN bit enables and disables using the NMI pin interrupt.

### OSTEN Bit (Oscillation Stop Detection Interrupt Enable)

The OSTEN bit enables and disables generation of a non-maskable interrupt by the oscillation stop detection interrupt. When the oscillation stop detection interrupt is used as a maskable interrupt, leave this bit set to 0.

### WDTEN Bit (WDT Underflow/Refresh Error Enable)

The WDTEN bit enables and disables generation of a non-maskable interrupt by the WDT underflow/refresh error interrupt.

When the WDT underflow/refresh error interrupt is used as a maskable interrupt, leave this bit set to 0.

### IWDTEN Bit (IWDT Underflow/Refresh Error Enable)

The IWDTEN bit enables and disables generation of a non-maskable interrupt by the IWDT underflow/refresh error interrupt.

When the IWDT underflow/refresh error interrupt is used as a maskable interrupt, leave this bit set to 0.

### LVD1EN Bit (Voltage Monitoring 1 Interrupt Enable)

The LVD1EN bit enables and disables generation of a non-maskable interrupt by the voltage monitoring 1 interrupt.

When the voltage monitoring 1 interrupt is used as a maskable interrupt, leave this bit set to 0.

**LVD2EN Bit (Voltage Monitoring 2 Interrupt Enable)**

The LVD2EN bit enables and disables generation of a non-maskable interrupt by the voltage monitoring 2 interrupt. When the voltage monitoring 2 interrupt is used as a maskable interrupt, leave this bit set to 0.

**RAMEN Bit (RAM Error Interrupt Enable)**

The RAMEN bit enables and disables generation of a non-maskable interrupt by the RAM error interrupt. When the RAM error interrupt is used as a maskable interrupt, leave this bit set to 0.

## 14.2.16 Non-Maskable Interrupt Status Clear Register (NMICLR)

Address(es): ICU.NMICLR 0008 7582h

|                    |    |    |             |             |             |            |            |            |
|--------------------|----|----|-------------|-------------|-------------|------------|------------|------------|
|                    | b7 | b6 | b5          | b4          | b3          | b2         | b1         | b0         |
|                    | —  | —  | LVD2C<br>LR | LVD1C<br>LR | IWDTC<br>LR | WDTCL<br>R | OSTCL<br>R | NMICL<br>R |
| Value after reset: | 0  | 0  | 0           | 0           | 0           | 0          | 0          | 0          |

| Bit   | Symbol   | Bit Name   | Description                                                                                                               | R/W   |
|-------|----------|------------|---------------------------------------------------------------------------------------------------------------------------|-------|
| b0    | NMICLR   | NMI Clear  | The read value is 0. When 1 is written to this bit, the NMISR.NMIST flag becomes 0. Writing 0 to this bit has no effect.  | R/(W) |
| b1    | OSTCLR   | OST Clear  | The read value is 0. When 1 is written to this bit, the NMISR.OSTST flag becomes 0. Writing 0 to this bit has no effect.  | R/(W) |
| b2    | WDTCLR   | WDT Clear  | The read value is 0. When 1 is written to this bit, the NMISR.WDTST flag becomes 0. Writing 0 to this bit has no effect.  | R/(W) |
| b3    | IWDTCCLR | IWDT Clear | The read value is 0. When 1 is written to this bit, the NMISR.IWDTST flag becomes 0. Writing 0 to this bit has no effect. | R/(W) |
| b4    | LVD1CLR  | LVD1 Clear | The read value is 0. When 1 is written to this bit, the NMISR.LVD1ST flag becomes 0. Writing 0 to this bit has no effect. | R/(W) |
| b5    | LVD2CLR  | LVD2 Clear | The read value is 0. When 1 is written to this bit, the NMISR.LVD2ST flag becomes 0. Writing 0 to this bit has no effect. | R/(W) |
| b7-b6 | —        | Reserved   | The read value is 0. The write value should be 0.                                                                         | R/W   |

The NMICLR register clears each flag in the NMISR register.

When writing 1 to a bit in this register, the corresponding status flag becomes 0.

## 14.2.17 NMI Pin Interrupt Control Register (NMICR)

Address(es): ICU.NMICR 0008 7583h

|                    |    |    |    |    |       |    |    |    |
|--------------------|----|----|----|----|-------|----|----|----|
|                    | b7 | b6 | b5 | b4 | b3    | b2 | b1 | b0 |
|                    | —  | —  | —  | —  | NMIMD | —  | —  | —  |
| Value after reset: | 0  | 0  | 0  | 0  | 0     | 0  | 0  | 0  |

| Bit      | Symbol | Bit Name          | Description                                       | R/W |
|----------|--------|-------------------|---------------------------------------------------|-----|
| b2 to b0 | —      | Reserved          | The read value is 0. The write value should be 0. | R/W |
| b3       | NMIMD  | NMI Detection Set | 0: Falling edge<br>1: Rising edge                 | R/W |
| b7 to b4 | —      | Reserved          | The read value is 0. The write value should be 0. | R/W |

The NMICR register selects a detection method for the NMI pin interrupt.

Write to the NMICR register while the NMIER.NMIEN bit is 0.

### 14.2.18 NMI Pin Digital Filter Enable Register (NMIFLTE)

Address(es): ICU.NMIFLTE 0008 7590h

| Bit      | Symbol | Bit Name                  | Description                                                     | R/W |
|----------|--------|---------------------------|-----------------------------------------------------------------|-----|
| b0       | NFLTEN | NMI Digital Filter Enable | 0: Digital filter is disabled.<br>1: Digital filter is enabled. | R/W |
| b7 to b1 | —      | Reserved                  | The read value is 0. The write value should be 0.               | R/W |

The NMIFLTE register enables or disables the digital filter for the NMI pin.

#### NFLTEN Bit (NMI Digital Filter Enable)

When the NFLTEN bit is 1, the digital filter is enabled. When the NFLTEN bit is 0, the digital filter is disabled.

The signal input to the NMI pin is sampled at the sampling clock set by the NMIFLTC.NFCLKSEL[1:0] bits. When the sampled signal level does not match three times in a row, the input signal is removed.

Refer to section 14.7.6, Digital Filter for details on the digital filter.

### 14.2.19 NMI Pin Digital Filter Setting Register (NMIFLTC)

Address(es): ICU.NMIFLTC 0008 7594h

| Bit      | Symbol        | Bit Name                          | Description                                                           | R/W |
|----------|---------------|-----------------------------------|-----------------------------------------------------------------------|-----|
| b1, b0   | NFCLKSEL[1:0] | NMI Digital Filter Sampling Clock | b1 b0<br>0 0: PCLKB<br>0 1: PCLKB/8<br>1 0: PCLKB/32<br>1 1: PCLKB/64 | R/W |
| b7 to b2 | —             | Reserved                          | The read value is 0. The write value should be 0.                     | R/W |

The NMIFLTC register sets the sampling clock of the digital filter for the NMI pin.

#### NFCLKSEL[1:0] Bits (NMI Digital Filter Sampling Clock)

The NFCLKSEL[1:0] bits select the sampling clock of the digital filter for the NMI pin.

Refer to section 14.7.6, Digital Filter for details on the digital filter.

### 14.2.20 Group BE0 Interrupt Request Register (GRPBE0), Group BL0/BL1 Interrupt Request Register (GRPBL0/GRPBL1), Group AL0 Interrupt Request Register (GRPAL0)

Address(es): ICU.GRPBE0 0008 7600h, ICU.GRPBL0 0008 7630h, ICU.GRPBL1 0008 7634h, ICU.GRPAL0 0008 7830h

|                    |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |

| b23 | IS23   | Interrupt Status Flag 23 |                                | R   |
| b24 | IS24   | Interrupt Status Flag 24 |                                | R   |
| b25 | IS25   | Interrupt Status Flag 25 |                                | R   |
| b26 | IS26   | Interrupt Status Flag 26 |                                | R   |
| b27 | IS27   | Interrupt Status Flag 27 |                                | R   |
| b28 | IS28   | Interrupt Status Flag 28 |                                | R   |
| b29 | IS29   | Interrupt Status Flag 29 |                                | R   |
| b30 | IS30   | Interrupt Status Flag 30 |                                | R   |
| b31 | IS31   | Interrupt Status Flag 31 |                                | R   |

These registers indicate the status of each interrupt request of group interrupt sources.

The GRPBE0 register contains the statuses of interrupt sources that are detected by edge detection and use PCLKB as the operating clock.

Registers GRPBL0 and GRPBL1 contain the statuses of interrupt sources that are detected by level detection and use PCLKB as the operating clock.

The GRPAL0 register contains the statuses of interrupt sources that are detected by level detection and use PCLKA as the operating clock.

These registers are collectively referred to as the “group interrupt request register”.

Refer to section 14.4.4, Group Interrupts for details on group interrupts.

### ISj Flag (Interrupt Status Flag j) (j = 0 to 31)

The ISj flag indicates the status of interrupt sources assigned to group interrupts.

The ISj flag becomes 1 only when the corresponding ENj bit in the group interrupt request enable register is 1. When any of the ISj flags becomes 1, the IRn.IR flag corresponding to the group interrupt becomes 1 (n = 016 to 255).

#### (1) Group BE0

This flag becomes 1 under the following condition:

- The GRPBE0.ISj flag becomes 1 when the corresponding peripheral module interrupt request is generated while the GENBE0.ENj bit is 1.

This flag becomes 0 under the following condition:

- The GRPBE0.ISj flag becomes 0 when the GCRBE0.CLRj bit is set to 1.

#### (2) Group BL0/BL1

This flag becomes 1 under the following condition:

- The GRPBL0/GRPBL1.ISj flag becomes 1 while the corresponding peripheral module interrupt request is generated when the GENBL0/GENBL1.ENj bit is 1.

This flag becomes 0 under any of the following conditions:

- The GRPBL0/GRPBL1.ISj flag becomes 0 when the corresponding peripheral module interrupt request is cleared.
- The GRPBL0/GRPBL1.ISj flag becomes 0 when the GENBL0/GENBL1.ENj bit is set to 0.

#### (3) Group AL0

This flag becomes 1 under the following condition:

- The GRPAL0.ISj flag becomes 1 while the corresponding peripheral module interrupt request is generated when the GENAL0.ENj bit is 1.

This flag becomes 0 under any of the following conditions:

- The GRPAL0.ISj flag becomes 0 when the corresponding peripheral module interrupt request is cleared.
- The GRPAL0.ISj flag becomes 0 when the GENAL0.ENj bit is set to 0.

### 14.2.21 Group BE0 Interrupt Request Enable Register (GENBE0), Group BL0/BL1 Interrupt Request Enable Register (GENBL0/GENBL1), Group AL0 Interrupt Request Enable Register (GENAL0)

Address(es): ICU.GENBE0 0008 7640h, ICU.GENBL0 0008 7670h, ICU.GENBL1 0008 7674h, ICU.GENAL0 0008 7870h

| b31 | EN31   | Interrupt Request Enable 31 |                                   | R/W |

Note: When a bit has no corresponding interrupt source (bit is reserved), set the bit to 0.

These registers select whether the IS<sub>j</sub> flag in the group interrupt request register is set to 1 when each interrupt request for group interrupt sources is generated. These registers are collectively referred to as the “group interrupt request enable register”.

Registers GENBE0, GENBL0/GENBL1, and GENAL0 control the IS<sub>j</sub> flag in registers GRPBE0, GRPBL0/GRPBL1, and GRPAL0, respectively.

Refer to section 14.4.4, Group Interrupts for details on group interrupts.

### **EN<sub>j</sub> Bits (Interrupt Request Enable j) (j = 0 to 31)**

The EN<sub>j</sub> bits select whether the corresponding IS<sub>j</sub> flag in the group interrupt request register is set to 1 when an interrupt request assigned to group interrupts is generated.

#### **(1) Group BE0**

When a peripheral module interrupt request is generated while the corresponding GENBE0.EN<sub>j</sub> bit is 1, the GRPBE0.IS<sub>j</sub> flag becomes 1. When the EN<sub>j</sub> bit is 0, the IS<sub>j</sub> flag does not become 1.

Even when the EN<sub>j</sub> bit is set to 0, the IS<sub>j</sub> flag does not change.

#### **(2) Group BL0/BL1**

When a peripheral module interrupt request is generated while the corresponding GENBL0/GENBL1.EN<sub>j</sub> bit is 1, the GRPBL0/GRPBL1.IS<sub>j</sub> flag becomes 1. When the EN<sub>j</sub> bit is 0, the IS<sub>j</sub> flag does not become 1.

When the EN<sub>j</sub> bit is set to 0, the IS<sub>j</sub> flag becomes 0.

#### **(3) Group AL0**

When a peripheral module interrupt request is generated while the corresponding GENAL0.EN<sub>j</sub> bit is 1, the GRPAL0.IS<sub>j</sub> flag becomes 1. When the EN<sub>j</sub> bit is 0, the IS<sub>j</sub> flag does not become 1.

When the EN<sub>j</sub> bit is set to 0, the IS<sub>j</sub> flag becomes 0.

## 14.2.22 Group BE0 Interrupt Clear Register (GCRBE0)

Address(es): ICU.GCRBE0 0008 7680h

| b26 | CLR26  | Interrupt Source Clear 26 |                                                                                                                                       | R/(W) |
| b27 | CLR27  | Interrupt Source Clear 27 |                                                                                                                                       | R/(W) |
| b28 | CLR28  | Interrupt Source Clear 28 |                                                                                                                                       | R/(W) |
| b29 | CLR29  | Interrupt Source Clear 29 |                                                                                                                                       | R/(W) |
| b30 | CLR30  | Interrupt Source Clear 30 |                                                                                                                                       | R/(W) |
| b31 | CLR31  | Interrupt Source Clear 31 |                                                                                                                                       | R/(W) |

Note: Write 1 to only the bit corresponding to the flag that is cleared, and write 0 to the other bits.

The GCRBE0 register clears the GRPBE0.ISj flag (j = 0 to 31).  
Refer to section 14.4.4, Group Interrupts for details on group interrupts.

**CLRj Bit (Interrupt Source Clear j) (j = 0 to 31)**

When the GCRBE0.CLRj bit is set to 1, the GRPBE0.ISj flag becomes 0.

### 14.2.23 Software Configurable Interrupt A Request Register k (PIARk) (k = 0h to 12h)

Address(es): ICU.PIAR0 0008 7900h, ICU.PIAR1 0008 7901h, ICU.PIAR2 0008 7902h, ICU.PIAR3 0008 7903h, ICU.PIAR4 0008 7904h, ICU.PIAR5 0008 7905h, ICU.PIAR6 0008 7906h, ICU.PIAR7 0008 7907h, ICU.PIAR8 0008 7908h, ICU.PIAR9 0008 7909h, ICU.PIARA 0008 790Ah, ICU.PIARB 0008 790Bh, ICU.PIARC 0008 790Ch, ICU.PIARD 0008 790Dh, ICU.PIARE 0008 790Eh, ICU.PIARF 0008 790Fh, ICU.PIAR10 0008 7910h, ICU.PIAR11 0008 7911h, ICU.PIAR12 0008 7912h

| b2  | PIR2   | Software Configurable Interrupt A Status Flag 2 | When writing *1<br>0: Ignored.<br>1: The Software Configurable interrupt A status flag is cleared. | R/W |
| b3  | PIR3   | Software Configurable Interrupt A Status Flag 3 |                                                                                                    | R/W |
| b4  | PIR4   | Software Configurable Interrupt A Status Flag 4 |                                                                                                    | R/W |
| b5  | PIR5   | Software Configurable Interrupt A Status Flag 5 |                                                                                                    | R/W |
| b6  | PIR6   | Software Configurable Interrupt A Status Flag 6 |                                                                                                    | R/W |
| b7  | PIR7   | Software Configurable Interrupt A Status Flag 7 |                                                                                                    | R/W |

Note 1. Do not use bit manipulation instructions. If a bit manipulation instruction is used, multiple status flags may be cleared. Write 1 only to the flag to be cleared and write 0 to the other flags (write to this register in 8-bit units).

The PIARk register is used for polling interrupt requests of interrupt sources that is assigned to software configurable interrupt A by software. For an interrupt request of software configurable interrupt A set in the SLIARn register, use the corresponding IRn.IR flag for polling (n = 208 to 255).

Refer to Table 14.3, Interrupt Sources for Software Configurable Interrupt A for correspondence between interrupt source numbers and interrupt sources for software configurable interrupt A.

#### PIRj Flag (Software Configurable Interrupt A Status Flag j) (j = 0 to 7)

When an interrupt request of interrupt sources assigned to software configurable interrupt A is generated, the corresponding PIARk.PIRj flag becomes 1 regardless of whether the interrupt source is selected in the SLIARn register. Although the PIRj flag does not become 0 after the interrupt request is accepted by the destination (CPU, DTC, DMAC), generation of interrupt requests is not affected.

When using the PIRj flag for polling, set the PIRj flag to 0 by writing 1 to the flag in advance.

This flag becomes 1 under the following condition:

- An interrupt request is generated

This flag becomes 0 under the following condition:

- 1 is written to the PIARk.PIRj flag

### 14.2.24 Software Configurable Interrupt A Source Select Register n (SLIARn) (n = 208 to 255)

Address(es): ICU.SLIAR208 0008 79D0h to ICU.SLIAR255 0008 79FFh

| Bit      | Symbol | Bit Name | Description                                                                                                                                         | R/W         |
|----------|--------|----------|-----------------------------------------------------------------------------------------------------------------------------------------------------|-------------|
| b7 to b0 | —      | —        | 00h: No interrupt source selected.<br>01h: Interrupt source number 1<br>:<br>FEh: Interrupt source number 254<br>FFh: No interrupt source selected. | R/(W)<br>*1 |

Note 1. Writing to these bits is ignored while the SLIPRCR.WPRC bit is set to 1.

The SLIARn register is used to assign interrupt vector numbers 208 to 255 to interrupt sources for software configurable interrupt A.

Table 14.3, Interrupt Sources for Software Configurable Interrupt A lists interrupt sources for software configurable interrupt A. Set the SLIARn register to an interrupt source number that is not reserved. When 00h or FFh are set, no interrupt source is assigned to interrupt vector number n.

Do not assign the same interrupt source to multiple SLIARn registers.

Some interrupt sources can be used to start the DTC or DMAC. Refer to Table 14.3, Interrupt Sources for Software Configurable Interrupt A for details on which sources can be used to start the DTC or DMAC.

Refer to section 14.7.7, Setting Software Configurable Interrupts for the procedure to set software configurable interrupts.

**Table 14.3 Interrupt Sources for Software Configurable Interrupt A (1/4)**

| Interrupt Source No. | Category | Interrupt Request Source | Name                                                              | Start the DTC | Start the DMAC | Interrupt Status Flag |
|----------------------|----------|--------------------------|-------------------------------------------------------------------|---------------|----------------|-----------------------|
| 0                    | —        | None                     | No interrupt selected (initial value)                             | N/A           | N/A            | PIAR0.PIR0            |
| 1                    | Edge     | MTU0                     | TGIA0 (TGRA input capture/compare match)                          | ✓             | ✓              | PIAR0.PIR1            |

| b7 to b1 | —      | Reserved                                                             | The read value is 0. The write value should be 0. | R           |

Note 1. Once this bit is set to 1, it cannot be set to 0 by software.

The SLIPRCR register protects registers that control assignment of software configurable interrupts from being written to.

### WPRC Bit (Software Configurable Interrupt Source Select Register Write Protect)

The WPRC bit disables writing to the SLIARn register.

Once this bit is set to 1, it cannot be set to 0 by software.

After assigning software configurable interrupts, confirm that the WPRC bit is 1 before the corresponding interrupt request is generated. Refer to section 14.7.7, Setting Software Configurable Interrupts for the procedure to set software configurable interrupts.

### 14.3 Vector Table

There are two types of exceptions detected by the ICU: maskable interrupts (hereinafter referred to as “interrupts”) and non-maskable interrupts.

When the CPU accepts an interrupt or non-maskable interrupt, it acquires a 4-byte vector address from the vector table.

#### 14.3.1 Interrupt Vector Table

The vector table that is used for maskable interrupts is called the interrupt vector table.

The interrupt vector table is allocated to a 1024-byte area (4 bytes × 256 sources) beginning with the address set in the INTB register in the CPU. Set the INTB register before enabling interrupts. Set a multiple of 4 in the INTB register.

An unconditional trap is generated when the INT or BRK instruction is executed. Interrupt vectors for unconditional traps use the same area as the interrupt vector table. The BRK instruction is assigned to interrupt vector number 0. The INT instruction is assigned to the interrupt vector number corresponding to the value set as the operand (0 to 255).

Table 14.4 lists details of the interrupt vectors. Details of the headings in Table 14.4 are listed below.

| Heading                        | Description                                                                                                                                |
|--------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------|
| Interrupt request generated by | Name of the source that generates the interrupt request (module symbol)                                                                    |
| Name                           | Name of the interrupt source (symbol)                                                                                                      |
| Vector no.                     | Interrupt vector number                                                                                                                    |
| Vector address offset          | Offset from the address set in the INTB register                                                                                           |
| Interrupt detection method     | “Edge” indicates that the interrupt is detected by edge detection.<br>“Level” indicates that the interrupt is detected by level detection. |
| CPU interrupt                  | Interrupt source indicated by “√” can be used as an interrupt source to the CPU.                                                           |
| Start the DTC                  | Interrupt source indicated by “√” can be used as the DTC trigger.                                                                          |
| Start the DMAC                 | Interrupt source indicated by “√” can be used as the DMAC trigger.                                                                         |
| Exit from SSBY                 | Interrupt source indicated by “√” can be used as a source to exit software standby mode.                                                   |
| Exit from ACS                  | Interrupt source indicated by “√” can be used as a source to exit all-module clock stop mode.                                              |
| IER                            | Name of the bit in the IER register corresponding to the interrupt vector number                                                           |
| IPR                            | Name of the IPR register corresponding to the interrupt source                                                                             |
| DTCER                          | Name of the DTCER register corresponding to the DTC trigger                                                                                |

Table 14.4 Interrupt Vector Table (1/6)

| Interrupt Request is Generated By | Name                      | Vector No. | Vector Address Offset | Interrupt Detection Method | CPU Interrupt | Start the DTC | Start the DMAC | Exit from SSBY | Exit from ACS | IER        | IPR    | DTCER    |
|-----------------------------------|---------------------------|------------|-----------------------|----------------------------|---------------|---------------|----------------|----------------|---------------|------------|--------|----------|

Note: This table lists the interrupt vectors for the maximum specification. The interrupt vectors for individual products correspond to the functions listed in Table 1.2. For details, refer to Table 1.2, Comparison of Functions for Different Packages.

Note 1. For the group interrupt sources, refer to Table 14.6, Group Interrupt Requests.

Note 2. This is the case where the corresponding non-maskable interrupt enable bit is set to 0 (disabled).

Note 3. For the software configurable interrupt A sources, refer to Table 14.3, Interrupt Sources for Software Configurable Interrupt A.

Note that some interrupt sources cannot start the DTC or DMAC.

### 14.3.2 Fast Interrupt Vector Area

The interrupt set as the fast interrupt uses the FINTV register in the CPU. Set the FINTV register before enabling the fast interrupt.

### 14.3.3 Non-maskable Interrupt Vector Area

Non-maskable interrupts use the vector area in the exception vector table.

The exception vector table is allocated to the 128-byte area (4 bytes × 32 sources) beginning with the address set in the EXTB register in the CPU. Set the EXTB register before enabling non-maskable interrupts. Set a multiple of 4 in the EXTB register.

## 14.4 Types of Interrupts

Interrupts are divided into maskable interrupts and non-maskable interrupts. Maskable interrupts can be masked by the PSW.I bit or IPL[3:0] bits of the processor status word in the CPU. Non-maskable interrupts can be accepted by the CPU regardless of those bits. While interrupt sources assigned to vector numbers 0 to 207 are fixed, an interrupt source assigned to each vector number from 208 to 255 (software configurable interrupt) can be selected from multiple sources. Note that maskable interrupts are referred to as interrupts in this chapter.

Figure 14.2 shows types of interrupts.

Figure 14.2 Types of Interrupts

### 14.4.1 Peripheral Interrupts

Peripheral interrupt is generated by peripherals. Peripheral interrupts sources assigned to vector numbers 0 to 207 cannot be assigned to the software configurable interrupts. Refer to section 14.4.5, Software Configurable Interrupts for details on software configurable interrupts.

### 14.4.2 Software Interrupts

When the SWINTR.SWINT bit and SWINT2R.SWINT2 bit are set to 1, the SWINT interrupt and SWINT2 interrupt occur, respectively.

### 14.4.3 External Pin Interrupt

An external pin interrupt is generated by signals input to the IRQ<sub>i</sub> pin (i = 0 to 15). Refer to section 14.7.4, Setting the External Pin Interrupt for the procedure to set the external pin interrupt.

### 14.4.4 Group Interrupts

Multiple peripheral interrupt requests (up to 32 requests) are grouped together as one interrupt request. Interrupts are grouped depending on the peripheral operating clock (ICLK, PCLKB, or PCLKA) and method to detect interrupt requests (edge detection or level detection).

#### (1) Types of Group Interrupts

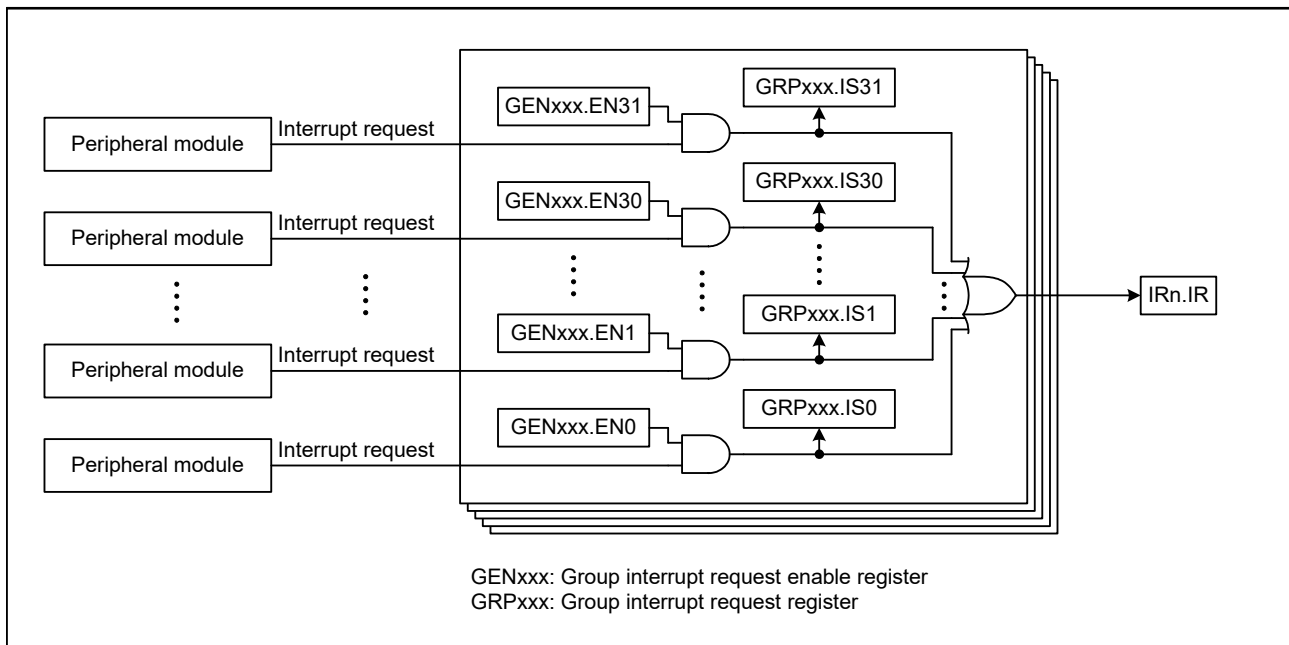

Table 14.5 lists types of group interrupts.

**Table 14.5 Types of Group Interrupts**

| Interrupt Vector Number | Interrupt Name | Group Interrupt Source     |                            |
|-------------------------|----------------|----------------------------|----------------------------|
|                         |                | Peripheral operating clock | Interrupt detection method |
| 17                      | GROUPIE0       | ICLK                       | Edge detection             |
| 106                     | GROUPBE0       | PCLKB                      |                            |
| 110                     | GROUPBL0       |                            |                            |
| 111                     | GROUPBL1       |                            |                            |
| 107                     | GROUPBL2       |                            |                            |
| 112                     | GROUPAL0       | PCLKA                      | Level detection            |
| 113                     | GROUPAL1       |                            |                            |

#### (2) Configuration of Group Interrupts

When an interrupt request is generated while the corresponding EN<sub>j</sub> bit in the group interrupt request enable register (GENIE0, GENBE0, GENBL0, GENBL1, GENBL2, GENAL0, GENAL1\*1) is 1, the IS<sub>j</sub> flag in the group interrupt request register (GRPIE0, GRPBE0, GRPBL0, GRPBL1, GRPBL2, GRPAL0, GRPAL1\*1) becomes 1 (j = 0 to 31). Figure 14.3 shows the configuration of group interrupts.

**Figure 14.3 Group Interrupt Configuration (n = 17, 106, 107, 110 to 113)**

Note 1. There is no register in the group to which no interrupt source is assigned.

## (3) Group Interrupt Sources

Table 14.6 lists peripheral interrupt sources that are assigned to group interrupts.
