| Bit      | Symbol      | Bit Name                    | Description                                                                                                                                                                                                                                                                                         | R/W   |
|----------|-------------|-----------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------|
| b3 to b0 | M4ASEL[3:0] | MTU4-A (MTIOC4A) Pin Select | b3 b0<br>0 0 0 0: Does not perform the output disabling control for any MTIOC4A pin.<br>0 0 0 1: Perform the output disabling control for the P72 as the MTIOC4A pin.<br>0 0 1 0: Perform the output disabling control for the P13 as the MTIOC4A pin.<br>Settings other than above are prohibited. | R/W*1 |
| b7 to b4 | M4CSEL[3:0] | MTU4-C (MTIOC4C) Pin Select | b7 b4<br>0 0 0 0: Does not perform the output disabling control for any MTIOC4C pin.<br>0 0 0 1: Perform the output disabling control for the P75 as the MTIOC4C pin.<br>0 0 1 0: Perform the output disabling control for the P16 as the MTIOC4C pin.<br>Settings other than above are prohibited. | R/W*1 |

Note 1. Can be modified only once after a reset.

The M4SELR1 register is an 8-bit readable/writable register, and selects relevant pins to the output disabling control from the MTU4-A and MTU4-C pins respectively.

### M4ASEL[3:0] Bits (MTU4-A (MTIOC4A) Pin Select)

Selects a relevant MTIOC4A pin to the output disabling control.

### M4CSEL[3:0] Bits (MTU4-C (MTIOC4C) Pin Select)

Selects a relevant MTIOC4C pin to the output disabling control.

## 23.2.46 MTU4 Pin Select Register 2 (M4SELR2)

Address(es): POE.M4SELR2 0009 E464h

| Bit      | Symbol      | Bit Name                    | Description                                                                                                                                                                                                                                                                                         | R/W   |
|----------|-------------|-----------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------|
| b3 to b0 | M4BSEL[3:0] | MTU4-B (MTIOC4B) Pin Select | b3 b0<br>0 0 0 0: Does not perform the output disabling control for any MTIOC4B pin.<br>0 0 0 1: Perform the output disabling control for the P73 as the MTIOC4B pin.<br>0 0 1 0: Perform the output disabling control for the P14 as the MTIOC4B pin.<br>Settings other than above are prohibited. | R/W*1 |
| b7 to b4 | M4DSEL[3:0] | MTU4-D (MTIOC4D) Pin Select | b7 b4<br>0 0 0 0: Does not perform the output disabling control for any MTIOC4D pin.<br>0 0 0 1: Perform the output disabling control for the P76 as the MTIOC4D pin.<br>0 0 1 0: Perform the output disabling control for the P17 as the MTIOC4D pin.<br>Settings other than above are prohibited. | R/W*1 |

Note 1. Can be modified only once after a reset.

The M4SELR2 register is an 8-bit readable/writable register, and selects relevant pins to the output disabling control from the MTU4-B and MTU4-D pins respectively.

### M4BSEL[3:0] Bits (MTU4-B (MTIOC4B) Pin Select)

Selects a relevant MTIOC4B pin to the output disabling control.

### M4DSEL[3:0] Bits (MTU4-D (MTIOC4D) Pin Select)

Selects a relevant MTIOC4D pin to the output disabling control.

### 23.2.47 MTU6 Pin Select Register (M6SELR)

Address(es): POE.M6SELR 0009 E465h

| Bit      | Symbol      | Bit Name                    | Description                                                                                                                                                                                                        | R/W   |
|----------|-------------|-----------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------|
| b3 to b0 | M6BSEL[3:0] | MTU6-B (MTIOC6B) Pin Select | b3 b0<br>0 0 0 0: Does not perform the output disabling control for any MTIOC6B pin.<br>0 0 0 1: Perform the output disabling control for the P95 as the MTIOC6B pin.<br>Settings other than above are prohibited. | R/W*1 |
| b7 to b4 | M6DSEL[3:0] | MTU6-D (MTIOC6D) Pin Select | b7 b4<br>0 0 0 0: Does not perform the output disabling control for any MTIOC6D pin.<br>0 0 0 1: Perform the output disabling control for the P92 as the MTIOC6D pin.<br>Settings other than above are prohibited. | R/W*1 |

Note 1. Can be modified only once after a reset.

The M6SELR register is an 8-bit readable/writable register, and selects relevant pins to the output disabling control from the MTU6-B and MTU6-D pins respectively.

#### M6BSEL[3:0] Bits (MTU6-B (MTIOC6B) Pin Select)

Selects a relevant MTIOC6B pin to the output disabling control.

#### M6DSEL[3:0] Bits (MTU6-D (MTIOC6D) Pin Select)

Selects a relevant MTIOC6D pin to the output disabling control.

### 23.2.48 MTU7 Pin Select Register 1 (M7SELR1)

Address(es): POE.M7SELR1 0009 E466h

| Bit      | Symbol      | Bit Name                    | Description                                                                                                                                                                                                        | R/W   |
|----------|-------------|-----------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------|
| b3 to b0 | M7ASEL[3:0] | MTU7-A (MTIOC7A) Pin Select | b3 b0<br>0 0 0 0: Does not perform the output disabling control for any MTIOC7A pin.<br>0 0 0 1: Perform the output disabling control for the P94 as the MTIOC7A pin.<br>Settings other than above are prohibited. | R/W*1 |
| b7 to b4 | M7CSEL[3:0] | MTU7-C (MTIOC7C) Pin Select | b7 b4<br>0 0 0 0: Does not perform the output disabling control for any MTIOC7C pin.<br>0 0 0 1: Perform the output disabling control for the P91 as the MTIOC7C pin.<br>Settings other than above are prohibited. | R/W*1 |

Note 1. Can be modified only once after a reset.

The M7SELR1 register is an 8-bit readable/writable register, and selects relevant pins to the output disabling control from the MTU7-A and MTU7-C pins respectively.

#### M7ASEL[3:0] Bits (MTU7-A (MTIOC7A) Pin Select)

Selects a relevant MTIOC7A pin to the output disabling control.

#### M7CSEL[3:0] Bits (MTU7-C (MTIOC7C) Pin Select)

Selects a relevant MTIOC7C pin to the output disabling control.

### 23.2.49 MTU7 Pin Select Register 2 (M7SELR2)

Address(es): POE.M7SELR2 0009 E467h

| Bit      | Symbol      | Bit Name                    | Description                                                                                                                                                                                                        | R/W   |
|----------|-------------|-----------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------|
| b3 to b0 | M7BSEL[3:0] | MTU7-B (MTIOC7B) Pin Select | b3 b0<br>0 0 0 0: Does not perform the output disabling control for any MTIOC7B pin.<br>0 0 0 1: Perform the output disabling control for the P93 as the MTIOC7B pin.<br>Settings other than above are prohibited. | R/W*1 |
| b7 to b4 | M7DSEL[3:0] | MTU7-D (MTIOC7D) Pin Select | b7 b4<br>0 0 0 0: Does not perform the output disabling control for any MTIOC7D pin.<br>0 0 0 1: Perform the output disabling control for the P90 as the MTIOC7D pin.<br>Settings other than above are prohibited. | R/W*1 |

Note 1. Can be modified only once after a reset.

The M7SELR2 register is an 8-bit readable/writable register, and selects relevant pins to the output disabling control from the MTU7-B and MTU7-D pins respectively.

#### M7BSEL[3:0] Bits (MTU7-B (MTIOC7B) Pin Select)

Selects a relevant MTIOC7B pin to the output disabling control.

#### M7DSEL[3:0] Bits (MTU7-D (MTIOC7D) Pin Select)

Selects a relevant MTIOC7D pin to the output disabling control.

### 23.2.50 MTU9 Pin Select Register 1 (M9SELR1)

Address(es): POE.M9SELR1 0009 E468h

| Bit      | Symbol      | Bit Name                    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            | R/W   |
|----------|-------------|-----------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------|
| b3 to b0 | M9ASEL[3:0] | MTU9-A (MTIOC9A) Pin Select | b3 b0<br>0 0 0 0: Does not perform the output disabling control for any MTIOC9A pin.<br>0 0 0 1: Perform the output disabling control for the PD7 as the MTIOC9A pin.<br>0 0 1 0: Perform the output disabling control for the P21 as the MTIOC9A pin.<br>0 0 1 1: Perform the output disabling control for the P00 as the MTIOC9A pin.<br>0 1 0 0: Perform the output disabling control for the P26 as the MTIOC9A pin.<br>0 1 0 1: Perform the output disabling control for the P35 as the MTIOC9A pin.<br>Settings other than above are prohibited. | R/W*1 |
| b7 to b4 | M9BSEL[3:0] | MTU9-B (MTIOC9B) Pin Select | b7 b4<br>0 0 0 0: Does not perform the output disabling control for any MTIOC9B pin.<br>0 0 0 1: Perform the output disabling control for the PE0 as the MTIOC9B pin.<br>0 0 1 0: Perform the output disabling control for the PC4 as the MTIOC9B pin.<br>0 0 1 1: Perform the output disabling control for the P10 as the MTIOC9B pin.<br>0 1 0 0: Perform the output disabling control for the P22 as the MTIOC9B pin.<br>0 1 0 1: Perform the output disabling control for the P34 as the MTIOC9B pin.<br>Settings other than above are prohibited. | R/W*1 |

Note 1. Can be modified only once after a reset.

The M9SELR1 register is an 8-bit readable/writable register, and selects relevant pins to the output disabling control from the MTU9-A and MTU9-B pins respectively.

#### M9ASEL[3:0] Bits (MTU9-A (MTIOC9A) Pin Select)

Selects a relevant MTIOC9A pin to the output disabling control.

#### M9BSEL[3:0] Bits (MTU9-B (MTIOC9B) Pin Select)

Selects a relevant MTIOC9B pin to the output disabling control.

### 23.2.51 MTU9 Pin Select Register 2 (M9SELR2)

Address(es): POE.M9SELR2 0009 E469h

| Bit      | Symbol      | Bit Name                    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            | R/W   |
|----------|-------------|-----------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------|
| b3 to b0 | M9CSEL[3:0] | MTU9-C (MTIOC9C) Pin Select | b3 b0<br>0 0 0 0: Does not perform the output disabling control for any MTIOC9C pin.<br>0 0 0 1: Perform the output disabling control for the PD6 as the MTIOC9C pin.<br>0 0 1 0: Perform the output disabling control for the P20 as the MTIOC9C pin.<br>0 0 1 1: Perform the output disabling control for the P01 as the MTIOC9C pin.<br>0 1 0 0: Perform the output disabling control for the P25 as the MTIOC9C pin.<br>0 1 0 1: Perform the output disabling control for the PC6 as the MTIOC9C pin.<br>Settings other than above are prohibited. | R/W*1 |
| b7 to b4 | M9DSEL[3:0] | MTU9-D (MTIOC9D) Pin Select | b7 b4<br>0 0 0 0: Does not perform the output disabling control for any MTIOC9D pin.<br>0 0 0 1: Perform the output disabling control for the PE1 as the MTIOC9D pin.<br>0 0 1 0: Perform the output disabling control for the PC3 as the MTIOC9D pin.<br>0 0 1 1: Perform the output disabling control for the PE5 as the MTIOC9D pin.<br>0 1 0 0: Perform the output disabling control for the P11 as the MTIOC9D pin.<br>0 1 0 1: Perform the output disabling control for the PC5 as the MTIOC9D pin.<br>Settings other than above are prohibited. | R/W*1 |

Note 1. Can be modified only once after a reset.

The M9SELR2 register is an 8-bit readable/writable register, and selects relevant pins to the output disabling control from the MTU9-C and MTU9-D pins respectively.

#### M9CSEL[3:0] Bits (MTU9-C (MTIOC9C) Pin Select)

Selects a relevant MTIOC9C pin to the output disabling control.

#### M9DSEL[3:0] Bits (MTU9-D (MTIOC9D) Pin Select)

Selects a relevant MTIOC9D pin to the output disabling control.

### 23.2.52 GPTW0 Pin Select Register (G0SELR)

Address(es): POE.G0SELR 0009 E46Ah

| Bit      | Symbol      | Bit Name                     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            | R/W   |
|----------|-------------|------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------|
| b3 to b0 | G0ASEL[3:0] | GPTW0-A (GTIOC0A) Pin Select | b3 b0<br>0 0 0 0: Does not perform the output disabling control for any GTIOC0A pin.<br>0 0 0 1: Perform the output disabling control for the P71 as the GTIOC0A pin.<br>0 0 1 0: Perform the output disabling control for the PD7 as the GTIOC0A pin.<br>0 0 1 1: Perform the output disabling control for the P12 as the GTIOC0A pin.<br>0 1 0 0: Perform the output disabling control for the PD2 as the GTIOC0A pin.<br>0 1 0 1: Perform the output disabling control for the PG1 as the GTIOC0A pin.<br>Settings other than above are prohibited. | R/W*1 |
| b7 to b4 | G0BSEL[3:0] | GPTW0-B (GTIOC0B) Pin Select | b7 b4<br>0 0 0 0: Does not perform the output disabling control for any GTIOC0B pin.<br>0 0 0 1: Perform the output disabling control for the P74 as the GTIOC0B pin.<br>0 0 1 0: Perform the output disabling control for the PD6 as the GTIOC0B pin.<br>0 0 1 1: Perform the output disabling control for the P15 as the GTIOC0B pin.<br>0 1 0 0: Perform the output disabling control for the PD1 as the GTIOC0B pin.<br>0 1 0 1: Perform the output disabling control for the PG2 as the GTIOC0B pin.<br>Settings other than above are prohibited. | R/W*1 |

Note 1. Can be modified only once after a reset.

The G0SELR register is an 8-bit readable/writable register, and selects relevant pins to the output disabling control from the GPTW0-A and GPTW0-B pins respectively.

#### **G0ASEL[3:0] Bits (GPTW0-A (GTIOC0A) Pin Select)**

Selects a relevant GTIOC0A pin to the output disabling control.

#### **G0BSEL[3:0] Bits (GPTW0-B (GTIOC0B) Pin Select)**

Selects a relevant GTIOC0B pin to the output disabling control.

### 23.2.53 GPTW1 Pin Select Register (G1SELR)

Address(es): POE.G1SELR 0009 E46Bh

| Bit      | Symbol      | Bit Name                     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            | R/W   |
|----------|-------------|------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------|
| b3 to b0 | G1ASEL[3:0] | GPTW1-A (GTIOC1A) Pin Select | b3 b0<br>0 0 0 0: Does not perform the output disabling control for any GTIOC1A pin.<br>0 0 0 1: Perform the output disabling control for the P72 as the GTIOC1A pin.<br>0 0 1 0: Perform the output disabling control for the PD5 as the GTIOC1A pin.<br>0 0 1 1: Perform the output disabling control for the P13 as the GTIOC1A pin.<br>0 1 0 0: Perform the output disabling control for the PD0 as the GTIOC1A pin.<br>0 1 0 1: Perform the output disabling control for the PK2 as the GTIOC1A pin.<br>Settings other than above are prohibited. | R/W*1 |

Note 1. Can be modified only once after a reset.

The G1SELR register is an 8-bit readable/writable register, and selects relevant pins to the output disabling control from the GPTW1-A and GPTW1-B pins respectively.

#### G1ASEL[3:0] Bits (GPTW1-A (GTIOC1A) Pin Select)

Selects a relevant GTIOC1A pin to the output disabling control.

#### G1BSEL[3:0] Bits (GPTW1-B (GTIOC1B) Pin Select)

Selects a relevant GTIOC1B pin to the output disabling control.

### 23.2.54 GPTW2 Pin Select Register (G2SELR)

Address(es): POE.G2SELR 0009 E46Ch

| Bit      | Symbol      | Bit Name                     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            | R/W   |

Note 1. Can be modified only once after a reset.

The G2SELR register is an 8-bit readable/writable register, and selects relevant pins to the output disabling control from the GPTW2-A and GPTW2-B pins respectively.

#### **G2ASEL[3:0] Bits (GPTW2-A (GTIOC2A) Pin Select)**

Selects a relevant GTIOC2A pin to the output disabling control.

#### **G2BSEL[3:0] Bits (GPTW2-B (GTIOC2B) Pin Select)**

Selects a relevant GTIOC2B pin to the output disabling control.

## 23.2.55 GPTW3 Pin Select Register (G3SELR)

Address(es): POE.G3SELR 0009 E46Dh

| Bit      | Symbol      | Bit Name                     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                           | R/W   |
|----------|-------------|------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------|
| b3 to b0 | G3ASEL[3:0] | GPTW3-A (GTIOC3A) Pin Select | b3 b0<br>0 0 0 0: Does not perform the output disabling control for any GTIOC3A pin.<br>0 0 0 1: Perform the output disabling control for the P32 as the GTIOC3A pin.<br>0 0 1 0: Perform the output disabling control for the PD1 as the GTIOC3A pin.<br>0 0 1 1: Perform the output disabling control for the PE5 as the GTIOC3A pin.<br>0 1 0 0: Perform the output disabling control for the PD7 as the GTIOC3A pin.<br>Settings other than above are prohibited. | R/W*1 |
| b7 to b4 | G3BSEL[3:0] | GPTW3-B (GTIOC3B) Pin Select | b7 b4<br>0 0 0 0: Does not perform the output disabling control for any GTIOC3B pin.<br>0 0 0 1: Perform the output disabling control for the P33 as the GTIOC3B pin.<br>0 0 1 0: Perform the output disabling control for the PD0 as the GTIOC3B pin.<br>0 0 1 1: Perform the output disabling control for the P11 as the GTIOC3B pin.<br>0 1 0 0: Perform the output disabling control for the PD6 as the GTIOC3B pin.<br>Settings other than above are prohibited. | R/W*1 |

Note 1. Can be modified only once after a reset.

The G3SELR register is an 8-bit readable/writable register, and selects relevant pins to the output disabling control from the GPTW3-A and GPTW3-B pins respectively.

### G3ASEL[3:0] Bits (GPTW3-A (GTIOC3A) Pin Select)

Selects a relevant GTIOC3A pin to the output disabling control.

### G3BSEL[3:0] Bits (GPTW3-B (GTIOC3B) Pin Select)

Selects a relevant GTIOC3B pin to the output disabling control.

### 23.2.56 GPTW4 Pin Select Register (G4SELR)

Address(es): POE.G4SELR 0009 E46Eh

| Bit      | Symbol      | Bit Name                     | Description                                                                                                                                                                                                                                                                                         | R/W   |
|----------|-------------|------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------|
| b3 to b0 | G4ASEL[3:0] | GPTW4-A (GTIOC4A) Pin Select | b3 b0<br>0 0 0 0: Does not perform the output disabling control for any GTIOC4A pin.<br>0 0 0 1: Perform the output disabling control for the P95 as the GTIOC4A pin.<br>0 0 1 0: Perform the output disabling control for the P71 as the GTIOC4A pin.<br>Settings other than above are prohibited. | R/W*1 |
| b7 to b4 | G4BSEL[3:0] | GPTW4-B (GTIOC4B) Pin Select | b7 b4<br>0 0 0 0: Does not perform the output disabling control for any GTIOC4B pin.<br>0 0 0 1: Perform the output disabling control for the P92 as the GTIOC4B pin.<br>0 0 1 0: Perform the output disabling control for the P74 as the GTIOC4B pin.<br>Settings other than above are prohibited. | R/W*1 |

Note 1. Can be modified only once after a reset.

The G4SELR register is an 8-bit readable/writable register, and selects relevant pins to the output disabling control from the GPTW4-A and GPTW4-B pins respectively.

#### G4ASEL[3:0] Bits (GPTW4-A (GTIOC4A) Pin Select)

Selects a relevant GTIOC4A pin to the output disabling control.

#### G4BSEL[3:0] Bits (GPTW4-B (GTIOC4B) Pin Select)

Selects a relevant GTIOC4B pin to the output disabling control.

### 23.2.57 GPTW5 Pin Select Register (G5SELR)

Address(es): POE.G5SELR 0009 E46Fh

| Bit      | Symbol      | Bit Name                     | Description                                                                                                                                                                                                                                                                                         | R/W   |
|----------|-------------|------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------|
| b3 to b0 | G5ASEL[3:0] | GPTW5-A (GTIOC5A) Pin Select | b3 b0<br>0 0 0 0: Does not perform the output disabling control for any GTIOC5A pin.<br>0 0 0 1: Perform the output disabling control for the P94 as the GTIOC5A pin.<br>0 0 1 0: Perform the output disabling control for the P72 as the GTIOC5A pin.<br>Settings other than above are prohibited. | R/W*1 |
| b7 to b4 | G5BSEL[3:0] | GPTW5-B (GTIOC5B) Pin Select | b7 b4<br>0 0 0 0: Does not perform the output disabling control for any GTIOC5B pin.<br>0 0 0 1: Perform the output disabling control for the P91 as the GTIOC5B pin.<br>0 0 1 0: Perform the output disabling control for the P75 as the GTIOC5B pin.<br>Settings other than above are prohibited. | R/W*1 |

Note 1. Can be modified only once after a reset.

The G5SELR register is an 8-bit readable/writable register, and selects relevant pins to the output disabling control from the GPTW5-A and GPTW5-B pins respectively.

#### G5ASEL[3:0] Bits (GPTW5-A (GTIOC5A) Pin Select)

Selects a relevant GTIOC5A pin to the output disabling control.

#### G5BSEL[3:0] Bits (GPTW5-B (GTIOC5B) Pin Select)

Selects a relevant GTIOC5B pin to the output disabling control.

### 23.2.58 GPTW6 Pin Select Register (G6SELR)

Address(es): POE.G6SELR 0009 E470h

| Bit      | Symbol      | Bit Name                     | Description                                                                                                                                                                                                                                                                                         | R/W   |
|----------|-------------|------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------|
| b3 to b0 | G6ASEL[3:0] | GPTW6-A (GTIOC6A) Pin Select | b3 b0<br>0 0 0 0: Does not perform the output disabling control for any GTIOC6A pin.<br>0 0 0 1: Perform the output disabling control for the P93 as the GTIOC6A pin.<br>0 0 1 0: Perform the output disabling control for the P73 as the GTIOC6A pin.<br>Settings other than above are prohibited. | R/W*1 |
| b7 to b4 | G6BSEL[3:0] | GPTW6-B (GTIOC6B) Pin Select | b7 b4<br>0 0 0 0: Does not perform the output disabling control for any GTIOC6B pin.<br>0 0 0 1: Perform the output disabling control for the P90 as the GTIOC6B pin.<br>0 0 1 0: Perform the output disabling control for the P76 as the GTIOC6B pin.<br>Settings other than above are prohibited. | R/W*1 |

Note 1. Can be modified only once after a reset.

The G6SELR register is an 8-bit readable/writable register, and selects relevant pins to the output disabling control from the GPTW6-A and GPTW6-B pins respectively.

#### **G6ASEL[3:0] Bits (GPTW6-A (GTIOC6A) Pin Select)**

Selects a relevant GTIOC6A pin to the output disabling control.

#### **G6BSEL[3:0] Bits (GPTW6-B (GTIOC6B) Pin Select)**

Selects a relevant GTIOC6B pin to the output disabling control.

### 23.2.59 GPTW7 Pin Select Register (G7SELR)

Address(es): POE.G7SELR 0009 E471h

| Bit      | Symbol      | Bit Name                     | Description                                                                                                                                                                                                                                                                                         | R/W   |
|----------|-------------|------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------|
| b3 to b0 | G7ASEL[3:0] | GPTW7-A (GTIOC7A) Pin Select | b3 b0<br>0 0 0 0: Does not perform the output disabling control for any GTIOC7A pin.<br>0 0 0 1: Perform the output disabling control for the P95 as the GTIOC7A pin.<br>0 0 1 0: Perform the output disabling control for the P12 as the GTIOC7A pin.<br>Settings other than above are prohibited. | R/W*1 |
| b7 to b4 | G7BSEL[3:0] | GPTW7-B (GTIOC7B) Pin Select | b7 b4<br>0 0 0 0: Does not perform the output disabling control for any GTIOC7B pin.<br>0 0 0 1: Perform the output disabling control for the P92 as the GTIOC7B pin.<br>0 0 1 0: Perform the output disabling control for the P15 as the GTIOC7B pin.<br>Settings other than above are prohibited. | R/W*1 |

Note 1. Can be modified only once after a reset.

The G7SELR register is an 8-bit readable/writable register, and selects relevant pins to the output disabling control from the GPTW7-A and GPTW7-B pins respectively.

#### **G7ASEL[3:0] Bits (GPTW7-A (GTIOC7A) Pin Select)**

Selects a relevant GTIOC7A pin to the output disabling control.

#### **G7BSEL[3:0] Bits (GPTW7-B (GTIOC7B) Pin Select)**

Selects a relevant GTIOC7B pin to the output disabling control.

## 23.2.60 GPTW8 Pin Select Register (G8SELR)

Address(es): POE.G8SELR 0009 E472h

| Bit      | Symbol      | Bit Name                     | Description                                                                                                                                                                                                                                                                                         | R/W   |
|----------|-------------|------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------|
| b3 to b0 | G8ASEL[3:0] | GPTW8-A (GTIOC8A) Pin Select | b3 b0<br>0 0 0 0: Does not perform the output disabling control for any GTIOC8A pin.<br>0 0 0 1: Perform the output disabling control for the P94 as the GTIOC8A pin.<br>0 0 1 0: Perform the output disabling control for the P13 as the GTIOC8A pin.<br>Settings other than above are prohibited. | R/W*1 |
| b7 to b4 | G8BSEL[3:0] | GPTW8-B (GTIOC8B) Pin Select | b7 b4<br>0 0 0 0: Does not perform the output disabling control for any GTIOC8B pin.<br>0 0 0 1: Perform the output disabling control for the P91 as the GTIOC8B pin.<br>0 0 1 0: Perform the output disabling control for the P16 as the GTIOC8B pin.<br>Settings other than above are prohibited. | R/W*1 |

Note 1. Can be modified only once after a reset.

The G8SELR register is an 8-bit readable/writable register, and selects relevant pins to the output disabling control from the GPTW8-A and GPTW8-B pins respectively.

### G8ASEL[3:0] Bits (GPTW8-A (GTIOC8A) Pin Select)

Selects a relevant GTIOC8A pin to the output disabling control.

### G8BSEL[3:0] Bits (GPTW8-B (GTIOC8B) Pin Select)

Selects a relevant GTIOC8B pin to the output disabling control.

### 23.2.61 GPTW9 Pin Select Register (G9SELR)

Address(es): POE.G9SELR 0009 E473h

| Bit      | Symbol      | Bit Name                     | Description                                                                                                                                                                                                                                                                                         | R/W   |
|----------|-------------|------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------|
| b3 to b0 | G9ASEL[3:0] | GPTW9-A (GTIOC9A) Pin Select | b3 b0<br>0 0 0 0: Does not perform the output disabling control for any GTIOC9A pin.<br>0 0 0 1: Perform the output disabling control for the P93 as the GTIOC9A pin.<br>0 0 1 0: Perform the output disabling control for the P14 as the GTIOC9A pin.<br>Settings other than above are prohibited. | R/W*1 |
| b7 to b4 | G9BSEL[3:0] | GPTW9-B (GTIOC9B) Pin Select | b7 b4<br>0 0 0 0: Does not perform the output disabling control for any GTIOC9B pin.<br>0 0 0 1: Perform the output disabling control for the P90 as the GTIOC9B pin.<br>0 0 1 0: Perform the output disabling control for the P17 as the GTIOC9B pin.<br>Settings other than above are prohibited. | R/W*1 |

Note 1. Can be modified only once after a reset.

The G9SELR register is an 8-bit readable/writable register, and selects relevant pins to the output disabling control from the GPTW9-A and GPTW9-B pins respectively.

#### **G9ASEL[3:0] Bits (GPTW9-A (GTIOC9A) Pin Select)**

Selects a relevant GTIOC9A pin to the output disabling control.

#### **G9BSEL[3:0] Bits (GPTW9-B (GTIOC9B) Pin Select)**

Selects a relevant GTIOC9B pin to the output disabling control.

### 23.3 Operation

The following shows the target pins and conditions for output disabling control.

#### (1) MTU3 pins (MTIOC3B, MTIOC3D)

When one of the following conditions is satisfied while the POECR2.MTU3BDZE bit is 1, the pins become high-impedance. Furthermore, when the POECR2.MTU3BDZE bit is 0 and the PMMCR1.MTU3BME and MTU3DME bits are 1 and when one of the following conditions is satisfied, the pins are switched to general I/O port pins.

- Operation for comparison of the output levels on the MTIOC3B and MTIOC3D signals  
When the OCSR1.OSF1 flag becomes 1 while the OCSR1.OCE1 bit is 1.
- SPOER setting  
When the SPOER.MTUCH34HIZ bit is set to 1.
- Conditions added by POECR4  
When the ICSR1.POE0F flag becomes 1 while the POECR4.IC1ADDMT34ZE bit is 1.  
When the ICSR2.POE4F flag becomes 1 while the POECR4.IC2ADDMT34ZE bit is 1.  
When the ICSR3.POE8F flag becomes 1 while the POECR4.IC3ADDMT34ZE bit and the ICSR3.POE8E bit are 1.  
When the ICSR4.POE10F flag becomes 1 while the POECR4.IC4ADDMT34ZE bit and the ICSR4.POE10E bit are 1.  
When the ICSR5.POE11F flag becomes 1 while the POECR4.IC5ADDMT34ZE bit and the ICSR5.POE11E bit are 1.  
When the ICSR7.POE12F flag becomes 1 while the POECR4.IC6ADDMT34ZE bit and the ICSR7.POE12E bit are 1.  
When the ICSR8.POE9F flag becomes 1 while the POECR4.IC8ADDMT34ZE bit and the ICSR8.POE9E bit are 1.  
When the ICSR9.POE13F flag becomes 1 while the POECR4.IC9ADDMT34ZE bit and the ICSR9.POE13E bit are 1.  
When the ICSR10.POE14F flag becomes 1 while the POECR4.IC10ADDMT34ZE bit and the ICSR10.POE14E bit are 1.
- Comparator output detection  
When the POECMPFR.C0FLAG flag becomes 1 while the POECR4.CMADDMT34ZE bit is 1 and the POECMPX0.POEREQ0 bit or the POECMPSEL.POEREQ0 bit is 1.  
When the POECMPFR.C1FLAG flag becomes 1 while the POECR4.CMADDMT34ZE bit is 1 and the POECMPX0.POEREQ1 bit or the POECMPSEL.POEREQ1 bit is 1.  
When the POECMPFR.C2FLAG flag becomes 1 while the POECR4.CMADDMT34ZE bit is 1 and the POECMPX0.POEREQ2 bit or the POECMPSEL.POEREQ2 bit is 1.  
When the POECMPFR.C3FLAG flag becomes 1 while the POECR4.CMADDMT34ZE bit is 1 and the POECMPX0.POEREQ3 bit or the POECMPSEL.POEREQ3 bit is 1.  
When the POECMPFR.C4FLAG flag becomes 1 while the POECR4.CMADDMT34ZE bit is 1 and the POECMPX0.POEREQ4 bit or the POECMPSEL.POEREQ4 bit is 1.  
When the POECMPFR.C5FLAG flag becomes 1 while the POECR4.CMADDMT34ZE bit is 1 and the POECMPX0.POEREQ5 bit or the POECMPSEL.POEREQ5 bit is 1.
- Detection of oscillation stop  
When the ICSR6.OSTSTF flag becomes 1 while the ICSR6.OSTSTE bit is 1.

#### (2) MTU4 pins (MTIOC4A, MTIOC4C)

When one of the following conditions is satisfied while the POECR2.MTU4ACZE bit is 1, the pins become high-impedance. Furthermore, when the POECR2.MTU4ACZE bit is 0 and the PMMCR1.MTU4AME and MTU4CME bits are 1 and when one of the following conditions is satisfied, the pins are switched to general I/O port pins.

- Operation for comparison of the output levels on the MTIOC4A and MTIOC4C signals  
When the OCSR1.OSF1 flag becomes 1 while the OCSR1.OCE1 bit is 1.

- SPOER setting  
When the SPOER.MTUCH34HIZ bit is set to 1.
- Conditions added by POECR4  
When the ICSR1.POE0F flag becomes 1 while the POECR4.IC1ADDMT34ZE bit is 1.  
When the ICSR2.POE4F flag becomes 1 while the POECR4.IC2ADDMT34ZE bit is 1.  
When the ICSR3.POE8F flag becomes 1 while the POECR4.IC3ADDMT34ZE bit and the ICSR3.POE8E bit are 1.  
When the ICSR4.POE10F flag becomes 1 while the POECR4.IC4ADDMT34ZE bit and the ICSR4.POE10E bit are 1.  
When the ICSR5.POE11F flag becomes 1 while the POECR4.IC5ADDMT34ZE bit and the ICSR5.POE11E bit are 1.  
When the ICSR7.POE12F flag becomes 1 while the POECR4.IC6ADDMT34ZE bit and the ICSR7.POE12E bit are 1.  
When the ICSR8.POE9F flag becomes 1 while the POECR4.IC8ADDMT34ZE bit and the ICSR8.POE9E bit are 1.  
When the ICSR9.POE13F flag becomes 1 while the POECR4.IC9ADDMT34ZE bit and the ICSR9.POE13E bit are 1.  
When the ICSR10.POE14F flag becomes 1 while the POECR4.IC10ADDMT34ZE bit and the ICSR10.POE14E bit are 1.
- Comparator output detection  
When the POECMPFR.C0FLAG flag becomes 1 while the POECR4.CMADDMT34ZE bit is 1 and the POECMPX0.POEREQ0 bit or the POECMPSEL.POEREQ0 bit is 1.  
When the POECMPFR.C1FLAG flag becomes 1 while the POECR4.CMADDMT34ZE bit is 1 and the POECMPX0.POEREQ1 bit or the POECMPSEL.POEREQ1 bit is 1.  
When the POECMPFR.C2FLAG flag becomes 1 while the POECR4.CMADDMT34ZE bit is 1 and the POECMPX0.POEREQ2 bit or the POECMPSEL.POEREQ2 bit is 1.  
When the POECMPFR.C3FLAG flag becomes 1 while the POECR4.CMADDMT34ZE bit is 1 and the POECMPX0.POEREQ3 bit or the POECMPSEL.POEREQ3 bit is 1.  
When the POECMPFR.C4FLAG flag becomes 1 while the POECR4.CMADDMT34ZE bit is 1 and the POECMPX0.POEREQ4 bit or the POECMPSEL.POEREQ4 bit is 1.  
When the POECMPFR.C5FLAG flag becomes 1 while the POECR4.CMADDMT34ZE bit is 1 and the POECMPX0.POEREQ5 bit or the POECMPSEL.POEREQ5 bit is 1.
- Detection of oscillation stop  
When the ICSR6.OSTSTF flag becomes 1 while the ICSR6.OSTSTE bit is 1.

### (3) MTU4 pins (MTIOC4B, MTIOC4D)

When one of the following conditions is satisfied while the POECR2.MTU4BDZE bit is 1, the pins become high-impedance. Furthermore, when the POECR2.MTU4BDZE bit is 0 and the PMMCR1.MTU4BME and MTU4DME bits are 1 and when one of the following conditions is satisfied, the pins are switched to general I/O port pins.

- Operation for comparison of the output levels on the MTIOC4B and MTIOC4D signals  
When the OCSR1.OSF1 flag becomes 1 while the OCSR1.OCE1 bit is 1.
- SPOER setting  
When the SPOER.MTUCH34HIZ bit is set to 1.
- Conditions added by POECR4  
When the ICSR1.POE0F flag becomes 1 while the POECR4.IC1ADDMT34ZE bit is 1.  
When the ICSR2.POE4F flag becomes 1 while the POECR4.IC2ADDMT34ZE bit is 1.  
When the ICSR3.POE8F flag becomes 1 while the POECR4.IC3ADDMT34ZE bit and the ICSR3.POE8E bit are 1.  
When the ICSR4.POE10F flag becomes 1 while the POECR4.IC4ADDMT34ZE bit and the ICSR4.POE10E bit are 1.  
When the ICSR5.POE11F flag becomes 1 while the POECR4.IC5ADDMT34ZE bit and the ICSR5.POE11E bit are 1.

When the ICSR7.POE12F flag becomes 1 while the POECR4.IC6ADDMT34ZE bit and the ICSR7.POE12E bit are 1.

When the ICSR8.POE9F flag becomes 1 while the POECR4.IC8ADDMT34ZE bit and the ICSR8.POE9E bit are 1.

When the ICSR9.POE13F flag becomes 1 while the POECR4.IC9ADDMT34ZE bit and the ICSR9.POE13E bit are 1.

When the ICSR10.POE14F flag becomes 1 while the POECR4.IC10ADDMT34ZE bit and the ICSR10.POE14E bit are 1.

- Comparator output detection

When the POECMPFR.C0FLAG flag becomes 1 while the POECR4.CMADDMT34ZE bit is 1 and the POECMPPEX0.POEREQ0 bit or the POECMPSEL.POEREQ0 bit is 1.

When the POECMPFR.C1FLAG flag becomes 1 while the POECR4.CMADDMT34ZE bit is 1 and the POECMPPEX0.POEREQ1 bit or the POECMPSEL.POEREQ1 bit is 1.

When the POECMPFR.C2FLAG flag becomes 1 while the POECR4.CMADDMT34ZE bit is 1 and the POECMPPEX0.POEREQ2 bit or the POECMPSEL.POEREQ2 bit is 1.

When the POECMPFR.C3FLAG flag becomes 1 while the POECR4.CMADDMT34ZE bit is 1 and the POECMPPEX0.POEREQ3 bit or the POECMPSEL.POEREQ3 bit is 1.

When the POECMPFR.C4FLAG flag becomes 1 while the POECR4.CMADDMT34ZE bit is 1 and the POECMPPEX0.POEREQ4 bit or the POECMPSEL.POEREQ4 bit is 1.

When the POECMPFR.C5FLAG flag becomes 1 while the POECR4.CMADDMT34ZE bit is 1 and the POECMPPEX0.POEREQ5 bit or the POECMPSEL.POEREQ5 bit is 1.

- Detection of oscillation stop

When the ICSR6.OSTSTF flag becomes 1 while the ICSR6.OSTSTE bit is 1.

#### (4) MTU6 pins (MTIOC6B, MTIOC6D)

When one of the following conditions is satisfied while the POECR2.MTU6BDZE bit is 1, the pins become high-impedance. Furthermore, when the POECR2.MTU6BDZE bit is 0 and the PMMCR1.MTU6BME and MTU6DME bits are 1 and when one of the following conditions is satisfied, the pins are switched to general I/O port pins.

- Operation for comparison of the output levels on the MTIOC6B and MTIOC6D signals

When the OCSR2.OSF2 flag becomes 1 while the OCSR2.OCE2 bit is 1.

- SPOER setting

When the SPOER.MTUCH67HIZ bit is set to 1.

- Conditions added by POECR4B

When the ICSR1.POE0F flag becomes 1 while the POECR4B.IC1ADDMT67ZE bit is 1.

When the ICSR2.POE4F flag becomes 1 while the POECR4B.IC2ADDMT67ZE bit is 1.

When the ICSR3.POE8F flag becomes 1 while the POECR4B.IC3ADDMT67ZE bit and the ICSR3.POE8E bit are 1.

When the ICSR4.POE10F flag becomes 1 while the POECR4B.IC4ADDMT67ZE bit and the ICSR4.POE10E bit are 1.

When the ICSR5.POE11F flag becomes 1 while the POECR4B.IC5ADDMT67ZE bit and the ICSR5.POE11E bit are 1.

When the ICSR7.POE12F flag becomes 1 while the POECR4B.IC6ADDMT67ZE bit and the ICSR7.POE12E bit are 1.

When the ICSR8.POE9F flag becomes 1 while the POECR4B.IC8ADDMT67ZE bit and the ICSR8.POE9E bit are 1.

When the ICSR9.POE13F flag becomes 1 while the POECR4B.IC9ADDMT67ZE bit and the ICSR9.POE13E bit are 1.

When the ICSR10.POE14F flag becomes 1 while the POECR4B.IC10ADDMT67ZE bit and the ICSR10.POE14E bit are 1.

- Comparator output detection

When the POECMPFR.C0FLAG flag becomes 1 while the POECR4B.CMADDMT67ZE bit is 1 and the POECMPEX1.POEREQ0 bit or the POECMPSEL.POEREQ0 bit is 1.

When the POECMPFR.C1FLAG flag becomes 1 while the POECR4B.CMADDMT67ZE bit is 1 and the POECMPEX1.POEREQ1 bit or the POECMPSEL.POEREQ1 bit is 1.

When the POECMPFR.C2FLAG flag becomes 1 while the POECR4B.CMADDMT67ZE bit is 1 and the POECMPEX1.POEREQ2 bit or the POECMPSEL.POEREQ2 bit is 1.

When the POECMPFR.C3FLAG flag becomes 1 while the POECR4B.CMADDMT67ZE bit is 1 and the POECMPEX1.POEREQ3 bit or the POECMPSEL.POEREQ3 bit is 1.

When the POECMPFR.C4FLAG flag becomes 1 while the POECR4B.CMADDMT67ZE bit is 1 and the POECMPEX1.POEREQ4 bit or the POECMPSEL.POEREQ4 bit is 1.

When the POECMPFR.C5FLAG flag becomes 1 while the POECR4B.CMADDMT67ZE bit is 1 and the POECMPEX1.POEREQ5 bit or the POECMPSEL.POEREQ5 bit is 1.

- Detection of oscillation stop  
When the ICSR6.OSTSTF flag becomes 1 while the ICSR6.OSTSTE bit is 1.

#### (5) MTU7 pins (MTIOC7A, MTIOC7C)

When one of the following conditions is satisfied while the POECR2.MTU7ACZE bit is 1, the pins become high-impedance. Furthermore, when the POECR2.MTU7ACZE bit is 0 and the PMMCR1.MTU7AME and MTU7CME bits are 1 and when one of the following conditions is satisfied, the pins are switched to general I/O port pins.

- Operation for comparison of the output levels on the MTIOC7A and MTIOC7C signals  
When the OCSR2.OSF2 flag becomes 1 while the OCSR2.OCE2 bit is 1.
- SPOER setting  
When the SPOER.MTUCH67HIZ bit is set to 1.
- Conditions added by POECR4B  
When the ICSR1.POE0F flag becomes 1 while the POECR4B.IC1ADDMT67ZE bit is 1.  
When the ICSR2.POE4F flag becomes 1 while the POECR4B.IC2ADDMT67ZE bit is 1.  
When the ICSR3.POE8F flag becomes 1 while the POECR4B.IC3ADDMT67ZE bit and the ICSR3.POE8E bit are 1.  
When the ICSR4.POE10F flag becomes 1 while the POECR4B.IC4ADDMT67ZE bit and the ICSR4.POE10E bit are 1.  
When the ICSR5.POE11F flag becomes 1 while the POECR4B.IC5ADDMT67ZE bit and the ICSR5.POE11E bit are 1.  
When the ICSR7.POE12F flag becomes 1 while the POECR4B.IC6ADDMT67ZE bit and the ICSR7.POE12E bit are 1.  
When the ICSR8.POE9F flag becomes 1 while the POECR4B.IC8ADDMT67ZE bit and the ICSR8.POE9E bit are 1.  
When the ICSR9.POE13F flag becomes 1 while the POECR4B.IC9ADDMT67ZE bit and the ICSR9.POE13E bit are 1.  
When the ICSR10.POE14F flag becomes 1 while the POECR4B.IC10ADDMT67ZE bit and the ICSR10.POE14E bit are 1.
- Comparator output detection  
When the POECMPFR.C0FLAG flag becomes 1 while the POECR4B.CMADDMT67ZE bit is 1 and the POECMPEX1.POEREQ0 bit or the POECMPSEL.POEREQ0 bit is 1.  
When the POECMPFR.C1FLAG flag becomes 1 while the POECR4B.CMADDMT67ZE bit is 1 and the POECMPEX1.POEREQ1 bit or the POECMPSEL.POEREQ1 bit is 1.  
When the POECMPFR.C2FLAG flag becomes 1 while the POECR4B.CMADDMT67ZE bit is 1 and the POECMPEX1.POEREQ2 bit or the POECMPSEL.POEREQ2 bit is 1.  
When the POECMPFR.C3FLAG flag becomes 1 while the POECR4B.CMADDMT67ZE bit is 1 and the POECMPEX1.POEREQ3 bit or the POECMPSEL.POEREQ3 bit is 1.

When the POECMPFR.C4FLAG flag becomes 1 while the POECR4B.CMADDMT67ZE bit is 1 and the POECMPEX1.POEREQ4 bit or the POECMPSEL.POEREQ4 bit is 1.

When the POECMPFR.C5FLAG flag becomes 1 while the POECR4B.CMADDMT67ZE bit is 1 and the POECMPEX1.POEREQ5 bit or the POECMPSEL.POEREQ5 bit is 1.

- Detection of oscillation stop  
When the ICSR6.OSTSTF flag becomes 1 while the ICSR6.OSTSTE bit is 1.

#### (6) MTU7 pins (MTIOC7B, MTIOC7D)

When one of the following conditions is satisfied while the POECR2.MTU7BDZE bit is 1, the pins become high-impedance. Furthermore, when the POECR2.MTU7BDZE bit is 0 and the PMMCR1.MTU7BME and MTU7DME bits are 1 and when one of the following conditions is satisfied, the pins are switched to general I/O port pins.

- Operation for comparison of the output levels on the MTIOC7B and MTIOC7D signals  
When the OCSR2.OSF2 flag becomes 1 while the OCSR2.OCE2 bit is 1.
- SPOER setting  
When the SPOER.MTUCH67HIZ bit is set to 1.
- Conditions added by POECR4B  
When the ICSR1.POE0F flag becomes 1 while the POECR4B.IC1ADDMT67ZE bit is 1.  
When the ICSR2.POE4F flag becomes 1 while the POECR4B.IC2ADDMT67ZE bit is 1.  
When the ICSR3.POE8F flag becomes 1 while the POECR4B.IC3ADDMT67ZE bit and the ICSR3.POE8E bit are 1.  
When the ICSR4.POE10F flag becomes 1 while the POECR4B.IC4ADDMT67ZE bit and the ICSR4.POE10E bit are 1.  
When the ICSR5.POE11F flag becomes 1 while the POECR4B.IC5ADDMT67ZE bit and the ICSR5.POE11E bit are 1.  
When the ICSR7.POE12F flag becomes 1 while the POECR4B.IC6ADDMT67ZE bit and the ICSR7.POE12E bit are 1.  
When the ICSR8.POE9F flag becomes 1 while the POECR4B.IC8ADDMT67ZE bit and the ICSR8.POE9E bit are 1.  
When the ICSR9.POE13F flag becomes 1 while the POECR4B.IC9ADDMT67ZE bit and the ICSR9.POE13E bit are 1.  
When the ICSR10.POE14F flag becomes 1 while the POECR4B.IC10ADDMT67ZE bit and the ICSR10.POE14E bit are 1.
- Comparator output detection  
When the POECMPFR.C0FLAG flag becomes 1 while the POECR4B.CMADDMT67ZE bit is 1 and the POECMPEX1.POEREQ0 bit or the POECMPSEL.POEREQ0 bit is 1.  
When the POECMPFR.C1FLAG flag becomes 1 while the POECR4B.CMADDMT67ZE bit is 1 and the POECMPEX1.POEREQ1 bit or the POECMPSEL.POEREQ1 bit is 1.  
When the POECMPFR.C2FLAG flag becomes 1 while the POECR4B.CMADDMT67ZE bit is 1 and the POECMPEX1.POEREQ2 bit or the POECMPSEL.POEREQ2 bit is 1.  
When the POECMPFR.C3FLAG flag becomes 1 while the POECR4B.CMADDMT67ZE bit is 1 and the POECMPEX1.POEREQ3 bit or the POECMPSEL.POEREQ3 bit is 1.  
When the POECMPFR.C4FLAG flag becomes 1 while the POECR4B.CMADDMT67ZE bit is 1 and the POECMPEX1.POEREQ4 bit or the POECMPSEL.POEREQ4 bit is 1.  
When the POECMPFR.C5FLAG flag becomes 1 while the POECR4B.CMADDMT67ZE bit is 1 and the POECMPEX1.POEREQ5 bit or the POECMPSEL.POEREQ5 bit is 1.
- Detection of oscillation stop  
When the ICSR6.OSTSTF flag becomes 1 while the ICSR6.OSTSTE bit is 1.

## (7) MTU0 pin (MTIOC0A)

When one of the following conditions is satisfied while the POECR1.MTU0AZE bit is 1, the pins become high-impedance. Furthermore, when the POECR1.MTU0AZE bit is 0 and the PMMCR0.MTU0AME bit is 1 and when one of the following conditions is satisfied, the pins are switched to general I/O port pins.

- SPOER setting
  - When the SPOER.MTUCH0HIZ bit is set to 1.
- Conditions added by POECR5
  - When the ICSR1.POE0F flag becomes 1 while the POECR5.IC1ADDMT0ZE bit is 1.
  - When the ICSR2.POE4F flag becomes 1 while the POECR5.IC2ADDMT0ZE bit is 1.
  - When the ICSR3.POE8F flag becomes 1 while the POECR5.IC3ADDMT0ZE bit and the ICSR3.POE8E bit are 1.
  - When the ICSR4.POE10F flag becomes 1 while the POECR5.IC4ADDMT0ZE bit and the ICSR4.POE10E bit are 1.
  - When the ICSR5.POE11F flag becomes 1 while the POECR5.IC5ADDMT0ZE bit and the ICSR5.POE11E bit are 1.
  - When the ICSR7.POE12F flag becomes 1 while the POECR5.IC6ADDMT0ZE bit and the ICSR7.POE12E bit are 1.
  - When the ICSR8.POE9F flag becomes 1 while the POECR5.IC8ADDMT0ZE bit and the ICSR8.POE9E bit are 1.
  - When the ICSR9.POE13F flag becomes 1 while the POECR5.IC9ADDMT0ZE bit and the ICSR9.POE13E bit are 1.
  - When the ICSR10.POE14F flag becomes 1 while the POECR5.IC10ADDMT0ZE bit and the ICSR10.POE14E bit are 1.
- Comparator output detection
  - When the POECMPFR.C0FLAG flag becomes 1 while the POECR5.CMADDMT0ZE bit is 1 and the POECMPX2.POEREQ0 bit or the POECMPSEL.POEREQ0 bit is 1.
  - When the POECMPFR.C1FLAG flag becomes 1 while the POECR5.CMADDMT0ZE bit is 1 and the POECMPX2.POEREQ1 bit or the POECMPSEL.POEREQ1 bit is 1.
  - When the POECMPFR.C2FLAG flag becomes 1 while the POECR5.CMADDMT0ZE bit is 1 and the POECMPX2.POEREQ2 bit or the POECMPSEL.POEREQ2 bit is 1.
  - When the POECMPFR.C3FLAG flag becomes 1 while the POECR5.CMADDMT0ZE bit is 1 and the POECMPX2.POEREQ3 bit or the POECMPSEL.POEREQ3 bit is 1.
  - When the POECMPFR.C4FLAG flag becomes 1 while the POECR5.CMADDMT0ZE bit is 1 and the POECMPX2.POEREQ4 bit or the POECMPSEL.POEREQ4 bit is 1.
  - When the POECMPFR.C5FLAG flag becomes 1 while the POECR5.CMADDMT0ZE bit is 1 and the POECMPX2.POEREQ5 bit or the POECMPSEL.POEREQ5 bit is 1.
- Detection of oscillation stop
  - When the ICSR6.OSTSTF flag becomes 1 while the ICSR6.OSTSTE bit is 1.

## (8) MTU0 pin (MTIOC0B)

When one of the following conditions is satisfied while the POECR1.MTU0BZE bit is 1, the pins become high-impedance. Furthermore, when the POECR1.MTU0BZE bit is 0 and the PMMCR0.MTU0BME bit is 1 and when one of the following conditions is satisfied, the pins are switched to general I/O port pins.

- SPOER setting
  - When the SPOER.MTUCH0HIZ bit is set to 1.
- Conditions added by POECR5
  - When the ICSR1.POE0F flag becomes 1 while the POECR5.IC1ADDMT0ZE bit is 1.
  - When the ICSR2.POE4F flag becomes 1 while the POECR5.IC2ADDMT0ZE bit is 1.
  - When the ICSR3.POE8F flag becomes 1 while the POECR5.IC3ADDMT0ZE bit and the ICSR3.POE8E bit are 1.
  - When the ICSR4.POE10F flag becomes 1 while the POECR5.IC4ADDMT0ZE bit and the ICSR4.POE10E bit are 1.

When the ICSR5.POE11F flag becomes 1 while the POECR5.IC5ADDMT0ZE bit and the ICSR5.POE11E bit are 1.

When the ICSR7.POE12F flag becomes 1 while the POECR5.IC6ADDMT0ZE bit and the ICSR7.POE12E bit are 1.

When the ICSR8.POE9F flag becomes 1 while the POECR5.IC8ADDMT0ZE bit and the ICSR8.POE9E bit are 1.

When the ICSR9.POE13F flag becomes 1 while the POECR5.IC9ADDMT0ZE bit and the ICSR9.POE13E bit are 1.

When the ICSR10.POE14F flag becomes 1 while the POECR5.IC10ADDMT0ZE bit and the ICSR10.POE14E bit are 1.

- Comparator output detection

When the POECMPFR.C0FLAG flag becomes 1 while the POECR5.CMADDMT0ZE bit is 1 and the POECMPX2.POEREQ0 bit or the POECMPSEL.POEREQ0 bit is 1.

When the POECMPFR.C1FLAG flag becomes 1 while the POECR5.CMADDMT0ZE bit is 1 and the POECMPX2.POEREQ1 bit or the POECMPSEL.POEREQ1 bit is 1.

When the POECMPFR.C2FLAG flag becomes 1 while the POECR5.CMADDMT0ZE bit is 1 and the POECMPX2.POEREQ2 bit or the POECMPSEL.POEREQ2 bit is 1.

When the POECMPFR.C3FLAG flag becomes 1 while the POECR5.CMADDMT0ZE bit is 1 and the POECMPX2.POEREQ3 bit or the POECMPSEL.POEREQ3 bit is 1.

When the POECMPFR.C4FLAG flag becomes 1 while the POECR5.CMADDMT0ZE bit is 1 and the POECMPX2.POEREQ4 bit or the POECMPSEL.POEREQ4 bit is 1.

When the POECMPFR.C5FLAG flag becomes 1 while the POECR5.CMADDMT0ZE bit is 1 and the POECMPX2.POEREQ5 bit or the POECMPSEL.POEREQ5 bit is 1.

- Detection of oscillation stop

When the ICSR6.OSTSTF flag becomes 1 while the ICSR6.OSTSTE bit is 1.

#### (9) MTU0 pin (MTIOC0C)

When one of the following conditions is satisfied while the POECR1.MTU0CZE bit is 1, the pins become high-impedance. Furthermore, when the POECR1.MTU0CZE bit is 0 and the PMMCR0.MTU0CME bit is 1 and when one of the following conditions is satisfied, the pins are switched to general I/O port pins.

- SPOER setting

When the SPOER.MTUCH0HIZ bit is set to 1.

- Conditions added by POECR5

When the ICSR1.POE0F flag becomes 1 while the POECR5.IC1ADDMT0ZE bit is 1.

When the ICSR2.POE4F flag becomes 1 while the POECR5.IC2ADDMT0ZE bit is 1.

When the ICSR3.POE8F flag becomes 1 while the POECR5.IC3ADDMT0ZE bit and the ICSR3.POE8E bit are 1.

When the ICSR4.POE10F flag becomes 1 while the POECR5.IC4ADDMT0ZE bit and the ICSR4.POE10E bit are 1.

When the ICSR5.POE11F flag becomes 1 while the POECR5.IC5ADDMT0ZE bit and the ICSR5.POE11E bit are 1.

When the ICSR7.POE12F flag becomes 1 while the POECR5.IC6ADDMT0ZE bit and the ICSR7.POE12E bit are 1.

When the ICSR8.POE9F flag becomes 1 while the POECR5.IC8ADDMT0ZE bit and the ICSR8.POE9E bit are 1.

When the ICSR9.POE13F flag becomes 1 while the POECR5.IC9ADDMT0ZE bit and the ICSR9.POE13E bit are 1.

When the ICSR10.POE14F flag becomes 1 while the POECR5.IC10ADDMT0ZE bit and the ICSR10.POE14E bit are 1.

- Comparator output detection

When the POECMPFR.C0FLAG flag becomes 1 while the POECR5.CMADDMT0ZE bit is 1 and the POECMPX2.POEREQ0 bit or the POECMPSEL.POEREQ0 bit is 1.

When the POECMPFR.C1FLAG flag becomes 1 while the POECR5.CMADDMT0ZE bit is 1 and the POECMPEX2.POEREQ1 bit or the POECMPSEL.POEREQ1 bit is 1.

When the POECMPFR.C2FLAG flag becomes 1 while the POECR5.CMADDMT0ZE bit is 1 and the POECMPEX2.POEREQ2 bit or the POECMPSEL.POEREQ2 bit is 1.

When the POECMPFR.C3FLAG flag becomes 1 while the POECR5.CMADDMT0ZE bit is 1 and the POECMPEX2.POEREQ3 bit or the POECMPSEL.POEREQ3 bit is 1.

When the POECMPFR.C4FLAG flag becomes 1 while the POECR5.CMADDMT0ZE bit is 1 and the POECMPEX2.POEREQ4 bit or the POECMPSEL.POEREQ4 bit is 1.

When the POECMPFR.C5FLAG flag becomes 1 while the POECR5.CMADDMT0ZE bit is 1 and the POECMPEX2.POEREQ5 bit or the POECMPSEL.POEREQ5 bit is 1.

- Detection of oscillation stop  
When the ICSR6.OSTSTF flag becomes 1 while the ICSR6.OSTSTE bit is 1.

#### (10) MTU0 pin (MTIOC0D)

When one of the following conditions is satisfied while the POECR1.MTU0DZE bit is 1, the pins become high-impedance. Furthermore, when the POECR1.MTU0DZE bit is 0 and the PMMCR0.MTU0DME bit is 1 and when one of the following conditions is satisfied, the pins are switched to general I/O port pins.

- SPOER setting  
When the SPOER.MTUCH0HIZ bit is set to 1.
- Conditions added by POECR5  
When the ICSR1.POE0F flag becomes 1 while the POECR5.IC1ADDMT0ZE bit is 1.  
When the ICSR2.POE4F flag becomes 1 while the POECR5.IC2ADDMT0ZE bit is 1.  
When the ICSR3.POE8F flag becomes 1 while the POECR5.IC3ADDMT0ZE bit and the ICSR3.POE8E bit are 1.  
When the ICSR4.POE10F flag becomes 1 while the POECR5.IC4ADDMT0ZE bit and the ICSR4.POE10E bit are 1.  
When the ICSR5.POE11F flag becomes 1 while the POECR5.IC5ADDMT0ZE bit and the ICSR5.POE11E bit are 1.  
When the ICSR7.POE12F flag becomes 1 while the POECR5.IC6ADDMT0ZE bit and the ICSR7.POE12E bit are 1.  
When the ICSR8.POE9F flag becomes 1 while the POECR5.IC8ADDMT0ZE bit and the ICSR8.POE9E bit are 1.  
When the ICSR9.POE13F flag becomes 1 while the POECR5.IC9ADDMT0ZE bit and the ICSR9.POE13E bit are 1.  
When the ICSR10.POE14F flag becomes 1 while the POECR5.IC10ADDMT0ZE bit and the ICSR10.POE14E bit are 1.
- Comparator output detection  
When the POECMPFR.C0FLAG flag becomes 1 while the POECR5.CMADDMT0ZE bit is 1 and the POECMPEX2.POEREQ0 bit or the POECMPSEL.POEREQ0 bit is 1.  
When the POECMPFR.C1FLAG flag becomes 1 while the POECR5.CMADDMT0ZE bit is 1 and the POECMPEX2.POEREQ1 bit or the POECMPSEL.POEREQ1 bit is 1.  
When the POECMPFR.C2FLAG flag becomes 1 while the POECR5.CMADDMT0ZE bit is 1 and the POECMPEX2.POEREQ2 bit or the POECMPSEL.POEREQ2 bit is 1.  
When the POECMPFR.C3FLAG flag becomes 1 while the POECR5.CMADDMT0ZE bit is 1 and the POECMPEX2.POEREQ3 bit or the POECMPSEL.POEREQ3 bit is 1.  
When the POECMPFR.C4FLAG flag becomes 1 while the POECR5.CMADDMT0ZE bit is 1 and the POECMPEX2.POEREQ4 bit or the POECMPSEL.POEREQ4 bit is 1.  
When the POECMPFR.C5FLAG flag becomes 1 while the POECR5.CMADDMT0ZE bit is 1 and the POECMPEX2.POEREQ5 bit or the POECMPSEL.POEREQ5 bit is 1.
- Detection of oscillation stop  
When the ICSR6.OSTSTF flag becomes 1 while the ICSR6.OSTSTE bit is 1.

## (11) MTU9 pin (MTIOC9A)

When one of the following conditions is satisfied while the POECR7.MTU9AZE bit is 1, the pins become high-impedance. Furthermore, when the POECR7.MTU9AZE bit is 0 and the PMMCR0.MTU9AME bit is 1 and when one of the following conditions is satisfied, the pins are switched to general I/O port pins.

- SPOER setting
  - When the SPOER.MTUCH9HIZ bit is set to 1.
- Conditions added by POECR8
  - When the ICSR1.POE0F flag becomes 1 while the POECR8.IC1ADDMT9ZE bit is 1.
  - When the ICSR2.POE4F flag becomes 1 while the POECR8.IC2ADDMT9ZE bit is 1.
  - When the ICSR3.POE8F flag becomes 1 while the POECR8.IC3ADDMT9ZE bit and the ICSR3.POE8E bit are 1.
  - When the ICSR4.POE10F flag becomes 1 while the POECR8.IC4ADDMT9ZE bit and the ICSR4.POE10E bit are 1.
  - When the ICSR5.POE11F flag becomes 1 while the POECR8.IC5ADDMT9ZE bit and the ICSR5.POE11E bit are 1.
  - When the ICSR7.POE12F flag becomes 1 while the POECR8.IC6ADDMT9ZE bit and the ICSR7.POE12E bit are 1.
  - When the ICSR8.POE9F flag becomes 1 while the POECR8.IC8ADDMT9ZE bit and the ICSR8.POE9E bit are 1.
  - When the ICSR9.POE13F flag becomes 1 while the POECR8.IC9ADDMT9ZE bit and the ICSR9.POE13E bit are 1.
  - When the ICSR10.POE14F flag becomes 1 while the POECR8.IC10ADDMT9ZE bit and the ICSR10.POE14E bit are 1.
- Comparator output detection
  - When the POECMPFR.C0FLAG flag becomes 1 while the POECR8.CMADDMT9ZE bit is 1 and the POECMPX3.POEREQ0 bit or the POECMPSEL.POEREQ0 bit is 1.
  - When the POECMPFR.C1FLAG flag becomes 1 while the POECR8.CMADDMT9ZE bit is 1 and the POECMPX3.POEREQ1 bit or the POECMPSEL.POEREQ1 bit is 1.
  - When the POECMPFR.C2FLAG flag becomes 1 while the POECR8.CMADDMT9ZE bit is 1 and the POECMPX3.POEREQ2 bit or the POECMPSEL.POEREQ2 bit is 1.
  - When the POECMPFR.C3FLAG flag becomes 1 while the POECR8.CMADDMT9ZE bit is 1 and the POECMPX3.POEREQ3 bit or the POECMPSEL.POEREQ3 bit is 1.
  - When the POECMPFR.C4FLAG flag becomes 1 while the POECR8.CMADDMT9ZE bit is 1 and the POECMPX3.POEREQ4 bit or the POECMPSEL.POEREQ4 bit is 1.
  - When the POECMPFR.C5FLAG flag becomes 1 while the POECR8.CMADDMT9ZE bit is 1 and the POECMPX3.POEREQ5 bit or the POECMPSEL.POEREQ5 bit is 1.
- Detection of oscillation stop
  - When the ICSR6.OSTSTF flag becomes 1 while the ICSR6.OSTSTE bit is 1.

## (12) MTU9 pin (MTIOC9B)

When one of the following conditions is satisfied while the POECR7.MTU9BZE bit is 1, the pins become high-impedance. Furthermore, when the POECR7.MTU9BZE bit is 0 and the PMMCR0.MTU9BME bit is 1 and when one of the following conditions is satisfied, the pins are switched to general I/O port pins.

- SPOER setting
  - When the SPOER.MTUCH9HIZ bit is set to 1.
- Conditions added by POECR8
  - When the ICSR1.POE0F flag becomes 1 while the POECR8.IC1ADDMT9ZE bit is 1.
  - When the ICSR2.POE4F flag becomes 1 while the POECR8.IC2ADDMT9ZE bit is 1.
  - When the ICSR3.POE8F flag becomes 1 while the POECR8.IC3ADDMT9ZE bit and the ICSR3.POE8E bit are 1.
  - When the ICSR4.POE10F flag becomes 1 while the POECR8.IC4ADDMT9ZE bit and the ICSR4.POE10E bit are 1.

When the ICSR5.POE11F flag becomes 1 while the POECR8.IC5ADDMT9ZE bit and the ICSR5.POE11E bit are 1.

When the ICSR7.POE12F flag becomes 1 while the POECR8.IC6ADDMT9ZE bit and the ICSR7.POE12E bit are 1.

When the ICSR8.POE9F flag becomes 1 while the POECR8.IC8ADDMT9ZE bit and the ICSR8.POE9E bit are 1.

When the ICSR9.POE13F flag becomes 1 while the POECR8.IC9ADDMT9ZE bit and the ICSR9.POE13E bit are 1.

When the ICSR10.POE14F flag becomes 1 while the POECR8.IC10ADDMT9ZE bit and the ICSR10.POE14E bit are 1.

- Comparator output detection

When the POECMPFR.C0FLAG flag becomes 1 while the POECR8.CMADDMT9ZE bit is 1 and the POECMPEX3.POEREQ0 bit or the POECMPSEL.POEREQ0 bit is 1.

When the POECMPFR.C1FLAG flag becomes 1 while the POECR8.CMADDMT9ZE bit is 1 and the POECMPEX3.POEREQ1 bit or the POECMPSEL.POEREQ1 bit is 1.

When the POECMPFR.C2FLAG flag becomes 1 while the POECR8.CMADDMT9ZE bit is 1 and the POECMPEX3.POEREQ2 bit or the POECMPSEL.POEREQ2 bit is 1.

When the POECMPFR.C3FLAG flag becomes 1 while the POECR8.CMADDMT9ZE bit is 1 and the POECMPEX3.POEREQ3 bit or the POECMPSEL.POEREQ3 bit is 1.

When the POECMPFR.C4FLAG flag becomes 1 while the POECR8.CMADDMT9ZE bit is 1 and the POECMPEX3.POEREQ4 bit or the POECMPSEL.POEREQ4 bit is 1.

When the POECMPFR.C5FLAG flag becomes 1 while the POECR8.CMADDMT9ZE bit is 1 and the POECMPEX3.POEREQ5 bit or the POECMPSEL.POEREQ5 bit is 1.

- Detection of oscillation stop

When the ICSR6.OSTSTF flag becomes 1 while the ICSR6.OSTSTE bit is 1.

### (13) MTU9 pin (MTIOC9C)

When one of the following conditions is satisfied while the POECR7.MTU9CZE bit is 1, the pins become high-impedance. Furthermore, when the POECR7.MTU9CZE bit is 0 and the PMMCR0.MTU9CME bit is 1 and when one of the following conditions is satisfied, the pins are switched to general I/O port pins.

- SPOER setting

When the SPOER.MTUCH9HIZ bit is set to 1.

- Conditions added by POECR8

When the ICSR1.POE0F flag becomes 1 while the POECR8.IC1ADDMT9ZE bit is 1.

When the ICSR2.POE4F flag becomes 1 while the POECR8.IC2ADDMT9ZE bit is 1.

When the ICSR3.POE8F flag becomes 1 while the POECR8.IC3ADDMT9ZE bit and the ICSR3.POE8E bit are 1.

When the ICSR4.POE10F flag becomes 1 while the POECR8.IC4ADDMT9ZE bit and the ICSR4.POE10E bit are 1.

When the ICSR5.POE11F flag becomes 1 while the POECR8.IC5ADDMT9ZE bit and the ICSR5.POE11E bit are 1.

When the ICSR7.POE12F flag becomes 1 while the POECR8.IC6ADDMT9ZE bit and the ICSR7.POE12E bit are 1.

When the ICSR8.POE9F flag becomes 1 while the POECR8.IC8ADDMT9ZE bit and the ICSR8.POE9E bit are 1.

When the ICSR9.POE13F flag becomes 1 while the POECR8.IC9ADDMT9ZE bit and the ICSR9.POE13E bit are 1.

When the ICSR10.POE14F flag becomes 1 while the POECR8.IC10ADDMT9ZE bit and the ICSR10.POE14E bit are 1.

- Comparator output detection

When the POECMPFR.C0FLAG flag becomes 1 while the POECR8.CMADDMT9ZE bit is 1 and the POECMPEX3.POEREQ0 bit or the POECMPSEL.POEREQ0 bit is 1.

When the POECMPFR.C1FLAG flag becomes 1 while the POECR8.CMADDMT9ZE bit is 1 and the POECMPEX3.POEREQ1 bit or the POECMPSEL.POEREQ1 bit is 1.

When the POECMPFR.C2FLAG flag becomes 1 while the POECR8.CMADDMT9ZE bit is 1 and the POECMPEX3.POEREQ2 bit or the POECMPSEL.POEREQ2 bit is 1.

When the POECMPFR.C3FLAG flag becomes 1 while the POECR8.CMADDMT9ZE bit is 1 and the POECMPEX3.POEREQ3 bit or the POECMPSEL.POEREQ3 bit is 1.

When the POECMPFR.C4FLAG flag becomes 1 while the POECR8.CMADDMT9ZE bit is 1 and the POECMPEX3.POEREQ4 bit or the POECMPSEL.POEREQ4 bit is 1.

When the POECMPFR.C5FLAG flag becomes 1 while the POECR8.CMADDMT9ZE bit is 1 and the POECMPEX3.POEREQ5 bit or the POECMPSEL.POEREQ5 bit is 1.

- Detection of oscillation stop  
When the ICSR6.OSTSTF flag becomes 1 while the ICSR6.OSTSTE bit is 1.

#### (14) MTU9 pin (MTIOC9D)

When one of the following conditions is satisfied while the POECR7.MTU9DZE bit is 1, the pins become high-impedance. Furthermore, when the POECR7.MTU9DZE bit is 0 and the PMMCR0.MTU9DME bit is 1 and when one of the following conditions is satisfied, the pins are switched to general I/O port pins.

- SPOER setting  
When the SPOER.MTUCH9HIZ bit is set to 1.
- Conditions added by POECR8  
When the ICSR1.POE0F flag becomes 1 while the POECR8.IC1ADDMT9ZE bit is 1.  
When the ICSR2.POE4F flag becomes 1 while the POECR8.IC2ADDMT9ZE bit is 1.  
When the ICSR3.POE8F flag becomes 1 while the POECR8.IC3ADDMT9ZE bit and the ICSR3.POE8E bit are 1.  
When the ICSR4.POE10F flag becomes 1 while the POECR8.IC4ADDMT9ZE bit and the ICSR4.POE10E bit are 1.  
When the ICSR5.POE11F flag becomes 1 while the POECR8.IC5ADDMT9ZE bit and the ICSR5.POE11E bit are 1.  
When the ICSR7.POE12F flag becomes 1 while the POECR8.IC6ADDMT9ZE bit and the ICSR7.POE12E bit are 1.  
When the ICSR8.POE9F flag becomes 1 while the POECR8.IC8ADDMT9ZE bit and the ICSR8.POE9E bit are 1.  
When the ICSR9.POE13F flag becomes 1 while the POECR8.IC9ADDMT9ZE bit and the ICSR9.POE13E bit are 1.  
When the ICSR10.POE14F flag becomes 1 while the POECR8.IC10ADDMT9ZE bit and the ICSR10.POE14E bit are 1.
- Comparator output detection  
When the POECMPFR.C0FLAG flag becomes 1 while the POECR8.CMADDMT9ZE bit is 1 and the POECMPEX3.POEREQ0 bit or the POECMPSEL.POEREQ0 bit is 1.  
When the POECMPFR.C1FLAG flag becomes 1 while the POECR8.CMADDMT9ZE bit is 1 and the POECMPEX3.POEREQ1 bit or the POECMPSEL.POEREQ1 bit is 1.  
When the POECMPFR.C2FLAG flag becomes 1 while the POECR8.CMADDMT9ZE bit is 1 and the POECMPEX3.POEREQ2 bit or the POECMPSEL.POEREQ2 bit is 1.  
When the POECMPFR.C3FLAG flag becomes 1 while the POECR8.CMADDMT9ZE bit is 1 and the POECMPEX3.POEREQ3 bit or the POECMPSEL.POEREQ3 bit is 1.  
When the POECMPFR.C4FLAG flag becomes 1 while the POECR8.CMADDMT9ZE bit is 1 and the POECMPEX3.POEREQ4 bit or the POECMPSEL.POEREQ4 bit is 1.  
When the POECMPFR.C5FLAG flag becomes 1 while the POECR8.CMADDMT9ZE bit is 1 and the POECMPEX3.POEREQ5 bit or the POECMPSEL.POEREQ5 bit is 1.
- Detection of oscillation stop  
When the ICSR6.OSTSTF flag becomes 1 while the ICSR6.OSTSTE bit is 1.

## (15) GPTW0 pins (GTIOC0A, GTIOC0B)

When one of the following conditions is satisfied while the POECR3.GPT0ABZE bit is 1, the pins become high-impedance. Furthermore, when the POECR3.GPT0ABZE bit is 0 and the PMMCR2.GPT0AME and GPT0BME bits are 1 and when one of the following conditions is satisfied, the pins are switched to general I/O port pins.

- Operation for comparison of the output levels on the GTIOC0A and GTIOC0B signals  
When the OCSR3.OSF3 flag becomes 1 while the OCSR3.OCE3 bit is 1.
- SPOER setting  
When the SPOER.GPT01HIZ bit is set to 1.  
When the SPOER.GPT02HIZ bit is set to 1.
- Conditions added by POECR6  
When the ICSR1.POE0F flag becomes 1 while the POECR6.IC1ADDGPT01ZE bit is 1.  
When the ICSR2.POE4F flag becomes 1 while the POECR6.IC2ADDGPT01ZE bit is 1.  
When the ICSR3.POE8F flag becomes 1 while the POECR6.IC3ADDGPT01ZE bit and the ICSR3.POE8E bit are 1.  
When the ICSR4.POE10F flag becomes 1 while the POECR6.IC4ADDGPT01ZE bit and the ICSR4.POE10E bit are 1.  
When the ICSR5.POE11F flag becomes 1 while the POECR6.IC5ADDGPT01ZE bit and the ICSR5.POE11E bit are 1.  
When the ICSR7.POE12F flag becomes 1 while the POECR6.IC6ADDGPT01ZE bit and the ICSR7.POE12E bit are 1.  
When the ICSR8.POE9F flag becomes 1 while the POECR6.IC8ADDGPT01ZE bit and the ICSR8.POE9E bit are 1.  
When the ICSR9.POE13F flag becomes 1 while the POECR6.IC9ADDGPT01ZE bit and the ICSR9.POE13E bit are 1.  
When the ICSR10.POE14F flag becomes 1 while the POECR6.IC10ADDGPT01ZE bit and the ICSR10.POE14E bit are 1.
- Conditions added by POECR9  
When the ICSR1.POE0F flag becomes 1 while the POECR9.IC1ADDGPT02ZE bit is 1.  
When the ICSR2.POE4F flag becomes 1 while the POECR9.IC2ADDGPT02ZE bit is 1.  
When the ICSR3.POE8F flag becomes 1 while the POECR9.IC3ADDGPT02ZE bit and the ICSR3.POE8E bit are 1.  
When the ICSR4.POE10F flag becomes 1 while the POECR9.IC4ADDGPT02ZE bit and the ICSR4.POE10E bit are 1.  
When the ICSR5.POE11F flag becomes 1 while the POECR9.IC5ADDGPT02ZE bit and the ICSR5.POE11E bit are 1.  
When the ICSR7.POE12F flag becomes 1 while the POECR9.IC6ADDGPT02ZE bit and the ICSR7.POE12E bit are 1.  
When the ICSR8.POE9F flag becomes 1 while the POECR9.IC8ADDGPT02ZE bit and the ICSR8.POE9E bit are 1.  
When the ICSR9.POE13F flag becomes 1 while the POECR9.IC9ADDGPT02ZE bit and the ICSR9.POE13E bit are 1.  
When the ICSR10.POE14F flag becomes 1 while the POECR9.IC10ADDGPT02ZE bit and the ICSR10.POE14E bit are 1.
- Comparator output detection  
When the POECMPFR.C0FLAG flag becomes 1 while the POECR6.CMADDGPT01ZE bit is 1 and the POECMPX4.POEREQ0 bit or the POECMPSEL.POEREQ0 bit is 1, or while the POECR9.CMADDGPT02ZE bit is 1 and the POECMPX6.POEREQ0 bit or the POECMPSEL.POEREQ0 bit is 1.  
When the POECMPFR.C1FLAG flag becomes 1 while the POECR6.CMADDGPT01ZE bit is 1 and the POECMPX4.POEREQ1 bit or the POECMPSEL.POEREQ1 bit is 1, or while the POECR9.CMADDGPT02ZE

bit is 1 and the POECMPEX6.POEREQ1 bit or the POECMPSEL.POEREQ1 bit is 1.

When the POECMPFR.C2FLAG flag becomes 1 while the POECR6.CMADDGPT01ZE bit is 1 and the POECMPEX4.POEREQ2 bit or the POECMPSEL.POEREQ2 bit is 1, or while the POECR9.CMADDGPT02ZE bit is 1 and the POECMPEX6.POEREQ2 bit or the POECMPSEL.POEREQ2 bit is 1.

When the POECMPFR.C3FLAG flag becomes 1 while the POECR6.CMADDGPT01ZE bit is 1 and the POECMPEX4.POEREQ3 bit or the POECMPSEL.POEREQ3 bit is 1, or while the POECR9.CMADDGPT02ZE bit is 1 and the POECMPEX6.POEREQ3 bit or the POECMPSEL.POEREQ3 bit is 1.

When the POECMPFR.C4FLAG flag becomes 1 while the POECR6.CMADDGPT01ZE bit is 1 and the POECMPEX4.POEREQ4 bit or the POECMPSEL.POEREQ4 bit is 1, or while the POECR9.CMADDGPT02ZE bit is 1 and the POECMPEX6.POEREQ4 bit or the POECMPSEL.POEREQ4 bit is 1.

When the POECMPFR.C5FLAG flag becomes 1 while the POECR6.CMADDGPT01ZE bit is 1 and the POECMPEX4.POEREQ5 bit or the POECMPSEL.POEREQ5 bit is 1, or while the POECR9.CMADDGPT02ZE bit is 1 and the POECMPEX6.POEREQ5 bit or the POECMPSEL.POEREQ5 bit is 1.

- Detection of oscillation stop

When the ICSR6.OSTSTF flag becomes 1 while the ICSR6.OSTSTE bit is 1.

#### (16) GPTW1 pins (GTIOC1A, GTIOC1B)

When one of the following conditions is satisfied while the POECR3.GPT1ABZE bit is 1, the pins become high-impedance. Furthermore, when the POECR3.GPT1ABZE bit is 0 and the PMMCR2.GPT1AME and GPT1BME bits are 1 and when one of the following conditions is satisfied, the pins are switched to general I/O port pins.

- Operation for comparison of the output levels on the GTIOC1A and GTIOC1B signals

When the OCSR3.OSF3 flag becomes 1 while the OCSR3.OCE3 bit is 1.

- SPOER setting

When the SPOER.GPT01HIZ bit is set to 1.

When the SPOER.GPT02HIZ bit is set to 1.

- Conditions added by POECR6

When the ICSR1.POE0F flag becomes 1 while the POECR6.IC1ADDGPT01ZE bit is 1.

When the ICSR2.POE4F flag becomes 1 while the POECR6.IC2ADDGPT01ZE bit is 1.

When the ICSR3.POE8F flag becomes 1 while the POECR6.IC3ADDGPT01ZE bit and the ICSR3.POE8E bit are 1.

When the ICSR4.POE10F flag becomes 1 while the POECR6.IC4ADDGPT01ZE bit and the ICSR4.POE10E bit are 1.

When the ICSR5.POE11F flag becomes 1 while the POECR6.IC5ADDGPT01ZE bit and the ICSR5.POE11E bit are 1.

When the ICSR7.POE12F flag becomes 1 while the POECR6.IC6ADDGPT01ZE bit and the ICSR7.POE12E bit are 1.

When the ICSR8.POE9F flag becomes 1 while the POECR6.IC8ADDGPT01ZE bit and the ICSR8.POE9E bit are 1.

When the ICSR9.POE13F flag becomes 1 while the POECR6.IC9ADDGPT01ZE bit and the ICSR9.POE13E bit are 1.

When the ICSR10.POE14F flag becomes 1 while the POECR6.IC10ADDGPT01ZE bit and the ICSR10.POE14E bit are 1.

- Conditions added by POECR9

When the ICSR1.POE0F flag becomes 1 while the POECR9.IC1ADDGPT02ZE bit is 1.

When the ICSR2.POE4F flag becomes 1 while the POECR9.IC2ADDGPT02ZE bit is 1.

When the ICSR3.POE8F flag becomes 1 while the POECR9.IC3ADDGPT02ZE bit and the ICSR3.POE8E bit are 1.

When the ICSR4.POE10F flag becomes 1 while the POECR9.IC4ADDGPT02ZE bit and the ICSR4.POE10E bit are 1.

When the ICSR5.POE11F flag becomes 1 while the POECR9.IC5ADDGPT02ZE bit and the ICSR5.POE11E bit are 1.

When the ICSR7.POE12F flag becomes 1 while the POECR9.IC6ADDGPT02ZE bit and the ICSR7.POE12E bit are 1.

When the ICSR8.POE9F flag becomes 1 while the POECR9.IC8ADDGPT02ZE bit and the ICSR8.POE9E bit are 1.

When the ICSR9.POE13F flag becomes 1 while the POECR9.IC9ADDGPT02ZE bit and the ICSR9.POE13E bit are 1.

When the ICSR10.POE14F flag becomes 1 while the POECR9.IC10ADDGPT02ZE bit and the ICSR10.POE14E bit are 1.

- Comparator output detection

When the POECMPFR.C0FLAG flag becomes 1 while the POECR6.CMADDGPT01ZE bit is 1 and the POECMPEX4.POEREQ0 bit or the POECMPSEL.POEREQ0 bit is 1, or while the POECR9.CMADDGPT02ZE bit is 1 and the POECMPEX6.POEREQ0 bit or the POECMPSEL.POEREQ0 bit is 1.

When the POECMPFR.C1FLAG flag becomes 1 while the POECR6.CMADDGPT01ZE bit is 1 and the POECMPEX4.POEREQ1 bit or the POECMPSEL.POEREQ1 bit is 1, or while the POECR9.CMADDGPT02ZE bit is 1 and the POECMPEX6.POEREQ1 bit or the POECMPSEL.POEREQ1 bit is 1.

When the POECMPFR.C2FLAG flag becomes 1 while the POECR6.CMADDGPT01ZE bit is 1 and the POECMPEX4.POEREQ2 bit or the POECMPSEL.POEREQ2 bit is 1, or while the POECR9.CMADDGPT02ZE bit is 1 and the POECMPEX6.POEREQ2 bit or the POECMPSEL.POEREQ2 bit is 1.

When the POECMPFR.C3FLAG flag becomes 1 while the POECR6.CMADDGPT01ZE bit is 1 and the POECMPEX4.POEREQ3 bit or the POECMPSEL.POEREQ3 bit is 1, or while the POECR9.CMADDGPT02ZE bit is 1 and the POECMPEX6.POEREQ3 bit or the POECMPSEL.POEREQ3 bit is 1.

When the POECMPFR.C4FLAG flag becomes 1 while the POECR6.CMADDGPT01ZE bit is 1 and the POECMPEX4.POEREQ4 bit or the POECMPSEL.POEREQ4 bit is 1, or while the POECR9.CMADDGPT02ZE bit is 1 and the POECMPEX6.POEREQ4 bit or the POECMPSEL.POEREQ4 bit is 1.

When the POECMPFR.C5FLAG flag becomes 1 while the POECR6.CMADDGPT01ZE bit is 1 and the POECMPEX4.POEREQ5 bit or the POECMPSEL.POEREQ5 bit is 1, or while the POECR9.CMADDGPT02ZE bit is 1 and the POECMPEX6.POEREQ5 bit or the POECMPSEL.POEREQ5 bit is 1.

- Detection of oscillation stop

When the ICSR6.OSTSTF flag becomes 1 while the ICSR6.OSTSTE bit is 1.

#### (17) GPTW2 pins (GTIOC2A, GTIOC2B)

When one of the following conditions is satisfied while the POECR3.GPT2ABZE bit is 1, the pins become high-impedance. Furthermore, when the POECR3.GPT2ABZE bit is 0 and the PMMCR2.GPT2AME and GPT2BME bits are 1 and when one of the following conditions is satisfied, the pins are switched to general I/O port pins.

- Operation for comparison of the output levels on the GTIOC2A and GTIOC2B signals

When the OCSR3.OSF3 flag becomes 1 while the OCSR3.OCE3 bit is 1.

- SPOER setting

When the SPOER.GPT23HIZ bit is set to 1.

When the SPOER.GPT02HIZ bit is set to 1.

- Conditions added by POECR6B

When the ICSR1.POE0F flag becomes 1 while the POECR6B.IC1ADDGPT23ZE bit is 1.

When the ICSR2.POE4F flag becomes 1 while the POECR6B.IC2ADDGPT23ZE bit is 1.

When the ICSR3.POE8F flag becomes 1 while the POECR6B.IC3ADDGPT23ZE bit and the ICSR3.POE8E bit are 1.

When the ICSR4.POE10F flag becomes 1 while the POECR6B.IC4ADDGPT23ZE bit and the ICSR4.POE10E bit are 1.

When the ICSR5.POE11F flag becomes 1 while the POECR6B.IC5ADDGPT23ZE bit and the ICSR5.POE11E bit

are 1.

When the ICSR7.POE12F flag becomes 1 while the POECR6B.IC6ADDGPT23ZE bit and the ICSR7.POE12E bit are 1.

When the ICSR8.POE9F flag becomes 1 while the POECR6B.IC8ADDGPT23ZE bit and the ICSR8.POE9E bit are 1.

When the ICSR9.POE13F flag becomes 1 while the POECR6B.IC9ADDGPT23ZE bit and the ICSR9.POE13E bit are 1.

When the ICSR10.POE14F flag becomes 1 while the POECR6B.IC10ADDGPT23ZE bit and the ICSR10.POE14E bit are 1.

- Conditions added by POECR9

When the ICSR1.POE0F flag becomes 1 while the POECR9.IC1ADDGPT02ZE bit is 1.

When the ICSR2.POE4F flag becomes 1 while the POECR9.IC2ADDGPT02ZE bit is 1.

When the ICSR3.POE8F flag becomes 1 while the POECR9.IC3ADDGPT02ZE bit and the ICSR3.POE8E bit are 1.

When the ICSR4.POE10F flag becomes 1 while the POECR9.IC4ADDGPT02ZE bit and the ICSR4.POE10E bit are 1.

When the ICSR5.POE11F flag becomes 1 while the POECR9.IC5ADDGPT02ZE bit and the ICSR5.POE11E bit are 1.

When the ICSR7.POE12F flag becomes 1 while the POECR9.IC6ADDGPT02ZE bit and the ICSR7.POE12E bit are 1.

When the ICSR8.POE9F flag becomes 1 while the POECR9.IC8ADDGPT02ZE bit and the ICSR8.POE9E bit are 1.

When the ICSR9.POE13F flag becomes 1 while the POECR9.IC9ADDGPT02ZE bit and the ICSR9.POE13E bit are 1.

When the ICSR10.POE14F flag becomes 1 while the POECR9.IC10ADDGPT02ZE bit and the ICSR10.POE14E bit are 1.

- Comparator output detection

When the POECMPFR.C0FLAG flag becomes 1 while the POECR6B.CMADDGPT23ZE bit is 1 and the POECMPEX5.POEREQ0 bit or the POECMPSEL.POEREQ0 bit is 1, or while the POECR9.CMADDGPT02ZE bit is 1 and the POECMPEX6.POEREQ0 bit or the POECMPSEL.POEREQ0 bit is 1.

When the POECMPFR.C1FLAG flag becomes 1 while the POECR6B.CMADDGPT23ZE bit is 1 and the POECMPEX5.POEREQ1 bit or the POECMPSEL.POEREQ1 bit is 1, or while the POECR9.CMADDGPT02ZE bit is 1 and the POECMPEX6.POEREQ1 bit or the POECMPSEL.POEREQ1 bit is 1.

When the POECMPFR.C2FLAG flag becomes 1 while the POECR6B.CMADDGPT23ZE bit is 1 and the POECMPEX5.POEREQ2 bit or the POECMPSEL.POEREQ2 bit is 1, or while the POECR9.CMADDGPT02ZE bit is 1 and the POECMPEX6.POEREQ2 bit or the POECMPSEL.POEREQ2 bit is 1.

When the POECMPFR.C3FLAG flag becomes 1 while the POECR6B.CMADDGPT23ZE bit is 1 and the POECMPEX5.POEREQ3 bit or the POECMPSEL.POEREQ3 bit is 1, or while the POECR9.CMADDGPT02ZE bit is 1 and the POECMPEX6.POEREQ3 bit or the POECMPSEL.POEREQ3 bit is 1.

When the POECMPFR.C4FLAG flag becomes 1 while the POECR6B.CMADDGPT23ZE bit is 1 and the POECMPEX5.POEREQ4 bit or the POECMPSEL.POEREQ4 bit is 1, or while the POECR9.CMADDGPT02ZE bit is 1 and the POECMPEX6.POEREQ4 bit or the POECMPSEL.POEREQ4 bit is 1.

When the POECMPFR.C5FLAG flag becomes 1 while the POECR6B.CMADDGPT23ZE bit is 1 and the POECMPEX5.POEREQ5 bit or the POECMPSEL.POEREQ5 bit is 1, or while the POECR9.CMADDGPT02ZE bit is 1 and the POECMPEX6.POEREQ5 bit or the POECMPSEL.POEREQ5 bit is 1.

- Detection of oscillation stop

When the ICSR6.OSTSTF flag becomes 1 while the ICSR6.OSTSTE bit is 1.

## (18) GPTW3 pins (GTIOC3A, GTIOC3B)

When one of the following conditions is satisfied while the POECR3.GPT3ABZE bit is 1, the pins become high-impedance. Furthermore, when the POECR3.GPT3ABZE bit is 0 and the PMMCR2.GPT3AME and GPT3BME bits are 1 and when one of the following conditions is satisfied, the pins are switched to general I/O port pins.

- SPOER setting
  - When the SPOER.GPT23HIZ bit is set to 1.
- Conditions added by POECR6B
  - When the ICSR1.POE0F flag becomes 1 while the POECR6B.IC1ADDGPT23ZE bit is 1.
  - When the ICSR2.POE4F flag becomes 1 while the POECR6B.IC2ADDGPT23ZE bit is 1.
  - When the ICSR3.POE8F flag becomes 1 while the POECR6B.IC3ADDGPT23ZE bit and the ICSR3.POE8E bit are 1.
  - When the ICSR4.POE10F flag becomes 1 while the POECR6B.IC4ADDGPT23ZE bit and the ICSR4.POE10E bit are 1.
  - When the ICSR5.POE11F flag becomes 1 while the POECR6B.IC5ADDGPT23ZE bit and the ICSR5.POE11E bit are 1.
  - When the ICSR7.POE12F flag becomes 1 while the POECR6B.IC6ADDGPT23ZE bit and the ICSR7.POE12E bit are 1.
  - When the ICSR8.POE9F flag becomes 1 while the POECR6B.IC8ADDGPT23ZE bit and the ICSR8.POE9E bit are 1.
  - When the ICSR9.POE13F flag becomes 1 while the POECR6B.IC9ADDGPT23ZE bit and the ICSR9.POE13E bit are 1.
  - When the ICSR10.POE14F flag becomes 1 while the POECR6B.IC10ADDGPT23ZE bit and the ICSR10.POE14E bit are 1.
- Comparator output detection
  - When the POECMPFR.C0FLAG flag becomes 1 while the POECR6B.CMADDGPT23ZE bit is 1 and the POECMPEX5.POEREQ0 bit or the POECMPSEL.POEREQ0 bit is 1.
  - When the POECMPFR.C1FLAG flag becomes 1 while the POECR6B.CMADDGPT23ZE bit is 1 and the POECMPEX5.POEREQ1 bit or the POECMPSEL.POEREQ1 bit is 1.
  - When the POECMPFR.C2FLAG flag becomes 1 while the POECR6B.CMADDGPT23ZE bit is 1 and the POECMPEX5.POEREQ2 bit or the POECMPSEL.POEREQ2 bit is 1.
  - When the POECMPFR.C3FLAG flag becomes 1 while the POECR6B.CMADDGPT23ZE bit is 1 and the POECMPEX5.POEREQ3 bit or the POECMPSEL.POEREQ3 bit is 1.
  - When the POECMPFR.C4FLAG flag becomes 1 while the POECR6B.CMADDGPT23ZE bit is 1 and the POECMPEX5.POEREQ4 bit or the POECMPSEL.POEREQ4 bit is 1.
  - When the POECMPFR.C5FLAG flag becomes 1 while the POECR6B.CMADDGPT23ZE bit is 1 and the POECMPEX5.POEREQ5 bit or the POECMPSEL.POEREQ5 bit is 1.
- Detection of oscillation stop
  - When the ICSR6.OSTSTF flag becomes 1 while the ICSR6.OSTSTE bit is 1.

## (19) GPTW4 pins (GTIOC4A, GTIOC4B)

When one of the following conditions is satisfied while the POECR3.GPT4ABZE bit is 1, the pins become high-impedance. Furthermore, when the POECR3.GPT4ABZE bit is 0 and the PMMCR2.GPT4AME and GPT4BME bits are 1 and when one of the following conditions is satisfied, the pins are switched to general I/O port pins.

- Operation for comparison of the output levels on the GTIOC4A and GTIOC4B signals
  - When the OCSR4.OSF4 flag becomes 1 while the OCSR4.OCE4 bit is 1.
- SPOER setting
  - When the SPOER.GPT46HIZ bit is set to 1.
- Conditions added by POECR10
  - When the ICSR1.POE0F flag becomes 1 while the POECR10.IC1ADDGPT46ZE bit is 1.

When the ICSR2.POE4F flag becomes 1 while the POECR10.IC2ADDGPT46ZE bit is 1.

When the ICSR3.POE8F flag becomes 1 while the POECR10.IC3ADDGPT46ZE bit and the ICSR3.POE8E bit are 1.

When the ICSR4.POE10F flag becomes 1 while the POECR10.IC4ADDGPT46ZE bit and the ICSR4.POE10E bit are 1.

When the ICSR5.POE11F flag becomes 1 while the POECR10.IC5ADDGPT46ZE bit and the ICSR5.POE11E bit are 1.

When the ICSR7.POE12F flag becomes 1 while the POECR10.IC6ADDGPT46ZE bit and the ICSR7.POE12E bit are 1.

When the ICSR8.POE9F flag becomes 1 while the POECR10.IC8ADDGPT46ZE bit and the ICSR8.POE9E bit are 1.

When the ICSR9.POE13F flag becomes 1 while the POECR10.IC9ADDGPT46ZE bit and the ICSR9.POE13E bit are 1.

When the ICSR10.POE14F flag becomes 1 while the POECR10.IC10ADDGPT46ZE bit and the ICSR10.POE14E bit are 1.

- Comparator output detection

When the POECMPFR.C0FLAG flag becomes 1 while the POECR10.CMADDGPT46ZE bit is 1 and the POECMPEX7.POEREQ0 bit or the POECMPSEL.POEREQ0 bit is 1.

When the POECMPFR.C1FLAG flag becomes 1 while the POECR10.CMADDGPT46ZE bit is 1 and the POECMPEX7.POEREQ1 bit or the POECMPSEL.POEREQ1 bit is 1.

When the POECMPFR.C2FLAG flag becomes 1 while the POECR10.CMADDGPT46ZE bit is 1 and the POECMPEX7.POEREQ2 bit or the POECMPSEL.POEREQ2 bit is 1.

When the POECMPFR.C3FLAG flag becomes 1 while the POECR10.CMADDGPT46ZE bit is 1 and the POECMPEX7.POEREQ3 bit or the POECMPSEL.POEREQ3 bit is 1.

When the POECMPFR.C4FLAG flag becomes 1 while the POECR10.CMADDGPT46ZE bit is 1 and the POECMPEX7.POEREQ4 bit or the POECMPSEL.POEREQ4 bit is 1.

When the POECMPFR.C5FLAG flag becomes 1 while the POECR10.CMADDGPT46ZE bit is 1 and the POECMPEX7.POEREQ5 bit or the POECMPSEL.POEREQ5 bit is 1.

- Detection of oscillation stop

When the ICSR6.OSTSTF flag becomes 1 while the ICSR6.OSTSTE bit is 1.

#### (20) GPTW5 pins (GTIOC5A, GTIOC5B)

When one of the following conditions is satisfied while the POECR3.GPT5ABZE bit is 1, the pins become high-impedance. Furthermore, when the POECR3.GPT5ABZE bit is 0 and the PMMCR2.GPT5AME and GPT5BME bits are 1 and when one of the following conditions is satisfied, the pins are switched to general I/O port pins.

- Operation for comparison of the output levels on the GTIOC5A and GTIOC5B signals

When the OCSR4.OSF4 flag becomes 1 while the OCSR4.OCE4 bit is 1.

- SPOER setting

When the SPOER.GPT46HIZ bit is set to 1.

- Conditions added by POECR10

When the ICSR1.POE0F flag becomes 1 while the POECR10.IC1ADDGPT46ZE bit is 1.

When the ICSR2.POE4F flag becomes 1 while the POECR10.IC2ADDGPT46ZE bit is 1.

When the ICSR3.POE8F flag becomes 1 while the POECR10.IC3ADDGPT46ZE bit and the ICSR3.POE8E bit are 1.

When the ICSR4.POE10F flag becomes 1 while the POECR10.IC4ADDGPT46ZE bit and the ICSR4.POE10E bit are 1.

When the ICSR5.POE11F flag becomes 1 while the POECR10.IC5ADDGPT46ZE bit and the ICSR5.POE11E bit are 1.

When the ICSR7.POE12F flag becomes 1 while the POECR10.IC6ADDGPT46ZE bit and the ICSR7.POE12E bit

are 1.

When the ICSR8.POE9F flag becomes 1 while the POECR10.IC8ADDGPT46ZE bit and the ICSR8.POE9E bit are 1.

When the ICSR9.POE13F flag becomes 1 while the POECR10.IC9ADDGPT46ZE bit and the ICSR9.POE13E bit are 1.

When the ICSR10.POE14F flag becomes 1 while the POECR10.IC10ADDGPT46ZE bit and the ICSR10.POE14E bit are 1.

- Comparator output detection

When the POECMPFR.C0FLAG flag becomes 1 while the POECR10.CMADDGPT46ZE bit is 1 and the POECMPX7.POEREQ0 bit or the POECMPSEL.POEREQ0 bit is 1.

When the POECMPFR.C1FLAG flag becomes 1 while the POECR10.CMADDGPT46ZE bit is 1 and the POECMPX7.POEREQ1 bit or the POECMPSEL.POEREQ1 bit is 1.

When the POECMPFR.C2FLAG flag becomes 1 while the POECR10.CMADDGPT46ZE bit is 1 and the POECMPX7.POEREQ2 bit or the POECMPSEL.POEREQ2 bit is 1.

When the POECMPFR.C3FLAG flag becomes 1 while the POECR10.CMADDGPT46ZE bit is 1 and the POECMPX7.POEREQ3 bit or the POECMPSEL.POEREQ3 bit is 1.

When the POECMPFR.C4FLAG flag becomes 1 while the POECR10.CMADDGPT46ZE bit is 1 and the POECMPX7.POEREQ4 bit or the POECMPSEL.POEREQ4 bit is 1.

When the POECMPFR.C5FLAG flag becomes 1 while the POECR10.CMADDGPT46ZE bit is 1 and the POECMPX7.POEREQ5 bit or the POECMPSEL.POEREQ5 bit is 1.

- Detection of oscillation stop

When the ICSR6.OSTSTF flag becomes 1 while the ICSR6.OSTSTE bit is 1.

#### (21) GPTW6 pins (GTIOC6A, GTIOC6B)

When one of the following conditions is satisfied while the POECR3.GPT6ABZE bit is 1, the pins become high-impedance. Furthermore, when the POECR3.GPT6ABZE bit is 0 and the PMMCR2.GPT6AME and GPT6BME bits are 1 and when one of the following conditions is satisfied, the pins are switched to general I/O port pins.

- Operation for comparison of the output levels on the GTIOC6A and GTIOC6B signals

When the OCSR4.OSF4 flag becomes 1 while the OCSR4.OCE4 bit is 1.

- SPOER setting

When the SPOER.GPT46HIZ bit is set to 1.

- Conditions added by POECR10

When the ICSR1.POE0F flag becomes 1 while the POECR10.IC1ADDGPT46ZE bit is 1.

When the ICSR2.POE4F flag becomes 1 while the POECR10.IC2ADDGPT46ZE bit is 1.

When the ICSR3.POE8F flag becomes 1 while the POECR10.IC3ADDGPT46ZE bit and the ICSR3.POE8E bit are 1.

When the ICSR4.POE10F flag becomes 1 while the POECR10.IC4ADDGPT46ZE bit and the ICSR4.POE10E bit are 1.

When the ICSR5.POE11F flag becomes 1 while the POECR10.IC5ADDGPT46ZE bit and the ICSR5.POE11E bit are 1.

When the ICSR7.POE12F flag becomes 1 while the POECR10.IC6ADDGPT46ZE bit and the ICSR7.POE12E bit are 1.

When the ICSR8.POE9F flag becomes 1 while the POECR10.IC8ADDGPT46ZE bit and the ICSR8.POE9E bit are 1.

When the ICSR9.POE13F flag becomes 1 while the POECR10.IC9ADDGPT46ZE bit and the ICSR9.POE13E bit are 1.

When the ICSR10.POE14F flag becomes 1 while the POECR10.IC10ADDGPT46ZE bit and the ICSR10.POE14E bit are 1.

- Comparator output detection

When the POECMPFR.C0FLAG flag becomes 1 while the POECR10.CMADDGPT46ZE bit is 1 and the POECMPEX7.POEREQ0 bit or the POECMPSEL.POEREQ0 bit is 1.

When the POECMPFR.C1FLAG flag becomes 1 while the POECR10.CMADDGPT46ZE bit is 1 and the POECMPEX7.POEREQ1 bit or the POECMPSEL.POEREQ1 bit is 1.

When the POECMPFR.C2FLAG flag becomes 1 while the POECR10.CMADDGPT46ZE bit is 1 and the POECMPEX7.POEREQ2 bit or the POECMPSEL.POEREQ2 bit is 1.

When the POECMPFR.C3FLAG flag becomes 1 while the POECR10.CMADDGPT46ZE bit is 1 and the POECMPEX7.POEREQ3 bit or the POECMPSEL.POEREQ3 bit is 1.

When the POECMPFR.C4FLAG flag becomes 1 while the POECR10.CMADDGPT46ZE bit is 1 and the POECMPEX7.POEREQ4 bit or the POECMPSEL.POEREQ4 bit is 1.

When the POECMPFR.C5FLAG flag becomes 1 while the POECR10.CMADDGPT46ZE bit is 1 and the POECMPEX7.POEREQ5 bit or the POECMPSEL.POEREQ5 bit is 1.

- Detection of oscillation stop  
When the ICSR6.OSTSTF flag becomes 1 while the ICSR6.OSTSTE bit is 1.

#### (22) GPTW7 pins (GTIOC7A, GTIOC7B)

When one of the following conditions is satisfied while the POECR3.GPT7ABZE bit is 1, the pins become high-impedance. Furthermore, when the POECR3.GPT7ABZE bit is 0 and the PMMCR2.GPT7AME and GPT7BME bits are 1 and when one of the following conditions is satisfied, the pins are switched to general I/O port pins.

- Operation for comparison of the output levels on the GTIOC7A and GTIOC7B signals  
When the OCSR5.OSF5 flag becomes 1 while the OCSR5.OCE5 bit is 1.
- SPOER setting  
When the SPOER.GPT79HIZ bit is set to 1.
- Conditions added by POECR11  
When the ICSR1.POE0F flag becomes 1 while the POECR11.IC1ADDGPT79ZE bit is 1.  
When the ICSR2.POE4F flag becomes 1 while the POECR11.IC2ADDGPT79ZE bit is 1.  
When the ICSR3.POE8F flag becomes 1 while the POECR11.IC3ADDGPT79ZE bit and the ICSR3.POE8E bit are 1.  
When the ICSR4.POE10F flag becomes 1 while the POECR11.IC4ADDGPT79ZE bit and the ICSR4.POE10E bit are 1.  
When the ICSR5.POE11F flag becomes 1 while the POECR11.IC5ADDGPT79ZE bit and the ICSR5.POE11E bit are 1.  
When the ICSR7.POE12F flag becomes 1 while the POECR11.IC6ADDGPT79ZE bit and the ICSR7.POE12E bit are 1.  
When the ICSR8.POE9F flag becomes 1 while the POECR11.IC8ADDGPT79ZE bit and the ICSR8.POE9E bit are 1.  
When the ICSR9.POE13F flag becomes 1 while the POECR11.IC9ADDGPT79ZE bit and the ICSR9.POE13E bit are 1.  
When the ICSR10.POE14F flag becomes 1 while the POECR11.IC10ADDGPT79ZE bit and the ICSR10.POE14E bit are 1.
- Comparator output detection  
When the POECMPFR.C0FLAG flag becomes 1 while the POECR11.CMADDGPT79ZE bit is 1 and the POECMPEX8.POEREQ0 bit or the POECMPSEL.POEREQ0 bit is 1.  
When the POECMPFR.C1FLAG flag becomes 1 while the POECR11.CMADDGPT79ZE bit is 1 and the POECMPEX8.POEREQ1 bit or the POECMPSEL.POEREQ1 bit is 1.  
When the POECMPFR.C2FLAG flag becomes 1 while the POECR11.CMADDGPT79ZE bit is 1 and the POECMPEX8.POEREQ2 bit or the POECMPSEL.POEREQ2 bit is 1.  
When the POECMPFR.C3FLAG flag becomes 1 while the POECR11.CMADDGPT79ZE bit is 1 and the POECMPEX8.POEREQ3 bit or the POECMPSEL.POEREQ3 bit is 1.

When the POECMPFR.C4FLAG flag becomes 1 while the POECR11.CMADDGPT79ZE bit is 1 and the POECMPEX8.POEREQ4 bit or the POECMPSEL.POEREQ4 bit is 1.

When the POECMPFR.C5FLAG flag becomes 1 while the POECR11.CMADDGPT79ZE bit is 1 and the POECMPEX8.POEREQ5 bit or the POECMPSEL.POEREQ5 bit is 1.

- Detection of oscillation stop  
When the ICSR6.OSTSTF flag becomes 1 while the ICSR6.OSTSTE bit is 1.

### (23) GPTW8 pins (GTIOC8A, GTIOC8B)

When one of the following conditions is satisfied while the POECR3.GPT8ABZE bit is 1, the pins become high-impedance. Furthermore, when the POECR3.GPT8ABZE bit is 0 and the PMMCR3.GPT8AME and GPT8BME bits are 1 and when one of the following conditions is satisfied, the pins are switched to general I/O port pins.

- Operation for comparison of the output levels on the GTIOC8A and GTIOC8B signals  
When the OCSR5.OSF5 flag becomes 1 while the OCSR5.OCE5 bit is 1.
- SPOER setting  
When the SPOER.GPT79HIZ bit is set to 1.
- Conditions added by POECR11  
When the ICSR1.POE0F flag becomes 1 while the POECR11.IC1ADDGPT79ZE bit is 1.  
When the ICSR2.POE4F flag becomes 1 while the POECR11.IC2ADDGPT79ZE bit is 1.  
When the ICSR3.POE8F flag becomes 1 while the POECR11.IC3ADDGPT79ZE bit and the ICSR3.POE8E bit are 1.  
When the ICSR4.POE10F flag becomes 1 while the POECR11.IC4ADDGPT79ZE bit and the ICSR4.POE10E bit are 1.  
When the ICSR5.POE11F flag becomes 1 while the POECR11.IC5ADDGPT79ZE bit and the ICSR5.POE11E bit are 1.  
When the ICSR7.POE12F flag becomes 1 while the POECR11.IC6ADDGPT79ZE bit and the ICSR7.POE12E bit are 1.  
When the ICSR8.POE9F flag becomes 1 while the POECR11.IC8ADDGPT79ZE bit and the ICSR8.POE9E bit are 1.  
When the ICSR9.POE13F flag becomes 1 while the POECR11.IC9ADDGPT79ZE bit and the ICSR9.POE13E bit are 1.  
When the ICSR10.POE14F flag becomes 1 while the POECR11.IC10ADDGPT79ZE bit and the ICSR10.POE14E bit are 1.
- Comparator output detection  
When the POECMPFR.C0FLAG flag becomes 1 while the POECR11.CMADDGPT79ZE bit is 1 and the POECMPEX8.POEREQ0 bit or the POECMPSEL.POEREQ0 bit is 1.  
When the POECMPFR.C1FLAG flag becomes 1 while the POECR11.CMADDGPT79ZE bit is 1 and the POECMPEX8.POEREQ1 bit or the POECMPSEL.POEREQ1 bit is 1.  
When the POECMPFR.C2FLAG flag becomes 1 while the POECR11.CMADDGPT79ZE bit is 1 and the POECMPEX8.POEREQ2 bit or the POECMPSEL.POEREQ2 bit is 1.  
When the POECMPFR.C3FLAG flag becomes 1 while the POECR11.CMADDGPT79ZE bit is 1 and the POECMPEX8.POEREQ3 bit or the POECMPSEL.POEREQ3 bit is 1.  
When the POECMPFR.C4FLAG flag becomes 1 while the POECR11.CMADDGPT79ZE bit is 1 and the POECMPEX8.POEREQ4 bit or the POECMPSEL.POEREQ4 bit is 1.  
When the POECMPFR.C5FLAG flag becomes 1 while the POECR11.CMADDGPT79ZE bit is 1 and the POECMPEX8.POEREQ5 bit or the POECMPSEL.POEREQ5 bit is 1.
- Detection of oscillation stop  
When the ICSR6.OSTSTF flag becomes 1 while the ICSR6.OSTSTE bit is 1.

## (24) GPTW9 pins (GTIOC9A, GTIOC9B)

When one of the following conditions is satisfied while the POECR3.GPT9ABZE bit is 1, the pins become high-impedance. Furthermore, when the POECR3.GPT9ABZE bit is 0 and the PMMCR3.GPT9AME and GPT9BME bits are 1 and when one of the following conditions is satisfied, the pins are switched to general I/O port pins.

- Operation for comparison of the output levels on the GTIOC9A and GTIOC9B signals  
When the OCSR5.OSF5 flag becomes 1 while the OCSR5.OCE5 bit is 1.
- SPOER setting  
When the SPOER.GPT79HIZ bit is set to 1.
- Conditions added by POECR11  
When the ICSR1.POE0F flag becomes 1 while the POECR11.IC1ADDGPT79ZE bit is 1.  
When the ICSR2.POE4F flag becomes 1 while the POECR11.IC2ADDGPT79ZE bit is 1.  
When the ICSR3.POE8F flag becomes 1 while the POECR11.IC3ADDGPT79ZE bit and the ICSR3.POE8E bit are 1.  
When the ICSR4.POE10F flag becomes 1 while the POECR11.IC4ADDGPT79ZE bit and the ICSR4.POE10E bit are 1.  
When the ICSR5.POE11F flag becomes 1 while the POECR11.IC5ADDGPT79ZE bit and the ICSR5.POE11E bit are 1.  
When the ICSR7.POE12F flag becomes 1 while the POECR11.IC6ADDGPT79ZE bit and the ICSR7.POE12E bit are 1.  
When the ICSR8.POE9F flag becomes 1 while the POECR11.IC8ADDGPT79ZE bit and the ICSR8.POE9E bit are 1.  
When the ICSR9.POE13F flag becomes 1 while the POECR11.IC9ADDGPT79ZE bit and the ICSR9.POE13E bit are 1.  
When the ICSR10.POE14F flag becomes 1 while the POECR11.IC10ADDGPT79ZE bit and the ICSR10.POE14E bit are 1.
- Comparator output detection  
When the POECMPFR.C0FLAG flag becomes 1 while the POECR11.CMADDGPT79ZE bit is 1 and the POECMPEX8.POEREQ0 bit or the POECMPSEL.POEREQ0 bit is 1.  
When the POECMPFR.C1FLAG flag becomes 1 while the POECR11.CMADDGPT79ZE bit is 1 and the POECMPEX8.POEREQ1 bit or the POECMPSEL.POEREQ1 bit is 1.  
When the POECMPFR.C2FLAG flag becomes 1 while the POECR11.CMADDGPT79ZE bit is 1 and the POECMPEX8.POEREQ2 bit or the POECMPSEL.POEREQ2 bit is 1.  
When the POECMPFR.C3FLAG flag becomes 1 while the POECR11.CMADDGPT79ZE bit is 1 and the POECMPEX8.POEREQ3 bit or the POECMPSEL.POEREQ3 bit is 1.  
When the POECMPFR.C4FLAG flag becomes 1 while the POECR11.CMADDGPT79ZE bit is 1 and the POECMPEX8.POEREQ4 bit or the POECMPSEL.POEREQ4 bit is 1.  
When the POECMPFR.C5FLAG flag becomes 1 while the POECR11.CMADDGPT79ZE bit is 1 and the POECMPEX8.POEREQ5 bit or the POECMPSEL.POEREQ5 bit is 1.
- Detection of oscillation stop  
When the ICSR6.OSTSTF flag becomes 1 while the ICSR6.OSTSTE bit is 1.

### 23.3.1 MTU/GPTW Pin Selection

In this MCU, the pin functions for MTU and GPTW are respectively multiplexed with multiple sets of port pins. The target pins for output disabling control can be selected by the pin select register in POE (M0SELR1, M0SELR2, M3SELR, M4SELR1, M4SELR2, M6SELR, M7SELR1, M7SELR2, M9SELR1, M9SELR2, G0SELR, G1SELR, G2SELR, G3SELR, G4SELR, G5SELR, G6SELR, G7SELR, G8SELR, or G9SELR register). Table 23.5 shows the correspondence between MTU pins and select registers. Table 23.6 shows the correspondence between GPTW pins and select registers.

Note that settings for pins to be used as MTU or GPTW must be separately made in the registers of the multi-function pin controller (MPC). Take care so that there are no differences between the pins selected in the POE registers and the pins selected in the MPC registers.

**Table 23.5 Correspondence between MTU Pins**

| MTU Pin Functions | Corresponding Ports | Select Registers |         |
|-------------------|---------------------|------------------|---------|
| MTIOC0A           | PB3                 | M0SELR1          |         |
|                   | P31                 |                  |         |
| MTIOC0B           | PB2                 |                  |         |
|                   | P30                 |                  |         |
|                   | PC0                 |                  |         |
| MTIOC0C           | PB1                 | M0SELR2          |         |
|                   | P27                 |                  |         |
|                   | PC1                 |                  |         |
| MTIOC0D           | PB0                 |                  | M3SELR  |
|                   | PC2                 |                  |         |
| MTIOC3B           | P71                 | M3SELR           |         |
|                   | P12                 |                  |         |
| MTIOC3D           | P74                 |                  | M4SELR1 |
|                   | P15                 |                  |         |
| MTIOC4A           | P72                 | M4SELR1          |         |
|                   | P13                 |                  |         |
| MTIOC4C           | P75                 |                  | M4SELR2 |
|                   | P16                 |                  |         |
| MTIOC4B           | P73                 | M4SELR2          |         |
|                   | P14                 |                  |         |

### 23.3.2 Input-Level Detection Operation

If the input conditions set by ICSR1 to ICSR5 and ICSR7 to ICSR10 occur on the POE0#, POE4#, POE8#, POE10#, POE11#, POE12#, POE9#, POE13#, and POE14# pins, the outputs of the MTU complementary PWM output pins (MTU3 and MTU4 or MTU6 and MTU7), MTU0, MTU9 pins, and GPTW pins are disabled.

#### (1) Falling-Edge Detection

When the input levels to the POE0#, POE4#, POE8#, POE10#, POE11#, POE12#, POE9#, POE13#, and POE14# pins change from high to low, outputs of the MTU complementary PWM output pins, MTU0 pins, MTU9 pins, and GPTW pins are disabled.

The falling edge is detected after the level is sampled with PCLK. Input a low level for at least one PCLK clock to the POE0#, POE4#, POE8#, POE10#, POE11#, POE12#, POE9#, POE13#, and POE14# pins.

Figure 23.12 shows a sample timing after the level changes in input to the POE0#, POE4#, POE8#, POE10#, POE11#, POE12#, POE9#, POE13#, and POE14# pins until the respective pins become high-impedance.

**Figure 23.12 Operation when A Falling Edge Detection and High-Impedance are Selected**

(2) Low-Level Detection

Figure 23.13 shows an example of changing pins to high-impedance state while a low-level detection is selected. When low is consecutively detected for the specified number of times with the sampling clock set in the ICSR1 to ICSR5 and ICSR7 to ICSR10 registers, it is considered that low has been input, and the outputs of the MTU complementary PWM output pins, MTU0 pins, MTU9 pins, and GPTW pins are disabled. At this time, if a high is detected even once, it is not considered that low has been input.

The timing when the outputs of the MTU complementary PWM output pins, MTU0 pins, MTU9 pins, and GPTW pins are disabled after the sampling clock is input is the same in both falling-edge detection and in low-level detection.

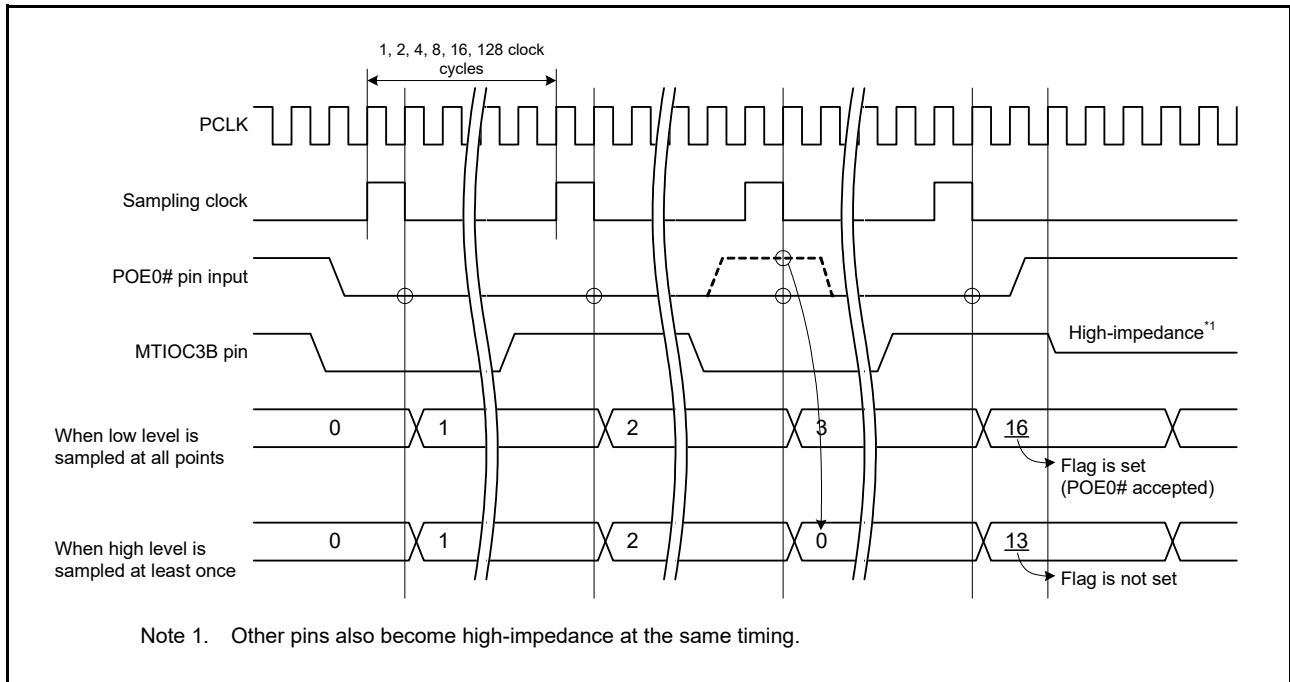

Figure 23.13 Operation when A Low-Level Detection and High-Impedance are Selected (16 samplings)

23.3.3 Output-Level Compare Operation

Figure 23.14 shows an example of the output-level compare operation for the combination of MTIOC3B and MTIOC3D. When the MTIOC3B and MTIOC3D signals simultaneously go to the active level for at least one cycle of PCLK, the outputs are disabled.

The operation is the same for the other signal combinations and switching to general I/O ports.

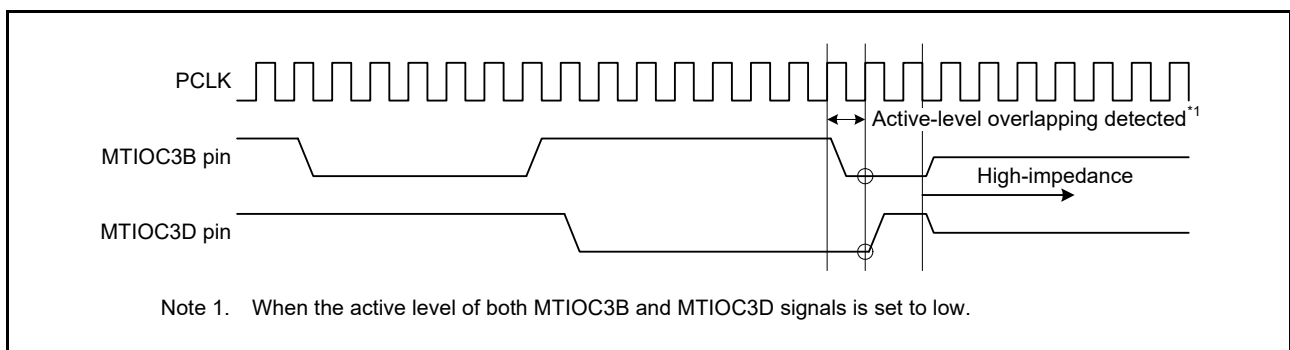

Figure 23.14 Output-Level Compare Operation

### 23.3.4 Output Disabling Control Using Registers

The output disabling request of the MTU pins (MTU0, MTU3, MTU4, MTU6, MTU7, and MTU9) and the GPTW pins (GPTW0 to GPTW9) can be directly controlled by using the SPOER register.

For instance, setting the SPOER.MTUCH34HIZ bit to 1 switches the MTU3 and MTU4 pins specified by the POECR2 register to the high-impedance state.

The output disabling request of other pins can also be controlled by setting the appropriate bits in the SPOER register.

### 23.3.5 Output Disabling Control through Detection of Oscillation Stop

When the oscillation stop detection function for the clock generation circuit detects the oscillation stop while the ICSR6.OSTSTE bit is 1, the MTU complementary PWM output pins, MTU0 pins, MTU9 pins, and GPTW pins specified by the registers POECR1 to POECR3 and POECR7 can be switched to high-impedance, and the MTU complementary PWM output pins, MTU0 pins, MTU9 pins, and GPTW pins specified by the registers PMMCR0 to PMMCR3 can be switched to a general I/O port.

### 23.3.6 Output Disabling Control through Detection of the Comparator Output

The outputs of the MTU complementary PWM output pins, MTU0 pins, MTU9 pins, and GPTW pins can be disabled in response to detection of the output of the comparator.

For instance, when the POECMPFR.CjFLAG flag ( $j = 0$  to 5) is added to the output disabling control conditions for the MTU3 and MTU4 pins by setting the POECR4.CMADDMT34ZE bit to 1, the MTU3 and MTU4 pins specified by the POECR2 register become high-impedance and the MTU3 and MTU4 pins specified by the PMMCR1 register are switched to general I/O port pins on comparator output detection.

The output disabling control of other pins can be controlled by the POECR1 to POECR8 registers and the PMMCR0 to PMMCR3 registers.

When using the CjFLAG flag ( $j = 0$  to 5) as a source for the output disabling control conditions, set the POECMPSEL or POECMPEX $m$  register ( $m = 0$  to 8). When the POECMPSEL.POEREQ $j$  bit is set to 1, the CjFLAG flag is used as a source for all target pins. When the POECMPEX $m$ .POEREQ $j$  bit is set to 1, the CjFLAG flag is used as a source for the corresponding pins.

### 23.3.7 Additional Functions for Output Disabling Control

Output disabling control conditions for the MTU complementary PWM output pins, MTU0 pins, MTU9 pins, and GPTW pins can be added by setting the POECR4 to POECR6, POECR4B, POECR6B, and POECR8 to POECR11 registers.

For instance, the settings listed below can be added as output disabling control conditions for the MTU3 and MTU4 pins.

- Setting the POECR4.CMADDMT34ZE bit to 1 adds comparator output detection
- Setting the POECR4.IC1ADDMT34ZE bit to 1 and adds the input-level detection by the POE0# pin
- Setting the POECR4.IC2ADDMT34ZE bit to 1 and adds the input-level detection by the POE4# pin
- Setting the POECR4.IC3ADDMT34ZE bit to 1 and adds the input-level detection by the POE8# pin
- Setting the POECR4.IC4ADDMT34ZE bit to 1 and adds the input-level detection by the POE11# pin
- Setting the POECR4.IC5ADDMT34ZE bit to 1 and adds the input-level detection by the POE8# pin
- Setting the POECR4.IC6ADDMT34ZE bit to 1 and adds the input-level detection by the POE12# pin
- Setting the POECR4.IC8ADDMT34ZE bit to 1 and adds the input-level detection by the POE9# pin
- Setting the POECR4.IC9ADDMT34ZE bit to 1 and adds the input-level detection by the POE13# pin
- Setting the POECR4.IC10ADDMT34ZE bit to 1 and adds the input-level detection by the POE14# pin

The output disabling control of other pins can also be controlled by setting the appropriate bits in the POECR4 to POECR6, POECR4B, POECR6B, and POECR8 to POECR11 registers.

### 23.3.8 Control in Response to an Output Disabling Request

When a request to disable outputs is generated, those pins for which the corresponding bits of the POECR1 to POECR3 and POECR7 registers is set to 1 become high-impedance and those pins for which the corresponding bits of the PMMCR0 to PMMCR3 registers are set to 1 are switched to general I/O port pins.

When both bits are set to 1 for the same pin, the settings of the POECR1 to POECR3 and POECR7 registers take priority and the pins become high-impedance.

After a pin is switched to a general I/O port pin, the settings of the corresponding bits in the PDR and PODR registers determine the state of the pin.

### 23.3.9 Recover from Output Disabled State

The outputs which have been disabled due to input-level detection can be recovered from the state either by returning them to their initial state with a reset, or by clearing all of the ICSR1.POE0F, ICSR2.POE4F, ICSR3.POE8F, ICSR4.POE10F, ICSR5.POE11F, ICSR7.POE12F, ICSR8.POE9F, ICSR9.POE13F, and ICSR10.POE14F flags. However, note that when low-level detection is selected with the ICSR1.POE0M[3:0], ICSR2.POE4M[3:0], ICSR3.POE8M[3:0], ICSR4.POE10M[3:0], ICSR5.POE11M[3:0], ICSR7.POE12M[3:0], ICSR8.POE9M[3:0], ICSR9.POE13M[3:0], and ICSR10.POE14M[3:0] bits, just writing 0 to a flag is ignored (the flag is not set to 0); flags can be cleared by writing 0 to it only after a high level is input to the POE0#, POE4#, POE8#, POE10#, POE11#, POE12#, POE9#, POE13#, and POE14# pins and is detected.

Pins whose outputs are disabled by detecting a simultaneous conduction can be released by resetting to return to the initial state or by writing 0 to the OCSR1.OSF1 flag, OCSR2.OSF2 flag, OCSR3.OSF3 flag, OCSR4.OSF4 flag, and OCSR5.OSF5 flag. However, note that just writing 0 to a flag is ignored (the flag is not set to 0); the flags can be cleared by writing 0 to it only after setting the signals to the inactive level. In the MTU, the inactive level (initial output level) can be output by stopping the count operation. In the GPTW, the inactive level can be output in accordance with the procedure described in section 24.9.2, Pin Initialization Due to Error during Operation.

The outputs which have been disabled due to comparator output detection can be recovered from the state either by returning them to their initial state with a reset or by setting the POECMPFR.CjFLAG flag (j = 0 to 5) to 0.

When setting the POECMPFR.CjFLAG flag to 0, be sure to confirm that the analog input signal that triggered comparator output detection has returned to a normal value by performing A/D conversion and so on.

Note that the above POECMPFR.CjFLAG flag is not set to 1 again in the following cases:

- This flag is cleared without confirmation that the analog input signal has returned to a normal value, and
  1. the analog input signal remains above the reference voltage when the comparator is set to non-inverted output, or
  2. the analog input signal remains below the reference voltage when the comparator is set to inverted output.

The outputs which have been disabled due to oscillation stop detection can be recovered from the state either by returning them to their initial state with a reset or by setting the SYSTEM.OSTDSR.OSTDF flag to 0 to set the ICSR6.OSTSTF flag to 0.

## 23.4 POE Setting Procedure

Figure 23.15 shows the procedure for setting the POE. It illustrates an example of high-impedance control in response to comparison of the output levels on the MTU3 signals (MTIOC3B/MTIOC3D). In the figure, the MTIOC3B signal is assigned to P71 pin and MTIOC3D signal to P74 pin.

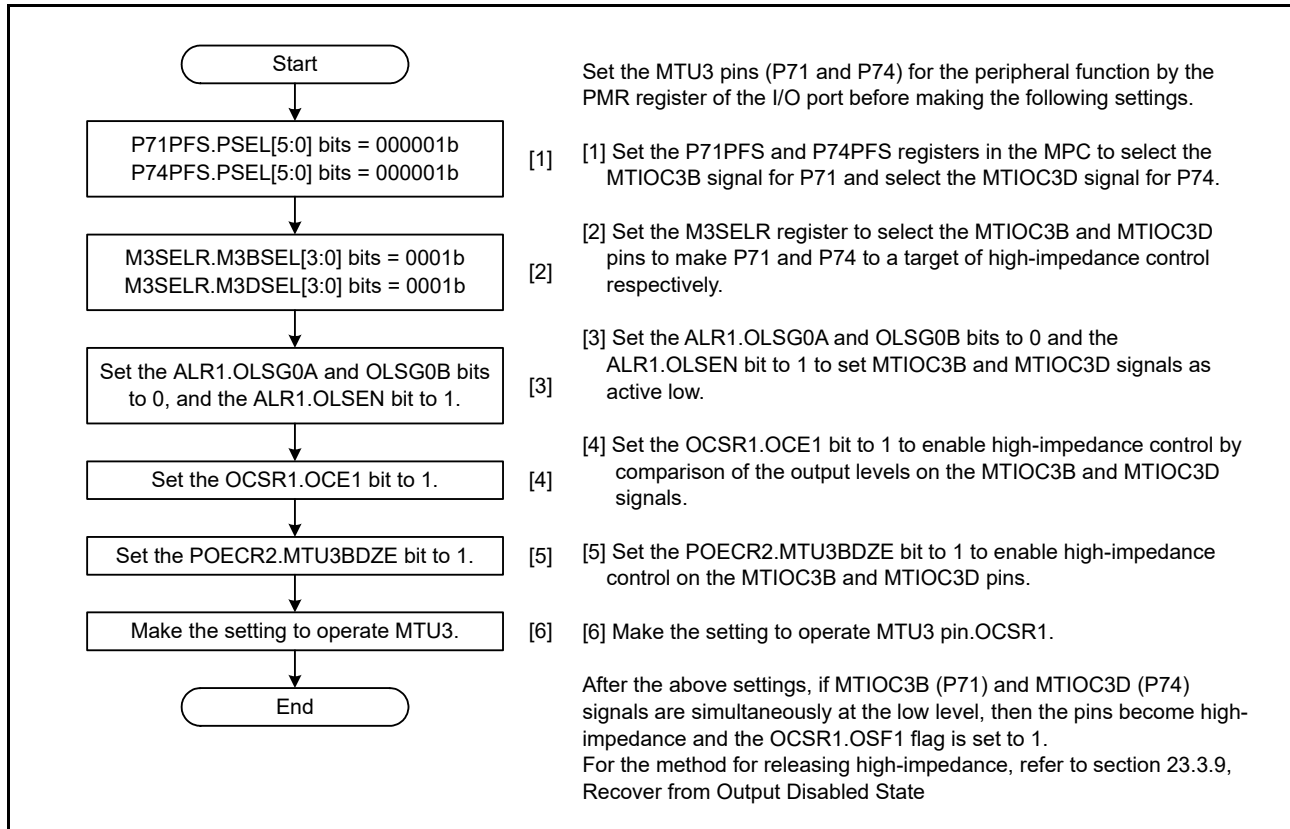

Figure 23.15 Procedure for Setting the POE

## 23.5 Interrupts

The POE issues a request to generate an interrupt when the specified condition is satisfied during input-level detection or output-level comparison. Table 23.7 shows the interrupt sources and their conditions.

**Table 23.7 Interrupt Sources and Conditions**

| Name | Interrupt Source          | Interrupt Flag                                 | Condition                                                                                                                                                                                                                                                                                                                                                                                                             |
|------|---------------------------|------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| OEI1 | Output enable interrupt 1 | POE0F, OSF1                                    | When the ICSR1.POE0F flag becomes 1 while the ICSR1.PIE1 bit is 1 or when the OCSR1.OSF1 flag becomes 1 while the OCSR1.OIE1 bit is 1                                                                                                                                                                                                                                                                                 |
| OEI2 | Output enable interrupt 2 | POE4F, OSF2                                    | When the ICSR2.POE4F flag becomes 1 while the ICSR2.PIE2 bit is 1 or when the OCSR2.OSF2 flag becomes 1 while the OCSR2.OIE2 bit is 1                                                                                                                                                                                                                                                                                 |
| OEI3 | Output enable interrupt 3 | POE8F, POE9F                                   | When the ICSR3.POE8F flag becomes 1 while the ICSR3.PIE3 bit is 1 or when the ICSR8.POE9F flag becomes 1 while the ICSR8.PIE8 bit is 1                                                                                                                                                                                                                                                                                |
| OEI4 | Output enable interrupt 4 | POE10F, POE11F                                 | When the ICSR4.POE10F flag becomes 1 while the ICSR4.PIE4 bit is 1 or when the ICSR5.POE11F flag becomes 1 while the ICSR5.PIE5 bit is 1                                                                                                                                                                                                                                                                              |
| OEI5 | Output enable interrupt 5 | POE12F, POE13F,<br>POE14F, OSF3,<br>OSF4, OSF5 | When the ICSR7.POE12F flag becomes 1 while the ICSR7.PIE7 bit is 1, when the ICSR9.POE13F flag becomes 1 while the ICSR9.PIE9 bit is 1, when the ICSR10.POE14F flag becomes 1 while the ICSR10.PIE10 bit is 1, when the OCSR3.OSF3 flag becomes 1 while the OCSR3.OIE3 bit is 1, when the OCSR4.OSF4 flag becomes 1 while the OCSR4.OIE4 bit is 1 or when the OCSR5.OSF5 flag becomes 1 while the OCSR5.OIE5 bit is 1 |

## 23.6 Usage Notes

### 23.6.1 Transition to Low Power Consumption Mode

When using the POE, do not transition to software standby or deep software standby modes. Output disabling control for pins cannot be performed as the POE operation is disabled in software standby or deep software standby modes.

### 23.6.2 Output Disabling Control When the MTU and GPTW Pins are Not Selected

When the control conditions are satisfied while the output disabling control for the MTU and GPTW pins are enabled by the POECR1 to POECR3 and POECR7 registers, and the PMMCR0 to PMMCR3 registers, outputs are disabled for the pins which have become controlled by the pin select register settings even when the MTU and GPTW functions are not selected by the PxyPFS register in the MPC.

To avoid unintended output disabling, ensure that there are no differences between the settings for MTU and GPTW pin selection in the PxyPFS registers of the MPC and for MTU and GPTW pin selection in the pin select register of the POE.

### 23.6.3 When the POE is Not Used

The output disabling control for the pins by the POE becomes enabled for some pins after resetting. Even when the POE is not used, write 0 to a relevant bit in the POECR2 register. Also write 0000b to relevant bits in the following pin select registers: M0SELR1, M0SELR2, M3SELR, M4SELR1, M4SELR2, M6SELR, M7SELR1, M7SELR2, M9SELR1, M9SELR2, G0SELR, G1SELR, G2SELR, G3SELR, G4SELR, G5SELR, G6SELR, G7SELR, G8SELR, and G9SELR.

### 23.6.4 Setting the Active Level When the Inverting Output Is Set for the MTU and GPTW

In this MCU, either of normal output or inverting output can be selected for an output of the MTU and GPTW by the MPC.PxyPFS register.

When inverting output of the MTU is selected, the active level specified by the MTU.TOCR1j and MTU.TOCR2j registers (j = A, B) and the active level of the signal which is output to the pins become inverted. At this time, to use detection of simultaneous conduction, specify, by the ALR1 and ALR2 registers, the active level with reference to signals which are output to the pins.

When the inverting output of the GPTW is selected, the active level of the signal which is output to the pins become inverted. At this time, to use detection of simultaneous conduction, specify, by the registers ALR3 to ALR5, the active level with reference to signals which are output to the pins.

### 23.6.5 Reading the Pins When in High-Impedance State

When the pins are in high-impedance state by the POE, the level of the relevant pins cannot be read. The value when read is indeterminable. To read the level of the pins, release from the high-impedance state.

When the port switching control is selected instead of high-impedance control, this is not applied.

### 23.6.6 Note for Using POE and POEG Together

When using the POE and POEG together, do not control the output disabling for the same GPTW output pin by both the POE and POEG.

## 24. General PWM Timer (GPTW)

This MCU has a general PWM timer (GPTW) consisting of a tens-channel 32-bit timer.

### 24.1 Overview

Table 24.1 lists the specifications for the GPTW, and Table 24.2 shows the functions of the GPTW. Figure 24.1 shows a block diagram of the GPTW.

**Table 24.1 GPTW Specifications**

| Item      | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

| b31 to b16 | —          | Reserved                       | These bits are read as 0. The write value should be 0.                                         | R/W |

GTWP enables or disables writing to registers to prevent accidental modification.

Protection by the GTWP register only covers the CPU write operation.

Such protection does not cover a register updating generated in coordination with the CPU write.

For registers that are write enabled or disabled depending on the setting of the GTWP register, see section 24.8.1, Write-Protection for Registers.

#### WP Bit (Register Write Disabled)

Write enable/disable to the GPTW can be selected with this bit.

Registers which are targets of write enable/disable are as follows:

GTSSR, GTPSR, GTCR, GTUPSR, GTDNSR, GTICASR, GTICBSR, GTCR, GTUDDTYC, GTIOR, GTINTAD, GTST, GTBER, GTITC, GTCNT, GTCCRA, GTCCRB, GTCCRC, GTCCRD, GTCCRE, GTCCRF, GTPR, GTPBR, GTPDBR, GTADTRA, GTADTBRA, GTADTDBRA, GTADTRB, GTADTBRB, GTADTDBRB, GTDTCR, GTDVU, GTDVD, GTDBU, GTDBD, GTSOS, GTSOTR, GTADSMR, GTEITC, GTEITLI1, GTEITLI2, GTEITLB

#### STRWP Bit (GTSTR.CSTRT Bit Write Disabled)

The STRWP bits enable or disable starting the updating of counter values by writing to the CSTRTn bit corresponding to a channel number in the GTSTR register.

The bit position of each CSTRTn bit in the GTSTR registers is allocated to the channel with the corresponding number,

and writing to the GTSTR register for any channel results in writing to the registers of all channels. The STRWP bit for each channel does not control writing but only controls updating of the CSTRT bit for the corresponding channel in the case of simultaneous writing to all channels.

Thus, in the case of writing to the CSTRT bits of a channel for which the setting of the STRWP bit is 1 (disabling writing), the CSTRT bit for the given channel will not be updated, but the CSTRT bits corresponding to channel for which the setting of the STRWP bit is 0 (enabling writing) will be updated. For example, when the setting of the GPTW0.GTWP.STRWP bit is 0 (enabling writing), writing 1 to the GPTW1.GTSTR.CSTRT0 bit when its current setting is 0 will lead to updating of the value, and the GPTW0.GTCNT counter starts running. When the setting of the GPTW0.GTWP.STRWP bit is 1 (disabling writing), writing 1 to the GPTW1.GTSTR.CSTRT0 bit when its current setting is 0 will leave the bit with the value 0, and the GPTW0.GTCNT counter will not start running.

If you want to protect all bits in the GTSTR register from being updated, set the STRWP bits of all channels to 1.

#### **STPWP Bit (GTSTP.CSTOP Bit Write Disabled)**

The STPWP bits enable or disable starting the updating of counter values by writing to the CSTOPn bit corresponding to a channel number in the GTSTP register.

The bit position of each CSTOPn bit in the GTSTP registers is allocated to the channel with the corresponding number, and writing to the GTSTP register for any channel results in writing to the registers of all channels. The STPWP bit for each channel does not control writing but only controls updating of the CSTOP bit for the corresponding channel in the case of simultaneous writing to all channels.

Thus, in the case of writing to the CSTOP bits of a channel for which the setting of the STPWP bit is 1 (disabling writing), the CSTOP bit for the given channel will not be updated, but the CSTOP bits corresponding to channel for which the setting of the STPWP bit is 0 (enabling writing) will be updated. For example, when the setting of the GPTW0.GTWP.STPWP bit is 0 (enabling writing), writing 1 to the GPTW1.GTSTP.CSTOP0 bit when its current setting is 0 will lead to updating of the value, and the GPTW0.GTCNT counter is stopped. When the setting of the GPTW0.GTWP.STPWP bit is 1 (disabling writing), writing 1 to the GPTW1.GTSTP.CSTOP0 bit when its current setting is 0 will leave the bit with the value 0, and the GPTW0.GTCNT counter will not be stopped.

If you want to protect all bits in the GTSTP register from being updated, set the STPWP bits of all channels to 1.

#### **CLRWP Bit (GTCLR.CCLR Bit Write Disabled)**

The CLRWP bits enable or disable starting the updating of counter values by writing to the CCLRn bit corresponding to a channel number in the GTCLR register.

The bit position of each CCLRn bit in the GTCLR registers is allocated to the channel with the corresponding number, and writing to the GTCLR register for any channel results in writing to the registers of all channels. The CLRWP bit for each channel does not control writing but only controls updating of the CCLR bit for the corresponding channel in the case of simultaneous writing to all channels.

Thus, in the case of writing to the CCLR bits of a channel for which the setting of the CLRWP bit is 1 (disabling writing), the CCLR bit for the given channel will not be updated, but the CCLR bits corresponding to channel for which the setting of the CLRWP bit is 0 (enabling writing) will be updated. For example, when the setting of the GPTW0.GTWP.CLRWP bit is 0 (enabling writing), writing 1 to the GPTW1.GTCLR.CCLR0 bit when its current setting is 0 will lead to updating of the value, and the GPTW0.GTCNT counter is cleared.

If you want to protect all bits in the GTCLR register from being updated, set the CLRWP bits of all channels to 1.

#### **CMNWP Bit (Common Register Write Disabled)**

The CMNWP bit enables or disables starting the updating of counter values by writing to the SECSELn bit (n = 0 to 9) corresponding to a channel number in the GTSECSR register or to the GTSECR register.

The bit position of each SECSEL bit in the GTSECSR registers is allocated to the channel with the corresponding number, and writing to the GTSECSR register for any channel results in writing to the registers of all channels. Writing to the GTSECR register of any channel leads to writing to the registers of all channels. The CMNWP bit for each channel does not control writing but only controls updating of the SECSEL bit and the GTSECR register value for the

corresponding channel in the case of simultaneous writing to all channels.

Thus, in the case of writing to the SECSEL bit and the GTSECR register value of a channel for which the setting of the CMNWP bit is 1 (disabling writing), the SECSEL bit and the GTSECR register value for the given channel will not be updated, but the SECSEL bit and the GTSECR register value corresponding to channel for which the setting of the CMNWP bit is 0 (enabling writing) will be updated.

For example, when the setting of the GPTW0.GTWP.CMNWP bit is 0 (enabling writing), writing to the GPTW1.GTSECSR.SECSEL0 bit will lead to updating of the value of the GPTW0.GTSECSR.SECSEL0 bit. In the same way, writing to the GPTW1.GTSECR register will update the value of the GPTW0.GTSECR register. When the setting of the GPTW0.GTWP.CMNWP bit is 1 (disabling writing), writing to the GPTW1.GTSECSR.SECSEL0 bit will not lead to updating of the value of the GPTW0.GTSECSR.SECSEL0 bit. In the same way, writing to the GPTW1.GTSECR register will not lead to updating of the value of the GPTW0.GTSECR register.

If you want to protect all bits in the GTSECSR and GTSECR registers from being updated, set the CMNWP bits of all channels to 1.

#### **PRKEY[7:0] Bits (GTWP Key Code)**

This bit controls whether the WP, STRWP, STPWP, CLRWP, and CMNWP bits can be overwritten.

| b31 to b10 | —      | Reserved              | These bits are read as 0. The write value should be 0.                   | R/W |

The GTSTR register starts the GTCNT counter operation.

A bit position of the GTSTR register indicates a channel number. The GTSTR register of each channel is a common register, and writing 1 to the GTSTR register in any channel and updating it can start operation of the GTCNT counter in all the channels related to the position of the bit written with 1. A change in counter operation and the register value is not generated by writing 0 to the bit.

### CSTRTn Bit (Channel n Count Start) (n = 0 to 9)

This bit starts the GTCNT counter for channel n.

A read value indicates the state of the counter operation in a corresponding channel (GTCR.CST bit). The bit with 0 indicates that the counter is stopped, while the bit with 1 indicates that the counter is in operation.

### 24.2.3 General PWM Timer Software Stop Register (GTSTP)

| b31 to b10 | —      | Reserved             | These bits are read as 0. The write value should be 0.                                                                                      | R/W |

The GTSTP register stops the GTCNT counter operation.

A bit position of the GTSTP register indicates a channel number. The GTSTP register of each channel is a common register, and writing 1 to the GTSTP register in any channel and updating it can stop operation of the GTCNT counter in all the channels related to the position of the bit written with 1. A change in counter operation and the register value is not generated by writing 0 to the bit.

#### CSTOPn Bit (Channel n Count Stop) (n = 0 to 9)

This bit stops the GTCNT counter for channel n.

A read value indicates the state of the counter operation in a corresponding channel (inverted GTCR.CST bit). The bit with 0 indicates that the counter is in operation, while the bit with 1 indicates that the counter is stopped.

The GTCLR register is a write-only register which sets clearing of the GTCNT counter.

A bit position of the GTCLR register indicates a channel number. The GTCLR register of each channel is a common register, and writing 1 to the GTCLR register in any channel and updating it changes to 0 of the GTCNT counter in all the channels related to the position of the bit written with 1. A change in counter operation and the register value is not generated by writing 0 to the bit.

### CCLRn Bit (Channel n Counter Clear) (n = 0 to 9)

When the counting direction flag is set for decrementation (GTST.TUCF flag = 0) with sawtooth-wave mode selected in the GTCR.MD[2:0] bits, the value of the GTCNT counter becomes that of the corresponding GTPR register in response to writing 1 to the CCLRn bit. The value of the counter becomes 0000 0000h with other settings.

n = 0 to 9

The GTSSR register sets a count start source for the GTCNT counter.

Inputs from the GTETRGA, GTETRGB, GTETRG, and GTETRGD pins are input to the GPTW via the POEG. Set the polarity of these signals with the POEG.

### 24.2.6 General PWM Timer Stop Source Select Register (GTPSR)

n = 0 to 9

The GTPSR register sets a count stop source for the GTCNT counter.

Inputs from the GTETRGA, GTETRGB, GTETRGC, and GTETRGD pins are input to the GPTW via the POEG. Set the polarity of these signals with the POEG.

n = 0 to 9

The GTCSR register sets a counter clear source for the GTCNT counter.

Counter clearing can be executed whether the counter is running (the GTCR.CST bit = 1) or stopped (the GTCR.CST bit = 0).

Inputs from the GTETRGA, GTETRGB, GTETRGC, and GTETRGD pins are input to the GPTW via the POEG. Set the polarity of these signals with the POEG.

## 24.2.8 General PWM Timer Count-Up Source Select Register (GTUPSR)

n = 0 to 9

The GTUPSR register sets a count-up source for the GTCNT counter.

When at least one bit among bits in the GTUPSR register is set as 1, counting of the GTCNT counter by the count clock set by the GTCR.TPCS[3:0] bits becomes invalid, and the count-up by a source set as 1 by the GTUPSR register is executed.

Number of increment in counting is one even when multiple sources are generated simultaneously.

Inputs from the GTETRGA, GTETRGB, GTETRGC, and GTETRGD pins are input to the GPTW via the POEG. Set the polarity of these signals with the POEG.

## 24.2.9 General PWM Timer Count-Down Source Select Register (GTDNSR)

n = 0 to 9

The GTDNSR register sets a count-down source for the GTCNT counter.

When at least one bit among bits in the GTDNSR register is set as 1, counting of the GTCNT counter by the count clock set by the GTCR.TPCS[3:0] bits becomes invalid, and the count-down by a source set as 1 by the GTDNSR register is executed.

Number of decrement in counting is one even when multiple sources are generated simultaneously.

Inputs from the GTETRGA, GTETRGB, GTETRGC, and GTETRGD pins are input to the GPTW via the POEG. Set the polarity of these signals with the POEG.

### 24.2.10 General PWM Timer Input Capture Source Select Register A (GTICASR)

| b31 to b24 | —      | Reserved                                      | These bits are read as 0. The write value should be 0.                                                              | R/W |

n = 0 to 9

The GTICASR register sets an input capture source for the GTCCRA register.

When at least one bit among bits in the GTICASR register is set to 1, input capture operation making the GTCCRA register as an input capture register is performed.

Inputs from the GTETRGA, GTETRGB, GTETRG, and GTETRGD pins are input to the GPTW via the POEG. Set the polarity of these signals with the POEG.

### 24.2.11 General PWM Timer Input Capture Source Select Register B (GTICBSR)

| b31 to b24 | —      | Reserved                                      | These bits are read as 0. The write value should be 0.                                                              | R/W |

n = 0 to 9

The GTICBSR register sets an input capture source for the GTCCRB register.

When at least one bit among bits in the GTICBSR register is set to 1, input capture operation making the GTCCRB register as an input capture register is performed.

Inputs from the GTETRGA, GTETRGB, GTETRGC, and GTETRGD pins are input to the GPTW via the POEG. Set the polarity of these signals with the POEG.

The GTCR register controls the GTCNT counter.

**CST Bit (Count Start)**

This bit controls start or stop for the GTCNT counter.

[Setting conditions]

- When 1 is written to a bit related to a channel number for the GTSTR register while the GTSSR.CSTRT bit is set to 1
- When an ELC event input, an external trigger, or a condition for the GTIOCnA pin input and GTIOCnB pin input (n = 0 to 9), which is enabled as a count start source by the GTSSR register, is generated
- 1 is written by software

[Clearing conditions]

- When 1 is written to a bit related to a channel number for the GTSTP register while the GTPSR.CSTOP bit is set to 1
- When an ELC event input, an external trigger, or a condition for the GTIOCnA pin input and GTIOCnB pin input, which is enabled as a count stop source by the GTPSR register, is generated
- 0 is written by software

**ICDS Bit (Input Capture Operation Select at Count Stop)**

This bit selects Input capture operation at count stop when the input capture function is selected.

**MD[2:0] Bits (Mode Select)**

These bits select the GPTW operating mode.

Only the MD[2] bit is valid at input capture.

Counting in sawtooth-wave mode is performed with 0 for the MD[2] bit, counting in triangle-wave mode is performed with 1 for the MD[2] bit.

Set the MD[2:0] bits while the GTCNT counter operation is stopped.

During the event count operation (when at least one bit among the bits for the GTUPSR and GTDNSR registers is set to 1), setting of the MD[2:0] bits are ignored, where counting in sawtooth-wave or triangle modes is not performed. Instead, up-counting or down-counting by a source set by the GTUPSR and GTDNSR registers is performed.

**TPCS[3:0] Bits (Timer Prescaler Select)**

These bits select a clock for the GTCNT counter. The clock source can be selected independently for each channel.

Set the TPCS[3:0] bits while the GTCNT counter operation is stopped.

When the GTETRGA, GTETRGB, GTETRGC, or GTETRGD is selected, output for the POEG at rising becomes a clock source. Set the polarity of these signals with the POEG.

n = 0 to 9

The GTUDDTYC register sets the count direction (up-counting/down-counting) for the GTCNT counter and configures duty setting for output from the GTIOCnA and GTIOCnB pins.

The setting is invalid during the event count operation.

## (1) Setting of Count Direction

- In sawtooth-wave mode

When the UD bit value is set to 0 during up-counting, the count direction is changed at an overflow (count clock when the GTCNT counter value is equal to the GTPR register value). When the UD bit value is set to 1 during down-counting, the count direction is changed at an underflow (count clock when the GTCNT counter value is equal to 0000 0000h). If the UD bit value is changed from 1 to 0 with the UDF bit being 0 and while counting is stopped, the counter starts up-counting and the count direction is changed at an overflow (count clock when the GTCNT counter value is equal to the GTPR register value).

If the UD bit value is changed from 0 to 1 with the UDF bit being 0 and while counting is stopped, the counter starts down-counting and the count direction is changed at an underflow (count clock when the GTCNT counter value is equal to 0000 0000h).

When the UDF bit is set to 1 while counting is stopped, the UD bit value at that time is reflected in the count direction when counting starts.

- In triangle-wave mode

Even if the UD bit value is changed during counting, the change will not be reflected in the count direction.

If the UD bit value is modified while the UDF bit is 0 and counting is stopped, the change will not be reflected in the count direction when counting starts. If the UDF bit is set to 1 while counting is stopped, the UD bit value at that time is reflected in the count direction when counting starts.

### UD Bit (Count Direction Setting)

This bit sets the count direction (up-counting or down-counting) for the GTCNT counter.

### UDF Bit (Forcible Count Direction Setting)

This bit forcibly sets the count direction when the GTCNT counter starts operation as the UD bit value.

Only 0 should be written to this bit during count operation.

When 1 has been written to this bit while counting is stopped, this bit should be returned to 0 before counting starts.

## (2) Setting of Output Duty

- In sawtooth-wave mode

When the OADTY[1:0]/OBDTY[1:0] bits are changed during up-count operation, the duty setting changed at an overflow is reflected.

When the OADTY[1:0]/OBDTY[1:0] bits are changed during down-count operation, the duty setting changed at an underflow is reflected.

When the OADTYF/OBDTYF bit is 0 while count operation is stopped and the OADTY[1:0]/OBDTY[1:0] bits are changed, the change in the duty-cycle setting is not reflected in the first count operation, but the change is reflected on an overflow in the case of counting up and on an underflow in the case of counting down.

When the OADTYF/OBDTYF bit is 1 while count operation is stopped and the OADTY[1:0]/OBDTY[1:0] bits are changed, the change in the duty-cycle setting is immediately reflected during the first count operation.

- In triangle-wave mode

When the OADTY[1:0]/OBDTY[1:0] bits are changed during count operation, the duty-cycle setting changed at an underflow is reflected.

When the OADTYF/OBDTYF bit is 0 during count operation and the OADTY[1:0]/OBDTY[1:0] bits are changed, the duty-cycle setting changed during the first count operation is not reflected, the duty-cycle setting changed at an underflow is reflected.

When the OADTYF/OBDTYF bit is 1 while count operation is stopped and the OADTY[1:0]/OBDTY[1:0] bits are changed, the change in the duty-cycle setting is immediately reflected during the first count operation.

**OmDTY[1:0] Bits (GTIOCnm Pin Output Duty Setting) (n = 0 to 9; m = A, B)**

These bits set the output of the duty cycle (0%, 100% or compare match control) on the GTIOCnm pin.

**OmDTYF Bit (GTIOCnm Pin Output Duty Forced Setting) (n = 0 to 9; m = A, B)**

This bit forcibly specifies the duty cycle at the start of the GTCNT counter in the OmDTY[1:0] bits.

Always write 0 to the bit during count operation.

When writing 1 to the bit while count operation is stopped, set the bit back to 0 by the end of the first cycle after the count operation started and specify the next cycle.

**OmDTYR Bit (Output after Release of GTIOCnm Pin Output 0%/100% Duty Cycle Settings)  
(n = 0 to 9; m = A, B)**

When the setting of a GTIOCnm pin for a 0% or 100% duty cycle is forcibly changed due to a compare match, the output level on the pin is maintained after the period has elapsed if the value of the GTIOR.GTIOM[3:2] bits is 00b, but maintenance and a value to control toggling are selected after the period has elapsed if the output has become toggled and the setting is 11b.

The GPTW internally continues to perform compare match operation during duty-cycle 0% or 100% operation. When the OmDTYR bit is 1, the value after the period has elapsed due this compare match operation is target for the GTIOM[3:2] bits.

n = 0 to 9

GTIOR sets the functions of the GTIOCnA and GTIOCnB pins.

#### **GTIOm[4:0] Bits (GTIOCnm Pin Function Select) (n = 0 to 9; m = A, B)**

These bits select the GTIOCnm pin function. For details, see Table 24.4.

#### **OmDFLT Bit (GTIOCnm Pin Output Value Setting at the Count Stop) (n = 0 to 9; m = A, B)**

This bit sets whether the GTIOCnm pin outputs high or low when counting is stopped.

#### **OmHLD Bit (GTIOCnm Pin Output Retention at the Start/Stop Count) (n = 0 to 9; m = A, B)**

This bit specifies whether the GTIOCnm pin output level is retained or the level depends on the register setting when counting is started or stopped.

[Setting conditions]

- The output is retained when counting starts or stops.

[Clearing conditions]

- The value specified by the GTIOm[4] bit is output when counting starts.
- The value specified by the OmDFLT bit is output when counting stops.
- If the OmDFLT bit is modified while counting is stopped, it is immediately reflected in the output.

#### **OmE Bit (GTIOCnm Pin Output Enable) (m = A, B)**

This bit selects whether the GTIOCnm pin output is performed or not.

When the GTCCRM register is used as an input capture register (at least one bit among the bits for the GTICmSR register is set to 1), the GTIOCnm pin output is not performed regardless of the setting of the OmE bit.

#### **OmDF[1:0] Bits (GTIOCnm Pin Negate Value Setting) (m = A, B)**

Select the value for output from the GTIOCnm pin in response to a request to disable output from the POEG.

#### **NFmEN Bit (GTIOCnm Pin Input Noise Filter Enable) (m = A, B)**

This bit sets enable or disable of the noise filter function for the GTIOCnm pin input. Switch these bits while the corresponding pin function for the timer I/O control register is set as the output compare function, because unintended internal edge may be generated when these bits are switched.

#### **NFCSm[1:0] Bits (GTIOCnm Pin Input Noise Filter Sampling Clock Select) (m = A, B)**

These bits set a sampling clock for the noise filter to the GTIOCnm pin input. Set to the input capture function after

waiting two cycles for the sampling clock cycle following the setting of these bits.

**Table 24.4 Settings of GTIOA[4:0] Bits (GTIOB[4:0] Bits)**

| GTIOA[4:0] (GTIOB[4:0]) Bits |    |    |    |    | Function                |                                       |                                                |
|------------------------------|----|----|----|----|-------------------------|---------------------------------------|------------------------------------------------|
| b4                           | b3 | b2 | b1 | b0 | b4                      | b3, b2                                | b1, b0                                         |
| 0                            | 0  | 0  | 0  | 0  | Initial output is Low.  | Output retained at the end of a cycle | Output retained at GTCCRA/GTCCRB compare match |
| 0                            | 0  | 0  | 0  | 1  |                         |                                       | Low output at GTCCRA/GTCCRB compare match      |
| 0                            | 0  | 0  | 1  | 0  |                         |                                       | High output at GTCCRA/GTCCRB compare match     |
| 0                            | 0  | 0  | 1  | 1  |                         |                                       | Output toggled at GTCCRA/GTCCRB compare match  |
| 0                            | 0  | 1  | 0  | 0  |                         | Low output at the end of a cycle      | Output retained at GTCCRA/GTCCRB compare match |
| 0                            | 0  | 1  | 0  | 1  |                         |                                       | Low output at GTCCRA/GTCCRB compare match      |
| 0                            | 0  | 1  | 1  | 0  |                         |                                       | High output at GTCCRA/GTCCRB compare match     |
| 0                            | 0  | 1  | 1  | 1  |                         |                                       | Output toggled at GTCCRA/GTCCRB compare match  |
| 0                            | 1  | 0  | 0  | 0  |                         | High output at the end of a cycle     | Output retained at GTCCRA/GTCCRB compare match |
| 0                            | 1  | 0  | 0  | 1  |                         |                                       | Low output at GTCCRA/GTCCRB compare match      |
| 0                            | 1  | 0  | 1  | 0  |                         |                                       | High output at GTCCRA/GTCCRB compare match     |

| 1                            | 1  | 1  | 0  | 1  |                         |                                       | Low output at GTCCRA/GTCCRB compare match      |
| 1                            | 1  | 1  | 1  | 0  |                         |                                       | High output at GTCCRA/GTCCRB compare match     |
| 1                            | 1  | 1  | 1  | 1  |                         |                                       | Output toggled at GTCCRA/GTCCRB compare match  |

Note: In sawtooth-wave mode, "end of a cycle" refers to an overflow (the value of the GTCNT counter changing from that of the GTPR register to 0000 0000h in up-counting), an underflow (the value of the GTCNT counter changing from 0000 0000h to that of the GTPR register in down-counting), or counter clearing. It refers to a trough in triangle-wave mode (the value of the GTCNT counter changing from 0000 0000h to 0000 0001h).

Note: When the timing of an end of a cycle and the timing of a GTCCRA/GTCCRB register compare match are the same in a compare-match operation, the b3 and b2 settings are given priority in sawtooth-wave PWM mode, and the b1 and b0 settings are given priority in any other mode.

Note: During the event count operation (when at least one bit among the bits for the GTUPSR and GTDNSR registers is set to 1), the b3 and b2 settings become invalid.

The GTINTAD register sets enabling or disabling for interrupt request, A/D conversion start request, and output stop detection.

#### **GTINTA Bit (GTCCRA Register Compare Match/Input Capture Interrupt Enable)**

This bit enables or disables interrupt requests by the GTCCRA register compare match/input capture (GTCIA).

#### **GTINTB Bit (GTCCRB Register Compare Match/Input Capture Interrupt Enable)**

This bit enables or disables interrupt requests by the GTCCRB register compare match/input capture (GTCIB).

#### **GTINTC Bit (GTCCRC Register Compare Match Interrupt Enable)**

This bit enables or disables interrupt requests by the GTCCRC register compare match (GTCIC).

#### **GTINTD Bit (GTCCRD Register Compare Match Interrupt Enable)**

This bit enables or disables interrupt requests by the GTCCRD register compare match (GTCID).

#### **GTINTE Bit (GTCCRE Register Compare Match Interrupt Enable)**

This bit enables or disables interrupt requests by the GTCCRE register compare match (GTCIE).

#### **GTINTF Bit (GTCCRF Register Compare Match Interrupt Enable)**

This bit enables or disables interrupt requests by the GTCCRF register compare match (GTCIF).

#### **GTINTPR[1:0] Bits (GTPR Register Compare Match Interrupt Enable)**

These bits enable or disable interrupt requests by a GTPR register compare match (GTCNT counter overflow) and those by a GTCNT counter underflow (GTCIV/GTCIU).

#### **ADTRAUEN Bit (GTADTRA Register Compare Match (Up-Counting) A/D Conversion Start Request Enable)**

This bit enables or disables A/D conversion start requests generated by the GTADTRA register compare matches during GTCNT counter up-counting.

The setting is invalid during the event count operation, and the A/D conversion start request is not generated.

#### **ADTRADEN Bit (GTADTRA Register Compare Match (Down-Counting) A/D Conversion Start Request Enable)**

This bit enables or disables A/D conversion start requests generated by the GTADTRA register compare matches during GTCNT counter down-counting.

The setting is invalid during the event count operation, and the A/D conversion start request is not generated.

**ADTRBUEN Bit (GTADTRB Register Compare Match (Up-Counting) A/D Conversion Start Request Enable)**

This bit enables or disables A/D conversion start requests generated by the GTADTRB register compare matches during GTCNT counter up-counting.

The setting is invalid during the event count operation, and the A/D conversion start request is not generated.

**ADTRBDEN Bit (GTADTRB Register Compare Match (Down-Counting) A/D Conversion Start Request Enable)**

This bit enables or disables A/D conversion start requests generated by the GTADTRB register compare matches during GTCNT counter down-counting.

The setting is invalid during the event count operation, and the A/D conversion start request is not generated.

**GRP[1:0] Bits (Output Stop Group Select)**

Select the group to detect disabling of output from the GPTW to the POEG and to request of disabling of output from the POEG to the GPTW.

Each signal indicating detection of disabling in response to a dead-time error or simultaneous driving of outputs to the high or low level is output to the group selected in the GRP[1:0] bits while the respective output disable detection enable bits are 1.

Requests to disabling output from the POEG for the group selected in the GRP[1:0] bits can be monitored with the GTST.ODF flag.

Set the GRP[1:0] bits while both of the OAE and OBE bits in the GTIOR register are set to 0.

**GRPDTE Bit (Dead Time Error Output Stop Detection Enable)**

This bit enables or disables the output stop detection by a dead time error.

The dead time error output stop detection is not generated during the event count operation.

**GRPABH Bit (Simultaneous High Output Stop Detection Enable)**

This bit enables or disables the output stop detection when the GTIOCnA and GTIOCnB pins have become high simultaneously.

**GRPABL Bit (Simultaneous Low Output Stop Detection Enable)**

This bit enables or disables the output stop detection when the GTIOCnA and GTIOCnB pins have become low simultaneously.

| b31        | —          | Reserved                                                                         | This bit is read as 0. The write value should be 0.                                                                                                                         | R/W         |

Note 1. Only 0 can be written to clear the flag. When clearing the ADTRAUF, ADTRADF, ADTRBUF, or ADTRBDF flag, be sure to write 0 only to the target flag or flags for clearing and to write 1 to the other flags not for clearing.

The GTST register indicates the status of the GPTW.

#### **ITCNT[2:0] Bits (GTCIV/GTCIU Interrupt Skipping Count Counter)**

When the GTCIV/GTCIU interrupt skipping function is used (the GTITC.IVTC[1:0] bits are set to a value other than 00b), the counter is incremented by 1 every time the GTCIV/GTCIU interrupt source is generated.

These bits are operated independently from the extended interrupt skipping by the GTEITC register.

[Clearing conditions]

- The GTCIV/GTCIU interrupt skipping function is not used (the GTITC.IVTT[2:0] bits are 000b when the IVTC[1:0] bits are 00b).
- The GTCIV/GTCIU interrupt skipping count matches the specified count (the ITCNT[2:0] bits match the skipping count specified by the IVTT[2:0] bits).
- When the count operation is stopped.

#### **TUCF Flag (Count Direction Flag)**

This flag indicates the count direction of the GTCNT counter.

This flag indicates 1 when in up-counting and indicates 0 when in down-counting during the event count operation.

#### **ADTRAUF Flag (GTADTRA Register Compare Match (Up-Counting) A/D Conversion Start Request Flag)**

This status flag indicates generation of a GTADTRA register compare match in up-counting.

[Setting condition]

- The GTCNT counter matches the GTADTRA register in up-counting

[Clearing conditions]

- 0 is written to the ADTRAUF flag

#### **ADTRADF Flag (GTADTRA Register Compare Match (Down-Counting) A/D Conversion Start Request Flag)**

This status flag indicates generation of a GTADTRA register compare match in down-counting.

[Setting condition]

- The GTCNT counter matches the GTADTRA register in down-counting

[Clearing conditions]

- 0 is written to the ADTRADF flag

#### **ADTRBUF Flag (GTADTRB Register Compare Match (Up-Counting) A/D Conversion Start Request Flag)**

This status flag indicates generation of a GTADTRB register compare match in up-counting.

[Setting condition]

- The GTCNT counter matches the GTADTRB register in up-counting

[Clearing conditions]

- 0 is written to the ADTRBUF flag

#### **ADTRBDF Flag (GTADTRB Register Compare Match (Down-Counting) A/D Conversion Start Request Flag)**

This status flag indicates generation of a GTADTRB register compare match in down-counting.

[Setting condition]

- The GTCNT counter matches the GTADTRB register in down-counting

[Clearing conditions]

- 0 is written to the ADTRBDF flag

### ODF Flag (Output Stop Request Flag)

This flag monitors the output stop request for the group selected by the GTINTAD.GRP[1:0] bits.

Even if a request to disable output is de-asserted after the request is made, releasing the control of negation on the PWM pins has to wait until the end of the PWM cycle.

### DTEF Flag (Dead Time Error Flag)

This flag indicates that the timer output toggle point after the automatic addition of dead time has exceeded the count period.

This flag returns to 0 when the timer output toggle point after the automatic addition of dead time is back within the period. This flag can only be read from. (Writing 0 to clear the flag is not allowed.)

When an interrupt by the DTEF flag is enabled (when the GTINTAD.GRPDTE bit is 1), the DTEF flag is output as detection of disabling of output to the POEG, and an GDTE interrupt is generated whenever the DTEF flag changes from 0 to 1.

[Setting condition]

- When a change point of the waveform after the automatic setting of dead time has exceeded the count period (in the following cases)
  - Up-counting in triangle-wave mode:  $GTCCRA$  register –  $GTDTVU$  register  $\leq 0$
  - Down-counting in triangle-wave mode:  $GTCCRA$  register –  $GTDVD$  register  $< 0$
  - Up-counting in sawtooth-wave one-shot pulse mode:
    - When  $GTCCRA$  register –  $GTDTVU$  register  $< 0$ , or  $GTCCRA$  register +  $GTDVD$  register  $> GTPR$  register
  - Down-counting in sawtooth-wave one-shot pulse mode:
    - When  $GTCCRA$  register +  $GTDTVU$  register  $> GTPR$  register, or  $GTCCRA$  register –  $GTDVD$  register  $< 0$

[Clearing condition]

- The timer output toggle point after the automatic addition of dead time is within the count period.

### OABHF Flag (Simultaneous High Output Flag)

This flag indicates that the simultaneous output of 1 both from the GTIOCnA and GTIOCnB pins.

When one of the GTIOCnA and GTIOCnB pins changes to 0, the flag changes to 0.

This flag can only be read from. (Writing 0 to clear the flag is not allowed.)

When the output stop detection by the OABHF flag is enabled (the GTINTAD.GRPABH bit is 1), the OABHF flag is output as the output stop detection to the POEG. The GPTW does not have an interrupt to indicate that outputs have been simultaneous driven to the high level. Use the interrupt function in the POEG if this is necessary.

[Setting condition]

- The GTIOCnA and GTIOCnB pins output 1 simultaneously while both the OAE and OBE bits in the GTIOR register are set to 1.

[Clearing conditions]

- The GTIOCnA and GTIOCnB pins output different values while both the OAE and OBE bits are set to 1.
- The GTIOCnA and GTIOCnB pins output 0 simultaneously while both the OAE and OBE bits are set to 1.
- At least one of the OAE and OBE bits is set to 0.

### OABLF Flag (Simultaneous Low Output Flag)

This flag indicates that the simultaneous output of 0 both from the GTIOCnA and GTIOCnB pins.

When one of the GTIOCnA and GTIOCnB pins changes to 1, the flag changes to 0.

This flag can only be read from. (Writing 0 to clear the flag is not allowed.)

When the output stop detection by the OABLF flag is enabled (the GTINTAD.GRPABL bit is 1), the OABLF flag is output as the output stop detection to the POEG. The GPTW does not have an interrupt to indicate that outputs have been

simultaneous driven to the high level. Use the interrupt function in the POEG if this is necessary.

[Setting condition]

- The GTIOCnA and GTIOCnB pins output 0 simultaneously while both the OAE and OBE bits in the GTIOR register are set to 1.

[Clearing conditions]

- The GTIOCnA and GTIOCnB pins output different values while both the OAE and OBE bits are set to 1.
- The GTIOCnA and GTIOCnB pins output 1 simultaneously while both the OAE and OBE bits are set to 1.
- At least one of the OAE and OBE bits is set to 0.

Comparison for the output value to generate the OABHF or OABLF flag uses the value before the compare match output (PWM output) is masked by the output negate function. Even during the output negate condition, compare match operation continues internally, where the OABHF or OABLF flag is updated based on the operation results.

The GTBER register makes settings for buffer operation.

Set the GTBER register except the BD[3:0] bits while the GTCNT counter is stopped.

#### BD[0] Bit (GTCCRA/GTCCRB Registers Buffer Operation Disable)

This bit disables buffer operation using the GTCCRA, GTCCRC, and GTCCRD registers together and buffer operation using the GTCCRB, GTCCRE, and GTCCRF registers together.

Even though the BD[0] bit is set to 0, buffer operation in the GTCCRB register is not performed if the GTDTCR.TDE bit is set to 1. Instead, the compare match value for negative-phase waveform with dead time is set automatically.

A value for the BD[0] bit in the channel related to the position of the bit written with 1 by the GTSECSR register can be set when 1 is written to the SBDCE or SBDCE bit in the GTSECR register.

When the DBRTEC<sub>m</sub> (m = A, B) bit is 1, setting the BD[0] bit to 1 while the mode of operation is sawtooth-wave one-shot pulse mode or triangle-wave PWM mode 3 results in transfer from the intermediate buffer to the GTCCR<sub>m</sub> register.

#### BD[1] Bit (GTPR Register Buffer Operation Disable)

This bit disables buffer operation using the GTPR, GTPBR, and GTPDBR registers together.

A value for the BD[1] bit in the channel related to the position of the bit written with 1 by the GTSECSR register can be set when 1 is written to the SBDPE or SBDPE bit in the GTSECR register.

**BD[2] Bit (GTADTRA/GTADTRB Registers Buffer Operation Disable)**

This bit disables buffer operation using the GTADTRA, GTADTBRA, and GTADTDBRA registers together and buffer operation using the GTADTRB, GTADTBRB, and GTADTDBRB registers together.

The setting is invalid during the event count operation, and the buffer operation using the GTADTRA and GTADTRB registers is not performed.

A value for the BD[2] bit in the channel related to the position of the bit written with 1 by the GTSECSR register can be set when 1 is written to the SBDAE or SBDAD bit in the GTSECR register.

**BD[3] Bit (GTDVU/GTDVD Registers Buffer Operation Disable)**

This bit disables buffer operation using the GTDVU and GTDBU registers together and buffer operation using the GTDVD and GTDBD registers together.

Even though the BD[3] bit is set to 0, buffer operation in the GTDVD register is not performed if the GTDTCR.TDFER bit is set to 1. Instead, the value in the GTDVU register is set automatically.

The setting is invalid during the event count operation, and the buffer operation using the GTDVU and GTDVD registers is not performed.

A value for the BD[3] bit in the channel related to the position of the bit written with 1 by the GTSECSR register can be set when 1 is written to the SBDDE or SBDDE bit in the GTSECR register.

**DBRTECm Bit (GTCCRm Register Double Buffer Repeat Operation Enable) (m = A, B)**

This setting enables the operation to repeat a transfer to the GTCCRm register from the intermediate buffer by cycle during the buffer transfer disable period when performing the double buffer operation using the GTCCRm register. It is valid in sawtooth-wave one-shot pulse mode or triangle-wave PWM mode 3.

The disabling period of buffer transfer indicates the period that buffer transfer is stopped by setting of the BD[0] bit (CPU writing or simultaneous buffer operation control by the GTSECSR register) and the period for buffer transfer extended skipping (except the case for skipping by counting both crests and troughs) by the GTEITLB register.

When the DBRTECm bit is 1, writing by the CPU to the GTCCRm register sets the same value in temporary register x (x = C, E). The value of the GTCCR<sub>x</sub> (x = C, E) register is also transferred to the temporary register x (x = C, E) by forcible buffer transfer.

**CCRA[1:0] Bits (GTCCRA Register Buffer Operation)**

These bits set buffer operation with the GTCCRA, GTCCRC, and GTCCRD registers combined. When buffer operation is restricted by the operating mode set in the GTCR register, the GTCR register setting is given priority.\*1

**CCRB[1:0] Bits (GTCCRB Register Buffer Operation)**

These bits set buffer operation with the GTCCRB, GTCCRE, and GTCCRF registers combined. When buffer operation is restricted by the operating mode set in the GTCR register, the GTCR register setting is given priority.\*1

**PR[1:0] Bits (GTPR Register Buffer Operation)**

These bits set buffer operation with the GTPR, GTPBR, and GTPDBR registers combined.

**CCRSWT Bit (GTCCRA and GTCCRB Registers Forcible Buffer Operation)**

Writing 1 to the CCRSWT bit forcibly performs buffer transfer of the GTCCRA and GTCCRB registers. This bit automatically returns to 0 after the writing of 1. This bit is read as 0.

This bit is valid only when counting is stopped with compare match operation specified.

**ADTTA[1:0] Bits (GTADTRA Register Buffer Transfer Timing Select)**

These bits set the transfer timing for buffer operation of the GTADTRA, GTADTBRA, and GTADTDBRA registers. The setting is invalid during the event count operation.

**ADTDA Bit (GTADTRA Register Double Buffer Operation)**

These bits set buffer operation with the GTADTRA, GTADTBRA, and GTADTDBRA registers combined.  
The setting is invalid during the event count operation.

**ADTTB[1:0] Bits (GTADTRB Register Buffer Transfer Timing Select)**

These bits set the transfer timing for buffer operation of the GTADTRB, GTADTBRB, and GTADTDBRB registers.  
The setting is invalid during the event count operation.

**ADTDB Bit (GTADTRB Register Double Buffer Operation)**

These bits set buffer operation with the GTADTRA, GTADTBRA, and GTADTDBRA registers combined.  
The setting is invalid during the event count operation.

Note 1. The buffer operation mode is fixed in sawtooth-wave one-shot pulse mode or triangle-wave PWM mode 3 (64-bit transfer at trough).

GTITC sets the skipping function for the GTCNT counter overflow (GTPR compare match) interrupt (GTCIV)/ underflow interrupt (GTCIU) and also sets whether to link the other interrupts and A/D conversion start requests with the GTCIV/GTCIU interrupt skipping function. Note that detection of disabling of output to the POEG and dead-time error interrupts cannot be linked with the GTCIV or GTCIU interrupt skipping function.

The setting is invalid during the event count operation. The setting is operated independently from the extended interrupt skipping by the GTEITC register.

#### **ITLA Bit (GTCCRA Register Compare Match/Input Capture Interrupt Link)**

This bit specifies whether to link the GTCCRA compare match/input capture interrupt (GTCIA) with the GTCIV/GTCIU interrupt skipping function.

#### **ITLB Bit (GTCCRB Register Compare Match/Input Capture Interrupt Link)**

This bit specifies whether to link the GTCCRB compare match/input capture interrupt (GTCIB) with the GTCIV/GTCIU interrupt skipping function.

#### **ITLC Bit (GTCCRC Register Compare Match Interrupt Link)**

This bit specifies whether to link the GTCCRC compare match interrupt (GTCIC) with the GTCIV/GTCIU interrupt skipping function.

#### **ITLD Bit (GTCCRD Register Compare Match Interrupt Link)**

This bit specifies whether to link the GTCCRD compare match interrupt (GTCID) with the GTCIV/GTCIU interrupt skipping function.

#### **ITLE Bit (GTCCRE Register Compare Match Interrupt Link)**

This bit specifies whether to link the GTCCRE compare match interrupt (GTCIE) with the GTCIV/GTCIU interrupt skipping function.

#### **ITLF Bit (GTCCRF Register Compare Match Interrupt Link)**

This bit specifies whether to link the GTCCRF compare match interrupt (GTCIF) with the GTCIV/GTCIU interrupt skipping function.

#### **IVTC[1:0] Bits (GTCIV/GTCIU Interrupt Skipping Function Select)**

These bits set the skipping function for the GTPR compare match (GTCNT counter overflow) interrupt (GTCIV)/ GTCNT counter underflow interrupt (GTCIU).

#### **IVTT[2:0] Bits (GTCIV/GTCIU Interrupt Skipping Count Select)**

These bits set the skipping count for the GTPR compare match (GTCNT counter overflow) interrupt (GTCIV)/GTCNT counter underflow interrupt (GTCIU).

When modifying the IVTT[2:0] bits, first set the IVTC[1:0] bits to 00b.

#### **ADTAL Bit (GTADTRA Register A/D Conversion Start Request Link)**

This bit specifies whether to link the A/D conversion start request, which is generated in response to a compare match with the GTCNT counter and the GTADTRA register, with the GTCIV/GTCIU interrupt skipping function.

#### **ADTBL Bit (GTADTRB Register A/D Conversion Start Request Link)**

This bit specifies whether to link the A/D conversion start request, which is generated in response to a compare match with the GTCNT counter and the GTADTRB register, with the GTCIV/GTCIU interrupt skipping function.

### 24.2.19 General PWM Timer Counter (GTCNT)

Address(es): GPTW0.GTCNT 000C 2048h, GPTW1.GTCNT 000C 2148h, GPTW2.GTCNT 000C 2248h, GPTW3.GTCNT 000C 2348h, GPTW4.GTCNT 000C 2448h, GPTW5.GTCNT 000C 2548h, GPTW6.GTCNT 000C 2648h, GPTW7.GTCNT 000C 2748h, GPTW8.GTCNT 000C 2848h, GPTW9.GTCNT 000C 2948h

The GTCNT counter is a 32-bit readable/writable counter. There is one GTCNT counter for each channel. Writing is available only when counting is stopped, and thus writing is disabled while counting is in progress (when CST = 1). Access in 8-bit or 16-bit units to the GTCNT counter is prohibited, and it should be accessed in 32-bit units. Set the range of the GTCNT counter within the range of  $0 \leq \text{GTCNT counter} \leq \text{GTPR register}$ .

### 24.2.20 General PWM Timer Compare Capture Register m (GTCCRm) (m = A to F)

Address(es): GPTW0.GTCCRA 000C 204Ch, GPTW1.GTCCRA 000C 214Ch, GPTW2.GTCCRA 000C 224Ch, GPTW3.GTCCRA 000C 234Ch, GPTW4.GTCCRA 000C 244Ch, GPTW5.GTCCRA 000C 254Ch, GPTW6.GTCCRA 000C 264Ch, GPTW7.GTCCRA 000C 274Ch, GPTW8.GTCCRA 000C 284Ch, GPTW9.GTCCRA 000C 294Ch,  
 GPTW0.GTCCRB 000C 2050h, GPTW1.GTCCRB 000C 2150h, GPTW2.GTCCRB 000C 2250h, GPTW3.GTCCRB 000C 2350h, GPTW4.GTCCRB 000C 2450h, GPTW5.GTCCRB 000C 2550h, GPTW6.GTCCRB 000C 2650h, GPTW7.GTCCRB 000C 2750h, GPTW8.GTCCRB 000C 2850h, GPTW9.GTCCRB 000C 2950h,  
 GPTW0.GTCCRC 000C 2054h, GPTW1.GTCCRC 000C 2154h, GPTW2.GTCCRC 000C 2254h, GPTW3.GTCCRC 000C 2354h, GPTW4.GTCCRC 000C 2454h, GPTW5.GTCCRC 000C 2554h, GPTW6.GTCCRC 000C 2654h, GPTW7.GTCCRC 000C 2754h, GPTW8.GTCCRC 000C 2854h, GPTW9.GTCCRC 000C 2954h,  
 GPTW0.GTCCRE 000C 2058h, GPTW1.GTCCRE 000C 2158h, GPTW2.GTCCRE 000C 2258h, GPTW3.GTCCRE 000C 2358h, GPTW4.GTCCRE 000C 2458h, GPTW5.GTCCRE 000C 2558h, GPTW6.GTCCRE 000C 2658h, GPTW7.GTCCRE 000C 2758h, GPTW8.GTCCRE 000C 2858h, GPTW9.GTCCRE 000C 2958h,  
 GPTW0.GTCCRD 000C 205Ch, GPTW1.GTCCRD 000C 215Ch, GPTW2.GTCCRD 000C 225Ch, GPTW3.GTCCRD 000C 235Ch, GPTW4.GTCCRD 000C 245Ch, GPTW5.GTCCRD 000C 255Ch, GPTW6.GTCCRD 000C 265Ch, GPTW7.GTCCRD 000C 275Ch, GPTW8.GTCCRD 000C 285Ch, GPTW9.GTCCRD 000C 295Ch,  
 GPTW0.GTCCRF 000C 2060h, GPTW1.GTCCRF 000C 2160h, GPTW2.GTCCRF 000C 2260h, GPTW3.GTCCRF 000C 2360h, GPTW4.GTCCRF 000C 2460h, GPTW5.GTCCRF 000C 2560h, GPTW6.GTCCRF 000C 2660h, GPTW7.GTCCRF 000C 2760h, GPTW8.GTCCRF 000C 2860h, GPTW9.GTCCRF 000C 2960h

The GTCCRm register is a 32-bit readable/writable register.

Access in 8-bit or 16-bit units to the GTCCRm register is prohibited, and it should be accessed in 32-bit units.

The GTCCRA and GTCCRB registers are registers used for both output compare and input capture.

The GTCCRC and GTCCRE registers are compare match registers, and can also function as buffer registers for the GTCCRA and GTCCRB registers.

The GTCCRD and GTCCRF registers are compare match registers, and can also function as buffer registers for the GTCCRC and GTCCRE registers (double buffer registers for the GTCCRA and GTCCRB registers).

### 24.2.21 General PWM Timer Period Setting Register (GTPR)

Address(es): GPTW0.GTPR 000C 2064h, GPTW1.GTPR 000C 2164h, GPTW2.GTPR 000C 2264h, GPTW3.GTPR 000C 2364h, GPTW4.GTPR 000C 2464h, GPTW5.GTPR 000C 2564h, GPTW6.GTPR 000C 2664h, GPTW7.GTPR 000C 2764h, GPTW8.GTPR 000C 2864h, GPTW9.GTPR 000C 2964h

The GTPR register is a 32-bit readable/writable register that sets the maximum count value of the GTCNT counter. Access in 8-bit or 16-bit units to the GTPR register is prohibited, and it should be accessed in 32-bit units. In sawtooth-wave mode, the value of (GTPR register + 1) is the count period. In triangle-wave mode, the value of (GTPR register value × 2) is the count period.

### 24.2.22 General PWM Timer Period Setting Buffer Register (GTPBR)

Address(es): GPTW0.GTPBR 000C 2068h, GPTW1.GTPBR 000C 2168h, GPTW2.GTPBR 000C 2268h, GPTW3.GTPBR 000C 2368h, GPTW4.GTPBR 000C 2468h, GPTW5.GTPBR 000C 2568h, GPTW6.GTPBR 000C 2668h, GPTW7.GTPBR 000C 2768h, GPTW8.GTPBR 000C 2868h, GPTW9.GTPBR 000C 2968h

The GTPBR register is a 32-bit readable/writable register that functions as a buffer register for the GTPR register. Access in 8-bit or 16-bit units to the GTPBR register is prohibited, and it should be accessed in 32-bit units.

### 24.2.23 General PWM Timer Period Setting Double-Buffer Register (GTPDBR)

Address(es): GPTW0.GTPDBR 000C 206Ch, GPTW1.GTPDBR 000C 216Ch, GPTW2.GTPDBR 000C 226Ch,  
GPTW3.GTPDBR 000C 236Ch, GPTW4.GTPDBR 000C 246Ch, GPTW5.GTPDBR 000C 256Ch,  
GPTW6.GTPDBR 000C 266Ch, GPTW7.GTPDBR 000C 276Ch, GPTW8.GTPDBR 000C 286Ch,  
GPTW9.GTPDBR 000C 296Ch

The GTPDBR register is a 32-bit readable/writable register that functions as a buffer register for the GTPBR register (a double buffer register for the GTPR register).

Access in 8-bit or 16-bit units to the GTPDBR register is prohibited, and it should be accessed in 32-bit units.

### 24.2.24 A/D Conversion Start Request Timing Register m (GTADTRm) (m = A, B)

Address(es): GPTW0.GTADTRA 000C 2070h, GPTW1.GTADTRA 000C 2170h, GPTW2.GTADTRA 000C 2270h,  
GPTW3.GTADTRA 000C 2370h, GPTW4.GTADTRA 000C 2470h, GPTW5.GTADTRA 000C 2570h,  
GPTW6.GTADTRA 000C 2670h, GPTW7.GTADTRA 000C 2770h, GPTW8.GTADTRA 000C 2870h,  
GPTW9.GTADTRA 000C 2970h,  
GPTW0.GTADTRB 000C 207Ch, GPTW1.GTADTRB 000C 217Ch, GPTW2.GTADTRB 000C 227Ch,  
GPTW3.GTADTRB 000C 237Ch, GPTW4.GTADTRB 000C 247Ch, GPTW5.GTADTRB 000C 257Ch,  
GPTW6.GTADTRB 000C 267Ch, GPTW7.GTADTRB 000C 277Ch, GPTW8.GTADTRB 000C 287Ch,  
GPTW9.GTADTRB 000C 297Ch

The GTADTRm register is 32-bit readable/writable register that set the timing of A/D conversion start request generation.

Access in 8-bit or 16-bit units to the GTADTRm register is prohibited, and it should be accessed in 32-bit units.

When the GTADTRm register value matches the GTCNT counter value, an A/D conversion start request is generated.

### 24.2.25 A/D Conversion Start Request Timing Buffer Register m (GTADTB<sub>Rm</sub>) (m = A, B)

Address(es): GPTW0.GTADTBRA 000C 2074h, GPTW1.GTADTBRA 000C 2174h, GPTW2.GTADTBRA 000C 2274h,  
GPTW3.GTADTBRA 000C 2374h, GPTW4.GTADTBRA 000C 2474h, GPTW5.GTADTBRA 000C 2574h,  
GPTW6.GTADTBRA 000C 2674h, GPTW7.GTADTBRA 000C 2774h, GPTW8.GTADTBRA 000C 2874h,  
GPTW9.GTADTBRA 000C 2974h,  
GPTW0.GTADTBRB 000C 2080h, GPTW1.GTADTBRB 000C 2180h, GPTW2.GTADTBRB 000C 2280h,  
GPTW3.GTADTBRB 000C 2380h, GPTW4.GTADTBRB 000C 2480h, GPTW5.GTADTBRB 000C 2580h,  
GPTW6.GTADTBRB 000C 2680h, GPTW7.GTADTBRB 000C 2780h, GPTW8.GTADTBRB 000C 2880h,  
GPTW9.GTADTBRB 000C 2980h

The GTADTB<sub>Rm</sub> register is 32-bit readable/writable register that function as buffer register for the GTADT<sub>Rm</sub> register. Access in 8-bit or 16-bit units to the GTADTB<sub>Rm</sub> register is prohibited, and it should be accessed in 32-bit units.

### 24.2.26 A/D Conversion Start Request Timing Double-Buffer Register m (GTADTDB<sub>Rm</sub>) (m = A, B)

Address(es): GPTW0.GTADTDBRA 000C 2078h, GPTW1.GTADTDBRA 000C 2178h, GPTW2.GTADTDBRA 000C 2278h,  
GPTW3.GTADTDBRA 000C 2378h, GPTW4.GTADTDBRA 000C 2478h, GPTW5.GTADTDBRA 000C 2578h,  
GPTW6.GTADTDBRA 000C 2678h, GPTW7.GTADTDBRA 000C 2778h, GPTW8.GTADTDBRA 000C 2878h,  
GPTW9.GTADTDBRA 000C 2978h,  
GPTW0.GTADTDBRB 000C 2084h, GPTW1.GTADTDBRB 000C 2184h, GPTW2.GTADTDBRB 000C 2284h,  
GPTW3.GTADTDBRB 000C 2384h, GPTW4.GTADTDBRB 000C 2484h, GPTW5.GTADTDBRB 000C 2584h,  
GPTW6.GTADTDBRB 000C 2684h, GPTW7.GTADTDBRB 000C 2784h, GPTW8.GTADTDBRB 000C 2884h,  
GPTW9.GTADTDBRB 000C 2984h

The GTADTDB<sub>Rm</sub> register is 32-bit readable/writable register that function as buffer register for the GTADTB<sub>Rm</sub> register (double buffer register for the GTADT<sub>Rm</sub> register).

Access in 8-bit or 16-bit units to the GTADTDB<sub>Rm</sub> register is prohibited, and it should be accessed in 32-bit units.

## 24.2.27 General PWM Timer Dead Time Control Register (GTDTCR)

Address(es): GPTW0.GTDTCR 000C 2088h, GPTW1.GTDTCR 000C 2188h, GPTW2.GTDTCR 000C 2288h, GPTW3.GTDTCR 000C 2388h, GPTW4.GTDTCR 000C 2488h, GPTW5.GTDTCR 000C 2588h, GPTW6.GTDTCR 000C 2688h, GPTW7.GTDTCR 000C 2788h, GPTW8.GTDTCR 000C 2888h, GPTW9.GTDTCR 000C 2988h

| b31 to b9 | —      | Reserved                               | These bits are read as 0. The write value should be 0.                                                                                                                                                                  | R/W |

The GTDTCR register enables automatic setting of a compare match value for negative-phase waveform with dead time. The setting is invalid during the event count operation.

### TDE Bit (Negative-Phase Waveform Setting)

This bit sets whether to use the GTDVU and GTDVD registers. When the GTDVU and GTDVD registers are used, the compare match value for a negative-phase waveform with dead time that was obtained by the compare match value of a positive-phase waveform (GTCCRA register) and the dead time value (GTDVU and GTDVD registers) is automatically set in the GTCCRB register.

The TDE bit setting is ignored in sawtooth-wave PWM mode, and the GTCCRB register is not automatic setting. The automatically set GTCCRB register value has the following upper and lower limit values.

- Triangle wave PWM mode
  - Upper limit value: the value set in the GTPR register – 1
  - Lower limit value: 0000 0001h in up-counting, 0000 0000h in down-counting
- Sawtooth-wave one-shot pulse mode
  - Upper limit value: the value set in the GTPR register
  - Lower limit value: 0000 0000h

If the obtained GTCCRB register value is not within the range between the upper and lower limits, the upper or lower limit is set in the GTCCRB register, and the GTST.DTEF flag becomes 1. However, if the obtained GTCCRB register value exceeds the upper limit in triangle-wave PWM mode, the DTEF flag becomes 0.

**TDBUE Bit (GTDVU Register Buffer Operation Enable)**

This bit enables buffer operation with the GTDVU and GTDBU registers combined.

The timing of buffer transfer is at troughs in triangle-wave mode, and at overflows or underflows in sawtooth-wave mode.

**TDBDE Bit (GTDVD Register Buffer Operation Enable)**

This bit enables buffer operation with the GTDVD and GTDBD registers combined.

The buffer transfer timing is the trough in triangle-wave mode, and at an overflow or underflow in sawtooth-wave mode.

When this bit and the TDFER bit are set to 1 simultaneously, the TDFER bit setting is given priority.

**TDFER Bit (GTDVD Register Setting)**

This bit sets whether or not the value written to the GTDVU register is also set to the GTDVD register automatically.

**24.2.28 General PWM Timer Dead Time Value Register m (GTDVm) (m = U, D)**

Address(es): GPTW0.GTDVU 000C 208Ch, GPTW1.GTDVU 000C 218Ch, GPTW2.GTDVU 000C 228Ch,  
GPTW3.GTDVU 000C 238Ch, GPTW4.GTDVU 000C 248Ch, GPTW5.GTDVU 000C 258Ch,  
GPTW6.GTDVU 000C 268Ch, GPTW7.GTDVU 000C 278Ch, GPTW8.GTDVU 000C 288Ch,  
GPTW9.GTDVU 000C 298Ch,  
GPTW0.GTDVD 000C 2090h, GPTW1.GTDVD 000C 2190h, GPTW2.GTDVD 000C 2290h,  
GPTW3.GTDVD 000C 2390h, GPTW4.GTDVD 000C 2490h, GPTW5.GTDVD 000C 2590h,  
GPTW6.GTDVD 000C 2690h, GPTW7.GTDVD 000C 2790h, GPTW8.GTDVD 000C 2890h,  
GPTW9.GTDVD 000C 2990h

The GTDVm register is 32-bit readable/writable register that set the dead time for generating PWM waveforms with dead time.

Access in 8-bit or 16-bit units to the GTDVm register is prohibited, and it should be accessed in 32-bit units.

The GTDVU register is used for up-counting. The GTDVD register is used for down-counting.

The setting which the value for the GTDVm register is equal to or larger than the value for the GTPR register is prohibited.

In addition, when using the automatic dead time setting function, do not set a value that makes a change point of the waveform exceeding the count period. The change point of the negative-phase waveform, which is automatically calculated, is obtained by reading the GTCCRB register. When using the GTDVm register, writing to the GTCCRB register is prohibited. When setting this register to 0, waveforms without dead time are output. When the GTDTCR.TDFER bit is 1, the writing to the GTDVD register has no effect. At this time, when the GTDVD register is read, the value for the GTDVU register is read.

### 24.2.29 General PWM Timer Dead Time Value Buffer Register m (GTDBm) (m = U, D)

Address(es): GPTW0.GTDBU 000C 2094h, GPTW1.GTDBU 000C 2194h, GPTW2.GTDBU 000C 2294h, GPTW3.GTDBU 000C 2394h, GPTW4.GTDBU 000C 2494h, GPTW5.GTDBU 000C 2594h, GPTW6.GTDBU 000C 2694h, GPTW7.GTDBU 000C 2794h, GPTW8.GTDBU 000C 2894h, GPTW9.GTDBU 000C 2994h, GPTW0.GTDBD 000C 2098h, GPTW1.GTDBD 000C 2198h, GPTW2.GTDBD 000C 2298h, GPTW3.GTDBD 000C 2398h, GPTW4.GTDBD 000C 2498h, GPTW5.GTDBD 000C 2598h, GPTW6.GTDBD 000C 2698h, GPTW7.GTDBD 000C 2798h, GPTW8.GTDBD 000C 2898h, GPTW9.GTDBD 000C 2998h

The GTDBm register is 32-bit readable/writable register that function as buffer register for the GTDVM register. Access in 8-bit or 16-bit units to the GTDBm register is prohibited, and it should be accessed in 32-bit units.

The GTSOS register is a status register that indicates the status of the output protection function. The output protection function is enabled only when the dead time is automatically set (the GTDTCR.TDE bit is 1) in triangle-wave mode.

#### SOS[1:0] Bits (Output Protection Function Status)

This bit indicates the status of the output protection function in triangle-wave PWM mode. For details of the output protection function, see section 24.8.4, Output Protection Function for GTIOCnm Pin Output (n = 0 to 9; m = A, B).

| b31 to b1 | —      | Reserved                                     | These bits are read as 0. The write value should be 0.               | R/W |

The GTSOTR register temporarily releases the protected state of GTIOCnB pin output (n = 0 to 9) when output protection has been set.

The protected state can be released only for the case of the GTSOS.SOS[1:0] bits are 10b (protected state in which GTCCRA register  $\geq$  GTPR register has occurred during transfer at trough). The protected state cannot be released for any other case.

#### SOTR Bit (Output Protection Function Temporary Release)

This bit sets whether to temporarily release the protected state of the GTIOCnB pin output in an output protected state. After the SOTR bit has been set to 1, the output protection function is canceled from the first trough. After the SOTR bit has been set to 0, output protection is resumed from the first trough.

The write value should be 0.                                                                                                                                                                                                                                                                                                                                                         | R/W |

This register is used to control monitors for the A/D conversion start request signal that is synchronized with a frame.

### ADSMSk[1:0] Bits (A/D Conversion Start Request Signal Monitor k Selection) (k = 0, 1)

These bits are used to select A/D conversion start request signal synchronized with a frame which is monitored by the GTADSMk pin.

### ADSMENk Bit (A/D Conversion Start Request Signal Monitor k Output Enabling) (k = 0, 1)

This bit enables or disables the monitor output to the GTADSMk pin.

When the output is disabled, the GTADSMk pin goes to the low level.

When the bit is 1, the signal on the GTADSMk pin goes to the high level on assertion of the signal to request to the start of A/D conversion selected by the ADSMSk[1:0] bits and returns to the low level at the end of the current cycle of the timer for the channel that generated the given signal to request the start of A/D conversion. When the counter stops, the value when the counter stopped is retained for output. Set the ADSMENk bit to 0 to output the low level.

When a signal to request the start of A/D conversion is generated at the end of a timer period, the generation of this signal has priority in terms of monitoring output and the output remains at the high level till the end of the next period.

When the output of the same A/D conversion start request signal monitoring output is enabled for multiple channels, ORed signals will be output from the GPTW.

| b31 to b28 | EITCNT2[3:0]   | Extended Interrupt Skipping Counter 2                     | The extended interrupt skipping counter 2                                                                                                                                                                                                                                                                                                                                                                  | R         |

Note 1. The EITCNT2IV[3:0] bits are only writable when the value other than 00b is written to the EIVTC2[1:0] bits that have been 00b.

The GTEITC register sets the extended interrupt skipping function to skip the interrupts, A/D conversion start requests, and buffer transfers independently by counting at overflow and underflow in the GTCNT counter. The setting is operated independently from the interrupt skipping by the GTITC register.

The setting is invalid during the event count operation.

### **EIVTCk[1:0] Bits (Extended Interrupt Skipping k Count Source Select) (k = 1, 2)**

These bits select the way of counting for the extended interrupt skipping counter k. Setting only with these bits does not skip the interrupts, A/D conversion start requests, and buffer transfers.

Skipping function for the interrupt, A/D conversion start request, and buffer transfer, all of which are a target of skipping, is set individually with the GTEITLI1, GTEITLI2, and GTEITLB registers.

### **EIVTTk[3:0] Bits (The Extended Interrupt Skipping k Skipping Count Setting) (k = 1, 2)**

A count for the period with continuous skipping is set as a skipping count, where a period is from a generation of a count source selected by the EIVTCk[1:0] bits to the next generation of the count source. When the count source is generated while the EIVTTk[3:0] bits match the EITCNTk[3:0] bits, the EITCNTk[3:0] bits are cleared.

When these bits are 0000b, skipping is not performed.

### **EITCNT1[3:0] Bits (Extended Interrupt Skipping Counter 1)**

The counting is incremented by 1 every time a count source (overflow/underflow/crest/trough) selected by the EIVTC1[1:0] bits is generated.

Counting is performed periodically within the range between 0 and the EIVTT1[3:0] bits.

Even if the GTCNT counter is stopped, the value is not cleared, and value at stop of the GTCNT counter is retained.

[Clearing conditions]

- 00b is written to the EIVTC1[1:0] bits
- 0000b is written to the EIVTT1[3:0] bits
- A count source (overflow/underflow/crest/trough) selected by the EIVTC1[1:0] bits is generated when the extended interrupt skipping 1 skipping count set by the EIVTT1[3:0] bits match the value for the EITCNT1[3:0]

### **EITCNT2IV[3:0] Bits (Extended Interrupt Skipping Counter 2 Initial Value)**

These bits are the value of the initial value for the extended interrupt skipping counter 2. Writing to the EITCNT2IV[3:0] is performed only when the writing value to the EIVTC2[1:0] bits are other than 00b and when the GTEITC register is written by the access of upper 16 bits or 32 bits while the EITCNT2[3:0] bits are set not to count (EIVTC2[1:0] bits are 00b). When the EITCNT2IV[3:0] bits are written, the value written to the EITCNT2IV[3:0] bits is written to the EITCNT2[3:0] bits simultaneously.

The writing to the EITCNT2IV[3:0] bits are ignored when the EITCNT2[3:0] bits are set to count (EIVTC2[1:0] bits are other than 00b) or perform the setting of not to count (00b is written to the EIVTC2[1:0] bits).

The EITCNT2IV[3:0] bits are not reset by the writing 00b to the EIVTC2[1:0] bits.

### **EITCNT2[3:0] Bits (Extended Interrupt Skipping Counter 2)**

The counting is incremented by 1 every time a count source (overflow/underflow/crest/trough) selected by the EIVTC2[1:0] bits is generated.

Counting is performed periodically within the range between 0 and the EIVTT2[3:0] bits.

Even if the GTCNT counter is stopped, the value is not cleared, and value at stop of the GTCNT counter is retained.

Setting of the initial value for the EITCNT2[3:0] bits are performed only when the writing value to the EIVTC2[1:0] bits are other than 00b and when the GTEITC register is written by the access of upper 16 bits or 32 bits while the extended interrupt skipping counter 2 is set as not to count (00b is written to the EIVTC2[1:0] bits).

When the initial value is set, the written value to the EITCNT2IV[3:0] bits is written to the EITCNT2[3:0] bits as the initial value.

[Clearing conditions]

- 00b is written to the EIVTC2[1:0] bits
- 0000b is written to the EIVTT2[3:0] bits

- The value other than 00b is written to the EIVTC2[1:0] bits and the 0000b is written to the EITCNT2IV[3:0] bits simultaneously while 00b is set to the EIVTC2[1:0] bits
- A count source (overflow/underflow/crest/trough) selected by the EIVTC2[1:0] bits is generated when the extended interrupt skipping 2 skipping count set by the EIVTT2[3:0] bits match the value for the EITCNT2[3:0]

| b30 to b28 | EITLU[2:0] | Underflow Interrupt Extended Skipping Function Select                                    | See Table 24.5.                                     | R/W |
| b31        | —          | Reserved                                                                                 | This bit is read as 0. The write value should be 0. | R/W |

The GTEITL1 register sets the extended skipping function for interrupts such as compare match/input capture, overflow, and underflow.

Setting only with this register does not perform skipping. The GTEITC register should be set so that a corresponding extended interrupt skipping counter operates the counting.

The setting is operated independently from the interrupt skipping by the GTITC register.

The setting is invalid during the event count operation.

### EITLm[2:0] Bits (GTCCRm Register Compare Match/Input Capture Interrupt Extended Skipping Function Select) (m = A, B)

These bits select the extended interrupt skipping function to skip the compare match/input capture interrupt (GTClm) in the GTCCRm register.

Refer to Table 24.5.

### EITLx[2:0] Bits (GTCCRx Register Compare Match Interrupt Extended Skipping Function Select) (x = C, D, E, F)

These bits select the extended interrupt skipping function to skip the compare match interrupt (GTClx) in the GTCCRx register.

Refer to Table 24.5.

### EITLV[2:0] Bits (Overflow Interrupt Extended Skipping Function Select)

These bits select the extended interrupt skipping function to skip the interrupt at overflow.

Refer to Table 24.5.

### EITLU[2:0] Bits (Underflow Interrupt Extended Skipping Function Select)

These bits select the extended interrupt skipping function to skip the interrupt at underflow.

Refer to Table 24.5.

**Table 24.5 Setting the Function Select for the GTEITL1 Register**

| EITLy[2:0] Bits | Function                                                                                                                                                                                                                           |
|-----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0 0 0           | Do not perform an extended interrupt skipping                                                                                                                                                                                      |
| 0 0 1           | Skip an interrupt in the period when the value for the extended interrupt skipping counter 1 is other than 0 (An interrupt is output in the period of EITCNT1 bit = 0)                                                             |
| 0 1 0           | Skip an interrupt in the period when the value for the extended interrupt skipping counter 2 is other than 0 (An interrupt is output in the period of EITCNT2 bit = 0)                                                             |
| 0 1 1           | Skip an interrupt in the period the value for the extended interrupt skipping counter 1 or 2 is other than 0 (An interrupt is output in the period of EITCNT1 bit = 0 and EITCNT2 bit = 0)                                         |
| 1 0 0           | Do not set this value                                                                                                                                                                                                              |
| 1 0 1           | Skip an interrupt in the period when the value for the extended interrupt skipping counter 1 is other than the skipping count (An interrupt is output in the period of EITCNT1 bit = EIVTT1 bit)                                   |
| 1 1 0           | Skip an interrupt in the period when the value for the extended interrupt skipping counter 2 is other than the skipping count (An interrupt is output in the period of EITCNT2 bit = EIVTT2 bit)                                   |
| 1 1 1           | Skip an interrupt in the period when the value for the extended interrupt skipping counter 1 or 2 is other than the skipping count (An interrupt is output in the period of EITCNT1 bit = EIVTT1 bit and EITCNT2 bit = EIVTT2 bit) |

y = A, B, C, D, E, F, V, U; k = 1, 2

Note: When the intended skipping counter is set as not to count (EIVTck[1:0]bits = 00b or EIVTTk[3:0] bits = 0000b), skipping is not performed.

Note: When the EITLy[2:0] bits are set to 011b or 111b, or when one of the skipping counters is set as not to count, skipping is not performed.

### 24.2.35 General PWM Timer Extended Interrupt Skipping Setting Register 2 (GTEITLI2)

Address(es): GPTW0.GTEITLI2 000C 20B0h, GPTW1.GTEITLI2 000C 21B0h, GPTW2.GTEITLI2 000C 22B0h, GPTW3.GTEITLI2 000C 23B0h, GPTW4.GTEITLI2 000C 24B0h, GPTW5.GTEITLI2 000C 25B0h, GPTW6.GTEITLI2 000C 26B0h, GPTW7.GTEITLI2 000C 27B0h, GPTW8.GTEITLI2 000C 28B0h, GPTW9.GTEITLI2 000C 29B0h

| Bit       | Symbol      | Bit Name                                                               | Description                                            | R/W |
|-----------|-------------|------------------------------------------------------------------------|--------------------------------------------------------|-----|
| b2 to b0  | EADTAL[2:0] | GTADTRA A/D Conversion Start Request Extended Skipping Function Select | See Table 24.6.                                        | R/W |
| b3        | —           | Reserved                                                               | This bit is read as 0. The write value should be 0.    | R/W |
| b6 to b4  | EADTBL[2:0] | GTADTRB A/D Conversion Start Request Extended Skipping Function Select | See Table 24.6.                                        | R/W |
| b31 to b7 | —           | Reserved                                                               | These bits are read as 0. The write value should be 0. | R/W |

The GTEITLI2 register sets the extended skipping function for A/D conversion start requests.

Setting only with this register does not perform skipping. The GTEITC register should be set so that a corresponding extended interrupt skipping counter operates the counting.

The setting is operated independently from the interrupt skipping by the GTITC register.

The setting is invalid during the event count operation.

#### EADTmL[2:0] Bits (GTADTRm A/D Conversion Start Request Extended Skipping Function Select) (m = A, B)

These bits select the extended interrupt skipping function to skip A/D conversion start requests for the compare match in the GTADTRm register.

Refer to Table 24.6.

**Table 24.6 Setting the Function Select for the GTEITLI2 Register**

| <b>EADTmL[2:0]<br/>Bits</b> | <b>Function</b>                                                                                                                                                                                                                                                             |
|-----------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0 0 0                       | Do not perform an extended interrupt skipping                                                                                                                                                                                                                               |
| 0 0 1                       | Skip an A/D conversion start request in the period when the value for the extended interrupt skipping counter 1 is other than 0<br>(An A/D conversion start request is output in the period of EITCNT1 bit = 0)                                                             |
| 0 1 0                       | Skip an A/D conversion start request in the period when the value for the extended interrupt skipping counter 2 is other than 0<br>(An A/D conversion start request is output in the period of EITCNT2 bit = 0)                                                             |
| 0 1 1                       | Skip an A/D conversion start request in the period when the value for the extended interrupt skipping counter 1 or 2 is other than 0<br>(An A/D conversion start request is output in the period of EITCNT1 bit = 0 and EITCNT2 bit = 0)                                    |
| 1 0 0                       | Do not set this value                                                                                                                                                                                                                                                       |
| 1 0 1                       | Skip an A/D conversion start request in the period when the value for the extended interrupt skipping counter 1 is other than the skipping count<br>(An A/D conversion start request is output in the period of EITCNT1 bit = EIVTT1 bit)                                   |
| 1 1 0                       | Skip an A/D conversion start request in the period when the value for the extended interrupt skipping counter 2 is other than the skipping count<br>(An A/D conversion start request is output in the period of EITCNT2 bit = EIVTT2 bit)                                   |
| 1 1 1                       | Skip an A/D conversion start request in the period when the value for the extended interrupt skipping counter 1 or 2 is other than the skipping count<br>(An A/D conversion start request is output in the period of EITCNT1 bit = EIVTT1 bit and EITCNT2 bit = EIVTT2 bit) |

m = A, B; k = 1, 2

Note: When the intended skipping counter is set as not to count (EIVTck[1:0]bits = 00b or EIVTTk[3:0] bits = 0000b), skipping is not performed.

Note: When the EADTmL[2:0] bits are set to 011b or 111b, or when one of the skipping counters is set as not to count, skipping is not performed.

## 24.2.36 General PWM Timer Extended Buffer Transfer Skipping Setting Register (GTEITLB)

| b22 to b20 | EBTLADB[2:0] | GTADTRB Register Buffer Transfer Extended Skipping Function Select | See Table 24.7.                                        | R/W |
| b23        | —            | Reserved                                                           | This bit is read as 0. The write value should be 0.    | R/W |
| b26 to b24 | EBTLDVU[2:0] | GTDVU Register Buffer Transfer Extended Skipping Function Select   | See Table 24.7.                                        | R/W |
| b27        | —            | Reserved                                                           | This bit is read as 0. The write value should be 0.    | R/W |
| b30 to b28 | EBTLDVD[2:0] | GTDVD Register Buffer Transfer Extended Skipping Function Select   | See Table 24.7.                                        | R/W |
| b31        | —            | Reserved                                                           | This bit is read as 0. The write value should be 0.    | R/W |

The GTEITLB register sets the extended skipping function for buffer transfers.

Setting only with this register does not perform skipping. The GTEITC register should be set so that a corresponding extended interrupt skipping counter operates the counting.

The setting is operated independently from the interrupt skipping by the GTITC register.

The setting is invalid during the event count operation.

### EBTLCA[2:0] Bits (GTCCRA Register Buffer Transfer Extended Skipping Function Select)

These bits select the extended buffer transfer skipping function to skip buffer transfers (transfers among the GTCCRA, GTCCRC, GTCCRD registers and a temporary register A) in the GTCCRA register.

An extended skipping of buffer transfers in the GTCCRA register is valid for forcible buffer transfers by the GTBER.CCRSWT bit while the count operation is stopped. Forcible buffer transfers in the GTCCRA register should be performed in the condition of not performing the extended buffer transfer skipping.

**EBTLCB[2:0] Bits (GTCCRB Register Buffer Transfer Extended Skipping Function Select)**

These bits select the extended buffer transfer skipping function to skip buffer transfers (transfers among the GTCCRB, GTCCRE, GTCCRF registers and a temporary register B) in the GTCCRB register.

An extended skipping of buffer transfers in the GTCCRB register is valid for forcible buffer transfers by the GTBER.CCRSWT bit while the count operation is stopped. Forcible buffer transfers in the GTCCRB register should be performed in the condition of not performing the extended buffer transfer skipping.

**EBTLPR[2:0] Bits (GTPR Register Buffer Transfer Extended Skipping Function Select)**

These bits select the extended buffer transfer skipping function to skip buffer transfers (transfers among the GTPR, GTPBR, and GTPDBR registers) in the GTPR register.

**EBTLADm[2:0] Bits (GTADTRm Register Buffer Transfer Extended Skipping Function Select) (m = A, B)**

These bits select the extended buffer transfer skipping function to skip buffer transfers (transfers among the GTADTRm, GTADTBm, and GTADTDBm registers) in the GTADTRm register.

**EBTLDVm[2:0] Bits (GTDVm Register Buffer Transfer Extended Skipping Function Select) (m = U, D)**

These bits select the extended buffer transfer skipping function to skip buffer transfers (transfers between the GTDVm and GTDBm registers) in the GTDVm register.

**Table 24.7 Setting the Function Select for the GTEITLB Register**

| EBTLx[2:0] Bits | Function                                                                                                                                                                                                                                     |
|-----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0 0 0           | Do not perform an extended interrupt skipping                                                                                                                                                                                                |
| 0 0 1           | Skip a buffer transfer in the period when the value for the extended interrupt skipping counter 1 is other than 0 (A buffer transfer is output in the period of EITCNT1 bit = 0)                                                             |
| 0 1 0           | Skip a buffer transfer in the period when the value for the extended interrupt skipping counter 2 is other than 0 (A buffer transfer is output in the period of EITCNT2 bit = 0)                                                             |
| 0 1 1           | Skip a buffer transfer in the period when the value for the extended interrupt skipping counter 1 or 2 is other than 0 (A buffer transfer is output in the period of EITCNT1 bit = 0 and EITCNT2 bit = 0)                                    |
| 1 0 0           | Do not set this value                                                                                                                                                                                                                        |
| 1 0 1           | Skip a buffer transfer in the period when the value for the extended interrupt skipping counter 1 is other than the skipping count (A buffer transfer is output in the period of EITCNT1 bit = EIVTT1 bit)                                   |
| 1 1 0           | Skip a buffer transfer in the period when the value for the extended interrupt skipping counter 2 is other than the skipping count (A buffer transfer is output in the period of EITCNT2 bit = EIVTT2 bit)                                   |
| 1 1 1           | Skip a buffer transfer in the period when the value for the extended interrupt skipping counter 1 or 2 is other than the skipping count (A buffer transfer is output in the period of EITCNT1 bit = EIVTT1 bit and EITCNT2 bit = EIVTT2 bit) |

x = CA, CB, PR, ADA, ADB, DVU, DVD; k = 1, 2

Note: When the intended skipping counter is set as not to count (EIVTCK[1:0]bits = 00b or EIVTTk[3:0] bits = 0000b), skipping is not performed.

Note: When the EBTLx[2:0] bits are set to 011b or 111b, or when one of the skipping counters is set as not to count, skipping is not performed.

The GTSECSR register selects an intended channel for updating an operation enable bit by the GTSECR register. A bit position for the GTSECSR register indicates a channel number. The GTSECSR register of each channel is a common register, and writing 1 to a bit in the GTSECSR register in any channel and updating it changes a channel, related to the position of the bit written with 1 by the GTSECSR register, to be simultaneously controlled of the operation enable bit by the GTSECR register.

Access in 8-bit or 16-bit units to the GTSECSR register is prohibited, and it should be accessed in 32-bit units.

#### SECSELn Bit (Operation Enable Bit Simultaneous Control Channel Select) (n = 0 to 9)

This bit enables or disables the simultaneous control of operation enable in channel n.

When the bit is set to 1, the simultaneous control is enabled, and disabled when the bit is 0.

| b31 to b12 | —      | Reserved                                              | These bits are read as 0. The write value should be 0.                                                                    | R/W |

The GTSECR register simultaneously updates the value for operation enable bits of a channel set by the GTSECSR register.

Writing 1 to a bit in the GTSECR register in any channel and updating it updates an operation enable bit for all channels, related to the position of the bit written with 1 by the all GTSECR registers. Setting enable and disable bits for the same operation enable bit to 1 in the GTSECR is prohibited.

A bit written to 1 is automatically cleared. When the GTSECR is read, 0 is read.

Access in 8-bit or 16-bit units to the GTSECR register is prohibited, and it should be accessed in 32-bit units.

#### SBDCE Bit (GTCCR Register Buffer Operation Simultaneous Enable)

When 1 is written to this bit, 0 is simultaneously set to a GTBER.BD[0] bit in the channels set to 1 by the GTSECSR register, and buffer operations using the GTCCRA, GTCCRC, and GTCCRD registers and using the GTCCRB, GTCCRE, and GTCCRF registers are enabled.

Simultaneous setting of SBDCE and SBDCE bits to 1 is prohibited.

#### SBDPE Bit (GTPR Register Buffer Operation Simultaneous Enable)

When 1 is written to this bit, 0 is simultaneously set to a GTBER.BD[1] bit in the channels set to 1 by the GTSECSR

register, and buffer operations using the GTPR, GTPBR, and GTPDBR registers are enabled.  
Simultaneous setting of SBDPE and SBDPD bits to 1 is prohibited.

**SBD AE Bit (GTADTR Register Buffer Operation Simultaneous Enable)**

When 1 is written to this bit, 0 is simultaneously set to a GTBER.BD[2] bit in the channels set to 1 by the GTSECSR register, and buffer operations using the GTADTRA, GTADTBRA, and GTADTDBRA registers and using the GTADTRB, GTADTBRB, and GTADTDBRB registers are enabled.  
Simultaneous setting of SBD AE and SBD AD bits to 1 is prohibited.

**SBD DE Bit (GTDV Register Buffer Operation Simultaneous Enable)**

When 1 is written to this bit, 0 is simultaneously set to a GTBER.BD[3] bit in the channels set to 1 by the GTSECSR register, and buffer operations using the GTDVU and GTDBU registers and using the GTDVD and GTDBD registers are enabled.  
Simultaneous setting of SBD DE and SBD DD bits to 1 is prohibited.

**SBD CD Bit (GTCCR Register Buffer Operation Simultaneous Disable)**

When 1 is written to this bit, 1 is simultaneously set to a GTBER.BD[0] bit in the channels set to 1 by the GTSECSR register, and buffer operations using the GTCCRA, GTCCRC, and GTCCRD registers and using the GTCCRB, GTCCRE, and GTCCRF registers are disabled.  
Simultaneous setting of SBD CE and SBD CD bits to 1 is prohibited.

**SBD PD Bit (GTPR Register Buffer Operation Simultaneous Disable)**

When 1 is written to this bit, 1 is simultaneously set to a GTBER.BD[1] bit in the channels set to 1 by the GTSECSR register, and buffer operations using the GTPR, GTPBR, and GTPDBR registers are disabled.  
Simultaneous setting of SBD PE and SBD PD bits to 1 is prohibited.

**SBD AD Bit (GTADTR Register Buffer Operation Simultaneous Disable)**

When 1 is written to this bit, 1 is simultaneously set to a GTBER.BD[2] bit in the channels set to 1 by the GTSECSR register, and buffer operations using the GTADTRA, GTADTBRA, and GTADTDBRA registers and using the GTADTRB, GTADTBRB, and GTADTDBRB registers are disabled.  
Simultaneous setting of SBD AE and SBD AD bits to 1 is prohibited.

**SBD DD Bit (GTDV Register Buffer Operation Simultaneous Disable)**

When 1 is written to this bit, 1 is simultaneously set to a GTBER.BD[3] bit in the channels set to 1 by the GTSECSR register, and buffer operations using the GTDVU and GTDBU registers and using the GTDVD and GTDBD registers are disabled.  
Simultaneous setting of SBD DE and SBD DD bits to 1 is prohibited.

## 24.3 Operation

### 24.3.1 Basic Operation

The timer in each channel performs cycle count operation by count clock or hardware source. The GTCNT counter performs up-counting, or down-counting. The timer period is controlled by the GTPR register. When the GTCNT counter value matches the values for GTCCRA or GTCCRB registers, the GTIOCnA or GTIOCnB pin outputs ( $n = 0$  to 9) can be changed respectively. Also, the GTCCRA or GTCCRB registers can be used as the input capture registers by hardware source. The GTCCRC and GTCCRD registers can be performed as buffer registers for GTCCRA register, and the GTCCRE and GTCCRF registers can be performed as buffer registers for GTCCRB register.

#### 24.3.1.1 Counter Operation

##### (1) Count Start/Count Stop

The counter in each channel starts counting operation when the corresponding GTCR.CST bit is set to 1, and stops counting when the bit is set to 0.

CST bit value can be changed by the following sources:

- Writing to the GTCR register
- Writing 1 to the bit corresponding to the channel number for the GTSTR register while the GTSSR.CSTRT bit is 1
- Writing 1 to the bit corresponding to the channel number for the GTSTP register while the GTPSR.CSTOP bit is 1
- Hardware source specified by the GTSSR register
- Hardware source specified by the GTPSR register

##### (2) Cycle Count Operation (In Up-Counting by the Count Clock)

The counter in each channel starts up-counting when the corresponding CST bit is set to 1 while the GTUPSR register and the GTDNSR register are 0000 0000h. When the value of the GTCNT counter changes from that of the GTPR register to 0000 0000h (an overflow) while the GTINTAD.GTINTPR[0] bit is 1, a GTCIV interrupt request is also issued. After GTCNT counter overflows, up-counting is resumed from 0000 0000h.

Figure 24.2 shows an example of cycle count operation in up-counting by count clock.

Figure 24.2 Example of Cycle Count Operation (In Up-Counting by the Count Clock)

Figure 24.3 shows an example for setting cycle count operation in up-counting.

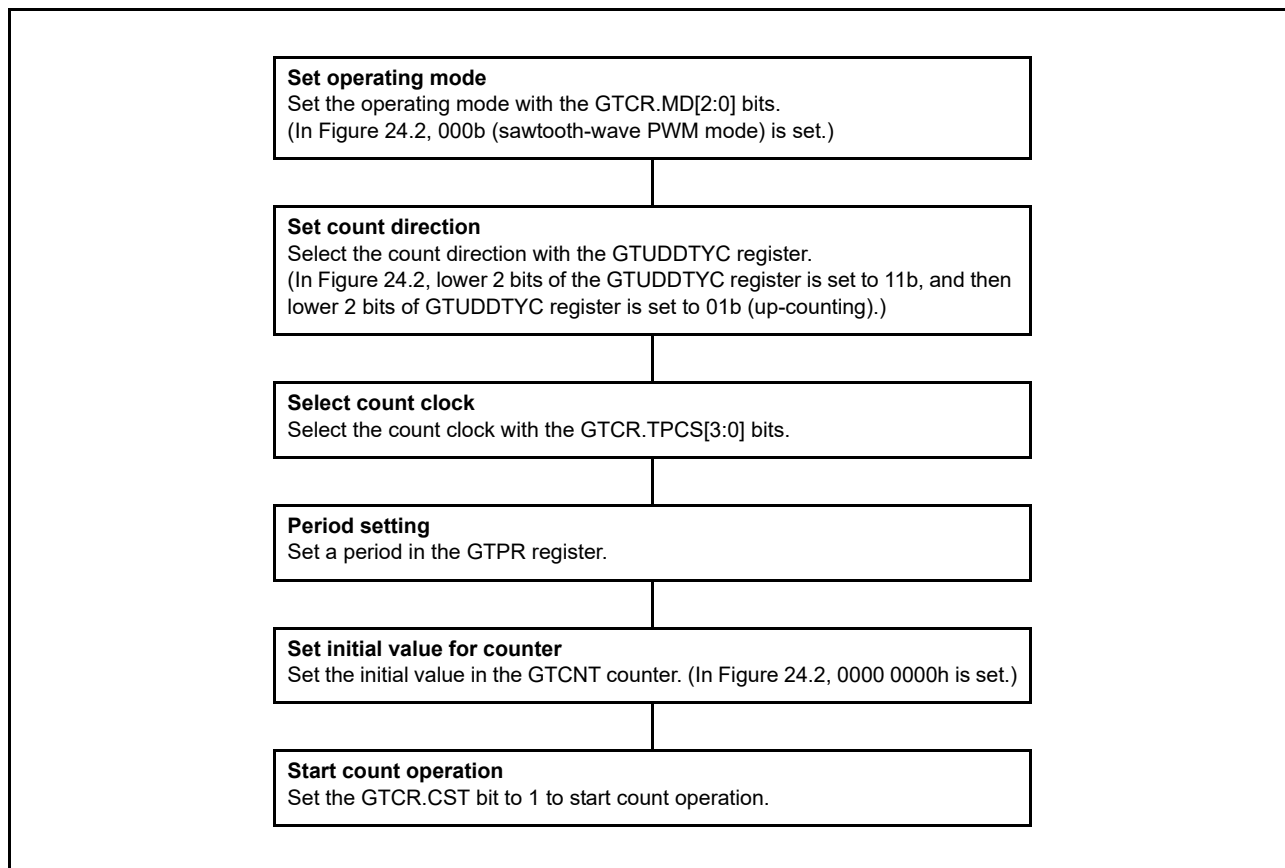

Figure 24.3 Example for Setting Cycle Count Operation (In Up-Counting by the Count Clock)

(3) Cycle Count Operation (In Down-Counting by the Count Clock)

The counter in each channel can start down-counting when the corresponding GTUDDTYC.UD bit is set in a state of the GTUPSR register and the GTDNSR register as 0000 0000h. When the value of the GTCNT counter changes from 0000 0000h to that of the GTPR register (an underflow) while the GTINTAD.GTINTPR[1] bit is 1, a GTCIU interrupt request is also issued. After the GTCNT counter underflows, down-counting is resumed from the GTPR register value.

Figure 24.4 shows an example of cycle count operation in down-counting by count clock.

Figure 24.4 Example of Cycle Count Operation (In Down-Counting by the Count Clock)

Figure 24.5 shows an example for setting cycle count operation in down-counting by count clock.

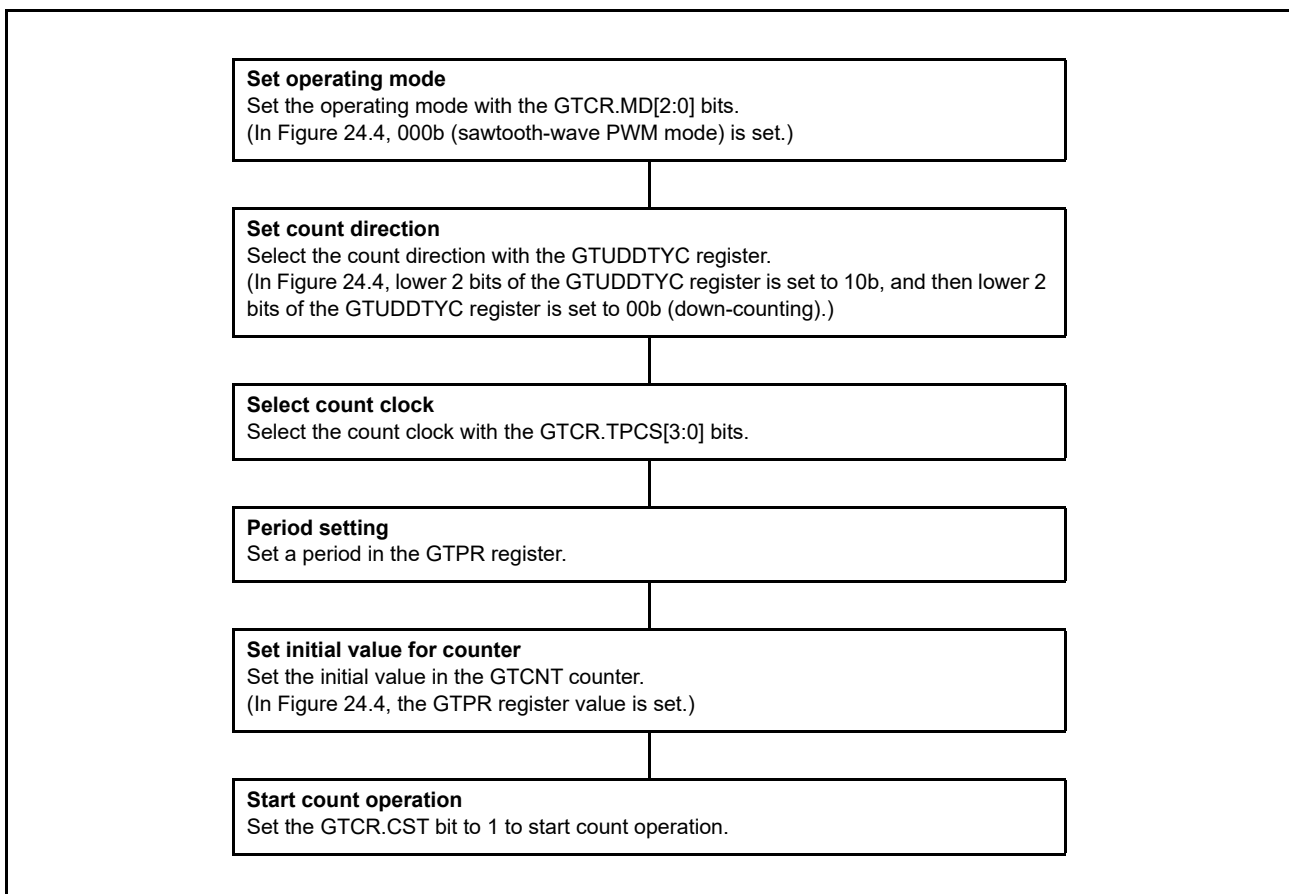

Figure 24.5 Example for Setting Cycle Count Operation (In Down-Counting by the Count Clock)

(4) Event Count Operation (In Up-Counting by Hardware Source)

The counter in each channel can start up-counting by hardware source by setting the GTUPSR register. When the GTUPSR register is set, the count clock selected by the GTCR.TPCS[3:0] bits and the count direction set by the GTUDDTYC.UD bit are invalid. If the hardware source in up-counting and the hardware source in down-counting are generated at the same time, the GTCNT counter value will not change.

Operation due to overflow in up-counting by hardware source is the same as the cycle count operation by the count clock.

To perform up-counting by hardware source, start count operation by setting the GTCR.CST bit to 1. As the starting the count operation is synchronized with the count clock selected by TPCS[3:0] bits, set the CST bit to 1, and wait until the first cycle of the count clock elapses to start up-counting operation. To start up-counting after one PCLKC from setting the CST bit to 1, set the TPCS[3:0] bits to 0000b.

Figure 24.6 to Figure 24.8 show examples of up-counting operation by hardware source .

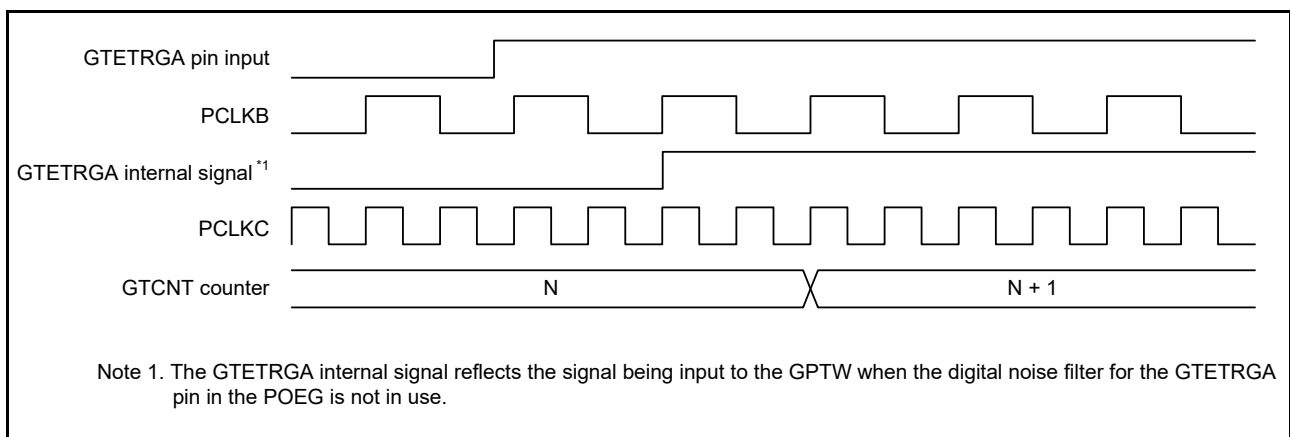

Figure 24.6 Example of Event Count Operation (Up-Counting of Rising Edges of the Input on the GTETRGA Pin)

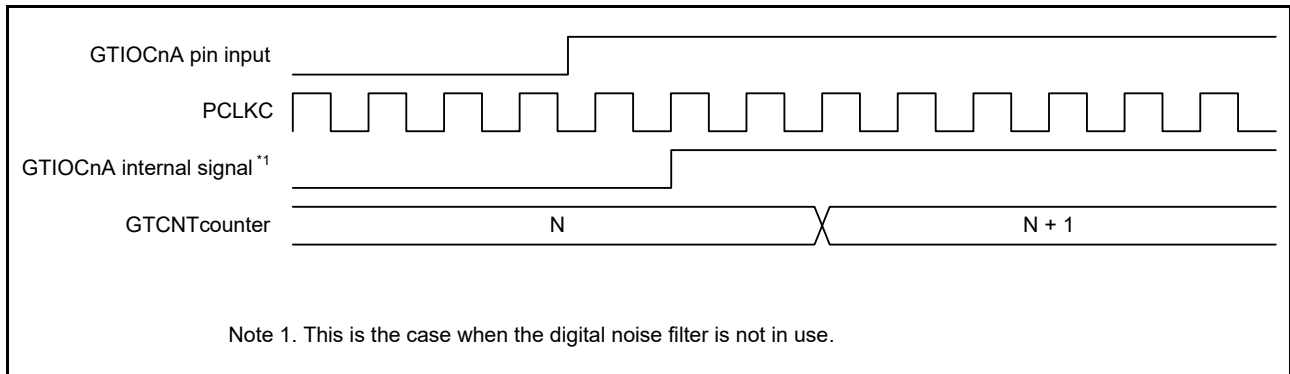

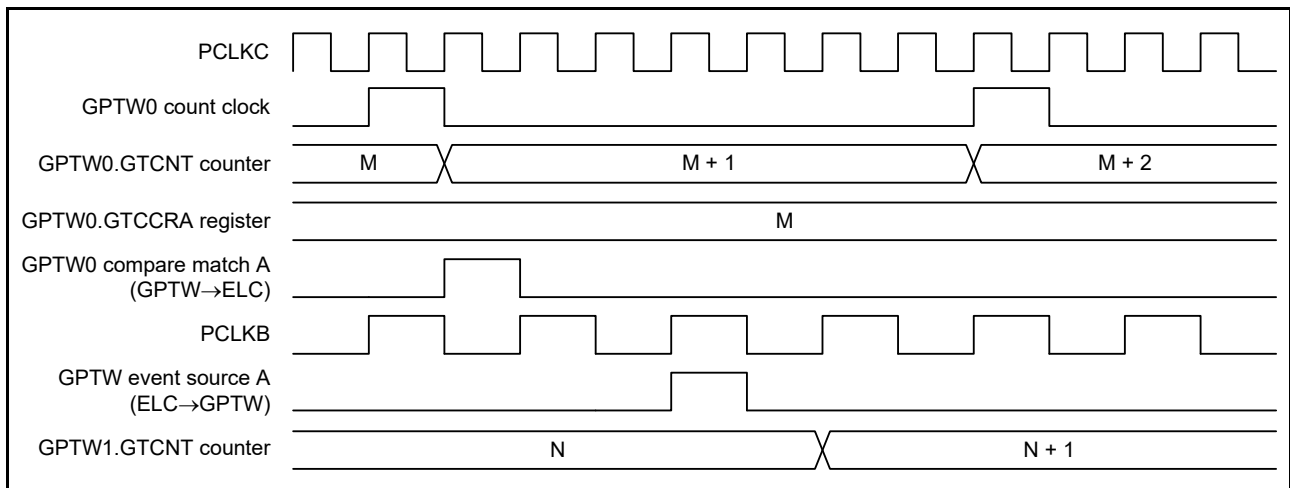

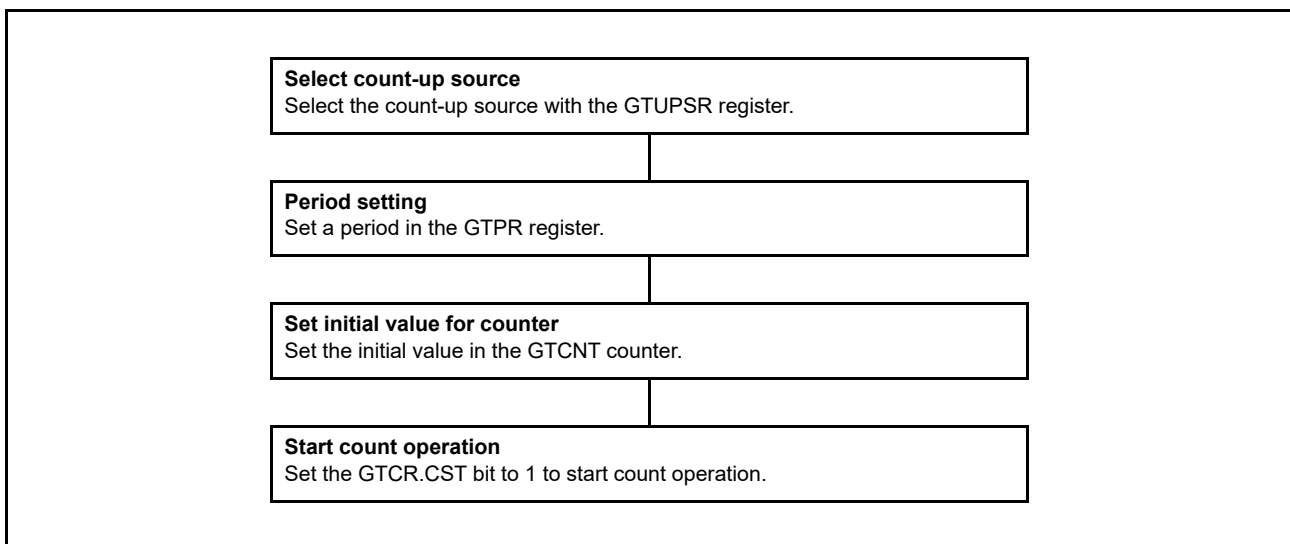

Figure 24.7 Example of Event Count Operation (Up-Counting of Rising Edges of the Input on the GTIOCnA Pin)

**Figure 24.8 Example of Event Count Operation (Up-Counting the Number of Event Signals Input from the ELCA)**

Figure 24.9 shows an example for setting cycle count operation in up-counting by hardware source.

**Figure 24.9 Example for Setting Event Count Operation (In Up-Counting by Hardware Source)**

(5) Event Count Operation (In Down-Counting by Hardware Source)

The counter in each channel can start down-counting by hardware source by setting the GTDNSR register. When the GTDNSR register is set, the count clock selected by the GTCR.TPCS[3:0] bits and the count direction set by the GTUDDTYC.UD bit are invalid. If the hardware source in up-counting and the hardware source in down-counting are generated at the same time, the GTCNT counter value will not change.

Operation due to underflow in down-counting by hardware source is the same as the cycle count operation by the count clock.

To perform down-counting by hardware source, start count operation by setting the GTCR.CST bit to 1. As the starting the count operation is synchronized with the count clock selected by TPCS[3:0] bits, set the CST bit to 1, and wait until the first cycle of the count clock elapses to start down-counting operation. To start down-counting after one PCLKC from setting the CST bit to 1, set the TPCS[3:0] bits to 0000b.

Figure 24.10 shows an example of down-counting operation by hardware source.

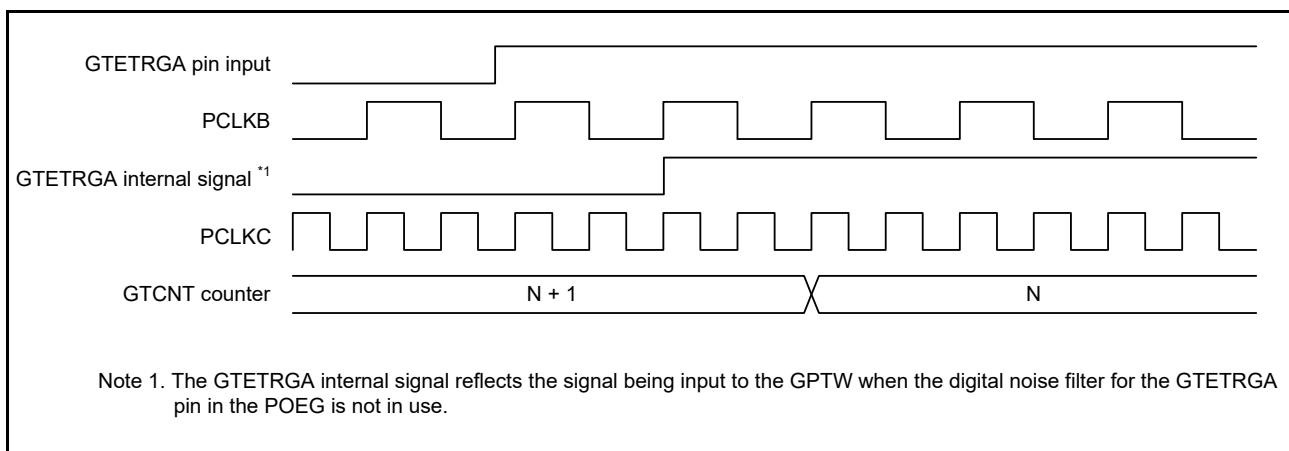

Figure 24.10 Example of Event Count Operation (Down-Counting of Rising Edges of the Input on the GTETRGA Pin)

Figure 24.11 shows an example for setting cycle count operation in down-counting by hardware source.

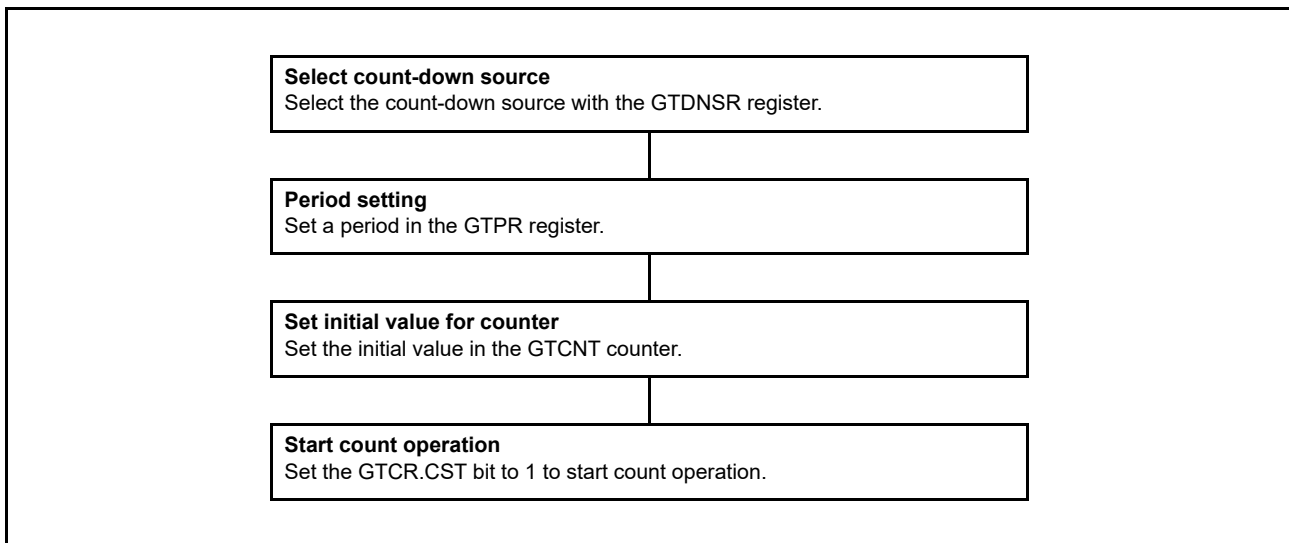

Figure 24.11 Example for Setting Event Count Operation (In Down-Counting by Hardware Source)

## (6) Counter Clearing Operation

The counter in each channel can be cleared by the following sources:

- Writing to the GTCNT counter
- Writing 1 to the bit corresponding to the channel number for the GTCLR register while the GTCSR.CCLR bit is 1
- Hardware source specified by the GTCSR register

Write access during counting (when CST = 1) is disabled.

GTCLR register can be written to and cleared by hardware source whether the count operation is performed (GTCR.CST bit = 1) or is stopped (CST bit = 0). When the count direction flag is set as decrement (GTST.TUCF flag = 0) in sawtooth-wave mode selected with GTCR.MD[2:0] bits, the GTCNT counter value for writing to the GTCLR register and for clearing by hardware source becomes the GTPR register value whether the counter is in operation or is stopped. The GTCNT counter value becomes 0000 0000h for other settings.

When the event count operation is set (at least one of bits for the GTUPSR or the GTDNSR register is set as 1), writing to the GTCLR register and clearing by hardware source are performed right after the clear source is generated (the operation is based on PCLKC). For other settings, clearing operation is synchronized with the count clock selected with the GTCR.TPCS[3:0] bits.

### 24.3.1.2 Waveform Output by Compare Match

Compare match refers to when the GTCNT counter value matches the GTCCRA or GTCCRB register value. The output of the corresponding GTIOCnA or GTIOCnB pin (n = 0 to 9) can be set to be driven low, high, or toggled in synchronization with the counter clock (including in the case of event counting) after the match.

In addition, the GTIOCnA or GTIOCnB pin output can be driven low, high, or toggled at the “end of the cycle” which is determined by the GTPR register. The end of the cycle is as follows:

- For sawtooth waves in up-counting: When the GTCNT counter value changes from the GTPR register value to 0000 0000h (overflow)
- For sawtooth waves in down-counting: When the GTCNT counter value changes from 0000 0000h to the GTPR register value (underflow)
- For sawtooth waves with the GTCNT counter clear
- For triangle waves: When the GTCNT counter value changes from 0000 0000h to 0000 0001h (trough)

#### (1) Low Output and High Output

Figure 24.12 shows an example of low output and high output operation by a compare match of the GTCNT counter and GTCCRA register and of the GTCNT counter and GTCCRB register.

In this example, the GPTW0.GTCNT counter performs up-counting, and settings have been made so that high is output from the GTIOC0A pin by a GPTW0.GTCCRA register compare match, and low is output from the GTIOC0B pin by a GPTW0.GTCCRB register compare match. The pin level does not change when the specified level and pin level match.

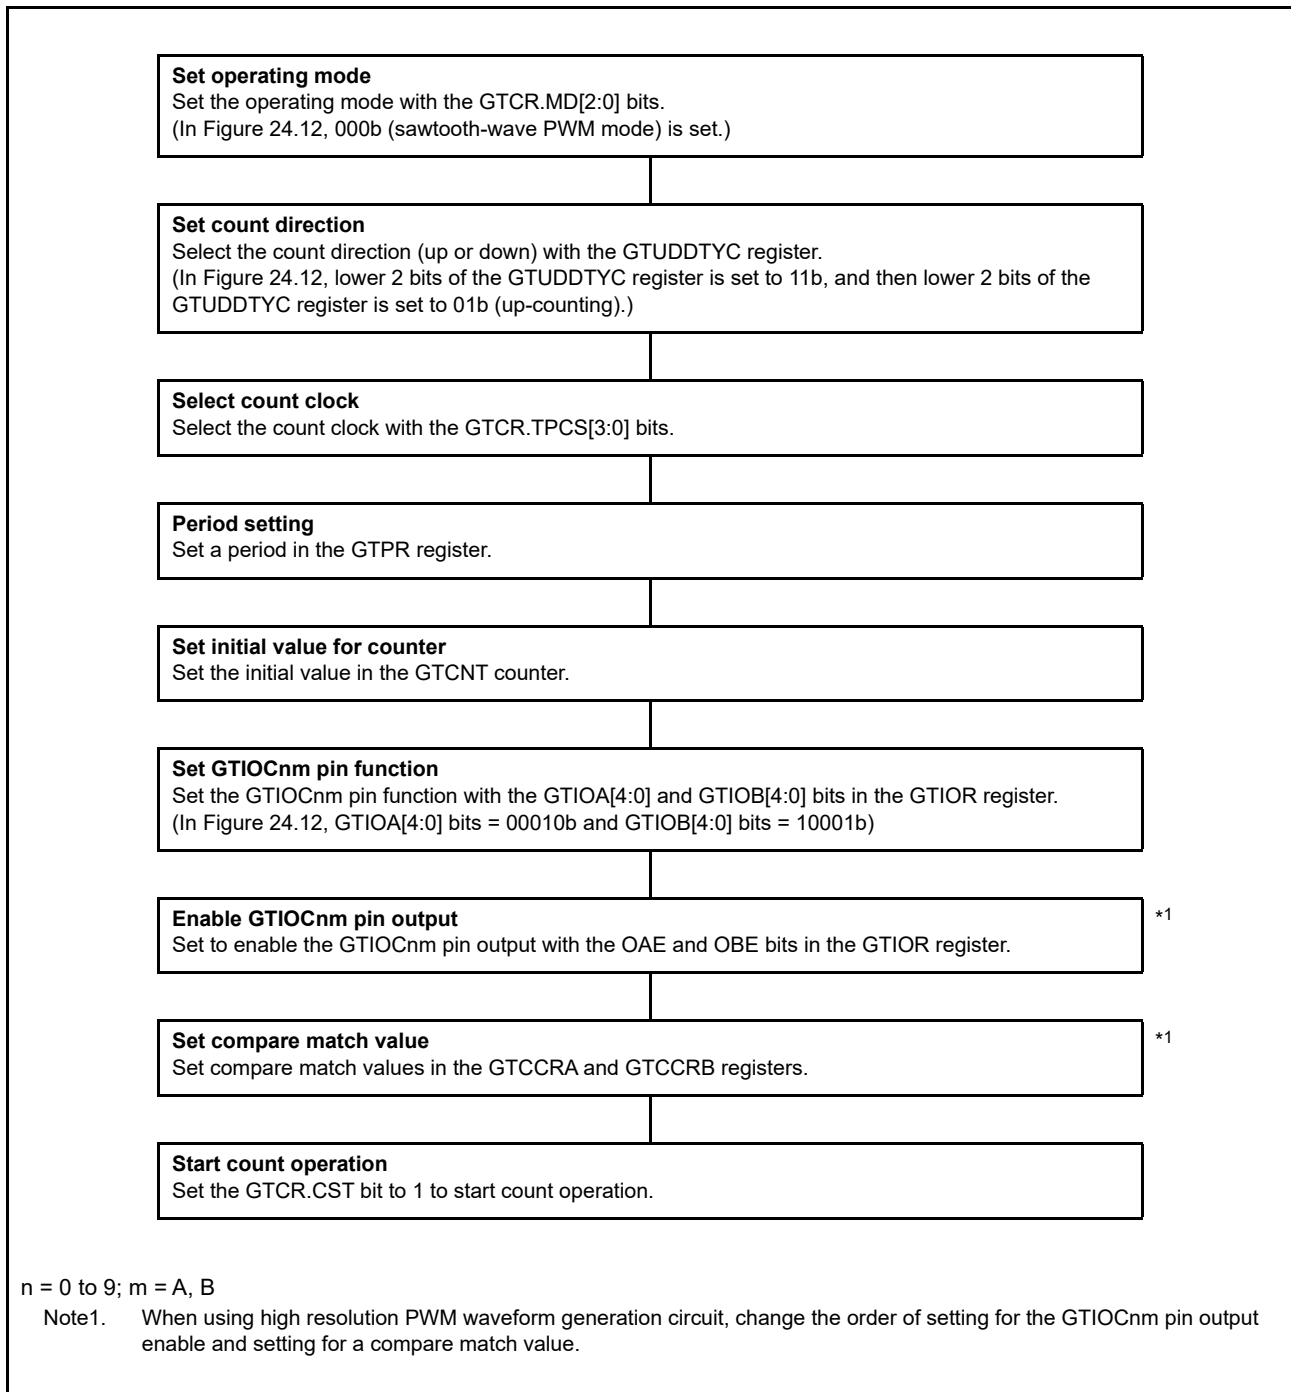

Figure 24.12 Example of Low Output and High Output Operation

Figure 24.13 shows an example for setting Low/High output operation.

**Figure 24.13 Example for Setting Low/High Output Operation**

(2) Toggled Output

Figure 24.14 and Figure 24.15 show examples of toggle output operations by compare match between the GPTW0.GTCNT counter and the GTCCRA and GTCCRB registers.

In Figure 24.14, the GPTW0.GTCNT counter performs up-counting, and settings have been made so that the GTIOC0A pin output by a GPTW0.GTCCRA register compare match and GTIOC0B pin output by a GPTW0.GTCCRB register compare match are toggled.

In Figure 24.15, the GPTW0.GTCNT counter performs up-counting, and settings have been made so that the GTIOC0A pin output is toggled by a compare match of GPTW0.GTCCRA register and the GTIOC0B pin output is toggled at the end of the cycle.

Figure 24.14 Example of Toggled Output Operation (1)

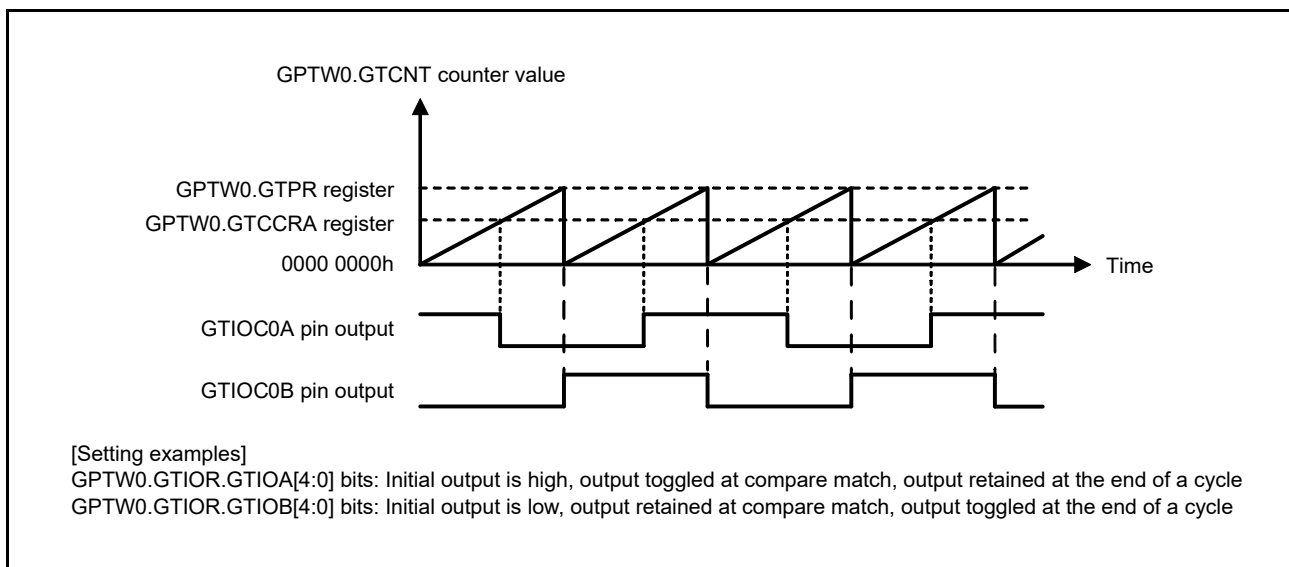

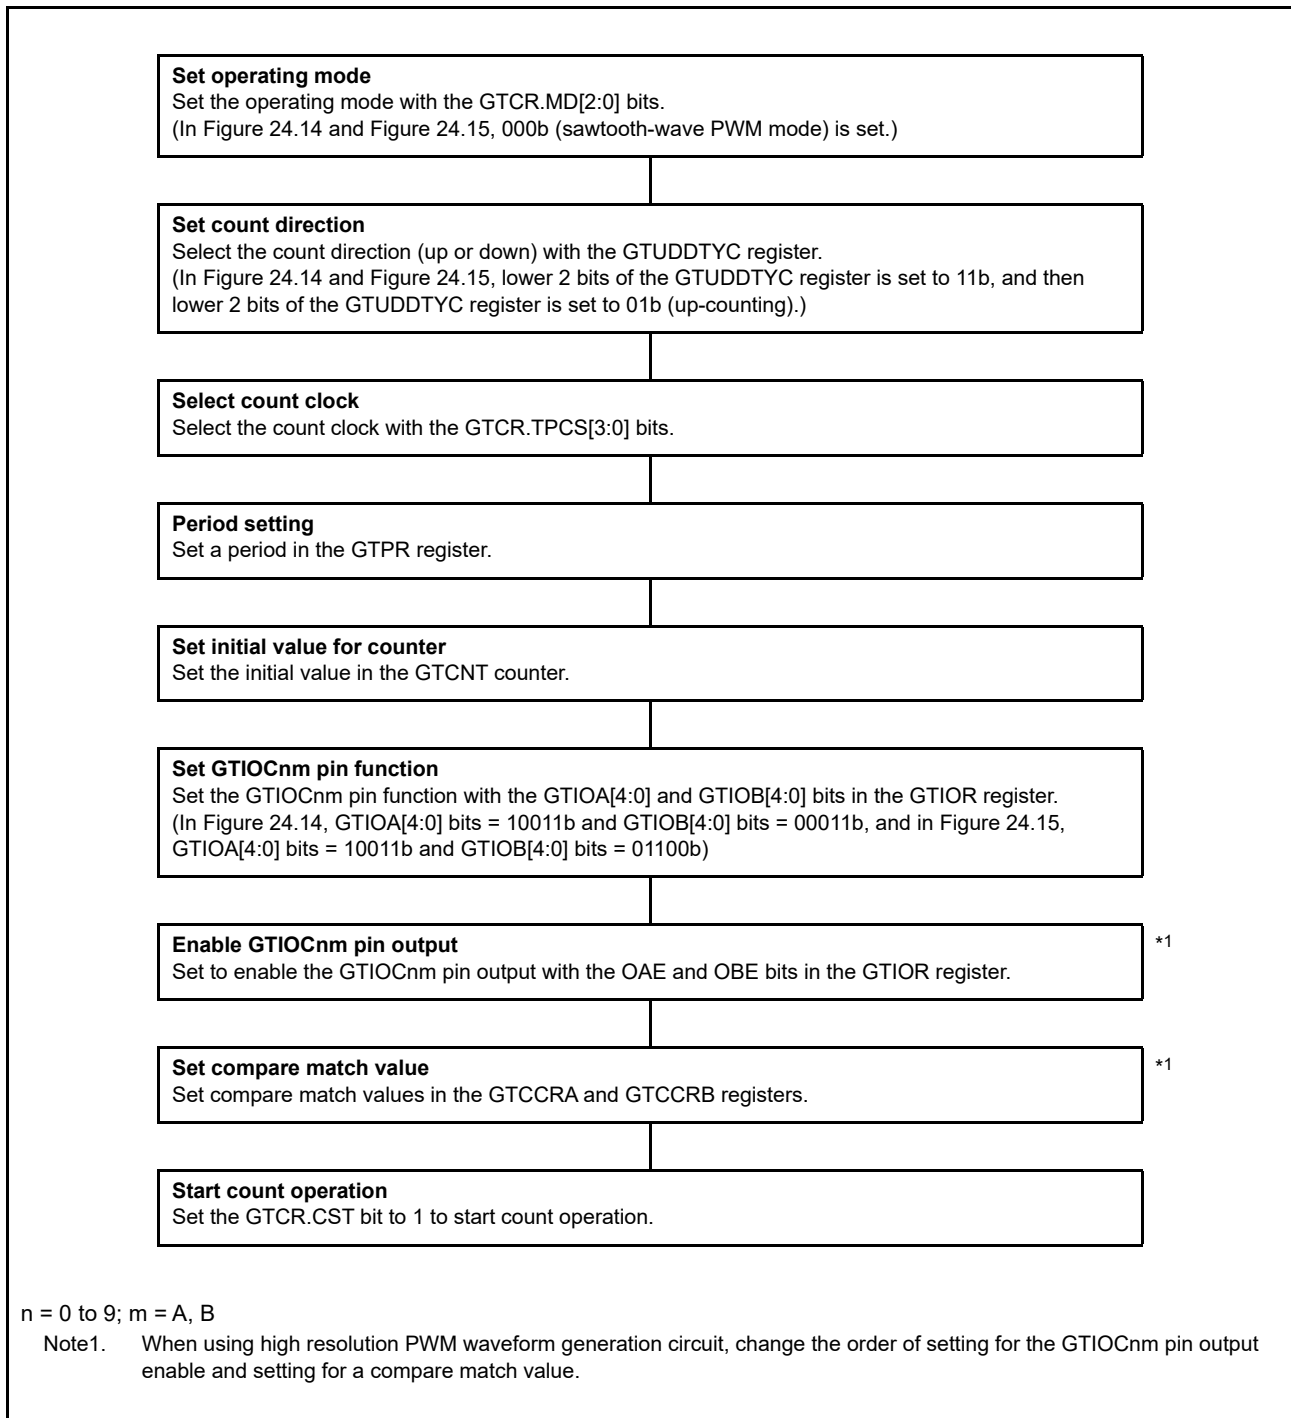

Figure 24.15 Example of Toggled Output Operation (2)

Figure 24.16 shows an example for setting toggled output operation.

**Figure 24.16 Example for Setting Toggled Output Operation**

### 24.3.1.3 Input Capture Function

Through detecting hardware sources selected by the GTICASR and GTICBSR registers, the GTCNT counter values can be transferred to the GTCCRA and GTCCRB registers respectively.

Figure 24.17 shows an example of input capture function operation.

In this example, the GPTW0.GTCNT counter performs up-counting, and settings have been made so that an input capture is performed at both edges of the GTIOC0A pin input and at the rising edge of the GTIOC0B pin input.

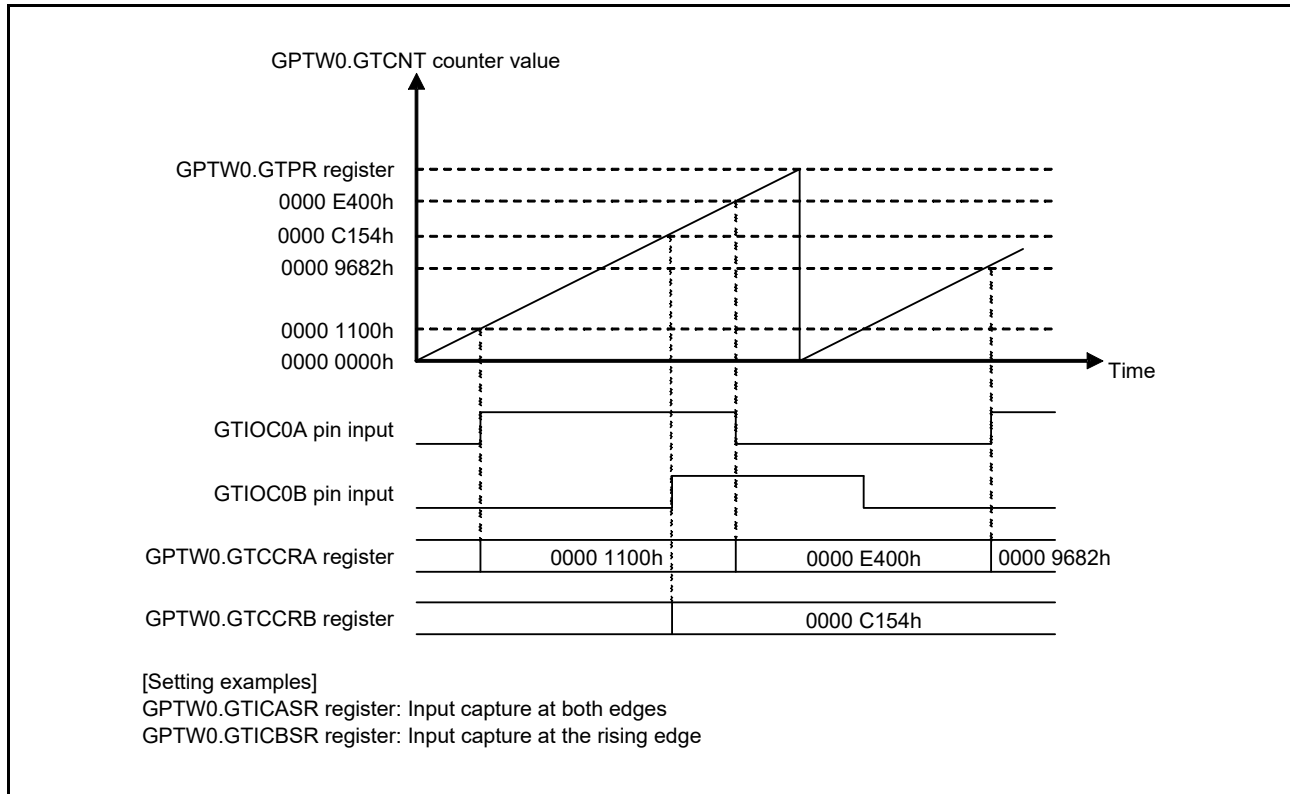

Figure 24.17 Example of Input Capture Operation

Figure 24.18 shows an example for setting input capture operation.

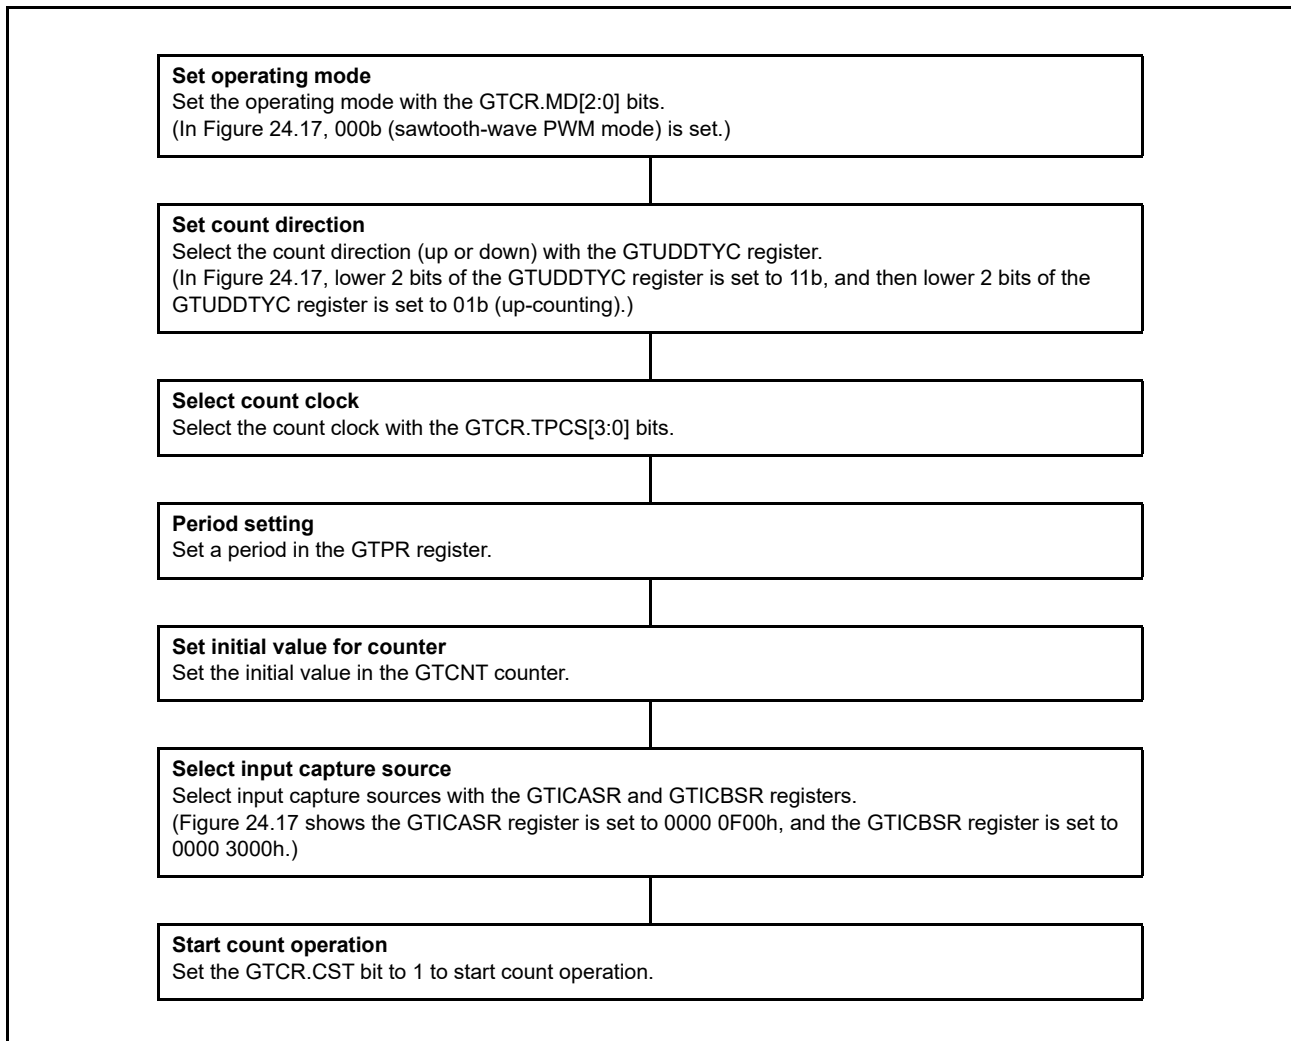

Figure 24.18 Example for Setting Input Capture Operation

Figure 24.19 shows an example of the timing of input capture operation in response to a rising edge of the input on the GTETRGA pin.

**Figure 24.19 Example of the Timing of Input Capture Operation in Response to a Rising Edge of the Input on the GTETRGA Pin**

Figure 24.20 shows an example of the timing of input capture operation in response to a rising edge of the input on the GTIOCnA pin.

**Figure 24.20 Example of the Timing of Input Capture Operation in Response to a Rising Edge of the Input on the GTIOCnA Pin**

Figure 24.21 shows an example of the timing of operations for input capture in response to event input from the ELCA. This is an example of capture of the counter value by the GPTW1.GTCCRA register in response to an input signal. An event signal is output to the ELC after matches in comparison with the GPTW0.GTCCRA register. This is selected as a trigger for output to the GPTW by the ELC as event source A. The GPTW0 compare match A signal is synchronized with PCLKC. The ELC receives the signal in synchronization with PCLKB, and outputs the GPTW event source A signal after 1 cycle of PCLKB has elapsed.

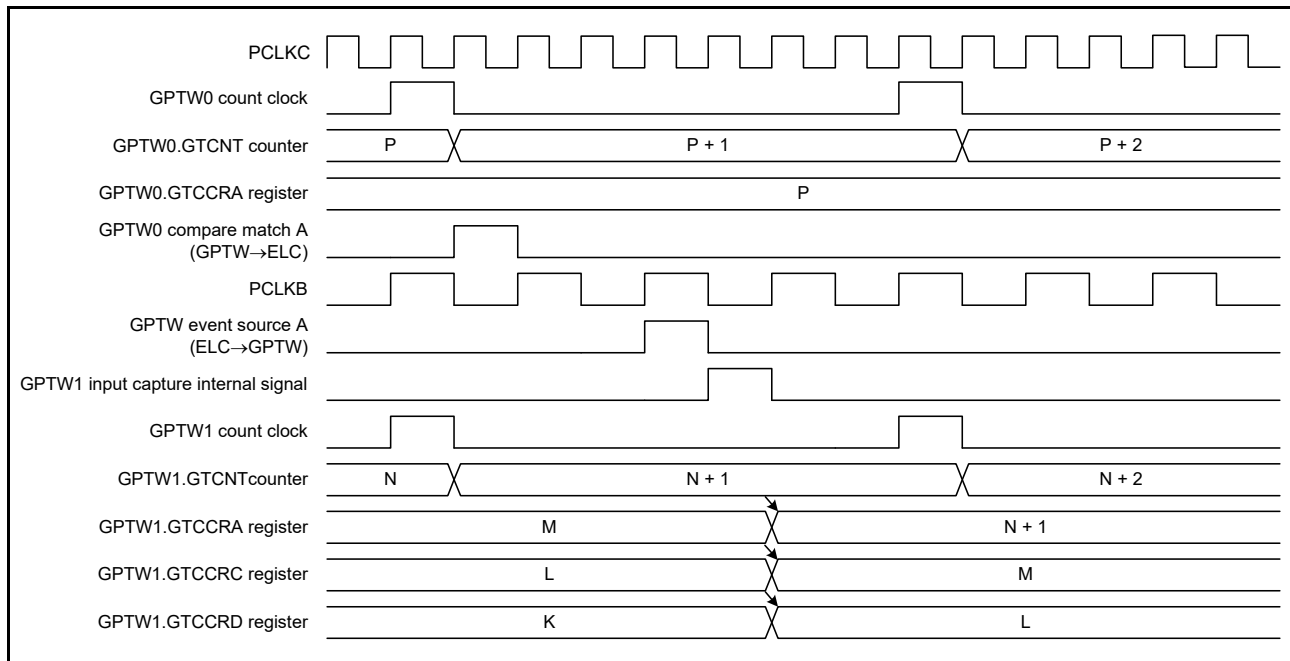

Figure 24.21 Example of the Timing of Operations for Input Capture in Response to Event Input from the ELCA

### 24.3.2 Buffer Operation

The following buffer operation can be set with the GTBER register.

- Buffer operation with the GTPR, GTPBR, and GTPDBR registers used together
- Buffer operation with the GTCCRA, GTCCRC, and GTCCRD registers used together
- Buffer operation with the GTCCRB, GTCCRE, and GTCCRF registers used together
- Buffer operation with the GTADTRA, GTADTBRA, and GTADTDBRA registers used together
- Buffer operation with the GTADTRB, GTADTBRB, and GTADTDBRB registers used together

The following buffer operation can be set with the GTDTCR register.

- Buffer operation with the GTDVU and GTDBU registers used together
- Buffer operation with the GTDVD and GTDBD registers used together

#### 24.3.2.1 GTPR Register Buffer Operation

The GTPBR register can function as a buffer register for the GTPR register, and the GTPDBR register can function as a buffer register for the GTPBR register (double buffer register for the GTPR register).

The buffer transfer is performed at an overflow (in up-counting) or underflow (in down-counting) in sawtooth-wave mode or in event counting, or at a trough in triangle-wave mode.

When in sawtooth-wave mode and in event counting, the buffer transfer is performed even when the counter clearing occurs during the count is in operation.

- Hardware source clearing

(Clear source selected with GTCSCR.CSGTRGAR, CSGTRGAF, CSGTRGBR, CSGTRGBF, CSGTRGCR, CSGTRGCF, CSGTRGDR, CSGTRGDF, CSCARBL, CSCARBH, CSCAFBL, CSCAFBH, CSCBRAL, CSCBRAH, CSCBFAL, CSCBFAH, CSELCA, CSELCB, CSELCC, CSELCD, CSELCE, CSELCF, CSELCG, or CSELCH bit)

- Clearing by software

(When the GTCLR.CCLRn bit is written to 1 during the GTCSCR.CCLR bit is set to 1) (n = 0 to 9)

To set the GTPR register to function as double buffer, set the GTBER.PR[1:0] bits to 10b or 11b. For single buffer operation, set 01b. Not to function as buffer, set 00b.

Figure 24.22 to Figure 24.24 show examples of the GTPR register buffer operation and Figure 24.25 shows an example for setting the GTPR register buffer operation.

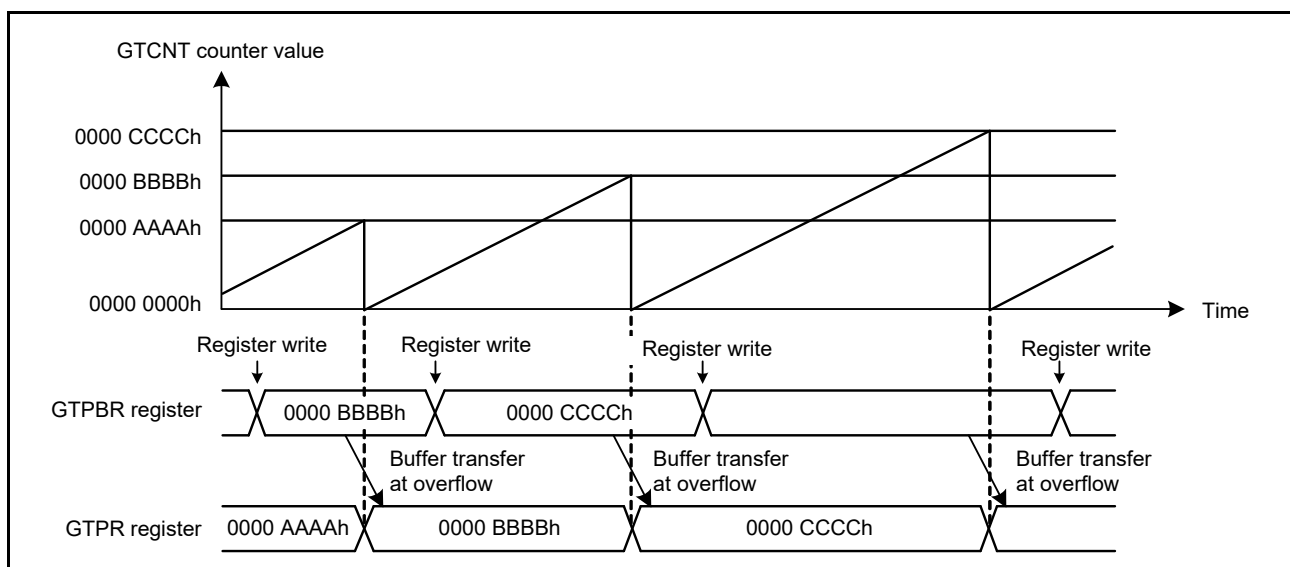

Figure 24.22 Example of the GTPR Register Buffer Operation (Sawtooth Waves in Up-Counting)

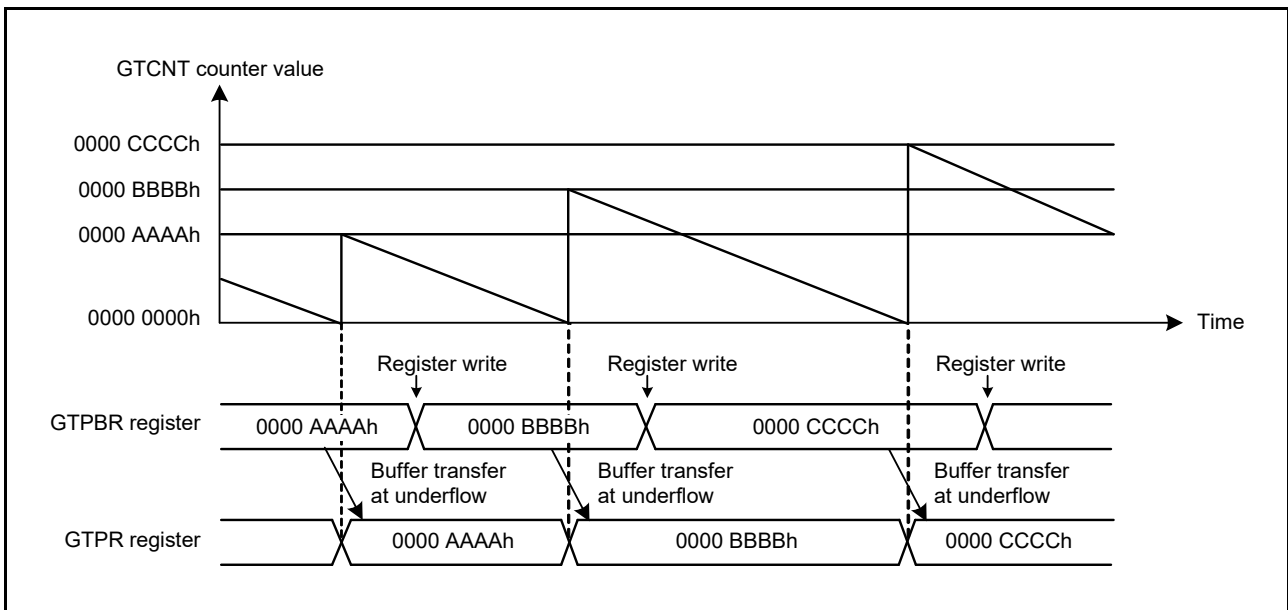

Figure 24.23 Example of the GTPR Register Buffer Operation (Sawtooth Waves in Down-Counting)

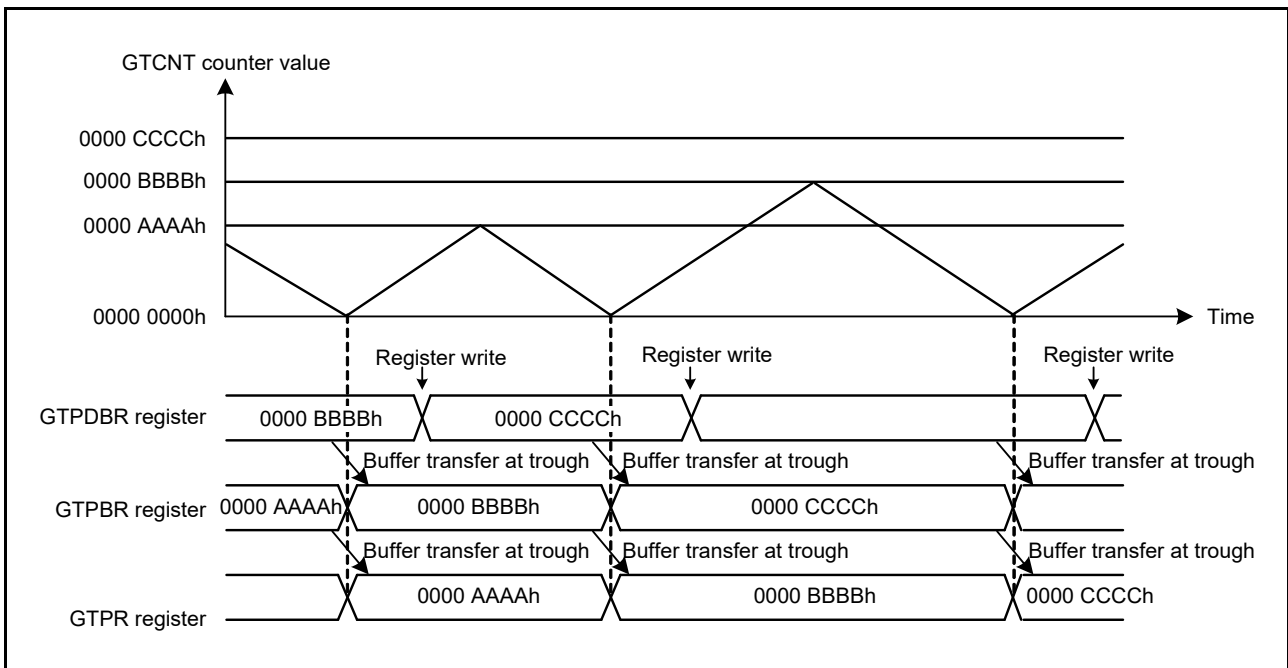

Figure 24.24 Example of the GTPR Register Double Buffer Operation (Triangle Waves)

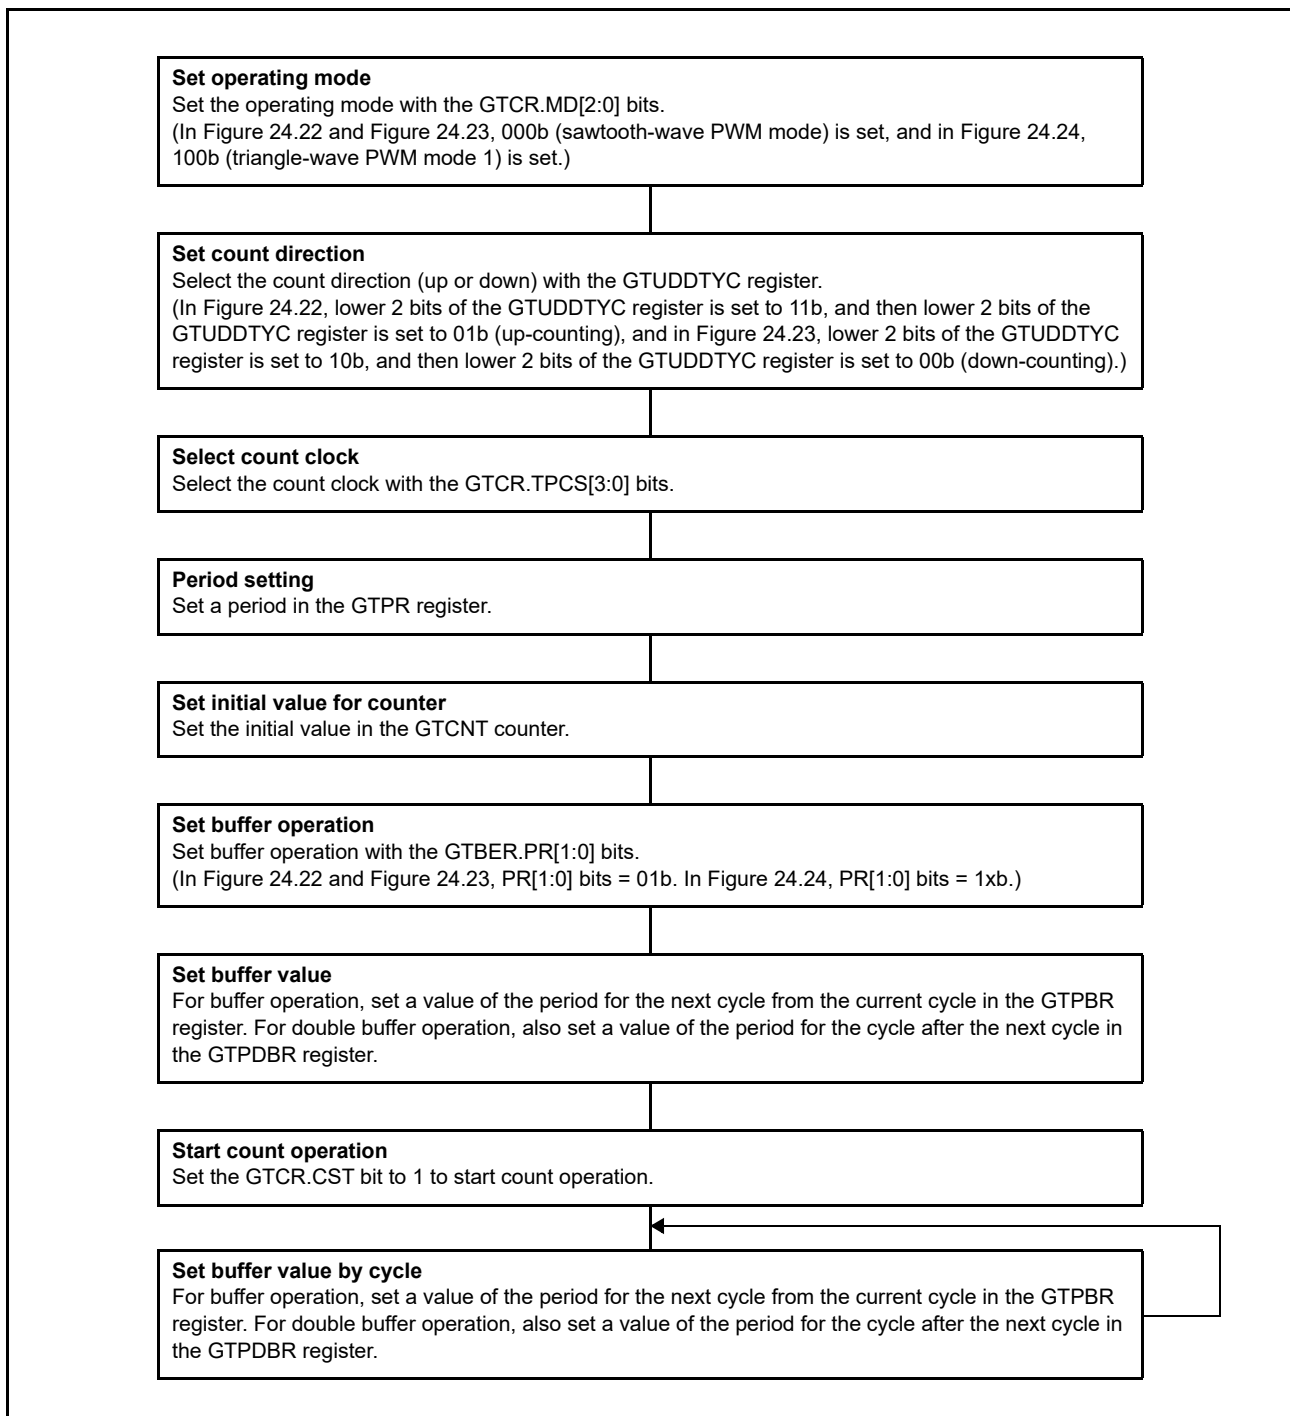

Figure 24.25 Example for Setting the GTPR Register Buffer Operation

### 24.3.2.2 Buffer Operation for the GTCCRA and GTCCRB Registers

The GTCCRC register can function as the GTCCRA buffer register and the GTCCRD register can function as the GTCCRC buffer register (double buffer register for the GTCCRA register). Similarly, the GTCCRE register can function as the GTCCRB buffer register and the GTCCRF register can function as the GTCCRE buffer register (double buffer register for the GTCCRB register).

To set the GTCCRA or GTCCRB register to function as a double buffer, set the GTBER.CCRA[1:0] or GTBER.CCRB[1:0] bits to 10b or 11b. For single buffer operation, set 01b. Not to function as buffer, set 00b. The following describes buffer operation during output compare and input capture operation.

#### (1) When the GTCCRA or GTCCRB Register Functions as Output Compare Register

Buffer transfer is performed for the following three cases:

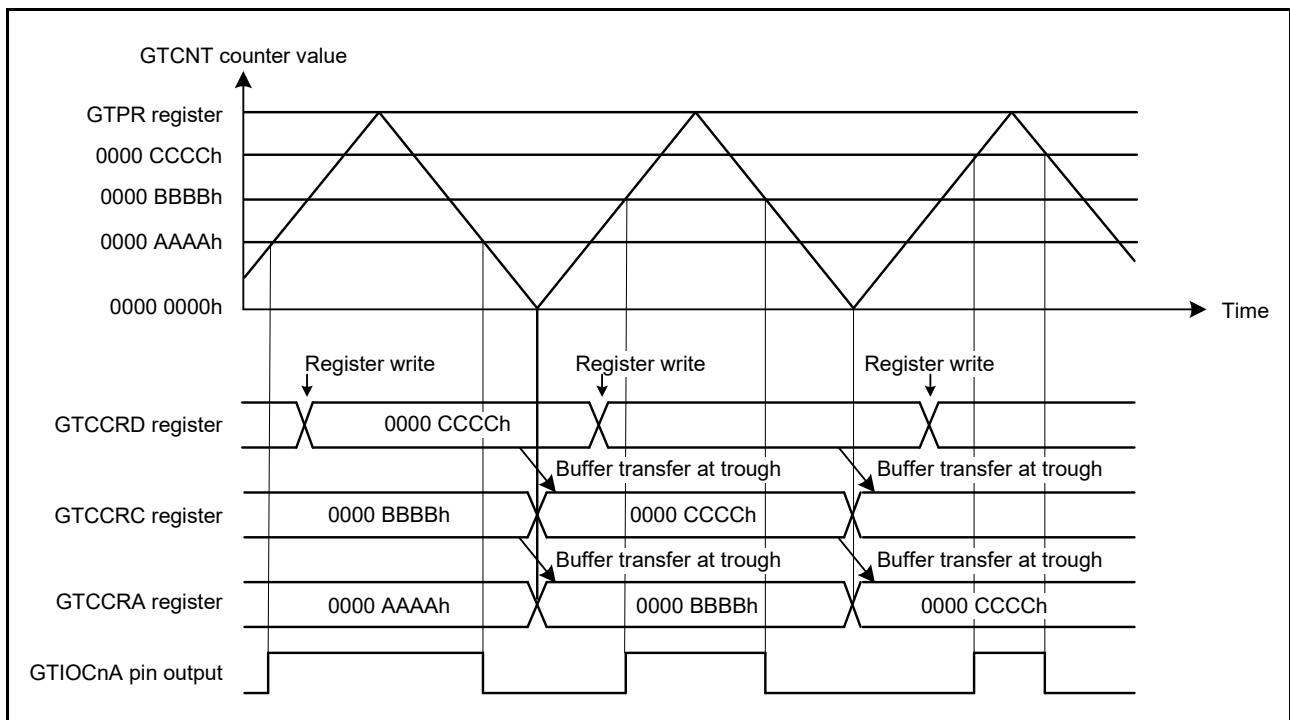

- Buffer transfer at an overflow (in up-counting) and underflow (in down-counting)  
Buffer transfer is performed at an overflow (in up-counting) or an underflow (in down-counting) in sawtooth-wave mode and in event counting, and at a trough (triangle-wave PWM mode 1) or at a crest/trough (triangle-wave PWM mode 2) in triangle-wave mode.
- Buffer transfer by counter clearing  
In sawtooth-wave mode and in event counting, the buffer transfer by similar counter clearing sources in counting operation and in section 24.3.2.1, GTPR Register Buffer Operation is performed in the same way at an overflow (in up-counting) or an underflow (in down-counting).  
In triangle-wave mode, buffer transfer by counter clearing is not performed.
- Forcible buffer transfer  
In both sawtooth-wave mode and triangle-wave mode, buffer transfer of the GTCCRA and GTCCRB registers is forcibly performed by writing 1 to the GTBER.CCRSWT bit while the counting is stopped.  
In sawtooth-wave one-shot pulse mode and triangle-wave PWM mode 3, buffer transfer from the GTCCRD register to the temporary register A and from the GTCCRF register to the temporary register B is also performed using the forcible buffer operation.

When the setting of the GTBER.DBRTCE<sub>m</sub> (m = A, B) bit is 1 in sawtooth-wave one-shot pulse mode or triangle-wave PWM mode 3, transfer from the intermediate buffers to the GTCCR<sub>m</sub> (m = A, B) registers is repeated on a cyclic basis even while buffer transfer is disabled by the setting of the GTBER.BD[0] bit or buffer transfer extended skipping function (function for repeated double-buffer operation while buffer transfer is disabled). For details, refer to section 24.8.2.2, Repeated Double-Buffered Operation When Disabling GTCCR Buffer Transfer.

Figure 24.26 to Figure 24.28 show examples of the GTCCRA and GTCCRB registers buffer operations, and Figure 24.29 shows an example for setting the GTCCRA and GTCCRB registers buffer operations.

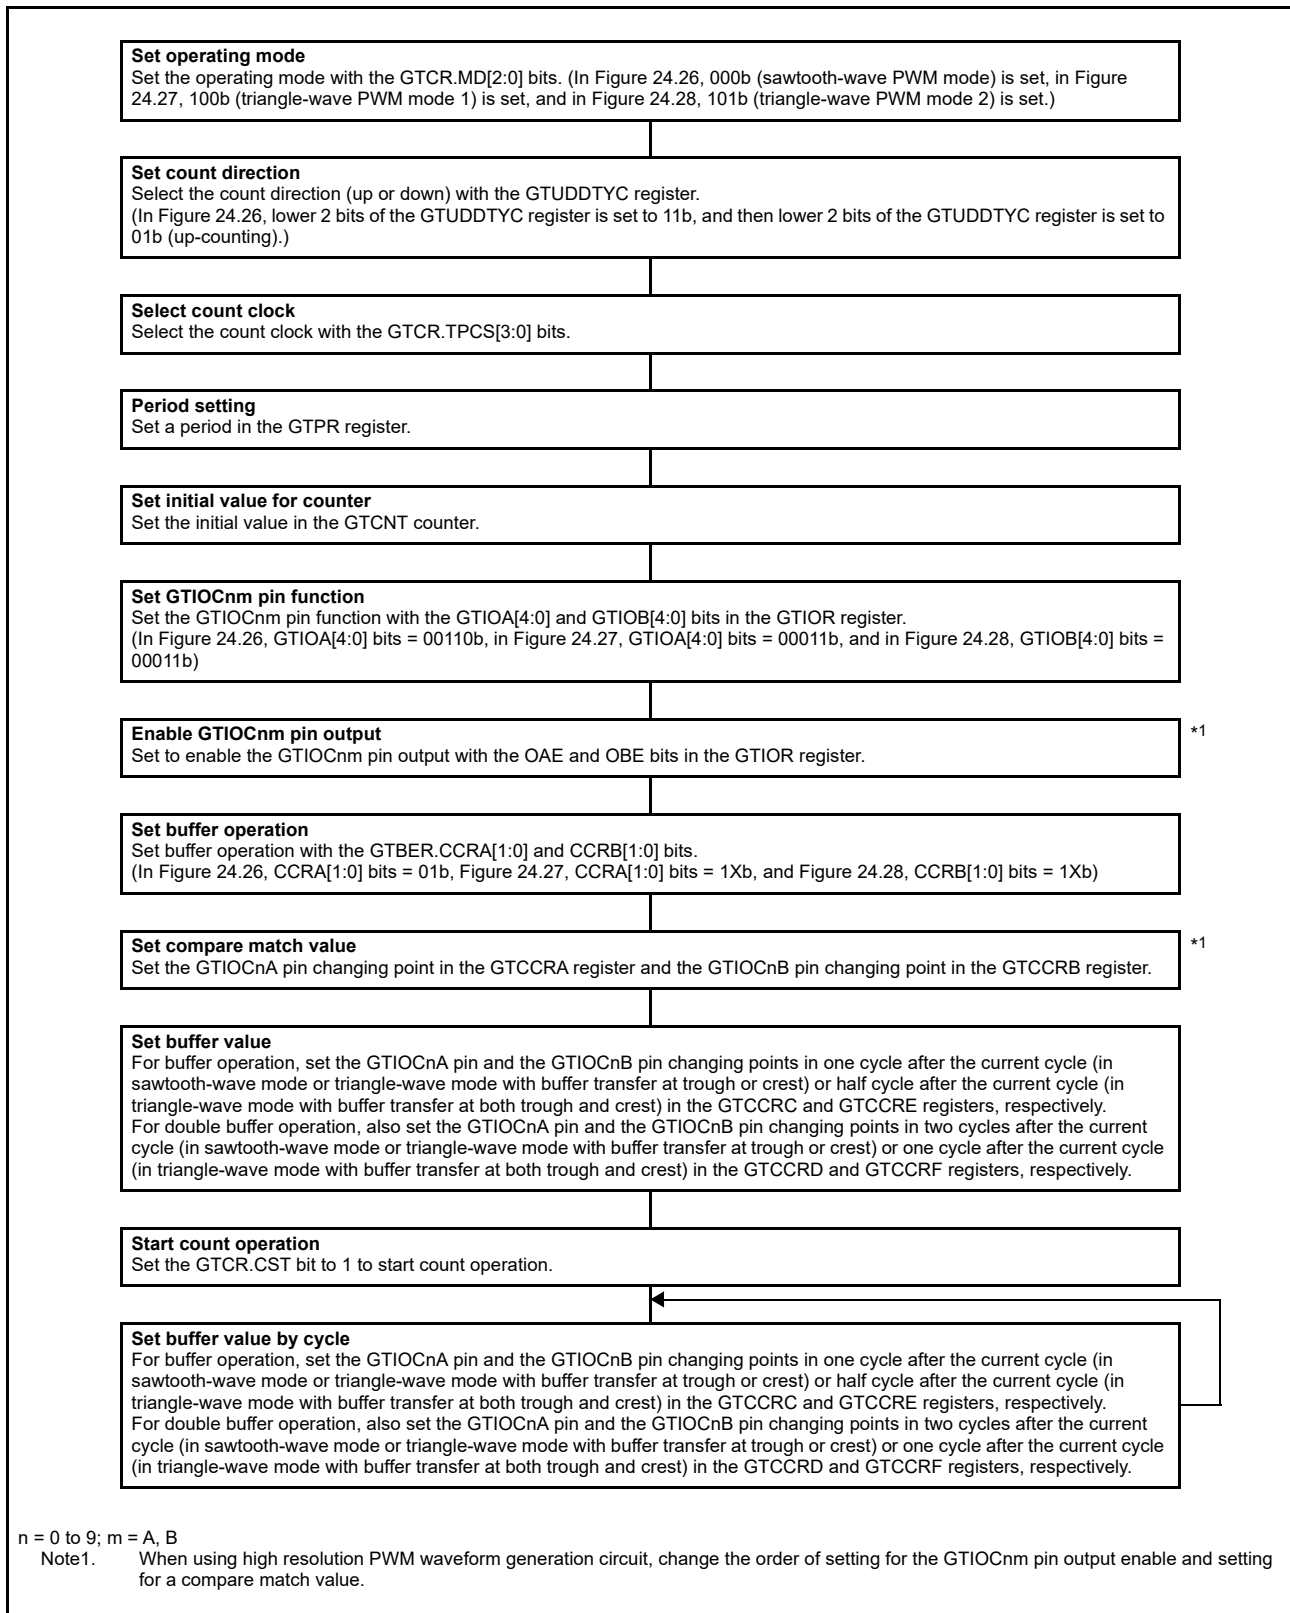

**Figure 24.26** Example of GTCCRA and GTCCRB Registers Buffer Operation (Output Compare, Sawtooth-Waves in Up-Counting, High Output at GTCCRA Register Compare Match, Low Output at the End of the Cycle) (n = 0 to 9)

**Figure 24.27** Example of GTCCRA and GTCCRB Registers Double Buffer Operation (Output Compare, Triangle Waves, Buffer Operation at Trough, Output Toggled at GTCCRA Register Compare Match, Output Retained at the End of the Cycle) (n = 0 to 9)

**Figure 24.28** Example of GTCCRc and GTCCRB Registers Double Buffer Operation (Output Compare, Triangle Waves, Buffer Operation at Both Troughs and Crests, Output Toggled at GTCCRB Register Compare Match, Output Retained at the End of the Cycle) (n = 0 to 9)

**Figure 24.29 Example for Setting Buffer Operation of the GTCCRA and GTCCRB Registers (for Output Compare)**

(2) When the GTCCRA or GTCCRB Register Functions as Input Capture Register

The timing of transfer to the buffers is when an input capture is generated. When an input capture is generated, the GTCNT counter value is transferred to GTCCRA and GTCCRB registers and the stored GTCCRA and GTCCRB registers values are transferred to buffer registers. Buffer transfer by counter clearing is not performed at input capture. Figure 24.30 and Figure 24.31 show examples of buffer operation of the GTCCRA and GTCCRB registers, and Figure 24.32 shows an example for setting buffer operation of the GTCCRA and GTCCRB registers.

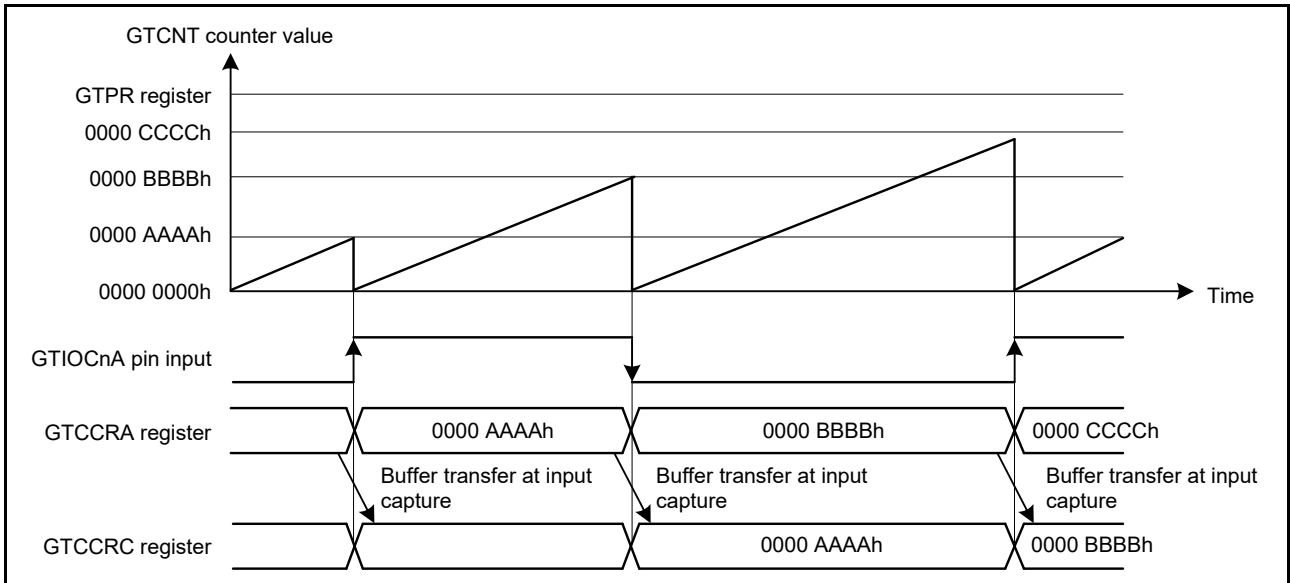

Figure 24.30 Example of Buffer Operation of the GTCCRA and GTCCRB Registers (Counting up to Produce a Sawtooth Wave, and Clearing the GTCNT Counter and Input Capture on Both Edges of the Input on the GTIOcNA Pin) (n = 0 to 9)

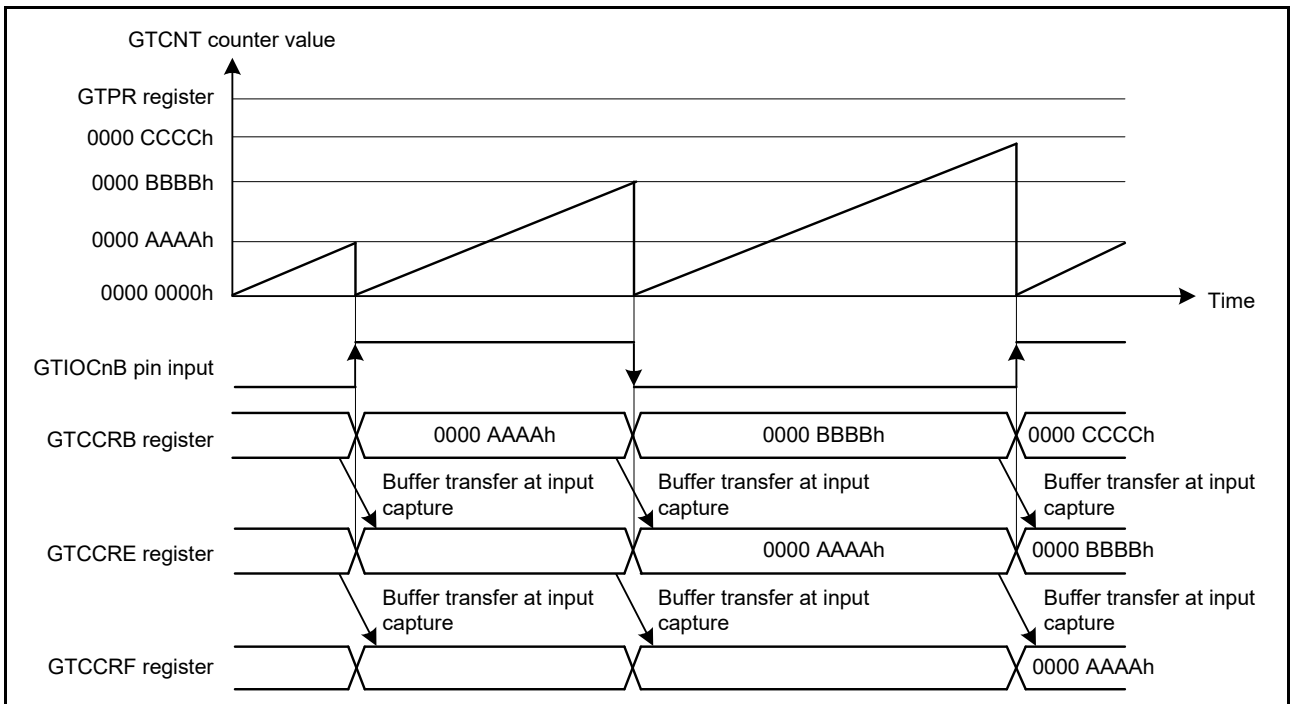

Figure 24.31 Example of Double Buffer Operation of the GTCCRA and GTCCRB Registers (Counting up to Produce a Sawtooth Wave, and Clearing the GTCNT Counter and Input Capture on Both Edges of the Input on the GTIOcNB Pin) (n = 0 to 9)

Figure 24.32 Example for Setting Buffer Operation of the GTCCRA and GTCCRB Registers (for Input Capture)

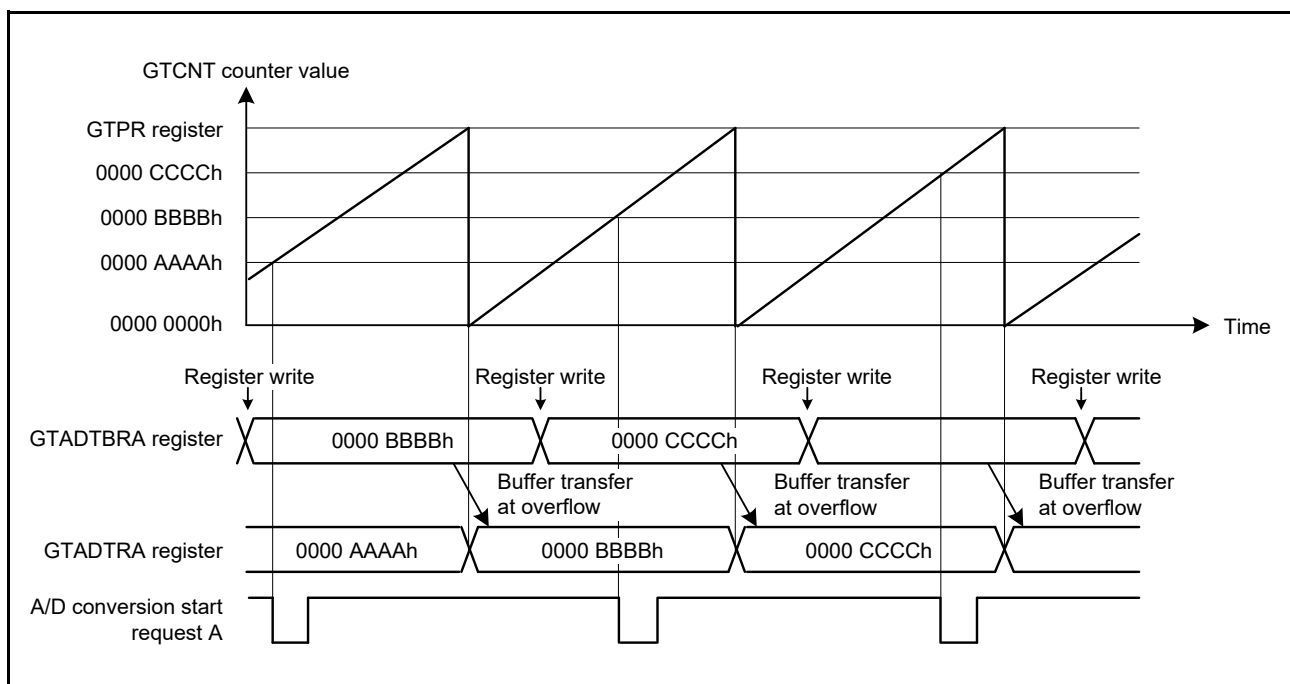

### 24.3.2.3 Buffer Operation for the GTADTRA and GTADTRB Registers

The GTADTBRA register can function as the GTADTRA buffer register and the GTADTDBRA register can function as the GTADTBRA buffer register (double buffer register for the GTADTRA register). Similarly, the GTADTBRB register can function as the GTADTRB buffer register and the GTADTDBRB register can function as the GTADTBRB buffer register (double buffer register for the GTADTRB register).

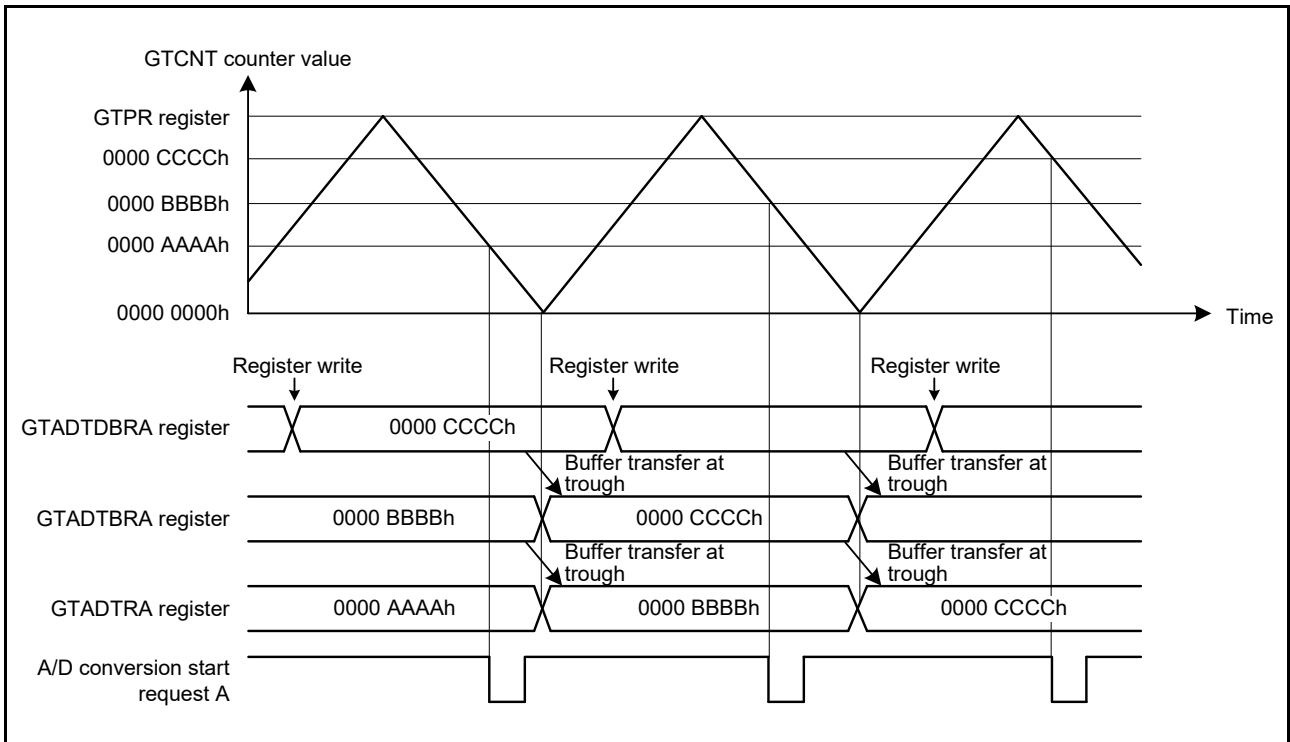

To set the GTADTRA or GTADTRB register to function as a double buffer, set the GTBER.ADTDA or ADTDB bit to 1. For single buffer operation, set 0. Not to function as buffer, set the GTBER.ADTTA[1:0] or ADTTB[1:0] bits to 00b. The buffer transfer timing can be set with the ADTTA[1:0] and ADTTB[1:0] bits to an overflow (in up-counting) or an underflow (in down-counting) in sawtooth-wave mode, with ADTTA[1:0] and ADTTB[1:0] bits to 01b for a crest, to 10b for a trough, or to 11b for both crest and trough in triangle-wave mode.

In sawtooth-wave mode, when the ADTTA[1:0] and ADTTB[1:0] bits are set to value other than 00b and in count operation, the buffer transfer, by similar counter clearing sources in section 24.3.2.1, GTPR Register Buffer Operation, is performed in the same way at an overflow (in up-counting) or an underflow (in down-counting).

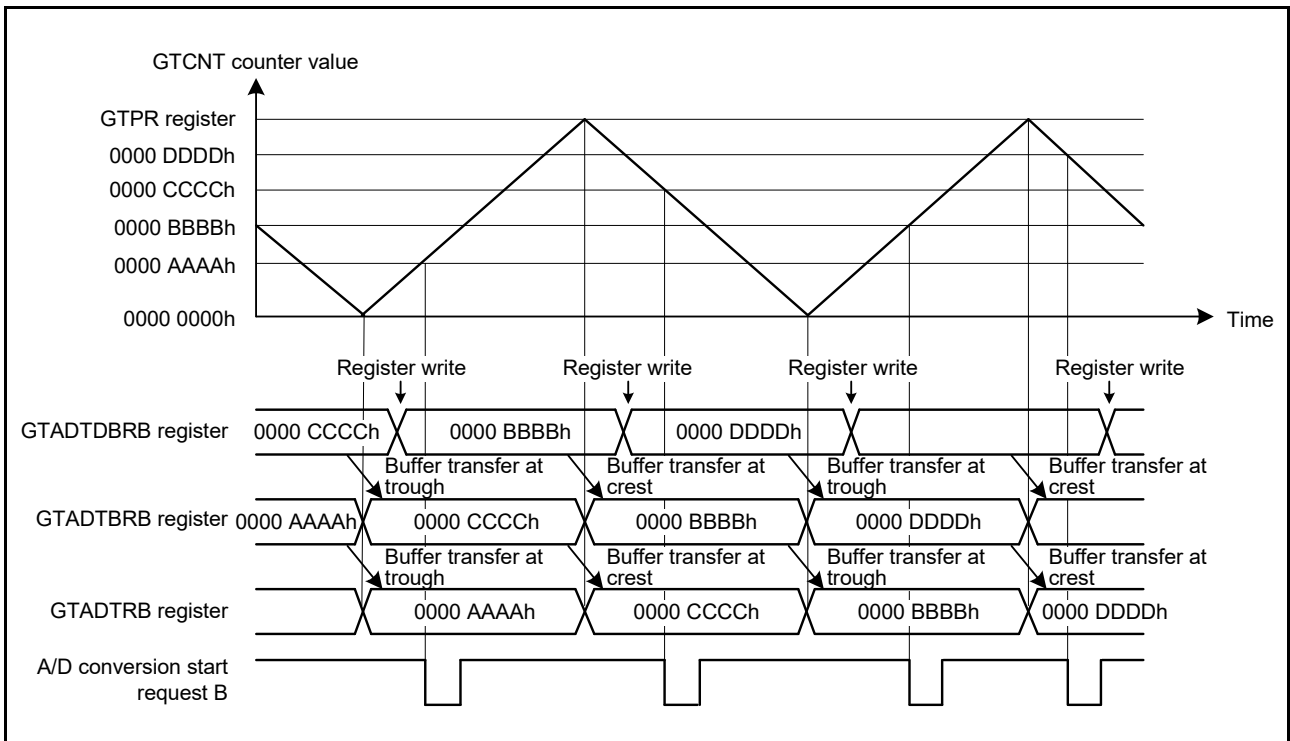

Figure 24.33 to Figure 24.35 show examples of buffer operation of the GTADTRA and GTADTRB registers, and Figure 24.36 shows an example for setting buffer operation of the GTADTRA and GTADTRB registers.

**Figure 24.33** Example of Buffer Operation of the GTADTRA and GTADTRB Registers (Sawtooth Waves in Up-Counting, A/D Conversion Start Request Generated by Up-Counting)

**Figure 24.34** Example of Buffer Operation of the GTADTRA and GTADTRB Registers (Sawtooth Waves in Up-Counting, Buffer Transfer at GTADTRA Compare Match, A/D Conversion Start Request Generated by Up-Counting)

**Figure 24.35** Example of Double Buffer Operation of the GTADTRA and GTADTRB Registers (Triangle Waves, Buffer Transfer at Both Troughs and Crests, A/D Conversion Start Request Generated by Both Up- and Down-Counting)

Figure 24.36 Example for Setting Buffer Operation of the GTADTRA and GTADTRB Registers

### 24.3.3 PWM Output Operating Mode

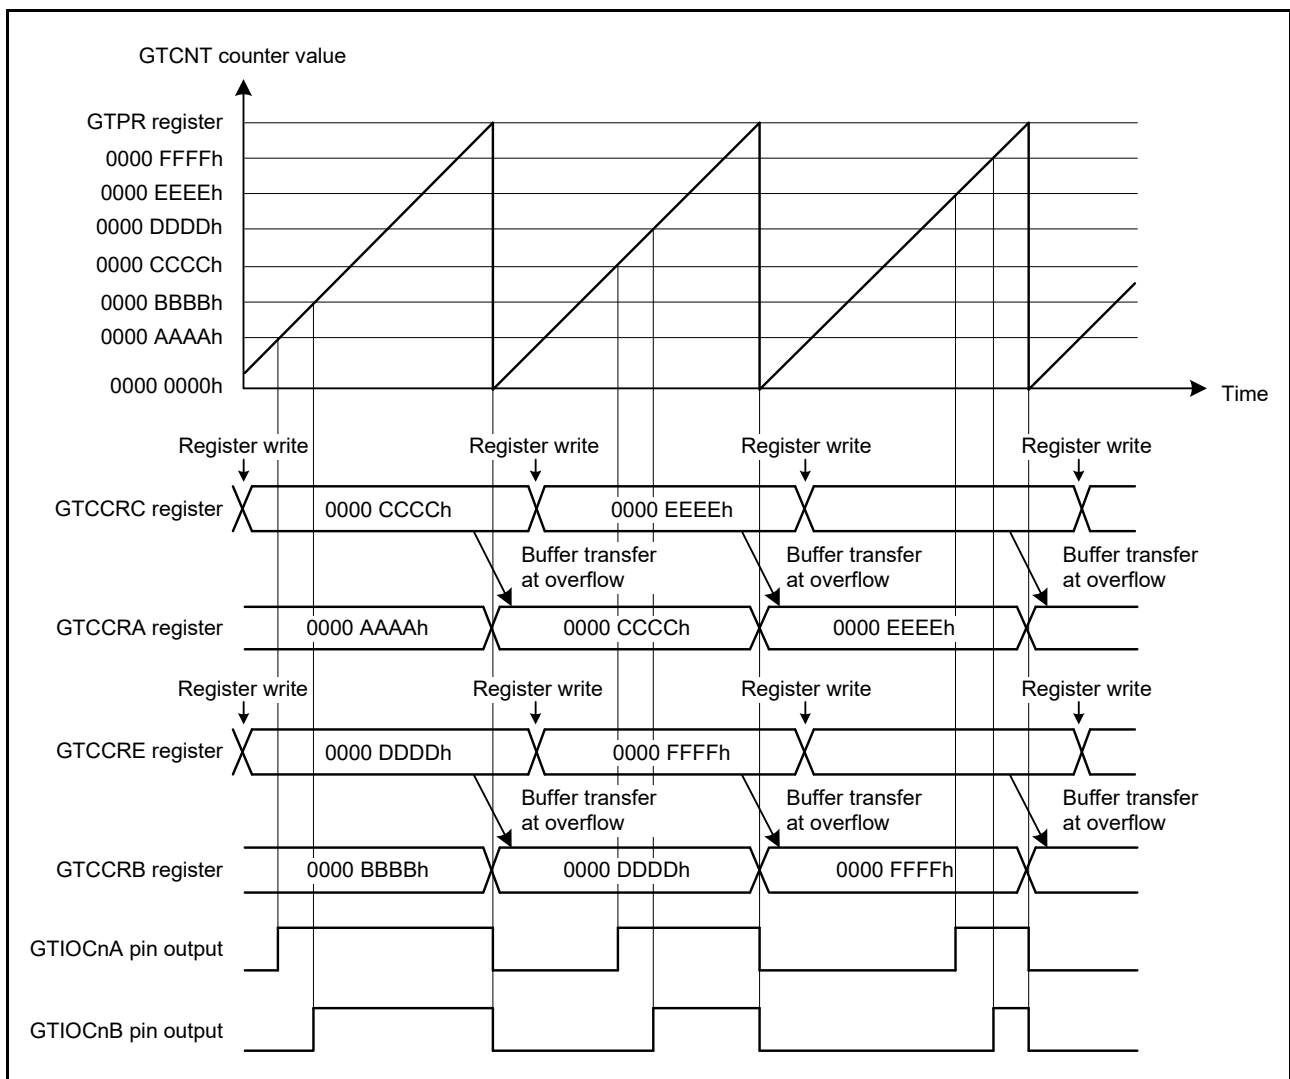

The GPTW can output PWM waveforms to the GTIOCnA pin or GTIOCnB pin (n = 0 to 9) by a compare match between the GTCNT counter and the GTCCRA or GTCCRB register.

By setting the GTDTCR, GTDVU, and GTDVD registers, the compare match value for a negative-phase waveform with dead time can automatically be set to the GTCCRB register.

#### (1) Sawtooth-Wave PWM Mode

In sawtooth-wave PWM mode, the GTCNT counter performs sawtooth-wave (half-wave) operation by setting the period in the GTPR register and a PWM waveform is output to the GTIOCnA or GTIOCnB pin when a GTCCRA or GTCCRB register compare match occurs. The pin output value can be selected from low output, high output, or toggle output separately for a compare match and for the end of the cycle according to the GTIOR register setting.

Figure 24.37 shows an example of sawtooth-wave PWM mode operation, and Figure 24.38 shows an example for setting sawtooth-wave PWM mode.

**Figure 24.37** Example of Sawtooth-Wave PWM Mode Operation (Up-Counting, Buffer Operation, High Output at GTCCRA/GTCCRB Register Compare Match, Low Output at the End of the Cycle) (n = 0 to 9)

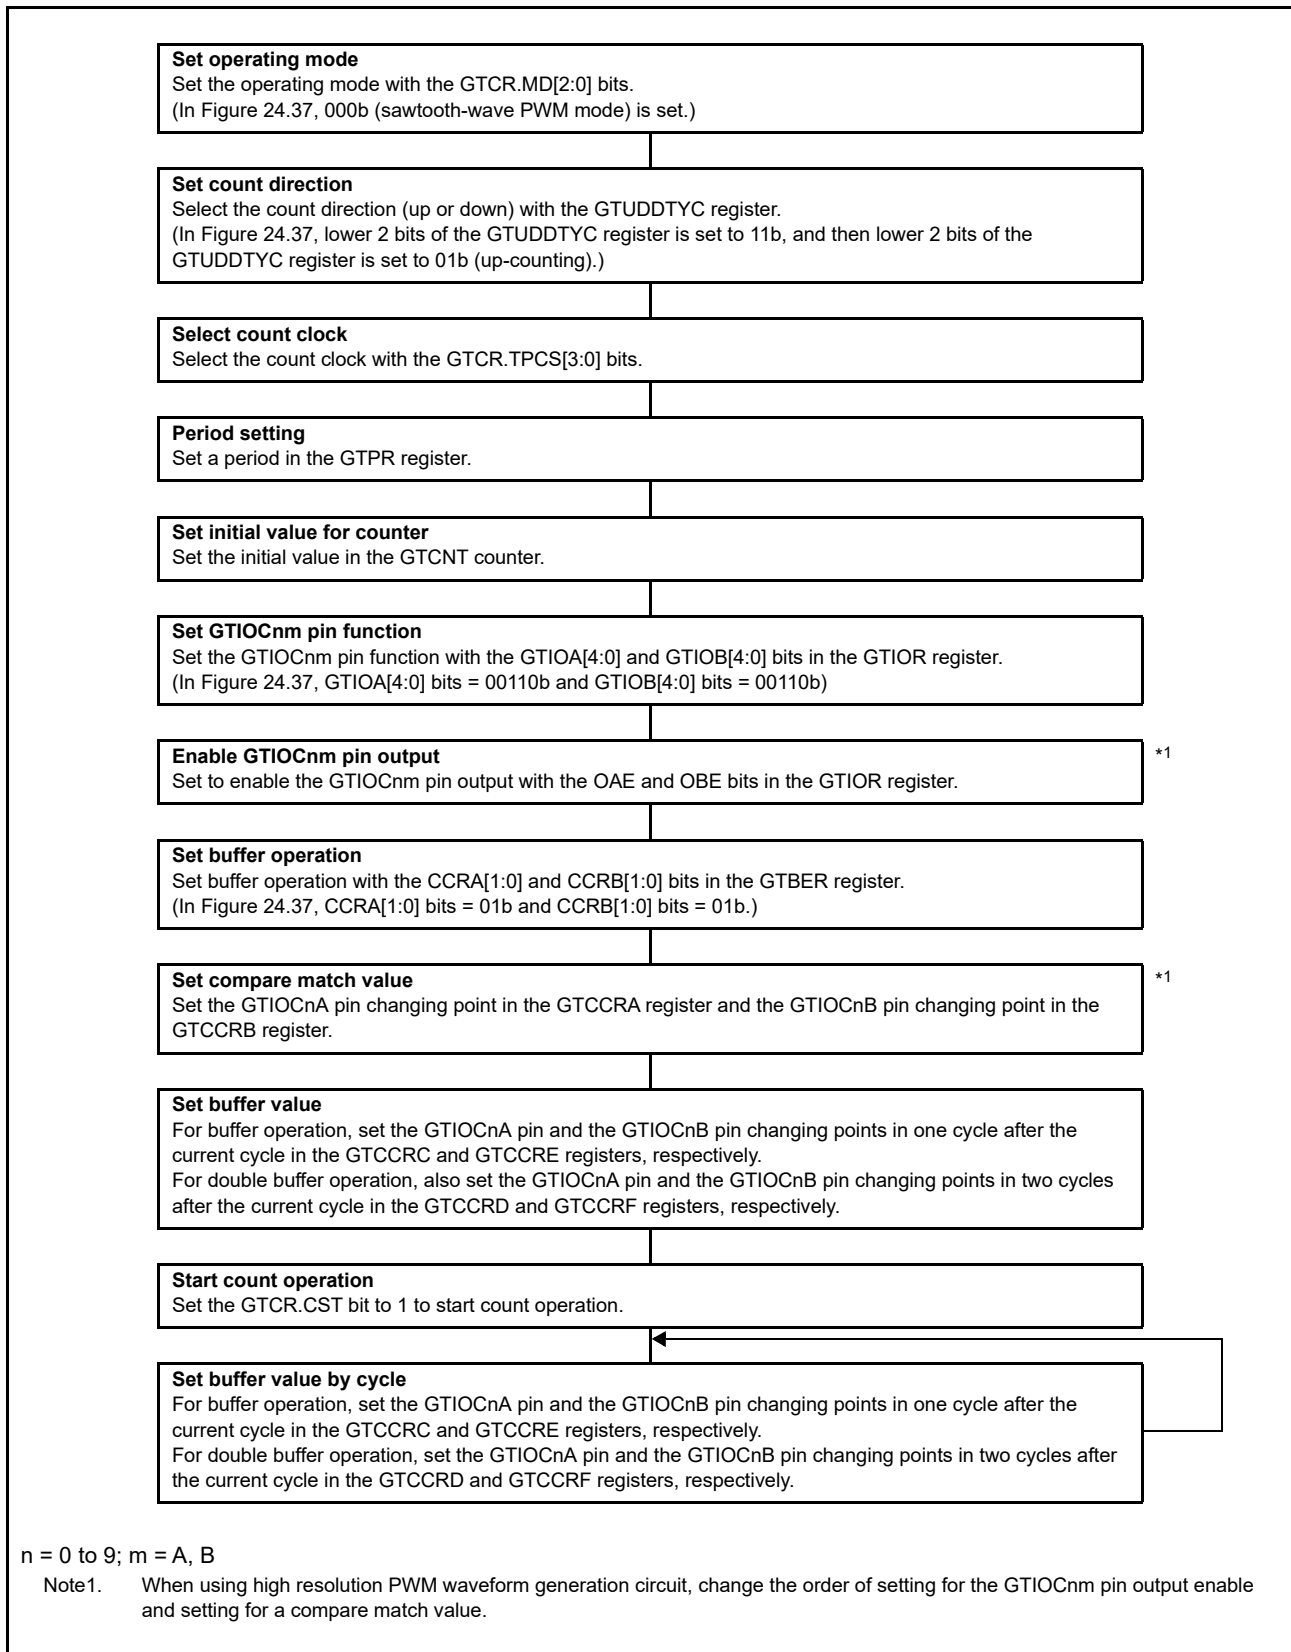

Figure 24.38 Example for Setting Sawtooth-Wave PWM Mode

## (2) Sawtooth-Wave One-Shot Pulse Mode

The sawtooth-wave one-shot pulse mode is a mode in which the period is set in the GTPR register, the GTCNT counter performs sawtooth-wave (half-wave) operation and a PWM waveform is output to the GTIOCnA or GTIOCnB pin at a compare match of the GTCCRA or GTCCRB register with buffer operation fixed ( $n = 0$  to 9).

Buffer operation in sawtooth-wave one-shot pulse mode is different from the usual buffer operation. Buffer transfer is performed from the GTCCRC register to the GTCCRA register, from the GTCCRE register to the GTCCRB register, from the GTCCRD register to the temporary register A, and from the GTCCRF register to the temporary register B at the end of the cycle, and from the temporary register A to the GTCCRA register at a GTCCRA register compare match and from the temporary register B to the GTCCRB register at a GTCCRB register compare match. The pin output value can be selected from low output, high output, or toggle output separately for a compare match and the end of the cycle according to the GTIOR register setting.

The temporary register A and the temporary register B can perform forcible buffer transfers from the GTCCRD register to the temporary register A and from the GTCCRF register to the temporary register B respectively by writing 1 to the GTBER.CCRSWT bit while the count is stopped.

By setting the GTDTCR, GTDVU, and GTDVD registers, a compare match value for a negative-phase waveform with dead time can automatically be set to the GTCCRB register.

When the GTBER.DBRTCEm ( $m = A, B$ ) bit is set to 1, transfer from an intermediate buffer to the GTCCRm ( $m = A, B$ ) register is repeated on a cyclic basis with using the temporary register  $x$  ( $x = C, E$ ) and temporary register  $m$  ( $m = A, B$ ) which operate as intermediate buffers for the GTCCRx ( $x = C, E$ ) and GTCCRm ( $m = A, B$ ) registers, respectively, even while buffer transfer is disabled (repeated double buffer operation function during disabling of buffer transfer). For details, refer to section 24.8.2.2, Repeated Double-Buffered Operation When Disabling GTCCR Buffer Transfer.

Figure 24.39 shows an example of sawtooth-wave one-shot pulse mode operation, and Figure 24.40 shows an example for setting sawtooth-wave one-shot pulse mode.

**Figure 24.39 Example of Sawtooth-Wave One-Shot Pulse Mode Operation (Up-Counting, Low Output from the GTIOCnA Pin and High Output from the GTIOCnB Pin at Initial Output, Output Toggled at GTCCRA/GTCCRB Register Compare Match, Output Retained at the End of the Cycle) (n = 0 to 9)**

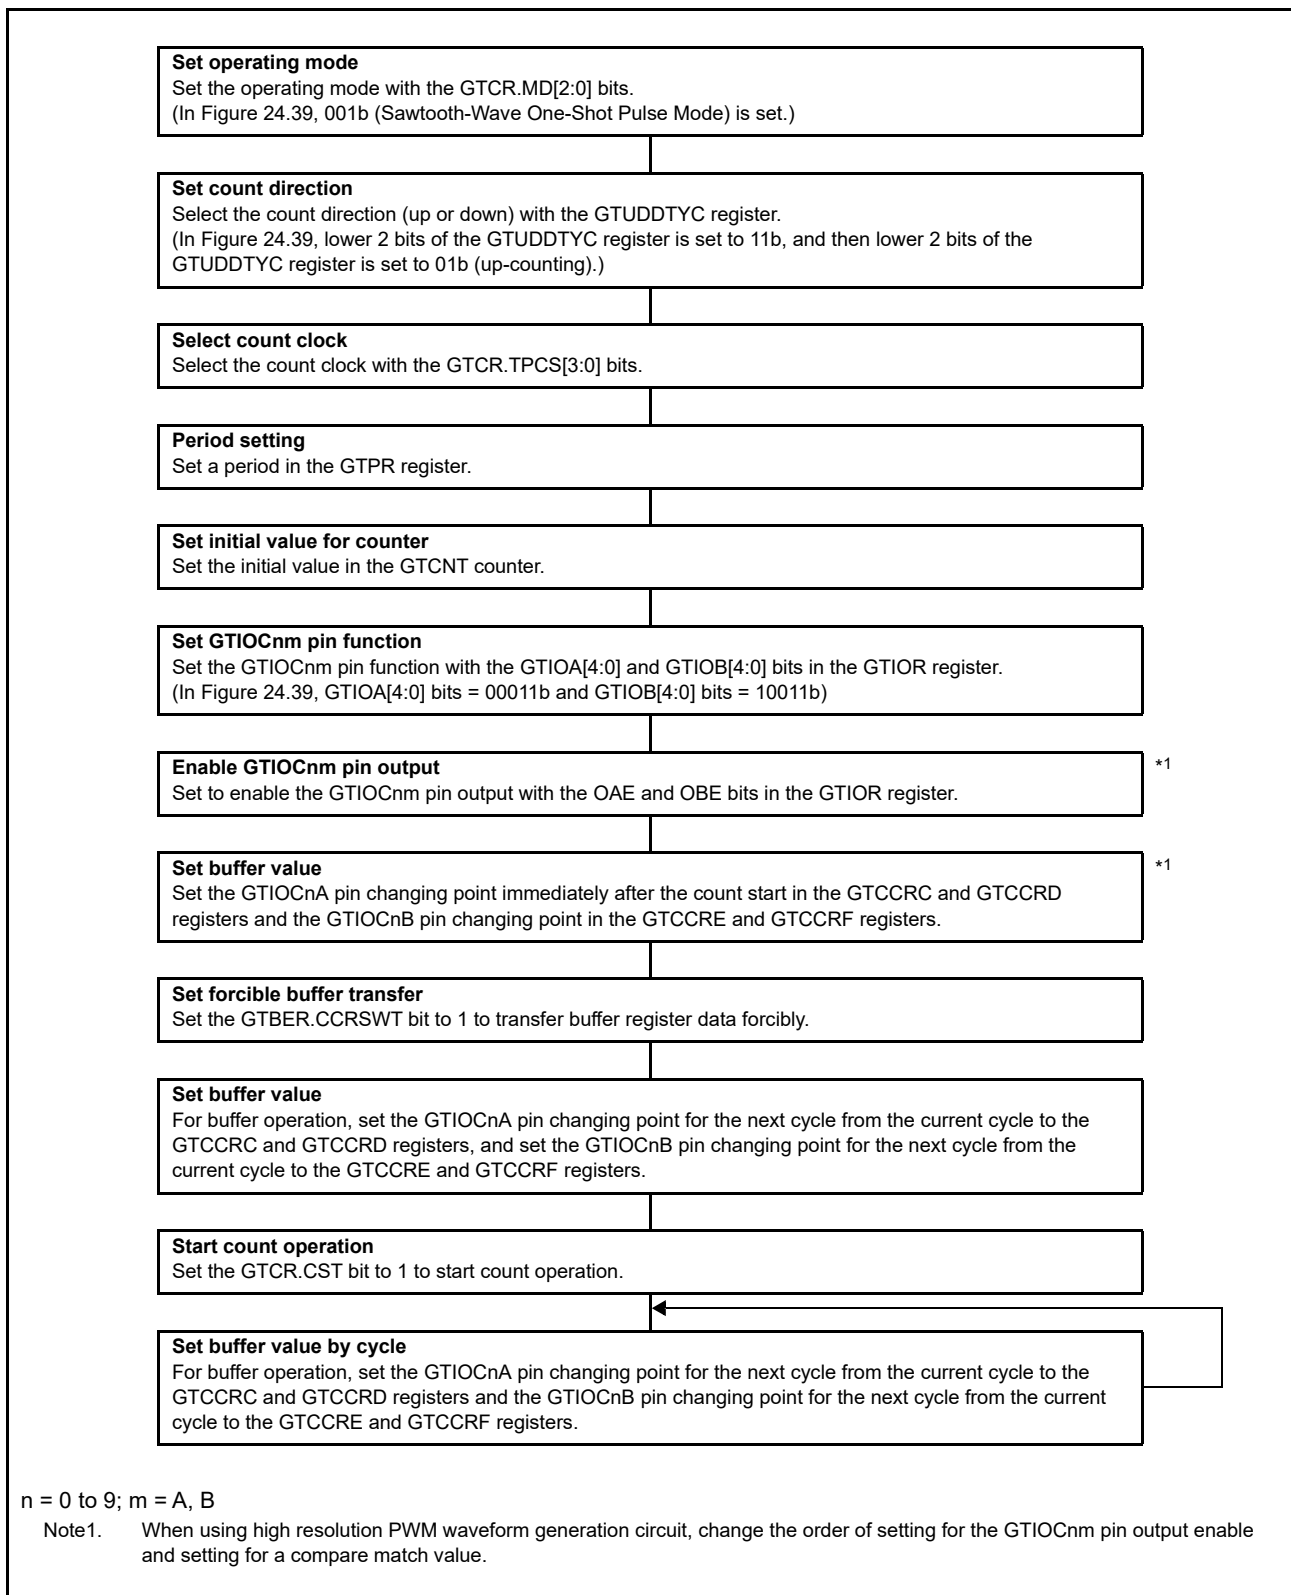

Figure 24.40 Example for Setting Sawtooth-Wave One-Shot Pulse Mode

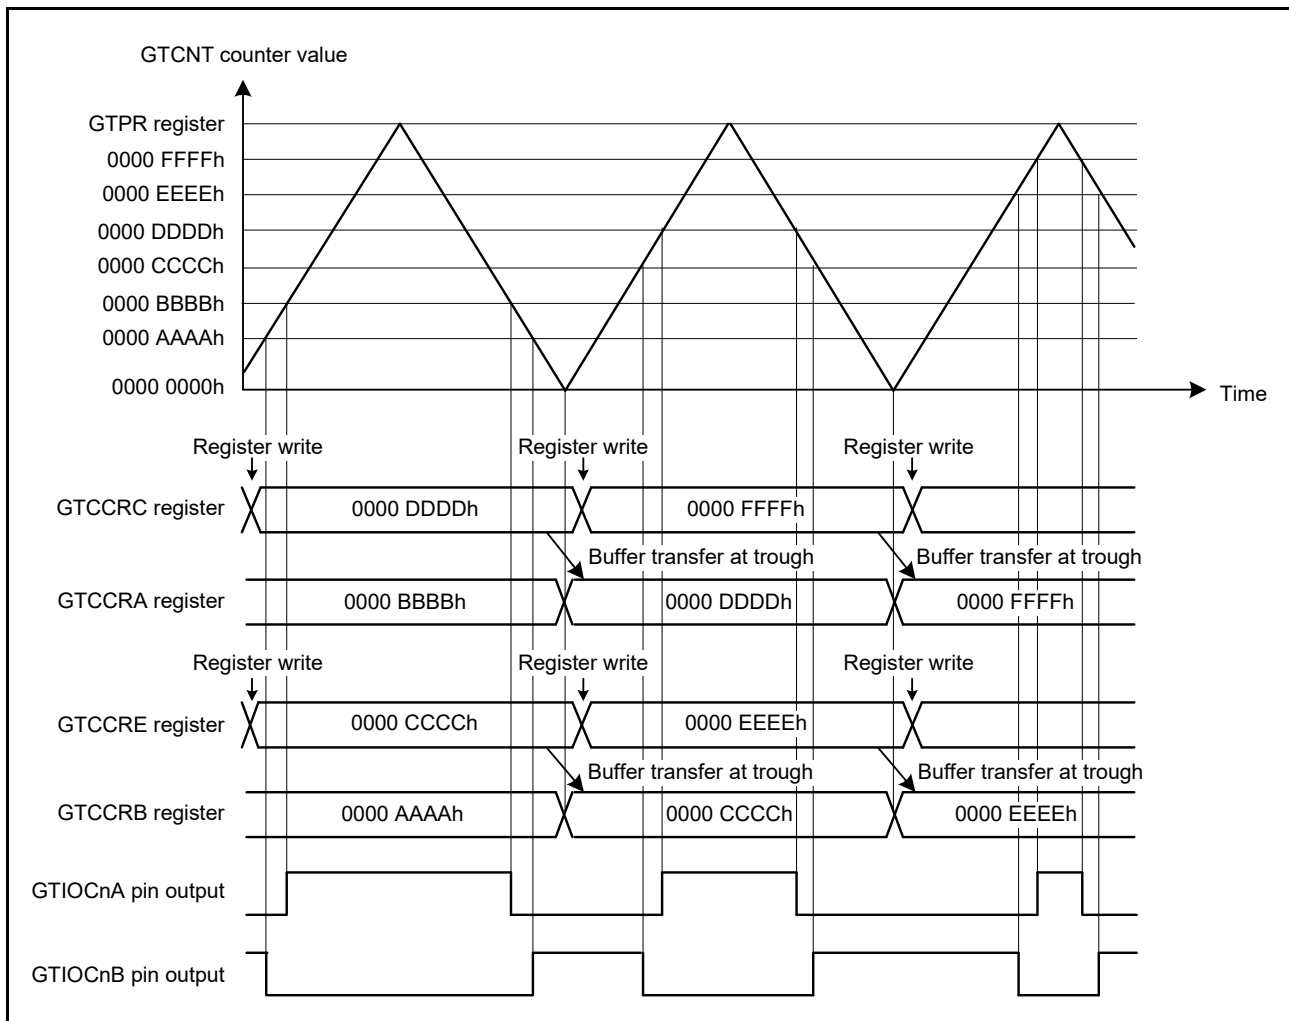

### (3) Triangle-Wave PWM Mode 1 (32-Bit Transfer at Trough)

The triangle-wave PWM mode 1 is a mode in which the period is set in the GTPR register, the GTCNT counter performs triangle-wave (full-wave) operation, and a PWM waveform is output to the GTIOCnA or GTIOCnB pin when a GTCCRA or GTCCRB register compare match occurs (n = 0 to 9).

Buffer transfer is performed at the trough. The pin output value can be selected from low output, high output, or toggle output separately for a compare match and for the end of the cycle according to the GTIOR register setting.

By setting the GTDTCR, GTDVU, and GTDVD registers, a compare match value for a negative-phase waveform with dead time can automatically be set to the GTCCRB register.

Figure 24.41 shows an example of triangle-wave PWM mode 1 operation, and Figure 24.42 shows an example for setting triangle-wave PWM mode 1.

**Figure 24.41 Example of Triangle-Wave PWM Mode 1 Operation**  
**(Buffer Operation, Low Output from the GTIOCnA Pin and High Output from the GTIOCnB Pin at Initial Output, Output Toggled at GTCCRA/GTCCRB Register Compare Match, Output Retained at the End of the Cycle) (n = 0 to 9)**

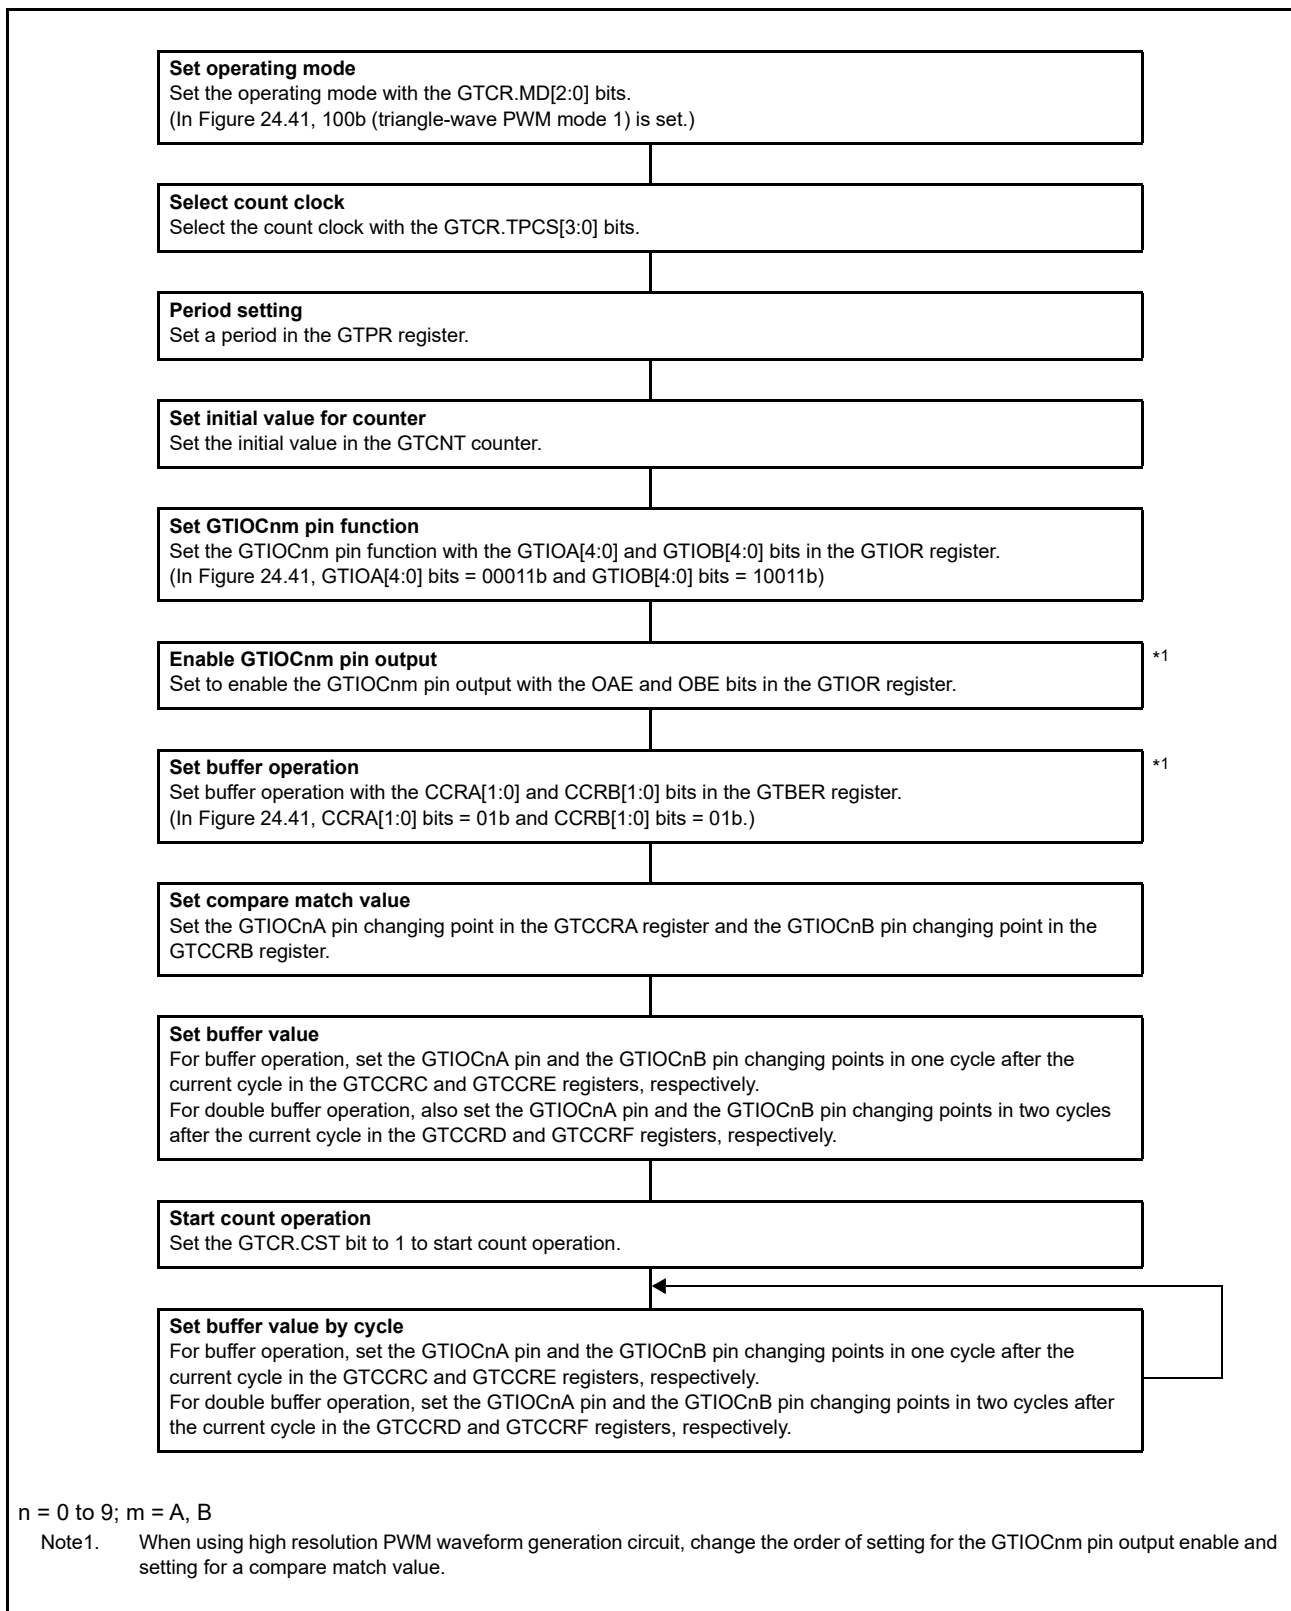

Figure 24.42 Example for Setting Triangle-Wave PWM Mode 1

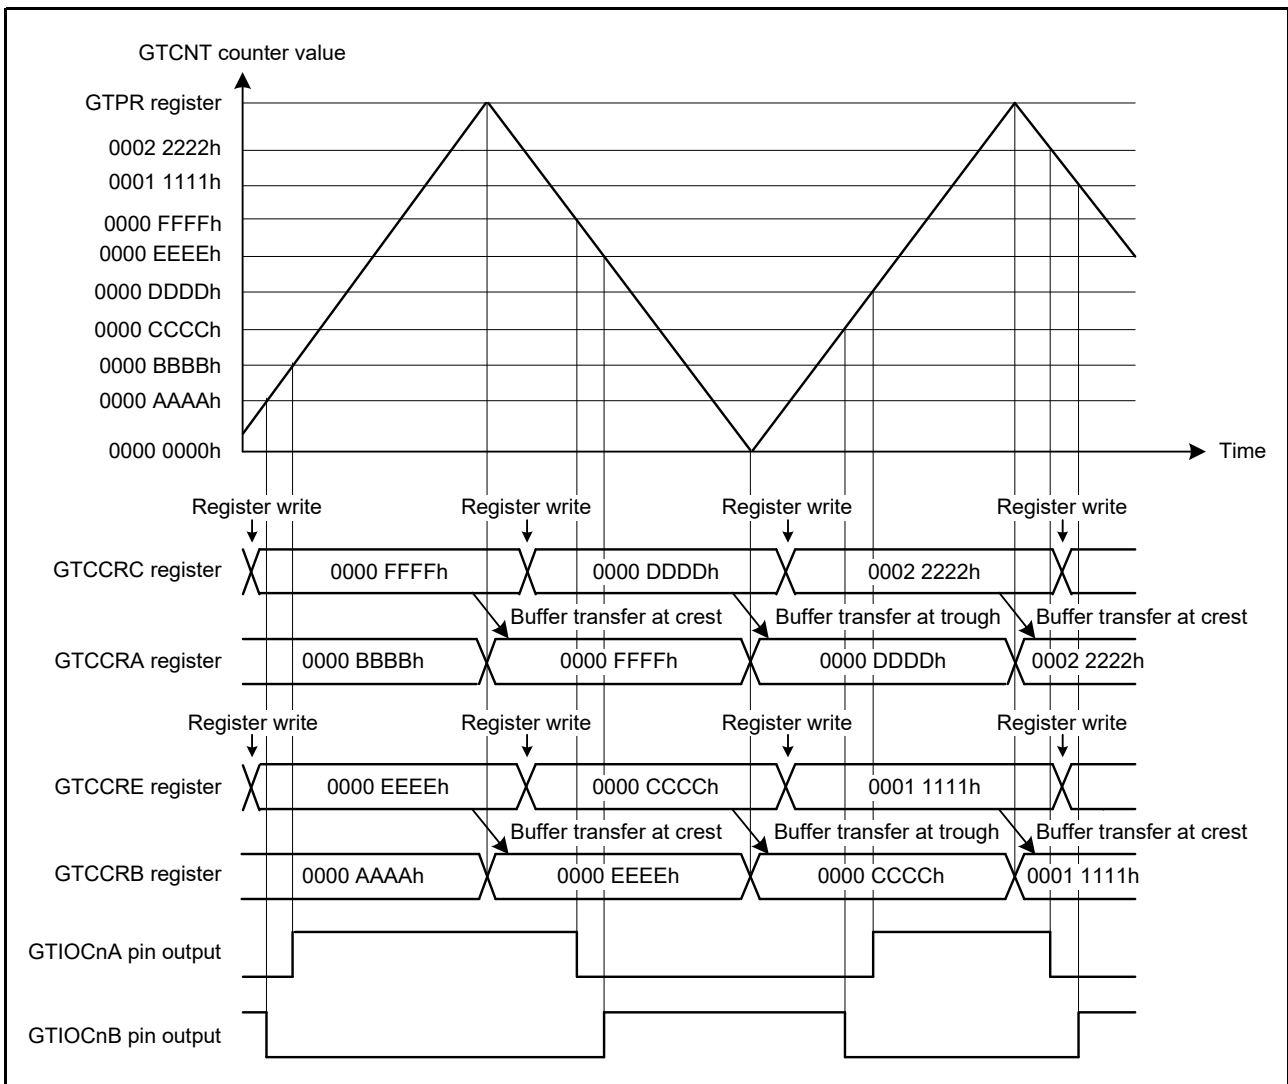

(4) Triangle-Wave PWM Mode 2 (32-Bit Transfer at Crest and Trough)

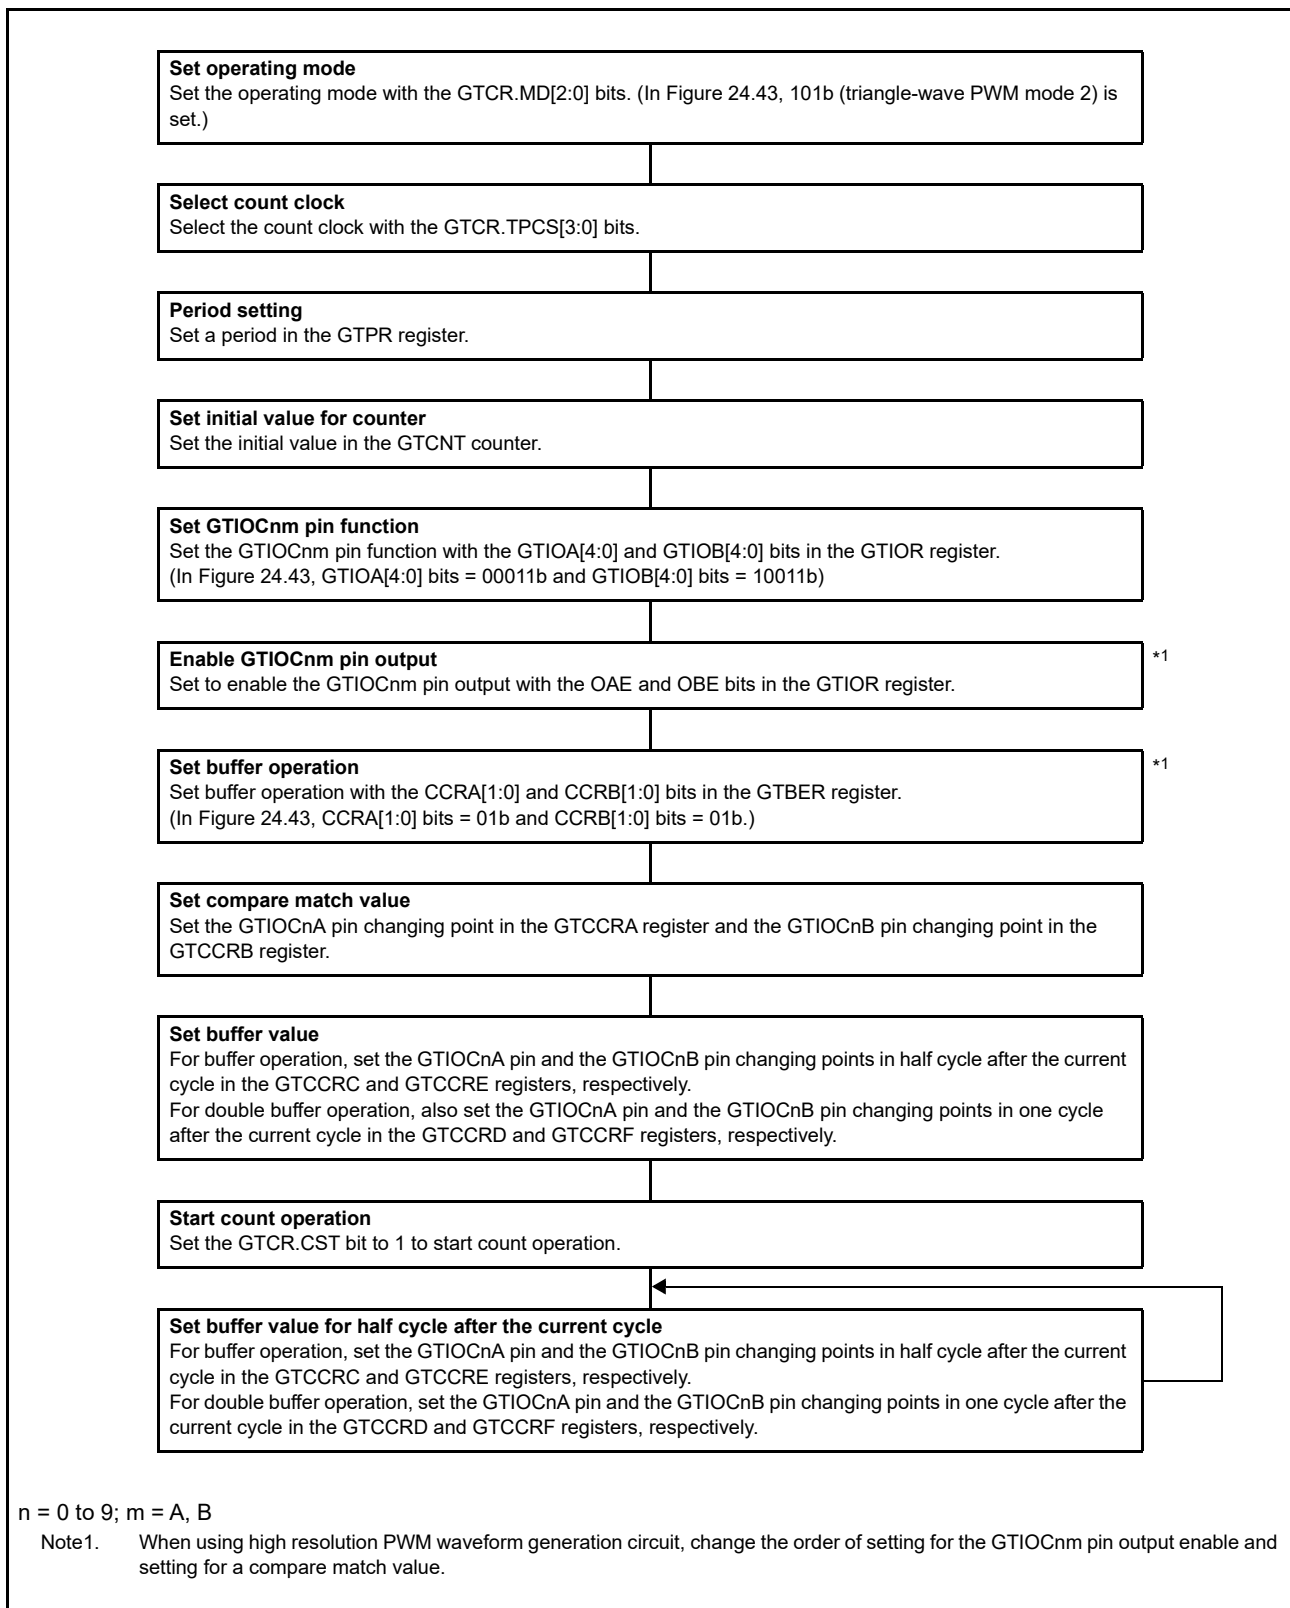

Similarly to triangle-wave PWM mode 1, in triangle-wave PWM mode 2 the period is set in the GTPR register, the GTCNT counter performs triangle-wave (full-wave) operation, and a PWM waveform is output to the GTIOCnA or GTIOCnB pin when a GTCCRA or GTCCRB register compare match occurs (n = 0 to 9). The buffer transfer is performed at both crests and troughs. The pin output value can be selected from low output, high output, or toggle output separately for a compare match and for the end of the cycle according to the GTIOR register setting.

By setting the GTDTCR, GTDVU, and GTDVD registers, a compare match value for a negative-phase waveform with dead time can automatically be set to the GTCCRB register.

Figure 24.43 shows an example of triangle-wave PWM mode 2 operation, and Figure 24.44 shows an example for setting triangle-wave PWM mode 2.

**Figure 24.43 Example of Triangle-Wave PWM Mode 2 Operation (Buffer Operation, Low Output from the GTIOCnA Pin and High Output from the GTIOCnB Pin at Initial Output, Output Toggled at GTCCRA/GTCCRB Register Compare Match, Output Retained at the End of the Cycle) (n = 0 to 9)**

**Figure 24.44 Example for Setting Triangle-Wave PWM Mode 2**

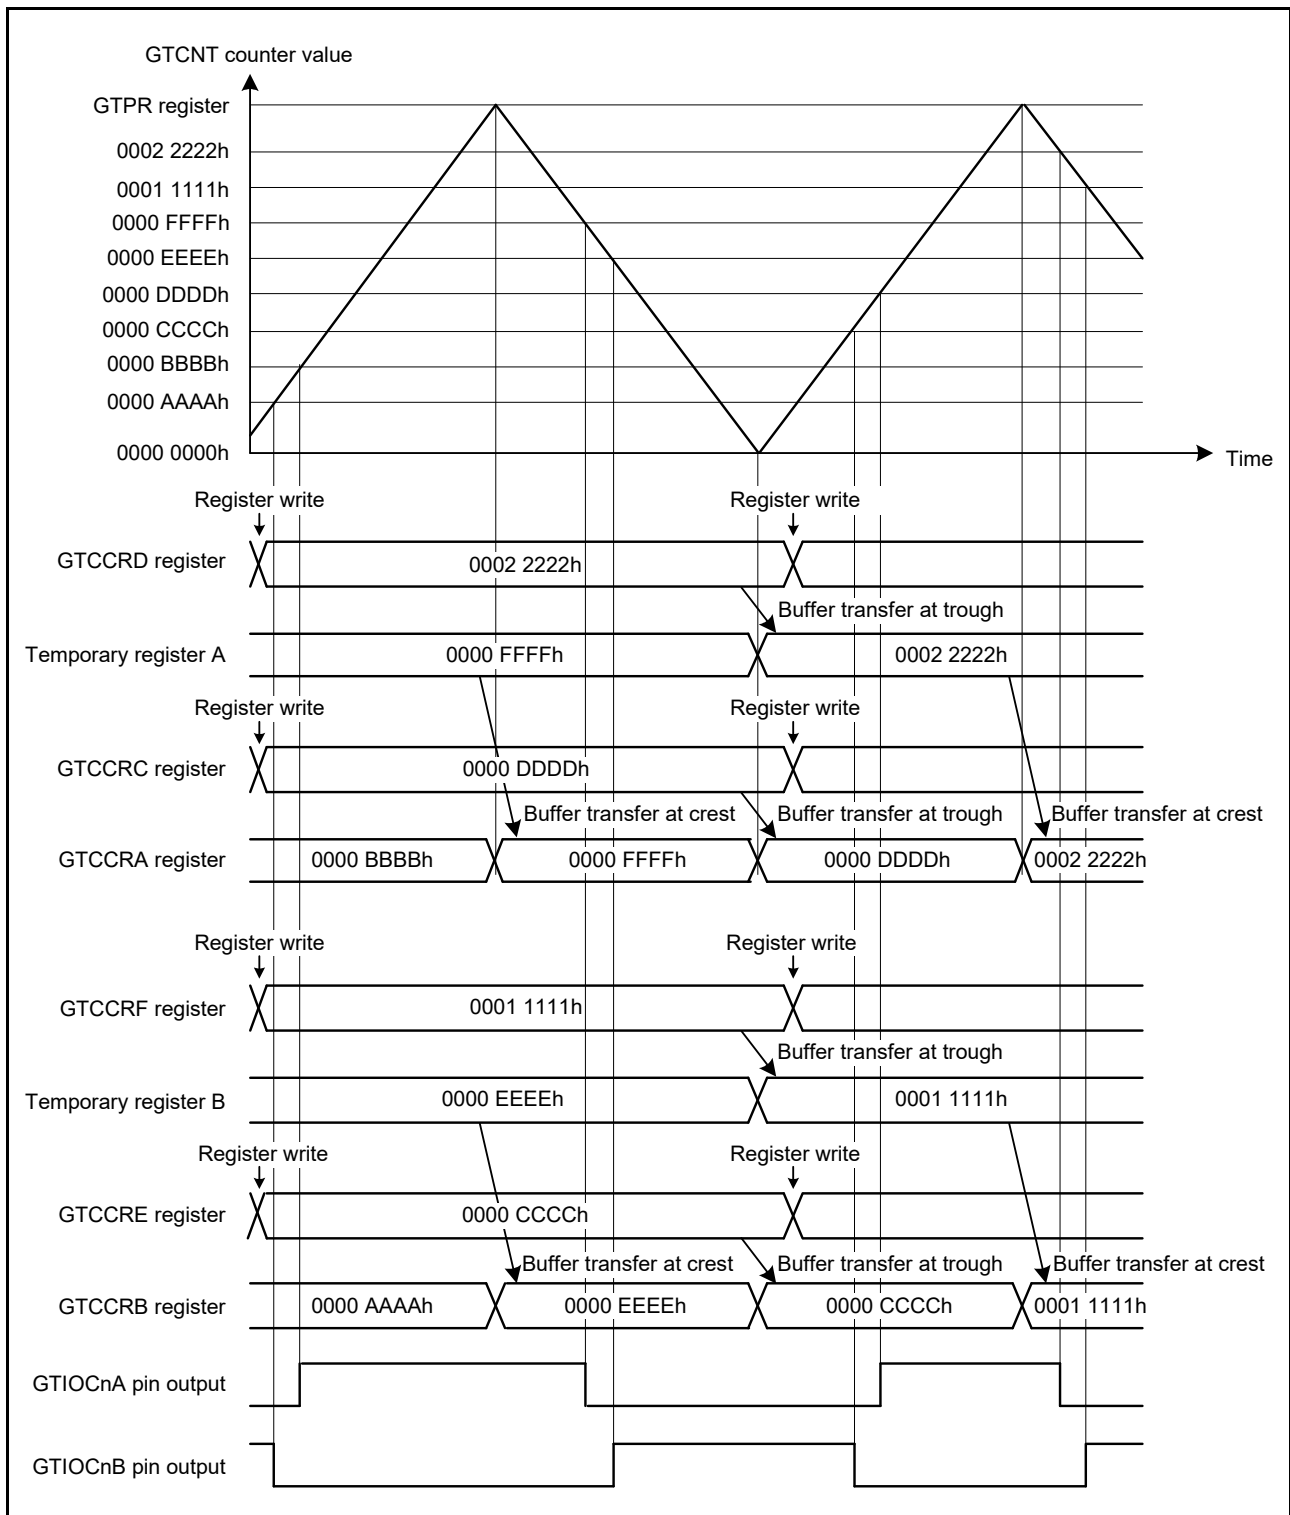

### (5) Triangle-Wave PWM Mode 3 (64-Bit Transfer at Trough)

The triangle-wave PWM mode 3 is a mode in which the period is set in the GTPR register, the GTCNT counter performs triangle-wave (full-wave) operation and a PWM waveform is output to the GTIOCnA or GTIOCnB pin at a compare match of the GTCCRA or GTCCRB register with buffer operation fixed ( $n = 0$  to 9). Buffer operation in triangle-wave PWM mode 3 is different from the usual buffer operation. Buffer transfer is performed from the GTCCRC register to the GTCCRA register, from the GTCCRE register to the GTCCRB register, from the GTCCRD register to the temporary register A, and from the GTCCRF register to the temporary register B at the trough, and from the temporary register A to the GTCCRA register and from the temporary register B to the GTCCRB register at the crest. The pin output value can be selected from low output, high output, or toggle output separately for a compare match and for the end of the cycle according to the GTIOR register setting.

By setting the GTDTCR, GTDVU, and GTDVD registers, a compare match value for a negative-phase waveform with dead time can automatically be set to the GTCCRB register.

When the GTBER.DBRTEC $m$  ( $m = A, B$ ) bit is set to 1, transfer from an intermediate buffer to the GTCCR $m$  ( $m = A, B$ ) register is repeated on a cyclic basis with using the temporary register  $x$  ( $x = C, E$ ) and temporary register  $m$  ( $m = A, B$ ) which operate as intermediate buffers for the GTCCR $x$  ( $x = C, E$ ) and GTCCR $m$  ( $m = A, B$ ) registers, respectively, even while buffer transfer is disabled (repeated double buffer operation function during disabling of buffer transfer). For details, refer to section 24.8.2.2, Repeated Double-Buffered Operation When Disabling GTCCR Buffer Transfer.

Figure 24.45 shows an example of triangle-wave PWM mode 3 operation, and Figure 24.46 shows an example for setting triangle-wave PWM mode 3.

**Figure 24.45** Example of Triangle-Wave PWM Mode 3 Operation (Low Output from the GTIOCnA Pin and High Output from the GTIOCnB Pin at Initial Output, Output Toggled at GTCCRA/GTCCRB Register Compare Match, Output Retained at the End of the Cycle) (n = 0 to 9)

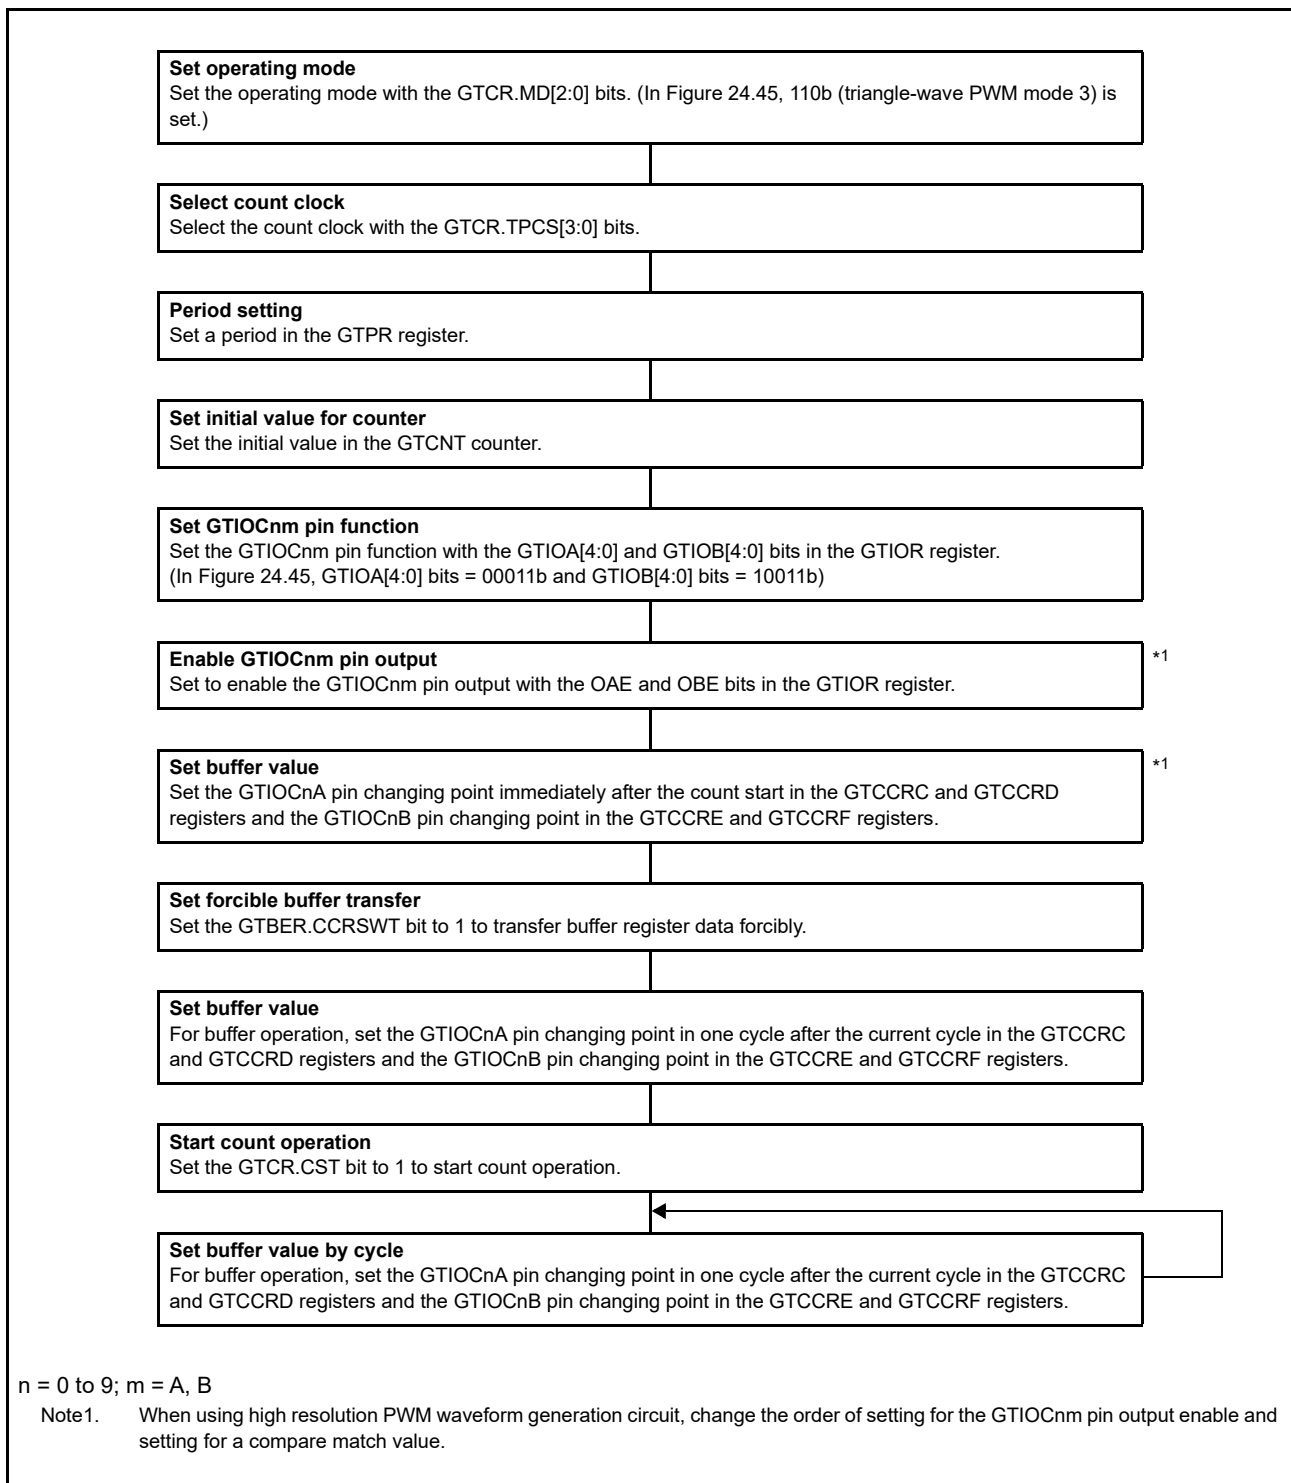

Figure 24.46 Example for Setting Triangle-Wave PWM Mode 3

### 24.3.4 Automatic Dead Time Setting Function

By setting the GTDTCR register, a compare match value for a negative waveform with dead time obtained by a compare match value for a positive waveform (the GTCCRA register value) and specified dead time values (the GTDVU and GTDVD registers values) can automatically be set to the GTCCRB register.

The automatic dead time setting function can be used in sawtooth-wave one-shot pulse mode and all the triangle PWM modes.

Dead time can be separately set for the first half and second half of a waveform. Dead time for the changing point in the first half of a negative waveform is set in the GTDVU register and that in the second half is set in the GTDVD register. The same dead time can also be set for the first and second halves by setting the GTDTCR.TDFER bit to 1.

The GTDBU register can be used as a buffer register of the GTDVU register, and the GTDBD register can be used as a buffer register of the GTDVD register. Buffer transfer is performed at the end of the cycle (in sawtooth-wave mode: either of an overflow of the GTCNT counter (up-counting), an underflow (down-counting), or the GTCNT counter clearing; in triangle-wave mode: a trough).

The change point of the negative-phase waveform, which is automatically calculated, is obtained by reading the GTCCRB register. Writing to the GTCCRB register is prohibited when the automatic dead time setting function is used.

Do not set the dead-time that makes the change point of the waveform exceeding the count period. When any dead-time setting which would generate a dead-time error is made, adjust the change points of the positive- and negative-phase waveforms to generate waveforms with secured dead-time as shown in Table 24.8. The adjusted change point of the negative-phase waveform is automatically set in the GTCCRB register. An internal signal is used to judge the change point of the positive-phase waveform, thus the value of the GTCCRA register is not updated by the adjusted value.

If the order of the change point becomes inconsistent by adjustment of the waveform change point due to occurrence of dead time errors, or if the change point exceeds the count period even after the adjustment, the complementary relation between the positive- and negative-phases cannot be guaranteed.

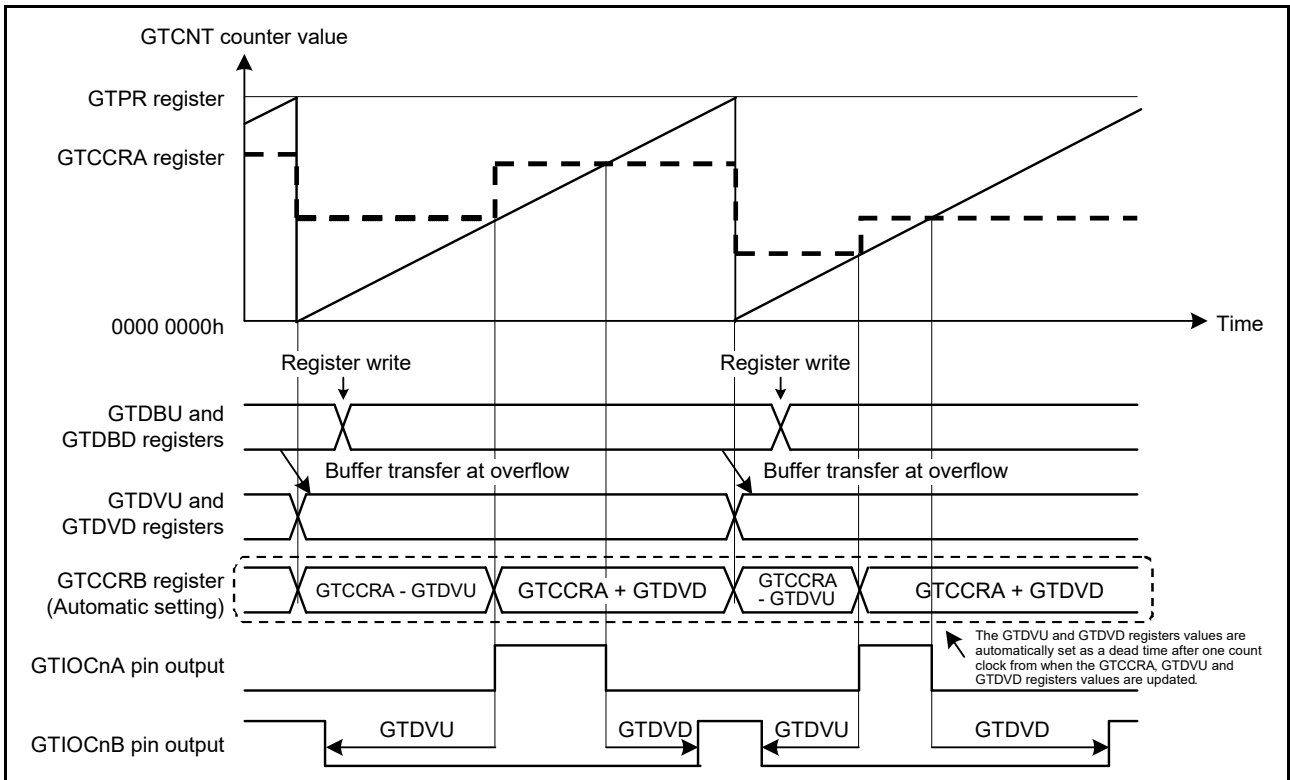

If dead-time exceeds the count period by setting 0000 0000h or a value greater than or equal to the setting value of the GTPR register is set in the GTCCRA register in triangle-wave PWM mode, output change is controlled by the output protection function (refer to section 24.8.4, Output Protection Function for GTIOCnm Pin Output (n = 0 to 9; m = A, B)). When GTCCRA register is greater than or equal to [GTPR register + GTDVm register], [GTPR register – 1] is set in the GTCCRB register as the upper limit. (m = U, D)

Automatic setting for a dead time value to the GTCCRB register is performed at the next count clock after the register value for calculating the automatic setting value is updated. In triangle-wave mode, it also can be done at the next count clock from the current crest.

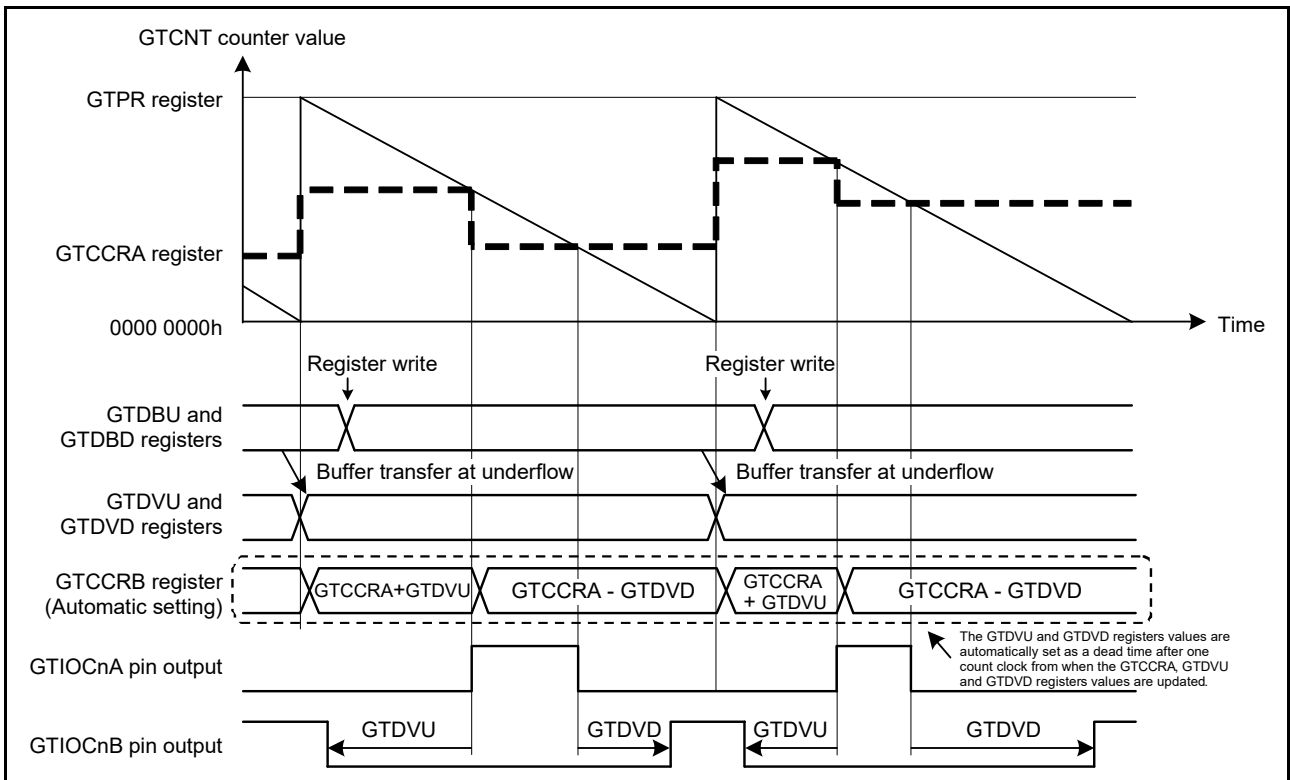

**Table 24.8 Adjustment of the Waveform Change Point When a Dead-Time Error Occurs**

| Mode                              | Count Direction | Period        | Condition for Dead-Time Error | Change Point of the Positive-Phase Waveform after Adjustment | Change Point of the Negative-Phase Waveform after Adjustment |
|-----------------------------------|-----------------|---------------|-------------------------------|--------------------------------------------------------------|--------------------------------------------------------------|
| Sawtooth-wave one-shot pulse mode | Up-counting     | First half    | $GTCCRA - GTDVU < 0$          | GTDVU                                                        | 0                                                            |
|                                   |                 | Second half   | $GTCCRA + GTDVD > GTPR$       | $GTPR - GTDVD$                                               | GTPR                                                         |
|                                   | Down-counting   | First half    | $GTCCRA + GTDVU > GTPR$       | $GTPR - GTDVU$                                               | GTPR                                                         |
|                                   |                 | Second half   | $GTCCRA - GTDVD < 0$          | GTDVD                                                        | 0                                                            |

### 24.3.5 Count Direction Changing Function

The count direction of the GTCNT counter can be changed by modifying the GTUDDTYC.UD bit.

In sawtooth-wave mode, if the UD bit is modified during count operation, the count direction is changed at an overflow (when modified during up-counting) or an underflow (when modified during down-counting). If the UD bit is modified while count operation is stopped and the GTUDDTYC.UDF bit is 0, the UD bit modification is not reflected at the start of counting and the count direction is changed at an overflow or an underflow. If the UDF bit is set to 1 while count operation is stopped, the UD bit value at that time is reflected at the start of counting.

In triangle-wave mode, changing the value of the GTUDDTYC.UD bit during counting does not switch the direction of counting. Likewise, changing the value of the GTUDDTYC.UD bit while the GTUDDTYC.UDF bit is 0 and counting is stopped does not actually update the value of the bit. If 1 is written to the GTUDDTYC.UDF bit while counting is stopped, the value of the GTUDDTYC.UD bit at that time is reflected from the time counting is started.

When counting direction is switched during count operation in sawtooth-wave mode, the value of the GTPR register after start of up-counting is reflected to the count period in up-counting operation, and the value of the GTPR register after the start of down-counting is reflected to the count period in down-counting operation.

Figure 24.53 shows an example of count direction changing function operation.

Figure 24.53 Example of Count Direction Changing Function Operation (during Buffer Operation)

### 24.3.6 Duty Cycle 0%/100% Output Function

Changing the value of the GTUDDTYC.OADTY[1:0] bits and GTUDDTYC.OBDTY[1:0] bits specifies the output duty setting on the GTIOCnA and GTIOCnB pins to 0% or 100%. (n = 0 to 9)

In sawtooth-wave mode, if the value of the OADTY[1:0] bits or OBDTY[1:0] bits is changed during the count operation, the output duty-cycle setting is reflected at an overflow (when changed during up-counting) or an underflow (when changed during down-counting). When the GTUDDTYC.OADTYF bit or GTUDDTYC.OBDTYF bit is 0 while count operation is stopped and the value of the OADTY[1:0] bits or OBDTY[1:0] bits is changed, the output duty-cycle setting changed at the start of counting is not reflected, but the output duty-cycle setting changed at an overflow or underflow is reflected. When the OADTYF bit or OBDTYF bit is 1 while count operation is stopped and the value of the OADTY[1:0] bits or OBDTY[1:0] bits is changed, the value of the OADTY[1:0] bits or OBDTY[1:0] bits at that time is reflected at the start of counting.

In triangle-wave mode, if the value of the OADTY[1:0] bits or OBDTY[1:0] bits is changed during the count operation, the output duty-cycle setting changed at an underflow is reflected.

When the OADTYF bit or OBDTYF bit is 0 while count operation is stopped and the value of the OADTY[1:0] bits or OBDTY[1:0] bits is changed, the output duty-cycle setting changed at the start of counting is not reflected, but the output duty-cycle setting changed at an underflow is reflected. When the OADTYF bit or OBDTYF bit is 1 while count operation is stopped and the value of the OADTY[1:0] bits or OBDTY[1:0] bits is changed, the value of the OADTY[1:0] bits or OBDTY[1:0] bits at that time is reflected at the start of counting.

During the operation under the settings of duty cycle for 0%/100%, compare match operation inside the GPTW continues to perform interrupt outputs and buffer operations.

When the output duty setting is changed from 0% or 100% due to a compare match, the GTIOR.GTIOA[3:2] bits and the OADTYR bits determine the level output on the GTIOCnA pin and GTIOR.GTIOB[3:2] bits and OBDTYR bits determine the level output on the GTIOCnB pin at the end of the cycle. When the GTIOA[3:2], GTIOB[3:2] bits are set as 01b, output is driven Low at the end of the cycle, and when set as 10b, output is driven High at the end of the cycle. The output is retained at the end of the cycles when the GTIOA[3:2] or GTIOB[3:2] bits are 00b, and toggled at the end of the cycles when the GTIOA[3:2] or GTIOB[3:2] bits are 11b. A value to be output is selectable in the OADTYR or OBDTYR bit when the corresponding GTIOA[3:2] or GTIOB[3:2] bits are either 00b or 11b. Table 24.9 lists the output values at the end of the cycle when the output setting is changed from duty 0% or 100% to compare match.

**Table 24.9 Output Value after Release of Duty 0%/100%**

| GTIOR.GTIOm[3:2]                              | Value at Compare Match Output at the End of the Cycle in the Case of Masking by a Duty Cycle 0% or 100% | The GTUDDTYC.OmDTYR Bit at Duty 0% Setting |   | The GTUDDTYC.OmDTYR Bit at Duty 100% Setting |   |
|-----------------------------------------------|---------------------------------------------------------------------------------------------------------|--------------------------------------------|---|----------------------------------------------|---|
|                                               |                                                                                                         | 0                                          | 1 | 0                                            | 1 |
| 00b (Output retained at the end of the cycle) | 0                                                                                                       | 0                                          | 0 | 1                                            | 0 |
|                                               | 1                                                                                                       | 0                                          | 1 | 1                                            | 1 |
| 01b (Low output at the end of the cycle)      | —                                                                                                       | 0                                          | 0 | 0                                            | 0 |
| 10b (High output at the end of the cycle)     | —                                                                                                       | 1                                          | 1 | 1                                            | 1 |
| 11b (Toggle output at the end of the cycle)   | 0                                                                                                       | 1                                          | 1 | 0                                            | 1 |
|                                               | 1                                                                                                       | 1                                          | 0 | 0                                            | 0 |

m = A, B

Figure 24.54 shows an example of operation of the output of the duty cycle 0% or 100% (n = 0 to 9).

Figure 24.54 Example of Operation of Output of Duty Cycle 0% or 100% (n = 0 to 9)

### 24.3.7 Hardware Count Start/Count Stop and Clear Operation

The GTCNT counter can be started, stopped, or cleared by hardware sources in this MCU. There are 3 types of hardware sources, including external trigger input, ELC event input, and GTIOCnm pin input (n = 0 to 9; m = A, B)

#### 24.3.7.1 Hardware Start Operation

The GTCNT counter can be started by a hardware source. Select a hardware source to start counting using the GTSSR register, and enable to start counting.

Figure 24.55 shows an example of count start operation by a hardware source. Figure 24.56 shows the setting example.

Figure 24.55 Example of Count Start Operation by Hardware Source (At starting by ELCA event)

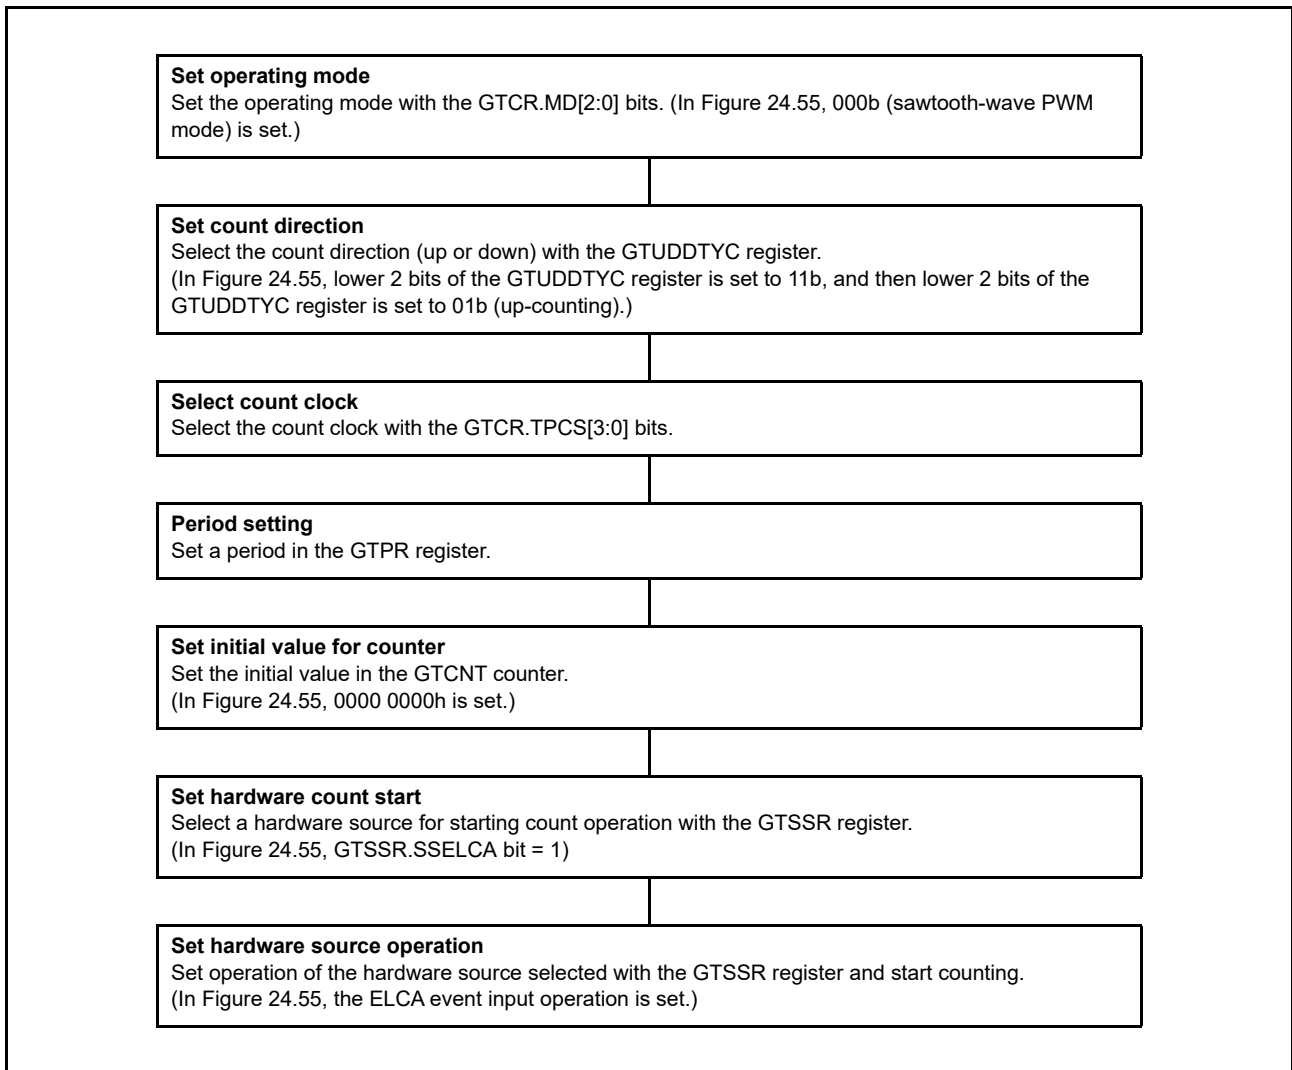

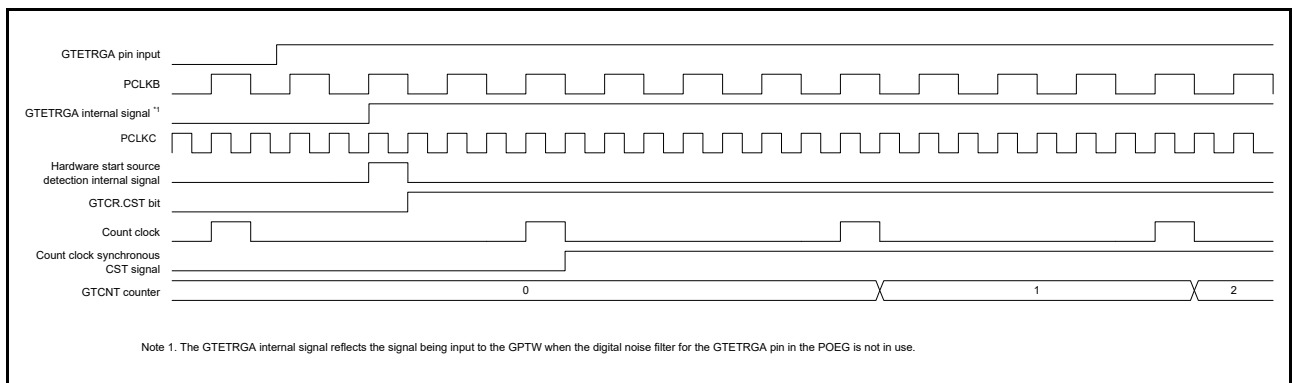

Figure 24.56 Example for Setting Count Start Operation by Hardware Source

Figure 24.57 shows an example of timing of operations to start counting in response to a rising edge of the input on the GTETRGA pin.

Note 1. The GTETRGA internal signal reflects the signal being input to the GPTW when the digital noise filter for the GTETRGA pin in the POEG is not in use.

Figure 24.57 Example of Timing of Operations to Start Counting in Response to a Rising Edge of the Input on the GTETRGA Pin

Figure 24.58 shows an example of timing of operations to start counting in response to a rising edge of the input on the GTIOCnA pin.

**Figure 24.58 Example of Timing of Operations to Start Counting in Response to a Rising Edge of the Input on the GTIOCnA Pin**

Figure 24.59 shows an example of timing of operations to start counting in response to event input from the ELCA. This is an example of operations to start counting by the GPTW1.GTCNT counter in response to a signal. An event signal is output to the ELC after matches in comparison with the GPTW0.GTCCRA register. This is selected as a trigger for output to the GPTW by the ELC as event source A. The GPTW0 compare match A signal is synchronized with PCLKC. The ELC receives the signal in synchronization with PCLKB, and outputs the GPTW event source A signal after 1 cycle of PCLKB has elapsed.

**Figure 24.59 Example of Timing of Operations to Start Counting in Response to Event Input from the ELCA**

### 24.3.7.2 Hardware Stop Operation

The GTCNT counter can be stopped by a hardware source. Select a hardware source to stop counting with the GTPSR register, and enable to stop counting.

Figure 24.60 shows an example of count stop operation by a hardware source. Figure 24.61 shows the setting example. In this example, the count operation is stopped by the ELCA event input, and is restarted by the ELCB event input.

**Figure 24.60 Example of Count Stop Operation by Hardware Source (Started by Software, Stopped at ELCA event input, and Restarted at ELCB event input)**

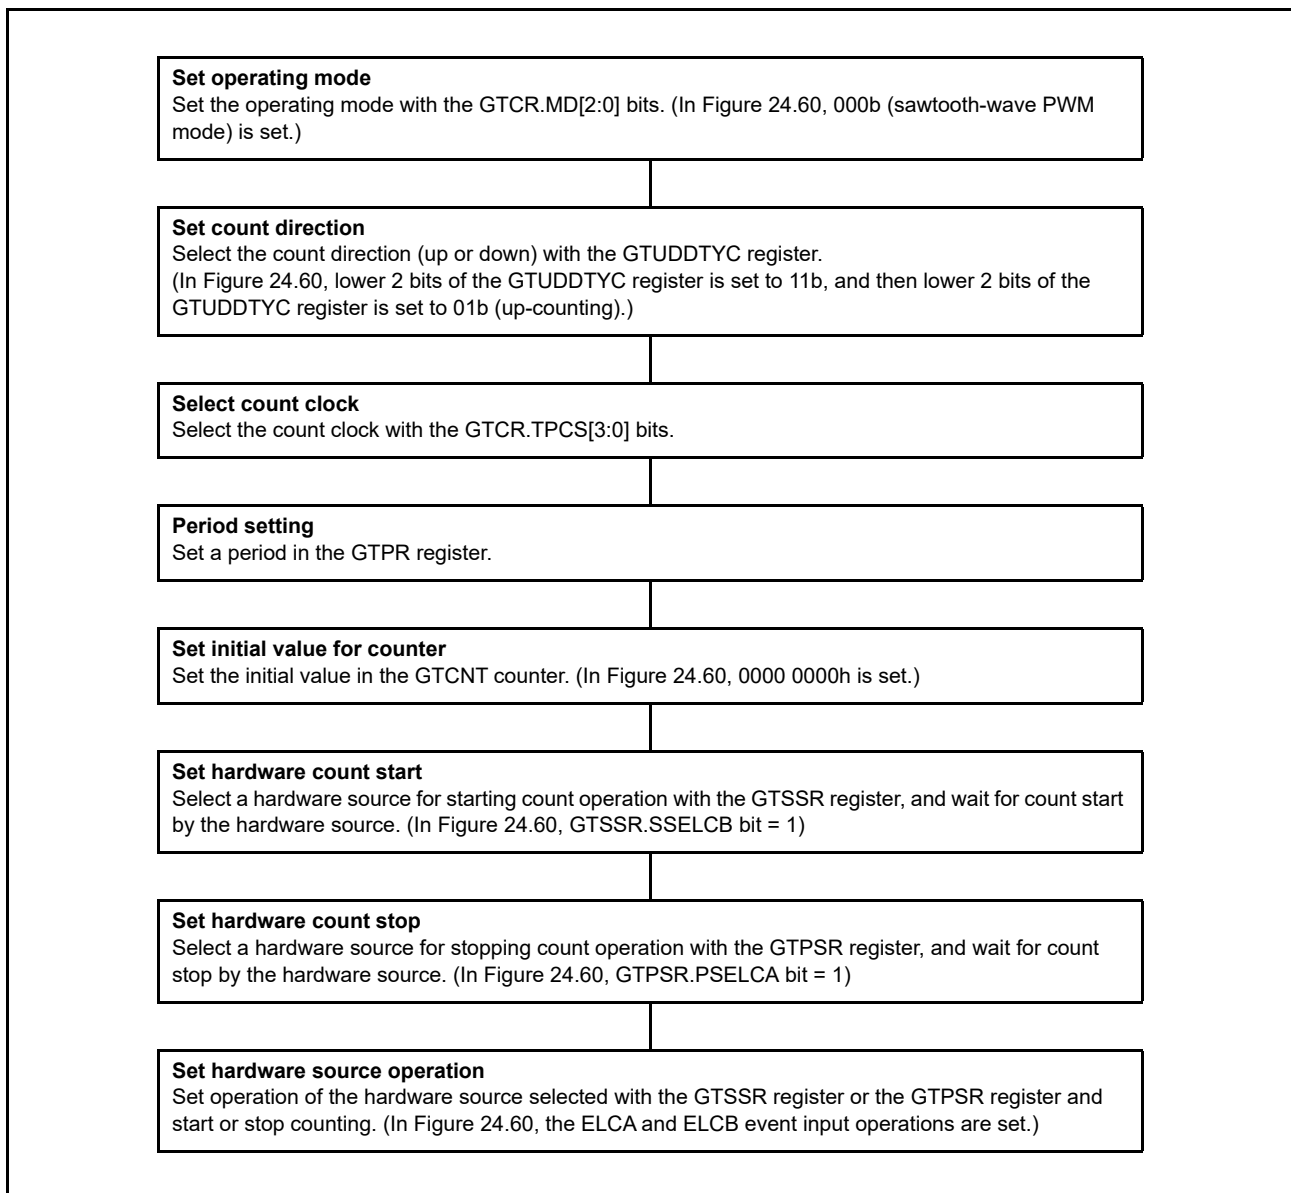

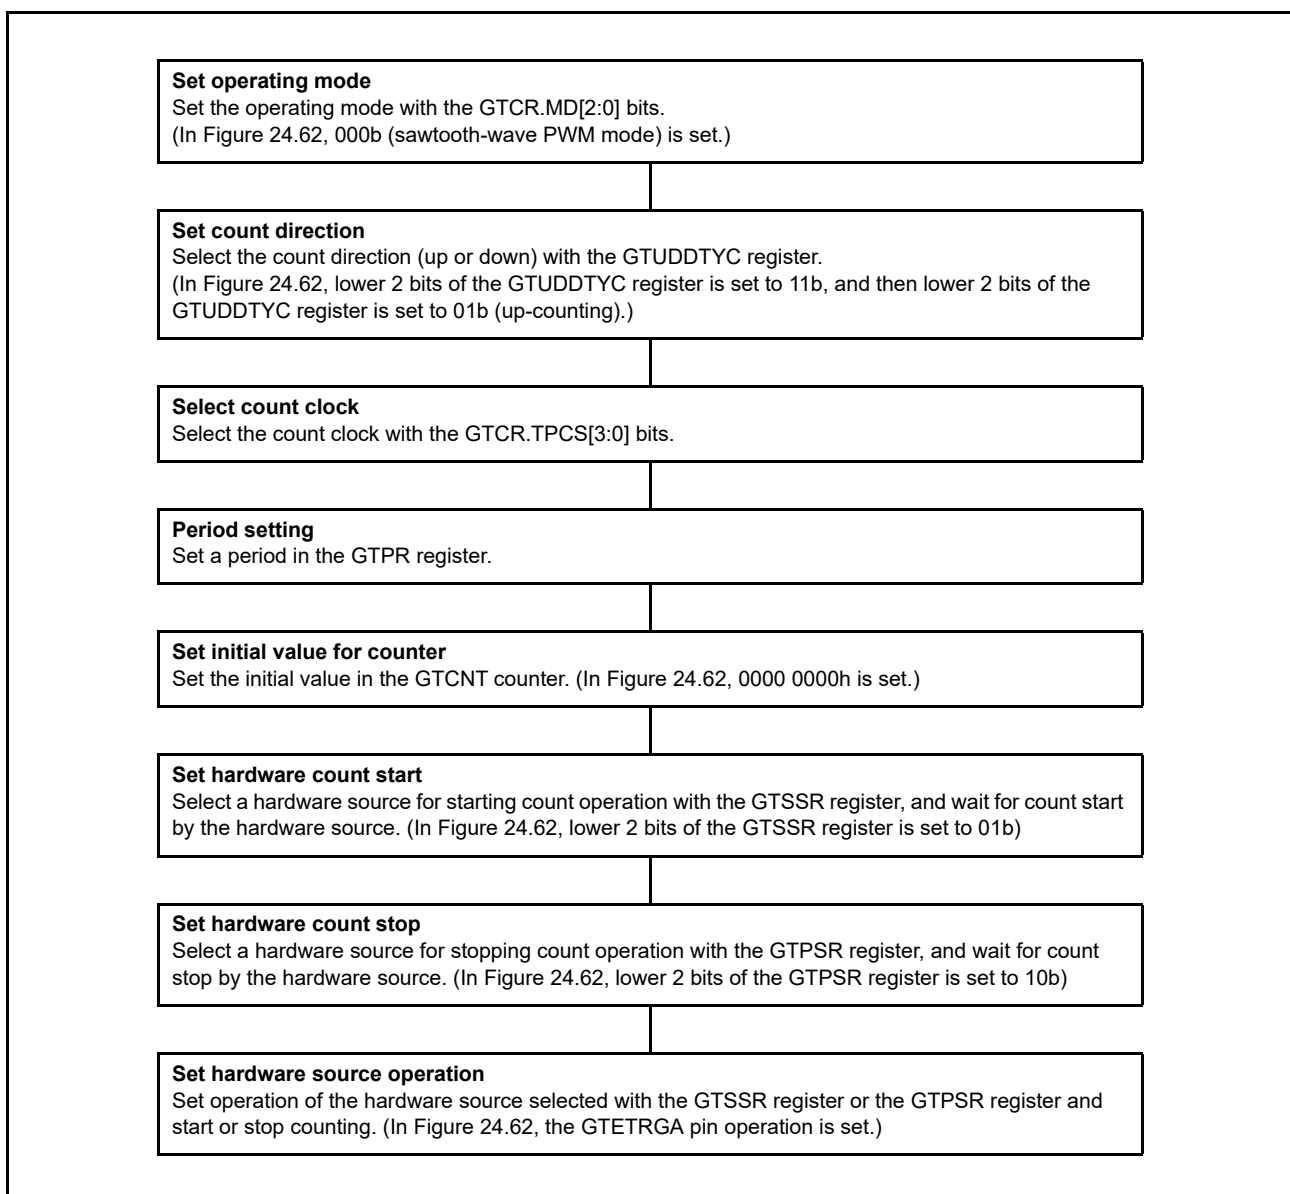

Figure 24.61 Example for Setting Count Stop Operation by Hardware Source

Figure 24.62 shows an example of count start/stop operation by a hardware source. Figure 24.63 shows the setting example. In this example, the counter operates during the high-level periods of the external trigger input GTETRGA pin.

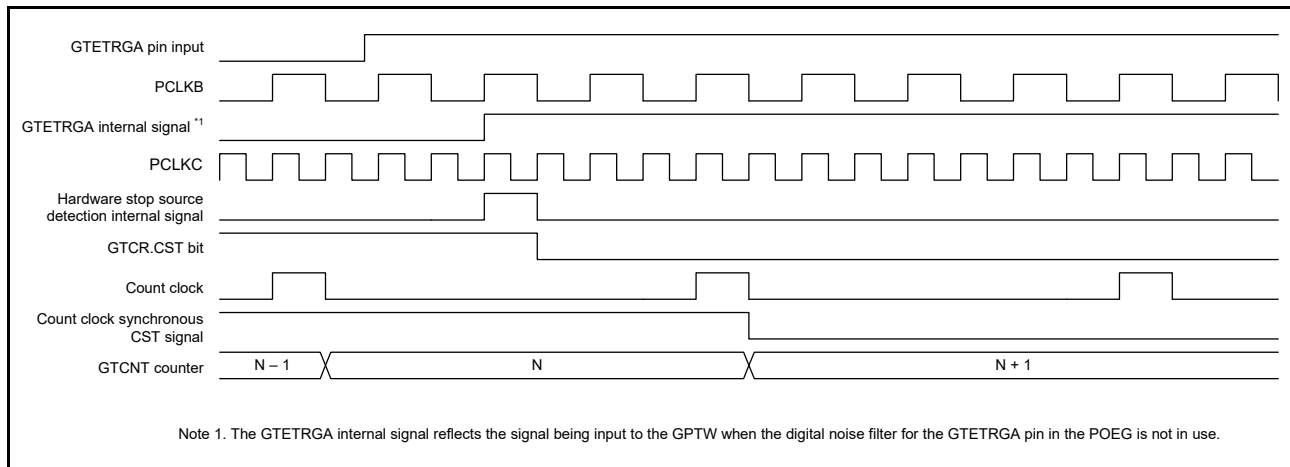

**Figure 24.62 Example of Count Start/Stop Operation by Hardware Source (Started at Rising Edge of GTETRGA Pin Input, Stopped at Falling Edge of GTETRGA Pin Input)**

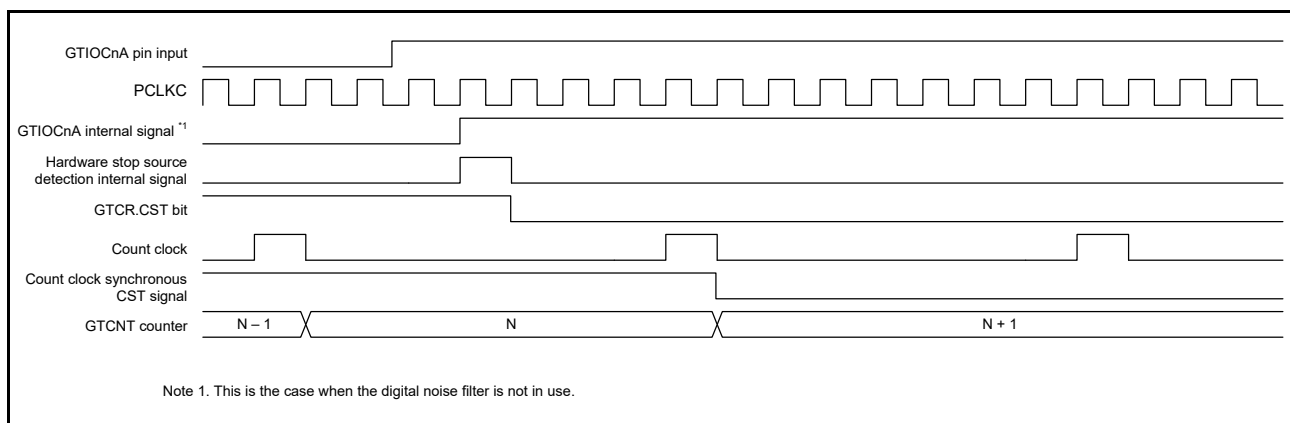

**Figure 24.63 Example for Setting Count Start/Stop Operation by Hardware Source**

Figure 24.64 shows an example of timing of operations to stop counting in response to a rising edge of the input on the GTETRGA pin.

**Figure 24.64 Example of Timing of Operations to Stop Counting in Response to a Rising Edge of the Input on the GTETRGA Pin**

Figure 24.65 shows an example of timing of operations to stop counting in response to a rising edge of the input on the GTIOCnA pin.

**Figure 24.65 Example of Timing of Operations to Stop Counting in Response to a Rising Edge of the Input on the GTIOCnA Pin**

Figure 24.66 shows an example of timing of operations to stop counting in response to event input from the ELCA. This is an example of operations to stop counting by the GPTW1.GTCNT counter in response to a signal. An event signal is output to the ELC after matches in comparison with the GPTW0.GTCCRA register. This is selected as a trigger for output to the GPTW by the ELC as event source A. The GPTW0 compare match A signal is synchronized with PCLKC. The ELC receives the signal in synchronization with PCLKB, and outputs the GPTW event source A signal after 1 cycle of PCLKB has elapsed.

**Figure 24.66** Example of Timing of Operations to Stop Counting in Response to Event Input from the ELCA

### 24.3.7.3 Hardware Clear Operation

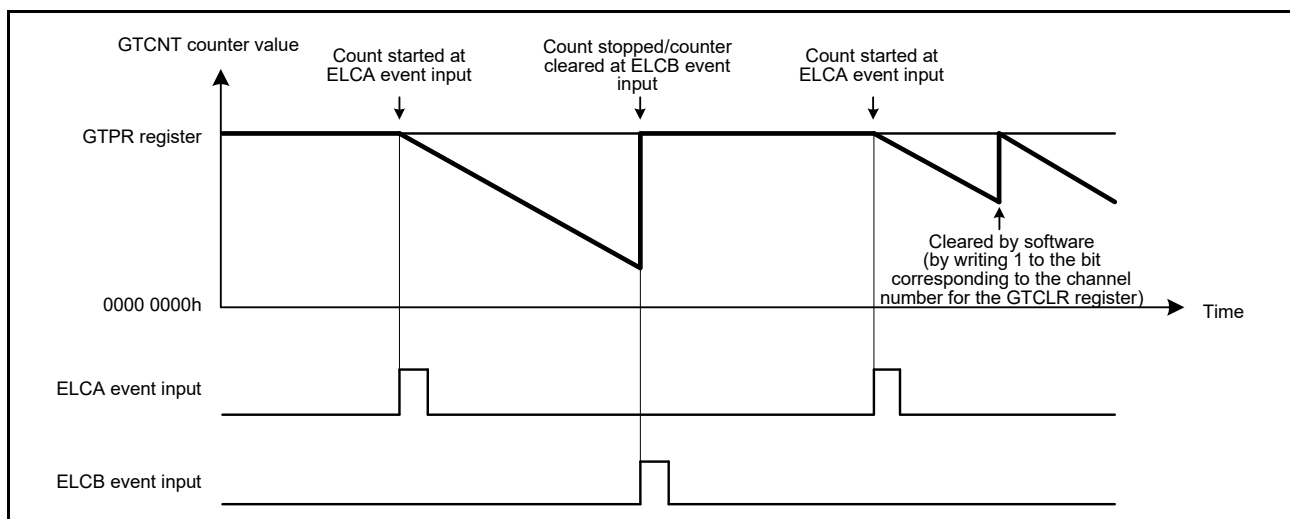

The GTCNT counter can be cleared by a hardware source. Select a hardware source to clear the counter with the GTCSR register, and enable clearing the counter.

Note that the GTCIV/GTCIU interrupt (overflow/underflow interrupt) is not generated when the GTCNT counter is cleared by a hardware source or by software.

Figure 24.67 and Figure 24.68 show examples of the GTCNT counter clearing operation by a hardware source. Figure 24.69 shows the setting example. In this example, the GTCNT counter is started at the ELCA event input, and is stopped/cleared at the ELCB event input.

**Figure 24.67** Examples of Counter Clearing Operation by Hardware Source (Sawtooth-Wave Up-Counting, Started at ELCA event input, and Count Stopped/Counter Cleared at ELCB event input)

**Figure 24.68** Examples of Counter Clearing Operation by Hardware Source (Sawtooth-Wave Down-Counting, Started at ELCA event input, and Count Stopped/Counter Cleared at ELCB event input)

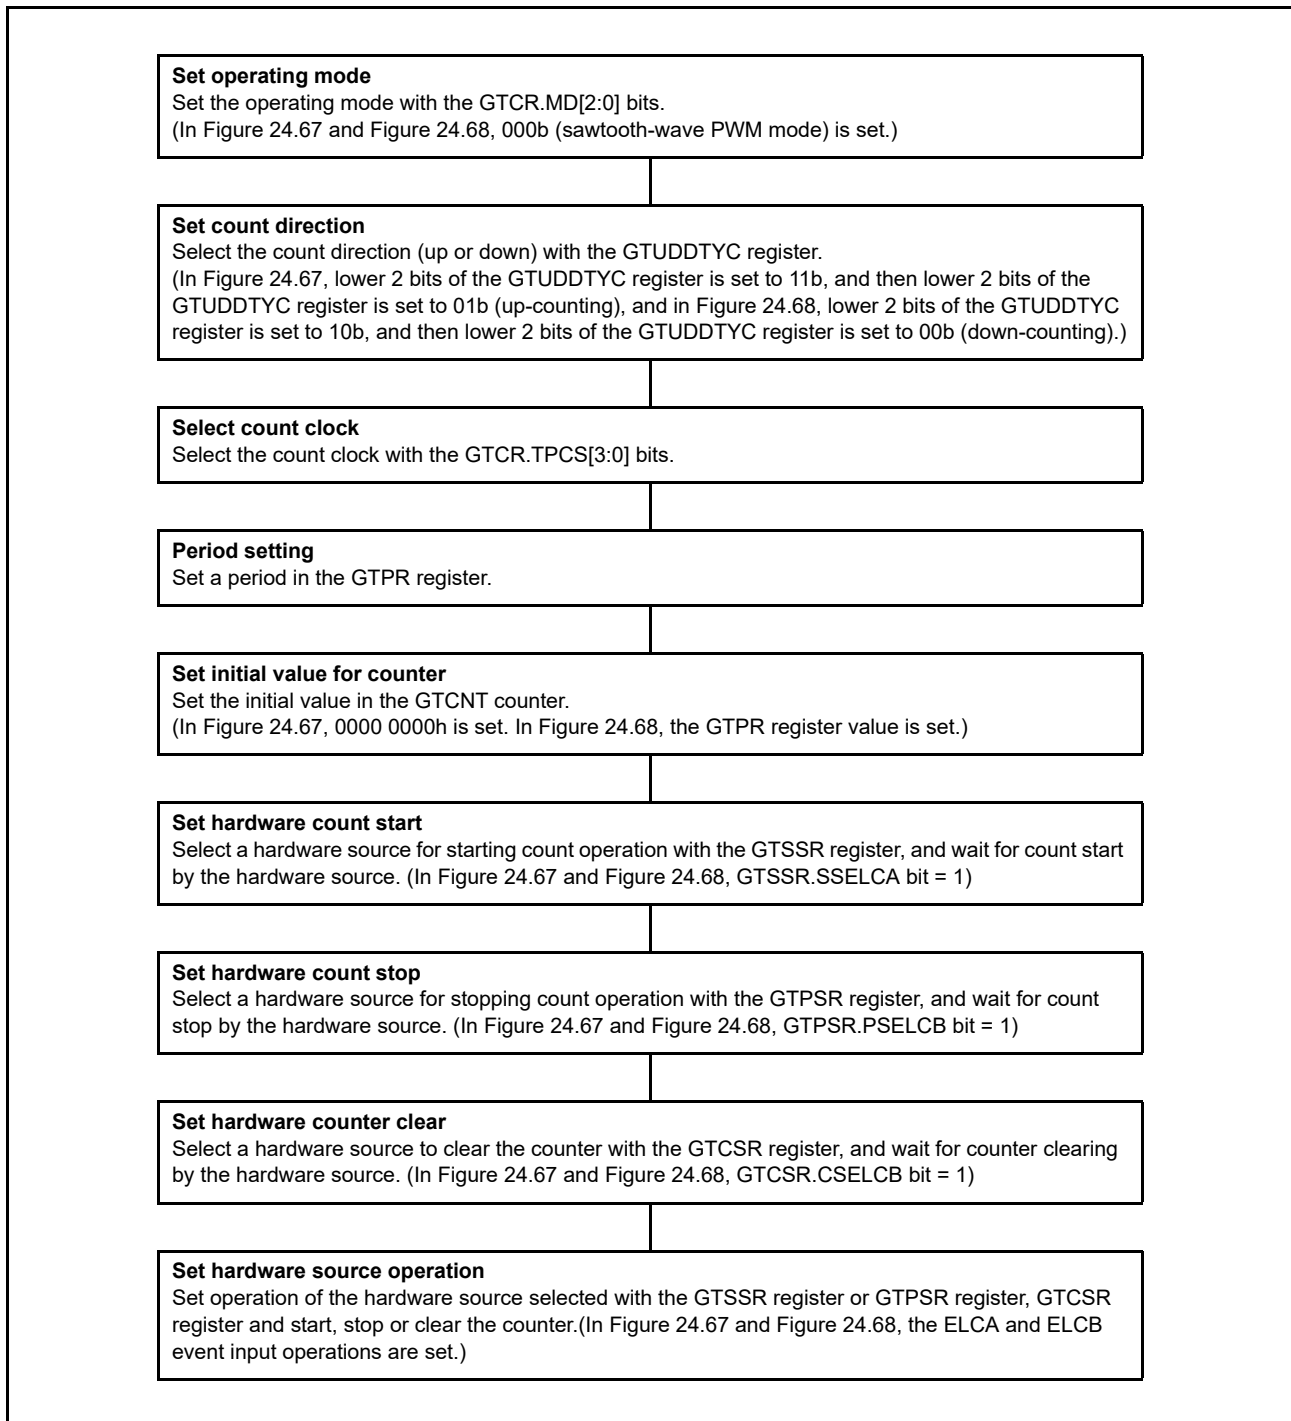

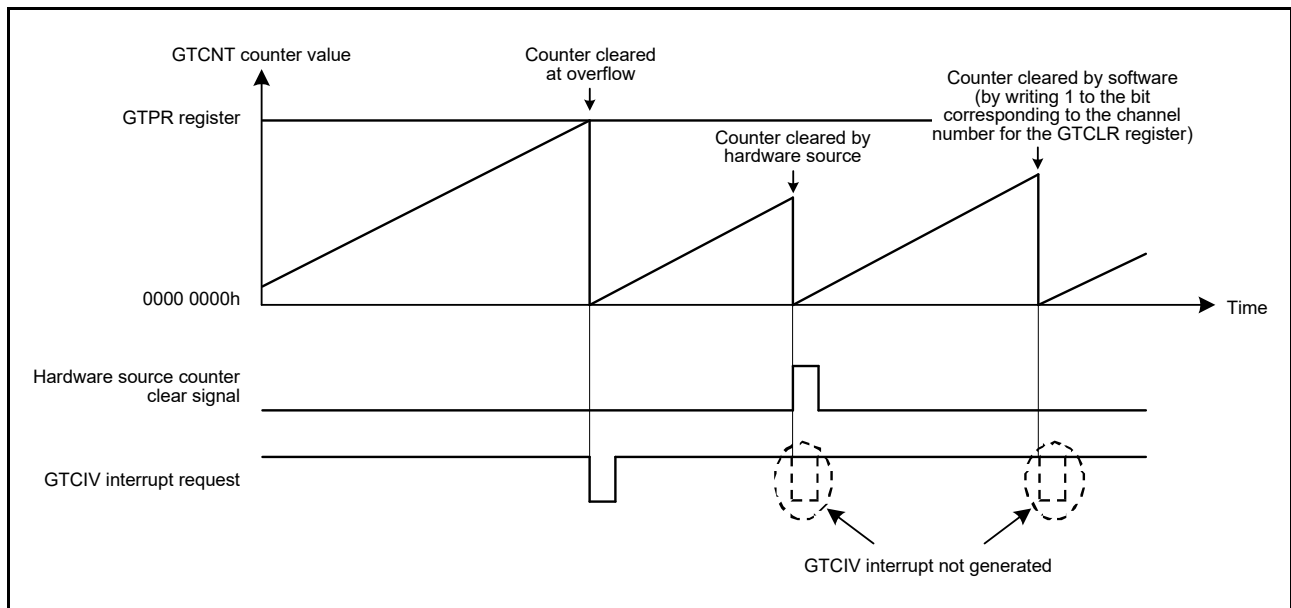

Figure 24.69 Example for Setting Counter Clearing Operation by Hardware Source

The GTCIV/GTCIU interrupt (overflow/underflow interrupt) does not occur when the counter is cleared by a hardware source. In the same way, the GTCIV/GTCIU interrupt does not occur when the counter is cleared by software. Figure 24.70 shows the relationship between counter clearing by a hardware source and the GTCIV interrupt.

**Figure 24.70 Relationship between Counter Clearing by Hardware Source and GTCIV Interrupt**

Figure 24.71 shows an example of the timing of operations to clear the counter in response to a rising edge of the input on the GTETRGA pin when a clock signal produced by frequency-dividing the PCLKC signal is used as the counter clock for the GTCNT counter.

The GTCNT counter is cleared when counting is in progress after the GPTW has detected the internal clearing signal.

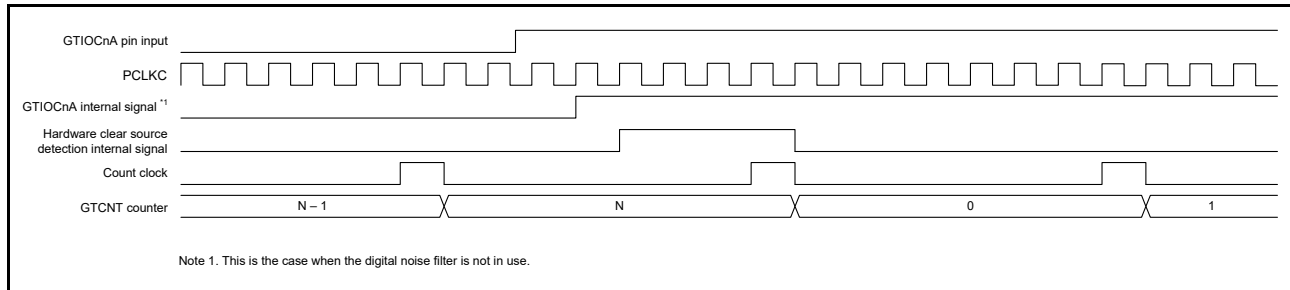

Note 1. The GTETRGA internal signal reflects the signal being input to the GPTW when the digital noise filter for the GTETRGA pin in the POEG is not in use.

**Figure 24.71 Example of the Timing of Operations for Counter Clearing in Response to a Rising Edge of the Input on the GTETRGA Pin (During the Counting of Cycles of Clock Signal Produced by Dividing the PCLKC Frequency)**

Figure 24.72 shows an example of the timing of operations to clear the counter in response to a rising edge of the input on the GTIOCnA pin when a clock signal produced by frequency-dividing the PCLKC signal is used as the counter clock for the GTCNT counter.

The GTCNT counter is cleared when counting is in progress after the GPTW has detected the internal clearing signal.

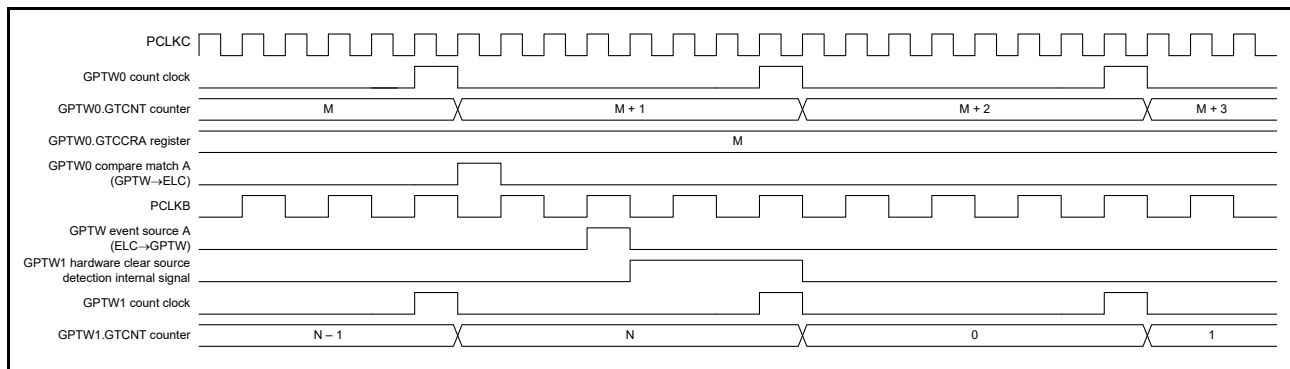

**Figure 24.72 Example of the Timing of Operations for Counter Clearing in Response to a Rising Edge of the Input on the GTIOCnA Pin (During the Counting of Cycles of Clock Signal Produced by Dividing the PCLKC Frequency)**

Figure 24.73 shows an example of the timing of operations to clear the counter in response to event input from the ELCA when a clock signal produced by frequency-dividing the PCLKC signal is used as the counter clock for the GTCNT counter.

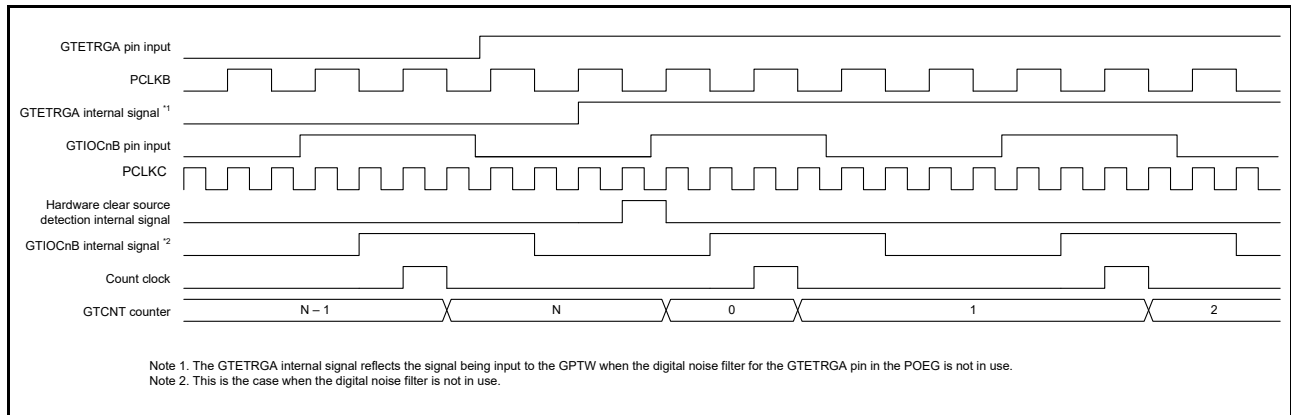

This is an example of operations to clear the GPTW1.GTCNT counter in response to a signal. An event signal is output to the ELC after matches in comparison with the GPTW0.GTCCRA register. This is selected as a trigger for output to the GPTW by the ELC as event source A.

The GPTW0 compare match A signal is synchronized with PCLKC. The ELC receives the signal in synchronization with PCLKB, and outputs the GPTW event source A signal after 1 cycle of PCLKB has elapsed. The GTCNT counter is cleared when counting is in progress after the GPTW has detected the internal clearing signal.

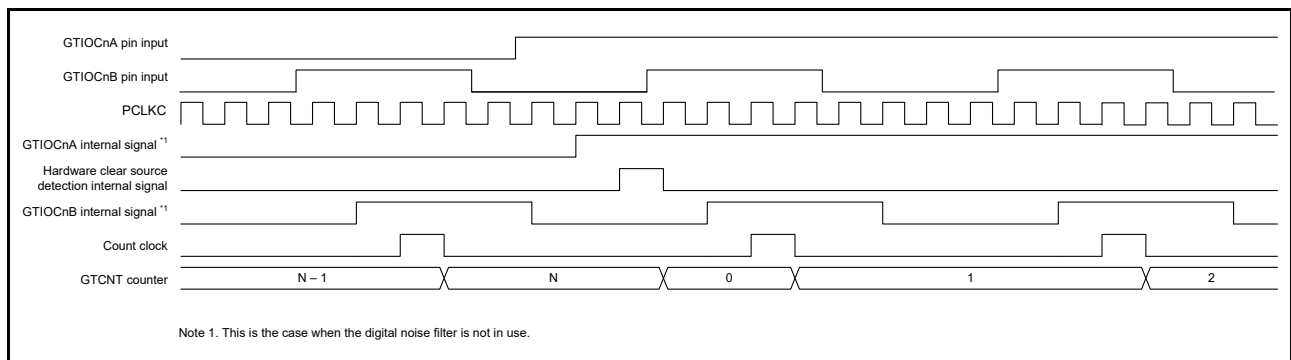

**Figure 24.73 Example of the Timing of Operations for Counter Clearing in Response to Event Input from the ELCA (During the Counting of Cycles of Clock Signal Produced by Dividing the PCLKC Frequency)**

Figure 24.74 shows an example of the timing of operations to clear the counter in response to a rising edge of the input on the GTETRGA pin input when counting is triggered by a hardware source. The GTCNT counter is cleared in synchronization with PCLKC after the GPTW has detected the internal clearing signal.

**Figure 24.74 Example of the Timing of Operations for Counter Clearing in Response to a Rising Edge of the Input on the GTETRGA Pin (During Counting Triggered by Hardware Source)**

Figure 24.75 shows an example of the timing of operations to clear the counter in response to a rising edge of the input on the GTIOCnA pin input when counting is triggered by a hardware source. The GTCNT counter is cleared in synchronization with PCLKC after the GPTW has detected the internal clearing signal.

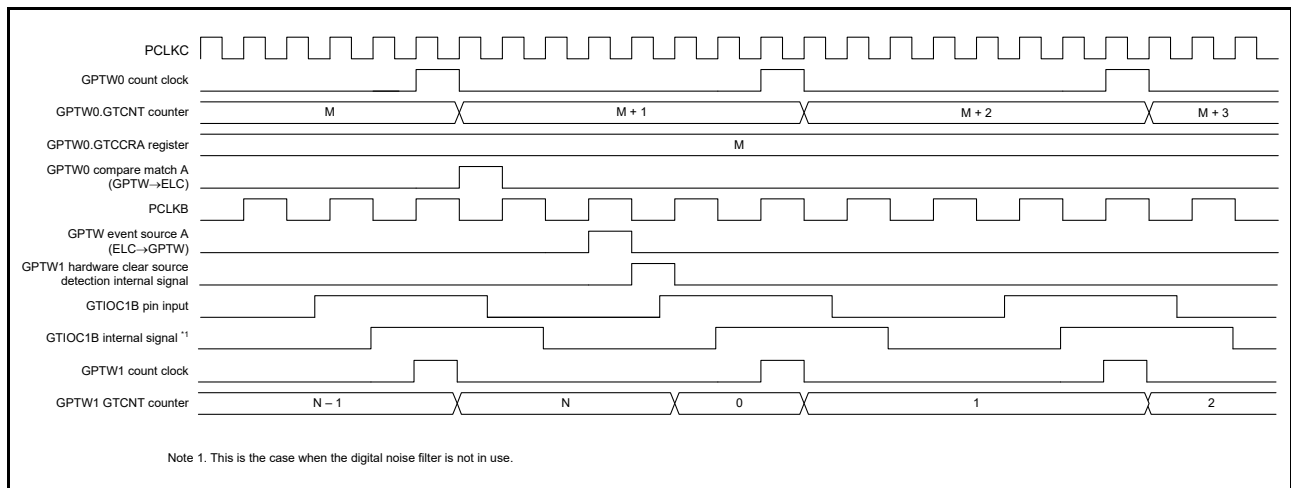

**Figure 24.75 Example of the Timing of Operations for Counter Clearing in Response to a Rising Edge of the Input on the GTIOCnA Pin (During Counting Triggered by Hardware Source)**

Figure 24.76 shows an example of the timing of operations for clearing the counter in response to the input of an event signal from the ELCA when counting is triggered by a hardware source.

This is an example of operations to clear the GPTW1.GTCNT counter in response to a signal. An event signal is output to the ELC after matches in comparison with the GPTW0.GTCCRA register. This is selected as a trigger for output to the GPTW by the ELC as event source A.

The GPTW0 compare match A signal is synchronized with PCLKC. The ELC receives the signal in synchronization with PCLKB, and outputs the GPTW event source A signal after 1 cycle of PCLKB has elapsed. The GTCNT counter is cleared in synchronization with PCLKC after the GPTW has detected the internal clearing signal.

**Figure 24.76 Example of the Timing of Operations for Counter Clearing in Response to Event Input from the ELCA (During Counting Triggered by Hardware Source)**

### 24.3.8 Synchronous Operation

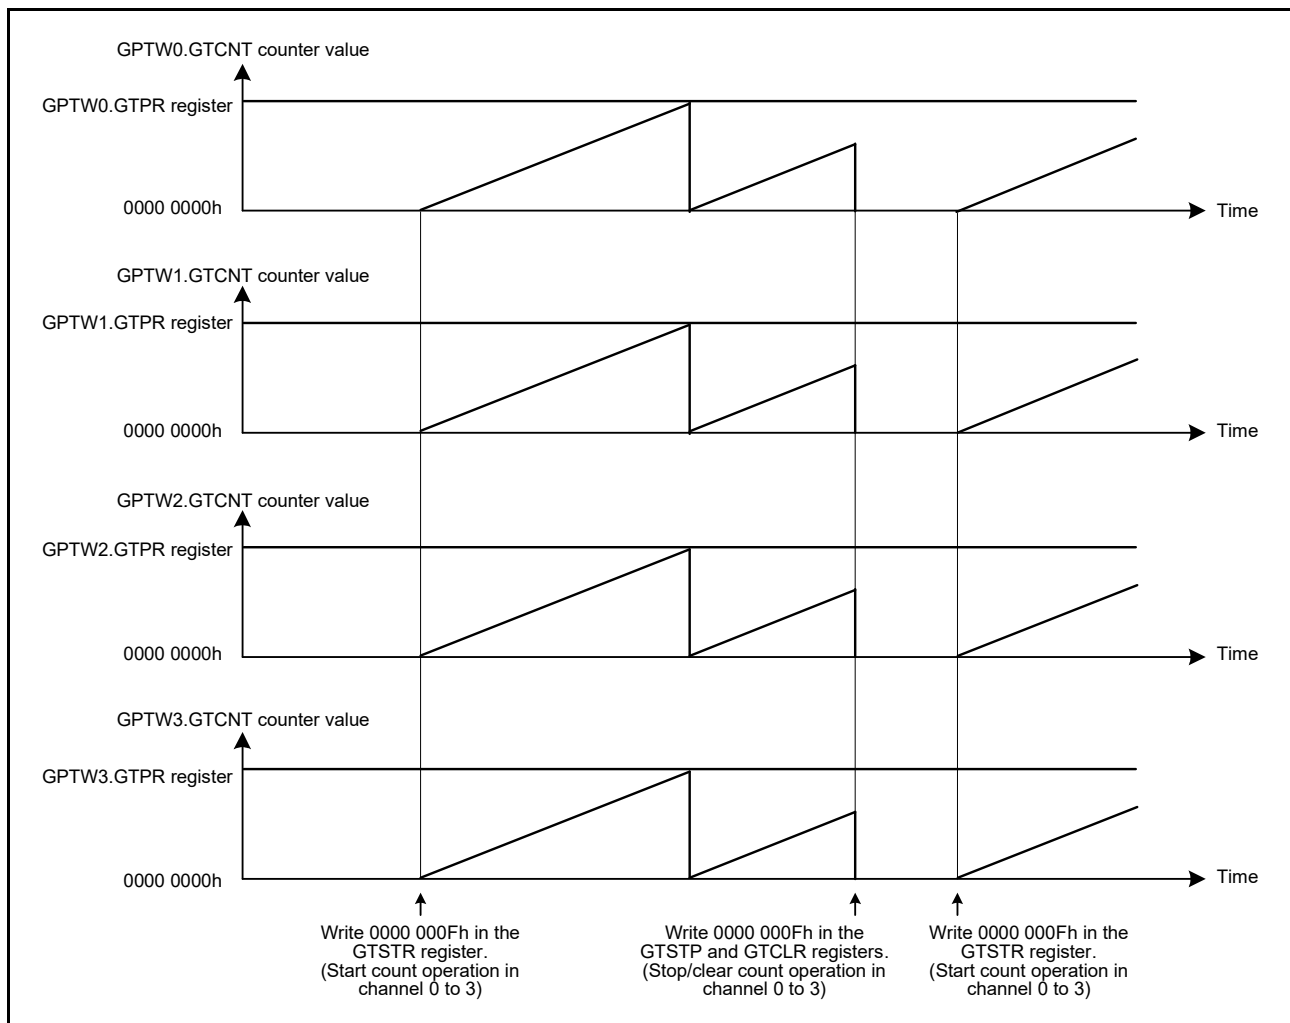

Synchronous operation on channels (synchronous start/stop/clear operation) can be performed.

#### 24.3.8.1 Synchronous Operation by Software

The count operations for respective channels can be started, stopped and cleared simultaneously by setting multiple bits of the GTSTR, GTSTP, and GTCLR registers to 1 at the same time.

Count start with phase differences among channels is possible firstly by setting the GTCNT counter value before counting starts, and then, by setting simultaneously multiple bits in the GTSTR register to 1.

The Figure 24.77 shows an example of simultaneous start/stop/clearing of four channels by software, and Figure 24.78 shows an example of phase shift start among four channels by software.

**Figure 24.77 Example of Simultaneous Start/Stop/Clearing Operation by Software (with the Same Count Period (GTPR Register Value))**

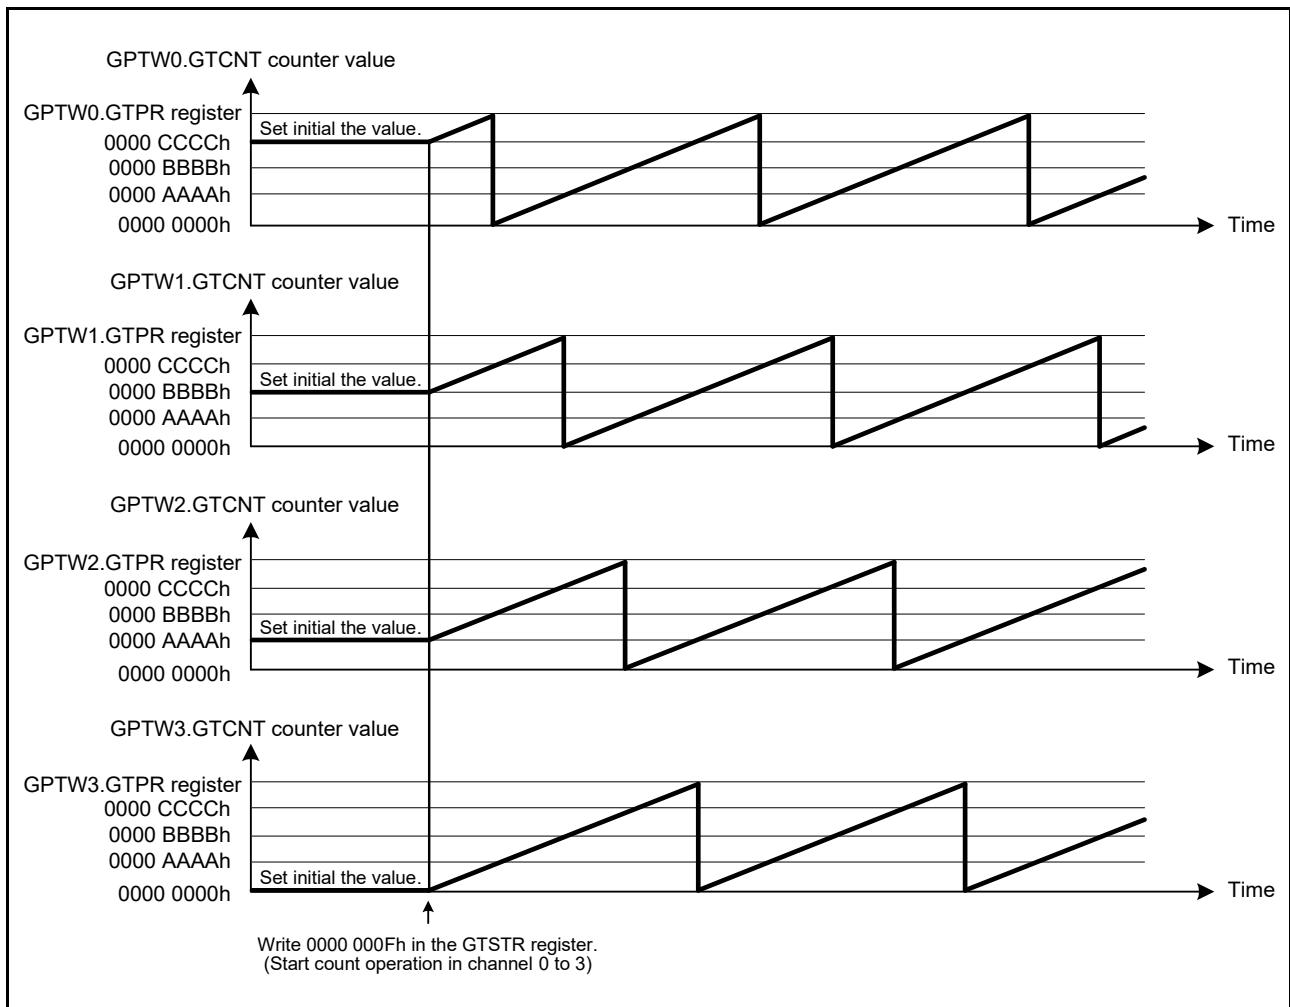

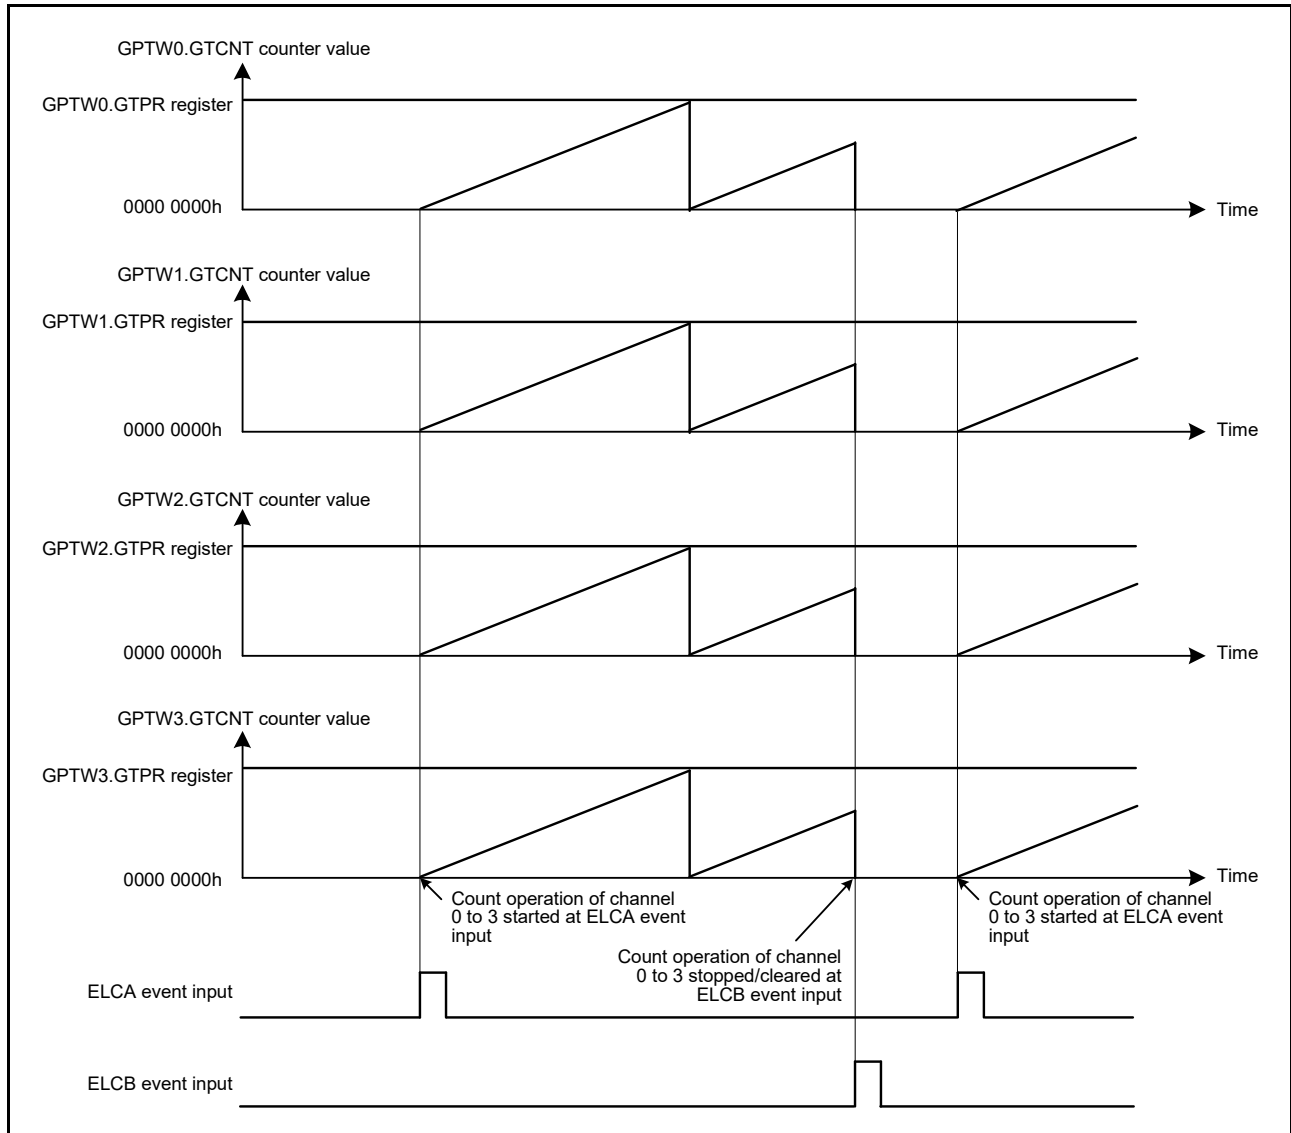

Figure 24.78 Example of Software Phase Shift Start (with Same Count Period (GTPR Register Value))

### 24.3.8.2 Synchronous Operation by Hardware Source

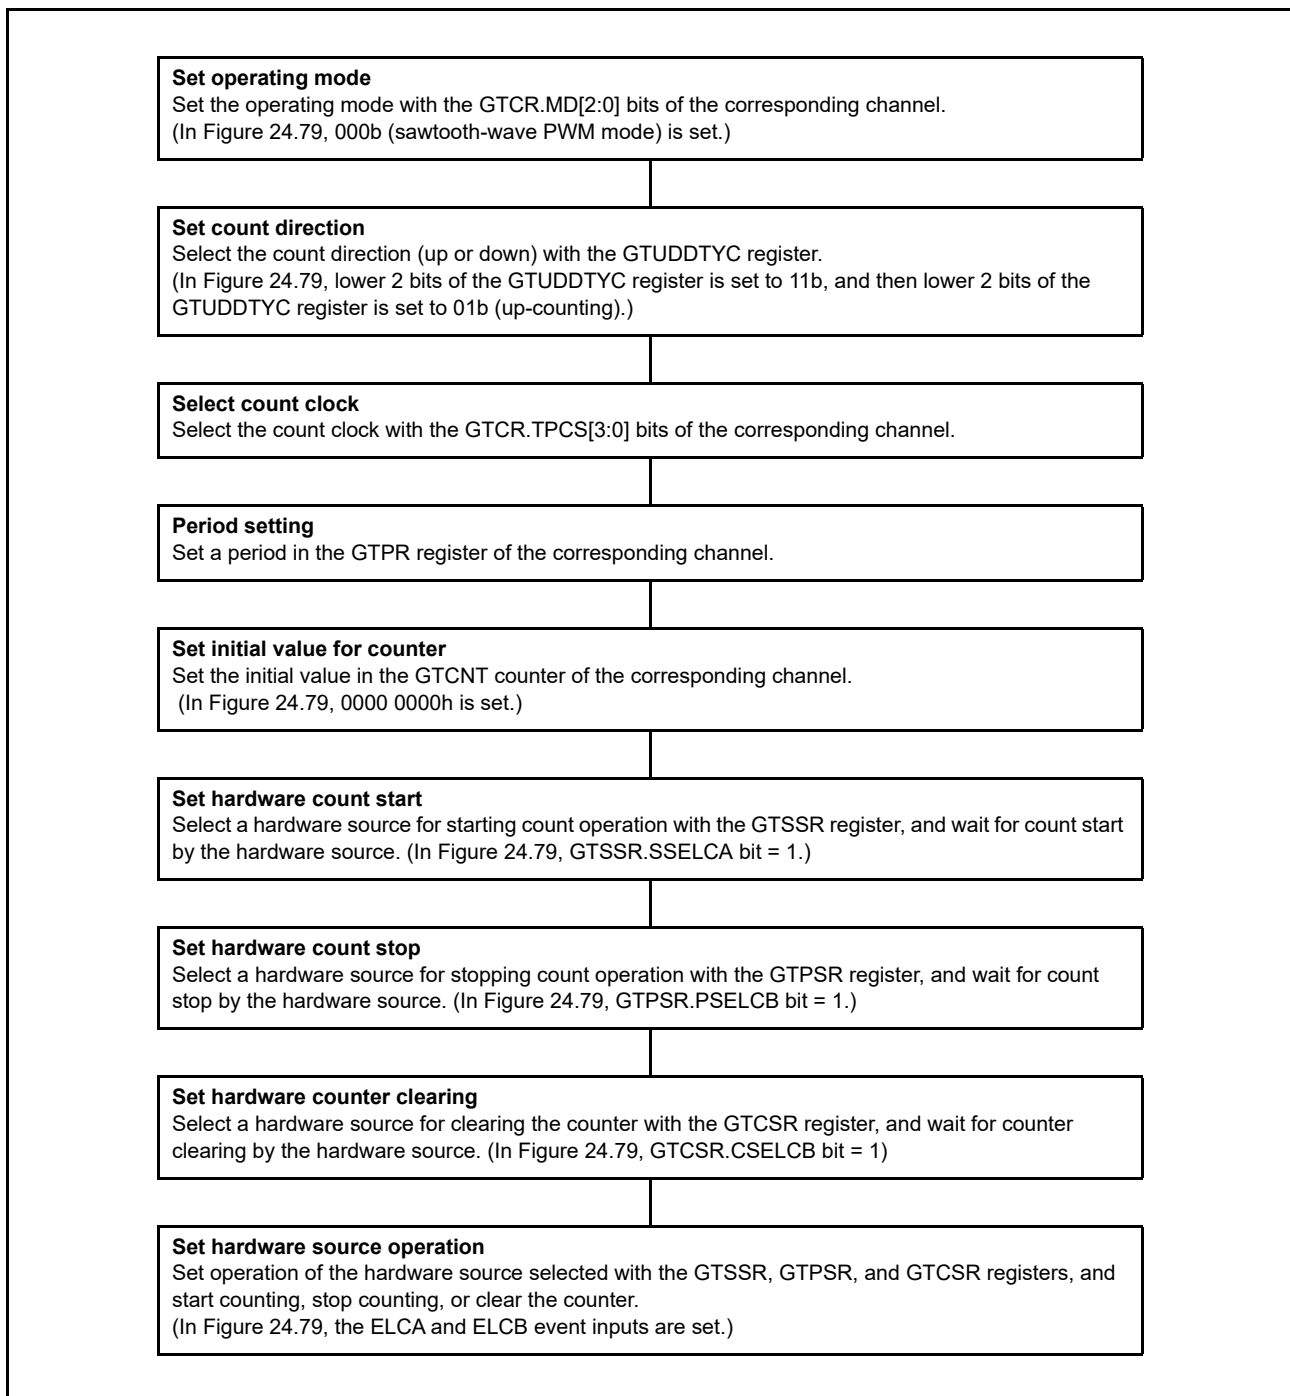

The count operations for respective channels can be started/stopped/cleared simultaneously by following hardware sources: external trigger input, and ELC event input.

Synchronous operation by the GTIOCnA and GTIOCnB pin inputs (n = 0 to 9) can be performed by setting the ELC event by input capture as a hardware source.

Figure 24.79 shows an example of simultaneous start/stop/clearing operation of four channels by hardware source.

**Figure 24.79 Example of Simultaneous Start/Stop/Clearing Operation by Hardware Source (with Same Count Period (GTPR Register Value))**

**Figure 24.80 Example for Setting Simultaneous Start by Hardware Source**

### 24.3.9 PWM Output Operation Examples

#### (1) Synchronous PWM Output

The GPTW can output two phases of linked PWM waveforms for one channel, or 20 phases of linked PWM waveforms for a maximum of 10 channels by synchronizing operation of the channels.

Figure 24.81 shows an example in which four channels perform synchronous operation in sawtooth-wave PWM mode and eight phases of PWM waveforms are output. The GTIOCnA pin ( $n = 0$  to 3) is set so that it will output low as the initial output, high at a GTCCRA register compare match, and low at the end of the cycle. The GTIOCnB pin is set so that it will output low as the initial output, high at a GTCCRB register compare match, and low at the end of the cycle.

Figure 24.81 Example of Synchronous PWM Output

(2) Three-Phase Sawtooth-Wave Complementary PWM Output

Figure 24.82 shows an example in which three channels perform synchronous operation in sawtooth-wave PWM mode and three-phase complementary PWM waveforms are output. The GTIOCnA pin (n = 0 to 2) is set so that it will output low as the initial output, high at a GTCCRA register compare match, and low at the end of the cycle. The GTIOCnB pin is set so that it will output high as the initial output, low at a GTCCRB register compare match, and high at the end of the cycle.

Figure 24.82 Example of Three-Phase Sawtooth-Wave Complementary PWM Output

(3) Three-Phase Sawtooth-Wave Complementary PWM Output with Automatic Dead Time Setting

Figure 24.83 shows an example in which three channels perform synchronous operation in sawtooth-wave one-shot pulse mode with automatic dead time setting and three-phase complementary PWM waveforms are output. The GTIOCnA pin (n = 0 to 2) is set so that it will output low as the initial output, toggle the output at a GTCCRA register compare match, and retain the output at the end of the cycle. The GTIOCnB pin is set so that it will output high as the initial output, toggle the output at a GTCCRB register compare match, and retain the output at the end of the cycle.

Figure 24.83 Example of Three-Phase Sawtooth-Wave Complementary PWM Output with Automatic Dead Time Setting

(4) Three-Phase Triangle-Wave Complementary PWM Output

Figure 24.84 shows an example in which three channels perform synchronous operation in triangle-wave PWM mode 1 and three-phase complementary PWM waveforms are output. The GTIOCnA pin (n = 0 to 2) is set so that it will output low as the initial output, toggle the output at a GTCCRA register compare match, and retain the output at the end of the cycle. The GTIOCnB pin is set so that it will output high as the initial output, toggle the output at a GTCCRB register compare match, and retain the output at the end of the cycle.

Figure 24.84 Example of Three-Phase Triangle-Wave Complementary PWM Output

(5) Three-Phase Triangle-Wave Complementary PWM Output with Automatic Dead Time Setting

Figure 24.85 shows an example in which three channels perform synchronous operation in triangle-wave PWM mode 1 with automatic dead time setting and three-phase complementary PWM waveforms are output. The GTIOCnA pin (n = 0 to 2) is set so that it will output low as the initial output, toggle the output at a GTCCRA register compare match, and retain the output at the end of the cycle. The GTIOCnB pin is set so that it will output high as the initial output, toggle the output at a GTCCRB register compare match, and retain the output at the end of the cycle.

**Figure 24.85 Example of Three-Phase Triangle-Wave Complementary PWM Output with Automatic Dead Time Setting**

(6) Three-Phase Asymmetric Triangle-Wave Complementary PWM Output with Automatic Dead Time Setting

Figure 24.86 shows an example in which three channels perform synchronous operation in triangle-wave PWM mode 3 with automatic dead time setting and three-phase complementary PWM waveforms are output. The GTIOCnA pin ( $n = 0$  to 2) is set so that it will output low as the initial output, toggle the output at a GTCCRA register compare match, and retain the output at the end of the cycle. The GTIOCnB pin is set so that it will output high as the initial output, toggle the output at a GTCCRB register compare match, and retain the output at the end of the cycle.

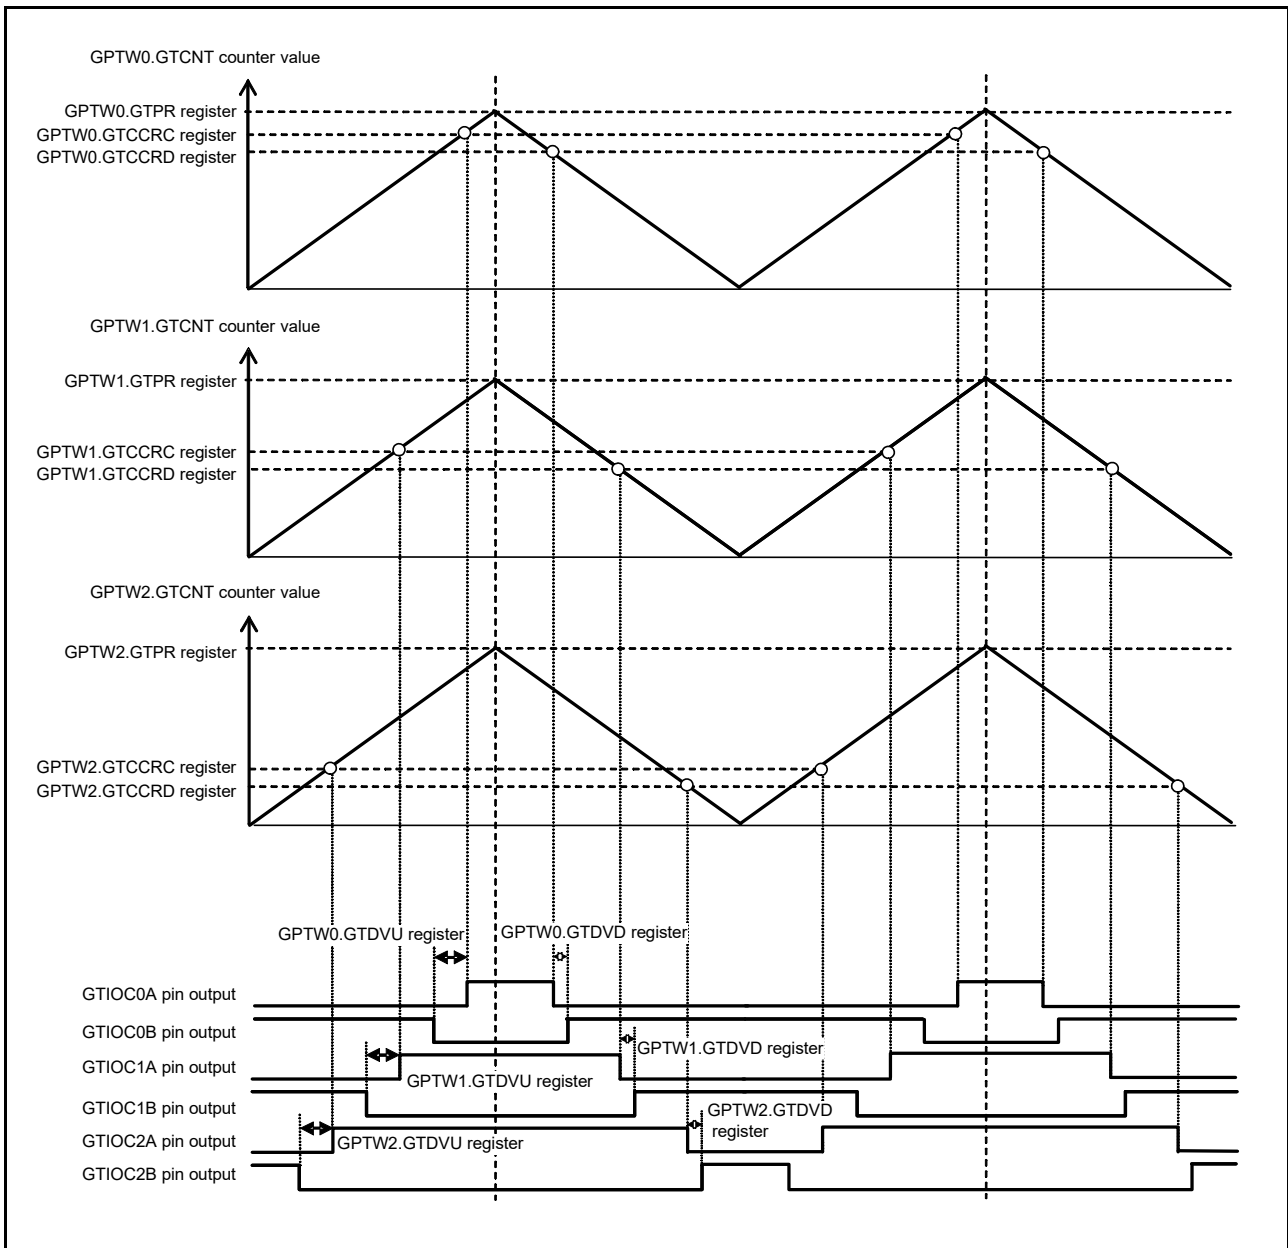

Figure 24.86 Example of Three-Phase Asymmetric Triangle-Wave Complementary PWM Output with Automatic Dead Time Setting

### 24.3.10 Phase Counting Mode

The GTCNT counter can be up-counting or down-counting by detecting the phase difference between the GTIOCnA pin input (n = 0 to 9) and the GTIOCnB pin input.

Detection of the phase difference can be performed by setting the relationship between the edge and the level of the GTIOCnA pin input and the GTIOCnB pin input using the GTUPSR and GTDNSR registers for input combination. Refer to section 24.3.1.1, Counter Operation for count operation.

Figure 24.87 to Figure 24.96 show the examples of setting procedure for the phase counting mode 1 to 5, and the Table 24.10 to Table 24.19 show the setting of the GTUPSR and GTDNSR registers and up-counting and down-counting conditions.

Figure 24.87 Example of setting procedure for the phase counting mode 1 (n = 0 to 9)

Table 24.10 Up-counting and down-counting conditions for the phase counting mode 1 (n = 0 to 9)

| GTIOCnA pin input | GTIOCnB pin input | Operation     | Setting of register                        |
|-------------------|-------------------|---------------|--------------------------------------------|
| High              |                   | Up-counting   | GTUPSR = 0000 6900h<br>GTDNSR = 0000 9600h |
| Low               |                   |               |                                            |
|                   | Low               |               |                                            |
|                   | High              |               |                                            |
| High              |                   | Down-counting |                                            |
| Low               |                   |               |                                            |
|                   | High              |               |                                            |
|                   | Low               |               |                                            |

## 24.4 Interrupt Sources

### 24.4.1 Interrupt Sources and Priorities

There are three kinds of interrupt sources; GTCCRm register (m = A to F) input capture/compare match, GTCNT counter overflow (GTPR register compare match)/underflow, and dead time error.

Each interrupt source has its own status flag and control bit for generating interrupt request signals, where the generation of interrupt request signals can be enabled or disabled individually.

When an interrupt source condition is satisfied, an interrupt request is generated if the corresponding interrupt request enable or disable bit is 1.

For details, refer to section 14, Interrupt Controller (ICUC). Table 24.20 shows a list of GPTW interrupt sources.

**Table 24.20 GPTW Interrupt Sources (n = 0 to 9)**

| Channel | Name               | Interrupt Source                                     |
|---------|--------------------|------------------------------------------------------|
| GPTWn   | GTCIA <sub>n</sub> | GTCCRA register input capture/compare match          |
|         | GTCIB <sub>n</sub> | GTCCRB register input capture/compare match          |
|         | GTCIC <sub>n</sub> | GTCCRC register compare match                        |
|         | GTCID <sub>n</sub> | GTCCRD register compare match                        |
|         | GDTEn              | Dead time error                                      |
|         | GTCIE <sub>n</sub> | GTCCRE register compare match                        |
|         | GTCIF <sub>n</sub> | GTCCRF register compare match                        |
|         | GTCIV <sub>n</sub> | GTCNT counter overflow (GTPR register compare match) |
|         | GTCIU <sub>n</sub> | GTCNT counter underflow                              |

#### (1) GTCIA<sub>n</sub> Interrupt (n = 0 to 9)

When the GTINTAD.GTINTA bit is 1, an interrupt request is generated under the following conditions.

- When the GTCCRA register functions as a compare match register, the GTCNT counter value matches with the GTCCRA register.
- When the GTCCRA register functions as an input capture register, the input-capture signal has caused transfer of the GTCNT counter value to the GTCCRA register.

#### (2) GTCIB<sub>n</sub> Interrupt (n = 0 to 9)

When the GTINTAD.GTINTB bit is 1, an interrupt request is generated under the following conditions.

- When the GTCCRB register functions as a compare match register, the GTCNT counter value matches with the GTCCRB register.
- When the GTCCRB register functions as an input capture register, the input-capture signal has caused transfer of the GTCNT counter value to the GTCCRB register.

#### (3) GTCIC<sub>n</sub> Interrupt (n = 0 to 9)

When the GTINTAD.GTINTC bit is 1, an interrupt request is generated under the following condition.

- When the GTCCRC register functions as a compare match register, the GTCNT counter value matches with the GTCCRC register.

A compare match is not performed and thus interrupt is not requested under the following conditions.

- GTCR.MD[2:0] bits = 001b (sawtooth-wave one-shot pulse mode)
- GTCR.MD[2:0] bits = 110b (triangle-wave PWM mode 3)
- GTBER.CCRA[1:0] bits = 01b, 10b, 11b (buffer operation with the GTCCRC register)

#### (4) GTCIDn Interrupt (n = 0 to 9)

When the GTINTAD.GTINTD bit is 1, an interrupt request is generated under the following condition.

- When the GTCCRD register functions as a compare match register, the GTCNT counter value matches with the GTCCRD register.

A compare match is not performed and thus interrupt is not requested under the following conditions.

- GTCR.MD[2:0] bits = 001b (sawtooth-wave one-shot pulse mode)
- GTCR.MD[2:0] bits = 110b (triangle-wave PWM mode 3)
- GTBER.CCRA[1:0] bits = 10b, 11b (buffer operation with the GTCCRD register)

#### (5) GTCIE n Interrupt (n = 0 to 9)

When the GTINTAD.GTINTE bit is 1, an interrupt request is generated under the following condition.

- When the GTCCRE register functions as a compare match register, the GTCNT counter value matches with the GTCCRE register.

A compare match is not performed and thus interrupt is not requested under the following conditions.

- GTCR.MD[2:0] bits = 001b (sawtooth-wave one-shot pulse mode)
- GTCR.MD[2:0] bits = 110b (triangle-wave PWM mode 3)
- GTBER.CCRB[1:0] bits = 01b, 10b, 11b (buffer operation with the GTCCRE register)

#### (6) GTCIFn Interrupt (n = 0 to 9)

When the GTINTAD.GTINTF bit is 1, an interrupt request is generated under the following condition.

- When the GTCCRF register functions as a compare match register, the GTCNT counter value matches with the GTCCRF register.

A compare match is not performed and thus interrupt is not requested under the following conditions.

- GTCR.MD[2:0] bits = 001b (sawtooth-wave one-shot pulse mode)
- GTCR.MD[2:0] bits = 110b (triangle-wave PWM mode 3)
- GTBER.CCRB[1:0] bits = 10b, 11b (buffer operation with the GTCCRF register)

#### (7) GTCIVn Interrupt (n = 0 to 9)

When the GTINTAD.GTINTPR[0] bit is 1, an interrupt request is generated under the following conditions.

- In sawtooth-wave mode, interrupt requests are enabled at overflows (the GTCNT counter value changes from the GTPR register value to 0 during up-counting).
- In triangle-wave mode, interrupt requests are enabled at crests (the GTCNT counter value changes from the GTPR register value to the GTPR register value minus 1).
- In counting driven by a hardware source, interrupt requests are enabled on overflows (that is, when the GTCNT counter value changes from the GTPR register value to 0 during up-counting).

#### (8) GTCIU n Interrupt (n = 0 to 9)

When the GTINTAD.GTINTPR[1] bit is 1, an interrupt request is generated under the following conditions.

- In sawtooth-wave mode, interrupt requests are enabled at underflows (the GTCNT counter value changes from 0 to the GTPR register value during down-counting).
- In triangle-wave mode, interrupt requests are enabled at troughs (the GTCNT counter value changes from 0 to 1).
- In count operation by a hardware source, interrupt requests are enabled at underflows (the GTCNT counter value

changes from 0 to the GTPR register value during down-counting).

### (9) GDTE<sub>n</sub> Interrupt (n = 0 to 9)

When automatic dead time setting has been made, the GTST.DTEF flag becomes 1 when the timer output toggle point with dead time added exceeds the count period. If the GTINTAD.GRPDTE bit is 1 at this time, a dead time error interrupt request (GDTE) is generated.

In addition, when the timer output toggle point with dead time added is back within the count period, the GTST.DTEF flag changes from 1 to 0.

**Table 24.21 Relationship between Interrupt Signals and Interrupt Enable Bits (n = 0 to 9)**

| Interrupt Signal   | Interrupt Enable Bit      |
|--------------------|---------------------------|
| GTCIA <sub>n</sub> | GTINTAD.GTINTA bit        |
| GTCIB <sub>n</sub> | GTINTAD.GTINTB bit        |
| GTCIC <sub>n</sub> | GTINTAD.GTINTC bit        |
| GTCID <sub>n</sub> | GTINTAD.GTINTD bit        |
| GDTE <sub>n</sub>  | GTINTAD.GRPDTE bit        |
| GTCIE <sub>n</sub> | GTINTAD.GTINTE bit        |
| GTCIF <sub>n</sub> | GTINTAD.GTINTF bit        |
| GTCIV <sub>n</sub> | GTINTAD.GTINTPR[1:0] bits |
| GTCIU <sub>n</sub> |                           |

## 24.4.2 DMAC/DTC Activation

The DMAC and DTC can be triggered by the interrupt request in each channel. For details, see section 14, Interrupt Controller (ICUC), section 17, DMA Controller (DMACa), section 18, Data Transfer Controller (DTCa).

## 24.4.3 Interrupt and A/D Conversion Start Request Skipping Function

### 24.4.3.1 Interrupt Skipping Function by GTITC Register

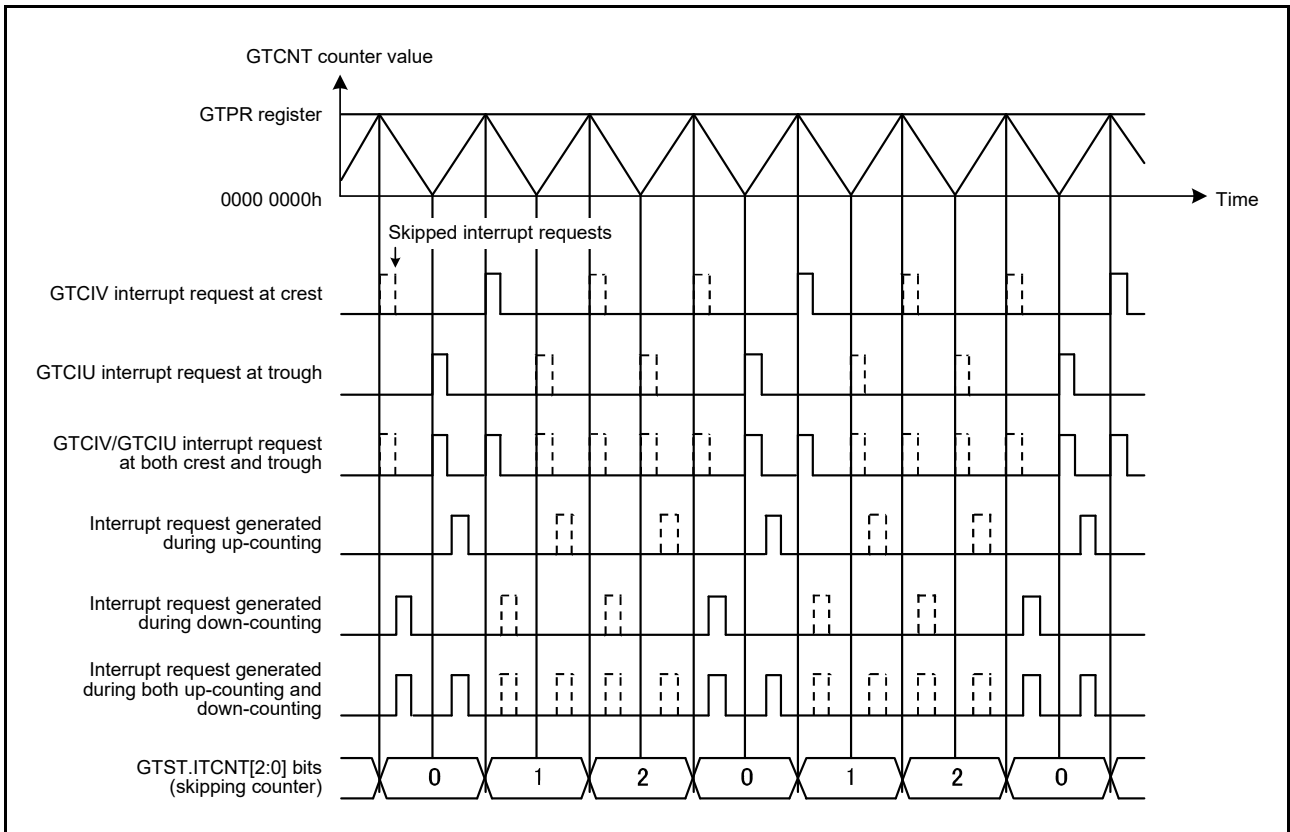

By setting the GTITC register, the GTCNT counter overflow (GTPR register compare match) interrupt (GTCIV) and underflow interrupt (GTCIU) can be skipped. Other interrupts and A/D conversion start request signals can be skipped in coordination with the GTCIV/GTCIU skipping function. However, the dead time error interrupts cannot be linked with the GTCIV/GTCIU skipping function.

The interrupt skipping function is related only to the GTITC register setting, and is not related to setting of the GTINTAD register interrupt enable bit.

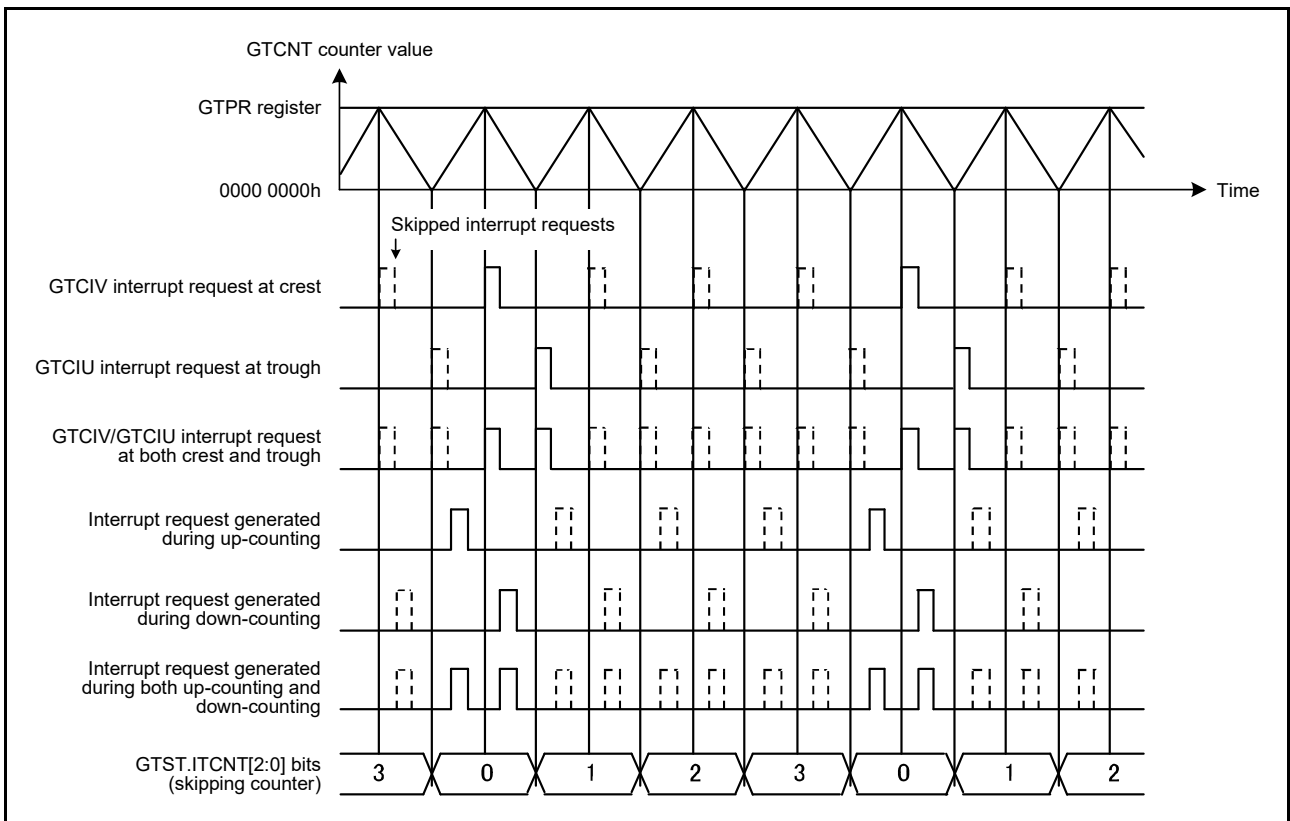

When both troughs and crests are counted and skipped in triangle-wave mode, if the number of times of skipping is odd, GTCIV/GTCIU interrupt requests cannot be generated at troughs only or at crests only depending on the skipping counter start timing. Therefore, in order to count both troughs and crests and generate the GTCIV/GTCIU interrupts at troughs only or crests only in triangle-wave mode, the number of times of skipping should be even.

Similarly, in sawtooth-wave mode, when both overflows and underflows are counted and skipped with the count direction changed, GTCIV/GTCIU interrupt requests cannot be generated at overflows only or at underflows only. Therefore, in order to count both overflows and underflows with the count direction changed and generate the GTCIV/GTCIU interrupts at overflows only or underflows only in sawtooth-wave mode, the skipping state should be carefully checked before using.

When changing the skipping count, be sure to release the skipping count setting (GTITC.IVTC[1:0] bits = 00b). Figure 24.97 to Figure 24.102 show examples of skipping function operation.

**Figure 24.97 Example of Interrupt Skipping Function Operation (Triangle Waves, Counting and Skipping Crests, Skipping Count: 2)**

**Figure 24.98 Example of Interrupt Skipping Function Operation (Triangle Waves, Counting and Skipping Troughs, Skipping Count: 3)**

Figure 24.99 Example of Interrupt Skipping Function Operation (Triangle Waves, Counting and Skipping Both Troughs and Crests, Skipping Count: 4)

**Figure 24.101 Example of Interrupt Skipping Function Operation (Triangle Waves, Counting and Skipping Both Troughs and Crests, Skipping Count: 3, Skipping Started at Down-Counting)**

**Figure 24.102 Example of Interrupt Skipping Function Operation (Sawtooth Waves, Operation with Count Direction Changed, Counting and Skipping Both Overflows and Underflows, Skipping Count: 4)**

### 24.4.3.2 Extended Interrupt Skipping Function

Overflow/underflow interrupt, compare match/input capture interrupt, A/D conversion start request, and buffer transfer can be skipped by counting the GTCNT counter overflow or underflow based on settings of the GTEITC, GTEITLI1, GTEITLI2 and GTEITLB registers. The dead time error interrupt cannot be skipped.

Overflow/underflow interrupt, compare match/input capture interrupt, A/D conversion start request, and buffer transfer can individually be set for skipping and the skipping period using the GTEITLI1, GTEITLI2, and GTEITLB registers. The skipping period is set, related to the operation of the two independent extended interrupt skipping counters (EITCNT1[3:0] and EITCNT2[3:0] bits in the GTEITC registers), as a period that either of the counter value for such skipping counters is other than 0 or other than the skipping count. The skipping period can also be set as a period that the both skipping counters are set as other than 0 or other than the skipping count for the counter value.

Figure 24.103 shows the counter operation for interrupt skipping by the GTITC register and extended interrupt skipping.

The counter operation for extended interrupt skipping is set by the GTEITC register.

The EITCNT1[3:0] bits count the count source (in Figure 24.103, a crest is selected) selected by the extended interrupt counter 1 count source select bit (EIVTC1[1:0] bits) when the initial value is set for 0, and repeat the count operation which returns to 0 when the skipping count (in Figure 24.103, count is 2) set by the extended interrupt skipping 1 skipping count setting bit (EIVTT1[3:0] bits) is achieved.

The EITCNT2[3:0] bits can set the initial value, count the count source (in Figure 24.103, a trough is selected) selected by the extended interrupt counter 2 count source select bit (EIVTC2[1:0] bits), and repeat the count operation which return to 0 when the skipping count (in Figure 24.103, count is 2) set by the EIVTT2[3:0] bits is achieved. The initial value is set when the GTEITC register is written by the access of upper 16 bits or 32 bits and when the written value to the EIVTC2[1:0] bits is other than 00b, while the setting for the extended interrupt skipping counter 2 is not in counting (EIVTC2[1:0] bits are 00b).

When the initial value is set, the written value to the extended interrupt skipping counter 2 initial value bit (EITCNT2IV[3:0] bits) is set as the initial value for the EITCNT2[3:0] bits.

The extended interrupt skipping counter starts up-counting at the first count clock after the setting is modified from not counting to counting.

The interrupt skipping count counter (GTST.ITCNT[2:0] bits) by the GTITC register is reset to 000b when the GTCNT counter operation is stopped: however, the EITCNT1[3:0] and EITCNT2[3:0] bits which are an extended interrupt skipping function retain the value even after the GTCNT counter operation is stopped, and the counting can be resumed from the value before the counter is stopped. When values for the EITCNT1[3:0] and EITCNT2[3:0] bits are to be reset (0000b), set the EIVTC1[1:0] and EIVTC2[1:0] bits to the setting for not counting (not skipping) (00b).

When the skipping count is to be changed, change the count after stopping the skipping counter operation (set either of the EIVTC1[1:0] bit or the EIVTC2[1:0] bit to 00b).

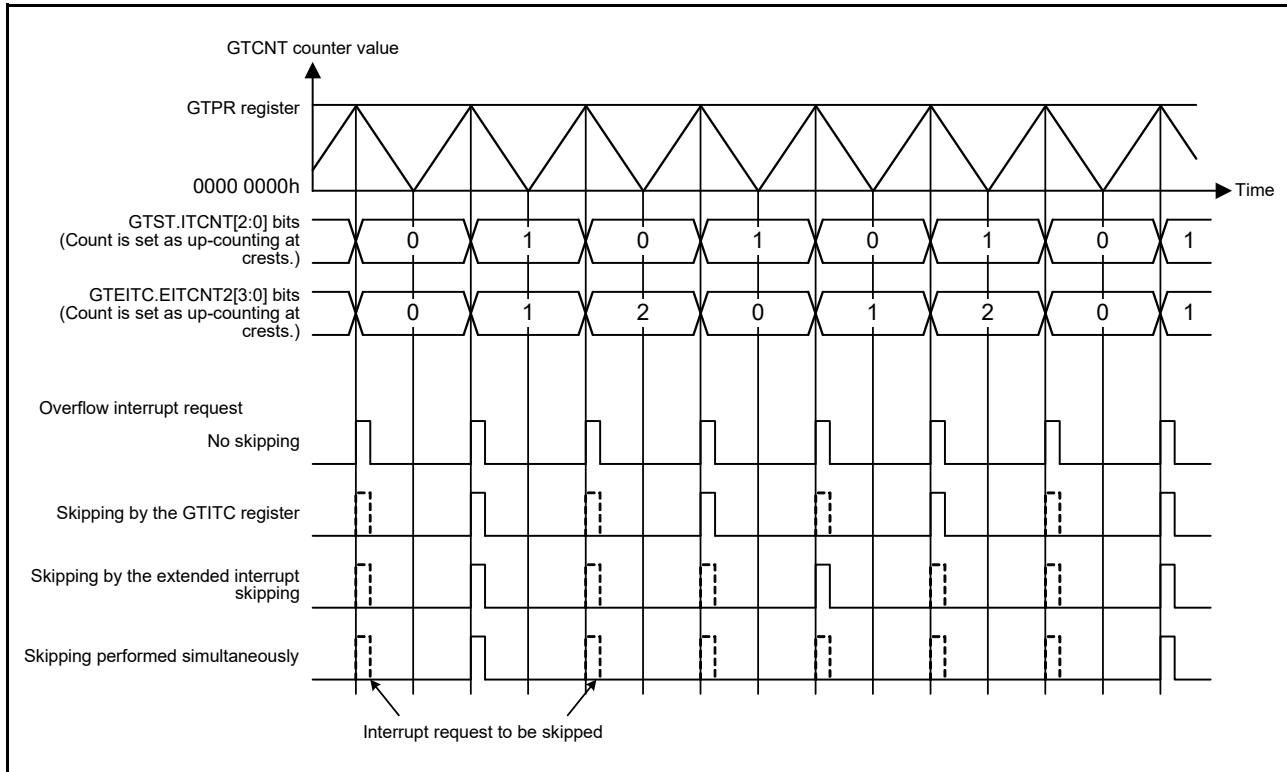

Figure 24.103 Counter Operation for Interrupt Skipping

Interrupt skipping by the GTEITLI1 register and A/D conversion start request skipping by the GTEITLI2 register can be performed simultaneously with interrupt skipping by the GTITC register. A skipping period at this time is represented by ORed skipping periods of respective registers.

Figure 24.104 shows corresponding interrupt skipping operations by different registers are performed simultaneously.

**Figure 24.104 Example of Interrupt Skipping Operation**  
**(Skipping by the GTITC Register: Counting Crests, Extended Interrupt Skipping: EIVTC1[1:0] bits = 00b, EIVTC2[1:0] bits = 01b, EITLV[2:0] bits = 010b)**

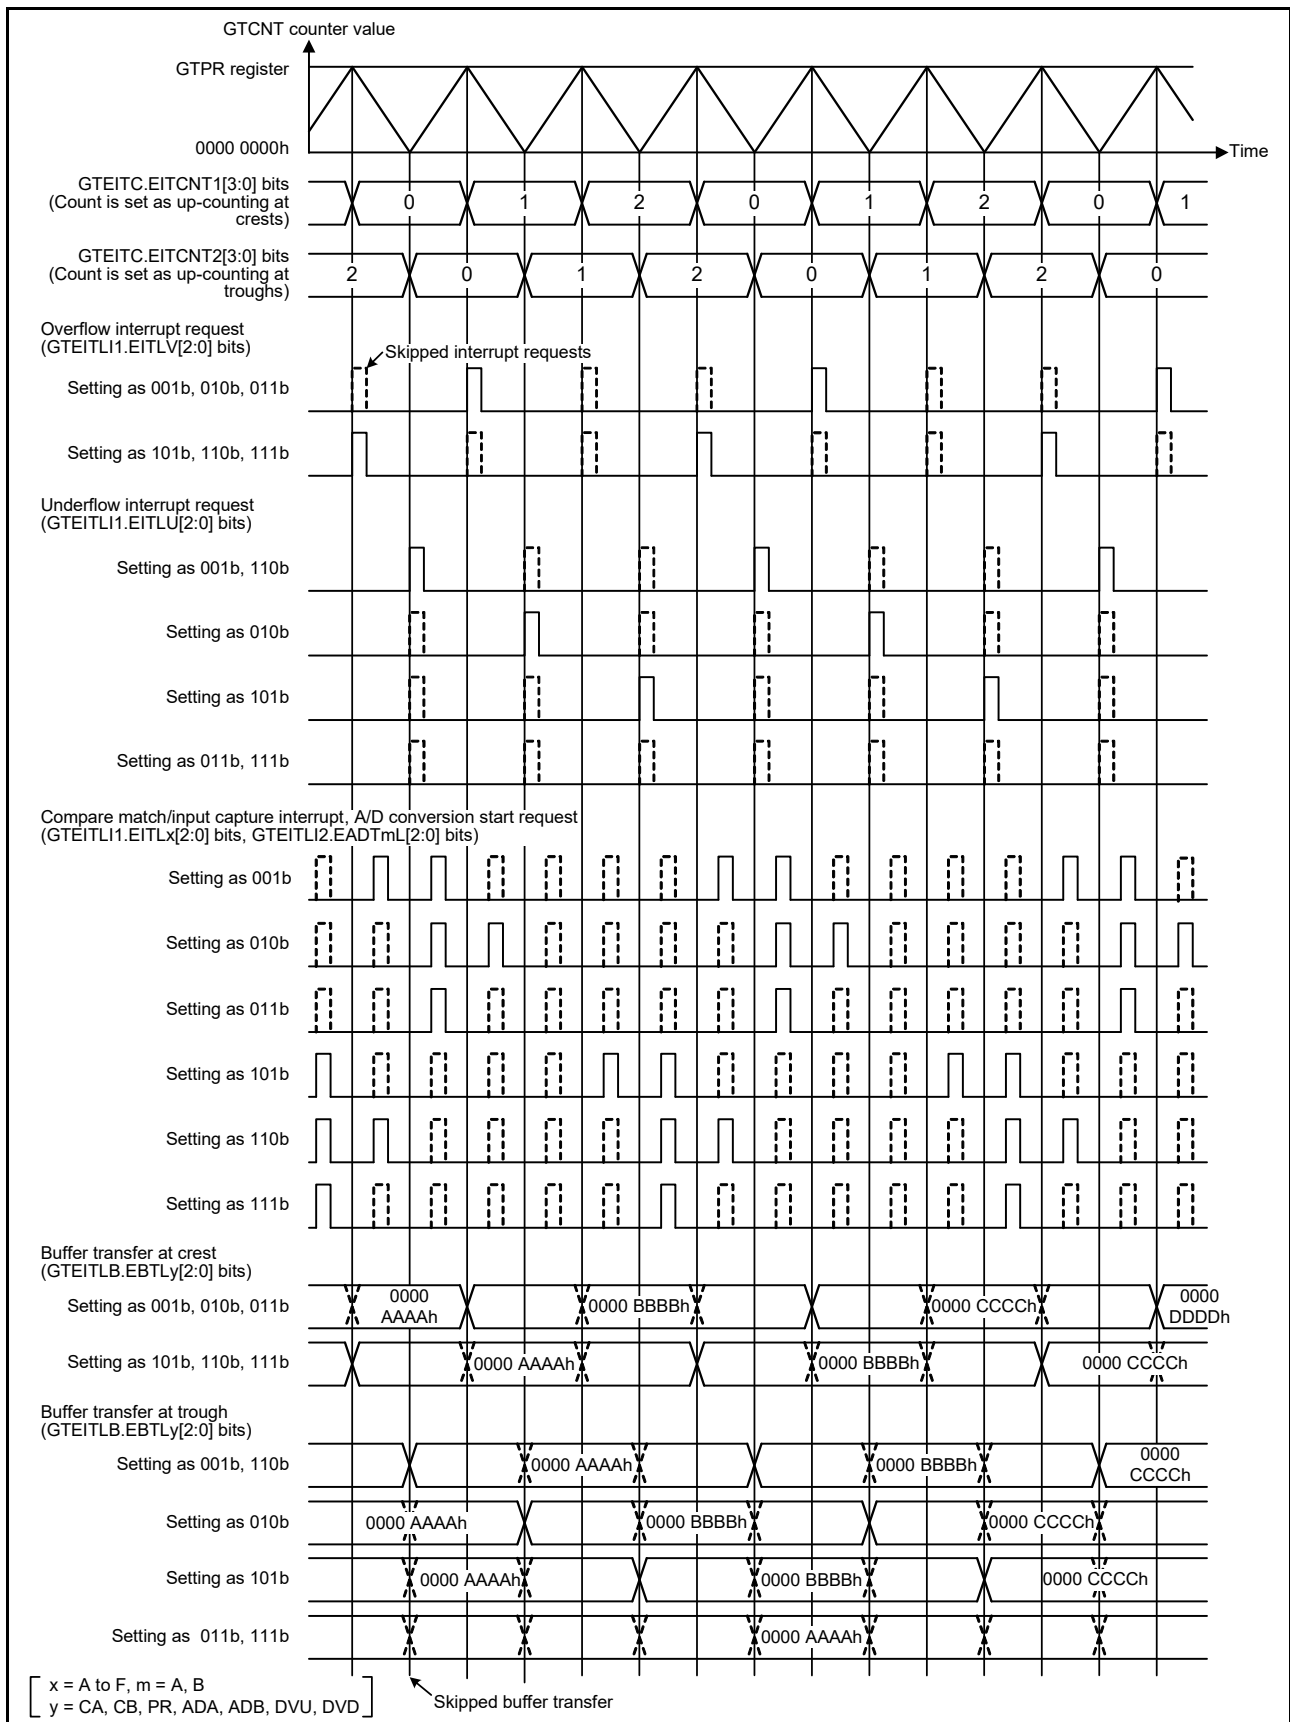

Skipping of ELC event source outputs corresponding to interrupts for which skipping can be set up in the GTEITLI1 register is only based on the settings of the GTITC register and the extended interrupt skipping register, and has no connection with the setting of the interrupt enable bit in the GTINTAD register. The interrupt enable bit is used only for the interrupt signal output after skipping.

When A/D conversion start request skipping which can be set by the GTEITLI2 register is performed, the ELC event output depend on the A/D conversion start request enable bit in the GTINTAD register. All the operations by A/D conversion start request which are set as disable by the GTINTAD register is not performed.

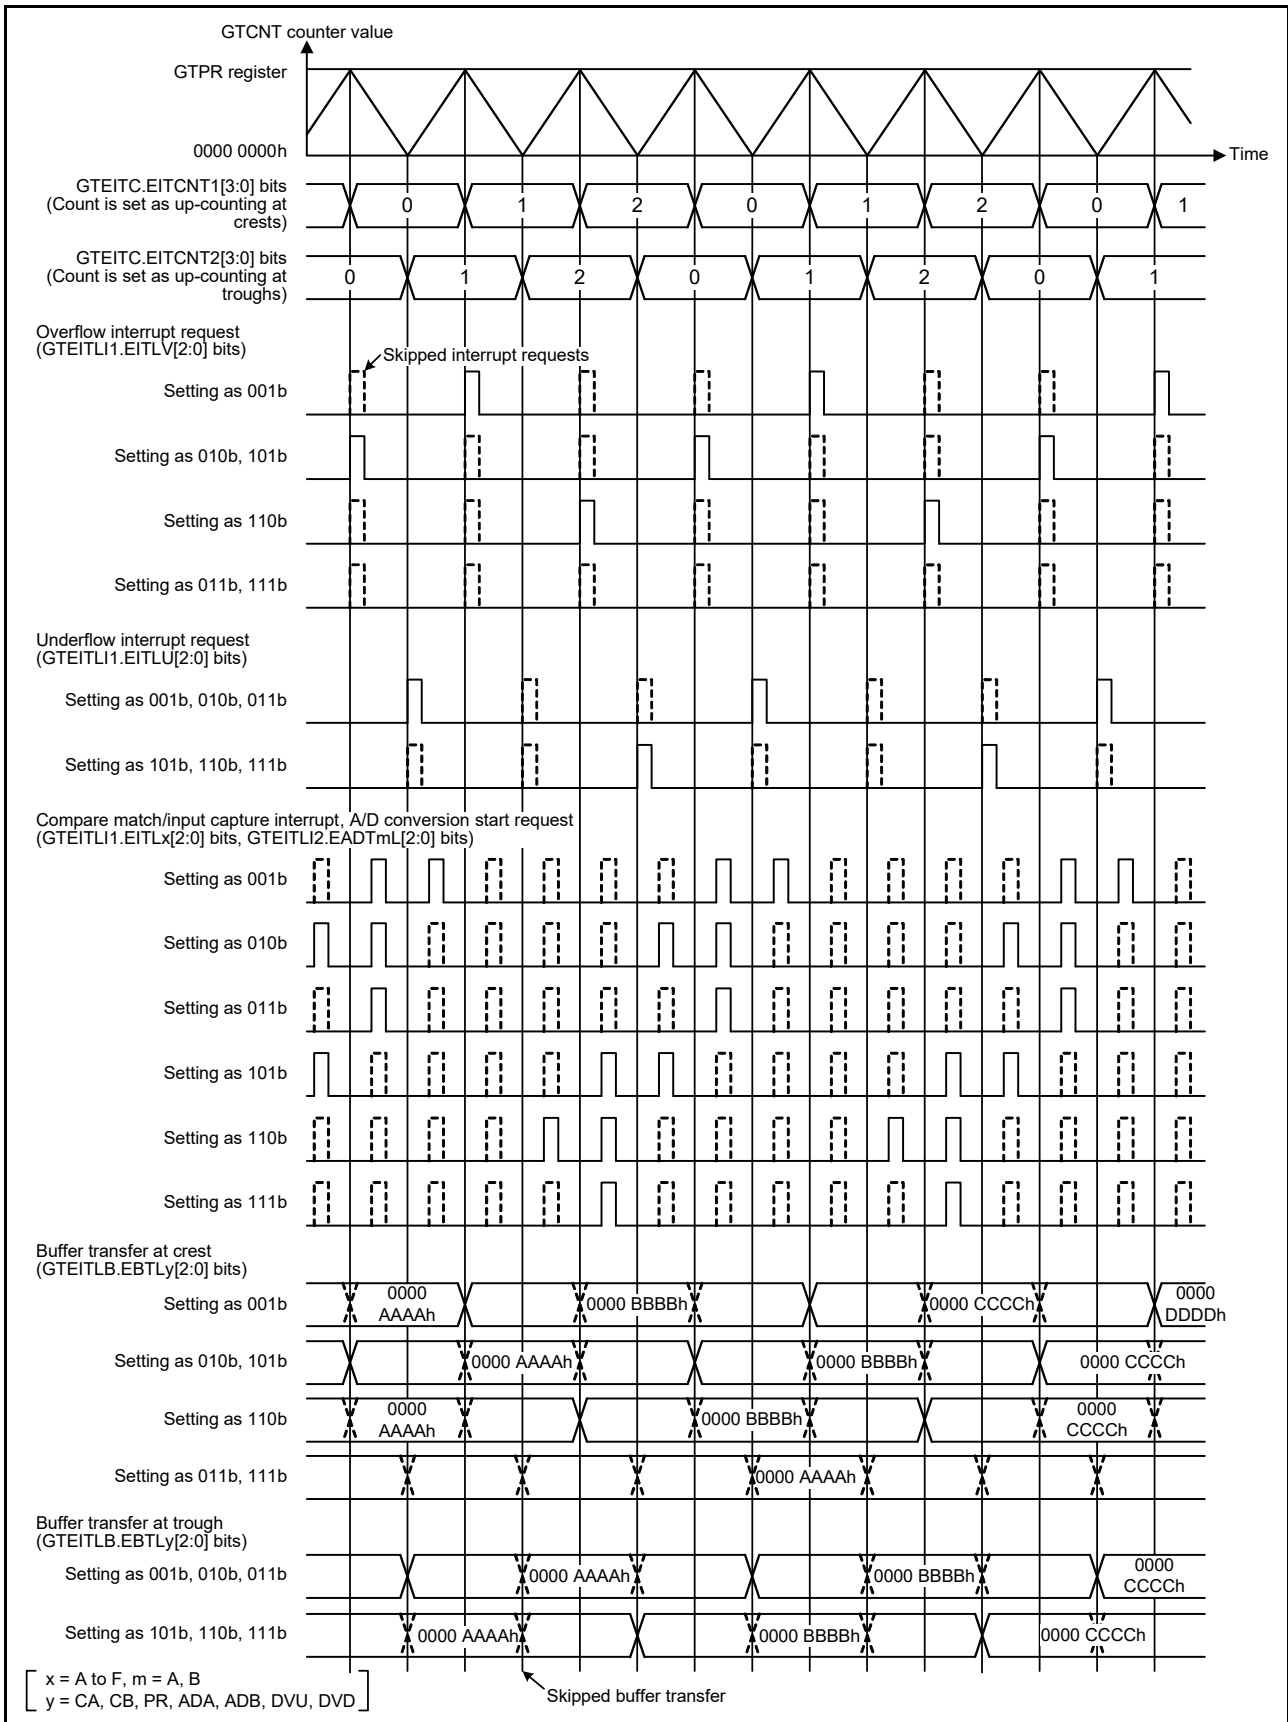

A buffer transfer skipping by the GTEITLB register is performed in all of buffer operation which is enabled in the GTBER and, GTDTCR registers, or all buffer operations performed by sawtooth-wave one-shot pulse mode or triangle-wave PWM mode 3.

An interrupt skipping and a buffer transfer skipping are operated individually. An interrupt output without performing a buffer transferred performing a buffer transfer without an interrupt output can also be operated.

Figure 24.105 to Figure 24.112 show examples of skipping function operation.

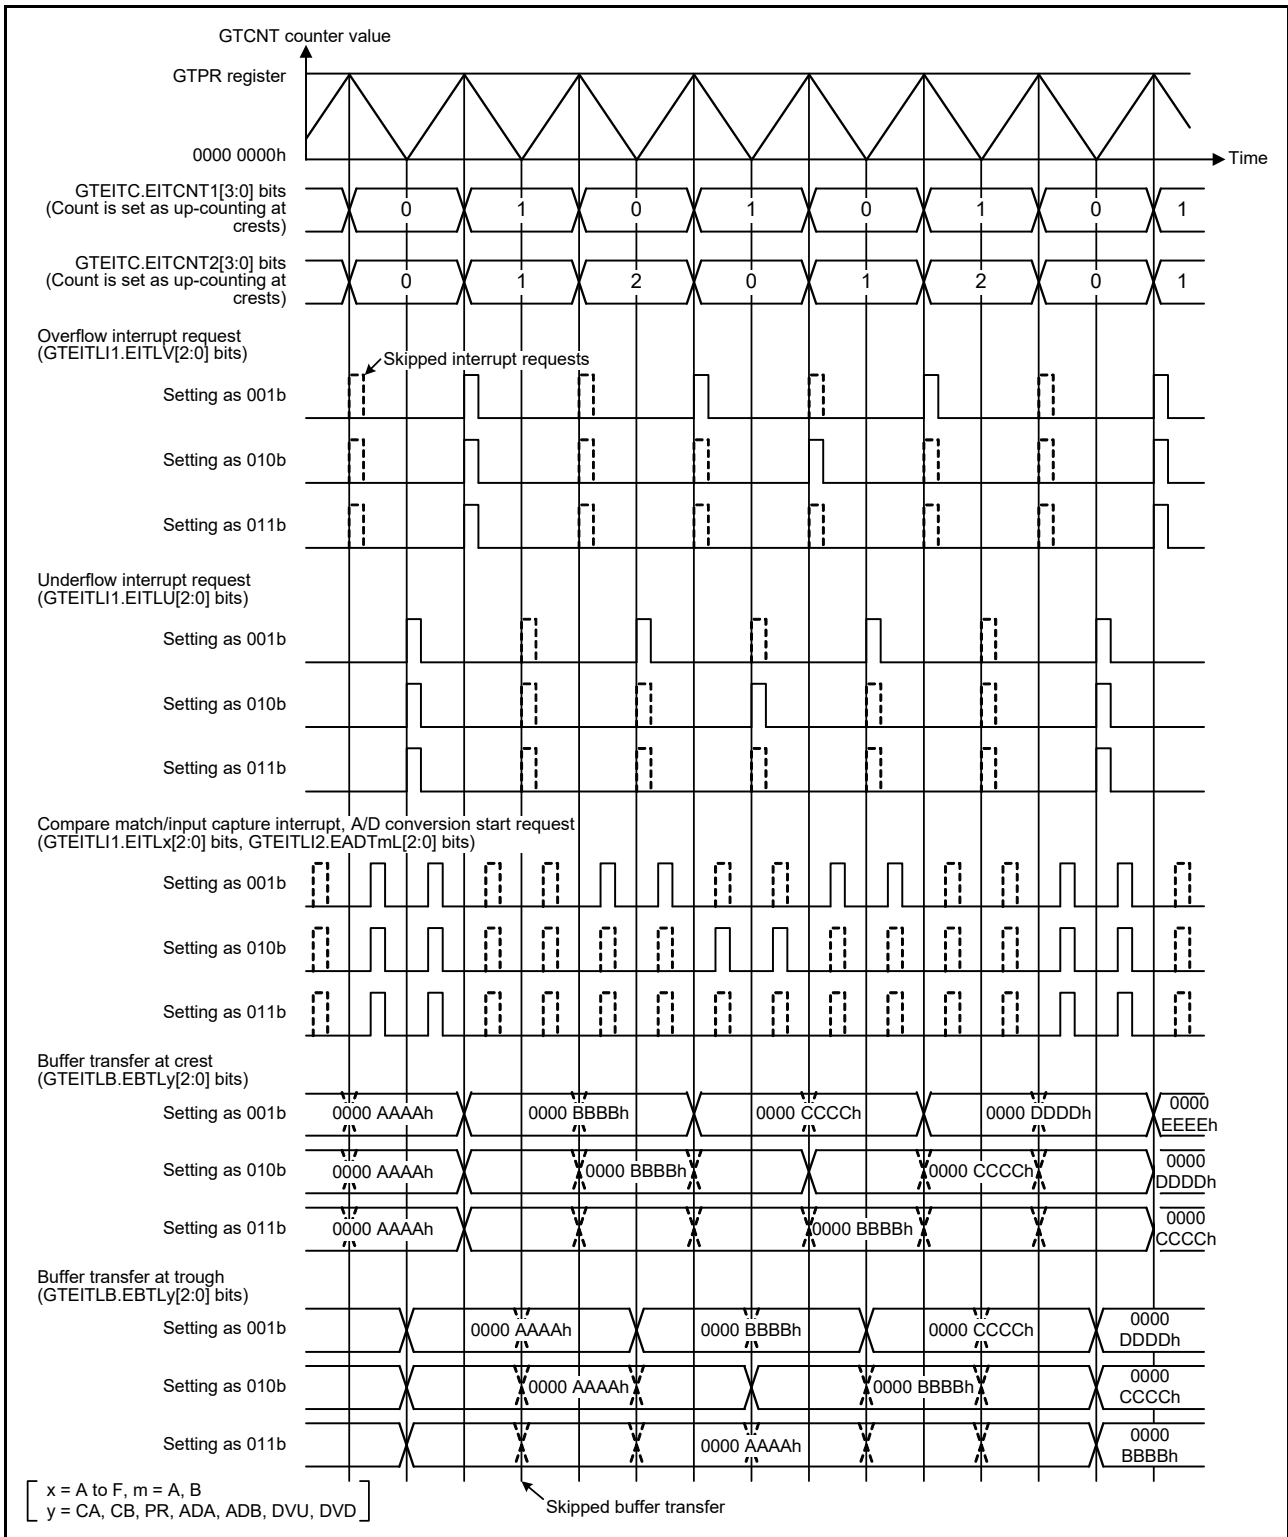

**Figure 24.105 Example of Extended Interrupt Skipping Function (Triangle Waves, Counting Crests, Extended Interrupt Skipping 1 Skipping Count: 2, Counting Troughs, Extended Interrupt Skipping 2 Skipping Count: 2, Extended Interrupt Skipping Counter 2 Initial Value: 0)**

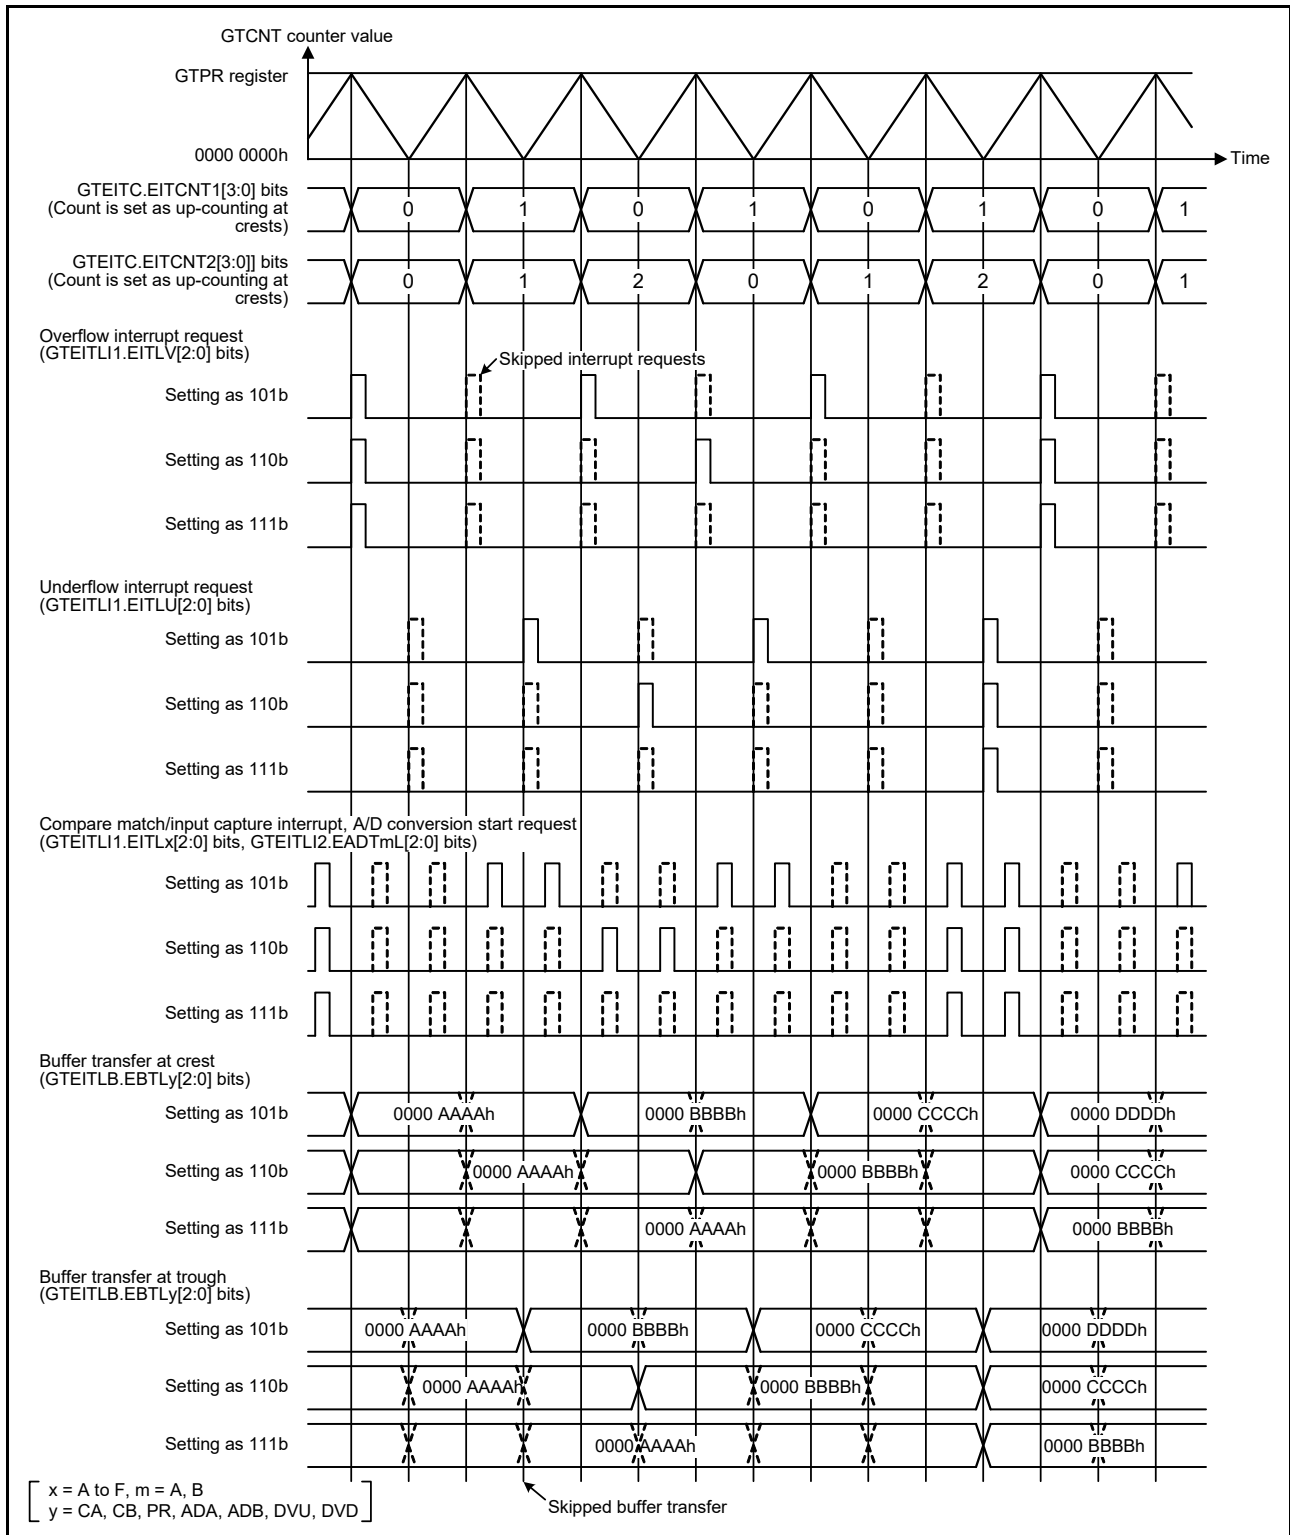

**Figure 24.106 Example of Extended Interrupt Skipping Function (Triangle Waves, Count Crests by the Extended Interrupt Skipping 1 with Skipping Count: 2, Count Troughs by the Extended Interrupt Skipping 2 with Skipping Count: 2, Extended Interrupt Skipping Counter 2 Initial Value: 1)**

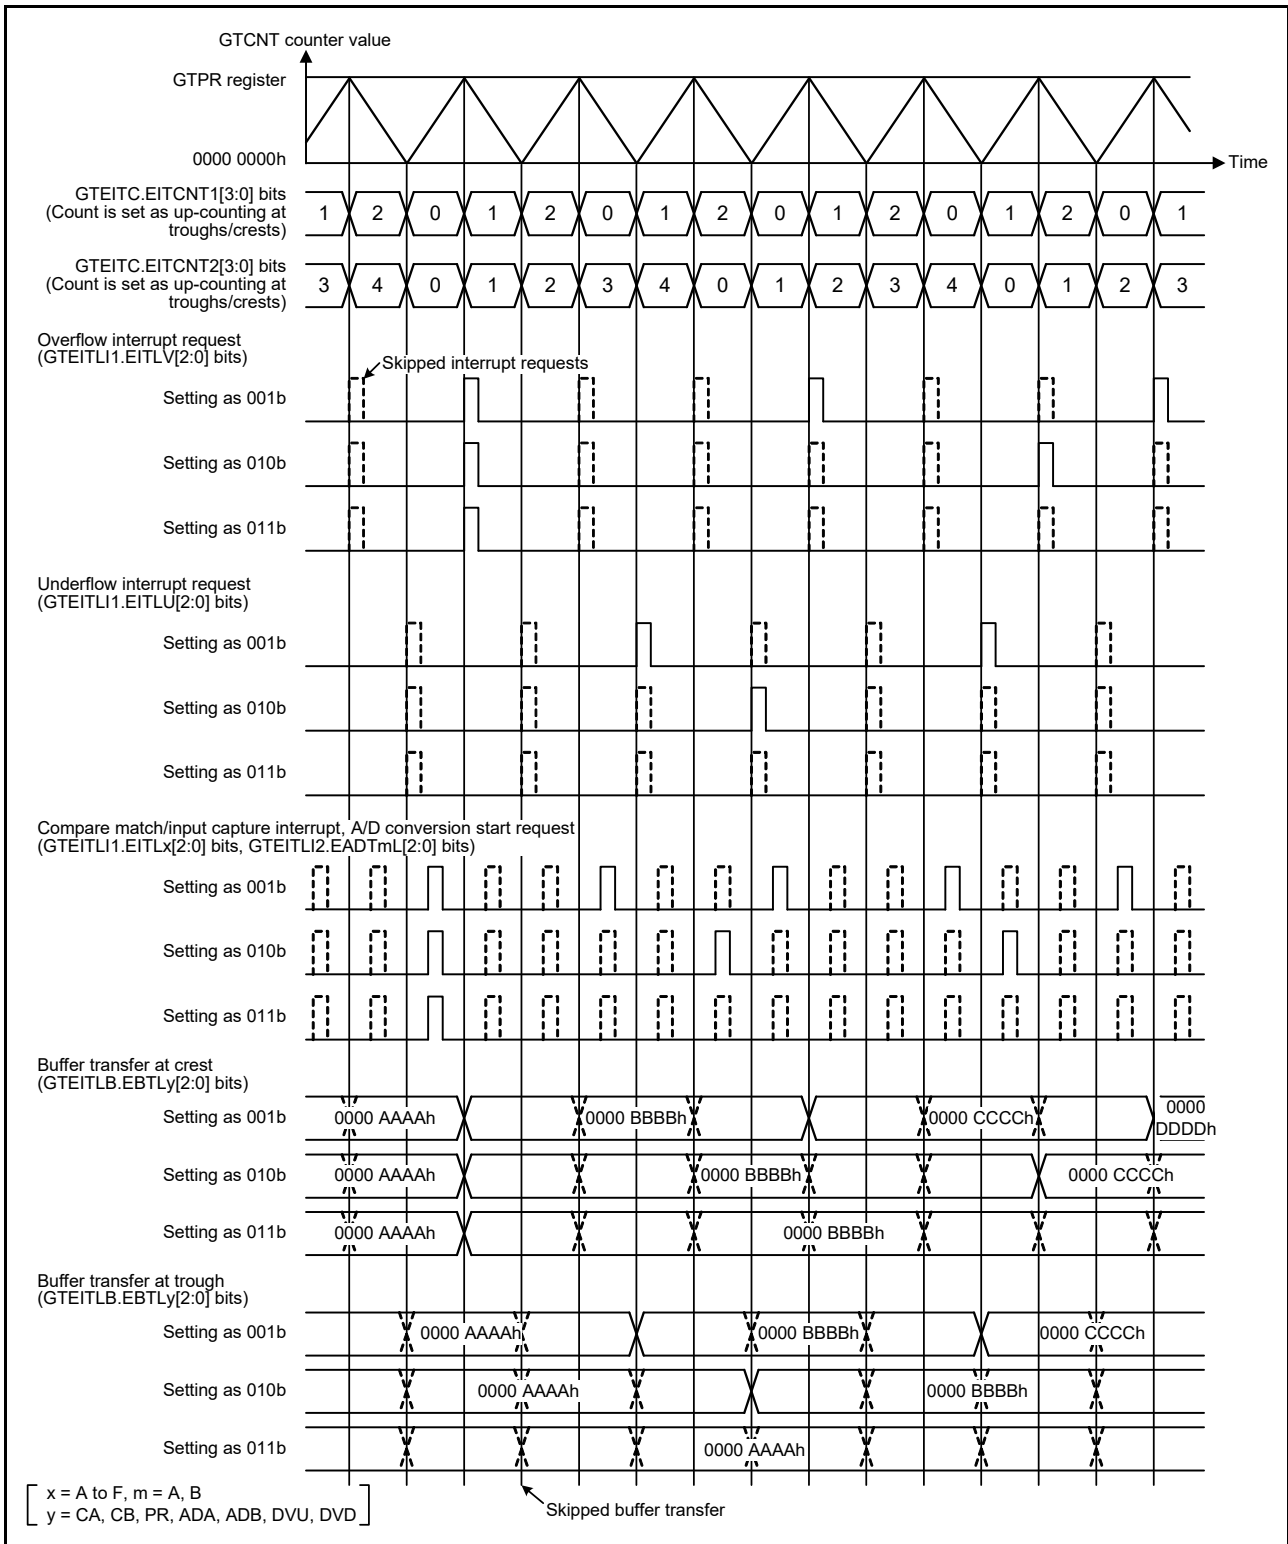

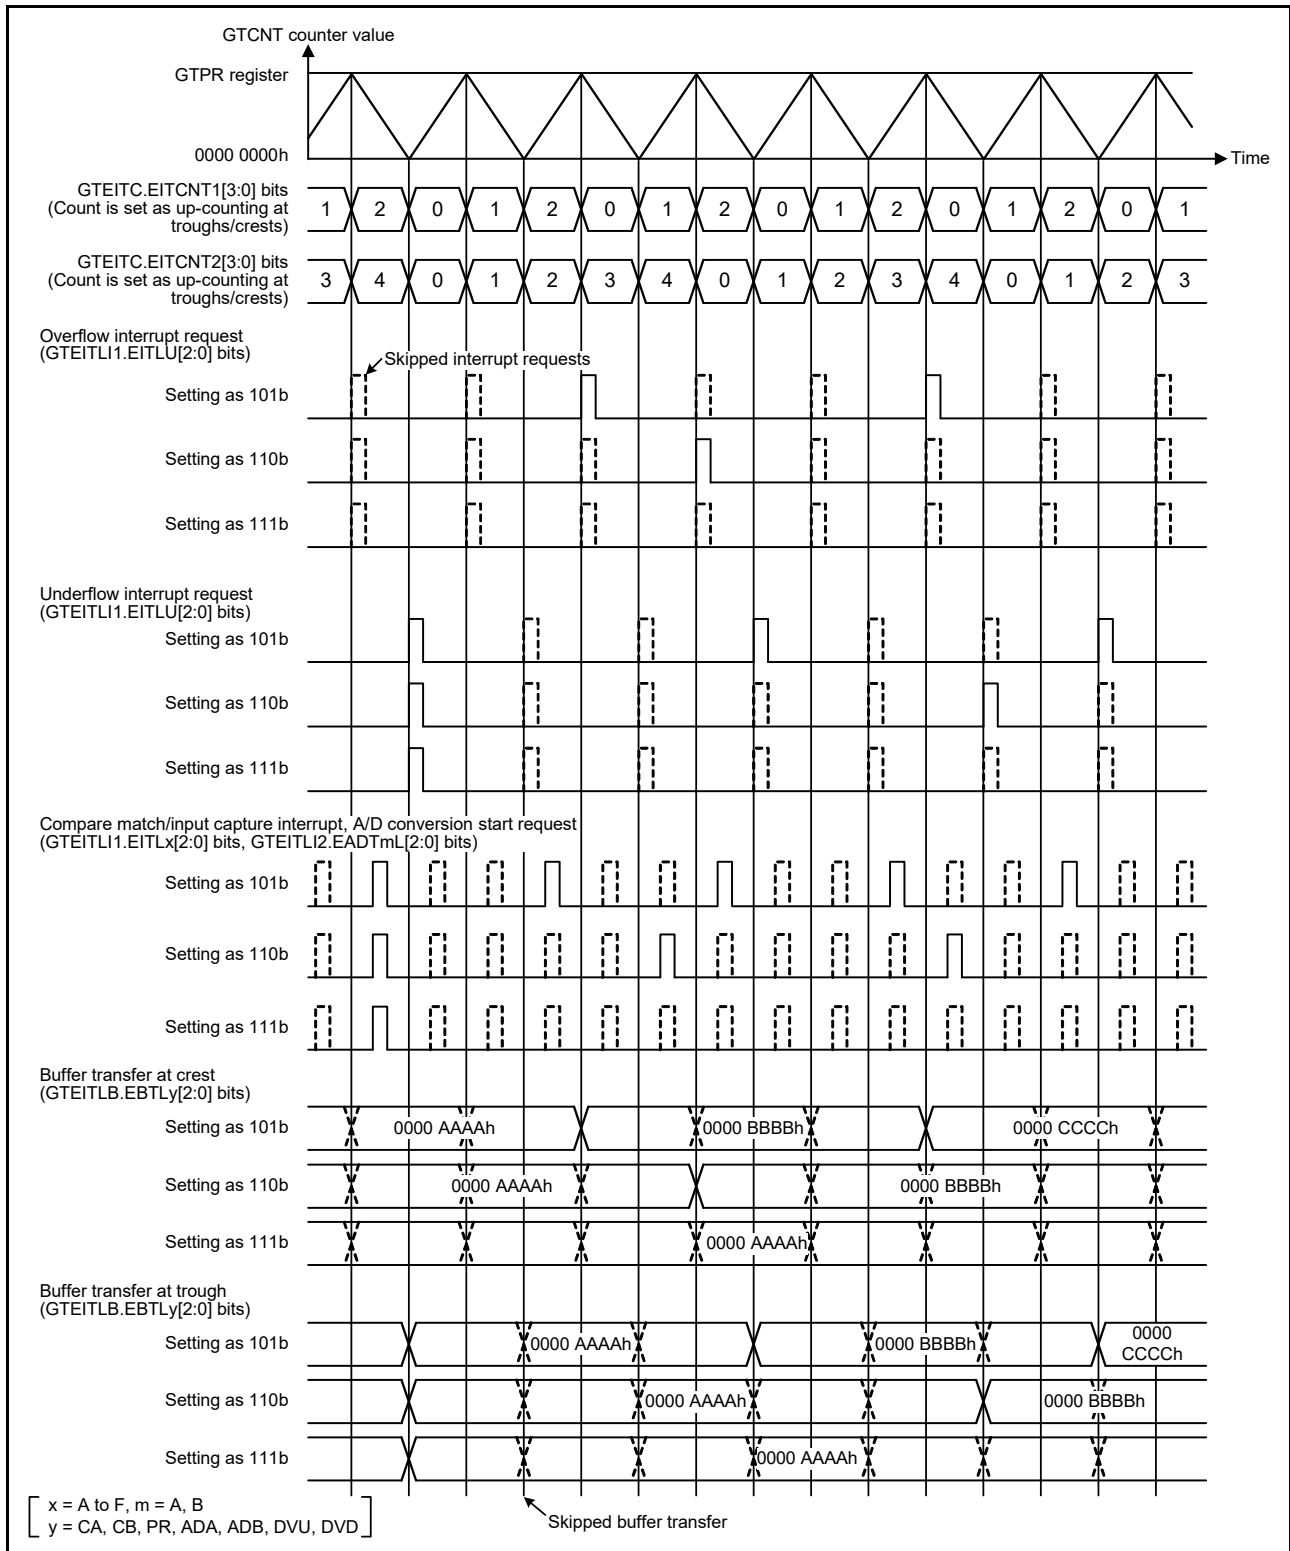

**Figure 24.107 Example of Extended Interrupt Skipping Function Operation**  
**(Triangle Waves, Counting Crests, Extended Interrupt Skipping 1 Skipping Count: 1, Counting Crests, Extended Interrupt Skipping 2 Skipping Count: 2, Extended Interrupt Skipping Counter 2 Initial Value: 0, Skipped in the Period other than GTEITC.EITCNTk bits (k = 1, 2) as 0)**

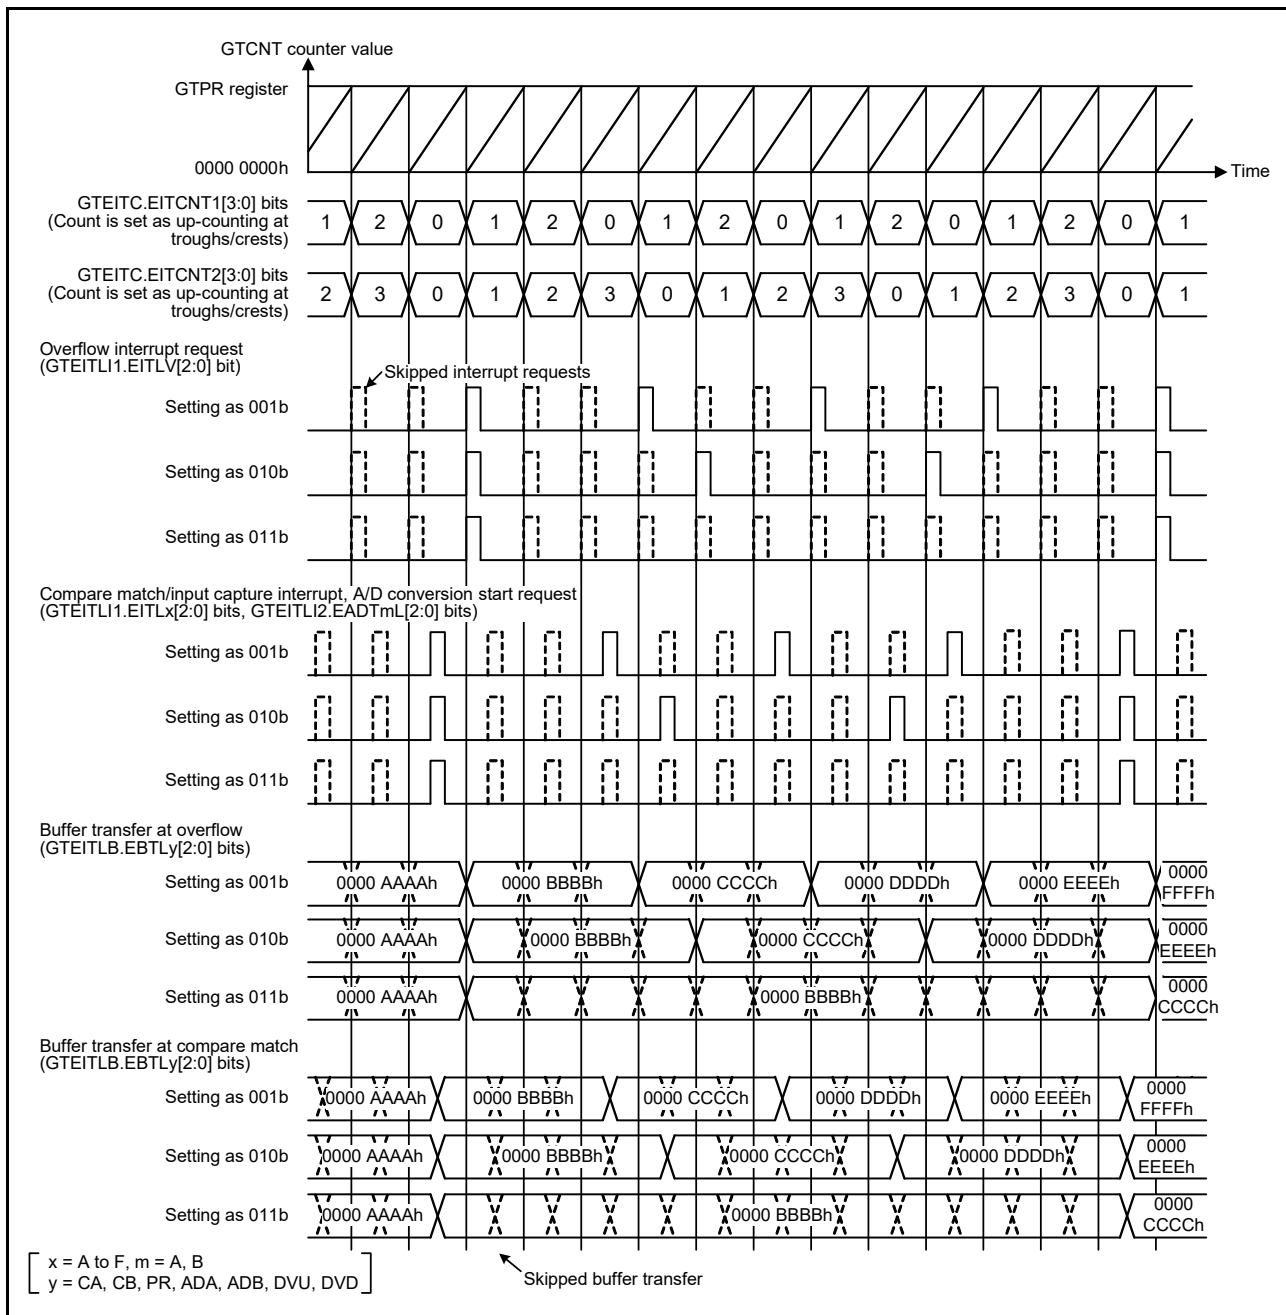

**Figure 24.108 Example of Extended Interrupt Skipping Function Operation**  
 (Triangle Waves, Counting Crests, Extended Interrupt Skipping 1 Skipping Count: 1, Counting Crests, Extended Interrupt Skipping 2 Skipping Count: 2, Extended Interrupt Skipping Counter 2 Initial Value: 0, Skipped in the Period other than GTEITC.EITCNTk bits (k = 1, 2) as GTEITC.EIVTTk bit.)

**Figure 24.109 Example of Extended Interrupt Skipping Function Operation**  
 (Triangle Waves, Counting both Crests and Troughs, Extended Interrupt Skipping 1 Skipping Count: 2, Counting both Crests and Troughs, Extended Interrupt Skipping 2 Skipping Count: 4, Extended Interrupt Skipping Counter 2 Initial Value: 0, Skipped in the Period other than GTEITC.EITCNTk bits (k = 1, 2) as 0)

**Figure 24.110 Example of Extended Interrupt Skipping Function Operation**  
 (Triangle Waves, Counting both Crests and Troughs, Extended Interrupt Skipping 1 Skipping Count: 2, Counting both Crests and Troughs, Extended Interrupt Skipping 2 Skipping Count: 4, Extended Interrupt Skipping Counter 2 Initial Value: 0, Skipped in the Period other than GTEITC.EITCNTk bits (k = 1, 2) as GTEITC.EIVTTk bit.)

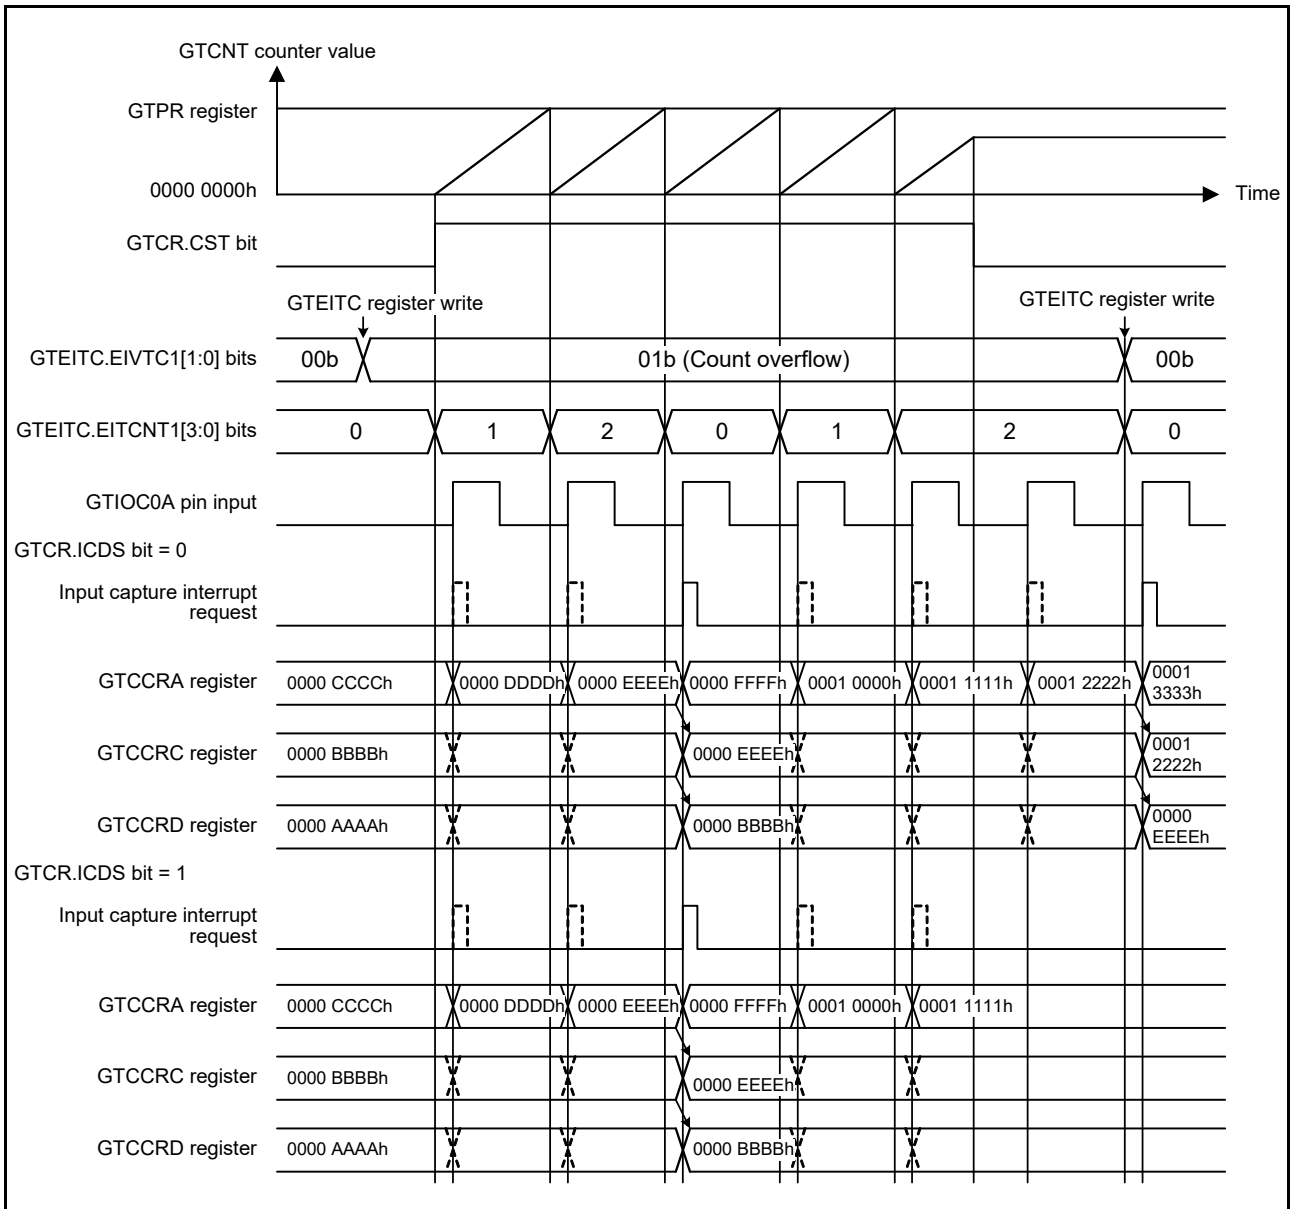

**Figure 24.111 Example of Extended Interrupt Skipping Function Operation**  
**(Up-Counting in Sawtooth Waves, Counting Overflow, Extended Interrupt Skipping 1 Skipping Count: 2, Counting Overflow, Extended Interrupt Skipping 2 Skipping Count: 3, Extended Interrupt Skipping Counter 2 Initial Value: 0, Skipped in the Period other than GTEITC.EITCNTk bits (k = 1, 2) as 0)**

**Figure 24.112 Example of Extended Interrupt Skipping Function Operation (Up-Counting Sawtooth Waves, Counting Overflow, Extended Interrupt Skipping 1 Skipping Count: 2, Counting Overflow, Extended Interrupt Skipping 2 Skipping Count: 3, Extended Interrupt Skipping Counter 2 Initial Value: 0, Skipped in the Period other than GTEITC.EIVTTk bits (k = 1, 2) as GTEITC.EIVTTk bit.)**

Figure 24.113 shows an example of the extended interrupt skipping operation on the input capture. When the setting is for the input capture operation setting (GTCR.ICDS bit = 0) at count stop of the GTCNT counter, the interrupt by the input capture and the extended skipping on buffer transfer is enabled even at count stop of the GTCNT counter. When the input capture is generated at count stop of the GTCNT counter by setting the ICDS bit as 0, an interrupt and a buffer transfer are skipped if the skipping counter value is the same with the skipping period set in a corresponding interrupt function select bit.

**Figure 24.113 Example of Input Capture Operation in the Extended Interrupt Skipping Function Operation (Up-Counting Sawtooth Waves, Counting Overflow, Extended Interrupt Skipping 1 Skipping Count: 2, Skipped in the Period other than the EITCNT1 as 0, Input Capture at the Input Rising)**

Figure 24.114 shows an example for setting the extended interrupt skipping.

The extended interrupt skipping counter 2 initial value is set by the written value to the ETICNT2IV[3:0] bits which is applied to change the setting from not counting the extended interrupt skipping counter 2 count source (GTEITC.EIVTC2[1:0] bits = 00b) to counting (EIVTC2[1:0] bits = other than 00b). Writing to the extended interrupt skipping counter 2 initial value bit (ETICNT2IV[3:0] bits) is performed only when the setting of the above mentioned extended interrupt skipping counter 2 initial value is written.

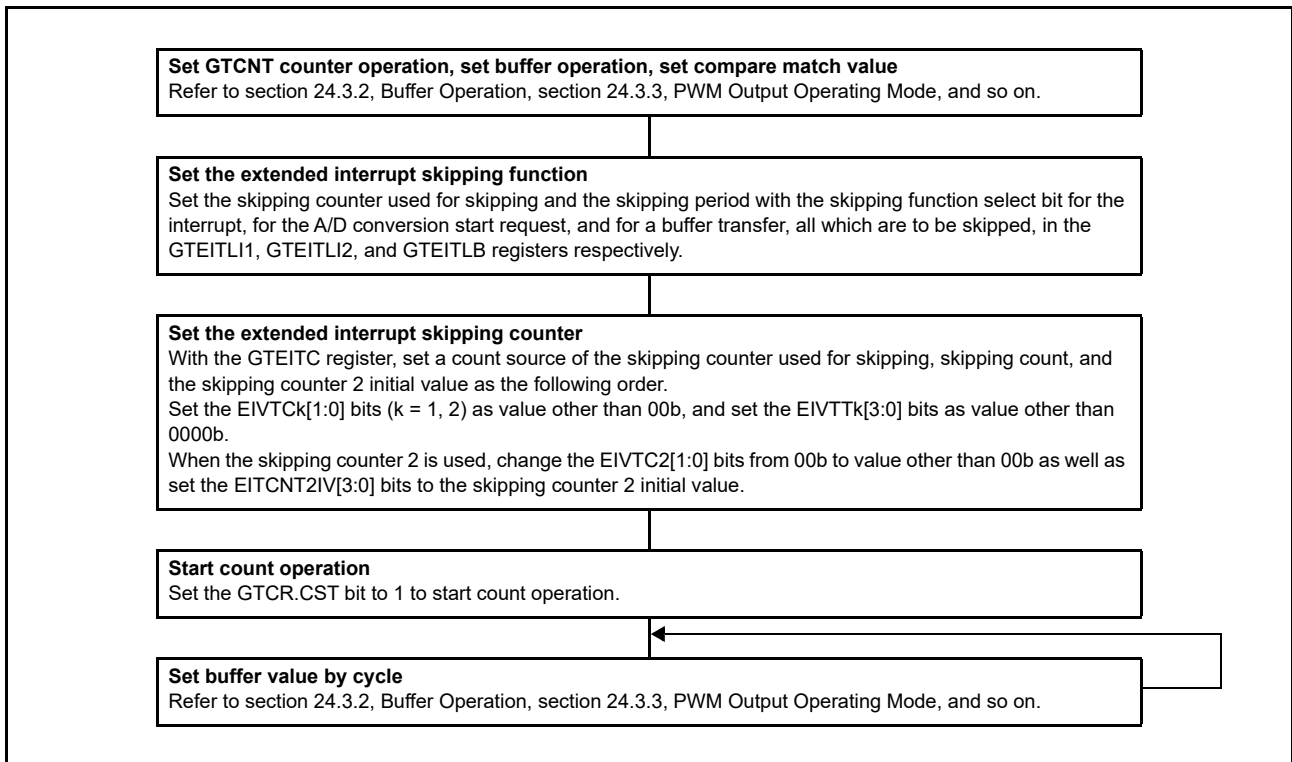

Figure 24.114 Example for Setting the Extended Interrupt Skipping

## 24.5 A/D Conversion Start Request

An A/D conversion start request can be issued at a compare match between the GTCNT counter and the GTADTRA or GTADTRB register, up-counting only, down-counting only, or both up-counting and down-counting can be specified by setting the GTINTAD register.

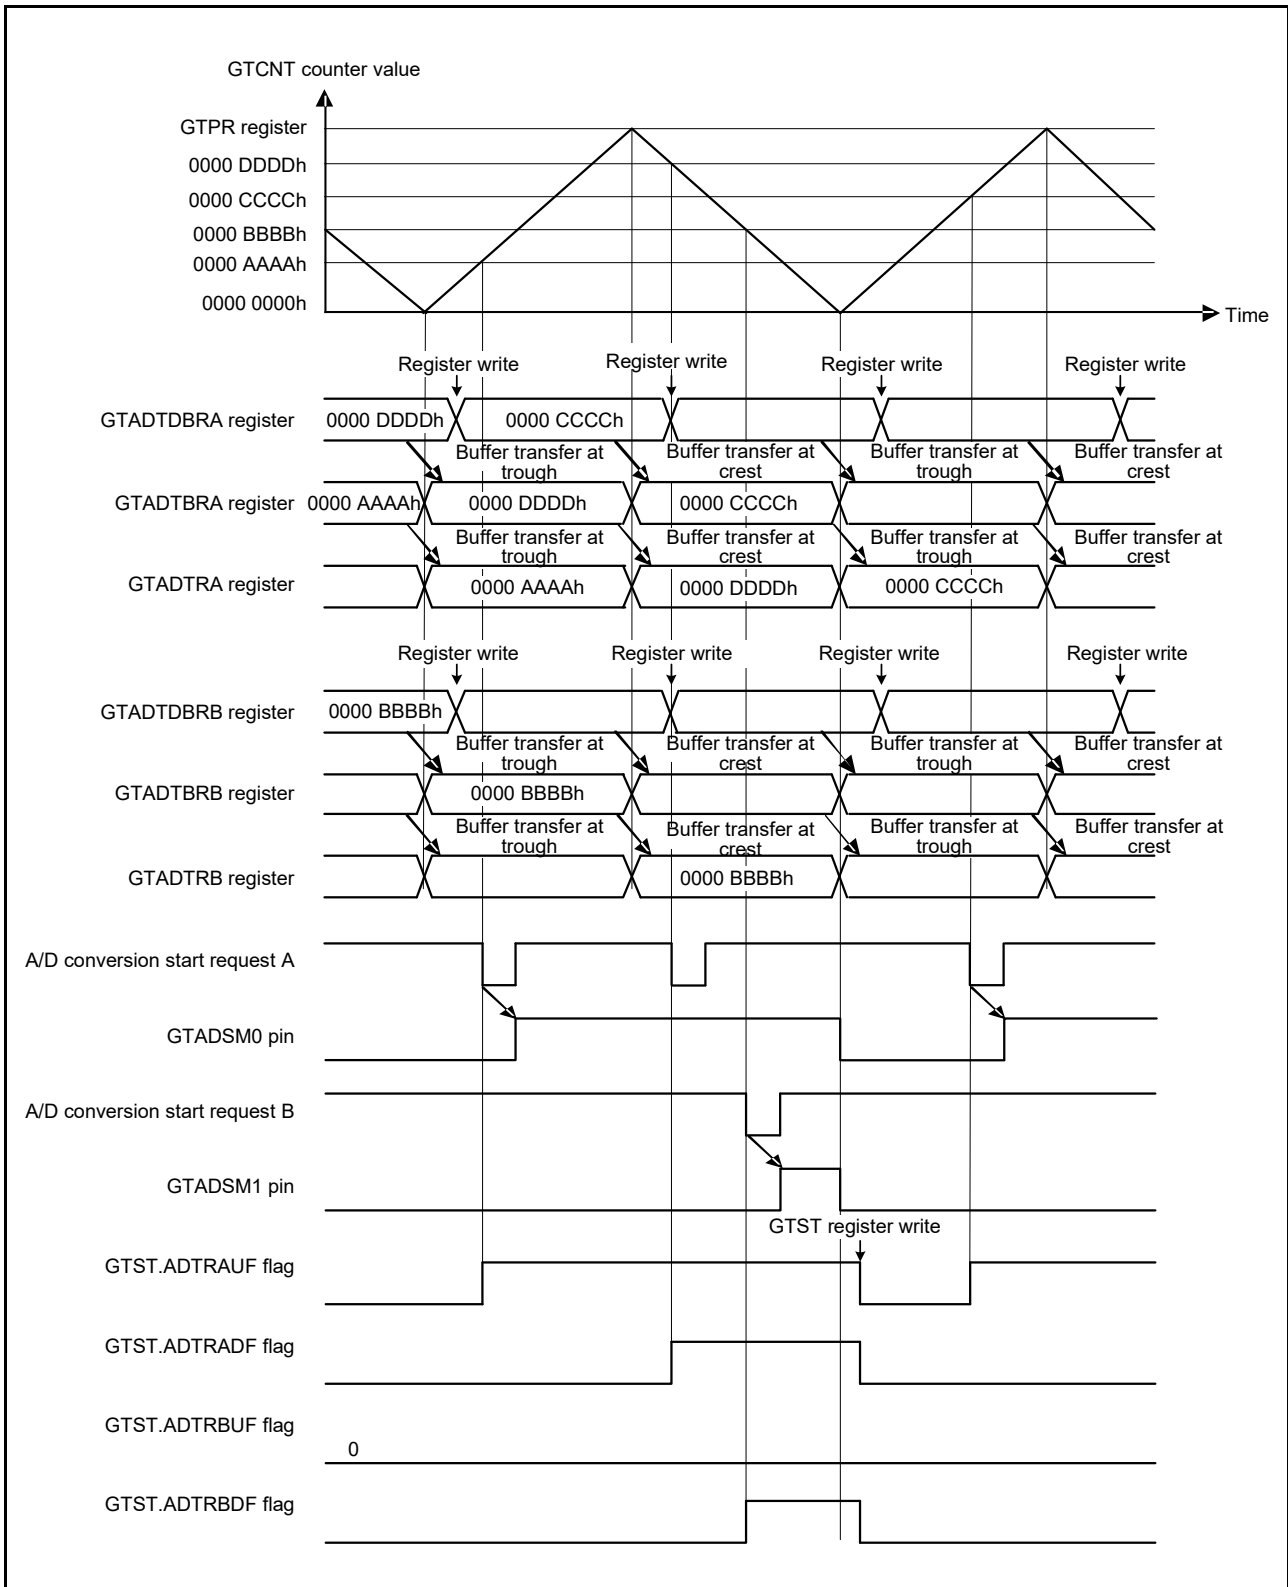

During event count operation, the A/D conversion start request cannot be generated.

The A/D conversion start request is not directly output to the A/D converter, but an event signal to the ELC are output. The GTADTRA and GTADTRB registers each has two buffer registers. Buffer operation with the GTADTRA register used together with the GTADTBRA and GTADTDBRA registers, and buffer operation with the GTADTRB register used together with the GTADTBRB and GTADTDBRB registers can be performed.

The timing of the generation of requests to start A/D conversion can be monitored by an external pin. When the A/D conversion start request signal to be monitored is selected in the GTADSMR.ADSMSk bit ( $k = 0, 1$ ) and when the output is enabled in the ADSMENk bit, a signal is output synchronized with a cycle frame of the timer used to generate the A/D conversion start request signal, of which the output is driven high at the generation of the A/D conversion start request signal by the GTADSMk pin, or at the end of the cycle of which the output is driven low. When a signal to request the start of A/D conversion is generated at the end of the cycle, the generation of this signal has priority in terms of monitoring output and the output remains at the high level till the end of the next cycle. The registers (GTADTRA and GTADTRB) that are sources of generating the A/D conversion start request signals and their counting directions can be checked by the A/D conversion start request flags (ADTRAUF, ADTRADF, ADTRBUF, and ADTRBDF) in the GTST register. When the output of the same A/D conversion start request signal monitoring output is enabled for multiple channels, ORed signals will be output from the GPTW.

Figure 24.115 shows an example of A/D conversion start request operation, Figure 24.116 shows an example for setting A/D conversion start request operation, and Figure 24.117 shows an example for A/D conversion start request timing operation.

Figure 24.117 shows an example of the output of A/D conversion start request A by the ELC as start source 0 for the A/D converter. The A/D conversion start request A signal is output by the ELC in response to a match in comparison with the GTADTRA register. The A/D conversion start request A signal is synchronized with PCLKC. The ELC receives the signal in synchronization with PCLKB, and then outputs the A/D conversion start source 0 signal after 1 cycle of the PCLKB has elapsed.

**Figure 24.115 Example of A/D Conversion Start Request Timing Operation**  
 (Triangle Waves, Double Buffer Operation, Buffer Transfer at Both Troughs and Crests, A/D Conversion Start Requested by GTADTRA Register at Both Up-Counting and Down-Counting, A/D Conversion Start Requested by GTADTRB Register at Down-Counting, Monitoring of the GTADTRA Register Up-Counting by the GTADSM0 Pin, Monitoring of the GTADTRB Register Down-Counting by the GTADSM1 Pin)

**Figure 24.117 Example of A/D Conversion Start Request Timing Operation**

## 24.6 Operations Linked by the ELC

### 24.6.1 Event Signal Output to the ELC

GPTW is capable of operation linked with another module set in advance when its interrupt request signal is used as an event signal by the event link controller (ELC).

The event signal can be output regardless of the setting of the corresponding interrupt request enable bits except the A/D conversion start request.

The A/D conversion start request during up-counting/down-counting can be enabled/disabled individually with the A/D conversion start request enable bit to output to the ELC.

Each GPTW channel has the following 10 event signals for output to the ELC. A dead time error interrupt does not have a corresponding event signal.

- Generation of compare match A interrupt
- Generation of compare match B interrupt
- Generation of compare match C interrupt
- Generation of compare match D interrupt
- Generation of compare match E interrupt
- Generation of compare match F interrupt
- Generation of overflow interrupt
- Generation of underflow interrupt
- Generation of A/D conversion start request A
- Generation of A/D conversion start request B

### 24.6.2 GPTW Operations in Response to Receiving Event Signals from the ELC

The GPTW can perform the following operations by the signals for sources A to H which are output from the ELC. Each signal is provided to all channels. Select an event source for a desired operation by a relevant source select register in a channel.

- Operation of count start/count stop/counter clearing
- Operation of up-counting/down-counting
- Operation of input capture A and B

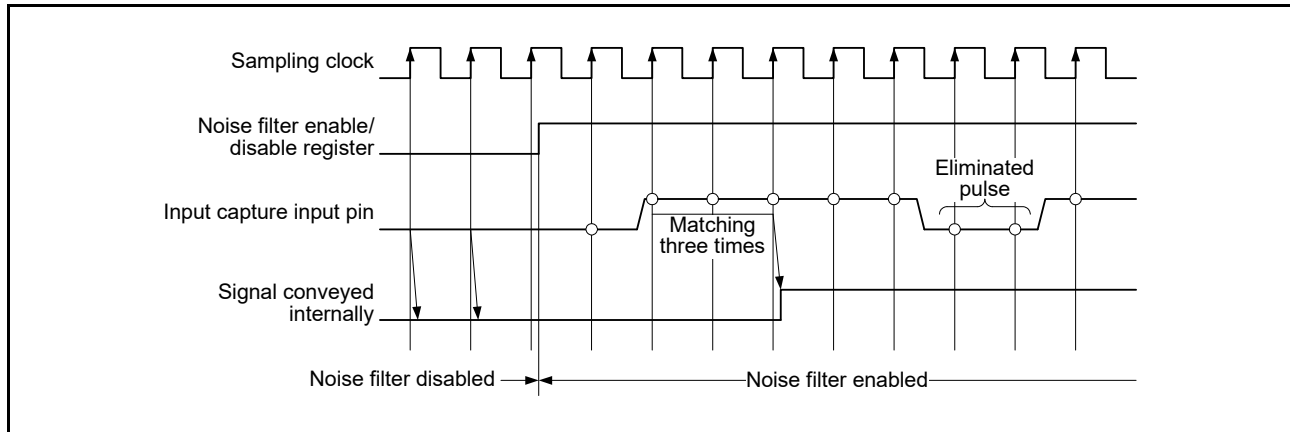

Refer to operation by hardware sources in section 24.3.1.1, Counter Operation for respective operations.

## 24.7 Noise Filter Function

Each pin for use in input capture to the GPTW is equipped with a noise filter. The noise filter samples input signals at the sampling clock and removes the pulses of which length is less than three sampling periods.

The noise filter functionality includes enabling and disabling of the noise filter for each pin and setting of the sampling clock for each channel.

Figure 24.118 shows the timing of noise filtering.

**Figure 24.118 Timing of Noise Filtering**

If noise filtering is enabled, input capture operation is performed on the edges of noise-filtered signal after a delay of (minimum sampling interval  $\times$  2 + PCLKC) due to noise filtering for the input capture input.

## 24.8 Protection Function

### 24.8.1 Write-Protection for Registers

In order to avoid incorrect writing to registers, write access to registers can be enabled or disabled per channel by setting the GTWP.WP bit for the given channel.

The WP bits enable or disable writing to the registers are listed below.

GTSSR, GTPSR, GTCSSR, GTUPSR, GTDNSR, GTICASR, GTICBSR, GTCR, GTUDDTYC, GTIOR, GTINTAD, GTST, GTBER, GTITC, GTCNT, GTCCRA, GTCCRB, GTCCRC, GTCCRD, GTCCRE, GTCCRF, GTPR, GTPBR, GTPDBR, GTADTRA, GTADTBRA, GTADTDBRA, GTADTRB, GTADTBRB, GTADTDBRB, GTDTCR, GTDVU, GTDVD, GTDBU, GTDBD, GTSOS, GTSOTR, GTADSMR, GTEITC, GTEITLI1, GTEITLI2, GTEITLB

Every bit in registers GTSTR, GTSTP, and GTCLR, which can update the corresponding registers in other channels and can be updated by any of the corresponding registers in other channels conversely, can be protected by setting the GTWP.STRWP, STWP, and CLRWP bits, respectively, per channel.

Likewise, writing to the GTSECSR and GTSECR registers, which can control all channels by writing to the GTSECSR and GTSECR registers of a given channel, can be enabled or disabled by the setting of the GTWP.CMNWP bit.

Protection by the GTWP register only targets writing operation by the CPU. Updating the register generated in related to the CPU writing is not protected.

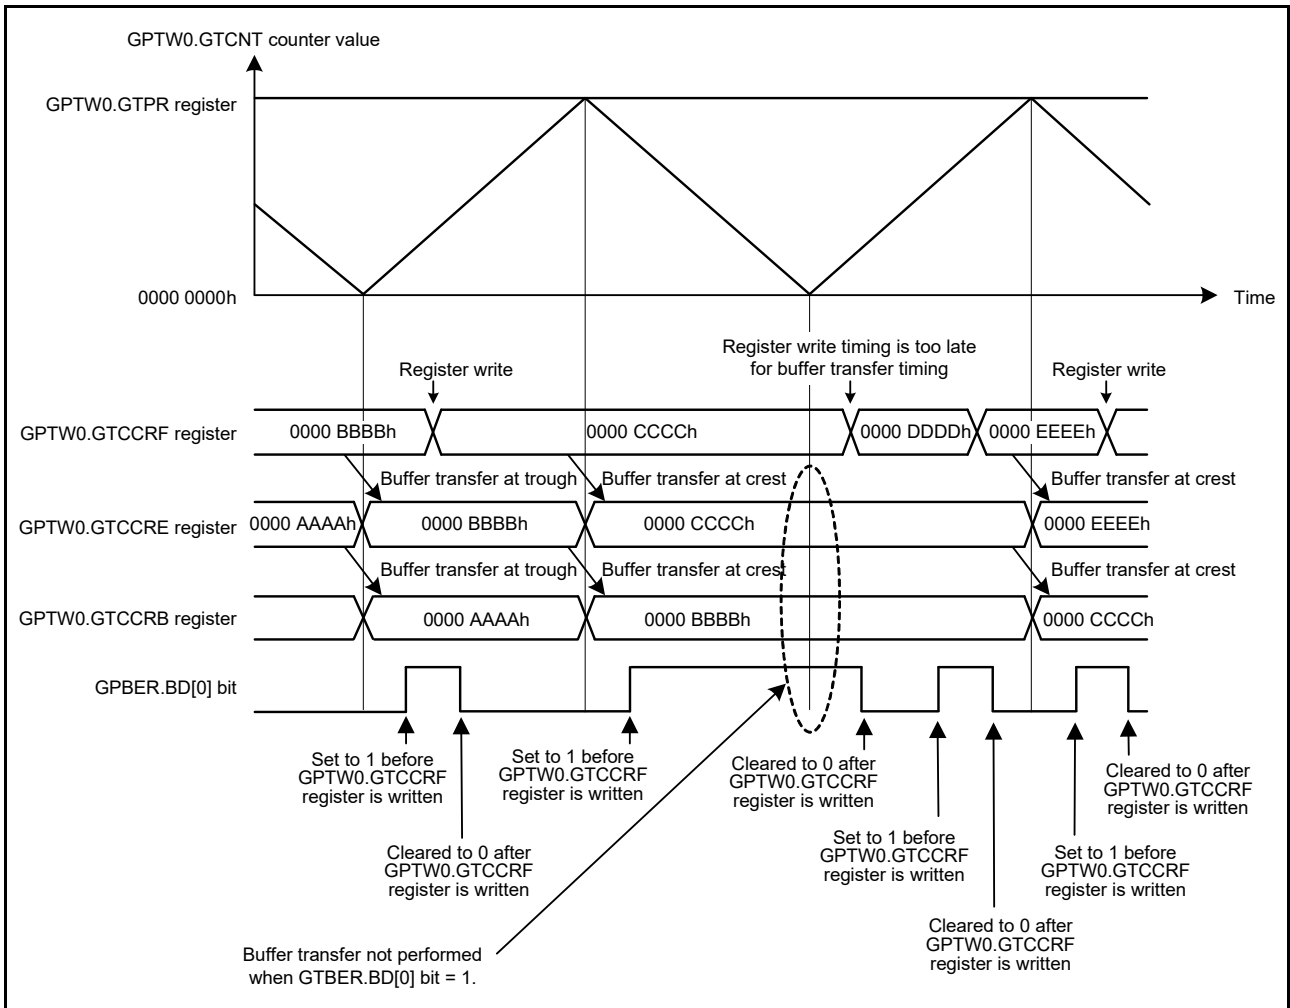

### 24.8.2 Disabling of Buffer Operation

If the timing of buffer register write is too late for the buffer transfer timing, buffer operation can be suspended with setting the BD[0], BD[1], BD[2], and BD[3] bits in the GTBER register.

Specifically, buffer transfer can be temporarily disabled, even though a buffer transfer condition is generated during buffer register write, by setting the BD[0], BD[1], BD[2], and BD[3] bits to 1 (buffer operation disabled) before buffer register write, and setting the bits to 0 (buffer operation enabled) after completion of writing to all the buffer registers.

The BD[0], BD[1], BD[2], and BD[3] bits can be set on channel basis by writing directly to the GTBER register or can be set simultaneously by setting the GTSECR register for multiple channels which were set by the GTSECSR register.

Figure 24.119 shows an example of operation for disabling buffer operation.

**Figure 24.119 Example of Operation for Disabling Buffer Operation (Triangle Waves, Double Buffer Operation, Buffer Transfer at Both Troughs and Crests)**

### 24.8.2.1 Simultaneous Control of Buffer Operations of Multiple Channels

The GTBER.BD bit can be set by writing directly to the GTBER register per channel or by making settings in the GTSECR register for multiple channels that have already set in the GTSECSR register.

Follow the procedure below to simultaneously set the GTBER.BD bits of multiple channels.

#### (1) Select the channels for simultaneously setting of the GTSECSR register

Set the GTSECSR register so that the values at the bit positions for the corresponding channels for simultaneously setting of the GTBER.BD bits become 1. All GTSECSR registers can be updated by writing to the GTSECSR register of any channel.

#### (2) Simultaneously set the GTBER.BD bits by updating the GTSECR register

In the GTSECR register, set the operation of the GTBER.BD bits (enabling or disabling of buffer operation) which are to be simultaneously set. Writing to a GTSECR register from any channel updates the GTBER.BD bits in all channels corresponding to the bits set as 1 in the GTSECSR register, in accordance with the value of the GTSECR register. Figure 24.120 shows an example of simultaneously controlling the enabling or disabling of buffer operation for multiple channels.

Figure 24.120 Example of Multiple Channel Operation for Disabling Buffer Operation (Triangle Waves, Double Buffer Operation)

### 24.8.2.2 Repeated Double-Buffered Operation When Disabling GTCCR Buffer Transfer

When a GTBER.DBRTEC<sub>m</sub> (m = A, B) bit is set to 1 in sawtooth-wave one-shot pulse mode or triangle-wave PWM mode 3, transfer from the intermediate buffer to the GTCCR<sub>m</sub> (m = A, B) register is repeated on a cyclic basis even while buffer transfer is disabled by the setting of the GTBER.BD[0] bit or by the buffer transfer extended skipping function.

#### (1) In sawtooth-wave one-shot pulse mode

In sawtooth-wave one-shot pulse mode, the compare match value for the first half of a waveform is stored in temporary register x (x = C, E) as the intermediate buffer for the GTCCR<sub>x</sub> (x = C, E) register and the compare match value for the second half of a waveform is stored in temporary register m (m = A, B) as the intermediate buffer for the GTCCR<sub>y</sub> (y = D, F) register, respectively, for compare match values during repeated buffer operation, and the given values are alternately transferred to the GTCCR<sub>m</sub> (m = A, B) registers.

Table 24.22 lists the types of buffer transfer of the GTCCR register during counting in sawtooth-wave one-shot pulse mode. While counting is stopped, the setting of the value in the temporary register is transferred through forcible buffer transfer.

In forcible buffer transfer, the values of the GTCCR<sub>y</sub> (y = D, F) registers are transferred to temporary registers m (m = A, B), and the values of the GTCCR<sub>x</sub> (x = C, E) are transferred to temporary registers x (x = C, E), when the setting of the corresponding GTBER.DBRTEC<sub>m</sub> (m = A, B) bit is 1, respectively.

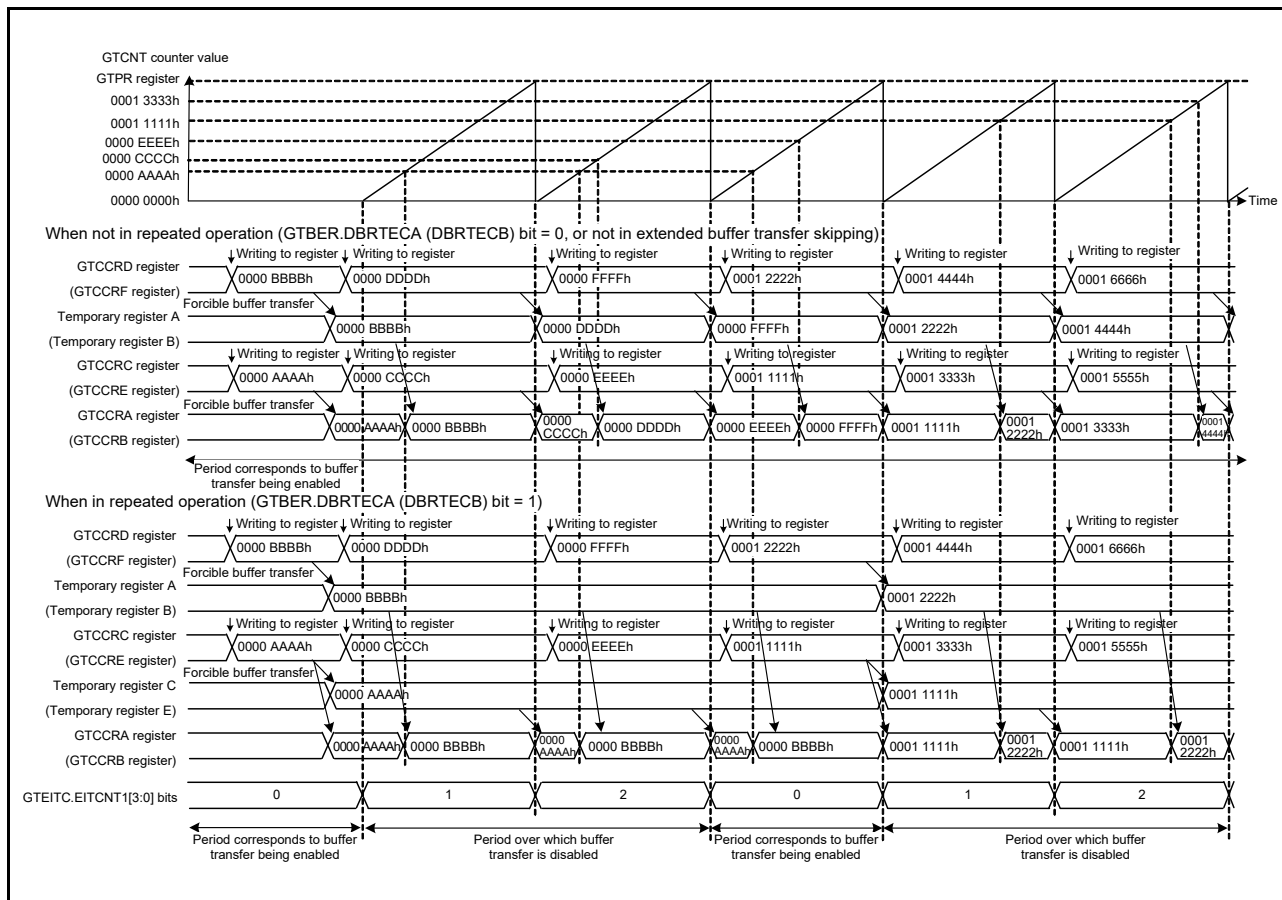

When the setting of the GTBER.DBRTEC<sub>m</sub> (m = A, B) bit is 1, values written by the CPU to the GTCCR<sub>m</sub> (m = A, B) registers are reflected as the values of temporary registers x (x = C, E).

**Table 24.22 GTCCR Buffer Operation in Sawtooth-Wave One-Shot Pulse Mode**

| GTBER.DBRTEC <sub>m</sub> | Buffer transfer          | Timing of transfer                            |                                                 |                                                 |                                                 |                                                 |
|---------------------------|--------------------------|-----------------------------------------------|-------------------------------------------------|-------------------------------------------------|-------------------------------------------------|-------------------------------------------------|
|                           |                          | GTCCR <sub>x</sub><br>↓<br>GTCCR <sub>m</sub> | GTCCR <sub>x</sub><br>↓<br>Temporary register x | Temporary register x<br>↓<br>GTCCR <sub>m</sub> | GTCCR <sub>y</sub><br>↓<br>Temporary register m | Temporary register m<br>↓<br>GTCCR <sub>m</sub> |
| 0                         | Transfer-enabled period  | Overflow or underflow                         | No transfer                                     | No transfer                                     | Overflow or underflow                           | GTCCR <sub>m</sub> compare match                |
|                           | Transfer-disabled period | No transfer                                   | No transfer                                     | No transfer                                     | No transfer                                     | No transfer                                     |
| 1                         | Transfer-enabled period  | Overflow or underflow                         | Overflow or underflow                           | No transfer                                     | Overflow or underflow                           | GTCCR <sub>m</sub> compare match                |
|                           | Transfer-disabled period | No transfer                                   | No transfer                                     | Overflow or underflow                           | No transfer                                     | GTCCR <sub>m</sub> compare match                |

Figure 24.121 shows the operation of generating transfer-disabled period by extended buffer transfer skipping as an example of repeated double buffer operations when the GTCCR buffer transfer disabled in sawtooth-wave one-shot pulse mode.

Figure 24.122 shows the operation of generating transfer-disabled period by updating the GTBER.BD[0] bit as an example of repeated double-buffer operations when the GTCCR buffer transfer is disabled in sawtooth-wave one-shot pulse mode.

**Figure 24.121 Example of Repeated Double-Buffer Operation When GTCCR Buffer Transfer is Disabled (Sawtooth-Wave One-Shot Pulse Mode, Using Extended Buffer Transfer Skipping, GTBER.BD[0] is Constantly 0)**

**Figure 24.122 Example of Repeated Double-Buffer Operation When GTCCR Buffer Transfer is Disabled (Sawtooth-Wave One-Shot Pulse Mode, Updating the GTBER.BD[0] Bit)**

## (2) In triangle-wave PWM mode 3

In triangle-wave PWM mode 3, the compare match value for the first half of a waveform is stored in the temporary register  $x$  ( $x = C, E$ ) as the intermediate buffer for the GTCCR $x$  ( $x = C, E$ ) register and the compare match value for the second half of a waveform is stored in temporary register  $m$  ( $m = A, B$ ) as the intermediate buffer for the GTCCR $y$  ( $y = D, F$ ) register, respectively, for compare match values during repeated buffer operation, and the given values are alternately transferred to the GTCCR $m$  ( $m = A, B$ ) register.

Table 24.23 lists the types of buffer transfer of the GTCCR register during counting operation in triangle-wave PWM mode 3.

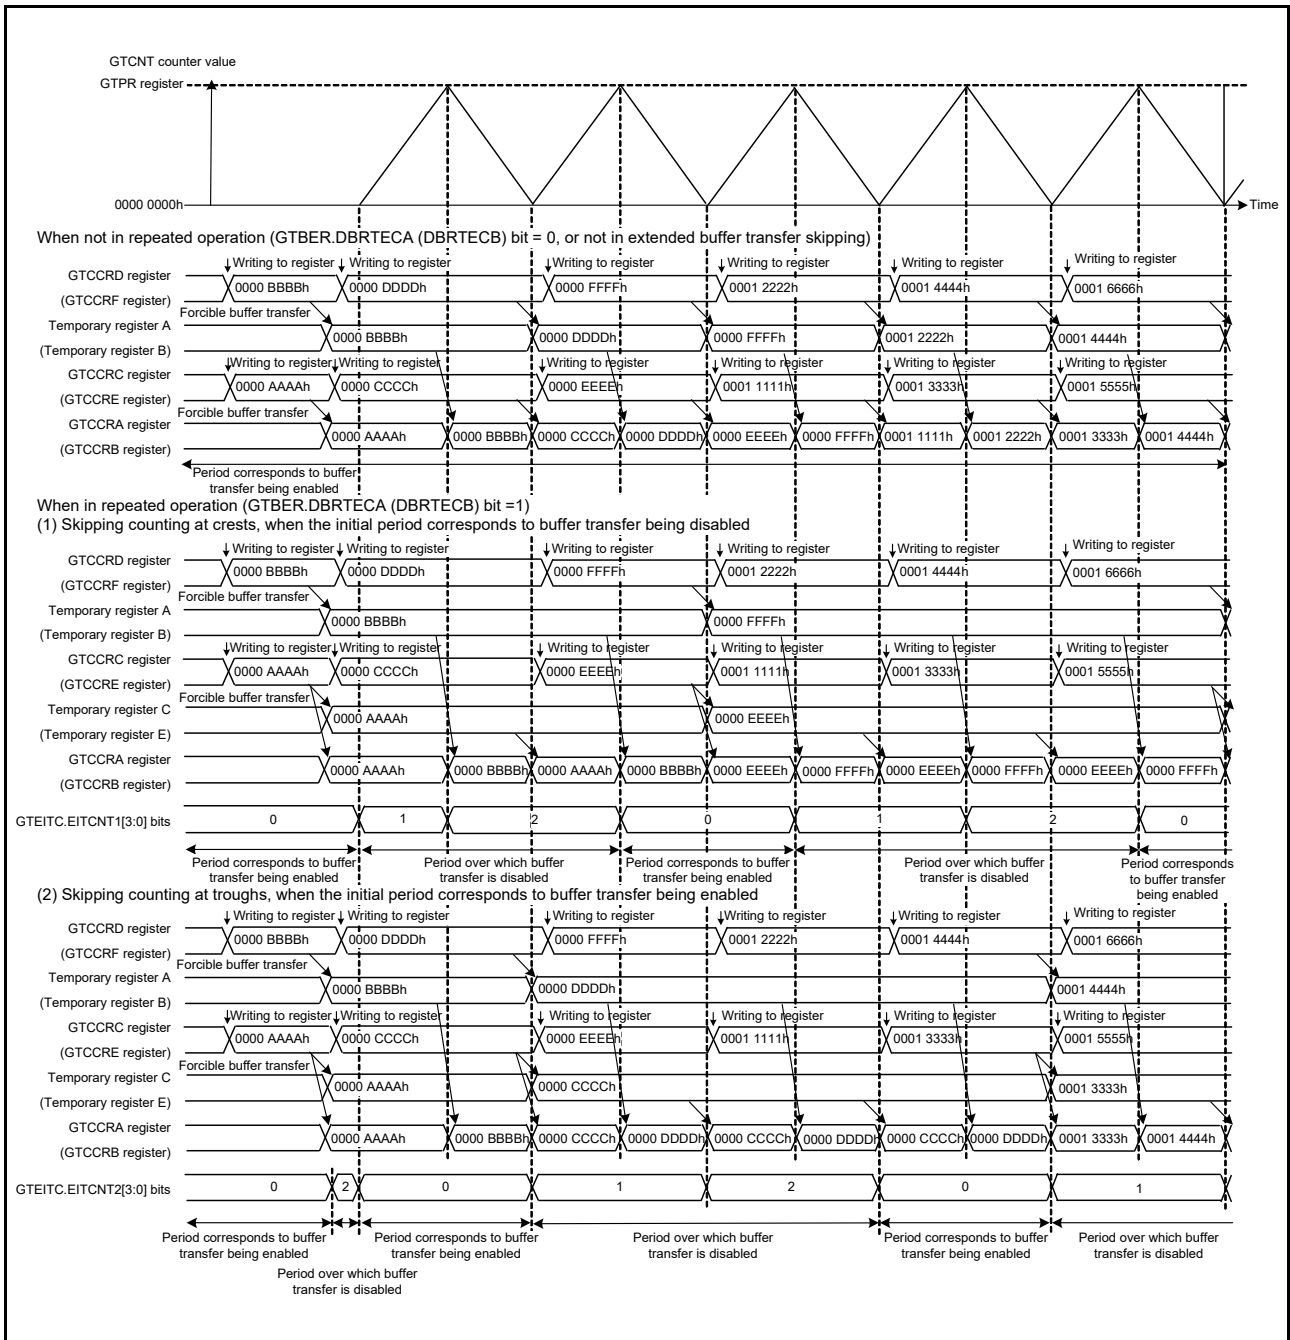

While counting is stopped, the setting of the value in the temporary register is transferred through forcible buffer transfer. In forcible buffer transfer, the values of the GTCCR $y$  ( $y = D, F$ ) registers are transferred to temporary registers  $m$  ( $m = A, B$ ), and the values of the GTCCR $x$  ( $x = C, E$ ) are transferred to temporary registers  $x$  ( $x = C, E$ ), when the setting of the corresponding GTBER.DBRTEC $m$  ( $m = A, B$ ) bit is 1, respectively.

When the setting of the GTBER.DBRTEC $m$  ( $m = A, B$ ) bit is set to 1, values written by the CPU to the GTCCR $m$  ( $m = A, B$ ) registers are reflected as the values of temporary registers  $x$  ( $x = C, E$ ).

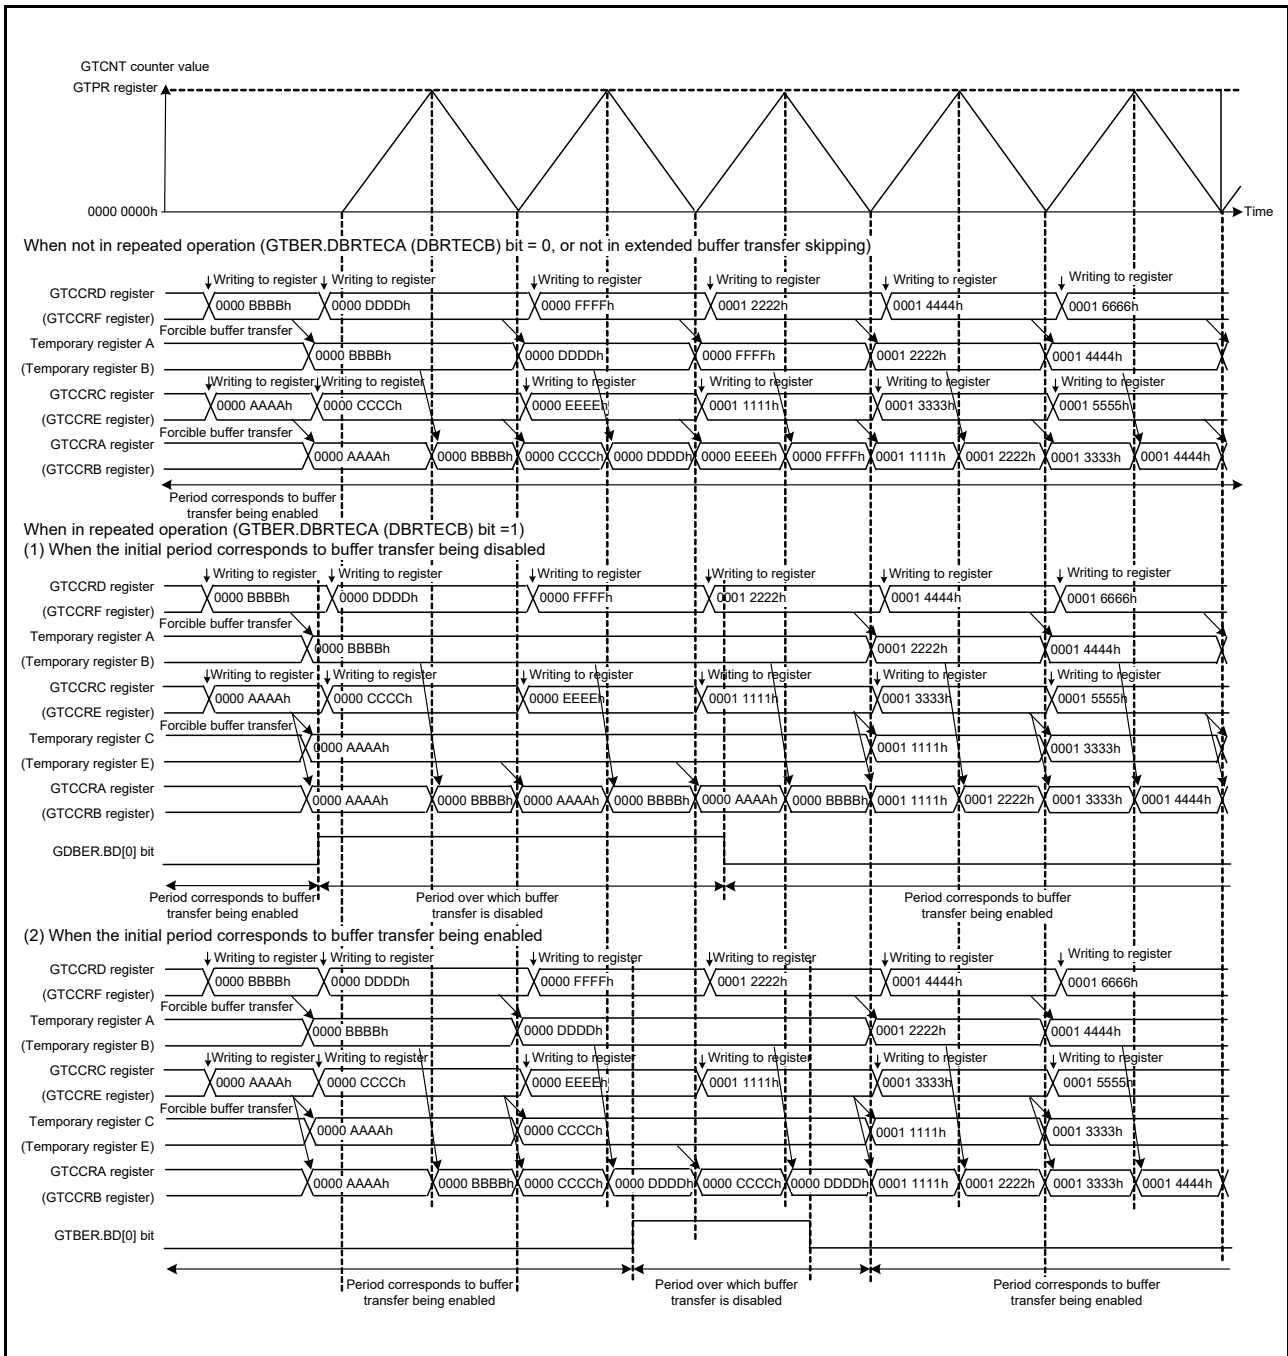

**Table 24.23 GTCCR Buffer Operation in Triangle-Wave PWM Mode 3**

| GTBER.DBRTEC $m$ | Buffer transfer          | Timing of transfer          |                                          |                                          |                                          |                                          |
|------------------|--------------------------|-----------------------------|------------------------------------------|------------------------------------------|------------------------------------------|------------------------------------------|
|                  |                          | GTCCR $x$<br>↓<br>GTCCR $m$ | GTCCR $x$<br>↓<br>Temporary register $x$ | Temporary register $x$<br>↓<br>GTCCR $m$ | GTCCR $y$<br>↓<br>Temporary register $m$ | Temporary register $m$<br>↓<br>GTCCR $m$ |
| 0                | Transfer-enabled period  | Trough                      | No transfer                              | No transfer                              | Trough                                   | Crest                                    |
|                  | Transfer-disabled period | No transfer                 | No transfer                              | No transfer                              | No transfer                              | No transfer                              |
| 1                | Transfer-enabled period  | Trough                      | Trough                                   | No transfer                              | Trough                                   | Crest                                    |
|                  | Transfer-disabled period | No transfer                 | No transfer                              | Trough                                   | No transfer                              | Crest                                    |

Figure 24.123 shows the operation of generating transfer-disabled period by extended buffer transfer skipping as an example of repeated double buffer operations when the GTCCR buffer transfer disabled in triangle-wave PWM mode 3. Figure 24.124 shows the operation of generating transfer-disabled period by updating the GTBER.BD[0] bit as an example of repeated double-buffer operations when the GTCCR buffer transfer is disabled in triangle-wave PWM mode 3.

**Figure 24.123 Example of Repeated Double-Buffer Operation When GTCCR Buffer Transfer is Disabled (Triangle-Wave PWM Mode 3, Using Extended Buffer Transfer Skipping, GTBER.BD[0] is Constantly 0)**

**Figure 24.124 Example of Repeated Double-Buffer Operation When GTCCR Buffer Transfer is Disabled (Triangle-Wave PWM Mode 3, Updating the GTBER.BD[0] Bit)**

### 24.8.3 GTIOCnm Pin Output Negate Control (n = 0 to 9; m = A, B)

For protection from system failure, the output negate control which changes the GTIOCnm pin output forcibly by the output stop request from the POEG is provided.

Output protection is required when a dead-time error or the same output level being on the GTIOCnA and GTIOCnB pins is detected. At that time, the detection of disabling of output is output to the group of the POEG set in the GTINTAD.GRP[1:0] bits based on the setting of the output disable detection enable bits, i.e. the GRPDTE, GRPABH, and GRPABL bits in the GTINTAD register. The POEG takes the logical OR of detection of the types described above and other forms of detection of the disabling of output, and outputs requests for the disabling of output to the GPTW. By setting the GTINTAD.GRP[1:0] bits, one output stop request can be selected out of four output stop requests which are input from the POEG as output stop request signal common in the GTIOCnA and GTIOCnB pins. Selected output stop request can be checked by reading the GTST.ODF flag.

The states of outputs at the time of control for their negation can be set with the GTIOR.OADF[1:0] bits for the GTIOCnA pin and with the GTIOR.OBDF[1:0] bits for the GTIOCnB pin.

Transition to the output negate condition by generating the output stop request from the POEG is performed asynchronously, while a release from the output negate condition by making the output stop request no longer satisfied is performed at the end of the cycle. It is after 3 PCLKC at shortest when the output negate condition is released after the output stop request becomes no longer satisfied. To reliably control output negation, clear the flag of POEG for which the condition for the request to disable the output is no longer satisfied after 4 cycles of PCLKC.

To release the output stop condition during event count operation or without waiting the end of the cycle, set the OADF[1:0] bits to 00b for the GTIOCnA pin, and set the OBDF[1:0] bits to 00b for the GTIOCnB pin.

Figure 24.125 shows the output negate control operation for the GTIOCnm pin output.

**Figure 24.125 Example of Operation for GTIOCnm Pin Output Negate Control (Sawtooth-Wave Up-Counting, Buffer Operation, Active Level: High Output at GTCCRA Register Compare Match, Low Output at the End of the Cycle) and Low Output at Output Negate) (n = 0 to 9; m = A, B)**

### 24.8.4 Output Protection Function for GTIOCn<sub>m</sub> Pin Output (n = 0 to 9; m = A, B)

To prepare for a case when an incorrect value (0000 0000h or a value greater than or equal to the GTPR register value) is set in the GTCCRA register, the output protection function for the GTIOCn<sub>m</sub> pin output (disabling function) is activated when the automatic dead time is set (GTDTCR.TDE bit = 1) in triangle-wave PWM mode.

The status of the output protection function can be read from the GTSOS.SOS[1:0] bits.

Figure 24.126 shows the output protection function state transition.

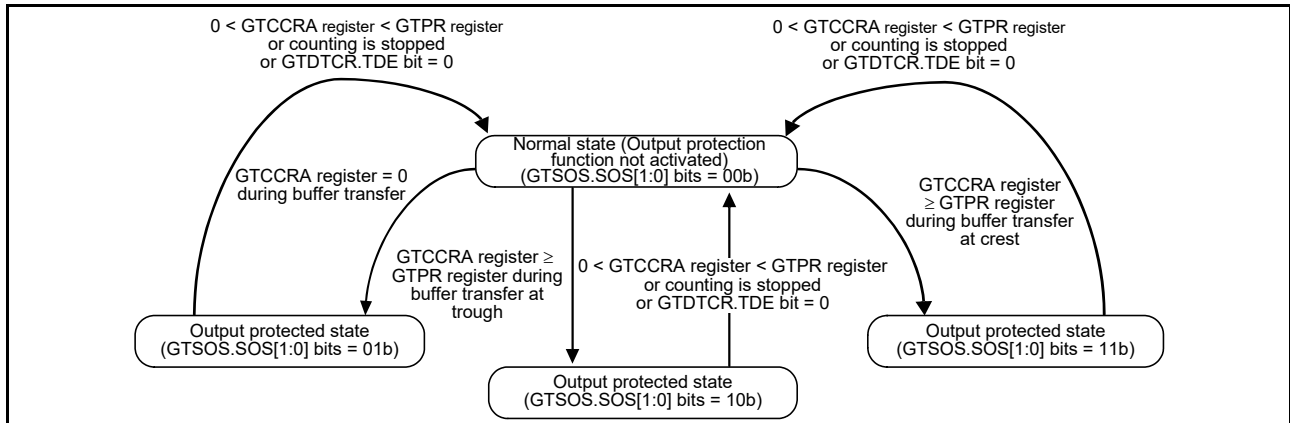

Figure 24.126 Output Protection Function

#### (1) Output Protection Function when the GTCCRA Register is Set to 0000 0000h during Buffer Transfer

Figure 24.127 and Figure 24.128 show examples of output protection function operation when the GTCCRA register is set to 0000 0000h during buffer transfer at troughs, and Figure 24.129 and Figure 24.130 show examples when the GTCCRA register is set to 0000 0000h during buffer transfer at crests.

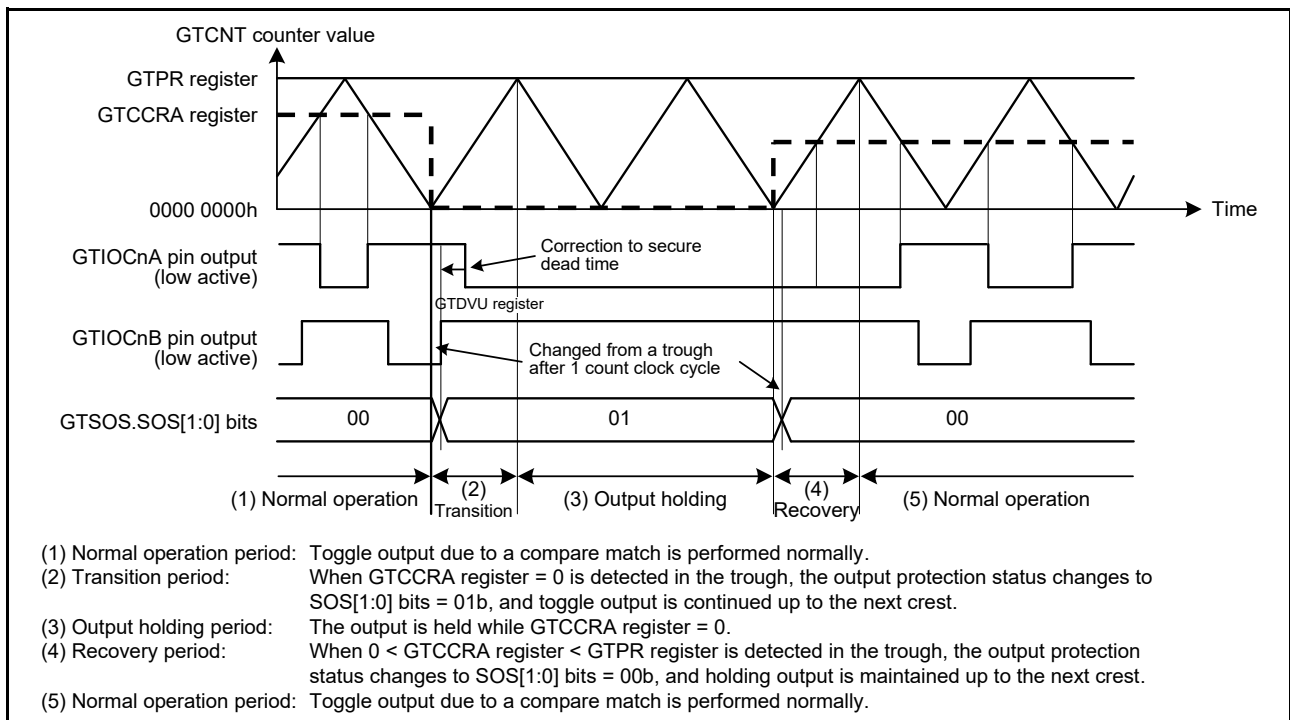

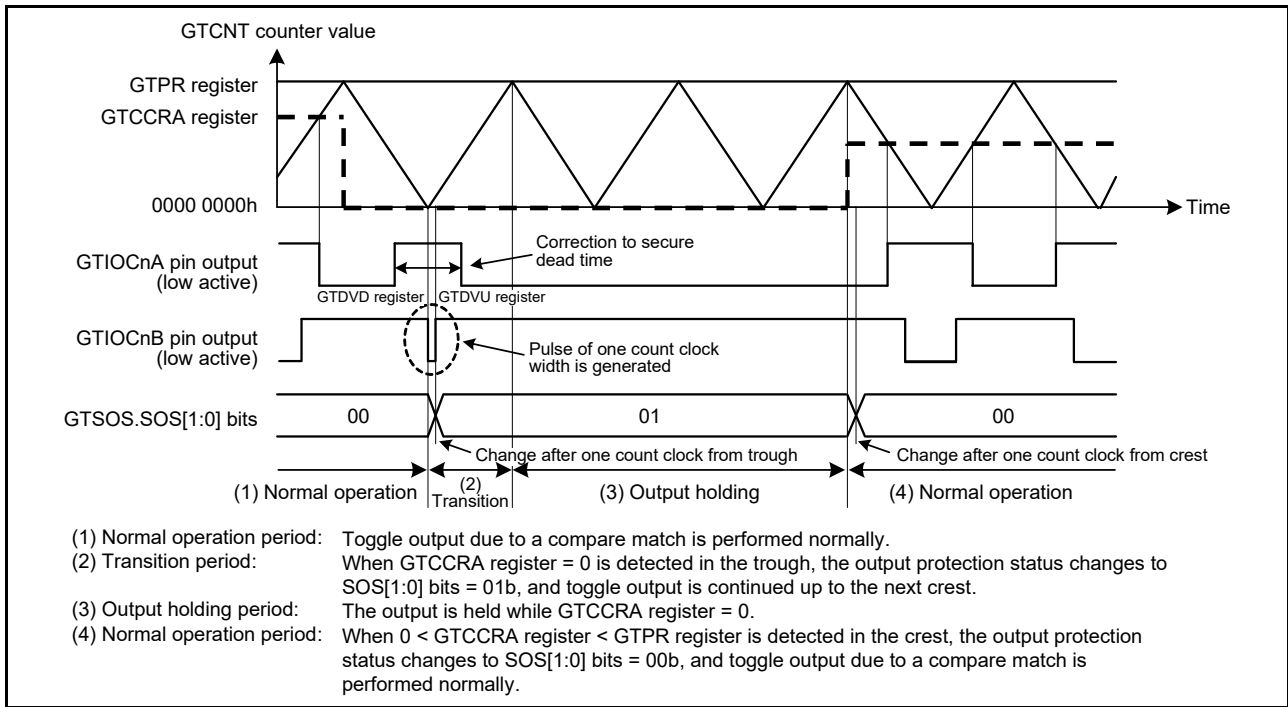

Figure 24.127 Example of Output Protection Function Operation When the GTCCRA Register is Set to 0000 0000h during Buffer Transfer at Troughs (Restored to 0 < GTCCRA Register < GTPR Register during Buffer Transfer at Troughs, Active Level: Low) (n = 0 to 9)

**Figure 24.128 Example of Output Protection Function Operation When the GTCCRA Register is Set to 0000 0000h during Buffer Transfer at Troughs (Restored to 0 < GTCCRA Register < GTPR Register during Buffer Transfer at Crests, Active Level: Low) (n = 0 to 9)**

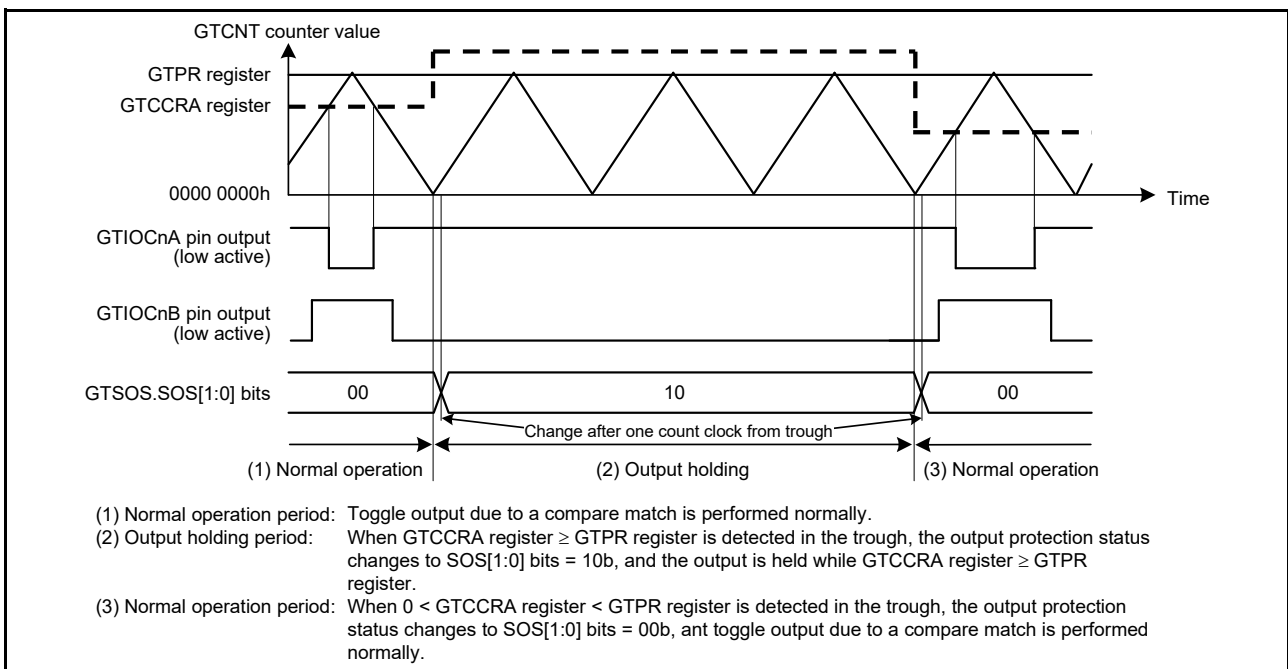

**Figure 24.129 Example of Output Protection Function Operation When the GTCCRA Register is Set to 0000 0000h during Buffer Transfer at Crests (Restored to 0 < GTCCRA Register < GTPR Register during Buffer Transfer at Troughs, Active Level: Low) (n = 0 to 9)**

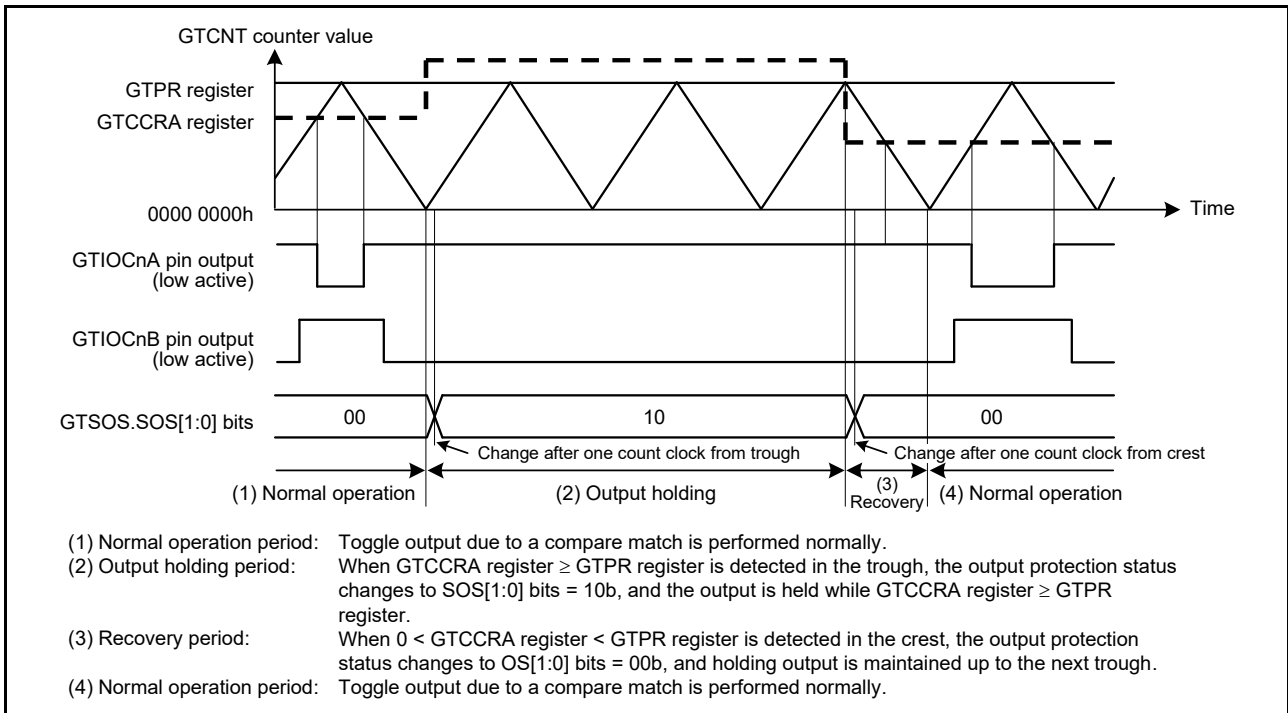

**Figure 24.130 Example of Output Protection Function Operation When the GTCCRA Register is Set to 0000 0000h during Buffer Transfer at Crests (Restored to  $0 < GTCCRA \text{ Register} < GTPR \text{ Register}$  during Buffer Transfer at Crests, Active Level: Low) ( $n = 0$  to  $9$ )**

(2) Output Protection Function when GTCCRA Register  $\geq$  GTPR Register is Set during Buffer Transfer at Troughs

Figure 24.131 and Figure 24.132 show examples of output protection function operation when GTCCRA register  $\geq$  GTPR register is set during buffer transfer at troughs.

**Figure 24.131 Example of Output Protection Function Operation When GTCCRA Register  $\geq$  GTPR Register is set during Buffer Transfer at Troughs (Restored to  $0 < GTCCRA \text{ Register} < GTPR \text{ Register}$  during Buffer Transfer at Troughs, Active Level: Low) ( $n = 0$  to  $9$ )**

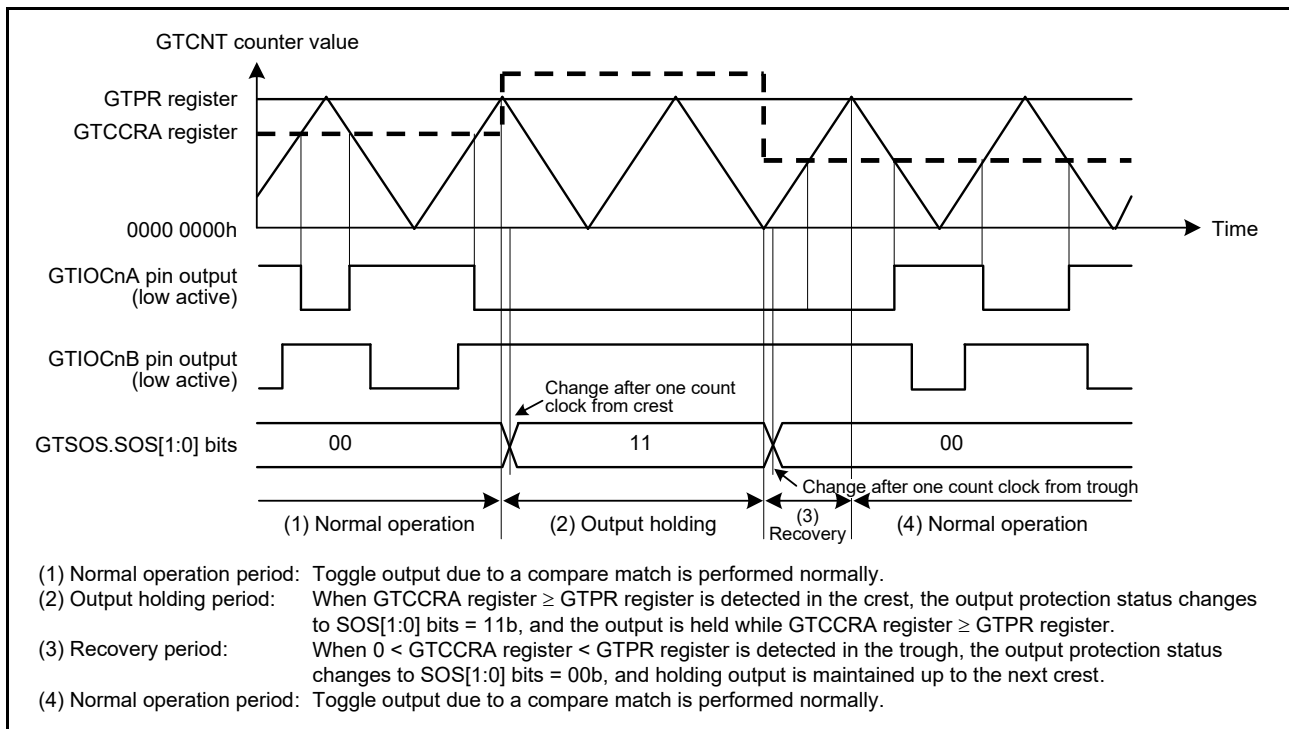

**Figure 24.132 Example of Output Protection Function Operation When GTCCRA Register  $\geq$  GTPR Register is Set during Buffer Transfer at Troughs (Restored to  $0 < GTCCRA \text{ Register} < GTPR \text{ Register}$  during Buffer Transfer at Crests, Active Level: Low) ( $n = 0$  to  $9$ )**

(3) Output Protection Function when GTCCRA Register  $\geq$  GTPR Register is Set during Buffer Transfer at Crests

Figure 24.133 and Figure 24.134 show examples of output protection function operation when GTCCRA register  $\geq$  GTPR register is set during buffer transfer at crests.

**Figure 24.133 Example of Output Protection Function Operation When GTCCRA Register  $\geq$  GTPR Register is Set during Buffer Transfer at Crests (Restored to  $0 < GTCCRA \text{ Register} < GTPR \text{ Register}$  during Buffer Transfer at Crests, Active Level: Low) ( $n = 0$  to  $9$ )**

**Figure 24.134 Example of Output Protection Function Operation When GTCCRA Register  $\geq$  GTPR Register is Set during Buffer Transfer at Crests (Restored to  $0 < GTCCRA \text{ Register} < GTPR \text{ Register}$  during Buffer Transfer at Troughs, Active Level: Low) (n = 0 to 9)**

#### (4) Restricted Specification of Output Protection Function

Even if an incorrect value (0000 0000h or a value greater than or equal to the GTPR register value) is set in the GTCCRA register during count operation, the output protection functions in a specific way such that one of the positive- and negative-phase outputs becomes non-active. However, the output protection does not operate normally.

- When the GTCCRA register value at the start of count operation is greater than 0000 0000h, and less than the setting value of the GTPR register

#### (5) Temporary Release of Output Protection Function

When the  $GTSOS.SOS[1:0] \text{ bits} = 10b$  (protected state in which  $GTCCRA \text{ register} \geq GTPR \text{ register}$  has occurred during transfer at trough), the protected state of the GTIOcNB pin output can be temporarily released by setting the  $GTSOTR.SOTR$  bit to 1. The  $SOS[1:0] \text{ bits}$  retain 10b even if the output protection function is released.

When the  $SOTR$  bit is set to 0, the GTIOcNB pin output protection can be restarted.

Figure 24.135 shows an example of the operation of temporary release of output protection when the setting of the  $GTCCRA \text{ register} \geq GTPR \text{ register}$  during buffer transfer at troughs.

**Figure 24.135 Example of the Operation of Temporary Release of Output Protection When the Setting of the GTCCRA Register  $\geq$  GTPR Register during Buffer Transfer at Troughs (Restored to  $0 < GTCCRA \text{ Register} < GTPR \text{ Register}$  during Buffer Transfer at Troughs, Active Level: Low) (n = 0 to 9)**

## 24.9 Initialization Method of Output Pins

### 24.9.1 Pin Settings after Reset

The GPTW registers are initialized at a reset. Initialize the GPTW for output to the external pins by making the port mode settings and setting the OAE and OBE bits in the GTIOR register, and then start the counter counting.

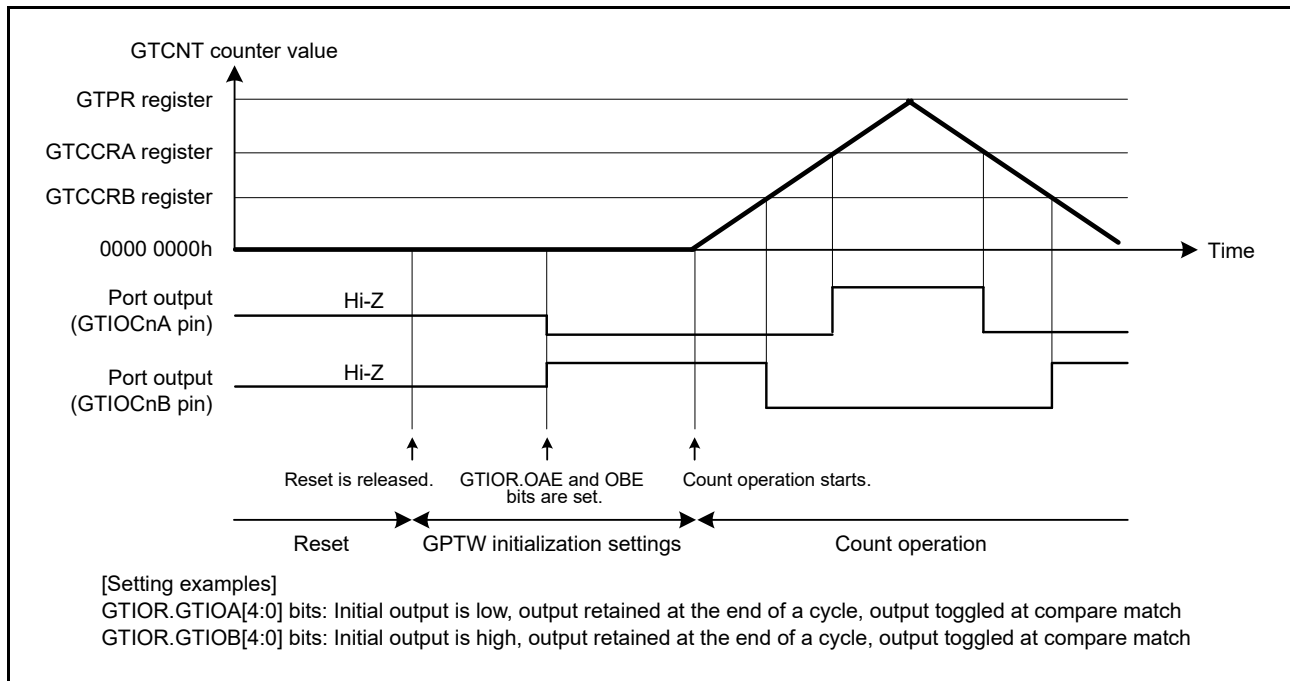

Figure 24.136 Example of Pin Settings after Reset (n = 0 to 9)

### 24.9.2 Pin Initialization Due to Error during Operation

If an error occurs during GPTW operation, the following four types of pin processing can be performed before pin initialization.

- (1) Set OAHLD and OBHLD bits in the GTIOR register to 1 and retain the outputs at count stop.
- (2) Set OAHLD and OBHLD bits to 0, specify arbitrary output values at OADFLT and OBDFLT bits in the GTIOR register, and output the arbitrary values at count stop.
- (3) Set the pin to output an arbitrary value as a general output port by setting the PDR, PODR, and PMR registers of the I/O port in advance. Set the OAE and OBE bits in the GTIOR register to 0 and the control bit in PMR register that corresponds to the pin to 0 to allow the arbitrary values to be output from the pin set as a general output port when an error occurs.
- (4) Drive the output to a high impedance state using the POEG function.

When automatic dead time setting has been made, set the GTDTCR.TDE bit to 0 once after counting is stopped.

When counting is stopped, only the values of registers that are changed by a GPTW external source will change. If counting is resumed, operation will carry on from where it was stopped.

If counting was stopped, registers should be initialized before counting is started.

## 24.10 Usage Notes

### 24.10.1 Module Stop Function Setting

Operation of the GPTW can be disabled or enabled by the module stop control register. The initial setting is for operation of the GPTW to be halted. Register access is enabled by clearing module stop state. For details, see section 11, Low Power Consumption.

### 24.10.2 Settings of the GTCCRm Register during Compare Match Operation (m = A to F)

#### (1) When Automatic Dead Time Setting has been Made in Triangle-Wave PWM Mode

The GTCCRA register should satisfy the following conditions:

- GTCCRA register > GTDVU register,
- GTCCRA register > GTDVD register, and
- GTCCRA register < GTPR register.

When the GTCCRA register is set to 0000 0000h or a value greater than or equal to the GTPR register value during count operation, the output protection function is activated.

However, if the following conditions are not satisfied, the output protection does not operate normally.

- When the GTCCRA register value at the start of count operation is 0000 0001h or greater, and less than the setting value of the GTPR register

For details, refer to section 24.8.4, Output Protection Function for GTIOcnm Pin Output (n = 0 to 9; m = A, B).

#### (2) When Automatic Dead Time Setting has not been Made in Triangle-Wave PWM Mode

Set a value greater than 0000 0000h, and less than the setting value of the GTPR register in the GTCCRA register. When 0000 0000h or the same value as that of the GTPR register is set in the GTCCRA register, compare match is generated in one cycle only when [GTCCRA register = 0000 0000h] or [GTCCRA register = GTPR register] is met. Furthermore, a value exceeding the setting value of the GTPR register is set in the GTCCRA register, compare match does not occur.

Similarly, set a value greater than 0000 0000h, and less than the setting value of the GTPR register in the GTCCRB register. When 0000 0000h or the same value as that of the GTPR register is set in the GTCCRB register, compare match is generated in one cycle only when [GTCCRB register = 0000 0000h] or [GTCCRB register = GTPR register] is met. Furthermore, a value exceeding the setting value of the GTPR register is set in the GTCCRB register, compare match does not occur.

#### (3) When Automatic Dead Time Setting has been Made in Sawtooth-Wave One-Shot Pulse Mode

The GTCCRC and GTCCRD registers should be set to satisfy the following restrictions. If the restrictions are not satisfied, correct output waveforms with secured dead time may not be obtained.

- In up-counting:
  - GTCCRC register < GTCCRD register
  - GTCCRC register > GTDVU register
  - GTCCRD register < GTPR register – GTDVD register
- In down-counting:
  - GTCCRC register > GTCCRD register
  - GTCCRC register < GTPR register – GTDVU register
  - GTCCRD register > GTDVD register

#### (4) When Automatic Dead Time Setting has not been Made in Sawtooth-Wave One-Shot Pulse Mode

The GTCCRC and GTCCRD registers should be set to satisfy the following restrictions. If the restrictions are not satisfied, two compare matches do not occur and pulse output cannot be performed.

- In up-counting:  $0 < \text{GTCCRC register} < \text{GTCCRD register} < \text{GTPR register}$
- In down-counting:  $\text{GTPR register} > \text{GTCCRC register} > \text{GTCCRD register} > 0$

Similarly, GTCCRE and GTCCRF registers should be set to satisfy the following restrictions. If the restrictions are not satisfied, two compare matches do not occur and pulse output cannot be performed.

- In up-counting:  $0 < \text{GTCCRE register} < \text{GTCCRF register} < \text{GTPR register}$
- In down-counting:  $\text{GTPR register} > \text{GTCCRE register} > \text{GTCCRF register} > 0$

#### (5) In Sawtooth-Wave PWM Mode

The GTCCRA register should be set with the range of  $0000\ 0000\text{h} < \text{GTCCRA register} < \text{GTPR register}$ . If  $\text{GTCCRA register} = 0000\ 0000\text{h}$  or  $\text{GTCCRA register} = \text{GTPR register}$  is set, a compare match occurs within the cycle only when  $\text{GTCCRA register} = 0000\ 0000\text{h}$  or  $\text{GTCCRA register} = \text{GTPR register}$  is satisfied. If  $\text{GTCCRA register} > \text{GTPR register}$  is set, no compare match occurs.

Similarly, GTCCRB register should be set with the range of  $0000\ 0000\text{h} < \text{GTCCRB register} < \text{GTPR register}$ . If  $\text{GTCCRB register} = 0000\ 0000\text{h}$  or  $\text{GTCCRB register} = \text{GTPR register}$  is set, a compare match occurs within the cycle only when  $\text{GTCCRB register} = 0000\ 0000\text{h}$  or  $\text{GTCCRB register} = \text{GTPR register}$  is satisfied. If  $\text{GTCCRB register} > \text{GTPR register}$  is set, no compare match occurs.

### 24.10.3 Setting Range of the GTCNT Counter

Set the range of the GTCNT counter within the range of  $0 \leq \text{GTCNT counter} \leq \text{GTPR register}$ .

### 24.10.4 The GTCNT Counter Start/Stop

The GTCNT counter start/stop control by the GTCR.CST bit is synchronized with the count clock selected by the GTCR.TPCS[3:0] bits. Since the GTCNT counter starts or stops after one count clock cycle selected by the TPCS[3:0] bits following the CST bit updating, events until the GTCNT counter actually starts are ignored, where events may be accepted and the interrupt may be generated after the CST bit becomes 0.

## 24.10.5 Order of Priority in Events

### (1) GTCNT Counter

Order of priority in events to update the GTCNT counter is shown below.

**Table 24.24 Order of Priority in Updating GTCNT Counter**

| The GTCNT counter updating source                                                     | Order of priority |
|---------------------------------------------------------------------------------------|-------------------|
| CPU writing (GTCNT counter writing/GTCLR register writing)                            | High              |
| Clearing by a hardware source set by the GTCSR register                               | ↑                 |
| Up-counting/down-counting by a hardware source set by the GTUPSR and GTDNSR registers |                   |
| Count operation                                                                       |                   |

In case of contention between up-counting by the GTUPSR register and down-counting by the GTDNSR register, the counter value is not updated.

When updating of the GTCNT counter conflicts with reading by the CPU, the value before updating is reflected.

### (2) The GTCR.CST Bit

In case that start/stop by a hardware source set by the GTSSR and GTPSR registers conflicts with the CPU writing (GTCR register writing/GTSTR register writing /GTSTP register writing), the CPU writing takes priority.

In case of contention between start by a hardware source set by the GTSSR register and stop by a hardware source set by the GTPSR register, the state of the CST bit does not change.

In case of contention between the CST bit updating and the CPU reading (GTCR register reading/GTSTR register reading /GTSTP register reading), data before updating is read.

### (3) GTCCRm Register (m = A to F)

In case of contention between the GTCCRm register writing and an input capture/buffer transfer, an input capture/buffer transfer takes priority over the GTCCRm register writing.

In case that an input capture conflicts with the CPU writing or the counter updating by a hardware source, the counter value before updating is captured.

In case of contention between the GTCCRm register updating and the CPU reading, data before updating is read.

### (4) GTPR Register

In case of contention between a buffer transfer and the GTPR register writing, the GTPR register writing takes priority over a buffer transfer.

In case of contention between the GTPR register updating and the CPU reading, data before updating is read.

### (5) GTADTRm Register (m = A, B)

In case of contention between a buffer transfer and the GTADTRm register writing, the GTADTRm register writing takes priority over a buffer transfer.

In case of contention between the GTADTRm register updating and the CPU reading, data before updating is read.

### (6) GTDVM Register (m = U, D)

In case of contention between a buffer transfer and the GTDVM register writing, the GTDVM register writing takes priority over a buffer transfer.

In case of contention between the GTDVM register updating and the CPU reading, data before updating is read.

## 25. High Resolution PWM Waveform Generation Circuit (HRPWM)

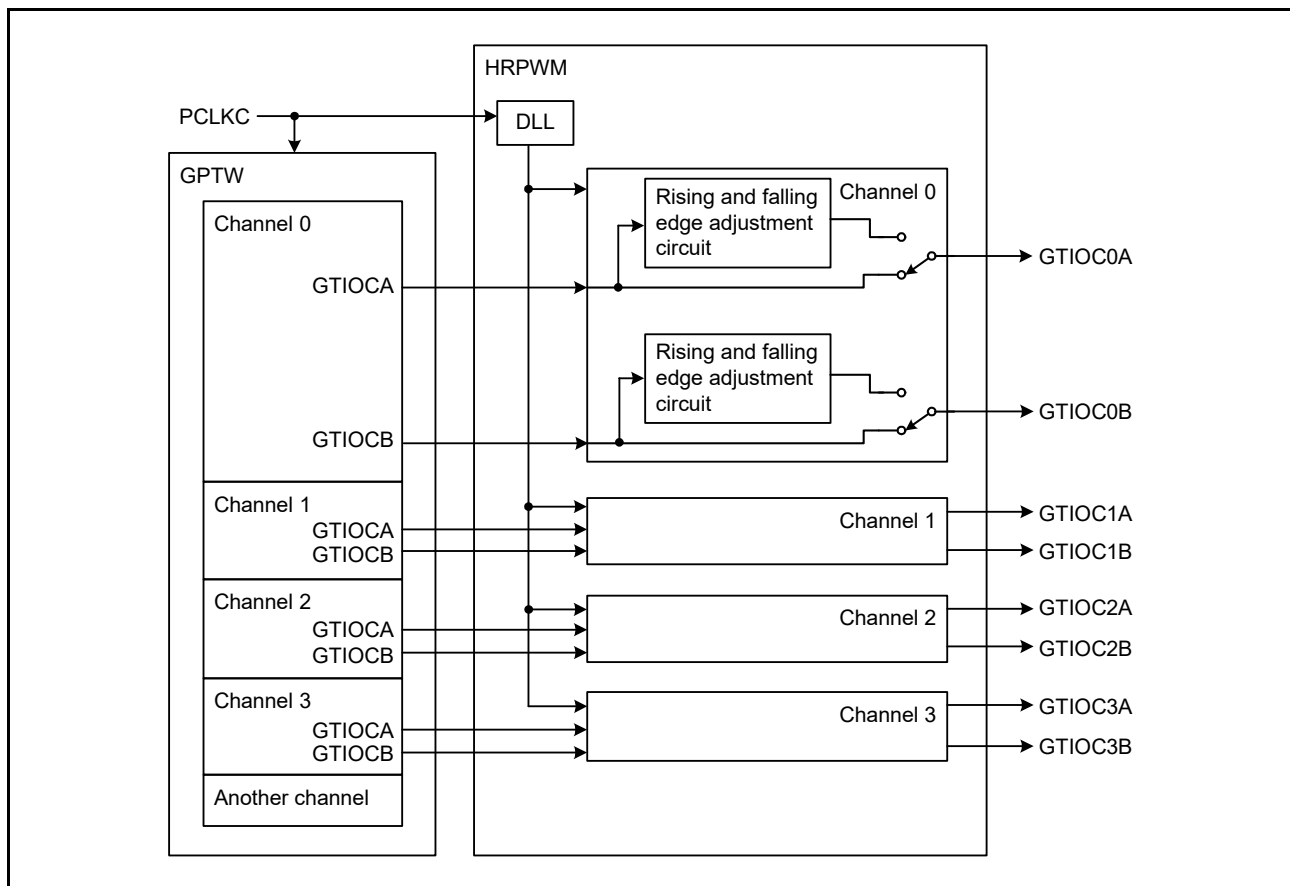

### 25.1 Overview

This MCU has a high resolution PWM waveform generation circuit (HRPWM) which finely adjusts a PWM waveform generated by GPTW0 to GPTW3 with a resolution of at least around 195 ps. Using the HRPWM, a digital power supply control with high conversion efficiency can be realized. Table 25.1 lists the specifications of the HRPWM, Figure 25.1 shows a block diagram, and Table 25.2 lists the I/O pins.

**Table 25.1 Specifications of the HRPWM**

| Item                           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|--------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Function                       | <ul style="list-style-type: none"> <li>• A maximum of four channels of complementary PWM waveforms are finely adjusted at high resolution.</li> <li>• Using a delay locked loop (DLL) circuit, a high resolution of 1/32 times of a PCLKC period (minimum of around 195 ps).</li> <li>• Timing for rising and falling of the PWM waveform can be adjusted individually.*1</li> <li>• A waveform generated by the GPTW can be output directly by bypassing the HRPWM.</li> </ul> |
| Operating frequency (f(PCLKC)) | 80 to 160 MHz                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

Note 1. Adjustment of timing for rising and falling of PWM signals which are output from the GPTW0 to GPTW3 is realized by a delay of a resolution of 1/32 times of a PCLKC period.

**Figure 25.1 Block Diagram of the HRPWM**

**Table 25.2 I/O Pins of the HRPWM**

| Pin Name | I/O    | Function                                                        |
|----------|--------|-----------------------------------------------------------------|
| GTIOC0A  | Output | High resolution output of a PWM waveform generated by the GPTW0 |
| GTIOC0B  | Output | High resolution output of a PWM waveform generated by the GPTW0 |
| GTIOC1A  | Output | High resolution output of a PWM waveform generated by the GPTW1 |
| GTIOC1B  | Output | High resolution output of a PWM waveform generated by the GPTW1 |
| GTIOC2A  | Output | High resolution output of a PWM waveform generated by the GPTW2 |
| GTIOC2B  | Output | High resolution output of a PWM waveform generated by the GPTW2 |
| GTIOC3A  | Output | High resolution output of a PWM waveform generated by the GPTW3 |
| GTIOC3B  | Output | High resolution output of a PWM waveform generated by the GPTW3 |

## 25.2 Register Descriptions

### 25.2.1 HRPWM Operation Control Register (HROCR)

Address(es): HRPWM.HROCR 000C 2A00h

|                    |     |     |     |     |     |     |    |    |    |    |    |    |    |    |       |      |
|--------------------|-----|-----|-----|-----|-----|-----|----|----|----|----|----|----|----|----|-------|------|
|                    | b15 | b14 | b13 | b12 | b11 | b10 | b9 | b8 | b7 | b6 | b5 | b4 | b3 | b2 | b1    | b0   |
|                    | —   | —   | —   | —   | —   | —   | —  | —  | —  | —  | —  | —  | —  | —  | HRRST | DLEN |
| Value after reset: | 0   | 0   | 0   | 0   | 0   | 0   | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0     | 0    |

| Bit       | Symbol | Bit Name                                              | Description                                                 | R/W |
|-----------|--------|-------------------------------------------------------|-------------------------------------------------------------|-----|
| b0        | DLEN   | DLL Operation Enable                                  | 0: DLL operation is disabled<br>1: DLL operation is enabled | R/W |
| b1        | HRRST  | High Resolution PWM Waveform Generation Circuit Reset | 0: Release from reset<br>1: Reset                           | R/W |
| b15 to b2 | —      | Reserved                                              | These bits are read as 0. The write value should be 0.      | R/W |

This register controls the operation of the entire HRPWM module. The register can be written when the register write disable bit in the GPTW write-protection register is enabled (GPTW0.GTWP.WP = 0).

#### DLEN Bit (DLL Operation Enable)

This bit selects whether the internal DLL in the HRPWM is activated or not. After activation, wait for 20  $\mu$ s until the output of the DLL becomes stable.

#### HRRST Bit (High Resolution PWM Waveform Generation Circuit Reset)

This bit resets the internal state of the HRPWM. After releasing from reset, wait for 12 cycles of PCLKC. When resetting during operation, the PWM output is fixed to low after five cycles of PCLKC.

## 25.2.2 HRPWM Operation Control Register 2 (HROCR2)

Address(es): HRPWM.HROCR2 000C 2A02h

|                    |     |     |     |     |            |            |            |            |    |    |    |    |            |            |            |            |

| b7 to b4   | —      | Reserved                                                     | These bits are read as 0. The write value should be 0.                                                                                                                    | R/W |
| b8         | HRDIS0 | Channel 0 Rising and Falling Edge Adjustment Circuit Disable | 0: Enable operation of Channel 0 rising and falling edge adjustment circuit<br>1: Disable operation of Channel 0 rising and falling edge adjustment circuit               | R/W |
| b9         | HRDIS1 | Channel 1 Rising and Falling Edge Adjustment Circuit Disable | 0: Enable operation of Channel 1 rising and falling edge adjustment circuit<br>1: Disable operation of Channel 1 rising and falling edge adjustment circuit               | R/W |
| b10        | HRDIS2 | Channel 2 Rising and Falling Edge Adjustment Circuit Disable | 0: Enable operation of Channel 2 rising and falling edge adjustment circuit<br>1: Disable operation of Channel 2 rising and falling edge adjustment circuit               | R/W |
| b11        | HRDIS3 | Channel 3 Rising and Falling Edge Adjustment Circuit Disable | 0: Enable operation of Channel 3 rising and falling edge adjustment circuit<br>1: Disable operation of Channel 3 rising and falling edge adjustment circuit               | R/W |
| b15 to b12 | —      | Reserved                                                     | These bits are read as 0. The write value should be 0.                                                                                                                    | R/W |

This register controls the HRPWM module by channel. The register can be written when the register write disable bit in the GPTW write-protection register is enabled (GPTW0.GTWP.WP = 0).

### HRSELn Bit (Channel n High Resolution PWM Waveform Output Select) (n = 0 to 3)

This bit allows to select whether to output a waveform generated by the HRPWM from the GTIOCnA and GTIOCnB pins (n = 0 to 3) or to output an original waveform of the GPTW by bypassing the circuit.

The PWM waveform generated by the HRPWM is output with a delay of three full cycles of PCLKC from the output when the circuit is bypassed, even if the setting for the amount of delay is 0.

### HRDISn Bit (Channel n Rising and Falling Edge Adjustment Circuit Disable) (n = 0 to 3)

This bit enables/disables the operation of the rising and falling edge adjustment circuit by relevant channel in the GPTW.

Set this bit to 1 for a channel which will not be used.

### 25.2.3 GTIOCnA Pin Rising Edge Adjustment Register (HRREARnA) (n = 0 to 3)

Address(es): HRPWM.HRREAR0A 000C 2A18h, HRPWM.HRREAR1A 000C 2A1Ch, HRPWM.HRREAR2A 000C 2A20h,  
HRPWM.HRREAR3A 000C 2A24h

This register specifies the amount of delay to apply to rising edge of a PWM waveform output from the GTIOCnA pin. For the transfer timing of register settings, refer to section 25.3.2, Transfer Timing of HRREARnA, HRREARnB, HRFEARnA, and HRFEARnB Register Settings (n = 0 to 3).

This register can be written when the register write disable bit in the GPTW write-protection register is enabled (GPTWn.GTWP.WP = 0).

### 25.2.4 GTIOCnA Pin Falling Edge Adjustment Register (HRFEARnA) (n = 0 to 3)

This register specifies the amount of delay to apply to falling edge of a PWM waveform output from the GTIOCnA pin. For the transfer timing of register settings, refer to section 25.3.2, Transfer Timing of HRREARnA, HRREARnB, HRFEARnA, and HRFEARnB Register Settings (n = 0 to 3).

This register can be written when the register write disable bit in the GPTW write-protection register is enabled (GPTWn.GTWP.WP = 0).

### 25.2.5 GTIOCnB Pin Rising Edge Adjustment Register (HRREARnB) (n = 0 to 3)

This register specifies the amount of delay to apply to rising edge of a PWM waveform output from the GTIOCnB pin. For the transfer timing of register settings, refer to section 25.3.2, Transfer Timing of HRREARnA, HRREARnB, HRFEARnA, and HRFEARnB Register Settings (n = 0 to 3).

This register can be written when the register write disable bit in the GPTW write-protection register is enabled (GPTWn.GTWP.WP = 0).

This register specifies the amount of delay to apply to falling edge of a PWM waveform output from the GTIOCnB pin. For the transfer timing of register settings, refer to section 25.3.2, Transfer Timing of HRREARnA, HRREARnB, HRFEARnA, and HRFEARnB Register Settings (n = 0 to 3).

This register can be written when the register write disable bit in the GPTW write-protection register is enabled (GPTWn.GTWP.WP = 0).

### 25.3 Operation

#### 25.3.1 Adjustment to the Timing of Rising and Falling Edges in PWM Waveforms

The HRPWM delays timing for rising and falling of the PWM signals which are output from the GPTW with a resolution of 1/32 times (at least around 195 ps) of a PCLKC period ( $t_C(\text{PCLKC})$ ) based on the delay locked loop (DLL) operating with PCLKC as a reference clock. The PWM signal which was delayed is output from the GTIOCnA and GTIOCnB pins ( $n = 0$  to 3).

The amount of delay can be adjusted within a range of 0/32 to 31/32 of  $t_C(\text{PCLKC})$ . The amount of delay out of this range cannot be specified. When setting the amount of delay with the value out of such range, change the setting in the general PWM timer compare capture register m (GTCCRm) in the GPTW.

The HRPWM is required to set the HROCR.DLLEN bit to 1 before operation and wait for stabilization time as it has the DLL. In addition, wait for 12 cycles of PCLKC after setting the HROCR.HRRST bit to 0 in order to output the reliable PWM waveform. Refer to Figure 25.2 for the detailed procedures.

Specify the amount of delay by the HRREARnA and HRFEARnA registers for the GTIOCnA pin and by the HRREARnB and HRFEARnB registers for the GTIOCnB pin. The PWM waveform has specific setting registers for delay at rising and at falling respectively, which allows fine adjustments for the width of high and low. Refer to Table 25.3 for the correspondence between pins and registers.

The amount of delay specified by a relevant register is reflected to the pin via a temporary register. Timing for reflecting the setting differs by PWM output operation mode in the general PWM timer. Refer to section 25.3.2, Transfer Timing of HRREARnA, HRREARnB, HRFEARnA, and HRFEARnB Register Settings ( $n = 0$  to 3).

In the HRPWM, setting of DLL enabling/disabling and reset setting/releasing is common for all channels; however, the rest of settings can be specified individually by channel.

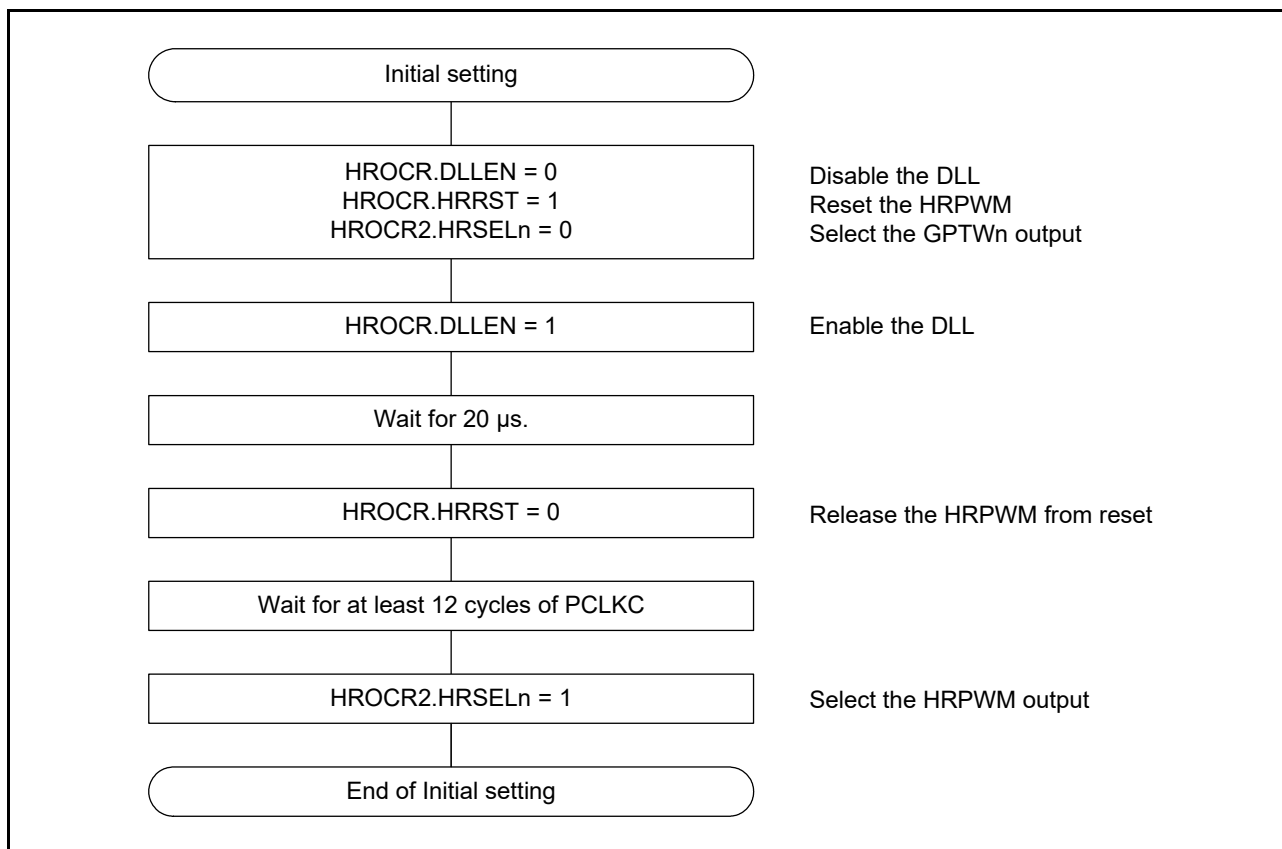

Figure 25.2 Initialization flow for the HRPWM ( $n = 0$  to 3)

**Table 25.3 Correspondence between PWM Waveform Output Pins and Delay Setting Registers**

| PWM Waveform Output Pin | Rising Edge Adjustment Register | Falling Edge Adjustment Register |
|-------------------------|---------------------------------|----------------------------------|
| GTIOC0A                 | HRREAR0A                        | HRFEAR0A                         |
| GTIOC0B                 | HRREAR0B                        | HRFEAR0B                         |
| GTIOC1A                 | HRREAR1A                        | HRFEAR1A                         |
| GTIOC1B                 | HRREAR1B                        | HRFEAR1B                         |
| GTIOC2A                 | HRREAR2A                        | HRFEAR2A                         |
| GTIOC2B                 | HRREAR2B                        | HRFEAR2B                         |
| GTIOC3A                 | HRREAR3A                        | HRFEAR3A                         |
| GTIOC3B                 | HRREAR3B                        | HRFEAR3B                         |

### 25.3.2 Transfer Timing of HRREARnA, HRREARnB, HRFEARnA, and HRFEARnB Register Settings (n = 0 to 3)

Settings of the HRREARnA, HRREARnB, HRFEARnA, and HRFEARnB registers are transferred to a temporary register first, and reflected to the amount of delay for the PWM waveform in the GTIOCnA and GTIOCnB pins then. Such settings are transferred to a temporary register at the end of PWM period (at an overflow (during up-count operation) or an underflow (during down-count operation) in sawtooth wave mode, and at a trough in triangle wave mode).

Figure 25.3 and Figure 25.4 show examples of the operation of the HRREAR0A and HRFEAR0A registers.

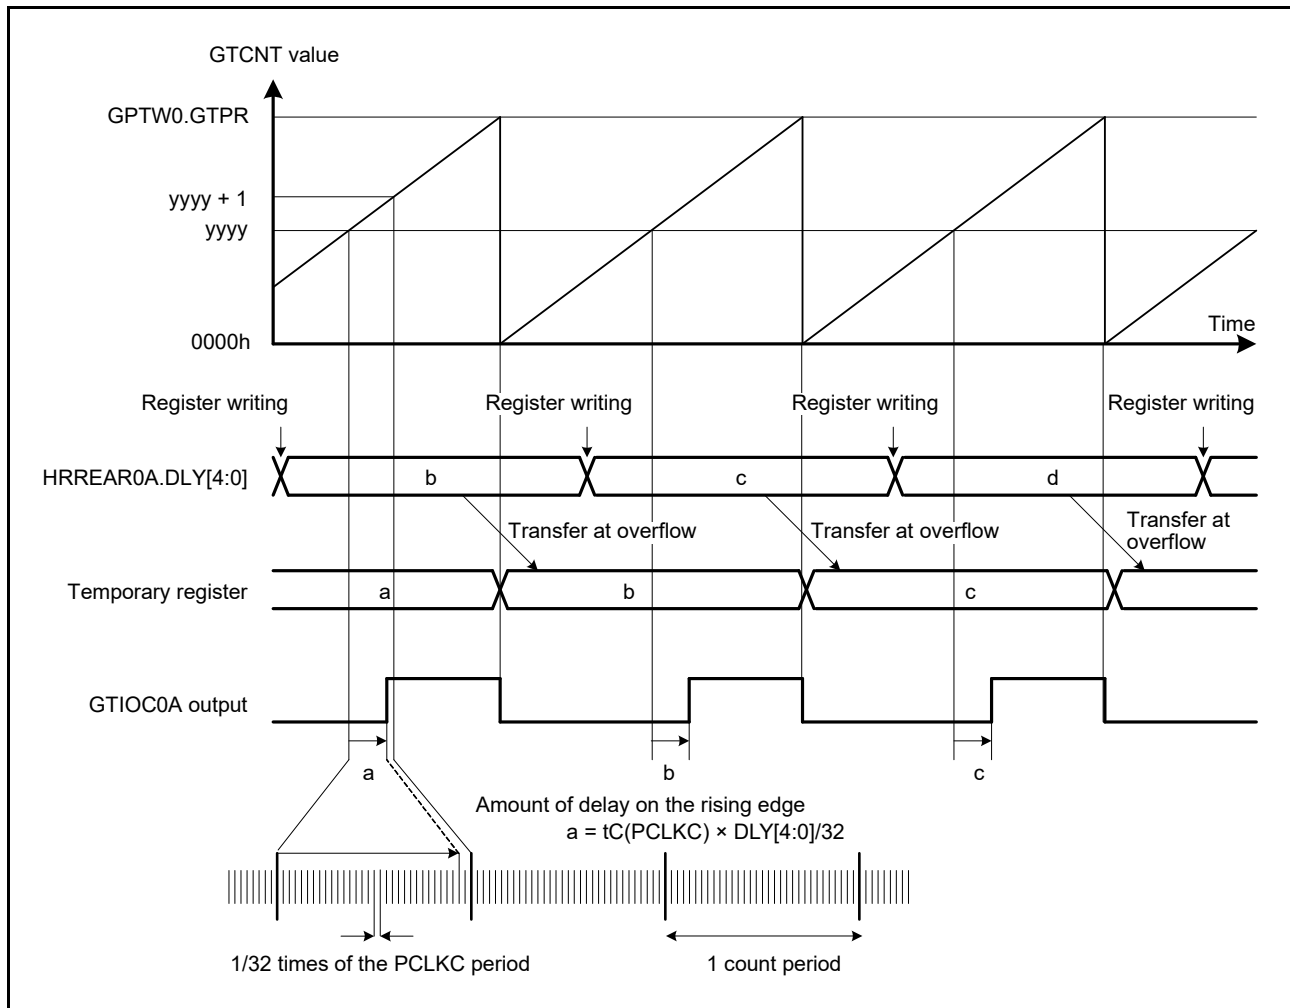

Figure 25.3 Operation Example When Changing the HRREAR0A Register Setting (in Sawtooth Wave Mode)

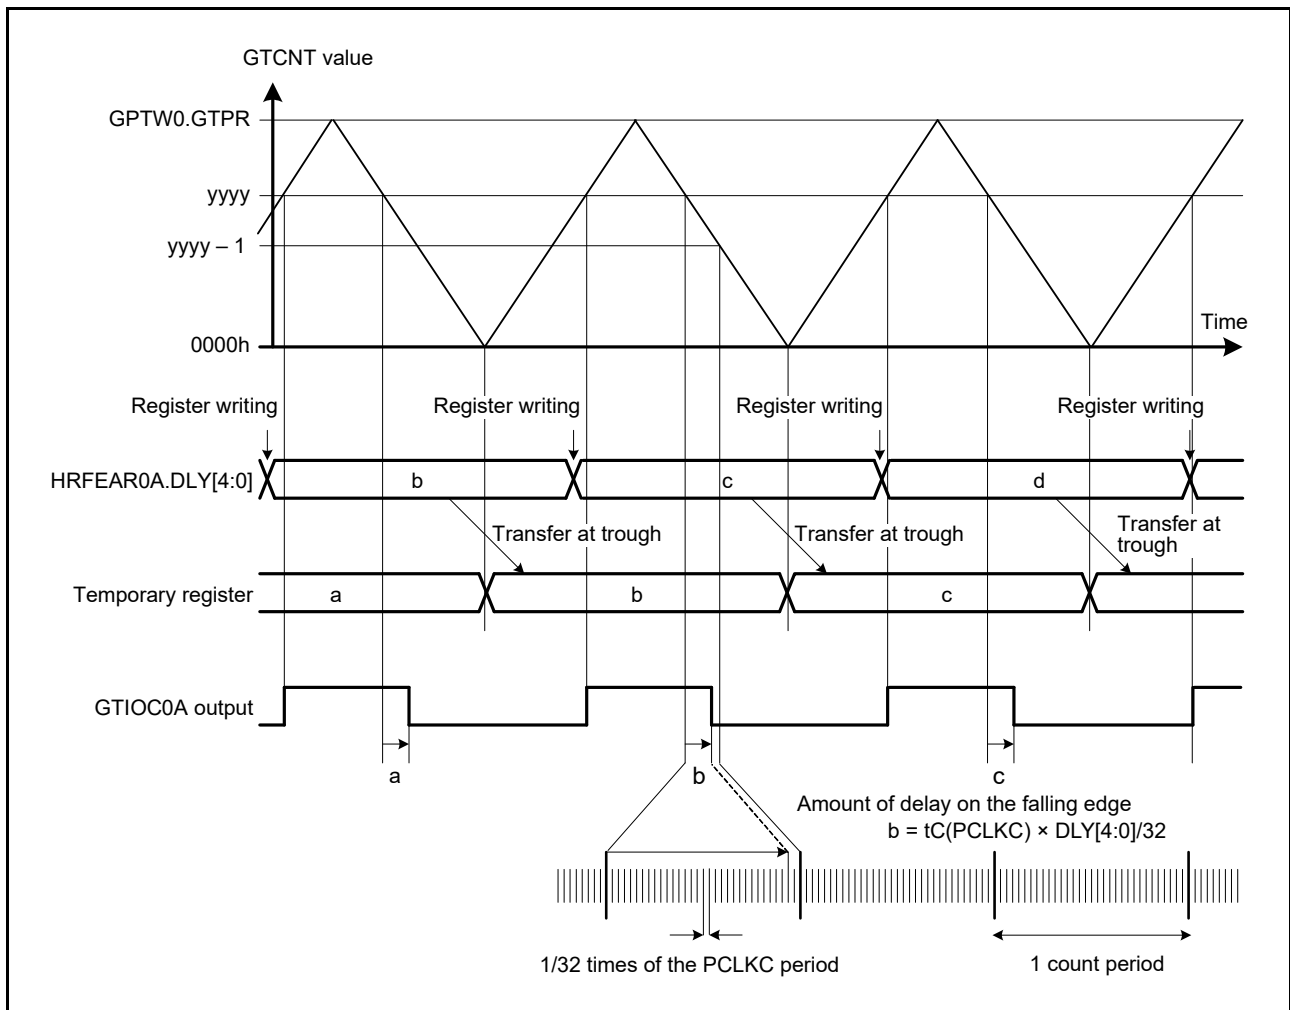

Figure 25.4 Operation Example When Changing the HRFEAR0A Register Setting (in Triangle Wave Mode)

## 25.4 Usage Notes

### 25.4.1 Settings for the Module-Stop Function

Operation of the HRPWM can be disabled or enabled using Module Stop Control Register (MSTPCRA). The HRPWM is initially stopped after reset. Releasing the module-stop state enables access to the registers. For details, refer to **section 11, Low Power Consumption**.

### 25.4.2 Note on Selecting Timer Prescaler in the GTCNT Counter While Using the HRPWM

The PWM signals output from the GPTW are generated based on the GTCNT counter operating at resolution equivalent to one clock period which is set by the GPTWn.GTCR.TPCS[3:0] bits (n = 0 to 3). Note that a delay at resolution of  $0/32 \times tC(PCLKC)$  to  $31/32 \times tC(PCLKC)$  is applied to edges of the PWM signals at low resolution generated based on a selected clock when a setting for the GPTWn.GTCCRm register (m = A to F) is changed while the TPCS[3:0] bits are specified to the setting other than 0000b (PCLKC/1).

### 25.4.3 Notes on Delay Settings for HRPWM

Within three cycles of PCLKC from the end of the PWM period, do not change the settings for the HRFEARnA, HRREARnA, HRFEARnB, and HRREARnB registers. Any changes made during the above period will be reflected with a delay of one cycle of the PWM waveform.

## 26. GPTW Port Output Enable (POEG)

### 26.1 Overview

The POEG issues requests to stop output from output pins of the general PWM timer (GPTW). The combination of output pins of the POEG to be stopped can be specified from any channel of the GPTW, which is a different form of operation from that of the POE3. Use the POE3 to stop output from pins of the MTU3 and GPTW at the same time. Select the method of detection for stopping the output from the list below.

- Input level detection on the GTETR<sub>Gn</sub> pin (n = A to D)
- Detection from the GPTW to stop output
- Detection by comparator (edge detection or level detection)
- Detection of stopping of oscillation by the oscillation stop detection circuit for the main clock
- Register setting

The GTETR<sub>Gn</sub> pin can be used for output to the external trigger input pins of the GPTW.

Table 26.1 shows specifications, Figure 26.1 shows a schematic view of the system, Figure 26.2 shows a block diagram, and Table 26.2 shows input pins.

**Table 26.1 POEG Specifications**

| Item                                                                           | Description                                                                                                                                                                                                                                                                                                                                                                                                                             |
|--------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

Note 1. Only 0 to clear the flag can be written.

Note 2. This bit can be written only once after resetting.

The POEG<sub>Gn</sub> register (n = A to D) controls requests for stopping output and an external trigger for the GPTW based in response to the detection of various signals.

### SSF Flag (Software Stop Flag)

Writing 1 to the SSF flag leads to a request to stop output being issued to the GPTW, and writing 0 to the flag releases the GPTW from the request to stop output. In addition, requests to stop output issued by software can be monitored by reading the flag.

## 26.2.2 GPTW Output Stopping Control Group n Write Protection Register (GTONCWPn) (n = A to D)

Address(es): POEG.GTONCWPA 0009 E040h, POEG.GTONCWPB 0009 E140h, POEG.GTONCWPC 0009 E240h, POEG.GTONCWPD 0009 E340h

The GTONCCRn register (n = A to D) set up requests for stopping output in response to detected signals.

#### NE Bit (Direct Stopping Request Setting)

Writing 1 to the NE bit leads to direct output of the stopping request signal in response to the signal for detection selected by the NFS[3:0] bits.

## 26.3 Operation

### 26.3.1 Request to Stop Output in Response to Detection of Input Level on the Corresponding GTETR<sub>Gn</sub> Pin (n = A to D)

There are two types of output stopping request: requests in response to setting of the POEG<sub>Gn</sub>.PIDF flag (n = A to D), and requests directly in response to the detected signal.

- (1) To request stopping of output in response to setting of the PIDF flag, the input set in the POEG<sub>Gn</sub> register (inversion or non-inversion set in the INV bit, filtering enabled or disabled by the NFEN bit, sample clock for filtering set in the NFCS[1:0] bits) is detected while the POEG<sub>Gn</sub>.PIDE bit is 1. After the POEG<sub>Gn</sub>.PIDF flag is set to 1 in response to this, the request to stop output is issued per group to each channel of the GPTW. To de-assert the request signal for stopping output, clear the POEG<sub>Gn</sub>.PIDF flag. For canceling requests to stop output, refer to section 26.3.6, Canceling Requests to Stop Output.
- (2) To request stopping of output in direct response to detection of the input level of a selected signal, the input set in the POEG<sub>Gn</sub> (inversion or non-inversion set in the INV bit, filtering enabled or disabled by the NFEN bit, sample clock for filtering set in the NFCS[1:0] bits) and GTONCCR<sub>n</sub> registers (active sense set in the NFV bit) to the GTETR<sub>Gn</sub> pin selected in the GTONCCR<sub>n</sub>.NFS[3:0] bits is detected while the GTONCCR<sub>n</sub>.NE bit is 1, and a request to stop output is then directly issued per channel group of the GPTW. The signal to request stopping of output is de-asserted when the detected input level does not match the conditions for issuing a request. For details, refer to section 26.3.7, Requests to Stop Output in Response to Detected Signals and Canceling the Requests.

#### 26.3.1.1 Digital Noise Filter

Each GTETR<sub>Gn</sub> pin input has a digital noise filter. Figure 26.3 shows the operation example in detection of the high level with the use of the filter. When the digital noise filter is enabled (POEG<sub>Gn</sub>.NFEN bit = 1) and the high level is detected 3 consecutive times with the sampling clock cycle selected by the POEG<sub>Gn</sub>.NFCS[1:0] bits while inverted or non-inverted according to the setting of the POEG<sub>Gn</sub>.INV bit, this is regarded as detection of the high level, and the request to stop output is issued to the GPTW.

At this time, if the low level is detected even once in the sequence, it is not regarded as detection of the high level. In addition, changes in the levels on pins GTETR<sub>GA</sub> through GTETR<sub>GD</sub> are ignored while the sampling clock is not being output.

Digital noise filters can be used with requests to stop output in response to setting of the POEG<sub>Gn</sub>.PIDF flags (n = A to D), requests to stop output in direct response to a detected signal, and the output of external triggers to the GPTW.

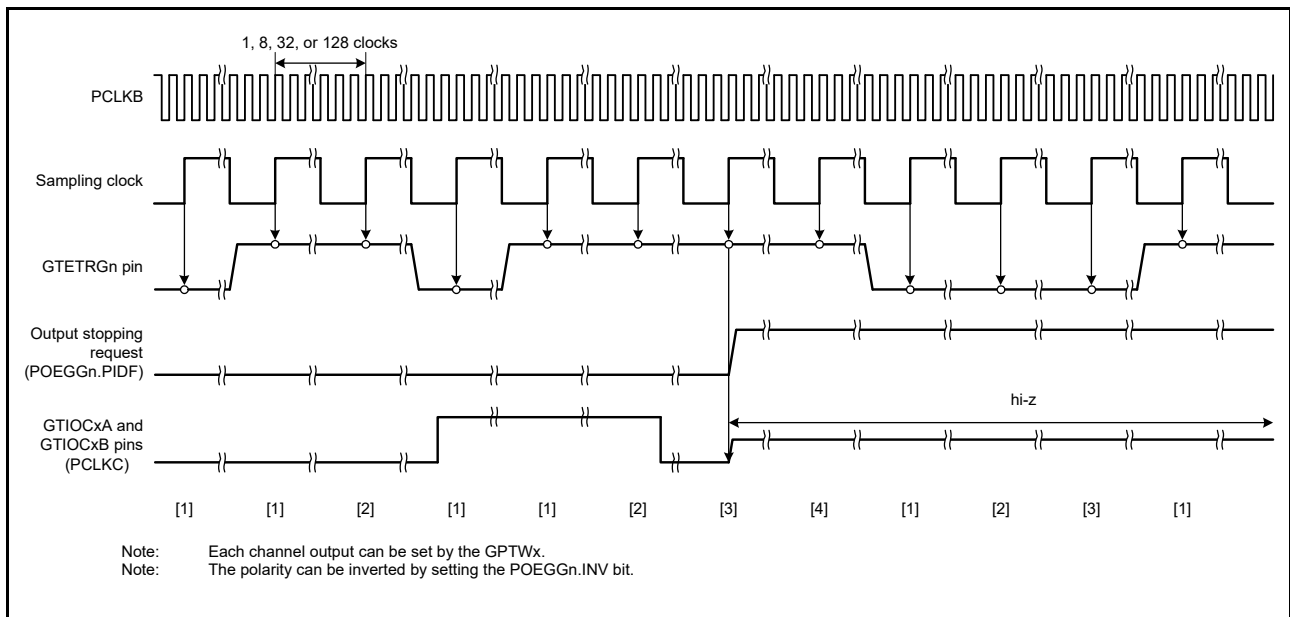

Figure 26.3 Example for Operation of Digital Noise Filter

### 26.3.2 Requests to Stop Output in Response to Detection of Output Stopping from GPTW

When any among a dead-time error or simultaneous high- or low-level output from the GPTW is detected, the corresponding POEGGn.IOCF flag is set to 1 and the request to stop output per group is issued to each channel in the GPTW. The POEGGn.IOCF flag is used to indicate both edge detection by the comparator and requests to stop output. To cancel a request to stop output, clear the given POEGGn.IOCF flag. For details, refer to section 26.3.6, Canceling Requests to Stop Output.

To detect any among a dead-time error or simultaneous high- or low-level output from the GPTW, detection of output stopping must be permitted in the GRPDTE, GRPABH, and GRPABL bits of the given GPTWn.GTINTAD register. Specify the group of the GPTW for which stopping is to be detected in the GPTWn.GTINTAD.GRP[1:0] bits. For details, refer to section 24.2.15, General PWM Timer Interrupt Output Setting Register (GTINTAD).

### 26.3.3 Request to Stop Output in Response to Comparator Detection

A request to stop output can be issued to the GPTW in response to detection by a comparator. There are two types of request to stop output: requests output in response to setting of a POEGGn.IOCF flag ( $n = A$  to  $D$ ) due to edge detection by the comparator and requests that are directly output in response to level detection by the comparator.

- (1) To stop output in response to setting of an IOCF flag, the corresponding edge is detected by the comparator while the POEGGn.CDRE[5:0] bits are 1. The POEGGn.IOCF flag is then set to 1, which leads to a request to stop output from the given group for each channel of the GPTW. The POEGGn.IOCF flag is used for both comparator edge detection and the request to stop output. To cancel the request to stop output, clear the POEGGn.IOCF flag. For details, refer to section 26.3.6, Canceling Requests to Stop Output.
- (2) The output can also be stopped by using a detected signal as a direct request to stop output. When the comparator level detection signal selected in the GTONCCRn.NFS[3:0] bits matches the level set in the GTONCCRn.NFV bit, the request to stop output per group is issued to each channel of the GPTW. The request to stop output is released when the comparator level detection does not match the issuing conditions. For details, refer to section 26.3.7, Requests to Stop Output in Response to Detected Signals and Canceling the Requests.

### 26.3.4 Requests to Stop Output by Oscillation Stop Detection

When the circuit for detecting stopping of oscillation by the main clock oscillator detects the stopping of the oscillation while a POEGGn.OSTPE bit is 1, the POEGGn.OSTPF flag is set to 1 and a request to stop output per group is issued to each channel of the GPTW. To cancel the request to stop output, clear the POEGGn.OSTPF flag. For details, refer to section 26.3.6, Canceling Requests to Stop Output.

### 26.3.5 Requests to Stop Output by a Register

Writing 1 to the software stop flag (POEGGn.SSF) leads to a request to stop output per group to each channel in the GPTW. To release from the request to stop output, clear the POEGGn.SSF flag. For details, refer to section 26.3.6, Canceling Requests to Stop Output.

### 26.3.6 Canceling Requests to Stop Output

Requests to stop output are canceled in any of the following three ways.

- (1) Cancellation by a reset (return to the initial state)
- (2) Cancellation by clearing all flags in the POEGGn register
- (3) Cancellation in response to direct input of a detected signal

#### (1) Cancellation by a reset

Any type of reset can cancel a request to stop output. For details, refer to section 6, Resets.

#### (2) Cancellation by clearing all flags in the POEGGn register

- POEGGn.PIDF
- POEGGn.IOCF
- POEGGn.OSTPF
- POEGGn.SSF

Cancellation of the request is taken into the GPTW at the end of the cycle of counting by the GPTW, and the output pins are released from being stopped no less than 3 PCLKC cycles from that time. Figure 26.4 shows the timing of release from the output-stopped state. To clear each of the flags, read the status flag for each source to check that the source condition is not being detected, and then write 0. Sources other than the edge detection by the comparators cannot be cleared even if the flag is cleared in the detected state. Since the comparators detect edges in edge detection, writing 0 in the detected state clears the flag, and the flag is not set until the relevant source generates the next edge. Status flags for the respective sources are listed below.

- Detection of input level POEGGn.ST (GTETRGN input status flag)
- Comparator edge detection CMPCn.CMPMON.CMPMON0 (comparator output monitoring flag)
- Oscillation stop detection OSTDSR.OSTDF (oscillation stop detection flag)
- Stopping detection from the GPTW GPTWn.GTST.DTEF (dead time error flag)  
GPTWn.GTST.OABLF (simultaneous low output flag)  
GPTWn.GTST.OABHF (simultaneous high output flag)

Note 1. CMPCn.CMPMON.CMPMON0 are the monitoring flags for the comparator outputs.

**Figure 26.4** Timing of Re-enabling Output from the GPTW Output Pins Following Cancellation of a Request to Stop Output

#### (3) Cancellation in response to direct input of a detected signal

For details, refer to section 26.3.7, Requests to Stop Output in Response to Detected Signals and Canceling the Requests.

### 26.3.7 Requests to Stop Output in Response to Detected Signals and Canceling the Requests

The input level detection signals on the GTETR<sub>Gn</sub> pin (n = A to D) and comparator level detection signals on the CMPC<sub>m</sub> pin (m = 0 to 5) can be used as direct requests to stop output in response to detected signals. The sources of the signals for detection are selected in the GTONCCR<sub>n</sub>.NFS[3:0] bits, and the active senses of the signals for detection are set in the GTONCCR<sub>n</sub>.NFV bit. Setting a GTONCCR<sub>n</sub>.NE bit to activate direct requests to stop output results in the issuing of a request to stop output to the GPTW when the selected source signal for output stopping detection is generated.

The request to stop output is released when the input level detection signal on the given GTETR<sub>Gn</sub> pin or comparator level detection does not match the issuing conditions. To cancel a request, confirm that the values of the PIDF and IOCF flags in the POEG<sub>Gn</sub> register have become 0.

Figure 26.5 shows the operation of a request to stop output issued in response to level detection by the COMP0. The example shows the case where the comparator detects the analog input voltage on CMPC0 becoming higher than the reference voltage while the GPTW is producing PWM waveforms on the GTIOC0A pin on a cyclic-counting basis, and the level-detection signal from the comparator is input to the POEG. The POEG outputs a request to stop output to the GPTW on the basis of detection as described above, and the GPTW remains stopped until the end of the cycle of counting, even if the request to stop output is canceled before then.

If the request to stop output has not been canceled at the end of the cycle of counting cycle, output from the GPTW remains stopped until the end of the next cycle of counting, and so on.

The output-stopped state can be checked by reading the ODF flag in General PWM Timer Status Register (GTST) of the GPTW. For details, refer to the description of the ODF flag in section 24.2.16, General PWM Timer Status Register (GTST). Figure 26.6 shows the procedure for setting requests to stop output in response to detected signals.

Figure 26.5 Example of Operation to Stop Output from the GTIOC Pin in Response to Level Detection by a Comparator

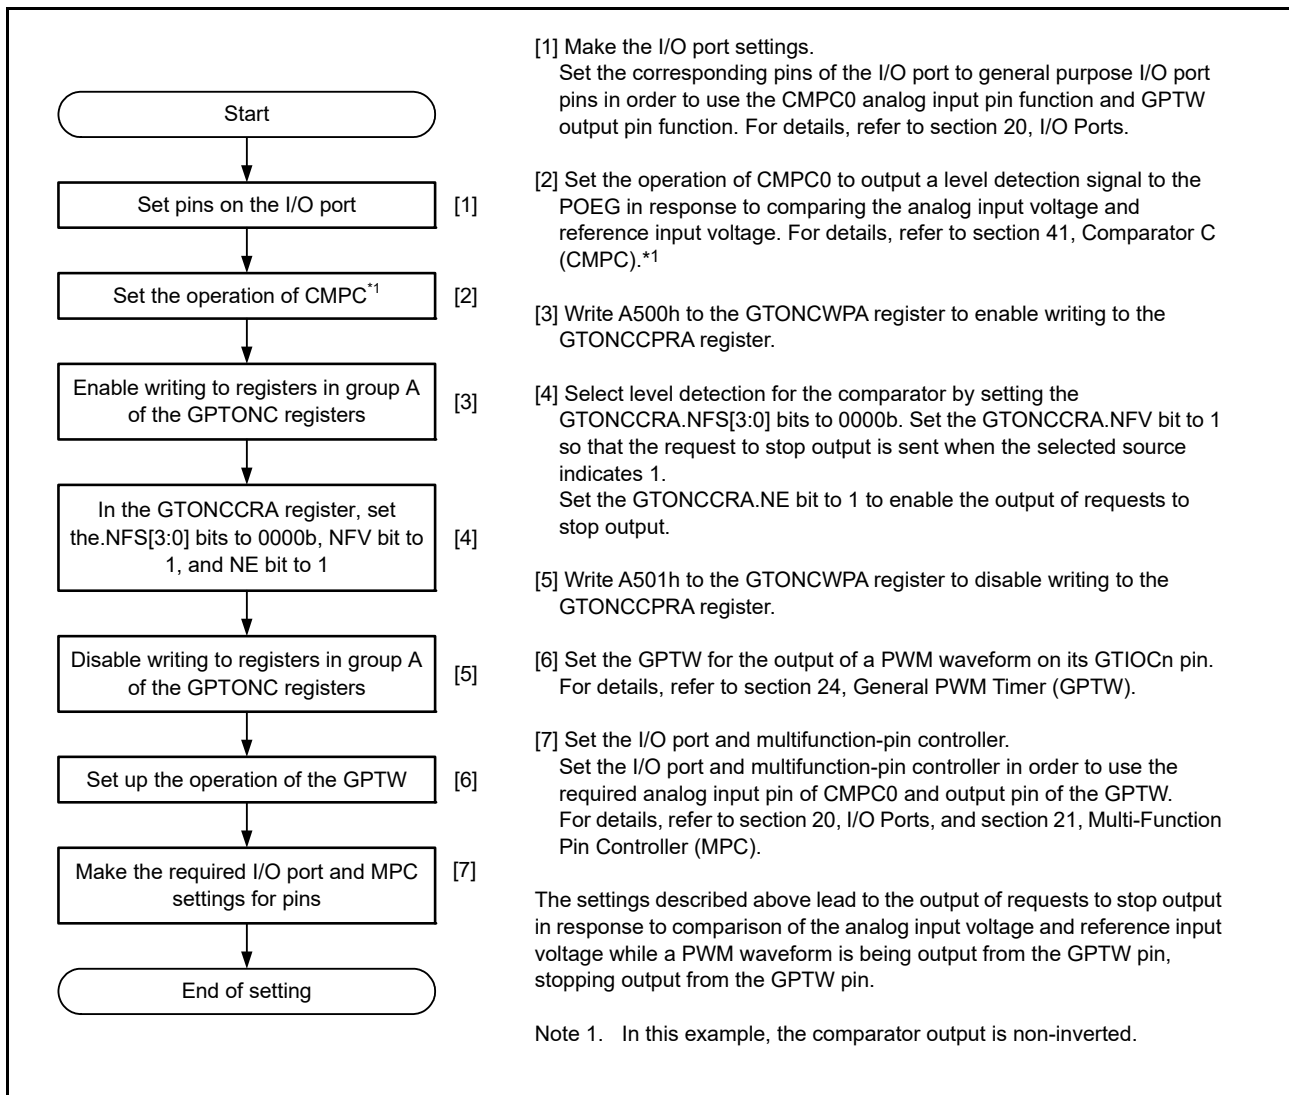

Figure 26.6 Example of Settings to Stop Output on the GTIOC Pin in Response to Level Detection by a Comparator

## 26.4 Interrupt Sources

The POEG generates interrupts for the interrupt controller when any of the following is detected.

- Detection of level of input, indicated by the POEGGn.PIDF flag
- Detection of stopping of output from the GPTW, indicated by the POEGGn.IOCF flag
- Detection of edges by the comparator, indicated by the POEGGn.IOCF flag

Table 26.3 shows interrupt sources and conditions.

**Table 26.3 Interrupt sources and conditions**

| Interrupt Source       | Symbol  | Corresponding Flag | Trigger Condition                                 |
|------------------------|---------|--------------------|---------------------------------------------------|
| POEG Group A Interrupt | POEGGAI | POEGGA.IOCF        | Detection of stopping of output from the GPTW     |
|                        |         |                    | Detection of edges by the comparator              |
|                        |         | POEGGA.PIDF        | Detection of the level input from the GTETRGA pin |
| POEG Group B Interrupt | POEGGBI | POEGGB.IOCF        | Detection of stopping of output from the GPTW     |
|                        |         |                    | Detection of edges by the comparator              |
|                        |         | POEGGB.PIDF        | Detection of the level input from the GTETRGB pin |
| POEG Group C Interrupt | POEGGCI | POEGGC.IOCF        | Detection of stopping of output from the GPTW     |
|                        |         |                    | Detection of edges by the comparator              |
|                        |         | POEGGC.PIDF        | Detection of the level input from the GTETRGC pin |
| POEG Group D Interrupt | POEGGDI | POEGGD.IOCF        | Detection of stopping of output from the GPTW     |
|                        |         |                    | Detection of edges by the comparator              |
|                        |         | POEGGD.PIDF        | Detection of the level input from the GTETRGD pin |

## 26.5 External Trigger Output to GPTW

The POEG outputs the inputs on the GTETRGN pin (n = A to D) as external trigger signals. The external trigger signals can be monitored by the POEGn.ST flag via active-sense selection and digital noise filtering. The GPTW can function as follows in response to external trigger signals.

- Count start
- Count stop
- Counter clearing
- Up-counting
- Down-counting
- Input capture

For details of the above functions, refer to section 24, General PWM Timer (GPTW).

## 26.6 Usage Notes

### 26.6.1 Transitions to Low-Power Consumption Mode

When the POEG is used, it should not be transitioned to software standby or deep software standby modes. In this mode, the stopping of output cannot be requested since the POEG is stopped.

### 26.6.2 Setting the Function for Stopping the Module

The module-stop control register can be set to enable or disable operation of the POEG. The POEG is stopped immediately after a reset. Registers of the POEG become accessible following release from the module-stopped state. For details, refer to section 11, Low Power Consumption. The module-stop bit for the POEG also stops and starts the GPTW.

### 26.6.3 Duplication of Requests to Stop Output

While either the PIDF or IOCF flag in the POEGGn register is 1, cancellation of requests to stop by the detection signal set in the GTONCCRn register does not work due to the request to stop still being output because of the value of the flag. That is, note that requests to stop output will not be canceled when a corresponding flag is set stop output in response to detection. Request signals to stop output in response to flag setting are obtained as the logical OR of the corresponding detection signals for stopping output.

## 27. 8-Bit Timer (TMRb)

This MCU has four units (unit 0, unit 1, unit 2, unit 3) of an on-chip 8-bit timer (TMR) module that comprise two 8-bit counter channels, totaling eight channels. The 8-bit timer module can be used to count external events and also be used as a multi-function timer in a variety of applications, such as generation of counter reset signal, interrupt requests, and pulse output with a desired duty cycle using a compare-match signal with two registers.

Unit 0, unit 1, unit 2, and unit 3 have the same functions, and unit 0 and unit 1 can generate a base clock for the SCI.

In this section, “PCLK” is used to refer to PCLKB.

### 27.1 Overview

Table 27.1 lists the specifications of the TMR. Table 27.2 and Table 27.3 list the TMR functions.

Figure 27.1 shows a block diagram of the 8-bit timer module (unit 0), Figure 27.2 shows that of the 8-bit timer module (unit 1), Figure 27.3 shows that of the 8-bit timer module (unit 2), and Figure 27.3 shows that of the 8-bit timer module (unit 3).

**Table 27.1 Specifications of TMR**

| Item                                              | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

### 27.2.1 Timer Counter (TCNT)

Address(es): TMR0.TCNT 0008 8208h, TMR1.TCNT 0008 8209h, TMR2.TCNT 0008 8218h, TMR3.TCNT 0008 8219h, TMR4.TCNT 0008 8228h, TMR5.TCNT 0008 8229h, TMR6.TCNT 0008 8238h, TMR7.TCNT 0008 8239h, TMR01.TCNT 0008 8208h, TMR23.TCNT 0008 8218h, TMR45.TCNT 0008 8228h, TMR67.TCNT 0008 8238h

TCNT is an 8-bit readable/writable up-counter.

TMR0.TCNT and TMR1.TCNT (TMR2.TCNT and TMR3.TCNT, TMR4.TCNT and TMR5.TCNT, TMR6.TCNT and TMR7.TCNT) comprise a single 16-bit counter (TMR01.TCNT, TMR23.TCNT, TMR45.TCNT, TMR67.TCNT) so they can be accessed together in 16-bit units.

The TCCR.CSS[1:0] and CKS[2:0] bits are used to select a count clock.

TCNT can be cleared by an external counter reset signal, compare match A, or compare match B. Which compare match to be used for clearing is selected by the TCR.CCLR[1:0] bits.

When TCNT overflows (its value changes from FFh to 00h), an overflow interrupt is output provided the interrupt request is enabled by the TCR.OVIE bit.

For details on the corresponding interrupt vector number, refer to section 14, Interrupt Controller (ICUC), and Table 27.7, TMR Interrupt Sources.

## 27.2.2 Time Constant Register A (TCORA)

Address(es): TMR0.TCORA 0008 8204h, TMR1.TCORA 0008 8205h, TMR2.TCORA 0008 8214h, TMR3.TCORA 0008 8215h, TMR4.TCORA 0008 8224h, TMR5.TCORA 0008 8225h, TMR6.TCORA 0008 8234h, TMR7.TCORA 0008 8235h, TMR01.TCORA 0008 8204h, TMR23.TCORA 0008 8214h, TMR45.TCORA 0008 8224h, TMR67.TCORA 0008 8234h

TCORA is an 8-bit readable/writable register.

TMR0.TCORA and TMR1.TCORA (TMR2.TCORA and TMR3.TCORA, TMR4.TCORA and TMR5.TCORA, TMR6.TCORA and TMR7.TCORA) comprise a single 16-bit register (TMR01.TCORA, TMR23.TCORA, TMR45.TCORA, TMR67.TCORA) so they can be accessed together in 16-bit units.

The value in TCORA is continually compared with the value in TCNT. When a match is detected, the corresponding compare match A is generated, and a compare match A interrupt is output provided the interrupt request is enabled by the TCR.CMIEA bit.

However, comparison is not performed during writing to TCORA. The timer output from the TMO<sub>n</sub> pin can be freely controlled by this compare match A and the settings of the TCSR.OSA[1:0] bits.

## 27.2.3 Time Constant Register B (TCORB)

Address(es): TMR0.TCORB 0008 8206h, TMR1.TCORB 0008 8207h, TMR2.TCORB 0008 8216h, TMR3.TCORB 0008 8217h, TMR4.TCORB 0008 8226h, TMR5.TCORB 0008 8227h, TMR6.TCORB 0008 8236h, TMR7.TCORB 0008 8237h, TMR01.TCORB 0008 8206h, TMR23.TCORB 0008 8216h, TMR45.TCORB 0008 8226h, TMR67.TCORB 0008 8236h

TCORB is an 8-bit readable/writable register.

TMR0.TCORB and TMR1.TCORB (TMR2.TCORB and TMR3.TCORB, TMR4.TCORB and TMR5.TCORB, TMR6.TCORB and TMR7.TCORB) comprise a single 16-bit register (TMR01.TCORB, TMR23.TCORB, TMR45.TCORB, TMR67.TCORB) so they can be accessed together in 16-bit units.

The value in TCORB is continually compared with the value in TCNT. When a match is detected, the corresponding compare match B is generated, and a compare match B interrupt is output provided the interrupt request is enabled by the TCR.CMIEB bit.

However, comparison is not performed during writing to TCORB. The timer output from the TMO<sub>n</sub> pin can be freely controlled by this compare match B and the settings of the TCSR.OSB[1:0] bits.

## 27.2.4 Timer Control Register (TCR)

Address(es): TMR0.TCR 0008 8200h, TMR1.TCR 0008 8201h, TMR2.TCR 0008 8210h, TMR3.TCR 0008 8211h,  
TMR4.TCR 0008 8220h, TMR5.TCR 0008 8221h, TMR6.TCR 0008 8230h, TMR7.TCR 0008 8231h

Value after reset: 0 0 0 0 0 0 0 0

| Bit      | Symbol    | Bit Name                         | Description                                                                                                                                                                                                         | R/W |

| b4, b3   | CCLR[1:0] | Counter Clear                    | b4 b3<br>0 0: Clearing is disabled<br>0 1: Cleared by compare match A<br>1 0: Cleared by compare match B<br>1 1: Cleared by the external counter reset signal*1<br>(Select edge or level by the TMRIS bit in TCCR.) | R/W |
| b5       | OVIE      | Overflow Interrupt Enable        | 0: Overflow interrupt requests (OVIn) are disabled<br>1: Overflow interrupt requests (OVIn) are enabled                                                                                                             | R/W |
| b6       | CMIEA     | Compare Match A Interrupt Enable | 0: Compare match A interrupt requests (CMIAIn) are disabled<br>1: Compare match A interrupt requests (CMIAIn) are enabled                                                                                           | R/W |
| b7       | CMIEB     | Compare Match B Interrupt Enable | 0: Compare match B interrupt requests (CMIBIn) are disabled<br>1: Compare match B interrupt requests (CMIBIn) are enabled                                                                                           | R/W |

Note 1. To use an external counter reset signal, set the corresponding pin function. For details, refer to section 20, I/O Ports and section 21, Multi-Function Pin Controller (MPC).

### CCLR[1:0] Bits (Counter Clear)

Select the condition by which TCNT is cleared.

### OVIE Bit (Overflow Interrupt Enable)

Selects whether overflow interrupt requests (OVIn) issued by TCNT are enabled or disabled.

### CMIEA Bit (Compare Match A Interrupt Enable)

Selects whether compare match A interrupt requests (CMIAIn) that are issued when the value of TCORA corresponds to that of TCNT are enabled or disabled.

### CMIEB Bit (Compare Match B Interrupt Enable)

Selects whether compare match B interrupt requests (CMIBIn) that are issued when the value of TCORB corresponds to that of TCNT are enabled or disabled.

## 27.2.5 Timer Counter Control Register (TCCR)

Address(es): TMR0.TCCR 0008 820Ah, TMR1.TCCR 0008 820Bh, TMR2.TCCR 0008 821Ah, TMR3.TCCR 0008 821Bh, TMR4.TCCR 0008 822Ah, TMR5.TCCR 0008 822Bh, TMR6.TCCR 0008 823Ah, TMR7.TCCR 0008 823Bh, TMR01.TCCR 0008 820Ah, TMR23.TCCR 0008 821Ah, TMR45.TCCR 0008 822Ah, TMR67.TCCR 0008 823Ah

Value after reset: 0 0 0 0 0 0 0 0

| Bit      | Symbol   | Bit Name                               | Description                                                                                                                 | R/W |
|----------|----------|----------------------------------------|-----------------------------------------------------------------------------------------------------------------------------|-----|
| b2 to b0 | CKS[2:0] | Clock Select*1                         | See Table 27.6.                                                                                                             | R/W |
| b4, b3   | CSS[1:0] | Clock Source Select                    | See Table 27.6.                                                                                                             | R/W |
| b6, b5   | —        | Reserved                               | These bits are read as 0. The write value should be 0.                                                                      | R/W |
| b7       | TMRIS    | Timer Reset Detection Condition Select | 0: Cleared at rising edge of the external counter reset signal<br>1: Cleared when the external counter reset signal is high | R/W |

Note 1. To use an external count clock, set the corresponding pin function. For details, refer to section 20, I/O Ports and section 21, Multi-Function Pin Controller (MPC).

TCCR register is a 8-bit register used to configure the basic operation of the counter. Two TCCR registers can be accessed simultaneously by accessing the address of the even channel TCCR register in 16-bit units.

### CKS[2:0] Bits (Clock Select)

### CSS[1:0] Bits (Clock Source Select)

The CKS[2:0] and CSS[1:0] bits select a clock. For details, see Table 27.6.

### TMRIS Bit (Timer Reset Detection Condition Select)

This bit is enabled when the TCR.CCLR[1:0] bits are 11b (cleared by external counter reset signal) and selects the condition for detecting counter reset (level or edge).

**Table 27.6 Clock Input to TCNT and Count Condition**

| Channel                       | TCCR Register |    |          |    |    | Description                                                              |                                           |

|                               |               |    |          | 1  | 0  | 0                                                                        | Uses internal clock. Counts at PCLK/64.   |
|                               |               |    |          |    |    | 1                                                                        | Uses internal clock. Counts at PCLK/1024. |
|                               |               |    |          |    |    | 0                                                                        | Uses internal clock. Counts at PCLK/8192. |
|                               |               |    |          |    |    | 1                                                                        | Clock input prohibited                    |
|                               | 1             | 0  | —        | —  | —  | Setting prohibited                                                       |                                           |
|                               | 1             | 1  | —        | —  | —  | Counts at TMR0.TCNT (TMR2.TCNT, TMR4.TCNT, TMR6.TCNT) compare match A*2. |                                           |

Note 1. To use an external count clock, set the corresponding pin function. For details, refer to section 20, I/O Ports and section 21, Multi-Function Pin Controller (MPC).

Note 2. If the clock input of TMR0 (TMR2, TMR4, TMR6) is the overflow signal of the TMR1.TCNT (TMR3.TCNT, TMR5.TCNT, TMR7.TCNT) counter and that of TMR1 (TMR3, TMR5, TMR7) is the compare match signal of the TMR0.TCNT (TMR2.TCNT, TMR4.TCNT, TMR6.TCNT) counter, no TCNT count clock is generated. Do not use this setting.

## 27.2.6 Timer Control/Status Register (TCSR)

- TMR0.TCSR, TMR2.TCSR, TMR4.TCSR, TMR6.TCSR

Address(es): TMR0.TCSR 0008 8202h, TMR2.TCSR 0008 8212h, TMR4.TCSR 0008 8222h, TMR6.TCSR 0008 8232h

| Bit      | Symbol   | Bit Name           | Description                                                                                                                                               | R/W |
|----------|----------|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------|-----|
| b1, b0   | OSA[1:0] | Output Select A*1  | b1 b0<br>0 0: No change<br>0 1: Low is output<br>1 0: High is output<br>1 1: Output is inverted (toggle output)                                           | R/W |
| b3, b2   | OSB[1:0] | Output Select B*1  | b3 b2<br>0 0: No change<br>0 1: Low is output<br>1 0: High is output<br>1 1: Output is inverted (toggle output)                                           | R/W |
| b4       | ADTE     | A/D Trigger Enable | 0: A/D conversion start request in response to compare match A is disabled.<br>1: A/D conversion start request in response to compare match A is enabled. | R/W |
| b7 to b5 | —        | Reserved           | These bits are read as an undefined value. The write value should be 1.                                                                                   | R/W |

Note 1. When all OSA[1:0] and OSB[1:0] bits are 0, the output enable signal corresponding to the TMO<sub>n</sub> pin is negated and a request for high-impedance output is issued to the I/O port. Timer output pin is driven low until the first compare-match occurs after a reset when at least one of the OSA[1:0] and OSB[1:0] bits is 1.

### OSA[1:0] Bits (Output Select A)

These bits select a method of TMO<sub>n</sub> pin output when compare match A of TCORA and TCNT occurs.

### OSB[1:0] Bits (Output Select B)

These bits select a method of TMO<sub>n</sub> pin output when compare match B of TCORB and TCNT occurs.

- TMR1.TCSR, TMR3.TCSR, TMR5.TCSR, TMR7.TCSR

Address(es): TMR1.TCSR 0008 8203h, TMR3.TCSR 0008 8213h, TMR5.TCSR 0008 8223h, TMR7.TCSR 0008 8233h

| Bit      | Symbol   | Bit Name          | Description                                                                                                     | R/W |
|----------|----------|-------------------|-----------------------------------------------------------------------------------------------------------------|-----|

| b4       | —        | Reserved          | This bit is read as 1. The write value should be 1.                                                             | R/W |
| b7 to b5 | —        | Reserved          | These bits are read as an undefined value. The write value should be 1.                                         | R/W |

Note 1. When all OSA[1:0] and OSB[1:0] bits are 0, the output enable signal corresponding to the TMO<sub>n</sub> pin is negated and a request for high-impedance output is issued to the I/O port. Timer output pin is driven low until the first compare match occurs after a reset when at least one of the OSA[1:0] and OSB[1:0] bits is 1.

#### OSA[1:0] Bits (Output Select A)

These bits select a method of TMO<sub>n</sub> pin output when compare match A of TCORA and TCNT occurs.

#### OSB[1:0] Bits (Output Select B)

These bits select a method of TMO<sub>n</sub> pin output when compare match B of TCORB and TCNT occurs.

### 27.2.7 Timer Counter Start Register (TCSTR)

Address(es): TMR0.TCSTR 0008 820Ch, TMR1.TCSTR 0008 820Dh, TMR2.TCSTR 0008 821Ch, TMR3.TCSTR 0008 821Dh

x: Undefined

| Bit      | Symbol | Bit Name             | Description                                                                            | R/W |
|----------|--------|----------------------|----------------------------------------------------------------------------------------|-----|
| b0       | TCS    | Timer Counter Status | 0: Count stopped state in response to ELC.<br>1: Count start state in response to ELC. | R/W |
| b7 to b1 | —      | Reserved             | These bits are read as an undefined value. The write value should be 0.                | R/W |

#### TCS Bit (Timer Counter Status)

The TCS bit is used to check the state of the timer count in response to ELC.

When this bit is read as 1, it shows the timer start state in response to ELC. When this bit is read as 0, it shows the timer stopped state in response to ELC.

This bit is cleared by writing 0. Do not write 1 to this bit.

The TCS bit is valid only when the count start operation is selected by the ELOPD register of the event controller (ELC). For details, refer to section 27.7, Link Operation by ELC, or section 19, Event Link Controller (ELC).

## 27.3 Operation

### 27.3.1 Pulse Output

Figure 27.5 shows an example of the 8-bit timer being used to generate a pulse output with a desired duty cycle.

1. Set the TCR.CCLR[1:0] bits to 01b (cleared by compare match A) so that TCNT is cleared at a compare match of TCORA.
2. Set the TCSR.OSA[1:0] bits to 10b (high is output) and TCSR.OSB[1:0] bits to 01b (low is output), causing the output to change to high at a compare match of TCORA and to low at a compare match of TCORB.

With these settings, the 8-bit timer provides pulses output at a cycle determined by TCORA with a pulse width determined by TCORB. No software intervention is required.

The timer output pin is low after the TCSR.OSA[1:0] or TCSR.OSB[1:0] bits are set until the first compare match occurs after a reset.

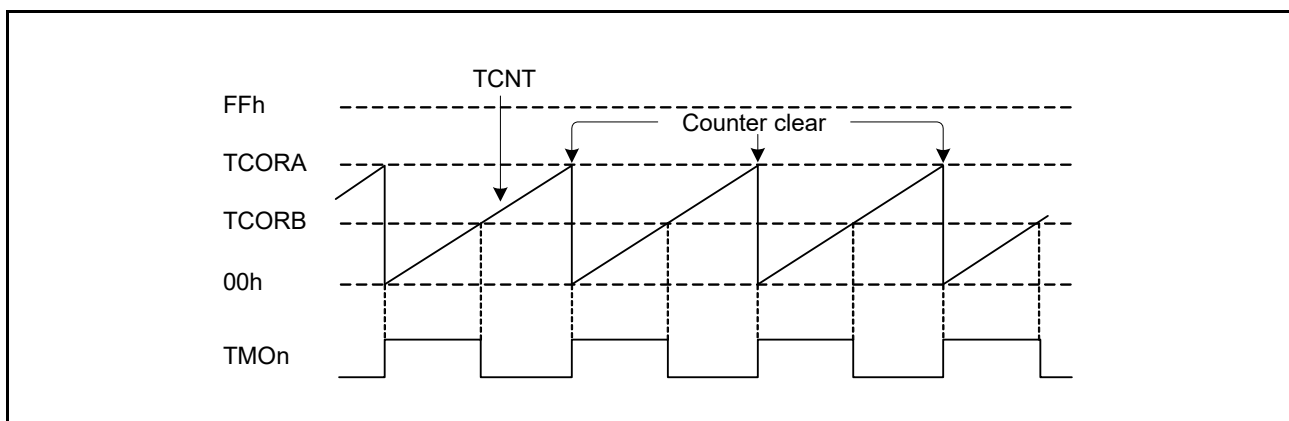

Figure 27.5 Example of Pulse Output (n = 0 to 7)

### 27.3.2 External Counter Reset Input

Figure 27.6 shows an example of the 8-bit timer being used to generate a pulse which is output after a desired delay time from a TMRIn input.

1. Set the TCR.CCLR[1:0] bits to 11b (cleared by external counter reset signal) and set the TMRIS bit in TCCR to 1 (cleared when the external counter reset signal is high) so that TCNT is cleared at the high level input of the TMRIn signal.
2. Set the TCSR.OSA[1:0] bits to 10b (high output) and the TCSR.OSB[1:0] bits to 01b (low output), causing the output to change to high at a compare match of TCORA and to low at a compare match of TCORB.

With these settings, the 8-bit timer provides pulses output at a desired delay time from a TMRIn input determined by TCORA and with a pulse width determined by TCORB and TCORA.

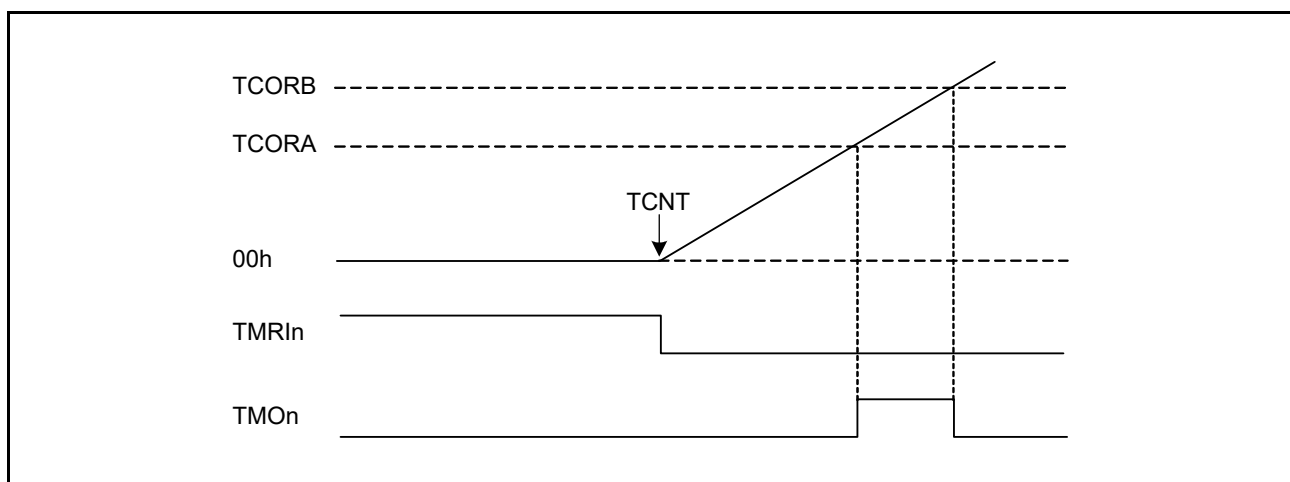

Figure 27.6 Example of External Counter Reset Signal Input (n = 0 to 7)

## 27.4 Operation Timing

### 27.4.1 TCNT Count Timing

Figure 27.7 shows the count timing of TCNT for internal clock. Figure 27.8 shows the count timing of TCNT for external clock.

Note that the external clock pulse width must be at least 1.5 PCLK cycles for increment at a single edge, and at least 2.5 PCLK cycles for increment at both edges. The counter will not increment correctly if the pulse width is less than these values.

Figure 27.7 Count Timing for Internal Clock

Figure 27.8 Count Timing for External Clock (at Both Edges)

### 27.4.2 Timing of Interrupt Signal Output on a Compare Match

A compare match refers to a match between the value of the TCORA or TCORB register and the TCNT, and a compare match interrupt signal is output at this time if the interrupt request is enabled. The compare match is generated in the last cycle in which the values match (at the time at which the value counted by TCNT to produce the match is updated). Accordingly, after a match between TCNT and the TCORA or TCORB register is detected, the compare match is not actually generated until the next cycle of the TCNT count clock. Figure 27.9 shows the timing of output of the interrupt signal.

For the corresponding interrupt vector number, refer to section 14, Interrupt Controller (ICUC) and Table 27.7.

Figure 27.9 Timing of Interrupt Flag Setting to 1 at Compare Match (n = 0 to 7)

### 27.4.3 Timing of Timer Output Signal at Compare Match

When a compare match signal is generated, the output value specified by the TCSR.OSA[1:0] and OSB[1:0] bits is output on the timer output pin (TMO<sub>n</sub>).

Figure 27.10 shows the timing when the timer output is toggled by the compare match A signal.

Figure 27.10 Timing of Timer Output Signal at Compare Match A Signal (n = 0 to 7)

### 27.4.4 Timing of Counter Clear by Compare Match

TCNT is cleared when compare match A or B occurs, depending on the settings of the TCR.CCLR[1:0] bits. Figure 27.11 shows the timing of this operation.

Figure 27.11 Timing of Counter Clear by Compare Match

### 27.4.5 Timing of the External Reset for TCNT

TCNT is cleared at the rising edge or high level of an external counter reset signal, depending on the settings of the TCR.CCLR[1:0] bits. At least 2 PCLK cycles are required from a reset input to clearing of TCNT. Figure 27.12 and Figure 27.13 show the timing of this operation.

Figure 27.12 Clear Timing by External Counter Reset Signal (Rising Edge)

Figure 27.13 Clear Timing by External Counter Reset Signal (High Level)

### 27.4.6 Timing of Interrupt Signal Output on an Overflow

When TCNT overflows (changes from FFh to 00h), an overflow interrupt signal is output if this interrupt request is enabled.

Figure 27.14 shows the timing of output of the interrupt signal.

For the corresponding interrupt vector number, refer to section 14, Interrupt Controller (ICUC) and Table 27.7.

Figure 27.14 Timing of Overflow Interrupt Flag Setting to 1 (n = 0 to 7)

## 27.5 Operation with Cascaded Connection

If the CSS[1:0] bits in either TMR0.TCCR or TMR1.TCCR are set to 11b, the TMR of the two channels are cascaded. With this configuration, a single 16-bit timer could be used (16-bit counter mode) or compare matches of TMR0 could be counted by TMR1 (compare match count mode).

This section describes unit 0. The operation of unit 1, unit 2, and unit 3 with cascaded connection is the same as unit 0.

### 27.5.1 16-Bit Count Mode

When the TMR0.TCCR.CSS[1:0] bits are set to 11b, the timer functions as a single 16-bit timer with TMR0 occupying the upper 8 bits and TMR1 occupying the lower 8 bits.

#### (1) Counter Clear Specification

- The settings of the TMR0.TCR.CCLR[1:0] bits become effective for the 16-bit counter. If the TMR0.TCR.CCLR[1:0] bits have been set for counter clear at compare match, the 16-bit counter (TMR0.TCNT and TMR1.TCNT together) is cleared when a 16-bit compare match event occurs. The 16-bit counter (TMR0.TCNT and TMR1.TCNT together) is cleared even if counter clear by the TMRIO pin has been set.
- The settings of the TMR1.TCR.CCLR[1:0] bits are ignored.

#### (2) Pin Output

- Control of output from the TMO0 pin by the TMR0.TCSR.OSA[1:0] and OSB[1:0] bits is in accordance with the 16-bit compare match conditions.
- Control of output from the TMO1 pin by the TMR1.TCSR.OSA[1:0] and OSB[1:0] bits is in accordance with the lower 8-bit compare match conditions.

### 27.5.2 Compare Match Count Mode

When the TMR1.TCCR.CSS[1:0] bits are set to 11b, TMR1.TCNT counts the number of occurrences of compare match A for TMR0. TMR0 and TMR1 are controlled independently. Conditions such as generation of interrupts, output from the TMO<sub>n</sub> pin (n = 0, 1), and counter clear are in accordance with the settings for each channel.

## 27.6 Interrupt Sources

### 27.6.1 Interrupt Sources and DTC Activation

There are three interrupt sources for TMRn: CMIA<sub>n</sub>, CMIB<sub>n</sub>, and OVIn. Their interrupt sources and priorities are listed in Table 27.7.

It is also possible to activate the DTC by means of CMIA<sub>n</sub> and CMIB<sub>n</sub> interrupts.

**Table 27.7 TMR Interrupt Sources**

| Name  | Interrupt Sources        | DTC Activation |
|-------|--------------------------|----------------|
| CMIA0 | TMR0.TCORA compare match | Possible       |
| CMIB0 | TMR0.TCORB compare match | Possible       |
| OV10  | TMR0.TCNT overflow       | Not possible   |
| CMIA1 | TMR1.TCORA compare match | Possible       |
| CMIB1 | TMR1.TCORB compare match | Possible       |
| OV11  | TMR1.TCNT overflow       | Not possible   |
| CMIA2 | TMR2.TCORA compare match | Possible       |
| CMIB2 | TMR2.TCORB compare match | Possible       |
| OV12  | TMR2.TCNT overflow       | Not possible   |
| CMIA3 | TMR3.TCORA compare match | Possible       |
| CMIB3 | TMR3.TCORB compare match | Possible       |
| OV13  | TMR3.TCNT overflow       | Not possible   |
| CMIA4 | TMR4.TCORA compare match | Possible       |
| CMIB4 | TMR4.TCORB compare match | Possible       |
| OV14  | TMR4.TCNT overflow       | Not possible   |
| CMIA5 | TMR5.TCORA compare match | Possible       |
| CMIB5 | TMR5.TCORB compare match | Possible       |
| OV15  | TMR5.TCNT overflow       | Not possible   |
| CMIA6 | TMR6.TCORA compare match | Possible       |
| CMIB6 | TMR6.TCORB compare match | Possible       |
| OV16  | TMR6.TCNT overflow       | Not possible   |
| CMIA7 | TMR7.TCORA compare match | Possible       |
| CMIB7 | TMR7.TCORB compare match | Possible       |
| OV17  | TMR7.TCNT overflow       | Not possible   |

## 27.6.2 Startup of the A/D Converter

The compare match A of TMR0, TMR2, TMR4, and TMR6 allows the A/D converter to be started.

An A/D conversion start request is issued to the A/D converter in response to a generation of compare match A when the TMRn.TCSR.ADTE bit is 1 (i.e., when an A/D conversion request in response to compare match A is enabled). In this case, the conversion trigger for the 8-bit timer should be selected in the A/D converter to start A/D conversion.

**Table 27.8 Startup of A/D Converter**

| A/D Converter                                   | TMR Unit No. | Target                                         | A/D Conversion Start Request |
|-------------------------------------------------|--------------|------------------------------------------------|------------------------------|
| S12AD, S12AD1, S12AD2<br>(12-bit A/D converter) | 0            | Compare match between TMR0.TCORA and TMR0.TCNT | TMTRG0AN_0                   |
|                                                 | 1            | Compare match between TMR2.TCORA and TMR2.TCNT | TMTRG0AN_1                   |
|                                                 | 2            | Compare match between TMR4.TCORA and TMR4.TCNT | TMTRG0AN_2                   |
|                                                 | 3            | Compare match between TMR6.TCORA and TMR6.TCNT | TMTRG0AN_3                   |

## 27.7 Link Operation by ELC

### 27.7.1 Event Signal Output to ELC

The TMR uses the event link controller (ELC) to perform link operation to the previously specified module using the interrupt request signal as the event signal. The TMR outputs compare match A, compare match B, and overflow signals as event signals. Channels that can be used in this way are TMR0 to TMR3.

The event signal can be output regardless of the setting of the corresponding interrupt request enable bits (TMRn.TCR.OVIE, TMRn.TCR.CMIEA, and TMRn.TCR.CMIEB (n = 0 to 3)). For details, refer to section 19, Event Link Controller (ELC).

The event output function can be used for the cascaded operation.

### 27.7.2 TMR Operation when Receiving an Event Signal from ELC

The TMR can perform either of the following operations upon the event previously specified by the ELSRn register of the ELC. However, the ELC does not support the cascaded operation.

#### (1) Count Start

When the TMR count start operation is selected by the ELOPD register of the ELC and the event specified by ELSRn occurs, the TCSTR.TCS bit is set to 1, starting the TMR count operation. After the TMR count start operation is selected by the ELOPD register of the ELC, use the TCCR.CKS[2:0] and CSS[1:0] bits to select the count source.

If the specified event occurs while the TCS bit is 1, the event is ignored.

Write 0 to the TCSTR.TCS bit to stop counting.

When the count start event is input in the count stopped state, the TMR starts counting again according to the CKS[2:0] and CSS[1:0] bits.

The TCS bit is valid only when the ELOPD.TMR0MD[1:0], ELOPD.TMR1MD[1:0], ELOPD.TMR2MD[1:0], and ELOPD.TMR3MD[1:0] bits of the ELC select the count start operation.

#### (2) Event Count

When the TMR event count operation is selected by the ELOPD register of the ELC and the event specified by ELSRn occurs, the events are counted as the count source regardless of the TCCR.CKS[2:0] and CSS[1:0] bit settings. Reading the counter value returns the number of events that have been actually input.

#### (3) Count Restart

When the TMR count restart operation is selected by the ELOPD register of the ELC and the event specified by ELSRn occurs, the TCNT counter value is modified to the initial value. If the CKS[2:0] and CSS[1:0] bit settings are not disabling the clock input, the count operation is continued.

### 27.7.3 Notes on Operating TMR According to an Event Signal from ELC

The following describes the notes on operating the TMR using the event link feature.

#### (1) Count Start

When the event specified by ELSRn occurs during the write cycle to the TCSTR.TCS bit, the cycle is not completed; setting 1 according to the event occurrence takes priority.

#### (2) Event Count

When the event specified by ELSRn occurs during the write cycle to the TCNT, the cycle is not completed; event count operation according to the event occurrence takes priority.

#### (3) Count Restart

When the event specified by ELSRn occurs during the write cycle to the TCNT, the cycle is not completed; count value initialization according to the event occurrence takes priority.

## 27.8 Usage Notes

### 27.8.1 Module Stop State Setting

Operation of the TMR can be disabled or enabled by using the module stop control registers. The initial setting is for halting of TMR operation. Register access becomes possible after release from the module stop state. For details, refer to section 11, Low Power Consumption.

### 27.8.2 Notes on Setting Cycle

If the compare match is selected for counter clear, TCNT is cleared at the last PCLK in the cycle in which the value of TCNT matches with that of TCORA or TCORB. TCNT updates the counter value at this last state. Therefore, the counter frequency is obtained by the following formula (f: Counter frequency, PCLK: Operating frequency, N: TCORA and TCORB register setting value).

$$f = \text{PCLK} / (N + 1)$$

### 27.8.3 Conflict between TCNT Write and Counter Clear

If a counter clear signal is generated concurrently with CPU write to TCNT, the clear takes priority and the write is not performed as shown in Figure 27.15.

Figure 27.15 Conflict between TCNT Write and Counter Clear

### 27.8.4 Conflict between TCNT Write and Increment

Even if a counting-up signal is generated concurrently with CPU write to TCNT, the counting-up is not performed and the write takes priority as shown in Figure 27.16.

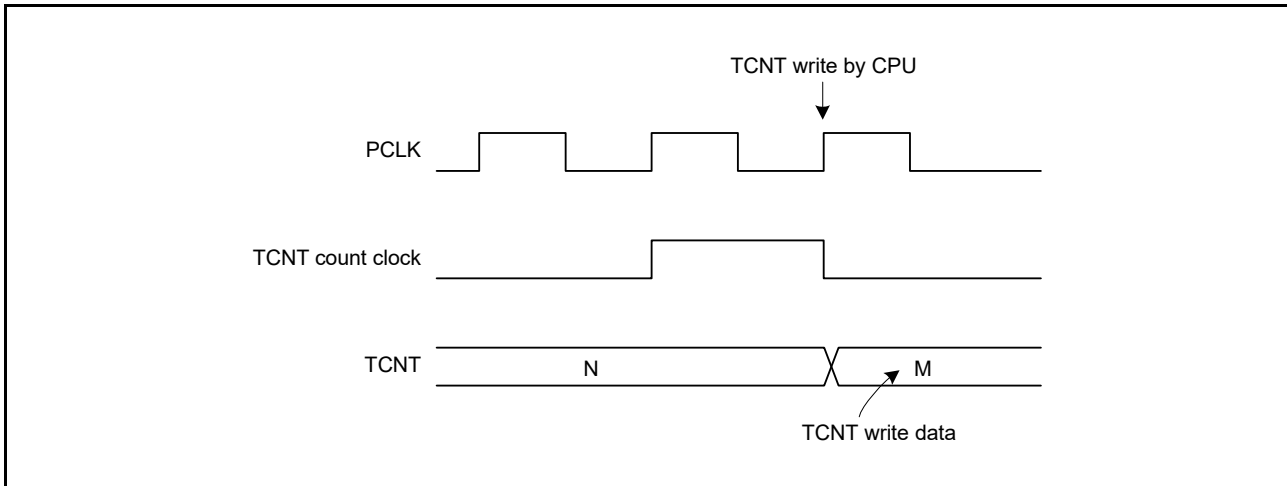

Figure 27.16 Conflict between TCNT Write and Increment

### 27.8.5 Conflict between TCORA or TCORB Write and Compare Match

Even if a compare match signal is generated simultaneously with CPU write to TCORA or TCORB as shown in Figure 27.17, the write takes priority and the compare match signal does not reach High level.

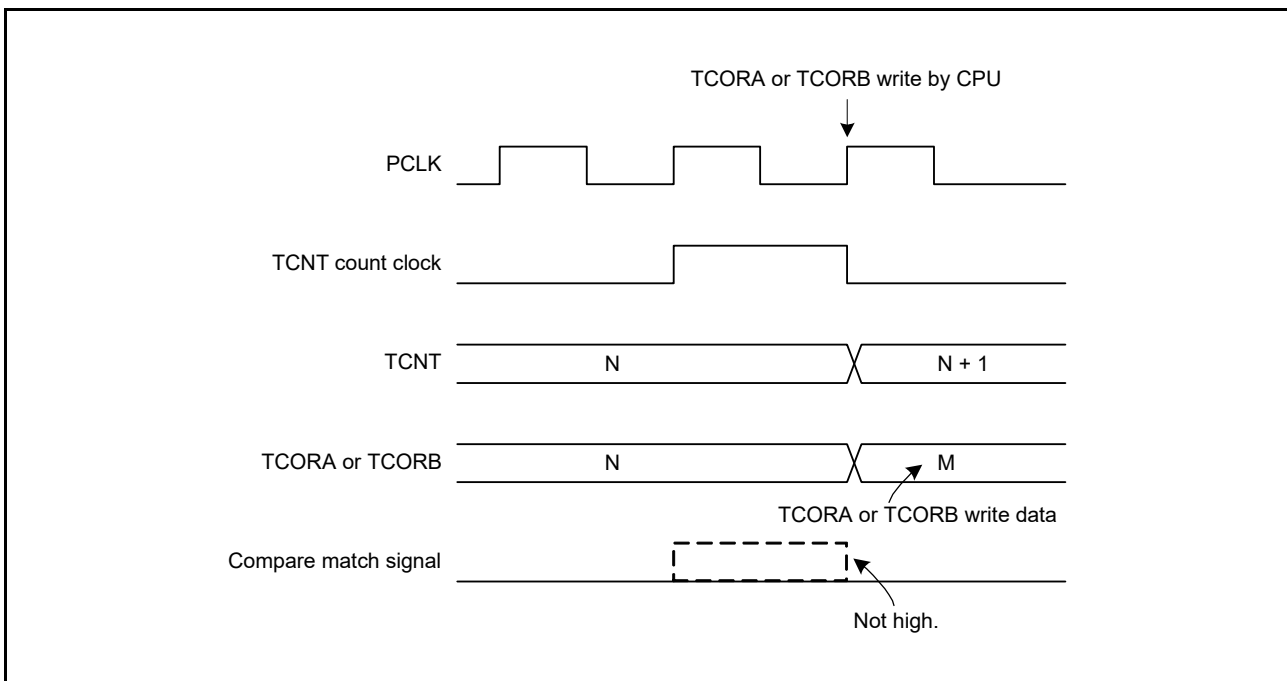

Figure 27.17 Conflict between TCORA or TCORB Write and Compare Match

### 27.8.6 Conflict between Compare Matches A and B

If compare match events A and B occur at the same time, the 8-bit timer operates in accordance with the priorities for the output methods high for compare match A and compare match B, as listed in Table 27.9.

**Table 27.9 Timer Output Priorities**

| Output Setting | Priority |
|----------------|----------|
| Toggle output  | High     |
| High output    | ↑        |
| Low output     |          |
| No change      | Low      |

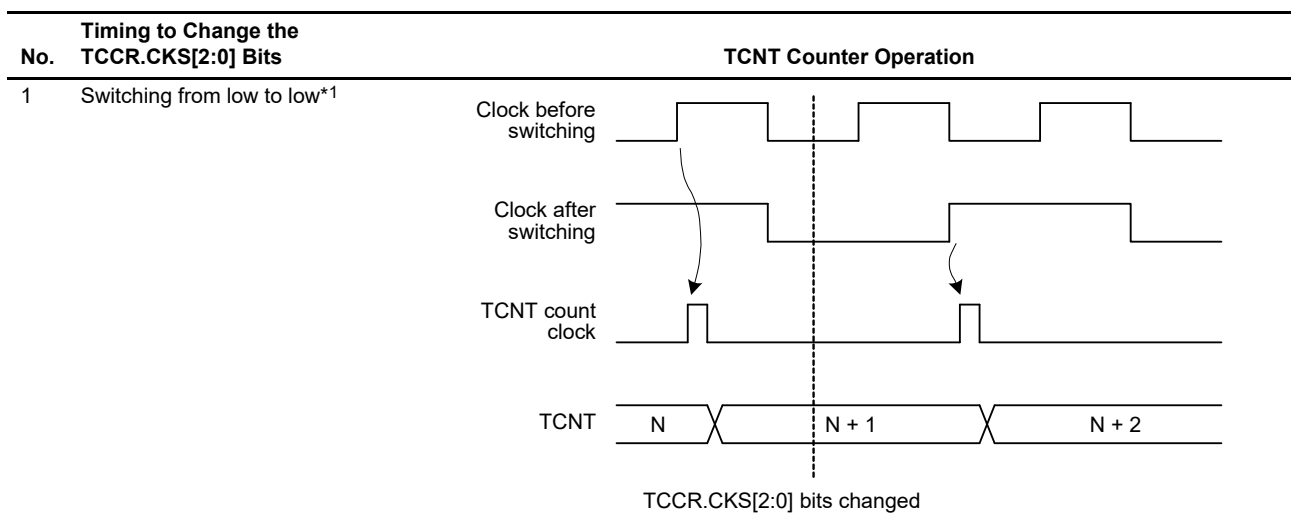

### 27.8.7 Switching of Internal Clocks and TCNT Operation

TCNT may be incremented erroneously depending on when the internal clock is switched. Table 27.10 lists the relationship between the timing at which the internal clock is switched (by writing to the TCCR.CKS[2:0] bits) and the operation of TCNT.

When TCNT count clock is generated from an internal clock, the rising edge of the internal clock pulse are always monitored. If the signal levels of the clocks before and after switching change from low to high as shown in No. 2 in Table 27.10, the change is considered as an edge. Therefore, a TCNT count clock is generated and TCNT is incremented.

The erroneous increment of TCNT can also happen when switching between internal and internal clocks.

**Table 27.10 Switching of Internal Clocks and TCNT Operation (1/2)**

**Table 27.10 Switching of Internal Clocks and TCNT Operation (2/2)**

| No. | Timing to Change the TCCR.CKS[2:0] Bits | TCNT Counter Operation |
|-----|-----------------------------------------|------------------------|
| 2   | Switching from low to high*2            |                        |
| 3   | Switching from high to low*4            |                        |
| 4   | Switching from high to high             |                        |

Note 1. Includes switching from low to stop, and from stop to low.

Note 2. Includes switching from stop to high.

Note 3. Generated because the change of the signal levels is considered as an edge; TCNT counter is incremented.

Note 4. Includes switching from high to stop.

### 27.8.8 Clock Source Setting with Cascaded Connection

If 16-bit counter mode and compare match count mode are specified at the same time, count clocks for TMR0.TCNT and TMR1.TCNT (TMR2.TCNT and TMR3.TCNT, TMR4.TCNT and TMR5.TCNT, TMR6.TCNT and TMR7.TCNT) are not generated, and the counter stops. Do not specify 16-bit counter mode and compare match count mode simultaneously.

### 27.8.9 Continuous Output of Compare Match Interrupt Signal

When TCORA or TCORB is set to 00h, PCLK/1 is set as the internal clock, and compare match is set as the counter clear source, the TCNT counter remains 00h and is not updated, and a compare match interrupt signal is output continuously to form a flat signal level.

At this time, the interrupt controller cannot detect the second and subsequent interrupts.

Figure 27.18 shows operation timing when the compare match interrupt signal is continuously output.

Figure 27.18 Continuous Output of Compare Match Interrupt Signal (n = 0 to 7)

## 28. Compare Match Timer (CMT)

This MCU has two on-chip compare match timer (CMT) units (unit 0 and unit 1), each consisting of a two-channel 16-bit timer (i.e., a total of four channels). The CMT has a 16-bit counter, and can generate interrupts at set intervals.

In this section, “PCLK” is used to refer to PCLKB.

### 28.1 Overview

Table 28.1 lists the specifications for the CMT.

Figure 28.1 shows a block diagram of the CMT (unit 0). A two-channel CMT constitutes a unit. Unit 0 and unit 1 are the same in terms of specifications. Compare match timer start register 0 (CMSTR0) and compare match interrupts (CMI0 and CMI1) of unit 0 correspond to compare match timer start register 1 (CMSTR1) and compare match interrupts (CMI2 and CMI3) of unit 1.

**Table 28.1 CMT Specifications**

| Item                           | Description                                                                                                                                                                        |
|--------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Count clocks                   | <ul style="list-style-type: none"> <li>Four frequency dividing clocks</li> <li>One clock from PCLK/8, PCLK/32, PCLK/128, and PCLK/512 can be selected for each channel.</li> </ul> |
| Interrupt                      | A compare match interrupt can be requested for each channel.                                                                                                                       |
| Event link function (output)   | An event signal is output upon a CMT1 compare match.                                                                                                                               |
| Event link function (input)    | Linking to the specified module is possible.<br>CMT1 count start, event counter, or count restart operation is possible.                                                           |
| Low power consumption function | Each unit can be placed in a module stop state.                                                                                                                                    |

**Figure 28.1 CMT (Unit 0) Block Diagram**

## 28.2 Register Descriptions

### 28.2.1 Compare Match Timer Start Register 0 (CMSTR0)

Address(es): 0008 8000h

| Bit       | Symbol | Bit Name      | Description                                                        | R/W |
|-----------|--------|---------------|--------------------------------------------------------------------|-----|
| b0        | STR0   | Count Start 0 | 0: CMT0.CMCNT count is stopped.<br>1: CMT0.CMCNT count is started. | R/W |
| b1        | STR1   | Count Start 1 | 0: CMT1.CMCNT count is stopped.<br>1: CMT1.CMCNT count is started. | R/W |
| b15 to b2 | —      | Reserved      | These bits are read as 0. The write value should be 0.             | R/W |

### 28.2.2 Compare Match Timer Start Register 1 (CMSTR1)

Address(es): 0008 8010h

| Bit       | Symbol | Bit Name      | Description                                                        | R/W |
|-----------|--------|---------------|--------------------------------------------------------------------|-----|
| b0        | STR2   | Count Start 2 | 0: CMT2.CMCNT count is stopped.<br>1: CMT2.CMCNT count is started. | R/W |
| b1        | STR3   | Count Start 3 | 0: CMT3.CMCNT count is stopped.<br>1: CMT3.CMCNT count is started. | R/W |
| b15 to b2 | —      | Reserved      | These bits are read as 0. The write value should be 0.             | R/W |

### 28.2.3 Compare Match Timer Control Register (CMCR)

Address(es): CMT0.CMCR 0008 8002h, CMT1.CMCR 0008 8008h, CMT2.CMCR 0008 8012h, CMT3.CMCR 0008 8018h

| Bit       | Symbol   | Bit Name                       | Description                                                                             | R/W |
|-----------|----------|--------------------------------|-----------------------------------------------------------------------------------------|-----|
| b1, b0    | CKS[1:0] | Clock Select                   | b1 b0<br>0 0: PCLK/8<br>0 1: PCLK/32<br>1 0: PCLK/128<br>1 1: PCLK/512                  | R/W |
| b5 to b2  | —        | Reserved                       | These bits are read as 0. The write value should be 0.                                  | R/W |
| b6        | CMIE     | Compare Match Interrupt Enable | 0: Compare match interrupt (CMIn) disabled<br>1: Compare match interrupt (CMIn) enabled | R/W |
| b7        | —        | Reserved                       | This bit is read as undefined. The write value should be 1.                             | R/W |
| b15 to b8 | —        | Reserved                       | These bits are read as 0. The write value should be 0.                                  | R/W |

#### CKS[1:0] Bits (Clock Select)

These bits select the count source from four frequency dividing clocks obtained by dividing the peripheral module clock (PCLK).

When the CMSTRm.STRn (m = 0, 1; n = 0 to 3) bit is set to 1, the CMCNT counter starts counting up on the clock selected with the CKS[1:0] bits.

#### CMIE Bit (Compare Match Interrupt Enable)

The CMIE bit enables or disables compare match interrupt (CMIn) (n = 0 to 3) generation when the CMCNT counter and the CMCOR register values match.

### 28.2.4 Compare Match Counter (CMCNT)

Address(es): CMT0.CMCNT 0008 8004h, CMT1.CMCNT 0008 800Ah, CMT2.CMCNT 0008 8014h, CMT3.CMCNT 0008 801Ah

The CMCNT counter is a readable/writable up-counter.

When an frequency dividing clock is selected by the CMCR.CKS[1:0] bits and the CMSTRm.STRn (m = 0, 1; n = 0 to 3) bit is set to 1, the CMCNT counter starts counting up using the selected clock.

When the value in the CMCNT counter and the value in the CMCOR register match, the CMCNT counter is set to 0000h. At the same time, a compare match interrupt (CMIn) (n = 0 to 3) is generated.

### 28.2.5 Compare Match Constant Register (CMCOR)

Address(es): CMT0.CMCOR 0008 8006h, CMT1.CMCOR 0008 800Ch, CMT2.CMCOR 0008 8016h, CMT3.CMCOR 0008 801Ch

The CMCOR register is a readable/writable register to set a value for compare match with the CMCNT counter.

### 28.3 Operation

#### 28.3.1 Periodic Count Operation

When an frequency dividing clock is selected by the CMCR.CKS[1:0] bits and the CMSTRm.STRn (m = 0, 1; n = 0 to 3) bit is set to 1, the CMCNT counter starts counting up using the selected clock.

When the value in the counter and the value in the register match, a compare match interrupt (CMIn) (n = 0 to 3) is generated. The CMCNT counter then starts counting up again from 0000h. Figure 28.2 shows the operation of the CMCNT counter.

Figure 28.2 CMCNT Counter Operation

#### 28.3.2 CMCNT Count Timing

As the count clock to be input to the CMCNT counter, one of four frequency dividing clocks (PCLK/8, PCLK/32, PCLK/128, and PCLK/512) obtained by dividing the peripheral module clock (PCLK) can be selected with the CMCR.CKS[1:0] bits. Figure 28.3 shows the timing of the CMCNT counter.

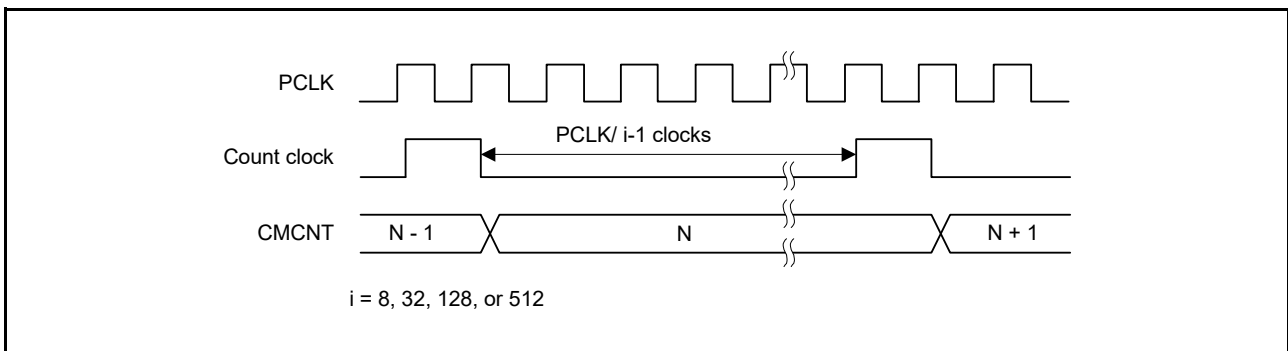

Figure 28.3 CMCNT Count Timing

## 28.4 Interrupts

### 28.4.1 Interrupt Sources

The CMT has channels and each of them to which a different vector address is allocated has a compare match interrupt (CMI<sub>n</sub>) (n = 0 to 3). When a compare match interrupt occurs, the corresponding interrupt request is output.

When the interrupt request is used to generate a CPU interrupt, the priority of channels can be changed by the interrupt controller settings. For details, see section 14, Interrupt Controller (ICUC).

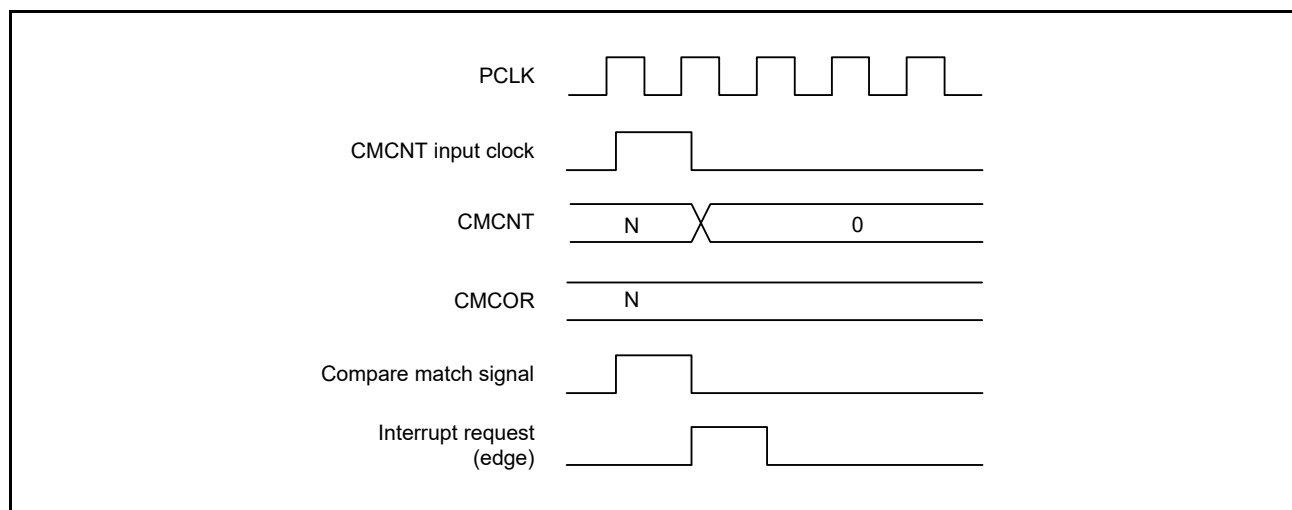

**Table 28.2 CMT Interrupt Sources**

| Name | Interrupt Sources     | DTC Activation | DMAC Activation |
|------|-----------------------|----------------|-----------------|
| CMI0 | Compare match in CMT0 | Possible       | Possible        |
| CMI1 | Compare match in CMT1 | Possible       | Possible        |
| CMI2 | Compare match in CMT2 | Possible       | Possible        |

### 28.4.2 Timing of Compare Match Interrupt Generation

When the CMCNT counter and the CMCOR register match, a compare match interrupt (CMI<sub>n</sub>) (n = 0 to 3) is generated. A compare match signal is generated at the last state in which the values match (the timing when the CMCNT counter updates the matched count value). That is, after a match between the CMCOR register and the CMCNT counter, the compare match signal is not generated until the next the CMCNT counter input clock.

Figure 28.4 shows the timing of a compare match interrupt.

**Figure 28.4 Timing of a Compare Match Interrupt**

## 28.5 Link Operations by ELC

### 28.5.1 Event Signal Output to ELC

The CMT uses the event link controller (ELC) to perform link operation to a preset module using the interrupt request signal as the event signal. The CMT outputs the event signal upon a CMT1 compare match.

The event signal can be output regardless of the setting of the corresponding interrupt request enable bit (CMTn.CMCR.CMIE).

### 28.5.2 CMT Operation When Receiving an Event Signal from ELC

The CMT can perform either of the following operations upon the event preset by the ELSR7 register of the ELC.

#### (1) Count Start

When the CMT count start operation is selected by the ELOPC register of the ELC and the event specified by ELSR7 occurs, the CMSTR0.STR1 bit is set to 1, starting the CMT count operation.

However, if the specified event occurs while the CMSTR0.STR1 bit is 1, the event is ignored.

#### (2) Event Count

When the CMT event count operation is selected by the ELOPC register of the ELC and the event specified by ELSR7 occurs with the CMSTR0.STR1 bit being 1, the events are counted as the count source regardless of the CMT1.CMCR.CKS[1:0] bit setting. Reading the counter value returns the number of events that have been actually input.

#### (3) Count Restart

When the CMT count restart operation is selected by the ELOPC register of the ELC and the event specified by ELSR7 occurs, the CMT1.CMCNT counter value is modified to the initial value. If the CMSTR0.STR1 bit is 1 here, the count operation can be continued.

### 28.5.3 Notes on Operating CMT According to an Event Signal from ELC

The following describes the notes on operating the CMT using the event link feature.

#### (1) Count Start

When the event specified by ELSR7 occurs during the write cycle to the CMSTR0.STR1 bit, the cycle is not completed; setting 1 according to the event occurrence takes priority.

#### (2) Event Count

When the event specified by ELSR7 occurs during the write cycle to the CMT1.CMCNT, the cycle is not completed; event count operation according to the event occurrence takes priority.

#### (3) Count Restart

When the event specified by ELSR7 occurs during the write cycle to the CMT1.CMCNT, the cycle is not completed; count value initialization according to the event occurrence takes priority.

## 28.6 Usage Notes

### 28.6.1 Setting the Module Stop Function

The CMT can be enabled or disabled using the module stop control register. After a reset, the CMT is in the module stop state. The registers can be accessed by releasing the module stop state. For details, refer to section 11, Low Power Consumption.

### 28.6.2 Conflict between CMCNT Counter Writing and Compare Match

When the compare match signal is generated while writing to the CMCNT counter, clearing the CMCNT counter has priority over writing to it. In this case, the CMCNT counter is not written to. Figure 28.5 shows the timing to clear the CMCNT counter.

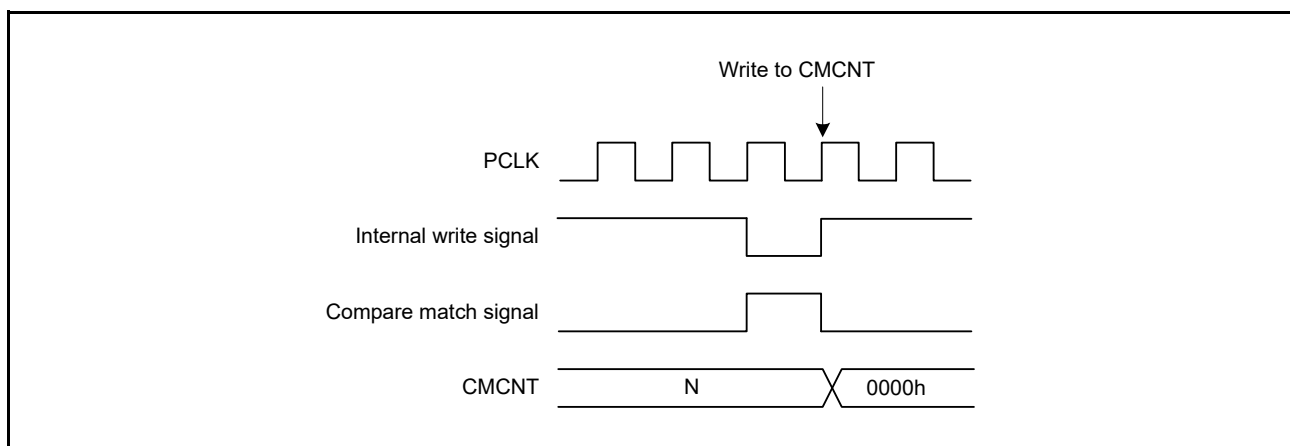

Figure 28.5 Conflict between CMCNT Counter Writing and Compare Match

### 28.6.3 Conflict between CMCNT Counter Writing and Incrementing

If writing to the counter and the incrementing conflict, the writing has priority over the incrementing. Figure 28.6 shows the timing to write the CMCNT counter.

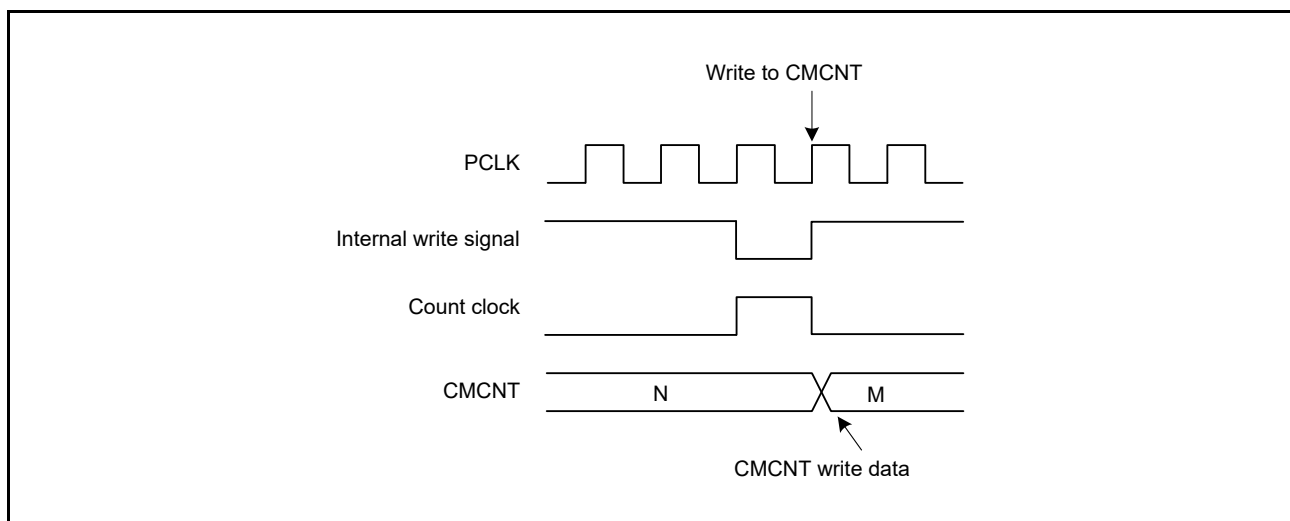

Figure 28.6 Conflict between CMCNT Counter Writing and Incrementing

## 29. Watchdog Timer (WDTA)

The watchdog timer (WDT) is a 14-bit down-counter. It can be used to reset this MCU when the counter underflows because its value cannot be refreshed due to the system being out of control.

In addition, a non-maskable interrupt can be generated by an underflow.

The refresh-permitted period can be set to refresh the counter and used as the condition to detect when the system runs out of control.

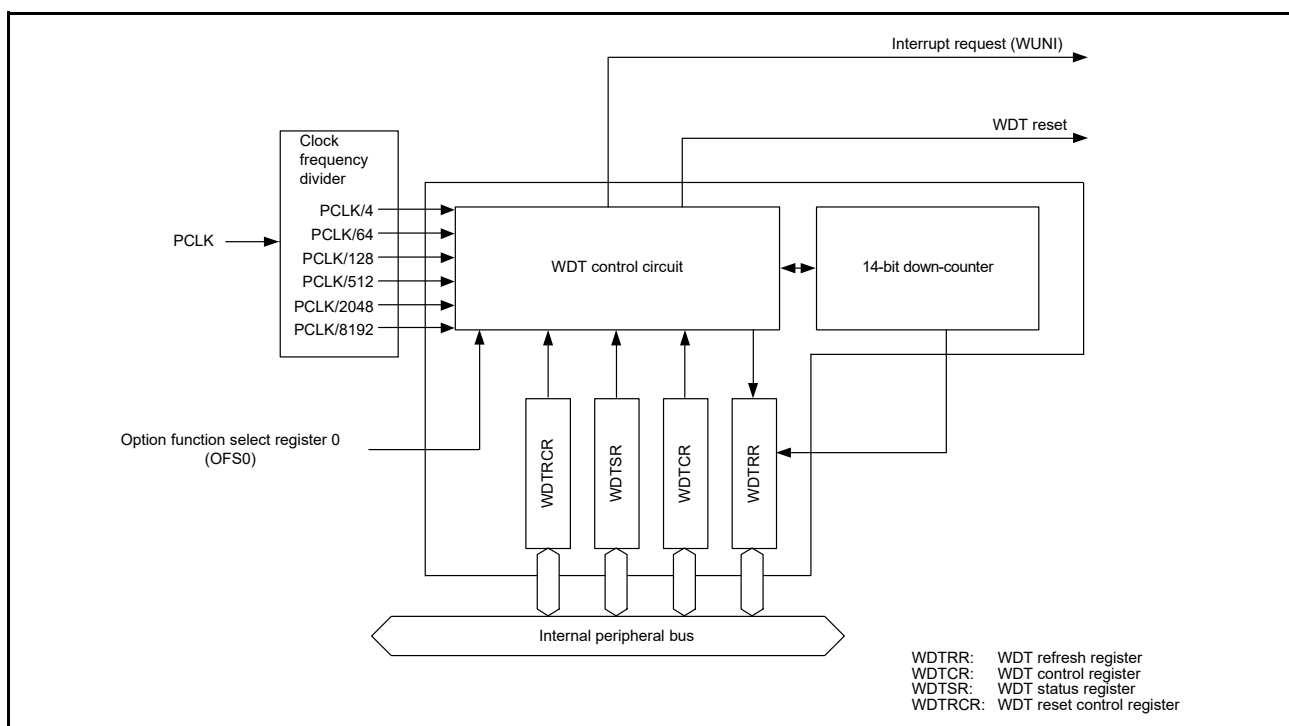

In this section, “PCLK” is used to refer to PCLKB.

### 29.1 Overview

Table 29.1 lists the specifications of the WDT and Figure 29.1 shows a block diagram of the WDT.

**Table 29.1 WDT Specifications**

| Item                                     | Specifications                                                                                                                                                                                                                                     |

**Figure 29.1 WDT Block Diagram**

## 29.2 Register Descriptions

### 29.2.1 WDT Refresh Register (WDTRR)

Address(es): 0008 8020h

| Bit      | Description                                                                        | R/W |
|----------|------------------------------------------------------------------------------------|-----|
| b7 to b0 | The down-counter is refreshed by writing 00h and then writing FFh to this register | R/W |

WDTRR refreshes the down-counter of the WDT.

The down-counter of the WDT is refreshed by writing 00h and then writing FFh to WDTRR (refresh operation) within the refresh-permitted period.

After the down-counter has been refreshed, it starts counting down from the value selected by setting the WDTTOPS[1:0] bits in option function select register 0 (OFS0) in auto-start mode. In register start mode, counting down starts from the value selected by setting the WDTCR.TOPS[1:0] bits.

When 00h is written, the read value is 00h, when a value other than 00h is written, the read value is FFh.

For details of the refresh operation, refer to [section 29.3.3, Refresh Operation](#).

## 29.2.2 WDT Control Register (WDTCR)

| b15, b14 | —         | Reserved                        | These bits are read as 0 and cannot be modified.                                                                                                                                                             | R   |

There are some restrictions on writing to the WDTCR register. For details, refer to section 29.3.2, Control over Writing to the WDTCR and WDTRCR Registers.

In auto-start mode, the settings in the WDTCR register are disabled, and the settings in option function select register 0 (OFS0) are enabled. The bit setting made to the WDTCR register can also be made in OFS0 register. For details, refer to section 29.3.7, Correspondence between Option Function Select Register 0 (OFS0) and WDT Registers.

### TOPS[1:0] Bits (Timeout Period Selection)

These bits select the timeout period (period until the down-counter underflows) from among 1024, 4096, 8192, and 16384 cycles, taking the divided clock specified by the CKS[3:0] bits as one cycle.

After the down-counter is refreshed, the combination of the CKS[3:0] and TOPS[1:0] bits determines the time (number of PCLK cycles) until the counter underflows.

Relations between the CKS[3:0] and TOPS[1:0] bit settings, the timeout period, and the number of PCLK cycles are listed in Table 29.2.

**Table 29.2 Timeout Period Settings**

| CKS[3:0] Bits |    |    |    | TOPS[1:0] Bits |    | Clock Division Ratio | Timeout Period<br>(Number of Cycles) | Cycles of PCLK Clock |
|---------------|----|----|----|----------------|----|----------------------|--------------------------------------|----------------------|

| 0             | 1  | 1  | 0  | 0              | 0  | Divide-by-512        | 1024                                 | 524288               |
|               |    |    |    | 0              | 1  |                      | 4096                                 | 2097152              |
|               |    |    |    | 1              | 0  |                      | 8192                                 | 4194304              |
|               |    |    |    | 1              | 1  |                      | 16384                                | 8388608              |
| 0             | 1  | 1  | 1  | 0              | 0  | Divide-by-2048       | 1024                                 | 2097152              |
|               |    |    |    | 0              | 1  |                      | 4096                                 | 8388608              |
|               |    |    |    | 1              | 0  |                      | 8192                                 | 16777216             |
|               |    |    |    | 1              | 1  |                      | 16384                                | 33554432             |
| 1             | 0  | 0  | 0  | 0              | 0  | Divide-by-8192       | 1024                                 | 8388608              |
|               |    |    |    | 0              | 1  |                      | 4096                                 | 33554432             |
|               |    |    |    | 1              | 0  |                      | 8192                                 | 67108864             |
|               |    |    |    | 1              | 1  |                      | 16384                                | 134217728            |

**CKS[3:0] Bits (Clock Division Ratio Selection)**

These bits specify the division ration of the clock used for the down-counter. The division ration can be selected from among the peripheral module clock (PCLK) divided by 4, 64, 128, 512, 2048, and 8192. Combined with the TOPS[1:0] bit setting, a count period between 4,096 and 134,217,728 cycles of the PCLK clock can be selected for the WDT.

**RPES[1:0] Bits (Window End Position Selection)**

These bits specify the window end position that indicates the refresh-permitted period. 75%, 50%, 25%, or 0% of the timeout period can be selected for the window end position. The selected window end position should be a value smaller than the window start position (window start position > window end position). If the window end position is greater than the window start position, only the window start position setting is enabled.

**RPSS[1:0] Bits (Window Start Position Selection)**

These bits specify the window start position that indicates the refresh-permitted period. 25%, 50%, 75%, or 100% of the timeout period can be selected for the window end position. The window start position should be set to a value greater the window end position. If the window start position is set to a value smaller than or equal to the window end position, the window end position is set to 0%.

Table 29.3 lists the counter values for the window start and end positions and Figure 29.2 shows the refresh-permitted period set by the RPSS[1:0], RPES[1:0], and TOPS[1:0] bits.

**Table 29.3 Relationship between Timeout Period and Window Start and End Counter Values**

| TOPS[1:0] Bits |   | Timeout Period |               | Window Start and End Counter Value |       |       |       |
|----------------|---|----------------|---------------|------------------------------------|-------|-------|-------|
|                |   | Cycles         | Counter Value | 100%                               | 75%   | 50%   | 25%   |
| 0              | 0 | 1024           | 03FFh         | 03FFh                              | 02FFh | 01FFh | 00FFh |
| 0              | 1 | 4096           | 0FFFh         | 0FFFh                              | 0BFFh | 07FFh | 03FFh |
| 1              | 0 | 8192           | 1FFFh         | 1FFFh                              | 17FFh | 0FFFh | 07FFh |
| 1              | 1 | 16384          | 3FFFh         | 3FFFh                              | 2FFFh | 1FFFh | 0FFFh |

**Figure 29.2 RPSS[1:0] and RPES[1:0] Bit Settings and the Refresh-Permitted Period**

### 29.2.3 WDT Status Register (WDTSR)

Address(es): 0008 8024h

| Bit       | Symbol       | Bit Name           | Description                                               | R/W         |
|-----------|--------------|--------------------|-----------------------------------------------------------|-------------|
| b13 to b0 | CNTVAL[13:0] | Down-Counter Value | Value counted by the down-counter                         | R           |
| b14       | UNDFE        | Underflow Flag     | 0: No underflow occurred<br>1: Underflow occurred         | R(/W)<br>*1 |
| b15       | REFEF        | Refresh Error Flag | 0: No refresh error occurred<br>1: Refresh error occurred | R(/W)<br>*1 |

Note 1. Only 0 can be written to clear the flag.

#### CNTVAL[13:0] Bits (Down-Counter Value)

Read these bits to confirm the value of the down-counter, but note that the read value may differ from the actual count by a value of one count.

#### UNDFE Flag (Underflow Flag)

Read this flag to confirm whether or not an underflow has occurred in the down-counter.

The value 1 indicates that the down-counter has underflowed. The value 0 indicates that the down-counter has not underflowed.

Write 0 to the UNDFE flag to set the value to 0. Writing 1 has no effect.

#### REFEF Flag (Refresh Error Flag)

Read this flag to confirm whether or not a refresh error (performing a refresh operation during a refresh-prohibited period) has occurred.

The value 1 indicates that a refresh error has occurred. The value 0 indicates that no refresh error has occurred.

Write 0 to the REFEF flag to set the value to 0. Writing 1 has no effect.

### 29.2.4 WDT Reset Control Register (WDTRCR)

Address(es): 0008 8026h

|                    | b7          | b6 | b5 | b4 | b3 | b2 | b1 | b0 |
|--------------------|-------------|----|----|----|----|----|----|----|
|                    | RSTIR<br>QS | —  | —  | —  | —  | —  | —  | —  |
| Value after reset: | 1           | 0  | 0  | 0  | 0  | 0  | 0  | 0  |

| Bit      | Symbol  | Bit Name                          | Description                                                                                            | R/W |
|----------|---------|-----------------------------------|--------------------------------------------------------------------------------------------------------|-----|
| b6 to b0 | —       | Reserved                          | These bits are read as 0 and cannot be modified.                                                       | R   |
| b7       | RSTIRQS | Reset Interrupt Request Selection | 0: Non-maskable interrupt request or interrupt request output is enabled<br>1: Reset output is enabled | R/W |

There are some restrictions on writing to the WDTRCR register. For details, refer to section 29.3.2, Control over Writing to the WDTCR and WDTRCR Registers.

In auto-start mode, the WDTRCR register settings are disabled, and the settings in option function select register 0 (OFS0) are enabled. The bit setting made to the WDTCR register can also be made in the OFS0 register. For details, refer to section 29.3.7, Correspondence between Option Function Select Register 0 (OFS0) and WDT Registers.

### 29.2.5 Option Function Select Register 0 (OFS0)

For details on the OFS0 register, refer to section 29.3.7, Correspondence between Option Function Select Register 0 (OFS0) and WDT Registers.

## 29.3 Operation

### 29.3.1 Count Operation in Each Start Mode

The WDT has two start modes: auto-start mode, in which counting automatically starts after a reset is released, and register start mode, in which counting is started by refresh operation (writing to the register).

In auto-start mode, counting automatically starts after a reset is released in accordance with the settings in option function select register 0 (OFS0) in the ROM.

In register start mode, counting is started by refresh operation (writing to the register) after the respective registers are set after a reset is released.

Select auto-start mode or register start mode by setting the OFS0.WDTSTRT bit.

When the auto-start mode is selected, the settings in the WDTCR and WDTRCR registers are disabled, and the settings in the OFS0 register are enabled.

On the other hand, when the register start mode is selected, the setting of the OFS0 register is disabled, and the settings of the WDTCR and WDTRCR registers are enabled.

#### 29.3.1.1 Register Start Mode

When the OFS0.WDTSTRT bit is 1, register start mode is selected, and the WDTCR and WDTRCR registers are enabled.

After a reset is released, set the clock division ratio, window start and end positions, and timeout period in the WDTCR register, and the reset output or interrupt request output in the WDTRCR register. Then, refresh the down-counter to start counting down from the value set by the WDTCR.TOPS[1:0] bits.

Thereafter, as long as the counter is refreshed in the refresh-permitted period, the value in the counter is re-set each time the counter is refreshed and counting down continues. The WDT does not output the reset signal as long as this continues. However, if the down-counter underflows because the down-counter cannot be refreshed due to a program runaway, or if a refresh error occurs because the counter was refreshed outside the refresh-permitted period, the WDT outputs a reset signal or a non-maskable interrupt request/interrupt request (WUNI). Reset output or interrupt request output can be selected by setting the WDTRCR.RSTIRQS bit.

Figure 29.3 shows an example of operation under the following conditions.

- Register start mode (OFS0.WDTSTRT = 1)
- Reset output is enabled (WDTRCR.RSTIRQS = 1)
- The window start position is 75% (WDTCR.RPSS[1:0] = 10b)
- The window end position is 25% (WDTCR.RPES[1:0] = 10b)

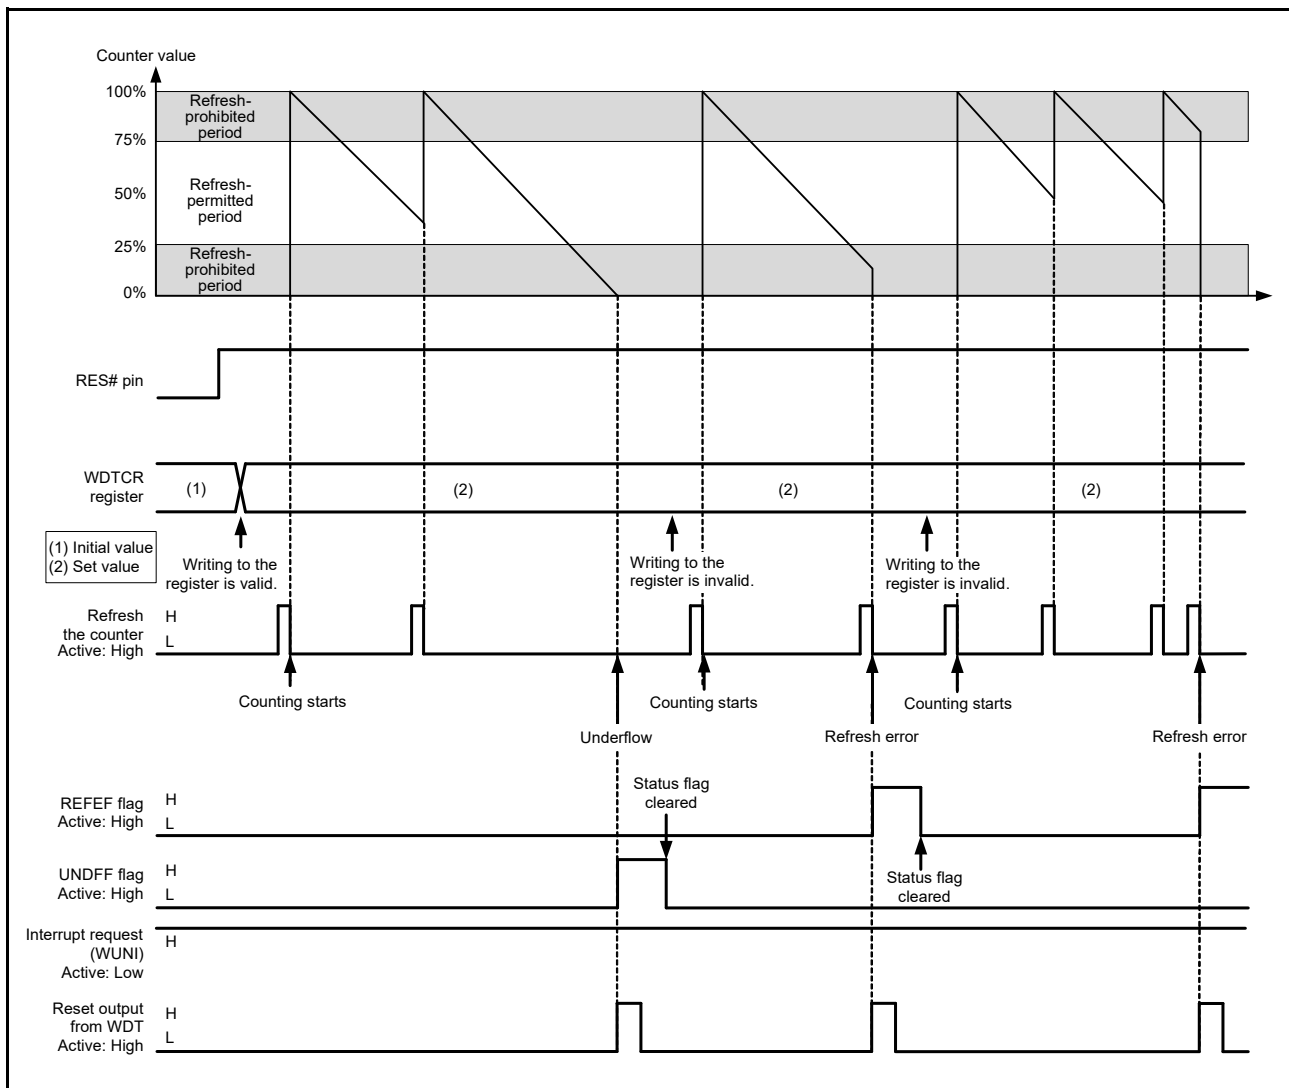

Figure 29.3 Operation Example in Register Start Mode

### 29.3.1.2 Auto-Start Mode

When the WDTSTRT bit in option function select register 0 (OFS0) is 0, auto-start mode is selected, the WDTCR and WDTRCR registers are disabled, and the settings in the OFS0 register are enabled.

Within the reset state, the setting values (clock division ratio, window start and end positions, timeout period, and reset output or interrupt request) of the OFS0 register are set in the WDT registers.

When the reset is released, the down-counter automatically starts counting down from the value set by the OFS0.WDTPS[1:0] bits.

After that, as long as the counter is refreshed in the refresh-permitted period, the value in the counter is re-set each time the counter is refreshed and counting down continues. The WDT does not output the reset signal as long as this continues.

However, if the down-counter underflows because refreshing of the down-counter is not possible due to the program having entered crashed execution or if a refresh error occurs due to refreshing outside the refresh-permitted period, the WDT outputs the reset signal or non-maskable interrupt request/interrupt request (WUNI).

After the reset signal or non-maskable interrupt request/interrupt request is output of for one cycle of counting, the value of the timeout period is set in the down-counter counting is restarted.

Reset output or interrupt request output can be selected by setting the OFS0.WDTRSTIRQS bit.

Figure 29.4 shows an example of operation (non-maskable interrupt) under the following conditions.

- Auto start mode (OFS0.WDTSTRT = 0)
- Non-maskable interrupt request output is enabled (OFS0.WDTRSTIRQS = 0)
- The window start position is 75% (OFS0.WDTRPSS[1:0] = 10b)
- The window end position is 25% (OFS0.WDTRPES[1:0] = 10b)

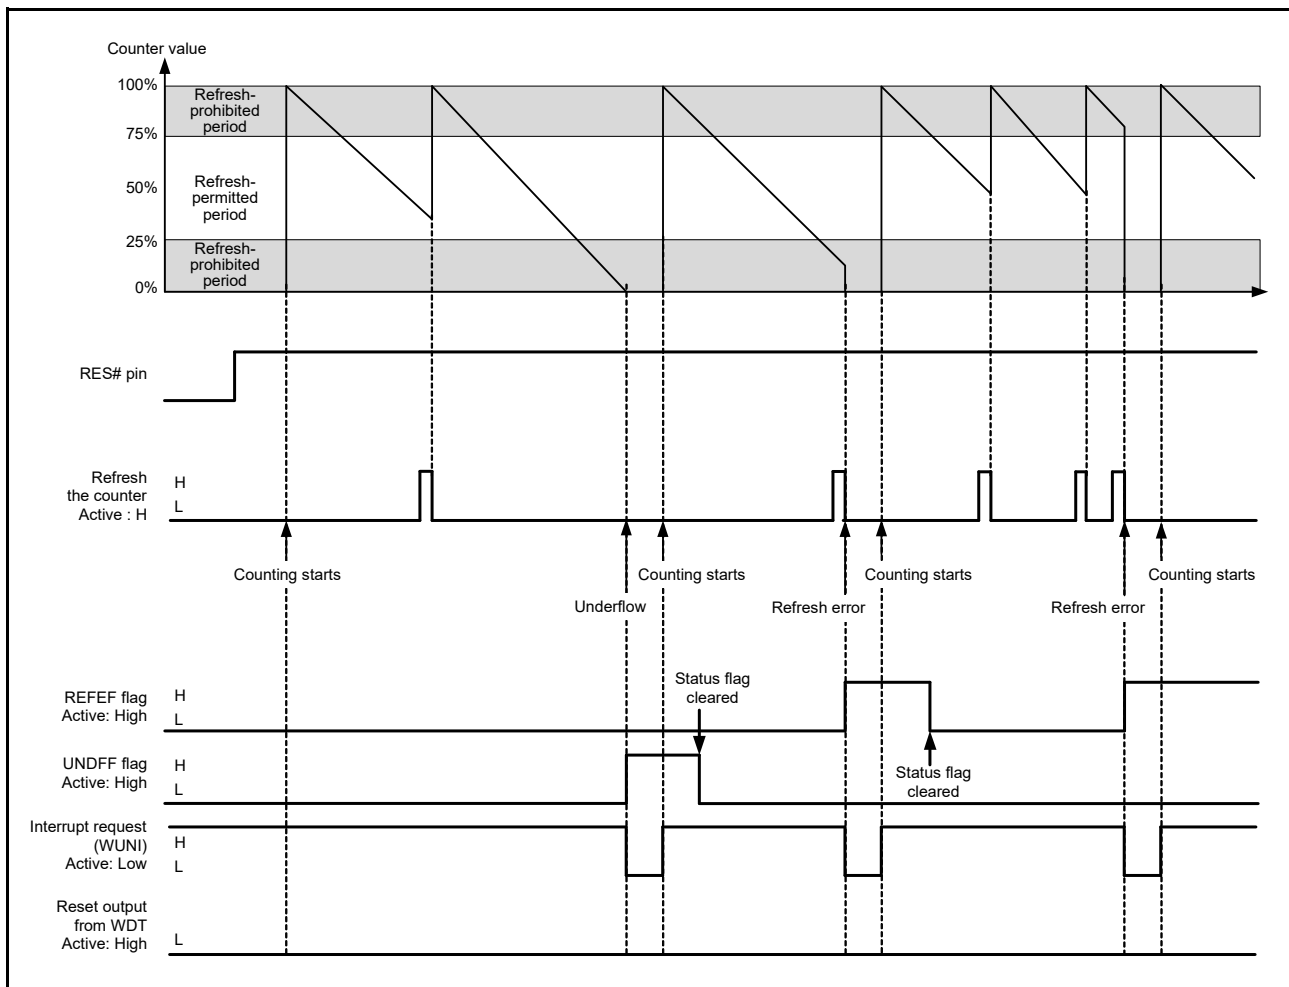

Figure 29.4 Operation Example in Auto-Start Mode

### 29.3.2 Control over Writing to the WDTCR and WDTRCR Registers

Writing to the WDTCR or WDTRCR register is only possible once between the release from the reset state and the first refresh operation.

After a refresh operation (counting starts) or by writing to the WDTCR or WDTRCR register, the protection signal in the WDT becomes 1 to protect the WDTCR and WDTRCR registers against subsequent attempts at writing.

This protection is released by the reset source of the WDT. With other reset sources, the protection is not released.

Figure 29.5 shows control waveforms produced in response to writing to the WDTCR register.

**Figure 29.5 Control Waveforms Produced in Response to Writing to the WDTCR Register**

### 29.3.3 Refresh Operation

The down-counter is refreshed by writing the values 00h and then FFh to the WDTRR register. If a value other than FFh is written after 00h, the down-counter is not refreshed. After such invalid writing, correct refreshing is performed by again writing to 00h and then FFh to the WDTRR register.

Even if a register other than the WDTRR register is accessed or the WDTRR register is read between writing 00h and writing FFh to the WDTRR register, correct refreshing will be done.

Writing to refresh the counter must be performed within the refresh-permitted period. Whether writing is done within the refresh-permitted period is determined when writing FFh. For this reason, correct refreshing will be done even if 00h is written outside the refresh-permitted period.

[Sample sequences of writing that are valid for refreshing the counter]

- 00h → FFh
- 00h (n-1-th time) → 00h (nth time) → FFh
- 00h → access to another register or read from the WDTRR register → FFh

[Sample sequences of writing that are not valid for refreshing the counter]

- 23h (a value other than 00h) → FFh
- 00h → 54h (a value other than FFh)
- 00h → AAh (00h and a value other than FFh) → FFh

After FFh is written to the WDTRR register, refreshing the down-counter requires up to four cycles of the signal for counting. Therefore, writing FFh to the WDTRR register should be completed four-count cycles before the down-counter underflows.

Figure 29.6 shows the WDT refresh-operation waveforms when the clock division ratio = PCLK/64.

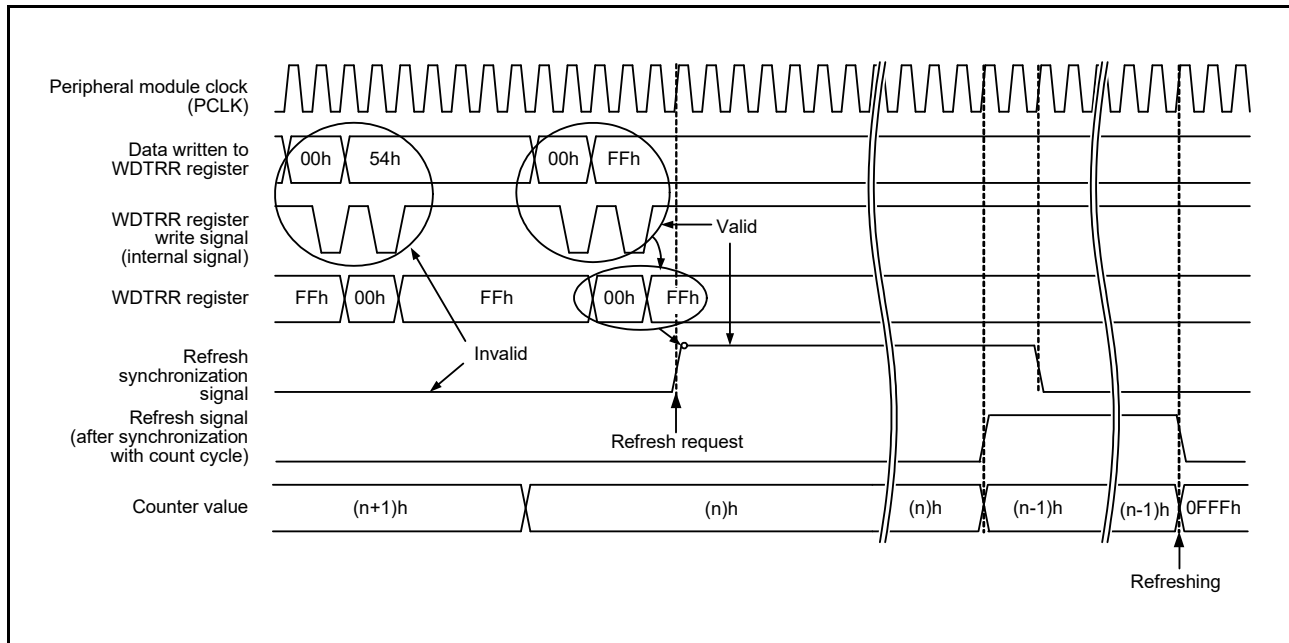

Figure 29.6 WDT Refresh Operation Waveforms (WDTCR.CKS[3:0] = 0100b, WDTCR.TOPS[1:0] = 01b)

### 29.3.4 Reset Output

When the WDTRCR.RSTIRQS bit is set to 1 in register start mode or when the WDTRSTIRQS bit in option function select register 0 (OFS0) is set to 1 in auto-start mode, a reset signal is output for one-count cycle when an underflow in the down-counter or a refresh error occurs.

In register start mode, the down-counter is initialized (all bits set to 0) and stopped in that state after output of the reset signal. After the reset is released and the program is restarted, the counter is set up again and counting down is started by refreshing.

In auto-start mode, counting down automatically starts after the reset is released.

### 29.3.5 Interrupt Source

When the WDTRCR.RSTIRQS bit is set to 0 in register start mode or when the OFS0.WDTRSTIRQS bit is set to 0 in auto-start mode, an interrupt (WUNI) signal is generated when an underflow in the counter or a refresh error occurs. This interrupt can be used as a non-maskable interrupt and an interrupt. For details, refer to section 14, Interrupt Controller (ICUC).

Table 29.4 WDT Interrupt Source

| Name | Interrupt Source                        | DTC Activation | DMAC Activation |
|------|-----------------------------------------|----------------|-----------------|
| WUNI | Down-counter underflow<br>Refresh error | Not possible   | Not possible    |

### 29.3.6 Reading the Down-Counter Value

The WDT stores the counter value in the WDTSR.CNTVAL[13:0] bits. Thus, the counter value can be checked through the WDTSR.CNTVAL[13:0] bits.

Figure 29.7 shows the processing for reading the WDT down-counter value when the clock division ratio = PCLK/64.

**Figure 29.7 Processing for Reading WDT Down-Counter Value**  
(WDTCR.CKS[3:0] = 0100b, WDTCR.TOPS[1:0] = 01b)

### 29.3.7 Correspondence between Option Function Select Register 0 (OFS0) and WDT Registers

Table 29.5 lists the correspondence between option function select register 0 (OFS0) used in auto-start mode and the registers used in register start mode.

Do not change the OFS0 register setting during WDT operation.

For details on the OFS0 register, refer to section 7.2.3, Option Function Select Register 0 (OFS0).

**Table 29.5 Correspondence between Option Function Select Register 0 (OFS0) and WDT Registers**

| Target of Control                        | Function                                           | OFS0 Register<br>(Enabled in Auto-Start Mode)<br>OFS0.WDTSTRT = 0 | WDT Registers<br>(Enabled in Register Start Mode)<br>OFS0.WDTSTRT = 1 |
|------------------------------------------|----------------------------------------------------|-------------------------------------------------------------------|-----------------------------------------------------------------------|
| Down-counter                             | Timeout period selection                           | OFS0.WDTPSS[1:0]                                                  | WDTCR.TOPS[1:0]                                                       |
|                                          | Clock division ratio selection                     | OFS0.WDTCCKS[3:0]                                                 | WDTCR.CKS[3:0]                                                        |
|                                          | Window start position selection                    | OFS0.WDTRPSS[1:0]                                                 | WDTCR.RPSS[1:0]                                                       |
|                                          | Window end position selection                      | OFS0.WDTRPES[1:0]                                                 | WDTCR.RPES[1:0]                                                       |

## 30. Independent Watchdog Timer (IWDTa)

In this section, “PCLK” is used to refer to PCLKB.

### 30.1 Overview

The independent watchdog timer (IWDT) can be used to detect programs being out of control.

The user can detect when a program runs out of control if an underflow occurs, by creating a program that refreshes the IWDT counter before it underflows.

The functions of the IWDT are different from those of the WDT in the following respects.

- The divided IWDT-dedicated clock (IWDTCLK) is used as the count source (not affected by the PCLK).
- When making a transition to sleep mode, software standby mode, deep software standby mode, or all-module clock stop mode, the IWDTCSLTPR.SLCSTP bit or the OFS0.IWDTSLCSTP bit can be used to select whether to stop the counter or not.

Table 30.1 lists the specifications of the IWDT and Figure 30.1 shows a block diagram of the IWDT.

**Table 30.1 IWDT Specifications**

| Item                                                                     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

| Register start mode (controlled by the IWDT registers)                   | <ul style="list-style-type: none"> <li>• Selecting the clock frequency divide ratio after refreshing (IWDTCR.CKS[3:0] bits)</li> <li>• Selecting the timeout period of the independent watchdog timer (IWDTCR.TOPS[1:0] bits)</li> <li>• Selecting the window start position in the independent watchdog timer (IWDTCR.RPSS[1:0] bits)</li> <li>• Selecting the window end position in the independent watchdog timer (IWDTCR.RPES[1:0] bits)</li> <li>• Selecting the reset output or interrupt request output (IWDTCR.RSTIRQS bit)</li> <li>• Selecting the down-count stop function at transition to sleep mode, software standby mode, deep software standby mode, or all-module clock stop mode (IWDTCSLTPR.SLCSTP bit)</li> </ul>    |

Note 1. Satisfy the frequency of the peripheral module clock (PCLK)  $\geq 4 \times$  (the frequency of the count source after divide).

Note 2. When the OFS0.IWDTSLCSTP bit is 1 in auto-start mode, and when the IWDTCSLTPR.SLCSTP bit is 1 in register start mode.

To use the IWDT, the IWDT-dedicated clock (IWDTCLK) should be supplied so that the IWDT operates even if the peripheral module clock (PCLK) stops. The bus interface and registers operate with PCLK, and the 14-bit counter and control circuits operate with IWDTCLK.

Figure 30.1 is a block diagram of the IWDT.

## 30.2 Register Descriptions

### 30.2.1 IWDt Refresh Register (IWDTRR)

Address(es): IWDt.IWDTRR 0008 8030h

| Bit      | Description                                                                    | R/W |
|----------|--------------------------------------------------------------------------------|-----|
| b7 to b0 | The counter is refreshed by writing 00h and then writing FFh to this register. | R/W |

The IWDTRR register refreshes the counter of the IWDt.

The counter of the IWDt is refreshed by writing 00h and then writing FFh to the IWDTRR register (refresh operation) within the refresh-permitted period.

After the counter has been refreshed, it starts counting down from the value selected by the IWDTTOPS[1:0] bits in option function select register 0 (OFS0) in auto-start mode. In register start mode, counting down starts from the value selected by setting the IWDTCR.TOPS[1:0] bits in the first refresh operation after a reset is released.

When 00h is written, the read value is 00h. When a value other than 00h is written, the read value is FFh.

For details of the refresh operation, refer to [section 30.3.3, Refresh Operation](#).

### 30.2.2 IWDT Control Register (IWDTCR)

Address(es): IWDT.IWDTCR 0008 8032h

| b15, b14 | —         | Reserved                     | These bits are read as 0. Writing to these bits has no effect.                                                                                                                                 | R   |

There are some restrictions on writing to the IWDTCR register. For details, refer to section 30.3.2, Control over Writing to the IWDTCR, IWDTRCR, and IWDTCSPTPR Registers.

In auto-start mode, the settings in the IWDTCR register are disabled, and the settings in option function select register 0 (OFS0) are enabled. The bit setting made to the IWDTCR register can also be made in the OFS0 register. For details, refer to section 30.3.8, Correspondence between Option Function Select Register 0 (OFS0) and IWDT Registers.

**TOPS[1:0] Bits (Timeout Period Select)**

These bits select the timeout period (period until the counter underflows) from among 1024, 4096, 8196, or 16384 cycles, taking the divided clock specified by the CKS[3:0] bits as one cycle.

After the counter is refreshed, the combination of the CKS[3:0] and TOPS[1:0] bits determines the time (number of IWDTCLK cycles) until the counter underflows.

Relations between the CKS[3:0] and TOPS[1:0] bit setting, the timeout period, and the number of IWDTCLK cycles are listed in Table 30.2.

**Table 30.2 Settings and Timeout Periods**

| CKS[3:0] Bits |    |    |    | TOPS[1:0] Bits |    | Clock Divide Ratio | Timeout Period<br>(Number of Cycles) | Cycles of IWDTCLK |

| 0             | 1  | 0  | 1  | 0              | 0  | Divide-by-256      | 1024                                 | 262144            |
|               |    |    |    | 0              | 1  |                    | 4096                                 | 1048576           |
|               |    |    |    | 1              | 0  |                    | 8192                                 | 2097152           |
|               |    |    |    | 1              | 1  |                    | 16384                                | 4194304           |

**CKS[3:0] Bits (Clock Divide Ratio Select)**

These bits select the IWDTCLK clock divide ratio from among divide-by 1, 16, 32, 64, 128, and 256. Combination with the TOPS[1:0] bit setting, a count period between 1024 and 4194304 cycles of the IWDTCLK clock can be selected for the IWDT.

**RPES[1:0] Bits (Window End Position Select)**

These bits select 75%, 50%, 25% or 0% of the count period for the window end position of the counter. The window end position should be a value smaller than the window start position (window start position > window end position). If the window end position is greater than the window start position, only the window start position setting is enabled.

The counter values for the window start and end positions selected by setting the RPSS[1:0] and RPES[1:0] bits change depending on the TOPS[1:0] bit setting.

Table 30.3 lists the counter values for the window start and end positions corresponding to TOPS[1:0] bit values.

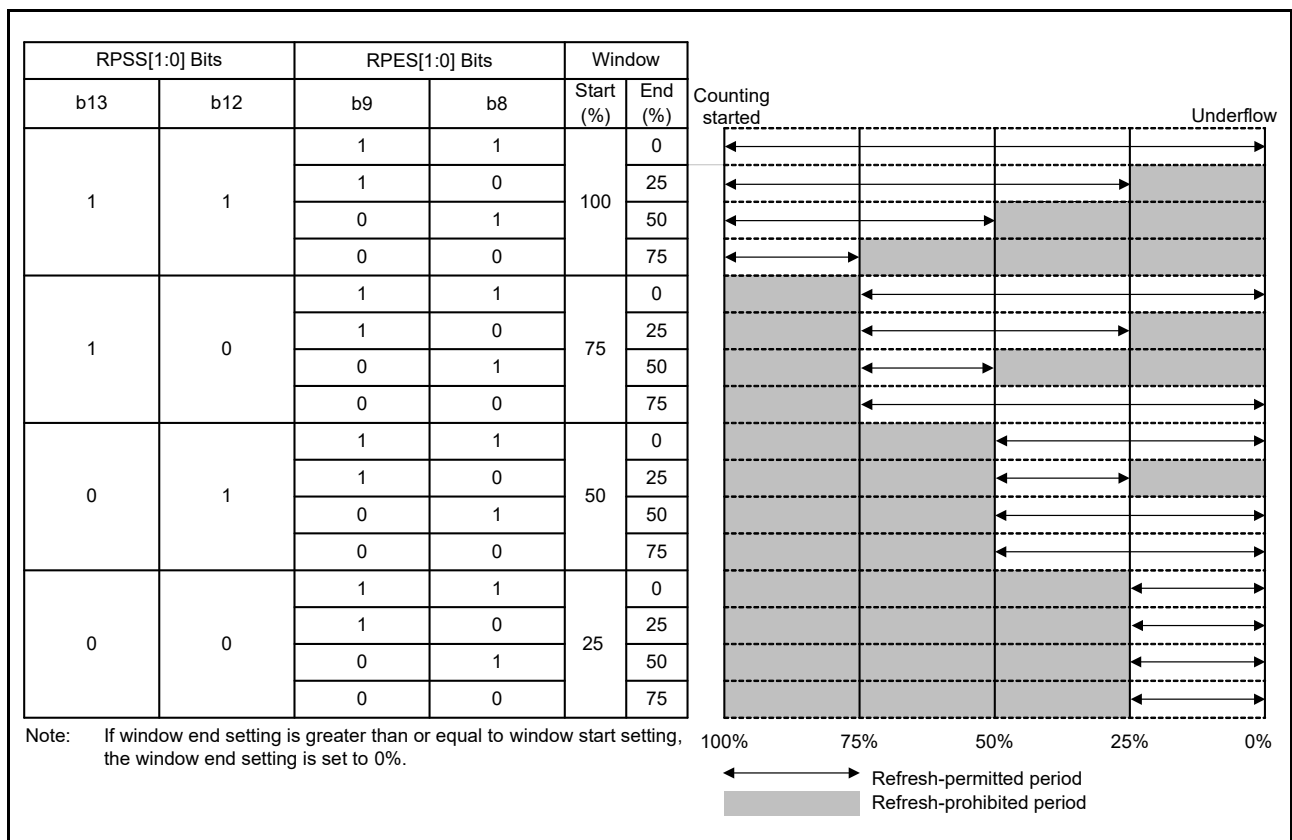

**Table 30.3 Relationship between Timeout Period and Window Start and End Counter Values**

| TOPS[1:0] Bits |    | Timeout Period |               | Window Start and End Counter Value |       |       |       |
|----------------|----|----------------|---------------|------------------------------------|-------|-------|-------|
| b1             | b0 | Cycles         | Counter Value | 100%                               | 75%   | 50%   | 25%   |
| 0              | 0  | 1024           | 03FFh         | 03FFh                              | 02FFh | 01FFh | 00FFh |
| 0              | 1  | 4096           | 0FFFh         | 0FFFh                              | 0BFFh | 07FFh | 03FFh |
| 1              | 0  | 8192           | 1FFFh         | 1FFFh                              | 17FFh | 0FFFh | 07FFh |
| 1              | 1  | 16384          | 3FFFh         | 3FFFh                              | 2FFFh | 1FFFh | 0FFFh |

**RPSS[1:0] Bits (Window Start Position Select)**

These bits select a counter window start position from 100%, 75%, 50%, or 25% of the count period (100% when the count starts and 0% when the counter underflows). The interval between the window start position and window end position is the refresh-permitted period and the other periods are refresh-prohibited periods.

Figure 30.2 shows the relationship between of the RPSS[1:0] and RPES[1:0] bit setting and the refresh-permitted and refresh-prohibited periods.

**Figure 30.2 RPSS[1:0] and RPES[1:0] Bit Settings and the Refresh-Permitted Period**

### 30.2.3 IWDt Status Register (IWDtSR)

Address(es): IWDt.IWDtSR 0008 8034h

| Bit       | Symbol       | Bit Name           | Description                                               | R/W         |
|-----------|--------------|--------------------|-----------------------------------------------------------|-------------|
| b13 to b0 | CNTVAL[13:0] | Counter Value      | Value counted by the counter                              | R           |
| b14       | UNDFE        | Underflow Flag     | 0: No underflow occurred<br>1: Underflow occurred         | R/(W)<br>*1 |
| b15       | REFEF        | Refresh Error Flag | 0: No refresh error occurred<br>1: Refresh error occurred | R/(W)<br>*1 |

Note 1. Only 0 can be written to clear the flag.

#### CNTVAL[13:0] Bits (Counter Value)

These bits are used to confirm the counter value of the counter, but note that the read value may differ from the actual count by a value of one count.

#### UNDFE Flag (Underflow Flag)

This bit is used to confirm whether or not an underflow has occurred in the counter.

The value 1 indicates that the counter has underflowed. The value 0 indicates that the counter has not underflowed.

Write 0 to the UNDFE flag to set the value to 0. Writing 1 has no effect.

#### REFEF Flag (Refresh Error Flag)

This bit is used to confirm whether or not a refresh error (performing a refresh operation during a refresh-prohibited period).

The value 1 indicates that a refresh error has occurred. The value 0 indicates that no refresh error has occurred.

Write 0 to the REFEF flag to set the value to 0. Writing 1 has no effect.

### 30.2.4 IWDt Reset Control Register (IWDTRCR)

Address(es): IWDt.IWDTRCR 0008 8036h

|             |    |    |    |    |    |    |    |
|-------------|----|----|----|----|----|----|----|
| b7          | b6 | b5 | b4 | b3 | b2 | b1 | b0 |
| RSTIR<br>QS | —  | —  | —  | —  | —  | —  | —  |

Value after reset: 1 0 0 0 0 0 0 0

| Bit      | Symbol  | Bit Name                       | Description                                                                                              | R/W |
|----------|---------|--------------------------------|----------------------------------------------------------------------------------------------------------|-----|
| b6 to b0 | —       | Reserved                       | These bits are read as 0. Writing to these bits has no effect.                                           | R   |
| b7       | RSTIRQS | Reset Interrupt Request Select | 0: Non-maskable interrupt request or interrupt request output is enabled.<br>1: Reset output is enabled. | R/W |

There are some restrictions on writing to the IWDTRCR register. For details, refer to section 30.3.2, Control over Writing to the IWDTCR, IWDTRCR, and IWDTCSTPR Registers.

In auto-start mode, the IWDTRCR register setting are disabled, and the settings in option function select register 0 (OFS0) are enabled. The bit setting mode to the IWDTRCR register can also be made in the OFS0 register. For details, refer to section 30.3.8, Correspondence between Option Function Select Register 0 (OFS0) and IWDt Registers.

### 30.2.5 IWDT Count Stop Control Register (IWDTCSSTPR)

Address(es): IWDT.IWDTCSSTPR 0008 8038h

|                    |            |    |    |    |    |    |    |    |
|--------------------|------------|----|----|----|----|----|----|----|
|                    | b7         | b6 | b5 | b4 | b3 | b2 | b1 | b0 |
|                    | SLCST<br>P | —  | —  | —  | —  | —  | —  | —  |
| Value after reset: | 1          | 0  | 0  | 0  | 0  | 0  | 0  | 0  |

| Bit      | Symbol | Bit Name                      | Description                                                                                                                                                        | R/W |
|----------|--------|-------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----|
| b6 to b0 | —      | Reserved                      | These bits are read as 0. Writing to these bits has no effect.                                                                                                     | R   |
| b7       | SLCSTP | Sleep Mode Count Stop Control | 0: Count stop is disabled.<br>1: Count is stopped at a transition to sleep mode, software standby mode, deep software standby mode, or all-module clock stop mode. | R/W |

The IWDTCSSTPR register controls whether to stop the IWDT counter in a low power consumption state. There are some restrictions on writing to the IWDTCSSTPR register. For details, refer to section 30.3.2, Control over Writing to the IWDTCSR, IWDTCSR, and IWDTCSSTPR Registers.

In auto-start mode, the IWDTCSSTPR register setting are disabled, and the settings in option function select register 0 (OFS0) are enabled. The bit setting mode to the IWDTCSSTPR register can also be made in the OFS0 register. For details, refer to section 30.3.8, Correspondence between Option Function Select Register 0 (OFS0) and IWDT Registers.

#### SLCSTP Bit (Sleep Mode Count Stop Control)

This bit selects whether to stop counting at a transition to sleep mode, software standby mode, deep software standby mode, or all-module clock stop mode.

### 30.2.6 Option Function Select Register 0 (OFS0)

For option function select register 0 (OFS0), refer to section 30.3.8, Correspondence between Option Function Select Register 0 (OFS0) and IWDT Registers.

## 30.3 Operation

### 30.3.1 Count Operation in Each Start Mode

Select the IWDT start mode by setting the IWDTSTRT bit in option function select register 0 (OFS0).

When the OFS0.IWDTSTRT bit is 1 (register start mode), the IWDTCR, IWDTRCR, and IWDTCSSTPR registers are enabled, and counting is started by refresh operation (writing) to the IWDTRR register. When the OFS0.IWDTSTRT bit is 0 (auto-start mode), the setting of the OFS0 register is enabled, and counting automatically starts after reset.

#### 30.3.1.1 Register Start Mode

When the OFS0.IWDTSTRT bit in option function select register 0 is 1, register start mode is selected, and the IWDTCR, IWDTRCR, and IWDTCSSTPR registers are enabled.

After a reset is released, set the clock divide ratio, window start and end positions, and timeout period in the IWDTCR register, the reset output or interrupt request output in the IWDTRCR register, and the counter stop control at transitions to low power consumption states in the IWDTCSSTPR register. Then refresh the counter to start counting down from the value selected by setting the IWDTCR.TOPS[1:0] bits.

Thereafter, as long as the program continues normal operation and the counter is refreshed in the refresh-permitted period, the value in the counter is re-set each time the counter is refreshed and counting down continues. The IWDT does not output the reset signal as long as this continues. However, if the counter underflows because the counter cannot be refreshed due to a program runaway, or if a refresh error occurs because the counter was refreshed outside the refresh-permitted period, the IWDT outputs a reset signal or a non-maskable interrupt request/interrupt request (IWUNI). Set the IWDTRCR.RSTIRQS bit to select either reset output or interrupt request output.

Figure 30.3 shows an example of operation under the following conditions.

- Register start mode (OFS0.IWDTSTRT = 1)
- Reset output is enabled (IWDTRCR.RSTIRQS = 1)
- The window start position is 75% (IWDTCR.RPSS[1:0] = 10b)
- The window end position is 25% (IWDTCR.RPES[1:0] = 10b)

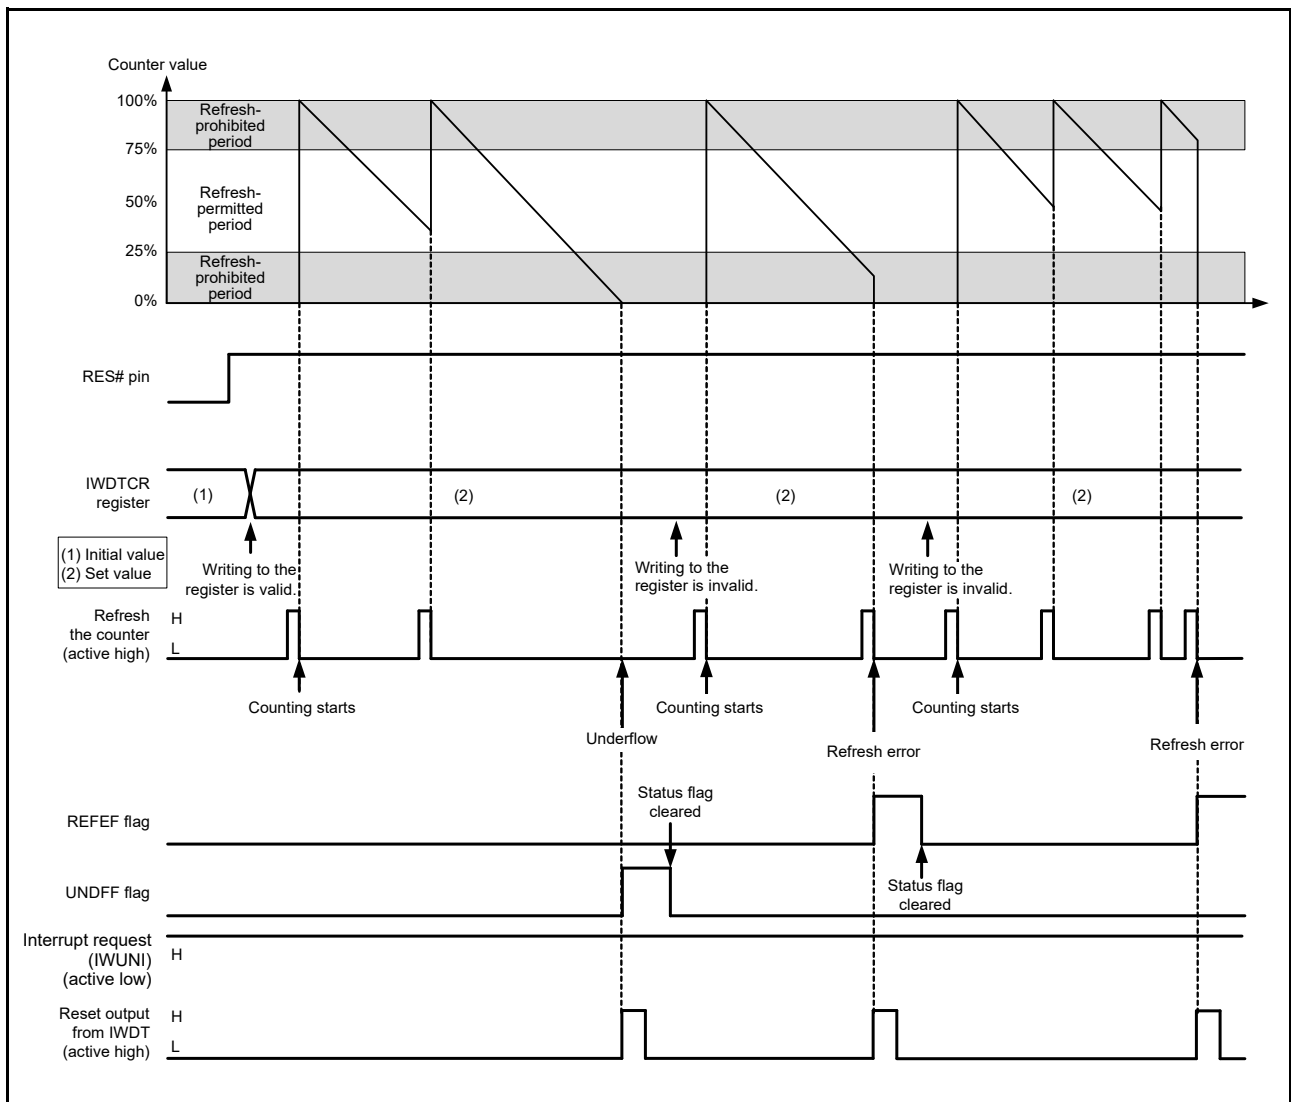

Figure 30.3 Operation Example in Register Start Mode

### 30.3.1.2 Auto-Start Mode

When the IWDTSTRT bit in option function select register 0 (OFS0) is 0, auto-start mode is selected, and the IWDTCR, IWDTRCR, and IWDTCSTPR registers are disabled.

Within the reset state, the clock divide ratio, window start and end positions, timeout period, reset output or interrupt request output, and counter stop control at transitions to low power consumption states are set using the values specified in the OFS0 register. When the reset is released, the counter automatically starts counting down from the value selected by the OFS0.IWDTTOPS[1:0] bits.

After that, as long as the program continues normal operation and the counter is refreshed in the refresh-permitted period, the value in the counter is re-set each time the counter is refreshed and counting down continues. The IWDT does not output the reset signal as long as this continues. However, if the counter underflows because refreshing of the counter is not possible due to the program having entered crashed execution or if a refresh error occurs due to refreshing outside the refresh-permitted period, the IWDT outputs the reset signal or non-maskable interrupt request/interrupt request (IWUNI). After the reset signal or non-maskable interrupt request/interrupt request (IWUNI) is generated, the counter reloads the timeout period after counting for one cycle, and restarts counting. Set the OFS0.IWDTRSTIRQS bit to select either reset output or interrupt request output.

Figure 30.4 shows an example of operation under the following conditions.

- Auto-start mode (OFS0.IWDTSTRT = 0)
- Non-maskable interrupt request output is enabled (OFS0.IWDTRSTIRQS = 0)
- The window start position is 75% (OFS0.IWDTRPSS[1:0] = 10b)
- The window end position is 25% (OFS0.IWDTRPES[1:0] = 10b)

Figure 30.4 Operation Example in Auto-Start Mode

### 30.3.2 Control over Writing to the IWDTCR, IWDTRCR, and IWDTCS TPR Registers

Writing to the IWDTCR, IWDTRCR, or IWDTCS TPR register is only possible once between the release from the reset state and the first refresh operation.

After a refresh operation (counting starts) or the IWDTCR, IWDTRCR, or IWDTCS TPR register is written to, the protection signal in the IWDT becomes 1 to protect registers IWDTCR, IWDTRCR, and IWDTCS TPR against subsequent attempts at writing.

This protection is released by the reset source of the IWDT. With other reset sources, the protection is not released. Figure 30.5 shows control waveforms produced in response to writing to the IWDTCR register.

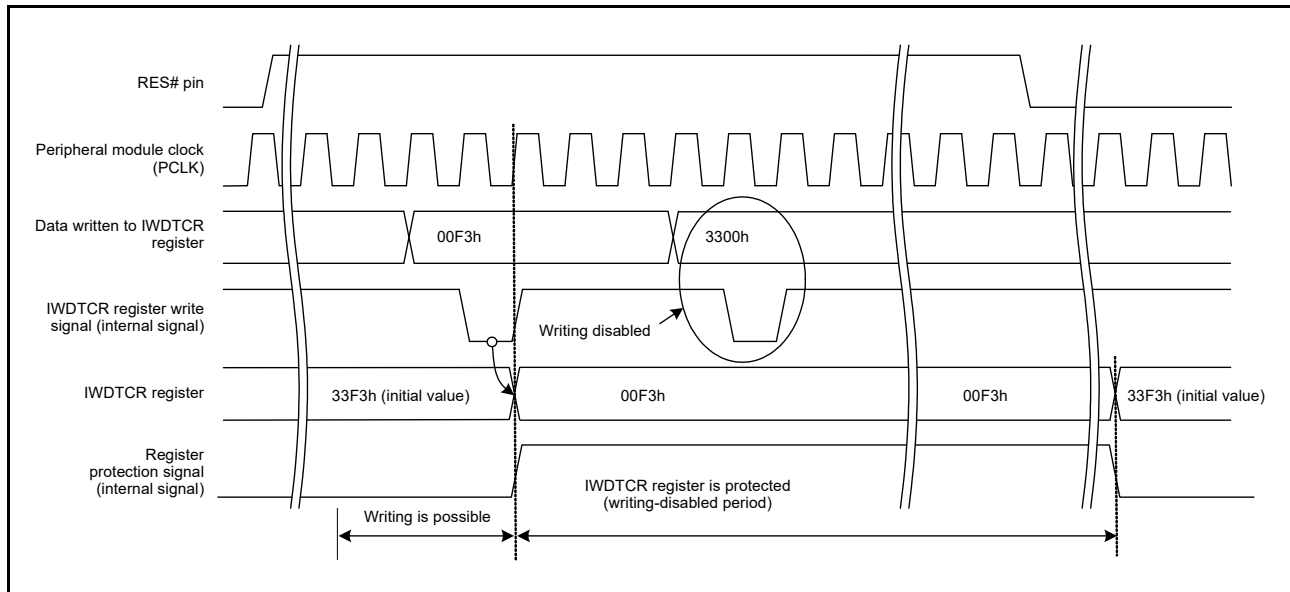

Figure 30.5 Control Waveforms Produced in Response to Writing to the IWDTCR Register

### 30.3.3 Refresh Operation

The counter is refreshed and starts operation (counting is started by refreshing) by writing the values 00h and then FFh to the IWDTRR register. If a value other than FFh is written after 00h, the counter is not refreshed. After such invalid writing, correct refreshing is performed by again writing 00h and then FFh to the IWDTRR register.

When writing is done in the order of 00h (first time) → 00h (second time), and if FFh is written after that, the writing order 00h → FFh is satisfied; writing 00h (n-1-th time) → 00h (nth time) → FFh is valid and correct refreshing will be done. Even when the first value written before 00h is not 00h, correct refreshing will be done if the operation contains the set of writing 00h → FFh. Moreover, even if a register other than the IWDTRR register is accessed or the IWDTRR register is read between writing 00h and writing FFh to the IWDTRR register, correct refreshing will be done.

[Sample sequences of writing that are valid for refreshing the counter]

- 00h → FFh
- 00h (n-1-th time) → 00h (nth time) → FFh
- 00h → access to another register or read from the IWDTRR register → FFh

[Sample sequences of writing that are not valid for refreshing the counter]

- 23h (a value other than 00h) → FFh
- 00h → 54h (a value other than FFh)
- 00h → AAh (00h and a value other than FFh) → FFh

Even when 00h is written to the IWDTRR register outside the refresh-permitted period, if FFh is written to the IWDTRR register in the refresh-permitted period, the writing sequence is valid and refreshing will be done.

After FFh is written to the IWDTRR register, refreshing the counter requires up to four cycles of the signal for counting (the IWDTCR.CKS[3:0] bits determine how many cycles of the IWDT-dedicated clock (IWDTCLK) make up one cycle for counting). Therefore, writing FFh to the IWDTRR register should be completed four-count cycles before the end position of the refresh-permitted period or a counter underflow. The value of the counter can be checked by the IWDTSR.CNTVAL[13:0] bits.

[Sample refreshing timings]

- When the window start position is set to 1FFFh, even if 00h is written to the IWDTRR register before 1FFFh is reached (2002h, for example), refreshing is done if FFh is written to the IWDTRR register after the value of the IWDTSR.CNTVAL[13:0] bits has reached 1FFFh.
- When the window end position is set to 1FFFh, refreshing is done if 2003h (four-count cycles before 1FFFh) or a greater value is read from the IWDTSR.CNTVAL[13:0] bits immediately after writing 00h → FFh to the IWDTRR register.
- When the refresh-permitted period continues until count 0000h, refreshing can be done immediately before an underflow. In this case, if 0003h (four-count cycles before an underflow) or a greater value is read from the IWDTSR.CNTVAL[13:0] bits immediately after writing 00h → FFh to the IWDTRR register, no underflow occurs and refreshing is done.

Figure 30.6 shows the IWDT refresh-operation waveforms when  $PCLK > IWDTCLK$  and clock divide ratio =  $IWDTCLK$ .

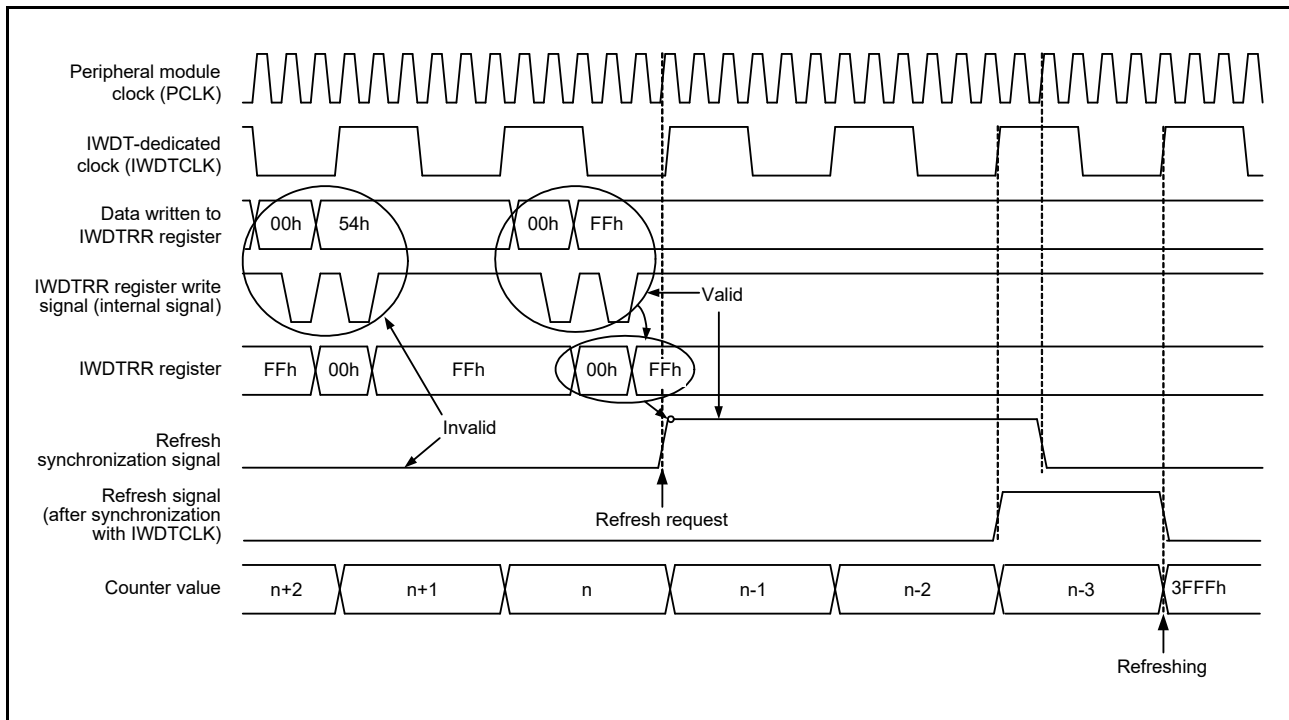

Figure 30.6 IWDT Refresh Operation Waveforms (IWDTCR.CKS[3:0] = 0000b, IWDTCR.TOPS[1:0] = 11b)

### 30.3.4 Status Flags

The IWDTSR.REFEF and IWDTSR.UNDFE flags retain the source of the reset signal output from the IWDT or the source of the interrupt request from the IWDT.

Thus, after release from the reset state or interrupt request generation, read the IWDTSR.REFEF and IWDTSR.UNDFE flags to check for the reset or interrupt source.

For each flag, writing 0 clears the bit and writing 1 has no effect.

Leaving the status flags unchanged does not affect operation. If the flags are not cleared, at the time of the next reset or interrupt request from the IWDT, the earlier reset or interrupt source is cleared and the new reset or interrupt source is written.

After 0 is written to each flag, up to three IWDTCLK cycles and two PCLK cycles are required before the value is reflected.

### 30.3.5 Reset Output

When the IWDTRCR.RSTIRQS bit is set to 1 in register start mode or when the IWDTRSTIRQS bit in option function select register 0 (OFS0) is set to 1 in auto-start mode, a reset signal is output when an underflow in the counter or a refresh error occurs.

In register start mode, the counter is initialized (0000h) and kept in that state after assertion of the reset signal. After the reset is released and the program is restarted, the counter is set up again and counting down is started by refreshing.

In auto-start mode, counting down automatically starts after the reset output.

### 30.3.6 Interrupt Sources

When the IWDTRCR.RSTIRQS bit is set to 0 in register start mode or when the OFS0.IWDTRSTIRQS bit is set to 0 in auto-start mode, an interrupt (IWUNI) signal is output when an underflow in the counter or a refresh error occurs. This interrupt can be used as a non-maskable interrupt or a maskable interrupt. For details, refer to section 14, Interrupt Controller (ICUC).

**Table 30.4 IWDT Interrupt Source**

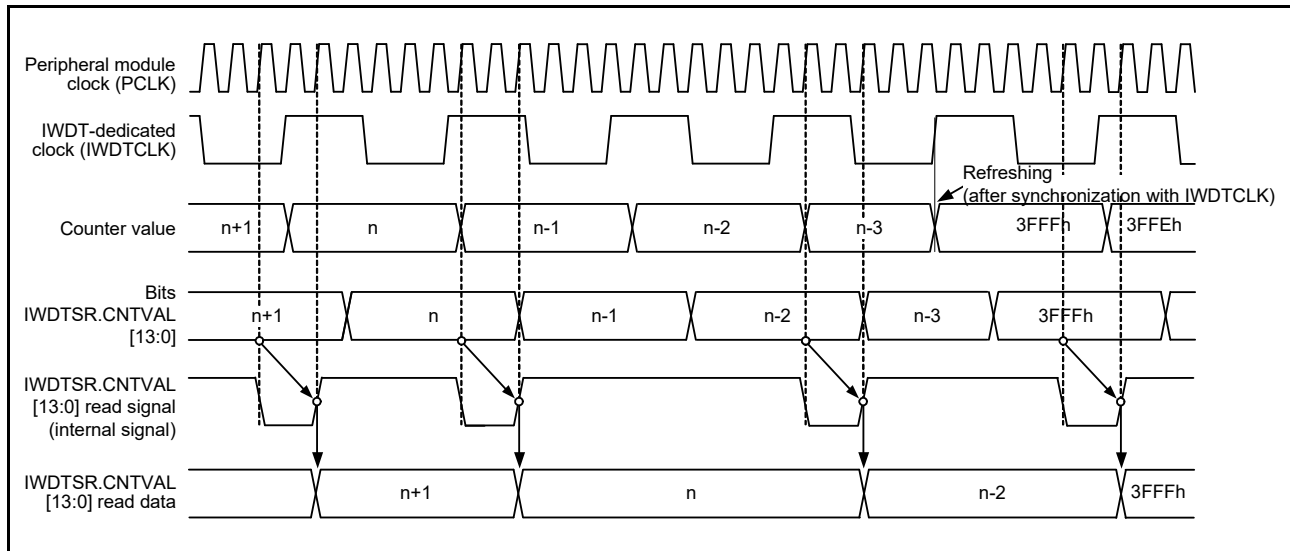

| Name  | Interrupt Source                   | DTC Activation | DMAC Activation |
|-------|------------------------------------|----------------|-----------------|
| IWUNI | Counter underflow<br>Refresh error | Not possible   | Not possible    |

### 30.3.7 Reading the Counter Value

As the counter in IWDT-dedicated clock (IWDTCLK), the counter value cannot be read directly. The IWDT synchronizes the counter value with the peripheral module clock (PCLK) and stores it in the IWDTSR.CNTVAL[13:0] bits. Thus, the counter value can be checked indirectly through the IWDTSR.CNTVAL[13:0] bits.

Reading the counter value requires multiple PCLK clock cycles (up to four clock cycles), and the read counter value may differ from the actual counter value by a value of one count.

Figure 30.7 shows the processing for reading the IWDT counter value when  $PCLK > IWDTCLK$  and clock divide ratio = IWDTCLK.

**Figure 30.7** Processing for Reading IWDT Counter Value  
(IWDTCR.CKS[3:0] = 0000b, IWDTCR.TOPS[1:0] = 11b)

### 30.3.8 Correspondence between Option Function Select Register 0 (OFS0) and IWDT Registers

Table 30.5 lists the correspondence between option function select register 0 (OFS0) used in auto-start mode and the registers used in register start mode.

Do not change the OFS0 register setting during IWDT operation.

For details on the OFS0 register, refer to section 7.2.3, Option Function Select Register 0 (OFS0).

**Table 30.5 Correspondence between Option Function Select Register 0 (OFS0) and IWDT Registers**

| Target of Control                        | Function                                           | OFS0 Register<br>(Enabled in Auto-Start Mode)<br>OFS0.IWDTSTRT = 0 | IWDT Registers<br>(Enabled in Register Start Mode)<br>OFS0.IWDTSTRT = 1 |
|------------------------------------------|----------------------------------------------------|--------------------------------------------------------------------|-------------------------------------------------------------------------|
| Counter                                  | Timeout period selection                           | OFS0.IWDTTOPS[1:0]                                                 | IWDTCR.TOPS[1:0]                                                        |
|                                          | Clock frequency divide ratio selection             | OFS0.IWDTCKS[3:0]                                                  | IWDTCR.CKS[3:0]                                                         |
|                                          | Window start position selection                    | OFS0.IWDRPSS[1:0]                                                  | IWDTCR.RPSS[1:0]                                                        |

## 30.4 Link Operation by ELC

The event link controller (ELC) can use the interrupt request signal generated by the IWDT as the event signal.

Therefore, the ELC generates an event to the module specified previously when the IWDT outputs an interrupt request.

The event signal is output by the counter underflow and refresh error.

An event signal is output regardless of the setting of the IWDRCR.RSTIRQS bit in register start mode or the OFS0.IWDRSTIRQS bit in auto-start mode. An event signal can also be output upon generation of the next interrupt source while the IWDTSR.REFEF or IWDTSR.UNDFE flag is 1.

For details, see section 19, Event Link Controller (ELC).

## 30.5 Usage Notes

### 30.5.1 Refresh Operations

When making the settings to control the timing of refreshing, consider variations in the range of errors due to the accuracy of the PCLK and IWDTCLK and set values which ensure that refreshing is possible.

### 30.5.2 Clock Divide Ratio Setting

Satisfy the frequency of the peripheral module clock ( $PCLK \geq 4 \times$  (the frequency of the count source after divide)).

## 31. USB 2.0 FS Host/Function Module (USBb)

### 31.1 Overview

This MCU incorporates a USB 2.0 FS host/function module (USB0).

The USB module is a USB controller that is equipped to operate as a host controller or function controller. The module supports full-speed and low-speed (only for the host controller) transfer as defined in Universal Serial Bus (USB) Specification 2.0. The module has an internal USB transceiver and supports all of the transfer types defined in USB Specification 2.0.

The USB has buffer memory for data transfer, providing a maximum of 10 pipes. Pipes 1 to 9 can be assigned any endpoint number based on peripheral devices used for communication or based on the user system.

Table 31.1 shows the specifications of the USB.

**Table 31.1 USB Specifications**

| Item                             | Specifications                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

|        | VSS_USB                      | Input  | USB ground pin                                                                                                                                                                                                      |

## 31.2 Register Descriptions

### 31.2.1 System Configuration Control Register (SYSCFG)

Address(es): USB0.SYSCFG 000A 0000h

|                    |     |     |     |     |     |      |    |    |    |      |      |       |    |    |    |      |
|--------------------|-----|-----|-----|-----|-----|------|----|----|----|------|------|-------|----|----|----|------|
|                    | b15 | b14 | b13 | b12 | b11 | b10  | b9 | b8 | b7 | b6   | b5   | b4    | b3 | b2 | b1 | b0   |
|                    | —   | —   | —   | —   | —   | SCKE | —  | —  | —  | DCFM | DRPD | DPRPU | —  | —  | —  | USBE |
| Value after reset: | 0   | 0   | 0   | 0   | 0   | 0    | 0  | 0  | 0  | 0    | 0    | 0     | 0  | 0  | 0  | 0    |

| Bit        | Symbol | Bit Name                    | Description                                                                                          | R/W |
|------------|--------|-----------------------------|------------------------------------------------------------------------------------------------------|-----|
| b0         | USBE   | USB Operation Enable        | 0: USB operation is disabled.<br>1: USB operation is enabled.                                        | R/W |
| b3 to b1   | —      | Reserved                    | These bits are read as 0. The write value should be 0.                                               | R/W |
| b4         | DPRPU  | D+ Line Resistor Control    | 0: Pulling up the line is disabled.<br>1: Pulling up the line is enabled.                            | R/W |
| b5         | DRPD   | D+/D– Line Resistor Control | 0: Pulling down the lines is disabled.<br>1: Pulling down the lines is enabled.                      | R/W |
| b6         | DCFM   | Controller Function Select  | 0: Function controller is selected.<br>1: Host controller is selected.                               | R/W |
| b9 to b7   | —      | Reserved                    | These bits are read as 0. The write value should be 0.                                               | R/W |
| b10        | SCKE   | USB Clock Enable*1          | 0: Stops supplying the clock signal to the USB.<br>1: Enables supplying the clock signal to the USB. | R/W |
| b15 to b11 | —      | Reserved                    | These bits are read as 0. The write value should be 0.                                               | R/W |

Note 1. After writing 1 to the SCKE bit, read it and confirm it is set to 1.

#### USBE Bit (USB Operation Enable)

The USBE bit enables or disables operation of the USB.

Modifying the USBE bit from 1 to 0 initializes the register bits listed in Table 31.3.

This bit should be modified while the SCKE bit is 1.

When the host controller is selected, this bit should be set to 1 after setting the DRPD bit to 1, eliminating SYSSTS0.LNST[1:0] flag chattering, and confirming that the USB bus state is stabilized.

**Table 31.3 Registers Initialized by Writing 0 to the SYSCFG.USBE Bit**

| Selected Function   | Register | Bit                                  | Remarks                                                         |
|---------------------|----------|--------------------------------------|-----------------------------------------------------------------|
| Function controller | SYSSTS0  | LNST[1:0]                            | The value is retained when the host controller is selected.     |
|                     | DVSTCTR0 | RHST[2:0]                            |                                                                 |
|                     | INTSTS0  | DVSQ[2:0]                            | The value is retained when the host controller is selected.     |
|                     | USBREQ   | BREQUEST[7:0],<br>BMREQUESTTYPE[7:0] | The value is retained when the host controller is selected.     |
|                     | USBVAL   | —                                    | The value is retained when the host controller is selected.     |
|                     | USBINDX  | —                                    | The value is retained when the host controller is selected.     |
|                     | USBLENG  | —                                    | The value is retained when the host controller is selected.     |
| Host controller     | DVSTCTR0 | RHST[2:0]                            |                                                                 |
|                     | FRMNUM   | FRNM[10:0]                           | The value is retained when the function controller is selected. |

**DPRPU Bit (D+ Line Resistor Control)**

The DPRPU bit enables or disables pulling up the D+ line when the function controller is selected.

When the DPRPU bit is set to 1 while the function controller is selected, the bit forces a pull-up of the D+ line to notify the USB host of connection. Modifying the DPRPU bit from 1 to 0 allows the USB to release the D+ line, thus notifying the USB host of disconnection.

This bit should be set to 1 if the function controller is selected, and should be set to 0 if the host controller is selected.

**DRPD Bit (D+/D- Line Resistor Control)**

The DRPD bit enables or disables pulling down D+ and D- lines when the host controller is selected.

This bit should be set to 1 if the host controller is selected, and should be set to 0 if the function controller is selected.

**DCFM Bit (Controller Function Select)**

The DCFM bit selects the function of the USB.

This bit should be modified when the DPRPU and DRPD bits are all 0.

**SCKE Bit (USB Clock Enable)**

The SCKE bit stops or enables supplying 48-MHz clock signals to the USB.

When this bit is 0, only SYSCFG can be read from and written to; the other registers related to the USB cannot be read from or written to.

### 31.2.2 System Configuration Status Register 0 (SYSSTS0)

Address(es): USB0.SYSSTS0 000A 0004h

| Bit       | Symbol      | Bit Name                               | Description                                                                                                                          | R/W |
|-----------|-------------|----------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------|-----|
| b1, b0    | LNST[1:0]   | USB Data Line Status Monitor Flag      | Refer to Table 31.4.                                                                                                                 | R   |
| b2        | IDMON       | ID Input Pin Monitor Flag              | 0: USB0_ID pin is low<br>1: USB0_ID pin is high                                                                                      | R   |
| b5 to b3  | —           | Reserved                               | These bits are read as 0 and cannot be modified.                                                                                     | R   |
| b6        | HTACT       | USB Host Sequencer Status Monitor Flag | 0: Host sequencer of the USB is completely stopped.<br>1: Host sequencer of the USB is not completely stopped.                       | R   |
| b13 to b7 | —           | Reserved                               | These bits are read as 0 and cannot be modified.                                                                                     | R   |
| b15, b14  | OVCMON[1:0] | OVRCURA/OVRCURB Input Pin Monitor Flag | The OVCMON[1] flag indicates the status of the USB0_OVRCURA pin.<br>The OVCMON[0] flag indicates the status of the USB0_OVRCURB pin. | R   |

Note 1. Depends on the status of the USB0\_OVRCURA/USB0\_OVRCURB and USB0\_ID pins.

#### LNST[1:0] Flags (USB Data Line Status Monitor Flag)

The LNST[1:0] flags indicate the state of the USB data lines (D+ and D– lines). Refer to Table 31.4.

The LNST[1:0] flags should be read after the connection processing (SYSCFG.DPRPU bit = 1) when the function controller is selected; whereas after enabling pull-down of the lines (SYSCFG.DRPD bit = 1) when the host controller is selected.

#### HTACT Flag (USB Host Sequencer Status Monitor Flag)

The HTACT flag is 0 when the host sequencer of the USB is completely stopped.

#### OVCMON[1:0] Flags (OVRCURA/OVRCURB Input Pin Monitor Flag)

The OVCMON[1:0] flags indicate the status of overcurrent from an external power supply chip.

**Table 31.4 Status of USB Data Bus Lines (D+ Line, D– Line)**

| LNST[1:0] Flags | During Low-Speed Operation<br>(Only in Host Controller Operation) | During Full-Speed Operation |
|-----------------|-------------------------------------------------------------------|-----------------------------|
| 00b             | SE0                                                               | SE0                         |
| 01b             | K-State                                                           | J-State                     |
| 10b             | J-State                                                           | K-State                     |
| 11b             | SE1                                                               | SE1                         |

## 31.2.3 Device State Control Register 0 (DVSTCTR0)

Address(es): USB0.DVSTCTR0 000A 0008h

|                    |     |     |     |         |        |        |      |       |          |        |      |    |           |    |    |

x: Don't care

**RHST[2:0] Flags (USB Bus Reset Status Flag)**

The RHST[2:0] flags indicate the status of the USB bus reset.

When the host controller is selected, the RHST[2:0] flags indicate 100b after the USBRST bit has been set to 1 by software.

The USB fixes the value of the RHST[2:0] flags when 0 is written to the USBRST bit by software and the USB completes SE0 driving.

When the function controller is selected, the RHST[2:0] flags indicate 010b (connection while DPRPU = 1) when the USB detects the USB bus reset, and a DVST interrupt is generated.

**UACT Bit (USB Bus Enable)**

The UACT bit enables operation of the USB bus (controls the SOF packet transmission to the USB bus) when the host controller is selected.

With this bit set to 1, the USB puts the USB port to the USB-bus enabled state and performs SOF output and data transmission and reception.

This module starts outputting SOF packets within one frame after 1 has been written to the UACT bit by software.

With this bit set to 0, the USB enters the idle state after outputting SOF packets.

The USB sets the UACT bit to 0 on any of the following conditions.

- A DTCH interrupt is detected during communication (while UACT = 1).
- An EOFERR interrupt is detected during communication (while UACT = 1).

Writing 1 to this bit should be done at the end of the USB reset processing (writing 0 to the USBRST bit) or at the end of the resume processing from the suspended state (writing 0 to the RESUME bit).

This bit should be set to 0 if the function controller is selected.

**RESUME Bit (Resume Output)**

The RESUME bit controls the resume signal output when the host controller is selected.

Setting the RESUME bit to 1 allows the USB to drive the port to the K-state and output the resume signal.

The USB sets the RESUME bit to 1 on detecting the remote wakeup signal while RWUPE is 1 in the USB suspended state.

The USB continues outputting K-state while the RESUME bit = 1 (until the RESUME bit is set to 0 by software). The RESUME bit should be 1 (= resume period) for the time defined by USB Specification 2.0.

This bit should be set to 1 in the suspended state.

Write 1 to the UACT bit simultaneously with the end of the resume processing (writing 0 to the RESUME bit).

This bit should be set to 0 if the function controller is selected.

**USBRST Bit (USB Bus Reset Output)**

The USBRST bit controls the USB bus reset signal output when the host controller is selected.

When the host controller is selected, setting this bit to 1 allows the USB to drive SE0 of the USB port to reset the USB bus.

The USB continues outputting SE0 while USBRST = 1 (until the USBRST bit is set to 1 by software). The USBRST bit should be 1 (= USB bus reset period) for the time defined by USB Specification 2.0.

Writing 1 to this bit during communication (the UACT bit = 1) or during the resume processing (the RESUME bit = 1) prevents the USB from starting the USB bus reset processing until both the UACT and RESUME bits become 0.

Write 1 to the UACT bit simultaneously with the end of the USB bus reset processing (writing 0 to the USBRST bit).

This bit should be set to 0 if the function controller is selected.

**RWUPE Bit (Wakeup Detection Enable)**

The RWUPE bit enables or disables the downstream port peripheral device to use the remote wakeup function (resume signal output) when the host controller is selected.

With this bit set to 1, on detecting the remote wakeup signal, the USB detects the resume signal (K-state for 2.5  $\mu$ s) from the downstream port device and performs the resume processing (drives the port to the K-state).

With this bit set to 0, the USB ignores the detected remote wakeup signal (K-state) from the peripheral device connected to the USB port.

While the RWUPE bit is 1, the internal clock should not be stopped even in the suspended state (SYSCFG.SCKE bit should be set to 1).

This bit should be set to 0 if the function controller is selected.

**WKUP Bit (Wakeup Output)**

The WKUP bit enables or disables outputting the remote wakeup signal (resume signal) to the USB bus when the function controller is selected.

The USB controls the output time of a remote wakeup signal. When this bit is set to 1, the USB sets this bit to 0 after outputting the 10-ms K-state.

According to USB Specification 2.0, the USB bus idle state must be kept for 5 ms or longer before a remote wakeup signal is sent. If the USB writes 1 to this bit right after detection of the suspended state, the K-state will be output after 2 ms.

Do not write 1 to this bit, unless the device state is in the suspended state (INTSTS0.DVSQ[2:0] flags = 1xxb) and the USB host enables the remote wakeup signal. When this bit is set to 1, the internal clock must not be stopped even in the suspended state (write 1 to this bit while the SYSCFG.SCKE bit = 1).

This bit should be set to 0 if the host controller is selected.

**HNPBTOA Bit (Host Negotiation Protocol (HNP) Control)**

The HNPBTOA bit is used when switching from device B to device A while in OTG mode. If the HNPBTOA bit is 1, the internal function control keeps the suspended state until the HNP processing ends even though the SYSCFG.DPRPU bit = 0 or SYSCFG.DCFM = 1 is set. Even if the falling edge of the D+ signal is detected at this time, no resume (RESM) interrupt is generated.

After this bit is set to 1, write 0 to this bit by software to terminate the HNP processing when connection to the host (pull-up on the target side) or timeout of the HNP processing is detected.

### 31.2.4 CFIFO Port Register (CFIFO), D0FIFO Port Register (D0FIFO), D1FIFO Port Register (D1FIFO)

#### (1) When the MBW bit is 1

Address(es): USB0.CFIFO 000A 0014h, USB0.D0FIFO 000A 0018h, USB0.D1FIFO 000A 001Ch

| Bit       | Symbol | Bit Name  | Description                                                                                                   | R/W |
|-----------|--------|-----------|---------------------------------------------------------------------------------------------------------------|-----|
| b15 to b0 | —      | FIFO Port | This port is used for reading receive data from the FIFO buffer and writing transmit data to the FIFO buffer. | R/W |

#### (2) When the MBW bit is 0

Address(es): USB0.CFIFO.L 000A 0014h, USB0.D0FIFO.L 000A 0018h, USB0.D1FIFO.L 000A 001Ch

| Bit      | Symbol | Bit Name  | Description                                                                                                   | R/W |
|----------|--------|-----------|---------------------------------------------------------------------------------------------------------------|-----|
| b7 to b0 | —      | FIFO Port | This port is used for reading receive data from the FIFO buffer and writing transmit data to the FIFO buffer. | R/W |

There are three FIFO ports: CFIFO, D0FIFO, and D1FIFO. Each FIFO port is configured of a port register (CFIFO, D0FIFO, or D1FIFO) that handles reading of data from the FIFO buffer memory and writing of data to the FIFO buffer memory, a port select register (CFIFOSEL, D0FIFOSEL, or D1FIFOSEL) that is used to select the pipe assigned to the FIFO port, and a port control register (CFIFOCTR, D0FIFOCTR, or D1FIFOCTR).

Each FIFO port has the following precautions.

- The FIFO buffer for DCP (control transfer) should be accessed through the CFIFO port.
- Accessing a FIFO buffer using DMA/DTC transfer should be performed through the D0FIFO or D1FIFO port.
- The D0FIFO and D1FIFO ports can also be accessed by the CPU.
- When using functions specific to a FIFO port, the pipe number (selected pipe) specified by the CURPIPE[3:0] bits in the port select register cannot be changed (when the DMA/DTC transfer function is used, etc.).
- The same pipe should not be assigned to two or more FIFO ports.
- There are two FIFO buffer states: the access right for a FIFO buffer can be on the CPU side or on the Serial Interface Engine (SIE) side. When the access right for a FIFO buffer is on the SIE side, the FIFO buffer cannot be accessed from the CPU.

### FIFO Port Bit

Accessing the FIFO port bits allows reading the received data from the FIFO buffer or writing the transmit data to the FIFO buffer.

Each FIFO port register can be accessed only while the FRDY flag in each FIFO port control register (CFIFOCTR, D0FIFOCTR, or D1FIFOCTR) is 1.

The valid bits in a FIFO port register depend on the settings of the corresponding MBW bit of the FIFO port select register (CFIFOSEL, D0FIFOSEL, or D1FIFOSEL).

When the MBW bit is 1 (16-bit width), the data arrangement may differ from the data arrangement on the RAM depending on the value of the MDE.MDE[2:0] bits and the setting of the BIGEND bit (CFIFOSEL.BIGEND, D0FIFOSEL.BIGEND, or D1FIFOSEL.BIGEND). Table 31.5 lists the endian operation in 16-bit access. Note that if the total number of transmit data bytes is odd, access the lower byte in bytes when writing the last data.

When the MBW bit is 0 (8-bit width), access the lower byte in bytes.

**Table 31.5 Endian Operation in 16-Bit Access**

| MDE.MDE[2:0] bits    | CFIFOSEL.BIGEND Bit<br>D0FIFOSEL.BIGEND Bit<br>D1FIFOSEL.BIGEND Bit |  | Bits 15 to 8          | Bits 7 to 0           | Remarks        |
|----------------------|---------------------------------------------------------------------|--|-----------------------|-----------------------|----------------|
|                      |                                                                     |  |                       |                       |                |
| 000b (big endian)    | 0 (little endian)                                                   |  | Data in address N + 1 | Data in address N     | Bytes reversed |
|                      | 1 (big endian)                                                      |  | Data in address N     | Data in address N + 1 |                |
| 111b (little endian) | 0 (little endian)                                                   |  | Data in address N + 1 | Data in address N     |                |
|                      | 1 (big endian)                                                      |  | Data in address N     | Data in address N + 1 | Bytes reversed |

(In double buffer mode, the DTLN[8:0] flag value is set to 000h when all the data has been read from only a single plane.)<br>1: The CFIFOCTR.DTLN[8:0] flags are decremented each time the receive data is read from the CFIFO. | R/W   |

Note 1. Only 0 can be read.

The same pipe should not be specified by the CURPIPE[3:0] bits in the CFIFOSEL, D0FIFOSEL, and D1FIFOSEL registers. When the CURPIPE[3:0] bits in the D0FIFOSEL and D1FIFOSEL registers are set to 0000b, no pipe is selected.

The pipe number should not be changed while the DMA/DTC transfer is enabled.

**CURPIPE[3:0] Bits (CFIFO Port Access Pipe Specification)**

The CURPIPE[3:0] bits specify the pipe number using which data is read or written through the CFIFO port.

After writing to these bits, read these bits to check that the written value agrees with the read value before proceeding to the next process.

Do not set the same pipe number to the CURPIPE[3:0] bits in the CFIFOSEL, D0FIFOSEL, and D1FIFOSEL registers. Even if an attempt is made to modify the setting of these bits during access to the FIFO buffer, the current access setting is retained until the access is completed. Then, the modification becomes effective, thus enabling continuous access.

**ISEL Bit (CFIFO Port Access Direction When DCP is Selected)**

After writing to the ISEL bit with the DCP being a selected pipe, read this bit to check that the written value agrees with the read value before proceeding to the next process.

Set this bit and the CURPIPE[3:0] bits simultaneously.

**MBW Bit (CFIFO Port Access Bit Width)**

The MBW bit specifies the bit width for accessing the CFIFO port.

When the selected pipe is in the receiving direction, once reading data is started after setting this bit, this bit should not be modified until all the data has been read.

When the selected pipe is in the receiving direction, set the CURPIPE[3:0] bits to a different value once, and then set these bits and the MBW bit simultaneously. For the procedure for modifying the CURPIPE[3:0] bits, follow the description of these bits.

When the selected pipe is in the transmitting direction, the bit width cannot be changed from 8-bit width to 16-bit width while data is being written to the buffer memory.

An odd number of bytes can also be written through byte-access control even when 16-bit width is selected.

**REW Bit (Buffer Pointer Rewind)**

The REW bit specifies whether or not to rewind the buffer pointer.

When the selected pipe is in the receiving direction, setting the REW bit to 1 while the FIFO buffer is being read allows re-reading the FIFO buffer from the first data (in double buffer mode, re-reading the currently-read FIFO buffer plane from the first data is allowed).

Do not set the REW bit to 1 simultaneously with modifying the CURPIPE[3:0] bits. Before setting the REW bit to 1, be sure to check that the FRDY flag is 1.

To re-write to the FIFO buffer again from the first data for the pipe in the transmitting direction, use the BCLR bit.

| b15      | RCNT             | Read Count Mode                                                     | 0: The DnFIFOCTR.DTLN[8:0] flags are set to 000h when all of the receive data has been read from the DnFIFO. (In double buffer mode, the DTLN[8:0] flag value is set to 000h when all the data has been read from only a single plane.)<br>1: The DnFIFOCTR.DTLN[8:0] flags are decremented each time the receive data is read from the DnFIFO.<br>(n = 0, 1) | R/W   |

Note 1. Only 0 can be read.

The same pipe should not be specified by the CURPIPE[3:0] bits in the CFIFOSEL, D0FIFOSEL, and D1FIFOSEL registers. When the CURPIPE[3:0] bits in the D0FIFOSEL and D1FIFOSEL registers are set to 0000b, no pipe is selected.

The pipe number should not be changed while the DMA/DTC transfer is enabled.

**CURPIPE[3:0] Bits (FIFO Port Access Pipe Select)**

The CURPIPE[3:0] bits specify the pipe number using which data is read or written through the D0FIFO port or D1FIFO port.

After writing to these bits, read these bits to check that the written value agrees with the read value before proceeding to the next process.

Do not set the same pipe number to the CURPIPE[3:0] bits in the CFIFOSEL, D0FIFOSEL, and D1FIFOSEL registers. Even if an attempt is made to modify the setting of these bits during access to the FIFO buffer, the current access setting is retained until the access is completed. Then, the modification becomes effective, thus enabling continuous access.

**MBW Bit (FIFO Port Access Bit Width)**

The MBW bit specifies the bit width for accessing the D0FIFO port or D1FIFO port.

When the selected pipe is in the receiving direction, once reading data is started after setting this bit, this bit should not be modified until all the data has been read.

When the selected pipe is in the receiving direction, set the CURPIPE[3:0] bits to a different value once, and then set these bits and the MBW bit simultaneously. For the procedure for modifying the CURPIPE[3:0] bits, follow the description of these bits.

When the selected pipe is in the transmitting direction, the bit width cannot be changed from 8-bit width to 16-bit width while data is being written to the buffer memory.

An odd number of bytes can also be written through byte-access control even when 16-bit width is selected.

**DREQE Bit (DMA/DTC Transfer Request Enable)**

The DREQE bit enables or disables the DMA/DTC transfer request to be issued.

Before setting the DREQE bit to 1 to enable the DMA/DTC transfer request to be issued, set the CURPIPE[3:0] bits.

When modifying the setting of the CURPIPE[3:0] bits, set this bit to 0 first.

**DCLRM Bit (Automatic FIFO Buffer Memory Clear Mode after Selected Pipe is Read)**

The DCLRM bit enables or disables the buffer memory to be cleared automatically after data in the selected pipe has been read.

With this bit set to 1, the USB sets the BCLR bit to 1 for the FIFO buffer of the selected pipe on receiving a zero-length packet while the FIFO buffer assigned to the selected pipe is empty, or on receiving a short packet and reading the data while the PIPECFG.BFRE bit is 1.

When using the USB with the SOFCFG.BRDYM bit set to 1, set this bit to 0.

**REW Bit (Buffer Pointer Rewind)**

The REW bit specifies whether or not to rewind the buffer pointer.

When the selected pipe is in the receiving direction, setting the REW bit to 1 while the FIFO buffer is being read allows re-reading the FIFO buffer from the first data (in double buffer mode, re-reading the currently-read FIFO buffer plane from the first data is allowed).

Do not set the REW bit to 1 simultaneously with modifying the CURPIPE[3:0] bits. Before setting the REW bit to 1, be sure to check that the FRDY flag is 1.

To re-write to the FIFO buffer again from the first data for the pipe in the transmitting direction, use the BCLR bit.

**RCNT Bit (Read Count Mode)**

The RCNT bit specifies the read mode for the value in the DnFIFOCTR.DTLN[8:0] flags.

When accessing DnFIFO with the PIPECFG.BFRE bit set to 1, set the RCNT bit to 0.

### 31.2.6 CFIFO Port Control Register (CFIFOCTR), D0FIFO Port Control Register (D0FIFOCTR), D1FIFO Port Control Register (D1FIFOCTR)

| b12 to b9 | —         | Reserved                 | These bits are read as 0. The write value should be 0.                                                                                                                                                                        | R/W   |
| b13       | FRDY      | FIFO Port Ready Flag     | 0: FIFO port access is disabled.<br>1: FIFO port access is enabled.                                                                                                                                                           | R     |
| b14       | BCLR      | CPU Buffer Clear         | 0: Does not operate.<br>1: Clears the buffer memory on the CPU side.                                                                                                                                                          | R/W*1 |
| b15       | BVAL      | Buffer Memory Valid      | 0: Invalid<br>1: Writing ended                                                                                                                                                                                                | R/W   |

Note 1. Only 0 can be read.

Registers CFIFOCTR, D0FIFOCTR, and D1FIFOCTR correspond to CFIFO, D0FIFO, and D1FIFO, respectively.

#### DTLN[8:0] Flags (Receive Data Length Flag)

The DTLN[8:0] flags indicate the length of the receive data.

While the FIFO buffer is being read, the DTLN[8:0] flags indicate different values depending on the DnFIFOSEL.RCNT bit (n = 0, 1) value as described below.

- RCNT = 0

The USB sets the DTLN[8:0] flags to indicate the length of the receive data until the CPU or DMAC/DTC has read all the received data from a single FIFO buffer plane.

While the PIPECFG.BFRE bit = 1, these bits retain the length of the receive data until the BCLR bit is set to 1 even after all the data has been read.

- RCNT = 1

The USB decrements the value indicated by the DTLN[8:0] flags each time data is read from the FIFO buffer. (The value is decremented by one when the MBW bit is 0, and by two when the MBW bit is 1.)

The USB sets these bits to 0 when all the data has been read from one FIFO buffer plane. However, in double buffer mode, if data has been received in one FIFO buffer plane before all the data has been read from the other plane, the USB sets these bits to indicate the length of the receive data in the former plane when all the data has been read from the latter plane.

**FRDY Flag (FIFO Port Ready Flag)**

The FRDY flag indicates whether the FIFO port can be accessed by the CPU or DMAC/DTC.

In the following cases, the USB sets the FRDY flag to 1 but data cannot be read via the FIFO port because there is no data to be read. In these cases, set the BCLR bit to 1 to clear the FIFO buffer, and enable transmission and reception of the next data.

- A zero-length packet is received when the FIFO buffer assigned to the selected pipe is empty.
- A short packet is received and the data is completely read while the PIPECFG.BFRE bit = 1.

**BCLR Bit (CPU Buffer Clear)**

The BCLR bit should be set to 1 to clear the FIFO buffer on the CPU side for the selected pipe.

When double buffer mode is set for the FIFO buffer assigned to the selected pipe, the USB clears only the FIFO buffer on the CPU side even when both planes are read-enabled.

When the selected pipe is the DCP, setting the BCLR bit to 1 allows the USB to clear the FIFO buffer regardless of whether the FIFO buffer is on the CPU side or SIE side. To clear the buffer on the SIE side, set the DCPCTR.PID[1:0] bits for the DCP to 00b (NAK) before setting the BCLR bit to 1.

When the selected pipe is in the transmitting direction, if 1 is written to the BVAL bit and the BCLR bit simultaneously, the USB clears the data that has been written before it, enabling transmission of a zero-length packet.

When the selected pipe is not the DCP, writing 1 to the BCLR bit should be done while the FRDY flag in the FIFO port control register is 1 (set by the USB).

**BVAL Bit (Buffer Memory Valid)**

The BVAL bit should be set to 1 when data has been completely written to the FIFO buffer on the CPU side for the pipe selected using the CURPIPE[3:0] bits (selected pipe).

When the selected pipe is in the transmitting direction, set the BVAL bit to 1 in the following cases. Then, the USB switches the FIFO buffer from the CPU side to the SIE side, thus enabling transmission.

- To transmit a short packet, set the BVAL bit to 1 after data has been written.
- To transmit a zero-length packet, set the BVAL bit to 1 before data is written to the FIFO buffer.

When data of the maximum packet size has been written for the pipe in continuous transfer mode, the USB sets the BVAL bit to 1 and switches the FIFO buffer from the CPU side to the SIE side, thus enabling transmission.

Writing 1 to the BVAL bit should be done while the FRDY flag is 1 (set by the USB).

When the selected pipe is in the receiving direction, do not set the BVAL bit to 1.

| b15      | VBSE   | VBUS Interrupt Enable                                | 0: Interrupt output disabled<br>1: Interrupt output enabled | R/W |

Note 1. The RSME, DVSE, and CTRE bits can be set to 1 only when the function controller is selected. Set these bits to 0 when the host controller is selected.

On detecting the interrupt corresponding to the bit in the INTENB0 register to which 1 has been set by software, the USB generates the USB interrupt request.

The USB sets 1 to each status bit in the INTSTS0 register when a detection condition of the corresponding interrupt source has been satisfied regardless of the setting in the INTENB0 register (regardless of whether the interrupt output is enabled or disabled).

While the status bit in the INTSTS0 register corresponding to the interrupt source indicates 1, the USB generates the USB interrupt request when the corresponding interrupt enable bit in the INTENB0 register is modified from 0 to 1 by software.

### 31.2.8 Interrupt Enable Register 1 (INTENB1)

Address(es): USB0.INTENB1 000A 0032h

|                    |        |       |     |       |         |     |    |    |    |         |       |       |    |    |    |    |

| b10 to b7 | —       | Reserved                                           | These bits are read as 0. The write value should be 0.      | R/W |
| b11       | ATTCH E | Connection Detection Interrupt Enable              | 0: Interrupt output disabled<br>1: Interrupt output enabled | R/W |
| b12       | DTCHE   | Disconnection Detection Interrupt Enable           | 0: Interrupt output disabled<br>1: Interrupt output enabled | R/W |
| b13       | —       | Reserved                                           | This bit is read as 0. The write value should be 0.         | R/W |
| b14       | BCHGE   | USB Bus Change Interrupt Enable                    | 0: Interrupt output disabled<br>1: Interrupt output enabled | R/W |
| b15       | OVRCRE  | Overcurrent Input Change Interrupt Enable          | 0: Interrupt output disabled<br>1: Interrupt output enabled | R/W |

Note: The bits in the INTENB1 register can be set to 1 only when the host controller is selected. Set these bits to 0 when the function controller is selected.

The INTENB1 register specifies the interrupt masks when the host controller is selected, and for the setup transaction. On detecting the interrupt corresponding to the bit in the INTENB1 register to which 1 has been set by software, the USB generates the USB interrupt request.

The USB sets 1 to each status bit in the INTSTS1 register when a detection condition of the corresponding interrupt source has been satisfied regardless of the setting in the INTENB1 register (regardless of whether the interrupt output is enabled or disabled).

While the status bit in the INTSTS1 register corresponding to the interrupt source indicates 1, the USB generates the USB interrupt request when the corresponding interrupt enable bit in the INTENB1 register is modified from 0 to 1 by software.

When the function controller is selected, the interrupts should not be enabled.

### 31.2.9 BRDY Interrupt Enable Register (BRDYENB)

Address(es): USB0.BRDYENB 000A 0036h

|                    |     |     |     |     |     |     |                |                |                |                |                |                |                |                |                |                |

| b7         | PIPE7BRDYE | BRDY Interrupt Enable for Pipe 7 | 0: Interrupt output disabled<br>1: Interrupt output enabled | R/W |
| b8         | PIPE8BRDYE | BRDY Interrupt Enable for Pipe 8 | 0: Interrupt output disabled<br>1: Interrupt output enabled | R/W |
| b9         | PIPE9BRDYE | BRDY Interrupt Enable for Pipe 9 | 0: Interrupt output disabled<br>1: Interrupt output enabled | R/W |
| b15 to b10 | —          | Reserved                         | These bits are read as 0. The write value should be 0.      | R/W |

The BRDYENB register enables or disables the INTSTS0.BRDY flag to be set to 1 when the BRDY interrupt is detected for each pipe.

On detecting the BRDY interrupt for the pipe corresponding to the bit in the BRDYENB register to which 1 has been set by software, the USB sets 1 to the corresponding BRDYSTS.PIPEnBRDY flag ( $n = 0$  to 9) and the INTSTS0.BRDY flag. If INTENB0.BRDYE = 1 at this time, the USB generates the BRDY interrupt request.

While at least one PIPEnBRDY flag indicates 1, the USB generates the BRDY interrupt request when the corresponding interrupt enable bit in the BRDYENB register is modified from 0 to 1 by software.

### 31.2.10 NRDY Interrupt Enable Register (NRDYENB)

Address(es): USB0.NRDYENB 000A 0038h

|                    |     |     |     |     |     |     |            |            |            |            |            |            |            |            |            |            |
|--------------------|-----|-----|-----|-----|-----|-----|------------|------------|------------|------------|------------|------------|------------|------------|------------|------------|

|------------|------------|----------------------------------|-------------------------------------------------------------|-----|
| b0         | PIPE0NRDYE | NRDY Interrupt Enable for Pipe 0 | 0: Interrupt output disabled<br>1: Interrupt output enabled | R/W |
| b1         | PIPE1NRDYE | NRDY Interrupt Enable for Pipe 1 | 0: Interrupt output disabled<br>1: Interrupt output enabled | R/W |
| b2         | PIPE2NRDYE | NRDY Interrupt Enable for Pipe 2 | 0: Interrupt output disabled<br>1: Interrupt output enabled | R/W |
| b3         | PIPE3NRDYE | NRDY Interrupt Enable for Pipe 3 | 0: Interrupt output disabled<br>1: Interrupt output enabled | R/W |
| b4         | PIPE4NRDYE | NRDY Interrupt Enable for Pipe 4 | 0: Interrupt output disabled<br>1: Interrupt output enabled | R/W |
| b5         | PIPE5NRDYE | NRDY Interrupt Enable for Pipe 5 | 0: Interrupt output disabled<br>1: Interrupt output enabled | R/W |
| b6         | PIPE6NRDYE | NRDY Interrupt Enable for Pipe 6 | 0: Interrupt output disabled<br>1: Interrupt output enabled | R/W |
| b7         | PIPE7NRDYE | NRDY Interrupt Enable for Pipe 7 | 0: Interrupt output disabled<br>1: Interrupt output enabled | R/W |
| b8         | PIPE8NRDYE | NRDY Interrupt Enable for Pipe 8 | 0: Interrupt output disabled<br>1: Interrupt output enabled | R/W |
| b9         | PIPE9NRDYE | NRDY Interrupt Enable for Pipe 9 | 0: Interrupt output disabled<br>1: Interrupt output enabled | R/W |
| b15 to b10 | —          | Reserved                         | These bits are read as 0. The write value should be 0.      | R/W |

The NRDYENB register enables or disables the INTSTS0.NRDY flag to be set to 1 when the NRDY interrupt is detected for each pipe.

On detecting the NRDY interrupt for the pipe corresponding to the bit in the NRDYENB register to which 1 has been set by software, the USB sets 1 to the corresponding NRDYSTS.PIPE $n$ NRDY flag ( $n = 0$  to 9) and the INTSTS0.NRDY flag. If INTENB0.NRDYE = 1 at this time, the USB generates the NRDY interrupt request.

While at least one PIPE $n$ NRDY flag indicates 1, the USB generates the NRDY interrupt request when the corresponding interrupt enable bit in the NRDYENB register is modified from 0 to 1 by software.

### 31.2.11 BEMP Interrupt Enable Register (BEMPENB)

Address(es): USB0.BEMPENB 000A 003Ah

|                    |     |     |     |     |     |     |                |                |                |                |                |                |                |                |                |                |

| b3         | PIPE3BEMPE | BEMP Interrupt Enable for Pipe 3 | 0: Interrupt output disabled<br>1: Interrupt output enabled | R/W |
| b4         | PIPE4BEMPE | BEMP Interrupt Enable for Pipe 4 | 0: Interrupt output disabled<br>1: Interrupt output enabled | R/W |
| b5         | PIPE5BEMPE | BEMP Interrupt Enable for Pipe 5 | 0: Interrupt output disabled<br>1: Interrupt output enabled | R/W |
| b6         | PIPE6BEMPE | BEMP Interrupt Enable for Pipe 6 | 0: Interrupt output disabled<br>1: Interrupt output enabled | R/W |
| b7         | PIPE7BEMPE | BEMP Interrupt Enable for Pipe 7 | 0: Interrupt output disabled<br>1: Interrupt output enabled | R/W |
| b8         | PIPE8BEMPE | BEMP Interrupt Enable for Pipe 8 | 0: Interrupt output disabled<br>1: Interrupt output enabled | R/W |
| b9         | PIPE9BEMPE | BEMP Interrupt Enable for Pipe 9 | 0: Interrupt output disabled<br>1: Interrupt output enabled | R/W |
| b15 to b10 | —          | Reserved                         | These bits are read as 0. The write value should be 0.      | R/W |

The BEMPENB register enables or disables the INTSTS0.BEMP flag to be set to 1 when the BEMP interrupt is detected for each pipe.

On detecting the BEMP interrupt for the pipe corresponding to the bit in the BEMPENB register to which 1 has been set by software, the USB sets 1 to the corresponding BEMPSTS.PIPEnBEMP flag ( $n = 0$  to  $9$ ) and the INTSTS0.BEMP flag. If INTENB0.BEMPE = 1 at this time, the USB generates the BEMP interrupt request.

While at least one PIPEnBEMP flag in the BEMPSTS register indicates 1, the USB generates the BEMP interrupt request when the corresponding interrupt enable bit in the BEMPENB register is modified from 0 to 1 by software.

### 31.2.12 SOF Output Configuration Register (SOFCFG)

Address(es): USB0.SOFCFG 000A 003Ch

|                    |     |     |     |     |     |     |    |          |    |        |    |         |    |    |    |    |

| b7        | —        | Reserved                                    | This bit is read as 0. The write value should be 0.                                                                                                      | R/W |
| b8        | TRNENSEL | Transaction-Enabled Time Select*1           | 0: For non-low-speed communication<br>1: For low-speed communication                                                                                     | R/W |
| b15 to b9 | —        | Reserved                                    | These bits are read as 0. The write value should be 0.                                                                                                   | R/W |

Note 1. Confirm that this bit is 0 before stopping the clock supply to the USB module.

#### EDGESTS Flag (Edge Interrupt Output Status Monitor Flag)

The EDGESTS flag indicates 1 when the edge interrupt output signal is in the middle of the edge processing.

Confirm that this flag is 0 before stopping the clock supply to the USB.

#### BRDYM Bit (BRDY Interrupt Status Clear Timing)

The BRDYM bit specifies the timing for clearing the BRDY interrupt status for each pipe.

#### TRNENSEL Bit (Transaction-Enabled Time Select)

The TRNENSEL bit selects, for full-speed or low-speed communication, the transaction-enabled time in which the USB issues tokens in a frame via the port.

Set the TRNENSEL bit to 1 when a low-speed device is connected.

The TRNENSEL bit is valid only when the host controller is selected.

This bit should be set to 0 if the function controller is selected.

## 31.2.13 Interrupt Status Register 0 (INTSTS0)

Address(es): USB0.INTSTS0 000A 0040h

|                                                                  |      |      |      |       |      |      |      |       |           |    |       |           |    |    |    |

x: Don't care

Note 1. The value is 0 when the MCU is reset and 1 after a USB bus reset.

Note 2. The value is 1 when the USB0\_VBUS pin is high and 0 when the USB0\_VBUS pin is low.

Note 3. The value is 000b when the MCU is reset and 001b after a USB bus reset.

Note 4. To clear the VBINT, RESM, SOFR, DVST, CTRTR, or VALID flag, write 0 only to the flags to be cleared; write 1 to the other flags. Do not write 0 to the status flags indicating 0.

Note 5. The status of the RESM, DVST, and CTRTR flags are changed only when the function controller is selected. Set the corresponding interrupt enable bits to 0 (disabled) when the host controller is selected.

Note 6. A change in the status indicated by the VBINT and RESM flags can be detected even while the clock supply is stopped (the SCKE bit = 0), and the interrupts are output when the corresponding interrupt enable bits are enabled. Clearing the status through software should be done after enabling the clock supply.

**CTSQ[2:0] Flags (Control Transfer Stage Flag)**

When the host controller is selected, the read value is invalid.

**VALID Flag (USB Request Reception Flag)**

When the host controller is selected, the read value is invalid.

**DVSQ[2:0] Flags (Device State Flag)**

The DVSQ[2:0] flags are initialized by a USB bus reset.

When the host controller is selected, the read value is invalid.

**BRDY Flag (Buffer Ready Interrupt Status Flag)**

Indicates the BRDY interrupt status.

The USB sets the BRDY flag to 1 when at least one PIPE<sub>n</sub>BRDY flag (n = 0 to 9) is set to 1 among the PIPE<sub>n</sub>BRDY flags. These bits correspond to the BRDYENB.PIPE<sub>n</sub>BRDYE bits (n = 0 to 9) to which 1 has been set, when the USB detects the BRDY interrupt status in at least one pipe among the pipes for which the BRDY interrupt output is enabled by software.

For the conditions for PIPE<sub>n</sub>BRDY status assertion, refer to section 31.3.3.1, BRDY Interrupt.

The USB sets the BRDY flag to 0 when 0 is written by software to all the PIPE<sub>n</sub>BRDY flags corresponding to the PIPE<sub>n</sub>BRDYE bits that have been set to 1.

The BRDY flag cannot be set to 0 even if 0 is written to this bit by software.

**NRDY Flag (Buffer Not Ready Interrupt Status Flag)**

The USB sets the NRDY flag to 1 when at least one PIPE<sub>n</sub>NRDY flag (n = 0 to 9) is set to 1 among the PIPE<sub>n</sub>NRDY flags corresponding to the PIPE<sub>n</sub>NRDYE bits (n = 0 to 9) to which 1 has been set (when the USB detects the NRDY interrupt status in at least one pipe among the pipes for which software enables the NRDY interrupt output).

For the conditions for PIPE<sub>n</sub>NRDY status assertion, refer to section 31.3.3.2, NRDY Interrupt.

The USB sets the NRDY flag to 0 when 0 is written by software to all the PIPE<sub>n</sub>NRDY flags corresponding to the PIPE<sub>n</sub>NRDYE bits that have been set to 1.

The NRDY flag cannot be set to 0 even if 0 is written to this bit by software.

**BEMP Flag (Buffer Empty Interrupt Status Flag)**

The USB sets the BEMP flag to 1 when at least one PIPE<sub>n</sub>BEMP flag (n = 0 to 9) is set to 1 among the PIPE<sub>n</sub>BEMP flags corresponding to the PIPE<sub>n</sub>BEMPE bits (n = 0 to 9) to which 1 has been set (when the USB detects the BEMP interrupt status in at least one pipe among the pipes for which the BEMP interrupt output is enabled by software).

For the conditions for PIPE<sub>n</sub>BEMP status assertion, refer to section 31.3.3.3, BEMP Interrupt.

The USB sets the BEMP flag to 0 when 0 is written by software to all the PIPE<sub>n</sub>BEMP flags corresponding to the PIPE<sub>n</sub>BEMPE bits that have been set to 1.

The BEMP flag cannot be set to 0 even if 0 is written to this bit by software.

**CTRT Flag (Control Transfer Stage Transition Interrupt Status Flag)**

When the function controller is selected, the USB updates the value of the CTSQ[2:0] flags and sets the CTRT flag to 1 on detecting a change in the control transfer stage.

When a control transfer stage transition interrupt is generated, clear the status before the USB detects the next control transfer stage transition.

When the host controller is selected, the read value is invalid.

**DVST Flag (Device State Transition Interrupt Status Flag)**

When the function controller is selected, the USB updates the DVSQ[2:0] value and sets the DVST flag to 1 on detecting a change in the device state.

When a device state transition interrupt is generated, clear the status before the USB detects the next device state transition.

When the host controller is selected, the read value is invalid.

**SOFR Flag (Frame Number Refresh Interrupt Status Flag)**

(1) When the host controller is selected

The USB sets the SOFR flag to 1 on updating the frame number when the DVSTCTR0.UACT bit has been set to 1 by software. (A frame number refresh interrupt is detected every 1 ms.)

(2) When the function controller is selected

The USB sets the SOFR flag to 1 on updating the frame number. (A frame number refresh interrupt is detected every 1 ms.)

The USB can detect an SOFR interrupt through the internal interpolation function even when a damaged SOF packet is received from the USB host.

**RESM Flag (Resume Interrupt Status Flag)**

When the function controller is selected, the USB sets the RESM flag to 1 on detecting the falling edge of the signal on the USB0\_DP pin in the suspended state (DVSQ[2:0] = 1xxb).

When the host controller is selected, the read value is invalid.

**VBINT Flag (VBUS Interrupt Status Flag)**

The USB sets the VBINT flag to 1 on detecting a level change (high to low or low to high) in the USB0\_VBUS pin input value. The USB sets the VBSTS flag to indicate the USB0\_VBUS pin input value. When the VBUS interrupt is generated, use software to repeat reading the VBSTS flag until the same value is read three or more times, and eliminate chattering.

| b15       | OVRCCR | Overcurrent Input Change Interrupt Status Flag *2       | 0: OVRCCR interrupts are not generated.<br>1: OVRCCR interrupts are generated. | R/W<br>*1 |

Note 1. To clear the status indicated by the flags in the INTSTS1 register, write 0 only to the flags to be cleared; write 1 to the other flags.

Note 2. A change in the status indicated by the OVRCCR or BCHG flag can be detected even while the clock supply is stopped (while the SYSCFG.SCKE bit = 0), and the interrupt is output when the corresponding interrupt enable bit is enabled. Clearing the status through software should be done after setting the SYSCFG.SCKE bit to 1.

No interrupts other than those indicated by the BCHG and OVRCCR flags can be detected while the clock supply is stopped (while the SYSCFG.SCKE bit = 0).

The INTSTS1 register is used to confirm the status of each interrupt when the host controller is selected.

The various status change interrupts indicated by the flags in the INTSTS1 register should be enabled only when the host controller is selected.

#### SACK Flag (Setup Transaction Normal Response Interrupt Status Flag)

Indicates the status of the setup transaction normal response interrupt when the host controller is selected.

The USB detects the SACK interrupt when ACK response is returned from the peripheral device during the setup transactions issued by the USB, and sets the SACK flag to 1. Here, if the corresponding interrupt enable bit has been set to 1 by software, the USB generates the SACK interrupt.

When the function controller is selected, the read value is invalid.

**SIGN Flag (Setup Transaction Error Interrupt Status Flag)**

Indicates the status of the setup transaction error interrupt when the host controller is selected.

The USB detects the SIGN interrupt when ACK response is not returned from the peripheral device three consecutive times during the setup transactions issued by this module, and sets the SIGN flag to 1. Here, if the corresponding interrupt enable bit has been set to 1 by software, the USB generates the SIGN interrupt.

Specifically, the USB detects the SIGN interrupt when any of the following response conditions occur for three consecutive setup transactions.

- Timeout is detected by the USB when the peripheral device has returned no response.
- A damaged ACK packet is received.
- A handshake other than ACK (NAK, NYET, or STALL) is received.

When the function controller is selected, the read value is invalid.

**EOFERR Flag (EOF Error Detection Interrupt Status Flag)**

Indicates the status of the EOFERR interrupt when the host controller is selected.

The USB detects the EOFERR interrupt on detecting that communication is not completed at the EOF2 timing prescribed by USB Specification 2.0, and sets the EOFERR flag to 1. Here, if the corresponding interrupt enable bit has been set to 1 by software, the USB generates the EOFERR interrupt.

After detecting the EOFERR interrupt, the USB controls hardware as described below (irrespective of the setting of the corresponding interrupt enable bit). All pipes in which communications are currently carried out for the USB port should be terminated by software and perform re-enumeration of the USB port.

- Modifies the DVSTCTR0.UACT bit for the port in which an EOFERR interrupt has been detected to 0.
- Puts the port in which an EOFERR interrupt has been generated into the idle state.

When the function controller is selected, the read value is invalid.

**ATTCH Flag (ATTCH Interrupt Status Flag)**

Indicates the status of the ATTCH interrupt when the host controller is selected.

The USB detects the ATTCH interrupt on detecting J-state or K-state of the full-speed or low-speed signal level for 2.5  $\mu$ s, and sets the ATTCH flag to 1. Here, if the corresponding interrupt enable bit has been set to 1 by software, the USB generates the interrupt.

Specifically, the USB detects the ATTCH interrupt on any of the following conditions.

- K-state, SE0, or SE1 changes to J-state, and J-state continues for 2.5  $\mu$ s.
- J-state, SE0, or SE1 changes to K-state, and K-state continues for 2.5  $\mu$ s.

When the function controller is selected, the read value is invalid.

**DTCH Flag (USB Disconnection Detection Interrupt Status Flag)**

Indicates the status of the USB disconnection detection interrupt when the host controller is selected.

The USB detects the DTCH interrupt on detecting USB bus disconnection, and sets the DTCH flag to 1. Here, if the corresponding interrupt enable bit has been set to 1 by software, the USB generates the interrupt.

The USB detects bus disconnection based on USB Specification 2.0.

After detecting the DTCH interrupt, the USB controls hardware as described below (irrespective of the setting of the corresponding interrupt enable bit). All the pipes in which communications are currently carried out for the USB port should be terminated by software and make a transition to the wait state for bus connection to the USB port (wait state for ATTCH interrupt generation).

- Modifies the DVSTCTR0.UACT bit for the port in which a DTCH interrupt has been detected to 0.
- Puts the port in which a DTCH interrupt has been generated into the idle state.

When the function controller is selected, the read value is invalid.

**BCHG Flag (USB Bus Change Interrupt Status Flag)**

Indicates the status of the USB bus change interrupt.

The USB detects the BCHG interrupt when a change in the full-speed or low-speed signal level occurs on the USB port (a change from J-state, K-state, or SE0 to J-state, K-state, or SE0), and sets the BCHG flag to 1. Here, if the corresponding interrupt enable bit has been set to 1 by software, the USB generates the interrupt.

The USB sets the LNST[1:0] flags to indicate the current input state of the USB port. When the BCHG interrupt is generated, use software to repeat reading the LNST[1:0] flags until the same value is read three or more times, and eliminate chattering.

A change in the USB bus state can be detected even while the internal clock supply is stopped.

When the function controller is selected, the read value is invalid.

**OVRCCR Flag (Overcurrent Input Change Interrupt Status Flag)**

Indicates the status of the USB0\_OVRCURA and USB0\_OVRCURB input pin change interrupt.

The USB detects the OVRCCR interrupt when a change (high to low or low to high) occurs in at least one of the input values to the USB0\_OVRCURA and USB0\_OVRCURB pins, and sets the OVRCCR flag to 1. Here, if the corresponding interrupt enable bit has been set to 1 by software, the USB generates the interrupt.

### 31.2.15 BRDY Interrupt Status Register (BRDYSTS)

Address(es): USB0.BRDYSTS 000A 0046h

|                    | b15 | b14 | b13 | b12 | b11 | b10 | b9            | b8            | b7            | b6            | b5            | b4            | b3            | b2            | b1            | b0            |
|--------------------|-----|-----|-----|-----|-----|-----|---------------|---------------|---------------|---------------|---------------|---------------|---------------|---------------|---------------|---------------|

| b3         | PIPE3NRDY | NRDY Interrupt Status Flag for Pipe 3 | 0: Interrupts are not generated.<br>1: Interrupts are generated. | R/W<br>*1 |
| b4         | PIPE4NRDY | NRDY Interrupt Status Flag for Pipe 4 | 0: Interrupts are not generated.<br>1: Interrupts are generated. | R/W<br>*1 |
| b5         | PIPE5NRDY | NRDY Interrupt Status Flag for Pipe 5 | 0: Interrupts are not generated.<br>1: Interrupts are generated. | R/W<br>*1 |
| b6         | PIPE6NRDY | NRDY Interrupt Status Flag for Pipe 6 | 0: Interrupts are not generated.<br>1: Interrupts are generated. | R/W<br>*1 |
| b7         | PIPE7NRDY | NRDY Interrupt Status Flag for Pipe 7 | 0: Interrupts are not generated.<br>1: Interrupts are generated. | R/W<br>*1 |
| b8         | PIPE8NRDY | NRDY Interrupt Status Flag for Pipe 8 | 0: Interrupts are not generated.<br>1: Interrupts are generated. | R/W<br>*1 |
| b9         | PIPE9NRDY | NRDY Interrupt Status Flag for Pipe 9 | 0: Interrupts are not generated.<br>1: Interrupts are generated. | R/W<br>*1 |
| b15 to b10 | —         | Reserved                              | These bits are read as 0. The write value should be 0.           | R/W       |

Note 1. To clear the status indicated by the flags in the NRDYSTS register, write 0 only to the flags to be cleared; write 1 to the other flags.

### 31.2.17 BEMP Interrupt Status Register (BEMPSTS)

Address(es): USB0.BEMPSTS 000A 004Ah

|                    | b15 | b14 | b13 | b12 | b11 | b10 | b9            | b8            | b7            | b6            | b5            | b4            | b3            | b2            | b1            | b0            |
|--------------------|-----|-----|-----|-----|-----|-----|---------------|---------------|---------------|---------------|---------------|---------------|---------------|---------------|---------------|---------------|
|                    | —   | —   | —   | —   | —   | —   | PIPE9B<br>EMP | PIPE8B<br>EMP | PIPE7B<br>EMP | PIPE6B<br>EMP | PIPE5B<br>EMP | PIPE4B<br>EMP | PIPE3B<br>EMP | PIPE2B<br>EMP | PIPE1B<br>EMP | PIPE0B<br>EMP |
| Value after reset: | 0   | 0   | 0   | 0   | 0   | 0   | 0             | 0             | 0             | 0             | 0             | 0             | 0             | 0             | 0             | 0             |

| Bit        | Symbol    | Bit Name                              | Description                                                      | R/W       |
|------------|-----------|---------------------------------------|------------------------------------------------------------------|-----------|
| b0         | PIPE0BEMP | BEMP Interrupt Status Flag for Pipe 0 | 0: Interrupts are not generated.<br>1: Interrupts are generated. | R/W<br>*1 |
| b1         | PIPE1BEMP | BEMP Interrupt Status Flag for Pipe 1 | 0: Interrupts are not generated.<br>1: Interrupts are generated. | R/W<br>*1 |
| b2         | PIPE2BEMP | BEMP Interrupt Status Flag for Pipe 2 | 0: Interrupts are not generated.<br>1: Interrupts are generated. | R/W<br>*1 |
| b3         | PIPE3BEMP | BEMP Interrupt Status Flag for Pipe 3 | 0: Interrupts are not generated.<br>1: Interrupts are generated. | R/W<br>*1 |
| b4         | PIPE4BEMP | BEMP Interrupt Status Flag for Pipe 4 | 0: Interrupts are not generated.<br>1: Interrupts are generated. | R/W<br>*1 |
| b5         | PIPE5BEMP | BEMP Interrupt Status Flag for Pipe 5 | 0: Interrupts are not generated.<br>1: Interrupts are generated. | R/W<br>*1 |
| b6         | PIPE6BEMP | BEMP Interrupt Status Flag for Pipe 6 | 0: Interrupts are not generated.<br>1: Interrupts are generated. | R/W<br>*1 |
| b7         | PIPE7BEMP | BEMP Interrupt Status Flag for Pipe 7 | 0: Interrupts are not generated.<br>1: Interrupts are generated. | R/W<br>*1 |
| b8         | PIPE8BEMP | BEMP Interrupt Status Flag for Pipe 8 | 0: Interrupts are not generated.<br>1: Interrupts are generated. | R/W<br>*1 |
| b9         | PIPE9BEMP | BEMP Interrupt Status Flag for Pipe 9 | 0: Interrupts are not generated.<br>1: Interrupts are generated. | R/W<br>*1 |
| b15 to b10 | —         | Reserved                              | These bits are read as 0. The write value should be 0.           | R/W       |

Note 1. To clear the status indicated by the flags in the BEMPSTS register, write 0 only to the flags to be cleared; write 1 to the other flags.

### 31.2.18 Frame Number Register (FRMNUM)

Address(es): USB0.FRNUM 000A 004Ch

| Bit        | Symbol     | Bit Name                               | Description                                            | R/W               |
|------------|------------|----------------------------------------|--------------------------------------------------------|-------------------|
| b10 to b0  | FRNM[10:0] | Frame Number Flag                      | Latest frame number                                    | R                 |
| b13 to b11 | —          | Reserved                               | These bits are read as 0. The write value should be 0. | R/W               |
| b14        | CRCE       | Receive Data Error Flag                | 0: No error<br>1: An error occurred                    | R/W <sup>*1</sup> |
| b15        | OVRN       | Overrun/Underrun Detection Status Flag | 0: No error<br>1: An error occurred                    | R/W <sup>*1</sup> |

Note 1. To clear the status, write 0 only to the bits to be cleared; write 1 to the other bits.

#### FRNM[10:0] Flags (Frame Number Flag)

These bits indicate the latest frame number for the USB after the issuing of an SOF packet every 1 ms or writing to the FRNM[10:0] flags at the SOF packet reception.

#### CRCE Flag (Receive Data Error Flag)

Indicates whether a CRC error or bit stuffing error has been detected in the pipe during isochronous transfer.

The CRCE flag can be set to 0 by writing 0 to the CRCE flag by software. Here, 1 should be written to the other bits in FRMNUM.

On detecting a CRC error, the USB generates the internal NRDY interrupt request.

#### OVRN Flag (Overrun/Underrun Detection Status Flag)

Indicates whether an overrun/underrun error has been detected in the pipe during isochronous transfer.

The OVRN flag can be set to 0 by writing 0 to the OVRN flag by software. Here, 1 should be written to the other bits in FRMNUM.

(1) When the host controller is selected

The USB sets the OVRN flag to 1 on any of the following conditions.

- For the isochronous transfer pipe in the transmitting direction, the time to issue an OUT token comes before all the transmit data has been written to the FIFO buffer.
- For the isochronous transfer pipe in the receiving direction, the time to issue an IN token comes when no FIFO buffer planes are empty.

(2) When the function controller is selected

The USB sets the OVRN flag to 1 on any of the following conditions.

- For the isochronous transfer pipe in the transmitting direction, the IN token is received before all the transmit data has been written to the FIFO buffer.
- For the isochronous transfer pipe in the receiving direction, the OUT token is received when no FIFO buffer planes are empty.

### 31.2.19 USB Request Type Register (USBREQ)

Address(es): USB0.USBREQ 000A 0054h

| Bit       | Symbol             | Bit Name     | Description                                           | R/W       |
|-----------|--------------------|--------------|-------------------------------------------------------|-----------|
| b7 to b0  | BMREQUESTTYPE[7:0] | Request Type | These bits store the USB request bmRequestType value. | R/W<br>*1 |
| b15 to b8 | BREQUEST[7:0]      | Request      | These bits store the USB request bRequest value.      | R/W<br>*1 |

Note 1. When the function controller is selected, these bits can only be read from, and writing to these bits is invalid. When the host controller is selected, these bits can be read from and written to.

The USBREQ register stores setup requests for control transfers.

When the function controller is selected, the values of bRequest and bmRequestType that have been received are stored.

When the host controller is selected, the values of bRequest and bmRequestType to be transmitted are set.

The USBREQ register is initialized by a USB bus reset.

#### BMREQUESTTYPE[7:0] Bits (Request Type)

These bits hold the value of the bmRequestType field of a USB request.

- When the host controller is selected:  
Set these bits to the value of the USB request data in setup transactions for transmission. Do not modify the value of the BMREQUESTTYPE[7:0] bits while the DCPCTR.SUREQ bit is 1.
- When the function controller is selected:  
These bits indicate the value of the USB request data in setup transactions for reception. Writing to the bits has no effect.

#### BREQUEST[7:0] Bits (Request)

These bits store bRequest value of the USB request.

- When the host controller is selected:  
Set these bits to the value of the USB request data in setup transactions for transmission. Do not modify the value of the BREQUEST[7:0] bits while the DCPCTR.SUREQ bit is 1.
- When the function controller is selected:  
These bits indicate the value of the USB request data in setup transactions for reception. Writing to the bits has no effect.

### 31.2.20 USB Request Value Register (USBVAL)

Address(es): USB0.USBVAL 000A 0056h

When the function controller is selected, the value of wValue that has been received is stored in the USBVAL register.

When the host controller is selected, the value of wValue to be transmitted is set.

The USBVAL register is initialized by a USB bus reset.

- When the host controller is selected:  
Set these bits to the value of the wValue field in USB requests of setup transactions for transmission. Do not modify the value of the USBVAL register while the DCPCTR.SUREQ bit is 1.
- When the function controller is selected:  
These bits indicate the value of the wValue field in USB requests received in setup transactions for reception. Writing to the USBVAL register has no effect.

### 31.2.21 USB Request Index Register (USBINDX)

Address(es): USB0.USBINDX 000A 0058h

The USBINDX register stores setup requests for control transfers.

When the function controller is selected, the value of wIndex that has been received is stored. When the host controller is selected, the value of wIndex to be transmitted is set.

The USBINDX register is initialized by a USB bus reset.

- When the host controller is selected:  
Set these bits to the value of the wIndex field in USB requests of setup transactions for transmission. Do not modify the value of the USBINDX register while the DCPCTR.SUREQ bit is 1.
- When the function controller is selected:  
These bits indicate the value of the wIndex field in USB requests received in setup transactions for reception. Writing to the USBINDX register has no effect.

### 31.2.22 USB Request Length Register (USBLENG)

Address(es): USB0.USBLENG 000A 005Ah

The USBLENG register stores setup requests for control transfers.

When the function controller is selected, the value of wLength that has been received is stored. When the host controller is selected, the value of wLength to be transmitted is set.

The USBLENG register is initialized by a USB bus reset.

- When the host controller is selected:  
Set these bits to the value of the wLength field in USB requests of setup transactions for transmission. Do not modify the value of the USBLENG register while the DCPCTR.SUREQ bit is 1.
- When the function controller is selected:  
These bits indicate the value of the wLength field in USB requests received in setup transactions for reception. Writing to the USBLENG register has no effect.

### 31.2.23 DCP Configuration Register (DCPCFG)

Address(es): USB0.DCPCFG 000A 005Ch

| Bit       | Symbol | Bit Name                           | Description                                                                         | R/W |
|-----------|--------|------------------------------------|-------------------------------------------------------------------------------------|-----|
| b3 to b0  | —      | Reserved                           | These bits are read as 0. The write value should be 0.                              | R/W |
| b4        | DIR    | Transfer Direction*1               | 0: Data receiving direction<br>1: Data transmitting direction                       | R/W |
| b6, b5    | —      | Reserved                           | These bits are read as 0. The write value should be 0.                              | R/W |
| b7        | SHTNAK | Pipe Disabled at End of Transfer*1 | 0: Pipe continued at the end of transfer<br>1: Pipe disabled at the end of transfer | R/W |
| b15 to b8 | —      | Reserved                           | These bits are read as 0. The write value should be 0.                              | R/W |

Note 1. Modify this bit while DCPCTR.PID[1:0] bits are 00b (NAK). Before modifying this bit after modifying the DCPCTR.PID[1:0] bits for the DCP from 01b (BUF) to 00b (NAK), check that the DCPCTR.PBUSY flag is 0. However, if the USB changes the PID[1:0] bits to 00b (NAK), the PBUSY flag does not need to be checked by software.

#### DIR Bit (Transfer Direction)

When the host controller is selected, the DIR bit sets the transfer direction of the data stage and status stage.  
When the function controller is selected, the DIR bit should be set to 0.

#### SHTNAK Bit (Pipe Disabled at End of Transfer)

The SHTNAK bit specifies whether to modify PID[1:0] bits to 00b (NAK) upon the end of transfer when the selected pipe is in the receiving direction.

The SHTNAK bit is valid when the selected pipe in the receiving direction.

When the SHTNAK bit is set to 1, the USB modifies the DCPCTR.PID[1:0] bits for the DCP to 00b (NAK) on determining the end of the transfer. The USB determines that the transfer has ended on the following condition.

- A short packet (including a zero-length packet) is successfully received.

### 31.2.24 DCP Maximum Packet Size Register (DCPMAXP)

Address(es): USB0.DCPMAXP 000A 005Eh

| Bit        | Symbol      | Bit Name              | Description                                                                                                                                                                                                | R/W |
|------------|-------------|-----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----|
| b6 to b0   | MXPS[6:0]   | Maximum Packet Size*1 | These bits set the maximum amount of data (maximum packet size) in payloads for the DCP.                                                                                                                   | R/W |
| b11 to b7  | —           | Reserved              | These bits are read as 0. The write value should be 0.                                                                                                                                                     | R/W |
| b15 to b12 | DEVSEL[3:0] | Device Select*2       | b15 b12<br>0 0 0 0: Address 0000<br>0 0 0 1: Address 0001<br>0 0 1 0: Address 0010<br>0 0 1 1: Address 0011<br>0 1 0 0: Address 0100<br>0 1 0 1: Address 0101<br>Settings other than above are prohibited. | R/W |

Note 1. Modify the MXPS[6:0] bits while PID[1:0] bits are 00b (NAK). Before modifying these bits after modifying the DCPCTR.PID[1:0] bits for the DCP from 01b (BUF) to 00b (NAK), check that the DCPCTR.PBUSY flag is 0. However, if the USB changes the PID[1:0] bits to 00b (NAK), the PBUSY flag does not need to be checked by software. After modifying the MXPS[6:0] bits and the DCP has been set to the CURPIPE[3:0] bits in a port select register, clear the buffer by setting the BCLR bit the port control register to 1.

Note 2. Modify the DEVSEL[3:0] bits while PID[1:0] bits are 00b (NAK) and the DCPCTR.SUREQ bit is 0. To modify these bits after modifying the DCPCTR.PID[1:0] bits for the DCP from 01b (BUF) to 00b (NAK), check that the DCPCTR.PBUSY flag is 0. However, if the USB changes the PID[1:0] bits to 00b (NAK), the PBUSY flag does not need to be checked by software.

#### MXPS[6:0] Bits (Maximum Packet Size)

The MXPS[6:0] bits specify the maximum amount of data (maximum packet size) in payloads for the DCP. The initial value of the bits is 40h (64 bytes).

Ensure that the setting of the MXPS[6:0] bits is in compliance with USB Specification 2.0.

Do not write to the FIFO buffer or set PID[1:0] = 01b (BUF) while the setting of the MXPS[6:0] bits is 0.

#### DEVSEL[3:0] Bits (Device Select)

When the host controller is selected, these bits specify the address of the peripheral device which is the communication target during control transfer.

The DEVSEL[3:0] bits should be set after setting the address to the DEVADDn (n = 0 to 5) register corresponding to the value to be set in the DEVSEL[3:0] bits. For example, before setting the DEVSEL[3:0] bits to 0010b, the address should be set to DEVADD2.

When the function controller is selected, the DEVSEL[3:0] bits should be set to 0000b.

### 31.2.25 DCP Control Register (DCPCTR)

Address(es): USB0.DCPCTR 000A 0060h

|                    |      |       |     |     |           |     |    |       |       |       |       |    |    |      |          |    |

| b7       | SQSET    | Sequence Toggle Bit Set*2        | 0: Invalid<br>1: Specifies DATA1.                                                                                             | R/W*1 |
| b8       | SQCLR    | Sequence Toggle Bit Clear*2      | 0: Invalid<br>1: Specifies DATA0.                                                                                             | R/W*1 |
| b10, b9  | —        | Reserved                         | These bits are read as 0. The write value should be 0.                                                                        | R/W   |
| b11      | SUREQCLR | SUREQ Bit Clear                  | 0: Invalid<br>1: Clears the SUREQ bit to 0.                                                                                   | R/W   |
| b13, b12 | —        | Reserved                         | These bits are read as 0. The write value should be 0.                                                                        | R/W   |
| b14      | SUREQ    | Setup Token Transmission         | 0: Invalid<br>1: Transmits the setup packet.                                                                                  | R/W   |
| b15      | BSTS     | Buffer Status Flag               | 0: Buffer access is disabled.<br>1: Buffer access is enabled.                                                                 | R     |

Note 1. Only 0 can be read.

Note 2. Write 1 to the SQSET and SQCLR bits while PID[1:0] bits are 00b (NAK). Before modifying these bits after modifying the PID[1:0] bits for the DCP from 01b (BUF) to 00b (NAK), check that the PBUSY flag is 0. However, if the USB changes the PID[1:0] bits to 00b (NAK), the PBUSY flag does not need to be checked by software.

#### PID[1:0] Bits (Response PID)

The PID[1:0] bits control the response type of the USB during control transfer.

(1) When the host controller is selected

Modify the setting of the PID[1:0] bits from 00b (NAK) to 01b (BUF) using the following procedure.

- When the transmitting direction is set  
Write all the transmit data to the FIFO buffer while the DVSTCTR0.UACT bit is 1 and PID[1:0] bits are 00b (NAK), and then write 01b (BUF response). After PID[1:0] have been set to 01b (BUF), the USB executes the OUT transaction.
- When the receiving direction is set  
Check that the FIFO buffer is empty (or empty the buffer) while the DVSTCTR0.UACT bit is 1 and PID[1:0] bits are 00b (NAK), and then set PID[1:0] bits to 01b (BUF). After PID[1:0] bits have been set to 01b (BUF), the USB executes the IN transaction.

The USB modifies the setting of the PID[1:0] bits as follows.

- The USB sets PID[1:0] bits to 11b (STALL) on receiving the data of a size exceeding the maximum packet size when the PID[1:0] bits has been set to 01b (BUF) by software.
- The USB sets PID[1:0] bits to 00b (NAK) on detecting a receive error, such as a CRC error, three consecutive times.
- The USB also sets PID[1:0] bits to 11b (STALL) on receiving the STALL handshake.

(2) When the function controller is selected

The USB modifies the setting of the PID[1:0] bits as follows.

- The USB modifies the PID[1:0] bits to 00b (NAK) on receiving the setup packet. Here, the USB sets the INTSTS0.VALID flag to 1. The setting of the PID[1:0] bits cannot be modified until the VALID flag is set to 0 by software.
- The USB sets PID[1:0] bits to 11b (STALL) on receiving the data of a size exceeding the maximum packet size when the PID[1:0] bits have been set to 01b (BUF) by software.
- The USB sets PID[1:0] bits to 1xb (STALL) on detecting the control transfer sequence error.
- The USB sets PID[1:0] bits to 00b (NAK) on detecting the USB bus reset.

The USB does not check the setting of the PID[1:0] bits while the SET\_ADDRESS request is processed.

The PID[1:0] bits are initialized by a USB bus reset.

#### **CCPL Bit (Control Transfer End Enable)**

When the function controller is selected, setting the CCPL bit to 1 enables the status stage of the control transfer to be completed.

When the CCPL bit is set to 1 by software while the corresponding PID[1:0] bits are set to 01b (BUF), the USB completes the control transfer status stage.

During control read transfer, the USB transmits the ACK handshake in response to the OUT transaction from the USB host, and transmits the zero-length packet in response to the IN transaction from the USB host during control write or no-data control transfer. However, on detecting the SET\_ADDRESS request, the USB operates in auto response mode from the setup stage up to the status stage completion irrespective of the setting of the CCPL bit.

The USB modifies the CCPL bit from 1 to 0 on receiving a new setup packet.

1 cannot be written to the CCPL bit by software while the INTSTS0.VALID flag is 1.

The CCPL bit is initialized by a USB bus reset.

When the host controller is selected, be sure to write 0 to the CCPL bit.

#### **PBUSY Flag (Pipe Busy Flag)**

The PBUSY flag indicates whether DCP is used or not for the transaction when USB changes the PID[1:0] bits from 01b (BUF) to 00b (NAK).

The USB modifies the PBUSY flag from 0 to 1 upon start of the USB transaction for the relevant pipe, and modifies the PBUSY flag from 1 to 0 upon completion of one transaction.

Reading the PBUSY flag after the PID[1:0] bits have been set to 00b (NAK) by software allows checking whether modification of the pipe settings is possible.

For details, refer to section 31.3.4.1, Pipe Control Register Switching Procedures.

**SQMON Flag (Sequence Toggle Bit Monitor Flag)**

The SQMON flag indicates the expected value of the sequence toggle bit for the next transaction during the DCP transfer.

The USB allows the SQMON flag to toggle upon normal completion of the transaction. However, the SQMON flag is not allowed to toggle when a data PID mismatch occurs during the transfer in the receiving direction.

When the function controller is selected, the USB sets the SQMON flag to 1 (specifies DATA1 as the expected value) upon successful reception of the setup packet.

When the function controller is selected, the USB does not reference the SQMON flag during the IN/OUT transaction of the status stage, and does not allow the SQMON flag to toggle upon normal completion.

**SQSET Bit (Sequence Toggle Bit Set)**

The SQSET bit specifies DATA1 as the expected value of the sequence toggle bit for the next transaction during the DCP transfer.

Do not set the SQCLR and SQSET bits to 1 simultaneously.

**SQCLR Bit (Sequence Toggle Bit Clear)**

The SQCLR bit specifies DATA0 as the expected value of the sequence toggle bit for the next transaction during the DCP transfer. The SQCLR bit indicates 0.

Do not set the SQCLR and SQSET bits to 1 simultaneously.

**SUREQCLR Bit (SUREQ Bit Clear)**

When the host controller is selected, setting the SUREQCLR bit to 1 clears the SUREQ bit to 0. The SUREQCLR bit indicates 0.

Set the SUREQCLR bit to 1 through software when communication has stopped with the SUREQ bit being 1 during the setup transaction. However, for normal setup transactions, the USB automatically clears the SUREQ bit to 0 upon completion of the transaction; therefore, clearing the SUREQ bit through software is not necessary.

Controlling the SUREQ bit through the SUREQCLR bit must be done while the DVSTCTR0.UACT bit is 0 and thus communication is halted or while no transfer is being performed with bus disconnection detected.

When the function controller is selected, be sure to write 0 to the SUREQCLR bit.

**SUREQ Bit (Setup Token Transmission)**

The USB transmits the setup packet by setting the SUREQ bit to 1 when the host controller is selected.

After completing the setup transaction process, the USB generates either the SACK or SIGN interrupt and sets the SUREQ bit to 0.

The USB also sets the SUREQ bit to 0 when software sets the SUREQCLR bit to 1.

Before setting the SUREQ bit to 1, set the DCPMAXP.DEVSEL[3:0] bits, registers USBREQ, USBVAL, USBINDX, and USBLENG appropriately to transmit the desired USB request in the setup transaction. Before setting this bit to 1, check that the PID[1:0] bits for the DCP are set to 00b (NAK). After setting the SUREQ bit to 1, do not modify the DCPMAXP.DEVSEL[3:0] bits, registers USBREQ, USBVAL, USBINDX, or USBLENG until the setup transaction is completed (the SUREQ bit = 1).

Write 1 to the SUREQ bit only when transmitting the setup token; for other purposes, write 0.

When the function controller is selected, be sure to write 0 to the SUREQ bit.

**BSTS Flag (Buffer Status Flag)**

Indicates whether DCP FIFO buffer access is enabled or disabled.

The meaning of the BSTS flag depends on the setting of ISEL bit in the port select register as shown below.

- When the ISEL bit = 0, the BSTS flag indicates whether the received data can be read from the buffer.
- When the ISEL bit = 1, the BSTS flag indicates whether the data to be transmitted can be written to the buffer.

### 31.2.26 Pipe Window Select Register (PIPESEL)

Address(es): USB0.PIPESEL 000A 0064h

| Bit       | Symbol       | Bit Name           | Description                                                                                                                                                                                                                                                   | R/W |
|-----------|--------------|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----|
| b3 to b0  | PIPESEL[3:0] | Pipe Window Select | b3    b0<br>0 0 0 0: No pipe selected<br>0 0 0 1: Pipe 1<br>0 0 1 0: Pipe 2<br>0 0 1 1: Pipe 3<br>0 1 0 0: Pipe 4<br>0 1 0 1: Pipe 5<br>0 1 1 0: Pipe 6<br>0 1 1 1: Pipe 7<br>1 0 0 0: Pipe 8<br>1 0 0 1: Pipe 9<br>Settings other than above are prohibited. | R/W |
| b15 to b4 | —            | Reserved           | These bits are read as 0. The write value should be 0.                                                                                                                                                                                                        | R/W |

Pipes 1 to 9 should be set using registers PIPESEL, PIPECFG, PIPEMAXP, PIPEPERI, PIPEnCTR, PIPEnTRE, and PIPEnTRN.

After selecting the pipe using the PIPESEL register, functions of the pipe should be set using registers PIPECFG, PIPEMAXP, and PIPEPERI. PIPEnCTR, PIPEnTRE, and PIPEnTRN can be set regardless of the pipe selection in the PIPESEL register.

#### PIPESEL[3:0] Bits (Pipe Window Select)

The PIPESEL[3:0] bits select the pipe number corresponding to registers PIPECFG, PIPEMAXP, and PIPEPERI which data are written to or read from.

Selecting a pipe number through the PIPESEL[3:0] bits allows writing to and reading from registers PIPECFG, PIPEMAXP, and PIPEPERI which correspond to the selected pipe number.

When PIPESEL[3:0] = 0000b, 0 is read from all of the bits in registers PIPECFG, PIPEMAXP, and PIPEPERI. Writing to these bits is invalid.

### 31.2.27 Pipe Configuration Register (PIPECFG)

| b15, b14   | TYPE[1:0]  | Transfer Type*1                              | <ul style="list-style-type: none"> <li>• Pipes 1 and 2<br/>b15 b14<br/>0 0: Pipe not used<br/>0 1: Bulk transfer<br/>1 0: Setting prohibited<br/>1 1: Isochronous transfer</li> <li>• Pipes 3 to 5<br/>b15 b14<br/>0 0: Pipe not used<br/>0 1: Bulk transfer<br/>1 0: Setting prohibited<br/>1 1: Setting prohibited</li> <li>• Pipes 6 to 9<br/>b15 b14<br/>0 0: Pipe not used<br/>0 1: Setting prohibited<br/>1 0: Interrupt transfer<br/>1 1: Setting prohibited</li> </ul> | R/W |

Note 1. Modify the TYPE[1:0], SHTNAK, and EPNUM[3:0] bits while the PIPEnCTR.PID[1:0] bits are 00b (NAK). Before modifying these bits after modifying the PIPEnCTR.PID[1:0] bits for the selected pipe from 01b (BUF) to 00b (NAK), check that the PIPEnCTR.PBUSY flag is 0. However, if the USB changes the PID[1:0] bits to 00b (NAK), the PBUSY flag does not need to be checked by software.

Note 2. Modify the BFRE, DBLB, and DIR bits while the PIPEnCTR.PID[1:0] bits are 00b (NAK) and before the pipe is selected by the CURPIPE[3:0] bits in the port select register. Before modifying these bits after modifying the PIPEnCTR.PID[1:0] bits for the selected pipe from 01b (BUF) to 00b (NAK), check that the PIPEnCTR.PBUSY flag is 0. However, if the USB changes the PID[1:0] bits to 00b (NAK), checking the PIPEnCTR.PBUSY flag through software is not necessary.

Note 3. To modify the BFRE, DBLB, and DIR bits after completing USB communication using the selected pipe, write 1 and then 0 to the PIPEnCTR.ACLRM bit continuously through software to clear the FIFO buffer assigned to the selected pipe while the PID[1:0] bits and CURPIPE[3:0] bits are in the state described in the above note 2.

The PIPECFG register specifies the transfer type, buffer memory access direction, and endpoint numbers for pipes 1 to 9. It also selects single or double buffer mode, and whether to continue or disable pipe operation at the end of transfer.

**EPNUM[3:0] Bits (Endpoint Number)**

The EPNUM[3:0] bits specify the endpoint number for the selected pipe.

Setting 0000b means an unused pipe.

Do not make the settings such that the combination of the settings of the DIR and EPNUM[3:0] bits should be the same for two or more pipes (EPNUM[3:0] bits = 0000b can be set for all of the pipes).

**DIR Bit (Transfer Direction)**

The DIR bit specifies the transfer direction for the selected pipe.

When the DIR bit has been set to 0 by software, the USB uses the selected pipe in the receiving direction, and when software has set the DIR bit to 1, the USB uses the selected pipe in the transmitting direction.

**SHTNAK Bit (Pipe Disabled at End of Transfer)**

The SHTNAK bit specifies whether to modify the PID[1:0] bits to 00b (NAK) upon the end of transfer when the selected pipe is in the receiving direction.

The SHTNAK bit is valid when the selected pipe is pipe 1 to 5 in the receiving direction.

When the SHTNAK bit has been set to 1 by software for the selected pipe in the receiving direction, the USB modifies the PIPEnCTR.PID[1:0] bits corresponding to the selected pipe to 00b (NAK) on determining the end of the transfer. The USB determines that the transfer has ended on any of the following conditions.

- A short packet (including a zero-length packet) is successfully received.
- The transaction counter is used and the number of packets specified by the counter are successfully received.

**DBLB Bit (Double Buffer Mode)**

The DBLB bit selects either single or double buffer mode for the FIFO buffer used by the selected pipe.

The DBLB bit is valid when the selected pipe is pipe 1 to 5.

**BFRE Bit (BRDY Interrupt Operation Specification)**

The BFRE bit specifies the BRDY interrupt generation timing from the USB to the CPU with respect to the selected pipe.

When the BFRE bit has been set to 1 by software and the selected pipe is in the receiving direction, the USB detects the transfer completion and generates the BRDY interrupt on having read the relevant packet.

When the BRDY interrupt is generated with the above conditions, 1 should be written to the BCLR bit in the port control register by software. The FIFO buffer assigned to the selected pipe is not enabled for reception until 1 is written to the BCLR bit.

When the BFRE bit has been set to 1 by software and the selected pipe is in the transmitting direction, the USB does not generate the BRDY interrupt.

For details, refer to section 31.3.3.1, BRDY Interrupt.

**TYPE[1:0] Bits (Transfer Type)**

The TYPE[1:0] bits select the transfer type for the pipe selected by the PIPESEL.PIPESEL[3:0] bits (selected pipe).

Before setting the PID[1:0] bits to 01b (BUF) for the selected pipe (before starting USB communication using the selected pipe), set the TYPE[1:0] bits to a value other than 00b.

### 31.2.28 Pipe Maximum Packet Size Register (PIPEMAXP)

| 0 1 0 1    | 0           | Address 0101          |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |     |    |  |         |   |              |         |   |              |         |   |              |         |   |              |         |   |              |         |   |              |     |

- Note 1. The value of these bits is 0000h when no pipe is selected with the PIPESEL.PIPESEL[3:0] bits and 0040h when a pipe is selected.
- Note 2. Modify the MXPS[8:0] bits while the PIPEnCTR.PID[1:0] bits are 00b (NAK) and before the pipe is selected by the CURPIPE[3:0] bits in the port select register. Before modifying these bits after modifying the PIPEnCTR.PID[1:0] bits for the selected pipe from 01b (BUF) to 00b (NAK), check that the PIPEnCTR.PBUSY flag is 0. However, if the USB changes the PID[1:0] bits to 00b (NAK), the PBUSY flag does not need to be checked by software.
- Note 3. Modify the DEVSEL[3:0] bits while the PIPEnCTR.PID[1:0] bits are 00b (NAK). To modify these bits after modifying the PIPEnCTR.PID[1:0] bits for the selected pipe from 01b (BUF) to 00b (NAK), check that the PIPEnCTR.PBUSY flag is 0. However, if the USB changes the PID[1:0] bits to 00b (NAK), the PBUSY flag does not need to be checked by software.

The PIPEMAXP register specifies the maximum packet size for pipes 1 to 9.

#### MXPS[8:0] Bits (Maximum Packet Size)

The MXPS[8:0] bits specify the maximum data payload (maximum packet size) for the selected pipe. These bits should be set to the appropriate value for each transfer type based on USB Specification 2.0. Note that the maximum value of pipes 1 and 2 is 256. While MXPS[8:0] = 000h, do not write to the FIFO buffer or do not set the PID[1:0] bits to 01b (BUF).

#### DEVSEL[3:0] Bits (Device Select)

When the host controller is selected, these bits specify the USB device address of the peripheral device which is the communication target. The DEVSEL[3:0] bits should be set after setting the address to the DEVADDn (n = 0 to 5) register corresponding to the value to be set in the DEVSEL[3:0] bits. For example, before setting the DEVSEL[3:0] bits to 0010b, the address should be set to DEVADD2. When the function controller is selected, the DEVSEL[3:0] bits should be set to 0000b.

### 31.2.29 Pipe Cycle Control Register (PIPEPERI)

Address(es): USB0.PIPEPERI 000A 006Eh

|------------|-----------|-----------------------------------------|-----------------------------------------------------------------------------------------------------------------------------|-----|
| b2 to b0   | IITV[2:0] | Interval Error Detection Interval<br>*1 | Specify the interval error detection timing for the selected pipe in terms of frames, which is expressed as nth power of 2. | R/W |
| b11 to b3  | —         | Reserved                                | These bits are read as 0. The write value should be 0.                                                                      | R/W |
| b12        | IFIS      | Isochronous IN Buffer Flush             | 0: The buffer is not flushed.<br>1: The buffer is flushed.                                                                  | R/W |
| b15 to b13 | —         | Reserved                                | These bits are read as 0. The write value should be 0.                                                                      | R/W |

Note 1. Modify the IITV[2:0] bits while the PIPEnCTR.PID[1:0] bits are 00b (NAK). To modify these bits after modifying the PIPEnCTR.PID[1:0] bits for the selected pipe from 01b (BUF) to 00b (NAK), check that the PIPEnCTR.PBUSY flag is 0. However, if the USB changes the PID[1:0] bits to 00b (NAK), the PBUSY flag does not need to be checked by software.

The PIPEPERI register selects whether the buffer is flushed or not when an interval error occurred during isochronous IN transfer, and sets the interval error detection interval for pipes 1 to 9.

#### IITV[2:0] Bits (Interval Error Detection Interval)

Before modifying the IITV[2:0] bits after USB communication has been completed with the IITV[2:0] bits set to a certain value, set the PID[1:0] bits to 00b (NAK) and then set the PIPEnCTR.ACLRM bit to 1 to initialize the interval timer.

The IITV[2:0] bits are invalid for pipes 3 to 5; set the IITV[2:0] bits to 000b for pipes 3 to 5.

#### IFIS Bit (Isochronous IN Buffer Flush)

Specifies whether to flush the buffer when the pipe selected by the PIPESEL.PIPESEL[3:0] bits (selected pipe) is used for isochronous IN transfers.

When the function controller is selected and the selected pipe is for isochronous IN transfers, the USB automatically clears the FIFO buffer when the USB fails to receive the IN token from the USB host within the interval set by the IITV[2:0] bits in terms of frames.

In double buffer mode (the PIPECFG.DBLB bit = 1), the USB only clears the data in the plane used earlier.

The USB clears the FIFO buffer on receiving the SOF packet immediately after the frame in which the USB has expected to receive the IN token. Even if the SOF packet is damaged, the USB also clears the FIFO buffer at the right timing to receive the SOF packet by using the internal interpolation function.

When the host controller is selected, set the IITV[2:0] bits to 000b.

When the selected pipe is not for isochronous transfer, set the IITV[2:0] bits to 000b.

### 31.2.30 Pipe n Control Registers (PIPEnCTR) (n = 1 to 9)

- PIPEnCTR (n = 1 to 5)

Address(es): USB0.PIPE1CTR 000A 0070h, USB0.PIPE2CTR 000A 0072h, USB0.PIPE3CTR 000A 0074h, USB0.PIPE4CTR 000A 0076h, USB0.PIPE5CTR 000A 0078h

Note 1. Only 0 can be read.

Note 2. Modify the ATREPM bit or write 1 to the SQCLR or SQSET bit while the PID[1:0] bits are 00b (NAK). Before modifying these bits after modifying the PID[1:0] bits for the selected pipe from 01b (BUF) to 00b (NAK), check that the PBUSY flag is 0. However, if the USB changes the PID[1:0] bits to 00b (NAK), the PBUSY flag does not need to be checked by software.

Note 3. Modify the ACLRM bit while PID[1:0] bits are 00b (NAK) and before the pipe is selected by the CURPIPE[3:0] bits in the port select register. Before modifying this bit after modifying the PID[1:0] bits for the selected pipe from 01b (BUF) to 00b (NAK), check that the PBUSY flag is 0. However, if the USB changes the PID[1:0] bits to 00b (NAK), the PBUSY flag does not need to be checked by software.

The PIPEnCTR register can be set regardless of the pipe selection in the PIPESEL register.

### PID[1:0] Bits (Response PID)

The PID[1:0] bits specify the response type for the next transaction of the relevant pipe.

The default setting of the PID[1:0] bits are 00b (NAK). Modify the setting of the PID[1:0] bits to 01b (BUF) to use the relevant pipe for USB transfer. Table 31.6 and Table 31.7 show the basic operation (operation when there are no errors in the transmitted and received packets) of the USB depending on the PID[1:0] bit setting.

After modifying the setting of the PID[1:0] bits through software from 01b (BUF) to 00b (NAK) during USB communication using the relevant pipe, check that the PBUSY flag is 1 to see if USB transfer using the relevant pipe has actually entered the NAK state. However, if the USB changes the PID[1:0] bits to 00b (NAK), the PBUSY flag does not need to be checked by software.

The USB modifies the setting of the PID[1:0] bits in the following cases.

- The USB sets the PID[1:0] bits to 00b (NAK) on recognizing the completion of the transfer when the relevant pipe is in the receiving direction and the PIPECFG.SHTNAK bit for the selected pipe has been set to 1 by software.
- The USB sets the PID[1:0] bits to 11b (STALL) on receiving a data packet with a payload exceeding the maximum packet size of the relevant pipe.
- The USB sets the PID[1:0] bits to 00b (NAK) on detecting a USB bus reset when the function controller is selected.
- The USB sets the PID[1:0] bits to 00b (NAK) on detecting a receive error, such as a CRC error, three consecutive times when the host controller is selected.
- The USB sets the PID[1:0] bits to 11b (STALL) on receiving the STALL handshake when the host controller is selected.

To specify each response type, set the PID[1:0] bits as follows.

- To make a transition from NAK (00b) to STALL, set 10b.
- To make a transition from BUF (01b) to STALL, set 11b.
- To make a transition from STALL (11b) to NAK, set 10b and then 00b.
- To make a transition from STALL (11b) to BUF, set 10b, 00b, and then 01b.
- To make a transition from STALL (10b) to BUF, set 00b and then 01b.

### PBUSY Flag (Pipe Busy Flag)

The PBUSY flag indicates whether the relevant pipe is being currently used or not for the transaction.

The USB modifies the PBUSY flag from 0 to 1 upon start of the USB transaction for the relevant pipe, and modifies the PBUSY flag from 1 to 0 upon completion of one transaction.

Reading the PBUSY flag after the PID[1:0] bits have been set to 00b (NAK) by software allows checking whether modification of the pipe settings is possible.

For details, refer to section 31.3.4.1, Pipe Control Register Switching Procedures.

### SQMON Bit (Sequence Toggle Bit Confirmation)

The SQMON flag indicates the expected value of the sequence toggle bit for the next transaction of the relevant pipe.

When the relevant pipe is not for the isochronous transfer, the USB allows the SQMON flag to toggle upon normal completion of the transaction. However, the SQMON flag is not allowed to toggle when a data PID mismatch occurs during the transfer in the receiving direction.

### SQSET Bit (Sequence Toggle Bit Set)

The SQSET bit should be set to 1 to set DATA1 as the expected value of the sequence toggle bit for the next transaction of the relevant pipe.

Setting the SQSET bit to 1 through software allows the USB to set DATA1 as the expected value of the sequence toggle bit of the relevant pipe. The USB sets the SQSET bit to 0.

**SQCLR Bit (Sequence Toggle Bit Clear)**

The SQCLR bit should be set to 1 to clear the expected value (to set DATA0 as the expected value) of the sequence toggle bit for the next transaction of the relevant pipe.

Setting the SQCLR bit to 1 through software allows the USB to set DATA0 as the expected value of the sequence toggle bit of the relevant pipe. The USB sets the SQCLR bit to 0.

**ACLRM Bit (Auto Buffer Clear Mode)**

Enables or disables auto buffer clear mode for the relevant pipe.

To delete the information in the FIFO buffer assigned to the relevant pipe completely, write 1 and then 0 to the ACLRM bit continuously.

Table 31.8 shows the information cleared by writing 1 and 0 to the ACLRM bit continuously and the cases in which clearing the information is necessary.

**ATREPM Bit (Auto Response Mode)**

Enables or disables auto response mode for the relevant pipe.

When the function controller is selected and the relevant pipe is for bulk transfer, the ATREPM bit can be set to 1.

When the ATREPM bit is set to 1, the USB responds to the token from the USB host as described below.

(1) When the relevant pipe is for bulk IN transfer (the PIPECFG.TYPE[1:0] bits = 01b and the PIPECFG.DIR bit = 1)  
When the ATREPM bit = 1 and PID[1:0] = 01b (BUF), the USB transmits a zero-length packet in response to the IN token.

The USB updates (allows toggling of) the sequence toggle bit (data PID) each time the USB receives ACK from the USB host (in a single transaction, IN token is received, zero-length packet is transmitted, and then ACK is received.).

In this case, the USB does not generate the BRDY or BEMP interrupt.

(2) When the relevant pipe is for bulk OUT transfer (the PIPECFG.TYPE[1:0] bits = 01b and the PIPECFG.DIR bit = 0)  
When the ATREPM bit = 1 and PID[1:0] = 01b (BUF), the USB returns NAK in response to the OUT token and generates the NRDY interrupt.

For USB communication in auto response mode, set the ATREPM bit to 1 while the FIFO buffer is empty. Do not write to the FIFO buffer during USB communication in auto response mode.

When the relevant pipe is for isochronous transfer, be sure to set the ATREPM bit to 0.

When the host controller is selected, be sure to set the ATREPM bit to 0.

**INBUFM Flag (Transmit Buffer Monitor Flag)**

Indicates the relevant FIFO buffer status when the relevant pipe is in the transmitting direction.

When the relevant pipe is in the transmitting direction (the PIPECFG.DIR bit = 1), the USB sets the INBUFM flag to 1 when the CPU or DMAC/DTC completes writing data to at least one FIFO buffer plane.

The USB sets the INBUFM flag to 0 when the USB completes transmitting the data from the FIFO buffer plane to which all the data has been written. In double buffer mode (the PIPECFG.DBLB bit = 1), the USB sets the INBUFM flag to 0 when the USB completes transmitting the data from the two FIFO buffer planes before the CPU or DMAC/DTC completes writing data to one FIFO buffer plane.

The INBUFM flag indicates the same value as the BSTS flag when the relevant pipe is in the receiving direction (the PIPECFG.DIR bit = 0).

**BSTS Flag (Buffer Status Flag)**

Indicates the FIFO buffer status for the relevant pipe.

The meaning of the BSTS flag depends on the settings of the PIPECFG.DIR bit, PIPECFG.BFRE bit, and DnFIFOSEL.DCLRM bits as shown in Table 31.9.

**Table 31.6 Operation of USB depending on PID[1:0] Bits Setting (When Host Controller is Selected)**

| PID[1:0] Bits              | Transfer Type                             | Transfer Direction (DIR Bit)              | Operation of USB                                                                                                                                                                                                                                                                                           |

| b15        | BSTS     | Buffer Status Flag                    | 0: Buffer access is disabled.<br>1: Buffer access is enabled.                                                                 | R         |

Note 1. Only 0 can be read. Only 1 can be written.

Note 2. Write 1 to the SQCLR or SQSET bit while the PID[1:0] bits are 00b (NAK). Before modifying these bits after modifying the PID[1:0] bits for the selected pipe from 01b (BUF) to 00b (NAK), check that the PBUSY flag is 0. However, if the USB changes the PID[1:0] bits to 00b (NAK), the PBUSY flag does not need to be checked by software.

Note 3. Modify the ACLRM bit while the PID[1:0] bits are 00b (NAK) and before the pipe is selected by the CURPIPE[3:0] bits in the port select register. Before modifying this bit after modifying the PID[1:0] bits for the selected pipe from 01b (BUF) to 00b (NAK), check that the PBUSY flag is 0. However, if the USB changes the PID[1:0] bits to 00b (NAK), the PBUSY flag does not need to be checked by software.

### **PID[1:0] Bits (Response PID)**

The PID[1:0] bits specify the response type for the next transaction of the relevant pipe.

The default setting of the PID[1:0] bits are 00b (NAK). Modify the setting of the PID[1:0] bits to 01b (BUF) to use the relevant pipe for USB transfer. Table 31.6 and Table 31.7 show the basic operation (operation when there are no errors in the transmitted and received packets) of the USB depending on the setting of the PID[1:0] bits.

After modifying the setting of the PID[1:0] bits through software from 01b (BUF) to 00b (NAK) during USB communication using the relevant pipe, check that the PBUSY flag is 1 to see if USB transfer using the relevant pipe has actually entered the NAK state. However, if the USB changes the PID[1:0] bits to 00b (NAK), the PBUSY flag does not need to be checked by software.

The USB modifies the setting of the PID[1:0] bits in the following cases.

- The USB sets the PID[1:0] bits to 11b (STALL) on receiving a data packet with a payload exceeding the maximum packet size of the relevant pipe.
- The USB sets the PID[1:0] bits to 00b (NAK) on detecting a USB bus reset when the function controller is selected.
- The USB sets the PID[1:0] bits to 00b (NAK) on detecting a receive error, such as a CRC error, three consecutive times when the host controller is selected.
- The USB sets the PID[1:0] bits to 11b (STALL) on receiving the STALL handshake when the host controller is selected.

To specify each response type, set the PID[1:0] bits as follows.

- To make a transition from NAK (00b) to STALL, set 10b.
- To make a transition from BUF (01b) to STALL, set 11b.
- To make a transition from STALL (11b) to NAK, set 10b and then 00b.
- To make a transition from STALL (11b) to BUF, set 10b, 00b, and then 01b.
- To make a transition from STALL (10b) to BUF, set 00b and then 01b.

### **PBUSY Flag (Pipe Busy Flag)**

The PBUSY flag indicates whether the relevant pipe is being currently used or not for the transaction.

The USB modifies the PBUSY flag from 0 to 1 upon start of the USB transaction for the relevant pipe, and modifies the PBUSY flag from 1 to 0 upon completion of one transaction.

Reading the PBUSY flag after the PID[1:0] bits has been set to 00b (NAK) by software allows checking whether modification of the pipe settings is possible.

### **SQMON Flag (Sequence Toggle Bit Confirmation Flag)**

The SQMON flag indicates the expected value of the sequence toggle bit for the next transaction of the relevant pipe.

The USB allows the SQMON flag to toggle upon normal completion of the transaction. However, the SQMON flag is not allowed to toggle when a data PID mismatch occurs during the transfer in the receiving direction.

### **SQSET Bit (Sequence Toggle Bit Set)**

The SQSET bit should be set to 1 to set DATA1 as the expected value of the sequence toggle bit for the next transaction of the relevant pipe.

Setting the SQSET bit through software allows the USB to set DATA1 as the expected value of the sequence toggle bit of the relevant pipe. The USB sets the SQSET bit to 0.

### **SQCLR Bit (Sequence Toggle Bit Clear)**

The SQCLR bit should be set to 1 to clear the expected value (to set DATA0 as the expected value) of the sequence toggle bit for the next transaction of the relevant pipe.

Setting the SQCLR bit to 1 through software allows the USB to set DATA0 as the expected value of the sequence toggle bit of the relevant pipe. The USB sets the SQCLR bit to 0.

**ACLRM Bit (Auto Buffer Clear Mode)**

Enables or disables auto buffer clear mode for the relevant pipe.

To delete the information in the FIFO buffer assigned to the relevant pipe completely, write 1 and then 0 to the ACLRM bit continuously.

Table 31.10 shows the information cleared by writing 1 and 0 to the ACLRM bit continuously and the cases in which clearing the information is necessary.

**BSTS Flag (Buffer Status Flag)**

Indicates the FIFO buffer status for the relevant pipe.

The meaning of the BSTS flag depends on the settings of the PIPECFG.DIR bit, PIPECFG.BFRE bit, and DnFIFOSEL.DCLRM bits as shown in Table 31.9.

**Table 31.10 Information Cleared by USB by Setting the ACLRM Bit = 1**

| No. | Information Cleared by ACLRM Bit Manipulation                                                                 | Cases in which Clearing Information is Necessary           |
|-----|---------------------------------------------------------------------------------------------------------------|------------------------------------------------------------|
| 1   | All the information in the FIFO buffer assigned to the selected pipe                                          | When the pipe is to be initialized                         |
| 2   | The interval count value when the selected pipe is for interrupt transfer and the host controller is selected | When the interval count value is to be reset               |
| 3   | Internal flags concerning the PIPECFG.BFRE bit                                                                | When the PIPECFG.BFRE setting is modified                  |
| 4   | Internal flags concerning the transaction count                                                               | When the transaction count function is forcibly terminated |

### 31.2.31 Pipe n Transaction Counter Enable Register (PIPEnTRE) (n = 1 to 5)

Address(es): USB0.PIPE1TRE 000A 0090h, USB0.PIPE2TRE 000A 0094h, USB0.PIPE3TRE 000A 0098h, USB0.PIPE4TRE 000A 009Ch, USB0.PIPE5TRE 000A 00A0h

|                    |     |     |     |     |     |       |       |    |    |    |    |    |    |    |    |
|--------------------|-----|-----|-----|-----|-----|-------|-------|----|----|----|----|----|----|----|----|
| b15                | b14 | b13 | b12 | b11 | b10 | b9    | b8    | b7 | b6 | b5 | b4 | b3 | b2 | b1 | b0 |
| —                  | —   | —   | —   | —   | —   | TRENB | TRCLR | —  | —  | —  | —  | —  | —  | —  | —  |
| Value after reset: |     |     |     |     |     |       |       |    |    |    |    |    |    |    |    |
| 0                  | 0   | 0   | 0   | 0   | 0   | 0     | 0     | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  |

| Bit        | Symbol | Bit Name                   | Description                                                               | R/W |
|------------|--------|----------------------------|---------------------------------------------------------------------------|-----|
| b7 to b0   | —      | Reserved                   | These bits are read as 0. The write value should be 0.                    | R/W |
| b8         | TRCLR  | Transaction Counter Clear  | 0: Invalid<br>1: The current counter value is cleared.                    | R/W |
| b9         | TRENB  | Transaction Counter Enable | 0: Transaction counter is disabled.<br>1: Transaction counter is enabled. | R/W |
| b15 to b10 | —      | Reserved                   | These bits are read as 0. The write value should be 0.                    | R/W |

Note: Modify each bit in the PIPEnTRE register while the PID[1:0] bits are 00b (NAK). Before modifying these bits after modifying the PIPEnCTR.PID[1:0] bits for the selected pipe from 01b (BUF) to 00b (NAK), check that the PIPEnCTR.PBUSY flag is 0. However, if the USB changes the PID[1:0] bits to 00b (NAK), the PBUSY flag does not need to be checked by software.

#### TRCLR Bit (Transaction Counter Clear)

Clears the current value of the transaction counter corresponding to the relevant pipe and then sets the TRCLR bit to 0.

#### TRENB Bit (Transaction Counter Enable)

Enables or disables the transaction counter.

For the pipe in the receiving direction, setting the TRENB bit to 1 after setting the total number of the packets to be received in the PIPEnTRN register through software allows the USB to control hardware as described below on having received the number of packets equal to the setting of the PIPEnTRN register.

- While the PIPECFG.SHTNAK bit is 1, the USB modifies the PID[1:0] bits to 00b (NAK) for the corresponding pipe on having received the number of packets equal to the setting of the PIPEnTRN register.
- While the PIPECFG.BFRE bit is 1, the USB asserts the BRDY interrupt on having received the number of packets equal to the setting of the PIPEnTRN register and then reading the last received data.

For the pipe in the transmitting direction, set the TRENB bit to 0.

When the transaction counter is not used, set the TRENB bit to 0.

When the transaction counter is used, set the PIPEnTRN register before setting the TRENB bit to 1. Set the TRENB bit to 1 before receiving the first packet to be counted by the transaction counter.

### 31.2.32 Pipe n Transaction Counter Register (PIPE<sub>n</sub>TRN) (n = 1 to 5)

Address(es): USB0.PIPE1TRN 000A 0092h, USB0.PIPE2TRN 000A 0096h, USB0.PIPE3TRN 000A 009Ah, USB0.PIPE4TRN 000A 009Eh,  
USB0.PIPE5TRN 000A 00A2h

The PIPE<sub>n</sub>TRN register retains the setting by a USB bus reset.

- When written to:  
This register specifies the total of packets (number of transactions) to be received in corresponding pipe.
- When read from:  
This register indicates the specified number of transactions if the PIPE<sub>n</sub>TRE.TRENB bit is 0.  
This register indicates the number of currently counted transactions if the PIPE<sub>n</sub>TRE.TRENB bit is 1.

The USB increments the value of the PIPE<sub>n</sub>TRN register by one when all of the following conditions are satisfied on receiving the packet.

- The PIPE<sub>n</sub>TRE.TRENB bit = 1
- (PIPE<sub>n</sub>TRN set value  $\neq$  current counter value + 1) on receiving the packet.
- The payload of the received packet agrees with the setting of the PIPEMAXP.MXPS[8:0] bits.

The USB sets the value of the PIPE<sub>n</sub>TRN register to 0000h when any of the following conditions are satisfied.

- (1) All of the following conditions are satisfied.
  - The PIPE<sub>n</sub>TRE.TRENB bit = 1
  - (PIPE<sub>n</sub>TRN set value = current counter value + 1) on receiving the packet.
  - The payload of the received packet agrees with the setting of the PIPEMAXP.MXPS[8:0] bits.
- (2) All of the following conditions are satisfied.
  - The PIPE<sub>n</sub>TRE.TRENB bit = 1
  - The USB has received a short packet.
- (3) All of the following conditions are satisfied.
  - The PIPE<sub>n</sub>TRE.TRENB bit = 1
  - The PIPE<sub>n</sub>TRE.TRCLR bit has been set to 1 by software.

For the pipe in the transmitting direction, set the PIPE<sub>n</sub>TRN register to 0000h.

When the transaction counter is not used, set the PIPE<sub>n</sub>TRN register to 0000h.

Setting the number of transactions to be transferred to the PIPE<sub>n</sub>TRN register is only enabled when the PIPE<sub>n</sub>TRE.TRENB bit is 0. To modify the number of transactions to be transferred, set the TRCLR bit to 1 (to clear the current counter value) before setting the PIPE<sub>n</sub>TRE.TRENB bit to 1.

### 31.2.33 Device Address n Configuration Register (DEVADDn) (n = 0 to 5)

Address(es): USB0.DEVADD0 000A 00D0h, USB0.DEVADD1 000A 00D2h, USB0.DEVADD2 000A 00D4h, USB0.DEVADD3 000A 00D6h,  
USB0.DEVADD4 000A 00D8h, USB0.DEVADD5 000A 00DAh

| Bit       | Symbol      | Bit Name                                      | Description                                                                                       | R/W |
|-----------|-------------|-----------------------------------------------|---------------------------------------------------------------------------------------------------|-----|
| b5 to b0  | —           | Reserved                                      | These bits are read as 0. The write value should be 0.                                            | R/W |
| b7, b6    | USBSPD[1:0] | Transfer Speed of Communication Target Device | b7 b6<br>0 0: DEVADDn is not used<br>0 1: Low-speed<br>1 0: Full-speed<br>1 1: Setting prohibited | R/W |
| b15 to b8 | —           | Reserved                                      | These bits are read as 0. The write value should be 0.                                            | R/W |

The DEVADDn register specifies the transfer speed of the peripheral device which is the communication target for pipes 0 to 9.

When the host controller is selected, the bits in the DEVADDn register should be set before starting communication using each pipe.

The bits in the DEVADDn register should be modified while no valid pipes are using the settings of the bits. Valid pipes refer to the pipes satisfying both of the following conditions:

- The DEVADDn register is selected by the DEVSEL[3:0] bits.
- The PID[1:0] bits are set to 01b (BUF) for the selected pipe or the selected pipe is the DCP with the DCPCTR.SUREQ bit set to 1.

#### USBSPD[1:0] Bits (Transfer Speed of Communication Target Device)

The USBSPD[1:0] bits specify the USB transfer speed of the communication target peripheral device.

Set these bits to 10b when a full-speed device is connected via the HUB.

When the host controller is selected, the USB refers to the setting of the USBSPD[1:0] bits to generate packets.

When the function controller is selected, set these bits to 00b.

### 31.2.34 PHY Cross Point Adjustment Register (PHYSLEW)

Address(es): USB0.PHYSLEW 000A 00F0h

| Value after reset: | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 1           | 1           | 1           | 0           |

| Bit       | Symbol  | Bit Name                         | Description                                            | R/W |
|-----------|---------|----------------------------------|--------------------------------------------------------|-----|
| b0        | SLEWR00 | Driver Cross Point Adjustment 00 | Set this bit to 1.                                     | R/W |
| b1        | SLEWR01 | Driver Cross Point Adjustment 01 | Set this bit to 0.                                     | R/W |
| b2        | SLEWF00 | Driver Cross Point Adjustment 00 | Set this bit to 1.                                     | R/W |
| b3        | SLEWF01 | Driver Cross Point Adjustment 01 | Set this bit to 0.                                     | R/W |
| b31 to b4 | —       | Reserved                         | These bits are read as 0. The write value should be 0. | R/W |

The PHYSLEW register adjusts the cross point of the driver.  
Set the value (00000005h) to the register before starting the USB operation.

## 31.3 Operation

### 31.3.1 System Control

This section describes the register settings that are necessary for initialization of this module and power consumption control.

#### 31.3.1.1 Setting Data to the USB Related Register

Setting the SYSCFG.USBE bit to 1 after starting the clock supply to the USB (SYSCFG.SCKE bit = 1) enables and starts USB operation.

#### 31.3.1.2 Controller Function Selection

For the USB, the host or function controller can be selected using the SYSCFG.DCFM bit. Note that the DCFM bit should be modified in the initial settings immediately after a reset is released or when pull-up resistor of the D+line and pull-down resistors of the D+ and D– lines are disabled (the SYSCFG.DPRPU bit = 0 and DRPD bit = 0).

#### 31.3.1.3 Controlling USB Data Bus Resistors

The USB has pull-up and pull-down resistors for the D+ and D– lines. Pull up or pull down these lines by setting the SYSCFG.DPRPU and DRPD bits.

When the function controller is selected, confirm that connection to the USB host is made, then set the DPRPU bit to 1 and pull up the D+ line (during full-speed).

When the DPRPU bit is set to 0 during communication with the PC, the USB module disables the pull-up resistor of the USB data line, thus notifying the USB host of disconnection.

When the host controller is selected, set the DRPD bit and pull down the D+ and D– lines.

**Table 31.11 USB Data Bus Resistor Control**

| SYSCFG register |           | D–        | D+        | Function                                                  |
|-----------------|-----------|-----------|-----------|-----------------------------------------------------------|
| DRPD bit        | DPRPU bit |           |           |                                                           |
| 0               | 0         | Open      | Open      | Not in use                                                |
| 0               | 1         | Open      | Pull-up   | When operating as the function controller (in full-speed) |
| 1               | 0         | Pull-down | Pull-down | When operating as the host controller                     |
| 1               | 1         | —         | —         | Setting prohibited                                        |

### 31.3.1.4 Example of USB External Connection Circuit

Figure 31.2 shows an example of connection between OTG device and USB connector in the self-powered state. The USB controls the signals for enabling a pull-up resistor for the D+ signal and pull-down resistors for the D+ and D- signals. These signals can be pulled up or down using the SYSCFG.DPRPU and DRPD bits. When the function controller is selected and the DPRPU bit is set to 0 during communication with the host controller, the pull-up resistor of the USB data line is disabled, making it possible to notify the USB host of the device disconnection.

Figure 31.2 Example of Connection between Self-Powered OTG Device and USB Connector

Figure 31.3 shows an example of connection between function controller and USB connector in self-powered state.

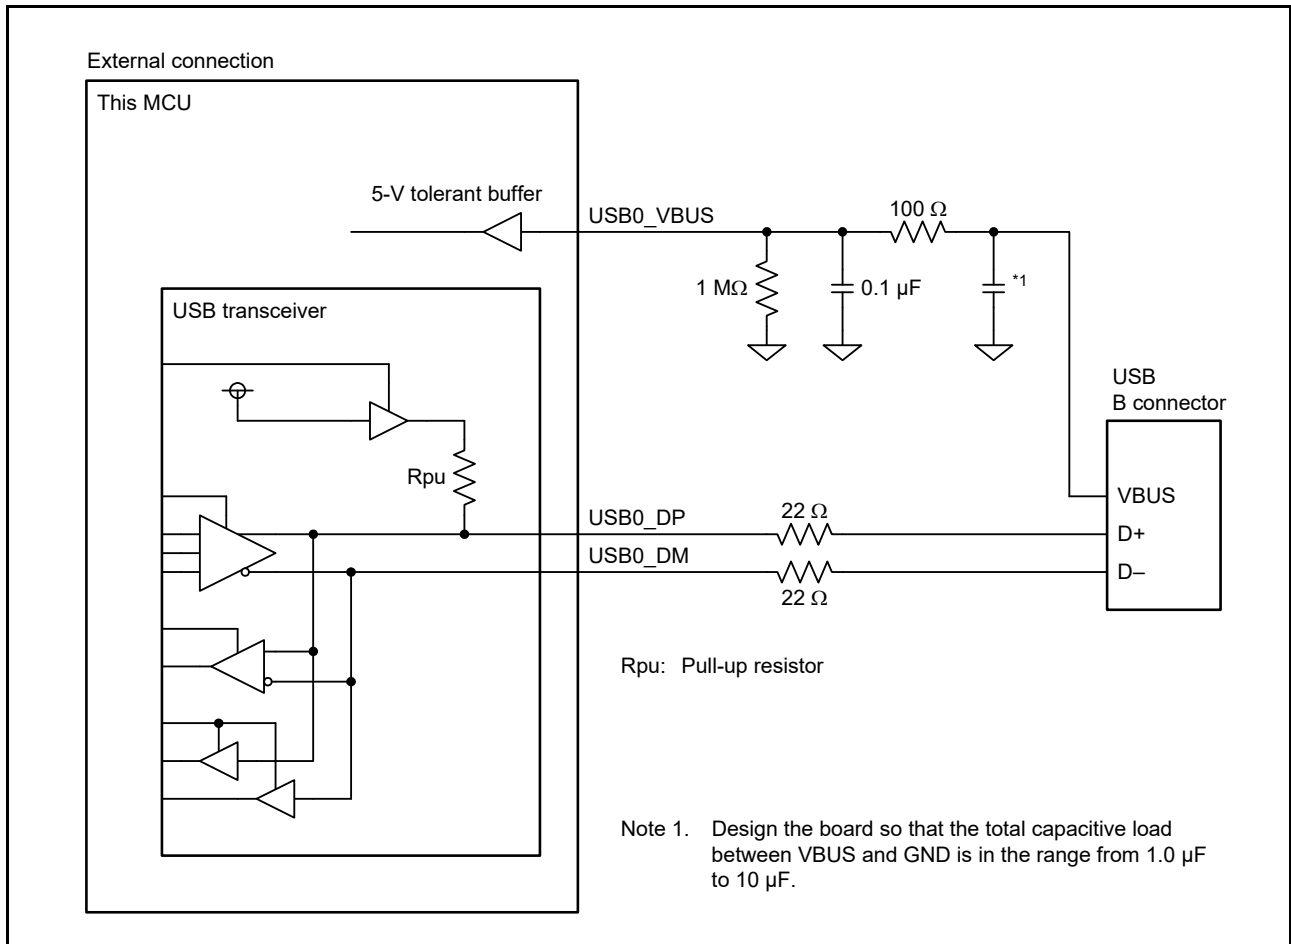

Figure 31.3 Example of Connection between Self-Powered Function and USB Connector

Figure 31.4 shows an example of connection between host controller and USB connector.

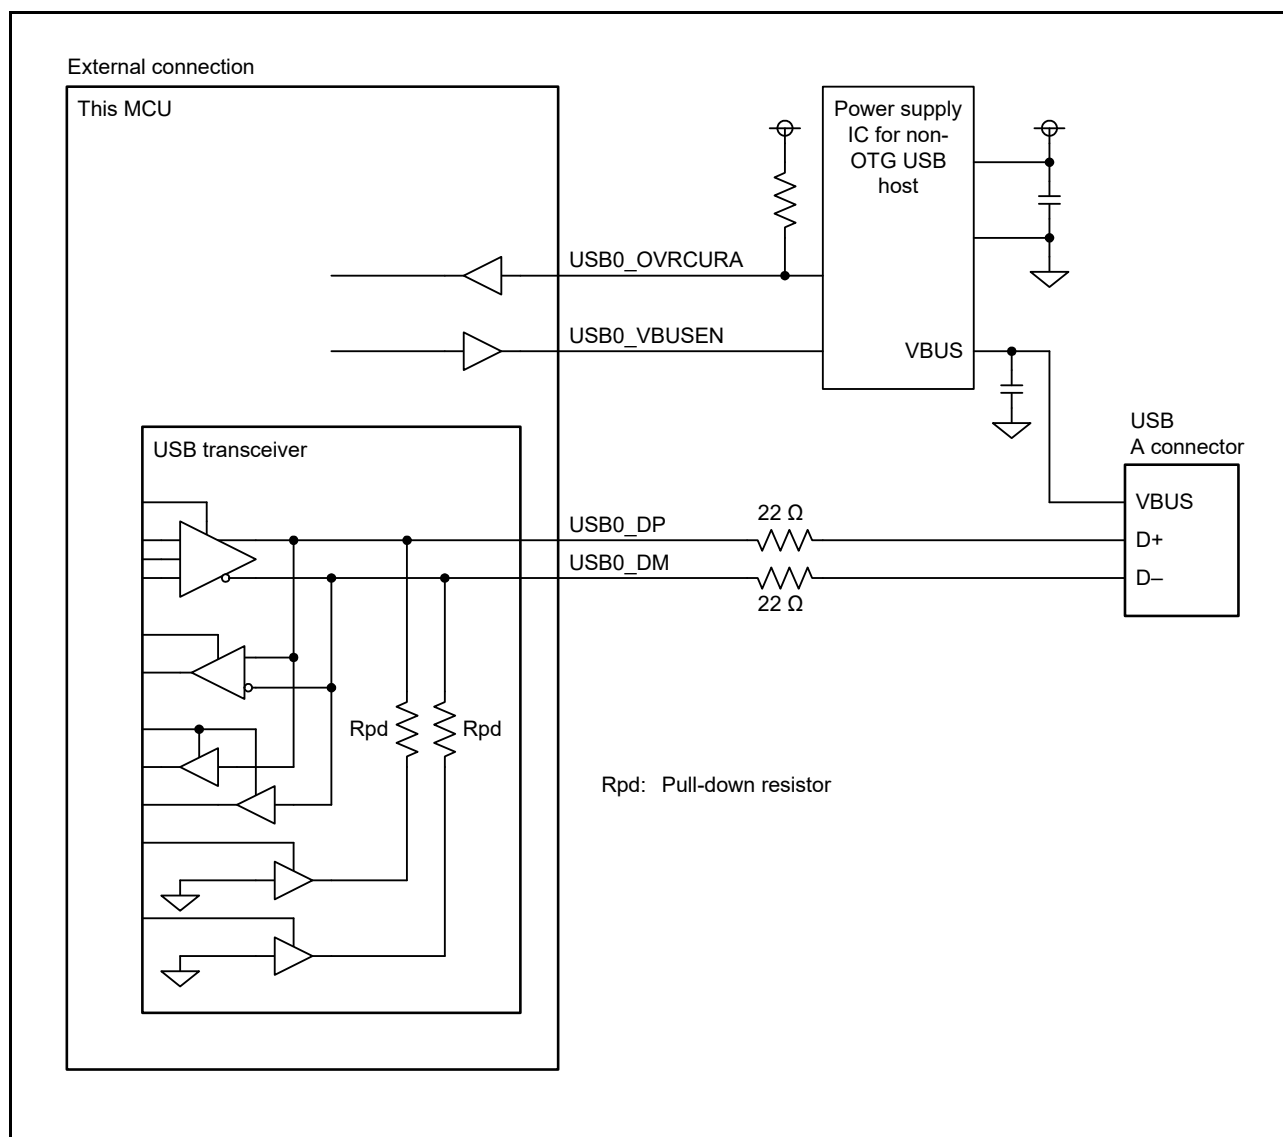

Figure 31.4 Example of Connection between Host and USB Connector

Figure 31.5 shows an example of connection between function controller and USB connector in bus powered state.

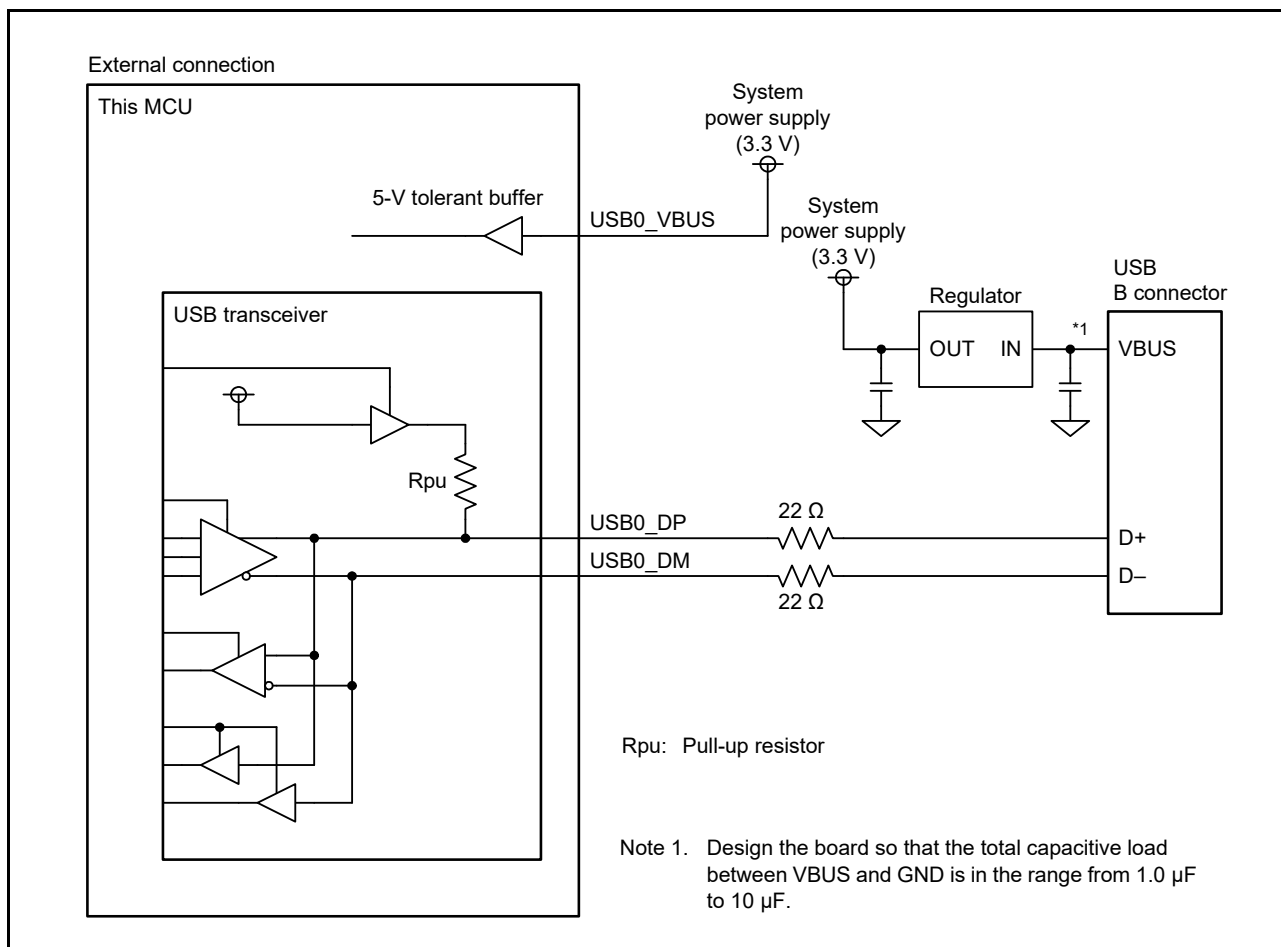

Figure 31.5 Example of Connection between Bus-Powered Function and USB Connector

The examples of external circuits given in this section are simplified circuits, and their operation in every system is not guaranteed.

### 31.3.2 Interrupt Sources

Table 31.12 lists the interrupt sources in the USB.

When an interrupt generation condition is satisfied and the interrupt output is enabled using the corresponding interrupt enable register, a USB interrupt request is issued the Interrupt Controller (ICU) and an USB interrupt will be generated.

**Table 31.12 Interrupt Sources**

| Bit to be Set | Name                                                | Interrupt Source                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | Function That Generates the Interrupt | Status Flag        |
|---------------|-----------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------|--------------------|

### 31.3.3 Interrupt Descriptions

#### 31.3.3.1 BRDY Interrupt

The BRDY interrupt is generated when either of the host controller or function controller is selected. The following shows the conditions under which the USB sets 1 to a corresponding bit in the BRDYSTS register. Under this condition, the USB generates a BRDY interrupt if software has set 1 to the BRDYENB.PIPEnBRDYE bit that corresponds to the pipe and 1 to the INTENB0.BRDYE bit.

The conditions for generating and clearing the BRDY interrupt depend on the settings of the SOFCFG.BRDYM bit and PIPECFG.BFRE bit for each pipe as described below.

##### (1) When the SOFCFG.BRDYM Bit = 0 and the PIPECFG.BFRE Bit = 0

With these settings, the BRDY interrupt indicates that the FIFO port is accessible.

On any of the following conditions, the USB generates an internal BRDY interrupt request trigger and sets 1 to the BRDYSTS.PIPEnBRDY flag corresponding to the pertinent pipe.

##### (a) For the pipe in the transmitting direction:

- When the DIR bit is changed from 0 to 1 by software.
- When packet transmission is completed using the pertinent pipe while write-access from the CPU to the FIFO buffer for the pertinent pipe is disabled (when the BSTS flag is read as 0).
- When one FIFO buffer is empty on completion of writing data to the other FIFO buffer in double buffer mode.
- No request trigger is generated until completion of writing data to the currently-written FIFO buffer even if transmission to the other FIFO buffer is completed.
- When the hardware flushes the buffer of the pipe for isochronous transfers.
- When 1 is written to the PIPEnCTR.ACLRM bit, which causes the FIFO buffer to make transition from the write-disabled to write-enabled state.

No request trigger is generated for the DCP (that is, during data transmission for control transfers).

## (b) For the pipe in the receiving direction:

- When packet reception is completed successfully thus enabling the FIFO buffer to be read while read-access from the CPU to the FIFO buffer for the pertinent pipe is disabled (when the BSTS flag is read as 0).  
No request trigger is generated for the transaction in which data PID mismatch has occurred.
- When one FIFO buffer is read-enabled on completion of reading data from the other FIFO buffer in double buffer mode.  
No request trigger is generated until completion of reading data from the currently-read FIFO buffer even if reception by the other FIFO buffer is completed.

When the function controller is selected, the BRDY interrupt is not generated in the status stage of control transfers. The BRDY interrupt status of the pertinent pipe can be set to 0 by writing 0 to the corresponding PIPEnBRDY flag through software. In this case, 1s should be written to the PIPEnBRDY flags for the other pipes. Clear the BRDY status before accessing the FIFO buffer.

## (2) When the SOFCFG.BRDYM Bit = 0 and the PIPECFG.BFRE Bit = 1

With these settings, the USB generates a BRDY interrupt on completion of reading all data for a single transfer using the pipe in the receiving direction, and sets 1 to the bit in the BRDYSTS register corresponding to the pertinent pipe. On any of the following conditions, the USB determines that the last data for a single transfer has been received.

- When a short packet including a zero-length packet is received.
- When the pipe n transaction counter register (PIPEnTRN) is used and the number of packets specified by the PIPEnTRN register are completely received.

When the pertinent data is completely read after any of the above conditions has been satisfied, the USB determines that all data for a single transfer has been completely read.

When a zero-length packet is received while the FIFO buffer is empty, the USB module determines that all data for a single transfer has been completely read when the FRDY flag in the FIFO port control register is 1 and the DTLN[8:0] flags are 0. In this case, to start the next transfer, write 1 to the BCLR bit in the corresponding port control register through software.

With these settings, the USB does not detect a BRDY interrupt for the pipe in the transmitting direction.

The BRDY interrupt status of the pertinent pipe can be set to 0 by writing 0 to the corresponding BRDYSTS.PIPEnBRDY flag through software. In this case, 1s should be written to the PIPEnBRDY flags for the other pipes.

In this mode, the PIPECFG.BFRE bit setting should not be modified until all data for a single transfer has been processed. When it is necessary to modify the PIPECFG.BFRE bit before completion of processing, all FIFO buffers for the pertinent pipe should be cleared using the PIPEnCTR.ACLRM bit.

(3) When the SOFCFG.BRDYM Bit = 1 and the PIPECFG.BFRE Bit = 0

With these settings, the BRDYSTS.PIPEnBRDY values are linked to the BSTS flag setting for each pipe. In other words, the BRDY interrupt status flags (PIPEnBRDY) are set to 1 or 0 by the USB depending on the FIFO buffer status.

(a) For the pipe in the transmitting direction:

The BRDY interrupt status bits are set to 1 when the FIFO buffer is ready for write access, and are set to 0 when it is not ready.

However, the BRDY interrupt is not generated even if the DCP in the transmitting direction is ready for write access.

(b) For the pipe in the receiving direction:

The BRDY interrupt status bits are set to 1 when the FIFO buffer is ready for read access, and are set to 0 when all data have been read (not ready for read access).

When a zero-length packet is received while the FIFO buffer is empty, the pertinent bit is set to 1 and the BRDY interrupt is continuously generated until BCLR = 1 is written through software.

With this setting, the PIPEnBRDY flag cannot be set to 0 through software.

When the SOFCFG.BRDYM bit is set to 1, all PIPECFG.BFRE bits (for all pipes) should be set to 0.

Figure 31.7 shows the timing of BRDY interrupt generation.

**Figure 31.7** Timing of BRDY Interrupt Generation

The condition that USB clears the INTSTS0.BRDY flag depends on the SOFCFG.BRDYM bit setting. Table 31.14 shows the condition for clearing the BRDY flag.

**Table 31.14** Condition for Clearing BRDY Flag

| BRDYM Bit | Condition for Clearing BRDY Flag                                                                      |
|-----------|-------------------------------------------------------------------------------------------------------|
| 0         | The USB sets the BRDY flag to 0 when all bits in the BRDYSTS register have been set to 0 by software. |
| 1         | The USB sets the BRDY flag to 0 when the BSTS flags for all pipes have become 0.                      |

### 31.3.3.2 NRDY Interrupt

On generating an internal NRDY interrupt request for the pipe whose PID[1:0] bits are set to 01b (BUF) by software, the USB sets the corresponding NRDYSTS.PIPEnNRDY flag to 1. If the corresponding bit in the NRDYENB register has been set to 1 by software, the USB sets the INTSTS0.NRDY flag to 1 and generates a USB interrupt.

The following describes the conditions on which the USB generates the internal NRDY interrupt request for a given pipe.

Note that the internal NRDY interrupt request is not generated during setup transaction execution when the host controller is selected. During setup transactions when the host controller is selected, the SACK or SIGN interrupt is detected.

The internal NRDY interrupt request is not generated during status stage execution of the control transfer when the function controller is selected.

#### (1) When Host Controller is Selected

##### (a) For the pipe in the transmitting direction:

On any of the following conditions, the USB detects an NRDY interrupt.

- For the pipe for isochronous transfers, when the time to issue an OUT token comes while there is no data to be transmitted in the FIFO buffer.

In this case, the USB transmits a zero-length packet following the OUT token and sets the bit corresponding to the NRDYSTS.PIPEnNRDY flag and the FRMNUM.OVRN flag to 1.

- During communications other than setup transactions using the pipe for the transfers other than isochronous transfers, when any combination of the following two cases occur three consecutive times: 1) no response is returned from the peripheral device (when timeout is detected before detection of the handshake packet from the peripheral device) and 2) an error is detected in the packet from the peripheral device.

In this case, the USB sets the bit corresponding to the PIPEnNRDY flag to 1 and modifies the setting of the PID[1:0] bits of the corresponding pipe to 00b (NAK).

- During communications other than setup transactions, when the STALL handshake is received from the peripheral device.

In this case, the USB sets the bit corresponding to the PIPEnNRDY flag to 1 and modifies the setting of the PID[1:0] bits of the corresponding pipe to 11b (STALL).

##### (b) For the pipe in the receiving direction:

- For the pipe for isochronous transfers, when the time to issue an IN token comes while there is no space available in the FIFO buffer.

In this case, the USB discards the received data for the IN token and sets the PIPEnNRDY flag corresponding to the pipe and the OVRN flag to 1.

When a packet error is detected in the received data for the IN token, the USB also sets the FRMNUM.CRCE flag to 1.

- For the pipe for the transfers other than isochronous transfers, when any combination of the following two cases occur three consecutive times: 1) no response is returned from the peripheral device for the IN token issued by the USB (when timeout is detected before detection of the DATA packet from the peripheral device) and 2) an error is detected in the packet from the peripheral device.

In this case, the USB sets the PIPEnNRDY flag corresponding to the pipe to 1 and modifies the setting of the PID[1:0] bits of the corresponding pipe to 00b (NAK).

- For the pipe for isochronous transfers, when no response is returned from the peripheral device for the IN token (when timeout is detected before detection of the DATA packet from the peripheral device) or an error is detected in the packet from the peripheral device.

In this case, the USB sets the PIPEnNRDY flag corresponding to the pipe to 1. (The setting of the PID[1:0] bits of the pipe is not modified.)

- For the pipe for isochronous transfers, when a CRC error or a bit stuffing error is detected in the received data packet.  
In this case, the USB sets the PIPEnNRDY flag corresponding to the pipe and the CRCE flag to 1.
- When the STALL handshake is received.  
In this case, the USB sets the PIPEnNRDY flag corresponding to the pipe to 1 and modifies the setting of the PID[1:0] bits of the corresponding pipe to 11b (STALL).

## (2) When Function Controller is Selected

### (a) For the pipe in the transmitting direction:

- When an IN token is received while there is no data to be transmitted in the FIFO buffer.  
In this case, the USB generates a NRDY interrupt request at the reception of the IN token and sets the NRDYSTS.PIPEnNRDY flag to 1.  
For the pipe for the isochronous transfers in which an interrupt is generated, the USB transmits a zero-length packet and sets the FRMNUM.OVRN flag to 1.

### (b) For the pipe in the receiving direction:

- When an OUT token is received while there is no space available in the FIFO buffer.  
For the pipe for the isochronous transfers in which an interrupt is generated, the USB generates a NRDY interrupt request at the reception of the OUT token and sets the PIPEnNRDY flag to 1 and OVRN flag to 1.  
For the pipe for the transfers other than isochronous transfers in which an interrupt is generated, the USB generates a NRDY interrupt request when a NAK handshake is transferred after the data following the OUT token is received, and sets the PIPEnNRDY flag to 1.  
However, during re-transmission (due to data PID mismatch), the NRDY interrupt request is not generated. In addition, if an error occurs in the DATA packet, the NRDY interrupt request is not generated.
- For the pipe for isochronous transfers, when a token is not received successfully within an interval frame.  
In this case, the USB generates a NRDY interrupt request when SOF is received, and sets the PIPEnNRDY flag to 1.

Figure 31.8 shows the timing of NRDY interrupt generation when the function controller is selected.

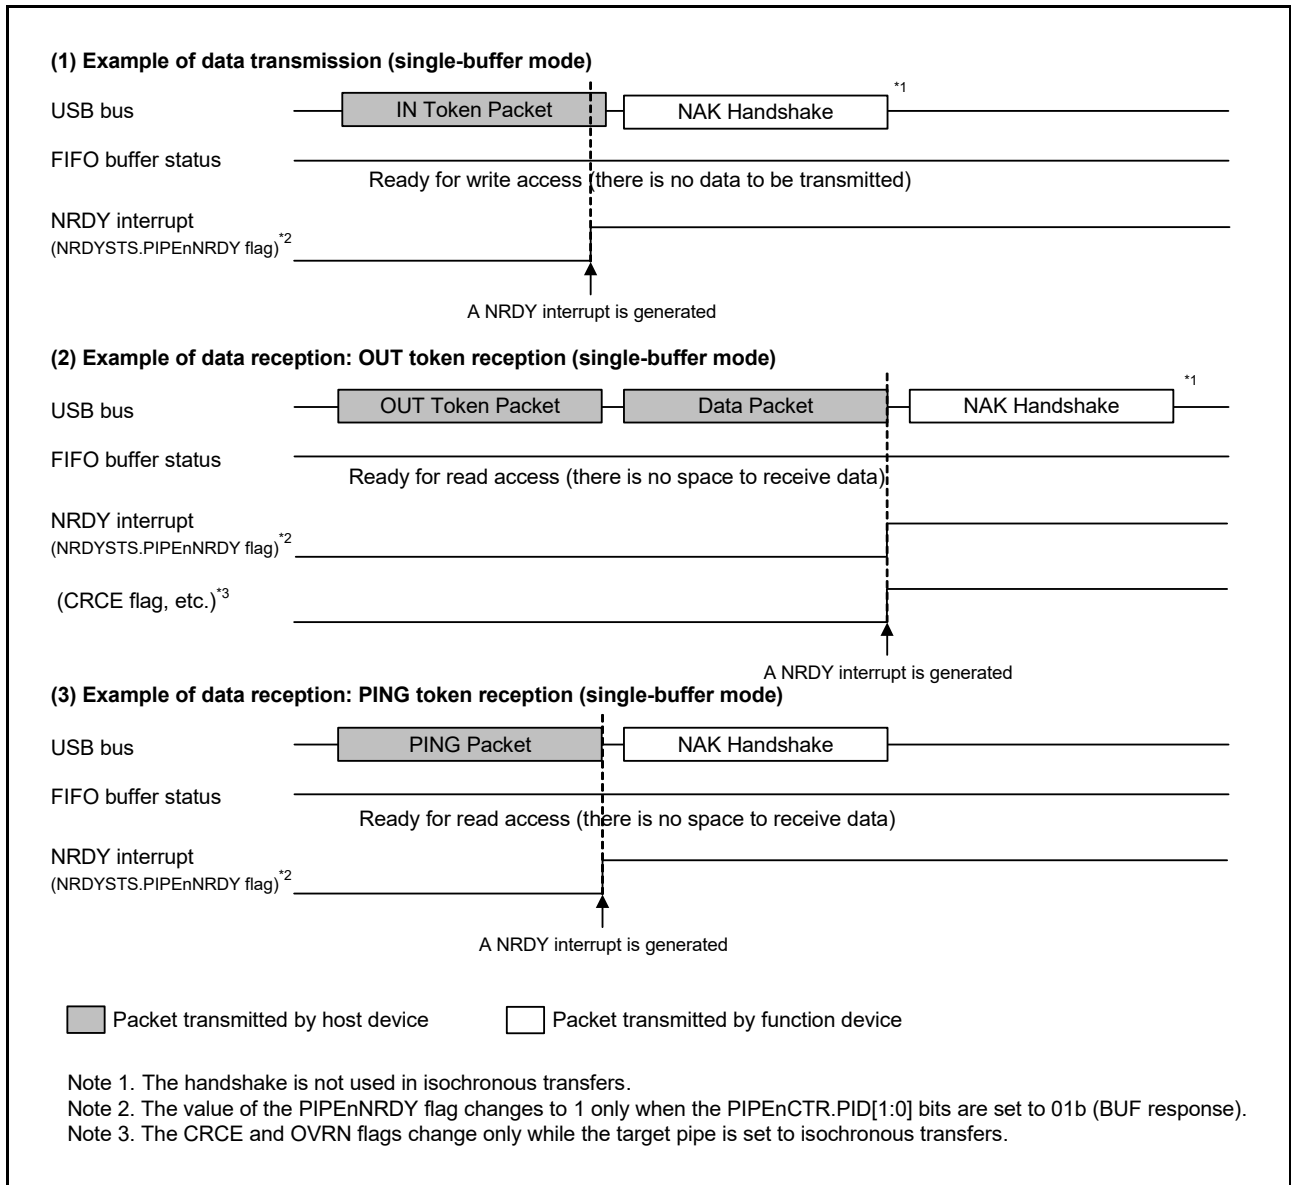

Figure 31.8 Timing of NRDY Interrupt Generation (When Function Controller is Selected)

### 31.3.3.3 BEMP Interrupt

On detecting a BEMP interrupt for the pipe whose PID[1:0] bits are set to 01b (BUF) by software, the USB sets the corresponding BEMPSTS.PIPEnBEMP flag to 1. If the corresponding bit in the BEMPENB register has been set to 1 by software, the USB sets the INTSTS0.BEMP flag to 1 and generates a USB interrupt.

The following describes the conditions on which the USB generates an internal BEMP interrupt request.

**(1) For the pipe in the transmitting direction:**

When the FIFO buffer of the corresponding pipe is empty on completion of transmission (including zero-length packet transmission).

In single buffer mode, an internal BEMP interrupt request is generated simultaneously with the BRDY interrupt for the pipe other than DCP. However, the internal BEMP interrupt request is not generated on any of the following conditions.

- When the CPU or DMAC/DTC has already started writing data to the FIFO buffer of the CPU on completion of transmitting data from one FIFO buffer in double buffer mode.
- When the buffer is cleared (emptied) by setting the PIPEnCTR.ACLRM or the BCLR bit in the port control register to 1.
- When IN transfer (zero-length packet transmission) is performed during the control transfer status stage while the function controller is selected.

**(2) For the pipe in the receiving direction:**

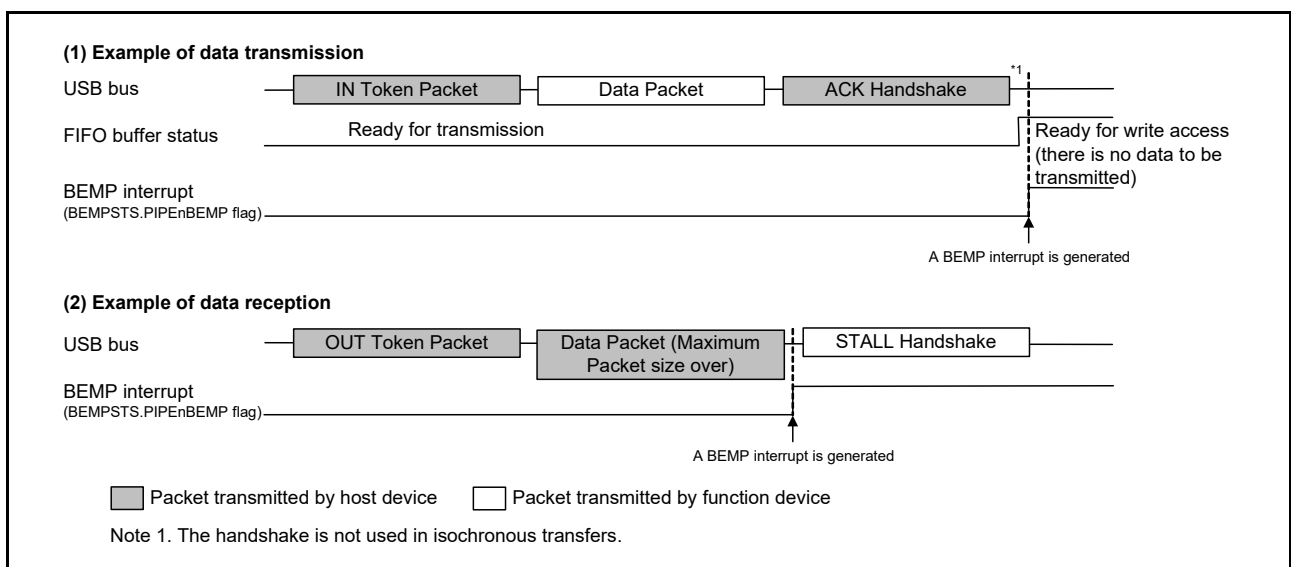

When the successfully-received data packet size exceeds the specified maximum packet size.

In this case, the USB generates a BEMP interrupt request, sets the corresponding BEMPSTS.PIPEnBEMP flag to 1, discards the received data, and modifies the setting of the PID[1:0] bits of the corresponding pipe to 11b (STALL). Here, the USB returns no response when used as the host controller, and returns STALL response when used as the function controller.

However, the internal BEMP interrupt request is not generated on any of the following conditions.

- When a CRC error or a bit stuffing error is detected in the received data.
- When a setup transaction is being performed,  
Writing 0 to the BEMPSTS.PIPEnBEMP flag clears the status.  
Writing 1 to the BEMPSTS.PIPEnBEMP flag has no effect.

Figure 31.9 shows the timing of BEMP interrupt generation when the function controller is selected.

**Figure 31.9 Timing of BEMP Interrupt Generation (When Function Controller is Selected)**

### 31.3.3.4 Device State Transition Interrupt

Figure 31.10 is a diagram of device state transitions in the USB. The USB controls device state and generates device state transition interrupts. However, recovery from the suspended state (resume signal detection) is detected by means of the resume interrupt. The device state to which a transition was made can be confirmed using the INTSTS0.DVSQ[2:0] flags.

When a transition is made to the default state, a device state transition interrupt is generated after a USB bus reset is detected.

Device state can be controlled only when the function controller is selected. The device state transition interrupts can also be generated only when the function controller is selected.

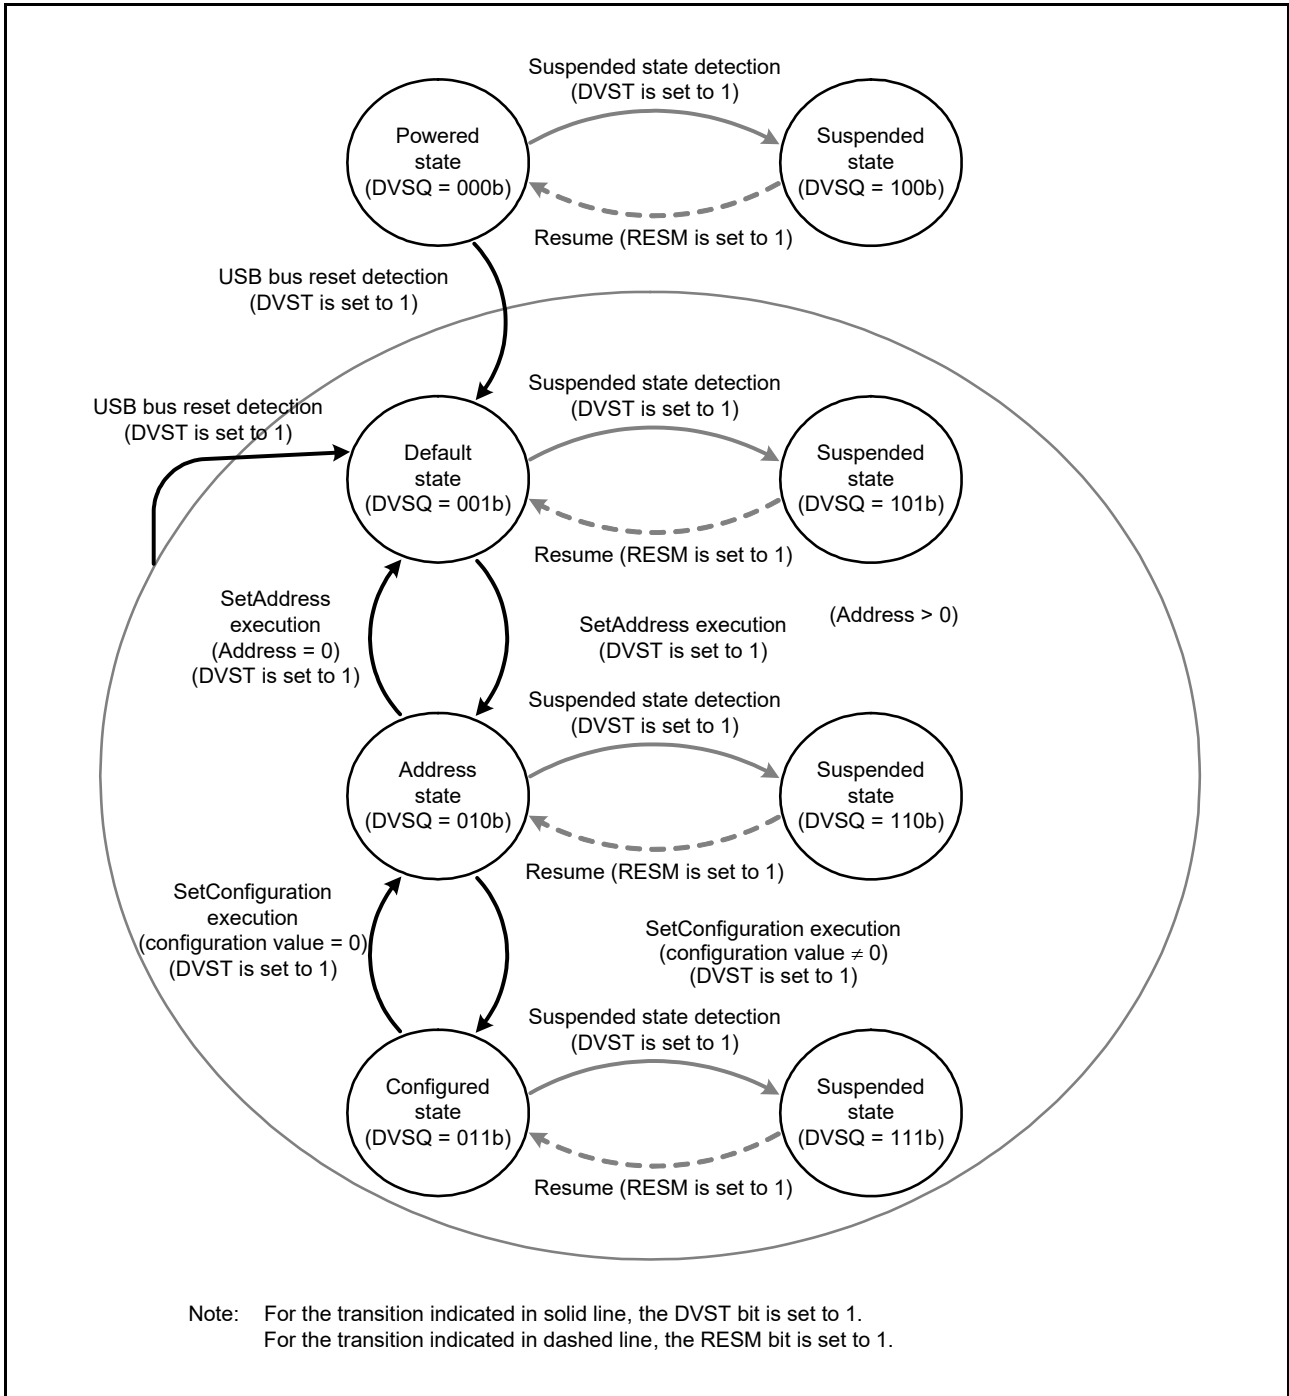

Figure 31.10 Device State Transitions

### 31.3.3.5 Control Transfer Stage Transition Interrupt

Figure 31.11 is a diagram of control transfer stage transitions in the USB. The USB controls the control transfer sequence and generates control transfer stage transition interrupts. The control transfer stage transition interrupts can be enabled or disabled individually using INTENB0. The transfer stage to which a transition was made can be confirmed using the INTSTS0.CTSQ[2:0] flags.

Control transfer stage transition interrupts are generated only when the function controller is selected.

The control transfer sequence errors are listed below. If an error occurs, the DCPCTR.PID[1:0] bits are set to 1xb (STALL response).

During control read transfer:

- An OUT token is received while no data has been transferred for the IN token at the data stage.
- An IN token is received at the status stage.
- A data packet with PID = DATA0 is received at the status stage.

During control write transfer:

- An IN token is received while no ACK response has been returned for the OUT token at the data stage.
- A data packet with PID = DATA0 is received for the first data packet at the data stage.
- An OUT token is received at the status stage

During no-data control transfers:

- An OUT token is received at the status stage.

At the control write transfer data stage, if the number of receive data exceeds the wLength value of the USB request, it cannot be recognized as a control transfer sequence error. At the control read transfer status stage, packets other than zero-length packets are received by an ACK response and the transfer ends normally.

When a CTRT interrupt occurs in response to a sequence error (INTSTS0.CTRT = 1), CTSQ[2:0] = 110b value is retained until the CTRT flag = 0 is written from the system (the interrupt status is cleared). Therefore, while CTSQ[2:0] = 110b is being held, the CTRT interrupt that ends the setup stage will not be generated even if a new USB request is received. (The USB retains the setup stage end, and after the interrupt status has been cleared by software, a setup stage end interrupt is generated.)

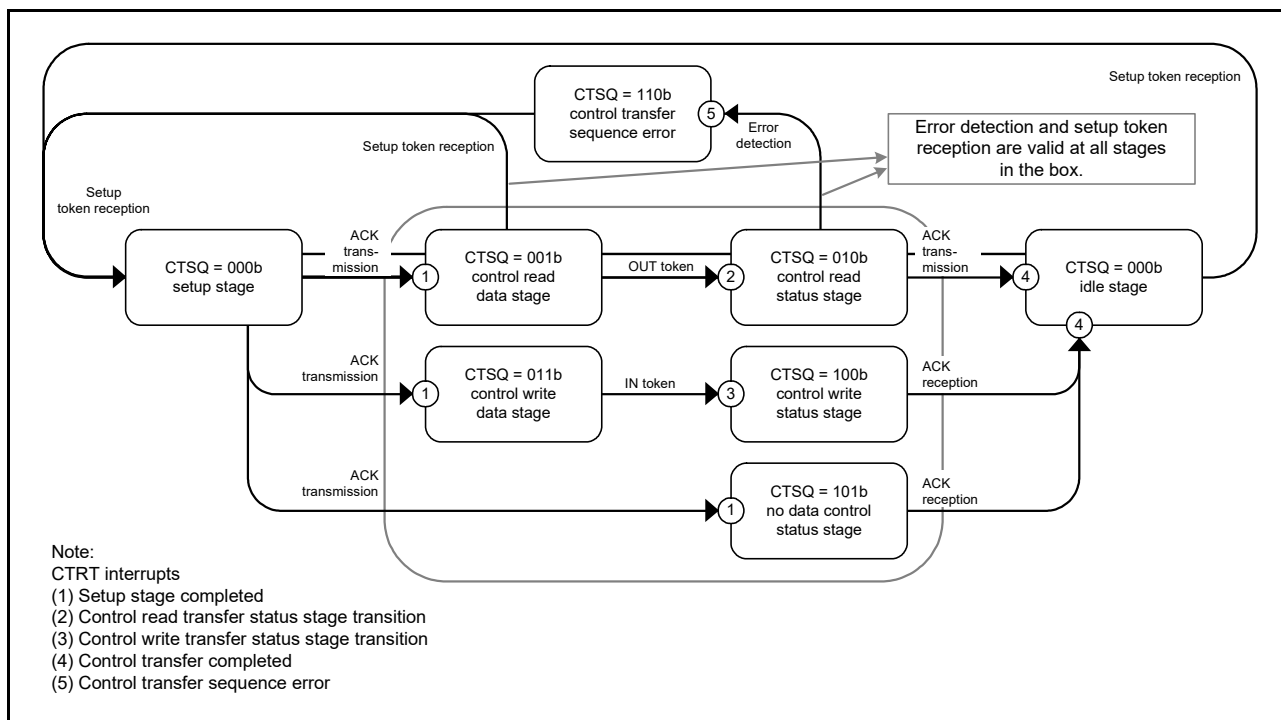

Figure 31.11 Control Transfer Stage Transitions

### 31.3.3.6 Frame Update Interrupt

With the host controller selected, an interrupt is generated at the timing when the frame number is updated. With the function controller selected, an SOFR interrupt is generated when the frame number is updated.

When the function controller is selected, the USB updates the frame number and generates an SOFR interrupt if it detects a new SOF packet during full-speed operation.

### 31.3.3.7 VBUS Interrupt

When the USB0\_VBUS pin level changes, a VBUS interrupt is generated. The level of the USB0\_VBUS pin can be checked with the INTSTS0.VBSTS flag. Whether the host controller is connected or disconnected can be confirmed using the VBUS interrupt. However, if the system is activated with the host controller connected, the first VBUS interrupt is not generated because there is no change in the USB0\_VBUS pin level.

### 31.3.3.8 Resume Interrupt

When the function controller is selected, a resume interrupt is generated when the device state is the suspended state and the USB bus state has changed (from J-state to K-state, or from J-state to SE0). Recovery from the suspended state is detected by means of the resume interrupt.

When the host controller is selected, no resume interrupt is generated. Use the BCHG interrupt to detect a change in the USB bus state.

### 31.3.3.9 OVRCCR Interrupt

An OVRCCR interrupt is generated when the USB0\_OVRCURA or USB0\_OVRCURB pin level has changed. The levels of the USB0\_OVRCURA and USB0\_OVRCURB pins can be checked with the SYSSTS0.OVCMON[1:0] bits. The external power supply IC can check whether overcurrent has been detected using the OVRCCR interrupt.

For OTG connection, whether a change has been detected in the VBUS comparator can be checked using the OVRCCR interrupt.

### 31.3.3.10 BCHG Interrupt

A BCHG interrupt is generated when the USB bus state has changed. The BCHG interrupt can be used to detect whether the peripheral device is connected and can also be used to detect a remote wakeup when the host controller is selected. The BCHG interrupt is generated regardless of whether the host controller or function controller is selected.

### 31.3.3.11 DTCH Interrupt

A DTCH interrupt is generated when disconnection of the USB bus is detected while the host controller is selected. The USB detects bus disconnection based on USB Specification 2.0.

After detecting a DTCH interrupt, the USB controls hardware as described below (irrespective of the value set in the corresponding interrupt enable bit). All pipes in which communications are currently carried out for the pertinent port should be terminated by software and make a transition to the wait state for bus connection to the pertinent port (wait state for ATTCH interrupt generation).

- Modifies the DVSTCTR0.UACT bit for the port in which a DTCH interrupt has been detected to 0.
- Puts the port in which a DTCH interrupt has been generated into the idle state.

### 31.3.3.12 SACK Interrupt

A SACK interrupt is generated when an ACK response for the transmitted setup packet has been received from the peripheral device with the host controller selected. The SACK interrupt can be used to confirm that the setup transaction has been completed successfully.

### 31.3.3.13 SIGN Interrupt

A SIGN interrupt is generated when an ACK response for the transmitted setup packet has not been correctly received from the peripheral device three consecutive times with the host controller selected. The SIGN interrupt can be used to detect no ACK response transmitted from the peripheral device or corruption of an ACK packet.

### 31.3.3.14 ATTCH Interrupt

An ATTCH interrupt is generated when J-state or K-state of the full-speed signal level is detected on the USB port for 2.5  $\mu$ s with the host controller selected. To be more specific, an ATTCH interrupt is detected on any of the following conditions.

- When K-state, SE0, or SE1 changes to J-state, and J-state continues 2.5  $\mu$ s.
- When J-state, SE0, or SE1 changes to K-state, and K-state continues 2.5  $\mu$ s.

### 31.3.3.15 EOFERR Interrupt

An EOFERR interrupt is generated when it is detected that communication is not completed at the EOF2 timing prescribed in USB Specification 2.0.

After detecting an EOFERR interrupt, the USB controls hardware as described below (irrespective of the value set in the corresponding interrupt enable bit). All pipes in which communications are currently carried out for the pertinent port should be terminated by software and perform re-enumeration of the pertinent port.

- Modifies the DVSTCTR0.UACT bit for the port in which an EOFERR interrupt has been detected to 0.
- Puts the port in which an EOFERR interrupt has been generated into the idle state.

### 31.3.4 Pipe Control

Table 31.15 lists the pipe settings for the USB. With USB data transfer, data transfer is carried out using the pipe that the software has associated with the endpoint. The USB has ten pipes that are used for data transfer.

Appropriate settings should be made for each of the pipes according to the specifications of the system.

**Table 31.15 Pipe Settings**

| Register Name       | Bit Name    | Setting                                            | Remarks                                                                                                     |
|---------------------|-------------|----------------------------------------------------|-------------------------------------------------------------------------------------------------------------|
| DCPCFG<br>PIPECFG   | TYPE[1:0]   | Specifies the transfer type                        | Pipes 1 to 9: Can be set                                                                                    |
|                     | BFRE        | Selects the BRDY interrupt mode                    | Pipes 1 to 5: Can be set                                                                                    |
|                     | DBLB        | Selects double buffer mode                         | Pipes 1 to 5: Can be set                                                                                    |
|                     | DIR         | Selects transfer direction                         | IN or OUT can be set                                                                                        |
|                     | EPNUM[3:0]  | Endpoint number                                    | Pipes 1 to 9: Can be set<br>A value other than 0000b should be set when the pipe is used.                   |
|                     | SHTNAK      | Selects disabled state for pipe when transfer ends | Pipes 1 and 2: Can be set (only when bulk transfer has been selected)<br>Pipes 3 to 5: Can be set           |
| DCPMAXP<br>PIPEMAXP | DEVSEL[3:0] | Selects a device                                   | Referenced only when the host controller is selected.                                                       |
|                     | MXPS[8:0]   | Maximum packet size                                | Compliant with USB Specification 2.0.                                                                       |
| PIPEPERI            | IFIS        | Buffer flush                                       | Pipes 1 and 2: Can be set (only when isochronous transfer has been selected)<br>Pipes 3 to 9: Cannot be set |
|                     |             |                                                    | IITV[2:0]                                                                                                   |
| DCPCTR<br>PIPEnCTR  | BSTS        | Buffer status                                      | For the DCP, receive buffer status and transmit buffer status are switched with the ISEL bit.               |
|                     | INBUFM      | IN buffer monitor                                  | Available only for pipes 1 to 5.                                                                            |
|                     | SUREQ       | SETUP request                                      | Can be set only for the DCP.<br>Can be controlled only when the host controller has been selected.          |
|                     | SUREQCLR    | SUREQ clear                                        | Can be set only for the DCP.<br>Can be controlled only when the host controller has been selected.          |
|                     | ATREPM      | Auto response mode                                 | Pipes 1 to 5: Can be set<br>Can be set only when the function controller has been selected.                 |
|                     | ACLRM       | Auto buffer clear                                  | Pipes 1 to 9: Can be set                                                                                    |
|                     | SQCLR       | Sequence clear                                     | Clears the data toggle bit.                                                                                 |
|                     | SQSET       | Sequence set                                       | Sets the data toggle bit.                                                                                   |
|                     | SQMON       | Sequence monitor                                   | Monitors the data toggle bit.                                                                               |
|                     | PBUSY       | Pipe busy status                                   |                                                                                                             |
|                     | PID[1:0]    | Response PID                                       | Refer to section 31.3.4.6, Response PID.                                                                    |
| PIPEnTRE            | TRENB       | Transaction counter enable                         | Pipes 1 to 5: Can be set                                                                                    |
|                     | TRCLR       | Current transaction counter clear                  | Pipes 1 to 5: Can be set                                                                                    |
| PIPEnTRN            | —           | Transaction counter                                | Pipes 1 to 5: Can be set                                                                                    |

### 31.3.4.1 Pipe Control Register Switching Procedures

The following bits in the pipe control registers can be modified only when USB communication is prohibited (PID[1:0] = 00b (NAK)).

The following shows the registers and bits that should not be modified when USB communication is enabled (PID[1:0] = 01b (BUF)).

- Bits in the DCPCFG and DCPMAXP registers
- The SQCLR and SQSET bits in the DCPCTR register
- Bits in registers PIPECFG, PIPEMAXP, and PIPEPERI
- The ATREPM, ACLRM, SQCLR, and SQSET bits in the PIPEnCTR register
- Bits in the PIPEnTRE and PIPEnTRN registers

In order to modify the above bits in the USB communication enabled (PID[1:0] = 01b (BUF)) state, follow the procedure shown below:

1. A request to modify bits in the pipe control register occurs.
2. Modify the PID[1:0] bits corresponding to the pipe to 00b (NAK).
3. Wait until the corresponding PBUSY flag is set to 0.
4. Modify the bits in the pipe control register.

The following bits in the pipe control registers can be modified only when the pertinent pipe information has not been set by the CURPIPE[3:0] bits in registers CFIFOSEL, D0FIFOSEL, and D1FIFOSEL.

Registers that should not be set when the CURPIPE[3:0] bits are set:

- Bits in the DCPCFG and DCPMAXP register
- Bits in registers PIPECFG, PIPEMAXP and PIPEPERI

In order to modify pipe information, the CURPIPE[3:0] bits in the port select registers should be set to a pipe other than the pipe to be modified. For the DCP, the buffer should be cleared using the BCLR bit in the port control register after the pipe information is modified.

### 31.3.4.2 Transfer Types

The PIPECFG.TYPE[1:0] bits are used to specify the transfer type for each pipe. The transfer types that can be set for the pipes are as follows.

- DCP: No setting is necessary (fixed at control transfer).
- Pipes 1 and 2: These should be set to bulk transfer or isochronous transfer.
- Pipes 3 to 5: These should be set to bulk transfer.
- Pipes 6 to 9: These should be set to interrupt transfer.

### 31.3.4.3 Endpoint Number

The PIPECFG.EPNUM[3:0] bits are used to set the endpoint number for each pipe. The DCP is fixed at endpoint 0. The other pipes can be set from endpoint 1 to endpoint 15.

- DCP: No setting is necessary (fixed at endpoint 0).
- Pipes 1 to 9: The endpoint numbers from 1 to 15 should be selected and set.  
These should be set so that the combination of the PIPECFG.DIR bit and EPNUM[3:0] bits is unique.

### 31.3.4.4 Maximum Packet Size Setting

The DCPMAXP.MXPS[6:0] bits and the PIPEMAXP.MXPS[8:0] bits are used to specify the maximum packet size for each pipe. DCP and pipes 1 to 5 can be set to any of the maximum pipe sizes defined by USB Specification 2.0. For pipes 6 to 9, 64 bytes are the upper limit of the maximum packet size. The maximum packet size should be set before beginning the transfer (PID[1:0] = 01b (BUF)).

- DCP: Set 8, 16, 32, or 64.
- Pipes 1 to 5: Set 8, 16, 32, or 64 when using bulk transfer.
- Pipes 1 and 2: Set a value between 1 and 256 when using isochronous transfer.
- Pipes 6 to 9: Set a value between 1 and 64.

### 31.3.4.5 Transaction Counter (For Pipes 1 to 5 in Reading Direction)

When the specified number of transactions has been completed in the data packet receiving direction, the USB recognizes that the transfer has ended. Two transaction counters are provided: one is the PIPEnTRN register that specifies the number of transactions to be executed and the other is the current counter that internally counts the number of executed transactions. With the PIPECFG.SHTNAK bit set to 1, when the current counter value matches the specified number of transactions, the corresponding PIPEnCTR.PID[1:0] bits are set to 00b (NAK) and the subsequent transfer is disabled. The transactions can be counted again from the beginning by initializing the current counter of the transaction counter function through the PIPEnTRE.TRCLR bit. The information read from PIPEnTRN differs depending on the setting of the PIPEnTRE.TRENB bit.

- The TRENB bit = 0: The specified transaction counter value can be read.
- The TRENB bit = 1: The current counter value indicating the internally counted number of executed transactions can be read.

When operating the TRCLR bit, the following should be noted.

- If the transactions are being counted and PID[1:0] = 01b (BUF), the current counter cannot be cleared.
- If there is any data left in the buffer, the current counter cannot be cleared.

### 31.3.4.6 Response PID

The PID[1:0] bits in the DCPCTR and PIPEnCTR registers are used to set the response PID for each pipe. The following shows the USB operation with various response PID settings:

#### (1) Response PID settings when the host controller is selected:

The response PID is used to specify the execution of transactions.

- NAK setting: Using pipes is disabled. No transaction is executed.
- BUF setting: Transactions are executed based on the status of the buffer memory.  
For OUT direction: If there are transmit data in the buffer memory, an OUT token is issued.  
For IN direction: If there is an area to receive data in the buffer memory, an IN token is issued.
- STALL setting: Using pipes is disabled. No transaction is executed.

Note: Setup transactions for the DCP are set with the DCPCTR.SUREQ bit.

#### (2) Response PID settings when the function controller is selected:

The response PID is used to specify the response to transactions from the host.

- NAK setting: The NAK response is returned in response to the generated transaction.
- BUF setting: Responses are made to transactions according to the status of the buffer memory.
- STALL setting: The STALL response is returned in response to the generated transaction.

Note: For setup transactions, an ACK response is returned regardless of the PID[1:0] bits setting, and the USB request is stored in the register.

The USB may write to the PID[1:0] bits, depending on the results of the transaction as described below.

#### (3) When the host controller has been selected and the response PID is set by hardware:

- NAK setting: In the following cases, PID[1:0] = 00b (NAK) is set and issuing of tokens is automatically stopped:  
When a transfer other than isochronous transfer has been performed and an NRDY interrupt is generated.  
(For details, refer to section 31.3.3.2, NRDY Interrupt.)  
- If a short packet is received when the PIPECFG.SHTNAK bit has been set to 1 for bulk transfer.  
- If the transaction counting ends when the SHTNAK bit has been set to 1 for bulk transfer.
- BUF setting: There is no BUF writing by the USB.
- STALL setting: In the following cases, PID[1:0] = 1xb (STALL) is set and issuing of tokens is automatically stopped:  
When STALL is received in response to the transmitted token.  
When the size of the receive data packet exceeds the maximum packet size.

#### (4) When the function controller has been selected and the response PID is set by hardware:

- NAK setting: In the following cases, PID[1:0] = 00b (NAK) is set and NAK is returned in response to transactions:  
When the SETUP token is received normally (DCP only).  
If the transaction counting ends or a short packet is received when the PIPECFG.SHTNAK bit has been set to 1 for bulk transfer.
- BUF setting: There is no BUF writing by the USB.
- STALL setting: In the following cases, PID[1:0] = 1xb (STALL) is set and STALL is returned in response to transactions:  
When a maximum packet size exceeded error is detected in the received data packet.  
When a control transfer sequence error has been detected (DCP only).

### 31.3.4.7 Data PID Sequence Bit

The USB automatically toggles the sequence bit in the data PID when data is transferred successfully in the control transfer data stage, bulk transfer, and interrupt transfer. The sequence bit of the next data PID to be transmitted can be confirmed with the SQMON flag in the DCPCTR and PIPEnCTR registers. When data is transmitted, the sequence bit switches at the timing of ACK handshake reception. When data is received, the sequence bit switches at the timing of ACK handshake transmission. The DCPCTR.SQCLR bit and the PIPEnCTR.SQSET bit can be used to change the data PID sequence bit.

When the function controller has been selected and control transfer is used, the USB automatically sets the sequence bit when a stage transition is made. DATA1 is returned when the setup stage is ended. The sequence bit is not referenced and PID = DATA1 is returned in a status stage. Therefore, software settings are not required. However, when the host controller has been selected and control transfer is used, the sequence bit should be set by software at a stage transition. For the ClearFeature request transmission or reception, the data PID sequence bit should be set by software regardless of whether the host controller or function controller is selected.

### 31.3.4.8 Response PID = NAK Function

The USB has a function that disables pipe operation (response PID = NAK) at the timing at which the final data packet of a transaction is received (the USB automatically distinguishes this based on reception of a short packet or the transaction counter) by setting the PIPECFG.SHTNAK bit to 1.

When the double buffer mode is being used for the buffer memory, using this function enables reception of data packets in transfer units. If pipe operation has been disabled, software should set the pipe to the enabled state again (response PID = BUF).

The response PID = NAK function can be used only when bulk transfers are used.

### 31.3.4.9 Auto Response Mode

With the pipes for bulk transfer (pipe 1 to pipe 5), when the PIPEnCTR.ATREPM bit is set to 1, a transition is made to auto response mode. During an OUT transfer (the PIPECFG.DIR bit = 0), OUT-NAK mode is entered, and during an IN transfer (the DIR bit = 1), null auto response mode is entered.

### 31.3.4.10 OUT-NAK Mode

With the pipes for bulk OUT transfer, NAK is returned in response to an OUT token and an NRDY interrupt is output when the PIPEnCTR.ATREPM bit is set to 1. To make a transition from normal mode to OUT-NAK mode, OUT-NAK mode should be specified in the pipe operation disabled state (response PID = NAK) before enabling pipe operation (response PID = BUF). After pipe operation has been enabled, OUT-NAK mode becomes valid. However, if an OUT token is received immediately before pipe operation is disabled, the token data is normally received, and an ACK is returned to the host.

To make a transition from OUT-NAK mode to normal mode, OUT-NAK mode should be canceled in the pipe operation disabled state (response PID = NAK) before enabling pipe operation (response PID = BUF). In normal mode, reception of OUT data is enabled.

### 31.3.4.11 Null Auto Response Mode

With the pipes for bulk IN transfer, zero-length packets are continuously transmitted when the PIPEnCTR.ATREPM bit is set to 1.

To make a transition from normal mode to null auto response mode, null auto response mode should be set in the pipe operation disabled state (response PID = NAK) before enabling pipe operation (response PID = BUF). After pipe operation has been enabled, null auto response mode becomes valid. Before setting null auto response mode, the PIPEnCTR.INBUFM = 0 should be confirmed because the mode can be set only when the buffer is empty. If the INBUFM flag is 1, the buffer should be emptied with the PIPEnCTR.ACLRM bit. While a transition to null auto response mode is being made, data should not be written from the FIFO port.

To make a transition from null auto response mode to normal mode, pipe operation disabled state (response PID = NAK) should be retained for the period of zero-length packet transmission (about 10  $\mu$ s) before canceling null auto response mode. In normal mode, data can be written from the FIFO port; therefore, packet transmission to the host is enabled by enabling pipe operation (response PID = BUF).

## 31.3.5 FIFO Buffer Memory

### 31.3.5.1 FIFO Buffer Memory

The USB has FIFO buffer memory for data transfer. The memory area used for each pipe is managed by the USB. The FIFO buffer memory has two states depending on whether the access right is assigned to the system (CPU side) or the USB (SIE side).

#### (1) Buffer Status

Table 31.16 and Table 31.17 show the buffer status in the USB. The buffer memory status can be confirmed using the DCPCTR.BSTS flag and the PIPEnCTR.INBUFM flag. The transfer direction for the buffer memory can be specified using either the PIPECFG.DIR bit or the CFIFOSEL.ISEL bit (when DCP is selected).

The INBUFM flag is valid for pipe 0 to pipe 5 in the transmitting direction.

When a transmitting pipe uses the double buffer configuration, software can read the BSTS flag to monitor the buffer memory status on the CPU side and the INBUFM flag to monitor the buffer memory status on the SIE side. When the BEMP interrupt may not show the buffer empty status because the write access to the FIFO port by the CPU or DMAC/DTC is slow, software can use the INBUFM flag to confirm the end of transmission.

**Table 31.16 Buffer Status Indicated by the BSTS Flag**

| ISEL or DIR                | BSTS | Buffer Memory Status                                                                                                                                                                                                     |
|----------------------------|------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0 (receiving direction)    | 0    | There is no received data, or data is being received.<br>Reading from the FIFO port is disabled.                                                                                                                         |
| 0 (receiving direction)    | 1    | There is received data, or a zero-length packet has been received.<br>Reading from the FIFO port is allowed.<br>Note that when a zero-length packet is received, reading is not possible and the buffer must be cleared. |
| 1 (transmitting direction) | 0    | The transmission has not been completed.<br>Writing to the FIFO port is disabled.                                                                                                                                        |
| 1 (transmitting direction) | 1    | The transmission has been completed.<br>CPU write is allowed.                                                                                                                                                            |

**Table 31.17 Buffer Status Indicated by the INBUFM Flag**

| DIR                        | INBUFM  | Buffer Memory Status                                                                |
|----------------------------|---------|-------------------------------------------------------------------------------------|
| 0 (receiving direction)    | Invalid | Invalid                                                                             |
| 1 (transmitting direction) | 0       | The transmission has been completed.<br>There is no waiting data to be transmitted. |
| 1 (transmitting direction) | 1       | The FIFO port has written data to the buffer.<br>There is data to be transmitted.   |

### 31.3.5.2 FIFO Buffer Clearing

Table 31.18 shows the clearing of the FIFO buffer memory by the USB. The buffer memory can be cleared using the BCLR, DnFIFOSEL.DCLRM, and PIPEnCTR.ACLRM bit in the port control register.

Either a single or double buffer configuration can be selected for pipes 1 to 5, using the PIPECFG.DBLB bit.

**Table 31.18 List of Buffer Clearing Methods**

| FIFO Buffer Clearing Mode | Clearing Buffer Memory on CPU Side | Mode for Automatically Clearing Buffer Memory after Reading Specified Pipe Data | Auto Buffer Clear Mode for Discarding All Received Packets |
|---------------------------|------------------------------------|---------------------------------------------------------------------------------|------------------------------------------------------------|
| Register used             | CFIFOCTR<br>DnFIFOCTR              | DnFIFOSEL                                                                       | PIPEnCTR                                                   |
| Bit used                  | BCLR                               | DCLRM                                                                           | ACLRM                                                      |
| Clearing condition        | Cleared by writing 1               | 1: Mode valid<br>0: Mode invalid                                                | 1: Mode valid<br>0: Mode invalid                           |

#### (1) Auto Buffer Clear Mode Function

With the USB, all received data packets are discarded if the PIPEnCTR.ACLRM bit is set to 1. If a correct data packet has been received, the ACK response is returned to the host controller. The auto buffer clear mode function can be set only in the buffer memory reading direction.

If the ACLRM bit is set to 1 and then to 0, the buffer memory of the selected pipe can be cleared regardless of the access direction.

An access cycle of at least 100 ns is required for the internal hardware sequence processing time between ACLRM = 1 and ACLRM = 0.

### 31.3.5.3 FIFO Port Functions

Table 31.19 shows the settings for the FIFO port functions of the USB. In write access, writing data until the maximum packet size is reached automatically enables transmission of the data. To enable transmission before the maximum packet size is reached, the BVAL bit in the port control register should be set to end writing. To send a zero-length packet, the BCLR bit in the register should be used to clear the buffer and then the BVAL bit set in order to end writing.

In reading, reception of new packets is automatically enabled when all data has been read. Data cannot be read when a zero-length packet has been received (the DTLN[8:0] flags = 0), so the BCLR bit in the register should be used to clear the buffer. The length of the receive data can be confirmed using the DTLN[8:0] flags in the port control register.

**Table 31.19 FIFO Port Function Settings**

| Register                             | Bit          | Description                                                                                            |
|--------------------------------------|--------------|--------------------------------------------------------------------------------------------------------|
| CFIFOSEL,<br>DnFIFOSEL<br>(n = 0, 1) | RCNT         | Selects DTLN[8:0] read mode.                                                                           |
|                                      | REW          | Buffer memory rewind (re-read, rewrite).                                                               |
|                                      | DCLRM        | Automatically clears receive data for a specified pipe after the data has been read (only for DnFIFO). |
|                                      | DREQE        | Enables DMA/DTC transfers (only for DnFIFO).                                                           |
|                                      | MBW          | FIFO port access bit width.                                                                            |
|                                      | BIGEND       | Selects FIFO port endian.                                                                              |
|                                      | ISEL         | FIFO port access direction (only for DCP).                                                             |
|                                      | CURPIPE[3:0] | Selects the current pipe.                                                                              |
| CFIFOCTR,<br>DnFIFOCTR<br>(n = 0, 1) | BVAL         | Ends writing to the buffer memory.                                                                     |
|                                      | BCLR         | Clears the buffer memory on the CPU side.                                                              |
|                                      | DTLN[8:0]    | Checks the length of receive data.                                                                     |

#### (1) FIFO Port Selection

Table 31.20 shows the pipes that can be selected with the various FIFO ports. The pipe to be accessed should be selected using the CURPIPE[3:0] bits in the port select register. After the pipe is selected, whether the written value can be correctly read from the CURPIPE[3:0] bits should be checked. (If the previous pipe number is read, it indicates that the pipe modification is being executed by the USB controller.) Then, the FRDY flag in a port control register = 1 is checked.

In addition, the bus width to be accessed should be selected using the MBW bit in the port select register. The buffer memory access direction conforms to the PIPECFG.DIR bit. Only for the DCP, the ISEL bit in the port select register determines the direction.

**Table 31.20 FIFO Port Access Categorized by Pipe**

| Pipe             | Access Method   | Port that can be Used                              |
|------------------|-----------------|----------------------------------------------------|
| DCP              | CPU access      | CFIFO port register                                |
| Pipe 1 to pipe 9 | CPU access      | CFIFO port register<br>D0FIFO/D1FIFO port register |
|                  | DMAC/DTC access | D0FIFO/D1FIFO port register                        |

#### (2) REW Bit

It is possible to temporarily stop access to the pipe currently being accessed, access a different pipe, and then continue processing for the current pipe again. The REW bit in the port select register is used for this processing.

If a pipe is selected through the CURPIPE[3:0] bits in the port select register with the REW bit set to 1, the pointer used for reading from and writing to the buffer memory is reset, and reading or writing can be carried out from the first byte.

If a pipe is selected with 0 set for the REW bit, data can be read and written in continuation from the previous selection, without the pointer being reset.

To access the FIFO port, the FRDY flag in the port control register = 1 should be checked after selecting a pipe.

### 31.3.5.4 DMA Transfers (D0FIFO and D1FIFO Ports)

#### (1) Overview of DMA Transfers

For pipes 1 to 9, the FIFO port can be accessed using the DMAC. When accessing the buffer for the pipe targeted for DMA transfer is enabled, a DMA transfer request is issued.

The unit of transfer to the FIFO port should be selected using the DnFIFOSEL.MBW bit and the pipe targeted for the DMA transfer should be selected using the DnFIFOSEL.CURPIPE[3:0] bits. The selected pipe should not be changed during the DMA transfer.

#### (2) DnFIFO Auto Clear Mode (D0FIFO and D1FIFO Port Reading Direction)

If 1 is set in the DnFIFOSEL.DCLRM bit, the USB automatically clears the buffer memory of the selected pipe when reading of data from the buffer memory has been completed.

Table 31.21 shows the packet reception and buffer memory clearing processing by software for each of the various settings. As shown in Table 31.21, the buffer clearing conditions depend on the value set in the PIPECFG.BFRE bit. Using the DnFIFOSEL.DCLRM bit eliminates the need for the buffer to be cleared by software in any situation that requires buffer clearing. This enables DMA transfers without involving software.

The DnFIFO auto clear mode can be set only in the buffer memory reading direction.

**Table 31.21 Packet Reception and Buffer Memory Clearing Processing by Software**

| Buffer Status<br>When Packet is Received | Register Setting          |                           |                           |                           |
|------------------------------------------|---------------------------|---------------------------|---------------------------|---------------------------|
|                                          | DCLRM = 0                 |                           | DCLRM = 1                 |                           |
|                                          | BFRE = 0                  | BFRE = 1                  | BFRE = 0                  | BFRE = 1                  |
| Buffer full                              | Clearing is not necessary | Clearing is not necessary | Clearing is not necessary | Clearing is not necessary |
| Zero-length packet reception             | Clearing is necessary     | Clearing is necessary     | Clearing is not necessary | Clearing is not necessary |
| Normal short packet reception            | Clearing is not necessary | Clearing is necessary     | Clearing is not necessary | Clearing is not necessary |
| Transaction count end                    | Clearing is not necessary | Clearing is necessary     | Clearing is not necessary | Clearing is not necessary |

### 31.3.6 Control Transfers Using DCP

In the data stage of control transfers, data is transferred using the default control pipe (DCP).

The DCP buffer memory is a 64-byte single buffer and is a fixed area that is shared for both control reading and control writing. The buffer memory can be accessed only through the CFIFO port.

#### 31.3.6.1 Control Transfers When the Host Controller is Selected

##### (1) Setup Stage

Registers USBREQ, USBVAL, USBINDEX, and USBLENG are the registers that are used to transmit a USB request for setup transactions. Writing setup packet data to the registers and writing 1 to the DCPCTR.SUREQ bit transmits the specified data for setup transactions. Upon completion of the transaction, the SUREQ bit is set to 0. The above USB request registers should not be modified while SUREQ = 1.

After the attached state of the connected function device is detected, the first setup transaction for the device should be issued by using the sequence described above with the DCPMAXP.DEVSEL[3:0] bits set to 0 and the DEVADD0.USBSPEED[1:0] bits set appropriately.

After the connected function device is shifted to the Address state, setup transactions should be issued by using the sequence described above with the assigned USB address set in the DEVSEL[3:0] bits and the bits in the DEVADDn register corresponding to the specified USB address set appropriately. For example, when PIPEMAXP.DEVSEL[3:0] = 0010b, make appropriate settings in the DEVADD2 register; when PIPEMAXP.DEVSEL[3:0] = 0101b, make appropriate settings in the DEVADD5 register.

When the setup transaction data has been sent, an interrupt request is generated according to the response received from the peripheral device (SIGN or SACK flag in the INTSTS1 register), by means of which the result of the setup transactions can be confirmed.

A data packet of DATA0 (USB request) is transmitted as the data packet for a setup transaction regardless of the setting of the DCPCTR.SQMON flag.

##### (2) Data Stage

Data is transferred using the DCP buffer memory.

The access direction of the DCP buffer memory should be specified using the CFIFOSEL.ISEL bit. The transfer direction should be specified using the DCPCFG.DIR bit.

For the first data packet of the data stage, the data PID should be transferred as DATA1. Set data PID = DATA1 in the DCPCTR.SQSET bit and the PID[1:0] bits = 01b (BUF). Completion of data transfer is detected using the BRDY or BEMP interrupt.

For control write transfers, when the number of data bytes to be sent is an integer multiple of the maximum packet size, software should control so as to send a zero-length packet at the end.

##### (3) Status Stage

Zero-length packet data is transferred in the direction opposite to that in the data stage. As in the data stage, data is transferred using the DCP buffer memory. Transactions are done in the same manner as the data stage.

For the data packets of the status stage, the data PID should be set to DATA1 using the DCPCTR.SQSET bit.

For reception of a zero-length packet, the received data length should be confirmed using the CFIFOCTR.DTLN[8:0] flags after a BRDY interrupt is generated, and the buffer memory should then be cleared using the CFIFOCTR.BCLR bit.

### 31.3.6.2 Control Transfers When the Function Controller is Selected

#### (1) Setup Stage

The USB sends an ACK response for a correct setup packet targeted to the USB. The operation of the USB in the setup stage is described below.

When receiving a new setup packet, the USB sets the following bits.

- Set the INTSTS0.VALID flag to 1.
- Set the DCPCTR.PID[1:0] bits to 00b (NAK).
- Set the DCPCTR.CCPL bit to 0.

When receiving a data packet right after the setup packet, the USB stores the USB request parameters in registers USBREQ, USBVAL, USBINDX, and USBLENG.

Response processing with respect to the control transfer should be carried out after setting the VALID flag = 0. In the VALID flag = 1 state, PID[1:0] = 01b (BUF) cannot be set, and the data stage cannot be terminated.

Using the function of the VALID flag, the USB can suspend the current request processing when receiving a new USB request during a control transfer, and can send a response to the newest request.

In addition, the USB automatically detects the direction bit (bit 8 of bmRequestType) and the request data length (wLength) of the received USB request, distinguishes between control read transfer, control write transfer, and no-data control transfer, and controls stage transitions. For a wrong sequence, the sequence error of the control transfer stage transition interrupt is generated, and the software is notified of occurrence of the error. For the stage control of the USB, refer to Figure 31.11.

#### (2) Data Stage

Data transfers corresponding to received USB requests should be done using the DCP. Before accessing the DCP buffer memory, the access direction should be specified using the CFIFOSEL.ISEL bit.

If the transfer data is larger than the size of the DCP buffer memory, the data transfer should be carried out using the BRDY interrupt for control write transfers and the BEMP interrupt for control read transfers.

#### (3) Status Stage

Control transfers are terminated by setting the DCPCTR.CCPL bit to 1 while the DCPCTR.PID[1:0] bits are set to 01b (BUF).

After the above settings have been made, the USB automatically executes the status stage in accordance with the data transfer direction determined at the setup stage. The specific procedure is as follows.

- For control read transfers  
A zero-length packet is received from the USB host and an ACK response is sent.
- For control write transfers and no-data control transfers  
A zero-length packet is transmitted and an ACK response is received from the USB host.

#### (4) Control Transfer Auto Response Function

The USB automatically responds to a correct SET\_ADDRESS request. If any of the following errors occurs in the SET\_ADDRESS request, a response from the software is necessary.

- bmRequestType is not 00h: Any transfer other than a control write transfer
- wIndex is not 00h: Request error
- wIndex is not 00h: Any transfer other than a no-data control transfer
- wValue is larger than 7Fh: Request error
- INTSTS0.DVSQ[2:0] are 011b (Configured state): Control transfer of a device state error

For all requests other than the SET\_ADDRESS request, a response is required from the corresponding software.

### 31.3.7 Bulk Transfers (Pipes 1 to 5)

The buffer memory usage (single/double buffer setting) can be selected for bulk transfers. The USB provides the following functions for bulk transfers.

- BRDY interrupt function (PIPECFG.BFRE bit: refer to section 31.3.3.1, (2) When the SOFCFG.BRDYM Bit = 0 and the PIPECFG.BFRE Bit = 1)
- Transaction count function (PIPEnTRE.TRENB and TRCLR bits and PIPEnTRN register: refer to section 31.3.4.5, Transaction Counter (For Pipes 1 to 5 in Reading Direction))
- Response PID = NAK function (PIPECFG.SHTNAK bit: refer to section 31.3.4.8, Response PID = NAK Function)
- Auto response mode (PIPEnCTR.ATREPM bit: refer to section 31.3.4.9, Auto Response Mode)

### 31.3.8 Interrupt Transfers (Pipes 6 to 9)

When the function controller is selected, the USB carries out interrupt transfers in accordance with the timing controlled by the host controller.

When the host controller is selected, the timing of issuing a token can be specified using the interval counter.

#### 31.3.8.1 Interval Counter during Interrupt Transfers When the Host Controller is Selected

For interrupt transfers, intervals between transactions are set in the PIPEPERI.IITV[2:0] bits. The USB controller issues interrupt transfer tokens based on the specified intervals.

##### (1) Counter Initialization

The interval counter is initialized when the MCU is reset or when the PIPEnCTR.ACLRM bit is set to 1. Note that the PIPEPERI.IITV[2:0] bits are not initialized when the ACLRM bit is used for initialization.

Note that the interval counter is not initialized in the following case.

- USB bus reset or USB suspended  
The IITV[2:0] bits are not initialized. Setting 1 to the DVSTCTR0.UACT bit starts counting from the value before entering the USB bus reset state or USB suspended state.

##### (2) Operation When Transmission/Reception is Impossible at Token Issuance Timing

The USB cannot issue tokens even at token issuance timing in the following cases. In such a case, the USB attempts transactions at the subsequent interval.

- When the PID[1:0] bits are set to 00b (NAK) or 1xb (STALL).
- When the buffer memory is full at the token sending timing in the receiving (IN) direction.
- When there is no data to be sent in the buffer memory at the token sending timing in the transmitting (OUT) direction.

### 31.3.9 Isochronous Transfers (Pipes 1 and 2)

The USB has the following functions for isochronous transfers.

- Notification of isochronous transfer error information
- Interval counter (specified by the PIPEPERI.IITV[2:0] bits)
- Isochronous IN transfer data setup control (IDLX function)
- Isochronous IN transfer buffer flush function (specified by the PIPEPERI.IFIS bit)

#### 31.3.9.1 Error Detection in Isochronous Transfers

The USB has a function for detecting the error information described below, so that when errors occur in isochronous transfers, they can be controlled by software. Table 31.22 and Table 31.23 show the priority in which errors are confirmed and the interrupts generated corresponding to errors.

##### (a) PID errors

- If the PID of the received packet is illegal.

##### (b) CRC errors and bit stuffing errors

- If an error occurs in the CRC of the received packet or the bit stuffing is illegal.

##### (c) Maximum packet size exceeded

- The data of the received packet is larger than the specified maximum packet size.

##### (d) Overrun and underrun errors

- When the host controller is selected  
When the buffer memory is full at the token sending timing in the IN (receiving) direction.  
When there is no data to be sent in the buffer memory at the token sending timing in the OUT (transmitting) direction.
- When the function controller is selected  
When there is no data to be sent in the buffer memory at the token receiving timing in the IN (transmitting) direction.  
When the buffer memory is full at the token receiving timing in the OUT (receiving) direction.

##### (e) Interval errors

An interval error is generated on any of the following conditions when the function controller is selected.

- During an isochronous IN transfer, an IN token could not be received in the interval frame.
- During an isochronous OUT transfer, an OUT token could not be received in the interval frame.

**Table 31.22 Error Detection When a Token is Received**

| Detection Priority | Error                              | Generated Interrupt and Status                                                                                                                                                                                                                                                                                                    |
|--------------------|------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1                  | PID errors                         | No interrupts are generated in both cases when the host controller is selected and the function controller is selected (ignored as a corrupted packet).                                                                                                                                                                           |
| 2                  | CRC errors and bit stuffing errors | No interrupts generated in both cases when the host controller is selected and the function controller is selected (ignored as a corrupted packet).                                                                                                                                                                               |
| 3                  | Overrun and underrun errors        | An NRDY interrupt is generated to set the FRMNUM.OVRN flag to 1 in both cases when the host controller is selected and function controller is selected.<br>When the function controller is selected, a zero-length packet is transmitted in response to IN token. However, no data packets are received in response to OUT token. |
| 4                  | Interval errors                    | An NRDY interrupt is generated when the function controller is selected. It is not generated when the host controller is selected.                                                                                                                                                                                                |

**Table 31.23 Error Detection When a Data Packet is Received**

| Detection Priority | Error                               | Generated Interrupt and Status                                                                                                                                    |
|--------------------|-------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1                  | PID errors                          | No interrupts are generated (ignored as a corrupted packet).                                                                                                      |
| 2                  | CRC errors and bit stuffing errors  | An NRDY interrupt is generated to set the FRMNUM.CRCE to 1 bit in both cases when the host controller is selected and the function controller is selected.        |
| 3                  | Maximum packet size exceeded errors | A BEMP interrupt is generated to set the PID[1:0] bits to 1xb (STALL) in both cases when the host controller is selected and the function controller is selected. |

### 31.3.9.2 Data PID

When the function controller is selected, the USB operates as follows in response to the received PID.

IN direction

- DATA0: Sent as data packet PID
- DATA1: Not sent
- DATA2: Not sent
- mData: Not sent

OUT direction

- DATA0: Received normally as data packet PID
- DATA1: Received normally as data packet PID
- DATA2: Packets are ignored
- mData: Packets are ignored

### 31.3.9.3 Interval Counter

The isochronous transfer interval can be set using the PIPEPERI.IITV[2:0] bits. The interval counter enables the functions shown in Table 31.24 when the function controller is selected. When the host controller is selected, the USB generates the token issuance timing. When the host controller is selected, the interval counter operation is the same as that in the interrupt transfer.

**Table 31.24 Interval Counter Function When the Function Controller is Selected**

| Transfer Direction | Function                                 | Conditions for Detection                                                                                   |
|--------------------|------------------------------------------|------------------------------------------------------------------------------------------------------------|
| IN                 | Flushes transmit buffer                  | When an IN token cannot be successfully received in the interval frame during an isochronous IN transfer   |
| OUT                | Notifies that a token not being received | When an OUT token cannot be successfully received in the interval frame during an isochronous OUT transfer |

The interval count is carried out when an SOF is received or for interpolated SOFs, so the isochronism can be maintained even if an SOF is damaged. The frame interval that can be set is the  $2^{IITV[2:0]}$  frames.

(1) Counter Initialization When the Function Controller is Selected

The interval counter is initialized when the MCU is reset or when the PIPEnCTR.ACLRM bit is set to 1. Note that the PIPEPERI.IITV[2:0] bits are not initialized when the ACLRM bit is used for initialization.

After the interval counter has been initialized, counting is started under either of the following conditions 1 and 2 when a packet has been transferred successfully.

1. An SOF is received after transmission of data in response to an IN token while the PID[1:0] bits are 01b (BUF).
2. An SOF is received after reception of data of an OUT token while the PID[1:0] bits are 01b (BUF).

Note that the interval counter is not initialized under the following conditions.

- When the PID[1:0] bits are set to 00b (NAK) or 1xb (STALL)  
The interval timer does not stop. The USB attempts transactions at the subsequent interval.
- When the USB bus is reset or USB is suspended  
The IITV[2:0] bits are not initialized. When an SOF has been received, counting is restarted from the value prior to the reception of the SOF.

(2) Interval Counting and Transfer Control When the Host Controller is Selected

The USB controls the interval between token issuance operations based on the PIPEPERI.IITV[2:0] bit settings. Specifically, the USB issues a token for a selected pipe once every  $2^{IITV[2:0]}$  frames.

The USB starts counting the token issuance interval at the frame following the frame in which the PID[1:0] bits have been set to 01b (BUF) by software.

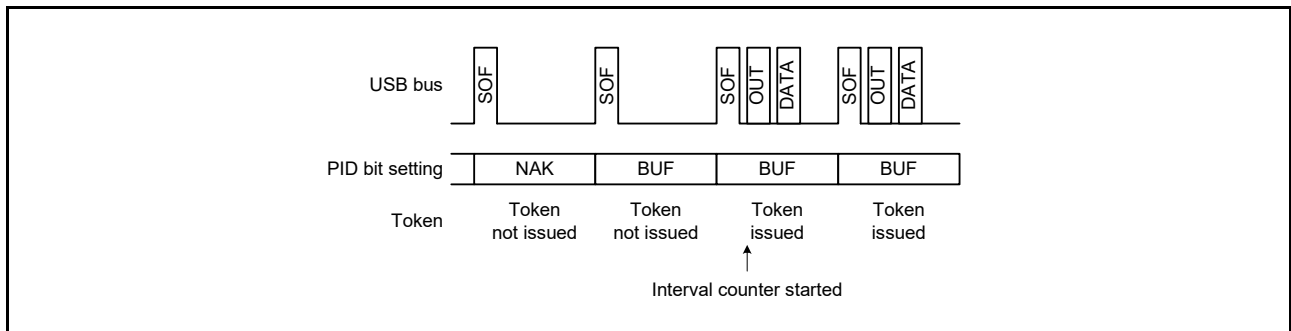

Figure 31.12 Token Issuance When IITV[2:0] = 000b

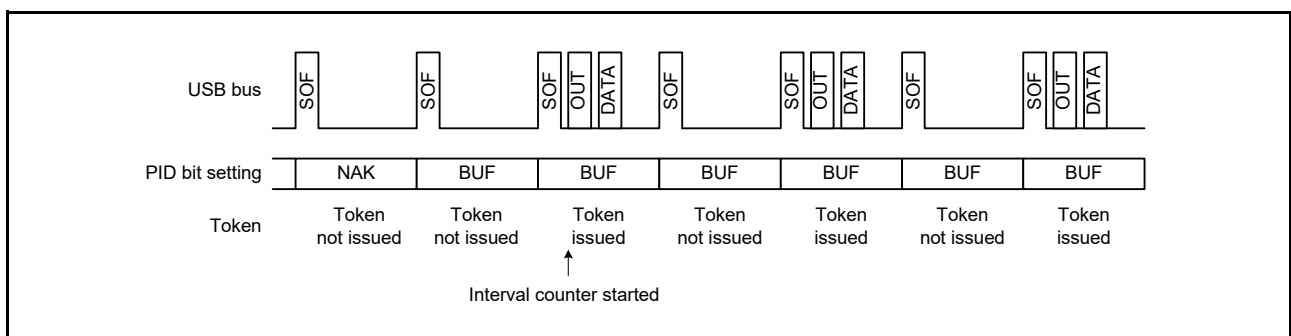

Figure 31.13 Token Issuance When IITV[2:0] = 001b

When the selected pipe is set for isochronous transfers, the USB carries out the following operation in addition to controlling the token issuance interval. The USB issues a token even when the NRDY interrupt generation condition is satisfied.

(a) When the selected pipe is for isochronous IN transfers

The USB generates an NRDY interrupt when the USB issues an IN token but does not receive a packet successfully from a peripheral device (no response or packet error).

The USB sets the FRMNUM.OVRN flag to 1 generating an NRDY interrupt when the time to issue an IN token comes while the USB cannot receive data because the FIFO buffer is full (due to the fact that the CPU or DMAC/DTC is too slow to read data from the FIFO buffer).

(b) When the selected pipe is for isochronous OUT transfers

The USB sets the OVRN flag to 1 generating an NRDY interrupt and transmitting a zero-length packet when the time to issue an OUT token comes while there is no data to be transmitted in the FIFO buffer (because the CPU or DMAC/DTC is too slow to write data to the FIFO buffer).

The token issuance interval is reset on any of the following conditions.

- When the USB is reset through a reset pin (The IITV[2:0] bits are also set to 0).
- When the PIPEnCTR.ACLRM bit has been set to 1 by software.

(3) Interval Counting and Transfer Control When the Function Controller is Selected

(a) When the selected pipe is for isochronous OUT transfers

The USB generates an NRDY interrupt when the USB fails to receive a data packet within the interval set by the PIPEPERI.IITV[2:0] bits.

The USB also generates an NRDY interrupt when the USB fails to receive data because of a CRC error or other errors contained in the data packet or because of the FIFO buffer being full.

The NRDY interrupt is generated at the timing of SOF packet reception. Even if the SOF packet is corrupted, the internal interpolation allows the interrupt to be generated at the timing to receive the SOF packet.

However, when the IITV[2:0] bits are set to a value other than 0, the USB generates an NRDY interrupt on receiving an SOF packet for every interval after starting interval counting operation.

When the PID[1:0] bits are set to 00b (NAK) by software after starting the interval timer, the USB does not generate an NRDY interrupt on receiving an SOF packet.

The timing to start interval counting depends on the setting of IITV[2:0] bits as shown below.

- When the IITV[2:0] = 000b: The interval counting starts when software has set the PID[1:0] bits for the selected pipe to 01b (BUF).

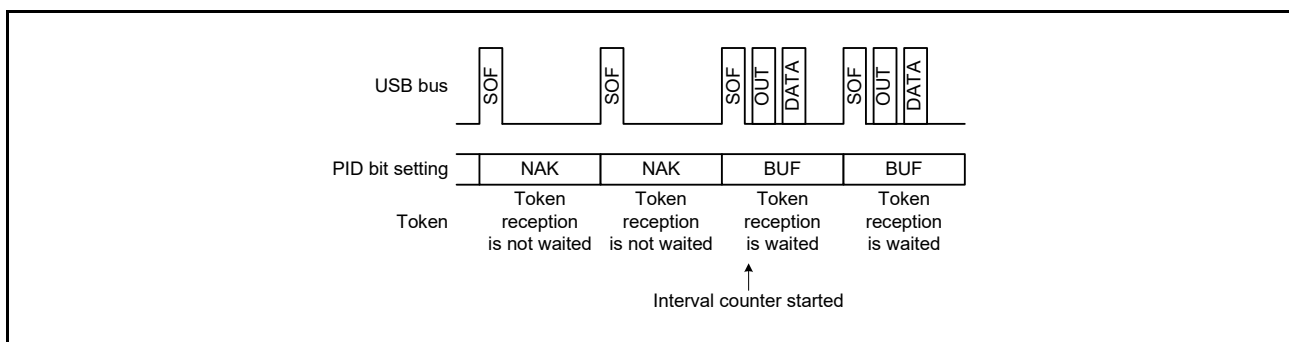

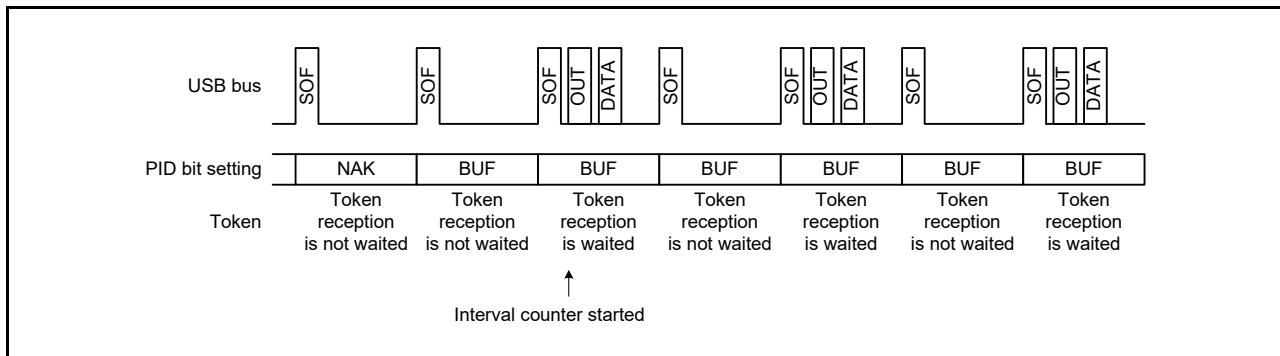

Figure 31.14 Relationship between Frames and Expected Token Reception When IITV[2:0] = 000b

- When the IITV[2:0] ≠ 000b: The interval counting starts on completion of successful reception of the first data packet after the PID[1:0] bits for the selected pipe have been modified to 01b (BUF).

**Figure 31.15 Relationship between Frames and Expected Token Reception When IITV[2:0] ≠ 000b**

**(b) When the selected pipe is for isochronous IN transfers**

The PIPEPERI.IFIS bit should be 1 for this use. When IFIS = 0, the USB transmits a data packet in response to the received IN token irrespective of the setting of the PIPEPERI.IITV[2:0] bits.

When IFIS = 1, the USB clears the FIFO buffer when the USB fails to receive an IN token in the frame at the interval set by the IITV[2:0] bits while there is data to be transmitted in the FIFO buffer.

The USB also clears the FIFO buffer when the USB fails to receive an IN token successfully because of a bus error such as a CRC error contained in the IN token.

The FIFO buffer is cleared at the timing of SOF packet reception. Even if the SOF packet is corrupted, the internal interpolation allows the FIFO buffer to be cleared at the timing to receive the SOF packet.

The timing to start interval counting depends on the setting of the IITV[2:0] bits (similar to the timing during OUT transfers).

The interval is counted on any of the following conditions in function controller mode.

- When a hardware-reset is applied to the USB (here, the IITV[2:0] bits are also set to 000b).
- When the PIPEnCTR.ACLRM bit is set to 1 by software.
- When the USB detects a USB bus reset.

(4) Setup of Data to be Transmitted Using Isochronous Transfer When the Function Controller is Selected

With isochronous data transmission using the USB in the function controller, after data has been written to the buffer memory, a data packet can be transmitted with the next frame after the frame in which an SOF packet is detected. This function is called the isochronous transfer transmission data setup function, and it makes it possible to designate the frame from which transmission began.

In a double buffer configuration, even after the writing of data to both buffers has been completed, transmission will be enabled for only one buffer to which data writing was completed first. Accordingly, even if multiple IN tokens are received, only one packet of data is transmitted from a single buffer.

When an IN token is received, if the buffer memory is in the transmission enabled state, the USB transmits data as a normal response. If the buffer memory is not in the transmission enabled state, however, a zero-length packet is sent and an underrun error occurs.

Figure 31.16 shows an example of transmission using the isochronous transfer transmission data setup function with the USB when IITV[2:0] = 000b (every frame) has been set.

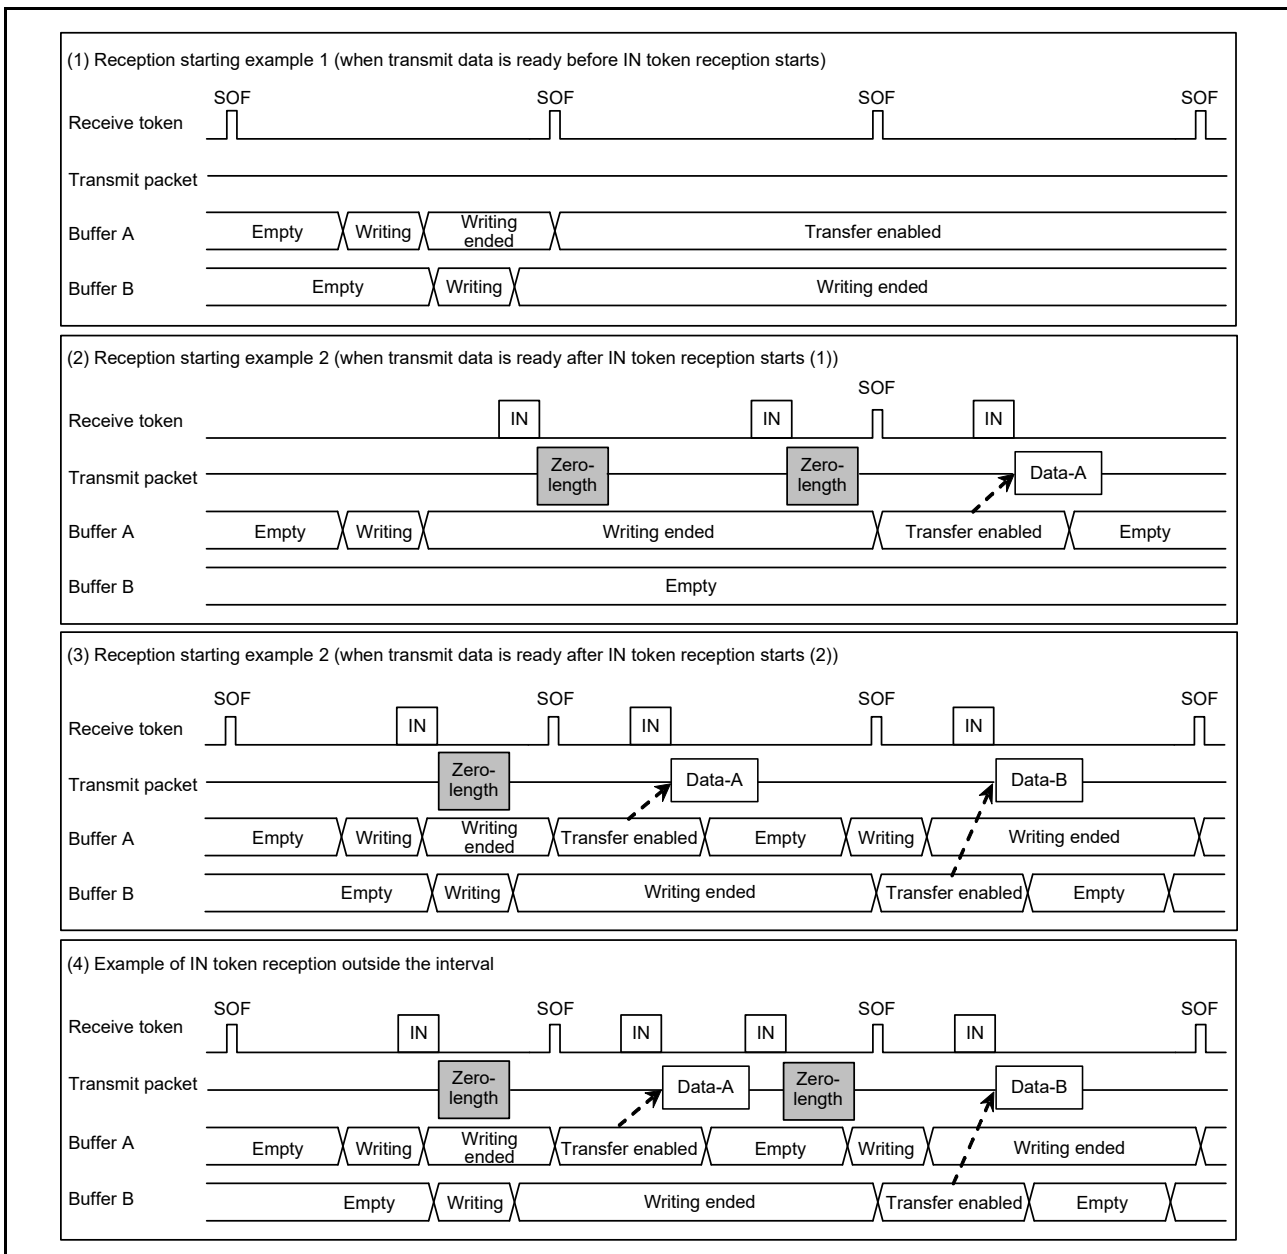

Figure 31.16 Example of Data Setup Function Operation

(5) Isochronous Transfer Transmission Buffer Flush When the Function Controller is Selected

If an SOF packet of the next frame is received without receiving an IN token in an interval frame during isochronous data transmission, the USB operates as if an IN token had been corrupted, and clears the buffer for which transmission is enabled, putting that buffer in the writing enabled state.

If a double buffer configuration is used and writing to both buffers has been completed, the buffer memory that was cleared is assumed as the data having been sent in the interval frame, and transmission is enabled for the buffer memory that is not cleared with SOF packet reception.

The timing of the buffer flush function depends on the setting of the PIPEPERI.IITV[2:0] bits.

- When the IITV[2:0] = 000b  
The buffer flush operation starts from the next frame after the pipe becomes valid.
- When the IITV[2:0] ≠ 000b  
The buffer flush operation is carried out after the first successful transaction.

Figure 31.17 shows an example of the buffer flush function in the USB. When an unanticipated token is received before the interval frame, the USB sends the write data or a zero-length packet as an underrun error according to the data setup state.

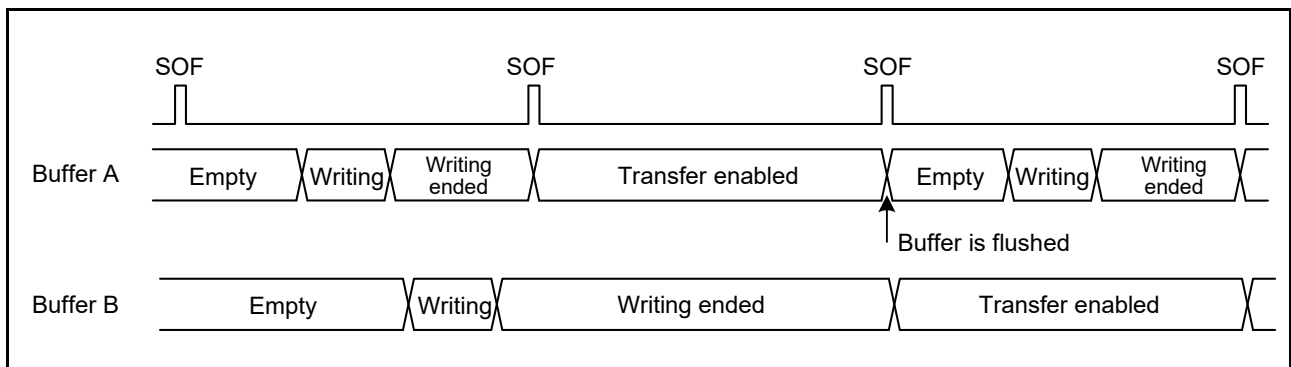

Figure 31.17 Example of Buffer Flush Operation

Figure 31.18 shows an example of interval error occurrence in the USB. There are five types of interval errors, as shown below. The interval error is generated at the timing indicated by ① in the figure, and the buffer flush function is activated.

If an interval error occurs during an IN transfers, the buffer flush function is activated; if it occurs during an OUT transfer, an NRDY interrupt is generated.

The FRMNUM.OVRN flag should be used to distinguish between NRDY interrupts such as received packet errors and overrun errors.

In response to tokens that are shaded in the figure, responses are sent according to the buffer memory status.

IN direction

- If the buffer is in the transmission enabled state, the data is transferred as a normal response.
- If the buffer is in the transmission disabled state, a zero-length packet is sent and an underrun error occurs.

OUT direction

- If the buffer is in the reception enabled state, the data is received as a normal response.
- If the buffer is in the reception disabled state, the data is discarded and an overrun error occurs.

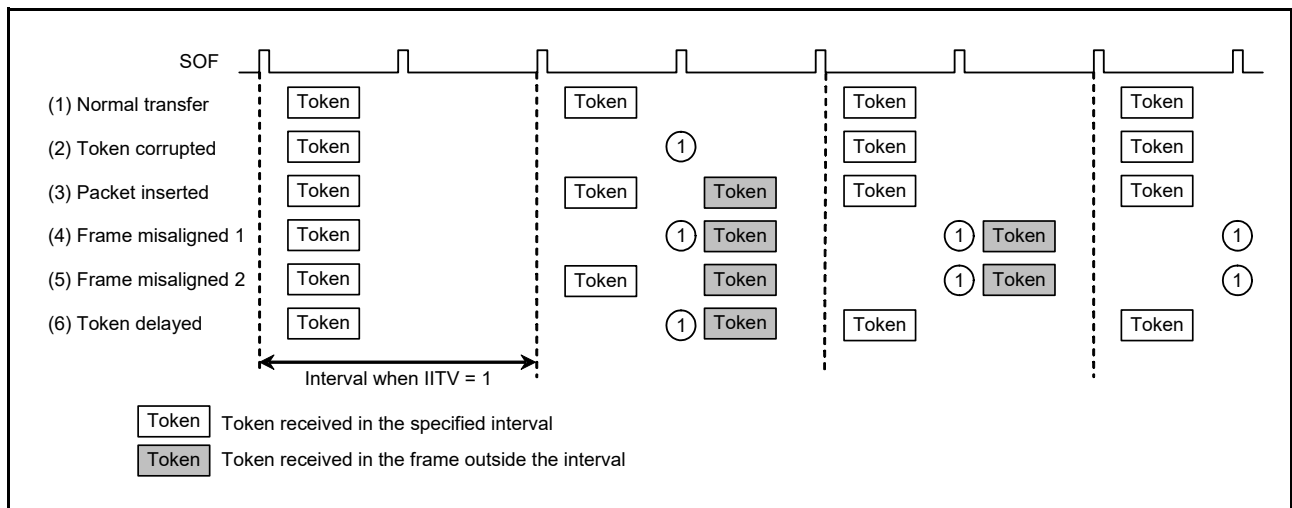

Figure 31.18 Example of Interval Error Occurrence When IITV[2:0] = 001b

### 31.3.10 SOF Interpolation Function

When the function controller is selected and if data could not be received at intervals of 1 ms because an SOF packet was corrupted or missing, the USB interpolates the SOF. The SOF interpolation operation begins when the USBE and SCKE bits in the SYSCFG register have been set to 1 and an SOF packet is received. The interpolation function is initialized under the following conditions.

- MCU reset
- USB bus reset
- Suspended state detected

The SOF interpolation operates as follows.

- The interpolation function is not activated until an SOF packet is received.
- After the first SOF packet is received, interpolation is carried out by counting 1 ms with an internal clock of 48 MHz.
- After the second and subsequent SOF packets are received, interpolation is carried out at the previous reception interval.
- Interpolation is not carried out in the suspended state or while a USB bus reset is being received.

The USB supports the following functions based on the SOF packet reception. These functions also operate normally with SOF interpolation, if the SOF packet was missing.

- Updating of the frame number
- SOFR interrupt timing
- Isochronous transfer interval count

If an SOF packet is missing during full-speed operation, the FRMNUM.FRNM[10:0] flags are not updated.

### 31.3.11 Pipe Schedule

#### 31.3.11.1 Conditions for Generating a Transaction

When the host controller is selected and the DVSTCTR0.UACT bit has been set to 1, the USB generates a transaction under the conditions shown in Table 31.25.

**Table 31.25 Conditions for Generating a Transaction**

| Transaction                                              | Conditions for Generation |          |         |                      |           |
|----------------------------------------------------------|---------------------------|----------|---------|----------------------|-----------|
|                                                          | DIR                       | PID[1:0] | IITV[0] | Buffer State         | SUREQ     |
| Setup                                                    | —*1                       | —*1      | —*1     | —*1                  | 1 setting |
| Control transfer data stage, status stage, bulk transfer | IN                        | BUF      | Invalid | Receive area exists  | —*1       |
|                                                          | OUT                       | BUF      | Invalid | Transmit data exists | —*1       |
| Interrupt transfer                                       | IN                        | BUF      | Valid   | Receive area exists  | —*1       |
|                                                          | OUT                       | BUF      | Valid   | Transmit data exists | —*1       |
| Isochronous transfer                                     | IN                        | BUF      | Valid   | *2                   | —*1       |
|                                                          | OUT                       | BUF      | Valid   | *3                   | —*1       |

Note 1. Symbols (—) in the table indicate that the condition is unrelated to the generating of tokens. "Valid" indicates that, for interrupt transfers and isochronous transfers, a transaction is generated only in transfer frames that are based on the interval counter. "Invalid" indicates that a transaction is generated regardless of the interval counter.

Note 2. This indicates that a transaction is generated regardless of whether there is a receive area. If there is no receive area, however, the received data is discarded.

Note 3. This indicates that a transaction is generated regardless of whether there is any data to be transmitted. If there is no data to be transmitted, however, a zero-length packet is transmitted.

#### 31.3.11.2 Transfer Schedule

This section describes the transfer scheduling within a frame of the USB. After the USB sends an SOF, the transfer is carried out in the sequence described below.

1. Execution of periodic transfers

A pipe is searched in the order of Pipe 1 → Pipe 2 → Pipe 6 → Pipe 7 → Pipe 8 → Pipe 9, and then, if there is a pipe for which an isochronous or interrupt transfer transaction can be generated, the transaction is generated.

2. Setup transactions for control transfers

The DCP is checked, and if a setup transaction is possible, it is sent.

3. Execution of bulk transfers, control transfer data stages, and control transfer status stages

A pipe is searched in the order of DCP → Pipe 1 → Pipe 2 → Pipe 3 → Pipe 4 → Pipe 5, and then, if there is a pipe for which a transaction for a bulk transfer, a control transfer data stage, or a control transfer status stage can be generated, the transaction is generated.

When a transaction is generated, processing moves to the next pipe transaction regardless of whether the response from the peripheral device is ACK or NAK. If there is time for transfer within the frame, step 3 is repeated.

#### 31.3.11.3 Enabling USB Communication

Setting the DVSTCTR0.UACT bit to 1 initiates SOF transmission and transaction generation is enabled.

Setting the UACT bit to 0 stops SOF transmission and a suspend state is entered. If the setting of the UACT bit is changed from 1 to 0, processing stops after the next SOF is sent.

## 31.4 Usage Notes

### 31.4.1 Setting the Module-Stop Function

Operation of the USB module can be disabled or enabled by setting a bit in the module stop control register B (MSTPCR<sub>B</sub>). The USB is initially disabled after a reset. Registers in the USB only become accessible after it has been released from the module-stop state. For details, refer to section 11, Low Power Consumption.

## 32. Serial Communications Interface (SCIj, SCIl, SCIlh)

This MCU has seven independent serial communications interface (SCI) channels. The SCI consists of the SCIj module (SCI1, SCI5, SCI6, SCI8, and SCI9), the SCIl module (SCI11), and the SCIlh module (SCI12).

The SCIj module (SCI1, SCI5, SCI6, SCI8, and SCI9) and SCIl module (SCI11) can handle both asynchronous and clock synchronous serial communications.

Asynchronous serial data communications can be carried out with standard asynchronous communications chips such as a Universal Asynchronous Receiver/Transmitter (UART) or Asynchronous Communications Interface Adapter (ACIA). As an extended function in asynchronous communications mode, the SCI also supports smart card (IC card) interfaces conforming to ISO/IEC 7816-3 (standard for Identification Cards). The SCI is also supports simple SPI interfaces, and simple I<sup>2</sup>C-bus interfaces when configured for single-master systems.

The SCIlh module includes the functions of the SCIlg module, and supports an extended serial communication protocol formed of Start Frames and Information Frames.

In this section, “PCLK” for SCI1, SCI5, SCI6, SCI8, SCI9, and SCI12 is used to refer to PCLKB and “PCLK” for SCI11 is used to refer to PCLKA.

### 32.1 Overview

Table 32.1 lists the specifications of the SCIj module, Table 32.2 lists the specifications of the SCIl module, Table 32.3 lists the specifications of the SCIlh module, and Table 32.4 lists the specifications of the individual SCI channels. Figure 32.1 shows the block diagram of SCI1, SCI8, and SCI9, Figure 32.2 shows the block diagram of SCI5 and SCI6, Figure 32.3 shows the block diagram of SCI11, and Figure 32.4 shows the block diagram of SCI12 (SCIlh).

**Table 32.1 SCIj Specifications (1/2)**

| Item                           | Description                                                                                                                                                                                                   |

| Transfer speed                 | Bit rate specifiable with the on-chip baud rate generator.                                                                                                                                                    |
| Full-duplex communications     | Transmitter: Continuous transmission possible using double-buffer structure.<br>Receiver: Continuous reception possible using double-buffer structure.                                                        |
| I/O pins                       | Refer to Table 32.5 to Table 32.7.                                                                                                                                                                            |
| Data transfer                  | Selectable as LSB first or MSB first transfer*1                                                                                                                                                               |
| Interrupt sources              | Transmit end, transmit data empty, receive data full, receive error, and data match<br>Completion of generation of a start condition, restart condition, or stop condition (for simple I <sup>2</sup> C mode) |
| Low power consumption function | Module stop state can be set for each channel.                                                                                                                                                                |

**Table 32.1 SCIj Specifications (2/2)**

| Item                                         | Description                                                                   |                                                                                                                                                                           |
|----------------------------------------------|-------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Asynchronous mode                            | Data length                                                                   | 7, 8, or 9 bits                                                                                                                                                           |
|                                              | Transmission stop bit                                                         | 1 or 2 bits                                                                                                                                                               |
|                                              | Parity                                                                        | Even parity, odd parity, or no parity                                                                                                                                     |
|                                              | Receive error detection                                                       | Parity, overrun, and framing errors                                                                                                                                       |
|                                              | Hardware flow control                                                         | CTS <sub>n</sub> # and RTS <sub>n</sub> # pins can be used in controlling transmission/reception.                                                                         |
|                                              | Data match detection                                                          | Compares receive data and comparison data, and generates interrupt when they are matched.                                                                                 |
|                                              | Start-bit detection                                                           | Low level or falling edge is selectable.                                                                                                                                  |
|                                              | Break detection                                                               | When a framing error occurs, a break can be detected by reading the RXD <sub>n</sub> pin level directly or reading the SPTR.RXD <sub>MON</sub> flag.                      |
|                                              | Clock source                                                                  | An internal or external clock can be selected.<br>Transfer rate clock input from the TMR can be used. (SCI5 and SCI6)                                                     |
|                                              | Double-speed mode                                                             | Baud rate generator double-speed mode is selectable.                                                                                                                      |
|                                              | Multi-processor communications function                                       | Serial communication among multiple processors                                                                                                                            |
|                                              | Noise cancellation                                                            | The signal paths from input on the RXD <sub>n</sub> pins incorporate digital noise filters.                                                                               |
|                                              | Clock synchronous mode                                                        | Data length                                                                                                                                                               |
| Receive error detection                      |                                                                               | Overrun error                                                                                                                                                             |
| Hardware flow control                        |                                                                               | CTS <sub>n</sub> # and RTS <sub>n</sub> # pins can be used in controlling transmission/reception.                                                                         |
| Smart card interface mode                    | Error processing                                                              | An error signal can be automatically transmitted when detecting a parity error during reception                                                                           |
|                                              |                                                                               | Data can be automatically retransmitted when receiving an error signal during transmission                                                                                |
|                                              | Data type                                                                     | Both direct convention and inverse convention are supported.                                                                                                              |
| Simple I <sup>2</sup> C mode                 | Transfer format                                                               | I <sup>2</sup> C-bus format                                                                                                                                               |
|                                              | Operating mode                                                                | Master (single-master operation only)                                                                                                                                     |
|                                              | Transfer rate                                                                 | Fast mode is supported (refer to section 32.2.13, Bit Rate Register (BRR) to set the transfer rate).                                                                      |
|                                              | Noise cancellation                                                            | The signal paths from input on the SSCL <sub>n</sub> and SSDA <sub>n</sub> pins incorporate digital noise filters, and the interval for noise cancellation is adjustable. |
| Simple SPI bus                               | Data length                                                                   | 8 bits                                                                                                                                                                    |
|                                              | Detection of errors                                                           | Overrun error                                                                                                                                                             |
|                                              | SS input pin function                                                         | Applying the high level to the SS <sub>n</sub> # pin can cause the output pins to enter the high-impedance state.                                                         |
|                                              | Clock settings                                                                | Four kinds of settings for clock phase and clock polarity are selectable.                                                                                                 |
| Bit rate modulation function                 | Correction of outputs from the on-chip baud rate generator can reduce errors. |                                                                                                                                                                           |
| Event link function (supported by SCI5 only) | Error (receive error or error signal detection) event output                  | Receive data full event output                                                                                                                                            |
|                                              |                                                                               | Transmit data empty event output                                                                                                                                          |

## 32.2 Register Descriptions

### 32.2.1 Receive Shift Register (RSR)

The RSR register is a shift register which is used to receive serial data input from the RXDn pin and converts it into parallel data.

When one frame of data has been received, it is automatically transferred to the RDR register.

The RSR register cannot be directly accessed by the CPU.

### 32.2.2 Receive Data Register (RDR)

Address(es): SCI1.RDR 0008 A025h, SCI5.RDR 0008 A0A5h, SCI6.RDR 0008 A0C5h, SCI8.RDR 0008 A105h, SCI9.RDR 0008 A125h, SCI11.RDR 000D 0005h, SCI12.RDR 0008 B305h

The RDR register is an 8-bit register that stores receive data.

When one frame of serial data has been received, the received serial data is transferred from the RSR register to the RDR register. Then the RSR register can receive the next data.

Since the RSR and RDR registers function as a double buffer in this way, continuous receive operations can be performed.

Read the RDR register only once after a receive data full interrupt (RXI) has occurred. Note that if next one frame of data is received before reading receive data from the RDR register, an overrun error occurs.

The RDR register cannot be written to by the CPU.

### 32.2.3 Receive Data Register H, L, HL (RDRH, RDRL, RDRHL)

- Receive Data Register H (RDRH)

Address(es): SCI1.RDRH 0008 A030h, SCI5.RDRH 0008 A0B0h, SCI6.RDRH 0008 A0D0h, SCI8.RDRH 0008 A110h, SCI9.RDRH 0008 A130h, SCI11.RDRH 000D 0010h, SCI12.RDRH 0008 B310h

- Receive Data Register L (RDRL)

Address(es): SCI1.RDRL 0008 A031h, SCI5.RDRL 0008 A0B1h, SCI6.RDRL 0008 A0D1h, SCI8.RDRL 0008 A111h, SCI9.RDRL 0008 A131h, SCI11.RDRL 000D 0011h, SCI12.RDRL 0008 B311h

- Receive Data Register HL (RDRHL)

Address(es): SCI1.RDRHL 0008 A030h, SCI5.RDRHL 0008 A0B0h, SCI6.RDRHL 0008 A0D0h, SCI8.RDRHL 0008 A110h, SCI9.RDRHL 0008 A130h, SCI11.RDRHL 000D 0010h, SCI12.RDRHL 0008 B310h

The RDRH and RDRL registers are 8-bit registers that store receive data. Use these registers when asynchronous mode and 9-bit data length are selected.

The RDRL register is the shadow register of the RDR register; i.e. access to the RDRL register is equivalent to access to the RDR register.

After one frame of data is received, the received data is transferred from the RSR register to these registers, thus allowing the RSR register to receive the next data.

The RSR, RDRH and RDRL registers have a double-buffered construction to enable continuous reception.

Read the RDRH and RDRL registers should be performed only once in the order from the RDRH register to the RDRL register when a receive data full interrupt (RXI) request is issued. Note that an overrun error occurs when the next frame of data is received before the received data has been read from the RDRL register.

The CPU cannot write to the RDRH and RDRL registers. Bits 0 to 7 in the RDRH register are fixed to 0. These bits are read as 0.

The RDRHL register can be accessed in 16-bit units.

### 32.2.4 Receive FIFO Data Register (FRDR)

Address(es): SCI11.FRDR 000D 0010h,  
SCI11.FRDR.H 000D 0010h,  
SCI11.FRDR.L 000D 0011h

| Bit      | Symbol    | Bit Name                         | Description                                                                                                                                                                           | R/W |
|----------|-----------|----------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----|
| b8 to b0 | RDAT[8:0] | Receive Data                     | Received data can be read                                                                                                                                                             | R   |

| b10      | DR        | Receive Data Ready Flag*1        | 0: The FRDR register does not contain valid data<br>1: The FRDR register contains valid data                                                                                          | R   |
| b11      | PER       | Parity Error Flag                | 0: No parity error occurred<br>1: A parity error has occurred                                                                                                                         | R   |
| b12      | FER       | Framing Error Flag               | 0: No framing error occurred<br>1: A framing error has occurred                                                                                                                       | R   |
| b13      | ORER      | Overrun Error Flag*1             | 0: No overrun error occurred<br>1: An overrun error has occurred                                                                                                                      | R   |
| b14      | RDF       | Receive FIFO Full Flag*1         | 0: The number of data stored in the receive FIFO is less than the threshold value<br>1: The number of data stored in the receive FIFO is equal to or greater than the threshold value | R   |
| b15      | —         | Reserved                         | The read value is undefined                                                                                                                                                           | R   |

Note 1. These flags are the same as the flags of the same name in the SSRFIFO register. To clear these flags, clear the corresponding flag in the SSRFIFO register.

This register is used to read the data at the top of the sixteen-stage receive FIFO. This register is enabled when the FCR.FM bit is 1 (FIFO mode).

Reading the FRDR register when the receive FIFO is empty results in an undefined value.

When reading the lower 8 bits (FRDR.L), the value of the FRDR register is updated with the next data in the receive FIFO. When reading the upper 8 bits (FRDR.H), the FRDR register is not updated. When reading the FRDR register in 8-bit units, read first from the FRDR.H register and then the FRDR.L register.

When the character length is 8 bits 0 is stored in the RDAT[8] bit and when the character length is 7 bits 00b is stored in the RDAT[8:7] bits.

The MPB flag holds the value of the multi-processor bit that was added to the data at the top of the receive FIFO. The SSR.MPB flag is not used when the FCR.FM bit is 1 (FIFO mode).

The FER and PER flags indicate whether the relevant error exists in the data at the top of the receive FIFO. Its value is updated each time the FRDR register is read.

The RDF, ORER, and DR flags are the same as the flags of the same name in the SSRFIFO register. When these flags are read with a value of 1, the flag can be cleared simply by writing 0 to the corresponding flag in the SSRFIFO register.

### 32.2.5 Transmit Data Register (TDR)

Address(es): SCI1.TDR 0008 A023h, SCI5.TDR 0008 A0A3h, SCI6.TDR 0008 A0C3h, SCI8.TDR 0008 A103h, SCI9.TDR 0008 A123h, SCI11.TDR 000D 0003h, SCI12.TDR 0008 B303h

The TDR register is an 8-bit register that stores transmit data.

When the SCI detects that the TSR register is empty, it transfers the transmit data written in the TDR register to the TSR register and starts transmission.

The double-buffered structures of the TDR register and the TSR register enable continuous serial transmission. If the next transmit data has already been written to the TDR register when one frame of data is transmitted, the SCI transfers the written data to the TSR register to continue transmission.

The CPU is able to read from or write to the TDR register at any time. Only write transmit data to the TDR register once after each instance of the transmit data empty interrupt (TXI).

### 32.2.6 Transmit Data Register H, L, HL (TDRH, TDRL, TDRHL)

- Transmit Data Register H (TDRH)

Address(es): SCI1.TDRH 0008 A02Eh, SCI5.TDRH 0008 A0AEh, SCI6.TDRH 0008 A0CEh, SCI8.TDRH 0008 A10Eh, SCI9.TDRH 0008 A12Eh, SCI11.TDRH 000D 000Eh, SCI12.TDRH 0008 B30Eh

- Transmit Data Register L (TDRL)

Address(es): SCI1.TDRL 0008 A02Fh, SCI5.TDRL 0008 A0AFh, SCI6.TDRL 0008 A0CFh, SCI8.TDRL 0008 A10Fh, SCI9.TDRL 0008 A12Fh, SCI11.TDRL 000D 000Fh, SCI12.TDRL 0008 B30Fh

- Transmit Data Register HL (TDRHL)

Address(es): SCI1.TDRHL 0008 A02Eh, SCI5.TDRHL 0008 A0AEh, SCI6.TDRHL 0008 A0CEh, SCI8.TDRHL 0008 A10Eh, SCI9.TDRHL 0008 A12Eh, SCI11.TDRHL 000D 000Eh, SCI12.TDRHL 0008 B30Eh

The TDRH and TDRL registers are 8-bit registers that store transmit data. Use these registers when asynchronous mode and 9-bit data length are selected.

The TDRL register is the shadow register of the TDR register; i.e. access to the TDRL register is equivalent to access to the TDR register.

When empty space is detected in the TSR register, the transmit data stored in the TDRH and TDRL registers is transferred to the TSR register; i.e., transmitting is started.

The TSR, TDRH and TDRL registers have a double-buffered construction to realize continuous reception. When the next data to be transmitted is stored in the TDRL register after one frame of data has been transmitted, the transmitting operation is continued by transfer to the TSR register.

The CPU can read and write to the TDRH and TDRL registers. Bits 0 to 7 in the RDRH register are fixed to 1. These bits are read as 1. The write value should be 1.

Writing transmit data to the TDRH and TDRL registers should be performed only once in the order from the TDRH register to the TDRL register when a transmit data empty interrupt (TXI) request is issued.

The TDRHL register can be accessed in 16-bit units.

### 32.2.7 Transmit FIFO Data Register (FTDR)

Address(es): SCI11.FTDR 000D 000Eh,  
SCI11.FTDR.H 000D 000Eh,  
SCI11.FTDR.L 000D 000Fh

| Bit        | Symbol    | Bit Name                 | Description                                                                                                                      | R/W |
|------------|-----------|--------------------------|----------------------------------------------------------------------------------------------------------------------------------|-----|
| b8 to b0   | TDAT[8:0] | Transmit Data            | Specifies the data to be transmitted                                                                                             | W   |
| b9         | MPBT      | Transmit Multi-Processor | Specifies the value of the multi-processor bit in the transmit frame<br>0: Data transmission cycles<br>1: ID transmission cycles | W   |
| b15 to b10 | —         | Reserved                 | The write value should be 1                                                                                                      | W   |

This register is used to write data to the 16-stage transmit FIFO. This register is enabled when the FCR.FM bit is 1 (FIFO mode) and the SCR.TE bit is 1.

When the transmit FIFO contains 16 frames of data, no transmit data can be set in the FTDR register.

When writing a value to the lower 8 bits (FTDR.L), the data in the FTDR register is transferred to the transmit FIFO.

When writing a value to the upper 8 bits (FTDR.H), no data is transferred to the transmit FIFO. When writing a 16-bit data to the FTDR register in 8-bit units, write first to the FTDR.H register and then the FTDR.L register.

#### MPBT Bit (Transmit Multi-Processor)

This bit is used to set the value of the multi-processor bit to add to the transmit frame. The SSR.MPBT bit is not used when the FCR.FM bit is 1 (FIFO mode).

### 32.2.8 Transmit Shift Register (TSR)

The TSR register is a shift register that transmits serial data.

To perform serial data transmission, the SCI first automatically transfers transmit data from the TDR register to the TSR register, and then sends the data to the TXDn pin.

The TSR register cannot be directly accessed by the CPU.

### 32.2.9 Serial Mode Register (SMR)

Some bits in the SMR register have different functions in smart card interface mode and non-smart card interface mode.

#### (1) Non-Smart Card Interface Mode (SCMR.SMIF = 0)

Address(es): SCI1.SMR 0008 A020h, SCI5.SMR 0008 A0A0h, SCI6.SMR 0008 A0C0h, SCI8.SMR 0008 A100h, SCI9.SMR 0008 A120h, SCI11.SMR 000D 0000h, SCI12.SMR 0008 B300h

| b7                 | b6  | b5 | b4 | b3   | b2 | b1       | b0 |

Note 1. n is the decimal notation of the value of n in the BRR register (refer to section 32.2.13, Bit Rate Register (BRR)).

Note 2. In other than asynchronous mode, this bit setting is invalid and a fixed data length of 8 bits is used.

Note 3. LSB first is fixed and the MSB (bit 7) in the TDR register is not transmitted in transmission.

Note 4. Writable only when the SCR.TE bit is 0 and the SCR.RE bit is 0 (both serial transmission and reception are disabled).

#### CKS[1:0] Bits (Clock Select)

These bits select the clock source for the on-chip baud rate generator.

For the relation between the settings of these bits and the baud rate, refer to section 32.2.13, Bit Rate Register (BRR).

#### MP Bit (Multi-Processor Mode)

Disables/enables the multi-processor communications function. The settings of the PE bit and PM bit are invalid in multi-processor mode.

**STOP Bit (Stop Bit Length)**

Selects the stop bit length in transmission.

In reception, only the first stop bit is checked regardless of this bit setting. If the second stop bit is 0, it is treated as the start bit of the next transmit frame.

**PM Bit (Parity Mode)**

Selects the parity mode (even or odd) for transmission and reception.

The setting of the PM bit is invalid in multi-processor mode.

**PE Bit (Parity Enable)**

When this bit is set to 1, the parity bit is added to transmit data, and the parity bit is checked in reception.

Irrespective of the setting of the PE bit, the parity bit is not added or checked in multi-processor format.

**CHR Bit (Character Length)**

Selects the data length for transmission and reception.

Selects in combination with the SCMR.CHR1 bit.

In other than asynchronous mode, a fixed data length of 8 bits is used.

## (2) Smart Card Interface Mode (SCMR.SMIF = 1)

Address(es): SMC11.SMR 0008 A020h, SMC15.SMR 0008 A0A0h, SMC16.SMR 0008 A0C0h, SMC18.SMR 0008 A100h, SMC19.SMR 0008 A120h, SMC111.SMR 000D 0000h, SMC112.SMR 0008 B300h

| Bit    | Symbol   | Bit Name            | Description                                                                                                                                                     | R/W   |

| b5     | PE       | Parity Enable       | When this bit is set to 1, a parity bit is added to transmit data, and the parity of received data is checked. Set this bit to 1 in smart card interface mode.  | R/W*2 |
| b6     | BLK      | Block Transfer Mode | 0: Non-block transfer mode operation<br>1: Block transfer mode operation                                                                                        | R/W*2 |
| b7     | GM       | GSM Mode            | 0: Non-GSM mode operation<br>1: GSM mode operation                                                                                                              | R/W*2 |

Note 1. n is the decimal notation of the value of n in the BRR register (refer to section 32.2.13, Bit Rate Register (BRR)).

Note 2. Writable only when the SCR.TE bit is 0 and the SCR.RE bit is 0 (both serial transmission and reception are disabled).

**CKS[1:0] Bits (Clock Select)**

These bits select the clock source for the on-chip baud rate generator.

For the relationship between the settings of these bits and the baud rate, refer to section 32.2.13, Bit Rate Register (BRR).

**BCP[1:0] Bits (Base Clock Pulse)**

These bits select the number of base clock cycles in a 1-bit data transfer time in smart card interface mode.

Set these bits in combination with the SCMR.BCP2 bit.

For details, refer to section 32.6.4, Receive Data Sampling Timing and Reception Margin.

**Table 32.9 Combinations of the SCMR.BCP2 Bit and SMR.BCP[1:0] Bits**

| SCMR.BCP2 Bit | SMR.BCP[1:0] Bits |   | Number of Base Clock Cycles for 1-Bit Transfer Period |
|---------------|-------------------|---|-------------------------------------------------------|
| 0             | 0                 | 0 | 93 clock cycles (S = 93)*1                            |
| 0             | 0                 | 1 | 128 clock cycles (S = 128)*1                          |
| 0             | 1                 | 0 | 186 clock cycles (S = 186)*1                          |
| 0             | 1                 | 1 | 512 clock cycles (S = 512)*1                          |
| 1             | 0                 | 0 | 32 clock cycles (S = 32)*1 (Initial Value)            |
| 1             | 0                 | 1 | 64 clock cycles (S = 64)*1                            |
| 1             | 1                 | 0 | 372 clock cycles (S = 372)*1                          |
| 1             | 1                 | 1 | 256 clock cycles (S = 256)*1                          |

Note 1. S is the value of S in the BRR register (refer to section 32.2.13, Bit Rate Register (BRR)).

**PM Bit (Parity Mode)**

Selects the parity mode for transmission and reception (even or odd).

For details on the usage of this bit in smart card interface mode, refer to section 32.6.2, Data Format (Except in Block Transfer Mode).

**PE Bit (Parity Enable)**

Set the PE bit to 1.

The parity bit is added to transmit data before transmission, and the parity bit is checked in reception.

**BLK Bit (Block Transfer Mode)**

Setting this bit to 1 allows block transfer mode operation.

For details, refer to section 32.6.3, Block Transfer Mode.

**GM Bit (GSM Mode)**

Setting this bit to 1 allows GSM mode operation.

In GSM mode, the SSR.TEND flag set timing is put forward to 11.0 etu (elementary time unit = 1-bit transfer time) from the start and the clock output control function is appended. For details, refer to section 32.6.6, Serial Data Transmission (Except in Block Transfer Mode) and section 32.6.8, Clock Output Control.

### 32.2.10 Serial Control Register (SCR)

Some bits in the SCR register have different functions in smart card interface mode and non-smart card interface mode.

#### (1) Non-Smart Card Interface Mode (SCMR.SMIF = 0)

Address(es): SCI1.SCR 0008 A022h, SCI5.SCR 0008 A0A2h, SCI6.SCR 0008 A0C2h, SCI8.SCR 0008 A102h, SCI9.SCR 0008 A122h, SCI11.SCR 000D 0002h, SCI12.SCR 0008 B302h

Value after reset: 0 0 0 0 0 0 0 0

| Bit    | Symbol   | Bit Name                         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          | R/W   |

x: Don't care

Note 1. Writable only when TE = 0 and RE = 0.

Note 2. TMR clock is selectable for SCI5, SCI6, and SCI12.

Note 3. 1 can be written only when TE = 0 and RE = 0, while the SMR.CM bit is 1. After setting TE or RE to 1, only 0 can be written to TE and RE. While the SMR.CM bit is 0 and the SIMR1.IICM bit is 0, writing is enabled under any condition.

**CKE[1:0] Bits (Clock Enable)**

These bits select the clock source and SCKn pin function.

The combination of the settings of these bits and of the SEMR.ACS0 bit sets the internal TMR clock.

**TEIE Bit (Transmit End Interrupt Enable)**

Enables or disables a TEI interrupt request.

A TEI interrupt request is disabled by setting the TEIE bit to 0.

In simple I<sup>2</sup>C mode, the TEI is allocated to the interrupt on completion of issuing a start, restart, or stop condition (STI).

In this case, the TEIE bit can be used to enable or disable the STI.

**MPIE Bit (Multi-Processor Interrupt Enable)**

When this bit is set to 1 and the data with the multi-processor bit set to 0 is received, the data is not read and setting the status flags RDRF, ORER, and FER in the SSR register (and SSRFIFO.DR flag for SCI11) to 1 is disabled. When the data with the multi-processor bit set to 1 is received, the MPIE bit is automatically cleared to 0, and normal reception is resumed. For details, refer to section 32.4, Multi-Processor Communications Function.

When the data with the multi-processor bit set to 0 is received, the receive data is not transferred from the RSR register to the RDR register, a receive error is not detected, and setting the flags RDRF, ORER, and FER (and SSRFIFO.DR flag for SCI11) to 1 is disabled.

When the data with the multi-processor bit set to 1 is received, the MPB bit is set to 1, the MPIE bit is automatically cleared to 0, the RXI and ERI interrupt requests are enabled (if the SCR.RIE bit is set to 1), and setting the flags RDRF, ORER, and FER (and SSRFIFO.DR flag for SCI11) to 1 is enabled.

Set the MPIE bit to 0 if multi-processor communications function is not to be used.

**RE Bit (Receive Enable)**

Enables or disables serial reception.

When this bit is set to 1, serial reception is started by detecting the start bit in asynchronous mode or the synchronous clock input in clock synchronous mode. Note that the SMR register should be set prior to setting the RE bit to 1 in order to designate the reception format.

Even if reception is halted by setting the RE bit to 0 while the FCR.FM bit is 0 (non-FIFO mode), the ORER, FER, PER, and RDRF flags in the SSR register are not affected and the previous value is retained.

Even if reception is halted by setting the RE bit to 0 while the FCR.FM bit is 1 (FIFO mode), the RDF, ORER, FER, PER, DR flags in the SSRFIFO register are not affected and the previous value is retained.

**TE Bit (Transmit Enable)**

Enables or disables serial transmission.

When this bit is set to 1, serial transmission is started by writing transmit data to the TDR register. Note that the SMR register should be set prior to setting the TE bit to 1 in order to designate the transmission format.

**RIE Bit (Receive Interrupt Enable)**

Enables or disables RXI and ERI interrupt requests.

An RXI interrupt request is disabled by setting the RIE bit to 0.

An ERI interrupt request can be canceled by reading 1 from the ORER, FER, or PER flag in the SSR register and then setting the flag to 0, or setting the RIE bit to 0.

**TIE Bit (Transmit Interrupt Enable)**

Enables or disables TXI interrupt request.

A TXI interrupt request is disabled by setting the TIE bit to 0.

## (2) Smart Card Interface Mode (SCMR.SMIF = 1)

x: Don't care

Note 1. Writable only when TE = 0 and RE = 0.

Note 2. 1 can be written only when TE = 0 and RE = 0. After setting TE or RE to 1, only 0 can be written in TE and RE.

For details on interrupt requests, refer to section 32.12, Interrupt Sources.

**CKE[1:0] Bits (Clock Enable)**

These bits control the clock output from the SCKn pin.

In GSM mode, clock output can be dynamically switched. For details, refer to section 32.6.8, Clock Output Control.

**TEIE Bit (Transmit End Interrupt Enable)**

This bit should be 0 in smart card interface mode.

**MPIE Bit (Multi-Processor Interrupt Enable)**

This bit should be 0 in smart card interface mode.

**RE Bit (Receive Enable)**

Enables or disables serial reception.

When this bit is set to 1, serial reception is started by detecting the start bit. Note that the SMR register should be set prior to setting the RE bit to 1 in order to designate the reception format.

Even if reception is halted by setting the RE bit to 0, the ORER, FER, and PER flags in the SSR register are not affected and the previous value is retained.

**TE Bit (Transmit Enable)**

Enables or disables serial transmission.

When this bit is set to 1, serial transmission is started by writing transmit data to the TDR register. Note that the SMR register should be set prior to setting the TE bit to 1 in order to designate the transmission format.

**RIE Bit (Receive Interrupt Enable)**

Enables or disables RXI and ERI interrupt requests.

An RXI interrupt request is disabled by setting the RIE bit to 0.

An ERI interrupt request can be canceled by reading 1 from the ORER, FER, or PER flag in the SSR register and then setting the flag to 0, or setting the RIE bit to 0.

**TIE Bit (Transmit Interrupt Enable)**

Enables or disables TXI interrupt request.

A TXI interrupt request is disabled by setting the TIE bit to 0.

### 32.2.11 Serial Status Register (SSR/SSRFIFO)

Some bits in the SSR register have different functions in smart card interface mode and non-smart card interface mode or FIFO mode and non-FIFO mode.

#### (1) Non-Smart Card Interface Mode and non-FIFO Mode (SCMR.SMIF = 0 and FCR.FM = 0)

Address(es): SCI1.SSR 0008 A024h, SCI5.SSR 0008 A0A4h, SCI6.SSR 0008 A0C4h, SCI8.SSR 0008 A104h, SCI9.SSR 0008 A124h, SCI11.SSR 000D 0004h, SCI12.SSR 0008 B304h

|                    | b7   | b6   | b5   | b4  | b3  | b2   | b1  | b0   |
|--------------------|------|------|------|-----|-----|------|-----|------|
|                    | TDRE | RDRF | ORER | FER | PER | TEND | MPB | MPBT |
| Value after reset: | 1    | 0    | 0    | 0   | 0   | 1    | 0   | 0    |

| Bit | Symbol | Bit Name                     | Description                                                                                                                   | R/W         |
|-----|--------|------------------------------|-------------------------------------------------------------------------------------------------------------------------------|-------------|
| b0  | MPBT   | Multi-Processor Bit Transfer | Sets the multi-processor bit for adding to the transmission frame<br>0: Data transmission cycles<br>1: ID transmission cycles | R/W         |
| b1  | MPB    | Multi-Processor              | Value of the multi-processor bit in the reception frame<br>0: Data transmission cycles<br>1: ID transmission cycles           | R           |
| b2  | TEND   | Transmit End Flag            | 0: A character is being transmitted.<br>1: Character transfer has been completed.                                             | R           |
| b3  | PER    | Parity Error Flag            | 0: No parity error occurred<br>1: A parity error has occurred                                                                 | R/(W)<br>*1 |
| b4  | FER    | Framing Error Flag           | 0: No framing error occurred<br>1: A framing error has occurred                                                               | R/(W)<br>*1 |
| b5  | ORER   | Overrun Error Flag           | 0: No overrun error occurred<br>1: An overrun error has occurred                                                              | R/(W)<br>*1 |
| b6  | RDRF   | Receive Data Full Flag       | 0: No valid data is held in the RDR register<br>1: Received data is held in the RDR register                                  | R/(W)<br>*2 |
| b7  | TDRE   | Transmit Data Empty Flag     | 0: Data to be transmitted is held in the TDR register<br>1: No data is held in the TDR register                               | R/(W)<br>*2 |

Note 1. Only 0 can be written to this bit, to clear the flag. To clear this flag, confirm that the flag is 1 and then set it to 0.

Note 2. Write 1 when writing is necessary.

#### MPB Bit (Multi-Processor)

Holds the value of the multi-processor bit in the reception frame. This bit does not change when the SCR.RE bit is 0.

#### TEND Flag (Transmit End Flag)

Indicates completion of transmission.

[Setting conditions]

- When the SCR.TE bit is set to 0 (serial transmission is disabled)  
When the SCR.TE bit is changed from 0 to 1, the TEND flag is not affected and retains the value 1.
- When the TDR register is not updated at the time of transmission of the tail-end bit of a character being transmitted

[Clearing condition]

- When transmit data are written to the TDR register while the SCR.TE bit is 1  
When setting the TEND flag to 0 to complete the interrupt handling, refer to section 14.5.2, Level Detection.

### PER Flag (Parity Error Flag)

Indicates that a parity error has occurred during reception in asynchronous mode and the reception ends abnormally.

[Setting condition]

- When a parity error is detected during reception while data match detection is disabled (for SCI1, SCI5, SCI6, SCI8, SCI9, and SCI11)
- When a parity error is detected during reception (for SCI12)  
Although receive data when the parity error occurs is transferred to the RDR register, no RXI interrupt request occurs. Note that when the PER flag is being set to 1, the subsequent receive data is not transferred to the RDR register.

[Clearing condition]

- When 0 is written to the PER flag after reading PER = 1  
When setting the PER flag to 0 to complete the interrupt handling, refer to section 14.5.2, Level Detection. Even when the SCR.RE bit is set to 0 (serial reception is disabled), the PER flag is not affected and retains its previous value.

### FER Flag (Framing Error Flag)

Indicates that a framing error has occurred during reception in asynchronous mode and the reception ends abnormally.

[Setting condition]

- When the stop bit is 0 while data match detection is disabled (for SCI1, SCI5, SCI6, SCI8, SCI9, and SCI11)
- When the stop bit is 0 (for SCI12)  
In 2-stop-bit mode, only the first stop bit is checked whether it is 1 but the second stop bit is not checked. Note that although receive data when the framing error occurs is transferred to the RDR register, no RXI interrupt request occurs. In addition, when the FER flag is being set to 1, the subsequent receive data is not transferred to the RDR register.

[Clearing condition]

- When 0 is written to the FER flag after reading FER = 1  
When setting the FER flag to 0 to complete the interrupt handling, refer to section 14.5.2, Level Detection. Even when the SCR.RE bit is set to 0, the FER flag is not affected and retains its previous value.

### ORER Flag (Overrun Error Flag)

Indicates that an overrun error has occurred during reception and the reception ends abnormally.

[Setting condition]

- When the next data is received before receive data is read from the RDR register  
In the RDR register, receive data prior to an overrun error occurrence is retained, but data received after the overrun error occurrence is lost. When the ORER flag is set to 1, subsequent serial reception cannot be performed. Note that, in clock synchronous mode, serial transmission also cannot continue.

[Clearing condition]

- When 0 is written to the ORER flag after reading ORER = 1  
When setting the ORER flag to 0 to complete the interrupt handling, refer to section 14.5.2, Level Detection. Even when the SCR.RE bit is set to 0, the ORER flag is not affected and retains its previous value.

### RDRF Flag (Receive Data Full Flag)

Indicates whether the RDR register has received data.

[Setting condition]

- When data has been received normally, and transferred from the RSR register to the RDR register

[Clearing condition]

- When data is read from the RDR register

**TDRE Flag (Transmit Data Empty Flag)**

Indicates whether the TDR register has data to be transmitted.

[Setting condition]

- When data is transferred from the TDR register to the TSR register

[Clearing condition]

- When data is written to the TDR register

**(2) Smart Card Interface Mode (SCMR.SMIF = 1)**

Address(es): SMC11.SSR 0008 A024h, SMC15.SSR 0008 A0A4h, SMC16.SSR 0008 A0C4h, SMC18.SSR 0008 A104h, SMC19.SSR 0008 A124h, SMC111.SSR 000D 0004h, SMC112.SSR 0008 B304h

|      |      |      |     |     |      |     |      |
|------|------|------|-----|-----|------|-----|------|
| b7   | b6   | b5   | b4  | b3  | b2   | b1  | b0   |
| TDRE | RDRF | ORER | ERS | PER | TEND | MPB | MPBT |

Value after reset: 1 0 0 0 0 1 0 0

| Bit | Symbol | Bit Name                     | Description                                                                                     | R/W         |
|-----|--------|------------------------------|-------------------------------------------------------------------------------------------------|-------------|
| b0  | MPBT   | Multi-Processor Bit Transfer | This bit should be set to 0 in smart card interface mode.                                       | R/W         |
| b1  | MPB    | Multi-Processor              | This bit is not used in smart card interface mode. It should be set to 0.                       | R           |
| b2  | TEND   | Transmit End Flag            | 0: A character is being transmitted.<br>1: Character transfer has been completed.               | R           |
| b3  | PER    | Parity Error Flag            | 0: No parity error occurred<br>1: A parity error has occurred                                   | R/(W)<br>*1 |
| b4  | ERS    | Error Signal Status Flag     | 0: Low error signal not responded<br>1: Low error signal responded                              | R/(W)<br>*1 |
| b5  | ORER   | Overflow Error Flag          | 0: No overflow error occurred<br>1: An overflow error has occurred                              | R/(W)<br>*1 |
| b6  | RDRF   | Receive Data Full Flag       | 0: No valid data is held in the RDR register<br>1: Received data is held in the RDR register    | R/(W)<br>*2 |
| b7  | TDRE   | Transmit Data Empty Flag     | 0: Data to be transmitted is held in the TDR register<br>1: No data is held in the TDR register | R/(W)<br>*2 |

Note 1. Only 0 can be written to this bit, to clear the flag. To clear this flag, confirm that the flag is 1 and then set it to 0.

Note 2. Write 1 when writing is necessary.

**TEND Flag (Transmit End Flag)**

With no error signal from the receiving side, this bit is set to 1 when further data for transfer is ready to be transferred to the TDR register.

[Setting conditions]

- When the SCR.TE bit is 0 (serial transmission is disabled)  
When the SCR.TE bit is changed from 0 to 1, the TEND flag is not affected and retains the value 1.
- When a specified period has elapsed after the latest transmission of 1 byte, the ERS flag is 0, and the TDR register is not updated

The set timing is determined by register settings as listed below.

When SMR.GM = 0 and SMR.BLK = 0, 12.5 etu after the start of transmission

When SMR.GM = 0 and SMR.BLK = 1, 11.5 etu after the start of transmission

When SMR.GM = 1 and SMR.BLK = 0, 11.0 etu after the start of transmission

When SMR.GM = 1 and SMR.BLK = 1, 11.0 etu after the start of transmission

[Clearing condition]

- When transmit data are written to the TDR register while the SCR.TE bit is 1  
When setting the TEND flag to 0 to complete the interrupt handling, refer to section 14.5.2, Level Detection.

**PER Flag (Parity Error Flag)**

Indicates that a parity error has occurred during reception in asynchronous mode and the reception ends abnormally.

[Setting condition]

- When a parity error is detected during reception  
Although receive data when the parity error occurs is transferred to the RDR register, no RXI interrupt request occurs. Note that when the PER flag is being set to 1, the subsequent receive data is not transferred to the RDR register.

[Clearing condition]

- When 0 is written to the PER flag after reading PER = 1  
When setting the PER flag to 0 to complete the interrupt handling, refer to section 14.5.2, Level Detection.  
Even when the SCR.RE bit is set to 0 (serial reception is disabled), the PER flag is not affected and retains its previous value.

**ERS Flag (Error Signal Status Flag)**

[Setting condition]

- When a low error signal is sampled

[Clearing condition]

- When 0 is written to the ERS flag after reading ERS = 1  
When setting the ERS flag to 0 to complete the interrupt handling, refer to section 14.5.2, Level Detection.  
Even when the SCR.RE bit is set to 0, the ERS flag is not affected and retains its previous value.

**ORER Flag (Overrun Error Flag)**

Indicates that an overrun error has occurred during reception and the reception ends abnormally.

[Setting condition]

- When the next data is received before receive data is read from the RDR register  
In the RDR register, the receive data prior to an overrun error occurrence is retained, but data received following the overrun error occurrence is lost. When the ORER flag is set to 1, subsequent serial reception cannot be performed.

[Clearing condition]

- When 0 is written to the ORER flag after reading ORER = 1  
When setting the ORER flag to 0 to complete the interrupt handling, refer to section 14.5.2, Level Detection.  
Even when the SCR.RE bit is set to 0, the ORER flag is not affected and retains its previous value.

**RDRF Flag (Receive Data Full Flag)**

Indicates whether the RDR register has received data.

[Setting condition]

- When data has been received normally, and transferred from the RSR register to the RDR register

[Clearing condition]

- When data is read from the RDR register

**TDRE Flag (Transmit Data Empty Flag)**

Indicates whether the TDR register has data to be transmitted.

[Setting condition]

- When data is transferred from the TDR register to the TSR register

[Clearing condition]

- When data is written to the TDR register

## (3) Non-Smart Card Interface Mode and FIFO Mode (SCMR.SMIF = 0 and FCR.FM = 1)

Address(es): SCI11.SSRFIFO 000D 0004h

|                   | b7   | b6  | b5   | b4  | b3  | b2   | b1 | b0 |
|-------------------|------|-----|------|-----|-----|------|----|----|
|                   | TDFE | RDF | ORER | FER | PER | TEND | —  | DR |
| Value after reset | 1    | 0   | 0    | 0   | 0   | 1    | 0  | 0  |

| Bit | Symbol | Bit Name                  | Description                                                                                                                                                                             | R/W         |
|-----|--------|---------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------|
| b0  | DR     | Receive Data Ready Flag*1 | 0: Reception in progress, or receive FIFO is empty<br>1: Reception completed, and number of data in the receive FIFO is less than the threshold value                                   | R/(W)<br>*2 |
| b1  | —      | Reserved                  | The read value is undefined. The write value should be 1                                                                                                                                | R/W         |
| b2  | TEND   | Transmit End Flag         | 0: A character is being transmitted<br>1: Character transfer has been completed                                                                                                         | R/(W)<br>*2 |
| b3  | PER    | Parity Error Flag         | 0: No parity error occurred<br>1: A parity error has occurred                                                                                                                           | R/(W)<br>*2 |
| b4  | FER    | Framing Error Flag        | 0: No framing error occurred<br>1: A framing error has occurred                                                                                                                         | R/(W)<br>*2 |
| b5  | ORER   | Overrun Error Flag        | 0: No overrun error occurred<br>1: An overrun error has occurred                                                                                                                        | R/(W)<br>*2 |
| b6  | RDF    | Receive FIFO Full Flag    | 0: The number of data stored in the receive FIFO is less than the threshold value<br>1: The number of data stored in the receive FIFO is equal to or greater than the threshold value   | R/(W)<br>*2 |
| b7  | TDFE   | Transmit FIFO Empty Flag  | 0: The number of data stored in the transmit FIFO is greater than the threshold value<br>1: The number of data stored in the transmit FIFO is equal to or less than the threshold value | R/(W)<br>*2 |

Note 1. This flag is only enabled in asynchronous mode. This flag does not become 1 in clock synchronous mode.

Note 2. This flag can only be written to 0 to clear the flag. To clear this flag, confirm that the flag is 1 and then set it to 0.

**DR Flag (Receive Data Ready Flag)**

After receiving data, this flag indicates when 15 etus (Elementary Time Unit: time required to transmit a single bit) have elapsed since the number of data stored in the receive FIFO has dropped to less than the threshold value (FCR.RTRG[3:0]).

[Setting condition]

- When the last received data has neither framing nor parity error, and the number of data in the receive FIFO is less than the threshold value at the time that data is transferred from the RSR register, and the next data is not yet fully received even after 15 etus have elapsed since the last stop bit.

[Clearing condition]

- When 0 is written to the DR flag, after all data in the receive FIFO is read and the DR flag is confirmed to be 1.
- When the FCR.FM bit is changed from 0 to 1.

When the FCR.DRES bit is 1 (ERI interrupt), refer to section 14.5.2, Level Detection when setting the DR flag to 0 to exit from the interrupt handling routine.

**TEND Flag (Transmit End Flag)**

This flag indicates that transmission has completed.

[Setting condition]

- When transmitting the last bit of a transmit character, and there is no transmit data in the FTDR register.

[Clearing condition]

- When the SCR.TE bit is 1 and transmit data is written to the FTDR register.
- When the SCR.TE bit is 1, and 0 is written to the TEND flag after it is confirmed to be 1.
- When the FCR.FM bit is changed from 0 to 1.

**PER Flag (Parity Error Flag)**

In asynchronous mode when data match detection is disabled, this flag indicates that a parity error was detected for data in the receive FIFO.

[Setting condition]

- When data match detection is disabled, and a parity error is detected in the received data.

[Clearing condition]

- When 0 is written to the PER flag after it is confirmed to be 1.

When setting the PER flag to 0 to exit from the interrupt handling routine, refer to [section 14.5.2, Level Detection](#).

Unlike in non-FIFO mode, the receive operation continues even after a parity error is detected in the receive data.

Even when the SCR.RE bit is set to 0 (serial reception is disabled), the PER flag is not affected and retains its previous value.

**FER Flag (Framing Error Flag)**

In asynchronous mode when data match detection is disabled, this flag indicates that a framing error was detected for data in the receive FIFO.

[Setting condition]

- When the stop bit of the received data is 0 while data match detection is disabled.

[Clearing condition]

- When 0 is written to the FER flag after it is confirmed to be 1.

When setting the FER flag to 0 to exit from the interrupt handling routine, refer to [section 14.5.2, Level Detection](#).

Unlike in non-FIFO mode, the receive operation continues even after a framing error is detected in the receive data.

Even when the SCR.RE bit is set to 0, the FER flag is not affected and retains its previous value.

**ORER Flag (Overrun Error Flag)**

This flag indicates that an overrun error has occurred during reception and the reception ends abnormally

[Setting condition]

- When the receive FIFO has 16 frames of data, and the next data reception has completed.

[Clearing condition]

- When 0 is written to the ORER flag after it is confirmed to be 1.

When setting the ORER flag to 0 to exit from the interrupt handling routine, refer to [section 14.5.2, Level Detection](#).

Even when the SCR.RE bit is set to 0, the ORER flag is not affected and retains its previous value.

**RDF Flag (Receive FIFO Full Flag)**

This flag indicates when the number of data stored in the receive FIFO is equal to or greater than the threshold value (FCR.RTRG[3:0]).

[Setting condition]

- When the data stored in the receive FIFO becomes equal to or greater than the threshold value.

[Clearing condition]

- When 0 is written to the RDF flag after it is confirmed to be 1.
- When the receive FIFO contains fewer receive data than the receive FIFO threshold value on completion of DTC or DMA transfer to read receive data from the FRDR register.

When the conditions for this flag to become 0 and 1 occur simultaneously, the RDF flag initially becomes 0. At this time, if the data stored in the receive FIFO is equal to or greater than the threshold value, the RDF flag becomes 1 after 1 PCLK.

**TDFE Flag (Transmit FIFO Empty Flag)**

This flag indicates that data has been transferred from the transmit FIFO to the TSR register, and the number of data remaining in the transmit FIFO is equal to or less than the threshold value (FCR.TTRG[3:0]).

[Setting condition]

- When the SCR.TE bit is 0.
- When the data stored in the transmit FIFO becomes equal to or less than the threshold value.

[Clearing condition]

- When the transmit FIFO contains more transmit data than the transmit FIFO threshold value on completion of DTC or DMA transfer to write transmit data to the FTDR register.
- When 0 is written to the TDFE flag after it is confirmed to be 1.

When the SCR.TE bit is set to 0, the TDFE flag becomes 1 regardless of any other condition. In all other cases, when the conditions for this flag to become 1 and 0 occur simultaneously, the TDFE flag initially becomes 0. At this time, if the data stored in the transmit FIFO is equal to or less than the threshold value, the TDFE flag becomes 1 after 1 PCLK.

To enable use of DMA or DTC transfer, do not write 0 to the TDFE flag.

### 32.2.12 Smart Card Mode Register (SCMR)

Address(es): SCI1.SCMR 0008 A026h, SCI5.SCMR 0008 A0A6h, SCI6.SCMR 0008 A0C6h, SCI8.SCMR 0008 A106h, SCI9.SCMR 0008 A126h, SCI11.SCMR 000D 0006h, SCI12.SCMR 0008 B306h, SMC11.SCMR 0008 A026h, SMC15.SCMR 0008 A0A6h, SMC16.SCMR 0008 A0C6h, SMC18.SCMR 0008 A106h, SMC19.SCMR 0008 A126h, SMC111.SCMR 000D 0006h, SMC112.SCMR 0008 B306h

| b7     | BCP2   | Base Clock Pulse 2                                 | Selects the number of base clock cycles in combination with the SMR.BCP[1:0] bits.<br>Table 32.10 lists the combinations of the SCMR.BCP2 bit and SMR.BCP[1:0] bits.                                                                                                                                                                       | R/W*1 |

Note 1. Writable only when the SCR.TE bit is 0 and the SCR.RE bit is 0 (both serial transmission and reception are disabled).

Note 2. This bit can be used in the smart card interface mode, asynchronous mode (multi-processor mode), clock synchronous mode, and simple SPI mode.

Note 3. Set this bit to 0 if operation is to be in simple I<sup>2</sup>C mode.

Note 4. Set this bit to 1 if operation is to be in simple I<sup>2</sup>C mode.

Note 5. This bit is only valid in asynchronous mode. The setting is invalid and a fixed data length of 8 bits is used in modes other than asynchronous mode.

Note 6. LSB first should be selected and the value of MSB (b7) in the TDR register cannot be transmitted.

#### SMIF Bit (Smart Card Interface Mode Select)

When this bit is set to 1, smart card interface mode is selected.

When this bit is set to 0, non-smart card interface mode, i.e., asynchronous mode (including multi-processor mode), clock synchronous mode, simple SPI mode, or simple I<sup>2</sup>C mode is selected.

#### SINV Bit (Transmitted/Received Data Invert)

This bit is used to invert the logic level of the data bits when the data is transferred between data register and shift register. This bit does not affect the logic level of the parity bit. To invert the parity bit, invert the SMR.PM bit.

#### CHR1 Bit (Character Length 1)

Selects the data length of transmit/receive data.

Selects in combination with the SMR.CHR bit.

A fixed data length of 8 bits is used in modes other than asynchronous mode.

### BCP2 Bit (Base Clock Pulse 2)

Selects the number of base clock cycles in a 1-bit data transfer time in smart card interface mode. Set this bit in combination with the SMR.BCP[1:0] bits.

**Table 32.10 Combinations of the SCMR.BCP2 Bit and SMR.BCP[1:0] Bits**

| SCMR.BCP2 Bit | SMR.BCP[1:0] Bits |   | Number of Base Clock Cycles for 1-Bit Transfer Period  |
|---------------|-------------------|---|--------------------------------------------------------|
| 0             | 0                 | 0 | 93 clock cycles (S = 93)* <sup>1</sup>                 |
| 0             | 0                 | 1 | 128 clock cycles (S = 128)* <sup>1</sup>               |
| 0             | 1                 | 0 | 186 clock cycles (S = 186)* <sup>1</sup>               |
| 0             | 1                 | 1 | 512 clock cycles (S = 512)* <sup>1</sup>               |
| 1             | 0                 | 0 | 32 clock cycles (S = 32)* <sup>1</sup> (Initial Value) |
| 1             | 0                 | 1 | 64 clock cycles (S = 64)* <sup>1</sup>                 |
| 1             | 1                 | 0 | 372 clock cycles (S = 372)* <sup>1</sup>               |
| 1             | 1                 | 1 | 256 clock cycles (S = 256)* <sup>1</sup>               |

Note 1. S is the value of S in the BRR register (refer to section 32.2.13, Bit Rate Register (BRR)).

### 32.2.13 Bit Rate Register (BRR)

Address(es): SCI1.BRR 0008 A021h, SCI5.BRR 0008 A0A1h, SCI6.BRR 0008 A0C1h, SCI8.BRR 0008 A101h, SCI9.BRR 0008 A121h, SCI11.BRR 000D 0001h, SCI12.BRR 0008 B301h

The BRR register is an 8-bit register that adjusts the bit rate.

As each SCI channel has independent baud rate generator control, different bit rates can be set for each. Table 32.11 and Table 32.12 shows the relationship between the setting (N) in the BRR register and the bit rate (B) for normal asynchronous mode, multi-processor communication, clock synchronous mode, smart card interface mode, simple SPI mode, and simple I<sup>2</sup>C mode.

For SCI11, do not set the BRR register to 00h when the SMR.CM bit is 1 (clock synchronous mode or simple SPI mode), the FCR.FM bit is 1 (FIFO mode), and the SMR.CKS[1:0] bits are 00b (PCLK).

The BRR register is writable only when the TE and RE bits in the SCR register are 0.

**Table 32.11 Relationship between N Setting in the BRR Register and Bit Rate B (for SCI1, SCI5, SCI6, SCI8, SCI9, and SCI11)**

| Mode                                        | SEMR Settings |          |           | BRR Setting                                                    | Error (%)                                                                                                   |
|---------------------------------------------|---------------|----------|-----------|----------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------|

B: Bit rate (bps)

N: BRR setting for on-chip baud rate generator ( $0 \leq N \leq 255$ )

PCLK: Operating frequency (MHz)

n and S: Determined by the settings of the SMR and SCMR registers as listed in Table 32.14 and Table 32.15.

Note 1. Adjust the bit rate so that the widths at high and low level of the SCL output in simple I<sup>2</sup>C mode satisfy the I<sup>2</sup>C-bus standard.

**Table 32.12 Relationship between N Setting in the BRR Register and Bit Rate B (for SCI12)**

| Mode                                        | SEMR Settings |          | BRR Setting                                                    | Error (%)                                                                                                   |

| Simple I <sup>2</sup> C*1                   |               |          | $N = \frac{PCLK \times 10^6}{64 \times 2^{2n-1} \times B} - 1$ |                                                                                                             |

B: Bit rate (bps)

N: BRR setting for on-chip baud rate generator ( $0 \leq N \leq 255$ )

PCLK: Operating frequency (MHz)

n and S: Determined by the settings of the SMR and SCMR registers as listed in Table 32.14 and Table 32.15.

Note 1. Adjust the bit rate so that the widths at high and low level of the SCL output in simple I<sup>2</sup>C mode satisfy the I<sup>2</sup>C-bus standard.

**Table 32.13 Calculating Widths at High and Low Level for SCL**

| Mode             | SCL                         | Formula (Result in Seconds)                                                 |
|------------------|-----------------------------|-----------------------------------------------------------------------------|
| I <sup>2</sup> C | High period (minimum value) | $(N+1) \times 4 \times 2^{2n-1} \times 7 \times \frac{1}{PCLK \times 10^6}$ |
|                  | Low period (minimum value)  | $(N+1) \times 4 \times 2^{2n-1} \times 8 \times \frac{1}{PCLK \times 10^6}$ |

**Table 32.14 Clock Source Settings**

| SMR.CKS[1:0] Bit Setting | Clock Source | n |
|--------------------------|--------------|---|
| 0 0                      | PCLK         | 0 |
| 0 1                      | PCLK/4       | 1 |
| 1 0                      | PCLK/16      | 2 |
| 1 1                      | PCLK/64      | 3 |

**Table 32.15 Base Clock Settings in Smart Card Interface Mode**

| SCMR.BCP2 Bit Setting | SMR.BCP[1:0] Bit Setting | Base Clock Cycles for 1-bit Period | S   |
|-----------------------|--------------------------|------------------------------------|-----|
| 0                     | 0 0                      | 93 clock cycles                    | 93  |
| 0                     | 0 1                      | 128 clock cycles                   | 128 |
| 0                     | 1 0                      | 186 clock cycles                   | 186 |
| 0                     | 1 1                      | 512 clock cycles                   | 512 |
| 1                     | 0 0                      | 32 clock cycles                    | 32  |
| 1                     | 0 1                      | 64 clock cycles                    | 64  |
| 1                     | 1 0                      | 372 clock cycles                   | 372 |
| 1                     | 1 1                      | 256 clock cycles                   | 256 |

Table 32.16 lists examples of N settings in the BRR register in normal asynchronous mode. Table 32.18 lists the maximum bit rate settable for each operating frequency. Examples of BRR (N) settings in clock synchronous mode and simple SPI mode are listed in Table 32.21. Examples of BRR (N) settings in smart card interface mode are listed in Table 32.23. Examples of BRR (N) settings in simple I<sup>2</sup>C mode are listed in Table 32.25. In smart card interface mode, the number of base clock cycles S in a 1-bit data transfer time can be selected. For details, refer to section 32.6.4, Receive Data Sampling Timing and Reception Margin. Table 32.19 and Table 32.22 list the maximum bit rates with external clock input.

When either the SEMR.ABCS or BGDM bit is set to 1 in asynchronous mode, the bit rate becomes twice that listed in Table 32.16. When both of those bits are set to 1, the bit rate becomes four times the listed value.

Table 32.16 Examples of BRR Settings for Various Bit Rates (Asynchronous Mode)

| Bit Rate<br>(bps) | Operating Frequency PCLK (MHz) |     |           |        |     |           |    |     |           |    |     |           |        |     |           |
|-------------------|--------------------------------|-----|-----------|--------|-----|-----------|----|-----|-----------|----|-----|-----------|--------|-----|-----------|
|                   | 8                              |     |           | 9.8304 |     |           | 10 |     |           | 12 |     |           | 12.288 |     |           |
|                   | n                              | N   | Error (%) | n      | N   | Error (%) | n  | N   | Error (%) | n  | N   | Error (%) | n      | N   | Error (%) |

Note: This is an example when the ABCS, ABCSE, and BGDM bits in the SEMR register are 0.  
 When either the ABCS bit or BGDM bit is set to 1, the bit rate doubles.  
 When both ABCS and BGDM bits in the SEMR register are set to 1, the bit rate increases four times.  
 When the ABCSE bit is set to 1, the bit rate increases 16/3 times.

Note 1. Supported by SCI11 only.

**Table 32.17 Maximum Bit Rate for Each Operating Frequency (Asynchronous Mode) (for SCI1, SCI5, SCI6, SCI8, SCI9, and SCI11)**

| PCLK<br>(MHz) | SEMR Settings |             |              |   |   | Maximum<br>Bit Rate<br>(bps) | PCLK<br>(MHz) | SEMR Settings |             |              |   |   | Maximum<br>Bit Rate<br>(bps) |          |

Blank cell: Cannot be set since the bit rate error exceeds 5%.

—: Can be set, but a bit rate error of 1 to 5% will occur.

Note 1. Supported by SCI11 only.

Note 2. For SCI11, this setting cannot be used when the FCR.FM bit is 1 (FIFO mode).

When this setting is used while the FCR.FM bit is 0 (non-FIFO mode) or with other channel, continuous transmission or reception is not possible. After transmitting/receiving one frame of data, there is an interval of a 1-bit period before starting transmitting/receiving the next frame of data. The output of the synchronization clock is stopped for a 1-bit period. For this reason, it takes 9 bits worth of time to transfer one frame (8 bits) of data, and the average transfer rate is 8/9 times the bit rate.

**Table 32.22 Maximum Bit Rate with External Clock Input (Clock Synchronous Mode, Simple SPI Mode)**

| PCLK (MHz) | External Input Clock (MHz) | Maximum Bit Rate (Mbps) |

Note 1. Supported by SCi11 only.

### 32.2.14 Modulation Duty Register (MDDR)

Address(es): SCI1.MDDR 0008 A032h, SCI5.MDDR 0008 A0B2h, SCI6.MDDR 0008 A0D2h, SCI8.MDDR 0008 A112h, SCI9.MDDR 0008 A132h, SCI11.MDDR 000D 0012h, SCI12.MDDR 0008 B312h

The MDDR register corrects the bit rate adjusted by the BRR register.

When the SEMR.BRME bit is set to 1, the bit rate generated by the on-chip baud rate generator is evenly corrected according to the settings of the MDDR register (M/256). The relationship between the MDDR register setting (M) and the bit rate (B) is given in Table 32.27 and Table 32.28.

The range of the value that can be set in the MDDR register is from 80h to FFh. A value other than these cannot be set. The MDDR register is writable only when the TE and RE bits in the SCR register are 0.

**Table 32.27 Relationship between MDDR Setting (M) and Bit Rate (B) When Bit Rate Modulation Function is Used (for SCI1, SCI5, SCI6, SCI8, SCI9, and SCI11)**

- B: Bit rate (bps)
- M: MDDR setting (128 ≤ MDDR ≤ 256)
- N: BRR setting for baud rate generator (0 ≤ N ≤ 255)
- PCLK: Operating frequency (MHz)
- n and S: Determined by the settings of the SMR and SCMR registers as listed in Table 32.14 and Table 32.15, section 32.2.13, Bit Rate Register (BRR).

Note 1. Do not use this function in clock synchronous mode and in the highest speed settings in simple SPI mode (SMR.CKS[1:0] = 00b, SCR.CKE[1] = 0, and BRR = 0).

Note 2. Adjust the bit rate so that the widths at high and low level of the SCL output in simple I<sup>2</sup>C mode satisfy the I<sup>2</sup>C-bus standard.

**Table 32.28 Relationship between MDDR Setting (M) and Bit Rate (B) When Bit Rate Modulation Function is Used (for SCI12)**

| Smart card interface                        |               |          | $N = \frac{PCLK \times 10^6}{S \times 2^{2n+1} \times \frac{256}{M} \times B} - 1$  | $\text{Error} = \left\{ \frac{PCLK \times 10^6}{B \times S \times 2^{2n+1} \times \frac{256}{M} \times (N+1)} - 1 \right\} \times 100$  |
| Simple I <sup>2</sup> C*2                   |               |          | $N = \frac{PCLK \times 10^6}{64 \times 2^{2n-1} \times \frac{256}{M} \times B} - 1$ |                                                                                                                                         |

B: Bit rate (bps)

M: MDDR setting (128 ≤ MDDR ≤ 256)

N: BRR setting for baud rate generator (0 ≤ N ≤ 255)

PCLK: Operating frequency (MHz)

n and S: Determined by the settings of the SMR and SCMR registers as listed in Table 32.14 and Table 32.15, section 32.2.13, Bit Rate Register (BRR).

Note 1. Do not use this function in clock synchronous mode and in the highest speed settings in simple SPI mode (SMR.CKS[1:0] = 00b, SCR.CKE[1] = 0, and BRR = 0).

Note 2. Adjust the bit rate so that the widths at high and low level of the SCL output in simple I<sup>2</sup>C mode satisfy the I<sup>2</sup>C-bus standard.

Smaller settings of the SMR.CKS[1:0] bits and larger settings of the BRR register reduce difference in the length of the 1-bit period.

| b7  | RXDESEL | Asynchronous Start Bit Edge Detection Select   | (Valid only in asynchronous mode)<br>0: The low level on the RXDn pin is detected as the start bit.<br>1: A falling edge on the RXDn pin is detected as the start bit.                                                                                                                                                                                                                                                                       | R/W*1 |

Note 1. Writable only when the SCR.TE bit is 0 and the SCR.RE bit is 0 (both serial transmission and reception are disabled).

Note 2. This bit is reserved for SCI12. It is read as 0. The write value should be 0.

The SEMR register is used to select a clock source for 1-bit period in asynchronous mode or a detection method of the start bit.

### ACS0 Bit (Asynchronous Mode Clock Source Select)

Selects the clock source in the asynchronous mode.

The ACS0 bit is valid in asynchronous mode (SMR.CM bit = 0) and when an external clock input is selected (SCR.CKE[1:0] bits = 10b or 11b). This bit is used to select an external clock input or the logical AND of compare matches output from the internal TMR.

Set the ACS0 bit to 0 in other than asynchronous mode.

For SCI5, SCI6, and SCI12, the TMO<sub>n</sub> output (n = 0 to 3) of TMR units 0 and 1 can be set as the base clock source.

Refer to Table 32.29 for details.

The ACS0 bits for SCI1, SCI8, SCI9, and SCI11 are reserved. The write values to these bits for SCI1, SCI8, SCI9, and SCI11 should be 0.

**Table 32.29 Correspondence between SCI Channels and Compare Match Outputs**

| SCI   | TMR    | Compare Match Output |
|-------|--------|----------------------|
| SCI5  | Unit 0 | TMO0, TMO1           |
| SCI6  | Unit 1 | TMO2, TMO3           |
| SCI12 | Unit 0 | TMO0, TMO1           |

Figure 32.5 shows a setting example of when TMO0 and TMO1 in the TMR unit 0 are selected for output.

**Figure 32.5 Example of Average Transfer Rate Setting When TMR Clock is Input**

**BRME Bit (Bit Rate Modulation Enable)**

This bit enables and disables the bit rate modulation function. The bit rate generated by on-chip baud rate generator is evenly corrected when this function is enabled.

**ABCSE Bit (Asynchronous Mode Base Clock Select Extended)**

When setting this bit to 1, the 1-bit period becomes 6 cycles of the base clock and the clock of doubled frequency is output from the baud rate generator.

This bit is valid when the on-chip baud rate generator is selected as the clock source ( $SCR.CKE[1] = 0$ ) in asynchronous mode ( $SMR.CM = 0$ ).

When the bit rate is made to be 1/6 of PCLK frequency, set this bit to 1, the  $SMR.CKS[1:0]$  bits to 00b, and the BRR register to 00h.

**NFEN Bit (Digital Noise Filter Function Enable)**

This bit enables or disables the digital noise filter function.

When the function is enabled, noise cancellation is applied to the  $RXDn$  input signal in asynchronous mode, and noise cancellation is applied to the  $SSDAn$  and  $SSCLn$  input signals in simple I<sup>2</sup>C mode.

In any mode other than above, set the NFEN bit to 0 to disable the digital noise filter function.

When the function is disabled, input signals are transferred as is, as internal signals.

**BGDM Bit (Baud Rate Generator Double-Speed Mode Select)**

Selects the cycle of output clock for the baud rate generator.

This bit is valid when the on-chip baud rate generator is selected as the clock source ( $SCR.CKE[1] = 0$ ) in asynchronous mode ( $SMR.CM = 0$ ). For the clock output from the baud rate generator, either normal or doubled frequency can be selected. The base clock is generated by the clock output from the baud rate generator. When the BGDM bit is set to 1, the base clock cycle is halved and the bit rate is doubled.

Set this bit to 0 in modes other than asynchronous mode.

**RXDESEL Bit (Asynchronous Start Bit Edge Detection Select)**

Selects the detection method of the start bit for reception in asynchronous mode. When a break occurs, data receiving operation depends on the settings of this bit. Set this bit to 1 when reception should be stopped while a break occurs or when reception should be started without retaining the  $RXDn$  pin input at high level for the period of one data frame or longer after completion of the break.

Set this bit to 0 in modes other than asynchronous mode.

### 32.2.16 Noise Filter Setting Register (SNFR)

Address(es): SCI1.SNFR 0008 A028h, SCI5.SNFR 0008 A0A8h, SCI6.SNFR 0008 A0C8h, SCI8.SNFR 0008 A108h, SCI9.SNFR 0008 A128h, SCI11.SNFR 000D 0008h, SCI12.SNFR 0008 B308h

| Bit      | Symbol    | Bit Name                  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | R/W   |

| b7 to b3 | —         | Reserved                  | These bits are read as 0. The write value should be 0.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        | R/W   |

Note 1. Writing to these bits is only possible when the RE and TE bits in the SCR register are 0 (serial reception and transmission disabled).

#### NFCS[2:0] Bits (Noise Filter Clock Select)

These bits select the sampling clock for the digital noise filter. To use the noise filter in asynchronous mode, set these bits to 000b. In simple I<sup>2</sup>C mode, set the bits to a value in the range from 001b to 100b.

### 32.2.17 I<sup>2</sup>C Mode Register 1 (SIMR1)

Address(es): SCI1.SIMR1 0008 A029h, SCI5.SIMR1 0008 A0A9h, SCI6.SIMR1 0008 A0C9h, SCI8.SIMR1 0008 A109h, SCI9.SIMR1 0008 A129h, SCI11.SIMR1 000D 0009h, SCI12.SIMR1 0008 B309h

| Bit      | Symbol     | Bit Name                            | Description                                                                                                                                                                                                                                                                                                                               | R/W   |
|----------|------------|-------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------|

| b2, b1   | —          | Reserved                            | These bits are read as 0. The write value should be 0.                                                                                                                                                                                                                                                                                    | R/W   |
| b7 to b3 | IICDL[4:0] | SSDA Output Delay Select            | (Cycles below are of the clock signal from the on-chip baud rate generator.)<br>b7      b3<br>0 0 0 0 0: No output delay<br>0 0 0 0 1: 0 to 1 cycle<br>0 0 0 1 0: 1 to 2 cycles<br>0 0 0 1 1: 2 to 3 cycles<br>0 0 1 0 0: 3 to 4 cycles<br>0 0 1 0 1: 4 to 5 cycles<br>:<br>:<br>1 1 1 1 0: 29 to 30 cycles<br>1 1 1 1 1: 30 to 31 cycles | R/W*1 |

Note 1. Writing to these bits is only possible when the RE and TE bits in the SCR register are 0 (both serial transmission and reception are disabled).

SIMR1 is used to select simple I<sup>2</sup>C mode and the number of delay stages for the SSDA output.

#### IICM Bit (Simple I<sup>2</sup>C Mode Select)

In conjunction with the SCMR.SMIF bit, this bit selects the operating mode.

#### IICDL[4:0] Bits (SSDA Output Delay Select)

These bits are used to set a delay for output on the SSDAn pin relative to the falling edge of the output on the SSCLn pin. The available delay settings range from no delay to 31 cycles, with the clock signal from the on-chip baud rate generator as the base. The signal obtained by frequency-dividing PCLK by the divisor set in the SMR.CKS[1:0] bits is supplied as the clock signal from the on-chip baud rate generator. Set these bits to 00000b unless operation is in simple I<sup>2</sup>C mode. In simple I<sup>2</sup>C mode, set the bits to a value in the range from 00001b to 11111b.

| b4 to b2 | —       | Reserved                               | These bits are read as 0. The write value should be 0.                                  | R/W   |
| b5       | IICACKT | ACK Transmission Data                  | 0: ACK transmission<br>1: NACK transmission and reception of ACK/NACK                   | R/W   |
| b7, b6   | —       | Reserved                               | These bits are read as 0. The write value should be 0.                                  | R/W   |

Note 1. Writing to these bits is only possible when the RE and TE bits in the SCR register are 0 (serial reception and transmission disabled).

SIMR2 is used to select how reception and transmission are controlled in simple I<sup>2</sup>C mode.

#### IICINTM Bit (I<sup>2</sup>C Interrupt Mode Select)

This bit selects the sources of interrupt requests in simple I<sup>2</sup>C mode.

#### IICCSC Bit (Clock Synchronization)

Set the IICCSC bit to 1 if the internally generated SSCLn clock signal is to be synchronized when the SSCLn pin has been placed at the low level in the case of a wait inserted by the other device, etc.

The SSCLn clock signal is not synchronized if the IICCSC bit is 0. The SSCLn clock signal is generated in accord with the rate selected in the BRR regardless of the level being input on the SSCLn pin.

Set the IICCSC bit to 1 except during debugging.

#### IICACKT Bit (ACK Transmission Data)

Transmitted data contains ACK bits. Set this bit to 1 when ACK and NACK bits are received.

32.2.19 I<sup>2</sup>C Mode Register 3 (SIMR3)

Address(es): SCI1.SIMR3 0008 A02Bh, SCI5.SIMR3 0008 A0ABh, SCI6.SIMR3 0008 A0CBh, SCI8.SIMR3 0008 A10Bh, SCI9.SIMR3 0008 A12Bh, SCI11.SIMR3 000D 000Bh, SCI12.SIMR3 0008 B30Bh

Value after reset: 0 0 0 0 0 0 0 0

| Bit    | Symbol       | Bit Name                                                    | Description                                                                                                                                                                                     | R/W |
|--------|--------------|-------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----|
| b0     | IICSTAREQ    | Start Condition Generation                                  | 0: A start condition is not generated.<br>1: A start condition is generated.*1, *3, *4, *5                                                                                                      | R/W |
| b1     | IICRSTAREQ   | Restart Condition Generation                                | 0: A restart condition is not generated.<br>1: A restart condition is generated.*2, *3, *4, *5                                                                                                  | R/W |
| b2     | IICSTPREQ    | Stop Condition Generation                                   | 0: A stop condition is not generated.<br>1: A stop condition is generated.*2, *3, *4, *5                                                                                                        | R/W |
| b3     | IICSTIF      | Issuing of Start, Restart, or Stop Condition Completed Flag | 0: There are no requests for generating conditions or a condition is being generated.<br>1: A start, restart, or stop condition is completely generated.                                        | R/W |
| b5, b4 | IICSDAS[1:0] | SSDA Output Select                                          | b5 b4<br>0 0: Serial data output<br>0 1: Generate a start, restart, or stop condition.<br>1 0: Output the low level on the SSDAn pin.<br>1 1: Place the SSDAn pin in the high-impedance state.  | R/W |
| b7, b6 | IICSCLS[1:0] | SSCL Output Select                                          | b7 b6<br>0 0: Serial clock output<br>0 1: Generate a start, restart, or stop condition.<br>1 0: Output the low level on the SSCLn pin.<br>1 1: Place the SSCLn pin in the high-impedance state. | R/W |

Note 1. Generate a start condition only when the SSCLn and SSDAn pins are both high (the corresponding bits in the corresponding PIDR registers are 1).

Note 2. Generate a restart or stop condition only when the SSCLn pin is low (the corresponding bit in the PIDR register is 0).

Note 3. Do not set more than one from among the IICSTAREQ, IICRSTAREQ, and IICSTPREQ bits to 1 at a given time.

Note 4. Execute the generation of a condition after the value of the IICSTIF flag is 0.

Note 5. Do not write 0 to this bit while it is 1. Generation of a condition is suspended by writing 0 to this bit while it is 1.

SIMR3 is used to control the simple I<sup>2</sup>C mode start and stop conditions, and to hold the SSDAn and SSCLn pins at fixed levels.

**IICSTAREQ Bit (Start Condition Generation)**

When a start condition is to be generated, set both the IICSDAS[1:0] and IICSCLS[1:0] bits to 01b as well as setting the IICSTAREQ bit to 1.

[Setting condition]

- Writing 1 to the bit

[Clearing condition]

- Completion of generation of the start condition

**IICRSTAREQ Bit (Restart Condition Generation)**

When a restart condition is to be generated, set both the IICSDAS[1:0] and IICSCLS[1:0] bits to 01b as well as setting the IICRSTAREQ bit to 1.

[Setting condition]

- Writing 1 to the bit

[Clearing condition]

- Completion of generation of the restart condition

**IICSTPREQ Bit (Stop Condition Generation)**

When a stop condition is to be generated, set both the IICSDAS[1:0] and IICSCLS[1:0] bits to 01b as well as setting the IICSTPREQ bit to 1.

[Setting condition]

- Writing 1 to the bit

[Clearing condition]

- Completion of generation of the stop condition

**IICSTIF Flag (Issuing of Start, Restart, or Stop Condition Completed Flag)**

After generating a condition, this bit indicates that the generation is completed. When using the IICSTAREQ, IICRSTAREQ, or IICSTPREQ bit to cause generation of a condition, do so after setting the IICSTIF flag to 0. When the IICSTIF flag is 1 while an interrupt request is enabled by setting the SCR.TEIE bit, an STI request is output.

[Setting condition]

- Completion of the generation of a start, restart, or stop condition (however, in cases where this conflicts with any of the conditions for the flag becoming 0 listed below, the other condition takes precedence)

[Clearing conditions]

- Writing 0 to the bit (confirm that the IICSTIF flag is 0 before doing so)
- Writing 0 to the SIMR1.IICM bit (when operation is not in simple I<sup>2</sup>C mode)
- Writing 0 to the SCR.TE bit

**IICSDAS[1:0] Bits (SSDA Output Select)**

These bits control output from the SSDAn pin.

Set the IICSDAS[1:0] and IICSCLS[1:0] bits to the same value during normal operations.

**IICSCLS[1:0] Bits (SSCL Output Select)**

These bits control output from the SSCLn pin.

Set the IICSCLS[1:0] and IICSDAS[1:0] bits to the same value during normal operations.

### 32.2.20 I<sup>2</sup>C Status Register (SISR)

Address(es): SCI1.SISR 0008 A02Ch, SCI5.SISR 0008 A0ACh, SCI6.SISR 0008 A0CCh, SCI8.SISR 0008 A10Ch, SCI9.SISR 0008 A12Ch, SCI11.SISR 000D 000Ch, SCI12.SISR 0008 B30Ch

|    |    |    |    |    |    |    |         |

| b7 | b6 | b5 | b4 | b3 | b2 | b1 | b0      |
| —  | —  | —  | —  | —  | —  | —  | IICACKR |

Value after reset: 0 0 x x 0 x 0 0

x: Undefined

| Bit    | Symbol  | Bit Name                | Description                                            | R/W   |
|--------|---------|-------------------------|--------------------------------------------------------|-------|
| b0     | IICACKR | ACK Reception Data Flag | 0: ACK received<br>1: NACK received                    | R/W*1 |
| b1     | —       | Reserved                | This bit is read as 0. The write value should be 0.    | R/W   |
| b2     | —       | Reserved                | The read value is undefined.                           | R     |
| b3     | —       | Reserved                | This bit is read as 0. The write value should be 0.    | R/W   |
| b5, b4 | —       | Reserved                | The read value is undefined.                           | R     |
| b7, b6 | —       | Reserved                | These bits are read as 0. The write value should be 0. | R/W   |

Note 1. Only 0 can be written to this bit, to clear the flag.

SISR is used to monitor state in relation to simple I<sup>2</sup>C mode.

#### IICACKR Flag (ACK Reception Data Flag)

Received ACK and NACK bits can be read from this bit.

The IICACKR flag is updated at the rising of SSCLn clock for the ACK/NACK receiving bit.

### 32.2.21 SPI Mode Register (SPMR)

Address(es): SCI1.SPMR 0008 A02Dh, SCI5.SPMR 0008 A0ADh, SCI6.SPMR 0008 A0CDh, SCI8.SPMR 0008 A10Dh, SCI9.SPMR 0008 A12Dh, SCI11.SPMR 000D 000Dh, SCI12.SPMR 0008 B30Dh

|      |       |    |     |    |     |      |     |

Value after reset: 0 0 0 0 0 0 0 0

| Bit | Symbol | Bit Name                 | Description                                                                                                                                                                                       | R/W   |
|-----|--------|--------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------|
| b0  | SSE    | SSn# Pin Function Enable | 0: SSn# pin function is disabled.<br>1: SSn# pin function is enabled.                                                                                                                             | R/W*1 |
| b1  | CTSE   | CTS Enable               | 0: CTS function is disabled (RTS output function is enabled).<br>1: CTS function is enabled.                                                                                                      | R/W*1 |
| b2  | MSS    | Master Slave Select      | 0: Transmission is through the SMOSIn pin and reception is through the SMISO pin (master mode).<br>1: Reception is through the SMOSIn pin and transmission is through the SMISO pin (slave mode). | R/W*1 |
| b3  | —      | Reserved                 | This bit is read as 0. The write value should be 0.                                                                                                                                               | R/W   |
| b4  | MFF    | Mode Fault Flag          | 0: No mode fault error<br>1: Mode fault error                                                                                                                                                     | R/W*2 |
| b5  | —      | Reserved                 | This bit is read as 0. The write value should be 0.                                                                                                                                               | R/W   |
| b6  | CKPOL  | Clock Polarity Select    | 0: Clock polarity is not inverted.<br>1: Clock polarity is inverted.                                                                                                                              | R/W*1 |
| b7  | CKPH   | Clock Phase Select       | 0: Clock is not delayed.<br>1: Clock is delayed.                                                                                                                                                  | R/W*1 |

Note 1. Writing to these bits is only possible when the RE and TE bits in the SCR register are 0 (both serial transmission and reception are disabled).

Note 2. Only 0 can be written to these bits, which clears the flag.

SPMR is used to select the extension settings in asynchronous and clock synchronous modes.

#### SSE Bit (SSn# Pin Function Enable)

Set this bit to 1 if the SSn# pin is to be used in control of transmission and reception (in simple SPI mode). Set this bit to 0 in any other mode. Furthermore, even for usage in simple SPI mode, the SSn# pin on the master side is not required to control reception and transmission when master mode (SCR.CKE[1:0] = 00b and MSS = 0) is selected and there is a single master, so the setting for the SSE bit is 0. Do not set both the SSE and CTSE bits to enabled (even if this setting is made, operation is the same as that when these bits are set to 0).

#### CTSE Bit (CTS Enable)

Set this bit to 1 if the SSn# pin is to be used for inputting of the CTS control signal to control of transmission and reception. The RTS signal is output when this bit is set to 0. Set this bit to 0 in smart card interface mode, simple SPI mode, and simple I<sup>2</sup>C mode. Do not set both the CTSE and SSE bits to enabled (even if this setting is made, operation is the same as that when these bits are set to 0).

#### MSS Bit (Master Slave Select)

This bit selects between master and slave operation in simple SPI mode. When the MSS bit is set to 1, data is received through the SMOSIn pin and transmitted through the SMISO pin.

Set this bit to 0 in modes other than simple SPI mode.

**MFF Flag (Mode Fault Flag)**

This bit indicates mode fault errors.

In a multi-master configuration, determine the mode fault error occurrence by reading the MFF flag.

[Setting condition]

- Input on the SSn# pin being at the low level during master operation in simple SPI mode (SSE bit = 1 and MSS bit = 0)

[Clearing condition]

- Writing 0 to the bit after it was read as 1

**CKPOL Bit (Clock Polarity Select)**

This bit selects the polarity of the clock signal output through the SCKn pin. Refer to Figure 32.62 for details.

Set the bit to 0 in other than simple SPI mode and clock synchronous mode.

**CKPH Bit (Clock Phase Select)**

This bit selects the phase of the clock signal output through the SCKn pin. Refer to Figure 32.62 for details.

Set the bit to 0 in other than simple SPI mode and clock synchronous mode.

### 32.2.22 FIFO Control Register (FCR)

Address(es): SCI11.FCR 000D 0014h,  
SCI11.FCR.H 000D 0014h,  
SCI11.FCR.L 000D 0015h

| Bit        | Symbol     | Bit Name                            | Description                                                                                                                                                                                                                          | R/W   |
|------------|------------|-------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------|
| b0         | FM         | FIFO Mode Select*1                  | 0: Non-FIFO mode (TDR and RDR registers are used for transmit and receive)<br>1: FIFO mode (FTDR and FRDR registers are used for transmit and receive)                                                                               | R/W*2 |
| b1         | RFRST      | Receive FIFO Reset*3                | Writing 1 clears the number of data stored in the receive FIFO to 0                                                                                                                                                                  | R/W   |
| b2         | TFRST      | Transmit FIFO Reset*3               | Writing 1 clears the number of data stored in the transmit FIFO to 0                                                                                                                                                                 | R/W   |
| b3         | DRES       | Receive Data Ready Interrupt Select | 0: Receive data full interrupt (RXI)<br>1: Error interrupt (ERI)                                                                                                                                                                     | R/W*2 |
| b7 to b4   | TTRG[3:0]  | Transmit FIFO Threshold Setting*1   | Specifies the threshold value for the SSRFIFO.TDFE flag to become 1<br>b7 b4<br>0 0 0 0: Transmit FIFO threshold value is 0<br>0 0 0 1: Transmit FIFO threshold value is 1<br>:<br>:<br>1 1 1 1: Transmit FIFO threshold value is 15 | R/W   |
| b11 to b8  | RTRG[3:0]  | Receive FIFO Threshold Setting*1    | Specifies the threshold value for the SSRFIFO.RDF flag to become 1<br>b11 b8<br>0 0 0 0: Setting prohibited<br>0 0 0 1: Receive FIFO threshold value is 1<br>:<br>:<br>1 1 1 1: Receive FIFO threshold value is 15                   | R/W   |
| b15 to b12 | RSTRG[3:0] | RTS# Output Threshold Setting*4     | Specifies the threshold value for the RTSn# pin to be driven high<br>b15 b12<br>0 0 0 0: Setting prohibited<br>0 0 0 1: Receive FIFO threshold value is 1<br>:<br>:<br>1 1 1 1: Receive FIFO threshold value is 15                   | R/W   |

Note 1. These bits are enabled in asynchronous mode and clock synchronous mode only.

Note 2. These bits can be rewritten only when the TE and RE bits in the SCR register are both 0.

Note 3. These bits are enabled only when the FM bit is 1.

Note 4. These bits are enabled when the FM bit is 1, and the CTSE and SSE bits in the SPMR register are both 0 (RTS# output is enabled).

#### FM Bit (FIFO Mode Select)

This bit is used to enable FIFO mode. Setting this bit to 1 enables FIFO, and causes FTDR and FRDR to be used as the data register for transmit and receive, respectively.

Setting this bit to 0 disables FIFO, and causes the TDR and RDR registers, or the TDRHL, TDRH, TDRL, RDRHL, RDRH, and RDRL registers to be used as the data register for transmit and receive.

This bit is enabled in asynchronous mode and clock synchronous mode only. This bit should be set to 0 in any other mode. When rewriting this bit, transmit and receive should be disabled.

**RFRST Bit (Receive FIFO Reset)**

Setting the RFRST bit to 1, causes the FDR.R[4:0] bits to become 0. The value of the RFRST bit automatically returns to 0 after 1 PCLK.

**TFRST Bit (Transmit FIFO Reset)**

Setting the TFRST bit to 1, causes the FDR.T[4:0] bits to become 0. The value of the TFRST bit automatically returns to 0 after 1 PCLK.

**DRES Bit (Receive Data Ready Interrupt Select)**

This bit is used to select the interrupt request that is generated when the SSRFIFO.DR flag becomes 1. When this bit is 0, a DR flag of 1 generates a receive data full interrupt (RXI) request. When this bit is 1, a DR flag of 1 generates a receive error interrupt (ERI) request.

**TTRG[3:0] Bits (Transmit FIFO Threshold Setting)**

The SSRFIFO.TDFE flag becomes 1 when the value of the FDR.T[4:0] bits becomes equal to or less than the value set in the TTRG[3:0] bits. At this time, if the SCR.TIE bit is 1, a transmit data empty interrupt (TXI) request is generated.

**RTRG[3:0] Bits (Receive FIFO Threshold Setting)**

The SSRFIFO.RDF flag becomes 1 when the values of the FDR.R[4:0] bits are equal to or greater than the values set in the RTRG[3:0] bits. At this time, if the SCR.RIE bit is 1, a receive data full interrupt (RXI) request is generated.

**RSTRG[3:0] Bits (RTSn# Output Threshold Setting)**

When the values of the FDR.R[4:0] bits becomes equal to or greater than the values set in the RSTRG[3:0] bits, the RTSn# pin is driven high. When using this function, set both the CTSE and SSE bits in the SPMR register to 0 to enable RTSn# output.

### 32.2.23 FIFO Data Count Register (FDR)

Address(es): SCI11.FDR 000D 0016h,  
SCI11.FDR.H 000D 0016h,  
SCI11.FDR.L 000D 0017h

| Bit        | Symbol | Bit Name                   | Description                                                        | R/W |
|------------|--------|----------------------------|--------------------------------------------------------------------|-----|
| b4 to b0   | R[4:0] | Receive FIFO Data Count*1  | These bits indicate the number of data stored in the receive FIFO  | R   |
| b7 to b5   | —      | Reserved                   | These bits are read as 0. The write value should be 0.             | R   |
| b12 to b8  | T[4:0] | Transmit FIFO Data Count*1 | These bits indicate the number of data stored in the transmit FIFO | R   |
| b15 to b13 | —      | Reserved                   | These bits are read as 0. The write value should be 0.             | R   |

Note 1. These bits are valid only in asynchronous mode or clock synchronous mode.

#### R[4:0] Bits (Receive FIFO Data Count)

These bits indicate the number of data stored in the receive FIFO. 00h indicates that no received data is in FIFO, and 10h indicates that 16 frame data received have been stored in FIFO.

These bits never have values in the range from 11h to 1Fh.

#### T[4:0] Bits (Transmit FIFO Data Count)

These bits indicate the number of untransmitted data in the transmit FIFO. 00h indicates that no untransmitted data is in FIFO, and 10h indicates that 16 frames of untransmitted data are stored in FIFO.

These bits never have values in the range from 11h to 1Fh.

### 32.2.24 Line Status Register (LSR)

Address(es): SCI11.LSR 000D 0018h,  
SCI11.LSR.H 000D 0018h,  
SCI11.LSR.L 000D 0019h

| Bit        | Symbol    | Bit Name                         | Description                                                                                                                            | R/W             |
|------------|-----------|----------------------------------|----------------------------------------------------------------------------------------------------------------------------------------|-----------------|
| b0         | ORER      | Overrun Error Flag <sup>*1</sup> | The same value as that in the SSRFIFO.ORER flag is read.<br>0: An overrun error has not occurred.<br>1: An overrun error has occurred. | R <sup>*2</sup> |
| b1         | —         | Reserved                         | This bit are read as 0. The write value should be 0.                                                                                   | R               |
| b6 to b2   | FNUM[4:0] | Framing Error Count              | These bits indicate the number of data with a framing error among the data stored in the receive FIFO.                                 | R               |
| b7         | —         | Reserved                         | This bit are read as 0. The write value should be 0.                                                                                   | R               |
| b12 to b8  | PNUM[4:0] | Parity Error Count               | These bits indicate the number of data with a parity error among the data stored in the receive FIFO.                                  | R               |
| b15 to b13 | —         | Reserved                         | This bit are read as 0. The write value should be 0.                                                                                   | R               |

Note 1. The bit can be read only in FIFO mode, and asynchronous mode or clock synchronous mode.

Note 2. To clear this flag, confirm that the SSRFIFO.ORER flag is 1 first, and then write 0 to the SSRFIFO.ORER flag.

#### ORER Flag (Overrun Error Flag)

This bit becomes 1 when an overrun error occurs. The value of the SSRFIFO.ORER flag is reflected to this bit. To clear this flag, clear the SSRFIFO.ORER flag.

#### FNUM[4:0] Bits (Framing Error Count)

These bits indicate the number of data in which a framing error has occurred among the received data in the receive FIFO.

#### PNUM[4:0] Bits (Parity Error Count)

These bits indicate the number of data in which a parity error has occurred among the received data in the receive FIFO.

### 32.2.25 Comparison Data Register (CDR)

Address(es): SCI1.CDR 0008 A03Ah, SCI5.CDR 0008 A0BAh, SCI6.CDR 0008 A0DAh, SCI8.CDR 0008 A11Ah, SCI9.CDR 0008 A13Ah,  
 SCI11.CDR 000D 001Ah,  
 SCI1.CDR.H 0008 A03Ah, SCI5.CDR.H 0008 A0BAh, SCI6.CDR.H 0008 A0DAh, SCI8.CDR.H 0008 A11Ah, SCI9.CDR.H 0008 A13Ah,  
 SCI11.CDR.H 000D 001Ah,  
 SCI1.CDR.L 0008 A03Bh, SCI5.CDR.L 0008 A0BBh, SCI6.CDR.L 0008 A0DBh, SCI8.CDR.L 0008 A11Bh, SCI9.CDR.L 0008 A13Bh,  
 SCI11.CDR.L 000D 001Bh

| Bit       | Symbol    | Bit Name        | Description                                                                                    | R/W |
|-----------|-----------|-----------------|------------------------------------------------------------------------------------------------|-----|
| b8 to b0  | CMPD[8:0] | Comparison Data | These bits specify the data of comparison source when using the data match detection function. | R/W |
| b15 to b9 | —         | Reserved        | These bits are read as 0. The write value should be 0.                                         | R   |

#### CMPD[8:0] Bits (Comparison Data)

These bits are used for detecting a data match. The length of the valid bit is the same as the character length set in the SMR.CHR and SCMR.CHR1 bits.

The DCCR.DCMF flag becomes 1 when the received data matches with the value of these bits.

### 32.2.26 Data Comparison Control Register (DCCR)

Address(es): SCI1.DCCR 0008 A033h, SCI5.DCCR 0008 A0B3h, SCI6.DCCR 0008 A0D3h, SCI8.DCCR 0008 A113h, SCI9.DCCR 0008 A133h, SCI11.DCCR 000D 0013h

|                   | b7   | b6    | b5 | b4   | b3   | b2 | b1 | b0   |
|-------------------|------|-------|----|------|------|----|----|------|
|                   | DCME | IDSEL | —  | DFER | DPER | —  | —  | DCMF |
| Value after reset | 0    | 1     | 0  | 0    | 0    | 0  | 0  | 0    |

| Bit    | Symbol | Bit Name                      | Description                                                                                              | R/W         |
|--------|--------|-------------------------------|----------------------------------------------------------------------------------------------------------|-------------|
| b0     | DCMF   | Data Match Flag               | 0: Data is not matched<br>1: Data is matched                                                             | R/(W)<br>*1 |
| b2, b1 | —      | Reserved                      | These bits are read as 0. The write value should be 0                                                    | R/W         |
| b3     | DPER   | Match Data Parity Error Flag  | 0: A parity error is not found in the matched data.<br>1: A parity error is found in the matched data.   | R/(W)<br>*1 |
| b4     | DFER   | Match Data Framing Error Flag | 0: A framing error is not found in the matched data.<br>1: A framing error is found in the matched data. | R/(W)<br>*1 |
| b5     | —      | Reserved                      | This bit is read as 0. The write value should be 0                                                       | R/W         |
| b6     | IDSEL  | ID Frame Select*2             | 0: All data is to be compared<br>1: The data with the multi-processor bit set to 1 is to be compared     | R/W         |
| b7     | DCME   | Data Match Detection Enable*2 | 0: Data match detection is disabled<br>1: Data match detection is enabled                                | R/W         |

Note 1. Only 0 can be written to this bit, which clears the flag. To clear this flag, confirm that the flag is 1, and then write 0 to the flag.

Note 2. This bit is only valid in asynchronous mode.

#### DCMF Flag (Data Match Flag)

This flag indicates the comparison result of the received data and the value of the CDR register.

[Setting condition]

- When the received data matches with the value in the CDR register while the DCME bit is 1

[Clearing condition]

- When 0 is written to the flag after reading this flag as 1

Even when the SCR.RE bit is set to 0, the DCMF flag has no effect and retains the previous state.

#### DPER Flag (Match Data Parity Error Flag)

This flag indicates if a parity error has occurred in the matched data.

[Setting condition]

- When a parity error is found in the received data in which a data match is detected.

[Clearing condition]

- When 0 is written to the flag after reading the flag as 1.

Refer to section 14.5.2, Level Detection to exit from the interrupt handling routine after setting the DPER flag to 0.

Even when the SCR.RE bit is set to 0, the DPER flag has no effect and retains the previous state.

#### DFER Flag (Match Data Framing Error Flag)

This flag indicates if a framing error has occurred in the matched data.

[Setting condition]

- When the stop bit of the received frame in which a data match is detected is 0

[Clearing condition]

- When 0 is written to the flag after reading the flag as 1.

Refer to section 14.5.2, Level Detection to exit from the interrupt handling routine after setting the DFER flag to 0.

Even when the SCR.RE bit is set to 0, the DFER flag has no effect and retains the previous state.

### IDSEL Bit (ID Frame Select)

This bit specifies the condition of the received data to be compared. The bit is valid only when the DCME bit is 1.

When setting this bit to 1, only data in received frames (ID frames) in which the multi-processor bit has the value 1 are compared.

When this bit is set to 0, all received data is compared.

### DCME Bit (Data Match Detection Enable)

This bit enables or disables the data match detection function. The function is valid only in asynchronous mode. In other modes, set this bit to 0.

This bit automatically becomes 0 when a data match is detected.

## 32.2.27 Serial Port Register (SPTR)

Address(es): SCI1.SPTR 0008 A03Ch, SCI5.SPTR 0008 A0BCh, SCI6.SPTR 0008 A0DCh, SCI8.SPTR 0008 A11Ch, SCI9.SPTR 0008 A13Ch, SCI11.SPTR 000D 001Ch

|                   | b7 | b6 | b5 | b4 | b3 | b2         | b1         | b0                 |
|-------------------|----|----|----|----|----|------------|------------|--------------------|
|                   | —  | —  | —  | —  | —  | SPB2I<br>O | SPB2D<br>T | RXD<br>M<br>O<br>N |
| Value after reset | 0  | 0  | 0  | 0  | 0  | 0          | 1          | 1                  |

| Bit      | Symbol | Bit Name                 | Description                                                                                        | R/W |
|----------|--------|--------------------------|----------------------------------------------------------------------------------------------------|-----|
| b0       | RXDMON | RXD Line Monitoring Flag | 0: The RXDn pin level is low<br>1: The RXDn pin level is high                                      | R   |
| b1       | SPB2DT | Serial Port Break Data*1 | Combine bits SPB2DT, SPB2IO, and SCR.TE to control the TXDn pin. Refer to Table 32.30 for details. | R/W |
| b2       | SPB2IO | Serial Port Break I/O*1  |                                                                                                    | R/W |
| b7 to b3 | —      | Reserved                 | These bits are read as 0. The write value should be 0.                                             | R   |

Note 1. This bit is only valid in asynchronous mode.

### RXDMON Flag (RXD Line Monitoring Flag)

This flag is used for monitoring the level of the RXDn pin.

### SPB2DT Bit (Serial Port Break Data)

This bit specifies the output level of the TXDn pin when the SCR.TE bit is 0. Refer to Table 32.30 for details.

### SPB2IO Bit (Serial Port Break I/O)

This bit specifies input or output of the TXDn pin when the SCR.TE bit is 0. Set this bit to 1 (output) when controlling the TXDn pin by software.

**Table 32.30 Controlling the TXDn pin**

| SCR.TE Bit Setting        | SPB2IO Bit Setting | SPB2DT Bit Setting | TXDn Pin Status          |
|---------------------------|--------------------|--------------------|--------------------------|
| 0 (Transmission disabled) | 0 (Input)          | 0 or 1             | Hi-Z                     |
|                           | 1 (Output)         | 0 (Low)            | Low is output            |
|                           |                    | 1 (High)           | High is output           |
| 1 (Transmission enabled)  | 0 or 1             | 0 or 1             | Transmit data output pin |

### 32.2.28 Extended Serial Module Enable Register (ESMER)

Address(es): SCI12.ESMER 0008 B320h

| Bit      | Symbol | Bit Name                    | Description                                                                         | R/W |
|----------|--------|-----------------------------|-------------------------------------------------------------------------------------|-----|
| b0       | ESME   | Extended Serial Mode Enable | 0: The extended serial mode is disabled.<br>1: The extended serial mode is enabled. | R/W |
| b7 to b1 | —      | Reserved                    | These bits are read as 0. The write value should be 0.                              | R/W |

#### ESME Bit (Extended Serial Mode Enable)

When the ESME bit is 1, the facilities of the extended serial mode control section are enabled.

When the ESME bit is 0, the extended serial mode control section is initialized.

**Table 32.31 Settings of the ESME Bit and Timer Operation Mode**

| ESME Bit | Timer Mode  | Break Field Low Width Determination Mode | Break Field Low Width Output Mode |
|----------|-------------|------------------------------------------|-----------------------------------|
| 0        | Available*1 | Not available                            | Not available                     |
| 1        | Available   | Available                                | Available                         |

Note 1. Operation is only possible with PCLK selected.

### 32.2.29 Control Register 0 (CR0)

Address(es): SCI12.CR0 0008 B321h

| Bit      | Symbol | Bit Name                    | Description                                                                                     | R/W |
|----------|--------|-----------------------------|-------------------------------------------------------------------------------------------------|-----|
| b0       | —      | Reserved                    | This bit is read as 0. The write value should be 0.                                             | R/W |
| b1       | SFSF   | Start Frame Status Flag     | 0: Start Frame detection function is disabled.<br>1: Start Frame detection function is enabled. | R   |
| b2       | RXDSF  | RXDX12 Input Status Flag    | 0: RXDX12 input is enabled.<br>1: RXDX12 input is disabled.                                     | R   |
| b3       | BRME   | Bit Rate Measurement Enable | 0: Measurement of bit rate is disabled.<br>1: Measurement of bit rate is enabled.               | R/W |
| b7 to b4 | —      | Reserved                    | These bits are read as 0. The write value should be 0.                                          | R/W |

## 32.2.30 Control Register 1 (CR1)

Address(es): SCI12.CR1 0008 B322h

| Bit      | Symbol     | Bit Name                             | Description                                                                                                                                                                                                                                                                                                   | R/W |

### 32.2.36 Status Clear Register (STCR)

Address(es): SCI12.STCR 0008 B328h

| Bit    | Symbol  | Bit Name    | Description                                                             | R/W |
|--------|---------|-------------|-------------------------------------------------------------------------|-----|
| b0     | BFDCCL  | BFDF Clear  | Setting this bit to 1 clears the STR.BFDF flag. This bit is read as 0.  | R/W |
| b1     | CF0MCL  | CF0MF Clear | Setting this bit to 1 clears the STR.CF0MF flag. This bit is read as 0. | R/W |
| b2     | CF1MCL  | CF1MF Clear | Setting this bit to 1 clears the STR.CF1MF flag. This bit is read as 0. | R/W |
| b3     | PIBDCCL | PIBDF Clear | Setting this bit to 1 clears the STR.PIBDF flag. This bit is read as 0. | R/W |
| b4     | BCDCL   | BCDF Clear  | Setting this bit to 1 clears the STR.BCDF flag. This bit is read as 0.  | R/W |
| b5     | AEDCL   | AEDF Clear  | Setting this bit to 1 clears the STR.AEDF flag. This bit is read as 0.  | R/W |
| b7, b6 | —       | Reserved    | These bits are read as 0. The write value should be 0.                  | R/W |

### 32.2.37 Control Field 0 Data Register (CF0DR)

Address(es): SCI12.CF0DR 0008 B329h

The CF0DR register is an 8-bit readable and writable register that holds a value for comparison with Control Field 0.

### 32.2.38 Control Field 0 Compare Enable Register (CF0CR)

Address(es): SCI12.CF0CR 0008 B32Ah

| Bit | Symbol | Bit Name                             | Description                                                                                                         | R/W |

| b0  | CF0CE0 | Control Field 0 Bit 0 Compare Enable | 0: Comparison with bit 0 of Control Field 0 is disabled.<br>1: Comparison with bit 0 of Control Field 0 is enabled. | R/W |
| b1  | CF0CE1 | Control Field 0 Bit 1 Compare Enable | 0: Comparison with bit 1 of Control Field 0 is disabled.<br>1: Comparison with bit 1 of Control Field 0 is enabled. | R/W |
| b2  | CF0CE2 | Control Field 0 Bit 2 Compare Enable | 0: Comparison with bit 2 of Control Field 0 is disabled.<br>1: Comparison with bit 2 of Control Field 0 is enabled. | R/W |
| b3  | CF0CE3 | Control Field 0 Bit 3 Compare Enable | 0: Comparison with bit 3 of Control Field 0 is disabled.<br>1: Comparison with bit 3 of Control Field 0 is enabled. | R/W |
| b4  | CF0CE4 | Control Field 0 Bit 4 Compare Enable | 0: Comparison with bit 4 of Control Field 0 is disabled.<br>1: Comparison with bit 4 of Control Field 0 is enabled. | R/W |
| b5  | CF0CE5 | Control Field 0 Bit 5 Compare Enable | 0: Comparison with bit 5 of Control Field 0 is disabled.<br>1: Comparison with bit 5 of Control Field 0 is enabled. | R/W |
| b6  | CF0CE6 | Control Field 0 Bit 6 Compare Enable | 0: Comparison with bit 6 of Control Field 0 is disabled.<br>1: Comparison with bit 6 of Control Field 0 is enabled. | R/W |
| b7  | CF0CE7 | Control Field 0 Bit 7 Compare Enable | 0: Comparison with bit 7 of Control Field 0 is disabled.<br>1: Comparison with bit 7 of Control Field 0 is enabled. | R/W |

### 32.2.39 Control Field 0 Receive Data Register (CF0RR)

Address(es): SCI12.CF0RR 0008 B32Bh

CF0RR is a readable register that holds the value received in Control Field 0.

### 32.2.40 Primary Control Field 1 Data Register (PCF1DR)

Address(es): SCI12.PCF1DR 0008 B32Ch

PCF1DR is an 8-bit readable and writable register that holds the 8-bit primary value for comparison with Control Field 1.

### 32.2.41 Secondary Control Field 1 Data Register (SCF1DR)

Address(es): SCI12.SCF1DR 0008 B32Dh

PCF1DR is an 8-bit readable and writable register that holds the 8-bit secondary value for comparison with Control Field 1.

### 32.2.42 Control Field 1 Compare Enable Register (CF1CR)

Address(es): SCI12.CF1CR 0008 B32Eh

| Bit | Symbol | Bit Name                             | Description                                                                                                         | R/W |
|-----|--------|--------------------------------------|---------------------------------------------------------------------------------------------------------------------|-----|
| b0  | CF1CE0 | Control Field 1 Bit 0 Compare Enable | 0: Comparison with bit 0 of Control Field 1 is disabled.<br>1: Comparison with bit 0 of Control Field 1 is enabled. | R/W |
| b1  | CF1CE1 | Control Field 1 Bit 1 Compare Enable | 0: Comparison with bit 1 of Control Field 1 is disabled.<br>1: Comparison with bit 1 of Control Field 1 is enabled. | R/W |
| b2  | CF1CE2 | Control Field 1 Bit 2 Compare Enable | 0: Comparison with bit 2 of Control Field 1 is disabled.<br>1: Comparison with bit 2 of Control Field 1 is enabled. | R/W |
| b3  | CF1CE3 | Control Field 1 Bit 3 Compare Enable | 0: Comparison with bit 3 of Control Field 1 is disabled.<br>1: Comparison with bit 3 of Control Field 1 is enabled. | R/W |
| b4  | CF1CE4 | Control Field 1 Bit 4 Compare Enable | 0: Comparison with bit 4 of Control Field 1 is disabled.<br>1: Comparison with bit 4 of Control Field 1 is enabled. | R/W |
| b5  | CF1CE5 | Control Field 1 Bit 5 Compare Enable | 0: Comparison with bit 5 of Control Field 1 is disabled.<br>1: Comparison with bit 5 of Control Field 1 is enabled. | R/W |
| b6  | CF1CE6 | Control Field 1 Bit 6 Compare Enable | 0: Comparison with bit 6 of Control Field 1 is disabled.<br>1: Comparison with bit 6 of Control Field 1 is enabled. | R/W |
| b7  | CF1CE7 | Control Field 1 Bit 7 Compare Enable | 0: Comparison with bit 7 of Control Field 1 is disabled.<br>1: Comparison with bit 7 of Control Field 1 is enabled. | R/W |

### 32.2.43 Control Field 1 Receive Data Register (CF1RR)

Address(es): SCI12.CF1RR 0008 B32Fh

CF1RR is a readable register that holds the value received in Control Field 1.

### 32.2.44 Timer Control Register (TCR)

Address(es): SCI12.TCR 0008 B330h

| Bit      | Symbol | Bit Name          | Description                                                 | R/W |
|----------|--------|-------------------|-------------------------------------------------------------|-----|
| b0       | TCST   | Timer Count Start | 0: Stops the timer counting<br>1: Starts the timer counting | R/W |
| b7 to b1 | —      | Reserved          | These bits are read as 0. The write value should be 0.      | R/W |

### 32.2.45 Timer Mode Register (TMR)

Address(es): SCI12.TMR 0008 B331h

| Bit      | Symbol    | Bit Name                          | Description                                                                                                                                      | R/W |
|----------|-----------|-----------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------|-----|
| b1, b0   | TOMS[1:0] | Timer Operating Mode Select*1     | b1 b0<br>0 0: Timer mode<br>0 1: Break Field low width determination mode<br>1 0: Break Field low width output mode<br>1 1: Setting prohibited   | R/W |
| b2       | —         | Reserved                          | This bit is read as 0. The write value should be 0.                                                                                              | R/W |
| b3       | TWRC      | Counter Write Control             | 0: Data is written to the reload register and counter<br>1: Data is written to the reload register only                                          | R/W |
| b6 to b4 | TCSS[2:0] | Timer Count Clock Source Select*1 | b6 b4<br>0 0 0: PCLK<br>0 0 1: PCLK/2<br>0 1 0: PCLK/4<br>0 1 1: PCLK/8<br>1 0 0: PCLK/16<br>1 0 1: PCLK/32<br>1 1 0: PCLK/64<br>1 1 1: PCLK/128 | R/W |
| b7       | —         | Reserved                          | This bit is read as 0. The write value should be 0.                                                                                              | R/W |

Note 1. Rewrite the TOMS[1:0] and TCSS[2:0] bits only when the timer is stopped (TCST = 0).

#### TWRC Bit (Counter Write Control)

This bit determines whether a value written to the TPRES or TCNT register is written to the reload register only or is written to both the reload register and the counter.

### 32.2.46 Timer Prescaler Register (TPRE)

Address(es): SCI12.TPRE 0008 B332h

TPRE consists of an 8-bit reload register, a read buffer, and a counter, each of which has FFh as its initial value. The counter counts down in synchronization with the counter clock selected by the TMR.TCSS[2:0] bits, and is reloaded with the value in the reload register when it underflows. Underflows of this register provide the clock source to drive counting by the TCNT register. The reload register and read buffer are allocated to the same address. Data is written to the reload register in writing, and the counter value that has been transferred to the read buffer is returned in reading.

It takes one PCLK cycle to load a value from the reload register to the counter.

### 32.2.47 Timer Count Register (TCNT)

Address(es): SCI12.TCNT 0008 B333h

TCNT consists of an 8-bit reload register, a read buffer, and a counter, each of which has FFh as its initial value. This down-counter counts underflows of the TPRE register until the TCNT register underflows, and is then reloaded with the value from the reload register. The reload register and read buffer are allocated to the same address. Data is written to the reload register in writing, and the counter value that has been transferred to the read buffer is returned in reading.

It takes one PCLK cycle to load a value from the reload register to the counter.

### 32.3 Operation in Asynchronous Mode

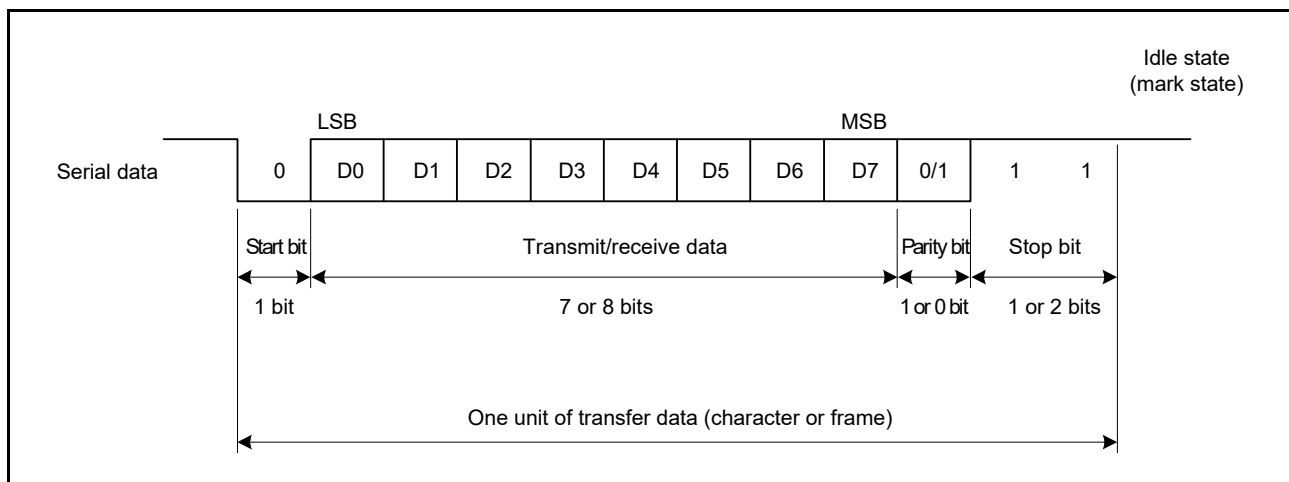

Figure 32.6 shows the general format for asynchronous serial communications.

One frame consists of a start bit (low level), transmit/receive data, a parity bit, and stop bits (high level).

In asynchronous serial communications, the communications line is usually held in the mark state (high level).

The SCI monitors the communications line. When the SCI detects a low, it regards that as a start bit and starts serial communication.

Inside the SCI, the transmitter and receiver are independent units, enabling full-duplex communications. Both the transmitter and the receiver also have a double-buffered structure, so that data can be read or written during transmission or reception, enabling continuous data transmission and reception. As SCI11 incorporate a FIFO, data can be received and transmitted more efficiently.

**Figure 32.6 Data Format in Asynchronous Serial Communications  
(Example with 8-Bit Data, Parity, 2 Stop Bits)**

#### 32.3.1 Serial Data Transfer Format

Table 32.32 lists the serial data transfer formats that can be used in asynchronous mode.

Any of 18 transfer formats can be selected according to the SMR and SCMR setting. For details of multi-processor function, refer to section 32.4, Multi-Processor Communications Function.

**Table 32.32 Serial Transfer Formats (Asynchronous Mode)**

| SCMR Setting SMR Setting |     |    |    |      | Serial Transfer Format and Frame Length |            |   |   |   |   |   |   |      |      |      |      |      |  |  |  |
|--------------------------|-----|----|----|------|-----------------------------------------|------------|---|---|---|---|---|---|------|------|------|------|------|--|--|--|
| CHR1                     | CHR | PE | MP | STOP | 1                                       | 2          | 3 | 4 | 5 | 6 | 7 | 8 | 9    | 10   | 11   | 12   | 13   |  |  |  |

 MPB: Multi-processor bit

### 32.3.2 Receive Data Sampling Timing and Reception Margin in Asynchronous Mode

In asynchronous mode, the SCI operates on a base clock with a frequency of 16 times\*1 the bit rate.

In reception, the SCI samples the falling edge of the start bit using the base clock, and performs internal synchronization. Since receive data is sampled at the rising edge of the 8th pulse\*1 of the base clock, data is latched at the middle of each bit, as shown in Figure 32.7. Thus the reception margin in asynchronous mode is determined by formula (1) below.

$$M = \left| \left( 0.5 - \frac{1}{2N} \right) - (L - 0.5)F - \frac{|D - 0.5|}{N} (1 + F) \right| \times 100 (\%) \quad \cdots \text{Formula (1)}$$

M: Reception margin

N: Ratio of bit rate to clock

(N = 16 when SEMR.ABCSE = 0 and SEMR.ABCS = 0, N = 8 when SEMR.ABCSE = 0 and SEMR.ABCS = 1, N = 6 when SEMR.ABCSE = 1)

D: Duty cycle of clock (D = 0.5 to 1.0)

L: Frame length (L = 9 to 13)

F: Absolute value of clock frequency deviation

Assuming values of F = 0 and D = 0.5 in formula (1), the reception margin is determined by the formula below.

$$M = \{0.5 - 1/(2 \times 16)\} \times 100 (\%) = 46.875 (\%)$$

However, this is only the computed value, and a margin of 20% to 30% should be allowed in system design.

Note 1. These are values when the ABCSE and ABCS bits in the SEMR register are 0. When the ABCSE bit is 0 and the ABCS bit is 1, a frequency of 8 times the bit rate is used as a base clock and receive data is sampled at the rising edge of the 4th pulse of the base clock. When the ABCSE bit is 1, a frequency of 6 times the bit rate is used as a base clock and receive data is sampled at the rising edge of the 3rd pulse of the base clock.

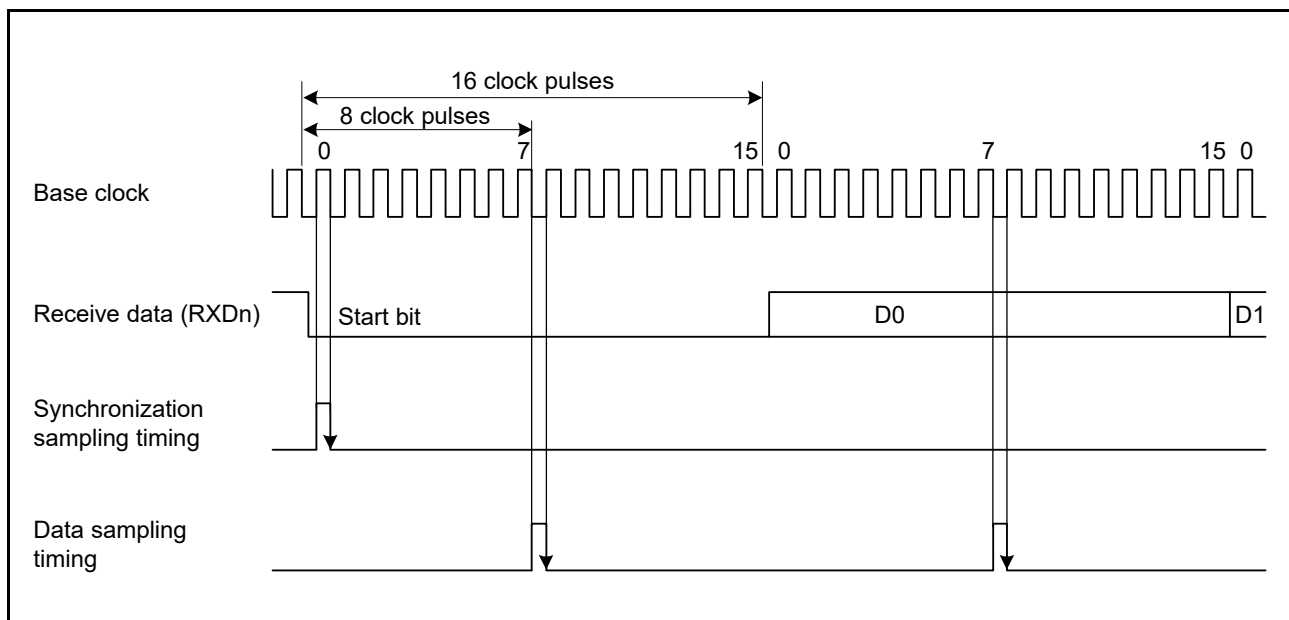

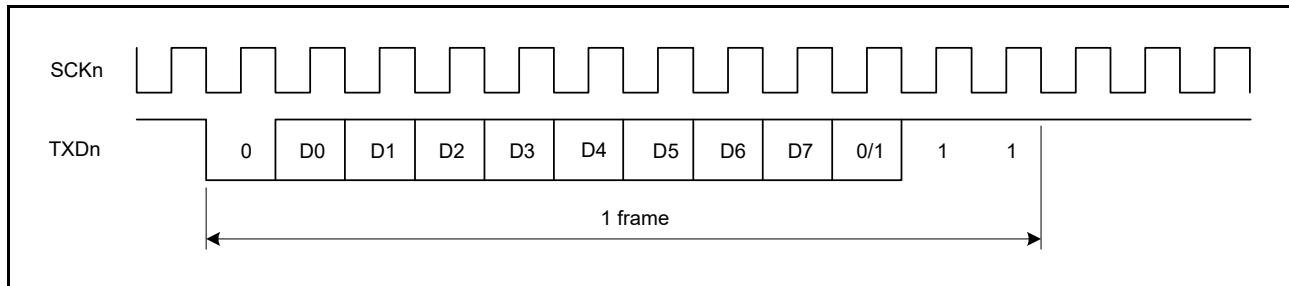

Figure 32.7 Receive Data Sampling Timing in Asynchronous Mode

### 32.3.3 Clock

Either an internal clock generated by the on-chip baud rate generator or an external clock input to the SCKn pin can be selected as the SCI's transfer clock, according to the setting of the SMR.CM bit and the SCR.CKE[1:0] bits.

When an external clock is input to the SCKn pin, the clock frequency should be 16 times the bit rate (when SEMR.ABCS bit = 0) and 8 times the bit rate (when SEMR.ABCS bit = 1). In addition, when an external clock is specified, the base clock of TMR0 and TMR1 can be selected by the SCIn.SEMR.ACS0 bit (n = 5, 6, 12).

When the SCI is operated on an internal clock, the clock can be output from the SCKn pin. The frequency of the clock output in this case is equal to the bit rate, and the phase is such that the rising edge of the clock is in the middle of the transmit data, as shown in Figure 32.8.

**Figure 32.8** Phase Relationship between Output Clock and Transmit Data  
(Asynchronous Mode: SMR.CHR = 0, PE = 1, MP = 0, STOP = 1)

### 32.3.4 Double-Speed Mode and Divide-by-6 Mode

The output clock frequency of the on-chip baud rate generator is doubled by setting the SEMR.BGDM bit to 1, enabling high-speed communication at a doubled bit rate. If the SEMR.ABCS bit is set to 1 under the above condition, the number of base clock cycles changes from 16 to 8, so the bit rate becomes four times faster than the initial state.

When the SEMR.ABCSE bit is set to 1, the number of base clock pulses in 1-bit period becomes 6 and the period of the base clock becomes 1/2, where the bit rate becomes 16/3 times faster compared to a case that all of the ABCS, BDGM, and ABCSE bits are set to 0.

As shown by Formula (1) in section 32.3.2, Receive Data Sampling Timing and Reception Margin in Asynchronous Mode, setting the SEMR.ABCS bit to 1 changes the number of cycles to 8, and the sampling interval becomes longer. This causes the reception margin to decrease. Therefore, setting the SEMR.BGDM bit to 1 and the SEMR.ABCS bit to 0 is recommended instead of setting the SEMR.BGDM bit to 0 and the SEMR.ABCS bit to 1 for high-speed operation at a doubled bit rate.

### 32.3.5 CTS and RTS Functions

The CTS function is the use of input on the CTSn# pin in transmission control. Setting the SPMR.CTSE bit to 1 enables the CTS function. When the CTS function is enabled, placing the low level on the CTSn# pin causes transmission to start.

Applying the high level to the CTS# pin while transmission is in progress does not affect transmission of the current frame, which continues.

In the RTS function, by using the function of output on the RTSn# pin, a low level is output when reception becomes possible. Conditions for output of the low and high level are shown below.

#### (a) SCI1, SCI5, SCI6, SCI8, SCI9, and SCI12, and SCI11 when FIFO is Disabled

[Conditions for low-level output]

When the following conditions are all satisfied.

- The SCR.RE bit is 1.
- Reception is not in progress.
- There are no received data yet to be read.
- The ORER, FER, and PER flags in the SSR register are all 0.

[Condition for high-level output]

When the conditions for low-level output are not satisfied.

#### (b) SCI11 When FIFO is Enabled

[Conditions for low-level output]

When the following conditions are all satisfied.

- The SCR.RE bit is 1.
- The number of data stored in the receive FIFO is less than the threshold (FCR.RTRG[3:0]).
- The SSRFIFO.ORER flag is 0.

[Condition for high-level output]

When the conditions for low-level output are not satisfied.

Note that either one of CTS and RTS can be selected.

### 32.3.6 Data Match Detection

The data match detection function is available in asynchronous mode for SCI1, SCI5, SCI6, SCI8, SCI9, and SCI11.

When the DCCR.DCME bit is set to 1, the received data is compared with the contents of the CDR.CMPD[8:0] bits\*1.

Upon a match of the value, a receive data full interrupt (RXI) request is generated.

When the SMR.MP bit is 0, all received data is compared.

When the SMR.MP bit is set to 1 and if the DCCR.IDSEL bit is 1, only the data in which the multiprocessor bit is 1 is compared and data in which the bit is 0 is ignored. When the DCCR.IDSEL bit is 0, all of the received data is compared regardless of the value of the multiprocessor bit.

The received data is not stored or the flag is not updated until the received data matches with the value of the CDR.CMPD[8:0] bits. When the data is matched, the DCCR.DCME bit is automatically set to 0 and the DCMF flag becomes 1. At this time, if the DCCR.IDSEL bit is 1, the SCR.MPIE bit is automatically set to 0. In addition, an receive data full interrupt (RXI) request is generated when the SCR.RIE bit is 1.

When a framing error is found in the matched data, the DCCR.DFER flag becomes 1. When a parity error is found in the matched data, the DCCR.DPER flag becomes 1. The received data matched with the value of the CDR.CMPD[8:0] bits is not stored in the received buffer or the SSR.RDRF flag (the SSRFIFO.RDF flag when the FCR.FM bit is 1) does not become 1.

After a data match is detected and the DCCR.DCME bit is set to 0, data is normally received.

When the DCCR.DFER or DCCR.DPER flag is 1, a data match is not detected. These flags should be set to 0 before enabling the data match detection function.

Note 1. Only the portion that corresponds to the character length specified by the SMR.CHR and SCMR.CHR1 bits is compared.

Figure 32.9 and Figure 32.10 show examples of data match detection.

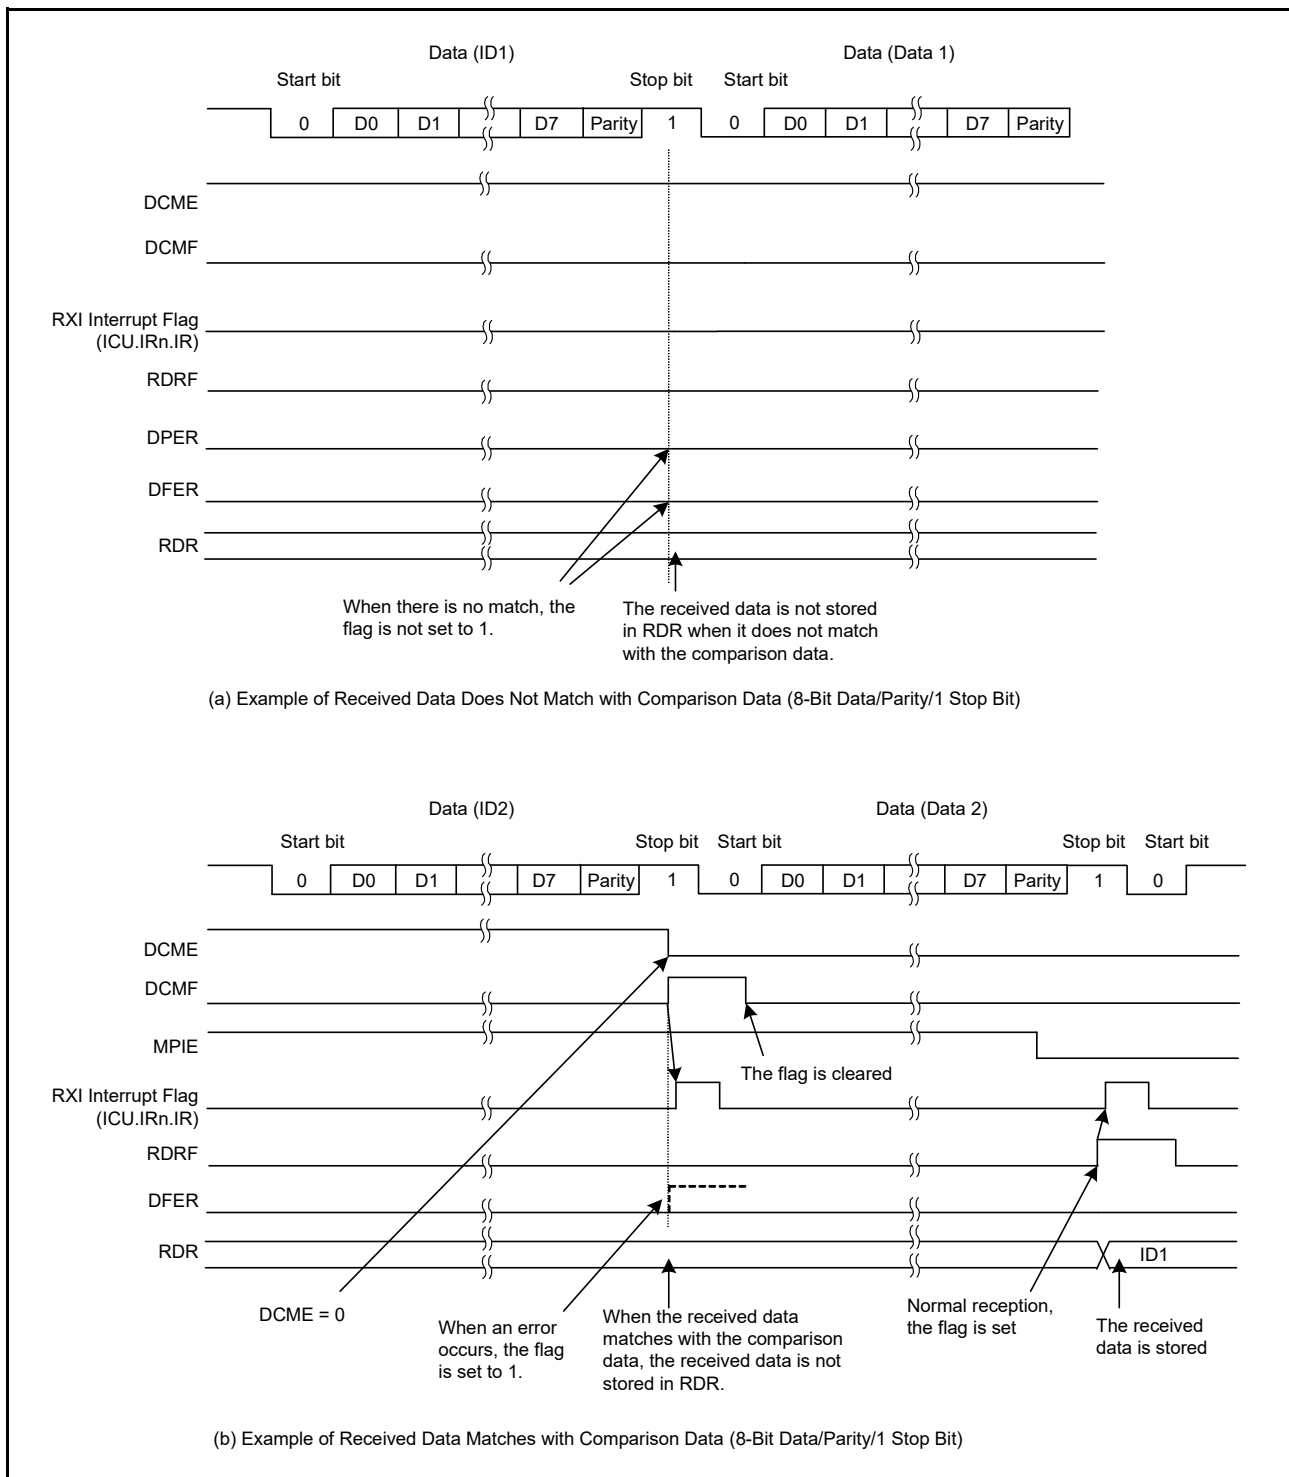

Figure 32.9 Example of Data Match Detection (1) Non Multi-Processor Mode

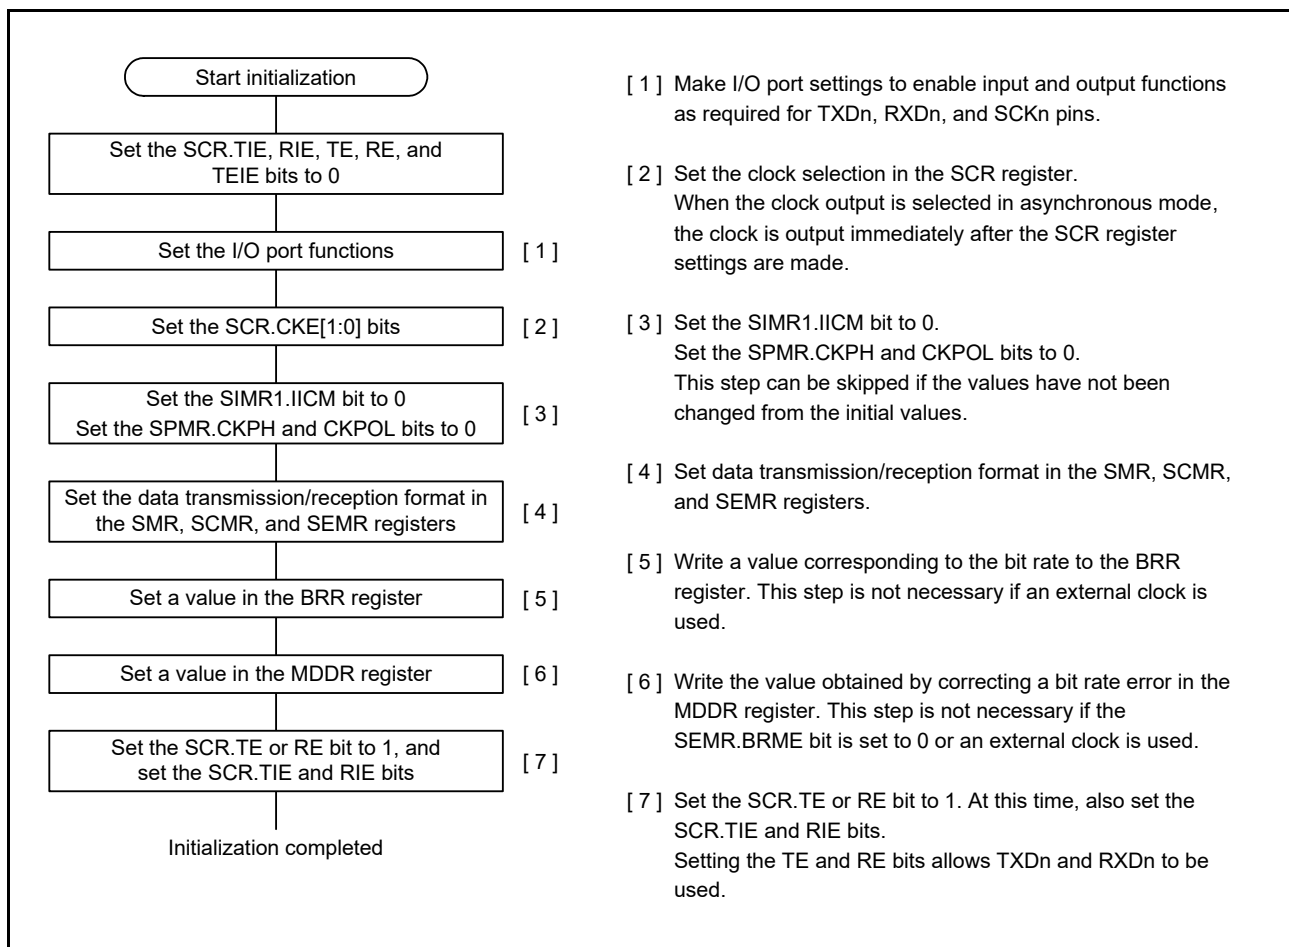

Figure 32.10 Example of Data Match Detection (2) Non Multi-Processor Mode

### 32.3.7 SCI Initialization (Asynchronous Mode)

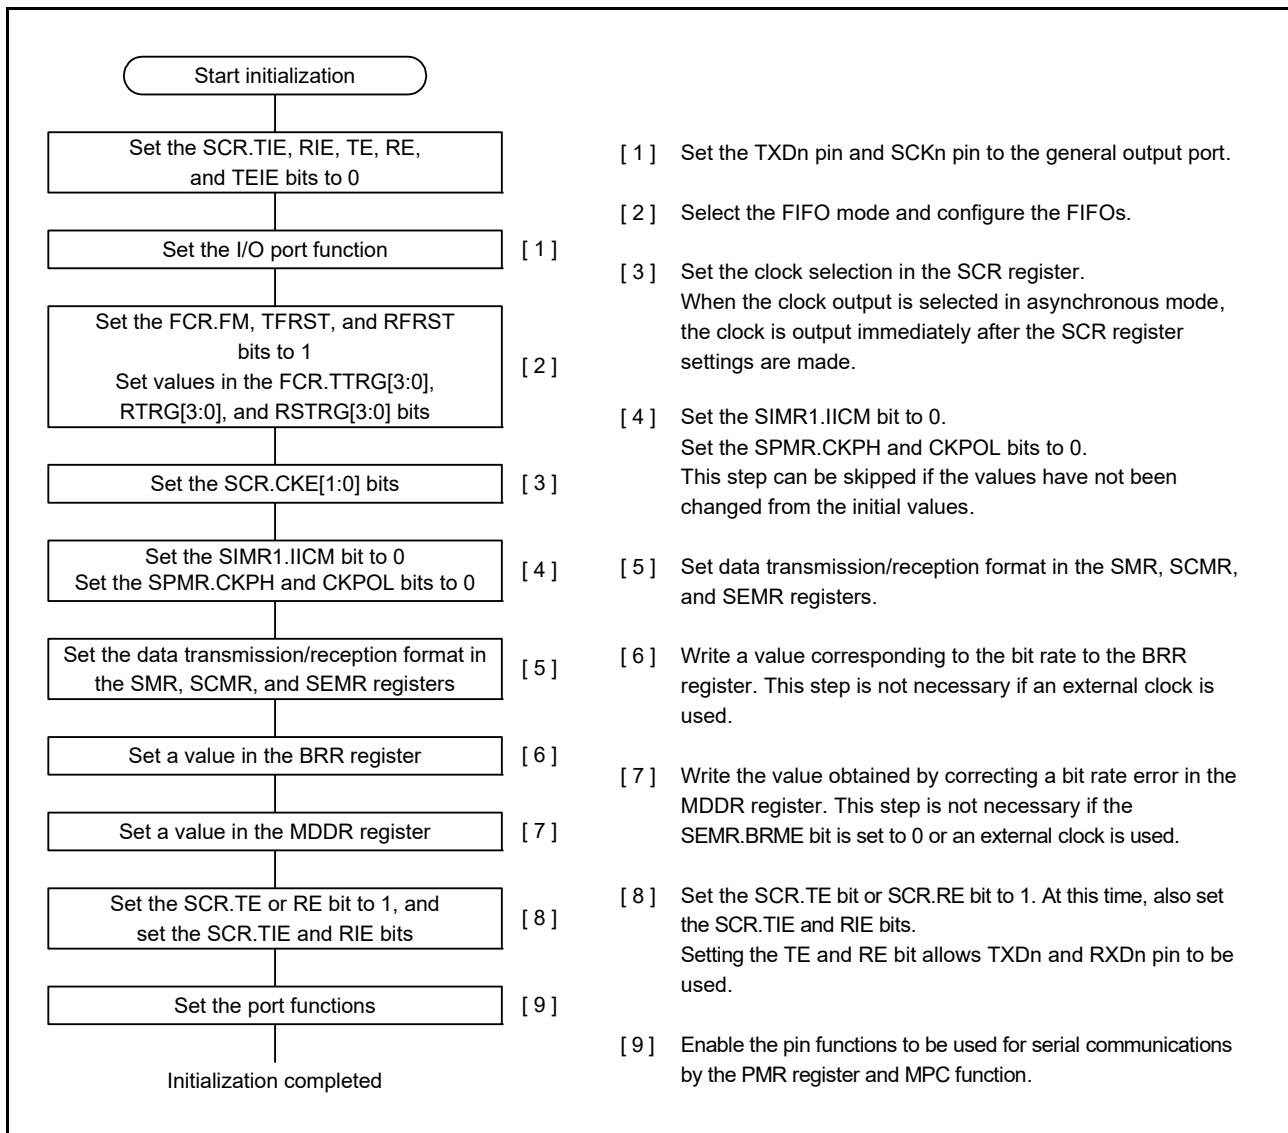

Before transmitting and receiving data, start by writing the initial value 00h to the SCR register and then continue through the procedure for SCI given in Figure 32.11 or Figure 32.12. Whenever the operating mode or transfer format is changed, the SCR register must be initialized before the change is made.

When the external clock is used in asynchronous mode, ensure that the clock signal is supplied even during initialization. Note that setting the SCR.RE bit to 0 initializes neither the ORER, FER, PER, and RDRF flags in the SSR register nor registers RDR, RDRH, and RDRL. Note also that the SSRFIFO.TEND flag does not become 1 even when the SCR.TE bit is set to 0.

In addition, note that setting bits TIE, TE, and TEIE in the SCR register to 1 simultaneously leads to the generation of a transmit end interrupt (TEI) request before the generation of a transmit data empty interrupt (TXI) request.

**Figure 32.11** Sample SCI Initialization Flowchart (Asynchronous Mode) (for SCI1, SCI5, SCI6, SCI8, SCI9, and SCI12)

**Figure 32.12 Sample SCI Initialization Flowchart (Asynchronous Mode, FIFO enabled) (for SCI11)**

Figure 32.13 shows an example of data transmission when the SCI is set to asynchronous mode according to the flow described in Figure 32.11 after a reset. When the pin function is set to the TXD pin, it is still high-impedance because the SCR.TE bit is 0. When the transmit data is written after setting the TE bit to 1, a data transmission starts. After the TE bit is set to 1, one frame of high is output from TXD pin (internal wait time) and then the data transmission starts.

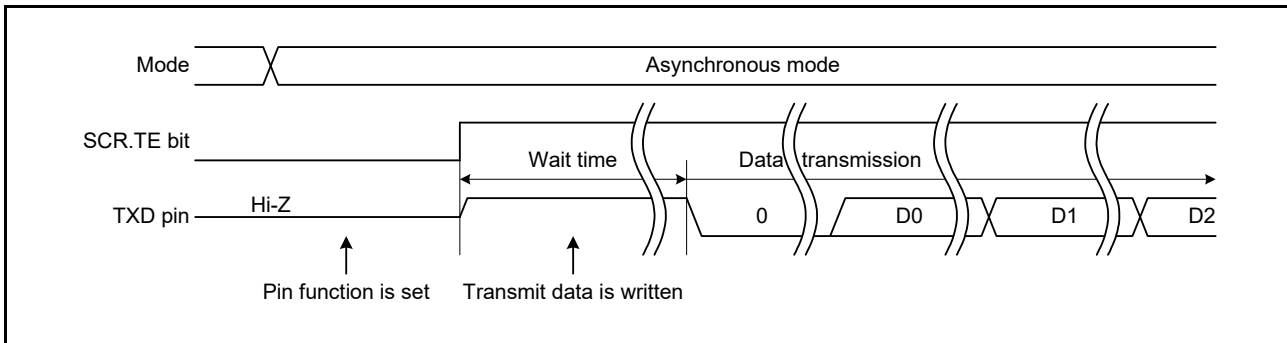

Figure 32.13 Example of Data Transmission Timing in Asynchronous Mode

### 32.3.8 Serial Data Transmission (Asynchronous Mode)

#### (1) SCI1, SCI5, SCI6, SCI8, SCI9, and SCI12, and SCI11 when FIFO is Disabled

Figure 32.14 to Figure 32.16 show an example of the operation for serial transmission in asynchronous mode. In serial transmission, the SCI operates as described below.

1. The SCI transfers data from the TDR register\*<sup>1</sup> to the TSR register when data is written to the TDR register\*<sup>1</sup> in the TXI interrupt handling routine. The TXI interrupt request at the beginning of transmission is generated when the SCR.TE bit is set to 1 after the SCR.TIE bit is set to 1 or when these 2 bits are set to 1 simultaneously by a single instruction.
2. Transmission starts after the SPMR.CTSE bit is set to 0 (CTS function is disabled) and a low level on the CTSn# pin causes data transfer from the TDR register\*<sup>1</sup> to the TSR register. If the SCR.TIE bit is 1 at this time, a TXI interrupt request is generated. Continuous transmission is obtainable by writing the next transmit data to the TDR register\*<sup>1</sup> in the TXI interrupt handling routine before transmission of the current transmit data is completed. When TEI interrupt requests are in use, set the SCR.TIE bit to 0 (a TXI interrupt request is disabled) and the SCR.TEIE bit to 1 (a TEI interrupt request is enabled) after the last of the data to be transmitted are written to the TDR register\*<sup>1</sup>, \*<sup>2</sup> from the handling routine for TXI requests.
3. Data is sent from the TXDn pin in the following order: start bit, transmit data, parity bit or multi-processor bit (may be omitted depending on the format), and stop bit.
4. The SCI checks for updating of (writing to) the TDR register\*<sup>3</sup> at the time of stop bit output.
5. When the TDR register\*<sup>3</sup> is updated, setting of the SPMR.CTSE bit to 0 (CTS function is disabled) or a low level input on the CTSn# pin cause the next transfer of the next transmit data from the TDR register\*<sup>1</sup> to the TSR register and sending of the stop bit, after which serial transmission of the next frame starts.
6. If the TDR register\*<sup>3</sup> is not updated, the SCI sets the SSR.TEND flag to 1, sends the stop bit, and then outputs high to put the line in the mark state. If the SCR.TEIE bit is 1 at this time, the SSR.TEND flag is set to 1 and a TEI interrupt request is generated.

Note 1. Write data not to the TDR register but to the TDRH and TDRL registers when 9-bit data length is selected.

Note 2. Write data in the order from the TDRH register to the TDRL register when 9-bit data length is selected.

Note 3. The SCI checks for updating of the TDRL register only and does not check for updating of the TDRH register when 9-bit data length is selected.

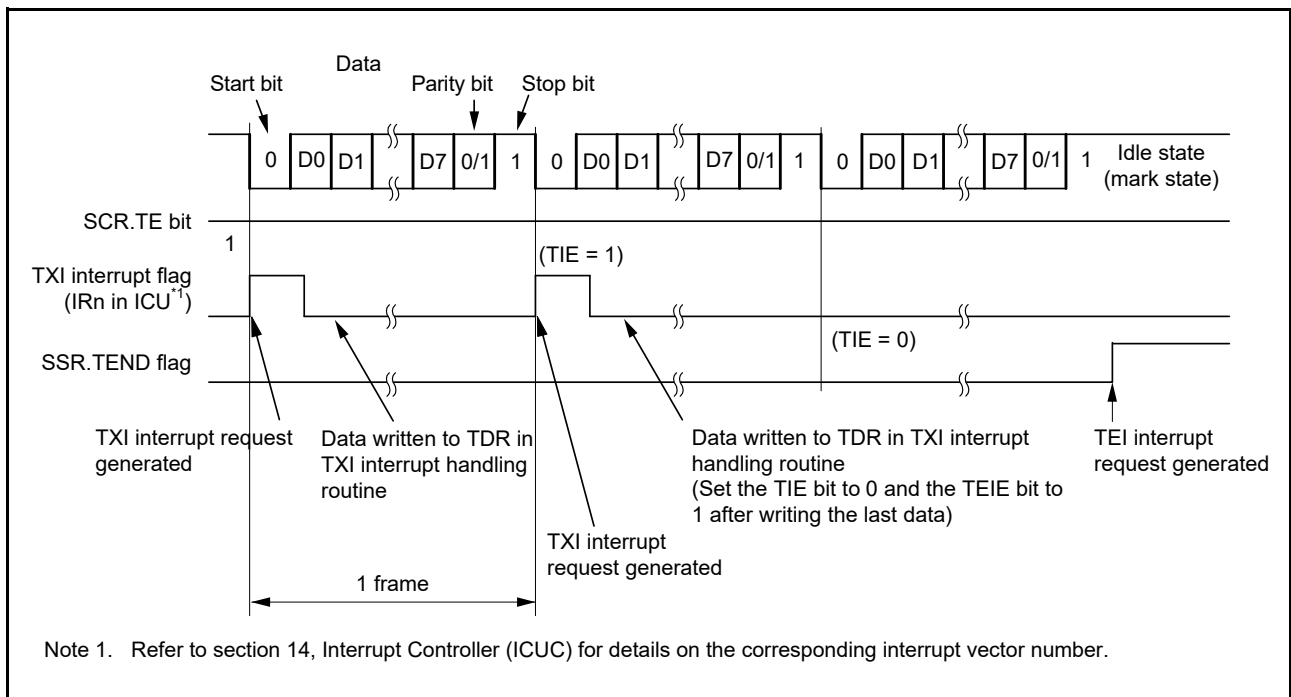

Figure 32.17 shows a sample flowchart for serial transmission in asynchronous mode.

**Figure 32.14** Example of Operation for Serial Transmission in Asynchronous Mode (1) (with 8-Bit Data, Parity, 1 Stop Bit, CTS Function Not Used, at the Beginning of Transmission)

**Figure 32.15** Example of Operation for Serial Transmission in Asynchronous Mode (2) (with 8-Bit Data, Parity, 1 Stop Bit, CTS Function Used, at the Beginning of Transmission)

**Figure 32.16 Example of Operation for Serial Transmission in Asynchronous Mode (3) (with 8-Bit Data, Parity, 1 Stop Bit, CTS Function Not Used, from the Middle of Transmission until Transmission Completion)**

Figure 32.17 Example of Serial Transmission Flowchart in Asynchronous Mode

## (2) SCI11 When FIFO is Enabled

The TXI interrupt request at the beginning of transmission is generated when the SCR.TE and SCR.TIE bits are set to 1 simultaneously.

Set the transmit data to the FTDR register (the FTDR.L register for 7-bit and 8-bit) instead of the TDR register. When data is transferred from the transmit FIFO to the TSR register and if the number of data stored in the transmit FIFO is less than or equal to the threshold (FCR.TTRG[3:0] bits), a transmit data empty interrupt (TXI) request is generated.

Up to 16 minus FDR.T[4:0] frames of transmit data can be set within the TXI interrupt processing routine. When the settings of all transmit data are completed, set the SSRFIFO.TDFE flag to 0.

When the transmit data is set by using the DMAC or DTC, the TDFE flag is automatically set to 0.

When sending a break, use the SPB2IO and SPB2DT bits in the SPTR register. Upon completion of the setting, a break is sent by setting the SCR.TE bit to 0.

### 32.3.9 Serial Data Reception (Asynchronous Mode)

#### (1) SCI1, SCI5, SCI6, SCI8, SCI9, and SCI12, and SCI11 when FIFO is Disabled

Figure 32.18 and Figure 32.19 show an example of the operation for serial data reception in asynchronous mode. In serial data reception, the SCI operates as described below.

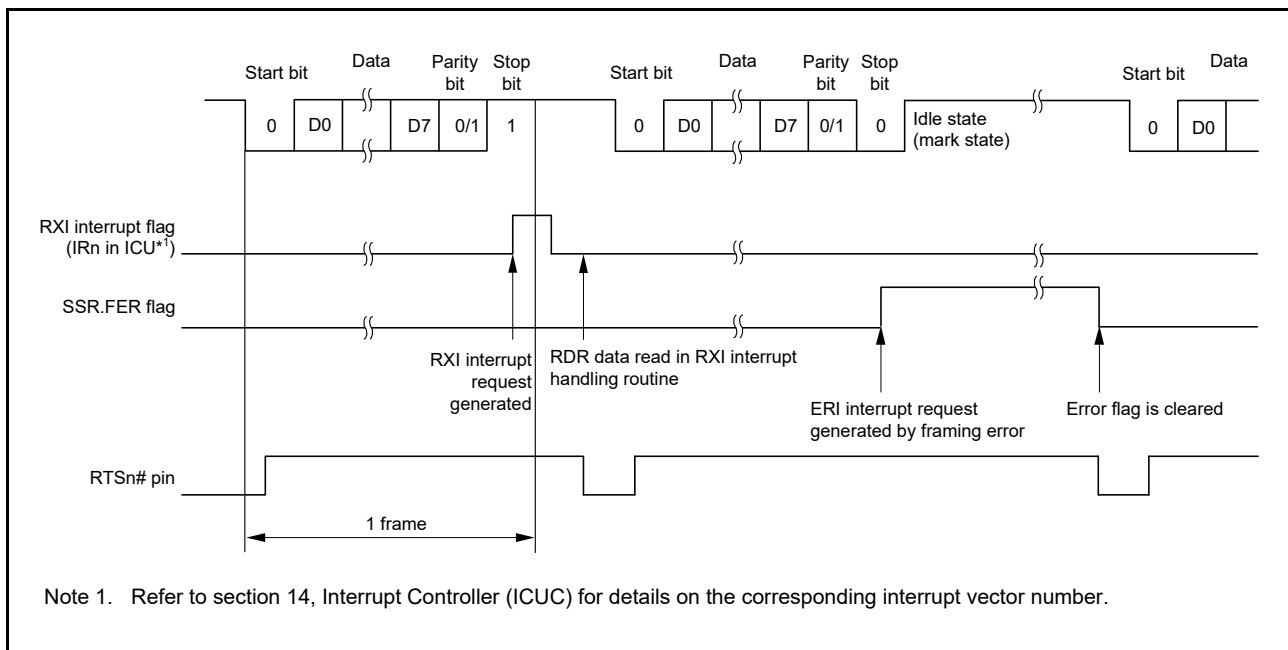

1. When the value of the SCR.RE bit becomes 1, the output signal on the RTSn# pin goes to the low level.
2. When the SCI monitors the communications line and detects a start bit, it performs internal synchronization, stores receive data in the RSR register, and checks the parity bit and stop bit.
3. If an overrun error occurs, the SSR.Over flag is set to 1. If the SCR.RIE bit is 1 at this time, an ERI interrupt request is generated. Receive data is not transferred to the RDR register\*1.
4. If a parity error is detected, the SSR.PER flag is set to 1 and receive data is transferred to the RDR register\*1. If the SCR.RIE bit is 1 at this time, an ERI interrupt request is generated.
5. If a framing error (when the stop bit is 0) is detected, the SSR.FER flag is set to 1 and receive data is transferred to the RDR register\*1. If the SCR.RIE bit is 1 at this time, an ERI interrupt request is generated.
6. When reception finishes successfully, receive data is transferred to the RDR register\*1. If the SCR.RIE bit is 1 at this time, an RXI interrupt request is generated. Continuous reception is enabled by reading the receive data transferred to the RDR register\*1 in this RXI interrupt handling routine before reception of the next receive data is completed. Reading the received data that have been transferred to the RDR register\*1 causes the RTSn# pin to output the low level.

Note 1. Read data not in the RDR register but in the RDRH and RDRL registers when 9-bit data length is selected.

Note 2. The SCI checks for reading of the RDRL register only and does not check for reading of the RDRH register when 9-bit data length is selected.

**Figure 32.18 Example of SCI Operation for Serial Reception in Asynchronous Mode (1) (When RTS Function is Not Used) (Example with 8-Bit Data, Parity, 1 Stop Bit)**

**Figure 32.19 Example of SCI Operation for Serial Reception in Asynchronous Mode (2) (When RTS Function is Used) (Example with 8-Bit Data, Parity, 1 Stop Bit)**

Table 32.33 lists the states of the status flags in the SSR register and receive data handling when a receive error is detected.

If a receive error is detected, an ERI interrupt request is generated but an RXI interrupt request is not generated. Data reception cannot be resumed while the receive error flag is 1. Accordingly, set the ORER, FER, and PER flags to 0 before resuming reception. Moreover, be sure to read the RDR (or the RDRL) register during overrun error processing. When a reception is forcibly terminated by setting the SCR.RE bit to 0 during operation, read the RDR (or the RDRL) register because received data which has not yet been read may be left in the RDR (or the RDRL) register. Figure 32.20 and Figure 32.21 show samples of flowcharts for serial data reception.

**Table 32.33 Status Flags in the SSR Register and Receive Data Handling**

| Status Flags in the SSR Register |     |     | Receive Data                      | Receive Error Type                           |
|----------------------------------|-----|-----|-----------------------------------|----------------------------------------------|
| ORER                             | FER | PER |                                   |                                              |
| 1                                | 0   | 0   | Lost                              | Overrun error                                |
| 0                                | 1   | 0   | Transferred to the RDR register*1 | Framing error                                |
| 0                                | 0   | 1   | Transferred to the RDR register*1 | Parity error                                 |
| 1                                | 1   | 0   | Lost                              | Overrun error + framing error                |
| 1                                | 0   | 1   | Lost                              | Overrun error + parity error                 |
| 0                                | 1   | 1   | Transferred to the RDR register*1 | Framing error + parity error                 |
| 1                                | 1   | 1   | Lost                              | Overrun error + framing error + parity error |

Note 1. Read data not in the RDR register but in the RDRH and RDRL registers when 9-bit data length is selected.

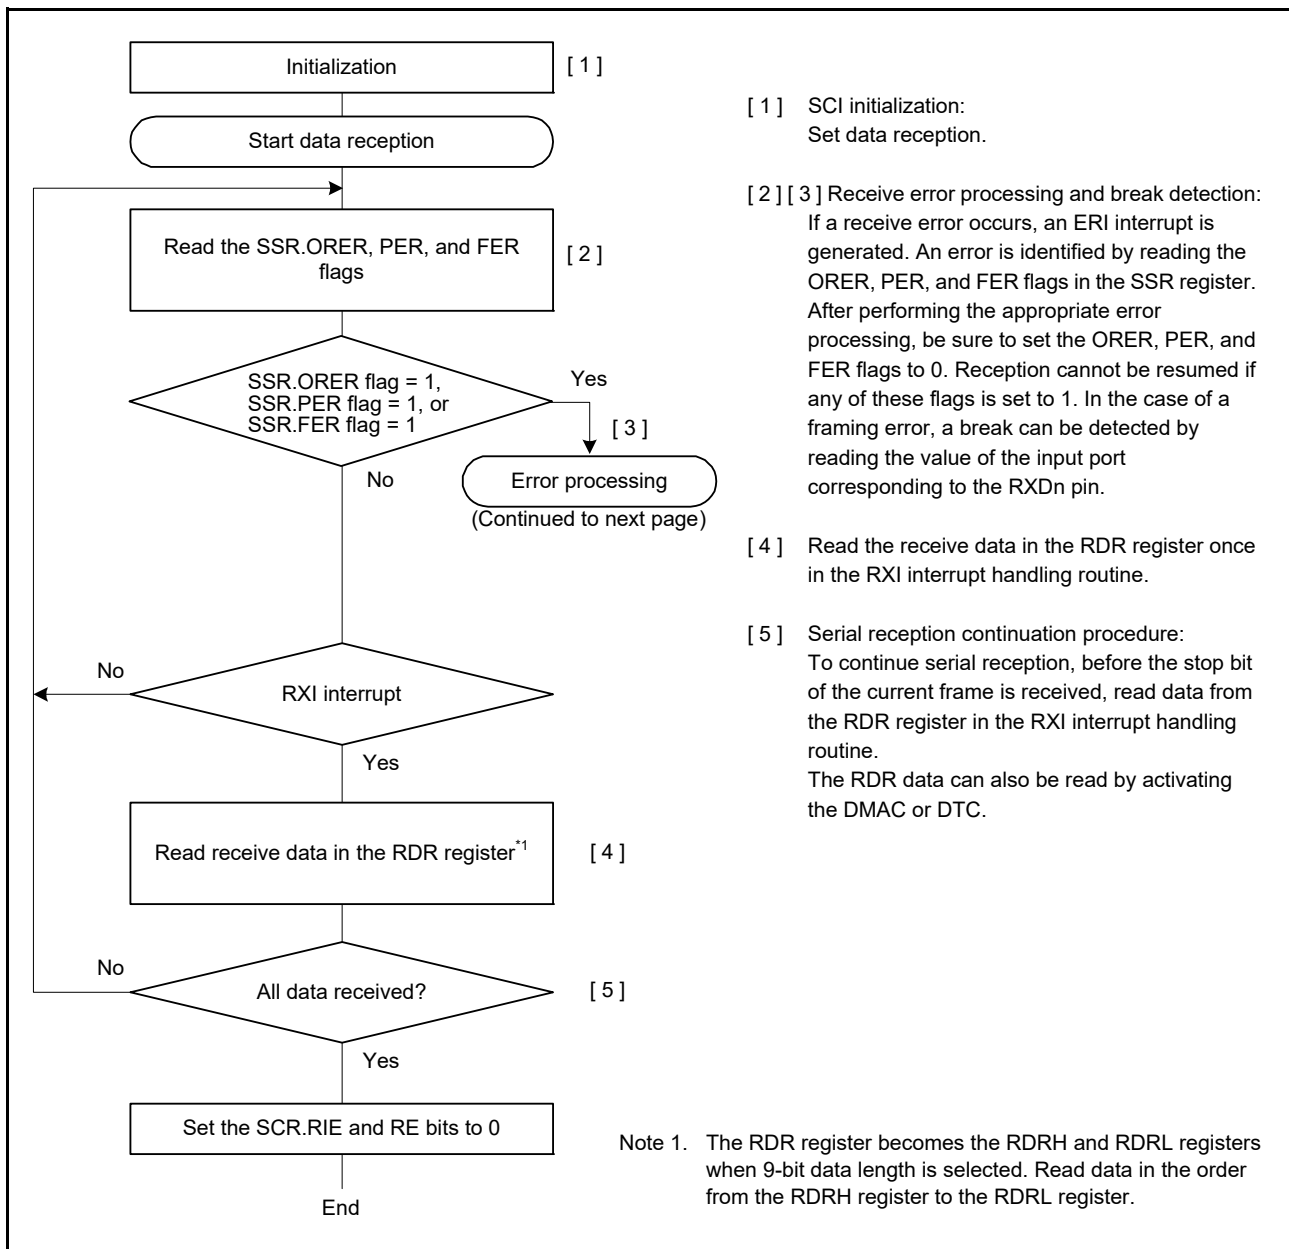

Figure 32.20 Example Flowchart of Serial Reception in Asynchronous Mode (1)

Figure 32.21 Example Flowchart of Serial Reception in Asynchronous Mode (2)

## (2) SCI11 When FIFO is Enabled

The received data and status flag are read from the FRDR register instead of the RDR register. When reading in byte units, read the FRDR.H register and then the FRDR.L register in this order. Reading the FRDR.L register updates the FER, PER, and RDAT[8:0] bits in the FRDR register. The value of the RDF, ORER, and DR flags in the FRDR register is the same as that of the SSRFIFO register.

When receiving serial data, the SCI operates as follows.

1. If the SCR.RE bit is set to 1 and the RTSn# function is in use, the SCI drives the RTSn# pin low.
2. When the SCI monitors the communications line and detects a start bit, it performs internal synchronization, stores the received data to the RSR register, and checks the parity and stop bits.
3. When there is no space in the receive FIFO, an overrun error occurs. When an overrun error occurs, the SCI sets the SSRFIFO.ORER flag to 1. At this time, if the SCR.RIE bit is 1, an ERI interrupt request is generated. The received data is not transferred to the receive FIFO.
4. When a parity error is detected, the SCI transfers the received data to the receive FIFO and sets the PER flag in the receive FIFO to 1. At this time, if the SCR.RIE bit is 1, an ERI interrupt request is generated.
5. When a framing error (the stop bit is 0) is detected, the SCI transfers the received data to the receive FIFO and sets the FER flag in the receive FIFO to 1. At this time, if the SCR.RIE bit is 1, an ERI interrupt request is generated.
6. When a framing error is detected and the following one-frame data received is all 0s, the SCI stops receiving operation.
7. If the number of data stored in the receive FIFO is less than the threshold (FCR.RTRG[3:0] bits) and reception of the next frame is not completed even after 15 etus have elapsed from the stop bit of the previously received frame, the SSRFIFO.DR flag is set to 1. At this time, if the SCR.RIE bit is 1, an RXI interrupt request (when the FCR.DRES bit is 0) or an ERI interrupt request (when the FCR.DRES bit is 1) is generated.
8. When the frame is successfully received, the SCI transfers the received data to the receive FIFO. If the number of data stored in the receive FIFO is equal to or greater than the threshold (FCR.RTRG[3:0] bits), the SCI sets the SSRFIFO.RDF flag to 1. At this time, if the SCR.RIE bit is 1, an RXI interrupt request is generated. Using the RXI interrupt processing routine allows reading of the received data in the RDRF register before an overrun error occurs, thus enabling the sequence reception of data. When the received data that have been transferred to the receive FIFO are read and the number of unread data is less than the value of the FCR.RSTRG[3:0] bits, the SCI drives the RTSn# pin low.

## 32.4 Multi-Processor Communications Function

Using the multi-processor communication functions enables to transmit and receive data by sharing a communication line between multiple processors by using asynchronous serial communication in which the multi-processor bit is added. In multi-processor communication, a unique ID code is allocated to each receiving station. Serial communication cycles consist of an ID transmission cycle to specify the receiving station and a data transmission cycle to transmit data to the specified receiving station. The multi-processor bit is used to distinguish between the ID transmission cycle and the data transmission cycle. When the multi-processor bit is set to 1, it indicates the ID transmission cycle and when the multi-processor bit is set to 0, it indicates the data transmission cycle. Figure 32.22 shows an example of communication between processors by using a multi-processor format. First, a transmitting station transmits communication data in which the multi-processor bit set to 1 is added to the ID code of the receiving station. Next, the transmitting station transmits the communication data in which the multi-processor bit set to 0 is added to the transmit data. Upon receiving the communication data in which the multi-processor bit is set to 1, the receiving station compares the received ID with the ID of the receiving station itself and if the two match, receives the communication data that is subsequently transmitted. If the received ID does not match with the ID of the receiving station, the receiving station skips the communication data until again receiving the communication data in which the multi-processor bit is set to 1.

### (1) SCI1, SCI5, SCI6, SCI8, SCI9, and SCI12, and SCI11 when FIFO is Disabled

For supporting this function, the SCI provides the SCR.MPIE bit. When the MPIE bit is set to 1, transfer of receive data from the RSR register to the RDR register (the RDRH and RDRL registers when 9-bit data length is selected), detection of a receive error, and setting the respective status flags RDRF, ORER, and FER in the SSR register are disabled until reception of data in which the multi-processor bit is set to 1. Upon receiving a reception character in which the multi-processor bit is set to 1, the SSR.MPB bit is set to 1 and the SCR.MPIE bit is automatically cleared, thus returning to a normal reception operation. During this time, an RXI interrupt is generated if the SCR.RIE bit is 1. When the multi-processor format is specified, specification of the parity bit is disabled. Apart from this, there is no difference from the operation in the normal asynchronous mode. A clock which is used for the multi-processor communication is also the same as the clock used in the normal asynchronous mode.

**Figure 32.22 An Example of Communication using the Multi-Processor Format (Example of Transmission of Data AAh to Receiving Station A)**

## (2) SCI11 When FIFO is Enabled

In transmitting data, the SCI uses the FTDR.MPBT bit instead of the SSR.MPBT bit. Set a value and the transmit data to the FTDR register at the same timing.

In receiving data, the SCI uses the FRDR.MPB flag instead of the SSR.MPB flag. Upon completion of data reception, when the data in the RSR register is stored to the receive FIFO, the value of the multi-processor bit is stored at the same time.

Setting the SCR.MPIE bit to 1 disables transfer of the received data from the RSR register to the receive FIFO, detection of receive errors, and settings of the RDF, ORER, or FER flag in the SSRFIFO register until the data in which the multi-processor bit has the value 1 is received.

When the reception character in which the multi-processor bit has the value 1 is received, the multi-processor bit and received data are stored in the receive FIFO and the SCR.MPIE bit is set to 0, and then the SCI returns to the normal reception operation. At this time, if the SCR.RIE bit is 1, an RXI interrupt is generated.

When the multi-processor format is specified, setting of the parity bit is disabled. Specifying a format other than that, the serial transfer format is the same as that in normal asynchronous mode.

### 32.4.1 Multi-Processor Serial Data Transmission

Figure 32.23 is a sample flowchart of multi-processor data transmission. In the ID transmission cycle, the ID should be transmitted with the SSR.MPBT bit set to 1. In the data transmission cycle, the data should be transmitted with the MPBT bit set to 0. The other operations are the same as the operations in asynchronous mode.

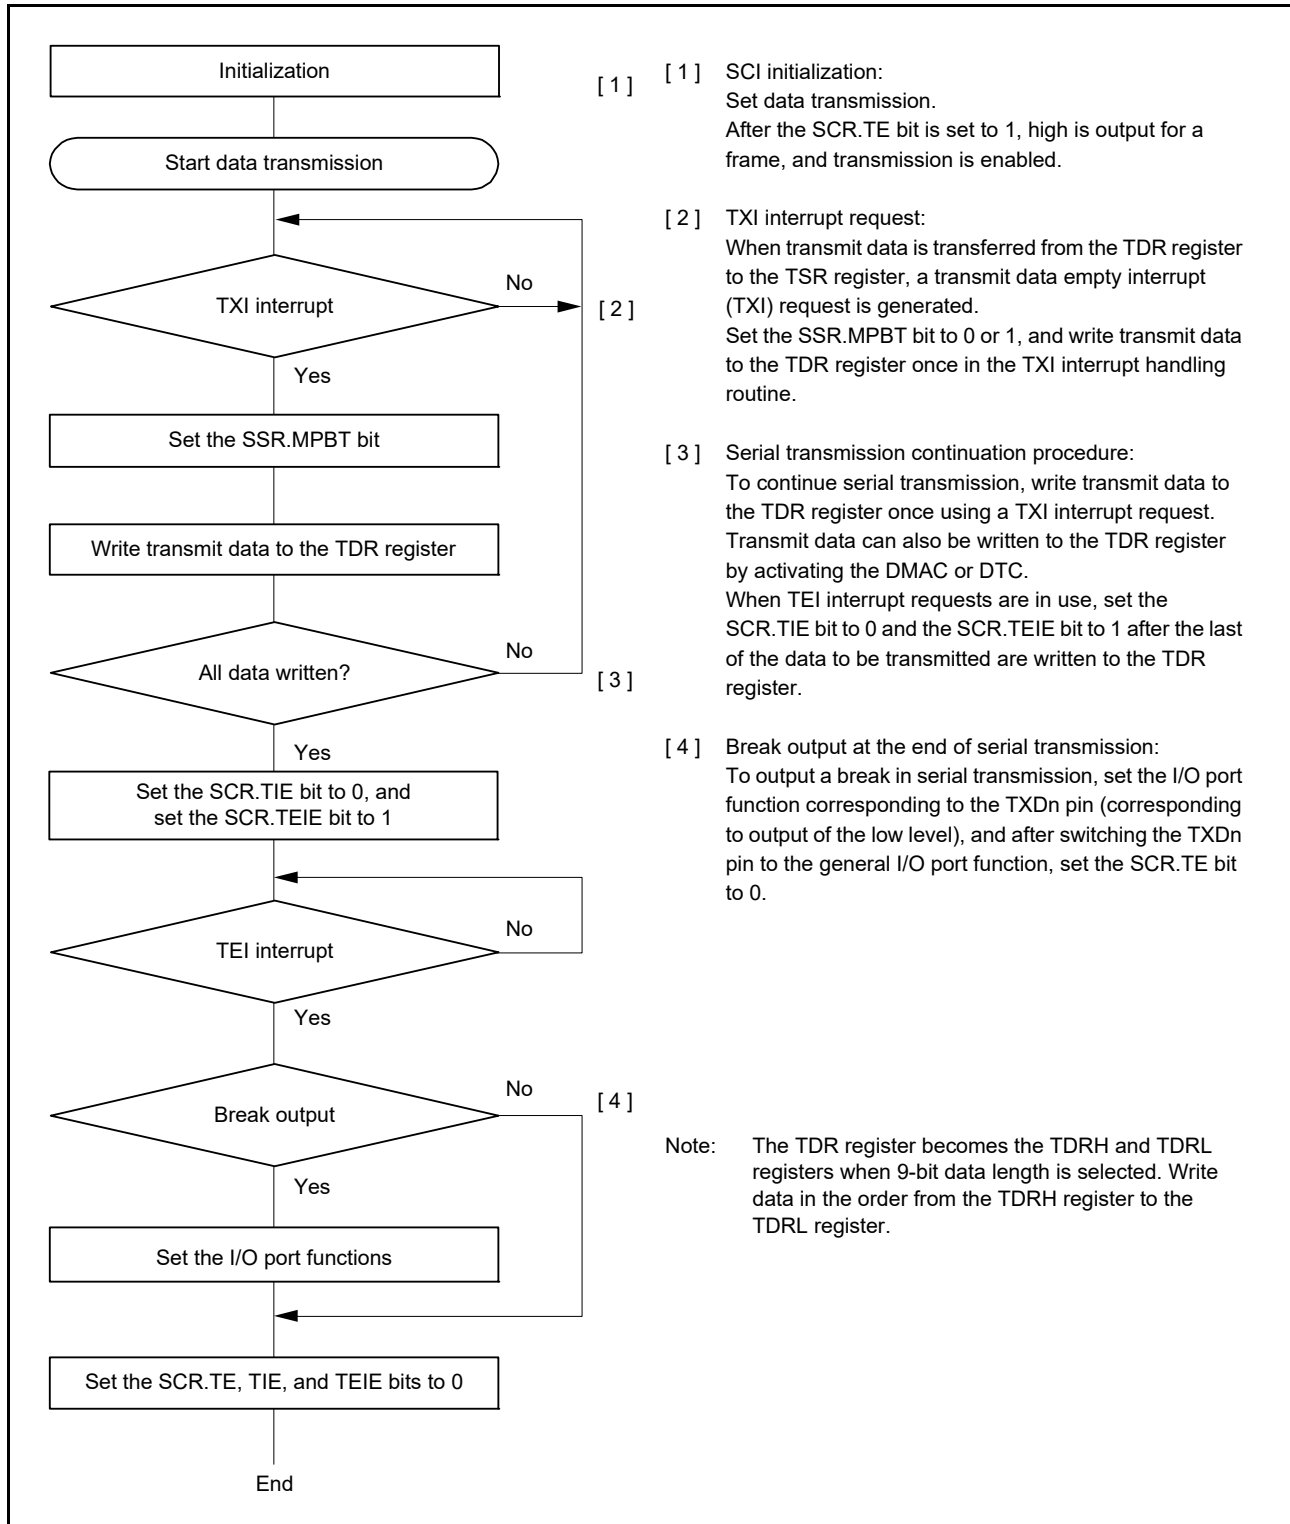

Figure 32.23 Example of Multi-Processor Serial Transmission Flowchart

### 32.4.2 Multi-Processor Serial Data Reception

Figure 32.25 and Figure 32.26 are sample flowcharts of multi-processor data reception. When the SCR.MPIE bit is set to 1, reading the communication data is skipped until reception of the communication data in which the multi-processor bit is set to 1. When the communication data in which the multi-processor bit is set to 1 is received, the received data is transferred to the RDR register (the RDRH and RDRL registers when 9-bit data length is selected). During this time, the RXI interrupt request is generated. The other operations are the same as the operations in asynchronous mode. Figure 32.24 is the example of operation for reception.

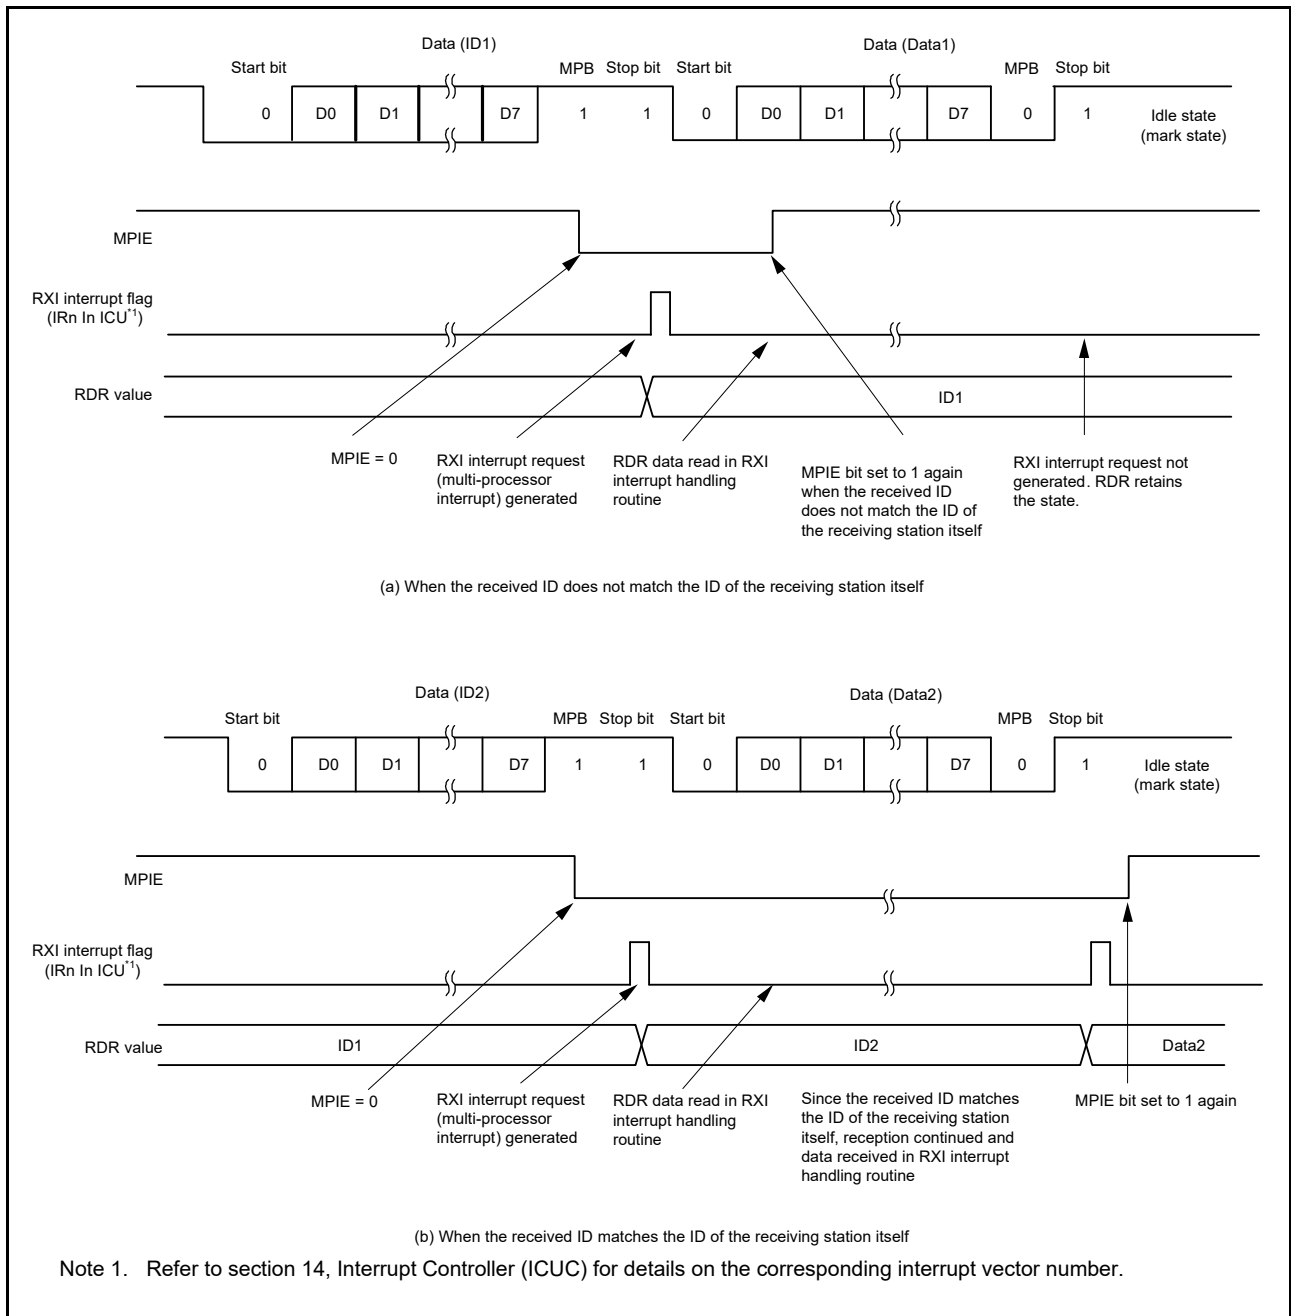

Figure 32.24 Example of SCI Reception (8-Bit Data/Multi-Processor Bit/1 Stop Bit)

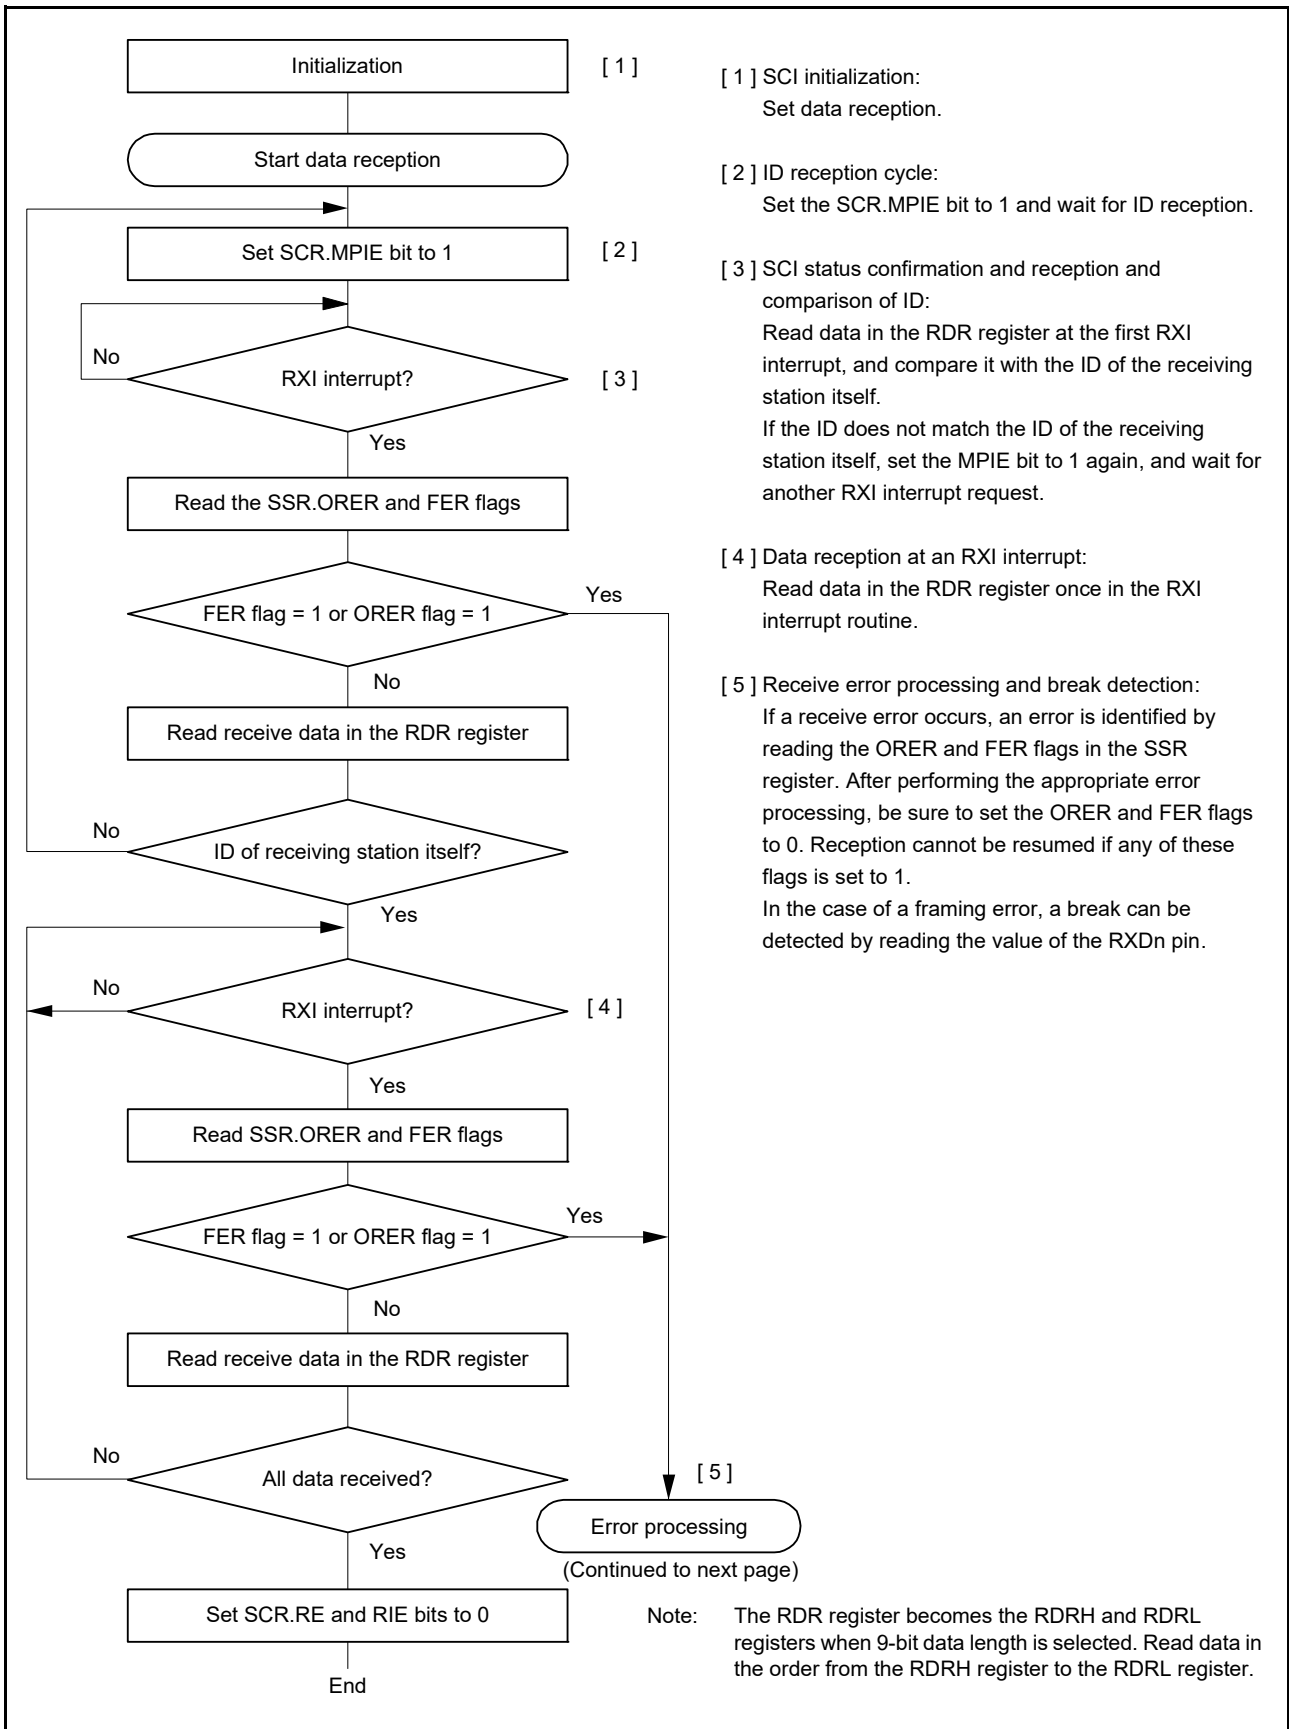

Figure 32.25 Example of Multi-Processor Serial Reception Flowchart (1)

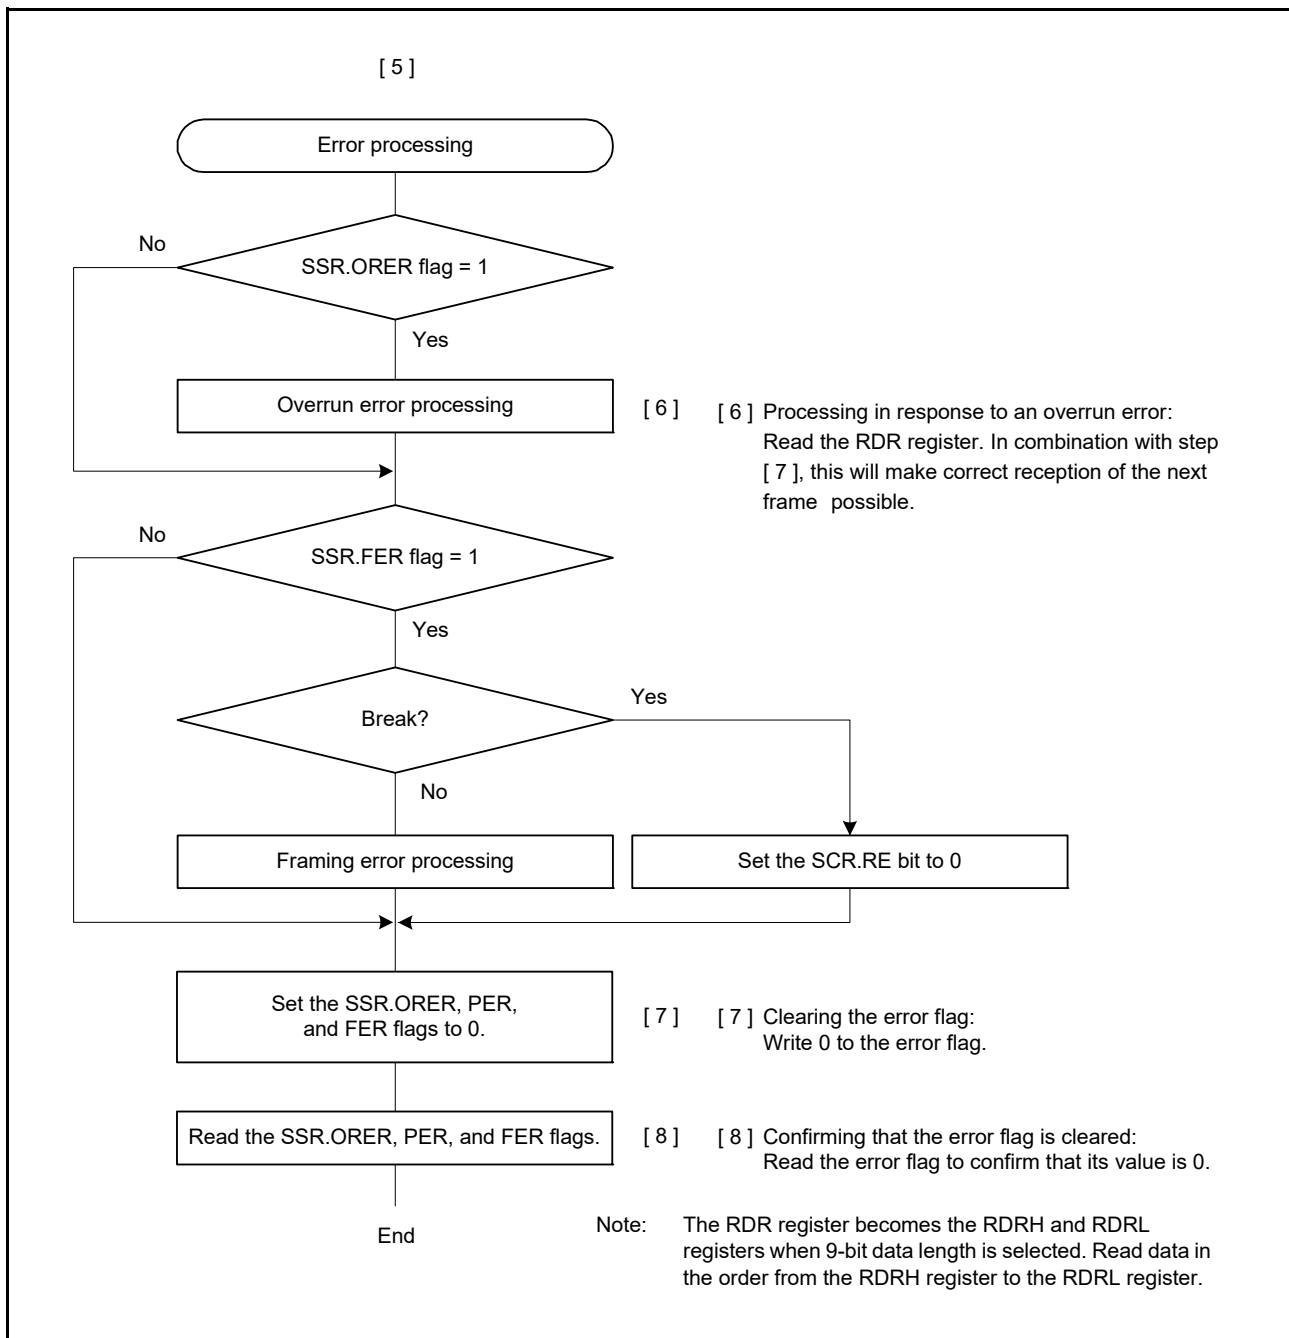

Figure 32.26 Example of Multi-Processor Serial Reception Flowchart (2)

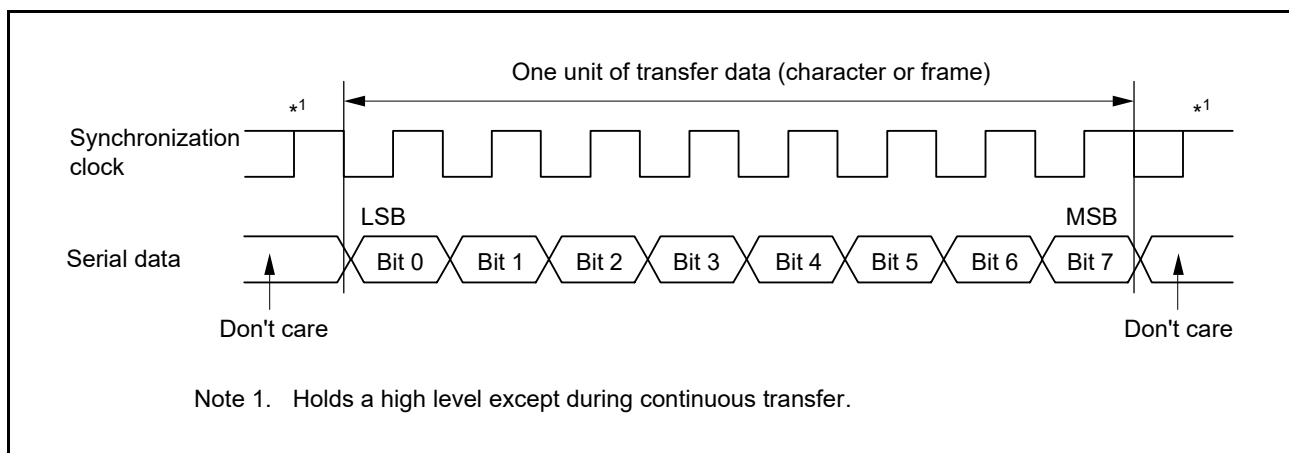

## 32.5 Operation in Clock Synchronous Mode

Figure 32.27 shows the data format for clock synchronous serial data communications.

In clock synchronous mode, data is transmitted or received in synchronization with clock pulses. One character in transfer data consists of 8-bit data. In clock synchronous mode, no parity bit can be added.

In data transmission, the SCI outputs data from one falling edge of the synchronization clock to the next. In data reception, the SCI receives data in synchronization with the rising edge of the synchronization clock. After 8-bit data is output, the communication line holds the last bit output state.

Inside the SCI, the transmitter and receiver are independent units, enabling full-duplex communications by use of a common clock. Both the transmitter and the receiver also have a double-buffered structure, so that the next transmit data can be written during transmission or the previous receive data can be read during reception, enabling continuous data transfer.

**Figure 32.27 Data Format in Clock Synchronous Serial Communications (LSB First)**

### 32.5.1 Clock

Either an internal clock generated by the on-chip baud rate generator or an external synchronization clock input at the SCKn pin can be selected, according to the setting of the SCR.CKE[1:0] bits.

When the SCI is operated on an internal clock, the synchronization clock is output from the SCKn pin. Eight synchronization clock pulses are output in the transfer of one character, and when no transfer is performed the clock is held high. However, when only data reception is performed while the CTS function is disabled, the synchronization clock output is started at the same time when the SCR.RE bit set to 1. The synchronization clock is stopped at the high level when an overrun error occurs or the SCR.RE bit is set to 0.

When only data reception is performed and the CTS function is enabled, the clock output is not started even when the SCR.RE bit set to 1 if the CTSn# pin input is high when the SCR.RE bit is 0. The synchronization clock output is started when the SCR.RE bit is set to 1 and the CTSn# pin input is low. After that, if the CTSn# pin input is high on completion of the frame reception, the synchronization clock output is stopped at the high level. If the CTSn# pin input continues to be low, the synchronization clock is stopped at the high level when an overrun error occurs or the SCR.RE bit is set to 0.

### 32.5.2 CTS and RTS Functions

In the CTS function, CTSn# pin input is used to control reception/transmission start when the clock source is the internal clock. Setting the SPMR.CTSE bit to 1 enables the CTS function.

When the CTS function is enabled, placing the low level on the CTSn# pin causes reception/transmission to start. Applying the high level to the CTS# pin while reception/transmission are in progress does not affect reception/transmission of the current frame, which continues.

In the RTS function, RTSn# pin output is used to request reception/transmission start when the clock source is an external synchronizing clock. A low level is output when serial communications become possible. Conditions for output of the low and high level are shown below.

#### (a) SCI1, SCI5, SCI6, SCI8, SCI9, and SCI12, and SCI11 when FIFO is Disabled

[Conditions for low-level output]

When the following conditions are all satisfied.

- The SCR.RE or SCR.TE bit is 1.
- Transmission or reception is not in progress.
- There are no received data yet to be read (when the SCR.RE bit is 1).
- Untransmitted data is present (when the SCR.TE bit is 1).
- The SSR.ORER flag is 0.

[Condition for high-level output]

The conditions for low-level output have not been satisfied.

#### (b) SCI11 When FIFO is Enabled

[Conditions for low-level output]

When the following conditions are all satisfied.

- The SCR.RE or SCR.TE bit is 1.
- Transmission or reception is not in progress.
- The number of data stored in the receive FIFO is less than the threshold (FCR.RTRG[3:0] bits) (when the SCR.RE bit is 1).
- Untransmitted data is present (when the SCR.TE bit is 1).
- The SSRFIFO.ORER flag is 0.

[Condition for high-level output]

When the conditions for low-level output are not satisfied.

### 32.5.3 SCI Initialization (Clock Synchronous Mode)

Before transmitting and receiving data, start by writing the initial value 00h to the SCR register and then continue through the procedure for SCI given in Figure 32.28. Whenever the operating mode or transfer format is changed, the SCR register must be initialized before the change is made.

Note that setting the SCR.RE bit to 0 initializes neither the ORER, FER, and PER flags in the SSR register nor the RDR register.

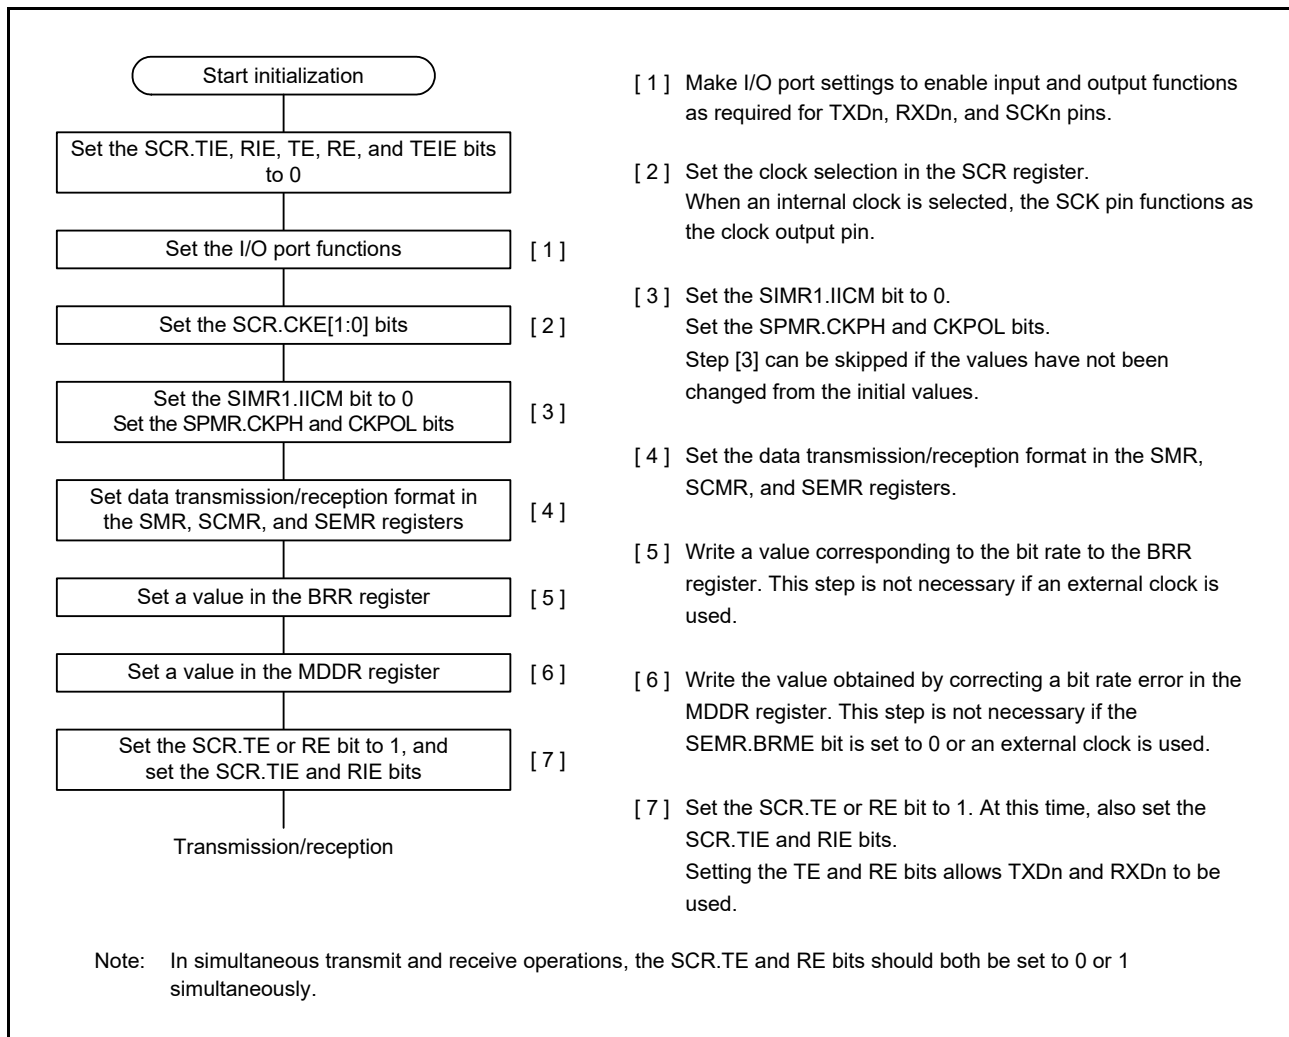

Figure 32.28 Example of SCI Initialization Flowchart (Clock Synchronous Mode)

### 32.5.4 Serial Data Transmission (Clock Synchronous Mode)

#### (1) SCI1, SCI5, SCI6, SCI8, SCI9, and SCI12, and SCI11 when FIFO is Disabled

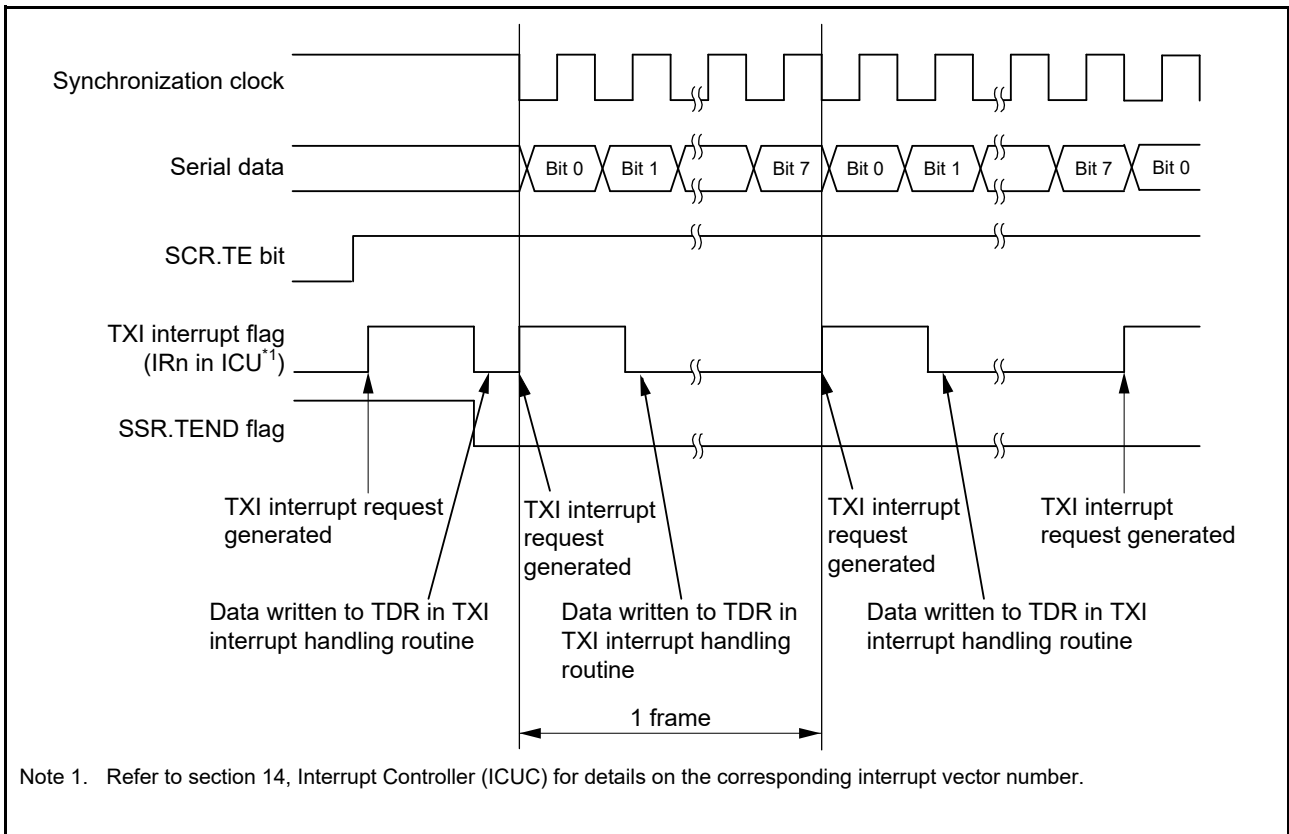

Figure 32.29, Figure 32.30, and Figure 32.31 show an example of the operation for serial transmission in clock synchronous mode.

In serial data transmission, the SCI operates as described below.

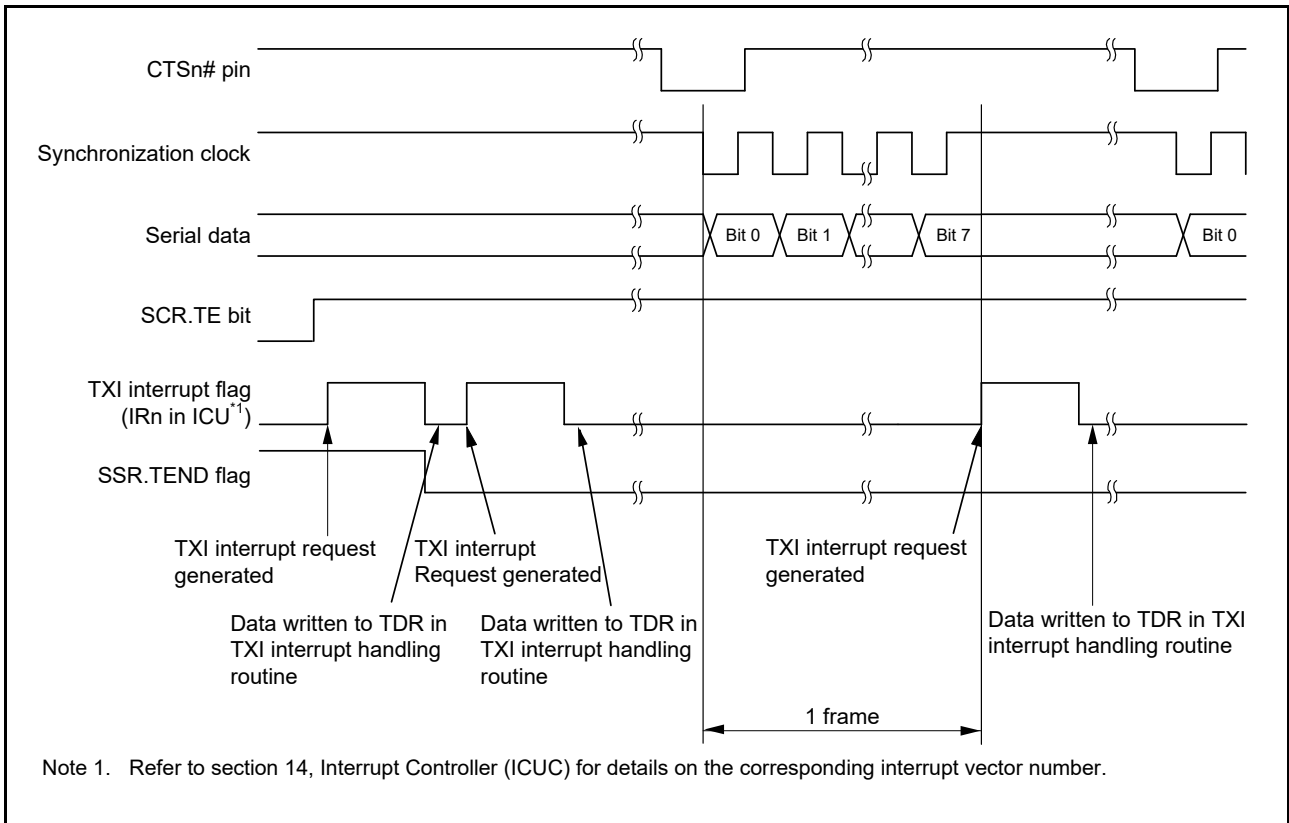

1. The SCI transfers data from the TDR register to the TSR register when data is written to the TDR register in the TXI interrupt handling routine. The TXI interrupt request at the beginning of transmission is generated when the SCR.TE bit is set to 1 after the SCR.TIE bit is set to 1 or when these 2 bits are set to 1 simultaneously by a single instruction.
2. After transferring data from the TDR register to the TSR register, the SCI starts transmission. When the SCR.TIE bit is set to 1 at this time, a TXI interrupt request is generated. Continuous transmission is enabled by writing the next transmit data to the TDR register in this TXI interrupt handling routine before transmission of the current transmit data has finished. When TEI interrupt requests are in use, set the SCR.TIE bit to 0 (a TXI interrupt request is disabled) and the SCR.TEIE bit to 1 (a TEI interrupt request is enabled) after the last of the data to be transmitted are written to the TDR register from the handling routine for TXI requests.
3. 8-bit data is sent from the TXDn pin in synchronization with the output clock when clock output mode has been specified and in synchronization with the input clock when use of an external clock has been specified. Output of the clock signal is suspended until the input CTS signal is at the low level while the SPMR.CTSE bit is 1 (CTS function is enabled).
4. The SCI checks for updating of (writing to) the TDR register at the time of the last bit output.
5. When TDR is updated, the next transmit data is transferred from the TDR register to the TSR register, and serial transmission of the next frame is started.
6. If the TDR register is not updated, set the SSR.TEND flag to 1 and the TXDn pin retains the output state of the last bit. If the SCR.TEIE bit is 1 at this time, a TEI interrupt request is generated. The SCKn pin is held high.

Figure 32.32 shows a sample flowchart of serial data transmission.

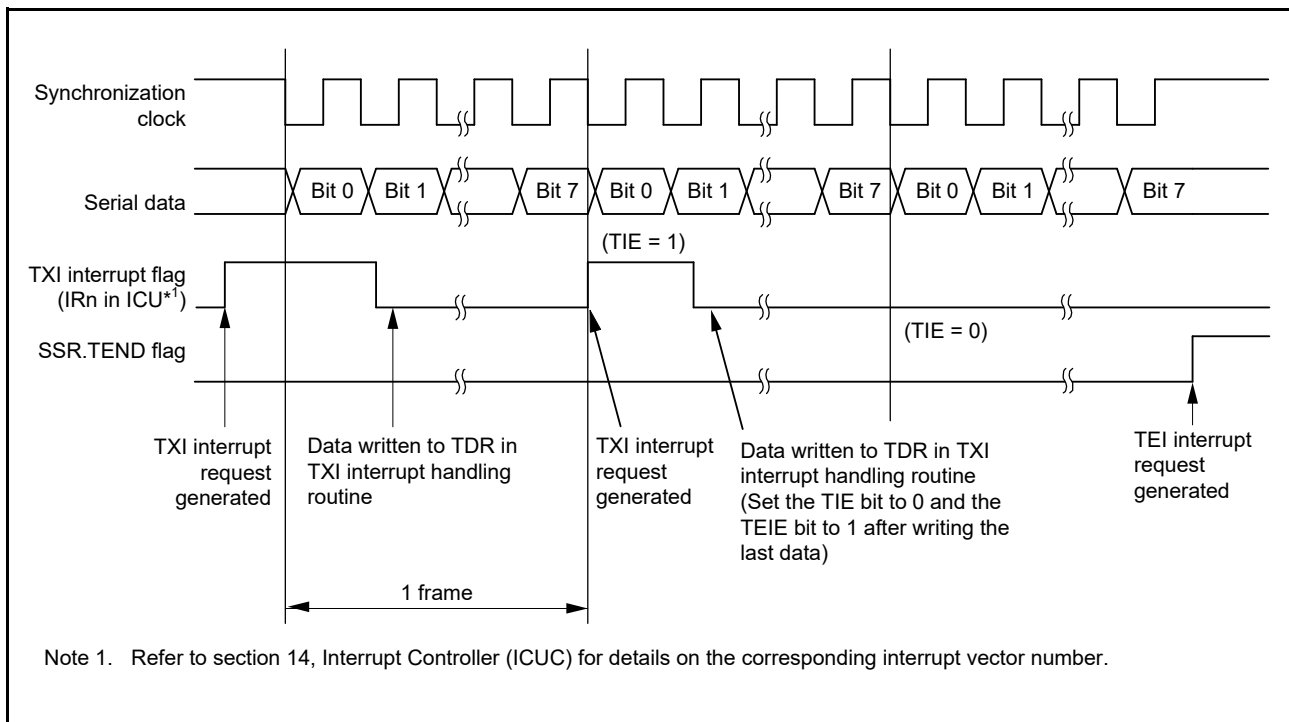

Transmission will not start while a receive error flag (ORER, FER, or PER in the SSR register) is set to 1. Be sure to set the receive error flags to 0 before starting transmission. Note that setting the SCR.RE bit to 0 does not clear the receive error flags.

**Figure 32.29** Example of Serial Data Transmission in Clock Synchronous Mode When the CTS Function is Not Used at the Beginning of Transmission

**Figure 32.30** Example of Serial Data Transmission in Clock Synchronous Mode When the CTS Function is Used at the Beginning of Transmission

**Figure 32.31 Example of Serial Data Transmission in Clock Synchronous Mode from the Middle of Transmission until Transmission Completion**

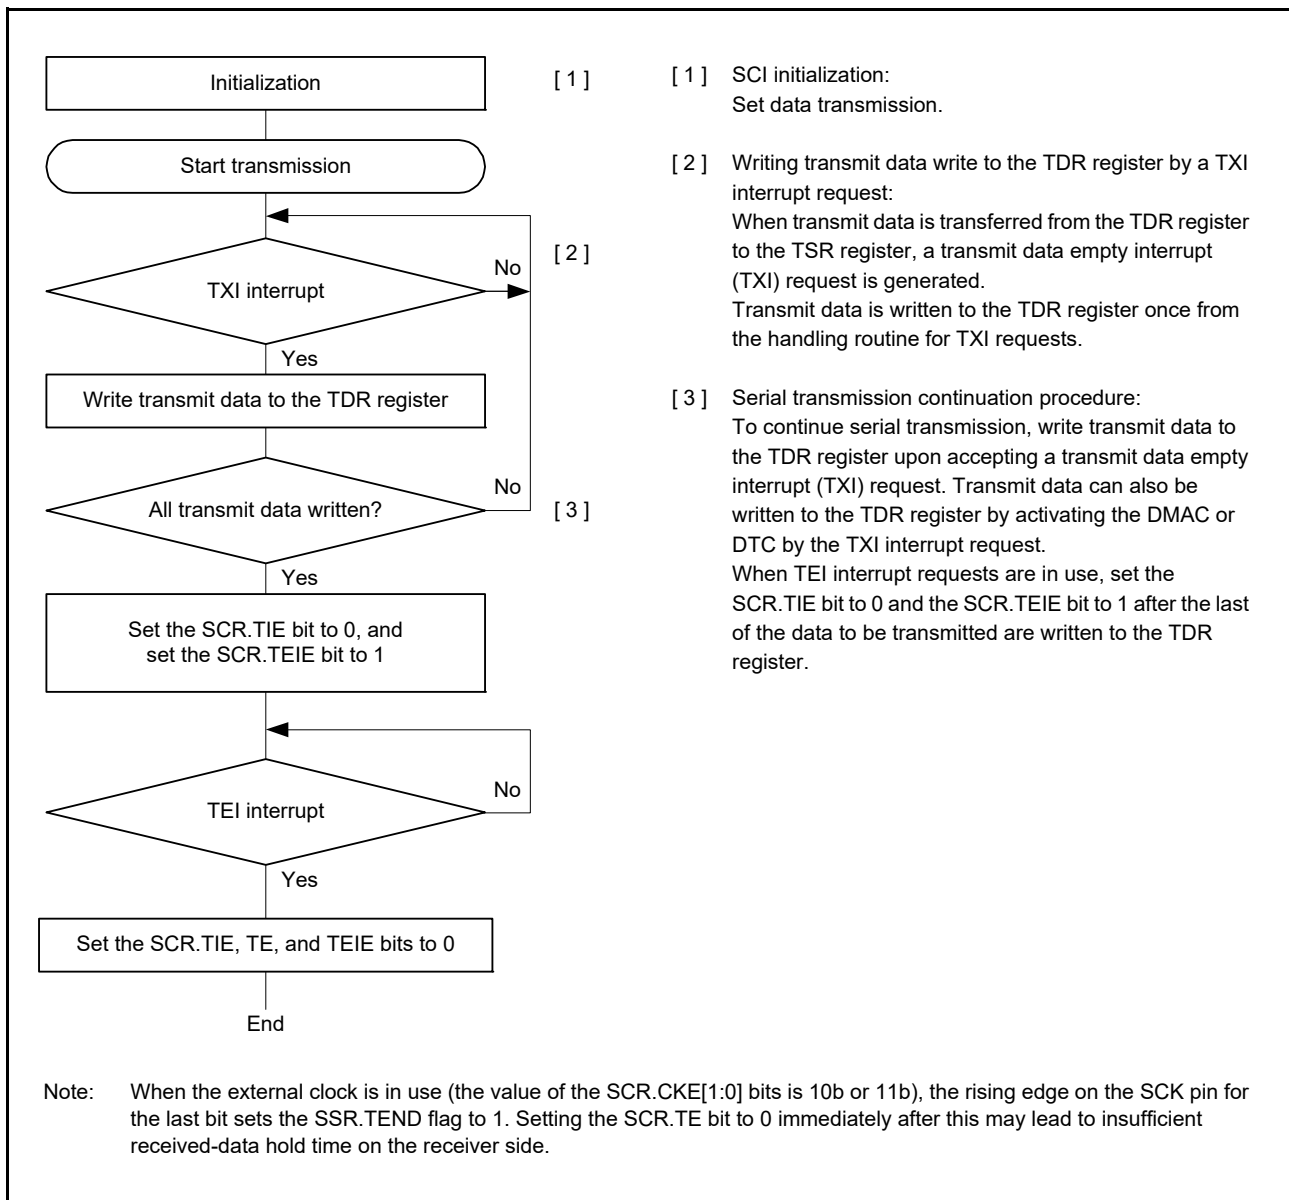

Figure 32.32 Example Flowchart of Serial Transmission in Clock Synchronous Mode

## (2) SCI11 When FIFO is Enabled

Set the transmit data in the FTDR register (FTDR.L register) instead of the TDR register. When data is transferred from the transmit FIFO to the TSR register and if the number of data stored in the transmit FIFO is less than or equal to the threshold (FCR.TTRG[3:0] bits), a transmit data empty interrupt (TXI) request is generated.

Up to 16 minus FDR.T[4:0] frames of transmit data can be set within the TXI interrupt processing routine. When the settings of all transmit data are completed, set the SSRFIFO.TDFE flag to 0.

When the transmit data is set by using the DMAC or DTC, the TDFE flag is automatically set to 0.

When transmitting serial data, the SCI operates as follows.

1. When the SCR.TIE and SCR.TE bits are simultaneously set to 1, a TXI interrupt request is generated. Up to 16 minus FDR.T[4:0] bytes of transmit data can be set in the FTDR register (FTDR.L register) within the TXI interrupt processing routine.
2. After the transmit data is written to the FTDR register, the SCI starts transmission by transferring the data to the TSR register in sequence starting from the top of the transmit FIFO. When the number of untransmitted data in the transmit FIFO is less than or equal to the specified threshold (FCR.TTRG[3:0] bits), the SSRFIFO.TDFE flag is set to 1. At this time, if the SCR.TIE bit is 1, a TXI interrupt request is generated. Writing the transmit data to the FTDR register by using the TXI interrupt processing routine before the transmit FIFO becomes empty enables sequence transmission. When a TEI interrupt request is used, the SCI writes the last transmit data to the FTDR register by using the TXI interrupt processing routine, and then sets the SCR.TIE bit to 0 and the SCR.TEIE bit to 1.
3. The SCI outputs 8-bits of data from the TXDn pin in synchronization with the clock for output when the SCR.CKE[1] bit is 0 (internal clock) and in synchronization with the clock for input when the SCR.CKE[1] bit is 1 (external clock). When the SPMR.CTSE bit is 1 (with the CTS function enabled), the SCI waits until the low is input to the CTSn# pin and starts transmission.
4. The SCI checks whether any untransmitted data is in the transmit FIFO when it transmits the last bit.
5. When any untransmitted data is in the transmit FIFO, the SCI transfers the data to the TSR register from the transmit FIFO and starts transmission of the next frame data.
6. When no untransmitted data remains in the transmit FIFO, the SCI sets the SSRFIFO.TEND flag to 1 and stops shifting by the TSR register. At this time, if the SCR.TEIE bit is 1, a TEI interrupt request is generated. The TXDn pin is fixed to the value of the last bit of the last transmitted data and the SCKn pin is fixed to high.

### 32.5.5 Serial Data Reception (Clock Synchronous Mode)

#### (1) SCI1, SCI5, SCI6, SCI8, SCI9, and SCI12, and SCI11 when FIFO is Disabled

Figure 32.33 and Figure 32.34 show an example of SCI operation for serial reception in clock synchronous mode. In serial data reception, the SCI operates as described below.

1. The value of the SCR.RE bit becoming 1 places the signal output on the RTSn# pin at the low level (when the RTS function is in use).
2. The SCI performs internal initialization and starts receiving data in synchronization with a synchronization clock input or output, and stores the receive data in the RSR register.
3. If an overrun error occurs, the SSR.ORER flag is set to 1. If the SCR.RIE bit is 1 at this time, an ERI interrupt request is generated. Receive data is not transferred to the RDR register.
4. When reception finishes successfully, receive data is transferred to the RDR register. If the SCR.RIE bit is 1 at this time, an RXI interrupt request is generated. Continuous reception is enabled by reading the receive data transferred to the RDR register in this RXI interrupt handling routine before reception of the next receive data is completed. Reading out the received data that have been transferred to the RDR register causes the RTSn# pin to output the low level (when the RTS function is in use).

**Figure 32.33 Example of Operation for Serial Reception in Clock Synchronous Mode (1)  
(When RTS Function is Not Used)**

**Figure 32.34 Example of Operation for Serial Reception in Clock Synchronous Mode (2) (When RTS Function is Used)**

Data transfer cannot be resumed while a receive error flag is 1. Accordingly, clear the ORER, FER, and PER flags in the SSR register before resuming reception. Moreover, be sure to read the RDR register during overrun error processing. When a reception is forcibly terminated by setting the SCR.RE bit to 0 during operation, read the RDR register because received data which has not yet been read may be left in the RDR register.

Figure 32.35 shows a sample flowchart for serial data reception.

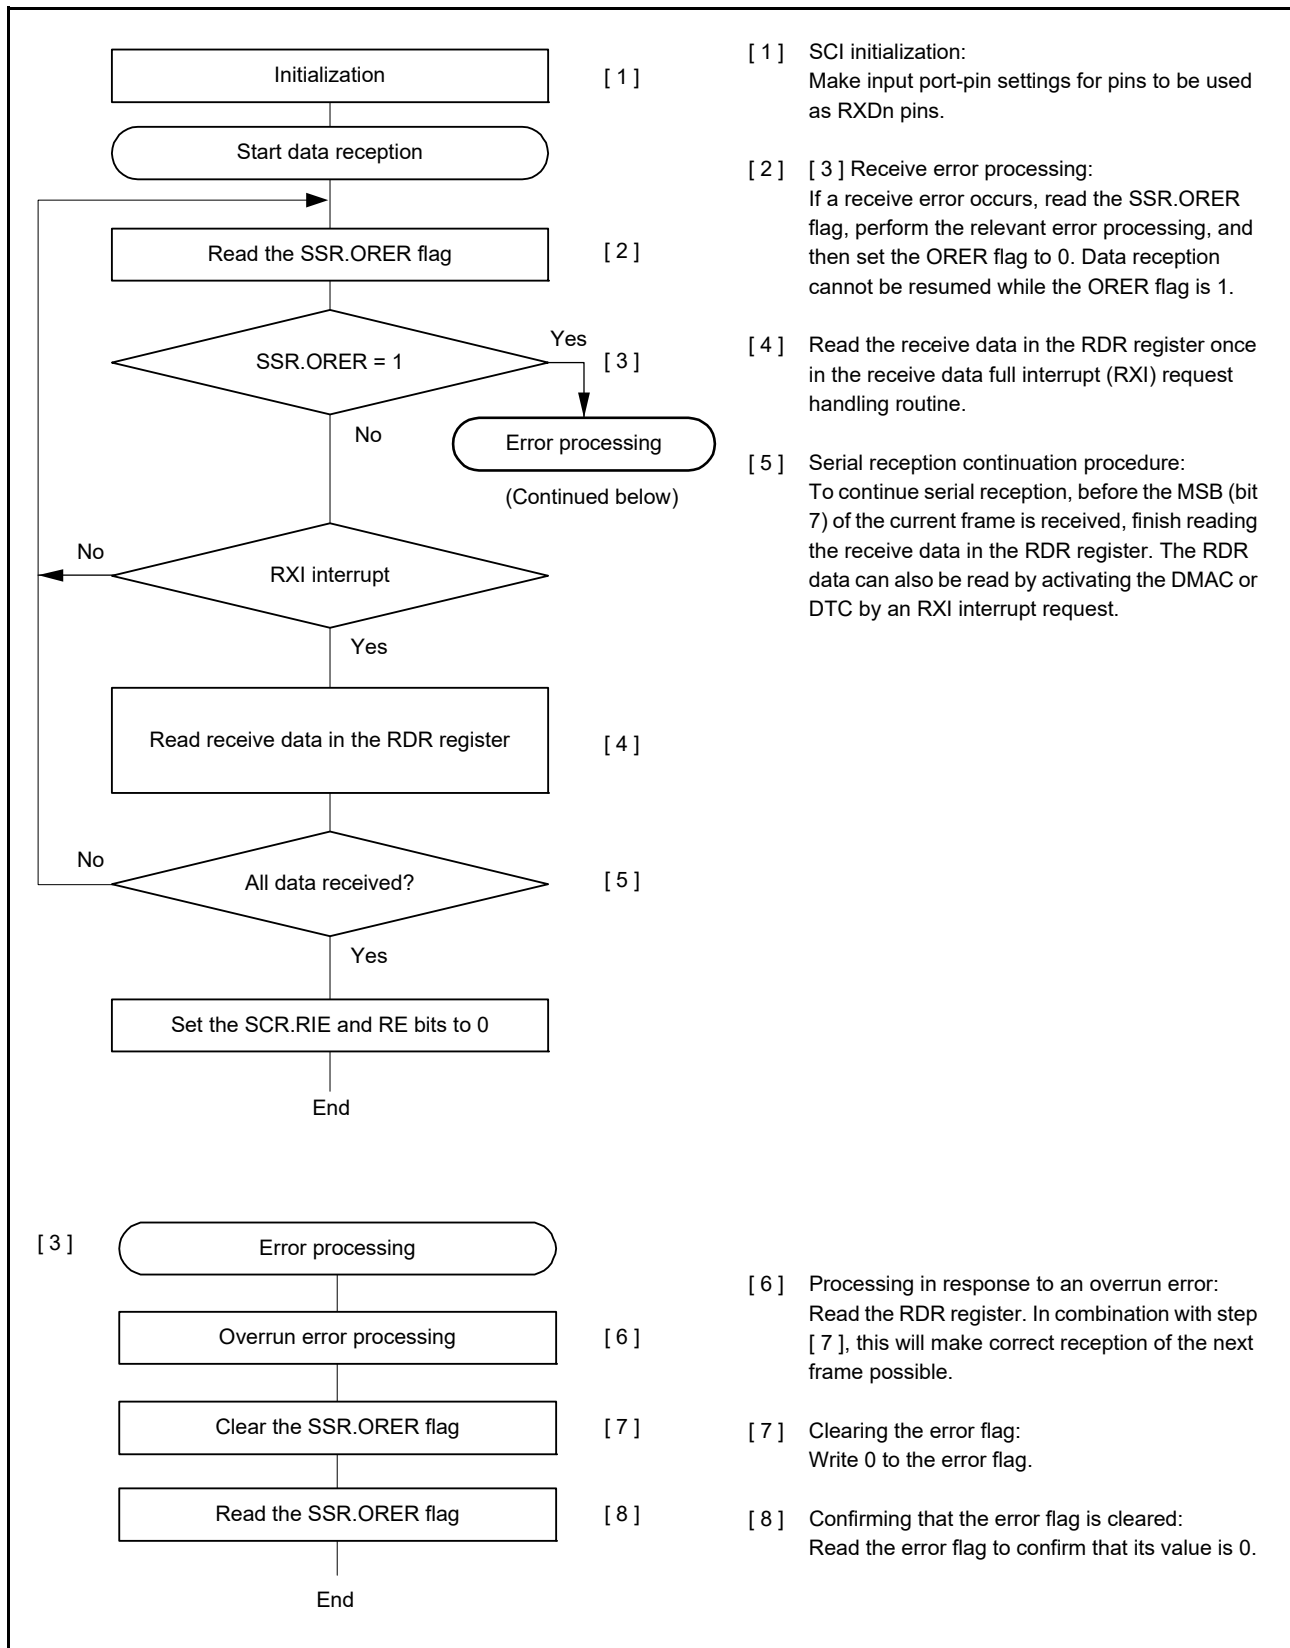

Figure 32.35 Example Flowchart of Serial Reception in Clock Synchronous Mode

## (2) SCI11 When FIFO is Enabled

The received data and status flag are read from the FRDR register instead of the RDR register. When reading in byte units, read the FRDR.H register and then the FRDR.L register in this order. Reading the FRDR.L register updates the FRDR.RDAT[7:0] bits. The value of the RDF and ORER flags in the FRDR register is the same as that of the SSRFIFO register.

When receiving serial data, the SCI operates as follows.

1. If the SCR.RE bit is set to 1 and the RTSn# function is in use, the SCI drives the RTSn# pin low.
2. The SCI starts receiving data in synchronization with the clock input or output and stores the received data in the RSR register.
3. When there is no space in the receive FIFO, an overrun error occurs. When an overrun error occurs, the SCI sets the SSRFIFO.ORER flag to 1. At this time, if the SCR.RIE bit is 1, an ERI interrupt request is generated. The received data is not transferred to the receive FIFO.
4. When the data is successfully received, the SCI transfers the received data to the receive FIFO. If the number of data stored in the receive FIFO is equal to or greater than the threshold (FCR.RTRG[3:0] bits), the SCI sets the SSRFIFO.RDF flag to 1. At this time, if the SCR.RIE bit is 1, an RXI interrupt request is generated. Using the RXI interrupt processing routine allows reading of the received data in the RDRF register before an overrun error occurs, thus enabling the sequence reception of data. When the received data that have been transferred to the receive FIFO are read and the number of unread data is less than the value of the FCR.RSTRG[3:0] bits, the SCI drives the RTSn# pin low.

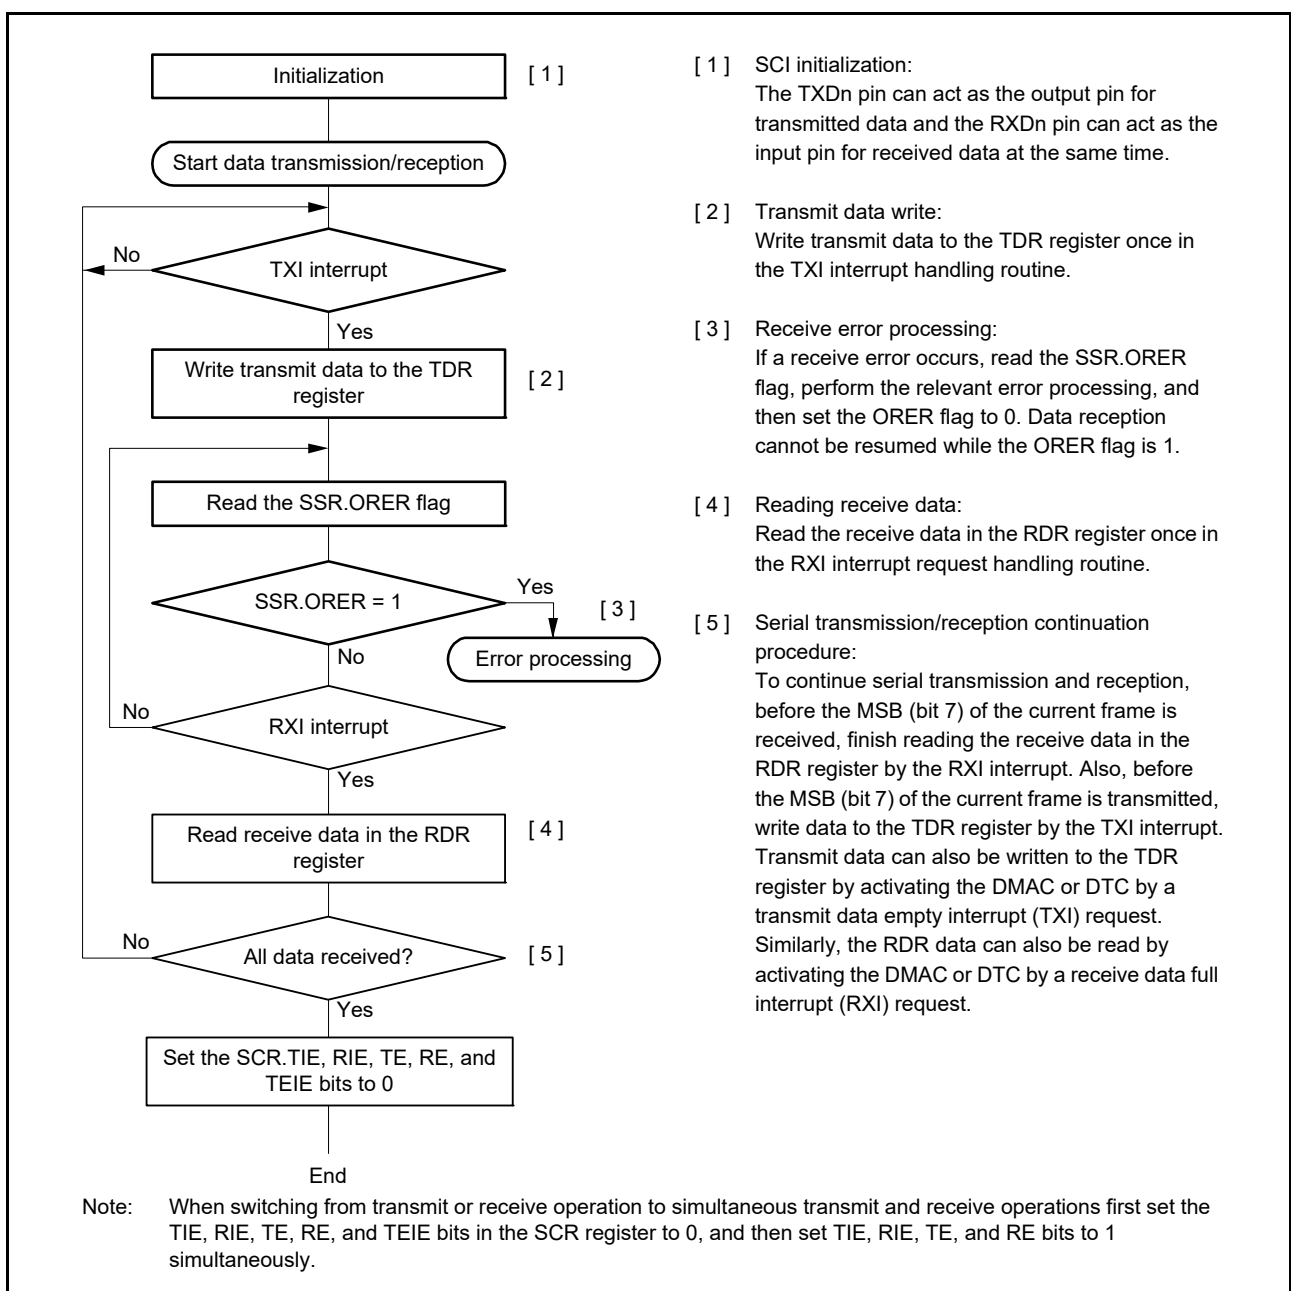

### 32.5.6 Simultaneous Serial Data Transmission and Reception (Clock Synchronous Mode)

Figure 32.36 shows a sample flowchart for simultaneous serial transmit and receive operations in clock synchronous mode.

After initializing the SCI, the following procedure should be used for simultaneous serial data transmit and receive operations.

To switch from transmit mode to simultaneous transmit and receive mode, check that the SCI has finished transmission by reading that the SSR.TEND flag is 1, and then initialize the SCR register. Then set the TIE, RIE, TE, and RE bits in the SCR register to 1 simultaneously by a single instruction.

To switch from receive mode to simultaneous transmit and receive mode, check that the SCI has finished reception, and then set the RIE and RE bits to 0. Then check that the receive error flags (ORER, FER, and PER in the SSR register) are 0, and then set the TIE, RIE, TE, and RE bits in the SCR register to 1 simultaneously by a single instruction.

**Figure 32.36 Example Flowchart of Simultaneous Serial Transmission and Reception in Clock Synchronous Mode**

## 32.6 Operation in Smart Card Interface Mode

The SCI supports smart card (IC card) interfaces conforming to ISO/IEC 7816-3 (standard for Identification Cards), as an extended function of the SCI.

Smart card interface mode can be selected using the appropriate register.

### 32.6.1 Sample Connection

Figure 32.37 shows a sample connection between a smart card (IC card) and this MCU.

As in the figure, since this MCU communicates with an IC card using a single transmission line, interconnect the TXDn and RXDn pins and pull up the data transmission line to VCC using a resistor.

Setting the TE and RE bits in the SCR register to 1 with an IC card disconnected enables closed transmission/reception allowing self-diagnosis.

To supply an IC card with the clock pulses generated by the SCI, input the SCKn pin output to the CLK pin of an IC card. The output port of the this MCU can be used to output a reset signal.

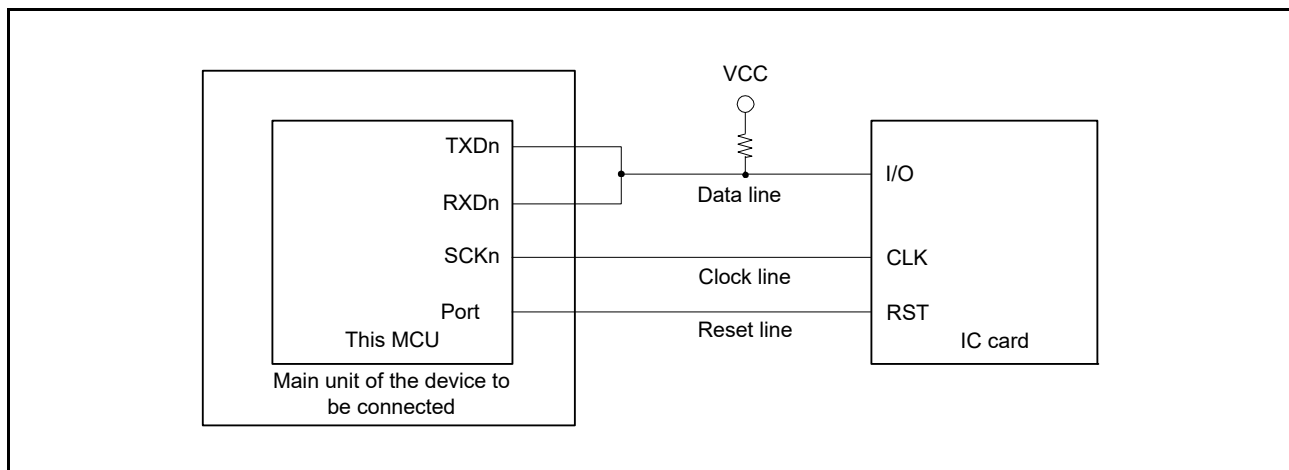

Figure 32.37 Sample Connection with a Smart Card (IC Card)

### 32.6.2 Data Format (Except in Block Transfer Mode)

Figure 32.38 shows the data transfer formats in smart card interface mode.

- One frame consists of 8-bit data and a parity bit in asynchronous mode.
- During transmission, at least 2 etu (elementary time unit: time required for transferring 1 bit) is secured as a guard time from the end of the parity bit until the start of the next frame.
- If a parity error is detected during reception, a low-level error signal is output for 1 etu after 10.5 etu has passed from the start bit.
- If an error signal is sampled during transmission, the same data is automatically retransmitted after at least 2 etu.

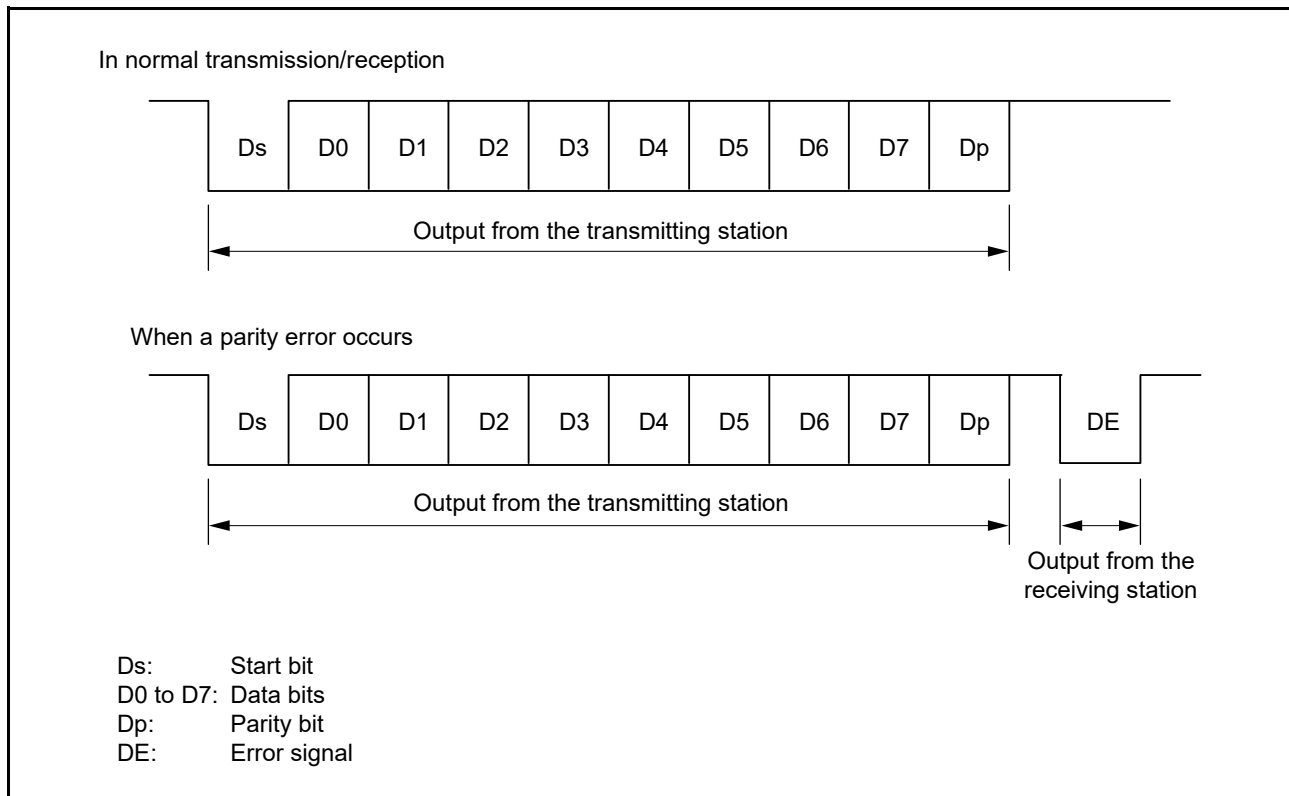

Figure 32.38 Data Formats in Smart Card Interface Mode

For communications with IC cards of the direct convention type and inverse convention type, follow the procedure below.

### (1) Direct Convention Type

For the direct convention type, logic levels 1 and 0 correspond to states Z and A, respectively, and data is transferred with LSB first as the start character, as shown in Figure 32.39. Therefore, data in the start character in the figure is 3Bh. When using the direct convention type, write 0 to both the SDIR and SINV bits in the SCMR register. Write 0 to the SMR.PM bit in order to use even parity, which is prescribed by the smart card standard.

Figure 32.39 Direct Convention (SCMR.SDIR bit = 0, SCMR.SINV bit = 0, SMR.PM bit = 0)

### (2) Inverse Convention Type

For the inverse convention type, logic levels 1 and 0 correspond to states A and Z, respectively and data is transferred with MSB first as the start character, as shown in Figure 32.40. Therefore, data in the start character in the figure is 3Fh. When using the inverse convention type, write 1 to both the SDIR and SINV bits in the SCMR register. The parity bit is logic level 0 to produce even parity, which is prescribed by the smart card standard, and corresponds to state Z. Since the SINV bit of this MCU only inverts data bits D7 to D0, write 1 to the SMR.PM bit to invert the parity bit for both transmission and reception.

Figure 32.40 Inverse Convention (SCMR.SDIR bit = 1, SCMR.SINV bit = 1, SMR.PM bit = 1)

## 32.6.3 Block Transfer Mode

Block transfer mode is different from non-block transfer mode in the following respects.

- Even if a parity error is detected during reception, no error signal is output. Since the SSR.PER flag is set by error detection, clear the PER flag before receiving the parity bit of the next frame.
- During transmission, at least 1 etu is secured as a guard time from the end of the parity bit until the start of the next frame.
- Since the same data is not retransmitted during transmission, the SSR.TEND flag is set 11.5 etu after transmission start.
- In block transfer mode, the SSR.ERS flag indicates the error signal status as in non-block transfer mode, but the flag is read as 0 because no error signal is transferred.

### 32.6.4 Receive Data Sampling Timing and Reception Margin

Only the base clock generated by the on-chip baud rate generator can be used as a transmit/receive clock in smart card interface mode.

In this mode, the SCI can operate on a base clock with a frequency of 32, 64, 372, 256, 93, 128, 186, or 512 times the bit rate according to the settings of the SCMR.BCP2 bit and the SMR.BCP[1:0] bits.

For data reception, the falling edge of the start bit is sampled with the base clock to perform synchronization. Receive data is sampled on the 16th, 32nd, 186th, 128th, 46th, 64th, 93rd, and 256th rising edges of the base clock so that it can be latched at the middle of each bit as shown in Figure 32.41. The reception margin here is determined by the following formula.

$$M = \left| \left( 0.5 - \frac{1}{2N} \right) - (L - 0.5)F - \frac{|D - 0.5|}{N}(1 + F) \right| \times 100 (\%)$$

M: Reception margin (%)

N: Ratio of bit rate to clock (N = 32, 64, 372, 256)

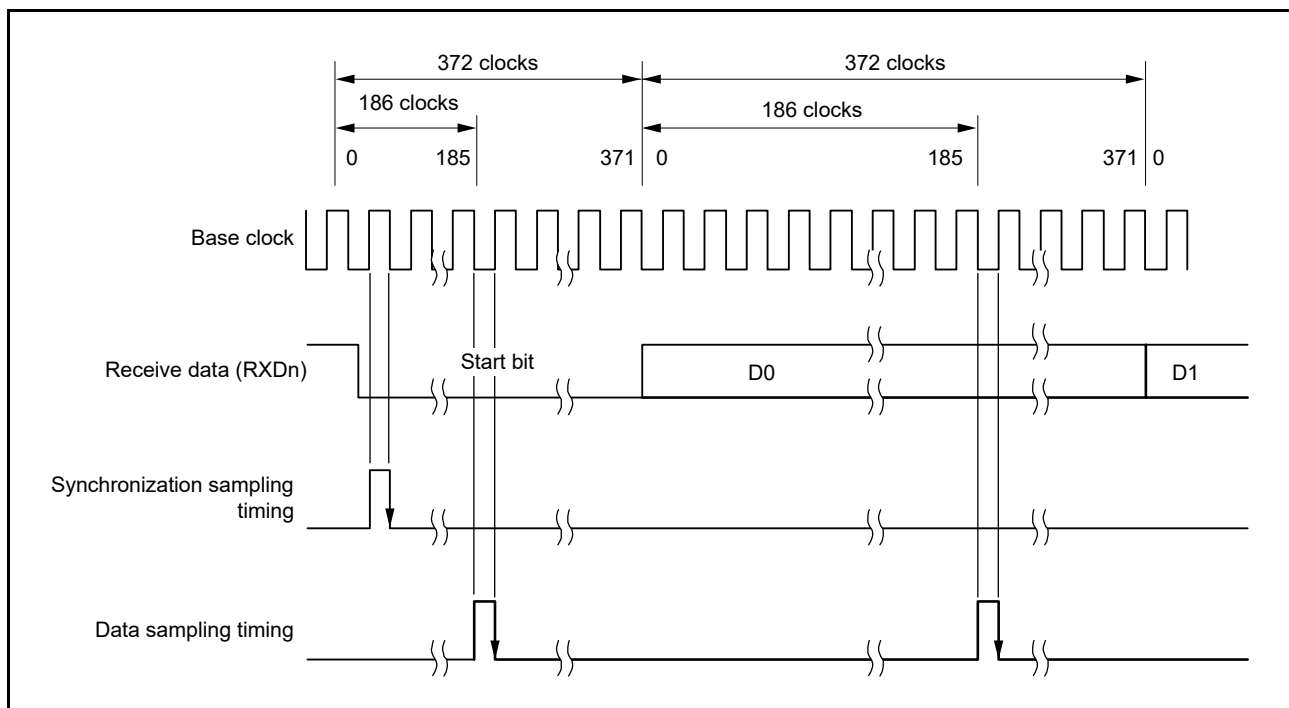

D: Duty cycle of clock (D = 0 to 1.0)

L: Frame length (L = 10)

F: Absolute value of clock frequency deviation

Assuming values of F = 0, D = 0.5, and N = 372 in the above formula, the reception margin is determined by the formula below.

$$M = \{0.5 - 1/(2 \times 372)\} \times 100 (\%) = 49.866 (\%)$$

**Figure 32.41 Receive Data Sampling Timing in Smart Card Interface Mode (When Clock Frequency is 372 Times the Bit Rate)**

### 32.6.5 SCI Initialization (Smart Card Interface Mode)

Initialize the SCI following the example of flowchart shown in Figure 32.42.

Initialize the SCR and SSR registers before switching from transmit mode to receive mode and vice versa. When not changing the bit rate, it is not necessary to set the CKE[1:0] bits to 00b. Even if the RE bit is set to 0, the RDR register is not initialized.

To change receive mode to transmit mode, first check that reception has completed, and then execute steps [1] and [3] in Figure 32.42. Set TE = 1 and RE = 0 at step [11]. Reception completion can be verified by reading the RXI request, SSR.ORER, or SSR.PER flag.

To change transmit mode to receive mode, first check that transmission has completed, and then execute steps [1] and [3] in Figure 32.42. Set TE = 0 and RE = 1 at step [11]. Transmission completion can be verified by reading the SSR.TEND flag.

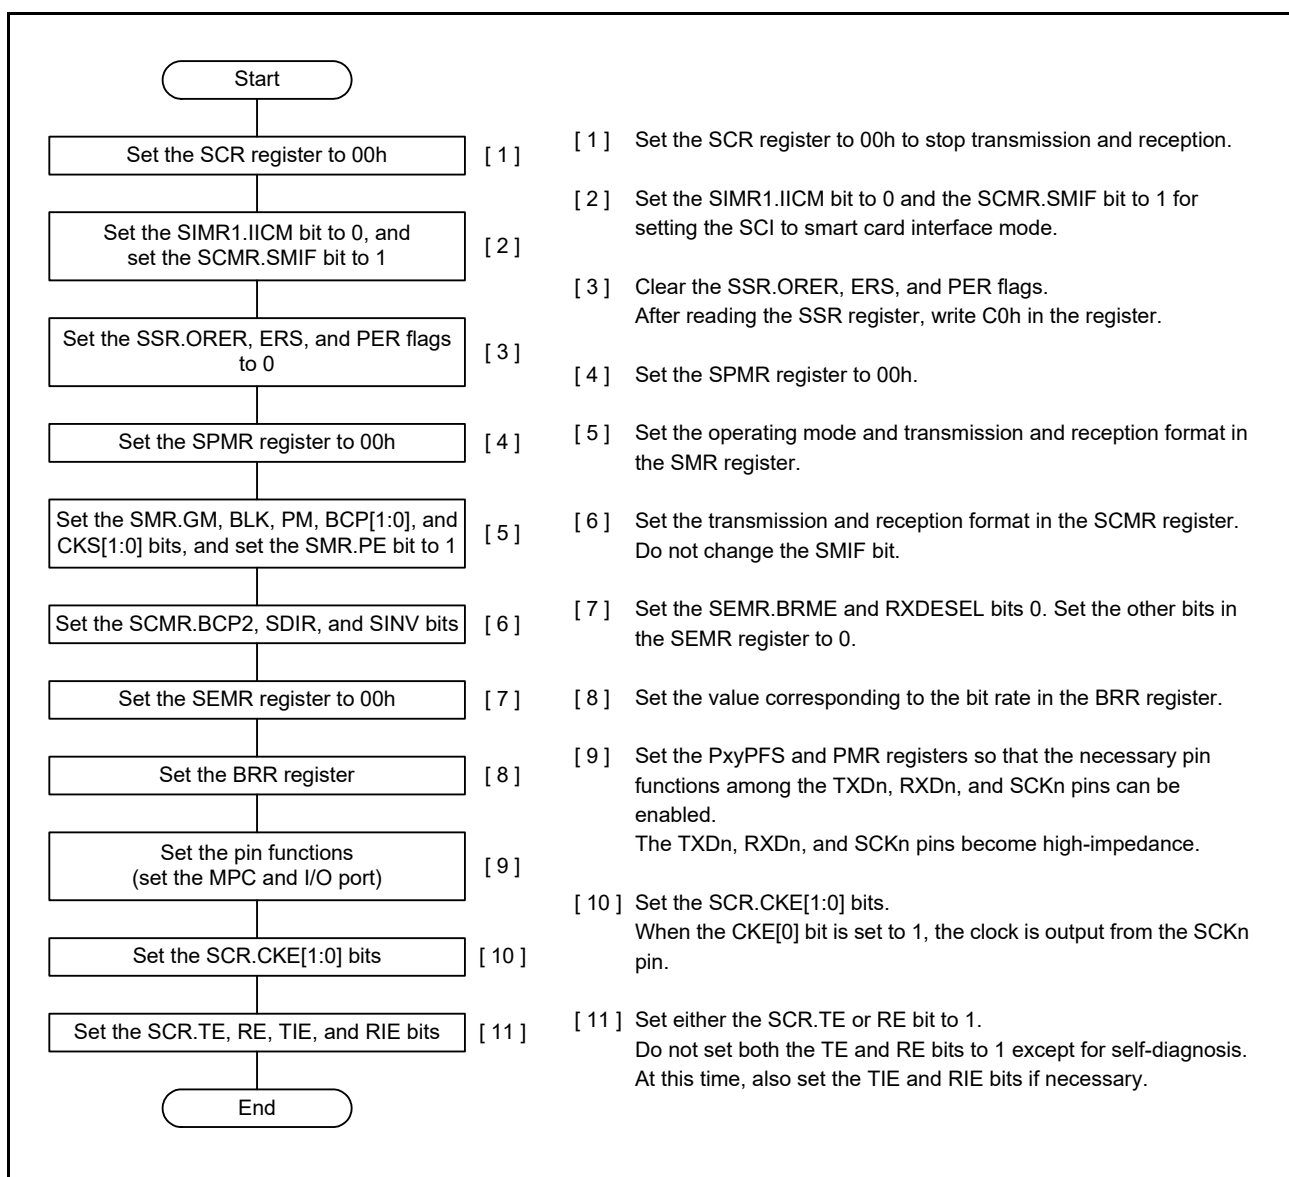

Figure 32.42 Example of SCI Initialization Flowchart (Smart Card Interface Mode)

Figure 32.43 shows an example of data transmission when the SCI is set to smart card interface mode according to the flow described in Figure 32.42 after a reset. When the pin functions are set to the SCK and TXD pins, they are still high-impedance because the SCR.CKE[0] and SCR.TE bits are 0. When the CKE[0] bit is set to 1, clock is output from the SCK pin. When the transmit data is written after setting the TE bit to 1, a data transmission starts. After the TE bit is set to 1, one frame of high-impedance is output from TXD pin (internal wait time) and then the data transmission starts. In smart card interface mode, the clock is continuously output while the CKE[0] bit is set to 1 (clock output) even if both the TE and RE bits are set to 0.

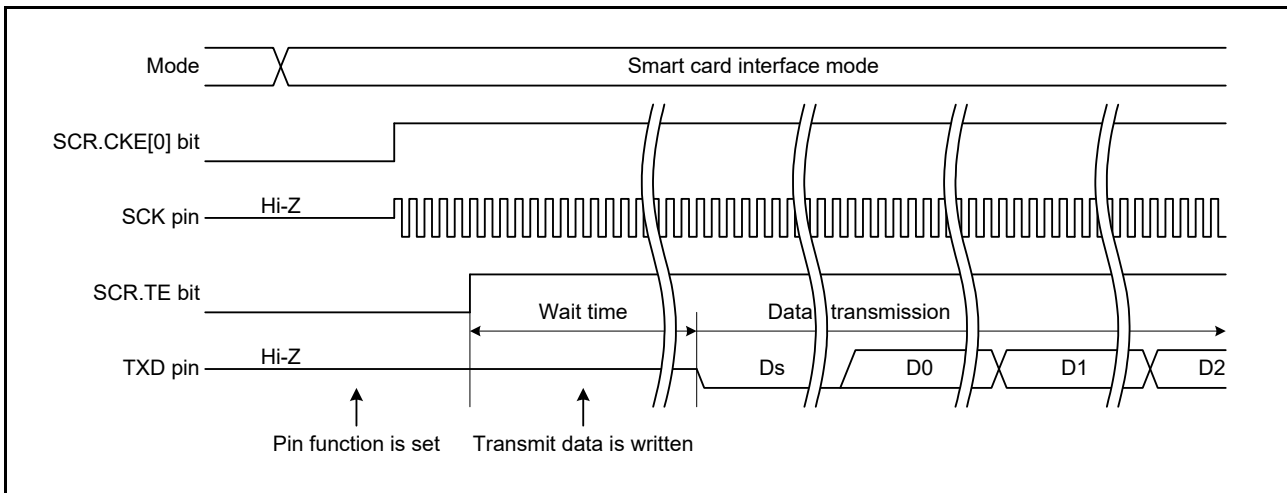

Figure 32.43 Example of Data Transmission Timing in Smart Card Interface Mode

### 32.6.6 Serial Data Transmission (Except in Block Transfer Mode)

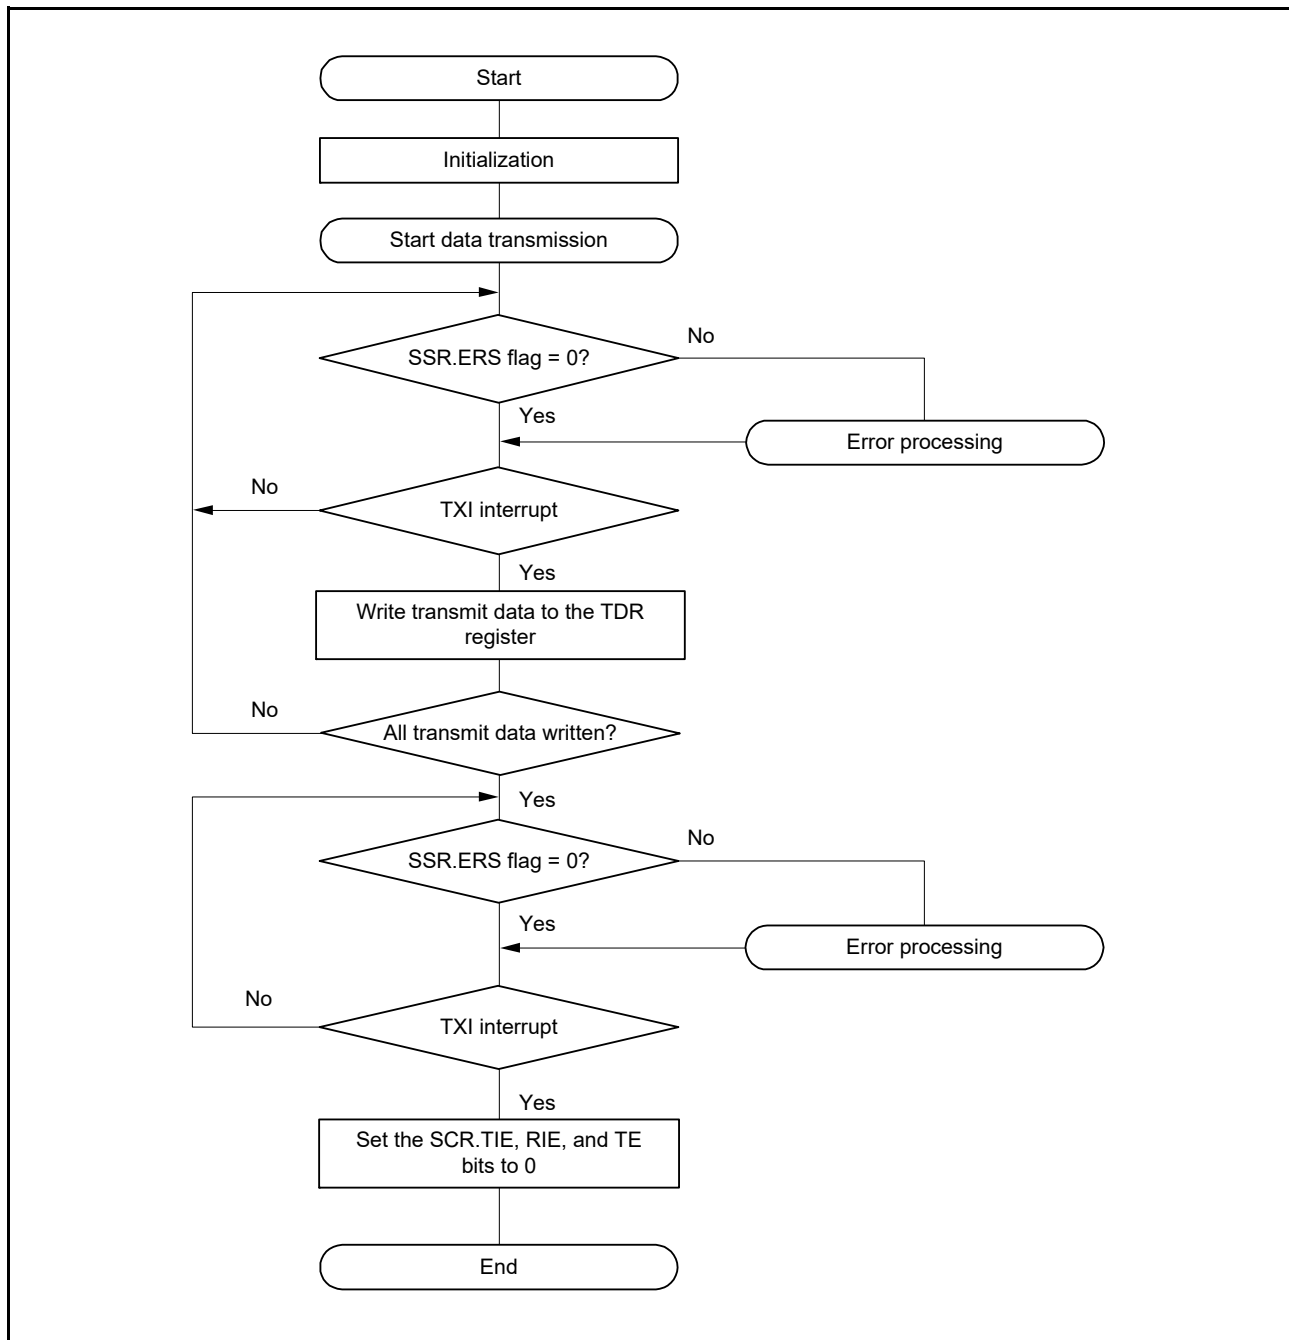

Serial data transmission in smart card interface mode (except in block transfer mode), in that an error signal is sampled and data can be retransmitted, is different from that in non-smart card interface mode. Figure 32.44 shows the data retransmit operation during transmission.

**Figure 32.44** Data Retransmit Operation in SCI Transmit Mode

- (1) When an error signal from the receiver end is sampled after one-frame data has been transmitted, the SSR.ERS flag is set to 1. If the SCR.RIE bit is 1 at this time, an ERI interrupt request is generated. Clear the ERS flag before the next parity bit is sampled.
- (2) For a frame in which an error signal is received, the SSR.TEND flag is not set. Data is retransferred from the TDR register to the TSR register allowing automatic data retransmission.
- (3) If no error signal is returned from the receiver, the ERS flag is not set to 1.
- (4) In this case, the SCI judges that transmission of one-frame data (including retransmission) has been completed, and the TEND flag is set. If the SCR.TIE bit is 1 at this time, a TXI interrupt request is generated. Writing transmit data to the TDR register starts transmission of the next data.

Figure 32.45 shows a sample flowchart of serial transmission.

**Figure 32.45 Sample Smart Card Interface Transmission Flowchart**

All the processing steps are automatically performed using a TXI interrupt request to activate the DTC or DMAC. When the SSR.TEND flag is set to 1 in transmission, if the SCR.TIE bit is 1, a TXI interrupt request is generated. The DTC or DMAC is activated by a TXI interrupt request if the TXI interrupt request is specified as a source of DTC or DMAC activation beforehand, allowing transfer of transmit data. The TEND flag is automatically set to 0 when the DTC or DMAC transfers the data.

If an error occurs, the SCI automatically retransmits the same data. During this retransmission, the TEND flag is kept to 0 and the DTC or DMAC is not activated. Therefore, the SCI and DTC or DMAC automatically transmit the specified number of bytes, including retransmission in the case of error occurrence. However, since the ERS flag is not automatically cleared, set the RIE bit to 1 beforehand to enable an ERI interrupt request to be generated at error occurrence, and clear the ERS flag.

When transmitting/receiving data using the DTC or DMAC, be sure to make settings to enable the DTC or DMAC before making SCI settings.

For DTC or DMAC settings, refer to section 18, Data Transfer Controller (DTCa), section 17, DMA Controller (DMACAa).

Note that the SSR.TEND flag is set in different timings depending on the SMR.GM bit setting. Figure 32.46 shows the TEND flag generation timing.

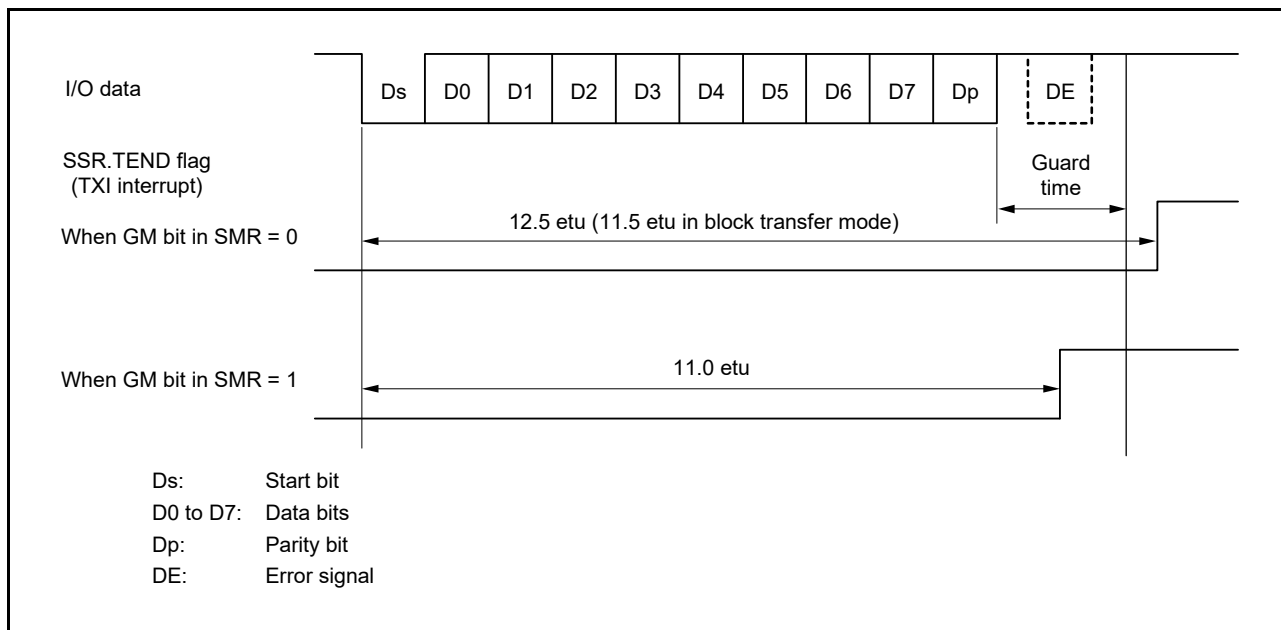

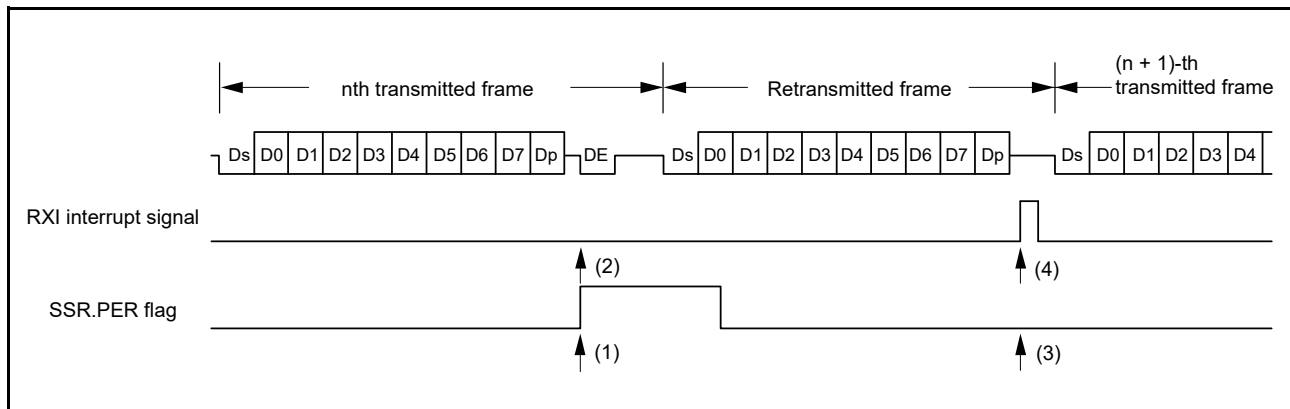

Figure 32.46 SSR.TEND Flag Generation Timing during Transmission

### 32.6.7 Serial Data Reception (Except in Block Transfer Mode)

Serial data reception in smart card interface mode is similar to that in non-smart card interface mode. Figure 32.47 shows the data retransmit operation in receive mode.

**Figure 32.47 Data Retransmit Operation in SCI Receive Mode (Data Retransmit Operation during Reception)**

- (1) If a parity error is detected in receive data, the SSR.PER flag is set to 1. When the SCR.RIE bit is 1 at this time, an ERI interrupt request is generated. Clear the PER flag before the next parity bit is sampled.
- (2) For a frame in which a parity error is detected, no RXI interrupt is generated.
- (3) When no parity error is detected, the SSR.PER flag is not set to 1.
- (4) In this case, data is determined to have been received successfully. When the SCR.RIE bit is 1, an RXI interrupt request is generated.

Figure 32.48 shows a sample flowchart for serial data reception.

**Figure 32.48** Sample Smart Card Interface Reception Flowchart

All the processing steps are automatically performed using an RXI interrupt request to activate the DTC or DMAC.

In reception, setting the RIE bit to 1 allows an RXI interrupt request to be generated. The DTC or DMAC is activated by an RXI interrupt request if the RXI interrupt request is specified as a source of DTC or DMAC activation beforehand, allowing transfer of receive data.

If an error occurs during reception and either the ORER or PER flag in the SSR register is set to 1, a receive error interrupt (ERI) request is generated. Clear the error flag after the error occurrence. If an error occurs, the DTC or DMAC is not activated and receive data is skipped. Therefore, the number of bytes of receive data specified in the DTC or DMAC is transferred.

Even if a parity error occurs and the PER flag is set to 1 during reception, receive data is transferred to the RDR register, thus allowing the data to be read.

When a reception is forcibly terminated by setting the SCR.RE bit to 0 during operation, read the RDR register because the received data which has not yet been read may be left in the RDR register.

Note 1. For operations in block transfer mode, refer to section 32.3, Operation in Asynchronous Mode.

### 32.6.8 Clock Output Control

Clock output can be fixed to high or low using the SCR.CKE[1:0] bits when the SMR.GM bit is 1. When the CKE[1:0] bits are set to 01b (clock output), the base clock is output from the SCK pin. For the settings of the base clock frequency (bit rate), refer to section 32.2.13, Bit Rate Register (BRR). When the CKE[1:0] bits are set to 00b (output fixed low) or 10b (output fixed to high), the SCK pin can be fixed to low or high.

Figure 32.49 shows a timing chart when the clock output is controlled.

If changing the CKE[1:0] bits while the SMR.GM bit is 0 (non-GSM mode), a pulse of unexpected width may output from SCK pin because the result is immediately reflected to the SCK pin.

Figure 32.49 Clock Output Control

### 32.7 Operation in Simple I<sup>2</sup>C Mode

Simple I<sup>2</sup>C-bus format is composed of 8 data bits and an acknowledge bit. By continuing into a slave-address frame after a start condition or restart condition, a master device is able to specify a slave device as the partner for communications. The currently specified slave device remains valid until a new slave device is specified or a stop condition is satisfied.

The 8 data bits in all frames are transmitted in order from the MSB.

The I<sup>2</sup>C-bus format and timing of the I<sup>2</sup>C-bus are shown in Figure 32.50 and Figure 32.51.

Figure 32.50 I<sup>2</sup>C-bus Format

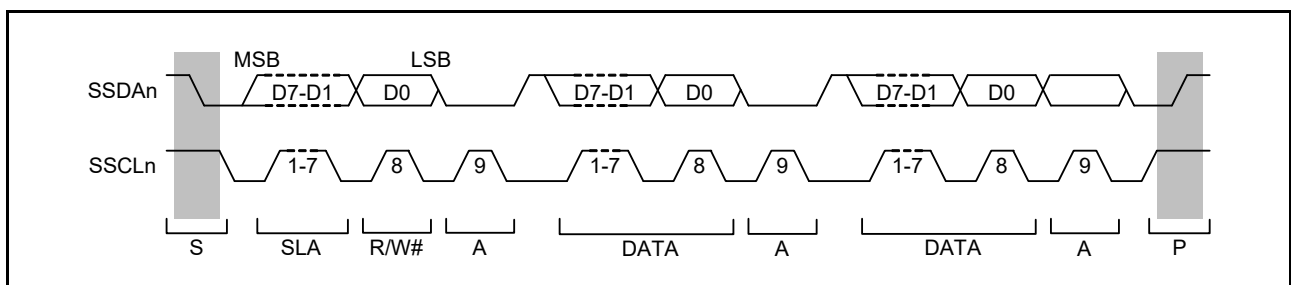

Figure 32.51 I<sup>2</sup>C-bus Timing (When SLA is 7 Bits)

- S: Indicates a start condition, i.e. the master device changing the level on the SSDAn line from the high to the low level while the SSCLn line is at the high level.
- SLA: Indicates a slave address, by which the master device selects a slave device.
- R/W#: Indicates the direction of transfer (reception or transmission). The value 1 corresponds to transfer from the slave device to the master device and 0 corresponds to transfer from the master device to the slave device.
- A/A#: Indicates an acknowledge bit. This is returned by the slave device for master transmission and by the master device for master reception. Return of the low level indicates ACK and return of the high level indicates NACK.
- Sr: Indicates a restart condition, i.e. the master device changing the level on the SSDAn line from the high to the low level while the SSCLn line is at the high level and after the setup time has elapsed.
- DATA: Indicates the data being received or transmitted.
- P: Indicates a stop condition, i.e. the master device changing the level on the SSDAn line from the low to the high level while the SSCLn line is at the high level.

### 32.7.1 Generation of Start, Restart, and Stop Conditions

Writing 1 to the SIMR3.IICSTAREQ bit causes the generation of a start condition. The generation of a start condition proceeds through the following operations.

- The level on the SSDAn line falls (from the high level to the low level) and the SSCLn line is kept in the released state.
- The hold time for the start condition is secured as half of a bit period at the bit rate determined by the setting of the BRR.
- The level on the SSCLn line falls (from the high level to the low level), the SIMR3.IICSTAREQ bit is set (to 0), and a start-condition generated interrupt is output.

Writing 1 to the SIMR3.IICRSTAREQ bit causes the generation of a start condition. The generation of a start condition proceeds through the following operations.

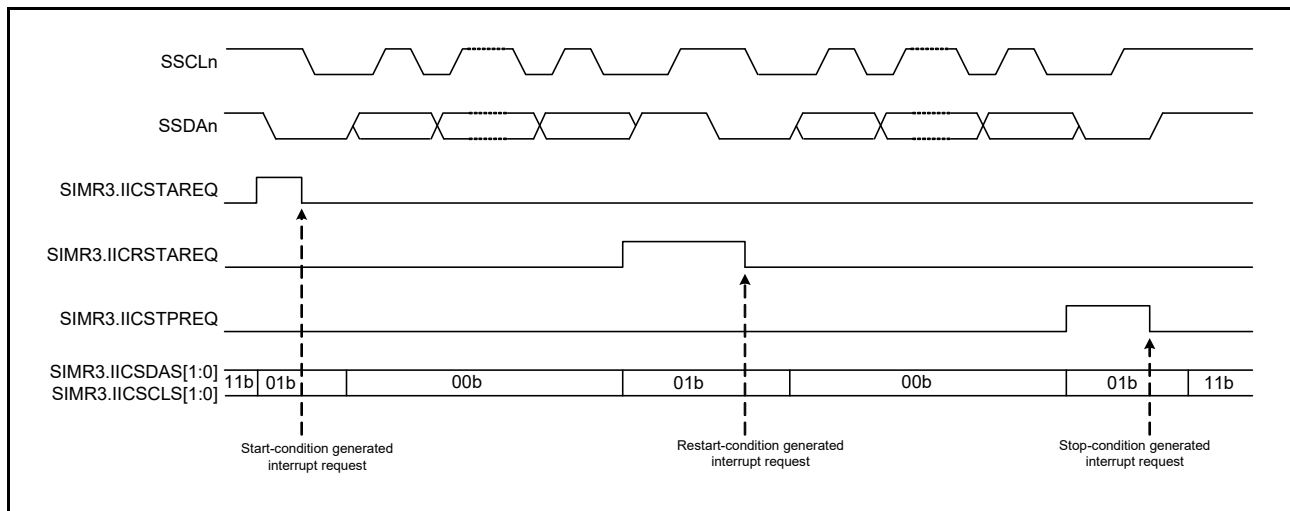

- The SSDAn line is released and the SSCLn line is kept at the low level.
- The period at low level for the SSCLn line is secured as half of a bit period at the bit rate determined by the setting of the BRR.
- The SSCLn line is released (transition from the low to the high level).
- Once the high level on the SSCLn line is detected, the setup time for the restart condition is secured as half of a bit period at the bit rate determined by the setting of the BRR.
- The level on the SSDAn line falls (from the high level to the low level).
- The hold time for the restart condition is secured as half of a bit period at the bit rate determined by the setting of the BRR.
- The level on the SSCLn line falls (from the high level to the low level), the SIMR3.IICRSTAREQ bit is set (to 0), and a restart-condition generated interrupt is output.

Writing 1 to the SIMR3.IICSTPREQ bit causes the generation of a stop condition. The generation of a stop condition proceeds through the following operations.

- The level on the SSDAn line falls (from the high level to the low level) and the SSCLn line is kept at the low level.
- The period at low level for the SSCLn line is secured as half of a bit period at the bit rate determined by the setting of the BRR.
- The SSCLn line is released (transition from the low to the high level).
- Once the high level on the SSCLn line is detected, the setup time for the stop condition is secured as half of a bit period at the bit rate determined by the setting of the BRR.
- The SSDAn is released (transition from the low to the high level), the SIMR3.IICSTPREQ bit is set (to 0), and a stop-condition generated interrupt is output.

Figure 32.52 shows the timing of operations in the generation of start, restart, and stop conditions.

**Figure 32.52** Timing of Operations in the Generation of Start, Restart, and Stop Conditions

### 32.7.2 Clock Synchronization

The SSCLn line may be placed at the low level in the case of a wait inserted by a slave device as the other side of transfer. Setting the SIMR2.IICCSC bit to 1 applies control to obtain synchronization when the levels of the internal SSCLn clock signal and the level being input on the SSCLn pin differ.

When the SIMR2.IICCSC bit is set to 1, the level of the internal SSCLn clock signal changes from low to high, counting to determine the period at high level is stopped while the low level is being input on the SSCLn pin, and counting to determine the period at high level starts after the transition of the input on the SSCLn pin to the high level. The interval from this time until counting to determine the period at high level starts on the transition of the SSCLn pin to the high level is the total of the delay of SSCLn output, delay for noise filtering of the input on the SSCLn pin (2 or 3 cycles of sampling clock for the noise filter), and delay for internal processing (1 or 2 cycles of PCLK). The period at high level of the internal SSCLn clock is extended even if other devices are not placing the low level on the SSCLn line. If the SIMR2.IICCSC bit is 1, synchronization is obtained for the transmission and reception of data by taking the logical AND of the input on the SSCLn pin and the internal SSCLn clock. If the SIMR2.IICCSC bit is 0, synchronization with the internal SSCLn clock is obtained for the transmission and reception of data.

If a slave device inserts a period of waiting into the interval until the transition of the internal SSCLn clock signal from the low to the high level after a request for the generation of a start, restart, or stop condition is issued, the time until generation is prolonged by that period.

If a slave device inserts a period of waiting after the transition of the internal SSCLn clock signal from the low to the high level, although the generation-completed interrupt is issued without stopping the period of waiting, generation of the condition itself is not guaranteed. Figure 32.53 shows an example of operations to synchronize the clocks.

Figure 32.53 Example of Operations for Clock Synchronization

### 32.7.3 SSDA Output Delay

The SIMR1.IICDL[4:0] bits can be used to set a delay for output on the SSDAn pin relative to falling edges of output on the SSCLn pin. Delay-time settings from 0 to 31 are selectable, representing periods of the corresponding numbers of cycles of the clock signal from the on-chip baud rate generator (derived by frequency-dividing the base clock, PCLK, by the divisor selected by the SMR.CKS[1:0] bits). A delay for output on the SSDAn pin is for the start condition/restart condition/stop condition signal, 8-bit transmit data, and an acknowledge bit.

If the SSDA output delay is shorter than the time for the level on the SSCLn pin to fall, the change of the output on the SSDAn pin will start while the output level on the SSCLn pin is falling, creating a possibility of erroneous operation for slave devices. Ensure that settings for the delay of output on the SSDAn pin are for times greater than the time output on the SSCLn pin takes to fall (300 ns for I<sup>2</sup>C-bus in normal mode and fast mode).

Figure 32.54 shows the timing of delays in SSDA output.

Figure 32.54 Timing of Delays in SSDA Output

### 32.7.4 SCI Initialization (Simple I<sup>2</sup>C Mode)

Before transferring data, write the initial value (00h) to the SCR register and initialize the interface following the example shown in Figure 32.55.

When changing the operating mode, transfer format, and so on, be sure to set the SCR register to its initial value before proceeding with the changes.

In simple I<sup>2</sup>C mode, the open-drain setting for the communication ports should be made on the port side.

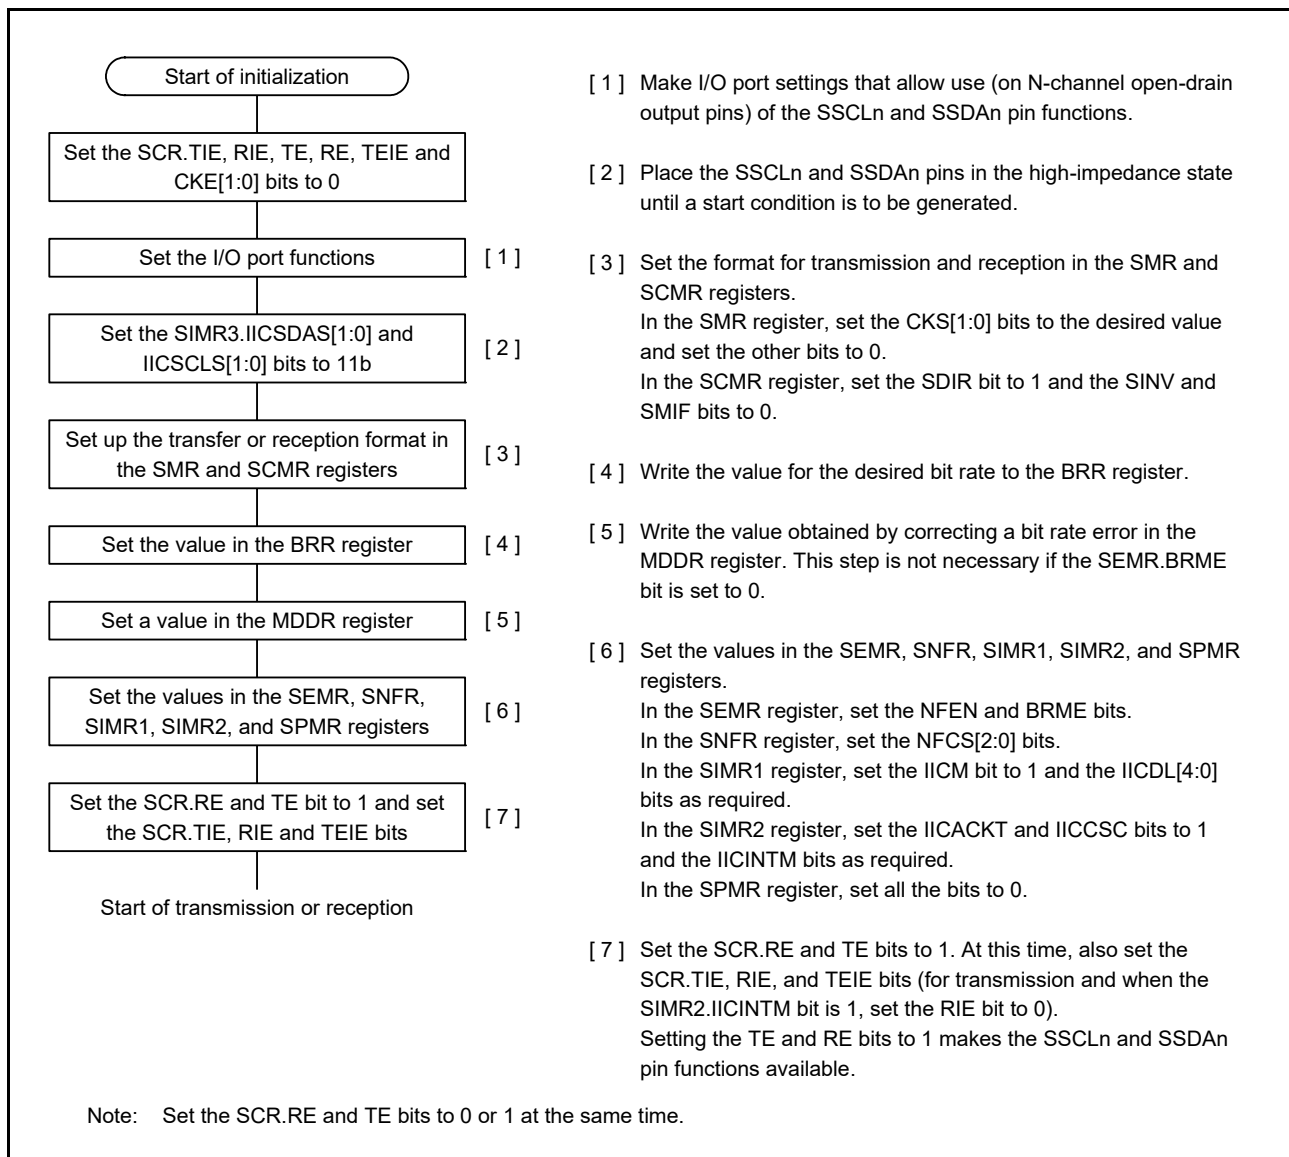

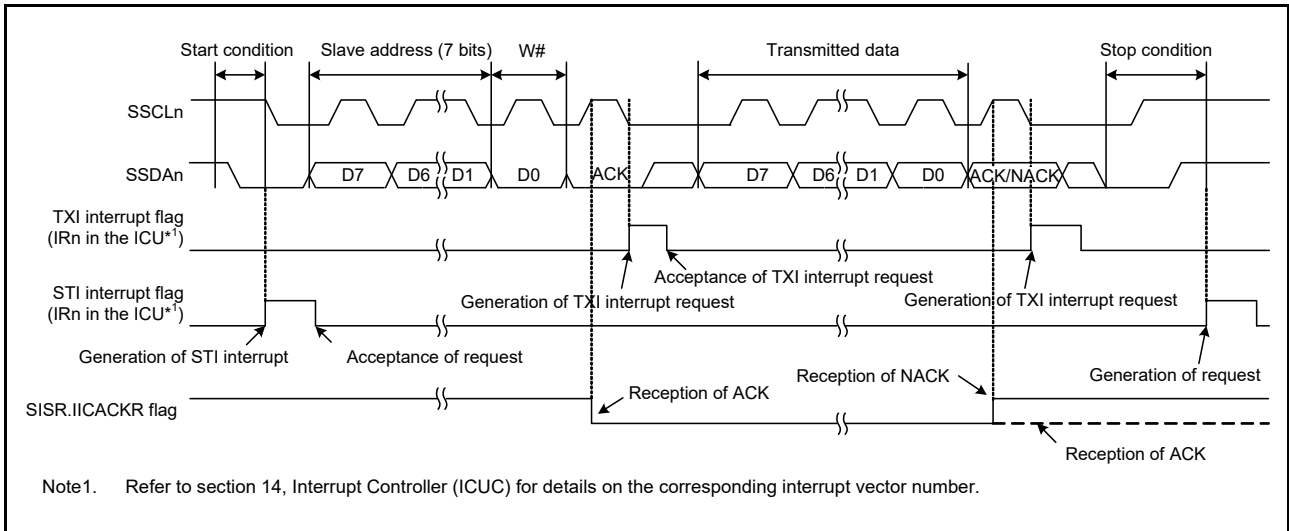

Figure 32.55 Example of the Flowchart of SCI Initialization (for Simple I<sup>2</sup>C Mode)

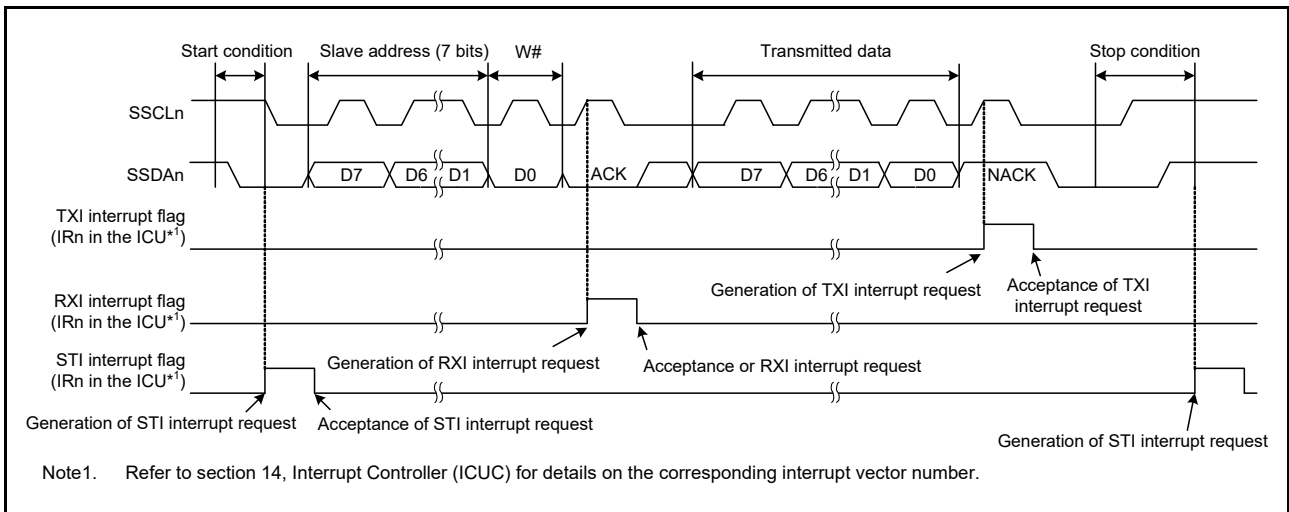

### 32.7.5 Operation in Master Transmission (Simple I<sup>2</sup>C Mode)

Figure 32.56 and Figure 32.57 show examples of operations in master transmission and Figure 32.58 is a flowchart showing the procedure for data transmission. Refer to Table 32.39 for more information on the STI interrupt. When 10-bit slave addresses are in use, steps [3] and [4] in Figure 32.58 are repeated twice. In simple I<sup>2</sup>C mode, the transmit data empty interrupt (TXI) is generated when communication of one frame is completed, unlike the TXI interrupt request generation timing during clock synchronous transmission.

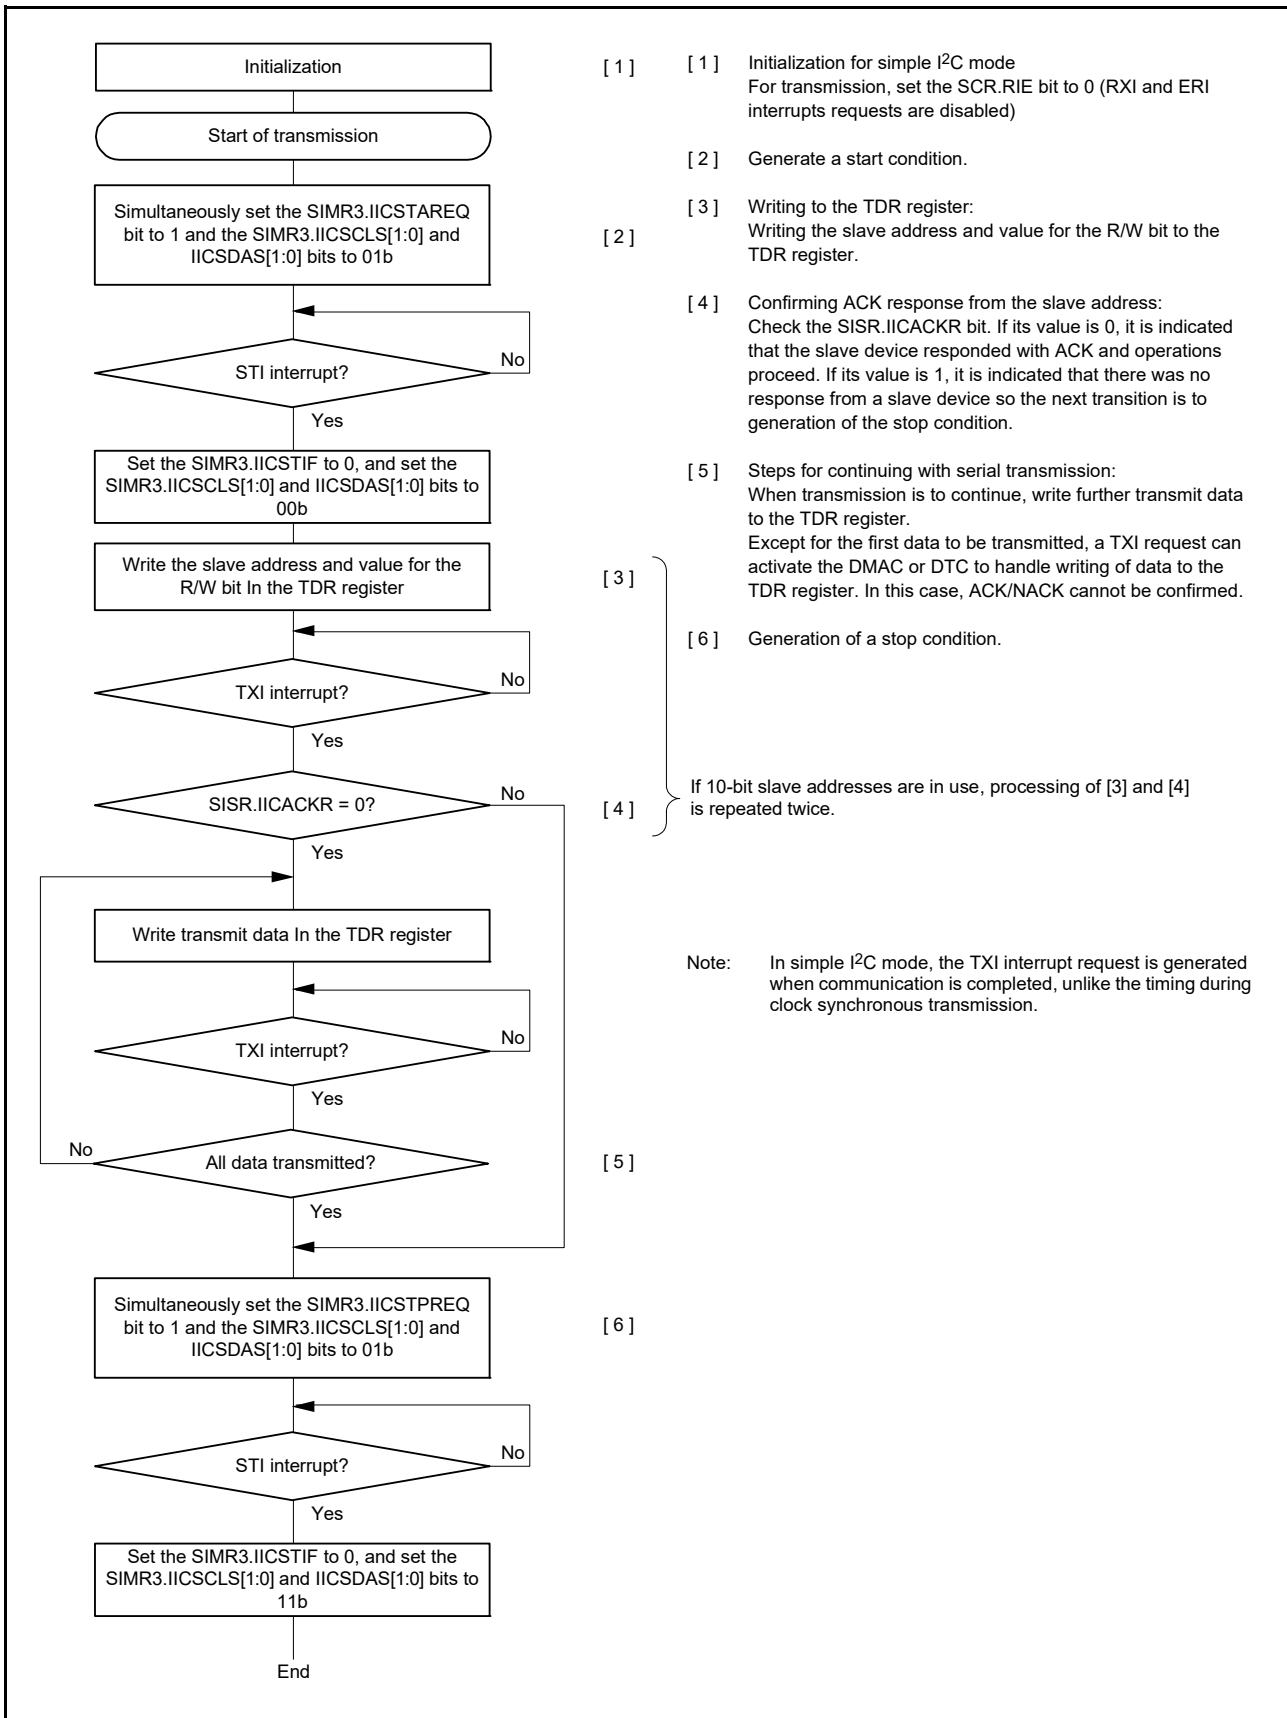

**Figure 32.56 Example 1 of Operations for Master Transmission in Simple I<sup>2</sup>C-bus Mode (with 7-Bit Slave Addresses, Transmission Interrupts, and Reception Interrupts in Use)**

When the SIMR2.IICINTM bit is set to 0 (use ACK/NACK interrupts) during master transmission, the DTC or DMAC is activated by the ACK interrupt as the trigger and necessary number of data bytes are transmitted. When the NACK is received, error processing, such as transmission stop and retransmission, is performed by the NACK interrupt as the trigger.

**Figure 32.57 Example 2 of Operations for Master Transmission in Simple I<sup>2</sup>C-bus Mode (with 7-Bit Slave Addresses, ACK Interrupts, and NACK Interrupts in Use)**

**Figure 32.58 Example of the Procedure for Master Transmission Operations in Simple I<sup>2</sup>C Mode (with Transmission Interrupts and Reception Interrupts in Use)**

### 32.7.6 Master Reception (Simple I<sup>2</sup>C Mode)

Figure 32.59 shows an example of operations in simple I<sup>2</sup>C mode master reception and Figure 32.60 is a flowchart showing the procedure for master reception.

The value of the SIMR2.IICINTM bit is assumed to be 1 (use reception and transmission interrupts).

In simple I<sup>2</sup>C mode, the transmit data empty interrupt (TXI) is generated when communication of one frame is completed, unlike the TXI interrupt request generation timing during clock synchronous transmission.

**Figure 32.59 Example of Operations for Master Reception in Simple I<sup>2</sup>C-bus Mode (with 7-Bit Slave Addresses, Transmission Interrupts, and Reception Interrupts in Use)**

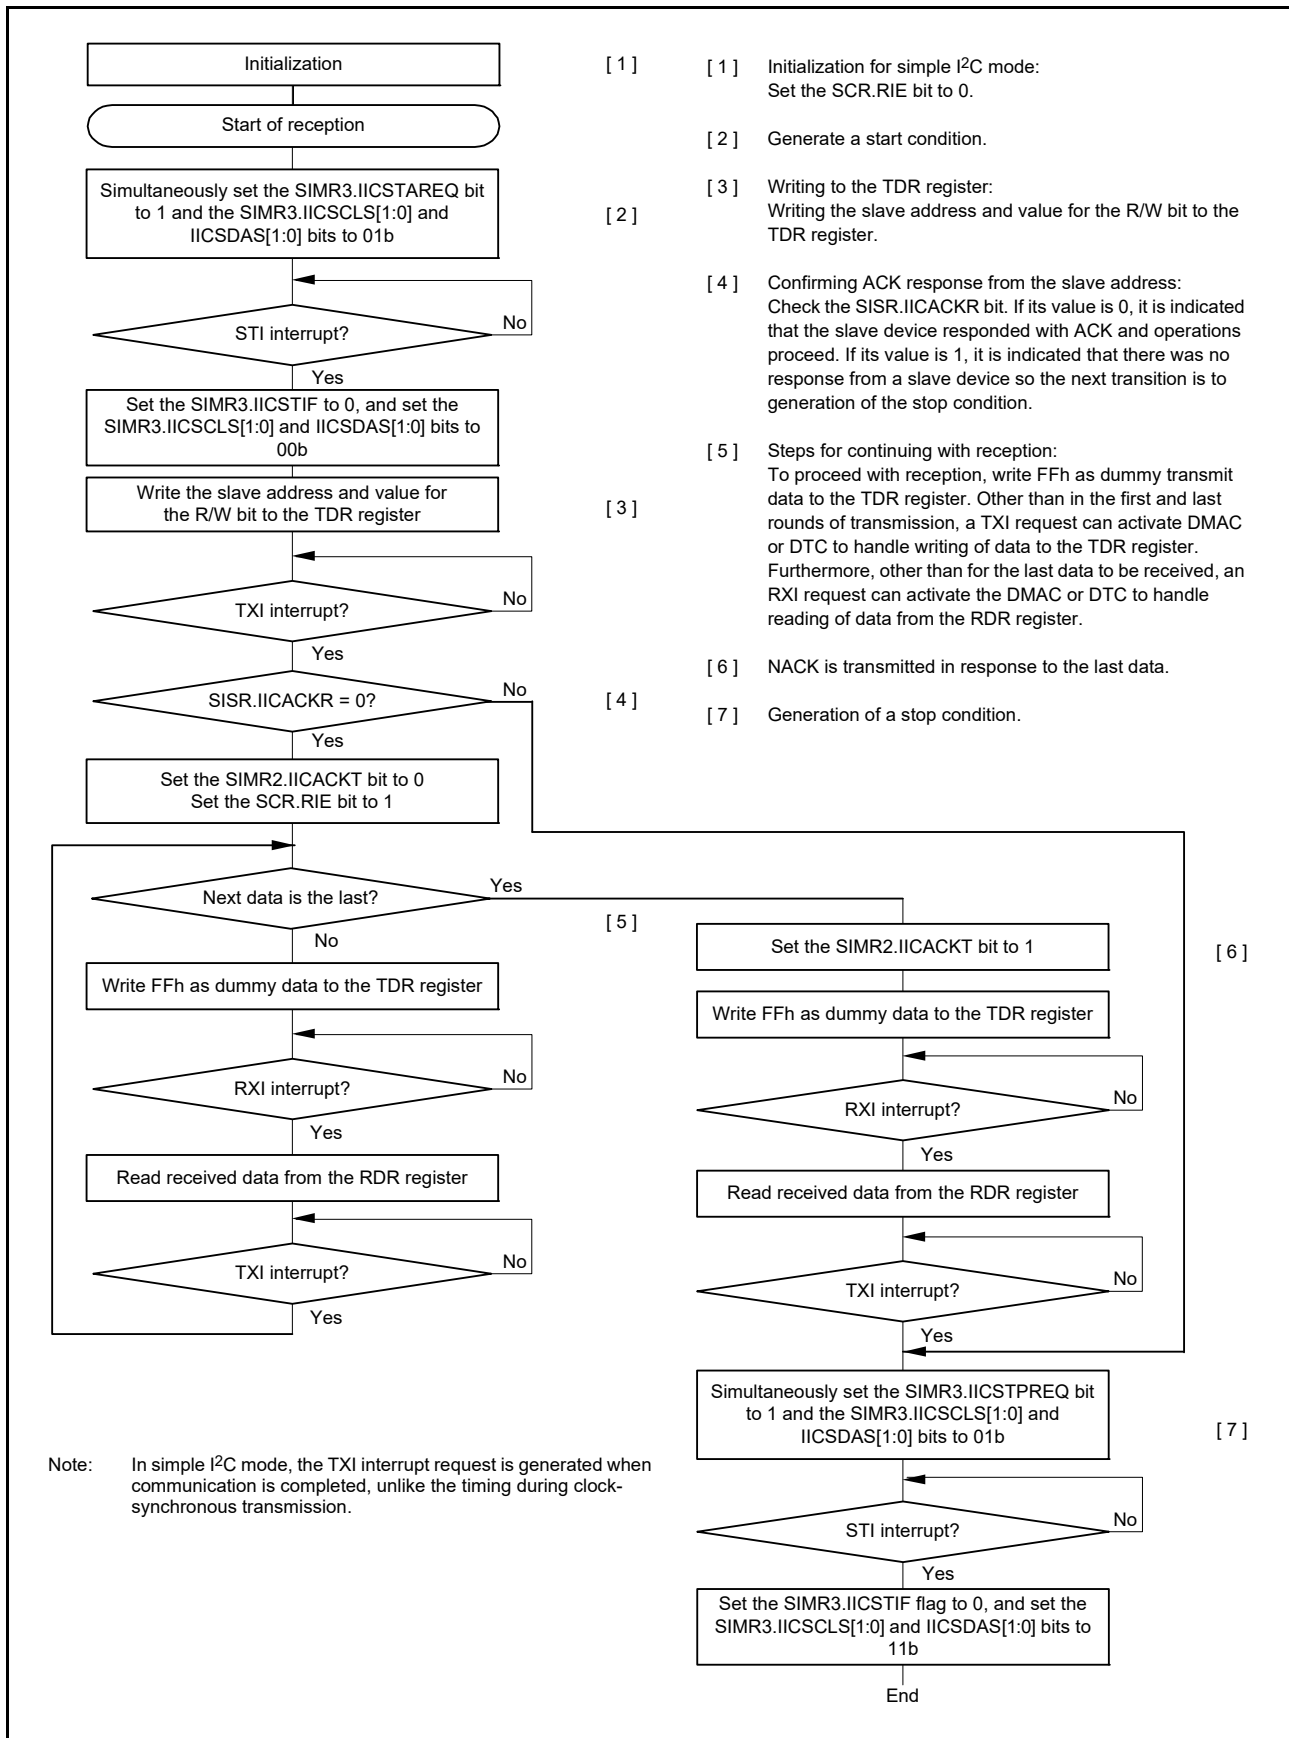

Figure 32.60 Example of the Procedure for Master Reception Operations in Simple I<sup>2</sup>C Mode (with Transmission Interrupts and Reception Interrupts in Use)

### 32.7.7 Recovery from Bus Hang-up

If the bus is stuck by an abnormal state in SCI because of the communication error, reset the SCI according to the following steps and release the bus.

- (1) Set the SCR.TE and RE bit to 0 at the same time to reset SCI.
- (2) Set the SIMR3 register to F0h to release the bus.
- (3) If the SSR.RDRF flag is 1, dummy-read the RDR register to clear the flag.
- (4) Set the SCR.TE and RE bit to 1 at the same time.

### 32.8 Operation in Simple SPI Mode

As an extended function, the SCI supports a simple SPI mode that handles transfer among one or multiple master devices and multiple slave devices.

Making the settings for clock synchronous mode (SCMR.SMIF = 0, SIMR1.IICM = 0, SMR.CM = 1) plus setting the SPMR.SSE bit to 1 places the SCI in simple SPI mode. However, the SS pin function on the master side is unnecessary for connection of the device used as the master in simple SPI mode when the configuration only has a single master, so set the SPMR.SSE bit to 0 in such cases.

Figure 32.61 shows an example of connections for simple SPI mode. Control a general port pin to produce the SS output signal from the master.

In simple SPI mode, data are transferred in synchronization with clock pulses in the same way as in clock synchronous mode. One character of data for transfer consists of 8 bits of data, and parity bits cannot be appended to this. The data can be inverted by setting the SCMR.SINV bit to 1.

Since the receiver and transmitter are independent of each other within the SCI module, full-duplex communications are possible, with a common clock signal. Furthermore, since both the transmitter and receiver have a double-buffered structure, writing of further transmit data while transmission is in progress and reading of previously received data while reception is in progress are both possible. Continuous transfer is thus possible.

Figure 32.61 Example of Connections via a Simple SPI Mode (In Single Master Mode, SPMR.SSE Bit = 0)

### 32.8.1 States of Pins in Master and Slave Modes

The direction (input or output) of pins for the simple SPI mode interface differs according to whether the device is a master (SCR.CKE[1:0] = 00b or 01b and SPMR.MSS = 0) or slave (SCR.CKE[1:0] = 10b or 11b and SPMR.MSS = 1).

Table 32.34 lists the states of pins according to the mode and the level on the SSn# pin.

**Table 32.34 States of Pins by Mode and Input Level on the SSn# Pin**

| Mode          | Input on SSn# Pin                       | State of SMOSIn Pin                       | State of SMISOn Pin                       | State of SCKn Pin             |
|---------------|-----------------------------------------|-------------------------------------------|-------------------------------------------|-------------------------------|
| Master mode*1 | High level<br>(transfer can proceed)    | Output for data<br>transmission*2         | Input for received data                   | Clock output*3                |
|               | Low level<br>(transfer cannot proceed)  | High-impedance                            | Input for received data<br>(but disabled) | High-impedance                |
| Slave mode    | High level<br>(transfer cannot proceed) | Input for received data<br>(but disabled) | High-impedance                            | Clock input<br>(but disabled) |
|               | Low level<br>(transfer can proceed)     | Input for received data                   | Output for data<br>transmission           | Clock input                   |

Note 1. When there is only a single master (SPMR.SSE = 0), transfer is possible regardless of the input level on the SSn# pin (this is equivalent to input of a high level on the SSn# pin). Since the SSn# pin function is not required, the pin is available for other purposes.

Note 2. The SMOSIn pin output is in the high-impedance state when serial transmission is disabled (SCR.TE bit = 0).

Note 3. The SCKn pin output is in the high-impedance state when serial transmission is disabled (SCR.TE and RE bits = 00b) in a multi-master configuration (SPMR.SSE = 1).

### 32.8.2 SS Function in Master Mode

Setting the SCR.CKE[1:0] bits to 00b and the SPMR.MSS bit to 0 selects master operation. The SSn# pin is not used in single-master configurations (SPMR.SSE = 0), so transmission or reception can proceed regardless of the value of the SSn# pin.

When the level on the SSn# pin is high in a multi-master configuration (SPMR.SSE = 1), a master device outputs clock signals from the SCKn pin before starting transmission or reception to indicate that there are no other masters or another master is performing reception or transmission. When the level on the SSn# pin is low in a multi-master configuration (SPMR.SSE = 1), there are other masters, and this indicates that transmission or reception is in progress. At this time the SMOSIn output and SCKn pins will be placed in the high-impedance state and starting transmission or reception will not be possible. Furthermore, the value of the SPMR.MFF bit will be 1, indicating a mode fault error. In a multi-master configuration, start error processing by reading SPMR.MFF flag. Also, even if a mode fault error occurs while transmission or reception is in progress, transmission or reception will not be stopped, but the SMOSIn and SCKn pin output will be placed in the high-impedance state after the completion of the transfer.

Control a general port pin to produce the SS output signal from the master.

### 32.8.3 SS Function in Slave Mode

Setting the SCR.CKE[1:0] bits to 10b and the SPMR.MSS bit to 1 selects slave operation. When the level on the SSn# pin is high, the SMISOn output pin will be in the high-impedance state and clock input through the SCKn pin will be ignored. When the level on the SSn# pin is low, clock input through the SCKn pin will be effective and transmission or reception can proceed.

If the input on the SSn# pin changes from low to high level during transmission or reception, the SMISOn output pin will be placed in the high-impedance state. Meanwhile, the internal processing for transmission or reception will continue at the rate of the clock input through the SCKn pin until processing for the character currently being transmitted or received is completed, after which it stops. At that time, an interrupt (the appropriate one from among TXI, RXI, and TEI) will be generated.

### 32.8.4 Relationship between Clock and Transmit/Receive Data

The CKPOL and CKPH bits in the SPMR register can be used to set up the clock for use in transmission and reception in four different ways. The relation between the clock signal and the transmission and reception of data is shown in Figure 32.62. The relation is the same for both master and slave operation.

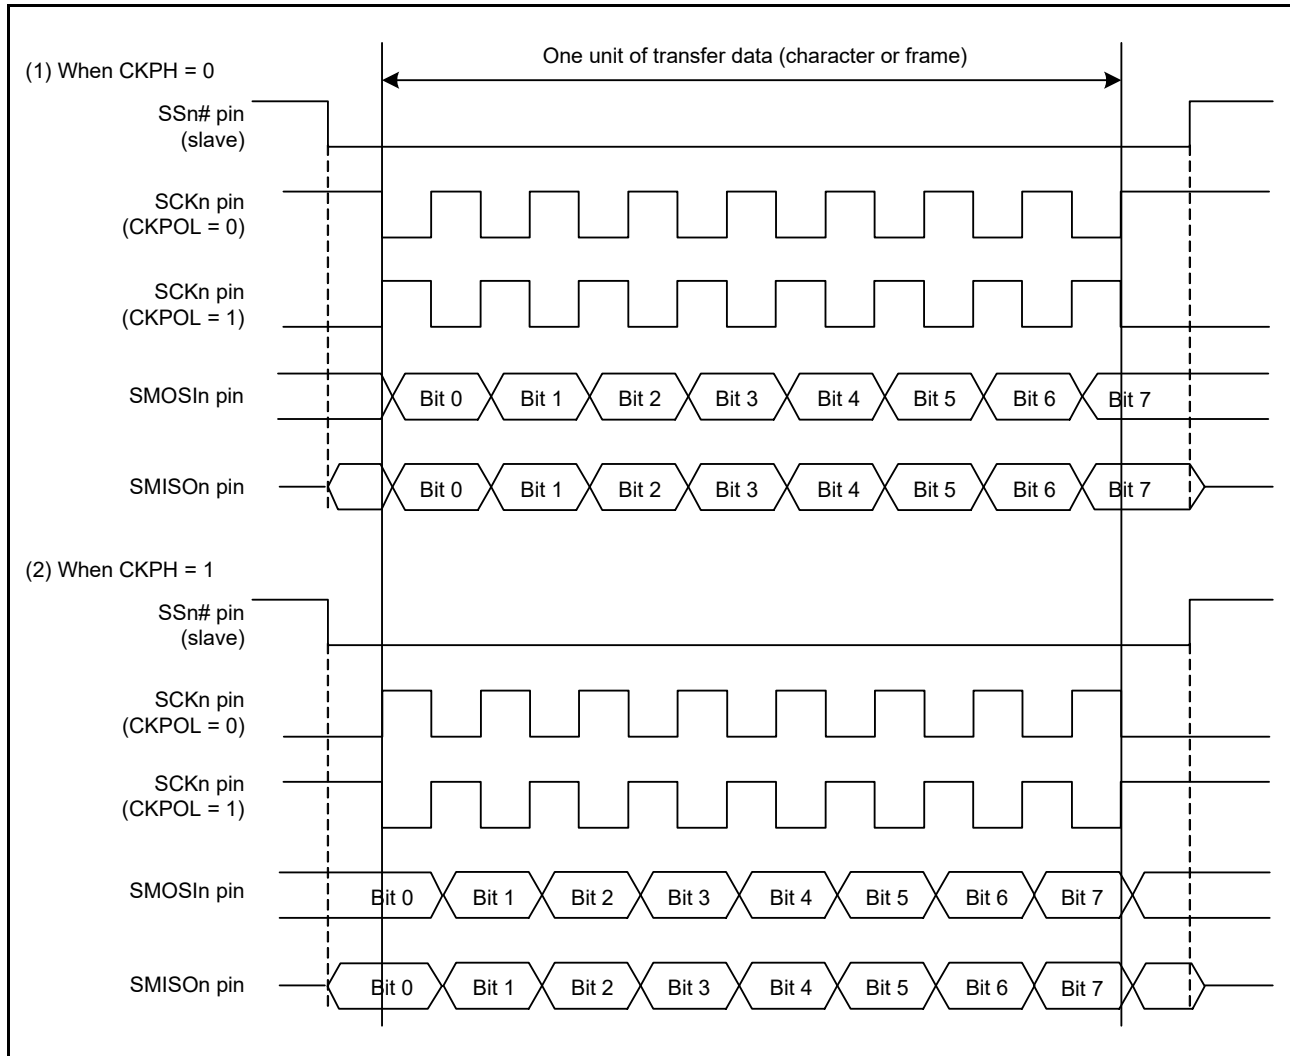

Figure 32.62 Relation between Clock Signal and Transmit/Receive Data in Simple SPI Mode

### 32.8.5 SCI Initialization (Simple SPI Mode)

The procedure is the same as for initialization in clock synchronous mode Figure 32.28, Sample SCI Initialization Flowchart. The CKPOL and CKPH bits in the SPMR register must be set to ensure that the kind of clock signal they select is suitable for both master and slave devices.

For initialization, changes to the operating mode, changes to the transfer format, and so on, initialize the SCR register before proceeding with changes.

As well as setting the RE bit to 0, note that the SSR. ORER, FER, and PER flags, as well as the RDR register, are not initialized.

### 32.8.6 Transmission and Reception of Serial Data (Simple SPI Mode)

In master operation, ensure that the SSn# pin of the slave device on the other side of the transfer is at the low level before starting the transfer and at the high level on completion of the transfer. Otherwise, the procedures are the same as in clock synchronous mode.

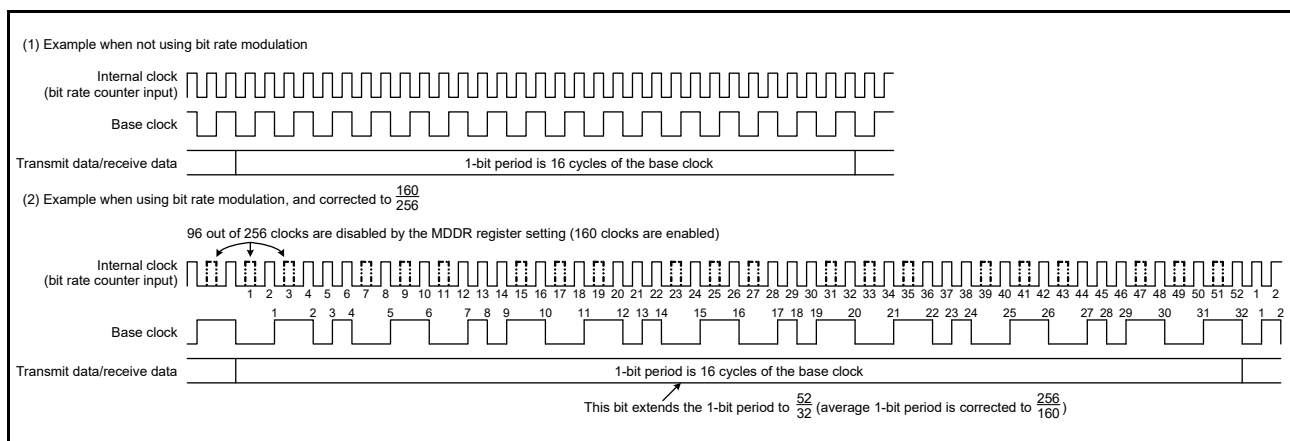

## 32.9 Bit Rate Modulation Function

The bit rate modulation function corrects the bit rate by thinning out the specified amount of clocks from those input to the baud rate generator.

When the SEMR.BRME bit is 1, the baud rate generator validates and counts the average interval of the number of clocks set in the MDDR register out of the total 256 clocks input.

Figure 32.63 assumes the SCI is in asynchronous mode, bits SMR.CKS[1:0] are 00b, the BRR register is 00h, and the MDDR register is 160. In this example, the cycle of the base clock is evenly corrected to 256/160, and the bit rate is corrected to 160/256. Note that there is an imbalance in thinning out the internal clock, and expansion and contraction occur in the pulse width of the base clock.

**Note:** Do not use this function in the highest speed settings (SMR.CKS[1:0] = 00b, SCR.CKE[1] = 0, and BRR = 0) in clock synchronous mode and simple SPI mode.

**Figure 32.63 Example of the Base Clock When the Bit Rate Modulation Function is Used**

The input of a clock signal with a shorter period to the baud rate generator reduces difference in the generated base clock period and, since the division ratio of the baud rate generator also becomes larger, reduces difference in the length of the 1-bit period.

### 32.10 Extended Serial Mode Control Section: Description of Operation

#### 32.10.1 Serial Transfer Protocol

The extended serial mode control section of the SCI12 can realize the serial transfer protocol composed of Start Frames and Information Frames that is shown in Figure 32.64.

A Start Frame is composed of a Break Field, Control Field 0, and Control Field 1. An Information Frame is composed of a number of Data Fields, a CRC16 Upper Field, and a CRC16 Lower Field.

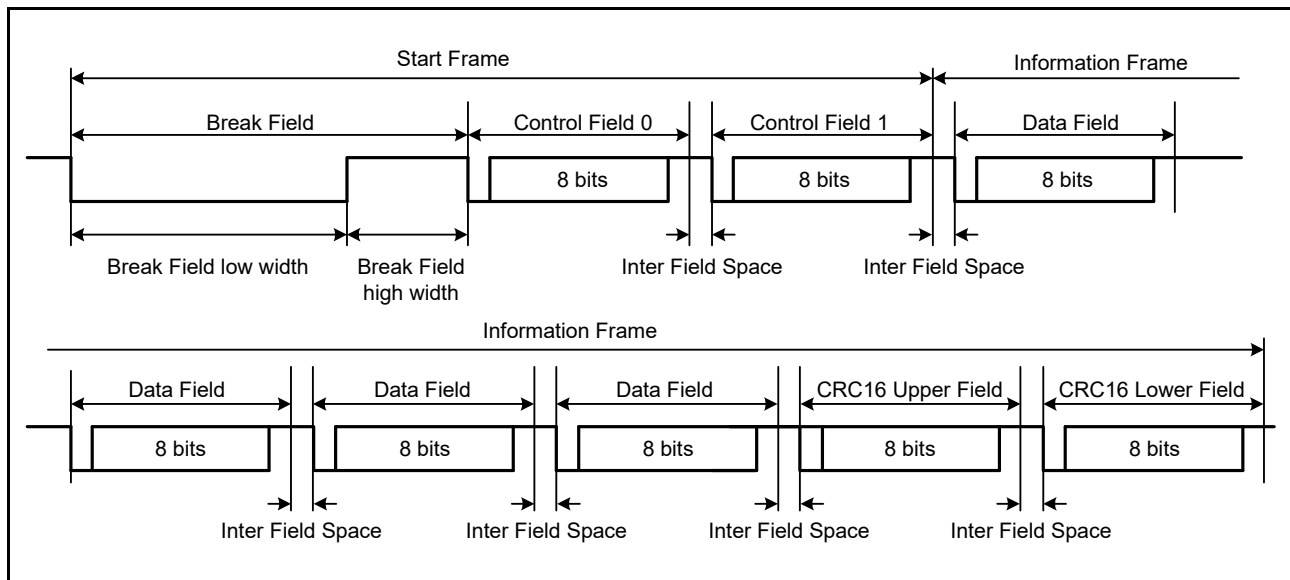

Figure 32.64 Protocol for Serial Transfer by the Extended Serial Mode Control Section

### 32.10.2 Transmitting a Start Frame

Figure 32.65 shows an example of operations to transmit a Start Frame, which is composed of the Break Field low width, Control Field 0, and Control Field 1. Figure 32.66 and Figure 32.67 are flowcharts for the transmission of a Start Frame.

Operations when the extended serial mode control section is to be used to transmit a Start Frame are as listed below. Be sure to use the SCI12 in asynchronous mode.

- (1) With Break Field low width output mode as the operating mode for the timer, writing 1 to the TCR.TCST bit starts counting by the timer, and the low level will be output from the TXDX12 pin over the period corresponding to registers TCNT and TPRE settings.
- (2) The output on the TXDX12 pin is inverted when the timer counter underflows, and the STR.BFDF flag is set to 1. An SCIX0 interrupt is also generated if the value of the ICR.BFDIE bit is 1.
- (3) Write 0 to the TCR.TCST bit to stop counting by the timer, and send the data for Control Field 0. After the Break Field low width output, stop counting before the next underflow occurs.
- (4) When the data for Control Field 0 have been transmitted, the data for Control Field 1 is transmitted.
- (5) When the data for Control Field 1 have been transmitted, an Information Frame is transmitted.

Omit the Break Field and Control Field 0 to suit the structure of the Start Frame.

**Figure 32.65** Example of Operations When Transmitting a Start Frame

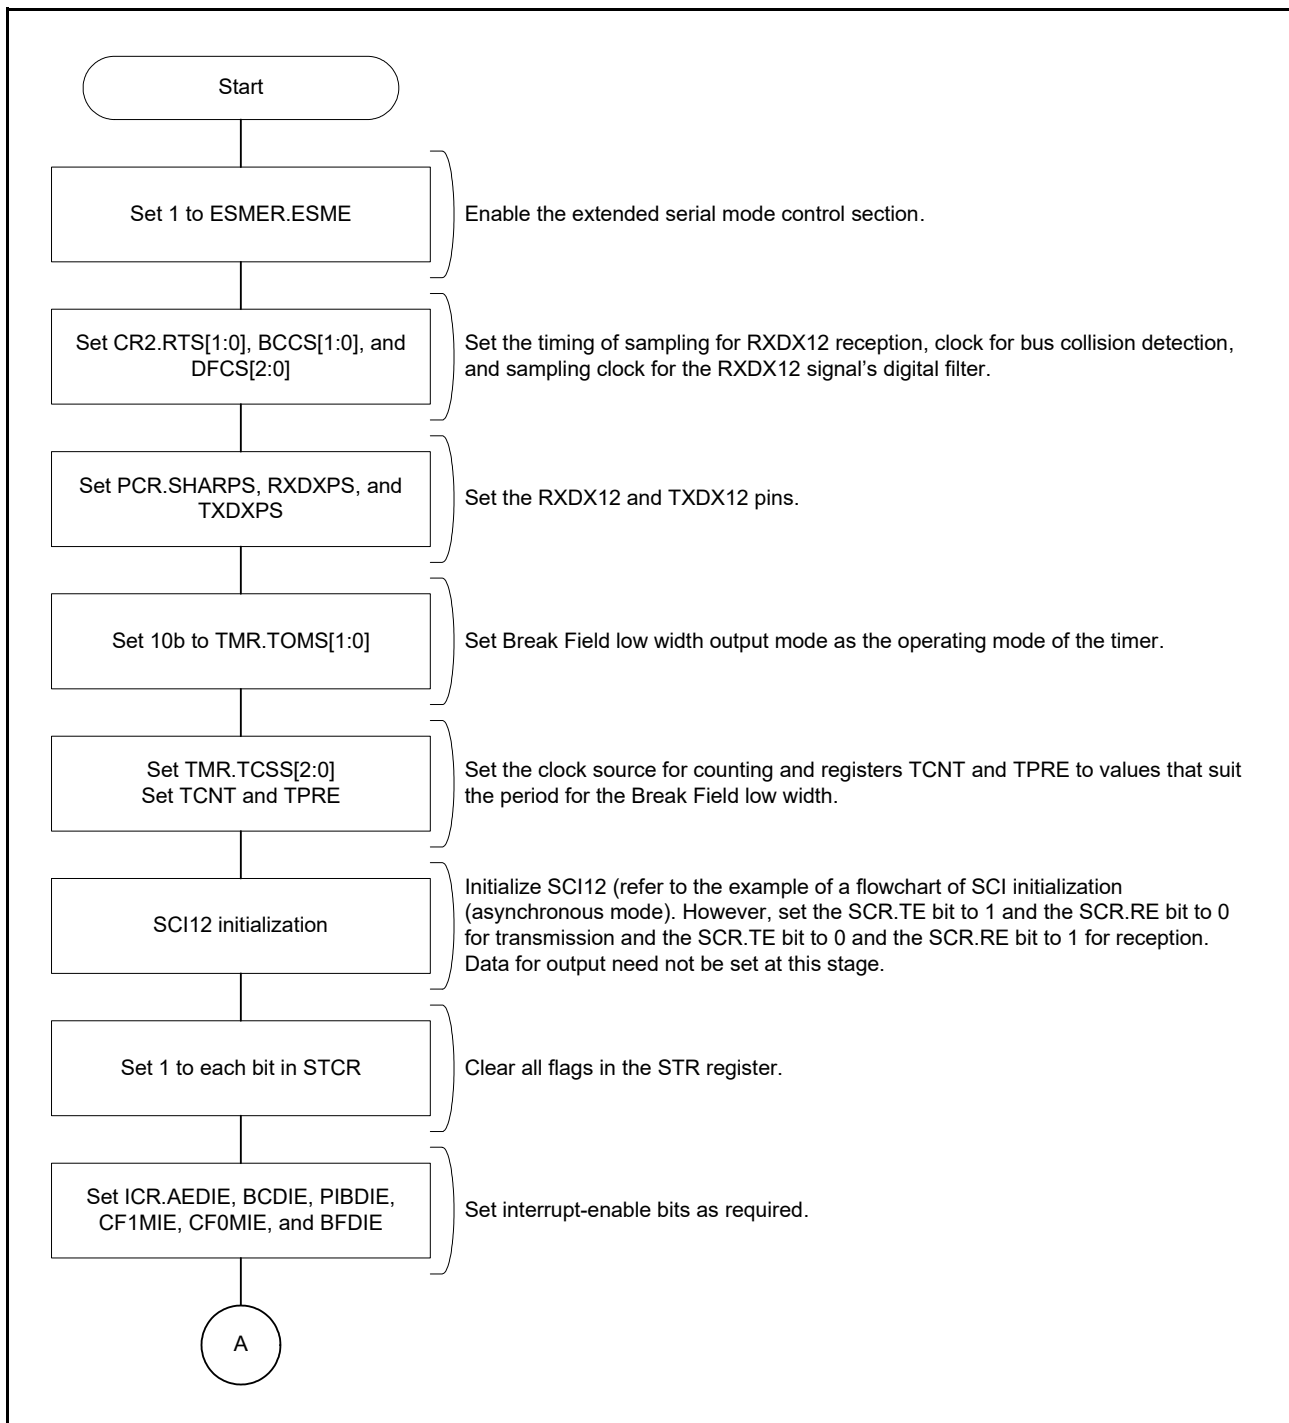

Figure 32.66 Example of Start Frame Transmission (1/2)

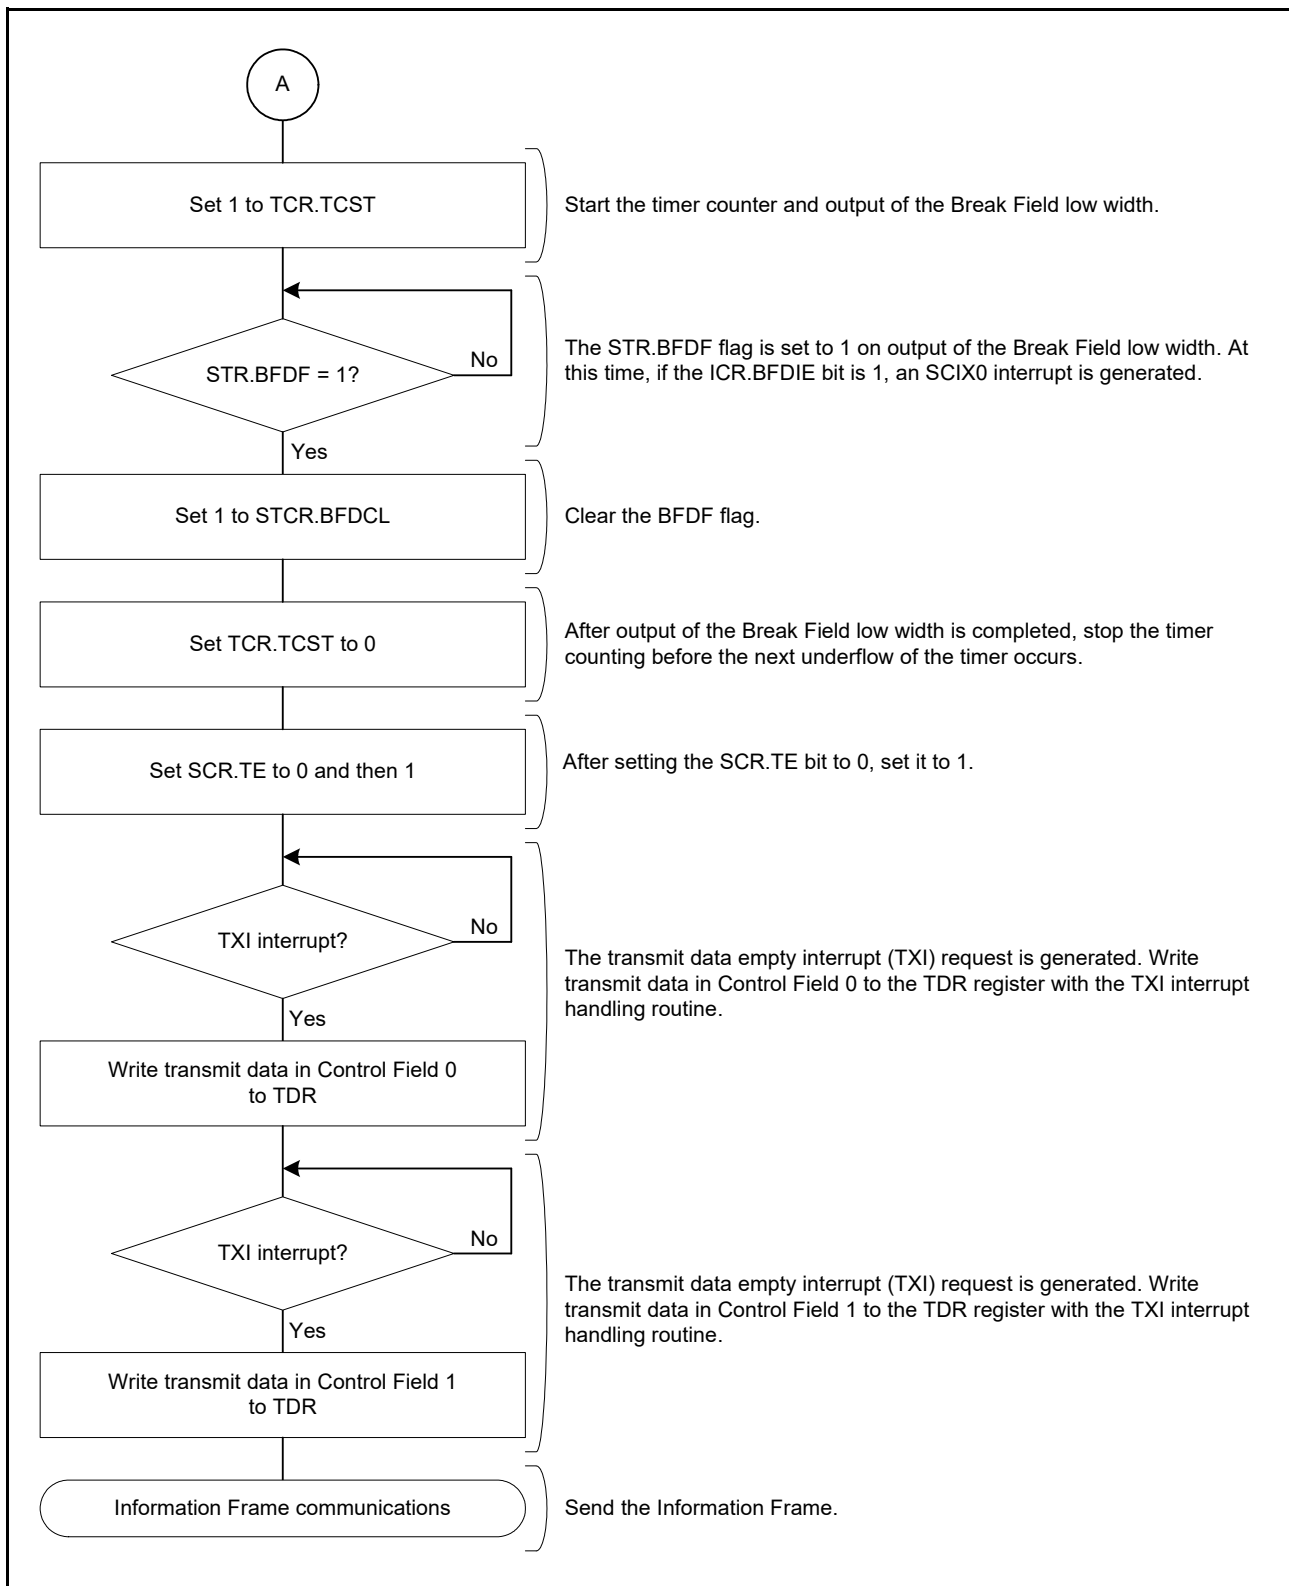

Figure 32.67 Example of Start Frame Transmission (2/2)

### 32.10.3 Receiving a Start Frame

The extended serial mode control section is capable of receiving Start Frames with the structures listed in Table 32.35.

**Table 32.35 Structures of Start Frames**

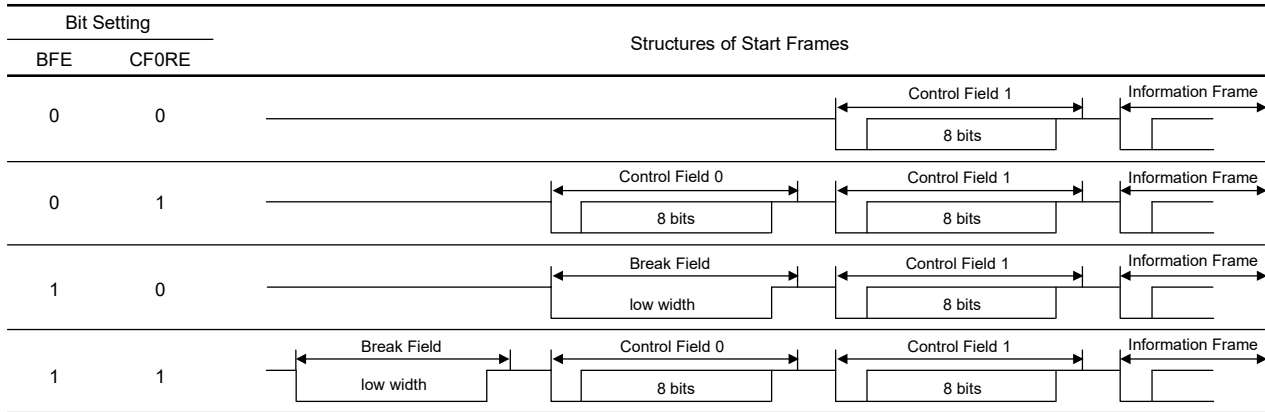

Figure 32.68 shows an example of operations to receive a Start Frame, which is composed of the Break Field low width, Control Field 0, and Control Field 1. Figure 32.69 and Figure 32.70 are flowcharts for the reception of a Start Frame, and Figure 32.71 is a state transition diagram when receiving a Start Frame.

Operations when the extended serial mode control section is to be used to receive a Start Frame are as listed below. Be sure to use the SCI12 in asynchronous mode.

- (1) With Break Field low width detection mode as the operating mode for the timer, writing 1 to the CR3.SDST bit enables detection of the Break Field low width.
- (2) Low-level input on the RXDX12 pin continuing over a period longer than that corresponding to the settings of registers TCNT and TPRES is detected as the Break Field low width. At this time, the STR.BFDF flag is set to 1. An SCIX0 interrupt is also generated if the value of the ICR.BFDIE bit is 1.
- (3) When the input from the RXDX12 pin goes high after the Break Field low width, the CR0.RXDSF flag becomes 0 and reception of Control Field 0 starts.
- (4) If the data received in Control Field 0 match the data set in the CF0DR register, the STR.CF0MF flag is set to 1. An SCIX1 interrupt is also generated if the value of the ICR.CF0MIE bit is 1. Reception of Control Field 1 starts after that. If the data received in Control Field 0 do not match the data set in the CF0DR register, a transition to the state prior to Break Field low width detection proceeds.
- (5) If the data received in Control Field 1 match the data set in registers PCF1DR and SCF1DR, the STR.CF1MF flag is set to 1. An SCIX1 interrupt is also generated if the value of the ICR.CF1MIE bit is 1. Transfer of the Information Frame starts after that. If the data received in Control Field 1 do not match the data set in either or both of registers PCF1DR and SCF1DR, a transition to the state prior to Break Field low width detection proceeds.

Omit the Break Field and Control Field 0 to suit the structure of the Start Frame.

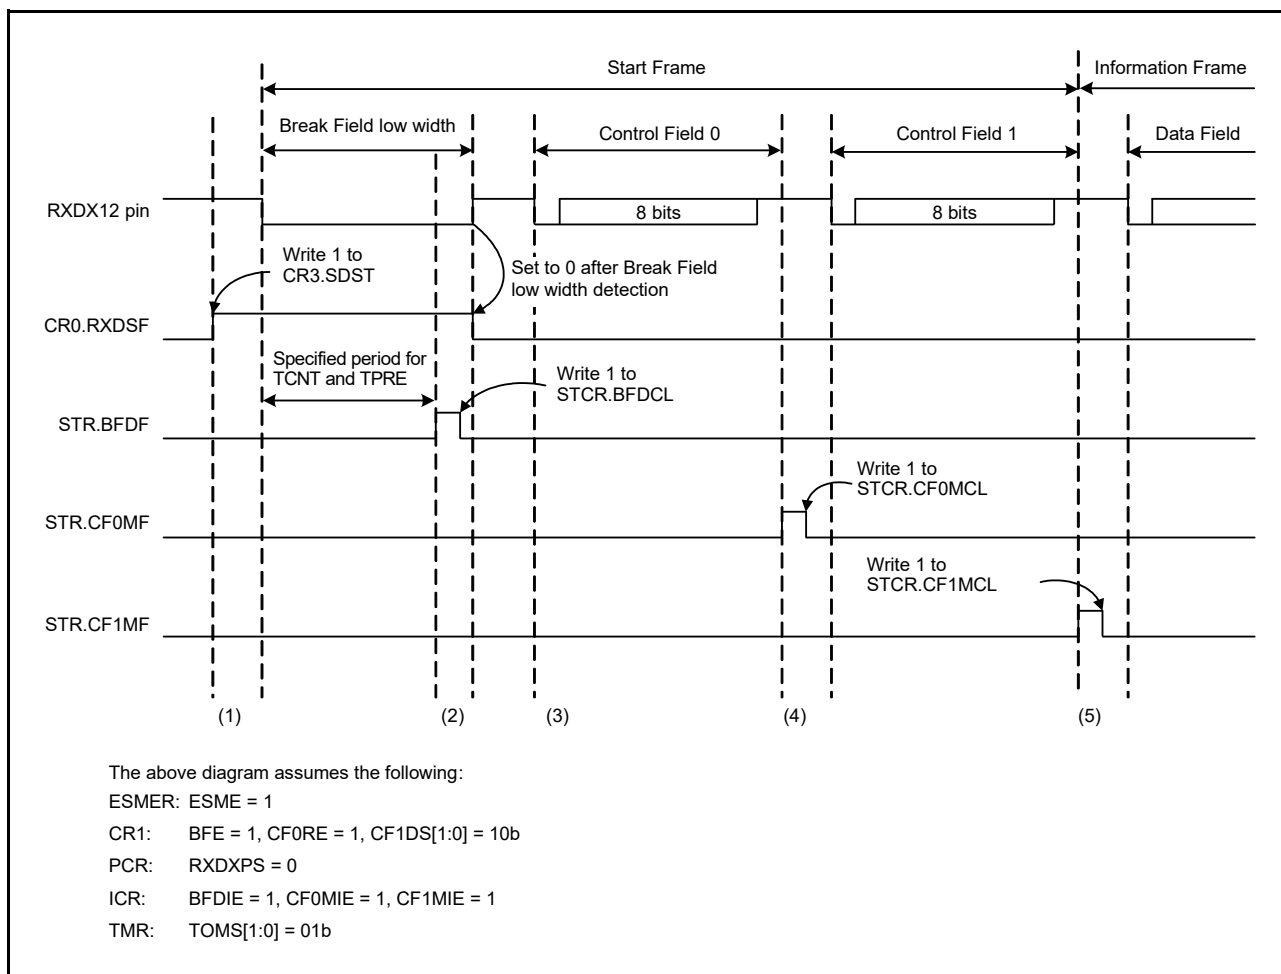

Figure 32.68 Example of Operations at the Time of Start Frame Reception

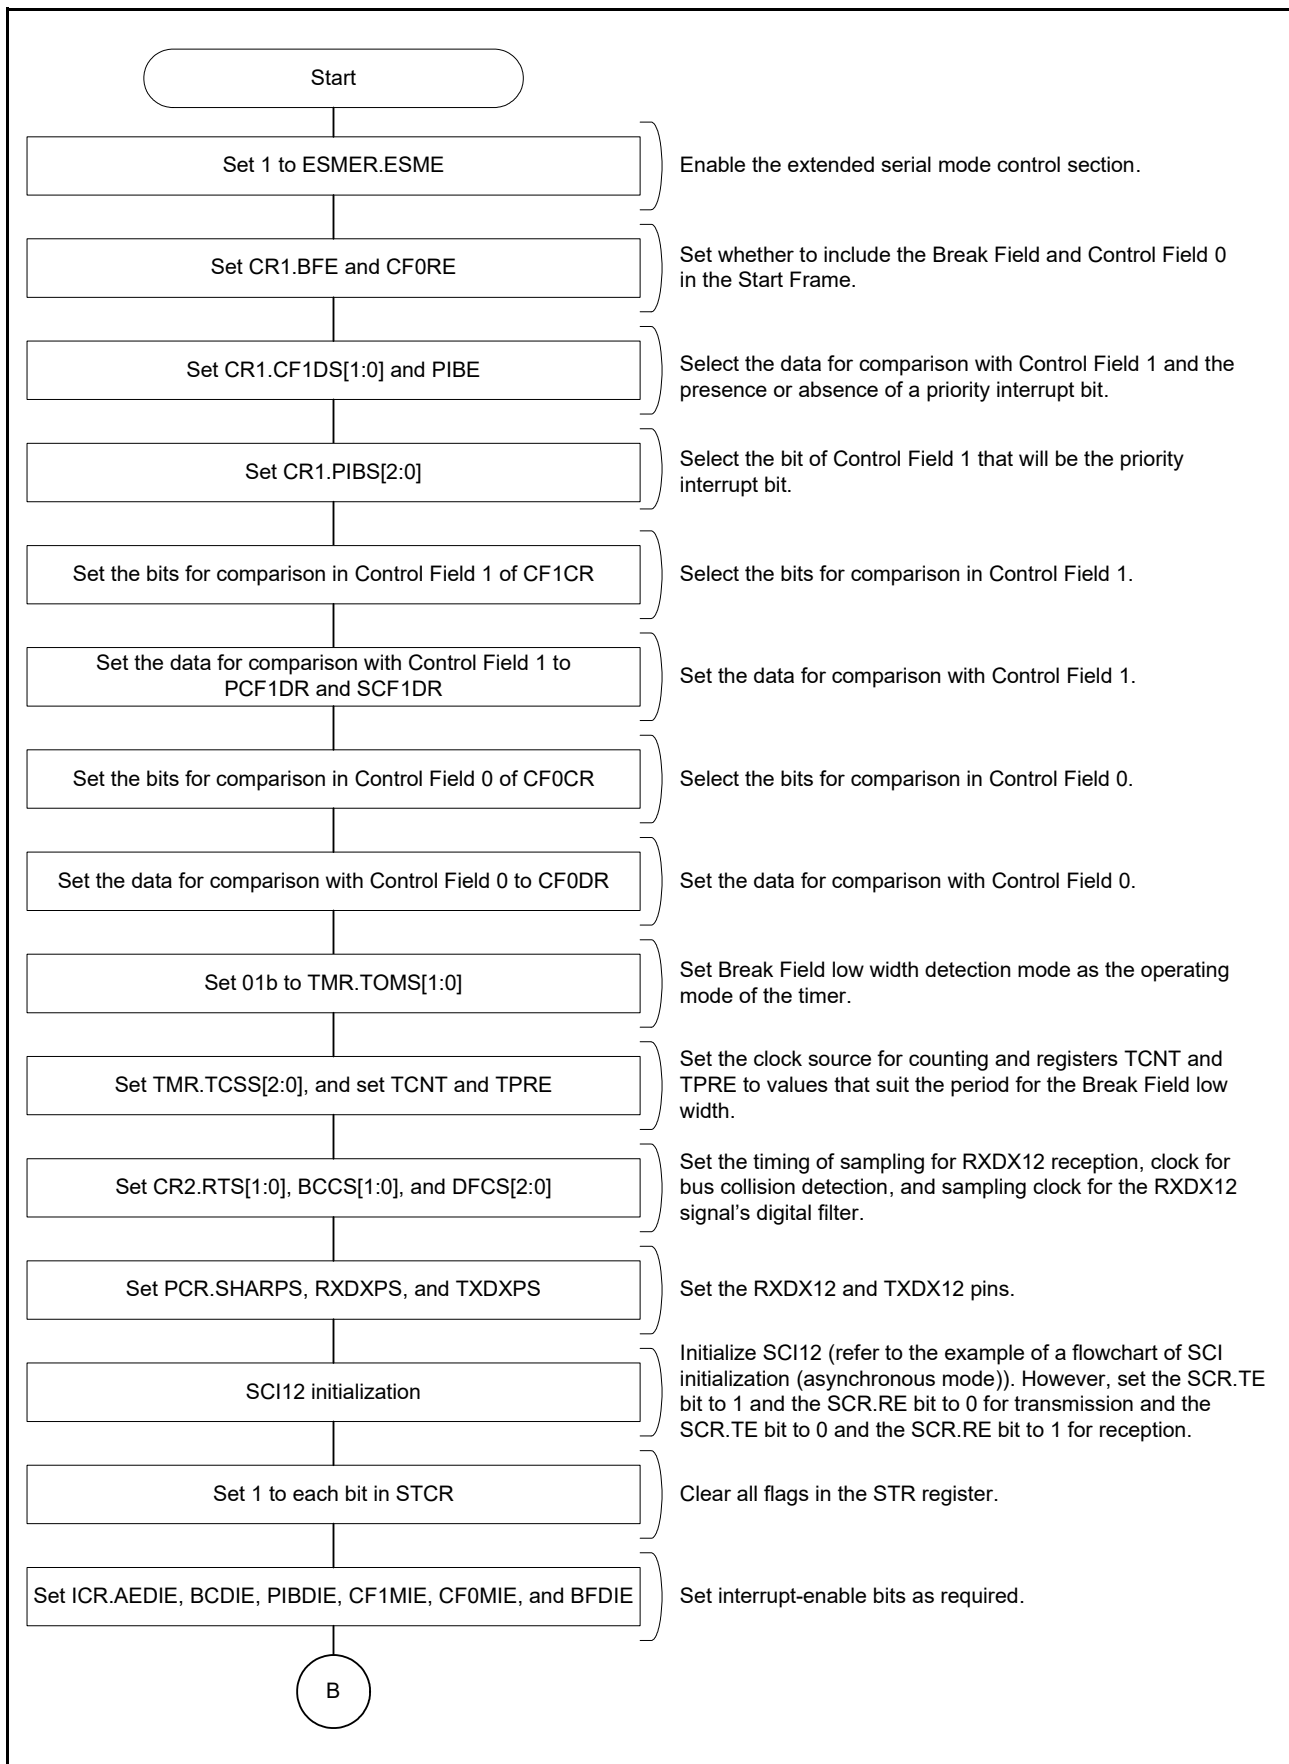

Figure 32.69 Sample Flowchart for Reception of a Start Frame (1)

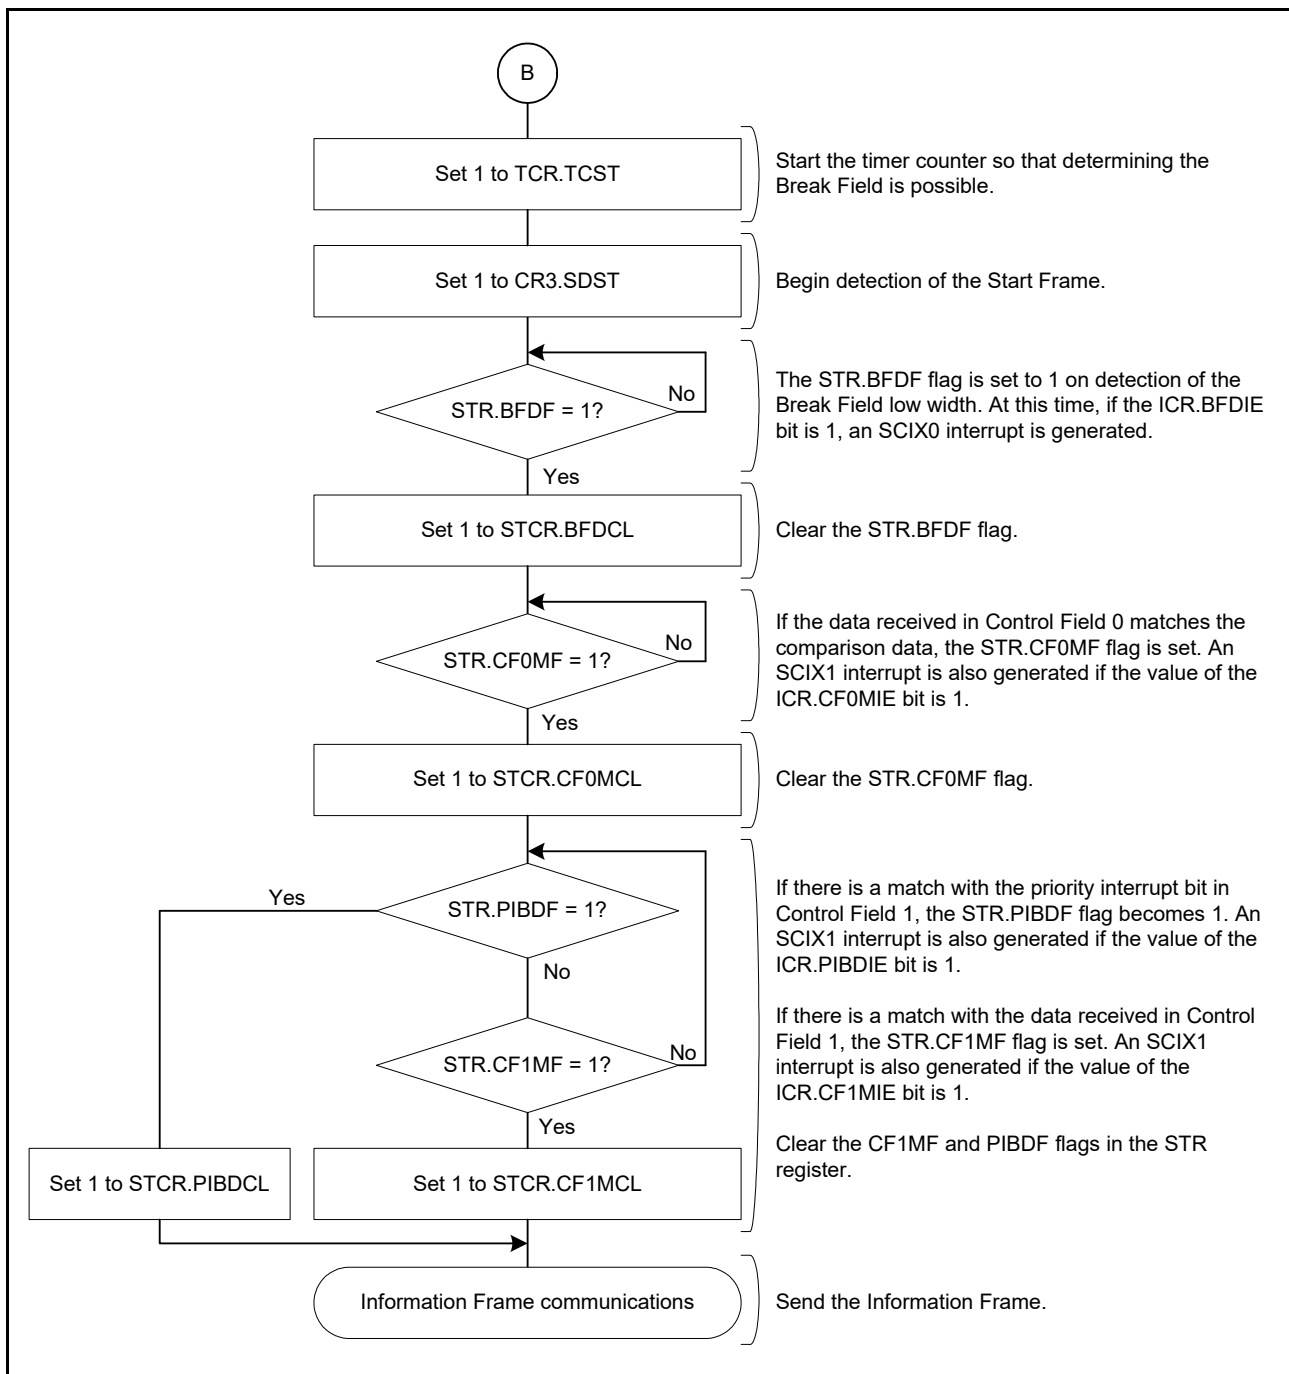

Figure 32.70 Sample Flowchart for Reception of a Start Frame (2)

Figure 32.71 State Transitions When Receiving a Start Frame

### 32.10.3.1 Priority Interrupt Bit

Figure 32.72 shows an example of operation in Start Frame reception where a priority interrupt bit is in use. Setting the CR1.PIBE bit to 1 enables the use of a priority interrupt bit.

Operations of the extended serial mode control section in start Frame reception where a priority interrupt bit is in use are as described below.

Steps (1) to (4) are the same as in Figure 32.68, for Start Frame reception.

- (5) If the value of the bit selected by the CR1.PIBS[2:0] bits matches the corresponding bit in the PCF1DR register, the STR.PIBDF flag is set to 1. An SCIX1 interrupt is also generated if the value of the ICR.PIBDIE bit is 1. Transfer of the Information Frame starts after that. If the data received in Control Field 1 do not match the data set in either or both of registers PCF1DR and SCF1DR and the priority interrupt bit is not detected, a transition to the state prior to Break Field low width detection proceeds.

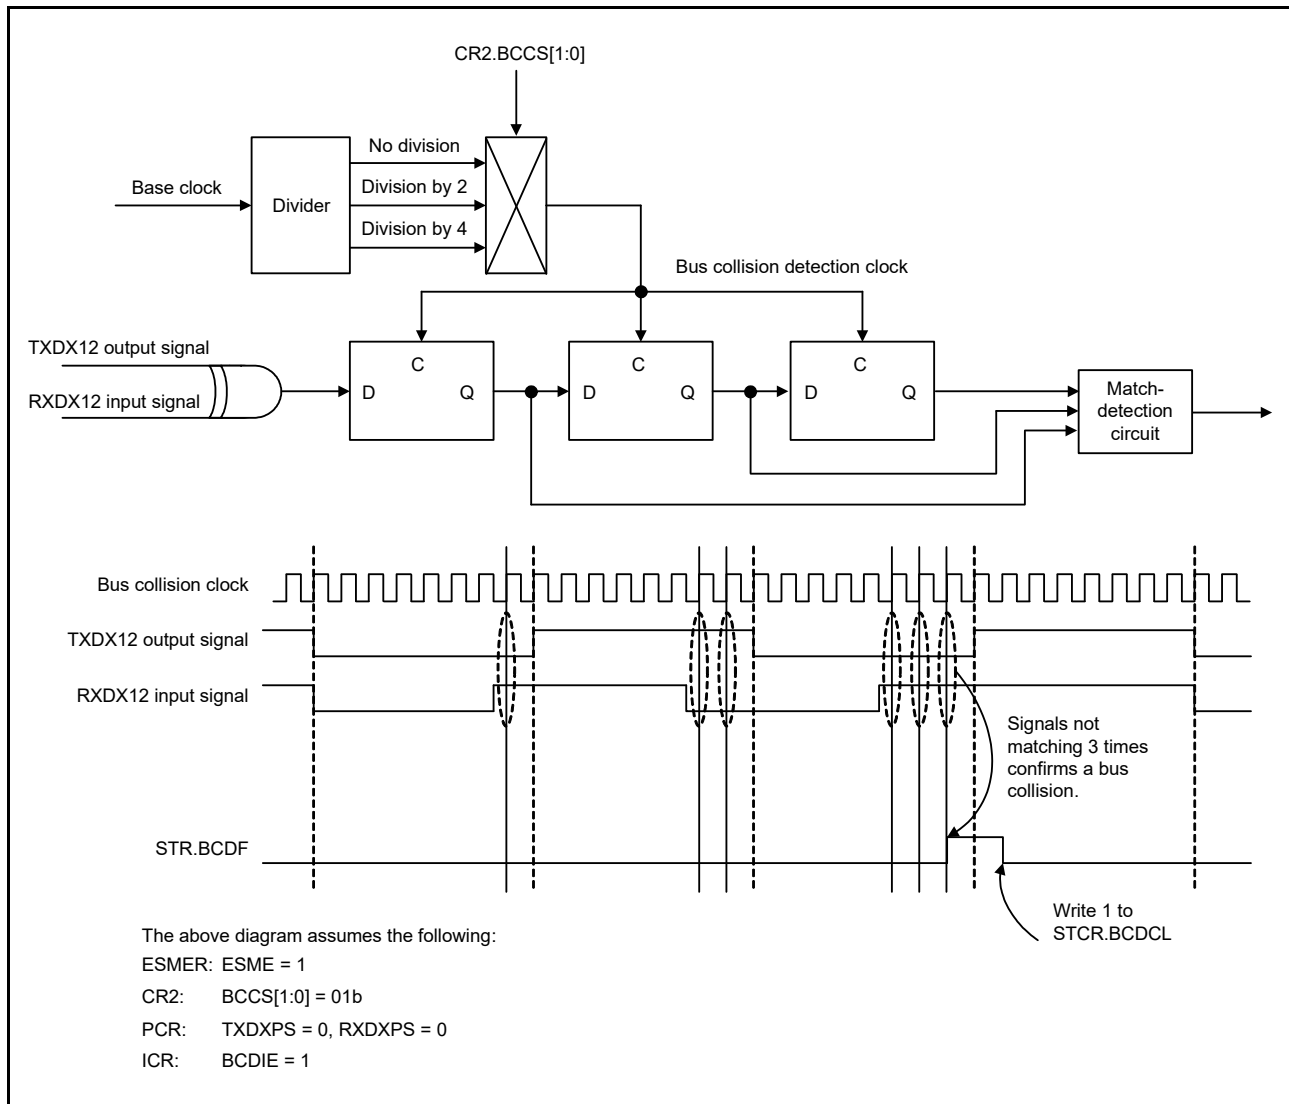

Figure 32.72 Example of Operations When Receiving a Start Frame While the CR1.PIBE Bit is 1

### 32.10.4 Detection of Bus Collisions

Detection of bus collisions operate for cases where output of the Break Field low width and transmission of data are in progress when the ESMER.ESME bit and the SCR.TE bit are set to 1.

Figure 32.73 shows an example of operations with bus collision detection. Signals output through TXDX12 and input through RXDX12 are sampled with the bus collision detection clock set with the CR2.BCCS[1:0] bits as the sampling clock, and the STR.BCDF flag is set to 1 if the signals fail to match three times in a row. An SCIX2 interrupt is also generated if the value of the ICR.BCDIE bit is 1.

**Figure 32.73 Example of Operations with Bus Collision Detection**

### 32.10.5 Digital Filter for Input on the RXDX12 Pin

Signals input through the RXDX12 pin can be passed through a digital filter before they are conveyed to the internal circuits. The digital filter consists of three flip-flop circuit stages connected in series and a match-detecting circuit. The CR2.DFCS[2:0] bits select the sampling clock for the RXDX12 pin input signals. If the outputs of all three latches match, the given level is conveyed to subsequent circuits. If the levels do not match, the previous value is retained. In other words, levels are confirmed as being the signal if they are retained for at least three cycles of the sampling clock but judged to be noise rather than changes in the signal level if they change within three cycles of the sampling clock. Figure 32.74 shows an example of operations with the digital filter.

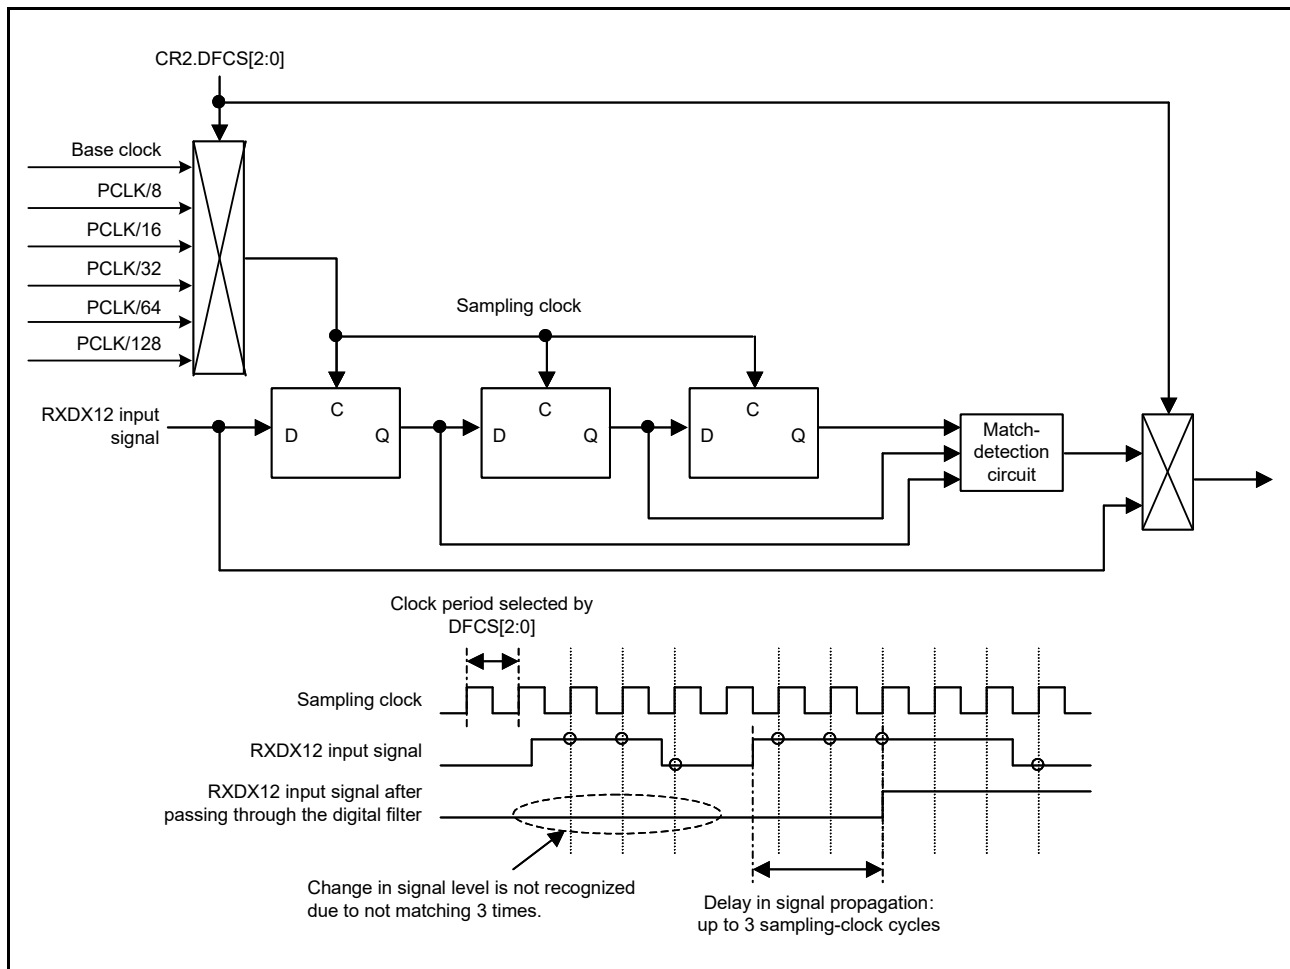

Figure 32.74 Example of Operations with the Digital Filter

### 32.10.6 Bit Rate Measurement

The bit rate measurement function measures the intervals between rising and falling edges and between falling and rising edges of the signal input from the RXDX12 pin. Figure 32.75 shows an example of operations for bit rate measurement.

- (1) Writing 1 to the CR0.BRME bit enables bit rate measurement. Only set the BRME bit to 1 when you wish to proceed with bit rate measurement. Furthermore, bit rate measurement will not proceed during a Break Field, even if the BRME bit is set to 1.
- (2) After detection of the Break Field low width, bit rate measurement starts when the level input on the RXDX12 pin becomes high.
- (3) Once bit rate measurement has started, counter values from the timer are retained in the read buffers on the input of valid edges from the RXDX12 pin (rising and falling edges) and the counter is reloaded. An SCIX3 interrupt is also generated if the value of the ICR.AEDIE bit is 1. Retention by registers TCNT and TPRES is released by reading these registers.
- (4) The bit rate as calculated from the values counted during intervals between valid edges can be used for adjusting the rate by changing the settings of the BRR register. To disable the bit rate measurement after a match with Control Field 1, write 0 to the CR0.BRME bit.

Figure 32.75 Example of Operations for Bit Rate Measurement

### 32.10.7 Selectable Timing for Sampling Data Received through RXDX12

The extended serial mode control section provides a way of adjusting the timing for the sampling of data received through the RXDX12 pin by setting the CR2.RTS[1:0] bits to select the rising edges of 8th, 10th, 12th, or 14th cycle of the base clock. If the value of the SEMR.ABCS bit is 1, the bits select the rising edges of 4th, 5th, 6th, or 7th cycle of the base clock. Figure 32.76 shows timing for the sampling of data received through RXDX12.

**Figure 32.76** Timing for Sampling of Data Received through RXDX12

### 32.10.8 Timer

The timer has the following operating modes.

#### (1) Break Field Low Width Output Mode

This mode is for output through the TXDX12 pin of the low level over the Break Field low width at the transmission of a Start Frame. Setting the TMR.TOMS[1:0] bits to 10b switches operation to Break Field low width output mode. The TMR.TCSS[2:0] bits select the clock source for the counter. When the TCR.TCST bit is set to 1, the output on the TXDX12 pin goes to the low level and counting starts. When the timer underflows, the output on the TXDX12 pin goes to the high level and the STR.BFDF flag is set to 1. An SCIX0 interrupt is also generated if the value of the ICR.BFDIE bit is 1. When 0 is written to the TCR.TCST bit, counting stops after reloading of registers TPRES and TCNT. After output of the Break Field low width is completed, stop the timer before it underflows again. Figure 32.77 shows an example of operations in Break Field low width output mode.

Figure 32.77 Example of Operations in Break Field Low Width Output Mode

(2) Break Field Low Width Determination Mode

This mode is for determining the Break Field low width in the input signal on the RXDX12 pin at the reception of a Start Frame. Setting the TMR.TOMS[1:0] bits to 01b switches operation to Break Field low width determination mode. The TMR.TCSS[2:0] bits select the clock source for the counter. When the TCR.TCST bit is set to 1, the interface enters the Break Field low width determinable state. Determination starts when a low level is input from the RXDX12 pin. When a high level is then input on the RXDX12 pin, registers TPRE and TCNT are reloaded and the interface enters the Break Field low width determinable state. When the timer underflows during Break Field low width determination, the STR.BFDF flag is set to 1. An SCIX0 interrupt is also generated if the value of the ICR.BFDIE bit is 1. If an underflow of the timer during data transfer cause a problem in the form of interrupt generation, stop the timer after Break Field low width determination. Figure 32.78 shows an example of operations in Break Field low width output mode.

Figure 32.78 Example of Operations in Break Field Low Width Determination Mode

(3) Timer Mode

This mode is for counting cycles of the internal clock as the clock source. Setting the TMR.TOMS[1:0] bits to 00b switches operation to timer mode. The TMR.TCSS[2:0] bits select the clock source for the counter. Counting starts when 1 is written to the TCR.TCST bit and stops when 0 is written to the TCST bit. Registers TPRE and TCNT both count down. The TPRE register counts cycles of the clock source for counting, and underflows of the TPRE register provide the clock source for counting by the TCNT register. When the timer underflows, the STR.BFDF flag is set to 1. An SCIX0 interrupt is also generated if the value of the ICR.BFDIE bit is 1.

### 32.11 Noise Cancellation Function

Figure 32.79 shows the configuration of the noise filter used for noise cancellation. The noise filter consists of two stages of flip-flop circuits and a match-detection circuit. When the level on the pin matches in three consecutive samples taken at the set sampling interval, the matching level continues to be conveyed internally until the level on the pin again matches in three consecutive samples.

In asynchronous mode, the noise cancellation function can be applied on the RXDn input signal. The period of the base clock ( $1/16$ th of a bit-period when SEMR.ABCSE = 0 and SEMR.ABCS = 0,  $1/8$ th of a bit-period when SEMR.ABCSE = 0 and SEMR.ABCS = 1, and  $1/6$ th of a bit-period when SEMR.ABCSE = 1) is the sampling interval.

In simple I<sup>2</sup>C mode, the noise cancellation function can be applied on the SSDAn and SSCLn input signals. The sampling clock is the clock signal produced by frequency-dividing the signal from the clock source for the internal baud-rate generator by one, two, four, or eight as selected by the setting of the SNFR.NFCS[2:0] bits.

If the base clock is stopped with the noise filter enabled and then the clock input is started again, the noise filter operation resumes from where the clock was stopped. If SCR.TE and SCR.RE are set to 0 during base clock input, all of the noise filter flip-flop values are initialized to 1. Accordingly, if the input data is 1 when reception operation resumes, it is determined that a level match is detected and is conveyed to the internal signal. When the level being input corresponds to 0, the initial output of the noise filter is retained until the level matches in three consecutive samples.

Figure 32.79 Block Diagram of Digital Noise Filter

## 32.12 Interrupt Sources

### 32.12.1 Buffer Operations for TXI and RXI Interrupts

#### (1) SCI1, SCI5, SCI6, SCI8, SCI9, and SCI12, and SCI11 when FIFO is Disabled

If the conditions for a TXI and RXI interrupt are satisfied while the interrupt status flag in the interrupt controller is 1, the SCI does not output the interrupt request but retains it internally (with a capacity for retention of one request per source). When the value of the interrupt status flag in the interrupt controller becomes 0, the interrupt request retained within the SCI is output. The internally retained interrupt request is automatically discarded once the actual interrupt is output. Clearing of the corresponding interrupt enable bit (the TIE or RIE bit in the SCR register) can also be used to discard an internally retained interrupt request.

#### (2) SCI11 When FIFO is Enabled

When the FCR.FM bit is 1, the SCI does not retain the interrupt request internally. When the interrupt status flag in the interrupt controller is 1 and the condition for interrupt generation is satisfied, the status flag is updated, but an interrupt request is not generated.

### 32.12.2 Interrupts in Asynchronous Mode, Clock Synchronous Mode, and Simple SPI Mode

#### (1) SCI1, SCI5, SCI6, SCI8, SCI9, and SCI12, and SCI11 when FIFO is Disabled

Table 32.36 lists interrupt sources in asynchronous mode, clock synchronous mode, and simple SPI mode. Individual interrupt sources can be enabled or disabled with the enable bits in the SCR register.

If the SCR.TIE bit is 1, a TXI interrupt request is generated when transmit data is transferred from the TDR or TDRL register\*1 to the TSR register. A TXI interrupt request can also be generated by setting the SCR.TE bit to 1 after setting the SCR.TIE bit to 1 or by using a single instruction to set the SCR.TE and SCR.TIE bit to 1 at the same time. A TXI interrupt request can activate the DTC or DMAC to handle data transfer.

A TXI interrupt request is not generated by setting the SCR.TE bit to 1 while the setting of the SCR.TIE bit is 0 or by setting the SCR.TIE bit to 1 while the setting of the SCR.TE bit is 1.\*2

Note that setting the SCR.TE bit to 0 while the SCR.TIE bit is 1 leads to the generation of a TXI interrupt.

When new data is not written by the time of transmission of the last bit of the current transmit data and the setting of the SCR.TEIE bit is 1, the SSR.TEND flag becomes 1 and a TEI interrupt request is generated. Furthermore, when the setting of the SCR.TE bit is 1, the SSR.TEND flag retains the value 1 until further transmit data are written to the TDR or TDRL register\*1, and setting the SCR.TEIE bit to 1 leads to the generation of a TEI interrupt request.

Writing data to the TDR or TDRL register\*1 leads to clearing of the SSR.TEND flag and, after a certain time, discarding of the TEI interrupt request.

If the SCR.RIE bit is 1, an RXI interrupt request is generated when received data is stored in the RDR register. An RXI interrupt request can activate the DTC or DMAC to handle data transfer.

Setting of any from among the ORER, FER, and PER flags in the SSR register to 1 while the SCR.RIE bit is 1 leads to the generation of an ERI interrupt request. An RXI interrupt request is not generated at this time. Clearing all three flags (ORER, FER, and PER) leads to discarding of the ERI interrupt request.

Note 1. In the case where asynchronous mode and 9-bit data length are selected

Note 2. To temporarily disable TXI interrupts at the time of transmission of the last of the data and so on when you wish a new round of transmission to start after handling of the transmission-completed interrupt, control disabling and enabling of the interrupt by using the interrupt request enable bit in the interrupt controller rather than using the SCR.TIE bit. This can prevent the suppression of TXI interrupt requests in the transfer of new data.

**Table 32.36 Interrupt Sources**

| Name | Interrupt Source    | Interrupt Flag                    | DTC Activation | DMAC Activation |
|------|---------------------|-----------------------------------|----------------|-----------------|
| ERI  | Receive error       | ORER, FER, PER, DFER*1, or DPER*1 | Not possible   | Not possible    |
| RXI  | Receive data full   | RDRF                              | Possible       | Possible        |
|      | Data match*1        | DCMF*1                            |                |                 |
| TXI  | Transmit data empty | TDRE                              | Possible       | Possible        |
| TEI  | Transmit end        | TEND                              | Not possible   | Not possible    |

Note 1. Available in SCI1, SCI5, SCI6, SCI8, SCI9, and SCI11 only.

## (2) SCI11 When FIFO is Enabled

Table 32.37 lists the interrupt sources in asynchronous mode and clock synchronization mode when the FIFO is enabled. Each interrupt source is enabled independently by using the enable bit in the SCR register.

When the SCR.TIE bit is 1, the number of data to be transmitted in the transmit FIFO is less than or equal to the threshold (FCR.TTRG[3:0] bits), a TXI interrupt request is generated. A TXI interrupt request is generated when the SCR.TE bit is set to 1 and then SCR.TIE bit is 1, or when the SCR.TIE and SCR.TE bit are simultaneously set to 1.

A TXI interrupt request is not generated when the SCR.TE bit is set to 1 while the SCR.TIE bit is 0 or the SCR.TE bit is set to 1 while the SCR.TIE bit is 1.

Note that setting the SCR.TIE bit to 1 while the SCR.TE bit is 0 leads to the generation of a TXI interrupt.

When the SCR.TEIE bit is 1 and if the next data is not yet written to the FTDR register by the timing when the last bit of the transmit data is transmitted, the SSRFIFO.TEND flag is 1 and a TEI interrupt request is generated.

When the SCR.RIE bit is 1, the number of the data stored in the receive FIFO is equal to or greater than the threshold (FCR.RTRG[3:0] bits), an RXI interrupt request is generated.

When the SCR.RIE bit is 1 and the SSRFIFO.ORER flag is 1 or the data with a framing or parity error is stored in the receive FIFO, an ERI interrupt request is generated. At this time, if the number of the data stored in the receive FIFO is equal to or greater than the threshold (FCR.RTRG[3:0] bits), an RXI interrupt request is generated. Clearing the ORER, FER, and PER flags in the SSRFIFO register cancels an ERI interrupt request.

**Table 32.37 Interrupt Source**

| Name | Interrupt Source    | Interrupt Flag                                          | DTC Activation | DMAC Activation |
|------|---------------------|---------------------------------------------------------|----------------|-----------------|
| ERI  | Receive error       | ORER, FER, PER, DFER, or DPER<br>DR (when FCR.DRES = 1) | Not possible   | Not possible    |
| RXI  | Receive FIFO full   | RDF                                                     | Possible       | Possible        |
|      | Receive data ready  | DR (when FCR.DRES = 0)                                  |                |                 |
|      | Data match          | DCMF                                                    |                |                 |
| TXI  | Transmit FIFO empty | TDRE                                                    | Possible       | Possible        |
| TEI  | Transmit end        | TEND                                                    | Not possible   | Not possible    |

### 32.12.3 Interrupts in Smart Card Interface Mode

Table 32.38 lists interrupt sources in smart card interface mode. A transmit end interrupt (TEI) request cannot be used in this mode.

**Table 32.38 SCI Interrupt Sources**

| Name | Interrupt Source                        | Interrupt Flag    | DTC Activation | DMAC Activation |
|------|-----------------------------------------|-------------------|----------------|-----------------|
| ERI  | Receive error or error signal detection | ORER, PER, or ERS | Not possible   | Not possible    |
| RXI  | Receive data full                       | —                 | Possible       | Possible        |
| TXI  | Transmit data empty                     | TEND              | Possible       | Possible        |

Data transmission/reception using the DTC or DMAC is also possible in smart card interface mode, similar to in the normal SCI mode. In transmission, when the SSR.TEND flag is set to 1, a TXI interrupt request is generated. This TXI interrupt request activates the DTC or DMAC allowing transfer of transmit data if the TXI request is specified beforehand as a source of DTC or DMAC activation. The TEND flag is automatically set to 0 when the DTC or DMAC transfers the data.

If an error occurs, the SCI automatically retransmits the same data. During the retransmission, the TEND flag is kept to 0 and the DTC or DMAC is not activated. Therefore, the SCI and DTC or DMAC automatically transmit the specified number of bytes, including retransmission in the case of error occurrence. However, the SSR.ERS flag is not automatically cleared to 0 at error occurrence. Therefore, the ERS flag must be cleared by previously setting the SCR.RIE bit to 1 to enable an ERI interrupt request to be generated at error occurrence.

When transmitting/receiving data using the DTC or DMAC, be sure to make settings to enable the DTC or DMAC before making SCI settings. For DTC or DMAC settings, refer to section 18, Data Transfer Controller (DTCa) and section 17, DMA Controller (DMACa).

In reception, an RXI interrupt request is generated when receive data is set to the RDR register. This RXI interrupt request activates the DTC or DMAC allowing transfer of receive data if the RXI request is specified beforehand as a source of DTC or DMAC activation. If an error occurs, the error flag is set. Therefore, the DTC or DMAC is not activated and an ERI interrupt request is issued to the CPU instead; the error flag must be cleared.

### 32.12.4 Interrupts in Simple I<sup>2</sup>C Mode

The interrupt sources in simple I<sup>2</sup>C mode are listed in Table 32.39. The STI interrupt is allocated to the transmit end interrupt (TEI) request. The receive error interrupt (ERI) request cannot be used.

The DTC or DMAC can also be used to handle transfer in simple I<sup>2</sup>C mode.

When the value of the SIMR2.IICINTM bit is 1, an RXI request will be generated on the falling edge of the SSCLn signal for the eighth bit. If the RXI has been set up as an activating request for the DTC or DMAC beforehand, the RXI request will activate the DTC or DMAC to handle transfer of the received data. Furthermore, a TXI request is generated on the falling edge of the SSCLn signal for the ninth bit (acknowledge bit). If the TXI has been set up as an activating request for the DTC or DMAC beforehand, the TXI request will activate the DTC or DMAC to handle transfer of the transmit data.

When the value of the SIMR2.IICINTM bit is 0, an RXI request (ACK detection) if the input on the SSDAn pin is at the low level or a TXI request (NACK detection) if the input on the SSDAn pin is at the high level will be generated on the rising edge of the SSCLn signal for the ninth bit (acknowledge bit). If the RXI has been set up as an activating request for the DTC or DMAC beforehand, the RXI request will activate the DTC or DMAC to handle transfer of the received data. Also, if the DTC or DMAC is used for data transfer in reception or transmission, be sure to set up and enable the DTC or DMAC before setting up the SCI.

When the IICSTAREQ, IICRSTAREQ, and IICSTPREQ bits in the SIMR3 register are used to generate a start condition, restart condition, or stop condition, the STI request is issued when generation is complete.

**Table 32.39 SCI Interrupt Sources**

| Name | Interrupt Source                                                |                 | Interrupt Flag | DTC Activation | DMAC Activation |
|------|-----------------------------------------------------------------|-----------------|----------------|----------------|-----------------|
|      | IICINTM bit = 0                                                 | IICINTM bit = 1 |                |                |                 |
| RXI  | ACK detection                                                   | Reception       | —              | Possible       | Possible        |
| TXI  | NACK detection                                                  | Transmission    | —              | Possible*1     | Possible*1      |
| STI  | Completion of generation of a start, restart, or stop condition |                 | IICSTIF        | Not possible   | Not possible    |

Note 1. Activation of the DTC or DMAC is only possible when the SIMR2.IICINTM bit is 1 (use reception and transmission interrupts).

### 32.12.5 Interrupt Requests from the Extended Serial Mode Control Section

The extended serial mode control section has a total of six types of interrupt request for generating the SCIX0 interrupt (Break Field low width detected), SCIX1 interrupt (Control Field 0 match, Control Field 1 match, priority interrupt bit detected), SCIX2 interrupt (bus collision detected), and SCIX3 interrupt (valid edge detected). When any of the interrupt factors is generated, the corresponding status flag is set to 1. Details of all of the interrupt requests are listed in Table 32.40.

**Table 32.40 Interrupt Sources of the Extended Serial Mode Control Section**

| Interrupt Request                                 | Status Flag | Interrupt Factors                                                                                                                                                                                                                                                                                          |
|---------------------------------------------------|-------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| SCIX0 interrupt (Break Field low width detected)  | BFDF        | <ul style="list-style-type: none"> <li>• Detection of a Break Field low width longer than the interval corresponding to the timer setting</li> <li>• Completion of the output of a Break Field low width over the interval corresponding to the timer setting</li> <li>• Underflow of the timer</li> </ul> |
| SCIX1 interrupt (Control Field 0 match)           | CF0MF       | The data received in Control Field 0 matching the value set in the CF0DR register                                                                                                                                                                                                                          |
| SCIX1 interrupt (Control Field 1 match)           | CF1MF       | The data received in Control Field 1 matching the value set in the PCF1DR or SCF1DR register                                                                                                                                                                                                               |
| SCIX1 interrupt (priority interrupt bit detected) | PIBDF       | The value of the bit specified as the priority interrupt bit matching the value set in the PCF1DR register                                                                                                                                                                                                 |
| SCIX2 interrupt (bus collision detected)          | BCDF        | The output level on the TXDX12 pin and the input level on the RXDX12 pin not matching on three consecutive cycles of the bus collision detection clock                                                                                                                                                     |
| SCIX3 interrupt (valid edge detected)             | AEDF        | Detection of a valid edge during bit rate measurement                                                                                                                                                                                                                                                      |

### 32.13 Event Linking

By employing interrupt request signals as event signals, SCI5 is able to provide linked operation through the event link controller (ELC) for modules selected in advance.

Event signals can be output regardless of the values of the corresponding interrupt request enable bits.

- (1) Error (receive error, error signal detected) event output
  - Indicates abnormal termination due to a parity error during reception in asynchronous mode.
  - Indicates abnormal termination due to a framing error during reception in asynchronous mode.
  - Indicates abnormal termination due to an overrun error during reception.
  - Indicates detection of the error signal during transmission in smart card interface mode.
  
- (2) Receive data full event output
  - Indicates that received data have been set in the receive data register (RDR or RDRL).
  - Indicates that ACK has been detected if the SIMR2.IICINTM bit is 0 in simple I<sup>2</sup>C mode.
  - Indicates that the 8th-bit SSCL5 falling edge has been detected if the SIMR2.IICINTM bit is 1 in simple I<sup>2</sup>C mode.
  - When the SIMR2.IICINTM bit is 1 during master transmission in simple I<sup>2</sup>C mode, set the event link controller (ELC) so that receive data full events are not used.
  
- (3) Transmit data empty event output
  - Indicates that the SCR.TE bit has been changed from 0 to 1.
  - Indicates that transmit data have been transferred from the transmit data register (TDR or TDRL) to the transmit shift register (TSR).
  - Indicates that transmission has been completed in smart card interface mode.
  - Indicates that NACK has been detected if the SIMR2.IICINTM bit is 0 in simple I<sup>2</sup>C mode.
  - Indicates that the ninth-bit SSCL5 falling edge has been detected if the SIMR2.IICINTM bit is 1 in simple I<sup>2</sup>C mode.
  
- (4) Transmit end event output
  - Indicates the completion of transmission.
  - Indicates that the starting condition, resumption condition, or termination condition has been generated in simple I<sup>2</sup>C mode.

## 32.14 Usage Notes

### 32.14.1 Setting the Module Stop Function

Module stop control register B (MSTPCRB) and module stop control register C (MSTPCRC) are used to stop and start SCI operations. With the value after a reset, SCI operations are stopped. Register access is enabled by releasing the module stop state. For details, refer to section 11, Low Power Consumption.

### 32.14.2 Break Detection and Processing

#### (1) SCI1, SCI5, SCI6, SCI8, SCI9, and SCI12, and SCI11 when FIFO is Disabled

When a framing error is detected, a break can be detected by reading the RXDn pin value directly or reading the value of the SPTR.RXDMON flag (only for SCI1, SCI5, SCI6, SCI8, SCI9, and SCI11). In a break, the input from the RXDn pin becomes all 0s, and so the SSR.FER flag is set to 1 (framing error has occurred), and the SSR.PER flag may also be set to 1 (parity error has occurred). When the SEMR.RXDESEL bit is 0, the SCI continues the receive operation even after a break is received. Therefore, note that even if the FER flag is set to 0 (no framing error occurred), it will be set to 1 again. When the SEMR.RXDESEL bit is 1, the SCI sets the SSR.FER flag to 1 and stops receiving operation until a start bit of the next data frame is detected. If the SSR.FER flag is set to 0 at this time, the SSR.FER flag retains 0 during the break. When the RXDn pin becomes high and the break ends, detecting the beginning of the start bit at the first falling edge of the RXDn pin allows the SCI to start the receiving operation.

#### (2) SCI11 When FIFO is Enabled

When a framing error is detected and the following one-frame data received is all 0s, the SCI stops receiving operation. Upon the detection of a framing error, reading the value of the SPTR.RXDMON flag detects a break. After the RXDn pin becomes high and the break ends, the SCI resumes receiving operation.

### 32.14.3 Mark State and Sending Breaks

When the SCR.TE bit is 0 (serial transmission is disabled), the TXDn pin becomes high-impedance. To forcibly set the TXDn pin to mark or space state while the TE bit is 0, set the I/O port associated registers and switch the TXDn pin to general output port.

For holding the communication line in the mark ("1") state until the TE bit is set to 1 (serial transmission is enabled), set the corresponding bit in the PODR register to 1 for high output from general output port. To start communications, set the TE bit to 1 and then the corresponding bit in the PMR register to 1.

To send a break (the space state for longer than a certain period of time) while data transmission, set the corresponding bit in the PODR register to 0 (low output), and set the corresponding bit in the PMR register to 0 (general I/O port). Then set the TE bit to 0 if necessary. When the TE bit is set to 0, the transmitter is initialized regardless of the current transmit status.

The SPTR register, if it is included, can set the TXDn pin in mark/space state without switching the pin function to general output port. Set the SPTR.SPB2IO bit to 1 (output) and the SPB2DT bit to 1 (mark) or 0 (space), and then set the TE bit to 0.

### 32.14.4 Receive Error Flags and Transmit Operations (Clock Synchronous Mode and Simple SPI Mode)

Transmission cannot be started when a receive error flag (SSR.ORER) is set to 1, even if data is written to the TDR register (FTDR register). Be sure to set the receive error flags to 0 before starting transmission. Note also that the receive error flags cannot be set to 0 even if the SCR.RE bit is set to 0 (serial reception is disabled).

### 32.14.5 Writing Data to the TDR Register

Data can be written to registers TDR, TDRH, and TDRL. However, if new data is written to registers TDR, TDRH, and TDRL when transmit data is remaining in registers TDR, TDRH, and TDRL, the previous data in registers TDR, TDRH, and TDRL is lost because it has not been transferred to the TSR register yet. Be sure to write transmit data to registers TDR, TDRH, and TDRL in the TXI interrupt request handling routine.

### 32.14.6 Restrictions on Clock Synchronous Transmission (Clock Synchronous Mode and Simple SPI Mode)

When the external clock source is used as a synchronization clock, the following restrictions apply.

(1) Start of transmission

Update the TDR register by the CPU, DMAC, or DTC and wait for at least five PCLK cycles before allowing the transmit clock to be input (refer to Figure 32.80).

(2) Continuous transmission

- (a) Write the next transmit data to the TDR or TDRL register before the falling edge of the transmit clock (bit 7) (refer to Figure 32.80).
- (b) When updating the TDR register after bit 7 has started to transmit, update the TDR register while the synchronization clock is in the low-level period, and set the high-level width of the transmit clock (bit 7) to four PCLK cycles or longer (refer to Figure 32.80).

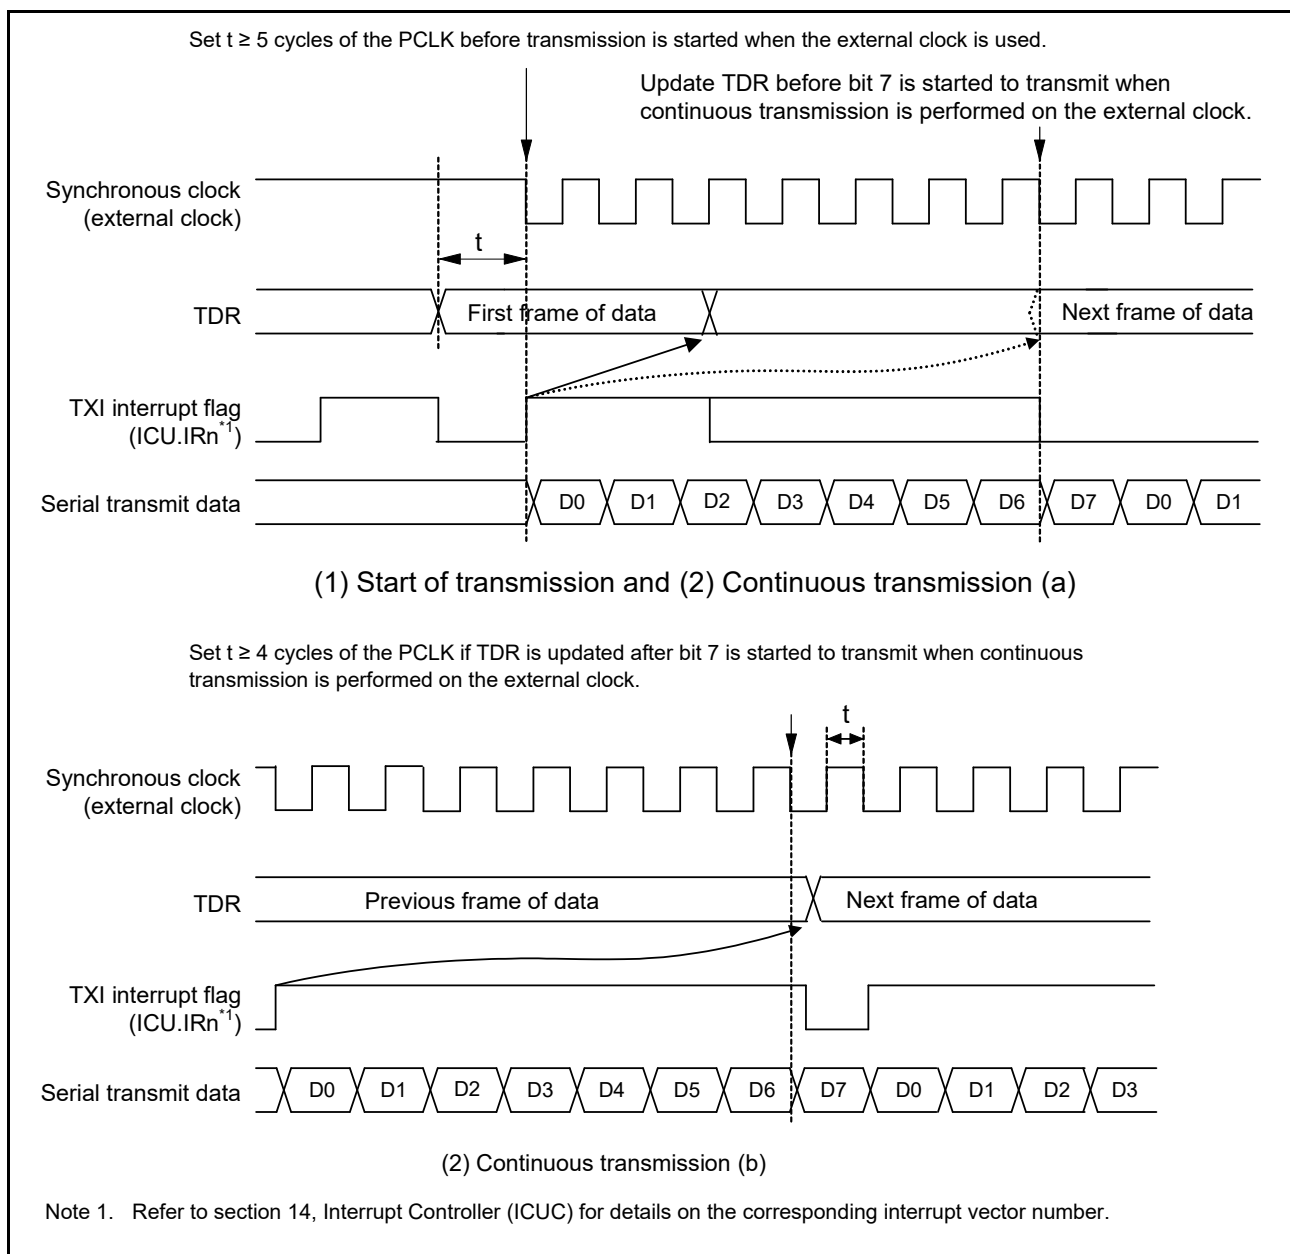

Figure 32.80 Restrictions on Use of External Clock in Clock Synchronous Transmission

### 32.14.7 Restrictions on Using DMAC or DTC

When using the DMAC or DTC to read the RDR, RDRH, and RDRL registers, be sure to set the receive data full interrupt (RXI) as the activation source of the relevant SCI.

### 32.14.8 Notes on Starting Transfer

At the point where transfer starts when the interrupt status flag (IRn.IR flag) in the interrupt controller is 1, follow the procedure below to clear interrupt requests before permitting operations (by setting the SCR.TE or SCR.RE bit to 1). For details on the interrupt status flag, refer to section 14, Interrupt Controller (ICUC).

- Confirm that transfer has stopped (the setting of the SCR.TE or SCR.RE bits is 0).
- Set the corresponding interrupt enable bit (SCR.TIE or SCR.RIE) to 0.
- Read the corresponding interrupt enable bit (SCR.TIE or SCR.RIE bit) to check that it has become 0.
- Set the interrupt status flag (IRn.IR flag) in the interrupt controller to 0.

### 32.14.9 SCI Operations during Low Power Consumption State

#### (1) Transmission

When making settings for the module stopped state or in transitions to software standby, stop operations (by setting the TIE, TE, and TEIE bits in the SCR register to 0) after switching the TXDn pin to the general I/O port pin function or fix the output level of the TXDn pin by the SPTR register (only for SCI1, SCI5, SCI6, SCI8, SCI9, and SCI11). Setting the TE bit to 0 resets the TSR register and the SSR.TEND flag. The SSRFIFO.TEND flag in the SCI11 is not initialized. Depending on the port settings or SPTR register setting (only for SCI1, SCI5, SCI6, SCI8, SCI9, and SCI11), output pins may output the level before a transition to the low power consumption state is made after release from the module stopped state or software standby mode. When transitions to these states are made during transmission, the data being transmitted become indeterminate.

To transmit data in the same transmit mode after cancellation of the low power consumption state, set the TE bit to 1, read the SSR register, and write data to the TDR register sequentially to start data transmission. To transmit data with a different transmit mode, initialize the SCI first.

Figure 32.81 shows a sample flowchart for transition to software standby mode during transmission. Figure 32.82 and Figure 32.83 show the port pin states during transition to software standby mode.

Before specifying the module stop state or making a transition to software standby mode from the transmit mode using DTC/DMA transfer, stop the transmit operations (TE = 0). To start transmission after cancellation using the DTC/DMAC, set the TE and TIE bits to 1. The TXI interrupt flag is set to 1 and transmission starts using the DTC/DMAC.

#### (2) Reception

##### (a) When the data match function is not used for release from the low-power consumption state

Before specifying the module stop state or making a transition to software standby mode, stop the receive operations (SCR.RE = 0). If transition is made during data reception, the data being received will be invalid.

To receive data in the same receive mode after cancellation of the low power consumption state, set the RE bit to 1, and then start reception. To receive data in a different receive mode, initialize the SCI first.

Figure 32.84 shows a sample flowchart for transition to software standby mode during reception.

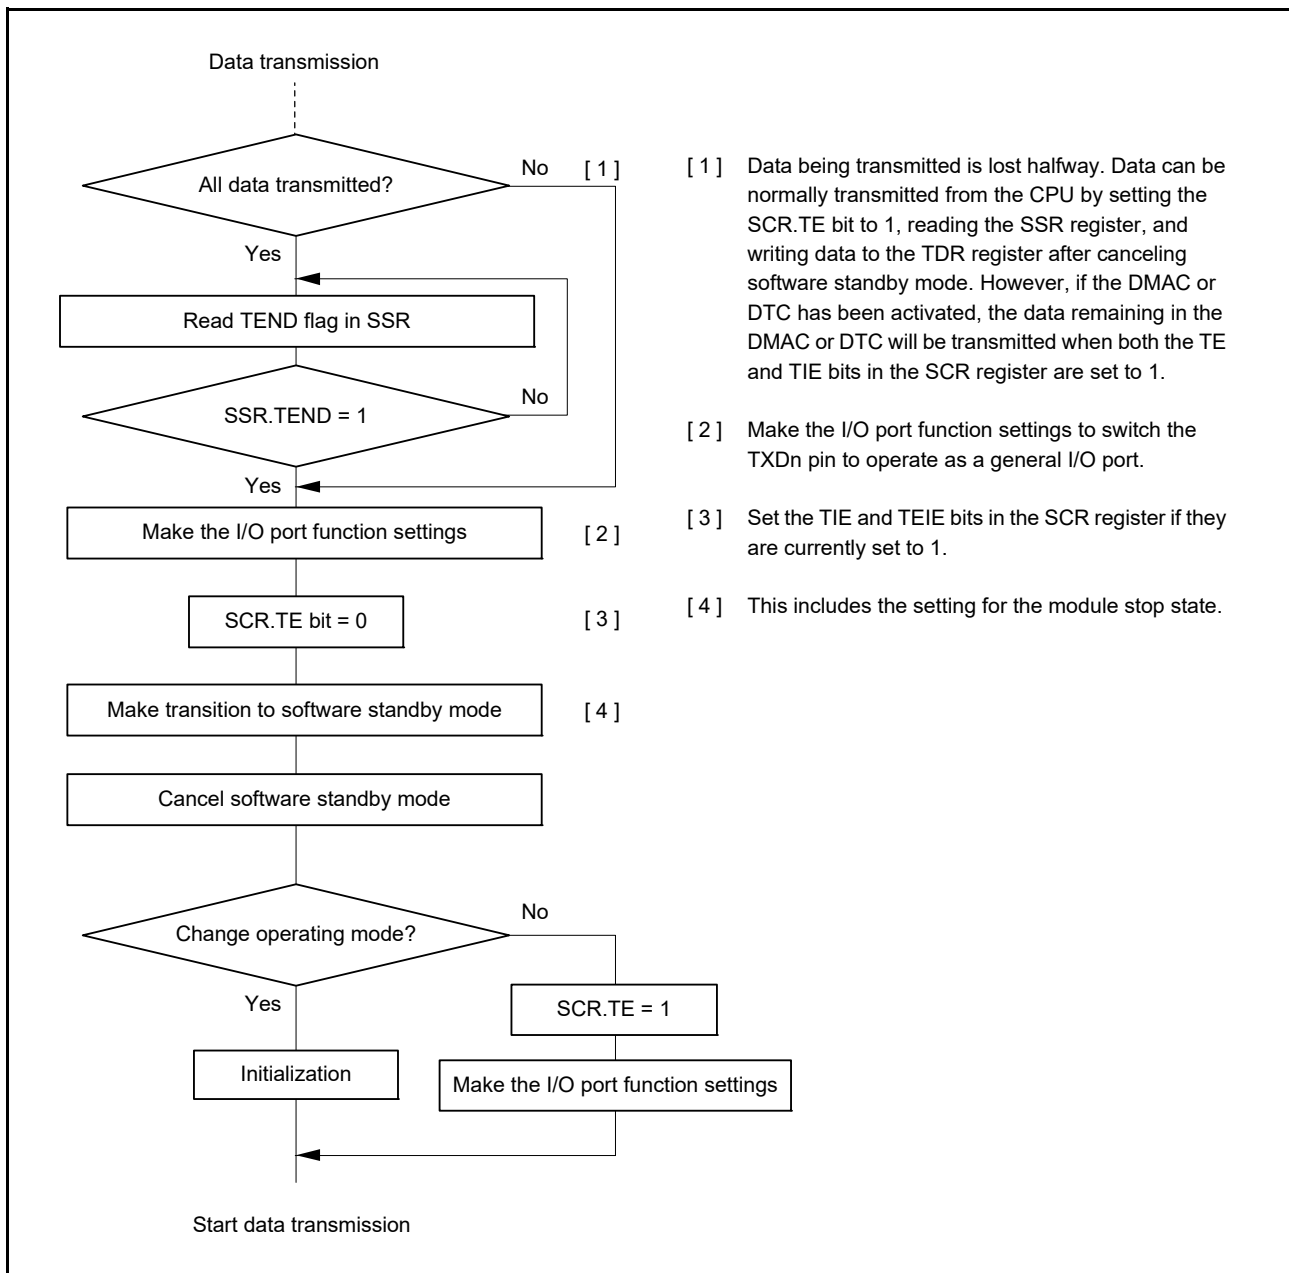

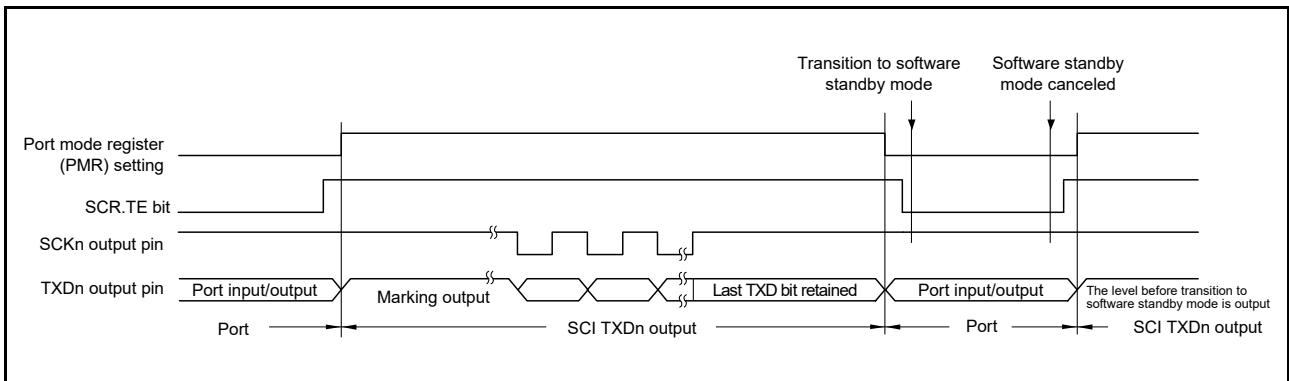

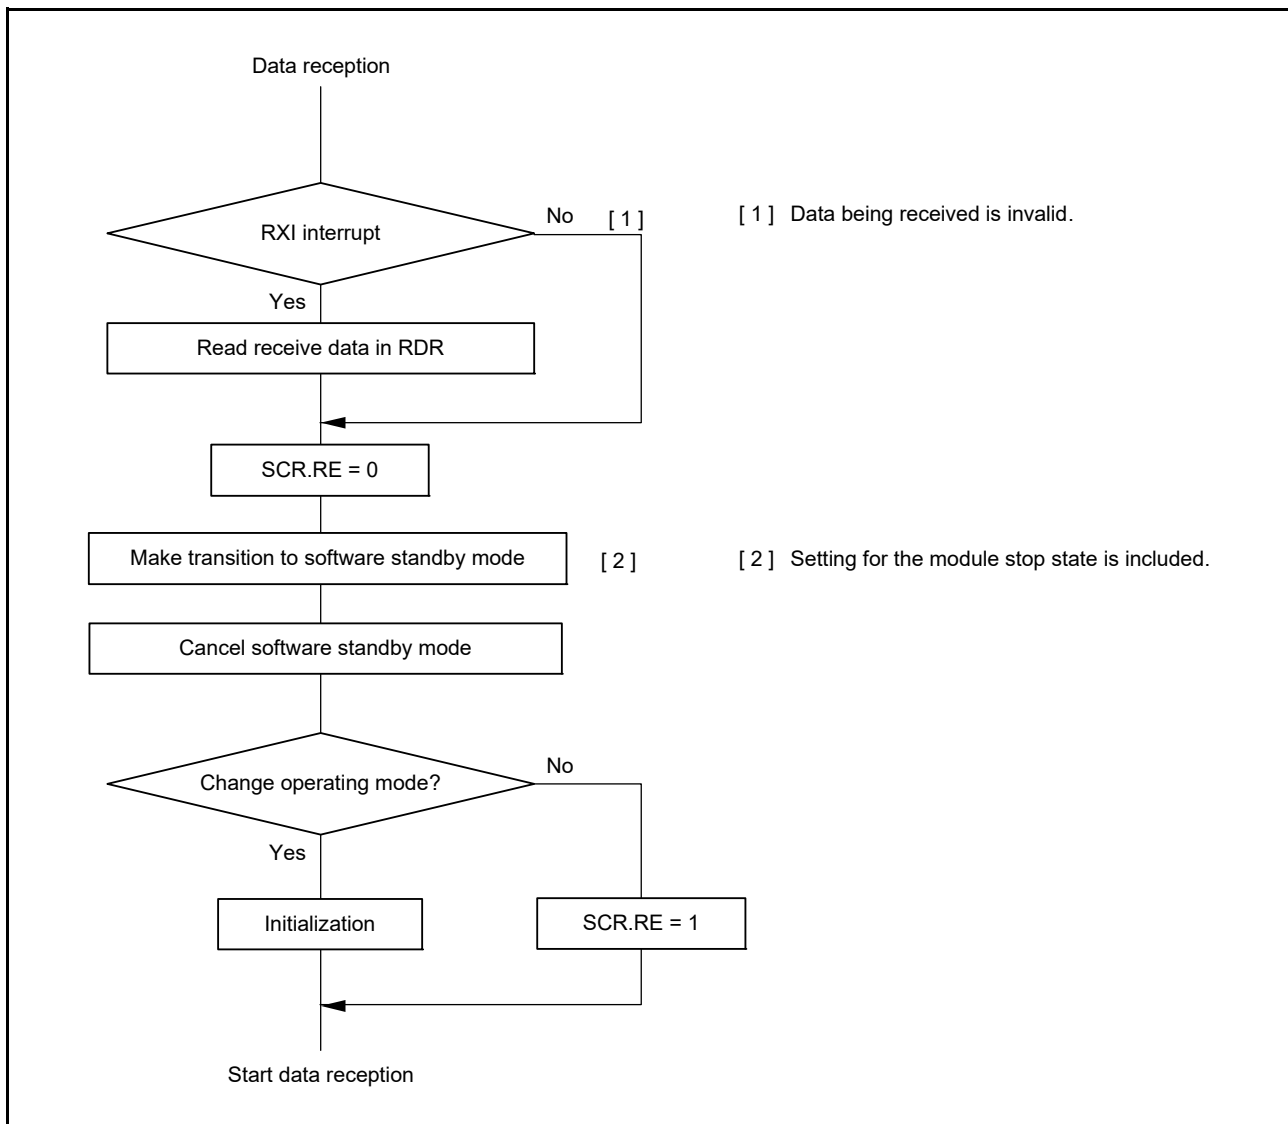

Figure 32.81 Example of Flowchart for Transition to Software Standby Mode during Transmission

**Figure 32.82 Port Pin States during Transition to Software Standby Mode (Internal Clock, Asynchronous Transmission)**

**Figure 32.83 Port Pin States during Transition to Software Standby Mode (Internal Clock, Clock Synchronous Transmission)**

**Figure 32.84** Example of Flowchart for Transition to Software Standby Mode during Reception

(b) When the data match function is used for release from the low-power consumption state

Set an operating mode to be set after release from the low-power consumption state before reducing power consumed by the SCI by using the function of reducing power consumption. Afterwards, set the comparison data in the CDR.CMPD[8:0] bits and set the DCCR.DCME bit to 1. While the SCR.RE bit is 1, enter to the low-power consumption state.

If transition to the low-power consumption state may take place while the RXDn pin is driven low, set the SEMR.RXDESEL bit to 0. When the SEMR.RXDESEL bit is 1, the start bit may not be detected at the time of release from the low-power consumption state.

### 32.14.10 External Clock Input in Clock Synchronous Mode and Simple SPI Mode

In clock synchronous mode and simple SPI mode, the external clock SCKn must be input as follows:

High-pulse period, low-pulse period = 2 PCLK cycles or more, period = 6 PCLK cycles or more

### 32.14.11 Limitations on Simple SPI Mode

#### (1) Master Mode

- Use a resistor to pull up or pull down the clock line matching the initial settings for the transfer clock set by the SPMR.CKPH and CKPOL bits when the SPMR.SSE bit is 1.  
This prevents the clock line from being placed in the high-impedance state when the SCR.TE bit is set to 0 or unexpected edges from being generated on the clock line when the SCR.TE bit is changed from 0 to 1. When the SPMR.SSE bit is 0 in single master mode, pulling up or pulling down the clock line is not necessary because the clock line is not placed in the high-impedance state even when the SCR.TE bit is set to 0.
- In the case of the setting for clock delay (SPMR.CKPH bit is 1), the receive data full interrupt (RXI) is generated before the final clock edge on the SCKn pin as indicated in Figure 32.85. If the TE and RE bits in the SCR register become 0 at this time before the final edge of the clock signal on the SCKn pin, the SCKn pin is placed in the high-impedance state, so the width of the last clock pulse of the transfer clock is shortened. Furthermore, an RXI interrupt may lead to the input signal on the SSn# pin of a connected slave going to the high level before the final edge of the clock signal on the SCKn pin, leading to incorrect operation of the slave.
- In a multi-master configuration, take care because the SCKn pin output becomes high-impedance while the input on the SSn# pin is at the low level if a mode fault error occurs as the current character is being transferred, stopping supply of the clock signal to the connected slave. Remake the settings for the connected slave to avoid misaligned bits when transfer is restarted.

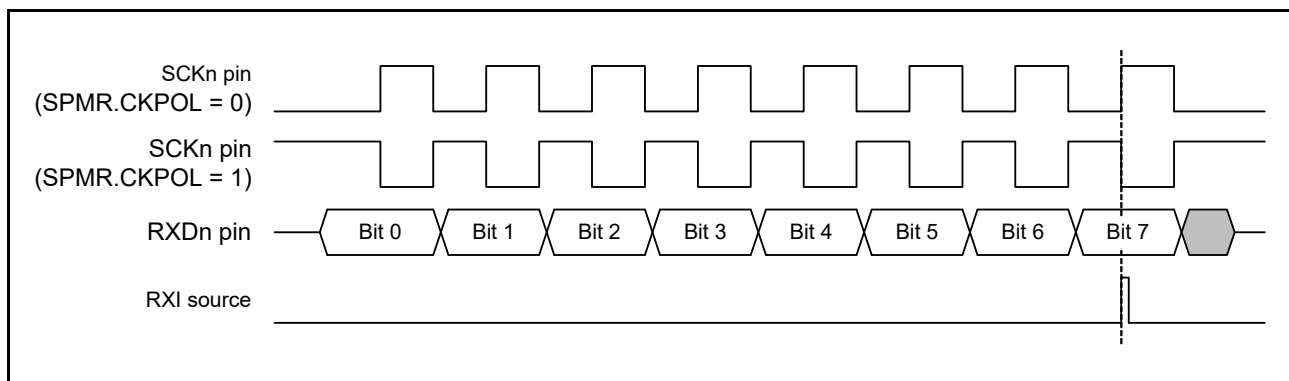

Figure 32.85 Timing of the RXI Interrupt in Simple SPI Mode (with Clock Delay)

#### (2) Slave Mode

- Secure at least five cycles of the PCLK from writing transmit data in the TDR register to start of the external clock input. Also secure at least five cycles of the PCLK from input of low level on the SSn# pin to start of the external clock input.
- Provide an external clock signal from the master the same as the transmit/receive data length.
- Control the input on the SSn# pin before the start and after the end of data transfer.
- When the level being input on the SSn# pin is to be changed from low to high while the current character is being transferred, set the TE and RE bits in the SCR register to 0 and, after remaking the settings, restart transfer of the first byte.

### 32.14.12 Limitation 1 on Usage of the Extended Serial Mode Control Section

When the PCR.SHARPS bit is set to 1, output on the TXDX12/RXDX12 pin is only possible when the following conditions apply.

- The timer is in Break Field low width output mode and the value of the TCR.TCST bit is 1 (when the TCST bit is set to 1, the high level continues to be output for up to one cycle of the clock source for counting by the timer counter before output of the low level)
- The value of the SCR.TE bit is 1.

### 32.14.13 Limitation 2 on Usage of the Extended Serial Mode Control Section

The TXI, RXI, ERI, and TEI interrupt requests are generated even if the extended serial mode is enabled. However, the RXI interrupt should not be enabled during reception of a Start Frame because the extended serial mode control section uses the receive data full signal.

To use the RXI interrupts during a reception of the Information Frame, use it in accordance with one of the following procedures. When a receive error is detected, clear the receive error flag and initialize the extended serial mode control section.

- (1) Set the SCR.RIE bit to 0 to disable the output of interrupt requests. Check the error flags in the SSR register on completion of the reception of a Start Frame, because an ERI interrupt is not generated if a receive error occurs. After reception of the Start Frame is completed, set the SCR.RIE bit to 1 by the time the first byte of the Information Frame is received.
- (2) Set the SCR.RIE bit to 1 to disable RXI interrupts and enable ERI interrupts for ICU. Clear the IRn.IR flag to enable the acceptance of RXI interrupts by ICU by the time the first byte of the Information Frame is received after the completion of Start Frame reception.

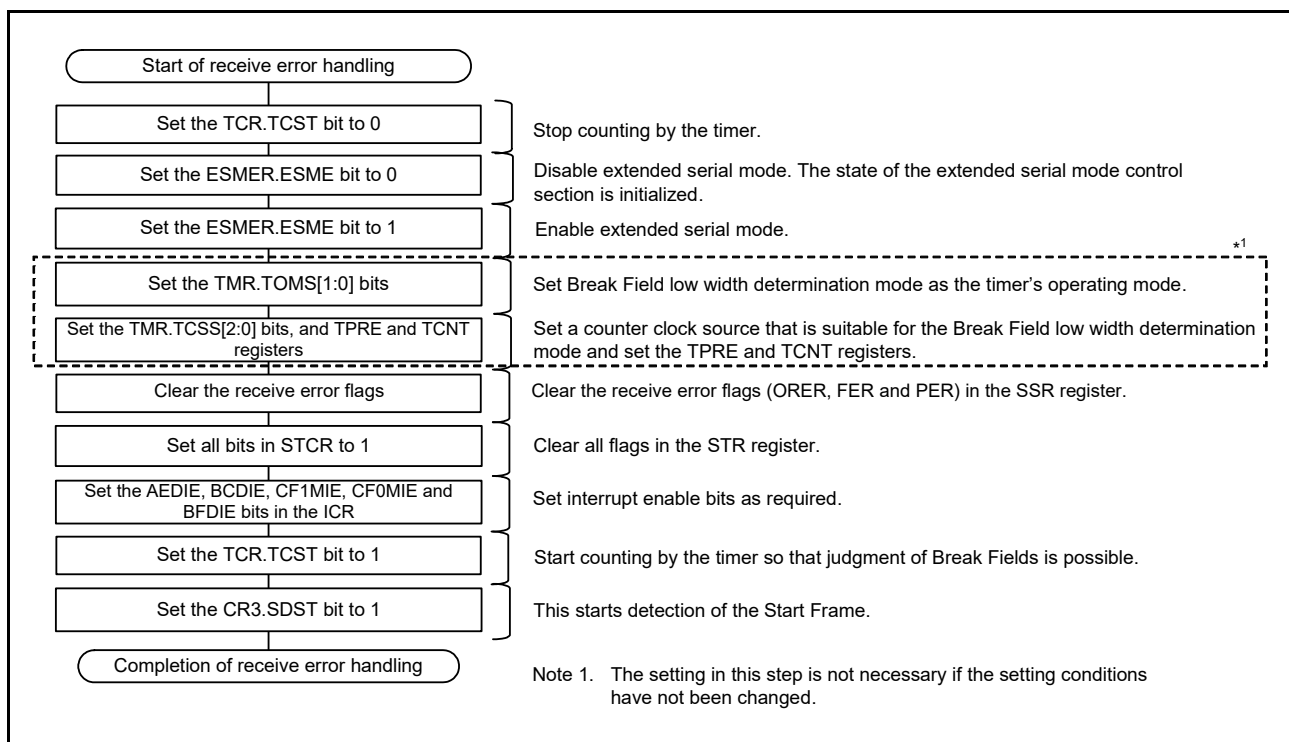

Figure 32.86 Example of Flowchart for Receive Error Handling (during Reception of the Start Frame)

### 32.14.14 Note on Transmit Enable Bit (TE Bit)

When setting the pin function to “TXDn” while the SCR.TE bit is 0 (serial transmission is disabled) or setting the TE bit to 0 while the pin function is “TXDn”, output of the TXDn pin becomes high-impedance.

Prevent the TXDn line from becoming high-impedance by any of the following ways:

- (1) Connect a pull-up resistor to the TXDn line.
- (2) Set the TE bit to 1\*1 before changing the pin function to “TXDn”. Before setting the TE bit to 0, change the pin function to “general-purpose I/O port” and drive the pin high or low.
- (3) Set the SPTR.SPB2IO bit to 1 first, and change the pin function to “TXDn”. Leave the value of the SPB2IO bit as 1 after that (for SCI1, SCI5, SCI6, SCI8, SCI9, and SCI11).

Note 1. An interrupt is generated when the TE bit is set to 1 while the TXI interrupt is enabled (SCI1, SCI5, SCI6, SCI8, SCI9, and SCI12, and SCI11 when FIFO is Disabled). If this creates a problem, change the pin function to “TXDn” first, and then set the corresponding ICU.IERm.IENj bit to 1.

### 32.14.15 Note on Stopping Reception When Using the RTS Function in Asynchronous Mode

One clock cycle of PCLK is required for the time from setting the SCR.RE bit to 0 to stopping the RTS signal generator in asynchronous mode.

When reading the RDR (or RDRL) register after setting the SCR.RE bit to 0, confirm that the RE bit has been set to 0 before reading the RDR (or RDRL) register to prevent these two processes from being performed consecutively.

## 33. I<sup>2</sup>C-bus Interface (RIICa)

This MCU has a single-channel I<sup>2</sup>C-bus interface (RIIC0).

The RIIC module conforms with the NXP I<sup>2</sup>C-bus (Inter-IC bus) interface and provides a subset of its functions.

In this section, “PCLK” is used to refer to PCLKB.

### 33.1 Overview

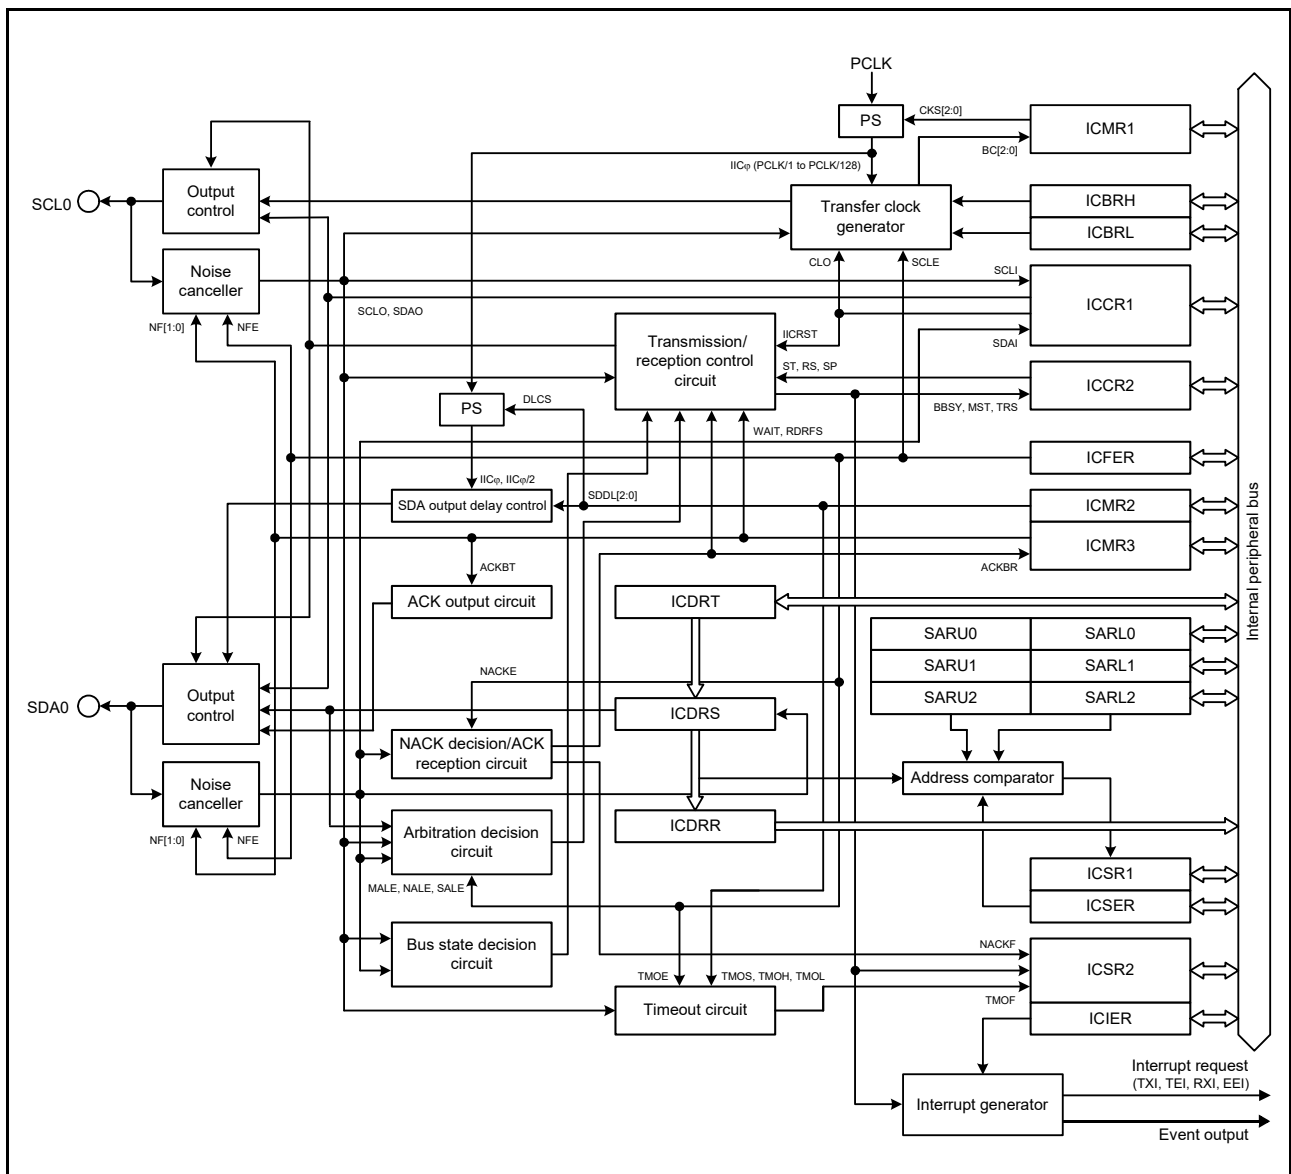

Table 33.1 lists the specifications of the RIIC, Figure 33.1 shows a block diagram of the RIIC. Table 33.2 lists the I/O pins of the RIIC.

**Table 33.1 RIIC Specifications (1/2)**

| Item                                | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

| Serial clock (SCL)                  | For master operation, the duty cycle of the SCL is selectable in the range from 4 to 96%.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Generating and detecting conditions | Start, restart, and stop conditions are automatically generated. Start conditions (including restart conditions) and stop conditions are detectable.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

#### SDAO Bit (SDA Output Control/Monitor) and SCLO Bit (SCL Output Control/Monitor)

These bits are used to directly control the SDA0 and SCL0 signals output from the RIIC.

When writing to these bits, also write 0 to the SOWP bit.

The result of setting these bits is input to the RIIC via the input buffer. When slave mode is selected, a start condition may be detected and the bus may be released depending on the bit settings.

Do not rewrite these bits during a start condition, stop condition, restart condition, or during transmission or reception.

Operation after rewriting under the above conditions is not guaranteed.

When reading these bits, the state of signals output from the RIIC can be read.

**CLO Bit (Additional SCL Output)**

This bit is used to output an additional SCL for debugging or error processing.

Normally, set the bit to 0. Setting the bit to 1 in a normal communication state causes a communication error.

For details on this function, refer to section 33.11.2, Additional SCL Output Function.

**IICRST Bit (I<sup>2</sup>C-bus Interface Internal Reset)**

This bit is used to reset the internal states of the RIIC.

Setting this bit to 1 initiates an RIIC reset or internal reset.

Whether an RIIC reset or internal reset is initiated is determined according to the combination with the ICE bit. Table 33.3 lists the resets of the RIIC.

The RIIC reset initializes all registers and internal states of the RIIC, and the internal reset initializes the bit counter (ICMR1.BC[2:0] bits), the I<sup>2</sup>C-bus shift register (ICDRS), and the I<sup>2</sup>C-bus status registers (ICSR1 and ICSR2) as well as the internal states of the RIIC. For the reset conditions for each register, refer to section 33.14, Initialization of Registers and Functions When a Reset is Applied or a Condition is Detected.

An internal reset initiated with the IICRST bit set to 1 during operation (with the ICE bit set to 1) resets the internal states of the RIIC without initializing the port settings and the control and setting registers of the RIIC when the bus or RIIC hangs up due to a communication error.

If the RIIC hangs up in a low level output state, resetting the internal states cancels the low level output state and releases the bus with the SCL0 pin and SDA0 pin at a high impedance.

**Note:** If an internal reset is initiated using the IICRST bit for a bus hang-up occurred during communication with the master device in slave mode, the states may become different between the slave device and the master device (due to the difference in the bit counter information). For this reason, do not initiate an internal reset in slave mode, but initiate restoration processing from the master device. If it is necessary to perform an internal reset in slave mode, perform it during bus free state. If an internal reset is necessary because the RIIC has hung with the SCL0 line in a low level output state in slave mode, initiate an internal reset and then generate a restart condition from the master device or resume communications from the start condition after having generated a stop condition. If communication is restarted by initiating a reset solely in the slave device without generating a start condition or restart condition from the master device, synchronization will be lost because the master and slave devices operate asynchronously.

**Table 33.3 RIIC Resets**

| IICRST | ICE | State          | Specifications                                                                                         |
|--------|-----|----------------|--------------------------------------------------------------------------------------------------------|
| 1      | 0   | RIIC reset     | Resets all registers and internal states of the RIIC.                                                  |
|        | 1   | Internal reset | Resets the ICMR1.BC[2:0] bits, registers ICSR1, ICSR2, and ICDRS, and the internal states of the RIIC. |

**ICE Bit (I<sup>2</sup>C-bus Interface Enable)**

This bit selects the active or inactive state of the SCL0 and SDA0 pins. It can also be combined with the IICRST bit to initiate two types of resets. See Table 33.3, RIIC Resets, for the types of resets.

Set the ICE bit to 1 when using the RIIC. The SCL0 and SDA0 pins are placed in the active state when the ICE bit is set to 1.

Set the ICE bit to 0 when the RIIC is not to be used. The SCL0 and SDA0 pins are placed in the inactive state when the ICE bit is set to 0. Do not assign the SCL0 or SDA0 pin to the RIIC when setting up the multi-function pin controller (MPC). Note that the slave address comparison operation is carried out if the pins are assigned to the RIIC.

| b7  | BBSY   | Bus Busy Detection Flag              | 0: The I <sup>2</sup> C-bus is released (bus free state).<br>1: The I <sup>2</sup> C-bus is occupied (bus busy state). | R     |

Note 1. When the ICMR1.MTWP bit is set to 1, bits MST and TRS can be written to.

#### ST Bit (Start Condition Generation Request)

This bit is used to request transition to master mode and generation of a start condition.

When this bit is set to 1 to request to generate a start condition, a start condition is generated when the BBSY flag is set to 0 (bus free state).

For details on the start condition generation, refer to section 33.10, Start Condition/Restart Condition/Stop Condition Generating Function.

[Setting condition]

- When 1 is written to the ST bit

[Clearing conditions]

- When 0 is written to the ST bit
- When a start condition has been generated (a start condition is detected)
- When the ICSR2.AL (arbitration-lost) flag is set to 1
- When 1 is written to the ICCR1.IICRST bit to apply an RIIC reset or an internal reset

Note: Set the ST bit to 1 (requests to generate a start condition) when the BBSY flag is set to 0 (bus free state). Note that arbitration may be lost due to a start condition generation error if the ST bit is set to 1 (requests to generate a start condition) when the BBSY flag is set to 1 (bus busy state).

**RS Bit (Restart Condition Generation Request)**

This bit is used to request that a restart condition be generated in master mode.

When this bit is set to 1 to request to generate a restart condition, a restart condition is generated when the BBSY flag is set to 1 (bus busy state) and the MST bit is set to 1 (master mode).

For details on the restart condition generation, refer to section 33.10, Start Condition/Restart Condition/Stop Condition Generating Function.

[Setting condition]

- When 1 is written to the RS bit with the ICCR2.BBSY flag set to 1

[Clearing conditions]

- When 0 is written to the RS bit
- When a restart condition has been generated (a start condition is detected)
- When the ICSR2.AL (arbitration-lost) flag is set to 1
- When 1 is written to the ICCR1.IICRST bit to apply an RIIC reset or an internal reset

Note: Do not set the RS bit to 1 while generating a stop condition.

Note: If 1 (requests to generate a restart condition) is written to the RS bit in slave mode, the restart condition is not generated but the RS bit remains set to 1. If the operating mode changes to master mode with the bit not being cleared, note that the restart condition may be generated.

**SP Bit (Stop Condition Generation Request)**

This bit is used to request that a stop condition be generated in master mode.

When this bit is set to 1 to request to generate a stop condition, a stop condition is generated when the BBSY flag is set to 1 (bus busy state) and the MST bit is set to 1 (master mode).

For details on the stop condition generation, refer to section 33.10, Start Condition/Restart Condition/Stop Condition Generating Function.

[Setting condition]

- When 1 is written to the SP bit with both the BBSY flag and the ICCR2.MST bit set to 1

[Clearing conditions]

- When 0 is written to the SP bit
- When a stop condition has been generated (a stop condition is detected)
- When the ICSR2.AL (arbitration-lost) flag is set to 1
- When a start condition and a restart condition are detected
- When 1 is written to the ICCR1.IICRST bit to apply an RIIC reset or an internal reset

Note: Writing to the SP bit is not possible while the setting of the BBSY flag is 0 (bus free state).

Note: Do not set the SP bit to 1 while a restart condition is being generated.

**TRS Bit (Transmit/Receive Mode)**

This bit indicates transmit or receive mode.

The RIIC is in receive mode when the TRS bit is set to 0 and is in transmit mode when the bit is set to 1. Combination of this bit and the MST bit indicates the operating mode of the RIIC.

The value of the TRS bit is automatically changed to 1 for transmission or 0 for reception in response to the generation or detection of a start condition and setting of the R/W# bit. Although writing to the TRS bit is possible when the ICMR1.MTWP bit is set to 1, writing to this bit is not necessary during normal usage.

[Setting conditions]

- When a start condition is generated normally according to the start condition generation request (when a start condition is detected with the ST bit set to 1)
- When a restart condition is generated normally according to the restart condition generation request (when a restart condition is detected with the RS bit set to 1)
- When the R/W# bit added to the slave address is set to 0 in master mode
- When the address received in slave mode matches the address enabled in the ICSE register, with the R/W# bit set to 1
- When 1 is written to the TRS bit with the ICMR1.MTWP bit set to 1

[Clearing conditions]

- When a stop condition is detected
- The ICSR2.AL (arbitration-lost) flag being set to 1
- In master mode, reception of a slave address to which an R/W# bit with the value 1 is appended
- In slave mode, a match between the received address and the address enabled in the ICSE register when the value of the received R/W# bit is 0 (including cases where the received address is the general call address)
- In slave mode, a restart condition is detected (that is, a start condition is detected while the ICCR2.BBSY flag is 1 and the ICCR2.MST bit is 0)
- When 0 is written to the TRS bit with the ICMR1.MTWP bit set to 1
- When 1 is written to the ICCR1.IICRST bit to apply an RIIC reset or an internal reset

**MST Bit (Master/Slave Mode)**

This bit indicates master or slave mode.

The RIIC is in slave mode when the MST bit is set to 0 and is in master mode when the bit is set to 1. Combination of this bit and the TRS bit indicates the operating mode of the RIIC.

The value of the MST bit is automatically changed to 1 for master mode or 0 for slave mode by generating of a start condition and generating or detection of a stop condition, etc. Although writing to the MST bit is possible when the ICMR1.MTWP bit is set to 1, writing to this bit is not necessary during normal usage.

[Setting conditions]

- When a start condition is generated normally according to the start condition generation request (when a start condition is detected with the ST bit set to 1)
- When 1 is written to the MST bit with the ICMR1.MTWP bit set to 1

[Clearing conditions]

- When a stop condition is detected
- When the ICSR2.AL (arbitration-lost) flag is set to 1
- When 0 is written to the MST bit with the ICMR1.MTWP bit set to 1
- When 1 is written to the ICCR1.IICRST bit to apply an RIIC reset or an internal reset

**BBSY Flag (Bus Busy Detection Flag)**

The BBSY flag indicates whether the I<sup>2</sup>C-bus is occupied (bus busy state) or released (bus free state).

This bit is set to 1 when the SDA0 line changes from high to low under the condition of SCL0 line = high, assuming that a start condition has been generated.

The RIIC recognizes the SDA0 line changing from low to high while the SCL0 line is high as generation of the stop condition. After that, this flag becomes 0 if the RIIC does not detect a start condition during the bus free time (the period set in the ICBRL register).

[Setting condition]

- When a start condition is detected

[Clearing conditions]

- When the bus free time (specified in the ICBRL register) start condition is not detected after detecting a stop condition
- When 1 is written to the ICCR1.IICRST bit with the ICCR1.ICE bit set to 0 (RIIC reset)

### 33.2.3 I<sup>2</sup>C-bus Mode Register 1 (ICMR1)

Note 1. Rewrite the BC[2:0] bits and set the BCWP bit to 0 at the same time.

#### BC[2:0] Bits (Bit Counter)

These bits function as a counter that indicates the number of bits remaining to be transferred at the detection of a rising edge on the SCL0 line. Although these bits are writable and readable, it is not necessary to access these bits under normal conditions.

To write to these bits, specify the number of bits to be transferred plus one (data is transferred with an additional acknowledgment bit) between transferred bytes when the SCL0 line is low.

The values of the BC[2:0] bits return to 000b at the end of a data transfer including the acknowledgment bit or when a start condition including a restart condition is detected.

Note 1. The DLCS bit setting of 1 (IIC $\phi$ /2) only becomes valid when SCL pin is low. When SCL pin is high, the DLCS bit setting of 1 becomes invalid and the clock source becomes the internal reference clock (IIC $\phi$ ).

#### TMOS Bit (Timeout Detection Time Select)

This bit is used to select long mode or short mode for the timeout detection time when the timeout function is enabled (ICFER.TMOE bit is 1). When this bit is set to 0, long mode is selected. When this bit is set to 1, short mode is selected. In long mode, the timeout detection internal counter functions as a 16-bit counter. In short mode, the counter functions as a 14-bit counter. While the SCL0 line is in the state that enables this counter as specified by bits TMOH and TMOL, the counter counts up in synchronization with the internal reference clock (IIC $\phi$ ) as a count source.

For details on the timeout function, refer to section 33.11.1, Timeout Function.

**TMOL Bit (Timeout L Count Control)**

This bit is used to enable or disable the internal counter of the timeout function to count up while the SCL0 line is held low when the timeout function is enabled (ICFER.TMOE bit is 1).

**TMOH Bit (Timeout H Count Control)**

This bit is used to enable or disable the internal counter of the timeout function to count up while the SCL0 line is held high when the timeout function is enabled (ICFER.TMOE bit is 1).

**SDDL[2:0] Bits (SDA Output Delay Counter)**

The SDA output can be delayed by the SDDL[2:0] setting. This counter works with the clock source selected by the DLCS bit. The setting of this function can be used for all types of SDA output, including the transmission of the acknowledgment bit.

Set the SDA output delay time to meet the I<sup>2</sup>C-bus specification (within the data valid time/data valid acknowledge time\*<sup>1</sup>) or the SMBus specification (more than the data hold time (300 ns) and less than “clock low period – data setup time (250 ns)”). Note that, if a value outside the specification is set, communication with communication devices may malfunction or it may seemingly become a start condition or stop condition depending on the bus state.

For details on this function, refer to section 33.5, SDA Output Delay Function.

Note 1. Data valid time/data valid acknowledge time  
3,450 ns (up to 100 kbps: Standard-mode (Sm))  
900 ns (up to 400 kbps: Fast-mode (Fm))

| b6     | WAIT    | WAIT                              | 0: No WAIT<br>(The period between ninth clock pulse and first clock pulse is not held low.)<br>1: WAIT<br>(The period between ninth clock pulse and first clock pulse is held low.)<br>Low-hold is released by reading the ICDRR register.                                                                                                                 | R/W*2 |
| b7     | SMBS    | SMBus/I <sup>2</sup> C-bus Select | 0: The I <sup>2</sup> C-bus is selected.<br>1: The SMBus is selected.                                                                                                                                                                                                                                                                                      | R/W   |

Note 1. Write to the ACKBT bit only while the ACKWP bit is already 1. If it is attempted to write 1 to both the ACKWP and ACKBT bits at the same time, the ACKBT bit will not be set to 1.

Note 2. The WAIT and RDRFS bits are valid only in receive mode (invalid in transmit mode).

#### NF[1:0] Bits (Noise Filter Stage Select)

These bits are used to select the number of stages in the digital noise filter.

For details on the digital noise filter function, refer to section 33.6, Digital Noise Filters.

Note: Set the noise range to be filtered out by the noise filter within a range less than the SCL0 line high period or low period. If the noise filter width is set to a value of [the shorter one of either SCL high width or SCL low width] – 1.5 ×  $t_{IICcyc}$  (cycle time of internal reference clock (IIC $\phi$ )) or a greater value, the serial clock is regarded as noise by the noise filter function of the RIIC, which may prevent the RIIC from operating normally.

**ACKBR Bit (Received Acknowledge)**

This bit is used to store the value of the acknowledgment bit received from the receiver in transmit mode.

[Setting condition]

- When 1 is received as the acknowledgment bit with the ICCR2.TRS bit set to 1

[Clearing conditions]

- When 0 is received as the acknowledgment bit with the ICCR2.TRS bit set to 1
- When 1 is written to the ICCR1.IICRST bit while the ICCR1.ICE bit is 0 (RIIC reset)

**ACKBT Bit (Transmit Acknowledge)**

This bit is used to set the bit to be sent at the acknowledgment timing in receive mode.

[Setting condition]

- When 1 is written to this bit with the ACKWP bit set to 1

[Clearing conditions]

- When 0 is written to this bit with the ACKWP bit set to 1
- When stop condition generation is detected (when a stop condition is detected with the ICCR2.SP bit set to 1)
- When 1 is written to the ICCR1.IICRST bit while the ICCR1.ICE bit is 0 (RIIC reset)

**ACKWP Bit (ACKBT Write Protect)**

This bit is used to control the modification of the ACKBT bit.

**RDRFS Bit (RDRF Flag Set Timing Select)**

This bit is used to select the RDRF flag set timing in receive mode and also to select whether to hold the SCL0 line low at the falling edge of the eighth SCL.

When the RDRFS bit is 0, the SCL0 line is not held low at the falling edge of the eighth SCL, and the RDRF flag is set to 1 at the rising edge of the ninth SCL.

When the RDRFS bit is 1, the RDRF flag is set to 1 at the rising edge of the eighth SCL and the SCL0 line is held low at the falling edge of the eighth SCL. The low-hold of the SCL0 line is released by writing a value to the ACKBT bit.

After data is received with this setting, the SCL0 line is automatically held low before the acknowledgment bit is sent.

This enables processing to send ACK (ACKBT bit is 0) or NACK (ACKBT bit is 1) according to receive data.

**WAIT Bit (WAIT)**

This bit is used to control whether to hold the period between the ninth SCL and the first SCL low until the I<sup>2</sup>C-bus receive data register (ICDRR) is completely read each time single-byte data is received in receive mode.

When the WAIT bit is 0, the receive operation is continued without holding the period between the ninth and the first SCL low. When both the RDRFS and WAIT bits are 0, continuous receive operation is enabled with the double buffer.

When the WAIT bit is 1, the SCL0 line is held low from the falling edge of the ninth SCL until the ICDRR register value is read each time single-byte data is received. This enables receive operation in byte units.

Note: When the value of the WAIT bit is to be read, be sure to read the ICDRR register beforehand.

**SMBS Bit (SMBus/I<sup>2</sup>C-bus Select)**

Setting this bit to 1 selects the SMBus and enables the IC SER.HOAE bit.

### 33.2.6 I<sup>2</sup>C-bus Function Enable Register (ICFER)

| b7  | —      | Reserved                                            | This bit is read as 0. The write value should be 0.                                                                                                                                                                                                                                                                                                                                  | R/W |

#### TMOE Bit (Timeout Function Enable)

This bit is used to enable or disable the timeout function.

For details on the timeout function, refer to section 33.11.1, Timeout Function.

#### MALE Bit (Master Arbitration-Lost Detection Enable)

This bit is used to specify whether to use the arbitration-lost detection function in master mode. Normally, set this bit to 1.

#### NALE Bit (NACK Transmission Arbitration-Lost Detection Enable)

This bit is used to specify whether to cause arbitration to be lost when ACK is detected during transmission of NACK in receive mode (such as when slaves with the same address exist on the bus or when two or more masters select the same slave device simultaneously with different number of receive bytes).

#### SALE Bit (Slave Arbitration-Lost Detection Enable)

This bit is used to specify whether to cause arbitration to be lost when a value different from the value being transmitted is detected on the bus in slave transmit mode (such as when slaves with the same address exist on the bus or when a mismatch with the transmit data occurs due to noise).

**NACKE Bit (NACK Reception Transfer Suspension Enable)**

This bit is used to specify whether to continue or discontinue the data transfer when NACK is received in transmit mode. Normally, set this bit to 1.

When NACK is received with the NACKE bit set to 1, the next transfer operation is suspended.

When the NACKE bit is 0, the next transfer operation is continued regardless of the value of the received acknowledgment bit.

For details on the NACK reception transfer suspension function, refer to section 33.8.2, NACK Reception Transfer Suspension Function.

**SCLE Bit (SCL Synchronization Enable)**

This bit is used to specify whether the SCL output is to be synchronized with the SCL input. Normally, set this bit to 1. When the SCLE bit is set to 0 (SCL synchronization is disabled), the RIIC does not synchronize the SCL output with the SCL input. In this setting, the RIIC outputs the clock with the transfer rate set in registers ICBRH and ICBRL regardless of the SCL0 line state. For this reason, if the load of the I<sup>2</sup>C-bus line is much larger than the specification value or if the SCL output overlaps in multiple masters, the short-cycle SCL that does not meet the specification may be output. When the SCL synchronization is not used, it also affects the generation of a start condition, restart condition, and stop condition, and the continuous output of additional SCL.

This bit must not be set to 0 except for checking the output of the set transfer rate.

### 33.2.7 I<sup>2</sup>C-bus Status Enable Register (ICSER)

| b7  | HOAE   | Host Address Enable                | 0: Host address detection is disabled.<br>1: Host address detection is enabled.                                         | R/W |

#### SAR<sub>y</sub>E Bit (Slave Address Register *y* Enable) (*y* = 0 to 2)

This bit is used to enable or disable the slave address set in registers SARL<sub>y</sub> and SARU<sub>y</sub>.

When this bit is set to 1, the slave address set in registers SARL<sub>y</sub> and SARU<sub>y</sub> is enabled and is compared with the received slave address.

When this bit is set to 0, the slave address set in registers SARL<sub>y</sub> and SARU<sub>y</sub> is disabled and is ignored even if it matches the received slave address.

#### GCAE Bit (General Call Address Enable)

This bit is used to specify whether to ignore the general call address (0000 000b + 0 (write): All 0) when it is received.

When this bit is set to 1, if the received slave address matches the general call address, the RIIC recognizes the received slave address as the general call address independently of the slave addresses set in registers SARL<sub>y</sub> and SARU<sub>y</sub> (*y* = 0 to 2) and performs data receive operation.

When this bit is set to 0, the received slave address is ignored even if it matches the general call address.

#### DIDE Bit (Device-ID Address Detection Enable)

This bit is used to specify whether to recognize and execute the device-ID address when a device ID (1111 100b) is received in the first byte after a start condition or restart condition is detected.

When this bit is set to 1, if the received first byte matches the device ID, the RIIC recognizes that the device-ID address has been received. When the following R/W# bit is 0 (write), the RIIC recognizes the second and the following bytes as slave addresses and continues the receive operation.

When this bit is set to 0, the RIIC ignores the received first byte even if it matches the device ID address and recognizes the first byte as a normal slave address.

For details on the device-ID address detection, refer to section 33.7.3, Device-ID Address Detection.

**HOAE Bit (Host Address Enable)**

This bit is used to specify whether to ignore received host address (0001 000b) when the ICMR3.SMBS bit is 1.

When this bit is set to 1 while the ICMR3.SMBS bit is 1, if the received slave address matches the host address, the RIIC recognizes the received slave address as the host address independently of the slave addresses set in registers SARLy and SARUy (y = 0 to 2) and performs the receive operation.

When the ICMR3.SMBS bit or the HOAE bit is set to 0, the received slave address is ignored even if it matches the host address.

### 33.2.8 I<sup>2</sup>C-bus Interrupt Enable Register (ICIER)

Address(es): RIIC0.ICIER 0008 8307h

| b7  | TIE    | Transmit Data Empty Interrupt Request Enable       | 0: Transmit data empty interrupt (TXI) request is disabled.<br>1: Transmit data empty interrupt (TXI) request is enabled.             | R/W |

#### TMOIE Bit (Timeout Interrupt Request Enable)

This bit is used to enable or disable timeout interrupt (TMOI) requests when the ICSR2.TMOF flag is set to 1. A TMOI interrupt request is canceled by setting the TMOF flag or the TMOIE bit to 0.

#### ALIE Bit (Arbitration-Lost Interrupt Request Enable)

This bit is used to enable or disable arbitration-lost interrupt (ALI) requests when the ICSR2.AL flag is set to 1. An ALI interrupt request is canceled by setting the AL flag or the ALIE bit to 0.

#### STIE Bit (Start Condition Detection Interrupt Request Enable)

This bit is used to enable or disable start condition detection interrupt (STI) requests when the ICSR2.START flag is set to 1. An STI interrupt request is canceled by setting the START flag or the STIE bit to 0.

#### SPIE Bit (Stop Condition Detection Interrupt Request Enable)

This bit is used to enable or disable stop condition detection interrupt (SPI) requests when the ICSR2.STOP flag is set to 1. An SPI interrupt request is canceled by setting the STOP flag or the SPIE bit to 0.

#### NAKIE Bit (NACK Reception Interrupt Request Enable)

This bit is used to enable or disable NACK reception interrupt (NAKI) requests when the ICSR2.NACKF flag is set to 1. An NAKI interrupt request is canceled by setting the NACKF flag or the NAKIE bit to 0.

#### RIE Bit (Receive Data Full Interrupt Request Enable)

This bit is used to enable or disable receive data full interrupt (RXI) requests when the ICSR2.RDRF flag is set to 1.

**TEIE Bit (Transmission End Interrupt Request Enable)**

This bit is used to enable or disable transmission end interrupt (TEI) requests when the ICSR2.TEND flag is set to 1. An TEI interrupt request is canceled by setting the TEND flag or the TEIE bit to 0.

**TIE Bit (Transmit Data Empty Interrupt Request Enable)**

This bit is used to enable or disable transmit data empty interrupt (TXI) requests when the ICSR2.TDRE flag is set to 1.

Note 1. Only 0 can be written to clear the flag.

#### AAS<sub>y</sub> Flag (Slave Address y Detection Flag) (y = 0 to 2)

[Setting conditions]

For 7-bit address format: SARU<sub>y</sub>.FS bit = 0

- When the received slave address matches the SARL<sub>y</sub>.SVA[6:0] bits value with the ICSE<sub>R</sub>.SAR<sub>y</sub>E bit set to 1 (slave address y detection enabled)

This flag is set to 1 at the rising edge of the ninth SCL in the first byte.

For 10-bit address format: SARU<sub>y</sub>.FS bit = 1

- When the received slave address matches a value of (11110b + SARU<sub>y</sub>.SVA[1:0] bits) and the following address matches the SARL<sub>y</sub> value with the ICSE<sub>R</sub>.SAR<sub>y</sub>E bit set to 1 (slave address y detection enabled)

This flag is set to 1 at the rising edge of the ninth SCL in the second byte.

[Clearing conditions]

- When 0 is written to the AAS<sub>y</sub> flag after reading the AAS<sub>y</sub> flag to be 1
- When a stop condition is detected
- When 1 is written to the ICCR1.IICRST bit to apply an RIIC reset or an internal reset

For 7-bit address format: SARU<sub>y</sub>.FS bit = 0

- When the received slave address does not match the SARL<sub>y</sub>.SVA[6:0] bits value with the ICSE<sub>R</sub>.SAR<sub>y</sub>E bit set to 1 (slave address y detection enabled)

This flag is set to 0 at the rising edge of the ninth SCL in the first byte.

For 10-bit address format: SARUy.FS bit = 1

- When the received slave address does not match a value of (11110b + SARUy.SVA[1:0] bits) with the ICSEr.SARyE bit set to 1 (slave address y detection enabled)  
This flag is set to 0 at the rising edge of the ninth SCL in the first byte.
- When the received slave address matches a value of (11110b + SARUy.SVA[1:0] bits) and the following address does not match the SARLy value with the ICSEr.SARyE bit set to 1 (slave address y detection enabled)  
This flag is set to 0 at the rising edge of the ninth SCL in the second byte.

### GCA Flag (General Call Address Detection Flag)

[Setting condition]

- When the received slave address matches the general call address (0000 000b + 0 (write)) with the ICSEr.GCAE bit set to 1 (general call address detection is enabled)  
This flag is set to 1 at the rising edge of the ninth SCL in the first byte.

[Clearing conditions]

- When 0 is written to the GCA flag after reading GCA flag to be 1
- When a stop condition is detected
- When the received slave address does not match the general call address (0000 000b + 0 (write)) with the ICSEr.GCAE bit set to 1 (general call address detection is enabled)  
This flag is set to 0 at the rising edge of the ninth SCL in the first byte.
- When 1 is written to the ICCR1.IICRST bit to apply an RIIC reset or an internal reset

### DID Flag (Device-ID Address Detection Flag)

[Setting condition]

- When the first byte received immediately after a start condition or restart condition is detected matches a value of (device ID (1111 100b) + 0 (write)) with the ICSEr.DIDE bit set to 1 (device-ID address detection is enabled)  
This flag is set to 1 at the rising edge of the ninth SCL in the first byte.

[Clearing conditions]

- When 0 is written to the DID flag after reading DID flag to be 1
- When a stop condition is detected
- When the first byte received immediately after a start condition or restart condition is detected does not match a value of (device ID (1111 100b)) with the ICSEr.DIDE bit set to 1 (device-ID address detection is enabled)  
This flag is set to 0 at the rising edge of the ninth SCL in the first byte.
- When the first byte received immediately after a start condition or restart condition is detected matches a value of (device ID (1111 100b) + 0 (write)) and the second byte does not match any of slave addresses 0 to 2 with the ICSEr.DIDE bit set to 1 (device-ID address detection is enabled)  
This flag is set to 0 at the rising edge of the ninth SCL in the second byte.
- When 1 is written to the ICCR1.IICRST bit to apply an RIIC reset or an internal reset

### HOA Flag (Host Address Detection Flag)

[Setting condition]

- When the received slave address matches the host address (0001 000b) with the ICSEr.HOAE bit set to 1 (host address detection is enabled)  
This flag is set to 1 at the rising edge of the ninth SCL in the first byte.

[Clearing conditions]

- When 0 is written to the HOA flag after reading HOA flag to be 1
- When a stop condition is detected
- When the received slave address does not match the host address (0001 000b) with the ICSEr.HOAE bit set to 1

(host address detection is enabled)

This flag is set to 0 at the rising edge of the ninth SCL in the first byte.

- When 1 is written to the ICCR1.IICRST bit to apply an RIIC reset or an internal reset

### 33.2.10 I<sup>2</sup>C-bus Status Register 2 (ICSR2)

| b5  | RDRF   | Receive Data Full Flag         | 0: The ICDRR register contains no receive data.<br>1: The ICDRR register contains receive data.   | R/(W)<br>*1 |
| b6  | TEND   | Transmission End Flag          | 0: Data is being transmitted.<br>1: Data has been transmitted.                                    | R/(W)<br>*1 |
| b7  | TDRE   | Transmit Data Empty Flag       | 0: The ICDRT register contains transmit data.<br>1: The ICDRT register contains no transmit data. | R           |

Note 1. Only 0 can be written to clear the flag.

#### TMOF Flag (Timeout Detection Flag)

This flag is set to 1 when the RIIC recognizes timeout after the SCL0 line state remains unchanged for a certain period.  
[Setting condition]

- When the SCL0 line state remains unchanged for the period specified by bits ICMR2.TMOH, TMOL, and TMOS while the ICFER.TMOE bit is 1 (the timeout function is enabled) in master mode or in slave mode and the received slave address matches.

[Clearing conditions]

- When 0 is written to the TMOF bit after reading TMOF = 1
- When 1 is written to the ICCR1.IICRST bit to apply an RIIC reset or an internal reset

#### AL Flag (Arbitration-Lost Flag)

This flag shows that bus mastership has been lost (loss in arbitration) due to a bus conflict or some other reason when a start condition is generated or an address and data are transmitted. The RIIC monitors the level on the SDA0 line during transmission and, if the level on the line does not match the value of the bit being output, sets the value of the AL flag to 1 to indicate that the bus is occupied by another device.

The RIIC can also detect loss of arbitration during NACK transmission in receive mode or during data transmission in slave mode.

## [Setting conditions]

When master arbitration-lost detection is enabled: ICFER.MALE = 1

- When the internal SDA output state does not match the SDA0 line level at the rising edge of SCL except for the ACK period during data (including slave address) transmission in master transmit mode (when the SDA0 line is driven low while the internal SDA output is high (the SDA0 pin is in the high-impedance state))
- When a start condition is detected while the ICCR2.ST bit is 1 (requests to generate a start condition) or the internal SDA output state does not match the SDA0 line level
- When the ICCR2.ST bit is set to 1 (requests to generate a start condition) with the ICCR2.BBSY flag set to 1.

When NACK arbitration-lost detection is enabled: ICFER.NALE = 1

- When the internal SDA output state does not match the SDA0 line level at the rising edge of SCL in the ACK period during NACK transmission in receive mode

When slave arbitration-lost detection is enabled: ICFER.SALE = 1

- When the internal SDA output state does not match the SDA0 line level at the rising edge of SCL except for the ACK period during data transmission in slave transmit mode

## [Clearing conditions]

- When 0 is written to the AL flag after reading AL = 1
- When 1 is written to the ICCR1.IICRST bit to apply an RIIC reset or an internal reset

**Table 33.4 Relationship between Arbitration-Lost Generation Sources and Arbitration-Lost Enable Functions**

| ICFER |      |      | ICSR2 | Error                            | Arbitration-Lost Generation Source                                                                                                                                                          |

| x     | x    | 1    | 1     | Transmit data mismatch           | When transmit data does not match the bus state in slave transmit mode                                                                                                                      |

x: Don't care

### START Flag (Start Condition Detection Flag)

## [Setting condition]

- When a start condition (or a restart condition) is detected

## [Clearing conditions]

- When 0 is written to the START bit after reading START = 1
- When a stop condition is detected
- When 1 is written to the ICCR1.IICRST bit to apply an RIIC reset or an internal reset

### STOP Flag (Stop Condition Detection Flag)

## [Setting condition]

- When a stop condition is detected

## [Clearing conditions]

- When 0 is written to the STOP bit after reading STOP = 1
- When 1 is written to the ICCR1.IICRST bit to apply an RIIC reset or an internal reset

**NACKF Flag (NACK Detection Flag)**

[Setting condition]

- When ACK is not received (NACK is received) from the receiver in transmit mode with the ICFER.NACKE bit set to 1 (transfer suspension enabled)

[Clearing conditions]

- When 0 is written to the NACKF bit after reading NACKF = 1
- When 1 is written to the ICCR1.IICRST bit to apply an RIIC reset or an internal reset

Note: When the NACKF flag is set to 1, the RIIC suspends data transmission/reception. Writing to the ICDRT register in transmit mode or reading from the ICDRR register in receive mode with the NACKF flag set to 1 does not enable data transmit/receive operation. To restart data transmission/reception, set the NACKF flag to 0.

**RDRF Flag (Receive Data Full Flag)**

[Setting conditions]

- When receive data has been transferred from the ICDRS register to the ICDRR register  
This flag is set to 1 at the rising edge of the eighth or ninth SCL (selected by the ICMR3.RDRFS bit)
- When the received slave address matches after a start condition (or a restart condition) is detected with the ICCR2.TRS bit set to 0

[Clearing conditions]

- When 0 is written to the RDRF bit after reading RDRF = 1
- When data is read from the ICDRR register
- When 1 is written to the ICCR1.IICRST bit to apply an RIIC reset or an internal reset

**TEND Flag (Transmission End Flag)**

[Setting condition]

- At the rising edge of the ninth SCL while the TDRE flag is 1

[Clearing conditions]

- When 0 is written to the TEND bit after reading TEND = 1
- When data is written to the ICDRT register
- When a stop condition is detected
- When 1 is written to the ICCR1.IICRST bit to apply an RIIC reset or an internal reset

**TDRE Flag (Transmit Data Empty Flag)**

[Setting conditions]

- When data has been transferred from the ICDRT register to the ICDRS register and the ICDRT register becomes empty
- When the ICCR2.TRS bit is set to 1
- When the received slave address matches while the TRS bit is 1

[Clearing conditions]

- When data is written to the ICDRT register
- When the ICCR2.TRS bit is set to 0
- When 1 is written to the ICCR1.IICRST bit to apply an RIIC reset or an internal reset

Note: The NACKF flag becoming 1 while the ICFER.NACKE bit is 1 suspends data transmission and reception by the RIIC. Even if the next data for transmission has already been written to the ICDRT register (the TDRE flag is 0), the data in the ICDRT register is retained but not transferred to the ICDRS register. At this point, the TDRE flag does not become 1.

### 33.2.11 Slave Address Register Ly (SARLy) (y = 0 to 2)

Address(es): RIIC0.SARL0 0008 830Ah, RIIC0.SARL1 0008 830Ch, RIIC0.SARL2 0008 830Eh

| Bit      | Symbol   | Bit Name                                | Description         | R/W |
|----------|----------|-----------------------------------------|---------------------|-----|
| b0       | SVA0     | 10-Bit Address LSB                      | Set a slave address | R/W |
| b7 to b1 | SVA[6:0] | 7-Bit Address/10-Bit Address Lower Bits | Set a slave address | R/W |

#### SVA0 Bit (10-Bit Address LSB)

When the 10-bit address format is selected (SARUy.FS bit is 1), this bit functions as the LSB of a 10-bit address and forms the lower 8 bits of a 10-bit address in combination with the SVA[6:0] bits.

When the ICSEr.SARyE bit is set to 1 (SARLy and SARUy enabled) and the SARUy.FS bit is 1, this bit is valid. While the SARUy.FS bit or SARyE bit is 0, the setting of this bit is ignored.

#### SVA[6:0] Bits (7-Bit Address/10-Bit Address Lower Bits)

When the 7-bit address format is selected (SARUy.FS bit is 0), these bits function as a 7-bit address. When the 10-bit address format is selected (SARUy.FS bit is 1), these bits function as the lower 8 bits of a 10-bit address in combination with the SVA0 bit.

While the ICSEr.SARyE bit is 0, the setting of these bits is ignored.

### 33.2.12 Slave Address Register Uy (SARUy) (y = 0 to 2)

Address(es): RIIC0.SARU0 0008 830Bh, RIIC0.SARU1 0008 830Dh, RIIC0.SARU2 0008 830Fh

| Bit      | Symbol   | Bit Name                           | Description                                                                           | R/W |
|----------|----------|------------------------------------|---------------------------------------------------------------------------------------|-----|
| b0       | FS       | 7-Bit/10-Bit Address Format Select | 0: The 7-bit address format is selected.<br>1: The 10-bit address format is selected. | R/W |
| b2, b1   | SVA[1:0] | 10-Bit Address Upper Bits          | Set a slave address                                                                   | R/W |
| b7 to b3 | —        | Reserved                           | These bits are read as 0. The write value should be 0.                                | R/W |

#### FS Bit (7-Bit/10-Bit Address Format Select)

This bit is used to select 7-bit address or 10-bit address for slave address y (in registers SARLy and SARUy).

When the IC SER.SARyE bit is set to 1 (registers SARLy and SARUy enabled) and the SARUy.FS bit is 0, the 7-bit address format is selected for slave address y, the SARLy.SVA[6:0] bits setting is valid, and the settings of the SVA[1:0] bits and the SARLy.SVA0 bit are ignored.

When the IC SER.SARyE bit is set to 1 (registers SARLy and SARUy enabled) and the SARUy.FS bit is 1, the 10-bit address format is selected for slave address y and the settings of the SVA[1:0] bits and SARLy are valid.

While the IC SER.SARyE bit is 0 (registers SARLy and SARUy disabled), the setting of the SARUy.FS bit is invalid.

#### SVA[1:0] Bits (10-Bit Address Upper Bits)

When the 10-bit address format is selected (FS = 1), these bits function as the upper 2 bits of a 10-bit address.

When the IC SER.SARyE bit is set to 1 (SARLy and SARUy enabled) and the SARUy.FS bit is 1, these bits are valid.

While the SARUy.FS bit or SARyE bit is 0, the setting of these bits is ignored.

### 33.2.13 I<sup>2</sup>C-bus Bit Rate Low-Level Register (ICBRL)

Address(es): RIIC0.ICBRL 0008 8310h

| Bit      | Symbol   | Bit Name            | Description                                            | R/W |
|----------|----------|---------------------|--------------------------------------------------------|-----|
| b4 to b0 | BRL[4:0] | Bit Rate Low Period | Low period of SCL                                      | R/W |
| b7 to b5 | —        | Reserved            | These bits are read as 1. The write value should be 1. | R/W |

ICBRL is a 5-bit register to set the low period of SCL.

It also works to generate the data setup time for automatic SCL low-hold operation (refer to section 33.8, Automatic Low-Hold Function for SCL); when the RIIC is used only in slave mode, this register needs to be set to a value longer than the data setup time\*1.

ICBRL counts the low period with the internal reference clock ( $IIC\phi$ ) specified by the ICMR1.CKS[2:0] bits.

If the digital noise filter is enabled (the ICFER.NFE bit is 1), set the ICBRL register to a value at least one greater than the number of stages in the noise filter. Regarding the number of stages in the noise filter, see the description of the ICMR3.NF[1:0] bits.

Note 1. Data setup time (t<sub>SU</sub>: DAT)

250 ns (up to 100 kbps: Standard-mode (Sm))

100 ns (up to 400 kbps: Fast-mode (Fm))

### 33.2.14 I<sup>2</sup>C-bus Bit Rate High-Level Register (ICBRH)

Address(es): RIIC0.ICBRH 0008 8311h

| Bit      | Symbol   | Bit Name             | Description                                            | R/W |
|----------|----------|----------------------|--------------------------------------------------------|-----|
| b4 to b0 | BRH[4:0] | Bit Rate High Period | High period of SCL                                     | R/W |
| b7 to b5 | —        | Reserved             | These bits are read as 1. The write value should be 1. | R/W |

ICBRH is a 5-bit register to set the high period of SCL. ICBRH is valid in master mode. If the RIIC is used only in slave mode, this register need not to set the high period.

ICBRH counts the high period with the internal reference clock ( $IIC\phi$ ) specified by the ICMR1.CKS[2:0] bits.

If the digital noise filter is enabled (the ICFER.NFE bit is 1), set the ICBRH register to a value at least one greater than the number of stages in the noise filter. Regarding the number of stages in the noise filter, see the description of the ICMR3.NF[1:0] bits.

The I<sup>2</sup>C transfer rate and the SCL duty are calculated using the following expression.

$$\text{Transfer rate} = 1 / \{[(ICBRH + 1) + (ICBRL + 1)] / IIC\phi + SCL0 \text{ line rise time } [tr] + SCL0 \text{ line fall time } [tf]\}$$

$$\text{Duty cycle} = \{SCL0 \text{ line rise time } [tr]^2 + (ICBRH + 1) / IIC\phi\} / \{SCL0 \text{ line fall time } [tf]^2 + (ICBRL + 1) / IIC\phi\}$$

Note 1.  $IIC\phi = PCLK \times \text{Division ratio}$

Note 2. The SCL0 line rise time [tr] and SCL0 line fall time [tf] depend on the total bus line capacitance [Cb] and the pull-up resistor [Rp]. For details, refer to the I<sup>2</sup>C-bus specification from NXP Semiconductors.

Table 33.5 lists examples of ICBRH/ICBRL settings.

Table 33.5 Examples of ICBRH/ICBRL Settings for Transfer Rate

| Transfer Rate (kbps) | Operating Frequency PCLK (MHz) |          |          |          |          |          |          |          |          |
|----------------------|--------------------------------|----------|----------|----------|----------|----------|----------|----------|----------|
|                      | 8                              |          |          | 10       |          |          | 12.5     |          |          |
|                      | CKS[2:0]                       | ICBRH    | ICBRL    | CKS[2:0] | ICBRH    | ICBRL    | CKS[2:0] | ICBRH    | ICBRL    |
| 10                   | 100b                           | 22 (F6h) | 25 (F9h) | 101b     | 13 (EDh) | 15 (EFh) | 101b     | 16 (F0h) | 20 (F4h) |
| 50                   | 010b                           | 16 (F0h) | 19 (F3h) | 010b     | 21 (F5h) | 24 (F8h) | 011b     | 12 (ECh) | 15 (EFh) |
| 100                  | 001b                           | 15 (EFh) | 18 (F2h) | 001b     | 19 (F3h) | 23 (F7h) | 001b     | 24 (F8h) | 29 (FDh) |

| Transfer Rate (kbps) | Operating Frequency PCLK (MHz) |          |          |          |          |          |          |          |          |
|                      | 16                             |          |          | 20       |          |          | 25       |          |          |
|                      | CKS[2:0]                       | ICBRH    | ICBRL    | CKS[2:0] | ICBRH    | ICBRL    | CKS[2:0] | ICBRH    | ICBRL    |
| 10                   | 101b                           | 22 (F6h) | 25 (F9h) | 110b     | 13 (EDh) | 15 (EFh) | 110b     | 16 (F0h) | 20 (F4h) |
| 50                   | 011b                           | 16 (F0h) | 19 (F3h) | 011b     | 21 (F5h) | 24 (F8h) | 100b     | 12 (ECh) | 15 (EFh) |
| 100                  | 010b                           | 15 (EFh) | 18 (F2h) | 010b     | 19 (F3h) | 23 (F7h) | 010b     | 24 (F8h) | 29 (FDh) |
| 400                  | 000b                           | 9 (E9h)  | 20 (F4h) | 000b     | 11 (EBh) | 25 (F9h) | 001b     | 7 (E7h)  | 16 (F0h) |
| Transfer Rate (kbps) | Operating Frequency PCLK (MHz) |          |          |          |          |          |          |          |          |
|                      | 30                             |          |          | 32       |          |          | 33       |          |          |
|                      | CKS[2:0]                       | ICBRH    | ICBRL    | CKS[2:0] | ICBRH    | ICBRL    | CKS[2:0] | ICBRH    | ICBRL    |
| 10                   | 110b                           | 20 (F4h) | 24 (F8h) | 110b     | 22 (F6h) | 25 (F9h) | 110b     | 22 (F6h) | 26 (FAh) |
| 50                   | 100b                           | 15 (EFh) | 18 (F2h) | 100b     | 16 (F0h) | 19 (F3h) | 100b     | 17 (F1h) | 20 (F4h) |
| 100                  | 011b                           | 14 (EEh) | 17 (F1h) | 011b     | 15 (EFh) | 18 (F2h) | 011b     | 16 (F0h) | 19 (F3h) |
| 400                  | 001b                           | 8 (E8h)  | 19 (F3h) | 001b     | 9 (E9h)  | 20 (F4h) | 001b     | 9 (E9h)  | 21 (F5h) |
| Transfer Rate (kbps) | Operating Frequency PCLK (MHz) |          |          |          |          |          |          |          |          |
|                      | 40                             |          |          | 50       |          |          | 60       |          |          |
|                      | CKS[2:0]                       | ICBRH    | ICBRL    | CKS[2:0] | ICBRH    | ICBRL    | CKS[2:0] | ICBRH    | ICBRL    |
| 10                   | 111b                           | 13 (EDh) | 15 (EFh) | 111b     | 16 (F0h) | 20 (F4h) | 111b     | 20 (F4h) | 24 (F8h) |
| 50                   | 100b                           | 21 (F5h) | 24 (F8h) | 100b     | 26 (FAh) | 31 (FFh) | 101b     | 15 (EFh) | 18 (F2h) |
| 100                  | 011b                           | 19 (F3h) | 23 (F7h) | 011b     | 24 (F8h) | 29 (FDh) | 100b     | 14 (EEh) | 17 (F1h) |
| 400                  | 001b                           | 11 (EBh) | 25 (F9h) | 010b     | 7 (E7h)  | 16 (F0h) | 010b     | 8 (E8h)  | 19 (F3h) |

Note: ICBRH/ICBRL settings in these tables are calculated using the following values:  
SCL0 line rise time (tr): 100 kbps or less (Sm): 1000 ns, 400 kbps or less (Fm): 300 ns  
SCL0 line fall time (tf): 400 kbps or less (Sm/Fm): 300 ns  
For the specified values of rise time (tr) and fall time (tf) of the SCL0 signal, refer to the I<sup>2</sup>C-bus specification from NXP Semiconductors.

### 33.2.15 I<sup>2</sup>C-bus Transmit Data Register (ICDRT)

Address(es): RIIC0.ICDRT 0008 8312h

When the ICDRT register detects a space in the I<sup>2</sup>C-bus shift register (ICDRS), it transfers the transmit data that has been written to the ICDRT register to the ICDRS register and starts transmitting data in transmit mode.

The double-buffer structure of the ICDRT register and the ICDRS register allows continuous transmit operation if the next transmit data has been written to the ICDRT register while the ICDRS register data is being transmitted.

The ICDRT register can always be read and written. Write transmit data to the ICDRT register once when a transmit data empty interrupt (TXI) request is generated.

### 33.2.16 I<sup>2</sup>C-bus Receive Data Register (ICDRR)

Address(es): RIIC0.ICDRR 0008 8313h

When 1 byte of data has been received, the received data is transferred from the I<sup>2</sup>C-bus shift register (ICDRS) to the ICDRR register to enable the next data to be received.

The double-buffer structure of the ICDRS register and the ICDRR register allows continuous receive operation if the received data has been read from the ICDRR register while the ICDRS register is receiving data.

The ICDRR register cannot be written. Read data from the ICDRR register once when a receive data full interrupt (RXI) request is generated.

If the ICDRR register receives the next receive data before the current data is read from the ICDRR register (while the ICSR2.RDRF flag is 1), the RIIC automatically holds the SCL line low one cycle before the RDRF flag is set to 1 next.

### 33.2.17 I<sup>2</sup>C-bus Shift Register (ICDRS)

The ICDRS register is an 8-bit shift register to transmit and receive data.

During transmission, transmit data is transferred from the ICDRT register to the ICDRS register and is sent from the SDA0 pin. During reception, data is transferred from the ICDRS register to the ICDRR register after 1 byte of data has been received.

The ICDRS register cannot be accessed directly.

### 33.3 Operation

#### 33.3.1 Communication Data Format

The I<sup>2</sup>C-bus format consists of 8-bit data and 1-bit acknowledgment. The first byte following a start condition or restart condition is an address byte used to specify a slave device with which the master device communicates. The specified slave is valid until a new slave is specified or a stop condition is generated.

Figure 33.2 shows the I<sup>2</sup>C-bus format, and Figure 33.3 shows the I<sup>2</sup>C-bus timing.

**Figure 33.2 I<sup>2</sup>C-bus Format**

**Figure 33.3 I<sup>2</sup>C-bus Timing (SLA = 7 Bits)**

- S: Start condition. The master device drives the SDA0 line low from high while the SCL0 line is high.
- SLA: Slave address, by which the master device selects a slave device.
- R/W#: Indicates the direction of data transfer: from the slave device to the master device when R/W is 1, or from the master device to the slave device when R/W is 0.
- A: Acknowledge. The receiver drives the SDA0 line low. (In master transmit mode, the slave device returns acknowledge. In master receive mode, the master device returns acknowledge.)
- A#: Not Acknowledge. The receiver drives the SDA0 line high.
- Sr: Restart condition. The master device drives the SDA0 line low from high after the setup time has elapsed with the SCL0 line high.
- DATA: Transmitted or received data
- P: Stop condition. The master device drives the SDA0 line high from low while the SCL0 line is high.

### 33.3.2 Initial Settings

Before starting data transmission and reception, initialize the RIIC according to the procedure in Figure 33.4. Set the ICCR1.ICE bit to 1 (internal reset) after setting the ICCR1.IICRST bit to 1 (RIIC reset) with the ICCR1.ICE bit set to 0 (SCL0 and SDA0 pins in inactive state). This initializes the various flags and internal state of the ICSR1 register. After that, set registers SARLy, SARUy, ICSEr, ICMR1, ICBRH, and ICBRL (y = 0 to 2), and set the other registers as necessary (for initial settings of the RIIC, see Figure 33.4). When the necessary register settings have been completed, set the ICCR1.IICRST bit to 0 (releases the RIIC reset). This step is not necessary if initialization of the RIIC has already been completed.

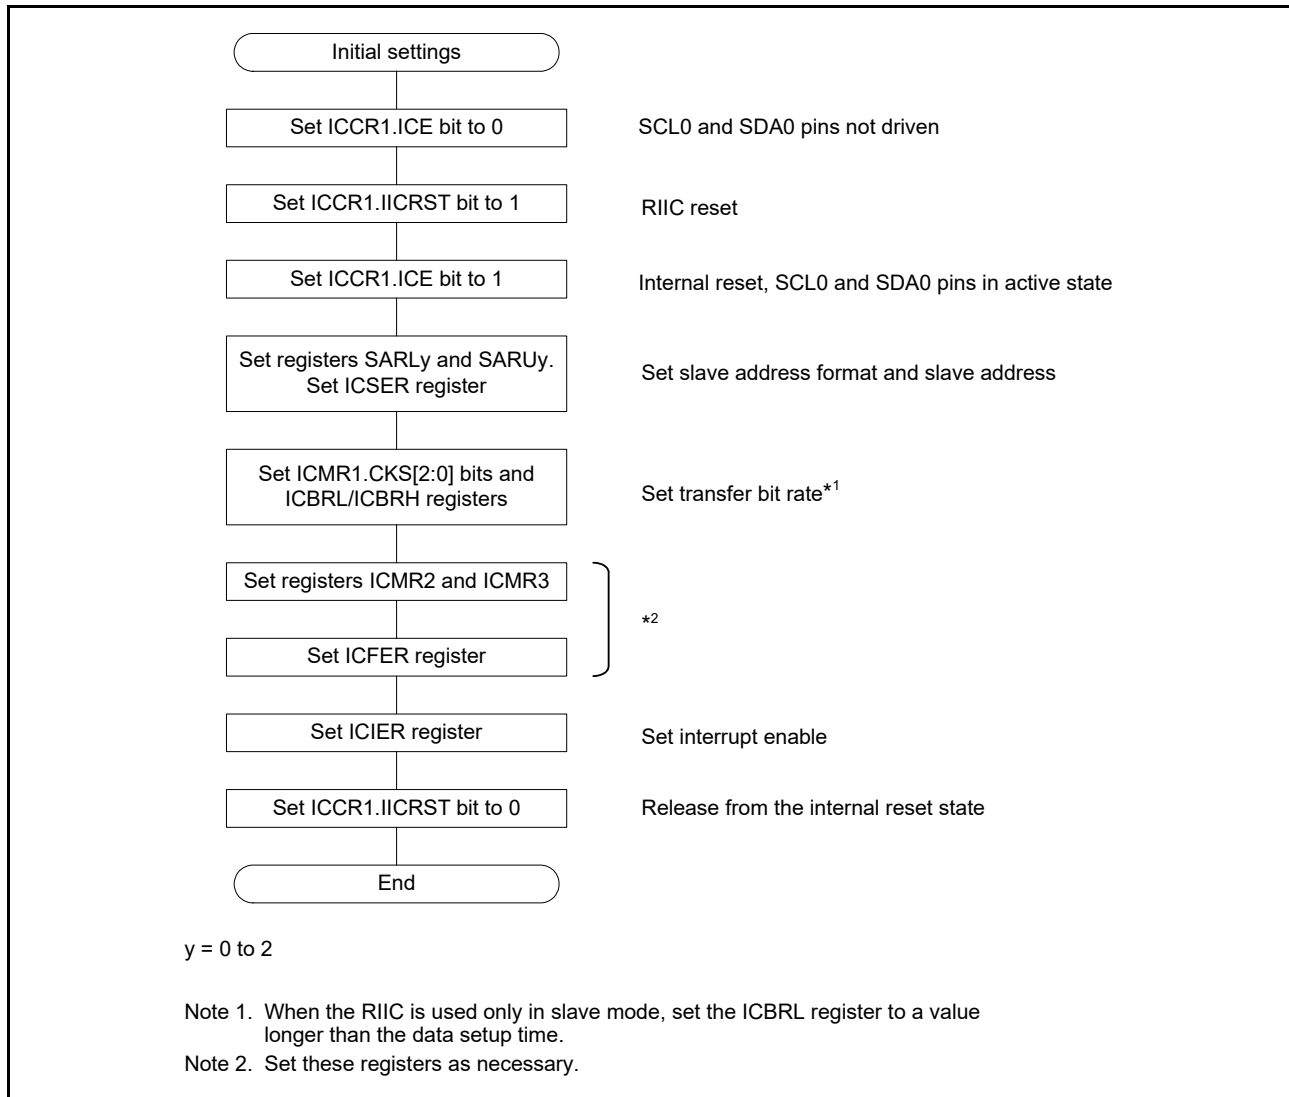

Figure 33.4 Example of RIIC Initialization Flowchart

### 33.3.3 Master Transmit Operation

In master transmit operation, the RIIC generates clock signals and sends data as the master device, and the slave device returns acknowledgments. Figure 33.5 shows an example of usage of master transmission and Figure 33.6 to Figure 33.8 show the timing of operations in master transmission.

The following describes the procedure and operations for master transmission.

- (1) Initial settings. For details, refer to section 33.3.2, Initial Settings.
- (2) Read the ICCR2.BBSY flag to check that the bus is open, and then set the ICCR2.ST bit to 1 (requests to generate a start condition). Upon receiving the request, the RIIC generates a start condition. At the same time, the BBSY flag and the ICSR2.START flag are automatically set to 1 and the ST bit is automatically set to 0. At this time, if the start condition is detected and the internal levels for the SDA output state and the levels on the SDA0 line have matched while the ST bit is 1, the RIIC recognizes that generating of the start condition as requested by the ST bit has been successfully completed, and bits MST and TRS in the ICCR2 register are automatically set to 1, placing the RIIC in master transmit mode. The ICSR2.TDRE flag is also automatically set to 1 in response to setting of the TRS bit to 1.
- (3) Check that the ICSR2.TDRE flag is 1, and then write the value for transmission (the slave address and the R/W# bit) to the ICDRT register. Once the data for transmission are written to the ICDRT register, the TDRE flag is automatically set to 0, the data are transferred from the ICDRT register to the ICDRS register, and the TDRE flag is again set to 1. After the byte containing the slave address and R/W# bit has been transmitted, the value of the TRS bit is automatically updated to select master transmit or master receive mode in accord with the value of the transmitted R/W# bit. If the value of the R/W# bit was 0, the RIIC continues in master transmit mode. Because the ICSR2.NACKF flag being 1 at this time indicates that no slave device recognized the address or there was an error in communications, write 1 to the ICCR2.SP bit to generate a stop condition. For data transmission with an address in the 10-bit format, start by writing 1111 0b, the 2 higher-order bits of the slave address, and W to the ICDRT register as the first address transmission. Then, as the second address transmission, write the 8 lower-order bits of the slave address to the ICDRT register.
- (4) After confirming that the ICSR2.TDRE flag is 1, write the data for transmission to the ICDRT register. The RIIC automatically holds the SCL0 line low until the data for transmission are ready or a stop condition is generated.
- (5) After all bytes of data for transmission have been written to the ICDRT register, wait until the ICSR2.NACKF or ICSR2.TEND flag becomes 1, and then set the ICCR2.SP bit to 1 (requests to generate a stop condition). Upon receiving a stop condition generation request, the RIIC generates the stop condition.
- (6) Upon detecting the stop condition, the RIIC automatically sets bits MST and TRS in the ICCR2 register to 00b and enters slave receive mode. Furthermore, it automatically sets the TDRE and TEND flags to 0, and sets the ICSR2.STOP flag to 1.
- (7) After checking that the ICSR2.STOP flag is 1, set the ICSR2.NACKF and STOP flags to 0 for the next transfer operation.

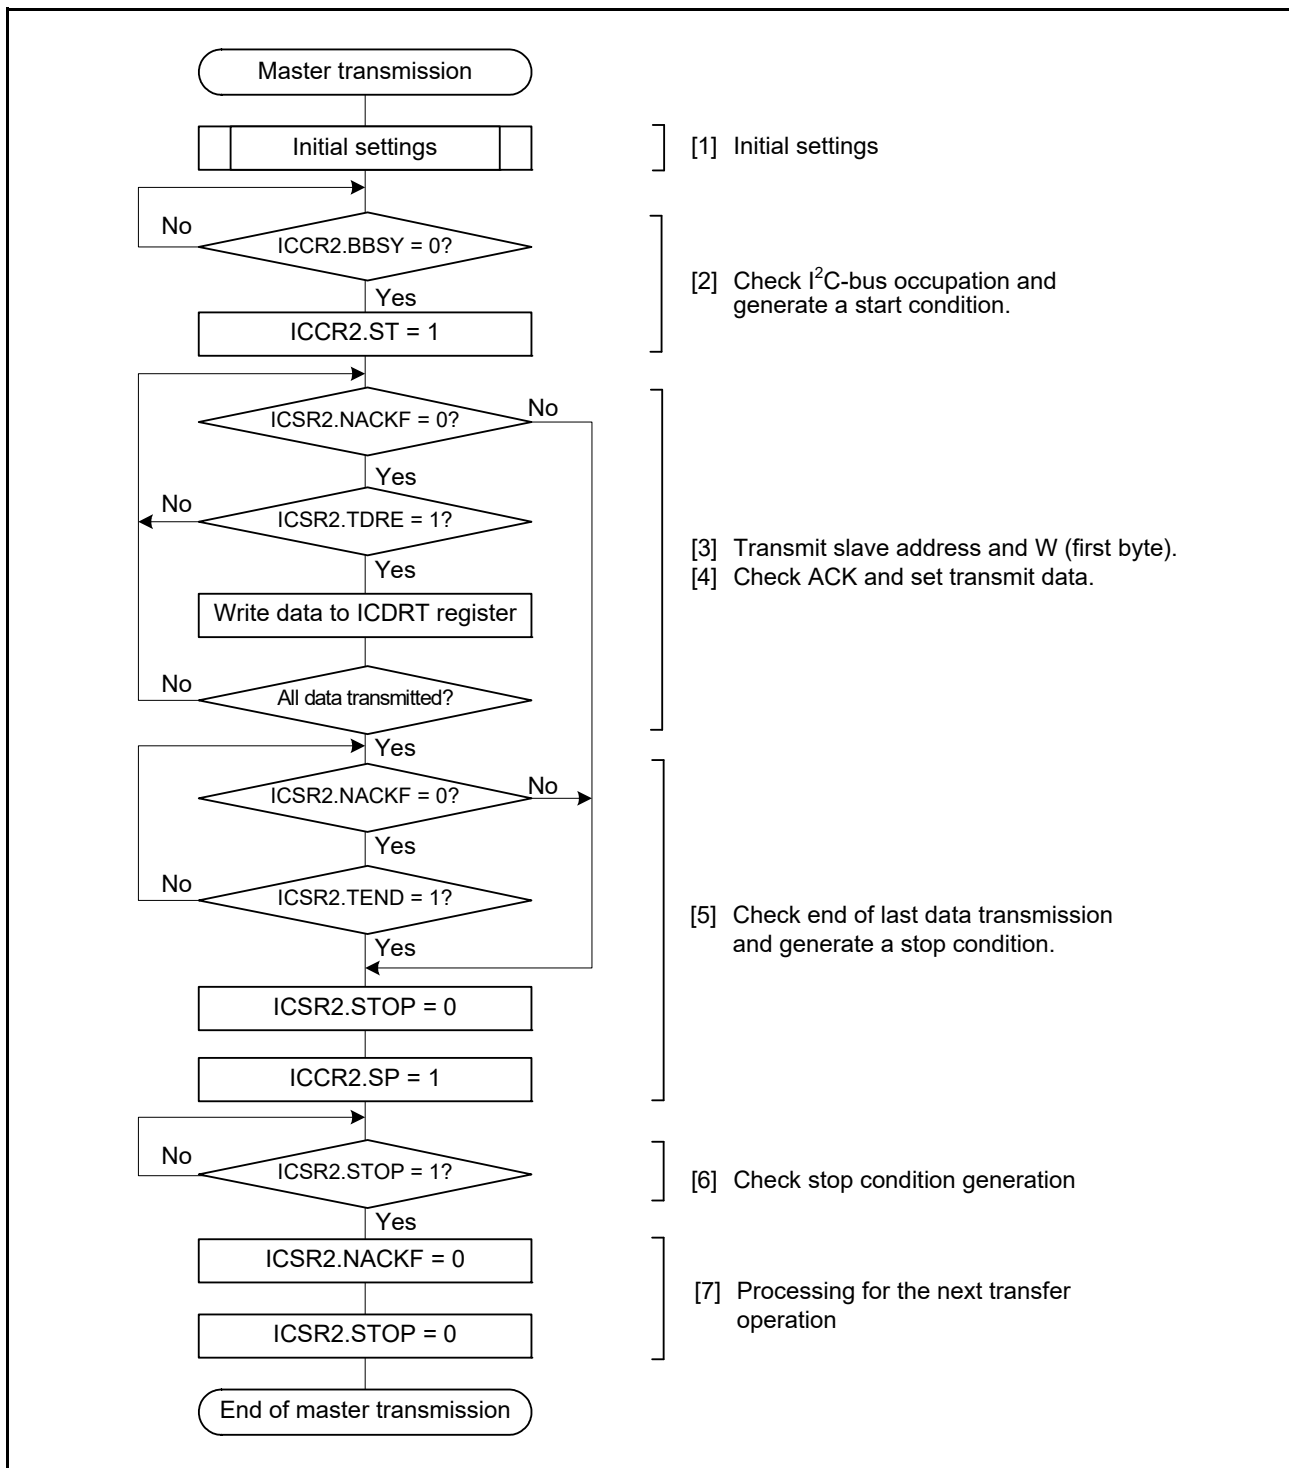

Figure 33.5 Example of Master Transmission Flowchart

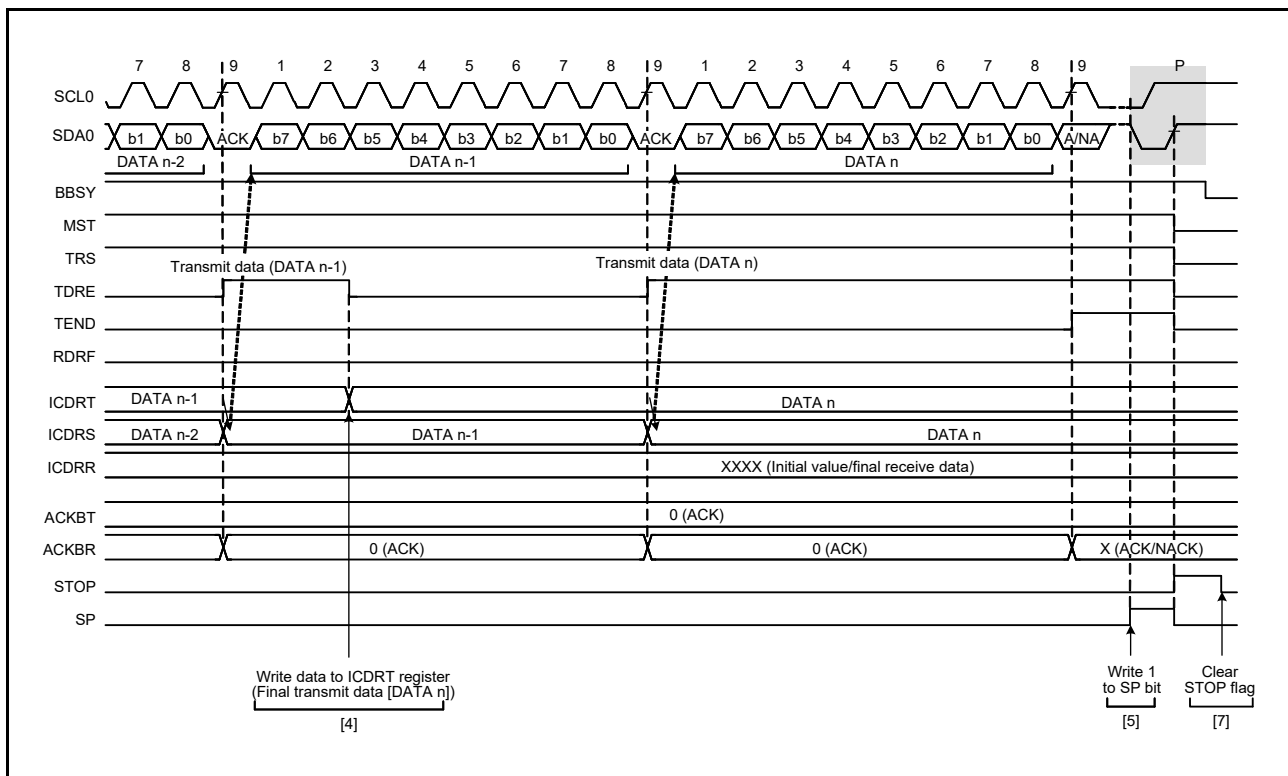

Figure 33.8 Master Transmit Operation Timing (3)

### 33.3.4 Master Receive Operation

In master receive operation, the RIIC as a master device generates clock signals, receives data from the slave device, and returns acknowledgments. Because the RIIC must start by sending a slave address to the corresponding slave device, this part of the procedure is performed in master transmit mode, but the subsequent steps are in master receive mode.

Figure 33.9 and Figure 33.10 show examples of usage of master reception (7-bit address format) and Figure 33.11 to Figure 33.13 show the timing of operations in master reception.

The following describes the procedure and operations for master reception.

- (1) Initial settings. For details, refer to section 33.3.2, Initial Settings.
- (2) Read the ICCR2.BBSY flag to check that the bus is open, and then set the ICCR2.ST bit to 1 (requests to generate a start condition). Upon receiving the request, the RIIC generates a start condition. When the RIIC detects the start condition, the BBSY flag and the ICSR2.START flag are automatically set to 1 and the ST bit is automatically set to 0. At this time, if the start condition is detected and the levels for the SDA output and the levels on the SDA0 line have matched while the ST bit is 1, the RIIC recognizes that generating of the start condition as requested by the ST bit has been successfully completed, and bits MST and TRS in the ICCR2 register are automatically set to 1, placing the RIIC in master transmit mode. The ICSR2.TDRE flag is also automatically set to 1 in response to setting of the TRS bit to 1.
- (3) Check that the ICSR2.TDRE flag is 1, and then write the value for transmission (the first byte indicates the slave address and value of the R/W# bit) to the ICDRT register. Once the data for transmission are written to the ICDRT register, the TDRE flag is automatically set to 0, the data are transferred from the ICDRT register to the ICDRS register, and the TDRE flag is again set to 1. Once the byte containing the slave address and R/W# bit has been transmitted, the value of the ICCR2.TRS bit is automatically updated to select transmit or receive mode in accord with the value of the transmitted R/W# bit. If the value of the R/W# bit was 1, the TRS bit is set to 0 on the rising edge of the ninth SCL, placing the RIIC in master receive mode. At this time, the TDRE flag is set to 0 and the ICSR2.RDRF flag is automatically set to 1.

Because the ICSR2.NACKF flag being 1 at this time indicates that no slave device recognized the address or there was an error in communications, write 1 to the ICCR2.SP bit to generate a stop condition.

For master reception from a device with a 10-bit address, start by using master transmission to send the 10-bit address, and then generate a restart condition. After that, transmitting 1111 0b, the two higher-order bits of the slave address, and the R bit places the RIIC in master receive mode.

- (4) Dummy read the ICDRR register after confirming that the ICSR2.RDRF flag is 1; this makes the RIIC start output of the SCL and start data reception.
- (5) After 1 byte of data has been received, the ICSR2.RDRF flag is set to 1 on the rising edge of the eighth or ninth SCL (the clock signal) as selected by the ICMR3.RDRFS bit. Reading the ICDRR register at this time will produce the received data, and the RDRF flag is automatically set to 0 at the same time. Furthermore, the value of the acknowledgment bit received during the ninth SCL is returned as the value set in the ICMR3.ACKBT bit. Furthermore, if the next byte to be received is the next to last byte, set the ICMR3.WAIT bit to 1 (for wait insertion) before reading the ICDRR register (containing the second byte from last). As well as enabling NACK output even in the case of delays in processing to set the ICMR3.ACKBT bit to 1 (NACK) in step (6), due to other interrupts, etc., this fixes the SCL0 line to low on the falling edge of the ninth clock pulse in reception of the last byte, so the state is such that generating a stop condition is possible.
- (6) When the ICMR3.RDRFS bit is 0 and the slave device must be notified that it is to end transfer for data reception after transfer of the next (final) byte, set the ICMR3.ACKBT bit to 1 (NACK).
- (7) After reading the byte before last from the ICDRR register, if the value of the ICSR2.RDRF flag is confirmed to be 1, write 1 to the ICCR2.SP bit (requests to generate a stop condition) and then read the last byte from the ICDRR register. When the ICDRR register is read, the RIIC is released from the wait state and generates the stop condition after low-level output in the ninth clock pulse is completed or the SCL0 line is released from the low-hold state.
- (8) Upon detecting the stop condition, the RIIC automatically sets bits MST and TRS in the ICCR2 register to 00b and enters slave receive mode. Furthermore, detection of the stop condition leads to setting of the ICSR2.STOP flag to 1.
- (9) After checking that the ICSR2.STOP flag is 1, set the ICSR2.NACKF and STOP flags to 0 for the next transfer operation.

### 33.3.5 Slave Transmit Operation

In slave transmit operation, the master device outputs the SCL, the RIIC transmits data as a slave device, and the master device returns acknowledgments.

Figure 33.14 shows an example of usage of slave transmission and Figure 33.15 and Figure 33.16 show the timing of operations in slave transmission.

The following describes the procedure and operations for slave transmission.

- (1) Initial settings. For details, refer to section 33.3.2, Initial Settings.  
After initial settings, the RIIC will stay in the standby state until it receives a slave address that it matches.
- (2) After receiving a matching slave address, the RIIC sets one of the corresponding bits ICSR1.HOA, GCA, and AASy (y = 0 to 2) to 1 on the rising edge of the ninth SCL (the clock signal) and outputs the value set in the ICMR3.ACKBT bit to the acknowledgment bit on the ninth SCL. If the value of the R/W# bit that was also received at this time is 1, the RIIC automatically places itself in slave transmit mode by setting both the ICCR2.TRS bit and the ICSR2.TDRE flag to 1.
- (3) After the ICSR2.TDRE flag is confirmed to be 1, write the data for transmission to the ICDRT register. At this time, if the RIIC does not receive ACK from the master device (receives a NACK signal) while the ICFER.NACKF bit is 1, the RIIC suspends transfer of the next data.
- (4) Wait until the ICSR2.TEND flag is set to 1 while the ICSR2.TDRE flag is 1, after the ICSR2.NACKF flag is set to 1 or the last byte for transmission is written to the ICDRT register. When the ICSR2.NACKF flag or the TEND flag is 1, the RIIC drives the SCL0 line low on the falling edge of ninth SCL.
- (5) When the ICSR2.NACKF flag or the ICSR2.TEND flag is 1, dummy read the ICDRR register to complete the processing. This releases the SCL0 line.
- (6) Upon detecting the stop condition, the RIIC automatically sets bits ICSR1.HOA, GCA, and AASy (y = 0 to 2), flags ICSR2.TDRE and TEND, and the ICCR2.TRS bit to 0, and enters slave receive mode.
- (7) After checking that the ICSR2.STOP flag is 1, set the ICSR2.NACKF and STOP flags to 0 for the next transfer operation.

Figure 33.14 Example of Slave Transmission Flowchart

Figure 33.15 Slave Transmit Operation Timing (1) (7-Bit Address Format)

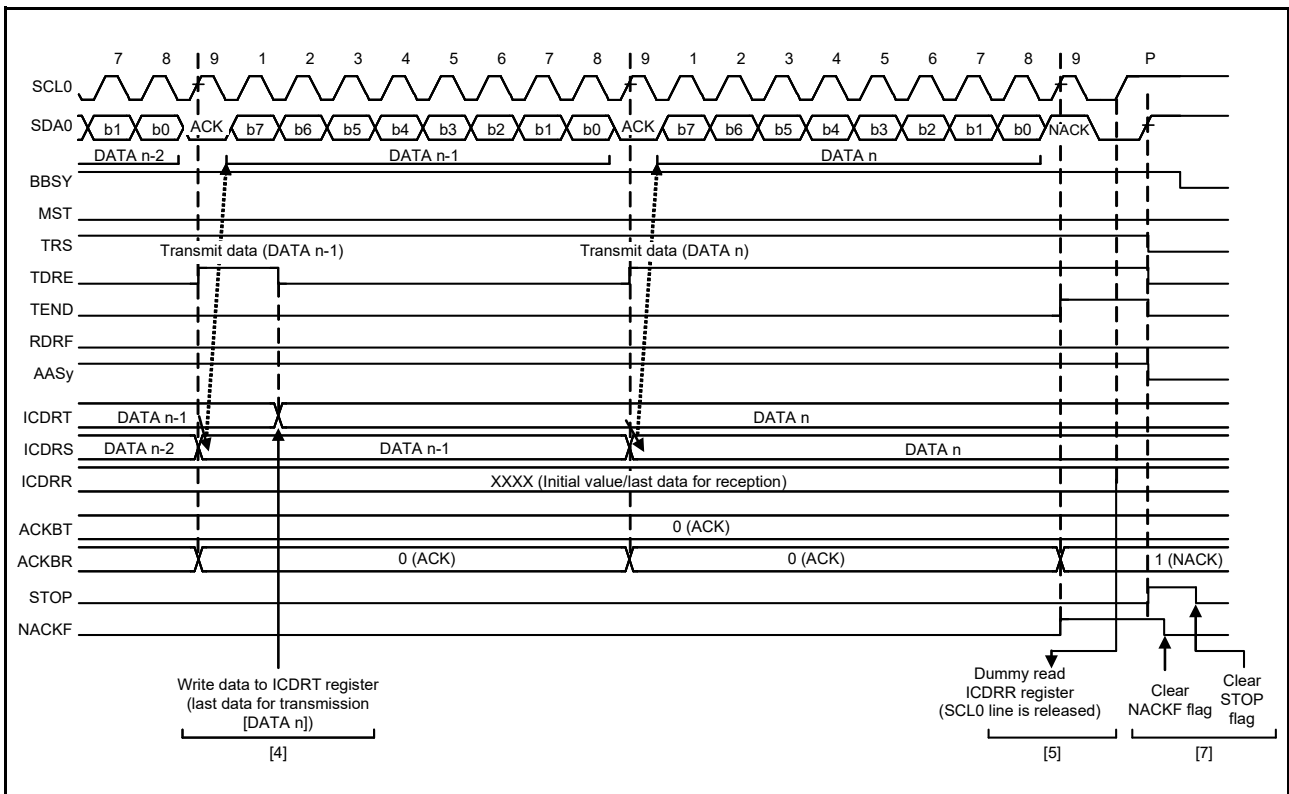

Figure 33.16 Slave Transmit Operation Timing (2)

### 33.3.6 Slave Receive Operation

In slave receive operation, the master device outputs the SCL and transmit data, and the RIIC returns acknowledgments as a slave device.

Figure 33.17 shows an example of usage of slave reception and Figure 33.18 and Figure 33.19 show the timing of operations in slave reception.

The following describes the procedure and operations for slave reception.

- (1) Initial settings. For details, refer to section 33.3.2, Initial Settings.  
After initial settings, the RIIC will stay in the standby state until it receives a slave address that it matches.
- (2) After receiving a matching slave address, the RIIC sets one of the corresponding bits ICSR1.HOA, GCA, and AASy (y = 0 to 2) to 1 on the rising edge of the ninth SCL (the clock signal) and outputs the value set in the ICMR3.ACKBT bit to the acknowledgment bit on the ninth SCL. If the value of the R/W# bit that was also received at this time is 0, the RIIC continues to place itself in slave receive mode and sets the ICSR2.RDRF flag to 1.
- (3) After the ICSR2.STOP flag is confirmed to be 0 and the ICSR2.RDRF flag to be 1, dummy read the ICDRR register (the dummy value consists of the slave address and R/W# bit when the 7-bit address format is selected, or the lower 8 bits when the 10-bit address format is selected).
- (4) When the ICDRR register is read, the RIIC automatically sets the ICSR2.RDRF flag to 0. If reading of the ICDRR register is delayed and a next byte is received while the RDRF flag is still set to 1, the RIIC holds the SCL0 line low from one SCL cycle before the timing with which RDRF should be set. In this case, reading the ICDRR register releases the SCL0 line from being held low.  
When the ICSR2.STOP flag is 1 and the ICSR2.RDRF flag is also 1 or when all the data is completely received, read the ICDRR register.
- (5) Upon detecting the stop condition, the RIIC automatically clears bits ICSR1.HOA, GCA, and AASy (y = 0 to 2) to 0.
- (6) After checking that the ICSR2.STOP flag is 1, set the ICSR2.STOP flag to 0 for the next transfer operation.

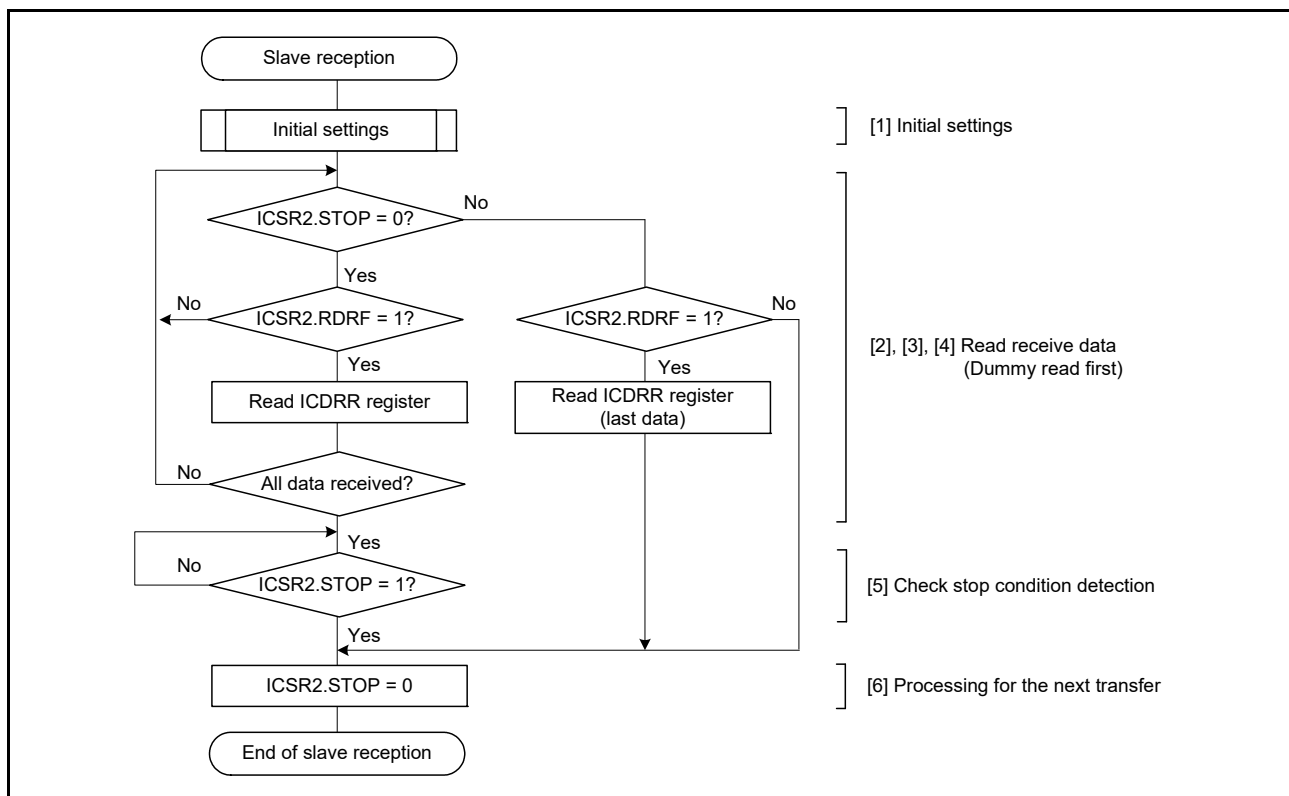

Figure 33.17 Example of Slave Reception Flowchart

Figure 33.19 Slave Receive Operation Timing (2) (when RDRFS bit is 0)

### 33.4 SCL Synchronization Circuit

In generation of the SCL, the RIIC starts counting out the value for width at high level specified in the ICBRH register when it detects a rising edge on the SCL0 line and drives the SCL0 line low once counting of the width at high level is complete. When the RIIC detects the falling edge of the SCL0 line, it starts counting out the width at low period specified in the ICBRL register, and then stops driving the SCL0 line (releases the line) once counting of the width at low level is complete. The SCL is thus generated.

If multiple master devices are connected to the I<sup>2</sup>C-bus, a collision of SCL signals may arise due to contention with another master device. In such cases, the master devices have to synchronize their SCL signals. Since synchronization of the SCL signals must be handled bit by bit, the RIIC is equipped with a facility (the SCL synchronization circuit) for obtaining bit-by-bit synchronization of the SCL signals by monitoring the SCL0 line while in master mode.

When the RIIC has detected a rising edge on the SCL0 line and thus started counting out the width at high level specified in the ICBRH register, and the level on the SCL0 line falls because an SCL signal is being generated by another master device, the RIIC stops counting when it detects the falling edge, drives the level on the SCL0 line low, and starts counting out the width at low level specified in the ICBRL register. When the RIIC finishes counting out the width at low level, it stops driving the SCL0 line low (i.e. releases the line). At this time, if the width at low level of the SCL signal from the other master device is longer than the width at low level set in the RIIC, the width at low level of the SCL signal will be extended. Once the width at low level for the other master device has ended, the SCL signal rises because the SCL0 line has been released. When the RIIC finishes outputting the low period of the SCL, the SCL0 line is released and the SCL rises. That is, in cases of contention of SCL signals from more than one master, the width at high level of the SCL signal is synchronized with that of the clock having the narrower width, and the width at low level of the SCL signal is synchronized with that of the clock having the broader width. However, such synchronization of the SCL signal is only enabled when the ICFER.SCLE bit is set to 1.

**Figure 33.20** Generation and Synchronization of the SCL Signal from the RIIC

### 33.5 SDA Output Delay Function

The RIIC module incorporates a function for delaying output on the SDA line. The delay can be applied to all output (generation of the start, restart, and stop conditions, data, and the ACK and NACK signals) on the SDA line.

The SDA output delay function is used to delay the SDA output timing relative to falling edges of SCL to ensure that the SDA signal changes while the SCL is low and can be used to prevent erroneous operation of communications devices.

This function is also used to satisfy the 300 ns (min.) data hold time prescribed by the SMBus specification.

The output delay function is enabled by setting the ICMR2.SDDL[2:0] bits to any value other than 000b, and disabled by setting the same bits to 000b.

When the SDA output delay function is enabled (the SDDL[2:0] bits are not “000b”), the SDA output delay counter counts the number of cycles set in the SDDL[2:0] bits of the count source selected by the ICMR2.DLCS bit (the internal reference clock (IIC $\phi$ ) or internal reference clock divided by 2 (IIC $\phi$ /2)). On completion of counting of cycles of delay, the RIIC changes the bit being output as the SDA signal (generation of the start, restart, or stop condition, a new bit, or an ACK or NACK signal).

Figure 33.21 SDA Output Delay Function

### 33.6 Digital Noise Filters

The states of the SCL0 and SDA0 pins are conveyed to the internal circuitry through digital noise filters. Figure 33.22 is a block diagram of the digital noise filter.

The on-chip digital noise filter of each RIIC consists of four flip-flop circuit stages connected in series and a match detection circuit.

The number of effective stages in the digital noise filter is selected by the ICMR3.NF[1:0] bits. The selected number of effective stages determines the noise-filtering capability as a period from one to four cycles of IIC $\phi$ .

The input signal to the SCL0 pin (or SDA0 pin) is sampled on falling edges of the IIC $\phi$  signal. When the input signal level matches the output level for the number of effective flip-flop circuit stages selected by the ICMR3.NF[1:0] bits, the signal level is conveyed to the subsequent stages. If the signal levels do not match, the previous value is retained.

If the ratio between the frequency of the internal operating clock (PCLK) and the transfer rate is relatively small (e.g. data transfer at 400 kbps with PCLK = 4 MHz), the characteristics of the digital noise filter may lead to the elimination of needed signals as noise.

Figure 33.22 Block Diagram of the Digital Noise Filter

### 33.7 Address Match Detection

The RIIC can set three unique slave addresses in addition to the general call address and host address, and also can set 7-bit or 10-bit slave addresses.

#### 33.7.1 Slave-Address Match Detection

The RIIC can set three unique slave addresses, and has a slave address detection function for each unique slave address. When the ICSER.SARyE bit ( $y = 0$  to 2) is set to 1, the slave addresses set in registers SARUy and SARLy ( $y = 0$  to 2) can be detected.

When the RIIC detects a match with its set slave address, the corresponding ICSR1.AASy flag ( $y = 0$  to 2) is set to 1 on the rising edge of the ninth SCL, and the ICSR2.RDRF flag or the ICSR2.TDRE flag is set to 1 according to the level of the R/W# bit. This causes a receive data full interrupt (RXI) or transmit data empty interrupt (TXI) to be generated. The AASy flag is used to identify which slave address has been specified.

Figure 33.23 to Figure 33.25 show the AASy flag set timing in three cases.

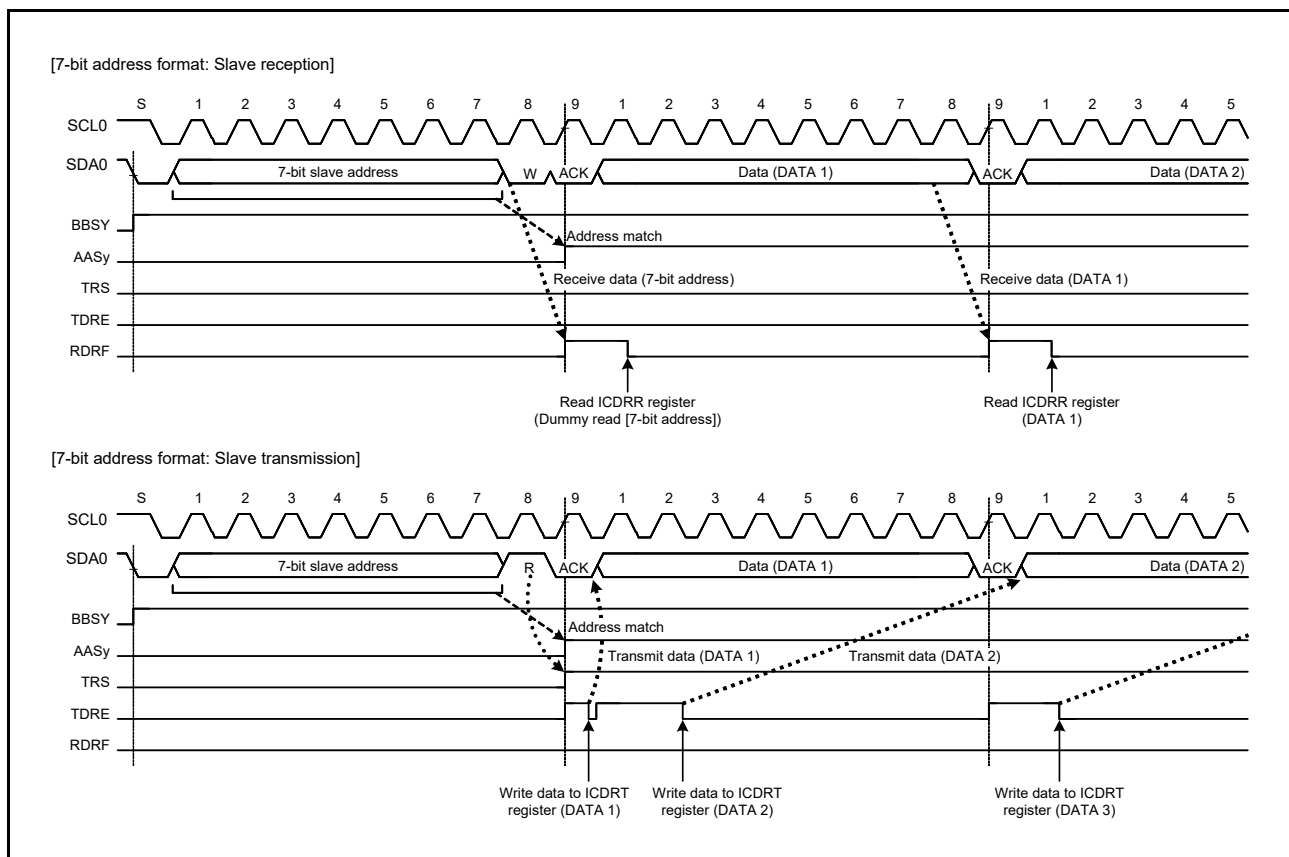

Figure 33.23 AASy Flag Set Timing with 7-Bit Address Format Selected

Figure 33.24 AASy Flag Set Timing with 10-Bit Address Format Selected

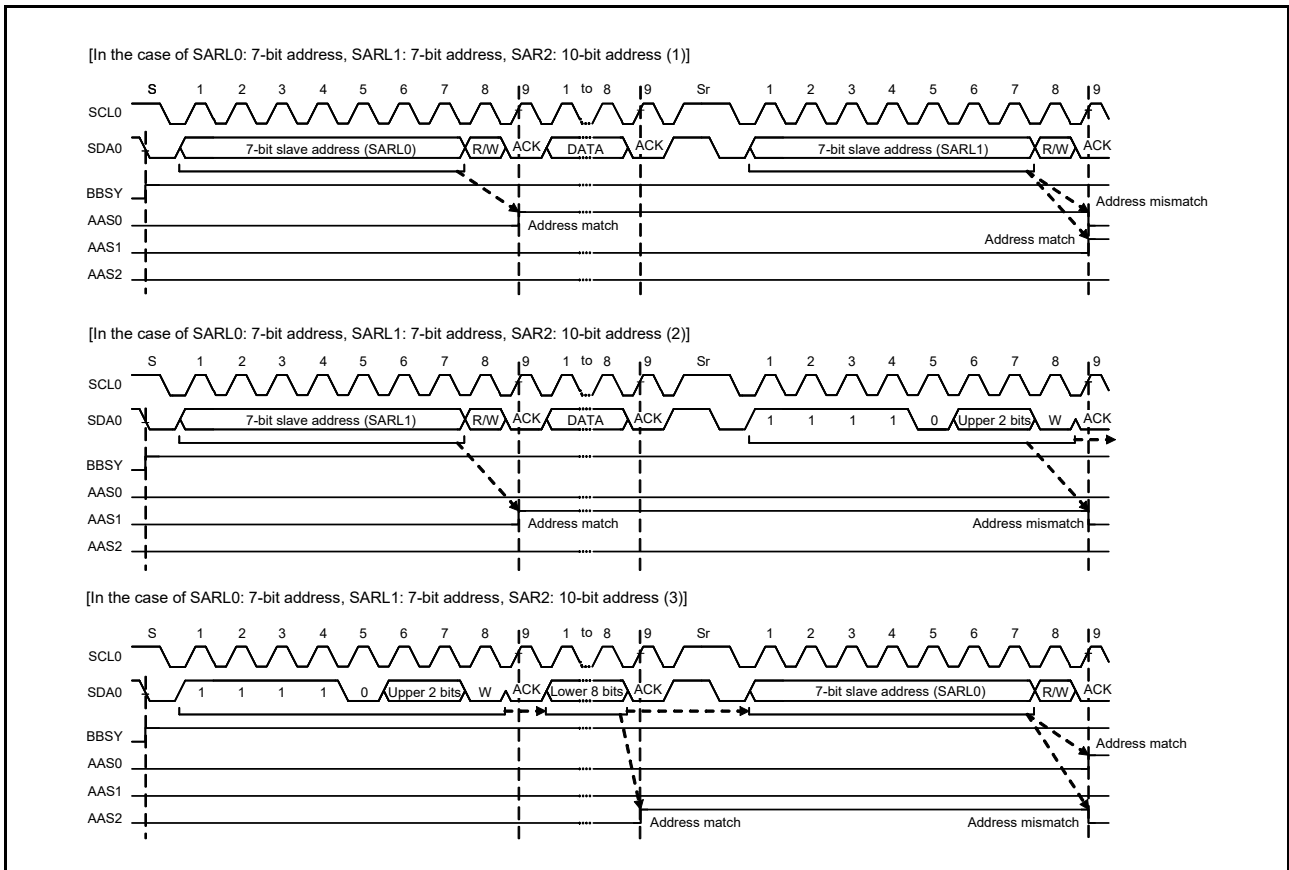

Figure 33.25 AASy Flag Set/Clear Timing with 7-Bit/10-Bit Address Formats Mixed

### 33.7.2 Detection of the General Call Address

The RIIC also has a facility for detecting the general call address (0000 000b + 0 (write)). This is enabled by setting the IC SER.GCAE bit to 1.

If the address following a start or restart condition is 0000 000b + 1 (read) (start byte), the RIIC recognizes this as the address of a slave device with an “all-zero” address but not as the general call address.

When the RIIC detects the general call address, both the IC SR1.GCA flag and the IC SR2.RDRF flag are set to 1 on the rising edge of the ninth SCL. This leads to the generation of a receive data full interrupt (RXI). The value of the GCA flag can be confirmed to recognize that the general call address has been transmitted.

Operation after detection of the general call address is the same as normal slave receive operation.

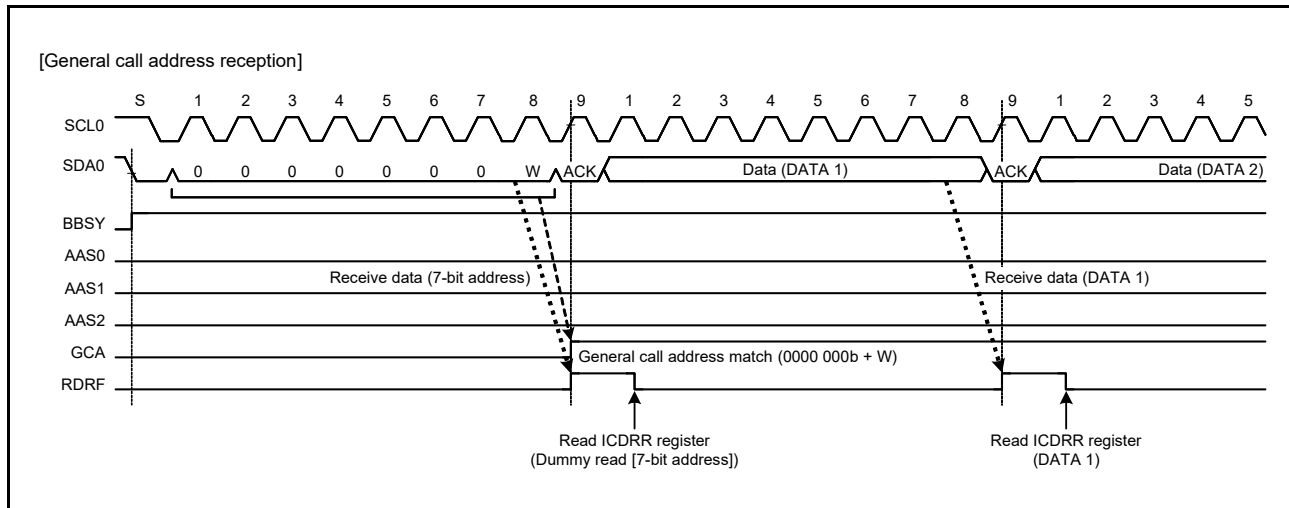

Figure 33.26 Timing of GCA Flag Setting during Reception of General Call Address

### 33.7.3 Device-ID Address Detection

The RIIC module has a function to detect device-ID addresses complying with the I<sup>2</sup>C-bus specification. When the RIIC receives 1111 100b as the first seven bits of the first byte following a start condition or a restart condition while the ICSER.DIDE bit is 1, the RIIC recognizes the address as a device-ID address, sets the ICSR1.DID flag to 1 on the rising edge of the ninth SCL when the following R/W# bit is 0, and then compares the second and following bytes with its own slave address. If the received address matches the value in the slave address register, the RIIC sets the corresponding ICSR1.AASy flag (y = 0 to 2) to 1.

After that, when the first byte received after a start or restart condition is generated matches the device ID address (1111 100b) again and the following R/W# bit is 1, the RIIC does not compare the second and subsequent bytes and sets the ICSR2.TDRE flag to 1.

In the device-ID address detection function, the RIIC sets the DID flag to 0 if a match with the RIIC's own slave address is not obtained or a match with the device ID address is not obtained after a match with the RIIC's own slave address and the detection of a restart condition. If the first byte after detection of a start or restart condition matches the device ID address (1111 100b) and the R/W# bit is 0, the RIIC sets the DID flag to 1 and compares the second and subsequent bytes with the RIIC's slave address. If the R/W# bit is 1, the DID flag holds the previous value and the RIIC does not compare the second and subsequent bytes. Therefore, the reception of a device-ID address can be checked by reading the DID flag after confirming that TDRE flag is 1.

Furthermore, prepare the device-ID fields (3 bytes: 12 bits indicating the manufacturer + 9 bits identifying the part + 3 bits indicating the revision) that must be sent to the host after reception of a continuous device-ID field as normal data for transmission. For details of the information that must be included in device-ID fields, contact NXP Semiconductors.

Figure 33.27 Set/Clear Timing of the AASy and DID Flags during Reception of Device-ID Address

### 33.7.4 Host Address Detection

The RIIC has a function to detect the host address while the SMBus is operating. When the ICSER.HOAE bit is set to 1 while the ICMR3.SMBS bit is 1, the RIIC can detect the host address (0001 000b) in slave receive mode (bits MST and TRS in the ICCR2 register are 00b).

When the RIIC detects the host address, the ICSR1.HOA flag is set to 1 at the rising edge of the ninth SCL, and at the same time, the ICSR2.RDRF flag is set to 1 when the R/W# bit is 0 (Wr bit). This causes a receive data full interrupt (RXI) to be generated. The HOA flag is used to recognize that the host address was sent from the smart battery or other devices.

If the bit following the host address (0001 000b) is an Rd bit (R/W# bit is 1), the RIIC can also detect the host address. After the host address is detected, the RIIC operates in the same manner as normal slave operation.

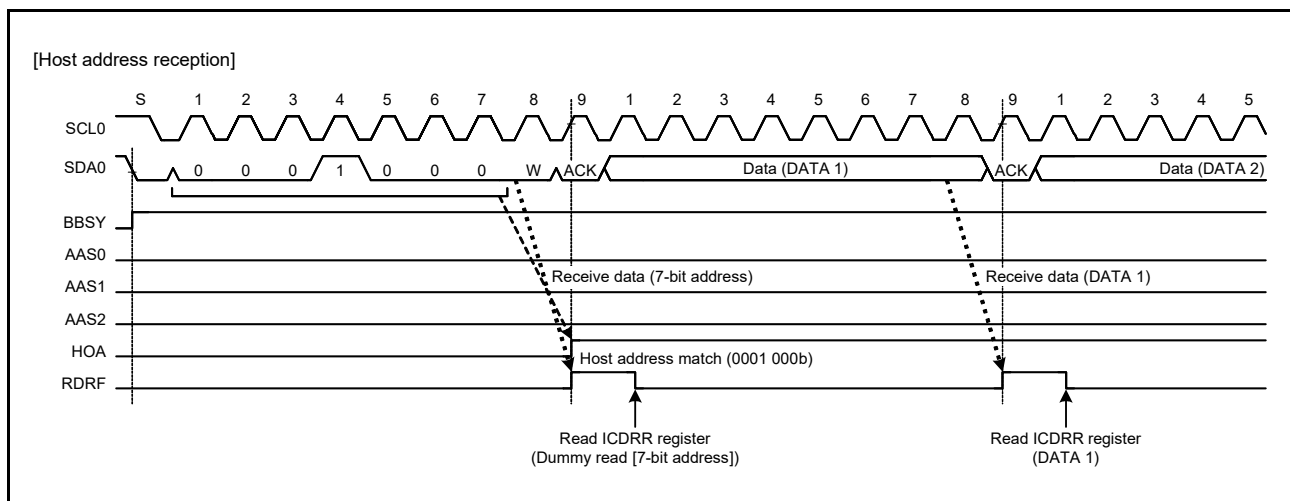

Figure 33.28 HOA Flag Set Timing during Reception of Host Address

### 33.8 Automatic Low-Hold Function for SCL

#### 33.8.1 Function to Prevent Wrong Transmission of Transmit Data

If the shift register (ICDRS) is empty when data have not been written to the I<sup>2</sup>C-bus transmit data register (ICDRT) with the RIIC in transmission mode (ICCR2.TRS bit is 1), the SCL0 line is automatically held low over the intervals shown below. This low period is extended until data for transmission have been written, which prevents the unintended transmission of erroneous data.

##### Master transmit mode

- Low period after a start condition or restart condition is generated
- Low period between the ninth clock pulse of one transfer and the first clock pulse of the next

##### Slave transmit mode

- Low period between the ninth clock pulse of one transfer and the first clock pulse of the next

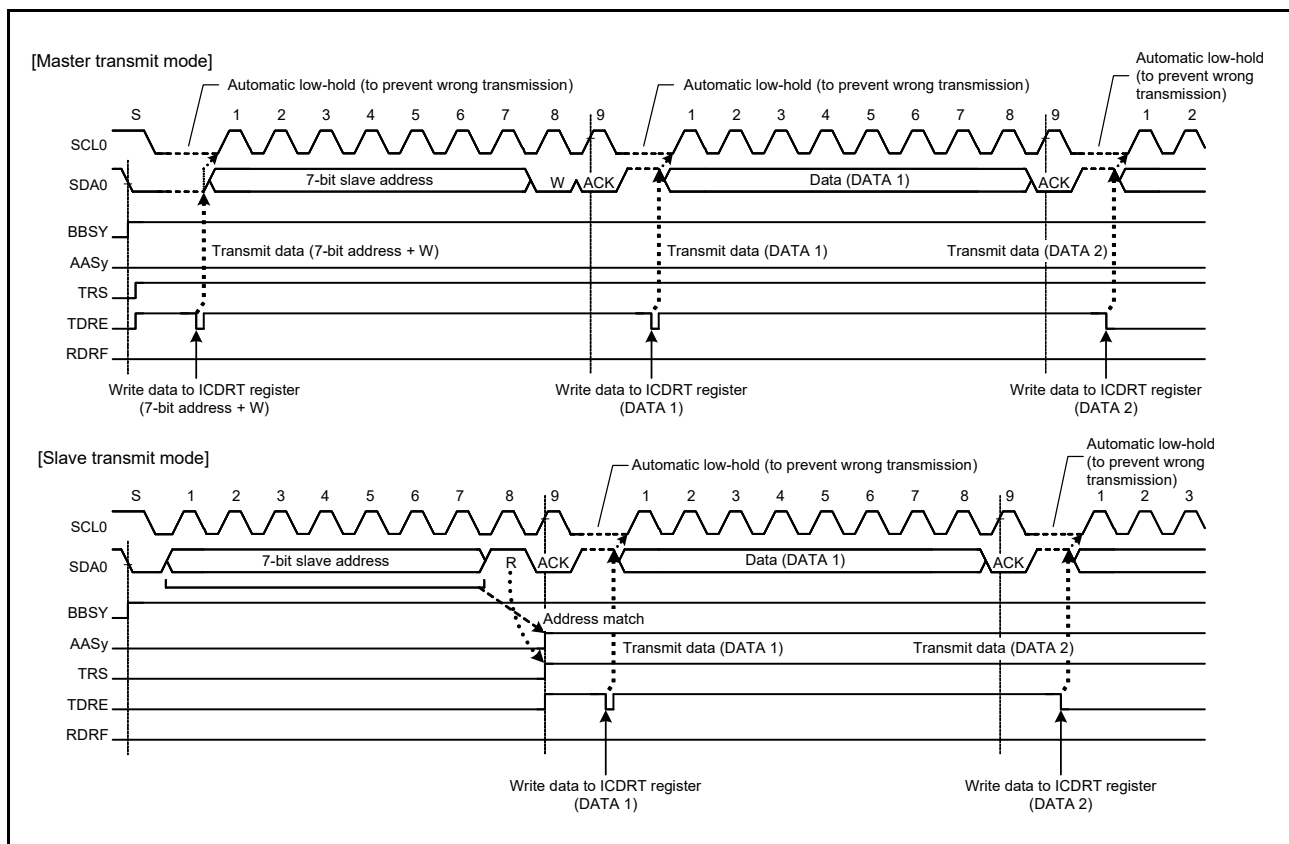

Figure 33.29 Automatic Low-Hold Operation in Transmit Mode

### 33.8.2 NACK Reception Transfer Suspension Function

The RIIC has a function to suspend transfer operation when NACK is received in transmit mode (ICCR2.TRS bit is 1). This function is enabled when the ICFER.NACKE bit is set to 1 (transfer suspension enabled). If the next transmit data has already been written (ICSR2.TDRE flag is 0) when NACK is received, next data transmission at the falling edge of the ninth SCL is automatically suspended. This prevents the SDA0 line output level from being held low when the MSB of the next transmit data is 0.

If the data transmission is suspended (ICSR2.NACKF flag is 1) by this function, the following data transmission and data reception are not started. To resume data transfer, set the NACKF flag to 0. In master transmit mode, restart data transfer by setting the NACKF flag to 0 after generating a restart condition, or restart data transfer from a start condition after generating a stop condition then setting the NACKF flag to 0.

Figure 33.30 Suspension of Data Transmission When NACK is Received (NACKE = 1)

### 33.8.3 Function to Prevent Failure to Receive Data

If response processing is delayed when receive data (ICDRR) read is delayed for a period of one transfer byte or more with receive data full (ICSR2.RDRF flag is 1) in receive mode (ICCR2.TRS bit is 0), the RIIC holds the SCL0 line low automatically immediately before the next data is received to prevent failure to receive data.

This function to prevent failure to receive data using the automatic low-hold function is also enabled even if the read processing of the final receive data is delayed and, in the meantime, the RIIC's own slave address is designated after a stop condition is generated. This function does not disturb other communication because the RIIC does not hold the SCL0 line low when a mismatch with its own slave address occurs after a stop condition is generated.

Sections in which the SCL0 line is held low can be selected with a combination of the WAIT and RDRFS bits in the ICMR3 register.

#### (1) 1-Byte Receive Operation and Automatic Low-Hold Function Using the WAIT Bit

When the ICMR3.WAIT bit is set to 1, the RIIC performs 1-byte receive operation using the WAIT bit function.

Furthermore, when the ICMR3.RDRFS bit is 0, the RIIC automatically sends the ICMR3.ACKBT bit value for the acknowledgment bit in the period from the falling edge of the eighth SCL to the falling edge of the ninth SCL, and automatically holds the SCL0 line low at the falling edge of the ninth SCL using the WAIT bit function. This low-hold is released by reading data from the ICDRR register, which enables bitwise receive operation.

The WAIT bit function is enabled for receive bytes after a match with the RIIC's own slave address (including the general call address and host address) is obtained in master receive mode or slave receive mode.

#### (2) 1-Byte Receive Operation (ACK/NACK Transmission Control) and Automatic Low-Hold Function Using the RDRFS Bit

When the ICMR3.RDRFS bit is set to 1, the RIIC performs 1-byte receive operation using the RDRFS bit function.

When the RDRFS bit is set to 1, the ICSR2.RDRF flag (receive data full) is set to 1 at the rising edge of the eighth SCL, and the SCL0 line is automatically held low at the falling edge of the eighth SCL. This low-hold is released by writing a value to the ICMR3.ACKBT bit, but cannot be released by reading data from the ICDRR register, which enables receive operation by the ACK/NACK transmission control according to the data received in byte units.

The RDRFS bit function is enabled for receive bytes after a match with the RIIC's own slave address (including the general call address and host address) is obtained in master receive mode or slave receive mode.

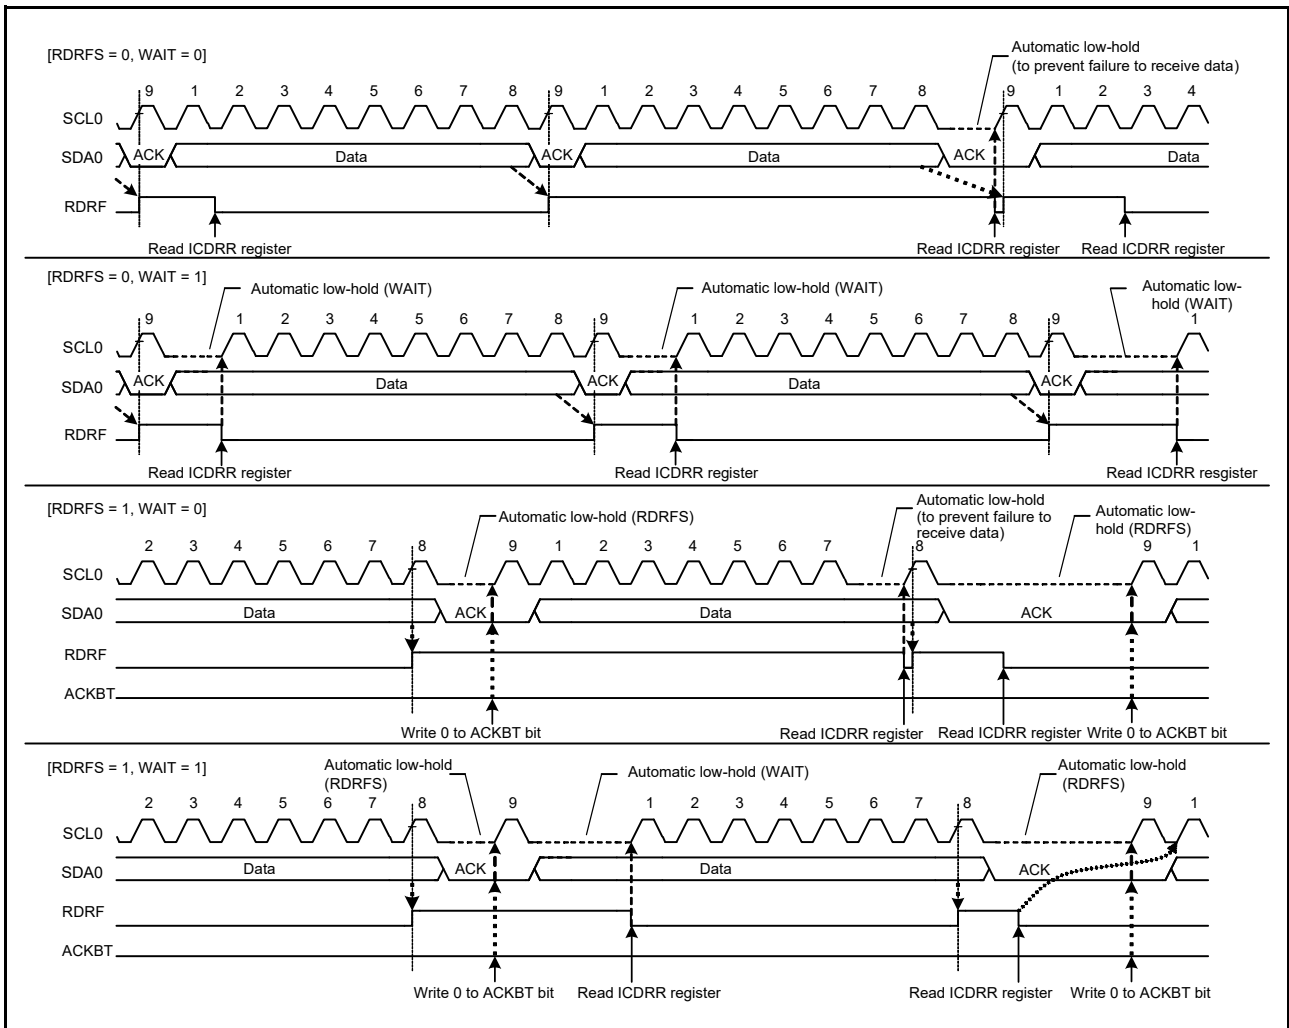

Figure 33.31 Automatic Low-Hold Operation in Receive Mode (Using RDRFS and WAIT Bits)

## 33.9 Arbitration-Lost Detection Functions

In addition to the normal arbitration-lost detection function defined by the I<sup>2</sup>C-bus specification, the RIIC has functions to prevent double-generation of a start condition, to detect arbitration-lost during transmission of NACK, and to detect arbitration-lost in slave transmit mode.

### 33.9.1 Master Arbitration-Lost Detection (MALE Bit)

The RIIC drives the SDA0 line low to generate a start condition. However, if the SDA0 line has already been driven low by another master device generating a start condition, the RIIC causes arbitration to be lost, so priority is given to transfer by the other master device. Similarly, if the ICCR2.ST bit is set to 1 while the ICCR2.BBSY flag is 1 (bus busy state), arbitration is lost, so priority is given to transfer by the other master device. No start condition is generated in this case. When a start condition is generated successfully, if the data for transmission including the address bits (i.e. the internal SDA output level) and the level on the SDA0 line do not match (the high output as the internal SDA output; i.e. the SDA0 pin is in the high-impedance state) and the low is detected on the SDA0 line, the RIIC loses the arbitration.

After a master arbitration-lost is generated, the RIIC immediately enters slave receive mode. If a slave address (including the general call address) matches its own address at this time, the RIIC continues in slave operation.

A master arbitration-lost is detected when the following conditions are met while the ICFER.MALE bit is 1 (master arbitration-lost detection enabled).

#### Conditions for detecting master arbitration-lost

- Non-matching of the internal level for output on SDA and the level on the SDA0 line after a start condition was generated by setting the ICCR2.ST bit to 1 while the ICCR2.BBSY flag was set to 0 (erroneous generation of a start condition)
- Setting of the ICCR2.ST bit to 1 while the BBSY flag is set to 1 (start condition double-generation error)
- When the transmit data excluding acknowledgment bit (internal SDA output level) does not match the level on the SDA0 line in master transmit mode (bits MST and TRS in the ICCR2 register = 11b)

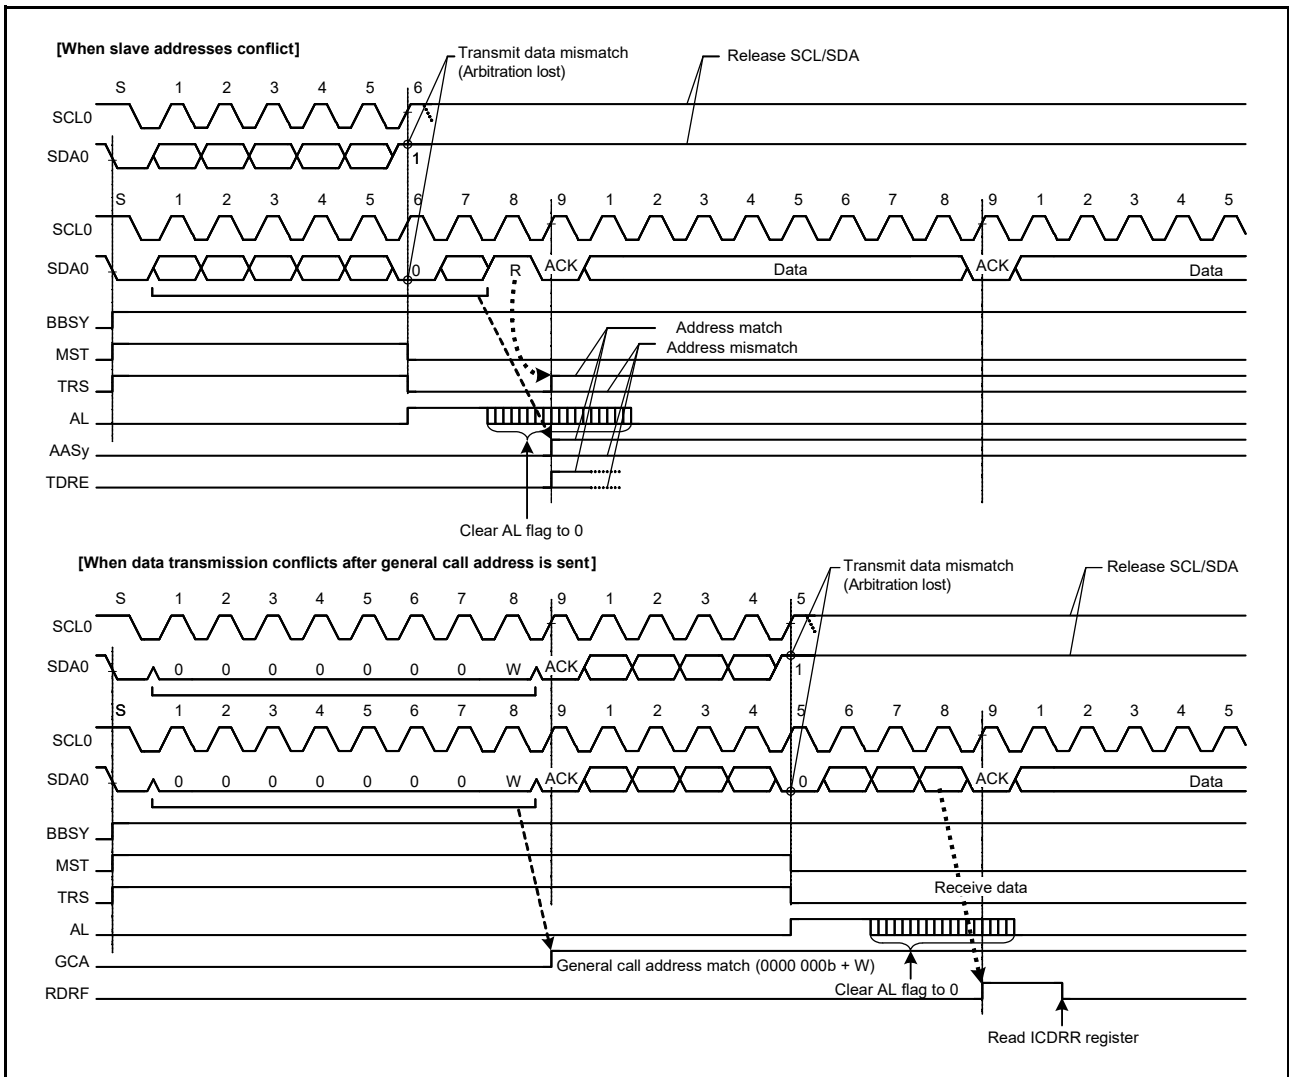

Figure 33.32 Examples of Master Arbitration-Lost Detection (MALE = 1)

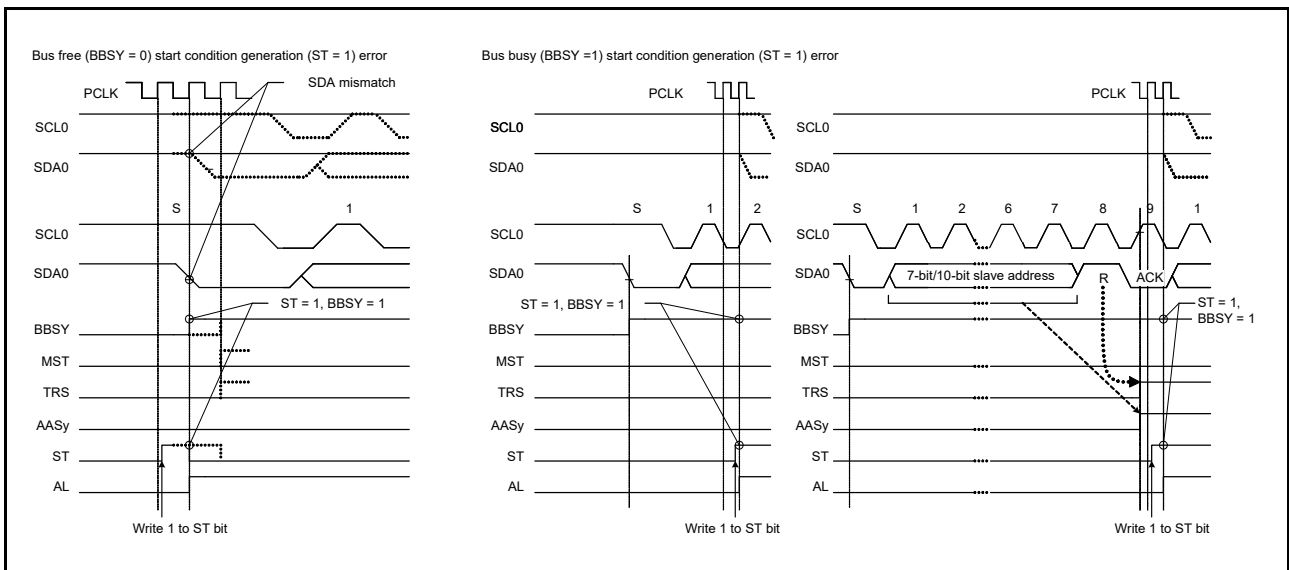

Figure 33.33 Arbitration-Lost When a Start Condition is Generated (MALE = 1)

### 33.9.2 NACK Transmission Arbitration-Lost Detection Function (NALE Bit)

The RIIC has a function to cause arbitration to be lost if the internal SDA output level does not match the level on the SDA0 line (the high output as the internal SDA output; i.e. the SDA0 pin is in the high-impedance state) and the low is detected on the SDA0 line during transmission of NACK in receive mode. Arbitration is lost due to a conflict of NACK transmission and ACK transmission when two or more master devices receive data from the same slave device simultaneously in a multi-master system. Such conflict occurs when multiple master devices send/receive the same information through a single slave device. Figure 33.34 shows an example of NACK transmission arbitration-lost detection.

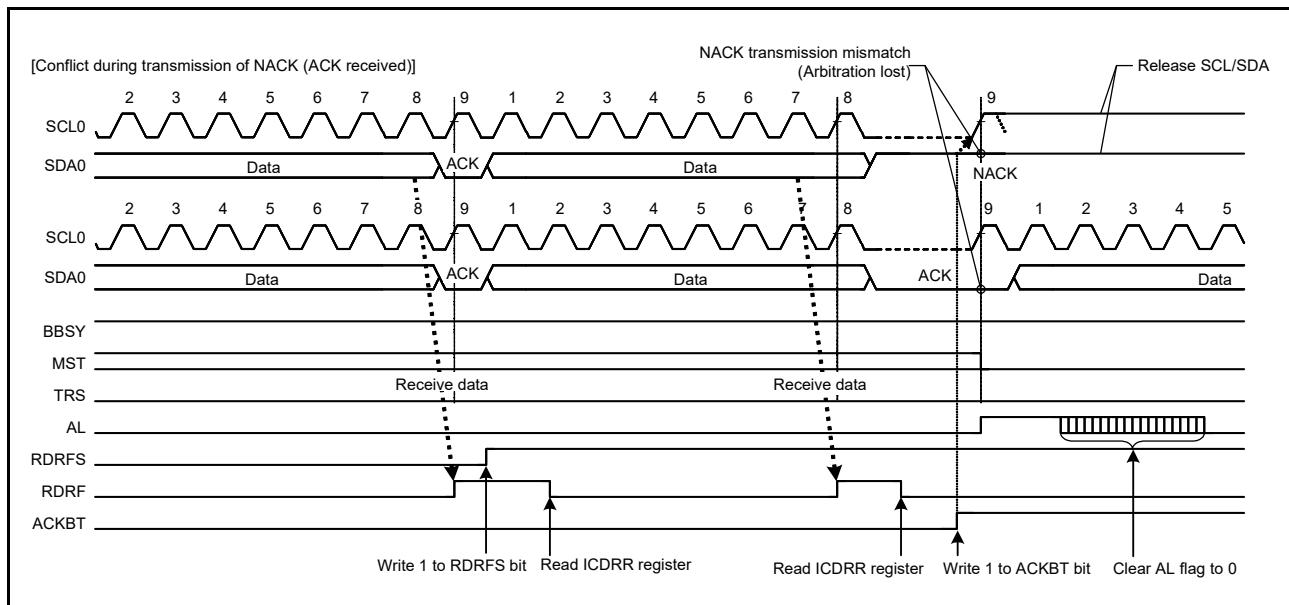

Figure 33.34 Example of NACK transmission arbitration-lost Detection (NALE = 1)

The following explains arbitration-lost detection using an example where two master devices (master A and master B) and a single slave device are connected through the bus. In this example, master A receives two bytes of data from the slave device, and master B receives four bytes of data from the slave device.

If master A and master B access the slave device simultaneously, because the slave address is identical, arbitration is not lost in both master A and master B during access to the slave device. Therefore, both master A and master B recognize that they have obtained the bus mastership and operate as such. Here, master A sends NACK when it has received second byte of data from the slave device. Meanwhile, master B sends ACK because it has not received necessary four bytes of data. At this time, the NACK transmission from master A and the ACK transmission from master B conflict. In general, if a conflict like this occurs, master A cannot detect ACK transmitted by master B and generates a stop condition.

Therefore, the generation of the stop condition conflicts with the SCL output of master B, which disturbs communication.

When the RIIC receives ACK during transmission of NACK, it detects a defeat in conflict with other master devices and causes arbitration to be lost.

If a NACK transmission arbitration-lost occurs, the RIIC immediately cancels the slave address matched state and enters slave receive mode. This prevents a stop condition from being generated, preventing a communication failure on the bus. Also, in the ARP command processing of SMBus, it is possible to omit surplus processing (FFh transmission processing) after NACK transmission when the UDID (Unique Device Identifier) of "Assign Address" does not match and after the NACK transmission of the "Get UDID (General)" after the "Assign Address" is confirmed.

The RIIC detects NACK transmission arbitration-lost when the following condition is met with the ICFER.NALE bit set to 1 (NACK transmission arbitration-lost is enabled).

**Condition for detecting NACK transmission arbitration-lost**

- When the internal SDA output level does not match the SDA0 line (ACK is received) during transmission of NACK (ICMR3.ACKBT bit = 1)

**33.9.3 Slave Arbitration-Lost Detection (SALE Bit)**

The RIIC has a function to cause arbitration to be lost if the data for transmission (i.e. the internal SDA output level) and the level on the SDA0 line do not match (the high output as the internal SDA output; i.e. the SDA0 pin is in the high-impedance state and the low is detected on the SDA0 line in slave transmit mode). The slave arbitration-lost detection function is mainly used when transmitting a UDID (Unique Device Identifier) of SMBus.

When the slave arbitration-lost occurs, the RIIC is immediately released from the slave address matched state and enters slave receive mode. This function can detect a data conflict during UDID transmission of SMBus and omit surplus processing (FFh transmission processing) after the data conflict.

The RIIC detects slave arbitration-lost when the following condition is met with the ICFER.SALE bit set to 1 (slave arbitration-lost detection enabled).

**Condition for detecting slave arbitration-lost**

- When transmit data excluding acknowledgment bit (internal SDA output level) does not match the SDA0 line in slave transmit mode (bits MST and TRS in the ICCR2 register are 01b)

**Figure 33.35 Example of Slave Arbitration-Lost Detection (SALE = 1)**

## 33.10 Start Condition/Restart Condition/Stop Condition Generating Function

### 33.10.1 Generating a Start Condition

The RIIC generates a start condition when the ICCR2.ST bit is set to 1.

When the ST bit is set to 1, a start condition generation request is made and the RIIC generates a start condition when the ICCR2.BBSY flag is 0 (bus free state). When a start condition is generated normally, the RIIC automatically shifts to the master transmit mode.

A start condition is generated in the following sequence.

#### Start condition generation

- (1) Drive the SDA0 line low (high to low).
- (2) Secure the time set in the ICBRH register and the start condition hold time.
- (3) Drive the SCL0 line low (high to low).
- (4) Detect the low level on the SCL0 line and secure the low period of the signal on the SCL0 line set in the ICBRL register.

### 33.10.2 Generating a Restart Condition

The RIIC generates a restart condition when the ICCR2.RS bit is set to 1.

When the RS bit is set to 1, a restart condition generation request is made and the RIIC generates a restart condition when the ICCR2.BBSY flag is 1 (bus busy state) and the ICCR2.MST bit is 1 (master mode).

A restart condition is generated in the following sequence.

#### Restart condition generation

- (1) Release the SDA0 line.
- (2) Secure the low period of the signal on the SCL0 line set in the ICBRL register.
- (3) Release the SCL0 line (low to high).
- (4) Detect the high level on the SCL0 line and secure the time set in the ICBRL register and the restart condition setup time.
- (5) Drive the SDA0 line low (high to low).
- (6) Secure the time set in the ICBRH register and the restart condition hold time.
- (7) Drive the SCL0 line low (high to low).
- (8) Detect the low level on the SCL0 line and secure the low period of the signal on the SCL0 line set in the ICBRL register.

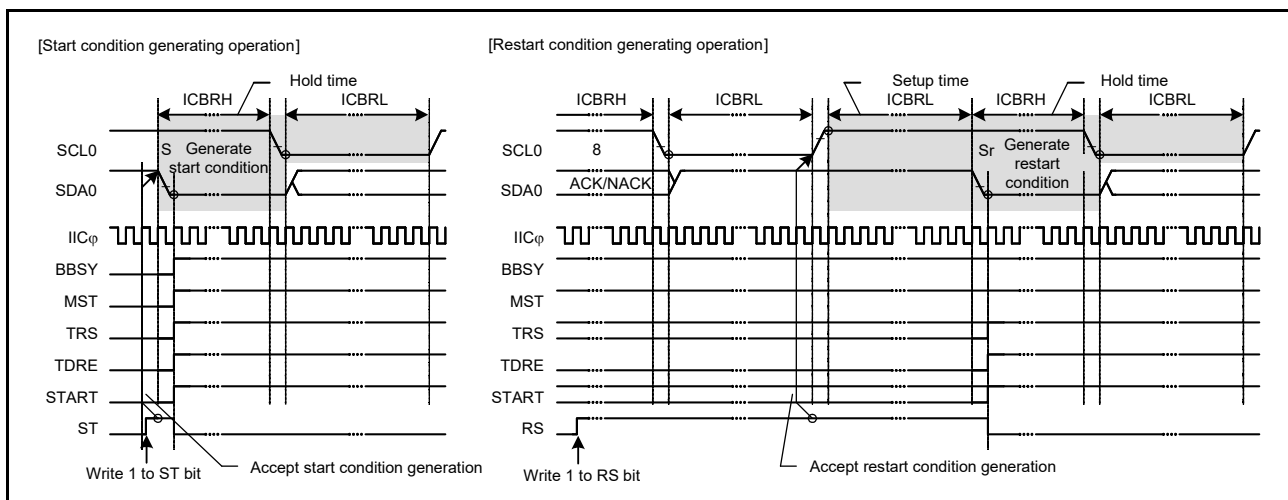

Figure 33.36 Start Condition/Restart Condition Generation Timing (ST and RS Bits)

### 33.10.3 Generating a Stop Condition

The RIIC generates a stop condition when the ICCR2.SP bit is set to 1.

When the SP bit is set to 1, a stop condition generation request is made and the RIIC generates a stop condition when the ICCR2.BBSY flag is 1 (bus busy state) and the ICCR2.MST bit is 1 (master mode).

A stop condition is generated in the following sequence.

#### Stop condition generation

- (1) Drive the SDA0 line low (high to low).
- (2) Secure the low period of the signal on the SCL0 line set in the ICBRL register.
- (3) Release the SCL0 line (low to high).
- (4) Detect the high level on the SCL0 line and secure the time set in the ICBRH register and the stop condition setup time.
- (5) Release the SDA0 line (low to high).
- (6) Secure the time set in the ICBRL register and the bus free time.
- (7) Set the BBSY flag to 0 (to release the bus mastership).

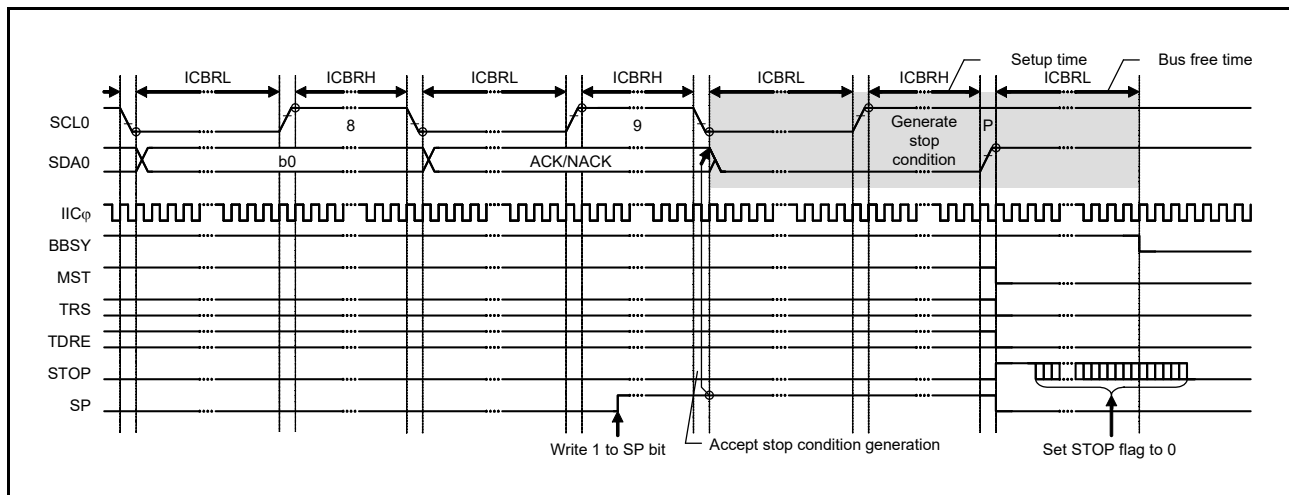

Figure 33.37 Stop Condition Generation Timing (SP Bit)

## 33.11 Bus Hanging

If the clock signals from the master and slave devices go out of synchronization due to noise or other factors, the I<sup>2</sup>C-bus might hang with a fixed level on the SCL0 line and/or SDA0 line.

As measures against the bus hanging, the RIIC has a timeout function to detect hanging by monitoring the SCL0 line, a function for the output of an additional SCL to release the bus from a hung state due to clock signals being out of synchronization, the RIIC reset function, and internal reset function.

By checking bits SCLO, SDAO, SCLI, and SDAI in the ICCR1 register, it is possible to see whether the RIIC or its partner in communications is placing the low level on the SCL0 or SDA0 lines.

### 33.11.1 Timeout Function

The RIIC includes a timeout function for detecting when the SCL0 line has been stuck longer than the predetermined time. The RIIC can detect an abnormal bus state by monitoring that the SCL0 line is stuck low or high for a predetermined time.

The timeout function monitors the SCL0 line state and counts the low period or high period using the internal counter. The timeout function resets the internal counter each time the SCL0 line changes (rising or falling), but continues to count unless the SCL0 line changes. If the internal counter overflows due to no SCL0 line change, the RIIC can detect the timeout and report the bus hung state.

This timeout function is enabled when the ICFER.TMOE bit is 1. It detects a hung state that the SCL0 line is stuck low or high during the following conditions:

- The bus is busy (ICCR2.BBSY flag is 1) in master mode (ICCR2.MST bit is 1).
- The RIIC's own slave address is detected (ICSR1 register is not 00h) and the bus is busy (ICCR2.BBSY flag is 1) in slave mode (ICCR2.MST bit is 0).
- The bus is free (ICCR2.BBSY flag is 0) while generation of a start condition is requested (ICCR2.ST bit is 1).

The internal counter of the timeout function works using the internal reference clock (IIC $\phi$ ) set by the ICMR1.CKS[2:0] bits as a count source. It functions as a 16-bit counter when long mode is selected (ICMR2.TMOS bit is 0) or a 14-bit counter when short mode is selected (TMOS bit is 1).

The SCL0 line level (low/high or both levels) during which this counter is activated can be selected by the setting of bits TMOH and TMOL in the ICMR2 register. If both bits TMOL and TMOH are set to 0, the internal counter does not work.

Figure 33.38 Timeout Function

### 33.11.2 Additional SCL Output Function

In master mode, the RIIC module has a facility for the output of additional SCL to release the SDA0 line from being held low by the slave device due to the master being out of synchronization with the slave device.

This function is mainly used in master mode to release the SDA0 line from the state of being stuck low by including additional SCL output from the RIIC with single cycles of the SCL as the unit if the RIIC cannot generate a stop condition because the slave device is holding the SDA0 line low. Do not use this function in normal situations. Using it when communications are proceeding correctly will lead to malfunctions.

When the ICCR1.CLO bit is set to 1, an additional clock pulse at the frequency set by the ICMR1.CKS[2:0] bits and the ICBRH and ICBRL registers is output from the SCL0 pin. After output of this clock pulse, the CLO bit automatically becomes 0. The SCL0 pin is held low when the ICCR2.BBSY flag is 1 and held high when the BBSY flag is 0.

Consecutive additional clock pulses can be output by writing 1 to the CLO bit after confirming the CLO bit to be 0.

When the RIIC module is in master mode and the slave device is holding the SDA0 line low because synchronization with the slave device has been lost due to the effects of noise, etc., the output of a stop condition is not possible. The additional SCL output function can be used to output additional clock pulses one by one to make the slave device release the SDA0 line from being held low, thus recovering the bus from an unusable state. Release of the SDA0 line by the slave device can be monitored by reading the ICCR1.SDAI bit. After confirming release of the SDA0 line by the slave device, complete communications by regenerating a stop condition.

Use this function with the ICFER.MALE bit set to 0 (master arbitration-lost detection disabled).

#### Conditions for using the ICCR1.CLO bit

- When the bus is free (ICCR2.BBSY flag is 0) or in master mode (ICCR2.MST bit is 1 and ICCR2.BBSY flag is 1)
- When the communication device does not hold the SCL0 line low

Figure 33.39 shows the operation timing of the additional SCL output function (CLO bit).

Figure 33.39 Additional SCL Output Function (CLO Bit)

### 33.11.3 RIIC Reset and Internal Reset

The RIIC module incorporates a function for resetting itself. There are two types of reset. One is referred to as an RIIC reset; this initializes all registers including the ICCR2.BBSY flag. The other is referred to as an internal reset; this releases the RIIC from the slave-address matched state and initializes the internal counter while retaining other settings. After applying a reset, be sure to set the ICCR1.IICRST bit to 0.

Both types of reset are effective for release from bus-hung states because both restore the output state of the SCL0 and SDA0 pins to the high-impedance state.

Applying a reset during slave operation may lead to a loss of synchronization between the master device clock and the slave device clock, so avoided this where possible. Note that monitoring of the bus state, such as for the presence of a start condition, is not possible during an RIIC reset (bits ICE and IICRST in the ICCR1 register are 01b).

For a detailed description of the RIIC and internal resets, refer to section 33.14, Initialization of Registers and Functions When a Reset is Applied or a Condition is Detected.

## 33.12 SMBus Operation

The RIIC is available for data communication conforming to the SMBus (Version 2.0). To perform SMBus communication, set the ICMR3.SMBS bit to 1. To use the transfer rate within a range of 10 kbps to 100 kbps of the SMBus specification, set the ICMR1.CKS[2:0] bits, the ICBRH register, and the ICBRL register. In addition, determine the values of the ICMR2.DLCS bit and the ICMR2.SDDL[2:0] bits to meet the data hold time (300 ns (min.)). If the RIIC is used only as a slave device, the transfer rate setting is not necessary, whereas the ICBRL register needs to be set to a value longer than the data setup time (250 ns).

For the SMBus device default address (1100 001b), use one of the slave address registers L0 to L2 (registers SARL0, SARL1, and SARL2), and set the corresponding SARUy.FS bit (7-bit/10-bit address format select) ( $y = 0$  to 2) to 0 (7-bit address format).

When transmitting the UDID (Unique Device Identifier), set the ICFER.SALE bit to 1 to enable the slave arbitration-lost detection function.

### 33.12.1 SMBus Timeout Measurement

#### (1) Measuring timeout of slave device

The following period (timeout interval:  $T_{\text{LOW:SEXT}}$ ) must be measured for slave devices in SMBus communication.

- From start condition to stop condition

To measure timeout for slave devices, measure the period from start condition detection to stop condition detection with the MTU or TMR timer using a start condition detection interrupt (STI) and stop condition detection interrupt (SPI) of the RIIC. The measured timeout period must be within the cumulative clock low extend time (slave device) ( $T_{\text{LOW:SEXT}}$ : 25 ms (max.)) of the SMBus specification.

If the time measured with the MTU or TMR exceeds the detect clock low timeout ( $T_{\text{TIMEOUT}}$ : 25 ms (min.)) of the SMBus specification, the slave device must release the bus by writing 1 to the ICCR1.IICRST bit to apply an internal reset of the RIIC. When an internal reset is applied to the RIIC, it stops driving the SCL0 and SDA0 pins of the bus and makes the SCL0/SDA0 pin outputs high-impedance, thus releasing the bus.

#### (2) Measuring timeout of master device

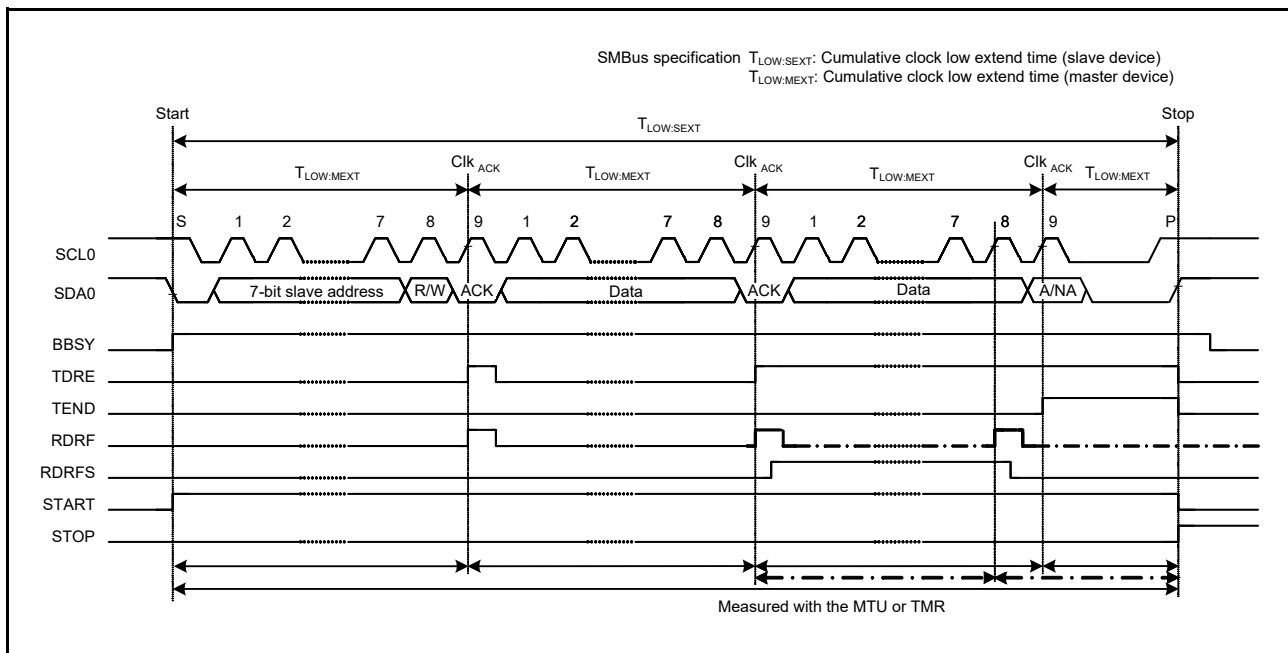

The following periods (timeout interval:  $T_{\text{LOW:MEXT}}$ ) must be measured for master devices in SMBus communication.

- From start condition to acknowledgment bit
- Between acknowledgment bits
- From acknowledgment bit to stop condition

To measure timeout for master devices, measure these periods with the MTU or TMR timer using a start condition detection interrupt (STI), stop condition detection interrupt (SPI), and transmission end interrupt (TEI) or receive data full interrupt (RXI) of the RIIC. The measured timeout period must be within the cumulative clock low extend time (master device) ( $T_{\text{LOW:MEXT}}$ : 10 ms (max.)) of the SMBus specification, and the total of all  $T_{\text{LOW:MEXT}}$  from start condition to stop condition must be within  $T_{\text{LOW:SEXT}}$ : 25 ms (max.).

For the ACK receive timing (rising edge of the ninth SCL), monitor the ICSR2.TEND flag in master transmit mode (master transmitter) and the ICSR2.RDRF flag in master receive mode (master receiver). For this reason, perform bitwise transmit operation in master transmit mode, and hold the ICMR3.RDRFS bit 0 until the byte just before reception of the final byte in master receive mode. While the RDRFS bit is 0, the RDRF flag is set to 1 at the rising edge of the ninth SCL.

If the period measured with the MTU or TMR exceeds the cumulative clock low extend time (master device) ( $T_{\text{LOW:MEXT}}$ : 10 ms (max.)) of the SMBus specification or the total of measured periods exceeds the detect clock low timeout ( $T_{\text{TIMEOUT}}$ : 25 ms (min.)) of the SMBus specification, the master device must stop the transaction by generating a stop condition. In master transmit mode, immediately stop the transmit operation (writing data to the ICDRT register).

**Figure 33.40 SMBus Timeout Measurement**

### 33.12.2 Packet Error Code (PEC)

This MCU incorporates a CRC calculator. The CRC calculator enables transmission of a packet error code (PEC) or checking the received data of the SMBus in data communication of the RIIC. For the CRC generating polynomials of the CRC calculator, refer to section 36, CRC Calculator (CRCA).

The PEC data in master transmit mode can be generated by writing all transmit data to the CRC data input register (CRCDIR) in the CRC calculator.

The PEC data in master receive mode can be checked by writing all receive data to CRCDIR in the CRC calculator and comparing the obtained value in the CRC data output register (CRCDOR) with the received PEC data.

To send ACK or NACK according to the match or mismatch result when the final byte is received as a result of the PEC code check, set the ICMR3.RDRFS bit to 1 before the rising edge of the eighth SCL during reception of the final byte, and hold the SCL0 line low at the falling edge of the eighth clock pulse.

### 33.12.3 SMBus Host Notification Protocol (Notify ARP Master Command)

In communications over an SMBus, a slave device can temporarily act as a master device to notify the SMBus host (or ARP master) of its own slave address or to request its own slave address from the SMBus host.

For a product of this MCU to operate as an SMBus host (or ARP master), the host address (0001 000b) sent from the slave device must be detected as a slave address, so the RIIC has a function for detecting the host address. To detect the host address as a slave address, set the ICMR3.SMBS bit and the IC SER.HOAE bit to 1. Operation after the host address has been detected is the same as normal slave operation.

### 33.13 Interrupt Sources

The RIIC generates four types of interrupt requests: communication error or communication event (arbitration-lost detection, NACK detection, timeout detection, start condition detection, and stop condition detection), receive data full, transmit data empty, and transmission end.

Table 33.6 lists details of the several interrupt requests. The receive data full and transmit data empty interrupt requests allow the DTC or DMAC to start data transfer.

**Table 33.6 Interrupt Sources**

| Symbol | Interrupt Source                            | Interrupt Flag | Start DTC/DMA Transfer | Interrupt Generation Condition |
|--------|---------------------------------------------|----------------|------------------------|--------------------------------|
| EEI    | Communication error/<br>communication event | AL             | Not possible           | AL = 1 and ALIE = 1            |
|        |                                             | NACKF          |                        | NACKF = 1 and NAKIE = 1        |
|        |                                             | TMOF           |                        | TMOF = 1 and TMOIE = 1         |
|        |                                             | START          |                        | START = 1 and STIE = 1         |
|        |                                             | STOP           |                        | STOP = 1 and SPIE = 1          |
| RXI*2  | Receive data full                           | RDRF           | Possible               | RDRF = 1 and RIE = 1           |
| TXI*1  | Transmit data empty                         | TDRE           | Possible               | TDRE = 1 and TIE = 1           |
| TEI*3  | Transmission end                            | TEND           | Not possible           | TEND = 1 and TEIE = 1          |

Note: There is a delay time between the execution of a write instruction for a peripheral module by the CPU and actual writing to the module. Thus, when an interrupt flag has been cleared or an interrupt request has been masked, read the relevant flag again to check whether clearing or masking has been completed, and then return from interrupt handling. Returning from interrupt handling without checking that writing to the module has been completed creates a possibility of repeated processing of the same interrupt.

Note 1. Because TXI is an edge-detected interrupt, it does not require clearing. Furthermore, the ICSR2.TDRE flag (a condition for TXI) is automatically set to 0 when data for transmission are written to the ICDRT register or a stop condition is detected (ICSR2.STOP flag is 1).

Note 2. Because RXI is an edge-detected interrupt, it does not require clearing. Furthermore, the ICSR2.RDRF flag (a condition for RXI) is automatically set to 0 when data are read from the ICDRR register.

Note 3. When using the TEI interrupt, clear the ICSR2.TEND flag in the TEI interrupt handling.

Note that the ICSR2.TEND flag is automatically set to 0 when data for transmission are written to the ICDRT register or a stop condition is detected (ICSR2.STOP flag is 1).

Clear the each flag or mask the interrupt request during interrupt handling.

#### 33.13.1 Buffer Operation for TXI and RXI Interrupts

If the conditions for generating a TXI and RXI interrupt are satisfied while the corresponding ICU.IRn.IR flag is 1, the interrupt request is not output for the ICU but retained internally (the capacity for internal retention is one request per source).

An interrupt request that was being retained internally is output to the ICU when the value of the IR flag becomes 0.

Internally retained interrupt requests are automatically cleared under normal conditions of usage.

Internally retained interrupt requests can also be cleared by writing 0 to the corresponding interrupt enable bit in the ICIER register.

### 33.14 Initialization of Registers and Functions When a Reset is Applied or a Condition is Detected

The RIIC can be reset by MCU reset, RIIC reset, and internal reset functions. Table 33.7 lists the reset states of registers and functions when a reset is applied or a condition is detected.

**Table 33.7 Reset States of Registers and Functions When a Reset is Applied or a Condition is Detected**

|                                             |             | MCU Reset   | RIIC Reset<br>(ICE = 0, IICRST = 1) | Internal Reset<br>(ICE = 1, IICRST = 1) | Start Condition/<br>Restart Condition<br>Detection | Stop Condition<br>Detection |
|---------------------------------------------|-------------|-------------|-------------------------------------|-----------------------------------------|----------------------------------------------------|-----------------------------|
| ICCR1                                       | SDAO, SCLO  | To be reset | To be reset                         | To be reset                             | Retained                                           | Retained                    |
|                                             | IICRST, ICE |             | Retained                            | Retained                                |                                                    |                             |
|                                             | Others      |             | To be reset                         |                                         |                                                    |                             |
| ICCR2                                       | ST, RS      | To be reset | To be reset                         | To be reset                             | To be reset                                        | Retained                    |
|                                             | SP          |             |                                     |                                         | See note 1                                         | To be reset                 |
|                                             | TRS         |             |                                     |                                         |                                                    |                             |
|                                             | MST         |             |                                     |                                         |                                                    |                             |

Note 1. This bit is not reset. This bit becomes 0 or 1 in accordance with the conditions.

### 33.15 Event Link Function (Output)

The RIIC0 handles event output for the event link controller (ELC) corresponding to the following sources.

- Communication error/communication event
- Receive data full
- Transmit data empty
- Transmission end

#### 33.15.1 Interrupt Handling and Event Linking

The RIIC has four types of interrupts: communication error or communication event (arbitration-lost detection, NACK detection, timeout detection, start condition detection, or stop condition detection), receive data full, transmit data empty, and transmission end. Each of these has an enable bit to control enabling and disabling of the interrupt signal. An interrupt request signal is output for the ICU when an interrupt source condition is satisfied while the setting of the corresponding enable bit is enabled.

The corresponding event signals are sent to other modules via the ELC when the interrupt source conditions are satisfied, regardless of the settings of the interrupt enable bits.

For details on interrupt sources, see Table 33.6.

## 33.16 Usage Notes

### 33.16.1 Setting Module Stop Function

Module stop state can be entered or released using module stop control register B (MSTPCRB). The initial setting is for operation of the RIIC to be stopped. RIIC register access is enabled by releasing the module stop state.

For details on module stop control register B, refer to section 11, Low Power Consumption.

### 33.16.2 Notes on Starting Transfer

If the IR flag corresponding to the RIIC interrupt is 1 when transfer is started (ICCR1.ICE bit is 1), follow the procedure below to clear interrupts before enabling operations. Starting transfer with the IR flag set to 1 while the ICCR1.ICE bit is 1 leads to an interrupt request being internally retained after transfer starts, and this can lead to unanticipated behavior of the IR flag.

1. Confirm that the ICCR1.ICE bit is 0.
2. Set the relevant interrupt enable bits (ICIER.TIE, etc.) on the peripheral function side to 0.
3. Read the relevant interrupt enable bits (ICIER.TIE, etc.) on the peripheral function side and confirm that its value is 0.
4. Set the IR flag to 0.

## 34. CAN Module (CAN)

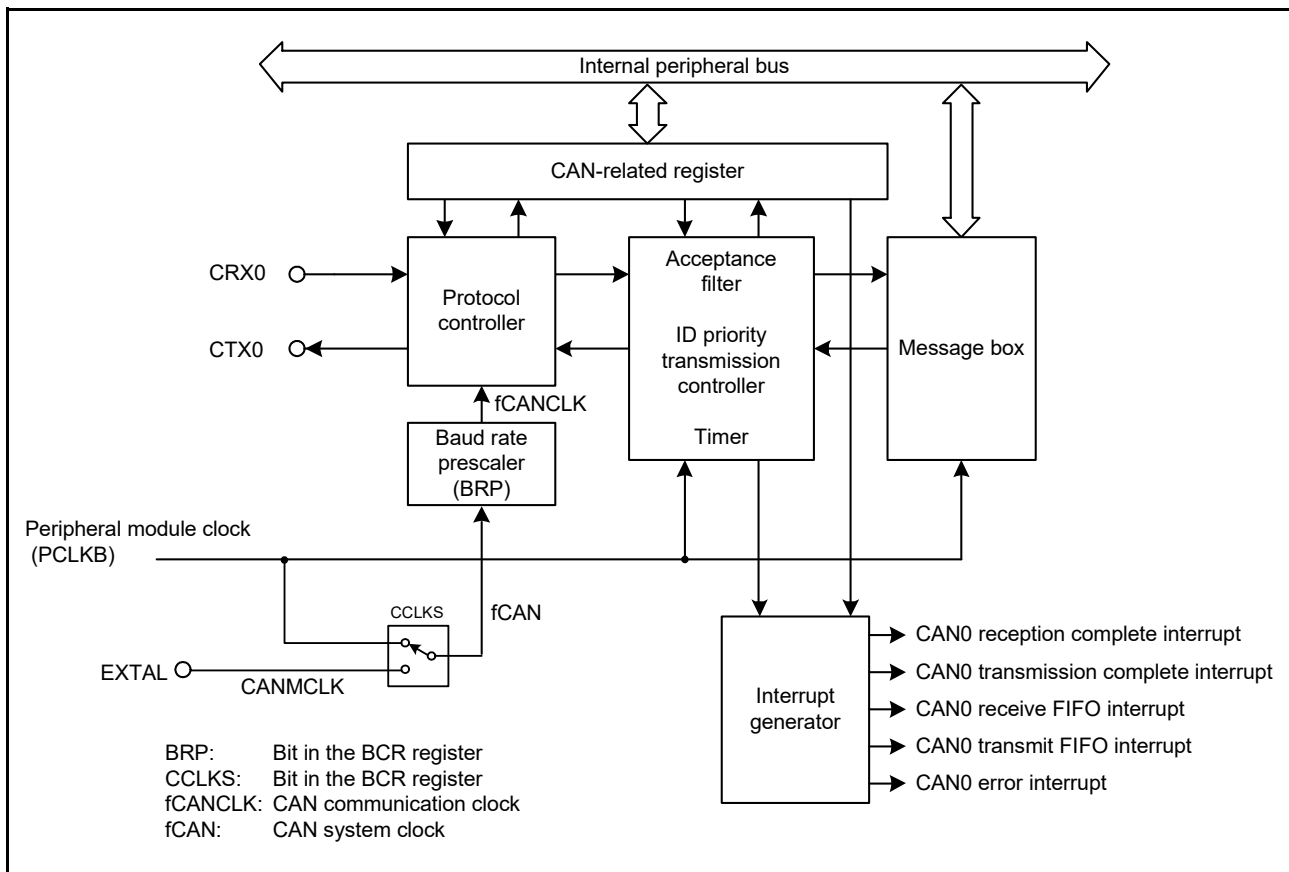

### 34.1 Overview

This MCU implements one channel of the CAN (Controller Area Network) module that complies with the ISO 11898-1 Standards. The CAN module transmits and receives both formats of messages, namely the standard identifier (11 bits) (identifier is hereafter referred to as ID) and extended ID (29 bits).

Table 34.1 lists the specifications of the CAN module, and Figure 34.1 shows a block diagram of the CAN module. Connect the CAN bus transceiver externally.

**Table 34.1 Specifications of CAN Module**

**Figure 34.1 Block Diagram of CAN Module**

- **CRX0 and CTX0**  
CAN input and output pins
- **Protocol controller**  
Handles CAN protocol processing such as bus arbitration, bit timing at transmission and reception, stuffing, and error handling, etc.
- **Message box**  
Consists of 32 mailboxes which can be configured as either transmit or receive mailboxes. Each mailbox has an individual ID, data length code, a data field (8 bytes), and a time stamp.
- **Acceptance filter**  
Performs filtering of received messages. MKR0 to MKR7 are used for the filtering process.
- **Timer**  
Used for the time stamp function. The timer value when a message is stored into the mailbox is written as the time stamp value.
- **Interrupt generator:**  
Generates the following five types of interrupts:
  - CAN0 reception complete interrupt
  - CAN0 transmission complete interrupt
  - CAN0 receive FIFO interrupt
  - CAN0 transmit FIFO interrupt
  - CAN0 error interrupt

Table 34.2 lists the CAN module pins.

The CAN functions should be selected for the pins multiplexed with other signals. For details, see section 20, I/O Ports.

**Table 34.2 Pin Configuration**

| Pin Name | I/O    | Function                  |
|----------|--------|---------------------------|
| CRX0     | Input  | Pin for receiving data    |
| CTX0     | Output | Pin for transmitting data |

| b15, b14 | —         | Reserved                            | These bits are read as 0. The write value should be 0.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      | R/W |

Note 1. Write to the BOM[1:0], TSPS[1:0], TPM, MLM, IDFM[1:0], and MBM bits in CAN reset mode.

Note 2. Set the RBOC bit to 1 in the bus-off state.

Note 3. This bit is automatically set back to 0 after being set to 1. It should be read as 0.

Note 4. Set the TSRC bit to 1 in CAN operation mode.

Note 5. When the CANM[1:0] and SLPM bits are changed, check STR to ensure that the mode has been switched. Do not change the CANM[1:0] bits or SLPM bit until the mode has been switched.

Note 6. Write to the SLPM bit in CAN reset mode or CAN halt mode. When changing the SLPM bit, write 0 or 1 to only the SLPM bit.

### **MBM Bit (CAN Mailbox Mode Select)**

When the MBM bit is 0 (normal mailbox mode), mailboxes [0] to [31] are configured as transmit or receive mailboxes. When the MBM bit is 1 (FIFO mailbox mode), mailboxes [0] to [23] are configured as transmit or receive mailboxes. Mailboxes [24] to [27] are configured as a transmit FIFO and mailboxes [28] to [31] as a receive FIFO. Transmit data is written into mailbox [24] (mailbox [24] is a window mailbox for the transmit FIFO). Receive data is read from mailbox [28] (mailbox [28] is a window mailbox for the receive FIFO). Table 34.3 lists the mailbox configuration.

### **IDFM[1:0] Bits (ID Format Mode Select)**

The IDFM[1:0] bits specify the ID format.

### **MLM Bit (Message Lost Mode Select)**

The MLM bit specifies the operation when a new message is captured in the unread mailbox. Overwrite mode or overrun mode can be selected. All mailboxes (including the receive FIFO) are set to either overwrite mode or overrun mode. When the MLM bit is 0, all mailboxes are set to overwrite mode and the new message is overwriting the old message. When the MLM bit is 1, all mailboxes are set to overrun mode and the new message is discarded.

### **TPM Bit (Transmission Priority Mode Select)**

The TPM bit specifies the priority of modes when transmitting messages.

ID priority transmit mode or mailbox number transmit mode can be selected. All mailboxes are set for either ID priority transmission or mailbox number priority transmission.

When the TPM bit is 0, ID priority transmit mode is selected and transmission priority complies with the CAN bus arbitration rule, as defined in the ISO 11898-1 Standards. In ID priority transmit mode, mailboxes [0] to [31] (in normal mailbox mode), and mailboxes [0] to [23] (in FIFO mailbox mode), and the transmit FIFO are compared for the IDs of mailboxes configured for transmission. If two or more mailbox IDs are the same, the mailbox with the smaller number has higher priority.

Only the next message to be transmitted from the transmit FIFO is included in the transmission arbitration. If a transmit FIFO message is being transmitted, the next pending message within the transmit FIFO is included in the transmission arbitration.

When the TPM bit is 1, mailbox number transmit mode is selected and the transmit mailbox with the smallest mailbox number has the highest priority. In FIFO mailbox mode, the transmit FIFO has lower priority than normal mailboxes (mailboxes [0] to [23]).

### **TSRC Bit (Time Stamp Counter Reset Command)**

The TSRC bit is used to reset the time stamp counter. When the TSRC bit is set to 1, TSR is set to 0000h. This bit is automatically set to 0.

### **TSPS[1:0] Bits (Time Stamp Prescaler Select)**

The TSPS[1:0] bits select the prescaler for the time stamp. The reference clock for the time stamp can be selected to be either 1-, 2-, 4- or 8-bit time periods.

### **CANM[1:0] Bits (CAN Operating Mode Select)**

The CANM[1:0] bits select one of the following modes for the CAN module: CAN operation mode, CAN reset mode, or CAN halt mode. CAN sleep mode is set by the SLPM bit. For details, refer to section 34.3, Operating Mode.

When the CAN module enters CAN halt mode according to the setting of the BOM[1:0] bits, the CANM[1:0] bits are automatically set to 10b.

**SLPM Bit (CAN Sleep Mode)**

When the SLPM bit is set to 1, the CAN module enters CAN sleep mode. When the SLPM bit is set to 0, the CAN module exits CAN sleep mode. For details, refer to section 34.3, Operating Mode.

**BOM[1:0] Bits (Bus-Off Recovery Mode)**

The BOM[1:0] bits are used to select bus-off recovery mode for the CAN module.

When the BOM[1:0] bits are 00b, the recovery from bus-off is compliant with the ISO 11898-1 Standards, i.e. the CAN module reenters CAN communication (error-active state) after detecting 11 consecutive recessive bits 128 times. A bus-off recovery interrupt request is generated when recovering from bus-off.

When the BOM[1:0] bits are 01b and the CAN module reaches the bus-off state, the CANM[1:0] bits in CTRLR are set to 10b (CAN halt mode) to enter CAN halt mode. No bus-off recovery interrupt request is generated when recovering from bus-off, and TECR and RECR are set to 00h.

When the BOM[1:0] bits are 10b, the CANM[1:0] bits are set to 10b as soon as the CAN module reaches the bus-off state. The CAN module enters CAN halt mode after the recovery from the bus-off state, i.e. after detecting 11 consecutive recessive bits 128 times. A bus-off recovery interrupt request is generated when recovering from bus-off, and TECR and RECR are set to 00h.

When the BOM[1:0] bits are 11b, the CAN module enters CAN halt mode by setting the CANM[1:0] bits to 10b while the CAN module is still in the bus-off state. No bus-off recovery interrupt request is generated when recovering from bus-off and TECR and RECR are set to 00h. However, if the CAN module recovers from bus-off after detecting 11 consecutive recessive bits 128 times before the CANM[1:0] bits are set to 10b, a bus-off recovery interrupt request is generated.

If the CPU requests an entry to CAN reset mode at the same time as the CAN module attempts to enter CAN halt mode (at bus-off entry when the BOM[1:0] bits are 01b, or at bus-off end when the BOM[1:0] bits are 10b), then the CPU request to enter CAN reset mode has higher priority.

**RBOC Bit (Forcible Return From Bus-Off)**

When the RBOC bit is set to 1 (force return from bus-off) in the bus-off state, the CAN module forcibly returns from the bus-off state. This bit is automatically set to 0. The error state changes from bus-off to error-active. When the RBOC bit is set to 1, RECR and TECR are set to 00h and the BOST bit in STR is set to 0 (the CAN module is not in bus-off state). The other registers remain unchanged even when the RBOC bit is set to 1. No bus-off recovery interrupt request is generated by this recovery from the bus-off state. Use the RBOC bit only when the BOM[1:0] bits are 00b (normal mode).

**Table 34.3 Mailbox Configuration**

| Mailbox                | MBM Bit = 0<br>(Normal Mailbox Mode) | MBM Bit = 1<br>(FIFO Mailbox Mode) |
|------------------------|--------------------------------------|------------------------------------|
| Mailboxes [0] to [23]  | Normal mailbox                       | Normal mailbox                     |
| Mailboxes [24] to [27] |                                      | Transmit FIFO                      |
| Mailboxes [28] to [31] |                                      | Receive FIFO                       |

Points 1 to 5 below should be considered when the CTRLR.MBM bit is set to 1.

Note 1. Transmit FIFO is controlled by TFCR. MCTLj of mailboxes [24] to [27] is disabled. MCTL24 to MCTL27 cannot be used by the transmit FIFO.

Note 2. Receive FIFO is controlled by RFCR. MCTLj of mailboxes [28] to [31] is disabled. MCTL28 to MCTL31 cannot be used by the receive FIFO.

Note 3. Refer to MIER about the FIFO interrupts.

Note 4. The corresponding bits in MKIVLR for mailboxes [24] to [31] are disabled. Set 0 to these bits.

Note 5. Transmit/receive FIFOs can be used for both data frames and remote frames.

### 34.2.2 Bit Configuration Register (BCR)

Address(es): CAN0.BCR 0009 0844h

| 1          | 1          | 0 1: 14 Tq                           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |     |     |  |   |   |                       |   |   |                       |   |   |                         |   |   |           |     |   |           |   |   |           |   |   |           |   |   |           |     |   |           |   |   |            |   |   |            |   |   |            |   |   |            |   |   |            |   |   |            |   |   |            |     |
| 1          | 1          | 1 0: 15 Tq                           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |     |     |  |   |   |                       |   |   |                       |   |   |                         |   |   |           |     |   |           |   |   |           |   |   |           |   |   |           |     |   |           |   |   |            |   |   |            |   |   |            |   |   |            |   |   |            |   |   |            |   |   |            |     |
| 1          | 1          | 1 1: 16 Tq                           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |     |     |  |   |   |                       |   |   |                       |   |   |                         |   |   |           |     |   |           |   |   |           |   |   |           |   |   |           |     |   |           |   |   |            |   |   |            |   |   |            |   |   |            |   |   |            |   |   |            |   |   |            |     |

Tq: Time Quantum

Note 1. Do not select the value less than 1 while the SCKCR3.CKSEL[2:0] bits are 010b (selecting the main clock oscillator).

For bit timing setting, refer to section 34.4, CAN Communication Speed Setting.

Set BCR before entering CAN halt mode or CAN operation mode from CAN reset mode. After the setting is made once, this register can be written to in CAN reset mode or CAN halt mode.

BCR consists of 24 bits. A 32-bit read/write access should be performed carefully not to rewrite bits b0 to b7.

#### **CCLKS Bit (CAN Clock Source Selection)**

When the CCLKS bit is 0, the peripheral module clock (PCLKB) produced by the PLL frequency synthesizer is used as the CAN clock source (fCAN).

When the CCLKS bit is 1, CANMCLK produced externally by the EXTAL pins is used as the CAN clock source (fCAN).

#### **TSEG2[2:0] Bits (Time Segment 2 Control)**

The TSEG2[2:0] bits are used to specify the length of the phase buffer segment 2 (PHASE\_SEG2) with a Tq value. A value from 2 to 8 Tq can be set. Set a value smaller than that of the TSEG1[3:0] bits.

#### **SJW[1:0] Bits (Resynchronization Jump Width Control)**

The SJW[1:0] bits are used to specify the resynchronization jump width with a Tq value. A value from 1 to 4 Tq can be set. Set a value smaller than or equal to that of the TSEG2[2:0] bits.

#### **BRP[9:0] Bits (Prescaler Division Ratio Select)**

The BRP[9:0] bits are used to set the frequency of the CAN communication clock (fCANCLK). The fCANCLK cycle is 1 Tq. If the setting is P (0 to 1023), the baud rate prescaler divides fCAN by P + 1.

#### **TSEG1[3:0] Bits (Time Segment 1 Control)**

The TSEG1[3:0] bits are used to specify the total length of the propagation time segment (PROP\_SEG) and phase buffer segment 1 (PHASE\_SEG1) with a time quantum (Tq) value.

A value from 4 to 16 Tq can be set.

### 34.2.3 Mask Register k (MKRk) (k = 0 to 7)

Address(es): CAN0.MKR0 0009 0400h, CAN0.MKR1 0009 0404h, CAN0.MKR2 0009 0408h, CAN0.MKR3 0009 040Ch,  
CAN0.MKR4 0009 0410h, CAN0.MKR5 0009 0414h, CAN0.MKR6 0009 0418h, CAN0.MKR7 0009 041Ch

| Bit        | Symbol    | Bit Name    | Description                                                                                  | R/W |
|------------|-----------|-------------|----------------------------------------------------------------------------------------------|-----|
| b17 to b0  | EID[17:0] | Extended ID | 0: Corresponding EID[17:0] bit is not compared<br>1: Corresponding EID[17:0] bit is compared | R/W |
| b28 to b18 | SID[10:0] | Standard ID | 0: Corresponding SID[10:0] bit is not compared<br>1: Corresponding SID[10:0] bit is compared | R/W |
| b31 to b29 | —         | Reserved    | The read value is undefined. The write value should be 0.                                    | R/W |

For the mask function in FIFO mailbox mode, refer to section 34.6, Acceptance Filtering and Masking Functions. Write to MKR0 to MKR7 in CAN reset mode or CAN halt mode.

#### EID[17:0] Bits (Extended ID)

The EID[17:0] bits are the filter mask bits for the CAN extended ID bits.

These bits are used to receive extended ID messages.

When the EID[17:0] bit is set to 0, the received ID is not compared with the mailbox ID for the corresponding EID[17:0] bit.

When the EID[17:0] bit is set to 1, the received ID is compared with the mailbox ID for the corresponding EID[17:0] bit.

#### SID[10:0] Bits (Standard ID)

The SID[10:0] bits are the filter mask bits corresponding to the CAN standard ID bits.

These bits are used to receive both standard ID and extended ID messages.

When the SID[10:0] bit is set to 0, the received ID is not compared with the mailbox ID for the corresponding SID[10:0] bit.

When the SID[10:0] bit is set to 1, the received ID is compared with the mailbox ID for the corresponding SID[10:0] bit.

### 34.2.4 FIFO Received ID Compare Registers 0 and 1 (FIDCR0 and FIDCR1)

Address(es): CAN0.FIDCR0 0009 0420h, CAN0.FIDCR1 0009 0424h

| Bit        | Symbol    | Bit Name                    | Description                                                                    | R/W |
|------------|-----------|-----------------------------|--------------------------------------------------------------------------------|-----|
| b17 to b0  | EID[17:0] | Extended ID                 | 0: Corresponding EID[17:0] bits are 0<br>1: Corresponding EID[17:0] bits are 1 | R/W |
| b28 to b18 | SID[10:0] | Standard ID                 | 0: Corresponding SID[10:0] bits are 0<br>1: Corresponding SID[10:0] bits are 1 | R/W |
| b29        | —         | Reserved                    | The read value is undefined. The write value should be 0.                      | R/W |
| b30        | RTR       | Remote Transmission Request | 0: Data frame<br>1: Remote frame                                               | R/W |
| b31        | IDE       | ID Extension*1              | 0: Standard ID<br>1: Extended ID                                               | R/W |

Note 1. When the IDFM[1:0] bits are not 10b, the IDE bit should be written with 0 and read as 0.

FIDCR0 and FIDCR1 are enabled when the MBM bit in CTRLR is set to 1 (FIFO mailbox mode). Bits EID[17:0], SID[10:0], RTR, and IDE in MB28 to MB31 are disabled.

For the usage of FIDCR0 and FIDCR1, refer to section 34.6, Acceptance Filtering and Masking Functions. Write to FIDCR0 and FIDCR1 in CAN reset mode or CAN halt mode.

#### EID[17:0] Bits (Extended ID)

The EID[17:0] bits set the extended ID of data frames and remote frames. These bits are used to receive extended ID messages.

#### SID[10:0] Bits (Standard ID)

The SID[10:0] bits set the standard ID of data frames and remote frames. These bits are used to receive both standard ID and extended ID messages.

#### RTR Bit (Remote Transmission Request)

The RTR bit sets the specified frame format of data frames or remote frames.

- When both RTR bits in FIDCR0 and FIDCR1 are set to 0, only data frames can be received.
- When both RTR bits in FIDCR0 and FIDCR1 are set to 1, only remote frames can be received.
- When the RTR bits in FIDCR0 and FIDCR1 are set to 0 or 1 individually, both data frames and remote frames can be received.

### IDE Bit (ID Extension)

The IDE bit sets the ID format to standard ID or extended ID. The IDE bit is enabled when the IDFM[1:0] bits in CTRLR are 10b (mixed ID mode).

- When both IDE bits in FIDCR0 and FIDCR1 are set to 0, only standard ID frames can be received.
- When both IDE bits in FIDCR0 and FIDCR1 are set to 1, only extended ID frames can be received.
- When the IDE bits in FIDCR0 and FIDCR1 are set to 0 or 1 individually, both standard ID and extended ID frames can be received.

### 34.2.5 Mask Invalid Register (MKIVLR)

Address(es): CAN0.MKIVLR 0009 0428h

x: Undefined

| Bit       | Symbol      | Bit Name     | Description                      | R/W |
|-----------|-------------|--------------|----------------------------------|-----|
| b31 to b0 | MB31 to MB0 | Mask Invalid | 0: Mask valid<br>1: Mask invalid | R/W |

Each bit in MKIVLR corresponds to a mailbox.

The correspondence between the bits and mailboxes is shown below.

Bit 0 in MKIVLR corresponds to mailbox 0 (MB0) and bit 31 corresponds to mailbox 31 (MB31).<sup>\*1</sup>

When a bit is set to 1, the relevant acceptance mask register becomes invalid for the corresponding mailbox. When a mask invalid bit is set to 1, a message is received by the corresponding mailbox only if the receive message ID matches the mailbox ID exactly.

Write to MKIVLR in CAN reset mode or CAN halt mode.

Note 1. Set bits 31 to 24 to 0 in FIFO mailbox mode.

### 34.2.6 Mailbox Register j (MBj) (j = 0 to 31)

Table 34.4 lists the CAN0 mailbox memory mapping, and Table 34.5 lists the CAN data frame configuration. The value after reset of the CAN0 mailbox is undefined.

Write to MBj only when the related MCTLj (j = 0 to 31) is 00h and the corresponding mailbox is not processing an abort request.

See Table 34.4 for detailed register addresses.

**Table 34.4 CAN0 Mailbox Memory Mapping**

| Address                  | Message Content             |
|--------------------------|-----------------------------|
| <b>CAN0</b>              | <b>Memory Mapping</b>       |
| 0009 0200h + 16 × j + 0  | IDE, RTR, SID10 to SID6     |
| 0009 0200h + 16 × j + 1  | SID5 to SID0, EID17, EID16  |
| 0009 0200h + 16 × j + 2  | EID15 to EID8               |
| 0009 0200h + 16 × j + 3  | EID7 to EID0                |
| 0009 0200h + 16 × j + 4  | —                           |
| 0009 0200h + 16 × j + 5  | Data length code (DLC[3:0]) |
| 0009 0200h + 16 × j + 6  | Data byte 0                 |
| 0009 0200h + 16 × j + 7  | Data byte 1                 |
| 0009 0200h + 16 × j + 8  | Data byte 2                 |
| 0009 0200h + 16 × j + 9  | Data byte 3                 |
| 0009 0200h + 16 × j + 10 | Data byte 4                 |
| 0009 0200h + 16 × j + 11 | Data byte 5                 |
| 0009 0200h + 16 × j + 12 | Data byte 6                 |
| 0009 0200h + 16 × j + 13 | Data byte 7                 |
| 0009 0200h + 16 × j + 14 | Time stamp upper byte       |
| 0009 0200h + 16 × j + 15 | Time stamp lower byte       |

Note: When accessing to the content of the MBj register, access to an address of a multiple of 4 (the suffix of the address is 0h, 4h, 8h, or Ch) in 32-bit units and to an even address in 16-bit units.

**Table 34.5 CAN Data Frame Configuration**

|               |              |                |               |              |              |       |       |     |       |
|---------------|--------------|----------------|---------------|--------------|--------------|-------|-------|-----|-------|
| SID10 to SID6 | SID5 to SID0 | EID17 to EID16 | EID15 to EID8 | EID7 to EID0 | DLC3 to DLC1 | DATA0 | DATA1 | ... | DATA7 |
|---------------|--------------|----------------|---------------|--------------|--------------|-------|-------|-----|-------|

The previous value of each mailbox is retained unless a new message is received.

Address(es): CAN0.MB0 to CAN0.MB31 0009 0200h to 0009 03FFh

| Bit        | Symbol    | Bit Name             | Description                                                                    | R/W |
|------------|-----------|----------------------|--------------------------------------------------------------------------------|-----|
| b17 to b0  | EID[17:0] | Extended ID*1        | 0: Corresponding EID[17:0] bits are 0<br>1: Corresponding EID[17:0] bits are 1 | R/W |
| b28 to b18 | SID[10:0] | Standard ID          | 0: Corresponding SID[10:0] bits are 0<br>1: Corresponding SID[10:0] bits are 1 | R/W |
| b29        | —         | Reserved             | The read value is undefined. The write value should be 0.                      | R/W |
| b30        | RTR       | Remote Frame Request | 0: Data frame<br>1: Remote frame                                               | R/W |
| b31        | IDE       | ID Extension*2       | 0: Standard ID<br>1: Extended ID                                               | R/W |

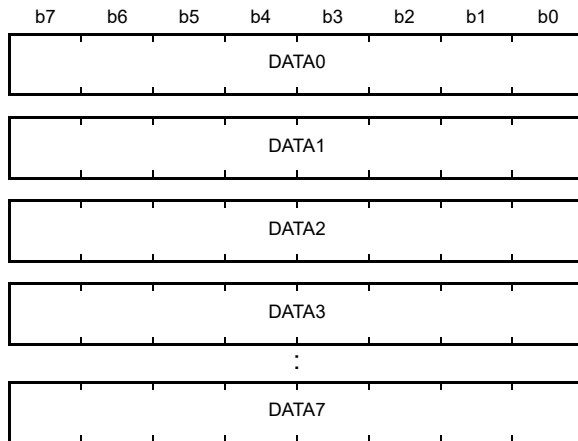

- Note 1. If the mailbox has received a standard ID message, the EID bits in the mailbox are undefined.  
 Note 2. The IDE bit is enabled when the IDFM[1:0] bits in CTLR are 10b (mixed ID mode). When the IDFM[1:0] bits are not 10b, it should be written with 0 and read as 0.

| Bit       | Symbol   | Bit Name           | Description                                                                                                                                                                                                                                                                                                           | R/W |

| b15 to b4 | —        | Reserved           | The read value is undefined. The write value should be 0.                                                                                                                                                                                                                                                             | R/W |

- x: Don't care  
 Note 1. If the mailbox has received a message whose data length set by the DLC[3:0] bits is less than 8 bytes, the values of DATA larger than the data length set by the DLC[3:0] bits in the mailbox are undefined.

Value after reset: x x x x x x x x

x: Undefined

| Bit      | Symbol         | Bit Name                    | Description                                                                                                                                                                                                 | R/W |
|----------|----------------|-----------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----|
| b7 to b0 | DATA0 to DATA7 | Data Bytes 0 to 7*1, *2, *3 | DATA0 to DATA7 store the transmitted or received CAN message data. Transmission or reception starts from DATA0. The bit order on the CAN bus is MSB first, and transmission or reception starts from bit 7. | R/W |

- Note 1. If the mailbox has received a message with n bytes less than 8 bytes, the values of DATAn to DATA7 in the mailbox are undefined.
- Note 2. If the mailbox has received a remote frame, the previous values of DATA0 to DATA7 in the mailbox are retained.
- Note 3. DATA0 to DATA3 or DATA4 to DATA7 cannot be accessed in 32-bit units at one time. The access must be divided into 3 times: DATA0 to DATA1, DATA2 to DATA5, and DATA6 to DATA7, or 4 times: DATA0 to DATA1, DATA2 to DATA3, DATA4 to DATA5, and DATA6 to DATA7.

Value after reset: x x x x x x x x x x x x x x x x

x: Undefined

| Bit       | Symbol   | Bit Name               | Description                                                                                                            | R/W |
|-----------|----------|------------------------|------------------------------------------------------------------------------------------------------------------------|-----|
| b7 to b0  | TSL[7:0] | Time Stamp Lower Byte  | Bits TSH[7:0] and TSL[7:0] store the counter value of the time stamp when received messages are stored in the mailbox. | R/W |
| b15 to b8 | TSH[7:0] | Time Stamp Higher Byte |                                                                                                                        | R/W |

### EID[17:0] Bits (Extended ID)

The EID[17:0] bits set the extended ID of data frames and remote frames. These bits are used to transmit or receive extended ID messages.

### SID[10:0] Bits (Standard ID)

The SID[10:0] bits set the standard ID of data frames and remote frames. These bits are used to transmit or receive both standard ID and extended ID messages.

**RTR Bit (Remote Frame Request)**

The RTR bit sets the frame format of data frames or remote frames.

- Receive mailbox receives only frames with the format specified by the RTR bit.
- Transmit mailbox transmits according to the frame format specified by the RTR bit.
- Receive FIFO mailbox receives the data frame, remote frame, or both frames specified by the RTR bit in FIDCR0 and FIDCR1.
- Transmit FIFO mailbox transmits the data frame or remote frame specified by the RTR bit in the relevant transmit message.

**IDE Bit (ID Extension)**

The IDE bit sets the ID format of standard IDs or extended IDs. The IDE bit is enabled when the IDFM[1:0] bits in CTLR is 10b (mixed ID mode).

- Receive mailbox receives only the ID format specified by the IDE bit.
- Transmit mailbox transmits with the ID format specified by the IDE bit.
- Receive FIFO mailbox receives messages with the standard ID and extended ID specified by the IDE bit in FIDCR0 and FIDCR1.
- Transmit FIFO mailbox transmits messages with the standard ID or extended ID specified by the IDE bit in the relevant transmit message.

**DLC[3:0] Bits (Data Length Code)**

The DLC[3:0] bits specify the number of bytes of data to be transmitted in data frames. When a remote frame is used to request data, this field specifies the requested number of bytes of data.

When a data frame is received, the number of bytes received is stored in this field. When a remote frame is received, this field is used to store the number requested by the frame.

### 34.2.7 Mailbox Interrupt Enable Register (MIER)

| b25       | MB25        | Transmit FIFO Interrupt Generation Timing Control  | 0: Every time transmission is completed<br>1: When the transmit FIFO becomes empty due to completion of transmission                | R/W |
| b27, b26  | —           | Reserved                                           | The read value is undefined. The write value should be 0.                                                                           | R/W |
| b28       | MB28        | Receive FIFO Interrupt Enable                      | 0: Interrupt disabled<br>1: Interrupt enabled                                                                                       | R/W |
| b29       | MB29        | Receive FIFO Interrupt Generation Timing Control*1 | 0: Every time reception is completed<br>1: When the receive FIFO becomes buffer warning by completion of reception                  | R/W |
| b31, b30  | —           | Reserved                                           | The read value is undefined. The write value should be 0.                                                                           | R/W |

Note 1. No interrupt request is generated when the receive FIFO becomes buffer warning from full. "Buffer warning" indicates a state in which the third message is stored in the receive FIFO.

MIER can individually enable interrupts for each mailbox.

In normal mailbox mode (all bits) and in FIFO mailbox mode (bits 24 to 0 in MIER), each bit corresponds to the mailbox with the related number. These bits enable or disable transmission/reception complete interrupts for the corresponding mailboxes.

- Bit 0 in MIER corresponds to mailbox 0 (MB0).
- Bit 31 in MIER corresponds to mailbox 31 (MB31).

In FIFO mailbox mode, bits 29, 28, 25, and 24 of MIER specify whether transmit/receive FIFO interrupts are enabled/disabled and the timing when interrupt requests are generated.

Write to MIER only when the related MCTLj (j = 0 to 31) is 00h and the corresponding mailbox is not processing a transmission or reception abort request. In FIFO mailbox mode, change the bits in MIER for the related FIFO only when the TFE bit in TFCR is 0 and the TFEST flag is 1, and the RFE bit in RFCR is 0 and the RFEST flag in RFCR is 1.

### 34.2.8 Message Control Register j (MCTLj) (j = 0 to 31)

| b5  | —          | Reserved                                  | This bit is read as 0. The write value should be 0.                                                                                                                                                          | R/W |
| b6  | RECREQ     | Receive Mailbox Request<br>*2, *3, *4, *5 | 0: Not configured for reception<br>1: Configured for reception                                                                                                                                               | R/W |
| b7  | TRMREQ     | Transmit Mailbox Request<br>*2, *4        | 0: Not configured for transmission<br>1: Configured for transmission                                                                                                                                         | R/W |

Note 1. Write 0 only. Writing 1 has no effect.

Note 2. When writing 0 to bits NEWDATA, SENTDATA, MSGLOST, TRMABT, RECREQ, and TRMREQ by a program, do not use the logic operation instruction (AND). Write 0 to only the specified bit and write 1 to the other bits before using the transfer (MOV) instruction.

Note 3. To enter one-shot receive mode, write 1 to the ONESHOT bit at the same time as setting the RECREQ bit to 1.  
To exit one-shot receive mode, write 0 to the ONESHOT bit after writing 0 to the RECREQ bit and confirming that it has been set to 0.

To enter one-shot transmit mode, write 1 to the ONESHOT bit at the same time as setting the TRMREQ bit to 1.  
To exit one-shot transmit mode, write 0 to the ONESHOT bit after the message has been transmitted or aborted.

Note 4. Do not set both the RECREQ and TRMREQ bits to 1.

Note 5. When setting the RECREQ bit to 0, set bits MSGLOST, NEWDATA, and RECREQ to 0 simultaneously.

Write to the MCTLj in CAN operation mode or CAN halt mode.  
Do not use MCTL24 to MCTL31 in FIFO mailbox mode.

#### **SENTDATA Flag (Transmission Complete Flag)**

The SENTDATA flag is set to 1 when data transmission from the corresponding mailbox is completed. The SENTDATA flag is set to 0 by writing 0 by a program.

To set the SENTDATA flag to 0, first set the TRMREQ bit to 0. Bits SENTDATA and TRMREQ cannot be set to 0 simultaneously. To transmit a new message from the corresponding mailbox, set the SENTDATA flag to 0.

#### **NEWDATA Flag (Reception Complete Flag)**

The NEWDATA flag is set to 1 when a new message is being stored or has been stored to the mailbox. The timing for setting this bit to 1 is simultaneous with the INVALIDDATA flag. The NEWDATA flag is set to 0 by writing 0 by a program. The NEWDATA flag cannot be set to 0 by writing 0 by a program while the related INVALIDDATA flag is 1.

#### **TRMACTIVE Flag (Transmission-in-Progress Status Flag)**

The TRMACTIVE flag is set to 1 when the corresponding mailbox of the CAN module begins transmitting a message. The TRMACTIVE flag is set to 0 when the CAN module has lost CAN bus arbitration, a CAN bus error occurs, or data transmission is completed.

#### **INVALIDDATA Flag (Reception-in-Progress Status Flag)**

After the completion of a message reception, the INVALIDDATA flag is set to 1 while the received message is being updated into the corresponding mailbox. The INVALIDDATA flag is set to 0 immediately after the message has been stored. If the mailbox is read while the INVALIDDATA flag is 1, the data is undefined.

#### **TRMABT Flag (Transmission Abort Complete Flag)**

The TRMABT flag is set to 1 in the following cases:

- Following a transmission abort request, when the transmission abort is completed before starting transmission.
- Following a transmission abort request, when the CAN module detects CAN bus arbitration-lost or a CAN bus error.
- In one-shot transmission mode (RECREQ bit = 0, TRMREQ bit = 1, and ONESHOT bit = 1), when the CAN module detects CAN bus arbitration-lost or a CAN bus error.

The TRMABT flag is not set to 1 when data transmission is completed. In this case, the SENTDATA flag is set to 1. The TRMABT flag is set to 0 by writing 0 by a program.

#### **MSGLOST Flag (Message Lost Flag)**

The MSGLOST flag is set to 1 when the mailbox is overwritten or overrun by a new received message while the NEWDATA flag is 1. The MSGLOST flag is set to 1 at the end of the 6th bit of EOF. The MSGLOST flag is set to 0 by writing 0 by a program.

In both overwrite and overrun modes, the MSGLOST flag cannot be set to 0 by writing 0 by a program during five peripheral module clock (PCLKB) cycles following the sixth bit of EOF.

**ONESHOT Bit (One-Shot Enable)**

The ONESHOT bit can be used in the following two ways, receive mode and transmit mode.

- One-shot receive mode
 

When the ONESHOT bit is set to 1 in receive mode (RECREQ bit = 1 and TRMREQ bit = 0), the mailbox receives a message only one time. (The mailbox does not behave as a receive mailbox after having received a message one time.) The behavior of flags NEWDATA and INVALIDDATA is the same as in normal receive mode. In one-shot receive mode, the MSGLOST flag is not set to 1. To set the ONESHOT bit to 0, first write 0 to the RECREQ bit and ensure that it has been set to 0.
- One-shot transmit mode
 

When the ONESHOT bit is set to 1 in transmit mode (RECREQ bit = 0 and TRMREQ bit = 1), the CAN module transmits a message only one time. (The CAN module does not transmit the message again if a CAN bus error or CAN bus arbitration-lost occurs.) When transmission is completed, the SENTDATA flag is set to 1. If transmission is not completed due to a CAN bus error or CAN bus arbitration-lost, the TRMABT flag is set to 1. Set the ONESHOT bit to 0 after the SENTDATA or TRMABT flag is set to 1.

**RECREQ Bit (Receive Mailbox Request)**

The RECREQ bit selects receive modes listed in Table 34.10.

When the RECREQ bit is set to 1, the corresponding mailbox is configured for reception of a data frame or a remote frame.

When the RECREQ bit is set to 0, the corresponding mailbox is not configured for reception of a data frame or a remote frame.

Due to hardware protection, the RECREQ bit cannot be set to 0 by writing 0 by a program during the following period.

- Hardware protection is started
 

From the acceptance filter processing (the beginning of CRC field)
- Hardware protection is released
  - For the mailbox that is specified to receive the incoming message, after the received data is stored into the mailbox or a CAN bus error occurs (i.e. maximum period of hardware protection is from the beginning of CRC field to the end of the 7th bit of EOF)
  - For the other mailboxes, after the acceptance filter processing
  - If no mailbox is specified to receive the message, after the acceptance filter processing
