

V850E2/ML4

User's Manual: Hardware

32-bit Single-Chip Microcontroller
V850E2/Mx4 microcontrollers

μ PD70F4021

μ PD70F4022

All information contained in these materials, including products and product specifications, represents information on the product at the time of publication and is subject to change by Renesas Electronics Corp. without notice. Please review the latest information published by Renesas Electronics Corp. through various means, including the Renesas Electronics Corp. website (<http://www.renesas.com>).

Notice

1. Descriptions of circuits, software and other related information in this document are provided only to illustrate the operation of semiconductor products and application examples. You are fully responsible for the incorporation of these circuits, software, and information in the design of your equipment. Renesas Electronics assumes no responsibility for any losses incurred by you or third parties arising from the use of these circuits, software, or information.
2. Renesas Electronics has used reasonable care in preparing the information included in this document, but Renesas Electronics does not warrant that such information is error free. Renesas Electronics assumes no liability whatsoever for any damages incurred by you resulting from errors in or omissions from the information included herein.
3. Renesas Electronics does not assume any liability for infringement of patents, copyrights, or other intellectual property rights of third parties by or arising from the use of Renesas Electronics products or technical information described in this document. No license, express, implied or otherwise, is granted hereby under any patents, copyrights or other intellectual property rights of Renesas Electronics or others.
4. You should not alter, modify, copy, or otherwise misappropriate any Renesas Electronics product, whether in whole or in part. Renesas Electronics assumes no responsibility for any losses incurred by you or third parties arising from such alteration, modification, copy or otherwise misappropriation of Renesas Electronics product.
5. Renesas Electronics products are classified according to the following two quality grades: "Standard" and "High Quality". The recommended applications for each Renesas Electronics product depends on the product's quality grade, as indicated below.
"Standard": Computers; office equipment; communications equipment; test and measurement equipment; audio and visual equipment; home electronic appliances; machine tools; personal electronic equipment; and industrial robots etc.
"High Quality": Transportation equipment (automobiles, trains, ships, etc.); traffic control systems; anti-disaster systems; anti-crime systems; and safety equipment etc.

Renesas Electronics products are neither intended nor authorized for use in products or systems that may pose a direct threat to human life or bodily injury (artificial life support devices or systems, surgical implantations etc.), or may cause serious property damages (nuclear reactor control systems, military equipment etc.). You must check the quality grade of each Renesas Electronics product before using it in a particular application. You may not use any Renesas Electronics product for any application for which it is not intended. Renesas Electronics shall not be in any way liable for any damages or losses incurred by you or third parties arising from the use of any Renesas Electronics product for which the product is not intended by Renesas Electronics.
6. You should use the Renesas Electronics products described in this document within the range specified by Renesas Electronics, especially with respect to the maximum rating, operating supply voltage range, movement power voltage range, heat radiation characteristics, installation and other product characteristics. Renesas Electronics shall have no liability for malfunctions or damages arising out of the use of Renesas Electronics products beyond such specified ranges.
7. Although Renesas Electronics endeavors to improve the quality and reliability of its products, semiconductor products have specific characteristics such as the occurrence of failure at a certain rate and malfunctions under certain use conditions. Further, Renesas Electronics products are not subject to radiation resistance design. Please be sure to implement safety measures to guard them against the possibility of physical injury, and injury or damage caused by fire in the event of the failure of a Renesas Electronics product, such as safety design for hardware and software including but not limited to redundancy, fire control and malfunction prevention, appropriate treatment for aging degradation or any other appropriate measures. Because the evaluation of microcomputer software alone is very difficult, please evaluate the safety of the final products or systems manufactured by you.
8. Please contact a Renesas Electronics sales office for details as to environmental matters such as the environmental compatibility of each Renesas Electronics product. Please use Renesas Electronics products in compliance with all applicable laws and regulations that regulate the inclusion or use of controlled substances, including without limitation, the EU RoHS Directive. Renesas Electronics assumes no liability for damages or losses occurring as a result of your noncompliance with applicable laws and regulations.
9. Renesas Electronics products and technology may not be used for or incorporated into any products or systems whose manufacture, use, or sale is prohibited under any applicable domestic or foreign laws or regulations. You should not use Renesas Electronics products or technology described in this document for any purpose relating to military applications or use by the military, including but not limited to the development of weapons of mass destruction. When exporting the Renesas Electronics products or technology described in this document, you should comply with the applicable export control laws and regulations and follow the procedures required by such laws and regulations.
10. It is the responsibility of the buyer or distributor of Renesas Electronics products, who distributes, disposes of, or otherwise places the product with a third party, to notify such third party in advance of the contents and conditions set forth in this document, Renesas Electronics assumes no responsibility for any losses incurred by you or third parties as a result of unauthorized use of Renesas Electronics products.
11. This document may not be reproduced or duplicated in any form, in whole or in part, without prior written consent of Renesas Electronics.
12. Please contact a Renesas Electronics sales office if you have any questions regarding the information contained in this document or Renesas Electronics products, or if you have any other inquiries.

(Note 1) "Renesas Electronics" as used in this document means Renesas Electronics Corporation and also includes its majority-owned subsidiaries.

(Note 2) "Renesas Electronics product(s)" means any product developed or manufactured by or for Renesas Electronics.

General Precautions in the Handling of MPU/MCU Products

The following usage notes are applicable to all MPU/MCU products from Renesas. For detailed usage notes on the products covered by this document, refer to the relevant sections of the document as well as any technical updates that have been issued for the products.

1. Handling of Unused Pins

Handle unused pins in accordance with the directions given under Handling of Unused Pins in the manual.

- The input pins of CMOS products are generally in the high-impedance state. In operation with an unused pin in the open-circuit state, extra electromagnetic noise is induced in the vicinity of LSI, an associated shoot-through current flows internally, and malfunctions occur due to the false recognition of the pin state as an input signal become possible. Unused pins should be handled as described under Handling of Unused Pins in the manual.

2. Processing at Power-on

The state of the product is undefined at the moment when power is supplied.

- The states of internal circuits in the LSI are indeterminate and the states of register settings and pins are undefined at the moment when power is supplied.
In a finished product where the reset signal is applied to the external reset pin, the states of pins are not guaranteed from the moment when power is supplied until the reset process is completed. In a similar way, the states of pins in a product that is reset by an on-chip power-on reset function are not guaranteed from the moment when power is supplied until the power reaches the level at which resetting has been specified.

3. Prohibition of Access to Reserved Addresses

Access to reserved addresses is prohibited.

- The reserved addresses are provided for the possible future expansion of functions. Do not access these addresses; the correct operation of LSI is not guaranteed if they are accessed.

4. Clock Signals

After applying a reset, only release the reset line after the operating clock signal has become stable. When switching the clock signal during program execution, wait until the target clock signal has stabilized.

- When the clock signal is generated with an external resonator (or from an external oscillator) during a reset, ensure that the reset line is only released after full stabilization of the clock signal. Moreover, when switching to a clock signal produced with an external resonator (or by an external oscillator) while program execution is in progress, wait until the target clock signal is stable.

5. Differences between Products

Before changing from one product to another, i.e. to a product with a different part number, confirm that the change will not lead to problems.

- The characteristics of an MPU or MCU in the same group but having a different part number may differ in terms of the internal memory capacity, layout pattern, and other factors, which can affect the ranges of electrical characteristics, such as characteristic values, operating margins, immunity to noise, and amount of radiated noise. When changing to a product with a different part number, implement a system-evaluation test for the given product.

How to Use This Manual

Readers This manual is intended for users who wish to understand the functions of the V850E2/ML4 and design application systems using the V850E2/ML4 (μ PD70F4021 and 70F4022).

Purpose This manual is intended to give users an understanding of the hardware functions of the V850E2/ML4 shown in the Organization below.
Organization

This manual is divided into two parts: Hardware (this manual) and Architecture (V850E2M Architecture User's Manual).

Hardware	Architecture
Pin functions	Data types
CPU function	Register set
On-chip peripheral functions	Instruction format and instruction set
Flash memory programming	Interrupts and exceptions
Electrical specifications	Pipeline operation

How to read this manual It is assumed that the readers of this manual have general knowledge in the fields of electrical engineering, logic circuits, and microcontrollers.

To understand the overall functions of the V850E2/ML4.

Read this manual according to the Contents.

To understand the details of an instruction function

Refer to the V850E2M Architecture User's Manual available separately.

The mark <R> shows major revised points.

The revised points can be easily searched by copying an "<R>" in the PDF file and specifying it in the "Find what:" field.

Chapter 1	Introduction	23
1.1	Overview	23
1.2	Features	24
1.3	Application Fields	26
1.4	Ordering Information	26
1.5	Function Block Diagrams	27
1.5.1	Single-core product	27
Chapter 2	Pin Function	28
2.1	Pin Assignment	28
2.2	Pin Functions	35
2.3	Duplication of Pin Functions	56
2.4	Pin State After Reset	63
2.5	Default States and Recommended Connection of Unused Pins	69
2.6	Pin Input Circuit Types	77
2.6.1	Input circuit types for port input pins and input pins that have port or other functions	77
2.7	Cautions on 5-V tolerant supporting pins	77
Chapter 3	Operation Modes	78
3.1	Features	78
3.2	Operation Modes	78
3.2.1	Normal operation mode	78
3.2.2	Flash memory programming mode	78
3.2.3	Boundary scan mode	78
3.3	Specifying the Operation Mode	79
Chapter 4	CPU	80
4.1	Features	80
4.2	Configuration	81
4.3	CPU Core	81
4.4	Address Space	82
4.4.1	CPU address space	82
4.4.2	CPU address space wraparound	83
4.4.3	Memory map	84
4.4.4	Areas	85
4.5	Processor Elements (PE)	90
4.6	Bus Architecture	90
4.6.1	Internal system bus	90
4.6.2	P bus	90
4.6.3	H bus	90
4.6.4	E bus	94
4.6.5	Arbitration	95
4.7	Flash Cache	96
4.7.1	Configuration	96
4.7.2	Control registers	97
4.7.3	Operation	99
Chapter 5	Reset Function	100

5.1	Features	100
5.2	Configuration	100
5.3	Control Registers	101
5.3.1	Reset source flag register (RESF)	101
5.3.2	Reset source clear register (RESC)	102
5.3.3	Software reset enable register (SWRSTEN)	103
5.3.4	Software reset trigger register (SWREST)	103
5.4	Operation	104
5.4.1	Operation for system resets triggered by RESET pin input	104
5.4.2	System resets triggered by a watchdog timer overflow	105
5.4.3	System resets triggered by software	106
Chapter 6 Clock Generator		107
6.1	Features	107
6.2	Configuration	108
6.3	Control Registers	109
6.3.1	Special clock frequency control register (SFRCTL3)	109
6.3.2	SFRCTL3 clock selection status register (SFR3CKST)	111
6.4	Operation	113
6.4.1	Operating status of each clock	113
Chapter 7 Option Bytes		114
7.1	Features	114
7.2	Data Structure	115
7.2.1	Option bytes	115
7.3	Control Register	117
7.3.1	Option byte storage register (OPBT0)	117
Chapter 8 Port Functions		119
8.1	Features	120
8.2	Overview	120
8.2.1	Terms	122
8.2.2	Overview of pin functions	123
8.2.3	Pin data input/output	124
8.2.4	Port control logic diagram	127
8.2.5	Write protected registers	128
8.3	Port Group Configuration Registers	129
8.3.1	Overview	129
8.3.2	Pin function configuration	131
8.3.3	Pin data input/output	138
8.3.4	Configuration of electrical characteristics	142
8.3.5	Port register protection	150
8.3.6	Example port settings	152
8.4	V850E2/ML4 Port Functions	156
8.4.1	Input circuit types of port input pins and alternate-function input pins ..	156
8.4.2	General I/O function	156
8.4.3	V850E2/ML4 port control registers	161
8.4.4	V850E2/ML4 port control register settings	167
8.5	Port Filters	208

8.5.1	Analog and digital filter assignments.	208
8.5.2	Functional Description.	211
Chapter 9	Interrupt Functions	223
9.1	Features	223
9.2	Interrupt Causes	225
9.2.1	FE level non-maskable interrupts	225
9.2.2	FE level maskable interrupts	225
9.2.3	EI level maskable interrupts	226
9.3	Interrupt Controller Control Registers.	235
9.3.1	EICn (n = 0 to 255): EI level interrupt control registers	235
9.3.2	IMRm (m = 0 to 15): EI level interrupt mask registers.	236
9.3.3	ISPR: In-service priority register	237
9.3.4	PMR: Priority mask register	238
9.3.5	ISPC: In-service priority clear register	239
9.3.6	SCR: Selected channel hold register	240
9.3.7	ICSR: Interrupt controller status register.	241
9.3.8	FNC: FE level NMI control register	242
9.3.9	FIC: FE level INT control register	243
9.4	Interrupt Acknowledgment and Restoring	244
9.4.1	FE level non-maskable interrupt caused by FENMI interrupt request.	244
9.4.2	Restore from FE level non-maskable interrupt (FENMI)	246
9.4.3	FE level maskable interrupt caused by FEINT interrupt request.	246
9.4.4	Restore from FE level maskable interrupt (FEINT) servicing	248
9.4.5	EI level maskable interrupt caused by EIINT interrupt request	249
9.4.6	Restore from EI level maskable interrupt (EIINT)	251
9.5	Interrupt Operation	252
9.5.1	Mask function of EI level maskable interrupt (EIINT)	252
9.5.2	Interrupt priority level judgment.	252
9.5.3	Priority mask function	258
9.5.4	Pended interrupt report function	258
9.5.5	In-service priority clear function	259
9.6	Exception Handler Address Switching Function	259
Chapter 10	DMA Function	260
10.1	V850E2/ML4 DMA Features	260
10.2	Terms	263
10.3	General	264
10.3.1	DMA controller (DMAC) function.	264
10.3.2	DMA trigger factor register (DTFR) function	264
10.3.3	Data transfer service (DTS) function.	264
10.3.4	DTS factor selector (DTSFSL) function.	264
10.3.5	DMA access memory map	266
10.3.6	Prioritization of channels.	266
10.3.7	Arbitration of transfer requests	267
10.4	DMAC Function	268
10.4.1	Features	268
10.4.2	DMAC setting registers	270
10.4.3	Enabling or disabling writing control registers.	275

10.5	DMA Control Registers	276
10.5.1	DTRC _x (x = 0): DMA transfer request control register	276
10.5.2	DTRSn (n = 0 to 7): DMA transfer request select register.	277
10.5.3	DSAnL (n = 0 to 7): DMA source address register L.	278
10.5.4	DSAnH (n = 0 to 7): DMA source address register H	279
10.5.5	DSCn (n = 0 to 7): DMA source chip select register	280
10.5.6	DNSAnL (n = 0 to 7): DMA next source address register L	281
10.5.7	DNSAnH (n = 0 to 7): DMA next source address register H	282
10.5.8	DNSCn (n = 0 to 7): DMA next source chip select register	283
10.5.9	DDAnL (n = 0 to 7): DMA destination address register L	284
10.5.10	DDAnH (n = 0 to 7): DMA destination address register H.	285
10.5.11	DDCn (n = 0 to 7): DMA destination chip select register.	286
10.5.12	DNDAnL (n = 0 to 7): DMA next destination address register L	287
10.5.13	DNDAnH (n = 0 to 7): DMA next destination address register H.	288
10.5.14	DNDCn (n = 0 to 7): DMA next destination chip select register	289
10.5.15	DTCn (n = 0 to 7): DMA transfer count register.	290
10.5.16	DNTCn (n = 0 to 7): DMA next transfer count register	291
10.5.17	DTCCn (n = 0 to 7): DMA transfer count compare register.	292
10.5.18	DTCTn (n = 0 to 7): DMA transfer control register	293
10.5.19	DTSn (n = 0 to 7): DMA transfer status register	295
10.6	DMAC Function Details	297
10.6.1	DMAC transfer setting flow	297
10.6.2	DMAC transfer modes	299
10.6.3	DMAC channel priority control	302
10.6.4	Valid DMA transfer request conditions	303
10.6.5	Next address function	304
10.6.6	Aborting/resuming DMA transfer.	305
10.6.7	Error response support	306
10.7	DTFR Function	307
10.7.1	Features	307
10.8	DTFR Control Registers	308
10.8.1	DTFR _n (n = 0 to 7): DTFR _n register	308
10.8.2	DRQCLR: DMA request clear register	309
10.8.3	DRQSTR: DMA request check register.	309
10.9	DTS Function	310
10.9.1	Features	310
10.10	DTS Control Registers	313
10.10.1	DTS0TSR: DTS transfer status register [register group A]	314
10.10.2	DTS0TRC: DTS transfer request control register [register group A].	315
10.10.3	DTS0ICR: DTS initialization control register [register group A].	316
10.10.4	DTS0BTR: DTS base table register [register group A]	318
10.10.5	DTS0BVR: DTS base vector register [register group A]	319
10.10.6	DTS0ACR: DTS active channel register [register group A].	320
10.10.7	DTS0HST: DTS TI hold status register [register group A].	321
10.10.8	DTS0HC: DTS TI hold channel number register [register group A]	322
10.10.9	DTS0SAR: DTS source address register [register group B]	324
10.10.10	DTS0DAR: DTS destination address register [register group B].	325
10.10.11	DTS0TCEA: DTS transfer counter or else address register [register group B].	326
10.10.12	DTS0SCS: DTS source address count size register [register group B]	328

10.10.13	DTS0DCS: DTS destination address count size register [register group B].	329
10.10.14	DTS0CIR: DTS control information register [register group B]	330
10.10.15	DTS0ECSRA: DTS extension address count size/repeat address registers [register group B].	332
10.11	DTS Function Details	334
10.11.1	Transfer information (TI)	334
10.11.2	DTS transfer setting flow	338
10.11.3	Basic operations of DTS	339
10.11.4	Transfer modes	340
10.11.5	Transfer types	341
10.11.6	Special functions	358
10.11.7	Transfer count	360
10.11.8	Chain function	361
10.11.9	TI hold function	363
10.11.10	Interrupt output function	364
10.11.11	Interrupt and chain of transfers during block transfer	364
10.11.12	TI write back skip function	365
10.11.13	DTS channel priority control	365
10.11.14	Valid DTS transfer request conditions	366
10.11.15	Aborting/resuming DTS transfer	366
10.11.16	Error response support	367
10.12	DTSFSL Function	368
10.12.1	Features	368
10.13	DTSFSL Control Registers	372
10.13.1	DTSEN _x (x = 000 to 127): DTS transfer enable register	372
10.13.2	DTSHEN _m (m = 0 to 3): DTS hold enable register	373
10.13.3	DTSEL _m (m = 0 to 11): DTS transfer end interrupt select register	375
Chapter 11 Memory Controller		377
11.1	Overview	377
11.1.1	Operation mode, connectable memory types	379
11.1.2	Chip select output function	379
11.1.3	Bus sizing function	379
11.1.4	Data endian setting function	379
11.1.5	Programmable wait setting functions	379
11.1.6	External wait function	380
11.1.7	External wait error detection function	380
11.1.8	Bus hold function	380
11.1.9	DMA cycle output function	380
11.2	Registers	381
11.2.1	Bus size configuration register (BSC)	382
11.2.2	Data endian configuration register (DEC)	383
11.2.3	Data wait configuration registers 0 (DWC0)	384
11.2.4	Data hold wait configuration register (DHC)	386
11.2.5	Idle cycle configuration registers 0 and 1 (ICC0, ICC1)	387
11.2.6	External wait error configuration register (EWC)	389
11.2.7	SDRAM enable control register (SEN)	390
11.2.8	SDRAM configuration register (SDCR)	391
11.2.9	SDRAM status register (STR)	394

	11.2.10 SDRAM refresh control register (RFS)	395
11.3	Bus Cycle Type Setting Function	397
	11.3.1 SRAM bus cycle type	397
	11.3.2 SDRAM bus cycle type	398
11.4	Bus Control Function	399
	11.4.1 Chip select output function	399
	11.4.2 Bus size setting function	400
	11.4.3 Data endian setting function	401
	11.4.4 SDRAM setting function	402
11.5	Wait Functions	409
	11.5.1 Programmable data wait function	409
	11.5.2 External wait function	410
	11.5.3 External wait error detection function	411
	11.5.4 Data setup wait function	413
	11.5.5 Idle insertion function	414
11.6	Bus Hold Function	415
11.7	DMA Cycle Output Function	419
11.8	Memory Connection Examples	420
	11.8.1 SRAM connection example	420
	11.8.2 SDRAM connection example	422
11.9	Data Flow	425
	11.9.1 Data flow during byte access	427
 Chapter 12 Timer Array Unit A (TAUA)		437
12.1	V850E2/ML4 TAUA Features	437
12.2	Functional Overview	440
	12.2.1 Terms	442
12.3	Functional Description	443
	12.3.1 Timer operation functions	445
12.4	General Operating Procedure	446
12.5	Operation Modes	447
12.6	Concepts of Synchronous Channel Operation	448
	12.6.1 Rules	448
	12.6.2 Simultaneous start and stop of synchronous channel counters	450
12.7	Simultaneous Rewrite	451
	12.7.1 Introduction	451
	12.7.2 How to control simultaneous rewrite	453
	12.7.3 Other general rules of simultaneous rewrite	454
	12.7.4 Types of simultaneous rewrite	455
12.8	Channel Output Modes	463
	12.8.1 General procedure for specifying a channel output mode	465
	12.8.2 Channel output modes controlled independently by TAUAn signals	466
	12.8.3 Channel output modes controlled synchronously by TAUAn signals	468
12.9	Start Timing of Operating Modes	473
	12.9.1 Interval Timer Mode, Judge Mode, Capture Mode, Up Down Count Mode	473
	12.9.2 Event Mode	474
	12.9.3 All other operating modes	474
12.10	TAUAnTTOUTm Output and INTTAUAnIm Generation when Counter Starts or Restarts	475

12.11	Interrupt Generation upon Overflow	476
	12.11.1 Capture Mode	477
	12.11.2 Capture and One Count Mode	478
	12.11.3 Count Capture Mode	479
	12.11.4 Capture and Gate Count Mode	480
12.12	TAUAnTTINm Edge Detection	481
12.13	Assigning DMA Window Addresses	482
12.14	Independent Channel Operation Functions	483
12.15	Independent Channel Interrupt Functions	483
	12.15.1 Interval Timer Function	484
	12.15.2 TAUAnTTINm Input Interval Timer Function	491
	12.15.3 Delay Count Function	497
	12.15.4 One-Pulse Output Function	501
12.16	Independent Channel Signal Measurement Functions	506
	12.16.1 TAUAnTTINm Input Pulse Interval Measurement Function	507
	12.16.2 TAUAnTTINm Input Signal Width Measurement Function	513
	12.16.3 Overflow Interrupt Output Function (During TAUAnTTINm Width Measurement)	519
	12.16.4 TAUAnTTINm Input Period Count Detection Function	523
	12.16.5 Overflow Interrupt Output Function (During TAUAnTTINm Input Period Count Detection)	528
	12.16.6 TAUAnTTINm Input Pulse Interval Judgment Function	532
	12.16.7 TAUAnTTINm Input Signal Width Judgment Function	536
12.17	Independent Channel Real-Time Functions	540
	12.17.1 Real-Time Output Function Type 1	541
	12.17.2 Real-Time Output Function Type 2	548
12.18	Independent Channel Simultaneous Rewrite Functions	554
	12.18.1 Simultaneous Rewrite Trigger Generation Function Type 1	555
	12.18.2 Simultaneous Rewrite Trigger Generation Function Type 2	561
12.19	Independent Channel One-Phase PWM Function	568
	12.19.1 One-Phase PWM Output Function	569
12.20	Other Independent Channel Functions	575
	12.20.1 External Event Count Function	576
	12.20.2 Clock Divide Function	582
	12.20.3 TAUAnTTINm Input Position Detection Function	588
12.21	Synchronous Channel Operation Functions	593
12.22	Synchronous PWM Signal Functions Triggered at Regular Intervals	593
	12.22.1 PWM Output Function	594
	12.22.2 Trigger Start PWM Output Function	605
	12.22.3 Delay Pulse Output Function	616
	12.22.4 AD Conversion Trigger Output Function Type 1	630
12.23	Synchronous PWM Signal Functions Triggered by an External Signal	632
	12.23.1 One-Shot Pulse Output Function	633
	12.23.2 Offset Trigger Output Function	641
12.24	Synchronous Triangle PWM Functions	649
	12.24.1 Triangle PWM Output Function	650
	12.24.2 Triangle PWM Output Function with Dead Time	661
	12.24.3 AD Conversion Trigger Output Function Type 2	675
12.25	Synchronous Non-Complementary and Complementary Functions	677
	12.25.1 Non-Complementary Modulation Output Function Type 1	678

12.25.2	Non-Complementary Modulation Output Function Type 2	691
12.25.3	Complementary Modulation Output Function	705
12.26	Other Synchronous Channel Functions	723
12.26.1	Interrupt Culling Function	724
12.27	Registers	733
12.27.1	TAUAn registers overview	733
12.27.2	TAUAn prescaler registers details	735
12.27.3	TAUAn control registers details	740
12.27.4	TAUAn output registers details	751
12.27.5	TAUAn channel output level registers details	757
12.27.6	TAUAn simultaneous rewrite register details	758
12.27.7	TAUAn DMA window registers	761
Chapter 13	Timer Array Unit J (TAUJ)	763
13.1	V850E2/ML4 TAUJ Features	763
13.2	Functional Overview	765
13.2.1	Terms	767
13.3	Functional Description	768
13.3.1	Timer operation functions	769
13.4	General Operating Procedure	770
13.5	Operation Modes	771
13.6	Concepts of Synchronous Channel Operation	772
13.6.1	Rules	772
13.6.2	Simultaneous start and stop of synchronous channel counters	774
13.7	Simultaneous Rewrite	775
13.7.1	Introduction	775
13.7.2	How to control simultaneous rewrite	776
13.7.3	Other general rules of simultaneous rewrite	777
13.7.4	Simultaneous rewrite procedure	778
13.8	Channel Output Modes	780
13.8.1	General procedure for specifying a channel output mode	782
13.8.2	Channel output modes controlled independently by TAUJn signals	783
13.8.3	Channel output modes controlled synchronously by TAUJn signals	784
13.9	Count Start Timing in Each Operating Mode	785
13.9.1	Interval Timer Mode, Capture Mode	785
13.9.2	Other operating modes	786
13.10	TAUJnTTOUtm Output and INTTAUJnIm Generation when Counter Starts or Restarts (by TAUJnMD0 Bit)	787
13.11	Interrupt Generation upon Overflow	788
13.11.1	Capture Mode	789
13.11.2	Capture and One Count Mode	790
13.11.3	Count Capture Mode	791
13.11.4	Capture and Gate Count Mode	792
13.12	TAUJnTTINm Edge Detection	793
13.13	Independent Channel Operation Functions	794
13.14	Independent Channel Interrupt Functions	794
13.14.1	Interval Timer Function	795
13.14.2	TAUJnTTINm Input Interval Timer Function	802
13.15	Independent Channel Signal Measurement Functions	808
13.15.1	TAUJnTTINm Input Pulse Interval Measurement Function	809

13.15.2	TAUJnTTINm Input Signal Width Measurement Function	815
13.15.3	Overflow Interrupt Output Function (During TAUJnTTINm Width Measurement)	821
13.15.4	TAUJnTTINm Input Period Count Detection Function	825
13.15.5	Overflow Interrupt Output Function (During TAUJnTTINm Input Period Count Detection)	830
13.16	Other Independent Channel Function	834
13.16.1	TAUJnTTINm Input Position Detection Function	835
13.17	Synchronous PWM Signal Functions Triggered at Regular Intervals	840
13.17.1	PWM Output Function	841
13.18	Registers	851
13.18.1	TAUJn registers overview	851
13.18.2	TAUJn prescaler registers details	852
13.18.3	TAUJn control registers details	856
13.18.4	TAUJn output registers details	866
13.18.5	TAUJn channel output level registers details	868
13.18.6	TAUJn simultaneous rewrite register details	869
Chapter 14	Encoder Timer (ENCA)	871
14.1	V850E2/ML4 ENCA Features	871
Chapter 15	Timer Option Function (TAPA)	922
15.1	Timer Option Function Features	922
15.1.1	Block diagram	926
15.2	Functional Overview	927
15.2.1	Peak and valley interrupts - Peak and valley of timer counter	927
15.3	Registers	928
15.3.1	Registers overview	928
15.3.2	Registers details	929
15.4	Basic Functions	934
15.4.1	Asynchronous Hi-Z control function	934
15.4.2	INT signal output selection function	941
15.4.3	A/D conversion trigger selection function	942
Chapter 16	Peripheral Interconnection (PIC)	946
16.1	V850E2/ML4 PIC Features	946
16.2	Functional Overview	948
16.2.1	Block diagrams	949
16.3	Control Registers	951
16.3.1	Registers used to set up timer simultaneous start function	951
16.3.2	Registers used to make connections between TAUA and TAPA	954
16.3.3	Registers used to make connections between TAUA and the A/D converter	955
16.4	Functions	956
16.4.1	Timer simultaneous start function	956
16.4.2	TAUA and TAPA connection function (including Hi-Z output control)	957
16.4.3	TAUA and A/D converter connection function	957
16.5	Connection between CAN controllers and timers (CAN time stamp function)	958
16.5.1	Overview	958
16.5.2	Configuration	958

16.5.3	Register	959
Chapter 17 Window Watchdog Timer A (WDTA) 960		
17.1	V850E2/ML4 WDTA Features	960
17.2	WDTA Start-up Options	962
17.3	Functional Overview	963
17.4	Functional Description	964
17.4.1	WDTA after reset release	965
17.4.2	WDTA trigger	968
17.4.3	Error detection	969
17.4.4	75% interrupt output	970
17.4.5	Window function	972
17.5	Registers	973
17.5.1	WDTA register overview	973
17.5.2	WDTA registers details	974
Chapter 18 OS Timer (OSTM) 979		
18.1	V850E2/ML4 OSTM Features	979
18.2	Functional Overview	981
18.3	Functional Description	982
18.3.1	Count clock	982
18.3.2	Output modes	983
18.3.3	Interrupt request generation	983
18.3.4	Starting and stopping the timer	984
18.3.5	Interval timer mode	985
18.3.6	Free-run compare mode	989
18.4	Registers	992
18.4.1	OS timer register overview	992
18.4.2	OS timer register details	992
Chapter 19 Asynchronous Serial Interface E (UARTEn) 997		
19.1	V850E2/ML4 UARTEn Features	997
19.2	Features	999
19.3	Configuration	1000
19.4	UARTEn Registers	1001
19.5	Interrupt Request Signals	1015
19.5.1	Transmission interrupt request INTUAEnTIT	1015
19.5.2	Reception interrupt request INTUAEnTIR	1016
19.5.3	Status interrupt request INTUAEnTIS	1017
19.5.4	Receive/status interrupt request INTUAEnTRA	1017
19.6	Operation	1018
19.6.1	Data formats	1018
19.6.2	BF transmission/reception format	1020
19.6.3	BF transmission	1022
19.6.4	BF reception	1024
19.6.5	Transmission data consistency check	1026
19.6.6	UARTEn transmission	1027
19.6.7	Continuous transmission procedure	1029
19.6.8	UARTEn reception	1031

19.6.9	Reception errors	1037
19.6.10	Parity types and operations	1038
19.6.11	Digital receive data noise filter	1039
19.7	Baud Rate Generator	1040
Chapter 20	Asynchronous Serial Interface J (UARTJn)	1042
20.1	V850E2/ML4 UARTJn Features	1042
20.2	Functional Overview	1044
20.3	Configuration	1045
20.4	UARTJn Registers	1046
20.5	Interrupt request signals	1064
20.5.1	Transmission interrupt request INTUAJnTIT	1064
20.5.2	Reception interrupt request INTUAJnTIR	1066
20.5.3	Status interrupt request INTUAJnTIS	1067
20.6	Operation	1069
20.6.1	Data formats	1069
20.6.2	BF transmission/reception format	1071
20.6.3	BF transmission	1073
20.6.4	BF reception	1075
20.6.5	UARTJn transmission	1077
20.6.6	UARTJn reception	1081
20.6.7	Reception errors	1087
20.6.8	Parity types and operations	1088
20.6.9	Digital receive data noise filter	1089
20.7	Baud Rate Generator	1090
Chapter 21	Clocked Serial Interface G (CSIG)	1092
21.1	V850E2/ML4 CSIG Features	1092
21.2	Functional Overview	1094
21.3	Functional Description	1096
21.3.1	Operating modes (master/slave)	1097
21.3.2	Master/slave connections	1098
21.3.3	Serial clock selection	1100
21.3.4	Data transfer modes	1101
21.3.5	Data length selection	1102
21.3.6	Serial data direction selection	1104
21.3.7	Communication in slave mode	1105
21.3.8	CSIG interrupts	1106
21.3.9	Handshake function	1109
21.3.10	Error detection	1111
21.3.11	Loop-back mode	1115
21.4	CSIG Control Registers	1116
21.5	Operating Procedure Example	1130
Chapter 22	Clocked Serial Interface H (CSIH)	1138
22.1	V850E2/ML4 CSIH Features	1138
22.2	Functional Overview	1141
22.3	Functional Description	1143
22.3.1	Operating modes (master/slave)	1144

22.3.2	Master/slave connections	1146
22.3.3	Chip selection (CS) features	1148
22.3.4	Chip select timing details	1150
22.3.5	Job concept	1152
22.3.6	Serial clock selection	1153
22.3.7	CSIH buffer memory	1155
22.3.8	Data transfer modes	1157
22.3.9	Data length selection	1159
22.3.10	Serial data direction selection	1161
22.3.11	Communication in slave mode	1162
22.3.12	CSIH interrupt requests	1163
22.3.13	Handshake function	1172
22.3.14	Error detection	1176
22.3.15	Loop-back mode	1186
22.4	CSIH Control Registers	1187
22.4.1	CSIH register details	1188
22.5	Operating Procedures	1215
22.5.1	Procedures in direct access mode	1216
22.5.2	Procedures in transmit-only buffer mode	1227
22.5.3	Procedures in dual buffer mode	1239
22.5.4	Procedures in FIFO mode	1251
Chapter 23	I²C BUS (IICB)	1263
23.1	V850E2/ML4 IICB Features	1263
23.2	Functional Overview	1265
23.3	IIC Bus Mode Functions	1267
23.3.1	Pin configuration	1267
23.4	IIC Bus Definition	1268
23.4.1	Start Condition	1269
23.4.2	Addresses	1269
23.4.3	Extension Code	1270
23.4.4	Transfer direction specification	1270
23.4.5	Acknowledge (ACK)	1271
23.4.6	Data	1272
23.4.7	Stop condition	1272
23.4.8	Wait state	1273
23.4.9	Arbitration	1275
23.5	Registers	1276
23.6	Operation	1300
23.6.1	Single transfer mode	1300
23.6.2	Continuous transfer mode	1305
23.6.3	Arbitration	1310
23.6.4	Entering and exiting wait state	1311
23.6.5	Extension code	1316
23.7	Interrupt Request Signals	1317
23.7.1	Single transfer mode	1318
23.7.2	Continuous transfer mode	1321
23.8	Interrupt Outputs and Statuses	1327
23.8.1	Single transfer mode (master device operation)	1328
23.8.2	Single transfer mode (slave device operation: during slave address reception)	

	(IICBnSTR0.IICBnSSC0 bit = 1))	1331
23.8.3	Single transfer mode (slave device operation: during extension code reception (IICBnSTR0.IICBnSSEX bit = 1))	1335
23.8.4	Single transfer mode (non-participation in communications)	1339
23.8.5	Single transfer mode (arbitration loss operation (IICBnSTR0.IICBnALDF bit = 1): operation as slave after arbitration loss)	1340
23.8.6	Single transfer mode (arbitration loss operation (IICBnSTR0.IICBnALDF bit = 1): non-participation in communications after arbitration loss)	1342
23.8.7	Single transfer mode (arbitration loss operation (IICBnSTR0.IICBnALDF bit = 1): non-participation in communications after arbitration loss (during extension code transfer))	1348
23.8.8	Continuous transfer mode (master device operation (reception))	1349
23.8.9	Continuous transfer mode (master device operation (transmission))	1352
23.8.10	Continuous transfer mode (slave device operation (reception): during slave address reception (IICBnSTR0.IICBnSSC0 bit = 1))	1355
23.8.11	Continuous transfer mode (slave device operation (reception): during extension code reception (IICBnSTR0.IICBnSSEX bit = 1))	1359
23.8.12	Continuous transfer mode (slave device operation (transmission): during slave address reception (IICBnSTR0.IICBnSSC0 bit = 1))	1363
23.8.13	Continuous transfer mode (slave device operation (transmission): during extension code reception (IICBnSTR0.IICBnSSEX bit = 1))	1367
23.8.14	Continuous transfer mode (non-participation in communications)	1371
23.8.15	Continuous transfer mode (arbitration loss operation (IICBnSTR0.IICBnALDF bit = 1) (when address was transferred during reception): operation as slave after arbitration loss)	1372
23.8.16	Continuous transfer mode (arbitration loss operation (IICBnSTR0.IICBnALDF bit = 1) (when address was transferred during reception): non-participation in communications after arbitration loss)	1374
23.8.17	Continuous transfer mode (arbitration loss operation (IICBnSTR0.IICBnALDF bit = 1) (when address was transferred during reception): non-participation in communications after arbitration loss (during extension code transfer))	1379
23.9	Setting Sequence	1381
23.9.1	Single master environment	1381
23.9.2	Multi-master environment	1385
Chapter 24	CAN Controller (FCN)	1393
24.1	FCN Features of V850E2/ML4	1393
24.2	Features	1395
24.2.1	Overview of functions	1396
24.2.2	Configuration	1397
24.3	Internal Registers of FCN	1398
24.3.1	CAN Controller configuration	1398
24.3.2	CAN Controller Registers Overview	1400
24.3.3	Register bit configuration	1402
24.4	Bit Set/Clear Function	1409
24.5	Control Registers	1411
24.5.1	FCN global registers	1411
24.5.2	FCN module registers	1419
24.5.3	FCN message buffer registers	1442
24.6	CAN Controller Initialization	1453
24.6.1	Initialization of FCN module	1453

24.6.2	Initialization of message buffer	1453
24.6.3	Redefinition of message buffer	1453
24.6.4	Transition from initialization mode to operation mode	1455
24.7	Message Reception	1456
24.7.1	Message reception	1456
24.7.2	Receive data read	1457
24.7.3	Receive history list function	1458
24.7.4	Mask function	1460
24.7.5	Multi buffer receive block function	1462
24.7.6	Remote frame reception	1463
24.8	Message Transmission	1465
24.8.1	Message transmission	1465
24.8.2	Transmit history list function	1467
24.8.3	Automatic block transmission (ABT)	1469
24.8.4	Transmission abort process	1471
24.8.5	Remote frame transmission	1472
24.9	Power Saving Modes	1473
24.9.1	FCN sleep mode	1473
24.9.2	FCN stop mode	1476
24.9.3	Example of using power saving modes	1477
24.10	Interrupt Function	1478
24.11	Diagnosis Functions and Special Operational Modes	1479
24.11.1	Receive-only mode	1479
24.11.2	Single-shot mode	1480
24.11.3	Self-test mode	1481
24.11.4	Receive/transmit operation in each operation mode	1482
24.12	Time Stamp Function	1483
24.12.1	Time stamp function	1483
24.13	Baud Rate Settings	1485
24.13.1	Baud rate setting conditions	1485
24.13.2	Representative examples of baud rate settings	1489
24.14	Operation of the CAN Controller	1493
24.14.1	Initialization	1493
24.14.2	Message transmission	1499
24.14.3	Message reception	1512
24.14.4	Power save modes	1517
Chapter 25	A/D Converter (ADCA)	1524
25.1	V850E2/ML4 Features	1525
25.1.1	Conditions for transitioning to the stand-by mode	1528
25.1.2	Operation while in the power saving mode	1528
25.2	Function Overview	1529
25.3	Description of Functions	1531
25.3.1	Basic operation	1532
25.3.2	Clock usage	1533
25.3.3	Channels and channel groups	1533
25.3.4	A/D conversion modes	1535
25.3.5	Starting A/D conversion (start triggers)	1538
25.3.6	Stopping A/D conversion (stop triggers)	1540
25.3.7	Stand-by mode (product dependent)	1542

25.3.8	Pausing and resuming A/D conversion (ADCHALT mode) (product dependent)	1542
25.3.9	Resolution, sampling, and conversion times	1543
25.3.10	Interrupt generation	1546
25.3.11	Storage of A/D conversion results	1547
25.3.12	Result check functions	1550
25.3.13	Self-diagnosis functions (product dependent)	1552
25.3.14	Channel sample & hold circuit function (product dependent)	1560
25.3.15	Discharge function (product dependent)	1567
25.3.16	Buffer amplifier function	1567
25.3.17	Stabilization control	1568
25.4	Registers	1569
25.4.1	Overview of the ADCAn registers	1569
25.4.2	Control registers	1570
25.4.3	Conversion status registers	1578
25.4.4	Software trigger registers	1582
25.4.5	A/D conversion result registers	1584
25.4.6	A/D conversion result limit comparison registers	1592
25.4.7	Diagnostic function control registers (product dependent)	1596
25.4.8	Channel sample & hold function setup register (product dependent)	1599
25.5	Precautions on Usage	1600
25.5.1	Channel input voltage range	1600
25.5.2	Stopping conversion operation	1600
25.5.3	Restrictions when using the channel S/H function	1600
25.5.4	Notes on application design	1600
25.6	How to Read A/D Converter Characteristics Table	1603
 Chapter 26 H-Bus-Shared Memory		1610
26.1	Features	1610
26.2	Configuration	1610
26.3	Operation	1611
26.3.1	Parallel operation	1611
26.3.2	Arbitration	1612
 Chapter 27 USB Function Controller (USBF)		1613
27.1	V850E2/ML4 USBF Features	1614
27.1.1	V850E2/ML4 USBF control register	1615
27.2	Overview	1616
27.3	Configuration	1617
27.3.1	Block diagram	1617
27.4	External Circuit Configuration	1618
27.4.1	Overview	1618
27.4.2	Connection configuration	1619
27.5	Cautions	1621
27.6	Requests	1622
27.6.1	Automatic requests	1622
27.6.2	Other requests	1632
27.7	Register Configuration	1633
27.7.1	USB function controller registers	1633
27.7.2	EPC control registers	1648

27.7.3	Data hold registers	1701
27.7.4	EPC request data registers	1725
27.7.5	Bridge registers	1742
27.8	STALL Handshake or No Handshake	1752
27.9	Register Values in Specific Status	1753
27.10	FW Processing	1755
27.10.1	Initialization	1757
27.10.2	Interrupt servicing	1760
27.10.3	Main USB processing	1761
27.10.4	Suspend/Resume processing	1788
27.10.5	Processing after power application	1791
Chapter 28	USB Host Controller (USBH)	1794
28.1	V850E2/ML4 USBH Features	1795

Chapter 1 Introduction

The V850E2/ML4 is a Renesas Electronics V850 single-chip microcontroller.

1.1 Overview

The V850E2/ML4 is a 32-bit single-chip microcontroller that integrates V850E2M 32-bit RISC CPU core, which was developed by enhancing the performance of the V850E1 CPU and V850E2 CPU. The V850E2/ML4 includes flash memory, RAM, and various peripheral functions, and is used to perform large-capacity data processing and advanced real-time control.

(1) V850E2M CPU

The V850E2M CPU further enhances the performance of the V850E2 CPU.

The V850E2M CPU improves the CPU processing performance through optimization of the two-way superscalar seven-stage pipeline control. A floating point unit (FPU) that conforms to IEEE754-1985 is also included.

Note that, because the instruction codes are compatible with the V850, V850E1, and V850E2 CPUs at the object code level, conventional system software assets can be used as is.

(2) Multi-layer internal system bus

The internal system bus that connects each CPU and DMA controller to the peripheral functions has multiple layers. The bus has a total of three layers: one layer for each CPU, and one layer for the DMA controller. The multilayer internal system bus reduces the overhead due to bus arbitration, achieving high-speed real-time operation.

(3) On-chip flash memory

The V850E2/ML4 includes large-capacity flash memory for which high-speed access is possible, and, because programs can be rewritten with the V850E2/ML4 mounted in an application system, the system development time can be reduced. The maintainability can also be dramatically improved after shipment.

(4) External memory interface

A memory controller that has a separate-bus configuration is included as an external memory interface. A memory controller that can be connected to SRAM/SDRAM is included.

In addition, the DMA controller can be used to perform CPU-internal calculations and data transfers while data is transferred with the external memory. Therefore, while large-capacity data such as video and audio data is being processed, it is possible to simultaneously perform real-time control such as motor and communication control, by using the internal flash memory and RAM to execute high-speed instructions.

(5) Various peripheral functions

The V850E2/ML4 includes peripheral functions such as a DMA controller, timer array, UART, CSI, CAN, A/D converter, USB function controller, USB host controller, Ethernet controller, on-chip debugger, and memory controller. Because a system can be set up without externally attaching the above functions, the cost, number of components, and mounting area can be reduced.

1.2 Features

Minimum instruction execution time	5.0 ns (during 200-MHz operation using internal system clock)								
Instruction set	V850E2M Two-way superscalar seven-stage pipeline control General-purpose registers: 32 bits x 32 registers FPU that conforms to the ANSI/IEEE 754-1985 standards								
Flash memory	μ PD70F4021: 768 KB μ PD70F4022: 1 MB								
Flash cache	16 KB (four-way set associative)								
Internal RAM	64 KB								
H-bus-shared memory	64 KB								
Clock generator	Multiplied by 20 using a PLL								
External bus interface	Can connect to SRAM/SDRAM								
Interrupts and exceptions	<table border="1"> <thead> <tr> <th>Interrupt Sources</th> <th>V850E2/ML4</th> </tr> </thead> <tbody> <tr> <td>FE level non-maskable interrupt (FENMI)</td> <td>1 (external source)</td> </tr> <tr> <td>FE level maskable interrupts (FEINT)</td> <td>1</td> </tr> <tr> <td>EI level maskable interrupt (EIINT)</td> <td>149</td> </tr> </tbody> </table>	Interrupt Sources	V850E2/ML4	FE level non-maskable interrupt (FENMI)	1 (external source)	FE level maskable interrupts (FEINT)	1	EI level maskable interrupt (EIINT)	149
Interrupt Sources	V850E2/ML4								
FE level non-maskable interrupt (FENMI)	1 (external source)								
FE level maskable interrupts (FEINT)	1								
EI level maskable interrupt (EIINT)	149								
	16-level programmable priority control								
DMA	DMA controller: 8 channels DTS: Up to 128 channels								
I/O	Input: 7 pins, I/O: 113 pins								
Timers	16-bit timer array: Two units x 16 channels 32-bit timer array: One unit x 4 channels 16-bit encoder timer: 2 channels OS timer: 1 channel Watchdog timer: 1 channel								

Serial interface	Asynchronous serial interface (UART): 2 channels Clock synchronous serial interface (CSI): 2 channels Asynchronous serial interface (UART) (FIFO): 2 channels Clock synchronous serial interface (CSI) (FIFO): 2 channels I ² C: 2 channels CAN: 1 channel USB function controller: 1 channel USB host controller: 1 channel Ethernet controller: 1 channel
A/D converter	10-bit resolution A/D converter: 12 channels (The resolution is 12 bits when using a 5.0 V A/D converter power supply.)
Package	216-pin plastic LQFP (24 x 24)
CMOS structure	Completely static circuit

Note The numbers of channels indicate how many are included in the product. The actual number of usable channels depends on the multiple-function pins.

1.3 Application Fields

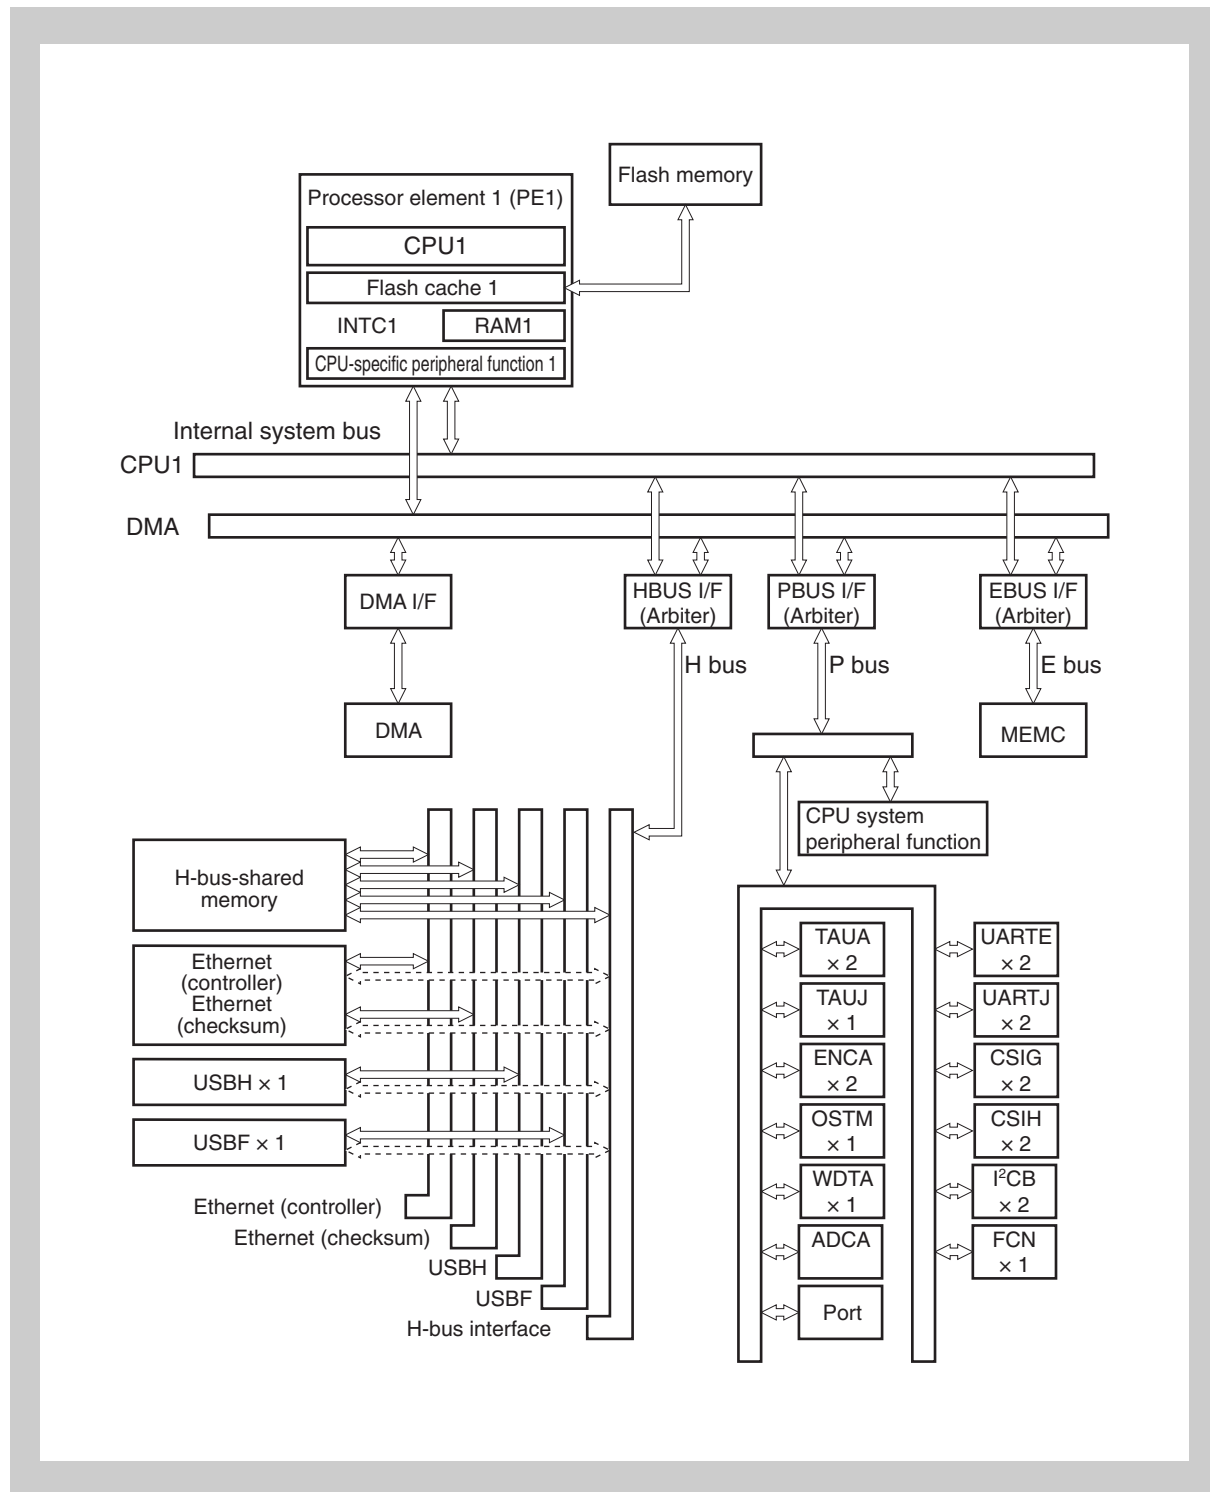

The V850E2/ML4 can be used in servos, inverters, robots, NC machine tools, various printers, information appliances, home appliances, manufacturing devices, and other devices.

1.4 Ordering Information

Product Name	Package	CPU Core	Internal Flash Memory	Internal RAM
μ PD70F4021GM-GBY-AX	216-pin plastic LQFP (fine pitch) (24 x 24)	V850E2M	768 KB	64 KB
μ PD70F4022GM-GBY-AX	216-pin plastic LQFP (fine pitch) (24 x 24)	V850E2M	1 MB	64 KB

X2	145	–		–

2.3 Duplication of Pin Functions

For some functions of this product, the input and/or output is assigned to two different pins. Note, however, that the function can be enabled for only one of the corresponding pins at a time. In other words, it is prohibited to enable the function for both the corresponding pins at the same time.

For example, while the a/b/c pin functions as b, the b/d/e pin must not function as b. Specify the d or e function for the b/d/e pin at this time.

Caution When using the Pn_m port as the alternative output function (PMn.PMCnm = 1, PMn.PMnm = 0), the level of the Pn_m pin can be read by PPRn.PPRnm by enabling the bidirectional mode (PBDCn.PBDCnm = 1). However, note that in this case, the level of the Pn_m pin is input to the same alternative input function.

Table 2-4 Duplication of Pin Functions (1/7)

I/O	Assigned Function	Alternate Functions	Pin No.
Output	ADCNV0	P2_6/ESO3/TA1_I2/SO1F/DMAAK3/TA1_O2	163

2.5 Default States and Recommended Connection of Unused Pins

Table 2-6 Default States and Recommended Connection of Unused Pins (1/8)

Pin No.	Pin Name	Default State		Recommended Connection of Unused Pins
		Function	I/O	
1	EV _{DD}	EV _{DD}	–	Always connect to the power supply.
2	V _{SS}	V _{SS}	–	Always connect to the ground directly.
3	MODE2	MODE2	Input	Independently connect to V _{SS} via a resistor.
4	MODE3	MODE3	Input	Independently connect to V _{SS} via a resistor.
5	IV _{DD}	IV _{DD}	–	Always connect to the power supply.
6	V _{SS}	V _{SS}	–	Always connect to the ground directly.
7	P3_11/A11/CSI0F_CS7	P3_11	Input	Independently connect to EV _{DD} or V _{SS} via a resistor.
8	P3_10/A10	P3_10		
9	P3_9/A9	P3_9		
10	P3_8/A8	P3_8		
11	P3_7/A7	P3_7		
12	P3_6/A6	P3_6		
13	P3_5/A5	P3_5		
14	P3_4/A4	P3_4		
15	P3_3/A3	P3_3		
16	P3_2/A2	P3_2		
17	P3_1/A1	P3_1		
18	P3_0/A0	P3_0		
19	EV _{DD}	EV _{DD}	–	Always connect to the power supply.
20	EV _{DD}	EV _{DD}	–	Always connect to the power supply.
21	V _{SS}	V _{SS}	–	Always connect to the ground directly.
22	FLMD0	FLMD0	Input	Independently connect to V _{SS} via a resistor (100 kΩ is recommended) when in a mode other than flash memory programming mode or boundary scan mode.
23	FLMD1	FLMD1	Input	Directly connect to V _{DD} . When in flash memory programming mode or when the on-chip debugging is used, however, independently connect to V _{SS} via a resistor (100 kΩ is recommended).
24	V _{SS}	V _{SS}	–	Always connect to the ground directly.
25	P0_0/D0	P0_0	Input	Independently connect to EV _{DD} or V _{SS} via a resistor.
26	P0_1/D1	P0_1		
27	P0_2/D2	P0_2		
28	P0_3/D3	P0_3		
29	P0_4/D4	P0_4		

Table 2-6 Default States and Recommended Connection of Unused Pins (2/8)

Pin No.	Pin Name	Default State		Recommended Connection of Unused Pins
		Function	I/O	
30	P0_5/D5	P0_5	Input	Independently connect to EV _{DD} or V _{SS} via a resistor.
31	P0_6/D6	P0_6		
32	P0_7/D7	P0_7		
33	P0_8/D8	P0_8		
34	P0_9/D9	P0_9		
35	P0_10/D10	P0_10		
36	EV _{DD}	EV _{DD}	–	Always connect to the power supply.
37	V _{SS}	V _{SS}	–	Always connect to the ground directly.
38	P0_11/D11	P0_11	Input	Independently connect to EV _{DD} or V _{SS} via a resistor.
39	P0_12/D12	P0_12		
40	P0_13/D13	P0_13		
41	P0_14/D14	P0_14		
42	P0_15/D15	P0_15		
43	IV _{DD}	IV _{DD}	–	Always connect to the power supply.
44	IV _{DD}	IV _{DD}	–	Always connect to the power supply.
45	V _{SS}	V _{SS}	–	Always connect to the ground directly.
46	V _{SS}	V _{SS}	–	Always connect to the ground directly.
47	UDMF	UDMF	Input	Independently connect to V _{SS} via a resistor.
48	UDPF	UDPF	Input	Independently connect to V _{SS} via a resistor.
49	UV _{DD}	UV _{DD}	–	Always connect to the power supply.
50	V _{SS}	V _{SS}	–	Always connect to the ground directly.
51	UDMH	UDMH	Output	Leave open.
52	UDPH	UDPH	Output	Leave open.
53	EV _{DD}	EV _{DD}	–	Always connect to the power supply.
54	V _{SS}	V _{SS}	–	Always connect to the ground directly.
55	P1_0/D16/TA0_I0/TE0_TI0/INTP5/TA0_O0	P1_0	Input	Independently connect to EV _{DD} or V _{SS} via a resistor.

2.6 Pin Input Circuit Types

2.6.1 Input circuit types for port input pins and input pins that have port or other functions

The input circuit type is determined by the settings of the port function control registers PIS, PISE, and PISA, as shown in the table below.

Table 2-7 Input Circuit Types for Pins That Have Port Input Function

PISnm	PISEnm	PISAnm	Input Circuit Type
0	0	0	CMOS
1	0	0	Schmitt 2
0	1	0	Schmitt 1
×	×	1	LVTTTL
Settings other than the above are prohibited.			

Note For details about the setting of each pin, see 8.4.4 “V850E2/ML4 port control register settings” on page 167 .

2.7 Cautions on 5-V tolerant supporting pins

The following pins support 5-V tolerant input/outputs:

- P2_12/TJ_I0/SCL0/RXD0F/TJ_O0
- P2_13/TJ_I1/ADTRG01/SDA0/TJ_O1/TXD0F
- P2_14/TJ_I2/ADTRG11/SCL1/TJ_O2/CAN0RXD
- P2_15/TJ_I3/ADTRG21/SDA1/TJ_O3/CAN0TXD

Note, however, that they support 5-V tolerant input only.

They support 5-V tolerant output in the case of N-ch open drain output only.

If a voltage exceeding EV_{DD} is externally applied to a 5-V tolerant supported pin with a pull-up resistor connected, output operation at P-ch side is disabled.

Chapter 3 Operation Modes

3.1 Features

- The operation mode is specified according to the levels of the FLMD0, FLMD1, MODE2, and MODE3 pins.
- There are three operation modes:
 - Normal operation mode (single-chip mode)
 - Flash memory programming mode
 - Boundary scan mode

3.2 Operation Modes

3.2.1 Normal operation mode

This mode makes it possible to start instruction processing by branching to the reset entry address in the internal flash memory after a system reset ends.

3.2.2 Flash memory programming mode

This mode makes it possible to use a flash memory programmer to program the internal flash memory.

3.2.3 Boundary scan mode

This mode makes it possible to use a test method specified by IEEE 1149.1 to check the connections between devices mounted on an application system board.

3.3 Specifying the Operation Mode

The operation mode is specified according to the status of the FLMD0, FLMD1, MODE2, and MODE3 pins. The specifications of these pins are fixed for the application system, and, if they are changed during operation, the operation is not guaranteed. (However, this does not include changing the FLMD0 pin during flash memory self programming.)

Table 3-1 Operation Modes

FLMD0	FLMD1	MODE2	MODE3	Operation Mode
L	L	L	L	Normal operation mode
H	L	L	L	Flash memory programming mode
H	H	L	L	Boundary scan mode
Other than the above				Setting prohibited

Note L: Low level
H: High level

Chapter 4 CPU

4.1 Features

- V850E2M CPU core
- Protection functions
 - System register protection
 - Memory protection
 - Peripheral-device protection
 - Timing monitoring
- Multi-layer system bus

4.2 Configuration

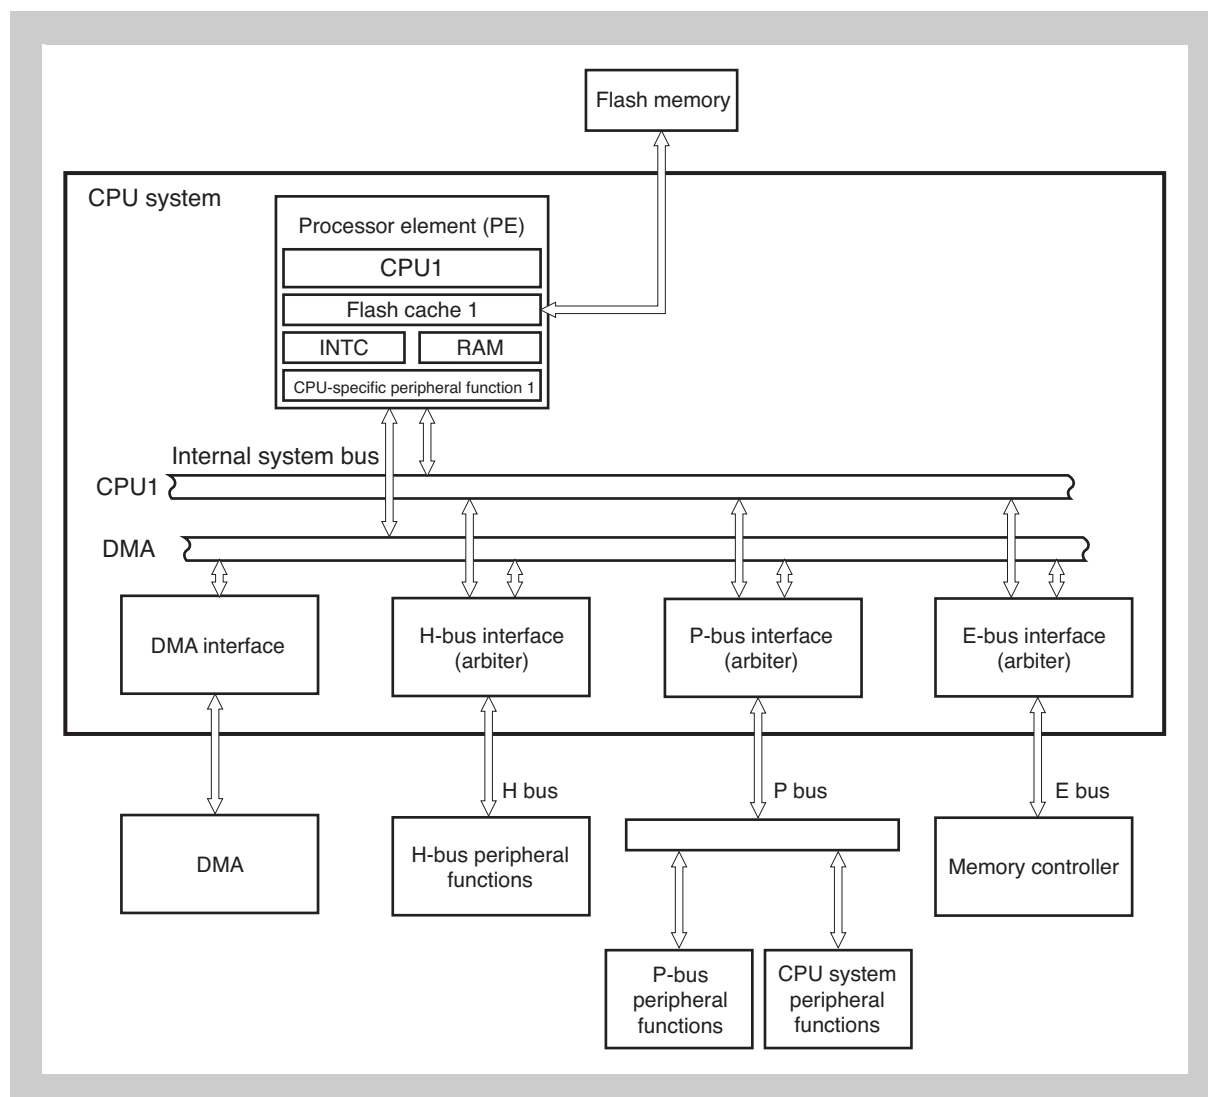

Figure 4-1 CPU system configuration

4.3 CPU Core

The V850E2/ML4 uses a V850E2M CPU.

This CPU complies with the V850E2v3 architecture, is designed to provide high performance, advanced functionality, and high reliability, and is intended for device controlling microcontrollers used in embedded systems. The CPU uses seven-stage pipeline control to enable single-clock execution of address calculations, arithmetic logic operations, data transfers, and almost all other instruction processing.

Note that, because the V850E2M CPU is compatible with the V850, V850E1, and V850E2 CPUs at the object code level, conventional system software assets can be used as is.

For details about the V850E2M CPU, see the *V850E2M Architecture User's Manual (R01US0001EJ)*.

4.4 Address Space

4.4.1 CPU address space

The V850E2M CPU uses a 32-bit architecture that supports a linear address space of up to 4 GB.

However, for this product, instruction fetch addresses and data access addresses are 29 bits, and the accessible address range, which includes both the program space and data space, is a maximum of 512 MB.

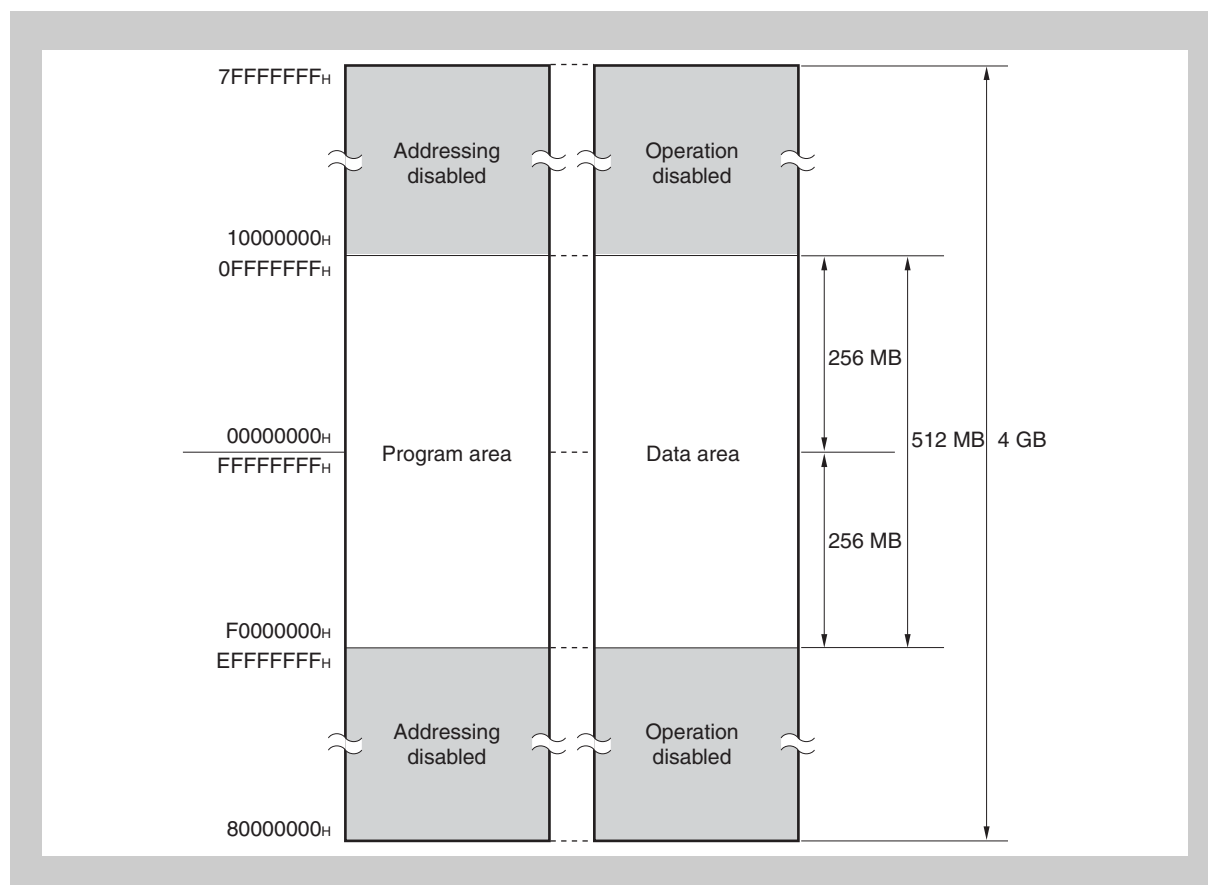

Figure 4-2 CPU address space

<R>

For instruction address addressing, a value whose 29th bit is sign-extended is automatically specified for the higher 3 bits of the register holding the instruction address. Therefore, the addressable range is 00000000_H to 0FFFFFFE_H and F0000000_H to FFFFFFFE_H (and the least significant bit is always 0). Be sure to place the instructions and the tables referenced using the SWITCH, CALLT, and SYSCALL instructions in the instruction addressable address range.

Because, when addressing a physically placed area exceeding 512 MB, mirroring is performed using addresses excluding the higher 3 bits, data access is possible regardless of the placement within the 4 GB space. However, to ensure future compatibility, it is prohibited to run data addressing assuming such mirroring.

4.4.2 CPU address space wraparound

(1) Program space

For instruction address addressing, a value whose 28th bit is sign-extended is automatically specified for the higher 3 bits of the register holding the instruction address.

Therefore, the highest address of the program space, FFFFFFFFH, and the lowest address, 00000000H, as well as the addresses 10000000H and 0FFFFFFFH, are contiguous, and wraparound occurs at the boundaries of these addresses.

<R>

Figure 4-3 Program space wraparound

(2) Data space

The result of an operand address calculation operation that exceeds 29 bits is ignored.

Therefore, the highest address of the data space, FFFFFFFFH, and the lowest address, 00000000H, are contiguous, and wraparound occurs at the boundary of these addresses.

Figure 4-4 Data space wraparound

4.4.3 Memory map

The areas shown below are reserved for the V850E2/ML4.

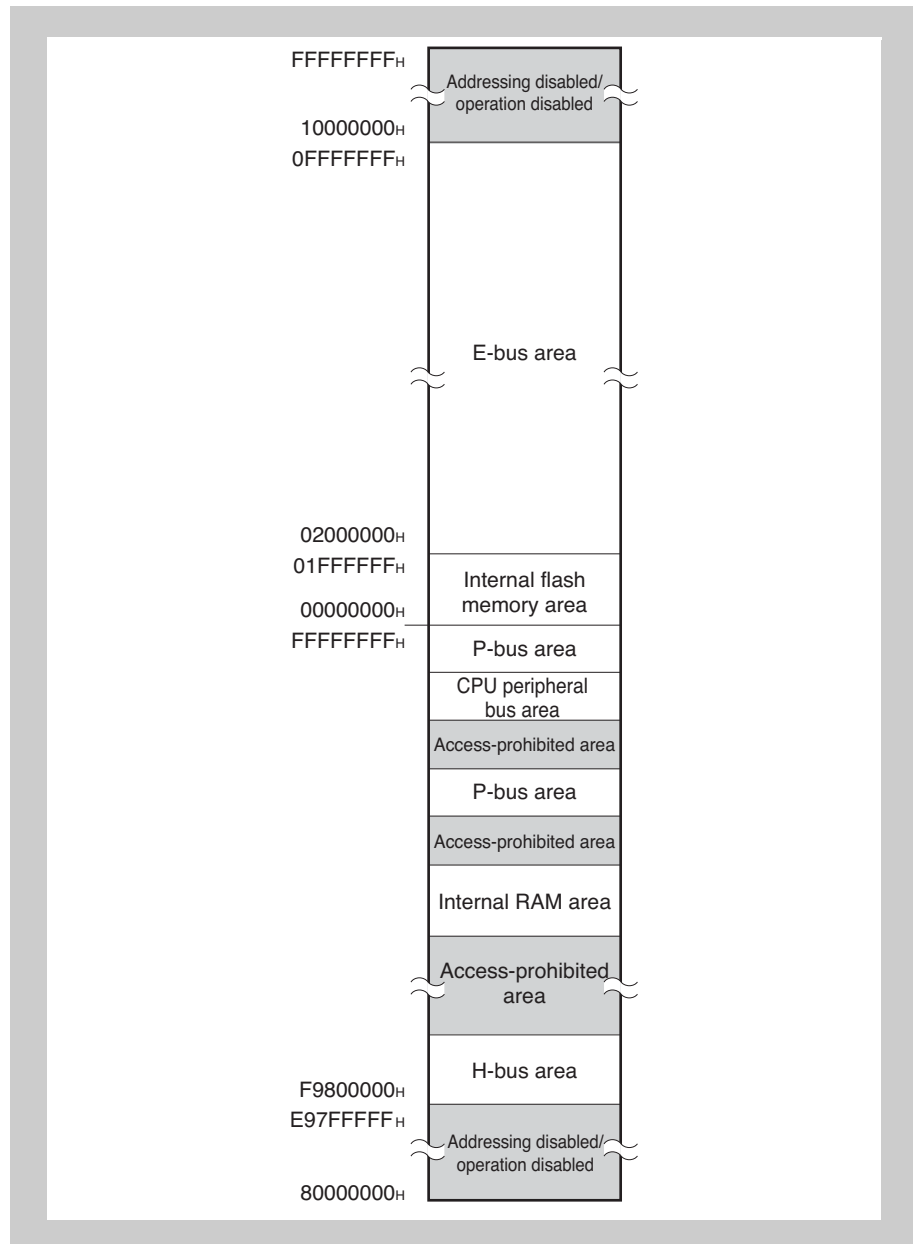

Figure 4-5 Memory map

4.4.4 Areas

(1) Internal flash memory area

The 32 MB from 00000000_H to 01FFFFFF_H are reserved as the internal flash memory area.

(a) Internal flash memory (768 KB)

For the μ PD70F4021, 768 KB is provided from 00000000_H to 000BFFFF_H.

Accessing the addresses 00100000_H to 01FFFFFF_H is prohibited.

Figure 4-6 Internal flash memory area

(b) Internal flash memory (1 MB)

For the μ PD70F4022, 1MB are provided from 00000000_H to 001FFFFFF_H.

Accessing the addresses 00200000_H to 01FFFFFF_H is prohibited.

Figure 4-7 Internal flash memory area

(2) Internal RAM area

The 4 MB from FEA00000_H to FEDFFFFFF_H are reserved as the internal RAM area.

(a) Internal RAM (64 KB)

For the V850E2/ML4, 64 KB are provided from FEDF0000_H to FEDFFFFFF_H.

Accessing the addresses FEA00000_H to FEDEFFFFFF_H is prohibited.

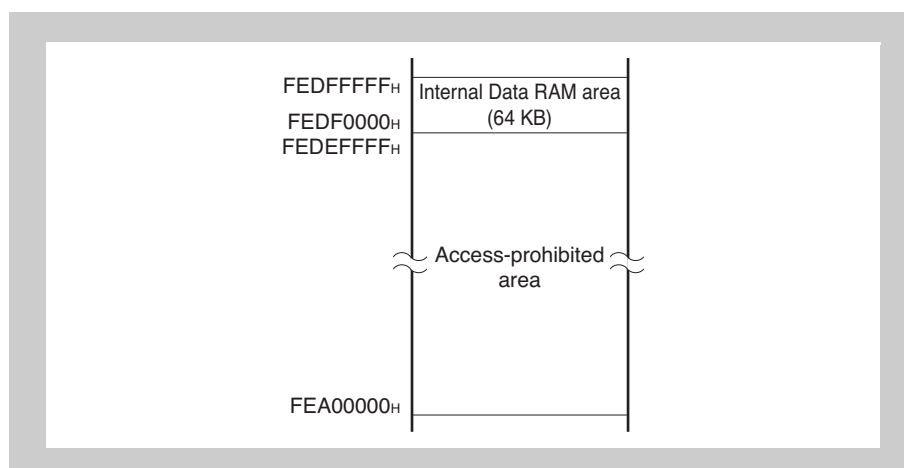

Figure 4-8 Internal RAM area (64 KB)

(3) External memory area and on-chip peripheral I/O area**(a) CPU peripherals**

12 KB are provided from FFFF5000_H to FFFF7FFF_H as the area for CPU-specific peripheral functions and CPU system peripheral functions.

Peripheral I/O registers that have functions to specify the operation mode for and monitor the status of the on-chip peripheral I/O are mapped to the on-chip peripheral I/O area.

Figure 4-9 On-chip peripheral I/O area (12 KB)

(b) E bus

This is a 224 MB external memory area for the memory controller. The external memory area is the area from 02000000_H to 0FFFFFFF_H.

Accessing the external memory area uses chip select signals assigned to each memory block.

Table 4-1 CS spaces (E bus)

CS	Address	Size
CS1	02000000 _H -03FFFFFF _H	32 MB
CS2	04000000 _H -07FFFFFF _H	64 MB
CS3	08000000 _H -0BFFFFFF _H	64 MB
CS4	0C000000 _H -0FFFFFFF _H	64 MB

Note Note CS4 is the space for SDRAM.

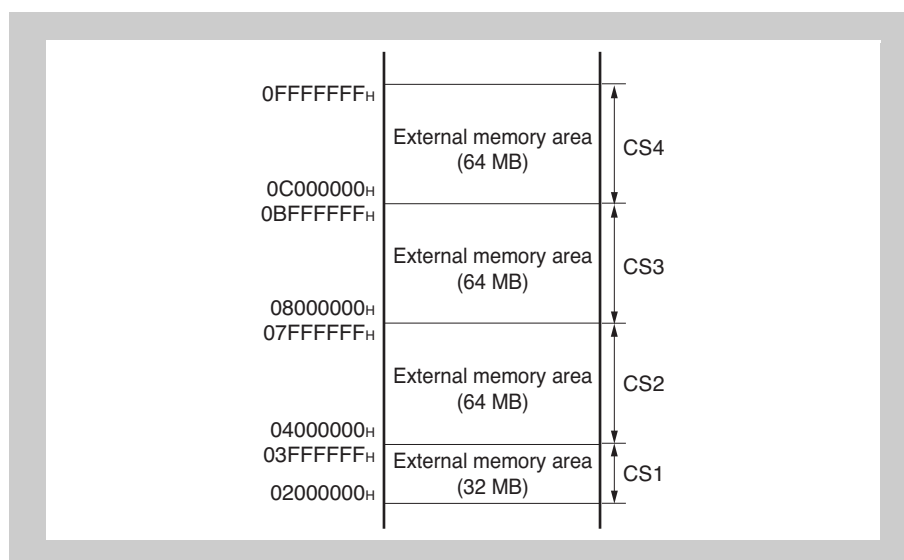

Figure 4-10 CS spaces (E bus)

(c) P bus

The 32 KB from FFFF8000_H to FFFFFFFF_H, as well as the 4 MB + 256 KB from FF400000_H to FF83FFFF_H, are provided as the area for the P bus.

Peripheral I/O registers that have functions to specify the operation mode for and monitor the status of the on-chip peripheral I/O are mapped to the on-chip peripheral I/O area.

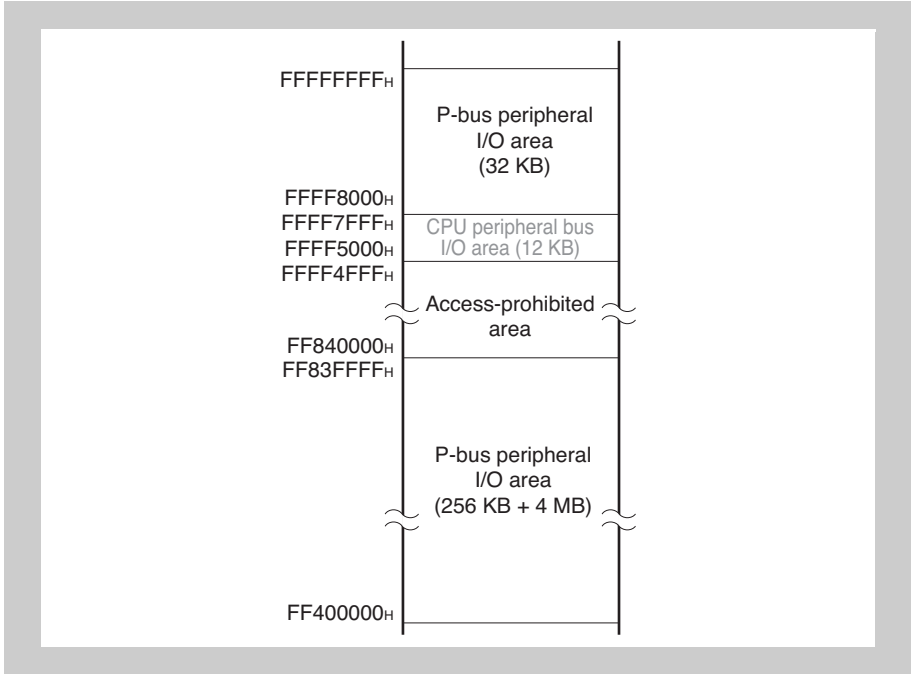

Figure 4-11 On-chip peripheral I/O space (P bus)

(d) H bus

The 160 MB from F0000000_H to F9FFFFFF_H are provided as the on-chip peripheral I/O area for the H bus.

Peripheral I/O registers that have functions to specify the operation mode for and monitor the status of the on-chip peripheral I/O are mapped to the on-chip peripheral I/O area.

Figure 4-12 Memory map (H bus)

4.5 Processor Elements (PE)

The entity to which the CPU, flash cache, RAM, interrupt controller, and CPU-specific peripheral functions are connected is called a processor element (PE).

4.6 Bus Architecture

4.6.1 Internal system bus

This internal system bus connects each PE and DMA to the P bus, H bus, and E bus. This internal system bus is in a multi-layer configuration, and PE and DMA each has its own layer. This makes it possible to simultaneously access different buses (the P bus, H bus, and E bus) for each PE. Note that arbitration is performed using each bus interface if there is a conflict when trying to access the same bus.

4.6.2 P bus

This is the bus to which P bus peripherals (TAUA, TAUJ, ENCA, OSTM, WDTA, ADCA, ports, UARTE, UARTJ, CSIG, CSIH, I2CB, and FCN) are connected.

4.6.3 H bus

This is the bus to which the H-bus-shared memory, H-bus memory side cache, USB function controller, USB host controller, and Ethernet controller are connected.

(1) Initial settings

Initial settings are necessary to use the H bus. After a reset, perform the following procedure to specify these settings before accessing the H bus:

- <1> Set the area to normal access by using the ETARCFG0 register.
Set the MODE bits (bits 7 to 4) to "0000"_B (normal access).
- <2> Specify the base address for the area by using the ETARADRS0 register.
Set the base address of the target area to F0000000_H by using bits 28 to 12.
- <3> Specify the area size by using the ETARMASK0 register.
Set the mask value for the base address of the target area to 1FFFFFFF_H by using bits 28 to 12.
- <4> Enable the area by using the ETARCFG0 register.
Set the EN bit (bit 0) to "1" (enabled).

(a) ETA area 0 setting register (ETARCFG0)

This register is used to specify whether area 0 is enabled or disabled and its operation mode.

Access This register can be read or written in 16-bit units.

Address FFFF7140_H

Initial value 0000_H. This register is initialized by any reset.

Caution Be sure to clear bits 15 to 1 to "0".

15	14	13	12	11	10	9	8
0	0	0	0	0	0	0	0
R	R	R	R	R	R	R	R
7	6	5	4	3	2	1	0
MODE				0	0	0	EN
R/W	R/W	R/W	R/W	R	R	R	R/W

Table 4-2 ETARCFG0 register contents

Bit Position	Bit Name	Description
7:4	MODE	These bits specify the operation mode for area 0. Set these bits to "0000". All other values are prohibited.
0	EN	This bit specifies whether area 0 is enabled or disabled. 0: Disabled 1: Enabled.

(b) ETA area 0 address register (ETARADRS0)

This register is used to set the base address that specifies area 0.

Access This register can be read or written in 32-bit units. However, if the higher 16 bits of the ETARADRS0 register are used as the ETARADRS0H register, and the lower 16 bits are used as the ETARADRS0L register, the ETARADRS0 register can be read or written in 16-bit units.

Address ETARADRS0: FFFF7150_H, ETARADRS0L: FFFF7150_H,
ETARADRS0H: FFFF7152_H

Initial value After power-on: Undefined

After a reset: The previous value is retained. This register is initialized by any reset.

31	30	29	28	27	26	25	24
ETARADRS[31:24]							
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

7	6	5	4	3	2	1	0
ETARADRS[7:0]							
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 4-3 ETARADRS0 register contents

Bit Position	Bit Name	Description
31:0	ETARADRS [31:0]	These bits specify the base address that specifies area 0. Bit 28 is regarded as the sign bit for bits 31 to 29, in which a sign extended value is stored. Be sure to set this to F0000000 _H .

(c) ETA area 0 mask register (ETARMASK0)

This register is used to specify the mask value for the base address that specifies area 0.

When setting this register, be sure to specify a value that consists of consecutive 1s from the lower bits.

Access This register can be read or written in 32-bit units. However, if the higher 16 bits of the ETARMASK0 register are used as the ETARMASK0H register, and the lower 16 bits are used as the ETARMASK0L register, the ETARMASK0 register can be read or written in 16-bit units.

Address ETARMASK0: FFFF7154_H, ETARMASK0L: FFFF7154_H,
ETARMASK0H: FFFF7156_H

Initial value After power-on: Undefined

After a reset: The previous value is retained. This register is initialized by any reset.

31	30	29	28	27	26	25	24

R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 4-4 ETARMASK0 register contents

Bit Position	Bit Name	Description
31:0	ETARMASK [31:0]	These bits are used to specify a mask value for the base address that specifies area 0. Be sure to set this to 1FFFFFFF _H .

(2) Multi-layer structure

The H bus has a multi-layer internal configuration, so, as long as no slaves are duplicated, each bus master can access each slave.

The transfer targets are shown below.

Table 4-5 H-bus transfer targets

Master (Transfer Source)	Slave (Transfer Destination)				
	Shared H-Bus Memory	USB Function	USB Host	Ethernet Controller (Dedicated DMA)	Ethernet Controller (Tx Checksum)
CPU	Available	Available ^a	Available ^a	Available ^a	Available ^a
DMA	Available	Not available	Not available	Not available	Not available
USB function	Available	Not available	Not available	Not available	Not available
USB host	Available	Not available	Not available	Not available	Not available
Ethernet controller (dedicated DMA)	Available	Not available	Not available	Not available	Not available
Ethernet controller (Tx checksum dedicated DMA)	Available	Not available	Not available	Not available	Not available

a) Only control register access is possible.

4.6.4 E bus

This is the bus to which the memory controller is connected.

For details about the memory controller, see *Chapter 11 Memory Controller*.

4.6.5 Arbitration

(1) Flash cache

There are two types of access requests to the flash cache: instruction fetch requests and data access requests. For the flash cache, a data access request is always prioritized (according to a fixed priority).

(2) Flash memory

If there is a fetch request from the CPU, the flash memory accepts that request. If no fetch request is issued, the flash memory accepts a preload request from the CPU.

(3) Internal RAM

Internal RAM arbitrates the following two types of access requests: instruction fetch requests and data access requests.

The arbitration policy of internal RAM is shown below.

- Between a data access request and an instruction access request:
The data access request is prioritized as the initial status, and round-robin arbitration is performed when there are successive requests.

(4) E bus I/F, P bus I/F, H bus I/F

For the interfaces of the E bus, P bus, and H bus, arbitration is performed on access requests from the masters (CPU and DMA) on each layer of a system bus in a multi-layer configuration.

4.7 Flash Cache

4.7.1 Configuration

For the V850E2/ML4, a 16 KB, four-way set associative cache dedicated to the flash memory (called the flash cache below) is mounted between the CPU and flash memory. The flash cache and flash memory are interconnected by a 128-bit dedicated bus, minimizing the penalty when a cache miss hit occurs.

The flash cache is made up of the following functions:

- Cache function
- Preload function
- Data buffer function
- Cache clear function

4.7.2 Control registers

(a) Flash cache operation setting register (FCCTL0)

This register is used to set up the functions of the flash cache.

When the setting of this register has been changed, clear the contents of the cache by manipulating the FCCTL1 register.

Access This register can be read or written in 16-bit units. However, when the higher 8 bits and lower 8 bits of the FCCTL0 register are used as the FCCTL0H register and FCCTL0L register, respectively, this register can be read or written in 8-/1-bit units.

Address FCCTL0: FFFF6480_H,
FCCTL0L: FFFF6480_H, FCCTL0H: FFFF6481_H

Initial value 40B7_H. This register is initialized by any reset.

Caution Be sure to set this to 40B7_H or 41B7_H. For details, see *Table 4-8 “FCCTL0 register settings”*.

15	14	13	12	11	10	9	8
R/W	R/W	R	R	R	R	R/W	R/W
7	6	5	4	3	2	1	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 4-6 FCCTL0 register contents

Bit Position	Bit Name	Description
15:0	–	Be sure to set this to 40B7 _H or 41B7 _H . For details, see <i>Table 4-8 “FCCTL0 register settings”</i> .

(b) Flash cache trigger function register (FCCTL1)

This register is used to clear the flash cache.

Access This register can be written in 16-bit units. However, when the higher 8 bits and lower 8 bits of the FCCTL1 register are used as the FCCTL1H register and FCCTL1L register, respectively, this register can be read in 8-/1-bit units.

Address FCCTL1: FFFF6482_H,
FCCTL1L: FFFF6482_H, FCCTL1H: FFFF6483_H

Initial value 0000_H. This register is initialized by any reset.

Caution Be sure to clear bits 15 to 1 to "0".

15	14	13	12	11	10	9	8
0	0	0	0	0	0	0	0
R	R	R	R	R	R	R	R
7	6	5	4	3	2	1	0
0	0	0	0	0	0	0	CHCLR
R	R	R	R	R	R	R	W

Table 4-7 FCCTL1 register contents

Bit Position	Bit Name	Description
0	CHCLR	Cache clear trigger This bit clears the cache. This bit is always 0 when it is read. 0: No function 1: Clears the cache contents.

4.7.3 Operation

(1) Cache function

A 16 KB 4-way set associative cache has four ways consisting of 256 entry blocks each, where one line consists of 4 words, to make up 16 KB of capacity. If a cache miss occurs, refilling is performed in line units (= 16 bytes) by using a pseudo-LRU switching algorithm.

(a) FCCTL0 register settings

The settings below can be specified for flash cache operations by using the FCCTL0 register.

Be sure to specify one of the operation modes after a reset. All other values are prohibited.

Table 4-8 FCCTL0 register settings

Type	FCCTL0 Register Setting	Operation
Standard setting	40B7 _H	This setting specifies the use of the flash cache as an instruction cache. This setting increases the performance. The access cycle fluctuates according to the cache hit/miss-hit rate.
Performance prioritizing setting	41B7 _H	This setting specifies the use of the flash cache as a mixed instruction/data cache. This increases the data access speed. If using a lot of data, instructions stored in the cache might be flushed out, decreasing performance.

(2) Preload function

In the case of instruction fetch address access from the CPU, the flash memory contents at addresses +16 bytes, +32 bytes, and +48 bytes are stored in the flash cache before access from the CPU. As a result, when the CPU fetches subsequent instructions, it can use the instructions stored in the cache without having to fetch the flash memory contents anew, thereby realizing efficient CPU instruction execution.

(3) Data buffer function

Two 128-bit data-access-dedicated buffers are provided in the flash cache. The contents of past data access are stored in this data buffer. During data access, reading from the flash memory is performed in 128-bit units, and 128 bits of data are stored in two data buffers. During the next data access, in the case of access to data already stored in these data buffers, that data is fetched from these data buffers, and the flash memory is not accessed. Therefore, constant value access to the flash memory is performed at high speed.

(4) Cache clear function

The flash cache contents and data buffer contents can be cleared by writing "1" to the CHCLR bit of the FCCTL1 register. The internal data of the cache is invalidated in batch. When the flash memory contents are rewritten through flash self programming, clear the cache contents by using this function.

Chapter 5 Reset Function

5.1 Features

Three types of reset sources

- System resets triggered by $\overline{\text{RESET}}$ pin input
- System resets triggered by a watchdog timer overflow
- System resets triggered by software

5.2 Configuration

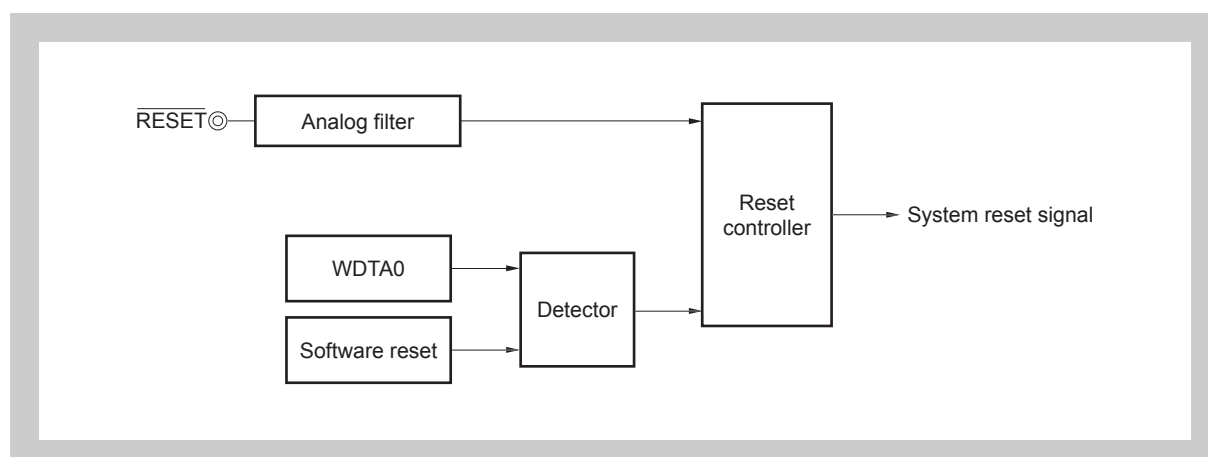

Figure 5-1 Block Diagram of the Reset Circuit

5.3 Control Registers

5.3.1 Reset source flag register (RESF)

This register indicates which reset source a received reset request is from. The bit that corresponds to this source is set.

Access This register is read-only, in 8-bit units.

Address FF42 0040_H

Initial value 00_H. $\overline{\text{RESET}}$ pin input clears this register to 00H. The initial value of this register differs for a reset due to a source other than $\overline{\text{RESET}}$ pin input. Note that bits of this register that have been set are cleared by setting the corresponding bits of the RESC register.

	7	6	5	4	3	2	1	0
RESF	0	0	0	0	0	RESSTG2IN2	0	RESSTG2IN0
	R	R	R	R	R	R	R	R

Table 5-1 RESF Register Contents

Bit Position	Bit Name	Description
2	RESSTG2IN2	This bit indicates whether the software reset signal has been generated. 0: Not generated 1: Generated
0	RESSTG2IN0	This bit indicates whether the WDTA0 overflow signal (WDTA0RES) has been generated. 0: Not generated 1: Generated

Note When an emulator is connected, the above bits are not set if the reset mask is enabled.

5.3.2 Reset source clear register (RESC)

This register clears the RESF register. Note that bits of the RESF register that have been set are cleared by setting the corresponding bits of the RESC register.

Access This register is write-only, in 8-bit units. When read, 00_H is always returned.

Address FF42 0044_H

Initial value 00_H

	7	6	5	4	3	2	1	0
RESC	0	0	0	0	0	STG2 RESCR2	0	STG2 RESCR0
	W	W	W	W	W	W	W	W

Table 5-2 RESC Register Contents

Bit Position	Bit Name	Description
2	STG2RESCR2	This bit clears the software reset flag. Setting this bit clears the RESSTG2IN2 bit.
0	STG2RESCR0	This bit clears the WDTA0 overflow signal (WDTA0RES) generation flag. Setting this bit clears the RESSTG2IN0 bit.

Note When an emulator is connected, the above bits are not set if the reset mask is enabled.

5.3.3 Software reset enable register (SWRSTEN)

Access This register can be read or written in 32-bit units.

Address FFFF DA04_H

Initial value 0000 0000_H. This register is initialized by any reset.

	31	30	29	28	27	26	25	24
SWRSTEN	0	0	0	0	0	0	0	0
	R	R	R	R	R	R	R	R
	23	22	21	20	19	18	17	16
	0	0	0	0	0	0	0	0
	R	R	R	R	R	R	R	R
	15	14	13	12	11	10	9	8
	0	0	0	0	0	0	0	0
	R	R	R	R	R	R	R	R
	7	6	5	4	3	2	1	0
	0	0	0	0	0	0	0	SWRSTEN
	R	R	R	R	R	R	R	R/W

Table 5-3 SWRSTEN Register Contents

Bit Position	Bit Name	Description
0	SWRSTEN	This bit enables or disables the generation of software resets. 0: Disable the generation of software resets. 1: Enable the generation of software resets.

5.3.4 Software reset trigger register (SWREST)

This trigger register generates software resets. When the SWRSTEN.SWRSTEN bit is set, a software reset can be generated by writing 00_H to SWREST.

Access This register can be read or written in 8-bit units.

Address FF42 0000_H

Initial value 2C_H

	7	6	5	4	3	2	1	0
SWREST	SWREST7	0	1	0	1	1	0	0
	R/W	R	R	R	R	R	R	R

5.4 Operation

5.4.1 Operation for system resets triggered by $\overline{\text{RESET}}$ pin input

When a low-level signal is input to the $\overline{\text{RESET}}$ pin, a system reset occurs, and the hardware is initialized as specified.

When the $\overline{\text{RESET}}$ pin input is changed from low to high, the reset ends and the CPU starts executing a program from address 0000 0000_H.

Note that no oscillation stabilization time is inserted when the input is changed in this way. Therefore, for $\overline{\text{RESET}}$ pin input while the clock generator is stopped (a reset while the power is on), the oscillation stabilization time must be secured by adjusting the low-level width of the $\overline{\text{RESET}}$ pin input.

Table 5-4 Hardware Statuses When a Reset Signal Is Input

Hardware Name	During Reset Period	After the Reset
Clock generator	For details, see 6.4.1 "Operating status of each clock" on page 113 .	
CPU	Operation stopped	Operation started
Internal RAM, H-bus shared memory	Undefined	
Debugging function	Operation stopped	Operation possible
On-chip peripheral registers	Initialized to the specified status	
On-chip peripheral functions other than the above	Operation stopped	Starting operation possible
Pin functions	For details, see 2.4 "Pin State After Reset".	For details, see 2.5 "Default States and Recommended Connection of Unused Pins".

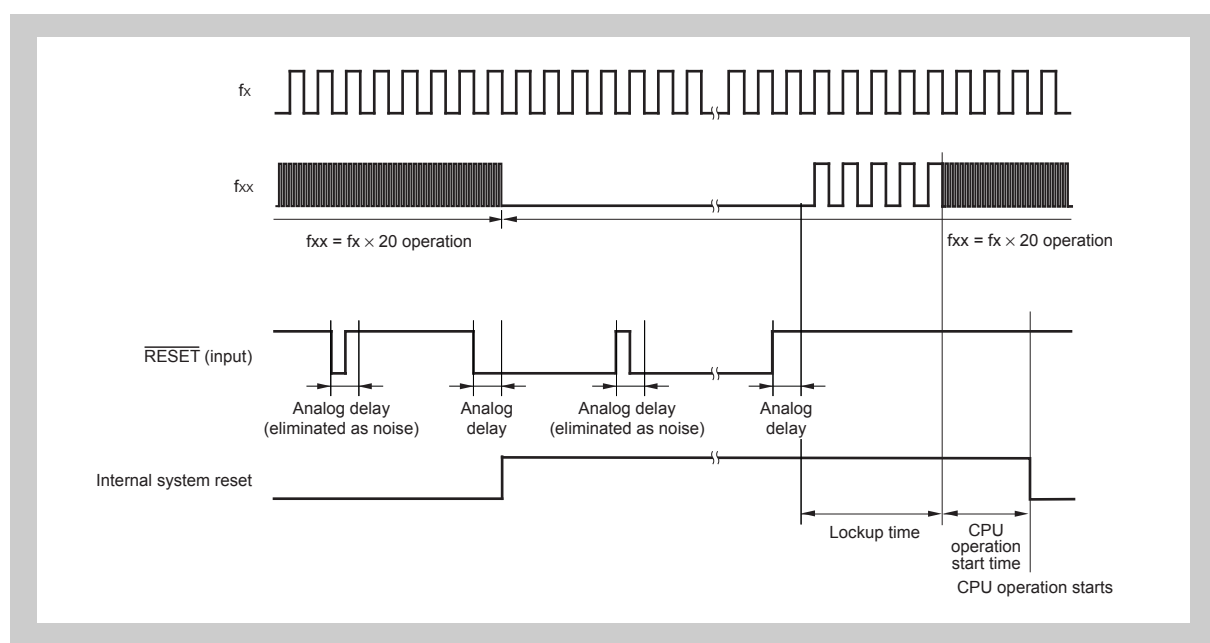

Figure 5-2 Operation for Resets Triggered by the $\overline{\text{RESET}}$ Pin

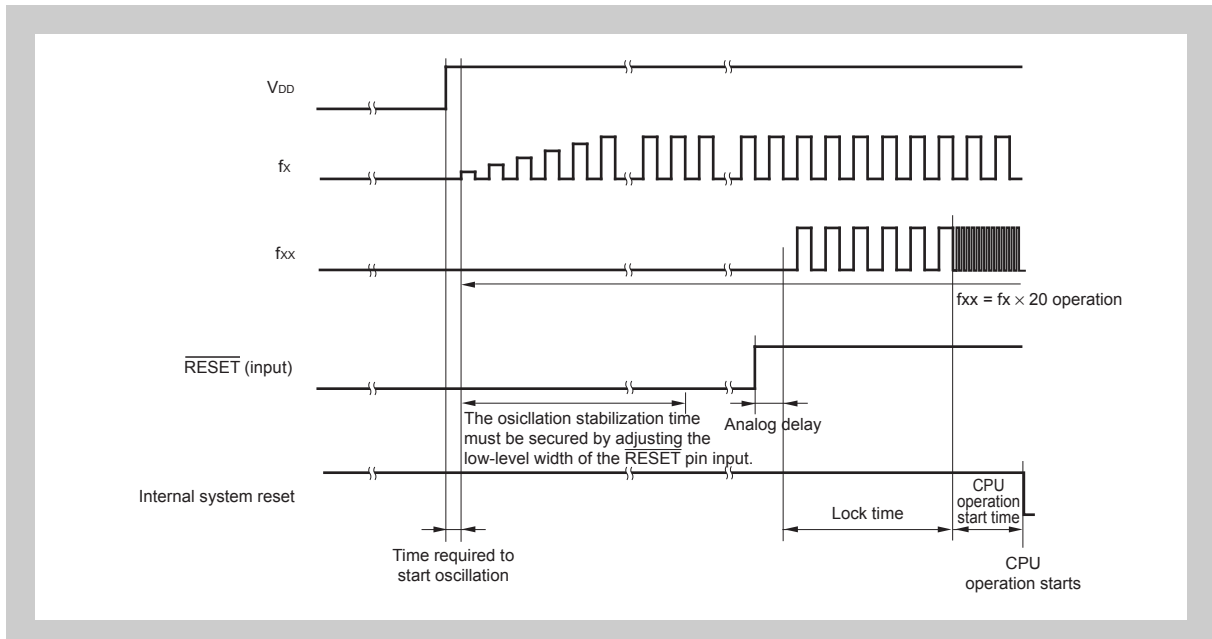

Figure 5-3 Operation for Resets While the Power Is On

5.4.2 System resets triggered by a watchdog timer overflow

When the watchdog timer is set up such that an overflow triggers a reset, a system reset occurs if the watchdog timer overflows, and the hardware is initialized as specified. After the watchdog timer overflows, the system is reset, and then this reset automatically ends.

5.4.3 System resets triggered by software

After the SWRSTEN bit of the software reset enable register SWRSTEN is set to enable the generation of software resets, if 00_H is written to the software reset trigger register, a system reset occurs, and the hardware is initialized as specified.

After writing to the software reset trigger register, the system is reset, and then this reset automatically ends.

To perform a software reset:

1. Interrupt or stop all peripheral functions being used and DMA operations, thereby stopping operation.
2. Disable interrupts.
3. Set the SWRSTEN.SWRSTEN bit.
4. Write 00_H to the SWREST register.
5. Set up an infinite loop so that subsequent instructions are not executed.

Chapter 6 Clock Generator

The clock generator is a circuit that generates the clocks supplied to the CPU and peripheral hardware. The generator includes a PLL circuit used to multiply the oscillated or supplied clock frequency by 20. The generator also makes it possible to divide the clock frequency supplied to the CPU and internal peripheral functions, or to stop supplying clocks to achieve low power consumption.

The features of the clock generator are described below.

6.1 Features

- Oscillation by connecting to an oscillator
- A PLL (Phase Locked Loop) is used to multiply the oscillator input frequency f_x by 20.
- Oscillator input frequency $f_x = 7.2$ MHz to 10 MHz
- PLL lockup time control
- USB-dedicated clock input
- MII-dedicated clock input
- Power saving control
- HALT mode

6.2 Configuration

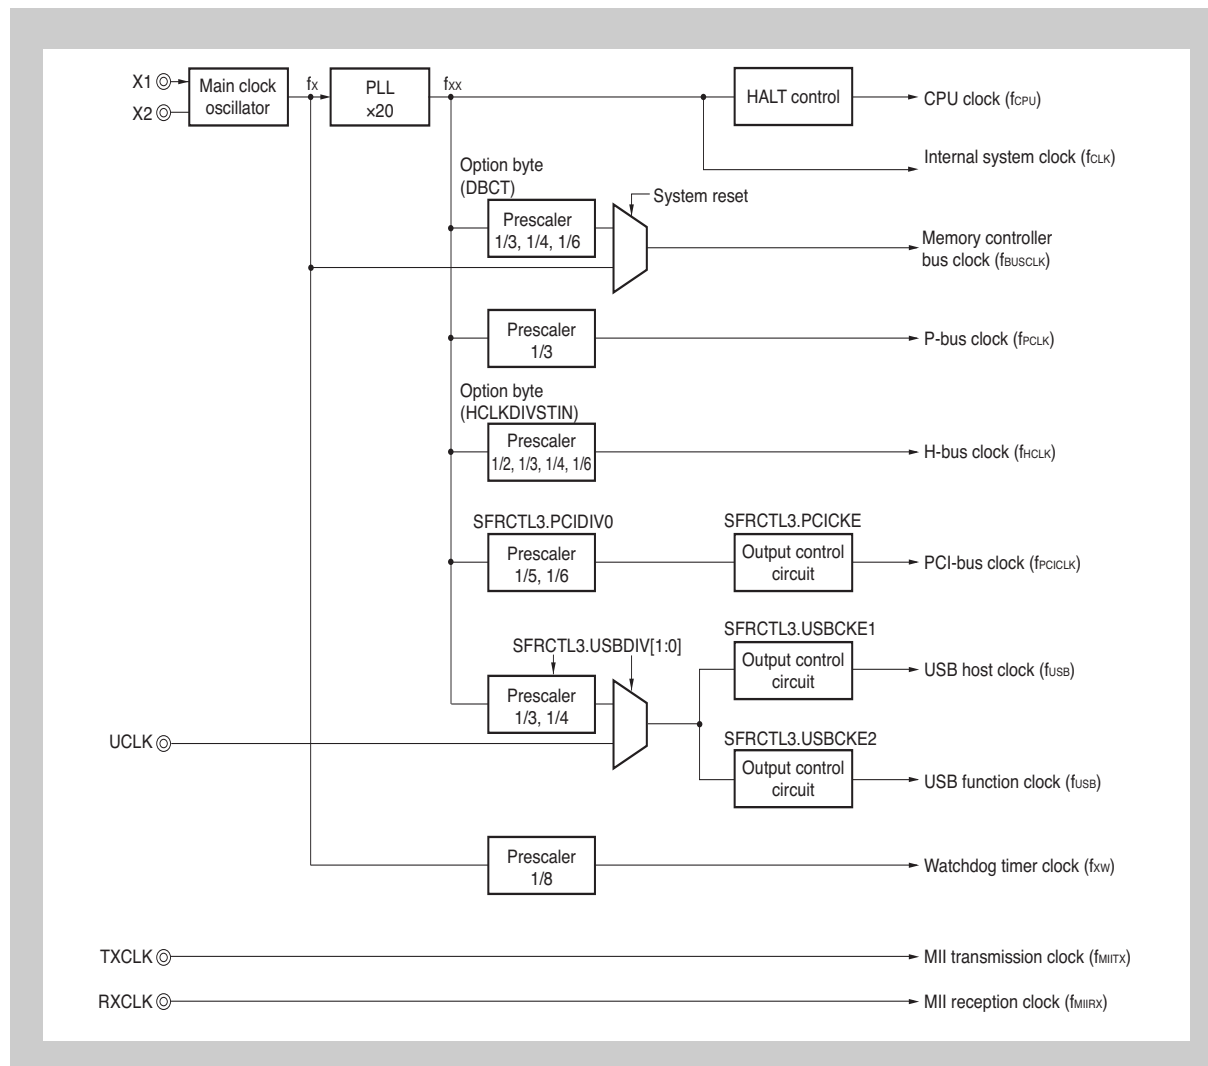

Figure 6-1 Clock Generator Block Diagram

6.3 Control Registers

6.3.1 Special clock frequency control register (SFRCTL3)

The SFRCTL3 register is used to control the clock supplied to the USB function and USB host controllers.

When the clock settings for the SFRCTL3 register are changed, check the new setting values by using the SFR3CKST register, and then access the register of the target peripheral function.

Access This register can be read or written in 8-bit units.

Address FF42 0038_H

Default value DC_H. This register is initialized by any reset.

-
- Notes**
1. Be sure to set bit 6 to 1 and clear bit 5 to 0.
 2. Do not access the registers related to the USB function controller when clock supply to the USB function controller is prohibited (USBCKE2 = 0). Do not access the registers related to the USB host controller when clock supply to the USB host controller is prohibited (USBCKE1 = 0) or when PCI bus clock supply to the USB host controller is prohibited (PCICKE = 0).
-

	7	6	5	4	3	2	1	0
SFRCTL3	PCICKE	1	0	PCIDIV0	USBCLK2	USBCKE1	USBDIV1	USBDIV0
	R/W	R	R	R/W	R/W	R/W	R/W	R/W

Table 6-1 SFRCTL3 Register Contents

Bit Position	Bit Name	Meaning															
7	PCICKE	Specify whether to enable supplying the PCI-bus clock to the USB host controller. 0: Disable supplying the clock. 1: Enable supplying the clock.															
4	PCIDIV0	Select the division factor for the PCI-bus clock supplied to the USB host controller. 0: $f_{XX}/5$ (f_{XX} : 144 MHz to 166 MHz) 1: $f_{XX}/6$ (f_{XX} : 166 MHz to 200 MHz)															
3	USBCKE2	Specify whether to enable supplying the clock to the USB function controller. 0: Disable supplying the clock. 1: Enable supplying the clock.															
2	USBCKE1	Specify whether to enable supplying the clock to the USB host controller. 0: Disable supplying the clock. 1: Enable supplying the clock.															
1, 0	USBDIV[1:0]	Select the clock supplied to the USB function or USB host controller. Be sure to specify settings so the supplied clock (f_{USB}) is 48 MHz. <table border="1" data-bbox="646 824 1331 1037"> <thead> <tr> <th>USBDIV1</th> <th>USBDIV0</th> <th>Clock Selection</th> </tr> </thead> <tbody> <tr> <td>0</td> <td>0</td> <td>External clock (UCLK)</td> </tr> <tr> <td>0</td> <td>1</td> <td>Setting prohibited</td> </tr> <tr> <td>1</td> <td>0</td> <td>$f_{XX}/3$ ($f_{XX} = 144$ MHz operation)</td> </tr> <tr> <td>1</td> <td>1</td> <td>$f_{XX}/4$ ($f_{XX} = 192$ MHz operation)</td> </tr> </tbody> </table>	USBDIV1	USBDIV0	Clock Selection	0	0	External clock (UCLK)	0	1	Setting prohibited	1	0	$f_{XX}/3$ ($f_{XX} = 144$ MHz operation)	1	1	$f_{XX}/4$ ($f_{XX} = 192$ MHz operation)
USBDIV1	USBDIV0	Clock Selection															
0	0	External clock (UCLK)															
0	1	Setting prohibited															
1	0	$f_{XX}/3$ ($f_{XX} = 144$ MHz operation)															
1	1	$f_{XX}/4$ ($f_{XX} = 192$ MHz operation)															

6.3.2 SFRCTL3 clock selection status register (SFR3CKST)

The SFR3CKST register is used to indicate the values specified for the SFRCTL3 register.

Access This register is read-only, in 16-bit units.

Address FF42 003C_H

Default value 40DC_H. This register is initialized by any reset.

	15	14	13	12	11	10	9	8
SFR3CKST	HCLKDIV2S	HCLKDIV1S	HCLKDIV0S	0	0	0	0	0
	R	R	R	R	R	R	R	R

1	1	$f_{XX}/4$ ($f_{XX} = 192$ MHz operation)															

6.4 Operation

6.4.1 Operating status of each clock

Table 6-3 Operating Status of Each Clock

Clock		Normal Operation	HALT Mode	Reset Period	PLL Lockup Time
Name	Symbol				
Main clock oscillator	f_X	✓	✓	✓	✓
Main clock frequency	f_{XX}	✓	✓	×	✓
CPU clock frequency	f_{CPU}	✓	×	×	×
Internal system clock frequency	f_{CLK}	✓	✓	×	×
Primary memory controller bus clock frequency	f_{BUSCLK}	✓	✓	✓ ^a	✓ ^a
P-bus clock frequency	f_{PCLK}	✓	✓	×	×
H-bus clock frequency	f_{HCLK}	✓ ^b	✓ ^b	×	×
PCI-bus clock frequency	f_{PCICLK}	✓ ^b	✓ ^b	×	×
USB host controller clock frequency	f_{USB}	✓ ^c	✓ ^c	×	×
USB function controller clock frequency	f_{USB}	✓ ^c	✓ ^c	×	×
WDT clock frequency	f_{XW}	✓	✓	×	×
MII transmission clock frequency	f_{MIITX}	✓ ^d	✓ ^d	×	×
MII reception clock frequency	f_{MIIRX}	✓ ^d	✓ ^d	×	×

- a) The main clock oscillator frequency (f_X) is output.
 b) This might be “x” depending on the output control settings.
 c) This might be “x” depending on the output control settings and pin settings.
 d) This might be “x” depending on the pin settings.

Note ✓: The clock oscillates or is supplied.

×: The clock does not oscillate or is not supplied.

Chapter 7 Option Bytes

7.1 Features

- The option bytes are stored as 32 bits of data in a dedicated internal flash memory area.
- This 32-bit data is used to set the clock generator division factor.
- Be sure to specify values for the option bytes by using a dedicated flash memory programmer or by performing flash memory self programming.

7.2 Data Structure

7.2.1 Option bytes

The option bytes are 32 bits of data stored in a dedicated internal flash memory area. When writing a program to the V850E2/ML4, be sure to specify values for the option bytes by using a dedicated flash memory programmer or by performing flash memory self programming.

The data in this area cannot be rewritten during program execution.

7.3 Control Register

7.3.1 Option byte storage register (OPBT0)

The OPBT0 register is used to indicate the values of the option bytes stored in a dedicated internal flash memory area.

The data in the OPBT0 register cannot be rewritten during program execution.

Access This register is read-only, in 32-bit units.

Address FF47 000C_H

Default value This depends on which values are written to the option bytes.

Chapter 8 Port Functions

This chapter provides a generic description of the port functions.

8.1 “Features” describes the specifications specific to each product, such as the pin groups and the base addresses of registers.

8.2 “Overview” describes the features of the port function provided for all the ports.

8.4 “V850E2/ML4 Port Functions” covers the individual functions of the pins of the V850E2/ML4.

8.1 Features

Port group This microcontroller has port groups, numbered as shown in the following table.

Table 8-1 Port groups of V850E2/ML4

Port group	
Number of groups	9
Group name	P0 to P8

- Cautions**
1. The V850E2/ML4 does not have the port universal control register (PUCC) and port special buffer control register (PSBC). Do not access the areas for these registers (<PORTn_base_OS> + 4900_H + n x 4 and <PORTn_base_OS> + 4D00_H + n x 4).
 2. To use the P8_[5:0] port that is shared with the A/D converter function as the port function, set the ADCAnCTL1.ADCAnGPS bit to turn on the A/D converter (ADCA0). For details, see 25.4.2 (2) ADCAnCTL1 – A/D converter mode control register 1.

Port group index n Throughout this chapter, the individual port groups are identified by the index “n” (n = 0 to 15), for example PMCn indicates the port mode control register for the Pn pin.

Register addresses All port register addresses are given as addresses offset from the individual base address <PORTn_base_USER> or <PORTn_base_OS>. The base addresses <PORTn_base_USER> and <PORTn_base_OS> are listed in the following table:

Table 8-2 Port base addresses

Base address	Address
<PORTn_base_OS>	FF40 0000 _H
<PORTn_base_USER>	FFFF 8000 _H

8.2 Overview

This microcontroller has various pins for input/output functions, known as ports. The ports are organized in port groups.

This microcontroller also has several control registers to allocate other than general purpose input/output functions to the pins.

For a description of the terms pin, port, or port group, see 8.2.1 “Terms” on page 122.

- Features summary**
- Configuration possible for individual pins.
 - The following functions can be selected for the main pins:

- 5 types of input buffer characteristics
- 2 types of output buffer characteristics
- Open drain emulation
- Pull-up or pull-down resistor connection
- The following registers are provided for the main ports:
 - Register for reading the pin values
 - Port register
 - Port set/reset register
 - Register for output inversion

8.2.1 Terms

In this section, the following terms are used:

- **Pin**

Denotes the physical pin. Every pin is denoted by a unique pin number.

A pin can be used in several modes. The pin name is determined by the selected mode, with a name indicating the pin function.

- **Port group**

Denotes a group of pins. A port control register is provided for pins belonging to the same port group.

- **Port mode / Port**

A pin in port mode works as a general purpose input/output pin. It is then called "port".

The corresponding name is Pn_m. For example, P0_7 denotes port 7 of port group 0. It is referenced as "port P0_7".

- **Alternative mode**

In alternative mode, a pin can be used for in various non-general purpose input/output functions, for example as the input/output pin of on-chip peripherals.

The corresponding pin name depends on the selected function. For example, pin INTP0 denotes the pin for one of the external interrupt inputs.

Note that two or more different names can refer to the same physical pin, for example P0_0 and INTP0. The different names indicate the function in which the pin is being operated.

- **Port type**

The control circuit is determined through specification of the setting register. Control circuits of different types are referred to by their port type.

8.2.2 Overview of pin functions

Pins can function in three modes.

- Port mode (PMn.PMCnm = 0)

In the port mode, pins function as general purpose I/O ports.

Input/output is selected with PMn.PMnm.

- S/W I/O control mode (PMn.PMCnm = 1, PIPn.PIPCnm = 0)

In the S/W I/O control mode, pins are used for the alternative function. Input/output is selected by setting the Mn.PMnm control bit by software.

- Direct I/O control mode (PMn.PMCnm = 1, PIPn.PIPCnm = 1)

In the direct I/O control mode, pins are used for the alternative function.

Unlike the S/W I/O control mode, input/output is directly controlled by the alternative function.

The register settings are outlined in the table below.

Table 8-3 Pin function settings (overview)

Mode	Bit			I/O
	PMn.PMCnm	PMn.PMnm	PIPn.PIPCnm	
Port mode	0	0	X	Output
		1 ^a		Input
S/W I/O control mode	1	0	0	Output
		1	0	Input
Direct I/O control mode		X	1	Control by alternative function

a) Be sure to enable the input buffer (PIBCnm = 1).

When a pin is used in the alternative mode (PMn.PMCnm = 1), one of up to four different alternative functions is selected with the PFCn and PFCEn registers.

- S/W I/O control function (PIPn.PIPCnm = 0):
 - Output (PMnm = 0): ALT-OUT1 to ALT-OUT4
 - Input (PMnm = 1): ALT-IN1 to ALT-IN4
- Direct I/O control function (PIPn.PIPCnm = 1):
 - I/Os of ALT-OUT1 to ALT-OUT4 and ALT-IN1 to ALT-IN4 are directly selected by the alternative function.

Table 8-4 Alternative mode selection (PM_{Cn}.PM_{Cnm} = 1)

Function	Register			I/O
	PM	PFCE	PFC	
Alternative output mode 1 (ALT-OUT1)	0	0	0	Output
Alternative input mode 1 (ALT-OUT1)	1			Input
Alternative output mode 2 (ALT-OUT2)	0	0	1	Output
Alternative input mode 2 (ALT-OUT2)	1			Input
Alternative output mode 3 (ALT-OUT3)	0	1	0	Output
Alternative input mode 3 (ALT-OUT3)	1			Input
Alternative output mode 4 (ALT-OUT4)	0	1	1	Output
Alternative input mode 4 (ALT-OUT4)	1			Input

When a pin is in the alternative mode (PM_{Cn}.PM_{Cnm} = 1), one of up to four different alternative functions is selected with the PFC_n, PFCE_n registers.

8.2.3 Pin data input/output

The registers used for data input/output are described below.

The location that is read via the PPR_n register differs according to the pin mode.

Output data In the port mode (PM_{Cn}.PM_{Cnm} = 0), the value of P_n.P_{nm} is output from the P_{n_m} pin.

Input data In the read operation of the PPR_n register, one of the value of the P_{n_m} pin, value of the port related bit P_n.P_{nm}, or output value from the alternative function is read.

The read source of PPR_n depends on the pin mode and the setting of control bits.

The PPR_n read mode differences are shown in the following table.

Table 8-5 PPRnm read values

PMC nm	PM nm	PIBC nm	PIPC nm	PODC nm	Mode	PPRnm read value
0	1	0	X	X	Port input, input buffer disabled	Pn.Pnm register
		1		X	Port input, input buffer enabled	Pn_m pin
	0	X		0	Port push-pull output	Pn.Pnm register ^a
				1	Port open drain output	
1	1	X	0	X	Input for S/W I/O control	Pn_m pin
				0	Push-pull output for S/W I/O control	Internal output signal for alternative function ^a
				1	Open drain output for S/W I/O control	
	X		1	0	Push-pull output for direct output control	I/O port in alternative function mode: <ul style="list-style-type: none"> • Input: Pn_m pin • Output: Internal output signal for alternative function^a
				1	Open drain output for direct output control	

a) When PBDcnm = 1, the Pn_m pin level is read by the PPRnm register.

Effect of each control bit listed in the above table:

- PMcn.PMCnm

This bit selects the port mode (PMcnm = 0) or the alternative function mode (PMcnm = 1).

- PMn.PMnm

This bit selects input (PMnm = 1) or output (PMnm = 0) in the port mode (PMcnm = 0) and S/W I/O control mode (PMcnm = 1, PIPcnm = 0).

- PIBcn.PIBCnm

This bit disables (PIBCnm = 0) or enables (PIBCnm = 1) the input buffer in the input port mode (PMcnm = 0, PMnm = 1). When the input buffer is disabled, PPRnm reads the Pn.Pnm bit, and when the input buffer is enabled, the level of the Pn_m pin is read.

- PIPcn.PIPCnm

This bit selects the S/W I/O control mode or the direct I/O control mode.

- PODcn.PODcnm

This bit selects push-pull (PODCnm = 0) or open drain (PODCnm = 1) output.

The following pins support 5-V tolerant input/outputs:

- P2_12/TJ_I0/SCL0/RXD0F/TJ_O0
- P2_13/TJ_I1/ADTRG01/SDA0/TJ_O1/TXD0F
- P2_14/TJ_I2/ADTRG11/TJ_O2/CAN0RXD
- P2_15/TJ_I3/ADTRG21/TJ_O3/CAN0TXD

Note, however, that they support 5-V tolerant input only.

They support 5-V tolerant output in the case of N-ch open drain output only.

If a voltage exceeding EV_{DD} is externally applied to a 5-V tolerant supported pin with a pull-up resistor connected, output operation at P-ch side is disabled.

- PBDCn.PBDCnm

When this bit is set to 1, the level of the Pn_m pin is forcibly read. In other words, when the port is in the output mode, the bidirectional mode is enabled, allowing the level of the Pn_m pin to be read.

Caution When using the Pn_m port as the alternative output function (PMcn.PMCnm = 1, PMn.PMnm = 0), the level of the Pn_m pin can be read by PPRn.PPRnm by enabling the bidirectional mode (PBDCn.PBDCnm = 1). However, note that in this case, the level of the Pn_m pin is input to the same alternative input function.

Pn register write In the port mode (PMcn.PMCnm = 0), the data output from the Pn_m port is stored in the Pn register.

The Pn data can be rewritten with two different methods.

- Direct write to Pn register

New data can be written directly to the Pn register.

- Indirect bit manipulation of Pn register (set/reset/not)

Bit manipulation of the Pn register (set/reset/not) can be performed indirectly using two registers.

- Port set/reset register PSRn

When PSRn.PSRn (m+16) = 1, the value of the PSRn.PSRnm bit determines the value of the Pn.Pnm bit.

In other words, the Pnm bit can be set/reset without a direct write to the Pn register.

- Port NOT register PNOTn

When PNOTn.PNOTnm = 1 is set, the Pn.Pnm bit can be inverted without a direct write to the Pn register.

Indirect bit manipulation (set/reset/not) of the Pn register allows rewrite of the bit or bits that need to be updated, without affecting the other bits in the Pn register that do not need updating.

8.2.4 Port control logic diagram

The following figure shows the logic diagram of the port control functions.

Caution The logic shown in this figure is for reference purposes only and does not represent the actual circuit.

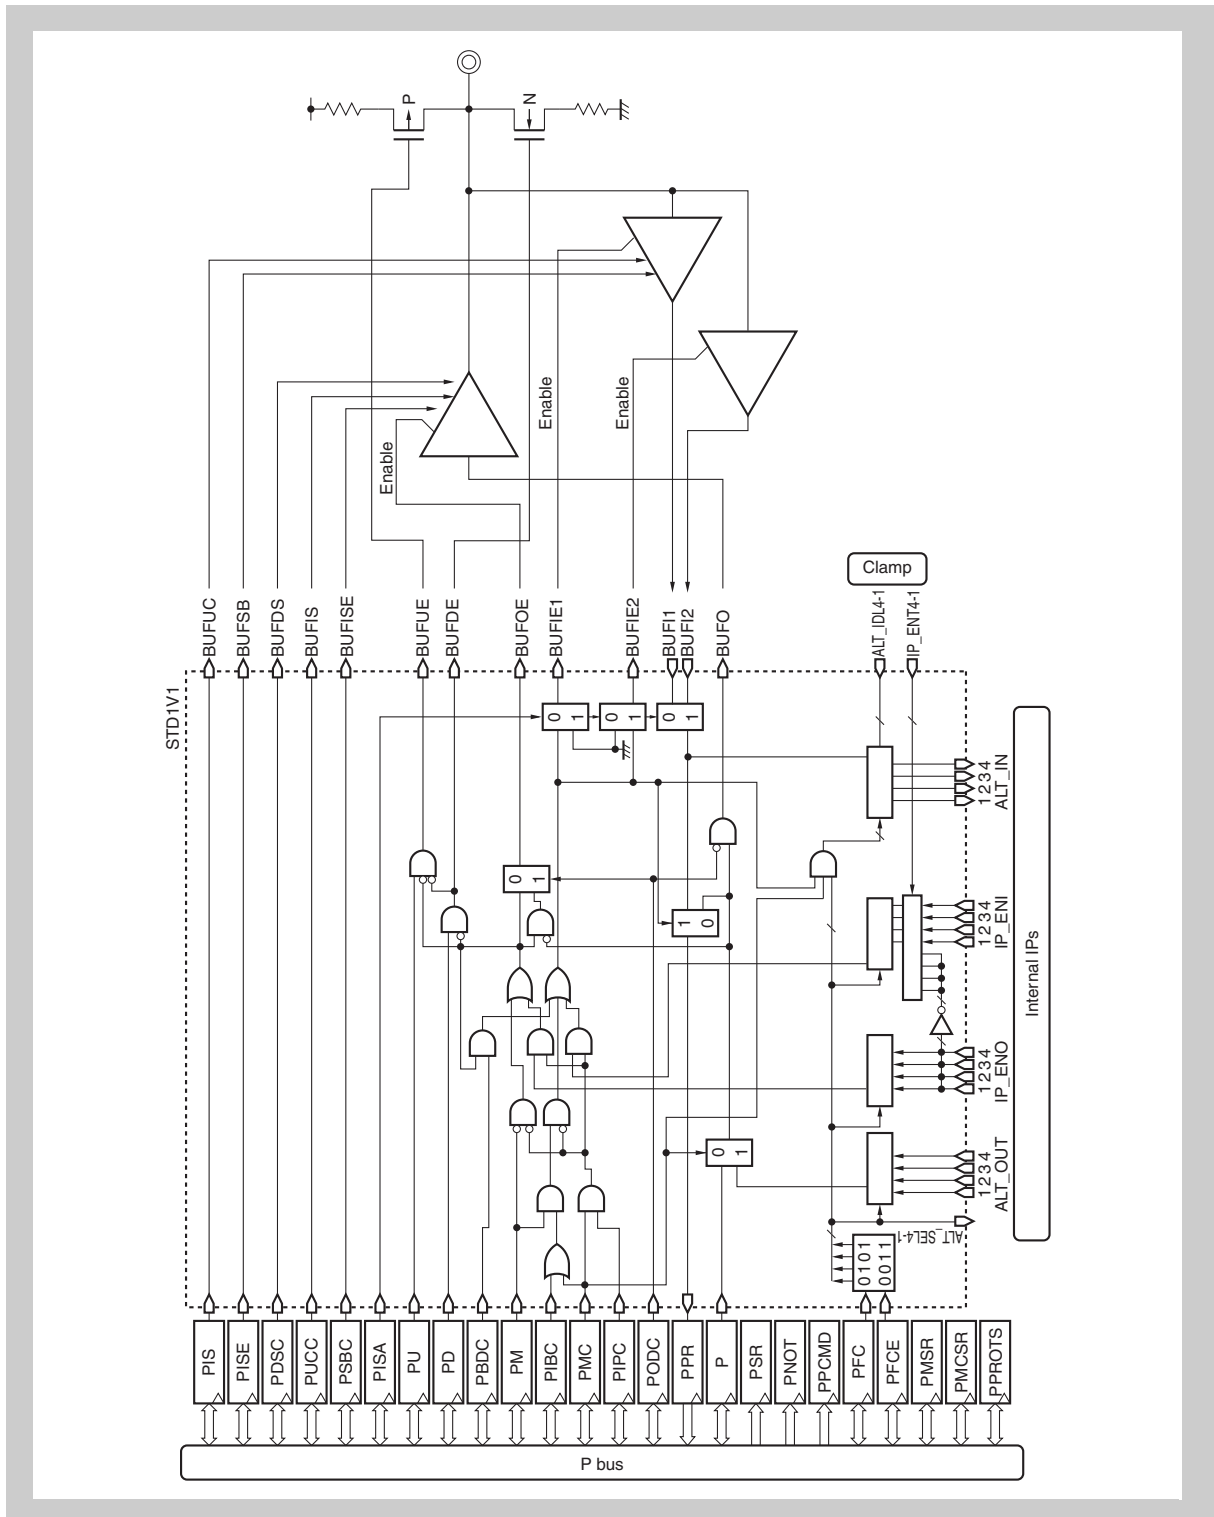

Figure 8-1 Logic diagram of port control

8.2.5 Write protected registers

The write protected registers are protected from accidental write access due to incorrect program execution, etc.

The following port registers have this special write protection function.

- Port drive strength control registers PDSCn
- Port open drain control registers PODCn
- Port universal control registers PUCCn
- Port special buffer control registers PSBCn

(1) Port protection release sequence

Write access to write protected registers is possible only with a special protection release sequence.

1. Write fixed value A5H to protection command register PPCMDn.
2. Write the required value to the protected register.
3. Write the required bit inverted value to the protected register.
4. Write the required value to the protected register.
5. Check that PPROTSn.PPROTSn_0 = 0, and that the required values have been correctly written to the protected register.

8.3 Port Group Configuration Registers

This section starts with an overview of all configuration registers and then presents all registers in detail. The configuration registers are grouped as follows:

- 8.3.2 “Pin function configuration” on page 131
- 8.3.3 “Pin data input/output” on page 138
- 8.3.4 “Configuration of electrical characteristics” on page 142

8.3.1 Overview

The following registers are used for the configuration of the individual pins of the port groups:

Table 8-6 Registers for port group configuration

Register name	Shortcut	Address
Pin function configuration		
Port mode control register	PMCn	<PORTn_base_USER> + 0400 _H + n x 4
Port mode control set/reset register	PMCSR	<PORTn_base_USER> + 0900 _H + n x 4
Port IP control register	PIPCn	<PORTn_base_OS> + 4200 _H + n x 4
Port mode register	PMn	<PORTn_base_USER> + 0300 _H + n x 4
Port mode set/reset register	PMSR	<PORTn_base_USER> + 0800 _H + n x 4
Port input buffer control register	PIBCn	<PORTn_base_OS> + 4000 _H + n x 4
Port function control register	PFCn	<PORTn_base_USER> + 0500 _H + n x 4
Port function control expansion register	PFCEn	<PORTn_base_USER> + 0600 _H + n x 4
Pin data input/output		
Port bi-direction control register	PBDCn	<PORTn_base_OS> + 4100 _H + n x 4
Port pin read register	PPRn	<PORTn_base_USER> + 0200 _H + n x 4
Port register	Pn	<PORTn_base_USER> + 0000 _H + n x 4
Port NOT register	PNOTn	<PORTn_base_USER> + 0700 _H + n x 4
Port set/reset register	PSRn	<PORTn_base_USER> + 0100 _H + n x 4
Configuration of electrical characteristics		
Pull-up option register	PUn	<PORTn_base_OS> + 4300 _H + n x 4
Pull-down option register	PDn	<PORTn_base_OS> + 4400 _H + n x 4
Port universal control register	PUCCn	<PORTn_base_OS> + 4900 _H + n x 4
Port drive strength control register	PDSCn	<PORTn_base_OS> + 4600 _H + n x 4
Port open drain control register	PODCn	<PORTn_base_OS> + 4500 _H + n x 4
Port input buffer selection register	PISn	<PORTn_base_OS> + 4700 _H + n x 4
Port input buffer selection expansion register	PISEn	<PORTn_base_OS> + 4800 _H + n x 4
Port input buffer selection addition register	PISAn	<PORTn_base_OS> + 4A00 _H + n x 4
Port special buffer control register	PSBCn	<PORTn_base_OS> + 4D00 _H + n x 4
Port register protection		
Port register protection command register	PPCMDn	<PORTn_base_OS> + 4C00 _H + n x 4
Port protection status register	PPROTSn	<PORTn_base_OS> + 4B00 _H + n x 4

- <PORTn_base>** The base addresses <PORTn_base_OS> and <PORTn_base_USER> of PORTn are defined in the first section of this chapter under the key word “Register addresses”.
- Initial value of registers** The initial value after reset depends on the port. The initial values are provided in 8.4.3 “V850E2/ML4 port control registers” on page 161, not in the following register descriptions.

8.3.2 Pin function configuration

(1) PMcN - Port mode control register

This register specifies whether the individual pins of port group n are in port mode or in alternative mode.

Access This register can be read/written in 16-bit units.

Address <PORTn_base_USER> + 0400_H + n x 4

Initial Value See 8.4.3 “V850E2/ML4 port control registers” on page 161.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
PMcN15	PMcN14	PMcN13	PMcN12	PMcN11	PMcN10	PMcN9	PMcN8	PMcN7	PMcN6	PMcN5	PMcN4	PMcN3	PMcN2	PMcN1	PMcN0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 8-7 PMcN register contents

Bit position	Bit name	Function
15 to 0	PMc[15:0]	Specifies the operation mode of the corresponding pin: 0: Port mode 1: Alternative mode

(2) PMCSRn - Port mode control set/reset register

This register provides an alternative method for writing data to any bit in the PMCn register.

The upper 16 bits of PMCSRn specify whether to write data to the PMCn.PMCnm bits specified by the lower 16 bits of PMCSRn.

Access This register can be read/written in 32-bit units.
Bits 31 to 16 are always read as 0000_H.
Reading bits 15 to 0 returns the value of PMCn.

Address <PORTn_base_USER> + 0900_H + n x 4

Initial Value See 8.4.3 "V850E2/ML4 port control registers" on page 161.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
PMC SRn31	PMC SRn30	PMC SRn29	PMC SRn28	PMC SRn27	PMC SRn26	PMC SRn25	PMC SRn24	PMC SRn23	PMC SRn22	PMC SRn21	PMC SRn20	PMC SRn19	PMC SRn18	PMC SRn17	PMC SRn16
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
PMC SRn15	PMC SRn14	PMC SRn13	PMC SRn12	PMC SRn11	PMC SRn10	PMC SRn9	PMC SRn8	PMC SRn7	PMC SRn6	PMC SRn5	PMC SRn4	PMC SRn3	PMC SRn2	PMC SRn1	PMC SRn0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 8-8 PMCSRn register contents

Bit position	Bit name	Function
31 to 16	PMC SRn[31:16]	Enable bits that specify whether to write the values of the lower bits of the corresponding PMCSRnm to PMCnm. 0: PMCnm is independent of PMCSRnm. 1: The value of PMCnm is that of PMCSRnm. Example: If PMCSRn.PMCSRn31 = 1, the value of the PMCSRn.PMCSRn15 bit is written to the PMCn.PMCn15 bit.
15 to 0	PMC SRn[15:0]	Data bits that specify the value of PMCnm when the value of PMCSRn (m+16) of the corresponding upper bits is 1. 0: PMCnm = 0 1: PMCnm = 1

(3) PIPcN - Port IP control register

This register specifies whether the I/O direction of the Pn_m pin is controlled by the port mode register PMn.PMnm or the alternative function.

If the Pn_m pin is used in the alternative mode (PMcN.PMCnm = 1), PIPcN.PIPcNm must be set to 1 for the alternative function to control the I/O direction of Pn_m directly.

As a result, the alternative function performs I/O control and the setting of PMn.PMnm is disabled.

Access This register can be read/written in 16-bit units.

Address <PORTn_base_OS> + 4200_H + n x 4

Initial Value See 8.4.3 "V850E2/ML4 port control registers" on page 161.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
PIPcN15	PIPcN14	PIPcN13	PIPcN12	PIPcN11	PIPcN10	PIPcN9	PIPcN8	PIPcN7	PIPcN6	PIPcN5	PIPcN4	PIPcN3	PIPcN2	PIPcN1	PIPcN0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 8-9 PIPcN register contents

Bit position	Bit name	Function
15 to 0	PIPcN[15:0]	Specifies the I/O control mode. 0: The I/O mode is controlled by PMn.PMnm (S/W I/O control). 1: The I/O mode is controlled by the peripheral function (direct I/O control).

(4) PMn - Port mode register

The PMn register specifies whether the individual pins of the port group n are in input mode or in output mode.

Access This register can be read/written in 16-bit units.

Address <PORTn_base_USER> + 0300_H + n x 4

Initial Value See 8.4.3 "V850E2/ML4 port control registers" on page 161.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
PMn15	PMn14	PMn13	PMn12	PMn11	PMn10	PMn9	PMn8	PMn7	PMn6	PMn5	PMn4	PMn3	PMn2	PMn1	PMn0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 8-10 PMn register contents

Bit position	Bit name	Function
15 to 0	PMn[15:0]	Specifies input/output mode of the corresponding pin: 0: Output mode (output enabled) 1: Input mode (output disabled)

- Notes**
1. To use a port in input port mode (PMn.PMnm = 0 and PMn.PMnm = 1), the input buffer must be enabled (PIBCn.PIBCnm = 1).
 2. By default, PMnm specifies the I/O direction in port mode (PMn.PMnm = 0) and alternative mode (PMn.PMnm=1), since PIPCn.PIPCnm = 0 after reset.

(5) PMSRn - Port mode set/reset register

This register provides an alternative method for writing data to any bit in the PMn register.

The upper 16 bits of PMSRn specify whether to write data to the PMn.PMnm bits specified by the lower 16 bits of PMSRn.

Access This register can be read/written in 32-bit units.
Bits 31 to 16 are always read as 0000_H.
Reading bits 15 to 0 returns the value of PMn.

Address <PORTn_base_USER> + 0800_H + n x 4

Initial Value See 8.4.3 "V850E2/ML4 port control registers" on page 161.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
PM SRn31	PM SRn30	PM SRn29	PM SRn28	PM SRn27	PM SRn26	PM SRn25	PM SRn24	PM SRn23	PM SRn22	PM SRn21	PM SRn20	PM SRn19	PM SRn18	PM SRn17	PM SRn16
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 8-11 PMSRn register contents

Bit position	Bit name	Function
31 to 16	PM SRn[31:16]	Enable bits that specify whether to write the values of the lower bits of the corresponding PMSRnm to PMnm. 0: PMnm is independent of PMSRnm. 1: The value of PMnm is that of PMSRnm. Example: If PMSRn.PMSRn31 = 1, the value of the PMSRn.PMSRn15 bit is written to the PMn.PMn15 bit.
15 to 0	PM SRn[15:0]	Data bits that specify the value of PMnm when the value of PMSRn (m+16) of the corresponding upper bits is 1. 0: PMnm = 0 1: PMnm = 1

(6) PIBCn - Port input buffer control register

In input port mode ($PMn.PMCnm = 0$ and $PMn.PMnm = 1$) this register enables/disables the port pin's input buffer.

Access This register can be read/written in 16-bit units.

Address $\langle PORTn_base_OS \rangle + 4000_H + n \times 4$

Initial Value See 8.4.3 "V850E2/ML4 port control registers" on page 161.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
PIBCn	PIBCn	PIBCn	PIBCn	PIBCn	PIBCn	PIBCn	PIBCn	PIBCn	PIBCn	PIBCn	PIBCn	PIBCn	PIBCn	PIBCn	PIBCn
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 8-12 PIBCn register contents

Bit position	Bit name	Function
15 to 0	PIBCn[15:0]	Enables/disables the input buffer: 0: Input buffer disabled 1: Input buffer enabled

Note When the input buffer is disabled, it does not consume current even when the pin level is Hi-Z state. Thus the pin does not need to be fixed to a high or low level externally.

Caution Settings in this register are overruled in bi-directional mode ($PBDCn.PBDCnm = 1$).

(7) PFCn - Port function control register

This register specifies the alternative functions of pins, together with the PFCEn register.

Some alternative functions perform direct I/O control of the Pn_m pin. In the case of such alternative functions, $PIPCn.PIPCnm$ must be set to 1.

For the other alternative functions, I/O is specified by $PMn.PMnm$.

Access This register can be read/written in 16-bit units.

Address $\langle PORTn_base_USER \rangle + 0500_H + n \times 4$

Initial Value See 8.4.3 "V850E2/ML4 port control registers" on page 161.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 8-13 PFCn register contents

Bit position	Bit name	Function
15 to 0	PFCn[15:0]	Specifies the alternative function of a pin. See Table 8-4 "Alternative mode selection ($PMn.PMCnm = 1$)" on page 124 for details.

(8) PFCEn - Port function control expansion register

This register specifies the alternative functions of pins, together with the PFCn register.

Some alternative functions perform direct I/O control of the Pn_m pin. In the case of such alternative functions, PIPCN.PIPCnm must be set to 1.

For the other alternative functions, I/O is specified by PMn.PMnm.

Access This register can be read/written in 16-bit units.

Address <PORTn_base_USER> + 0600_H + n x 4

Initial Value See 8.4.3 "V850E2/ML4 port control registers" on page 161.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Table 8-14 PFCEn register contents

Bit position	Bit name	Function
15 to 0	PFCEn[15:0]	Specifies the alternative function of a pin. See Table 8-4 "Alternative mode selection (PMcn.PMCnm = 1)" on page 124 for details.

8.3.3 Pin data input/output

(1) PBDCn - Port bi-direction control register

This register enables the input buffer and allows the level of the Pn_m pin to be always read via PPRn.PPRnm.

Access This register can be read/written in 16-bit units.

Address <PORTn_base_OS> + 4100_H + n x 4

Initial Value See 8.4.3 “V850E2/ML4 port control registers” on page 161.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
PBDCn	PBDCn	PBDCn	PBDCn	PBDCn	PBDCn	PBDCn	PBDCn	PBDCn	PBDCn	PBDCn	PBDCn	PBDCn	PBDCn	PBDCn	PBDCn
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 8-15 PBDCn register contents

Bit position	Bit name	Function
15 to 0	PBDCn[15:0]	Enables/disables bi-directional mode of the corresponding pin: 0: Bi-directional mode disabled 1: Bi-directional mode enabled

Caution When the Pn_m port is used as an alternative output function (PMcn.PMCnm = 1, PMn.PMnm = 0), the level of the Pn_m pin can be read by PPRn.PPRnm by enabling the bidirectional mode (PBDCn.PBDCnm = 1). However, note that in this case, the level of the Pn_m pin is input to the same alternative input function.

Note When PBDCn = 1 is set, the port mode setting of PMn.PMnm is ignored.

(2) PPRn - Port pin read register

This register indicates the actual Pn_m pin level, Pn.Pnm bit value, or the output level of an alternative function. The value that is read differs according to the control setting, as shown in *Table 8-5 “PPRnm read values” on page 125.*

Access This register is read-only, in 16-bit units.

Address <PORTn_base_USER> + 0200_H + n x 4

Initial Value See 8.4.3 “V850E2/ML4 port control registers” on page 161.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 8-16 PPRn register contents

Bit position	Bit name	Function
15 to 0	PPRn[15:0]	Pn_m pin, Pn.Pnm value, or alternative function output

(3) Pn - Port register

This register specifies or holds the data Pn.Pnm to be output via the related port Pn_m in output port mode (PMcn.PMCnm = 0 and PMn.PMnm = 0).

Access This register can be read/written in 16-bit units.

Address <PORTn_base_USER> + 0000_H + n x 4

Initial Value See 8.4.3 “V850E2/ML4 port control registers” on page 161.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 8-17 Pn register contents

Bit position	Bit name	Function
15 to 0	Pn[15:0]	Sets the output level of pin m (m = 0 to 15): 0: Outputs low level 1: Outputs high level

Note The bits of this register can be manipulated by different means. Refer to 8.2.3 “Pin data input/output” under the keyword “Pn register write”.

(4) PNOTn - Port NOT register

This register allows to invert a bit Pnm of the port register Pn without directly writing to Pn.

Access This register can be read/written in 16-bit units. It is always read as 0000_H.

Address <PORTn_base_USER> + 0700_H + n x 4

Initial Value See 8.4.3 "V850E2/ML4 port control registers" on page 161.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
W	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W

Table 8-18 PNOTn register contents

Bit position	Bit name	Function
15 to 0	PNOTn[15:0]	Specifies if Pn.Pnm is inverted: 0: Pn.Pnm is not inverted ($Pnm \rightarrow Pnm$) 1: Pn.Pnm is inverted ($\overline{Pnm} \rightarrow Pnm$)

(5) PSRn - Port set/reset register

This register provides an alternative method for writing data to any bit in the Pn register.

The upper 16 bits of PSRn specify whether to write data to the Pn.Pnm bits specified by the lower 16 bits of PSRn.

Access This register can be read/written in 32-bit units.
Bits 31 to 16 are always read as 0000_H.
Reading bits 15 to 0 returns the value of Pn.

Address <PORTn_base_USER> + 0100_H + n x 4

Initial Value See 8.4.3 “V850E2/ML4 port control registers” on page 161.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 8-19 PSRn register contents

Bit position	Bit name	Function
31 to 16	PSRn[31:16]	Enable bits that specify whether to write the values of the lower bits of the corresponding PSRnm to Pnm. 0: Pnm is independent of PSRnm. 1: The value of Pnm is that of PSRnm. Example: If PSRn.PSRn31 = 1, the value of bit PSRn.PSRn15 is written to bit Pn.Pn15 and output.
15 to 0	PSRn[15:0]	Data bits that specify the value of Pnm when the value of PSRn (m+16) of the corresponding upper bits is 1. 0: Pnm = 0 1: Pnm = 1

8.3.4 Configuration of electrical characteristics

(1) PUn - Pull-up option register

This register specifies whether to connect an internal pull-up resistor to an input pin.

Access This register can be read/written in 16-bit units.

Address <PORTn_base_OS> + 4300_H + n x 4

Initial Value See 8.4.3 “V850E2/ML4 port control registers” on page 161.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
PUn15	PUn14	PUn13	PUn12	PUn11	PUn10	PUn9	PUn8	PUn7	PUn6	PUn5	PUn4	PUn3	PUn2	PUn1	PUn0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 8-20 PUn register contents

Bit position	Bit name	Function
15 to 0	PUn[15:0]	Specifies whether to connect an internal pull-up resistor to the corresponding pin: 0: No internal pull-up resistor connected 1: An internal pull-up resistor connected

- Notes**
1. If a pin is configured that both an internal pull-up resistor (PUn.PUnm = 1) and pull-down resistor (PDn.PDnm = 1) are connected, the pull-down resistor is automatically selected and the pull-up resistor is not connected.
 2. The internal pull-up resistor has no effect when the pin is operated in output mode.

(2) PDn - Pull-down option register

This register specifies whether to connect an internal pull-down resistor to an input pin.

Access This register can be read/written in 16-bit units.

Address <PORTn_base_OS> + 4400_H + n x 4

Initial Value See 8.4.3 “V850E2/ML4 port control registers” on page 161.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 8-21 PDn register contents

Bit position	Bit name	Function
15 to 0	PDn[15:0]	Specifies whether to connect an internal pull-down resistor to the corresponding pin: 0: No internal pull-down resistor connected 1: An internal pull-down resistor connected

- Notes**
1. If a pin is configured that both an internal pull-up resistor (PUn.PUnm = 1) and pull-down resistor (PDn.PDnm = 1) are connected, the pull-down resistor is automatically selected and the pull-up resistor is not connected.
 2. The internal pull-down resistor has no effect when the pin is operated in output mode.

(3) PDSCn - Port drive strength control register

This register specifies the output driver strength of the port pin. This function is also related to the fast mode (high drive strength) and slow mode (low drive strength) of the output buffer.

This register is one of the OS registers of SPF.

Access This register can be read/written in 32-bit units.

The correct write sequence using the PPCMD register is required in order to update this register.

Address <PORTn_base_OS> + 4600_H + n x 4

Initial Value See 8.4.3 "V850E2/ML4 port control registers" on page 161.

Caution The upper 16 bits are also inverted through a sequence for writing to a protected port register. For details, see 8.3.5 "Port register protection".

Table 8-22 PDSCn register contents

Bit position	Bit name	Function
15 to 0	PDSCn[15:0]	<p>Specifies the port drive strength of the output buffer of the port pin.</p> <p>0: Low drive strength (slow mode) 1: High drive strength (fast mode)</p> <p>Note To use this register together with an I/O buffer that can control the output current limit, specify the current limiting function.</p> <p>0: Current limiting function enabled 1: Current limiting function disabled</p>

(4) PUCn - Port universal control register

This register expands the function for specifying output buffer characteristics.

This register can specify up to 4 output buffer characteristics, together with port drive strength control register PDSCn.

This register is one of the OS registers of SPF.

Access This register can be read/written in 32-bit units.

The correct write sequence using the PPCMD register is required in order to update this register.

Address <PORTn_base_OS> + 4900_H + n x 4

Initial Value See 8.4.3 "V850E2/ML4 port control registers" on page 161.

Caution The upper 16 bits are also inverted through a sequence for writing to a protected port register. For details, see 8.3.5 "Port register protection".

0	1	Selection 2															
1	0	Selection 3															
1	1	Selection 4															

(5) PODCn - Port open drain control register

This register selects push-pull or open-drain as output buffer function.

Access This register can be read/written in 32-bit units.

Writing to this register is protected by a special sequence of instructions. See 8.3.5 "Port register protection" on page 150 for details.

Address <PORTn_base_OS> + 4500_H + n x 4

Initial Value See 8.4.3 "V850E2/ML4 port control registers" on page 161.

- Cautions**
- The upper 16 bits are also inverted through a sequence for writing to a protected port register. For details, see 8.3.5 "Port register protection".
 - The following pins support 5-V tolerant input/outputs:
 - P2_12/TJ_I0/SCL0/RXD0F/TJ_O0
 - P2_13/TJ_I1/ADTRG01/SDA0/TJ_O1/TXD0F
 - P2_14/TJ_I2/ADTRG11/TJ_O2/CAN0RXD
 - P2_15/TJ_I3/ADTRG21/TJ_O3/CAN0TXD
- Note, however, that they support 5-V tolerant input only.
They support 5-V tolerant output in the case of N-ch open drain output only.
If a voltage exceeding EV_{DD} is externally applied to a 5-V tolerant supported pin with a pull-up resistor connected, output operation at P-ch side is disabled.

Table 8-24 PODCn register contents

Bit position	Bit name	Function
15 to 0	PODCn[15:0]	Specifies the output buffer function: 0: Push-pull 1: Open-drain

(6) PISn - Port input buffer selection register

This register specifies the input buffer characteristics.

If a port has up to four input buffer characteristics, the port input buffer selection expansion register PISEn is also valid.

If a port has up to five input buffer characteristics, the port input buffer selection expansion register PISEn and the port input buffer selection addition register PISAn are also valid.

Access This register can be read/written in 16-bit units.

Address <PORTn_base_OS> + 4700_H + n x 4

Initial Value See 8.4.3 “V850E2/ML4 port control registers” on page 161.

Bit position	Bit name	Function
15 to 0	PISn[15:0]	Specifies the input buffer characteristic: 0: Type 1 1: Type 2

Note The definition of type 1 and type 2 is given in 8.4.1 “Input circuit types of port input pins and alternate-function input pins” on page 156. Refer also to the Electrical Target Specification for input buffer characteristics details.

(7) PISEn - Port input buffer selection expansion register

This register specifies the input buffer characteristics, together with the port input buffer selection register PISn.

If a port has up to five input buffer characteristics, the port input buffer selection addition register PISAn is also valid.

Access This register can be read/written in 16-bit units.

Address <PORTn_base_OS> + 4800_H + n x 4

Initial Value See 8.4.3 "V850E2/ML4 port control registers" on page 161.

(8) PISAn - Port input buffer selection addition register

This register specifies the input buffer characteristics, together with the port input buffer selection register PISn and the port input buffer selection expansion register PISEn.

Access This register can be read/written in 16-bit units.

Address <PORTn_base_OS> + 4A00_H + n x 4

Initial Value See 8.4.3 “V850E2/ML4 port control registers” on page 161.

	1	1	Type 4																				
1	X	X	Type 5																				

Note The definition of type 1 to type 5 is given in 8.4.1 “Input circuit types of port input pins and alternate-function input pins” on page 156. Refer also to the Electrical Target Specification for detailed input buffer characteristics.

(9) PSBCn - Port special buffer control register

This microcontroller may be equipped with I/O buffers with dedicated properties for special functions. This register specifies whether the individual pins of port group n are general purpose I/O pins or if they are special I/O pins.

Access This register can be read/written in 32-bit units.

Writing to this register is protected by a special sequence of instructions. See 8.3.5 “Port register protection” on page 150 for details.

Address <PORTn_base_OS> + 4D00_H + n x 4

Initial Value See 8.4.3 “V850E2/ML4 port control registers” on page 161.

Caution The upper 16 bits are also inverted through a sequence for writing to a protected port register. For details, see 8.3.5 “Port register protection”.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 8-28 PSBCn register contents

Bit position	Bit name	Function
15 to 0	PSBC[15:0]	Specifies the I/O mode: 0: General purpose I/O 1: Special I/O

Note For details about the ports that have the special buffers of the V850E2/ML4, see *Port group* in 8.2 “Overview”.

8.3.5 Port register protection

(1) PPCMDn - Port register protection command register

This register is the command register for port registers that are protected.

Access This register can be written in 8-bit units.

“0” is always read for bits 7 to 0.

Address <PORTn_base_OS> + 4C00_H + n x 4

Initial Value 00_H. This register is initialized by any reset.

7	6	5	4	3	2	1	0
0	0	0	0	0	0	0	0
W	W	W	W	W	W	W	W

Table 8-29 PPCMDn register contents

Bit position	Bit name	Function
7 to 0	–	Command allowing write to port register that are protected

(2) PPROTSn - Port protection status register

This register indicates the status of the write sequence for the port registers that are protected.

Access This register can be read in 8-bit units.

Write operation to this register is ignored.

Address <PORTn_base_OS> + 4B00_H + n x 4

Initial Value 00_H. This register is initialized by any reset.

7	6	5	4	3	2	1	0
0	0	0	0	0	0	0	PPROTSn_0
R	R	R	R	R	R	R	R

Table 8-30 PPROTSn register contents

Bit position	Bit name	Function
0	PPROTSn_0	Checks for the occurrence of write sequence errors in the port registers that are protected. 0: No protection error 1: Protection error occurred

(3) Protected port registers

PDSCn - Port drive strength control register

PUCn - Port universal control register

PODCn - Port open drain control register

PSBCn - Port special buffer control register

(4) Write sequence of protected port register

Figure 8-2 Write sequence of protected port register

- Step 1** Write A5H to the PPCMD register to initialize the write sequence.
- Step 2** Write data in 32-bit nits to the protected register (the register is not updated).
- Step 3** Write the inverted data in 32-bit units to the same protected register (the register is not updated).
- Step 4** Again write data in 32-bit units to the same protected register (update is successful).

8.3.6 Example port settings

Examples of the port settings are shown in the flowchart below.

Caution If the port has been set to alternative output mode by setting PIPn.PIPCnm to 0, the port might briefly enter alternative input mode. This will occur between when the PMn.PMnm bit is set to 1 and when the PMn.PMnm bit is set to 0. If an interrupt-related signal is specified as an alternate function of a port, the mode becomes the alternative input mode temporarily, and the interrupt either does not occur or is ignored in port mode.

(1) Batch setting

An example of specifying batch port settings is shown in the flowchart below.

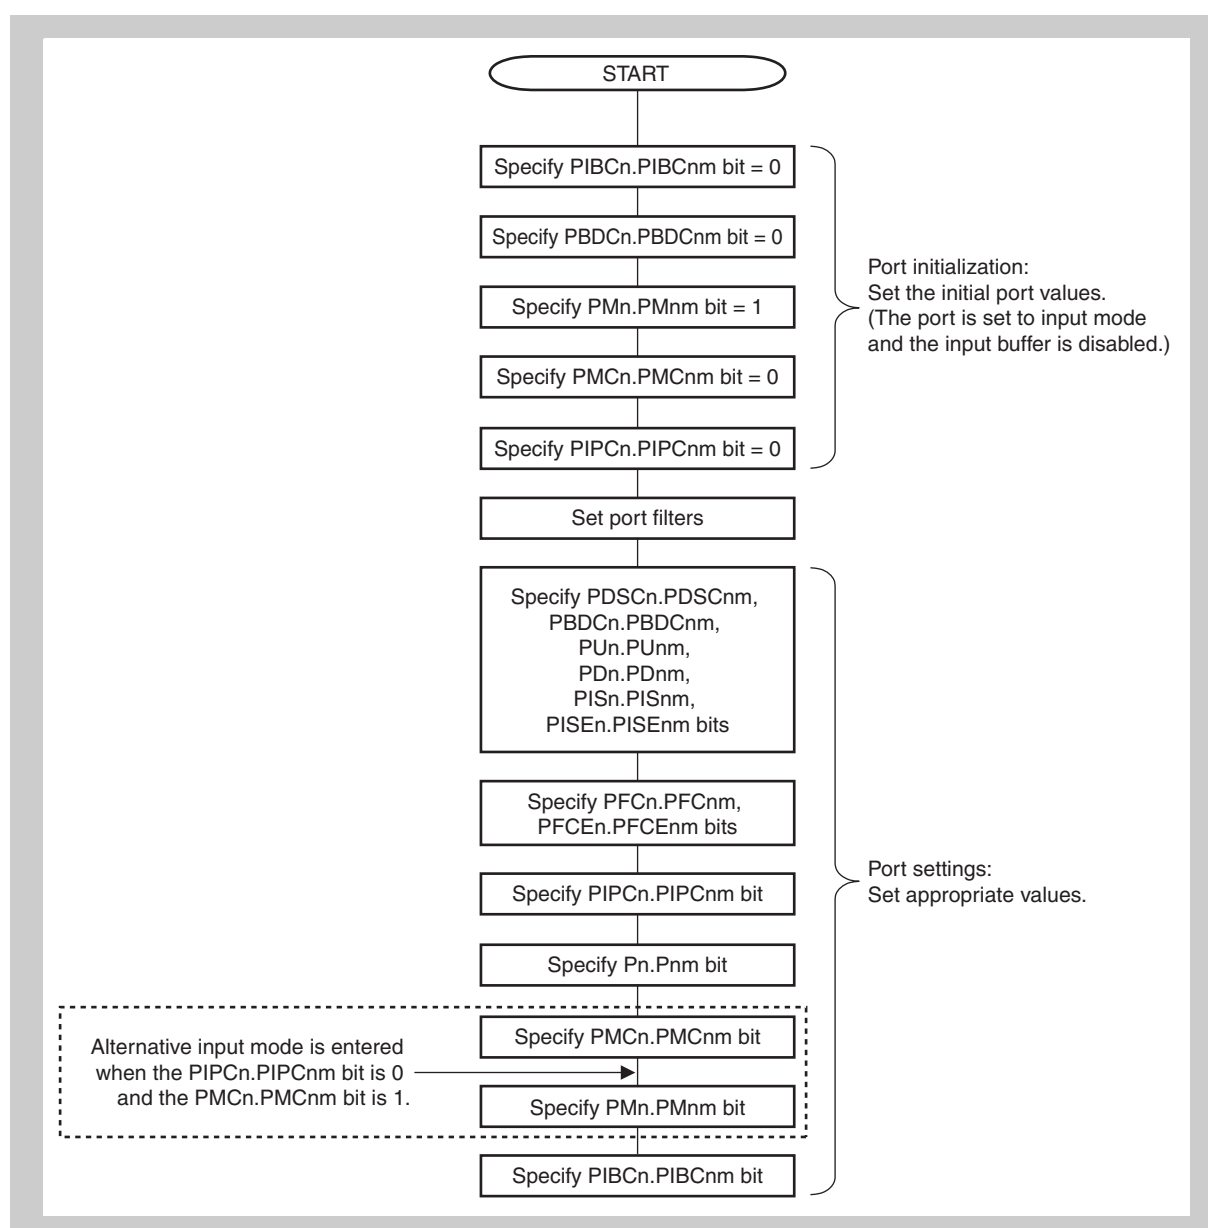

Figure 8-3 Example of port settings (when specified in batch)

(2) Individual settings

An example of specifying individual port settings is shown in the flowchart below

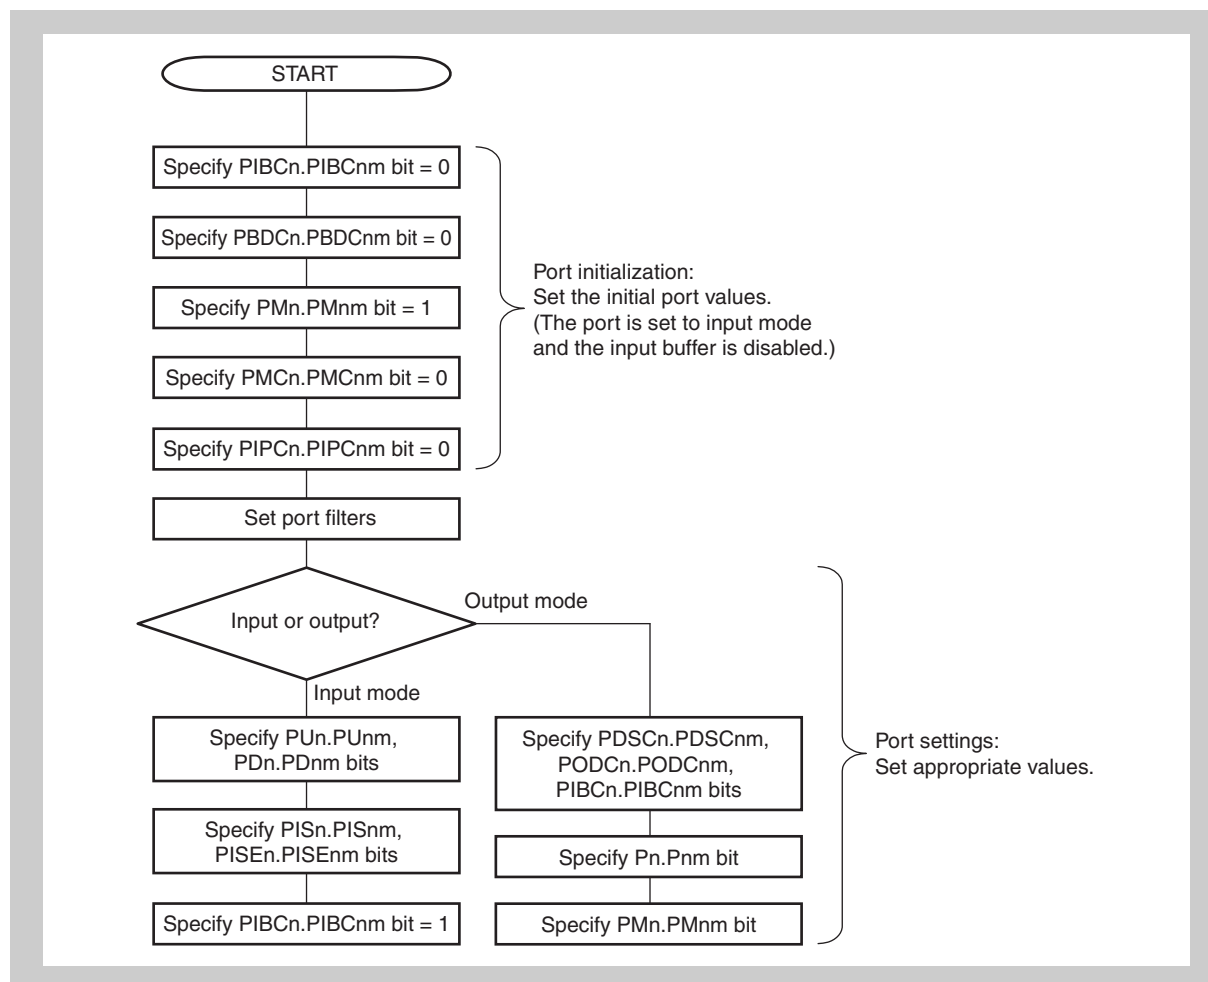

Figure 8-4 Example of port settings (in port mode)

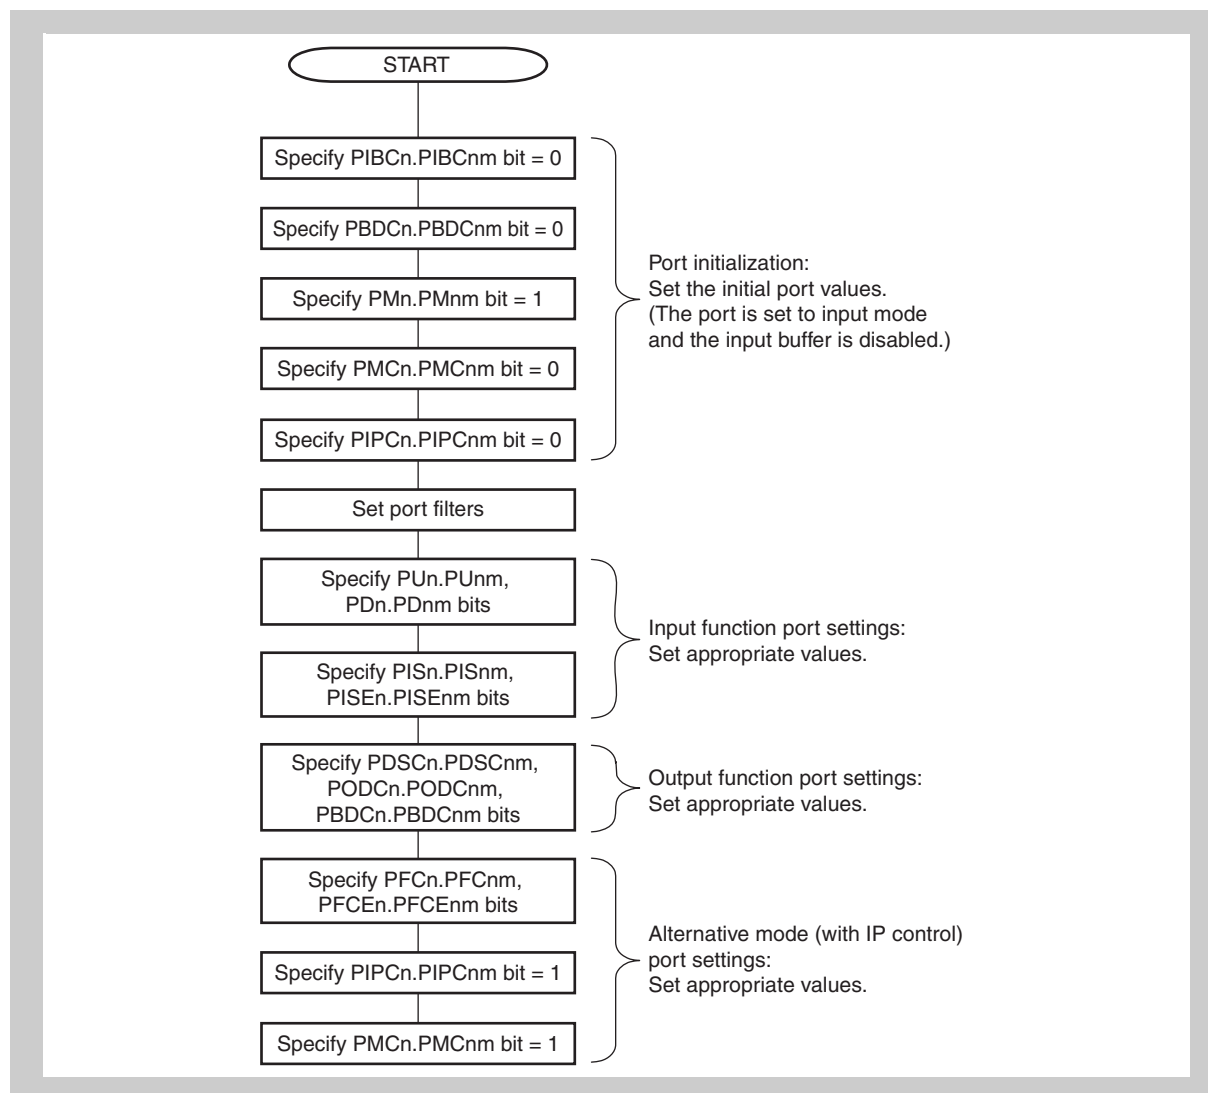

Figure 8-5 Example of port settings (in alternative mode, with IP control)

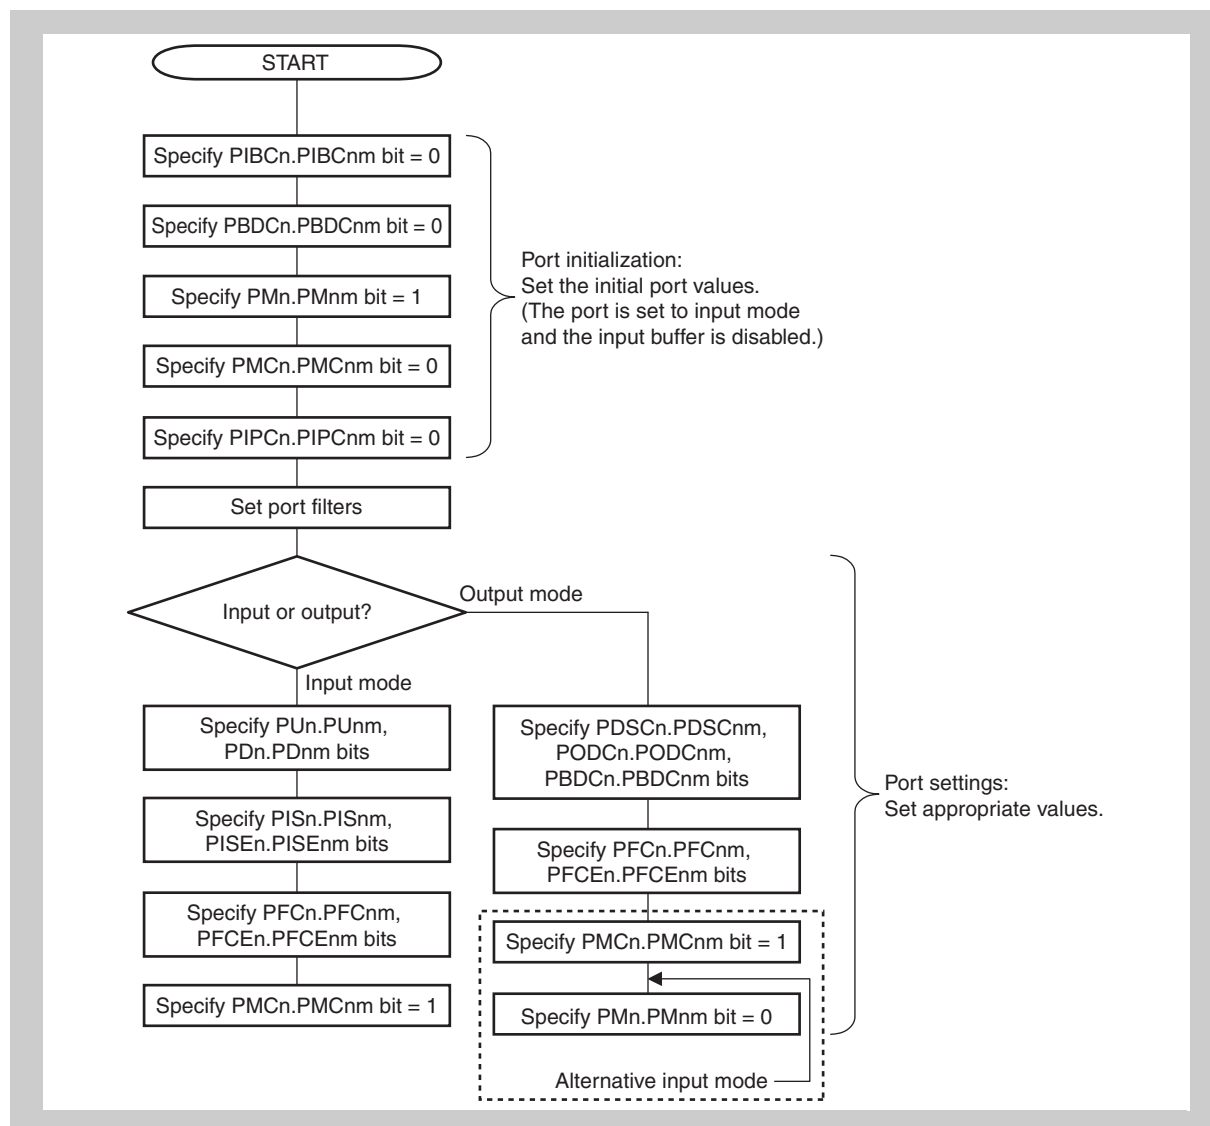

Figure 8-6 Example of port settings (in alternative mode, without IP control)

8.4 V850E2/ML4 Port Functions

This section describes port functions, alternative functions, and port control registers for the V850E2/ML4.

8.4.1 Input circuit types of port input pins and alternate-function input pins

The input circuit type is determined by the settings of the port function control registers PIS, PISE, and PISA, as follows:

Table 8-31 Input circuit types of port input pins and alternate-function input pins

PIS _n m	PISE _n m	PISA _n m	Input circuit type
0	0	0	CMOS
1	0	0	Schmitt 2
0	1	0	Schmitt 1
×	×	1	LVTTL
The settings other than the above are prohibited.			

For details about how to set each pin, see *Table 8-37 "Register setting for each pin function"*.

8.4.2 General I/O function

Table 8-32 "List of port pins and alternative functions for port groups 0 to 7" shows the port functions and alternative functions of the V850E2/ML4.

Various modes can be specified by changing the values of the PMC_n_m, PFC_n_m, PFCEn_m, and PMn_m bits.

Table 8-32 List of port pins and alternative functions for port groups 0 to 7 (1/5)

Port mode	Alternative mode							
	PMC _n _m = 1

8.4.3 V850E2/ML4 port control registers

Table 8-34 “V850E2/ML4 port control registers for groups 0 to 3” through Table 8-36 “V850E2/ML4 port control registers for group 8” list the registers for controlling the V850E2/ML4 ports, as well as their address and initial value. When writing to an invalid bit (indicated as “X”), always write the initial value.

Conventions A: Register address

I: Initial value

B: Valid or invalid

– 1: Valid, X: Invalid, -: Not supported

Right: bit 0 Left: bit 15

8.4.4 V850E2/ML4 port control register settings

Table 8-37 “Register setting for each pin function” shows the setting of each register for alternative functions of the pins.

When using each function, be sure to specify the corresponding bits of the control register by referring to this table.

Be sure to specify “0” for bits indicated by “0”, and “1” for bits indicated by “1”.

Specify “0” or “1” as necessary for bits indicated by “1/0”.

When it is necessary to write a value to a bit that is indicated by “N/A”, be sure to specify the initial value. Do not access bits indicated by “-” because no function is assigned for these bits in the corresponding register.

Pins that have an I/O function are divided into pins that require the settings for input and output and pins that require the setting for either input or output.

For pins that require the settings for input and output, the registers that have the specified setting for input and output must be set up with the appropriate value.

For pins that require the settings for input or output, specify the register setting according to the function used.

Table 8-37 Register setting for each pin function (1/41)

- The settings for input and output must be specified. For registers that have the specified setting for input or output, specify the appropriate value.
- Specify the setting for input or output according to the function to use.
- Be sure to turn on the A/D converter by setting the ADCA0CTL1.ADCA0GPS, even if this pin is used for port input.

8.5 Port Filters

The input signals at some pins are passed through a filter to remove noise and glitches. The microcontroller supports both analog and digital filters.

The first section provides an overview, which port input signals are equipped with which kind of filter, their control registers an bits and the register addresses.

A detailed description of the analog and digital filter functions and their control registers follow.

8.5.1 Analog and digital filter assignments

Table 8-38 “Input signals that have analog filters and their control registers” lists the input signals that are equipped with an analog filter and their control registers.

Table 8-39 “Input signals that have digital filters and their control registers 1” and *Table 8-40 “Input signals that have digital filters and their control registers 2”* list the input signals that are equipped with a digital filter and their control registers.

Table 8-41 “Input signals that have analog/digital common noise filters and their control registers” lists the input signals that are equipped with an analog/digital common noise filter.

a) The noise filter functions as a digital filter when DNFA_nEN.DNFA_nNFEN_m = 1, or as an analog filter when DNFA_nEN.DNFA_nNFEN_m = 0.

8.5.2 Functional Description

Two types of filters are used to generate two kinds of signals, according to the purpose of the input signal.

Event output Event output signals are used to transmit an external event. The waveform of the input signal after passing through a filter is not retained as the signal to be transmitted internally, because level and edge detection are performed on the signals after they pass through the filter. An external interrupt is a typical example of an event signal.

Alternative function Alternative function signals are used to input an input signal to an alternative function block. When an input signal passes through a filter, noise and spikes are eliminated. The waveform of the internal signal after passing through a filter is retained as the signal to be transmitted internally. A timer signal input to measure the frequency is a typical example of an alternative function signal.

(1) Analog filters

The block diagram of the analog filters is shown in the diagram below.

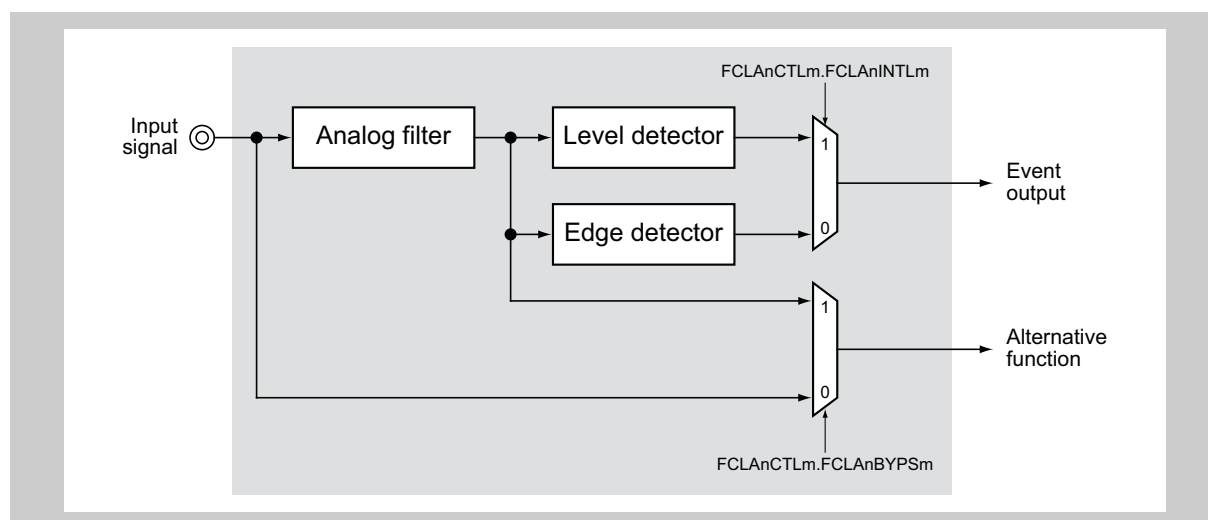

Figure 8-7 Analog filter block diagram

(a) Event signals

When an input signal passes through an analog filter, noise and spikes are eliminated. After passing through an analog filter, the level or edge of the signal is used to judge whether an event has occurred, and an event output signal is generated if an event is detected.

The detection mode is selected by the control bit FCLAnCTLm.FCLAnINTLm:

- FCLAnINTLm = 0: edge detection mode
The detection of a rising or falling edge can be activated separately by FCLAnCTLm.FCLAnINTRm and FCLAnCTLm.FCLAnINTFm respectively.
- FCLAnINTLm = 1: level detection mode
The detection of a high level or low level can be selected by FCLAnCTLm.FCLAnINTRm.

The table below summarizes the detection conditions of the analog filter.

Table 8-42 Analog filter event detection conditions

FCLAnINTLm	FCLAnINTFm	FCLAnINTRm	Edge detection	Level detection
0	0	0	no detection	not active
	0	1	rising edge	
	1	0	falling edge	
	1	1	both edges	
1	X	0	not active	low level
		1		high level

(b) Signals for alternative functions

The input signal is passed through an analog filter to eliminate noise and spikes.

Bypass In case the alternative function requires the original signal at its input, the analog filter can be bypassed by setting FCLAnCTLm.FCLAnBYPSm = 1.

Wake-up Analog filtered alternative function signals have wake-up capability. That means, an input signal can wake-up the microcontroller from stand-by modes, even if the clock supply is stopped.

Note that edge and level detection are not operable, if the clock is stopped in stand-by. Thus the event output signals can not issue a wake-up.

(c) Analog filter characteristic

The characteristics of the analog filter as well as of the level and edge detectors are specified in the Electrical Target Specification document.

(d) Analog filters control registers

For each input signal, that is equipped with an analog filter, a dedicated control register FCLAnCTL_m is provided.

The registers are ordered in groups of 8 registers with the same index *n*. The register index *m* ranges from 0 to 7:

FCLA group *n*: FCLAnCTL0 to FCLAnCTL7

The assignment of the input signals to the control registers and their addresses is given in Table 8-38 “Input signals that have analog filters and their control registers” in 8.5.1 “Analog and digital filter assignments”.

(2) Digital filters

The block diagram of the analog filters is shown in the diagram below.

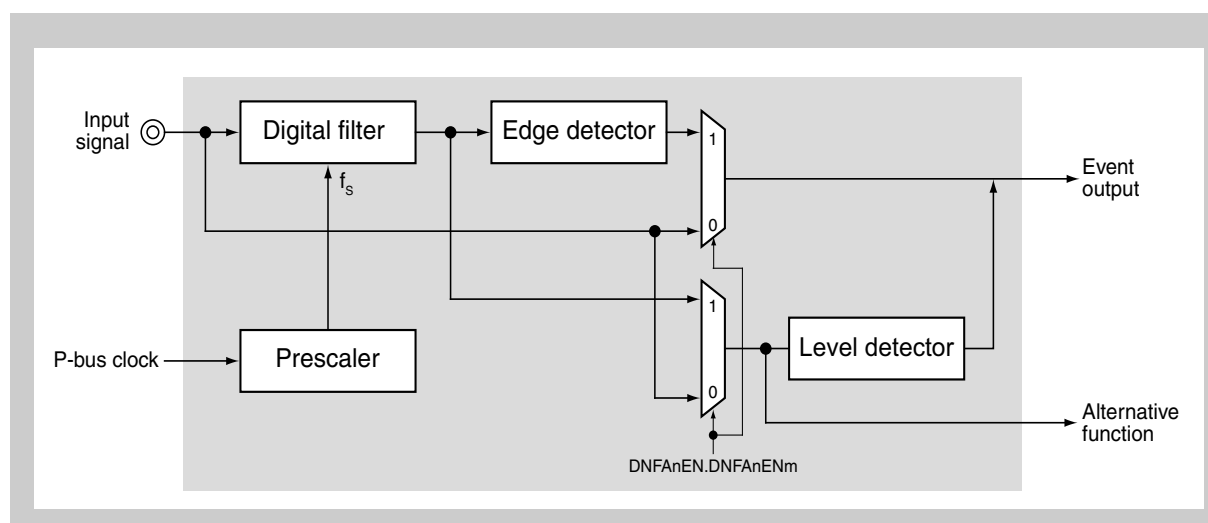

Figure 8-8 Digital filter block diagram

(a) Digital filter function

The input signal is sampled at the sampling frequency f_s .

If the level of the input signal remains unchanged for the specified number of samples, the signal level is judged to be valid, and the output signal changes accordingly.

If the level of the input signal changes before the specified number of samples have been obtained, the input signal is judged to be noise or a spike, and the output signal does not change.

Caution If noise occurs during sampling, the noise is sampled. Therefore, if noise is input during sampling and its level remains unchanged for the specified number of samples, the output signal changes to the level of the noise.

The pulse length used to judge whether an input signal is noise depends on the sampling frequency and the specified number of samples.

Either of the following parameters can be specified:

- Use DNFA_nCTL.DNFA_nPRS[2:0] to select the sampling frequency, using the following expression:

$$f_s = f_{PCLK} / 2^{DNFA_nPRS[1:0]}$$
 where f_{PCLK} is the frequency of the P-busclock.
 (Refer to "Clock Controller" on page xx for details about the P-bus clock.)
- Use DNFA_nCTL.DNFA_nNFSTS[1:0] to specify the number of samples (from 2 to 5).

External signal pulses shorter than the following are always suppressed:

$$(\text{Number of samples} - 1) \times 1/f_s$$

External signal pulses longer than the following are always judged to be valid and passed to the filter output:

$$(\text{Number of samples}) \times 1/f_s$$

External signal pulses within the range below are sometimes suppressed, and sometimes judged to be valid:

$$(\text{Number of samples} - 1) \times 1/f_s \text{ to } (\text{Number of samples}) \times 1/f_s$$

The filter operation is illustrated in the figure below with DNFA_nNFSTS[1:0] = 01_B (3 samples).

Figure 8-9 Digital filter function

Digital filter groups Input signals with digital filters are ordered in groups of up to 16 signals. The digital filter characteristics, specified by DNFA_nCTL.DNFA_nPRS[2:0] and DNFA_nCTL.DNFA_nNFSTS[1:0], apply to the filters of the entire group. However the digital filter for each signal can be enabled and disabled separately by using DNFA_nEN.DNFA_nNFEN_m.

- Cautions**
1. To input the output signal of the digital filter to the alternative function pin, enable the digital filter by setting DNFAEN.DNAFnENm, and then switch the port pin to the alternative function pin after the lapse of time below:

$$\text{DNFAnNFSTS}[1:0] \times 1/f_s + 4 \times 1/f_{\text{PCLK}}$$

2. To use the event output signal of the digital filter as an interrupt, enable the digital filter in the interrupt prohibit state by setting DNFAEN.DNAFnENm. Next, after the lapse of time below following the enabling of the digital filter, clear the interrupt request flag and then enable interrupts.

$$\text{DNFAnNFSTS}[1:0] \times 1/f_s + 5 \times 1/f_{\text{PCLK}}$$

(b) Event signals

The input signal is passed through a digital filter to eliminate noise and spikes. After passing through a digital filter, the level of the signal is used to judge whether an event has occurred, and an event output signal is generated if an event is detected.

The edge detection can be configured to detect a rising or falling edge separately by the control bits FCLAnCTLm.FCLAnINTRm and FCLAnCTLm.FCLAnINTFm respectively.

The table below summarizes the detection conditions of the digital filter.

Table 8-43 Digital filter event detection conditions

FCLAnINTFm	FCLAnINTRm	Edge detection
0	0	no detection
0	1	rising edge
1	0	falling edge
1	1	both edges

(c) Signals for alternative functions

The input signal is passed through the digital filter to eliminate noise and spikes.

Bypass All digital filter functions can be completely disabled by setting DNFAEN.DNFAFnENm = 0. In this case the input signal is output as an event output and to the alternative function.

Note Since digital noise elimination requires the clock supply the P-bus clock to operate, digitally filtered signals can not serve as a wake-up event, if the P-bus clock is stopped during the stand-by mode.

(d) Digital filters control registers

The digital noise elimination control register DNFA_nCTL and digital noise elimination enable register DNFA_nEN are provided for each group of up to 16 digital filters to enable all filters to be set up in a group (n = group number).

While the filter settings specified by the DNFA_nCTL register apply to the entire corresponding group, the control bit DNFA_nNFEN_m in the DNFA_nEN register enables and disables each filter separately. The register index m is in a range from 0 to 15:

The edge detection setup is done via the filter control register FCLAnCTL_m.

The FCLAnCTL_m registers are ordered in groups of 8 registers with the same index n. The register index m is in the range from 0 to 7:

The assignment of the input signals to the control registers and their addresses is given in *Table 8-39 "Input signals that have digital filters and their control registers 1"* and *Table 8-40 "Input signals that have digital filters and their control registers 2"* in 8.5.1 "Analog and digital filter assignments".

Caution Do not change any control register settings, while the concerned digital filter filter is enabled by setting DNFA_nEN.DNFA_nNFEN_m to 1. Otherwise an unintended filter output may be generated.

(3) Filter control registers

The analog and digital filters are controlled and operated by the following registers:

Table 8-44 Filter registers overview

Register Name	Shortcut	Address
Filter control register m	FCLAnCTL _m	The addresses are given in the tables in 8.5.1 "Analog and digital filter assignments".
Digital noise elimination control register	DNFA _n CTL	
Digital noise elimination enable register	DNFA _n EN	

(a) FCLAnCTLm – Filter control register

This register controls the analog and digital filter operation.

Since the control options for analog and digital filters are partly different, the register description for both is given separately.

Access This register can be read/written in 8-bit or 1-bit units.

Address The assignment of the input signals to the FCLAnCTLm registers and their addresses is given in the tables in 8.5.1 “Analog and digital filter assignments” on page 208.

Initial Value 00_H. This register is initialized by any reset.

Control for analog filters For analog filters, FCLAnCTLm provides the following control options:

7	6	5	4	3	2	1	0
FCLAn BYPSm	0	0	0	0	FCLAn INTLm	FCLAn INTFm	FCLAn INTRm
R/W	R	R	R	R	R/W	R/W	R/W

Table 8-45 FCLAnCTLm register contents for analog filters

Bit position	Bit name	Function
7	FCLAn BYPSm	Filter bypass control for alternative function 0: filter bypass disabled 1: filter bypass enabled
2	FCLAn INTLm	Level/edge detection mode selection 0: edge detection mode 1: level detection mode
1	FCLAn INTFm	<ul style="list-style-type: none"> In level detection mode (FCLAnINTLm = 1): FCLAnINTFm has no effect In edge detection mode (FCLAnINTLm = 0): falling edge detection control 0: falling edge detection disabled 1: falling edge detection enabled
0	FCLAn INTRm	<ul style="list-style-type: none"> In level detection mode (FCLAnINTLm = 1): detection level selection 0: low level detection 1: high level detection In edge detection mode (FCLAnINTLm = 0): rising edge detection control 0: rising edge detection disabled 1: rising edge detection enabled

Control for digital filters For digital filters FCLAnCTLM provides the following control options:

7	6	5	4	3	2	1	0
0 ^a	0	0	0	0	FCLAn INTLm	FCLAn INTFm	FCLAn INTRm
R	R	R	R	R	R	R/W	R/W

a) The default value “0” of these bits must not be changed.

- Cautions**
1. The default value “0” of bits 7 and 2 must not be changed.
 2. When using an input pin that has a digital filter, be sure to enable digital noise elimination by using the DNFAEn register. If digital noise elimination is not enabled, the operation is not guaranteed.

Table 8-46 FCLAnCTLM register contents for digital filters

Bit position	Bit name	Function
2	FCLAn INTLm	Level/edge detection mode selection 0: edge detection mode 1: level detection mode
1	FCLAn INTFm	Falling edge detection control 0: falling edge detection disabled 1: falling edge detection enabled
0	FCLAn INTRm	Rising edge detection control 0: rising edge detection disabled 1: rising edge detection enabled

Depending on a channel, some bits of the FCLAnCTLM register can be used as usual while the others must be set to their initial value. *Table 8-47 “Usable bits of the FCLAnCTLM register”* shows the details:

Table 8-47 Usable bits of the FCLAnCTLM register (1/2)

Signal	Bit position	7	6	5	4	3	2	1	0

ESO3	FCLA16CTL3	0	0	0	0	0	0	0/1	0/1

Caution Specify a value as required for bits indicated by *0/1*. Be sure to clear the bits indicated by *0* in the table.

(b) DNFACTL – Digital noise elimination control register

This register specifies the filter characteristics of the digital noise elimination filter.

Access This register can be read/written in 8-bit units.

Address The assignment of the input signals to the DNFACTL registers and their addresses is given in Table 8-39 “Input signals that have digital filters and their control registers 1” and Table 8-40 “Input signals that have digital filters and their control registers 2” in 8.5.1 “Analog and digital filter assignments”.

Initial Value 00_H. This register is initialized by any reset.

(c) DNFA_nEN – Digital noise elimination enable register

This register enables and disables digital noise elimination for a certain input signal.

Access This register can be read/written in 16-bit units.
To read or write this register in 8-bit or 1-bit units, access DNFA_nENH[7:0] and DNFA_nENL[7:0], which are mirror bits of the higher byte DNFA_nNFEN[15:8] and lower byte DNFA_nNFEN[7:0], respectively.

Address The assignment of the input signals to DNFA_nEN registers and their addresses is given in the table “Input signals with digital filters” in the previous section “Analog and digital filter assignments”.

Initial Value 0000_H. This register is initialized by any reset.

15	14	13	12	11	10	9	8
DNFA _n NFEN15	DNFA _n NFEN14	DNFA _n NFEN13	DNFA _n NFEN12	DNFA _n NFEN11	DNFA _n NFEN10	DNFA _n NFEN9	DNFA _n NFEN8

DNFA14EN	0	0	0	0	0	0	0	0	0	1	1	1	1	1	1	1

- Cautions**
1. Specify a value as required for bits indicated by 0/1.
 2. Be sure to set the bits indicated by 1 in the table.
 3. Bits indicated by 0 in the table are fixed to 0 by hardware. Even if such a bit is set, therefore, it is ignored.

Chapter 9 Interrupt Functions

9.1 Features

The phenomenon of forcing a branch operation from a currently running program to another program, due to a specific cause, is called an exception. This microcontroller supports the following types of exceptions.

For details about interrupt functions, see the *V850E2 Architecture User's Manual*.

Table 9-1 Exception cause list

Exception name	Symbol	Cause group	Priority group	Exception level
CPU initialization	RESET	Reset input	P1	–
FE level non-maskable interrupt	FENMI	FENMI input	P2	FE
System error exception	SYSERR	SYSERR input (4 causes)	P3	FE
Peripheral device protection exception	PPI	Peripheral device protection violation	P4	FE
Timing monitoring exception	TSI	Timing monitoring violation	P5	FE
FE level maskable interrupt	FEINT	FEINT input	P6	FE
Floating-point operation exception (imprecise)	FPI	FPU instruction	P7	EI
EI level maskable interrupt	EIINT	Maskable interrupt input	P8	EI
Execution protection exception	MIP	Execution protection violation	P9	FE
Memory error exception	MEP	Instruction access error input	P10	FE
Data protection exception	MDP	Data protection violation	P11	FE
Floating-point operation exception (precise)	FPP	FPU instruction		EI
Coprocessor unusable exception	UCPOP	Coprocessor instruction		FE
Reserved instruction exception	RIEX	Reserved instruction		FE
FE level software exception	FETRAPEX	FETRAP instruction (vector = 1 _H to F _H)		FE
EI level software exception	EITRAP0	TRAP0n instruction (vector = 00 _H to 0F _H)		EI
EI level software exception	EITRAP1	TRAP1n instruction (vector = 10 _H to 1F _H)		EI
System call exception	SYSALLEX	SYSCALL instruction (vector = 00 _H to FF _H)		EI

- Priority order** Priority group P1 has the highest, P11 the lowest priority.
- Interrupts** The following three types of exceptions in *Table 9-1 “Exception cause list”* are called interrupts.
- FE level non-maskable interrupt (FENMI)
 - FENMI is served immediately, even if another FE level interrupt - FENMI or FEINT - is in service (CPU system register PSW.NP = 1).
 - Resume disabled, recover disabled (for error report)
 - FE level maskable interrupt (FEINT)
 - FEINT is served immediately, if no other FE level interrupt - FENMI or FEINT - is in service (CPU system register PSW.NP = 0). Thus PSW.NP = 1 would mask an FEINT.
 - Resume enabled, recover enabled
 - Highest priority interrupt (except FENMI)
 - EI level maskable interrupt (EIINT)
 - EIINT may only be served, if no FE level interrupt - FENMI or FEINT - is in service (CPU system register PSW.NP = 0).
 - Resume enabled, recover enabled
 - Interrupt masking can be specified by each interrupt channel
 - 16 interrupt priority levels can be specified for each interrupt channel.
 - This chapter describes EIINT corresponding to interrupt channel n into EIINT_n.
- Resume:** Indicates whether execution restart from the last position at which program execution was interrupted is possible.
- Recover:** Indicates whether recovery to the processor status (status of processor resources including general-purpose registers and system registers) at the time of program execution interruption is possible.

The following table shows the number of valid interrupts in the V850E2/ML4.

Table 9-2 Number of valid interrupts

Interrupt cause	V850E2/ML4
FE level non-maskable interrupt (FENMI)	1 (including one external interrupt)
FE level non-maskable interrupt (FEINT)	1
EI level non-maskable interrupt (EIINT)	149

These interrupt causes are described below.

9.2 Interrupt Causes

9.2.1 FE level non-maskable interrupts

Priority group The FE level non-maskable interrupts have the priority P2.

Return PC An FE non-maskable interrupt does not allow to resume or recover.

Control register FE level NMI control register

See 9.3.8 “FNC: FE level NMI control register”.

Return instruction The return instruction from FE level non-maskable interrupt service routines is FERET.

Table 9-3 FE level non-maskable interrupt requests

Interrupt			Interrupt request		Unit	Priority group	Exception case code	Handler address 0000...
Symbol	Control register		Name	Cause				
	Name	Address FFFF...						
FENMI	FNC	645C _H	WDTA0NMI	Watchdog Timer 0 error NMI interrupt	WDTA0	P2	00020 _H	0020 _H

9.2.2 FE level maskable interrupts

Priority group The FE level maskable interrupts have the priority P6.

Return PC The program counter (PC) value, set after returning from any interrupt service routine by the RETI instruction is always the next address.

Control register FE level maskable interrupt control register

See 9.3.9 “FIC: FE level INT control register”.

Return instruction The return instruction from FE level maskable interrupt service routines is FERET.

Table 9-4 FE level maskable interrupt requests

Interrupt			Interrupt request		Unit	Priority group	Exception cause code	Handler address 0000...
Symbol	Control register		Name	Cause				
	Name	Address FFFF...						
FEINT	FIC	645E _H	NMI0	NMI	Pin	P6	00001 _H	0010 _H

9.2.3 EI level maskable interrupts

Interrupt naming The composition of the interrupt request signal names, their assigned interrupt control registers and the bits in these registers follow special rules.

In the following the name of the interrupt request is represented by *<name>*.

- Interrupt request name: **INT<name>**
The prefix “**INT**” is put in front of *<name>*.
- Interrupt request control register: **IC<name>**
The prefix “**IC**” is put in front of *<name>*.
The 16 bit of the 16-bit register **IC<name>** can also be accessed byte-wise with the following names:
 - low byte (bits[7:0]): **IC<name>L** at the address of **IC<name>**
The suffix “**L**” is appended to the register name **IC<name>**.
 - high byte (bits[15:8]): **IC<name>H** at the address of **IC<name>** + 1
The suffix “**H**” is appended to the register name **IC<name>**.
- Interrupt control register bit names: **RF<name>**, **MK<name>**, **P3<name>**, **P2<name>**, **P1<name>**, **P0<name>**
The bit prefix “**RF**”, “**MK**”, “**P3**”, “**P2**”, “**P1**”, “**P0**” is appended to the interrupt *<name>*.
- Each interrupt request is assigned to a certain interrupt channel number *n* = 0 to 255.
The functional description of the Interrupt Controller in this chapter refers to general names of the interrupt requests and their control registers.
If **INT<name>** is assigned to the interrupt channel number *n*, throughout this chapter
 - the interrupt request is named **EIINT_n**
 - the assigned interrupt control register is named **EIC_n**
 - the interrupt control bits are named **EIRF_n**, **EIMK_n**, **EIP3_n**, **EIP2_n**, **EIP1_n**, **EIP0_n**.

Example The interrupt request of the second TAUA0 channel (*<name>* = *TAUA0I2*) is named

INTTAUA0I2

The related interrupt control registers are

ICTAUA0I2, **ICTAUA0I2L**, **ICTAUA0I2H**

The bits in this register are

RFTAUA0I2, **MKTAUA0I2**, **P3TAUA0I2**, **P2TAUA0I2**,
P1TAUA0I2, **P0TAUA0I2**

The interrupt channel for **INTTAUA0I2** is *n* = 53. Thus in the functional description of the Interrupt Controller this interrupt is referred to as

EIINT53,

the related control register as

EIC53,

and their control register bit names

EIRF53, **EIMK53**, **EIP353**, **EIP253**, **EIP153**, **EIP053**.

The following tables list the references between the interrupt channel number *n*, the assigned V850E2/ML4 interrupt requests and control register names.

Priority group The EI level maskable interrupts have the priority P8.

Return PC The program counter (PC) value, set after returning from any interrupt service routine by the EIRET instruction is always the next address.

Control register FE level maskable interrupt control register

Return instruction EIRET instruction

Table 9-5 EI level maskable interrupt requests (1/8)

9.3 Interrupt Controller Control Registers

9.3.1 EICn (n = 0 to 255): EI level interrupt control registers

These registers, each of which is for a channel of EI level maskable interrupt (EIINT), are used to set a condition to control each channel. The values of bits 15 to 13, bits 11 to 8, and bits 6 to 4 are always 0.

Update the EICn register by a byte write access or a halfword access.

Access This register can be read/written in 16-bit or 8-bit units.

Address FFFF 6000_H + n × 02_H

Initial Value 008F_H. This register is initialized by any reset.

Caution Do not access EICn registers of interrupt channels, not listed in the above interrupt request tables.

15	14	13	12	11	10	9	8
0	0	0	EIRFn	0	0	0	0
R	R	R	R/W	R	R	R	R
7	6	5	4	3	2	1	0
EIMKn	0	0	0	EIP3n	EIP2n	EIP1n	EIP0n
R/W	R	R	R	R/W	R/W	R/W	R/W

Table 9-6 EICn register contents

Bit position	Bit name	Function
12	EIRFn	Interrupt request flag The EIRFn bit can be written from a program. Setting the EIRFn bit (1) generates an EI level maskable interrupt (EIINTn), just as when an interrupt request is acknowledged. 0: No interrupt request (initial value) 1: Interrupt request Caution If setting an EI level interrupt, be sure to clear the EIRFn flag last.
7	EIMKn	Interrupt mask bit. When the EIMKn bit is set, the interrupt request set to the interrupt request flag (EIRFn) is masked, so that the interrupt request is not issued from that channel to the CPU core. From a channel with the EIMKn bit set, interrupt pending status is not displayed by the ICSR.PMF bit. The EIMKn bit does not mask a signal input from an interrupt input pin itself and, therefore, the corresponding interrupt request flag is set even when the EIMKn bit is set. The setting of the corresponding bit of the interrupt mask register (IMR) is also reflected. 0: Enables interrupt servicing. 1: Disables interrupt servicing (initial value).
3:0	EIP3n to EIP0n	These bits specify 16 levels of interrupt priorities. The highest priority is 0 and the lowest is 15. If two or more interrupt requests of EI level are generated at the same time, the interrupt source having the higher priority specified by these bits is selected and reported to the CPU core. If the priority specified by the EIP3n to EIP0n bits is the same, the source having the lower channel number is selected by a fixed priority.

9.3.2 IMRm (m = 0 to 15): EI level interrupt mask registers

These registers are a collection of the EIMKn bits of the EICn register. Each bit of the IMRm register reflects the setting of the corresponding EIMKn bit. Setting the IMRm register reflects on the corresponding EIMKn bit.

Access When this register is accessed in 16-bit, 8-bit, or 1-bit units, the upper 8 bits [15:8] and lower 8 bits [7:0] correspond to the IMRmH and IMRmL registers, respectively.

Address

IMR0: FFFF 6400 _H	IMR1: FFFF 6402 _H
IMR2: FFFF 6404 _H	IMR3: FFFF 6406 _H
IMR4: FFFF 6408 _H	IMR5: FFFF 640A _H
IMR6: FFFF 640C _H	IMR7: FFFF 640E _H
IMR8: FFFF 6410 _H	IMR9: FFFF 6412 _H
IMR10: FFFF 6414 _H	IMR11: FFFF 6416 _H
IMR12: FFFF 6418 _H	IMR13: FFFF 641A _H
IMR14: FFFF 641C _H	IMR15: FFFF 641E _H

Initial Value FFFF_H. This register is initialized by any reset.

Caution Be sure to set the EIMKn bit corresponding to interrupt channels not listed in the above interrupt request tables to 1.

15	14	13	12	11	10	9	8
EIMK m×16+15	EIMK m×16+14	EIMK m×16+13	EIMK m×16+12	EIMK m×16+11	EIMK m×16+10	EIMK m×16+9	EIMK m×16+8

R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 9-7 IMRm register contents

Bit position	Bit name	Function
15:0	EIMK15 to EIMK0	These bits mask an interrupt from channels 0 to 15 of EI level maskable interrupt (EIINT). 0: Enables interrupt servicing. 1: Disables interrupt servicing.

9.3.3 ISPR: In-service priority register

This register holds the interrupt priority of EI level maskable interrupt (EIINT) that is being processed by the CPU core. When a response of acknowledging an interrupt request is received from the CPU core, the bit of this register corresponding to the priority of that interrupt request is set. When it is reported by the CPU core that interrupt servicing has been completed, the bit of this register having the highest priority of those that are set is automatically cleared. The bit of this register is not cleared if execution has returned from an FE level interrupt. If multiple interrupts of EI level maskable interrupt (EIINT) are generated, the bits of this register corresponding to the priorities of the interrupts that have been acknowledged are sequentially set, and the history of the priorities of the multiple interrupts is held.

After 1 has been simultaneously written in 16-bit units to the ISPC register, all the bits of the ISPR register can be cleared by writing 0 to the 16 bits of the ISPR register at the same time. Each bit of this register cannot be cleared or set by software. Once one of the bits has been cleared, it is impossible to restore its original value.

Access This register is read-only, in 16-bit or 8-bit units. When this register is accessed in 8-bit units, the upper 8 bits [15:8] and lower 8 bits [7:0] correspond to the ISPRH and ISPRL registers, respectively.

Address FFFF 6440_H

Initial Value 0000_H. This register is initialized by any reset.

15	14	13	12	11	10	9	8
ISPR15	ISPR14	ISPR13	ISPR12	ISPR11	ISPR10	ISPR9	ISPR8
R	R	R	R	R	R	R	R
7	6	5	4	3	2	1	0
ISPR7	ISPR6	ISPR5	ISPR4	ISPR3	ISPR2	ISPR1	ISPR0
R	R	R	R	R	R	R	R

Table 9-8 ISPR register contents

Bit position	Bit name	Function
15:0	ISPR15 to ISPR0	These bits indicate the priority of the interrupt being acknowledged. 0: Interrupt request of the priority corresponding to a specified bit position is not acknowledged. 1: Interrupt request of the priority corresponding to a specified bit position is being processed by the CPU core.

9.3.4 PMR: Priority mask register

This register specifies an interrupt priority by which an interrupt request flag of EI level maskable interrupt (EIINT) is to be masked. It disables all at once the interrupt requests from the EIINT channel for which the interrupt priority specified by this register is set.

The position of each bit of this register corresponds to an interrupt priority. For example, if 1 is set to bit 0, channel of interrupt priority 0 can be masked.

Access This register can be read/written in 16-bit, 8-bit, or 1-bit units. When this register is accessed in 8-bit or 1-bit units, the upper 8 bits [15:8] and lower 8 bits [7:0] correspond to the PMRH and PMRL registers, respectively.

Address FFFF 6448_H

Initial Value 0000_H. This register is initialized by any reset.

15	14	13	12	11	10	9	8
PMR15	PMR14	PMR13	PMR12	PMR11	PMR10	PMR9	PMR8
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
7	6	5	4	3	2	1	0
PMR7	PMR6	PMR5	PMR4	PMR3	PMR2	PMR1	PMR0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 9-9 PMR register contents

Bit position	Bit name	Function
15:0	PMR15 to PMR0	These bits specify an interrupt priority by which an interrupt request flag. 0: Enables interrupt servicing of the priority corresponding to a specified bit position (initial value). 1: Disables interrupt servicing of the priority corresponding to a specified bit position.

9.3.5 ISPC: In-service priority clear register

When 1 is written to all the bits of this ISPC register and then 0 is written to all the bits of the ISPR register, all the bits of the ISPR register can be cleared to 0. At the same time, all the processing modes of FE level NMI, FE level maskable interrupt (FEINT), and EI level maskable interrupt (EIINT) of the ICSR register are canceled. As a result, the internal mode registers of INTC for interrupt servicing, which indicate that an interrupt request is being processed by the CPU core, are cleared. The contents of these registers that once have been cleared cannot be restored by software.

When the ISPR register is cleared by writing 0 to all the bits of the ISPR register, the value of the ISPC register is also automatically cleared to 0. The value that is to be read from all the bits of this register when the register is read is 1 if 1 has been written to all the bits, or 0 after reset or after the ISPR register has been cleared. The value of the bits of this register does not change even if the register is written when all its bits are not 1 or 0 at the same time. If 0 is written to all the bits while they are 1, the value of all the bits of the ISPC register is cleared to 0, and the value of the ISPR register does not change.

Access This register can be read/written only in 16-bit units.

Address FFFF 6450_H

Initial Value 0000_H. This register is initialized by any reset.

Table 9-10 ISPC register contents

Bit position	Bit name	Function
15:0	ISPC15 to ISPC0	1 or 0 is read from all these bits. ISPR can be cleared if 0 is written to all the bits of ISPR when 1 is read from all the bits of this register.

9.3.6 SCR: Selected channel hold register

This register holds the channel number of the EI level maskable interrupt (EIINT) acknowledged by the CPU. It is read-only in 16-bit or 8-bit units, and cannot be written by software. The value of this register is updated when an interrupt vector is reported to the CPU core. Note that this register is overwritten when multiple interrupt requests of EI level INT are acknowledged. This register is not updated when an interrupt request of FE level is acknowledged.

Access This register is read-only, in 16-bit or 8-bit units. When this register is accessed in 8-bit units, the upper 8 bits [15:8] and lower 8 bits [7:0] correspond to the SCRH and SCRL registers, respectively.

Address FFFF 6458_H

Initial Value 0000_H. This register is initialized by any reset.

15	14	13	12	11	10	9	8
0	0	0	0	0	0	0	0
R	R	R	R	R	R	R	R
7	6	5	4	3	2	1	0
SCR7	SCR6	SCR5	SCR4	SCR3	SCR2	SCR1	SCR0
R	R	R	R	R	R	R	R

Table 9-11 SCR register contents

Bit position	Bit name	Function
7:0	SCR7 to SCR0	Holds the channel number of the maskable interrupt that has been acknowledged by the CPU. The value of these bits is updated when an interrupt vector is reported to the CPU core. It is overwritten when multiple interrupts of EI level maskable interrupt (EIINT) are acknowledged. These bits are not updated when an FE level interrupt is acknowledged. Nothing happens if this register is accessed for write.

9.3.7 ICSR: Interrupt controller status register

This register indicates the operation status of the interrupt controller. Especially, bits 2 to 0 of this register serve as a mode register of interrupt servicing.

Access This register is read-only, in 16-bit, 8-bit, or 1-bit units. When this register is accessed in 8-bit or 1-bit units, the upper 8 bits [15:8] and lower 8 bits [7:0] correspond to the ICSRH and ICSRL registers, respectively.

Address FFFF 645A_H

Initial Value 0000_H. This register is initialized by any reset.

15	14	13	12	11	10	9	8
0	0	0	0	0	0	0	PMF

R	R	R	R	R	R	R	R

Table 9-12 ICSR register contents

Bit position	Bit name	Function
8	PMF	Indicates 1 if the request flag of a channel of EI level INT that has the interrupt priority prohibited by the setting of PMR from being serviced is set.
6	FNR	Indicates 1 if an FE level non-maskable interrupt (FENMI) has been issued to the CPU.
5	FIR	Indicates 1 if an FE level maskable interrupt (FEINT) has been issued to the CPU.
4	EIR	Indicates 1 if an EI level maskable interrupt (EIINT) has been issued to the CPU.
2	FNE	Indicates 1 if an CPU is processing the FE level non-maskable interrupt (FENMI).
1	FIE	Indicates 1 if an CPU is processing the FE level maskable interrupt (FEINT).
0	EIE	Indicates 1 if an CPU is processing the EI level maskable interrupt (EIINT).

9.3.8 FNC: FE level NMI control register

This register is used to set a condition to control the FE level non-maskable interrupt (FENMI).

Access This register is read-only, in 16-bit, 8-bit, or 1-bit units. When this register is accessed in 8-bit or 1-bit units, the upper 8 bits [15:8] correspond to the FNCH register.

Address FFFF 645C_H

Initial Value 0000_H. This register is initialized by any reset.

9.4 Interrupt Acknowledgment and Restoring

This section describes the operation during interrupt acknowledgment and restoring from interrupt servicing.

9.4.1 FE level non-maskable interrupt caused by FENMI interrupt request

When an FENMI interrupt is requested, an FE level non-maskable interrupt is generated in CPU. This FE level non-maskable interrupt is used when a fatal system error occurs.

Caution Upon acknowledgment of the FENMI interrupt, generation of the next FENMI, FEINT, or EIINT interrupt is pended until the FERET instruction is executed (interrupt request is acknowledged and held.) FENMI can be acknowledged even when the NP bit is set to 1. Therefore, if the FENMI interrupt occurs during the processing of an FEINT exception, PPI exception, or other FE level exceptions, the save address is lost and cannot be restored. After a FENMI interrupt is requested and the required processing has been completed, execute a system reset, etc. Return to the original processing is not possible.

Figure 9-1 Processing upon occurrence of FENMI interrupt request

9.4.2 Restore from FE level non-maskable interrupt (FENMI)

An FE level non-maskable interrupt (FENMI) cannot be restored since it is an interrupt used in cases such as when a fatal system error occurs.

Execute a system reset after exception processing.

9.4.3 FE level maskable interrupt caused by FEINT interrupt request

When an FEINT interrupt is requested by the FEINT pin, an FE level maskable interrupt is generated. This interrupt is a recoverable FE level interrupt.

Upon acknowledgment of the FEINT interrupt, generation of the next FEINT or EIINT interrupt is pended until the FERET instruction is executed. Interrupt request is acknowledged and held.

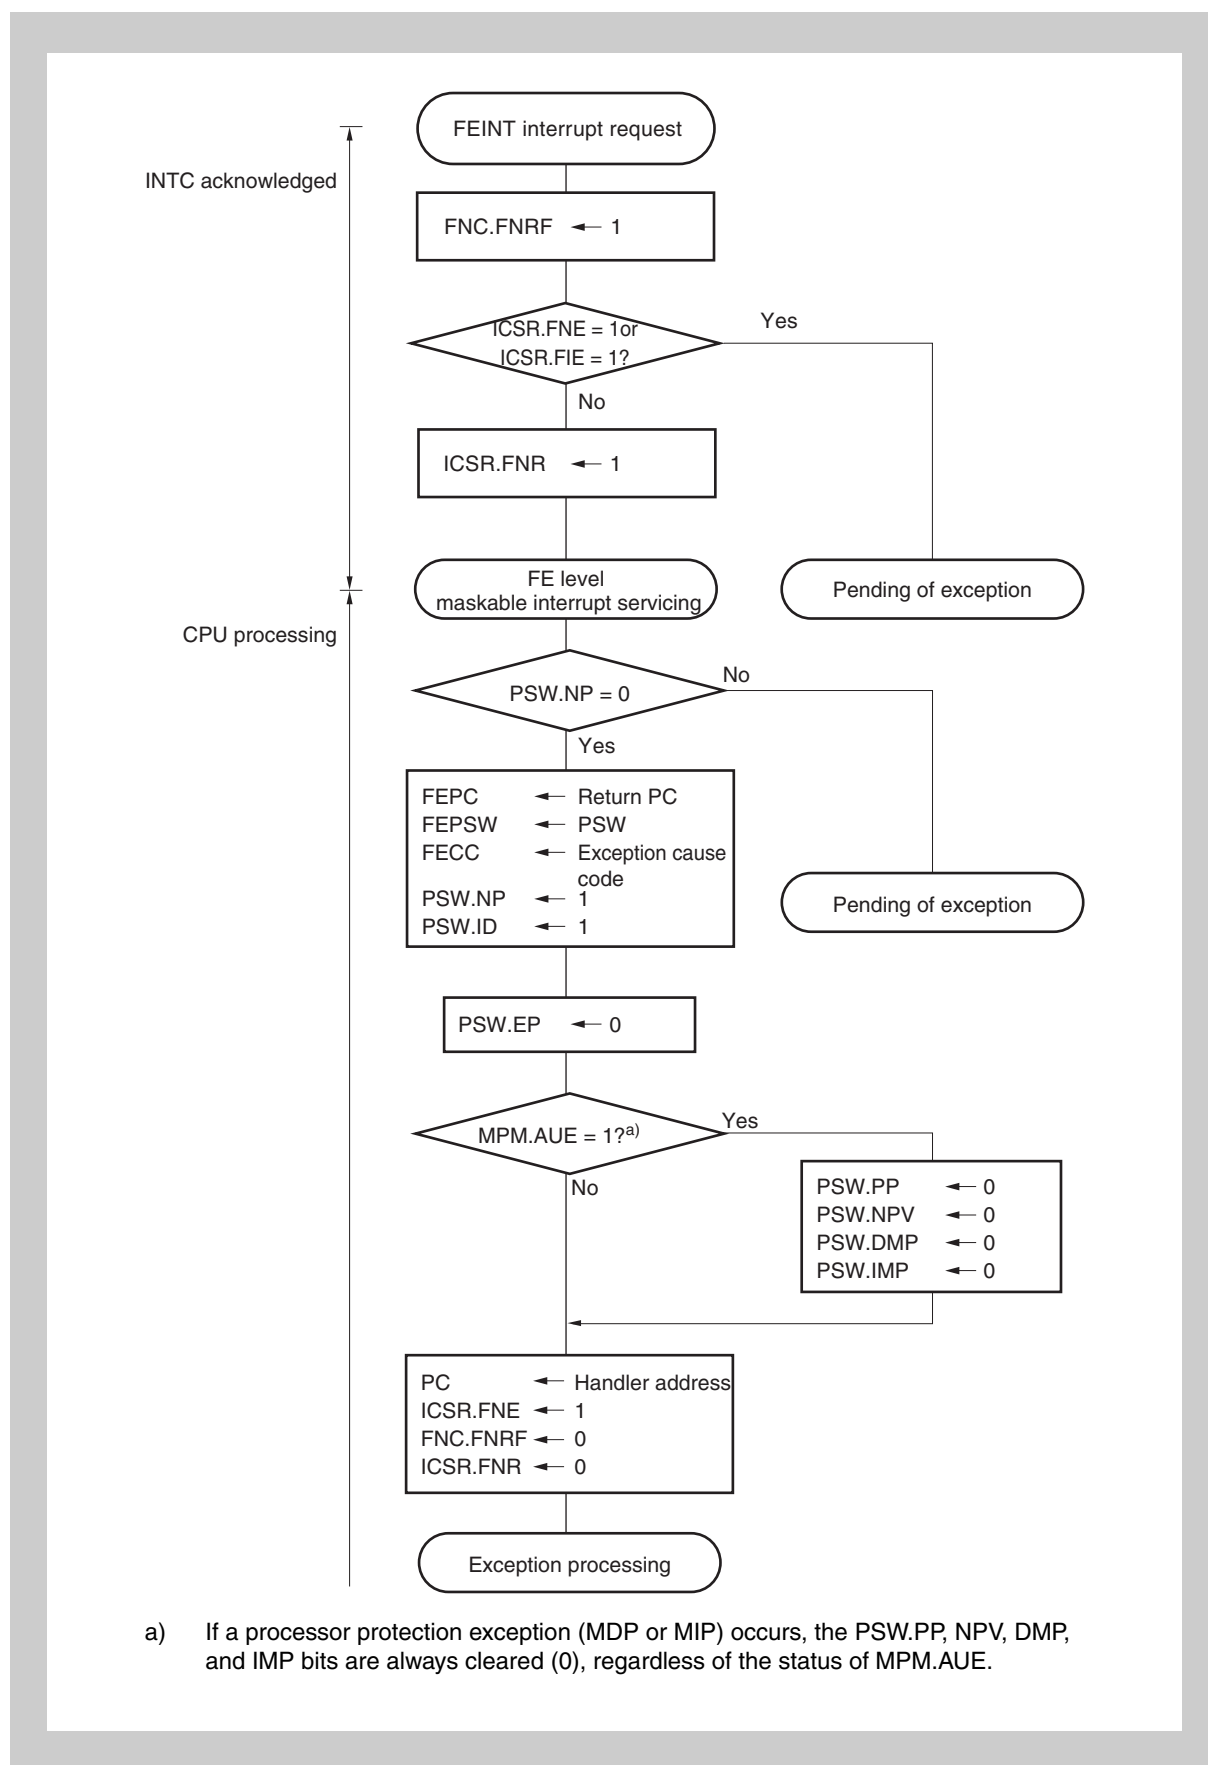

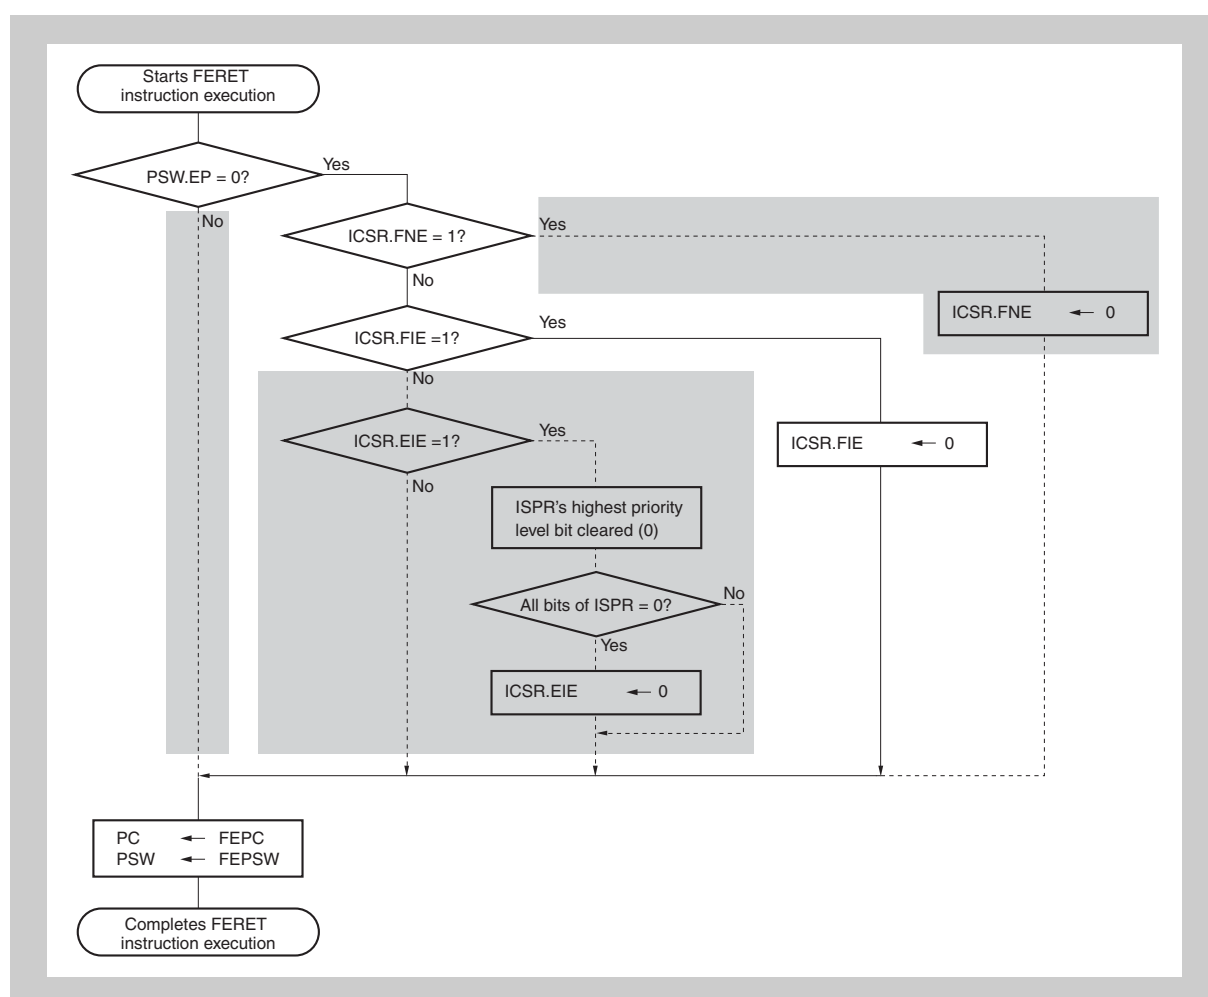

Figure 9-2 Processing upon occurrence of FEINT interrupt request

9.4.4 Restore from FE level maskable interrupt (FEINT) servicing

Restore from FE level maskable interrupt (FEINT) servicing is performed using the FERET instructions. Execution of the FERET instruction while the PSW.EP bit status is cleared (0) causes restore processing from the FE level maskable interrupt interrupt (FEINT). Completely restoring from interrupt servicing when the PSW.EP bit is "1" is not possible (clearing of the ICSR, ISPR, and other registers is not performed). For return from FE level maskable interrupts, execute the FERET instruction with the PSW.EP bit always cleared (0).

Caution In the V850E2M CPU core, although RETI instructions are provided for backward compatibility with V850E1 and V850E2 architectures, but their use is, in principle, prohibited. Replace all RETI instructions other than existing programs that cannot be modified with EIRET or FERET instructions.

Note Shaded portions indicate processing which do not branch during restoring from an FE level maskable interrupt (FEINT) servicing.

Figure 9-3 Restore from FE level maskable interrupt (FEINT) servicing

9.4.5 EI level maskable interrupt caused by EIINT interrupt request

When an EI level maskable interrupt is requested, an EIINT interrupt is requested to CPU (the transition to the interrupt handler occurs from the setting of the IMR register of the INTC). This interrupt is a recoverable EI level interrupt.

In the case of an EIINT interrupt, the channel number where the interrupt input occurred is set to the SCR register. As a result, the channel number can be easily known when wishing to share the same interrupt vectors among several channels.

Caution Upon acknowledgment of the EI level interrupt, the priority level of the currently acknowledged interrupt is registered to the ISPR register (in-service priority register). Then, until execution of the EIRET instruction, interrupt with a priority level lower than that of this ISPR register are not generated. Interrupt request is acknowledged and held.

Registration of the priority level of the currently acknowledged interrupt and deletion of the priority level of the interrupt during EIRET to/from the ISPR register are automatically performed by the hardware. Write to the ISPR register cannot be performed by software. Write operations are ignored.

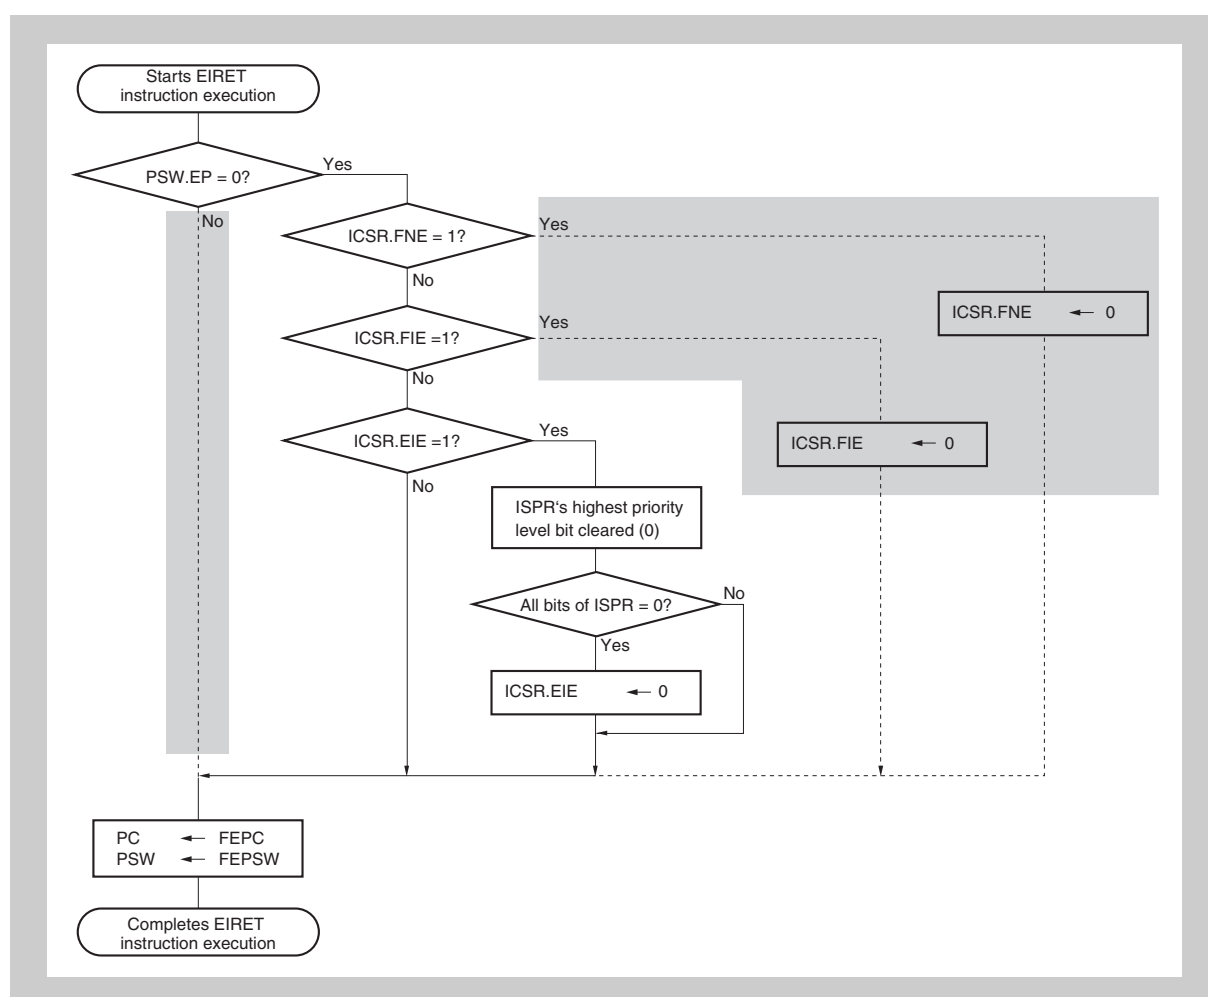

Figure 9-4 Processing upon occurrence of EIINT interrupt request

9.4.6 Restore from EI level maskable interrupt (EIINT)

Restore from EI level maskable interrupt (EIINT) is performed using the EIRET instruction. Execution of the EIRET instruction while the PSW.EP bit status is cleared (0) causes restore processing from the interrupt. Completely restoring from interrupt servicing when the PSW.EP bit is "1" is not possible (clearing of the ICSR, ISPR, and other registers is not performed). For return from EI level maskable interrupt, execute the EIRET instruction with the PSW.EP bit always cleared (0).

Caution In the V850E2M CPU core, although RETI instructions are provided for backward compatibility with V850E1 and V850E2 architectures, but their use is, in principle, prohibited. Replace all RETI instructions other than existing programs that cannot be modified with EIRET or FERET instructions.

Note Shaded portions indicate processing which do not branch during restoring from an EI level maskable interrupt (EIINT) servicing.

Figure 9-5 Restore from EI level maskable interrupt (EIINT)

9.5 Interrupt Operation

9.5.1 Mask function of EI level maskable interrupt (EIINT)

Interrupt masking can be specified for each respective interrupt channel of EIINT. Interrupt masking is performed by doing the following register settings.

EICn.EIMKn	Operation
1	Masks interrupt.
0	Enables interrupt.

The EICn.EIMKn bits can be read and written from the EIMKn bits corresponding to IMRm registers. They share the same registers.

- [Operation example]**
- (1) When "1" is written to IMRm.EIMKn bits, interrupts are prohibited for the corresponding channels.
 - (2) When the EICn.EIMKn bits are read, "1" is read.

Caution For EIMKn bit, the processing after interrupt hold is masked. Even if the EIMKn bit is set to 1, interrupt request acknowledgment and hold are performed. Therefore, even if software interrupts are requested for interrupts for which interrupt prohibit has been specified with EIMK, no interrupt occurs. Moreover, when EIMKn bit is again set to 0 while an interrupt request is held, that interrupts occur at that timing. To delete an interrupt request that is already being held, clear (0) the corresponding EIRFn bit.

9.5.2 Interrupt priority level judgment

When FENMI, FEINT, and EIINT interrupts are input, priorities including other exceptions are determined, and the exception with the highest priority (including interrupts) is requested. Exceptions requested at the same time (including interrupts) are processed in a pre-allocated priority order (the default priority order). The priority orders of FENMI, FEINT, and EIINT interrupts are as follows.

FENMI > FEINT > EIINT

(See Table 9-1 "Exception cause list" on page 223 and the V850E2M Architecture User's Manual for other exceptions.)

For EIINT interrupts, the priority level can be set independently for each interrupt source. The priority level is specified with EIC0-EIC255.EIP3-EIP0. Priority levels from 0 to 15 can be set. 0 is the highest priority level, and 15 the lowest. In the case of multiple EIINT interrupts with the same priority level, the interrupt with the lowest interrupt channel number has priority.

Table 9-15 Example of EIINT interrupt priority level settings and priority levels

EIINT	EIP3 to EIP0 setting	Priority level during operation
EIINT0	3	10
EIINT1	4	11
EIINT2	0	1
EIINT3	0	2
EIINT4	1	3
EIINT5	2	6
EIINT6	2	7
EIINT7	1	4
EIINT8	1	5
EIINT9	2	8
EIINT10	2	9

During interrupt servicing, the interrupt controller also processes multiple interrupts acknowledging other interrupts. When multiple EIINT interrupts are requested at the same time, the interrupt to be acknowledged is determined with the following procedure.

(1) Comparison with the priority level as the interrupt currently being serviced

Interrupts with the same or lower priority level as the interrupt currently being serviced are held.

The priority level of the interrupt currently being serviced is held in the ISPR register.

Interrupts with a higher priority level than the interrupt currently being serviced are go on to the next priority judgment stage.

(2) Masking through priority mask register (PMR)

Only interrupts enabled by the PMR register go on to the next priority judgment stage.

(3) Of the requested interrupt sources, that with the highest priority level is selected.

When interrupts are being simultaneously requested from multiple sources, of the interrupt sources with the highest priority level, that with the smallest interrupt channel number is selected.

(4) Interrupt hold by CPU

Interrupt acknowledgment is pended according to the state of the NP and ID bits of the PSW register. At this time, priority judgment among EIINT interrupts, and priority judgment among EIINT interrupts, FEINT interrupts, and FENMI interrupts is performed even while interrupt acknowledgment is pended, and the interrupt with the highest priority is selected upon realization of the acknowledgment condition.

Example When a priority level 5 EIINT interrupt has already been requested and interrupt generation is pended because the value of the PSW.ID bit is "1", a subsequent priority level 3 EIINT interrupt is requested. Then, if the PSW.ID bit is cleared (0), the priority level 3 EIINT interrupt is generated.

Multiple interrupt servicing in which an interrupt is acknowledged while another interrupt is being serviced is shown *Figure 9-6*.

When an interrupt request signal is acknowledged, the PSW.ID flag is automatically set to 1. Therefore, when multiple interrupts are to be used, clear the ID flag to 0 beforehand (for example, by placing the EI instruction in the interrupt service program) to set the interrupt enable mode.

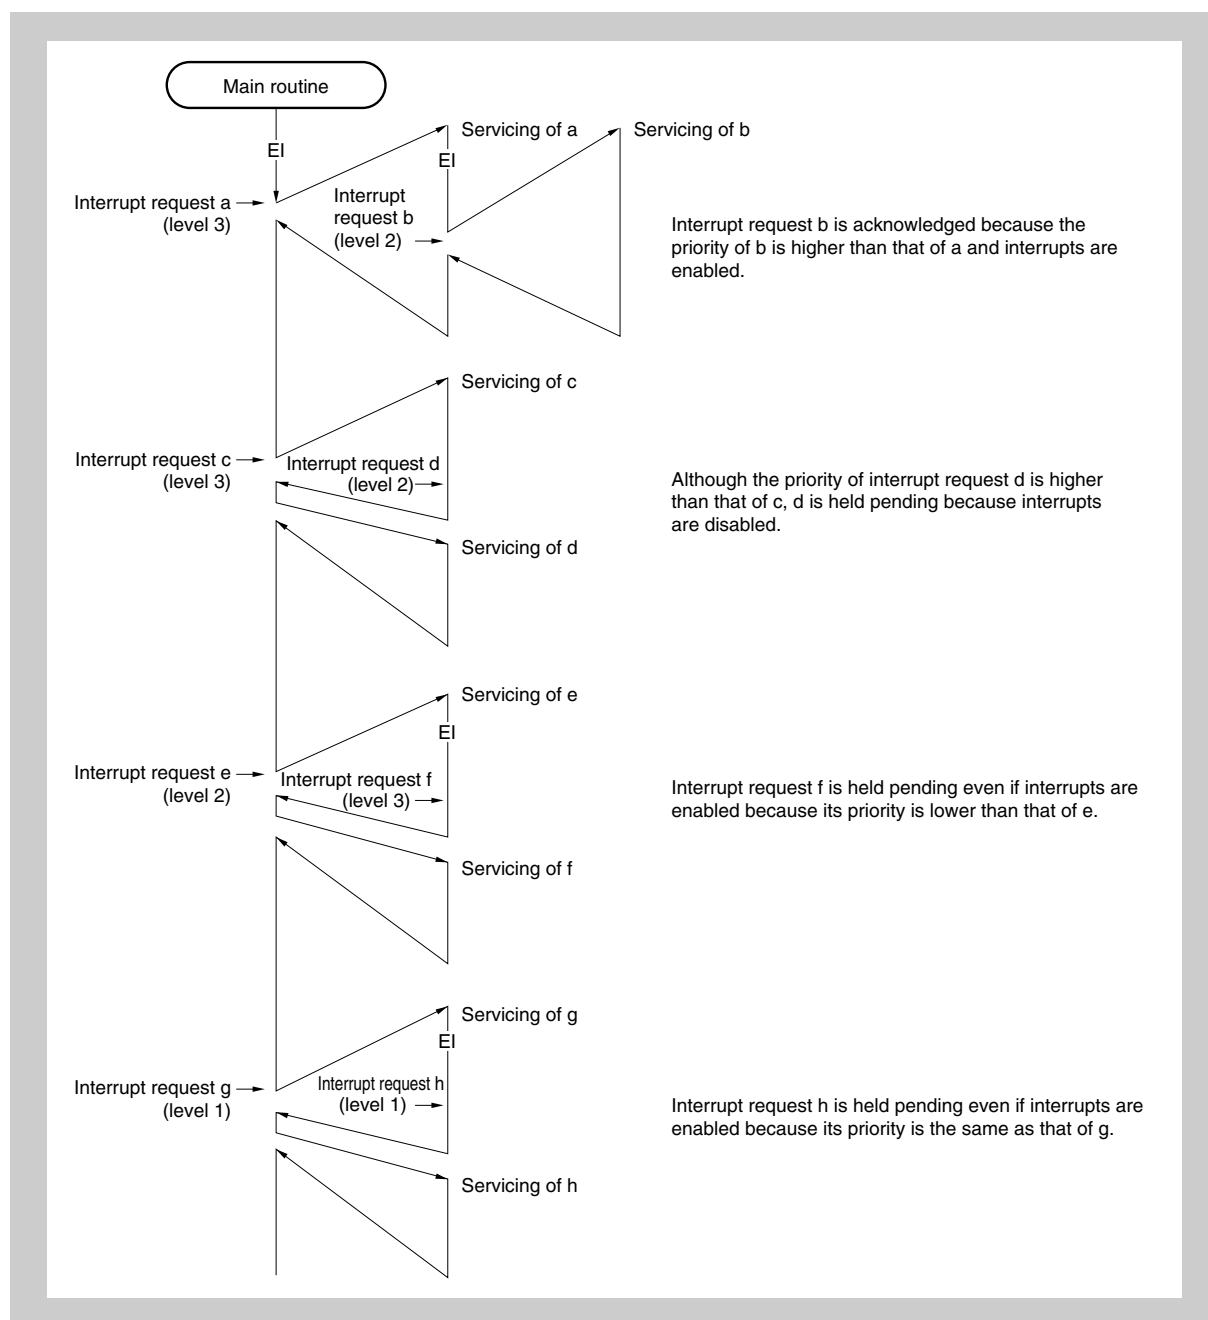

Figure 9-6 Example of processing in which another interrupt request signal is issued while an interrupt is being serviced (1/2)

Caution To perform multiple interrupt servicing, the values of the EIPC and EIPSW registers must be saved before executing the EI instruction. When returning from multiple interrupt servicing, restore the values of EIPC and EIPSW after executing the DI instruction.

- Notes**
1. a to u in the figure are the temporary names of interrupt request signals shown for the sake of explanation.
 2. The default priority in the figure indicates the relative priority between two interrupt request signals.

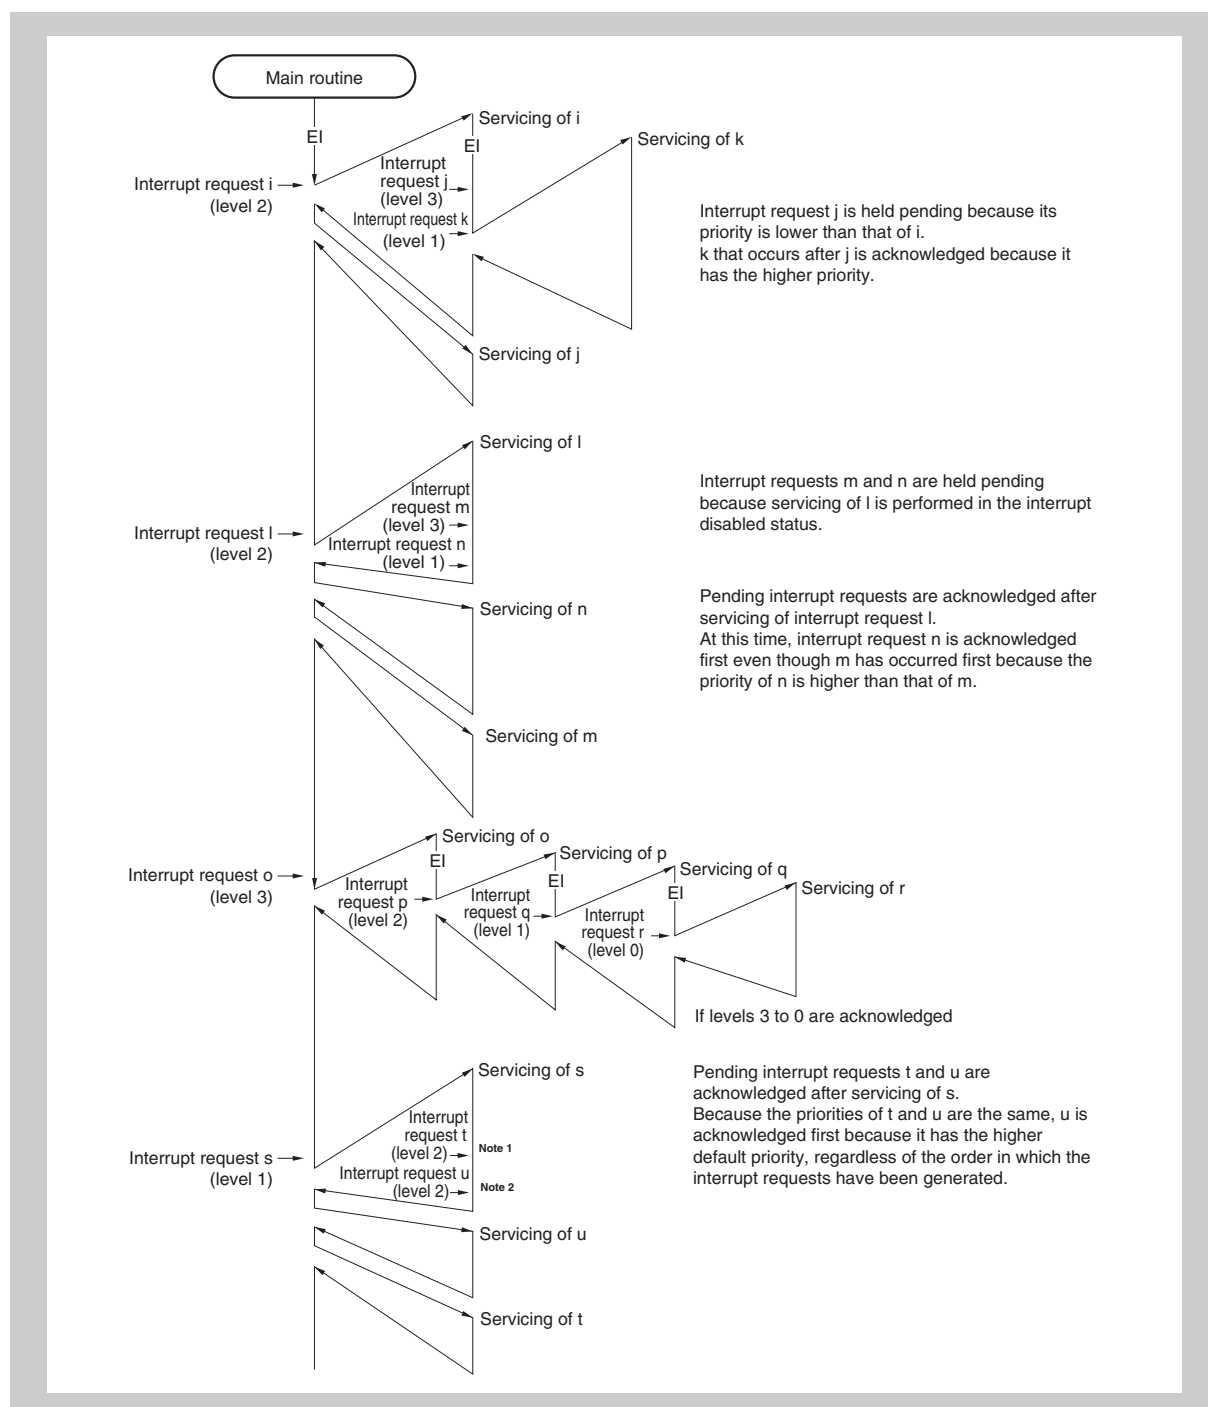

Figure 9-7 Example of processing in which another interrupt request signal is issued while an interrupt is being serviced (2/2)

Caution To perform multiple interrupt servicing, the values of the EIPC and EIPSW registers must be saved before executing the EI instruction. When returning from multiple interrupt servicing, restore the values of EIPC and EIPSW after executing the DI instruction.

- Notes**
1. Lower default priority.
 2. Higher default priority.

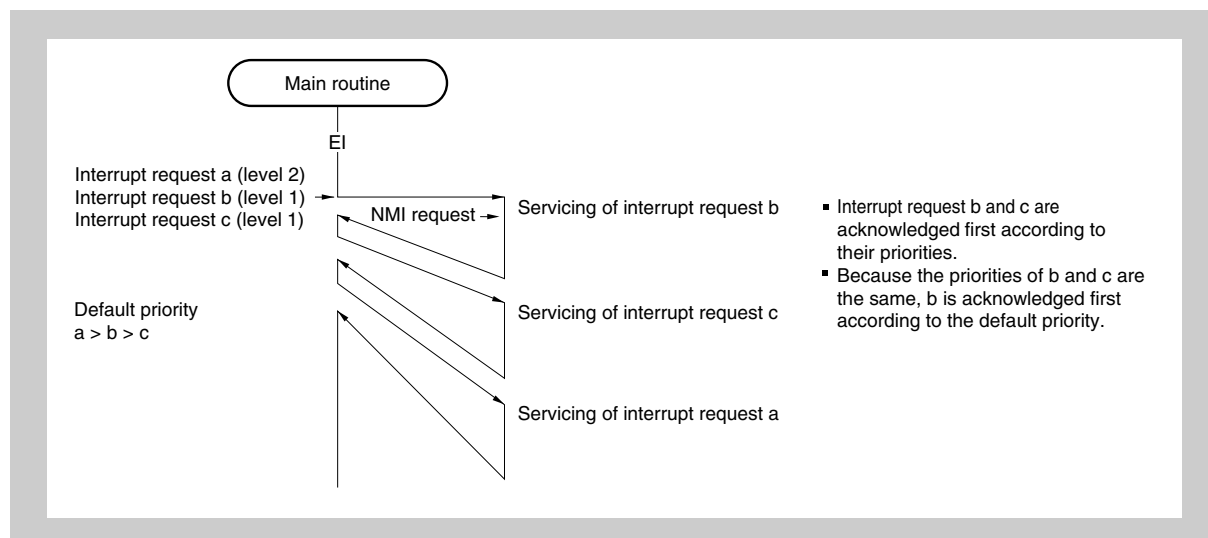

Figure 9-8 Example of servicing interrupt request signals simultaneously generated

Caution To perform multiple interrupt servicing, the values of the EIPC and EIPSW registers must be saved before executing the EI instruction. When returning from multiple interrupt servicing, restore the values of EIPC and EIPSW after executing the DI instruction.

- Notes**
1. a to c in the figure are the temporary names of interrupt request signals shown for the sake of explanation.
 2. The default priority in the figure indicates the relative priority between two interrupt request signals.

9.5.3 Priority mask function

The priority mask function prohibits in batch EIINT interrupts of the specified interrupt priority level.

The interrupt masking priority level is specified with the PMR register. Masking and acknowledgment can be set for each priority level.

The following operations are possible using this function.

- Temporary prohibition of interrupts that have a priority level that is lower than a given priority level
- Temporary prohibition of interrupts that have a given priority level

PMR.PMRm	Operation
0	Acknowledges requests from priority level m interrupt source.
1	Masks requests from priority level m interrupt source.

Note m = 0 to 15

The PMR register prohibits interrupt occurrence. Interrupt request is acknowledged and held even while the interrupt occurrence is prohibited.

The presence of EIINT interrupts held pending with this function can be checked with the next section, 9.4.4 “Restore from FE level maskable interrupt (FEINT) servicing” on page 248 .

9.5.4 Pended interrupt report function

The state of the currently pended interrupt can be checked with the pended interrupt report function.

This function allows checking of the following states.

- When interrupts that are masked only by the priority mask function (PMR) exist
The ICSR.PMF bit is set to 1.
The ICSR.PMF bit is not set to 1 only when interrupts that are priority masked through ISPR register or interrupts masked through EIMK bit exist. Thus, the existence of priority requests pended through the priority mask function can be checked while interrupts are prohibited through priority masking.
- When EI level maskable interrupt request is not output to the CPU
The ICSR.EIR bit is set to 1.
By looking at the ICSR.EIR bit in the interval during which PSW.ID = 1, it is possible to check whether an EIINT interrupt request exists.
- When FE level maskable interrupt request is not output to the CPU
ICSR.FIR bit is set to 1.
By looking at the ICSR.FIR bit in the interval during which PSW.NP = 1, it is possible to check whether a FEINT interrupt request exists.

9.5.5 In-service priority clear function

This function initializes the internal status of the interrupt controller. It operates when the ISPC register is accessed. The following operations are possible using this function.

- Clear all contents of ISPR register
- Clear ICSR.EIE, FIE, and FNE bits

All the bits of ISPR register can be cleared to 0 by writing "1" to all the bits of this register and then writing "0" to all the bits of ISPR register. Moreover, the ICSR.EIE, FIE, and FNE bits, which all indicates the state in which an interrupt request is being processed in the CPU core, are all be cleared.

The value of this register is automatically cleared to 0 by writing 0 to all the bits of ISPR. The values of the bits of ISPR remain unchanged in the case of write access that is not performed simultaneously to all the bits.

9.6 Exception Handler Address Switching Function

Interrupt handler addresses can be switched by software.

For details, refer to 6.4 "Exception Handler Address Switching Function" in PART 2 of the V850E2M Architecture User's Manual.

Chapter 10 DMA Function

This chapter contains a generic description of the DMAC/DTS (DMA).
The first section describes all properties specific to the V850E2/ML4.
The subsequent sections describe the features that apply to all implementations.

10.1 V850E2/ML4 DMA Features

Instances This microcontroller has the following number of DMAs.

Table 10-1 Instances of DMAC

DMA	
Instances	8

Instances index n Throughout this chapter, the individual instances of DMAC are identified by the index “n” (n = 0 to 7).

(1) DMAC start sources

The DMAC start source can be selected by specifying DTFRn.IFCn[6:0].

The table below lists the DMA start sources that can be selected using the DTFRn register.

For details about the interrupts, see *Table 9-5 “EI level maskable interrupt requests” on page 227*.

For details about the transfer sources of the DTS function, see *10.12 “DTSFSL Function” on page 368*.

Table 10-2 DMA start sources (0 to 63)

10.2 Terms

The terms used in this chapter are defined as follows.

Table 10-4 Definition of terms

Term	Function
DMA transfer	Period from the start of the first DMA cycle to assertion of INTDMA
DMA cycle	Period of transferring one unit of data (since a read cycle of the internal system bus has been started and until a write cycle is completed. In the case of 128-bit transfer, until the read cycle is completed four times and the write cycle is completed four times)
Hardware DMA transfer request	DMA transfer request by external pins
Software DMA transfer request	DMA transfer request by internal register (DTSnSR bit of DTSn register)
DMA transfer request	Hardware DMA transfer request or software DMA transfer request
Transfer information (TI)	Information required for DMA transfer, such as transfer address, transfer data size, and transfer count. In particular, the DTS's transfer information is called TI (Transfer Information).
TI fetch	When DTS reads transfer information from internal RAM
TI write back	When DTS writes transfer information back internal RAM
TI fetch cycle	Period during which DTS reads transfer information from internal RAM
DTS cycle	Period during which DTS performs a transfer according to the TI
TI write back cycle	Period during which DTS writes transfer information back to internal RAM
Single transfer	In the case of DMAC, one DMA cycle is executed per transfer request. In the case of DTS, one cycle of DTS operations that include a TI fetch cycle, DTS cycle, and TI write back cycle is executed per transfer request.
Single step transfer	This function is used only with DMAC. The number of transfers set in the transfer count setting register (DTC) is executed per software DMA transfer request. Since the bus is released for each transfer, the CPU is able to generate interrupts. If a higher-priority transfer request occurs during execution of a single step transfer, the single step transfer is aborted while the higher-priority transfer request is executed.
Block transfer	This function is used only with DTS. For each transfer request, one TI fetch cycle, the DTS cycles for the number specified in the transfer count setting register (TI-A's bits [31:16]), and one TI write back cycle are executed. Since the bus is released for each transfer, the CPU is able to generate interrupts. If a higher-priority DTS request occurs during execution of a block transfer, DTS ignores (cannot acknowledge) the request until the block transfer is completed.

10.3 General

Direct memory access (DMA) function is used to access data without going via the CPU.

The V850E2/ML4 incorporates five types of DMA subsystem units: DTFR, DTSFSL, DMAC (one unit), DTS, and DMAT. DMAC can be used to perform high-speed data transfers.

DTS provides slower data transfers, chain functions, etc.

DMAT drives the internal system bus for data access. DTFR and DTSFSL have functions that select DMA transfer factors from among interrupt requests.

10.3.1 DMA controller (DMAC) function

- Registers to store transfer information (transfer address, transfer size, etc.) and registers to control DMAC are included.
- When a DMA transfer request is accepted, a transfer request is output to DMAT, according to the contained transfer information.
- Hardware DMA transfer requests, DMA acknowledge signals, and DMA transfer completion interrupts are input and output.
- Write back information is written back to registers.

10.3.2 DMA trigger factor register (DTFR) function

- DMA transfer factors are selected from among interrupt signals. (8 channels are selected from 128-channel interrupt signals.)

10.3.3 Data transfer service (DTS) function

- A register that controls DTS is included (transfer information is set in internal RAM).
- When a DTS transfer request is accepted, transfer information set in internal RAM is read, and a transfer request is output to DMAT, according to the transfer information.
- Hardware DTS transfer requests, DTS acknowledge signals, and DTS transfer completion interrupts are output.
- Write back information (next time's transfer information) is written back to internal RAM.

10.3.4 DTS factor selector (DTSFSL) function

- DTS transfer factors are selected from among interrupt signals. (Up to 128 transfer factors can be assigned.)
- Various interrupt sources from the DTS and interrupt signals from peripherals are selected.

Table 10-5 Transfer target spaces (DMAC)

Transfer source	Transfer destination				
	P-bus peripheral I/O	External memory (memory controller)	Internal RAM	Internal flash memory	H-bus peripheral I/O
P-bus peripheral I/O	√	√	√	×	√
External memory (memory controller)	√	√	√	×	√
Internal RAM	√	√	√	×	√
Internal flash memory	√	√	√	×	√
H-bus peripheral I/O	√	√	√	×	√

Caution Be careful not to specify the same address as the transfer source and transfer destination. Doing so might corrupt the transfer data.

Table 10-6 Transfer target spaces (DTS)

Transfer source	Transfer destination				
	P-bus peripheral I/O	External memory (memory controller)	Internal RAM	Internal flash memory	H-bus peripheral I/O
P-bus peripheral I/O	√	√	√	×	√
External memory (memory controller)	√	√	√	×	√
Internal RAM	√	√	√	×	√
Internal flash memory	√	√	√	×	√
H-bus peripheral I/O	√	√	√	×	√

10.3.5 DMA access memory map

The memory map that shows areas that can be accessed by DMA is shown below.

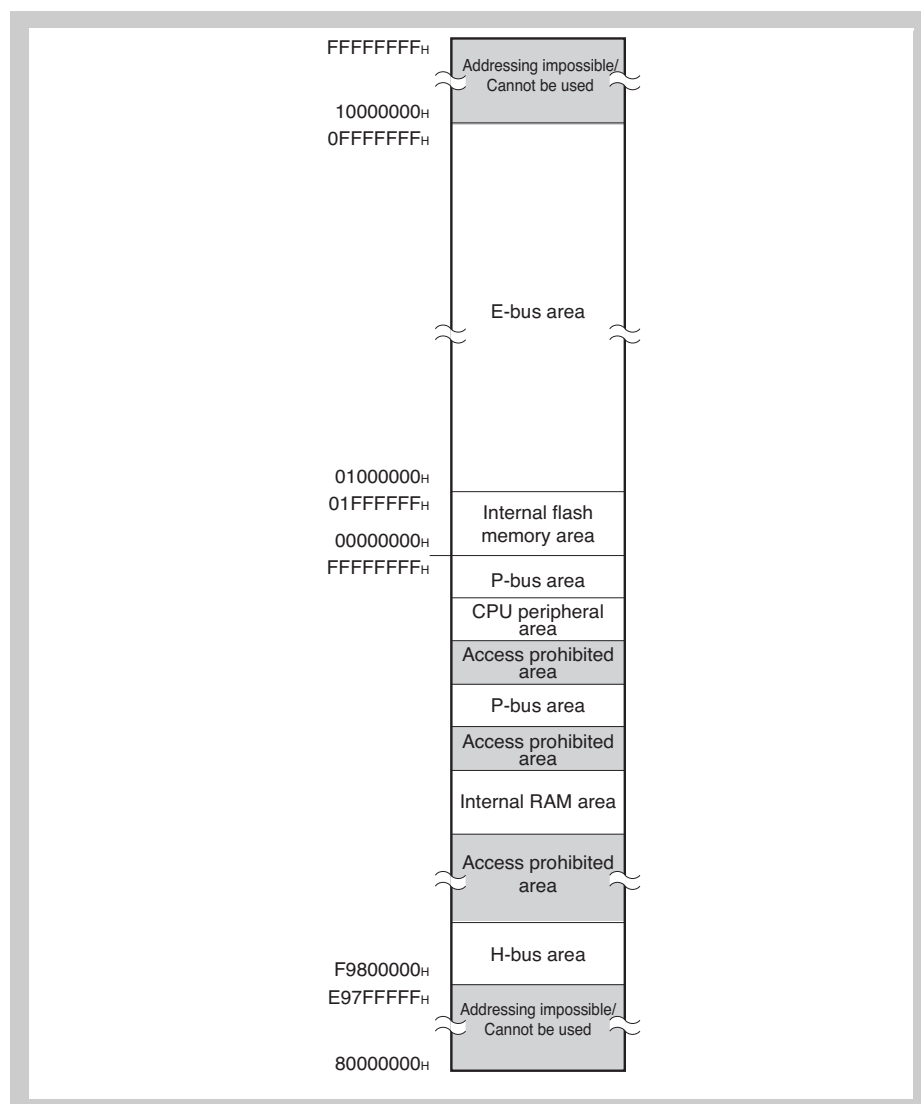

Figure 10-1 Memory map from DMA point of view

10.3.6 Prioritization of channels

The following describes how the prioritization of the DMA subsystem's various transfer channels is determined. Prioritization is determined via two stages: the first stage is when the priority level in each group between DMAC0 and DTS is determined separately.

Between DMAC0, the priority is set as CH0 > CH1 > CH2 > CH3 > CH4 > CH5 > CH6 > CH7, in which CH0 has the highest priority.

Between DTS, where four levels of priority settings are possible, the priority is determined using the default priority channels: CH000 > CH001 > CH002... > CH127.

10.3.7 Arbitration of transfer requests

Since the DMA subsystem includes two transfer controllers (DMAC0 and DTS), these transfer requests are arbitrated internally. This arbitration is always performed using the fixed prioritization: DMAC0 > DTS. DMAC0's priority level is the highest.

However, when DMAC0 or DTS completes one transfer request, the request is temporarily withdrawn, so the following phenomena occur.

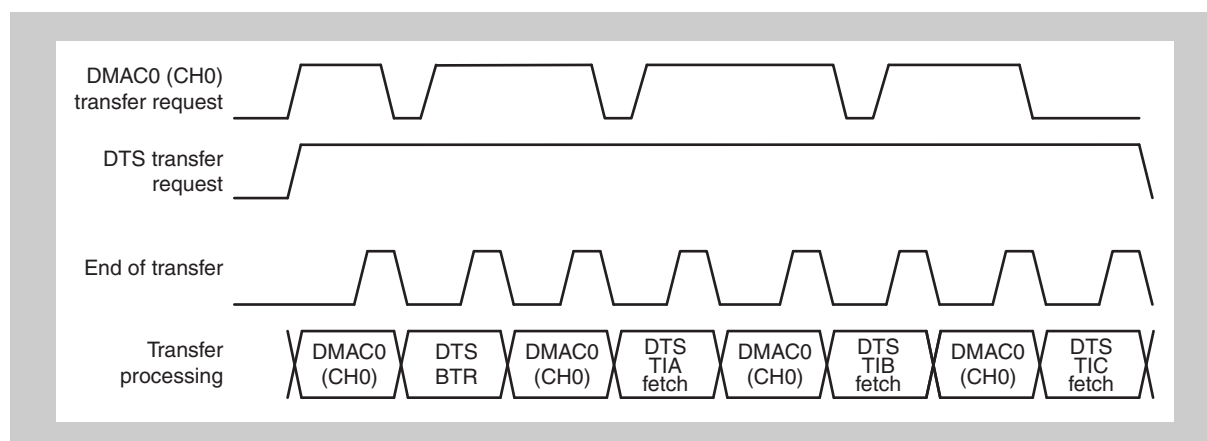

Figure 10-2 Alternation of DMAC0 and DTS

Even when CH0's transfer requests occur continuously, the DMAC0 temporarily withdraws transfer requests. As a result, DTS's requests take priority. After a base table read (BTR) cycle, DTS continues to output TIA fetch requests, but since DMAC0 has a higher priority level than DTS, DMAC0 takes priority as a result of arbitration. When DMAC0's transfer is completed, DMAC0 temporarily withdraws requests, and DTS's request is executed.

10.4 DMAC Function

10.4.1 Features

Number of channels	8 channels
Transfer data size	8 bits, 16 bits, 32 bits, and 128 bits
Transfer data	Fixed to little endian Misaligned data not supported
Maximum transfer count	32,768 (2^{15}) times (MSB of the 16-bit register is used for the next address function.)
Channel priority control	Fixed priority (highest priority (CH0) → lowest priority (CH7))
Subject to transfer	Internal flash memory, internal RAM, external memory area, P-bus peripheral I/O area, and H-bus peripheral I/O area
DMA transfer cycle output function	$\overline{\text{DMAAK}}[0:5]$ pin outputs (CH5 to CH0)
DMA last transfer cycle output function	$\overline{\text{DMATC}}[0:5]$ pin outputs (CH5 to CH0)
Transfer type	2-cycle transfer (dual address transfer) The address at both the transfer source and destination is accessed. Two bus cycles are required to execute transfer once (read cycle + write cycle). Because the bus is not locked between the read cycle and write cycle, the CPU cycle may interrupt. When a 128-bit access is made, the write cycle is executed four times after the read cycle has been executed four times. Because the bus is not locked between the read cycles and between the write cycles, the CPU cycle may interrupt.
Transfer mode	<ul style="list-style-type: none"> • Single transfer mode (when hardware DMA transfer request is generated) When a hardware DMA transfer request is generated, the bus mastership is acquired, and the bus is always released after transfer has been executed once. If another hardware DMA transfer request is generated after that, transfer is executed once again. This operation is repeated until transfer has been executed the number of times specified by the transfer count register (DTC). • Single-step transfer mode (when software DMA transfer request is generated) When a software DMA transfer request is generated, the bus mastership is acquired, and the bus is released each time transfer has been executed once. Once a software DMA transfer request has been acknowledged, this operation is repeated until transfer has been executed the number of times specified by the transfer count register (DTC).

Transfer address control	Incremental, decremental, and fixed
Transfer error support	When the data from the transfer source contains an error, or if an error occurs at the transfer source, DMA transfer is aborted, and a SysError exception is output for the CPU.
DMA transfer request	A hardware DMA transfer request or a software DMA transfer request can be selected for each channel (by setting the DTRS register). The software DMA transfer request can be set by software (by setting the DTS register). This register also has a status bit (DTS register) that indicates that a hardware DMA transfer request has been generated. The function for notifying the INTC about peripheral I/O interrupts not assigned to DMA transfer requests depends on the system configuration. Refer to the product's user's manual.
Transfer count match interrupt output function	This function has a transfer count compare register (DTCC) for each channel and outputs an interrupt signal (INTCT15 to INTCT0) upon a match with the transfer count register (DTC) of each channel.
Transfer completion interrupt output function	This function outputs a transfer completion interrupt signal (INTDMA15 to INTDMA0) when DMA transfer of each channel has been completed the number of times specified by the transfer count register (DTC).
Next address setting function	This function has a register for each channel for setting the transfer address and transfer count (Current) of the DMA transfer currently being executed, and a register for setting the transfer address and transfer count (Next) of the DMA transfer to be executed next, following completion of the DMA transfer currently being executed. This function also has a bit for each register for setting whether to copy Next to Current upon completion of DMA transfer.
DMA transfer abort function	This function supports aborting DMA transfer by software.

10.4.2 DMAC setting registers

Table 10-7 DMAC setting registers (1/5)

Address	Symbol	Function register name	R/W	Operable bits				Initial value

Caution If an unmapped address is accessed, a write access is ignored and “0” is returned in response to a read access.

10.4.3 Enabling or disabling writing control registers

The following control registers cannot be written while DMA transfer is enabled. All these registers can always be read, however.

Table 10-8 Enabling/disabling writing control registers

Always writable	DTRCx, DNSAnL, DNSAnH, DNSCn, DNDA nL, DNDA nH, DNDCn, DNTCn, DTSn
Writing prohibited while DMA transfer is enabled (DTSn.DTSnDTE = 1) (Operation is not guaranteed if these registers are written.)	DTRS n, DSA nL, DSA nH, DSCn, DDA nL, DDA nH, DDCn, DTCn, DTCCn, DTCTn

Note n = 0 to 15, x = 0, 1

10.5 DMA Control Registers

10.5.1 DTRC_x (x = 0): DMA transfer request control register

Access This register can be read or written in 8- or 1-bit units.

Address DTRC0: FFFF 7300_H

Initial Value 00_H

	7	6	5	4	3	2	1	0
DTRC _x ERR	0	0	0	0	0	0	0	DTRC _x ADS
	R/W	R	R	R	R	R	R	R/W

Table 10-9 DTRC_x register contents

Bit position	Bit name	Function
7	DTRC _x ERR	DMA transfer error status This bit indicates that an error response has been received from the transfer target during DMA transfer. If an error response is received, the DTRC _x ERR and DTRC _x ADS bits are set and a SysError exception is generated by the CPU. To clear this bit, write "0" to it. 0: No DMA transfer error 1: DMA transfer error
0	DTRC _x ADS	DMA transfer aborted This bit indicates that DMA transfer has been aborted by a transfer stop request. In addition, the current DMA transfer can be aborted if the user writes "1" to this bit. 0: DMA transfer not aborted 1: DMA transfer aborted/DMA transfer abort request

DTRC0 corresponds to DMA channels 0 to 7.

10.5.2 DTRSn (n = 0 to 7): DMA transfer request select register

Access This register can be read or written in 16-bit units.

Address DTRS7: FFFF 7460_H, DTRS6: FFFF 7430_H, DTRS5: FFFF 7400_H,
DTRS4: FFFF 73D0_H, DTRS3: FFFF 73A0_H, DTRS2: FFFF 7370_H,
DTRS1: FFFF 7340_H, DTRS0: FFFF 7310_H

Initial Value 0000_H

15	14	13	12	11	10	9	8
0	0	0	0	0	0	0	0
R	R	R	R	R	R	R	R
7	6	5	4	3	2	1	0
0	0	0	0	DTR3	DTR2	DTR1	DTR0
R	R	R	R	R/W	R/W	R/W	R/W

Table 10-10 DTRSn register contents

Bit position	Bit name	Function																				
3:0	DTR3 to DTR0	DMA transfer request assignment These bits specify assignment of a DMA transfer request to channel n.																				
		<table border="1"> <thead> <tr> <th>DTR3</th><th>DTR2</th><th>DTR1</th><th>DTR0</th><th>DMA transfer request</th></tr> </thead> <tbody> <tr> <td>0</td><td>0</td><td>0</td><td>0</td><td>Software DMA transfer request</td></tr> <tr> <td>0</td><td>0</td><td>0</td><td>1</td><td>Hardware DMA transfer request</td></tr> <tr> <td colspan="4">Other than above</td><td>Setting prohibited</td></tr> </tbody> </table>	DTR3	DTR2	DTR1	DTR0	DMA transfer request	0	0	0	0	Software DMA transfer request	0	0	0	1	Hardware DMA transfer request	Other than above				Setting prohibited
DTR3	DTR2	DTR1	DTR0	DMA transfer request																		
0	0	0	0	Software DMA transfer request																		
0	0	0	1	Hardware DMA transfer request																		
Other than above				Setting prohibited																		

- Cautions**
1. Writing these bits is prohibited while DMA transfer is enabled (DTSn.DTSnDTE bit = 1). If they are written, the operation is not guaranteed.
 2. The operation is not guaranteed if DTR[3:0] are set to a prohibited status.

10.5.3 DSAnL (n = 0 to 7): DMA source address register L

Access This register can be read or written in 16-bit units.

Address DSA7L: FFFF 7464_H, DSA6L: FFFF 7434_H, DSA5L: FFFF 7404_H,
DSA4L: FFFF 73D4_H, DSA3L: FFFF 73A4_H, DSA2L: FFFF 7374_H,
DSA1L: FFFF 7344_H, DSA0L: FFFF 7314_H

Initial Value 0000_H

15	14	13	12	11	10	9	8
SA15	SA14	SA13	SA12	SA11	SA10	SA9	SA8
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

SA7	SA6	SA5	SA4	SA3	SA2	SA1	SA0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 10-11 DSAnL register contents

Bit position	Bit name	Function
15:0	SA15 to SA0	DMA source address These bits set the lower 16 bits of the transfer source address of channel n. If this register is referenced during DMA transfer, the address from which data is to be transferred next can be read. When referencing this register, it is recommended to access this register together with DSAnH in 32-bit units. If the NSAV bit of the DNSAnH register is not set (to "1") when DMA transfer has been completed, the values of these bits return to the values when DMA transfer was started.

- Cautions**
1. Writing these bits is prohibited while DMA transfer is enabled (DTSn.DTSnDTE bit = 1). If they are written, the operation is not guaranteed.
 2. Set an address by accessing in 32-bit units while the DTSnDTE bit is "0" in order to avoid data being transferred from an address that has not been completely set.
 3. DMA transfer of misaligned data is not supported. The lower 4 bits of an address corresponding to the transfer data size are as follows (x indicates any bit).
The operation is not guaranteed if a setting other than the following is made.

Data size	SA3	SA2	SA1	SA0
8 bits	x	x	x	x
16 bits	x	x	x	0
32 bits	x	x	0	0
128 bits	0	0	0	0

10.5.4 DSAnH (n = 0 to 7): DMA source address register H

Access This register can be read or written in 16-bit units.

Address DSA7H: FFFF 7466_H, DSA6H: FFFF 7436_H, DSA5H: FFFF 7406_H,
DSA4H: FFFF 73D6_H, DSA3H: FFFF 73A6_H, DSA2H: FFFF 7376_H,
DSA1H: FFFF 7346_H, DSA0H: FFFF 7316_H

Initial Value 0000_H

Table 10-23 DTCn register contents

Bit position	Bit name	Function										
14:0	DTC14 to DTC0	DMA transfer count These bits specify the number of times of DMA transfers (DMA transfer count) for channel n. When this register is referenced during DMA transfer, the remaining number of times DMA transfer to be executed can be read. If the NTCV bit of the DNTCn register is not set (to "1"), these bits hold the values when DMA transfer has been completed (0000H). <table border="1" data-bbox="582 1099 1382 1373"> <thead> <tr> <th>DTC[14:0]</th><th>The operation</th></tr> </thead> <tbody> <tr> <td>0000H</td><td>Transfer executed 32,768 times or until completion of transfer</td></tr> <tr> <td>0001H</td><td>Transfer executed once or transfer to be executed once</td></tr> <tr> <td>...</td><td>...</td></tr> <tr> <td>7FFFH</td><td>Transfer executed 32,767 times or 32,767 times of transfer to be executed</td></tr> </tbody> </table>	DTC[14:0]	The operation	0000H	Transfer executed 32,768 times or until completion of transfer	0001H	Transfer executed once or transfer to be executed once	7FFFH	Transfer executed 32,767 times or 32,767 times of transfer to be executed
DTC[14:0]	The operation											
0000H	Transfer executed 32,768 times or until completion of transfer											
0001H	Transfer executed once or transfer to be executed once											
...	...											
7FFFH	Transfer executed 32,767 times or 32,767 times of transfer to be executed											

- Cautions**
1. Writing these bits is prohibited while DMA transfer is enabled (DTSn.DTSnDTE bit = 1). If they are written, the operation is not guaranteed.
 2. If an error occurs in the transfer target in the read cycle of DMA transfer, the write cycle is not executed but the destination address is updated.

10.5.16 DNCTn (n = 0 to 7): DMA next transfer count register

Access This register can be read or written in 16-bit units.

Address DNCT7: FFFF 7484_H, DNCT6: FFFF 7454_H, DNCT5: FFFF 7424_H,
DNCT4: FFFF 73F4_H, DNCT3: FFFF 73C4_H, DNCT2: FFFF 7394_H,

0	DSM	<p>DMA signal mode This bit specifies the output timing for the $\overline{\text{DMAAK}}[0:5]$ and $\overline{\text{DMATC}}[0:5]$ output pins. 0: Read cycle 1: Write cycle The DSM bit is provided only for the DTCD0 to DTCD5 registers. The DTCD6 to DTCD15 registers do not have this bit.</p>															

- Cautions**
1. Writing these bits is prohibited while DMA transfer is enabled (DTSn.DTSnDTE bit = 1). If they are written, the operation is not guaranteed.
 2. The operation cannot be guaranteed if the SACM[1:0] and DACM[1:0] bits are set to a prohibited status
 3. Be sure to set bits 11 and 0 to "0".

10.5.19 DTSn (n = 0 to 7): DMA transfer status register

Access This register can be read or written in 8- or 1-bit units.

Address DTS7: FFFF 748A_H, DTS6: FFFF 745A_H, DTS5: FFFF 742A_H,
DTS4: FFFF 73FA_H, DTS3: FFFF 73CA_H, DTS2: FFFF 739A_H,
DTS1: FFFF 736A_H, DTS0: FFFF 733A_H

Initial Value 00_H

7	6	5	4	3	2	1	0
DTSnTC	DTSnDT	0	0	DTSnER	DTSnDR	DTSnSR	DTSnDTE
R/W	R/W	R	R	R	R	R/W	R/W

Table 10-27 DTSn register contents (1/2)

Bit position	Bit name	Function
7	DTSnTC	DMA transfer end status This bit indicates that DMA transfer has been completed. Write “0” to this bit to clear it after reading “1” from it. It is recommended to write this bit using bit manipulation such as CLR1. 0: DMA transfer not completed 1: DMA transfer completed
6	DTSnDT	DT DMA transfer status This bit indicates that a DMA transfer request has been acknowledged and that DMA transfer is in progress. It is not set (to “1”) when only a DMA transfer request is issued. This bit is cleared (to “0”) when DMA transfer has been completed. If the DTSnDTE bit is “0”, this bit can be cleared by the user. (It can also be written at the same time as the DTSnDTE bit.) 0: DMA transfer request acknowledged 1: DMA transfer in progress
3	DTSnER	DMA transfer error flag This bit indicates that a DMA transfer error has occurred in channel n. It is cleared (to “0”) when the DTRCx.DTRCxERR bit is cleared. Note that this bit is read-only. 0: No DMA transfer error 1: DMA transfer error
2	DTSnDR	Hardware DMA transfer request flag This bit indicates that channel n has a hardware DMA transfer request. It is cleared (to “0”) when the hardware DMA transfer request is deasserted. This bit operates regardless of the status of the DTSnDTE bit. It is not set (to “1”) by a software DMA transfer request, or by a hardware DMA transfer request when a software DMA transfer request is selected by the DMA transfer request select register. Note that this bit is read-only. 0: No hardware DMA transfer request 1: Hardware DMA transfer request
1	DTSnSR	Software DMA transfer request This bit selects a software DMA transfer request. If a software DMA transfer request is selected by the DMA transfer request select register, writing “1” to this bit and the DTSnDTE bit starts DMA transfer. This bit is automatically cleared (to “0”) when DMA transfer has been completed. Writing “0” to this bit aborts DMA transfer. 0: No software DMA transfer request 1: Software DMA transfer request

Table 10-27 DTSn register contents (2/2)

Bit position	Bit name	Function
0	DTSnDTE	DMA transfer enable This bit enables or disables DMA transfer. DMA transfer is executed if “1” is written to this bit and a DMA transfer request is issued. This bit is automatically cleared (to “0”) if the MLE bit is “0” when DMA transfer has been completed. DMA transfer is aborted if “0” is written to this bit during DMA transfer. 0: Disables DMA transfer 1: Enables DMA transfer

10.6 DMAC Function Details

10.6.1 DMAC transfer setting flow

Figure 10-3 “DMAC transfer setting flow” shows the flow for setting DMAC transfer.

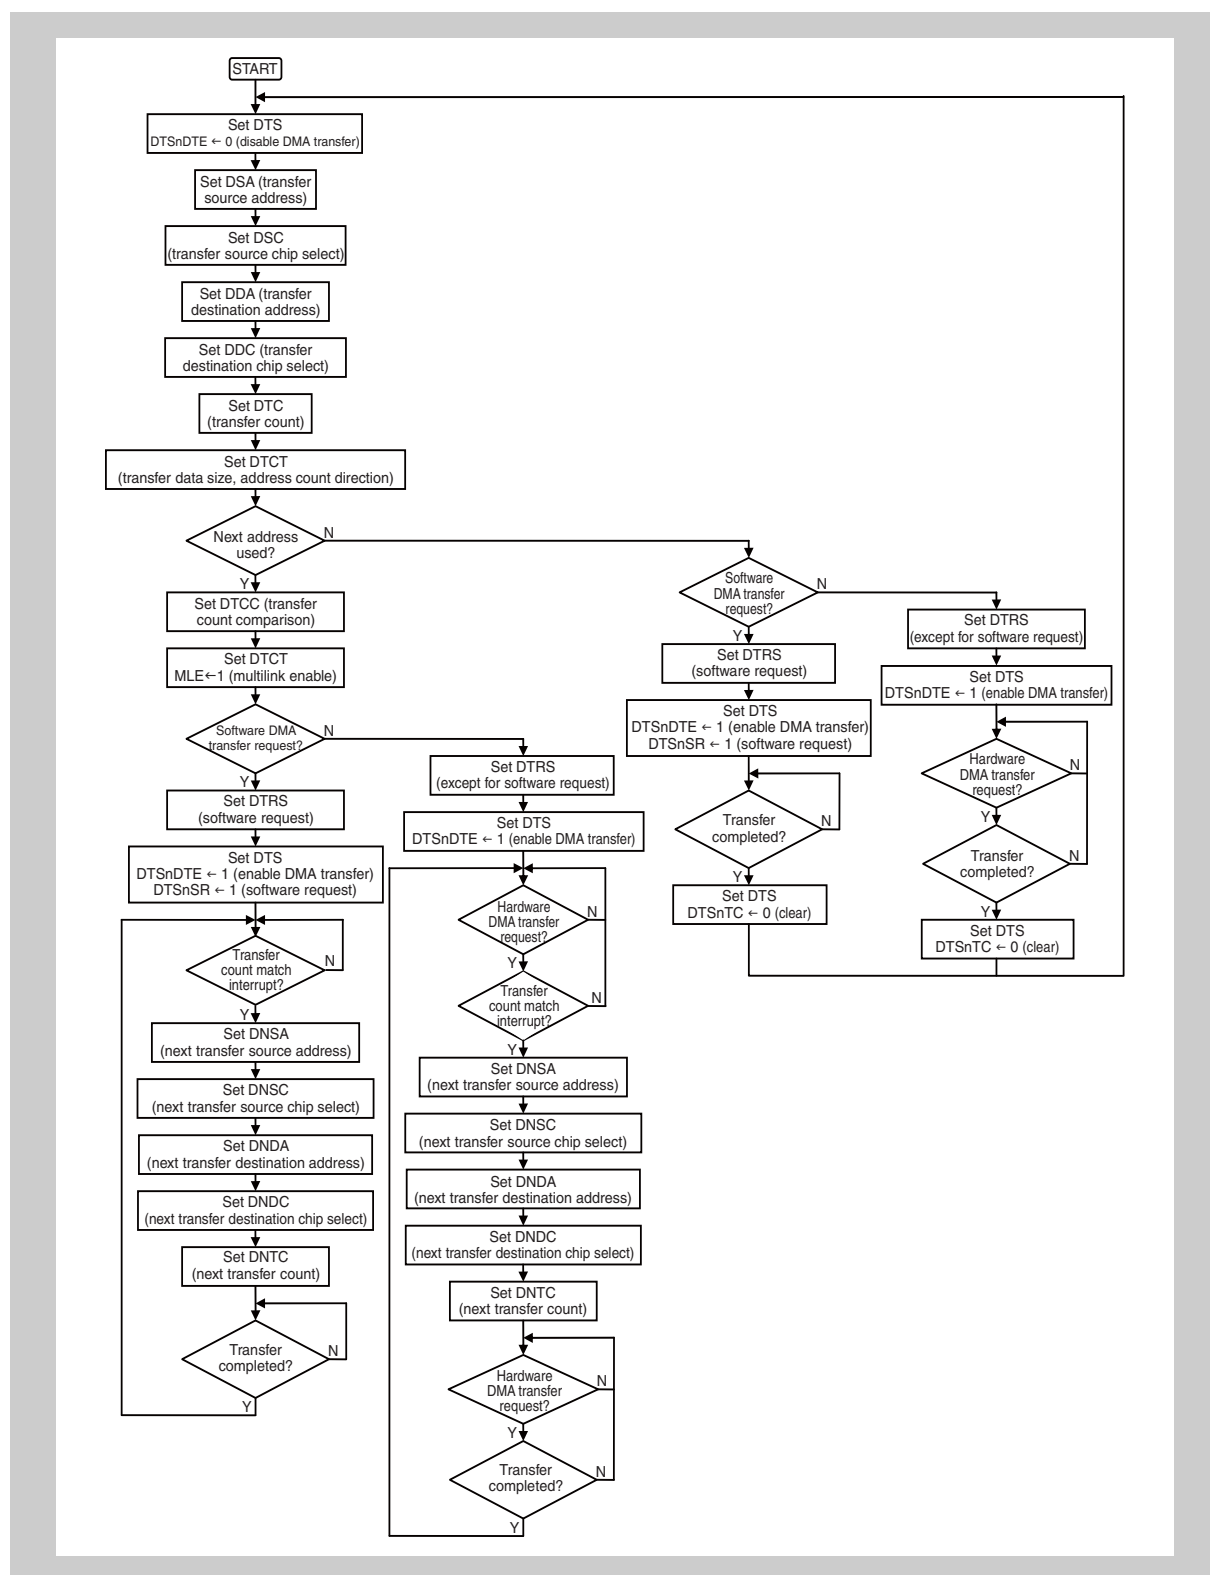

Figure 10-3 DMAC transfer setting flow

10.6.2 DMAC transfer modes

A single-transfer mode and a single-step transfer mode are supported as transfer modes.

In either mode, transfer is executed in two cycles (dual address transfer) and therefore, a read cycle and a write cycle are generated each time transfer is executed. In the case of 128-bit transfer, the read cycle is generated four times and the write cycle is generated four times, in that order.

Note that the bus is not locked. Consequently, a CPU cycle may interrupt between the read and write cycles, and between the four read cycles and four write cycles during 128-bit transfer.

(1) Single transfer mode (when hardware DMA transfer request is generated)

When a hardware DMA transfer request is acknowledged, data of the transfer data size (8, 16, 32, or 128 bits) is transferred. Each time transfer has been executed, the bus is released and the DMA controller waits for a DMA transfer request. At this time, the acknowledge n signal that indicates that the hardware DMA transfer request has been acknowledged is also output ($n = 7$ to 0).

Each time a hardware DMA transfer request has been acknowledged, transfer is executed once. This operation is repeated the number of times specified by the DMA transfer count register n (DTCn) ($n = 7$ to 0).

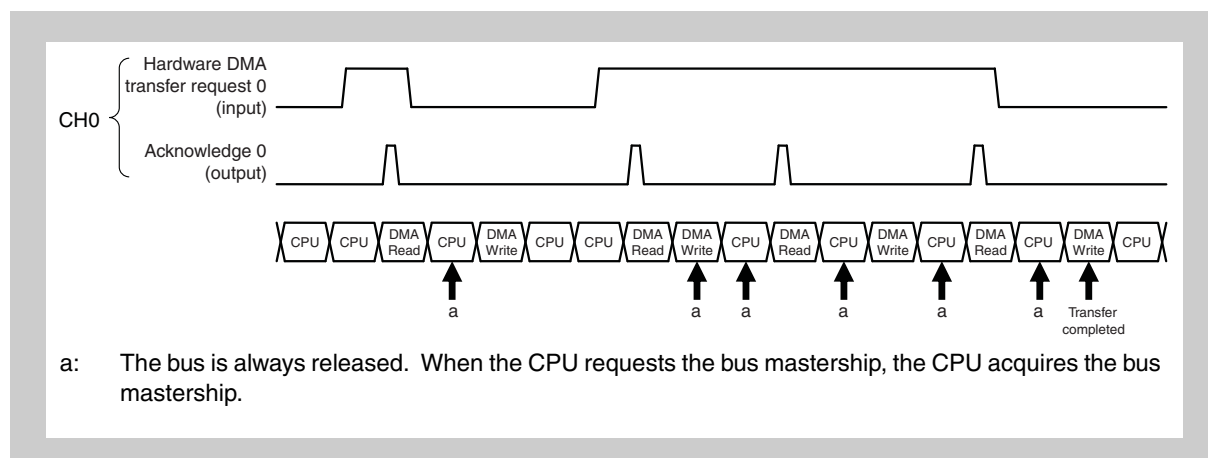

Figure 10-4 Example of single transfer (8/16/32 bits)

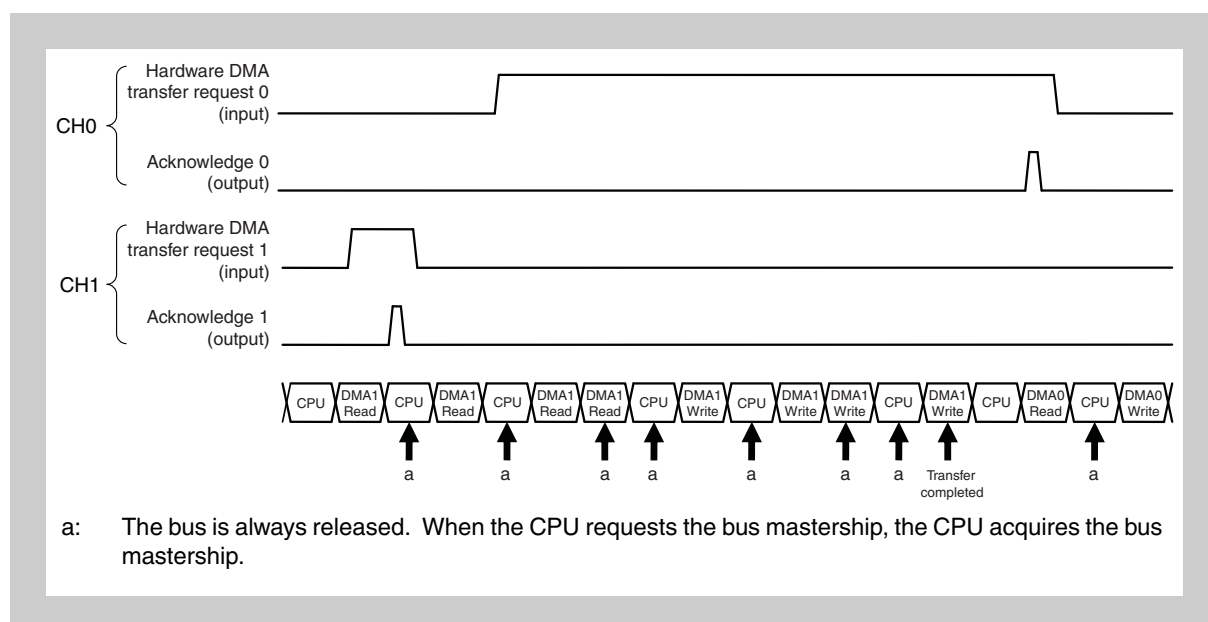

Figure 10-5 Example of single transfer (128 bits, DMA channel priority: CH0 (high) > CH1 (low))

(2) Single-step transfer mode (when software DMA transfer request is generated)

When a software DMA transfer request is acknowledged, data of the transfer data size (8, 16, 32, or 128 bits) is transferred. Each time transfer has been executed, the bus is released. At this time, the acknowledge signal that indicates that a hardware DMA transfer request has been acknowledged is not output ($n = 7$ to 0).

Once a software DMA transfer request has been acknowledged, this operation is repeated the number of times specified by the DMA transfer count register n (DTCn) ($n = 7$ to 0). Because the priority is identified each time transfer is executed, the DMA cycle of a channel having the higher priority may interrupt.

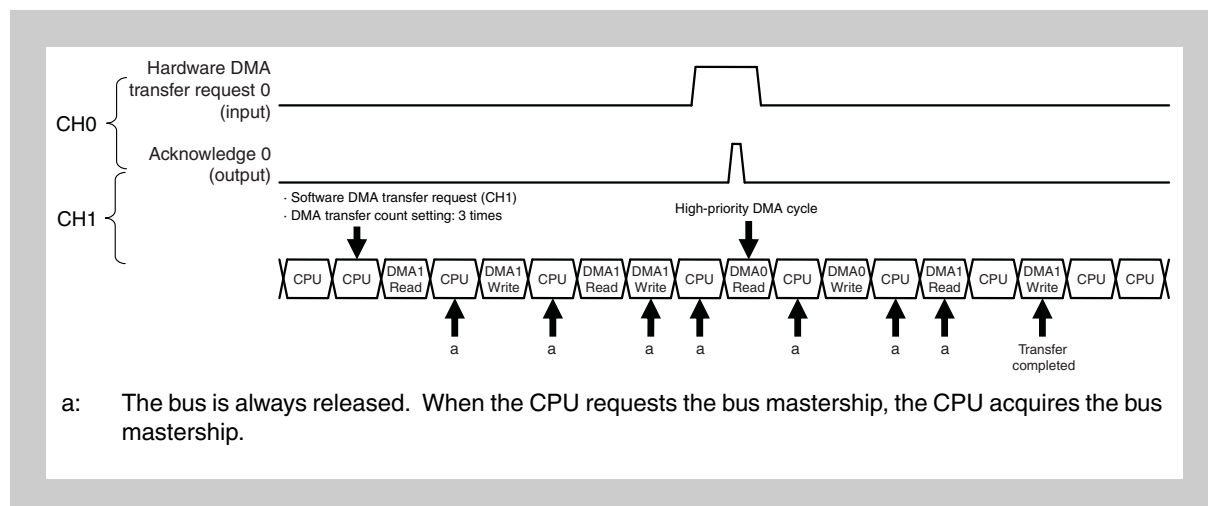

Figure 10-6 Example of single-step transfer (8/16/32 bits, DMA channel priority: CH0 (high) > CH1 (low))

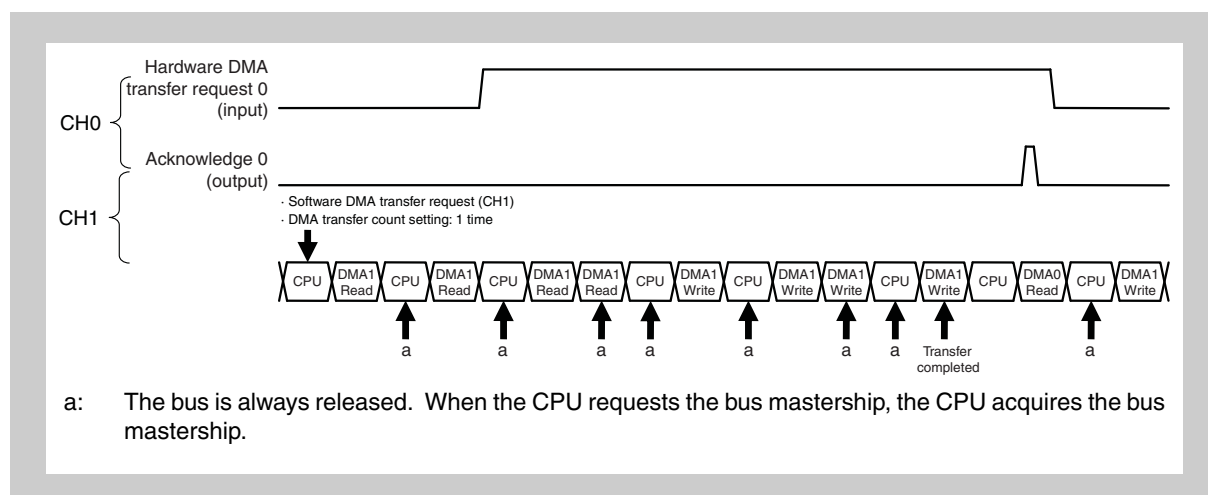

Figure 10-7 Example of single-step transfer (128 bits, DMA channel priority: CH0 (high) > CH1 (low))

10.6.3 DMAC channel priority control

The priority of each channel is fixed and is as follows.

DMAC0: CH0 > CH1 > CH2 > CH3 > CH4 > CH5 > CH6 > CH7

If another DMA transfer request with a high priority is generated, the DMA transfer request with the higher priority always takes precedence. When a software DMA transfer request is generated, the bus is also released each time a DMA cycle has been completed. If a DMA transfer request with a high priority is generated, therefore, the DMA transfer request with the higher priority always takes precedence.

An example where another DMA transfer request with a high priority is generated when DMA transfer is executed is shown below.

Figure 10-8 Example of priority control

10.6.4 Valid DMA transfer request conditions

Whether a DMA transfer request of channel *n* is acknowledged depends on the setting of the DTRCxERR and DTRCxADS bits of the DMA transfer request control register (DTRCx), the MLE bit of the DMA transfer control register (DTCTn), and the DTSnTC and DTSnDTE bits of the DMA transfer status register (DTSn). Table 10-28 “Valid DMA transfer request conditions of channel *n*” shows the relationship between the setting of each of the above bits and whether a DMA transfer request is acknowledged.

Table 10-28 Valid DMA transfer request conditions of channel *n*

Register.bit name	DTSn. DTSnDTE	DTSn. DTSnTC	DTCTn.MLE	DTRCx. DTRCxERR	DTRCx. DTRCxADS	DMA transfer request
When DMA transfer is disabled	0	×	×	×	×	Invalid
When DMA transfer error occurs	×	×	×	1	×	Invalid
When DMA transfer is aborted	×	×	×	×	1	Invalid
When DMA transfer is completed (multilink disabled)	×	1	0	×	×	Invalid
When DMA transfer is completed/not completed (multilink enabled)	1	×	1	0	0	Valid
When DMA transfer is enabled	1	0	0	0	0	Valid

Note *n* = 0 to 7

10.6.5 Next address function

(1) Next address setting register

This register is used to set beforehand the transfer information to be transferred next during DMA transfer. This information is copied to the corresponding register at the start of the last DMA cycle. The following registers are provided.

- DMA next source address register (DNSAnH/DNSAnL)
- DMA next source chip select register (DNSCn)
- DMA next destination address register (DNDAH/DNDAnL)
- DMA next destination chip select register (DNDCn)
- DMA next transfer count register (DNTCn)

Each one of these registers has a valid bit in the most significant position (address register: most significant bit on H side), and whether to copy the transfer information to the current register at the start of the last DMA cycle can be selected. When the transfer information to be transferred next is copied to the current register, the valid bit is cleared.

(2) Processing upon DMA transfer completion when using next address function

Normally, upon completion of DMA transfer, the DMA transfer enable bit (DTSnDTE) is cleared at the same time the DMA transfer completion status bit (DTSnTC) of the DMA transfer status register (DTSn) is set, and subsequent DMA transfer requests are no longer acknowledged. However, if the multilink enable bit (MLE) is set, DTSnDTE is not cleared and DMA transfer requests can be acknowledged even if DTSnTC is set. Therefore, when using the next address function, it is possible to eliminate the need to clear DTSnTC upon DMA transfer completion and set DTSnDTE by setting MLE.

(3) Timing at which next address is set

The next address setting register can always be rewritten. However, to prevent a conflict between copying to the current register and a write operation by the user, complete setting the next address setting register before the last DMA cycle starts.

Use of the DMA transfer count match interrupt is recommended as the trigger for setting the next address setting register. In this case, set the DMA transfer count compare register (DTCCn) so as to secure the time required for setting the next address setting register.

10.6.6 Aborting/resuming DMA transfer

(1) Aborting or resuming DMA transfer for all channels through software

By setting the DMA transfer abort bit (DTRCxADS) of the DMA transfer request control register (DTRCx), the next DMA transfer and those that follow can be aborted. During a DMA cycle, the next DMA transfer is aborted after the ongoing DMA cycle has been completed. Note that the DMA transfer enable bit (DTSnDTE) and the software DMA transfer request bit (DTSnSR) of the DMA transfer status register (DTSn) are not cleared.

To resume the aborted DMA transfer, clear the DTRCxADS bit. If a DMA transfer is requested at that point, the transfer of the channel having the highest priority at that time is executed. To end DMA transfer, clear the DMA transfer request with the DTSnDTE bit cleared.

(2) Aborting or resuming DMA transfer by using DMA transfer enable bit (DTSnDTE)

By clearing the DMA transfer enable bit (DTSnDTE) of the DMA transfer status register (DTSn), the next DMA transfer and those that follow can be aborted. During a DMA cycle, the next DMA transfer is aborted after the ongoing DMA cycle is completed. Note that the software DMA transfer request bit (DTSnSR) of DTS is not cleared.

To resume the aborted DMA transfer, set the DTSnDTE bit. If another channel is not executing DMA transfer at that point, the priority is identified as usual. If another channel is executing DMA transfer, the priority is identified after that transfer has been completed. To end DMA transfer, clear the DMA transfer request with the DTSnDTE bit cleared.

(3) Aborting or resuming DMA transfer by using software DMA transfer request bit (DTSnSR)

By clearing the software DMA transfer request bit (DTSnSR) of the DMA transfer status register, the next DMA transfer and those that follow can be aborted (DTSn). During a DMA cycle, the next DMA transfer is aborted after the ongoing DMA cycle has been completed.

To resume the aborted DMA transfer, set the DTSnSR bit. If another channel is not executing DMA transfer at that point, the priority is identified as usual. If another channel is executing DMA transfer, the priority is identified after that transfer has been completed.

10.6.7 Error response support

(1) Aborting DMA transfer by error response

When an error occurs at the DMA transfer source or transfer destination, the DMA transfer abort bit (DTRCxADS) of the DMA transfer request control register (DTRCx) is set to abort the next and subsequent DMA transfers. At the same time, the DMA transfer error status bit (DTRCxERR) is set and a SysError exception is generated by the CPU. The user can learn in which channel the error has occurred, by using the DMA transfer error flag (DTSnER) of the DMA transfer status register (DTSn), when the user has confirmed that DTRCxERR has been set.

In this case, note that, if an error response is acknowledged in the read cycle, the write cycle is not executed, but the transfer address and the transfer count are updated.

(2) Canceling transfer abort by error response

DMA transfer abort can be canceled by clearing the DMA transfer abort bit (DTRCxADS) and DMA transfer error status bit (DTRCxERR) of the DMA transfer request control register (DTRCx).

Clear the DMA transfer enable bit (DTSnDTE) of the DMA transfer status register (DTSn) in advance, so that DMA transfer is not resumed after its abort has been canceled. In the case of a software DMA transfer request, also clear the software DMA transfer request bit (DTSnSR).

10.7 DTFR Function

The DMA trigger factor register (DTFR) selects DMA trigger factors from among interrupt signals, and requests DMAC for DMA transfer. DTFR_n (n = 7 to 0) registers are included for selecting the signals to be used for DMA transfer requests from among the 128 input interrupt signals.

10.7.1 Features

- Number of transfer factors** DMA transfer requests (for 16 channels) are selected from among 128 interrupt signals.
- DMAC interface** The DMA transfer request signal n (n = 7 to 0) is output.
The DMA transfer request signal n is cleared by an acknowledge signal from DMA.
- CPU interface** The last transfer signal from DMA is output as a CPU interrupt signal.
- Clearing of transfer request** A function that clears transfer request signals sent to DMA through register access is provided.
- Confirmation of transfer request** A function that checks transfer request signals sent to DMA through register access is provided.

10.8 DTFR Control Registers

10.8.1 DTFRn (n = 0 to 7): DTFRn register

Access This register can be read or written in 16-bit units.

Address DTFR0: FFFF 7B00_H, DTFR1: FFFF 7B02_H, DTFR2: FFFF 7B04_H,
DTFR3: FFFF 7B06_H, DTFR4: FFFF 7B08_H, DTFR5: FFFF 7B0A_H,
DTFR6: FFFF7B0C_H, DTFR7: FFFF 7B0E_H

Initial Value 0000_H

Table 10-31 DRQSTR register contents

Bit position	Bit name	Function
15:0	RQST15 to RQST0	DMA transfer request status flag 1: Request issued (DMA transfer request signal n is "1".) 0: No request (DMA transfer request signal n is "0".)

10.9 DTS Function

The data transfer service (DTS) does not include registers for setting transfer information (TI). Consequently, each time a transfer request is generated, TI corresponding to the request number is fetched (read from internal RAM), and the transfer request for the TI is then sent to DMAT to execute data transfers, etc.

10.9.1 Features

Number of channels	Number of channels is freely set (channels 1 to 128)
Transfer data size	8 bits, 16 bits, and 32 bits
Transfer data	Fixed to little endian Misaligned data not supported
Maximum transfer count	When the DTS transfer count register is used as a 16-bit register: 65535 times When the DTS transfer count register is split into two 8-bit registers: $255 \times n$: (n indicates no limitation) Therefore, the number of transfers is not limited.
Channel priority control	No priority control function is provided (control must be done outside of DTS).
Subject to transfer	Internal flash memory Internal RAM External memory area P-bus peripheral I/O area H-bus peripheral I/O area
Chain function	This function enables DTS to be started multiple times by one request. After writing back TI, other TI is continuously fetched, so that data transfer (etc.) can be executed.

-
- Transfer type**
- 2-cycle transfer (dual address transfer) function

After TI is fetched, data is read from the transfer source, and then the read data is written to the transfer destination. Afterward, updated TI is written back. This operation is the same as a DMA transfer, except for the TI fetch and write back. Since the bus remains unlocked during all cycles, a CPU cycle may interrupt.
 - Compare function

After TI is fetched, data is read from the comparison source and the comparison destination, and these two data are then compared. Afterward, updated TI is written back. A true/false judgment of the compare results can then be used to select whether to output an interrupt to the CPU or to continue processing using the chain function.
 - Flag check function (bit check function)

This function is used to check whether any data bit is “1” or “0”. After TI is fetched, mask data for flag checking and flagged check data are read, then any bit is determined. Afterward, the updated TI is written back. A true/false judgment of the flag check results can then be used to select whether to output an interrupt to the CPU or to continue processing using the chain function.
- Transfer count register split mode**
- Split

In this mode, the 16-bit transfer count register is split into upper (8 bits) and lower (8 bits) sides which are used separately. The lower side is used as a transfer count register and the upper side is used as a transfer count hold register. Although the maximum transfer count is 255 times, when the lower side is zero, the upper side's values can be copied to the lower side, so transfers can be performed continuously without resetting the transfer count.
 - Combined

The entire 16 bits of the transfer count register are used. The maximum transfer count is 65535 times.
- Transfer mode**
- Single transfer mode

When a DTS transfer request is generated, one DTS cycle is performed. Afterward, when a DTS transfer request is generated, another DTS cycle is performed. This operation is repeated until the transfer count register value reaches “0”.
 - Block transfer mode

When a DTS transfer request is generated, the number of DTS cycles specified in the transfer count register is performed. Other DTS transfer requests are not accepted until the number of DTS cycles specified in the transfer count register is completed. However, because the bus is not locked, a CPU cycle may interrupt.
- Transfer address control**
- Incremental
 - Decremental
 - Fixed

Transfer error support	When an error response from the internal system bus occurs, the DTS cycle is aborted and an error flag is set. Also, a SysError exception is generated.
Interrupt output function	An interrupt source signal is output (by the DTSFSL function) when the number of DTS transfers specified in the bus cycle count register has been completed, or depending on a flag check result and a compare result.
DTS transfer abort function	This function supports aborting DTS transfer by software, but not by hardware.

10.10 DTS Control Registers

DTS uses the following control registers to control operation settings.

The DTS's registers include registers that can be accessed from the CPU (register group A) and internal registers that cannot be accessed from the CPU (register group B). Transfer information read from internal RAM is stored in the DTS internal register.

Register group B is comprised of DTS0SAR, DTS0DAR, DTS0TCEA, DTS0CIR, DTS0SCS, DTS0DCS, and DTS0ECSRA.

Table 10-32 List of DTS control registers

	Address ^a	Symbol	Function register name	R/W	Operable bits			Initial value
					8	16	32	
Register group A	FFFF7C00 _H	DTS0TSR	DTS transfer status register	R	√	–	–	00 _H

Register group B	–	DTS0SAR	DTS source address register	–	–	–	–	00000000 _H
	–	DTS0DAR	DTS destination address register	–	–	–	–	00000000 _H
	–	DTS0TCEA	DTS transfer counter or else address register	–	–	–	–	0000 _H
	–	DTS0CIR	DTS control information register	–	–	–	–	0000 _H
	–	DTS0SCS	DTS source address count size register	–	–	–	–	00 _H
	–	DTS0DCS	DTS destination address count size register	–	–	–	–	00 _H
	–	DTS0ECSRA	DTS extension address count size/ repeat address register	–	–	–	–	00000000 _H

- a) If an address that is not mapped to DTS is accessed, write operations are ignored and a zero is returned when read.

10.10.1 DTS0TSR: DTS transfer status register [register group A]

Access This register is read-only, in 8-bit units.

Address FFFF 7C00_H

Initial Value 00_H

7	6	5	4	3	2	1	0
0	0	0	0	0	0	DTS0STPE	DTS0STPU
R	R	R	R	R	R	R	R

Table 10-33 DTS0TSR register contents

Bit position	Bit name	Function
1	DTS0STPE	DTS SToPped by Error response (DTS transfer abort by error response) This bit indicates whether a DTS transfer is aborted by an error response received from the transfer target. When an error response is received, "1" is set to this bit and a SysError exception is generated to abort the DTS transfer. When this bit is "1", no transfers are accepted. This is a read-only bit. To clear this bit, write "1" to the DTS0ECL bit in the DTS0TRC register.
0	DTS0STPU	DTS SToPped by User request (DTS transfer abort by user request) This bit indicates whether a DTS transfer is aborted by a user request. "1" is set to this bit by writing "1" to the DTS0UST bit in the DTS0TRC register, and transfer is aborted. When this bit is "1", no transfers are accepted. This is a read-only bit. To clear this bit, write "1" to the DTS0UCL bit in the DTS0TRC register.

10.10.2 DTS0TRC: DTS transfer request control register [register group A]

Access This register can be read or written in 8-bit units.

Address FFFF 7C04_H

Initial Value 00_H

	7	6	5	4	3	2	1	0
DTS0UST	0	0	0	0	0	0	DTS0ECL	DTS0UCL
	W	R	R	R	R	R	W	W

Table 10-34 DTS0TRC register contents

Bit position	Bit name	Function
7	DTS0UST	DTS User request STop Trigger (DTS abort request trigger bit) This is the transfer interrupt request trigger for all DTS channels. When "1" is written to this bit, the DTS0STPU bit in DTS0TSR is set to "1" and DTS transfer is aborted. This bit is always "0" when read, and writing "0" to this bit is ignored. When this bit and DTS0UCL are set to "1" at the same time, this bit takes priority.
1	DTS0ECL	DTS dts0stpE CLear Trigger (DTS0STPE clear request trigger bit) This is the clear request trigger bit for the DTS0STPE bit in DTS0TSR. When this bit is set to "1", the DTS0STPE bit in DTS0TSR is cleared to "0", and DTS transfers can be accepted. This bit is always "0" when read, and writing "0" to this bit is ignored.
0	DTS0UCL	DTS dts0stpU CLear Trigger (DTS0STPU clear request trigger bit) This is the clear request trigger bit for the DTS0STPU bit in DTS0TSR. When this bit is set to "1", the DTS0STPU bit in DTS0TSR is cleared to "0", and DTS transfers can be accepted. If a transfer has been aborted, the aborted transfer is restarted. This bit is always "0" when read, and writing "0" to this bit is ignored.

10.10.3 DTS0ICR: DTS initialization control register [register group A]

Access This register can be read or written in 16-bit units.
However, when the higher 8 bits and lower 8 bits of the DTS0ICR register are used as the DTS0ITR register and DTS0ICH register, respectively, this register can be read or written in 8-bit units.

Address DTS0ICR: FFFF 7C08_H, DTS0ITR: FFFF 7C09_H, DTS0ICH: FFFF 7C08_H

Initial Value 0000_H

- DTS0ICR

15	14	13	12	11	10	9	8
0	0	0	0	0	DTS0ICS	DTS0HIT	DTS0TIT

R	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 10-35 DTS0ICR register contents

Bit position	Bit name	Function
10	DTS0ICS	DTS Initialization Continuous Status (transfer abort status flag) This status flag indicates whether the DTS transfer is being aborted. When this flag is "1", writing to this register is prohibited (writing to this register is ignored). When DTS0HIT or DTS0TIT in this register is set to "1", this bit is set to "1". When the transfer abort processing requested by using DTS0HIT or DTS0TIT in this register is completed, this bit is cleared. 0: Normal status 1: Transfer is being aborted.
9	DTS0HIT	DTS Hold Initialization Trigger (transfer abort and TI hold buffer initialization trigger bit) This is the trigger bit used to request aborting the current DTS transfer and clearing of all TI held in DTS. When "1" is written to this bit, all the held TI is cleared once the DTS cycle is completed. While waiting for the DTS cycle to be completed, the DTS0ICS bit is set to "1". This bit is always "0" when read.
8	DTS0TIT	DTS Transfer Initialization Trigger (transfer abort trigger bit) This is the trigger bit used to request aborting the DTS transfer for the channel specified by the DTS0ICH6 to DTS0ICH0 bits in this register. When "1" is written to this bit the channel for current DTS transfer is compared with the channel specified by the DTS0ICH bit, once the DTS cycle is completed. If the two match, all subsequent transfers are stopped. While waiting for the DTS cycle to be completed, the DTS0ICS bit is set to "1". If TI hold is set for the specified channel, the TI hold is also cleared. This bit is always "0" when read.
6:0	DTS0ICH6 to DTS0ICH0	DTS Initialization CHannel (initialization stop request channel) This bit specifies the channel for which initialization is to be aborted by the DTS0TIT bit. "1" can be written to these bits at the same time as when writing "1" to the DTS0HIT and DTS0TIT bits in this register.

10.10.4 DTS0BTR: DTS base table register [register group A]

Access This register can be read or written in 32-bit units.

Table 10-42 DTS0DAR register contents

Bit position	Bit name	Function
28:0	DTS0DAR28 to DTS0DAR0	Destination Address Register (destination address register) These bits comprise the destination address register. Bits 31 to 29 are fixed to "0".

Caution DTS transfer of misaligned data is not supported. The lower 2 bits of an address corresponding to the transfer data size are as follows (× indicates any bit).

Operation is not guaranteed if a setting other than the following is made.

Data size	DTS0DAR1	DTS0DAR0
8 bits	×	×
16 bits	×	0
32 bits	0	0

10.10.11 DTS0TCEA: DTS transfer counter or else address register [register group B]

This register is a DTS internal register. It is neither write-accessible nor read-accessible from the CPU.

Access —

Address —

Initial Value 0000_H

(1) Transfer count 255 mode

Table 10-43 DTS0TCEA register contents for transfer count 255 mode

Bit position	Bit name	Function
15:8	DTS0STR7 to DTS0STR0	Short Transfer Number Register (transfer count hold register) During transfer count 255 mode, this register holds the transfer count. If a DTS request is generated when the DTS0STC bit is "0", the contents of this register are copied to the DTS0STC bit.
7:0	DTS0STC7 to DTS0STC0	Short Transfer Counter (short transfer count register) During transfer count 255 mode, this register counts the transfer count. The count is decremented once per DTS cycle. When 1 is set, one DTS is triggered, and when FFH is set, 255 DTS cycles are triggered. When the value of this register reaches "0", an interrupt occurs (or the chain function can be selected). Continued execution of transfers can be selected. If a DTS request is generated when this register is "0", the contents of the DTS0STR bits are copied to this register, and another decrementation count is performed.

(2) Transfer count 65535 mode

Table 10-44 DTS0TCEA register contents for transfer count 65,535 mode

Bit position	Bit name	Function
15 to 0	DTS0LTC15 to DTS0LTC0	Long Transfer Counter (long transfer count register) During transfer count 65535 mode, this register counts the transfer count. The count is decremented once per DTS cycle. When 1 is set, one DTS is triggered, and when FFFFH is set, 65,535 DTS cycles are triggered. When the value of this register reaches "0", an interrupt occurs (or the chain function can be selected).

(3) Extended chain mode**Table 10-45 DTS0TCEA register contents for extended chain mode**

Bit position	Bit name	Function
15:0	DTS0EA15 to DTS0EA0	Else Address (ELSE address) During extended chain mode, this register specifies the position of TI that is read when the condition is false (ELSE). To specify the TI position, set an offset using this register from the current position (TI-A address where the extended chain is specified). The value is specified as a signed 16-bit value from -32,768 to 32,760 (lower 3 bits are 3'b000).

10.10.12 DTS0SCS: DTS source address count size register [register group B]

This register is a DTS internal register. It is neither write-accessible nor read-accessible from the CPU. When DTS0IMM in DTS0CIR is “1”, the following operations are performed.

- When the data size indicated by DTS0DS1 and DTS0DS0 in DTS0CIR is 32 bits:
DTS0SCS becomes “0”.
- When the data size indicated by DTS0DS1 and DTS0DS0 in DTS0CIR is 16 bits:
DTS0SAR (IMM15 to IMM0) is counted (incremented/decremented) by DTS0SCS.
- When the data size indicated by DTS0DS1 and DTS0DS0 in DTS0CIR is 8 bits:
DTS0SAR (IMM7 to IMM0) is counted (incremented/decremented) by DTS0SCS.

However, when in SG mode, this register's settings are ignored.

Bit position	Bit name	Function
15	DTS0CAF	Condition Accumulation Flag This is the flag check and comp check result accumulation flag. When the results of a flag check or comp check (comparison) are false, DTS0CAF is set to “1” and this value is written back to TI-A. If this bit is “1” when TI-A is read, then “1” must be written back. Condition for setting (to “1”): <ul style="list-style-type: none"> • When compare result is false. • When flag check result is false. • When DTS0CAF read data is “1” (bit 15 is “1” at TI-A fetch). In other words, when “1” is set to bit 15 of TI-A, the value of DTS0CAF remains “1”. Condition for clearing (to “0”): <ul style="list-style-type: none"> • When the DTS0CAF bit read data is “0” (bit 15 is “0” at TI-A fetch).
14	DTS0DPE1	Destination select PE1 (destination PE1 select) This bit specifies the address range on the destination side. 0: Selects external memory area, P-bus peripheral I/O area, and H-bus peripheral I/O area. 1: Selects internal flash memory and internal RAM.
13	DTS0SPE1	Source select PE1 (source PE1 select) This bit specifies the address range on the source side. 0: Selects external memory area, P-bus peripheral I/O area, and H-bus peripheral I/O area. 1: Selects internal flash memory and internal RAM.
12	DTS0DISI	DISable Interruption (interrupt output disabled) This bit prohibits interrupt requests for DTSFSL. 0: Interrupt enabled. 1: Interrupt disabled.
11 10	DTS0CM1 DTS0CM0	Chain Mode (chain mode) 00: Does not perform a chain of transfers. [if (counter==0) then Interrupt else no operation] 01: Performs a chain of transfers when counter = 0. [if (counter==0) then chain & Interrupt else no operation] 10: Performs a chain of transfers if true. [if (true) then chain else Interrupt] 11: Always perform a chain of transfers.

Table 10-48 DTS0CIR register contents (2/2)

Bit position	Bit name	Function
9 8	DTS0DS1 DTS0DS0	Data Size (data size) These bits set the data size for transfer, compare, and flag check. 00: 8 bits 01: 16 bits 10: 32 bits 11: Setting prohibited
7	DTS0BEN	Block Enable This is the block enable signal. 0: Single mode 1: Block mode
6	DTS0IMM	IMMEDIATE enable (immediate function) This bit enables/disables the immediate function. When the immediate function is enabled, DTS0SAR functions as the immediate register. 0: Immediate disabled 1: Immediate enabled
5 4 3 2 1 0	DTS0TTYP5 DTS0TTYP4 DTS0TTYP3 DTS0TTYP2 DTS0TTYP1 DTS0TTYP0	Transfer TYPE (transfer type select) These bits select the transfer type. When a transfer type is selected, a special function and transfer count are selected at the same time. See 10.11.5 "Transfer types" for the list of transfer types.

10.10.15 DTS0ECSRA: DTS extension address count size/repeat address registers [register group B]

These registers are DTS internal registers. They are neither write-accessible nor read-accessible from the CPU.

Access —

Address —

Initial Value 0000 0000_H

(1) SG (Scatter & Gather) mode

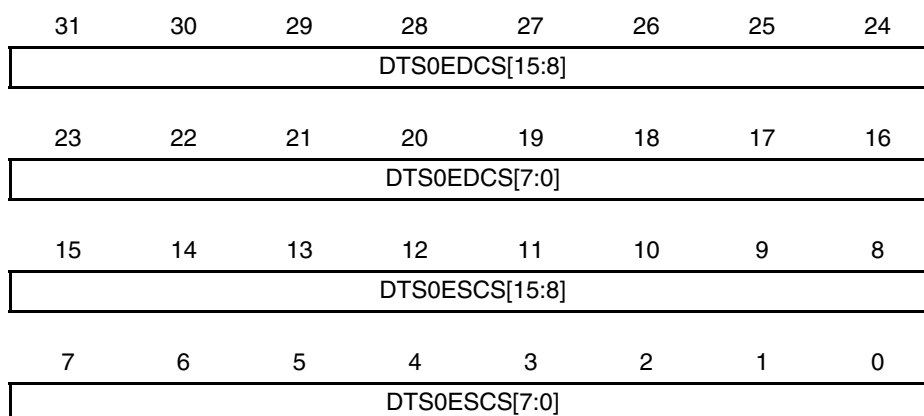

Table 10-49 DTS0ECSRA register contents for SG (Scatter & Gather) mode

Bit position	Bit name	Function
31:16	DTS0EDCS15 to DTS0EDCS0	These bits specify the count size for the destination address. Any signed 16-bit value from -32,768 to 32,767 can be specified. This register is valid only when SG mode is selected by the DTS's special function. When not in SG mode, the count size is determined by DTS0DCS.
15:0	DTS0ESCS15 to DTS0ESCS0	This bit specifies the count size for the source address. Any signed 16-bit value from -32,768 to 32,767 can be specified. This register is valid only when SG mode is selected by the DTS's special function. When not in SG mode, the count size is determined by DTS0SCS.

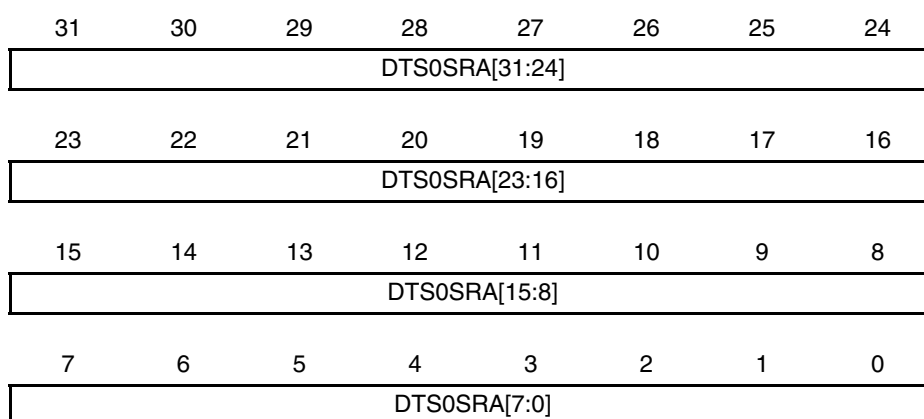

(2) SREP (Source Repeat) mode

Table 10-50 DTS0ECSRA register contents for SREP (Source Repeat) mode

Bit position	Bit name	Function
31 to 0	DTS0SRA31 to DTS0SRA0	These bits comprise an area where the repeat address is held. The source repeat becomes valid only when SREP is selected by the DTS's special function.

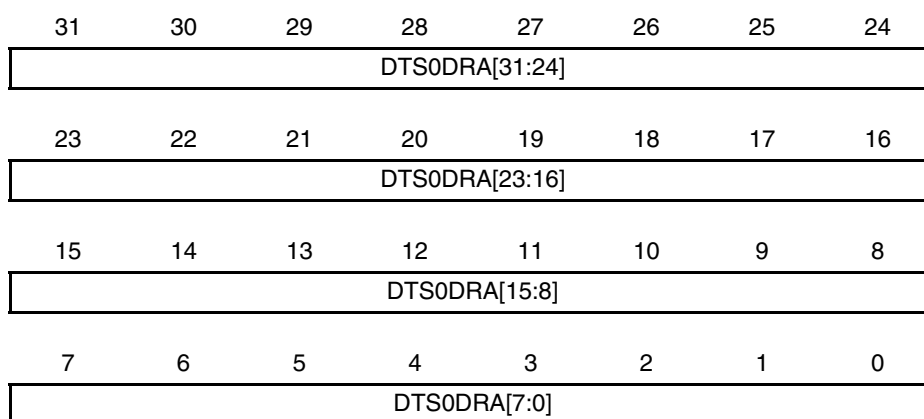

(3) DREP (Destination Repeat) mode

Table 10-51 DTS0ECSRA register contents for DREP (Destination Repeat) mode

Bit position	Bit name	Function
31 to 0	DTS0DRA31 to DTS0DRA0	These bits comprise an area where the repeat address is held. The destination repeat becomes valid only when DREP is selected by the DTS's special function.

10.11 DTS Function Details

10.11.1 Transfer information (TI)

DTS internal registers (register group B) cannot be operated directly from an external source. The DTS reads transfer information from internal RAM, and then sets values to the internal registers. This transfer information is called TI.

TI is configured of either 96 bits (TI-A to TI-C) or 128 bits (TI-A to TI-D), and the setting in DTS0CIR.DTS0TTYP5 to DTS0CIR.DTS0TTYP0 determines which type is used.

“TI0” refers to a set of “TI-A, TI-B, and TI-C” or a set of “TI-A, TI-B, TI-C, and TI-D”. “TI0, TI1, TI2” indicates there are three sets of “TI-A, TI-B, and TI-C” or “TI-A, TI-B, TI-C, and TI-D”.

(1) Configuration of TI

Each TI should be 32-bit aligned (the lower 2 bits of the address are 00).

The 128 bits from TI-A to TI-D should be allocated to internal RAM1 as one set.

Caution TI can only be allocated to internal RAM1, not internal RAM2.

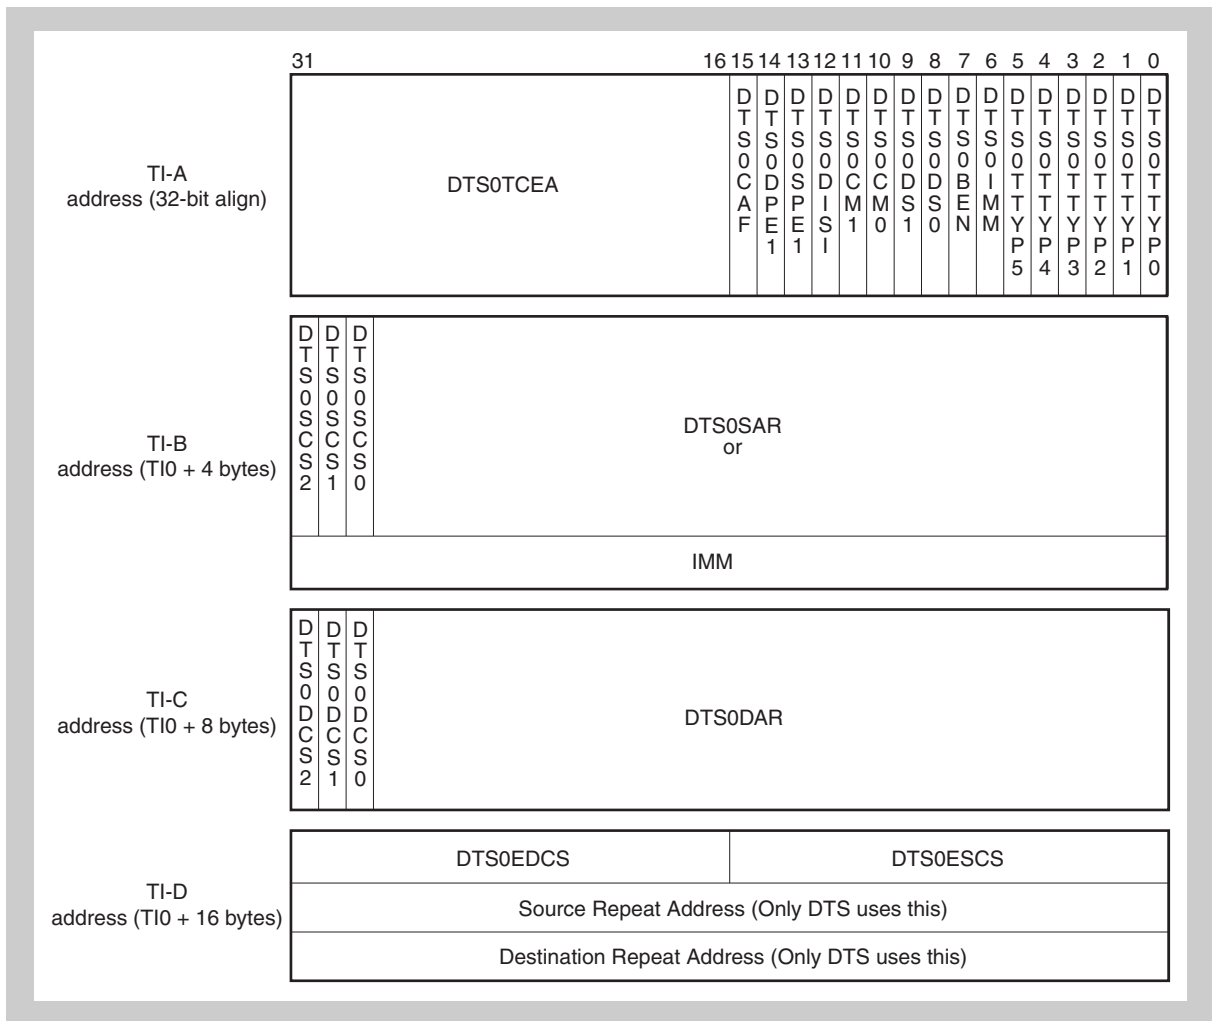

Figure 10-9 Configuration of TI

(2) Address where TI is allocated

The DTS uses DTS0BTR and DTS0BVR to determine the TI address corresponding to a channel.

TI can be freely allocated anywhere in the range from the address specified by DTS0BVR to the address to which FFFCH is added.

The method for determining DTS's TI address is as follows.

1. A 16-bit offset address is read from the table address [table address = DTS0BTR + channel number x 2] (the lower 2 bits of the offset address are ignored).
2. TI is read from the vector address [TI address = DTS0BVR + offset address]. In this case as well, the lower 2 bits are fixed to 00.

In the following figure, in which the request from CH3 is used as an example, the data for table address ($1EC0_1000_H + 4 \times 2$) is 0320_H and the vector address is $DTS0BVR + 0320_H$.

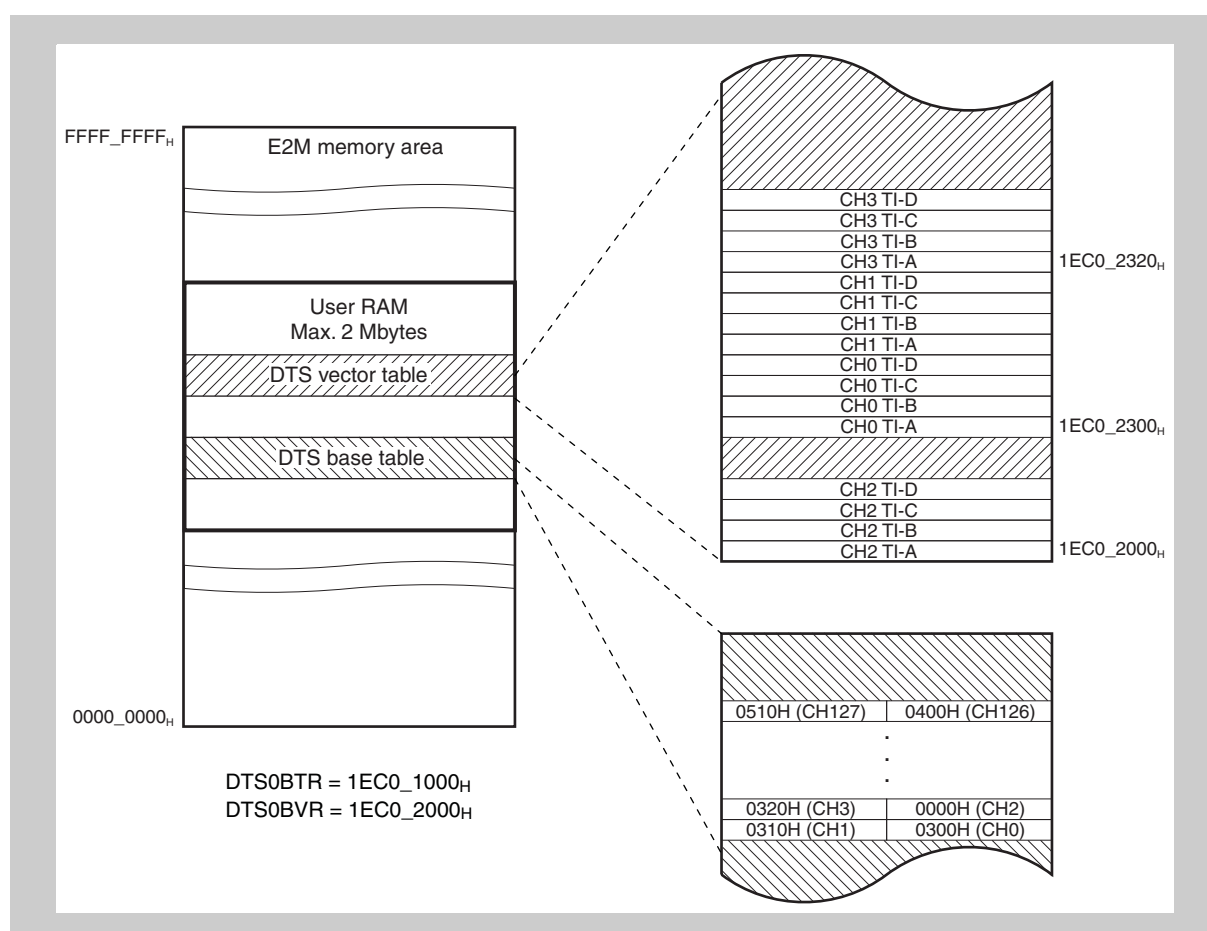

Figure 10-10 Example of address where TI is allocated

(3) Base table

The DTS references a base table to find the TI's position. This base table must be created by the user. The address set by DTS0BTR is the base table's start address, and 16 bits are allocated for each address, starting from channel 0. Data set to the table is offset from the DTS0BVR value (the offset range is 0 to 65,524 when using TI-A, TI-B, and TI-C and 0 to 65,520 when using TI-A, TI-B, TI-C, and TI-D).

Figure 10-11 Description of base table

10.11.2 DTS transfer setting flow

Figure 10-12 “DTS transfer setting flow” shows the flow for setting DTS transfer by hardware when DTSEN is enabled after TI is set.

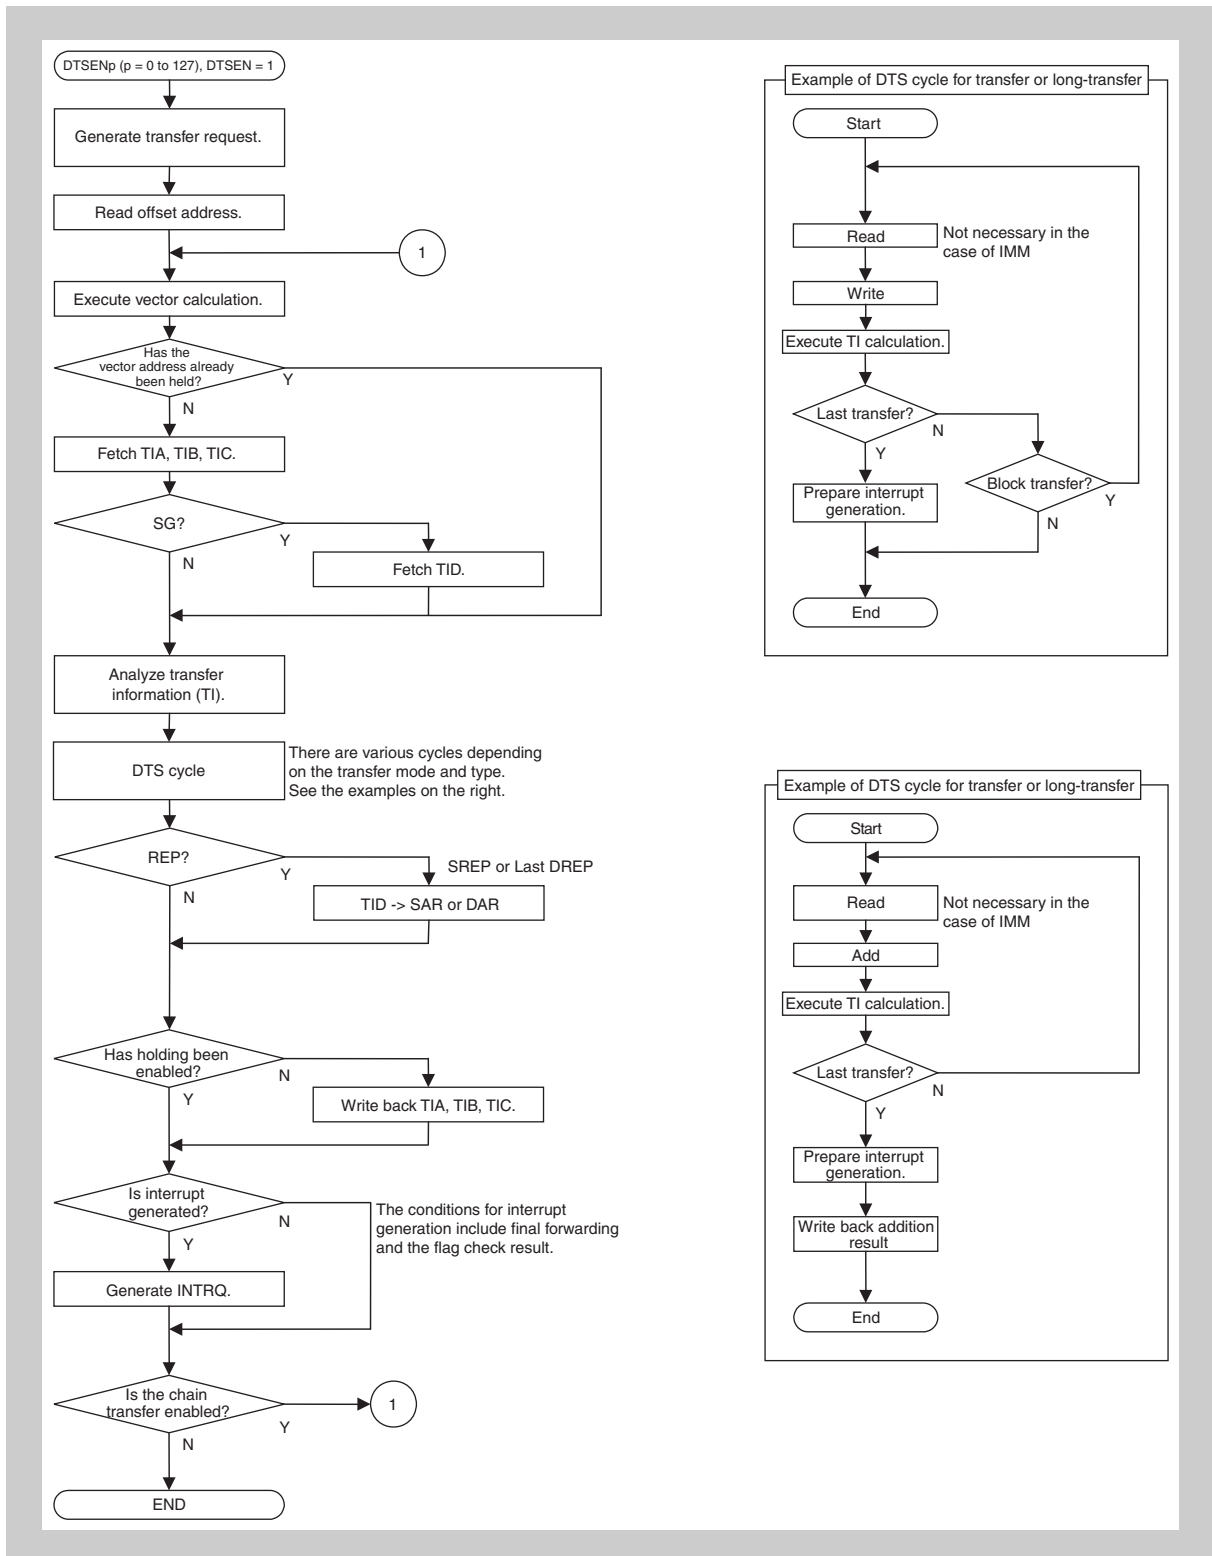

Figure 10-12 DTS transfer setting flow

10.11.3 Basic operations of DTS

The DTS fetches the information required for transfers (TI) from internal RAM, then executes transfers according to this TI, after which it updates the TI and writes it back to internal RAM.

(1) TI fetch and write back

For each DTS request, one round of “TI fetch cycle → DTS cycle → TI write back cycle” occurs. Since the bus is not locked, a CPU cycle may interrupt.

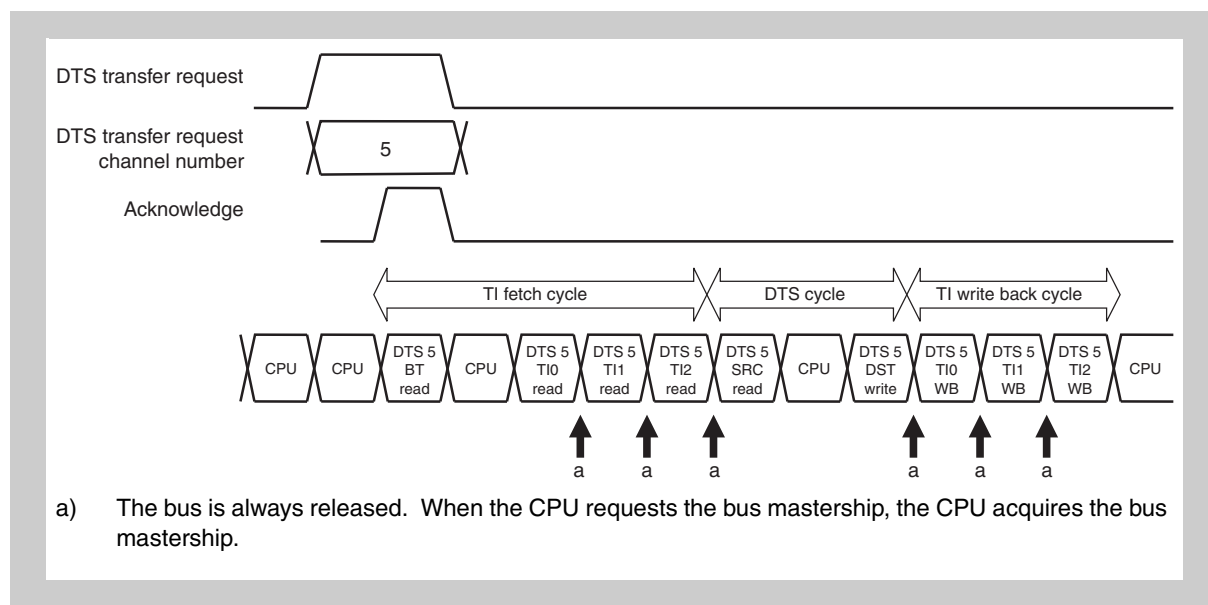

Figure 10-13 Example of TI fetch and write back

10.11.4 Transfer modes

A single-transfer mode and a block transfer mode are supported as transfer modes.

(1) Single transfer mode

When a DTS request is generated in single transfer mode, one round of “TI fetch → DTS cycle → TI write back” is performed and then transfer request wait status is set. When the next DTS request is generated, these cycles are executed again starting from a TI fetch. These operations are repeated until the value of DTS0STC (or DTS0LTC when in 65535 mode) reaches “0”. Since the bus is not locked, a CPU cycle may interrupt.

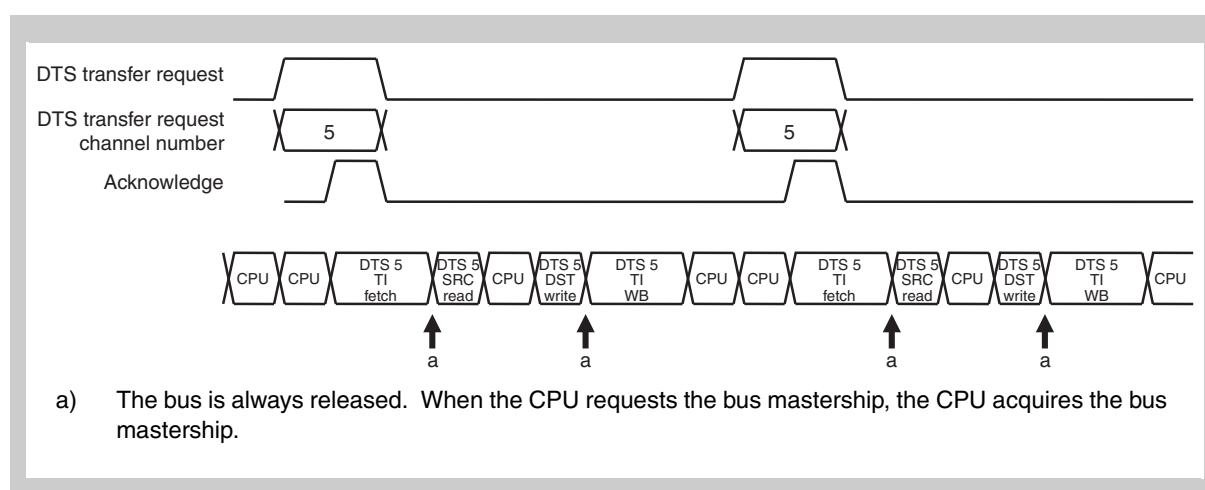

Figure 10-14 Example of single transfer

(2) Block transfer mode

When a DTS request is generated in block transfer mode, TI is fetched and then the DTS cycle is repeated until the value of DTS0STC (or DTS0LTC when in 65535 mode) reaches “0”, after which the TI is written back. Since the bus is not locked, a CPU cycle may interrupt.

Other DTS requests cannot be received during a block transfer (they are held pending in DTSFSL).

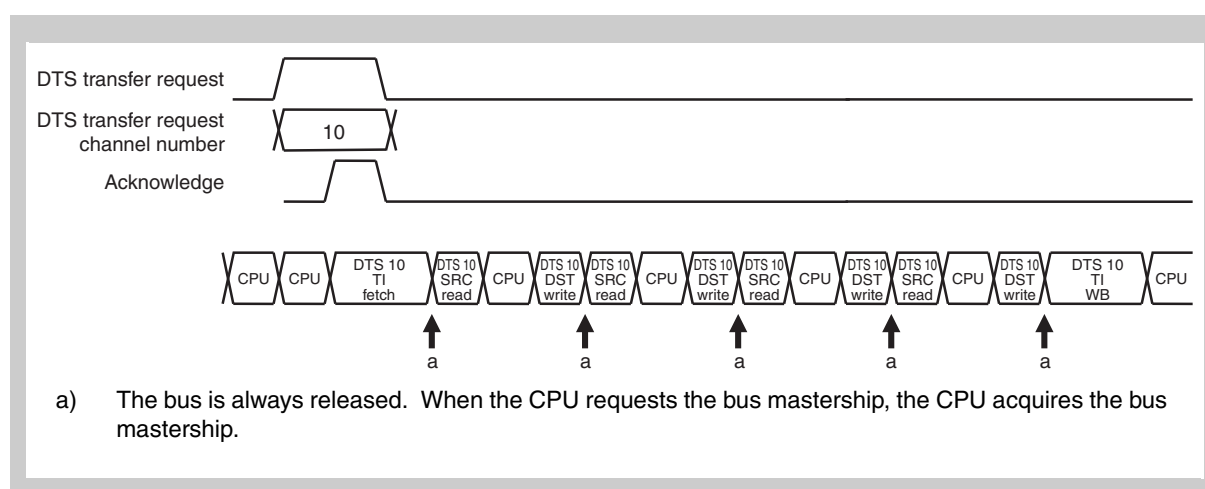

Figure 10-15 Example of block transfer

10.11.5 Transfer types

Transfer (2-cycle transfer), flag check, compare, and add are supported as transfer types. Although transfer types are specified by DTS0TTYP5 to DTS0TTYP0 in DTS0CIR, at the same time the transfer count and the special function^a are also set.

The DTS transfer types are listed below. The operation of each transfer type varies depending on the setting of the DTS0IMM bit in DTS0CIR.

a) For a description of the special function, see 10.11.6 "Special functions" on page 358.

Table 10-52 List of DTS transfer types (1/2)

DTS0TTYP5 to DTS0TTYP0			MAX transfer count	Transfer type	Special function	TI-D
0	000	00	255	Transfer	None	Not used
		01			SREP	Used
		10			DREP	
		11			SG	
0	001	00		Add	None	Not used
		01			SREP	Used

	100			comp[=]		
	101			comp[!]=]		
	110			comp[<]		
	111			comp[>]		

(1) Transfer: DTS0TTYP5 to DTS0TTYP2 are 0000 or 1000

- When DTS0TTYP5 to DTS0TTYP2 are 0000 and DTS0CIR.DTS0IMM is “0”

When the transfer type is set to “transfer”, the DTS cycle is used for data transfer. DTS0TCEA is split into DTS0STR and DTS0STC, and DTS0STC can be used to specify a transfer count value up to 255 times. When the value of DTS0STC reaches “0”, the value of DTS0STR is copied to DTS0STC and another transfer can be performed.

The chain mode specification can be 00 (no chain), 01 (transfer count 0 chain), or 11 (always chain), and SREP (Source Repeat), DREP (Destination Repeat), or SG (Scatter & Gather) can be selected as the special function.

Operation Data read from address SAR is written to address DAR.

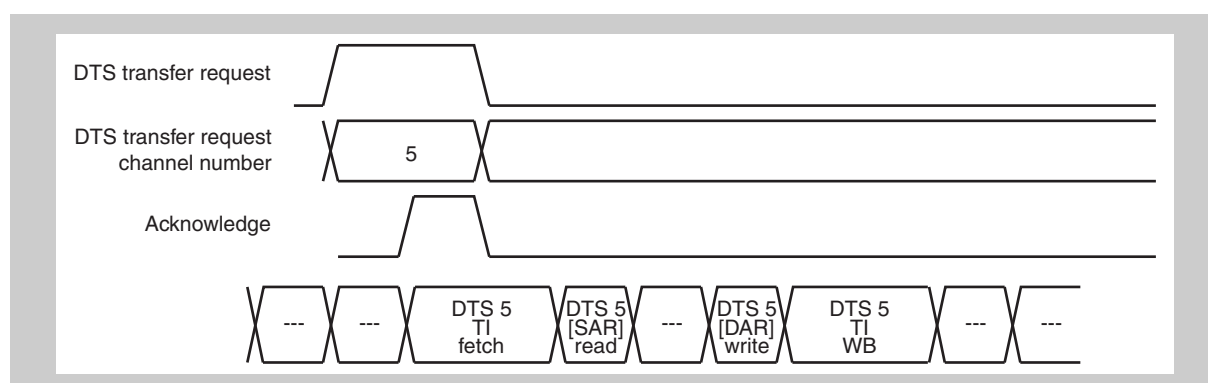

Figure 10-16 When DTS0TTYP5 to DTS0TYYP2 are 0000 and DTS0CIR.DTS0IMM is “0”

- When DTS0TTYP5 to DTS0TYYP2 are 0000 and immediate function is enabled (DTS0CIR.DTS0IMM is “1”)

When DTS0IMM is “1”, DTS0SAR becomes IMM and the DTS0SAR value is written to address DTS0DAR.

DTS0TCEA is split into DTS0STR and DTS0STC, and DTS0STC can be used to specify a transfer count value up to 255 times. When the value of DTS0STC reaches “0”, the value of DTS0STR is copied to DTS0STC and another transfer can be performed.

The chain mode specification can be 00, 01, or 11, and DREP or SG can be selected as the special function.

Operation The SAR data is written to address DAR without modification.

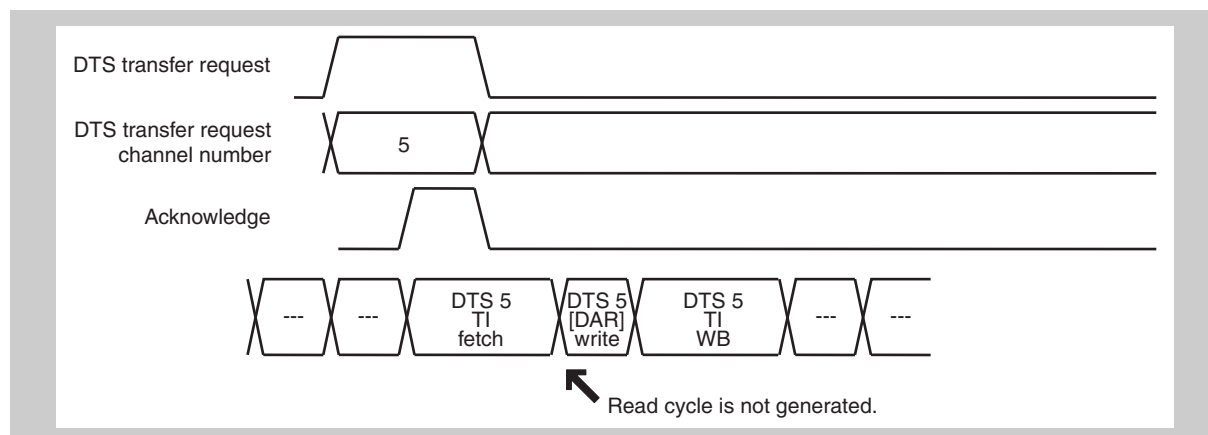

Figure 10-17 When DTS0TTYP5 to DTS0TYYP2 are 0000 and immediate function is enabled (DTS0CIR.DTS0IMM is “1”)

- When DTS0TTYP5 to DTS0TTYP2 are 1000 and DTS0CIR.DTS0IMM is “0”
When the transfer type is set to “long transfer”, the DTS cycle is used for data transfer. DTS0TCEA becomes DTS0LTC and a transfer count up to 65,535 times can be specified. Once the value of DTS0LTC reaches “0”, no more transfer requests can be accepted. Before executing a transfer, set DTS0LTC (TIA's DTS0TCEA) again.
The chain mode specification can be 00, 01, or 11, and SG can be selected as the special function.

Operation Data read from address SAR is written to address DAR.

The transfer cycle is the same as *Figure 10-16 “When DTS0TTYP5 to DTS0TYYP2 are 0000 and DTS0CIR.DTS0IMM is “0”*.

- When DTS0TTYP5 to DTS0TYYP2 are 1000 and immediate function is enabled (DTS0CIR.DTS0IMM is “1”)
When DTS0IMM is “1”, DTS0SAR becomes IMM and the DTS0SAR value is written to address DTS0DAR.
DTS0TCEA becomes DTS0LTC and a transfer count up to 65,535 times can be specified. When the value of DTS0LTC reaches “0”, no more transfer requests can be accepted. Before executing a transfer, set DTS0LTC (TIA's DTS0TCEA) again.
The chain mode specification can be 00, 01, or 11, and SG can be selected as the special function.

Operation The SAR data is written to address DAR without modification.

The transfer cycle is the same as *Figure 10-17 “When DTS0TTYP5 to DTS0TYYP2 are 0000 and immediate function is enabled (DTS0CIR.DTS0IMM is “1”)”*.

(2) Add: When DTS0TTYP5 to DTS0TTYP2 are 0001 or 1001

- When DTS0TTYP5 to DTS0TTYP2 are 0001 and DTS0CIR.DTS0IMM is “0”

When the transfer type is set to “add”, the DTS cycle becomes an accumulation cycle.

DTS0TCEA is split into DTS0STR and DTS0STC, and DTS0STC can be used to specify a transfer count value up to 255 times.

When the value of DTS0STC reaches “0”, the value of DTS0STR is copied to DTS0STC and another transfer can be performed.

The chain mode specification can be 00 or 01, and SREP, DREP, or SG can be selected as the special function.

DTS0BEN in DTS0CIR is ignored and block transfer mode is always set.

Operation Data is read from address SAR until DTS0STC reaches “0”.

The read data is added each time as unsigned data.

When DTS0STC reaches “0”, the addition result is written to address DAR.

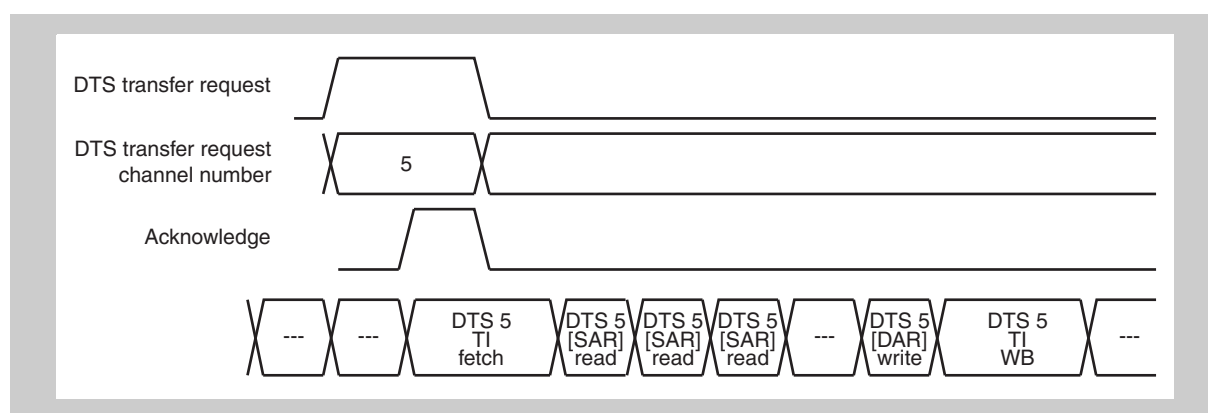

Figure 10-18 When DTS0TTYP5 to DTSTTYP2 are 0001 and DTS0CIR.DTS0IMM is “0”

The cumulative value is stored to a 32-bit register regardless of the data size, and when the transfer count reaches “0”, data is written to DAR in 32-bit units. Any data exceeding 32 bits is truncated.

Accordingly, when the transfer size is 32 bits, if an overflow or borrow occurs the calculation result will not be correct. When the transfer size is 16 bits or 8 bits, an overflow or borrow will not occur if the maximum transfer count of 65,535 times is specified.

- When DTS0TTYP5 to DTS0TYYP2 are 0001 and immediate function is enabled (DTS0CIR.DTS0IMM is “1”)

When DTS0IMM is “1”, DTS0SAR becomes IMM.

DTS0TCEA is split into DTS0STR and DTS0STC, and DTS0STC can be used to specify a transfer count value up to 255 times.

DTS0BEN in DTS0CIR is ignored and block transfer mode is always set. In other words, the DTS0SAR value is added the number of times specified by DTS0STC, and when the value of DTS0STC reaches “0”, the result is written to address DAR.

The chain mode specification can be 00 or 01, and DREP or SG can be selected as the special function.

- When DTS0TTYP5 to DTS0TTYP2 are 1001 and DTS0CIR.DTS0IMM is “0”
When the transfer type is set to “long add”, the DTS cycle becomes an accumulation cycle. DTS0TCEA becomes DTS0LTC and a transfer count up to 65,535 times can be specified. When the value of DTS0LTC reaches “0”, no more transfer requests can be accepted.
Before executing a transfer, set DTS0LTC (TIA's DTS0TCEA) again.
The chain mode specification can be 00 or 01, and SG can be selected as the special function.
DTS0BEN in DTS0CIR is ignored and block transfer mode is always set.
- When DTS0TTYP5 to DTS0TYYP2 are 1001 and immediate function is enabled (DTS0CIR.DTS0IMM is “1”)
When DTS0IMM is “1”, DTS0SAR becomes IMM.
DTS0TCEA becomes DTS0LTC and a transfer count up to 65,535 times can be specified.
DTS0BEN in DTS0CIR is ignored and block transfer mode is always set. In other words, the DTS0SAR value is added the number of times specified by DTS0LTC, and when the value of DTS0LTC reaches “0”, the addition result is written to address DAR.
The chain mode specification can be 00, or 01, and SG can be selected as the special function.

(3) flag[0]: When DTS0TTYP5 to DTS0TTYP2 are 0010 or 1010

- When DTS0TTYP5 to DTS0TTYP2 are 0010 and DTS0CIR.DTS0IMM is “0”
When the transfer type is set to “flag [0]”, the DTS cycle becomes a flag check [0] cycle.
DTS0TCEA is split into DTS0STR and DTS0STC, and DTS0STC can be used to specify a transfer count value up to 255 times.
When the value of DTS0STC reaches “0”, the value of DTS0STR is copied to DTS0STC and another transfer can be performed.
A special function (SREP, DREP, or SG) and all chain modes can be selected.
The function of flag check [0] is to check whether an arbitrary bit in the data read from address DAR is “0”.
If at least one bit is “0”, the check result is “true”. The check result can be used as a chain condition or as interrupt output.

Operation First, the check bit specification data is read from address SAR, and then the data to be checked is read from address DAR to execute a flag check.

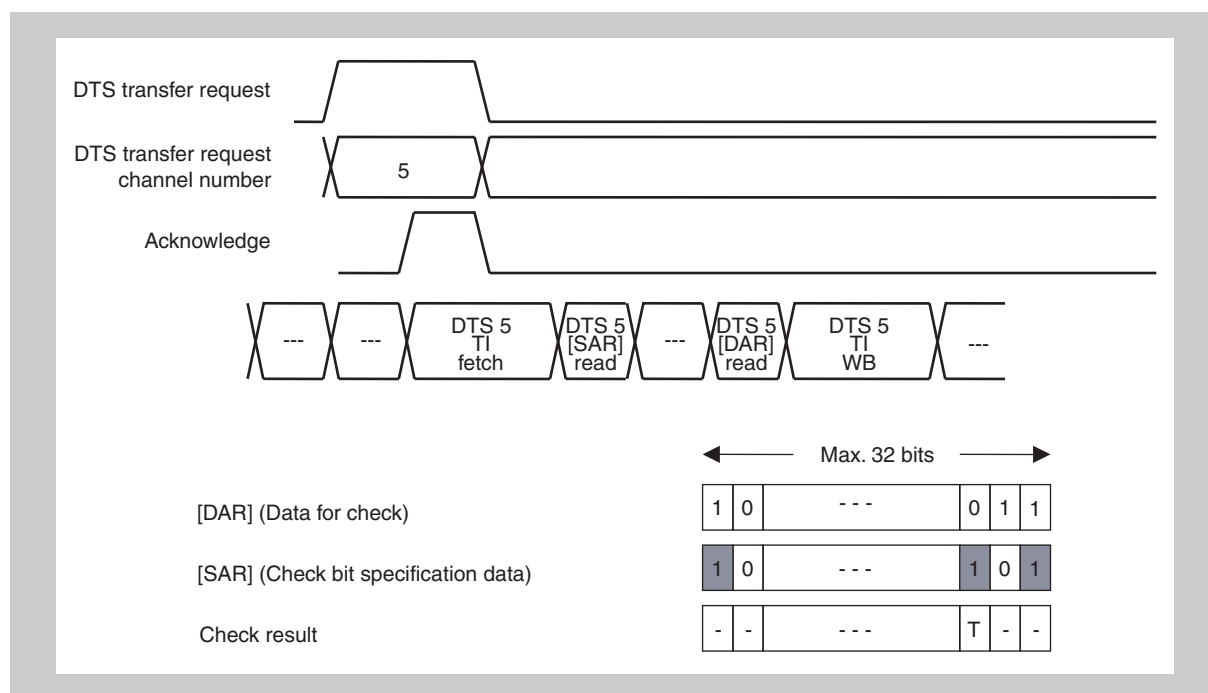

Figure 10-19 When DTS0TTP5 to DTS0TTP2 are 0010 and DTS0CIR.DTS0IMM is “0”

- When DTS0TTP5 to DTS0TTP2 are 0010 and immediate function is enabled (DTS0CIR.DTS0IMM is “1”)

When DTS0IMM is “1”, DTS0SAR becomes IMM, and DTS0SAR becomes the check bit.

DTS0TCEA is split into DTS0STR and DTS0STC, and DTS0STC can be used to specify a transfer count value up to 255 times.

When the value of DTS0STC reaches “0”, the value of DTS0STR is copied to DTS0STC and another transfer can be performed.

A special function (DREP or SG) and all chain modes can be selected.

The function of flag check [0] is to check whether an arbitrary bit in the data read from address DAR is “0”.

If at least one bit is “0”, the check result is “true”.

The check result can be used as a chain condition or as interrupt output.

Operation The data to be checked is read from address DAR, and a flag check is executed using the SAR value as the check bit specification data.

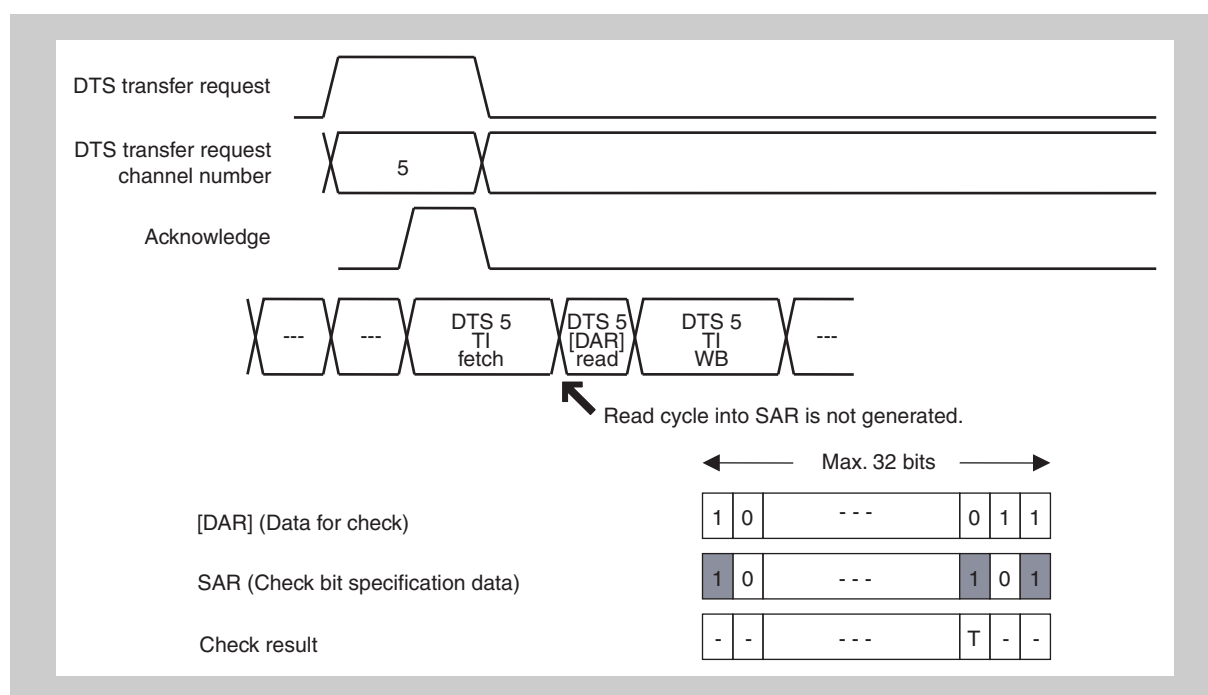

Figure 10-20 When DTS0TTY5 to DTS0TYYP2 are 0010 and immediate function is enabled (DTS0CIR.DTS0IMM is “1”)

- When DTS0TTY5 to DTS0TTY2 are 1010 and DTS0CIR.DTS0IMM is “0”

When the transfer type is set to “extended flag[0]”, the DTS cycle becomes a flag check [0] cycle.

DTS0TCEA becomes DTS0EA, functioning as a register that specifies an offset address used when the check result is “false”.

Accordingly, the transfer count cannot be specified. When the check result is “true”, TI is fetched from the current TI fetch address added to 10H to perform a chain of transfers. When the check result is “false”, TI is fetched from the current TI fetch address added to the value of DTS0EA to perform a chain of transfers.

Neither the chain mode nor a special function can be selected.

Operation First, the check bit specification data is read from address SAR, and then the data to be checked is read from address DAR to execute a flag check. A chain of transfers is always performed.

- When DTS0TTY5 to DTS0TYYP2 are 1010 and immediate function is enabled (DTS0CIR.DTS0IMM is “1”)

When DTS0IMM is “1”, DTS0SAR becomes IMM, and DTS0SAR becomes the check bit.

DTS0TCEA becomes DTS0EA, functioning as a register that specifies an offset address used when the check result is “false”.

Accordingly, the transfer count cannot be specified. When the check result is “true”, TI is fetched from the current TI fetch address added to 10H to perform a chain of transfers. When the check result is “false”, TI is fetched from the current TI fetch address added to the value of DTS0EA to perform a chain of transfers.

Neither the chain mode nor a special function can be selected.

Operation The data to be checked is read from address DAR, and a flag check is executed using the SAR value as the check bit specification data. A chain of transfers is always performed.

(4) flag[1]: When DTS0TTYP5 to DTS0TTYP2 are 0011 or 1011

- When DTS0TTYP5 to DTS0TTYP2 are 0011 and DTS0CIR.DTS0IMM is “0”

When the transfer type is set to “flag [1]”, the DTS cycle becomes a flag check [1] cycle.

DTS0TCEA is split into DTS0STR and DTS0STC, and DTS0STC can be used to specify a transfer count value up to 255 times.

When the value of DTS0STC reaches “0”, the value of DTS0STR is copied to DTS0STC and another transfer can be performed.

A special function (SREP, DREP, or SG) and all chain modes can be selected. The function of flag check [1] is to check whether an arbitrary bit in the data read from address DAR is “1”.

If at least one bit is “1”, the check result is “true”.

The check result can be used as a chain condition or as interrupt output.

Operation First, the check bit specification data is read from address SAR, and then the data to be checked is read from address DAR to execute a flag check.

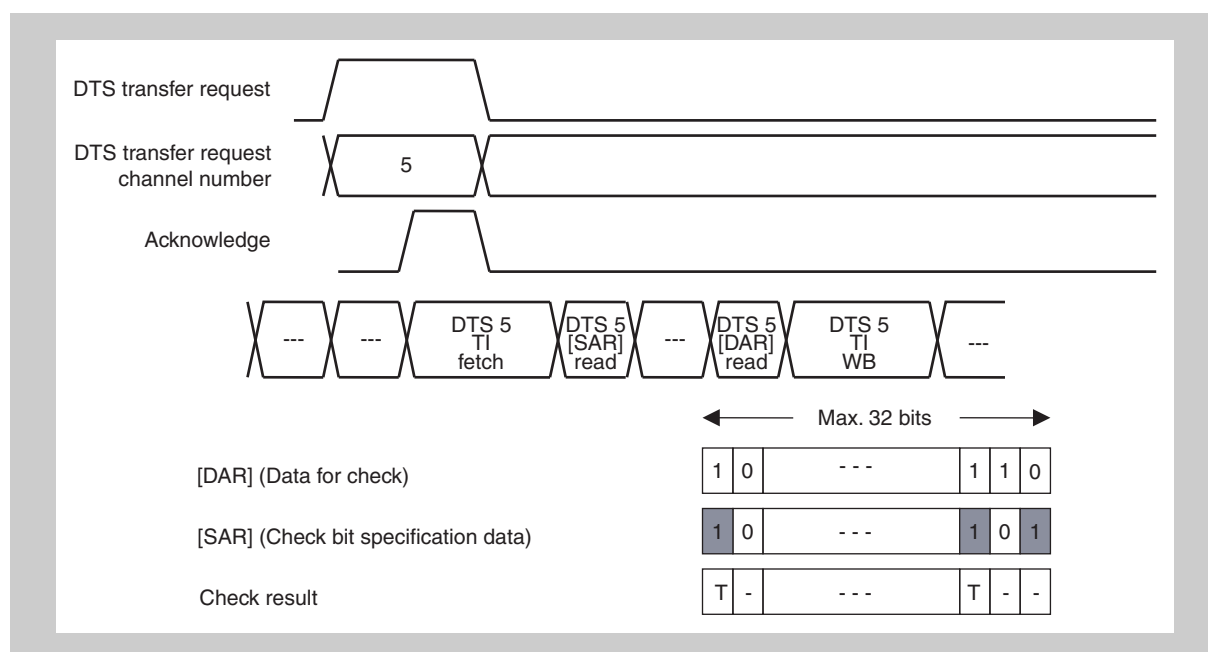

Figure 10-21 When DTS0TTYP5 to DTS0TTYP2 are 0011 and DTS0CIR.DTS0IMM is “0”

- When DTS0TTYP5 to DTS0TYYP2 are 0011 and immediate function is enabled (DTS0CIR.DTS0IMM is “1”)

When DTS0IMM is “1”, DTS0SAR becomes IMM, and DTS0SAR becomes the check bit.

DTS0TCEA is split into DTS0STR and DTS0STC, and DTS0STC can be used to specify a transfer count value up to 255 times.

When the value of DTS0STC reaches “0”, the value of DTS0STR is copied to DTS0STC and another transfer can be performed.

A special function (DREP or SG) and all chain modes can be selected.

The function of flag check [1] is to check whether an arbitrary bit in the data read from address DAR is “1”.

If at least one bit is “1”, the check result is “true”. The check result can be used as a chain condition or as interrupt output.

Operation The data to be checked is read from address DAR, and a flag check is executed using the SAR value as the check bit specification data.

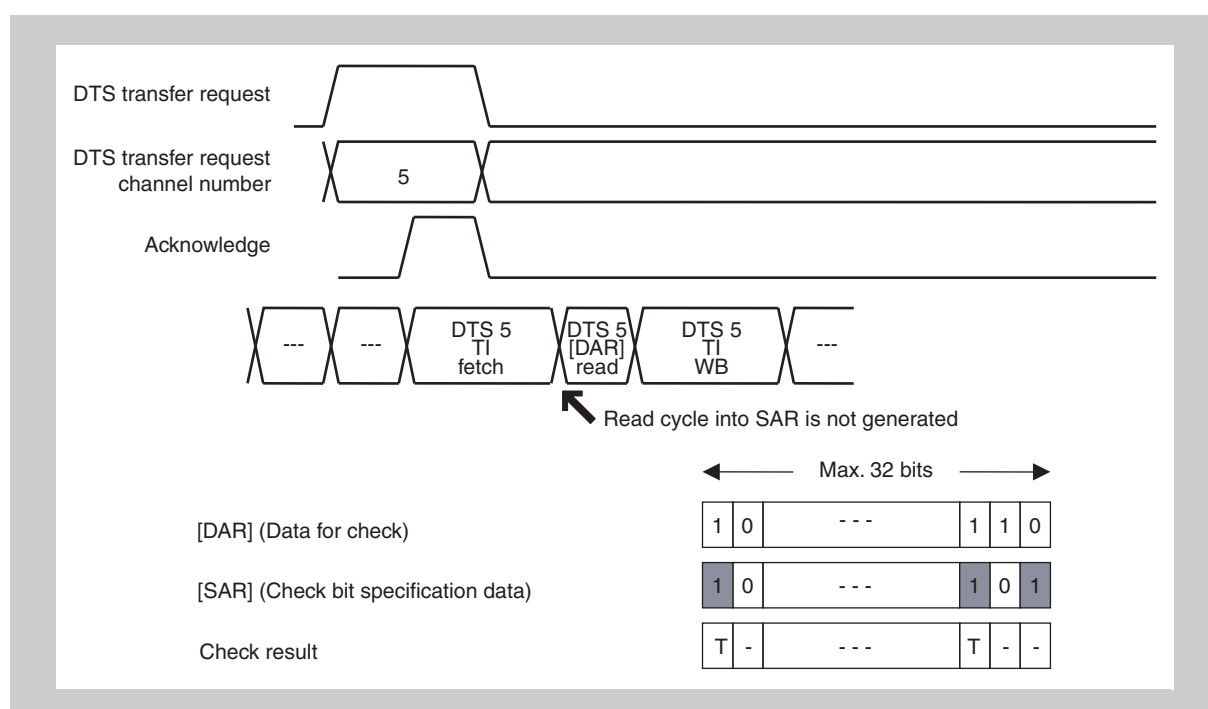

Figure 10-22 When DTS0TTYP5 to DTS0TYYP2 are 0011 and immediate function is enabled (DTS0CIR.DTS0IMM is “1”)

- When DTS0TTYP5 to DTS0TTYP2 are 1011 and DTS0CIR.DTS0IMM is “0”

When the transfer type is set to “extended flag[1]”, the DTS cycle becomes a flag check [1] cycle.

DTS0TCEA becomes DTS0EA, functioning as a register that specifies an offset address used when the check result is “false”.

Accordingly, the transfer count cannot be specified. When the check result is “true”, TI is fetched from the current TI fetch address added to 10H to perform a chain of transfers. When the check result is “false”, TI is fetched from the current TI fetch address added to the value of DTS0EA to perform a chain of transfers.

Neither the chain mode nor a special function can be selected.

Operation First, the check bit specification data is read from address SAR, and then the data to be checked is read from address DAR to execute a flag check. A chain of transfers is always performed.

- When DTS0TTYP5 to DTS0TYYP2 are 1011 and immediate function is enabled (DTS0CIR.DTS0IMM is “1”)

When DTS0IMM is “1”, DTS0SAR becomes IMM, and DTS0SAR becomes the check bit.

DTS0TCEA becomes DTS0EA, functioning as a register that specifies an offset address used when the check result is “false”.

Accordingly, the transfer count cannot be specified. When the check result is “true”, TI is fetched from the current TI fetch address added to 10H to perform a chain of transfers. When the check result is “false”, TI is fetched from the current TI fetch address added to the value of DTS0EA to perform a chain of transfers.

Neither the chain mode nor a special function can be selected.

Operation The data to be checked is read from address DAR, and a flag check is executed using the SAR value as the check bit specification data. A chain of transfers is always performed.

(5) **comp[=]: When DTS0TTYP5 to DTS0TTYP2 are 0100 or 1100**

- When DTS0TTYP5 to DTS0TTYP2 are 0100 and DTS0CIR.DTS0IMM is “0”

When the transfer type is set to “comp[=]”, the DTS cycle becomes a comparison [=] cycle. DTS0TCEA is split into DTS0STR and DTS0STC, and DTS0STC can be used to specify a transfer count value up to 255 times.

When the value of DTS0STC reaches “0”, the value of DTS0STR is copied to DTS0STC and another transfer can be performed.

A special function (SREP, DREP, or SG) and all chain modes can be selected.

With comp[=], data read from address SAR is compared with data read from address DAR, and if these data match, the compare result is “true”.

The check result can be used as a chain condition or as interrupt output.

Operation First, data is read from address SAR, then data is read from address DAR. Next, whether [SAR] == [DAR] is checked.

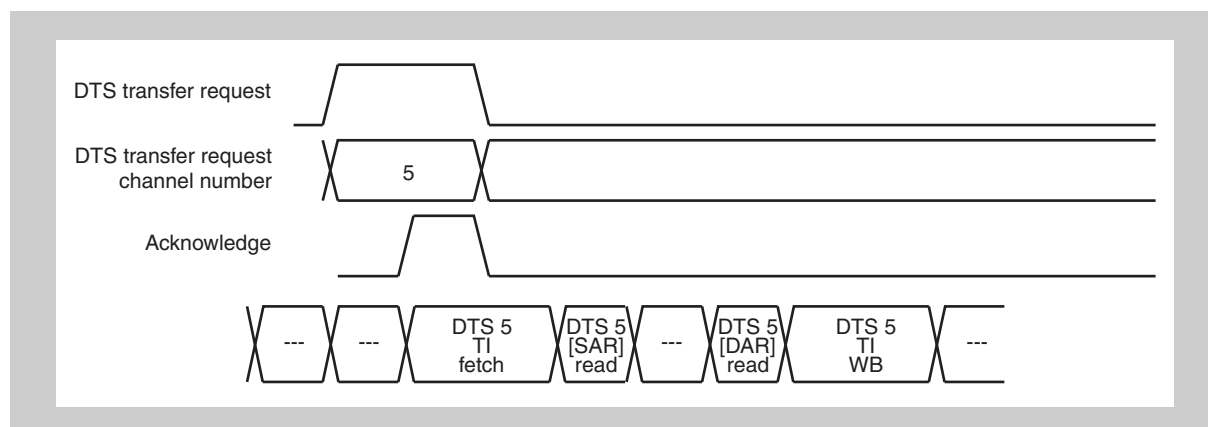

Figure 10-23 When DTS0TTYP5 to DTS0TTYP2 are 0100 and DTS0CIR.DTS0IMM is “0”

- When DTS0TTYP5 to DTS0TYYP2 are 0100 and immediate function is enabled (DTS0CIR.DTS0IMM is “1”)

When DTS0IMM is “1”, DTS0SAR becomes IMM, and DTS0SAR becomes the data to be compared.

DTS0TCEA is split into DTS0STR and DTS0STC, and DTS0STC can be used to specify a transfer count value up to 255 times.

When the value of DTS0STC reaches “0”, the value of DTS0STR is copied to DTS0STC and another transfer can be performed.

A special function (DREP or SG) and all chain modes can be selected.

The check result can be used as a chain condition or as interrupt output.

Operation Data is read from address DAR, and whether SAR == [DAR] is checked.

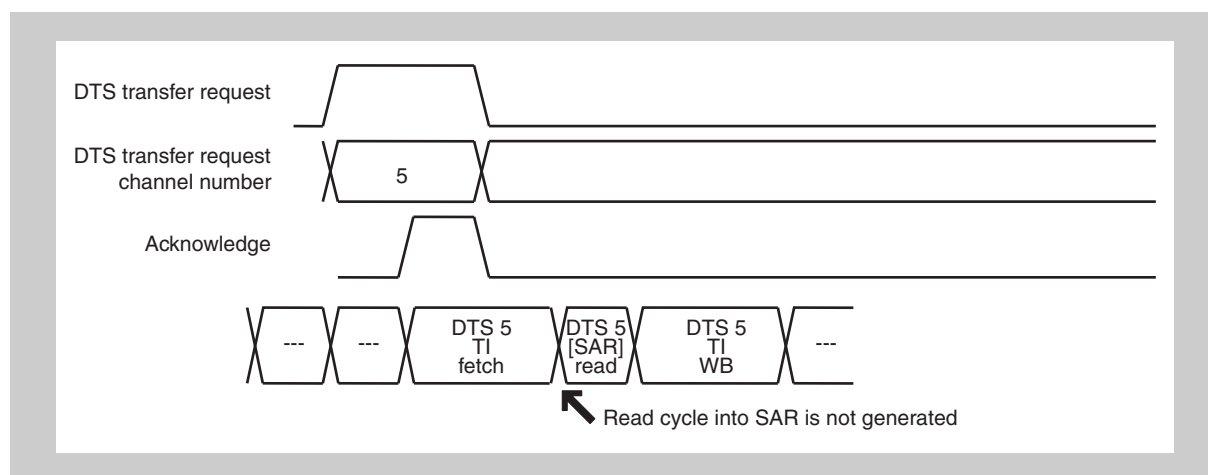

Figure 10-24 When DTS0TTYP5 to DTS0TYYP2 are 0100 and immediate function is enabled (DTS0CIR.DTS0IMM is “1”)

- When DTS0TTYP5 to DTS0TYYP2 are 1100 and DTS0CIR.DTS0IMM is “0”

When the transfer type is set to “extended comp[=]”, the DTS cycle becomes a comparison [=] cycle.

DTS0TCEA becomes DTS0EA, functioning as a register that specifies an offset address used when the check result is “false”.

Accordingly, the transfer count cannot be specified. When the check result is “true”, TI is fetched from the current TI fetch address added to 10H to perform a chain of transfers. When the check result is “false”, TI is fetched from the current TI fetch address added to the value of DTS0EA to perform a chain of transfers.

Neither the chain mode nor a special function can be selected.

Operation First, data is read from address SAR, then data is read from address DAR. Next, whether [SAR] == [DAR] is checked. A chain of transfers is always performed.

- When DTS0TTYP5 to DTS0TYYP2 are 1100 and immediate function is enabled (DTS0CIR.DTS0IMM is “1”)

When DTS0IMM is “1”, DTS0SAR becomes IMM, and DTS0SAR becomes the data to be compared.

DTS0TCEA becomes DTS0EA, functioning as a register that specifies an offset address used when the check result is “false”.

Accordingly, the transfer count cannot be specified. When the check result is “true”, TI is fetched from the current TI fetch address added to 10H to perform a chain of transfers. When the check result is “false”, TI is fetched from the current TI fetch address added to the value of DTS0EA to perform a chain of transfers.

Neither the chain mode nor a special function can be selected.

Operation The data to be compared is read from address DAR, and then compared with the SAR value.
A chain of transfers is always performed.

(6) **comp[!]=: When DTS0TTYP5 to DTS0TTYP2 are 0101 or 1101**

- When DTS0TTYP5 to DTS0TTYP2 are 0101 and DTS0CIR.DTS0IMM is “0”

When the transfer type is set to “comp[!]=”, the DTS cycle becomes a comparison [!]= cycle.

DTS0TCEA is split into DTS0STR and DTS0STC, and DTS0STC can be used to specify a transfer count value up to 255 times.

When the value of DTS0STC reaches “0”, the value of DTS0STR is copied to DTS0STC and another transfer can be performed.

A special function (SREP, DREP, or SG) and all chain modes can be selected.

With comp[!]=, data read from address SAR is compared with data read from address DAR, and if these data do not match, the compare result is “true”.

The check result can be used as a chain condition or as interrupt output.

Operation First, data is read from address SAR, then data is read from address DAR. Next, whether [SAR] != [DAR] is checked.

The transfer cycle is the same as *Figure 10-23 “When DTS0TTYP5 to DTS0TTYP2 are 0100 and DTS0CIR.DTS0IMM is “0”*.

- When DTS0TTYP5 to DTS0TYYP2 are 0101 and immediate function is enabled (DTS0CIR.DTS0IMM is “1”)

When DTS0IMM is “1”, DTS0SAR becomes IMM, and DTS0SAR becomes the data to be compared.

DTS0TCEA is split into DTS0STR and DTS0STC, and DTS0STC can be used to specify a transfer count value up to 255 times.

When the value of DTS0STC reaches “0”, the value of DTS0STR is copied to DTS0STC and another transfer can be performed.

A special function (DREP or SG) and all chain modes can be selected.

The check result can be used as a chain condition or as interrupt output.

Operation Data is read from address DAR, and whether SAR != [DAR] is checked.

The transfer cycle is the same as *Figure 10-24 “When DTS0TTYP5 to DTS0TYYP2 are 0100 and immediate function is enabled (DTS0CIR.DTS0IMM is “1”*).

- When DTS0TTYP5 to DTS0TTYP2 are 1101 and DTS0CIR.DTS0IMM is “0”
When the transfer type is set to “extended comp[!]=”, the DTS cycle becomes a comparison [!]= cycle.
DTS0TCEA becomes DTS0EA, functioning as a register that specifies an offset address used when the check result is “false”.
Accordingly, the transfer count cannot be specified. When the check result is “true”, TI is fetched from the current TI fetch address added to 10H to perform a chain of transfers. When the check result is “false”, TI is fetched from the current TI fetch address added to the value of DTS0EA to perform a chain of transfers.
Neither the chain mode nor a special function can be selected.

Operation First, data is read from address SAR, then data is read from address DAR. Next, whether [SAR] != [DAR] is checked. A chain of transfers is always performed.

- When DTS0TTYP5 to DTS0TYYP2 are 1101 and immediate function is enabled (DTS0CIR.DTS0IMM is “1”)
When DTS0IMM is “1”, DTS0SAR becomes IMM, and DTS0SAR becomes the data to be compared.
DTS0TCEA becomes DTS0EA, functioning as a register that specifies an offset address used when the check result is “false”.
Accordingly, the transfer count cannot be specified. When the check result is “true”, TI is fetched from the current TI fetch address added to 10H to perform a chain of transfers. When the check result is “false”, TI is fetched from the current TI fetch address added to the value of DTS0EA to perform a chain of transfers.
Neither the chain mode nor a special function can be selected.

Operation The data to be compared is read from address DAR, and then compared with the SAR value. A chain of transfers is always performed.

(7) comp[<]: When DTS0TTYP5 to DTS0TTYP2 are 0110 or 1110

- When DTS0TTYP5 to DTS0TTYP2 are 0110 and DTS0CIR.DTS0IMM is “0”
When the transfer type is set to “comp[<]”, the DTS cycle becomes a comparison [<] cycle.
DTS0TCEA is split into DTS0STR and DTS0STC, and DTS0STC can be used to specify a transfer count value up to 255 times.
When the value of DTS0STC reaches “0”, the value of DTS0STR is copied to DTS0STC and another transfer can be performed.
A special function (SREP, DREP, or SG) and all chain modes can be selected.
With comp[<], data read from address SAR is compared with data read from address DAR, and if the data read from address SAR is smaller, the compare result is “true”.
The check result can be used as a chain condition or as interrupt output.

Operation First, data is read from address SAR, then data is read from address DAR. Next, whether [(unsigned) SAR] < [(unsigned) DAR] is checked.

The transfer cycle is the same as *Figure 10-23 “When DTS0TTYP5 to DTS0TTYP2 are 0100 and DTS0CIR.DTS0IMM is “0”*.

- When DTS0TTYP5 to DTS0TTYP2 are 0110 and immediate function is enabled (DTS0CIR.DTS0IMM is “1”)

When DTS0IMM is “1”, DTS0SAR becomes IMM, and DTS0SAR becomes the data to be compared.

DTS0TCEA is split into DTS0STR and DTS0STC, and DTS0STC can be used to specify a transfer count value up to 255 times.

When the value of DTS0STC reaches “0”, the value of DTS0STR is copied to DTS0STC and another transfer can be performed.

A special function (DREP or SG) and all chain modes can be selected.

The check result can be used as a chain condition or as interrupt output.

Operation Data is read from address DAR, and whether (unsigned) SAR < [(unsigned) DAR] is checked.

The transfer cycle is the same as *Figure 10-24 “When DTS0TTYP5 to DTS0TYYP2 are 0100 and immediate function is enabled (DTS0CIR.DTS0IMM is “1”)”*.

- When DTS0TTYP5 to DTS0TTYP2 are 1110 and DTS0CIR.DTS0IMM is “0”

When the transfer type is set to “extended comp[<]”, the DTS cycle becomes a comparison [<] cycle.

DTS0TCEA becomes DTS0EA, functioning as a register that specifies an offset address used when the check result is “false”.

Accordingly, the transfer count cannot be specified. When the check result is “true”, TI is fetched from the current TI fetch address added to 10H to perform a chain of transfers. When the check result is “false”, TI is fetched from the current TI fetch address added to the value of DTS0EA to perform a chain of transfers.

Neither the chain mode nor a special function can be selected.

Operation First, data is read from address SAR, then data is read from address DAR. Next, whether [(unsigned) SAR] < [(unsigned) DAR] is checked.

A chain of transfers is always performed.

- When DTS0TTYP5 to DTS0TTYP2 are 1110 and immediate function is enabled (DTS0CIR.DTS0IMM is “1”)

When DTS0IMM is “1”, DTS0SAR becomes IMM, and DTS0SAR becomes the data to be compared.

DTS0TCEA becomes DTS0EA, functioning as a register that specifies an offset address used when the check result is “false”.

Accordingly, the transfer count cannot be specified. When the check result is “true”, TI is fetched from the current TI fetch address added to 10H to perform a chain of transfers. When the check result is “false”, TI is fetched from the current TI fetch address added to the value of DTS0EA to perform a chain of transfers.

Neither the chain mode nor a special function can be selected.

Operation The data to be compared is read from address DAR, and then compared with the SAR value.

A chain of transfers is always performed.

(8) comp[>]: When DTS0TTYP5 to DTS0TTYP2 are 0111 or 1111

- When DTS0TTYP5 to DTS0TTYP2 are 0111 and DTS0CIR.DTS0IMM is “0”

When the transfer type is set to “comp[>]”, the DTS cycle becomes a comparison [>] cycle.

DTS0TCEA is split into DTS0STR and DTS0STC, and DTS0STC can be used to specify a transfer count value up to 255 times.

When the value of DTS0STC reaches “0”, the value of DTS0STR is copied to DTS0STC and another transfer can be performed.

A special function (SREP, DREP, or SG) and all chain modes can be selected.

With comp[>], data read from address SAR is compared with data read from address DAR, and if the data read from address SAR is greater, the compare result is “true”.

The check result can be used as a chain condition or as interrupt output.

Operation First, data is read from address SAR, then data is read from address DAR. Next, whether [(unsigned) SAR] > [(unsigned) DAR] is checked.

The transfer cycle is the same as *Figure 10-23 “When DTS0TTYP5 to DTS0TTYP2 are 0100 and DTS0CIR.DTS0IMM is “0”*.

- When DTS0TTYP5 to DTS0TTYP2 are 0111 and immediate function is enabled (DTS0CIR.DTS0IMM is “1”)

When DTS0IMM is “1”, DTS0SAR becomes IMM, and DTS0SAR becomes the data to be compared.

DTS0TCEA is split into DTS0STR and DTS0STC, and DTS0STC can be used to specify a transfer count value up to 255 times.

When the value of DTS0STC reaches “0”, the value of DTS0STR is copied to DTS0STC and another transfer can be performed.

A special function (DREP or SG) and all chain modes can be selected.

The check result can be used as a chain condition or as interrupt output.

Operation Data is read from address DAR, and whether (unsigned) SAR > [(unsigned) DAR] is checked.

The transfer cycle is the same as *Figure 10-24 “When DTS0TTYP5 to DTS0TTYP2 are 0100 and immediate function is enabled (DTS0CIR.DTS0IMM is “1”*).

- When DTS0TTYP5 to DTS0TTYP2 are 1111 and DTS0CIR.DTS0IMM is “0”

When the transfer type is set to “extended comp[>]”, the DTS cycle becomes a comparison [>] cycle.

DTS0TCEA becomes DTS0EA, functioning as a register that specifies an offset address used when the check result is “false”.

Accordingly, the transfer count cannot be specified. When the check result is “true”, TI is fetched from the current TI fetch address added to 10H to perform a chain of transfers. When the check result is “false”, TI is fetched from the current TI fetch address added to the value of DTS0EA to perform a chain of transfers.

Neither the chain mode nor a special function can be selected.

Operation First, data is read from address SAR, then data is read from address DAR. Next, whether [(unsigned) SAR] > [(unsigned) DAR] is checked. A chain of transfers is always performed.

- When DTS0TTYP5 to DTS0TTYP2 are 1111 and immediate function is enabled (DTS0CIR.DTS0IMM is “1”)

When DTS0IMM is “1”, DTS0SAR becomes IMM, and DTS0SAR becomes the data to be compared.

DTS0TCEA becomes DTS0EA, functioning as a register that specifies an offset address used when the check result is “false”.

Accordingly, the transfer count cannot be specified. When the check result is “true”, TI is fetched from the current TI fetch address added to 10H to perform a chain of transfers. When the check result is “false”, TI is fetched from the current TI fetch address added to the value of DTS0EA to perform a chain of transfers.

Neither the chain mode nor a special function can be selected.

Operation The data to be compared is read from address DAR, and then compared with the SAR value.

A chain of transfers is always performed.

10.11.6 Special functions

SREP, DREP, and SG are supported as special functions.

The special function is selected using DTS0TTYP1 and DTS0TTYP0 in DTS0CIR.

(1) SREP (Source address REPeat)

When the value of DTS0STC reaches "0", this function returns DTS0SAR to its initial value. The TI-D area is used.

Set a value equal to the DTS0SAR value in advance to the TI-D area.

DTS cycles are executed until DTS0STC reaches "0", then when the last transfer occurs the TI-D area's value is read to DTS0SAR, and a write back is performed to achieve SREP. With SREP, when DTS0STC reaches "0", a write back of TIB is always performed (it is never skipped).

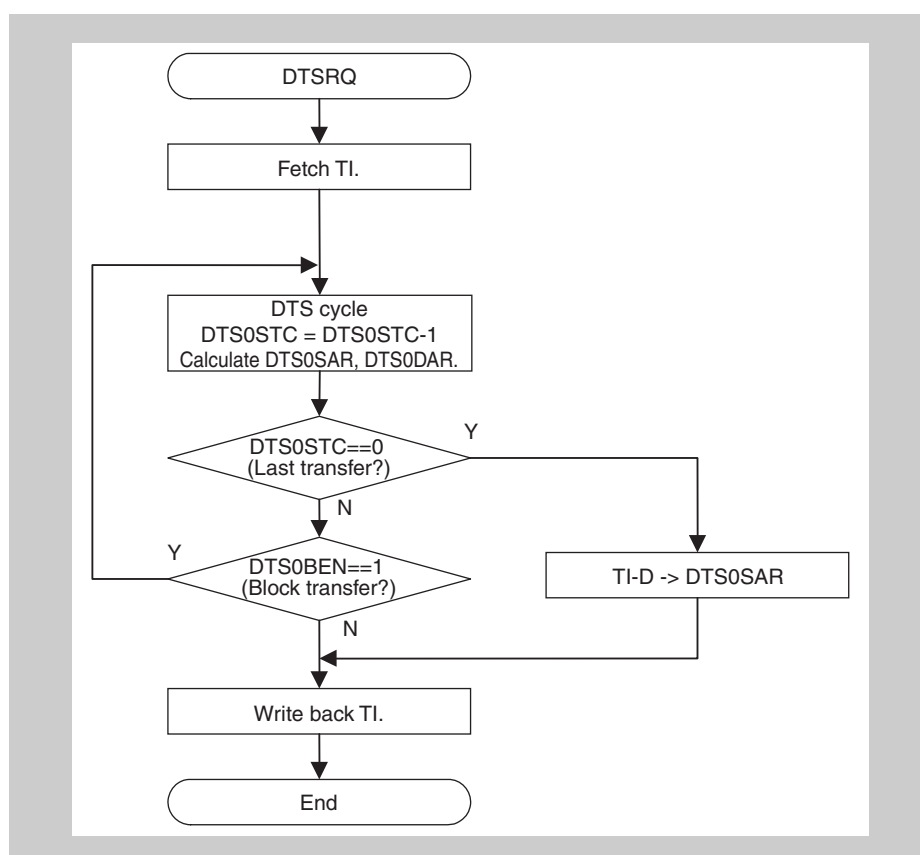

Figure 10-25 SREP processing flow

(2) DREP (Destination address REPeat)

When the value of DTS0STC reaches "0", this function returns DTS0DAR to its initial value. The TI-D area is used.

The value is returned using the same method as for SREP, and the TI-D value is written back to DTS0DAR.

With DREP, when DTS0STC reaches "0", a write back of TIC is always performed (it is never skipped).

Note SREP and DREP cannot be set at the same time (since the TI-D area is used).

(3) SG (Scatter & Gather)

In this mode, the count sizes of the source address and destination address are specified as signed 16-bit values. The TI-D area is used. When in modes other than SG, the DTS's address count size can only be specified using DTS0SCS and DTS0DCS, as a value in the range from -4 to +8, but in SG mode DTS0ESCS and DTS0EDCS are used, which enables the count size to become much larger (data in the TI-D area is read to DTS internal registers DTS0ESCS and DTS0EDCS).

10.11.7 Transfer count

The transfer count is MAX255 times or MAX65535 times. In either case, when the specified number of transfers is completed, an interrupt request is output to DTSFSL.

(1) MAX255 times

Although the maximum transfer count is 255 times, the transfer count can be recovered when the transfer count (DTS0STC) reaches "0", so in fact unlimited transfers are supported.

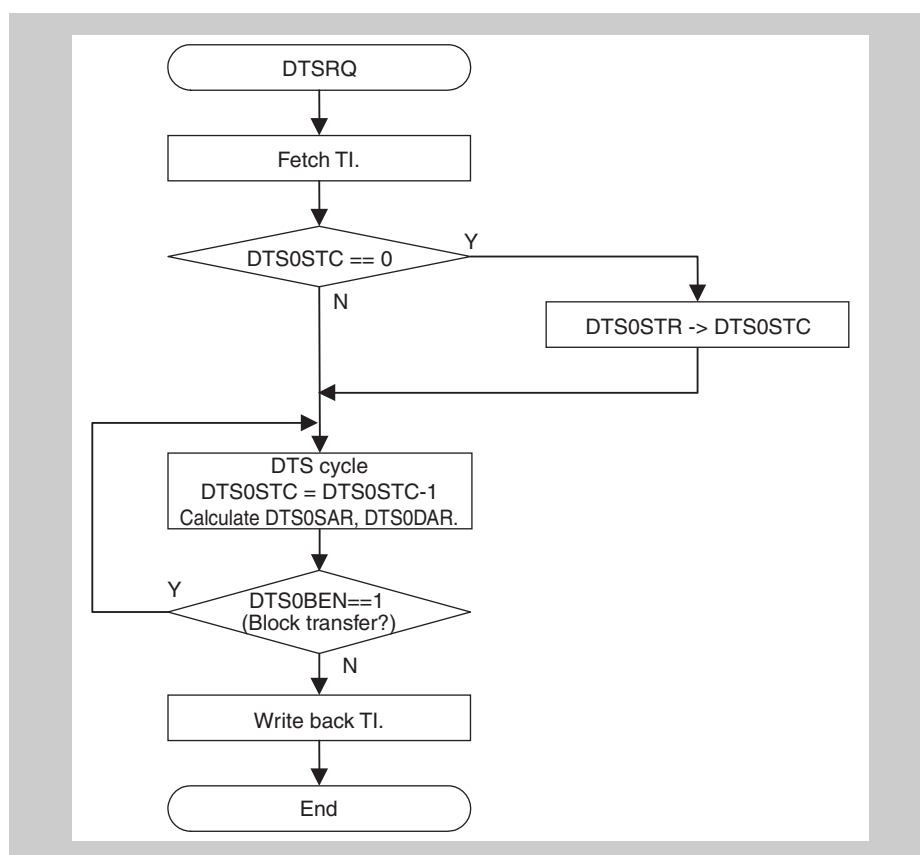

Figure 10-26 Transfer count processing flow

(2) MAX65535 times

When DTS0TCEA is used as a 16-bit counter, a transfer count of up to 65,535 times can be specified.

10.11.8 Chain function

DTS includes a chain function that performs multiple data transfers in succession.

The condition for the chain function can be set by using DTS0CM1 and DTS0CM0 in DTS0CIR. Also, DTS0TTY4 to DTS0TTY0 in DTS0CIR can be used to select an extended chain function.

When special flag[0], special flag[1], or special comp[=, !=, <, >] has been selected, the settings in DTS0CM1 and DTS0CM0 are ignored. After TI fetch → DTS cycle → TI write back is completed, the chain function performs a TI fetch, achieving a chain of transfers. The fetch address for this TI fetch operation is the address TI-C + 4 when only TI-A to TI-C are used, and is the address TI-D + 4 when TI-A to TI-D are used (consecutive addresses in internal RAM).

Table 10-53 List of chain functions (1/2)

Transfer mode	Special mode	Settings of DTS0CM1 and DTS0CM0 in DTS0CIR	Operation
transfer	—	00 (No chain)	Does not perform chain of transfers.
		01 (Last transfer)	Performs chain of transfers when DTS0STC (or DTS0LTC when 65535) is 0.
		10 (Chain if true)	Does not perform chain of transfers.
		11 (Always chain)	Performs chain of transfers following DTS cycle. Same as “01” during block transfer.
add	—	00 (No chain)	Does not perform chain of transfers.
		01 (Last transfer)	Performs chain of transfers when DTS0STC (or DTS0LTC when 65535) is 0.
		10 (Chain if true)	Does not perform chain of transfers.
		11 (Always chain)	Performs chain of transfers following DTS cycle. Same as “01” during block transfer.
flag	None SREP DREP	00 (No chain)	Does not perform chain of transfers.
		01 (Last transfer)	Performs chain of transfers when DTS0STC is 0.
		10 (Chain if true)	Performs chain of transfers only when condition is true. An interrupt is generated when it is false.
		11 (Always chain)	Performs chain of transfers following DTS cycle. Same as “01” during block transfer.
	Extended chain	Ignored	Always performs chain of transfers. When condition is true, TI is fetched from current TI fetch address added to 10H to perform chain of transfers (same manner as normal chain transfer). When condition is false, TI is fetched from current TI fetch address added to ±DTS0TCEA to perform chain of transfers.

Table 10-53 List of chain functions (2/2)

Transfer mode	Special mode	Settings of DTS0CM1 and DTS0CM0 in DTS0CIR	Operation
comp	None SREP DREP	00 (No chain)	Does not perform chain of transfers.
		01 (Last transfer)	Performs chain of transfers when DTS0STC is 0.
		10 (Chain if true)	Performs chain of transfers only when condition is true. An interrupt is generated when it is false.
		11 (Always chain)	Performs chain of transfers following DTS cycle. Same as "01" during block transfer.
	Extended chain	Ignored	Always performs chain of transfers. When condition is true, TI is fetched from current TI fetch address added to 10H to perform chain of transfers (same manner as normal chain transfer). When condition is false, TI is fetched from current TI fetch address added to \pm DTS0TCEA to perform chain of transfers.

10.11.9 TI hold function

The DTSHEN m ($m = 0$ to 3) register of DTSFSL can be used to enable the TI hold function (ON).

(1) Single transfer when TI hold is ON

When the TI hold function is set to ON in single transfer mode, TI fetch \rightarrow DTS cycle is executed for one DTS request, then transfer request wait status is set (TI is set to TI hold status). After this, if a DTS request occurs for another channel, TI fetch \rightarrow DTS cycle \rightarrow TI write back is executed for that channel. If a DTS request occurs for the same channel as the TI hold, processing goes as far as reading the BT (base table), but since the TI has already been set to TI hold status, a TI fetch is not executed when the DTS cycle occurs.

This operation is repeated until the value of DTS0STC (or DTS0LTC when in 65535 mode) reaches "0".

When DTS0STC (or DTS0LTC) reaches "0", TI hold is set to OFF and the TI is written back.

Since the bus is not locked, a CPU cycle may interrupt.

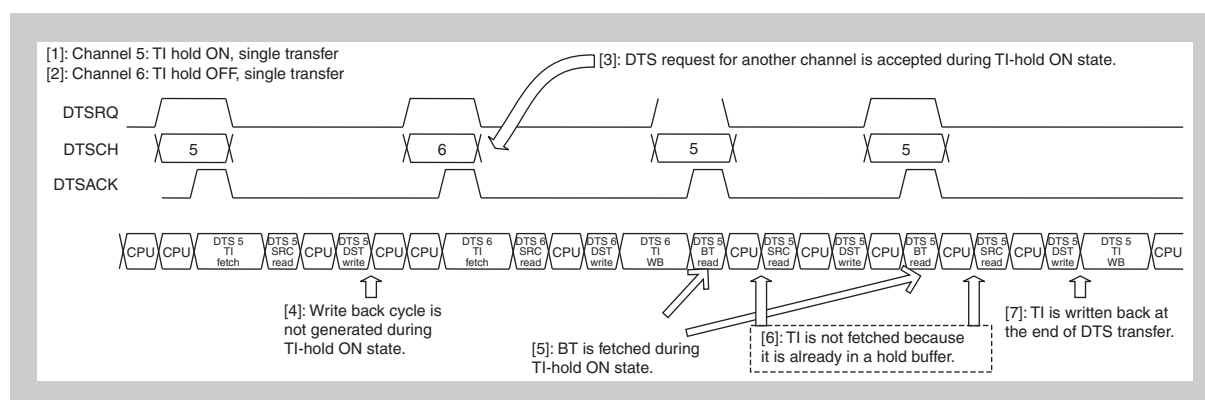

Figure 10-27 TI hold function

(2) Number of TI hold buffers

Four sets of TI hold buffers are provided. The hold instruction for these hold buffers is specified using the DTSHEN m ($m = 3$ to 0) register of DTSFSL.

10.11.10 Interrupt output function

DTS is able to output interrupts to the CPU via DTSFSL. DTS outputs an interrupt source signal to DTSFSL, and DTSFSL then decodes this signal and transmits it to the CPU as an interrupt signal.

The conditions for enabling the interrupt source signal (DTSINTRQ) involves the transfer count, flag check result, and compare result.

With regard to the transfer count, when only one transfer remains (the last transfer), DTSINTRQ activates upon completion of this transfer.

With regard to the flag check and compare results, if either of their judgment results is false, DTSINTRQ activates upon completion of the transfer.

The interrupt source signal (DTSINTRQ) can be masked using the DTS0DISI bit in DTS0CIR.

DTSINTRQ does not become active when the DTS0DISI bit in DTS0CIR is "1".

10.11.11 Interrupt and chain of transfers during block transfer

In the case of a block transfer, judgments concerning interrupts and chain of transfers are performed only once when the number of transfers specified by DTS0TCEA has been completed.

With regard to interrupts, an interrupt is always output when the specified number of transfers has been completed (the counter has reached "0"). (Note that interrupt masking is possible using DTS0DISI in DTS0CIR.)

With regard to a chain of transfers, when DTS0CM1 and DTS0CM0 in DTS0CIR are "01" (chain when counter is 0) or "11" (always chain), a chain of transfers is always performed. When these bits are "10" (chain if true), a chain of transfers is performed only when all the flag check and compare results are true (and a chain of transfers is not performed if any result is false).

DTS0TCF in DTS0CIR becomes "1" if any of the flag check and compare results is false.

10.11.12 TI write back skip function

DTS skips any TI write back that is not necessary. The conditions for skipping write back are as follows.

Table 10-54 Write back skip conditions

	DTS0CIR				Transfer count	SCS	SAM
	DS	IMM	Type	Special function			
TIB write back skip conditions	—	—	—	SG	—	—	0
	—	0	Not add	SREP	Some remain	0	—
	—	0	—	DREP/None	—	0	—
	32 bits	1	Not add	SREP	Some remain	—	—
	8/16 bits	1	Not add	SREP	Some remain	0	—
	32 bits	1	—	DREP/None	—	—	—
	8/16 bits	1	—	DREP/None	—	0	—

	DTS0CIR		Transfer count	SCS	SAM
	Type	Special function			
TIB write back skip conditions	—	SG	—	—	0
	—	SREP	—	0	—
	Not add	DREP	Some remain	0	—
	—	None	—	0	—

10.11.13 DTS channel priority control

The priority function can set up to four priority levels using DTSFSL.

10.11.14 Valid DTS transfer request conditions

When the DTSSEN bit in DTSSEN000 to DTSSEN127 of DTSFSL is set to “0”, a transfer request to the DTS is not generated for the corresponding channel, but sampling of DTS transfer factors [127:0] is performed. When sampled, if the DTSSEN bit is set to “1”, a DTS transfer request is generated.

When the DTSSEN bit is “1”, if INTIN occurs when the DTS is transferring data or is stopped either by a transfer error response or by a user, the INTIN is held pending in DTSFSL until the DTS is able to accept it.

Table 10-55 Valid DTS transfer request conditions

DTS	DTS	DTSFSL	Status of DTS	Transfer request by DTS transfer factors [127:0]
DTS0TSR.bit1	DTS0TSR.bit0	DTSSEN		
×	×	0	—	Invalid (held)
0	0	1	Acceptable	Valid (if next request occurs during a transfer, it is held)
×	1	1	Not acceptable	Held in DTSFSL
1	×	1	Not acceptable	Held in DTSFSL

10.11.15 Aborting/resuming DTS transfer

Table 10-56 DTS transfer abort timing

Transfer mode	Transfer count	Aborted after:
Single transfer with TI hold OFF	Last transfer	TI write back
	Some remain	
Block transfer with TI hold OFF	Last transfer	TI write back
	Some remain	DTS cycle
Single transfer with TI hold ON	Last transfer	TI write back
	Some remain	DTS cycle
Block transfer with TI hold ON	Last transfer	TI write back
	Some remain	DTS cycle

(1) Aborting or resuming DTS transfer for all channels through hardware (NMI)

Not supported

(2) Aborting or resuming DTS transfer for all channels through software

By setting the DTS transfer abort request trigger bit (DTS0UST) in the DTS transfer request control register (DTS0TRC), the next DTS transfer and those that follow can be aborted. If this occurs during a DTS cycle, the next DTS transfer is aborted according to the condition shown in *Table 10-56 “DTS transfer abort timing”*.

To resume the aborted DTS transfer, set the DTS0UCL bit in the DTS transfer request control register (DTS0TRC), and then clear the DTS0STPU bit. If a DTS transfer is requested at that point, the DTS transfer is resumed.

(Additional information will be provided.)

(3) Aborting or resuming DTS transfer by using DTS transfer enable bit (DTSSEN)

This function is performed by the DTSFSL side.

10.11.16 Error response support

(1) Aborting DTS transfer by error response

When DMAT receives an error response from the internal system bus, the DTS cycle end signal and the the internal system bus transfer error detection signal are asserted at the same time. When the transfer error detection signal is detected at high level, DTS sets the DTS0STPE bit in the DTS transfer status register (DTS0TSR) to “1” to abort the DTS transfer immediately. Subsequent DTS transfer requests are not accepted. Meanwhile, the DTS transfer error interrupt signal (DTSERR) is asserted for one clock cycle. This abort occurs as soon as an error response is received, regardless of the transfer mode and TI hold ON/OFF status.

The user can learn in which channel the error has occurred, by reading the DTS active channel register, after confirming that DTS0STPE has been set.

- Notes**
1. If an error response is received on a channel with TI hold ON, TI write back is not performed.
 2. It is not possible to determine the cycle (TI fetch cycle, etc.) where the error response occurred.

(2) Canceling transfer abort caused by error response

To cancel a DTS transfer abort caused by an error response, check the DTS active channel register (DTS0ACR), use the DTS0TIT and DTS0ICH bits in the DTS initialization control register (DTS0ICR) to clear the TI for the channel in which the error has occurred, and then set the DTS0ECL bit in the DTS transfer request control register (DTS0TRC) to “1” to clear DTS0STPE in the DTS transfer status register (DTS0TSR) to “0”.

10.12 DTSFSL Function

The DTS factor selector (DTSFSL) function selects DTS trigger factors from among interrupt signals. Four priority levels can be set for DTS trigger factors. Factors that are not used with DTS can be input to the interrupt controller via DTS transfer-factor-through outputs (IRQ[127:0]).

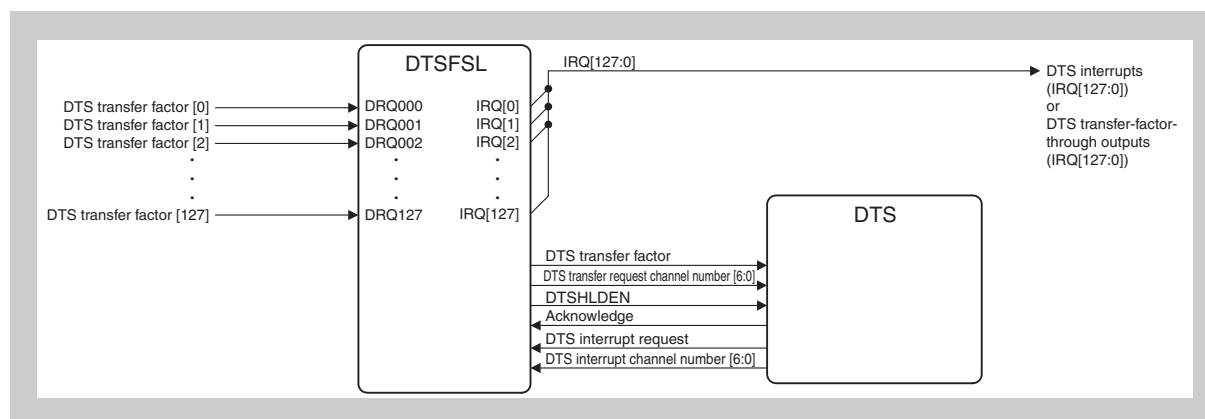

Figure 10-28 Connections between DTSFSL and DTS

10.12.1 Features

A maximum of up to 128 factors can be assigned as DTS transfer factors.

Any of four priority levels can be set for each of these factors.

Based on an interrupt request source from the DTS, an interrupt is output (shared output) to the CPU via a DTS interrupt (IRQ[127:0]) corresponding to the particular channel.

Note The types of interrupt request sources from the DTS are “all transfer counts ended”, “flag check result is false”, and “compare result is false”.

Factors that are not used with DTS are input to the interrupt controller via DTS transfer-factor-through outputs (IRQ[127:0]) (shared output).

Table 10-57 DTS transfer sources (1/4)

Channel	Interrupt to start DTS	Corresponding DTSENx register	
		Address	Symbol

10.13 DTFSL Control Registers

10.13.1 DTSENx (x = 000 to 127): DTS transfer enable register

Access This register can be read or written in 8-bit units.

Address See Table 10-57 "DTS transfer sources".

Initial Value 00_H

7	6	5	4	3	2	1	0
DRQ	0	DRQCLR	0	0	DTSEN	DTSPR1	DTSPR0
R	R/W	R/W	R	R	R/W	R/W	R/W

Table 10-58 DTSENx register contents

Bit position	Bit name	Function
7	DRQ	This bit indicates whether a transfer request to the DTS is being held pending. This is a read-only bit, and writing to this bit is ignored. 0: No DTS transfer requests 1: DTS transfer requests exists (wait status) Condition for setting (to "1"): When the rising edge of DTS transfer source x is detected Condition for clearing (to "0"): When "1" is written to the DRQCLR bit, or when the DTS accepts a transfer request
5	DRQCLR	Writing "1" to this bit clears the DRQ bit to "0". Writing "0" to this bit is ignored.
2	DTSEN	DTS transfer request enable bit for DTS transfer source x 0: Does not use DTS transfer source x as DTS transfer request (DTS request disabled) 1: Uses DTS transfer source x as DTS transfer request (DTS request enabled)
1 0	DTSPR1 DTSPR0	These bits specify the priority order. "00" specifies the highest priority level and "11" specifies the lowest priority level.

10.13.2 DTSHENm (m = 0 to 3): DTS hold enable register

Access This register can be read or written in 16-bit units.

Address DTSHEN0: FFFF 7E00_H, DTSHEN1: FFFF 7E02_H, DTSHEN2: FFFF 7E04_H,
DTSHEN3: FFFF 7E06_H

Initial Value 0000_H

15	14	13	12	11	10	9	8
HEN	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R
7	6	5	4	3	2	1	0
0	dtsch6	dtsch5	dtsch4	dtsch3	dtsch2	dtsch1	dtsch0
R	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 10-59 DTSHENm register contents

Bit position	Bit name	Function
15	HEN	This bit enables/disables operation of the DTS hold enable register. 1: Enables operation of hold enable register. 0: Disables operation of hold enable register.
6:0	dtsch6 to dtsch0	These bits select the target channel for hold. Settings to these bits are valid only when HEN is "1". The set values are listed in the table below.

Table 10-60 List of channels subject to hold selected by setting dtsch6 to dtsch0

<R>

10.13.3 DTSSELm (m = 0 to 11): DTS transfer end interrupt select register

This register is used to switch between a DTS transfer end interrupt and internal or external interrupt.

Access This register can be read or written in 32-bit units.

Address DTSSEL0: FFFF FE00_H DTSSEL1: FFFF FE04_H
 DTSSEL2: FFFF FE08_H DTSSEL3: FFFF FE0C_H
 DTSSEL4: FFFF FE10_H DTSSEL5: FFFF FE14_H
 DTSSEL6: FFFF FE18_H DTSSEL7: FFFF FE1C_H
 DTSSEL8: FFFF FE20_H DTSSEL9: FFFF FE24_H
 DTSSEL10: FFFF FE28_H DTSSEL11: FFFF FE2C_H

Initial Value 0000 0000_H. This register is initialized by any reset.

- Cautions**
1. Be sure to clear the DSEL[127:0] bits corresponding to the channels that are not listed or indicated as *Reserved* in *Table 10-57 "DTS transfer sources" on page 368*.
 2. When changing a DTSSELm.DSEL[127:0] bit, make sure that the interrupt request signal corresponding to the DTS transfer source to be changed will not be generated.
 3. Set a DTS transfer end interrupt to the same DTS transfer source.

Table 10-61 DTSSSELm register contents

Bit position	Bit name	Function
7:0	DSELMx8+7 to DSELMx8+0	<p>These bits select an interrupt request signal that triggers DTS transfer.</p> <p>1: Selects the internal or external interrupt source. 0: Selects the DTS transfer end interrupt.</p> <p>To start a DTS transfer, enable transfer requests by using DTS transfer enable register n (DTSENn) of the DTSFSL, and select the DTS transfer end interrupt by setting the DTSSSELm.DSEL[127:0] bit.</p> <p>To cancel the DTS transfer, disable transfer requests by using DTS transfer enable register n (DTSENn) of the DTSFSL, and select the internal/external interrupt source by clearing the DTSSSELm.DSEL[127:0] bit.</p> <p>If the DTSSSELm.DSEL[127:0] bit is cleared to select the internal or external interrupt source while transfer requests are enabled, or if the DTSSSELm.DSEL[127:0] bit is set to select the DTS transfer end interrupt while transfer requests are disabled, the interrupt request signal will not reach the CPU even if an interrupt corresponding to the source assigned to DTS channel n is generated.</p>

Chapter 11 Memory Controller

11.1 Overview

The external memory access function of this microcontroller provides an interface for connecting memory, ASICs, etc., outside this microcontroller. This microcontroller allows the connection of the following 2 types of memory.

- SRAM
- SDRAM

This microcontroller provides 4 chip select areas (CS1 to CS4), and the bus size and wait time can be set independently for each chip select area. 128-bit burst read is possible by selecting SDRAM as the bus cycle type.

In addition to an external wait function, this microcontroller has various programmable wait functions that can be set for each chip select area, allowing the connection of various types of memory.

This microcontroller has also an external bus hold function that allows the creation of a memory system with a multi-master configuration.

Input/output signals The following table shows the input/output signals of the memory controller.

Table 11-1 Input/output signals of memory controller (1/2)

P_MEMC signal	Function	Connected to
MDIxx MADxx	Data bus	Port D[0:31]
BENZxx	Byte enable signal output (D0 to D7)	Port $\overline{\text{LLBE}}$
	Byte enable signal output (D8 to D15)	Port $\overline{\text{LUBE}}$
	Byte enable signal output (D16 to D23)	Port $\overline{\text{ULBE}}$
	Byte enable signal output (D24 to D31)	Port $\overline{\text{UUBE}}$
RDZ	Read strobe signal output	Port $\overline{\text{RD}}$
DVCLK	Bus clock output	Port BUSCLK
WRZ	Write strobe signal output	Port $\overline{\text{WR}}$
RWZ	Read/write status signal output	Port $\overline{\text{RW}}$
xxWRZ	Write strobe signal output (D0 to D7)	Port $\overline{\text{LLWR}}$
	Write strobe signal output (D8 to D15)	Port $\overline{\text{LUWR}}$
	Write strobe signal output (D16 to D23)	Port $\overline{\text{ULWR}}$
	Write strobe signal output (D24 to D31)	Port $\overline{\text{UUWR}}$
DQMxx	I/O mask signal output for SDRAM (D0 to D7)	Port LLDQM
	I/O mask signal output for SDRAM (D8 to D15)	Port LUDQM
	I/O mask signal output for SDRAM (D16 to D23)	Port ULDQM
	I/O mask signal output for SDRAM (D24 to D31)	Port UUDQM
REFRQZ	Refresh request	Port $\overline{\text{REFRQ}}$
SDRASZ	Row address strobe signal output for SDRAM	Port $\overline{\text{SDRAS}}$
SDCASZ	Column address strobe signal output for SDRAM	Port $\overline{\text{SDCAS}}$

Table 11-1 Input/output signals of memory controller (2/2)

P_MEMC signal	Function	Connected to
CKE	SDRAM clock enable output signal	Port SDCKE
CPBUSRQ	CPU bus request report output	Port BUSRQ
SDWEZ	Data write enable output for SDRAM	Port $\overline{\text{SDWE}}$
LBAZ	Bus cycle start for SRAM cycle	Not used
MAOxx	Address bus for external memory	Port A[0:25]
CSZxx	Chip select signal output	Port $\overline{\text{CS}}[1:4]$
WAITZ	External wait request input	Port $\overline{\text{WAIT}}$
HLDKZ	Bus hold acknowledge output	Port $\overline{\text{HLDK}}$
HLDRQZ	Bus hold request input	Port $\overline{\text{HLDRQ}}$

11.1.1 Operation mode, connectable memory types

(1) Separate bus mode

This is an operation mode that connects address output and data input/output to external memory using independent signal lines. By using this mode, any of the following three types of memory can be connected to individual chip select areas.

- SRAM
- SDRAM^a

11.1.2 Chip select output function

The external bus area of the memory space is divided into four chip select areas, and a chip select signal can be output for each chip select area. The allocation of these chip select areas is fixed by the system and cannot be changed through programming.

11.1.3 Bus sizing function

The bus size can be selected from 8 bits, 16 bits, or 32 bits for each chip select area. To execute access when the data size exceeds the selected bus width, divide the data into sizes smaller than the bus width by using the bus sizing function.

11.1.4 Data endian setting function

The data endian (little endian/big endian) can be specified for the chip select areas. However, since the software development tools made by Renesas Electronics (assemblers and debuggers) only support little endian, instruction fetch operations in big endian are not possible.

The initial status of all chip select areas is little endian.

Misaligned access to these areas is prohibited when big endian has been selected.

11.1.5 Programmable wait setting functions

This microcontroller has the following wait functions, which can be set for each chip select area.

- Programmable data wait
- Data hold wait
- Idle cycle function
- RAS latency (in SDRAM)
- CAS latency (in SDRAM)

a).SDRAM can only be selected for a specific chip select area (CS4).

11.1.6 External wait function

When SRAM, or during write access to page-ROM memory or Sync-Flash memory, data waits of any width can be inserted from outside from the $\overline{\text{WAIT}}$ pin. The $\overline{\text{WAIT}}$ pin is sampled just before the data output cycle, and the data latch timing can be delayed by any amount.

11.1.7 External wait error detection function

This microcontroller has a function to forcibly cancel a wait state if an external wait is continuously input for 128 clock cycles and generate a SYSERROR interrupt, in order to prevent a system hang-up if an external wait is continuously input due to a defect of the external wait pin.

11.1.8 Bus hold function

A bus hold request from outside can be input through the $\overline{\text{HLDRQ}}$ pin.

This microcontroller also has the CPBUSRQ pin, which is used to report the fact that there was a transfer request from inside this microcontroller during the bus hold period. By controlling bus hold requests from the outside using this pin function, it is possible to create a multi-master system that minimizes the effect of an external bus hold on the execution of CPU processes.

11.1.9 DMA cycle output function

This pin function indicates that an external bus cycle has been generated by the DMA.

This microcontroller features eight DMA channels, but only channels 0 through 5 support the DMA cycle output function.

11.2 Registers

These registers are used to control the memory controller.

Note The clock counts shown in this section indicate the clock count when operating on the external bus clock unless otherwise specified.

Table 11-2 External memory access control registers

Address	Register name	Symbol	R/W	Manipulable bit unit			Initial value
				1	8	16	
FFFF7200 _H	Bus size configuration register	BSC	R/W			√	AAAA _H
FFFF7202 _H	Data endian configuration register	DEC	R/W			√	0000 _H

FFFF7224 _H	SDRAM status register	STR	R		√		00 _H
FFFF7226 _H	SDRAM refresh control register	RFS	R/W			√	0000 _H

11.2.1 Bus size configuration register (BSC)

The BSC register is used to set the bus size of the external bus for each chip select area.

Access This register can be read or written in 16-bit units.

Address FFFF7200_H

Initial Value AAAA_H.

Caution Only bits 9 to 2 can be set. Be sure to set bits 15, 13, 11, and 1 to “1”, and bits 14, 12, 10, and 0 to “0”.

15	14	13	12	11	10	9	8
BS71	BS70	BS61	BS60	BS51	BS50	BS41	BS40
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 11-3 BSC register contents

Bit position	Bit name	Function															
15:14, 13:12, 11:10, 9:8, 7:6, 5:4, 3:2, 1:0	BSn1, BSn0	Bus size setting bits These bits set the bus width of each chip select area. <table border="1" style="margin-left: 20px;"> <thead> <tr> <th>BSn1</th><th>BSn0</th><th>Bus size</th></tr> </thead> <tbody> <tr> <td>0</td><td>0</td><td>8 bits</td></tr> <tr> <td>0</td><td>1</td><td>16 bits</td></tr> <tr> <td>1</td><td>0</td><td>32 bits</td></tr> <tr> <td>1</td><td>1</td><td>Setting prohibited</td></tr> </tbody> </table>	BSn1	BSn0	Bus size	0	0	8 bits	0	1	16 bits	1	0	32 bits	1	1	Setting prohibited
BSn1	BSn0	Bus size															
0	0	8 bits															
0	1	16 bits															
1	0	32 bits															
1	1	Setting prohibited															

11.2.2 Data endian configuration register (DEC)

The DEC register is used to set the endianness of the external bus.

Access This register can be read or written in 16-bit units.

Address FFFF7202_H

Initial Value 0000_H. This register is initialized by any reset.

- Cautions**
1. Only bits 8, 6, 4, and 2 can be set. Be sure to set bits 15 to 9, 7, 5, 3, 1, and 0 to "0".
 2. Misaligned access to these areas is prohibited when big endian has been selected.

15	14	13	12	11	10	9	8
0	DE7	0	DE6	0	DE5	0	DE4
R	R/W	R	R/W	R	R/W	R	R/W

0	DE3	0	DE2	0	DE1	0	DE0
R	R/W	R	R/W	R	R/W	R	R/W

Table 11-4 DEC register contents

Bit position	Bit name	Function
14, 12, 10, 8, 6, 4, 2, 0	DEn	Data endian setting bits These bits set the endian of each chip select area. 0: Little endian 1: Big endian

11.2.3 Data wait configuration registers 0 (DWC0)

The DWC0 register is used to set the number of data wait states of the external bus.

The value set to the DWC0 register becomes valid in the following bus cycles.

- Data transfer cycle of SRAM bus cycle type

Access These registers can be read or written in 16-bit units.

Address FFFF7208_H

Initial Value 7777_H

Caution Only bits 15 to 4 can be set. Be sure to set bit 3 to “0”, and bits 2 to 0 to “1”.

	15	14	13	12	11	10	9	8
DWC0	DW33	DW32	DW31	DW30	DW23	DW22	DW21	DW20

1	1	1	0	14 clock cycles																																																																																			
1	1	1	1	15 clock cycles																																																																																			

11.2.4 Data hold wait configuration register (DHC)

The DHC register is used to set the number of extended data hold wait states for each chip select area in the write cycle of the external bus.

The number of data hold wait states determined by the set value of the DHC register + 1 cycle is inserted in a write cycle.

Access This register can be read or written in 16-bit units.

Address FFFF720C_H

Initial Value 0000_H. This register is initialized by any reset.

Caution Bits 7 to 2 can be set. Be sure to clear bits 15 to 8, 1, and 0 to “0”.

15	14	13	12	11	10	9	8
DH71	DH70	DH61	DH60	DH51	DH50	DH41	DH40
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
7	6	5	4	3	2	1	0

R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 11-6 DHC register contents

Bit position	Bit name	Function															
15:14, 13:12, 11:10, 9:8, 7:6, 5:4, 3:2, 1:0	DHn1, DHn0	Data hold wait setting bits These bits set the number of data hold wait states for each chip select area. <table border="1" style="margin-left: 20px;"> <thead> <tr> <th>DHn1</th><th>DHn0</th><th>Number of data hold wait states</th></tr> </thead> <tbody> <tr> <td>0</td><td>0</td><td>No data hold wait</td></tr> <tr> <td>0</td><td>1</td><td>1 clock cycle</td></tr> <tr> <td>1</td><td>0</td><td>2 clock cycles</td></tr> <tr> <td>1</td><td>1</td><td>3 clock cycles</td></tr> </tbody> </table>	DHn1	DHn0	Number of data hold wait states	0	0	No data hold wait	0	1	1 clock cycle	1	0	2 clock cycles	1	1	3 clock cycles
DHn1	DHn0	Number of data hold wait states															
0	0	No data hold wait															
0	1	1 clock cycle															
1	0	2 clock cycles															
1	1	3 clock cycles															

11.2.5 Idle cycle configuration registers 0 and 1 (ICC0, ICC1)

The ICC registers are used to set the number of idle cycles of the external bus. The number of idle cycles can be set for each chip select area and in the read cycle or write cycle.

Access These registers can be read or written in 16-bit units.

Address FFFF7214_H: ICC0

FFFF7216_H: ICC1

Initial Value 3333_H. These registers are initialized by any reset.

- Cautions**
1. The number of idle cycles set by the ICC_m register (m = 0, 1) is invalid during the burst read cycle and bus sizing cycle.
 2. Bits 15 to 4 of the ICC0 register can be set. Be sure to set bits 3 to 0 to "0".
 3. Bits 3 to 0 of the ICC1 register can be set. Be sure to set bits 15 to 4 to "0".

	15	14	13	12	11	10	9	8

0	0	No idle cycle															
0	1	1 clock cycle															
1	0	2 clock cycles															
1	1	3 clock cycles															

11.2.6 External wait error configuration register (EWC)

The EWC register is used to enable or disable the external wait error function for each chip select area.

Setting the EWC register is enabled in the following bus cycles.

- SRAM bus cycle type (separate bus mode)

Access This register can be read or written in 16-bit units.

Address FFFF721A_H

Initial Value 0000_H. This register is initialized by any reset.

- Cautions**
1. Only bits 6, 4, and 2 can be specified. Be sure to clear bits 14, 12, 10, 8, and 0.
 2. When using the bus hold function of the memory controller, set this register to 0000_H.

15	14	13	12	11	10	9	8
0	EW7	0	EW6	0	EW5	0	EW4
R	R/W	R	R/W	R	R/W	R	R/W
7	6	5	4	3	2	1	0
0	EW3	0	EW2	0	EW1	0	EW0
R	R/W	R	R/W	R	R/W	R	R/W

Table 11-8 EWC register contents

Bit position	Bit name	Function
14, 12, 10, 8, 6, 4, 2, 0	EWn	<p>External wait error setting bits</p> <p>These bits enable or disable an external wait error in each chip select area.</p> <p>0: Disables external wait error.</p> <p>1: Enables external wait error.</p> <p>When this function is enabled, this microcontroller forcibly cancels the wait state when it has detected the external wait signal for the duration of 128 consecutive clock cycles, and the CPU generates the SYSERROR exception.</p>

11.2.7 SDRAM enable control register (SEN)

The SEN register controls whether SDRAM controller operations are enabled or disabled.

Access This register can be read or written in 8-bit units.

Address FFFF7220_H

Initial Value 00_H. This register is initialized by any reset.

7	6	5	4	3	2	1	0
0	0	0	0	0	0	0	SE
R	R	R	R	R	R	R	R/W

Table 11-9 SEN register contents

Bit position	Bit name	Function
0	SE	This bet sets whether SDRAM controller operations are enabled or disabled. 0: Operation stopped (No external bus cycles) 1: Operation enabled

11.2.8 SDRAM configuration register (SDCR)

The SDCR register is used to set the number of waits and address multiplexed width when SDRAM is accessed. When this register is written, a register write operation is started.

Access This register can be read or written in 16-bit units.

Address FFFF7222_H

Initial Value 30C0_H. This register is initialized by any reset.

- Cautions**
1. Before a register write operation is performed, there are no SDRAM read or write cycles. Before accessing SDRAM, read the STR register values and make sure that the WCF bit is set to 1.
 2. Before setting the SDCR register, set the SDRAM refresh control register (RFS).
 3. After accessing SDRAM, to again write to the SDCR register, first clear the SE bit of the SEN register to 0.
 4. When the SE bit is cleared to 0, be sure to write to the SDCR register before setting the SE bit to 1 again. At this time, if the SDCR register value does not need to be changed, write the same values.
 5. Be sure to clear bits 11, 10, and 8 to "0".

15	14	13	12	11	10	9	8
BST	LTM2	LTM1	LTM0	0	0	PDM	0

a) The value is 1 when read and 0 when written.

11.2.9 SDRAM status register (STR)

The STR register indicates the SDRAM status.

Access This register is read-only, in 8-bit units.

Address FFFF7224_H

Initial Value 00_H. This register is initialized by any reset.

7	6	5	4	3	2	1	0
0	0	0	0	0	0	WBF	WCF
R	R	R	R	R	R	R	R

Table 11-13 STR register contents

Bit position	Bit name	Function
1	WBF	This bit indicates whether data is stored in the SDRAMC write buffer. 0: No data in write buffer (initial value) 1: Data in write buffer
0	WCF	After the SDCR register is set, this bit indicates that a register write command for the SDRAM is complete. If the SE bit of the SEN register is cleared to 0, the WCF bit is also cleared to 0. 0: Settings not complete (initial value) 1: Settings complete

11.2.10 SDRAM refresh control register (RFS)

The RFS register is used to set the CBR refresh cycle and self refresh cycle for SDRAM. This register can also be used to set the refresh cycle when SDRAM is initially set (when a register write operation is executed).

Access This register can be read or written in 16-bit units.

Address FFFF7226_H

Initial Value 0000_H. This register is initialized by any reset.

Caution To change the setting of the RFS register during SDRAMC operation (SE bit = 1), use the following procedure.

1. Clear the SE bit of the SEN register to 0.
2. Clear the REN bit to 0.
3. While specifying new values for the RIN12 to RIN0 bits, set the REN bit to 1.
4. Set the SDCR register.
5. Make sure that the WCF bit of the STR register is 1, and then set the SE bit of the SEN register to 1.

When switching the refresh interval, set a value that enables the refresh to be in time even during the switch.

Table 11-15 Example of SDRAM Refresh Intervals

Target refresh interval setting (μs)	Interval factor (Ifac) ^a
	When $f_{\text{BUSCLK}} = 50 \text{ MHz}$
15	750 (15.0)
30	1,500 (30.0)
60	3,000 (60.0)

a) The values in parentheses are the calculated refresh intervals (μs).

<Calculating the interval factor>

Ifac = $X (\mu\text{s}) / (1 / f_{\text{BUSCLK}} (\text{MHz}))$: Disregard any fractional component.

X: Target refresh interval setting

f_{BUSCLK} : SDRAM operating frequency

11.3 Bus Cycle Type Setting Function

In the separate bus mode, the type of bus cycle listed below can be used.

- SRAM bus cycle type

Note that the CS4 area is fixed to the SDRAM bus cycle type and cannot be changed.

11.3.1 SRAM bus cycle type

The SRAM cycle is the most basic bus cycle in the separate bus mode. This microcontroller accesses the external memory using address and chip select signals, and the read strobe signal during the read cycle or the write strobe signal during the write cycle.

In the separate bus mode, this bus cycle is selected for all the chip select areas via initialization through reset.

The read strobe/write strobe cycle can be extended by up to 15 clock cycles with the DWC register. External wait is also enabled through these strobes

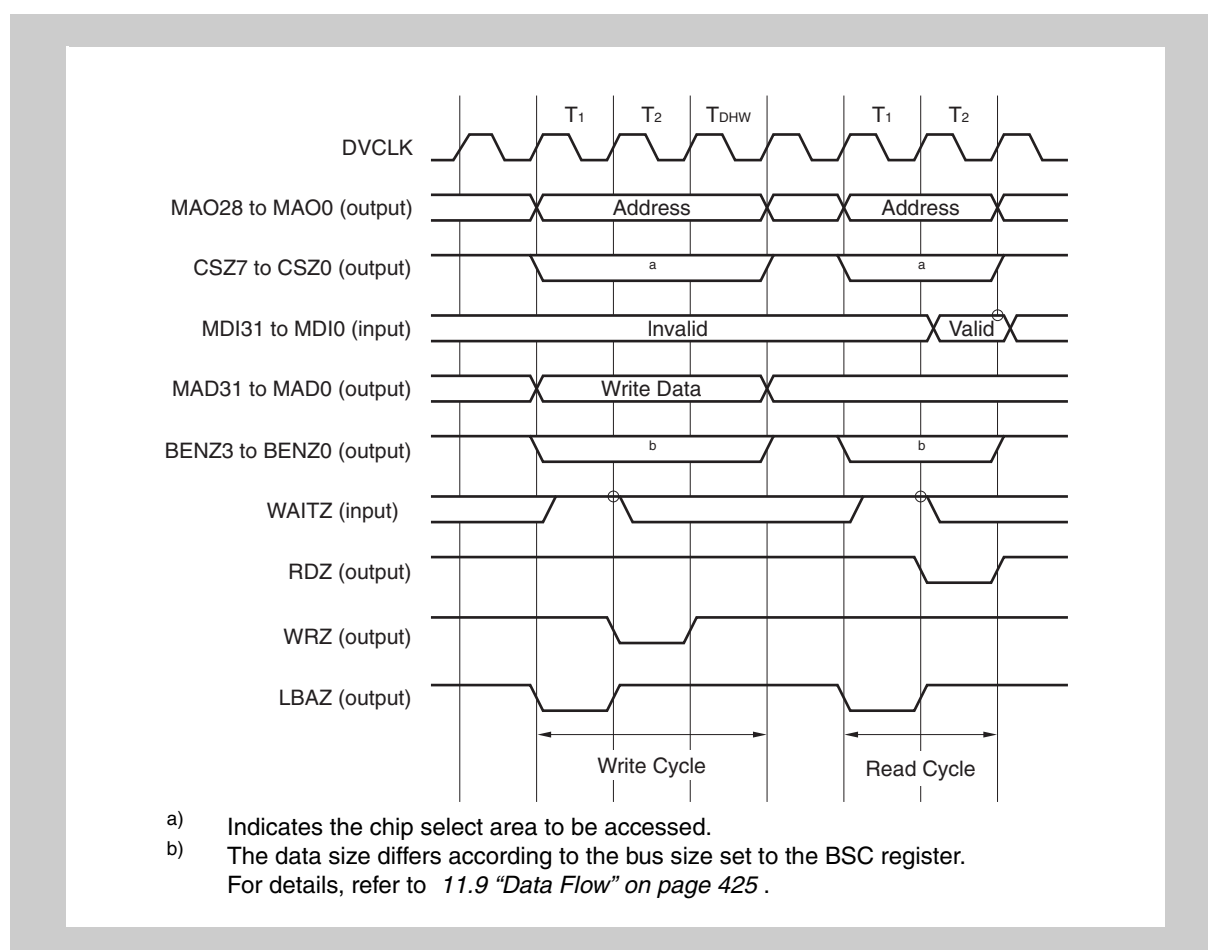

Figure 11-1 SRAM cycle (separate bus mode, read/write)

The valid wait functions in the SRAM cycle are listed below.

- Programmable data wait of 15 clock cycles max. through DWC register
- Data wait through external pin
- Insertion of idle cycle through ICC register
- Data hold wait of up to 3 clock cycles through DHC register

The LBAZ pin becomes active during the SRAM cycle in order to enable access to the Sync-Flash memory or page-ROM memory in the SRAM cycle. When only SRAM memory is used, the LBAZ pin is not used.

11.3.2 SDRAM bus cycle type

This bus cycle is used when connecting SDR-SDRAM that conforms to JEDEC (it is not supported for Mobile SDRAM or SGRAM).

Only the CS4 area is allocated as an SDRAM area. The maximum supported SDRAM memory size is 512 Mb. The row address width corresponds to bits 11, 12, 13, and 14, and the column address width corresponds to bits 8, 9, and 10. The maximum number of banks is four. Both little endian and big endian are supported.

When writing to SDRAM, single write access (burst length: 1) is always used. By buffering data into the SDRAM-controller internal buffer in response to a write cycle request from the CPU, the CPU can immediately perform the following processing. The buffer consists of eight stages, and, regardless of the SDRAM data bus width, can accumulate the data from up to eight writes. If even one item of data is accumulated in the write buffer, the WBF flag of the SDRAM status register is set to 1, and, when the write buffer empties, this flag is cleared to 0. Write access to SDRAM continues sequentially until the write buffer empties.

When reading from SDRAM, the burst read function can be used. This function is enabled when the BST bit of the SDRAM configuration register is set to 1. When this function is enabled, eight sequential read accesses are made in response to a read cycle request from the CPU. If the data bus width is 8 bits, 64 bits including the requested address are sequentially accessed; if the data bus width is 16 bits, 128 bits including the requested address are sequentially accessed; and, if the data bus width is 32 bits, 256 bits including the requested address are sequentially accessed. The read data is saved in the SDRAM-controller internal buffer, and then, when there is a read access request from the CPU, the address is compared to the address of the buffered data and, if the addresses are the same, the data is returned from the buffer without starting an external bus cycle. Any write access to SDRAM discards the read buffer data unconditionally. Also, read requests from the CPU are held pending until the eight data reads finish.

Regardless of whether the burst read function is enabled or disabled, when DRAM is accessed for reading, the SDRAM controller issues active commands followed by auto precharge read commands, regardless of which bank or page is accessed.

The wait function enabled for the SDRAM bus cycle type is as follows:

- Idle cycle insertion by the ICC register (but only the last cycle is enabled)

11.4 Bus Control Function

11.4.1 Chip select output function

The connected external memory area is managed divided into 4 chip select areas up to CSn (n = 1 to 4), as shown in *Figure 11-2 “External memory map”*.

When a bus cycle is generated for the external bus, This microcontroller makes the CSn (n = 1 to 4) output pins corresponding to the access target address active (low level), along with outputting the access target address from the MAO[23:0] pins.

The various settings for the external bus, such as the bus size and number of wait/idle states, can all be made for each chip select area.

By using these functions, different types of memory can be connected for each chip select area.

The allocation of the chip select areas is fixed by the system and cannot be changed through programming.

The memory map is shown next.

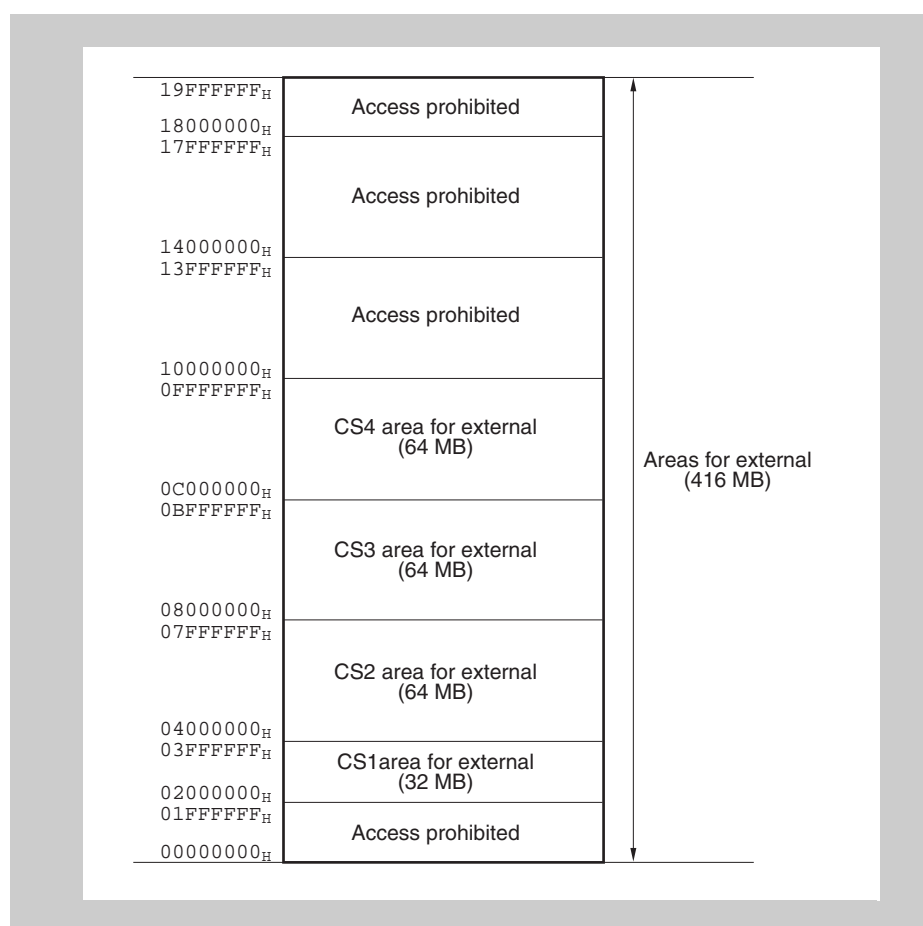

Figure 11-2 External memory map

11.4.2 Bus size setting function

Access requests from the CPU (or DMA) are executed after being divided in accordance with the bit width of the external bus of the access destination.

The bit width of the external bus can be selected from 32, 16, and 8 bits for each chip select area by setting the BSC register.

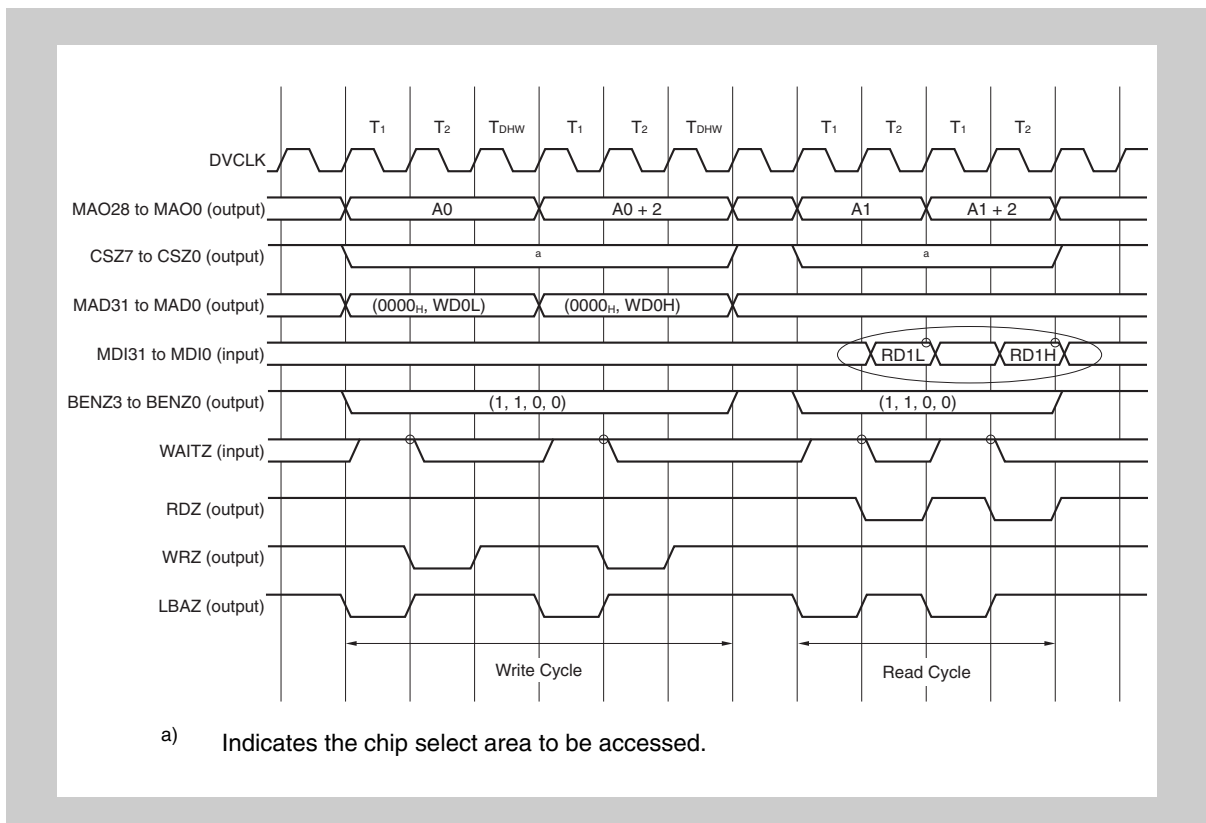

Figure 11-3 SRAM cycle for 16-bit bus size

11.4.3 Data endian setting function

Either little endian or big endian can be selected as the data endian of the external bus interface. This setting can be made for each chip select area with the DEC register. Initial setting through input pins is not possible. The initial status is little endian for all the chip select areas.

Access to a chip select area for which big endian has been specified as the data endian is performed in big endian.

This function can be used only for the SRAM access type.

-
- Cautions**
1. In this microcontroller, instruction fetch operation with big endian is not supported.
 2. Misaligned access to these areas is prohibited when big endian has been selected.
-

Note For details about the data flow for each external bus size and data size, refer to 11.9 “Data Flow” on page 425 .

11.4.4 SDRAM setting function

To use SDRAM, first set the SE bit of the SDRAM enable control register (SEN) to 1, and then set the SDRAM refresh control register (RFS). When the SDCR register is written to, a register write operation is performed. Before the execution of a register write operation, no SDRAM read/write cycles occur. When the register write operation ends, the STR.WCF bit is set to 1. Before starting to access SDRAM, be sure to read the STR register values, and make sure that the WCF bit is set.

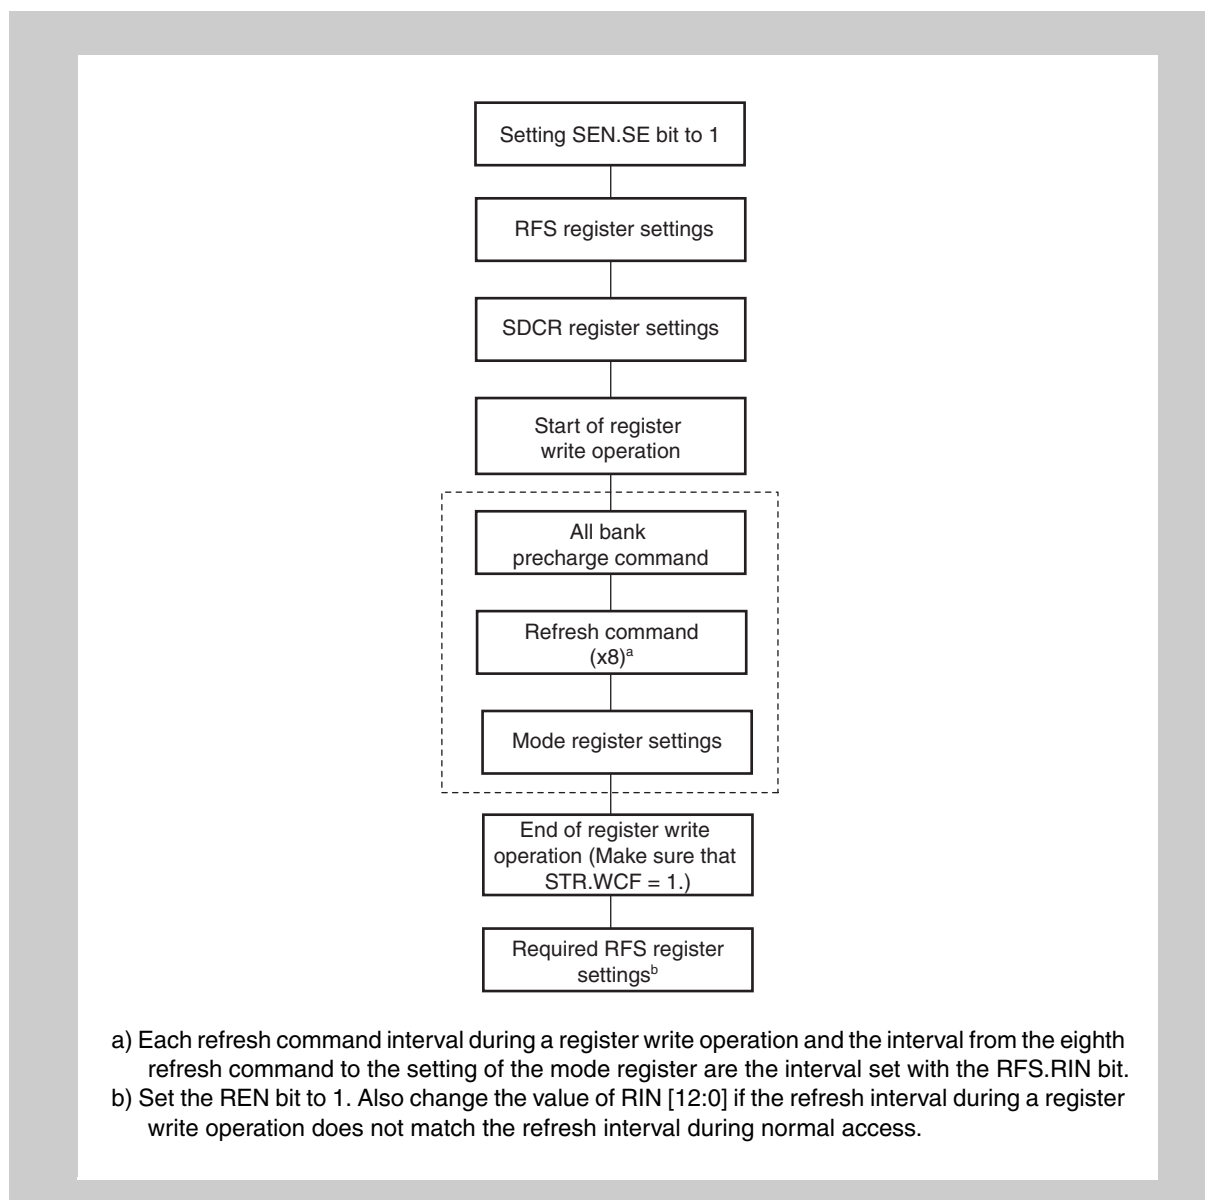

Figure 11-4 Initial register settings - register write operation flow

(1) SDRAM read access

When accessing SDRAM for reading, the burst read function can be used. When this function is enabled, eight sequential read accesses are made, regardless of the data bus width. Read requests from the CPU are held pending until the eight data reads are complete. The read data is saved in the SDRAM controller internal buffer, and then, when there is a read access request from the CPU, the address is compared to the address of the buffered data and, if the addresses are the same, the data is returned from the buffer without starting an external bus cycle. Any write access to SDRAM discards the read buffer data unconditionally.

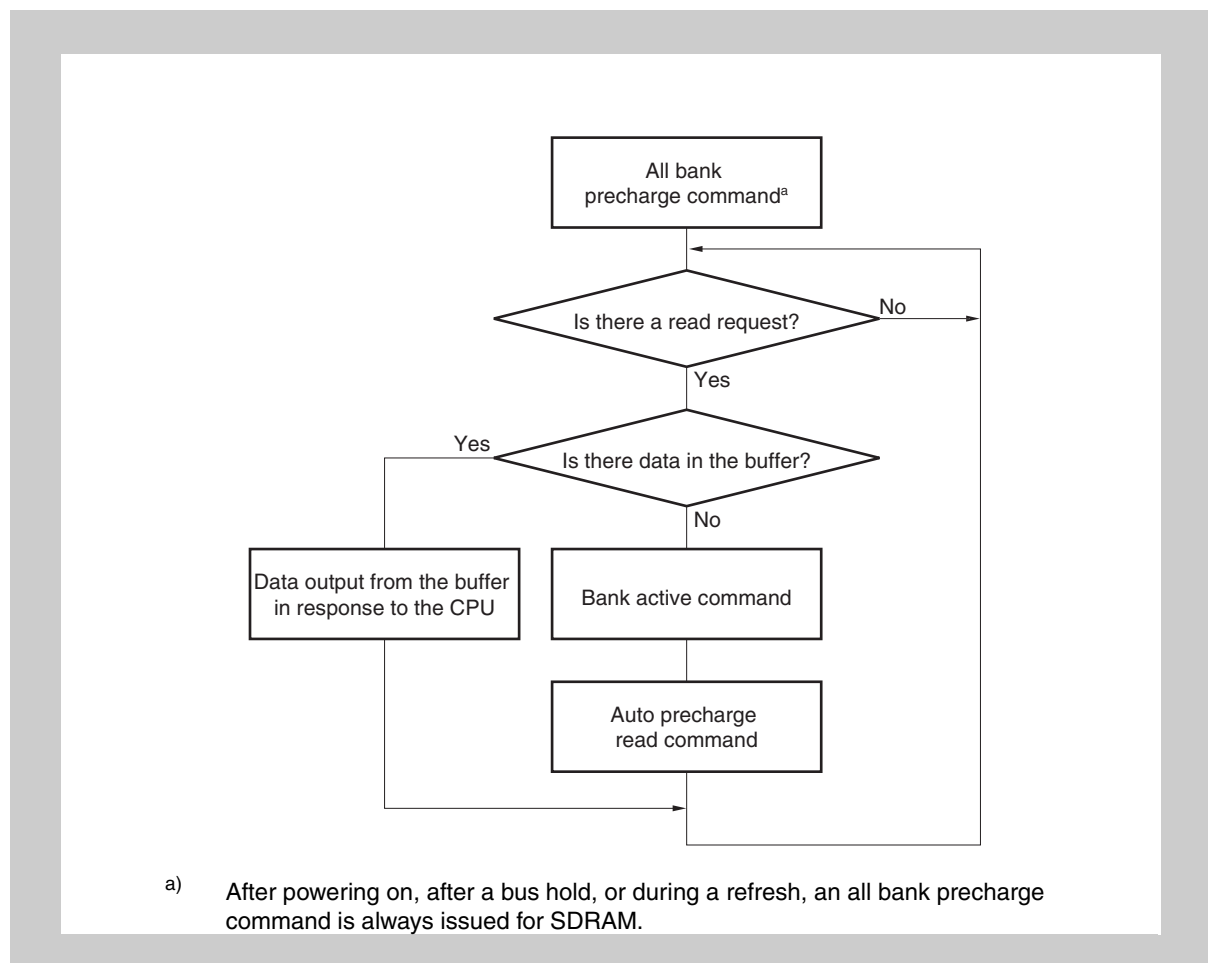

Figure 11-5 SDRAM read access status transitions

(2) Read buffer operation

The size of the SDRAM read buffer can be up to 256 bits. If the burst read function is enabled, this buffer can accumulate the data from up to eight reads. The method for storing data in the buffer differs depending on the data bus width. Operations for each data bus width are described below. If the write buffer is written to even once, or when the system goes into the bus hold state, all the data in the read buffer is deleted.

(a) Data bus width (8 bits)

During 8-bit access, 64 bits, including the address of the data to be read, are stored in the buffer. If the lower 4 bits of the address of the target data are in the range from 0_H to 7_H , 0_H is used as the starting address for reading, and the data from eight burst read accesses (up to 7_H) is stored in the buffer. If the lower 4 bits of the address of the target data are in the range from 8_H to F_H , 8_H is used as the starting address for reading, and the data from eight burst read accesses (up to F_H) is stored in the buffer.

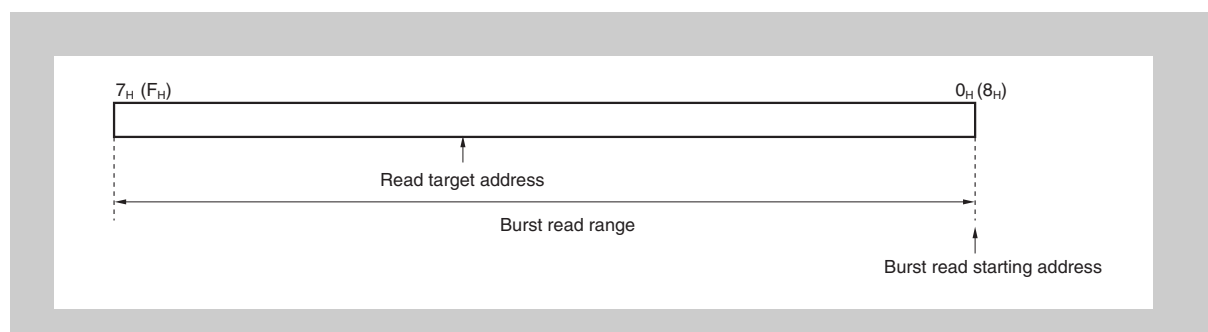

Figure 11-6 Data bus width (8 bits)

(b) Data bus width (16 bits)

During 16-bit access, 128 bits, including the address of the data to be read, are stored in the buffer. The lower 4 bits of the accessed address are monitored, and, within the 128-bit data range that includes the address of the target data, 0_H is used as the starting address for reading and the data from eight burst read accesses (in the range up to F_H) is stored in the buffer.

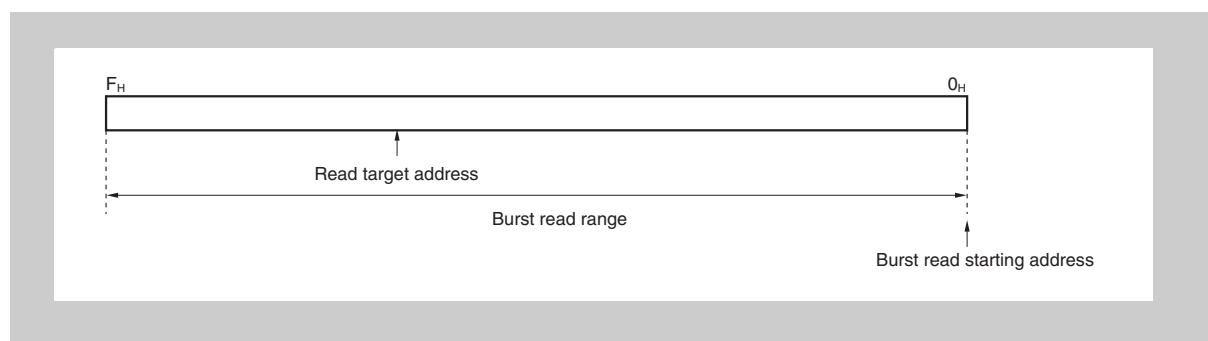

Figure 11-7 Data bus width (16 bits)

(c) Data bus width (32 bits)

During 32-bit access, 256 bits, including the address of the data to be read, are stored in the buffer. The lower 5 bits of the accessed address are monitored, and, within the 256-bit data range that includes the target data, 00_H is used as the starting address for reading and the data from eight burst read accesses (in the range up to 1F_H) is stored in the buffer.

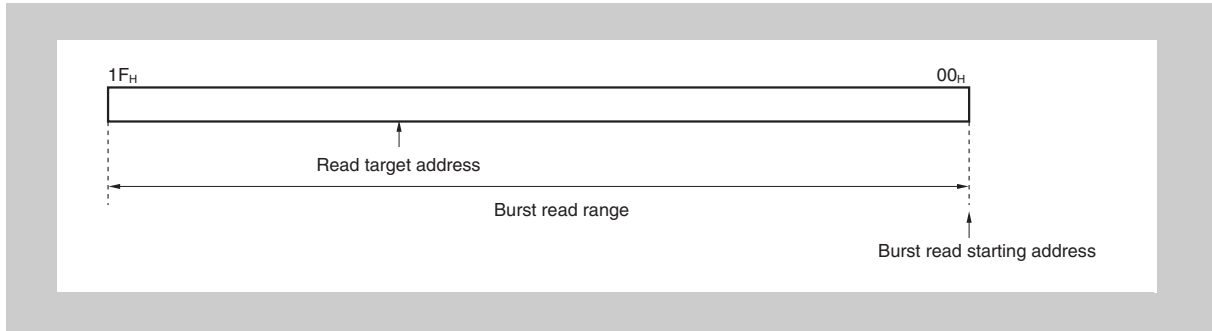

Figure 11-8 Data bus width (32 bits)

(3) SDRAM write access

When writing to SDRAM, single write access (burst length: 1) is always used. By buffering data into the SDRAM controller internal buffer in response to a write cycle request from the CPU, the CPU can immediately perform the following processing. The buffer consists of eight stages, and, regardless of the SDRAM data bus width, can accumulate the data from up to eight writes. Write access to SDRAM continues sequentially until the write buffer empties.

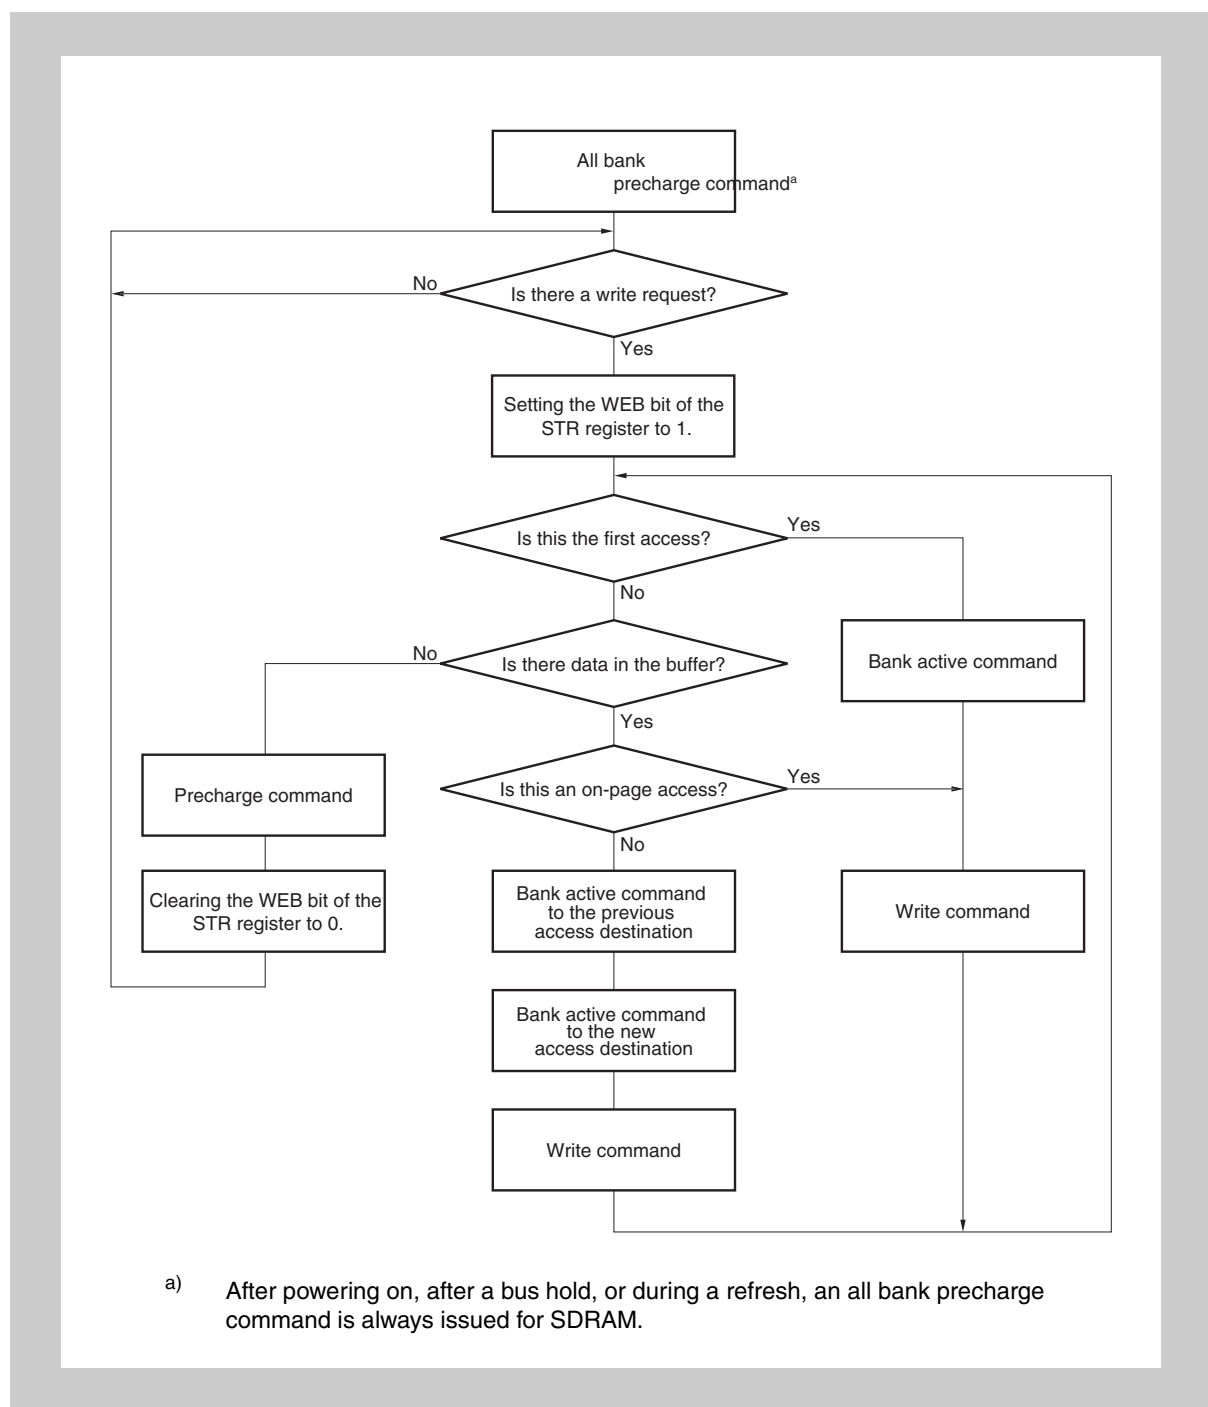

Figure 11-9 SDRAM write access status transitions

(4) Write buffer operation

The size of the SDRAM write buffer, which is an 8-stage FIFO buffer, is 256 bits. When the write buffer runs out of space, write access from the CPU is held pending. Also, read access from the CPU is held pending until there is no data in the write buffer.

(5) CBR refresh function

The SDRAM controller starts a CBR refresh cycle at the refresh interval specified by the RFS register. When a CBR refresh command is issued, if an external bus cycle is occurring, the CBR refresh command is held pending until this cycle ends. Also, if an external bus hold request conflicts with a CBR refresh request, the external bus hold request is prioritized. If a refresh is requested during an external bus hold, the REFRQZ signal can be activated to indicate that a refresh has been requested for the external bus master. If a refresh cycle must be entered during an external bus hold, this signal can be used to cancel the bus hold request.

Note Because the refresh counter performs free-running operations, if a CBR refresh command is held pending, the interval until the next CBR refresh cycle is shortened.

(6) Self refresh function

When the CPU enters standby mode, the SDRAM controller performs the following procedure to start an SDRAM self refresh cycle:

<1> If the memory controller is accessing the external bus, after waiting for the access to end, MEMC sends a standby request signal to the SDRAM controller. (At this time, the SDRAM controller does not access SDRAM.)

→ Go to <4>.

If the memory controller is not accessing the external bus, memory controller immediately sends a standby request signal to the SDRAM controller.

<2> If the SDRAM controller is accessing SDRAM for reading, MEMC waits for the end of read access to SDRAM.

- If the burst read function is enabled, MEMC waits for the completion of eight read accesses.
- If the timing at which a standby request conflicts with a read request to SDRAM, the reading of SDRAM is prioritized.

<3> If the SDRAM controller is accessing SDRAM for writing, MEMC waits for the end of the write access to SDRAM.

- All data accumulated in the write buffer is written to SDRAM.
- If the timing at which a standby request signal is activated conflicts with a write request to SDRAM, the write request is prioritized.

<4> The all bank precharge command, NOP command, and self refresh command are issued.

<5> SDRAM enters the self refresh status.

<6> Standby mode is entered.

<7> Processing to release the self refresh begins. (The NOP command is issued, and (BCW set value x 4) clock waits are inserted.)

<8> The SDRAM self refresh status is released.

<9> The system returns to the normal status.

If an external bus hold request conflicts with a request to enter standby mode, the request to enter standby mode is prioritized.

11.5 Wait Functions

Wait functions listed below.

Table 11-16 Wait functions

Wait function		Data wait		Data hold wait	Idle
		Programmable	External wait		
SRAM bus cycle type	Read	√	√	-	√
	Write	√	√	√	√
SDRAM bus cycle type	Read	-	-	-	√
	Write	-	-	-	√
Setting registers		DWC0	-	DHC	ICC0 ICC1
Max. number of waits		15	-	3	3

11.5.1 Programmable data wait function

This wait function is for delaying the data latch timing by extending the read strobe and write strobe periods.

This function is enabled during all write accesses and at the first data transfer timing in the SRAM.

Up to 15 cycles can be inserted.

Setting individual chip select areas with the DWC0 register is possible.

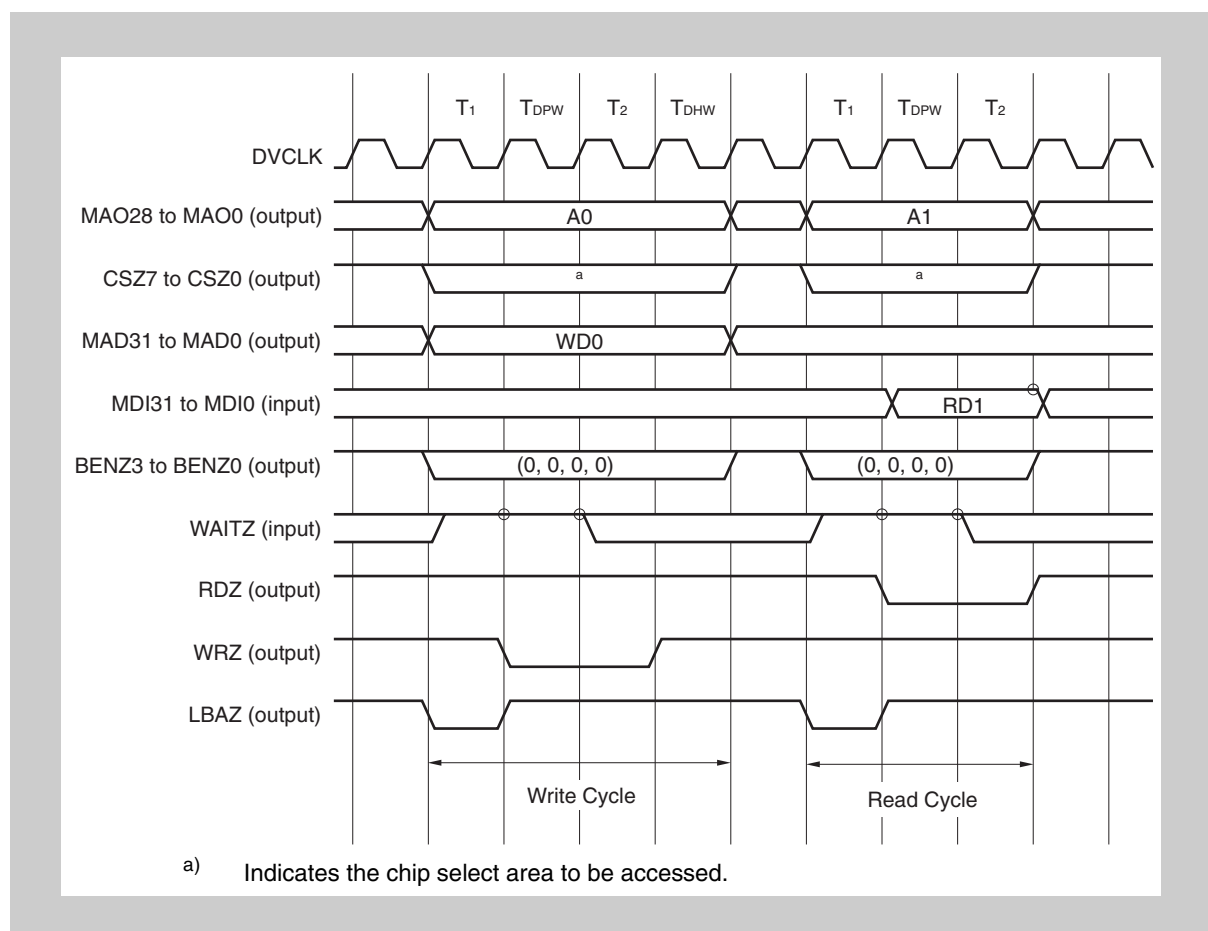

Figure 11-10 Programmable data wait in separate bus mode

11.5.2 External wait function

If the separate bus mode or the multiplexed bus mode is selected as the bus cycle type, data waits of any length can be inserted from the WAITZ pin.

The WAITZ pin input level is sampled immediately after completion of the T_A , T_1 cycles and the T_{DPW} , T_{DEW} cycles.

Data wait cycles obtained by ORing the programmable data wait set by data wait control registers 0 and 1 (DWC0 registers) and the external wait specification set by the WAITZ pin input, are inserted.

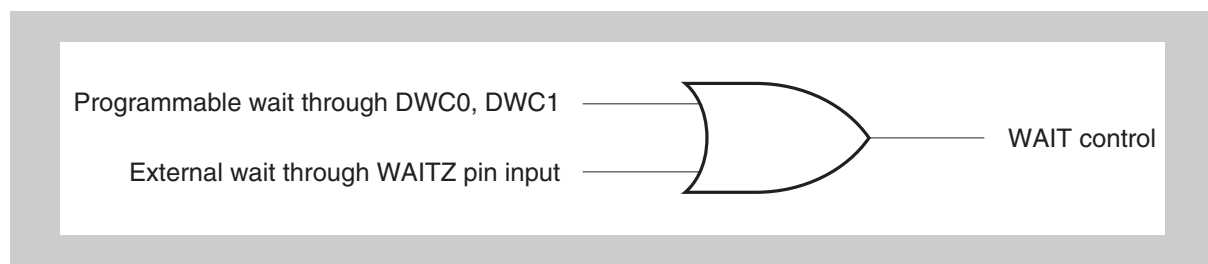

Figure 11-11 Internal data wait generator

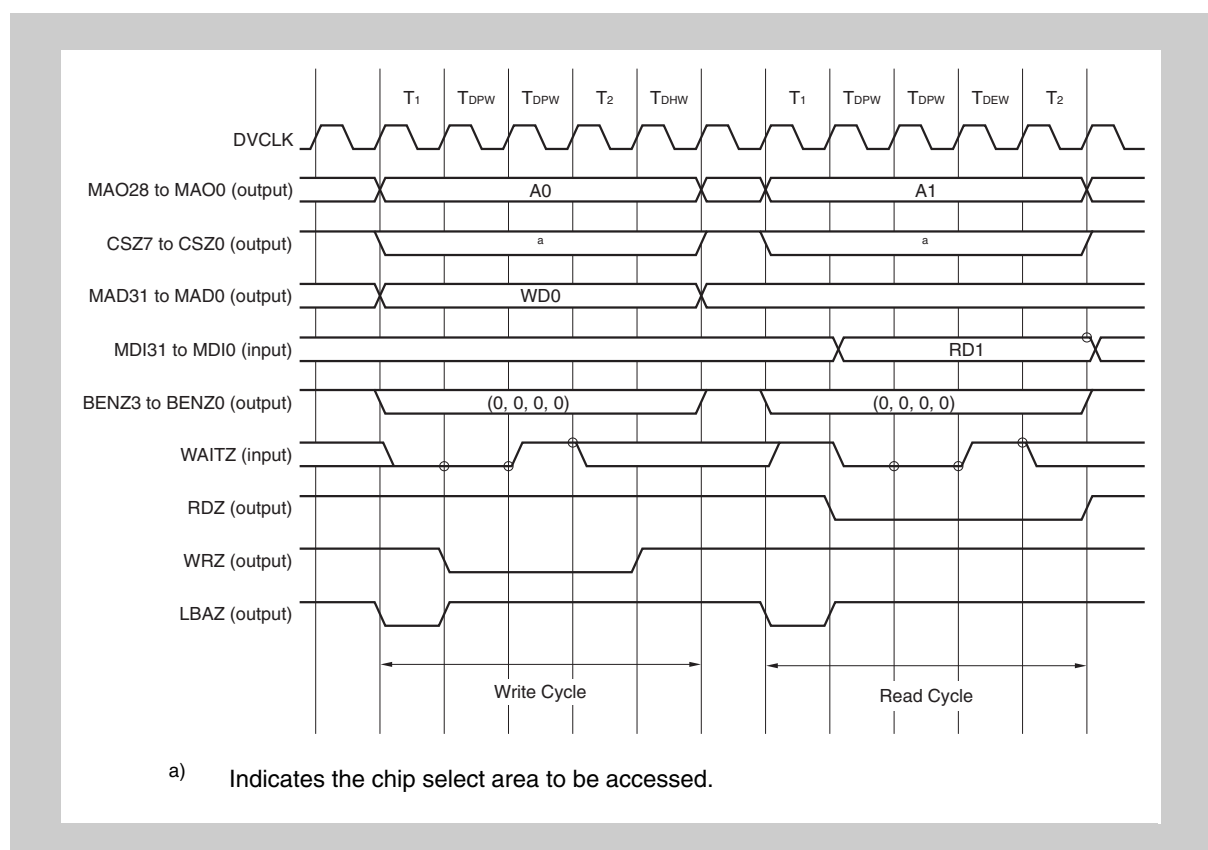

Figure 11-12 Relationship between external data wait and programmable data wait (When DWC = 2)

11.5.3 External wait error detection function

This microcontroller has a function to forcibly cancel the data wait if an external wait is continuously input for 128 cycles and report the error response to the CPU (or DMA) that issued the access request, by setting the EWN bit of the external wait error setting register (EWC register). A SysError exception occurs in the CPU at this time.

Using this function, even if an unforeseen bug occurs at the WAITZ input pin, the system does not hang up and exception processing for detecting the anomaly can be executed.

Figure 11-13 Operation timing upon external wait error detection

Following the occurrence of an error at the CPU that issued the access request, the external wait error detection circuit is initialized, and all transfer requests, including data wait requests from the WAITZ input pin, are processed normally.

At this time, when an external wait is continuously input for 128 cycles again, data wait is forcibly released, and an error is reported to the CPU that issued the access request.

11.5.4 Data setup wait function

This function inserts a wait prior to the transfer state in order to secure the setup time for the data write strobe.

This function is enabled only during write cycles in the multiplexed bus mode.

Up to 3 cycles can be inserted.

The number of wait cycles to be inserted can be set for each chip select area with the DSC register.

The initial status is no wait for any of the chip select areas.

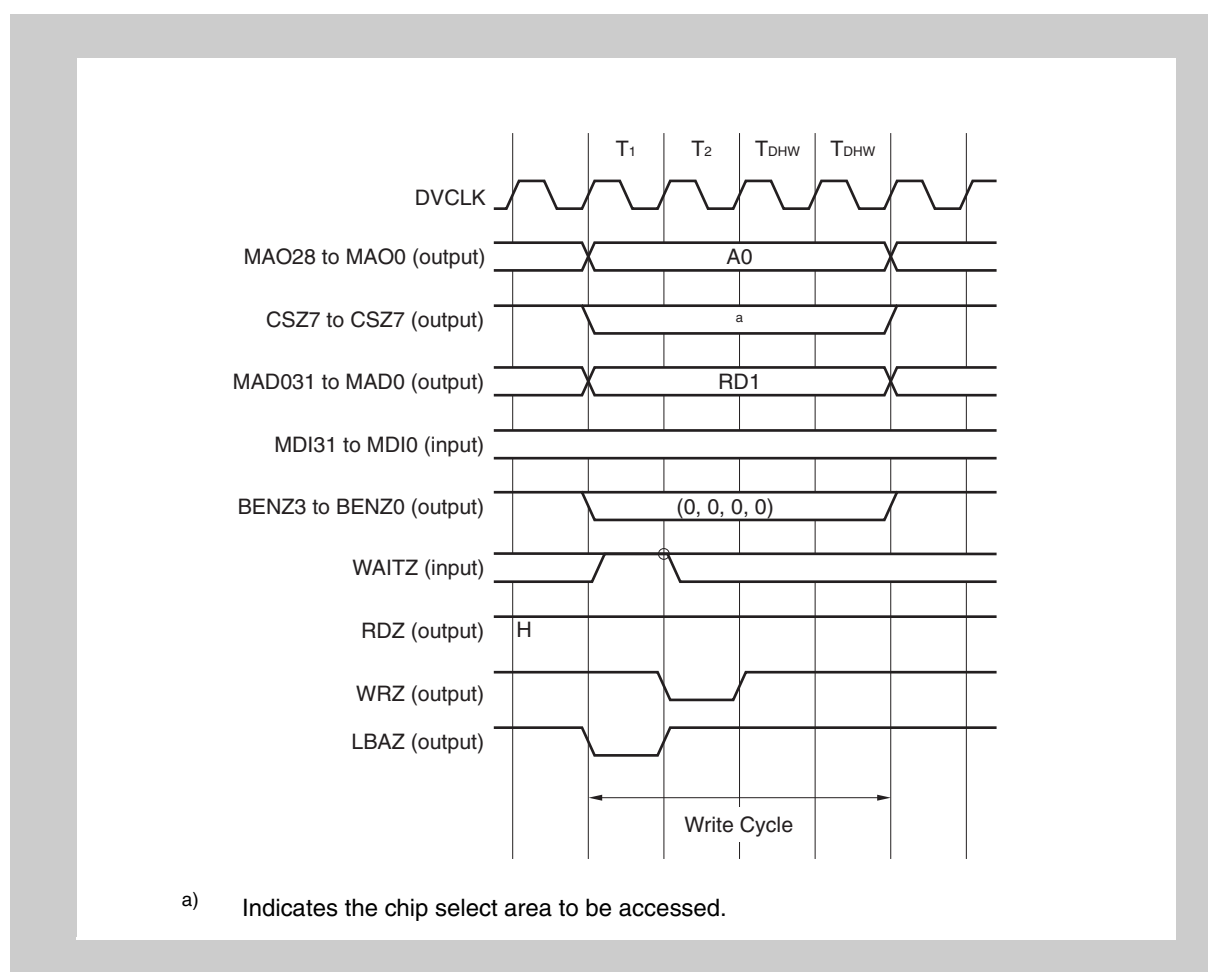

Figure 11-14 Data setup wait (separate bus mode)

11.5.5 Idle insertion function

This function inserts an idle state after the last state of each cycle in order to prevent bus conflicts between cycles.

Up to 3 cycles can be inserted for all memory types.

This function can be set independently after a read cycle or after a write cycle for each chip select area by setting the ICC0 and ICC1 registers.

The initial status is no idle cycle for any of the chip select areas.

Caution The interval from completion of a bus cycle until the occurrence of subsequent bus cycles from the CPU (or DMA) lasts 1 cycle, regardless of the idle cycle setting. Therefore, a 1-cycle interval occurs between bus cycles even if the setting is no idle cycle.

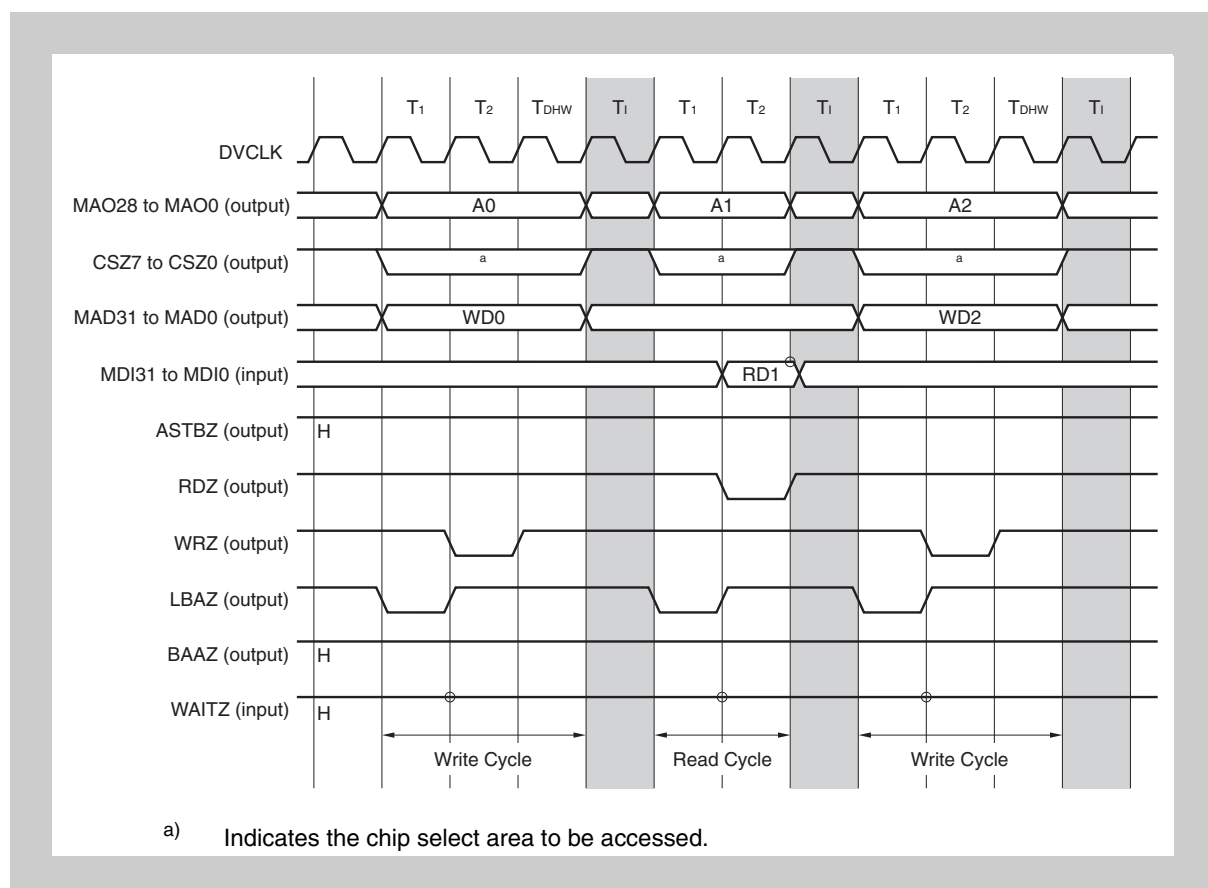

Figure 11-15 Idle cycle

11.6 Bus Hold Function

When the HLDRQZ pin input signal becomes active (low level) and a bus hold request is received from outside, this microcontroller enters the bus hold cycle following completion of the external bus cycle currently being executed. Upon completion of the transition to the bus hold cycle, the active level is output from the HLDKAZ output pin.

When the HLDRQZ pin becomes inactive (high level), the external bus goes into the normal operation mode.

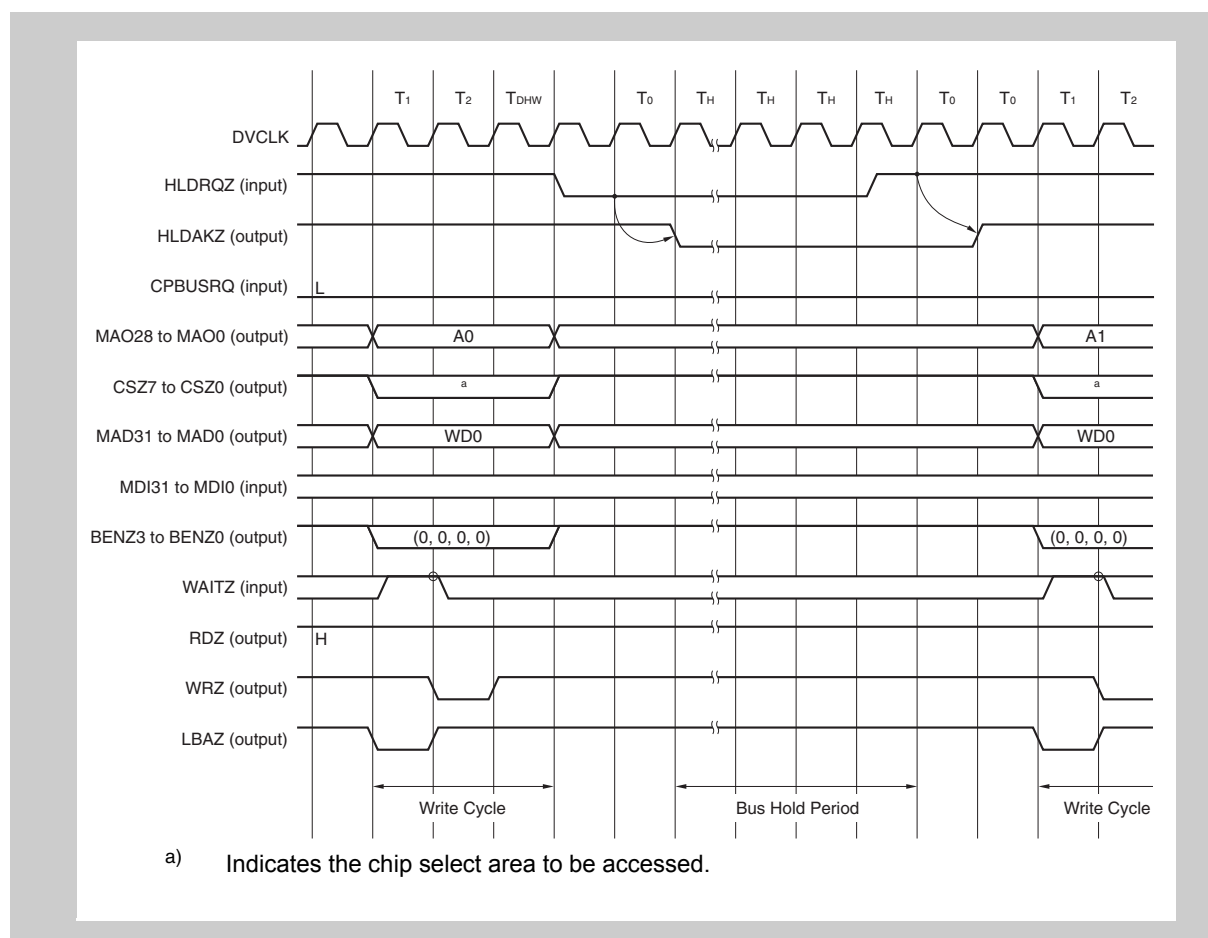

Figure 11-16 Bus hold function

During execution of bus cycles involving lock, such as read-modify-write from the CPU, the transition to the bus hold cycle is held pending until the bus cycle for that lock is completed.

Sampling of the HLDRQZ input pin is done at the same timing as the rising edge of the operation clock of the external bus.

When an external bus hold request is issued, the bank information internally held by the memory controller is deleted, and the memory controller cycle after the external bus hold is released always starts from the issuance of a bank active command. Also, if the external bus master accesses SDRAM, it must always start from the issuance of an all bank precharge command.

Figure 11-17 Delay of bus hold cycle through internal system bus lock

Figure 11-18 Delay of bus hold cycle through bus sizing

If a bus hold request and a transfer request from CPU occur at the same time, a wait response is returned for the transfer request and execution of the transition to the bus hold cycle is given priority.

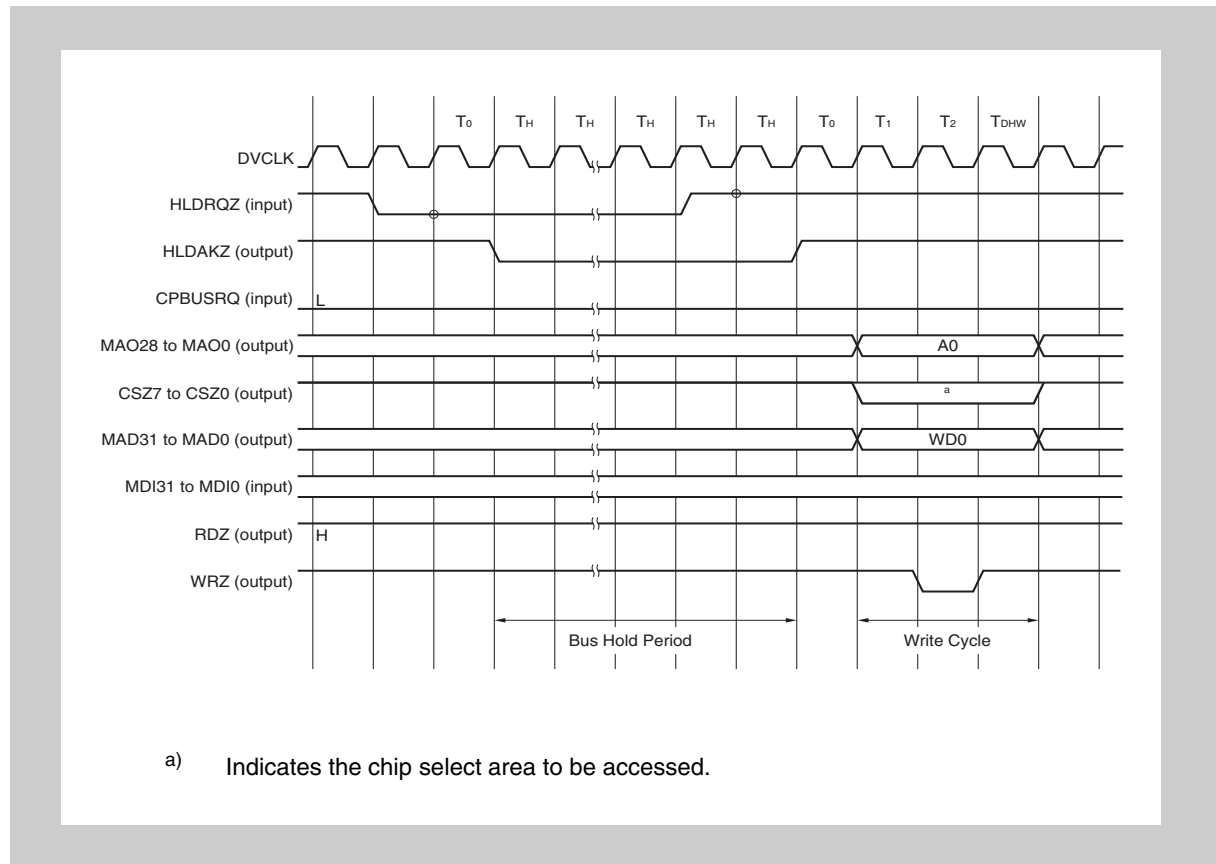

Figure 11-19 Operation during conflict between bus hold request and transfer request

11.7 DMA Cycle Output Function

When transfer is output from the DMA to the external bus, this microcontroller can output the DMA transfer cycle signal and DMA last transfer signal.

By using this function, whether or not the external bus cycle currently generated for a device outside the chip is caused by the DMA, and by DMA transfer of which channel if it is caused by the DMA, can be reported.

This microcontroller performs output the DMA transfer cycle signal from the $\overline{\text{DMAAK}}[5:0]$ pins, and the DMA last transfer signal from the $\overline{\text{DMATC}}[5:0]$ pins in synchronization with the external bus cycle.

For details about the $\overline{\text{DMAAK}}[5:0]$ occurrence timing, $\overline{\text{DMATC}}[5:0]$ output timing, and the output settings, refer to *Chapter 10 DMA Function*.

Caution This microcontroller allows the connection of a DMA subsystem equipped with 8 channels, but this pin function supports only a 6-channel connection.

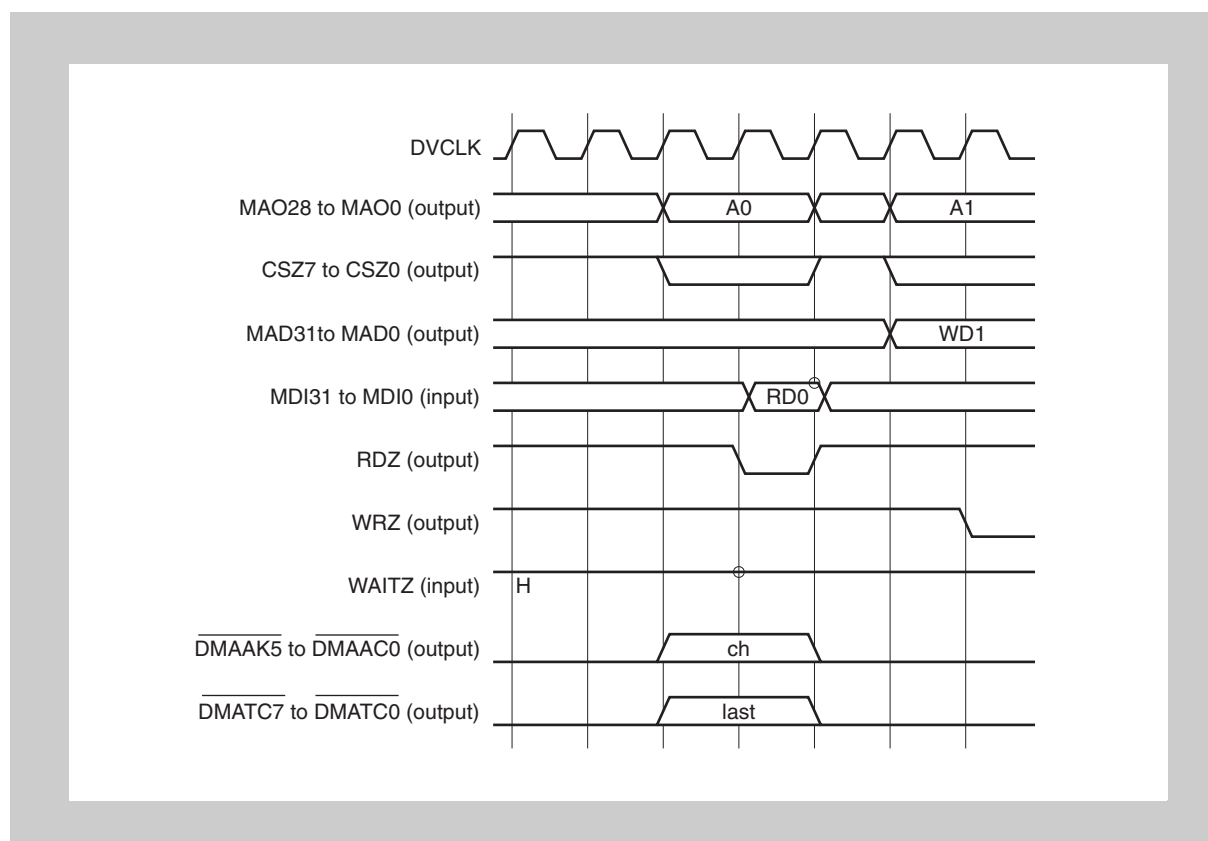

Figure 11-20 DMA channel output timing

11.8 Memory Connection Examples

11.8.1 SRAM connection example

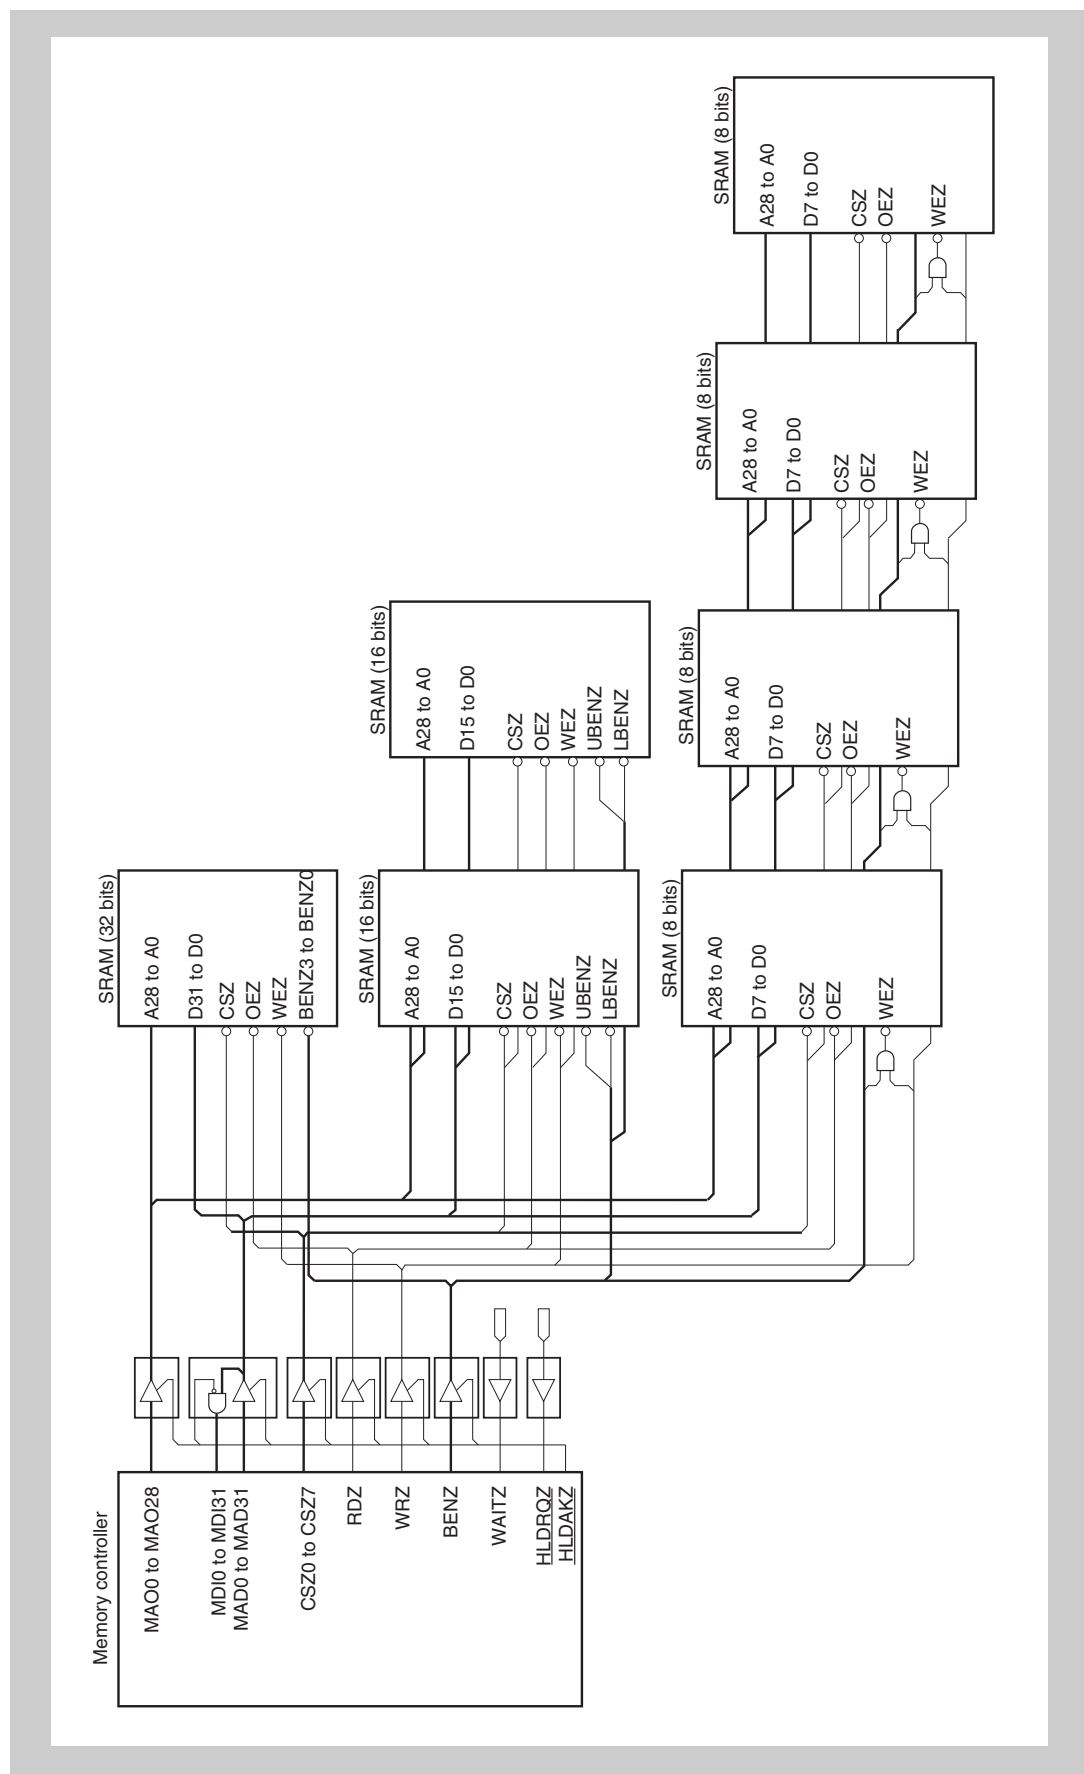

Figure 11-21 SRAM connection example

11.8.2 SDRAM connection example

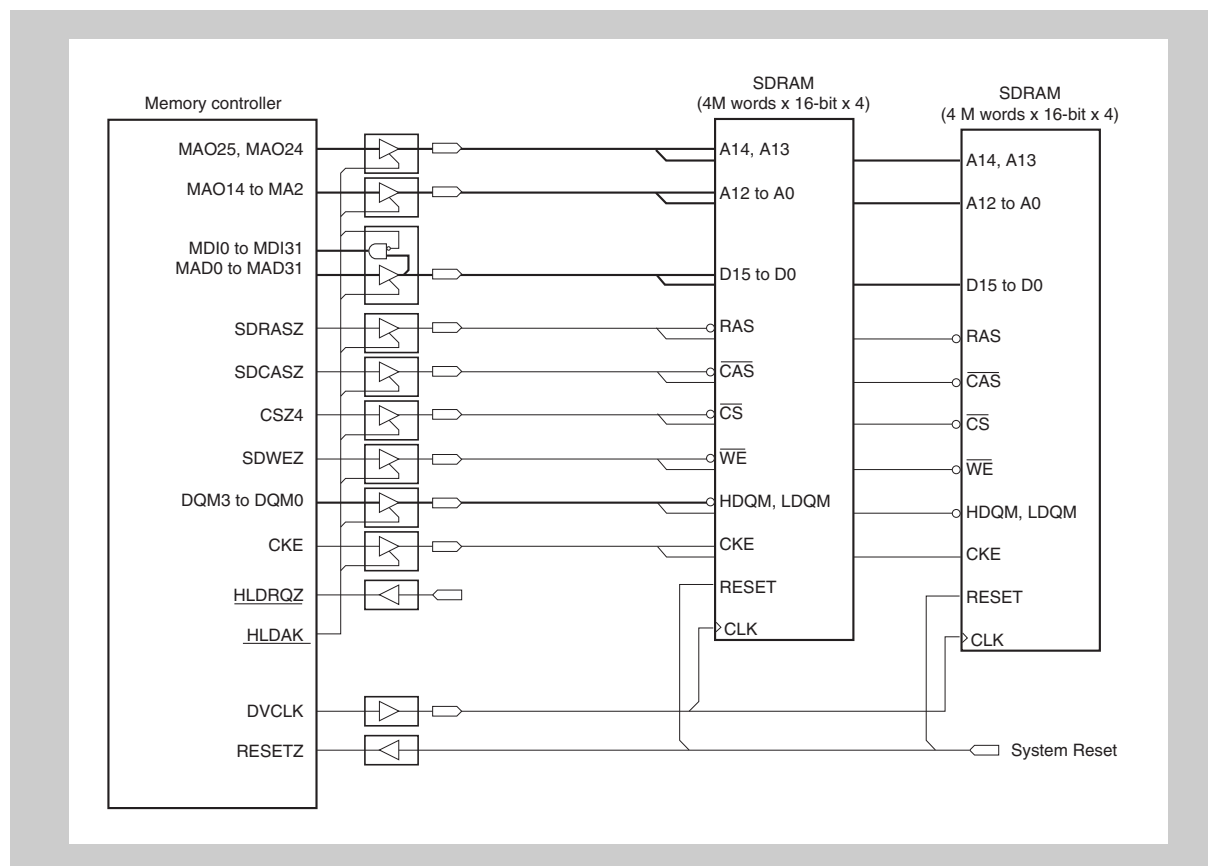

Figure 11-22 512 Mb SDRAM connection example (256-bit SDRAM (4M words × 16 bits × 4 banks) × 2)

(1) Address output and SDRAM connection

This section describes the settings of SDRAM configuration register n (SDCRn), the physical addresses, the address output from memory controller, and the connection between memory controller and SDRAM for each data bus width (8 bits, 16 bits, and 32 bits).

(a) 8-bit data bus width

The following shows an example of how to connect 64 Mb of SDRAM (2M words × 8 bits × 4 banks) for an 8-bit data bus width.

- SDCRn register settings

SSO1, SSO0 = 00: Data bus width = 8 bits

RAW1, RAW0 = 01: Row address width = 12 bits

SAW1, SAW0 = 01: Column address width = 9 bits

- Physical address

A22, A21: Bank address

A20 to A9: Row address

A8 to A0: Column address

- Address output from memory controller

A22, A21: Bank address

A11 to A0: Row address (12 bits), column address (9 bits)

Figure 11-23 Row address, bank address output when active command issued (8 bits)

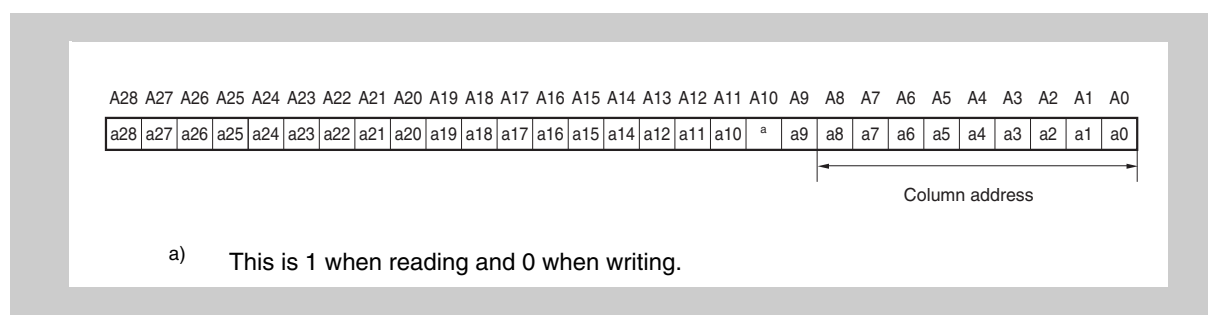

Figure 11-24 Column address output when read/write command issued (8 bits)

- Connection of memory controller and SDRAM

A22, A21 (memory controller): BA0 (A13), BA1 (A12) (SDRAM)

A11 to A0 (memory controller): A11 to A0 (SDRAM)

(b) 16-bit data bus width

The following shows an example of how to connect 512 Mb of SDRAM (8M words × 16 bits × 4 banks) for a 16-bit data bus width.

- SDCRn register settings
 - SSO1, SSO0 = 01: Data bus width = 16 bits
 - RAW1, RAW0 = 10: Row address width = 13 bits
 - SAW1, SAW0 = 10: Column address width = 10 bits
- Physical address
 - A25, A24: Bank address
 - A23 to A11: Row address
 - A10 to A1: Column address
- Address output from memory controller
 - A25, A24: Bank address
 - A13 to A1: Row address (13 bits), column address (10 bits)

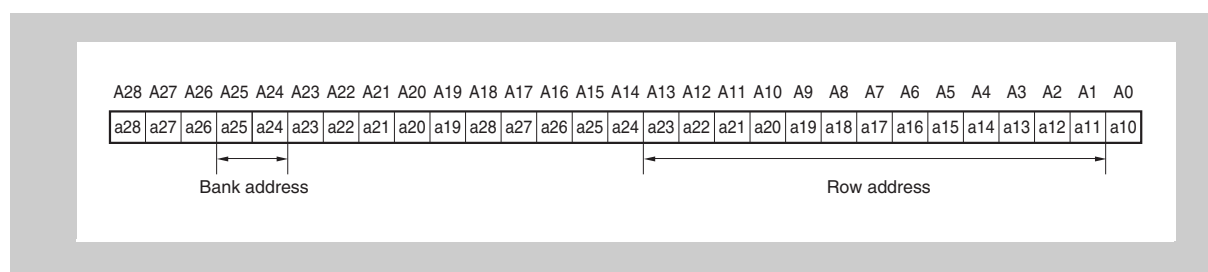

Figure 11-25 Row address, bank address output when active command issued (16 bits)

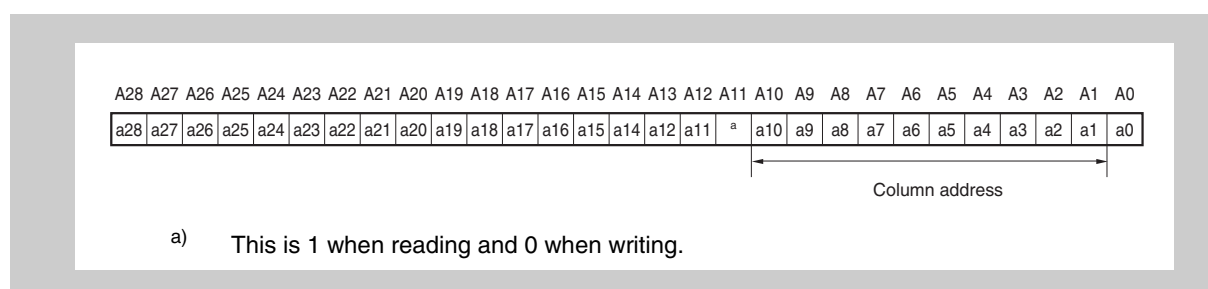

Figure 11-26 Column address output when read/write command issued (16 bits)

- Connection of memory controller and SDRAM
 - A25, A24 (memory controller): BA0 (A14), BA1 (A13) (SDRAM)
 - A13 to A1 (memory controller): A12 to A0 (SDRAM)

(c) 32-bit data bus width

The following shows an example of how to connect 512 Mb of SDRAM (256M words SDRAM (4M words × 16 bits × 4 banks) × 2) for a 32-bit data bus width.

- SDCRn register settings
 - SSO1, SSO0 = 10: Data bus width = 32 bits
 - RAW1, RAW0 = 10: Row address width = 13 bits
 - SAW1, SAW0 = 01: Column address width = 9 bits
- Physical address
 - A25, A24: Bank address
 - A23 to A11: Row address
 - A10 to A2: Column address
- Address output from memory controller
 - A25, A24: Bank address
 - A14 to A2: Row address (13 bits), column address (9 bits)

 - A23, A22 (memory controller): BA0 (A14), BA1 (A13) (SDRAM)
 - A13 to A2 (memory controller): A12 to A0 (SDRAM)

11.9 Data Flow

The data transfer flow to external memory differs according to factors such as the data width, endian specification, external bus width, and start address.

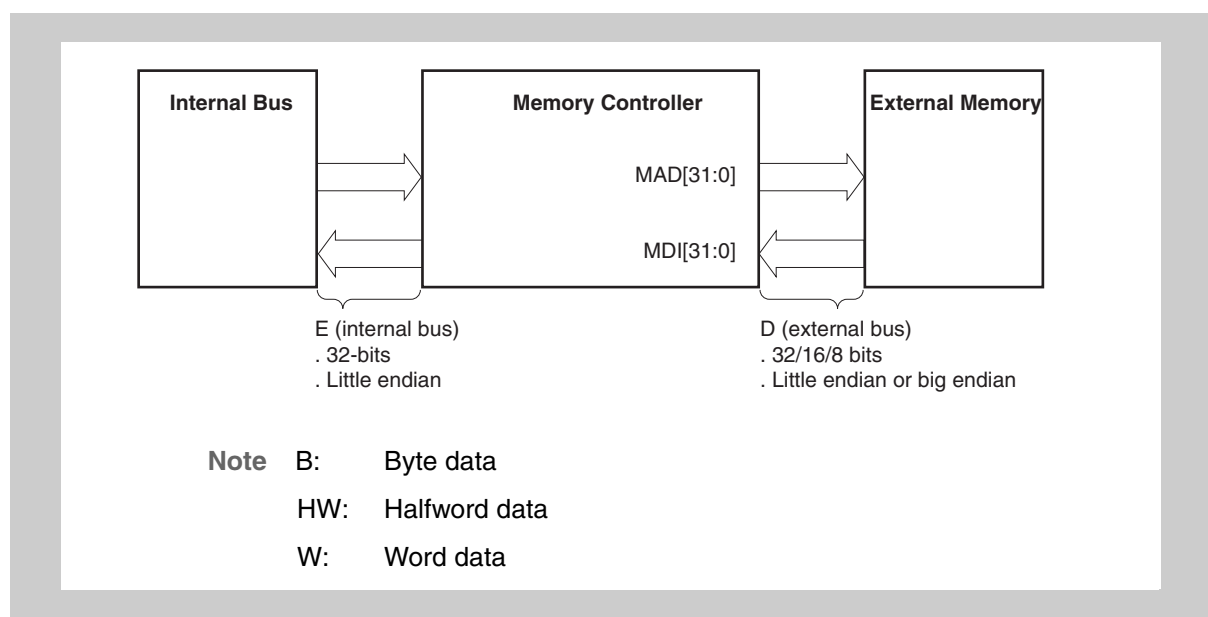

Figure 11-29 Internal bus, memory controller, external bus data flow

The data flows for various conditions are shown on the following pages.

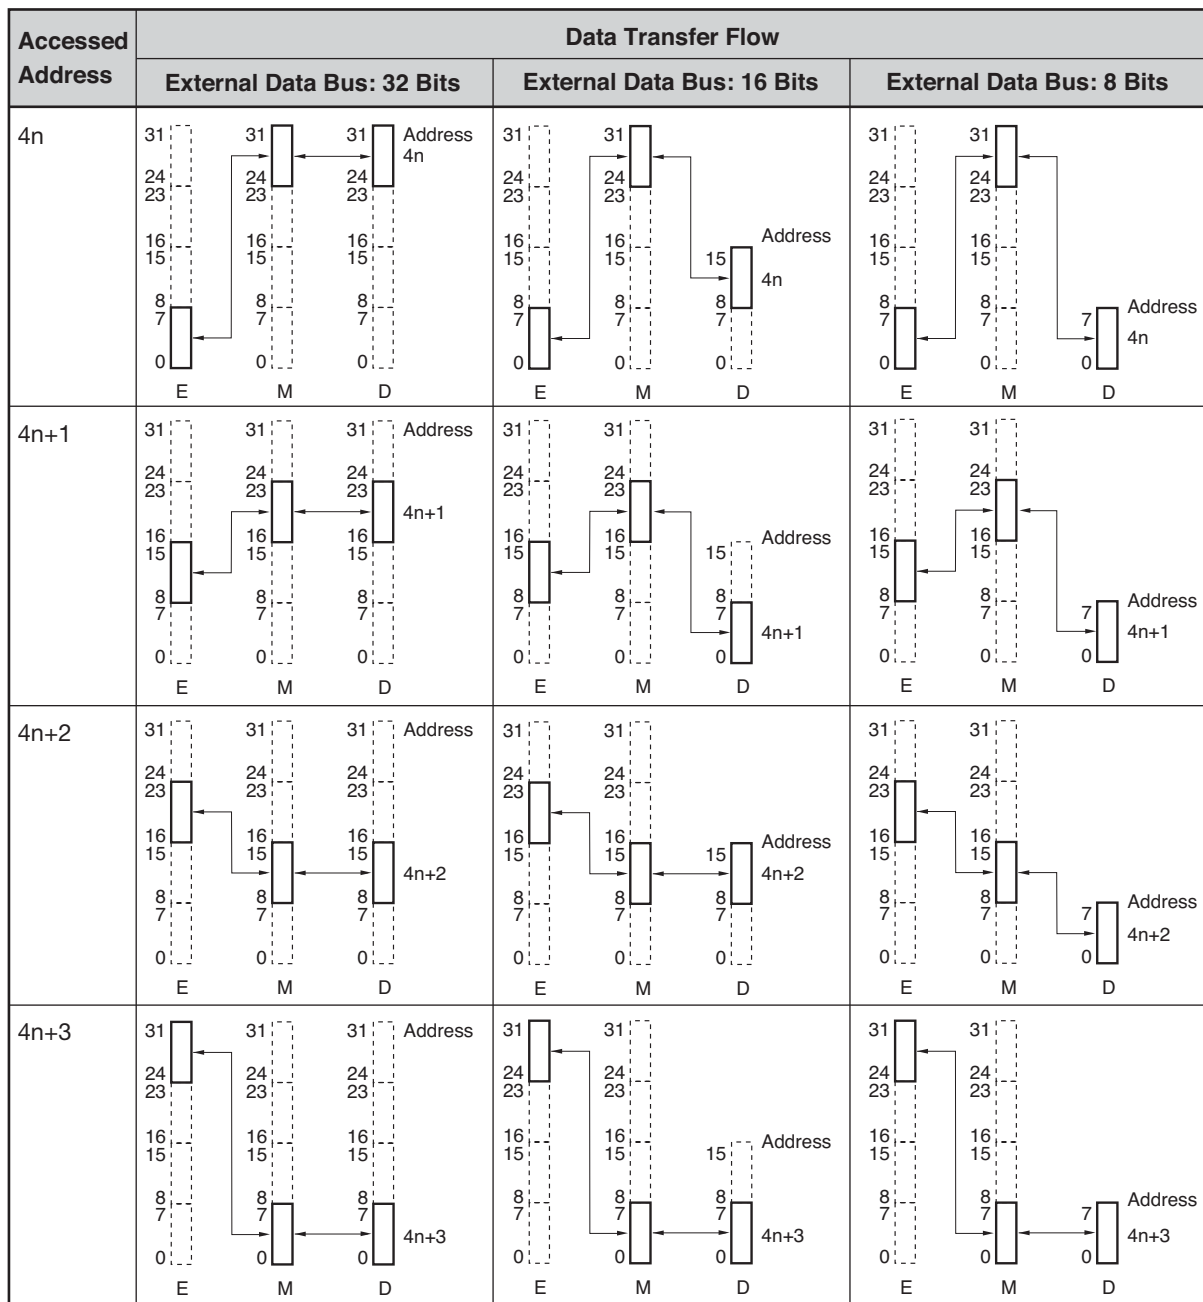

11.9.1 Data flow during byte access

Chapter 12 Timer Array Unit A (TAUA)

This chapter describes the Timer Array Unit A (TAUA).

The first section describes all V850E2/ML4 specific properties, such as instances, register base addresses, input/output signal names, etc. The subsequent sections describe the features that apply to all implementations.

12.1 V850E2/ML4 TAUA Features

Instances This microcontroller has the following number of instances of TAUA.

Table 12-1 Instances of TAUA

TAUA	
Instance	2
Name	TAUA0 and TAUA1

Instances index n Throughout this chapter, the individual instances of a TAUA is identified by the index "n" (n = 0, 1), for example, TAUAnTOM for the TAUAn channel output mode register.

Channel index m TAUA has 16 channels. Throughout this chapter, the individual channels are identified by the index "m" (m = 0 to 15), thus a certain channel is denoted as CHm. The even numbered channels (m = 0, 2, 4, 6, 8, 10, 12, 14) are denoted as CHm_even. The odd numbered channels (m = 1, 3, 5, 7, 9, 11, 13, 15) are denoted as CHm_odd.

Register addresses All TAUAn register addresses are given as address offsets to the individual base address <TAUAn_base_OS> or <TAUAn_base_USER>. The base addresses <TAUAn_base_OS> and <TAUAn_base_USER> of each TAUAn are listed in the following table:

Table 12-2 Register base addresses <TAUAn_base>

TAUAn instance	Base address	Address
TAUA0	<TAUAn_base_USER>	FFFF C400 _H
	<TAUAn_base_OS>	FF80 8000 _H
TAUA1	<TAUAn_base_USER>	FFFF CC00 _H
	<TAUAn_base_OS>	FF80 A000 _H

Clock supply TAUA provides one clock input:

Table 12-3 TAUA_n clock supply

TAUA _n instance	TAUA _n clock	Connected to
TAUA0	PCLK	f _{PCLK}
TAUA1	PCLK	f _{PCLK}

Interrupts and DMA/DTS TAUA can generate the following interrupt and DMA/DTS requests:

Table 12-4 TAUA_n interrupt and DMA/DTS requests

TAUA _n signals	Function	Connected to
TAUA0:		
INTTAUA0I[0:15]	Channel 0 to 15 interrupt	Interrupt Controller INTTAUA0I[0:15] DMA Controller trigger 32 to 47 DTS Controller trigger 32 to 47 PIC: INTTAUA0I[15:0]
TAUA1:		
INTTAUA1I[0:15]	Channel 0 to 15 interrupt	Interrupt Controller INTTAUA1I[0:15] DMA Controller trigger 48 to 63 DTS Controller trigger 48 to 63

I/O signals The I/O signals of TAUA are listed in the following table.

Table 12-5 TAUA_n I/O signals

TAUA signal	Function	Connected to
TAUA0:		
TAUA0TTIN[0:15]	Channel [0:15] input	Port TA0_I[0:15]
TAUA0TTOUT[0:15]	Channel [0:15] output	Port TA0_O[0:15] PIC (TAUA0UDC[0, 2, 8])
TAUA0TSST[0:15]	Channel [0:15] start trigger input	PIC0 TAUA0TSST[0:15]
TAUA1:		
TAUA1TTIN[0:15]	Channel [0:15] input	Port TA1_I[0:15]
TAUA1TTOUT[0:15]	Channel [0:15] output	Port TA1_O[0:15]
TAUA1TSST[12:15]	Channel [12:15] start trigger input	PIC (TAUJ1TSST[0:3])

All TAUAn interrupt and I/O signals are sketched in the following figure.

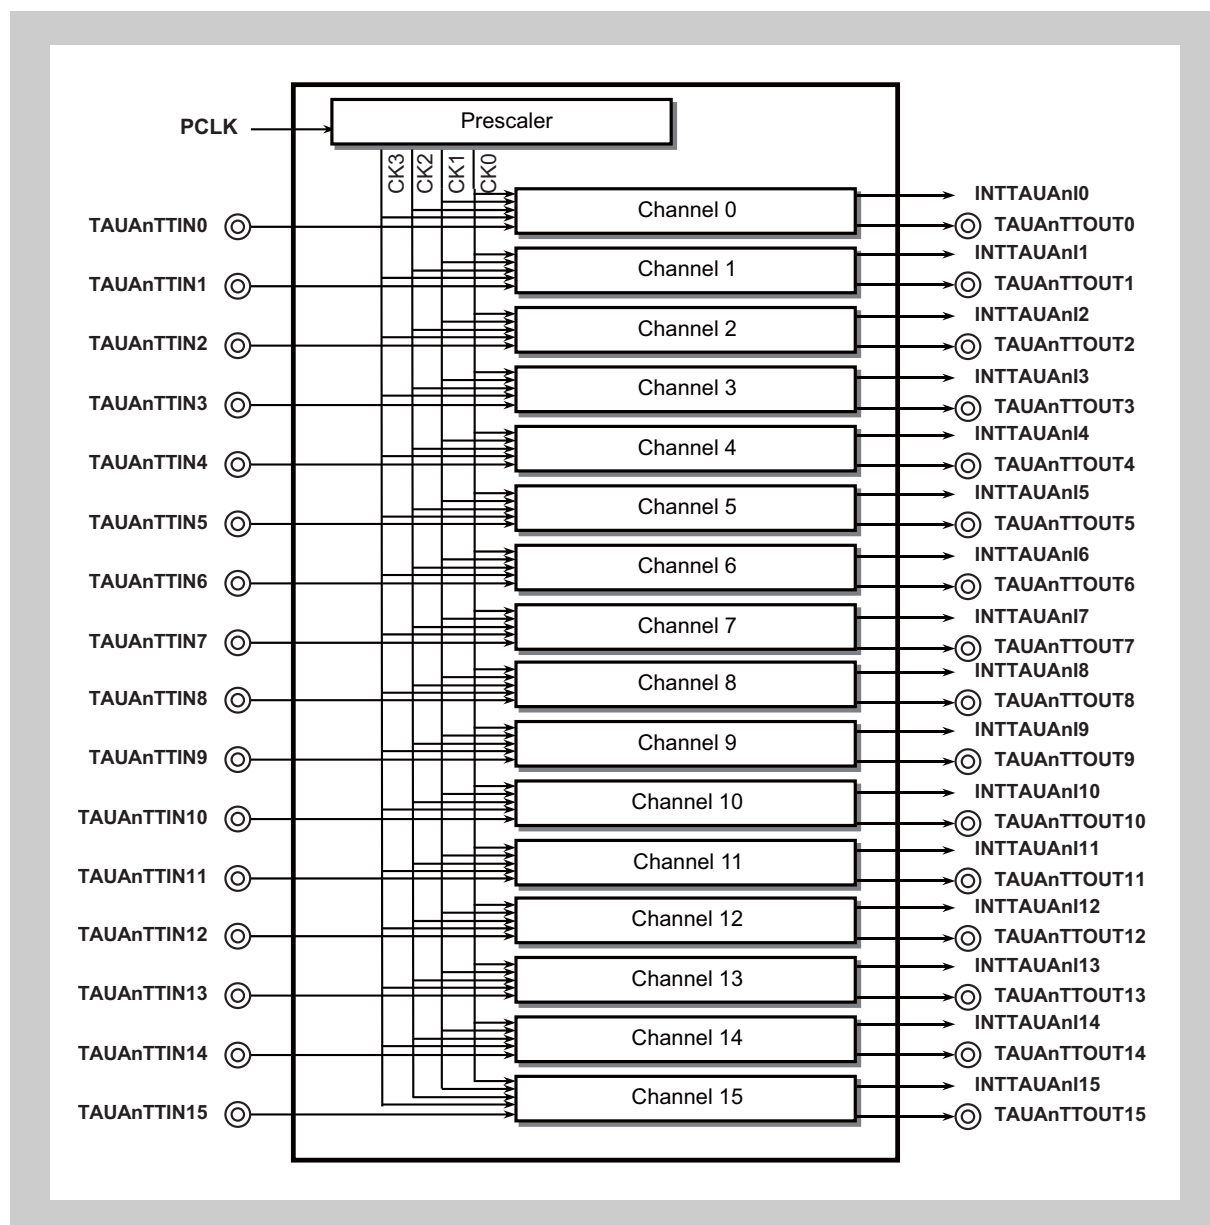

Figure 12-1 TAUA I/O and interrupt signals

Caution The V850E2/ML4 does not support the following functions because the timer input and timer output of the same channel share the same pin.

- Clock divide function
- TAUAnTTINm input interval timer function
- One-pulse output function
- Real-time output function type 2
- One-phase PWM output function

12.2 Functional Overview

Features summary The TAUA has the following functions:

- 16 channels
- 16-bit counter and 16-bit data register per channel
- Independent channel operation
- Synchronous channel operation (master and slave operation)
- Generation of different types of output signal
- Real-time output
- Counter can be triggered by external signal
- Interrupt generation

The following figure shows the main components of the TAUA:

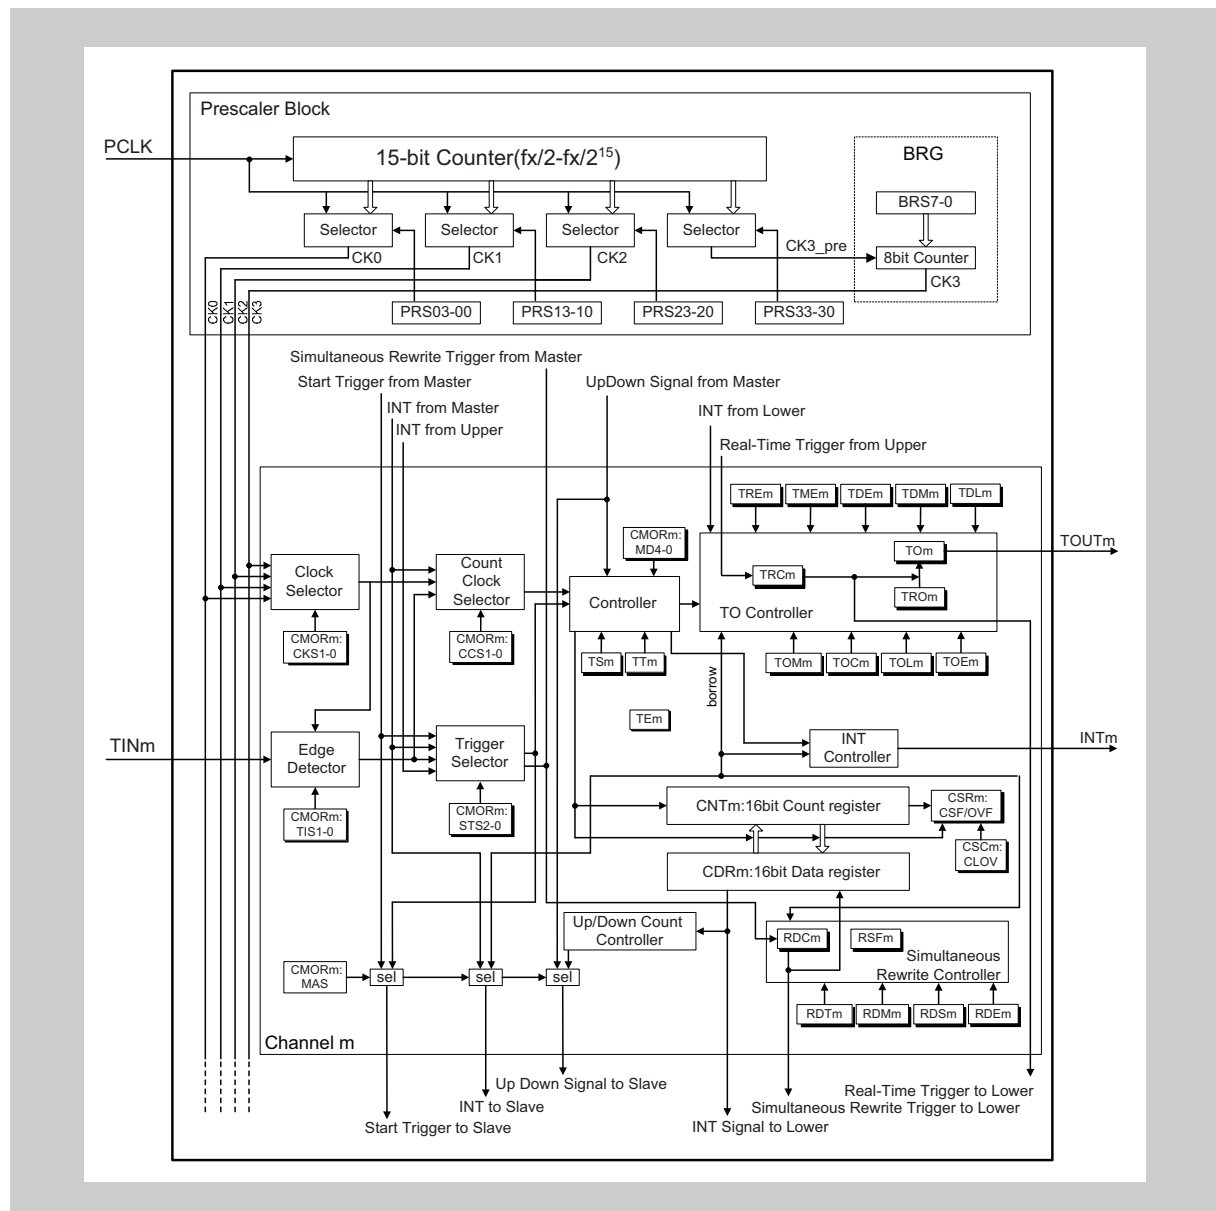

Figure 12-2 Block diagram of the TAUA

The prefix “TAUA_n” has been omitted from the register names for the sake of clarity in the above figure.

12.2.1 Terms

In this chapter, the following terms are used:

- **Independent / synchronous channel operation**

Independent or synchronous channel operation describes the dependency of channels on each other:

- If a channel operates independent of all other channels, this is called independent channel operation.
- If a channel operates depending on other channels, this is called synchronous channel operation.

- **Channel group**

In synchronous channel operation, all channels that depend on each other are referred to as a “channel group”.

A channel group has one master channel and one or more slave channels.

- **Operation mode**

An operation mode can be selected for every channel m . The operation mode defines the *basic* operation and features of a channel.

In synchronous channel operation, every channel in the channel group can operate in a different operation mode.

Examples are “Capture Mode”, “Event Count Mode”, and “Interval Timer Mode”.

- **Channel output mode**

The channel output mode defines the operation of $TAUAnTTOUTm$

- of a single channel (independent output operation) or
- of all channels in a channel group (synchronous output operation).

Examples are “Independent Channel Output Mode 1” and “Synchronous Channel Output Mode 2 with Dead Time Output”.

- **Channel operation function**

The channel operation function defines the *complete* function and all features

- of a single channel (independent channel operation) or
- of all channels in a channel group (synchronous channel operation).

- **Upper / lower channel**

Depending on the channel number m , a neighboring channel can be referred to as “upper” or “lower” channel:

- Upper channel: Channel with a smaller channel number
- Lower channel: Channel with a higher channel number

Example:

For channel 5, channel 3 is an upper channel and channel 9 is a lower channel.

12.3 Functional Description

TAUA is used to perform various count or timer operations and to output a signal which depends on the result of the operation. It contains one prescaler for count clock generation and 16 channels, each equipped with a 16 bit counter TAUAnCNTm and a 16-bit data register TAUAnCDRm to hold the start or compare value of the counter.

It also contains several control and status registers.

Independent and synchronous operation

Every channel can operate in different operation modes, either independently or in combination with other channels (synchronously). If a channel group has one master channel and one or more slave channels, the slave channels depend on the master channel.

When a channel is operated independently, its operation mode and functions are not affected by those of other channels. When a channel is operated synchronously it is either a master or a slave. A master channel can have multiple slaves, and the state of one channel affects that of the other channels. For example, this means that one channel can control when another starts to count, is reset, etc.

The following describes the functional blocks:

Prescaler

The prescaler provides up to 4 clock signals (CK0 to CK3) that can be used as count clocks for all channels.

For count clocks CK0 to CK2, a clock obtained by dividing PCLK by 2^0 to 2^{15} using the prescaler can be selected. For the fourth count clock CK3, a division factor that is not a power of 2 can be specified by using BRG.

Clock and count clock selection

For every channel, the count clock selector selects which of the following is used as the clock source:

- One of the clocks CK0 to CK3 (selected by the clock selector)
- INTTAUAnIm from master channel
- TAUAnTTINm input signal valid edge

Controller

The controller controls the main operations of the counter:

- Operation mode (selected by bits TAUAnCMORm.TAUAnMD[4:0])
- Counter start enable (TAUAnTS.TAUAnTSm) and counter stop (TAUAnTT.TAUAnTTm)

When counter start is enabled, status flag TAUAnTE.TAUAnTEm is set.

- Count direction (up/down) (can be controlled by master channel)

Trigger selector

Depending on the selected operation mode, the counter starts automatically when it is enabled (TAUAnTE.TAUAnTEm = 1), or it waits for an external start trigger signal. Any of the following signals can be used as the start trigger:

- Synchronous channel start trigger input TAUAnTSSTm
- TAUAnTTINm input valid edge
- INTTAUAnIm from the master or any upper channel
- Up/down output trigger signal of the master channel
- Dead-time output signal of the TAUAnTTOUTm generation unit.

- Simultaneous rewrite controller** Simultaneous rewrite control is a function that can be used in synchronous operation modes. The data registers (TAUAnCDRm) of all channels in a channel group can be rewritten at any time. The simultaneous rewrite controller ensures that new data register values of all channels become effective at the same time.
- TAUAnTO Controller** The output control of every channel enables the generation of various output signal forms such as PWM signals or triangular waves.

12.3.1 Timer operation functions

The functions below can be achieved by operating TAUA independently on each channel or by operating it on a combination of multiple channels.

Table 12-6 TAUA Operation Functions

Independent Channel Operation Function	Synchronous Channel Operation Function
Independent channel operation functions	Synchronous channel operation functions
Interval timer function	PWM output function
TAUAnTTINm input interval timer function	Trigger start PWM output function
Delay count function	Delay pulse output function
One-pulse output function	A/D conversion trigger output function type 1
Independent channel signal measurement functions	Synchronous PWM signal functions triggered by an external signal
TAUAnTTINm input pulse interval measurement function	One-shot pulse output function
TAUAnTTINm input signal width measurement function	Offset trigger output function
Overflow interrupt output function (during TAUAnTTINm width measurement)	Synchronous Triangle PWM output function
TAUAnTTINm input period count detection function	Triangle PWM output function
Overflow interrupt output function (during TAUAnTTINm input period count detection)	Triangle PWM output function with dead time
TAUAnTTINm input pulse interval judgment function	A/D conversion trigger output function type 2
TAUAnTTINm input signal width judgment function	Synchronous non-complementary modulation output function and synchronous complementary modulation output function
Independent channel real-time functions	Non-complementary modulation output function type 1
Real-time output function type 1	Non-complementary modulation output function type 2
Real-time output function type 2	Complementary modulation output function
Independent channel simultaneous rewrite functions	Other independent channel functions
Simultaneous rewrite trigger generation function type 1	Interrupt culling function
Simultaneous rewrite trigger generation function type 2	
Independent channel one-phase PWM function	
One-phase PWM output function	
Other independent channel functions	
External event count function	
Clock divide function	
TAUAnTTINm input position detection function	

12.4 General Operating Procedure

The following lists the general operation procedure for the TAUAn:

After reset release, the operation of each channel is stopped. Clock supply is started and writing to each register is enabled. The control register of TAUAnTTOUTm is also initialized and outputs a low level.

1. Set the TAUAnTPS and TAUAnBRS registers to specify the clock frequency of CK0 to CK3.
2. Configure the desired TAUAn function:
 - Set the operation mode
 - Set the channel output mode
 - Set any other control bits
3. Enable the counter by setting the TAUAnTS.TAUAnTSm bit to 1.

The counter starts to count immediately, or when an appropriate trigger is detected, depending on the bit settings.
4. During counting, if desired, and if possible for the configured function, stop the counter or perform a forced restart operation.
5. Stop the function by setting the TAUAnTT.TAUAnTTm bit to 1.

Note A detailed description of the required control bits and the operation of the individual functions is given in 12.14 “Independent Channel Operation Functions” on page 483 and 12.21 “Synchronous Channel Operation Functions” on page 593 .

12.5 Operation Modes

The TAUA contains 12 operation modes.

One operation mode can be set for each channel. It is specified using the TAUAnCMOR.TAUAnMD[4:0] bits.

Note For registers and bits, some values are fixed according to the operation function, and others are selected by the user.

For details about the settings for registers and bits, refer to the chapters describing each operation function.

12.6 Concepts of Synchronous Channel Operation

In synchronous channel operation, multiple channels depend on each other, or are affected by changes in another channel. Therefore, several rules apply for the use of synchronous channel functions. These rules are detailed in 12.6.1 “Rules”.

Two special features for synchronous channel operation are detailed in the following subchapters:

- 12.6.2 “Simultaneous start and stop of synchronous channel counters” on page 450
- 12.7 “Simultaneous Rewrite” on page 451

12.6.1 Rules

Number of masters and slaves

- Only even channels (CH0, CH2, CH4, ...) can be set as master channels. Any channel except CH0 can be set as a slave channel.
- Only channels lower than the master channel can be set as slave channels, and several slave channels can be set for one master channel.
Example: If CH2 is a master channel, CH3 and the lower channels (CH4, CH5, ...) can be set as slave channels.
- If multiple master channels are used, slave channels cannot cross the master channels.
Example: If CH0 and CH4 are master channels, CH1 to CH3 can be set as slave channels for CH0, but CH5 to CH15 cannot.

Operation clock

- The same operation clock must be set for the corresponding slave channel and the master channel. Specify the same value for the TAUAnCMORm.TAUAnCKS[1:0] bits of the synchronized master and slave channels.

The basic concepts of master/slave usage and operation clocks are illustrated in the following figure.

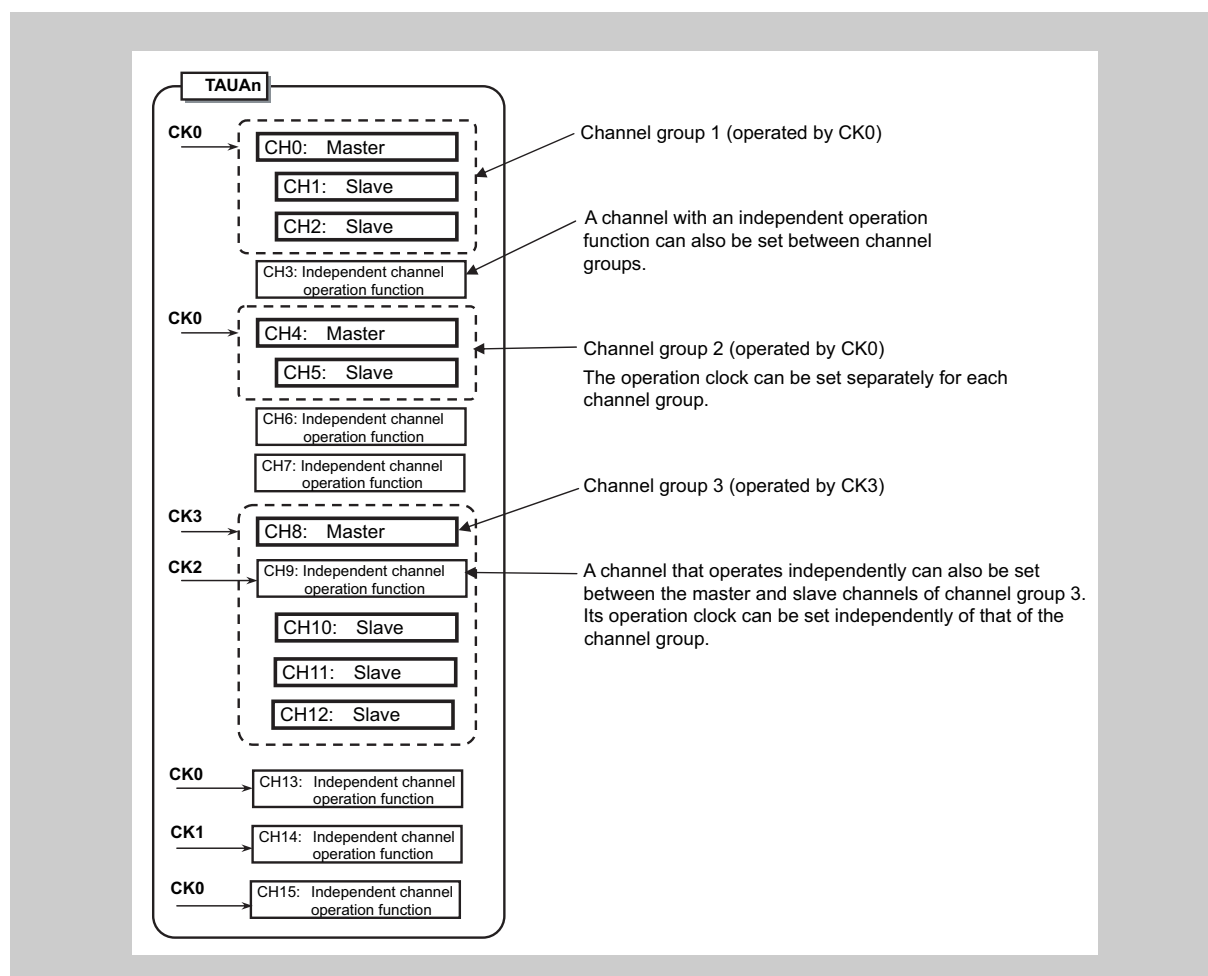

Figure 12-3 Grouping of the channels and assignment of operation clocks

Control trigger signals of the master and slave channels

- A master channel can output a control trigger signal to its slave channels.
- Slave channels can use the control trigger signal of the master channel but cannot transfer their control trigger signals to the lower channels.
- A master channel cannot use the control trigger signal of an upper master channel.

12.6.2 Simultaneous start and stop of synchronous channel counters

Channels that are operated synchronously can be started and stopped simultaneously, both within a unit, and between units.

(1) Simultaneous start and stop within a unit

- To simultaneously start synchronized channels, the TAUAnTS.TAUAnTSM bits of the channels must be set at the same time.
- To simultaneously stop synchronized channels, the TAUAnTT.TAUAnTTM bits of the channels must be set at the same time.

Setting a TAUAnTS.TAUAnTSM bit to 1 sets the corresponding TAUAnTE.TAUAnTEM bit to 1, enabling counting. When the counter starts counting depends on the operation mode.

12.7 Simultaneous Rewrite

12.7.1 Introduction

Simultaneous rewrite describes the ability to change the compare/start value and the output logic of multiple channels at the same time.

The corresponding data and control registers (TAUANCDRm and TAUANTOLm) can nevertheless be written at any time. The new value does not affect the counter operation or the output signal until simultaneous rewrite is triggered.

Simultaneous rewrite can be triggered by:

- The counter on the master channel or upper channel (depending on the selected operation mode) reaching a certain value
- INTTAUANIm being issued on the upper channel specified by TAUAnRDC.TAUAnRDCm

There are four methods for simultaneous rewrite. These are listed in the following table, along with how to specify them and when they cause simultaneous rewrite to be triggered.

Table 12-7 Simultaneous rewrite methods and when they are triggered

Method	Simultaneous rewrite triggered when	TAUAN RDE. TAUAn RDEm	TAUAN RDS. TAUAn RDSm	TAUAN RDM. TAUAn RDMm
-	No simultaneous rewrite	0	0	0
A	The master channel (re)starts counting	1	0	0
B	The slave channel starts counting down at the upper peak of a triangular cycle	1	0	1
C1	INTTAUANIm is generated on an upper channel specified by TAUAnRDC.TAUAnRDCm	1	1	0
C2	INTTAUANIm is generated on an upper channel specified by TAUAnRDC.TAUAnRDCm that in turn is triggered by an external signal	1	1	0

The following table lists which of these four methods is available for each channel operation function. For more information about the individual channel operation functions, see the corresponding sections in 12.14 “Independent Channel Operation Functions” on page 483 and 12.21 “Synchronous Channel Operation Functions” on page 593 .

Table 12-8 Channel operation functions and methods they use

Function	-	A	B	C1	C2

Non-Complementary Modulation Output Function Type 2			X	X	
Complementary Modulation Output Function			X	X	

12.7.2 How to control simultaneous rewrite

The following figure shows the general procedure for simultaneous rewrite. The three main blocks (Initial setup, Start counter & count operation, and Simultaneous rewrite) are explained afterwards.

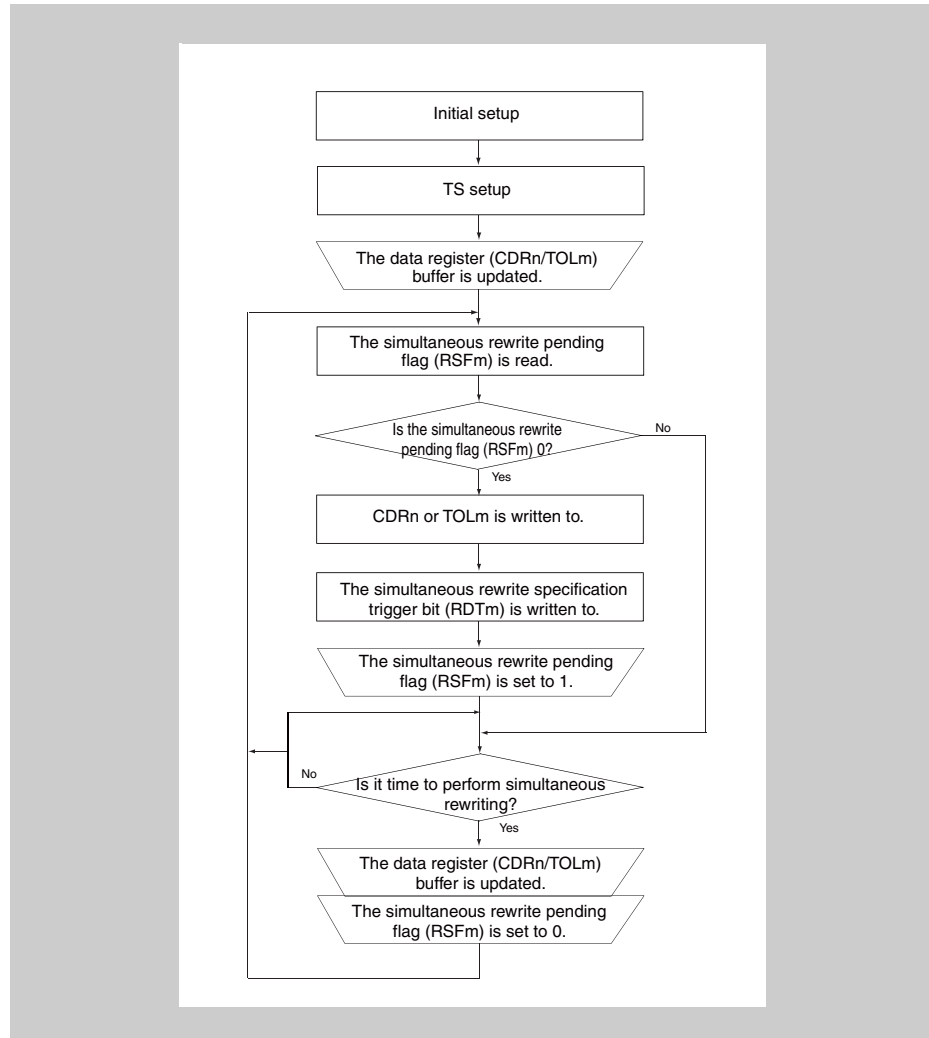

Figure 12-4 General procedure for simultaneous rewrite

(1) Initial settings

- To enable simultaneous rewrite in channel m, set `TAUAnRDE.TAUAnRDEm = 1`
- To select the type of simultaneous rewrite, set `TAUAnRDM.TAUAnRDMm` and `TAUAnRDS.TAUAnRDSm` according to the values in *Table 12-7 “Simultaneous rewrite methods and when they are triggered”* on page 451
- Specify the simultaneous rewrite trigger generation channel for `TAUAnRDC.TAUAnRDCm`. (Prerequisite: `TAUAnRDS.TAUAnRDSm` is specified as an upper channel.)

(2) Start counter and count operation

- To start all the TAUAnCNTm counters in the channel group, set the corresponding TAUAnTS.TAUAnTSM bits to 1. TAUAnTOL.TAUAnTOLm and the values in the data registers (TAUAnCDRm) are loaded to the corresponding TAUAnTOL.TAUAnTOLm buffer (TAUAnTOL.TAUAnTOLm buf) and data buffer registers (TAUAnCDRm buf) and the counters start.
- Setting the reload data trigger bit (TAUAnRDT.TAUAnRDTm) to 1 sets the reload flag (TAUAnRSF.RSFm) to 1, enabling simultaneous rewrite. TAUAnRSF.RSFm remains 1 until simultaneous rewrite has taken place.
- When the specified trigger for simultaneous rewrite is detected, the TAUAnRSF.TAUAnRSFm bit is checked to see if simultaneous rewrite is enabled (TAUAnRSF.TAUAnRSFm = 1). If it is, simultaneous rewrite is carried out. If such writing is disabled, simultaneous rewriting is not performed, and the system awaits the detection of the next simultaneous rewrite trigger.

(3) Simultaneous rewrite

- When the simultaneous rewrite trigger is detected and simultaneous rewrite is enabled (TAUAnRSF.TAUAnRSFm = 1), the current values of the data registers are copied to their buffers. These values are then loaded to the corresponding counters and the values are applied the next time the counter starts or restarts.
- When simultaneous rewriting finishes, the TAUAnRSF.TAUAnRSFm bit is cleared to 0, and the system awaits the next simultaneous rewrite trigger.

12.7.3 Other general rules of simultaneous rewrite

The following rules also apply:

- TAUAnRDE.TAUAnRDEm, TAUAnRDS.TAUAnRDSm, TAUAnRDM.TAUAnRDMm, and TAUAnRDC.TAUAnRDCm cannot be changed while the counter is in operation (TAUAnTE.TAUAnTEm = 1).
- TAUAnTOL.TAUAnTOLm can only be rewritten during operation when in PWM output function or triangle PWM output function. For all other output functions, TAUAnTOL.TAUAnTOLm must be written before the counter starts. If it is rewritten in another function, TAUAnTTOUTm outputs an invalid wave.
- When an upper channel is used as the channel issuing the simultaneous rewrite trigger (TAUAnRDS.TAUAnRDSm = 1), the TAUAnRDC.TAUAnRDCm bit controls all the lower channels. This means that if the TAUAnRDC.TAUAnRDCm bits of CH2 and CH7 are set to 1 and the TAUAnRDC.TAUAnRDCm bits of other channels are set to 0, CH2 and CH7 serve as simultaneous rewrite trigger generation channels. CH2 controls the lower channels CH3 to CH6, and CH7 controls the lower channels CH8 to CH15.
- If simultaneous rewrite is enabled and an upper channel is selected for the simultaneous rewrite trigger (TAUAnRDE.TAUAnRDEm and TAUAnRDS.TAUAnRDSm = 1) but no upper channel is set (TAUAnRDC.TAUAnRDC[15:0] = 0), simultaneous rewrite cannot take place.

12.7.4 Types of simultaneous rewrite

In the following section the four simultaneous rewrite methods are explained using timing diagrams.

(1) Simultaneous rewrite when the master channel (re)starts counting (method A)

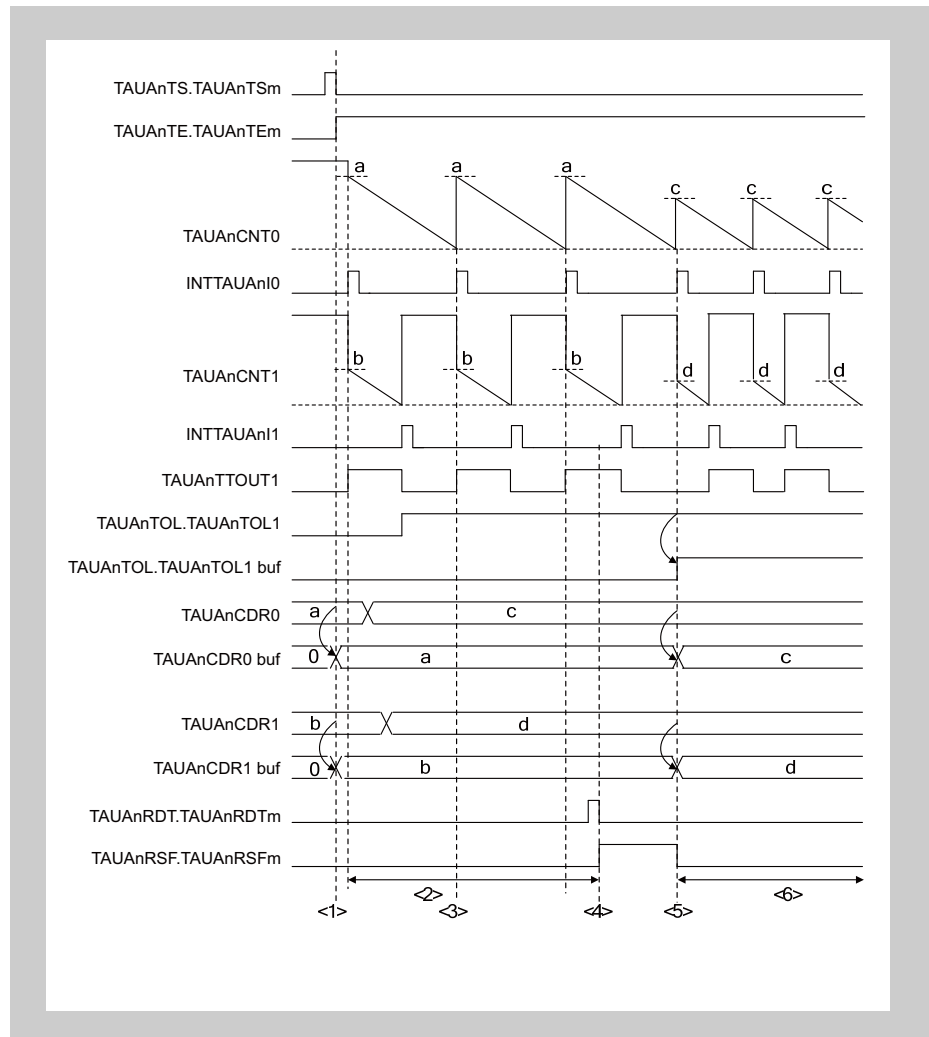

Figure 12-5 Simultaneous rewrite when the master channel (re)starts counting

Setup:

- CH0 is the master channel, counting down, CH1 represents an arbitrary slave channel, and simultaneous rewrite method A is applied.

Description:

1. When TAUAnTS.TAUAnTSM is set to 1, the value of TAUAnCDRm is copied to the TAUAnCDRm buffer, and the value of TAUAnTOL.TAUAnTOLm is copied to the TAUAnTOL.TAUAnTOLm buffer.
2. The TAUAnCDRm and TAUAnTOL.TAUAnTOLm registers can be written at any time.
3. CH0 restarts counting, but simultaneous rewrite does not occur because it is disabled (TAUAnRSF.TAUAnRSFm = 0).
4. The reload data trigger bit (TAUAnRDT.TAUAnRDTm) is set to 1 which sets the status flag (TAUAnRSF.TAUAnRSFm = 1), enabling simultaneous rewrite.
5. Because simultaneous rewriting is enabled, it is performed before counting on channel 0 resumes. The TAUAnCDRm value is loaded to the TAUAnCDRm buffer, and the TAUAnTOL.TAUAnTOLm value is loaded to the TAUAnTOL.TAUAnTOLm buffer.
6. The counters count down and await the next simultaneous rewrite trigger. The values of TAUAnCDRm and TAUAnTOL.TAUAnTOLm can be changed again.

(2) Simultaneous rewrite at the peak of a triangular cycle of the slave channel (method B)

Figure 12-6 Simultaneous rewrite at the peak of a triangular cycle of the slave channel

Setup:

- CH0 is the master channel, counting up and down, CH1 represents an arbitrary slave channel, and simultaneous rewrite method B is applied.

Description:

1. When TAUAnTS.TAUAnTSM is set to 1, the value of TAUAnCDRm is copied to the TAUAnCDRm buffer.
2. The TAUAnCDRm and TAUAnTOL registers can be written at any time.
3. Simultaneous rewrite does not occur because it is disabled (TAUAnRSF.TAUAnRSFm = 0).
4. The reload data trigger bit (TAUAnRDT.TAUAnRDTm) is set to 1 which sets the status flag (TAUAnRSF.TAUAnRSFm = 1), enabling simultaneous rewrite.
5. Simultaneous rewriting does not occur at the valley of a triangular wave cycle.
6. Simultaneous rewriting is performed at the peak of a triangular wave cycle. The TAUAnCDRm value is loaded to the TAUAnCDRm buffer, and the TAUAnTOL.TAUAnTOLm value is loaded to the TAUAnTOL.TAUAnTOLm buffer.
7. The counters count down and await the next simultaneous rewrite trigger. The values of TAUAnCDRm and TAUAnTOL.TAUAnTOLm can be changed again.

(3) Simultaneous rewrite when INTTAUAnIm is generated on an upper channel specified by TAUAnRDC.TAUAnRDCm (method C1)

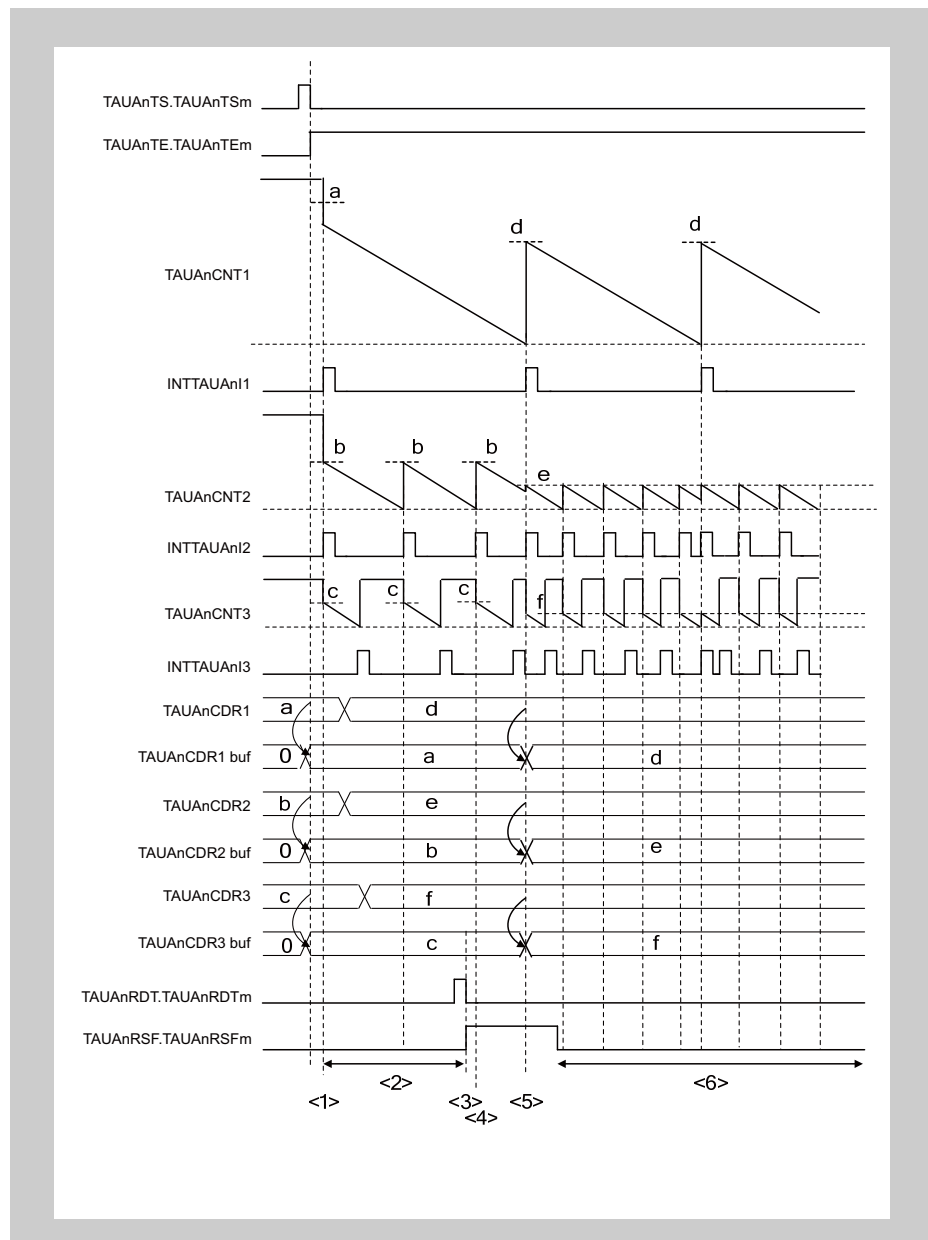

Figure 12-7 Simultaneous rewrite when INTTAUAnIm is generated on an upper channel specified by TAUAnRDC.TAUAnRDCm

Setup:

- CH1 is an upper channel, counting down. CH2 is a master channel, CH3 is the slave channel, and simultaneous rewrite method C1 is applied. The TAUAnRDC register specifies the channel to generate the simultaneous rewrite trigger.

Description:

1. When TAUAnTS.TAUAnTSM is set to 1, the value of TAUAnCDRm is copied to the TAUAnCDRm buffer.
2. The TAUAnCDRm register can be written at any time.
3. The reload data trigger bit (TAUAnRDT.TAUAnRDTm) is set to 1 which sets the status flag (TAUAnRSF.TAUAnRSFm = 1), enabling simultaneous rewrite.
4. Even though simultaneous rewrite is enabled, it does not take place because it is only triggered by an interrupt on channel 1.
5. Simultaneous rewriting is triggered by INT1, which is caused by counter 1 reaching 0000H. The TAUAnCDRm values are loaded to the corresponding TAUAnCDRm buffers.
6. The counter counts down and awaits the next simultaneous rewrite trigger. The values of the TAUAnCDRm registers can be changed again.

(4) Simultaneous rewrite when INTTAUAnIm is generated on an upper channel specified by TAUAnRDC.TAUAnRDCm that in turn is triggered by an external signal (method C2)

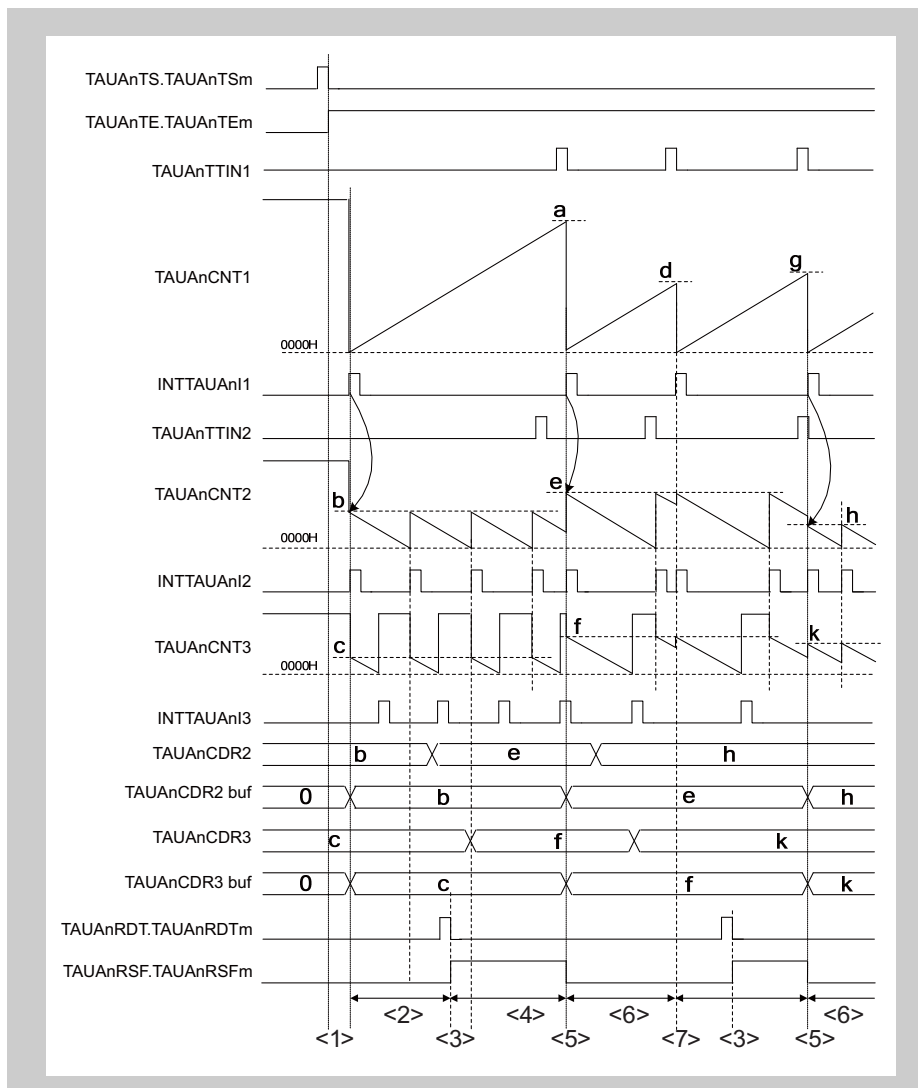

Figure 12-8 Simultaneous rewrite when INTTAUAnIm is generated on an upper channel specified by TAUAnRDC.TAUAnRDCm that in turn is triggered by an external signal

Setup:

- CH1 is an upper channel, counting down. CH2 is a master channel, CH3 is the slave channel, and synchronous channel operation method C2 is applied. The TAUAnRDC register specifies which upper channel is monitored for an INTTAUAnIm trigger.

Description:

1. When TAUAnTS.TAUAnTSM is set to 1, the value of TAUAnCDRm is copied to the TAUAnCDRm buffer.
2. The TAUAnCDRm register can be written at any time.
3. The reload data trigger bit (TAUAnRDT.TAUAnRDTm) is set to 1 which sets the status flag (TAUAnRSF.TAUAnRSFm = 1), enabling simultaneous rewrite.
4. Even though simultaneous rewrite is enabled, it does not take place because it is only triggered by an interrupt on channel 1.
5. Simultaneous rewriting is triggered by INT1, which is caused by the external signal TIN1. The TAUAnCDRm values are loaded to the corresponding TAUAnCDRm buffers.
6. The counters count down and await the next simultaneous rewrite trigger. The values of the TAUAnCDRm registers can be changed again.
7. An external signal occurs at TIN2 but simultaneous rewrite does not take place because it is disabled (TAUAnRSF.TAUAnRSFmTAUAnRSF.TAUAnRSFm = 0).

12.8 Channel Output Modes

The output of the TAUAnTTOUTm pin can be controlled in two ways, the latter of which can be further split into individual modes:

- By software (TAUAnTOE.TAUAnTOEm = 0)

When controlled by software, the output register bit (TAUAnTO.TAUAnTOM) can be written and the value of the bit is output from to the output pin (TAUAnTTOUTm).

- By TAUA signals (TAUAnTOE.TAUAnTOEm = 1)

When operated by TAUA signals, the output level of TAUAnTTOUTm is set or reset or toggled by internal signals. The value of TAUAnTO.TAUAnTOM is updated accordingly to reflect the value of TAUAnTTOUTm.

- Independently (TAUAnTOM.TAUAnTOMm = 0)

When operated independently, the output of the TAUAnTTOUTm pin is only affected by settings of channel m. Therefore, independent channel operation must be selected (TAUAnTOM.TAUAnTOMm = 0).

- Synchronously (TAUAnTOM.TAUAnTOMm = 1)

When operated synchronously, the output of the TAUAnTTOUTm pin is affected by settings of channel m and those of other channels. Therefore, synchronous channel operation must be selected for all participating channels (TAUAnTOM.TAUAnTOMm = 1).

The TAUAnTO.TAUAnTOM bit can always be read to determine the current value of TAUAnTTOUTm, regardless of whether the pin is controlled by software, operated independently, or operated synchronously.

Control bits The settings of the control bits required to select a specific channel output mode are listed in *Table 12-9 “Channel output modes” on page 464*.

The channel output modes are described in detail in

- *12.8.2 “Channel output modes controlled independently by TAUAn signals” on page 466*
- *12.8.3 “Channel output modes controlled synchronously by TAUAn signals” on page 468*.

Collective TAUAnTOM bit manipulation Whether to apply settings to the TAUAnTOM bits is controlled using the TAUAnTOE.TAUAnTOEm bits.

When writing to the TAUAnTO register, TAUAnTOM settings are only written to channels for which the TAUAnTOE.TAUAnTOEm bit is cleared to 0. The TAUAnTOM settings are not applied for channels for which the corresponding TAUAnTOE.TAUAnTOEm bit is set to 1.

Note The TAUAnTO.TAUAnTOM bits are allocated so that the bit numbers correspond to the channel numbers.

Output logic Positive logic or inverted logic of the output is specified by control bit TAUAnTOL.TAUAnTOLm.

The value of the TAUAnTOL.TAUAnTOLm bit must be set before the counter is started. It can only be changed during operation in PWM output function or triangle PWM output function. Otherwise, changes to TAUAnTOL.TAUAnTOLm result in an undefined TAUAnTTOUTm signal.

Refer to *12.7 “Simultaneous Rewrite” on page 451*.

The various channel output modes and the channel output control bits are listed in the following table.

Table 12-9 Channel output modes

Channel output mode	TAUAn TOE. TAUAn TOEm	TAUAn TOM. TAUAn TOMm	TAUAn TOC. TAUAn TOCm	TAUAn TDE. TAUAn TDEm	TAUAn TRE. TAUAn TREm	TAUAn TME. TAUAn TMEm	TAUAn TDM. TAUAn TDMm
By software							
Independent Channel Output Mode Controlled by Software	0	x					
By TAUA signals, independently							
Independent Channel Output Mode 1	1	0	0	0	0	0	0
with Real-Time Output					1		
Independent Channel Output Mode 2			1		0		
By TAUA signals, synchronously							
Synchronous Channel Output Mode 1	1	1	0	0	0	0	0
with Non-Complementary Modulation Output					1	1	
Synchronous Channel Output Mode 2			1	0	0	0	0
with Dead Time Output				1			
with One-Phase PWM Output							1
with Complementary Modulation Output					1	1	0
with Non-Complementary Modulation Output			1	0			

- All combinations not listed in this table are forbidden.
- Bits marked with an x can be set to any value.

Note The following bits cannot be changed during count operation (TAUAnTE.TAUAnTE = 1):

- TAUAnTOE.TAUAnTOEm,
- TAUAnTOM.TAUAnTOMm,
- TAUAnTOC.TAUAnTOCm,
- TAUAnTDE.TAUAnTDEm,
- TAUAnTRE.TAUAnTREm, and
- TAUAnTDM.TAUAnTDMm

The following bits cannot be changed during count operation (TAUAnTE.TAUAnTEm = 1) except in channel output modes with modulation output:

- TAUAnTME.TAUAnTMEm,
- TAUAnTDL.TAUAnTDLm

12.8.1 General procedure for specifying a channel output mode

The following steps describe the general procedure for specifying a TAUAnTTOUTm channel output mode. The prerequisite is that timer output operation is disabled (TAUAnTOE.TAUAnTOEm = 0).

1. Set TAUAnTO.TAUAnTOm to specify the initial level of the TAUAnTTOUTm output.
2. Set the channel output mode using *Table 12-9 “Channel output modes” on page 464* and the output logic using the TAUAnTOL.TAUAnTOLm bit.
3. Start the counter (TAUAnTS.TAUAnTSm = 1).

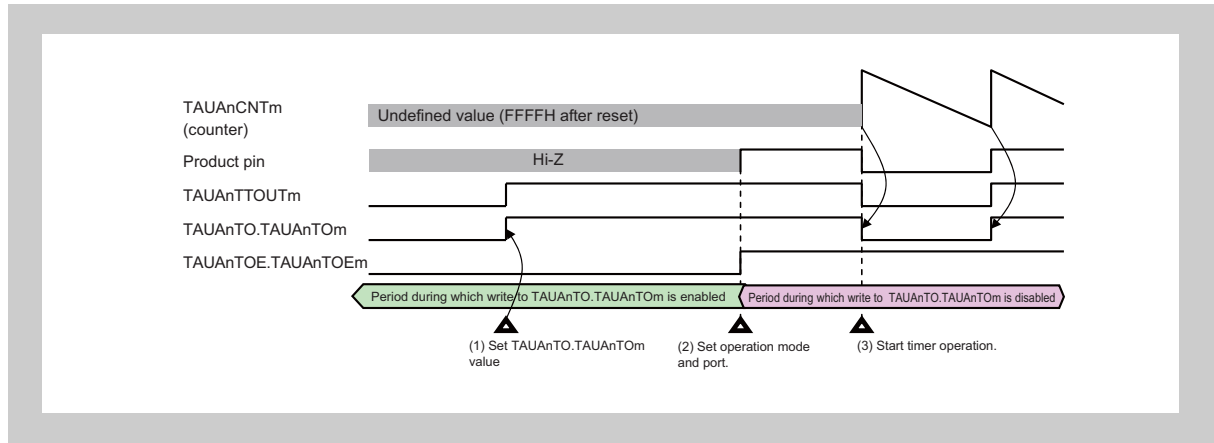

Figure 12-9 General procedure for specifying a TAUAnTTOUTm channel output mode

12.8.2 Channel output modes controlled independently by TAUAn signals

This chapter lists the channel output modes that are controlled independently by TAUAn signals. The control bits used to specify a mode are listed in *Table 12-9 “Channel output modes” on page 464*.

(1) Independent Channel Output Mode 1

Set/reset conditions In this output mode, TAUAnTTOUTm toggles when INTTAUAnIm is detected. The value of TAUAnTOL.TAUAnTOLm is ignored.

Prerequisites None, other than those in *Table 12-9 “Channel output modes” on page 464*.

(2) Independent Channel Output Mode 1 with Real-Time Output

In this output mode, the value of the TAUAnTRO.TAUAnTROm bit of the trigger channel is output to TAUAnTTOUTm. The trigger channel is specified by setting the corresponding TAUAnTRC.TAUAnTRCm bit to 1. It controls all lower channels for which TAUAnTRC.TAUAnTRCm = 0.

Set/reset conditions The value of the TAUAnTRO.TAUAnTROm bit is only sent to TAUAnTTOUTm when an interrupt INTTAUAnIm occurs on the trigger channel. The interrupt is generated either:

- at certain specified intervals or
- on detection of a valid TAUAnTTINm input edge / counter start

The type of trigger is set using the TAUAnCMORm.TAUAnMD[4:1] bits.

Prerequisites Both master and slave channels can be set as a trigger generation channel. A channel for which TAUAnTRC.TAUAnTRCm is set to 1 serves as the trigger generation channel even if TAUAnTRE.TAUAnTREM is set to 0. Real-time output cannot take place if there is no channel for which TAUAnTRE.TAUAnTREM is set to 1 or if TAUAnTRCm.TRC0 = 0.

This can be seen in the following figure.

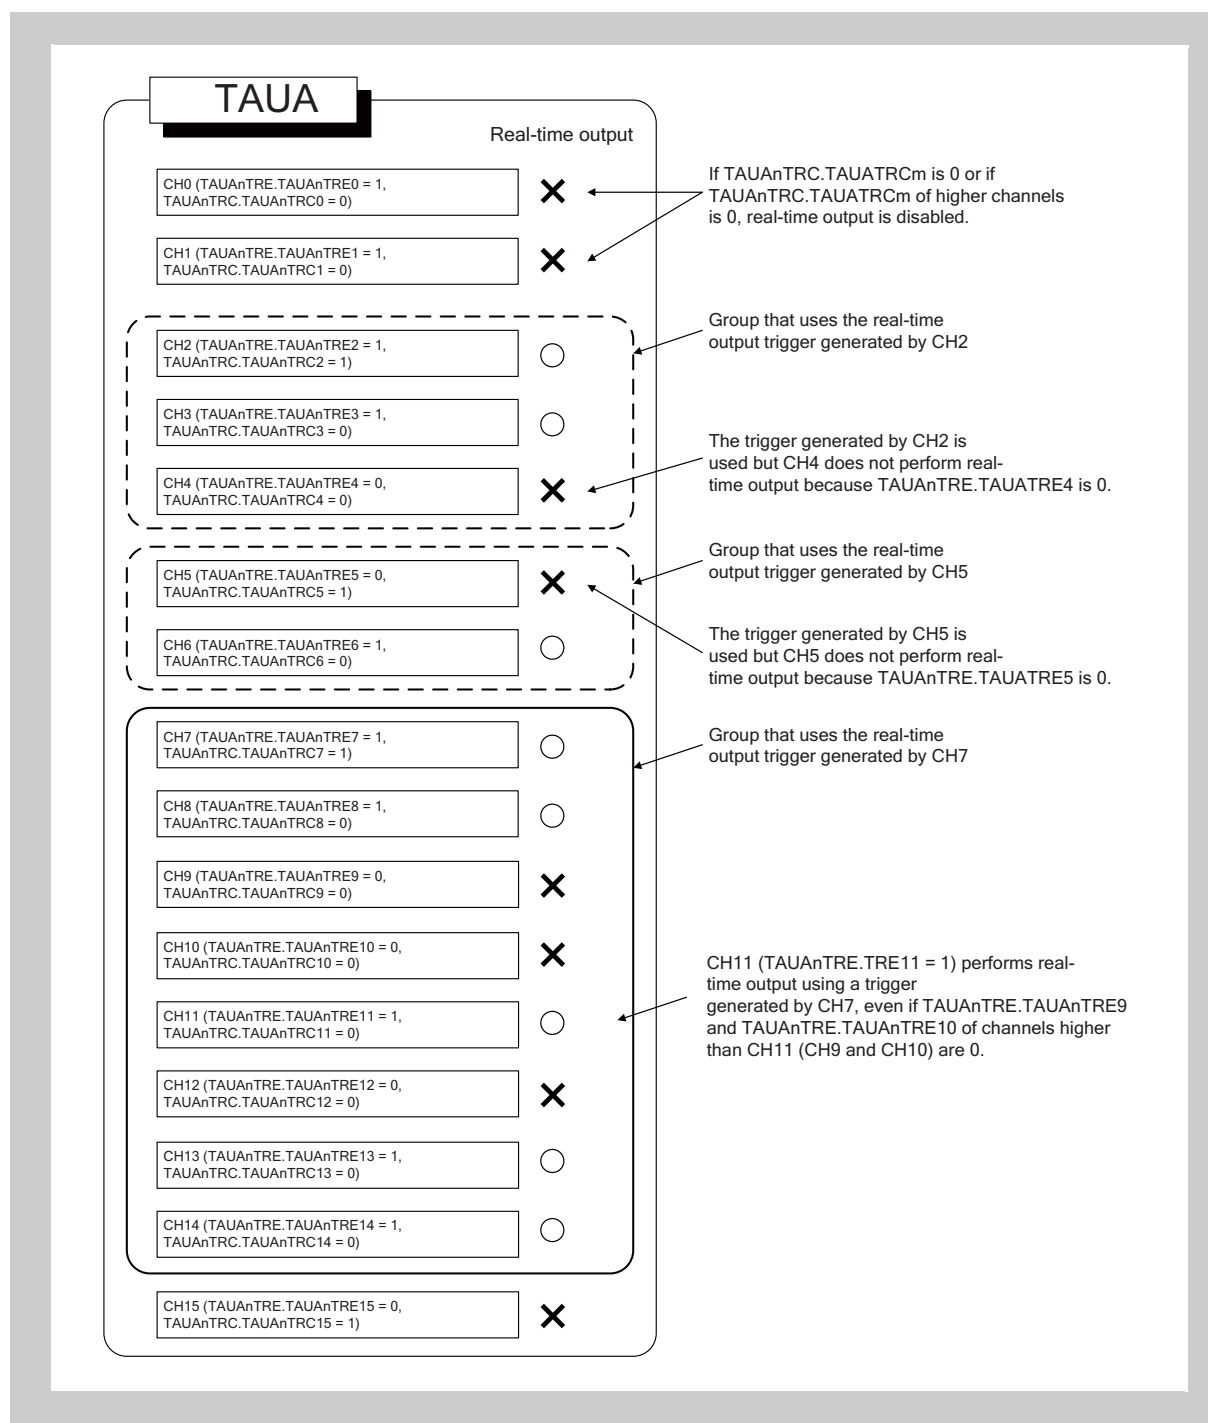

Figure 12-10 Real-time output

(3) Independent Channel Output Mode 2

Set/reset conditions In this output mode, TAUAnTTOUTm is set when INTTAUAnIm occurs upon count start and reset when INTTAUAnIm occurs due to a match between TAUAnCNTm and TAUAnCDRm.

Prerequisites None, other than those in *Table 12-9 “Channel output modes” on page 464*.

12.8.3 Channel output modes controlled synchronously by TAUAn signals

This chapter lists the channel output modes that are controlled synchronously by TAUAn signals. The control bits used to specify a mode are listed in *Table 12-9 “Channel output modes” on page 464*.

(1) Synchronous Channel Output Mode 1

Set/reset conditions In this output mode, INTTAUAnIm of the master channel serves as the set signal and INTTAUAnIm of the slave channel as the reset signal. If INTTAUAnIm of the master channel and INTTAUAnIm of the slave channel are generated at the same time, INTTAUAnIm of the slave channel (reset signal) has priority over INTTAUAnIm (set signal) of the master channel, i.e. the master channel is ignored.

Prerequisites None, other than those in *Table 12-9 “Channel output modes” on page 464*.

(2) Synchronous Channel Output Mode 1 with Non-Complementary Modulation Output

Set/reset conditions In this output mode, TAUAnTTOUm outputs the result of an AND operation between the PWM output of a channel and the real-time output bit (TAUAnTRO.TAUAnTROm).

The phase period to which the dead time is added is specified using the TAUAnTDL.TAUAnTDLm bit; for positive phase set TAUAnTDL.TAUAnTDLm = 0 and for negative phase set TAUAnTDL.TAUAnTDLm = 1.

Prerequisites A set of at least three channels is required to generate the PWM output. The master channel and slave 1 generate the period, and slave 2 generates the duty cycle. In typical applications, a further 5 slave channels are also used that operate in the same manner as slave 2.

Only the PWM output and the real-time output bit of the same channel can be combined.

TAUAnTRO.TAUAnTROm, TAUAnTME.TAUAnTMEem, and TAUAnTDL.TAUAnTDLm can only be changed during count operation.

- If TAUAnTME.TAUAnTMEem is changed, the new value of TAUAnTME.TAUAnTMEem is applied upon detection of INTTAUAnIm on the specified channel.
- If TAUAnTME.TAUAnTMEem and TAUAnTDL.TAUAnTDLm are changed, the new values are applied upon detection of INTTAUAnIm on the master channel.

(3) Synchronous Channel Output Mode 2

In this output mode, the operation mode must be set to Up Down Count mode. The result is a triangle PWM wave at TAUAnTTOUTm. For details refer to 12.24.1 Triangle PWM Output Function.

Set/reset conditions TAUAnCNTm of the slave channel counts down and up alternatively. When it passes 0001_H it generates an interrupt, causing TAUAnTTOUTm to toggle.

Prerequisites A set of two channels is required to generate the triangle PWM output. TAUAnTTOUTm must be set to 0 before the function starts.

(4) Synchronous Channel Output Mode 2 with Dead Time Output

In this output mode, a dead time delay is added to TAUAnTTOUTm. The set/reset conditions are shown in the following figure.

Set/reset conditions

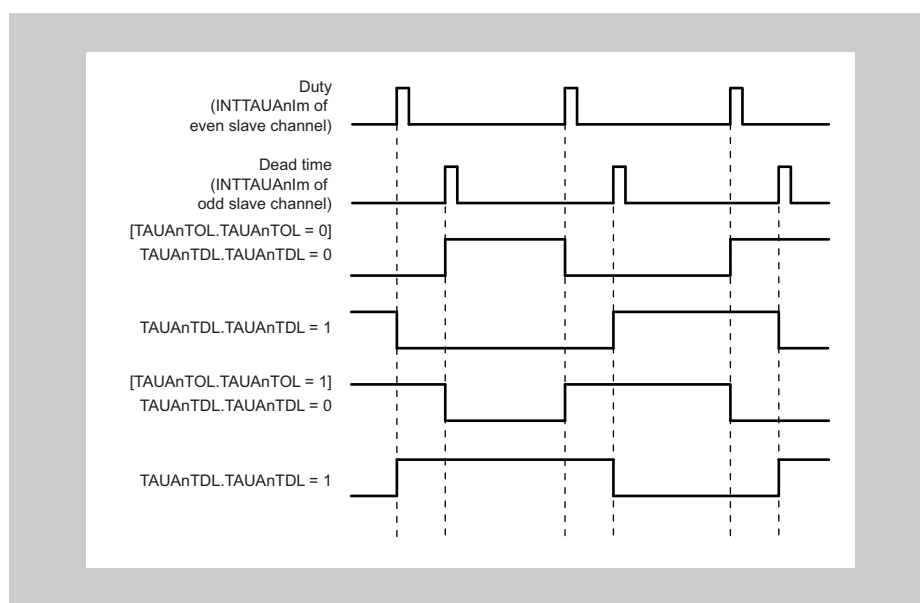

Figure 12-11 Set/reset conditions for Synchronous Channel Output Mode 2 with Dead Time Output

The edge to which the dead time is added is specified using the TAUAnTDL.TAUAnTDLm bit; for rising edge set TAUAnTDL.TAUAnTDLm = 0 and for falling edge set TAUAnTDL.TAUAnTDLm = 1.

Prerequisites Dead time control requires a set of three channels, each operating in the following modes:

- One master channel

The master channel must be set to Interval Timer Mode

- One even slave channel

The even slave channel must be set to Up Down Count Mode

- One odd slave channel (even channel + 1)

The odd slave channel must be set to One Count Mode

The values of the following bits must be the same for the odd channel and the even channel:

- TAUAnTOE.TAUAnTOEm,
- TAUAnTME.TAUAnTMEm,
- TAUAnTRE.TAUAnTREm,
- TAUAnTOM.TAUAnTOMm,
- TAUAnTOC.TAUAnTOCm,
- TAUAnTDE.TAUAnTDEm, and
- TAUAnTDM.TAUAnTDMm

(5) Synchronous Channel Output Mode 2 with One-Phase PWM Output

In this output mode, a dead time delay is added to $TAUAnTTOUTm$. The set/reset conditions are shown in the following figure.

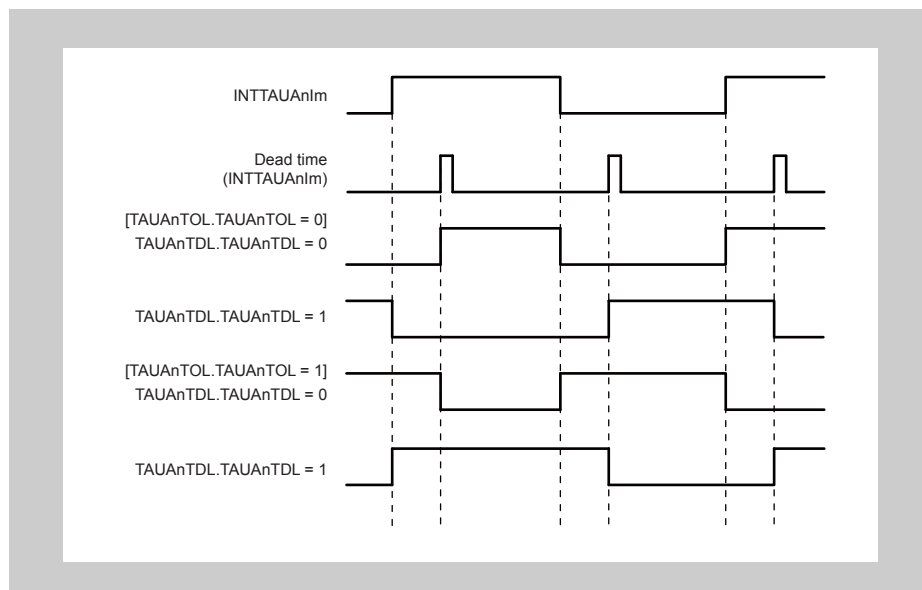

Set/reset conditions

Figure 12-12 Set/reset conditions for Synchronous Channel Output Mode 2 with One-Phase PWM Output

The edge to which the dead time is added is specified using the $TAUAnTDL.TAUAnTDLm$ bit; for rising edge set $TAUAnTDL.TAUAnTDLm = 0$ and for falling edge set $TAUAnTDL.TAUAnTDLm = 1$.

Prerequisites One-phase PWM output control requires a set of two channels:

- One even slave channel
- One odd slave channel (even channel + 1)

The odd slave channel must be set to “One Count Mode”

The values of the following bits must be the same for the odd channel and the even channel:

- $TAUAnTOE.TAUAnTOEm$,
- $TAUAnTME.TAUAnTMEm$,
- $TAUAnTRE.TAUAnTREm$,
- $TAUAnTOM.TAUAnTOMm$,
- $TAUAnTOC.TAUAnTOCm$,
- $TAUAnTDE.TAUAnTDEm$, and
- $TAUAnTDM.TAUAnTDMm$

(6) Synchronous Channel Output Mode 2 with Complementary Modulation Output

Set/reset conditions In this output mode, TAUAnTTOUTm outputs a PWM signal, a high signal, or a low signal depending on the value of the real-time output bit (TAUAnTRO.TAUAnTROm), the modulation output bit (TAUAnTME.TAUAnTMEm), and the output level bit (TAUAnTOL.TAUAnTOLm) of a pair of slave channels.

For details refer to 12.25.3 “Complementary Modulation Output Function” on page 705.

Prerequisites A set of at least four channels is required for this mode. The master channel and slave 1 generate the period, slave channel 2 generates the duty cycle, and slave 3 generates the dead time. Slave 2 and 3 are a pair. In typical applications, a further 4 channels are also used that operate in the same manner as slaves 2 and 3 respectively.

TAUAnTRO.TAUAnTROm, TAUAnTME.TAUAnTMEm, and TAUAnTDL.TAUAnTDLm can only be changed during count operation.

- If TAUAnTME.TAUAnTMEm is changed during operation, the new TAUAnTME.TAUAnTMEm value is applied upon detection of INTTAUAnIm at the specified channel.
- If TAUAnTME.TAUAnTMEm and TAUAnTDL.TAUAnTDLm are changed, the new values are applied upon detection of INTTAUAnIm on an even slave channel.

(7) Synchronous Channel Output Mode 2 with Non-Complementary Modulation Output

The difference to "Synchronous Channel Output Mode 1 with Non-Complementary Modulation Output" is the PWM wave shape.

It is a rectangular wave with mode 1 while it is a triangular wave with mode 2.

12.9 Start Timing of Operating Modes

This chapter describes when the counters of the different operating modes start after the TAUAnTS.TAUAnTSm bit is set to 1.

In all modes, the value of the data register and whether or not an interrupt is issued depends on the individual mode and corresponding register settings.

Caution The timing for starting counting in this section is only for reference. The timing for starting counting actually varies according to the count clock timing.

12.9.1 Interval Timer Mode, Judge Mode, Capture Mode, Up Down Count Mode

The counter starts at the start of the next count clock cycle after TAUAnTS.TAUAnTSm is set to 1. The value of data register is also loaded at the point the counter starts.

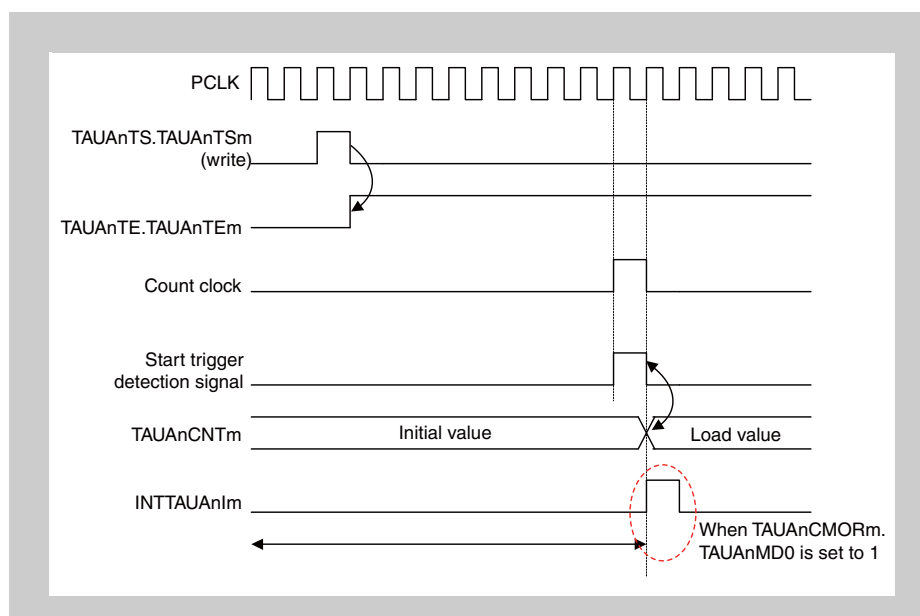

Figure 12-13 Start timing of Interval Timer Mode, Judge Mode, Capture Mode, Up Down Count Mode

12.9.2 Event Mode

The value of the data register is loaded as soon as TAUAnTS.TAUAnTSm is set to 1. The counter also starts immediately. The value of the data register increments at the start of each subsequent count clock cycle.

Figure 12-14 Start timing of Event Mode

12.9.3 All other operating modes

In all other operating modes, the count clock cycles are ignored with regard to starting the counter. The counter is only triggered by detection of a valid TAUAnTTINm edge. The value of data register is also loaded at the point the counter starts. Nevertheless, the count clock cycles determine the frequency with which all operations take place.

Figure 12-15 Start timing of all other operating modes

12.10 TAUAnTTOUTm Output and INTTAUAnIm Generation when Counter Starts or Restarts

When the counter starts, it is possible to specify whether an INTTAUAnIm is generated using the TAUAnCMORn.TAUAnMD0 bit. The effect of the bit depends on the selected mode, as shown in the following table. The effects of INTTAUAnIm on TAUAnTTOUTm depend on the selected channel operation function.

Table 12-10 Effect of TAUAnCMORm.TAUAnMD0 bit on generation of INTTAUAnIm when counter is triggered

Mode	TAUAnCMORm.TAUAnMD0 bit	INTTAUAnIm generated when counter starts
Interval Timer Mode	0	No
Capture Mode	1	Yes
Count Capture Mode	1	Yes
Capture & One Count Mode	0	No
Capture & Gate Count Mode	0	No
Event Count Mode	0	No
Up Down Count Mode	0	No
One Count Mode	0/1	No, regardless of setting of TAUAnCMORn.TAUAnMD0 bit.
Gate Count Mode	0/1	No, regardless of setting of TAUAnCMORn.TAUAnMD0 bit.
Pulse One Count Mode	0/1	Yes, regardless of setting of TAUAnCMORn.TAUAnMD0 bit.

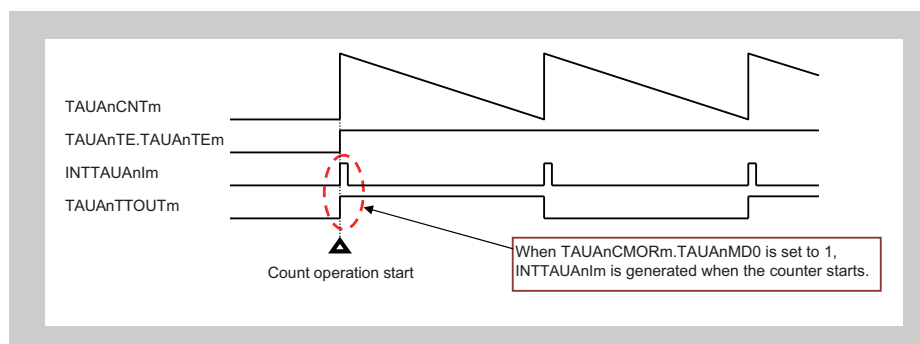

Figure 12-16 INTTAUAnIm generated when counter starts

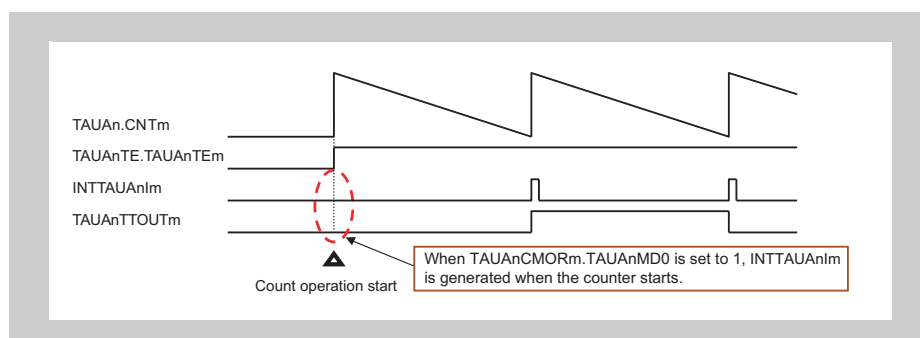

Figure 12-17 INTTAUAnIm not generated when counter starts

12.11 Interrupt Generation upon Overflow

Certain independent functions that count up, overflow without generating an interrupt when they reach $FFFF_H$. This section describes how it is possible to generate an interrupt, by combining a channel operating in one of these modes with a channel in a different operation mode which counts down.

The appropriate operation mode for the second channel depends on the operation mode of the first channel. Nevertheless, the principle is the same for all combinations:

- Find a operation mode for the second channel that counts down in such a manner, that it reaches 0000_H at the same time as the first channel overflows ($TAUAnCNTm = FFFF_H$).
- Set $TAUAnCDRm$ of the second channel to $FFFF_H$
- The two channels must count at the same speed (i.e. they must have the same count clock)
- Both channels are triggered by the same $TAUAnTTINm$ input

Result: The down-counter of the second channel reaches 0000_H at exactly the same time as the up-counter of the first channel overflows ($TAUAnCNTm = FFFF_H$). Thus the second channel generates the desired interrupt.

The following sections list the operating modes that count down that are required to match specific operating modes that count up, as well as example timing diagrams.

12.11.1 Capture Mode

- Applies to • TAUAnTTINm Input Pulse Interval Measurement Function
- Combine with Interval Timer Mode

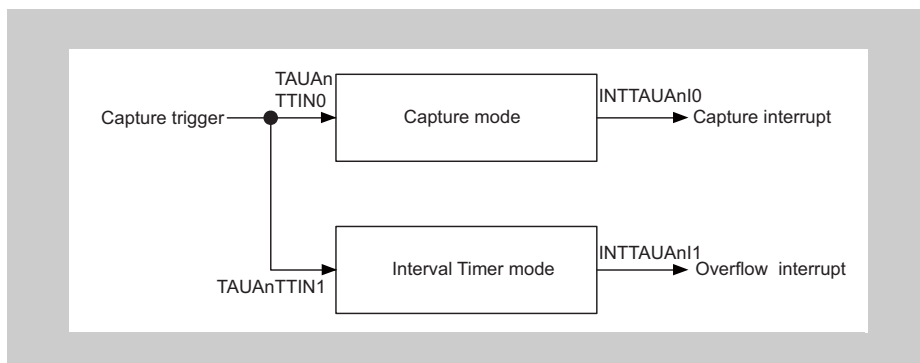

Figure 12-18 Combination of Capture Mode and Interval Timer Mode

Timing diagram

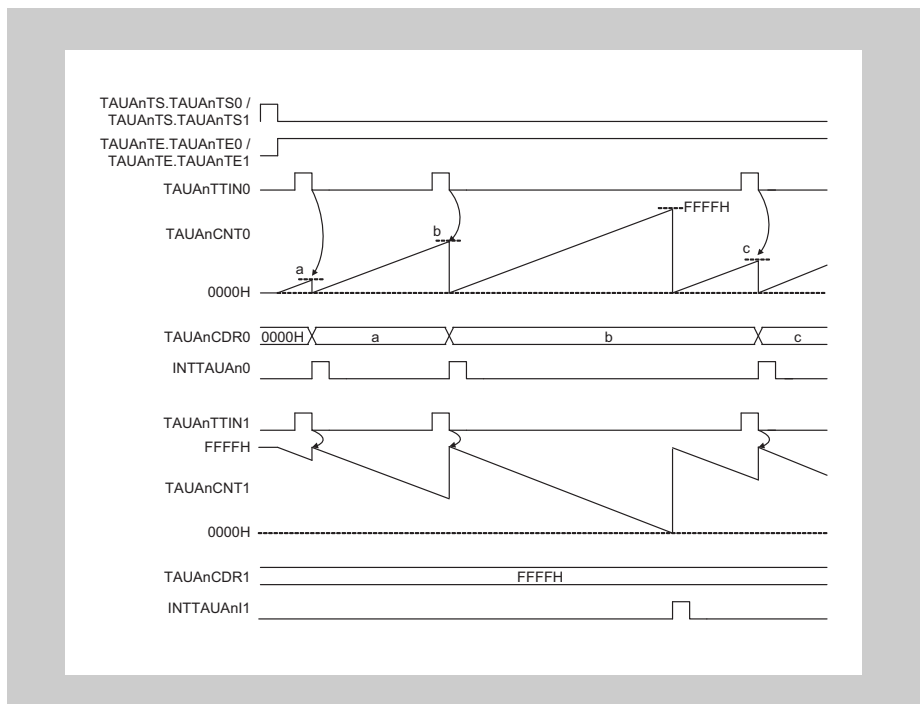

Figure 12-19 Interrupt generation via combination of Capture Mode and Interval Timer Mode

12.11.2 Capture and One Count Mode

Applies to • TAUAnTTINm Input Signal Width Measurement Function
 Combine with One Count Mode

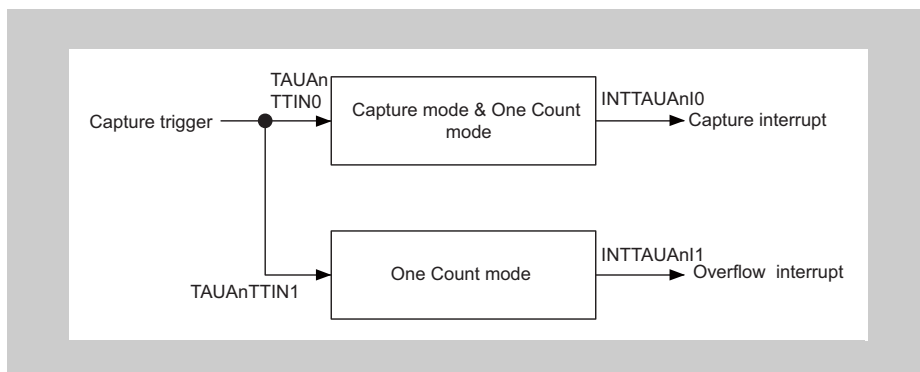

Figure 12-20 Combination of Capture and One Count Mode and One Count Mode

Timing diagram

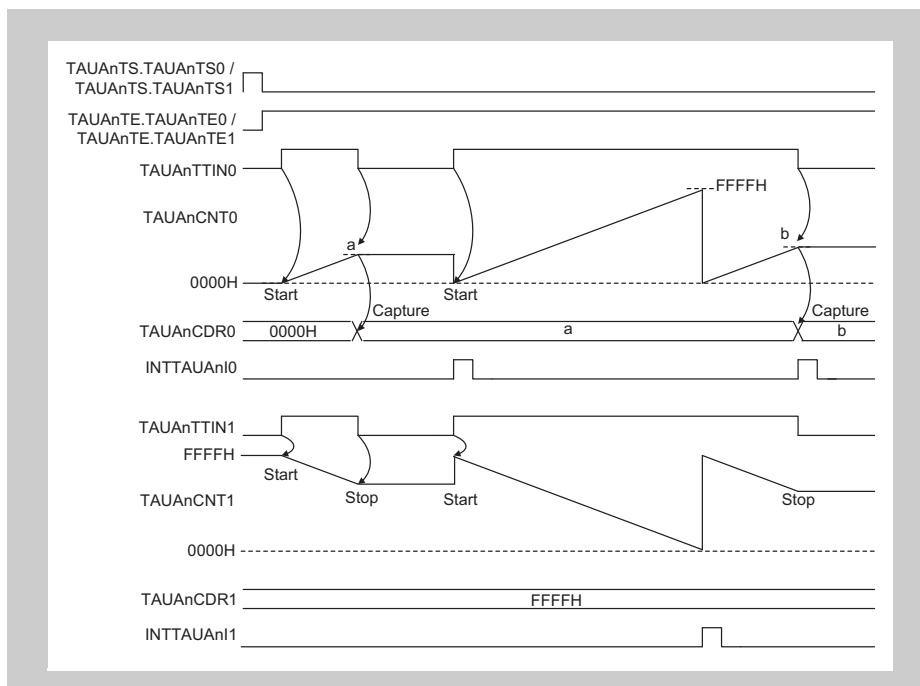

Figure 12-21 Interrupt generation via combination of Capture and One Count Mode and One Count Mode

12.11.3 Count Capture Mode

- Applies to • TAUAnTTINm Input Position Detection Function
Combine with Interval Timer Mode

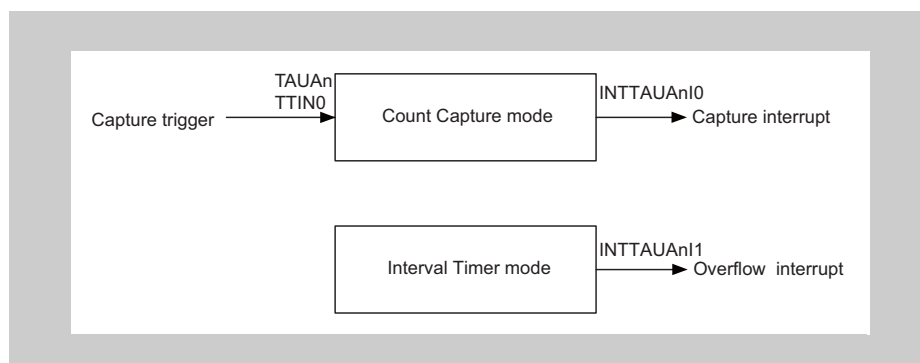

Figure 12-22 Combination of Count Capture Mode and Interval Timer Mode

Timing diagram

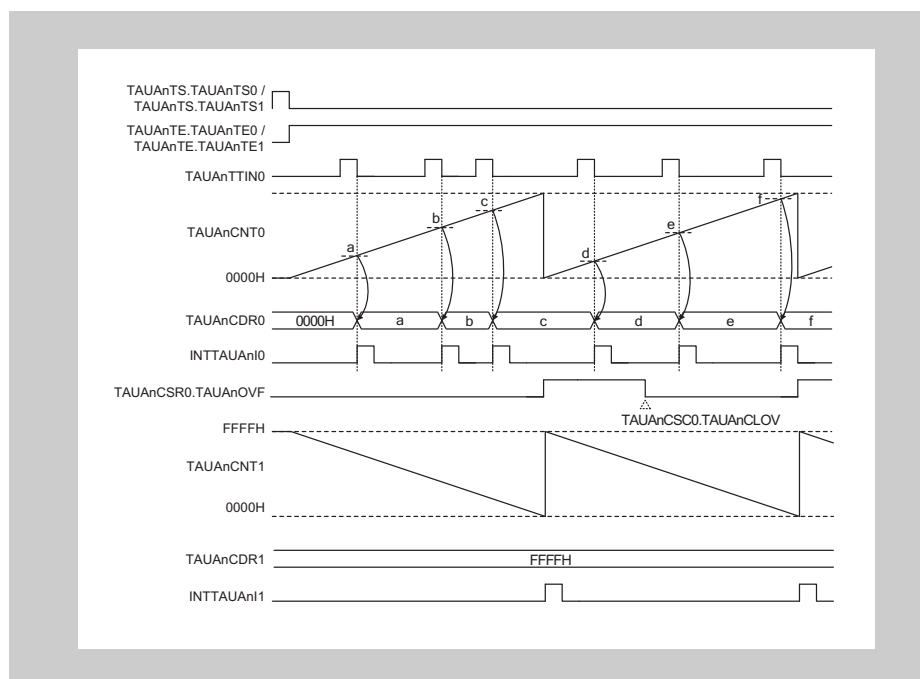

Figure 12-23 Interrupt generation via combination of Count Capture Mode and Interval Timer Mode

In the above timing diagram, TAUAnCSRm.TAUAnOVF is set to 1 when TAUAnCNTm overflows.

TAUAnCSRm.TAUAnOVF is cleared by writing 1 to TAUAnCSCm.TAUAnCLOV.

12.11.4 Capture and Gate Count Mode

- Applies to • TAUAnTTINm Input Period Count Detection Function
 Combine with Gate Count Mode

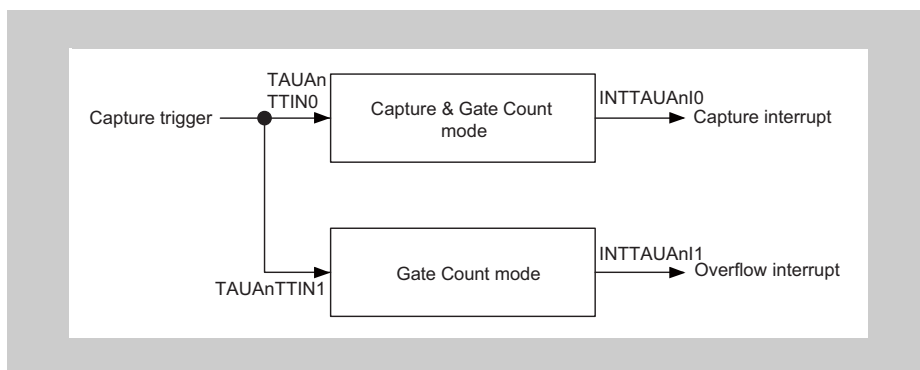

Figure 12-24 Combination of Capture and Gate Count Mode and Gate Count Mode

Timing diagram

Figure 12-25 Interrupt generation via combination of Capture and Gate Count Mode and Gate Count Mode

In the above timing diagram, TAUAnCSRm.TAUAnOVF is set to 1 when TAUAnCNTm overflows. TAUAnCSRm.TAUAnOVF is cleared by writing 1 to TAUAnCSCm.TAUAnCLOV.

12.12 TAUAnTTINm Edge Detection

Edge detection is based on the operation clock. This means that an edge can only be detected at the next rising edge of the operation clock. This can lead to a maximum delay of one operation clock cycle.

The following figure shows an edge detection timing example.

Figure 12-26 Basic edge detection timing

Figure 12-26 “Basic edge detection timing” shows the approximate operation timing. In actuality, there is delay due to the noise filter and synchronizer between the TAUAnIm pin and TAUAn.

12.13 Assigning DMA Window Addresses

DMA (direct memory access) can be used to store values in the TAUAnDWRj registers, for example the current values of the TAUAnCDRm register and the TAUAnTOL register.

For example, the following figure shows how to rewrite the period register, duty registers, and TAUAnTOL register to the TAUAnDWRj registers.

1. Specify the addresses of the selected registers (TAUAnCDR0, TAUAnCDR2, TAUAnCDR4, TAUAnCDR6, TAUAnCDR9, TAUAnCDR13, TAUAnTOL.TAUAnTOLm, and TAUAnRDT.TAUAnRDTm) to the TAUAnDAS registers.
2. The TAUAnDMA window address function then loads the values of the selected registers to the corresponding TAUAnDWRj registers.

Figure 12-27 Assigning DMA window addresses

Note When using the simultaneous rewrite function for a data register, it is recommended to allocate the TAUAnRDT register at the end of the specified area.

12.14 Independent Channel Operation Functions

The following sections list the independent channel operation functions provided by TAUA. For a general overview of independent channel operation, see 12.3 “*Functional Description*” on page 443 .

12.15 Independent Channel Interrupt Functions

This chapter describes functions that generate interrupts at regular intervals or with a specified delay.

- 12.15.1 “*Interval Timer Function*”
- 12.15.2 “*TAUANnTTINm Input Interval Timer Function*”
- 12.15.3 “*Delay Count Function*”
- 12.15.4 “*One-Pulse Output Function*”

12.15.1 Interval Timer Function

(1) Overview

Summary This function is used as a reference timer for generating timer interrupts (INTTAUAnIm) at regular intervals. When an interrupt is generated, the TAUAnTTOUTm signal toggles, resulting in a square wave.

- Prerequisites**
- The operation mode must be set to Interval Timer Mode. Refer to *Table 12-11 “TAUAnCMORm settings for Interval Timer Function” on page 486*.
 - The channel output mode must be set to Independent Channel Output Mode 1. Refer to *12.8 “Channel Output Modes” on page 463*.

Description The counter is started by setting the channel trigger bit (TAUAnTS.TAUAnTSM) to 1. This in turn sets TAUAnTE.TAUAnTEM = 1, enabling count operation. The current value of TAUAnCDRm is loaded to TAUAnCNTm and the counter starts to count down from this value.

When the counter reaches 0000_H, INTTAUAnIm is generated and the TAUAnTTOUTm signal toggles. Next, TAUAnCNTm loads the value of TAUAnCDRm, and then subsequently continues operation.

The value of TAUAnCDRm can be rewritten at any time, and the changed value of TAUAnCDRm is applied the next time the counter starts to count down.

The counter can be stopped by setting TAUAnTT.TAUAnTTm to 1, which in turn sets TAUAnTE.TAUAnTEM to 0. TAUAnCNTm and TAUAnTTOUTm stop but retain their values. The counter can be reset by setting TAUAnTS.TAUAnTSM to 1. The counter can also be forcibly restarted (without stopping it first) by setting TAUAnTS.TAUAnTSM to 1 during operation.

Conditions If the TAUAnCMORm.TAUAnMD0 bit is set to 0, the first interrupt after a start or restart is not generated, and therefore TAUAnTTOUTm does not toggle. This results in an inverted TAUAnTTOUTm signal compared to when TAUAnCMORm.TAUAnMD0 is set to 1. For details refer to *12.10 “TAUAnTTOUTm Output and INTTAUAnIm Generation when Counter Starts or Restarts” on page 475*.

(2) Equations

$$\text{INTTAUAnIm cycle} = \text{count clock cycle} \times (\text{TAUAnCDRm} + 1)$$

$$\text{TAUAnTTOUTm square wave cycle} = \text{count clock cycle} \times (\text{TAUAnCDRm} + 1) \times 2$$

Caution The minimum interval timer interrupt cycle is $1/(\text{PCLK}/2)$.

(3) Block diagram and general timing diagram

Figure 12-28 Block diagram for Interval Timer Function

The following settings apply to the general timing diagram:

- INTTAUAnIm is generated at operation start (TAUAnCMORm.TAUAnMD0 = 1)

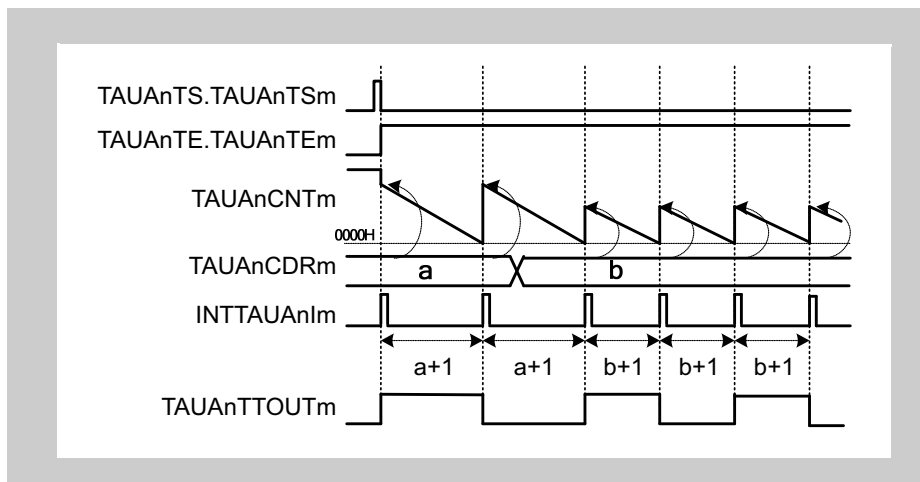

Figure 12-29 General timing diagram for Interval Timer Function

(4) Register settings**(a) TAUAnCMORM**

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
TAUAn CKS[1:0]	TAUAn CCS[1:0]	TAUAn MAS	TAUAn STS[2:0]		TAUAn COS[1:0]		-	TAUAn MD[4:1]				TAUAn MDO			

Table 12-11 TAUAnCMORM settings for Interval Timer Function

Bit name	Setting
TAUAnCKS[1:0]	00: Operation clock = CK0 01: Operation clock = CK1 10: Operation clock = CK2 11: Operation clock = CK3
TAUAnCCS[1:0]	00: Operation clock is used as the count clock
TAUAnMAS	0: Not used, so set to 0
TAUAnSTS[2:0]	000: Counter triggered by software trigger
TAUAnCOS[1:0]	00: Not used, so set to 00
TAUAnMD[4:1]	0000: Interval Timer Mode
TAUAnMDO	0: INTTAUAnIm not generated and TAUAnTTOUTm does not toggle at operation start or restart 1: Generates INTTAUAnIm and toggles TAUAnTTOUTm at operation start or restart

(b) TAUAnCMURm

-														TAUAnTIS[1:0]	

Table 12-12 TAUAnCMURm settings for Interval Timer Function

Bit name	Setting
TAUAnTIS[1:0]	00: Not used, so set to 00

(c) Channel output mode**Table 12-13 Control bit settings for Independent Channel Output Mode 1**

Bit name	Setting
TAUAnTOE.TAUAnTOEm	1: Enables Independent Channel Output Mode
TAUAnTOM.TAUAnTOMm	0: Independent channel output
TAUAnTOC.TAUAnTOCm	0: Operation mode 1 (= Toggle mode if TAUAnTOM.TAUAnTOMm = 0)
TAUAnTOL.TAUAnTOLm	0: Positive logic
TAUAnTDE.TAUAnTDEm	0: Disables dead time operation
TAUAnTDM.TAUAnTDMm	0: When dead time operation is disabled (TAUAnTDE.TAUAnTDEm = 0), set these bits to 0
TAUAnTDL.TAUAnTDLm	
TAUAnTRE.TAUAnTREm	0: Disables real-time output
TAUAnTRO.TAUAnTROM	0: When real-time output is disabled (TAUAnTRE.TAUAnTREm = 0), set these bits to 0
TAUAnTRC.TAUAnTRCm	
TAUAnTME.TAUAnTMEem	0: Disables modulation

Note The channel output mode can also be set to Channel Output Mode Controlled by Software by setting TAUAnTOE.TAUAnTOEm = 0. TAUAnTTOOUTm can then be controlled independently of the interrupts. For details refer to 12-9 “Channel output modes” on page 464 .

(d) Simultaneous rewrite

The simultaneous rewrite registers (TAUAnRDE, TAUAnRDS, TAUAnRDM, and TAUAnRDC) cannot be used with the Interval Timer Function. Therefore, these registers must be set to 0.

Table 12-14 Simultaneous rewrite settings for Interval Timer Function

Bit name	Setting
TAUAnRDE.TAUAnRDEm	0: Disables simultaneous rewrite
TAUAnRDS.TAUAnRDSm	0: When simultaneous rewrite is disabled (TAUAnRDE.TAUAnRDEm = 0), set these bits to 0
TAUAnRDM.TAUAnRDMm	
TAUAnRDC.TAUAnRDCm	

(5) Operating procedure for Interval Timer Function

Table 12-15 Operating procedure for Interval Timer Function

	Operation	Status of TAUAn
Restart	Initial channel setting Set the TAUAnCMORm register and TAUAnCMURm registers as described in <i>Table 12-11 "TAUAnCMORm settings for Interval Timer Function" on page 486</i> and <i>Table 12-12 "TAUAnCMURm settings for Interval Timer Function" on page 486</i> Set the value of the TAUAnCDRm register Set the channel output mode by setting the control bits as described in <i>Table 12-13 "Control bit settings for Independent Channel Output Mode 1" on page 487</i>	Channel operation is stopped.
	Start operation Set TAUAnTS.TAUAnTSm to 1. TAUAnTS.TAUAnTSm is a trigger bit, so it is automatically cleared to 0.	TAUAnTE.TAUAnTEm is set to 1 and the counter starts. TAUAnCNTm loads the TAUAnCDRm value. When TAUAnCMORm.TAUAnMD0 = 1, INTTAUAnIm is generated and TAUAnTTOUTm toggles.
	During operation The TAUAnCDRm register value can be changed at any time. The TAUAnCNTm register can be read at all times.	TAUAnCNTm counts down. When the counter reaches 0000 _H : <ul style="list-style-type: none"> TAUAnCNTm reloads the TAUAnCDRm value, and then continues count operation. INTTAUAnIm is generated and TAUAnTTOUTm toggles.
	Stop operation Set TAUAnTT.TAUAnTTm to 1. TAUAnTT.TAUAnTTm is a trigger bit, so it is automatically cleared to 0.	TAUAnTE.TAUAnTEm is cleared to 0 and the counter stops. TAUAnCNTm and TAUAnTTOUTm stop and retain their current values.

- (6) Specific timing diagrams
- (a) $\text{TAUAnCDRm} = 0000_{\text{H}}$, count clock = $\text{PCLK}/2$

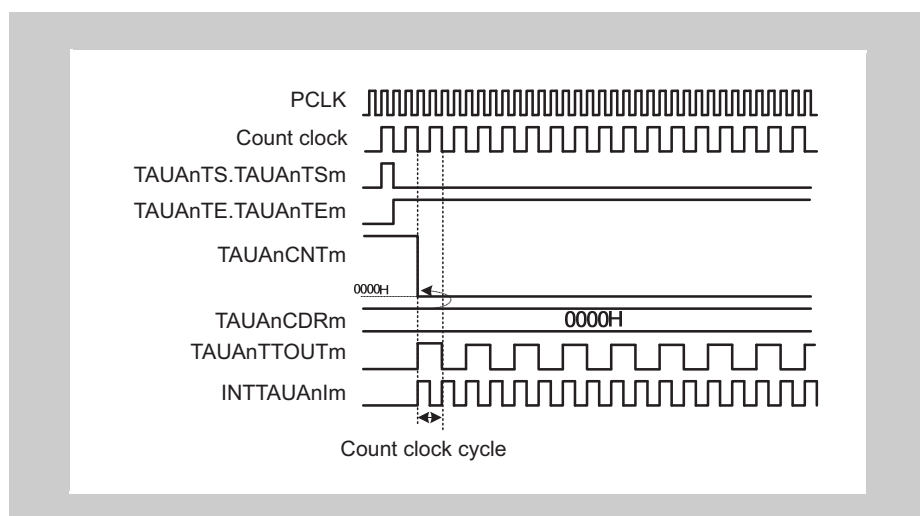

Figure 12-30 $\text{TAUAnCDRm} = 0000_{\text{H}}$, count clock = $\text{PCLK}/2$

- If $\text{TAUAnCDRm} = 0000_{\text{H}}$ and the count clock = $\text{PCLK}/2^1$, the TAUAnCDRm value is loaded to TAUAnCNTm every count clock, meaning that TAUAnCNTm is always 0000_{H} .
- INTTAUAnIm is generated every count clock, resulting in TAUAnTTOUTm toggling every count clock.

- (b) $\text{TAUAnCDRm} = 0000_{\text{H}}$, count clock = PCLK

Figure 12-31 $\text{TAUAnCDRm} = 0000_{\text{H}}$, count clock = PCLK

- If $\text{TAUAnCDRm} = 0000_{\text{H}}$ and the count clock = PCLK , the TAUAnCDRm value is loaded to TAUAnCNTm every PCLK clock, meaning that TAUAnCNTm is always 0000_{H} .
- INTTAUAnIm is generated continuously, resulting in TAUAnTTOUTm toggling every PCLK clock.

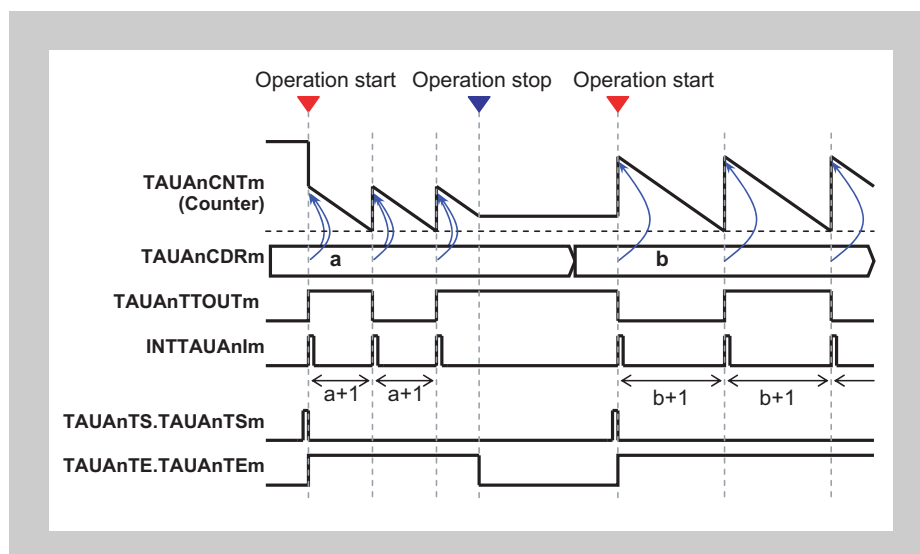

(c) Operation stop and restart

Figure 12-32 Operation stop and restart, $\text{TAUAnCMORm.TAUAnMD0} = 1$

- The counter can be stopped by setting TAUAnTT.TAUAnTTm to 1, which in turn sets TAUAnTE.TAUAnTEm to 0.
- TAUAnCNTm and TAUAnTTOUTm stop but retain their values.
- The counter can be restarted by setting TAUAnTS.TAUAnTSm to 1.

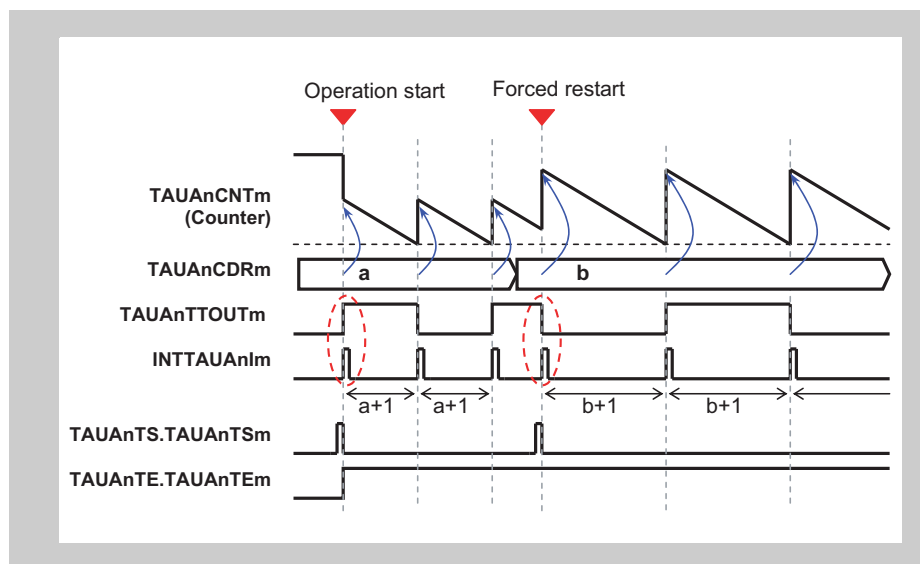

(d) Forced restart

Figure 12-33 Forced restart operation, $\text{TAUAnCMORm.TAUAnMD0} = 1$

- The counter can be forcibly restarted (without stopping it first) by setting TAUAnTS.TAUAnTSm to 1 during operation.
- If the $\text{TAUAnCMORm.TAUAnMD0}$ bit is set to 1, the first interrupt after a start or restart is generated.

12.15.2 TAUAnTTINm Input Interval Timer Function

(1) Overview

Summary This function is used as a reference timer for generating timer interrupts (INTTAUAnIm) at regular intervals or when a valid TAUAnTTINm input edge is detected. When an interrupt is generated, the TAUAnTTOUTm signal toggles, resulting in a square wave.

Prerequisites

- The operation mode must be set to Interval Timer Mode. Refer to Table 12-16 “TAUAnCMORm settings for TAUAnTTINm Input Interval Timer Function” on page 493.

- The channel output mode must be set to Independent Channel Output Mode 1. Refer to 12.8 “Channel Output Modes” on page 463.

Description This function operates in an identical manner to the Interval Timer Function (see 12.15.1 “Interval Timer Function” on page 484), except that this function is restarted by a valid TAUAnTTINm input edge. The type of edge used as the trigger is specified using the TAUAnCMURm.TAUAnTIS[1:0] bits. Either rising edge, falling edge, or rising and falling edge can be selected.

(2) Equations

$$\text{INTTAUAnIm cycle} = \text{count clock cycle} \times (\text{TAUAnCDRm} + 1)$$

$$\text{TAUAnTTOUTm square wave cycle} = \text{count clock cycle} \times (\text{TAUAnCDRm} + 1) \times 2$$

(3) Block diagram and general timing diagram

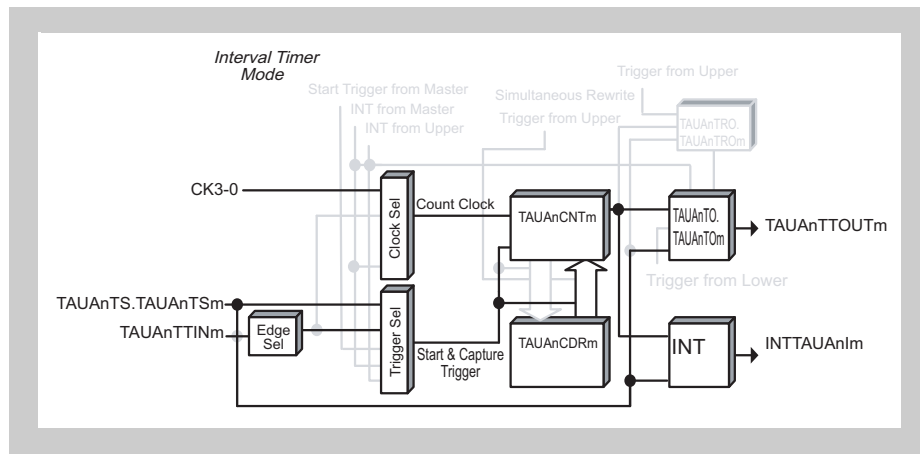

Figure 12-34 Block diagram for TAUAnTTINm Input Interval Timer Function

The following settings apply to the general timing diagram:

- INTTAUAnIm is generated at operation start (TAUAnCMORm.TAUAnMD0 = 1)
- Rising edge detection (TAUAnCMURm.TAUAnTIS[1:0] = 01_B)

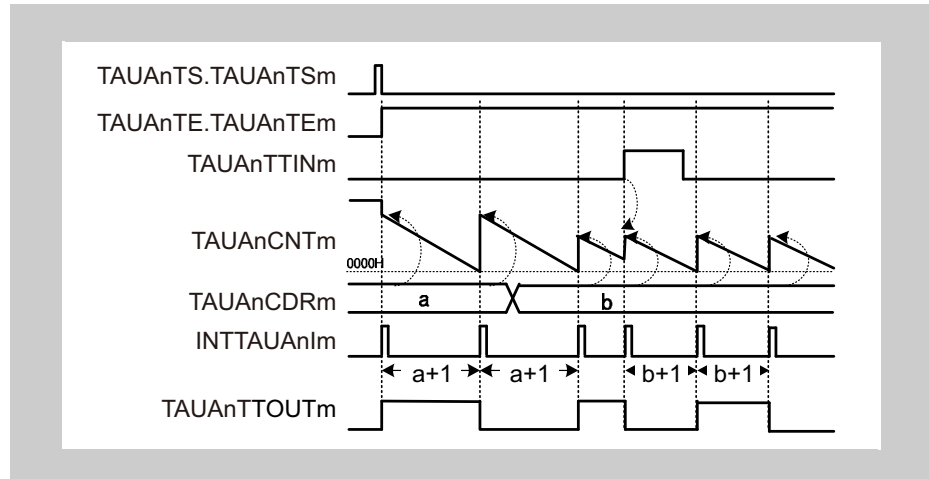

Figure 12-35 General timing diagram for TAUAnTTINm Input Interval Timer Function

(c) Channel output mode**Table 12-18 Control bit settings for Independent Channel Output Mode 1**

Bit name	Setting
TAUAnTOE.TAUAnTOEm	1: Enables Independent Channel Output Mode
TAUAnTOM.TAUAnTOMm	0: Independent channel output
TAUAnTOC.TAUAnTOCm	0: Operation mode 1 (= Toggle mode if TAUAnTOM.TAUAnTOMm = 0)
TAUAnTOL.TAUAnTOLm	0: Positive logic
TAUAnTDE.TAUAnTDEm	0: Disables dead time operation
TAUAnTDM.TAUAnTDMm	0: When dead time operation is disabled (TAUAnTDE.TAUAnTDEm = 0), set these bits to 0
TAUAnTDL.TAUAnTDLm	
TAUAnTRE.TAUAnTREM	0: Disables real-time output
TAUAnTRO.TAUAnTROM	0: When real-time output is disabled (TAUAnTRE.TAUAnTREM = 0), set these bits to 0
TAUAnTRC.TAUAnTRCm	
TAUAnTME.TAUAnTMEem	0: Disables modulation

Note The channel output mode can also be set to Channel Output Mode Controlled by Software by setting TAUAnTOE.TAUAnTOEm = 0. TAUAnTTOUTm can then be controlled independently of the interrupts. For details refer to 12-9 “Channel output modes” on page 464 .

(d) Simultaneous rewrite

The simultaneous rewrite registers (TAUAnRDE, TAUAnRDS, TAUAnRDM, and TAUAnRDC) cannot be used with the TAUAnTTINm Input Interval Timer Function. Therefore, these registers must be set to 0.

Table 12-19 Simultaneous rewrite settings for TAUAnTTINm Input Interval Timer Function

Bit name	Setting
TAUAnRDE.TAUAnRDEm	0: Disables simultaneous rewrite
TAUAnRDS.TAUAnRDSm	0: When simultaneous rewrite is disabled (TAUAnRDE.TAUAnRDEm = 0), set these bits to 0
TAUAnRDM.TAUAnRDMm	
TAUAnRDC.TAUAnRDCm	

(5) Operating procedure for TAUAnTTINm Input Interval Timer Function

Table 12-20 Operating procedure for TAUAnTTINm Input Interval Timer Function

	Operation	Status of TAUAn
Initial channel setting	<p>Set the TAUAnCMORm register and TAUAnCMURm registers as described in <i>Table 12-16 "TAUAnCMORm settings for TAUAnTTINm Input Interval Timer Function" on page 493</i> and <i>Table 12-17 "TAUAnCMURm settings for TAUAnTTINm Input Interval Timer Function" on page 493</i></p> <p>Set the value of the TAUAnCDRm register</p> <p>Set the channel output mode by setting the control bits as described in <i>Table 12-18 "Control bit settings for Independent Channel Output Mode 1" on page 494</i></p>	Channel operation is stopped.
Start operation	Set TAUAnTS.TAUAnTAUAnTSm to 1. TAUAnTS.TAUAnTAUAnTSm is a trigger bit, so it is automatically cleared to 0.	TAUAnTE.TAUAnTEm is set to 1 and the counter starts. TAUAnCNTm loads the TAUAnCDRm value. When TAUAnCMORm.TAUAnMD0 = 1, INTTAUAnIm is generated and TAUAnTTOUTm toggles.
During operation	<p>The values of the TAUAnCMURm.TAUAnTAUAnTIS[1:0] bits and the TAUAnCDRm register can be changed at any time. The TAUAnCNTm register can be read at all times.</p> <p>Detection of TAUAnTTINm edge</p>	<p>TAUAnCNTm counts down. When the counter reaches 0000_H:</p> <ul style="list-style-type: none"> TAUAnCNTm reloads the TAUAnCDRm value, and then continues count operation. INTTAUAnIm is generated and TAUAnTTOUTm toggles. <p>When a TAUAnTTINm input valid edge is detected during count operation, the TAUAnCDRm value and continues count operation continues. Afterwards, this procedure is repeated.</p>
Stop operation	Set TAUAnTT.TAUAnTTm to 1. TAUAnTT.TAUAnTTm is a trigger bit, so it is automatically cleared to 0.	TAUAnTE.TAUAnTEm is cleared to 0 and the counter stops. TAUAnCNTm and TAUAnTTOUTm stop and retain their current values.

Restart

(6) Specific timing diagrams

The timing diagrams in 12.15.1 “Interval Timer Function” on page 484 also apply, except for this function the counter can also be restarted by a valid TAUAnTTINm input edge.

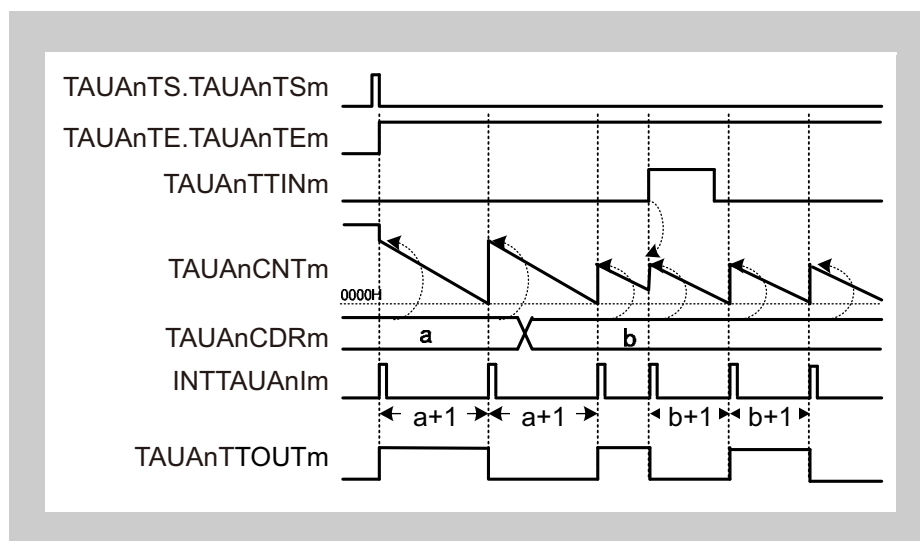

Figure 12-36 Counter triggered by rising TAUAnTTINm input edge
(TAUAnCMURm.TAUAnTIS[1:0] = 01_B), TAUAnCMORm.TAUAnMD0 = 1

- If a valid TAUAnTTINm input edge is detected, an interrupt is generated which causes TAUAnTTOUTm to toggle. In this example, the valid edge is a rising edge (TAUAnCMURm.TAUAnTIS[1:0] = 01_B).

12.15.3 Delay Count Function

(1) Overview

Summary This function generates interrupts (INTTAUAnIm), which have a defined delay to the TAUAnTTINm input signal. TAUAnTTINm input signal pulses that occur within the delay period are ignored.

- Prerequisites**
- The operation mode must be set to One Count Mode. Refer to *Table 12-21 “TAUAnCMORm settings for Delay Count Function” on page 499*.
 - TAUAnTTOUTm is not used for this function.
 - The start trigger must be disabled during counting (TAUAnCMORn.TAUAnMD0 = 0).

Description The counter is enabled by setting the channel trigger bit (TAUAnTS.TAUAnTSm) to 1. This in turn sets TAUAnTE.TAUAnTEm = 1, enabling count operation.

The counter starts when a valid TAUAnTTINm input start edge is detected. The value of TAUAnCDRm is loaded to TAUAnCNTm and the counter starts to count down from the TAUAnCDRm value.

When the counter reaches 0000_H an interrupt is generated. The counter returns to FFFF_H and awaits the next valid TAUAnTTINm input edge.

When the counter is counting down, further TAUAnTTINm input signals are ignored, i.e., the counter does not reset.

The value of TAUAnCDRm can be rewritten at any time, and the changed value of TAUAnCDRm is applied the next time the counter starts to count down.

Conditions The type of edge used as the trigger is specified by the TAUAnCMURm.TAUAnTIS[1:0] bits:

- If TAUAnCMURm.TAUAnTIS[1:0] = 00_B, falling edges trigger the counter.
- If TAUAnCMURm.TAUAnTIS[1:0] = 01_B, rising edges trigger the counter.
- If TAUAnCMURm.TAUAnTIS[1:0] = 10_B, rising and falling edges trigger the counter.

(2) Equations

Delay between TAUAnTTINm and INTTAUAnIm =
count clock cycle × (TAUAnCDRm + 1)

(3) Block diagram and general timing diagram

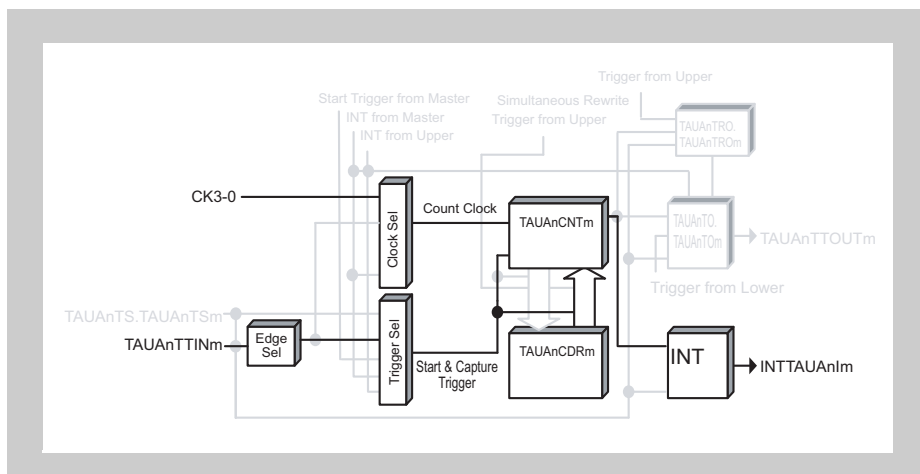

Figure 12-37 Block diagram for Delay Count Function

The following settings apply to the general timing diagram:

- Falling edge detection ($TAUAnCMURm.TAUAnTIS[1:0] = 00_B$)

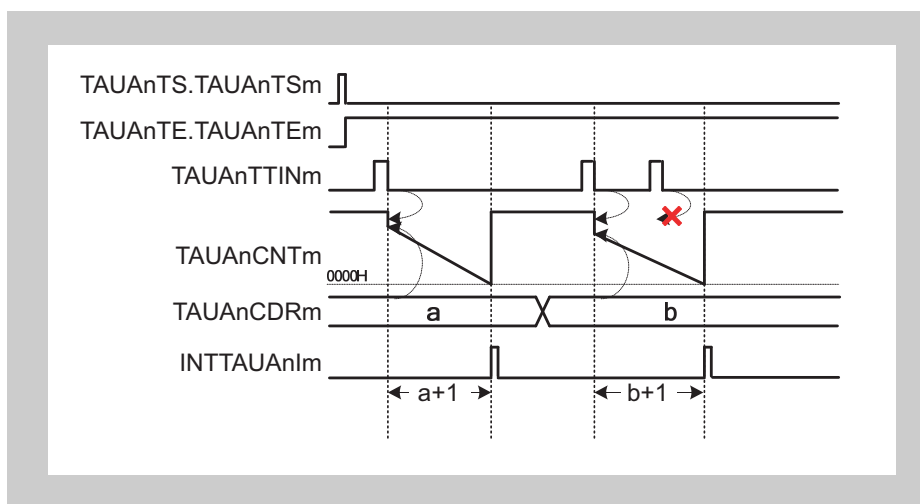

Figure 12-38 General timing diagram for Delay Count Function

(4) Register settings**(a) TAUAnCMORm**

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
TAUAn CKS[1:0]		TAUAn CCS[1:0]		TAUAn MAS	TAUAnSTS[2:0]			TAUAn COS[1:0]		-	TAUAn MD[4:1]				TAUAn MDO

Table 12-21 TAUAnCMORm settings for Delay Count Function

Bit name	Setting
TAUAnCKS[1:0]	00: Operation clock = CK0 01: Operation clock = CK1 10: Operation clock = CK2 11: Operation clock = CK3
TAUAnCCS[1:0]	00: Operation clock is used as the count clock
TAUAnMAS	0: Not used, so set to 0
TAUAnSTS[2:0]	001: Valid TAUAnTTINm input edge signal is used as the external start trigger
TAUAnCOS[1:0]	00: Not used, so set to 00
TAUAnMD[4:1]	0100: One Count Mode
TAUAnMDO	0: Disables the start trigger during operation

(b) TAUAnCMURm

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
														-	TAUAnTIS[1:0]

Table 12-22 TAUAnCMURm settings for Delay Count Function

Bit name	Setting
TAUAnTIS[1:0]	00: Falling edge detection 01: Rising edge detection 10: Rising and falling edge detection (low width measurement)

(c) Channel output mode

Because the channel output mode is not used by this function, clear TAUAnTOE.TAUAnTOEm. However, the channel output mode can be used in Independent Channel Output Mode Controlled by Software.

(d) Simultaneous rewrite

The simultaneous rewrite registers (TAUAnRDE, TAUAnRDS, TAUAnRDM, and TAUAnRDC) cannot be used with the Delay Count Function. Therefore, these registers must be set to 0.

Table 12-23 Simultaneous rewrite settings for Delay Count Function

Bit name	Setting
TAUAnRDEm	0: Disables simultaneous rewrite
TAUAnRDSm	0: When simultaneous rewrite is disabled (TAUAnRDE.TAUAnRDEm = 0), set these bits to 0
TAUAnRDMm	
TAUAnRDCm	

(5) Operating procedure for Delay Count Function**Table 12-24 Operating procedure for Delay Count Function**

	Operation	Status of TAUAn
Initial channel setting	Set the TAUAnCMORm register and TAUAnCMURm registers as described in <i>Table 12-21 "TAUAnCMORm settings for Delay Count Function" on page 499</i> and <i>Table 12-22 "TAUAnCMURm settings for Delay Count Function" on page 499</i> Set the value of the TAUAnCDRm register	Channel operation is stopped.
Start operation	Set TAUAnTS.TAUAnTSM to 1. TAUAnTS.TAUAnTSM is a trigger bit, so it is automatically cleared to 0. Detection of TAUAnTTINm start edge	TAUAnTE.TAUAnTEM is set to 1 and TAUAnCNTm waits for detection of the TAUAnTTINm start edge. When a start edge is detected, TAUAnCNTm loads the TAUAnCDRm value.
During operation	The values set in the TAUAnCDRm register can be changed at any time. The TAUAnCNTm register can be read at all times.	TAUAnCNTm counts down. When the counter reaches 0000 _H : INTTAUAnIm is generated. TAUAnCNTm stops counting, returns to FFFF _H , and waits for a trigger. If a trigger occurs while TAUAnCNTm is counting, the trigger is ignored. Afterwards, this procedure is repeated.
Stop operation	Set TAUAnTT.TAUAnTTM to 1. TAUAnTT.TAUAnTTM is a trigger bit, so it is automatically cleared to 0.	TAUAnTE.TAUAnTEM is cleared to 0 and the counter stops. TAUAnCNTm stops and retains its value.

Restart

12.15.4 One-Pulse Output Function

(1) Overview

- Summary** This function generates an interrupt (INTTAUAnIm) when a valid TAUAnTTINm input edge is detected and also a specific interval later. TAUAnTTINm input signal pulses that occur within the defined interval are ignored. When an interrupt is generated, the TAUAnTTOUTm signal toggles, resulting in a square wave.
- Prerequisites**
- The operation mode must be set to Pulse One Count Mode. Refer to *Table 12-25 “TAUAnCMORm settings for One-Pulse Output Function” on page 503*
 - The channel output mode must be set to Independent Channel Output Mode 1. Refer to *12.8 “Channel Output Modes” on page 463*.
 - Trigger detection must be disabled during counting (TAUAnCMORn.TAUAnMD0 = 0).
- Description** The counter is enabled by setting the channel trigger bit (TAUAnTS.TAUAnTSM) to 1. This in turn sets TAUAnTE.TAUAnTEM = 1, enabling count operation.
- The counter starts when a valid TAUAnTTINm input edge is detected. The value of TAUAnCDRm is loaded to TAUAnCNTm and the counter starts to count down from the TAUAnCDRm value. An interrupt is generated and TAUAnTTOUTm becomes active.
- When the counter reaches 0001_H an interrupt is generated and TAUAnTTOUTm becomes inactive. The counter stops at 0000_H and awaits the next valid TAUAnTTINm input edge.
- When the counter is counting down, further TAUAnTTINm input signals are ignored, i.e. the counter does not reset.
- The value of TAUAnCDRm can be rewritten at any time, and the changed value of TAUAnCDRm is applied the next time the counter starts to count down.
- Conditions** The type of edge used as the trigger is specified by the TAUAnCMURm.TAUAnTIS[1:0] bits:
- If TAUAnCMURm.TAUAnTIS[1:0] = 00_B, falling edges trigger the counter.
 - If TAUAnCMURm.TAUAnTIS[1:0] = 01_B, rising edges trigger the counter.
 - If TAUAnCMURm.TAUAnTIS[1:0] = 10_B, rising and falling edges trigger the counter.

(2) Equations

Interval between TAUAnTTINm and INTTAUAnIm = TAUAnTTOUTm (timer output) width = count clock cycle × TAUAnCDRm

TAUAnTRCm	
TAUAnTMEEm	0: Disables modulation

Note The channel output mode can also be set to Channel Output Mode Controlled by Software by setting TAUAnTOE.TAUAnTOEm = 0. TAUAnTTOOUTm can then be controlled independently of the interrupts. For details refer to *Table 12-9 “Channel output modes” on page 464*.

(d) Simultaneous rewrite

The simultaneous rewrite registers (TAUAnRDE, TAUAnRDS, TAUAnRDM, and TAUAnRDC) cannot be used with the One-Pulse Output Function. Therefore, these registers must be set to 0.

Table 12-28 Simultaneous rewrite settings for One-Pulse Output Function

(5) Operating procedure for One-Pulse Output Function

Table 12-29 Operating procedure for One-Pulse Output Function

	Operation	Status of TAUAn
Restart ↑	Initial channel setting Set the TAUAnCMORm register and TAUAnCMURm registers as described in Table 12-25 "TAUAnCMORm settings for One-Pulse Output Function" on page 503 and Table 12-26 "TAUAnCMURm settings for One-Pulse Output Function" on page 503 Set the value of the TAUAnCDRm register Set the channel output mode by setting the control bits as described in Table 12-27 "Control bit settings for Independent Channel Output Mode 1" on page 504	Channel operation is stopped.
	Start operation Set TAUAnTS.TAUAnTSm to 1. TAUAnTS.TAUAnTSm is a trigger bit, so it is automatically cleared to 0. Detection of TAUAnTTINm start edge	TAUAnTE.TAUAnTEm is set to 1 and TAUAnCNTm waits for detection of the TAUAnTTINm start edge. When a start edge is detected, TAUAnCNTm loads the TAUAnCDRm value.
	During operation The value of TAUAnCDRm can be changed at any time. The TAUAnCNTm register can be read at all times.	INTTAUAnIm is generated when TAUAnCNTm starts and TAUAnTTOUTm is set to its active level. TAUAnCNTm counts down. When the counter reaches 0001 _H : <ul style="list-style-type: none"> INTTAUAnIm is generated. TAUAnTTOUTm is set to its inactive level. TAUAnCNTm stops counting and waits for a trigger. If a trigger occurs while TAUAnCNTm is counting, the trigger is ignored. Afterwards, this procedure is repeated.
	Stop operation Set TAUAnTT.TAUAnTTm to 1. TAUAnTT.TAUAnTTm is a trigger bit, so it is automatically cleared to 0.	TAUAnTE.TAUAnTEm is cleared to 0 and the counter stops. TAUAnCNTm and TAUAnTTOUTm stop and retain their current values.

12.16 Independent Channel Signal Measurement Functions

This chapter describes functions that measure the widths of an individual TAUAnTTINm pulse or the total width of successive TAUAnTTINm pulses. It also describes functions that measure the interval of the signal or that compare the width of a pulse with a reference value.

- 12.16.1 *“TAUAnTTINm Input Pulse Interval Measurement Function”*
- 12.16.2 *“TAUAnTTINm Input Signal Width Measurement Function”*
- 12.16.3 *“Overflow Interrupt Output Function (During TAUAnTTINm Width Measurement)”*
- 12.16.4 *“TAUAnTTINm Input Period Count Detection Function”*
- 12.16.5 *“Overflow Interrupt Output Function (During TAUAnTTINm Input Period Count Detection)”*
- 12.16.6 *“TAUAnTTINm Input Pulse Interval Judgment Function”*
- 12.16.7 *“TAUAnTTINm Input Signal Width Judgment Function”*

12.16.1 TAUAnTTINm Input Pulse Interval Measurement Function

(1) Overview

Summary This function captures the count value and uses this value and the overflow bit TAUAnCSRm.TAUAnOVF to measure the interval of the TAUAnTTINm input signal.

- Prerequisites**
- The operation mode must be set to Capture Mode. Refer to *Table 12-31 “TAUAnCMORm settings for TAUAnTTINm Input Pulse Interval Measurement Function”* on page 509.
 - TAUAnTTOUTm is not used for this function.

Description The counter is started by setting the channel trigger bit (TAUAnTS.TAUAnTSm) to 1. This in turn sets TAUAnTE.TAUAnTEm = 1, enabling count operation. The counter TAUAnCNTm starts counting up from 0000_H. When a valid TAUAnTTINm edge is detected, the value of TAUAnCNTm is captured, transferred to TAUAnCDRm, and an interrupt INTTAUAnIm is generated. The counter resets to 0000_H and subsequently continues operation.

If the counter reaches FFFF_H before a valid TAUAnTTINm edge is detected, it overflows. The counter is reset to 0000_H and subsequently continues operation. The values transferred to TAUAnCDRm and TAUAnCSRm.TAUAnOVF respectively depend on the values of bits TAUAnCMORm.TAUAnCOS[1:0]:

Table 12-30 Effects of an overflow

TAUAnCMORm. TAUAnCOS[1:0]	When overflow occurs		When a valid TAUAnTTINm input is then detected	
	TAUAnCDRm	TAUAnCSRm. TAUAnOVF	TAUAnCDRm and TAUAnCNTm	TAUAnCSRm. TAUAnOVF
00	Unchanged	0	TAUAnCNTm loaded to TAUAnCDRm	1
01		1		
10	Set to FFFF _H	0	TAUAnCNTm set to 0, TAUAnCDRm unchanged	0
11		1		

When TAUAnCMORm.TAUAnCOS[0] is 1, the overflow bit TAUAnCSRm.TAUAnOVF can only be cleared by setting TAUAnCScm.TAUAnCLOV to 1.

The combination of the value of TAUAnCDRm and TAUAnCSRm.TAUAnOVF can be used to deduce the interval of the TAUAnTTINm signal. However, if an overflow occurs multiple times before a valid TAUAnTTINm input is detected, the overflow bit TAUAnCSRm.TAUAnOVF cannot indicate this.

The function can be stopped by setting TAUAnTT.TAUAnTTm = 1, which in turn sets TAUAnTE.TAUAnTEm = 0. TAUAnCNTm stops but retains its value. While the function is stopped, TAUAnTTINm input valid edge detection and TAUAnCNTm capture are not performed.

The function can be restarted by setting TAUAnTS.TAUAnTSm = 1. The counter is reset to 0000_H and subsequently continues operation. The counter can also be forcibly restarted (without stopping it first) by setting TAUAnTS.TAUAnTSm = 1 during operation.

Conditions If the TAUAnCMORm.TAUAnMD0 bit is set to 0, the first interrupt after a start or restart is not generated. For details refer to *12.10 “TAUAnTTOUTm Output and INTTAUAnIm Generation when Counter Starts or Restarts”* on page 475.

Note When $\text{TAUAnCMORm.TAUAnCOS}[1] = 1$, the value of TAUAnCNTm is *not* loaded to TAUAnCDRm when the first valid TAUAnTTINm input edge occurs after an overflow. However, an interrupt is generated.

(2) Equations

TAUAnTTINm input pulse interval = count clock cycle x
 $[(\text{TAUAnCSRm.TAUAnOVF} \times (\text{FFFF}_H + 1)) + \text{TAUAnCDRm capture value} + 1]$

(3) Block diagram and general timing diagram

Figure 12-41 Block diagram for TAUAnTTINm Input Pulse Interval Measurement Function

The following settings apply to the general timing diagram:

- INTTAUAnIm not generated at operation start ($\text{TAUAnCMORm.TAUAnMD0} = 0$)
- Falling edge detection ($\text{TAUAnCMURm.TAUAnTIS}[1:0] = 00_B$)
- When a valid TAUAnTTINm input is detected after an overflow TAUAnCDRm is changed and $\text{TAUAnCSRm.TAUAnOVF}$ is set to 1 ($\text{TAUAnCMORm.TAUAnCOS}[1:0] = 00_B$)

Figure 12-42 General timing diagram for TAUAnTTINm Input Pulse Interval Measurement Function

(4) Register settings**(a) TAUAnCMORM**

Table 12-31 TAUAnCMORM settings for TAUAnTTINm Input Pulse Interval Measurement Function

Bit name	Setting
TAUAnCKS[1:0]	00: Operation clock = CK0 01: Operation clock = CK1 10: Operation clock = CK2 11: Operation clock = CK3
TAUAnCCS[1:0]	00: Operation clock is used as the count clock
TAUAnMAS	0: Not used, so set to 0
TAUAnSTS[2:0]	001: Valid edge of the TAUAnTTINm input signal is the external capture trigger
TAUAnCOS[1:0]	See Table 12-30 "Effects of an overflow" on page 507 .
TAUAnMD[4:1]	0010: Capture Mode
TAUAnMDO	0: INTTAUAnIm not generated at operation start 1: Generates INTTAUAnIm at operation start

(b) TAUAnCMURm

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
-														TAUAnTIS[1:0]	

Table 12-32 TAUAnCMURm settings for TAUAnTTINm Input Pulse Interval Measurement Function

Bit name	Setting
TAUAnTIS[1:0]	00: Falling edge detection 01: Rising edge detection 10: Rising and falling edge detection

(c) Channel output mode

Because the channel output mode is not used by this function, clear TAUAnTOE.TAUAnTOEm. However, the channel output mode can be used in Independent Channel Output Mode Controlled by Software.

(d) Simultaneous rewrite

The simultaneous rewrite registers (TAUAnRDE, TAUAnRDS, TAUAnRDM, and TAUAnRDC) cannot be used with the TAUAnTTINm Input Pulse Interval Measurement Function. Therefore, these registers must be set to 0.

Table 12-33 Simultaneous rewrite settings for TAUAnTTINm Input Pulse Interval Measurement Function

Bit name	Setting
TAUAnRDE.TAUAnRDEm	0: Disables simultaneous rewrite
TAUAnRDS.TAUAnRDSm	0: When simultaneous rewrite is disabled (TAUAnRDE.TAUAnRDEm = 0), set these bits to 0
TAUAnRDM.TAUAnRDMm	
TAUAnRDC.TAUAnRDCm	

(5) Operating procedure for TAUAnTTINm Input Pulse Interval Measurement Function

Table 12-34 Operating procedure for TAUAnTTINm Input Pulse Interval Measurement Function

	Operation	Status of TAUAn
Restart	Initial channel setting Set the value of the TAUAnCDRm register	Channel operation is stopped.
	Start operation Set TAUAnTS.TAUAnTSm to 1. TAUAnTS.TAUAnTSm is a trigger bit, so it is automatically cleared to 0.	TAUAnTE.TAUAnTEm is set to 1 and the counter starts. TAUAnCNTm is cleared to 0000 _H . INTTAUAnIm is generated when TAUAnCMORm.TAUAnMD0 is set to 1.
	During operation Detection of TAUAnTTINm edges. The TAUAnCMURm.TAUAnTIS[1:0] bits can be changed at any time. The TAUAnCDRm and TAUAnCSRm registers can be read at any time. Writing 1 to the TAUAnCSCm.TAUAnCLOV bit is possible. (The TAUAnCSRm.TAUAnOVF bit is cleared to 0.)	TAUAnCNTm starts to count up from 0000 _H . When a TAUAnTTINm valid edge is detected: <ul style="list-style-type: none"> TAUAnCNTm transfers (captures) its value to TAUAnCDRm, and returns to 0000_H. INTTAUAnIm is then generated. Afterwards, this procedure is repeated.
	Stop operation Set TAUAnTT.TAUAnTTm to 1. TAUAnTT.TAUAnTTm is a trigger bit, so it is automatically cleared to 0.	TAUAnTE.TAUAnTEm is cleared to 0 and the counter stops. TAUAnCNTm stops and both it and TAUAnCSRm.TAUAnOVF retain their current values.

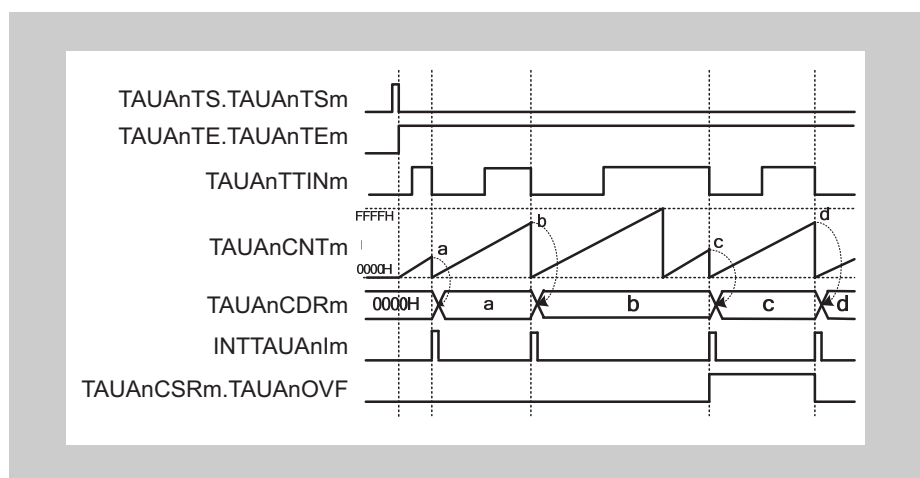

(6) Specific timing diagrams: overflow behavior**(a) TAUAnCMORm.TAUAnCOS[1:0] = 00_B**

Figure 12-43 TAUAnCMORm.TAUAnCOS[1:0] = 00_B, TAUAnCMORm.TAUAnMD0 = 0, TAUAnCMURm.TAUAnTIS[1:0] = 00_B

- When an overflow occurs, the value of TAUAnCDRm remains unchanged and TAUAnCSRm.TAUAnOVF remains = 0.
- Upon detection of the next valid TAUAnTTINm input edge, the value of TAUAnCNTm is loaded to TAUAnCDRm and TAUAnCSRm.TAUAnOVF is set to 1.
- Upon detecting the next valid TAUAnTTINm input edge while no overflow has occurred, TAUAnCSRm.TAUAnOVF is cleared to 0.

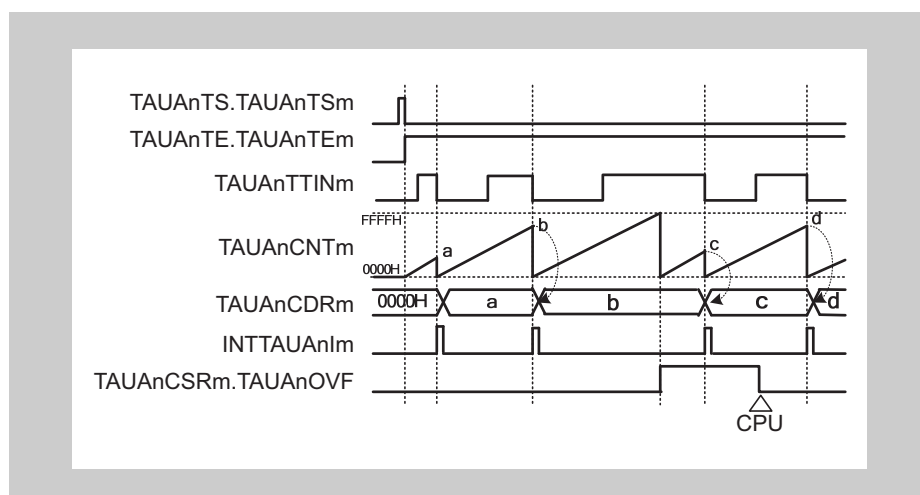

(b) TAUAnCMORm.TAUAnCOS[1:0] = 01_B

Figure 12-44 TAUAnCMORm.TAUAnCOS[1:0] = 01_B, TAUAnCMORm.TAUAnMD0 = 0, TAUAnCMURm.TAUAnTIS[1:0] = 00_B

- When an overflow occurs, the value of TAUAnCDRm remains unchanged and TAUAnCSRm.TAUAnOVF is set to 1.
- Upon detection of the next valid TAUAnTTINm input edge, the value of TAUAnCNTm is loaded to TAUAnCDRm.
- TAUAnCSRm.TAUAnOVF is only cleared by a CPU command (setting the TAUAnCScm.TAUAnCLOV bit to 1).

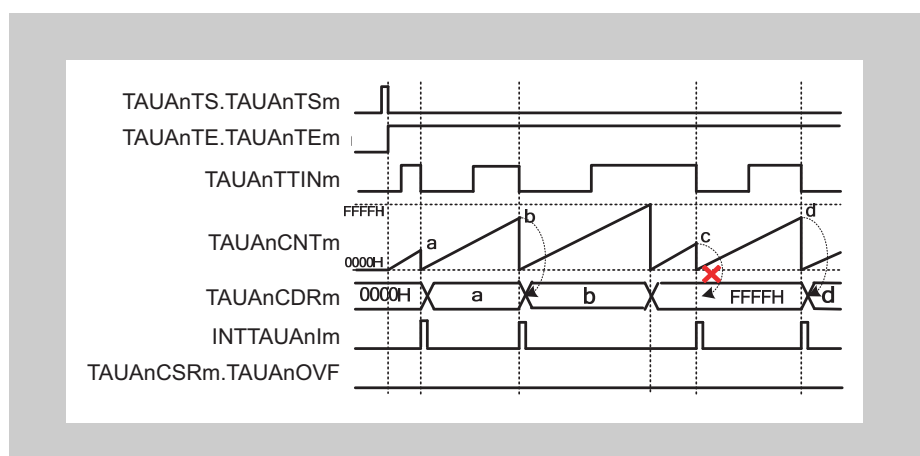

(c) $\text{TAUANCMORM.TAUANCOS}[1:0] = 10_B$ 

Figure 12-45 $\text{TAUANCMORM.TAUANCOS}[1:0] = 10_B$, $\text{TAUANCMORM.TAUANMD0} = 0$,
 $\text{TAUANCMURm.TAUANTIS}[1:0] = 00_B$

- When an overflow occurs, TAUANCDRm is set to FFFF_H and $\text{TAUANCSRm.TAUAnOVF}$ remains = 0.
- Upon detection of the next valid TAUANTTINm input edge, TAUANCNTm is reset to 0, but TAUANCDRm and $\text{TAUANCSRm.TAUAnOVF}$ remain unchanged.
- Thus, the next TAUANTTINm input valid edge after the overflow is ignored.

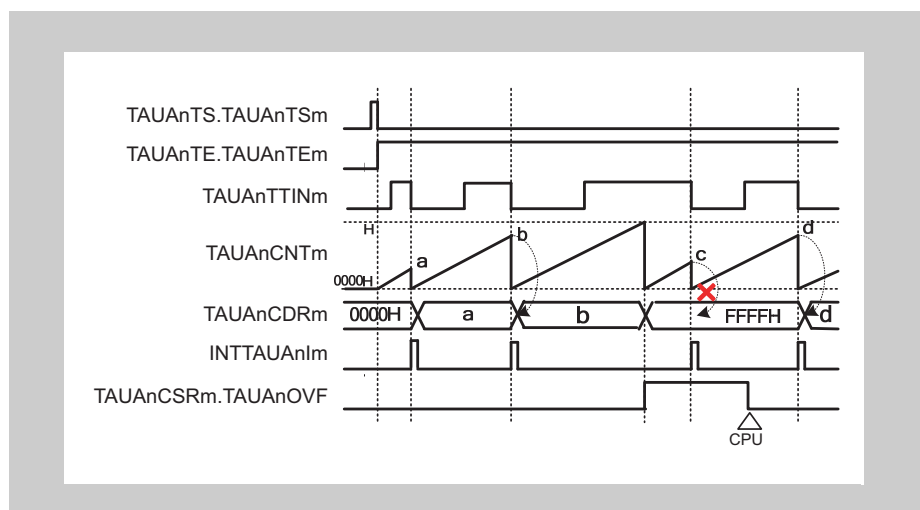

(d) $\text{TAUANCMORM.TAUANCOS}[1:0] = 11_B$ 

Figure 12-46 $\text{TAUANCMORM.TAUANCOS}[1:0] = 11_B$, $\text{TAUANCMORM.TAUANMD0} = 0$,
 $\text{TAUANCMURm.TAUANTIS}[1:0] = 00_B$

- When an overflow occurs, TAUANCDRm is set to FFFF_H , and $\text{TAUANCSRm.TAUAnOVF}$ is set to 1.
- Upon detection of the next valid TAUANTTINm input edge, TAUANCNTm is reset to 0, but TAUANCDRm and $\text{TAUANCSRm.TAUAnOVF}$ remain unchanged.
- Thus, the next TAUANTTINm input valid edge after the overflow is ignored.
- $\text{TAUANCSRm.TAUAnOVF}$ is cleared by setting $\text{TAUANCSm.TAUANCLOV} = 1$.

12.16.2 TAUAnTTINm Input Signal Width Measurement Function

(1) Overview

Summary This function measures the width of a TAUAnTTINm input signal.

- Prerequisites**
- The operation mode must be set to Capture & One Count Mode. Refer to Table 12-36 “TAUAnCMORm settings for TAUAnTTINm Input Signal Width Measurement Function” on page 515.
 - TAUAnTTOUTm is not used for this function.
 - TAUAnCMORm.TAUAnMD0 must be set to 0.

Description The counter is started by setting the channel trigger bit (TAUAnTS.TAUAnTSm) to 1. This in turn sets TAUAnTE.TAUAnTEm = 1, enabling count operation. When a valid TAUAnTTINm start edge is detected, the counter TAUAnCNTm starts counting up from 0000_H. When a valid TAUAnTTINm stop edge is detected, the value of TAUAnCNTm is captured, transferred to TAUAnCDRm, and an interrupt INTTAUAnIm is generated. The counter retains its value and awaits the next valid TAUAnTTINm input start edge.

If the counter reaches FFFF_H before a valid TAUAnTTINm stop edge is detected, it overflows. The counter is reset to 0000_H and subsequently continues operation. The values transferred to TAUAnCDRm and TAUAnCSRm.TAUAnOVF respectively depend on the values of bits TAUAnCMORm.TAUAnCOS[1:0].

Table 12-35 Effects of an overflow

TAUAnCMORm. COS[1:0]	When overflow occurs		When a valid TAUAnTTINm input stop edge is detected	
	TAUAnCDRm	TAUAnCSRm.TAUAnOVF	TAUAnCDRm and TAUAnCNTm	TAUAnCSRm.TAUAnOVF
00	Unchanged	0	TAUAnCNTm loaded to TAUAnCDRm	1
01		1		
10	Set to FFFF _H	0	TAUAnCNTm stops counting TAUAnCDRm unchanged	0
11		1		

When TAUAnCMORm.TAUAnCOS[0] is 1, the overflow bit TAUAnCSRm.TAUAnOVF can only be cleared by setting TAUAnCScm.TAUAnCLOV to 1.

The combination of the value of TAUAnCDRm and TAUAnCSRm.TAUAnOVF can be used to deduce the width of the TAUAnTTINm signal. However, if an overflow occurs multiple times before a valid TAUAnTTINm input is detected, the overflow bit TAUAnCSRm.TAUAnOVF cannot indicate this.

This function cannot be forcibly restarted.

Note When TAUAnCMORm.TAUAnCOS[2] = 1_B, the value of TAUAnCNTm is *not* loaded to TAUAnCDRm when the first valid TAUAnTTINm input edge occurs after an overflow. However, an interrupt is generated.

(2) Equations

TAUAnTTINm input signal width = count clock cycle x [(TAUAnCSRm.TAUAnOVF x (FFFF_H + 1)) + TAUAnCDRm capture value + 1]

(3) Block diagram and general timing diagram

Figure 12-47 Block diagram for TAUAnTTINm Input Signal Width Measurement Function

The following settings apply to the general timing diagram:

- Rising and falling edge detection = high width measurement (TAUAnCMURm.TAUAnTIS[1:0] = 11_B)
- When a valid TAUAnTTINm input is detected after an overflow TAUAnCDRm is changed and TAUAnCSRm.TAUAnOVF is set to 1 (TAUAnCMORM.TAUAnCOS[1:0] = 00_B)

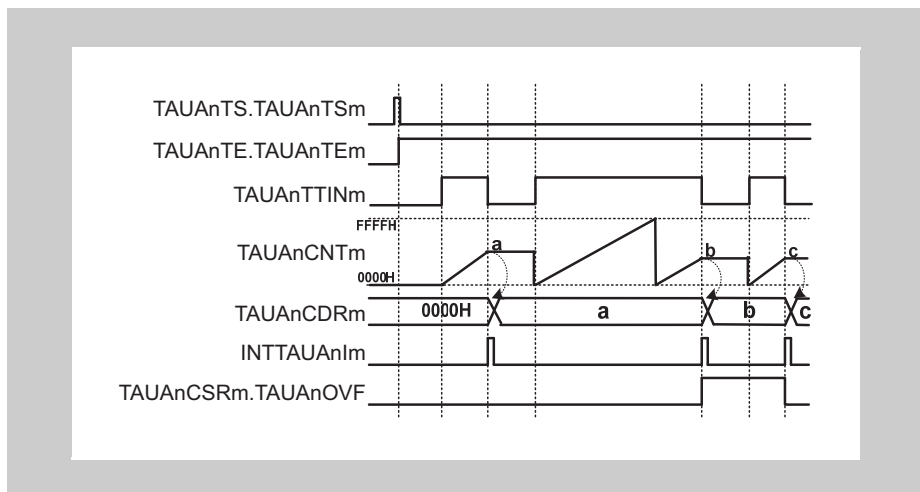

Figure 12-48 General timing diagram for TAUAnTTINm Input Signal Width Measurement Function

(4) Register settings**(a) TAUAnCMORm**

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

-														TAUAnTIS[1:0]	

Table 12-37 TAUAnCMURm settings for TAUAnTTINm Input Signal Width Measurement Function

Bit name	Setting
TAUAnTIS[1:0]	10: Rising and falling edge detection (low width measurement) 11: Rising and falling edge detection (high width measurement)

(c) Channel output mode

Because the channel output mode is not used by this function, clear TAUAnTOE.TAUAnTOEm. However, it can be used in Independent Channel Output Mode Controlled by Software.

(d) Simultaneous rewrite

The simultaneous rewrite registers (TAUAnRDE, TAUAnRDS, TAUAnRDM, and TAUAnRDC) cannot be used with the TAUAnTTINm Input Signal Width Measurement Function. Therefore, these registers must be set to 0.

Table 12-38 Simultaneous rewrite settings for TAUAnTTINm Input Signal Width Measurement Function

Bit name	Setting
TAUAnRDE.TAUAnRDEm	0: Disables simultaneous rewrite
TAUAnRDS.TAUAnRDSm	0: When simultaneous rewrite is disabled (TAUAnRDE.TAUAnRDEm = 0), set these bits to 0
TAUAnRDM.TAUAnRDMm	
TAUAnRDC.TAUAnRDCm	

(5) Operating procedure for TAUAnTTINm Input Signal Width Measurement Function

Table 12-39 Operating procedure for TAUAnTTINm Input Signal Width Measurement Function

	Operation	Status of TAUAn
Initial channel setting	Set the TAUAnCMORm register and TAUAnCMURm registers as described in <i>Table 12-36 "TAUAnCMORm settings for TAUAnTTINm Input Signal Width Measurement Function" on page 515</i> and <i>Table 12-37 "TAUAnCMURm settings for TAUAnTTINm Input Signal Width Measurement Function" on page 515</i> Set the value of the TAUAnCDRm register	Channel operation is stopped.
Start operation	Set TAUAnTS.TAUAnTSm to 1. TAUAnTS.TAUAnTSm is a trigger bit, so it is automatically cleared to 0.	TAUAnTE.TAUAnTEm is set to 1 and TAUAnCNTm waits for detection of the TAUAnTTINm start edge. When a TAUAnTTINm start is detected, TAUAnCNTm starts to count up.
During operation	Detection of TAUAnTTINm edges. The TAUAnCDRm, TAUAnCNTm, and TAUAnCSRm registers can be read at any time. The TAUAnCSC.CLOV bit can be set to 1.	TAUAnCNTm starts to count up from 0000 _H . When a TAUAnTTINm valid edge is detected: <ul style="list-style-type: none"> TAUAnCNTm transfers (captures) its value to TAUAnCDRm, and retains its value. INTTAUAnIm is then generated. Afterwards, this procedure is repeated.
Stop operation	Set TAUAnTT.TAUAnTTm to 1. TAUAnTT.TAUAnTTm is a trigger bit, so it is automatically cleared to 0.	TAUAnTE.TAUAnTEm is cleared to 0 and the counter stops. TAUAnCNTm stops and both it and TAUAnCSRm.TAUAnOVF retain their current values.

Restart

(6) Specific timing diagrams: overflow behavior**(a) TAUAnCMORm.TAUAnCOS[1:0] = 00_B**

Figure 12-49 TAUAnCMORm.TAUAnCOS[1:0] = 00_B, TAUAnCMORm.TAUAnMD0 = 0, TAUAnCMURm.TAUAnTIS[1:0] = 11_B

- When an overflow occurs, the value of TAUAnCDRm remains unchanged and TAUAnCSRm.TAUAnOVF remains = 0.
- Upon detection of the next valid TAUAnTTINm input edge, the value of TAUAnCNTm is loaded to TAUAnCDRm and TAUAnCSRm.TAUAnOVF is set to 1.
- Upon detecting the next valid TAUAnTTINm input edge while no overflow has occurred, TAUAnCSRm.TAUAnOVF is cleared to 0.

(b) TAUAnCMORm.TAUAnCOS[1:0] = 01_B

Figure 12-50 TAUAnCMORm.TAUAnCOS[1:0] = 01_B, TAUAnCMORm.TAUAnMD0 = 0, TAUAnCMURm.TAUAnTIS[1:0] = 11_B

- When an overflow occurs, the value of TAUAnCDRm remains unchanged and TAUAnCSRm.TAUAnOVF is set to 1.
- Upon detection of the next valid TAUAnTTINm input edge, the value of TAUAnCNTm is loaded to TAUAnCDRm.
- TAUAnCSRm.TAUAnOVF is only cleared by a CPU command (setting TAUAnCSCm.TAUAnCLOV = 1).

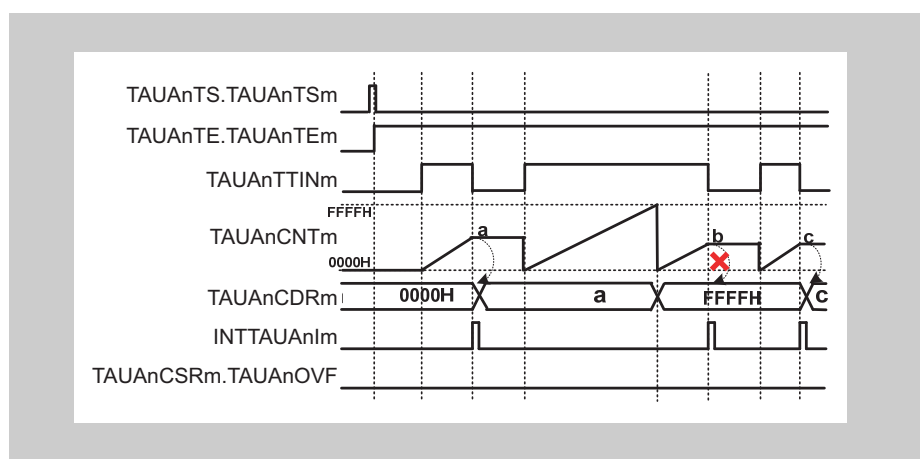

(c) $\text{TAUANCMORM.TAUANCOS}[1:0] = 10_B$ 

Figure 12-51 $\text{TAUANCMORM.TAUANCOS}[1:0] = 10_B$, $\text{TAUANCMORM.TAUANMD0} = 0$, $\text{TAUANCMURM.TAUANTIS}[1:0] = 11_B$

- When an overflow occurs, TAUANCDRm is set to FFFF_H and $\text{TAUANCSRm.TAUAnOVF}$ remains = 0.
- Upon detection of the next valid TAUAAnTTINm input edge, TAUANCNTm is reset to 0, but TAUANCDRm and $\text{TAUANCSRm.TAUAnOVF}$ remain unchanged.
- Thus, the next TAUAAnTTINm input valid edge after the overflow is ignored.

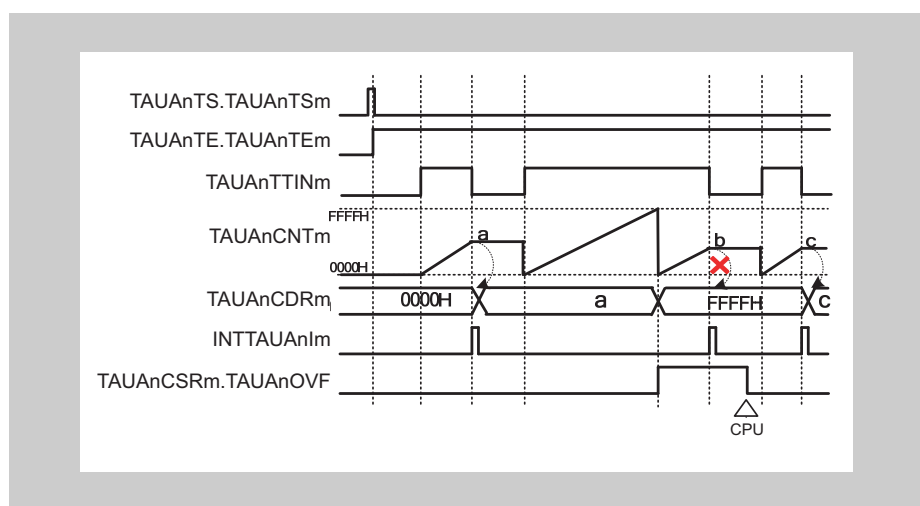

(d) $\text{TAUANCMORM.TAUANCOS}[1:0] = 11_B$ 

Figure 12-52 $\text{TAUANCMORM.TAUANCOS}[1:0] = 11_B$, $\text{TAUANCMORM.TAUANMD0} = 0$, $\text{TAUANCMURM.TAUANTIS}[1:0] = 11_B$

- When an overflow occurs, TAUANCDRm is set to FFFF_H , and $\text{TAUANCSRm.TAUAnOVF}$ is set to 1.
- Upon detection of the next valid TAUAAnTTINm input edge, TAUANCNTm is reset to 0, but TAUANCDRm and $\text{TAUANCSRm.TAUAnOVF}$ remain unchanged.
- Thus, the next TAUAAnTTINm input valid edge after the overflow is ignored.
- $\text{TAUANCSRm.TAUAnOVF}$ is cleared by setting $\text{TAUANCSM.TAUANCLOW} = 1$.

12.16.3 Overflow Interrupt Output Function (During TAUAnTTINm Width Measurement)

(1) Overview

- Summary** This function measures the width of an individual TAUAnTTINm input signal. An interrupt is generated if (FFFFH + 1) is exceeded following TAUAnTTINm input.
- Prerequisites**
- The operation mode must be set to One Count Mode. Refer to *Table 12-40 “TAUAnCMORm settings for Overflow Interrupt Output Function (During TAUAnTTINm Width Measurement)”* on page 521 .
 - TAUAnTTOUTm is not used for this function.
 - The value of TAUAnCDRm must be set to FFFF_H.
- Description** The counter is enabled by setting the channel trigger bit (TAUAnTS.TAUAnTSM) to 1. This in turn sets TAUAnTE.TAUAnTEM = 1, enabling count operation.
- The counter starts when a valid TAUAnTTINm input start edge is detected. FFFF_H is loaded to TAUAnCNTm and the counter starts to count down.
- When a valid stop edge is detected, the counter stops and retains the current value.
- When the next TAUAnTTINm input start edge is detected, TAUAnCNTm loads FFFF_H and starts to count down.
- If the counter reaches 0000_H before a stop edge is detected, an interrupt is generated.
- Conditions** The valid start and stop edges are specified by the TAUAnCMURm.TAUAnTIS[1:0] bits:
- If TAUAnCMURm.TAUAnTIS[1:0] = 10_B, the TAUAnTTINm input low width is measured. The start trigger is a falling edge and the stop trigger is a rising edge.
 - If TAUAnCMURm.TAUAnTIS[1:0] = 11_B, the TAUAnTTINm input high width is measured. The start trigger is a rising edge and the stop trigger is a falling edge.
- Note** The counter cannot be restarted during operation.

(2) Block diagram and general timing diagram

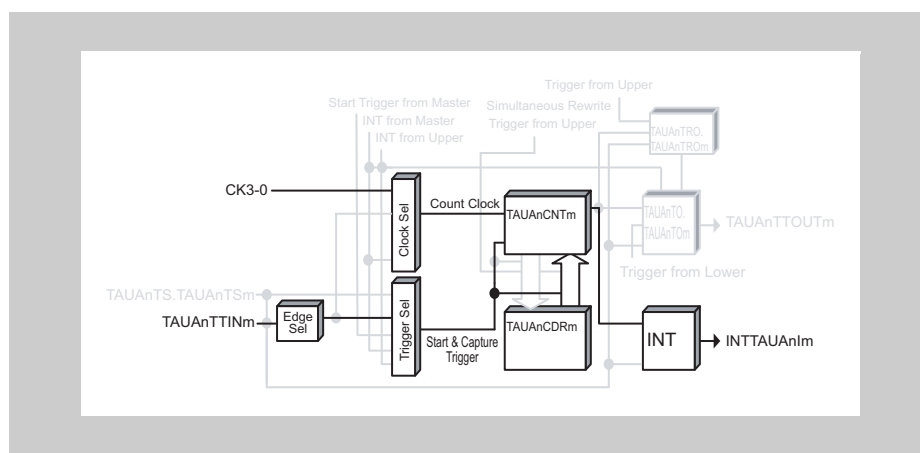

Figure 12-53 Block diagram for Overflow Interrupt Output Function (During TAUAnTTINm Width Measurement)

The following settings apply to the general timing diagram:

- Rising and falling edge detection = high width measurement (TAUAnCMURm.TAUAnTIS[1:0] = 11_B)

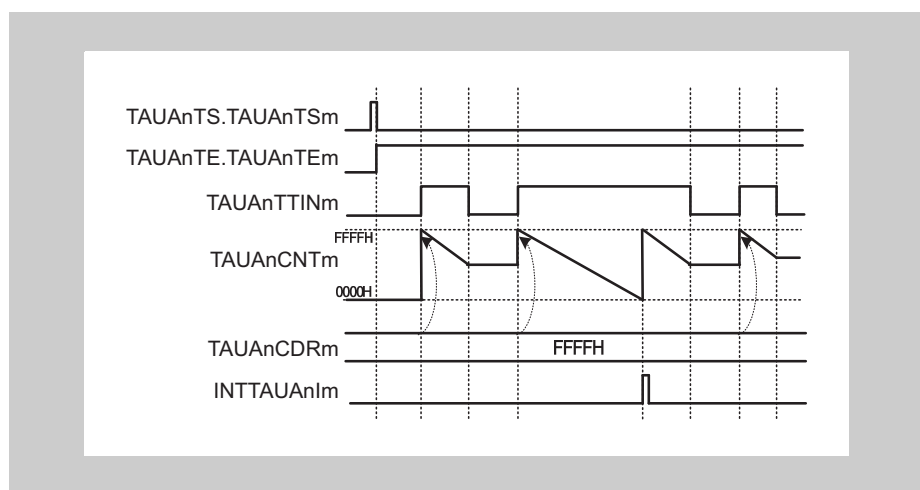

Figure 12-54 General timing diagram for Overflow Interrupt Output Function (During TAUAnTTINm Width Measurement)

(3) Register settings**(a) TAUAnCMORm**

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
TAUAn CKS[1:0]		TAUAn CCS[1:0]		TAUAn MAS	TAUAnSTS[2:0]			TAUAn COS[1:0]		-	TAUAnMD[4:1]				TAUAn MDO

(c) Channel output mode

Because channel output mode is not used by this function, TAUAnTOE.TAUAnTOEm is cleared. However, it can be used in Independent Channel Output Mode Controlled by Software.

(d) Simultaneous rewrite

The simultaneous rewrite registers (TAUAnRDE, TAUAnRDS, TAUAnRDM, and TAUAnRDC) cannot be used with the Overflow Interrupt Output Function (During TAUAnTTINm Width Measurement). Therefore, these registers must be set to 0.

Table 12-42 Simultaneous rewrite settings for Overflow Interrupt Output Function (During TAUAnTTINm Width Measurement)

Bit name	Setting
TAUAnRDEm	0: Disables simultaneous rewrite
TAUAnRDSm	0: When simultaneous rewrite is disabled (TAUAnRDE.TAUAnRDEm = 0), set these bits to 0
TAUAnRDMm	
TAUAnRDCm	

(4) Operating procedure for Overflow Interrupt Output Function (During TAUAnTTINm Width Measurement)

Table 12-43 Operating procedure for Overflow Interrupt Output Function (During TAUAnTTINm Width Measurement)

	Operation	Status of TAUAn
Restart ↓	Initial channel setting Set the TAUAnCMORm register and TAUAnCMURm registers as described in <i>Table 12-40 "TAUAnCMORm settings for Overflow Interrupt Output Function (During TAUAnTTINm Width Measurement)" on page 521</i> and <i>Table 12-41 "TAUAnCMURm settings Overflow Interrupt Output Function (During TAUAnTTINm Width Measurement)" on page 521</i> Set the value of the TAUAnCDRm register	Channel operation is stopped.
	Start operation Set TAUAnTS.TAUAnTSm to 1. TAUAnTS.TAUAnTSm is a trigger bit, so it is automatically cleared to 0. Detection of TAUAnTTINm start edge	TAUAnTE.TAUAnTEm is set to 1 and TAUAnCNTm waits for detection of the start edge. When a start edge is detected, TAUAnCNTm loads the TAUAnCDRm value (FFFF _H).
	During operation The TAUAnCNTm register can be read at any time. Detection of TAUAnTTINm edges.	TAUAnCNTm counts down. When the counter reaches 0000 _H : • INTTAUAnIm is generated. When a reverse edge of TAUAnTTINm is detected during count operation: • TAUAnCNTm stops counting and waits for a trigger. Afterwards, this procedure is repeated.
	Stop operation Set TAUAnTT.TAUAnTTm to 1. TAUAnTT.TAUAnTTm is a trigger bit, so it is automatically cleared to 0.	TAUAnTE.TAUAnTEm is cleared to 0 and the counter stops. TAUAnCNTm stops and retains its current value.

12.16.4 TAUAnTTINm Input Period Count Detection Function

(1) Overview

Summary This function measures the cumulative width of a TAUAnTTINm input signal.

- Prerequisites**
- The operation mode must be set to Capture & Gate Count Mode. Refer to *Table 12-44 “TAUAnCMORm settings for TAUAnTTINm Input Period Count Detection Function” on page 525*.
 - TAUAnTTOUTm is not used for this function.

Description The counter is enabled by setting the channel trigger bit (TAUAnTS.TAUAnTSm) to 1. This in turn sets TAUAnTE.TAUAnTEm = 1, enabling count operation. The counter awaits a valid TAUAnTTINm input edge.

When a valid TAUAnTTINm input start edge is detected, the counter starts to count from 0000_H.

When a valid TAUAnTTINm input stop edge is detected, the current TAUAnCNTm value is loaded to TAUAnCDRm and an interrupt (INTTAUAnIm) is generated. The counter stops and retains its value until the next valid TAUAnTTINm input start edge is detected.

When the next valid TAUAnTTINm input start edge is detected, the counter resumes counting, starting with its value upon stopping.

If the counter reaches FFFF_H the bit TAUAnCSRm.TAUAnOVF is set to 1 and the counter restarts from 0000_H. The value of TAUAnCSRm.TAUAnOVF is reset by the CPU by setting TAUAnCSCm.TAUAnCLOV = 1.

Note The input TAUAnTTINm is sampled at the frequency of the operation clock, specified by the TAUAnCMORm.TAUAnCKs[1:0] bits.

Conditions The valid start and stop edges are specified by the TAUAnCMURm.TAUAnTIS[1:0] bits:

- If TAUAnCMURm.TAUAnTIS[1:0] = 10_B, the TAUAnTTINm input low period is counted. The start trigger is a falling edge and the stop trigger is a rising edge.
- If TAUAnCMURm.TAUAnTIS[1:0] = 11_B, the TAUAnTTINm input high period is counted. The start trigger is a rising edge and the stop trigger is a falling edge.

(2) Equations

Cumulative TAUAnTTINm input width =
count clock cycle × ((FFFF_H × TAUAnCSRm.TAUAnOVF) + (TAUAnCDRm capture value + 1))

<R>

Caution If a capture signal in input when the counter value reaches the upper limit (0FFFF_H), the overflow flag (OVF) that should be set in response to the occurrence of an overflow in the next count clock cycle will not be set. The OVF flag is set normally at all other times.

(3) Block diagram and general timing diagram

Figure 12-55 Block diagram for TAUAnTTINm Input Period Count Detection Function

The following settings apply to the general timing diagram:

- Rising and falling edge detection = high width measurement (TAUAnCMURm.TAUAnTIS[1:0] = 11_B)

Figure 12-56 General timing diagram for TAUAnTTINm Input Period Count Detection Function

-														TAUAnTIS[1:0]	

Table 12-45 TAUAnCMURm settings for TAUAnTTINm Input Period Count Detection Function

Bit name	Setting
TAUAnTIS[1:0]	10: Rising and falling edge detection (Low width measurement) 11: Rising and falling edge detection (High width measurement)

(c) Channel output mode

Because the channel output mode is not used by this function, clear TAUAnTOE.TAUAnTOEm. However, it can be used in Independent Channel Output Mode Controlled by Software.

(d) Simultaneous rewrite

The simultaneous rewrite registers (TAUAnRDE, TAUAnRDS, TAUAnRDM, and TAUAnRDC) cannot be used with the TAUAnTTINm Input Period Count Detection Function. Therefore, these registers must be set to 0.

Table 12-46 Simultaneous rewrite settings for TAUAnTTINm Input Period Count Detection Function

Bit name	Setting
TAUAnRDEm	0: Disables simultaneous rewrite
TAUAnRDSm	0: When simultaneous rewrite is disabled (TAUAnRDE.TAUAnRDEm = 0), set these bits to 0
TAUAnRDMm	
TAUAnRDCm	

(5) Operating procedure for TAUAnTTINm Input Period Count Detection Function

Table 12-47 Operating procedure for TAUAnTTINm Input Period Count Detection Function

	Operation	Status of TAUAn
Restart ↓	Initial channel setting Set the TAUAnCMORm register and TAUAnCMURm registers as described in Table 12-44 “TAUAnCMORm settings for TAUAnTTINm Input Period Count Detection Function” on page 525 and Table 12-45 “TAUAnCMURm settings for TAUAnTTINm Input Period Count Detection Function” on page 525 Set the value of the TAUAnCDRm register	Channel operation is stopped.
	Start operation Set TAUAnTS.TAUAnTSm to 1. TAUAnTS.TAUAnTSm is a trigger bit, so it is automatically cleared to 0. Detection of TAUAnTTINm start edge	TAUAnTE.TAUAnTEm is set to 1 and TAUAnCNTm waits for detection of the TAUAnTTINm start edge. When a start edge is detected, TAUAnCNTm is cleared to 0000 _H and TAUAnCNTm starts to count up.
	During operation Detection of TAUAnTTINm edges. The TAUAnCDRm, TAUAnCNTm, and TAUAnCSRm registers can be read at any time. The TAUAnCSCm.TAUAnCLOV bit can be set to 1.	When a TAUAnTTINm start edge (rising edge for high width measurement, falling edge for low width measurement) is detected, TAUAnCNTm starts to count up from the stop value. When TAUAnCNTm detects a stop edge (falling edge for high width measurement, rising edge for low width measurement), it transfers the value to TAUAnCDRm and INTTAUANIm is generated. Counting stops at the “value transferred to TAUAnCDRm + 1” value and TAUAnCNTm waits for detection of the TAUAnTTINm start edge. If the TAUAnCNTm reaches FFFF _H , the counter overflows and TAUAnCSRm.TAUAnOVF is set to 1. Afterwards, this procedure is repeated.
	Stop operation Set TAUAnTT.TAUAnTTm to 1. TAUAnTT.TAUAnTTm is a trigger bit, so it is automatically cleared to 0.	TAUAnTE.TAUAnTEm is cleared to 0 and the counter stops. TAUAnCNTm stops and it and TAUAnCSRm.TAUAnOVF retain their current values.

(6) Specific timing diagrams
 (a) Operation stop and restart

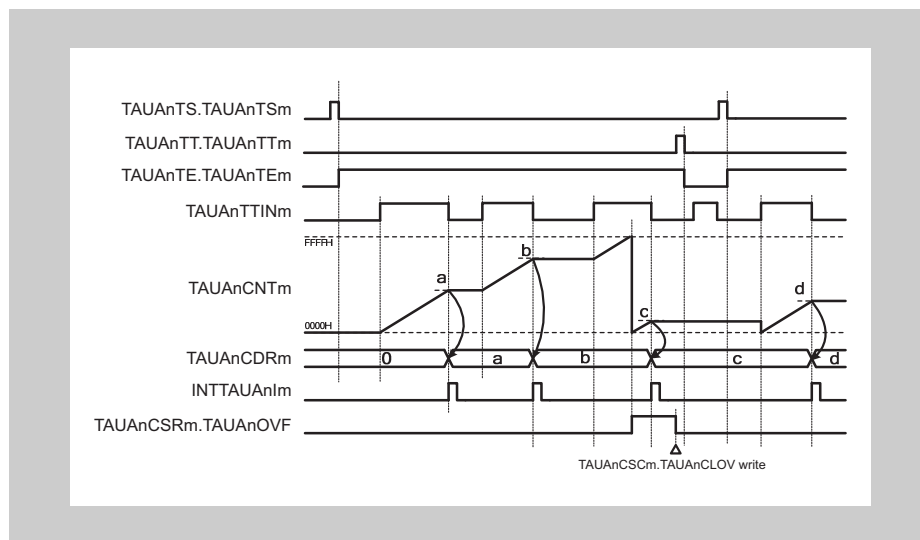

Figure 12-57 Operation stop and restart, $\text{TAUAnCMURm.TAUAnTIS}[1:0] = 11_{\text{B}}$

- The counter can be stopped by setting TAUAnTT.TAUAnTTm to 1, which in turn sets TAUAnTE.TAUAnTEm to 0.
- TAUAnCNTm stops and the current value is retained.
- If the counter is stopped, valid TAUAnTTINm input edges are ignored.
- The counter can be restarted by setting TAUAnTS.TAUAnTSM to 1. TAUAnCNTm restarts to count from 0000_{H} .

12.16.5 Overflow Interrupt Output Function (During TAUAnTTINm Input Period Count Detection)

(1) Overview

- Summary** This function measures the cumulative width of a TAUAnTTINm input signal. If the cumulative TAUAnTTINm input width is longer than $FFFF_H$, an interrupt can be generated to output an overflow interrupt.
- Prerequisites**
- The operation mode must be set to Gate Count Mode. Refer to *Table 12-48 “TAUAnCMORm settings for Overflow Interrupt Output Function (During TAUAnTTINm Input Period Count Detection)”* on page 530 .
 - TAUAnTTOUTm is not used for this function.
 - The value of TAUAnCDRm must be set to $FFFF_H$.
- Description** The counter is enabled by setting the channel trigger bit (TAUAnTS.TAUAnTSM) to 1. This in turn sets TAUAnTE.TAUAnTEM = 1, enabling count operation.
- The counter starts when a valid TAUAnTTINm input start edge is detected. $FFFF_H$ is loaded to TAUAnCNTm and the counter starts to count down.
- When a valid stop edge is detected, the counter stops and retains the current value. The counter awaits the next TAUAnTTINm input start edge and then continues to count down from the current value.
- When the counter reaches 0000_H an interrupt is generated. $FFFF_H$ is loaded to TAUAnCNTm and the counter continues to count down until a TAUAnTTINm input stop edge is detected.
- Conditions** The valid start and stop edges are specified by the TAUAnCMURm.TAUAnTIS[1:0] bits:
- If TAUAnCMURm.TAUAnTIS[1:0] = 10_B , the TAUAnTTINm input low period is counted. The start trigger is a falling edge and the stop trigger is a rising edge.
 - If TAUAnCMURm.TAUAnTIS[1:0] = 11_B , the TAUAnTTINm input high period is counted. The start trigger is a rising edge and the stop trigger is a falling edge.
- Note** The counter cannot be restarted during operation.

(2) Block diagram and general timing diagram

Figure 12-58 Block diagram for Overflow Interrupt Output Function (During TAUAnTTINm Input Period Count Detection)

The following settings apply to the general timing diagram:

- Rising and falling edge detection = high width measurement (TAUAnCMURm.TAUAnTIS[1:0] = 11_B)

Figure 12-59 General timing diagram for Overflow Interrupt Output Function (During TAUAnTTINm Input Period Count Detection)

(c) Channel output mode

Because the channel output mode is not used by this function, clear TAUAnTOE.TAUAnTOEm. However, it can be used in Independent Channel Output Mode Controlled by Software.

(d) Simultaneous rewrite

The simultaneous rewrite registers (TAUAnRDE, TAUAnRDS, TAUAnRDM, and TAUAnRDC) cannot be used with the Overflow Interrupt Output Function (During TAUAnTTINm Input Period Count Detection). Therefore, these registers must be set to 0.

Table 12-50 Simultaneous rewrite settings for Overflow Interrupt Output Function (During TAUAnTTINm Input Period Count Detection)

Bit name	Setting
TAUAnRDE.TAUAnRDEm	0: Disables simultaneous rewrite
TAUAnRDS.TAUAnRDSm	0: When simultaneous rewrite is disabled (TAUAnRDE.TAUAnRDEm = 0), set these bits to 0
TAUAnRDM.TAUAnRDMm	
TAUAnRDC.TAUAnRDCm	

(4) Operating procedure for Overflow Interrupt Output Function (during TAUAnTTINm input period count detection)

Table 12-51 Operating procedure for Overflow Interrupt Output Function (during TAUAnTTINm input period count detection)

	Operation	Status of TAUAn
Initial channel setting	Set the TAUAnCMORm register and TAUAnCMURm registers as described in Table 12-48 “TAUAnCMORm settings for Overflow Interrupt Output Function (During TAUAnTTINm Input Period Count Detection)” on page 530 and Table 12-49 “TAUAnCMURm settings for Overflow Interrupt Output Function (During TAUAnTTINm Input Period Count Detection)” on page 530 Set the value of the TAUAnCDRm register	Channel operation is stopped.
Start operation	Set TAUAnTS.TAUAnTSm to 1. TAUAnTS.TAUAnTSm is a trigger bit, so it is automatically cleared to 0. Detection of TAUAnTTINm start edge	TAUAnTE.TAUAnTEm is set to 1 and TAUAnCNTm waits for detection of the start edge. When a start edge is detected, TAUAnCNTm loads the TAUAnCDRm value (FFFF _H).
During operation	The TAUAnCNTm register can be read at all times.	TAUAnCNTm counts down. When the counter reaches 0000 _H : <ul style="list-style-type: none"> • INTTAUAnIm is generated. • TAUAnCNTm loads the TAUAnCDRm value (FFFF_H), and then continues counting down. When a reverse edge of TAUAnTTINm is detected during count operation: <ul style="list-style-type: none"> • TAUAnCNTm counts down from the stop value. Afterwards, this procedure is repeated.
Stop operation	Set TAUAnTT.TAUAnTTm to 1. TAUAnTT.TAUAnTTm is a trigger bit, so it is automatically cleared to 0.	TAUAnTE.TAUAnTEm is cleared to 0 and the counter stops. TAUAnCNTm stops and retains its current value.

12.16.6 TAUAnTTINm Input Pulse Interval Judgment Function

(1) Overview

Summary This function outputs the result of a comparison between the count value (TAUAnCNTm) and the value in the channel data register (TAUAnCDRm) when a TAUAnTTINm input pulse occurs. An interrupt signal INTTAUAnIm is generated if the result of the comparison is true.

- Prerequisites**
- The operation mode must be set to Judge Mode. Refer to *Table 12-52 “TAUAnCMORm settings for TAUAnTTINm Input Pulse Interval Judgment Function” on page 534*.
 - TAUAnTTOUTm is not used for this function.

Description The counter is started by setting the channel trigger bit (TAUAnTS.TAUAnTSm) to 1. This in turn sets TAUAnTE.TAUAnTEm = 1, enabling count operation. The current value of TAUAnCDRm is loaded to TAUAnCNTm and the counter starts to count down from this value.

When a TAUAnTTINm valid edge is detected or TAUAnTS.TAUAnTSm is set to 1, the function compares the current values of TAUAnCNTm and TAUAnCDRm. An interrupt signal INTTAUAnIm is generated if the result of the comparison is true. TAUAnCNTm reloads the value of TAUAnCDRm, and then subsequently continues operation, regardless of the result of the comparison.

If the counter reaches 0000_H before a TAUAnTTINm valid edge is detected, TAUAnCNTm overflows and is set to FFFF_H. It then continues to count down.

The value of TAUAnCDRm can be rewritten at any time, and the changed value of TAUAnCDRm is applied the next time the function starts to count down.

- Conditions** The TAUAnCMORm.TAUAnMD0 bit specifies the type of comparison:
- If TAUAnCMORm.TAUAnMD0 = 0, INTTAUAnIm is generated when TAUAnCNTm \leq TAUAnCDRm.
 - If TAUAnCMORm.TAUAnMD0 = 1, INTTAUAnIm is generated when TAUAnCNTm > TAUAnCDRm.

(2) Block diagram and general timing diagram

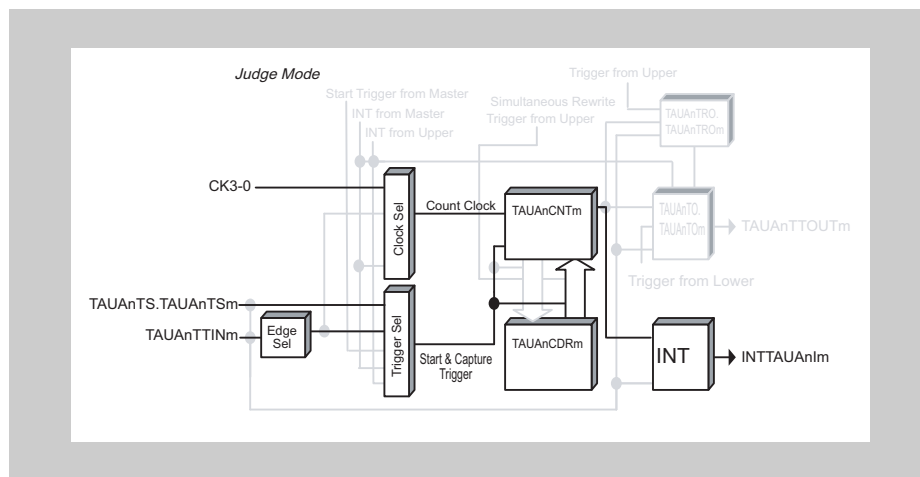

Figure 12-60 Block diagram for TAUAnTTINm Input Pulse Interval Judgment Function

The following settings apply to the general timing diagram:

- Falling edge detection (TAUAnCMURm.TAUAnTIS[1:0] = 00_B)

TAUAnRDE.TAUAnRDEm	0: Disables simultaneous rewrite
TAUAnRDS.TAUAnRDSm	0: When simultaneous rewrite is disabled (TAUAnRDE.TAUAnRDEm = 0), set these bits to 0
TAUAnRDM.TAUAnRDMm	
TAUAnRDC.TAUAnRDCm	

(4) Operating procedure for TAUAnTTINm Input Pulse Interval Judgment Function

Table 12-55 Operating procedure for TAUAnTTINm Input Pulse Interval Judgment Function

	Operation	Status of TAUAn
Initial channel setting	Set the TAUAnCMORm register and TAUAnCMURm registers as described in <i>Table 12-52 "TAUAnCMORm settings for TAUAnTTINm Input Pulse Interval Judgment Function" on page 534</i> and <i>Table 12-53 "TAUAnCMURm settings for TAUAnTTINm Input Pulse Interval Judgment Function" on page 534</i> Set the value of the TAUAnCDRm register	Channel operation is stopped.
Start operation	Set TAUAnTS.TAUAnTSm to 1. TAUAnTS.TAUAnTSm is a trigger bit, so it is automatically cleared to 0.	TAUAnTE.TAUAnTEm is set to 1 and the counter starts. TAUAnCNTm loads the TAUAnCDRm value.
During operation	Detection of TAUAnTTINm edges. The value of TAUAnCDRm can be changed at any time. The TAUAnCNTm register can be read at any time.	TAUAnCNTm counts down. When a TAUAnTTINm input edge is detected <ul style="list-style-type: none"> TAUAnCNTm reloads TAUAnCDRm, and then continues count operation. TAUAnCNTm compares the values and judges the condition according to the TAUAnCMORm.TAUAnMD0 setting. If the condition is satisfied, INTTAUAnIm is generated. Afterwards, this procedure is repeated.
Stop operation	Set TAUAnTT.TAUAnTTm to 1. TAUAnTT.TAUAnTTm is a trigger bit, so it is automatically cleared to 0.	TAUAnTE.TAUAnTEm is cleared to 0 and the counter stops. TAUAnCNTm stops and retains its current value.

Restart

12.16.7 TAUAnTTINm Input Signal Width Judgment Function

(1) Overview

Summary This function outputs the result of a comparison between the count value (TAUAnCNTm) and the value in the channel data register (TAUAnCDRm) at a valid stop edge of a TAUAnTTINm input signal. An interrupt signal INTTAUAnIm is generated if the result of the comparison is true.

- Prerequisites**
- The operation mode must be set to Judge & One Count Mode. Refer to Table 12-56 “TAUAnCMORm settings for TAUAnTTINm Input Signal Width Judgment Function” on page 538.
 - TAUAnTTOUTm is not used for this function.

Description The counter is started by setting the channel trigger bit (TAUAnTS.TAUAnTSm) to 1. This in turn sets TAUAnTE.TAUAnTEm = 1, enabling count operation. When a valid TAUAnTTINm input start edge is detected, the current value of TAUAnCDRm is loaded to TAUAnCNTm and the counter starts to count down from this value.

When a TAUAnTTINm valid stop edge is detected, the function compares the current values of TAUAnCNTm and TAUAnCDRm. An interrupt signal INTTAUAnIm is generated if the result of the comparison is true. The counter TAUAnCNTm retains its value until the next TAUAnTTINm valid start edge is detected, regardless of the result of the comparison.

If the counter reaches 0000_H before a valid TAUAnTTINm stop edge is detected, TAUAnCNTm overflows and is set to FFFF_H. It then continues to count down.

The value of TAUAnCDRm can be rewritten at any time, and the changed value of TAUAnCDRm is applied the next time the function starts to count down.

- Conditions**
- The TAUAnCMORm.TAUAnMD0 bit specifies the type of comparison:
 - If TAUAnCMORm.TAUAnMD0 = 0, INTTAUAnIm is generated when TAUAnCNTm \leq TAUAnCDRm.
 - If TAUAnCMORm.TAUAnMD0 = 1, INTTAUAnIm is generated when TAUAnCNTm > TAUAnCDRm.
 - The TAUAnCMURm.TAUAnTIS[1:0] bits specify the type of width measurement:
 - For high width measurement (TAUAnCMURm.TAUAnTIS[1:0] = 11_B), the start edge is a rising TAUAnTTINm edge and the stop edge is a falling TAUAnTTINm edge.
 - For low width measurement (TAUAnCMURm.TAUAnTIS[1:0] = 10_B), the start edge is a falling TAUAnTTINm edge and the stop edge is a rising TAUAnTTINm edge.
 - Forced restart is not possible for this function.

(2) Block diagram and general timing diagram

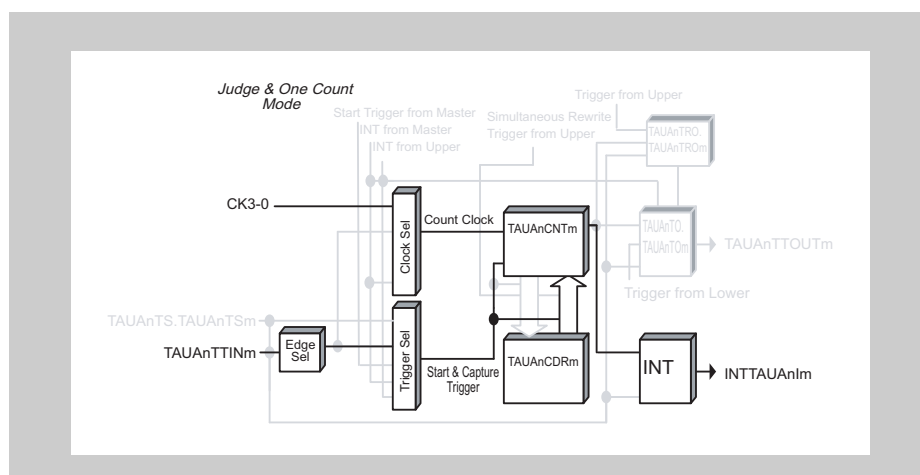

Figure 12-62 Block diagram for TAUAnTTINm Input Signal Width Judgment Function

The following settings apply to the general timing diagram:

- INTTAUAnIm is generated when TAUAnCNTm \neq TAUAnCDRm (TAUAnCMORm.TAUAnMD0 = 0)
- TAUAnTTINm valid start edge = rising edge, TAUAnTTINm valid stop edge = falling edge (TAUAnCMURm.TAUAnTIS[1:0] = 11_B)

Figure 12-63 General timing diagram for TAUAnTTINm Input Signal Width Judgment Function

(c) Channel output mode

Because the channel output mode is not used by this function, clear TAUAnTOE.TAUAnTOEm. However, it can be used in Independent Channel Output Mode Controlled by Software.

(d) Simultaneous rewrite

The simultaneous rewrite registers (TAUAnRDE, TAUAnRDS, TAUAnRDM, and TAUAnRDC) cannot be used with the TAUAnTTINm Input Signal Width Judgment Function. Therefore, these registers must be set to 0.

Table 12-58 Simultaneous rewrite settings for TAUAnTTINm Input Signal Width Judgment Function

Bit name	Setting
TAUAnRDE.TAUAnRDEm	0: Disables simultaneous rewrite
TAUAnRDS.TAUAnRDSm	0: When simultaneous rewrite is disabled (TAUAnRDE.TAUAnRDEm = 0), set these bits to 0
TAUAnRDM.TAUAnRDMm	
TAUAnRDC.TAUAnRDCm	

(4) Operating procedure for TAUAnTTINm Input Signal Width Judgment Function

Table 12-59 Operating procedure for TAUAnTTINm Input Signal Width Judgment Function

	Operation	Status of TAUAn
Initial channel setting	Set the TAUAnCMORm register and TAUAnCMURm registers as described in <i>Table 12-56 "TAUAnCMORm settings for TAUAnTTINm Input Signal Width Judgment Function" on page 538</i> and <i>Table 12-57 "TAUAnCMURm settings for TAUAnTTINm Input Signal Width Judgment Function" on page 538</i> Set the value of the TAUAnCDRm register	Channel operation is stopped.
Start operation	Set TAUAnTS.TAUAnTSm to 1. TAUAnTS.TAUAnTSm is a trigger bit, so it is automatically cleared to 0. Detection of TAUAnTTINm start edge	TAUAnTE.TAUAnTEm is set to 1 and TAUAnCNTm waits for detection of the TAUAnTTINm start edge. When a TAUAnTTINm start edge is detected, TAUAnCNTm loads the TAUAnCDRm value.
	During operation	TAUAnCNTm counts down. When a TAUAnTTINm stop edge is detected: <ul style="list-style-type: none"> TAUAnCNTm stops and waits for detection of the TAUAnTTINm start edge. TAUAnCNTm compares the values and judges the condition according to the TAUAnCMORm.TAUAnMD0. If the condition is satisfied, INTTAUAnIm is generated. Afterwards, this procedure is repeated.
Stop operation	Set TAUAnTT.TAUAnTTm to 1. TAUAnTT.TAUAnTTm is a trigger bit, so it is automatically cleared to 0.	TAUAnTE.TAUAnTEm is cleared to 0 and the counter stops. TAUAnCNTm stops and retains its current value.

Restart

12.17 Independent Channel Real-Time Functions

This chapter describes functions that output the value of the TAUAnTRO.TAUAnTROM bit in real time:

- 12.17.1 *“Real-Time Output Function Type 1”*
- 12.17.2 *“Real-Time Output Function Type 2”*

12.17.1 Real-Time Output Function Type 1

(1) Overview

- Summary** This function outputs the value of the TAUAnTRO.TAUAnTROm bit from TAUAnTTOUTm when a specified channel generates an interrupt (INTTAUAnIm). In this function, the interrupt is generated at certain specified intervals.
- The upper channel generates the real-time output trigger (TAUAnTRC.TAUAnTRCm = 1), and the lower channel receives this trigger and performs real-time output (TAUAnTRC.TAUAnTRCm = 0).
- Prerequisites**
- One channel using the TAUAnTTOUTm control of one of more other channels
 - The operation mode of the upper channel must be set to Interval Timer Mode. Refer to *Table 12-60 "TAUAnCMORm settings for Real-Time Output Function Type 1" on page 543*.
 - The operation mode of the lower channel(s) can be set as desired.
 - The channel output mode of all the channels must be set to Independent Channel Output Mode 1 with Real-Time Output. Refer to *12.8 "Channel Output Modes" on page 463*.
 - Real-time output must be enabled for the upper channel (TAUAnTRE.TAUAnTREM = 1).
- Description** The counter of the upper channel is started by setting the channel trigger bit (TAUAnTS.TAUAnTSm) to 1. This in turn sets TAUAnTE.TAUAnTEm, enabling count operation. The current value of the data register of the upper channel (TAUAnCDRm) is loaded to the counter (TAUAnCNTm) and the counter starts to count down from this value.
- When the counter of the upper channel reaches 0000_H, INTTAUAnIm is generated and TAUAnTTOUTm outputs the current value of the real-time output bit (TAUAnTRO.TAUAnTROm) in all the channels for which TAUAnTRE.TAUAnTREM is set. TAUAnCNTm reloads the TAUAnCDRm value, and then subsequently continues operation.
- The TAUAnTTOUTm signal only changes when an interrupt is generated, and then only when its value is different to current value of TAUAnTRO.TAUAnTROm at the moment that the interrupt is generated.
- Conditions**
- The channel that detects the generation of INTTAUAnIm is specified by setting TAUAnTRC.TAUAnTRCm to 1 for the corresponding channel. The TAUAnTRC.TAUAnTRCm bit must be cleared to 0 for all other channels that do not generate the real-time output trigger.
 - If real-time output of a lower channel is disabled (TAUAnTRE.TAUAnTREM = 0) or the channel itself is used as the rewrite trigger (TAUAnTRC.TAUAnTRCm = 1), the value of that channel's TAUAnTRO.TAUAnTROm bit is output when INTTAUAnIm is generated by that channel.
 - If real-time output of a lower channel is enabled (TAUAnTRE.TAUAnTREM = 1) and TAUAnTRC.TAUAnTRCm = 0, the value of that channel's TAUAnTRO.TAUAnTROm bit is output when INTTAUAnIm is generated by an upper channel.
 - If the TAUAnCMORm.TAUAnMD0 bit is set to 0, the first interrupt after a start or restart is not output. For details refer to *12.10 "TAUAnTTOUTm Output and INTTAUAnIm Generation when Counter Starts or Restarts" on page 475*.

(2) Equations

$$\text{INTTAUAnIm generation cycle} = \text{count clock cycle} \times (\text{TAUAnCDRm value} + 1)$$

(3) Block diagram and general timing diagram

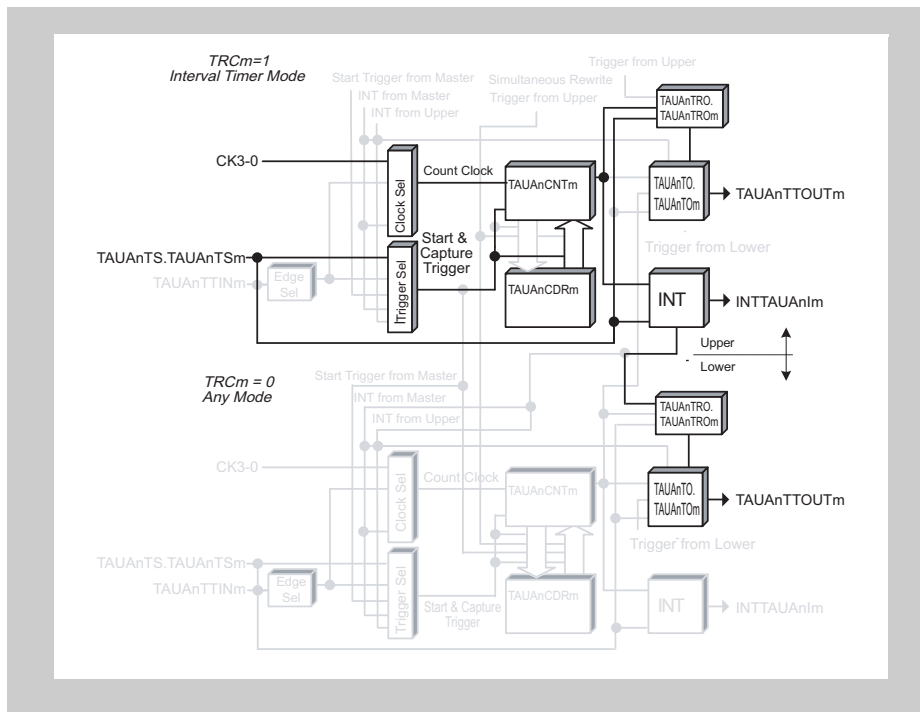

Figure 12-64 Block diagram for Real-Time Output Function Type 1

The following settings apply to the general timing diagram:

- INTTAUAnIm is generated at operation start (TAUAnCMORM.TAUAnMD0 = 1)

Bit name	Setting
TAUAnTIS[1:0]	00: Not used, so set to 00

(c) Channel output mode for the upper channel**Table 12-62 Control bit settings for Independent Channel Output Mode 1 with Real-Time Output**

Bit name	Setting
TAUAnTOE.TAUAnTOEm	1: Enables Independent Channel Output Mode
TAUAnTOM.TAUAnTOMm	0: Independent channel output
TAUAnTOC.TAUAnTOCm	0: Operation mode 1 (= Toggle mode if TAUAnTOM.TAUAnTOMm = 0)
TAUAnTOL.TAUAnTOLm	0: Positive logic
TAUAnTDE.TAUAnTDEm	0: Disables dead time operation
TAUAnTDM.TAUAnTDMm	0: When dead time operation is disabled (TAUAnTDE.TAUAnTDEm = 0), set these bits to 0
TAUAnTDL.TAUAnTDLm	
TAUAnTRE.TAUAnTREm	1: Enables real-time output
TAUAnTRO.TAUAnTROM	0: Real-time output is low 1: Real-time output is high
TAUAnTRC.TAUAnTRCm	1: Channel m generates its own real-time trigger
TAUAnTME.TAUAnTMEm	0: Disables modulation

(d) Simultaneous rewrite for the upper channel

The simultaneous rewrite registers (TAUAnRDE, TAUAnRDS, TAUAnRDM, and TAUAnRDC) cannot be used with the Real-Time Output Function Type 1. Therefore, these registers must be set to 0.

Table 12-63 Simultaneous rewrite settings for Real-Time Output Function Type 1

Bit name	Setting
TAUAnRDE.TAUAnRDEm	0: Disables simultaneous rewrite
TAUAnRDS.TAUAnRDSm	0: When simultaneous rewrite is disabled (TAUAnRDE.TAUAnRDEm = 0), set these bits to 0
TAUAnRDM.TAUAnRDMm	
TAUAnRDC.TAUAnRDCm	

(5) Register settings for the lower channel(s)**(a) TAUAnCMORm for the lower channel(s)**

The TAUAnCMORm register of the lower channel(s) can be set arbitrarily.

(b) TAUAnCMURm for the lower channel(s)

The TAUAnCMURm register of the lower channel(s) can be set arbitrarily.

(c) Channel output mode for the lower channel(s)

Table 12-64 Control bit settings for the lower channel in Independent Channel Output Mode 1 with Real-Time Output

Bit name	Setting
TAUAnTOE.TAUAnTOEm	1: Enables Independent Channel Output Mode
TAUAnTOM.TAUAnTOMm	0: Independent channel output
TAUAnTOC.TAUAnTOCm	0: Operation mode 1 (= Toggle mode if TAUAnTOM.TAUAnTOMm = 0)
TAUAnTOL.TTAUAnOLm	0: Positive logic
TAUAnTDE.TAUAnTDEm	0: Disables dead time operation
TAUAnTDM.TAUAnTDMm	0: When dead time operation is disabled (TAUAnTDE.TAUAnTDEm = 0), set these bits to 0
TAUAnTDL.TAUAnTDLm	0: When dead time operation is disabled (TAUAnTDE.TAUAnTDEm = 0), set these bits to 0
TAUAnTRE.TAUAnTREm	1: Enables real-time output
TAUAnTRO.TAUAnTROM	0: Real-time output is low 1: Real-time output is high
TAUAnTRC.TAUAnTRCm	0: The next upper channel generates the real-time trigger for channel m
TAUAnTME.TAUAnTMEem	0: Disables modulation

(d) Simultaneous rewrite for the lower channel(s)

The simultaneous rewrite registers of the lower channel(s) can be set arbitrarily.

(6) Operating procedure for Real-Time Output Function Type 1

Table 12-65 Operating procedure for Real-Time Output Function Type 1

	Operation	Status of TAUAn
Initial channel setting	<p>Set the TAUAnCMORm register and TAUAnCMURm registers for the upper channel as described in <i>Table 12-60 "TAUAnCMORm settings for Real-Time Output Function Type 1" on page 543</i> and <i>Table 12-61 "TAUAnCMURm settings for Real-Time Output Function Type 1" on page 543</i></p> <p>Set the TAUAnCMORm register and TAUAnCMURm registers for the lower channel as described in (5) <i>Register settings for the lower channel(s)</i></p> <p>Set the value of the TAUAnCDRm register (only for the channels for which TAUAnTRC.TAUAnTRCm is set)</p> <p>Set the channel output mode for the upper channel by setting the control bits as described in <i>Table 12-62 "Control bit settings for Independent Channel Output Mode 1 with Real-Time Output" on page 544</i></p> <p>Set the channel output mode for the lower channel by setting the control bits as described in <i>Table 12-64 "Control bit settings for the lower channel in Independent Channel Output Mode 1 with Real-Time Output" on page 545</i></p>	Channel operation is stopped.
Start operation	<p>Set TAUAnTS.TAUAnTSM = 1 in the channel where TAUAnTRC.TAUAnTRCm is set to 1. TAUAnTS.TAUAnTSM is a trigger bit, so it is automatically cleared to 0.</p>	[Channel where TAUAnTRC.TAUAnTRCm is set to 1] TAUAnTE.TAUAnTEm is set to 1 and the counter starts. TAUAnCNTm loads the TAUAnCDRm value. INTTAUAnIm is generated when TAUAnCMORm.TAUAnMD0 is set to 1.
During operation	<p>The TAUAnCDRm register and TAUAnTRO.TAUAnTROM can be changed at any time. The TAUAnCNTm register can be read at any time.</p>	<p>TAUAnCNTm counts down. When the counter reaches 0000_H:</p> <ul style="list-style-type: none"> • TAUAnCNTm reloads the TAUAnCDRm value, and then continues count operation. • INTTAUAnIm is generated. • TAUAnTTOUTm outputs the current value of the real-time output bit TAUAnTRO.TAUAnTROM. <p>The operation is then repeated</p>
Stop operation	<p>Set TAUAnTT.TAUAnTTm to 1. TAUAnTT.TAUAnTTm is a trigger bit, so it is automatically cleared to 0.</p>	<p>TAUAnTE.TAUAnTEm is cleared to 0 and the counter stops. TAUAnCNTm stops and both it and TAUAnTTOUTm retain their current values.</p>

Restart

(7) Specific timing diagrams

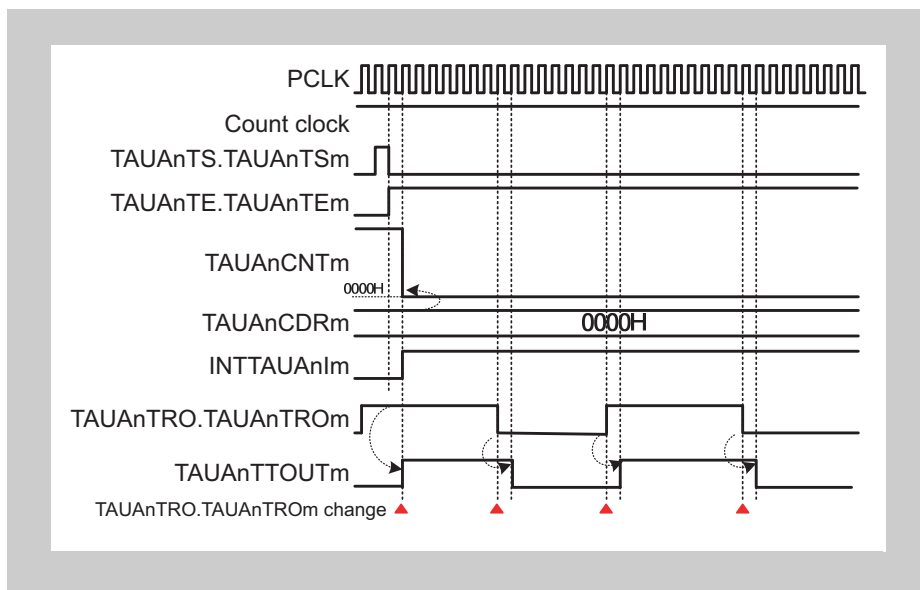

Figure 12-66 TAUAnCDRm = 0000_H, TAUAnCMORm.TAUAnMD0 = 1

- The value of TAUAnTTOUTm follows the TAUAnTRO.TAUAnTROm settings with once PCLK cycle delay.

12.17.2 Real-Time Output Function Type 2

(1) Overview

- Summary** This function outputs the value of the TAUAnTRO.TAUAnTROm bit from TAUAnTTOUTm when a specified channel generates an interrupt (INTTAUAnIm). In this function, the interrupt is generated when a valid TAUAnTTINm input edge is detected or the function starts.
- The upper channel generates the real-time output trigger (TAUAnTRC.TAUAnTRCm = 1), and the lower channel receives this trigger and performs real-time output (TAUAnTRC.TAUAnTRCm = 0).
- Prerequisites**
- One channel using the TAUAnTTOUTm control of one of more other channels
 - The operation mode of the upper channel must be set to Capture Mode. Refer to *Table 12-66 "TAUAnCMORm settings for Real-Time Output Function Type 2"* on page 550 .
 - The operation mode of the lower channel(s) can be set as desired.
 - The channel output mode of all the channels must be set to Independent Channel Output Mode 1 with Real-Time Output. Refer to *12.8 "Channel Output Modes"* on page 463 .
 - Real-time output must be enabled for the upper channel (TAUAnTRE.TAUAnTREM = 1).
- Description** The counter of the upper channel is started by setting the channel trigger bit (TAUAnTS.TAUAnTSm) to 1. This in turn sets TAUAnTE.TAUAnTEm, enabling count operation. The counter of the upper channel starts to count up.
- When a valid TAUAnTTINm input edge is generated on the upper channel, an interrupt is generated, and TAUAnTTOUTm outputs the current value of the real-time output bit (TAUAnTRO.TAUAnTROm) on all channels (only for channels for which TAUAnTRE.TAUAnTREM = 1).
- The TAUAnTTOUTm signal only changes when an interrupt is generated, and then only when its value is different to current value of TAUAnTRO.TAUAnTROm at the moment that the interrupt is generated.
- Conditions**
- The channel that detects the generation of INTTAUAnIm is specified by setting TAUAnTRC.TAUAnTRCm to 1 for the corresponding channel. The TAUAnTRC.TAUAnTRCm bit must be cleared to 0 for all other channels that do not generate the real-time output trigger.
 - If real-time output of a lower channel is disabled (TAUAnTRE.TAUAnTREM = 0) or the channel itself is used as the rewrite trigger (TAUAnTRC.TAUAnTRCm = 1), the value of that channel's TAUAnTRO.TAUAnTROm bit is output when INTTAUAnIm is generated by that channel.
 - If real-time output of a lower channel is enabled (TAUAnTRE.TAUAnTREM = 1) and TAUAnTRC.TAUAnTRCm = 0, the value of that channel's TAUAnTRO.TAUAnTROm bit is output when INTTAUAnIm is generated by an upper channel.
 - If the TAUAnCMORm.TAUAnMD0 bit is set to 0, the first interrupt after a start or restart is not output. For details refer to *12.10 "TAUAnTTOUTm Output and INTTAUAnIm Generation when Counter Starts or Restarts"* on page 475 .

(2) Block diagram and general timing diagram

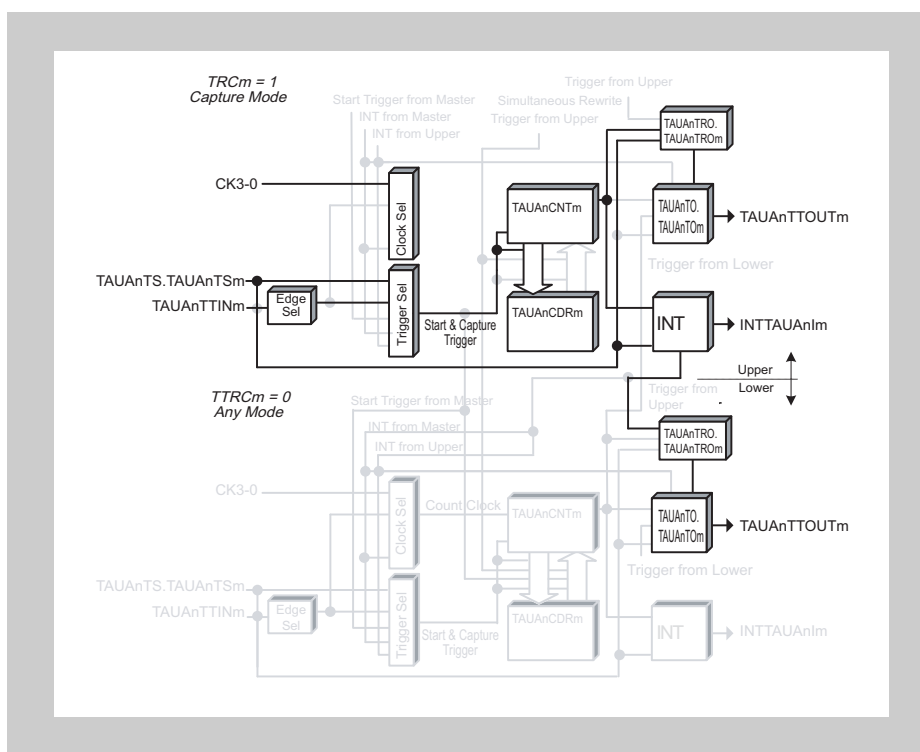

Figure 12-67 Block diagram for Real-Time Output Function Type 2

The following settings apply to the general timing diagram:

- INTTAUAnIm not output at operation start (TAUAnCMORm.TAUAnMD0 = 0)

TAUAnTRC.TAUAnTRCm	0: The upper channel generates the real-time trigger for channel m 1: Channel m generates its own real-time trigger
TAUAnTME.TAUAnTMEem	0: Disables modulation

(d) Simultaneous rewrite for the lower channel(s)

The simultaneous rewrite registers of the lower channel(s) can be set arbitrarily.

(5) Operating procedure for Real-Time Output Function Type 2

Table 12-71 Operating procedure for Real-Time Output Function Type 2

	Operation	Status of TAUAn	
Initial channel setting	Set the TAUAnCMORm register and TAUAnCMURm registers for the upper channel as described in Table 12-66 "TAUAnCMORm settings for Real-Time Output Function Type 2" on page 550 and Table 12-67 "TAUAnCMURm settings for Real-Time Output Function Type 2" on page 550	Channel operation is stopped.	
	Set the TAUAnCMORm register and TAUAnCMURm registers for the lower channel as described in (4) "Register settings for the lower channel(s)" on page 552		
	Set the channel output mode for the upper channel by setting the control bits as described in Table 12-68 "Control bit settings for Independent Channel Output Mode 1 with Real-Time Output" on page 551		
	Set the channel output mode for the lower channel by setting the control bits as described in Table 12-70 "Control bit settings for lower channel in Independent Channel Output Mode 1 with Real-Time Output" on page 552		
Restart	Start operation	Set TAUAnTS.TAUAnTSM of the channel where TAUAnTRC.TAUAnTRCm is set to 1. TAUAnTS.TAUAnTSM is a trigger bit, so it is automatically cleared to 0.	[Channel where TAUAnTRC.TAUAnTRCm is set to 1] TAUAnTE.TAUAnTEm is set to 1 and the counter starts. TAUAnCNTm is cleared to 0000 _H . When TAUAnCMORm.TAUAnMD0 is set to 1, INTTAUAnIm is generated.
	During operation	TAUAnTRO.TAUAnTROm can be changed at any time.	TAUAnCNTm starts to count up from 0000 _H . When a TAUAnTTINm input valid edge is detected: <ul style="list-style-type: none"> INTTAUAnIm is generated. TAUAnCSRm.TAUAnOVF is cleared to 0. TAUAnTTOUm outputs the current value of the real-time output bit TAUAnTRO.TAUAnTROm. Afterwards, this procedure is repeated.
	Stop operation	Set TAUAnTT.TAUAnTTm to 1. TAUAnTT.TAUAnTTm is a trigger bit, so it is automatically cleared to 0.	TAUAnTE.TAUAnTEm is cleared to 0 and the counter stops. TAUAnCNTm stops and both it, TAUAnCSRm.TAUAnOVF, and TAUAnTTOUm retain their current values.

12.18 Independent Channel Simultaneous Rewrite Functions

This chapter describes functions that carry out simultaneous rewrite:

- 12.18.1 “Simultaneous Rewrite Trigger Generation Function Type 1”
- 12.18.2 “Simultaneous Rewrite Trigger Generation Function Type 2”

12.18.1 Simultaneous Rewrite Trigger Generation Function Type 1

(1) Overview

- Summary** This function generates an interrupt on a specific channel that can be used by lower channels as a simultaneous rewrite trigger. The interrupt is generated at regular intervals.
- The upper channel generates the simultaneous rewrite trigger (TAUAnRDC.TAUAnRDCm = 1), and the lower channel receives this trigger and performs simultaneous rewriting (TAUAnRDC.TAUAnRDCm = 0).
- Prerequisites**
- At least two channels lower than a channel used as an upper channel, each with simultaneous rewriting enabled (TAUAnRDE.TAUAnRDEm = 1)
 - The operation mode of the upper channel must be set to Interval Timer Mode. Refer to *Table 12-72 "TAUAnCMORm settings for Simultaneous Rewrite Trigger Generation Function Type 1" on page 558*.
 - For details about which operation modes can be specified for lower channels, refer to *Table 12-7 "Simultaneous rewrite methods and when they are triggered" on page 451*.
 - TAUAnTTOUTm is not used for any channel in this function.
- Description** The counter is enabled by setting the channel trigger bit of the upper channel or lower channel (TAUAnTS.TAUAnTSM) to 1. This in turn sets TAUAnTE.TEm to 1, enabling counting. The current value of the data register buffer of the upper channel (TAUAnCDRm buf) is written to the counter (TAUAnCNTm) and the counter starts to count down from this value. The counter(s) of the lower channel(s) start to count as specified by their selected operating modes.
- When a counter reaches 0000_H, an interrupt is generated from the channel. The TAUAnCNTm loads the current value of the corresponding TAUAnCDRm buffer, and then subsequently continues operation.
- If the channel where the interrupt occurs is specified as the trigger channel for simultaneous rewrite (TAUAnRDC.TAUAnRDCm = 1) and is an upper channel, simultaneous rewrite takes place on all lower channels in which simultaneous rewrite is currently possible (TAUAnRSF.TAUAnRSFm = 1).
- The values of the data registers are copied to the corresponding data register buffers. Each time a counter starts to count down, it reads the value in the data register buffer and counts down from this value.
- The value of a data register can be changed at any time, but it is only transferred to the corresponding data register buffer when simultaneous rewrite occurs.
- Conditions**
- The channel that detects the generation of INTTAUAnIm is specified by setting TAUAnRDC.TAUAnRDCm to 1 for the corresponding channel. The TAUAnRDC.TAUAnRDCm bit must be 0 for all other channels in which simultaneous rewrite should take place.
 - If the TAUAnCMORm.TAUAnMD0 bit is set to 0, the first interrupt after a start or restart is not generated. For details refer to *12.10 "TAUAnTTOUTm Output and INTTAUAnIm Generation when Counter Starts or Restarts" on page 475*.

(2) Equations

Simultaneous rewrite trigger generation cycle = count clock cycle × (TAUAnCDRm + 1)

To control simultaneous rewrite, the following condition must be satisfied:

For PWM:

$TAUAnCDRm = [(value\ of\ TAUAnCDRm\ of\ master\ channel\ subject\ to\ simultaneous\ rewrite + 1) \times number\ of\ interrupts] - 1$

For triangle PWM:

$TAUAnCDRm = [(value\ of\ TAUAnCDRm\ of\ master\ channel\ subject\ to\ simultaneous\ rewriting + 1) \times 2 \times number\ of\ interrupts] - 1$

That is, the ratio of TAUAnCDRm + 1 and TAUAnCDRm_master + 1 must be an integer. This integer corresponds to the number of interrupts.

Note that, for triangle PWM, the cycle is doubled.

(3) Block diagram and general timing diagram

Figure 12-69 Block diagram for Simultaneous Rewrite Trigger Generation Function Type 1

The following settings apply to the general timing diagram:

- INTTAUAn1m generated at operation start (TAUAnCMORm.TAUAnMD0 = 1)

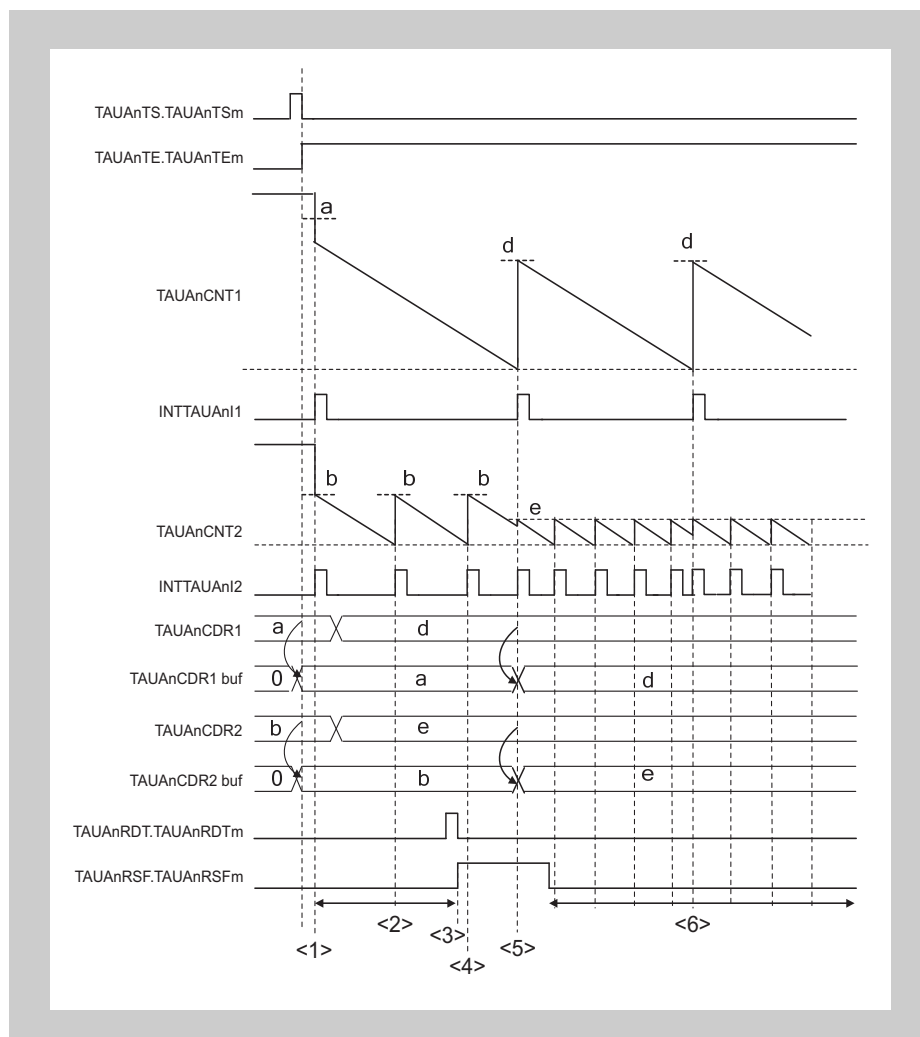

Figure 12-70 General timing diagram for Simultaneous Rewrite Trigger Generation Function Type 1

- Description:**
1. When TAUAnTS.TAUAnTsm is set to 1, the value of TAUAnCDRm is copied to the TAUAnCDRm buffer.
 2. The TAUAnCDRm register can always be written to.
 3. The reload data trigger bit (TAUAnRDT.TAUAnRDTm) is set to 1, which sets the status flag (TAUAnRSF.TAUAnRSFm = 1), enabling simultaneous rewriting.
 4. Even though simultaneous rewriting is enabled, it does not take place because it is only triggered by an interrupt on channel 1.
 5. Simultaneous rewriting is triggered by INT1, which is caused by counter 1 reaching 0000H. The TAUAnCDRm values are loaded to the corresponding TAUAnCDRm buffers.
 6. The counter counts down and awaits the next simultaneous rewrite trigger. The values of the TAUAnCDRm registers can be changed again.

(4) Register settings for the upper channel**(a) TAUAnCMORm for the upper channel**

TAUAnTIS[1:0]	00: Not used, so set to 00

(c) Channel output mode for the upper channel

Because the channel output mode is not used by this function, clear TAUAnTOE.TAUAnTOEm. However, it can be used in Independent Channel Output Mode Controlled by Software.

(d) Simultaneous rewrite for the upper channel

Table 12-74 Simultaneous rewrite settings for Simultaneous Rewrite Trigger Generation Function Type 1

Bit name	Setting
TAUAnRDE.TAUAnRDEm	1: Enables simultaneous rewrite
TAUAnRDS.TAUAnRDSm	1: Selects an upper channel as the control channel for simultaneous rewrite
TAUAnRDM.TAUAnRDMm	0: The signal that controls simultaneous rewrite is loaded when the master channel starts counting
TAUAnRDC.TAUAnRDCm	1: Channel is monitored for an INTTAUAnIm signal that is used as the simultaneous rewrite trigger

(5) Register settings for the lower channel(s)**(a) TAUAnCMORm for the lower channel(s)**

For the TAUAnCMORm registers of lower channels, use the TAUAnCMORm register settings of operation modes that can be specified. (For details, refer to *Table 12-7 “Simultaneous rewrite methods and when they are triggered” on page 451 .)*

(b) TAUAnCMURm for the lower channel(s)

For the TAUAnCMURm registers of lower channels, use the TAUAnCMURm register settings of operation modes that can be specified. (For details, refer to *Table 12-7 “Simultaneous rewrite methods and when they are triggered” on page 451 .)*

(c) Channel output mode for the lower channel(s)

Output is possible according to the operation mode setting (master or slave) of a lower channel.

(d) Simultaneous rewrite for the lower channel(s)

Table 12-75 Simultaneous rewrite settings for the lower channel in Simultaneous Rewrite Trigger Generation Function Type 1

Bit name	Setting
TAUAnRDE.TAUAnRDEm	1: Enables simultaneous rewrite
TAUAnRDS.TAUAnRDsm	1: Selects an upper channel as the control channel for simultaneous rewrite
TAUAnRDM.TAUAnRDMm	0: The signal that controls simultaneous rewrite is loaded when the master channel starts counting
TAUAnRDC.TAUAnRDCm	0: Channel is not monitored for an INTTAUAnIm signal that is used as the simultaneous-rewrite trigger

(6) Operating procedure for Simultaneous Rewrite Trigger Generation Function Type 1

Table 12-76 Operating procedure for Simultaneous Rewrite Trigger Generation Function Type 1

	Operation	Status of TAUAn
Restart	Initial channel setting Set the TAUAnCMORm register and TAUAnCMURm registers for the upper channel as described in <i>Table 12-72 "TAUAnCMORm settings for Simultaneous Rewrite Trigger Generation Function Type 1" on page 558</i> and <i>Table 12-73 "TAUAnCMURm settings for Simultaneous Rewrite Trigger Generation Function Type 1" on page 558</i> Set the TAUAnCMORm register and TAUAnCMURm registers for the lower channel as described in (5) <i>"Register settings for the lower channel(s)" on page 559</i> Set the value of the TAUAnCDRm register	Channel operation is stopped.
	Start operation Set TAUAnTS.TAUAnTSM to 1. TAUAnTS.TAUAnTSM is a trigger bit, so it is automatically cleared to 0.	TAUAnTE.TAUAnTEm is set to 1 and the counter starts. TAUAnCNTm loads the TAUAnCDRm value. When TAUAnCMORm.TAUAnMD0 = 1, INTTAUAnIm is generated.
	During operation TAUAnRDT.TAUAnRDTm can be changed. TAUAnRSF.TAUAnRSFm can be read at all times.	TAUAnCNTm counts down. When the counter reaches 0000 _H : <ul style="list-style-type: none"> TAUAnCNTm reloads the TAUAnCDRm value, and then continues count operation. INTTAUAnIm is generated. Simultaneous rewrite is controlled when INTTAUAnIm is generated from the channel where TAUAnRDC.TAUAnRDCm is set to 1. Afterwards, this procedure is repeated.
	Stop operation Set TAUAnTT.TAUAnTTm to 1. TAUAnTT.TAUAnTTm is a trigger bit, so it is automatically cleared to 0.	TAUAnTE.TAUAnTEm is cleared to 0 and the counter stops. TAUAnCNTm stops and retains the current value.

12.18.2 Simultaneous Rewrite Trigger Generation Function Type 2

(1) Overview

Summary This function generates an interrupt on a specific channel that can be used by lower channels as a simultaneous rewrite trigger. The interrupt is triggered by a valid TAUAnTTINm input edge or the function starting.

The upper channel generates the simultaneous rewrite trigger (TAUAnRDC.TAUAnRDCm = 1), and the lower channel receives this trigger and performs simultaneous rewriting (TAUAnRDC.TAUAnRDCm = 0).

- Prerequisites**
- At least two channels used as lower channels than upper channels, each with simultaneous rewriting enabled (TAUAnRDE.TAUAnRDEm = 1)
 - The operation mode of the upper channel must be set to Capture Mode. Refer to *Table 12-77 "TAUAnCMORm settings for Simultaneous Rewrite Trigger Generation Function Type 2"* on page 564 .
 - For details about which operation modes can be specified for lower channels, refer to *Table 12-7 "Simultaneous rewrite methods and when they are triggered"* on page 451 .
 - The channel output mode of the upper channel must be set to Independent Channel Output Mode Controlled by Software. Refer to *12.8 "Channel Output Modes"* on page 463 .
 - The channel output mode of the lower channel(s) can be set as desired.

Description The counter is enabled by setting the channel trigger bit of the upper channel or lower channel (TAUAnTS.TAUAnTSm) to 1. This in turn sets TAUAnTE.TEm to 1, enabling counting. The counter of the upper channel starts to count up, and the counter(s) of the lower channel(s) start to count as specified by their selected operating modes.

When a valid TAUAnTTINm input edge is generated on the upper channel, an interrupt is generated, and an interrupt is generated upon trigger detection on the lower channel.

TAUAnRDC.TAUAnRDCm = 1 on the upper channel, therefore simultaneous rewrite takes place on all lower channels in which simultaneous rewrite is currently possible (TAUAnRSF.TAUAnRSFm = 1).

The values of the data registers are copied to the corresponding data register buffers.

The value of a data register can be changed at any time, but it is only transferred to the corresponding data register buffer when simultaneous rewrite occurs.

- Conditions**
- The channel that detects the generation of INTTAUAnIm is specified by setting TAUAnRDC.TAUAnRDCm to 1 for the corresponding channel. The TAUAnRDC.TAUAnRDCm bit must be 0 for all other channels on which simultaneous rewriting must take place.
 - If the TAUAnCMORm.TAUAnMD0 bit is set to 1, an interrupt is generated when the function starts. For details refer to *12.10 "TAUAnTTOUTm Output and INTTAUAnIm Generation when Counter Starts or Restarts"* on page 475 .

(2) Block diagram and general timing diagram

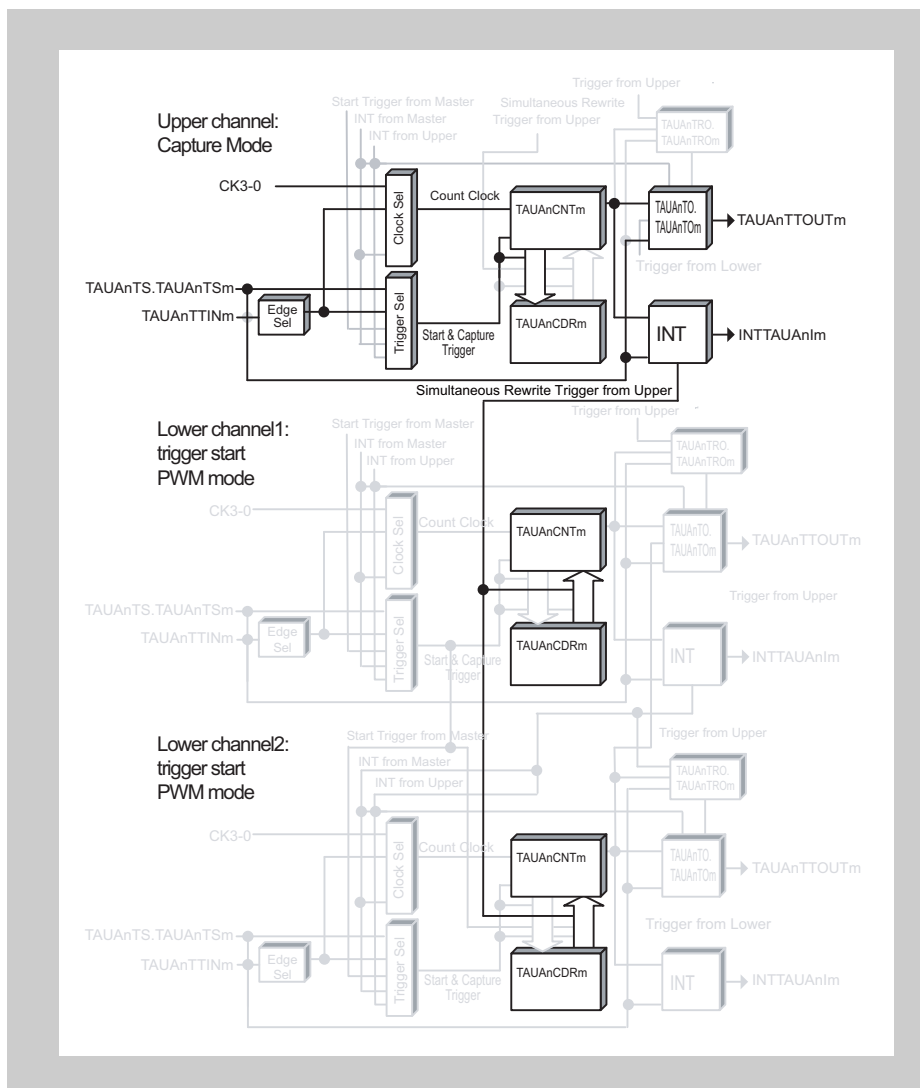

Figure 12-71 Block diagram for Simultaneous Rewrite Trigger Generation Function Type 2

The following settings apply to the general timing diagram:

- INTTAUAnIm not generated at operation start (TAUAnCMORm.TAUAnMD0 = 0)
- Falling edge detection (TAUAnCMURm.TAUAnTIS[1:0] = 00_B)
- Upper channel (channel 1) generates simultaneous rewrite trigger

Restart

12.19 Independent Channel One-Phase PWM Function

This chapter describes the One-Phase PWM Function:

- 12.19.1 *“One-Phase PWM Output Function”*

12.19.1 One-Phase PWM Output Function

(1) Overview

- Summary** This function adds dead time to a TAUAnTTINm input signal. The resulting PWM signal is output via TAUAnTTOUtm of the channel and TAUAnTTOUtm of (an) upper channel(s).
- Prerequisites**
- Two (or more) channels, each with dead time control enabled (TAUAnTDE.TAUAnTDEm = 1)
 - The operation mode of the lower channel must be set to One Count Mode. Refer to *Table 12-84 “TAUAnCMORm settings for One-Phase PWM Output Function” on page 571*.
 - The operation mode of the upper channel(s) can be set as desired.
 - The channel output mode of the upper and lower channels must be set to Synchronous Channel Output Mode 2 with One-Phase PWM Output. Refer to *12.8 “Channel Output Modes” on page 463*.
- Description** The counter is enabled by setting the channel trigger bit (TAUAnTS.TAUAnTSm) to 1. This in turn sets TAUAnTE.TAUAnTEm = 1, enabling count operation.
- The counter starts when a valid TAUAnTTINm input start edge is detected. The value of TAUAnCDRm is written to TAUAnCNTm and the counter starts to count down from the TAUAnCDRm value.
- When the counter reaches 0000_H an interrupt is generated. The counter returns to FFFF_H and awaits the next valid TAUAnTTINm input start edge.
- Conditions**
- The TAUAnCMURm.TAUAnTIS[1:0] bits specify the type of width measurement:
 - TAUAnCMURm.TAUAnTIS[1:0] = 10B:
Detect both rising and falling edges as valid (low-width measurement).
 - TAUAnCMURm.TAUAnTIS[1:0] = 11B:
Detect both rising and falling edges as valid (high-width measurement).
 - The TAUAnTDL.TAUAnTDLm bit specifies the behavior of TAUAnTTOUtm for each channel when an interrupt or valid TAUAnTTINm edge is detected on the lower channel:
 - If TAUAnTDL.TAUAnTDLm = 0, an interrupt is the trigger for setting TAUAnTTOUtm, and a valid TAUAnTTINm edge is the trigger for resetting TAUAnTTOUtm.
 - If TAUAnTDL.TAUAnTDLm = 1, a valid TAUAnTTINm edge is the trigger for setting TAUAnTTOUtm, and an interrupt is the trigger for resetting TAUAnTTOUtm.
 - Forced restart is not possible for this function.

(2) Block diagram and general timing diagram

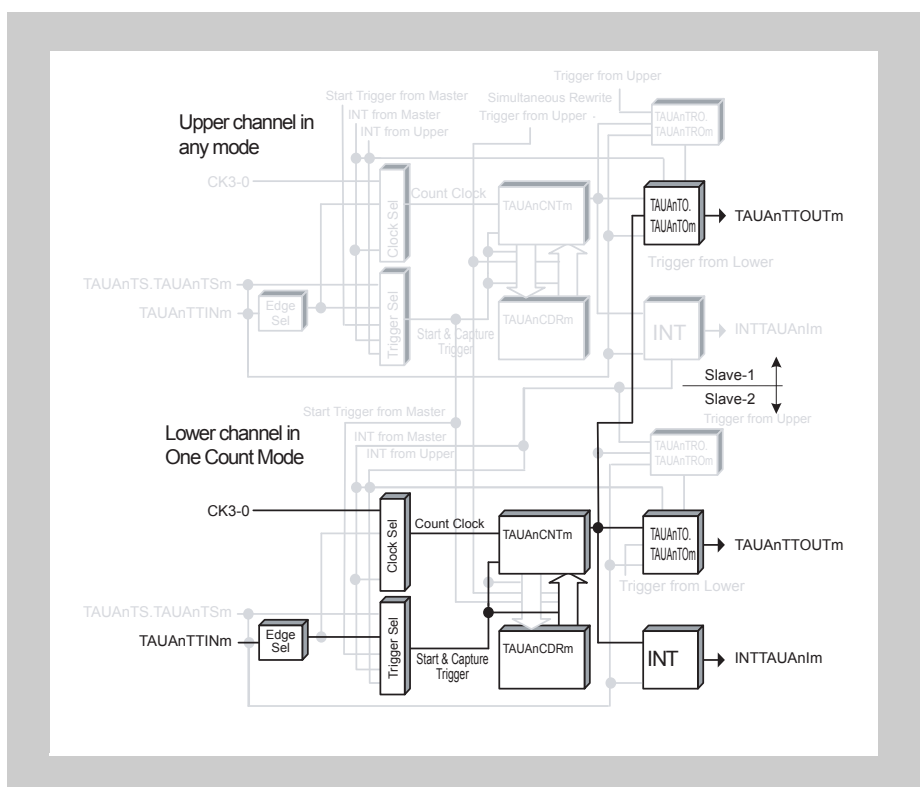

Figure 12-73 Block diagram for One-Phase PWM Output Function

The following settings apply to the general timing diagram:

- Rising and falling edge detection = high width measurement (TAUAnCMURm.TAUAnTIS[1:0] = 11_B)

For these settings, signals are assumed to be active when at high level.

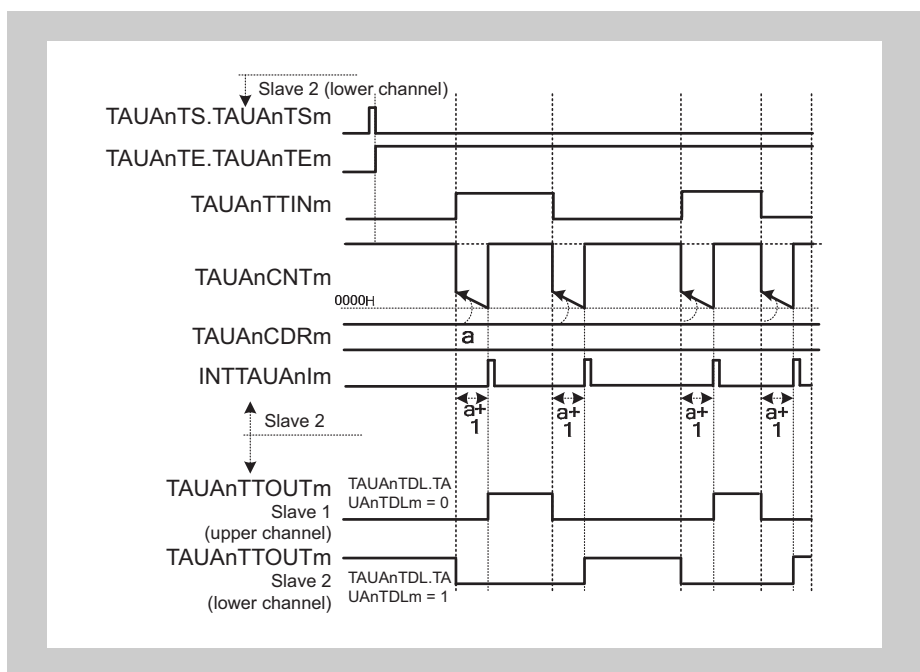

Figure 12-74 General timing diagram for One-Phase PWM Output Function

(3) Register settings for the lower channel**(a) TAUAnCMORm for the lower channel**

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

														TAUAnTIS[1:0]	

Table 12-85 TAUAnCMURm settings for One-Phase PWM Output Function

Bit name	Setting
TAUAnTIS[1:0]	10: Rising and falling edge detection (low width measurement) 11: Rising and falling edge detection (high width measurement)

(c) Channel output mode for the lower channel**Table 12-86 Control bit settings for Synchronous Channel Output Mode 2 with One-Phase PWM Output**

Bit name	Setting
TAUAnTOE.TAUAnTOEm	1: Enables Independent Channel Output Mode
TAUAnTOM.TAUAnTOMm	1: Synchronous channel output
TAUAnTOC.TAUAnTOCm	1: Operation mode 2
TAUAnTOL.TAUAnTOLm	0: Positive logic 1: Inverted logic
TAUAnTDE.TAUAnTDEm	1: Enables dead time operation
TAUAnTDM.TAUAnTDMm	1: Dead time is added upon detection of a TAUAnTTINm input edge from a lower odd channel
TAUAnTDL.TAUAnTDLm	0: An interrupt is the TAUAnTTOUTm set trigger and a valid TAUAnTTINm edge is the TAUAnTTOUTm reset trigger 1: A valid TAUAnTTINm edge is the TAUAnTTOUTm set trigger and an interrupt is the TAUAnTTOUTm reset trigger
TAUAnTRE.TAUAnTREm	0: Disables real-time output
TAUAnTRO.TAUAnTROM	0: When real-time output is disabled (TAUAnTRE.TAUAnTREm = 0), set these bits to 0
TAUAnTRC.TAUAnTRCm	
TAUAnTME.TAUAnTMEem	0: Disables modulation

Caution For TAUAnTDL.TAUAnTDLm, specify the setting that is opposite that of the upper channel.

(d) Simultaneous rewrite for the lower channel

The simultaneous rewrite registers (TAUAnRDE, TAUAnRDS, TAUAnRDM, and TAUAnRDC) cannot be used with the One-Phase PWM Output Function. Therefore, these registers must be set to 0.

Table 12-87 Simultaneous rewrite settings for One-Phase PWM Output Function

Bit name	Setting
TAUAnRDE.TAUAnRDEm	0: Disables simultaneous rewrite
TAUAnRDS.TAUAnRDSm	0: When simultaneous rewrite is disabled (TAUAnRDE.TAUAnRDEm = 0), set these bits to 0
TAUAnRDM.TAUAnRDMm	
TAUAnRDC.TAUAnRDCm	

(4) Register settings for the upper channel(s)**(a) TAUAnCMORm for the upper channel(s)**

The TAUAnCMORm register of the upper channel(s) can be set arbitrarily.

(b) TAUAnCMURm for the upper channel(s)

The TAUAnCMURm register of the upper channel(s) can be set arbitrarily.

(c) Channel output mode for the upper channel(s)

Table 12-88 Control bit settings for upper channel(s) for Synchronous Channel Output Mode 2 with One-Phase PWM Output

Bit name	Setting
TAUAnTOE.TAUAnTOEm	1: Enables Independent Channel Output Mode
TAUAnTOM.TAUAnTOMm	1: Synchronous channel output

TAUAnTDE.TAUAnTDEm	1: Enables dead time operation
TAUAnTDM.TAUAnTDMm	1: Dead time is added upon detection of a TAUAnTTINm input edge from a lower odd channel
TAUAnTDL.TAUAnTDLm	0: An interrupt on the lower channel is the TAUAnTTOUTm set trigger and a valid TAUAnTTINm edge on the lower channel is the TAUAnTTOUTm reset trigger 1: A valid TAUAnTTINm edge on the lower channel is the TAUAnTTOUTm set trigger and an interrupt on the lower channel is the TAUAnTTOUTm reset trigger
TAUAnTRE.TAUAnTREM	0: Disables real-time output
TAUAnTRO.TAUAnTROM	0: When real-time output is disabled (TAUAnTRE.TAUAnTREM = 0), set these bits to 0
TAUAnTRC.TAUAnTRCm	
TAUAnTME.TAUAnTMEEm	0: Disables modulation

Caution For TAUAnTDL.TAUAnTDLm, specify the setting that is opposite that of the lower channel.

(d) Simultaneous rewrite for the upper channel(s)

The simultaneous rewrite registers of the upper channel(s) can be set arbitrarily.

(5) Operating procedure for One-phase PWM Output Function

Table 12-89 Operating procedure for One-phase PWM Output Function

	Operation	Status of TAUAn
Initial channel setting	Set the TAUAnCMORm register and TAUAnCMURm registers for the lower channel as described in <i>Table 12-84 "TAUAnCMORm settings for One-Phase PWM Output Function" on page 571</i> and <i>Table 12-85 "TAUAnCMURm settings for One-Phase PWM Output Function" on page 571</i>	Channel operation is stopped.
	Set the TAUAnCMORm register and TAUAnCMURm registers for the upper channel as described in (4) <i>"Register settings for the upper channel(s)" on page 573</i>	
	Set the value of the TAUAnCDRm register	
	Set the channel output mode for the upper and lower channel by setting the control bits as described in <i>Table 12-86 "Control bit settings for Synchronous Channel Output Mode 2 with One-Phase PWM Output" on page 572</i>	
Restart	Start operation	
	<p>Set TAUAnTOE.TAUAnTOEm (slave channels 1 and 2) to 1 (at operation restart only). Set TAUAnTS.TAUAnTSm = 1 for slave channel 2. TAUAnTS.TAUAnTSm is a trigger bit, so it is automatically cleared to 0.</p> <p>Detection of TAUAnTTINm start edge</p>	<p>TAUAnTE.TAUAnTEm is set to 1 (slave channel 2) and TAUAnCNTm waits for TAUAnTTINm start edge detection. TAUAnCNTm loads the TAUAnCDRm value.</p>
During operation	<p>The value of the TAUAnCDRm register can be changed at any time. The TAUAnCNTm register can be read at any time.</p>	<p>TAUAnCNTm of slave channel 2 counts down. When it reaches 0000_H:</p> <ul style="list-style-type: none"> • INTTAUAnIm is generated. • TAUAnCNTm stops counting. <p>The TAUAnTTOUTm level is changed through the TAUAnTTINm edge detection signal and the INTTAUAnIm signal from slave channel 2 to output a one-phase PWM waveform with dead time. Afterwards, this procedure is repeated.</p>
	Stop operation	<p>Set TAUAnTT.TAUAnTTm = 1 for slave channel 2. TAUAnTT.TAUAnTTm is a trigger bit, so it is automatically cleared to 0.</p>

12.20 Other Independent Channel Functions

This chapter describes a function that generates an interrupt when a certain number of TAUAnTTINm pulses has occurred, a function that divides the frequency of TAUAnTTINm, and a function that measures the duration between the function start and a TAUAnTTINm input signal:

- 12.20.1 *“External Event Count Function”*
- 12.20.2 *“Clock Divide Function”*
- 12.20.3 *“TAUAnTTINm Input Position Detection Function”*

12.20.1 External Event Count Function

(1) Overview

Summary This function is used as an event timer. It generates an interrupt (INTTAUAnIm) when a specific number of TAUAnTTINm input pulses has occurred.

Prerequisites

- The operation mode must be set to Event Count Mode. Refer to *Table 12-90 “TAUAnCMORm settings for External Event Count Function” on page 578*.
- TAUAnTTOUTm is not used for this function.

Description The counter is enabled by setting the channel trigger bit (TAUAnTS.TAUAnTSm) to 1. This in turn sets TAUAnTE.TAUAnTEm = 1, enabling count operation. When the counter starts, the current value of TAUAnCDRm is loaded to TAUAnCNTm.

When a valid TAUAnTTINm input edge is detected, the value of TAUAnCNTm reduces by 1. TAUAnCNTm retains this value until a valid TAUAnTTINm input edge is detected or the counter is restarted.

When the counter value reaches 0000_H, INTTAUAnIm is generated.

TAUAnCNTm loads the TAUAnCDRm value, and then subsequently continues operation.

The counter can be stopped by setting TAUAnTT.TAUAnTTm to 1, which in turn sets TAUAnTE.TAUAnTEm to 0. TAUAnCNTm stops and retains its value. The counter can be restarted by setting TAUAnTS.TAUAnTSm to 1. The counter can also be restarted without stopping it first (forced restart) by setting TAUAnTS.TAUAnTSm to 1 during operation.

The value of TAUAnCDRm can be rewritten at any time, and the changed value of TAUAnCDRm is applied the next time the counter starts to count down.

Conditions The type of edge used as the trigger is specified by the TAUAnCMURm.TAUAnTIS[1:0] bits:

- If TAUAnCMURm.TAUAnTIS[1:0] = 00_B, the falling edges are counted.
- If TAUAnCMURm.TAUAnTIS[1:0] = 01_B, the rising edges are counted.
- If TAUAnCMURm.TAUAnTIS[1:0] = 10_B, the rising and falling edges are counted.

(2) Equations

Number of valid edges,
detected before INTTAUAnIm is generated = TAUAnCDRm + 1

(3) Block diagram and general timing diagram

Figure 12-75 Block diagram for External Event Count Function

The following settings apply to the general timing diagram:

- Rising edge detection (TAUAnCMURm.TAUAnTIS[1:0] = 01_B)

Bit name	Setting
TAUAnCKS[1:0]	00: Operation clock = CK0 01: Operation clock = CK1 10: Operation clock = CK2 11: Operation clock = CK3
TAUAnCCS[1:0]	01: Valid TAUAnTTINm input edge is used as the count clock
TAUAnMAS	0: Not used, so set to 0
TAUAnSTS[2:0]	000: Counter triggered by software trigger
TAUAnCOS[1:0]	00: Not used, so set to 00
TAUAnMD[4:1]	0011: Event Count Mode
TAUAnMDO	0: INTTAUAnIm not generated at operation start

(b) TAUAnCMURm

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
														-	TAUAnTIS[1:0]

Table 12-91 TAUAnCMURm settings for External Event Count Function

Bit name	Setting
TAUAnTIS[1:0]	00: Falling edge 01: Rising edge 10: Rising and falling edge

(c) Channel output mode

The channel output mode is not used by this function. However, it can be used in Independent Channel Output Mode Controlled by Software.

(d) Simultaneous rewrite

The simultaneous rewrite registers (TAUAnRDE, TAUAnRDS, TAUAnRDM, and TAUAnRDC) cannot be used with the External Event Count Function. Therefore, these registers must be set to 0.

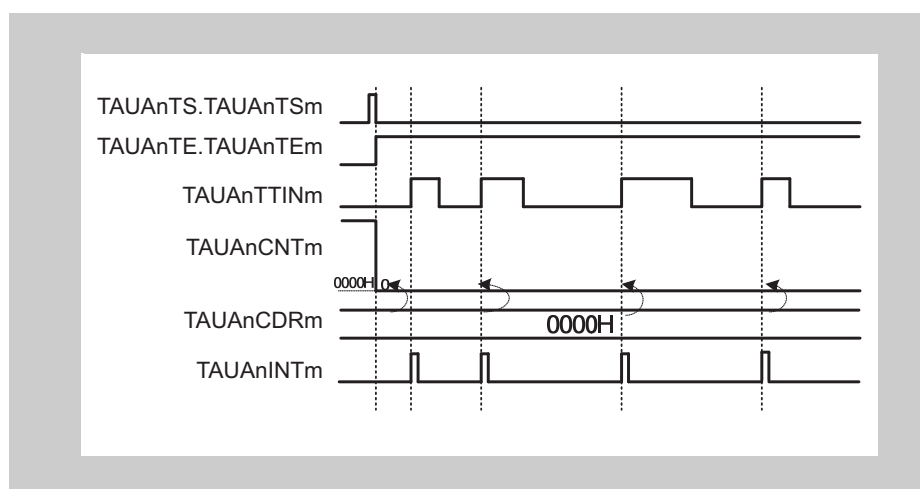

Table 12-92 Simultaneous rewrite settings for External Event Count Function

Bit name	Setting
TAUAnRDE.TAUAnRDEm	0: Disables simultaneous rewrite
TAUAnRDS.TAUAnRDSm	0: When simultaneous rewrite is disabled (TAUAnRDE.TAUAnRDEm = 0), set these bits to 0
TAUAnRDM.TAUAnRDMm	
TAUAnRDC.TAUAnRDCm	

(5) Operating procedure for External Event Count Function**Table 12-93 Operating procedure for External Event Count Function**

	Operation	Status of TAUAn
Initial channel setting	Set the TAUAnCMORm register and TAUAnCMURm registers as described in <i>Table 12-90 "TAUAnCMORm settings for External Event Count Function" on page 578</i> and <i>Table 12-91 "TAUAnCMURm settings for External Event Count Function" on page 578</i> Set the value of the TAUAnCDRm register	Channel operation is stopped.
Start operation	Set TAUAnTS.TAUAnTSm to 1. TAUAnTS.TAUAnTSm is a trigger bit, so it is automatically cleared to 0.	TAUAnTE.TAUAnTEm is set to 1 and the counter starts. TAUAnCNTm loads the TAUAnCDRm value, and then waits for detection of the TAUAnTTINm input edge.
During operation	Detection of TAUAnTTINm edges. The value of TAUAnCDRm can be changed at any time. The TAUAnCNTm register can be read at any time.	TAUAnCNTm performs count-down operation each time a TAUAnTTINm input edge is detected. When the counter reaches 0000 _H : <ul style="list-style-type: none"> TAUAnCNTm loads the TAUAnCDRm value, and then continues count operation. INTTAUANIm is generated. Afterwards, this procedure is repeated.
Stop operation	Set TAUAnTT.TAUAnTTm to 1. TAUAnTT.TAUAnTTm is a trigger bit, so it is automatically cleared to 0.	TAUAnTE.TAUAnTEm is cleared to 0 and the counter stops. TAUAnCNTm stops and retains its current value.

Restart

(6) Specific timing diagrams**(a) TAUAnCDRm = 0000_H****Figure 12-77** TAUAnCDRm = 0000_H, TAUAnCMURm.TAUAnTIS[1:0] = 01_B

- If 0000_H = TAUAnCDRm, 0000_H is loaded to TAUAnCNTm every time a valid TAUAnTTINm input edge is detected.

This means, INTTAUAnIm is generated every time a valid TAUAnTTINm input edge is detected.

(b) Operation stop and restart**Figure 12-78** Operation stop and restart, TAUAnCMURm.TAUAnTIS[1:0] = 01_B

- The counter can be stopped by setting TAUAnTT.TAUAnTTm to 1, which in turn sets TAUAnTE.TAUAnTEm to 0.
- TAUAnCNTm stops and the current value is retained. TAUAnTTINm continues and TAUAnCNTm ignores the valid edge.
- The counter can be restarted by setting TAUAnTS.TAUAnTSM to 1. TAUAnCNTm loads the TAUAnCDRm value, and then restarts count operation.

(c) Forced restart

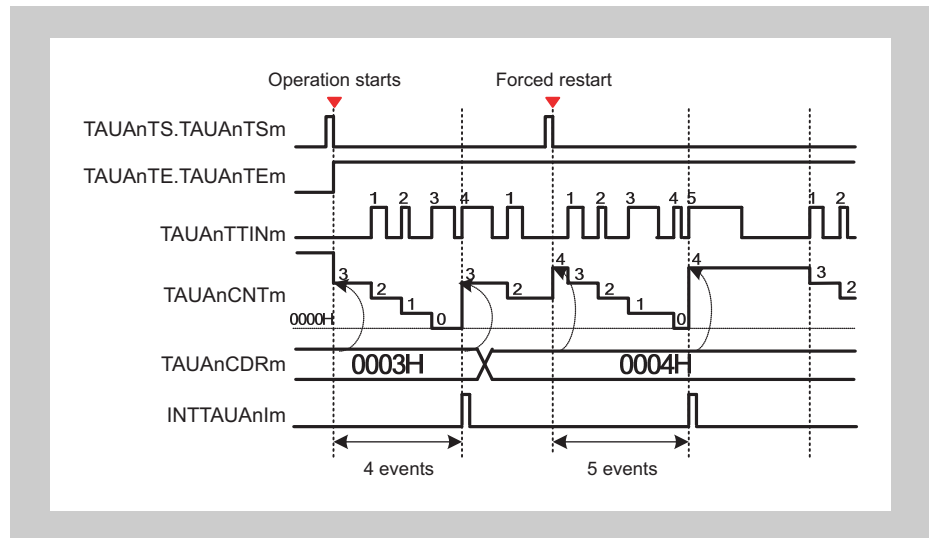

Figure 12-79 Forced restart, $\text{TAUAnCMURm.TAUAnTIS}[1:0] = 01_{\text{B}}$

A forced restart applies a change to TAUAnCDRm immediately.

- The counter can be restarted (without stopping it first), by setting TAUAnTS.TAUAnTSM to 1 during operation.
- The value of TAUAnCDRm is loaded to TAUAnCNTm and the counter awaits the next valid TAUAnTTINm input edge.

12.20.2 Clock Divide Function

(1) Overview

- Summary** This function is used as a frequency divider. The frequency of the input signal TAUAnTTINm is divided by a factor related to TAUAnCDRm, and the resulting signal is output to TAUAnTTOUTm.
- Prerequisites**
- TAUAnTTINm must have a fixed frequency.
 - The operation mode must be set to Interval Timer Mode. Refer to *Table 12-94 “TAUAnCMORm settings for Clock Divide Function” on page 584*.
 - The channel output mode must be set to Independent Channel Output Mode 1. Refer to *12.8 “Channel Output Modes” on page 463*.
- Description** The counter is started by setting the channel trigger bit (TAUAnTS.TAUAnTSM) to 1. This in turn sets TAUAnTE.TAUAnTEM = 1, enabling count operation. The current value of TAUAnCDRm is loaded to TAUAnCNTm and the counter starts to count down from this value, using TAUAnTTINm as the count clock.
- When the counter value reaches 0000_H, INTTAUAnIm is generated and the TAUAnTTOUTm signal toggles. TAUAnCNTm loads the TAUAnCDRm value, and then subsequently continues operation.
- The value of TAUAnCDRm can be rewritten at any time, and the changed value of TAUAnCDRm is applied the next time the function starts to count down.
- The counter can be stopped by setting TAUAnTT.TAUAnTTM = 1, which in turn sets TAUAnTE.TAUAnTEM = 0. TAUAnCNTm and TAUAnTTOUTm stop but retain their values. The function can be restarted by setting TAUAnTS.TAUAnTSM = 1. The counter can also be forcibly restarted (without stopping it first) by setting TAUAnTS.TAUAnTSM = 1 during operation.
- Conditions** If the TAUAnCMORm.TAUAnMD0 bit is set to 0, the first interrupt after a start or restart is not generated, and therefore TAUAnTTOUTm does not toggle. This results in an inverted TAUAnTTOUTm signal compared to when TAUAnCMORm.TAUAnMD0 is set to 1. For details refer to *12.10 “TAUAnTTOUTm Output and INTTAUAnIm Generation when Counter Starts or Restarts” on page 475*.
- Note** The input TAUAnTTINm is sampled at the frequency of the operation clock, specified by TAUAnCMORm.TAUAnCKS[1:0] bits. As a result, the output cycle of TAUAnTTOUTm has an error of ± 1 operation clock cycle.

(2) Equations

- When rising edge detection is selected:

$$\text{TAUAnTTOUTm frequency} = \text{TAUAnTTINm frequency} / [(\text{TAUAnCDRm} + 1) \times 2]$$
- When falling edge detection is selected:

$$\text{TAUAnTTOUTm frequency} = \text{TAUAnTTINm frequency} / [(\text{TAUAnCDRm} + 1) \times 2]$$
- When rising and falling edge detection is selected:

$$\text{TAUAnTTOUTm frequency} = \text{TAUAnTTINm frequency} / (\text{TAUAnCDRm} + 1)$$

(3) Block diagram and general timing diagram

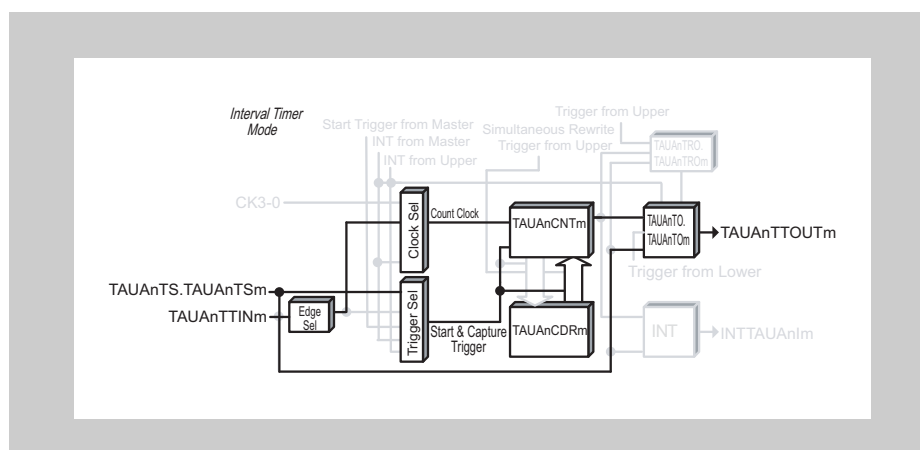

Figure 12-80 Block diagram for Clock Divide Function

The following settings apply to the general timing diagram:

- INTTAUAnIm generated at operation start (TAUAnCMORm.TAUAnMD0 = 1)
- Rising edge detection (TAUAnCMURm.TAUAnTIS[1:0] = 01_B)

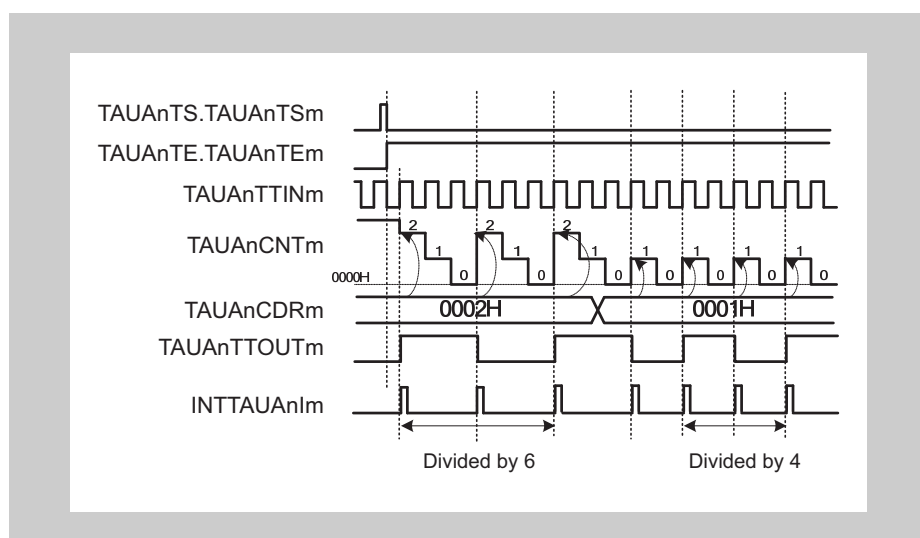

Figure 12-81 General timing diagram for Clock Divide Function

(c) Channel output mode**Table 12-96 Control bit settings for Independent Channel Output Mode 1**

Bit name	Setting
TAUAnTOE.TAUAnTOEm	1: Enables Independent Channel Output Mode
TAUAnTOM.TAUAnTOMm	0: Independent channel output
TAUAnTOC.TAUAnTOCm	0: Operation mode 1 (= Toggle mode if TAUAnTOM.TAUAnTOMm = 0)
TAUAnTOL.TAUAnTOLm	0: Positive logic
TAUAnTDE.TAUAnTDEm	0: Disables dead time operation
TAUAnTDM.TAUAnTDMm	0: When dead time operation is disabled (TAUAnTDE.TAUAnTDEm = 0), set these bits to 0
TAUAnTDL.TAUAnTDLm	
TAUAnTRE.TAUAnTREm	0: Disables real-time output
TAUAnTRO.TAUAnTROM	0: When real-time output is disabled (TAUAnTRE.TAUAnTREm = 0), set these bits to 0
TAUAnTRC.TAUAnTRCm	
TAUAnTME.TAUAnTMEm	0: Disables modulation

(d) Simultaneous rewrite

The simultaneous rewrite registers (TAUAnRDE, TAUAnRDS, TAUAnRDM, and TAUAnRDC) cannot be used with the Clock Divide Function. Therefore, these registers must be set to 0.

Table 12-97 Simultaneous rewrite settings for Clock Divide function

Bit name	Setting
TAUAnRDE.TAUAnRDEm	0: Disables simultaneous rewrite
TAUAnRDS.TAUAnRDSm	0: When simultaneous rewrite is disabled (TAUAnRDE.TAUAnRDEm = 0), set these bits to 0
TAUAnRDM.TAUAnRDMm	
TAUAnRDC.TAUAnRDCm	

(5) Operating procedure for Clock Divide Function

Table 12-98 Operating procedure for Clock Divide Function

	Operation	Status of TAUAn
Restart →	Initial channel setting Set the TAUAnCMORm register and TAUAnCMURm registers as described in Table 12-94 "TAUAnCMORm settings for Clock Divide Function" on page 584 and Table 12-95 "TAUAnCMURm settings for Clock Divide Function" on page 584 Set the value of the TAUAnCDRm register Set the channel output mode by setting the control bits as described in Table 12-96 "Control bit settings for Independent Channel Output Mode 1" on page 585	Channel operation is stopped.
	Start operation Set TAUAnTS.TAUAnTSM to 1. TAUAnTS.TAUAnTSM is a trigger bit, so it is automatically cleared to 0.	TAUAnTE.TAUAnTEm is set to 1 and the counter starts. TAUAnCNTm loads the TAUAnCDRm value. When TAUAnCMORm.TAUAnMD0 is set to 1, INTTAUAnIm is generated and TAUAnTTOUTm toggles.
	During operation The value of TAUAnCDRm can be changed at any time. The TAUAnCNTm register can be read at all times.	When a TAUAnTTINm input edge is detected, TAUAnCNTm counts down. When the counter reaches 0000H: <ul style="list-style-type: none"> TAUAnCNTm loads the TAUAnCDRm value, and then continues count operation. INTTAUAnIm is generated. TAUAnTTOUTm toggles. Afterwards, this procedure is repeated.
	Stop operation Set TAUAnTT.TAUAnTTm to 1. TAUAnTT.TAUAnTTm is a trigger bit, so it is automatically cleared to 0.	TAUAnTE.TAUAnTEm is cleared to 0 and the counter stops. TAUAnCNTm stops and both it and TAUAnTTOUTm retain their current values.

(6) Specific timing diagrams

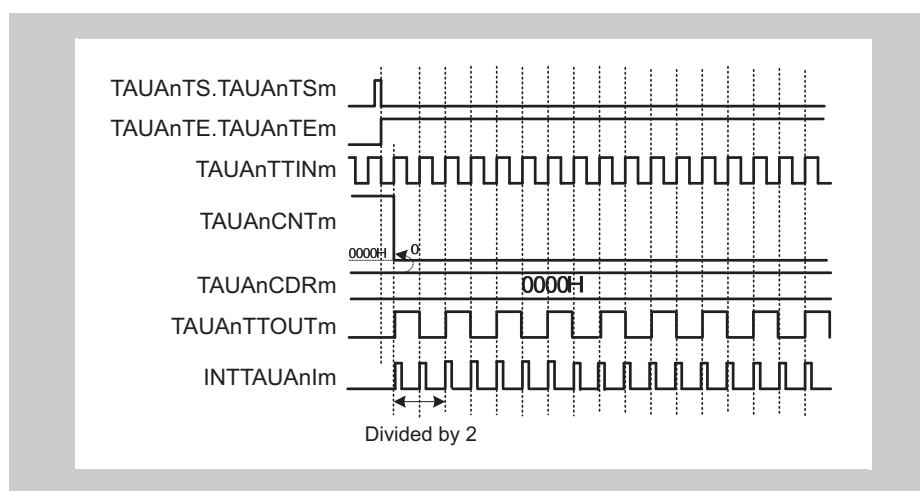

(a) $\text{TAUAnCDRm} = 0000_{\text{H}}$ 

Figure 12-82 $\text{TAUAnCDRm} = 0000_{\text{H}}$, $\text{TAUAnCMORm.TAUAnMD0} = 1$,
 $\text{TAUAnCMURm.TAUAnTIS}[1:0] = 01_{\text{B}}$

- If TAUAnCDRm is 0000_{H} , TAUAnCNTm is also always 0000_{H} .
- INTTAUAnIm is generated every count clock, resulting in TAUAnTTOUTm toggling every count clock.

Figure 12-82 “ $\text{TAUAnCDRm} = 0000_{\text{H}}$, $\text{TAUAnCMORm.TAUAnMD0} = 1$, $\text{TAUAnCMURm.TAUAnTIS}[1:0] = 01_{\text{B}}$ ” shows the approximate operation timing. In actuality, because there is delay due to the noise filter and synchronizer between the TAUAnIm pin and TAUAn , there is delay between TINm detection and TOUTm output.

(b) Restart

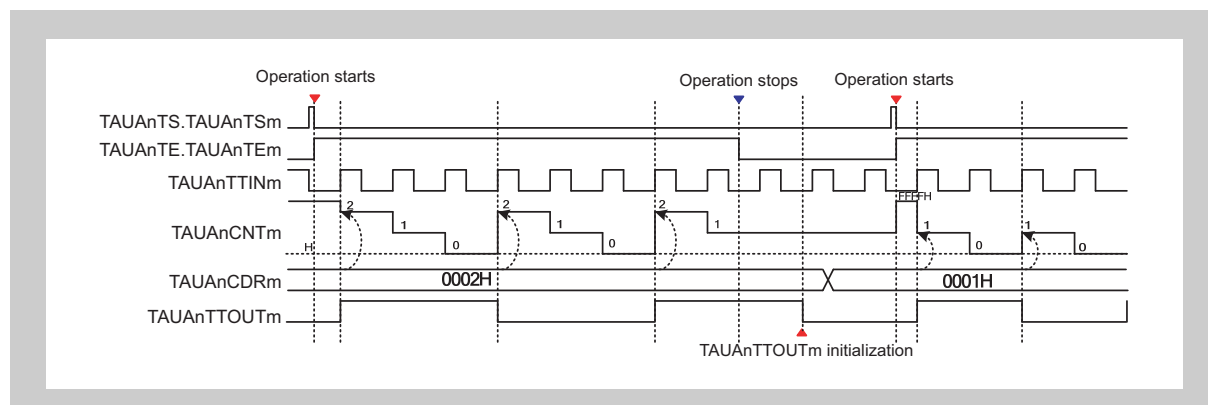

Figure 12-83 Restart, $\text{TAUAnCMORm.TAUAnMD0} = 1$,
 $\text{TAUAnCMURm.TAUAnTIS}[1:0] = 01_{\text{B}}$

To reset the value of TAUAnTTOUTm :

- Set $\text{TAUAnTOE.TAUAnTOEm} = 0$ when the counter is stopped ($\text{TAUAnTE.TAUAnTEm} = 0$)
- Then write the either 0 or 1 to TAUAnTO.TAUAnTOm to set the new start value of TAUAnTTOUTm

12.20.3 TAUAnTTINm Input Position Detection Function

(1) Overview

Summary This function measures the duration between the function start and a TAUAnTTINm input signal.

- Prerequisites**
- The operation mode must be set to Count Capture Mode. Refer to *Table 12-99 "TAUAnCMORm settings for TAUAnTTINm Input Position Detection Function" on page 590*.
 - TAUAnTTOUTm is not used for this function.

Description The counter is enabled by setting the channel trigger bit (TAUAnTS.TAUAnTSm) to 1. This in turn sets TAUAnTE.TAUAnTEm = 1, enabling count operation. The counter starts to count from 0000_H. When a valid TAUAnTTINm input stop edge is detected, the current TAUAnCNTm value is loaded to TAUAnCDRm and an interrupt (INTTAUAnIm) is generated. The counter continues counting.

When the counter reaches FFFF_H, the bit TAUAnCSRm.TAUAnOVF is set to 1 and the counter restarts from 0000_H. TAUAnCSRm.TAUAnOVF is cleared by setting TAUAnCSCm.CLOV.

Conditions If the TAUAnCMORm.TAUAnMD0 bit is set to 0, the first interrupt after a start or restart is not generated. For details refer to *12.10 "TAUAnTTOUTm Output and INTTAUAnIm Generation when Counter Starts or Restarts" on page 475*.

(2) Equations

Function duration at a TAUAnTTINm input pulse =

count clock cycle × [(FFFF_H+1 × TAUAnCSRm.TAUAnOVF) + (TAUAnCDRm capture value + 1)]

Caution If a capture signal in input when the counter value reaches the upper limit (0FFFF_H), the overflow flag (OVF) that should be set in response to the occurrence of an overflow in the next count clock cycle will not be set. The OVF flag is set normally at all other times.

<R>

(3) Block diagram and general timing diagram

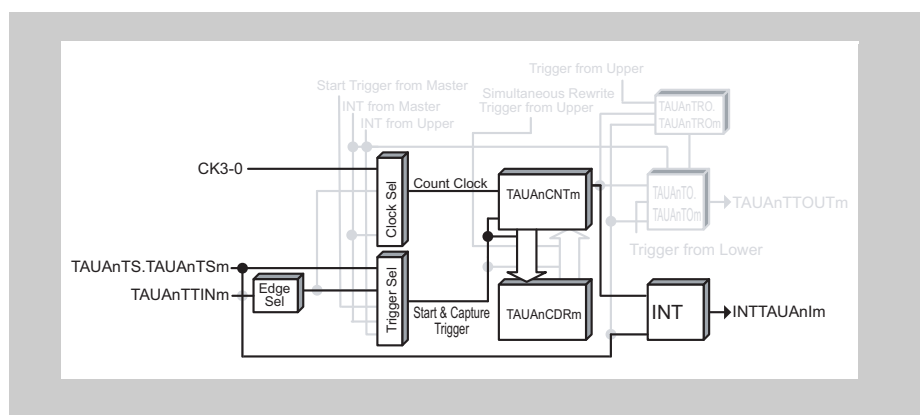

Figure 12-84 Block diagram for TAUAnTTINm Input Position Detection Function

The following settings apply to the general timing diagram:

- INTTAUAnIm not generated at operation start (TAUAnCMORm.TAUAnMD0 = 0)
- Falling edge detection (TAUAnCMURm.TAUAnTIS[1:0] = 00_B)

Figure 12-85 General timing diagram for TAUAnTTINm Input Position Detection Function

(4) Register settings**(a) TAUAnCMORm**

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
TAUAn CKS[1:0]		TAUAn CCS[1:0]		TAUAn MAS	TAUAnSTS[2:0]			TAUAn COS[1:0]		-	TAUAnMD[4:1]				TAUAn MDO

Table 12-99 TAUAnCMORm settings for TAUAnTTINm Input Position Detection Function

Bit name	Setting
TAUAnCKS[1:0]	00: Operation clock = CK0 01: Operation clock = CK1 10: Operation clock = CK2 11: Operation clock = CK3
TAUAnCCS[1:0]	00: Operation clock is used as the count clock
TAUAnMAS	0: Not used, so set to 0
TAUAnSTS[2:0]	001: Valid TAUAnTTINm input edge signal is used as the external capture trigger
TAUAnCOS[1:0]	01: Overflow (TAUAnCSRm.OVF) set upon counter overflow and cleared by a CPU instruction

(b) TAUAnCMURm

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
														TAUAnTIS[1:0]	

Table 12-100 TAUAnCMURm settings for TAUAnTTINm Input Position Detection Function

Bit name	Setting
TAUAnTIS[1:0]	00: Falling edge detection 01: Rising edge detection 10: Rising and falling edge detection

(c) Channel output mode

The channel output mode is not used by this function. However, it can be used in Independent Channel Output Mode Controlled by Software.

(d) Simultaneous rewrite

The simultaneous rewrite registers (TAUAnRDE, TAUAnRDS, TAUAnRDM, and TAUAnRDC) cannot be used with the TAUAnTTINm Input Position Detection Function. Therefore, these registers must be set to 0.

Table 12-101 Simultaneous rewrite settings for TAUAnTTINm Input Position Detection Function

Bit name	Setting
TAUAnRDE.TAUAnRDEm	0: Disables simultaneous rewrite
TAUAnRDS.TAUAnRDSm	0: When simultaneous rewrite is disabled (TAUAnRDE.TAUAnRDEm = 0), set these bits to 0
TAUAnRDM.TAUAnRDMm	
TAUAnRDC.TAUAnRDCm	

(5) Operating procedure for TAUAnTTINm Input Position Detection Function

Table 12-102 Operating procedure for TAUAnTTINm Input Position Detection Function

	Operation	Status of TAUAn
Initial channel setting	Set the TAUAnCMORm register and TAUAnCMURm registers as described in <i>Table 12-99 "TAUAnCMORm settings for TAUAnTTINm Input Position Detection Function" on page 590</i> and <i>Table 12-100 "TAUAnCMURm settings for TAUAnTTINm Input Position Detection Function" on page 590</i> Set the value of the TAUAnCDRm register	Channel operation is stopped.
Start operation	Set TAUAnTS.TAUAnTSM to 1. TAUAnTS.TAUAnTSM is a trigger bit, so it is automatically cleared to 0.	TAUAnTE.TAUAnTEm is set to 1 and the counter starts. INTTAUAnIm is generated when TAUAnCMORm.TAUAnMD0 is set to 1.
During operation	The TAUAnCMURm.TAUAnTIS[1:0] bits can be changed at any time. The TAUAnCDRm and TAUAnCSRm registers can be read at any time. The TAUAnCSC.CLOV bit can be set to 1.	TAUAnCNTm starts to count up from 0000 _H . When a TAUAnTTINm valid edge is detected: <ul style="list-style-type: none"> TAUAnCNTm transfers (captures) its value to TAUAnCDRm. INTTAUAnIm is output. The counter value is not cleared to 0000_H and TAUAnCNTm continues count operation. Afterwards, this procedure is repeated.
Stop operation	Set TAUAnTT.TAUAnTTm to 1. TAUAnTT.TAUAnTTm is a trigger bit, so it is automatically cleared to 0.	TAUAnTE.TAUAnTEm is cleared to 0 and the counter stops. TAUAnCNTm stops and both it and TAUAnCSRm.OVF retain their current values.

Restart

(6) Specific timing diagrams

(a) Operation stop and restart

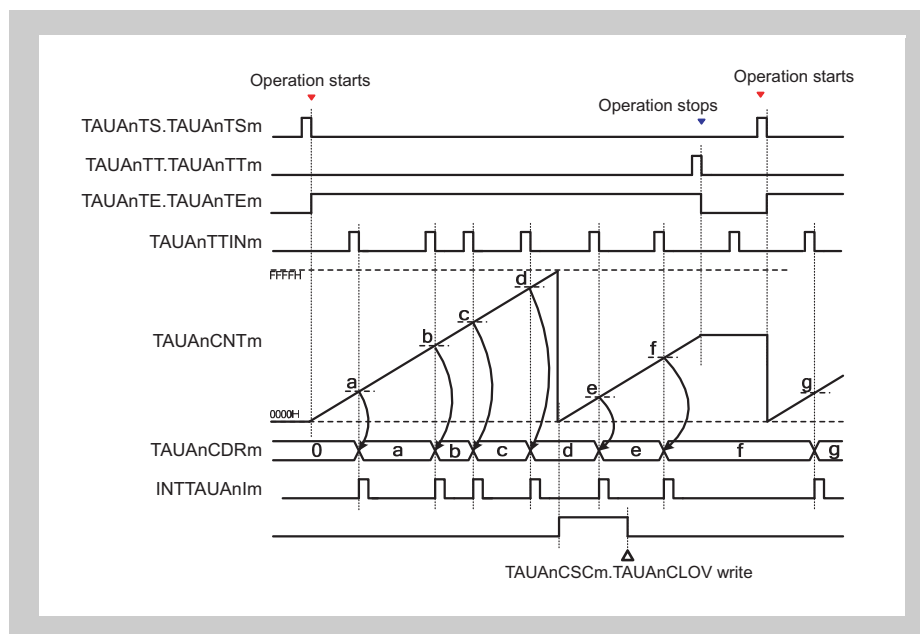

Figure 12-86 Operation stop and restart, TAUAnCMORm.TAUAnMD0 = 0, TAUAnCMURm.TAUAnTIS[1:0] = 00_B

- The counter can be stopped by setting TAUAnTT.TAUAnTTm to 1, which in turn sets TAUAnTE.TAUAnTEm to 0.
- TAUAnCNTm stops and the current value is retained.
- If the counter is stopped, valid TAUAnTTINm input edges are ignored.
- The counter can be restarted by setting TAUAnTS.TAUAnTSm to 1. TAUAnCNTm restarts to count from 0000_H.

12.21 Synchronous Channel Operation Functions

This section lists all the synchronous channel operation functions provided by TAUA. For a general overview of synchronous channel operation, see 12.3 “*Functional Description*” on page 443 .

12.22 Synchronous PWM Signal Functions Triggered at Regular Intervals

This chapter describes functions that generate PWM signals at regular intervals.

- 12.22.1 “*PWM Output Function*”
- 12.22.2 “*Trigger Start PWM Output Function*”
- 12.22.3 “*Delay Pulse Output Function*”
- 12.22.4 “*AD Conversion Trigger Output Function Type 1*”

12.22.1 PWM Output Function

(1) Overview

- Summary** This function generates multiple PWM outputs by using a master and multiple slave channels. It enables the pulse cycle (frequency) and the duty cycle of the TAUAnTTOUTm to be set. The pulse cycle is set in the master channel. The duty cycle is set in the slave channel.
- Prerequisites**
- Two channels
 - The operation mode of the master channel must be set to Interval Timer Mode. Refer to *Table 12-103 “TAUAnCMORm settings for the master channel of the PWM Output Function” on page 597*.
 - The operation mode of the slave channel(s) must be set to One Count Mode. Refer to *Table 12-106 “TAUAnCMORm settings for the slave channel of the PWM Output Function” on page 599*.
 - TAUAnTTOUTm is not used for the master channel of this function.
 - The channel output mode of the slave channel(s) must be set to Synchronous Channel Output Mode 1 (*12.8 “Channel Output Modes” on page 463*).
- Description** The counters are started by setting the channel trigger bits (TAUAnTS.TAUAnTSM) to 1. This in turn sets TAUAnTE.TAUAnTEM = 1, enabling count operation. The current value of TAUAnCDRm is loaded to TAUAnCNTm and the counters start to count down from these values. INTTAUAnIm is generated on the master channel, and PWM output is achieved by setting and resetting TAUAnTTOUTm (slave).
- Master channel:

When the counter of the master channel reaches 0000_H, pulse cycle time has elapsed and INTTAUAnIm is generated. TAUAnCNTm loads the TAUAnCDRm value, and then counts down.
 - Slave channel(s)

The INTTAUAnIm of the master channel triggers the counter of the slave channel(s). The current value of TAUAnCDRm (slave) is loaded to TAUAnCNTm (slave) and the counter starts to count down from this value. The TAUAnTTOUTm signal becomes active.

When the counter reaches 0000_H, i.e. duty time has elapsed, INTTAUAnIm is generated and the TAUAnTTOUTm signal becomes inactive. The counter returns to FFFF_H and awaits the next INTTAUAnIm of the master channel, and thus the start of the next pulse cycle.

The counter can be stopped by setting TAUAnTT.TAUAnTTm to 1 for the master and slave channel(s), which in turn sets TAUAnTE.TAUAnTEM to 0. TAUAnCNTm and TAUAnTTOUTm of master and slave channel(s) stop but retain their values. The counters can be restarted by setting TAUAnTS.TAUAnTSM to 1.
- Conditions** Simultaneous rewrite can be used with this function. Please refer to *12.7 “Simultaneous Rewrite” on page 451*

(2) Equations

Pulse cycle = (TAUAnCDRm (master) + 1) x count clock cycle

Duty cycle [%] = (TAUAnCDRm (slave) / (TAUAnCDRm (master) + 1)) x 100

– Duty cycle = 0 %

TAUAnCDRm (slave) = 0000_H

– Duty cycle = 100 %

TAUAnCDRm (slave) ³ TAUAnCDRm (master) + 1

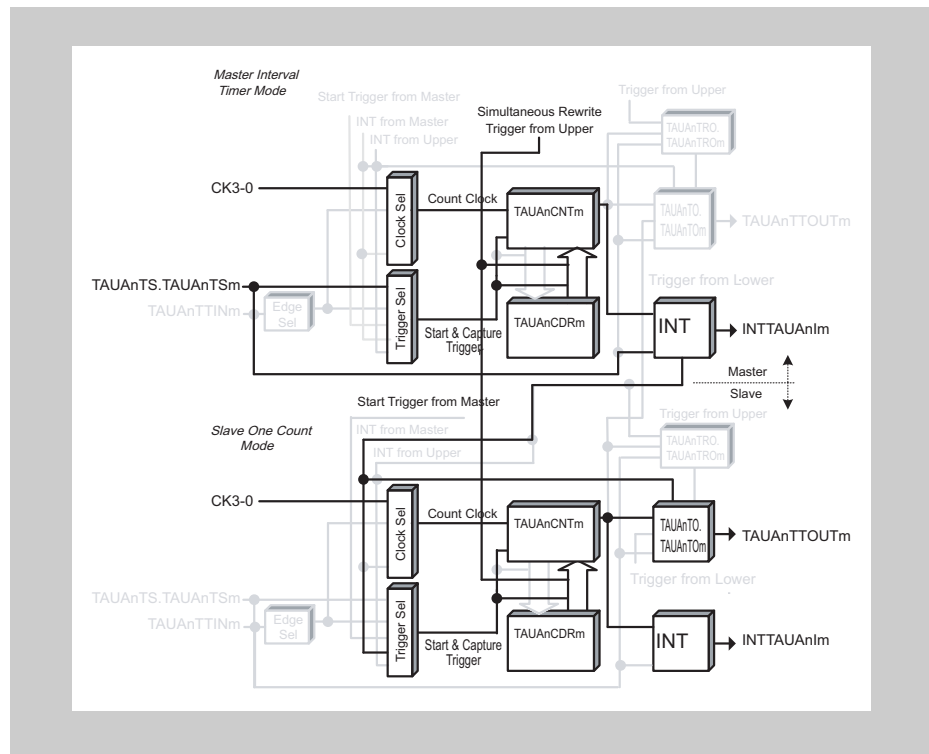

(3) Block diagram and general timing diagram

Figure 12-87 Block diagram for PWM Output Function

The following settings apply to the general timing diagram:

- Slave channel: Positive logic (TAUAnTOL.TAUAnTOLm = 0)

Figure 12-88 General timing diagram for PWM Output Function

Note The interval between the slave channel starting to count and an interrupt being generated is the value of corresponding TAUAnCDRm, whereas for the master channel the interval is the corresponding TAUAnCDRm + 1.

(4) Register settings for the master channel**(a) TAUAnCMORM for the master channel**

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Bit name	Setting
TAUAnTIS[1:0]	00: These are not used, so set them to 00.

(c) Channel output mode for the master channel

The channel output mode is not used by this function. However, it can be used by other functions or in Independent Channel Output Mode Controlled by Software.

(d) Simultaneous rewrite for the master channel

The simultaneous rewrite settings of the master and slave channel must be identical.

Table 12-105 Simultaneous rewrite settings for the master channel of the PWM Output Function

Bit name	Setting
TAUAnRDE.TAUAnRDEm	1: Enables simultaneous rewrite
TAUAnRDS.TAUAnRDSm	0: The master channel is monitored for the simultaneous rewrite trigger 1: An upper channel outside the channel group is monitored for the simultaneous rewrite trigger
TAUAnRDM.TAUAnRDMm	0: The simultaneous rewrite trigger signal is generated when the master channel starts counting
TAUAnRDC.TAUAnRDCm	0: Channel is not monitored for an INTTAUAnIm signal that is used as the simultaneous rewrite trigger. If TAUAnRDS.TAUAnRDSm = 0, the master channel is monitored for the simultaneous rewrite trigger regardless of the value of this bit.

Note If the TAUAnRDS.TAUAnRDSm bit is 1, there must be a channel higher than the master channel that operates with simultaneous rewrite trigger output function type 1.

- Set up the operation as follows:

Channel setting for simultaneous rewrite trigger output function type 1:
TAUAnRDCm = 1, TAUAnRDS = 1

Note that the TAUAnCDR setting for this channel is as follows:

= ((TAUAnCDR setting of master channel subject to simultaneous rewriting + 1) × number of interrupts) - 1

- Master channel: TAUAnRDCm = 0, TAUAnRDS = 1
- Slave channel: TAUAnRDCm = 0, TAUAnRDS = 1

(5) Register settings for the slave channel(s)**(a) TAUAnCMORM for the slave channel(s)**

TAUAnTRC.TAUAnTRCm	
TAUAnTME.TAUAnTMEm	0: Disables modulation

(d) Simultaneous rewrite for the slave channel(s)

The simultaneous rewrite settings of the master and slave channel must be identical.

Table 12-109 Simultaneous rewrite settings for the slave channel of the PWM Output Function

Bit name	Setting
TAUAnRDE.TAUAnRDEm	1: Enables simultaneous rewrite
TAUAnRDS.TAUAnRDSm	0: The master channel is monitored for the simultaneous rewrite trigger 1: An upper channel outside the channel group is monitored for the simultaneous rewrite trigger
TAUAnRDM.TAUAnRDMm	0: The simultaneous rewrite trigger signal is generated when the master channel starts counting
TAUAnRDC.TAUAnRDCm	0: Channel is not monitored for an INTTAUAnIm signal that is used as the simultaneous rewrite trigger. If TAUAnRDS.TAUAnRDSm = 0, the master channel is monitored for the simultaneous rewrite trigger regardless of the value of this bit.

(6) Operating procedure for PWM Output Function

Table 12-110 Operating procedure for PWM Output Function

	Operation	Status of TAUAn
Restart	Initial channel setting Master channel: set the TAUAnCMORm and TAUAnCMURm registers and the channel output mode as described in (4) "Register settings for the master channel" on page 597 Slave channel: set the TAUAnCMORm and TAUAnCMURm registers and the channel output mode as described in (5) "Register settings for the slave channel(s)" on page 599 Set the values of the TAUAnCDRm registers of all channels	Channel operation is stopped.
	Start operation Set TAUAnTS.TAUAnTSm of the master and slave channels to 1 simultaneously. TAUAnTS.TAUAnTSm is a trigger bit, so it is automatically cleared to 0.	TAUAnTE.TAUAnTEm (master and slave channels) is set to 1 and the counters of the master and slave channels start. INTTAUAnIm is generated on the master channel and TAUAnTTOUTm (slave) becomes active.
	During operation TAUAnCDRm can be changed at any time. TAUAnCNTm and TAUAnRSF.TAUAnRSFm can be read at any time. TAUAnRDT.TAUAnRDTm can be changed during operation.	TAUAnCNTm of the master channel loads TAUAnCDRm, and then counts down. When the counter reaches 0000H: <ul style="list-style-type: none"> INTTAUAnIm (master) is generated. TAUAnCNTm (master) loads the TAUAnCDRm value, and then continues count operation. TAUAnCNTm (slave) loads the TAUAnCDRm value, and then counts down. TAUAnTTOUTm (slave) becomes active. When TAUAnCNTm (slave) reaches 0000H: <ul style="list-style-type: none"> INTTAUAnIm (slave) is generated. TAUAnTTOUTm (slave) becomes inactive.
	Stop operation Set TAUAnTT.TAUAnTTm of the master and slave channels to 1 simultaneously. TAUAnTT.TAUAnTTm is a trigger bit, so it is automatically cleared to 0.	TAUAnTE.TAUAnTEm is cleared to 0 and the counter stops. TAUAnCNTm and TAUAnTTOUTm stop and retain their current values.

(7) Specific timing diagrams

(a) Duty cycle = 0%

Figure 12-89 TAUAnCDRm (slave) = 0000_H,
positive logic (TAUAnTOL.TAUAnTOLm (slave) = 0)

- Every time the master channel generates an interrupt (INTTAUAnIm), 0000_H is loaded to TAUAnCNTm (slave). Therefore, TAUAnCNTm (slave) cannot start to count and TAUAnTTOUTm remains at not active state.
- TAUAnCNTm (slave) loads the TAUAnCDRm value and an interrupt is generated.

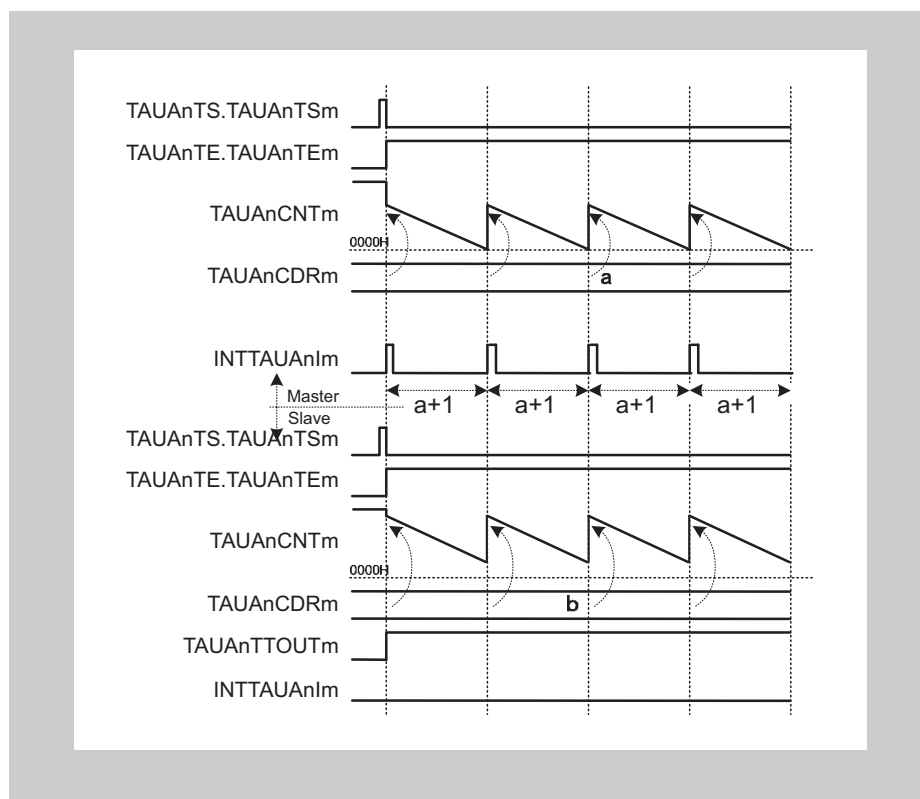

(b) Duty cycle = 100%

Figure 12-90 TAUA nCDRm (slave) ³ TAUA nCDRm (master) + 1, positive logic (TAUA nTOL.TAUA nTOLm (slave) = 0)

- If the value TAUA nCDRm (slave) is higher than the value TAUA nCDRm (master), the counter of the slave channel cannot reach 0000_H and interrupts are not generated. The TAUA nTTOUtm remains at active state.

(c) Stop and restart operation

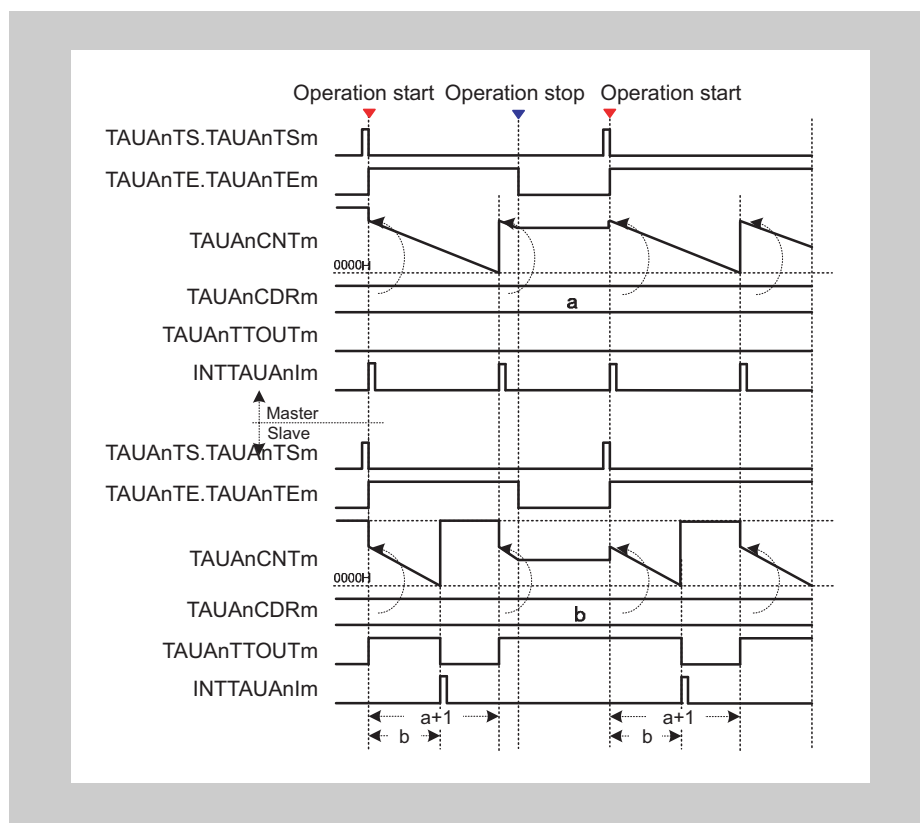

Figure 12-91 Stop and restart operation, positive logic (TAUAnTOL.TAUAnTOLm (slave) = 0)

- The counter can be stopped by setting TAUAnTT.TAUAnTTm of the master and slave channel(s) to 1, which in turn sets TAUAnTE.TAUAnTEM to 0.
- TAUAnCNTm and TAUAnTTOUTm of all channels stop and the current values are retained. No interrupts are generated.
- The counter can be restarted by setting TAUAnTS.TAUAnTSM of master and slave channel(s) to 1. TAUAnCNTm loads the TAUAnCDRm value of master and slave channels, and then starts counting down from this value.

12.22.2 Trigger Start PWM Output Function

(1) Overview

Summary This function generates a PWM output using a master and a slave channel. It enables the pulse cycle (frequency) and the duty cycle of the TAUAnTTOUTm to be set. The duty cycle is specified using the master channel. The pulse width is specified using the slave channel. The Trigger Start PWM Output Function is identical to PWM Output Function except that the master channel of this function can be reset by a valid TAUAnTTINm input edge.

- Prerequisites**
- Two channels
 - The operation mode of the master channel must be set to Interval Timer Mode. Refer to *Table 12-111 “TAUAnCMORm settings for the master channel of the Trigger Start PWM Output Function” on page 608*.
 - The operation mode of the slave channel must be set to One Count Mode. Refer to *Table 12-114 “TAUAnCMORm settings for the slave channel of the Trigger Start PWM Output Function” on page 610*.
 - The channel output mode of the slave channel must be set to Synchronous Channel Output Mode 1. Refer to *12.8 “Channel Output Modes” on page 463*.
 - TAUAnTTOUTm is not used for the master channel of this function.

Description The counters (master and slave) are started by setting the channel trigger bits (TAUAnTS.TAUAnTSm) to 1. This in turn sets TAUAnTE.TAUAnTEm, enabling count operation.

TAUAnCNTm loads the current value of TAUAnCDRm, and then starts counting down from this value. INTTAUAnIm is generated on the master channel, and PWM output is achieved by setting and resetting TAUAnTTOUTm (slave).

- Master channel:

The current value of TAUAnCDRm is loaded to the counter (TAUAnCNTm), INTTAUAnIm is generated and the counter starts to count down from this value.

When the counter reaches 0000_H, pulse cycle time has elapsed, INTTAUAnIm is generated and the TAUAnCNTm (master and slave) load the current TAUAnCDRm values.

If a valid TAUAnTTINm input edge is detected, the counter of the master channel loads the current TAUAnCDRm value, restarts counting down, and then generates an interrupt.

- Slave channel:

When the slave detects an interrupt from the master channel, it starts to count down from the current value of TAUAnCDRm. The TAUAnTTOUTm signal becomes active.

When the counter reaches 0000_H, duty time has elapsed, INTTAUAnIm is generated and the TAUAnTTOUTm signal is reset. The counter returns to FFFF_H and awaits the next INTTAUAnIm of the master channel.

The counter can be stopped by setting TAUAnTT.TAUAnTTm to 1 for the master and slave channel, which in turn sets TAUAnTE.TAUAnTEm to 0. TAUAnCNTm and TAUAnTTOUTm of master and slave channel stop but retain their values. The counters can be restarted by setting TAUAnTS.TAUAnTSm to 1.

Conditions Simultaneous rewrite can be used with this function. Please refer to 12.7 “Simultaneous Rewrite” on page 451

(2) Equations

Pulse cycle = (TAUAnCDRm (master) + 1) x count clock cycle

Duty cycle [%] = [TAUAnCDRm (slave) / (TAUAnCDRm (master) + 1)] x 100

– Duty cycle = 0 %

TAUAnCDRm (slave) = 0000_H

– Duty cycle = 100 %

TAUAnCDRm (slave) ³ TAUAnCDRm (master) + 1

(3) Block diagram and general timing diagram

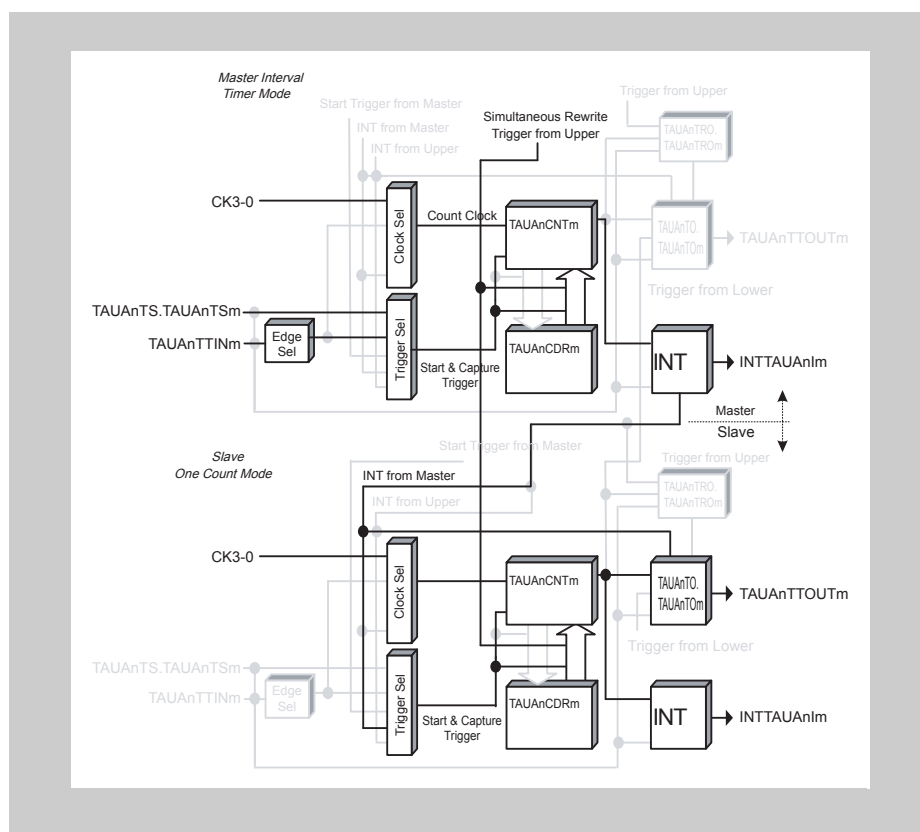

Figure 12-92 Block diagram for Trigger Start PWM Output Function

The following settings apply to the general timing diagram:

- Rising edge detection (TAUAnCMURm.TAUAnTIS[1:0] = 01_B)
- Positive logic (TAUAnTOL.TAUAnTOLm (slave) = 0)

Figure 12-93 General timing diagram for Trigger Start PWM Output Function

TAUAnTME.TAUAnTMEEm	0: Disables modulation

(d) Simultaneous rewrite for the slave channel

The simultaneous rewrite settings of the master and slave channel must be identical.

Table 12-117 Simultaneous rewrite settings for the slave channel of the Trigger Start PWM Output Function

Bit name	Setting
TAUAnRDE.TAUAnRDEm	1: Enables simultaneous rewrite
TAUAnRDS.TAUAnRDSm	0: The master channel is monitored for the simultaneous rewrite trigger 1: An upper channel outside the channel group is monitored for the simultaneous rewrite trigger
TAUAnRDM.TAUAnRDMm	0: The simultaneous rewrite trigger signal is generated when the master channel starts counting
TAUAnRDC.TAUAnRDCm	0: Channel is not monitored for an INTTAUAnIm signal that is used as the simultaneous rewrite trigger. If TAUAnRDS.TAUAnRDSm = 0, the master channel is monitored for the simultaneous rewrite trigger regardless of the value of this bit.

(6) Operating procedure for Trigger Start PWM Output Function

Table 12-118 Operating procedure for Trigger Start PWM Output Function

	Operation	Status of TAUAn
Restart ↑	Initial channel setting Master channel: set the TAUAnCMORm and TAUAnCMURm registers and the channel output mode as described in (4) "Register settings for the master channel" on page 608 Slave channel: set the TAUAnCMORm and TAUAnCMURm registers and the channel output mode as described in (5) "Register settings for the slave channel" on page 610 Set the values of the TAUAnCDRm registers of all channels	Channel operation is stopped.
	Start operation Set TAUAnTS.TAUAnTSm of the master and slave channels to 1 simultaneously. TAUAnTS.TAUAnTSm is a trigger bit, so it is automatically cleared to 0.	TAUAnTE.TAUAnTEm (master and slave channels) is set to 1 and the counters of the master and slave channels start. INTTAUAnIm is generated on the master channel.
	During operation TAUAnCDRm can be changed at any time. TAUAnCNTm and TAUAnRSF.TAUAnRSFm can be read at any time. TAUAnRDT.TAUAnRDTm can be changed during operation.	TAUAnCNTm of the master channel loads TAUAnCDRm, and then counts down. When the counter reaches 0000 _H : <ul style="list-style-type: none"> • INTTAUAnIm (master) is generated. • TAUAnCNTm (master) loads the TAUAnCDRm value, and then continues count operation. • TAUAnCNTm (slave) loads the TAUAnCDRm value, and then starts counting down. • TAUAnTTOUTm (slave) becomes active. When TAUAnCNTm of the slave = 0000 _H : <ul style="list-style-type: none"> • INTTAUAnIm (slave) is generated. • TAUAnTTOUTm (slave) becomes inactive. If a TAUAnTTINm input is detected on the master channel while the TAUAnCNTm of the master channel is counting down: <ul style="list-style-type: none"> • TAUAnCNTm (master and slave) loads the TAUAnCDRm value, and then counts down. • INTTAUAnIm (master) is generated. • TAUAnTTOUTm (slave) becomes active.
	Stop operation Set TAUAnTT.TAUAnTTm of the master and slave channels to 1 simultaneously. TAUAnTT.TAUAnTTm is a trigger bit, so it is automatically cleared to 0.	TAUAnTE.TAUAnTEm is cleared to 0 and the counter stops. TAUAnCNTm and TAUAnTTOUTm stop and retain their current values.

(7) Specific timing diagrams

(a) Duty cycle = 0%

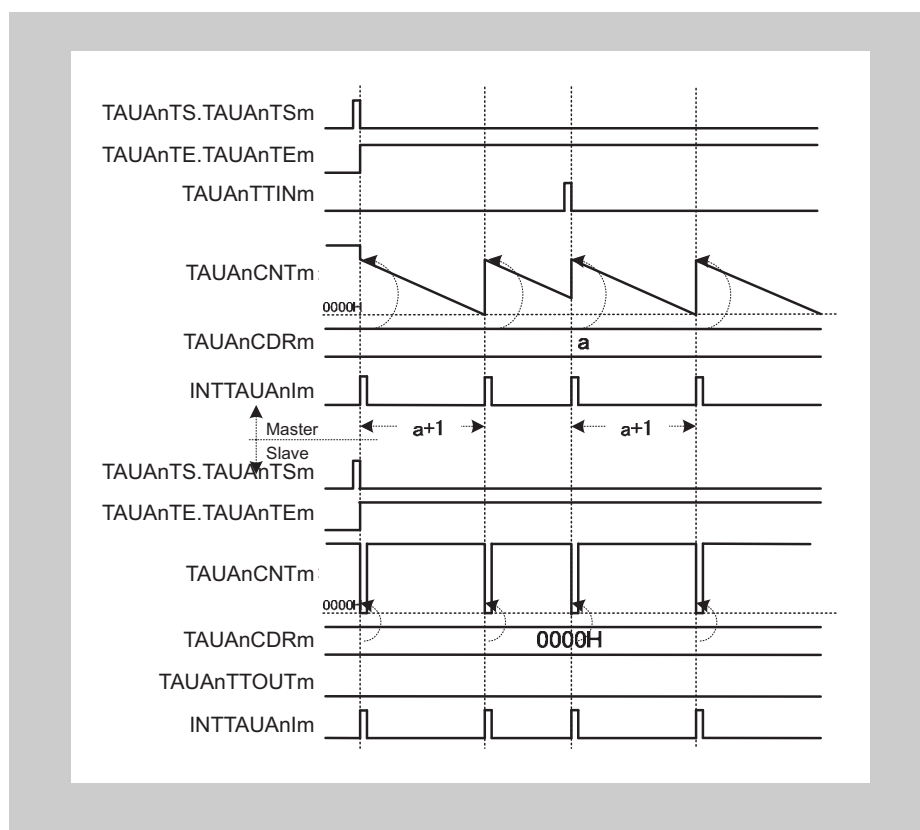

Figure 12-94 TAUAnCDRm (slave) = 0000_H,
 positive logic (TAUAN_{TOL}.TAUAN_{TOLm} (slave) = 0)
 falling edge detection (TAUAN_{CMURm}.TAUAN_{TIS}[1:0] = 00_B)

- Every time the master channel generates an interrupt (INTTAUAN_{Im}), 0000_H is loaded to TAUAnCNT_m (slave). Therefore, TAUAnCNT_m (slave) cannot start to count and TAUAnTTOUT_m remains at not active state.
- TAUAnCNT_m (slave) generates an interrupt every time the value of TAUAnCDR_m is loaded.

The detection of a valid TAUAnTTIN_m input edge has no effect on TAUAnTTOUT_m (slave).

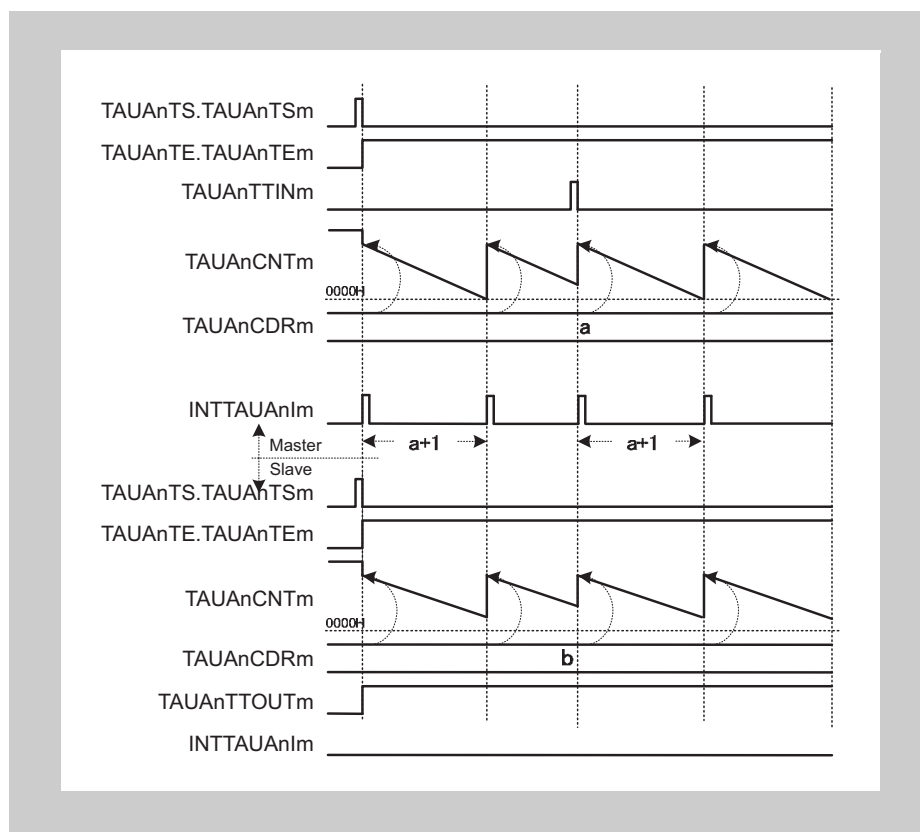

(b) Duty cycle = 100%

Figure 12-95 TAUAnCDRm (slave) ³ TAUAnCDRm (master) + 1,
 positive logic (TAUAnTOL.TAUAnTOLm (slave) = 0)
 falling edge detection (TAUAnCMURm.TAUAnTIS[1:0] = 00_B)

- If the value TAUAnCDRm (slave) is higher than the value TAUAnCDRm (master), the counter of the slave channel cannot reach 0000_H and no interrupt is generated.

The TAUAnTTOUTm remains at active state.

The detection of a valid TAUAnTTINm input edge has no effect on TAUAnTTOUTm (slave).

(c) TAUAnTTINm detection and active slave counter

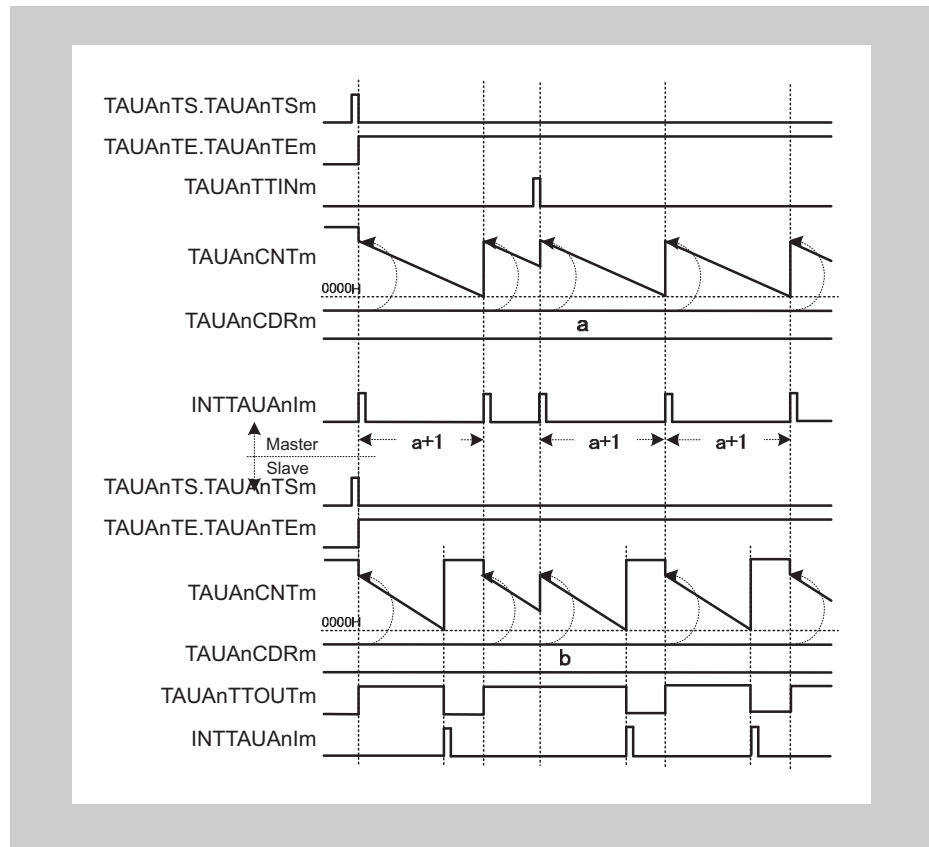

Figure 12-96 Positive logic (TAUAnTOL.TAUAnTOLm (slave) = 0), falling edge detection (TAUAnCMURm.TAUAnTIS[1:0] = 00_B)

- If TAUAnCNTm (slave) loads the value of TAUAnCDRm (slave) while it is counting down, TAUAnTTOUTm does not change and extends the duty cycle.

The duty cycle does not correspond to the value of the data register of the slave channel.

12.22.3 Delay Pulse Output Function

(1) Overview

Summary This function outputs two signals. The reference signal has a defined pulse width and pulse cycle specified using the master channel and slave channel 1. Slave channels 2 and 3 output the reference signal with a specified delay. The delay signal is identical to the reference signal, but delayed by amount specified in slave channel 2.

The signal values are specified in the following way:

- The pulse cycle is specified using the master channel.
- The duty cycle of the reference signal is specified using slave channel 1. The duty cycle of the delay signal is specified using slave channel 3.
- The delay is specified in slave channel 2.

- Prerequisites**
- Four channels
 - The operation mode of the master channel must be set to Interval Timer Mode. Refer to *Table 12-119 "TAUANCMORm settings for the master channel of the Delay Pulse Output Function" on page 620*.
 - The operation mode of slave channel 1 and 2 must be set to One Count Mode. Refer to *Table 12-122 "TAUANCMORm settings for slave channel 1 of the Delay Pulse Output Function" on page 622*.
 - The operation mode of slave channel 3 must be set to Pulse One Count Mode. Refer to *Table 12-126 "TAUANCMORm settings for slave channel 2 of the Delay Pulse Output Function" on page 624*.
 - TAUAnTTOUTm is not used for the master channel and slave channel 2.
 - The channel output mode of slave channel 1 must be set to Synchronous Channel Output Mode 1 (refer to *12.8 "Channel Output Modes" on page 463*).
 - The channel output mode of slave channel 3 must be set to Independent Channel Output Mode 2 (refer to *12.8 "Channel Output Modes" on page 463*).

Description The counters of the channel group are started by setting the channel trigger bit (TAUANtS.TAUAnTSm) to 1. This in turn sets TAUAnTE.TAUAnTEm, enabling count operation.

- Master channel:

The current value of TAUAnCDRm is loaded to TAUAnCNTm and the counter starts to count down from this value. INTTAUANIm is generated on the master channel.

When the counter of the master channel reaches 0000_H, pulse cycle time has elapsed and INTTAUANIm is generated. The counter reloads the TAUAnCDRm value, and then counts down.

- Slave channels 1 and 2:

When the slave channels 1 and 2 detect an interrupt from the master channel, they start to count down from the current value of TAUAnCDRm. The TAUAnTTOUTm signal (slave 1) becomes active.

– Slave channel 1:

When the counter of slave channel 1 reaches 0000_H , duty time has elapsed, INTTAUAnIm is generated and the TAUAnTTOUTm signal is reset. The counter returns to $FFFF_H$ and awaits the next INTTAUAnIm of the master channel.

– Slave channel 2:

When the counter of slave channel 2 reaches 0000_H , delay time has elapsed and INTTAUAnIm is generated. The counter returns to $FFFF_H$ and awaits the next INTTAUAnIm of the master channel.

INTTAUAnIm (slave 2) triggers the counter of slave channel 3

• Slave channel 3:

When slave channel 3 detects an interrupt from slave channel 2, it starts to count down from the current value of TAUAnCDRm. INTTAUAnIm is generated and the TAUAnTTOUTm signal (slave 3) is set.

When the counter of slave channel 3 reaches 0000_H , duty time has elapsed, INTTAUAnIm is generated and the TAUAnTTOUTm signal is reset.

The output from slave channel 3 is the delayed PWM pulse

The counter can be stopped by setting TAUAnTT.TAUAnTTm to 1 for the master and slave channels, which in turn sets TAUAnTE.TAUAnTEm to 0. TAUAnCNTm and TAUAnTTOUTm of master and slave channels stop but retain their values. The counters can be restarted by setting TAUAnTS.TAUAnTSm to 1.

Conditions Simultaneous rewrite can be used with this function. Please refer to 12.7 “Simultaneous Rewrite” on page 451

Equations Pulse cycle = (TAUAnCDRm (master) + 1) × count clock cycle
 Duty width 1 = (TAUAnCDRm (slave 1)) × count clock cycle
 Delay width = (TAUAnCDRm (slave 2) + 1) × count clock cycle
 Duty width 2 = (TAUAnCDRm (slave 3)) × count clock cycle
 However, the duty width setting is assumed to be in the following range:
 $0000_H \leq \text{TAUAnCDRm (slave 2)} < \text{TAUAnCDRm (master)}$

- Notes**
1. The output waveform of TAUAnTOUTm (slave 3) is the output waveform of TAUAnTOUTm (slave 1) delayed by the amount of delay generated by slave 2. It is not possible to delay the waveform by a pulse cycle or more.
 2. If the TAUAnINTm signal for slave 2 is generated during slave 3 counting, slave 3 resumes operation. Therefore, the output waveform of TAUAnTOUTm (slave 3) stays at the active level. (In this case, it is not possible for TOUTn (slave channel 3) to output a waveform that delays the TOUTn (slave channel 1) reference pulse.)

(2) Block diagram and general timing diagram

Figure 12-97 Block diagram for Delay Pulse Output Function

The following settings apply to the general timing diagram:

- All channels
 - INTTAUAnIm is generated at operation start (TAUAnCMORm.TAUAnMD0 = 1)

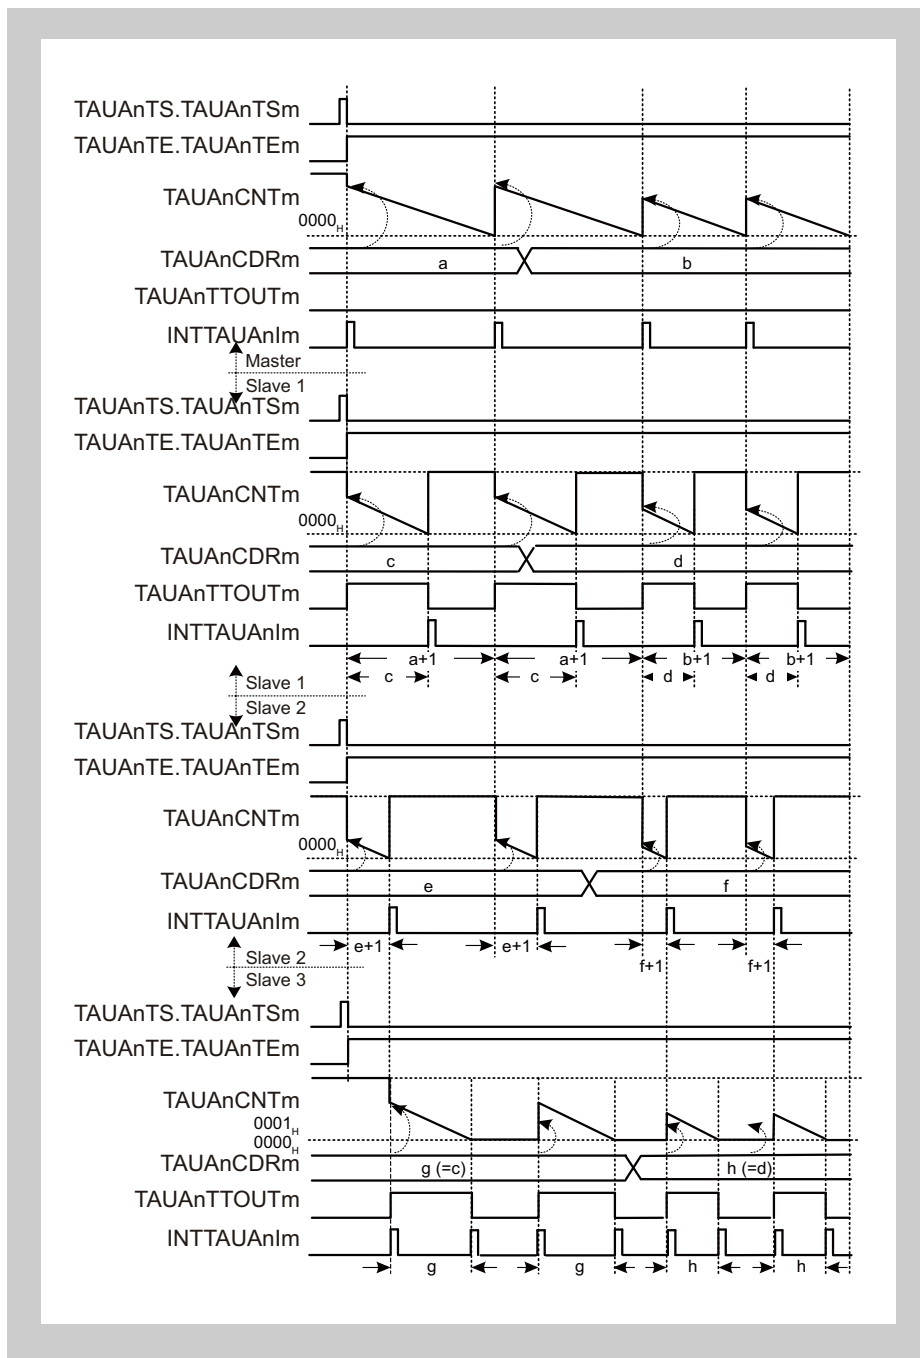

Figure 12-98 General timing diagram for Delay Pulse Output Function

TAUAnTIS[1:0]	00: These are not used, so set them to 00.

(c) Channel output mode for slave channel 3**Table 12-131 Control bit settings for Independent Channel Output Mode 2**

Bit name	Setting
TAUAnTOE.TAUAnTOEm	1: Enables Independent Channel Output Mode
TAUAnTOM.TAUAnTOMm	0: Independent channel output
TAUAnTOC.TAUAnTOCm	1: Operation mode 2
TAUAnTOL.TAUAnTOLm	0: Positive logic 1: Inverted logic
TAUAnTDE.TAUAnTDEm	0: Disables dead time operation
TAUAnTDM.TAUAnTDMm	0: When dead time operation is disabled (TAUAnTDE.TAUAnTDEm = 0), set these bits to 0
TAUAnTDL.TAUAnTDLm	
TAUAnTRE.TAUAnTREm	0: Disables real-time output
TAUAnTRO.TAUAnTROm	0: When real-time output is disabled (TAUAnTRE.TAUAnTREm = 0), set these bits to 0
TAUAnTRC.TAUAnTRCm	
TAUAnTME.TAUAnTMEem	0: Disables modulation

(d) Simultaneous rewrite for slave channel 3

The simultaneous rewrite settings of the master and slave channels must be identical.

Table 12-132 Simultaneous rewrite settings for slave channel 3 of the Delay Pulse Output Function

Bit name	Setting
TAUAnRDE.TAUAnRDEm	1: Enables simultaneous rewrite
TAUAnRDS.TAUAnRDSm	0: The master channel is the control channel for simultaneous rewrite
TAUAnRDM.TAUAnRDMm	0: The simultaneous rewrite trigger signal is generated when the master channel starts counting
TAUAnRDC.TAUAnRDCm	0: Channel is not used to detect an INTTAUAnIm signal that is used as the simultaneous rewrite trigger. If TAUAnRDS.TAUAnRDSm = 0, the master channel is used to detect the simultaneous rewrite trigger regardless of the value of this bit.

(7) Operating procedure for Delay Pulse Output Function**Table 12-133 Operating procedure for Delay Pulse Output Function (1/2)**

	Operation	Status of TAUAn
Initial channel setting	Master channel: set the TAUAnCMORm and TAUAnCMURm registers and the channel output mode as described in (3) "Register settings for the master channel" on page 620	Channel operation is stopped.
	Slave channel 1: set the TAUAnCMORm and TAUAnCMURm registers and the channel output mode as described in (4) "Register settings for slave channel 1" on page 622	
	Slave channel 2: set the TAUAnCMORm and TAUAnCMURm registers and the channel output mode as described in (5) "Register settings for slave channel 2" on page 624	
	Slave channel 3: set the TAUAnCMORm and TAUAnCMURm registers and the channel output mode as described in (6) "Register settings for slave channel 3" on page 626	
	Set the values of the TAUAnCDRm registers of all channels	

Table 12-133 Operating procedure for Delay Pulse Output Function (2/2)

	Operation	Status of TAUAn
Restart	Start operation Set TAUAnTS.TAUAnTSm of the master and slave channels to 1 simultaneously. TAUAnTS.TAUAnTSm is a trigger bit, so it is automatically cleared to 0.	TAUAnTE.TAUAnTEm (master and slave channels) is set to 1 and the counters of the master channel and slave channels 1 and 2 start. INTTAUAnIm is generated on the master channel and TAUAnTTOUTm (slave 1) is set.
	During operation TAUAnCDRm can be changed at any time. TAUAnCNTm and TAUAnRSF.TAUAnRSFm can be read at any time. TAUAnRDT.TAUAnRDTm can be changed during operation.	TAUAnCNTm loads the TAUAnCDRm value of the master channel and slave channels 1 and 2, and then counts down. When the counter of the master channel reaches 0000 _H : <ul style="list-style-type: none"> • INTTAUAnIm (master) is generated. • TAUAnCNTm (master) reloads the TAUAnCDRm value, and then continues count operation. • TAUAnCNTm (slave 1 and slave 2) reload the TAUAnCDRm value and start counting down. • TAUAnTTOUTm (slave 1) is set. When TAUAnCNTm (slave 1) reaches 0000 _H : <ul style="list-style-type: none"> • INTTAUAnIm (slave 1) is generated. • TAUAnTTOUTm (slave 1) is reset. When TAUAnCNTm (slave 2) reaches 0000 _H : <ul style="list-style-type: none"> • INTTAUAnIm (slave 2) is generated. • TAUAnTTOUTm (slave 3) is set. • TAUAnCNTm (slave 3) reloads the TAUAnCDRm value, and then starts counting down. When TAUAnCNTm (slave 3) reaches 0000 _H : <ul style="list-style-type: none"> • INTTAUAnIm (slave 3) is generated. • TAUAnTTOUTm (slave 3) is reset.
	Stop operation Set TAUAnTT.TAUAnTTm of the master and slave channels to 1 simultaneously. TAUAnTT.TAUAnTTm is a trigger bit, so it is automatically cleared to 0.	TAUAnTE.TAUAnTEm is cleared to 0 and the counter stops. TAUAnCNTm and TAUAnTTOUTm stop and retain their current values.

12.22.4 AD Conversion Trigger Output Function Type 1

(1) Overview

Summary This function is identical to 12.22.1 “PWM Output Function” on page 594 except that TAUAnTTOU_m is not output.

This is achieved by setting the channel output mode of the slave to Independent Channel Output Mode Controlled by Software.

(2) Block diagram and general timing diagram

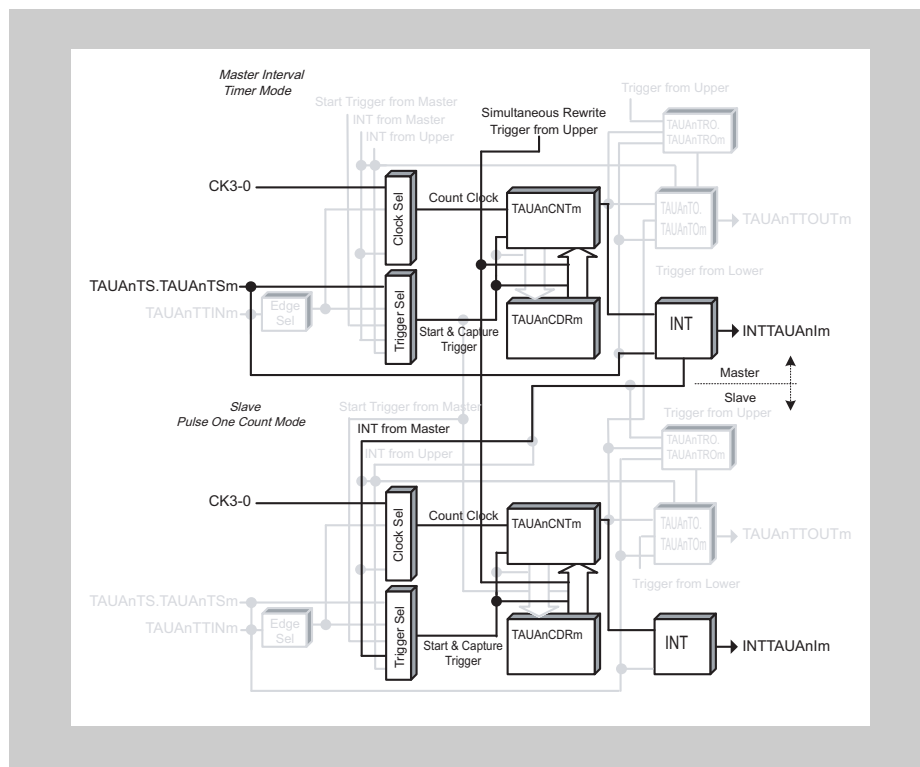

Figure 12-99 Block diagram for AD Conversion Trigger Output Function Type 1

(3) General timing diagram

The following settings apply to the general timing diagram:

- Slave channel: Positive logic (TAUANtOL.TAUAnTOLm = 0)

Figure 12-100 General timing diagram for AD Conversion Trigger Output Function Type 1

12.23 Synchronous PWM Signal Functions Triggered by an External Signal

This chapter describes functions that generate PWM signals and which are triggered by an external signal.

- 12.23.1 *“One-Shot Pulse Output Function”*
- 12.23.2 *“Offset Trigger Output Function”*

12.23.1 One-Shot Pulse Output Function

(1) Overview

Summary This function outputs a signal pulse with a defined pulse width and a specific delay time compared to an external input signal pulse by using a master and a slave channel. The delay time is specified using the master channel. The pulse width is specified using the slave channel.

- Prerequisites**
- Two channels
 - The operation mode of the master channel must be set to One Count Mode. Refer to *Table 12-134 "TAUAnCMORm settings for the master channel of the One-Shot Pulse Output Function" on page 636*.
 - The operation mode of the slave channel must be set to Pulse One Count Mode. Refer to *Table 12-137 "TAUAnCMORm settings for the slave channel of the One-Shot Pulse Output Function" on page 638*.
 - TAUAnTTOUTm is not used for the master channel of this function.
 - The channel output mode of the slave channel must be set to Synchronous Channel Output Mode 2 (refer to *12.8 "Channel Output Modes" on page 463*).
 - TAUAnTTINm (master) has to be detected while TAUAnCNTm (master) and TAUAnCNTm (slave) await a trigger. Furthermore, the slave is only triggered by an interrupt from the master channel and not by TAUAnTTINm (slave).

Description The counters are enabled by setting the channel trigger bits (TAUAnTS.TAUAnTSm) of the master and slave channels to 1. This in turn sets TAUAnTE.TAUAnTEm, enabling count operation.

- Master channel:

When the next valid TAUAnTTINm input edge is detected, the current value of TAUAnCDRm is loaded to TAUAnCNTm. The counter starts to count down from this value. If TAUAnCMORm.TAUAnMD0 = 0, a trigger (TAUAnTTINm) which is detected within the delay time is ignored.

When the counter of the master channel reaches 0000_H, INTTAUAnIm is generated. The counter returns to FFFF_H and awaits the next valid TAUAnTTINm input edge.

- Slave channel

The INTTAUAnIm of the master channel triggers the counter of the slave channel. The current value of TAUAnCDRm (slave) is loaded to TAUAnCNTm (slave) and the counter starts to count down from this value. An interrupt is generated and the TAUAnTTOUTm signal is set.

When the counter reaches 0001_H, INTTAUAnIm is generated and the TAUAnTTOUTm signal is reset. The counter stops at 0000_H and awaits the next INTTAUAnIm of the master channel.

The counter can be stopped by setting TAUAnTT.TAUAnTTm to 1 for the master and slave channel, which in turn sets TAUAnTE.TAUAnTEm to 0. TAUAnCNTm and TAUAnTTOUTm of master and slave channel stop but retain their values. The counters can be restarted by setting TAUAnTS.TAUAnTSm to 1.

The counter of the master channel can be restarted without stopping it first (forced restart) by setting TAUAnTS.TAUAnTSm to 1 during operation.

- Conditions**
- If TAUAnCMORm.TAUAnMD0 of the master channel is set to 0, during counting detected TAUAnTTINm input edges are ignored.
 - Simultaneous rewrite can be used with this function. Please refer to 12.7 “Simultaneous Rewrite” on page 451

Equations Delay to input pulse = (TAUAnCDRm (master) + 1) × count clock cycle
Pulse width = (TAUAnCDRm (slave)) × count clock cycle

(2) Block diagram and general timing diagram

Figure 12-101 Block diagram for One-Shot Pulse Output Function

The following settings apply to the general timing diagram:

- Start trigger detection disabled during counting (TAUAnCMORm.TAUAnMD0 = 0)
- Falling edge detection (TAUAnCMURm.TAUAnTIS[1:0] = 00_B)

Figure 12-102 General timing diagram for One-Shot Pulse Output Function

(3) Register settings for the master channel**(a) TAUAnCMORm for the master channel**

TAUAnTOL.TAUAnTOLm	0: Positive logic 1: Inverted logic
TAUAnTDE.TAUAnTDEm	0: Disables dead time operation
TAUAnTDM.TAUAnTDMm	0: When dead time operation is disabled (TAUAnTDE.TAUAnTDEm = 0), set these bits to 0
TAUAnTDL.TAUAnTDLm	0: When dead time operation is disabled (TAUAnTDE.TAUAnTDEm = 0), set these bits to 0
TAUAnTRE.TAUAnTREm	0: Disables real-time output
TAUAnTRO.TAUAnTROm	0: When real-time output is disabled (TAUAnTRE.TAUAnTREm = 0), set these bits to 0
TAUAnTRC.TAUAnTRCm	0: When real-time output is disabled (TAUAnTRE.TAUAnTREm = 0), set these bits to 0
TAUAnTME.TAUAnTMEm	0: Disables modulation

(d) Simultaneous rewrite for the slave channel

The simultaneous rewrite settings of the master and slave channel must be identical.

Table 12-140 Simultaneous rewrite settings for the slave channel of the One-Shot Pulse Output Function

Bit name	Setting
TAUAnRDE.TAUAnRDEm	1: Enables simultaneous rewrite
TAUAnRDS.TAUAnRDSm	0: The master channel is the control channel for simultaneous rewrite
TAUAnRDM.TAUAnRDMm	0: The simultaneous rewrite trigger signal is generated when the master channel starts counting
TAUAnRDC.TAUAnRDCm	0: Channel is not monitored for an INTTAUAnIm signal that is used as the simultaneous rewrite trigger. If TAUAnRDS.TAUAnRDSm = 0, the master channel is monitored for the simultaneous rewrite trigger regardless of the value of this bit.

(5) Operating procedure for One-Shot Pulse Output Function

Table 12-141 Operating procedure for One-Shot Pulse Output Function

	Operation	Status of TAUAn
Restart ↑	Initial channel setting Master channel: set the TAUAnCMORm and TAUAnCMURm registers and the channel output mode as described in (3) "Register settings for the master channel" on page 636 Slave channel: set the TAUAnCMORm and TAUAnCMURm registers and the channel output mode as described in (4) "Register settings for the slave channel" on page 638 Set the values of the TAUAnCDRm registers of all channels	Channel operation is stopped.
	Start operation Set TAUAnTS.TAUAnTSm of the master and slave channels to 1 simultaneously. TAUAnTS.TAUAnTSm is a trigger bit, so it is automatically cleared to 0.	TAUAnTE.TAUAnTEm (master and slave channels) is set to 1 and the master channel awaits a TAUAnTTINm input.
	During operation TAUAnCDRm can be changed at any time. TAUAnCNTm and TAUAnRSF.TAUAnRSFm can be read at any time. TAUAnRDT.TAUAnRDTm can be changed during operation.	When the valid edge of TAUAnTTINm input is detected, TAUAnCNTm loads the TAUAnCDRm value of the master channel, and then counts down. When the counter reaches 0000 _H : <ul style="list-style-type: none"> • INTTAUAnIm (master) is generated. • TAUAnCNTm (master) reloads the TAUAnCDRm value, and then continues count operation. • TAUAnCNTm (slave) reloads the TAUAnCDRm value, and then starts counting down. • INTTAUAnIm (slave) is generated. • TAUAnTTOUTm (slave) is set. When TAUAnCNTm (slave) reaches 0001 _H : <ul style="list-style-type: none"> • INTTAUAnIm (slave) is generated. • TAUAnTTOUTm (slave) is reset. If a TAUAnTTINm input is detected on the master channel while the counter is counting, the input is ignored when TAUAnCMORm.TAUAnMD0 = 0.
	Stop operation Set TAUAnTT.TAUAnTTm of the master and slave channels to 1 simultaneously. TAUAnTT.TAUAnTTm is a trigger bit, so it is automatically cleared to 0.	TAUAnTE.TAUAnTEm is cleared to 0 and the counter stops. TAUAnCNTm and TAUAnTTOUTm stop and retain their current values.

12.23.2 Offset Trigger Output Function

(1) Overview

- Summary** This function generates a PWM output using a master and a slave channel. It enables the pulse width (duration) of the TAUAnTTOUTm to be set. The pulse cycle is set by the detection of a valid input edge of the master channel. The pulse width is specified using the slave channel.
- Prerequisites**
- Two channels
 - The operation mode of the master channel must be set to Capture Mode. Refer to *Table 12-142 "TAUAnCMORm settings for the master channel of the Offset Trigger Output Function" on page 644*.
 - The operation mode of the slave channel must be set to One Count Mode. Refer to *Table 12-145 "TAUAnCMORm settings for the slave channel of the Offset Trigger Output Function" on page 646*.
 - The channel output mode of the slave channel must be set to Independent Channel Output Mode 2 (refer to *12.8 "Channel Output Modes" on page 463*).
 - TAUAnTTOUTm is not used for the master channel of this function.
- Description** The counters are started by setting the channel trigger bit (TAUAnTS.TAUAnTSM) to 1. This in turn sets TAUAnTE.TAUAnTEM, enabling count operation. The counter of the master channel (TAUAnCNTm) starts to count up from 0000_H.
- Master channel:

When a valid TAUAnTTINm input edge is detected, the current value of the counter (TAUAnCNTm) is loaded to the data register of the master channel (TAUAnCDRm). INTTAUAnIm is generated and the counter restarts counting up from 0000_H.
 - Slave channel:

The INTTAUAnIm of the master channel sets the TAUAnTTOUTm (slave) signal and triggers the counter of the slave channel. The current value of TAUAnCDRm (slave) is loaded to TAUAnCNTm (slave) and the counter starts to count down from this value.

When the counter reaches 0000_H, i.e. duty time has elapsed, INTTAUAnIm is generated and the TAUAnTTOUTm signal is reset. The counter returns to FFFF_H and awaits the next INTTAUAnIm of the master channel.

The counter can be stopped by setting TAUAnTT.TAUAnTTm to 1 for the master and slave channel(s), which in turn sets TAUAnTE.TAUAnTEM to 0. TAUAnCNTm and TAUAnTTOUTm of master and slave channel(s) stop but retain their values. The counters can be restarted by setting TAUAnTS.TAUAnTSM to 1.

(2) Equations

Pulse width = (TAUAnCDRm (slave) + 1) x count clock cycle

Duty cycle [%] = [TAUAnCDRm (slave) / TAUAnTTINm cycle + 1] x 100

– Duty cycle = 0 %

TAUAnCDRm (slave) = 0000_H

– Duty cycle = 100 %

TAUAnCDRm (slave) ³ TAUAnTTINm cycle + 1

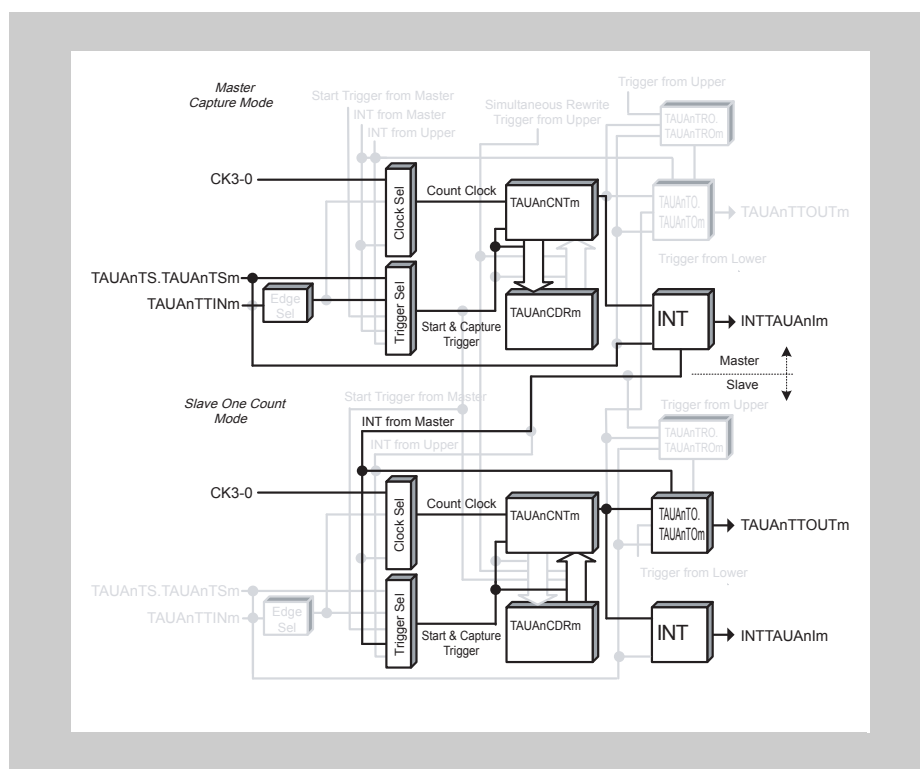

(3) Block diagram and general timing diagram

Figure 12-103 Block diagram for Offset Trigger Output Function

The following settings apply to the general timing diagram:

- Falling edge detection ($\text{TAUAnCMURm.TAUAnTIS}[1:0] = 00_{\text{B}}$)

Figure 12-104 General timing diagram for Offset Trigger Output Function

Bit name	Setting
TAUAnRDE.TAUAnRDEm	0: Disables simultaneous rewrite
TAUAnRDS.TAUAnRDSm	When simultaneous rewrite is disabled (TAUAnTAUAnRDE.TAUAnRDEm = 0), set these bits to 0
TAUAnRDM.TAUAnRDMm	
TAUAnRDC.TAUAnRDCm	

(6) Operating procedure for Offset Trigger Output Function**Table 12-149 Operating procedure for Offset Trigger Output Function**

	Operation	Status of TAUAn
Restart ↓	Initial channel setting Master channel: set the TAUAnCMORm and TAUAnCMURm registers and the channel output mode as described in (4) "Register settings for the master channel" on page 644 Slave channel: set the TAUAnCMORm and TAUAnCMURm registers and the channel output mode as described in (5) "Register settings for the slave channel" on page 646 Set the values of the TAUAnCDRm registers of all channels	Channel operation is stopped.
	Start operation Set TAUAnTS.TAUAnTSM of the master and slave channels to 1 simultaneously. TAUAnTS.TAUAnTSM is a trigger bit, so it is automatically cleared to 0.	TAUAnTE.TAUAnTEm (master and slave channels) is set to 1 and the counters of the master and slave channels start: <ul style="list-style-type: none"> TAUAnCNTm (master) counts up. TAUAnCNTm (slave) loads TAUAnCDRm, and then counts down. INTTAUAnIm is generated on the master channel and TAUAnTTOUTm (master) is set.
	During operation TAUAnCDRm can be changed at any time. TAUAnCSCm.TAUAnCLOV can be set to 1.	When TAUAnCNTm of the slave reaches 0000 _H : <ul style="list-style-type: none"> INTTAUAnIm (slave) is generated. TAUAnTTOUTm (slave) is reset. When a TAUAnTTINm input is detected on the master channel: <ul style="list-style-type: none"> INTTAUAnIm (master) is generated. TAUAnCNTm (master) is reset to 0000_H and continues count operation. TAUAnCNTm (slave) reloads the TAUAnCDRm value, and then counts down. TAUAnTTOUTm (slave) is set.
	Stop operation Set TAUAnTT.TAUAnTTm of the master and slave channels to 1 simultaneously. TAUAnTT.TAUAnTTm is a trigger bit, so it is automatically cleared to 0.	TAUAnTE.TAUAnTEm is cleared to 0 and the counter stops. TAUAnCNTm and TAUAnTTOUTm stop and retain their current values.

12.24 Synchronous Triangle PWM Functions

This chapter describes functions that generate a triangle PWM output.

- 12.24.1 *“Triangle PWM Output Function”*
- 12.24.2 *“Triangle PWM Output Function with Dead Time”*
- 12.24.3 *“AD Conversion Trigger Output Function Type 2”*

12.24.1 Triangle PWM Output Function

(1) Overview

Summary This function generates multiple triangle PWM outputs by using a master and one or more slave channels. It enables the pulse cycle (frequency) and the duty cycle of TAUAnTTOUTm to be set using the master and slave channel(s) respectively.

Carrier cycles are generated on the master channel. The first pulse of the master channel controls the down status and the second pulse controls the up status of the slaves counter.

- Prerequisites**
- Two channels
 - The operation mode of the master channel must be set to Interval Timer Mode. Refer to *Table 12-150 "TAUAnCMORm settings for the master channel of the Triangle PWM Output Function" on page 654*.
 - The operation mode of the slave channel(s) must be set to Up Down Count Mode. Refer to *Table 12-154 "TAUAnCMORm settings for the slave channel of the Triangle PWM Output Function" on page 656*.
 - The channel output mode of the master channel must be set to Independent Channel Output Mode 1 (refer to *12.8 "Channel Output Modes" on page 463*).
 - The channel output mode of the slave channel(s) must be set to Synchronous Channel Output Mode 2 (refer to *12.8 "Channel Output Modes" on page 463*).
 - The following settings establish TAUAnTTOUTm at high level for the down status of the carrier cycle.
 - If the TAUAnCMORm.TAUAnMD0 (master) bit is set to 0, TAUAnTO.TAUAnTOm must be set to 1 while TAUAnTOE.TAUAnTOEm is 0 (recommended).
 - If the TAUAnCMORm.TAUAnMD0 (master) bit is set to 1, TAUAnTO.TAUAnTOm must be set to 0 while TAUAnTOE.TAUAnTOEm is 0.

Description The counters are started by setting the channel trigger bit (TAUAnTS.TAUAnTSm) to 1 for every channel. This in turn sets TAUAnTE.TAUAnTEm, enabling count operation. The values of TAUAnCDRm (master and slave) are loaded to TAUAnCNTm (master and slave) and the counters start to count down from these values. If the master channel TAUAnCMORm.TAUAnMD0 bit is set, an interrupt is generated and TAUAnTTOUTm signal of the master toggles.

- Master channel:

When the counter of the master channel reaches 0000_H, pulse cycle time has elapsed, INTTAUAnIm is generated and the TAUAnTTOUTm signal toggles. TAUAnCNTm then reloads the TAUAnCDRm value, and then counts down.

- Slave channel:

The INTTAUAnIm of the master channel triggers the counter of the slave channel:

- If the slave counter currently counts down, it changes count direction.
- If the slave counter currently counts up, the value of TAUAnCDRm is reloaded and the counter counts down.

When the counter of the slave channel reaches 0001_H while counting up or down, INTTAUAnIm is generated and the TAUAnTTOUTm (slave) signal is set or reset.

The counter continues to count down or up and awaits the next INTTAUAnIm of the master channel.

TAUAnTTOUTm can be switched between positive and negative phase setting TAUAnTOL.TAUAnTOLm during operation.

The counters can be stopped by setting TAUAnTT.TAUAnTTm to 1 for the master and slave channel(s), which in turn sets TAUAnTE.TAUAnTEm to 0. TAUAnCNTm and TAUAnTTOUTm of master and slave channel(s) stop but retain their values.

Conditions Simultaneous rewrite can be used with this function. Please refer to 12.7 “Simultaneous Rewrite” on page 451

(2) Equations

Pulse cycle = (TAUAnCDRm (master) + 1) x count clock cycle

0000_H ≤ TAUAnCDR (master) < FFFF_H

Carrier cycle (down/up) = (TAUAnCDRm (master) + 1) × 2 × count clock cycle

Duty cycle [%] =

$$\frac{[(TAUAnCDRm (master) + 1 - TAUAnCDRm (slave)) / (TAUAnCDRm (master) + 1)] \times 100}{}$$

- Duty cycle = 100 %

TAUAnCDRm (slave) = 0000_H

- Duty cycle = 0 %

TAUAnCDRm (slave) = TAUAnCDRm (master) + 1

(3) Block diagram and general timing diagram

Figure 12-105 Block diagram for Triangle PWM Output Function

The following settings apply to the general timing diagram:

- Master channel
 - INTTAUAnIm is generated at operation start (TAUAnCMORm.TAUAnMD0 = 1)

Figure 12-106 General timing diagram for Triangle PWM Output Function

(4) Register settings for the master channel**(a) TAUAnCMORM for the master channel**

Bit name	Setting
TAUAnCKS[1:0]	00: Prescaler output CK0 01: Prescaler output CK1 10: Prescaler output CK2 11: Prescaler output CK3 The value of the TAUAnCKS[1:0] bit of the master and slave channel(s) must be identical.
TAUAnCCS[1:0]	00: Operation clock is used as the count clock
TAUAnMAS	1: Channel is master channel
TAUAnSTS[2:0]	000: Counter triggered by software trigger
TAUAnCOS[1:0]	00: Not used, so set to 00
TAUAnMD[4:1]	0000: Interval Timer Mode
TAUAnMDO	0: INTTAUAnIm not generated and TAUAnTTOUTm does not toggle at operation start 1: Generates INTTAUAnIm and toggles TAUAnTTOUTm at operation start

(b) TAUAnCMURm for the master channel

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
-														TAUAnTIS[1:0]	

Table 12-151 TAUAnCMURm settings for the master channel of the Triangle PWM Output Function

Bit name	Setting
TAUAnTIS[1:0]	00: These are not used, so set them to 00.

(c) Channel output mode for the master channel**Table 12-152 Control bit settings for Independent Channel Output Mode 1**

Bit name	Setting
TAUAnTOE.TAUAnTOEm	1: Enables Independent Channel Output Mode
TAUAnTOM.TAUAnTOMm	0: Independent channel output
TAUAnTOC.TAUAnTOCm	0: Operation mode 1 (= Toggle mode if TAUAnTOM.TAUAnTOMm = 0)
TAUAnTOL.TAUAnTOLm	0: Positive logic
TAUAnTDE.TAUAnTDEm	0: Disables dead time operation
TAUAnTDM.TAUAnTDMm	0: When dead time operation is disabled (TAUAnTDE.TAUAnTDEm = 0), set these bits to 0
TAUAnTDL.TAUAnTDLm	
TAUAnTRE.TAUAnTREm	0: Disables real-time output
TAUAnTRO.TAUAnTROm	0: When real-time output is disabled (TAUAnTRE.TAUAnTREm = 0), set these bits to 0
TAUAnTRC.TAUAnTRCm	
TAUAnTME.TAUAnTMEm	0: Disables modulation

(d) Simultaneous rewrite for the master channel

The simultaneous rewrite settings of the master and slave channel must be identical.

Table 12-153 Simultaneous rewrite settings for the master channel of the Triangle PWM Output Function

Bit name	Setting
TAUAnRDE.TAUAnRDEm	1: Enables simultaneous rewrite
TAUAnRDS.TAUAnRDSm	0: The master channel is monitored for the simultaneous rewrite trigger 1: An upper channel outside the channel group is monitored for the simultaneous rewrite trigger
TAUAnRDM.TAUAnRDMm	1: The simultaneous rewrite trigger signal is generated when the master channel starts counting and the corresponding slave channel is at the peak of a triangular wave
TAUAnRDC.TAUAnRDCm	0: Channel is not monitored for an INTTAUAnIm signal that is used as the simultaneous rewrite trigger. If TAUAnRDS.TAUAnRDSm = 0, the master channel is monitored for the simultaneous rewrite trigger regardless of the value of this bit.

Note If the TAUAnRDS.TAUAnRDSm bit is 1, there must be a channel higher than the master channel to which a simultaneous rewrite trigger signal is generated.

(5) Register settings for the slave channel(s)**(a) TAUAnCMORm for the slave channel(s)**

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

TAUAnTRC.TAUAnTRCm	
TAUAnTME.TAUAnTMEEm	0: Disables modulation

(d) Simultaneous rewrite for the slave channel(s)

The simultaneous rewrite settings of the master and slave channel must be identical.

Table 12-157 Simultaneous rewrite settings for the slave channel of the Triangle PWM Output Function

Bit name	Setting
TAUAnRDE.TAUAnRDEm	1: Enables simultaneous rewrite
TAUAnRDS.TAUAnRDSm	0: The master channel is monitored for the simultaneous rewrite trigger 1: An upper channel is monitored for the simultaneous rewrite trigger
TAUAnRDM.TAUAnRDMm	1: The simultaneous rewrite trigger signal is generated when the master channel starts counting and the corresponding slave channel is at the peak of a triangular wave
TAUAnRDC.TAUAnRDCm	0: Channel is not monitored for an INTTAUAnIm signal that is used as the simultaneous rewrite trigger. If TAUAnRDS.TAUAnRDSm = 0, the master channel is monitored for the simultaneous rewrite trigger regardless of the value of this bit.

(6) Operating procedure for Triangle PWM Output Function**Table 12-158 Operating procedure for Triangle PWM Output Function**

	Operation	Status of TAUAn
Restart ↑	Initial channel setting Master channel: set the TAUAnCMORm and TAUAnCMURm registers and the channel output mode as described in (4) "Register settings for the master channel" on page 654 Slave channel: set the TAUAnCMORm and TAUAnCMURm registers and the channel output mode as described in (5) "Register settings for the slave channel(s)" on page 656 Set the values of the TAUAnCDRm registers of all channels	Channel operation is stopped.
	Start operation Set TAUAnTS.TAUAnTSm of the master and slave channels to 1 simultaneously. TAUAnTS.TAUAnTSm is a trigger bit, so it is automatically cleared to 0.	TAUAnTE.TAUAnTEm (master and slave channels) is set to 1 and the counters of the master and slave channels start. If TAUAnCMORm.TAUAnMD0 is set to 1 on the master channel, INTTAUAnIm (master) is generated.
	During operation TAUAnCDRm can be changed at any time. TAUAnCNTm and TAUAnRSF.TAUAnRSFm can be read at any time. TAUAnRDT.TAUAnRDTm can be changed during operation.	TAUAnCNTm loads the TAUAnCDRm value of the master channel or slave channel, and then counts down. When the counter of the master channel reaches 0000 _H : <ul style="list-style-type: none"> • INTTAUAnIm (master) is generated. • TAUAnTTOUTm (master) toggles. • TAUAnCNTm (master) reloads the TAUAnCDRm value, and then continues count operation. • TAUAnCNTm (slave) reloads the TAUAnCDRm value or counts in the reverse direction. When TAUAnCNTm of the slave = 0001 _H : <ul style="list-style-type: none"> • INTTAUAnIm (slave) is generated. • TAUAnTTOUTm (slave) is set (in count-down status) or reset (in count-up status).
	Stop operation Set TAUAnTT.TAUAnTTm of the master and slave channels to 1 simultaneously. TAUAnTT.TAUAnTTm is a trigger bit, so it is automatically cleared to 0.	TAUAnTE.TAUAnTEm is cleared to 0 and the counter stops. TAUAnCNTm and TAUAnTTOUTm stop and retain their current values.

(7) Specific timing diagrams

(a) Duty cycle = 0%

The following settings apply to the general timing diagram:

- Master channel:
 - INTTAUAnIm is generated at operation start (TAUAnCMORm.TAUAnMD0 = 1)
 - TAUAnCDRm = a = 5_H
- Slave channel:
 - TAUAnCDRm = 6_H

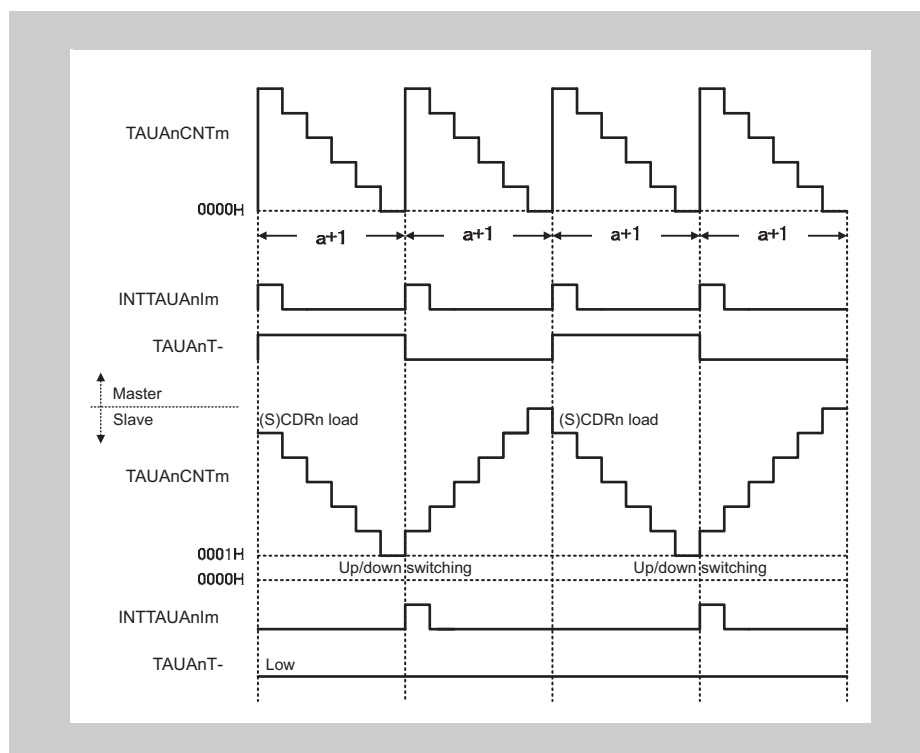

Figure 12-107 TAUAnCDRm (slave) ³ TAUAnCDRm (master) + 1

- If TAUAnCDRm (slave) ³ TAUAnCDRm (master) the counter of slave channel cannot reach 0001_H during *counting down*. The set signal is never detected, so TAUAnTOUTm remains at low state.

(b) Duty cycle = 100%

The following settings apply to the general timing diagram:

- Master channel:
 - INTTAUAnIm is generated at operation start (TAUAnCMORm.TAUAnMD0 = 1)
 - TAUAnCDRm = a = 5_H
- Slave channel:
 - TAUAnCDRm = 0_H

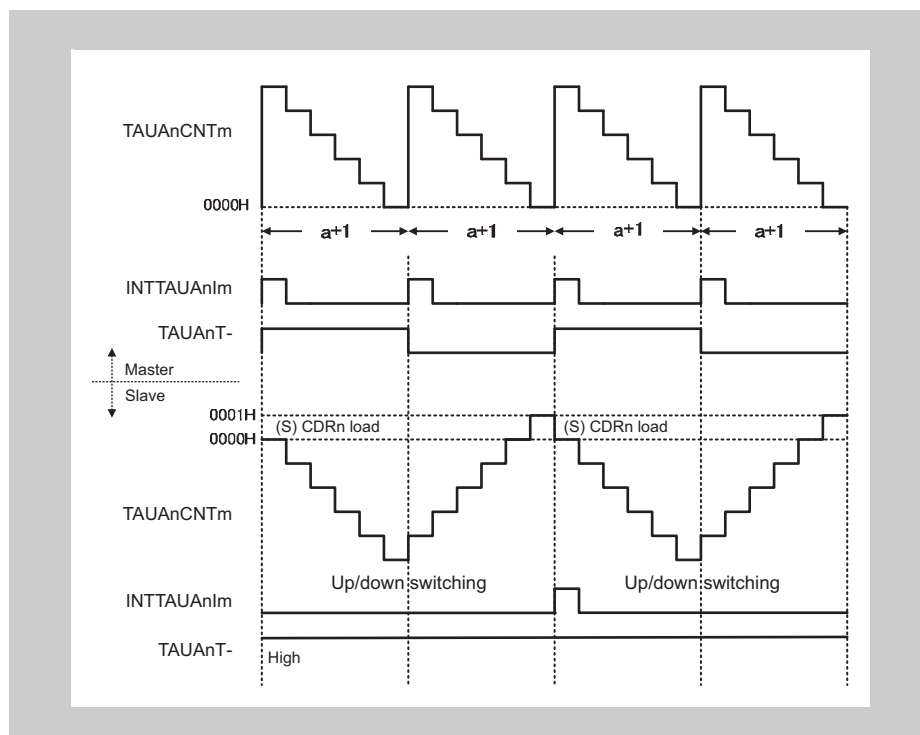

Figure 12-108 TAUAnCDRm (slave) = 0000_H

- If TAUAnCDRm (slave) = 0000_H the counter of slave channel cannot reach 0001_H during *counting up*. The reset signal is never detected, so TAUAnTTOUTm remains at high state.

12.24.2 Triangle PWM Output Function with Dead Time

(1) Overview

Summary This function generates multiple triangle PWM outputs with a defined dead time by using a master and two or more slave channels. The resulting PWM signals are output via TAUAnTTOUTm of the slave channel 3. It enables the pulse cycle (frequency) and the duty cycle of TAUAnTTOUTm to be set using the master and slave channel(s) respectively.

Carrier cycles are generated on the master channel. The first pulse cycle controls the down status of the slave counter, and the second pulse cycle controls the up status.

An interrupt on slave 2 causes TAUAnTTOUTm of the slave channels to be set or reset. Depending on the settings of TAUAnTDL.TAUAnTDLm, delay time is added to positive or negative logic side of the signal (i.e. whether TAUAnTTOUTm is set/reset immediately or after dead time has elapsed). The duration of the dead time is specified by slave channel 3.

- Prerequisites**
- Three channels. For slave channels 2 and 3, select the even channel CH (a) and the odd channel CH (a + 1).
 - The operation mode of the master channel must be set to Interval Timer Mode. Refer to *Table 12-160 "TAUAnCMORm settings for the master channel of the Triangle PWM Output Function with Dead Time" on page 666*.
 - Slave channel 1 is not used for this function. This ensures that slave channel 2 is an odd channel, and slave channel 3 is an even channel.
 - The operation mode of slave channel 2 must be set to Up Down Mode. Refer to *Table 12-164 "TAUAnCMORm settings for slave channel 2 of the Triangle PWM Output Function with Dead Time" on page 668*. Furthermore, slave channel 2 must be an even channel.
 - The operation mode of slave channel 3 must be set to One Count Mode. Refer to *Table 12-168 "TAUAnCMORm settings for slave channel 3 of the Triangle PWM Output Function with Dead Time" on page 670*. Furthermore, slave channel 3 must be an odd channel.
 - The channel output mode of the master channel must be set to Independent Channel Output Mode 1 (refer to *12.8 "Channel Output Modes" on page 463*).
 - The channel output mode of the slave channels 2 and 3 must be set to Synchronous Channel Output Mode 2 with Dead Time Output (refer to *12.8 "Channel Output Modes" on page 463*).
 - The following settings establish TAUAnTTOUTm at high level for the down status of the carrier cycle.
 - If the TAUAnCMORm.TAUAnMD0 (master) bit is set to 0, TAUAnTO.TAUAnTOM must be set to 1 while TAUAnTOE.TAUAnTOEm is 0 (recommended).
 - If the TAUAnCMORm.TAUAnMD0 (master) bit is set to 1, TAUAnTO.TAUAnTOM must be set to 0 while TAUAnTOE.TAUAnTOEm is 0.

Note Slave channel 1 is not used for Triangle PWM Output Function with Dead Time.

- Description** The counters are started by setting the channel trigger bits (TAUAnTS.TAUAnTSM) to 1. This in turn sets TAUAnTE.TAUAnTEm, enabling count operation. The current values of TAUAnCDRm is loaded to TAUAnCNTm and the counters start to count down from these values. If the master channel TAUAnCMORM.TAUAnMD0 bit is set, an interrupt is generated and TAUAnTTOUTm signal of the master toggles.
- Master channel:

When the counter of the master channel reaches 0000_H, INTTAUAnIm is generated and the TAUAnTTOUTm signal toggles. The counter reloads the TAUAnCDRm value, and then counts down.
 - Slave channel 2:

The INTTAUAnIm of the master channel triggers the counter of the slave channel 2:

 - If the slave counter currently counts down, it changes count direction.
 - If the slave counter currently counts up, the value of TAUAnCDRm is reloaded and the counter counts down.

The counter continues to count down or up and awaits the next INTTAUAnIm of the master channel.
 - Slave channel 3:

INTTAUAnIm of slave channel 2 triggers the counter of slave channel 3. The current value of TAUAnCDRm (slave 3) is loaded to TAUAnCNTm (slave 3) and the counter starts to count down from this value.

When the counter reaches 0000_H, INTTAUAnIm is generated. The counter returns to FFFF_H and awaits the next INTTAUAnIm of slave channel 2.

The TAUAnTDL.TAUAnTDLm settings of the corresponding channel specify whether it is set/reset immediately, or after dead time has elapsed, as shown in *Table 12-159 “Behavior of TAUAnTTOUTm when an interrupt occurs on slave channel 2” on page 663*.

The TAUAnTOL.TAUAnTOLm settings specify whether set corresponds to a high signal (TAUAnTOL.TAUAnTOLm = 0) or a low signal (TAUAnTOL.TAUAnTOLm = 1).

The counter can be stopped by setting TAUAnTT.TAUAnTTm to 1 for the master and slave channel(s), which in turn sets TAUAnTE.TAUAnTEm to 0. TAUAnCNTm and TAUAnTTOUTm of master and slave channel(s) stop but retain their values.

TAUAnCDRm value of slave channel 2 can be set to 0000_H to output 100 % TAUAnTTOUTm.

Conditions Simultaneous rewrite can be used with this function. Please refer to 12.7 “Simultaneous Rewrite” on page 451

TAUAnTOL.TAUAnTOLm and TAUAnTDL.TAUAnTDLm bits should be set before the counter starts, and slave channels 2 and 3 should have opposite TAUAnTOL.TAUAnTOLm settings or opposite TAUAnTDL.TAUAnTDLm settings.

Table 12-159 Behavior of TAUAnTTOUTm when an interrupt occurs on slave channel 2

TAUAnTDL. TAUAnTDLm	Count direction of slave channel 2 when interrupt is generated	TAUAnTTOUTm set/reset timing
0	Down	Set after dead time has elapsed
	Up	Reset immediately
1	Down	Set immediately
	Up	Reset after dead time has elapsed

(2) Equations

Pulse cycle = (TAUAnCDRm (master) + 1) x count clock cycle

$0000_H \leq \text{TAUAnCDR (master)} < \text{FFFF}_H$

Carrier cycle (down/up) = (TAUAnCDRm (master) + 1) × 2 × count clock cycle

PWM signal width (positive phase) = [(TAUAnCDRm (master) + 1 - TAUAnCDRm (slave 2) × 2) - (TAUAnCDRm (slave 3) + 1)] × count clock cycle

PWM signal width (negative phase) = [(TAUAnCDRm (master) + 1 - TAUAnCDRm (slave 2) × 2) + (TAUAnCDRm (slave 3) + 1)] × count clock cycle

(3) Block diagram and general timing diagram

Figure 12-109 Block diagram for Triangle PWM Output Function with Dead Time

The following settings apply to the general timing diagram:

- Master channel:
 - INTTAUAnIm is generated at operation start (TAUAnCMORm.TAUAnMD0 = 1)
- Slave channel 2:
 - INTTAUAnIm not generated at operation start (TAUAnCMORm.TAUAnMD0 = 0)
 - TAUAnTDL.TAUAnTDLm = 0
 - Positive logic (TAUAnTOL.TAUAnTOLm = 0)
- Slave channel 3:
 - INTTAUAnIm is generated at operation start (TAUAnCMORm.TAUAnMD0 = 1)
 - TAUAnTDL.TAUAnTDLm = 1
 - Negative logic (TAUAnTOL.TAUAnTOLm = 1)

Table 12-160 TAUAnCMORM settings for the master channel of the Triangle PWM Output Function with Dead Time

Bit name	Setting
TAUAnCKS[1:0]	00: Prescaler output CK0 01: Prescaler output CK1 10: Prescaler output CK2 11: Prescaler output CK3 The value of the TAUAnCKS[1:0] bit of the master and slave channel(s) must be identical.
TAUAnCCS[1:0]	00: Operation clock is used as the count clock
TAUAnMAS	1: Channel is master channel
TAUAnSTS[2:0]	000: Counter triggered by software trigger
TAUAnCOS[1:0]	00: Not used, so set to 00
TAUAnMD[4:1]	0000: Interval Timer Mode
TAUAnMDO	0: INTTAUAnIm not generated and TAUAnTTOUTm does not toggle at operation start 1: Generates INTTAUAnIm and toggles TAUAnTTOUTm at operation start

(b) TAUAnCMURm for the master channel

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
-														TAUAnTIS[1:0]	

Table 12-161 TAUAnCMURm settings for the master channel of the Triangle PWM Output Function with Dead Time

Bit name	Setting
TAUAnTIS[1:0]	00: These are not used, so set them to 00.

(c) Channel output mode for the master channel**Table 12-162 Control bit settings for Independent Channel Output Mode 1**

Bit name	Setting
TAUAnTOE.TAUAnTOEm	1: Enables Independent Channel Output Mode
TAUAnTOM.TAUAnTOMm	0: Independent channel output
TAUAnTOC.TAUAnTOCm	0: Operation mode 1 (= Toggle mode if TAUAnTOM.TAUAnTOMm = 0)
TAUAnTOL.TAUAnTOLm	0: Positive logic
TAUAnTDE.TAUAnTDEm	0: Disables dead time operation
TAUAnTDM.TAUAnTDMm	0: When dead time operation is disabled (TAUAnTDE.TAUAnTDEm = 0), set these bits to 0
TAUAnTDL.TAUAnTDLm	
TAUAnTRE.TAUAnTREM	0: Disables real-time output
TAUAnTRO.TAUAnTROM	0: When real-time output is disabled (TAUAnTRE.TAUAnTREM = 0), set these bits to 0
TAUAnTRC.TAUAnTRCm	
TAUAnTME.TAUAnTMEEm	0: Disables modulation

(d) Simultaneous rewrite for the master channel

The simultaneous rewrite settings of the master and slave channels must be identical.

Table 12-163 Simultaneous rewrite settings for the master channel of the Triangle PWM Output Function with Dead Time

Bit name	Setting
TAUAnRDE.TAUAnRDEm	1: Enables simultaneous rewrite
TAUAnRDS.TAUAnRDSm	0: The master channel is monitored for the simultaneous rewrite trigger 1: An upper channel outside the channel group is monitored for the simultaneous rewrite trigger
TAUAnRDM.TAUAnRDMm	1: The simultaneous rewrite trigger signal is generated when the master channel starts counting and the corresponding slave channel is at the peak of a triangular wave
TAUAnRDC.TAUAnRDCm	0: Channel is not monitored for an INTTAUAnIm signal that is used as the simultaneous rewrite trigger. If TAUAnRDS.TAUAnRDSm = 0, the master channel is monitored for the simultaneous rewrite trigger regardless of the value of this bit.

Note If the TAUAnRDS.TAUAnRDSm bit is 1, there must be a channel higher than the master channel to which a simultaneous rewrite trigger signal is generated.

(5) Register settings for slave channel 2**(a) TAUAnCMORm for slave channel 2**

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Table 12-164 TAUAnCMORm settings for slave channel 2 of the Triangle PWM Output Function with Dead Time

Bit name	Setting
TAUAnCKS[1:0]	00: Prescaler output CK0 01: Prescaler output CK1 10: Prescaler output CK2 11: Prescaler output CK3 The value of the TAUAnCKS[1:0] bit of the master and slave channel(s) must be identical.
TAUAnCCS[1:0]	00: Operation clock is used as the count clock
TAUAnMAS	0: Channel is a slave channel
TAUAnSTS[2:0]	111: The up/down output trigger signal of the master channel
TAUAnCOS[1:0]	00: Not used, so set to 00
TAUAnMD[4:1]	1001: Up Down Count Mode
TAUAnMDO	0: INTTAUAnIm not generated at operation start

(b) TAUAnCMURm for slave channel 2

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
-														TAUAnTIS[1:0]	

Table 12-165 TAUAnCMURm settings for slave channel 2 of the Triangle PWM Output Function with Dead Time

Bit name	Setting
TAUAnTIS[1:0]	00: These are not used, so set them to 00.

(c) Channel output mode for slave channel 2**Table 12-166 Control bit settings for Synchronous channel Output Mode 2 with Dead Time Output**

Bit name	Setting
TAUAnTOE.TAUAnTOEm	1: Enables Independent Channel Output Mode
TAUAnTOM.TAUAnTOMm	1: Synchronous channel operation
TAUAnTOC.TAUAnTOCm	1: Operation mode 2
TAUAnTOL.TAUAnTOLm	0: Positive logic 1: Inverted logic
TAUAnTDE.TAUAnTDEm	1: Enables dead time operation
TAUAnTDM.TAUAnTDMm	0: Dead time is added upon detection of an interrupt on the upper even channel, if the TAUAnTDL.TAUAnTDLm condition is also fulfilled.
TAUAnTDL.TAUAnTDLm	0: Dead time is added to the positive phase 1: Dead time is added to the negative phase
TAUAnTRE.TAUAnTREm	0: Disables real-time output
TAUAnTRO.TAUAnTROm	0: When real-time output is disabled (TAUAnTRE.TAUAnTREm = 0), set these bits to 0
TAUAnTRC.TAUAnTRCm	
TAUAnTME.TAUAnTMEm	0: Disables modulation

Caution For TAUAnTDL.TAUAnTDLm, specify the setting that is opposite that of the odd channel.

(d) Simultaneous rewrite for slave channel 2

The simultaneous rewrite settings of the master and slave channels must be identical.

Table 12-167 Simultaneous rewrite settings for slave channel 2 of the Triangle PWM Output Function

Bit name	Setting
TAUAnRDE.TAUAnRDEm	1: Enables simultaneous rewrite
TAUAnRDS.TAUAnRDSm	0: The master channel is monitored for the simultaneous rewrite trigger 1: An upper channel outside the channel group is monitored for the simultaneous rewrite trigger
TAUAnRDM.TAUAnRDMm	1: The simultaneous rewrite trigger signal is generated when the master channel starts counting and the corresponding slave channel is at the peak of a triangular wave
TAUAnRDC.TAUAnRDCm	0: Channel is not monitored for an INTTAUAnIm signal that is used as the simultaneous rewrite trigger. If TAUAnRDS.TAUAnRDSm = 0, the master channel is monitored for the simultaneous rewrite trigger regardless of the value of this bit.

(6) Register settings for slave channel 3**(a) TAUAnCMORm for slave channel 3**

Table 12-168 TAUAnCMORm settings for slave channel 3 of the Triangle PWM Output Function with Dead Time

Bit name	Setting
TAUAnCKS[1:0]	00: Prescaler output CK0 01: Prescaler output CK1 10: Prescaler output CK2 11: Prescaler output CK3 The value of the TAUAnCKS[1:0] bit of the master and slave channel(s) must be identical.
TAUAnCCS[1:0]	00: Operation clock is used as the count clock
TAUAnMAS	0: Channel is a slave channel
TAUAnSTS[2:0]	110: Dead time trigger
TAUAnCOS[1:0]	00: Not used, so set to 00
TAUAnMD[4:1]	0100: One Count Mode
TAUAnMDO	1: Enables start trigger detection during counting

(b) TAUAnCMURm for slave channel 3

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
-														TAUAnTIS[1:0]	

Table 12-169 TAUAnCMURm settings for slave channel 3 of the Triangle PWM Output Function with Dead Time

Bit name	Setting
TAUAnTIS[1:0]	00: These are not used, so set them to 00.

(c) Channel output mode for slave channel 3**Table 12-170 Control bit settings for Synchronous channel Output Mode 2 with Dead Time Output**

Bit name	Setting
TAUAnTOE.TAUAnTOEm	1: Enables Independent Channel Output Mode
TAUAnTOM.TAUAnTOMm	1: Synchronous channel operation
TAUAnTOC.TAUAnTOCm	1: Operation mode 2
TAUAnTOL.TAUAnTOLm	0: Positive logic 1: Inverted logic
TAUAnTDE.TAUAnTDEm	1: Enables dead time operation
TAUAnTDM.TAUAnTDMm	0: Dead time is added upon detection of an interrupt on the upper even channel, if the TAUAnTDL.TAUAnTDLm condition is also fulfilled.
TAUAnTDL.TAUAnTDLm	0: Dead time is added to the positive phase 1: Dead time is added to the negative phase
TAUAnTRE.TAUAnTREm	0: Disables real-time output
TAUAnTRO.TAUAnTROm	0: When real-time output is disabled (TAUAnTRE.TAUAnTREm = 0), set these bits to 0
TAUAnTRC.TAUAnTRCm	
TAUAnTME.TAUAnTMEm	0: Disables modulation

Caution For TAUAnTDL.TAUAnTDLm, specify the setting that is opposite that of the even channel.

(d) Simultaneous rewrite for slave channel 3

The simultaneous rewrite settings of the master and slave channel must be identical.

Table 12-171 Simultaneous rewrite settings for slave channel 3 of the Triangle PWM Output Function

Bit name	Setting
TAUAnRDE.TAUAnRDEm	1: Enables simultaneous rewrite
TAUAnRDS.TAUAnRDSm	0: The master channel is monitored for the simultaneous rewrite trigger 1: An upper channel outside the channel group is monitored for the simultaneous rewrite trigger
TAUAnRDM.TAUAnRDMm	1: The simultaneous rewrite trigger signal is generated when the master channel starts counting and the corresponding slave channel is at the peak of a triangular wave
TAUAnRDC.TAUAnRDCm	0: Channel is not monitored for an INTTAUAnIm signal that is used as the simultaneous rewrite trigger. If TAUAnRDS.TAUAnRDSm = 0, the master channel is monitored for the simultaneous rewrite trigger regardless of the value of this bit.

(7) Operating procedure for Triangle PWM Output Function with Dead Time

Table 12-172 Operating procedure for Triangle PWM Output Function with Dead Time

	Operation	Status of TAUAn
Restart	Initial channel setting Master channel: set the TAUAnCMORm and TAUAnCMURm registers and the channel output mode as described in (4) "Register settings for the master channel" on page 666 Slave channel 2: set the TAUAnCMORm and TAUAnCMURm registers and the channel output mode as described in (5) "Register settings for slave channel 2" on page 668 Slave channel 3: set the TAUAnCMORm and TAUAnCMURm registers and the channel output mode as described in (6) "Register settings for slave channel 3" on page 670 Set the values of the TAUAnCDRm registers of all channels	Channel operation is stopped.
	Start operation Set TAUAnTS.TAUAnTSm of the master and slave channels to 1 simultaneously. TAUAnTS.TAUAnTSm is a trigger bit, so it is automatically cleared to 0.	TAUAnTE.TAUAnTEm (master and slave channels) is set to 1 and the counters of the master and slave channels start. INTTAUAnIm is generated on the master channel, if TAUAnCMORm.TAUAnMD0 of the the master channel is set.
	During operation TAUAnCDRm can be changed at any time. TAUAnCNTm and TAUAnRSF.TAUAnRSFm can be read at any time. TAUAnRDT.TAUAnRDTm can be changed during operation.	TAUAnCNTm loads the TAUAnCDRm value of the master channel and slave channel 2, and then counts down. When the counter of the master channel reaches 0000 _H : <ul style="list-style-type: none"> INTTAUAnIm (master) is generated. TAUAnCNTm (master) reloads the value of TAUAnCDRm, and then continues counting. TAUAnCNTm (slave 2) reloads the value of TAUAnCDRm, or starts counting in the opposite direction. When TAUAnCNTm (slave 2) reaches 0001 _H : <ul style="list-style-type: none"> INTTAUAnIm (slave 2) is generated. TAUAnCNTm loads the TAUAnCDRm value of slave channel 3, and then counts down. When TAUAnCNTm of slave channel 3 = 0000 _H : <ul style="list-style-type: none"> INTTAUAnIm is generated.
	Stop operation Set TAUAnTT.TAUAnTTm of the master and slave channels to 1 simultaneously. TAUAnTT.TAUAnTTm is a trigger bit, so it is automatically cleared to 0.	TAUAnTE.TAUAnTEm is cleared to 0 and the counter stops. TAUAnCNTm and TAUAnTTOUTm stop and retain their current values.

(8) Specific timing diagrams**(a) Duty cycle = 0%**

The following settings apply to the diagram below:

- Slave channel 2:
 - Positive logic (TAUAnTOL.TAUAnTOLm = 0)
- Slave channel 3:
 - Negative logic (TAUAnTOL.TAUAnTOLm = 1)

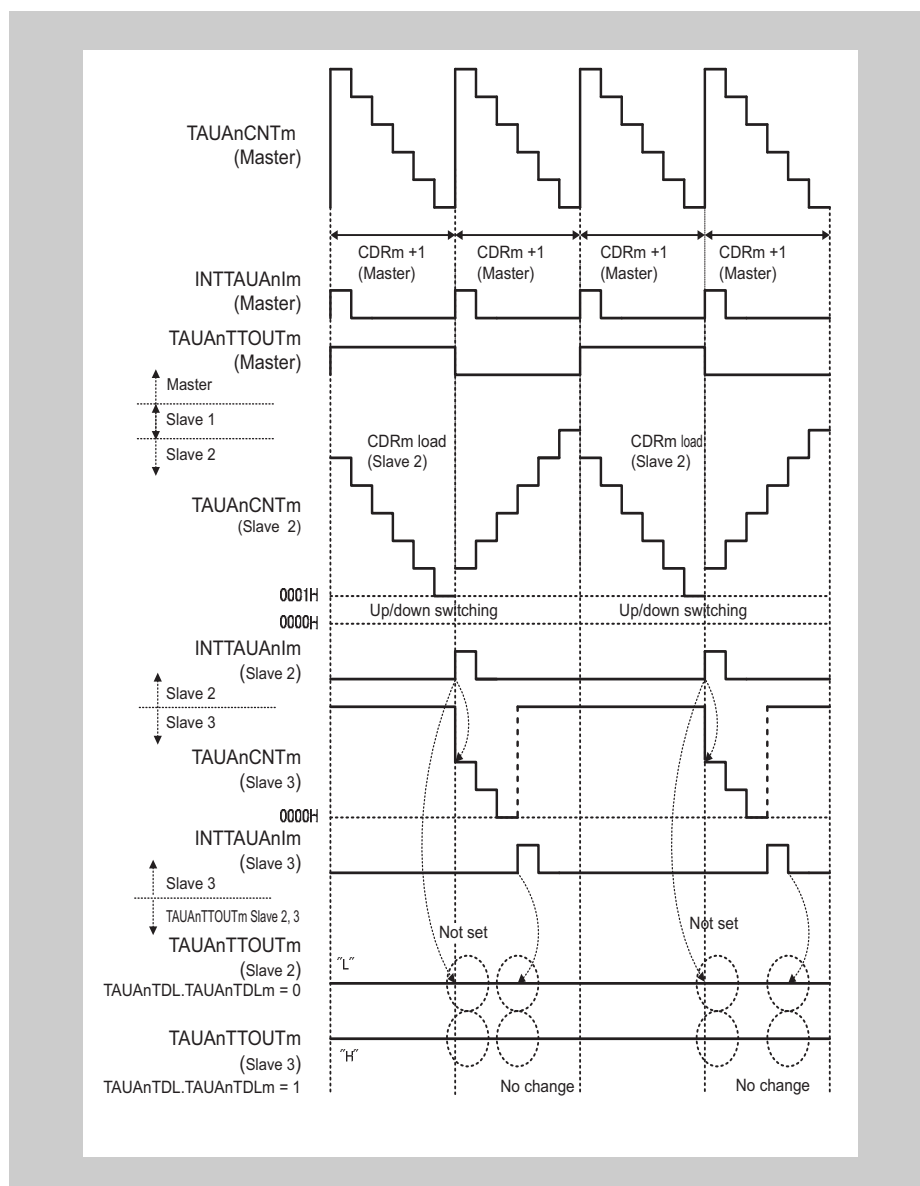

Figure 12-111 $TAUAnCDRm$ (slave) ³ $TAUAnCDRm$ (master) + 1

- If $TAUAnCDRm$ (slave 2) ³ $TAUAnCDRm$ (master) the counter of slave channel cannot reach 0000_H during counting down. Therefore $TAUAnTTOUm$ cannot be set or reset, and it remains at its initial state. The interrupt from slave channel 2 occurs during count up, therefore it is a reset signal.

(b) Duty cycle = 100%

The following settings apply to the diagram below:

- Slave channels 2:
 - Positive logic (TAUAnTOL.TAUAnTOLm = 0)
- Slave channels 3:
 - Negative logic (TAUAnTOL.TAUAnTOLm = 1)

Figure 12-112 TAUAnCDRm (slave) = 0000_H

- If TAUAnCDRm (slave 2) = 0000_H the counter of slave channel cannot reach 0001_H while counting up and therefore no INTTAUAnIm is generated while counting up.
 - The set conditions for a channel in which TAUAnTDL.TAUAnTDLm = 0 are met after dead time has elapsed. TAUAnTTOUTm is set/reset but remains in the new state because the reset conditions never occur for such a channel.
 - Slave channel 3 in the diagram above is set when the counter starts. However, the reset conditions for a channel in which TAUAnTDL.TAUAnTDLm = 1 never occur so TAUAnTTOUTm remains in its initial state for such a slave channel.

12.24.3 AD Conversion Trigger Output Function Type 2

(1) Overview

Summary This function is identical to 12.24.1 “Triangle PWM Output Function” on page 650 except that TAUAnTTOUm is not output.

This is achieved by setting the channel output mode of the slave to Independent Channel Output Mode Controlled by Software.

(2) Block diagram and general timing diagram

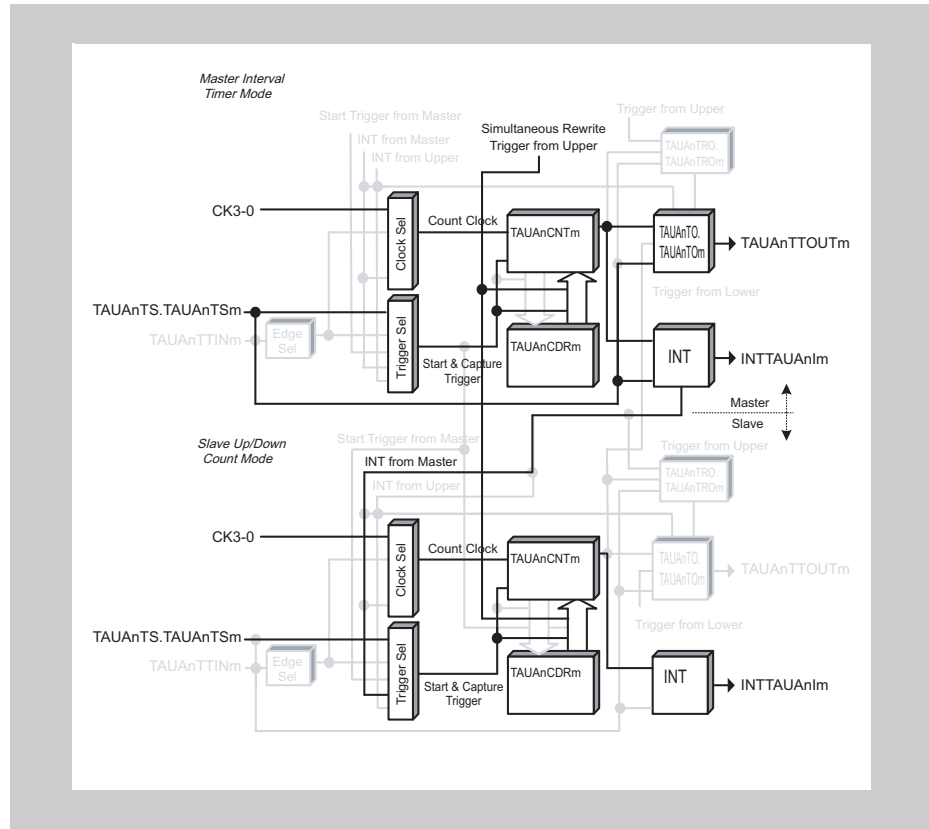

Figure 12-113 Block diagram for AD Conversion Trigger Output Function Type 2

The following settings apply to the general timing diagram:

- Master channel
 - INTTAUAnIm is generated at operation start (TAUAnCMORm.TAUAnMD0 = 1)

Figure 12-114 General timing diagram for AD Conversion Trigger Output Function Type 2

12.25 Synchronous Non-Complementary and Complementary Functions

This chapter describes functions that generate 6-phase triangle PWM using a master channel and 7 slaves.

- 12.25.1 *“Non-Complementary Modulation Output Function Type 1”*
- 12.25.2 *“Non-Complementary Modulation Output Function Type 2”*
- 12.25.3 *“Complementary Modulation Output Function”*

12.25.1 Non-Complementary Modulation Output Function Type 1

(1) Overview

Summary This function outputs a PWM signal, a high signal, or a low signal from TAUAnTTOUTm depending on the value of the real-time output bits (TAUAnTRO.TAUAnTROm) and the modulation output enable bits (TAUAnTME.TAUAnTMEem) of a pair of slave channels. Three pairs of channels are typically used.

- Prerequisites**
- One master channel and seven slave channels
 - The operation mode of the master channel must be set to Interval Timer Mode. Refer to *Table 12-174 “TAUAnCMORm settings for the master channel of Non-Complementary Modulation Output Function Type 1” on page 682*.
 - The operation mode of slave channels 1 to 7 must be set to One Count Mode. Refer to *Table 12-177 “TAUAnCMORm settings for slave channel 1 of Non-Complementary Modulation Output Function Type 1” on page 684*.
 - TAUAnTTOUTm is not used for the master channel of this function.
 - TAUAnTTOUTm of slave channel 1 is not used for this function, but TAUAnTRC.TAUAnTRCm must be set to 1. Refer to *12.8 “Channel Output Modes” on page 463*.
 - The channel output mode of slave channels 2 to 7 must be set to Simultaneous Channel Output Mode 1 with Non-Complementary Modulation Output. Refer to *12.8 “Channel Output Modes” on page 463*.
 - TAUAnCDRm of slave channel 1 must be set to 0000_H.

Description The counters of the master and slave channels are started by setting the channel trigger bit (TAUAnTS.TAUAnTSm) to 1. This in turn sets TAUAnTE.TAUAnTEem, enabling count operation. The values of the data registers (TAUAnCDRm) are loaded to the counters (TAUAnCNTm) and the counters start to count down. When the counters reach 0000_H, INTTAUAnIm is generated.

- Slave channel 1:

Because slave channel 1 is specified as the trigger channel for real-time output (TAUAnTRC.TAUAnTRCm = 1), when an interrupt is generated on slave channel 1 (for which TAUAnCDRm is fixed to 0), the real-time output bit (TAUAnTRO.TAUAnTROm) value of the channel that detects the generated interrupt of the corresponding channel is changed. After generating an interrupt, the counter returns to FFFF_H and awaits the next interrupt from the master channel.

- Slave channel 2:

Slave channel 2 generates a PWM output. The PWM output cycle is specified for the master channel, and the duty cycle is specified for slave channel 2. After generating an interrupt, the counter returns to FFFF_H and awaits the next interrupt from the master channel.

Slave channels 3 to 7 behave analogously to slave channel 2.

The signal that is output from TAUAnTTOUTm depends on the value of the real-time output bit (TAUAnTRO.TAUAnTROm) and the modulation output bit (TAUAnTME.TAUAnTMEem) of the slave channel, as shown in *Table 12-173 “TAUAnTTOUTm output of a pair of slave channels in Non-Complementary Modulation Output Function Type 1” on page 679*.

Forced restart is not possible with this function. The counter can be stopped by setting TAUAnTT.TAUAnTTm to 1 for the master and slave channels, which in turn sets TAUAnTE.TAUAnTEm to 0. TAUAnCNTm and TAUAnTTOUTm of master and slave channels stop but retain their values. The counters can be restarted by setting TAUAnTS.TAUAnTSm to 1.

- Conditions**
- If TAUAnTME.TAUAnTMEm = 0 for slave channels 2 to 7:
 - If TAUAnTRO.TAUAnTROm of the channel is 1, TAUAnTTOUTm outputs a high signal
 - If TAUAnTRO.TAUAnTROm of the channel is 0, TAUAnTTOUTm outputs a low signal
 - If TAUAnTME.TAUAnTMEm = 1 for slave channels 2 to 7:
 - If TAUAnTRO.TAUAnTROm of the channel is 1, TAUAnTTOUTm outputs the corresponding PWM of the channel
 - If TAUAnTRO.TAUAnTROm of the channel is 0, TAUAnTTOUTm outputs a low signal
 - If TAUAnTOL.TAUAnTOLm = 1 the high and low signals output from TAUAnTTOUTm are inverted. The PWM signals remain unaffected. Only the initial setting can be used for TAUAnTOL.TAUAnTOLm (and this setting cannot be changed during operation).

Table 12-173 TAUAnTTOUTm output of a pair of slave channels in Non-Complementary Modulation Output Function Type 1

TAUAnTME.TAUAnTMEm	TAUAnTRO.TAUAnTROm	TAUAnTTOUTm outputs
0	0	Low
	1	High
1	0	Low
	1	PWMm

- Simultaneous rewrite can be used with this function. Please refer to 12.7 “Simultaneous Rewrite” on page 451
- The value of TAUAnCDRm of slave channel 1 must be set to 0000_H so that the real-time output trigger occurs at the same time as the PWM is generated by slave channels 2 to 7.
- If TAUAnTOL.TAUAnTOLm is cleared to 0 on slave channels 2 to 7, TAUAnTO.TAUAnTOM is set to the low level before clearing TAUAnTE.TAUAnTEm to 0.
- If TAUAnTOL.TAUAnTOLm is set to 1 on slave channels 2 to 7, TAUAnTO.TAUAnTOM is set to the high level before clearing TAUAnTE.TAUAnTEm to 0.

(2) Equations

For slave channels 2 to 7:

PWM output cycle time = [TAUAnCDRm (master) + 1] x count clock

PWM output duty time = [TAUAnCDRm (slave)] x count clock

(3) Block diagram and general timing diagram

Figure 12-115 Block diagram for Non-Complementary Modulation Output Function Type 1

The following settings apply to the general timing diagram:

- Slave channels 2 to 7: positive logic (TAUAnTOL.TAUAnTOLm = 0)

TAUAnTIS[1:0]	00: Not used, so set to 00

(c) Channel output mode of slave channels 2 to 7**Table 12-182 Control bit settings for slave channels 2 to 7 of the Synchronous Channel Output Mode 1 with Non-Complementary Modulation Output**

Bit name	Setting
TAUAnTOE.TAUAnTOEm	1: Enables Independent Channel Output Mode
TAUAnTOM.TAUAnTOMm	1: Synchronous channel output
TAUAnTOC.TAUAnTOCm	0: Operation mode 1
TAUAnTOL.TAUAnTOLm	0: Positive logic 1: Inverted logic
TAUAnTDE.TAUAnTDEm	0: Disables dead time operation
TAUAnTDM.TAUAnTDMm	0: When dead time operation is disabled (TAUAnTDE.TAUAnTDEm = 0), set these bits to 0
TAUAnTDL.TAUAnTDLm	
TAUAnTRE.TAUAnTREM	1: Enables real-time output
TAUAnTRO.TAUAnTROm	0: Real-time output is low 1: Real-time output is high
TAUAnTRC.TAUAnTRCm	0: The upper channel generates the real-time trigger for channel m
TAUAnTME.TAUAnTMEem	0: Disables modulation 1: Enables modulation

(d) Simultaneous rewrite for slave channels 2 to 7

The simultaneous rewrite settings of the master and slave channels must be identical.

Table 12-183 Simultaneous rewrite settings for slave channels 2 to 7 of the Non-Complementary Modulation Output Function Type 1

Bit name	Setting
TAUAnRDE.TAUAnRDEm	1: Enables simultaneous rewrite
TAUAnRDS.TAUAnRDSm	0: The master channel is monitored for the simultaneous rewrite trigger 1: An upper channel outside the channel group is monitored for the simultaneous rewrite trigger
TAUAnRDM.TAUAnRDMm	0: The simultaneous rewrite trigger signal is generated when the master channel starts counting
TAUAnRDC.TAUAnRDCm	0: Channel is not monitored for an INTTAUAnIm signal that is used as the simultaneous rewrite trigger. If TAUAnRDS.TAUAnRDSm = 0, the master channel is monitored for the simultaneous rewrite trigger regardless of the value of this bit.

(7) Operating Procedure for Non-Complementary Modulation Output Function Type 1

Table 12-184 Operating procedure for Non-Complementary Modulation Output Function Type 1 (1/2)

	Operation	Status of TAUAn
Initial channel setting	<p>Master channel: set the TAUAnCMORm and TAUAnCMURm registers and the channel output mode as described in (4) "Register settings for the master channel" on page 682</p> <p>Slave channel 1: set the TAUAnCMORm and TAUAnCMURm registers and the channel output mode as described in (5) "Register settings for slave channel 1" on page 684</p> <p>Slave channel 2 to 7: set the TAUAnCMORm and TAUAnCMURm registers and the channel output mode as described in (6) "Register settings for slave channels 2 to 7" on page 686</p> <p>Set the values of the TAUAnCDRm registers of all channels: set the pulse cycle in TAUAnCDRm of the master channel, set TAUAnCDRm of slave channel 1 to 0000_H, and set the duty width in TAUAnCDRm of slave channels 2 to 7</p> <p>Set TAUAnTRC.TAUAnTRCm = 1 for slave channel 1</p>	Channel operation is stopped.

Table 12-184 Operating procedure for Non-Complementary Modulation Output Function Type 1 (2/2)

	Operation	Status of TAUAn
Restart	Start operation	TAUAnTE.TAUAnTEm of the master and slave channels is set to 1 and the counters start to count down.
	During operation	<p>TAUAnCDRm, TAUAnTRO.TAUAnTROm, and TAUAnTME.TAUAnTMEm can be changed at any time. TAUAnCNTm and TAUAnRSF.TAUAnRSFm can be read at any time.</p> <p>TAUAnRDT.TAUAnRDTm can be changed during operation.</p> <p>TAUAnCNTm loads the TAUAnCDRm value of the master channel and slave channels 1 to 7, and then counts down. When the counter of the master channel reaches 0000_H:</p> <ul style="list-style-type: none"> • INTTAUAnIm is generated. • TAUAnCNTm reloads the TAUAnCDRm value, and then continues counting down. • The PWM output signals of slave channels 2 to 7 are set/reset. • TAUAnCNTm reloads the TAUAnCDRm value of slave channel 1, and then counts down. • TAUAnCNTm reloads the TAUAnCDRm value of slave channels 2 to 7, and then counts down. • When the counter of slave channel 1 or slave channels 2 to 7 reaches 0000_H: <ul style="list-style-type: none"> - INTTAUAnIm is generated. • When the counter of slave channels 2 to 7 reaches 0000_H: <ul style="list-style-type: none"> - The PWM output signals of slave channels 2 to 7 are set/reset. <p>TAUAnTTOUTm of slave channels 2 to 7 outputs a PWM signal, a high signal, or a low signal depending on the value of the real-time output bits (TAUAnTRO.TAUAnTROm) and the modulation output bits (TAUAnTME.TAUAnTMEm) of a pair of slave channels.</p>
	Stop operation	<p>Set TAUAnTT.TAUAnTTm of the master and slave channels to 1 simultaneously. TAUAnTT.TAUAnTTm is a trigger bit, so it is automatically cleared to 0.</p> <p>TAUAnTE.TAUAnTEm is cleared to 0 and the counter stops. TAUAnCNTm and TAUAnTTOUTm stop and retain their current values.</p>

(8) Specific timing diagrams

The following settings apply to the specific timing diagram:

- Slave channels 2 to 7: positive logic (TAUAnTOL.TAUAnTOLm = 0)

Figure 12-117 Specific timing diagram for Non-Complementary Modulation Output Function Type 1

The above timing diagram shows how full modulation, first-half modulation, and second-half modulation can be achieved by modifying the TAUAnTME.TAUAnTME_m bits of the lower slave channels during operation.

The “Setting” symbol indicates the time period during which the values of TAUAnCDR_m, TAUAnTME.TAUAnTME_m and TAUAnTRO.TAUAnTRO_m can be changed.

The TAUAnTME.TAUAnTME_m setting is applied when counting starts or when a master channel cycle is detected. A modulation waveform is output from TAUAnTTOUT_m according to the changed setting.

The values of the TAUAnTRO.TAUAnTRO_m bits are specified by software, but the new values are only applied when an interrupt occurs on slave channel 1.

12.25.2 Non-Complementary Modulation Output Function Type 2

(1) Overview

Summary This function outputs a PWM signal, a high signal, or a low signal from TAUAnTTOUTm depending on the value of the real-time output bits (TAUAnTRO.TAUAnTROm) and the modulation output enable bits (TAUAnTME.TAUAnTME m) of a pair of slave channels. Three pairs of channels are typically used.

- Prerequisites**
- One master channel and seven slave channels
 - The operation mode of the master channel must be set to Interval Timer Mode. Refer to *Table 12-186 “TAUAnCMORm settings for the master channel of Non-Complementary Modulation Output Function Type 2” on page 696*.
 - The operation mode of slave channel 1 must be set to Event Count Mode. Refer to *Table 12-190 “TAUAnCMORm settings for slave channel 1 of Non-Complementary Modulation Output Function Type 2” on page 698*.
 - The operation mode of slave channels 2 to 7 must be set to Up Down Count Mode. Refer to *Table 12-193 “TAUAnCMORm settings for slave channels 2 to 7 of Non-Complementary Modulation Output Function Type 2” on page 700*.
 - TAUAnTTOUTm is not used for the master channel of this function.
 - TAUAnTTOUTm of slave channel 1 is not used for this function, but TAUAnTRC.TAUAnTRCm must be set to 1. Refer to *12.8 “Channel Output Modes” on page 463*.
 - The channel output mode of slave channels 2 to 7 must be set to Simultaneous Channel Output Mode 2 with Non-Complementary Modulation Output. Refer to *12.8 “Channel Output Modes” on page 463*.

- Description** The counters of the master and slave channels are started by setting the channel trigger bit (TAUAnTS.TAUAnTSm) to 1. This in turn sets TAUAnTE.TAUAnTE m, enabling count operation. The values of the data registers (TAUAnCDRm) are loaded to the counters (TAUAnCNTm).
- Master channel:

The counter of the master channel starts to count down. When the counter reaches 0000_H, INTTAUAnIm is generated.
 - Slave channel 1:

When slave channel 1 detects an interrupt on the master channel, counter reduces by 1. When the counter reaches 0000_H, it awaits the next interrupt from the master channel. Next, the value of TAUAnCDRm is reloaded to TAUAnCNTm (slave 1), and then INTTAUAnIm is generated.

Because slave channel 1 is specified as the trigger channel for real-time output (TAUAnTRC.TAUAnTRCm = 1), when an interrupt is generated on slave channel 1, the real-time output bit (TAUAnTRO.TAUAnTROm) value of the channel that detects the generated interrupt of the corresponding channel is changed.
 - Slave channel 2:

When an interrupt is detected from the master channel, the TAUAnCNTm counts in the reverse direction. If the interrupt is detected during up count, the TAUAnCNTm reloads the value of TAUAnCDRm, and then starts counting down.

When $TAUAnCNTm = 0001_H$, an interrupt is generated and the PWM output is set or reset.

The combination of the master channel and slave channel 2 generates a PWM output. The master channel generates the period of the PWM output, the slave channel the duty cycle.

Slave channels 3 to 7 behave analogously to slave channel 2.

The signal that is output from $TAUAnTTOUTm$ depends on the value of the real-time output bit ($TAUAnTRO.TAUAnTROm$) and the modulation output bit ($TAUAnTME.TAUAnTME m$) of the slave channel, as shown in *Table 12-185 "TAUAnTTOUTm output of a pair of slave channels in Non-Complementary Modulation Output Function Type 2" on page 692*.

Forced restart is not possible with this function. The counter can be stopped by setting $TAUAnTT.TAUAnTTm$ to 1 for the master and slave channels, which in turn sets $TAUAnTE.TAUAnTE m$ to 0. $TAUAnCNTm$ and $TAUAnTTOUTm$ of master and slave channels stop but retain their values. The counters can be restarted by setting $TAUAnTS.TAUAnTS m$ to 1.

- Conditions**
- If $TAUAnTME.TAUAnTME m$ of the slave channel is 1:
 - If $TAUAnTRO.TAUAnTRO m$ of the channel is 1, $TAUAnTTOUTm$ outputs the corresponding PWM of the channel
 - If $TAUAnTRO.TAUAnTRO m$ of the channel is 0, $TAUAnTTOUTm$ outputs a low signal
 - If $TAUAnTME.TAUAnTME m$ of the slave channel is 0:
 - If $TAUAnTRO.TAUAnTRO m$ of the channel is 1, $TAUAnTTOUTm$ outputs a high signal
 - If $TAUAnTRO.TAUAnTRO m$ of the channel is 0, $TAUAnTTOUTm$ outputs a low signal
 - If $TAUAnTOL.TAUAnTOL m = 1$ the high and low signals output from $TAUAnTTOUTm$ are inverted. The PWM signals remain unaffected. Only the initial setting can be used for $TAUAnTOL.TAUAnTOL m$ (and this setting cannot be changed during operation).

Table 12-185 TAUAnTTOUTm output of a pair of slave channels in Non-Complementary Modulation Output Function Type 2

$TAUAnTME.TAUAnTME m$	$TAUAnTRO.TAUAnTRO m$	$TAUAnTTOUTm$ outputs
0	0	Low
	1	High
1	0	Low
	1	PWMm

- Simultaneous rewrite can be used with this function. Please refer to *12.7 "Simultaneous Rewrite" on page 451*
- If $TAUAnTOL.TAUAnTOL m$ is cleared to 0 on slave channels 2 to 7, $TAUAnTO.TAUAnTO m$ is set to the low level before clearing $TAUAnTE.TAUAnTE m$ to 0.
- If $TAUAnTOL.TAUAnTOL m$ is set to 1 on slave channels 2 to 7, $TAUAnTO.TAUAnTO m$ is set to the high level before clearing $TAUAnTE.TAUAnTE m$ to 0.

(2) Equations

For slave channels 2 to 7:

PWM output cycle time

$$= [\text{TAUAnCDRm (master)} + 1] \times \text{count clock}$$

PWM output duty time

$$= [\text{TAUAnCDRm (master)} + 1 - \text{TAUAnCDRm (slave)}] \times 2 \times \text{count clock}$$

(3) Block diagram and general timing diagram

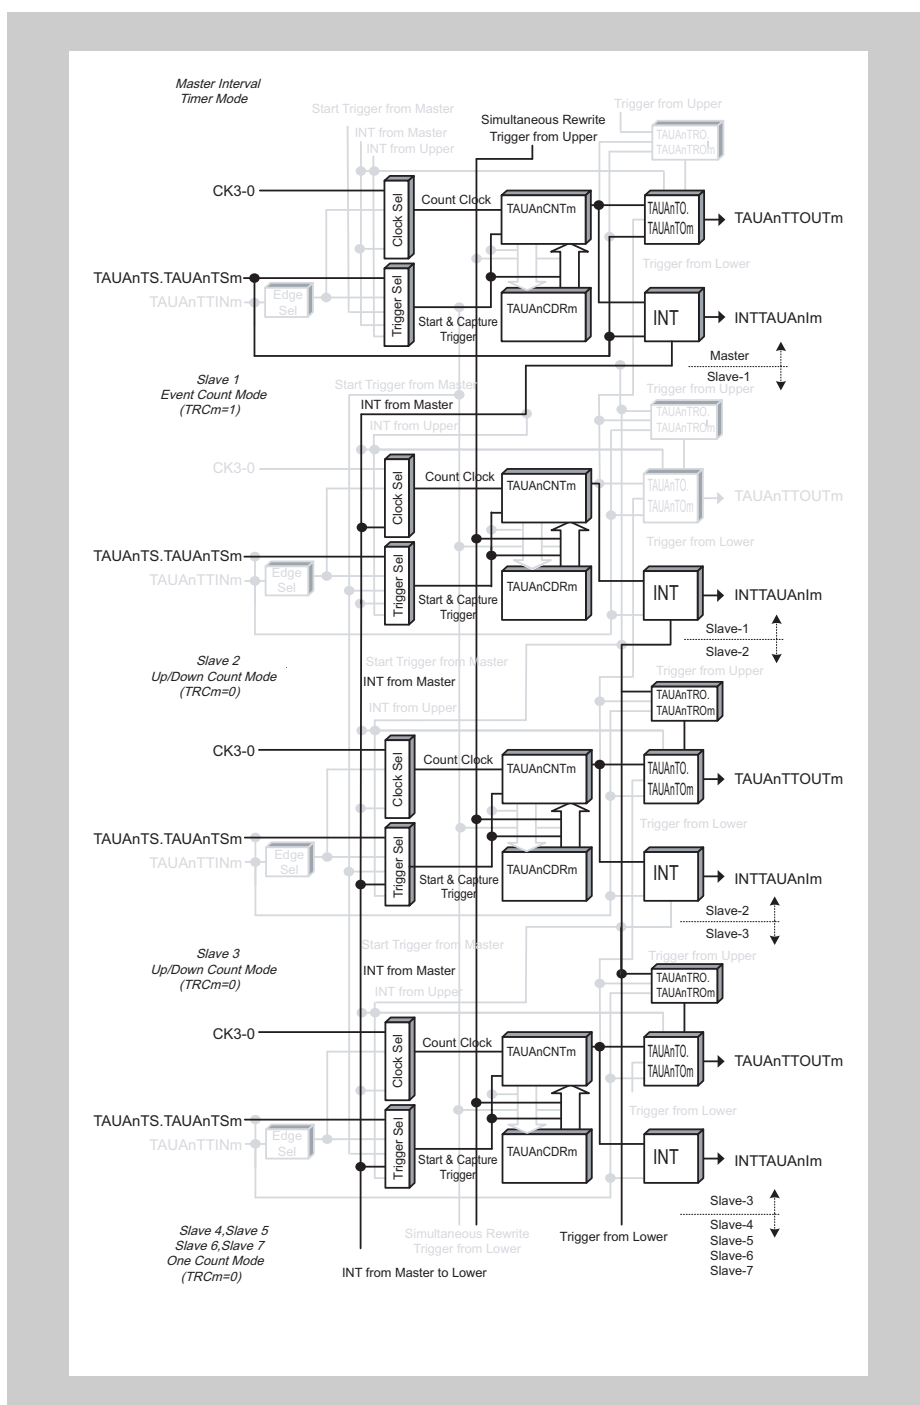

Figure 12-118 Block diagram for Non-Complementary Modulation Output Function Type 2

The following settings apply to the general timing diagram:

- Master channel: INTTAUAnIm not generated at operation start (TAUAnCMORm.TAUAnMD0 = 0)
- Slave channels 2 to 7: positive logic (TAUAnTOL.TAUAnTOLm = 0)

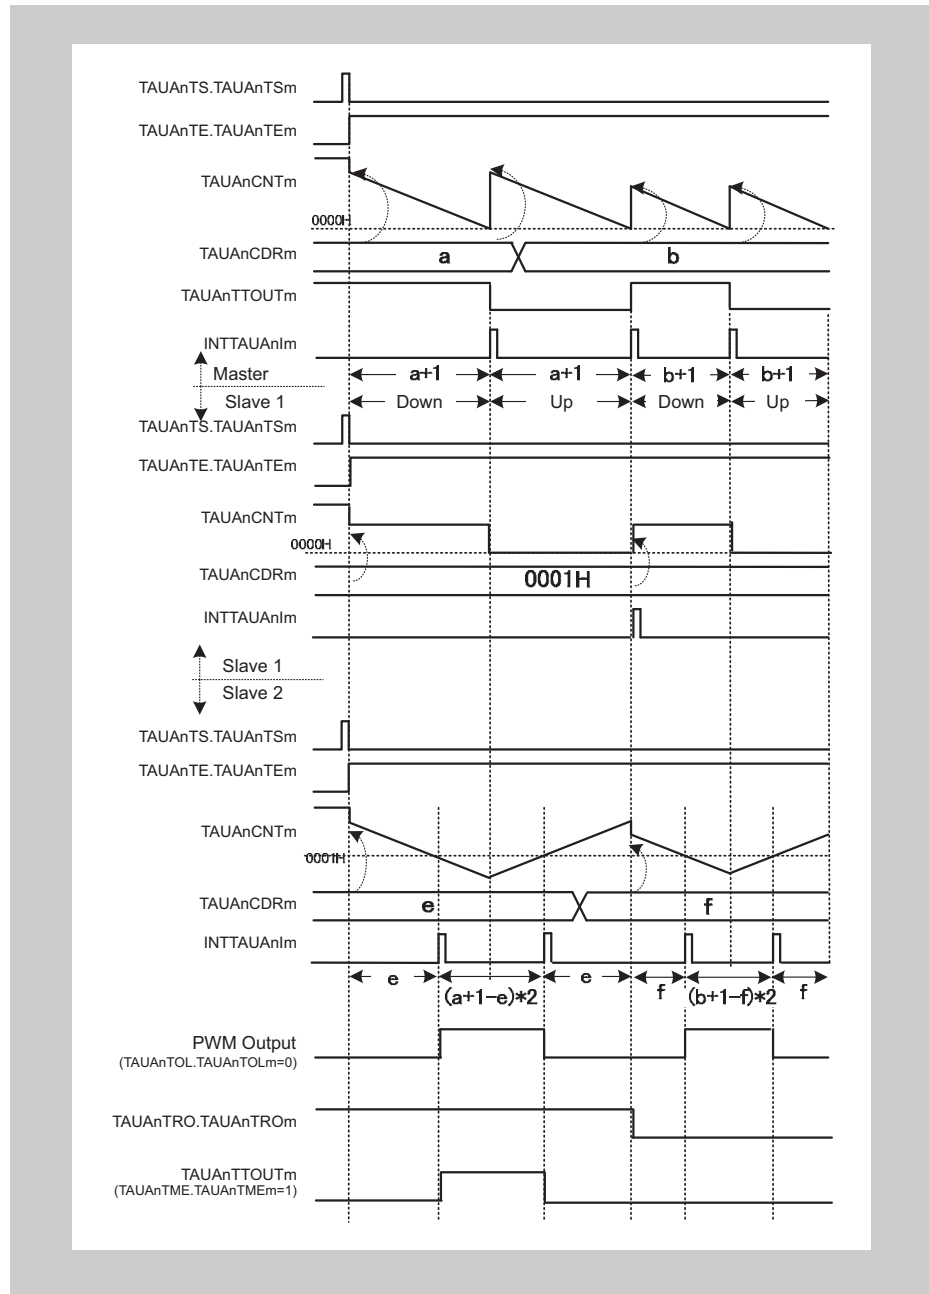

Figure 12-119 General timing diagram for Non-Complementary Modulation Output Function Type 2

-														TAUAnTIS[1:0]	

Table 12-187 TAUAnCMURm settings for the master channel of Non-Complementary Modulation Output Function Type 2

Bit name	Setting
TAUAnTIS[1:0]	00: Not used, so set to 00

(c) Channel output mode of the master channel**Table 12-188 Master Channel Control Bit Settings When Using Non-Complementary Modulation Output Function Type 2**

Bit name	Setting
TAUAnTOE.TAUAnTOEm	1: Enables the independent channel output mode.
TAUAnTOM.TAUAnTOMm	0: Independent channel output
TAUAnTOC.TAUAnTOCm	0: Operation mode 1 (the toggle mode if TAUAnTOM.TAUAnTOMm is 0)
TAUAnTOL.TAUAnTOLm	0: Positive logic
TAUAnTDE.TAUAnTDEm	0: Disables dead time operation.
TAUAnTDM.TAUAnTDMm	0: When dead time operation is disabled (TAUAnTDE.TAUAnTDEm = 0), clear these bits to 0.
TAUAnTDL.TAUAnTDLm	
TAUAnTRE.TAUAnTREm	0: Disables real-time output.
TAUAnTRO.TAUAnTROm	0: The real-time output is low.
TAUAnTRC.TAUAnTRCm	0: The next upper channel generates the real-time trigger for channel m.
TAUAnTME.TAUAnTMEm	0: Disables modulation.

(d) Simultaneous rewrite for the master channel

The simultaneous rewrite settings of the master and slave channels must be identical.

Table 12-189 Simultaneous rewrite settings for the master channel of Non-Complementary Modulation Output Function Type 2

Bit name	Setting
TAUAnRDE.TAUAnRDEm	1: Enables simultaneous rewrite
TAUAnRDS.TAUAnRDSm	0: The master channel is monitored for the simultaneous rewrite trigger 1: An upper channel outside the channel group is monitored for the simultaneous rewrite trigger
TAUAnRDM.TAUAnRDMm	1: The simultaneous rewrite trigger signal is generated when the master channel starts counting and the corresponding slave channel is at the peak of a triangular wave
TAUAnRDC.TAUAnRDCm	0: When simultaneous rewrite is disabled (TAUAnTAUAnRDE.TAUAnRDEm = 0), set these bits to 0. If TAUAnRDS.TAUAnRDSm = 0, the master channel is monitored for the simultaneous rewrite trigger regardless of the value of this bit.

Note If the TAUAnRDS.TAUAnRDSm bit is 1, there must be a channel higher than the master channel to which a simultaneous rewrite trigger signal is generated.

(5) Register settings for slave channel 1**(a) TAUAnCMORM for slave channel 1**

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Bit name	Setting
TAUAnCKS[1:0]	00: Operation clock = CK0 01: Operation clock = CK1 10: Operation clock = CK2 11: Operation clock = CK3 The value of the TAUAnCKS[1:0] bit of the master and slave channels must be identical.
TAUAnCCS[1:0]	00: Operation clock is used as the count clock
TAUAnMAS	0: Channel is a slave channel
TAUAnSTS[2:0]	111: The up/down output trigger signal TAUAnTUDSm of the master channel is the start trigger
TAUAnCOS[1:0]	00: Not used, so set to 00
TAUAnMD[4:1]	1001: Up Down Count Mode
TAUAnMDO	0: INTTAUAnIm not generated at operation start or restart

(b) TAUAnCMURm for slave channels 2 to 7

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Table 12-194 TAUAnCMURm settings slave channels 2 to 7 of Non-Complementary Modulation Output Function Type 2

Bit name	Setting
TAUAnTIS[1:0]	00: Not used, so set to 00

(c) Channel output mode of slave channels 2 to 7**Table 12-195 Control bit settings slave channels 2 to 7 of Synchronous Channel Output Mode 2 with Non-Complementary Modulation Output**

Bit name	Setting
TAUAnTOE.TAUAnTOEm	1: Enables Independent Channel Output Mode
TAUAnTOM.TAUAnTOMm	1: Synchronous channel output
TAUAnTOC.TAUAnTOCm	1: Operation mode 2
TAUAnTOL.TAUAnTOLm	0: Positive logic 1: Inverted logic
TAUAnTDE.TAUAnTDEm	0: Disables dead time operation
TAUAnTDM.TAUAnTDMm	0: When dead time operation is disabled (TAUAnTDE.TAUAnTDEm = 0), set these bits to 0
TAUAnTDL.TAUAnTDLm	
TAUAnTRE.TAUAnTREm	1: Enables real-time output
TAUAnTRO.TAUAnTROm	0: Real-time output is low 1: Real-time output is high
TAUAnTRC.TAUAnTRCm	0: The next upper channel generates the real-time trigger for channel m
TAUAnTME.TAUAnTMEm	0: Disables modulation 1: Enables modulation

(d) Simultaneous rewrite for slave channels 2 to 7

The simultaneous rewrite settings of the master and slave channels must be identical.

Table 12-196 Simultaneous rewrite settings slave channels 2 to 7 of Non-Complementary Modulation Output Function Type 2

Bit name	Setting
TAUAnRDE.TAUAnRDEm	1: Enables simultaneous rewrite
TAUAnRDS.TAUAnRDSm	0: The master channel is monitored for the simultaneous rewrite trigger 1: An upper channel outside the channel group is monitored for the simultaneous rewrite trigger
TAUAnRDM.TAUAnRDMm	1: The simultaneous rewrite trigger signal is generated when the master channel starts counting and the corresponding slave channel is at the peak of a triangular wave
TAUAnRDC.TAUAnRDCm	0: Channel is not monitored for an INTTAUAnIm signal that is used as the simultaneous rewrite trigger. If TAUAnRDS.TAUAnRDSm = 0, the master channel is monitored for the simultaneous rewrite trigger regardless of the value of this bit.

(7) Operating Procedure for Non-Complementary Modulation Output Function Type 2

Table 12-197 Operating procedure for Non-Complementary Modulation Output Function Type 2 (1/2)

	Operation	Status of TAUAn
Restart ↑	Start operation	TAUAnTE.TAUAnTEm of the master and slave channels is set to 1 and the counters start to count down.
	During operation	<p>TAUAnCDRm, TAUAnTRO.TAUAnTROm, and TAUAnTME.TAUAnTMEm can be changed at any time. TAUAnCNTm and TAUAnRSF.TAUAnRSFm can be read at any time.</p> <p>TAUAnRDT.TAUAnRDTm can be changed during operation.</p> <p>TAUAnCNTm loads the TAUAnCDRm value of the master channel and slave channels 2 and 7, and then counts down. The TAUAnCDRm value of slave channel 1 is loaded, and a master channel interrupt is awaited. When the counter of the master channel reaches 0000_H:</p> <ul style="list-style-type: none"> • INTTAUAnIm is generated. • TAUAnCNTm reloads the TAUAnCDRm value, and then continues counting down. • TAUAnCNTm of slave channel 1 reduces by 1 and awaits the next interrupt on the master channel. • TAUAnCNTm of slave channels 2 to 7 counts in the other direction. • When the counter of slave channel 1 reaches 0000_H it awaits the next interrupt from the master channel. When it is detected: <ul style="list-style-type: none"> - INTTAUAnIm is generated. • When the counter of slave channels 2 to 7 reaches 0001_H: <ul style="list-style-type: none"> - INTTAUAnIm is generated. - The PWM output signals of slave channels 2 to 7 are set/reset. <p>TAUAnTTOUTm of slave channels 2 to 7 outputs a PWM signal, a high signal, or a low signal depending on the value of the real-time output bits (TAUAnTRO.TAUAnTROm) and the modulation output bits (TAUAnTME.TAUAnTMEm) of a pair of slave channels.</p>
	Stop operation	TAUAnTE.TAUAnTEm is cleared to 0 and the counter stops. TAUAnCNTm and TAUAnTTOUTm stop and retain their current values.

(8) Specific timing diagrams

The following settings apply to the general timing diagram:

- Slave channels 2 to 7: positive logic (TAUAnTOL.TAUAnTOLm = 0)

Figure 12-120 Specific timing diagram for Non-Complementary Modulation Output Function Type 2

The above timing diagram shows how full modulation, first-half modulation, and second-half modulation can be achieved by modifying the TAUAnTME.TAUAnTMEm bits of the lower slave channels during operation.

The “Setting” symbol indicates the time period during which the values of TAUAnCDRm, TAUAnTME.TAUAnTMEm and TAUAnTRO.TAUAnTROm can be changed.

The TAUAnTME.TAUAnTMEm setting is applied when counting starts or when a triangle PWM carrier cycle (at the peak interrupt timing) is detected.

The values of the TAUAnTRO.TAUAnTROm bits are specified by software, but the new values are only applied when an interrupt occurs on slave channel 1.

12.25.3 Complementary Modulation Output Function

(1) Overview

Summary This function outputs a PWM signal, a high signal, or a low signal from TAUAnTTOUTm depending on the value of the real-time output bits (TAUAnTRO.TAUAnTROm), the modulation output bits (TAUAnTME.TAUAnTME m), and the output level bits (TAUAnTDL.TAUAnTDLm) of a pair of slave channels. Three pairs of channels are typically used.

- Prerequisites**
- One master channel and seven slave channels
 - The operation mode of the master channel must be set to Interval Timer Mode. Refer to *Table 12-200 “TAUAnCMORm settings for the master channel of the Complementary Modulation Output Function” on page 711*.
 - The operation mode of slave channel 1 must be set to Event Count Mode. Refer to *Table 12-204 “TAUAnCMORm settings for slave channel 1 of the Complementary Modulation Output Function” on page 713*.
 - The operation mode of slave channels 2, 4, and 6 must be set to Up Down Count Mode. Refer to *Table 12-207 “TAUAnCMORm settings for slave channels 2, 4, and 6 of the Complementary Modulation Output Function” on page 715*.
 - The operation mode of slave channels 3, 5, and 7 must be set to One Count Mode. Refer to *Table 12-211 “TAUAnCMORm settings for slave channels 3, 5, and 7 of the Complementary Modulation Output Function” on page 717*.
 - The channel output mode of the master channel must be set to Independent Channel Output Mode 1. Refer to *12.8 “Channel Output Modes” on page 463*.
 - TAUAnTTOUTm of slave channel 1 is not used for this function, but TAUAnTRC.TAUAnTRCm must be set to 1. Refer to *12.8 “Channel Output Modes” on page 463*.
 - The channel output mode of slave channels 2 to 7 must be set to Simultaneous Channel Output Mode 2 with Complementary Modulation Output. Refer to *12.8 “Channel Output Modes” on page 463*.

- Description**
- Master channel:

The counter of the master channel is started by setting the channel trigger bit (TAUAnTS.TAUAnTSm) to 1. This in turn sets TAUAnTE.TAUAnTE m, enabling count operation. The value of the data register of the master channel (TAUAnCDRm) is loaded to the counter (TAUAnCNTm) and the counter starts to count down from this value.

When the counter of the master channel reaches 0000_H, INTTAUAnIm is generated. This triggers the counter of slave channel 1 to reduce by 1 and the counter of slave channel 2 to count in the reverse direction.
 - Slave channel 1:

When the counter reaches 0000_H, it awaits the next interrupt from the master channel. Next, TAUAnCNTm (slave 1) reloads the value of INTTAUAnIm, and then INTTAUAnIm is generated.

Slave channel 1 is set as the channel that triggers real-time output (TAUAnTRC.TAUAnTRCm = 1). For each channel on which an interrupt generated on slave channel 1 is detected, the real-time output bit (TAUAnTRO.TAUAnTROm) value is applied. The value of the real-time output bits can be changed at any time by the application software, but the new values are only applied when the interrupt occurs on slave channel 1.

- Slave channel 2:
When the counter of slave channel 2 reaches 0001_H, the counter of slave channel 3 starts to count down. When the counter of slave channel 3 reaches 0000_H it generates an interrupt.
- Slave channels 2 and 3:
The combination of the master channel and slave channels 2 and 3 generates a PWM output. The master channel generates the period of the PWM output, slave channel 2 the duty cycle, and slave channel 3 generates the dead time.
- Slave channels 4 to 7:
Slave channels 4 and 6 behave analogously to slave channel 2. Slave channels 5 and 7 behave analogously to slave channel 3.

The signal that is output from TAUAnTTOUT_m depends on the value of the real-time output bits (TAUAnTRO.TAUAnTRO_m), the modulation output bits (TAUAnTME.TAUAnTME_m), and the output level bits (TAUAnTOL.TAUAnTOL_m) of a pair of slave channels, as shown in *Table 12-173 “TAUAnTTOUT_m output of a pair of slave channels in Non-Complementary Modulation Output Function Type 1” on page 679*.

However, the output of slave channels 2 and 3 must not be high simultaneously (for example to prevent a motor driver from short circuiting). To prevent both channels being high at the instant that one channel switches to low and the other switches to high, a delay must be added to the channel that switches to high so that this transition occurs later. This is achieved by adding dead time to either the positive or negative-phased PWM signal as specified by the value of the channel dead time output level register (TAUAnTDL.TAUAnTDL_m).

The counter can be stopped by setting TAUAnTT.TAUAnTT_m to 1 for the master and slave channels, which in turn sets TAUAnTE.TAUAnTE_m to 0. TAUAnCNT_m and TAUAnTTOUT_m of master and slave channels stop but retain their values. The counters can be restarted by setting TAUAnTS.TAUAnTS_m to 1.

- Conditions**
- If TAUAnTME.TAUAnTME_m of both channels in a pair is 1:
 - If the TAUAnTRO.TAUAnTRO_m value of one channel is 1, TAUAnTTOUT_m performs PWM output for that channel.
 - If the TAUAnTRO.TAUAnTRO_m value of one channel is 0, TAUAnTTOUT_m outputs a low level signal.
 - If TAUAnTME.TAUAnTME_m of both channels in a pair is 0:
 - If TAUAnTRO.TAUAnTRO_m of a channel is 1, TAUAnTTOUT_m outputs a high signal
 - If TAUAnTRO.TAUAnTRO_m of a channel is 0, TAUAnTTOUT_m outputs a low signal
 - If TAUAnTOL.TAUAnTOL_m = 1, the high and low signals output from TAUAnTTOUT_m are inverted. The PWM signal does not change in accordance with the TAUAnTOL.TAUAnTOL_m setting.

Table 12-198 TAUAnTTOUTm output of a pair of slave channels in Complementary Modulation Output Function for TAUAnTOL.TAUAnTOLm = 0

TAUAnTME. TAUAnTME2	TAUAnTME. TAUAnTME3	TAUAnTRO. TAUAnTRO2	TAUAnTRO. TAUAnTRO3	TAUAnTTOUT2 outputs	TAUAnTTOUT3 outputs
0	0	0	0	LOW	LOW
		0	1	LOW	HIGH
		1	0	HIGH	LOW
		1	1	Prohibited	Prohibited
1	1	0	0	LOW	LOW
		0	1	~PWMm	PWMm
		1	0	PWMm	~PWMm
		1	1	Prohibited	Prohibited

- Notes**
- ~PWM indicates an inverted PWM signal. PWM and -PWM are set up using TAUAnTDL.TAUAnTDLm.
 - All settings that are not listed in this table are not permitted.
- While TAUAnTRO.TAUAnTROM is set to 1 on one set of channels, if TAUAnTME.TAUAnTME_m is continuously set to 1, the modulation is entire modulation.
 - If TAUAnTME.TAUAnTME_m is set to 1 during the first half of the period during which TAUAnTRO.TAUAnTROM is set to 1 on one set of channels, the modulation is first-half modulation.
 - If TAUAnTME.TAUAnTME_m is set to 1 during the second half of the period during which TAUAnTRO.TAUAnTROM is set to 1 on one set of channels, the modulation is second-half modulation.
 - If two channels simultaneously output a high level signal, the TAUAnTDL.TAUAnTDL_m bit value determines whether the dead time is added to the positive-phase PWM signal or the negative-phase PWM signal.
 - If TAUAnTDL.TAUAnTDL_m = 0, dead time is added to the positive PWM signal
 - If TAUAnTDL.TAUAnTDL_m = 1 dead time is added to the negative PWM signal
 - The values of the TAUAnTDL.TAUAnTDL_m bits must be manipulated by the application software during operation. To change TAUAnTDL.TAUAnTDL_m, perform rewriting while TAUAnTRO.TAUAnTROM is 00B.

Table 12-199 TAUAnTDL.TAUAnTDLm settings for a pair of slave channels in Complementary Modulation Output Function for TAUAnTOL.TAUAnTOLm = 0

TAUAnTME. TAUAnTME2	TAUAnTME. TAUAnTME3	TAUAnTRO. TAUAnTRO2	TAUAnTRO. TAUAnTRO3	TAUAnTDL. TAUAnTDL2	TAUAnTDL. TAUAnTDL3
0	0	0	0	1	1
		0	1	1	0
		1	0	0	1
1	1	0	0	1	1
		0	1	1	0
		1	0	0	1

- The value of TAUAnCDRm of slave channel 1 must be set so that INTTAUAnIm is generated from slave 1 at the summit of a carrier cycle.
- Clear the TAUAnCMORm.TAUAnMD0 value of the master channel to 0.
- Simultaneous rewrite can be used with this function. Please refer to 12.7 “Simultaneous Rewrite” on page 451 .

(2) Equations

For slaves 2, 4, and 6

When TAUAnTOL.TAUAnTOLm = 0 and TAUAnCDR (slave 1):

PWM output cycle time = $2 \times [\text{TAUAnCDRm (master)} + 1] \times \text{count clock}$

PWM output duty time = $\{ [\text{TAUAnCDRm (master)} + 1 - \text{TAUAnCDRm (slave 2)}] \times 2 - [\text{TAUAnCDRm (slave 3)} + 1] \} \times \text{count clock}$

(3) Block diagram and general timing diagram

Figure 12-121 Block diagram for Complementary Modulation Output Function

The following settings apply to the general timing diagram:

- Master channel: INTTAUAnIm not generated at operation start (TAUAnCMORm.TAUAnMD0 = 0)
- Slave channels 2 to 7: positive logic (TAUAnTOL.TAUAnTOLm = 0)

Figure 12-122 General timing diagram for Complementary Modulation Output Function

Table 12-200 TAUAnCMORM settings for the master channel of the Complementary Modulation Output Function

Bit name	Setting
TAUAnCKS[1:0]	00: Operation clock = CK0 01: Operation clock = CK1 10: Operation clock = CK2 11: Operation clock = CK3 The value of the TAUAnCKS[1:0] bit of the master and slave channels must be identical.
TAUAnCCS[1:0]	00: Operation clock is used as the count clock
TAUAnMAS	1: Channel is master channel
TAUAnSTS[2:0]	000: Counter triggered by software trigger
TAUAnCOS[1:0]	00: Not used, so set to 00
TAUAnMD[4:1]	0000: Interval Timer Mode
TAUAnMDO	0: INTTAUAnIm not generated and TAUAnTTOUTm does not toggle at operation start or restart 1: Generates INTTAUAnIm and toggles TAUAnTTOUTm at operation start or restart

(b) TAUAnCMURm for the master channel

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
-														TAUAnTIS[1:0]	

Table 12-201 TAUAnCMURm settings for the master channel of the Complementary Modulation Output Function

Bit name	Setting
TAUAnTIS[1:0]	00: Not used, so set to 00

(c) Channel output mode**Table 12-202 Control bit settings for Independent Channel Output Mode 1**

Bit name	Setting
TAUAnTOE.TAUAnTOEm	1: Enables Independent Channel Output Mode
TAUAnTOM.TAUAnTOMm	0: Independent channel output
TAUAnTOC.TAUAnTOCm	0: Operation mode 1 (= Toggle mode if TAUAnTOM.TAUAnTOMm = 0)
TAUAnTOL.TAUAnTOLm	0: Positive logic
TAUAnTDE.TAUAnTDEm	0: Disables dead time operation
TAUAnTDM.TAUAnTDMm	0: When dead time operation is disabled (TAUAnTDE.TAUAnTDEm = 0), set these bits to 0
TAUAnTDL.TAUAnTDLm	
TAUAnTRE.TAUAnTREm	0: Disables real-time output
TAUAnTRO.TAUAnTROm	0: When real-time output is disabled (TAUAnTRE.TAUAnTREm = 0), set these bits to 0
TAUAnTRC.TAUAnTRCm	
TAUAnTME.TAUAnTMEem	0: Disables modulation

(d) Simultaneous rewrite for the master channel

The simultaneous rewrite settings of the master and slave channels must be identical.

Table 12-203 Simultaneous rewrite settings for the master channel of the Complementary Modulation Output Function

Bit name	Setting
TAUAnRDE.TAUAnRDEm	1: Enables simultaneous rewrite
TAUAnRDS.TAUAnRDSm	0: The master channel is monitored for the simultaneous rewrite trigger 1: An upper channel outside the channel group is monitored for the simultaneous rewrite trigger
TAUAnRDM.TAUAnRDMm	1: The simultaneous rewrite trigger signal is generated when the master channel starts counting and the corresponding slave channel is at the peak of a triangular wave
TAUAnRDC.TAUAnRDCm	0: Channel is not monitored for an INTTAUAnIm signal that is used as the simultaneous rewrite trigger. If TAUAnRDS.TAUAnRDSm = 0, the master channel is monitored for the simultaneous rewrite trigger regardless of the value of this bit.

Note If the TAUAnRDS.TAUAnRDSm bit is 1, there must be a channel higher than the master channel to which a simultaneous rewrite trigger signal is generated.

(5) Register settings for slave channel 1**(a) TAUAnCMORM for slave channel 1**

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
TAUAn CKS[1:0]		TAUAn CCS[1:0]		TAUAn MAS	TAUAnSTS[2:0]		TAUAn COS[1:0]		-	TAUAnMD[4:1]				TAUAn MDO	

Table 12-204 TAUAnCMORM settings for slave channel 1 of the Complementary Modulation Output Function

Bit name	Setting
TAUAnCKS[1:0]	00: Operation clock = CK0 01: Operation clock = CK1 10: Operation clock = CK2 11: Operation clock = CK3 The value of the TAUAnCKS[1:0] bit of the master and slave channels must be identical.
TAUAnCCS[1:0]	11: INTTAUAnIm of the master channel is used as the count clock
TAUAnMAS	0: Channel is a slave channel
TAUAnSTS[2:0]	000: Counter triggered by software trigger 011: Simultaneous rewrite trigger
TAUAnCOS[1:0]	00: Not used, so set to 00
TAUAnMD[4:1]	0011: Event Count Mode

Table 12-211 TAUAnCMORM settings for slave channels 3, 5, and 7 of the Complementary Modulation Output Function

Bit name	Setting
TAUAnCKS[1:0]	00: Operation clock = CK0 01: Operation clock = CK1 10: Operation clock = CK2 11: Operation clock = CK3
TAUAnCCS[1:0]	00: Operation clock is used as the count clock
TAUAnMAS	0: Channel is a slave channel
TAUAnSTS[2:0]	110: Dead time trigger
TAUAnCOS[1:0]	00: Not used, so set to 00
TAUAnMD[4:1]	0100: One count mode
TAUAnMDO	1: Enables start trigger detection during counting

(b) TAUAnCMURm for slave channels 3, 5, and 7

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
														TAUAnTIS[1:0]	

Table 12-212 TAUAnCMURm settings for slave channels 3, 5, and 7 of the Complementary Modulation Output Function

Bit name	Setting
TAUAnTIS[1:0]	00: Not used, so set to 00

(c) Channel output mode of slave channels 3, 5, and 7**Table 12-213 Control bit settings for Synchronous Channel Output Mode 2 with Complementary Modulation Output**

Bit name	Setting
TAUAnTOE.TAUAnTOEm	1: Enables Independent Channel Output Mode
TAUAnTOM.TAUAnTOMm	1: Synchronous channel output
TAUAnTOC.TAUAnTOCm	1: Operation mode 2
TAUAnTOL.TAUAnTOLm	0: Positive logic 1: Inverted logic
TAUAnTDE.TAUAnTDEm	1: Enables dead time operation
TAUAnTDM.TAUAnTDMm	0: Dead time is added upon detection of a duty cycle at the upper even channel
TAUAnTDL.TAUAnTDLm	0: Dead time is added to the positive phase 1: Dead time is added to the negative phase
TAUAnTRE.TAUAnTREm	1: Enables real-time output
TAUAnTRO.TAUAnTROm	0: Real-time output is low 1: Real-time output is high
TAUAnTRC.TAUAnTRCm	0: The upper channel generates the real-time trigger for channel m
TAUAnTME.TAUAnTMEm	0: Disables modulation 1: Enables modulation

Caution For TAUAnTDL.TAUAnTDLm, specify the setting that is opposite that of the even channel.

(d) Simultaneous rewrite for slave channels 3, 5, and 7

The simultaneous rewrite settings of the master and slave channel must be identical.

Table 12-214 Simultaneous rewrite settings for slave channels 3, 5, and 7 of the Complementary Modulation Output Function

Bit name	Setting
TAUAnRDE.TAUAnRDEm	1: Enables simultaneous rewrite
TAUAnRDS.TAUAnRDSm	0: The master channel is monitored for the simultaneous rewrite trigger 1: An upper channel outside the channel group is monitored for the simultaneous rewrite trigger
TAUAnRDM.TAUAnRDMm	1: The simultaneous rewrite trigger signal is generated when the master channel starts counting and the corresponding slave channel is at the peak of a triangular wave
TAUAnRDC.TAUAnRDCm	0: Channel is not monitored for an INTTAUAnIm signal that is used as the simultaneous rewrite trigger. If TAUAnRDS.TAUAnRDSm = 0, the master channel is monitored for the simultaneous rewrite trigger regardless of the value of this bit.

(8) Operating Procedure for Complementary Modulation Output Function**Table 12-215 Operating procedure for Complementary Modulation Output Function (1/2)**

	Operation	Status of TAUAn
Initial channel setting	<p>Master channel: set the TAUAnCMORm and TAUAnCMURm registers and the channel output mode as described in (4) "Register settings for the master channel" on page 711</p> <p>Slave channel 1: set the TAUAnCMORm and TAUAnCMURm registers and the channel output mode as described in (5) "Register settings for slave channel 1" on page 713</p> <p>Slave channels 2, 4, and 6: set the TAUAnCMORm and TAUAnCMURm registers and the channel output mode as described in (6) "Register settings for slave channels 2, 4, and 6" on page 715</p> <p>Slave channels 3, 5, and 7: set the TAUAnCMORm and TAUAnCMURm registers and the channel output mode as described in (7) "Register settings for slave channels 3, 5, and 7"</p> <p>Set the values of the TAUAnCDRm registers of all channels: set the pulse cycle in TAUAnCDRm of the master channel, set the number of interrupts on the master channel to be ignored using TAUAnCDRm of slave channel 1, and set the duty width in TAUAnCDRm of slave channels 2, 4, and 6, and set the dead time delay in slave channels 3, 5, and 7.</p> <p>Set TAUAnTRC.TAUAnTRCm = 1 for slave channel 1</p>	Channel operation is stopped.

Table 12-215 Operating procedure for Complementary Modulation Output Function (2/2)

	Operation	Status of TAUAn	
Restart	Start operation	<p>Set TAUAnTS.TAUAnTSM of the master and slave channels to 1 simultaneously (for channel restart, only slaves 2 to 7). TAUAnTS.TAUAnTSM is a trigger bit, so it is automatically cleared to 0.</p>	<p>TAUAnTE.TAUAnTEm of the master and slave channels is set to 1 and the counters start to count down.</p>
	During operation	<p>TAUAnCDRm, TAUAnTRO.TAUAnTROM, and TAUAnTME.TAUAnTMEem can be changed at any time. TAUAnCNTm and TAUAnRSF.TAUAnRSFm can be read at any time.</p> <p>TAUAnRDT.TAUAnRDTm can be changed during operation.</p>	<p>TAUAnCNTm loads the TAUAnCDRm value of the master channel and slave channels 2 and 7, and then counts down. The TAUAnCDRm value of slave channel 1 is loaded, and a master channel interrupt is awaited. When the counter of the master channel reaches 0000μ:</p> <ul style="list-style-type: none"> • INTTAUAnIm is generated. • TAUAnCNTm reloads the TAUAnCDRm value, and then continues counting down. • TAUAnCNTm of slave channel 1 reduces by 1 and awaits the next interrupt on the master channel. • TAUAnCNTm of slave channels 2, 4 and 6 counts in the reverse direction. • When the counter of slave channel 1 reaches 0000μ it awaits the next interrupt from the master channel. When it is detected: <ul style="list-style-type: none"> - TAUAnCNTm reloads the TAUAnCDRm value and awaits the next interrupt on the master channel. - INTTAUAnIm is generated. - TAUAnTRO.TAUAnTROM can change. • When the counter of slave channels 2, 4, and 6 reaches 0001μ: <ul style="list-style-type: none"> - INTTAUAnIm is generated. - The PWM output of slave channel m resets. - TAUAnCNTm loads the TAUAnCDRm value of slave channels 3, 5, and 7, and then counts down. • When the counter of slave channels 3, 5, and 7 reaches 0001μ: <ul style="list-style-type: none"> - INTTAUAnIm is generated. <p>TAUAnTTOUTm of slave channels 2 to 7 outputs a PWM signal, a high signal, or a low signal depending on the value of the real-time output bits (TAUAnTRO.TAUAnTROM), the modulation output bits (TAUAnTME.TAUAnTMEem), and the output level bits (TAUAnTOL.TAUAnTOLm) of a pair of slave channels.</p>
	Stop operation	<p>Set TAUAnTT.TAUAnTTm of the master and slave channels to 1 simultaneously. TAUAnTT.TAUAnTTm is a trigger bit, so it is automatically cleared to 0.</p>	<p>TAUAnTE.TAUAnTEm is cleared to 0 and the counter stops. TAUAnCNTm and TAUAnTTOUTm stop and retain their current values.</p>

(9) Specific timing diagrams

The following settings apply to the timing diagram:

- Slave channels 2 to 7: positive logic (TAUAnTOL.TAUAnTOLm = 0)

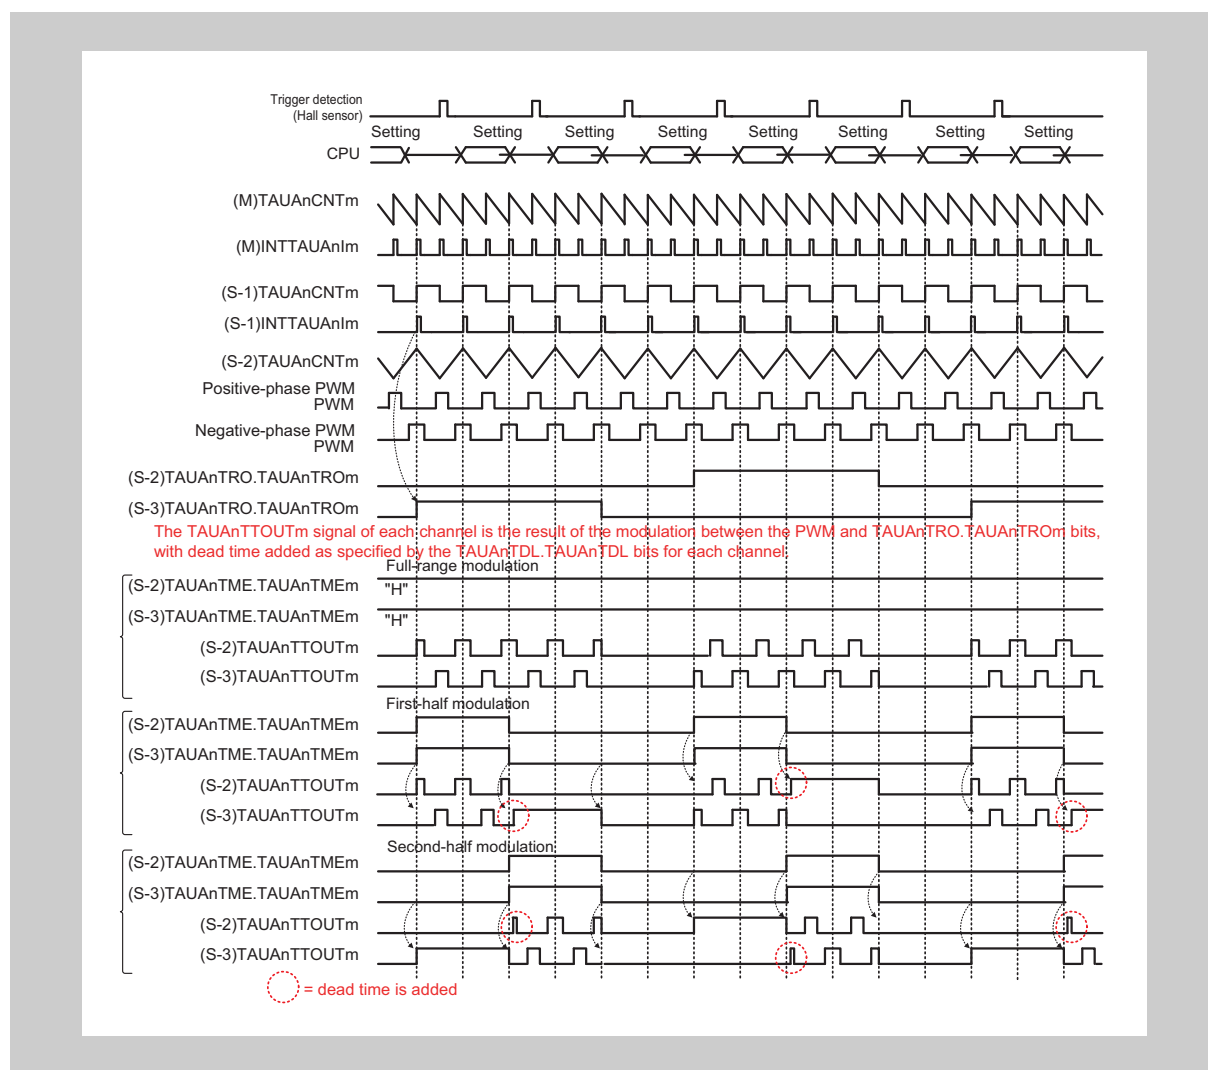

Figure 12-123 Specific timing diagram for Complementary Modulation Output Function

The above timing diagram shows how full modulation, first-half modulation, and second-half modulation can be achieved by modifying the TAUAnTME.TAUAnTMEem bits of the lower slave channels during operation.

The output of the channels 2 and 3 is the modulation of the PWM output and the value of the TAUAnTRO.TAUAnTROm bits. Thus the type of PWM signal (positive or negative) output by an individual channel varies depending on the value of these bits.

The TAUAnTRO.TAUAnTROm, TAUAnTME.TAUAnTMEem, and TAUAnTDL.TAUAnTDLm bit values are specified using software, but a newly specified value is not applied unless an interrupt is generated on slave channel 1.

Note Dead time is added to prevent the positive- and negative-phase PWM edges from changing simultaneously.

The “Setting” symbol indicates the time period during which the values of TAUAnCDRm, TAUAnTME.TAUAnTME_m, TAUAnTRO.TAUAnTRO_m, and TAUAnTDL.TAUAnTDL_m can be changed.

12.26 Other Synchronous Channel Functions

This chapter describes a function that is used to ignore a specified number of interrupts on the master channel.

- 12.26.1 *“Interrupt Culling Function”* on page 724

12.26.1 Interrupt Culling Function

(1) Overview

Summary This function divides the number of interrupts of the master channel by a specified value using a slave channel.

The Interrupt Culling Function is a sub function of the following functions:

- PWM Output Function
(12.22.1 “PWM Output Function” on page 594)
- Triangle PWM Output Function
(12.24.1 “Triangle PWM Output Function” on page 650)
- Triangle PWM Output Function with Dead Time
(12.24.2 “Triangle PWM Output Function with Dead Time” on page 661)

- Prerequisites**
- Two channels
 - The operation mode of the master channel must be set to Interval Timer Mode. Refer to *Table 12-216 “TAUAnCMORm settings for the master channel of the Interrupt Culling Function” on page 727* .
 - The operation mode of the slave channel must be set to Event Count Mode. Refer to *Table 12-219 “TAUAnCMORm settings for the slave channel of the Interrupt Culling Function” on page 729* .
 - TAUAnTTOUTm is not used for the slave channel of this function

Description The counters (master and slave) are started by setting the channel trigger bit (TAUAnTS.TAUAnTSm) to 1 for both channels. This in turn sets TAUAnTE.TAUAnTEm, enabling count operation. The current value of the data register of the master channel and slave channel (TAUAnCDRm) are loaded to the counter (TAUAnCNTm).

- Master channel:
When the counter of the master channel reaches 0000_H, INTTAUAnIm is generated and TAUAnCNTm loads the TAUAnCDRm value.
- Slave channel:
Every time the master channel generates an INTTAUAnIm, the counter of the slave channel reduces by one. When the counter reaches 0000_H, it awaits the next interrupt from the master channel. This causes TAUAnCNTm (slave) to load the value of TAUAnCDRm, and an INTTAUAnIm is generated.

Forced restart is not possible for this function. The counter can be stopped by setting TAUAnTT.TAUAnTTm to 1 for the master and slave channel, which in turn sets TAUAnTE.TAUAnTEm to 0. TAUAnCNTm and TAUAnTTOUTm of master and slave channel stop but retain their values.

Conditions Simultaneous rewrite can be used with this function. Please refer to 12.7 “Simultaneous Rewrite” on page 451 .

(2) Equations

Interrupt divider = TAUAnCDRm (slave channel)

- One INTTAUAnIm is generated for the number of INTTAUAnIm of the master channel defined as TAUAnCDRm (slave channel) + 1.

(3) Block diagram and general timing diagram

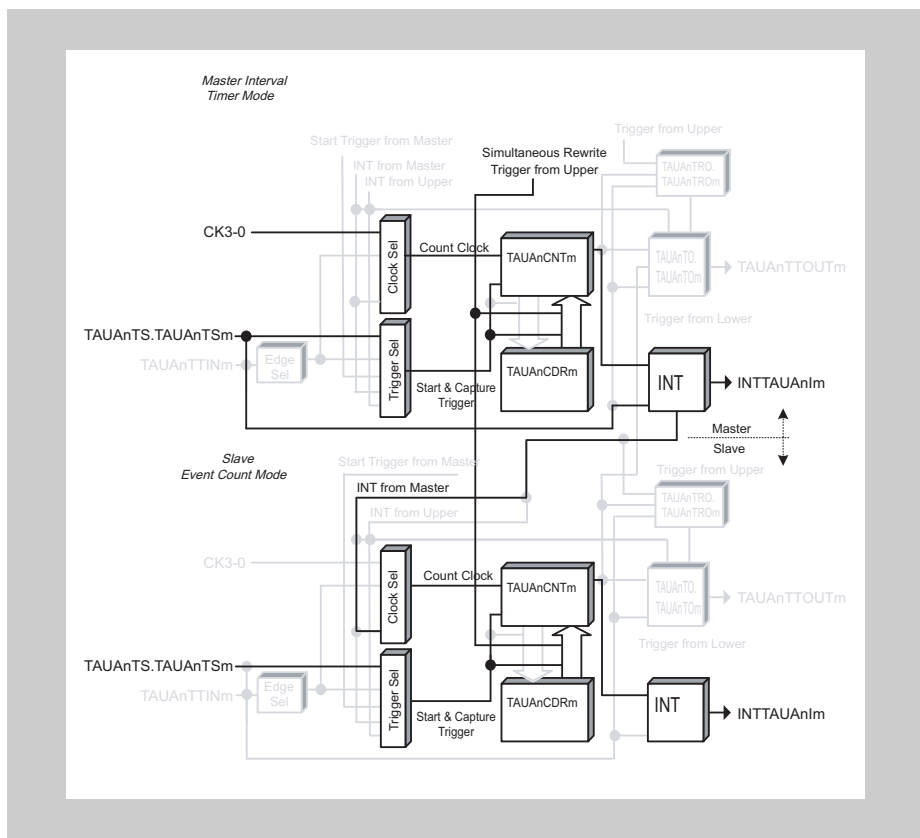

Figure 12-124 Block diagram for Interrupt Culling Function

The following settings apply to the general timing diagram:

Master channel:

- INTTAUAnIm is generated at operation start (TAUAnCMORm.TAUAnMD0 = 1)

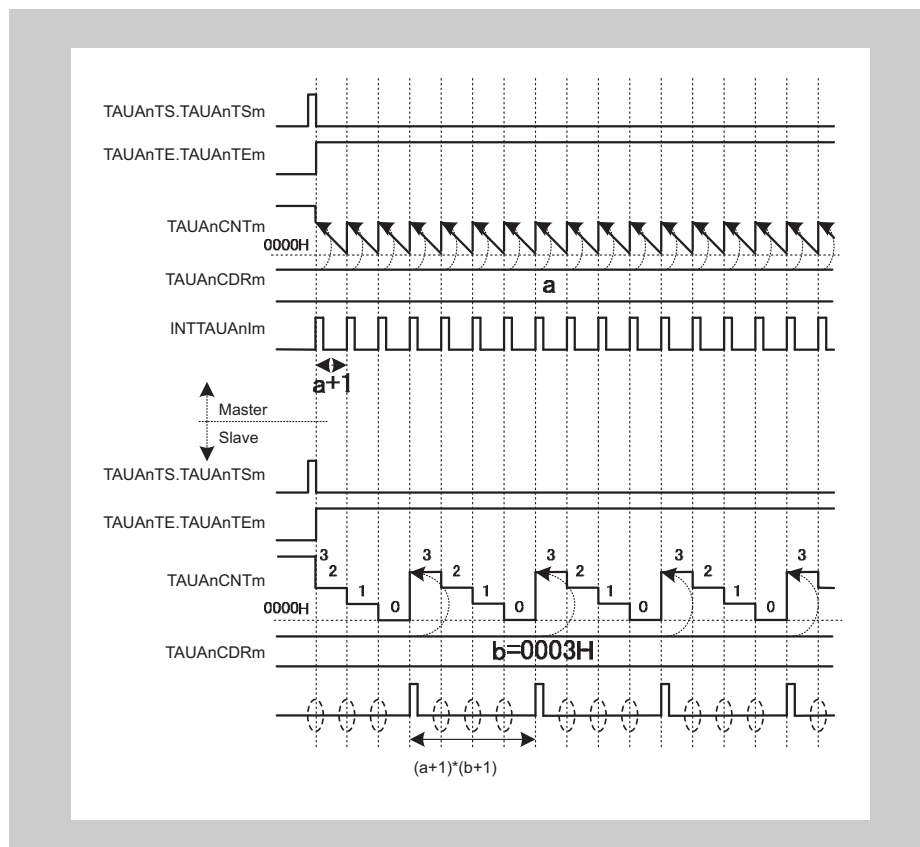

Figure 12-125 General timing diagram for Interrupt Culling Function

The simultaneous rewrite trigger signal is generated when the master channel starts counting and the corresponding slave channel is at the peak of a triangular wave.

(4) Register settings for the master channel**(a) TAUAnCMORM for the master channel**

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
TAUAn CKS[1:0]	TAUAn CCS[1:0]	TAUAn MAS	TAUAnSTS[2:0]	TAUAn COS[1:0]	-	TAUAnMD[4:1]				TAUAn MDO					

Table 12-216 TAUAnCMORM settings for the master channel of the Interrupt Culling Function

Bit name	Setting
TAUAnCKS[1:0]	00: Prescaler output CK0 01: Prescaler output CK1 10: Prescaler output CK2 11: Prescaler output CK3 The value of the TAUAnCKS[1:0] bit of the master and slave channel must be identical.
TAUAnCCS[1:0]	00: Operation clock is used as the count clock
TAUAnMAS	1: Channel is master channel
TAUAnSTS[2:0]	000: Counter triggered by software trigger
TAUAnCOS[1:0]	00: Not used, so set to 00
TAUAnMD[4:1]	0000: Interval Timer Mode
TAUAnMDO	0: INTTAUAnIm not output at operation startup 1: Generates INTTAUAnIm at operation startup

(b) TAUAnCMURM for the master channel

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
-														TAUAnTIS[1:0]	

Table 12-217 TAUAnCMURM settings for the master channel of the Interrupt Culling Function

Bit name	Setting
TAUAnTIS[1:0]	00: These are not used, so set them to 00.

(c) Channel output mode for the master channel

Because the channel output mode is not used by this function, clear TAUAnTOE.TAUAnTOEn. However, it can be used by other functions or in Independent Channel Output Mode Controlled by Software.

(d) Simultaneous rewrite for the master channel

The simultaneous rewrite settings of the master and slave channel must be identical.

Table 12-218 Simultaneous rewrite settings for the master channel of the Interrupt Culling Function

Bit name	Setting
TAUAnRDE.TAUAnRDEm	1: Enables simultaneous rewrite
TAUAnRDS.TAUAnRDSm	0: The master channel is monitored for the simultaneous rewrite trigger
TAUAnRDM.TAUAnRDMm	0: The simultaneous rewrite trigger signal is generated when the master channel starts counting 1: The simultaneous rewrite trigger signal is generated when the master channel starts counting and the corresponding slave channel is at the peak of a triangular wave
TAUAnRDC.TAUAnRDCm	0: Channel is not monitored for an INTTAUAnIm signal that is used as the simultaneous rewrite trigger. If TAUAnRDS.TAUAnRDSm = 0, the master channel is monitored for the simultaneous rewrite trigger regardless of the value of this bit.

(5) Register settings for the slave channel**(a) TAUAnCMORm for the slave channel**

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
TAUAn CKS[1:0]		TAUAn CCS[1:0]		TAUAn MAS	TAUAnSTS[2:0]			TAUAn COS[1:0]		-	TAUAnMD[4:1]				TAUAn MDO

Table 12-219 TAUAnCMORm settings for the slave channel of the Interrupt Culling Function

Bit name	Setting
TAUAnCKS[1:0]	00: Prescaler output CK0 01: Prescaler output CK1 10: Prescaler output CK2 11: Prescaler output CK3 The value of the TAUAnCKS[1:0] bit of the master and slave channel must be identical.
TAUAnCCS[1:0]	11: INTTAUAnIm of the master channel is used as the count clock
TAUAnMAS	0: Channel is a slave channel
TAUAnSTS[2:0]	000: Counter triggered by software trigger
TAUAnCOS[1:0]	00: Not used, so set to 00
TAUAnMD[4:1]	0011: Event Count Mode
TAUAnMDO	0: INTTAUAnIm not output at operation startup

(b) TAUAnCMURm for the slave channel

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
-														TAUAnTIS[1:0]	

Table 12-220 TAUAnCMURm settings for the slave channel of the Interrupt Culling Function

Bit name	Setting
TAUAnTIS[1:0]	00: These are not used, so set them to 00.

(c) Channel output mode for the slave channel

Because the channel output mode is not used by this function, clear TAUAnTOE.TAUAnTOEm. However, it can be used by other functions or in Independent Channel Output Mode Controlled by Software.

(d) Simultaneous rewrite for the slave channel

The simultaneous rewrite settings of the master and slave channel must be identical.

Table 12-221 Simultaneous rewrite settings for the slave channel of the Interrupt Culling Function

Bit name	Setting
TAUAnRDE.TAUAnRDEm	1: Enables simultaneous rewrite
TAUAnRDS.TAUAnRDSm	0: The master channel is monitored for the simultaneous rewrite trigger
TAUAnRDM.TAUAnRDMm	0: The simultaneous rewrite trigger signal is generated when the master channel starts counting 1: The simultaneous rewrite trigger signal is generated when the master channel starts counting and the corresponding slave channel is at the peak of a triangular wave
TAUAnRDC.TAUAnRDCm	0: Channel is not monitored for an INTTAUAnIm signal that is used as the simultaneous rewrite trigger. If TAUAnRDS.TAUAnRDSm = 0, the master channel is monitored for the simultaneous rewrite trigger regardless of the value of this bit.

(6) Operating procedure for Interrupt Culling Function

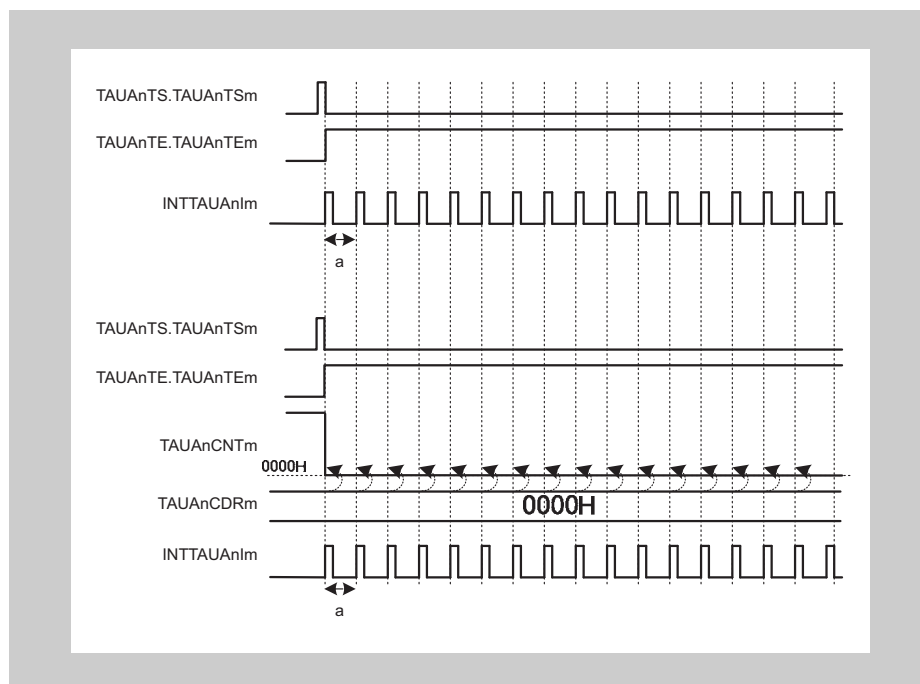

Table 12-222 Operating procedure for Interrupt Culling Function

	Operation	Status of TAUAn
Initial channel setting	<p>Master channel: set the TAUAnCMORm and TAUAnCMURm registers and the channel output mode as described in (4) "Register settings for the master channel" on page 727</p> <p>Slave channel: set the TAUAnCMORm and TAUAnCMURm registers and the channel output mode as described in (5) "Register settings for the slave channel" on page 729</p> <p>Set the values of the TAUAnCDRm registers of all channels</p>	Channel operation is stopped.
Start operation	<p>Set TAUAnTS.TAUAnTSM of the master and slave channels to 1 simultaneously. TAUAnTS.TAUAnTSM is a trigger bit, so it is automatically cleared to 0.</p>	<p>TAUAnTE.TAUAnTEM (master and slave channels) is set to 1 and the counters of the master and slave channels start.</p> <p>INTTAUAnIm is generated on the master channel.</p>
During operation	<p>TAUAnCDRm can be changed at any time. TAUAnCNTm and TAUAnRSF.TAUAnRSFm can be read at any time.</p> <p>TAUAnRDT.TAUAnRDTm can be changed during operation.</p>	<p>TAUAnCNTm of the master channel loads TAUAnCDRm, and then counts down. When the counter reaches 0000_H:</p> <ul style="list-style-type: none"> INTTAUAnIm (master) is generated. TAUAnCNTm (master) loads the TAUAnCDRm value, and then continues count operation. TAUAnCNTm of the slave channel counts down each time INTTAUAnIm is detected on the master channel. <p>When TAUAnCNTm of the slave reaches 0000_H:</p> <ul style="list-style-type: none"> INTTAUAnIm (slave) is generated.
Stop operation	<p>Set TAUAnTT.TAUAnTTm of the master and slave channels to 1 simultaneously. TAUAnTT.TAUAnTTm is a trigger bit, so it is automatically cleared to 0.</p>	<p>TAUAnTE.TAUAnTEM is cleared to 0 and the counter stops.</p> <p>TAUAnCNTm and TAUAnTTOUTm stop and retain their current values.</p>

Restart

(7) Specific timing diagrams

(a) Number of interrupts (master) = number of interrupts (slave)

Figure 12-126 TAUAnCDRm (slave) = 0000_H

- If TAUAnCDRm is 0000_H, the TAUAnCDRm value of the slave channel is loaded to TAUAnCNTm each time INTTAUAnIm is detected on the master channel. In other words, TAUAnCNTm is always read as 0000_H.
- Therefore, the slave channel generates an interrupt at the same time as an interrupt is generated on the master channel.

12.27 Registers

This section describes all TAUA registers.

12.27.1 TAUAn registers overview

The TAUAn is controlled and operated by the registers in the following table. Where there is one register per channel, this is indicated by an “m”, where m runs from 0 to 15.

Table 12-223 TAUAn registers overview (1/2)

Register name	Shortcut	Address
TAUAn prescaler registers

TAUAn DMA window register 7	TAUAnDWR7	<TAUAn_base_USER> + 11C _H
TAUAn DMA window register 8	TAUAnDWR8	<TAUAn_base_USER> + 120 _H
TAUAn DMA window register 9	TAUAnDWR9	<TAUAn_base_USER> + 124 _H
TAUAn DMA window register 10	TAUAnDWR10	<TAUAn_base_USER> + 128 _H
TAUAn DMA window register 11	TAUAnDWR11	<TAUAn_base_USER> + 12C _H
TAUAn DMA window register 12	TAUAnDWR12	<TAUAn_base_USER> + 130 _H
TAUAn DMA window register 13	TAUAnDWR13	<TAUAn_base_USER> + 134 _H
TAUAn DMA window register 14	TAUAnDWR14	<TAUAn_base_USER> + 138 _H
TAUAn DMA window register 15	TAUAnDWR15	<TAUAn_base_USER> + 13C _H

Note The <TAUAn_base_OS> and <TAUAn_base_USER> addresses of the registers are defined in the first section of this chapter under the keyword “Register addresses”.

12.27.2 TAUAn prescaler registers details

(1) TAUAnTPS - TAUAn prescaler clock select register

This register specifies the PCLK prescalers for clocks CK0, CK1, CK2, and CK3_PRE for all channels. CK3 is generated by dividing CK3_PRE by the factor specified in TAUAnBRS.

Access This register can be read/written in 16-bit units.

Address <TAUAn_base_OS> + 240_H

Initial Value FFFF_H. This register is initialized by any reset.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

		These bits can only be rewritten when all counters using CK0 are stopped (TAUAnTE.TAUAnTEm = 0).																																		

Note The TAUAn clock input PCLK is specified in the first section of this chapter under the keyword “Clock supply”.

(2) TAUAnBRS - TAUAn prescaler baud rate setting register

This register specifies the division factor of prescaler clock CK3.

CK3 is generated by dividing CK3_PRE by the factor specified in this register plus one. The PCLK prescaler for CK3_PRE is specified in TAUAnTPS.TAUAnPRS3[3:0].

Access This register can be read/written in 8-bit units.

Address <TAUAn_base_OS> + 244_H

Initial Value 00_H. This register is initialized by any reset.

Table 12-225 TAUAnBRS register contents

Bit position	Bit name	Function

12.27.3 TAUAn control registers details

(1) TAUAnCDRm - TAUAn channel data register

This register functions either as a compare register or as a capture register, depending on the operation mode specified in TAUAnCMORm.TAUAnMD[4:1].

Access This register can be read/written in 16-bit units.

- In capture mode, only reading is possible. Write operation is ignored.
- In compare mode, reading and writing is possible.

Address <TAUAn_base_USER> + m x 4_H

Initial Value 0000_H. This register is initialized by any reset.

Table 12-226 TAUAnCDRm register contents

Bit position	Bit name	Function
15 to 0	TAUAn CDR[15:0]	Data register for the capture/compare value.

(2) TAUAnCNTm - TAUAn channel counter register

This register is the channel m counter register.

Access This register can be read in 16-bit units.

Address <TAUAn_base_USER> + 80_H + m x 4_H

Initial Value 0000_H or FFFF_H The initial value depends on the operation mode, see *Table 12-228 "TAUAnCNTm read values after the counter is re-enabled" on page 742*. This register is initialized by any reset.

Table 12-227 TAUAnCNTm register contents

Bit position	Bit name	Function
15 to 0	TAUAn CNT[15:0]	16-bit counter value.

The read value depends on the counter, the operation mode change, and the values of the TAUAnTS.TAUAnTSm and TAUAnTT.TAUAnTTm bits.

The *initial* counter read value depends on the operation mode and how the counter was stopped:

- by a reset
- by a counter stop trigger (TAUAnTT.TAUAnTTm = 1)

The following table lists the initial counter read values after the counter has stopped (TAUAnTE.TAUAnTEm = 0) and re-enabled (TAUAnTS.TAUAnTSm = 1).

The table also contains the counter read value one count after the counter is enabled (TAUAnTS.TAUAnTSm = 1) for modes where the counter waits for a start trigger.

Table 12-228 TAUAnCNTm read values after the counter is re-enabled

Mode name	Count method (up/down)	TAUAnCNTm value		
		After reset	After stop trigger	After one count
Interval Timer mode	Count down	FFFF _H	Stop value	-
Judge mode	Count down	FFFF _H	Stop value	-
Capture mode	Count up	0000 _H	Stop value	-
Event Count mode	Count down	FFFF _H	Stop value	-
One Count mode	Count down	FFFF _H	Stop value	FFFF _H
Capture & One Count mode	Count up	0000 _H	Stop value	Captured value + 1 (TAUAnCDRm)
Judge & One Count mode	Count down	FFFF _H	Stop value	TAUAnCNTm value - 1
Up Down Count mode	Count up/down	FFFF _H	Stop value	-
Pulse One Count mode	Count down	FFFF _H	Stop value	0000 _H
Count Capture Mode	Count up	0000 _H	Stop value	-
Gate Count Mode	Count down	FFFF _H	Stop value	Stop value
Capture & Gate Count Mode	Count up	0000 _H	Stop value	Stop value

Note If the operation mode is changed while the counter is stopped, the initial counter value after counter restart is undefined. The operation mode is changed by register TAUAnCMORm.TAUAnMD[4:1].

(3) TAUAnCMORm - TAUAn channel mode OS register

This register controls channel m operation.

Access This register can be read or written in 16-bit units. Writing is only possible while the counter is stopped (TAUAnTE.TAUAnTE_m = 0).

Address <TAUAn_base_OS> + 200_H + m × 4_H

Initial Value 0000_H. This register is initialized by any reset.

11	TAUAnMAS	<p>Specifies the channel as master or slave channel during synchronous channel operation: 0: Slave 1: Master This bit is only valid for even channels (CH_{m_even}). For odd channels (CH_{m_odd}), it is fixed to 0.</p>															

Table 12-229 TAUAnCMORm register contents (2/4)

Bit position	Bit name	Function			
10 to 8	TAUAnSTS[2:0]	Selects the external start trigger:			
		TAUAnSTS2	TAUAnSTS1	TAUAnSTS0	Description
		0	0	0	Software trigger
		0	0	1	Valid edge of the TAUAnTTINm input signal. TAUAnCMURm.TAUAnTIS[1:0] specifies the valid edge.
		0	1	0	Valid edge of the TAUAnTTINm input signal is the start trigger and the reverse edge is the stop (capture) trigger
		0	1	1	Setting prohibited
		1	0	0	INTTAUAnI of the master channel
		1	0	1	INTTAUAnI of the upper channel (m-1), regardless of the master setting
		1	1	0	Dead-time output signal of the TAUAnTTOUTm generation unit
		1	1	1	Up/down output trigger signal TAUAnTUDSm of the master channel.

Table 12-229 TAUAnCMORm register contents (3/4)

Bit position	Bit name	Function			
7, 6	TAUAnCOS[1:0]	Specifies when the capture register TAUAnCDRm and the overflow flag TAUAnCSRm.TAUAnOVF of channel m are updated. These bits are only valid if channel m is in capture mode.			
		TAUAnCOS1	TAUAnCOS0	TAUAnCDRm	TAUAnCSRm.TAUAnOVF
		0	0	Updated upon detection of a TAUAnTTINm input valid edge.	Updated (cleared or set) upon detection of a TAUAnTTINm input valid edge: <ul style="list-style-type: none"> If a counter overflow has occurred since the last valid edge detection, TAUAnCSRm.TAUAnOVF is set. If no counter overflow has occurred since the last valid edge detection, TAUAnCSR.OVF is cleared.
		0	1		Set upon counter overflow and cleared by setting TAUAnCSCm.TAUAnCLOV.
		1	0	Updated upon detection of a TAUAnTTINm input valid edge and upon counter overflow:	Not set.
		1	1	<ul style="list-style-type: none"> TAUAnTTINm input valid edge: Counter value is written to TAUAnCDRm Overflow: FFFF_H is written to TAUAnCDRm. The next TAUAnTTINm input valid edge detection is ignored. 	Set upon counter overflow and cleared by setting TAUAnCSCm.TAUAnCLOV.

Table 12-229 TAUAnCMORm register contents (4/4)

Bit position	Bit name	Function					
4 to 0	TAUAn MD[4:0]	Specifies the operation mode.					
		TAUAn MD4	TAUAn MD3	TAUAn MD2	TAUAn MD1	TAUAn MD0	Description
		0	0	0	0	1/0	Interval Timer mode
		0	0	0	1	1/0	Judge mode
		0	0	1	0	1/0	Capture mode
		0	0	1	1	0	Event Count mode
		0	1	0	0	1/0	One Count mode
		0	1	0	1	1/0	Setting prohibited
		0	1	1	0	0	Capture & One Count mode
		0	1	1	1	1/0	Judge & One Count mode
		1	0	0	0	0	Setting prohibited
		1	0	0	1	0	Up Down Count mode
		1	0	1	0	1/0	Pulse One Count mode
		1	0	1	1	1/0	Count Capture mode
		1	1	0	0	0	Gate Count mode
1	1	0	1	0	Capture & Gate Count mode		
Mode	Role of the TAUAnMD0 bit						
Interval Timer mode Capture mode Count Capture mode	Specifies whether the INTTAUAnIm signal is output when the counter starts counting (when the start trigger is input). 0: No INTTAUAnIm generated 1: INTTAUAnIm generated						
Event Count mode Up Down Count mode	This bit must be set to 0.						
One Count mode Gate Count mode Pulse One Count mode	Enables/disables start trigger detection during counting. 0: Disabled 1: Enabled						
Capture & One Count mode Capture & Gate Count mode	This bit must be set to 0.						
Judge mode Judge One Count mode	Specifies when INTTAUAnIm is generated. 0: When TAUAnCNTm ≤ TAUAnCDRm 1: When TAUAnCNTm > TAUAnCDRm						

(4) TAUAnCMURm - TAUAn channel mode user register

This register specifies the type of valid edge detection used for the TAUAnTTINm input.

Access This register can be read/written in 8-bit units.

Address <TAUAn_base_USER> + C0_H + m x 4_H

Initial Value 00_H. This register is initialized by any reset.

(5) TAUAnCSRm - TAUAn channel status register

This register indicates the count direction and the overflow status of channel m's counter.

Access This register can be read in 8-bit units.

Address <TAUAn_base_USER> + 140_H + m x 4_H

Initial Value 00_H. This register is initialized by any reset.

7	6	5	4	3	2	1	0
-	-	-	-	-	-	TAUAnCSF	TAUAnOVF
R	R	R	R	R	R	R	R

Table 12-231 TAUAnCSRm register contents

Bit position	Bit name	Function
1	TAUAnCSF	Indicates the count direction: 0: Counts up 1: Counts down The read value of this bit is only valid in the following mode: <ul style="list-style-type: none"> • Up Down Count mode
0	TAUAnOVF	Indicates the counter overflow status: 0: No overflow occurred 1: Overflow occurred This bit is only used in the following modes: <ul style="list-style-type: none"> • Capture mode • Capture & One Count mode • Count Capture mode • Capture & Gate Count mode The function of this bit depends on the setting of control bits TAUAnCMORm.TAUAnCOS[1:0].

(6) TAUAnCSCm - TAUAn channel status clear register

This register is a trigger register for clearing the overflow flag TAUAnCSRm.TAUAnOVF of a channel m.

Access This register can be written in 8-bit units. It is always read as 00_H.

Address <TAUAn_base_USER> + 180_H + m x 4_H

Initial Value 00_H. This register is initialized by any reset.

7	6	5	4	3	2	1	0
-	-	-	-	-	-	0	TAUAnCLOV
R	R	R	R	R	R	R	W

Table 12-232 TAUAnCSCm register contents

Bit position	Bit name	Function
0	TAUAnCLOV	0: No function 1: Clears the overflow flag TAUAnCSRm.TAUAnOVF

(7) TAUAnTS - TAUAn channel start trigger register

This register enables the counter for each channel.

Access This register can be written in 16-bit units. It is always read as 0000_H.

Address <TAUAn_base_USER> + 1C4_H

Initial Value 0000_H. This register is initialized by any reset.

W	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W

Table 12-233 TAUAnTS register contents

Bit position	Bit name	Function
15 to 0	TAUAnTSM	Enables the counter for channel m: 0: No function 1: Enables the counter and sets TAUAnTE.TAUAnTEm = 1. TAUAnTE.TAUAnTEm = 1 only <i>enables</i> counter. Whether the counter <i>starts</i> depends on the selected operation mode.

(8) TAUAnTE - TAUAn channel enable status register

This register indicates whether counter is enabled or disabled.

Access This register can be read in 16-bit units.

Address <TAUAn_base_USER> + 1C0_H

Initial Value 0000_H. This register is initialized by any reset.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
TAUAn TE15	TAUAn TE14	TAUAn TE13	TAUAn TE12	TAUAn TE11	TAUAn TE10	TAUAn TE09	TAUAn TE08	TAUAn TE07	TAUAn TE06	TAUAn TE05	TAUAn TE04	TAUAn TE03	TAUAn TE02	TAUAn TE01	TAUAn TE00
R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 12-234 TAUAnTE register contents

Bit position	Bit name	Function
15 to 0	TAUAnTE _m	Indicates whether counter for channel m is enabled or disabled: 0: Counter disabled 1: Counter enabled This bit is set when TAUAnTSST _m (the synchronous channel start trigger signal) trigger input is detected or when TAUAnTS.TAUAnTS _m is set. Setting TAUAnTT.TAUAnTT _m to 1 resets this bit to 0.

(9) TAUAnTT - TAUAn channel stop trigger register

This register stops the counter for each channel.

Access This register can be written in 16-bit units. It is always read as 0000_H.

Address <TAUAn_base_USER> + 1C8_H

Initial Value 0000_H.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

W	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W

Table 12-235 TAUAnTT register contents

Bit position	Bit name	Function
15 to 0	TAUAnTT _m	Stops the counter of channel m: 0: No function 1: Stops the counter and reset TAUAnTE.TAUAnTE _m . TAUAnCNT _m , TAUAnTO.TAUAnTO _m , and TAUAnTTOUT _m retain their values from before the counter stopped.

12.27.4 TAUAn output registers details

(1) TAUAnTOE - TAUAn channel output enable register

This register enables and disables Independent Channel Output Mode Controlled by Software.

Access This register can be read/written in 16-bit units.

Address <TAUAn_base_USER> + 5C_H

Initial Value 0000_H. This register is initialized by any reset.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
TAUAn TOE15	TAUAn TOE14	TAUAn TOE13	TAUAn TOE12	TAUAn TOE11	TAUAn TOE10	TAUAn TOE09	TAUAn TOE08	TAUAn TOE07	TAUAn TOE06	TAUAn TOE05	TAUAn TOE04	TAUAn TOE03	TAUAn TOE02	TAUAn TOE01	TAUAn TOE00
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 12-236 TAUAnTOE register contents

Bit position	Bit name	Function
15 to 0	TAUAnTOEm	Enables/disables Independent Channel Output Mode Controlled by Software: 0: Enables Independent Channel Output Mode Controlled by Software 1: Disables Independent Channel Output Mode Controlled by Software

(2) TAUAnTOM - TAUAn channel output mode register

This register specifies the output mode of each channel.

Access This register can be read/written in 16-bit units. Writing is only possible while the counter is stopped (TAUAnTE.TAUAnTEm = 0).

Address <TAUAn_base_USER> + 248_H

Initial Value 0000_H. This register is initialized by any reset.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 12-237 TAUAnTOM register contents

Bit position	Bit name	Function
15 to 0	TAUAnTOMm	Specifies the channel output mode: 0: Independent channel output mode 1: Synchronous channel output mode The output mode depends on several channel output control bits, as can be seen in <i>Table 12-9 "Channel output modes" on page 464</i> .

(3) TAUAnTOC - TAUAn channel output configuration register

This register specifies the output mode of each channel in combination with TAUAnTOMm.

Access This register can be read/written in 16-bit units. Writing is only possible while the counter is stopped (TAUAnTE.TAUAnTEm = 0).

Address <TAUAn_base_OSbase_USER>> + 24C_H

Initial Value 0000_H. This register is initialized by any reset.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Table 12-238 TAUAnTOC register contents

Bit position	Bit name	Function													
15 to 0	TAUAn TOCm	<p>Specifies the output mode: 0: Operation mode 1 1: Operation mode 2 The output mode also depends on TAUAnTOM.TAUAnTOMm, as can be seen in the following table.</p> <table border="1"> <thead> <tr> <th>TOMm</th><th>TOCm</th><th>Description</th></tr> </thead> <tbody> <tr> <td rowspan="2">0</td><td>0</td><td>Toggle mode: TAUAnTTOUTm toggles when INTTAUAnIm occurs.</td></tr> <tr> <td>1</td><td>Set/reset mode: TAUAnTTOUTm set when INTTAUAnIm occurs upon count start and reset when INTTAUAnIm occurs due to detection of a match between TAUAnCNTm and TAUAnCDRm.</td></tr> <tr> <td rowspan="2">1</td><td>0</td><td>Synchronous Channel Operation Mode 1: TAUAnTTOUTm set when INTTAUAnI occurs on the master channel and reset when INTTAUAnI occurs on the slave channel.</td></tr> <tr> <td>1</td><td>Synchronous Channel Operation Mode 2: TAUAnTTOUTm set when INTTAUAnIm occurs while the slave channel is counting down and reset when INTTAUAnIm occurs while the slave channel is counting up.</td></tr> </tbody> </table>	TOMm	TOCm	Description	0	0	Toggle mode: TAUAnTTOUTm toggles when INTTAUAnIm occurs.	1	Set/reset mode: TAUAnTTOUTm set when INTTAUAnIm occurs upon count start and reset when INTTAUAnIm occurs due to detection of a match between TAUAnCNTm and TAUAnCDRm.	1	0	Synchronous Channel Operation Mode 1: TAUAnTTOUTm set when INTTAUAnI occurs on the master channel and reset when INTTAUAnI occurs on the slave channel.	1	Synchronous Channel Operation Mode 2: TAUAnTTOUTm set when INTTAUAnIm occurs while the slave channel is counting down and reset when INTTAUAnIm occurs while the slave channel is counting up.
TOMm	TOCm	Description													
0	0	Toggle mode: TAUAnTTOUTm toggles when INTTAUAnIm occurs.													
	1	Set/reset mode: TAUAnTTOUTm set when INTTAUAnIm occurs upon count start and reset when INTTAUAnIm occurs due to detection of a match between TAUAnCNTm and TAUAnCDRm.													
1	0	Synchronous Channel Operation Mode 1: TAUAnTTOUTm set when INTTAUAnI occurs on the master channel and reset when INTTAUAnI occurs on the slave channel.													
	1	Synchronous Channel Operation Mode 2: TAUAnTTOUTm set when INTTAUAnIm occurs while the slave channel is counting down and reset when INTTAUAnIm occurs while the slave channel is counting up.													

(4) TAUAnTDE - TAUAn channel dead time output enable register

This register enables/disables dead time operation for each channel.

Access This register can be read/written in 16-bit units. Writing is only possible while the counter is stopped (TAUAnTE.TAUAnTE_m = 0).

Address <TAUAn_base_OS> + 250_H

Initial Value 0000_H. This register is initialized by any reset.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
TAUAn TDE15	TAUAn TDE14	TAUAn TDE13	TAUAn TDE12	TAUAn TDE11	TAUAn TDE10	TAUAn TDE09	TAUAn TDE08	TAUAn TDE07	TAUAn TDE06	TAUAn TDE05	TAUAn TDE04	TAUAn TDE03	TAUAn TDE02	TAUAn TDE01	TAUAn TDE00
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 12-239 TAUAnTDE register contents

Bit position	Bit name	Function
15 to 0	TAUAnTDE _m	Enables/disables dead time control operation of channel m: 0: Disables dead time operation 1: Enables dead time operation The same settings must be set for the even and the odd slave channel that comprise a set. These bits only apply when: <ul style="list-style-type: none"> TAUAnTOE.TAUAnTOE_m, TAUAnTOM.TAUAnTOM_m, and TAUAnTOC.TAUAnTOC_m = 1.

(5) TAUAnTDM - TAUAn channel dead time output mode register

This register specifies when dead time is added during dead time output.

Access This register can be read/written in 16-bit units. Writing is only possible while the counter is stopped (TAUAnTE.TAUAnTE_m = 0).

Address <TAUAn_base_OS> + 254_H

Initial Value 0000_H. This register is initialized by any reset.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
TAUAn TDM15	TAUAn TDM14	TAUAn TDM13	TAUAn TDM12	TAUAn TDM11	TAUAn TDM10	TAUAn TDM09	TAUAn TDM08	TAUAn TDM07	TAUAn TDM06	TAUAn TDM05	TAUAn TDM04	TAUAn TDM03	TAUAn TDM02	TAUAn TDM01	TAUAn TDM00

Table 12-240 TAUAnTDM register contents

Bit position	Bit name	Function
15 to 0	TAUAnTDM _m	Specifies when dead time is added during dead time output: 0: Upon detection of a duty cycle at the upper even channel (duty dead time output) 1: Upon detection of a TAUAnTTIN input edge at the lower odd channel (one-phase dead time output) The same settings must be set for the even and the odd slave channel that comprise a set. These bits only apply when: <ul style="list-style-type: none"> TAUAnTOE.TAUAnTOE_m, TAUAnTOM.TAUAnTOM_m, TAUAnTOC.TAUAnTOC_m, and TAUAnTDE.TAUAnTDE_m = 1.

(6) TAUAnTDL - TAUAn channel dead time output level register

This register selects the phase period to which dead time is added.

Access This register can be read/written in 16-bit units.

Address <TAUAn_base_USER> + 54_H

Initial Value 0000_H. This register is initialized by any reset.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
TAUAn TDL15	TAUAn TDL14	TAUAn TDL13	TAUAn TDL12	TAUAn TDL11	TAUAn TDL10	TAUAn TDL09	TAUAn TDL08	TAUAn TDL07	TAUAn TDL06	TAUAn TDL05	TAUAn TDL04	TAUAn TDL03	TAUAn TDL02	TAUAn TDL01	TAUAn TDL00
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 12-241 TAUAnTDL register contents

Bit position	Bit name	Function
15 to 0	TAUAnTDLm	Selects the phase period to which dead time is added: 0: Positive phase period 1: Negative phase period These bits only apply when: <ul style="list-style-type: none"> TAUAnTOE.TAUAnTOEm, TAUAnTOM.TAUAnTOMm, TAUAnTOC.TAUAnTOCm, and TAUAnTDE.TAUAnTDEm = 1.

(7) TAUAnTRE - TAUAn channel real-time output enable register

This register enables or disables real-time output.

Access This register can be read/written in 16-bit units. Writing is only possible while TAUAnTE.TAUAnTEm is 0.

Address <TAUAn_base_OS> + 258_H

Initial Value 0000_H. This register is initialized by any reset.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
TAUAn TRE15	TAUAn TRE14	TAUAn TRE13	TAUAn TRE12	TAUAn TRE11	TAUAn TRE10	TAUAn TRE09	TAUAn TRE08	TAUAn TRE07	TAUAn TRE06	TAUAn TRE05	TAUAn TRE04	TAUAn TRE03	TAUAn TRE02	TAUAn TRE01	TAUAn TRE00
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 12-242 TAUAnTRE register contents

Bit position	Bit name	Function
15 to 0	TAUAnTREm	Enables or disables real-time output of channel m. 0: Disables real-time output 1: Enables real-time output These bits only apply when TAUAnTOE.TAUAnTOEm = 1. When TAUAnTRE.TAUAnTREm = 0, TAUAnTTOUTm is not affected by real-time output. When TAUAnTRE.TAUAnTREm = 1, TAUAnTTOUTm outputs the value of the real-time output bit TAUAnTRO.TAUAnTROM, dependent on the timer operation.

(8) TAUAnTRC - TAUAn channel real-time control register

This register controls the real-time output trigger for each channel.

Access This register can be read/written in 16-bit units. Writing is only possible while TAUAnTE.TAUAnTE_m is 0.

Address <TAUAn_base_OS> + 25C_H

Initial Value 0000_H. This register is initialized by any reset.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
TAUAn TRC15	TAUAn TRC14	TAUAn TRC13	TAUAn TRC12	TAUAn TRC11	TAUAn TRC10	TAUAn TRC09	TAUAn TRC08	TAUAn TRC07	TAUAn TRC06	TAUAn TRC05	TAUAn TRC04	TAUAn TRC03	TAUAn TRC02	TAUAn TRC01	TAUAn TRC00
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 12-243 TAUAnTRC register contents

Bit position	Bit name	Function
15 to 0	TAUAnTRC _m	Specifies which channel generates the real-time output trigger for channel m: 0: The next upper channel where this bit is set to 1 1: Channel m These bits only apply when TAUAnTRE.TAUAnTRE _m = 1.

(9) TAUAnTRO - TAUAn channel real-time output register

For this register, specify the value output to TAUAnTTOUT_m.

Access This register can be read/written in 16-bit units.

Address <TAUAn_base_USER> + 4C_H

Initial Value 0000_H. This register is initialized by any reset.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
TAUAn TRO15	TAUAn TRO14	TAUAn TRO13	TAUAn TRO12	TAUAn TRO11	TAUAn TRO10	TAUAn TRO09	TAUAn TRO08	TAUAn TRO07	TAUAn TRO06	TAUAn TRO05	TAUAn TRO04	TAUAn TRO03	TAUAn TRO02	TAUAn TRO01	TAUAn TRO00
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 12-244 TAUAnTRO register contents

Bit position	Bit name	Function
15 to 0	TAUAnTRO _m	Specifies the value output to TAUAnTTOUT _m . When TAUAnTRE.TAUAnTRE is 0, the TAUAnTRO _m value is not output to TAUAnTTOUT _m even if a real-time trigger is generated.

(10) TAUAnTME - TAUAn channel modulation output enable register

This register enables and disables modulation output for the timer output and real-time output.

Access This register can be read/written in 16-bit units.

Address <TAUAn_base_USER> + 50_H

Initial Value 0000_H. This register is initialized by any reset.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 12-245 TAUAnTME register contents

Bit position	Bit name	Function
15 to 0	TAUAnTME _m	Enables/disables modulation output for timer output and real-time output of channel m: 0: Disables modulation 1: Enables modulation These bits only apply when TAUAnTOE.TAUAnTOE _m and TAUAnTRE.TAUAnTRE _m = 1.

12.27.5 TAUAn channel output level registers details

(1) TAUAnTO - TAUAn channel output register

This register specifies and reads the level of TAUAnTTOUTm.

Access This register can be read/written in 16-bit units.

Address <TAUAn_base_USER> + 58_H

Initial Value 0000_H. This register is initialized by any reset.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
TAUAn TO15	TAUAn TO14	TAUAn TO13	TAUAn TO12	TAUAn TO11	TAUAn TO10	TAUAn TO09	TAUAn TO08	TAUAn TO07	TAUAn TO06	TAUAn TO05	TAUAn TO04	TAUAn TO03	TAUAn TO02	TAUAn TO01	TAUAn TO00
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 12-246 TAUAnTO register contents

Bit position	Bit name	Function
15 to 0	TAUAnTOm	Specifies/reads the level of TAUAnTTOUTm: 0: Low 1: High Only TAUAnTOm bits for which Independent Channel Output function is disabled (TAUAnTOEm = 0) can be written.

(2) TAUAnTOL - TAUAn channel output level register

This register specifies the output logic of the channel output bit (TAUAnTO.TAUAnTOm).

Access This register can be read/written in 16-bit units.

Address <TAUAn_base_USER> + 40_H

Initial Value 0000_H. This register is initialized by any reset.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

12.27.6 TAUAn simultaneous rewrite register details

(1) TAUAnRDE - TAUAn channel reload data enable register

This register enables and disables simultaneous rewriting of the data register TAUAnCDRm or TAUAnTOLm.

Access This register can be read/written in 16-bit units. Writing is only possible while TAUAnTE.TAUAnTEm is 0.

Address <TAUAn_base_OS> + 260_H

Initial Value 0000_H. This register is initialized by any reset.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Bit position	Bit name	Function
15 to 0	TAUAnRDEm	Enables/disables simultaneous rewrite of the data register of channel m: 0: Disables simultaneous rewrite 1: Enabled simultaneous rewrite

(2) TAUAnRDS - TAUAn channel reload data control channel select register

This register selects the control channel for simultaneous rewrite.

Access This register can be read/written in 16-bit or 1-bit units. Writing is only possible while TAUAnTE.TAUAnTEm is 0.

Address <TAUAn_base_OS> + 268_H

Initial Value 0000_H. This register is initialized by any reset.

(3) TAUAnRDM - TAUAn channel reload data mode register

This register selects when the signal that controls simultaneous rewrite is loaded.

Access This register can be read/written in 16-bit units. Writing is only possible while TAUAnTE.TAUAnTE_m is 0.

Address <TAUAn_base_OS> + 264_H

Initial Value 0000_H. This register is initialized by any reset.

12.27.7 TAUAn DMA window registers

(1) TAUAnDASi - TAUAn DMA window address setting register i (i = 0 to 7)

This register specifies addresses of the window registers used for DMA. Eight TAUAnDASi registers control sixteen TAUAnDWRj registers, i.e. each TAUAnDASi register controls two TAUAnDWRj registers independently.

Access This register can be read/written in 16-bit units.

Address <TAUAn_base_OSbase_USER> + 270_H + i x 4_H

Initial Value 0000_H. This register is initialized by any reset.

C0 _H to FC _H : Setting prohibited

Be sure to fix bits [9:8] and [1:0] to "0".

(2) TAUAnDWRj - TAUAn DMA window register j

This register is used for DMA ($j = 0$ to 15). TAUAnDWRj mirrors the addresses specified for the corresponding TAUAnDASi registers (where i is a value from 0 to 7). (See (1) "TAUAnDASi - TAUAn DMA window address setting register i ($i = 0$ to 7)" on page 761.)

Access This register can be read/written in 16-bit units.

Address <TAUAn_base_USER> + 0100_H + $j \times 4$ _H

Initial Value 0000_H. This register is initialized by any reset.

Chapter 13 Timer Array Unit J (TAUJ)

This chapter contains a generic description of the Timer Array Unit J (TAUJ).

The first section describes all V850E2/ML4 specific properties, such as instances, register base addresses, input/output signal names, etc. The subsequent sections describe the features that apply to all implementations.

13.1 V850E2/ML4 TAUJ Features

Instances This microcontroller has the following number of instances of the Timer Array Unit J.

Table 13-1 Instances of TAUJ

TAUJ	
Instance	1
Name	TAUJ0

Instances index n Throughout this chapter, the individual instances of a Timer Array Unit J is identified by the index "n" (n = 0), for example, TAUJnTOM for the TAUJn channel output mode register.

Channel index m The Timer Array Unit J has 4 channels. Throughout this chapter, the individual channels are identified by the index "m" (m = 0 to 3), thus a certain channel is denoted as CHm. The even numbered channels (m = 0, 2) are denoted as CHm_even. The odd numbered channels (m = 1, 3) are denoted as CHm_odd.

Register addresses All TAUJ n register addresses are given as address offsets to the individual base address <TAUJ n_base>. The <TAUJ n_base> address of each TAUJn are listed in the following table:

Table 13-2 Register base addresses <TAUJn_base>

TAUJn	Base address	Address
TAUJ0	<TAUJn_base_USER>	FFFF C200 _H
	<TAUJn_base_OS>	FF81 1000 _H

Clock supply All Timer Array Units J provide one clock input.

Table 13-3 TAUJn clock supply

TAUJn instance	TAUJn clock	Connected to
TAUJ0	PCLK	f _{PCLK}

Interrupts and DMA/DTS Timer Array Unit J can generate the following interrupt and DMA/DTS requests:

Table 13-4 TAUJn interrupt and DMA/DTS requests

TAUJn signals	Function	Connected to
TAUJ0:		
INTTAUJ0I0	Channel 0 interrupt	<ul style="list-style-type: none"> Interrupt Controller INTTAUJ0I0 DMA Controller trigger 64 DTS Controller trigger 64
INTTAUJ0I1	Channel 1 interrupt	<ul style="list-style-type: none"> Interrupt Controller INTTAUJ0I1 DMA Controller trigger 65 DTS Controller trigger 65
INTTAUJ0I2	Channel 2 interrupt	<ul style="list-style-type: none"> Interrupt Controller INTTAUJ0I2 DMA Controller trigger 66 DTS Controller trigger 66
INTTAUJ0I3	Channel 3 interrupt	<ul style="list-style-type: none"> Interrupt Controller INTTAUJ0I3 DMA Controller trigger 67 DTS Controller trigger 67

TAUJ H/W reset The Timer Array Units J and their registers are initialized by the following reset signal:

Table 13-5 TAUJn reset signal

TAUJn	Function	Reset signal
TAUJn		
TAUJ0TTIN0 to TAUJ0TTIN3	Channel 0 to 3 input	Port TJ_I0-TJ_I3
TAUJ0TTOUT0 to TAUJ0TTOUT3	Channel 0 to 3 input	Port TJ_O0-TJ_O3

I/O signals The I/O signals of the Timer Array Unit J are listed in the following table.

Table 13-6 TAUJn I/O signals

TAUJ signal	Function	Connected to
TAUJ0:		
TAUJnTSSTm	Synchronous channel start trigger input	PIC

Caution V850E2/ML4 does not support the following function because the timer input and timer output of the same channel share the same pin.

- TAUJnTTINm input interval timer function

13.2 Functional Overview

Features summary The TAUJ has the following functions:

- 4 channels
- 32-bit counter and 32-bit data register per channel
- Independent channel operation
- Synchronous channel operation (master and slave operation)
- Generation of different types of output signal
- Counter can be triggered by external signal
- Interrupt generation

The following figure shows the main components of the TAUJ:

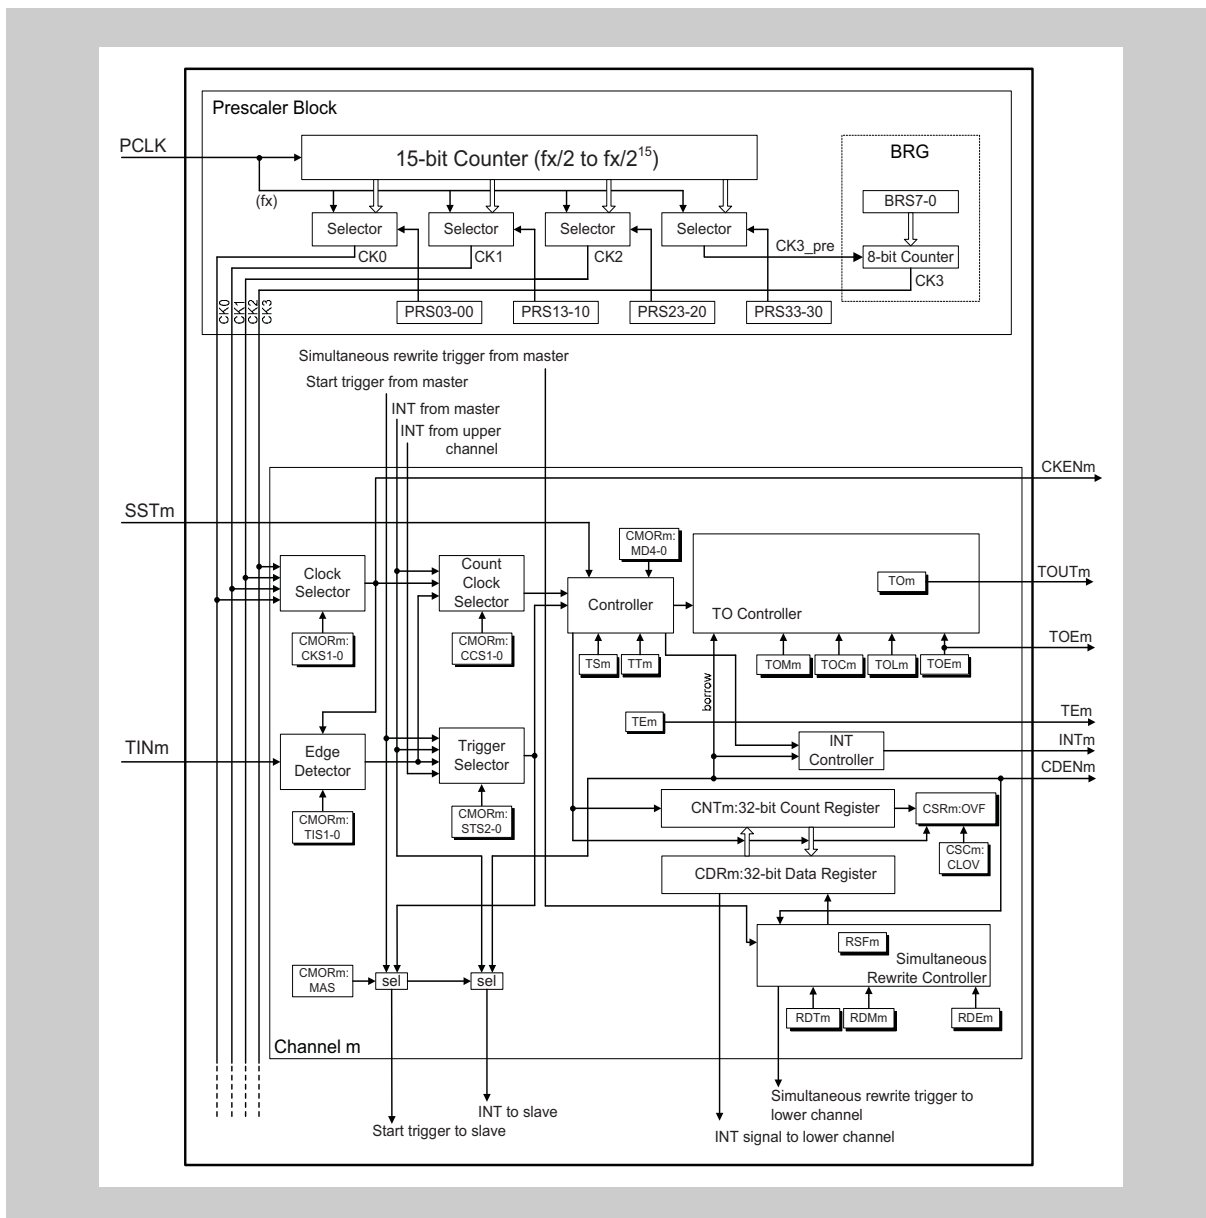

Figure 13-1 Block diagram of the TAUJ

The prefix *TAUJn* has been omitted from the register and block names in the above figure for the sake of clarity.

13.2.1 Terms

In this section, the following terms are used:

- **Independent / synchronous channel operation**

Independent or synchronous channel operation describes the dependency of channels on each other:

- If a channel operates independent of all other channels, this is called independent channel operation.
- If a channel operates depending on other channels, this is called synchronous channel operation.

- **Channel group**

In synchronous channel operation, all channels that depend on each other are referred to as a “channel group”.

A channel group has one master channel and one or more slave channels.

- **Operation mode**

An operation mode can be selected for every channel m . The operation mode defines the *basic* operation and features of a channel.

In synchronous channel operation, every channel in the channel group can operate in a different operation mode.

Examples are “Capture Mode”, and “Interval Timer Mode”.

- **Channel output mode**

The channel output mode defines the operation of $TAUJnTTOUTm$

- of a single channel (independent output operation) or
- of all channels in a channel group (synchronous output operation).

An example is “Independent Channel Output Mode 1”.

- **Channel operation function**

The channel operation function defines the *complete* function and all features

- of a single channel (independent channel operation) or
- of all channels in a channel group (synchronous channel operation).

- **Upper / lower channel**

Depending on the channel number m , a neighboring channel can be referred to as “upper” or “lower” channel:

- Upper channel: Channel that has a smaller number
- Lower channel: Channel that has a greater number

Example:

For channel 2, channel 1 is an upper channel and channel 3 is a lower channel.

13.3 Functional Description

TAUJ is used to perform various count or timer operations and to output a signal which depends on the result of the operation. It contains one prescaler for count clock generation and 4 channels, each equipped with a 32-bit counter TAUJnCNTm and a 32-bit data register TAUJnCDRm to hold the start or compare value of the counter.

It also contains several control and status registers.

Independent and synchronous operation Every channel can operate in two operation modes, either independently or in combination with other channels (synchronously). If a channel group has one master channel and one or more slave channels, the slave channels depend on the master channel.

When a channel is operated independently, its operation mode and functions are not affected by those of other channels. When a channel is operated synchronously it is either a master or a slave. A master channel can have multiple slaves, and the state of one channel affects that of the other channels. For example, a channel can be used to control the timing for starting counting and resetting for another channel.

The following describes the functional blocks:

- Prescaler** The prescaler provides up to 4 clock signals (CK0 to CK3) that can be used as count clocks for all channels.
- For count clocks CK0 to CK2, a clock obtained by dividing PCLK by 2^0 to 2^{15} using the prescaler can be selected. For the fourth count clock CK3, a division factor that is not a power of 2 can be specified by using BRG.
- Clock and count clock selection** For every channel, the count clock selector selects which of the following is used as the clock source:
- One of the clocks CK0 to CK3 (selected by the clock selector)
 - INTTAUJnIm from master channel
 - TAUJnTTINm input signal valid edge
- Controller** The controller controls the main operations of the counter:
- Operation mode (selected by bits TAUJnCMORm.TAUJnMD[4:0])
 - Counter start enable (TAUJnTS.TAUJnTSm) and counter stop (TAUJnTT.TAUJnTTm)
- When counter start is enabled, status flag TAUJnTE.TAUJnTEm is set.
- Trigger selector** If the counter is enabled (TAUJnTE.TAUJnTEm = 1), it starts automatically or waits for an external start trigger signal, depending on the selected operation mode. Any of the following signals can be used as the start trigger:
- Synchronous channel start trigger input TAUJnTSSTm
For details about the inter-unit simultaneous start method, refer to the simultaneous start control register in Chapter X "PIC Function". (Only include this information for a product that includes the PIC function.)
 - TAUJnTTINm input signal valid edge
 - INTTAUJnIm from the master channel

Simultaneous rewrite controller	Simultaneous rewrite control is a function that can be used in synchronous operation modes. The data registers of all channels in a channel group (TAUJnCDRm) can be rewritten at any time. The simultaneous rewrite controller ensures that new data register values of all channels become effective at the same time.
TAUJnTO Controller	The output control of every channel enables the generation of various output signal forms such as PWM signals.

13.3.1 Timer operation functions

The functions below can be achieved by operating TAUJ independently on each channel or by operating it on a combination of multiple channels.

Table 13-7 TAUJ operation functions

Independent channel operation function	Synchronous channel operation function
Independent channel operation functions	Synchronous channel operation function
Interval timer function	PWM output function
TAUJnTTINm input interval timer function	
Independent channel signal measurement functions	
Overflow interrupt output function (during TAUJnTTINm width measurement)	
TAUJnTTINm input period count detection function	
Overflow interrupt output function (during TAUJnTTINm input period count detection)	
TAUJnTTINm input pulse interval judgment function	
TAUJnTTINm input signal width judgment function	
Other independent channel function	
TAUJnTTINm input position detection function	

13.4 General Operating Procedure

The following lists the general operation procedure for the TAUJn:

After reset release, the operation of each channel is stopped. Writing to each register is enabled when clock supply is started. The control register of TAUJnTTOUTm is initialized and outputs a low level.

1. Set the TAUJnTPS and TAUJnBRS registers to specify the clock frequency of CK0 to CK3.
2. Configure the desired TAUJn function:
 - Set the operation mode
 - Set the channel output mode
 - Set any other control bits
3. Enable the counter by setting the TAUJnTS.TAUJnTSM bit to 1.
The counter starts counting immediately, or when an appropriate trigger is detected, depending on the bit settings.
4. During counting, if desired, and if possible for the configured function, stop the counter or perform a forced restart operation.
5. Stop the function by setting the TAUJnTT.TAUJnTTM bit to 1.

Note A detailed description of the required control bits and the operation of the individual functions is given in the following sections:

13.14 “Independent Channel Interrupt Functions” on page 794

13.15 “Independent Channel Signal Measurement Functions” on page 808

13.16 “Other Independent Channel Function” on page 834

13.5 Operation Modes

The TAUJ contains 7 operation modes.

One operation mode can be set for each channel. It is specified using the TAUJnCMORm.TAUJnMD[4:0] bits.

Note For registers and bits, some values are fixed according to the operation function, and others are selected by the user.

For details about the settings for registers and bits, refer to the sections describing each operation function.

13.6 Concepts of Synchronous Channel Operation

In synchronous channel operation, multiple channels depend on each other, or are affected by changes in another channel. Therefore, several rules apply for the use of synchronous channel functions. These rules are detailed in *13.6.1 “Rules”*.

Two special features for synchronous channel operation are detailed in the following subsections:

- *13.6.2 “Simultaneous start and stop of synchronous channel counters” on page 774*
- *13.7 “Simultaneous Rewrite” on page 775*

13.6.1 Rules

- | | |
|-------------------------------------|--|
| Number of masters and slaves | <ul style="list-style-type: none"> • Only even channels (CH0, CH2) can be set as master channels. Any channel except CH0 can be set as a slave channel. • Only channels lower than the master channel can be set as slave channels, and several slave channels can be set for one master channel.
Example: If CH2 is a master channel, CH3 can be set as slave channel. • If two master channels are used, slave channels cannot cross the master channels.
Example: If CH0 and CH2 are master channels, CH1 can be set as a slave channel for CH0, but CH3 cannot. |
| Operation clock | <ul style="list-style-type: none"> • The same operation clock must be set for the corresponding slave channel and the master channel. Specify the same value for the TAUJnCMORm.TAUJnCKS[1:0] bits of the synchronized master and slave channels. |

The basic concepts of master/slave usage and operation clocks are illustrated in the following figure.

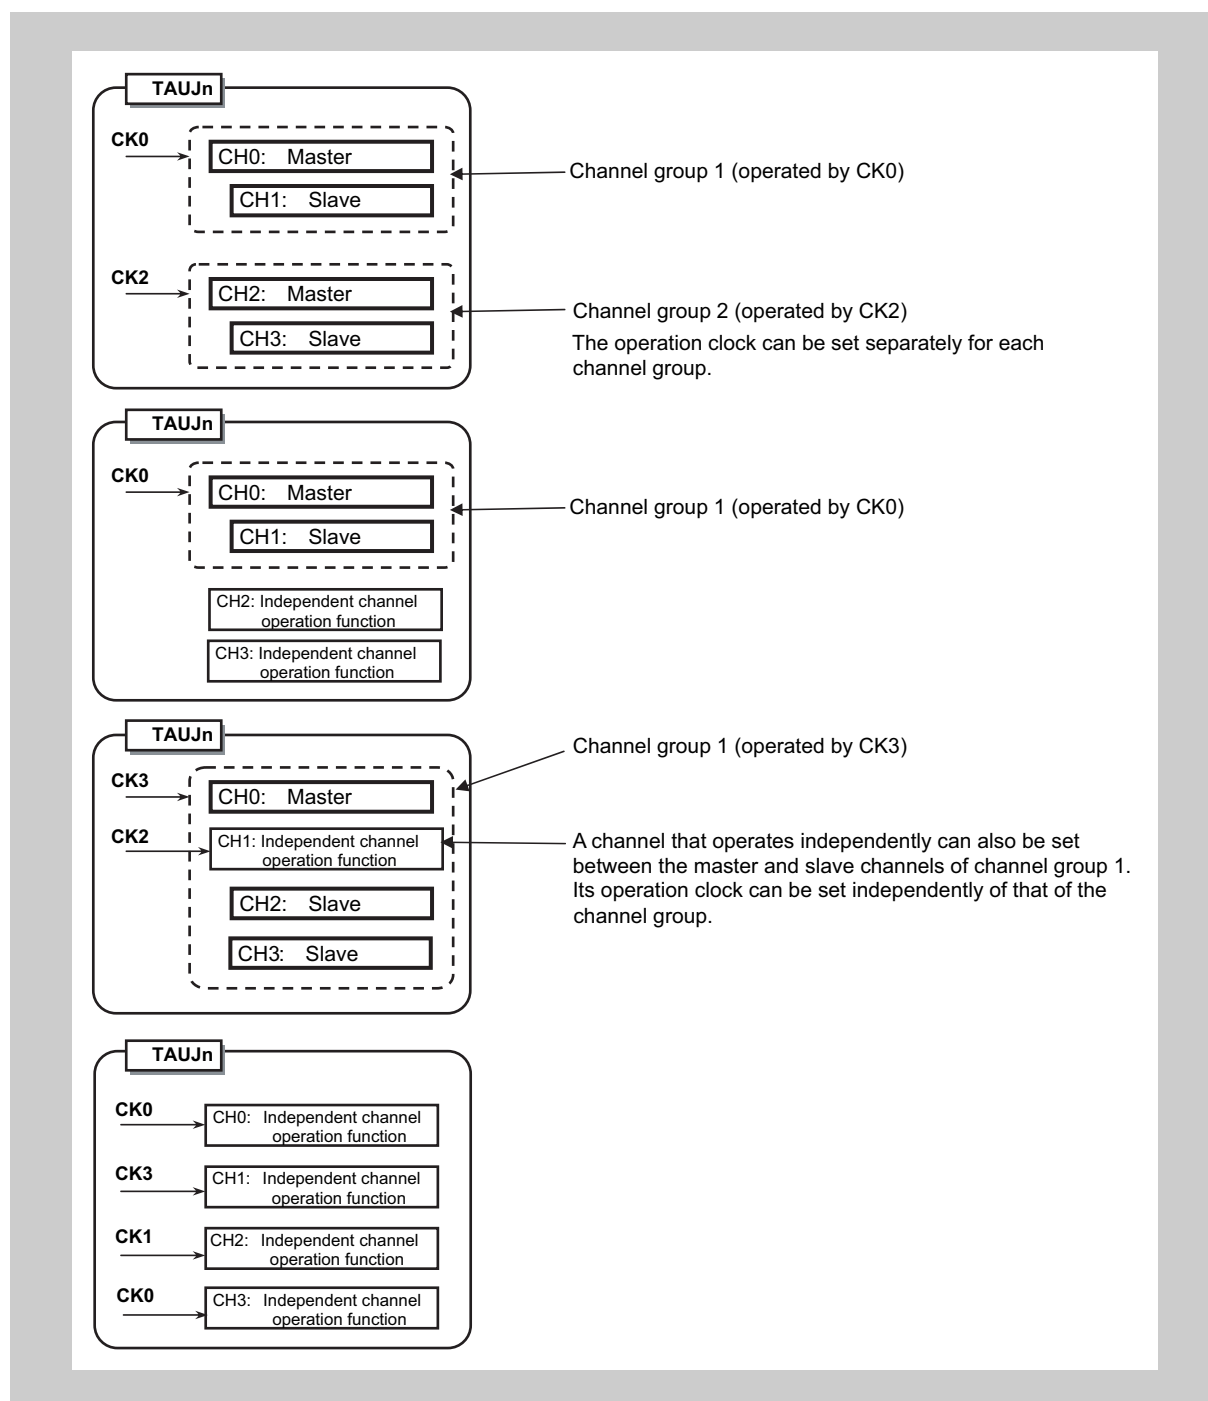

Figure 13-2 Grouping of the channels and assignment of operation clocks

Control trigger signals of the master and slave channels

- A master channel can output a control trigger signal to its slave channels.
- Slave channels can use the control trigger signal of the master channel but cannot transfer their control trigger signals to the lower channels.
- A master channel cannot use the control trigger signal of an upper master channel.

13.6.2 Simultaneous start and stop of synchronous channel counters

Channels that are operated synchronously can be started and stopped simultaneously, both within a unit, and between units.

(1) Simultaneous start and stop within a unit

- To simultaneously start synchronized channels, the TAUJnTS.TAUJnTSM bits of the channels must be set at the same time.
- To simultaneously stop synchronized channels, the TAUJnTT.TAUJnTTM bits of the channels must be set at the same time.

Setting a TAUJnTS.TAUJnTSM bit to 1 sets the corresponding TAUJnTE.TAUJnTEM bit to 1, enabling counting. When the counter starts counting depends on the operation mode.

(2) Simultaneous start between units

Counters in different units can also be started simultaneously if the corresponding counters are enabled before receiving the simultaneous trigger signal.

For details about the inter-unit simultaneous start method, see Chapter 16 “Peripheral Interconnection (PIC)”.

13.7 Simultaneous Rewrite

13.7.1 Introduction

Simultaneous rewrite describes the ability to change the compare/start value and the output logic of multiple channels at the same time.

The corresponding data and control registers (TAUJnCDRm and TAUJnTOLm) can be written at any time. The new value does not affect the counter operation or the output signal until simultaneous rewrite is triggered.

Simultaneous rewrite is triggered when the counter on the master channel reaches a certain value.

The following table shows the settings for simultaneous rewrite (TAUJnRDM.TAUJnRDMm = 0).

Table 13-8 Simultaneous rewrite settings

Method	Simultaneous rewrite triggered when	TAUJnRDE.TAUJnRDEm
-	No simultaneous rewrite	0
A	The master channel (re)starts counting	1

13.7.2 How to control simultaneous rewrite

The following figure shows the general procedure for simultaneous rewrite. The three main blocks (Initial settings, Start counter & count operation, and Simultaneous rewrite) are explained afterwards.

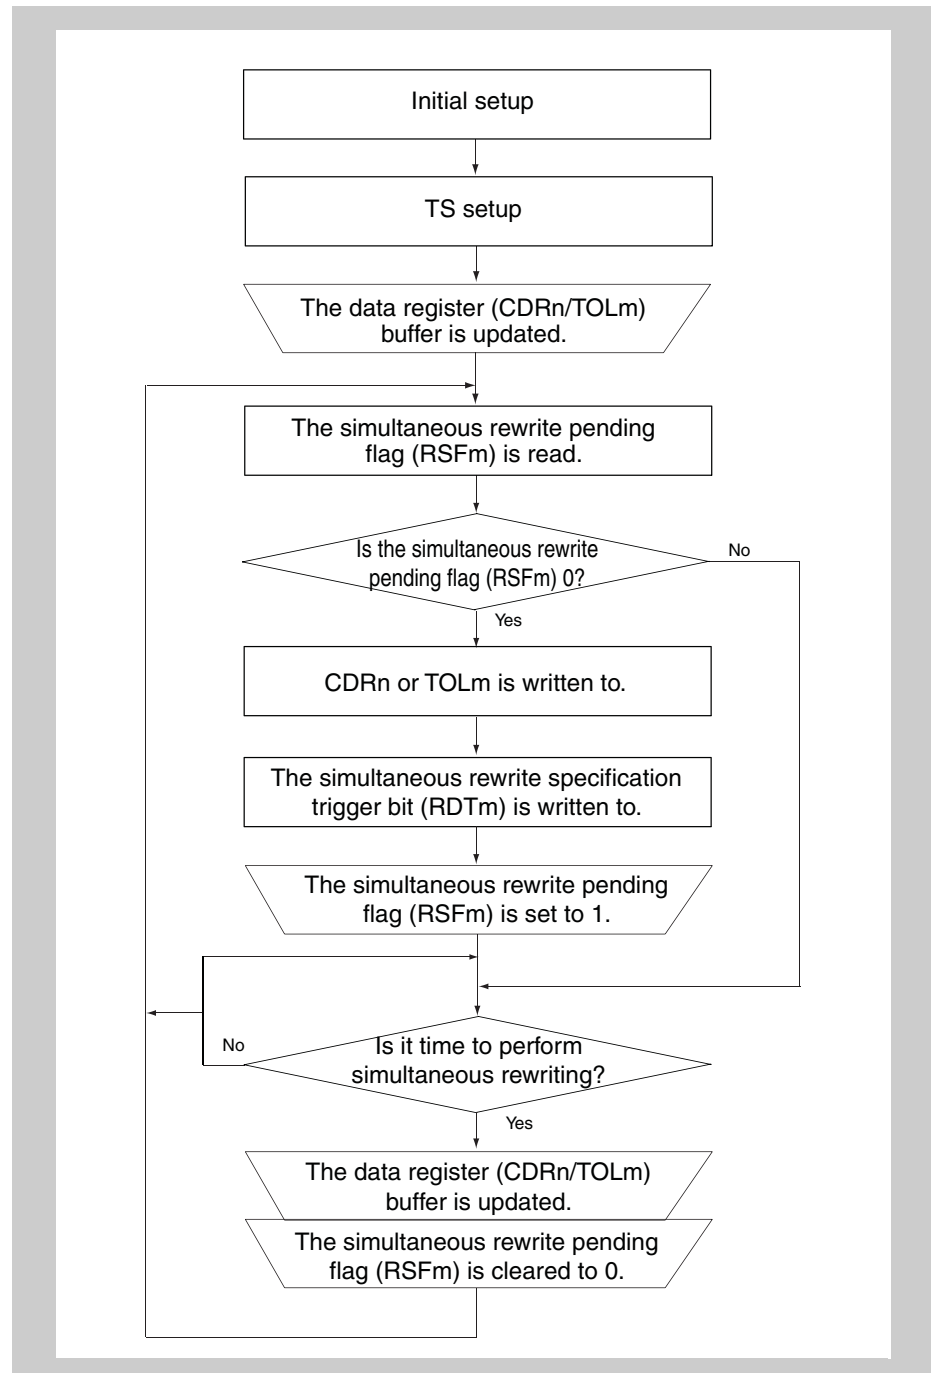

Figure 13-3 General procedure for simultaneous rewrite

(1) Initial settings

- To enable simultaneous rewrite in channel m, set $\text{TAUJnRDE.TAUJnRDEm} = 1$
- To select the type of simultaneous rewrite upon the start of counting by the master channel counter, specify the $\text{TAUJnRDM.TAUJnRDMm}$ bits.

(2) Start counter and count operation

- To start all the TAUJnCNTm counters in the channel group, set the corresponding TAUJnTS.TAUJnTSM bits to 1. $\text{TAUJnTOL.TAUJnTOLm}$ and the values in the data registers (TAUJnCDRm) are loaded to the corresponding $\text{TAUJnTOL.TAUJnTOLm}$ buffer ($\text{TAUJnTOL.TAUJnTOLm}$ buf) and data buffer registers (TAUJnCDRm buf) and the counters start.
- Setting the reload data trigger bit ($\text{TAUJnRDT.TAUJnRDTm}$) to 1 sets the reload flag ($\text{TAUJnRSF.TAUJnRSFm}$) to 1, enabling simultaneous rewrite. $\text{TAUJnRSF.TAUJnRSFm}$ remains at 1 until simultaneous rewrite has taken place.
- When the specified trigger for simultaneous rewrite is detected, the $\text{TAUJnRSF.TAUJnRSFm}$ bit is checked to see if simultaneous rewrite is enabled ($\text{TAUJnRSF.TAUJnRSFm} = 1$). If it is, simultaneous rewrite is carried out. If such writing is disabled, simultaneous rewriting is not performed, and the system awaits the detection of the next simultaneous rewrite trigger.

(3) Simultaneous rewrite

- When the simultaneous rewrite trigger is detected and simultaneous rewrite is enabled ($\text{TAUJnRSF.TAUJnRSFm} = 1$), the current values of the data registers are copied to their buffers. These values are then loaded to the corresponding counters and the values are applied the next time the counter starts or restarts.
- When simultaneous rewriting finishes, the $\text{TAUJnRSF.TAUJnRSFm}$ bit is cleared to 0, and the system awaits the next simultaneous rewrite trigger.

13.7.3 Other general rules of simultaneous rewrite

The following rules also apply:

- $\text{TAUJnRDE.TAUJnRDEm}$ and $\text{TAUJnRDM.TAUJnRDMm}$ cannot be changed while the counter is in operation ($\text{TAUJnTE.TAUJnTEm} = 1$).
- $\text{TAUJnTOL.TAUJnTOLm}$ can only be rewritten during operation when in PWM output function. For all other output functions, $\text{TAUJnTOL.TAUJnTOLm}$ must be written before the counter starts. If it is rewritten in another function, TAUJnTTOUTm outputs an invalid wave.

13.7.4 Simultaneous rewrite procedure

Simultaneous rewrite is executed when the master channel starts or restarts counting.

The simultaneous rewrite procedure is described in the following figure.

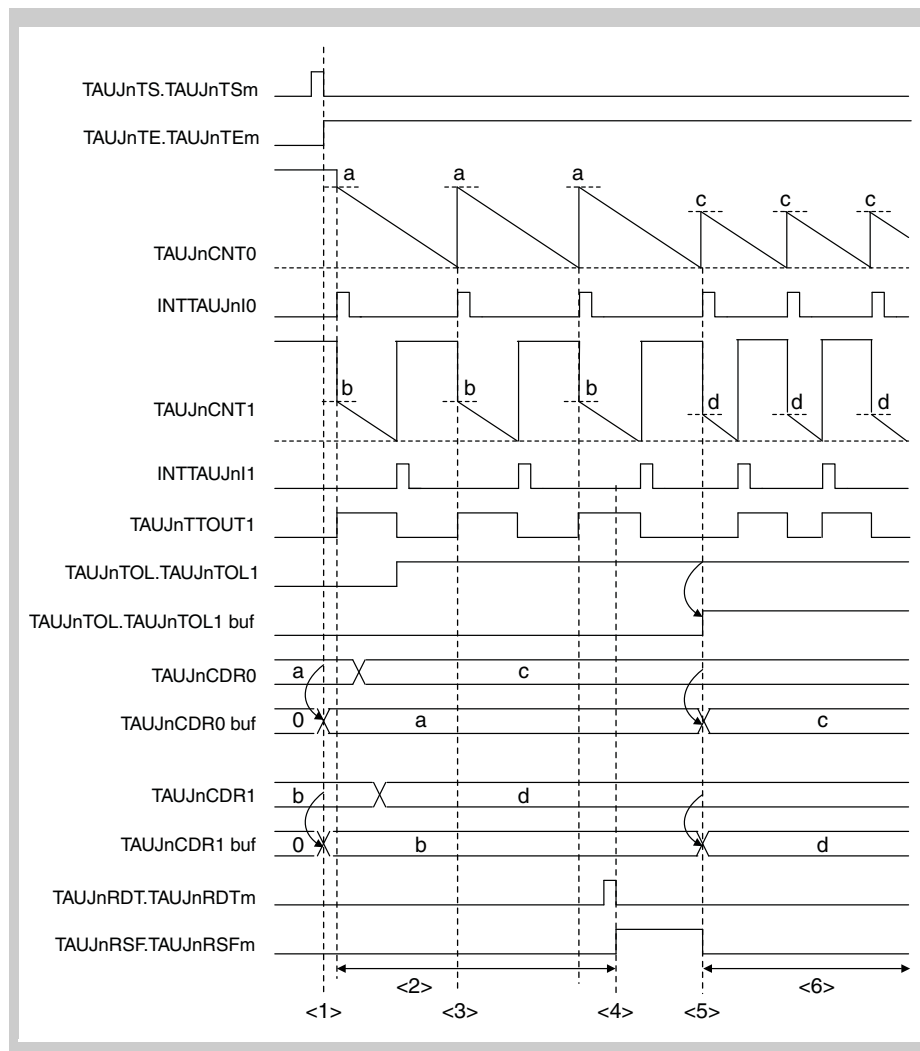

Figure 13-4 Simultaneous rewrite when the master channel (re)starts counting

Setup:

- CH0 is the master channel that counts down. CH1 represents an arbitrary slave channel. Simultaneous rewrite is executed when the master channel starts counting.

Description:

1. When TAUJnTS.TAUJnTSM is set to 1, the value of TAUJnCDRm is copied to the TAUJnCDRm buffer, and the value of TAUJnTOL.TAUJnTOLm is copied to the TAUJnTOL.TAUJnTOLm buffer.
2. The TAUJnCDRm and TAUJnTOL.TAUJnTOLm registers can be written at any time.
3. CH0 restarts counting, but simultaneous rewrite does not occur because it is disabled (TAUJnRSF.TAUJnRSFm = 0).
4. The reload data trigger bit (TAUJnRDT.TAUJnRDTm) is set to 1 which sets the status flag (TAUJnRSF.TAUJnRSFm = 1), enabling simultaneous rewrite.
5. Because simultaneous rewriting is enabled, it is performed before counting on channel 0 resumes. The TAUJnCDRm value is loaded to the TAUJnCDRm buffer, and the TAUJnTOL.TAUJnTOLm value is loaded to the TAUJnTOL.TAUJnTOLm buffer.
6. The counters count down and await the next simultaneous rewrite trigger. The values of TAUJnCDRm and TAUJnTOL.TAUJnTOLm can be changed again.

13.8 Channel Output Modes

The output of the TAUJnTTOUTm pin can be controlled in two ways, the latter of which can be further split into individual modes:

- By software (TAUJnTOE.TAUJnTOEm = 0)

When controlled by software, the value written in the output register bit (TAUJnTO.TAUJnTOm) is output from the output pin (TAUJnTTOUTm).

- By TAUJ signals (TAUJnTOE.TAUJnTOEm = 1)

When operated by TAUJ signals, the output level of TAUJnTTOUTm is set or reset or toggled by internal signals. The value of TAUJnTO.TAUJnTOm is updated accordingly to reflect the value of TAUJnTTOUTm.

- Independently (TAUJnTOM.TAUJnTOMm = 0)

When operated independently, the output of the TAUJnTTOUTm pin is only affected by settings of channel m. Therefore, independent channel operation must be specified (TAUJnTOM.TAUJnTOM = 0).

- Synchronously (TAUJnTOM.TAUJnTOMm = 1)

When operated synchronously, the output of the TAUJnTTOUTm pin is affected by settings of channel m and those of other channels. Therefore, synchronous channel operation must be selected for all participating channels (TAUJnTOM.TAUJnTOMm = 1).

The TAUJnTO.TAUJnTOm bit can always be read to determine the current value of TAUJnTTOUTm, regardless of whether the pin is controlled by software, operated independently, or operated synchronously.

Control bits The settings of the control bits required to select a specific channel output mode are listed in *Table 13-9 “Channel output modes” on page 781*.

The channel output modes are described in detail in

- *13.8.2 “Channel output modes controlled independently by TAUJn signals” on page 783* to
- *13.8.3 “Channel output modes controlled synchronously by TAUJn signals” on page 784*.

Collective TAUJnTOm bit manipulation Whether to apply settings to the TAUJnTOm bits is controlled using the TAUJnTOE.TAUJnTOEm bits.

When writing to the TAUJnTO register, TAUJnTOm settings are only written to bits (channels) for which the corresponding TAUJnTOE.TAUJnTOEm bit is cleared to 0. The TAUJnTOm settings are not applied for bits (channels) for which the corresponding TAUJnTOE.TAUJnTOEm bit is set to 1.

Note The TAUJnTO.TAUJnTOm bits are allocated so that the bit numbers correspond to the channel numbers.

Output logic Positive logic or inverted logic of the output is specified by control bit TAUJnTOL.TAUJnTOLm.

The value of the TAUJnTOL.TAUJnTOLm bit must be set before the counter is started. It can only be changed during operation in PWM output function. If the TAUJnTOL.TAUJnTOLm bit is changed after counter operation starts, the TAUJnTTOUTm signal output becomes undefined.

Refer to *13.7 “Simultaneous Rewrite” on page 775*.

The various channel output modes and the channel output control bits when TAUJnTOC.TAUJnTOCm = 0 are listed in the following table.

Table 13-9 Channel output modes

Channel output mode	TAUJnTOE. TAUJnTOEm	TAUJnTOM. TAUJnTOMm
By software		
Independent Channel Output Mode Controlled by Software	0	x
By TAUJ signals, independently		
Independent Channel Output Mode 1	1	0
By TAUJ signals, synchronously		
Synchronous Channel Output Mode 1	1	1

- The combinations not listed in this table are forbidden.
- The bit marked with an x can be set to any value.

Note The following bits cannot be changed during count operation (TAUJnTE.TAUJnTE = 1):

- TAUJnTOE.TAUJnTOEm
- TAUJnTOM.TAUJnTOMm
- TAUJnTOC.TAUJnTOCm

13.8.1 General procedure for specifying a channel output mode

The following steps describe the general procedure for specifying a TAUJnTTOUTm channel output mode. The prerequisite is that timer output operation is disabled (TAUJnTOE.TAUJnTOEm = 0).

1. Set TAUJnTO.TAUJnTOm to specify the initial level of the TAUJnTTOUTm output.
2. Set the channel output mode using *Table 13-9 "Channel output modes" on page 781* and the output logic using the TAUJnTOL.TAUJnTOLm bit.
3. Start the counter (TAUJnTS.TAUJnTSm = 1).

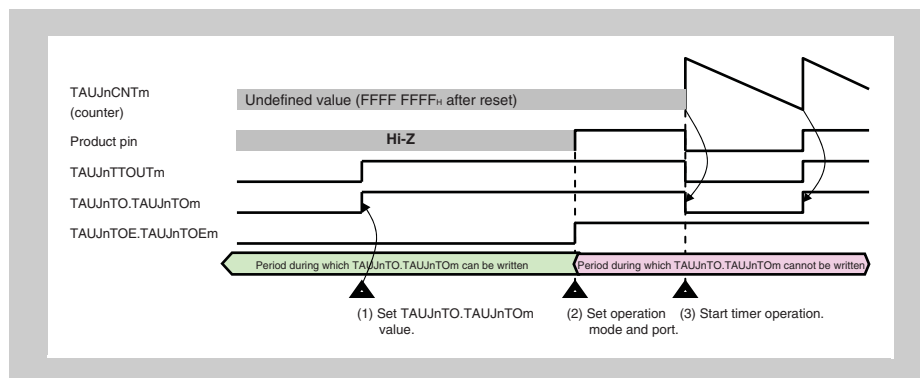

Figure 13-5 General procedure for specifying a TAUJnTTOUTm channel output mode

13.8.2 Channel output modes controlled independently by TAUJn signals

This section lists the channel output modes that are controlled independently by TAUJn signals. The control bits used to specify a mode are listed in *Table 13-9 “Channel output modes” on page 781*.

(1) Independent Channel Output Mode 1

Set/reset conditions In this output mode, TAUJnTTOUTm toggles when INTTAUJnIm is detected. The value of TAUJnTOL.TAUJnTOLm is ignored.

Prerequisites None, other than those in *Table 13-9 “Channel output modes” on page 781*.

13.8.3 Channel output modes controlled synchronously by TAUJn signals

This section lists the channel output modes that are controlled synchronously by TAUJn signals. The control bits used to specify a mode are listed in *Table 13-9 "Channel output modes" on page 781*.

(1) Synchronous Channel Output Mode 1

Set/reset conditions In this output mode, INTTAUJnIm of the master channel serves as the set signal and INTTAUJnIm of the slave channel as the reset signal. If INTTAUJnIm of the master channel and INTTAUJnIm of the slave channel are generated at the same time, INTTAUJnIm of the slave channel (reset signal) has priority over INTTAUJnIm (set signal) of the master channel, i.e. the master channel is ignored.

Prerequisites None, other than those in *Table 13-9 "Channel output modes" on page 781*.

13.9 Count Start Timing in Each Operating Mode

This section describes the timing for starting counting after the TAUJnTS.TAUJnTSM bit is set to 1, for each operation mode.

The value of the data register and whether an interrupt is generated depend on the individual mode and corresponding register settings.

Caution The timing for starting counting in this section is only for reference. The actual timing varies according to the count clock timing.

13.9.1 Interval Timer Mode, Capture Mode

The counter starts counting at the start of the next count clock cycle after TAUJnTS.TAUJnTSM is set to 1. The value of data register is also loaded at the point the counter starts.

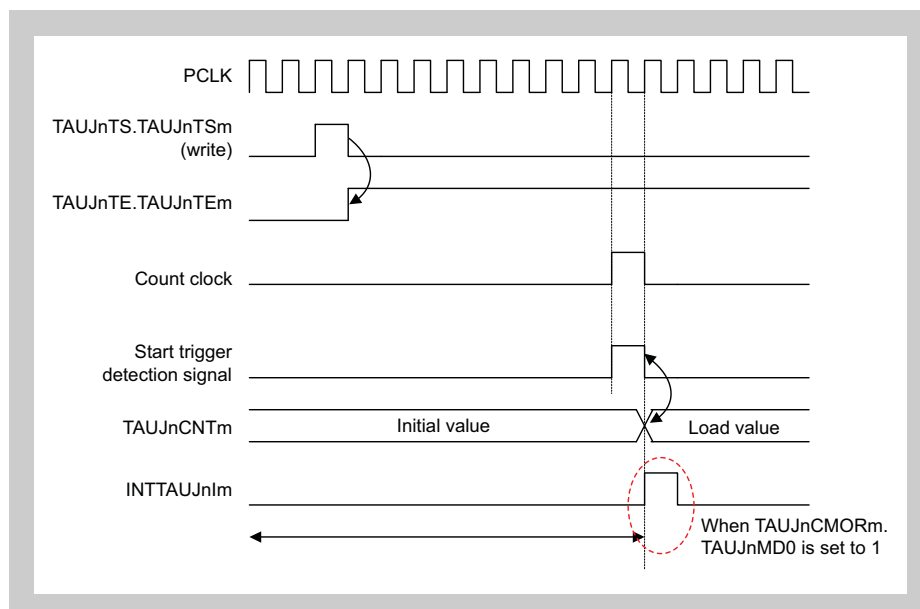

Figure 13-6 Start timing of Interval Timer Mode, Capture Mode

13.9.2 Other operating modes

In all other operating modes, the count clock cycles are ignored with regard to starting the counter. The counter operation is only triggered by detection of a valid TAUJnTTINm edge. The value of data register is also loaded at the point the counter starts. Although the count clock cycle does not affect the timing for starting the counter operation, it determines the frequency with which all operations take place.

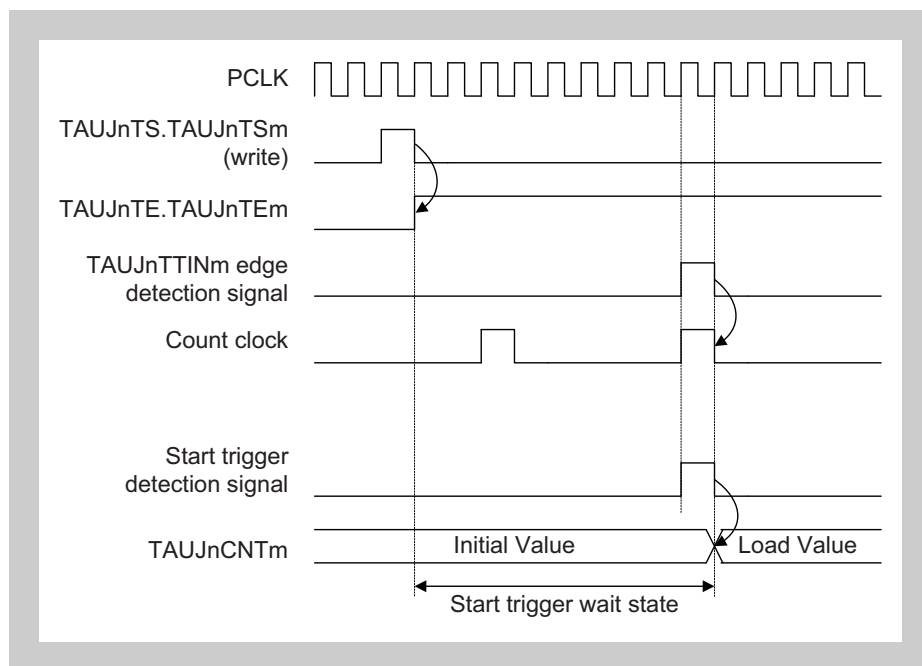

Figure 13-7 Start timing of all other operating modes

13.10 TAUJnTTOUTm Output and INTTAUJnIm Generation when Counter Starts or Restarts (by TAUJnMD0 Bit)

When the counter starts, it is possible to specify whether an INTTAUJnIm is generated using the TAUJnCMORm.TAUJnMD0 bit. The effect of the bit depends on the selected mode, as shown in the following table. The effects of INTTAUJnIm on TAUJnTTOUTm depend on the selected channel operation function.

Table 13-10 Effect of TAUJnCMORm.TAUJnMD0 bit on generation of INTTAUJnIm when counter is triggered

Mode	TAUJnCMORm.TAUJnMD0 bit	INTTAUJnIm generation upon start or restart of counting or upon trigger detection of TAUJnTTINm input signal
Interval Timer Mode	0	No
Capture Mode	1	Yes
Count Capture Mode		
Capture & One Count Mode	0	No
Capture & Gate Count Mode	0	No
One Count Mode	0/1	No, regardless of the TAUJnCMORm.TAUJnMD0 bit setting
Gate Count Mode		

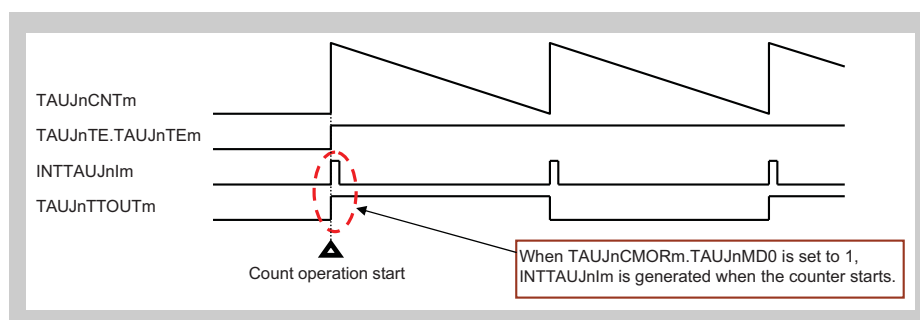

Figure 13-8 INTTAUJnIm generated when counter starts

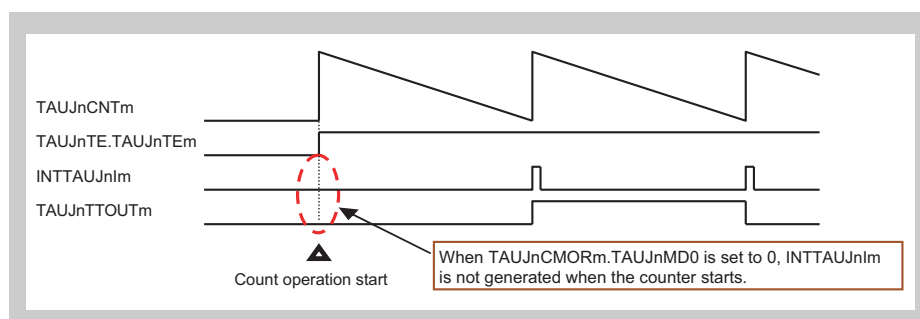

Figure 13-9 INTTAUJnIm not generated when counter starts

13.11 Interrupt Generation upon Overflow

For certain independent channel operation functions, no interrupt is generated even if the counter counts up to FFFF FFFF_H and an overflow occurs. This section describes how it is possible to generate an interrupt, by combining a channel operating in one of these modes with a channel in a different operation mode which counts down.

The appropriate operation mode for the second channel depends on the operation mode of the first channel. Nevertheless, the principle is the same for all combinations:

- For the second channel, specify an operation mode in which the counter counts down and reaches 0000 0000_H at the same time that an overflow occurs on the first channel (TAUJnCNTm = FFFF FFFF_H).
- Set TAUJnCDRm of the second channel to FFFF FFFF_H
- The two channels must count at the same speed (i.e., they must have the same count clock).
- Both channels are triggered by the same TAUJnTTINm input
- The trigger detection settings (TAUJnCMORm.TAUJnSTS[2:0] and TAUJnCMURm.TAUJnTIS[1:0]) must be identical for both channels

Result: the down-counter of the second channel reaches 0000 0000_H at exactly the same time as the up-counter of the first channel overflows (TAUJnCNTm = FFFF FFFF_H). Thus the second channel generates the desired interrupt.

The following sections list the operating modes that count down that are required to match specific operating modes that count up, as well as example timing diagrams.

13.11.1 Capture Mode

- Applies to • TAUJnTTINm Input Pulse Interval Measurement Function
- Combine with Interval Timer Mode

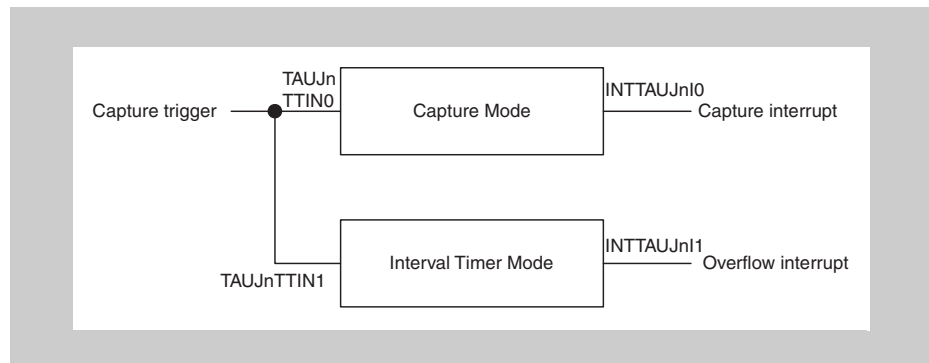

Figure 13-10 Combination of Capture Mode and Interval Timer Mode

Timing diagram

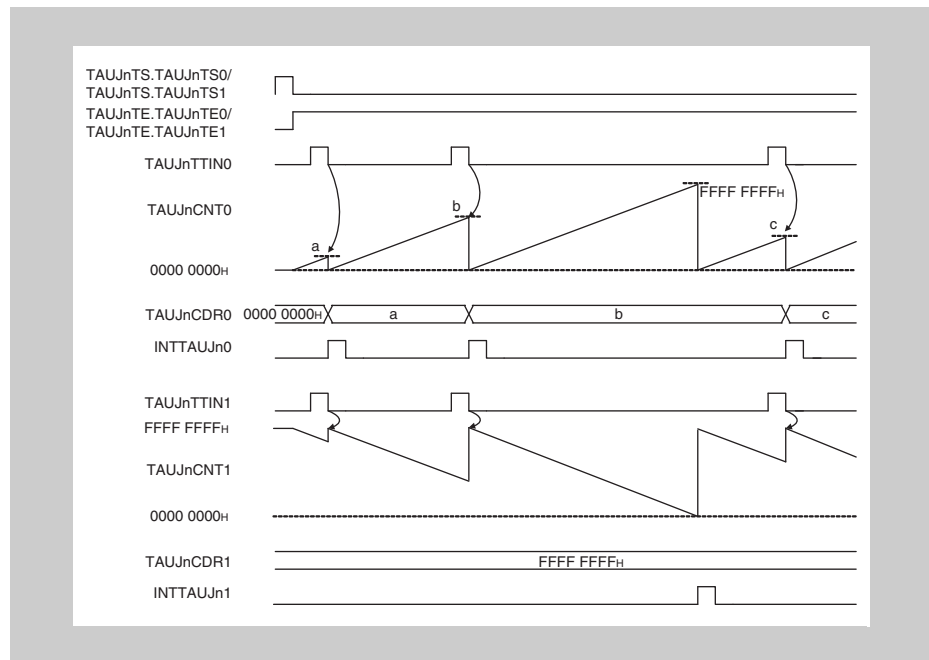

Figure 13-11 Interrupt generation via combination of Capture Mode and Interval Timer Mode

13.11.2 Capture and One Count Mode

- Applies to • TAUJnTTINm Input Signal Width Measurement Function
- Combine with One Count Mode

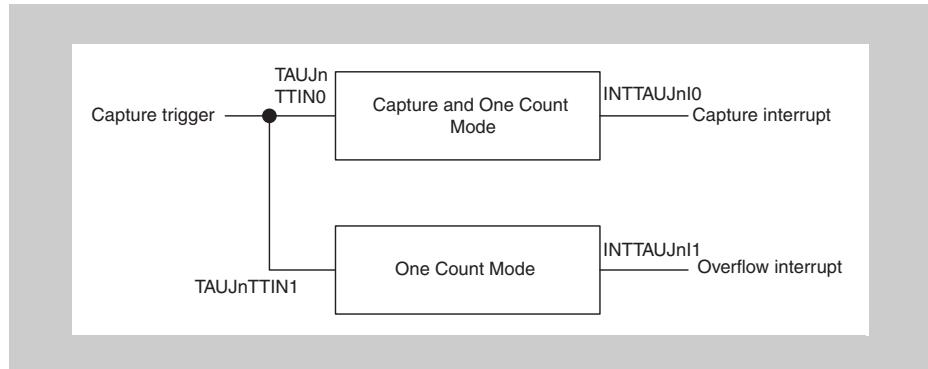

Figure 13-12 Combination of Capture and One Count Mode and One Count Mode

Timing diagram

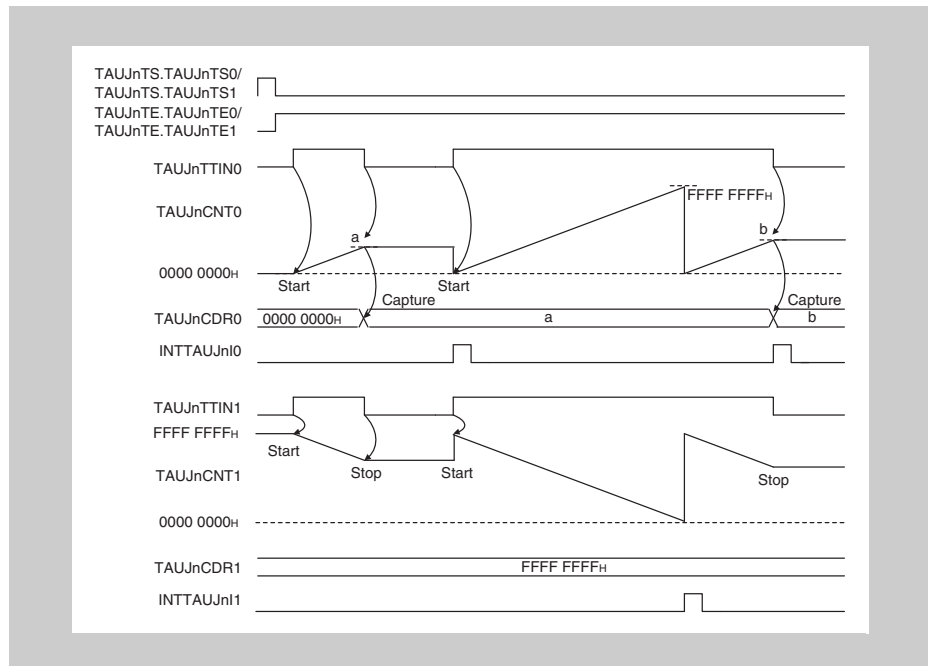

Figure 13-13 Interrupt generation via combination of Capture and One Count Mode and One Count Mode

13.11.3 Count Capture Mode

- Applies to • TAUJnTTINm Input Position Detection Function
Combine with Interval Timer Mode

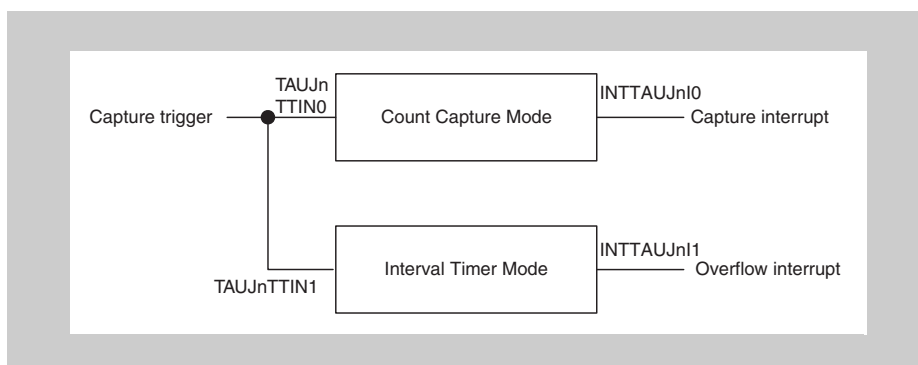

Figure 13-14 Combination of Count Capture Mode and Interval Timer Mode

Timing diagram

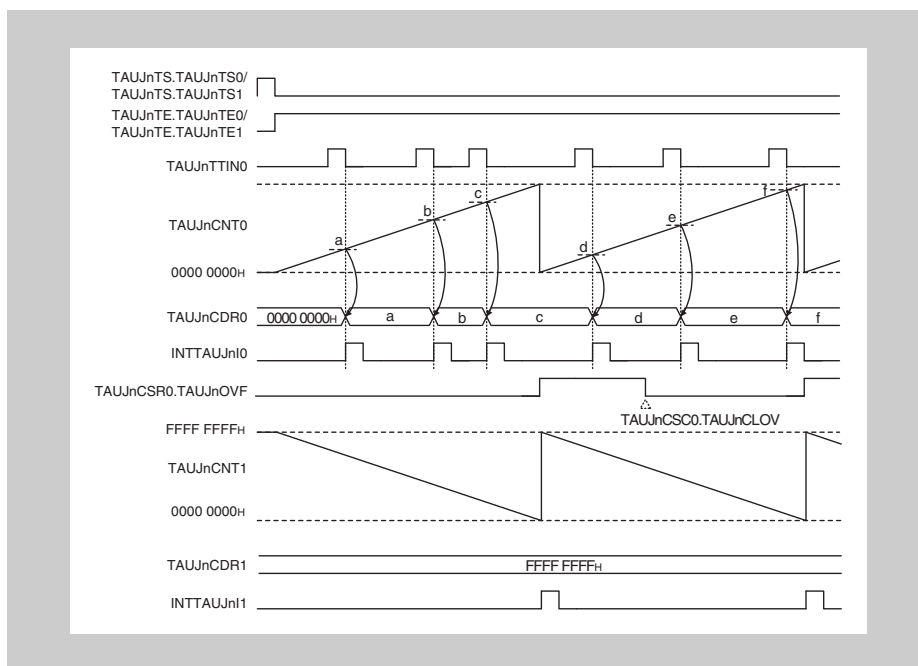

Figure 13-15 Interrupt generation via combination of Count Capture Mode and Interval Timer Mode

In the above timing diagram, TAUJnCSRm.TAUJnOVF is set to 1 when TAUJnCNTm overflows. TAUJnCSRm.TAUJnOVF is cleared by writing 1 to TAUJnCSCm.TAUJnCLOV.

13.11.4 Capture and Gate Count Mode

- Applies to • TAUJnTTINm Input Period Count Detection Function
- Combine with Gate Count Mode

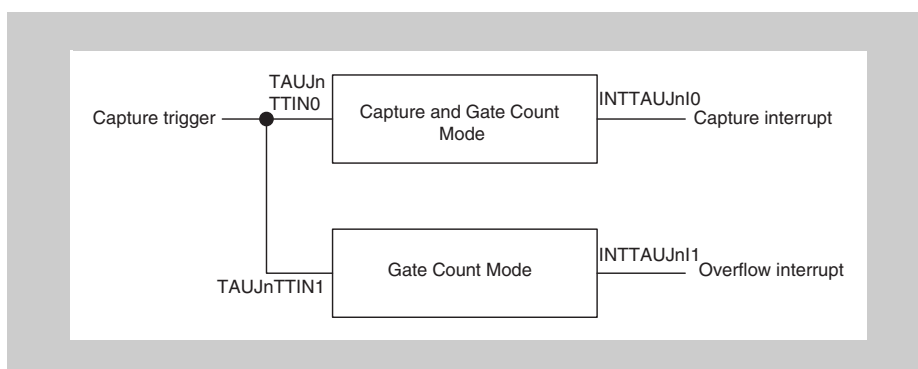

Figure 13-16 Combination of Capture and Gate Count Mode and Gate Count Mode

Timing diagram

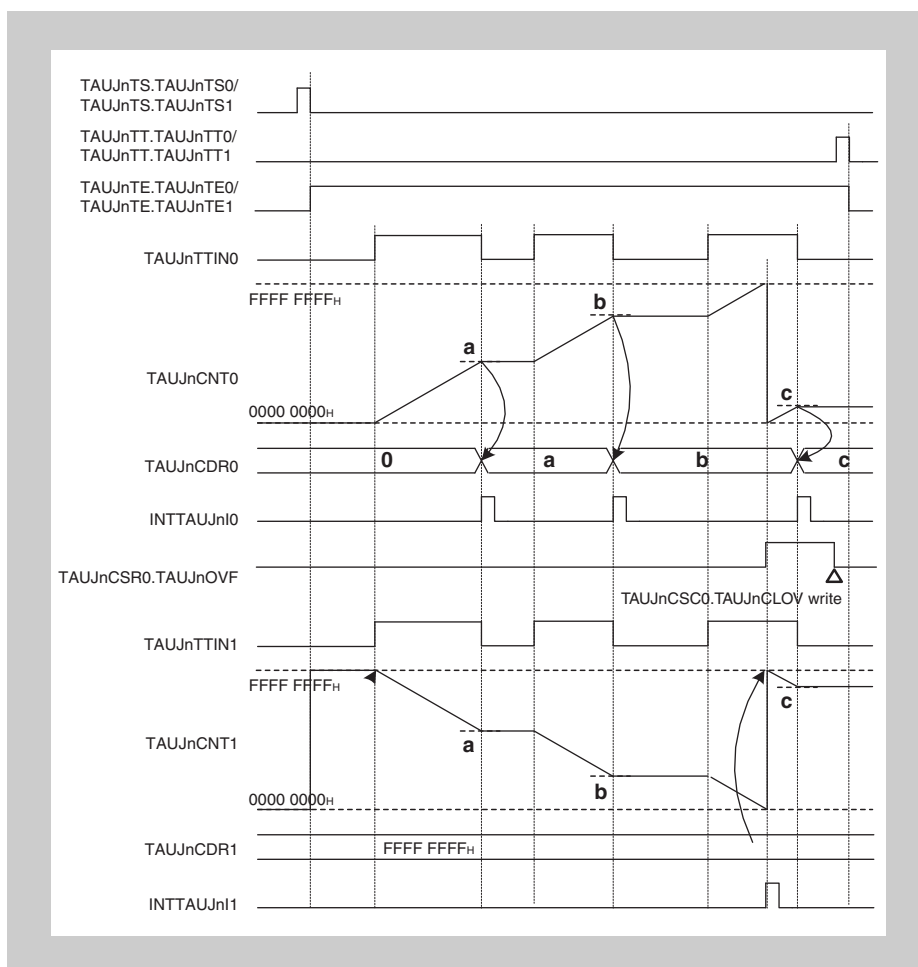

Figure 13-17 Interrupt generation via combination of Capture and Gate Count Mode and Gate Count Mode

In the above timing diagram, TAUJnCSRm.TAUJnOVF is set to 1 when TAUJnCNTm overflows. TAUJnCSRm.TAUJnOVF is cleared by writing 1 to TAUJnCSCm.TAUJnCLOV.

13.12 TAUJnTTINm Edge Detection

Edge detection is based on the operation clock. This means that an edge can only be detected at the next rising edge of the operation clock. This can lead to a maximum delay of one operation clock cycle.

The following figure shows an edge detection timing example.

Figure 13-18 Basic edge detection timing

Figure 13-18 “Basic edge detection timing” shows the approximate operation timing. Actually, there is delay due to the noise filter and synchronizer between the TAUJnIm pin and TAUJn.

13.13 Independent Channel Operation Functions

The following sections list the independent channel operation functions provided by TAUJ. For a general overview of independent channel operation, see 13.3 “*Functional Description*” on page 768 .

13.14 Independent Channel Interrupt Functions

This section describes functions that generate interrupts at regular intervals.

- 13.14.1 “*Interval Timer Function*”
- 13.14.2 “*TAUJnTTINm Input Interval Timer Function*”

13.14.1 Interval Timer Function

(1) Overview

Summary This function is used as a reference timer for generating timer interrupts (INTTAUJnIm) at regular intervals. When an interrupt is generated, the TAUJnTTOUTm signal toggles, resulting in a square wave.

- Prerequisites**
- The operation mode must be set to Interval Timer Mode, refer to *Table 13-11 “TAUJnCMORm settings for Interval Timer Function” on page 797*.
 - The channel output mode must be set to Independent Channel Output Mode 1, refer to *13.8 “Channel Output Modes” on page 780*.

Description The counter operation is enabled by setting the channel trigger bit (TAUJnTS.TAUJnTSM) to 1. This in turn sets TAUJnTE.TAUJnTEm = 1, enabling count operation. The current value of TAUJnCDRm is loaded to TAUJnCNTm and the counter starts counting down from this value.

When the counter reaches 0000 0000_H, INTTAUJnIm is generated and the TAUJnTTOUTm signal toggles. Next, TAUJnCNTm loads the value of TAUJnCDRm, and then subsequently continues operation.

The value of TAUJnCDRm can be rewritten at any time, and the changed value of TAUJnCDRm is applied the next time the counter starts counting down.

The counter can be stopped by setting TAUJnTT.TAUJnTTm to 1, which in turn sets TAUJnTE.TAUJnTEm to 0. TAUJnCNTm and TAUJnTTOUTm stop but retain their values. The counter can be reset by setting TAUJnTS.TAUJnTSM to 1. The counter can also be forcibly restarted (without stopping it first) by setting TAUJnTS.TAUJnTSM to 1 during operation.

Conditions If the TAUJnCMORm.TAUJnMD0 bit is set to 0, the first interrupt after a start or restart is not generated, and therefore TAUJnTTOUTm does not toggle. This results in an inverted TAUJnTTOUTm signal compared to when TAUJnCMORm.TAUJnMD0 is set to 1. For details refer to *13.10 “TAUJnTTOUTm Output and INTTAUJnIm Generation when Counter Starts or Restarts (by TAUJnMD0 Bit)” on page 787*.

(2) Equations

$$\text{INTTAUJnIm cycle} = \text{count clock cycle} \times (\text{TAUJnCDRm} + 1)$$

$$\text{TAUJnTTOUTm square wave cycle} = \text{count clock cycle} \times (\text{TAUJnCDRm} + 1) \times 2$$

Caution The minimum interval timer interrupt cycle is 1/(PCLK/2).

(3) Block diagram and general timing diagram

Figure 13-19 Block diagram for Interval Timer Function

The following settings apply to the general timing diagram:

- INTTAUJnIm is generated at operation start (TAUJnCMORm.TAUJnMD0 = 1)

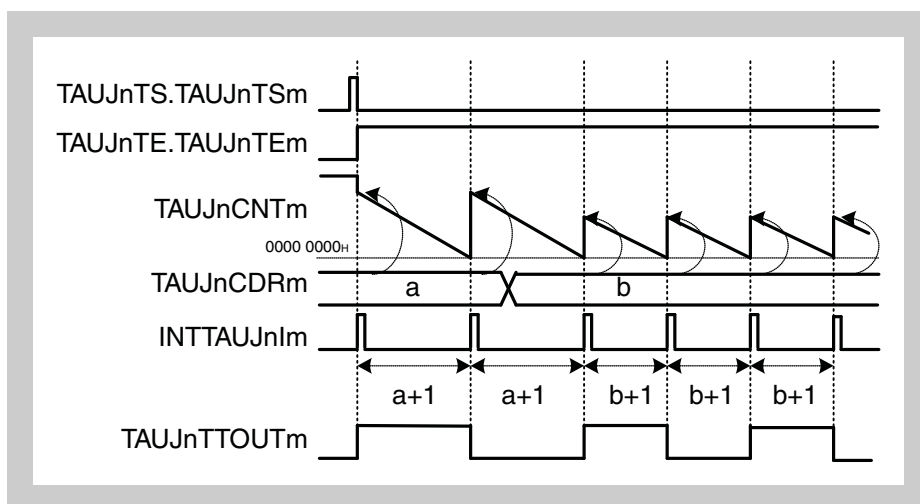

Figure 13-20 General timing diagram for Interval Timer Function

(4) Register settings**(a) TAUJnCMORM**

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
TAUJn CKS[1:0]		TAUJn CCS[1:0]		TAUJn MAS	TAUJnSTS[2:0]			TAUJn COS[1:0]		-	TAUJnMD[4:1]				TAUJn MD0

Table 13-11 TAUJnCMORM settings for Interval Timer Function

Bit name	Setting
TAUJnCKS[1:0]	00: Prescaler output = CK0 01: Prescaler output = CK1 10: Prescaler output = CK2 11: Prescaler output = CK3
TAUJnCCS[1:0]	00: Operation clock is used as the count clock
TAUJnMAS	0: Not used, so set to 0
TAUJnSTS[2:0]	000: Counter triggered by software trigger
TAUJnCOS[1:0]	00: Not used, so set to 00
TAUJnMD[4:1]	0000: Interval Timer Mode
TAUJnMD0	0: INTTAUJnIm not generated and TAUJnTTOUTm does not toggle at operation start or restart 1: Generates INTTAUJnIm and toggles TAUJnTTOUTm at operation start or restart

(b) TAUJnCMURm

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
-														TAUJnTIS[1:0]	

Table 13-12 TAUJnCMURm settings for Interval Timer Function

Bit name	Setting
TAUJnTIS[1:0]	00: Not used, so set to 00

(c) Channel output mode**Table 13-13 Control bit settings for Independent Channel Output Mode 1**

Bit name	Setting
TAUJnTOE.TAUJnTOEm	1: Enable the independent channel output mode.
TAUJnTOM.TAUJnTOMm	0: Independent channel output
TAUJnTOC.TAUJnTOCm	0: Operation mode 1 (= Toggle mode if TAUJnTOM.TAUJnTOMm = 0)
TAUJnTOL.TAUJnTOLm	0: Positive logic

Note The channel output mode can also be set to Channel Output Mode Controlled by Software by setting TAUJnTOE.TAUJnTOEm = 0. TAUJnTTOUTm can then be controlled independently of the interrupts. For details refer to 13.8 “Channel Output Modes” on page 780.

(d) Simultaneous rewrite

The simultaneous rewrite registers (TAUJnRDE and TAUJnRDM) cannot be used with the Interval Timer Function. Therefore, these registers must be set to 0.

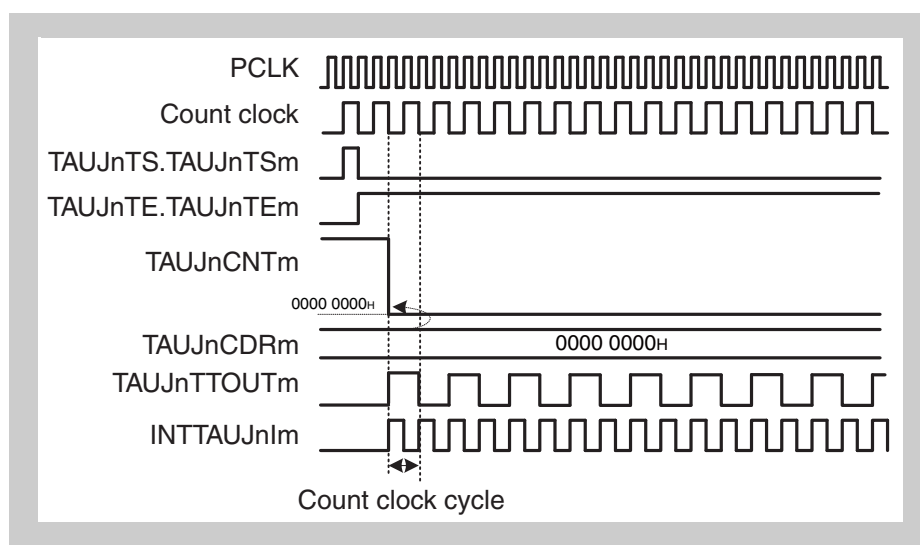

Table 13-14 Simultaneous rewrite settings for Interval Timer Function

Bit name	Setting
TAUJnRDE.TAUJnRDEm	0: Disables simultaneous rewrite
TAUJnRDM.TAUJnRDMm	0: When simultaneous rewrite is disabled (TAUJnRDE.TAUJnRDEm = 0), set these bits to 0

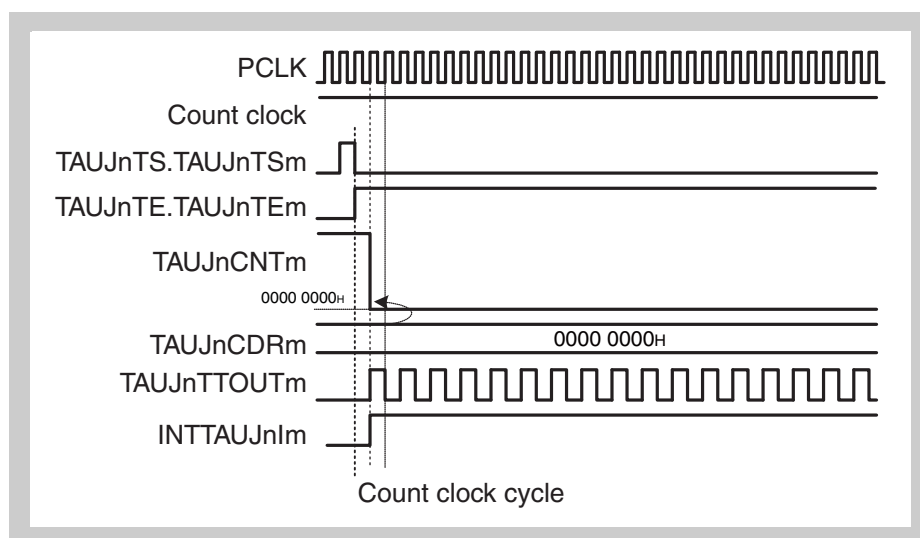

(5) Operating procedure for Interval Timer Function

Table 13-15 Operating procedure for Interval Timer Function

	Operation	Status of TAUJn
Restart ↓	Initial channel setting Set the TAUJnCMORm and TAUJnCMURm registers as described in <i>Table 13-11</i> "TAUJnCMORm settings for Interval Timer Function" on page 797 and <i>Table 13-12</i> "TAUJnCMURm settings for Interval Timer Function" on page 797 . Set the value of the TAUJnCDRm register. Set the channel output mode by setting the control bits as described in <i>Table 13-13</i> "Control bit settings for Independent Channel Output Mode 1" on page 798 .	Channel operation is stopped.
	Start operation Set TAUJnTS.TAUJnTSm to 1. TAUJnTS.TAUJnTSm is a trigger bit, so it is automatically cleared to 0.	TAUJnTE.TEm is set to 1 and the counter starts. TAUJnCnTm loads the TAUJnCDRm value. When TAUJnCMORm.TAUJnMD0 = 1, INTTAUJnIm is generated and TAUJnTTOUTm toggles.
	During operation The TAUJnCDRm register value can be changed at any time. The TAUJnCnTm register can be read at all times.	TAUJnCnTm counts down. When the counter reaches 0000 _μ : <ul style="list-style-type: none"> TAUJnCnTm reloads the TAUJnCDRm value, and then continues count operation. INTTAUJnIm is generated and TAUJnTTOUTm toggles.
	Stop operation Set TAUJnTT.TAUJnTTm to 1. TAUJnTT.TAUJnTTm is a trigger bit, so it is automatically cleared to 0.	TAUJnTE.TAUJnTEm is cleared to 0 and the counter stops. TAUJnCnTm and TAUJnTTOUTm stop and retain their current values.

(6) Specific timing diagrams**(a) TAUJnCDRm = 0000 0000_H, count clock = PCLK/2****Figure 13-21** TAUJnCDRm = 0000 0000_H, count clock = PCLK/2

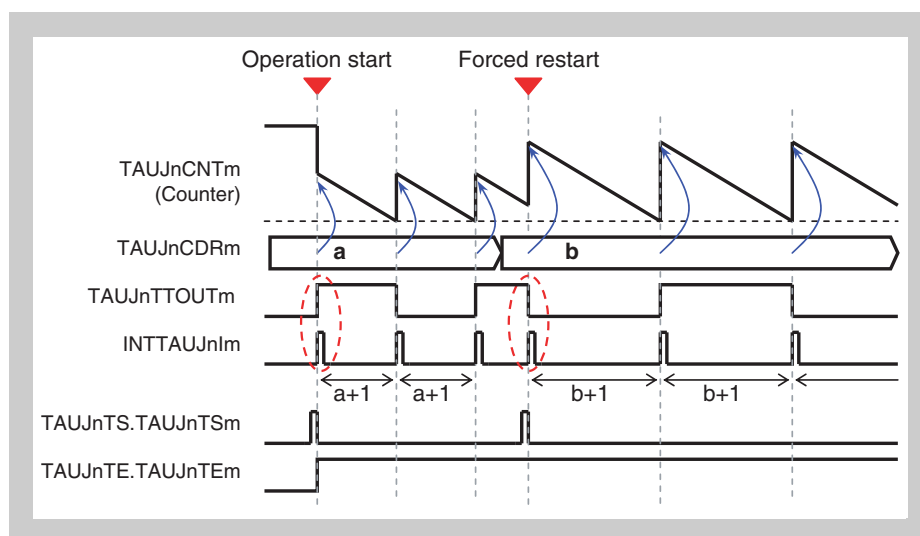

- If TAUJnCDRm = 0000 0000_H and the count clock = PCLK/2¹, the TAUJnCDRm value is loaded to TAUJnCNTm every count clock, meaning that TAUJnCNTm is always 0000 0000_H.
- INTTAUJnIm is generated every count clock, resulting in TAUJnTTOUTm toggling every count clock.

(b) TAUJnCDRm = 0000 0000_H, count clock = PCLK**Figure 13-22** TAUJnCDRm = 0000 0000_H, count clock = PCLK

- If TAUJnCDRm = 0000 0000_H and the count clock = PCLK, the TAUJnCDRm value is loaded to TAUJnCNTm every PCLK clock, meaning that TAUJnCNTm is always 0000 0000_H.
- INTTAUJnIm is generated continuously, resulting in TAUJnTTOUTm toggling every PCLK clock.

(c) Operation stop and restart**Figure 13-23 Operation stop and restart, TAUJnCMORM.TAUJnMD0 = 1**

- The counter can be stopped by setting TAUJnTT.TAUJnTTm to 1, which in turn sets TAUJnTE.TAUJnTEM to 0.
- TAUJnCNTm and TAUJnTTOUTm stop but retain their values.
- The counter can be restarted by setting TAUJnTS.TAUJnTSM to 1.

(d) Forced restart**Figure 13-24 Forced restart operation, TAUJnCMORM.TAUJnMD0 = 1**

- The counter can be forcibly restarted (without stopping it first) by setting TAUJnTS.TAUJnTSM to 1 during operation.
- If the TAUJnCMORM.TAUJnMD0 bit is set to 1, the first interrupt after a start or restart is generated.

13.14.2 TAUJnTTINm Input Interval Timer Function

(1) Overview

Summary This function is used as a reference timer for generating timer interrupts (INTTAUJnIm) at regular intervals or when a valid TAUJnTTINm input edge is detected. When an interrupt is generated, the TAUJnTTOUTm signal toggles, resulting in a square wave.

- Prerequisites**
- The operation mode must be set to Interval Timer Mode, refer to *Table 13-16 “TAUJnCMORm settings for TAUJnTTINm Input Interval Timer Function” on page 804*.
 - The channel output mode must be set to Independent Channel Output Mode 1, refer to *13.8 “Channel Output Modes” on page 780*.

Description This function operates in an identical manner to the Interval Timer Function (see *13.14.1 “Interval Timer Function” on page 795*), except that this function is restarted by a valid TAUJnTTINm input edge. The type of edge used as the trigger is specified using the TAUJnCMURm.TAUJnTIS[1:0] bits. Either rising edge, falling edge, or rising and falling edge can be selected.

(2) Equations

$$\text{INTTAUJnIm cycle} = \text{count clock cycle} \times (\text{TAUJnCDRm} + 1)$$

$$\text{TAUJnTTOUTm square wave cycle} = \text{count clock cycle} \times (\text{TAUJnCDRm} + 1) \times 2$$

(3) Block diagram and general timing diagram

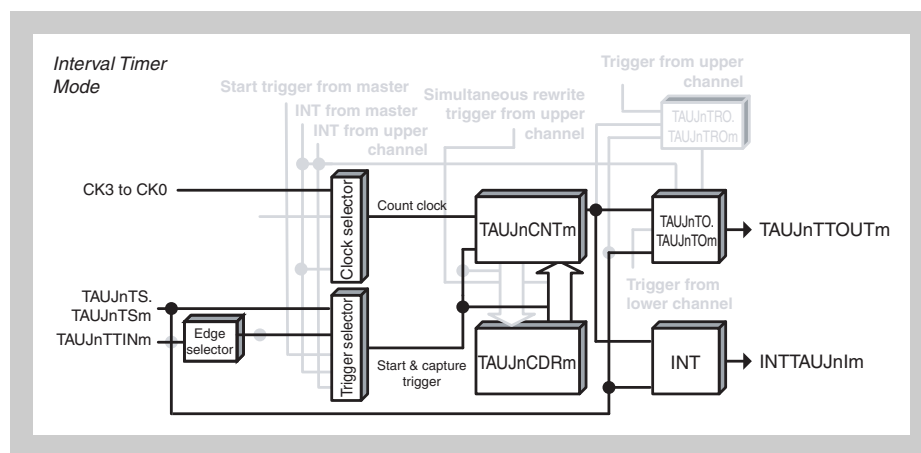

Figure 13-25 Block diagram for TAUJnTTINm Input Interval Timer Function

The following settings apply to the general timing diagram:

- INTTAUJnIm is generated at operation start (TAUJnCMORm.TAUJnMD0 = 1).
- Rising edge detection (TAUJnCMURm.TAUJnTIS[1:0] = 01_B)

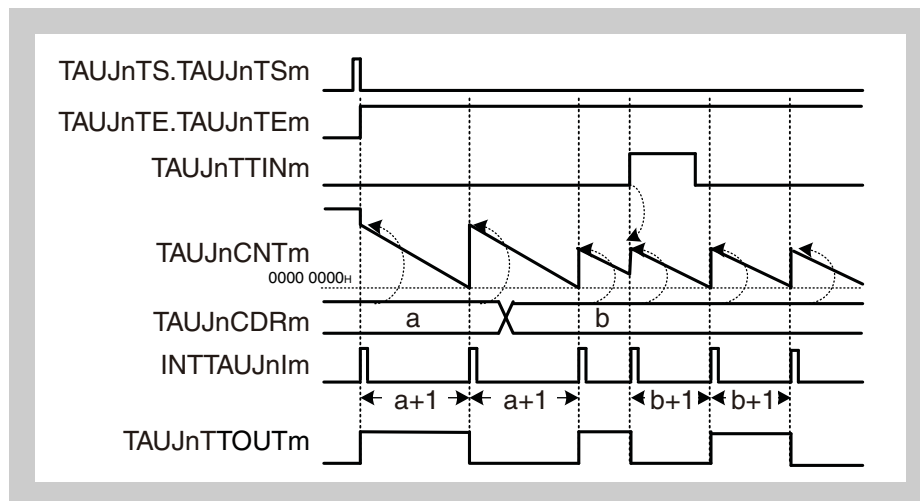

Figure 13-26 General timing diagram for TAUJnTTINm Input Interval Timer Function

Bit name	Setting
TAUJnTIS[1:0]	00: Falling edge detection 01: Rising edge detection 10: Rising and falling edge detection (low width measurement) 11: Rising and falling edge detection (high width measurement)

(c) Channel output mode**Table 13-18 Control bit settings for Independent Channel Output Mode 1**

Bit name	Setting
TAUJnTOE.TAUJnTOEm	1: Enable the independent channel output mode.
TAUJnTO.TAUJnTOm	0: Low level 1: High level
TAUJnTOM.TAUJnTOMm	0: Independent channel output
TAUJnTOC.TAUJnTOCm	0: Operation mode 1 (= Toggle mode if TAUJnTOM.TAUJnTOMm = 0)
TAUJnTOL.TAUJnTOLm	0: Positive logic

Note The channel output mode can also be set to Channel Output Mode Controlled by Software by setting TAUJnTOE.TAUJnTOEm = 0. TAUJnTTOUTm can then be controlled independently of the interrupts. For details refer to 13.8 “Channel Output Modes” on page 780 .

(d) Simultaneous rewrite

The simultaneous rewrite registers (TAUJnRDE and TAUJnRDM) cannot be used with the TAUJnTTINm Input Interval Timer Function. Therefore, these registers must be set to 0.

Table 13-19 Simultaneous rewrite settings for TAUJnTTINm Input Interval Timer Function

Bit name	Setting
TAUJnRDE.TAUJnRDEm	0: Disables simultaneous rewrite
TAUJnRDM.TAUJnRDMm	0: When simultaneous rewrite is disabled (TAUJnRDE.TAUJnRDEm = 0), set these bits to 0

(5) Operating procedure for TAUJnTTINm Input Interval Timer Function

Table 13-20 Operating procedure for TAUJnTTINm Input Interval Timer Function

	Operation	Status of TAUJn
Initial channel setting	<p>Set the TAUJnCMORm register and TAUJnCMURm registers as described in <i>Table 13-16 "TAUJnCMORm settings for TAUJnTTINm Input Interval Timer Function" on page 804</i> and <i>Table 13-17 "TAUJnCMURm settings for TAUJnTTINm Input Interval Timer Function" on page 804</i>.</p> <p>Set the value of the TAUJnCDRm register.</p> <p>Set the channel output mode by setting the control bits as described in <i>Table 13-18 "Control bit settings for Independent Channel Output Mode 1" on page 805</i>.</p>	Channel operation is stopped.
Restart Start operation	Set TAUJnTS.TAUJnTSM to 1. TAUJnTS.TAUJnTSM is a trigger bit, so it is automatically cleared to 0.	TAUJnTE.TAUJnTEM is set to 1 and the counter starts. TAUJnCNTm loads the TAUJnCDRm value. When TAUJnCMORm.TAUJnMD0 = 1, INTTAUJnIm is generated and TAUJnTTOUTm toggles.
During operation	<p>The values of the TAUJnCMURm.TAUJnTIS[1:0] and the TAUJnCDRm register can be changed at any time. The TAUJnCNTm register can be read at all times.</p> <p>Detection of TAUJnTTINm edge</p>	<p>TAUJnCNTm counts down. When the counter reaches 0000 0000_H:</p> <ul style="list-style-type: none"> TAUJnCNTm reloads the TAUJnCDRm value and continues count operation. INTTAUJnIm is generated and TAUJnTTOUTm toggles. <p>When a TAUJnTTINm input valid edge is detected during count operation, TAUJnCNTm reloads the TAUJnCDRm value and continues count operation. Afterwards, this procedure is repeated.</p>
Stop operation	Set TAUJnTT.TAUJnTTM to 1. TAUJnTT.TAUJnTTM is a trigger bit, so it is automatically cleared to 0.	TAUJnTE.TAUJnTEM is cleared to 0 and the counter stops. TAUJnCNTm and TAUJnTTOUTm stop and retain their current values.

(6) Specific timing diagrams

The timing diagrams in 13.14.1 “Interval Timer Function” on page 795 also apply, except for this function the counter can also be restarted by a valid TAUJnTTINm input edge.

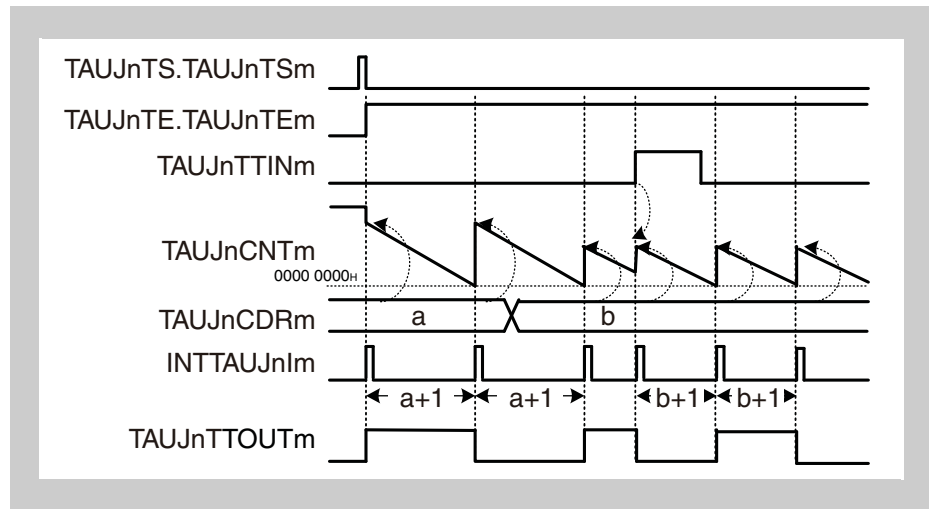

Figure 13-27 Counter triggered by rising TAUJnTTINm input edge
(TAUJnCMURm.TAUJnTIS[1:0] = 01_B), TAUJnCMORm.TAUJnMD0 = 1

- If a valid TAUJnTTINm input edge is detected, an interrupt is generated which causes TAUJnTTOUTm to toggle. In this example, the valid edge is a rising edge (TAUJnCMURm.TAUJnTIS[1:0] = 01_B).

13.15 Independent Channel Signal Measurement Functions

This section describes functions that measure the widths of an individual TAUJnTTINm pulse or the total width of successive TAUJnTTINm pulses. It also describes functions that measure the interval of the signal or that compare the width of a pulse with a reference value.

- *13.15.1 “TAUJnTTINm Input Pulse Interval Measurement Function”*
- *13.15.2 “TAUJnTTINm Input Signal Width Measurement Function”*
- *13.15.3 “Overflow Interrupt Output Function (During TAUJnTTINm Width Measurement)”*
- *13.15.4 “TAUJnTTINm Input Period Count Detection Function”*
- *13.15.5 “Overflow Interrupt Output Function (During TAUJnTTINm Input Period Count Detection)”*

13.15.1 TAUJnTTINm Input Pulse Interval Measurement Function

(1) Overview

Summary This function captures the count value and uses this value and the overflow bit TAUJnCSRm.TAUJnOVF to measure the interval of the TAUJnTTINm input signal.

- Prerequisites**
- The operation mode must be set to Capture Mode, refer to *Table 13-22 “TAUJnCMORm settings for TAUJnTTINm Input Pulse Interval Measurement Function” on page 811*.
 - TAUJnTTOUTm is not used for this function.

Description The counter operation is enabled by setting the channel trigger bit (TAUJnTS.TAUJnTsm) to 1. This in turn sets TAUJnTE.TAUJnTEm = 1, enabling count operation. The counter TAUJnCNTm starts counting up from 0000 0000_H. When a valid TAUJnTTINm edge is detected, the value of TAUJnCNTm is captured, transferred to TAUJnCDRm, and an interrupt INTTAUJnIm is generated. The counter resets to 0000 0000_H and subsequently continues operation.

If the counter reaches FFFF FFFF_H before a valid TAUJnTTINm edge is detected, it overflows to 0000 0000_H. The counter is reset to 0000 0000_H and subsequently continues operation. The values transferred to TAUJnCDRm and TAUJnCSRm.TAUJnOVF respectively depend on the values of bits TAUJnCMORm.TAUJnCOS[1:0]:

Table 13-21 Effects of an overflow

TAUJnCMORm. COS[1:0]	When overflow occurs		When a valid TAUJnTTINm input is then detected	
	TAUJnCDRm	TAUJnCSRm. TAUJnOVF	TAUJnCDRm and TAUJnCNTm	TAUJnCSRm. TAUJnOVF
00	Unchanged	0	TAUJnCNTm loaded to TAUJnCDRm	1
01		1		
10	Set to FFFF FFFF _H	0	TAUJnCNTm set to 0, TAUJnCDRm unchanged	0
11		1		

When TAUJnCMORm.TAUJnCOS[0] is 1, the overflow bit TAUJnCSRm.TAUJnOVF can only be cleared by setting TAUJnCSCm.TAUJnCLOV to 1.

The combination of the value of TAUJnCDRm and TAUJnCSRm.TAUJnOVF can be used to deduce the interval of the TAUJnTTINm signal. However, if an overflow occurs multiple times before a valid TAUJnTTINm input is detected, the overflow bit TAUJnCSRm.TAUJnOVF cannot indicate this.

The function can be stopped by setting TAUJnTT.TAUJnTTm = 1, which in turn sets TAUJnTE.TAUJnTEm = 0. TAUJnCNTm stops and retains its value. While the function is stopped, TAUJnTTINm input valid edge detection and TAUJnCNTm capture are not performed.

The counter is reset to 0000 0000_H and subsequently continues operation. The counter can also be forcibly restarted (without stopping it first) by setting TAUJnTS.TAUJnTsm = 1 during operation.

Conditions If the TAUJnCMORm.TAUJnMD0 bit is set to 0, the first interrupt after a start or restart is not generated. For details refer to *13.10 “TAUJnTTOUTm Output and INTTAUJnIm Generation when Counter Starts or Restarts (by TAUJnMD0 Bit)” on page 787*.

Note When $\text{TAUJnCMORm.TAUJnCOS}[1:0] = 11_{\text{B}}$, the value of TAUJnCNTm is *not* loaded to TAUJnCDRm when the first valid TAUJnTTINm input edge occurs after an overflow. However, an interrupt is generated.

(2) Equations

TAUJnTTINm input pulse interval = count clock cycle x
 $[(\text{TAUJnCSRm.TAUJnOVF} \times (\text{FFFF FFFF}_{\text{H}} + 1)) + \text{TAUJnCDRm}$ capture value
 $+ 1]$

(3) Block diagram and general timing diagram

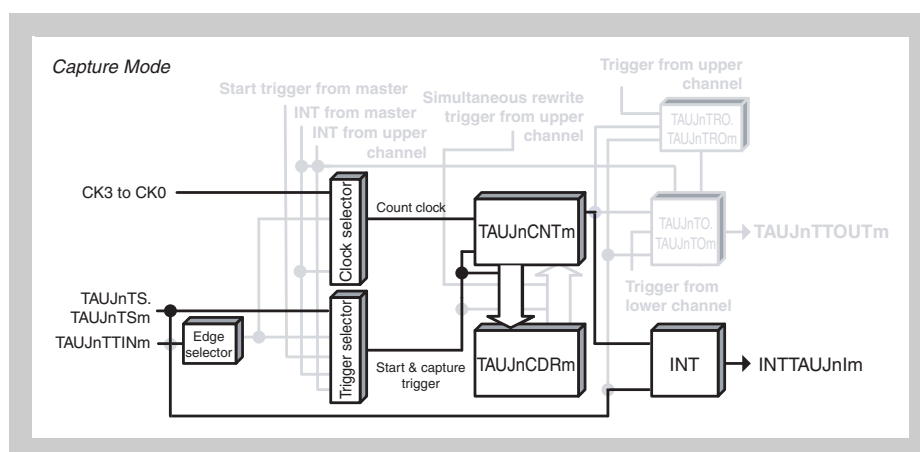

Figure 13-28 Block diagram for TAUJnTTINm Input Pulse Interval Measurement Function

The following settings apply to the general timing diagram:

- INTTAUJnIm not generated at operation start ($\text{TAUJnCMORm.TAUJnMD0} = 0$)
- Falling edge detection ($\text{TAUJnCMURm.TAUJnTIS}[1:0] = 00_{\text{B}}$)
- When a valid TAUJnTTINm input is detected after an overflow TAUJnCDRm is changed and $\text{TAUJnCSRm.TAUJnOVF}$ is set to 1 ($\text{TAUJnCMORm.TAUJnCOS}[1:0] = 00_{\text{B}}$)

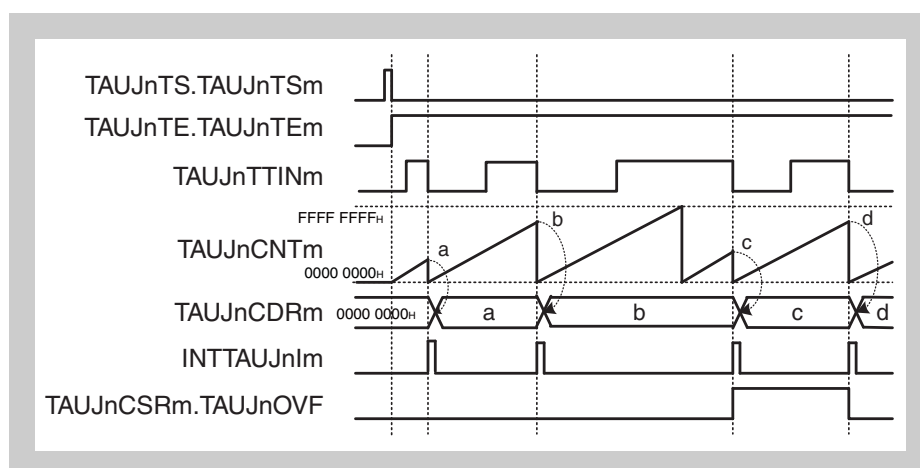

Figure 13-29 General timing diagram for TAUJnTTINm Input Pulse Interval Measurement Function

(4) Register settings**(a) TAUJnCMORM**

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
TAUJn CKS[1:0]		TAUJn CCS[1:0]		TAUJn MAS	TAUJnSTS[2:0]			TAUJn COS[1:0]		-	TAUJnMD[4:1]				TAUJn MD0

Table 13-22 TAUJnCMORM settings for TAUJnTTINm Input Pulse Interval Measurement Function

Bit name	Setting
TAUJnCKS[1:0]	00: Prescaler output = CK0 01: Prescaler output = CK1 10: Prescaler output = CK2 11: Prescaler output = CK3
TAUJnCCS[1:0]	00: Operation clock is used as the count clock
TAUJnMAS	0: Not used, so set to 0
TAUJnSTS[2:0]	001: Valid edge of the TAUJnTTINm input signal is the external capture trigger
TAUJnCOS[1:0]	See Table 13-21 "Effects of an overflow" on page 809
TAUJnMD[4:1]	0010: Capture Mode
TAUJnMD0	0: INTTAUJnIm not generated at operation start 1: Generates INTTAUJnIm at operation start

(b) TAUJnCMURm

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
														TAUJnTIS[1:0]	

Table 13-23 TAUJnCMURm settings for TAUJnTTINm Input Pulse Interval Measurement Function

Bit name	Setting
TAUJnTIS[1:0]	00: Falling edge detection 01: Rising edge detection 10: Rising and falling edge detection (low width measurement) 11: Rising and falling edge detection (high width measurement)

(c) Channel output mode

The channel output mode is not used by this function. However, it can be used in Independent Channel Output Mode Controlled by Software.

(d) Simultaneous rewrite

The simultaneous rewrite registers (TAUJnRDE and TAUJnRDM) cannot be used with the TAUJnTTINm Input Pulse Interval Measurement Function. Therefore, these registers must be set to 0.

Table 13-24 Simultaneous rewrite settings for TAUJnTTINm Input Pulse Interval Measurement Function

Bit name	Setting
TAUJnRDE.TAUJnRDEm	0: Disables simultaneous rewrite
TAUJnRDM.TAUJnRDMm	0: When simultaneous rewrite is disabled (TAUJnRDE.TAUJnRDEm = 0), set these bits to 0

(5) Operating procedure for TAUJnTTINm Input Pulse Interval Measurement Function

Table 13-25 Operating procedure for TAUJnTTINm Input Pulse Interval Measurement Function

	Operation	Status of TAUJn
Initial channel setting	Set the TAUJnCMORm register and TAUJnCMURm registers as described in <i>Table 13-22 “TAUJnCMORm settings for TAUJnTTINm Input Pulse Interval Measurement Function” on page 811</i> and <i>Table 13-23 “TAUJnCMURm settings for TAUJnTTINm Input Pulse Interval Measurement Function” on page 811</i> . Set the value of the TAUJnCDRm register.	Channel operation is stopped.
Start operation	Set TAUJnTS.TAUJnTSm to 1. TAUJnTS.TAUJnTSm is a trigger bit, so it is automatically cleared to 0.	TAUJnTE.TAUJnTEm is set to 1 and the counter starts. TAUJnCNTm is cleared to 0000 0000 _H . INTTAUJnIm is generated when TAUJnCMORm.TAUJnMD0 is set to 1.
During operation	Detection of TAUJnTTINm edges. The TAUJnCMURm.TAUJnTIS[1:0] bits can be changed at any time. The TAUJnCDRm and TAUJnCSRm registers can be read at any time. Writing 1 to the TAUJnCSCm.TAUJnCLOV bit is possible. (The TAUJnCSRm.TAUJnOVF bit is cleared to 0.)	TAUJnCNTm starts counting up from 0000 0000 _H . When a TAUJnTTINm valid edge is detected: <ul style="list-style-type: none"> TAUJnCNTm transfers (captures) its value to TAUJnCDRm, and returns to 0000 0000_H. INTTAUJnIm is then generated. Afterwards, this procedure is repeated.
Stop operation	Set TAUJnTT.TAUJnTTm to 1. TAUJnTT.TAUJnTTm is a trigger bit, so it is automatically cleared to 0.	TAUJnTE.TAUJnTEm is cleared to 0 and the counter stops. TAUJnCNTm stops and both it and TAUJnCSRm.TAUJnOVF retain their current values.

Restart

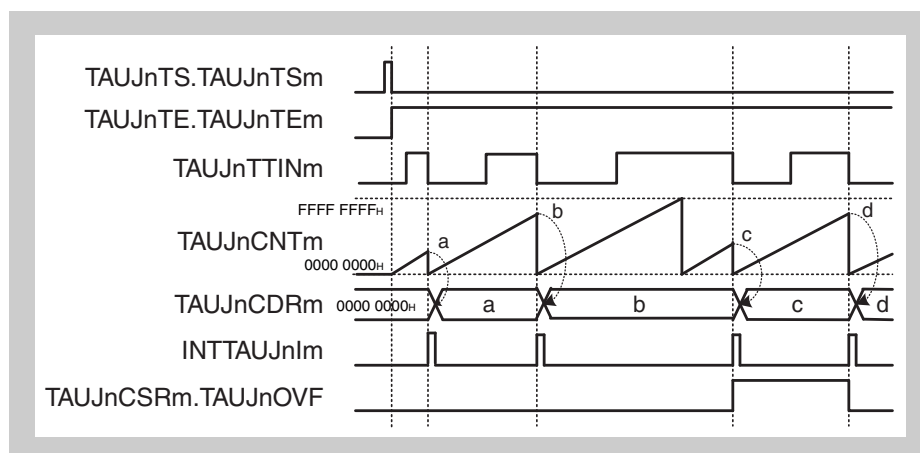

(6) Specific timing diagrams: overflow behavior**(a) TAUJnCMORM.TAUJnCOS[1:0] = 00_B**

Figure 13-30 TAUJnCMORM.TAUJnCOS[1:0] = 00_B, TAUJnCMORM.TAUJnMD0 = 0, TAUJnCMURm.TAUJnTIS[1:0] = 00_B

- When an overflow occurs, the value of TAUJnCDRm remains unchanged and TAUJnCSRm.TAUJnOVF remains 0.
- Upon detection of the next valid TAUJnTTINm input edge, the value of TAUJnCNTm is loaded to TAUJnCDRm and TAUJnCSRm.TAUJnOVF is set to 1.
- Upon detecting the next valid TAUJnTTINm input edge while no overflow has occurred, TAUJnCSRm.TAUJnOVF is cleared to 0.

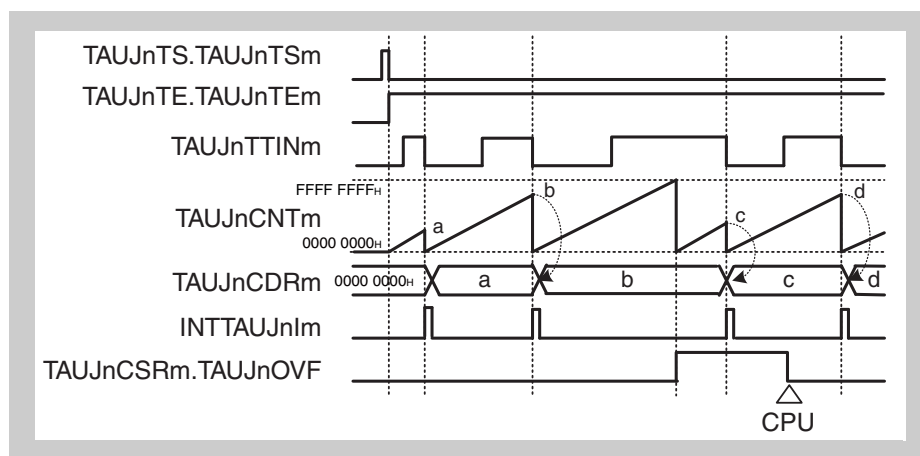

(b) TAUJnCMORM.TAUJnCOS[1:0] = 01_B

Figure 13-31 TAUJnCMORM.TAUJnCOS[1:0] = 01_B, TAUJnCMORM.TAUJnMD0 = 0, TAUJnCMURm.TAUJnTIS[1:0] = 00_B

- When an overflow occurs, the value of TAUJnCDRm remains unchanged and TAUJnCSRm.TAUJnOVF is set to 1.
- Upon detection of the next valid TAUJnTTINm input edge, the value of TAUJnCNTm is loaded to TAUJnCDRm.
- TAUJnCSRm.TAUJnOVF is only cleared by a CPU command (setting the TAUJnCSCm.TAUJnCLOV bit to 1).

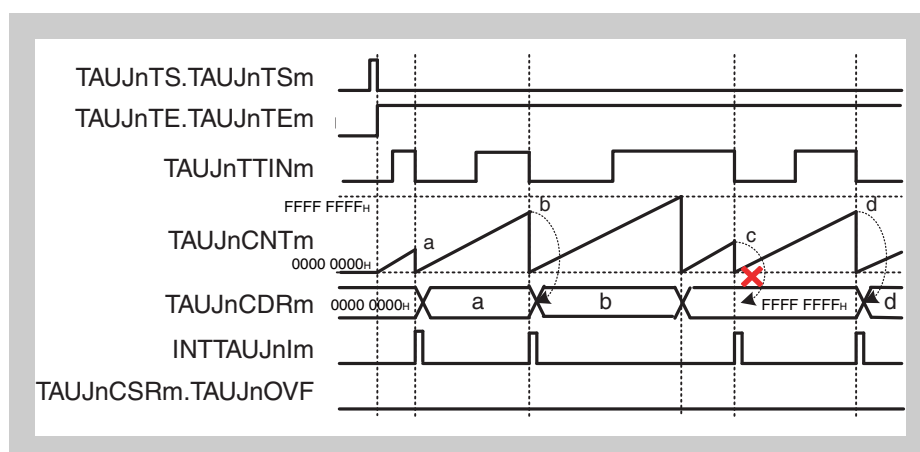

(c) $\text{TAUJnCMORM.TAUJnCOS}[1:0] = 10_{\text{B}}$ 

Figure 13-32 $\text{TAUJnCMORM.TAUJnCOS}[1:0] = 10_{\text{B}}$, $\text{TAUJnCMORM.TAUJnMD0} = 0$,
 $\text{TAUJnCMURm.TAUJnTIS}[1:0] = 00_{\text{B}}$

- When an overflow occurs, TAUJnCDRm is set to $\text{FFFF FFFF}_{\text{H}}$ and $\text{TAUJnCSRm.TAUJnOVF}$ remains 0.
- Upon detection of the next valid TAUJnTTINm input edge, TAUJnCNTm is reset to 0, but TAUJnCDRm and $\text{TAUJnCSRm.TAUJnOVF}$ remain unchanged.
- Thus, the next TAUJnTTINm input valid edge after the overflow is ignored.

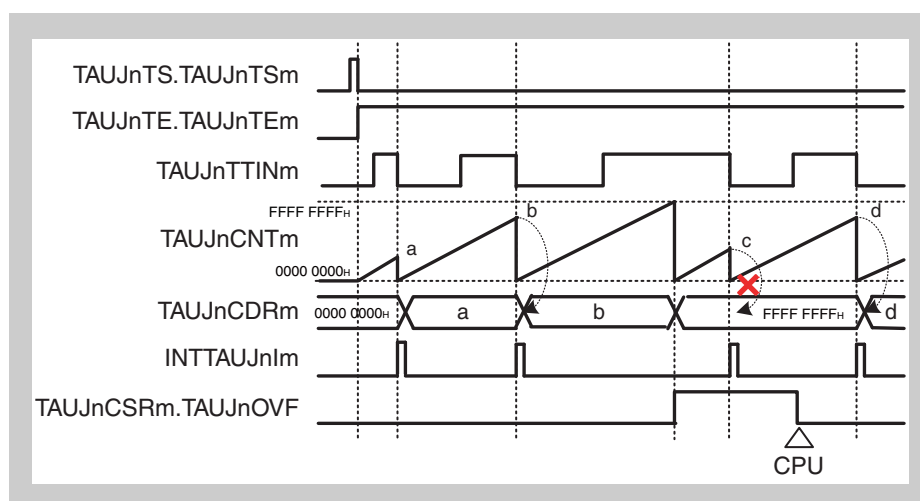

(d) $\text{TAUJnCMORM.TAUJnCOS}[1:0] = 11_{\text{B}}$ 

Figure 13-33 $\text{TAUJnCMORM.TAUJnCOS}[1:0] = 11_{\text{B}}$, $\text{TAUJnCMORM.TAUJnMD0} = 0$,
 $\text{TAUJnCMURm.TAUJnTIS}[1:0] = 00_{\text{B}}$

- When an overflow occurs, TAUJnCDRm is set to $\text{FFFF FFFF}_{\text{H}}$, and $\text{TAUJnCSRm.TAUJnOVF}$ is set to 1.
- Upon detection of the next valid TAUJnTTINm input edge, TAUJnCNTm is reset to 0, but TAUJnCDRm and $\text{TAUJnCSRm.TAUJnOVF}$ remain unchanged.
- Thus, the next TAUJnTTINm input valid edge after the overflow is ignored.
- $\text{TAUJnCSRm.TAUJnOVF}$ is cleared by setting $\text{TAUJnCSCm.TAUJnCLOV}$ to 1.

13.15.2 TAUJnTTINm Input Signal Width Measurement Function

(1) Overview

Summary This function measures the width of a TAUJnTTINm input signal.

- Prerequisites**
- The operation mode must be set to Capture & One Count Mode, refer to Table 13-27 “TAUJnCMORm settings for TAUJnTTINm Input Signal Width Measurement Function” on page 817.
 - TAUJnTTOUTm is not used for this function.
 - TAUJnCMORm.TAUJnMD0 must be set to 0.

Description The counter operation is enabled by setting the channel trigger bit (TAUJnTS.TAUJnTSm) to 1. This in turn sets TAUJnTE.TAUJnTEm = 1, enabling count operation. When a valid TAUJnTTINm start edge is detected, the counter TAUJnCNTm starts counting up from 0000 0000_H. When a valid TAUJnTTINm stop edge is detected, the value of TAUJnCNTm is captured, transferred to TAUJnCDRm, and an interrupt INTTAUJnIm is generated. The counter retains its value and awaits the next valid TAUJnTTINm input start edge.

If the counter reaches FFFF FFFF_H before a valid TAUJnTTINm stop edge is detected, it overflows. The counter is reset to 0000 0000_H and subsequently continues operation. The values transferred to TAUJnCDRm and TAUJnCSRm.TAUJnOVF respectively depend on the values of bits TAUJnCMORm.TAUJnCOS[1:0]:

Table 13-26 Effects of an overflow

TAUJnCMORm. COS[1:0]	When overflow occurs		When a valid TAUJnTTINm input stop edge is detected	
	TAUJnCDRm	TAUJnCSRm. TAUJnOVF	TAUJnCDRm and TAUJnCNTm	TAUJnCSRm. TAUJnOVF
00	Unchanged	0	TAUJnCNTm loaded to TAUJnCDRm	1
01		1		
10	Set to FFFF FFFF _H	0	TAUJnCNTm stops counting TAUJnCDRm unchanged	0
11		1		

When TAUJnCMORm.TAUJnCOS[0] is 1, the overflow bit TAUJnCSRm.TAUJnOVF can only be cleared by setting TAUJnCSCm.TAUJnCLOV to 1.

The combination of the value of TAUJnCDRm and TAUJnCSRm.TAUJnOVF can be used to deduce the width of the TAUJnTTINm signal. However, if an overflow occurs multiple times before a valid TAUJnTTINm input is detected, the overflow bit TAUJnCSRm.TAUJnOVF cannot indicate this.

This function cannot be forcibly restarted.

Note When TAUJnCMORm.TAUJnCOS[1] = 1, the value of TAUJnCNTm is not loaded to TAUJnCDRm when the first valid TAUJnTTINm input edge occurs after an overflow. However, an interrupt is generated.

(2) Equations

TAUJnTTINm input signal width = count clock cycle x [(TAUJnCSRm.TAUJnOVF x (FFFF FFFF_H + 1)) + TAUJnCDRm capture value + 1]

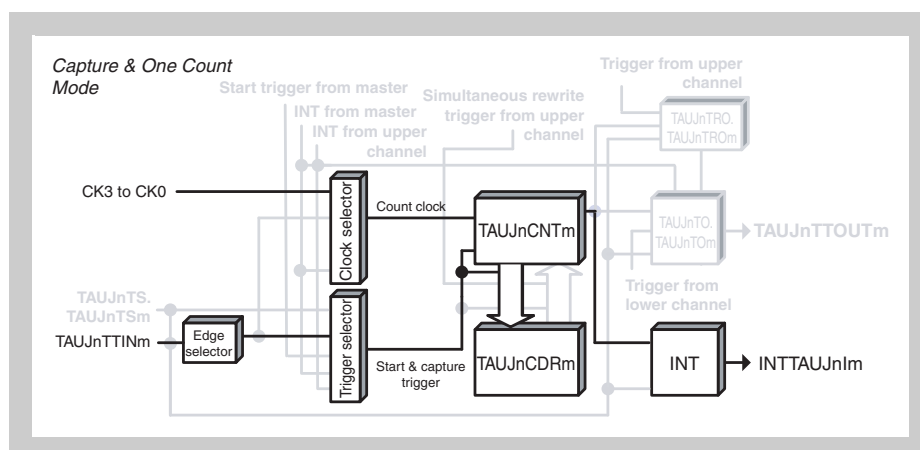

(3) Block diagram and general timing diagram

Figure 13-34 Block diagram for TAUJnTTINm Input Signal Width Measurement Function

The following settings apply to the general timing diagram:

- Rising and falling edge detection = high width measurement (TAUJnCMURm.TAUJnTIS[1:0] = 11_B)
- When a valid TAUJnTTINm input is detected after an overflow TAUJnCDRm is changed and TAUJnCSRm.TAUJnOVF is set to 1 (TAUJnCMORM.TAUJnCOS[1:0] = 00_B)

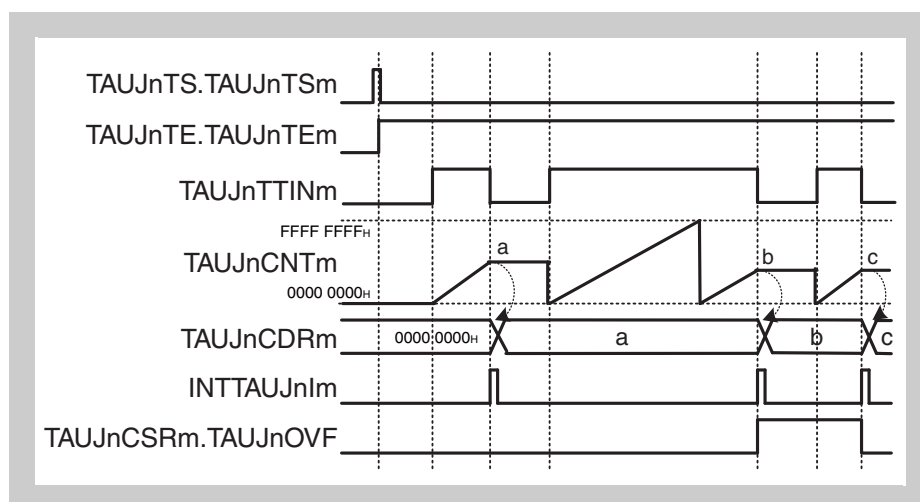

Figure 13-35 General timing diagram for TAUJnTTINm Input Signal Width Measurement Function

(4) Register settings**(a) TAUJnCMORM**

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
TAUJn CKS[1:0]		TAUJn CCS[1:0]		TAUJn MAS	TAUJnSTS[2:0]			TAUJn COS[1:0]		-	TAUJnMD[4:1]				TAUJn MD0

Table 13-27 TAUJnCMORM settings for TAUJnTTINm Input Signal Width Measurement Function

Bit name	Setting
TAUJnCKS[1:0]	00: Prescaler output = CK0 01: Prescaler output = CK1 10: Prescaler output = CK2 11: Prescaler output = CK3
TAUJnCCS[1:0]	00: Operation clock is used as the count clock
TAUJnMAS	0: Not used, so set to 0
TAUJnSTS[2:0]	010: Valid edge of the TAUJnTTINm input signal is the external start trigger and the reverse edge is the stop trigger
TAUJnCOS[1:0]	See Table 13-26 "Effects of an overflow" on page 815
TAUJnMD[4:1]	0110: Capture & One Count Mode
TAUJnMD0	0: Disables the start trigger during operation

(b) TAUJnCMURm

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
														TAUJnTIS[1:0]	

Table 13-28 TAUJnCMURm settings for TAUJnTTINm Input Signal Width Measurement Function

Bit name	Setting
TAUJnTIS[1:0]	10: Rising and falling edge detection (low width measurement) 11: Rising and falling edge detection (high width measurement)

(c) Channel output mode

Because the channel output mode is not used for this function, clear TAUJnTOE.TAUJnTOEm to 0. However, it can be used in Independent Channel Output Mode Controlled by Software.

(d) Simultaneous rewrite

The simultaneous rewrite registers (TAUJnRDE and TAUJnRDM) cannot be used with the TAUJnTTINm Input Signal Width Measurement Function. Therefore, these registers must be set to 0.

Table 13-29 Simultaneous rewrite settings for TAUJnTTINm Input Signal Width Measurement Function

Bit name	Setting
TAUJnRDE.TAUJnRDEm	0: Disables simultaneous rewrite
TAUJnRDM.TAUJnRDMm	0: When simultaneous rewrite is disabled (TAUJnRDE.TAUJnRDEm = 0), set these bits to 0

(5) Operating procedure for TAUJnTTINm Input Signal Width Measurement Function

Table 13-30 Operating procedure for TAUJnTTINm Input Signal Width Measurement Function

	Operation	Status of TAUJn
Initial channel setting	Set the TAUJnCMORm register and TAUJnCMURm registers as described in <i>Table 13-22 "TAUJnCMORm settings for TAUJnTTINm Input Pulse Interval Measurement Function" on page 811</i> and <i>Table 13-23 "TAUJnCMURm settings for TAUJnTTINm Input Pulse Interval Measurement Function" on page 811</i> . Set the value of the TAUJnCDRm register.	Channel operation is stopped.
Start operation	Set TAUJnTS.TAUJnTSm to 1. TAUJnTS.TAUJnTSm is a trigger bit, so it is automatically cleared to 0.	TAUJnTE.TAUJnTEm is set to 1 and TAUJnCNTm waits for detection of the TAUJnTTINm start edge. When a TAUJnTTINm start is detected, TAUJnCNTm starts counting up.
During operation	Detection of TAUJnTTINm edges. The TAUJnCDRm, TAUJnCNTm, and TAUJnCSRm registers can be read at any time. The TAUJnCSCm.CLOV bit can be set to 1.	TAUJnCNTm starts counting up from 0000 0000 _H . When a TAUJnTTINm valid edge is detected: <ul style="list-style-type: none"> • TAUJnCNTm transfers (captures) its value to TAUJnCDRm, and retains its value. • INTTAUJnIm is then generated. Afterwards, this procedure is repeated.
Stop operation	Set TAUJnTT.TAUJnTTm to 1. TAUJnTT.TAUJnTTm is a trigger bit, so it is automatically cleared to 0.	TAUJnTE.TAUJnTEm is cleared to 0 and the counter stops. TAUJnCNTm stops and both it and TAUJnCSRm.TAUJnOVF retain their current values.

Restart

(6) Specific timing diagrams: overflow behavior

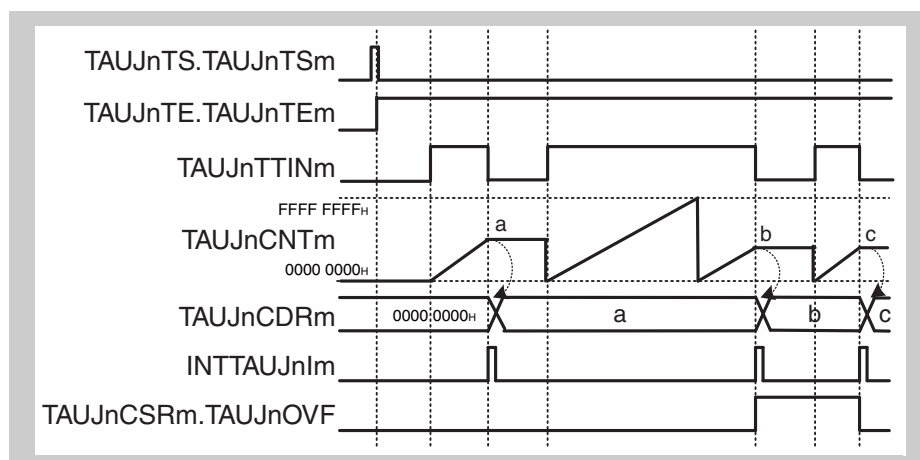

(a) $\text{TAUJnCMORm.TAUJnCOS}[1:0] = 00_{\text{B}}$ 

Figure 13-36 $\text{TAUJnCMORm.TAUJnCOS}[1:0] = 00_{\text{B}}$, $\text{TAUJnCMORm.TAUJnMD0} = 0$,
 $\text{TAUJnCMURm.TAUJnTIS}[1:0] = 11_{\text{B}}$

- When an overflow occurs, the value of TAUJnCDRm remains unchanged and $\text{TAUJnCSRm.TAUJnOVF}$ remains 0.
- Upon detection of the next valid TAUJnTTINm input edge, the value of TAUJnCNTm is loaded to TAUJnCDRm and $\text{TAUJnCSRm.TAUJnOVF}$ is set.
- Upon detecting the next valid TAUJnTTINm input edge while no overflow has occurred, $\text{TAUJnCSRm.TAUJnOVF}$ is cleared to 0.

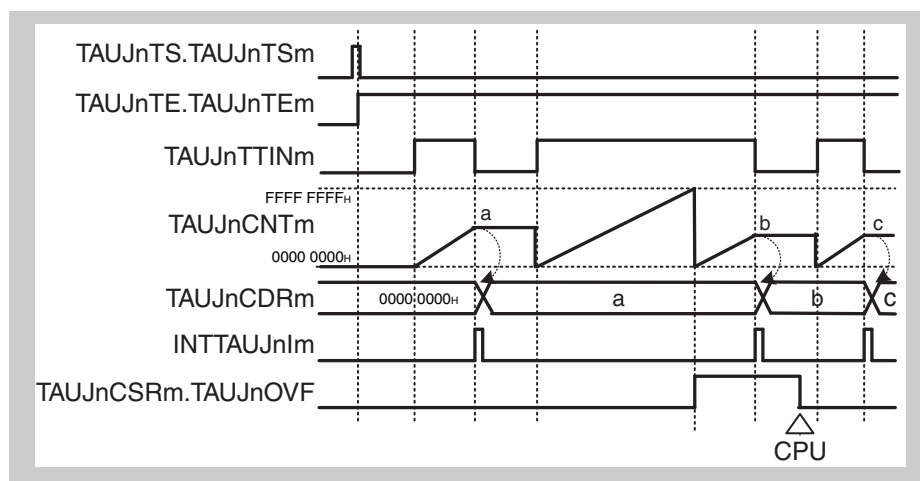

(b) $\text{TAUJnCMORm.TAUJnCOS}[1:0] = 01_{\text{B}}$ 

Figure 13-37 $\text{TAUJnCMORm.TAUJnCOS}[1:0] = 01_{\text{B}}$, $\text{TAUJnCMORm.TAUJnMD0} = 0$,
 $\text{TAUJnCMURm.TAUJnTIS}[1:0] = 11_{\text{B}}$

- When an overflow occurs, the value of TAUJnCDRm remains unchanged and $\text{TAUJnCSRm.TAUJnOVF}$ is set to 1.
- Upon detection of the next valid TAUJnTTINm input edge, the value of TAUJnCNTm is loaded to TAUJnCDRm .
- $\text{TAUJnCSRm.TAUJnOVF}$ is only cleared by a CPU command (setting the $\text{TAUJnCSCm.TAUJnCLOV}$ bit to 1).

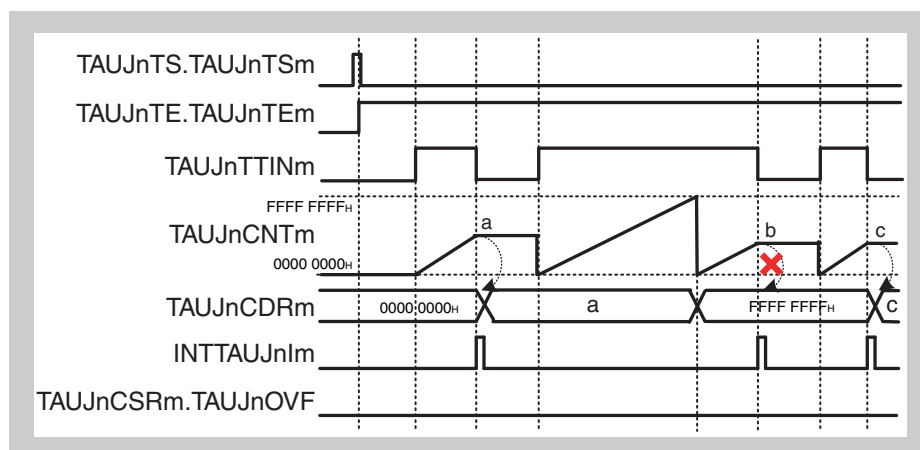

(c) $\text{TAUJnCMORM.TAUJnCOS}[1:0] = 10_{\text{B}}$ 

Figure 13-38 $\text{TAUJnCMORM.TAUJnCOS}[1:0] = 10_{\text{B}}$, $\text{TAUJnCMORM.TAUJnMD0} = 0$,
 $\text{TAUJnCMURm.TAUJnTIS}[1:0] = 11_{\text{B}}$

- When an overflow occurs, TAUJnCDRm is set to $\text{FFFF FFFF}_{\text{H}}$ and $\text{TAUJnCSRm.TAUJnOVF}$ remains 0.
- Upon detection of the next valid TAUJnTTINm input edge, TAUJnCNTm is reset to 0, but TAUJnCDRm and $\text{TAUJnCSRm.TAUJnOVF}$ remain unchanged.
- Thus, the next TAUJnTTINm input valid edge after the overflow is ignored.

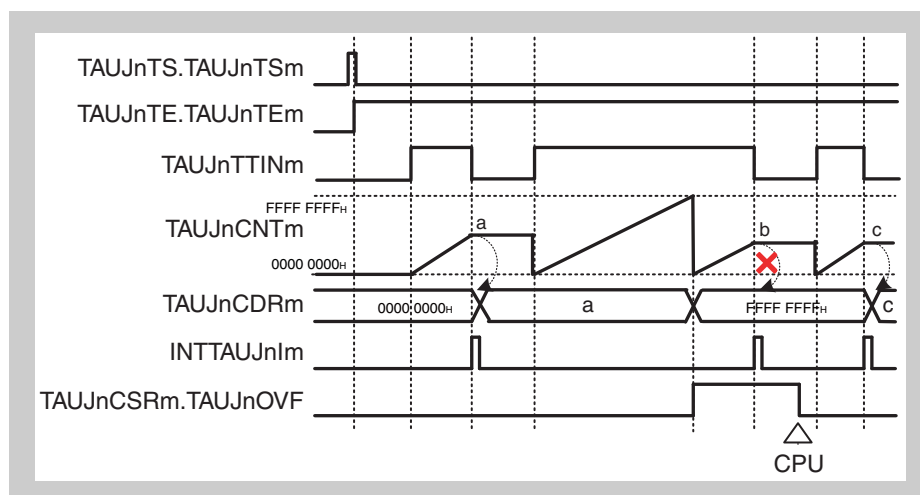

(d) $\text{TAUJnCMORM.TAUJnCOS}[1:0] = 11_{\text{B}}$ 

Figure 13-39 $\text{TAUJnCMORM.TAUJnCOS}[1:0] = 11_{\text{B}}$, $\text{TAUJnCMORM.TAUJnMD0} = 0$,
 $\text{TAUJnCMURm.TAUJnTIS}[1:0] = 11_{\text{B}}$

- When an overflow occurs, TAUJnCDRm is set to $\text{FFFF FFFF}_{\text{H}}$, and $\text{TAUJnCSRm.TAUJnOVF}$ is set to 1.
- Upon detection of the next valid TAUJnTTINm input edge, TAUJnCNTm is reset to 0, but TAUJnCDRm and $\text{TAUJnCSRm.TAUJnOVF}$ remain unchanged.
- Thus, the next TAUJnTTINm input valid edge after the overflow is ignored.
- $\text{TAUJnCSRm.TAUJnOVF}$ is cleared by setting $\text{TAUJnCSCm.TAUJnCLOV}$ to 1.

13.15.3 Overflow Interrupt Output Function (During TAUJnTTINm Width Measurement)

(1) Overview

Summary This function measures the width of an individual TAUJnTTINm input signal. An interrupt is generated if $(FFFF\ FFFF_H + 1)$ is exceeded following TAUJnTTINm input.

- Prerequisites**
- The operation mode must be set to One Count Mode, refer to *Table 13-31 “TAUJnCMORm settings for Overflow Interrupt Output Function (During TAUJnTTINm Width Measurement)” on page 823*.
 - TAUJnTTOUTm is not used for this function.
 - The value of TAUJnCDRm must be set to $FFFF\ FFFF_H$.

Description The counter is enabled by setting the channel trigger bit (TAUJnTS.TAUJnTSm) to 1. This in turn sets TAUJnTE.TAUJnTEm = 1, enabling count operation.

The counter starts when a valid TAUJnTTINm input start edge is detected. $FFFF\ FFFF_H$ is loaded to TAUJnCNTm and the counter starts counting down.

When a valid stop edge is detected, the counter stops and retains the current value.

When the next TAUJnTTINm input start edge is detected, TAUJnCNTm loads $FFFF\ FFFF_H$ and starts counting down.

If the counter reaches $0000\ 0000_H$ before a stop edge is detected, an interrupt is generated.

Conditions The valid start and stop edges are specified by the TAUJnCMURm.TAUJnTIS[1:0] bits:

- If TAUJnCMURm.TAUJnTIS[1:0] = 10_B , the TAUJnTTINm input low width is measured. The start trigger is a falling edge and the stop trigger is a rising edge.
- If TAUJnCMURm.TAUJnTIS[1:0] = 11_B , the TAUJnTTINm input high width is measured. The start trigger is a rising edge and the stop trigger is a falling edge.

Note The counter cannot be restarted during operation.

(2) Block diagram and general timing diagram

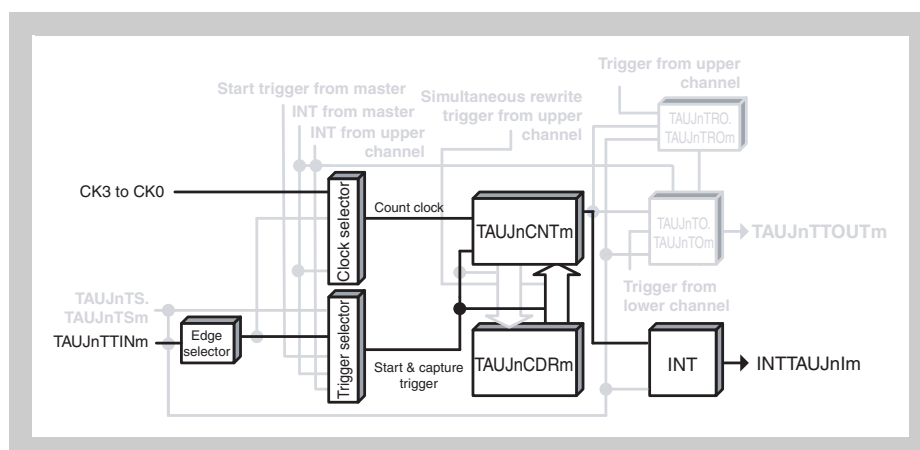

Figure 13-40 Block diagram for Overflow Interrupt Output Function (During TAUJnTTINm Width Measurement)

The following settings apply to the general timing diagram:

- Rising and falling edge detection = high width measurement (TAUJnCMURm.TAUJnTIS[1:0] = 11_B)

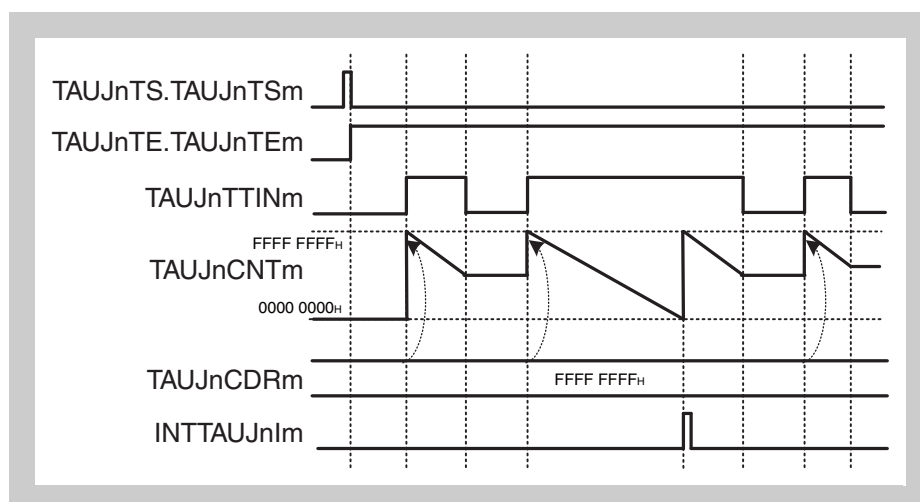

Figure 13-41 General timing diagram for Overflow Interrupt Output Function (During TAUJnTTINm Width Measurement)

(3) Register settings**(a) TAUJnCMORM**

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
TAUJn CKS[1:0]		TAUJn CCS[1:0]		TAUJn MAS	TAUJnSTS[2:0]			TAUJn COS[1:0]		-	TAUJnMD[4:1]				TAUJn MD0

Table 13-31 TAUJnCMORM settings for Overflow Interrupt Output Function (During TAUJnTTINm Width Measurement)

Bit name	Setting
TAUJnCKS[1:0]	00: Prescaler output = CK0 01: Prescaler output = CK1 10: Prescaler output = CK2 11: Prescaler output = CK3
TAUJnCCS[1:0]	00: Operation clock is used as the count clock
TAUJnMAS	0: Not used, so set to 0
TAUJnSTS[2:0]	010: Valid edge of the TAUJnTTINm input signal is the external start trigger and the reverse edge is the stop trigger
TAUJnCOS[1:0]	00: Not used, so set to 00
TAUJnMD[4:1]	0100: One Count Mode
TAUJnMD0	0: Disables the start trigger during operation

(b) TAUJnCMURm

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
														TAUJnTIS[1:0]	

Table 13-32 TAUJnCMURm settings Overflow Interrupt Output Function (During TAUJnTTINm Width Measurement)

Bit name	Setting
TAUJnTIS[1:0]	10: Rising and falling edge detection (low width measurement) 11: Rising and falling edge detection (high width measurement)

(c) Channel output mode

Because the channel output mode is not used for this function, clear TAUJnTOE.TAUJnTOEm to 0. However, it can be used in Independent Channel Output Mode Controlled by Software.

(d) Simultaneous rewrite

The simultaneous rewrite registers (TAUJnRDE and TAUJnRDM) cannot be used with the Overflow Interrupt Output Function (During TAUJnTTINm Width Measurement). Therefore, these registers must be set to 0.

Table 13-33 Simultaneous rewrite settings for Overflow Interrupt Output Function (During TAUJnTTINm Width Measurement)

Bit name	Setting
TAUJnRDE.TAUJnRDEm	0: Disables simultaneous rewrite
TAUJnRDM.TAUJnRDMm	0: When simultaneous rewrite is disabled (TAUJnRDE.TAUJnRDEm = 0), set these bits to 0

(4) Operating procedure for Overflow Interrupt Output Function (During TAUJnTTINm Width Measurement)

Table 13-34 Operating procedure for Overflow Interrupt Output Function (During TAUJnTTINm Width Measurement)

	Operation	Status of TAUJn
Restart ↓	Initial channel setting Set the TAUJnCMORm register and TAUJnCMURm registers as described in <i>Table 13-31 "TAUJnCMORm settings for Overflow Interrupt Output Function (During TAUJnTTINm Width Measurement)" on page 823</i> and <i>Table 13-32 "TAUJnCMURm settings Overflow Interrupt Output Function (During TAUJnTTINm Width Measurement)" on page 823</i> . Set the value of the TAUJnCDRm register.	Channel operation is stopped.
	Start operation Set TAUJnTS.TAUJnTSm to 1. TAUJnTS.TAUJnTSm is a trigger bit, so it is automatically cleared to 0. Detection of TAUJnTTINm start edge	TAUJnTE.TAUJnTEm is set to 1 and TAUJnCNTm waits for detection of the start edge. When a start edge is detected, TAUJnCNTm loads the TAUJnCDRm value (FFFF FFFF _H).
	During operation The TAUJnCNTm register can be read at any time. Detection of TAUJnTTINm edges	TAUJnCNTm counts down. When the counter reaches 0000 0000 _H : • INTTAUJnIm is generated. When a reverse edge of TAUJnTTINm is detected during count operation: • TAUJnCNTm stops counting and waits for a trigger. Afterwards, this procedure is repeated.
	Stop operation Set TAUJnTT.TAUJnTTm to 1. TAUJnTT.TAUJnTTm is a trigger bit, so it is automatically cleared to 0.	TAUJnTE.TAUJnTEm is cleared to 0 and the counter stops. TAUJnCNTm stops and retains its current value.

13.15.4 TAUJnTTINm Input Period Count Detection Function

(1) Overview

Summary This function measures the cumulative width of a TAUJnTTINm input signal.

- Prerequisites**
- The operation mode must be set to Capture & Gate Count Mode, refer to Table 13-35 “TAUJnCMORm settings for TAUJnTTINm Input Period Count Detection Function” on page 827.
 - TAUJnTTOUm is not used for this function.

Description The counter is enabled by setting the channel trigger bit (TAUJnTS.TAUJnTSm) to 1. This in turn sets TAUJnTE.TAUJnTEm = 1, enabling count operation. The counter awaits a valid TAUJnTTINm input edge.

When a valid TAUJnTTINm input start edge is detected, the counter starts counting from 0000 0000_H.

When a valid TAUJnTTINm input stop edge is detected, the current TAUJnCNTm value is loaded to TAUJnCDRm and an interrupt (INTTAUJnIm) is generated. The counter stops and retains its value until the next valid TAUJnTTINm input start edge is detected.

When the next valid TAUJnTTINm input start edge is detected, the counter resumes counting, starting with its value upon stopping.

If the counter reaches FFFF FFFF_H, the TAUJnCSRm.TAUJnOVF bit is set to 1 and the counter restarts counting from 0000 0000_H. The value of TAUJnCSRm.TAUJnOVF is reset by the CPU by setting TAUJnCSCm.TAUJnCLOV = 1.

Note The input TAUJnTTINm is sampled at the frequency of the operation clock, specified by the TAUJnCMORm.TAUJnCKS[1:0] bits.

Conditions The valid start and stop edges are specified by the TAUJnCMURm.TAUJnTIS[1:0] bits:

- If TAUJnCMURm.TAUJnTIS[1:0] = 10_B, the TAUJnTTINm input low period is counted. The start trigger is a falling edge and the stop trigger is a rising edge.
- If TAUJnCMURm.TAUJnTIS[1:0] = 11_B, the TAUJnTTINm input high period is counted. The start trigger is a rising edge and the stop trigger is a falling edge.

(2) Equations

Cumulative TAUJnTTINm input width =
count clock cycle × ((FFFF FFFF_H × TAUJnCSRm.TAUJnOVF) +
(TAUJnCDRm capture value + 1))

<R>

Caution If a capture signal in input when the counter value reaches the upper limit (0FFF FFFF_H), the overflow flag (OVF) that should be set in response to the occurrence of an overflow in the next count clock cycle will not be set. The OVF flag is set normally at all other times.

(3) Block diagram and general timing diagram

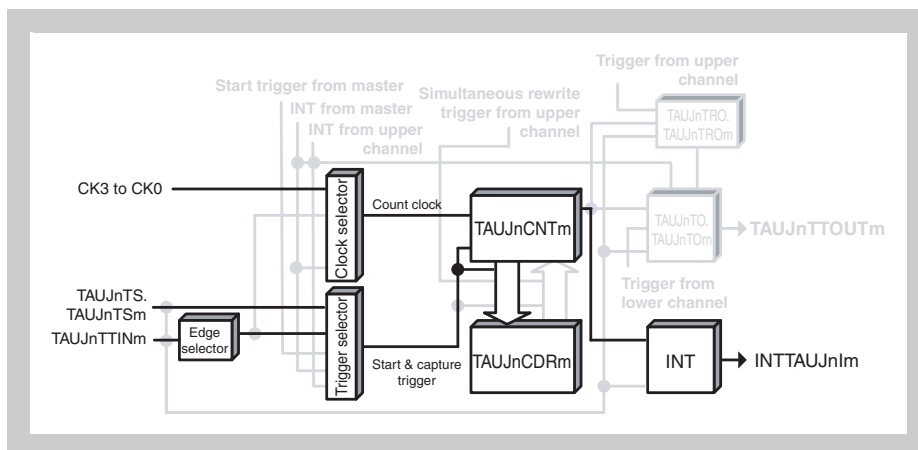

Figure 13-42 Block diagram for TAUJnTTINm Input Period Count Detection Function

The following settings apply to the general timing diagram:

- Rising and falling edge detection = high width measurement (TAUJnCMURm.TAUJnTIS[1:0] = 11_B)

Figure 13-43 General timing diagram for TAUJnTTINm Input Period Count Detection Function

Table 13-35 TAUJnCMORM settings for TAUJnTTINm Input Period Count Detection Function

Bit name	Setting
TAUJnCKS[1:0]	00: Prescaler output = CK0 01: Prescaler output = CK1 10: Prescaler output = CK2 11: Prescaler output = CK3
TAUJnCCS[1:0]	00: Operation clock is used as the count clock
TAUJnMAS	0: Not used, so set to 0
TAUJnSTS[2:0]	010: Valid edge of the TAUJnTTINm input signal is the external start trigger and the reverse edge is the stop trigger
TAUJnCOS[1:0]	01: Overflow (TAUJnCSRm.TAUJnOVF) set upon counter overflow and cleared by a CPU instruction
TAUJnMD[4:1]	1101: Capture & Gate Count Mode
TAUJnMD0	0: Disables the start trigger during operation

(b) TAUJnCMURm

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
														TAUJnTIS[1:0]	

Table 13-36 TAUJnCMURm settings for TAUJnTTINm Input Period Count Detection Function

Bit name	Setting
TAUJnTIS[1:0]	10: Rising and falling edge detection (low width measurement) 11: Rising and falling edge detection (high width measurement)

(c) Channel output mode

Because the channel output mode is not used for this function, clear TAUJnTOE.TAUJnTOEm to 0. However, it can be used in Independent Channel Output Mode Controlled by Software.

(d) Simultaneous rewrite

The simultaneous rewrite registers (TAUJnRDE and TAUJnRDM) cannot be used with the TAUJnTTINm Input Period Count Detection Function. Therefore, these registers must be set to 0.

Table 13-37 Simultaneous rewrite settings for TAUJnTTINm Input Period Count Detection Function

Bit name	Setting
TAUJnRDE.TAUJnRDEm	0: Disables simultaneous rewrite
TAUJnRDM.TAUJnRDMm	0: When simultaneous rewrite is disabled (TAUJnRDE.TAUJnRDEm = 0), set these bits to 0

(5) Operating procedure for TAUJnTTINm Input Period Count Detection Function

Table 13-38 Operating procedure for TAUJnTTINm Input Period Count Detection Function

	Operation	Status of TAUJn
Restart ↓	Initial channel setting Set the TAUJnCMORm register and TAUJnCMURm registers as described in <i>Table 13-35 “TAUJnCMORm settings for TAUJnTTINm Input Period Count Detection Function” on page 827</i> and <i>Table 13-36 “TAUJnCMURm settings for TAUJnTTINm Input Period Count Detection Function” on page 827</i> . Set the value of the TAUJnCDRm register.	Channel operation is stopped.
	Start operation Set TAUJnTS.TAUJnTSM to 1. TAUJnTS.TAUJnTSM is a trigger bit, so it is automatically cleared to 0. Detection of TAUJnTTINm start edge	TAUJnTE.TAUJnTEm is set to 1 and TAUJnCNTm waits for detection of the TAUJnTTINm start edge. When a start edge is detected, TAUJnCNTm is cleared to 0000 0000 _H and TAUJnCNTm starts counting up.
	During operation Detection of TAUJnTTINm edges The TAUJnCDRm, TAUJnCNTm, and TAUJnCSRm registers can be read at any time. The TAUJnCSCm.TAUJnCLOV bit can be set to 1.	When a TAUJnTTINm start edge (rising edge for high width measurement, falling edge for low width measurement) is detected, TAUJnCNTm starts counting up from the stop value. When TAUJnCNTm detects a stop edge (falling edge for high width measurement, rising edge for low width measurement), it transfers the value to TAUJnCDRm and INTTAUJnIm is generated. Counting stops at the “value transferred to TAUJnCDRm + 1” value and TAUJnCNTm waits for detection of the TAUJnTTINm start edge. If the TAUJnCNTm reaches FFFF FFFF _H , the counter overflows and TAUJnCSRm.TAUJnOVF is set to 1. Afterwards, this procedure is repeated.
	Stop operation Set TAUJnTT.TAUJnTTm to 1. TAUJnTT.TAUJnTTm is a trigger bit, so it is automatically cleared to 0.	TAUJnTE.TAUJnTEm is cleared to 0 and the counter stops. TAUJnCNTm stops and it and TAUJnCSRm.TAUJnOVF retain their current values.

(6) Specific timing diagrams

(a) Operation stop and restart

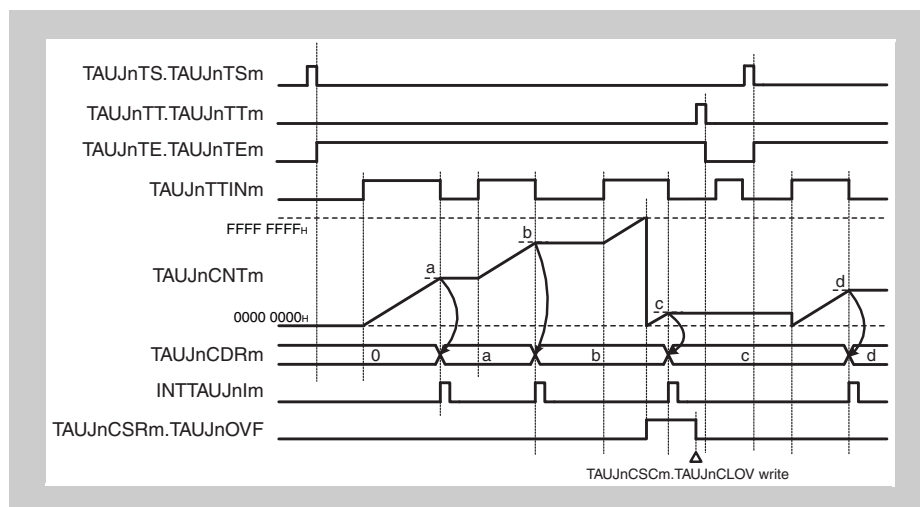

Figure 13-44 Operation stop and restart, TAUJnCMURm.TAUJnTIS[1:0] = 11_B

- The counter can be stopped by setting TAUJnTT.TAUJnTTm to 1, which in turn sets TAUJnTE.TAUJnTEm to 0.
- TAUJnCNTm stops and the current value is retained.
- If the counter is stopped, valid TAUJnTTINm input edges are ignored.
- The counter can be restarted by setting TAUJnTS.TAUJnTSM to 1. TAUJnCNTm restarts counting from 0000 0000_H.

13.15.5 Overflow Interrupt Output Function (During TAUJnTTINm Input Period Count Detection)

(1) Overview

- Summary** This function measures the cumulative width of a TAUJnTTINm input signal. If the cumulative TAUJnTTINm input width is longer than FFFF FFFF_H, an interrupt can be generated to output an overflow interrupt.
- Prerequisites**
- The operation mode must be set to Gate Count Mode, refer to *Table 13-39 “TAUJnCMORm settings for Overflow Interrupt Output Function (During TAUJnTTINm Input Period Count Detection)” on page 832*.
 - TAUJnTTOUTm is not used for this function.
 - The value of TAUJnCDRm must be set to FFFF FFFF_H.
- Description** The counter is enabled by setting the channel trigger bit (TAUJnTS.TAUJnTSm) to 1. This in turn sets TAUJnTE.TAUJnTEm = 1, enabling count operation.
- The counter starts when a valid TAUJnTTINm input start edge is detected. FFFF FFFF_H is loaded to TAUJnCNTm and the counter starts counting down.
- When a valid stop edge is detected, the counter stops and retains the current value. The counter awaits the next TAUJnTTINm input start edge and then continues counting down from the current value.
- When the counter reaches 0000 0000_H an interrupt is generated. FFFF FFFF_H is loaded to TAUJnCNTm and the counter continues counting down until a TAUJnTTINm input stop edge is detected.
- Conditions** The valid start and stop edges are specified by the TAUJnCMURm.TAUJnTIS[1:0] bits:
- If TAUJnCMURm.TAUJnTIS[1:0] = 10_B, the TAUJnTTINm input low period is counted. The start trigger is a falling edge and the stop trigger is a rising edge.
 - If TAUJnCMURm.TAUJnTIS[1:0] = 11_B, the TAUJnTTINm input high period is counted. The start trigger is a rising edge and the stop trigger is a falling edge.
- Note** The counter cannot be restarted during operation.

(2) Block diagram and general timing diagram

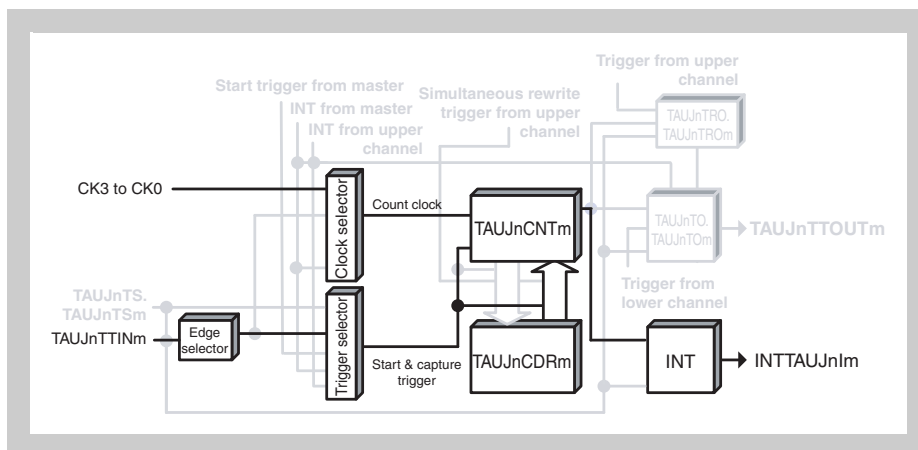

Figure 13-45 Block diagram for Overflow Interrupt Output Function (During $TAUJnTTINm$ Input Period Count Detection)

The following settings apply to the general timing diagram:

- Rising and falling edge detection = high width measurement ($TAUJnCMURm.TAUJnTIS[1:0] = 11_B$)

Bit name	Setting
TAUJnRDE.TAUJnRDEm	0: Disables simultaneous rewrite
TAUJnRDM.TAUJnRDMm	0: When simultaneous rewrite is disabled (TAUJnRDE.TAUJnRDEm = 0), set these bits to 0

(4) Operating procedure for Overflow Interrupt Output Function (during TAUJnTTINm input period count detection)

Table 13-42 Operating procedure for Overflow Interrupt Output Function (during TAUJnTTINm input period count detection)

	Operation	Status of TAUJn
Initial channel setting	Set the TAUJnCMORm register and TAUJnCMURm registers as described in <i>Table 13-39 "TAUJnCMORm settings for Overflow Interrupt Output Function (During TAUJnTTINm Input Period Count Detection)" on page 832</i> and <i>Table 13-40 "TAUJnCMURm settings for Overflow Interrupt Output Function (During TAUJnTTINm Input Period Count Detection)" on page 832</i> . Set the value of the TAUJnCDRm register.	Channel operation is stopped.
Restart Start operation	Set TAUJnTS.TAUJnTSm to 1. TAUJnTS.TAUJnTSm is a trigger bit, so it is automatically cleared to 0. Detection of TAUJnTTINm start edge	TAUJnTE.TAUJnTEm is set to 1 and TAUJnCNTm waits for detection of the start edge. When a start edge is detected, TAUJnCNTm loads the TAUJnCDRm value (FFFF FFFF _H).
During operation	The TAUJnCNTm register can be read at all times.	TAUJnCNTm counts down. When the counter reaches 0000 0000 _H : <ul style="list-style-type: none"> • INTTAUJnIm is generated. • TAUJnCNTm loads the TAUJnCDRm value (FFFF FFFF_H) and continues counting down. When a reverse edge of TAUJnTTINm is detected during count operation: <ul style="list-style-type: none"> • TAUJnCNTm counts down from the stop value. Afterwards, this procedure is repeated.
Stop operation	Set TAUJnTT.TAUJnTTm to 1. TAUJnTT.TAUJnTTm is a trigger bit, so it is automatically cleared to 0.	TAUJnTE.TAUJnTEm is cleared to 0 and the counter stops. TAUJnCNTm stops and retains its current value.

13.16 Other Independent Channel Function

This section describes a function that measures the duration between the function start and a TAUJnTTINm input signal.

13.16.1 TAUJnTTINm Input Position Detection Function

(1) Overview

Summary This function measures the duration between the function start and a TAUJnTTINm input signal.

- Prerequisites**
- The operation mode must be set to Count Capture Mode, refer to *Table 13-43 “TAUJnCMORm settings for TAUJnTTINm Input Position Detection Function” on page 837*.
 - TAUJnTTOUTm is not used for this function.

Description The counter operation is enabled by setting the channel trigger bit (TAUJnTS.TAUJnTSm) to 1. This in turn sets TAUJnTE.TAUJnTEm = 1, enabling count operation. The counter starts counting from 0000 0000_H. When a valid TAUJnTTINm input edge is detected, the current TAUJnCNTm value is loaded to TAUJnCDRm and an interrupt (INTTAUJnIm) is generated. The counter continues counting.

When the counter reaches FFFF FFFF_H, the TAUJnCSRm.TAUJnOVF bit is set to 1 and the counter restarts counting from 0000 0000_H.

TAUJnCSRm.TAUJnOVF is cleared by writing 1 to TAUJnCSCm.TAUJnCLOV.

Conditions If the TAUJnCMORm.TAUJnMD0 bit is set to 0, the first interrupt after a start or restart is not generated. For details refer to *13.10 “TAUJnTTOUTm Output and INTTAUJnIm Generation when Counter Starts or Restarts (by TAUJnMD0 Bit)” on page 787*.

(2) Equations

Function duration at a TAUJnTTINm input pulse =

$$\text{count clock cycle} \times [(FFFF\ FFFF_H + 1 \times \text{TAUJnCSRm.TAUJnOVF}) + (\text{TAUJnCDRm capture value} + 1)]$$

<R>

Caution If a capture signal in input when the counter value reaches the upper limit (0FFFF FFFF_H), the overflow flag (OVF) that should be set in response to the occurrence of an overflow in the next count clock cycle will not be set. The OVF flag is set normally at all other times.

(3) Block diagram and general timing diagram

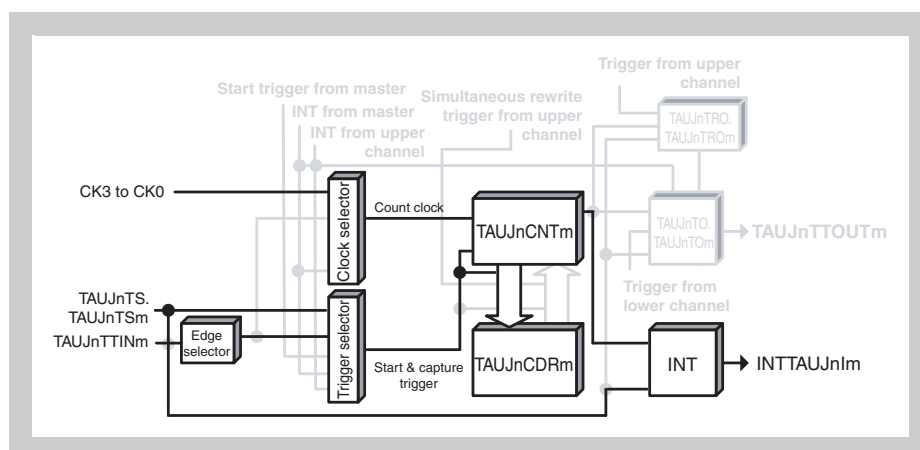

Figure 13-47 Block diagram for TAUJnTTINm Input Position Detection Function

The following settings apply to the general timing diagram:

- INTTAUJnIm not generated at operation start (TAUJnCMORm.TAUJnMD0 = 0)
- Falling edge detection (TAUJnCMURm.TAUJnTIS[1:0] = 00_B)

Figure 13-48 General timing diagram for TAUJnTTINm Input Position Detection Function

(4) Register settings**(a) TAUJnCMORM**

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
TAUJn CKS[1:0]		TAUJn CCS[1:0]		TAUJn MAS	TAUJnSTS[2:0]			TAUJn COS[1:0]		-	TAUJnMD[4:1]				TAUJn MD0

														TAUJnTIS[1:0]	

Table 13-44 TAUJnCMURm settings for TAUJnTTINm Input Position Detection Function

Bit name	Setting
TAUJnTIS[1:0]	00: Falling edge detection 01: Rising edge detection 10: Rising and falling edge detection (low width measurement) 11: Rising and falling edge detection (high width measurement)

(c) Channel output mode

The channel output mode is not used by this function. However, it can be used in Independent Channel Output Mode Controlled by Software.

(d) Simultaneous rewrite

The simultaneous rewrite registers (TAUJnRDE and TAUJnRDM) cannot be used with the TAUJnTTINm Input Position Detection Function. Therefore, these registers must be set to 0.

Table 13-45 Simultaneous rewrite settings for TAUJnTTINm Input Position Detection Function

Bit name	Setting
TAUJnRDE.TAUJnRDEm	0: Disables simultaneous rewrite
TAUJnRDM.TAUJnRDMm	0: When simultaneous rewrite is disabled (TAUJnRDE.TAUJnRDEm = 0), set these bits to 0

(5) Operating procedure for TAUJnTTINm Input Position Detection Function

Table 13-46 Operating procedure for TAUJnTTINm Input Position Detection Function

	Operation	Status of TAUJn
Initial channel setting	Set the TAUJnCMORm register and TAUJnCMURm registers as described in <i>Table 13-43 "TAUJnCMORm settings for TAUJnTTINm Input Position Detection Function" on page 837</i> and <i>Table 13-44 "TAUJnCMURm settings for TAUJnTTINm Input Position Detection Function" on page 837</i> . Set the value of the TAUJnCDRm register.	Channel operation is stopped.
Start operation	Set TAUJnTS.TAUJnTSM to 1. TAUJnTS.TAUJnTSM is a trigger bit, so it is automatically cleared to 0.	TAUJnTE.TAUJnTEM is set to 1 and the counter starts. INTTAUJnIm is generated when TAUJnCMORm.TAUJnMD0 is set to 1.
During operation	The TAUJnCMURm.TAUJnTIS[1:0] bits can be changed at any time. The TAUJnCDRm and TAUJnCSRm registers can be read at any time. The TAUJnCSC.CLOV bit can be set to 1.	TAUJnCNTm starts counting up from 0000 0000 _H . When a TAUJnTTINm valid edge is detected: <ul style="list-style-type: none"> TAUJnCNTm transfers (captures) its value to TAUJnCDRm. INTTAUJnIm is output. The counter value is not cleared to 0000 0000_H and TAUJnCNTm continues count operation. Afterwards, this procedure is repeated.
Stop operation	Set TAUJnTT.TAUJnTTM to 1. TAUJnTT.TAUJnTTM is a trigger bit, so it is automatically cleared to 0.	TAUJnTE.TAUJnTEM is cleared to 0 and the counter stops. TAUJnCNTm stops and both it and TAUJnCSRm.TAUJnOVF retain their current values.

Restart

(6) Specific timing diagrams

(a) Operation stop and restart

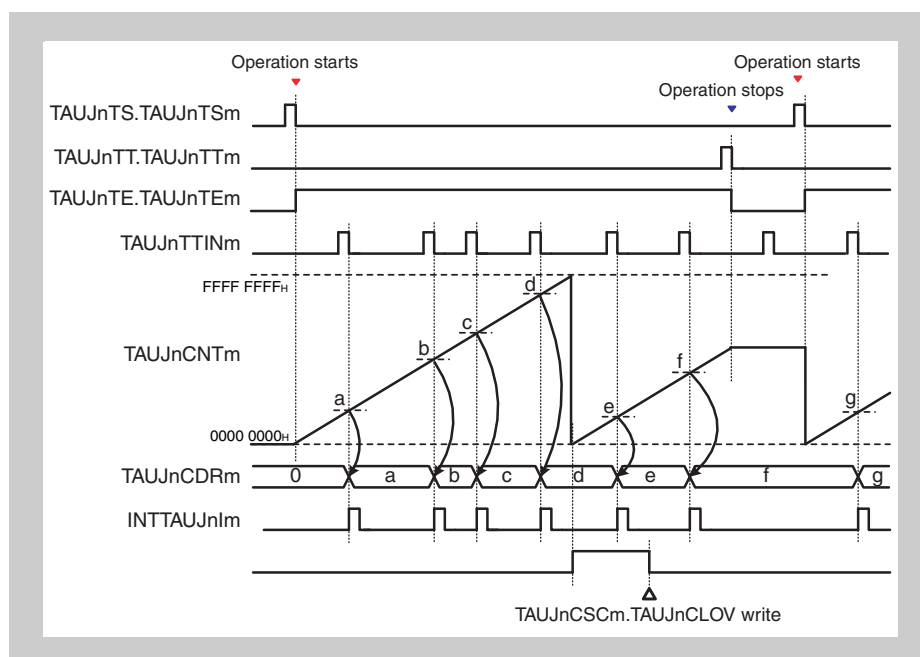

Figure 13-49 Operation stop and restart, $\text{TAUJnCMORM.TAUJnMD0} = 0$,
 $\text{TAUJnCMURm.TAUJnTIS}[1:0] = 00$

- The counter can be stopped by setting TAUJnTT.TAUJnTTm to 1, which in turn sets TAUJnTE.TAUJnTEm to 0.
- TAUJnCNTm stops and the current value is retained.
- If the counter is stopped, valid TAUJnTTINm input edges are ignored.
- The counter can be restarted by setting TAUJnTS.TAUJnTSm to 1. TAUJnCNTm restarts counting from $0000\ 0000_{\text{H}}$.

13.17 Synchronous PWM Signal Functions Triggered at Regular Intervals

This section describes a function that generates PWM signals at regular intervals. For a general overview of synchronous channel operation, see 13.3 “*Functional Description*” on page 768 .

13.17.1 PWM Output Function

(1) Overview

Summary This function generates multiple PWM outputs by using a master and multiple slave channels. It enables the pulse cycle (frequency) and the duty of the TAUJnTTOUTm to be set. The pulse cycle is set in the master channel. The duty is set in the slave channel.

- Prerequisites**
- Two channels
 - The operation mode of the master channel must be set to Interval Timer Mode, refer to *Table 13-47 “TAUJnCMORm settings for the master channel of the PWM Output Function” on page 844*.
 - The operation mode of the slave channel(s) must be set to One Count Mode, refer to *Table 13-50 “TAUJnCMORm settings for the slave channel of the PWM Output Function” on page 846*.
 - TAUJnTTOUTm is not used for the master channel of this function.
 - The channel output mode of the slave channel(s) must be set to Synchronous Channel Output Mode 1 (*13.8 “Channel Output Modes” on page 780*).

Description The counters are started by setting the channel trigger bits (TAUJnTS.TAUJnTSm) to 1. This in turn sets TAUJnTE.TAUJnTEm = 1, enabling count operation. The current value of TAUJnCDRm is loaded to TAUJnCNTm and the counters start counting down from these values. INTTAUJnIm is generated on the master channel, and PWM output is achieved by setting and resetting TAUJnTTOUTm (slave).

- Master channel:

When the counter of the master channel reaches 0000 0000_H, pulse cycle time has elapsed and INTTAUJnIm is generated. TAUJnCNTm loads the TAUJnCDRm value, and then counts down.

- Slave channel(s)

The INTTAUJnIm of the master channel triggers the counter operation of the slave channel(s). The current value of TAUJnCDRm (slave) is loaded to TAUJnCNTm (slave) and the counter starts counting down from this value. The TAUJnTTOUTm signal becomes active.

When the counter reaches 0000 0000_H, i.e., duty time has elapsed, INTTAUJnIm is generated and the TAUJnTTOUTm signal becomes inactive. The counter returns to FFFF FFFF_H and awaits the next INTTAUJnIm of the master channel, and thus the start of the next pulse cycle.

The counter can be stopped by setting TAUJnTT.TAUJnTTm to 1 for the master and slave channel(s), which in turn sets TAUJnTE.TAUJnTEm to 0. TAUJnCNTm and TAUJnTTOUTm of master and slave channel(s) stop but retain their values. The counters can be restarted by setting TAUJnTS.TAUJnTSm to 1.

Conditions Simultaneous rewrite can be used with this function. Refer to *13.7 “Simultaneous Rewrite” on page 775*.

(2) Equations

Pulse cycle = (TAUJnCDRm (master) + 1) x count clock cycle

Duty cycle [%] = (TAUJnCDRm (slave) / (TAUJnCDRm (master) + 1)) x 100

– Duty cycle = 0 %

TAUJnCDRm (slave) = 0000 0000_H

– Duty cycle = 100 %

TAUJnCDRm (slave) ≥ TAUJnCDRm (master) + 1

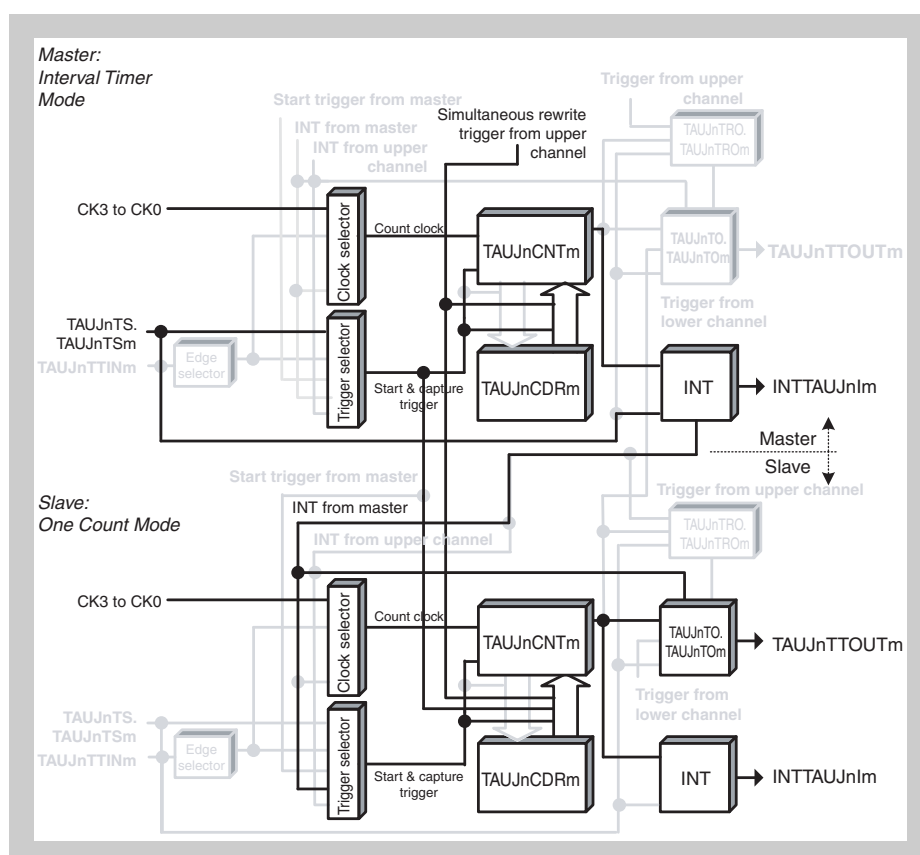

(3) Block diagram and general timing diagram

Figure 13-50 Block diagram for PWM Output Function

The following settings apply to the general timing diagram:

- Slave channel: Positive logic ($\text{TAUJnTOL}.\text{TAUJnTOLm} = 0$)

Figure 13-51 General timing diagram for PWM Output Function

Note The interval between the slave channel starting counting and an interrupt being generated is the value of corresponding TAUJnCDRm , whereas for the master channel the interval is the corresponding $\text{TAUJnCDRm} + 1$.

(4) Register settings for the master channel**(a) TAUJnCMORM for the master channel**

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
TAUJn CKS[1:0]		TAUJn CCS[1:0]		TAUJn MAS	TAUJnSTS[2:0]			TAUJn COS[1:0]		-	TAUJnMD[4:1]				TAUJn MD0

Table 13-47 TAUJnCMORM settings for the master channel of the PWM Output Function

Bit name	Setting
TAUJnCKS[1:0]	00: Prescaler output CK0 01: Prescaler output CK1 10: Prescaler output CK2 11: Prescaler output CK3 The value of the TAUJnCKS[1:0] bit of the master and slave channel(s) must be identical.
TAUJnCCS[1:0]	00: Operation clock is used as the count clock
TAUJnMAS	1: Channel is master channel
TAUJnSTS[2:0]	000: Counter triggered by software trigger
TAUJnCOS[1:0]	00: Not used, so set to 00
TAUJnMD[4:1]	0000: Interval Timer Mode
TAUJnMD0	1: Generates INTTAUJnIm at operation start

(b) TAUJnCMURm for the master channel

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
														TAUJnTIS[1:0]	

Table 13-48 TAUJnCMURm settings for the master channel of the PWM Output Function

Bit name	Setting
TAUJnTIS[1:0]	00: Not used so set to 00

(c) Channel output mode for the master channel

The channel output mode is not used by this function. However, it can be used by other functions or in Independent Channel Output Mode Controlled by Software.

(d) Simultaneous rewrite for the master channel

The simultaneous rewrite settings of the master and slave channel must be identical.

Table 13-49 Simultaneous rewrite settings for the master channel of the PWM Output Function

Bit name	Setting
TAUJnRDE.TAUJnRDEm	1: Enables simultaneous rewrite
TAUJnRDM.TAUJnRDMm	0: The simultaneous rewrite trigger signal is generated when the master channel starts counting

Note If the TAUJnRDS.TAUJnRDSm bit is 1, there must be a channel higher than the master channel that operates with simultaneous rewrite trigger output function type 1.

Set up the operation as follows:

- Channel setting for simultaneous rewrite trigger output function type 1:
TAUJnRDCm = 1, TAUJnRDS = 1
Note that the TAUJnCDR setting for this channel is as follows:
= ((TAUJnCDR setting of master channel subject to simultaneous rewriting + 1) × number of interrupts) – 1
- Master channel: TAUJnRDCm = 0, TAUJnRDS = 1
- Slave channel: TAUJnRDCm = 0, TAUJnRDS = 1

When the CDRn (slave) setting is greater than the CDRn (master) setting + 1, the duty ratio exceeds 100%, but 100% output is assumed.

(5) Register settings for the slave channel(s)**(a) TAUJnCMORM for the slave channel(s)**

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
TAUJn CKS[1:0]		TAUJn CCS[1:0]		TAUJn MAS	TAUJnSTS[2:0]			TAUJn COS[1:0]		-	TAUJnMD[4:1]				TAUJn MD0

Table 13-50 TAUJnCMORM settings for the slave channel of the PWM Output Function

Bit name	Setting
TAUJnCKS[1:0]	00: Prescaler output CK0 01: Prescaler output CK1 10: Prescaler output CK2 11: Prescaler output CK3 The value of the TAUJnCKS[1:0] bit of the master and slave channel(s) must be identical.
TAUJnCCS[1:0]	00: Operation clock is used as the count clock
TAUJnMAS	0: Channel is a slave channel
TAUJnSTS[2:0]	100: INTTAUJnIm of the master channel is the start trigger
TAUJnCOS[1:0]	00: Not used, so set to 00
TAUJnMD[4:1]	0100: One Count Mode
TAUJnMD0	1: Enables the start trigger during operation

(b) TAUJnCMURm for the slave channel(s)

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
														TAUJnTIS[1:0]	

Table 13-51 TAUJnCMURm settings for the slave channel of the PWM Output Function

Bit name	Setting
TAUJnTIS[1:0]	00: Not used so set to 00

(c) Channel output mode for the slave channel(s)**Table 13-52 Control bit settings for Independent Channel Output Mode 1**

Bit name	Setting
TAUJnTOE.TAUJnTOEm	1: Enable the independent channel output mode.
TAUJnTO.TAUJnTOm	0: Low level 1: High level
TAUJnTOM.TAUJnTOMm	1: Synchronous channel operation
TAUJnTOC.TAUJnTOCm	0: Operation mode 1
TAUJnTOL.TAUJnTOLm	0: Positive logic 1: Inverted logic

(d) Simultaneous rewrite for the slave channel(s)

The simultaneous rewrite settings of the master and slave channel must be identical.

Table 13-53 Simultaneous rewrite settings for the slave channel of the PWM Output Function

Bit name	Setting
TAUJnRDE.TAUJnRDEm	1: Enables simultaneous rewrite
TAUJnRDM.TAUJnRDMm	0: The simultaneous rewrite trigger signal is generated when the master channel starts counting

(6) Operating procedure for PWM Output Function

Table 13-54 Operating procedure for PWM Output Function

	Operation	Status of TAUJn
Restart ↓	Initial channel setting Master channel: set the TAUJnCMORm and TAUJnCMURm registers and the channel output mode as described in 4 "Register settings for the master channel" on page 844 . Slave channel: set the TAUJnCMORm and TAUJnCMURm registers and the channel output mode as described in 5 "Register settings for the slave channel(s)" on page 846 . Set the values of the TAUJnCDRm registers of all channels.	Channel operation is stopped.
	Start operation Set TAUJnTS.TAUJnTsm of the master and slave channels to 1 simultaneously. TAUJnTS.TAUJnTsm is a trigger bit, so it is automatically cleared to 0.	TAUJnTE.TAUJnTEm (master and slave channels) is set to 1 and the counters of the master and slave channels start. INTTAUJnIm is generated on the master channel and TAUJnTTOUTm (slave) is set.
	During operation TAUJnCDRm can be changed at any time. TAUJnCNTm and TAUJnRSF.TAUJnRSFm can be read at any time. TAUJnRDT.TAUJnRDTm can be changed during operation.	TAUJnCNTm of the master channel loads TAUJnCDRm and counts down. When the counter reaches 0000 0000 _H : <ul style="list-style-type: none"> • INTTAUJnIm (master) is generated. • TAUJnCNTm (master) loads the TAUJnCDRm value, and then continues count operation. • TAUJnCNTm (slave) loads the TAUJnCDRm value, and then counts down. • TAUJnTTOUTm (slave) becomes active. When TAUJnCNTm (slave) reaches 0000 0000 _H : <ul style="list-style-type: none"> • INTTAUJnIm (slave) is generated. • TAUJnTTOUTm (slave) becomes inactive.
	Stop operation Set TAUJnTT.TAUJnTTm of the master and slave channels to 1 simultaneously. TAUJnTT.TAUJnTTm is a trigger bit, so it is automatically cleared to 0.	TAUJnTE.TAUJnTEm is cleared to 0 and the counter stops. TAUJnCNTm and TAUJnTTOUTm stop and retain their current values.

(7) Specific timing diagrams

(a) Duty cycle = 0%

Figure 13-52 TAUJnCDRm (slave) = 0000 0000_H,
positive logic (TAUJnTOL.TAUJnTOLm (slave) = 0)

- Every time the master channel generates an interrupt (INTTAUJnIm), 0000 0000_H is loaded to TAUJnCNTm (slave). Therefore, TAUJnCNTm (slave) cannot start counting and TAUJnTTOUTm remains at not active state.
- TAUJnCNTm (slave) loads the TAUJnCDRm value and an interrupt is generated.

(b) Duty cycle = 100%

Figure 13-53 $TAUJnCDRm$ (slave) \geq $TAUJnCDRm$ (master) + 1, positive logic ($TAUJnTOL$. $TAUJnTOLm$ (slave) = 0)

- If the $TAUJnCDRm$ (slave) value is higher than the $TAUJnCDRm$ (master) value, the counter of the slave channel cannot reach 0000 0000_H and interrupts are therefore not generated. The $TAUJnTTOUtm$ remains at active state.

(c) Stop and restart operation

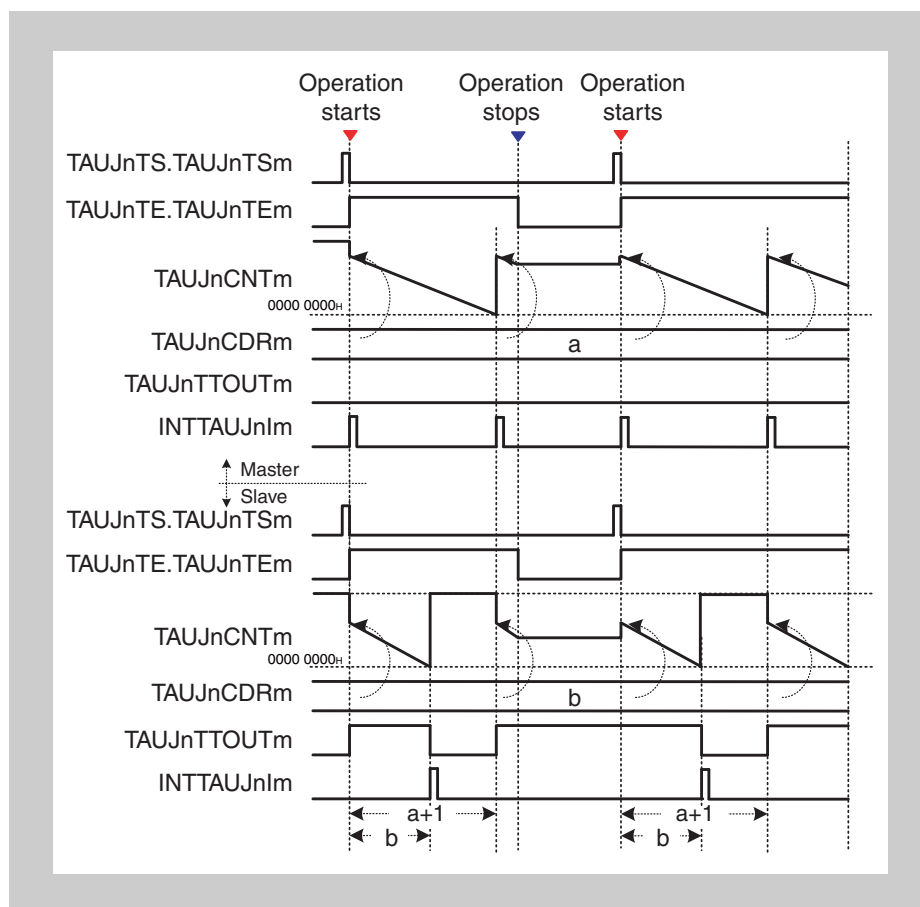

Figure 13-54 Stop and restart operation
Positive logic (TAUJnTOL.TAUJnTOLm (slave) = 0)

- The counter can be stopped by setting TAUJnTT.TAUJnTTm of the master and slave channel(s) to 1, which in turn sets TAUJnTE.TAUJnTEM to 0.
- TAUJnCNTm and TAUJnTTOUTm of all channels stop and the current values are retained. No interrupts are generated.
- The counter can be restarted by setting TAUJnTS.TAUJnTSM of master and slave channel(s) to 1. TAUJnCNTm loads the TAUJnCDRm value of master and slave channels, and then starts counting down from this value.

13.18 Registers

This section contains a description of all the registers of the 32-bit TAUJ.

13.18.1 TAUJn registers overview

The TAUJn is controlled and operated by the registers in the following table. Where there is one register per channel, this is indicated by an “m”, where m runs from 0 to 3.

Table 13-55 TAUJn registers overview

Register name	Shortcut	Address
TAUJn prescaler registers		
TAUJn prescaler clock select register	TAUJnTPS	<TAUJn_base> + 90 _H
TAUJn prescaler baud rate setting register	TAUJnBRS	<TAUJn_base> + 94 _H
TAUJn control registers		
TAUJn channel data register m	TAUJnCDRm	<TAUJn_base> + m x 4 _H
TAUJn channel counter register m	TAUJnCNTm	<TAUJn_base> + 10 _H + m x 4 _H
TAUJn channel mode OS register m	TAUJnCMORM	<TAUJn_base> + 80 _H + m x 4 _H
TAUJn channel mode user register m	TAUJnCMURm	<TAUJn_base> + 20 _H + m x 4 _H
TAUJn channel status register m	TAUJnCSRm	<TAUJn_base> + 30 _H + m x 4 _H
TAUJn channel status clear trigger register m	TAUJnCSCm	<TAUJn_base> + 40 _H + m x 4 _H
TAUJn channel start trigger register	TAUJnTS	<TAUJn_base> + 54 _H
TAUJn channel enable status register	TAUJnTE	<TAUJn_base> + 50 _H
TAUJn channel stop trigger register	TAUJnTT	<TAUJn_base> + 58 _H
TAUJn output registers		
TAUJn channel output enable register	TAUJnTOE	<TAUJn_base> + 60 _H
TAUJn channel output register	TAUJnTO	<TAUJn_base> + 5C _H
TAUJn channel output mode register	TAUJnTOM	<TAUJn_base> + 98 _H
TAUJn channel output configuration register	TAUJnTOC	<TAUJn_base> + 9C _H
TAUJn channel output active level register	TAUJnTOL	<TAUJn_base> + 64 _H
TAUJn reload data registers		
TAUJn channel reload data enable register	TAUJnRDE	<TAUJn_base> + A0 _H
TAUJn channel reload data mode register	TAUJnRDM	<TAUJn_base> + A4 _H
TAUJn channel reload data trigger register	TAUJnRDT	<TAUJn_base> + 68 _H
TAUJn channel reload status register	TAUJnRSF	<TAUJn_base> + 6C _H

Note The <TAUJn_base> addresses of the registers are defined in the first section of this chapter under the keyword “Register addresses”.

13.18.2 TAUJn prescaler registers details

(1) TAUJnTPS - TAUJn prescaler clock select register

This register specifies the PCLK prescalers for clocks CK0, CK1, CK2, and CK3_PRE for all channels. CK3 is generated by dividing CK3_PRE by the factor specified in TAUJnBRS.

Access This register can be read/written in 16-bit units.

Address <TAUJn_base> + 90_H

Initial Value FFFF_H. This register is initialized by any reset.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

1111 _B	PCLK/2 ¹⁵																																			

Note The TAUJn clock input PCLK is specified in the first section of this chapter under the keyword “Clock supply”.

(2) TAUJnBRS - TAUJn prescaler baud rate setting register

This register specifies the division factor of prescaler clock CK3.

CK3 is generated by dividing CK3_PRE by the factor specified in this register plus one. The PCLK prescaler for CK3_PRE is specified in TAUJnTPS.TAUJnPRS3[3:0].

Access This register can be read/written in 8-bit units.

Address <TAUJn_base> + 94_H

Initial Value 00_H. This register is initialized by any reset.

13.18.3 TAUJn control registers details

(1) TAUJnCDRm - TAUJn channel data register

This register functions either as a compare register or as a capture register, depending on the operation mode specified in TAUJnCMORm.TAUJnMD[4:0].

Access This register can be read/written in 32-bit units.

- In capture mode, only reading is possible. Write operation is ignored.
- In compare mode, reading and writing is possible.

Address <TAUJn_base> + m x 4_H

Initial Value 0000 0000_H. This register is initialized by any reset.

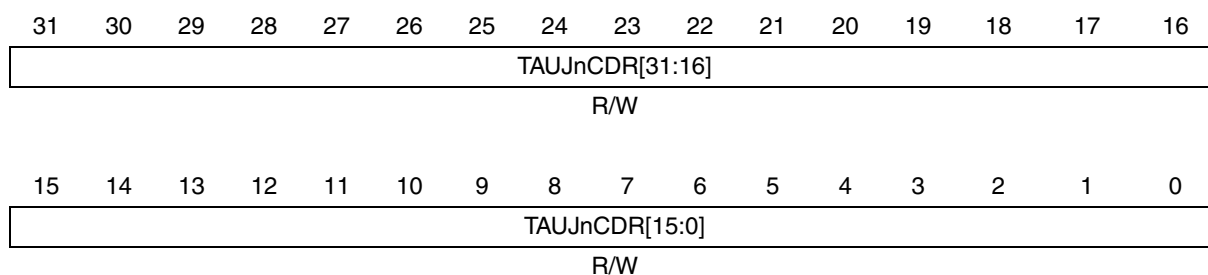

Table 13-58 TAUJnCDRm register contents

Bit position	Bit name	Function
31 to 0	TAUJnCDR[31:0]	Data register for the capture/compare value

(2) TAUJnCNTm - TAUJn channel counter register

This register is the channel m counter register.

Access This register can be read in 32-bit units.

Address <TAUJn_base> + 10_H + m x 4_H

Initial Value 0000 0000_H or FFFF FFFF_H. The initial value depends on the operation mode, see Table 13-60 “TAUJnCNTm read values after the counter is re-enabled” on page 858

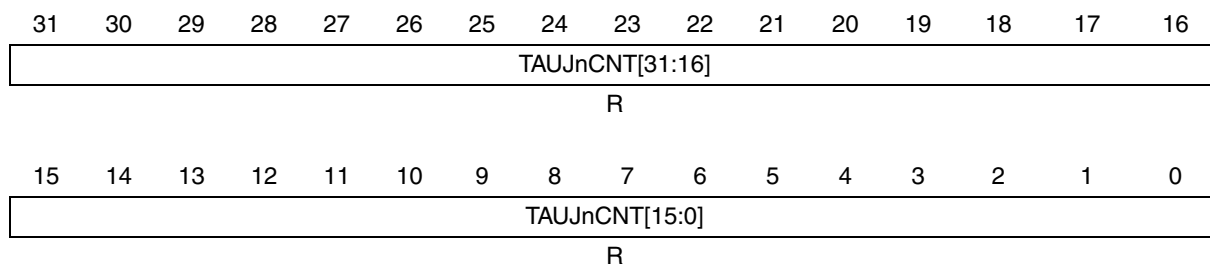

Table 13-59 TAUJnCNTm register contents

Bit position	Bit name	Function
31 to 0	TAUJnCNT[31:0]	32-bit counter value

The read value depends on the counter, the operation mode change, and the values of the TAUJnTS.TAUJnTSM and TAUJnTT.TAUJnTTm bits.

The *initial* counter read value depends on the operation mode and how the counter was stopped:

- by a reset
- by a counter stop trigger (TAUJnTT.TAUJnTTm = 1)

The following table lists the initial counter read values after the counter has stopped (TAUJnTE.TAUJnTEM= 0) and re-enabled (TAUJnTS.TAUJnTSM = 1).

The table also contains the counter read value one count after the counter is enabled (TAUJnTS.TAUJnTSM = 1) for modes where the counter waits for a start trigger.

Table 13-60 TAUJnCNTm read values after the counter is re-enabled

Mode name	Count method (up/down)	TAUJnCNTm value		
		When operation mode is changed after reset	After stop trigger	After one count
Interval Timer mode	Count down	FFFF FFFF _H	Stop value	-
Capture mode	Count up	0000 0000 _H	Stop value	-
One Count mode	Count down	FFFF FFFF _H	Stop value	FFFF FFFF _H
Capture & One Count mode	Count up	0000 0000 _H	Stop value	Captured value + 1 (TAUJnCDRm)
Count Capture Mode	Count up	0000 0000 _H	Stop value	-
Gate Count Mode	Count down	FFFF FFFF _H	Stop value	Stop value
Capture & Gate Count Mode	Count up	0000 0000 _H	Stop value	Stop value

Note If the operation mode is changed while the counter is stopped, the initial counter value after counter restart is undefined. The operation mode is changed by the TAUJnCMORm.TAUJnMD[4:1] bits.

(3) TAUJnCMORM - TAUJn channel mode OS register

This register controls channel m operation.

Access This register can be read or written in 16-bit units. Writing is only possible while the counter is stopped (TAUJnTE.TAUJnTEm = 0).

Address <TAUJn_base> + 80_H + m x 4_H

Initial Value 0000_H. This register is initialized by any reset.

		1	0	1	0		
		1	0	1	1	1/0	Count Capture mode
		1	1	0	0	0	Gate Count mode
1	1	0	1	0	Capture & Gate Count mode		
Mode	Role of the MD0 bit						
Interval Timer mode Capture mode Count Capture mode	Specifies whether the INTTAUJnIm signal is output when the counter starts counting (when the start trigger is input). 0: Does not output INTTAUJnIm. 1: Outputs INTTAUJnIm						
One Count mode Gate Count mode	Enables/disables start trigger detection during counting: 0: Disables 1: Enables						
Capture & One Count mode Capture & Gate Count mode	This bit must be set to 0.						

(4) TAUJnCMURm - TAUJn channel mode user register

This register specifies the type of valid edge detection used for the TAUJnTTINm input.

Access This register can be read/written in 8-bit units.

Address <TAUJn_base> + 20_H + m x 4_H

Initial Value 00_H. This bit is initialized by any reset.

7	6	5	4	3	2	1	0

1	1	Rising and falling edges (high-width measurement selection). Start trigger: rising edge Stop trigger (capture): falling edge															

(5) TAUJnCSRm - TAUJn channel status register

This register indicates the overflow status of channel m.

Access This register can be read in 8-bit units.

Address <TAUJn_base> + 30_H + m x 4_H

Initial Value 00_H. This bit is initialized by any reset.

7	6	5	4	3	2	1	0
-	-	-	-	-	-	-	TAUJnOVF
R	R	R	R	R	R	R	R

Table 13-63 TAUJnCSRm register contents

Bit position	Bit name	Function
0	TAUJnOVF	<p>Indicates the counter overflow status:</p> <p>0: No overflow occurred</p> <p>1: Overflow occurred</p> <p>This bit is only used in the following modes:</p> <ul style="list-style-type: none"> • Capture mode • Capture & One Count mode • Count Capture mode • Capture & Gate Count mode <p>The function of this bit depends on the setting of control bits TAUJnCMORm.TAUJnCOS[1:0].</p>

(6) TAUJnCSCm - TAUJn channel status clear register

This register is a trigger register for clearing the overflow flag TAUJnCSRm.TAUJnOVF of a channel m.

Access This register can be written in 8-bit units. It is always read as 00_H.

Address <TAUJn_base> + 40_H + m x 4_H

Initial Value 00_H. This bit is initialized by any reset.

7	6	5	4	3	2	1	0
-	-	-	-	-	-	0	TAUJnCLOV
R	R	R	R	R	R	R	W

Table 13-64 TAUJnCSCm register contents

Bit position	Bit name	Function
0	TAUJnCLOV	<p>0: No function</p> <p>1: Clears the overflow flag TAUJnCSRm.TAUJnOVF</p>

(7) TAUJnTS - TAUJn channel start trigger register

This register enables the counter for each channel.

Access This register can be written in 8-bit units. It is always read as 00_H.

Address <TAUJn_base> + 54_H

Initial Value 00_H. This bit is initialized by any reset.

7	6	5	4	3	2	1	0
-	-	-	-	TAUJnTS03	TAUJnTS02	TAUJnTS01	TAUJnTS00
W	W	W	W	W	W	W	W

Table 13-65 TAUJnTS register contents

Bit position	Bit name	Function
3 to 0	TAUJnTSm	Enables the counter for channel m. 0: No function 1: Enables the counter and sets TAUJnTE.TAUJnTEm = 1. TAUJnTE.TAUJnTEm = 1 only <i>enables</i> counter. Whether the counter <i>starts</i> depends on the selected operation mode.

(8) TAUJnTE - TAUJn channel enable status register

This register indicates whether counter is enabled or disabled.

Access This register can be read in 8-bit units.

Address <TAUJn_base> + 50_H

Initial Value 00_H. This bit is initialized by any reset.

7	6	5	4	3	2	1	0
-	-	-	-	TAUJnTE03	TAUJnTE02	TAUJnTE01	TAUJnTE00
R	R	R	R	R	R	R	R

Table 13-66 TAUJnTE register contents

Bit position	Bit name	Function
3 to 0	TAUJnTEm	Indicates whether counter for channel m is enabled or disabled. 0: Counter disabled 1: Counter enabled This bit is set when TAUJnTSSTm (the synchronous channel start trigger signal) trigger input is detected or when TAUJnTS.TAUJnTSm is set. Setting TAUJnTT.TAUJnTTm to 1 resets this bit to 0.

(9) TAUJnTT - TAUJn channel stop trigger register

This register stops the counter for each channel.

Access This register can be written in 8-bit units. It is always read as 00_H.

Address <TAUJn_base> + 58_H

Initial Value 00_H.

7	6	5	4	3	2	1	0
-	-	-	-	TAUJnTT03	TAUJnTT02	TAUJnTT01	TAUJnTT00
W	W	W	W	W	W	W	W

Table 13-67 TAUJnTT register contents

Bit position	Bit name	Function
3 to 0	TAUJnTTm	Stops the counter of channel m. 0: No function 1: Stop the counter and reset TAUJnTE.TAUJnTEm. TAUJnCNTm, TAUJnTO.TAUJnTOm, and TAUJnTTOUTm retain their values from before the counter stopped.

13.18.4 TAUJn output registers details

(1) TAUJnTOE - TAUJn channel output enable register

This register enables and disables Independent Channel Output Mode Controlled by Software.

Access This register can be read/written in 8-bit units.

Address <TAUJn_base> + 60_H

Initial Value 00_H. This bit is initialized by any reset.

7	6	5	4	3	2	1	0
-	-	-	-	TAUJnTOE03	TAUJnTOE02	TAUJnTOE01	TAUJnTOE00
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 13-68 TAUJnTOE register contents

Bit position	Bit name	Function
3 to 0	TAUJnTOEm	Enables or disables the independent timer output function. 0: Disables the independent timer output function. 1: Enables the independent timer output function.

(2) TAUJnTOM - TAUJn channel output mode register

This register specifies the output mode of each channel.

Access This register can be read/written in 8-bit units. Writing is only possible while the counter is stopped (TAUJnTE.TAUJnTEm = 0).

Address <TAUJn_base> + 98_H

Initial Value 00_H. This bit is initialized by any reset.

7	6	5	4	3	2	1	0
-	-	-	-	TAUJnTOM03	TAUJnTOM02	TAUJnTOM01	TAUJnTOM00
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 13-69 TAUJnTOM register contents

Bit position	Bit name	Function
3 to 0	TAUJnTOMm	Specifies the channel output mode. 0: Independent channel output mode 1: Synchronous channel output mode The output mode depends on several channel output control bits, as can be seen in Table 13-9 "Channel output modes" on page 781.

(3) TAUJnTOC - TAUJn channel output configuration register

This register specifies the output mode of each channel in combination with TAUJnTOMm.

Access This register can be read/written in 8-bit units. Writing is only possible while the counter is stopped (TAUJnTE.TAUJnTEm = 0).

Address <TAUJn_base> + 9C_H

Initial Value 00_H. This bit is initialized by any reset.

7	6	5	4	3	2	1	0
-	-	-	-	TAUJnTOC03	TAUJnTOC02	TAUJnTOC01	TAUJnTOC00
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 13-70 TAUJnTOC register contents

Bit position	Bit name	Function
3 to 0	TAUJnTOCm	Specifies the output mode. 0: Operation mode 1 (toggle mode) 1: No function

13.18.5 TAUJn channel output level registers details

(1) TAUJnTO - TAUJn channel output register

This register specifies and reads the level of TAUJnTTOUTm.

Access This register can be read/written in 8-bit units.

Address <TAUJn_base> + 5C_H

Initial Value 00_H. This bit is initialized by any reset.

7	6	5	4	3	2	1	0
-	-	-	-	TAUJnTO03	TAUJnTO02	TAUJnTO01	TAUJnTO00
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 13-71 TAUJnTO register contents

Bit position	Bit name	Function
3 to 0	TAUJnTOM	Specifies and reads the level of TAUJnTTOUTm. 0: Low level 1: High level Only TAUJnTOM bits for which the independent channel output function is disabled (TAUJnTOEm = 0) can be written.

(2) TAUJnTOL - TAUJn channel output level register

This register specifies the output logic of the channel output bit (TAUJnTO.TAUJnTOM).

Access This register can be read/written in 8-bit units.

Address <TAUJn_base> + 64_H

Initial Value 00_H. This bit is initialized by any reset.

7	6	5	4	3	2	1	0
-	-	-	-	TAUJnTOL03	TAUJnTOL02	TAUJnTOL01	TAUJnTOL00
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 13-72 TAUJnTOL register contents

Bit position	Bit name	Function
3 to 0	TAUJnTOLm	Specifies the output logic of the channel m output bit (TAUJnTO.TAUJnTOM). 0: Positive logic (active high) 1: Inverted logic (active low)

13.18.6 TAUJn simultaneous rewrite register details

(1) TAUJnRDE - TAUJn channel reload data enable register

This register enables and disables simultaneous rewrite of the data register TAUJnCDRm.

Access This register can be read/written in 8-bit units. Writing is only possible while TAUJnTE.TAUJnTEm is 0.

Address <TAUJn_base> + A0_H

Initial Value 00_H. This bit is initialized by any reset.

7	6	5	4	3	2	1	0
-	-	-	-	TAUJnRDE03	TAUJnRDE02	TAUJnRDE01	TAUJnRDE00
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 13-73 TAUJnRDE register contents

Bit position	Bit name	Function
3 to 0	TAUJnRDEm	Enables and disables simultaneous rewrite of the data register of channel m. 0: Disables simultaneous rewrite 1: Enabled simultaneous rewrite

(2) TAUJnRDM - TAUJn channel reload data mode register

This register selects the timing for generating a simultaneous rewrite control signal.

Access This register can be read/written in 8-bit units. Writing is only possible while TAUJnTE.TAUJnTEm is 0.

Address <TAUJn_base> + A4_H

Initial Value 00_H. This bit is initialized by any reset.

7	6	5	4	3	2	1	0
-	-	-	-	TAUJnRDM03	TAUJnRDM02	TAUJnRDM01	TAUJnRDM00
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 13-74 TAUJnRDM register contents

Bit position	Bit name	Function
3 to 0	TAUJnRDMm	Selects the timing for generating a simultaneous rewrite control signal. 0: When the master channel counter starts counting 1: No function These bits only apply when TAUJnRDE.TAUJnRDEm = 1.

(3) TAUJnRDT - TAUJn channel reload data trigger register

This register triggers the simultaneous rewrite pending state.

Access This register can be written in 8-bit units. It is always read as 00_H.

Address <TAUJn_base> + 68_H

Initial Value 00_H. This bit is initialized by any reset.

7	6	5	4	3	2	1	0
-	-	-	-	TAUJnRDT03	TAUJnRDT02	TAUJnRDT01	TAUJnRDT00
W	W	W	W	W	W	W	W

Table 13-75 TAUJnRDT register contents

Bit position	Bit name	Function
3 to 0	TAUJnRDTm	Triggers the simultaneous rewrite pending state. 0: No function 1: Simultaneous rewrite pending state is triggered. The simultaneous rewrite pending flag (TAUJnRSFm) is set to 1. The system waits for the simultaneous rewrite trigger.

(4) TAUJnRSF - TAUJn channel reload status register

This flag register indicates the simultaneous rewriting status.

Access This register can be read in 8-bit units.

Address <TAUJn_base> + 6C_H

Initial Value 00_H. This bit is initialized by any reset.

7	6	5	4	3	2	1	0
-	-	-	-	TAUJnRSF03	TAUJnRSF02	TAUJnRSF01	TAUJnRSF00
R	R	R	R	R	R	R	R

Table 13-76 TAUJnRSF register contents

Bit position	Bit name	Function
3 to 0	TAUJnRSFm	Indicates the simultaneous rewrite status. 0: Simultaneous rewriting was performed due to the generation of a simultaneous rewrite trigger. 1: Simultaneous rewriting is pending (TAUJnRDTm = 1).

Chapter 14 Encoder Timer (ENCA)

This chapter contains a generic description of the Encoder Timer (ENCA).

The first section describes the properties specific to the V850E2/ML4, such as instances, register base addresses, and input/output signal names. The subsequent sections describe the common features.

14.1 V850E2/ML4 ENCA Features

Instances This microcontroller has the following number of instances of the Encoder Timer.

Table 14-1 Instances of ENCA

Encoder Timer	
Instance	2
Name	ENCA0, ENCA1

Instances index n Throughout this chapter, the individual instances of a Encoder Timer is identified by the index "n" (n = 0, 1), for example, ENCA_nCTL for the ENCA_n control register.

Register addresses All ENCA_n register addresses are given as address offsets from the individual base address <ENCA_n_base_OS> or <ENCA_n_base_USER>. The base addresses <ENCA_n_base_OS> and <ENCA_n_base_USER> of each ENCA_n are listed in the following table.

Table 14-2 Register base addresses <ENCA_n_base>

ENCA _n instance	Base address	Address
ENCA0	ENCA _n _base_OS	FF81 9000 _H
	ENCA _n _base_USER	FFFF D800 _H
ENCA1	ENCA _n _base_OS	FF81 A000 _H
	ENCA _n _base_USER	FFFF D900 _H

Clock supply All Encoder Timers provide one clock input.

Table 14-3 ENCA_n clock supply

ENCA _n instance	ENCA _n clock	Connected to
ENCA0	PCLK	f _{PCLK}
ENCA1	PCLK	f _{PCLK}

Interrupts and DMA/DTS ENCA_n can generate the following interrupts and DMA/DTS requests:

Table 14-4 ENCA_n interrupts and DMA/DTS requests

ENCA _n signals	Function	Connected to
ENCA0:		
ENCATIOV	ENCA0 overflow interrupt	<ul style="list-style-type: none"> Interrupt Controller INTENCA0IOV DMA controller trigger 68 DTS controller trigger 68
ENCATIUD	ENCA0 underflow interrupt	<ul style="list-style-type: none"> Interrupt Controller INTENCA0IUD DMA controller trigger 69 DTS controller trigger 69
ENCATINT0	ENCA0 compare match 0 or capture 0 interrupt	<ul style="list-style-type: none"> Interrupt Controller INTENCA0I0 DMA controller trigger 70 DTS controller trigger 70
ENCATINT1	ENCA0 compare match 1 or capture 1 interrupt	<ul style="list-style-type: none"> Interrupt Controller INTENCA0I1 DMA controller trigger 71 DTS controller trigger 71 ADCA trigger (ADCA0TTIN004, ADCA0TTIN104, ADCA0TTIN204)
ENCATIEC	ENCA0 clear interrupt by encoder input (phase Z)	<ul style="list-style-type: none"> Interrupt Controller INTENCA0IEC DMA controller trigger 72 DTS controller trigger 72
ENCA1:

ENCATIUD	ENCA1 underflow interrupt	<ul style="list-style-type: none"> Interrupt Controller INTENCA1IUD DMA controller trigger 74 DTS controller trigger 74
ENCATINT0	ENCA1 compare match 0 or capture 0 interrupt	<ul style="list-style-type: none"> Interrupt Controller INTENCA1I0 DMA controller trigger 75 DTS controller trigger 75
ENCATINT1	ENCA1 compare match 1 or capture 1 interrupt	<ul style="list-style-type: none"> Interrupt Controller INTENCA1I1 DMA controller trigger 76 DTS controller trigger 76 ADCA trigger (ADCA0TTIN005, ADCA0TTIN105, ADCA0TTIN205)
ENCATIEC	ENCA1 clear interrupt by encoder input (phase Z)	<ul style="list-style-type: none"> Interrupt Controller INTENCA1IEC DMA controller trigger 77 DTS controller trigger 77

Internal signals The internal signals of the Encoder Timers are listed in the following table.

Table 14-5 ENCA_n interrupt requests

ENCA _n signals	Function	Connected to
ENCA0:		
ENCATSST	ENCA0 simultaneous start trigger input	PIC
ENCATSTT	ENCA0 simultaneous stop trigger input	Unused
ENCA1:		
ENCATSST	ENCA1 simultaneous start trigger input	PIC
ENCATSTT	ENCA1 simultaneous stop trigger input	Unused

I/O signals The I/O signals of the Encoder Timers are listed in the following table.

Table 14-6 ENCA_n I/O signals

ENCA _n signal	Function	Connected to
ENCA0:		
ENCATTIN0	ENCA0 capture trigger input 0	Port TE0_TI0
ENCATTIN1	ENCA0 capture trigger input 1	Port TE0_TI1
ENCATAIN	ENCA0 encoder input (phase A)	Port TE0_AI
ENCATBIN	ENCA0 encoder input (phase B)	Port TE0_BI
ENCATZIN	ENCA0 encoder input (phase Z)	Port TE0_ZI
ENCATCSO	ENCA0 count status output	Reserved
ENCA1:		
ENCATTIN0	ENCA1 capture trigger input 0	Port TE1_TI0
ENCATTIN1	ENCA1 capture trigger input 1	Port TE1_TI1
ENCATAIN	ENCA1 encoder input (phase A)	Port TE1_AI
ENCATBIN	ENCA1 encoder input (phase B)	Port TE1_BI
ENCATZIN	ENCA1 encoder input (phase Z)	Port TE1_ZI
ENCATCSO	ENCA1 count status output	Reserved

Functional Overview

Features summary

Generation of the counter control signal from the encoder input signal, and performs count operation in synchronization with PCLK.

Capture function for capturing the counter value with an external trigger signal

Compare function for compare match judgment with the counter value

Two capture compare registers that can be set separately for capture operation and for compare operation

Interrupt mask function for masking the interrupt signal output as a result of compare match judgment during compare operation

Function for loading the value of the capture compare register to the counter upon underflow occurrence

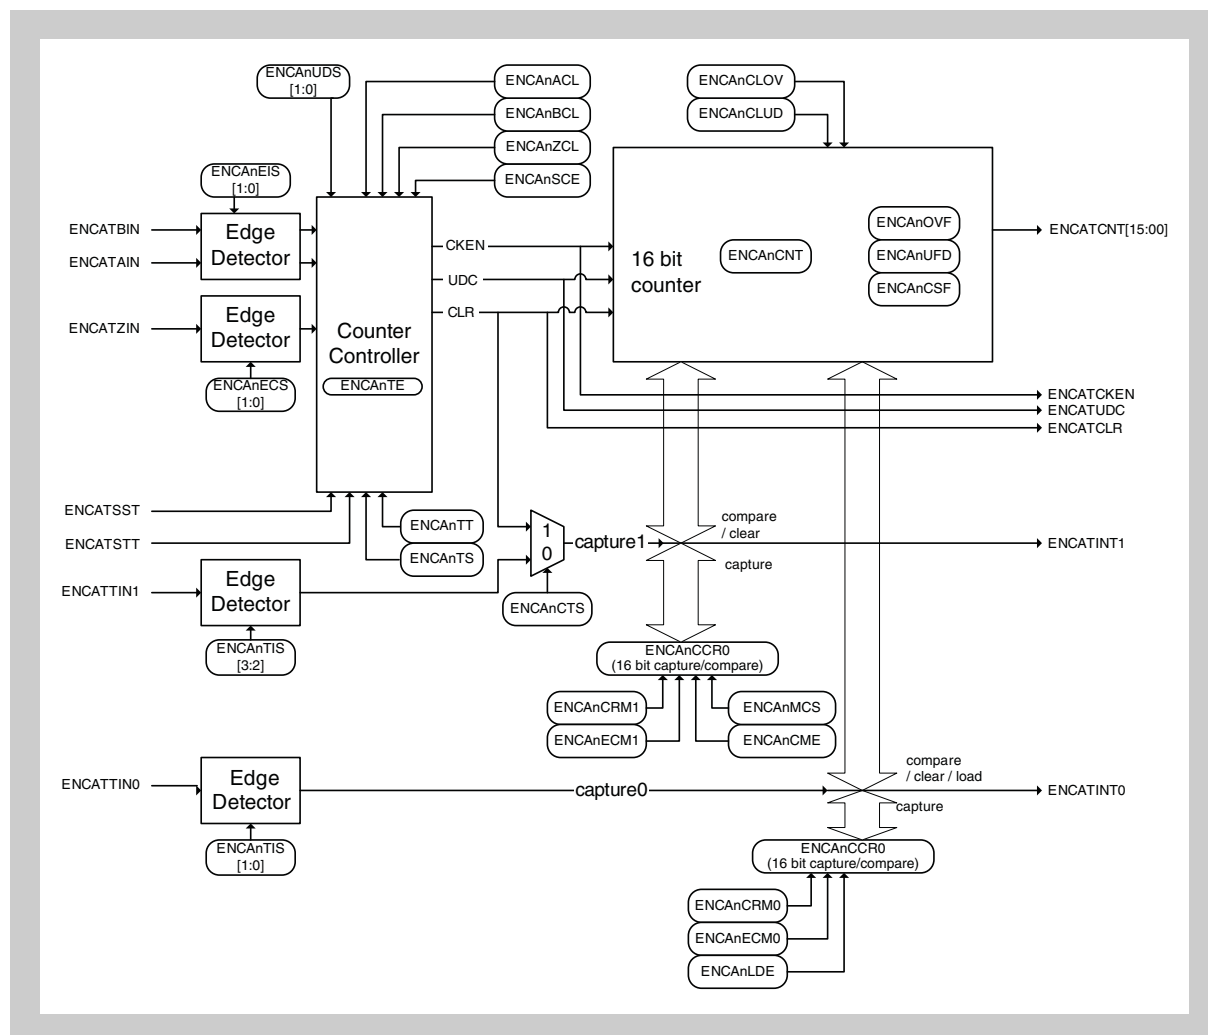

Encoder input signal can be applied to the timer counter clear condition

Edge or level for clearing the encoder input signal of the timer counter clear condition can be selected

Detection of counter overflow and underflow and output error flags and occurrence interrupts

Five interrupts: 2 capture compare interrupts, 1 counter clear interrupt, 1 overflow interrupt, and 1 underflow interrupt.

Block Diagram

Encoder Timer block diagram

Preliminary knowledge for understanding basic specifications

As this macro has an encoder counter function, the rotary encoder is explained below.

Rotary Encoder

The rotary encoder outputs a pulse according to the amount of displacement of the axis of rotation. The output pulse is output as a waveform that has two phase differences, from the fact that the light passing through two slits (phase A, phase B) is transmitted or blocked, when the disc, on which an optical pattern is written, rotates, along with the displacement of the axis of rotation.

The rotation can be detected by counting the output pulses with a counter.

Moreover, there is a pulse called phase Z, which indicates the origin within 1 rotation of the encoder.

Errors can be corrected by clearing the counter to 0000_H by using the phase Z pulse.

Position measurement and speed measurement applications can be achieved by using the rotation measured with the timer counter.

ENCA Control Registers

The ENCA_n is controlled and operated by means of the following registers:

Table 14-7 ENCA_n register overview

Register name	Shortcut	Address
ENCA capture compare register 0	ENCA _n CCR0	<ENCA _n _base_USER>
ENCA capture compare register 1	ENCA _n CCR1	<ENCA _n _base_USER> + 04 _H
ENCA counter register	ENCA _n CNT	<ENCA _n _base_USER> + 08 _H
ENCA status flag register	ENCA _n FLG	<ENCA _n _base_USER> + 0C _H
ENCA status flag clear register	ENCA _n FGC	<ENCA _n _base_USER> + 10 _H
ENCA timer enable status register	ENCA _n TE	<ENCA _n _base_USER> + 14 _H
ENCA timer start trigger register	ENCA _n TS	<ENCA _n _base_USER> + 18 _H
ENCA timer stop trigger register	ENCA _n TT	<ENCA _n _base_USER_USER> + 1C _H
ENCA I/O control register 0	ENCA _n IOC0	<ENCA _n _base_USER> + 20 _H
ENCA control register	ENCA _n CTL	<ENCA _n _base_OS> + 40 _H
ENCA I/O control register 1	ENCA _n IOC1	<ENCA _n _base_OS> + 44 _H

Base address

The base addresses <ENCA_n_base_USER> and <ENCA_n_base_OS> of the ENCA_n is defined in the first section of this chapter under the key word “Register addresses”.

ENCA_nCTL – ENCA control register

This register is used to configure various operation settings of the Encoder Timer.

Access

This register can be read/written in 16-bit units.
Writing to this register during operation is prohibited.

Address

<ENCA_n_base_OS> + 40_H

Initial value

Reset input initializes this register to 0000_H.

15	14	13	12	11	10	9	8

R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 14-8 ENCA_nCTL register contents (1/2)

Bit	Name	Function
15	ENCA _n CME	Encoder clear mask enable bit This bit is used to enable/disable masking of compare match interrupt detection when the compare function is used. 0: Disables the compare match interrupt (ENCATINT1) mask function for the ENCA _n CCR1 register 1: Enables the compare match interrupt (ENCATINT1) mask function for the ENCA _n CCR1 register. This bit is valid only when ENCA _n CRM1 = 0. When this bit is set to "1", setting ENCA _n ECM1 to "1" is prohibited.
14	ENCA _n MCS	Encoder mask clear select bit This bit is used to select the trigger for cancelling masking of compare match interrupt detection when the compare function is used. This bit is valid only when ENCA _n CRM1 = 0. 0 Masking of compare match interrupt detection is cancelled when the ENCA _n CCR1 register is written. 1: Masking of compare match interrupt detection is cancelled when one of the following three operations is performed. -Timer counter clear operation accompanying phase Z -Timer counter clear operation upon compare match between ENCA _n CNT and ENCA _n CCR0 when ENCA _n ECM0 = 1 -Loading from ENCA _n CCR0 to timer counter upon underflow detection when ENCA _n LDE = 1
9	ENCA _n CRM1	ENCA _n CCR1 register mode bit 0: ENCA _n CCR1 used as compare register. 1: ENCA _n CCR1 used as capture register.
8	ENCA _n CRM0	ENCA _n CCR0 register mode bit 0: ENCA _n CCR0 used as compare register. 1: ENCA _n CCR0 used as capture register.
7	ENCA _n CTS	ENCA _n CCR1 capture trigger select bit This is a trigger selection bit register for the capture operation to the ENCA _n CCR1 register. This bit selects the capture trigger to the ENCA _n CCR1 register. This bit is valid only when ENCA _n CRM1 = 1. 0: Uses ENCATIN1 of capture trigger 1 signal as the trigger for capturing to the ENCA _n CCR1 register. 1: Uses ENCATZIN of the phase Z encoder input signal as the trigger for capturing to the ENCA _n CCR1 register.

Table 14-8 ENCA_nCTL register contents (2/2)

Bit	Name	Function

Judgment of count operation combining both detected edge and level.</p>

ENCA_nIOC0 – ENCA I/O control register 0

This register is used to select the input edge of capture triggers 0 and 1 (ENCA_nTTIN0, ENCA_nTTIN1).

Access

This register can be read/written in 8-bit units.
Writing to this register during operation is prohibited.

Address

<ENCA_n_base_USER> + 20_H

Initial value

Reset input initializes this register to 00_H.

3, 2	ENCAnTIS[3:2]	Input edge selection bits for capture trigger 1. These bits are valid only when the ENCAAnCTL register's ENCAAnCRM1 = 1 and ENCAAnCTS = 0. All other settings of ENCAAnCRM1 and ENCAAnCTS are invalid. 00: No edge detection 01: Rising edge detection 10: Falling edge detection 11: Both edges detection
1, 0	ENCAnTIS[1:0]	Input edge selection bits for capture trigger 0. These bits are valid only when ENCAAnCTL.ENCAAnCRM0 = 1 00: No edge detection 01: Rising edge detection 10: Falling edge detection 11: Both edges detection

ENCAAnIOC1 – ENCA I/O control register 1

This register is used to perform the clear condition setting and edge selection upon encoder input.

Access

This register can be read/written in 8-bit units.
Writing to this register during operation is prohibited.

Address

<ENCAAn_base_OS> + 44_H

Initial value

Reset input initializes this register to 00_H.

Table 14-10 ENCA_nIOC1 register contents

Bit	Name	Function
7	ENCAnSCE	Encoder special-clear enable bit This is an encoder special clear enable bit. When cleared to 0, the counter is cleared upon phase Z edge detection. When set to 1, the counter is cleared using the level of ENCATZIN, ENCATAIN, and ENCATBIN (special clear). When setting this bit to 1, set ENCA _n UDS1 and ENCA _n UDS0 to {1, 0} or {1, 1}. The operation is not guaranteed if this bit is set to 1 with ENCA _n UDS1 and ENCA _n UDS0 set to {0, 0} or {0, 1}. 0: Clears the counter upon detection of ENCATZIN valid edge (set with ENCA _n ECS1 and ENCA _n ECS0). 1: Clears the counter upon detection of input level condition of ENCATZIN, ENCATBIN and ENCATAIN (set with ENCA _n ZCL bit, ENCA _n BCL bit, and ENCA _n ACL bit).
6	ENCAnZCL	Input-Z clear condition selection bit This bit is used to set the condition for clearing the phase Z encoder input (ENCAnZIN) when using the encoder special clear function. This bit is valid only when ENCA _n SCE = 1; it is invalid when ENCA _n SCE = 0. 0: Clear condition: Low level 1: Clear condition: High level
5	ENCAnBCL	Input-B clear condition selection bit This bit is used to set the condition for clearing the phase B encoder input (ENCAnBIN) when using the encoder special clear function. This bit is valid only when ENCA _n SCE = 1; it is invalid when ENCA _n SCE = 0. 0: Clear condition: Low level 1: Clear condition: High level
4	ENCAnACL	Input-A clear condition selection bit This bit is used to set the condition for clearing the phase A encoder input (ENCAnAIN) when using the encoder special clear function. This bit is valid only when ENCA _n SCE = 1; it is invalid when ENCA _n SCE = 0. 0: Clear condition: Low level 1: Clear condition: High level
3, 2	ENCAn ECS[1:0]	Encoder clear input edge selection bits 1 and 0 These are the encoder clear input edge selection bits (phase Z). These bits are valid only when ENCA _n SCE = 0; they are invalid when ENCA _n SCE = 1. 00: No edge detection 01: Rising edge detection 10: Falling edge detection 11: Both edges detection
1, 0	ENCAn EIS[1:0]	Encoder input selection bits 1 and 0 These are the encoder input edge selection bits (phase A, phase B). These bits are valid when ENCA _n UDS1 and ENCA _n UDS0 = {0, 0} or {0, 1}, and are invalid when ENCA _n UDS1 and ENCA _n UDS0 = {1, 0} or {1, 1}. 00: No edge detection 01: Rising edge detection 10: Falling edge detection 11: Both edges detection

ENCAnFLG – ENCA status flag register

This register is holds the status flags of the timer counter of the ENCA.

Access

This register can be read in 8-bit units.

Writing to this register during operation is prohibited.

Address

<ENCAn_base_USER> + 0C_H

Initial value

Reset input initializes this register to 00_H.

7	6	5	4	3	2	1	0
R	R	R	R	R	R	R	R

Table 14-11 ENCA_nFLG register contents

Bit	Name	Function
2	ENCAnCSF	Counter status flag This bit reflects the current timer counter operation. This bit is cleared at the start of count operation. 0: Timer counter in up-count status 1: Timer counter in down-count status
1	ENCAnUDF	Underflow flag This bit reflects the occurrence of an underflow during the timer counter operation. This bit is cleared at the start of count operation. 0: This flag is cleared upon any of the following events: - "1" is written to ENCAnFGC.ENCAnCLUD - ENCAnTS is set while ENCAnTE = 0 - "1" is written to XX.yy of PIC ^a 1: This flag is set to "1" upon occurrence of an underflow during the encoder timer count operation.
0	ENCAnOVF	Overflow flag This bit reflects the occurrence of an overflow during the timer counter operation. This bit is cleared at the start of count operation. 0: This flag is cleared upon any of the following events: - "1" is written to ENCAnFGC.ENCAnCLOV - ENCAnTS is set while ENCAnTE = 0 - "1" is written to XX.yy of PIC ^a 1: This flag is set to "1" upon occurrence of an overflow during the encoder timer count operation.

a) For details, see the chapter that describes PIC.

ENCAnFGC – ENCA status flag clear register

This register is used to clear the timer counter status flags of ENCA_nFLG.

Access

This register can be written in 8-bit units.

This register always returns 0 when read.

Address

<ENCAn_base_USER> + 10_H

Initial value

Reset input initializes this register to 00_H.

7	6	5	4	3	2	1	0

Table 14-12 ENCA_nFGC register contents

Bit	Name	Function
1	ENCA _n CLUD	Underflow flag clear This bit clears the underflow flag. 0: Writing is ignored. 1: Clears ENCA _n UDF of the ENCA _n FL register (clears underflow detection).
0	ENCA _n CLOV	Overflow flag clear This bit clears the overflow flag. 0: Writing is ignored. 1: Clears ENCA _n OVF of the ENCA _n FL register (clears overflow detection).

ENCA_nCCR0 – ENCA capture compare register 0

This register is a 16-bit capture compare register 0.

Access

This register can be written in 16-bit units when used as a compare register (ENCA_nCTL.ENCA_nCRM0 = 0).

When used as a capture register (ENCA_nCTL.ENCA_nCRM0 = 1), writing to this register during operation is invalid.

Address

<ENCA_n_base_USER>

Initial value

Reset input initializes this register to 0000_H.

Table 14-13 ENCA_nCCR0 register contents

Bit	Name	Function
15 to 0	ENCA _n CCR0[15:0]	Capture compare register 0 Upon occurrence of an underflow, the setting value of this register may be loaded to the counter according to the ENCA _n CTL.ENCA _n LDE setting. See the description of the ENCA _n LDE bit in ENCA control register ENCA _n CTL for details. <ul style="list-style-type: none"> if ENCA_nCTL.ENCA_nCRM0 = 0: ENCA_nCCR0 is compare register Set the value to be compared with the timer counter value. if ENCA_nCTL.ENCA_nCRM0 = 1: ENCA_nCCR0 is capture register The captured timer counter value is stored.

ENCA_nCCR1 – ENCA capture compare register 1

This register is a 16-bit capture compare register 1.

Access

This register can be written in 16-bit units when used as a compare register (ENCA_nCTL.ENCA_nCRM1 = 0).

When used as a capture register (ENCA_nCTL.ENCA_nCRM1 = 1), writing to this register during operation is invalid.

Address

<ENCA_n_base_USER> + 04_H

Initial value

Reset input initializes this register to 0000_H.

Table 14-14 ENCA_nCCR1 register contents

Bit	Name	Function
15 to 0	ENCA _n CCR1[15:0]	Capture compare register 1 During capture operation, the trigger for capturing to this register differs according to the ENCA _n CTL.ENCA _n CTS setting. See the description of the ENCA _n CTS bit in ENCA control register ENCA _n CTL for details. <ul style="list-style-type: none"> if ENCA_nCTL.ENCA_nCRM1 = 0: ENCA_nCCR1 is compare register Set the value to be compared with the timer counter value. if ENCA_nCTL.ENCA_nCRM1 = 1: ENCA_nCCR1 is capture register The captured timer counter value is stored.

ENCA_nCNT – ENCA counter register

This register is the 16-bit timer counter register.

Access

This register can be read/written in 16-bit units.

This register can be written only when the operation is stopped.

Address

<ENCA_n_base_USER> + 08_H

Initial value

Reset input initializes this register to 0000_H.

Table 14-15 ENCA_nCNT register contents

Bit	Name	Function

R	R	R	R	R	R	R	R

Table 14-16 ENCA_nTE register contents

Bit	Name	Function
0	ENCA _n TE	Timer status enable bit This is a status bit that indicates the operation enabled/stopped status of the ENCA _n . This bit is cleared to "0" when "1" is written to ENCA _n TT.ENCA _n TT, or when xxxx.yy of PIC is set. This bit is set to "1" when "1" is written to ENCA _n TS.ENCA _n TS, or when xxxx.zz of PIC is set. 0: Operation stopped status 1: Operation enabled status

ENCA_nTS – ENCA timer start trigger register

This register provides the trigger bit for setting the ENCA_n to the operation enabled state.

Access

This register can be written in 8-bit units.

This register always returns 0 when read. This register can be written only when ENCA_nTE.ENCA_nTE is 0.

Address

<ENCA_n_base_USER> + 18_H

Initial value

Reset input initializes this register to 00_H.

7	6	5	4	3	2	1	0
0	0	0	0	0	0	0	ENCA _n TS
R	R	R	R	R	R	R	W

Table 14-17 ENCA_nTS register contents

Bit	Name	Function
0	ENCA _n TS	Timer start trigger bit This is the trigger bit that sets the ENCA _n to the operation enabled state. 0: Writing is ignored. 1: ENCA _n is set to the operation enabled state by setting ENCA _n TE.ENCA _n TE = 1.

ENCA_nTT – ENCA timer stop trigger register

This register provides the trigger bit for setting the ENCA_n to the operation stopped state.

Access

This register can be written in 8-bit units.
This register always returns 0 when read.

Address

<ENCA_n_base_USER> + 1C_H

Initial value

Reset input initializes this register to 00_H.

0	0	0	0	0	0	0	ENCA _n TT
R	R	R	R	R	R	R	W

Table 14-18 ENCA_nTT register contents

Bit	Name	Function
0	ENCA _n TT	Timer stop trigger bit This is the trigger bit that sets the ENCA _n to the operation stopped state. 0: Writing is ignored. 1: Clears ENCA _n TE.ENCA _n TE to “0”, to set the ENCA _n to the count operation stopped state.

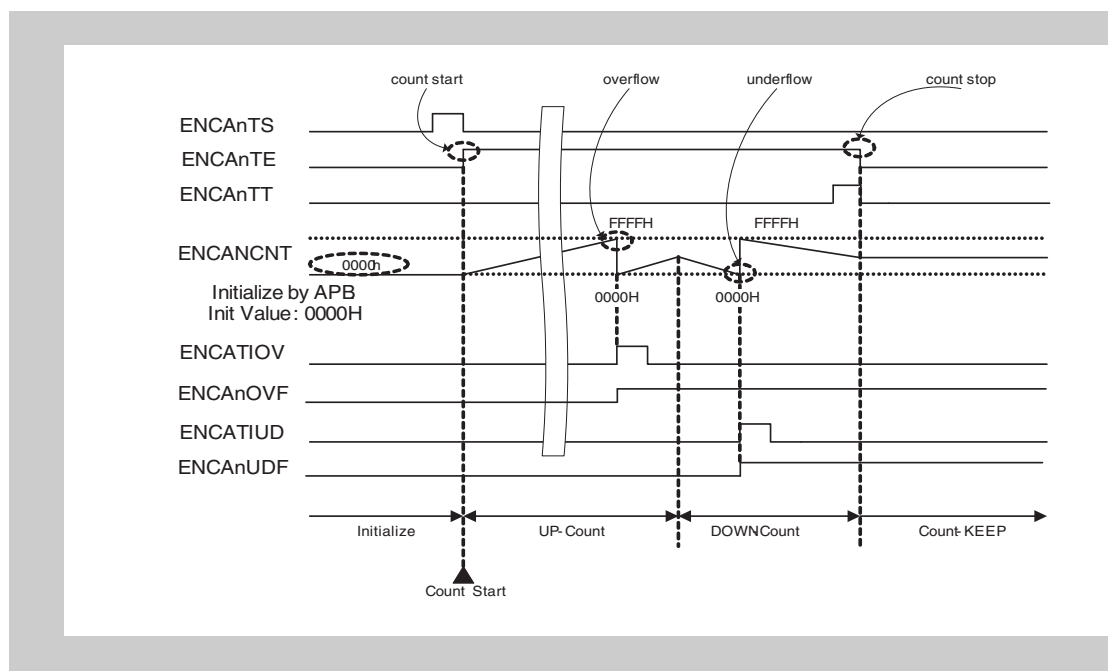

Functional Description

The ENCA_n operates the timer counter with counter up/down control and clear control by encoder inputs (phase A, phase B, phase Z). The ENCA_nCCR0 and ENCA_nCCR1 registers can be used as dedicated compare registers or as dedicated capture registers.

Timer counter operation

The timer counter operations of the ENCA_n are described below.

The figure below shows the operation phases. See the corresponding section with the section number for detailed descriptions on each operation.

Timer counter initial value setting/start/stop

Timer counter initial value setting

The initial value of the ENCA_n counter register (ENCA_nCNT) can be set in the counter operation stopped status (ENCA_nTE = 0).

Timer counter startup

By writing “1” to the timer start trigger bit (ENCA_nTS), the timer status enable bit (ENCA_nTE) is set to “1”, the count operation is enabled, and counting operation is performed upon detection of the valid edge of the encoder input.

Overflow operation

An overflow occurs when up-counting is performed when the counter value is FFFF_H. If the counter value changes from FFFF_H to 0000_H, an overflow interrupt (ENCA_nTIOV) is generated, and the overflow flag (ENCA_nOVF) is set to “1”. The overflow flag (ENCA_nOVF) is cleared to “0” when “1” is set to the overflow flag clear bit (ENCA_nCLOV).

Underflow operation

An underflow occurs when down-counting is performed when the counter value is 0000_H. If the counter value changes from 0000_H to FFFF_H, an underflow interrupt (ENCA_nIUD) is generated, and the underflow flag (ENCA_nUDF) is set to “1”. The underflow flag (ENCA_nUDF) is cleared to “0” when “1” is set to the underflow flag clear bit (ENCA_nCLUD).

Timer counter stop

By writing “1” to the timer stop trigger bit (ENCA_nTT), the timer status enable bit (ENCA_nTE) is cleared to “0”, and the count operation is stopped. At this

time, the timer counter is not reset to 0000_H and holds the value before count operation stop.

Up/down control of timer counter

Up/down control is performed by judging the phase of the encoder inputs (ENCATAIN, ENCTBIN) according to the settings of ENCAAnUDS1 and ENCAAnUDS0.

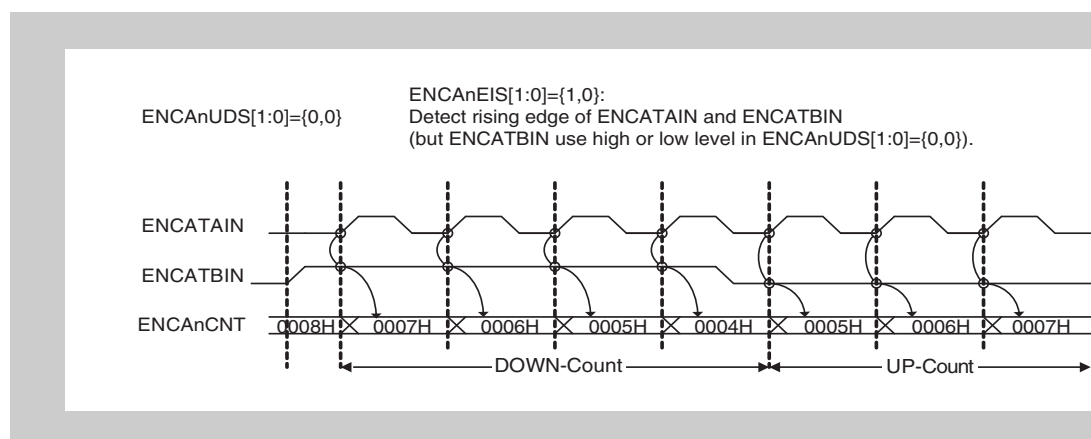

When ENCAAnUDS1 and ENCAAnUDS0 = {0, 0}

ENCAAnUDS1	ENCAAnUDS0	Operation Description		
		ENCATAIN input	ENCTBIN input	Count operation
0	0	Rising edge	High level	Down
		Falling edge		
		Both edges		
		Rising edge	Low level	Up
		Falling edge		
		Both edges		

The valid edge for ENCATAIN is specified by setting ENCAAnEIS1 and ENCAAnEIS0.

Count operation is performed when the valid edges of ENCATAIN and ENCTBIN overlap.

The following timing chart shows the count operation when ENCAAnUDS1 and ENCAAnUDS0 = {0, 0}.

Count operation when ENCAAnUDS1 and ENCAAnUDS0 = {0, 0}

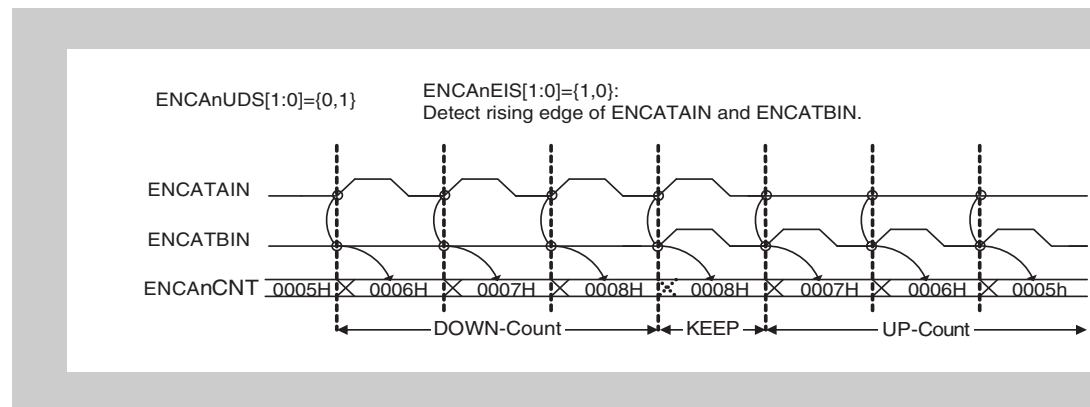

When ENCAAnUDS1 and ENCAAnUDS0 = {0, 1}

ENCAnUDS1	ENCAnUDS0	Operation description			
		ENCATAIN input	ENCTBIN input	Count operation	
0	1	Low level	Rising edge	Down	
			Falling edge		
			Both edges		
		High level	Rising edge		
			Falling edge		
			Both edges		
	Rising edge	Low level	Rising edge	Up	
					Falling edge
					Both edges
		High level	Rising edge		
			Falling edges		
			Both edges		
			Simultaneous input		Hold

The valid edges for ENCATAIN and ENCATBIN are specified by setting ENCAEIS1 and ENCAEIS0.

Count operation is performed when the valid edges of ENCATAIN and ENCATBIN overlap.

The following timing chart shows the count operation when ENCAEIS1 and ENCAEIS0 = {0, 1}.

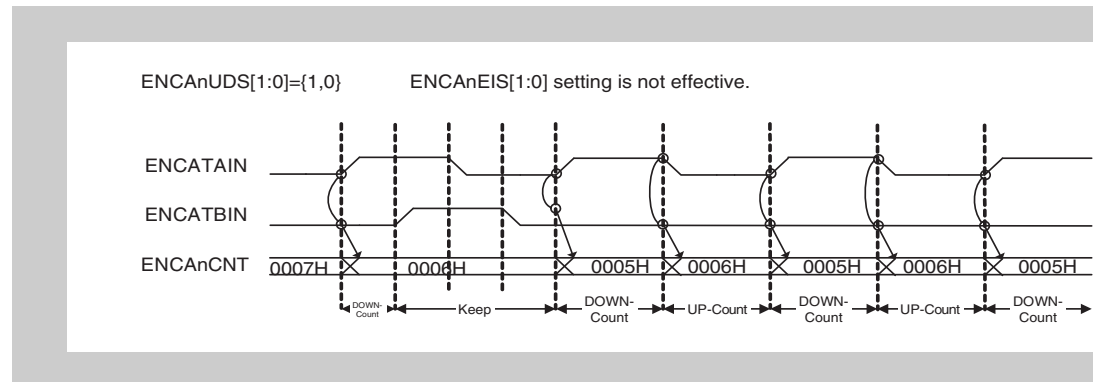

Count Operation when ENCAEIS1 and ENCAEIS0 = {0, 1}

When ENCAEIS1 and ENCAEIS0 = {1, 0}

ENCAnUDS1	ENCAnUDS0	Operation description		
		ENCATAIN input	ENCTBIN input	Count operation
1	0	Rising edge	Low level	Down
		Rising edge	Falling edge	
		Falling edge	Low level	Up
		Falling edge	Falling edge	
		Low level	Rising edge	Hold
		Rising edge	Rising edge	
		High level	Rising edge	
		Falling edge	Rising edge	
		Low level	Falling edge	
		Rising edge	High level	
		High level	Falling edge	
		Falling edge	High level	

Valid edge specification for ENCATAIN and ENCTBIN (settings of ENCAnEIS1 and ENCAnEIS0) is invalid.

The following timing chart shows the count operation when ENCAnUDS1 and ENCAnUDS0 = {1, 0}.

Count Operation when ENCAnUDS1 and ENCAnUDS0 = {1, 0}

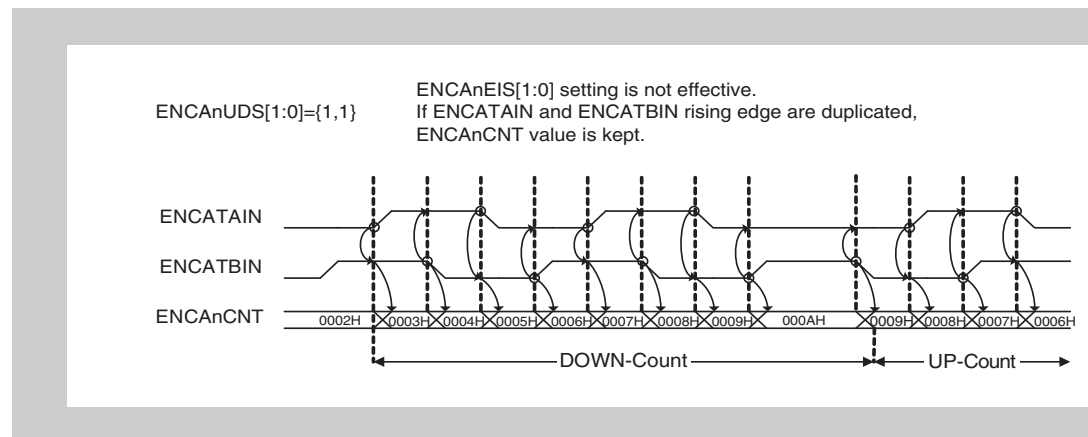

When ENCAnUDS1 and ENCAnUDS0 = {1, 1}

ENCAnUDS1	ENCAnUDS0	Operation description		
		ENCATAIN input	ENCTBIN input	Count operation
1	1	Low level	Falling edge	Down
		Rising edge	Low level	
		High level	Rising edge	
		Falling edge	High level	
		Rising edge	High level	Up
		High level	Falling edge	
		Falling edge	Low level	
		Low level	Rising edge	
		Simultaneous input		

Valid edge specification for ENCATAIN and ENCTBIN (settings of ENCAnEIS1 and ENCAnEIS0) is invalid.

The count value is held when the valid edges of ENCATAIN and ENCTBIN overlap.

The following timing chart shows the count operation when ENCAnUDS1 and ENCAnUDS0 = {1, 1}.

Count Operation when ENCAnUDS1 and ENCAnUDS0 = {1, 1}

Timer counter clear control by encoder input

The timer counter is cleared to 0000H by phase Z encoder input (ENCATZIN).

Two types of clearing methods can be selected by controlling the ENCAnSCE, ENCAnZCL, ENCAnBCL, ENCAnACL, ENCAnECS1, and ENCAnECS0 bits of the ENCAnIOC1 register.

Clearing Method	ENCAnSCE	ENCAnZCL	ENCAnBCL	ENCAnACL	ENCAnECS1, ENCAAnECS0
(1)	0	Invalid	Invalid	Invalid	Valid
(2)	1	Valid	Valid	Valid	Invalid

Clearing method when ENCAAnSCE = 0

Upon detection of the valid edge of ENCAATZIN, the timer counter is cleared to 0000_H in synchronization with the operation clock.

The valid edge of ENCAATZIN is specified by the setting of the ENCAAnECS1 and ENCAAnECS0 bits.

The settings of the ENCAAnZCL, ENCAAnBCL, and ENCAAnACL bits are invalid.

A clear interrupt signal (ENCAATIEC) is output simultaneously with timer counter clearing.

Clearing method when ENCAAnSCE = 1

The clear levels of the ENCAATZIN, ENCAATBIN, ENCAATAIN inputs are detected according to the settings of the ENCAAnZCL, ENCAAnBCL, and ENCAAnACL bits, and the timer counter is cleared to 0000_H in synchronization with the operating clock.

The settings of the ENCAAnECS1 and ENCAAnECS0 bits are invalid.

An encoder clear interrupt signal (ENCAATIEC) is output simultaneously with timer counter clearing.

The clearing conditions of the timer counter according to the ENCAAnZCL, ENCAAnBCL, and ENCAAnACL settings are listed in the table below.

Counter Clear Condition Setting			Encoder Input Level		
ENCAnZCL	ENCAnBCL	ENCAnACL	ENCAATZIN	ENCAATBIN	ENCAATAIN
0	0	0	Low	Low	Low
0	0	1	Low	Low	High
0	1	0	Low	High	Low
0	1	1	Low	High	High
1	0	0	High	Low	Low
1	0	1	High	Low	High
1	1	0	High	High	Low
1	1	1	High	High	High

Functions of ENCAAnCCR0

Compare function

When ENCAAnCRM0 = 0, the ENCAAnCCR0 register functions as a dedicated compare register.

Upon compare match between the value of the timer counter and the ENCAAnCCR0 setting value, a compare 0 match interrupt (ENCAATINT0) is output.

When $ENCA_nECM0 = 1$, the timer counter is cleared to 0000_H in synchronization with the operating clock upon compare match if the next count operation is up-count.

ENCA _n CCR0 function	Compare match clear control	Next count operation	Timer counter clearing upon compare match with ENCA _n CCR0
ENCA _n CRM0	ENCA _n ECM0		
0 (Compare)	0	Up-count	Does not clear (continues count operation).
		Down-count	
	1	Up-count	Clears timer counter to 0000_H .
		Down-count	Does not clear (continues count operation).

When $ENCA_nLD = 1$

Upon occurrence of an underflow, the setting value of the ENCA_nCCR0 register is loaded to the timer counter.

An underflow interrupt (ENCATIUD) is output.

Capture function

When $ENCA_nCRM0 = 1$, the ENCA_nCCR0 register functions as a dedicated capture register.

Upon valid edge detection of the capture trigger input 0 (ENCATTIN0), the value of the timer counter is stored into ENCA_nCCR0.

A capture 0 interrupt (ENCATINT0) is output during capture operation.

Functions of ENCA_nCCR1

Compare function

When $ENCA_nCRM1 = 0$, the ENCA_nCCR1 register functions as a dedicated compare register.

Upon compare match between the value of the timer counter and the ENCA_nCCR1 setting value, a compare 1 match interrupt (ENCATINT1) is output.

When $ENCA_nECM1 = 1$, the timer counter is cleared to 0000_H in synchronization with the operating clock upon compare match if the next count operation is down-count.

ENCA _n CCR1 function	Compare match clear control	Next count operation	Timer counter clearing upon compare match with ENCA _n CCR1
ENCA _n CRM1	ENCA _n ECM1		
0 (Compare)	0	Up-count	Does not clear (continues count operation).
		Down-count	
	1	Up-count	Does not clear (continues count operation).
		Down-count	Clears timer counter to 0000_H .

Compare match interrupt detection mask function

When ENCAN_{CME} = 1, the compare 1 match interrupt detection mask function is enabled. In this state, the compare 1 match interrupt is output upon the first match of the value of the timer counter and the ENCAN_{CCR1} setting value, and interrupts are then masked for the second and subsequent compare matches.

When ENCAN_{MCS} = 0, the compare 1 match interrupt detection mask function is disabled by a write operation to the ENCAN_{CCR1} register.

When ENCAN_{MCS} = 1, the compare 1 match interrupt detection mask function is disabled by a timer counter clear operation accompanying phase Z or by a timer counter clear operation upon match between the ENCAN_{CCR0} register value and the timer counter value.

When ENCAN_{MCS} = 1 and ENCAN_{LDE} = 1, the compare 1 match interrupt detection mask function is disabled by a loading operation of the ENCAN_{CCR0} register to the timer counter upon underflow detection.

Setting ENCAN_{ECM} to "1" is prohibited when enabling the compare 1 match interrupt detection mask function.

ENCAN _{CRM1}	Compare 1 match interrupt mask	Interrupt mask cancel trigger		Compare 1 match interrupt output upon compare match with ENCAN _{CCR1}
		ENCAN _{CME}	ENCAN _{MCS}	
0 (Compare)	0 (Mask function disabled)	– (Setting invalid)	–	Outputs compare 1 match interrupt upon each compare match.
	1 (Mask function enabled)	0 (Write operation to ENCAN _{CCR1})	1 (Timer counter clear operation)	Occurred (Loading of ENCAN _{CCR0} to timer counter)

Capture function

When ENCAN_{CRM1} = 1, the ENCAN_{CCR1} register functions as a dedicated capture register.

The operations for each of the ENCAN_{CTS} settings are shown in the table below.

ENCA _n CCR1 function	Capture trigger selection	Capture trigger signal	Timer counter clearing	Interrupt occurrence
ENCA _n CRM1	ENCA _n CTS			
1 (Capture)	0	Capture trigger 1 input (ENCATTIN1)	Does not clear timer counter.	(1) Capture 1 interrupt (ENCATINT1)
	1	Encoder clear input accompanying phase Z (ENCATZIN)	Clears timer counter.	(1) Capture 1 interrupt (ENCATINT1) (2) Encoder clear interrupt (ENCATIEC)

Timer counter clearing upon compare register match

Timer counter clearing upon compare match between the value of the timer counter and the ENCA_nCCR0/1 setting value, according to the settings of the ENCA_nECM1 and ENCA_nECM0 bits, is detailed in the following table.

ENCA _n ECM1 and ENCA _n ECM0	Next count operation	Timer counter clearing upon compare match with ENCA _n CCR1	Timer counter clearing upon compare match with ENCA _n CCR0
00	Up-count	Does not clear (continues count operation).	Does not clear (continues count operation).
	Down-count	Does not clear (continues count operation).	Does not clear (continues count operation).
01	Up-count	Does not clear (continues count operation).	Clears timer counter to 0000 _H .
	Down-count	Does not clear (continues count operation).	Does not clear (continues count operation).
10	Up-count	Does not clear (continues count operation).	Does not clear (continues count operation).
	Down-count	Clears timer counter to 0000 _H .	Does not clear (continues count operation).
11	Up-count	Does not clear (continues count operation).	Clears timer counter to 0000 _H .
	Down-count	Clears timer counter to 0000 _H .	Does not clear (continues count operation).

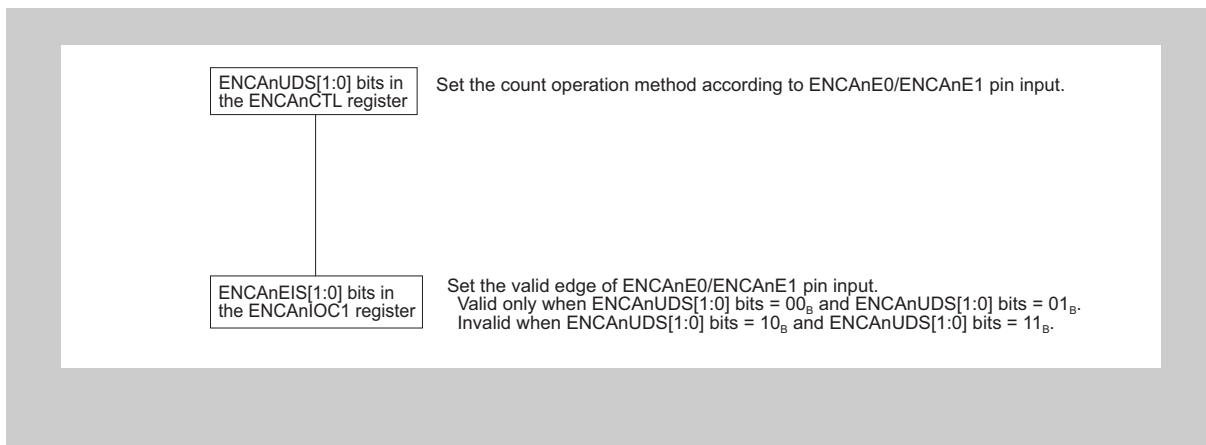

Setting Sequences

Encoder timer setting procedure

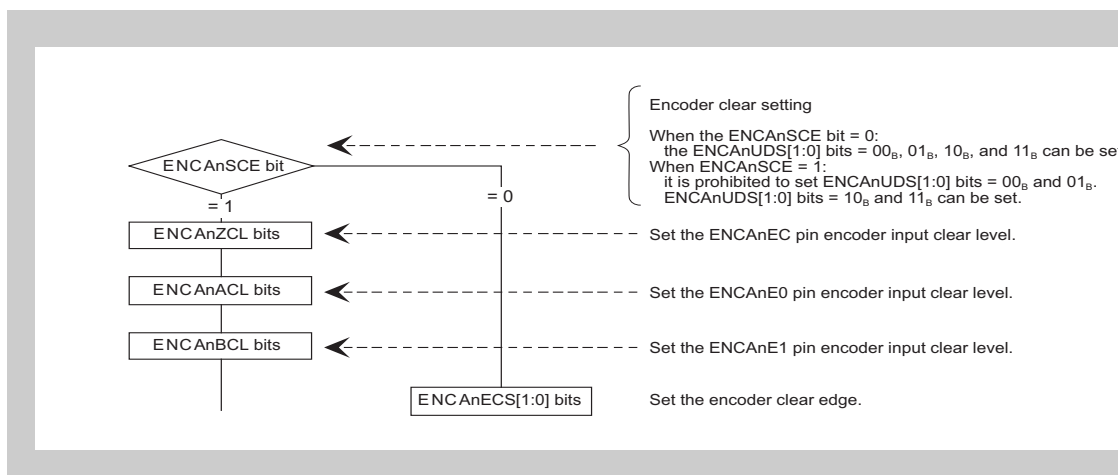

The encoder timer setting procedure is described below.

	Action	Setting status
Initial Setting		Power-off status (Writing to each register is disabled)
	Reset release	Power-on status, ENCA operation stopped status. (Writing to each register is enabled)
ENCA Initial Settings	Perform the following initial settings. <ul style="list-style-type: none"> Setting for counter Setting for counter clear Setting for ENCA nCCR0 register Setting for ENCA nCCR1 register 	This is the count operation stopped status. The value of the ENCA nTE bit indicating the operating status is 0.
	Perform the counter initial value settings. <ul style="list-style-type: none"> Set any 16-bit value to ENCA nCNT register. (When, after setting this register, the ENCA nTS bit is set to "1", the counter operation starts from the set count value.) 	The set value is set as the initial value of the counter register.
Operation Start	Perform the counter operation start setting. <ul style="list-style-type: none"> Set the ENCA nTS bit to "1". 	This is the counter operation starts status. The value of the ENCA nTE bit indicating the operating status is 1, and the count clock is supplied to the internal circuit.
Operating	Only those registers whose setting can be changed during operation can be rewritten. <ul style="list-style-type: none"> ENCA nCCR0 register setting can be changed. ENCA nCCR1 register setting can be changed. ENCA nLOC0 register setting can be changed. 	The count operation set with the initial setting is performed, and up/down counting is performed according to ENCA nAIN and ENCA nBIN.
Operation Stop	Perform the counter operation stop setting during operation. <ul style="list-style-type: none"> Set the ENCA nTT bit to "1". 	This is the counter operation stopped status. The value of the ENCA nTE bit indicating the operating status is 0.
ENCA stop	Reset	This is the power-off status. The entire circuit and all the setting registers are initialized.

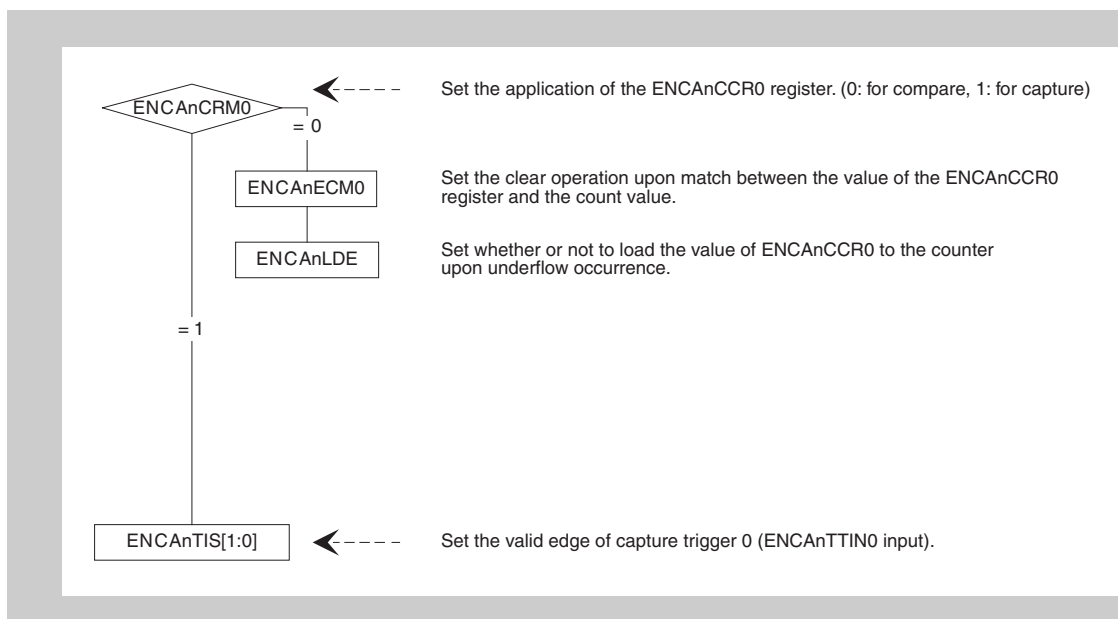

Initial setting procedure for counter

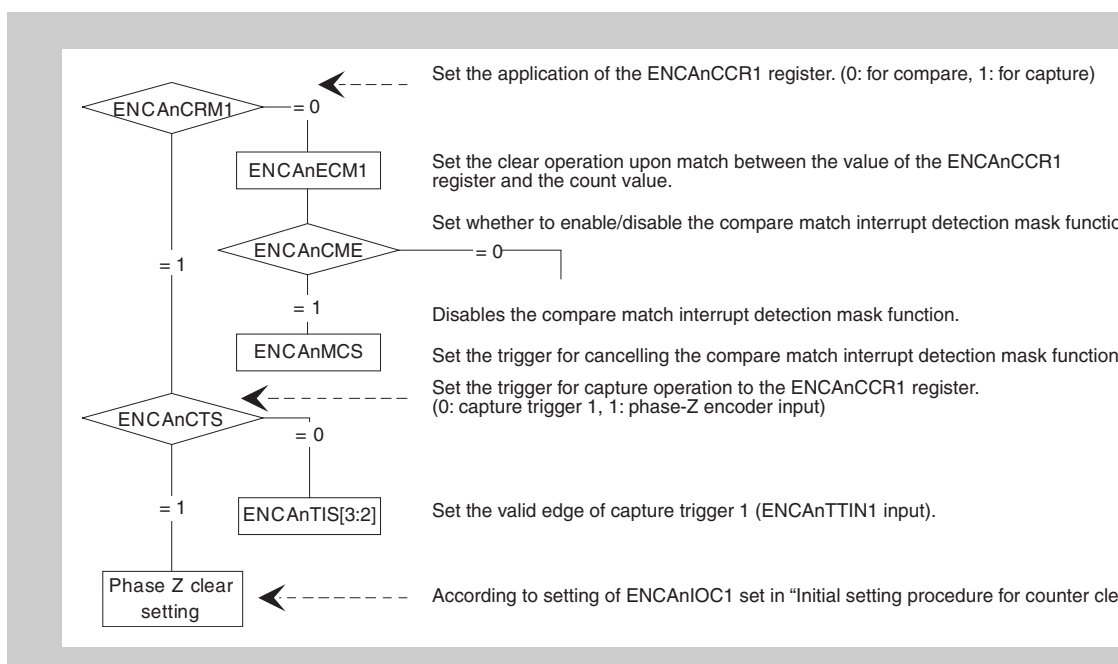

Initial setting procedure for counter clear

Setting procedure for ENCAAnCCR0 register

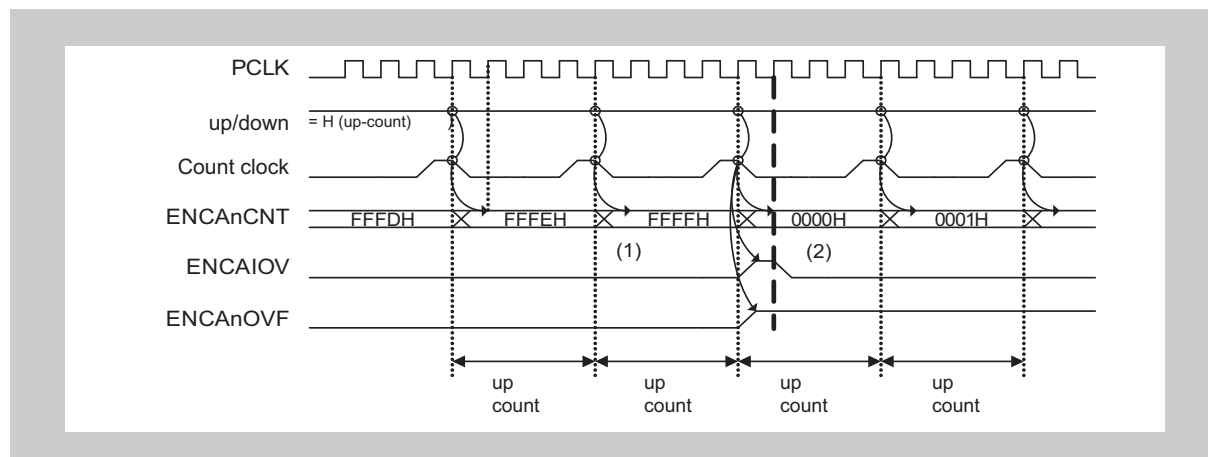

Setting procedure for ENCA_nCCR1 register

Timing Chart

Overflow Occurrence and Overflow Flag Clear Operation

The operations of overflow occurrence is described below.

Overflow Occurrence

An overflow occurs when up-counting is performed when the counter value is FFFF_H.

When the count value changes from FFFF_H to 0000_H, an overflow occurs. At the same time, an overflow interrupt is output and the overflow flag is set to 1.

The operations of overflow flag clearing is described below.

Overflow Flag Clear

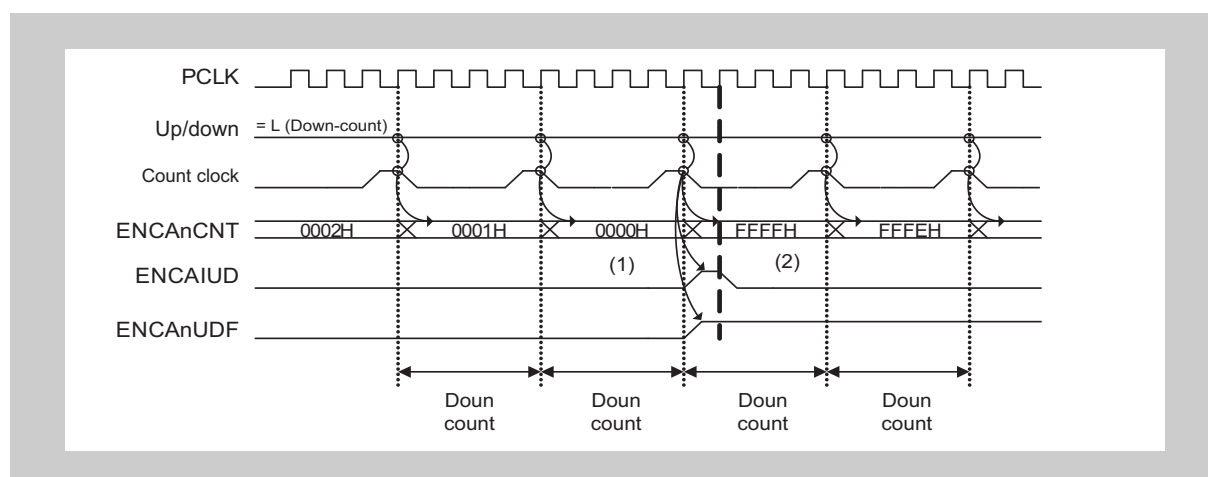

The count value is counted up from FFFE_H to FFFF_H.

When the count value changes from FFFF_H to 0000_H, an overflow occurs. At the same time, an overflow interrupt is output and the overflow flag is set to 1.

By setting the ENCAAnCLOV bit in the ENCAAnFGC register to 1 by the overflow flag clearing method, the overflow flag is cleared to 0. The overflow flag is also cleared by setting the ENCAAnTS bit in the ENCAAnTS register to 1 when the ENCAAnTE bit in the ENCAAnTE register is 0, or setting the input signal of ENCAAnTSST (simultaneous start trigger input) to "High".

Underflow Occurrence and Underflow Flag Clear Operation

The operations of underflow occurrence is described below.

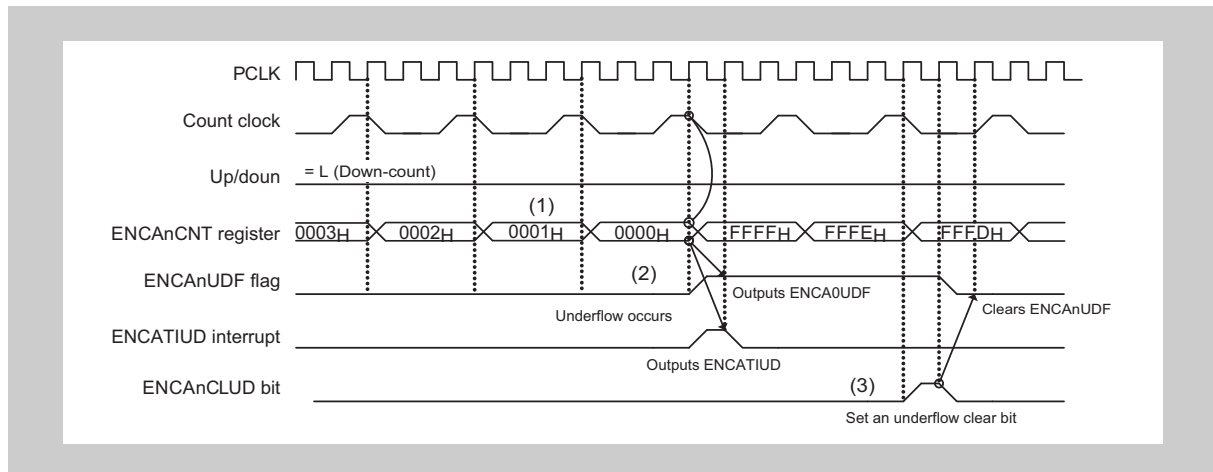

Underflow Occurrence

An underflow occurs when down-counting is performed when the counter value is 0000_H.

When the count value changes from 0000_H to FFFF_H, an underflow occurs. At the same time, an underflow interrupt is output and the underflow flag is set to 1.

The operations of underflow flag clearing is described below

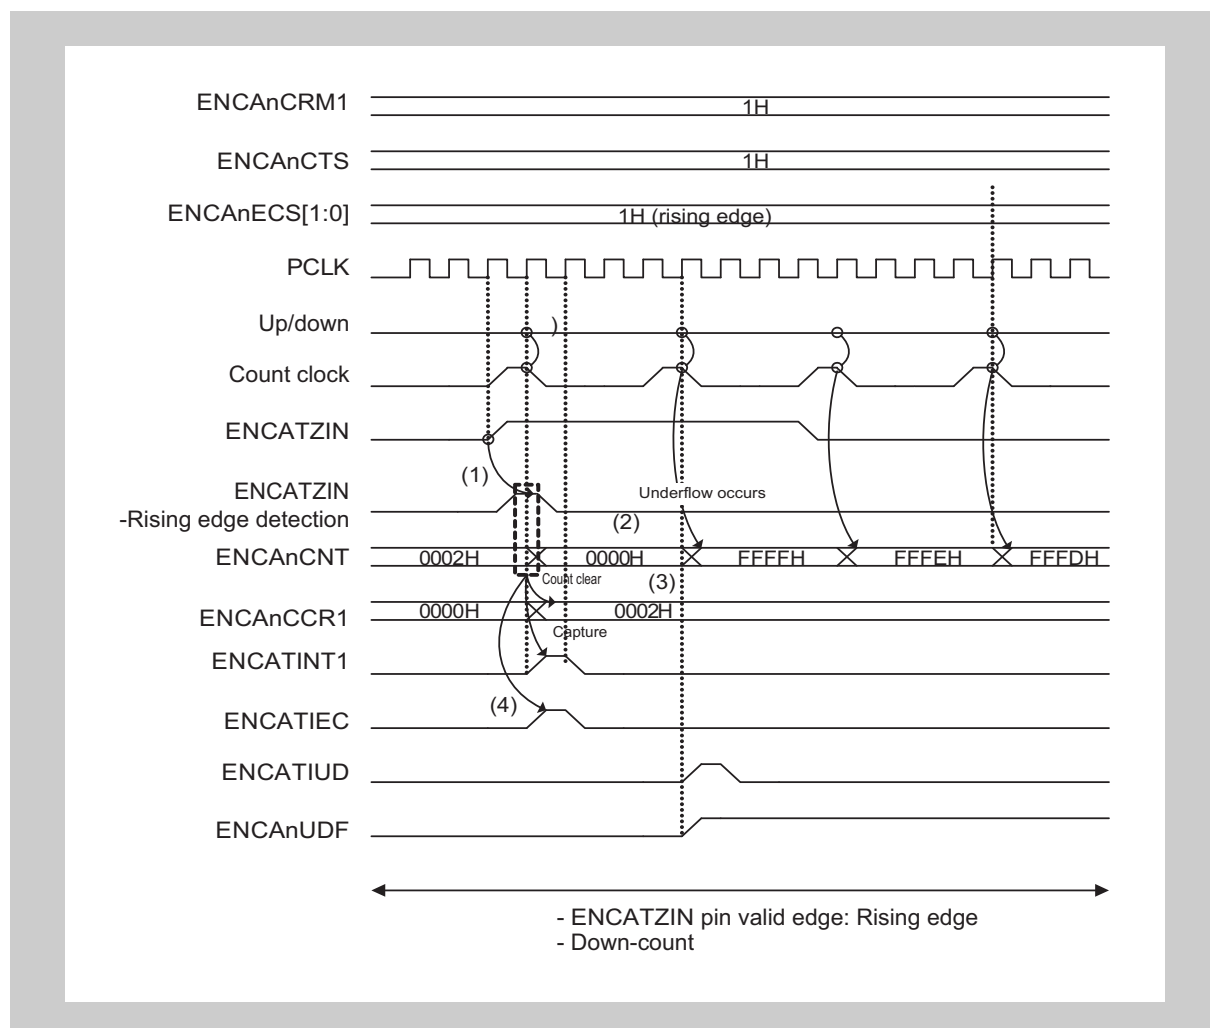

Underflow Flag Clear

The count value is counted down from 0001_H to 0000_H

When the count value changes from 0000_H to FFFF_H, an underflow occurs. At the same time, an underflow interrupt is output and the underflow flag is set to 1.

By setting the ENCAAnCLUD bit in the ENCAAnFGC register to 1 by the underflow flag clearing method, the underflow flag is cleared to 0. The underflow flag is also cleared by setting the ENCAAnTS bit in the ENCAAnTS register to 1 when the ENCAAnTE bit in the ENCAAnTE register is 0, or by setting the input signal of ENCAAnTSST (simultaneous start trigger) to "High".

Capture Operation by phase Z

Timing Chart of Capture Operation by phase Z

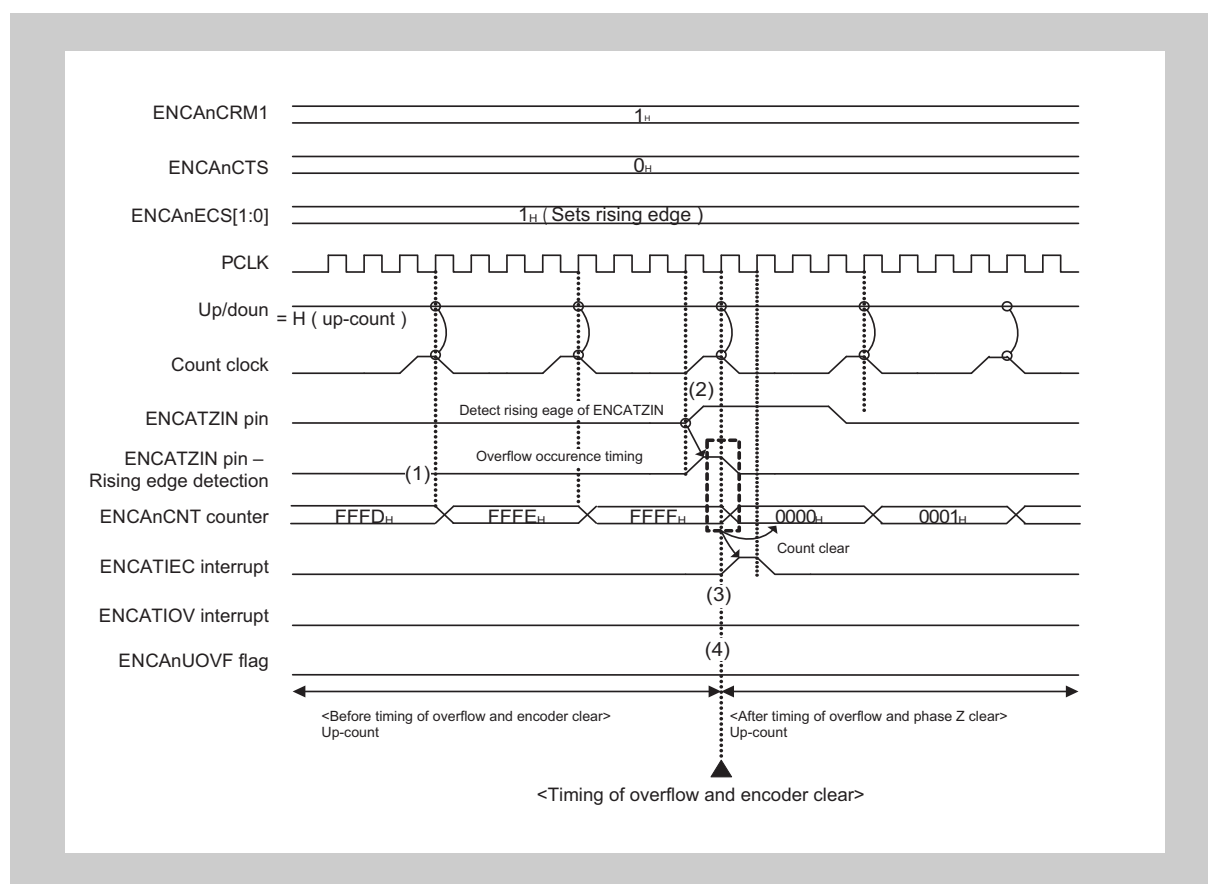

Capture operation is performed by the rising edge of the ENCATZIN pin input trigger (The rising edge: ENCAAnECS1 and ENCAAnECS0 = "01").

Clearing is performed by the phase Z and the count value is set to 0000_H.

The counter value (0002_H) is captured in the ENCAAnCCR1 register by the rising edge of the ENCAZIN pin input

At the same time, a clear interrupt (ENCATIEC) and capture interrupt (ENCATINT1) due to the phase Z are output.

Conflict between Overflow Occurrence and Clear Operation by phase Z Input

Conflict between Overflow Occurrence and Clear Operation by phase Z Input

An up-count from $FFFD_H$ is continuously performed.

When an overflow occurs if the count value is $FFFF_H$, and the rising edge of ENCATZIN is detected simultaneously, clear operation by the phase Z input is performed. The counter value is cleared to 0000_H .

When the counter value is cleared by the phase Z input, a clear interrupt (ENCATIEC) by phase Z input is output simultaneously. Because a clear operation by the phase Z input is performed simultaneously with the overflow occurrence, an overflow interrupt is not output (An overflow does not occur. Clear operation is performed by the phase Z input).

Because an overflow does not occur as is the case with step 3, the overflow flag is not set.

Conflict between Underflow Occurrence and Clear Operation by phase Z Input

Conflict between Underflow Occurrence and Clear Operation by phase Z Input

A down-count from 0002_H is continuously performed.

When an underflow occurs if the count value is 0000_H, and the rising edge of ENCATZIN is detected simultaneously, clear operation by the phase Z input is performed. Even if the next clock signal is input during clear operation, the counter value remains at 0000_H.

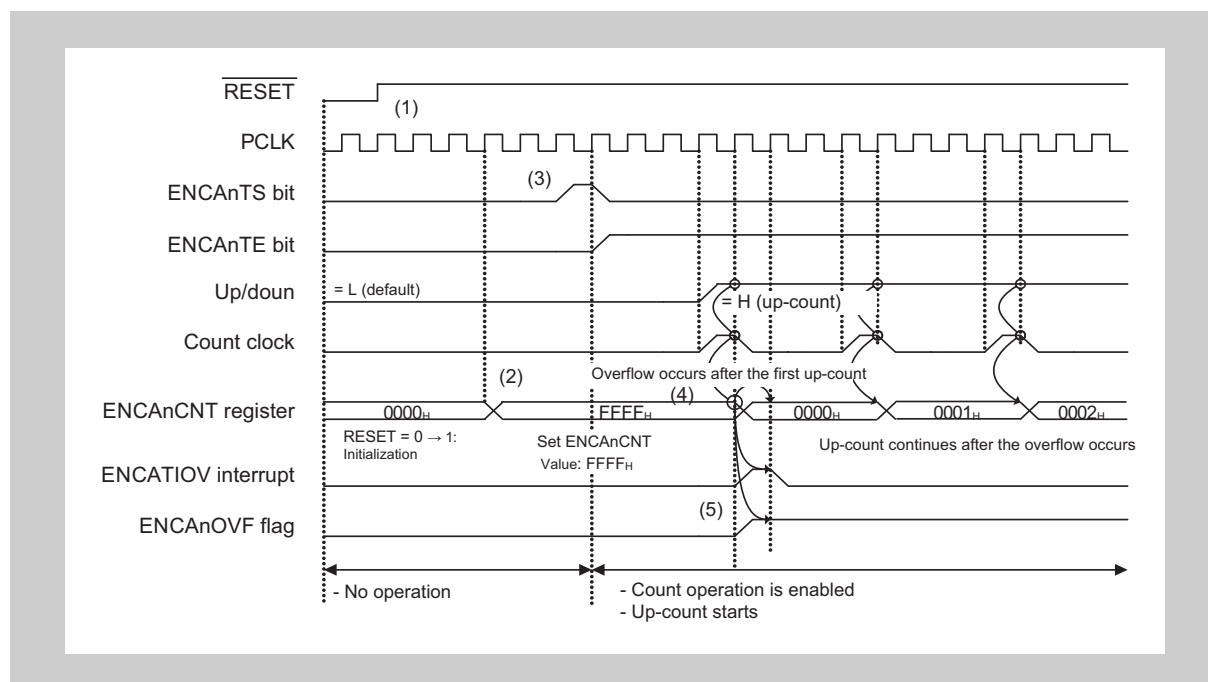

When the counter value is cleared by the phase Z input, a phase Z clear interrupt (ENCATIEC) is output simultaneously. Because a clear operation by the phase Z input is performed simultaneously with the underflow occurrence, an underflow interrupt is not output (An underflow does not occur. Clear operation is performed by the phase Z input).

Because an underflow does not occur as is the case with step 3, the underflow flag is not set.

When a further down-count is performed after the counter value changes to 0000_H by clear operation by the phase Z input, the counter value changes from 0000_H to FFFF_H, and an underflow occurs.

When an underflow occurs, an underflow interrupt (ENCATIUD) is output, and the underflow flag (ENCAAnUDF) is set.

Overflow Operation Immediately after Startup

Overflow Operation Immediately after Startup

When the $\overline{\text{RESET}}$ value changes from “0” to “1”, the status is changes from “reset” to “reset release”.

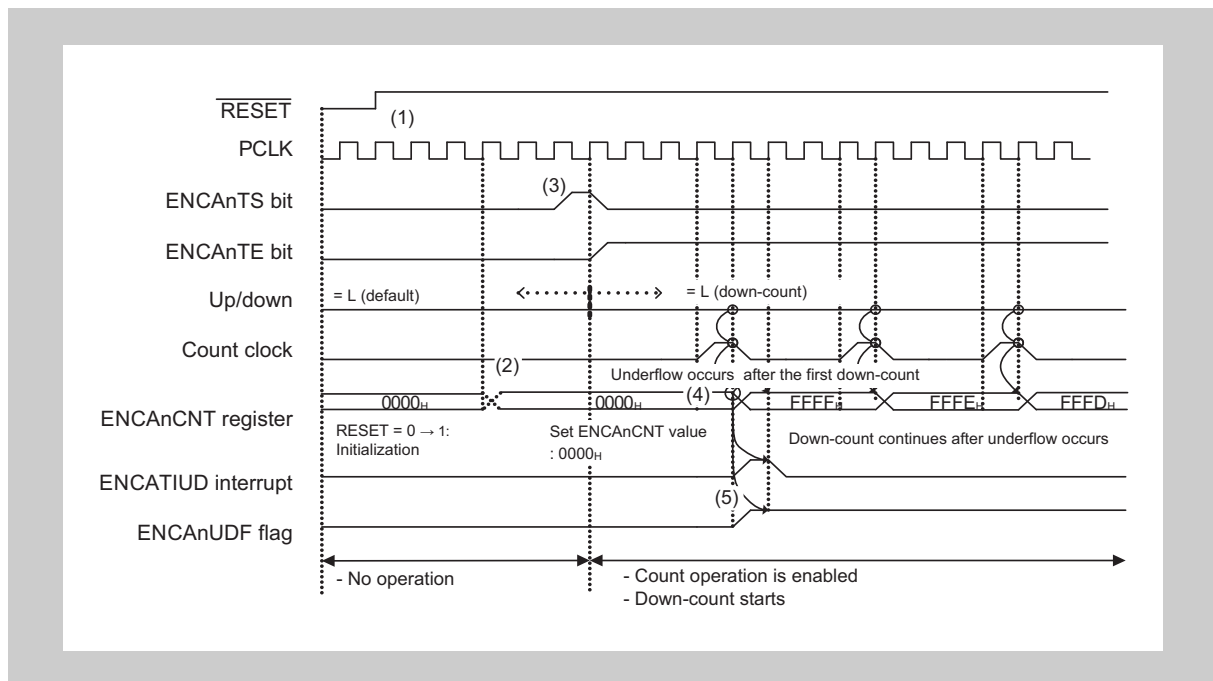

The timer counter is set to FFFF_H as the initial value.

ENCAAnTS is set to “1”, and operation starts. ENCAAnTE changes to “1”, which indicates that operation is enabled.

When an up-count is performed from FFFF_H which is the initially set count value, the counter value changes from FFFF_H to 0000_H , and an overflow occurs immediately after operation starts.

At the same time, by an overflow occurrence immediately after operation starts, an overflow interrupt (ENCAAnOVF) is output, and the overflow flag (ENCAAnOVF) is set

Underflow Operation Immediately after Startup

Underflow Operation Immediately after Startup

When the $\overline{\text{RESET}}$ value changes from "0" to "1", the status is changes from "reset" to "reset release".

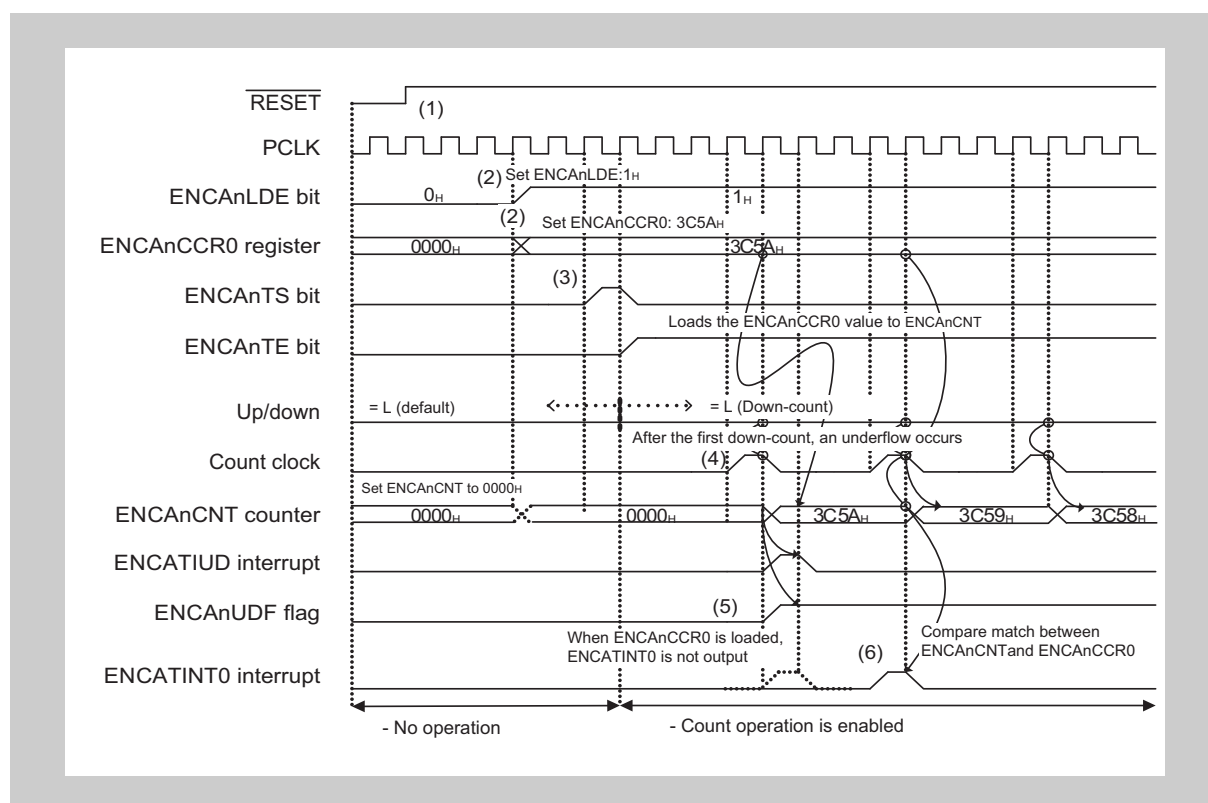

The timer counter is set to 0000_H as the initial value.

ENCA_nTS is set to "1", and operation starts. ENCA_nTE changes to "1", which indicates that operation is enabled.

When a down-count is performed from 0000_H which is the initially set count value, the counter value changes from 0000_H to FFFF_H, and an underflow occurs immediately after operation starts.

At the same time, by an underflow occurrence immediately after operation starts, an underflow interrupt (ENCA_nTIUD) is output, and the underflow flag (ENCA_nUDF) is set.

Using the ENCA_nLDE Function Immediately after Startup

Using the ENCA nLDE Function Immediately after Startup

When the $\overline{\text{RESET}}$ value changes from “0” to “1”, the status is changes from “reset” to “reset release”.

The load enable bit (ENCA nLDE) is set to “1”, capture/compare register 0 (ENCA nCCR0) is set to 3C5AH, and the timer counter is set to the initial value 0000H.

ENCA nTS is set to “1”, and operation starts. ENCA nTE changes to “1”, which indicates that operation is enabled.

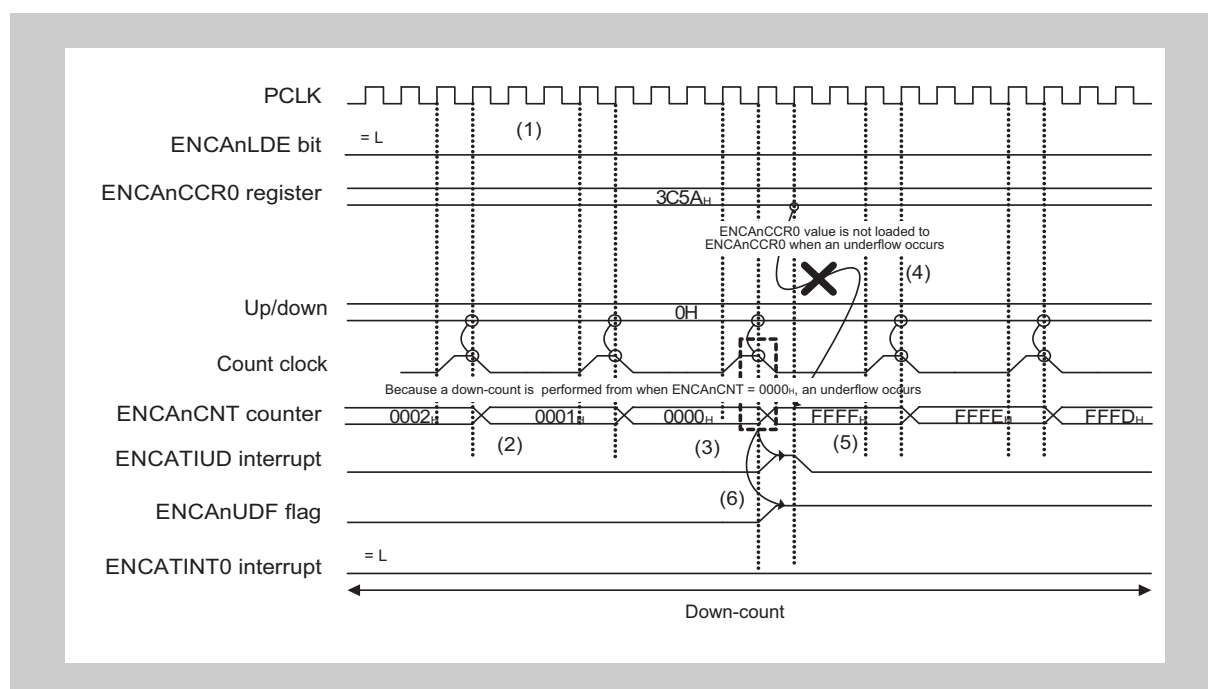

When a down-count is performed from 0000H which is the initially set count value, an underflow occurs immediately after operation starts. Because ENCA nLDE is set to “1”, the ENCA nCCR0 value, 3C5AH, is loaded to the timer counter (ENCA nTINT0 is not output during loading).

At the same time, by an underflow occurrence immediately after operation starts, an underflow interrupt (ENCA nTIUD) is output, and the underflow flag (ENCA nUDF) is set (After an underflow occurs, down-count operation from the loaded value (3C5AH) continues).

After the ENCA nCCR0 value is loaded to ENCA nCNT, a match with ENCA nCCR0 is detected, and ENCA nTINT0 is output.

ENCA nLDE Function (Loading Count Value)

<When ENCA nLDE = 0>

ENCA nLDE Function (when ENCA nLDE = 0)

ENCA nLDE is set to "0" (even if an underflow occurs, the ENCA nCCR0 value is not loaded).

A down-count is performed: $0002_H \rightarrow 0001_H \rightarrow 0000_H$

When a further down-count is performed after the counter value changes to 0000_H , an underflow occurs.

Because ENCA nLDE is set to "0", the setting value of the ENCA nCCR0 register is not loaded to the counter even if an underflow occurs.

Operation changes to underflow operation (counter value: $0000_H \rightarrow FFFF_H$).

An underflow interrupt (ENCA nTIUD) is output, and the underflow flag (ENCA nUDF) is set.

<When ENCA nLDE = 1>

ENCAAnLDE Function (when ENCAAnLDE = 1)

ENCAAnLDE is set to "1" (if an underflow occurs, the ENCAAnCCR0 value is loaded to the counter).

A down-count is performed: 0002_H → 0001_H → 0000_H.

When a further down-count is performed after the counter value changes to 0000_H, an underflow occurs.

An underflow interrupt is output, and the underflow flag is set.

Because ENCAAnLDE is set to "1", the setting value of the ENCAAnCCR0 register is loaded to the counter if an underflow occurs. ENCAAnCNT is set to 3C5A_H.

After the ENCAAnCCR0 value is set to ENCAAnCNT, if the ENCAAnCNT value matches the ENCAAnCCR0 value on a count clock, a compare match interrupt (ENCAAnTINT0) is output.

Conflict between ENCAAnLDE Function (Loading Counter Value) and Rewrite of ENCAAnCCR0 Register

Conflict between ENCAAnLDE Function and Rewrite Of ENCAAnCCR0 Register

The ENCAAnCCR0 register is currently set to 5555_H.

ENCAAnLDE is currently set to "1".

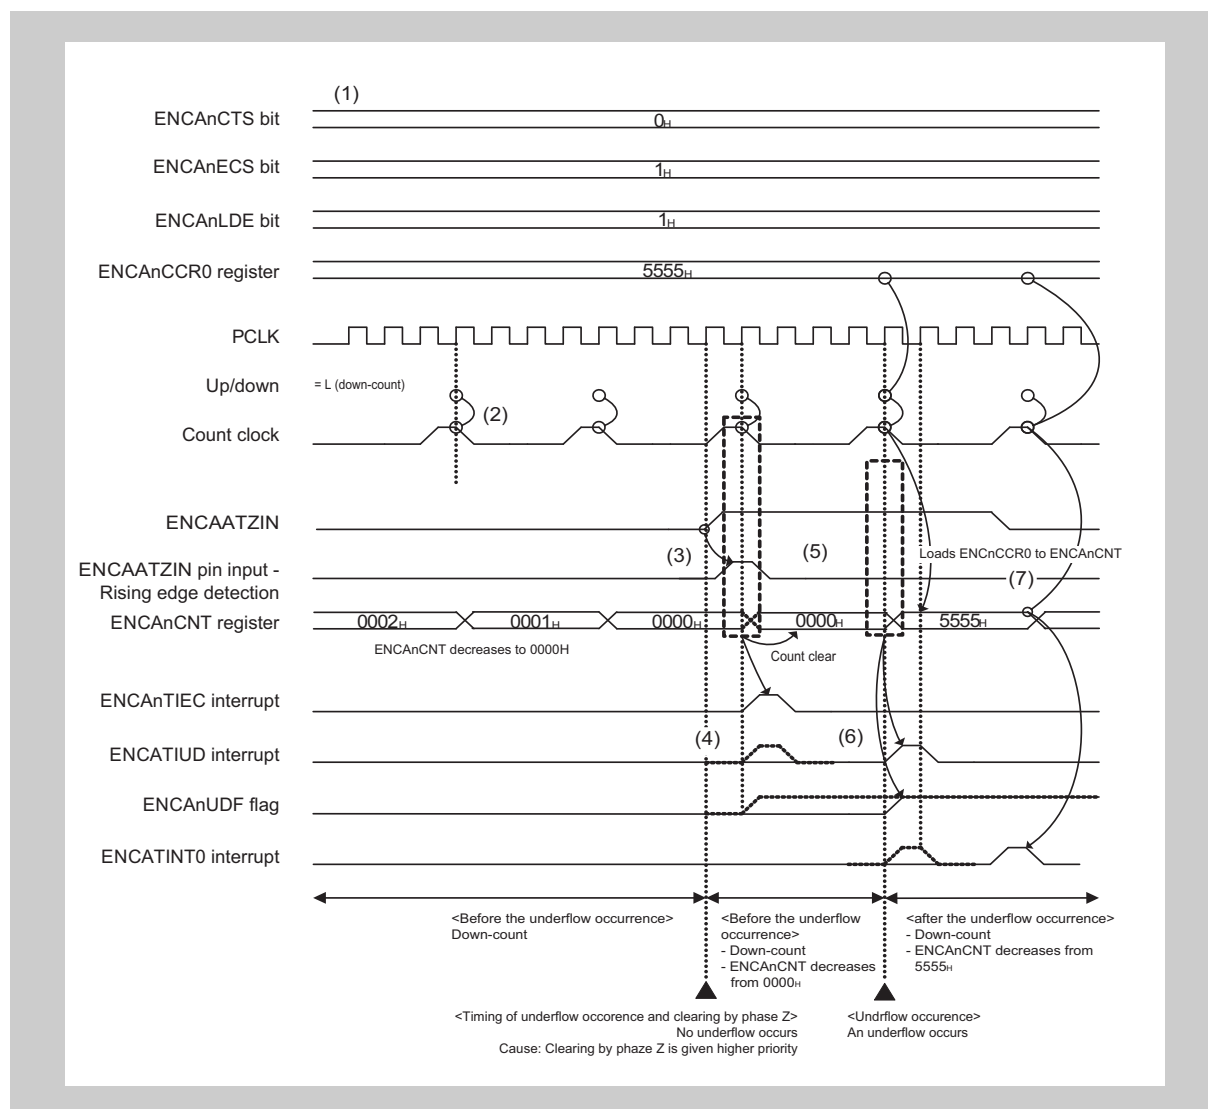

A down-count is performed (0002_H → 0001_H → 0000_H), and an underflow occurs.

An underflow interrupt (ENCAAnTIUD) is output, and the underflow flag (ENCAAnUDF) is set.

When an underflow occurs, the ENCAAnCCR0 register value is changed from 5555_H to AAAA_H.

Additionally, when an underflow occurs, the ENCAAnCCR0 value before the rewrite was performed (5555_H) is set in ENCAAnCNT.

Conflict between ENCAAnLDE Function (Loading Counter Value) and Clear Operation by Phase Z Input

Conflict between ENCAAnLDE Function (Loading Counter Value) and Clear Operation by Phase Z Input

The values are set as follows: ENCAAnCTS = 0, ENCAAnECS[1:0] = 01_B, ENCAAnLDE = 1, and ENCAAnCCR0 = 5555_H.

A down-count is performed: 0002_H → 0001_H → 0000_H

When the count value becomes 0000_H, the rising edge of ENCAAnEC pin is detected, and clear operation by the encoder clear input is performed.

Because a count clear is performed when the count value reaches 0000_H, a counter clear interrupt (ENCAAnTIEC) by the phase Z input is output. An underflow does not occur because a down-count is not performed when the count value is 0000_H. Therefore, an underflow interrupt (ENCAAnTIUD) is not output, and the underflow flag (ENCAAnUDF) is not set.

After the count value is cleared to 0000_H by clear operation by the phase Z input, a down-count is performed and an underflow occurs.

An underflow interrupt (ENCAAnTIUD) is output, and the underflow flag (ENCAAnUDF) is set.

Because ENCA_nLDE = "1", if an underflow occurs, the ENCA_nCCR0 value is loaded to ENCA_nCNT.

After the ENCA_nCCR0 value is set to ENCA_nCNT, a compare match is detected according to the count clock. If the ENCA_nCNT value matches the ENCA_nCCR0 value, a compare match interrupt (ENCATINT0) is output.

Up-count after Conflict between ENCA_nLDE Function (Loading Counter Value) and Clear Operation by the Phase Z Input

Up-count after Conflict between ENCA_nLDE Function (Loading Counter Value) and Clear Operation by Encoder Clear

The values are set as follows: ENCA_nCTS = 0, ENCA_nECS[1:0] = 01B, ENCA_nLDE = 1, and ENCA_nCCR0 = 5555_H.

A down-count is performed: 0002_H → 0001_H → 0000_H

When the count value becomes 0000_H, the rising edge of ENCATZIN pin is detected, and clear operation by the phase Z input is performed.

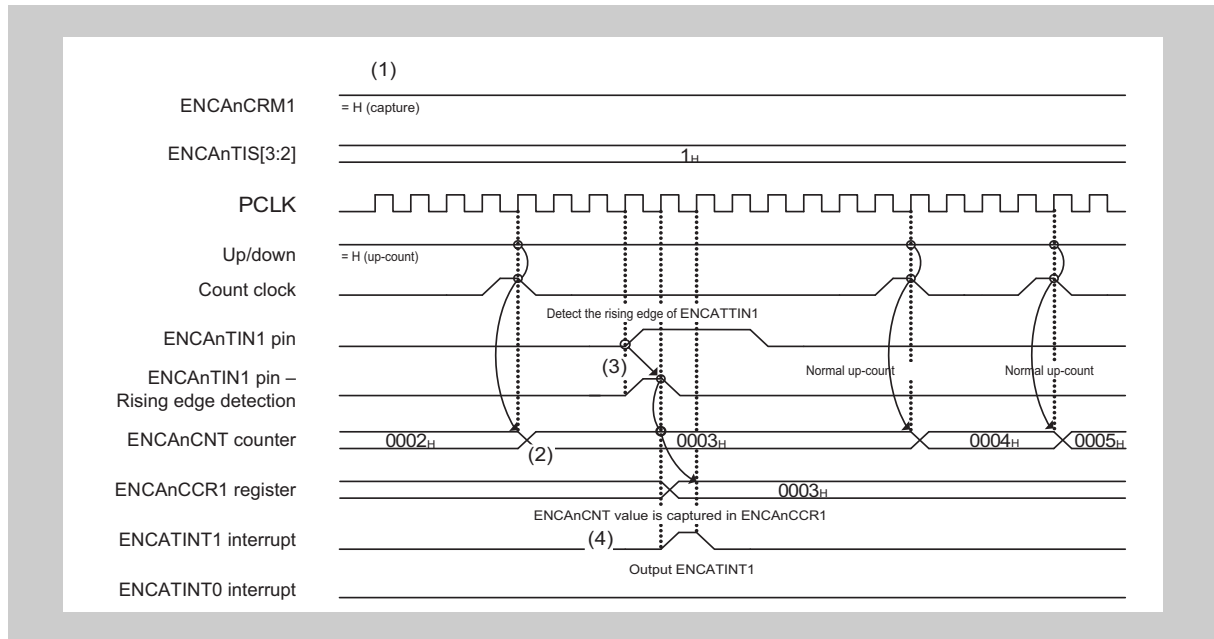

Because a count clear is performed when the count value reaches 0000_H, a counter clear interrupt (ENCATIEC) by the phase Z input is output. An underflow does not occur because a down-count is not performed when the

count value is 0000_H. Therefore, an underflow interrupt (ENCAIUD) is not output, and the underflow flag (ENCAAnUDF) is not set.

After the count value is cleared to 0000_H by clear operation by the phase Z input, an up-count is performed

An underflow interrupt (ENCATIUD) is not output, and the underflow flag (ENCAAnUDF) is not set.

Capture Operation between Count Clocks (ENCAAnCCR1)

Capture Operation between Count Clocks (ENCAAnCCR1)

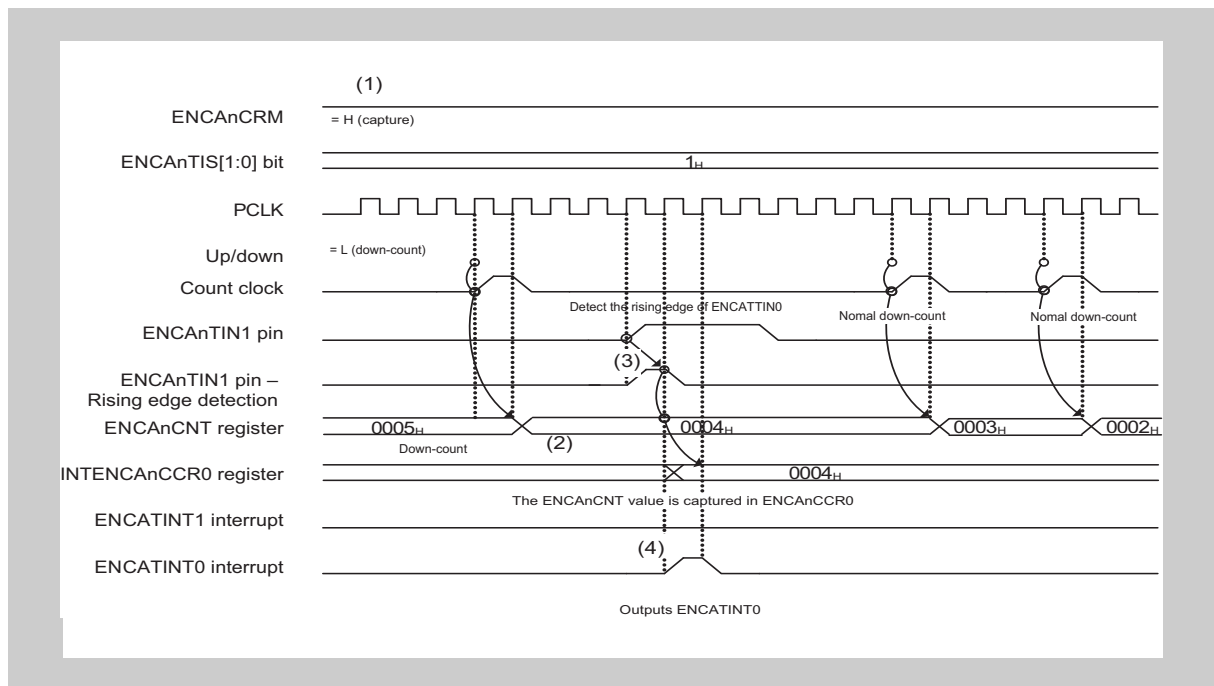

The values are set as follows: ENCAAnCRM1 = 1, and ENCAAnTIS[3:2] = 01_B.

An up-count is performed.

The rising edge of the ENCAAnTIN1 input is detected, and the count value is captured in ENCAAnCCR1.

An interrupt (ENCATINT1) corresponding to the capture to the ENCAAnCCR1 register is output.

Capture Operation between Count Clocks (ENCAAnCCR0)

Capture Operation between Count Clocks (ENCAAnCCR0)

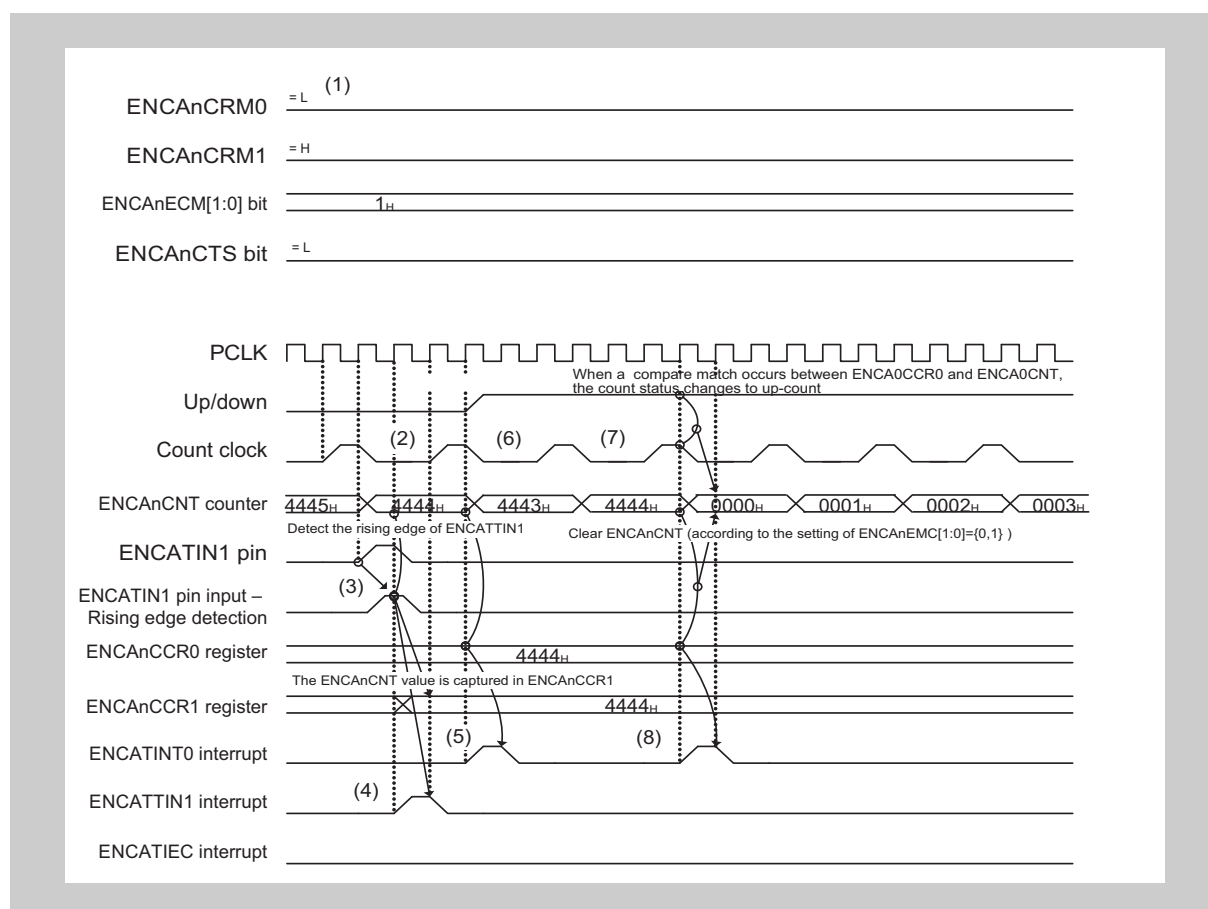

The values are set as follows: ENCAAnCRM0 = 1, and ENCAAnTIS[1:0] = 01_B.

A down-count is performed.

The rising edge of the ENCAAnTIN0 input is detected, and the count value is captured in ENCAAnCCR0.

An interrupt (ENCAAnTINT0) corresponding to the capture to the ENCAAnCCR0 register is output.

Encoder Operation when ENAnECM[1:0] = 0, 1 and ENCAAnCTS = 0

Encoder Operation when ENCA_nECM[1:0] = 0,1 and ENCA_nCTS = 0

The values are set as follows: ENCA_nCCR0 = 4444_H, ENCA_nCRM0 = 0, ENCA_nCRM1 = 1, ENCA_nECM[1:0] = 01_B, and ENCA_nCTS = 0.

A down-count is performed.

The rising edge of the ENCATTIN1 input is detected, and the ENCA_nCNT value (4444_H) is captured in the ENCA_nCCR1 register.

An interrupt signal (ENCATIEC) corresponding to the capture to the ENCA_nCCR1 register is output.

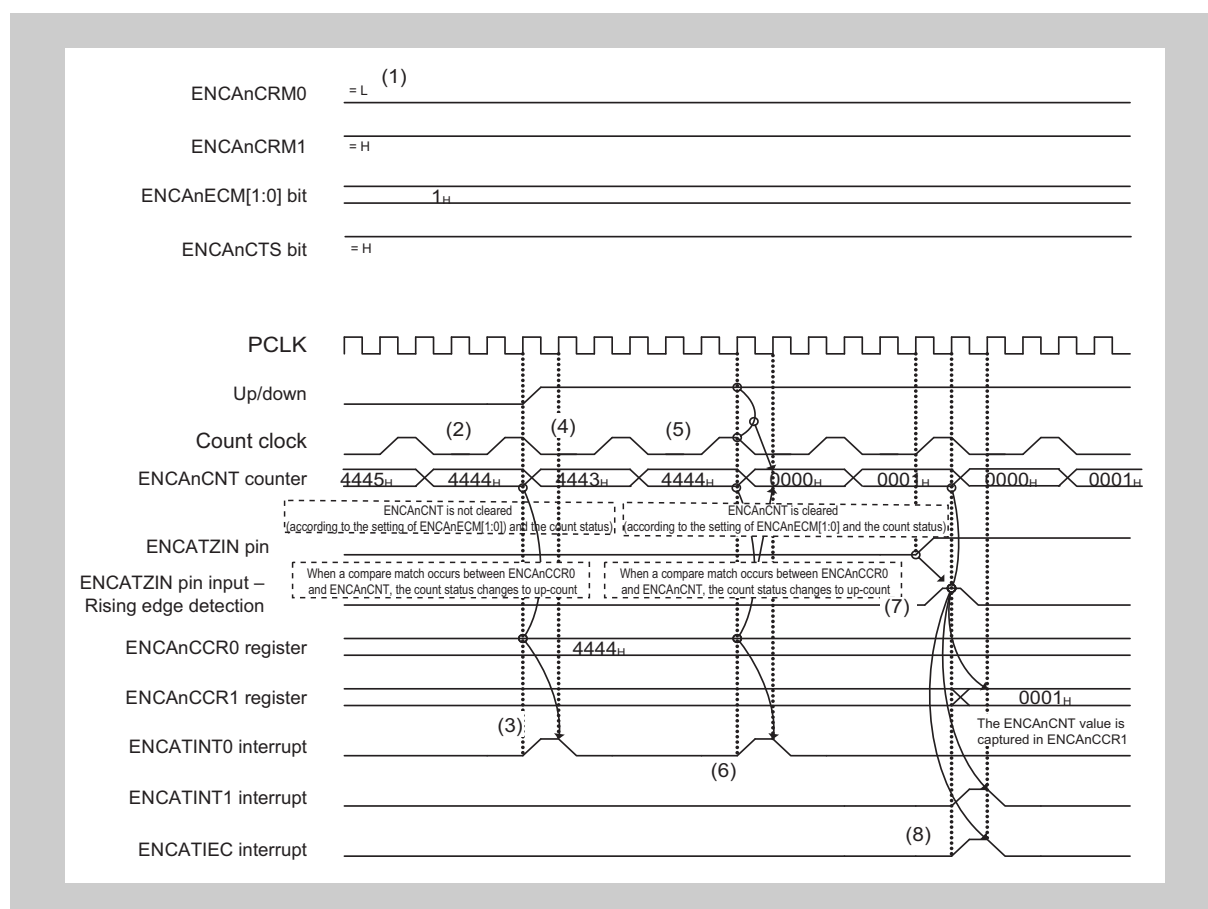

When a compare match occurs between ENCA_nCNT (counted down from 4445_H to 4444_H) and ENCA_nCCR0 (4444_H), a compare match interrupt (ENCATINT0) with ENCA_nCCR0 is output.

The count operation changes to up-count.

When ENCA_nCNT is counted up from 4443_H to 4444_H, a compare match with ENCA_nCCR0 occurs again. Because the count operation is up-count when the compare match occurs, the count value is cleared according to the setting of ENCA_nECM1 and ENCA_nECM0 (01_B), and the ENCA_nCNT value changes to 0000_H.

When ENCA_nCNT changes to 4444_H, a compare match interrupt (ENCATINT0) with ENCA_nCCR0 is output.

Encoder Operation when ENCA_nECM[1:0] = 0, 1 and ENCA_nCTS = 1

Encoder Operation when ENCAAnECM[1:0] = 0, 1 and ENCAAnCTS = 1

The values are set as follows: ENCAAnCCR0 = 4444_H, ENCAAnCRM0 = 0, ENCAAnCRM1 = 1, ENCAAnECM[1:0] = 01_B, and ENCAAnCTS = 1.

A down-count is performed.

When a compare match occurs between ENCAAnCNT (counted down from 4445_H to 4444_H) and ENCAAnCCR0 (4444_H), a compare/capture interrupt (ENCATINT0) is output.

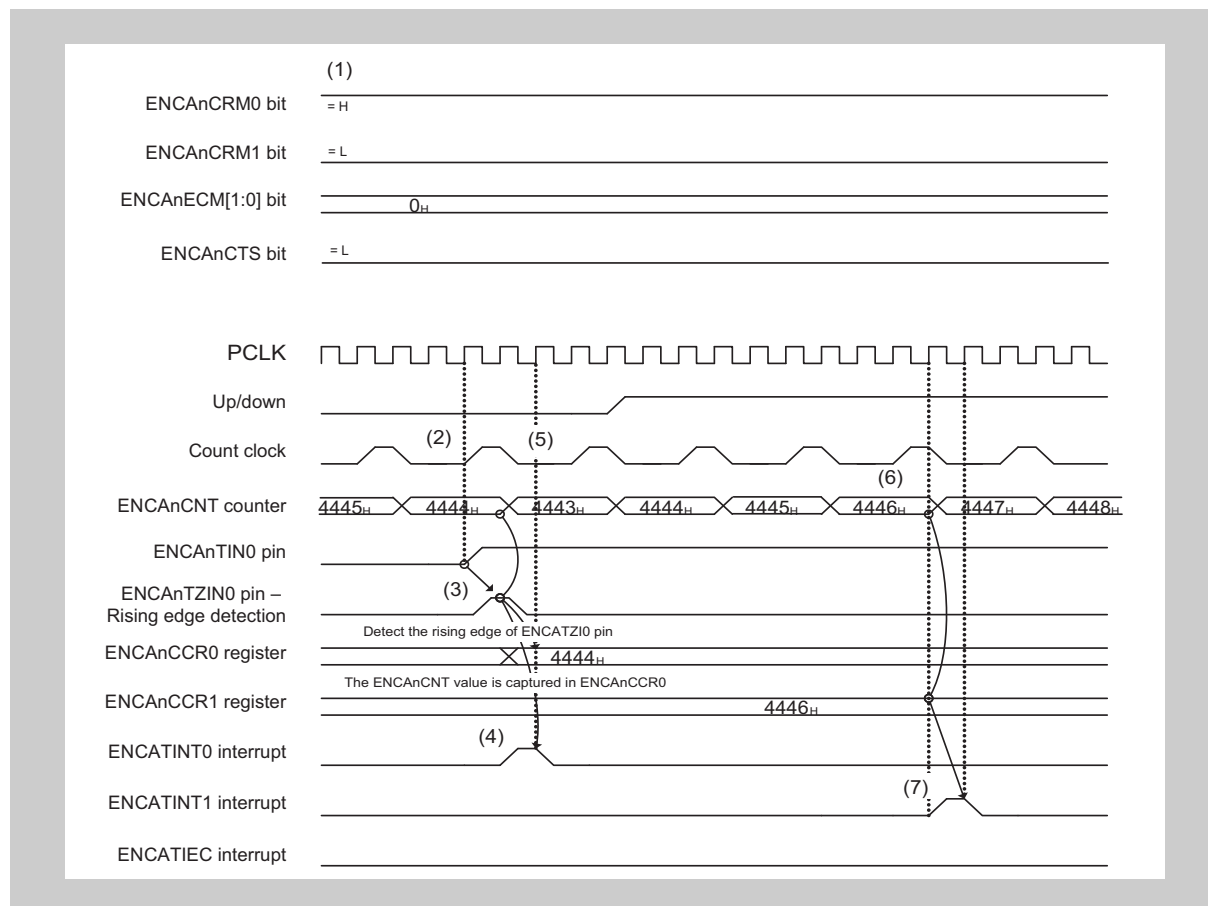

The count operation changes to up-count.

When ENCAAnCNT is counted up from 4443_H to 4444_H, a compare match with ENCAAnCCR0 occurs again. Because the count operation is up-count when the compare match occurs, the count value is cleared according to the setting of ENCAAnECM1 and ENCAAnECM0 (01_B), and the ENCAAnCNT value changes to 0000_H.

When ENCAAnCNT changes to 4444_H, a compare match interrupt (ENCATINT0) with ENCAAnCCR0 is output.

After the count value is cleared, an up-count is performed, and the count value changes to 0001_H. At this point, the ENCAAnCNT value (0001_H) is captured in ENCAAnCCR1 by detecting the rising edge of the ENCAAnEC signal, and the counter is cleared to 0000_H.

An interrupt (ENCATINT1) corresponding to the capture to the ENCAAnCCR1 register and a clear interrupt (ENCATIEC) by ENCAAnEC are output.

Encoder Operation when ENCA_nECM1-0 = 0, 0Encoder Operation when ENCA_nECM1-0 = 0, 0

The values are set as follows: ENCA_nCCR1 = 4446_H, ENCA_nCRM0 = 1, ENCA_nCRM1 = 0, ENCA_nECM[1:0] = 00_B, and ENCA_nCTS = 0.

A down-count is performed.

When the rising edge of ENCA_nTIN0 is detected, the ENCA_nCNT value (4444_H) is captured in ENCA_nCCR0.

An interrupt signal (ENCA_nTINT0) corresponding to the capture to the ENCA_nCCR0 register is output.

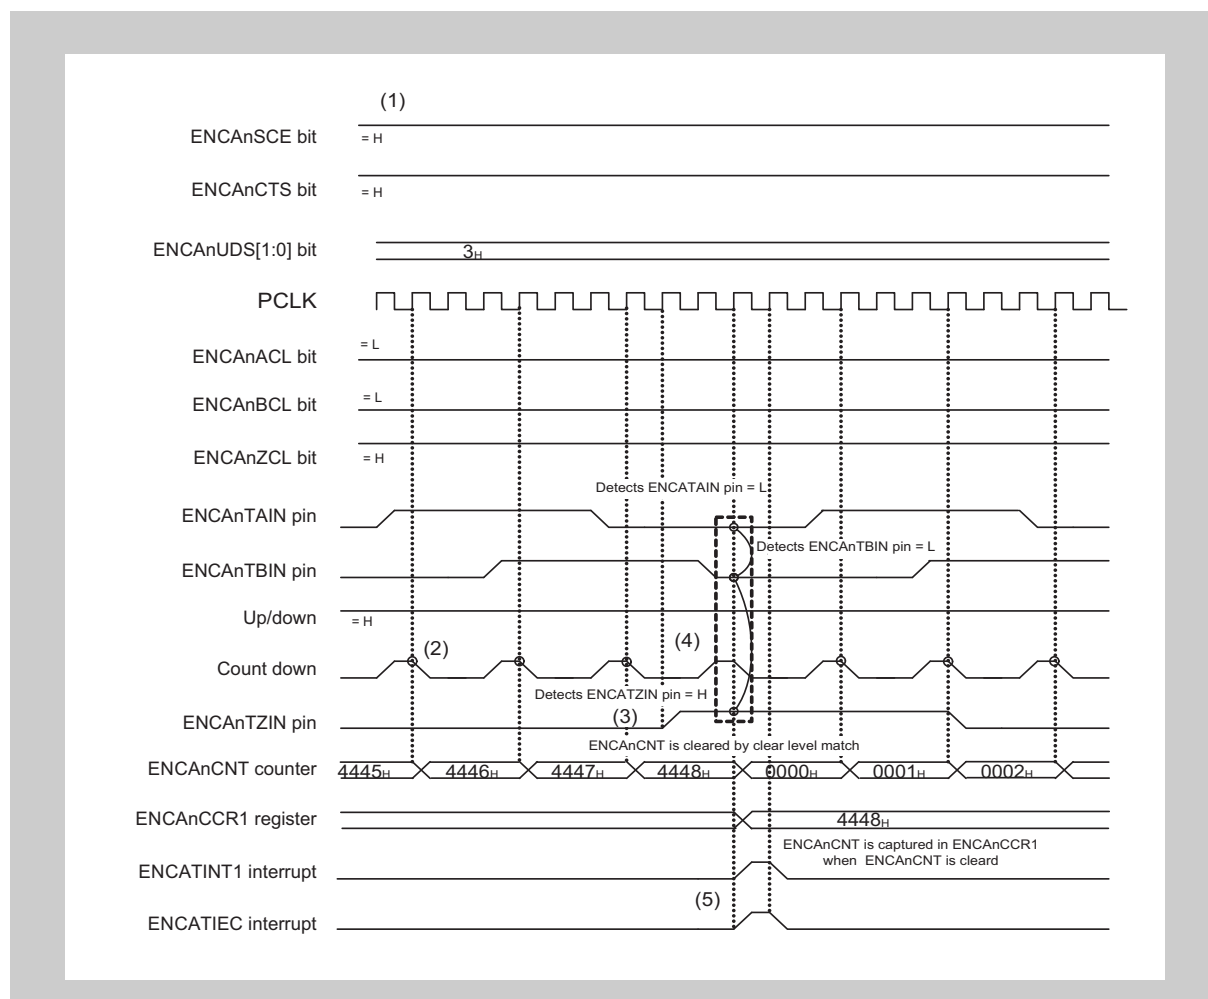

The count operation changes to up-count.

When ENCA_nCNT changes to 4446_H, a compare match with ENCA_nCCR1 is detected.

A compare match interrupt (ENCA_nTINT1) with ENCA_nCCR1 is output.

Capture Operation Performed upon Clearing by ENCA_nTZIN when ENCA_nSCE = 1

Accompanying capture operation

Capture Operation Performed upon Clearing by ENCATZIN when ENCAAnSCE = 1

The values are set as follows: ENCAAnSCE = 1, ENCAAnCTS = 1, ENCAAnUDS[1:0] = 11_B, ENCAAnACL = 0, ENCAAnBCL = 0, and ENCAAnZCL = 1.

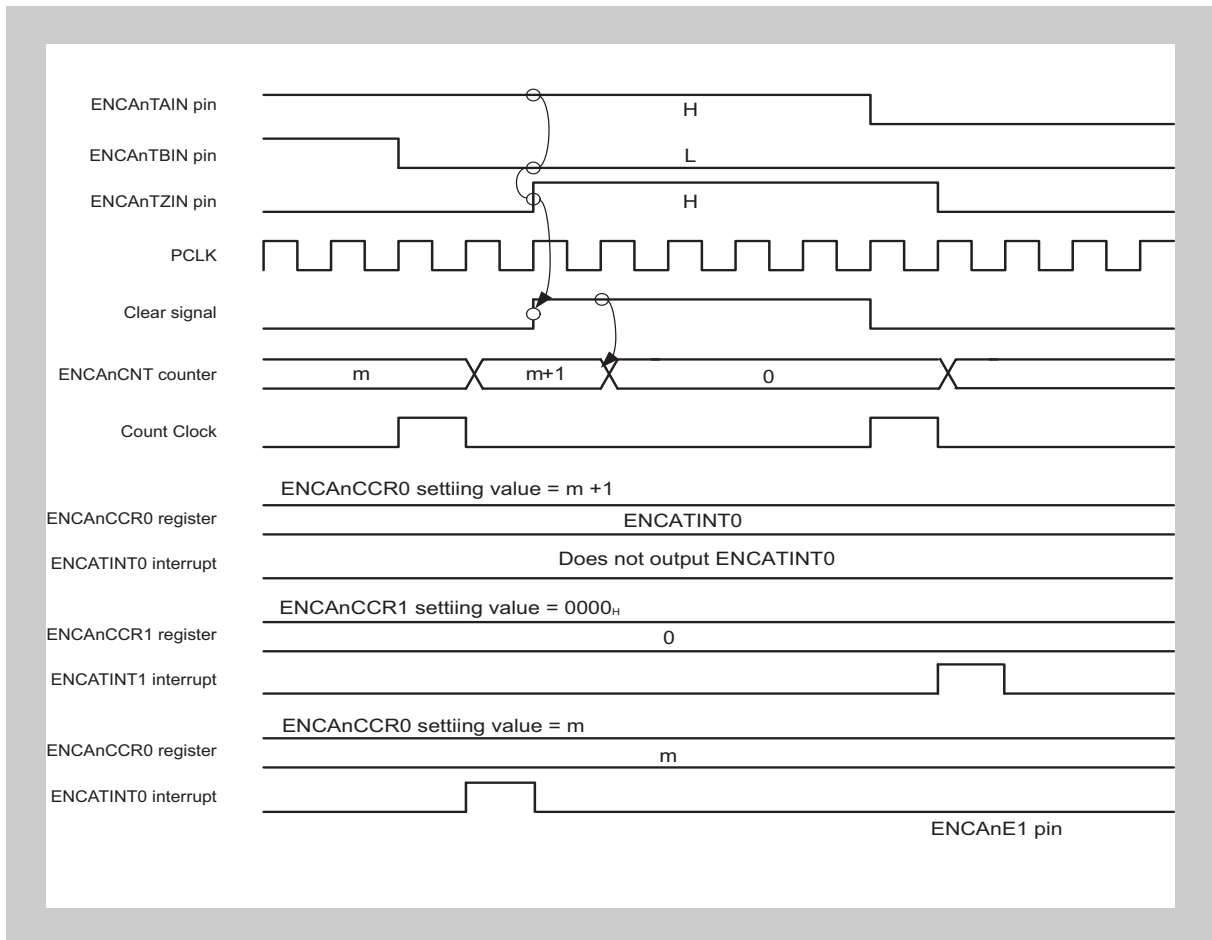

An up-count is performed.

The count value is not cleared upon the rising edge of ENCAAnEC.

When ENCATAIN, ENCATBIN and ENCATZIN reach the set clear level, the count value is cleared. The count value is captured in ENCAAnCCR1 at the time of the clearing.

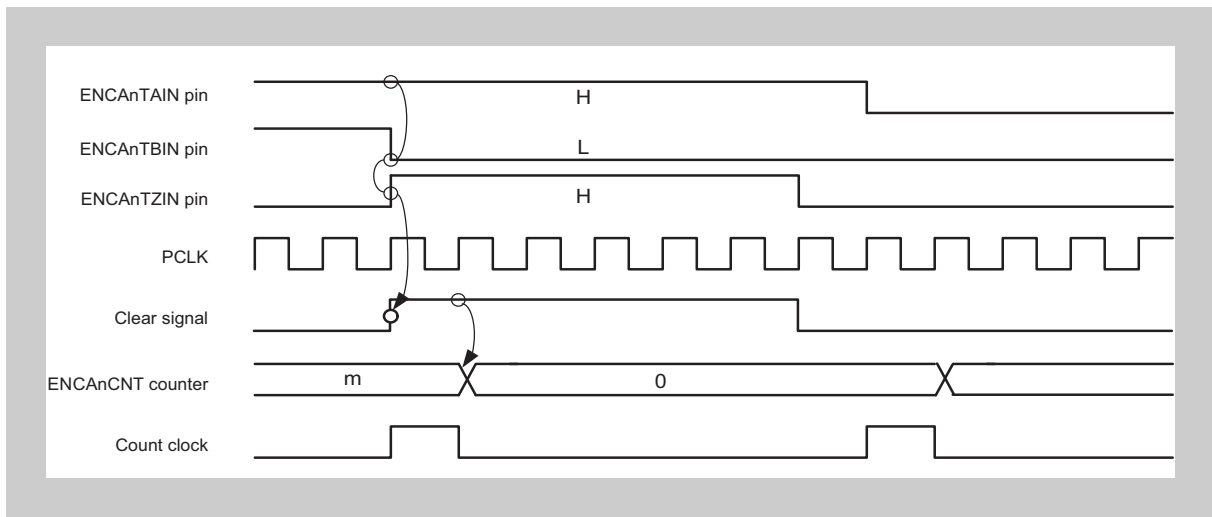

At the time of the clearing, an interrupt (ENCATINT1) corresponding to the capture to the ENCAAnCCR1 register and a clear interrupt (ENCATIEC) by ENCATZIN are output.

When the Timing of the ENCATZIN Input is Later than that of the ENCATBIN Input during Up-count (When ENCAAnACL = 1, ENCAAnBCL = 0, ENCAAnZCL = 1, and ENCAAnUDS[1:0] = 11_B)

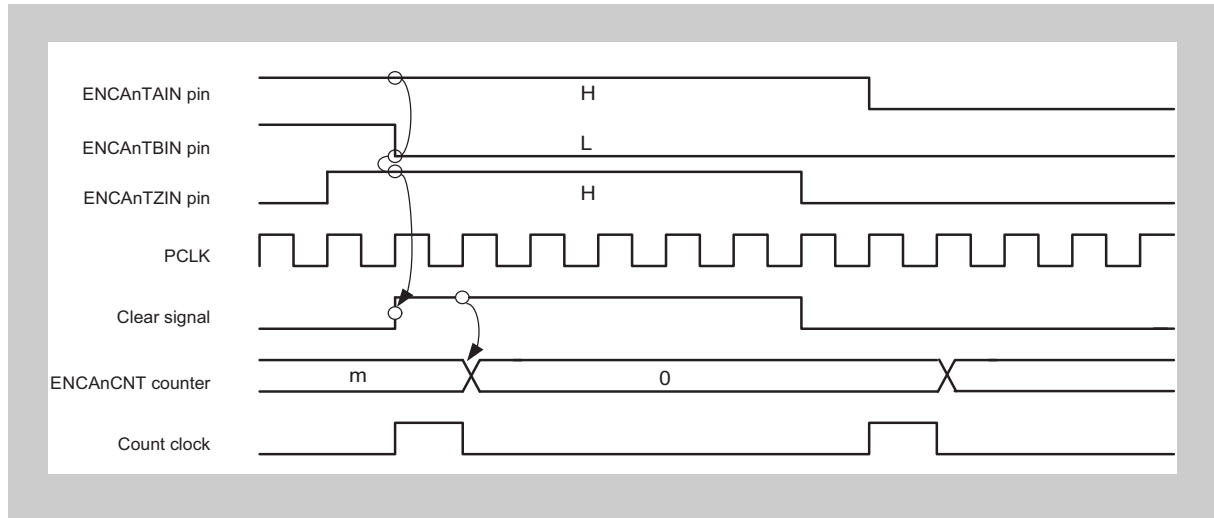

Clearing for when the Timing of the ENCA nTZIN Input is Later than that of the ENCA nTBIN Input during Up-count

When the Timing of the ENCA nTZIN Input is the Same as that of the ENCA nTBIN Input during Up-count (When ENCA nACL = 1, ENCA nBCL = 0, ENCA nZCL = 1, and ENCA nUDS[1:0] = 11_B)

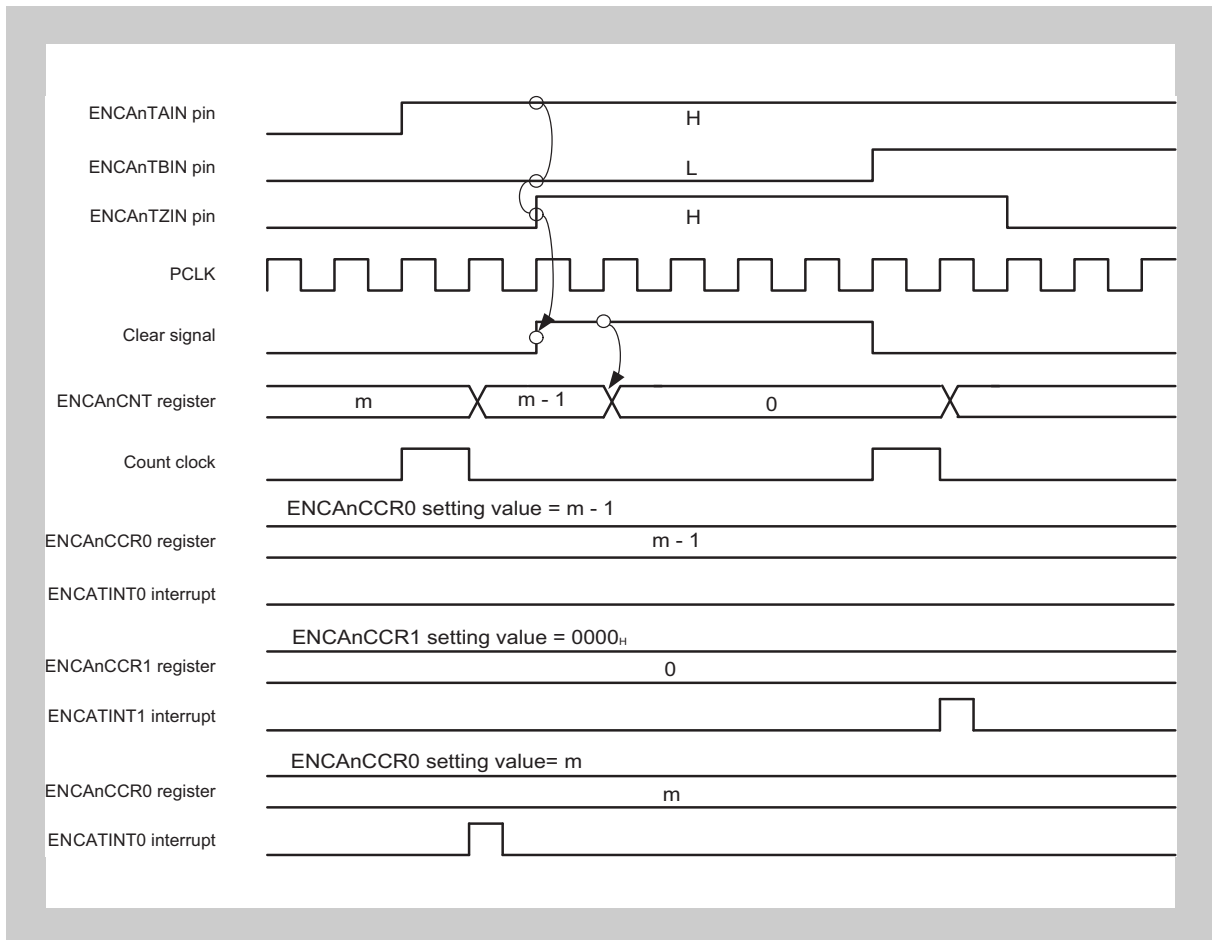

Clearing for when the Timing of the ENCATZIN Input is the Same as that of the ENCATBIN Input during Up-count

When the Timing of the ENCATZIN Input is Earlier than that of the ENCATBIN Input during Up-count (When ENCA_nACL = 1, ENCA_nBCL = 0, ENCA_nZCL = 1, and ENCA_nUDS[1:0] = 11_B)

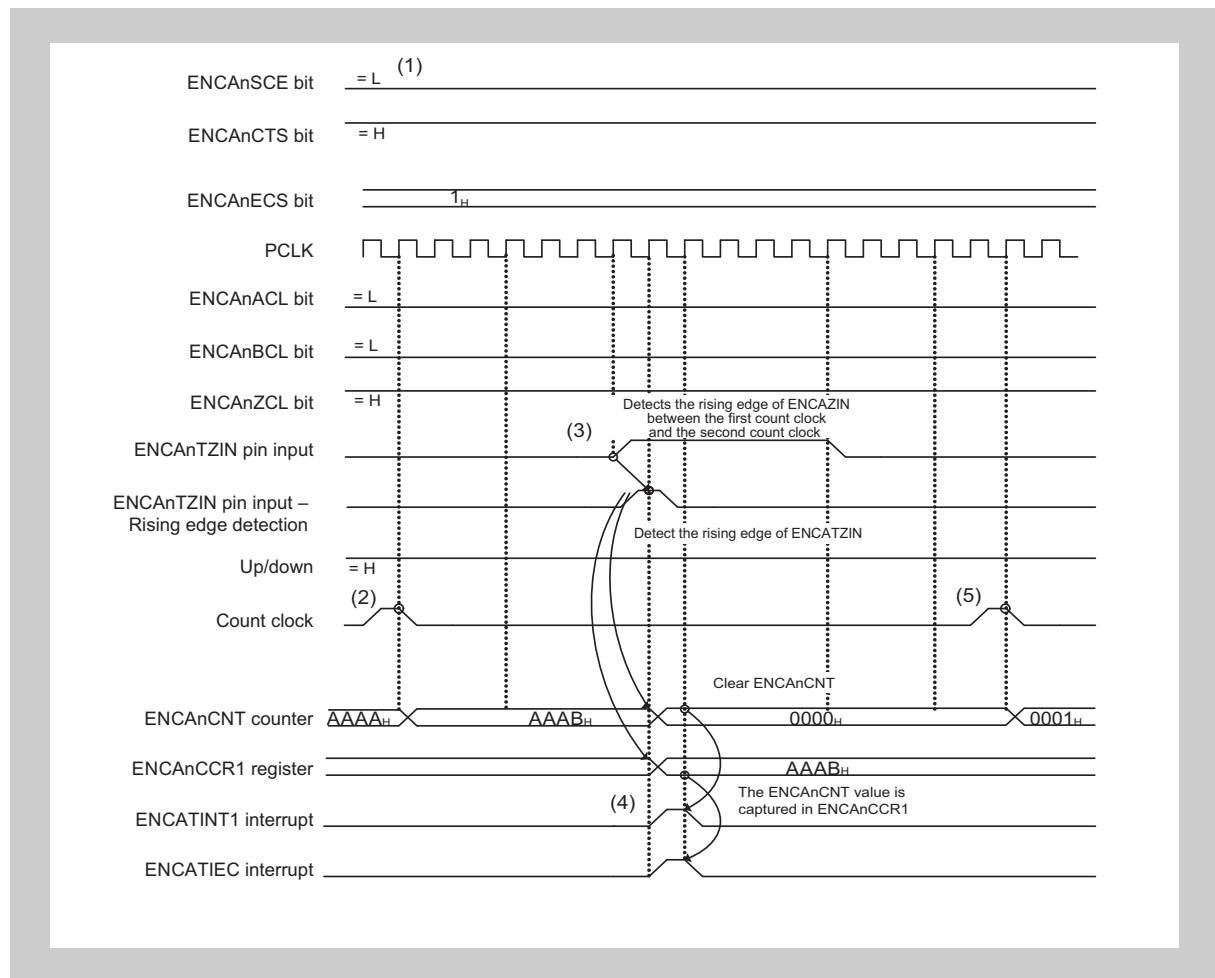

Clearing for when the Timing of the ENCATZIN Input is Earlier than that of the ENCATBIN Input during Up-count

When the Timing of the ENCATZIN Input is Later than that of the ENCA_nE1 Input during Down-count (When ENCA_nTBIN = 1, ENCA_nBCL = 0, ENCA_nZCL = 1, and ENCA_nUDS[1:0] = 11_B)

Clearing for when the Timing of the ENCATZIN Input is Later than that of the ENCATBIN Input during Down-count

Capture Operation Performed upon Clearing by ENCATZIN when ENCAcSCE = 0

Capture Operation Performed upon Clearing by ENCAAnTZIN when ENCAAnSCE = 0

The values are set as follows: ENCAAnSCE = 0, ENCAAnCTS = 1, and ENCAAnECS1 and ENCAAnECS[1:0] = 01_B.

An up-count is performed.

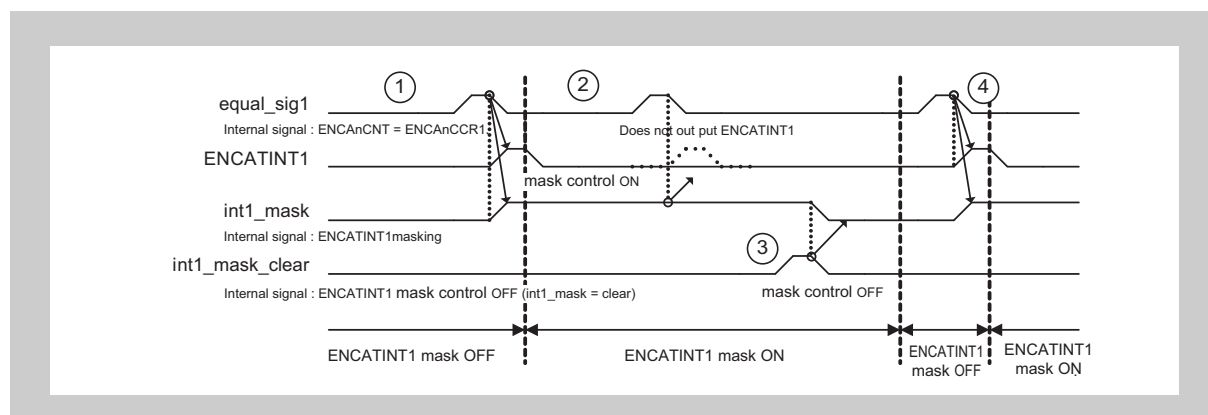

The rising edge of the ENCAAnTZIN input is detected, and the ENCAAnCNT value (AAAB_H) is captured in the ENCAAnCCR1 register. Concurrently, clear operation by ENCAAnTZIN is performed, and ENCAAnCNT is cleared to 0000_H.

A capture interrupt 1 (ENCAAnTINT1) to the ENCAAnCCR1 register and an encoder clear interrupt (ENCAAnTIEC) by ENCAAnTZIN are output.

After the count value is cleared, an up-count is performed, and the count value changes to 0001_H.

Match interrupt mask operation

Mask operation and cancellation of masking

Match interrupt mask operation and cancellation of masking

Signals on the above timing chart are described below:

- equal_sig1:** Internal signal generated when ENCA_nCNT matches with ENCA_nCCR1
- int1_mask:** Interrupt detection mask signal. This signal is set when the first compare match occurs between ENCA_nCNT and ENCA_nCCR1.
- int1_mask_clr:** Interrupt detection mask cancellation signal. A trigger for mask cancellation differs depending on the ENCA_nMCS setting.
- ENCA_nMCS = 0:** An interrupt detection mask is cancelled by writing to the ENCA_nCCR1 register.
- ENCA_nMCS = 1:** An interrupt detection mask is cancelled by timer counter clearing operation when ENCA_nCNT matches ENCA_nCCR0, timer counter clearing operation by phase Z, or underflow detection when ENCA_nLDE = 1.

The first compare match is detected when the match interrupt detection mask function is disabled.

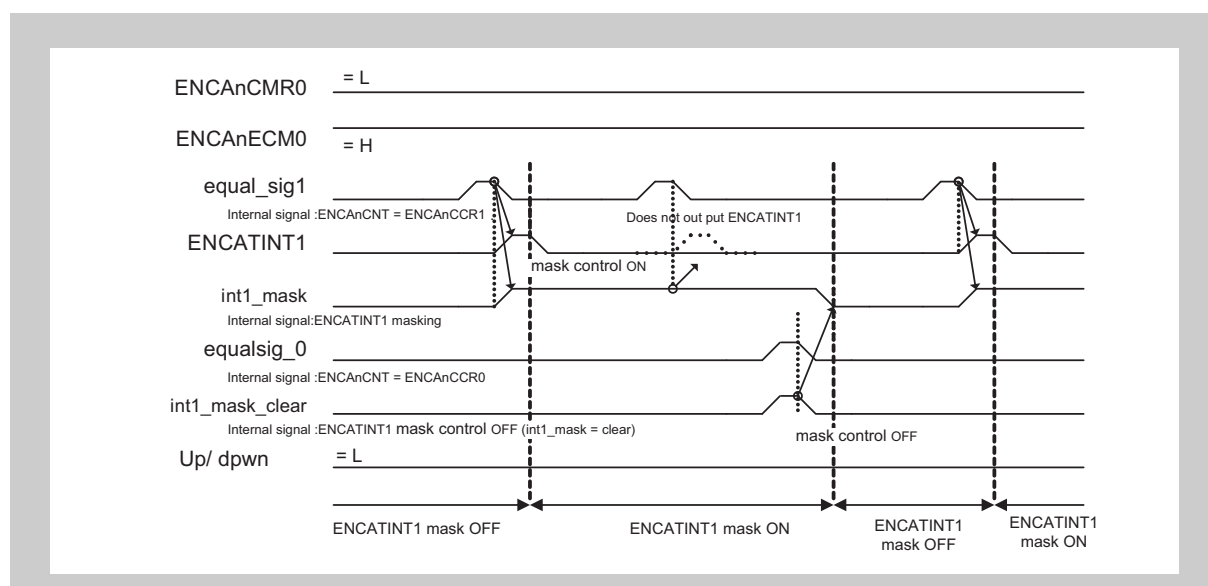

At this point, int1_mask, which masks detection of the second and subsequent compare match interrupts, is set to "1", and the match interrupt detection mask function is enabled.

Because int1_mask is "High", ENCA_nTINT1 is not output even if equal_sig1 becomes "High".

When a trigger which cancels a match interrupt detection mask occurs, int1_mask_clr is set to "1", int1_mask is cleared to "L", and the match interrupt detection mask function is disabled.

When the match interrupt detection mask function is disabled, the first compare match is detected, and concurrently, int1_mask is set to "1".

Mask operation and cancellation of masking (when ENCA_nCNT matches with ENCA_nCCR0)

Match interrupt mask operation and cancellation of masking (when ENCAAnCNT matches with ENCAAnCCR0)

Signals on the above timing chart are described below:

- equal_sig1:** Internal signal generated when ENCAAnCNT matches with ENCAAnCCR1
- int1_mask:** Interrupt detection mask signal. This signal is set when the first compare match occurs between ENCAAnCNT and ENCAAnCCR1.
- equal_sig0:** Internal signal generated when ENCAAnCNT matches with ENCAAnCCR0
- int1_mask_clr:** Interrupt detection mask cancellation signal. A trigger for mask cancellation differs depending on the ENCAAnMCS setting.
- ENCAAnMCS = 0:** An interrupt detection mask is cancelled by writing to the ENCAAnCCR1 register.
- ENCAAnMCS = 1:** An interrupt detection mask is cancelled by timer counter clearing operation when ENCAAnCNT matches ENCAAnCCR0, timer counter clearing operation by phase Z, or underflow detection when ENCAAnLDE = 1.
- Up/down:** Internal signal whose count status is controlled by the UDS value of the phase-A input signal and phase-B input signal.

The first compare match is detected when the match interrupt detection mask function is disabled.

At this point, int1_mask, which masks detection of the second and subsequent compare match interrupts, is set to "1", and the match interrupt detection mask function is enabled.

Because int1_mask is "High", ENCATINT1 is not output even if equal_sig1 becomes "High".

By clear operation for when a compare match occurs between ENCAAnCNT and ENCAAnCCR0, int1_mask_clr is set to "1", int1_mask is cleared to "L", and the match interrupt detection mask function is disabled.

When the match interrupt detection mask function is disabled, the first compare match is detected, and concurrently, int1_mask is set to "1".

Chapter 15 Timer Option Function (TAPA)

This chapter describes the Timer Option function (TAPA).

The first section describes all properties specific to the V850E2/ML4, such as instances, register base addresses, input/output signal names. The subsequent sections describe the features that apply to all implementations.

15.1 Timer Option Function Features

Instances This microcontroller has the following number of instances of TAPA.

Table 15-1 Instances of TAPA

TAPA	
Instance	3 (0, 2, 3)
Name	TAPAn

Instances index n Throughout this chapter, the individual instances of the TAPA are identified by the index “n” (n = 0, 2, 3), for example, TAPAnFLG for the TAPAn flag register.

Caution The following bits of the registers are not supported in the V850E2/ML4.

- TAPA2CTL1.TAPA2ATS3 and TAPA2CTL1.TAPA2ATS2 bits
- TAPA3CTL1.TAPA3ATS3 and TAPA3CTL1.TAPA3ATS2 bits

Block diagram for motor control The timer option function (TAPA), timer array unit A (TAUA), and/or peripheral interconnection (PIC) can be used as an inverter function that controls a motor.

When using this function, however, the available resources (channels) are limited as shown in Figure 15-1 “Block diagram for motor control” below.

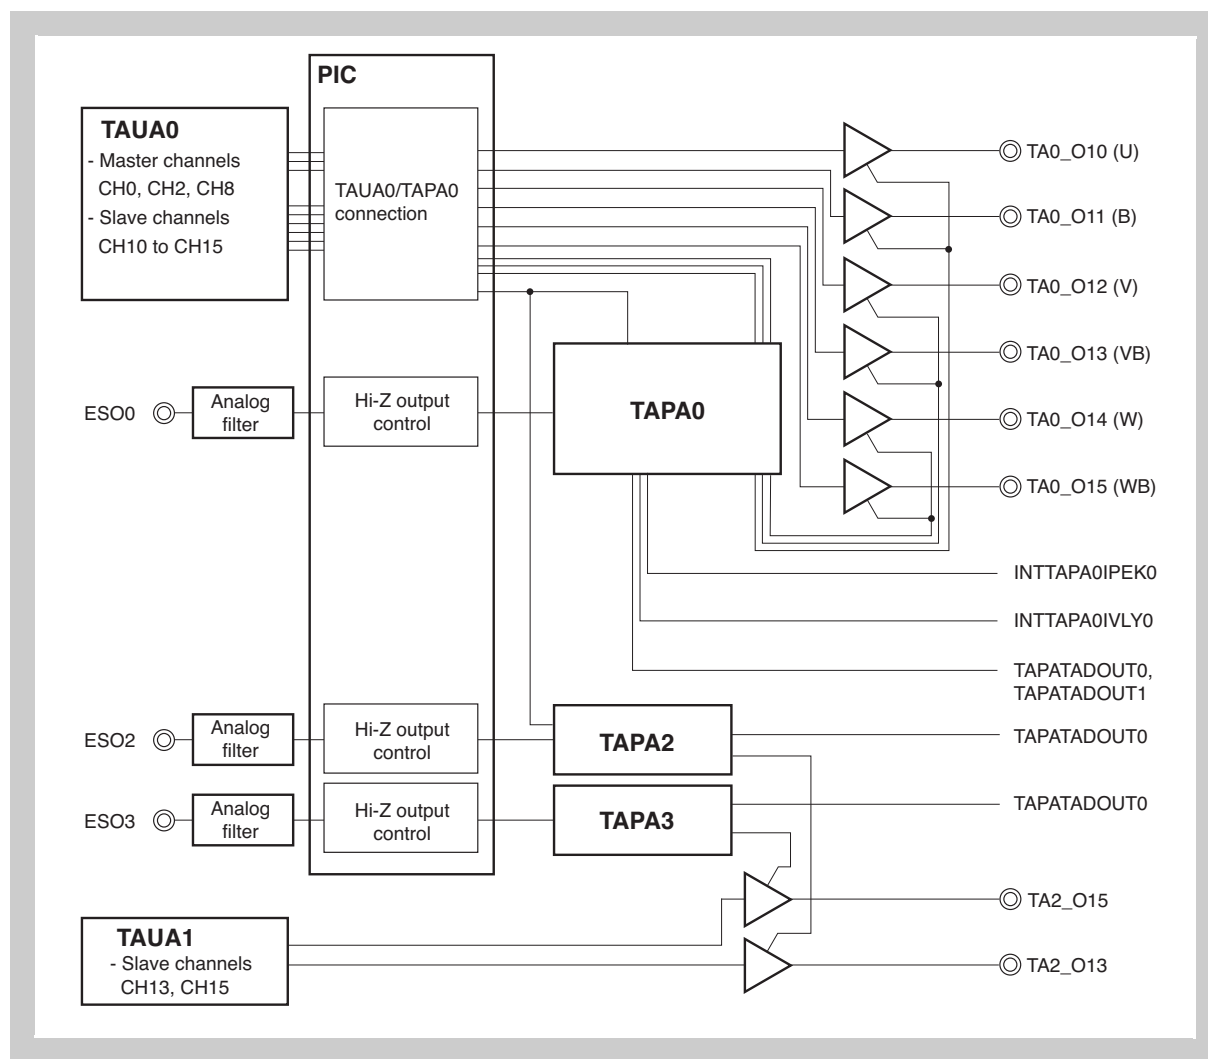

Figure 15-1 Block diagram for motor control

Register addresses All TAPAn register addresses are given as address offsets from the individual base addresses <TAPAn_base_OS> or <TAPAn_base_USER>. The register base addresses of each TAPAn are listed in the following table:

Table 15-2 Register base addresses <TAPAn_base>

TAPAn instance	Base address	Address
TAPA0	<TAPAn_base_OS>	FF81 5000 _H
	<TAPAn_base_USER>	FFFF D400 _H
TAPA2	<TAPAn_base_OS>	FF81 7000 _H
	<TAPAn_base_USER>	FFFF D600 _H
TAPA3	<TAPAn_base_OS>	FF81 8000 _H
	<TAPAn_base_USER>	FFFF D700 _H

Clock supply The following clock is supplied to TAPAn:

Table 15-3 TAPAn clock supply

TAPAn instance	Clock	Connected to:
TAPA0	PCLK	f _{PCLK}
TAPA2		
TAPA3		

Interrupts and DMA/DTS TAPA can generate the following interrupts and DMA/DTS requests:

Table 15-4 TAPAn interrupts and DMA/DTS requests

15.1.1 Block diagram

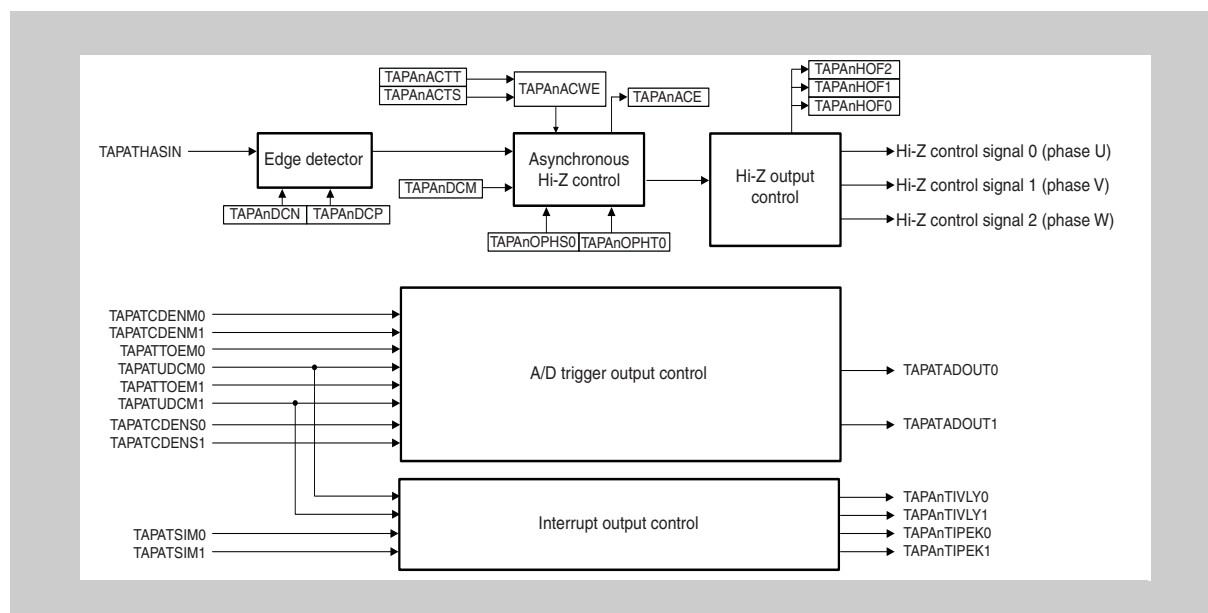

Figure 15-2 TAPA block diagram

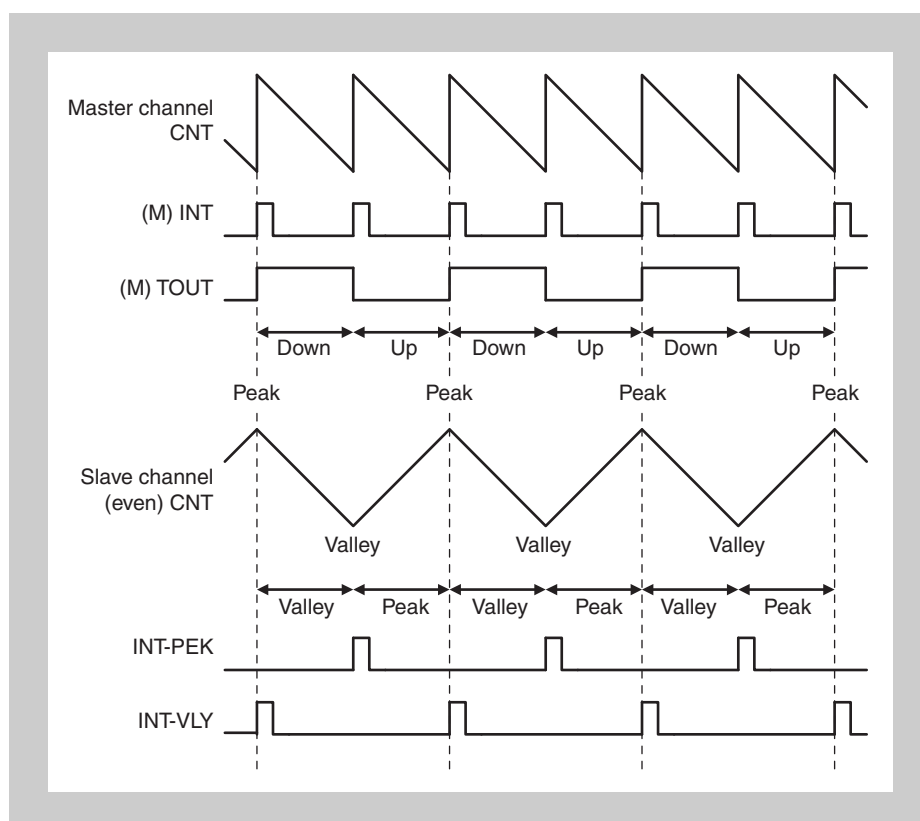

15.2 Functional Overview

Function overview The timer motor control function (TAPA) is to be connected to timer array unit A (TAUA) to implement motor systems.

- Asynchronous Hi-Z control functions
Timer output for motor control can be forcibly stopped by asynchronously setting its level to high-impedance.
- INT signal output selection function
Two types of interrupts, peak interrupts and valley interrupts, can be output based on the INTn signal output by the TAUA.
- A/D conversion trigger selection function
Two A/D conversion trigger signals can be output based on the INTn signal output by the TAUA.

15.2.1 Peak and valley interrupts - Peak and valley of timer counter

In this document, the period from a TAUA up status (counting-up status) to generation of INT from the master channel is defined as a peak period, and this INT is defined as a peak interrupt. In contrast, the period from a TAUA down status (counting-down status) to generation of INT from the master channel is defined as a valley period, and this INT is defined as a valley interrupt.

15.3 Registers

The timer motor control function is controlled and operated by means of the following registers.

15.3.1 Registers overview

Table 15-7 Control registers overview

Register name	Shortcut	Address
Control register 0	TAPAnCTL0	<TAPAn_base_OS> + 20 _H
Control register 1	TAPAnCTL1	<TAPAn_base_OS> + 24 _H
Flag register	TAPAnFLG	<TAPAn_base_USER> + 00 _H
Asynchronous Hi-Z control write enable register	TAPAnACWE	<TAPAn_base_USER> + 04 _H
Asynchronous Hi-Z control start trigger register	TAPAnACTS	<TAPAn_base_USER> + 08 _H
Asynchronous Hi-Z control stop trigger register	TAPAnACTT	<TAPAn_base_USER> + 0C _H
Hi-Z start trigger register	TAPAnOPHS	<TAPAn_base_USER> + 14 _H
Hi-Z stop trigger register	TAPAnOPHT	<TAPAn_base_USER> + 18 _H

<TAPAn_base> The base addresses <TAPAn_base_OS> and <TAPAn_base_USER> of the TAPAn is defined in the first section of this chapter under the key word “Register addresses”.

15.3.2 Registers details

(1) TAPAnCTL0 - Control register 0

This register is used to set up the asynchronous Hi-Z control function.

The values of this register can be rewritten only when TAPAnFLG.TAPAnASCE is 0 and the TAUAnTE bit for the corresponding TAU's master channel is 0.

Access This register can be read or written in 16-bit units.

Address <TAPAn_base_OS> + 20_H

Initial value 0000_H. This register is initialized by any reset.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	0	0	0	0	0	0	TAPAn DCM	TAPAn DCN	TAPAn DCP	0	0
R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R	R

Table 15-8 TAPAnCTL0 register contents

Bit position	Bit name	Function															
4	TAPAnDCM	Clear condition configuration bit This control bit specifies the clear conditions for Hi-Z control output. 0: Enables manipulation of TAPAnOPHT0, regardless of the TAPATHASIN signal input level. 1: Disables manipulation of TAPAnOPHT0 if the TAPATHASIN signal input is active. Enables manipulation of TAPAnOPHT0 if the TAPATHASIN signal input is inactive.															
3, 2	TAPAnDCN, TAPAnDCP	Hi-Z input edge selection bits These are control bits that specify the valid edge of TAPATHASIN. <table border="1" data-bbox="550 1216 1385 1487"> <thead> <tr> <th>TAPAnDCN</th><th>TAPAnDCP</th><th>Description</th></tr> </thead> <tbody> <tr> <td>0</td><td>0</td><td>Does not detect valid edges.</td></tr> <tr> <td>0</td><td>1</td><td>Detects a rising edge as the valid edge (active level = high).</td></tr> <tr> <td>1</td><td>0</td><td>Detects a falling edge as the valid edge (active level = low).</td></tr> <tr> <td>1</td><td>1</td><td>Setting prohibited</td></tr> </tbody> </table>	TAPAnDCN	TAPAnDCP	Description	0	0	Does not detect valid edges.	0	1	Detects a rising edge as the valid edge (active level = high).	1	0	Detects a falling edge as the valid edge (active level = low).	1	1	Setting prohibited

0	0	Does not detect valid edges.															
0	1	Detects a rising edge as the valid edge (active level = high).															
1	0	Detects a falling edge as the valid edge (active level = low).															
1	1	Setting prohibited															

(2) TAPAnCTL1 - Control register 1

This register is used to specify the A/D conversion trigger.

Access This register can be read or written in 8-bit units.

Address <TAPAn_base_OS> + 24_H

Initial value 00_H. This register is initialized by any reset.

TAPAnATS1	TAPAnATS0	Description															
0	0	INT signal output while the triangle wave is falling (counting down)															
0	1	INT signal output while the triangle wave is rising (counting up)															
1	0	INT signal output while the triangle wave is rising (counting up) or falling (counting down)															
1	1	INT signal and valley interrupt INTTAPAnIVLY0 output while the triangle wave is rising (counting up) or falling (counting down)															

(3) TAPAnFLG - Flag register

This flag register is for asynchronous Hi-Z control.

Access This register can be read in 16-bit units.

Address <TAPAn_base_USER> + 00_H

Initial value 0700_H. This register is initialized by any reset.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	0	0	TAPAn HOF0	0	0	0	0	0	0	0	TAPAn ACE
R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 15-10 TAPAnFLG register contents

Bit position	Bit name	Function
8	TAPAnHOF0	Hi-Z control monitor bit This bit is used to monitor the Hi-Z control status. 0: Hi-Z is not being controlled. 1: Hi-Z is being controlled.
0	TAPAnACE	Asynchronous Hi-Z control enable bit This bit indicates the status of the asynchronous Hi-Z control signal TAPATHASIN. 0: Indicates that the asynchronous Hi-Z control is stopped. 1: Indicates that the asynchronous Hi-Z control is enabled. The conditions for setting or clearing this bit are as follows: Clear condition: Writing 1 to TAPAnACTT while TAPAnACWE = 1 Set condition: Writing 1 to TAPAnACTS while TAPAnACWE = 1

(4) TAPAnACWE – Asynchronous Hi-Z control write enable register

This register is used to enable writing for asynchronous Hi-Z control.

Access This register can be read or written in 8-bit units.

Address <TAPAn_base_USER> + 04_H

Initial value 00_H. This register is initialized by any reset.

7	6	5	4	3	2	1	0
0	0	0	0	0	0	0	TAPAn ACWE
R	R	R	R	R	R	R	R/W

Table 15-11 TAPAnACWE register contents

Bit position	Bit name	Function
0	TAPAnACWE	Asynchronous control write enable bit This is a write enable bit for asynchronous Hi-Z control. After 1 is written, this bit is automatically cleared to 0 by writing 1 to TAPAnACTS and TAPAnACTT. 0: Disables writing to TAPAnACTS and TAPAnACTT. 1: Enables writing to TAPAnACTS and TAPAnACTT.

(5) TAPAnACTS - Asynchronous Hi-Z control start trigger register

This register is used to enable the start trigger for asynchronous Hi-Z control.

Access This register is write-only, in 8-bit units. This register is always read as 00_H.

Address <TAPAn_base_USER> + 08_H

Initial value 00_H. This register is initialized by any reset.

7	6	5	4	3	2	1	0
0	0	0	0	0	0	0	TAPAn ACTS
R	R	R	R	R	R	R	W

Table 15-12 TAPAnACTS register contents

Bit position	Bit name	Function
0	TAPAnACTS	Asynchronous Hi-Z control start trigger bit This bit enables the start trigger for asynchronous Hi-Z control. The setting of this bit is valid only when TAPAnACWE = 1. 0: Writing 0 to this bit is ignored (no function). 1: Enables asynchronous Hi-Z control and then sets TAPAnACE to 1.

(6) TAPAnACTT - Asynchronous Hi-Z control stop trigger register

This bit enables the stop trigger for asynchronous Hi-Z control.

Access This register is write-only, in 8-bit units. This register is always read as 00_H.

Address <TAPAn_base_USER> + 0C_H

Initial value 00_H. This register is initialized by any reset.

7	6	5	4	3	2	1	0
0	0	0	0	0	0	0	TAPAn ACTT
R	R	R	R	R	R	R	W

Table 15-13 TAPAnACTT register contents

Bit position	Bit name	Function
0	TAPAnACTT	Asynchronous Hi-Z control stop trigger bit This bit enables the stop trigger for asynchronous Hi-Z control. The setting of this bit is valid only when TAPAnACWE = 1. 0: Writing 0 to this bit is ignored (no function). 1: Disables asynchronous Hi-Z control and then clears TAPAnACE to 0.

(7) TAPAnOPHS - Hi-Z start trigger register

This software trigger register is used to start Hi-Z control for timer output pins.

Access This register is write-only, in 8-bit units. This register is always read as 00_H.

Address <TAPAn_base_USER> + 14_H

Initial value 00_H. This register is initialized by any reset.

7	6	5	4	3	2	1	0
0	0	0	0	0	0	0	TAPAn OPHS0
R	R	R	R	R	R	R	W

Table 15-14 TAPAnOPHS register contents

Bit position	Bit name	Function
0	TAPAnOPHS0	Hi-Z control start trigger bit This bit starts Hi-Z control for timer output pins. 0: Writing 0 to this bit is ignored (no function). 1: Starts Hi-Z control.

(8) TAPAnOPHT - Hi-Z stop trigger register

This software trigger register is used to stop Hi-Z control for timer output pins.

Access This register is write-only, in 8-bit units. This register is always read as 00_H.

Address <TAPAn_base_USER> + 18_H

Initial value 00_H. This register is initialized by any reset.

7	6	5	4	3	2	1	0
0	0	0	0	0	0	0	TAPAn OPHT0
R	R	R	R	R	R	R	W

Table 15-15 TAPAnOPHT register contents

Bit position	Bit name	Function
0	TAPAnOPHT0	Hi-Z control stop trigger bit This bit stops Hi-Z control for timer output pins. 0: Writing 0 to this bit is ignored (no function). 1: Stops Hi-Z control. Whether the setting of this bit is valid or invalid depends on the setting of TAPAnCTL0.TAPAnDCM.

15.4 Basic Functions

15.4.1 Asynchronous Hi-Z control function

(1) Purpose

If the operation of the timer motor control function controlled by the CPU becomes abnormal, the rotation of the external motor also becomes abnormal. This function can forcibly set the motor control output to the Hi-Z state upon detection of abnormal motor operation, independent of the CPU control.

(2) Overview

This function forcibly stops TAPAn output through asynchronous Hi-Z control.

When the TAPATHASIN signal becomes active, the levels of the timer output pins are set to Hi-Z, and timer output is forcibly stopped.

If TAPAnCTL0.TAPAnDCM is 0, setting the TAPAnACTT.TAPAnOPHT0 bit stops Hi-Z output control regardless of the TAPATHASIN signal input level.

If TAPAnCTL0.TAPAnDCM is 1, setting the TAPAnACTT.TAPAnOPHT0 bit while the TAPATHASIN signal input level is inactive stops Hi-Z output control.

(3) System configuration example

A system configuration example is shown below, where an external error detection signal (the ESO0 pin) is used for the Hi-Z control of the TAUAO outputs (the TAUAO010 to TAUAO015 pins).

When an external error detection signal is received, an interrupt is generated and the level of the motor control timer outputs (TAUA0 channels 10 to 15) is simultaneously set to Hi-Z.

Because the microcontroller might freeze when an error occurs, external error detection signals are continuously processed so that the motor control timer outputs can be set to Hi-Z even if no clock is supplied.

Note that an error is detected only when the valid edge of the error detection signal is detected. Therefore, no error is detected if the output level is fixed and the signal level does not change.

Figure 15-3 Hi-z control of TAU A

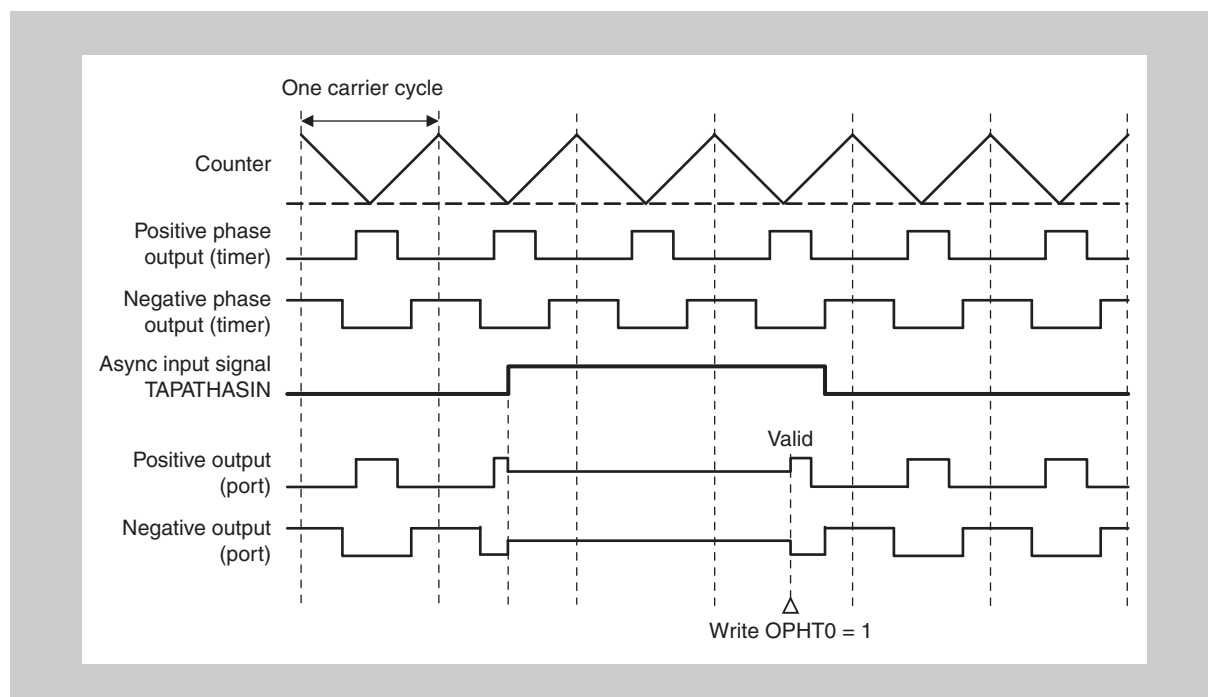

(4) Basic operation

Hi-Z control for timer output pins can be started as follows:

- Detecting the valid edge of TAPATHASIN
- Setting the start trigger bit TAPAnOPHS0 of the Hi-Z control signal

The levels of the timer output pins are set to Hi-Z until the stop trigger bit TAPAnOPHT0 of the Hi-Z control signal is set. Note that whether the setting of TAPAnOPHT0 is valid or invalid depends on the setting of TAPAnCTL0.TAPAnDCM.

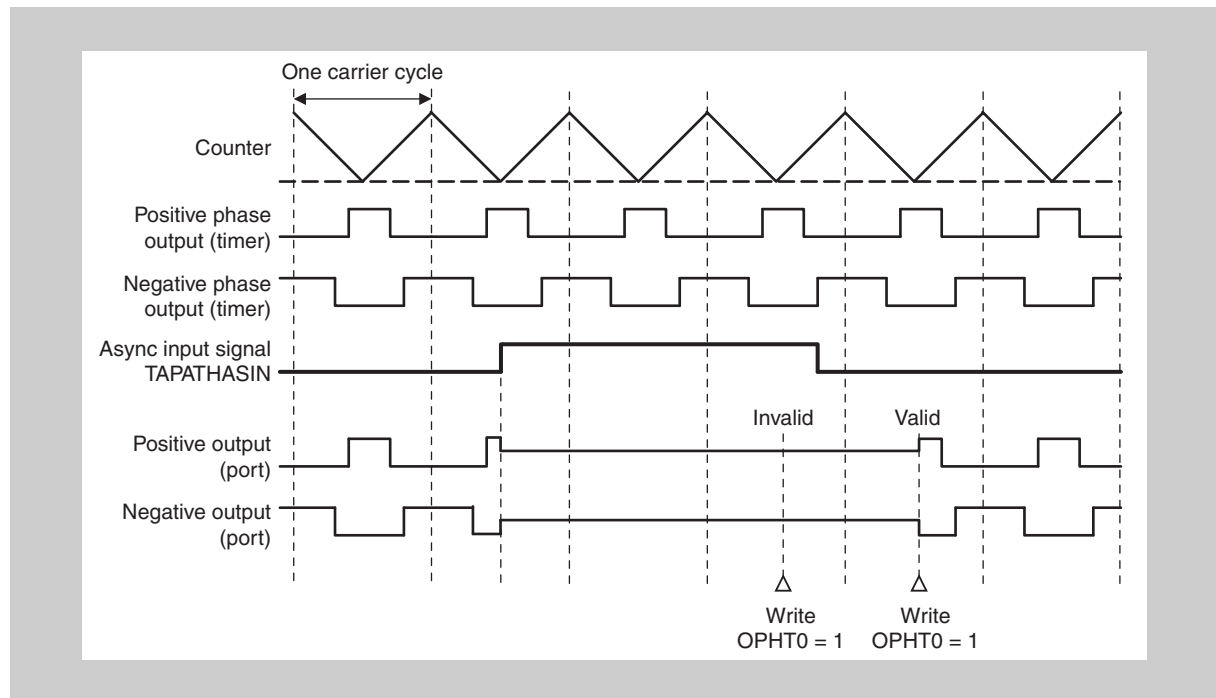

(a) Operation when TAPAnCTL0.TAPAnDCM = 0, TAPAnDCP = 0, and TAPAnDCN = 0

The timer outputs are forcibly stopped (Hi-Z output by port control) when the valid edge of the asynchronous input signal TAPATHASIN is detected.

The timer outputs restart when 1 is written to the Hi-Z stop trigger bit TAPAnOPHT0, regardless of the level of TAPATHASIN.

(b) Operation when TAPAnCTL0.TAPAnDCM = 1, TAPAnDCP = 1, and TAPAnDCN = 0

The timer outputs are forcibly stopped (Hi-Z output by port control) when the valid edge of asynchronous input signal TAPATHASIN is detected.

Writing 1 to the Hi-Z stop trigger bit TAPAnOPHT0 is ignored while the asynchronous input signal TAPATHASIN is active (high level because TAPAnDCP is 1).

The timer outputs restart when 1 is written to the Hi-Z stop trigger bit TAPAnOPHT0 after TAPATHASIN becomes inactive (low level because TAPAnDCP is 1).

(5) Asynchronous Hi-z control using software trigger

TAPA supports Hi-Z control using a software trigger.

Hi-Z control for timer outputs is possible by using the Hi-Z control start trigger bit TAPAnOPHS0 and Hi-Z control stop trigger bit TAPAnOPHT0.

(a) Function of Hi-Z control start trigger bit TAPAnOPHS0

TAPAnDCM	Function
0/1	Writing 1 to TAPAnOPHS0 starts Hi-Z control and forcibly stops the timer outputs (Hi-Z output by port control).

(b) Function of Hi-Z control stop trigger bit TAPAnOPHT0

Whether the Hi-Z control stop trigger is valid or invalid depends on the conditions below:

TAPAnDCM	Function
0	Writing 1 to TAPAnOPHT0 stops Hi-Z control and restarts timer outputs.
1	If TAPATHASIN is inactive, writing 1 to TAPAnOPHT0 stops Hi-Z control and restarts timer outputs. If TAPATHASIN is active, writing 1 to TAPAnOPHT0 is ignored.

(c) Operation when TAPAnCTL0.TAPAnDCM = 1, TAPAnDCP = 1, and TAPAnDCN = 0

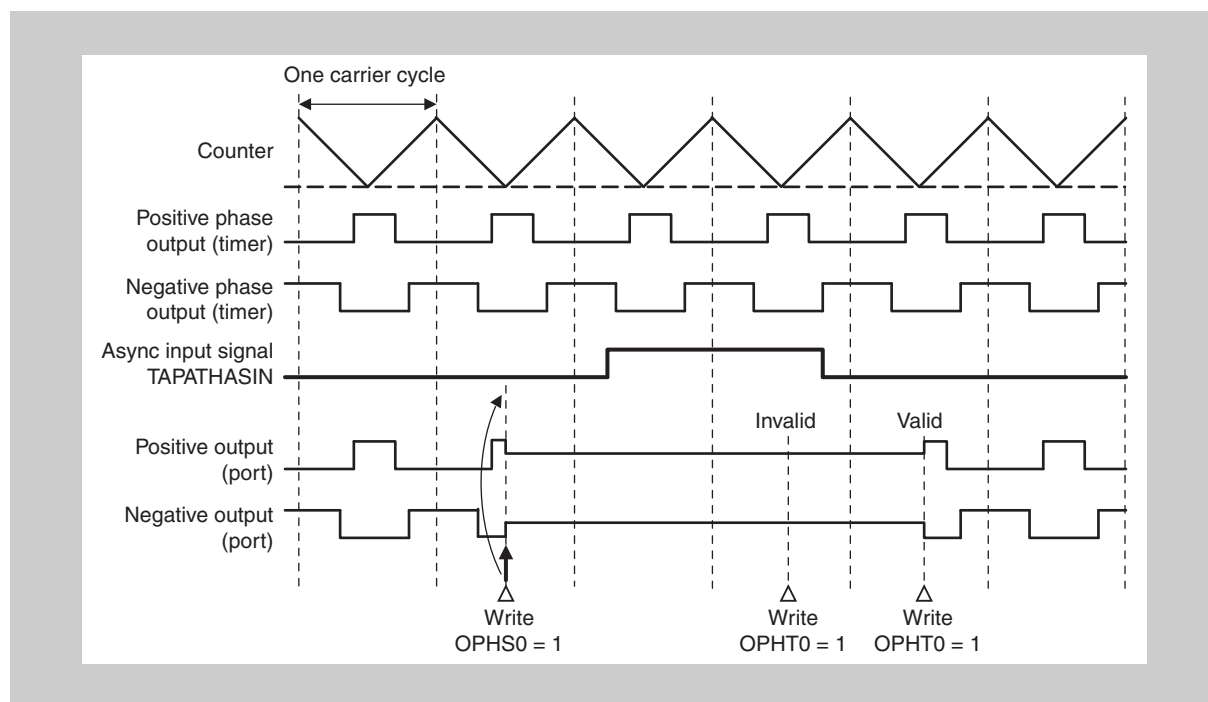

Figure 15-4 Operation of $\overline{\text{TAPATHZOUT0}}$ when TAPAnDCM = 0, TAPAnDCP = 1, TAPAnDCN = 0

The timer outputs are forcibly stopped (Hi-Z output by port control) when 1 is written to TAPANOPHS0.

After that, the levels of the timer outputs remain Hi-Z even if a rising edge of TAPATHASIN is detected.

Writing to TAPANOPHT0 is ignored while TAPATHASIN is active (high level because TAPAnDCN is 0 and TAPAnDCP is 1).

After detection of a falling edge of TAPATHASIN, the timer outputs restart when 1 is written to TAPANOPHT0 while TAPATHASIN is inactive (low level because TAPAnDCN is 0 and TAPAnDCP is 1).

(6) Operating procedure

The operating procedure for the asynchronous input Hi-Z control function is shown below:

	Operation	Status of TAPA
Initial setup	Set up the TAPAnCTL0 register. Specify TAPAnDCP and TAPAnDCN to select the input edge. Specify TAPAnDCM to select the clear mode.	Asynchronous Hi-Z control stopped (TAPAnFLG.TAPAnACE = 0)
Start operation	Set up the TAPAnACWE register. Set TAPAnACWE to 1. Set up the TAPAnACTS register. Set TAPAnACTS to 1.	Writing to TAPAnACTS is enabled. Asynchronous Hi-Z control enabled (TAPAnFLG.TAPAnACE = 1)
During operation	Hi-Z control for the timer function outputs can be started by controlling the following: <ul style="list-style-type: none"> • TAPAnOPHS register • Hi-Z control asynchronous input signal TAPATHASIN Hi-Z control for the timer function outputs can be stopped by controlling the following: <ul style="list-style-type: none"> • TAPAnOPHT register (If TAPAnDCM is 1, control by the TAPAnOPHT register is enabled only while TAPATHASIN is inactive.) The TAPA operating status can always be read using the TAPAnFLG register.	Hi-Z control for the timer output pins is started by detecting the valid edge of the Hi-Z control asynchronous input signal (TAPATHASIN) or by setting the start trigger bit TAPAnOPHS0. Hi-Z control for the timer output pins is stopped by setting the stop trigger bit TAPAnOPHT0 according to the operation mode specified by TAPAnCTL0.TAPAnDCM.
Stop operation	Set up the TAPAnACWE register. Set TAPAnACWE to 1. Set up the TAPAnACTT register. Set TAPAnACTT to 1.	Writing to TAPAnACTT is enabled. Asynchronous Hi-Z control stopped (TAPAnFLG.TAPAnACE = 0)

Restart

15.4.2 INT signal output selection function

(1) Configuration of the INT signal output selection function

This function generates the peak interrupt $INTTAPAnIPEK_m$ and valley interrupt $INTTAPAnIVLY_m$ by using the $TAPATSIM_m$ signal, which is connected to the INT signal on the TAU's triangular carrier cycle generation channel (master).

For the connection destination of $TAPATSIM_m$, see the table TAPAn internal signals in the first section of this chapter.

Figure 15-5 Basic timing chart of signals for the INT signal output selection function

Triangular carrier cycles are generated on the master channel.

An interrupt generated on the master channel in each half triangular carrier cycle is connected to $TAPATSIM_m$, and then input to TAPAn. From $TAPATSIM_m$, the peak interrupt $INTTAPAnIPEK_m$ is generated at the peak of the triangle wave, and the valley interrupt $INTTAPAnIVLY_m$ is generated at the valley of the triangle wave.

Caution $INTTAPAnIPEK_m$ and $INTTAPAnIVLY_m$ are generated regardless of the TAU mode.

When not using these peak and valley interrupts, mask them by using the $ICTAPAnIPEK_m$ and $ICTAPAnIVLY_m$ registers, respectively.

15.4.3 A/D conversion trigger selection function

This function outputs the A/D conversion trigger signals TAPATADOUT0 and TAPATADOUT1 from the signals TAPATCDENS0 and TAPATCDENS1, which are connected to a compare match interrupt with TAU's triangular carrier cycle.

(1) Configuration of A/D conversion trigger selection function

Table 15-16 Signals used for TAPATADOUT generation

Output signal	Slave match detection signal	Valley interrupt signal
TAPATADOUT0	TAPATCDENS0	TAPATIVLY0
TAPATADOUT1	TAPATCDENS1	TAPATIVLY0

Table 15-17 Operation of TAPATADOUT0 according to the setting of TAPANCTL1.TAPANATS[3:0]

TAPAN ATS3	TAPAN ATS2	Description
0	0	Outputs the INT signal while the triangle wave is falling (counting down).
0	1	Outputs the INT signal while the triangle wave is rising (counting up).
1	0	Outputs the INT signal while the triangle wave is rising (counting up) or falling (counting down).
1	1	Outputs the INT signal and valley interrupt INTTAPANIVLY1 while the triangle wave is rising (counting up) or falling (counting down).

TAPAN ATS1	TAPAN ATS0	Description
0	0	Outputs the INT signal while the triangle wave is falling (counting down).
0	1	Outputs the INT signal while the triangle wave is rising (counting up).
1	0	Outputs the INT signal while the triangle wave is rising (counting up) or falling (counting down).
1	1	Outputs the INT signal and valley interrupt INTTAPANIVLY0 while the triangle wave is rising (counting up) or falling (counting down).

(2) Waveforms of A/D conversion trigger output control operation in triangle PWM mode

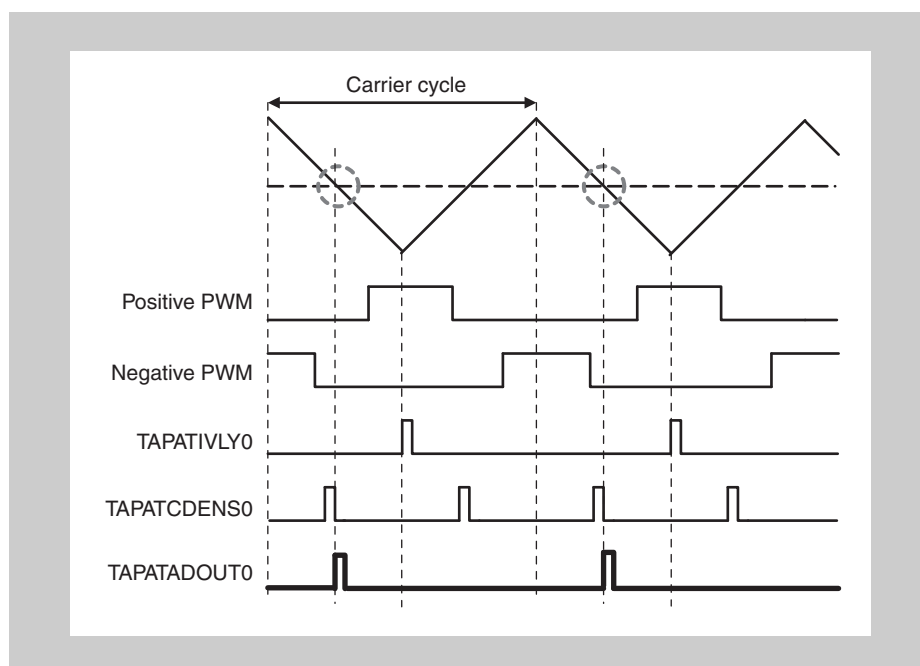

Figure 15-6 TAPAnATS[1:0] = 00B: Output of INT signal while the triangle wave is falling (counting down)

While the triangle wave is falling (counting down), the signals TAPATCDNS0 and TAPATCDNS1 are output as the A/D conversion trigger signals TAPATADOUT0 and TAPATADOUT1.

In this case, no A/D conversion trigger signal is output while the triangle wave is rising (counting up).

Figure 15-7 TAPAnATS[1:0] = 01B: Output of INT signal while the triangle wave is rising (counting up)

While the triangle wave is rising (counting up), the TAPATCDNS0 and TAPATCDNS1 signals are output as A/D conversion trigger signals TAPATADOUT0 and TAPATADOUT1.

In this case, no A/D conversion trigger signal is output while the triangle wave is falling (counting down).

Figure 15-8 TAPAnATS[1:0] = 10B: Output of INT signal while the triangle wave is rising (counting up) or falling (counting down)

The signals TAPATCDNS0 and TAPATCDNS1 are output as the A/D conversion trigger signals TAPATADOUT0 and TAPATADOUT1.

Figure 15-9 TAPAnATS[1:0] = 11B: Output of INT signal and valley interrupt while the triangle wave is rising (counting up) or falling (counting down)

The signals TAPATCDNS0 and TAPATCDNS1 and valley interrupt INTTAPAnIVLY0 are output as the A/D conversion trigger signals TAPATADOUT0 and TAPATADOUT1.

(3) Operating procedure for A/D conversion trigger selection function

The operating procedure for the A/D conversion trigger selection function is shown below.

	Operation	Status of TAU and TAPA
Restart ↑	Initial setup Initialize TAU. Specify the timer operation mode. Set up the TAPAnCTL1 register. Specify TAPAnATS[1:0] (TAPATADOUT0 setting). Specify TAPAnATS[3:2] (TAPATADOUT1 setting).	TAU and TAPA stop the operation.
	Start operation Start the TAU operation.	TAU starts count operation.
	During operation TAU operates according to the setting of each function.	The A/D conversion trigger selection function outputs either TAPATADOUT0 according to the setting of TAPAnATS[1:0] or TAPATADOUT1 according to the setting of TAPAnATS[3:2], based on the interrupt TAPATCDNS1 or TAPATCDNS0, which is input from TAU, and the valley interrupt TAPATIVLY1 or TAPATIVLY0, which is generated by TAPA.
	Stop operation Stop the TAU operation.	TAU stops the count operation.

Chapter 16 Peripheral Interconnection (PIC)

The PIC function implements a timer simultaneous start function, motor control function, and A/D trigger selection function by connecting timers and A/D converters.

16.1 V850E2/ML4 PIC Features

Instances This microcontroller has the following number of instances of the PIC.

Table 16-1 Instance

PIC	
Instances	1
Name	PIC0

Register addresses All PIC0 register addresses are given as address offsets to the individual base address <PIC0_base_USER> or <PIC0_base_OS>. The base addresses <PIC0_base_USER> and <PIC0_base_OS> of PIC0 are listed in the following table.

Table 16-2 Register base addresses

PIC0	Base address	Address
PIC0	<PIC0_base_USER>	FFFF DB00 _H
	<PIC0_base_OS>	FF81 C000 _H

Clock supply PIC provides one clock input.

Table 16-3 PIC0 clock supply

PIC0	PIC0 clock	Connected to:
PIC0	PCLK	f _{PCLK}

I/O signals The I/O signals connecting PIC with other functions are listed in the following table.

Table 16-4 I/O signals for PIC0 (1/2)

Signal name	I/O	Function	Connected to:
TOP0TAPATSIM0	O	TAUA master 0 INT input	TAPA0 TAPA2
TOP0TAPATUDCM0	O	TAUA master 0 up/down input	
TOP0TAPATHASIN	O	Asynchronous Hi-Z input signal	TAPA0

16.2 Functional Overview

Features summary The peripheral interconnection (PIC) function connects the internal I/O signals of the timers and A/D converters in the V850E2/ML4 to multiple macros. PIC is provided with the following functions:

- Inter-timer connection
 - Timer synchronous operation
- Connection to timer motor control function
- Connection between A/D converters and timers
 - A/D trigger selection
- Connection between CAN controllers and timers
 - CAN time stamp function

16.2.1 Block diagrams

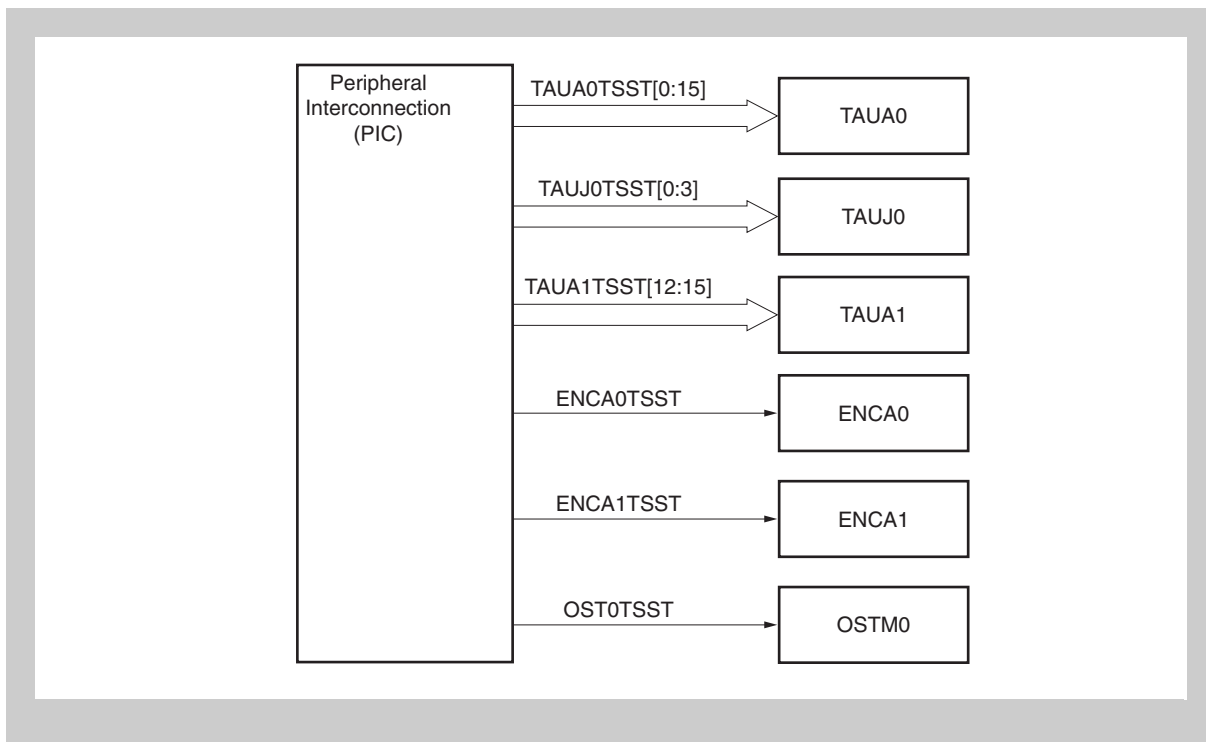

Figure 16-1 Block diagram of timer simultaneous start function

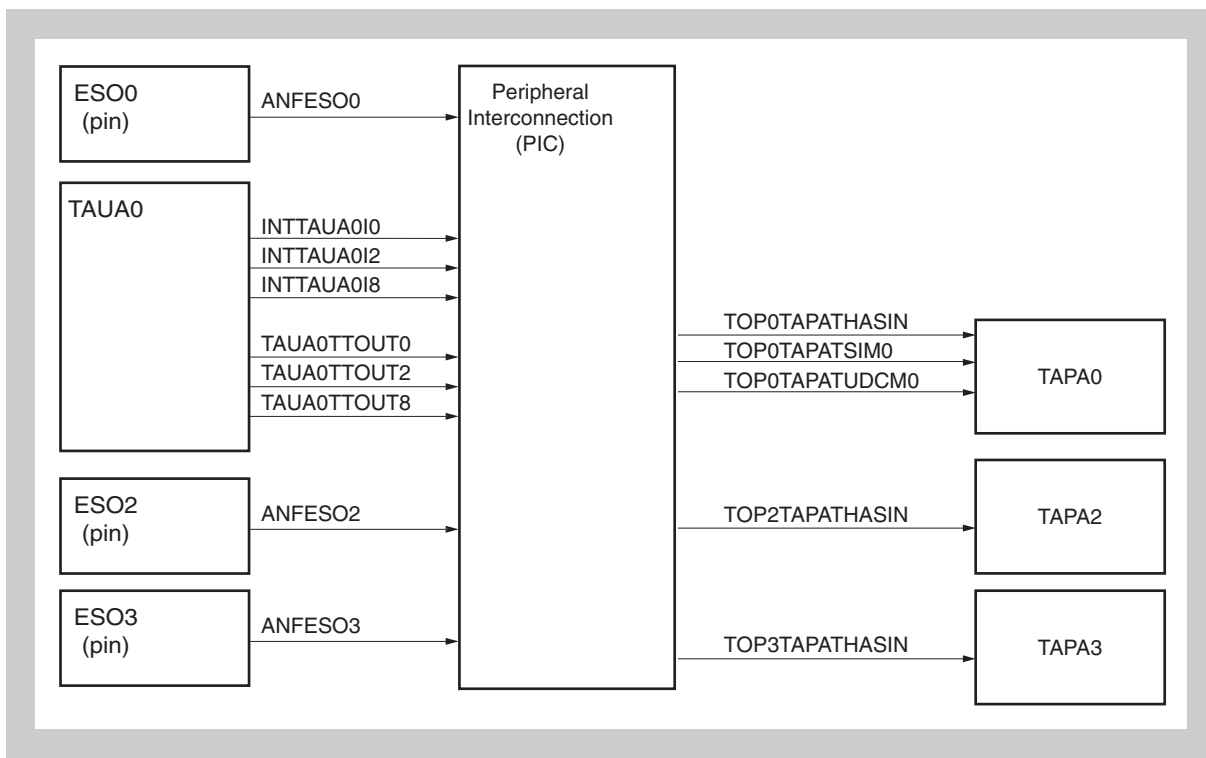

Figure 16-2 Block diagram of TAU0 and TAPA connection

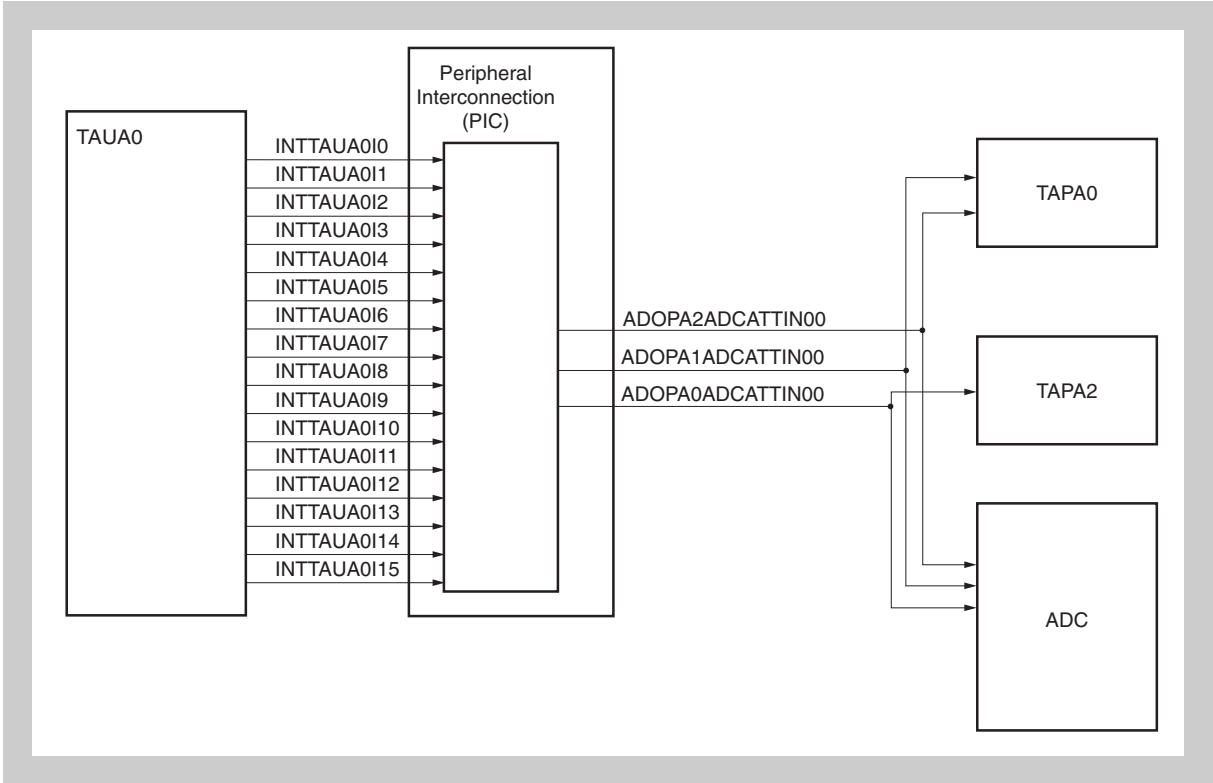

Figure 16-3 Block diagram of TAU0 and A/D converter connection

16.3 Control Registers

The PIC is controlled and operated by means of the following registers:

Table 16-5 PIC registers

Register function	Name	Address
Simultaneous start trigger control register	PIC0SST	<PIC0_base_USER> + 04 _H
Simultaneous start control register 0	PIC0SSER0	<PIC0_base_OS> + 80 _H
Simultaneous start control register 2	PIC0SSER2	<PIC0_base_OS> + 88 _H
PIC register 200	PIC0REG200	<PIC0_base_OS> + 8C _H
Hi-Z output control register 0	PIC0HIZCEN0	<PIC0_base_OS> + B4 _H
Hi-Z output control register 2	PIC0HIZCEN2	<PIC0_base_OS> + DC _H
Hi-Z output control register 3	PIC0HIZCEN3	<PIC0_base_OS> + E4 _H
A/D converter trigger output control register 400	PIC0ADTEN400	<PIC0_base_OS> + C4 _H
A/D converter trigger output control register 401	PIC0ADTEN401	<PIC0_base_OS> + C8 _H
A/D converter trigger output control register 402	PIC0ADTEN402	<PIC0_base_OS> + CC _H
PIC register 31	PIC0REG31	<PIC0_base_OS> + C0 _H

16.3.1 Registers used to set up timer simultaneous start function

(1) PIC0SST - Simultaneous start trigger control register

Access This register can be read/written in 8 and 1-bit units.

Address <PIC0_base_USER> + 04_H

Default value 00_H

7	6	5	4	3	2	1	0
0	0	0	0	0	0	0	SYNCTRG
R	R	R	R	R	R	R	R/W

Table 16-6 PIC0SST register contents

Bit position	Bit name	Functions
0	SYNCTRG	Specify whether to generate a start trigger for the timer for which simultaneous start is enabled. 0: Disable 1: Generate a simultaneous start trigger (output of a 1-PCLK-width pulse)

Note The SYNCTRG bit is always read as 0.

(2) PIC0SSER0 - Simultaneous start control register 0

This register is used to enable or disable simultaneous start trigger output for each channel of TAU0.

Access This register can be read or written in 16-bit units.

Address <PIC0_base_OS> + 80_H

Default value 0000_H

15	14	13	12	11	10	9	8
PIC0SS ER015	PIC0SS ER014	PIC0SS ER013	PIC0SS ER012	PIC0SS ER011	PIC0SS ER010	PIC0SS ER009	PIC0SS ER008
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
7	6	5	4	3	2	1	0
PIC0SS ER007	PIC0SS ER006	PIC0SS ER005	PIC0SS ER004	PIC0SS ER003	PIC0SS ER002	PIC0SS ER001	PIC0SS ER000
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 16-7 PIC0SSER0 register contents

Bit position	Bit name	Function
m	PIC0SSER0m	Enable or disable simultaneous start trigger output for CHm of TAU0. 0: Disable simultaneous start trigger output for CHm of TAU0. 1: Enable simultaneous start trigger output for CHm of TAU0.

(3) PIC0SSER 2 - Simultaneous start control register 2

This register is used to enable or disable simultaneous start trigger output for each channel of ENC, the OS timer, TAUJ1, and TAUJ0.

Access This register can be read or written in 16-bit units.

Address <PIC0_base_OS> + 88_H

Default value 0000_H

15	14	13	12	11	10	9	8
PIC0SS ER115	PIC0SS ER114	0	PIC0SS ER112	0	0	0	0
R/W	R/W	R	R/W	R	R	R	R
7	6	5	4	3	2	1	0
PIC0SS ER107	PIC0SS ER106	PIC0SS ER105	PIC0SS ER104	PIC0SS ER103	PIC0SS ER102	PIC0SS ER101	PIC0SS ER100
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 16-8 PIC0SSER2 register contents

Bit position	Bit name	Function
15	PIC0SSER215	Enable or disable simultaneous start trigger output for ENCA1. 0: Disable simultaneous start trigger output for ENCA1. 1: Enable simultaneous start trigger output for ENCA1.
14	PIC0SSER214	Enable or disable simultaneous start trigger output for ENCA0. 0: Disable simultaneous start trigger output for ENCA0. 1: Enable simultaneous start trigger output for ENCA0.
12	PIC0SSER212	Enable or disable simultaneous start trigger output for OSTM0. 0: Disable simultaneous start trigger output for OSTM0. 1: Enable simultaneous start trigger output for OSTM0.
7	PIC0SSER207	Enable or disable simultaneous start trigger output for CH15 of TAUJ0. 0: Disable simultaneous start trigger output for CH15 of TAUJ0. 1: Enable simultaneous start trigger output for CH15 of TAUJ0.
6	PIC0SSER206	Enable or disable simultaneous start trigger output for CH14 of TAUJ0. 0: Disable simultaneous start trigger output for CH14 of TAUJ0. 1: Enable simultaneous start trigger for output CH14 of TAUJ0.
5	PIC0SSER205	Enable or disable simultaneous start trigger output for CH13 of TAUJ0. 0: Disable simultaneous start trigger output for CH13 of TAUJ0. 1: Enable simultaneous start trigger output for CH13 of TAUJ0.
4	PIC0SSER204	Enable or disable simultaneous start trigger output for CH12 of TAUJ0. 0: Disable simultaneous start trigger output for CH12 of TAUJ0. 1: Enable simultaneous start trigger output for CH12 of TAUJ0.
3	PIC0SSER203	Enable or disable simultaneous start trigger output for CH3 of TAUJ0. 0: Disable simultaneous start trigger output for CH3 of TAUJ0. 1: Enable simultaneous start trigger output for CH3 of TAUJ0.
2	PIC0SSER202	Enable or disable simultaneous start trigger output for CH2 of TAUJ0. 0: Disable simultaneous start trigger output for CH2 of TAUJ0. 1: Enable simultaneous start trigger output for CH2 of TAUJ0.
1	PIC0SSER201	Enable or disable simultaneous start trigger output for CH1 of TAUJ0. 0: Disable simultaneous start trigger output for CH1 of TAUJ0. 1: Enable simultaneous start trigger output for CH1 of TAUJ0.
0	PIC0SSER200	Enable or disable simultaneous start trigger output for CH0 of TAUJ0. 0: Disable simultaneous start trigger output for CH0 of TAUJ0. 1: Enable simultaneous start trigger output for CH0 of TAUJ0.

16.3.2 Registers used to make connections between TAUA and TAPA

(1) PIC0HIZCENn - Hi-Z output control register n (n = 0, 2, 3)

This register is used to select the Hi-Z output control input signal of TAPAn.

Access This register can be read or written in 8-bit units.

Address PIC0HIZCEN0: <PIC0_base_OS> + B4_H
 PIC0HIZCEN2: <PIC0_base_OS> + DC_H
 PIC0HIZCEN3: <PIC0_base_OS> + E4_H

Default value 00_H. This register is initialized by any reset.

Caution The settings of this register must be specified with “No edge detection” specified as the valid edge of the Hi-Z request signal of TAPAn.

16.3.3 Registers used to make connections between TAUA and the A/D converter

(1) PIC0ADTEN40m - A/D converter trigger output control register 40m

This register is used to enable or disable selection of a signal from TAUA0 as the trigger source for channel group CGm (m = 0 to 2) of ADCA0.

Access This register can be read or written in 16-bit units.

Address PIC0ADTEN400: <PIC0_base_OS> + C4_H

PIC0ADTEN401: <PIC0_base_OS> + C8_H

PIC0ADTEN402: <PIC0_base_OS> + CC_H

16.4 Functions

16.4.1 Timer simultaneous start function

This function generates a start trigger input signal, which is used to operate TAU0, TAU1, TAUJ0, ENCA0, ENCA1, and OSTM0 synchronously.

For details about the start trigger input, see the description about the trigger input for each macro.

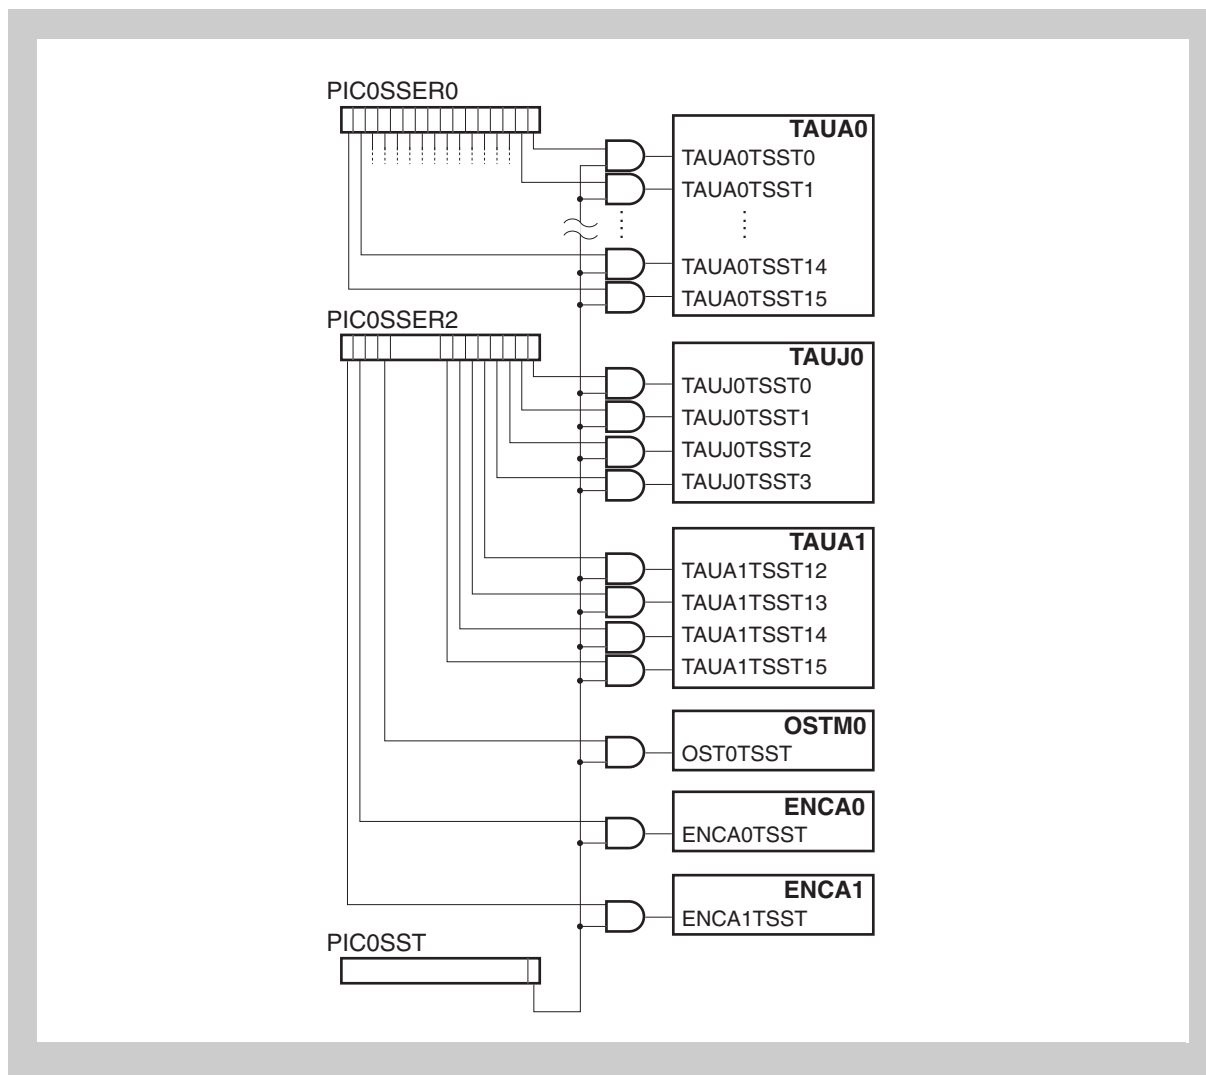

Figure 16-4 Block diagram of timer simultaneous start function

16.4.2 TAU0 and TAPA connection function (including Hi-Z output control)

- Hi-Z output control

This function controls the Hi-Z output control signal input to TAPATHASIN of each TAPA.

- TAU0 and TAPA connection

This function selects a pair of signals from among the signals output from TAU0 (the INTTAUA0Im and TAU0TTOUTm (m = 0, 2, or 8) signals) according to the setting of the PIC0REG200 register, and then outputs them to TAPA0 and TAPA2 as TOP0TAPATSIM0 and TAPA0TAPATUDCM0.

16.4.3 TAU0 and A/D converter connection function

Each A/D converter has three channel groups, and A/D converter hardware triggers are provided for each channel group.

The TAU0 and A/D converter connection function of PIC ORs the internal trigger signals output from TAU0, and then outputs the generated signal as the A/D converter hardware trigger signal for each channel group.

The internal trigger signals input from TAU0 are the cycle (borrow) detection signals specified by the CNTn register for each channel.

The A/D converter hardware trigger signals are also output to TAPA.

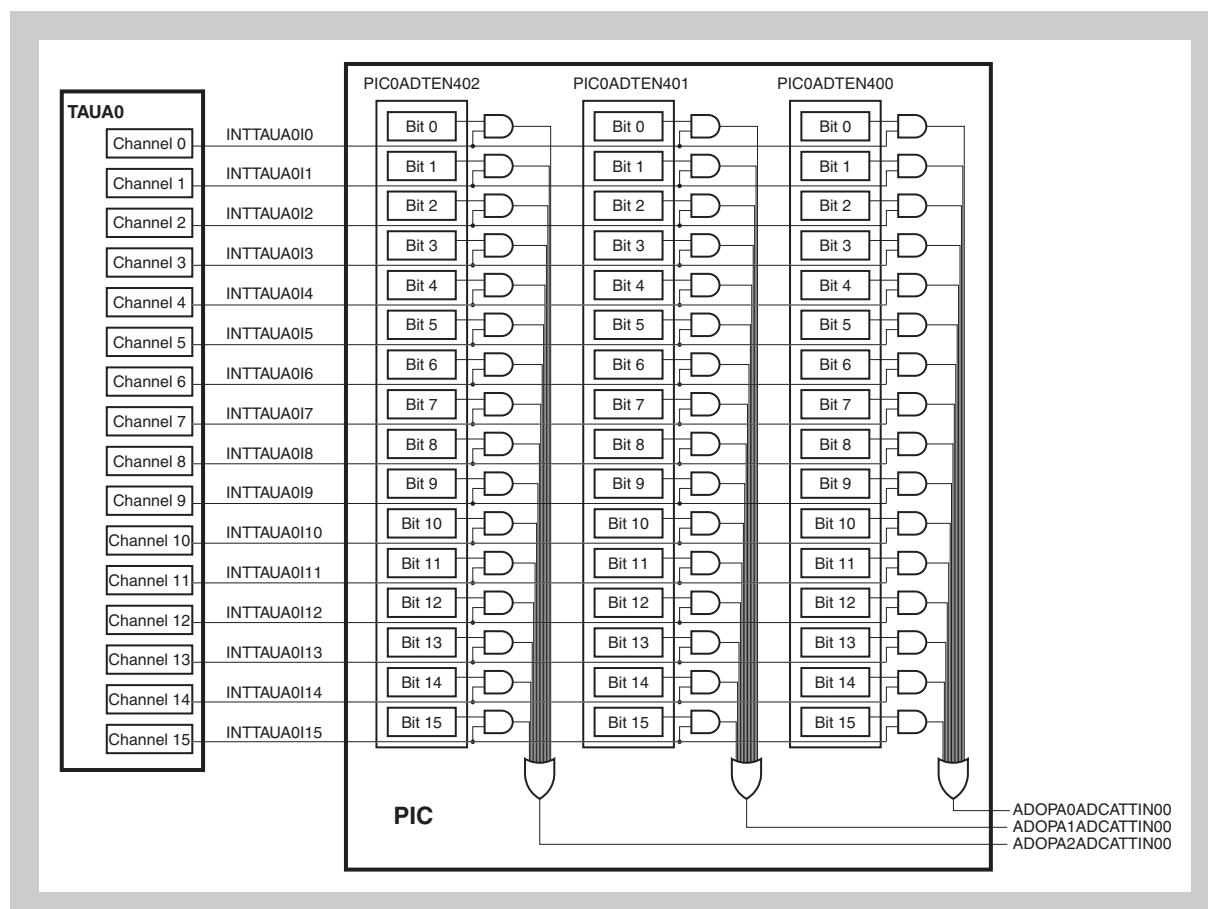

Figure 16-5 Block diagram of TAU0 and A/D converter connection function

16.5 Connection between CAN controllers and timers (CAN time stamp function)

16.5.1 Overview

A time stamp can be specified for received messages by using the CAN controller and timer array unit together.

With this function, the timer array unit captures a timer value according to the TSOUT signal that is output from the CAN controller upon data frame reception. The CPU reads the captured value to obtain the time that the capture event occurred; in other words, the time stamp of the message received on the CAN bus.

FCN0 can be used together with CH1 of TAUJ0.

16.5.2 Configuration

The instances and channels used for this function are as follows:

Table 16-11 Configuration of CAN time stamp function

CAN controller	Timer
FCN0	TAUJ0 CH1

Figure 16-6 Block diagram of CAN time stamp function

16.5.3 Register

(1) PIC0REG31 - Timer I/O control register 31

This register is used to select the timer input signal.

Access This register can be read or written in 32-bit units.

Address <PIC0_base_OS> + C0_H

Default value 0000 0000_H. This register is initialized by any reset.

31	30	29	28	27	26	25	24
0	0	0	0	0	0	0	0

Chapter 17 Window Watchdog Timer A (WDTA)

This chapter contains a generic description of window watchdog timer A.

17.1 “V850E2/ML4 WDTA Features” and 17.2 “WDTA Start-up Options” describe all properties specific to the V850E2/ML4, such as instances, register base addresses, and input/output signal names.

The subsequent sections describe the features that apply to all implementations.

17.1 V850E2/ML4 WDTA Features

Instances This microcontroller has two instances of window watchdog timer A.

Table 17-1 Instances of WDTA

Window watchdog timer A	V850E2/ML4
Instances	1
Names	WDTA0

Instances index n Throughout this chapter, the individual instances of window watchdog timer A are identified by the index “n” (n = 0, 1), for example, WDTAnWDTE for the WDTAn watchdog timer enable register.

Register addresses All WDTAn register addresses are given as addresses offset from the individual base address <WDTAn_base> of each WDTAn.

The <WDTAn_base> addresses of each WDTAn are listed in the following table:

Table 17-2 Register base addresses of WDTAn

WDTAn	<WDTAn_base> address
WDTA0	FFFF C000 _H

Clock supply The input clock for window watchdog timer A is WDTATCKI. WDTATCKI is connected to a clock generator.

Table 17-3 Clock of window watchdog timer A

WDTAn	Clock input signal	Connected to
WDTA0	WDTATCKI	f _{xw}

Interrupts and reset outputs The interrupts and reset outputs of WDTAn are listed in the table below.

Table 17-4 WDTA interrupts and reset outputs

WDTAn signals	Function	Connected to
WDTA0		
WDTA0TRES	WDTA0 error reset	Reset Controller WDTA0RES
WDTA0TNMI	WDTA0 error NMI	Interrupt Controller WDTA0NMI
INTWDT0	WDTA0 75% interrupt	Interrupt Controller INTWDT0

WDTATRTP The connections of the WDTA reset type input signals are listed in the table below.

Table 17-5 WDTATRTP connections

WDTAn signals	Connected to
WDTA0TRTP	0 (fixed)

Restrictions The V850E2/ML4 does not support the default start mode and variable activation code (VAC) for WDTA.

Accessing WDTAnEVAC and WDTAnREF is prohibited.

17.2 WDTA Start-up Options

The start-up options determine the start-up configuration of WDTA after reset release. They are described in the following table.

Table 17-6 WDTA start-up options

Start-up option	Function	Description
OPWDEN	WDTA enabler/disabler	Enables/disables WDTA: 1: WDTA is fixed to be enabled
OPWDOVF[2:0]	Count clock setting	Specifies the reset value of the count clock control bits WDTAnMD.WDTAnOVF[2:0]. These bits are fixed to 000
OPWDTPR	Start mode signal selector	Specifies the signal that sets the start mode: 0: This bit fixed to be OPWDRUN start-up option
OPWDRUN	Automatic start enabler	Specifies the start mode: 0: Software trigger start mode is fixed
OPWDVAC	Variable Activation Code (VAC) enabler	Enables/disables the Variable Activation Code function (VAC) 0: VAC is fixed to be disabled
OPWDWS[1:0]	Initial open window size setting	Specifies the reset value of the open window size control bits WDTAnMD.WDTAnWS[1:0]. These bits are fixed to 111 The open window size control bits only apply after the first WDTA trigger and not after reset release. After reset release the open window size is 100%. Refer to 17.4.5 “Window function” for details.
OPWDINT	INTWDTn (75% interrupt) request generation	Specifies the reset value of control bit WDTAnMD.WDTAnWIE. This bit enables/disables the output of the 75% interrupt request INTWDTn. This bit is fixed to be 1 Refer to 17.4.4 “75% interrupt output” for details.

17.3 Functional Overview

Features summary WDTA has the following functions:

- Operation mode after reset selectable by using start-up option
- Fixed activation code and variable activation code (VAC) selectable
- Two start modes available:
 - Automatic start mode
 - Software trigger mode
- Reset-dependent start mode selection
- Error mode:
- Operation upon error detection selectable:
 - Generation of NMI request WDTAnTNMI on error detection
 - Generation of reset WDTAnTRES on error detection
- Interrupt request generation at 75% of the counter overflow value
- Window function

The following figure shows the main components of WDTA:

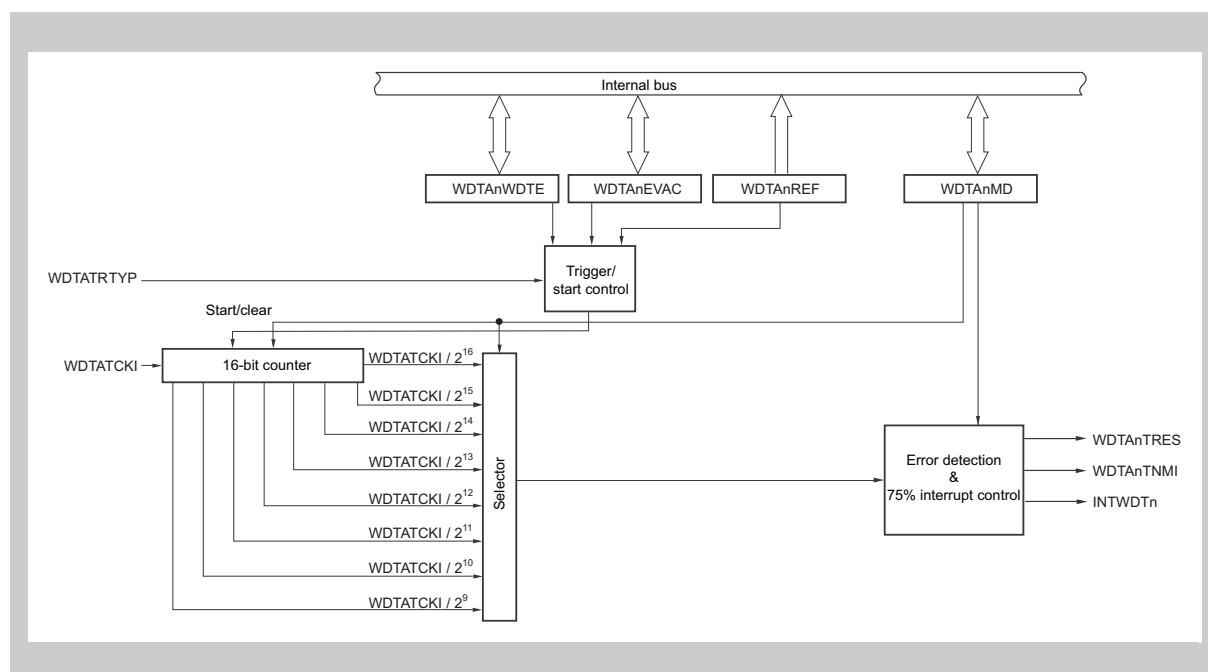

Figure 17-1 Block diagram of WDTA

17.4 Functional Description

WDTA generates a reset or a non-maskable interrupt if the 16-bit counter overflows or if any other error condition is fulfilled. For a description of all error conditions, refer to *17.4.3 “Error detection” on page 969*.

The counter is cleared and restarted every time a WDTA trigger occurs in the open window period. Refer to *17.4.2 “WDTA trigger” on page 968* and *17.4.5 “Window function” on page 972* for details.

At 75% of the maximum counter value, WDTA can generate an interrupt request INTWDTn. Refer to *17.4.4 “75% interrupt output” on page 970* for details.

The start-up option specifies the start mode and WDTA setting after reset release. The setting can be changed by writing to the watchdog timer mode register WDTAnMD. For details, see *17.4.1 “WDTA after reset release” on page 965*.

17.4.1 WDTA after reset release

(1) Start modes

WDTA provides two modes for the counter start after reset release:

- Software trigger start mode
The counter value remains 0000_H after reset release.
The counter is started with the first WDTA trigger.
- Automatic start mode
The counter starts automatically after reset release.

(2) Start mode selection

The start mode can be selected as follows:

- By start-up options
- By the WDTATRTYP input signal

This signal indicates the reset type. Thus, the selected start mode after reset release depends on the reset type.

The start mode selection is listed in the following table.

Table 17-7 Start mode selection

Start-up options		Input signal	Reset type	Start mode
OPWDTPR	OPWDRUN	WDTATRTYP		
0	0	Ignored	Ignored	Software trigger
0	1	Ignored	Ignored	Automatic
1	Ignored	0	Any apart from automatic start reset source	Software trigger
1	Ignored	1	Automatic start reset source	Automatic

(3) WDTA settings after reset release

The WDTA settings are as follows between reset release and the first trigger:

Function	Setting	Remark
Start mode	Specified by start-up options	For a description of the start modes, refer to 17.4.1 "WDTA after reset release" on page 965.
Count clock		
75% interrupt mode		
Error mode	Reset mode	Any error condition before the first trigger generates a reset.
Open window size	100%	If automatic start mode is specified, the first trigger is valid any time before the counter overflows.

Change WDTA settings After the first trigger, WDTA continues according to the settings of the watchdog timer mode register WDTAnMD.

To change the WDTA settings, WDTAnMD must be written *before* the first trigger. Changing the value of WDTAnMD *after* the first trigger leads to an error.

If WDTAnMD is not changed before the first trigger, the WDTA mode is specified by the initial value of WDTAnMD.

The new or initial value of WDTAnMD applies after the first trigger.

Automatic start mode timing The automatic start mode timing and the changes to the WDTA settings are illustrated in the following figure.

Figure 17-2 Timing diagram of WDTA start in automatic start mode

The timing diagram above shows the following:

1. After reset release, the counter starts immediately.
The count clock is specified by the start-up options, for example:
 - Count clock after reset release = $WDTATCKI / 2^{13}$
($OPWDOVF[2:0] = 100_B$)
2. WDTAnMD is written before the first trigger. However, the settings are not applied immediately.
3. The first trigger must occur before the counter overflows.
After the first trigger, the settings specified in WDTAnMD are applied, for example a new count clock.

Software trigger start mode timing

The software trigger start mode timing and the changes to the WDTA settings are illustrated in the following figure.

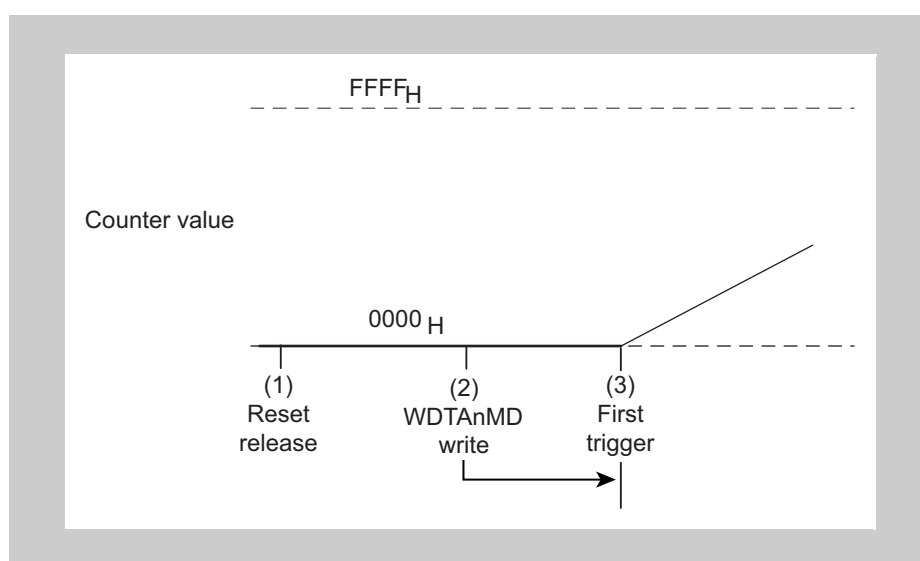

Figure 17-3 Timing diagram of WDTA start in software trigger start mode

The timing diagram above shows the following:

1. After reset release, the counter remains 0000_H until the first trigger.
The count clock is specified by the start-up options, but it does not have any effect.
2. WDTAnMD is written before the first trigger. However, the settings are not applied immediately.
3. The counter starts at the first trigger.
The count clock and other settings specified in WDTAnMD are applied.

17.4.2 WDTA trigger

The WDTA trigger has the following functions:

- Counter start trigger in software trigger start mode
- Counter restart trigger to avoid counter overflow

The trigger register used differs depending on whether the activation code is fixed or variable. The type of activation code and the associated trigger register are specified by using the start-up option OPWDVAC.

Table 17-8 Trigger register and activation code

Type of activation code	Trigger register	Activation code
Fixed	WDTAnWDTE	AC _H
Variable	WDTAnEVAC	Refer to (1) "Variable activation code calculation" on page 968 for details.

(1) Variable activation code calculation

The variable activation code (ExpectWDTE) is calculated using a reference value in register WDTAnREF. The reference value in WDTAnREF is updated each time the trigger register WDTAnEVAC is written.

Use the expression below to calculate the variable activation code (ExpectWDTE):

$$\text{ExpectWDTE} = \text{AC}_H - \text{WDTAnREF (old)}$$

Use the expression below to calculate how the WDTAnREF value is updated:

$$\text{WDTAnREF (new)} = \text{rotate left 1 bit (ExpectWDTE)}$$

WDTAnREF is also updated upon an erroneous WDTA trigger, i.e.:

- When the value written to WDTAnEVAC differs from the expected activation code.
- When writing to WDTAnEVAC outside the open window.

In either case, a WDTAnTRES reset or WDTAnTNMI interrupt request is generated.

The table below lists the variable activation codes according to the number of triggers.

Table 17-9 Variable activation code development

No ^a	WDTAnREF (old)		ExpectWDTE (AC _H - WDTAnREF)		WDTAnREF (new)	
0	0000 0000	00 _H	1010 1100	AC _H	0101 1001	59 _H
1	0101 1001	59 _H	0101 0011	53 _H	1010 0110	A6 _H
2	1010 0110	A6 _H	0000 0110	06 _H	0000 1100	0C _H
...

a) Number of triggers after reset

This generates a sequence of 122 different numbers that have to be used to re-trigger the Watchdog Timer.

Note Bit 7 of the WDTAnEVAC register (WDTAnEVAC7) cannot be cleared to 0 after WDTA has been started. Thus even if bit 7 of the activation code is 0, WDTA will not stop.

17.4.3 Error detection

The conditions for error detection are:

- Overflow interval time is exceeded (counter overflow)
- Wrong activation code is written to the trigger register
- Writing to the trigger register outside the open window.
- Illegal update of watchdog timer mode register WDTAnMD:
 - Writing a *new* value to WDTAnMD after the first trigger leads to an error detection.
 - Writing the same value to WDTAnMD after the first trigger does *not* lead to an error detection.

Error mode When an error is detected, either an NMI request (WDTAnTNMI) or a reset (WDTAnTRES) is generated.

WDTAnMD.WDTAnERM selects the error mode:

- WDTAnMD.WDTAnERM = 0: NMI mode
- WDTAnMD.WDTAnERM = 1: reset mode

The following figure shows the reset or NMI request generation when the counter overflows and automatic start mode is selected.

Figure 17-4 Timing diagram of WDTA NMI request or reset generation

The timing diagram above shows the following:

1. After reset release, the counter starts (automatic start mode is selected).
2. WDTAnMD is written before the first trigger. However, the settings are not applied immediately.
3. The counter is cleared at the first trigger and the new WDTA settings are applied.
4. When the counter overflows, an error is detected. Depending on the error mode, either interrupt request WDTAnTNMI or reset WDTAnTRES is generated.

The counter value remains until the system reset is performed.

5. When the system is reset, the counter is cleared and stopped until reset release.

17.4.4 75% interrupt output

When the counter reaches 75% of the maximum counter value, the interrupt request INTWDTn is generated.

This function can be automatically enabled with the start-up option OPWDINT = 1.

This function can be enabled or disabled by specifying a setting in the WDTAnMD.WDTAnWIE register.

The following figure shows 75% interrupt request generation under the following conditions:

- Automatic start mode selected
- Count clock changes after first trigger

Figure 17-5 Timing diagram of WDTA 75% interrupt output

17.4.5 Window function

When the open window size is set to less than 100%, an error is detected if the trigger occurs outside the open window.

The definition of the open window size differs before and after the first trigger:

- After reset release, the open window size is 100%.
OPWDWS[1:0] and bits WDTAnMD.WDTAnWS[1:0] are not applied.
- After the first trigger, the open window size is specified by bits WDTAnMD.WDTAnWS[1:0].

The following figure shows WDTA operation with an open window size of 25% and with automatic start mode selected.

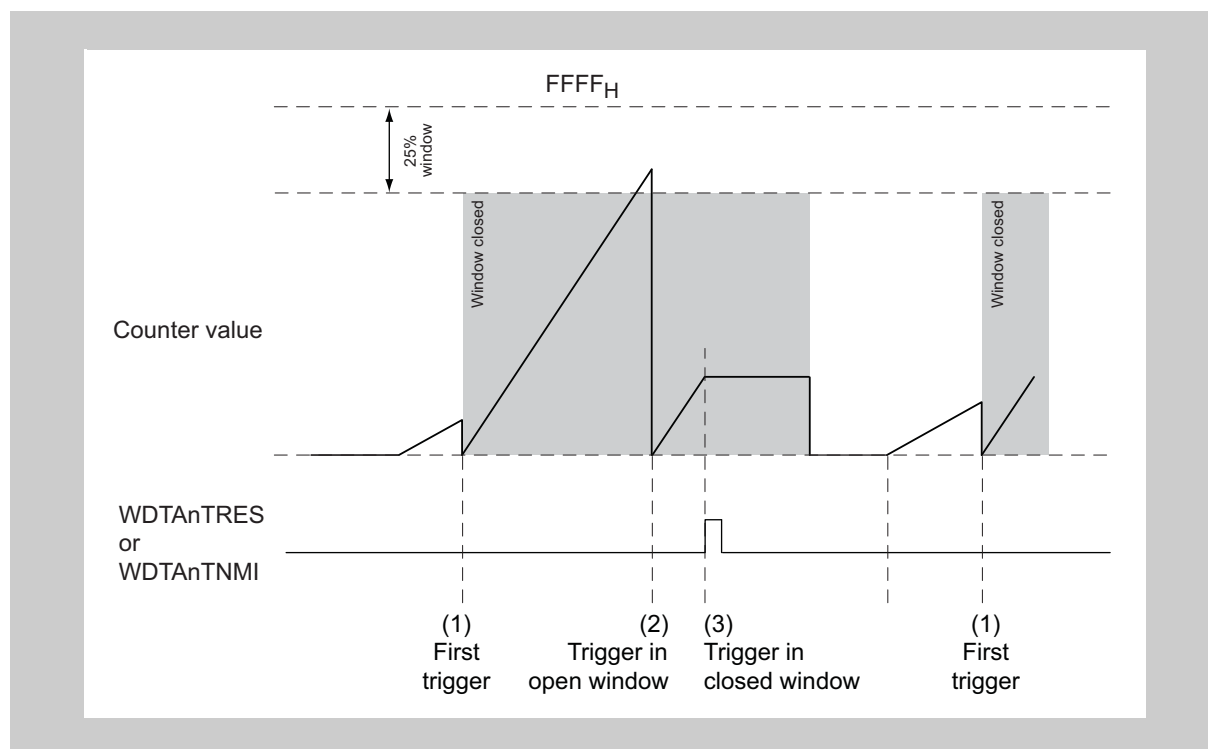

Figure 17-6 Timing diagram of WDTA window function

The timing diagram above shows the following:

1. The open window size is fixed to 100% for the first trigger.
2. A trigger that occurs in the open window does not generate an error.
3. A trigger that occurs in the closed window generates a WDTAnTNMI request or a WDTAnTRES reset, depending on the selected error mode.

17.5 Registers

This section contains a description of all registers of WDTA.

17.5.1 WDTA register overview

WDTA is controlled and operated by the following registers:

Table 17-10 WDTA register overview

Register name	Shortcut	Address
WDTA enable register	WDTAnWDTE	<WDTAn_base> + 0000 _H
WDTA enable register for VAC	WDTAnEVAC	<WDTAn_base> + 0004 _H
WDTA reference value register	WDTAnREF	<WDTAn_base> + 0008 _H
WDTA mode register	WDTAnMD	<WDTAn_base> + 000C _H

17.5.2 WDTA registers details

(1) WDTAnWDTE – WDTA enable register

This register is the WDTA start control and trigger register if the VAC function is not used (start-up option OPWDVAC = 0).

WDTA trigger Writing AC_H to this register restarts the counter. Refer to 17.4.2 “WDTA trigger” on page 968 for details.

The behaviour of this register depends on activation of the VAC function, refer to Table 17-13 “WDTAnWDTE behaviour”.

Access This register can be read/written in 8-bit units.

Address <WDTAn_base> + 0000_H

Initial Value Depends on start-up options OPWDEN, OPWDTPR, WDTATRTP, OPWDRUN and OPWDVAC. Refer to Table 17-12 “WDTAnRUN initial value”.

Reset input initializes this register to 0000H.

	7	6	5	4	3	2	1	0
	WDTAnRUN	0	1	0	1	1	0	0
	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 17-11 WDTAnWDTE register contents

Bit position	Bit name	Function
7	WDTAnRUN	Enables/disables WDTAn: 0: WDTAn disabled 1: WDTAn enabled Since WDTA cannot be stopped once it was started, this bit can only be cleared by a reset.

Initial value This bit is only valid if WDTA is enabled (OPWDEN = 1) and VAC is disabled (OPWDVAC = 0). In this case, the initial value of bit WDTAnRUN depending on other start-up options is listed below:

Table 17-12 WDTAnRUN initial value

Start-up options		Input signal	Start mode	Initial value of WDTAnRUN
OPWD TPR	OPWD RUN	WDTATRTP		
0	0	Ignored	Software trigger	0
0	1	Ignored	Automatic	1
1	0	Ignored	Software trigger	0
1	Ignored	0	Software trigger	0
1	Ignored	1	Automatic	1

The behaviour of WDTAnWDTE during read/write accesses depends on activation of the VAC mode, as shown in the table below.

Table 17-13 WDTAnWDTE behaviour

OPWDVAC	WDTAnWDTE		Remark
	Read	Write	
0	AC _H	Ignored	VAC disabled: WDTAnWDTE enabled
1	2C _H	Ignored WDTA trigger AC _H ^a	VAC enabled: WDTAnWDTE disabled

a) Any other write value will lead to an error detection.

(2) WDTAnEVAC – WDTA enable VAC register

This register is the start control and trigger register if the VAC function is used (start-up option OPWDVAC = 1).

WDTA trigger Writing the correct activation code to this register restarts the counter. Refer to 17.4.2 “WDTA trigger” on page 968 .

The behaviour of this register depends on activation of the VAC function, refer to Table 17-16 “WDTAnEVAC behaviour”.

Access This register can be read/written in 8-bit units.

Address <WDTAn_base> + 0004_H

Initial Value Depends on start-up options OPWDEN, OPWDTPR, WDTATRTP, OPWDRUN and OPWDVAC. Refer to Table 17-14 “WDTAnEVAC register contents”.

Reset input initializes this register to 0000_H.

	7	6	5	4	3	2	1	0
WDTAnEVAC7	0	1	0	1	1	0	0	
	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 17-14 WDTAnEVAC register contents

Bit position	Bit name	Function
7	WDTAnEVAC7	Starts or stops WDTAn. 0: Stop WDTAn. 1: Start WDTAn. Since WDTA cannot be stopped once it was started, this bit can only be cleared by a reset. Thus even if bit 7 of the activation code is 0, WDTA will not stop.

Initial value This bit is only valid if WDTA is enabled (OPWDEN = 1) and VAC is enabled (OPWDVAC = 1). In this case, the initial value of bit WDTAnEVAC7 depending on other start-up options is listed below:

Table 17-15 WDTAnEVAC7 initial value

Start-up options		Input signal	Start mode	Initial value of WDTAnEVAC7
OPWDTPR	OPWDRUN	WDTATRTP		
0	0	Ignored	Software trigger	0
0	1	Ignored	Automatic	1
1	Ignored	0	Software trigger	0
1	Ignored	1	Automatic	1

The behaviour of WDTAnEVAC during read/write accesses depends on activation of the VAC mode, as shown in the table below.

Table 17-16 WDTAnEVAC behaviour

OPWDVAC	WDTAnEVAC		Remark
	Read	Write	
0	2C _H	ignored	VAC disabled: WDTAnEVAC disabled
1	last written VAC	WDTA trigger VAC ^a	VAC enabled: WDTAnEVAC enabled

a) Any other write value will lead to an error detection.

(3) WDTAnREF – WDTA reference value register

This register contains the reference value for calculating the activation code of the VAC function. It is automatically updated after every trigger operation. Refer to 17.4.2 “WDTA trigger” on page 968.

If VAC is disabled (OPWDVAC = 0), reading this register returns 00_H.

Access This register can be read in 8-bit units.

Address <WDTAn_base> + 0008_H

Initial Value Reset input initializes this register to 00H.

7	6	5	4	3	2	1	0
WDTAnREF[7:0]							
R	R	R	R	R	R	R	R

Table 17-17 WDTAnREF register contents

Bit position	Bit name	Function
7 to 0	WDTAnREF[7:0]	Reference value for activation code calculation.

(4) WDTAnMD – WDTA mode register

This register specifies the overflow interval time, the 75% interrupt output mode, the error mode, and the open window size.

It can be updated only once after reset release and before the first trigger. The updated value is effective from the next WDTA trigger.

Updating this register after WDTA has been started leads to error detection, but the read value of this register can be written without generating an error.

Access This register can be read/written in 8-bit units.

Address <WDTAn_base> + 000C_H

Initial Value Depends on start-up options OPWDOVF[2:0], OPWDINT and OPWDWS[1:0]. Refer to 17.2 “WDTA Start-up Options”.
Reset input initializes this register to 0000H.

7	6	5	4	3	2	1	0
0	WDTAnOVF[2:0]			WDTAnWIE	WDTAnERM	WDTAnWS[1:0]	
R/W ^a	R/W	R/W	R/W	R	R/W	R/W	R/W

a) Writing to this bit is ignored, reading returns 0.

Table 17-18 WDTAnMD register contents

Bit position	Bit name	Function

Chapter 18 OS Timer (OSTM)

This chapter contains a generic description of the OS timer.

The first section describes all properties specific to the V850E2/ML4, such as instances, register base addresses, and input/output signal names. The subsequent sections describe the features that apply to all implementations.

18.1 V850E2/ML4 OSTM Features

Instances This microcontroller has the following number of instances of the OS timer.

Table 18-1 Instances of OS Timer

OS timer	V850E2/ML4
Instances	1
Names	OSTM0

Instances index n Throughout this chapter, the individual instances of OSTM is identified by the index “n” (n = 0), for example, OSTMnCTL for the OSTM control register.

Register addresses All OS timer register addresses are given as addresses offset from the individual base addresses <OSTMn_base>. The <OSTMn_base> addresses of each OSTMn are listed in the following table:

Table 18-2 Register base addresses <OSTMn_base>

OSTMn instance	<OSTMn_base> address
OSTM0	FF80 0000 _H

Clock supply The following clock is supplied to the OS timer:

Table 18-3 OSTM clock supply

OSTMn instance	OSTMn clock	Connected to
OSTM0	PCLK	f _{PCLK}

I/O signals The I/O signals of the OS timer are listed in the table below.

Table 18-4 OSTMn I/O signals

OSTMn signals	Function	Connected to
OSTMnTCKE	Count clock enable	Fixed to 1.
OSTMnTSST	Count start	PIC
OSTMnTOUT	OS Timer output	No connection

Interrupts The OS Timer can generate the following interrupt requests:

Table 18-5 OSTMn interrupt requests

OSTMn signals	Function	Connected to
OSTM0		
OSTM0TINT	OSTM0 interrupt	Interrupt Controller INTOSTM0

18.2 Functional Overview

Features summary The OS timer has the following features:

- Two operation modes
 - Interval timer mode
 - Free-run compare mode
- Two output modes (if OSTMnTTOUT signal is externally output)
 - Software control mode
 - Timer output toggle mode
- Synchronization with other peripheral functions (if a signal is input to OSTMnTSST)
- OSTMnTINT interrupt

The following block diagram shows the main components of the OS timer.

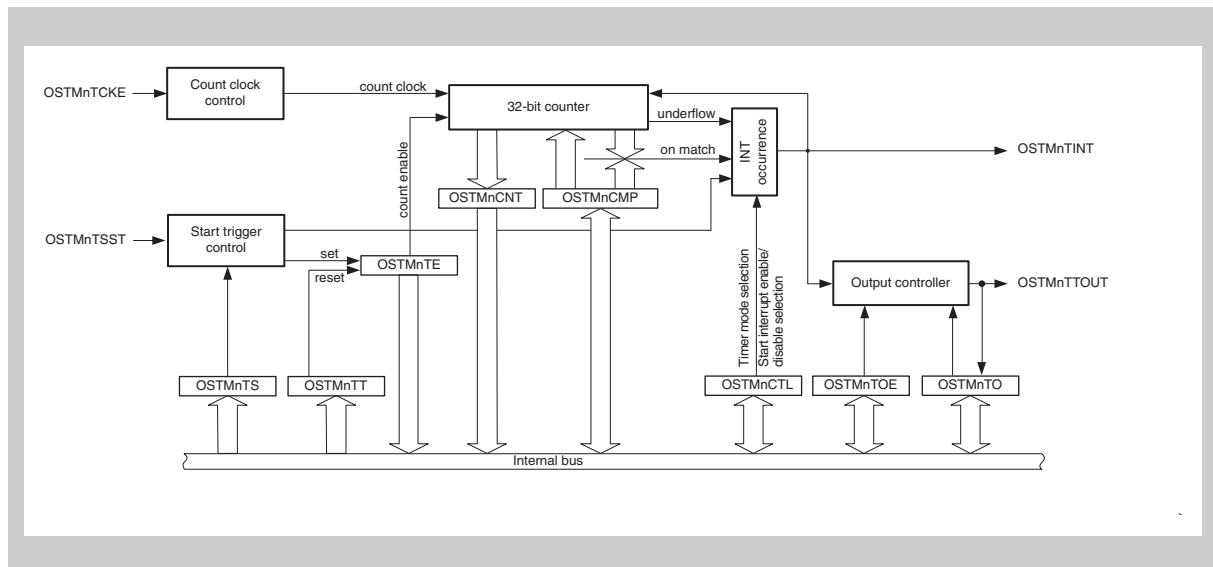

Figure 18-1 Block diagram of the OS timer

18.3 Functional Description

The OS timer is a 32-bit timer/counter.

It can be used as an interval timer or in free-run compare mode. The selected operation mode specifies the count direction (up/down) and controls the interrupt request generation.

The OS timer can be synchronized with other peripheral functions by using the count clock enable signal OSTMnTCKE and the count start signal OSTMnTSST. (See 18.3.1 “Count clock” on page 982 and 18.3.4 “Starting and stopping the timer” on page 984 for details.)

18.3.1 Count clock

The count clock of the OS timer is defined by PCLK and the OSTMnTCKE input:

- To use PCLK as the count clock, OSTMnTCKE must be fixed to 1.
- If the OSTMnTCKE signal is input, the count operation is based on this signal.

This is illustrated in the following figures.

Figure 18-2 Count operation with OSTMnTCKE fixed to 1

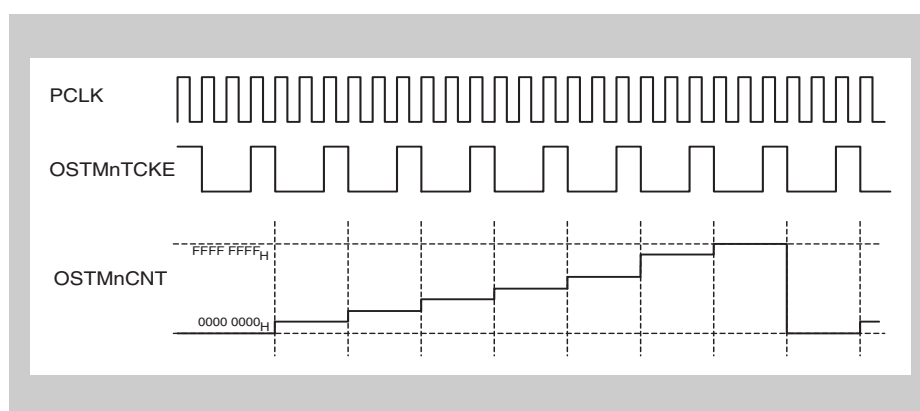

Figure 18-3 Count operation based on the OSTMnTCKE signal

18.3.2 Output modes

The OS timer has the following output modes:

- Software control mode:
The level set to OSTMnTO.OSTMnTO is output to OSTMnTTOUT.
- Timer output toggle mode:
OSTMnTTOUT toggles when the OSTMnTINT request is generated.
The output mode is selected by bit OSTMnTOE.OSTMnTOE.

Both output modes are illustrated in the following figure.

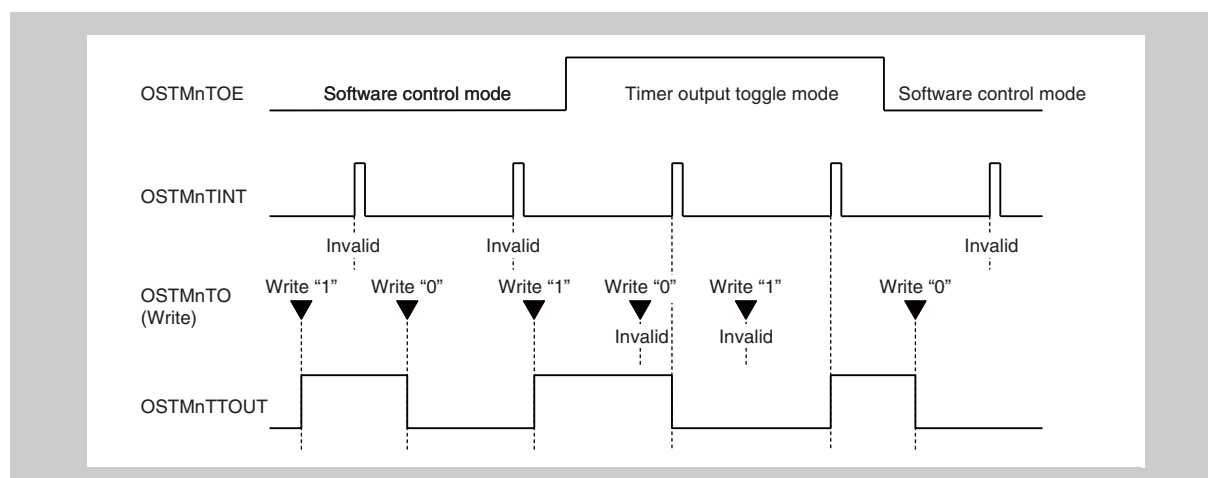

Figure 18-4 Timing diagram of output modes

The timing diagram above shows the following:

- In software control mode, OSTMnTTOUT changes to the value that was set in OSTMnTO.OSTMnTO.
- In timer output toggle mode, OSTMnTO.OSTMnTO and OSTMnTTOUT toggle when the OSTMnTINT interrupt request is generated.

18.3.3 Interrupt request generation

Interrupt request OSTMnTINT is generated on counter underflow (interval timer mode) or when the counter matches the compare value (free-run compare mode).

Additionally, an interrupt request can be generated at counter start or counter restart. This is controlled by bit OSTMnCTL.OSTMnMD0.

Since OSTMnTINT triggers toggling of OSTMnTTOUT in timer output toggle mode (OSTMnTOE.OSTMnTOE = 1), the setting of the OSTMnCTL.OSTMnMD0 bit also affects the output of OSTMnTTOUT.

This is illustrated in the following figure.

Figure 18-5 Interrupt generation at count start

18.3.4 Starting and stopping the timer

The OS timer is started and stopped as follows:

Start The timer is started

- by setting OSTMnTS.OSTMnTS, or
- when the OSTMnTSST signal changes from 0 to 1.

The status bit OSTMnTE.OSTMnTE is set to 1.

Depending on the operation mode, the counter starts to count down or to count up. Refer to 18.3.5 "Interval timer mode" on page 985 and 18.3.6 "Free-run compare mode" on page 989 for details.

Stop The timer is stopped by setting the bit OSTMnTT.OSTMnTT = 1.

Status bit OSTMnTE.OSTMnTE is cleared.

When the counter is stopped, the registers OSTMnTO and OSTMnCNT hold their current values until a new count operation starts.

Simultaneous start If the OSTMnTSST signal is connected to another internal peripheral function, the OS timer can be started in synchronization with the peripheral function.

18.3.5 Interval timer mode

In interval timer mode, the OSTM can be used as a reference timer generating interrupt requests at fixed intervals.

(1) Basic operation in interval timer mode

In interval timer mode, the timer counts down, starting from the value specified in the OSTMnCMP register. When the counter underflows (0000 0000_H is reached), an interrupt request OSTMnTINT is generated.

The interval timer mode is set by OSTMnCTL.OSTMnMD1 = 0.

The OSTMnCMP register can be rewritten at any time. If it is rewritten during count operation, the counter loads the new OSTMnCMP value when the next 0000 0000_H is reached. Then the counter continues with the new value.

OSTMnTINT and OSTMnTTOUT periods

The periods of OSTMnTINT and OSTMnTTOUT are:

- OSTMnTINT occurrence period = count clock period * (OSTMnCMP + 1)
- OSTMnTTOUT period = OSTMnTINT occurrence period * 2

The following figure shows the basic operation of the OS timer in interval timer mode with counter start interrupt enabled (OSTMnCTL.OSTMnMD0 = 1) and OSTMnTTOUT in timer output toggle mode (OSTMnTOE.OSTMnTOE = 1):

Figure 18-6 Timing diagram of OSTM in interval timer mode

The timing diagram above shows the following:

1. The counter starts counting when $OSTMnTS.OSTMnTS = 1$ or $OSTMnTSST = 1$. The $OSTMnTE.OSTMnTE$ bit is set, indicating that a count operation is in progress.
The counter starts counting down from the value of $OSTMnCMP$.
If $OSTMnCTL.OSTMnMD0 = 1$, the interrupt request $OSTMnTINT$ is generated when counting starts, and the $OSTMnTTOUT$ output toggles. The counter value is indicated by the $OSTMnCNT$ register.
2. When the counter reaches $0000\ 0000_H$, the interrupt request $OSTMnTINT$ is output and the $OSTMnTTOUT$ output toggles. The counter loads the new start value from $OSTMnCMP$ and continues to count down.
3. If $OSTMnTT.OSTMnTT$ is set and the counter stops, the $OSTMnTE.OSTMnTE$ bit is cleared, indicating that the counter is stopped.
The counter holds the current value until it restarts counting.
4. If $OSTMnTS.OSTMnTS$ or $OSTMnTSST$ is set to restart counting, the counter loads the value from $OSTMnCMP$ and starts counting down.

Forced restart A forced restart of the counter is performed by setting $OSTMnTS.OSTMnTS = 1$ or generating a high to low transition of the $OSTMnTSST$ signal during the count operation.

The counter loads the start value from the $OSTMnCMP$ register and continues to count down.

The following figure shows the forced restart of the OS timer in interval timer mode, with counter start interrupt enabled ($OSTMnCTL.OSTMnMD0 = 1$) and $OSTMnTTOUT$ in timer output toggle mode ($OSTMnTOE.OSTMnTOE = 1$):

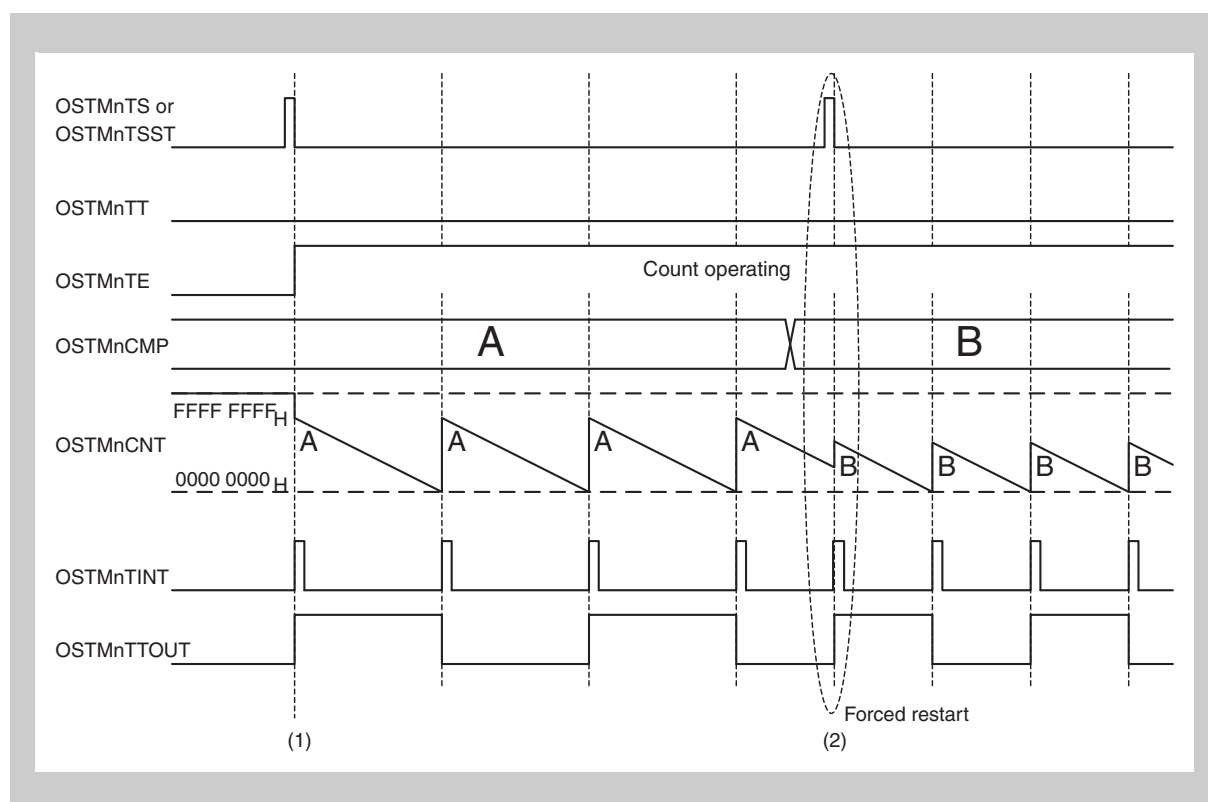

Figure 18-7 Timing diagram of forced restart in interval timer mode

The timing diagram above shows the following:

1. The counter is started as shown and explained in *Figure 18-6 “Timing diagram of OSTM in interval timer mode” on page 985*.
2. If $OSTMnTS.OSTMnTS$ or $OSTMnTSST$ is set while the counter is operating ($OSTMnTE.OSTMnTE = 1$), the counter restarts counting.

The counter immediately restarts counting down, starting with the current value of $OSTMnCMP$.

If $OSTMnCTL.OSTMnMD0 = 1$, the interrupt request $OSTMnTINT$ is generated when counting starts, and the $OSTMnTTOUT$ output toggles.

(2) Operation when $OSTMnCMP = 0000\ 0000_H$

When $OSTMnCMP = 0000\ 0000_H$ the OS timer behaves as follows:

- While the counter is enabled, the $OSTMnTINT$ interrupt request is always 1.
- If $OSTMnTTOUT$ output is in timer output toggle mode, $OSTMnTTOUT$ toggles at each count clock cycle.

The following figure shows the operation of the OS timer, when $OSTMnCMP = 0000\ 0000_H$, counter start interrupt is enabled ($OSTMnCTL.OSTMnMD0 = 1$) and $OSTMnTTOUT$ is in timer output toggle mode ($OSTMnTOE.OSTMnTOE = 1$).

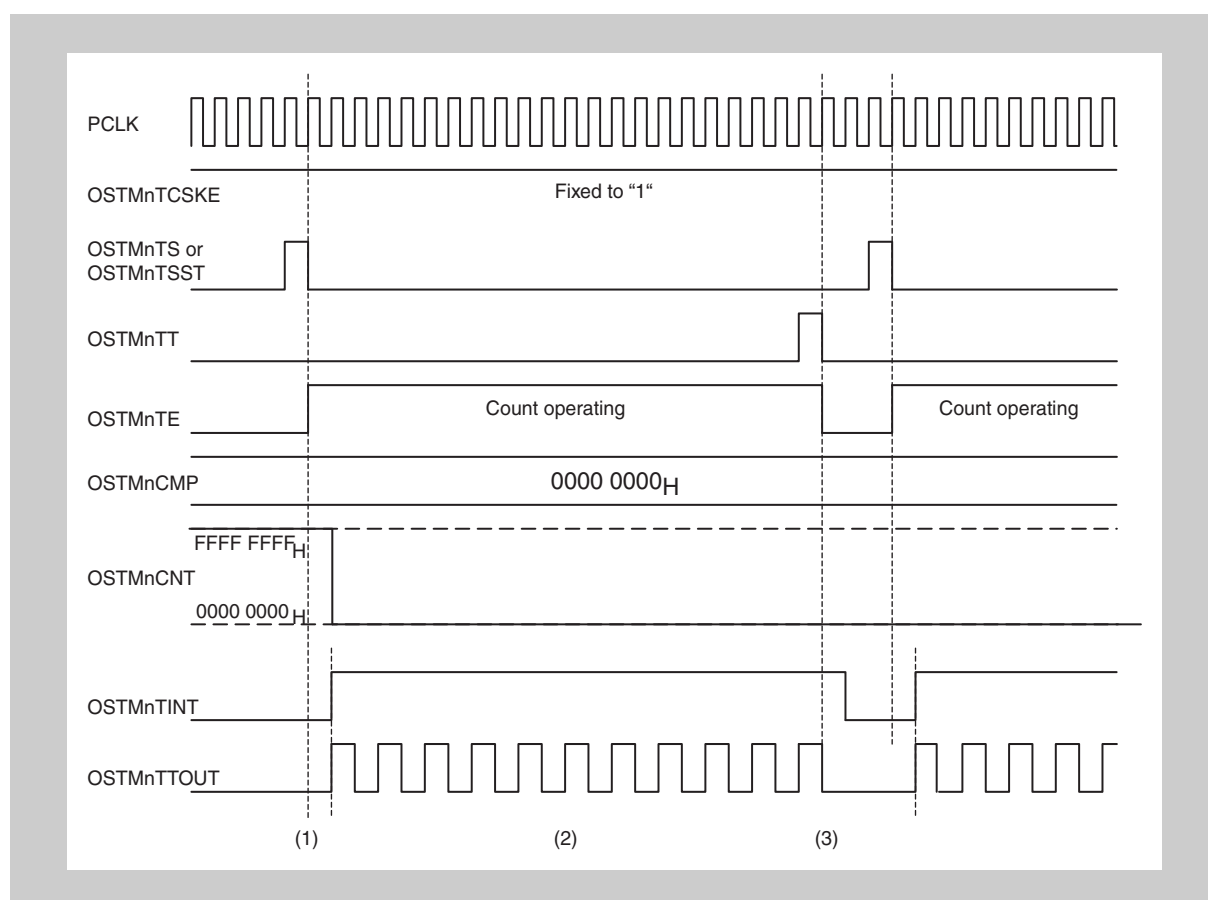

Figure 18-8 Timing diagram when $OSTMnCMP = 0000\ 0000_H$ in interval timer mode

The timing diagram above shows the following:

1. After counter start, the counter starts counting, but will be loaded with the OSTMnCMP value, and thus remains 0000 0000_H.
2. The interrupt request OSTMnTINT is continuously asserted and OSTMnTTOUT starts toggling at each count clock cycle.
3. After counter stop, the interrupt request OSTMnTINT is deasserted and OSTMnTTOUT stops toggling.

(3) Initialization for interval timer mode

The setting procedure in interval timer mode after a reset release is described below:

- Initialization**
1. Set the start value of the down-counter in the OSTMnCMP register.
 2. To use the OSTMnTTOUT output pin:
 - In software control mode, initialize OSTMnTO
 - Select the output mode (OSTMnTOE.OSTMnTOE = 1).
 3. Select the interval timer mode by clearing bit OSTMnCTL.OSTMnMD1.
 4. Select the interrupt mode at counter start (OSTMnCTL.OSTMnMD0 = 1).

18.3.6 Free-run compare mode

(1) Basic operation in free-run compare mode

In free-run compare mode, the counter counts up from 0000 0000_H to FFFF FFFF_H. When the value of the OSTMnCMP register matches the current count value, the OSTMnTINT interrupt request is output.

The free-run compare mode is selected by setting OSTMnCTL.OSTMnMD1 = 1.

The OSTMnCMP register can be rewritten at any time.

The following figure shows the basic operation of the OS timer in free-run compare mode with counter start enabled (OSTMnCTL.OSTMnMD0 = 1) and OSTMnTTOUT in timer output toggle mode (OSTMnTOE.OSTMnTOE = 1):

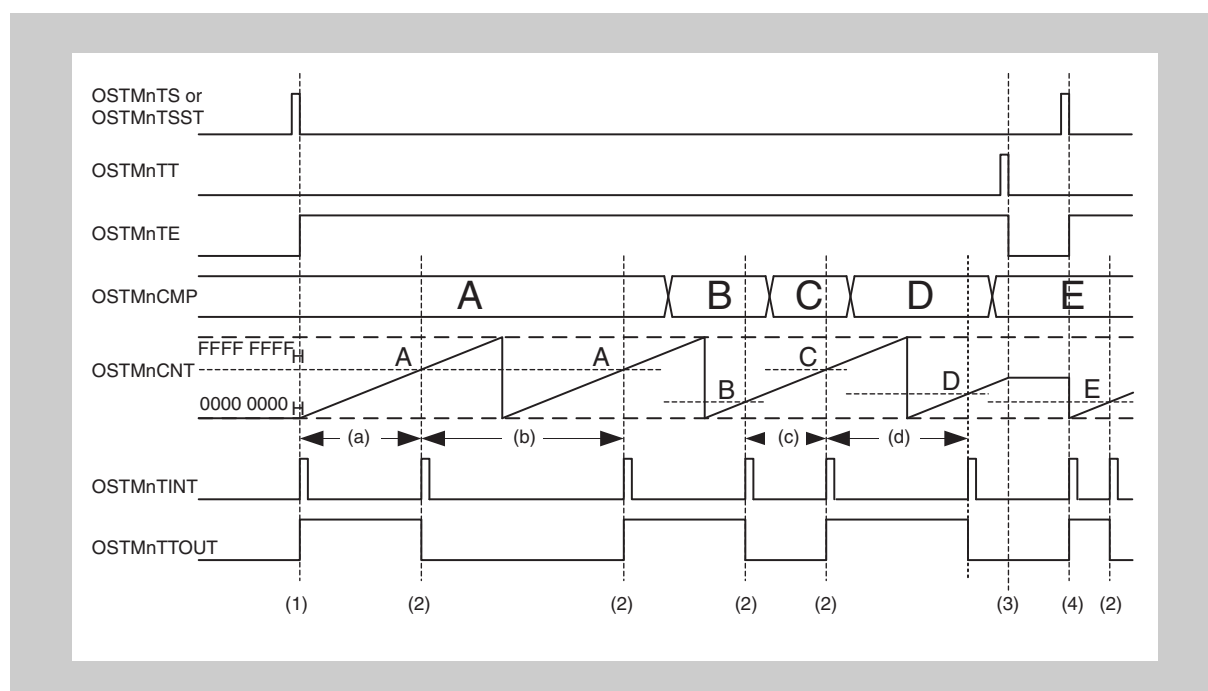

Figure 18-9 Timing diagram of OSTM in free-run compare mode

The timing diagram above shows the following:

1. The counter starts counting when OSTMnTS.OSTMnTS = 1 or OSTMnTSST = 1. The OSTMnTE.OSTMnTE bit is set, indicating that the counter is operating. The counter counts up from 0000 0000_H to FFFF FFFF_H. The counter value is indicated by OSTMnCNT register.
2. When the value of the OSTMnCMP register matches the current counter value, the interrupt request OSTMnTINT is output and the OSTMnTTOUT output toggles.
3. At counter stop (OSTMnTT.OSTMnTT = 1), the OSTMnTE.OSTMnTE bit is cleared, indicating that the counter is disabled. The counter holds the current value until it restarts counting.
4. If OSTMnTS.OSTMnTS or OSTMnTSST is set to restart counting, the counter starts counting from 0000 0000_H.

The OSTMnTINT occurrence period is different at count start and depends on the old and new compare value if OSTMnCMP is rewritten during operation:

Table 18-6 OSTMnTINT occurrence timing

Old compare	New compare	Counter value at time of rewrite	OSTMnTINT occurrence period	Label in timing diagram
Counter start			$(A + 1) \times \text{count clock period}$	(a)
A	A	No rewrite	$(\text{FFFF FFFF}_H + 1) \times \text{count clock period}$	(b)
B	$C > B$	$B < \text{counter value} < C$	$(C - B) * \text{count clock period}$	(c)
C	$D < C$	Counter value $> D, C$	$(\text{FFFF FFFF}_H - C + D + 1) \times \text{count clock period}$	(d)

Forced restart A forced restart operation is not performed even if the bit OSTMnTS.OSTMnTS is set or OSTMnTSST = 1 during the count operation. The counter ignores this setting and continues counting.

(2) Operation when OSTMnCMP = 0000 0000_H

The following figure shows the operation of the OS timer when OSTMnCMP = 0000 0000_H, counter start interrupt is enabled (OSTMnCTL.OSTMnMD0 = 1) and OSTMnTTOUT is in timer output toggle mode (OSTMnTOE.OSTMnTOE = 1).

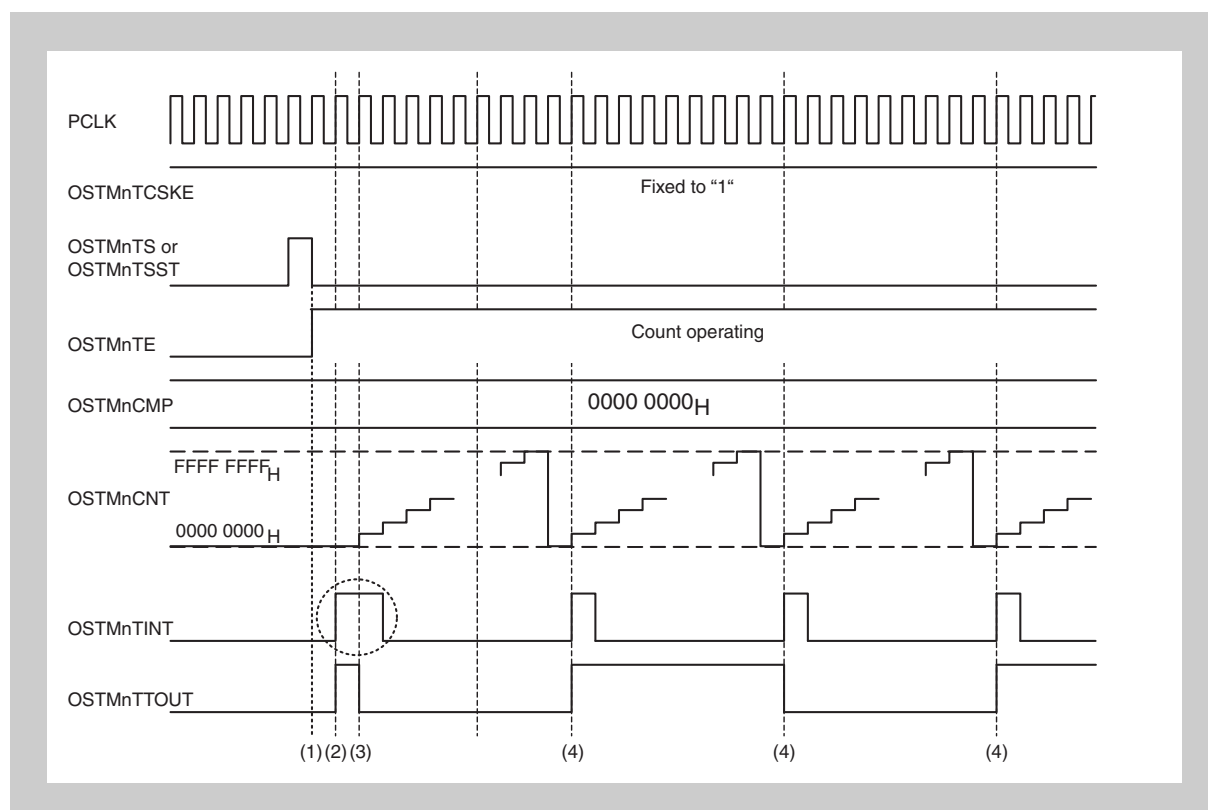

Figure 18-10 Timing diagram when OSTMnCMP = 0000 0000_H in free-run compare mode

The timing diagram above shows the following:

1. After counter start, the counter starts counting up from 0000 0000_H to FFFF FFFF_H.
2. The interrupt request OSTMnTINT at counter start is generated.
3. If the current count value matches OSTMnCMP, the compare interrupt is generated. In the above case with OSTMnCMP = 0000 0000_H, OSTMnTINT stays active for 2 PCLK periods.
4. Every FFFF FFFF_H clock cycles the interrupt request OSTMnTINT is output and OSTMnTTOUT toggles.

(3) Initialization for free-run compare mode

The setting procedure in free-run compare mode after a reset release is described below:

- Initialization**
1. Set the compare value in the OSTMnCMP register.
 2. To use the OSTMnTTOUT output pin:
 - In software control mode, initialize OSTMnTO.
 - Select the output mode (OSTMnTOE.OSTMnTOE = 1).
 3. Select the free-run compare mode by setting the bit OSTMnCTL.OSTMnMD1.
 4. Select the interrupt mode at counter start by the bit OSTMnCTL.OSTMnMD0.

18.4 Registers

This section contains a description of all registers of the OS timer.

18.4.1 OS timer register overview

The OS timer is controlled and operated by the following registers:

Table 18-7 OS timer register overview

Register name	Shortcut	Address
OSTM compare register	OSTMnCMP	<OSTMn_base>
OSTM counter register	OSTMnCNT	<OSTMn_base> + 04 _H
OSTM output register	OSTMnTO	<OSTMn_base> + 08 _H
OSTM output enable register	OSTMnTOE	<OSTMn_base> + 0C _H
OSTM count enable status register	OSTMnTE	<OSTMn_base> + 10 _H
OSTM count start trigger register	OSTMnTS	<OSTMn_base> + 14 _H
OSTM count stop trigger register	OSTMnTT	<OSTMn_base> + 18 _H
OSTM control register	OSTMnCTL	<OSTMn_base> + 20 _H

18.4.2 OS timer register details

(1) OSTMnCMP - OSTM compare register

This register stores the start value of the down-counter or the value with which the counter is compared, depending on the operation mode.

Access This register can be read/written in 32-bit units.

Address <OSTMn_base>

Initial Value 0000 0000_H. This register is initialized by any reset.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

31 to 0	OSTMnCMP[31:0]	<ul style="list-style-type: none"> In interval timer mode: start value of the down-counter In free-run compare mode: compare value

(2) OSTMnCNT - OSTM counter register

This register indicates the count value of the timer.

Access This register is read-only, in 32-bit units.

Address <OSTMn_base> + 4_H

Initial Value The initial value depends on the operation mode of the OS timer, see *Table 18-10 "Correlation between operation mode, counting direction and initial value" on page 993*. This register is initialized by any reset.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 18-9 OSTMnCNT register contents

Bit position	Bit name	Function
31 to 0	OSTMnCNT[31:0]	32-bit counter value

The following table shows the correlation between operation mode, counting direction and initial value. The initial value is the value that is read after the operating mode has been changed.

Table 18-10 Correlation between operation mode, counting direction and initial value

Timer operation mode	OSTMnCTL.OSTMnMD1	Counting direction	Initial value
Interval timer mode	0 ^a	Decrement	FFFF FFFF _H
Free-run compare mode	1	Increment	0000 0000 _H

a) Value after reset.

(3) OSTMnTO - OSTM output register

This register specifies and reads the level of OSTMnTTOUT.

Access This register can be read/written in 8-bit units. It can only be written when the software control mode is enabled (OSTMnTOE.OSTMnTOE = 0).

Address <OSTMn_base> + 8_H

Initial Value 00_H. This register is initialized by any reset.

7	6	5	4	3	2	1	0
0	0	0	0	0	0	0	OSTMnTO
R	R	R	R	R	R	R	R/W

Table 18-11 OSTMnTO register contents

Bit position	Bit name	Function
0	OSTMnTO	Specifies/reads the level of OSTMnTTOUT: 0: Low level 1: High level

(4) OSTMnTOE - OSTM output enable register

This register specifies OSTMnTTOUT output mode.

Access This register can be read/written in 8-bit units.

Address <OSTMn_base> + C_H

Initial Value 00_H. This register is initialized by any reset.

7	6	5	4	3	2	1	0
0	0	0	0	0	0	0	OSTMnTOE
R	R	R	R	R	R	R	R/W

Table 18-12 OSTMnTOE register contents

Bit position	Bit name	Function
0	OSTMnTOE	Specifies the OSTMnTTOUT output mode: 0: Software control mode: The level set to OSTMnTO.OSTMnTO is output to OSTMnTTOUT. 1: Timer output toggle mode: OSTMnTTOUT toggles when the interrupt request OSTMnTINT is generated.

(5) OSTMnTE - OSTM count enable status register

This register indicates whether the counter is enabled or disabled.

Access This register is read-only, in 8-bit units.

Address <OSTMn_base> + 10_H

Initial Value 00_H. This register is initialized by any reset.

7	6	5	4	3	2	1	0
0	0	0	0	0	0	0	OSTMnTE
R	R	R	R	R	R	R	R

Table 18-13 OSTMnTE register contents

Bit position	Bit name	Function
0	OSTMnTE	Indicates, whether the counter is enabled or disabled: 0: Counter disabled 1: Counter enabled This bit is set if OSTMnTS.OSTMnTS is set or OSTMnTSST becomes 1. This bit is cleared if OSTMnTT.OSTMnTT is set.

Note If the counter is disabled, the counter value OSTMnCNT remains its value.

If the counter is restarted again, it

- restarts from the value specified by OSTMnCMP in interval timer mode.
- restarts with count value 0000 0000_H in free-run compare mode.

(6) OSTMnTS - OSTM count start trigger register

This register starts the counter.

Access This register can be written in 8-bit units. It is always read as 00_H.

Address <OSTMn_base> + 14_H

Initial Value 00_H. This register is initialized by any reset.

7	6	5	4	3	2	1	0
0	0	0	0	0	0	0	OSTMnTS
R	R	R	R	R	R	R	W

Table 18-14 OSTMnTS register contents

Bit position	Bit name	Function
0	OSTMnTS	Starts the counter: 0: Ignored 1: Starts the counter and sets OSTMnTE.OSTMnTE = 1. • In interval timer mode, forced restart is executed when this bit is set while OSTMnTE.OSTMnTE = 1. • In free-run compare mode, setting this bit is ignored while OSTMnTE.OSTMnTE = 1.

(7) OSTMnTT - OSTM count stop trigger register

This register stops the counter.

Access This register can be written in 8-bit units. It is always read as 00_H.

Address <OSTMn_base> + 18_H

Initial Value 00_H. This register is initialized by any reset.

7	6	5	4	3	2	1	0
0	0	0	0	0	0	0	OSTMnTT
R	R	R	R	R	R	R	W

Table 18-15 OSTMnTT register contents

Bit position	Bit name	Function
0	OSTMnTT	Stops the counter: 0: Ignored 1: Stops the counter and clears the bit OSTMnTE.OSTMnTE.

(8) OSTMnCTL - OSTM control register

This register specifies the counter operation mode and controls the generation of the interrupt request OSTMnTINT at counter start.

Access This register can be read/written in 8-bit units. It can only be written when the counter is disabled (OSTMnTE.OSTMnTE = 0).

Address <OSTMn_base> + 20_H

Initial Value 00_H. This register is initialized by any reset.

7	6	5	4	3	2	1	0
0	0	0	0	0	0	OSTMnMD1	OSTMnMD0
R	R	R	R	R	R	R/W	R/W

Table 18-16 OSTMnCTL register contents

Bit position	Bit name	Function
1	OSTMnMD1	Specifies the counter operation mode: 0: Interval timer mode 1: Free-run compare mode
0	OSTMnMD0	Controls the OSTMnTINT interrupt request at counter start: 0: Disables interrupt at counter start 1: Enables interrupt at counter start

Chapter 19 Asynchronous Serial Interface E (UARTE_n)

This chapter contains a generic description of asynchronous serial interface E.

The first section describes all properties specific to the V850E2/ML4, such as instances, register base addresses, and input/output signal names.

The subsequent sections describe the features that apply to all implementations.

19.1 V850E2/ML4 UARTE_n Features

Instances This microcontroller has two instances of asynchronous serial interface E (UARTE_n).

Table 19-1 Instances of UARTE_n

Asynchronous serial interface E	
Instance	2
Name	UARTE0, UARTE1

Instances index n Throughout this chapter, the instance of UARTE is identified by the index "n" (n = 0, 1), for example, URTE_nCTL0 for UARTE_n control register 0.

Caution UARTE of the V850E2/ML4 does not support the LIN function.

Register addresses All UARTE_n register addresses are given as addresses offset from the individual base address <URTE_n_base_OS> or <URTE_n_base_USER> for UARTE_n. The <URTE_n_base_OS> and <URTE_n_base_USER> addresses of each UARTE_n are listed in the following table:

UARTE _n	Base address	Address
UARTE0	<URTE _n _base_OS>	FF60 0000 _H
	<URTE _n _base_USER>	FFFF EE00 _H
UARTE1	<URTE _n _base_OS>	FF61 0000 _H
	<URTE _n _base_USER>	FFFF EF00 _H

Clock supply All UARTE_n provide one clock input. It is connected to the P bus clock f_{PCLK} .

Table 19-2 UARTE_n clock supply

UARTE _n	Clock supply	Connected to
UARTE0, UARTE1	PCLK	f_{PCLK}

I/O signals The I/O signals of UARTE_n are listed in the table below.

Table 19-3 UARTE I/O signals

UARTE _n signal	Function	Connected to
URTE _n TTXD	Transmit data output	Port TXD _n
URTE _n TRXD	Receive data input	Port RXD _n

Interrupts The interrupts of UARTE_n are listed in the table below.

Table 19-4 UARTE interrupts

UARTE _n signal	Function	Connected to
UARTE0		
INTUAE0TIT	Transmission interrupt	<ul style="list-style-type: none"> Interrupt controller 165 (INTUARTE0IT) DMA controller trigger 93
INTUAE0TIR	Reception interrupt	<ul style="list-style-type: none"> Interrupt controller 164 (INTUARTE0IR) DMA controller trigger 92
INTUAE0TIS	Status interrupt	<ul style="list-style-type: none"> Interrupt controller 163 (INTUARTE0IS)
INTUAE0TRA	Receive/status interrupt	<ul style="list-style-type: none"> Not used.
UARTE1		
INTUAE1TIT	Transmission interrupt	<ul style="list-style-type: none"> Interrupt controller 168 (INTUARTE1IT) DMA controller trigger 95
INTUAE1TIR	Reception interrupt	<ul style="list-style-type: none"> Interrupt controller 167 (INTUARTE1IR) DMA controller trigger 94
INTUAE1TIS	Status interrupt	<ul style="list-style-type: none"> Interrupt controller 166 (INTUARTE1IS)
INTUAE1TRA	Receive/status interrupt	<ul style="list-style-type: none"> Not used.

19.2 Features

- Full-duplex communication:
 - Internal UARTEn receive data register n (URTE_nRX)
 - Internal UARTEn transmit data register n (URTE_nTX)
- 2-pin configuration:
 - URTE_nTTXD: Transmit data output pin
 - URTE_nTRXD: Receive data input pin
- Reception error and status output function
 - Parity error
 - Framing error
 - Overrun error
 - Data consistency error
- Interrupt requests: 4
 - Transmission interrupt INTUA_nTIT
 - Reception interrupt INTUA_nTIR
 - Status interrupt INTUA_nTIS
 - Receive/status interrupt INTUA_nTRA
- Character length: 7, 8 bits
- Parity function: odd, even, 0, none
- Transmission stop bit: 1, 2 bits
- MSB-/LSB-first transfer selectable
- Transmit/receive data inverted input/output possible
- 13 to 20 bits selectable for the BF (Break Field) in the LIN (Local Interconnect Network) communication format
 - Recognition of 11 bits or more possible for BF reception in LIN communication format
 - BF reception flag provided
- BF reception can be detected during data communication
- Bus monitor function to keep data consistency of the transmit data

19.3 Configuration

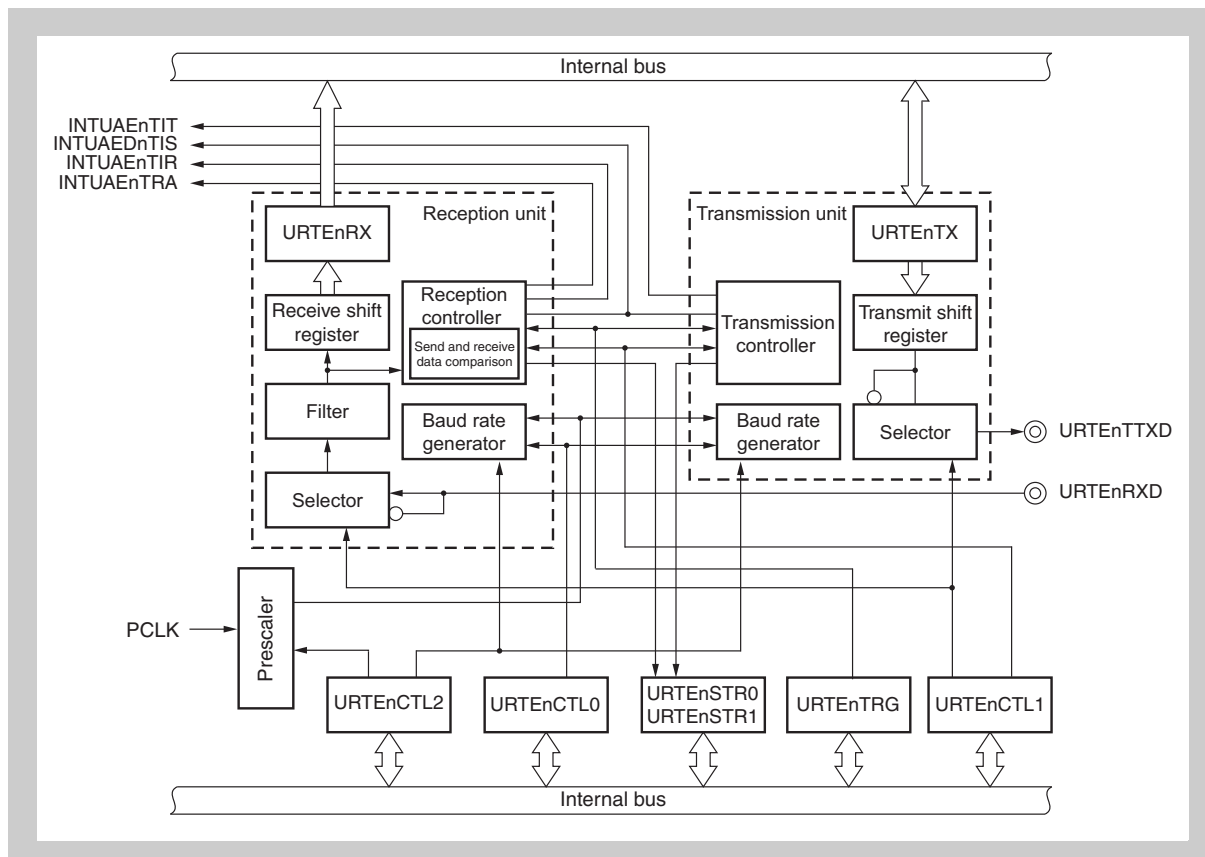

Figure 19-1 Block diagram of asynchronous serial interface UARTEn

19.4 UARTEn Registers

UARTEn is controlled and operated by means of the following registers:

Table 19-5 UARTEn registers

Register name	Symbol	Address
Control register 0	URTEnCTL0	<URTEn_base_USER> + 00 _H
Control register 1	URTEnCTL1	<URTEn_base_OS> + 20 _H
Control register 2	URTEnCTL2	<URTEn_base_OS> + 24 _H
Trigger register	URTEnTRG	<URTEn_base_USER> + 04 _H
Status register 0	URTEnSTR0	<URTEn_base_USER> + 08 _H
Status register 1	URTEnSTR1	<URTEn_base_USER> + 0C _H
Status clear register	URTEnSTC	<URTEn_base_USER> + 10 _H
Receive data register	URTEnRX	<URTEn_base_USER> + 14 _H
Transmit data register	URTEnTX	<URTEn_base_USER> + 18 _H

Base address The base addresses <URTEn_base_USER> and <URTEn_base_OS> of UARTEn are defined in the first section of this chapter under the key word "Register addresses".

(1) URTEEnCTL0 - UARTEn control register 0

This register controls the serial transfer operation of UARTEn.

Access This register can be read/written in 8-bit and 1-bit units.

Address <URTEEn_base_USER> + 00_H

Initial Value 00_H. This register is initialized by any reset.

7	6	5	4	3	2	1	0
URTEEn PW	URTEEn TXE	URTEEn RXE	0	0	0	0	URTEEn SLDC
R/W	R/W	R/W	R	R	R	R	R/W

Table 19-6 URTEEnCTL0 register contents

Bit position	Bit name	Function
7	URTEEnPW	UARTEn enable 0: Stop UARTEn operation 1: Enable UARTEn operation Changing this bit initializes all transmission and reception units.
6	URTEEnTXE	Transmission operation enable 0: Disable transmission operation 1: Enable transmission operation <ul style="list-style-type: none"> To start transmission, set URTEEnPW, and then set URTEEnTXE. To stop transmission, clear URTEEnTXE, and then clear URTEEnPW (they can be cleared at the same time). To initialize the transmission unit, clear URTEEnTXE, wait for two prescaler clock cycles, and then set URTEEnTXE again. For details about the prescaler clock, see (3) "URTEEnCTL2 - UARTEn control register 2" on page 1007.
5	URTEEnRXE	Reception operation enable 0: Disable reception operation 1: Enable reception operation <ul style="list-style-type: none"> To enable reception, set URTEEnPW, and then set URTEEnRXE. To stop reception, clear URTEEnRXE, and then clear URTEEnPW (they can be cleared at the same time). To initialize the reception unit, clear URTEEnRXE, wait for two prescaler clock cycles, and then set URTEEnRXE again. Reception is enabled when the time of two prescaler clock cycles has elapsed since URTEEnRXE is set. The rising edge detection of the URTEEnTRXD signal is enabled when four prescaler clock cycles has elapsed after URTEEnRXE is set. For details about the prescaler clock, see (3) "URTEEnCTL2 - UARTEn control register 2" on page 1007.
0	URTEEn SLDC	Data consistency check enable 0: Disable consistency check 1: Enable consistency check This bit selects the handling of data consistency error checks when transmitting data. When this bit is set to 1, the transmit data and receive data are compared, and if a mismatch is detected, URTEEnSTR1.URTEEnDCE is set to 1 and a status interrupt request INTUAEEnTIS is issued. This bit is referenced only when starting transmission. Consequently, if this bit value is changed later on during transmission processing, the transmission processing continues, using the value set at the start of transmission.

-
- Cautions**
1. Disable transmission if UARTEn meets all the conditions below:
 - Transmission and reception are enabled (URTECTL0.URTEPW = URTEenRXE = URTEenTXE = 1).
 - Data consistency check is enabled (URTECTL0.URTEenSLDC = 1).
 - Data is being transmitted or has been transmitted.

Use the following procedure to keep reception enabled:

 - Check that no data is pending for transmission (URTESTR0.URTEenSSBT = URTEenSST = 0).
 - Check that no data is pending for reception (URTESTR0.URTEenSSBR = URTEenSSR = 0).
 - Disable transmission by clearing URTECTL0.URTEenTXE.

The reason why this procedure is required is that the data consistency error flag URTESTR1.URTEenDCE is cleared if URTECTL0.URTEenTXE is cleared.
Thus a potential data consistency error would not occur if transmission is disabled during a data transfer or after its completion.
 2. Disable reception if UARTEn meets all the conditions below:
 - Transmission and reception are enabled (URTECTL0.URTEPW = URTEenRXE = URTEenTXE = 1).
 - Data consistency check is enabled (URTECTL0.URTEenSLDC = 1).
 - Data is being transmitted or has been transmitted.

Use the following procedure to keep transmission enabled:

 - Check that no data is pending for transmission (URTESTR0.URTEenSSBT = URTEenSST = 0).
 - Check that no data is pending for reception (URTESTR0.URTEenSSBR = URTEenSSR = 0).
 - Disable reception by clearing URTECTL0.URTEenRXE.

The reason why this procedure is required is that the data consistency error flag URTESTR1.URTEenDCE is cleared and invalid if URTECTL0.URTEenTXE is cleared.
Thus a potential data consistency error of already transmitted data would not occur.
 3. Do not start data transmission if all the conditions below are met:
 - Data consistency check is enabled (URTECTL0.URTEenSLDC = 1).
 - BF reception is enabled (URTESTR0.URTEenSSBR = 1).
 - BF detection during reception is disabled (URTECTL1.URTEenSLBM = 0).

A data consistency error will occur under above conditions when BF reception is completed. The status interrupt INTUAEnTIS will be asserted and the reception interrupt request INTUAEnTIR will not be generated (URTESTR1.URTEenBSF remains 0). Consequently BF reception completion will not be recognized.
-

(2) URTEEnCTL1 - UARTEn control register 1

This register defines the data frame properties of UARTEn serial data transfers.

Access This register can be read/written in 16-bit units.

Address <URTEEn_base_OS> + 20_H

Initial Value 5002_H. This register is initialized by any reset.

FFF _H	PCLK / (2 x 4095)	PCLK / 4095																						

Caution Writing to this register is only allowed if the UARTEn operation is disabled (URTECTL0.URTEEnPW = 0).

PCLK The value of the UARTEn input clock is defined in the first section of this chapter under the key word "Clock supply".

(4) URTEEnTRG - UARTEn trigger register

This register controls the UARTEn transmission/reception trigger of BF.

Access This register can be read/written in 8-bit and 1-bit units.

Address <URTEEn_base_USER> + 04_H

Initial Value 00H. This register is initialized by any reset.

7	6	5	4	3	2	1	0
0	URTEEn BRT	URTEEn BTT	0	0	0	0	0
R	R/W	R/W	R	R	R	R	R

Table 19-9 URTEEnTRG register contents

Bit position	Bit name	Function
6	URTEEnBRT	<p>BF reception trigger</p> <p>0: Read value is always 0, writing 0 is ignored</p> <p>1: Enable BF reception</p> <ul style="list-style-type: none"> When reception is enabled, writing 1 to this bit enables BF reception (URTEEnSTR0.URTEEnSSBR = 1) and BF reception processing begins when the falling edge of the receive serial signal is detected. If 1 is written to this bit during reception processing, the current reception processing is terminated. Consequently, the received data is not stored, the framing, parity and overflow error bits are not updated based on the data that was being received and no interrupts are generated. Meanwhile, the BF counter value is continuously being used. After BF reception, the reception status is set according to the URTEEnCTL1.URTEEnSLBM setting. Setting this bit to 1 is only allowed if reception is enabled (URTEEnCTL0.URTEEnPW = URTEEnCTL0.URTEEnRXE = 1). <p>After URTEEnBRT is set to 1, completion of BF reception is reported by either of the following two methods, based on the URTEEnCTL1.URTEEnSLBM setting:</p> <ul style="list-style-type: none"> if URTEEnCTL1.URTEEnSLBM = 0: When BF reception is complete, a reception interrupt request INTUAEnTIR is generated. if URTEEnCTL1.URTEEnSLBM = 1: When BF reception is complete, URTEEnSTR1.URTEEnBSF is set to 1 and the status interrupt request INTUAEnTIS is generated.
5	URTEEnBTT	<p>BF transmission trigger</p> <p>0: Read value is always 0, writing 0 is ignored</p> <p>1: Enable BF transmission</p> <ul style="list-style-type: none"> When this bit is set while URTEEnSTR0.URTEEnSSBT = 0 and transmission is enabled (URTEEnDCE = 0), a BF transmit request is set, and URTEEnSSBT is set to 1. When this bit is set during data transmission, a BF is transmitted after the current transmission processing is completed. Even if this bit is set before the BF transmission is completed, a BF is transmitted only once. When transmission is enabled (URTEEnPW = URTEEnTXE = 1), setting this bit clears all previously set data transmit requests (which have not been transmitted), leaving only BF transmit requests. If the URTEEnTX7 to URTEEnTX0 bits are written after setting this bit, data is transmitted after the BF is transmitted. If both a BF transmit request and a data transmit request have been set when a transmission starts, the BF transmission takes priority. When URTEEnDCE = 1, writing 1 to this bit is ignored. Setting this bit to 1 is only allowed if transmission is enabled (URTEEnCTL0.URTEEnPW = URTEEnCTL0.URTEEnTXE = 1).

(5) URTEnSTR0 - UARTEn status register 0

This register indicates the current status of serial data transmissions.

Access This register can be read in 8-bit or 1-bit units. Writing to this register is only allowed if UARTEn operation is disabled (URTEnCTL0.URTEnPW = 0). If UARTEn operation is enabled (URTEnCTL0.URTEnPW = 1), any written values are disregarded and the initial values are restored.

Address <URTEn_base_USER> + 08_H

Initial Value 00_H. This register is initialized by any reset and when URTEnCTL0.URTEnPW is set or cleared.

7	6	5	4	3	2	1	0
0	URTEn SSBR ^a	URTEn SSBT ^b	0	0	0	URTEn SSR ^a	URTEn SST ^b

0	0	0	URTEnBSF ^a	URTEnDCE ^b	URTEnPE ^a	URTEnFE ^a	URTEnOVE ^a
R	R	R	R	R	R	R	R

- a) These bits are also initialized if reception is disabled by URTEnCTL0.URTEnRXE = 0.
b) This bit is also initialized if transmission is disabled by URTEnCTL0.URTEnTXE = 0.

Table 19-11 URTEnSTR1 register contents (1/2)

Bit position	Bit name	Function
4	URTEnBSF	BF reception successful flag 0: BF transmission is disabled by clearing URTEnTRG.URTEnBTT. 1: BF transmission is enabled by setting URTEnTRG.URTEnBTT (BF transmission standby mode or BF transmission busy). The URTEnBSF bit is cleared by the following: - URTEnCTL0.URTEnPW = 1 - URTEnCTL0.URTEnRXE = 0 - URTEnSTC.URTEnCLBS = 1
3	URTEnDCE	Data consistency error flag 0: Transmit/receive data (transmit/receive BF) mismatch was not detected. 1: Transmit/receive data (transmit/receive BF) mismatch was detected. When the BF receive mode selection bit is set during LIN communication, it is necessary to read this bit by using status interrupt processing and to confirm the beginning of a new frame slot. The URTEnDCE bit is cleared by the following: - URTEnCTL0.URTEnPW = 0 - URTEnCTL0.URTEnTXE = 0 - URTEnSTC.URTEnCLDC = 1
2	URTEnPE	Parity error flag 0: No parity error was detected in the received data. 1: A parity error was detected in the received data. The operation of URTEnPE is controlled by the settings of URTEn.URTEnSLP[1:0]. The URTEnPE bit is cleared by the following: - URTEnCTL0.URTEnPW = 0 - URTEnCTL0.URTEnRXE = 0 - URTEnSTC.URTEnCLP = 1
1	URTEnFE	Framing error flag 0: No framing error was detected in the received data. 1: A framing error was detected in the received data. The URTEnFE bit is cleared by the following: - URTEnCTL0.URTEnPW = 0 - URTEnCTL0.URTEnRXE = 0 - URTEnSTC.URTEnCLF = 1

Table 19-11 URTEEnSTR1 register contents (2/2)

Bit position	Bit name	Function
0	URTEEnOVE	Overrun error flag 0: No overrun error was detected in the received data. 1: An overrun error was detected in the received data. If an overrun error occurs, the data is discarded, and the next data received will not be written to the receive data register URTEEnRX. The URTEEnOVE bit is cleared by the following: <ul style="list-style-type: none"> - URTEEnCTL0.URTEEnPW = 0 - URTEEnCTL0.URTEEnRXE = 0 - URTEEnSTC.URTEEnCLOV = 1

Note If the bits of these registers are set (1) and cleared (0) at the same time, setting takes priority over clearing.

For further information concerning error detections, refer to 19.6.5 "Transmission data consistency check" and 19.6.9 "Reception errors".

Caution In case reception and transmission is enabled and a consistency check error occurs (URTEEnSTR1.URTEEnDCE = 1), follow the procedure below prior next data transmission:

- disable transmission by URTEEnCTL0.URTEEnTXE = 0
- enable transmission by URTEEnCTL0.URTEEnTXE = 1
- initiate a transmission by URTEEnTRG.URTEEnBTT = 1 (BT transmission trigger) or writing any data to URTEEnTX

Afterwards new transmissions can be started.

(7) URTEEnSTC - UARTEn status clear register

This register is used to clear the status bits of the status register 1 URTEEnSTR1.

Access This register can be read/written in 8-bit and 1-bit units. Reading this register returns always 00_H.

Address <URTEEn_base_USER> +10_H

Initial Value 00_H. This register is initialized by any reset.

7	6	5	4	3	2	1	0
0	0	0	URTEEn CLBS	URTEEn CLDC	URTEEn CLP	URTEEn CLF	URTEEn CLOV
R	R	R	R/W	R/W	R/W	R/W	R/W

Table 19-12 URTEEnSTC register contents

Bit position	Bit name	Function
4	URTEEnCLBS	Clear BF reception successful flag 0: Writing 0 is ignored 1: Writing 1 clears URTEEnSTR1.URTEEnBSF
3	URTEEnCLDC	Clear data consistency error flag 0: Writing 0 is ignored 1: Writing 1 clears URTEEnSTR1.URTEEnDCE If URTEEnDCE is cleared by setting URTEEnCLDC, any pending data or BF transmit requests will be ignored.
2	URTEEnCLP	Clear parity error flag 0: Writing 0 is ignored 1: Writing 1 clears URTEEnSTR1.URTEEnPE
1	URTEEnCLF	Clear framing error flag 0: Writing 0 is ignored 1: Writing 1 clears URTEEnSTR1.URTEEnFE
0	URTEEnCLOV	Clear overrun error flag 0: Writing 0 is ignored 1: Writing 1 clears URTEEnSTR1.URTEEnOVE

(8) URTEnRX - UARTEn receive data register

This register stores received data.

The data stored in the receive shift register is transferred to URTEnRX upon completion of reception of 1 byte of data.

- 7-bit transfers** If the data length has been specified as 7 bits (URTEnCTL1.URTEnCLG = 0) and
- reception is LSB-first (URTEnCTL1.URTEnSLD = 1),:
The receive data is transferred to URTEnRX[6:0] and the MSB URTEnRX[7] always becomes 0.
 - reception is MSB-first (URTEnCTL1.URTEnSLD = 0),:
The receive data is transferred to URTEnRX[7:1] and the LSB URTEnRX[0] always becomes 0.

For further information on data formats, refer to 19.6.1 "Data formats".

- Overrun error** When an overrun error (URTEnSTR1.URTEnOVE = 1) occurs, the receive data at this time is not transferred to URTEnRX and is discarded.

When reception processing ends and data reception is confirmed without any overrun errors, the received data is stored to URTEnRX according to the specified storage format.

Access

This register can be read in 8-bit units.

Writing to this register is only allowed if UARTEn operation is disabled (URTEnCTL0.URTEnPW = 0). If UARTEn operation is enabled (URTEnCTL0.URTEnPW = 1), any written values are disregarded and the initial values are restored.

Access This register can be read in 8-bit units.

Address <URTEn_base_USER> + 14_H

Initial Value FF_H. This register is initialized by any reset and when UARTEn operation is enabled by setting URTEnCTL0.URTEnPW.

Table 19-13 URTEnRx register contents

Bit position	Bit name	Function
7 to 0	URTEnRX[7:0]	URTEn receive data

(9) URTEnTX - UARTEn transmit data register

This register is used to stores data to be transmitted.

Transmit data in URTEnTX is stored to the transmission shift register according to the specified transmit data format.

7-bit transfers If the data length has been specified as 7 bits (URTEnCTL1.URTEnCLG = 0) and

- transmission is LSB-first (URTEnCTL1.URTEnSLD = 1),; URTEnTX[6:0] is transferred to the shift register.
- transmission is MSB-first (URTEnCTL1.URTEnSLD = 0),; The LSB URTEnTX[0] is always set to "0" and URTEnTX[7:1] is transferred to the shift register.

For further information on data formats, refer to 19.6.1 "Data formats".

Access This register can be read/written in 8-bit units.

Address <URTEn_base_USER> + 18_H

Initial Value FF_H. This register is initialized by any reset.

Table 19-14 URTEnTx register contents

Bit position	Bit name	Function
7 to 0	URTEnTX[7:0]	URTEn transmit data

When transmission is enabled (URTEnCTL0 bits URTEnPW = URTETXE = 1), a write to URTEnTX starts transmission.

Note If the next data is written to URTEnTX before the current transmission is completed, continuous transmission can be enabled by waiting for the current data transmission to end before transmitting the next data.

19.5 Interrupt Request Signals

The following four interrupt request signals are generated by UARTEn.

- Transmission interrupt request INTUAE_nTIT
- Reception interrupt request INTUAE_nTIR
- Status interrupt request INTUAE_nTIS
- Receive/status interrupt request INTUAE_nTRA

19.5.1 Transmission interrupt request INTUAE_nTIT

If transmit data is transferred from the URTE_nTX register to transmit shift register with transmission enabled, the transmission interrupt request INTUAE_nTIT is generated.

The condition for generation of a transmit interrupt request depends on the setting of the URTE_nCTL1.URTE_nSLIT:

- at start of transmission process: URTE_nCTL1.URTE_nSLIT = 0

A transmission interrupt request is issued when starting transmission of the first bit (this is the start bit for data transmission or the first BF bit for BF transmission).

- at end of transmission process: URTE_nCTL1.URTE_nSLIT = 1

A transmission interrupt request is issued after completing transmission of the last bit (the first bit of the stop bit when the stop bit length is 1, or the second bit of the stop bit when the stop bit length is 2).

Note If a data consistency error is detecting, this interrupt is not generated.

The following diagrams show the timing of the transmission interrupt request for both cases.

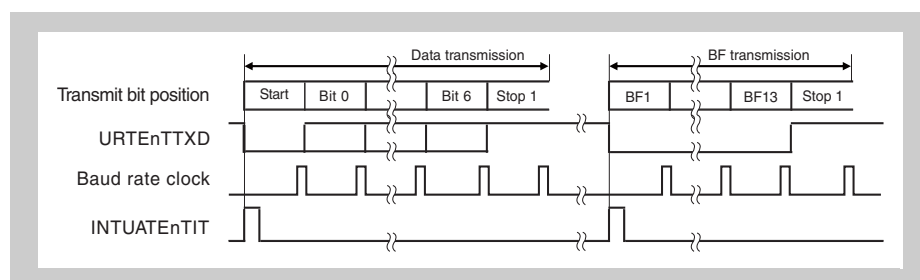

Figure 19-2 Transmission interrupt request timing for URTE_nCTL1.URTE_nSLIT = 0

Figure 19-3 Transmission interrupt request timing for URTE_nCTL1.URTE_nSLIT = 1

19.5.2 Reception interrupt request INTUAEnTIR

A reception interrupt request is generated when the first bit of the stop bit is sampled.

In case of erroneous reception, the status interrupt INTUAEnTIS is generated instead of INTUAEnTIR.

The reception interrupt request INTUAEnTIR is not generated in the reception disabled status.

The following diagrams show the timing of the reception interrupt request during data/BF reception.

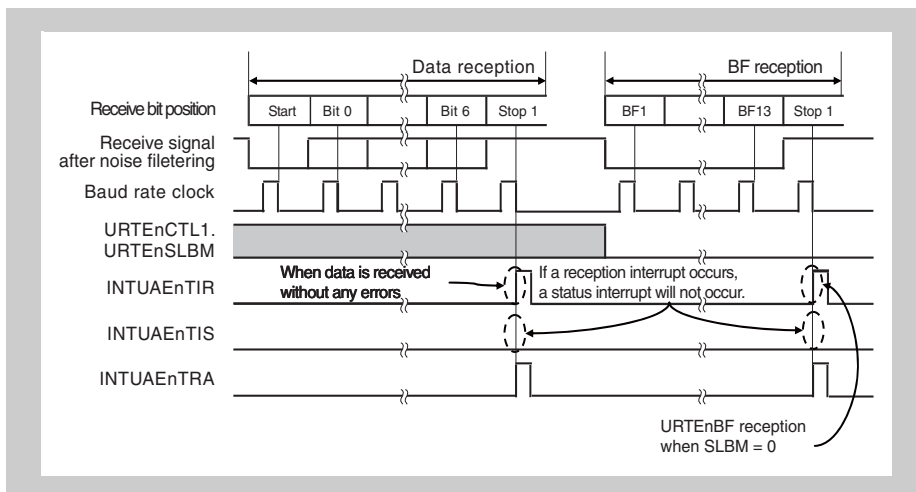

Figure 19-4 Reception interrupt request timing

19.5.3 Status interrupt request INTUAEnTIS

A status interrupt request is generated if an error condition occurred during reception or transmission, as reflected in the status register 1 URTEEnSTR1.

If BF reception is enabled (URTEEnCTL1.URTEEnSLBM = 1) during LIN communication, the status interrupt request signal is generated when a consecutive low level (BF) of 11 bits or more is received.

19.5.4 Receive/status interrupt request INTUAEnTRA

The reception/status interrupt request is asserted, if a reception or status interrupt request is generated. That means:

$$\text{INTUAEnTRA} = \text{INTUAEnTIR} \text{ or } \text{INTUAEnTIS}$$

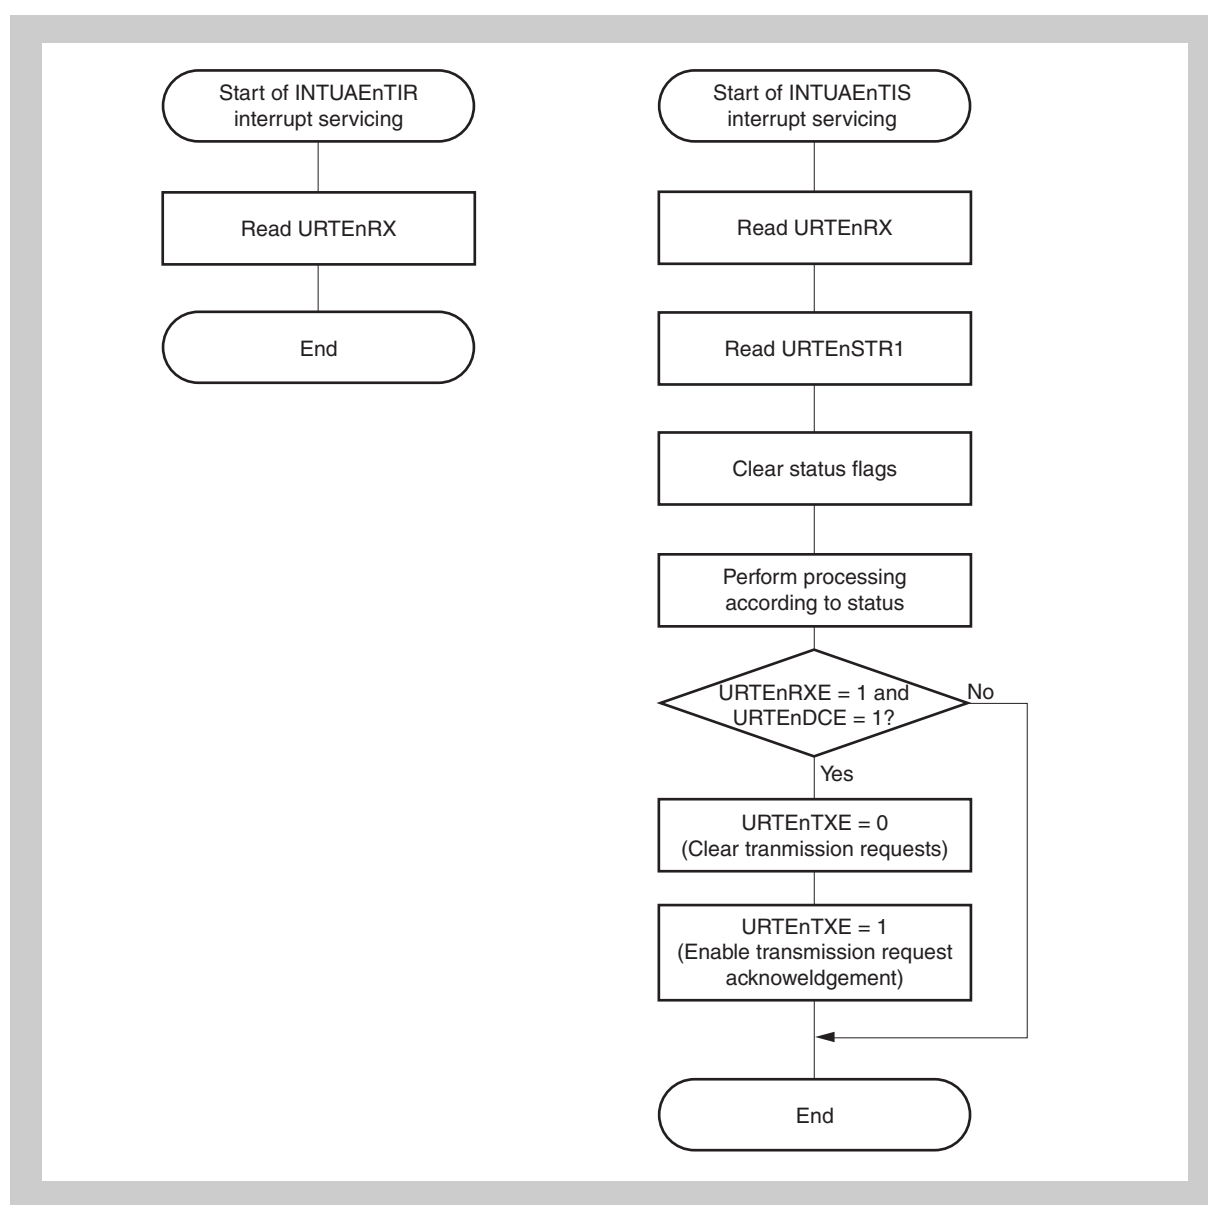

Figure 19-5 Processing flow after interrupt generation

19.6 Operation

19.6.1 Data formats

Full-duplex serial data reception and transmission is performed.

As shown in the figures below, one data frame of transmit/receive data consists of a start bit, character bits, parity bit, and stop bit(s).

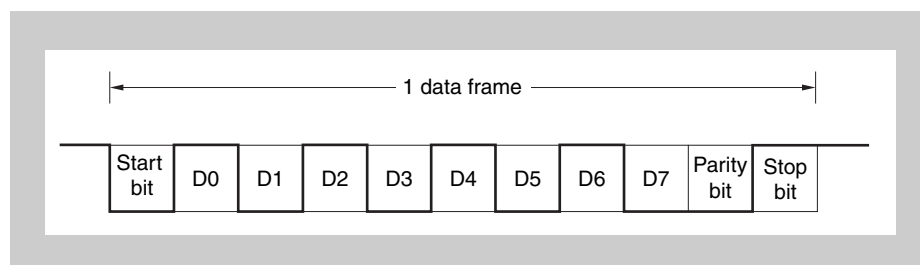

Several properties of a transmit/receive data frame can be specified by control bits of the URTECTL1 register:

Table 19-15 Data format specification

Item	Options	Control bits
Start bit	1 bit	Fixed
Character bits	7 bits / 8 bits	URTECTL1.URTECLG
Parity	Even parity/odd parity/ 0 parity/no parity	URTECTL1.URTESLP[1:0]
Stop bit	1 bit / 2 bits	URTECTL1.URTESLG
Data order	MSB first / LSB first	URTECTL1.URTESLD
Tx data level	inverted / not inverted	URTECTL1.URTESDL
Rx data level	inverted / not inverted	URTECTL1.URTERDL

(1) UARTEn transmit/receive data format

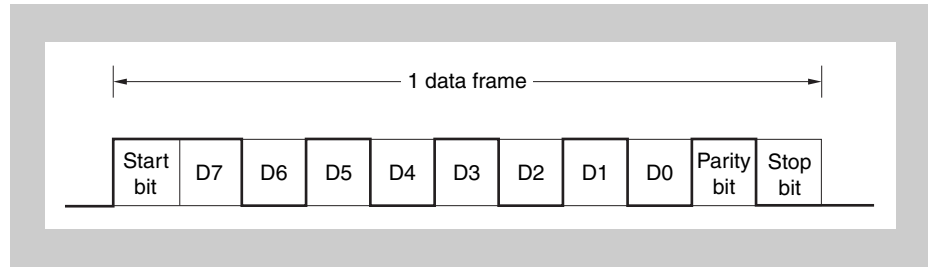

(a) 8-bit data length, LSB first, even parity, 1 stop bit, transfer data: 55_H

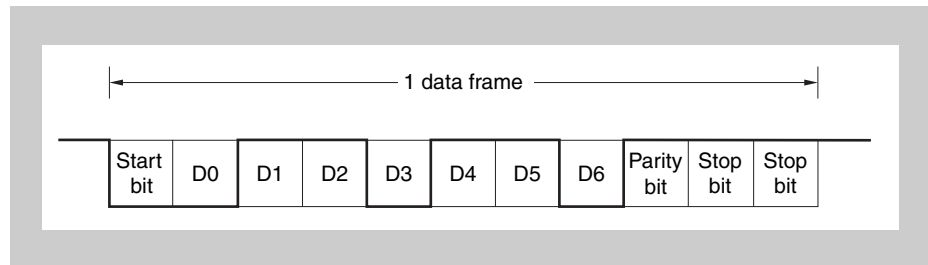

(b) 8-bit data length, MSB first, even parity, 1 stop bit, transfer data: 55_H

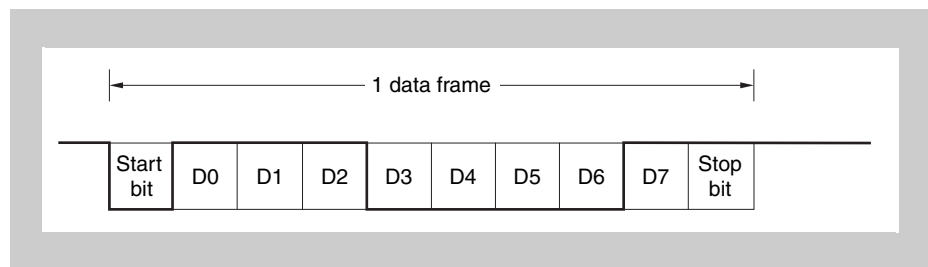

(c) 8-bit data length, MSB first, even parity, 1 stop bit, transfer data: 55_H,
URTE_{NTTXD} inversion

(d) 7-bit data length, LSB first, odd parity, 2 stop bits, transfer data: 36_H

(e) 8-bit data length, LSB first, no parity, 1 stop bit, transfer data: 87_H

19.6.2 BF transmission/reception format

The UARTEn has an BF (Break Field) transmission/reception control function to enable use of the LIN function.

About LIN LIN stands for Local Interconnect Network and is a low-speed (1 to 20 kbps) serial communication protocol intended to aid the cost reduction of an automotive network.

LIN communication is single-master communication, and up to 15 slaves can be connected to one master.

The LIN slaves are used to control the switches, actuators, and sensors, and these are connected to the LIN master via the LIN network.

Normally, the LIN master is connected to a network such as CAN (Controller Area Network).

In addition, the LIN bus uses a single-wire method and is connected to the nodes via a transceiver that complies with ISO9141.

In the LIN protocol, the master transmits a frame with baud rate information and the slave receives it and corrects the baud rate error. Therefore, communication is possible when the baud rate error in the slave is $\pm 14\%$ or less.

Figure 19-6 “LIN transmission outline” and Figure 19-7 “LIN reception outline” outline the transmission and reception manipulations of LIN.

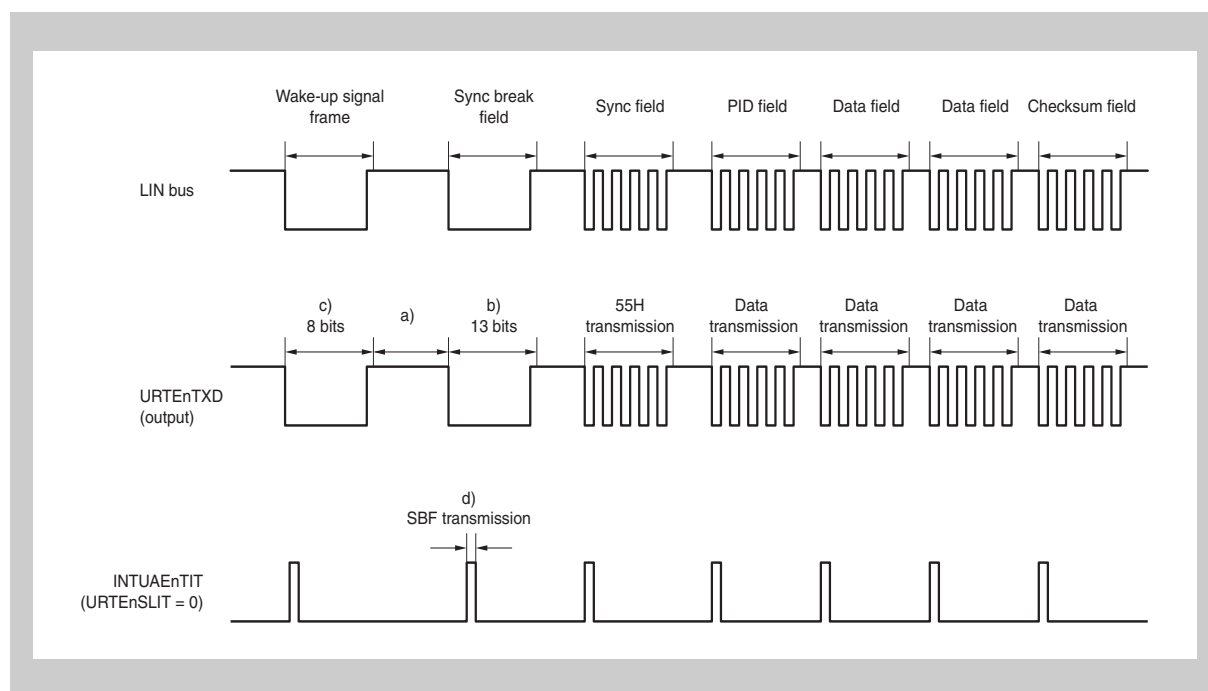

Figure 19-6 LIN transmission outline

- The interval between fields is controlled by software.
- BF output is performed by hardware. The output width is the bit length set by `URTEnCTL1.URTEnBLG[2:0]`. If even finer output width adjustments are required, such adjustments can be performed using `URTEnCTLn.URTEnBRS[11:0]`.
- 80μ s transfer in the 8-bit mode is substituted for the wakeup signal frame.
- A transmission enable interrupt `INTUAEnTIT` is generated at the start of each transmission. `INTUAEnTIT` is also generated at the start of each BF transmission.

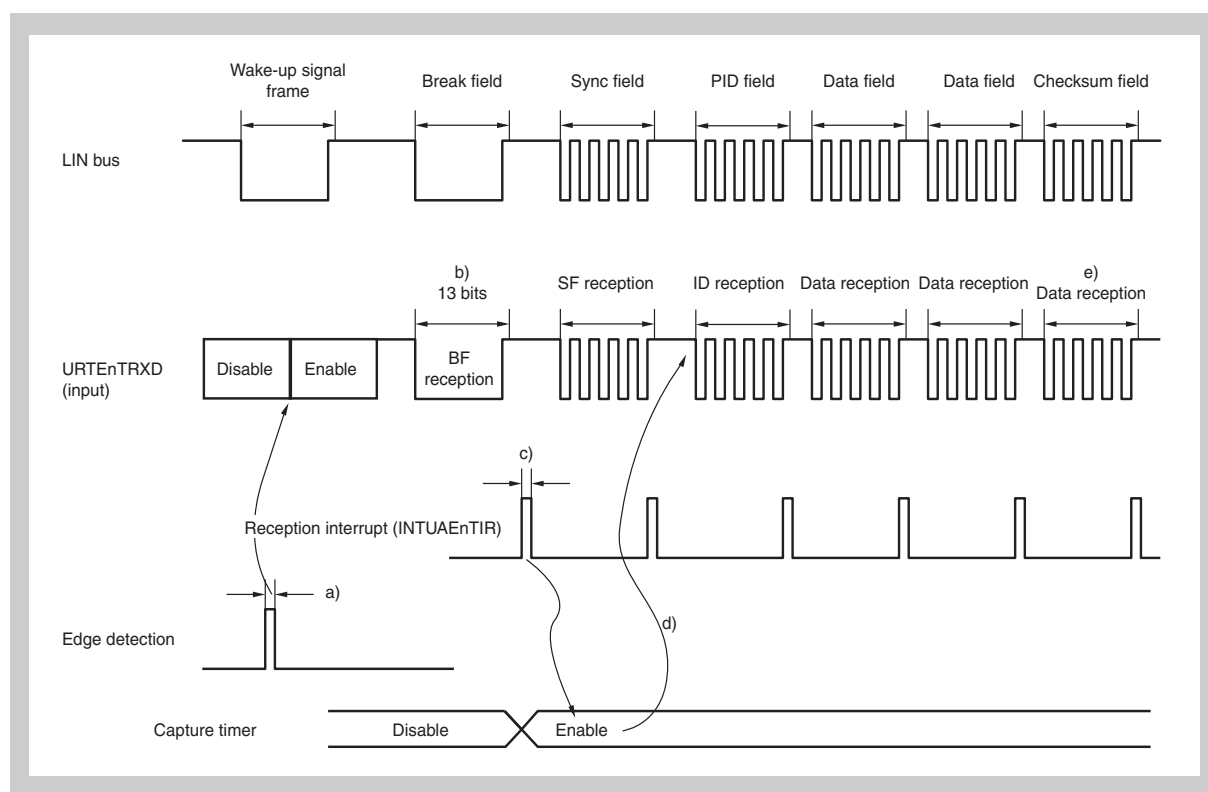

Figure 19-7 LIN reception outline

- a) The wakeup signal sent by the pin edge detector enables UARTEn, and sets the BF reception mode.
- b) BF reception is judged to end normally when a BF of 11 or more bits is received. An interrupt is generated as shown in the table below, according to the setting of the BF reception mode selection bit URTE nCTL1.URTE nSLBM and the value of the URTE nSTR0.URTE nSSBR bit.

URTE nSLBM	URTE nSSBR	Interrupts
1	x	INTUA nTIS
0	1	INTUA nTIR
0	0	A framing error has occurred, so and INTUA nTIS is generated.

- c) When BF reception ends normally, an interrupt is generated as follows according to the setting of the BF reception mode selection bit URTE nCTL1.URTE nSLBM:
- When URTE nDTL1.URTE nSLBM is 0, the reception interrupt INTUA nTIR is generated.
 - When URTE nDTL1.URTE nSLBM is 1, the status interrupt INTUA nTIS is generated and the BF reception success flag URTE nSTR1.URTE nBSF is set. If the BF reception trigger bit URTE nTRG.URTE nBRT is 1, error detection for overrun, parity, and framing errors is not performed during BF reception. Also, data transfer from the receive shift register to the receive data register URTE nRX is not performed. URTE nRX holds the previous value at this time.
- d) In order to adjust the baud rate clock properly, the URTE nTRXD signal must be connected to the timer capture input. The transfer rate and the baud rate error can be calculated by measuring the time between URTE nTRXD edges, and the baud rate can be adjusted by specifying a value for the baud rate setting bits URTE nCTL2.URTE nBRS[11:0].
- e) A checksum field is identified by software. When a checksum field is received, UARTEn is initialized and set to the BF reception mode by software. But if URTE nCTL1.URTE nSLBM is 1 at this time, UARTEn automatically starts BF reception without entering the BF reception mode.

19.6.3 BF transmission

When the URTECTL0 bits URTEenPW = URTEenTXE = 1, the transmission enabled status is entered, and BF transmission is started by setting the BF transmission trigger URTEenTRG.URTEenBTT = 1.

Thereafter, URTEenSTR0.URTEenSSBT is set to "1" and a low level width of 13 to 20 bits, as specified by URTEenCTL1.URTEenBLG[2:0], is output. A transmission interrupt INTUAenTIT) is generated upon BF

- transmission start, if URTEenCTL1.URTEenSLIT = 0
- transmission end, if URTEenCTL1.URTEenSLIT = 1.

Following the end of BF transmission, URTEenSTR0.URTEenSSBT is automatically cleared. Thereafter, the UARTEn transmission mode is restored.

Transmission is suspended until the data to transmit next is written to the URTEenTX register and URTEenSTR0.URTEenSST is set, or until the BF transmission trigger URTEenTRG.URTEenBTT is set and URTEenSTR0.URTEenSSBT changes to 1.

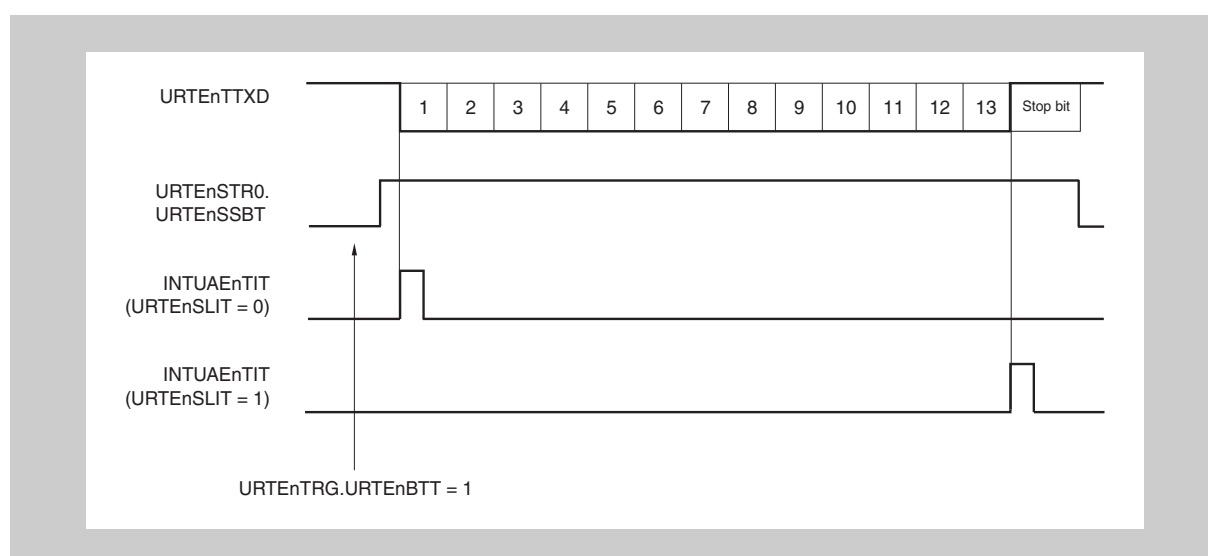

Figure 19-8 BF transmission

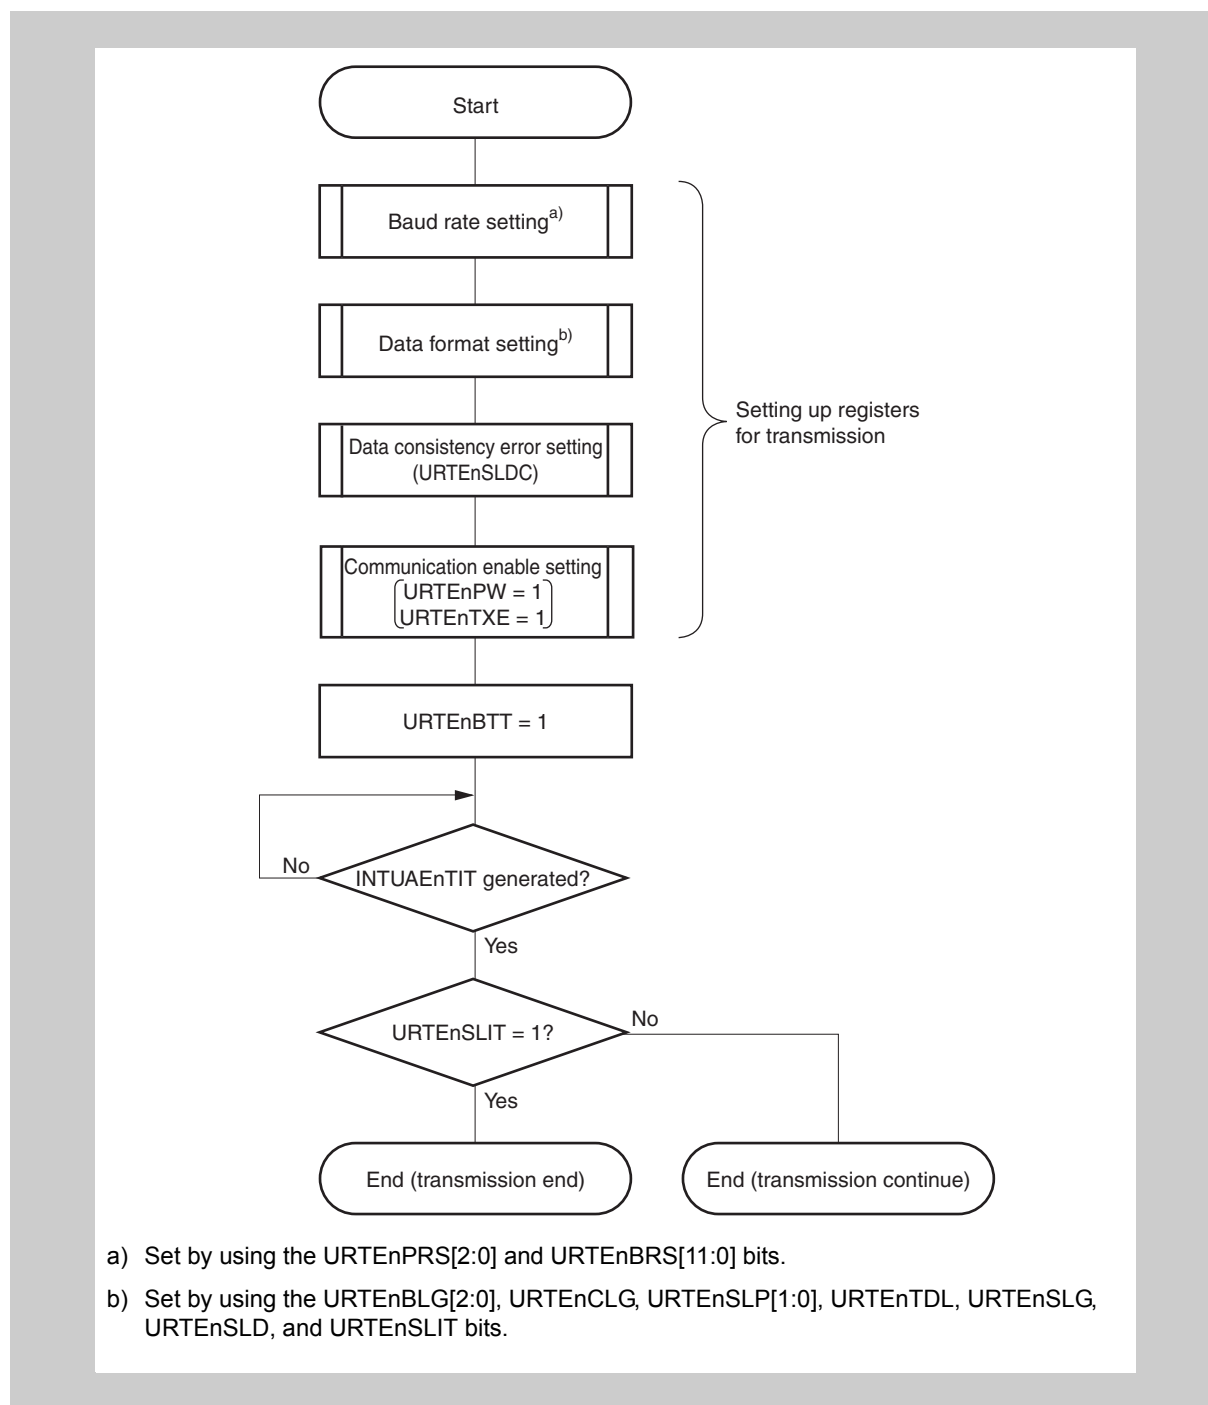

Figure 19-9 Flowchart of BF transmission

19.6.4 BF reception

The reception enabled status is achieved by setting the URTECTL0.URTEPW bit to 1 and then setting the URTECTL0.URTERXE bit to 1.

The BF reception wait status is set by setting the BF reception trigger URTESTRG.URTEBRT = 1.

In the BF reception wait status, similarly to the UARTEn reception wait status, the URTESTRXD pin is monitored and start bit detection is performed.

Following detection of the low level, reception is started and the internal counter counts up according to the set baud rate.

When a high level is received and if the BF width is 11 or more bits, while the BF receiving mode selection bit

- URTECTL1.URTESLBM = 0,
the reception interrupt INTUAEnTIR is generated.
- URTECTL1.URTESLBM = 1,
the status interrupt INTUAEnTIS is generated and BF reception success flag URTESTR1.URTEBSF is set at the same time.

The URTESTR0.URTESSBR bit is automatically cleared and BF reception ends.

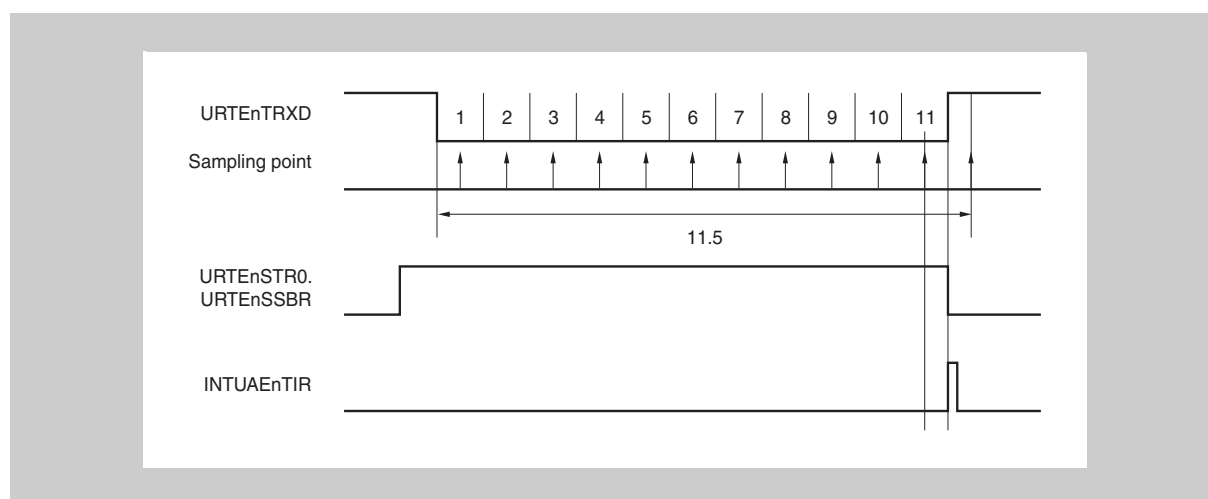

Figure 19-10 Normal BF reception (stop bit after more than 10.5 “L” bits)

Error detection for the URTESTR1 error flags URTEOVE, URTEPE, and URTEFE is suppressed and UARTEn communication error detection processing is not performed.

Moreover, the erroneous data is not stored in URTERX, but the initial value FFH is held.

If the BF width is 10 or fewer bits, reception is terminated as error processing without generating an interrupt, and the BF reception mode is returned to. URTESTR0.URTESSBR is not cleared at this time.

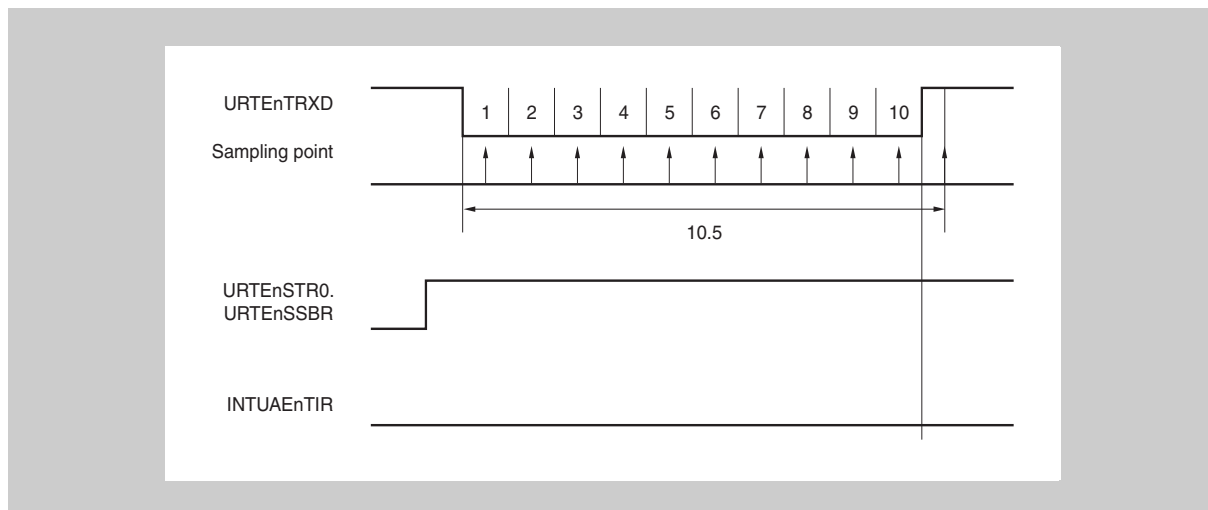

Figure 19-11 BF reception error (stop bit within 10.5 “L” bits)

The BF mode can be selected between a single BF receive mode and an any time BF receive mode in by URTEEnCTL1.URTEEnSLBM. The status of a successful reception of the BF is indicated by URTEEnSTR1.URTEEnBSF.

- Note** URTEEnSTR0.URTEEnSSBR is set to “1” when
- URTEEnTRG.URTEEnBRT is set to “1”, or
 - the error is cleared by normal BF reception.

19.6.5 Transmission data consistency check

The UARTEn incorporates a data consistency check function to detect a mismatch between the transmit data written to transmit register URTEnTX and the data on the bus when the device operates in master mode.

Data consistency check is enabled by URTEnCTL0.URTEnSLDC = 1.

The data consistency is checked by comparing the transmit data in the transmit register URTEnTX and the receive data in the receive register URTEnRX. In case of a mismatch the data consistency error flag URTEnSTR1.URTEnDCE is set and a status interrupt request INTUAEnTIS occurs.

The consistency check of data is not done in reception mode.

The consistency check of the send data and the input data terminal level is done even if the reception is disabled during sending. In that case also the reception completion interrupt request signal INTUAEnTIR, the URTEnSTR1 status bits URTEnBSF, URTEnFE, URTEnOVE and the status interrupt request signal INTUAEnTIS will not be generated as well. Receive data does not need to be read.

Refer to (6) "URTEnSTR1 - UARTEn status register 1" on page 1010 for details.

Figure 19-12 Timing example of data consistency error (no BF reception active, i.e. URTEnSTR0.URTEnSSBR = 0)

19.6.6 UARTEn transmission

- Transmission start** Set the transmission enabled status by performing the following procedures.
- Specify the baud rate by UARTEn control register 2 (URTECTL2).
 - Specify the transmit parity, data character length, stop bit length, transmit data order, transmission interrupt request timing and output logic level by UARTEn control register 1 (URTECTL1).
 - Enable UARTEn operation and transmission by URTECTL0.URTEPW = URTECTL0.URTETXE = 1)

Write of the transmit data to the transmission buffer register URTEenTX starts transmission. The data which is saved in the URTEenTX register is transferred to the transmit shift register URTEenTXS. Then, the start, parity and stop bits are added and the data frame is output serially via URTEenTTXD.

- Transmission stop** When URTECTL0.URTEPW or URTECTL0.URTETXE is set to 0, transmission operations are stopped immediately, even during transmission processing.

- Concurrent BF and data transmission** When a BF transmit request and a data transmit request have both been set, BF transmission takes priority.

- Data consistency check** If a data consistency error is detected, the subsequent data is not transmitted until URTEenCLDC is set to 1, URTEenPW is set to 0, or URTEenTXE is set to 0.

- INTUAEenTIT timing** The time required to generate the transmission interrupt INTUAEenTIT depends on the setting of the URTECTL1.URTEenSLIT bit:

- URTECTL1.URTEenSLIT = 0
INTUAEenTIT is generated at the start of transmission, i.e. when the data from the data register URTEenTX is transferred to the transmit shift register and transmission is started.
- URTECTL1.URTEenSLIT = 1
INTUAEenTIT is generated when the entire data transmission process is completed, i.e. when the last bit of the data frame has been transmitted.

Once INTUAEenTIT is generated, the next data can be written to URTEenTX.

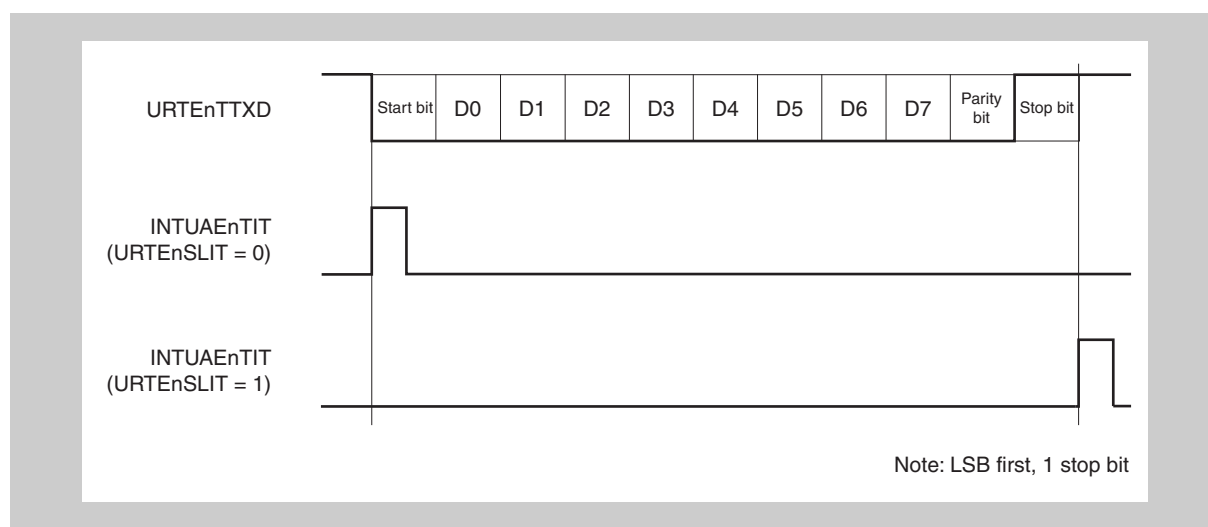

Figure 19-13 Transmission interrupt timing

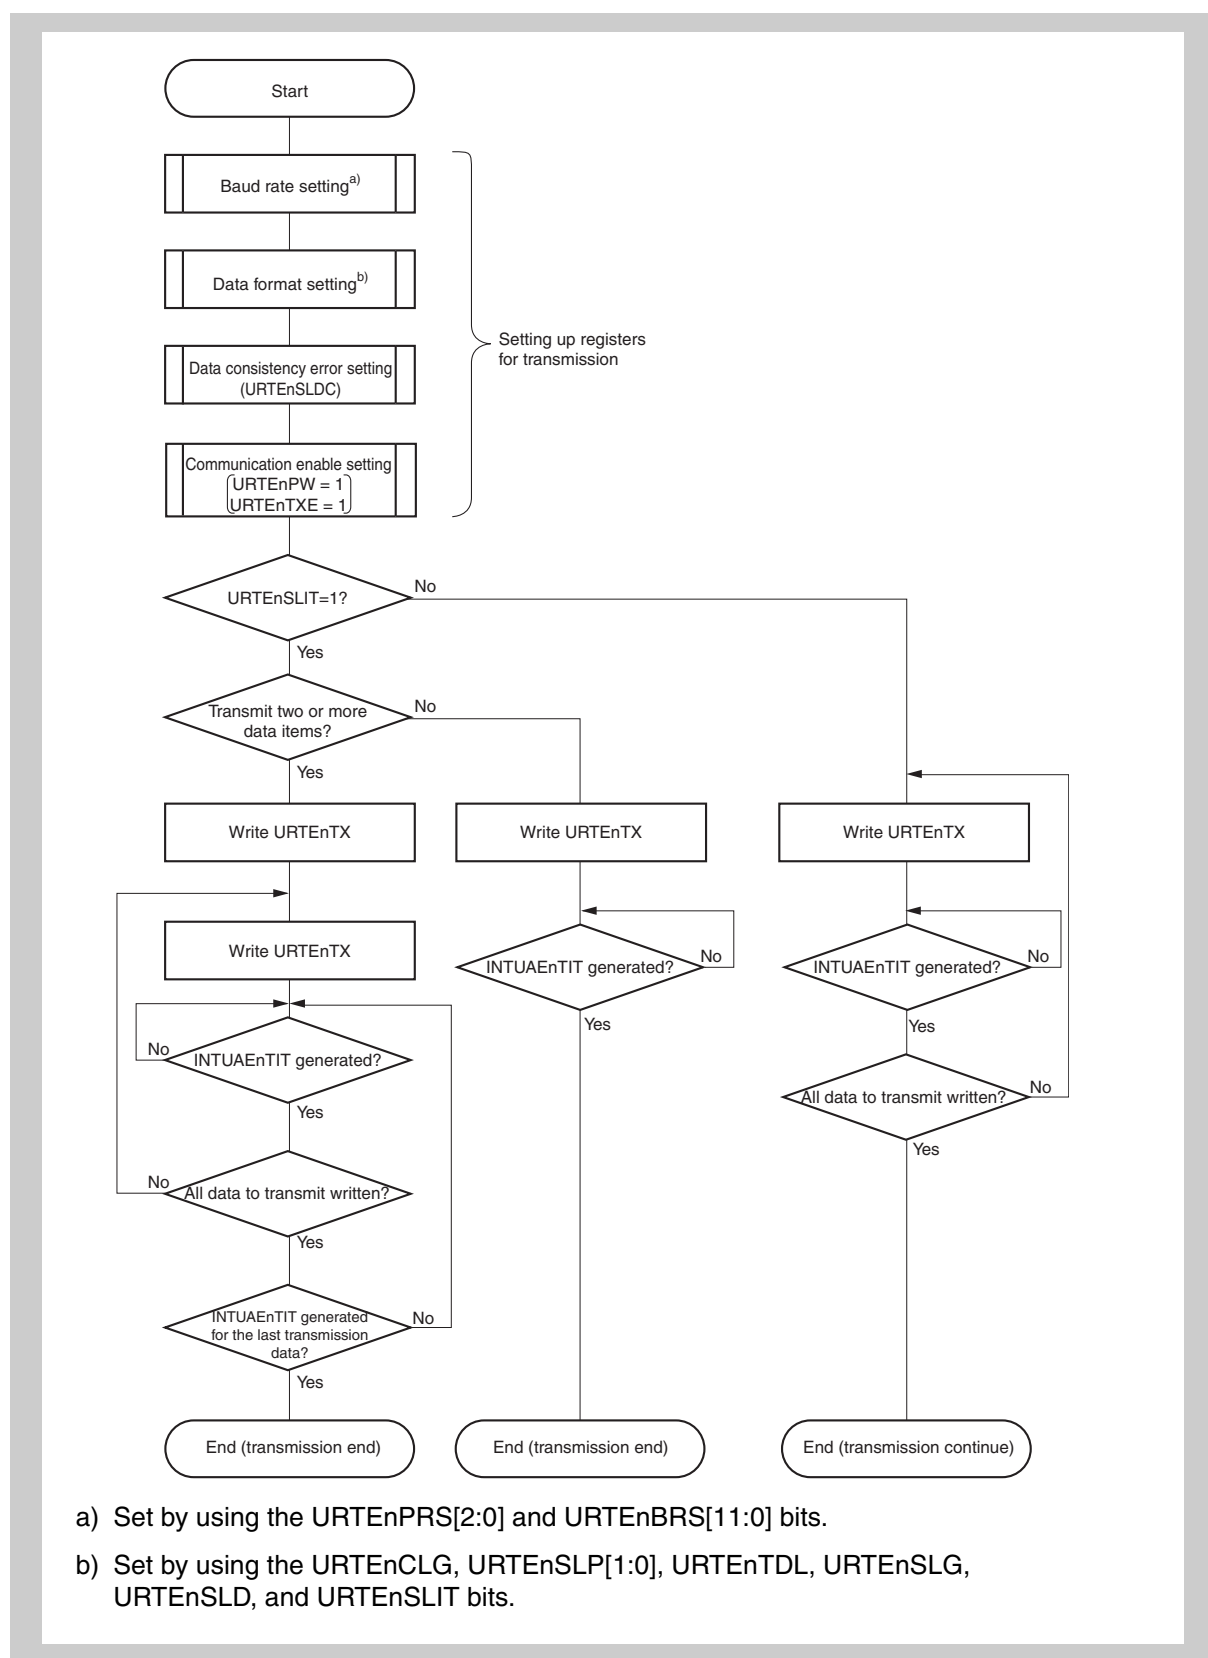

Figure 19-14 Flowchart of data transmission

19.6.7 Continuous transmission procedure

Continuous transmission is achieved by writing the next transmit data to the transmit data register, while shifting out of the previous data from the transmission shift register URTE_nTXS is ongoing.

Note In order to maintain correct write timing, the transmission interrupt INTUA_nEnTIT must be generated at the start of each transmission (URTE_nCTL1.URTE_nSLIT = 0).

Caution If the value is written to the URTE_nTX register before the INTUA_nEnTIT is generated, the transmit data set before is overwritten by the new transmit data. To initialize the transmission unit, confirm that no transmission is ongoing (URTE_nSTR0 bits URTE_nSSBT = URTE_nSST = 0). If the initialization is performed during an ongoing transmission, the transmission is aborted.

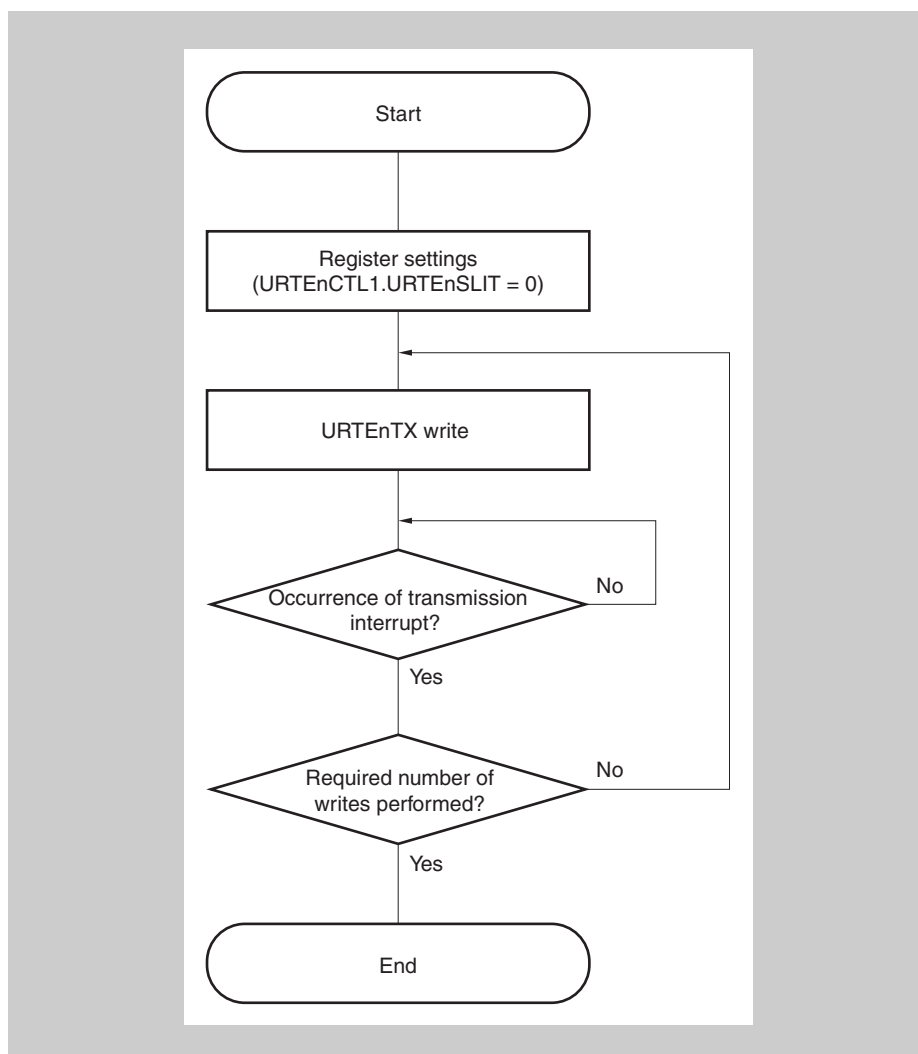

Figure 19-15 Continuous transmission processing flow

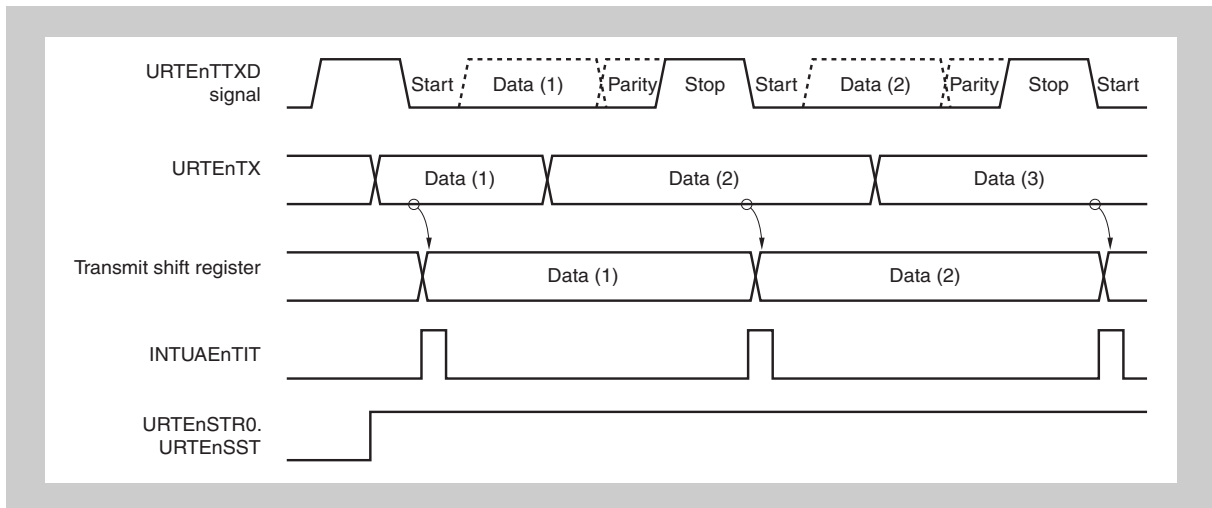

Figure 19-16 Continuous transmission operation timing - transmission start

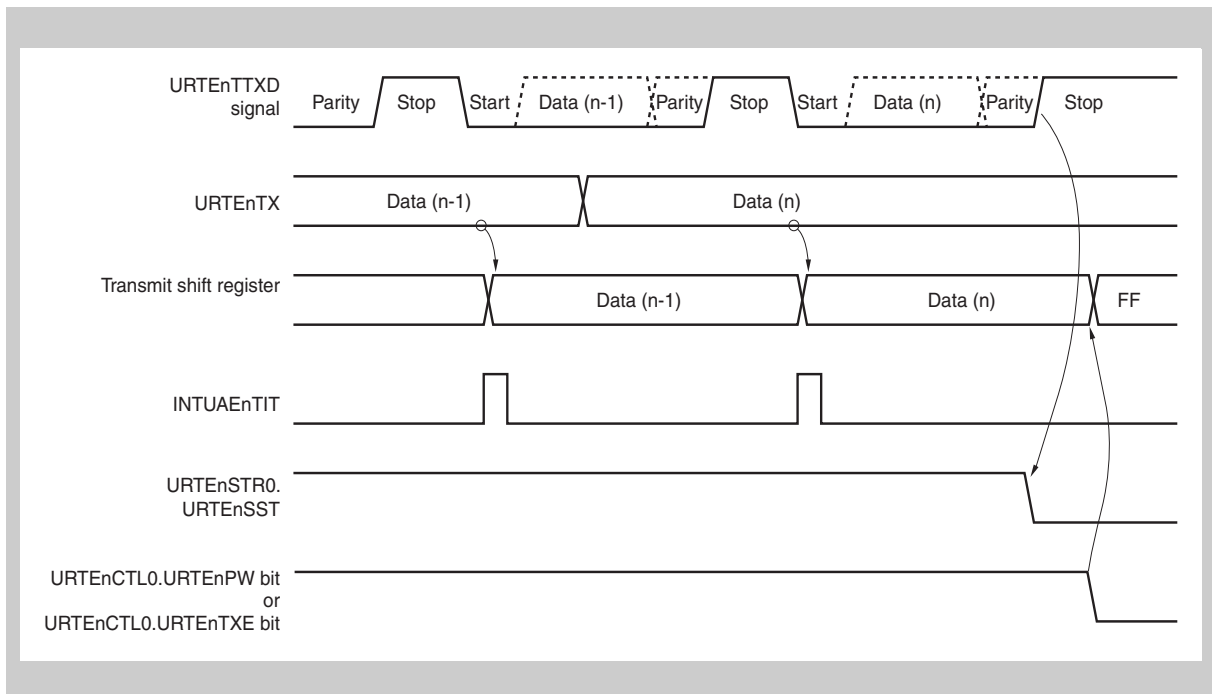

Figure 19-17 Continuous transmission operation timing - transmission end

19.6.8 UARTEn reception

Reception start Set the reception enabled status by using the following procedure:

- Specify the baud rate by URTECTL2.
- Specify the receive parity, data character length, stop bit length, receive data order and output logic level by URTECTL1.
- Enable UARTEn operation and reception by setting URTECTL0.URTEPW and URTECTL0.URTERXE.

When the falling edge of the URTESTRXD pin input level is detected, data sampling of the URTESTRXD input is started. The start bit is recognized if the URTESTRXD pin is low level after the time of a half bit is passed after the detection of the falling edge (shown in the figure below). After a start bit has been recognized, the receive operation starts, and serial data is stored in the receive shift register according to the set baud rate. When the reception interrupt INTUAEnTIR is asserted upon reception of the stop bit, the data stored in the receive shift register is written to the receive data register URTESTRX.

Reception stop When URTECTL0.URTEPW or URTECTL0.URTERXE is set to 0, reception operations are stopped immediately, even during reception processing.

Reception errors If an overrun error occurs (URTESTR1.URTEOVE = 1), the receive data at this time is not transferred to the URTESTRX register and is discarded. Even if a parity error (URTESTR1.URTEPE = 1) or a framing error (URTESTR1.URTEFE = 1) occurs during reception, reception continues until the reception position of the first stop bit, and the reception data is transferred to the URTESTRX.

When a reception error occurs, the status interrupt INTUAEnTIS –and therefore also the receive/status interrupt INTUAEnTRA– is generated, but not the reception interrupt INTUAEnTIR.

To change the receive data order, parity, data character length, or the stop bit length, clear the power bit (URTECTL0.URTEPW = 0) first.

Figure 19-18 UARTEn reception

- Cautions**
1. Be sure to read the URTEEnRX register even when a reception error occurs. If the URTEEnRX register is not read, an overrun error occurs during reception of the next data.
 2. The operation during reception is performed assuming that there is only one stop bit. A second stop bit is ignored.
 3. When reception is completed, read the URTEEnRX register after the reception interrupt INTUAEnTIR has been generated, and clear the URTEEnCTL0.URTEEnPW or URTEEnCTL0.URTEEnRXE bit to 0. If the URTEEnCTL0.URTEEnPW or URTEEnCTL0.URTEEnRXE bit is cleared to 0 before the INTUAEnTIR is generated, the read value of the URTEEnRX register cannot be guaranteed.
 4. If receive completion processing (INTUAEnTIR interrupt generation) and the URTEEnCTL0.URTEEnPW bit = 0 or URTEEnCTL0.URTEEnRXE bit = 0 conflict, INTUAEnTIR may be generated in spite of these being no data stored in the URTEEnRX register.

- Notes**
1. If low level is always input to the URTEEnTRXD pin, it is not judged as the start bit.
 2. In continuous reception, immediately after the stop bit is detected at the first reception bit (when the reception interrupt is generated), the next start bit can be detected.

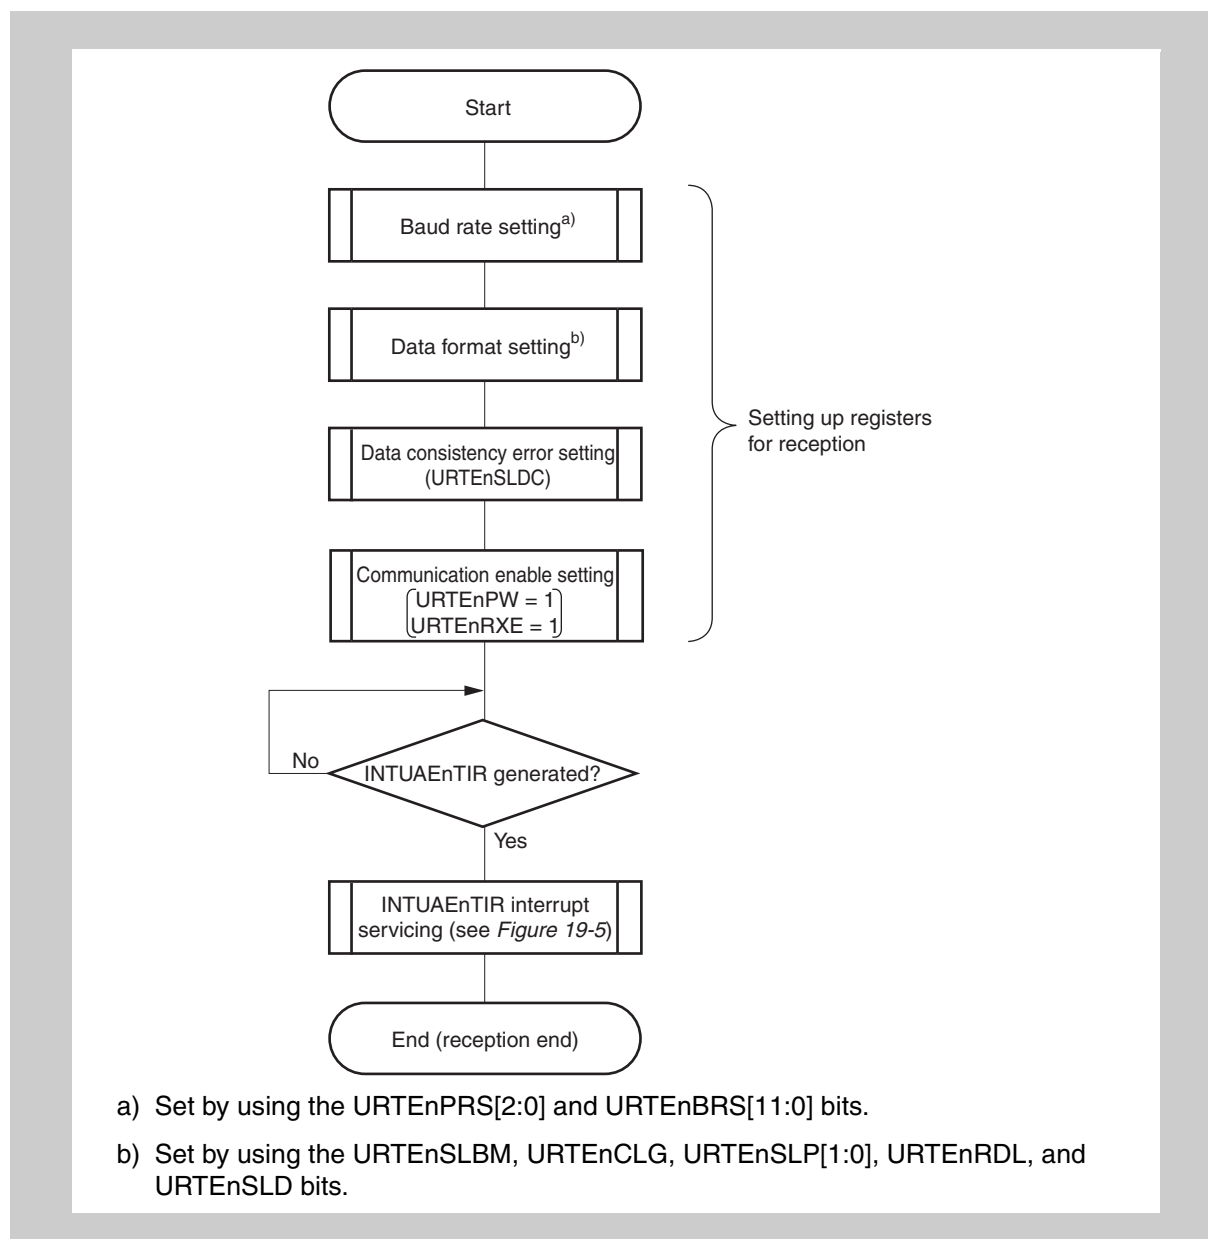

Figure 19-19 Flowchart of data reception when URTEEnSLBM = 0, URTEEnSSBR = 0

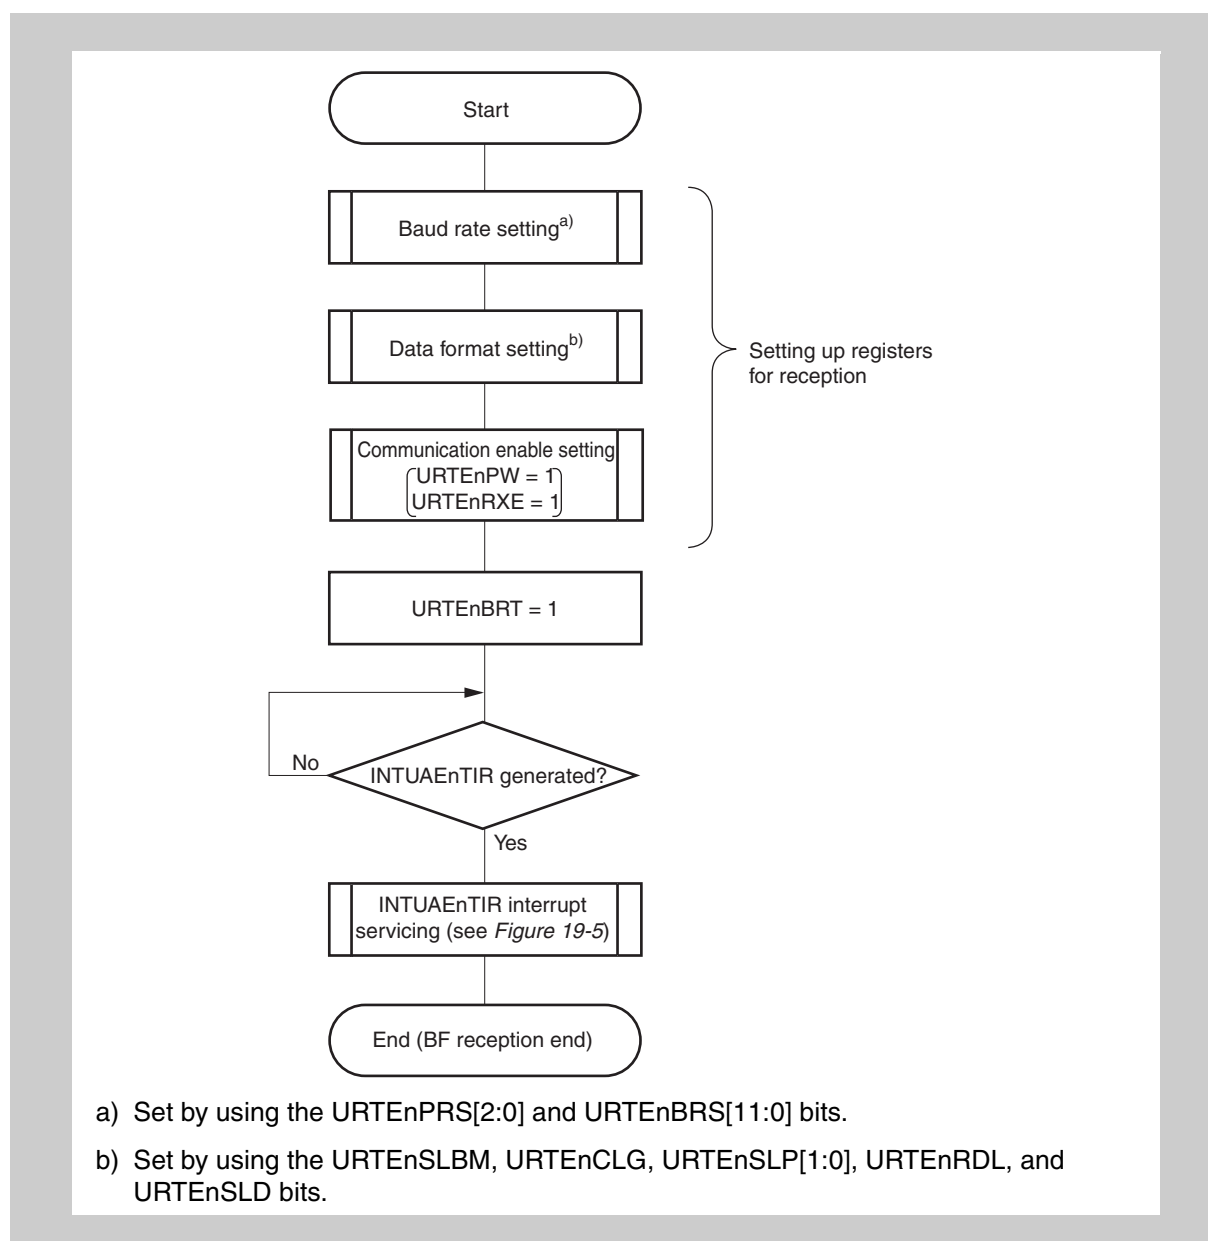

Figure 19-20 Flowchart of data reception when URTEEnSLBM = 0, URTEEnSSBR = 1

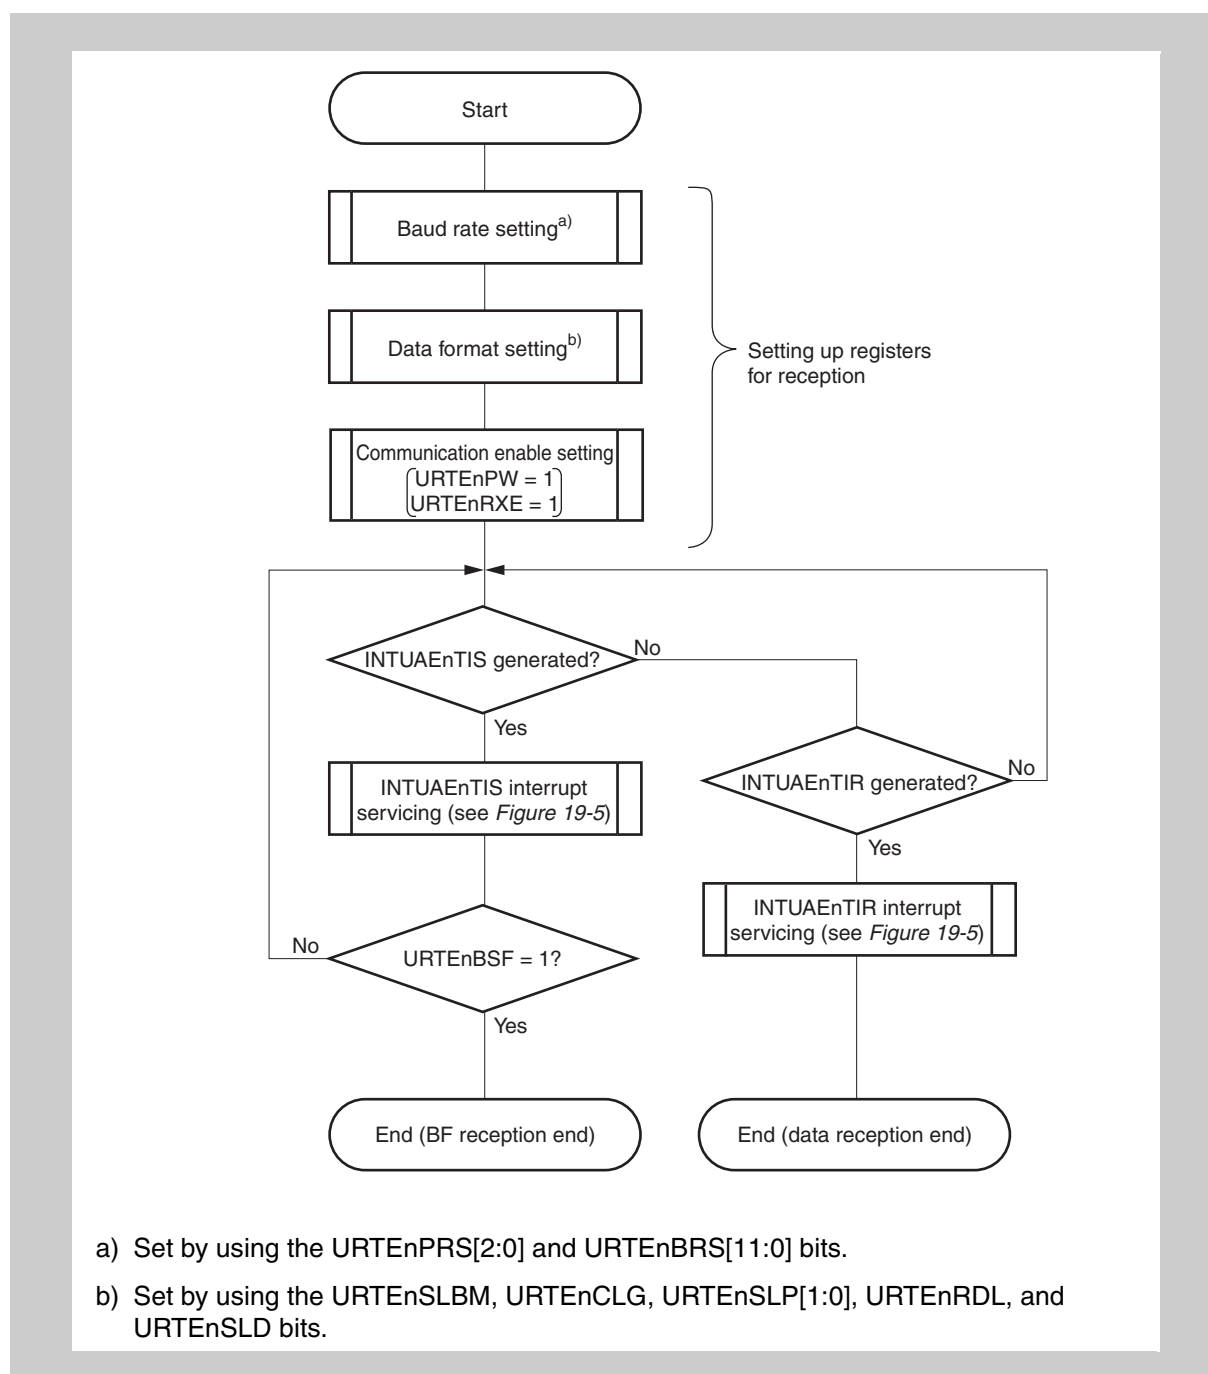

Figure 19-21 Flowchart of data reception when URTEEnSLBM = 0, URTEEnSSBR = 0

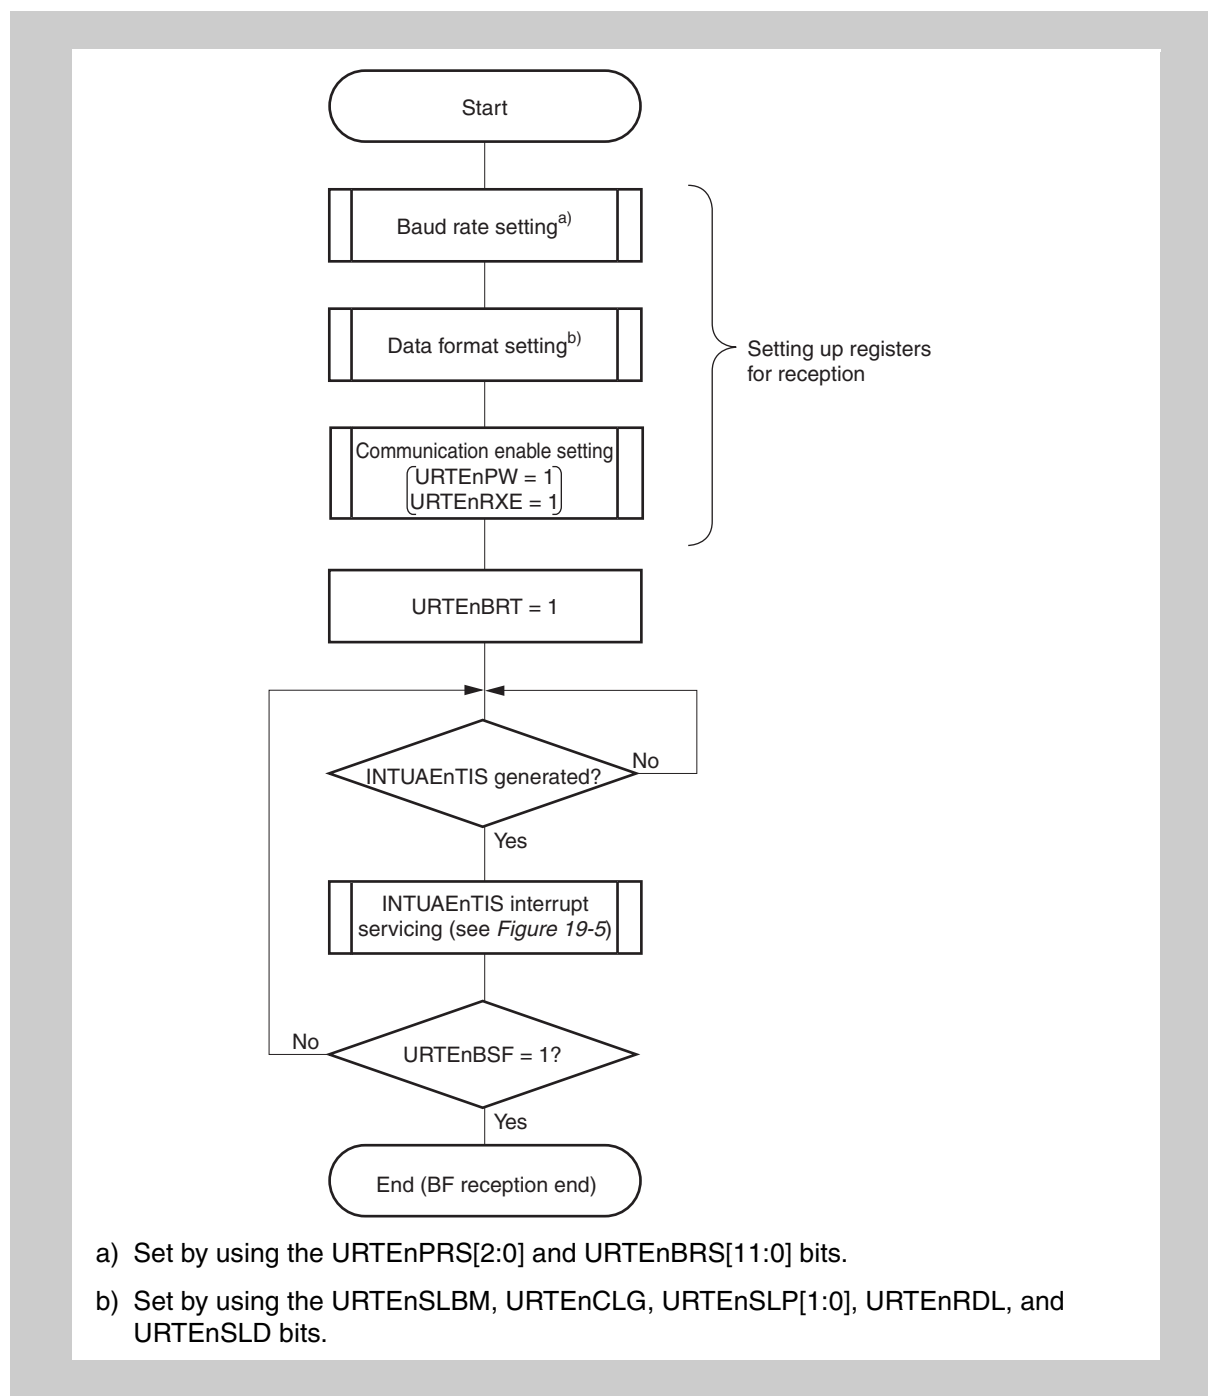

Figure 19-22 Flowchart of data reception when URTEenSLBM = 1, URTEenSSBR = 1

19.6.9 Reception errors

Errors during a receive operation are of three types: parity errors, framing errors, and overrun errors. Data reception result error flags are set in the URTESTR1 register and a status interrupt request signal INTUAEnTIS is generated when an error occurs.

It is possible to ascertain which error occurred during reception by reading the contents of the URTESTR1 register.

Clear a reception error flag by writing 1 to its associated bit in the status clear register URTESTC.

Table 19-16 Reception error causes

Error flag in URTESTR1	Reception error	Cause
URTEenPE	Parity error	Received parity bit does not match the setting
URTEenFE	Framing error	Stop bit not detected
URTEenOVE	Overrun error	Reception of next data completed before data was read from receive buffer

Note Even in case of a parity or framing error, data is transferred from the receive shift register to the receive data register URTEenRX. Consequently the data from URTEenRX must be read. Otherwise an overrun error URTEenSTR1.URTEenOVE will occur at reception of the next data.

In case of an overrun error, the receive shift register data is not transferred to URTEenRX, thus the previous data is not overwritten.

19.6.10 Parity types and operations

Caution When using the LIN function, fix the URTECTL1.URTEenSLP[1:0] to 00_B.

The parity bit is used to detect bit errors in the communication data. Normally the same parity is used on the transmission side and the reception side.

In the case of even parity and odd parity, it is possible to detect odd-count bit errors. In the case of 0 parity and no parity, errors cannot be detected.

(1) Even parity

- During transmission
The number of bits whose value is “1” among the transmit data, including the parity bit, is controlled so as to be an even number. The parity bit values are as follows:
 - Odd number of bits whose value is “1” among transmit data:1
 - Even number of bits whose value is “1” among transmit data:0
- During reception
The number of bits whose value is “1” among the reception data, including the parity bit, is counted, and if it is an odd number, a parity error is output.

(2) Odd parity

- During transmission
Opposite to even parity, the number of bits whose value is “1” among the transmit data, including the parity bit, is controlled so that it is an odd number. The parity bit values are as follows.
 - Odd number of bits whose value is “1” among transmit data: 0
 - Even number of bits whose value is “1” among transmit data: 1
- During reception
The number of bits whose value is “1” among the receive data, including the parity bit, is counted, and if it is an even number, a parity error is output.

(3) 0 parity

During transmission, the parity bit is always made 0, regardless of the transmit data.

During reception, parity bit check is not performed. Therefore, no parity error occurs, regardless of whether the parity bit is 0 or 1.

(4) No parity

No parity bit is added to the transmit data.

Reception is performed assuming that there is no parity bit. No parity error occurs since there is no parity bit.

19.6.11 Digital receive data noise filter

The receive data signal input URTE_nTRXD is equipped with a digital noise filter to eliminate noise and spikes.

This filter samples the URTE_nTRXD pin using the prescaler output clock PRSCLK.

When the same sampling value is read twice, the URTE_nTRXD signal is validated as the input data.

Therefore, data not exceeding the width of 1 prescaler output clock cycle is judged to be noise and thus eliminated.

The noise filter causes a delay of 4 prescaler output clock PRSCLK cycles when capturing the serial data URTE_nTRXD, until it is forwarded as valid.

19.7 Baud Rate Generator

The transmission and reception baud rate BRCLK are derived from the APB bus clock PCLK by use of a prescaler and a baud rate generator, as shown in the figure below.

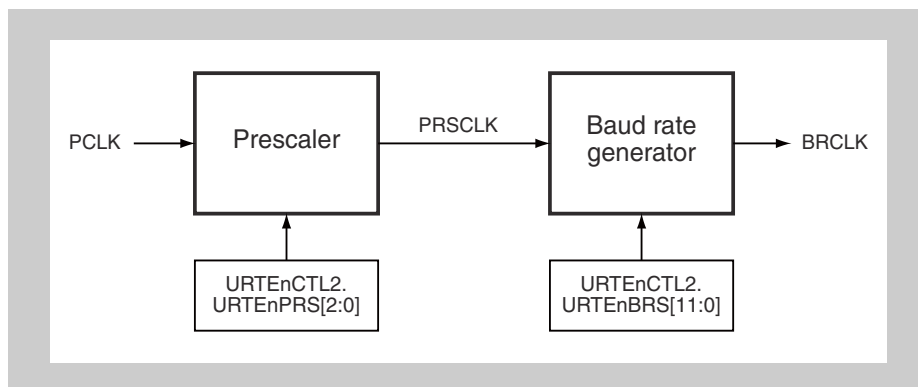

Figure 19-23 Configuration of baud rate generator

The prescaler output clock PRSCLK is a fraction of PCLK, the divisor is set up the value URTECTL2.URTEPRS[2:0]:

$$\text{PRSCLK} = \text{PCLK} / 2^{\text{URTEPRS}[2:0]}$$

PRSCLK is further divided by the baud rate generator by a value, determined by URTECTL2.URTEBRS[11:0].

The baud rate generator distinguishes between the baud rate for data frames and BF receptions, as listed in the table below. The BF reception clock is the double of the baud rate clock BRCLK.

Table 19-17 Baud rate generator clocks output

URTECTL2.URTEBRS[11:0]	Transmit/receive BRCLK	BF receive clock

Chapter 20 Asynchronous Serial Interface J (UARTJn)

This chapter contains a generic description of asynchronous serial interface J. The first section describes all properties specific to the V850E2/ML4, such as instances, register base addresses, and input/output signal names. The subsequent sections describe the features that apply to all implementations.

20.1 V850E2/ML4 UARTJn Features

Instances This microcontroller has two instances of asynchronous serial interface J UARTJn.

Table 20-1 Instances of UARTJn

Asynchronous serial interface J	
Instance	2
Name	UARTJ0, UARTJ1

Instances index n Throughout this chapter, the instance of UARTJ is identified by the index "n" (n = 0, 1), for example, UARTJnCTL0 for UARTJn control register 0.

Caution UARTJ of the V850E2/ML4 does not support the LIN function.

Register addresses All UARTJn register addresses are given as addresses offset from the individual base address <URTJn_base_OS> or <URTJn_base_USER>. The <URTJn_base_OS> and <URTJn_base_USER> addresses of each UARTJn are listed in the following table:

Table 20-2 Register base addresses <URTJn_base>

UARTJn instance	Base address	Address
UARTJ0	<URTJn_base_OS>	FF5C 0000 _H
	<URTJn_base_USER>	FFFF EA00 _H
UARTJ1	<URTJn_base_OS>	FF5D 0000 _H
	<URTJn_base_USER>	FFFF EB00 _H

Clock supply All UARTJn provide one clock input. It is connected to the P bus clock f_{PCLK} .

Table 20-3 UARTJn clock supply

UARTJn instance	UARTJn clock	Connected to
UARTJ0, UARTJ1	PCLK	f_{PCLK}

I/O signals The I/O signals of the asynchronous serial interface J are listed in the table below.

Table 20-4 UARTJn I/O signals

UARTJn signals	Function	Connected to
URTJnTTXD	Transmit data output	Port TXDnF
URTJnTRXD	Receive data input	Port RXDnF

Interrupts The interrupts of the asynchronous serial interface J are listed in the table below.

Table 20-5 UARTJn interrupts

UARTJn signals	Function	Connected to
UARTJ0		
INTUAJ0TIT	Transmission interrupt	<ul style="list-style-type: none"> Interrupt controller 159 (INTUARTJ0IT) DTS controller trigger 90
INTUAJ0TIR	Reception interrupt	<ul style="list-style-type: none"> Interrupt controller 158 (INTUARTJ0IR) DTS controller trigger 89
INTUAJ0TIS	Status interrupt	<ul style="list-style-type: none"> Interrupt controller 157 (INTUARTJ0IS)
UARTJ1		
INTUAJ1TIT	Transmission interrupt	<ul style="list-style-type: none"> Interrupt controller 162 (INTUARTJ1IT) DTS controller trigger 92
INTUAJ1TIR	Reception interrupt	<ul style="list-style-type: none"> Interrupt controller 161 (INTUARTJ1IR) DTS controller trigger 91
INTUAJ1TIS	Status interrupt	<ul style="list-style-type: none"> Interrupt controller 160 (INTUARTJ1IS)

20.2 Functional Overview

- Full-duplex communication via built-in receive and transmit FIFOs:
 - Internal UARTJn 10 bit x 16 receive data FIFO (URTJnFRX)
 - Internal UARTJn 8 bit x 16 transmit data FIFO (URTJnFTX)
- 2-pin configuration:
 - URTJnTTXD: Transmit data output pin
 - URTJnTRXD: Receive data input pin
- Various error detection functions
 - Rx parity error
 - Rx framing error
 - Tx data consistency error
- Tx FIFO overflow error
 - Rx FIFO overrun error
 - Rx timeout error
 - Rx BF receive error
- Various FIFO status information
 - Rx FIFO full/empty status
 - Tx FIFO empty/empty status
 - Rx FIFO fill level
 - Tx FIFO fill level
- Interrupt requests: 3
 - Transmission interrupt INTUAJnTIT
 - Reception interrupt INTUAJnTIR
 - Status interrupt INTUAJnTIS
- Character length: 7, 8 bits
- Parity function: odd, even, 0, none
- Transmission stop bit: 1, 2 bits
- MSB-/LSB-first transfer selectable
- Transmit/receive data inverted input/output possible
- 13 to 20 bits selectable for the BF (Break Field) in the LIN (Local Interconnect Network) communication format
 - Recognition of 11 bits or more possible for BF reception in LIN communication format
 - BF reception flag provided
- BF reception can be detected during data communication
- Bus monitor function to keep data consistency of the transmit data

20.3 Configuration

The block diagram shows the main components of UARTJn.

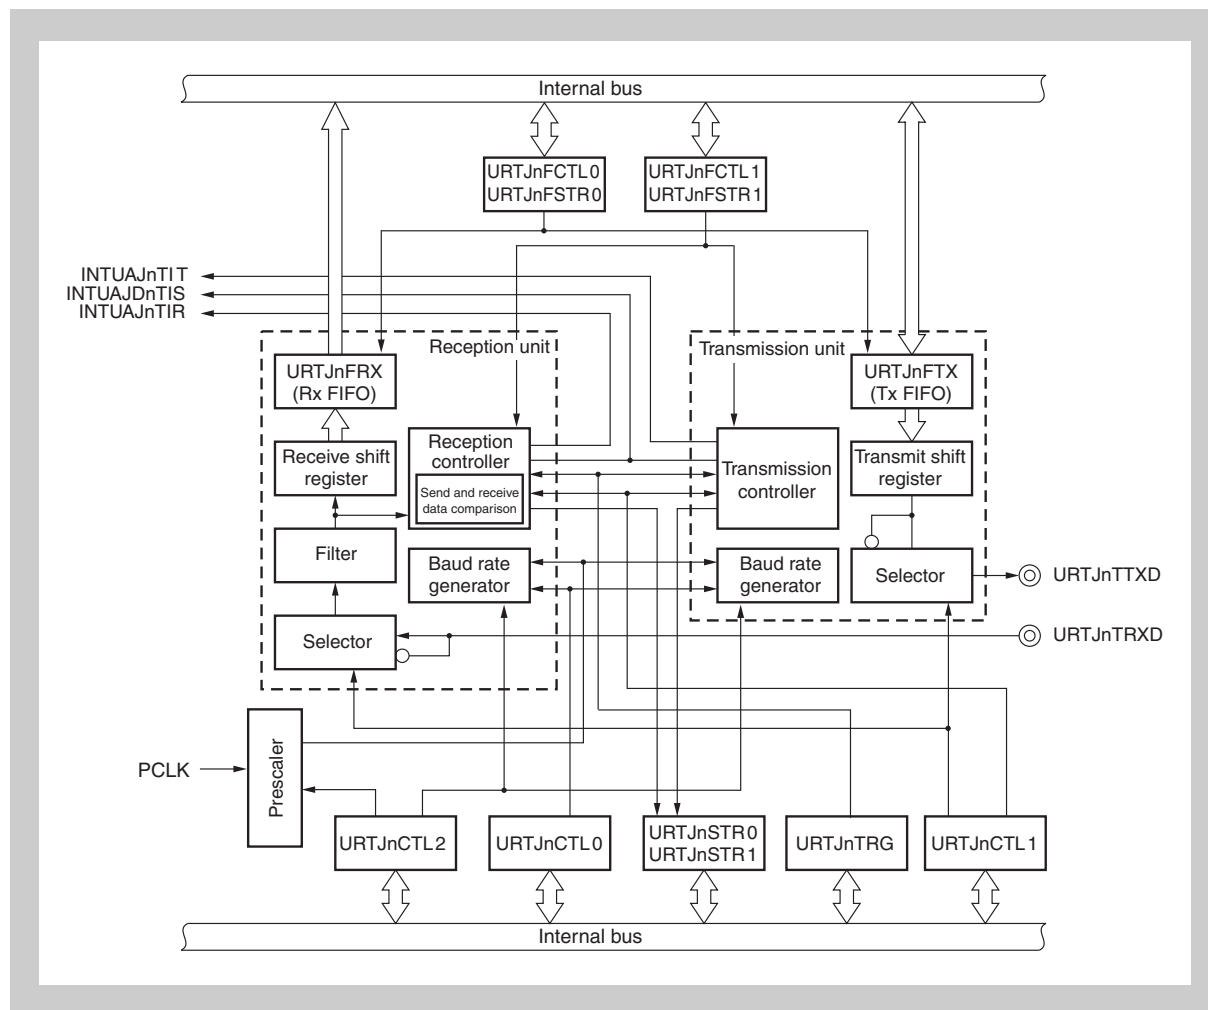

Figure 20-1 Block diagram of asynchronous serial interface UARTJn

20.4 UARTJn Registers

UARTJn is controlled and operated by means of the following registers:

Table 20-6 UARTJn registers

Register name	Symbol	Address
Control register 0	URTJnCTL0	<URTJn_base_USER> + 00 _H
Control register 1	URTJnCTL1	<URTJn_base_OS> + 20 _H
Control register 2	URTJnCTL2	<URTJn_base_OS> + 24 _H
Trigger register	URTJnTRG	<URTJn_base_USER> + 04 _H
Status register 0	URTJnSTR0	<URTJn_base_USER> + 08 _H
Status register 1	URTJnSTR1	<URTJn_base_USER> + 0C _H
Status clear register	URTJnSTC	<URTJn_base_USER> + 10 _H
FIFO control register 0	URTJnFCTL0	<URTJn_base_USER> + 80 _H
FIFO control register 1	URTJnFCTL1	<URTJn_base_OS> + 1020 _H
FIFO status register 0	URTJnFSTR0	<URTJn_base_USER> + 84 _H
FIFO status register 1	URTJnFSTR1	<URTJn_base_USER> + 88 _H
FIFO status clear register	URTJnFSTC	<URTJn_base_USER> + 8C _H
FIFO receive data register	URTJnFRX	<URTJn_base_USER> + 90 _H
FIFO transmit data register	URTJnFTX	<URTJn_base_USER> + 94 _H

Base address The register base addresses of UARTJn are defined in the first section of this chapter under the key word “Register addresses”.

(1) URTJnCTL0 - UARTJn control register 0

This register controls UARTJn the basic serial transfer operation.

Access This register can be read/written in 8-bit and 1-bit units.

Address <URTJn_base_USER> + 00_H

Initial Value 00_H. This register is initialized by any reset.

7	6	5	4	3	2	1	0
URTJnPW	URTJnTXE	URTJnRXE	0	0	0	0	URTJnSLDC
R/W	R/W	R/W	R	R	R	R	R/W

Table 20-7 URTJnCTL0 register contents

Bit position	Bit name	Function
7	URTJnPW	UARTJn enable 0: Stop UARTJn operation 1: Enable UARTJn operation Changing this bit initializes all transmission and reception units.
6	URTJnTXE	Transmission operation enable 0: Disable transmission operation 1: Enable transmission operation <ul style="list-style-type: none"> To start transmission, set URTJnPW and then set URTJnTXE. To stop transmission, clear URTJnTXE, and then clear URTJnPW (they can be cleared at the same time). To initialize the transmission unit, clear URTJnTXE, wait for two prescaler clock cycles, and then set URTJnTXE again. For details about the prescaler clock, see (3) "URTJnCTL2 - UARTJn control register 2" on page 1052.
5	URTJnRXE	Reception enable 0: Disable reception operation 1: Enable reception operation <ul style="list-style-type: none"> To enable reception, set URTJnPW, and then set URTJnRXE. To stop reception, clear URTJnRXE, and then clear URTJnPW (they can be cleared at the same time). To initialize the reception unit, clear URTJnRXE, wait for two prescaler clock cycles, and then set URTJnRXE again. Reception is enabled when the time of two prescaler clock cycles has elapsed since URTJnRXE is set. The rising edge detection of the URTJnTRXD signal is enabled when four prescaler clock cycles has elapsed after URTJnRXE is set. For details about the prescaler clock, see (3) "URTJnCTL2 - UARTJn control register 2" on page 1052.
0	URTJnSLDC	Data consistency check enable 0: Disable consistency check 1: Enable consistency check This bit selects the handling of data consistency error checks when transmitting data. When this bit is set to 1, the transmit data and receive data are compared, and if a mismatch is detected, URTJnSTR1.URTJnDCE is set to 1 and a status interrupt request INTUAJnTIS is issued. This bit is referenced only when starting transmission. Consequently, if this bit value is changed later on during transmission processing, the transmission processing continues, using the value set at the start of transmission.

-
- Cautions**
1. Disable transmission if UARTJn meets all the conditions below:
 - Transmission and reception are enabled (URTJnCTL0.URTJnPW = URTJnRXE = URTJnTXE = 1).
 - Data consistency check is enabled (URTJnCTL0.URTJnSLDC = 1).
 - Data is being transmitted or has been transmitted.

Use the following procedure to keep reception enabled:

 - Check that no data is pending for transmission (URTJnSTR0.URTJnSSBT = URTJnSST = 0).
 - Check that no data is pending for reception (URTJnSTR0.URTJnSSBR = URTJnSSR = 0).
 - Disable transmission by clearing URTJnCTL0.URTJnTXE.

The reason why this procedure is required is that the data consistency error flag URTJnSTR1.URTJnDCE is cleared if URTJnCTL0.URTJnTXE is cleared.

Thus a potential data consistency error would not occur if transmission is disabled during a data transfer or after its completion.
 2. Disable reception if UARTJn meets all the conditions below:
 - Transmission and reception are enabled (URTJnCTL0.URTJnPW = URTJnRXE = URTJnTXE = 1).
 - Data consistency check is enabled (URTJnCTL0.URTJnSLDC = 1).
 - Data is being transmitted or has been transmitted.

Use the following procedure to keep transmission enabled:

 - Check that no data is pending for transmission (URTJnSTR0.URTJnSSBT = URTJnSST = 0).
 - Check that no data is pending for reception (URTJnSTR0.URTJnSSBR = URTJnSSR = 0).
 - Disable reception by clearing URTJnCTL0.URTJnRXE.

The reason why this procedure is required is that the data consistency error flag URTJnSTR1.URTJnDCE is cleared and invalid if URTJnCTL0.URTJnTXE is cleared. Thus a potential data consistency error of already transmitted data would not occur.
 3. Do not start data transmission if all the conditions below are met:
 - Data consistency check is enabled (URTJnCTL0.URTJnSLDC = 1).
 - BF reception is enabled (URTJnSTR0.URTJnSSBR = 1).
 - BF detection during reception is disabled (URTJnCTL1.URTJnSLBM = 0).

A data consistency error will occur under above conditions when BF reception is completed. The status interrupt INTUAJnTIS will be asserted and the reception interrupt request INTUAJnTIR will not be generated (URTJnSTR1.URTJnBSF remains 0). Consequently BF reception completion will not be recognized.
-

(2) URTJnCTL1 - UARTJn control register 1

This register defines the data frame properties of UARTJn serial data transfers.

Access This register can be read/written in 16-bit units.

Address <URTJn_base_OS> + 20_H

Initial Value 5002_H. This register is initialized by any reset.

Caution Writing to this register is only allowed if the UARTJn operation is disabled (URTJnCTL0.URTJnPW = 0).

PCLK The value of the UARTJn input clock is defined in the first section of this chapter under the key word "Clock supply".

(4) URTJnTRG - UARTJn trigger register

This register controls the UARTJn transmission/reception trigger of BF.

Access This register can be read/written in 8-bit and 1-bit units.

Address <URTJn_base_USER> + 04_H

Initial Value 00_H. This register is initialized by any reset.

7	6	5	4	3	2	1	0
0	URTJn BRT	URTJn BTT	0	0	0	0	0
R	R/W	R/W	R	R	R	R	R

Table 20-10 URTJnTRG register contents

Bit position	Bit name	Function
6	URTJnBRT	<p>BF reception trigger</p> <p>0: Read value is always 0, writing 0 is ignored</p> <p>1: Enable BF reception</p> <ul style="list-style-type: none"> When reception is enabled, writing 1 to this bit enables BF reception (URTJnSTR0.URTJnSSBR = 1) and BF reception processing begins when the falling edge of the receive serial signal is detected. If 1 is written to this bit during reception processing, the current reception processing is terminated. Consequently, the received data is not stored, the framing, parity and overflow error bits are not updated based on the data that was being received and no interrupts are generated. Meanwhile, the BF counter value is continuously being used. After BF reception, the reception status is set according to the URTJnCTL1.URTJnSLBM setting. Setting this bit to 1 is only allowed if reception is enabled (URTJnCTL0.URTJnPW = URTJnCTL0.URTJnRXE = 1). <p>After URTJnBRT is set to 1, completion of BF reception is reported by either of the following two methods, based on the URTJnCTL1.URTJnSLBM setting:</p> <ul style="list-style-type: none"> if URTJnCTL1.URTJnSLBM = 0 When BF reception is complete, the reception interrupt request INTUAnTIR is output. if URTJnCTL1.URTJnSLBM = 1 When BF reception is complete, URTJnSTR1.URTJnBSF is set to 1 and a status interrupt request INTUAnTIS is output.
5	URTJnBTT	<p>BF transmission trigger</p> <p>0: Read value is always 0, writing 0 is ignored</p> <p>1: Enable BF transmission</p> <ul style="list-style-type: none"> When this bit is set while URTJnSTR0.URTJnSSBT = 0 and transmission is enabled (URTJnDCE = 0), a BF transmit request is set, and URTJnSSBT is set to 1. When this bit is set during data transmission, a BF is transmitted after the current transmission processing is completed. Even if this bit is set before the BF transmission is completed, a BF is transmitted only once. When transmission is enabled (URTJnPW = URTJnTXE = 1), setting this bit clears all previously set data transmit requests (which have not been transmitted), leaving only BF transmit requests. If the URTJnTX7 to URTJnTX0 bits are written after writing 1 to this bit, data is transmitted after the BF is transmitted. If both a BF transmit request and a data transmit request have been set when transmission starts, the BF transmission takes priority. When URTJnDCE = 1, writing 1 to this bit is ignored. Setting this bit to 1 is only allowed if transmission is enabled (URTJnCTL0.URTJnPW = URTJnCTL0.URTJnTXE = 1).

(5) URTJnSTR0 - UARTJn status register 0

This register indicates the current status of serial data transmissions.

Access This register can be read in 8-bit and 1-bit units. Writing to this register is only allowed if UARTJn operation is disabled (URTJnCTL0.URTJnPW = 0). If UARTJn operation is enabled (URTJnCTL0.URTJnPW = 1), any written values are disregarded and the initial values are restored.

Address <URTJn_base_USER> + 08_H

Initial Value 00_H. This register is initialized by any reset and when URTJnCTL0.URTJnPW is set or cleared.

7	6	5	4	3	2	1	0
0	URTJn SSBR ^a	URTJn SSBT ^b	0	0	0	URTJn SSR ^a	URTJn SST ^b
R	R	R	R	R	R	R	R

- a) These bits are also initialized if reception is disabled by URTJnCTL0.URTJnRXE = 0.
 b) These bits are also initialized if transmission is disabled by URTJnCTL0.URTJnTXE = 0.

Table 20-11 URTJnSTR0 register contents

Bit position	Bit name	Function
6	URTJnSSBR	BF reception enable status 0: BF reception is disabled 1: BF reception is enabled by setting URTJnTRG.URTJnBRT to 1 (BF reception standby mode or BF reception busy).
5	URTJnSSBT	BF transmission enable status 0: BF transmission is disabled 1: BF transmission is enabled by setting URTJnTRG.URTJnBTT to 1 (BF transmission standby mode or BF transmission busy).
1	URTJnSSR	Data reception status 0: No data reception ongoing 1: Data reception ongoing (data reception busy)
0	URTJnSST	Data transmission status 0: No transmission pending or ongoing 1: Data in URTJnTX[7:0] pending to be transmitted or transmission ongoing

(6) URTJnSTR1 - UARTJn status register 1

This register indicates results of serial data transmissions.

Access This register can be read in 8-bit and 1-bit units. Writing to this register is only allowed if UARTJn operation is disabled (URTJnCTL0.URTJnPW = 0). If UARTJn operation is enabled (URTJnCTL0.URTJnPW = 1), any written values are disregarded and the initial values are restored.

Address <URTJn_base_USER> + 0C_H

Initial Value 00_H. This register is initialized by any reset and when URTJnCTL0.URTJnPW is set or cleared.

7	6	5	4	3	2	1	0
0	0	0	URTJnBSF ^a	URTJnDCE ^b	URTJnPE ^a	URTJnFE ^a	0
R	R	R	R	R	R	R	R

- a) These bits are also initialized if reception is disabled by URTJnCTL0.URTJnRXE = 0.
 b) This bit is also initialized if transmission is disabled by URTJnCTL0.URTJnTXE = 0.

Table 20-12 URTJnSTR1 register contents (1/2)

Bit position	Bit name	Function
4	URTJnBSF	BF reception successful flag 0: BF transmission is disabled by clearing URTJnTRG.URTJnBTT. 1: BF transmission is enabled by setting URTJnTRG.URTJnBTT (BF transmission standby mode or BF transmission busy). The URTJnBSF bit is cleared by the following: <ul style="list-style-type: none"> • URTJnCTL0.URTJnPW = 0 • URTJnCTL0.URTJnRXE = 0 • URTJnSTC.URTJnCLBS = 1
3	URTJnDCE	Data consistency error flag 0: Transmit/receive data (transmit/receive BF) mismatch was not detected. 1: Transmit/receive data (transmit/receive BF) mismatch was detected. When the BF receive mode selection bit is set during LIN communication, it is necessary to read this bit by using status interrupt processing and to confirm the beginning of a new frame slot. The URTJnDCE bit is cleared by the following: <ul style="list-style-type: none"> • URTJnCTL0.URTJnPW = 0 • URTJnCTL0.URTJnTXE = 0 • URTJnSTC.URTJnCLDC = 1
2	URTJnPE	Parity error flag 0: No parity error was detected in the received data. 1: A parity error was detected in the received data. The operation of URTJnPE is controlled by the settings of URTJn.URTJnSLP[1:0]. The URTJnPE bit is cleared by the following: <ul style="list-style-type: none"> • URTJnCTL0.URTJnPW = 0 • URTJnCTL0.URTJnRXE = 0 • URTJnSTC.URTJnCLP = 1

Table 20-12 URTJnSTR1 register contents (2/2)

Bit position	Bit name	Function
1	URTJnFE	Framing error flag 0: No framing error was detected in the received data. 1: A framing error was detected in the received data. The URTJnFE bit is cleared by the following: <ul style="list-style-type: none"> • URTJnCTL0.URTJnPW = 0 • URTJnCTL0.URTJnRXE = 0 • URTJnSTC.URTJnCLF = 1

Note If the bits of these registers are set (1) and cleared (0) at the same time, setting takes priority over clearing.

For further information concerning error detections, refer to 20.6.5 “UARTJn transmission” and 20.6.7 “Reception errors”.

Caution In case reception and transmission is enabled and a consistency check error occurs (URTJnSTR1.URTJnDCE = 1), follow the procedure below prior next data transmission:

- disable transmission by URTJnCTL0.URTJnTXE = 0
- initiate transmission by URTJnTRG.URTJnBTT = 1 (BT transmission trigger) or writing any data to URTJnFTX
- enable transmission by URTJnCTL0.URTJnTXE = 1

Afterwards new transmissions can be started.

(7) URTJnSTC - UARTJn status clear register

This register is used to clear the status bits of the status register 1 URTJnSTR1.

Access This register can be read/written in 8-bit and 1-bit units. Reading this register returns always 00_H.

Address <URTJn_base_USER> +10_H

Initial Value 00_H. This register is initialized by any reset.

7	6	5	4	3	2	1	0
0	0	0	URTJn CLBS	URTJn CLDC	URTJn CLP	URTJn CLF	0

Bit position	Bit name	Function
4	URTJnCLBS	Clear BF reception successful flag 0: writing 0 is ignored 1: writing 1 clears URTJnSTR1.URTJnBSF
3	URTJnCLDC	Clear data consistency error flag 0: writing 0 is ignored 1: writing 1 clears URTJnSTR1.URTJnDCE If URTJnDCE is cleared by setting this bit, any pending data or BF transmit requests will be ignored.
2	URTJnCLP	Clear parity error flag 0: writing 0 is ignored 1: writing 1 clears URTJnSTR1.URTJnPE
1	URTJnCLF	Clear framing error flag 0: writing 0 is ignored 1: writing 1 clears URTJnSTR1.URTJnFE

(8) URTJnFCTL0 - FIFO control register 0

This register defines the fill stage of the Rx and Tx FIFOs, at which the reception (INTUAJnTIR) and transmission (INTUAJnTIT) interrupt requests are generated.

Access This register can be read/written in 16-bit units.

Address <URTJn_base_USER> + 80_H

Initial Value 0F00_H. This register is initialized by any reset.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	URTJnSLRP[3:0]				0	0	0	0	URTJnSLTP[3:0]

Bit position	Bit name	Function
11 to 8	URTJnSLRP[3:0]	Rx FIFO level interrupt setting URTJnSLRP[3:0] defines the Rx FIFO pointer status, at which the reception interrupt request INTUAJnTIR is generated. INTUAJnTIR is generated if URTJnFSTR0.URTJnSSRW[4:0] = (10 _H - URTJnSLRP[3:0]), in other words, readable data of (10 _H - URTJnSLRP[3:0]) words still remains in the Rx FIFO.
3 to 0	URTJnSLTP[3:0]	Tx FIFO level interrupt setting URTJnSLTP[3:0] defines the Tx FIFO pointer status, at which the transmission interrupt request INTUAJnTIT is generated. INTUAJnTIT is generated if URTJnFSTR0.URTJnSSTW[4:0] = (10 _H - URTJnSLTP[3:0]), in other words, writable space of (10 _H - URTJnSLTP[3:0]) words still remains in the Tx FIFO.

(9) URTJnFCTL1 - FIFO control register 1

This register controls the Rx time-out detection.

Access This register can be read/written in 8-bit and 1-bit units.

Address <URTJn_base_OS> + 1020_H

Initial Value 3F_H. This register is initialized by any reset.

7	6	5	4	3	2	1	0
0	0	URTJnSLRT[5:0]					
R	R	R/W	R/W	R/W	R/W	R/W	R/W

5 to 0	URTJnSLRT[5:0]	Rx time-out control: 00 _H :Time-out detection disabled 01 _H to 3F _H :Time-out time = (URTJnSLRT[5:0] x 8) cycles of baud rate clock BRCLK

(10) URTJnFSTR0 - FIFO status register 0

This register informs about the fill status of the Rx and Tx FIFOs.

Access This register can be read in 16-bits units, and can only be written if URTJnPW = 0.

Address <URTJn_base_USER> +84_H

Initial Value 0010_H. This register is initialized by any reset.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
0	0	0	URTJnSSRW[4:0]					0	0	0	URTJnSSTW[4:0]					
R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	

Table 20-16 URTJnFSTR0 register contents

Bit position	Bit name	Function
12 to 8	URTJnSSRW[4:0]	Rx FIFO status URTJnSSRW[4:0] indicates the number of unread received data words in the Rx FIFO. These bits can be written only if URTJnPW = 0, in a range from 00 _H to 10 _H . If these bits are read, a value of (10 _H - value written to URTJnSSRW[4:0]) is read. If 01 _H is written, for example, the value read will be 0F _H .
4 to 0	URTJnSSTW[4:0]	Tx FIFO status URTJnSSTW[4:0] indicates the amount of writable space (in words) in the Tx FIFO. These bits can be written only if URTJnPW = 0, in a range from 00 _H to 10 _H . If these bits are read, a value of (10 _H - value written to URTJnSSTW[4:0]) is read. If 01 _H is written, for example, the value read will be 0F _H .

(11) URTJnFSTR1 - FIFO status register 1

This register controls the Rx time-out detection.

Access This register can be read in 8-bits units, and can be only written if URTJnPW = 0.

Address <URTJn_base_USER> + 88_H

Initial Value 05_H. This register is initialized by any reset.

7	6	5	4	3	2	1	0
URTJn TMOE	URTJn TOFE	URTJn ROVE	0	URTJn SSTF	URTJn SSTE	URTJn SSRF	URTJn SSRE
R	R	R	R	R	R	R	R

Table 20-17 URTJnFSTR1 register contents

Bit position	Bit name	Function
7	URTJnTMOE	Time-out error detection 0: No time-out error was detected 1: A time-out error was detected To clear this bit after a time-out error has been detected, set URTJnFSTC.URTJnCLTM to 1. If a timeout error is detected at the same time as this bit is cleared, this bit remains set. URTJnTMOE can be written only if URTJnPW = 0. If 1 is written, the value read will be 1.
6	URTJnTOFE	Tx FIFO overflow error detection 0: No Tx FIFO overflow error was detected 1: A Tx FIFO overflow error was detected To clear this bit after a Tx FIFO overflow error has been detected, set URTJnFSTC.URTJnCLTO to 1. If a timeout error is detected at the same time as this bit is cleared, this bit remains set. URTJnTOFE can be written only if URTJnPW = 0. If 1 is written, the value read will be 1.
5	URTJnROVE	Rx FIFO overrun error detection 0: No Rx FIFO overrun error was detected 1: A Rx FIFO overrun error was detected To clear this bit after a Rx FIFO overrun error has been detected, set URTJnFSTC.URTJnCLRO to 1. If a timeout error is detected at the same time as this bit is cleared, this bit remains set. URTJnROVE can be written only if URTJnPW = 0. If 1 is written, the value read will be 1.
3	URTJnSSTF	Tx FIFO full status 0: Tx FIFO is not full 1: Tx FIFO is full
2	URTJnSSTE	Tx FIFO empty status 0: Tx FIFO is not empty 1: Tx FIFO is empty
1	URTJnSSRF	Rx FIFO full status 0: Rx FIFO is not full 1: Rx FIFO is full
0	URTJnSSRE	Rx FIFO empty status 0: Rx FIFO is not empty 1: Rx FIFO is empty

(12) URTJnFSTC - FIFO status clear register

By means of this register the error flags of URTJnFSTR1 can be cleared. Further on the pointers of the Rx and Tx FIFOs can be cleared, thus indicating empty status for both FIFOs.

Access This register can be read/written in 8-bit and 1-bit units. Reading this register returns always 00_H.

Address <URTJn_base_USER> + 8C_H

Initial Value 00_H. This register is initialized by any reset.

7	6	5	4	3	2	1	0
URTJn CLTM	URTJn CLTO	URTJn CLRO	0	0	0	URTJn CLTP	URTJn CLRP
R/W	R/W	R/W	R	R	R	R/W	R/W

Table 20-18 URTJnFSTC register contents

Bit position	Bit name	Function
7	URTJnCLTM	Time-out error flag clear 0: Read value is always 0, writing 0 is ignored 1: Writing 1 sets URTJnFSTR1.URTJnTMOE = 0
6	URTJnCLTO	Tx FIFO overflow error flag clear 0: Read value is always 0, writing 0 is ignored 1: Writing 1 sets URTJnFSTR1.URTJnTOFE = 0
5	URTJnCLRO	Rx FIFO overrun error flag clear 0: Read value is always 0, writing 0 is ignored 1: Writing 1 sets URTJnFSTR1.URTJnROVE = 0
1	URTJnCLTP	Tx FIFO pointer clear 0: Read value is always 0, writing 0 is ignored 1: Writing 1 sets the Tx FIFO pointer to 00 _H , thus - URTJnFSTR0.URTJnSSTW[4:0] = 00 _H (Tx FIFO pointer) - URTJnFSTR1.URTJnTOFE = 0 (no Tx FIFO overflow error status) - URTJnFSTR1.URTJnSSTF = 0 (Tx FIFO not full status) - URTJnFSTR1.URTJnSSTE = 1 (Tx FIFO empty status)
0	URTJnCLRP	Rx FIFO pointer clear 0: Read value is always 0, writing 0 is ignored 1: Writing 1 sets the Rx FIFO pointer to 00 _H , thus - URTJnFSTR0.URTJnSSRW[4:0] = 00 _H (Rx FIFO pointer) - URTJnFSTR1.URTJnROVE = 0 (no Rx FIFO overrun error status) - URTJnFSTR1.URTJnSSRF = 0 (Rx FIFO not full status) - URTJnFSTR1.URTJnSSRE = 1 (Rx FIFO empty status)

(13) URTJnFRX - FIFO receive data register

By this register the reception data is read from the Rx FIFO.
Each reception data is accompanied by flags, which indicate a parity and framing error during reception.

7-bit transfers If the data length has been specified as 7 bits (URTJnCTL1.URTJnCLG = 0) and

- reception is LSB-first (URTJnCTL1.URTJnSLD = 1),:
The receive data is transferred to the Rx FIFO URTJnFRX.URTJnRX[6:0] and the data MSB URTJnFRX.URTJnRX[7] always becomes 0.
- reception is MSB-first (URTJnCTL1.URTJnSLD = 0),:
The receive data is transferred to the Rx FIFO URTJnFRX.URTJnRX[7:1] and the data LSB URTJnFRX.URTJnRX[0] always becomes 0.

For further information on data formats, refer to 20.6.1 “Data formats”.

Access This register can be read in 16-bit units.

Address <URTJn_base_USER> + 90_H

Initial Value 00FF_H. This register is initialized by any reset.

15	14	13	12	11	10	9	8
URTJnPE	URTJnFE	0	0	0	0	0	0
R	R	R	R	R	R	R	R
7	6	5	4	3	2	1	0
URTJnRX[7:0]							
R	R	R	R	R	R	R	R

Table 20-19 URTJnFRX register contents

Bit position	Bit name	Function
15	URTJnPE	Parity error flag 0: No parity error was detected during URTJnRX[7:0] reception 1: A parity error was detected during URTJnRX[7:0] reception
14	URTJnFE	Framing error flag 0: No framing error was detected during URTJnRX[7:0] reception 1: A framing error was detected during URTJnRX[7:0] reception
7 to 0	URTJnRX[7:0]	Reception data

Pointer modification Each read from URTJnFRX decreases the amount unread data in the Rx FIFO and thus decreases URTJnFSTR0.URTJnSSRW[4:0].

(14) URTJnFTX - FIFO transmit data register

By this register the transmission data is written to the Tx FIFO.

- 7-bit transfers** If the data length has been specified as 7 bits (URTJnCTL1.URTJnCLG = 0) and
- transmission is LSB-first (URTJnCTL1.URTJnSLD = 1),:
The URTJnFTX.URTJnTX[6:0] value is transferred to the shift register as the Tx FIFO data.
 - transmission is MSB-first (URTJnCTL1.URTJnSLD = 0),:
The URTJnFTX.URTJnTX[7:1] value is transferred to the shift register as the Tx FIFO data.

For further information on data formats, refer to 20.6.1 “Data formats”.

Access This register can be read/written in 8-bit units.

Address <URTJn_base_USER> + 94_H

Initial Value FF_H. This register is initialized by any reset.

Table 20-20 URTJnFTX register contents

Bit position	Bit name	Function
7 to 0	URTJnTX[7:0]	Transmission data

Read access Reading URTJnFTX returns the most recent data, that was written to the Tx FIFO.

Pointer modification Each write to URTJnFTX decreases the amount of writable space (words) in the Tx FIFO and thus decreases URTJnFSTR0.URTJnSSTW[4:0].

Overflow error If URTJnFTX is written while the Tx FIFO is full (URTJnFSTR1.URTJnSSTF = 1, the written data is discarded, an overflow error is detected (URTJnFSTR1.URTJnROVE = 1) and the status interrupt INTUAJnTIS is generated.

20.5 Interrupt request signals

The following three interrupt request signals are generated by UARTJn.

- Transmission interrupt request INTUAJnTIT
- Reception interrupt request INTUAJnTIR
- Status interrupt request INTUAJnTIS

20.5.1 Transmission interrupt request INTUAJnTIT

A transmit interrupt request INTUAJnTIT can be configured to be generated upon a certain fill level of the Tx FIFO.

The Tx FIFO fill level for the transmit interrupt request can be set by $URTJnFCTL0.URTJnSLTP[3:0]$, whereas the interrupt is generated if

$$URTJnFCTL0.URTJnSLTP[3:0] = URTJnFSTR0.URTJnSSTW[4:0]$$

The amount of writable space in the Tx FIFO, at which INTUAJnTIT is generated, depends on the selected timing of the transmission interrupt request:

- if $URTJnCTL1.URTJnSLIT = 0$: $10_H - URTJnSLTP[3:0]$
- if $URTJnCTL1.URTJnSLIT = 1$: $0F_H - URTJnSLTP[3:0]$

Writable space of the number of words shown above remained in the Tx FIFO when the interrupt was generated.

- INTUAJnTIT timing** The time to generate the transmission interrupt INTUAJnTIT, and thus indicating the specified amount of writable space in the Tx FIFO, depends on the setting of the $URTJnCTL1.URTJnSLIT$ bit:
- $URTJnCTL1.URTJnSLIT = 0$: at start of transmission
The transmission interrupt request INTUAJnTIT is issued when transmission of the first bit is starting.
In case of data transmission, this indicates the transmission start of the FIFO data of fill level $URTJnFCTL0.URTJnSLTP[3:0]$.
In case of BF transmission every transmission start of a BF generates INTUAJnTIT.
 - $URTJnCTL1.URTJnSLIT = 1$: at end of transmission
INTUAJnTIT is generated when the entire data transmission process is completed, i.e. when the last bit of the transmit data has been transmitted.
The transmission interrupt request INTUAJnTIT is issued when transmission of the last bit is completed.
In case of data transmission, this indicates the transmission end of the FIFO data of fill level $URTJnFCTL0.URTJnSLTP[3:0]$.
In case of BF transmission every transmission completion of a BF generates INTUAJnTIT.
- The following diagram show the timing of the transmission interrupt request INTUAJnTIT during data transmission for both cases.

INTUAJnTIT at transmission errors If an error is detected during data consistency check, the interrupt INTUAJnTIT is not generated.

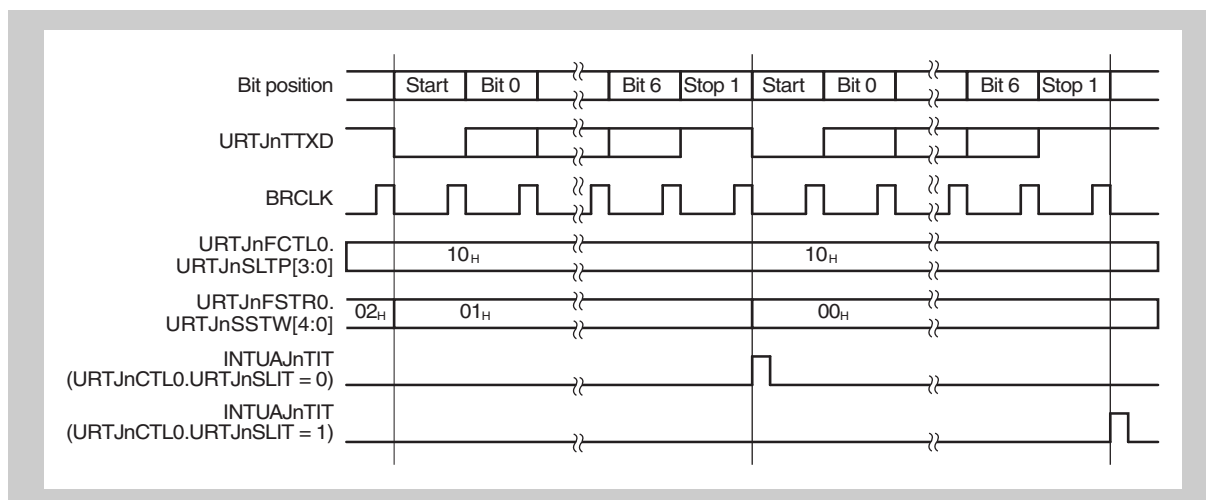

Figure 20-2 Transmission interrupt request timing

Caution After a transmission interrupt is generated, an additional transmission interrupt might be generated in a system that keeps transmission waiting for at least one frame when the FIFO is empty. Therefore, you must clear the interrupt request flag (EICn.EIRFn) in the interrupt routine to 0.

20.5.2 Reception interrupt request INTUAJnTIR

A reception interrupt request INTUAJnTIR can be configured to be generated upon a certain fill level of the Rx FIFO.

The Rx FIFO fill level for the reception interrupt request can be set by URTJnFCTL0.URTJnSLRP[3:0], whereas the interrupt is generated if

$$\text{URTJnFSTR0.URTJnSSRW}[4:0] = 10\text{H} - \text{URTJnSLRP}[3:0]$$

INTUAJnTIR at reception errors

INTUAJnTIR is also generated if a parity or framing error was detected, provided the above Rx FIFO fill condition is met.

In case of a Rx FIFO overrun error, no data is stored to the Rx FIFO, thus INTUAJnTIR is not generated.

After a reception interrupt is generated, an additional reception interrupt might be generated in a system that keeps reception waiting for at least one frame when the FIFO is full. Therefore, you must clear the interrupt request flag (EICn.EIRFn) in the interrupt routine to 0.

The following diagram shows the timing of the reception interrupt request during data reception.

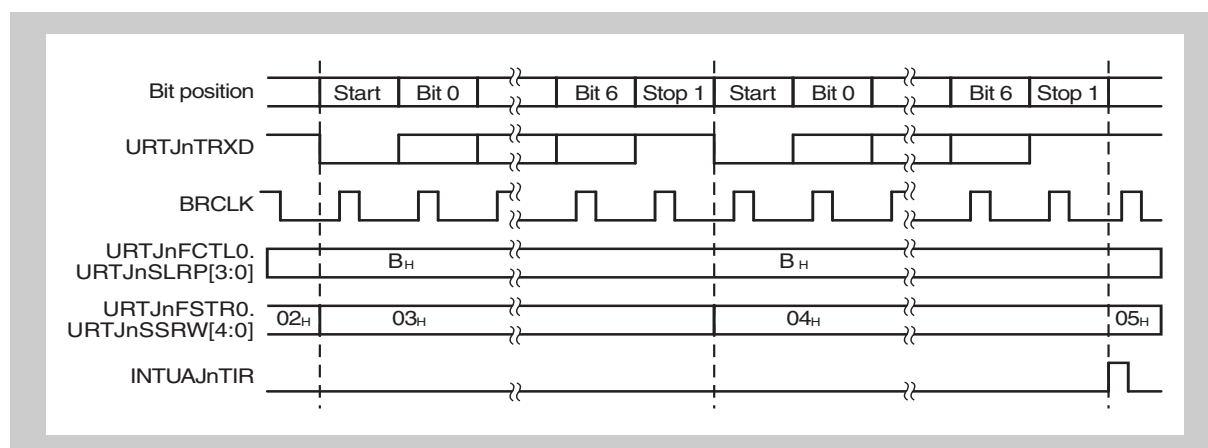

Figure 20-3 Reception interrupt request timing

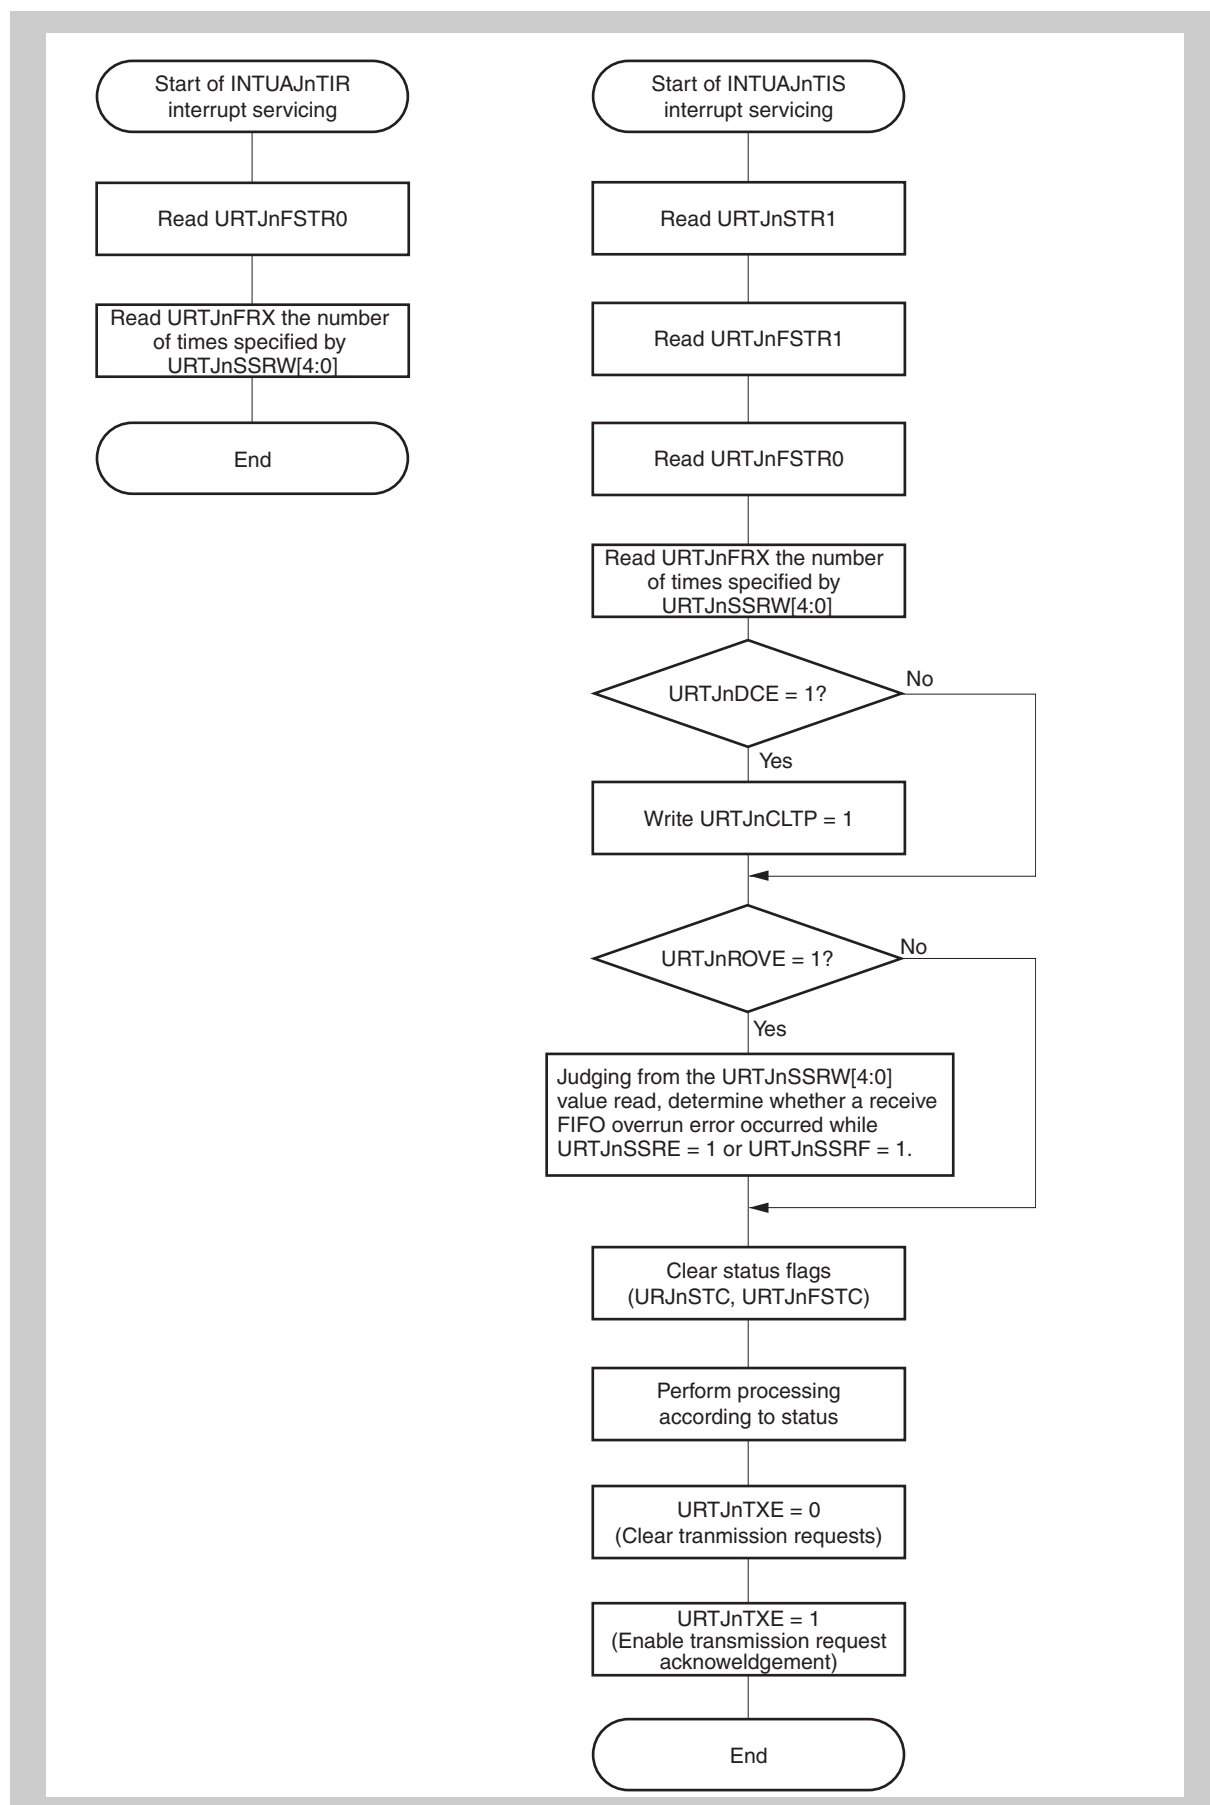

BF reception In case of BF reception, INTUAJnTIR is always generated upon completion of the BF reception.

20.5.3 Status interrupt request INTUAJnTIS

A status interrupt request is generated if an error condition occurred during reception or transmission:

- transmission data consistency check error (URTJnSTR1.URTJnDCE = 1)
- reception data parity error (URTJnSTR1.URTJnPE = 1)
- reception data framing error (URTJnSTR1.URTJnFE = 1)
- time-out error (URTJnFSTR1.URTJnTMOE = 1)
- Tx FIFO overflow error (URTJnFSTR1.URTJnTOFE = 1)
- Rx FIFO overrun error (URTJnFSTR1.URTJnROVE = 1)

if BF length of more than 10 bits is detected while BF reception is enabled during data reception (URTJnCTL1.URTJnSLBM = 1)

<R> Figure 20-4 Processing flow after interrupt generation

20.6 Operation

20.6.1 Data formats

Full-duplex serial data reception and transmission is performed.

As shown in the figures below, one data frame of transmit/receive data consists of a start bit, character bits, parity bit, and stop bit(s).

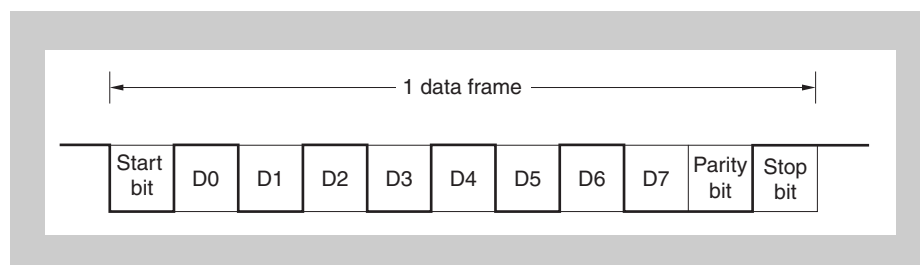

Several properties of a transmit/receive data frame can be specified by control bits of the URTJnCTL1 register:

Table 20-21 Data format specification

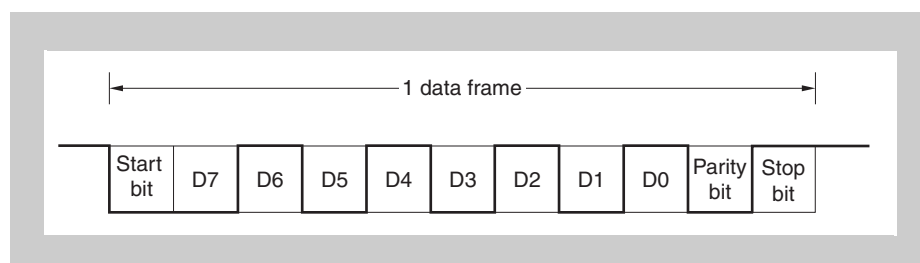

Item	Options	Control bits
Start bit	1 bit	Fixed
Character bits	7 bits / 8 bits	URTJnCTL1.URTJnCLG
Parity	Even parity/odd parity/ 0 parity no parity	URTJnCTL1.URTJnSLP[1:0]
Stop bit	1 bit / 2 bits	URTJnCTL1.URTJnSLG
Data order	MSB first / LSB first	URTJnCTL1.URTJnSLD
Tx data level	inverted / not inverted	URTJnCTL1.URTJnTDL
Rx data level	inverted / not inverted	URTJnCTL1.URTJnRDL

(1) UARTJn transmit/receive data format

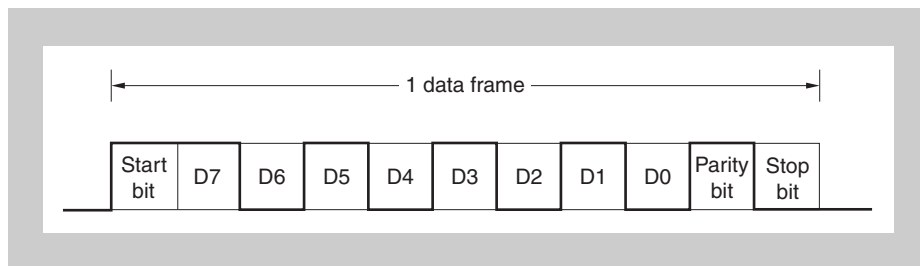

(a) 8-bit data length, LSB first, even parity, 1 stop bit, transfer data: 55_H

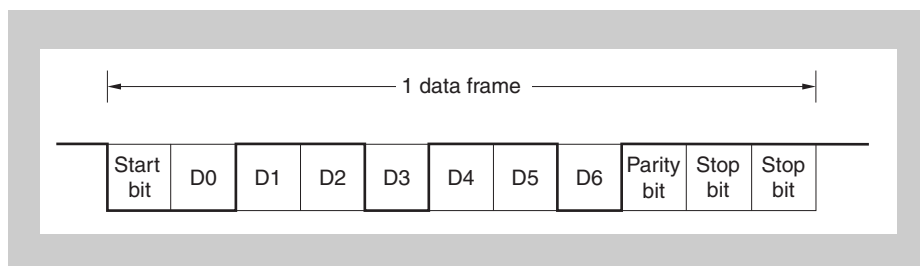

(b) 8-bit data length, MSB first, even parity, 1 stop bit, transfer data: 55_H

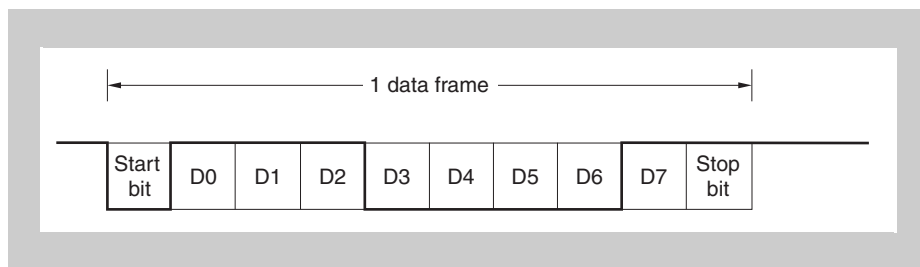

(c) 8-bit data length, MSB first, even parity, 1 stop bit, transfer data: 55_H, URTJnTTXD inversion

(d) 7-bit data length, LSB first, odd parity, 2 stop bits, transfer data: 36_H

(e) 8-bit data length, LSB first, no parity, 1 stop bit, transfer data: 87_H

20.6.2 BF transmission/reception format

The UARTJn has a BF (Break Field) transmission/reception control function to enable use of the LIN functions.

About LIN LIN stands for Local Interconnect Network and is a low-speed (1 to 20 kbps) serial communication protocol intended to aid the cost reduction of an automotive network.

LIN communication is single-master communication, and up to 15 slaves can be connected to one master.

The LIN slaves are used to control the switches, actuators, and sensors, and these are connected to the LIN master via the LIN network.

Normally, the LIN master is connected to a network such as CAN (Controller Area Network).

In addition, the LIN bus uses a single-wire method and is connected to the nodes via a transceiver that complies with ISO9141.

In the LIN protocol, the master transmits a frame with baud rate information and the slave receives it and corrects the baud rate error. Therefore, communication is possible when the baud rate error in the slave is $\pm 14\%$ or less.

Figure 20-5 “LIN transmission outline” and Figure 20-6 “LIN reception outline” outline the transmission and reception manipulations of LIN.

Figure 20-5 LIN transmission outline

- The interval between fields is controlled by software.
- BF output is performed by hardware. The output width is the bit length set by `URTJnCTL1.URTJnBLG[2:0]`.
If even finer output width adjustments are required, such adjustments can be performed using `URTJnCTLn.URTJnBRS[11:0]`.
- 80μ transfer in the 8-bit mode is substituted for the wakeup signal frame.
- A transmission enable interrupt `INTUAJnTIT` is generated at the start of each transmission. `INTUAJnTIT` is also generated at the start of each BF transmission.

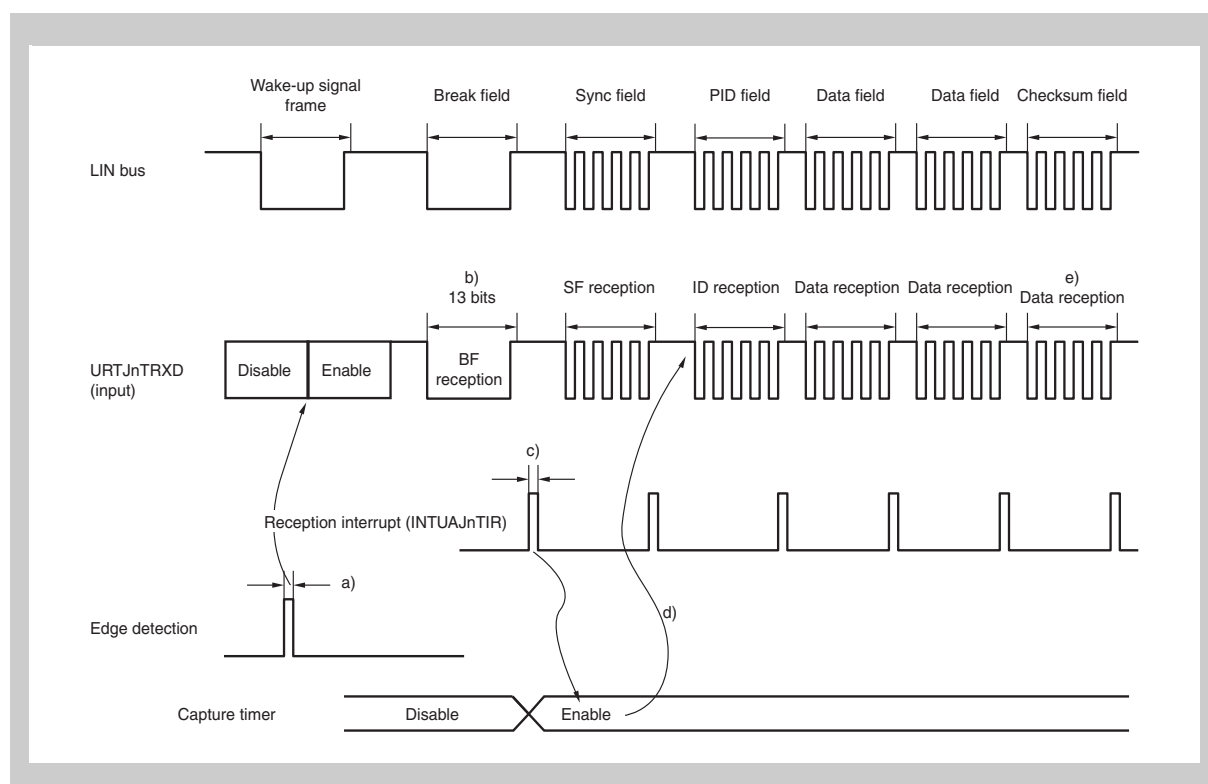

Figure 20-6 LIN reception outline

- a) The wakeup signal sent by the pin edge detector enables UARTJn, and sets the BF reception mode.
- b) BF reception is judged to end normally when a BF of 11 or more bits is received. An interrupt is generated as shown in the table below, according to the setting of the BF reception mode selection bit URTJnCTL1.URTJnSLBM and the value of the URTJnSTR0.URTJnSSBR bit.

URTJnSLBM	URTJnSSBR	Interrupts
1	x	INTUAJnTIS
0	1	INTUAJnTIR
0	0	A framing error has occurred, so INTUAJnTIS is generated.

- c) When BF reception ends normally, an interrupt is generated as follows according to the setting of the BF reception mode selection bit URTJnCTL1.URTJnSLBM:
- When URTJnDTL1.URTJnSLBM is 0, the reception interrupt INTUAJnTIR is generated.
 - When URTJnDTL1.URTJnSLBM is 1, the status interrupt INTUAJnTIS is generated and the BF reception success flag URTJnSTR1.URTJnBSF is set. If the BF reception trigger bit URTJnTRG.URTJnBRT is 1, error detection for the overrun, parity, and framing errors is not performed during BF reception. Also, data transfer from the receive shift register to the receive data register URTJnRX is not performed. URTJnRX holds the previous value at this time.
- d) In order to adjust the baud rate clock properly, the URTJnTRXD signal must be connected to the timer capture input. The transfer rate and the baud rate error can be calculated by measuring the time between URTJnTRXD edges, and the baud rate can be adjusted by specifying a value for the baud rate setting bits URTJnCTL2.URTJnBRS[11:0].
- e) A checksum field is identified by software. When a checksum field is received, UARTJn is initialized and set to the BF reception mode by software. But if URTJnCTL1.URTJnSLBM is 1 at this time, UARTJn automatically starts BF reception without entering the BF reception mode.

20.6.3 BF transmission

When the URTJnCTL0 bits URTJnPW = URTJnTXE = 1, the transmission enabled status is entered, and BF transmission is started by setting the BF transmission trigger URTJnTRG.URTJnBTT = 1.

Thereafter, URTJnSTR0.URTJnSSBT is set to "1" and a low level width of 13 to 20 bits, as specified by URTJnCTL1.URTJnBLG[2:0], is output. A transmission interrupt INTUAJnTIT) is generated upon BF

- transmission start, if URTJnCTL1.URTJnSLIT = 0
- transmission end, if URTJnCTL1.URTJnSLIT = 1.

Following the end of BF transmission, URTJnSTR0.URTJnSSBT is automatically cleared. Thereafter, the UARTJn transmission mode is restored.

Transmission is suspended until the data to transmit next is written to the URTJnTX register and URTJnSTR0.URTJnSST is set, or until the BF transmission trigger URTJnTRG.URTJnBTT is set and URTJnSTR0.URTJnSSBT changes to 1.

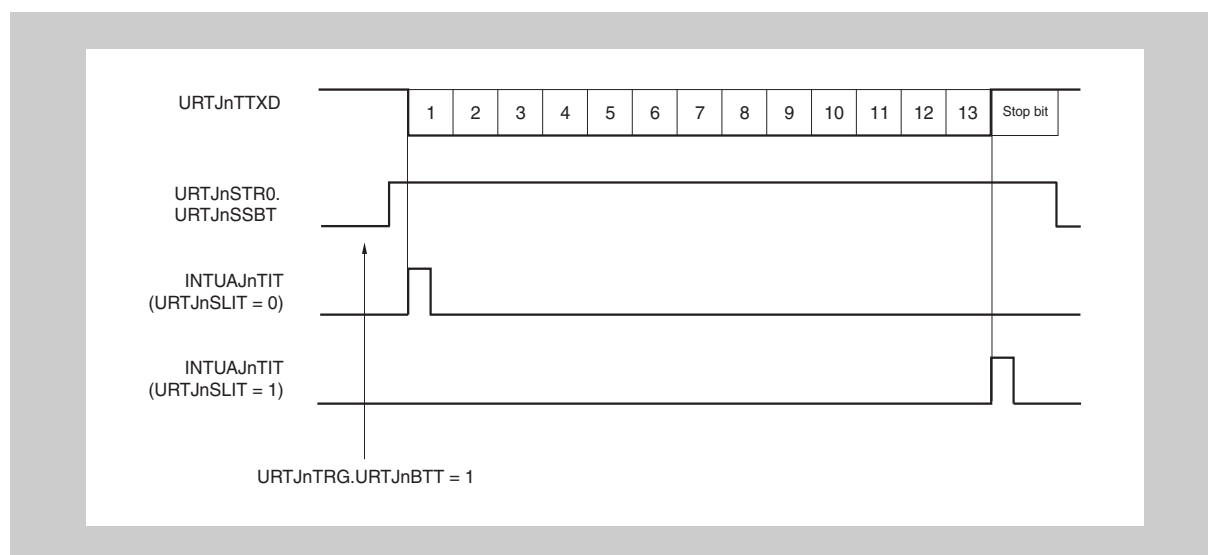

Figure 20-7 BF transmission

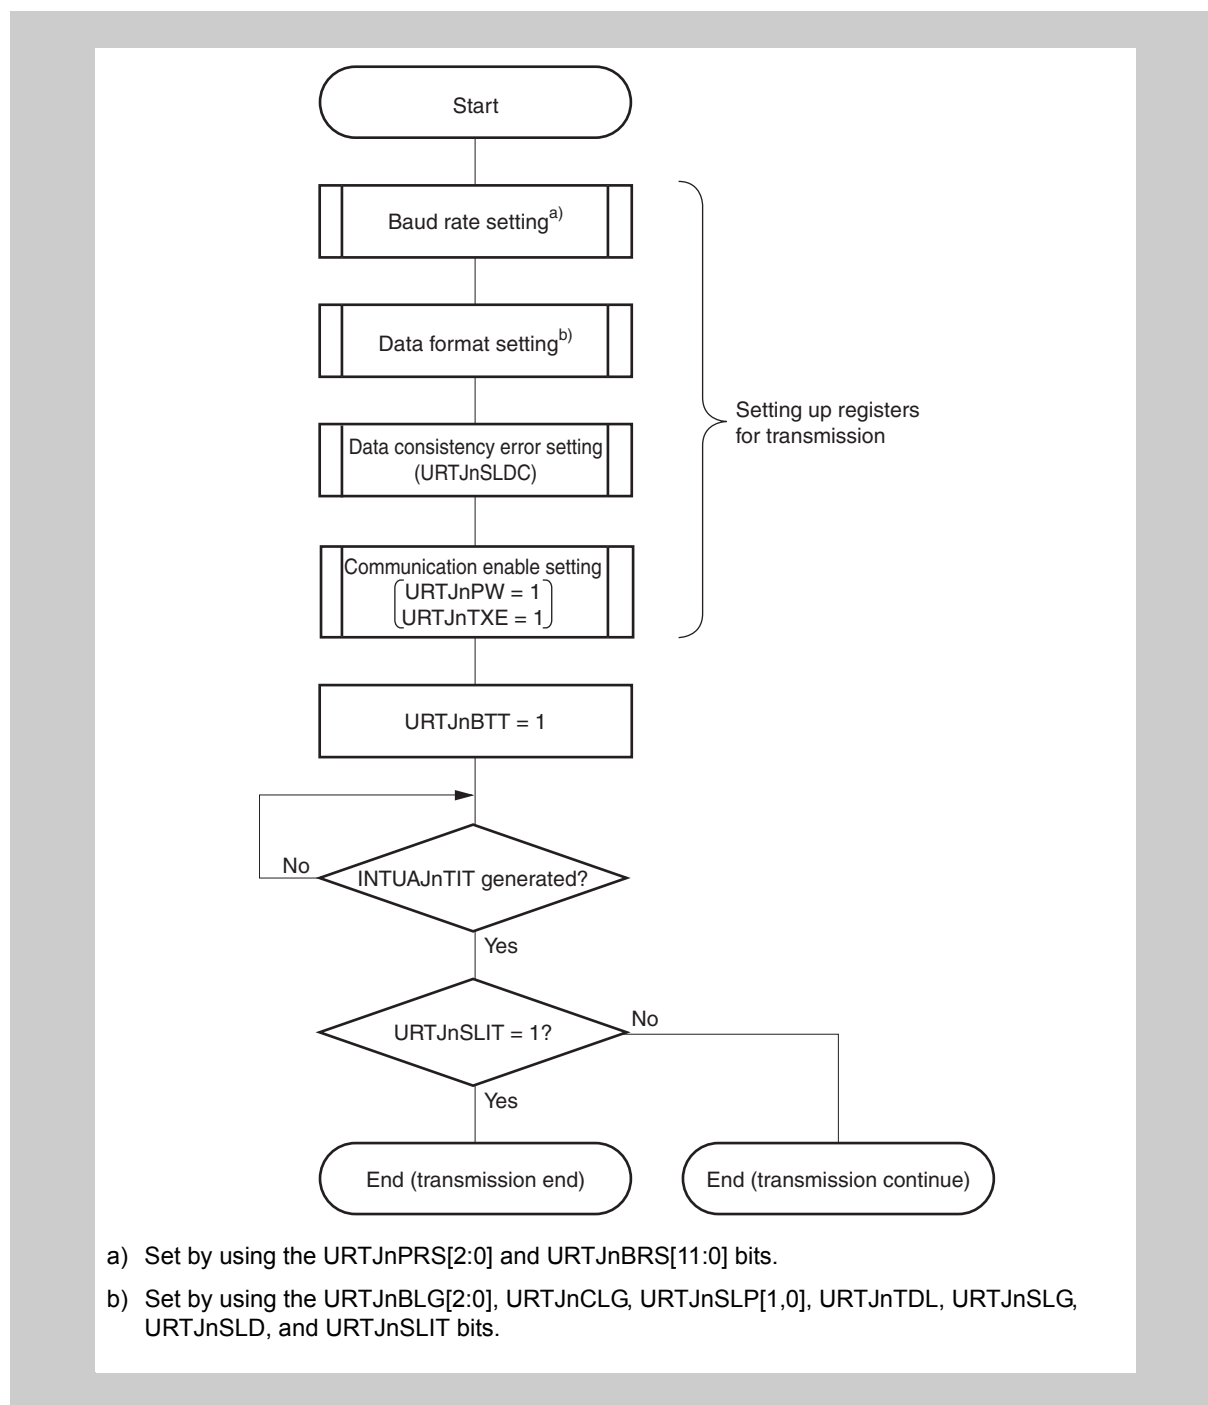

Figure 20-8 Flowchart of BF transmission

20.6.4 BF reception

The reception enabled status is achieved by setting the URTJnCTL0.URTJnPW bit to 1 and then setting the URTJnCTL0.URTJnRXE bit to 1.

The BF reception wait status is set by setting the BF reception trigger URTJnTRG.URTJnBRT = 1.

In the BF reception wait status, the URTJnTRXD pin is monitored and start bit detection is performed.

Following detection of the low level, reception is started and the internal counter counts up according to the set baud rate.

When a high level is received and if the BF width is 11 or more bits, while the BF receiving mode selection bit

- URTJnCTL1.URTJnSLBM = 0,
the reception interrupt INTUAJnTIR is generated.
- URTJnCTL1.URTJnSLBM = 1,
the status interrupt INTUAJnTIS is generated and BF reception success flag URTJnSTR1.URTJnBSF is set at the same time.

The URTJnSTR0.URTJnSSBR bit is automatically cleared and BF reception ends.

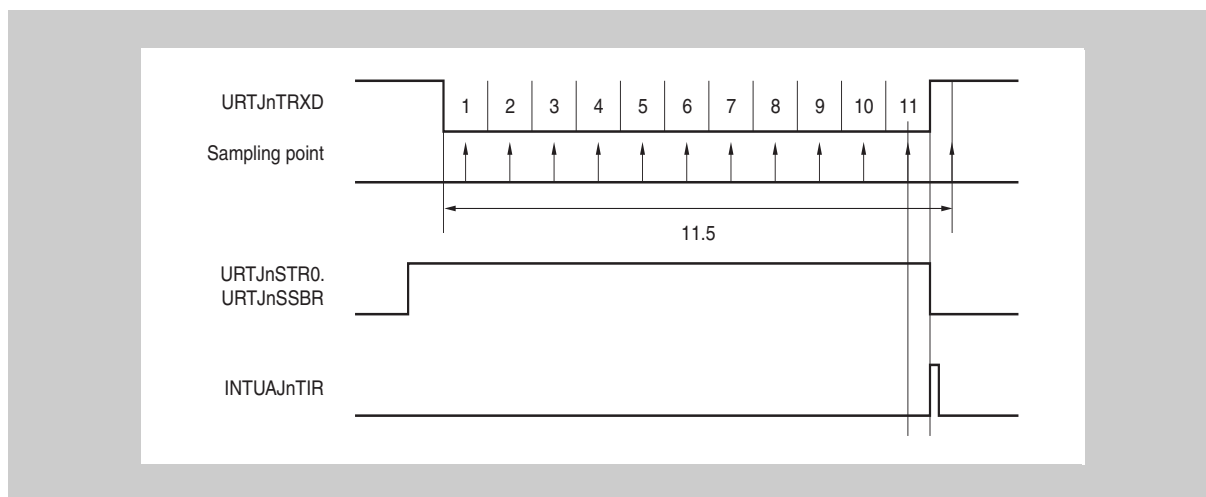

Figure 20-9 Normal BF reception (stop bit after more than 10.5 “L” bits)

Error detection for the URTJnSTR1 error flags URTJnOVE, URTJnPE, and URTJnFE is suppressed and UARTJn communication error detection processing is not performed.

Moreover, the erroneous data is not stored in URTJnRX, but the initial value FFH is held.

If the BF width is 10 or fewer bits, reception is terminated as error processing without generating an interrupt, and the BF reception mode is returned. URTJnSTR0.URTJnSSBR is not cleared at this time.

Figure 20-10 BF reception error (stop bit within 10.5 “L” bits)

The BF mode can be selected between a single BF receive mode and an any time BF receive mode in by URTJnCTL1.URTJnSLBM. The status of a successful reception of the BF is indicated by URTJnSTR1.URTJnBSF.

- Note** URTJnSTR0.URTJnSSBR is set to “1” when
- URTJnTRG.URTJnBRT is set to “1”, or
 - the error is cleared by normal BF reception.

20.6.5 UARTJn transmission

(1) Transmission FIFO

The Tx FIFO comprises 8 bit x 16 levels to hold the 8-bit data to be transmitted consecutively.

The Tx FIFO is filled by writing to the URTJnFTX register.

Tx FIFO status	<p>Various status information are provided to check the fill level of the Tx FIFO:</p> <ul style="list-style-type: none"> • The amount of writable space in the Tx FIFO can be checked by reading the Tx FIFO pointer URTJnFSTR0.URTJnSSTW[4:0] • FIFO full/not full status is indicated by URTJnSTR1.URTJnSSTF (= 1: full) • FIFO empty/not empty status is indicated by URTJnSTR1.URTJnSSTE (= 1: empty)
Pointer modification	Each write to URTJnFTX decreases the amount of writable space in the Tx FIFO and thus decreases URTJnFSTR0.URTJnSSTW[4:0].
Overflow error	If URTJnFTX is written while the Tx FIFO is full (URTJnFSTR1.URTJnSSTF = 1), the written data is discarded, an overflow error is detected (URTJnFSTR1.URTJnTOFE = 1) and the status interrupt INTUAnTIS is generated.
URTJnFTX read	Reading URTJnFTX returns the most recent data, that was written to the Tx FIFO.

(2) Transmission start and stop

Transmission start	<p>Set the transmission enabled status by performing the following procedures.</p> <ul style="list-style-type: none"> • Specify the baud rate by URTJnCTL2. • Specify the transmit parity, data character length, stop bit length, transmit data order, transmission interrupt request timing and output logic level by URTJnCTL1. • Enable UARTJn operation and transmission by URTJnCTL0.URTJnPW = URTJnCTL0.URTJnTXE = 1) <p>Write of the transmit data to the Tx FIFO via URTJnFTX starts transmission. The data which is saved in the Tx FIFO is transferred to the transmit shift register. Then, the start, parity and stop bits are added and the data frame is output serially via URTJnTTXD.</p>
Transmission stop	When URTJnCTL0.URTJnPW or URTJnCTL0.URTJnTXE is set to 0, transmission operations are stopped immediately, even during transmission processing.
Concurrent BF and data transmission	When a BF transmit request and a data transmit request have both been set, BF transmission takes priority.

(3) Transmission data consistency check

The UARTJn incorporates a data consistency check function to detect a mismatch between the transmit data output via the signal URTJnTTXD and the data received from the URTJnTRXD signal, when UARTJn operates in transmission mode.

Note For performing the data consistency check the URTJnTTXD signal must be fed back to URTJnTRXD externally.

Data consistency check is enabled by $URTJnCTL0.URTJnSLDC = 1$.

In case of a mismatch between the URTJnTTXD and URTJnTRXD signals the data consistency error flag URTJnSTR1.URTJnDCE is set and a status interrupt request INTUAJnTIS occurs.

Data consistency check can be performed with reception enabled or disabled.

If reception is disabled ($URTJnCTL0.URTJnRXE = 0$) the reception completion interrupt request INTUAJnTIR, the URTJnSTR1 status bits URTJnBSF, URTJnFE, URTJnPE and the status interrupt request signal INTUAJnTIS will not be generated. Receive data is not stored to the Rx FIFO.

If reception is enabled ($URTJnCTL0.URTJnRXE = 1$) the receive data is treated as in normal reception mode, i.e. all status bits and interrupts are handled, and the data is stored to the Rx FIFO.

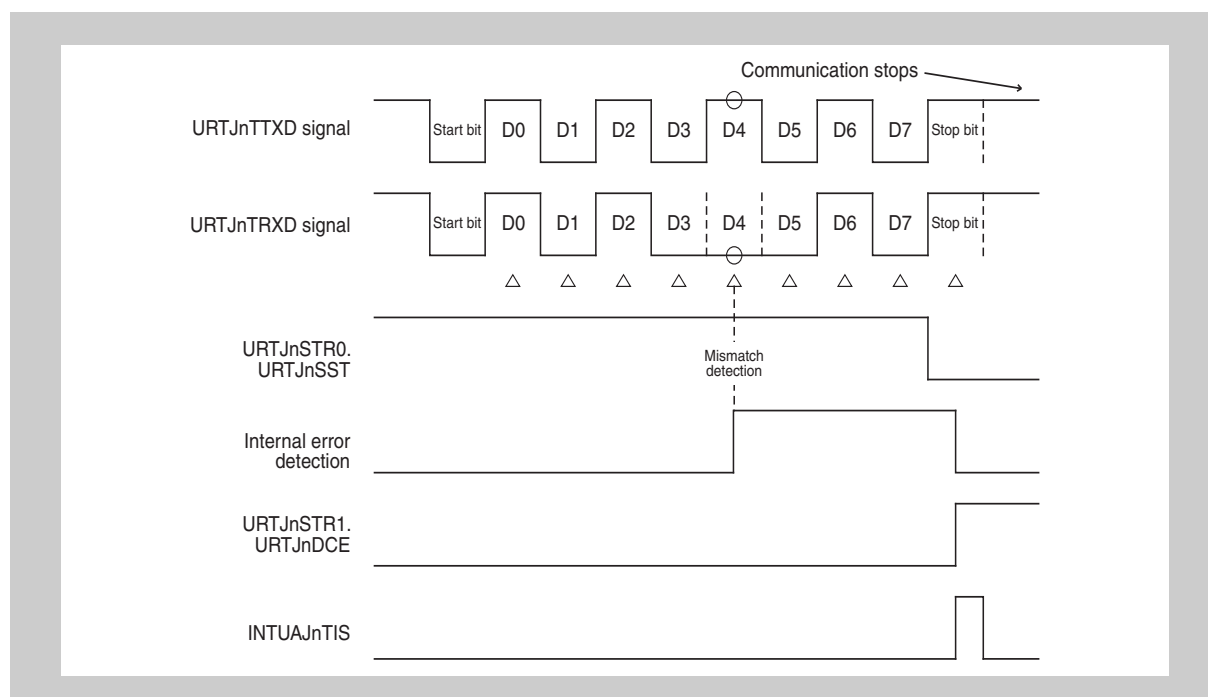

Figure 20-11 Timing example of data consistency error (no BF reception active, i.e. $URTJnSTR0.URTJnSSBR = 0$)

If a data consistency error was detected ($URTJnSTR1.URTJnDCE = 1$), the subsequent data is not transmitted until the data consistency error flag is cleared ($URTJnSTC.URTJnCLDC = 1$) or transmission is disabled ($URTJnCTL0.URTJnPW = 0$, or $URTJnCTL0.URTJnTXE = 0$).

(4) Continuous transmission procedure

Continuous transmission is achieved by maintaining a certain fill level of the Tx FIFO.

This means in particular to set the generation of the transmission interrupt INTUAnTIT, that indicates the Tx FIFO fill level, appropriately via the Tx FIFO level interrupt setting URTJnSLTP[3:0].

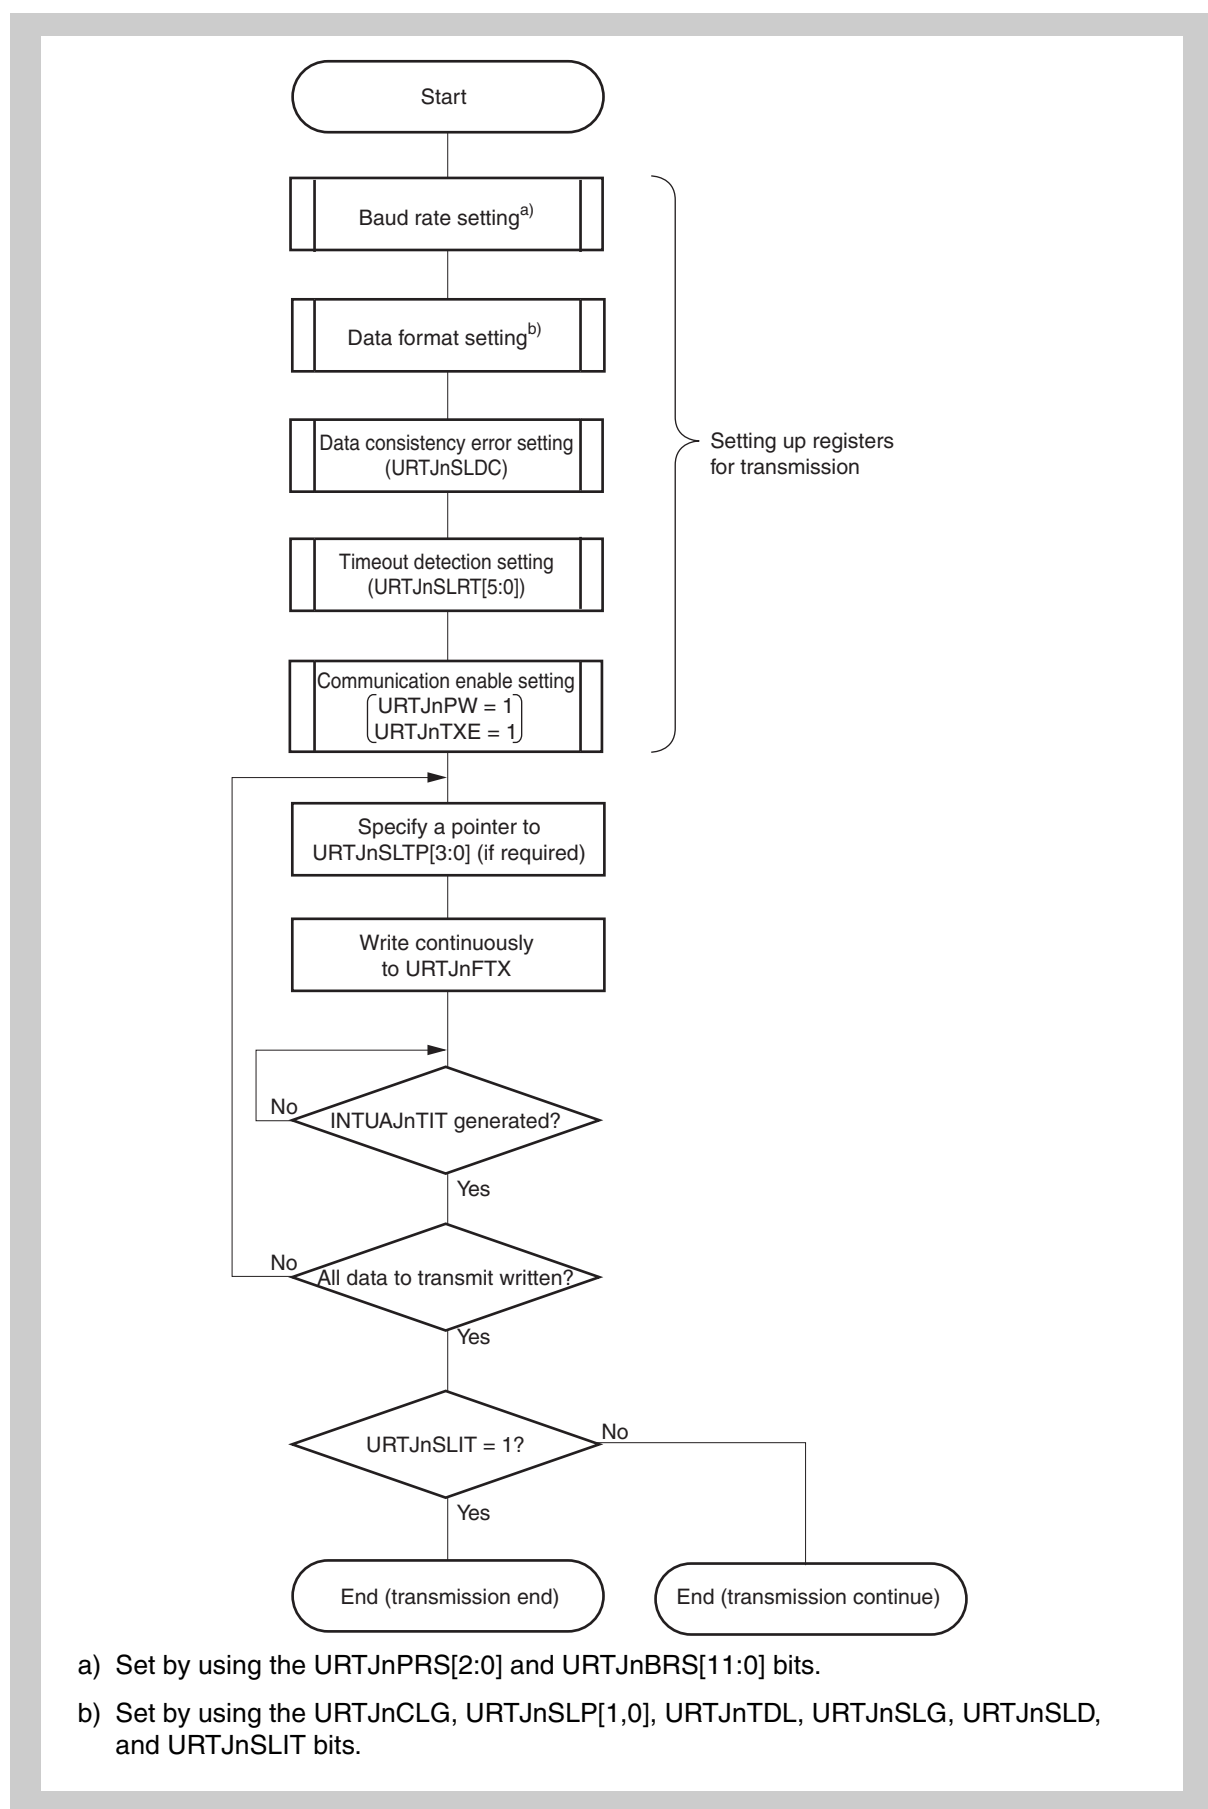

Figure 20-12 Flowchart of data transmission

20.6.6 UARTJn reception

(1) Reception FIFO

The Rx FIFO comprises 10 bit x 16 levels to store the 8-bit data that has been received and additionally two error flags, indicating parity and framing errors.

The Rx FIFO is emptied by reading from the URTJnFRX register.

- Rx FIFO status** Various status information are provided to check the fill level of the Rx FIFO:
- The number of received words in the Rx FIFO can be checked by reading the Rx FIFO pointer URTJnFSTR0.URTJnSSRW[4:0]
 - FIFO full/not full status is indicated by URTJnFSTR1.URTJnSSRF (= 1: full)
 - FIFO empty/not empty status is indicated by URTJnFSTR1.URTJnSSRE (= 1: empty)

Pointer modification Each read from URTJnFRX decreases the number of data words in the Rx FIFO and thus decreases URTJnFSTR0.URTJnSSRW[4:0].

Overrun error If new data is received while the Rx FIFO is full (URTJnFSTR1.URTJnSSRF = 1), the received data is discarded, an overrun error is detected (URTJnFSTR1.URTJnROVE = 1) and the status interrupt INTUAJnTIS is generated.

(2) Reception start and stop

- Reception start** Set the reception enabled status by the following procedure:
- Specify the baud rate by URTJnCTL2.
 - Specify the receive parity, data character length, stop bit length, receive data order and output logic level by URTJnCTL1.
 - Enable UARTJn operation and reception by URTJnCTL0.URTJnPW = URTJnCTL0.URTJnRXE = 1).

When the sampling of the input level of the URTJnTRXD pin is performed and the falling edge is detected, the data sampling of the URTJnTRXD input is started. The start bit is recognized if the URTJnTRXD pin is low level after the time of a half bit is passed after the detection of the falling edge (shown in the figure below). After a start bit has been recognized, the receive operation starts, and serial data is stored in the receive shift register according to the set baud rate. When the reception interrupt INTUAJnTIR is asserted upon reception of the stop bit, the data stored in the receive shift register is written to the Rx FIFO.

- Reception stop** When URTJnCTL0.URTJnPW or URTJnCTL0.URTJnRXE is set to 0, reception operations are stopped immediately, even during reception processing.

Rx format change When the receive data order, parity, data character length, and the stop bit length are changed, clear the power bit (URTJnCTL0.URTJnPW = 0) or clear both the transmission enabled bit and the reception enabled bit (URTJnTXE = 0, URTJnRXE = 0), and then change the setting.

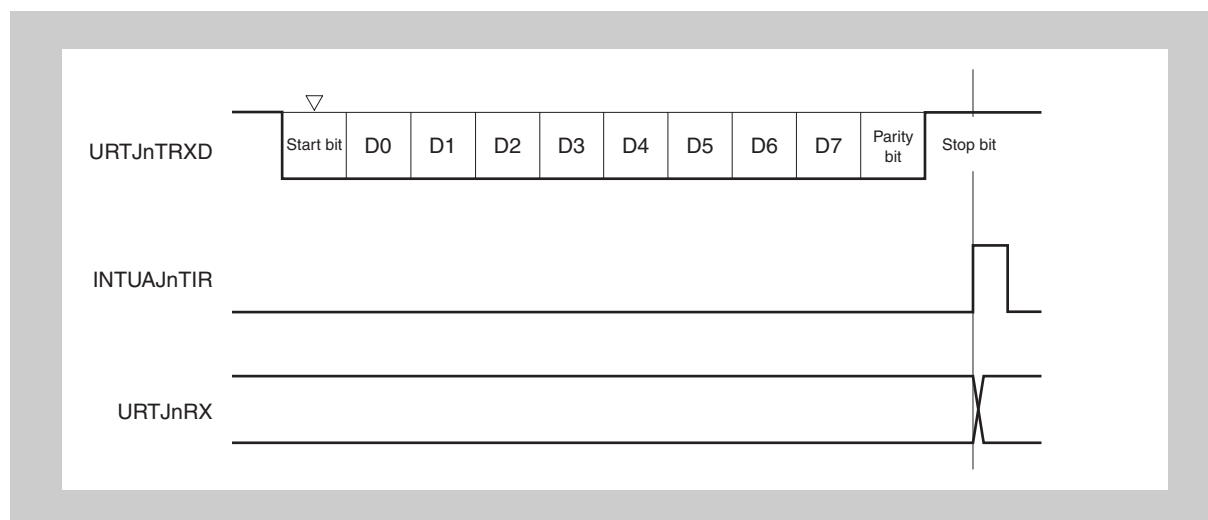

Figure 20-13 UARTJn reception

Caution The operation during reception is performed assuming that there is only one stop bit. A second stop bit is ignored.

- Notes**
1. If low level is always input to the URTJnTRXD pin, it is not judged as the start bit.
 2. In continuous reception, immediately after the stop bit is detected at the first reception bit (when the reception interrupt is generated), the next start bit can be detected.

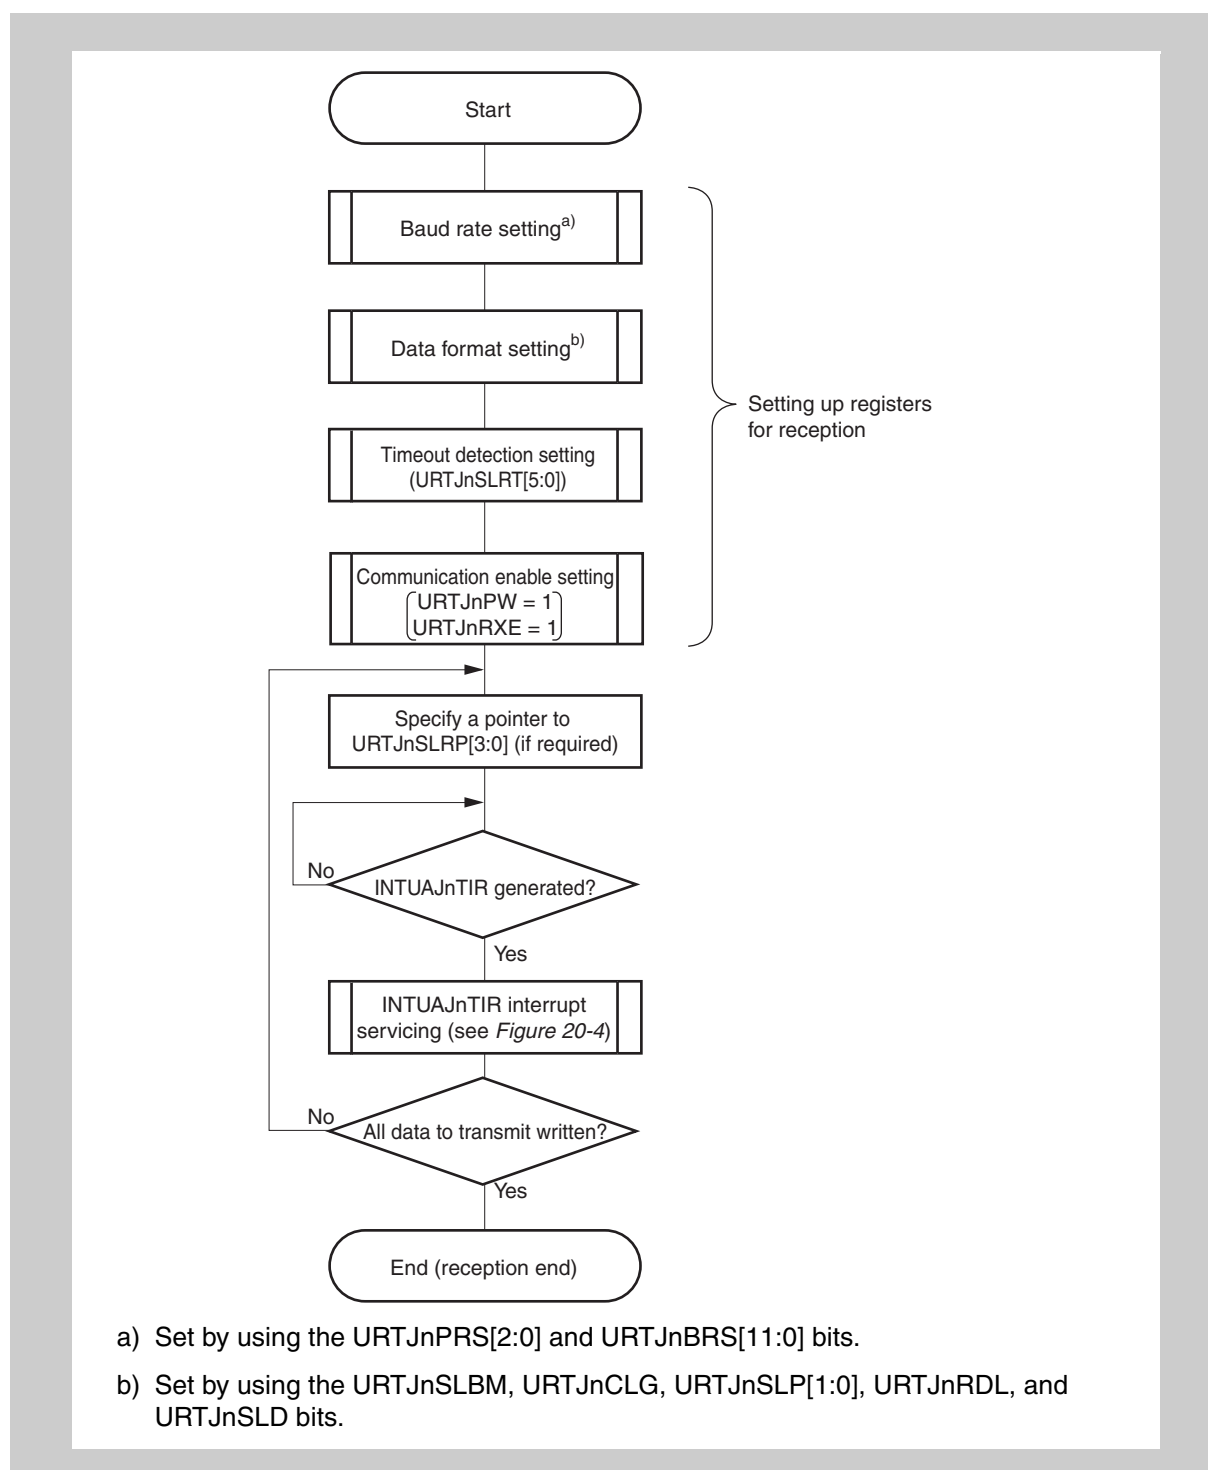

Figure 20-14 Flowchart of data reception when URTJnSLBM = 0, URTJnSSBR = 0

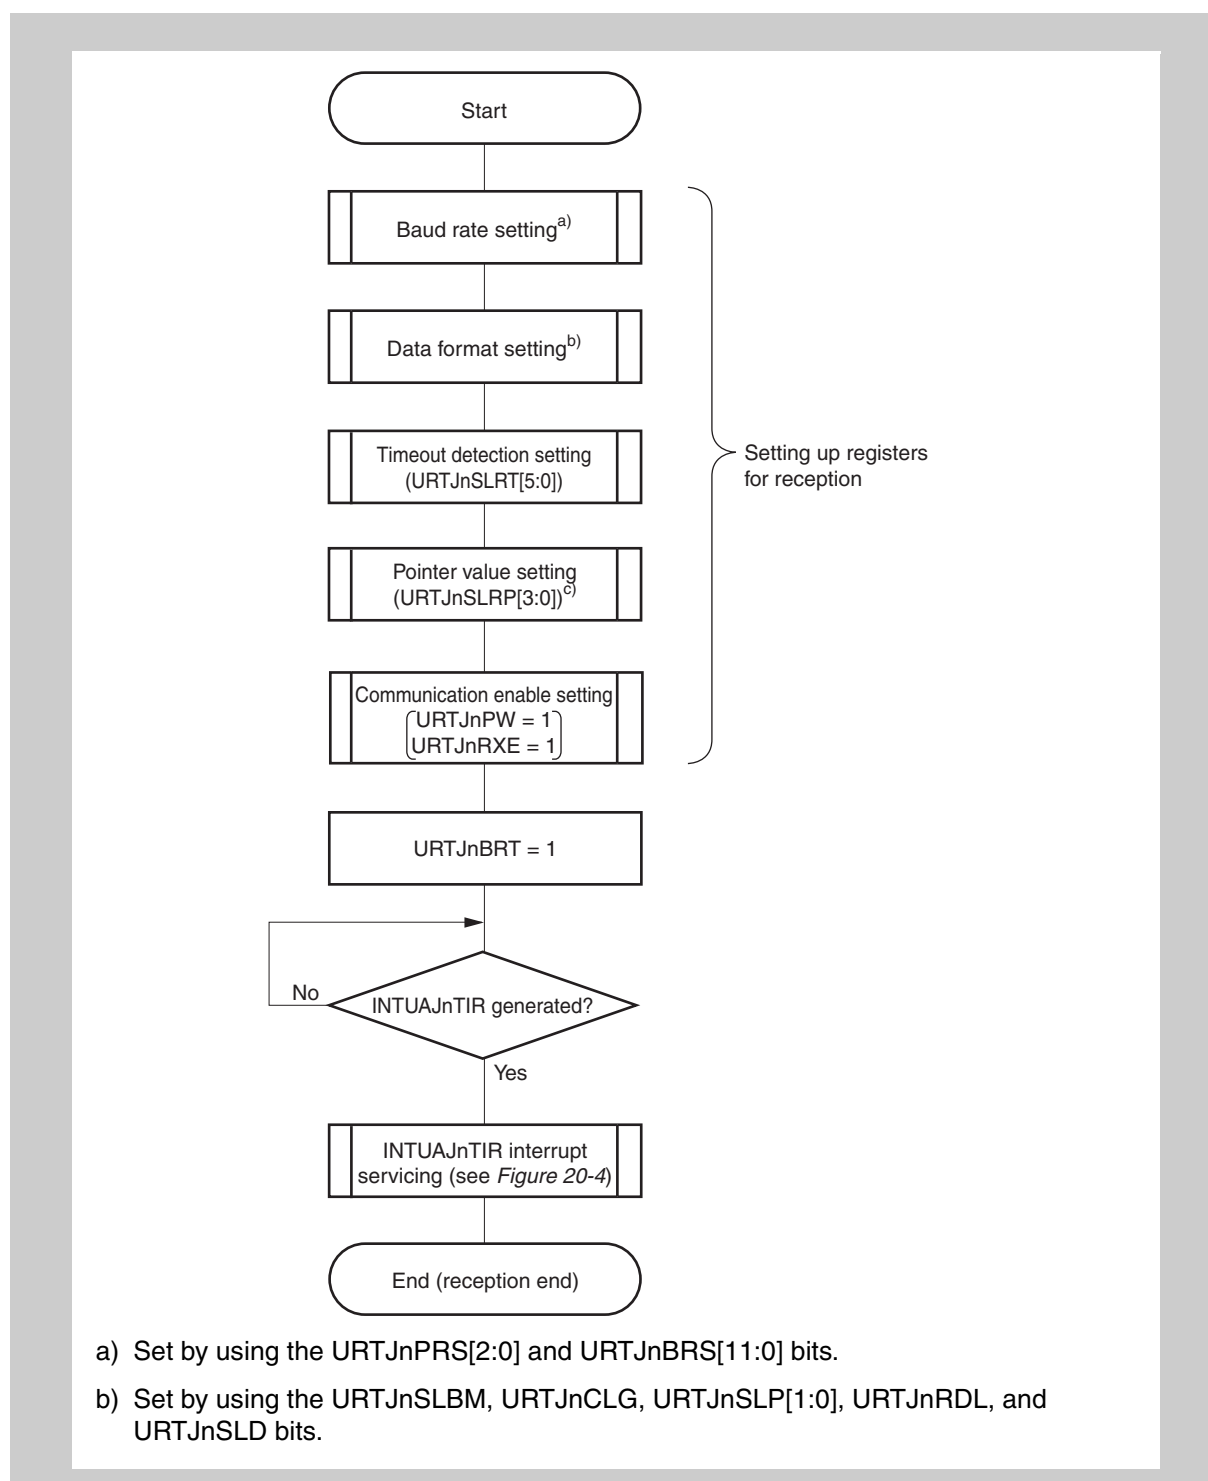

Figure 20-15 Flowchart of data reception when URTJnSLBM = 0, URTJnSSBR = 1

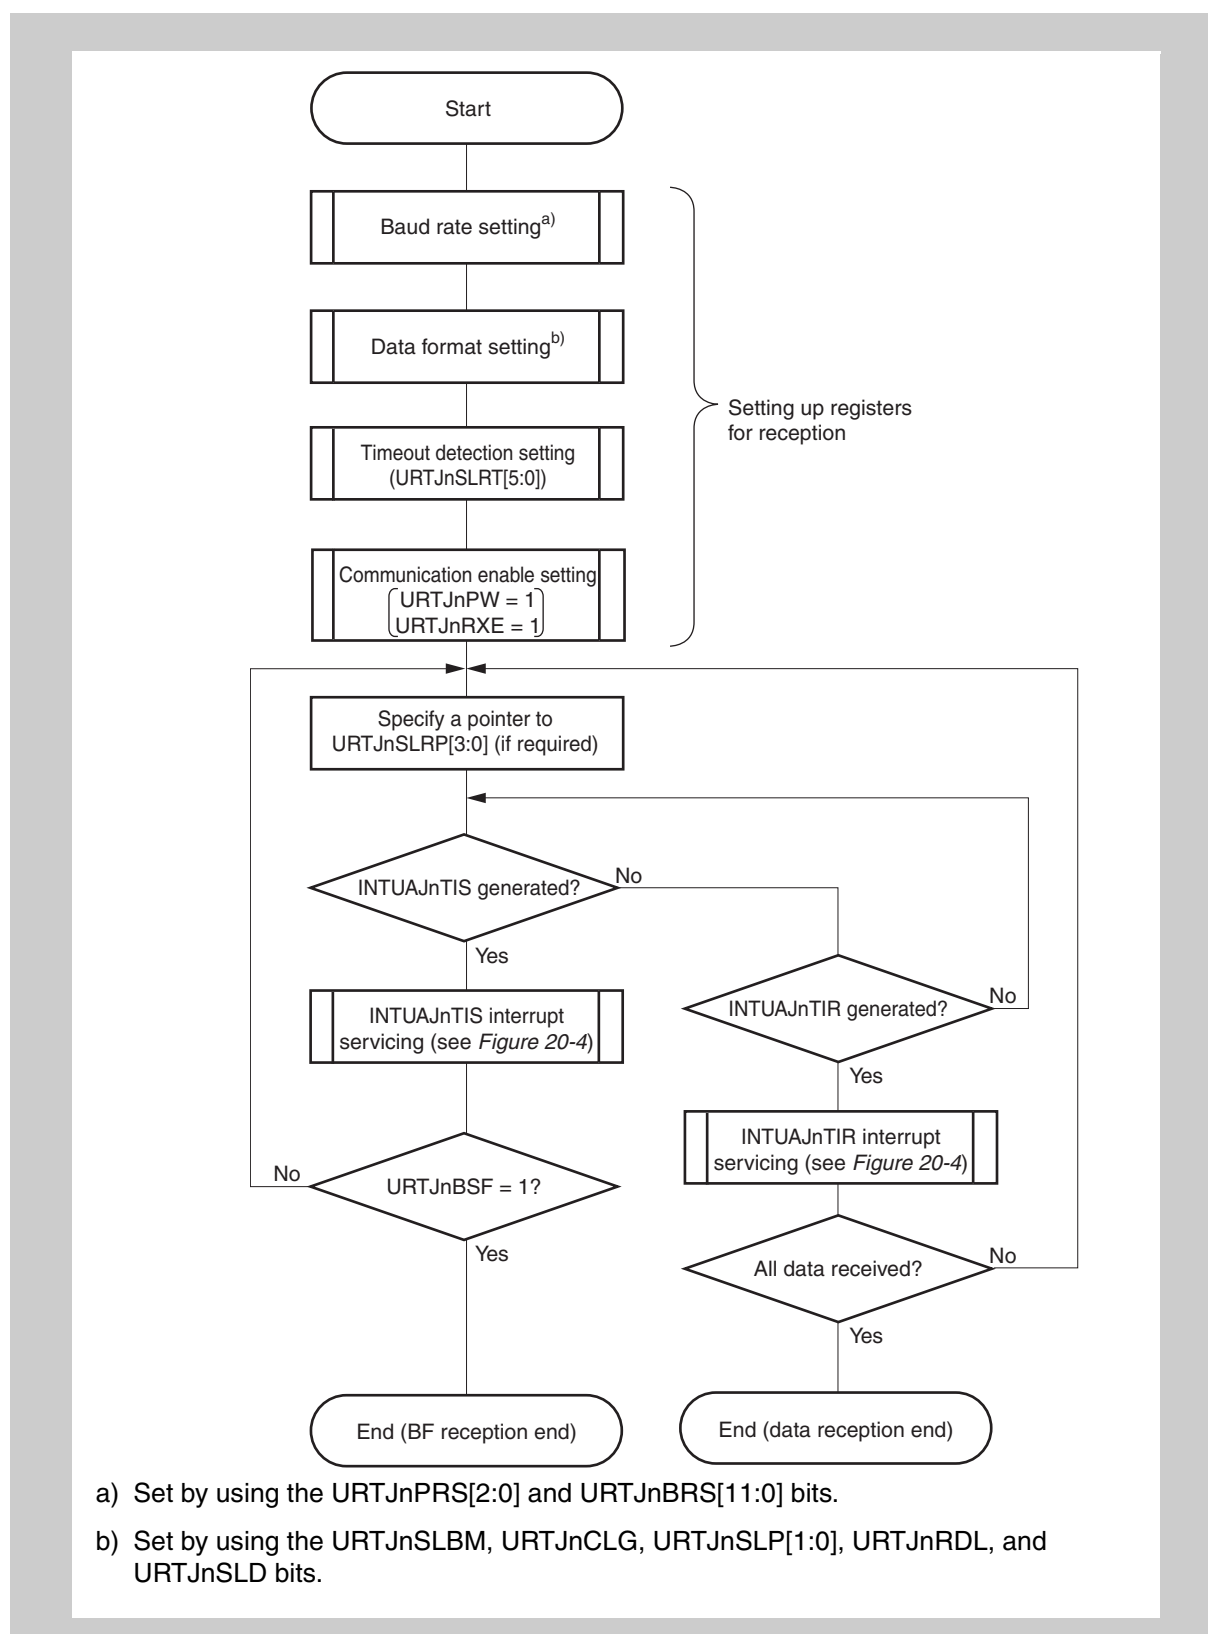

Figure 20-16 Flowchart of data reception when URTJnSLBM = 0, URTJnSSBR = 0

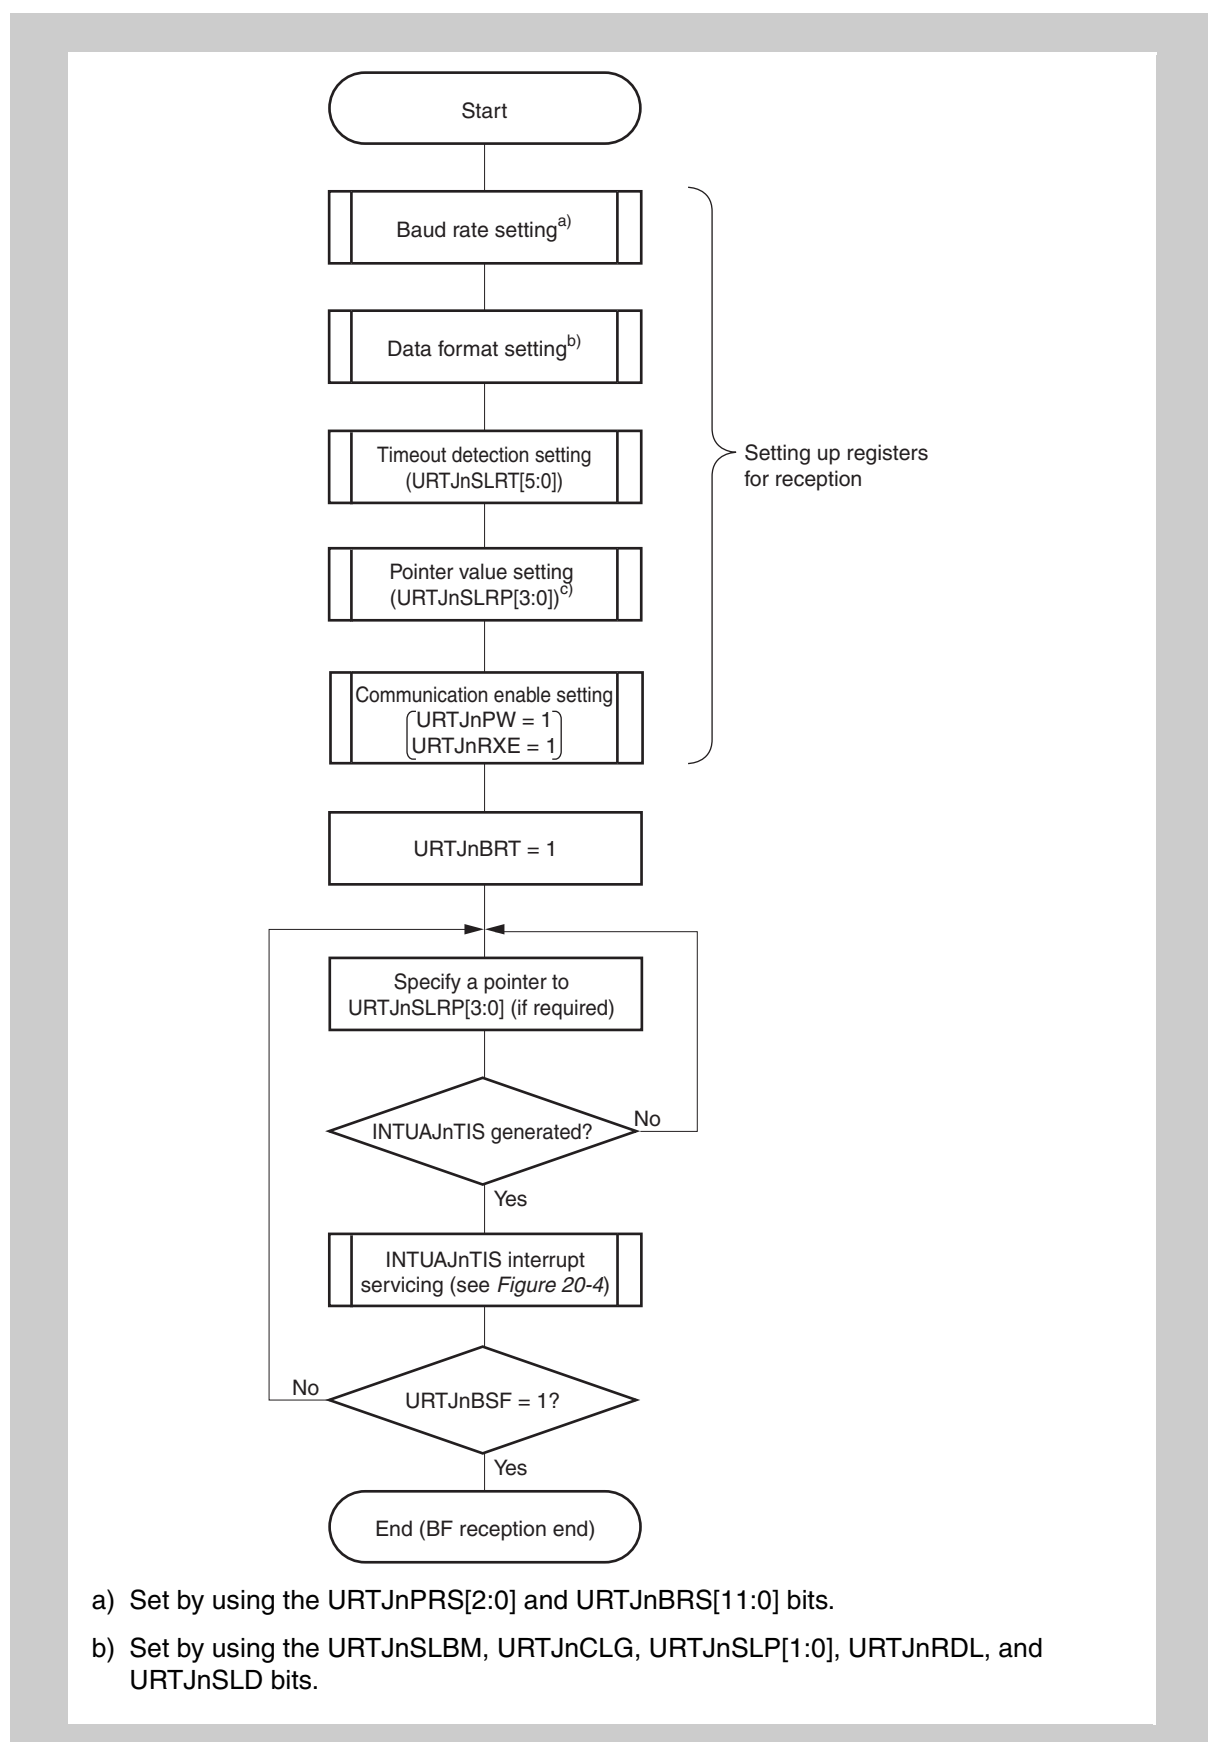

Figure 20-17 Flowchart of data reception when URTJnSLBM = 1, URTJnSSBR = 1

20.6.7 Reception errors

Errors during a receive operation are of four types:

- parity errors
- framing errors
- overrun errors
- timeout errors

Various data reception result error flags are provided to identify the error cause and the status interrupt request signal INTUAJnTIS is generated when an error occurs.

Table 20-22 Reception error causes and indicators

Reception error	Error flags	Cause
Parity error	URTJnSTR1.URTJnPE = 1 upon first parity error URTJnFRX.URTJnPE = 1 for each data in Rx FIFO	Received parity bit does not match the setting
Framing error	URTJnSTR1.URTJnFE = 1 upon first framing error URTJnFRX.URTJnFE = 1 for each data in Rx FIFO	Stop bit not detected
Overrun error	URTJnFSTR1.URTJnROVE = 1	Reception of next data completed while Rx FIFO is full
Timeout error	URTJnFSTR1.URTJnTMOE = 1	No Rx FIFO access within a certain time period

Overrun error An overrun error occurs (URTJnFSTR1.URTJnROVE = 1), when data has been received while the Rx FIFO is full. The received data is not transferred to the Rx FIFO, but is discarded.

Parity and framing error If a parity error or a framing error occurs during reception

- the associated error bit is set:
 - for a parity error: URTJnSTR1.URTJnPE = 1
 - for a framing error: URTJnSTR1.URTJnFE = 1,
- reception continues until the reception position of the first stop bit,
- the reception data and the error flag URTJnFRX.URTJnPE respectively URTJnFRX.URTJnFE is transferred to the Rx FIFO,
- the status interrupt INTUAJnTIS is generated,
- in case the Rx FIFO fill level reaches the predefined level URTJnFSTR0.URTJnSSRW[4:0], the reception interrupt INTUAJnTIR is generated.

Note The error flags URTJnFRX.URTJnPE and URTJnFRX.URTJnFE are set upon detection of the first parity respectively framing error and stay at 1 until they are cleared by URTJnSTC.URTJnCLP = 1 respectively URTJnSTC.URTJnCLF = 1.

Time-out error A time-out error occurs under following conditions:

- The Rx FIFO is not empty.
- Neither received data has been stored to nor data has been read from the Rx FIFO within a certain time period.

The time period is programmable by setting URTJnFCTL1.URTJnSLRT[5:0]. This value specifies the time period as multiple of the baud rate clock BRCLK period.

If a time-out error occurs, the flag URTJnFSTR1.URTJnTMOE is set to 1 and the status interrupt request INTUAJnTIS is asserted.

20.6.8 Parity types and operations

Caution When using the LIN function, fix the URTJnCTL1.URTJnSLP[1:0] to 00_B.

The parity bit is used to detect bit errors in the communication data. Normally the same parity is used on the transmission side and the reception side.

In the case of even parity and odd parity, it is possible to detect odd-count bit errors. In the case of 0 parity and no parity, errors cannot be detected.

(1) Even parity

- During transmission
The number of bits whose value is “1” among the transmit data, including the parity bit, is controlled so as to be an even number. The parity bit values are as follows:
 - Odd number of bits whose value is “1” among transmit data: 1
 - Even number of bits whose value is “1” among transmit data: 0
- During reception
The number of bits whose value is “1” among the reception data, including the parity bit, is counted, and if it is an odd number, a parity error is output.

(2) Odd parity

- During transmission
Opposite to even parity, the number of bits whose value is “1” among the transmit data, including the parity bit, is controlled so that it is an odd number. The parity bit values are as follows.
 - Odd number of bits whose value is “1” among transmit data: 0
 - Even number of bits whose value is “1” among transmit data: 1
- During reception
The number of bits whose value is “1” among the receive data, including the parity bit, is counted, and if it is an even number, a parity error is output.

(3) 0 parity

During transmission, the parity bit is always made 0, regardless of the transmit data.

During reception, parity bit check is not performed. Therefore, no parity error occurs, regardless of whether the parity bit is 0 or 1.

(4) No parity

No parity bit is added to the transmit data.

Reception is performed assuming that there is no parity bit. No parity error occurs since there is no parity bit.

20.6.9 Digital receive data noise filter

The receive data signal input URTJnTRXD is equipped with a digital noise filter to eliminate noise and spikes.

This filter samples the URTJnTRXD pin using the prescaler output clock PRSCLK.

When the same sampling value is read twice, the URTJnTRXD signal is validated as the input data.

Therefore, URTJnTRXD signal data not exceeding the width of 1 prescaler output clock cycle is judged to be noise and thus eliminated.

The noise filter causes a delay of 4 prescaler output clock PRSCLK cycles when capturing the serial data URTJnTRXD, until it is forwarded as valid.

20.7 Baud Rate Generator

The transmission and reception baud rate BRCLK are derived from the APB bus clock PCLK by use of a prescaler and a baud rate generator, as shown in the figure below.

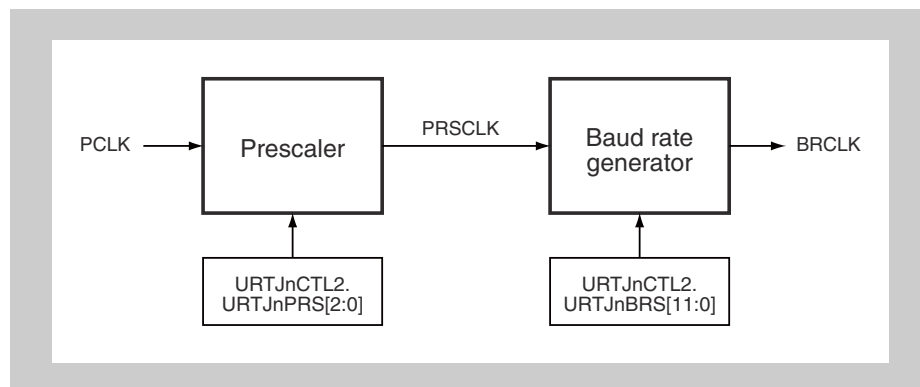

Figure 20-18 Configuration of baud rate generator

The prescaler output clock PRSCLK is a fraction of PCLK, the divisor is set up the value URTEnCTL2.URTJnPRS[2:0]:

$$\text{PRSCLK} = \text{PCLK} / 2^{\text{URTJnPRS}[2:0]}$$

PRSCLK is further divided by the baud rate generator by a value, determined by URTJnCTL2.URTJnBRS[11:0].

The baud rate generator distinguishes between the baud rate for data frames and BF receptions, as listed in the table below. The BF reception clock is the double of the baud rate clock BRCLK.

Table 20-23 Baud rate generator clocks output

URTJnCTL2. URTJnBRS[11:0]	Transmit/receive BRCLK	BF receive clock
000 _H	PCLK / (2 x 4)	PCLK / 4
001 _H		
002 _H		
003 _H		
004 _H		
005 _H	PCLK / (2 x 5)	PCLK / 5
...	PCLK / (2 x URTJnBRS[11:0])	PCLK / URTJnBRS[11:0]
FFE _H	PCLK / (2 x 4094)	PCLK / 4094
FFF _H	PCLK / (2 x 4095)	PCLK / 4095

Table 20-24 Example of baud rate generator settings

Baud rate	$f_{XX} = 200 \text{ MHz}$			$f_{XX} = 192 \text{ MHz}$			$f_{XX} = 160 \text{ MHz}$			$f_{XX} = 144 \text{ MHz}$

Chapter 21 Clocked Serial Interface G (CSIG)

This chapter contains a generic description of clocked serial interface G (CSIG).

The first section describes all V850E2/ML4 specific properties, such as instances, register base addresses, and input/output signal names. The subsequent sections describe the features that apply to all implementations.

21.1 V850E2/ML4 CSIG Features

Instances This microcontroller has the following number of instances of CSIG.

Table 21-1 Instances of CSIG

Clocked serial interface G	
Instance	2
Name	CSIG0, CSIG1

Instances index n Throughout this chapter, the individual instances of CSIG is identified by the index "n" (n = 0, 1), for example, CSIGNCTL0 for the CSIGN control register.

Register addresses All CSIGN register addresses are given as addresses offset from the individual base address <CSIGN_base_USER> or <CSIGN_base_OS>. The base addresses <CSIGN_base_USER> and <CSIGN_base_OS> of each CSIGN are listed in the following table:

Table 21-2 Register base addresses

CSIGN instance	Base address	<CSIGN_base> address
CSIG0	<CSIGN_base_USER>	FFFF E400 _H
	<CSIGN_base_OS>	FF70 0000 _H
CSIG1	<CSIGN_base_USER>	FFFF E500 _H
	<CSIGN_base_OS>	FF71 0000 _H

Clock supply All CSIG provide the following clock inputs:

Table 21-3 CSIGN clock supply

CSIGN instance	CSIGN clock	Connected to
CSIG0, CSIG1	PCLK	f _{PCLK}

Baud rate For CSIG, communication is possible at the maximum transfer speeds (baud rates) listed in the following table.

Table 21-4 Maximum CSIGn transfer speeds (baud rates)

Mode	Maximum transfer speed (baud rate)
Master mode	8.33 Mbps (target)
Slave mode	8.33 Mbps (target)

Interrupts and DMA/DTS CSIG can generate the following interrupt and DMA/DTS requests:

Table 21-5 CSIGn interrupt and DMA/DTS requests

CSIGn signals	Function	Connected to
CSIG0		
CSIG0TIC	Communication interrupt	<ul style="list-style-type: none"> Interrupt controller 153 (INTCSIG0IC) DMA controller trigger 88
CSIG0TIR	Reception interrupt	<ul style="list-style-type: none"> Interrupt controller 152 (INTCSIG0IR) DMA controller trigger 87
CSIG0TIRE	Communication error interrupt	<ul style="list-style-type: none"> Interrupt controller 151 (INTCSIG0IRE)
CSIG1		
CSIG1TIC	Communication interrupt	<ul style="list-style-type: none"> Interrupt controller 156 (INTCSIG1IC) DMA controller trigger 90
CSIG1TIR	Reception interrupt	<ul style="list-style-type: none"> Interrupt controller 155 (INTCSIG1IR) DMA controller trigger 89
CSIG1TIRE	Communication error interrupt	<ul style="list-style-type: none"> Interrupt controller 154 (INTCSIG1IRE)

I/O signals The I/O signals of the clocked serial interface G are listed in the following table.

Table 21-6 CSIGn I/O signals

CSIGn signal	Function	Connected to
CSIG0		
CSIG0TSCK	Serial clock signal	Port SCK0
CSIG0TSI	Serial data input signal	Port SI0
CSIG0TSO	Serial data output signal	Port SO0
$\overline{\text{CSIG0TSSI}}$	Slave select input signal	Port CSI0_SSI
CSIG0TRYO	Ready/busy output signal	Port CSI0_RYO
CSIG0TRYI	Ready/busy input signal	Port CSI0_RYI
CSIG1		
CSIG1TSCK	Serial clock signal	Port SCK1
CSIG1TSI	Serial data input signal	Port SI1
CSIG1TSO	Serial data output signal	Port SO1
$\overline{\text{CSIG1TSSI}}$	Slave select input signal	Port CSI1_SSI
CSIG1TRYO	Ready/busy output signal	Port CSI1_RYO
CSIG1TRYI	Ready/busy input signal	Port CSI1_RYI

21.2 Functional Overview

- Features summary**
- Three-wire serial synchronous data transfer
 - Master mode and slave mode selectable
 - Slave select input signal ($\overline{\text{CSIGNtSSI}}$)
 - Built-in baud rate generator
 - Adjustable baud rate; in slave mode it is determined by the input clock
 - Maximum transmission speed:
 - in master mode: PCLK/4
 - in slave mode: PCLK/6

Caution There might be restrictions on the maximum baud rate that can actually be used depending on the product. Specify the baud rate so as not to exceed the maximum rate for each product.

- Phase of clock and data selectable
- Data transfer with MSB or LSB first selectable
- Transfer data length selectable from 7 to 16 bits in 1-bit units
- Extended data length (EDL) function for transferring more than 16 bits of data
- Three selectable transfer modes:
 - Transmission mode
 - Reception mode
 - Transmission/reception mode
- Built-in handshake function
- Separate transmit and receive buffers (two 16-bit registers)
- Error detection (data consistency check, parity, overrun)
- Three different interrupt request signals (CSIGNtTIC, CSIGNtTIR, CSIGNtTIRE)
- Loop back mode (LBM) function for self test

The block diagram shows the main components of CSIG.

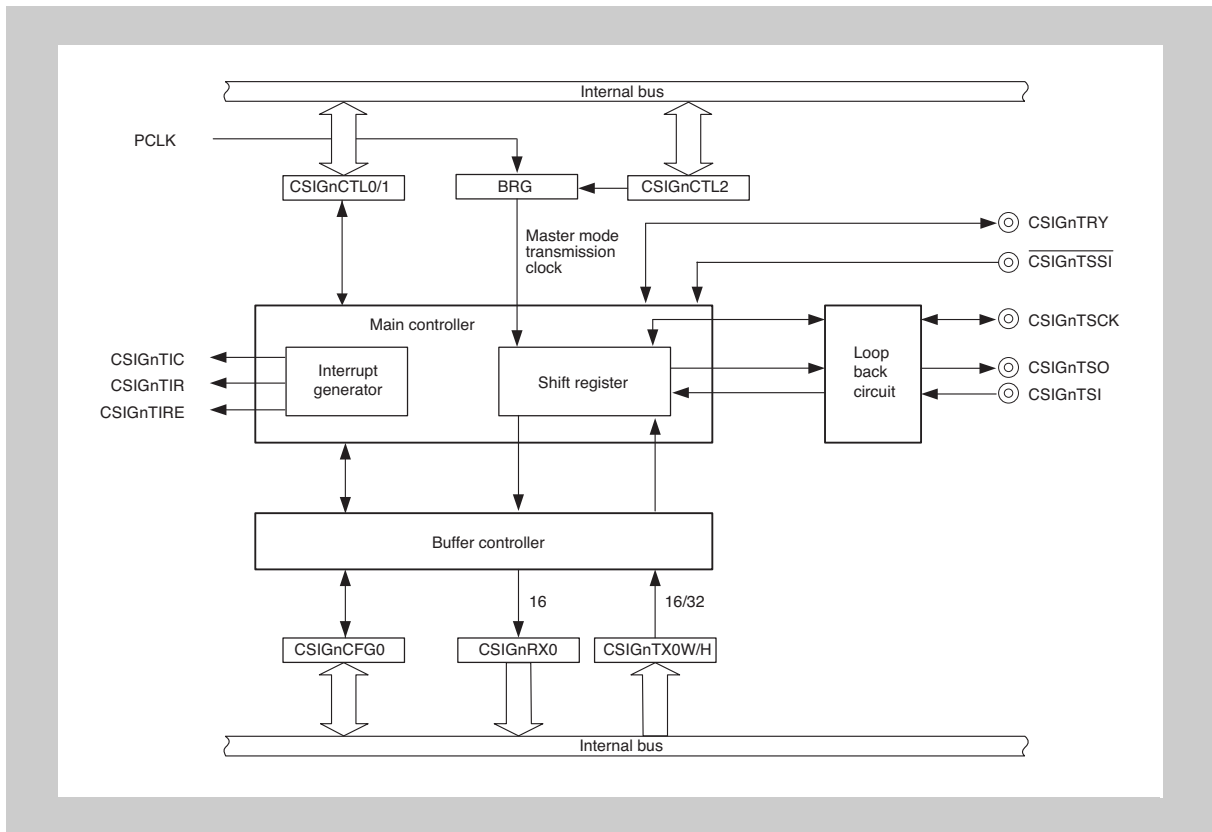

Figure 21-1 CSIG block diagram

In master mode, the serial clock CSIGnTSCCK is generated by the built-in baud rate generator (BRG). In slave mode, the serial clock is supplied from an external source.

21.3 Functional Description

The Clocked Serial Interface G uses three signals for communication:

- Serial clock CSIGnTSCK (output for the master mode or input for the slave mode)
- Data output signal CSIGnTSO
- Data input signal CSIGnTSI

Additional signals are available for external control and monitoring.

- $\overline{\text{CSIGnTSSI}}$: Slave select input signal
- CSIGnTRY: Handshake signal (input for the master mode or output for the slave mode)

Whether CSIG operates in the master or slave mode can be specified by using the CSIGCTL2 register.

Data transmission is bit-wise and serial and synchronous to the serial clock.

The most important registers for setting up CSIG are:

Register	Function
CSIGnCTL0	Enables/disables the operation clock (PCLK), data transmission, and data reception
CSIGnCTL1	Controls options like interrupt timing, extended data length, data consistency check, loop-back mode, handshake, etc.
CSIGnCTL2	Selects master/slave mode and – effective in master mode – the baud rate of the internal baud rate generator (BRG)
CSIGnCFG0	Configures the communication protocol

21.3.1 Operating modes (master/slave)

Master/slave selection is performed by using the CSIGNCTL2.CSIGNPRS[2:0] bits, and, when the master is selected, the source clock of the serial clock must also be selected.

(1) Master mode

In the master mode, the serial clock is generated by the internal baud rate generator (BRG) and provided to the slave(s) by signal CSIGNTSCK.

Master mode is enabled by setting CSIGNCTL2.CSIGNPRS[2:0] to anything but 111_B. In the master mode, the BRG frequency can be specified by specifying values for the CSIGNCTL2.CSIGNPRS[2:0] and CSIGNCTL2.CSIGNBRS[11:0] bits in combination.

Clock defaults The default level of CSIGNTSCK depends on the clock phase selection bit: It is high when CSIGNCTL1.CSIGNCKR = 0, and is low when CSIGNCTL1.CSIGNCKR = 1.

The example below shows the communication in master mode for eight data bits when CSIGNCTL1.CSIGNCKR = 0, CSIGNCFG0.CSIGNDAP = 0, and MSB first:

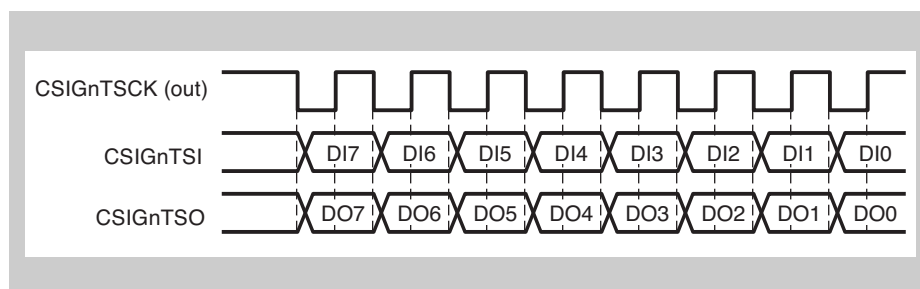

Figure 21-2 Transmission/reception in master mode

(2) Slave mode

In the slave mode, another device is the communication master. The external clock is supplied through the CSIGNTSCK signal. When the serial clock signal is detected, a transmission or reception operation immediately starts.

Slave mode is selected by setting CSIGNCTL2.CSIGNPRS[2:0] to 111_B.

Note When using the slave mode, the baud rate generator (BRG) can be disabled by clearing the CSIGNCTL2.CSIGNBRS[11:0] bits, reducing power consumption.

The example below shows the communication in the save mode for eight data bits when CSIGNCTL1.CSIGNCKR = 0, CSIGNCFG0.CSIGNDAP = 0, and the MSB is first.

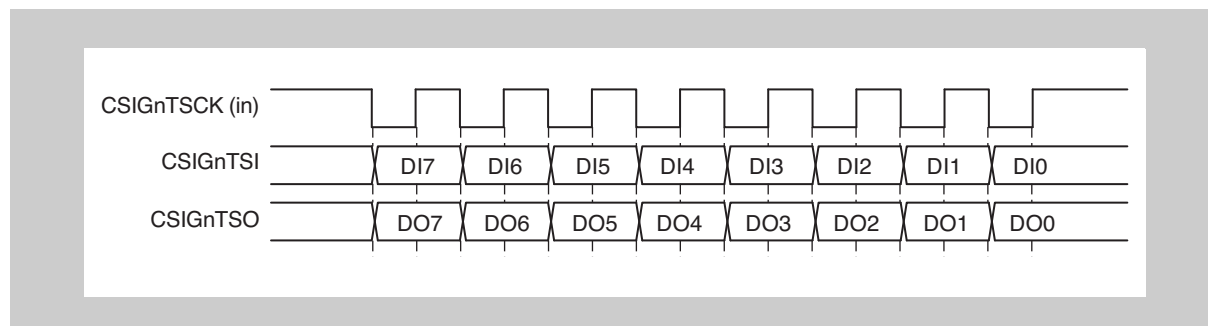

Figure 21-3 Transmission/reception in slave mode

21.3.2 Master/slave connections

(1) One master and one slave

The following figure illustrates the connections between one master and one slave.

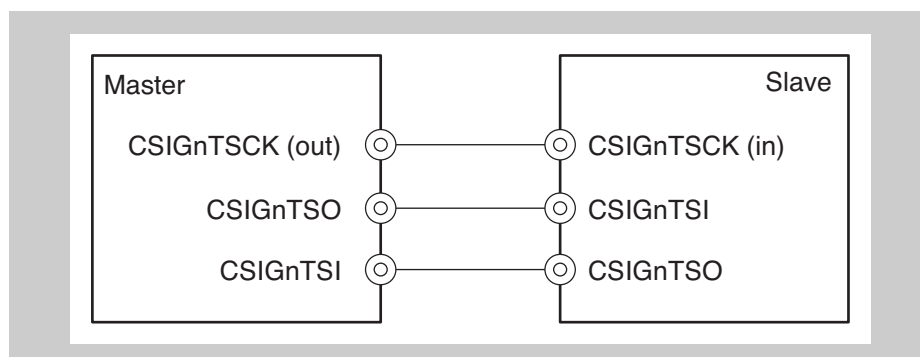

Figure 21-4 Simple master/slave connection

(2) One master and multiple slaves

The following figure illustrates the connections between one master and multiple slaves. In this example, a configuration in which the master supplies one slave select (SS) signal to each slave is possible. This signal is connected to the slave select input $\overline{\text{CSIGnTSSI}}$ of the slave.

The $\overline{\text{CSIGnTSSI}}$ signal recognition function can be enabled/disabled by bit CSIGnCTL1.CSIGnSSE.

Figure 21-5 Master to multiple slaves connection

A slave is selected (enabled) when its $\overline{\text{CSIGNTSSI}}$ signal is low.

If a slave is not selected, it will neither receive nor transmit data. In addition, its output CSIGNTSO is set to input mode in order to avoid interference with the output of another slave that was selected.

(3) CSIGNTSO output control

CSIG can output CSIGNTSO when all of the following conditions are satisfied:

- The CSIG is enabled (CSIGNCTL0.CSIGNPWR = 1).
- The CSIG is operated in transmission or transmission/reception mode (CSIGNCTL0.CSIGNTXE = 1).
- The CSIG is operated with slave select enabled (CSIGNCTL1.CSIGNSSE = 1).
- The slave mode selection signal $\overline{\text{CSIGNTSSI}}$ is inactive, i.e. on high level.

By this signal congestions on the external CSIGNTSO signal line are avoided.

21.3.3 Serial clock selection

In master mode, the transmission baud rate is selectable using the CSIGNPRS[2:0] and CSIGNBRS[11:0] bits in the CSIGNCTL2 register.

The following figure shows a block diagram of the BRG.

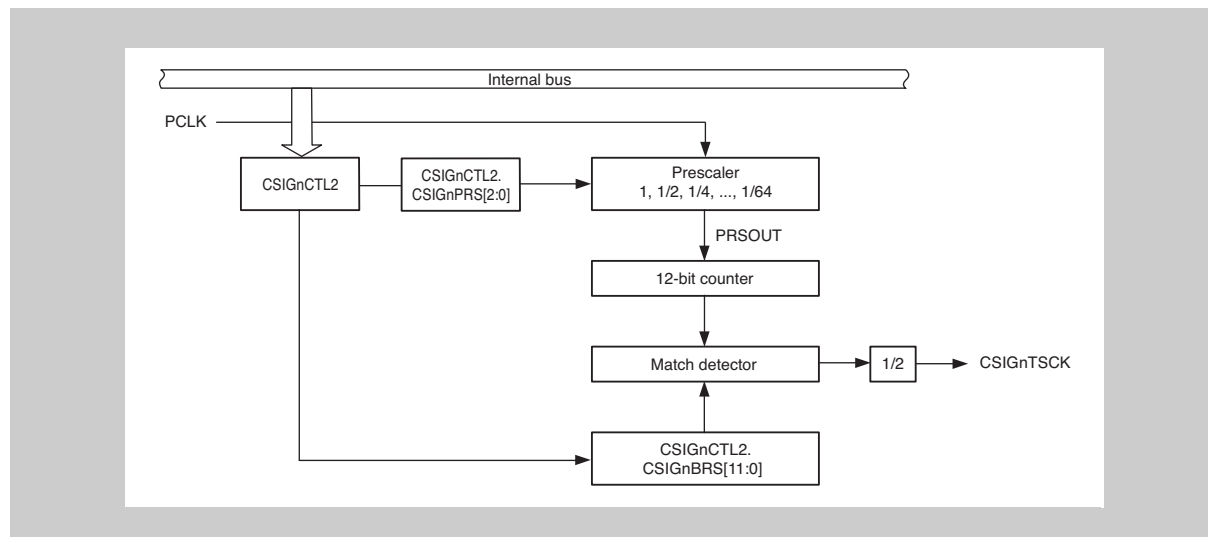

Figure 21-6 BRG block diagram

Clearing CSIGNCTL2.CSIGNBRS[11:0] disables the BRG.

Baud rate calculation

The baud rate is calculated as: $PCLK / (2^m \times k \times 2)$, where

$$m = CSIGNPRS[2:0] = 0 \text{ to } 6$$

$$k = CSIGNBRS[11:0] = 1 \text{ to } 4095$$

Baud rate limits

When setting the baud rate, please note:

- Maximum acceptable baud rate in master mode is $PCLK / 4$.
- Maximum acceptable baud rate in slave mode is $PCLK / 6$.
- Minimum baud rate in both modes is $PCLK / 524160$.

Caution

There might be restrictions on the maximum baud rate that can actually be used depending on the product. Specify the baud rate so as not to exceed the maximum rate for each product.

Example

If $PCLK = 80 \text{ MHz}$, the maximum baud rate is

- 20.0 Mbps ($PCLK / 4$) in master mode
- 13.3 Mbps ($PCLK / 6$) in slave mode

The slowest baud rate is 152.625 bps ($PCLK / 524160$).

21.3.4 Data transfer modes

(1) Transmission mode

Setting CSIGnCTL0.CSIGnTXE = 1 and CSIGnCTL0.CSIGnRXE = 0 puts CSIG in transmission mode. Transmission starts when transmission data is written in the CSIGnTX0W or CSIGnTX0H register.

(2) Reception mode

Setting CSIGnCTL0.CSIGnTXE = 0 and CSIGnCTL0.CSIGnRXE = 1 puts CSIG in reception mode.

In the master mode, reception starts when dummy data is read from the CSIGnRX0 register.

All following receptions are triggered by a read from the reception data register CSIGnRX0, as long as CSIGnBCTL0.CSIGnSCE = 1.

In the slave mode, reception starts when the serial clock CSIGnTSCK is supplied from the master.

Note In reception mode, any previously received data must be read from the reception data register CSIGnRX0 in order to avoid any overwrite situation.

Moreover the communication start bit CSIGnBCTL0.CSIGnSCE has to be set to 1 and has to set back to 0 before reading the last received data from CSIGnRX0.

The recommended procedure is:

1. Set CSIGnBCTL0.CSIGnSCE = 1.
2. Read CSIGnRX0 (dummy data).
3. Wait for the reception interrupt CSIGnTIR.
4. Read CSIGnRX0 (received data).

In case of further data receptions continue at step 3, repeat a read operation until all data has been received.

Before reading the last received data from CSIGnRX0, clear CSIGnBCTL0.CSIGnSCE.

(3) Transmission/reception mode

Setting CSIGnCTL0.CSIGnTXE = 1 and CSIGnCTL0.CSIGnRXE = 1 puts CSIG in transmission/reception mode.

Communication starts when transmission data is written to the CSIGnTX0W or CSIGnTX0H register.

21.3.5 Data length selection

(1) Data length between 7 and 16 bits

Transmission data length is selectable from 7 to 16 bits using the CSIGNCFG0.CSIGNDLS[3:0] bits. The examples below show the communication with MSB first (CSIGNCFG0.CSIGNDIR = 0):

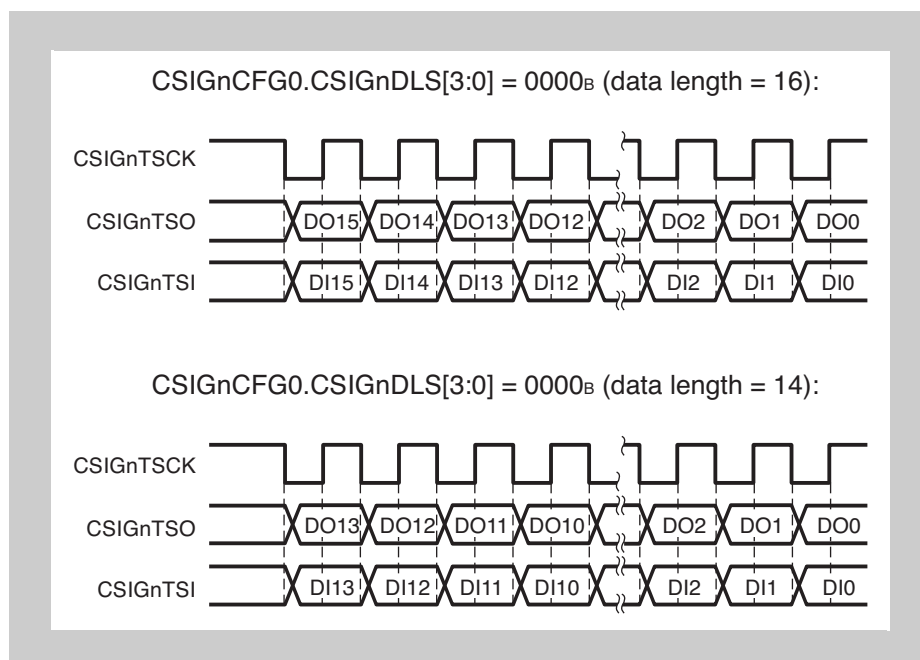

Figure 21-7 Data length select function

(2) Data length greater than 16 bits

If the length of the data to be sent/received exceeds 16 bits, the extended data length (EDL) feature can be used.

The EDL function is enabled by setting CSIGNCTL1.CSIGNEDLE.

The EDL function works as follows:

- Data is divided into 16-bit blocks and a remainder. For example, a 42-bit character string is divided into two 16-bit blocks and a 10-bit remainder.
- For the remainder, the data length is specified for the CSIGNCFG0.CSIGNDLS[3:0] bits.
- When transmitting 16-bit blocks, set the CSIGNTX0W.CSIGNEDL bit. In this case, the data written to CSIGNTX0W is sent as a 16-bit data length regardless of the CSIGNCFG0.CSIGNDLS[3:0] bits.
- When the specified length of data (the remainder when CSIGNTX0W.CSIGNEDL = 0) is transmitted, the transfer ends.

Example Example of transmitting the 40-bit data 123456789A_H

The 40-bit data is divided into two 16-bit blocks of data and one 8-bit block of data.

- Initialize CSIGnCFG0.CSIGnDLS[3:0] = 8_D.
- To send the string 123456789A_H with MSB first, write the following sequence to CSIGnTX0W:
 - 2000 1234_H (CSIGnTX0W.CSIGnEDL = 1)
 - 2000 5678_H (CSIGnTX0W.CSIGnEDL = 1)
 - 0000 009A_H (CSIGnTX0W.CSIGnEDL = 0)

The following figure illustrates the timing.

Figure 21-8 EDL timing chart

- Notes**
1. A data length less than 7 bits can be specified only when the EDL function is used.
 2. It is not possible to send two consecutive data with a data length of less than 7 bits.
 3. If parity is enabled, the parity bit is added after the last bit.
 4. The following describes an example where the transmitted data is 123456_H.
 - CSIGnCFG0.CSIGnDIR is cleared to 0 (MSB first).
2000 1234_H is written to CSIGnTX0W (CSIGnTX0W.CSIGnEDL = 1).
0000 0056_H is written to CSIGnTX0W (CSIGnTX0W.CSIGnEDL = 0).
 - CSIGnCFG0.CSIGnDIR is set to 1 (LSB first).
2000 3456_H is written to CSIGnTX0W (CSIGnTX0W.CSIGnEDL = 1).
0000 0012_H is written to CSIGnTX0W (CSIGnTX0W.CSIGnEDL = 0).
 5. The EDL function cannot be used in the slave mode (CSIGnCTL1.CSIGnPRS[2:0] = 1, 1, 1) and reception mode (CSIGnCTL0.CSIGnTXE = 0, CSIGnCTL0.CSIGnRXE = 1).

21.3.6 Serial data direction selection

The serial data direction is selectable using the CSIGNDIR bit in the CSIGNCFG0 register.

The examples below show the communication for a data length of 8 bit (CSIGNCFG0.CSIGNDLS[3:0] = 1000_B):

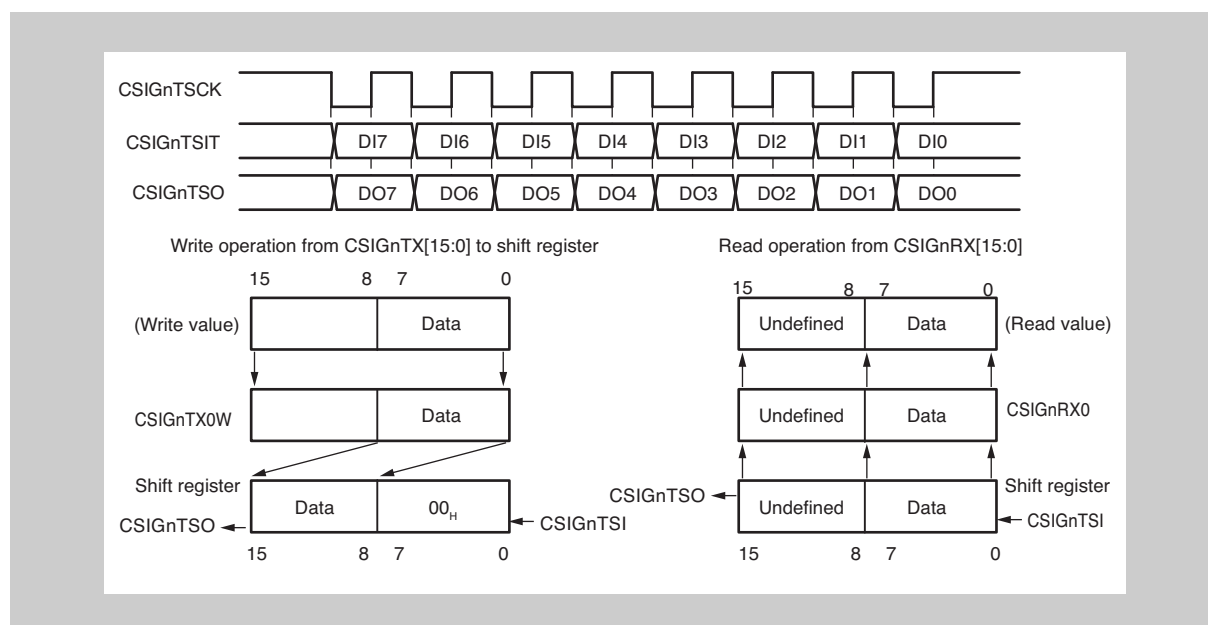

Figure 21-9 Serial data direction select function - MSB first (CSIGNDIR = 0)

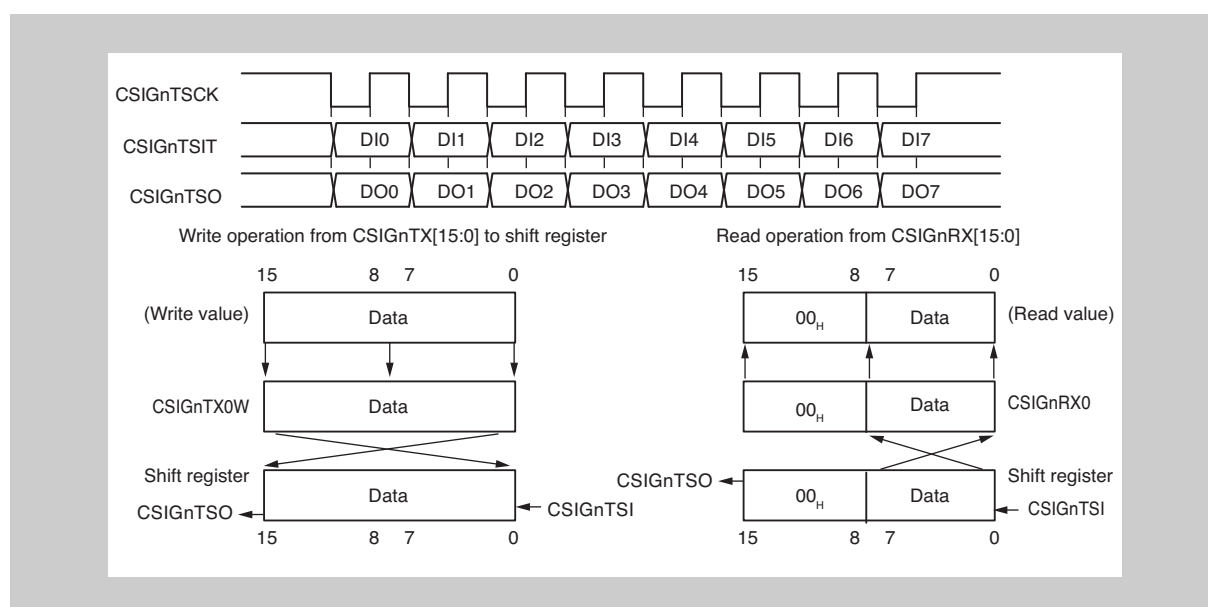

Figure 21-10 Serial data direction select function - LSB first (CSIGNDIR = 1)

21.3.7 Communication in slave mode

The following figure illustrates the communication signals and timings in slave mode.

Figure 21-11 Transmit/receive communication timing in slave mode

1. CSIG is placed in the slave mode by setting CSIGnCTL2.CSIGnPRS[2:0] to 111_B. The $\overline{\text{CSIGnTSSI}}$ signal is enabled (CSIGnCTL1.CSIGnSSE = 1).
2. CSIGnCTL1.CSIGnCKR and CSIGnCFG0.CSIGnDAP0 are 0, the data length is 8 bits (CSIGnCFG0.CSIGnDLS0[3:0] = 1000_B), and the data direction is MSB first (CSIGnCFG0.CSIGnDIR0 = 0).
3. CSIG is set to the transmission/reception mode (CSIGnCTL0.CSIGnPWR = 1, CSIGnCTL0.CSIGnTXE = 1, and CSIGnCTL0.CSIGnRXE = 1). Communication is enabled to start.
4. If transfer data is written to the transmission data register CSIGnTX0W or CSIGnTX0H, the transfer status flag CSIGnSTR0.CSIGnTSF is automatically set, and the system waits for the $\overline{\text{CSIGnTSSI}}$ signal to become low.
5. Data transmission/reception does not start while the $\overline{\text{CSIGnTSSI}}$ signal is high, even if the external serial clock CSIGnTSCCK is input. CSIGnTSO retains the value, and input to CSIGnTSI is ignored.
6. When the $\overline{\text{CSIGnTSSI}}$ signal becomes low, it indicates that CSIGnTSO is enabled and data transmission is possible.
7. If a serial clock is input while $\overline{\text{CSIGnTSSI}}$ is low, the transfer data is transmitted from CSIGnTSO in synchronization with the serial clock, and data is received from CSIGnTSI at the same time.
8. The CSIGnRX0 register is read.

21.3.8 CSIG interrupts

CSIG can generate the following interrupts:

- CSIGnTIC (communication interrupt)
- CSIGnTIR (reception interrupt)
- CSIGnTIRE (error interrupt)

(1) CSIGnTIC (communication interrupt)

This interrupt is normally generated after every data transfer. It can be used to trigger a DMA for writing new transmission data to register CSIGnTX0W or CSIGnTX0H.

The following example assumes:

- Master mode
- CSIGnCTL1.CSIGnSIT = 0 (no interrupt delay)
- CSIGnCTL1.CSIGnCKR = 0, CSIGnCFG0.CSIGnDAP = 0 (normal clock and data phase)
- CSIGnCFG0.CSIGnDLS[3:0] = 1000_B (data length 8 bits)
- CSIGnCTL1.CSIGnSLIT = 0 (normal interrupt timing)

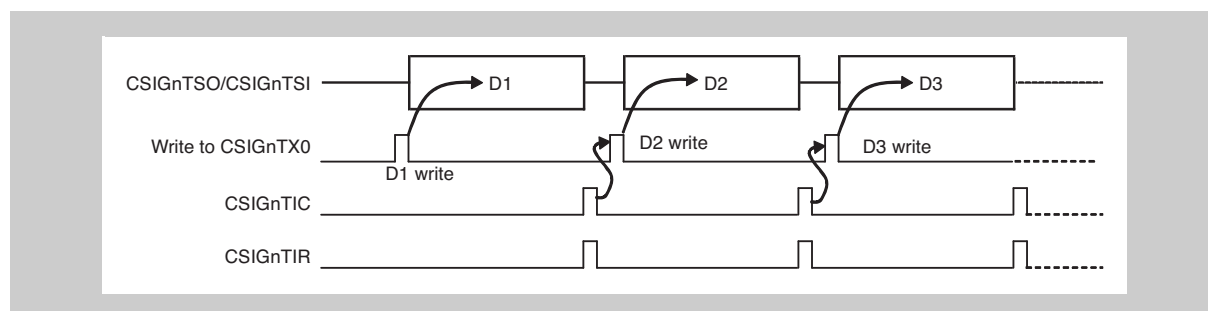

Figure 21-12 Generation of CSIGnTIC after communication (CSIGnCTL1.CSIGnSLIT = 0)

However, CSIGnTIC can also be set up to occur when the CSIGnTX0W or CSIGnTX0H register is free for the next data. This is specified by setting CSIGnCTL1.CSIGnSLIT = 1.

This mode allows more efficient data transfers.

The effect is illustrated in the figure below.

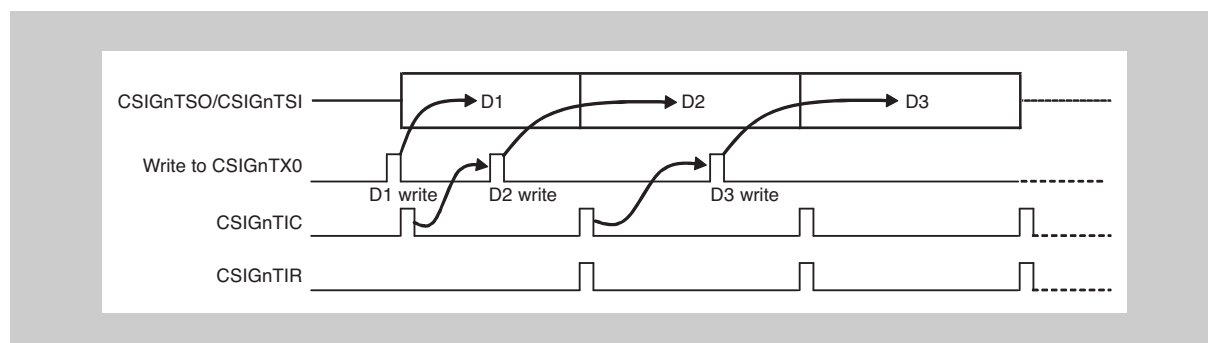

Figure 21-13 Generation of CSIGnTIC at the beginning of communication

(2) CSIGnTIR (reception interrupt)

This interrupt is generated in reception and transmission/reception mode after data has been received and is available in the reception data register.

The following example assumes:

- Master mode
- CSIGnCTL1.CSIGnSIT = 0 (no interrupt delay)
- CSIGnCTL1.CSIGnCKR = 0, CSIGnCFG0.CSIGnDAP = 0 (normal clock and data phase)
- CSIGnCFG0.CSIGnDLS[3:0] = 1000_B (data length 8 bits).

Figure 21-14 Generation of CSIGnTIR

(3) CSIGnTIRE (reception error interrupt)

This interrupt is generated whenever an error is detected.

Table 21-7 Data error types

Error type	Communication status after error interrupt
Parity error	Interrupt is generated and communication continues
Data consistency error	Interrupt is generated and communication continues
Overrun error	If CSIGnCTL1.CSIGnHSE = 0 (no handshake), communication continues after the interrupt is generated. (Communication does not stop.)
	If CSIGnCTL1.CSIGnHSE = 1 (handshake exists), communication is stopped according to the handshake. No interrupt is generated, and no overrun error occurs.

The type of error that caused the generation of CSIGnTIRE is indicated in register CSIGnSTR0.

For details about the various error types, refer to 21.3.10 "Error detection" on page 1111.

(4) Interrupt delay

In the master mode, all interrupts generated by the master can be delayed one half cycle of the serial clock CSIGNTSCK. This function cannot be used in the slave mode.

To specify this delay, set the CSIGNCTL1.CSIGNSIT bit to 1.

The figure below shows an example of using the interrupt delay function with the following settings: CSIGNCTL1.CSIGNSIT = 1 (interrupt delay enabled), CSIGNCTL1.CSIGNCKR = 0, CSIGNCFG0.CSIGNDAP = 0 (normal clock phase and data phase), and CSIGNCFG0.CSIGNDLS[3:0] = 1000_B (8-bit data length).

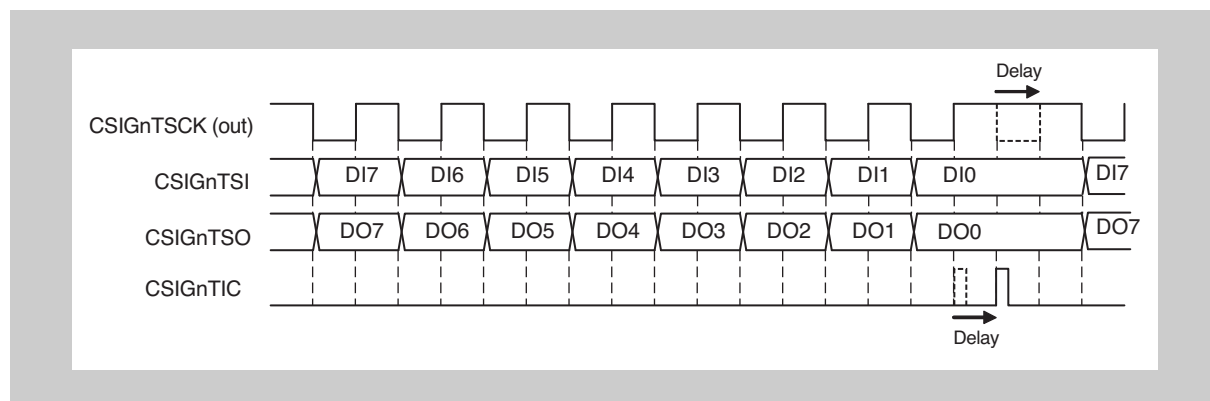

Figure 21-15 Interrupt delay function (CSIGNCTL1.CSIGNSIT = 1)

21.3.9 Handshake function

CSIG features a handshake function to synchronize the master and the slave devices. This function can be enabled/disabled by bit CSIGNCTL1.CSIGNHSE. For handshake, the signal CSIGNTRY is used. In addition, when the handshake function is disabled (CSIGNCTL1.CSIGNHSE = 0), the CSIGNTRY signal is output at the low level.

The timing depends on the data phase selection bit CSIGNCFG0.CSIGNDAP.

(1) Slave mode

When CSIGNCTL1.CSIGNHSE = 1 and the slave is busy, the CSIGNTRY signal is output at the low level. This happens when previous receive data is still in the CSIGNRX0 register, and new data cannot be copied from the shift register to CSIGNRX0 (CSIGNRX0 full condition).

The following examples assume a data length of 8 bits.

Figure 21-16 Ready/busy signal from slave (CSIGNCFG0.CSIGNDAP = 0)

As long as the slave is busy, the master has to wait (i.e. suspend the serial clock). The slave sets CSIGNTRY to high ("ready") as soon as the reception data register CSIGNRX0 has been read.

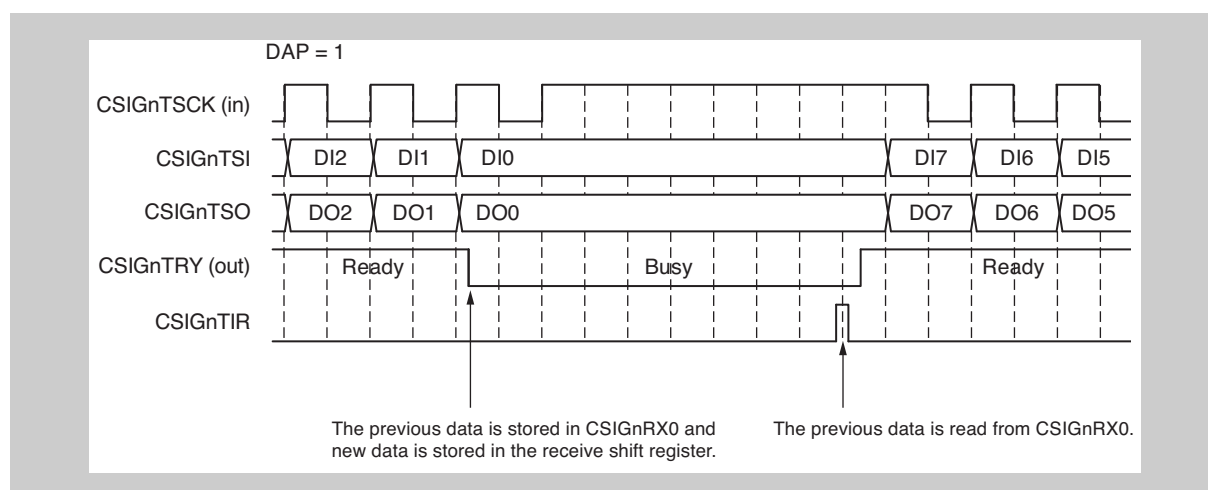

Figure 21-17 Ready/busy signal from slave (CSIGNCFG0.CSIGNDAP = 1)

(2) Master mode

When the master detects the CSIGNTRY is at the low level, the following transfer is put on hold, and the master goes into wait status. It suspends the clock CSIGNTSCK.

The CSIGNTRY level is checked at each half clock cycle of CSIGNTSCK.

Figure 21-18 Master's reaction to CSIGNTRY (CSIGNCFG0.CSIGNDAP = 0)

If the CSIGNTRY low signal comes from the slave while data transfer is in progress, the serial clock is suspended after the transfer is complete.

The master resumes the communication as soon as CSIGNTRY becomes high (slave is "ready").

Figure 21-19 Master's reaction to CSIGNTRY (CSIGNCFG0.CSIGNDAP = 1)

Caution If multiple slaves are connected, the master must only detect the CSIGNTRY signal of the slave it has selected for communication. CSIGNTRY must be pulled down by the external slave before the next transfer starts. Even if the signal is pulled down by the slave during the transfer, the transfer continues.

21.3.10 Error detection

CSIG can detect three error types:

- Data consistency error (transmission data)
- Parity error (reception data)
- Overrun error

Check for data consistency and parity errors can be enabled/disabled individually.

If one of these errors is detected, the interrupt CSIGNTIRE is generated and the corresponding flag is set.

(1) Data consistency check

The purpose of the data consistency check is to ensure that the data physically sent to the output signal is identical with the original data that was copied to the shift register.

The data consistency check can be enabled/disabled by bit CSIGNCTL1.CSIGNDCS. It is not active if data transmission is disabled (CSIGNCTL0.CSIGNTXE = 0).

When the data consistency check is active, the data transferred from CSIGNTX0W or CSIGNTX0H to the shift register is copied to a separate register. In addition, the physical levels at output signal CSIGNTSO are captured, and their logical interpretation is fed into an own shift register.

After completion of the transmission, the data sent is compared with the original transmission data.

Mismatch is considered as a data consistency error.

When a data consistency error occurs:

- Interrupt CSIGNTIRE is generated.
- Bit CSIGNSTR0.CSIGNDCE is set.

The function is illustrated in the following block diagram.

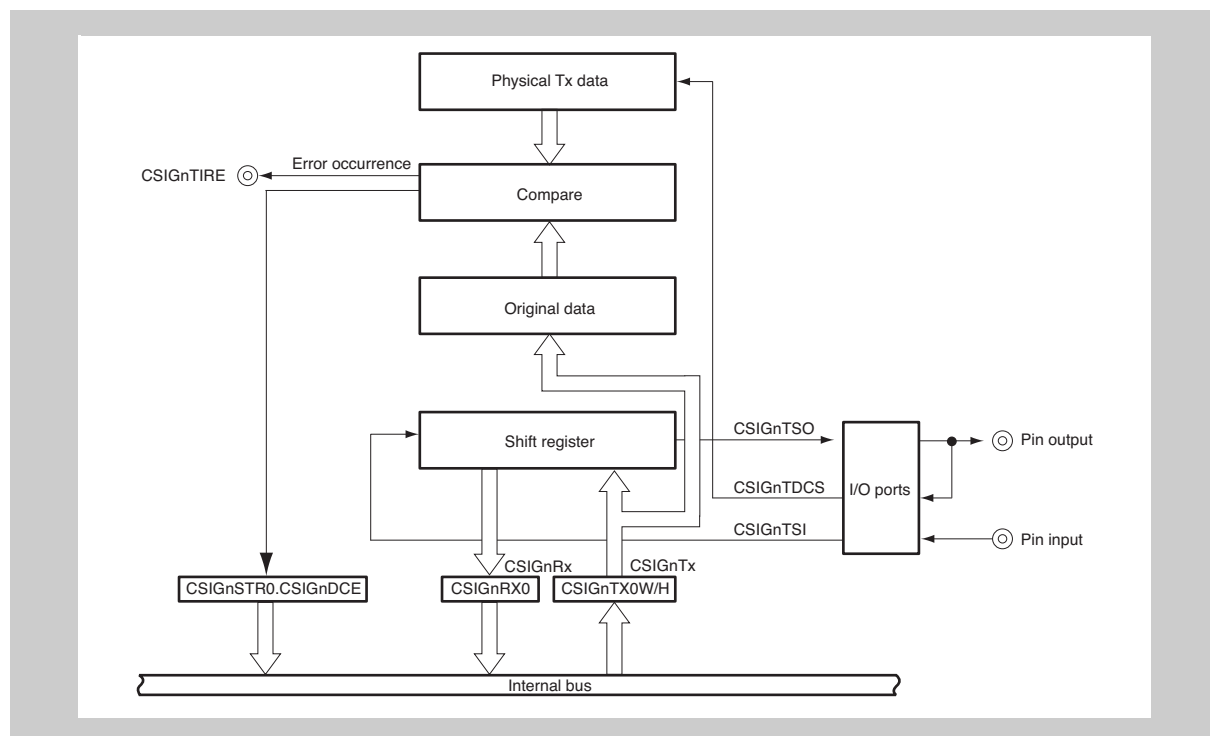

Figure 21-20 Functional block diagram of the data consistency check

(2) Parity check

Parity is a common mean to detect a single bit failure during data transmission. CSIG can append a parity bit to the last data bit (even if extended data length is used).

The use and type of parity is specified in CSIGNCFG0.CSIGNPS[1:0].

Parity check is enabled if CSIGNCFG0.CSIGNPS[1] = 1.

The parity bit is checked after reception is complete.

When a parity error occurs:

- Interrupt CSIGNTIRE is generated
- Bit CSIGNSTR0.CSIGNPE is set

The following figure shows an example.

- Data length is 8 bits.
- The data transmitted is 05_H and 35_H.
- Data direction is LSB first.
- Parity type is odd.

Figure 21-21 Parity check example

For the first 8 bits, the parity bit is 1. There is no parity error, because the total number of ones (including the parity bit) is odd.

For the second 8 bits, the parity bit is 0. This is detected as a parity error, because the total number of ones (including the parity bit) is even.

If using the extended data length (EDL) function, the parity bit is added after the last data bit.

(3) Overrun error

This error occurs when newly received data cannot be transferred from the shift register to the reception data register CSIGNRX0. This happens when CSIGNRX0 was not read and therefore contains previously received data.

In the master mode, because the serial clock is stopped until the CPU reads reception data, overrun errors do not occur. In the slave mode, the handshake function can be used to avoid this error.

When an overrun error occurs:

- The interrupt CSIGNTIRE is generated.
- CSIGNSTR0.CSIGNOVE is set.
- The CSIGNRX0 register is written with the reception data.
- Communication continues.

The following figure illustrates the function.

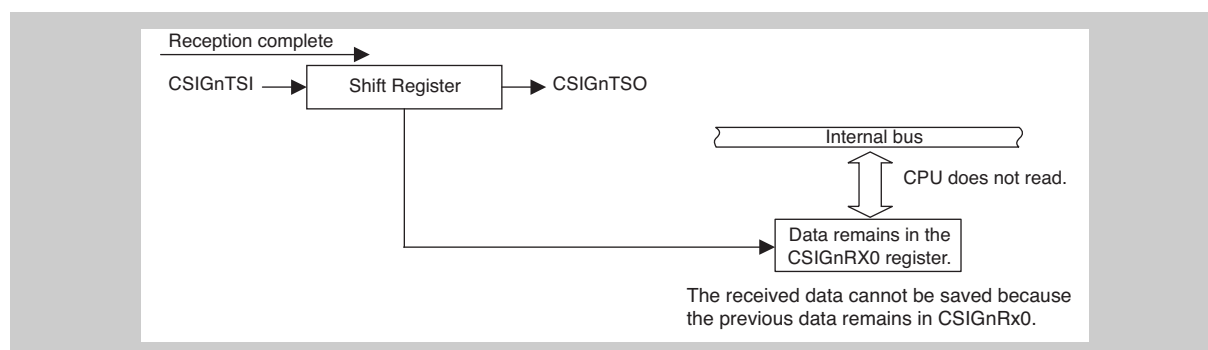

Figure 21-22 Overrun error detection

The following figure illustrates an example where:

- Rx data 3 was not read
- Rx data 4 was received, but cannot be stored

Thus an overrun error occurs.

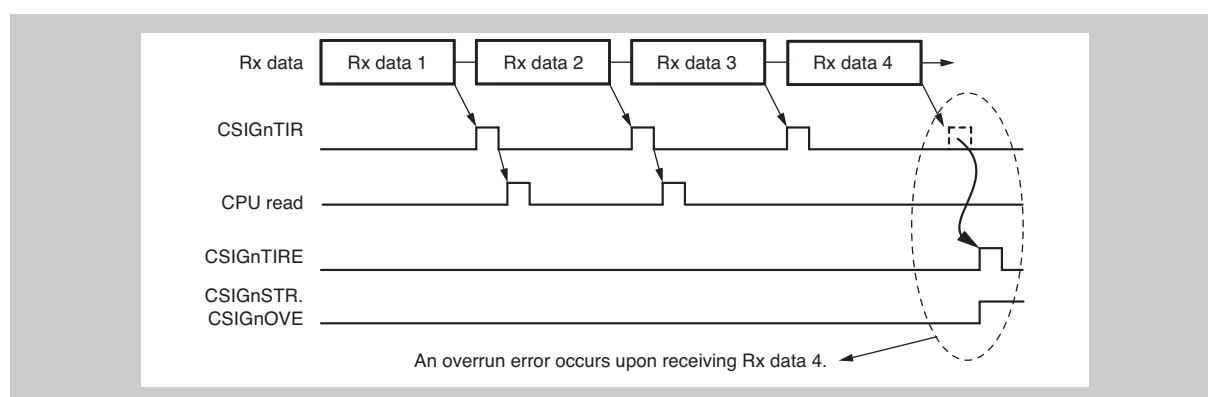

Figure 21-23 Overrun error detection - example

Note An overrun error can be avoided in slave mode by using the handshake.

When handshake is used in slave mode, the receiver (slave) signals to the transmitter (master) that it is busy. The transmitter then waits until the receiver has read its reception data register and is ready again.

For details, see 21.3.9 “Handshake function” on page 1109.

21.3.11 Loop-back mode

Loop-back mode is a special mode for self-test. This feature is only available in master mode.

When this mode is active, the transmission and reception signals are internally connected, as shown in the figures below. The signals CSIGnTSCO, CSIGnTSO, and CSIGnTSI are disconnected from the ports. In addition, the CSIGnTSO output level is fixed to low, and CSIGnTSCCK becomes inactive. The handshake function cannot be used at this time. The rest of CSIG works as in normal operation.

To perform a self-test of the CSIG, CSIGnCTL1.CSIGnLBM is set to 1, and a normal transfer operation is executed. Next, whether the reception data and transmission data are the same is checked.

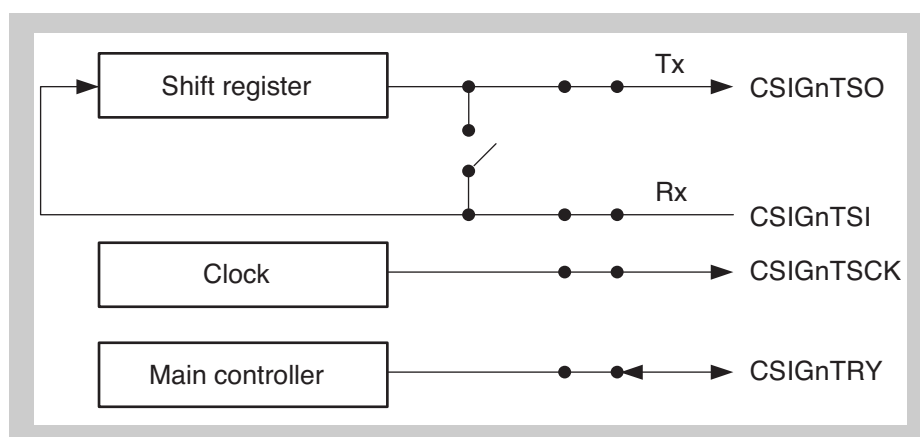

Figure 21-24 Normal operation (CSIGnLBM = 0)

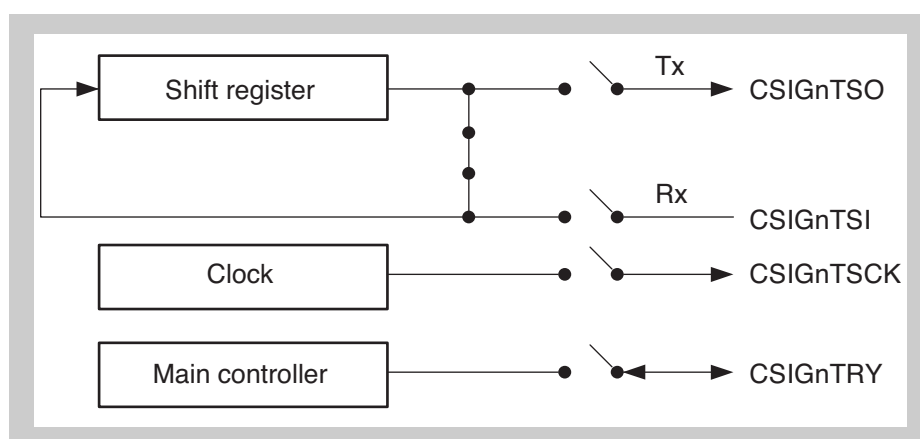

Figure 21-25 Operation in loop-back mode (CSIGnLBM = 1)

21.4 CSIG Control Registers

CSIGn is controlled and operated by means of the following registers:

Table 21-8 CSIGn register overview

Register name	Shortcut	Address
Control register 0	CSIGnCTL0	<CSIGn_base_USER> + 0000 _H
Control register 1	CSIGnCTL1	<CSIGn_base_OS> + 0010 _H
Control register 2	CSIGnCTL2	<CSIGn_base_OS> + 0014 _H
Status register 0	CSIGnSTR0	<CSIGn_base_USER> + 0004 _H
Status clear register 0	CSIGnSTCR0	<CSIGn_base_USER> + 0008 _H
Reception mode control register 0	CSIGnBCTL0	<CSIGn_base_USER> + 0080 _H
Configuration register 0	CSIGnCFG0	<CSIGn_base_OS> + 1010 _H
Transmission data register 0 for word access	CSIGnTX0W	<CSIGn_base_USER> + 0084 _H
Transmission data register 0 for half word access	CSIGnTX0H	<CSIGn_base_USER> + 0088 _H
Reception data register 0	CSIGnRX0	<CSIGn_base_USER> + 008C _H

<CSIGn_base> The base addresses <CSIGn_base> of CSIGn is defined in the first section of this chapter under the key word "Register addresses".

(1) CSIGNCTL0 - CSIG control register 0

This register controls the operation clock and enables/disables transmission/reception.

Access This register can be read/written in 8-bit or 1-bit units.

Address <CSIGN_base_USER> + 0000_H

Initial Value 00_H. This register is initialized by any reset.

Caution Be sure to set “0” to bits 4 to 1 and “1” to bit 0.

7	6	5	4	3	2	1	0
CSIGN PWR	CSIGN TXE	CSIGN RXE	0	0	0	0	^a
R/W	R/W	R/W	R	R	R	R	R/W

a) Be sure to set “1” to bit 0 though the initial value is 0.

Table 21-9 CSIGNCTL0 register contents

Bit position	Bit name	Function
7	CSIGNPWR	Controls operation clock. 0: Stop operation clock 1: Provide operation clock Clearing CSIGNPWR to 0 resets the internal circuits, stops operation, and sets CSIG to standby state. No clock is provided to internal circuits. If CSIGNPWR is cleared during communication, ongoing communication is immediately aborted. A restart of the communication is then required.
6	CSIGNTXE	Enables/disables transmission. 0: Transmission disabled 1: Transmission enabled
5	CSIGNRXE	Enables/disables reception. 0: Reception disabled 1: Reception enabled

-
- Cautions**
1. When CSIGNPWR = 0, do not change bits 6 (CSIGNTXE), 5 (CSIGNRXE), and 0.
However, these bits can be changed at the same time that the CSIGNPWR bit changes from 0 to 1.
 2. Do not modify CSIGNTXE or CSIGNRXE while a data transmission is pending or ongoing, i.e. if CSIGNSTR0.CSIGNTSF = 1.
-

(2) CSIGNCTL1 - CSIG control register 1

This register specifies the interrupt timing and the interrupt delay mode. It enables/disables extended data length control, data consistency check, loop-back mode, handshake function, and slave select function.

Access This register can be read/written in 32-bit units.

Address <CSIGN_base_OS> + 0010_H

Initial Value 0000 0000_H. This register is initialized by any reset.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0	0	0	0	0	0	0	0	0	0	0	0	0	0	CSIGNCKR	CSIGNSLIT
R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	0	0	0	CSIGNEDLE	0	CSIGNDCS	0	CSIGNLBM	CSIGNSIT	CSIGNHSE	CSIGNSSE
R	R	R	R	R	R	R	R	R/W	R	R/W	R	R/W	R/W	R/W	R/W

Caution Changing the contents of this register is only permitted when CSIGNCTL0.CSIGNPWR = 0.

Table 21-10 CSIGNCTL1 register contents (1/2)

Bit position	Bit name	Function
17	CSIGNCKR	Selects the CSIGNTSCK clock phase. 0: The CSIGNTSCK default level is high. 1: The CSIGNTSCK default level is low. This bit is used in combination with the CSIGNCFG0.CSIGNDAP bit. For details, refer to (7) "CSIGNCFG0 - CSIG configuration register 0" on page 1125.
16	CSIGNSLIT	Selects the timing of interrupt CSIGNTIC. 0: Normal interrupt timing (interrupt is generated after the transfer) 1: Interrupt generation when CSIGNTX0W or CSIGNTX0H is free for next data. For details, refer to (1) "CSIGNTIC (communication interrupt)" on page 1106.
7	CSIGNEDLE	Enables/disables extended data length (EDL) mode. 0: Extended data length mode disabled 1: Extended data length mode enabled For details, refer to (2) "Data length greater than 16 bits" on page 1102.
5	CSIGNDCS	Enables/disables data consistency check. 0: Data consistency check disabled 1: Data consistency check enabled For details, refer to (1) "Data consistency check" on page 1111.
3	CSIGNLBM	Controls loop-back mode (LBM). 0: Loop-back mode deactivated 1: Loop-back mode activated For details, refer to 21.3.10 "Error detection" on page 1111 . This bit cannot be changed in the slave mode.
2	CSIGNSIT	Selects interrupt delay mode. 0: No delay 1: Half clock delay for all interrupts This bit is only valid in master mode. In slave mode, no delay is generated. For details, refer to 21.3.8 "CSIG interrupts" on page 1106 .

Table 21-10 CSIGNCTL1 register contents (2/2)

Bit position	Bit name	Function
1	CSIGNHSE	Enables/disables handshake mode. 0: Handshake function disabled 1: Handshake function enabled For details, refer to 21.3.9 "Handshake function" on page 1109.
0	CSIGNSSE	Enables/disables slave select function (SS). 0: Input signal $\overline{\text{CSIGNTSSI}}$ is ignored 1: Input signal $\overline{\text{CSIGNTSSI}}$ is enabled If the slave select function is not used, this bit must be set to 0 (see also 21.3.2 "Master/slave connections" on page 1098).

Details about CSIGNCTL1.CSIGNSSE:

Table 21-11 Operation of the slave select function during reception

CSIGNCTL0. CSIGNRXE	CSIGNCTL1. CSIGNSSE	$\overline{\text{CSIGNTSSI}}$	Reception operation
0	–	–	Reception disabled
1	0	–	Possible
1	1	0	Possible
1	1	1	Impossible

Table 21-12 Operation of the slave select function during transmission

CSIGNCTL0. CSIGNTXE	CSIGNCTL1. CSIGNSSE	$\overline{\text{CSIGNTSSI}}$	Transmission operation
0	–	–	Transmission disabled
1	0	–	Possible
1	1	0	Possible
1	1	1	Impossible

(3) CSIGNCTL2 - CSIG control register 2

This register selects the operating mode, prescaler, and baud rate.

Access This register can be read/written in 16-bit units.

Address <CSIGN_base_OS> + 0014_H

Initial Value E000_H. This register is initialized by any reset.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CSIGNPRS[2:0]			0	CSIGNBRS[11:0]											
R/W	R/W	R/W	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Caution Changing the contents of this register is only permitted when CSIGNCTL0.CSIGNPWR = 0.

Table 21-13 CSIGNCTL2 register contents

Bit position	Bit name	Function

4095	PCLK / (2 ^m × 4095 × 2)																																					

(4) CSIGNSTR0 - CSIG status register 0

This register indicates the status of CSIG.

Access This register can be read in 32-bit units.

Address <CSIGN_base_USER> + 0004_H

Initial Value 0000 0010_H. This register is initialized by any reset.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 21-14 CSIGNSTR0 register contents (2/2)

Bit position	Bit name	Function
3	CSIGNDCE	<p>Data consistency error flag</p> <p>0: No data consistency error detected</p> <p>1: Data consistency error detected</p> <p>This bit is cleared by setting CSIGNSTCR0.CSIGNDCEC.</p> <p>This bit can be written to when CSIGNCTL0.CSIGNPWR = 0.</p> <p>This bit is initialized when CSIGNCTL0.CSIGNPWR changes from 0 to 1 or from 1 to 0.</p> <p>If this bit is set due to a data consistency error being detected and cleared by CSIGNSTCR0.CSIGNDCEC at the same time, setting the bit is prioritized.</p>
1	CSIGNPE	<p>Parity error flag</p> <p>0: No parity error detected</p> <p>1: Parity error detected</p> <p>This bit is cleared by setting CSIGNSTCR0.CSIGNPEC.</p> <p>This bit can be written to when CSIGNCTL0.CSIGNPWR = 0.</p> <p>This bit is initialized when CSIGNCTL0.CSIGNPWR changes from 0 to 1 or from 1 to 0.</p> <p>If this bit is set due to a parity error being detected and cleared by CSIGNSTCR0.CSIGNPEC at the same time, setting the bit is prioritized.</p>
0	CSIGNOVE	<p>Overrun error flag</p> <p>0: No overrun error detected</p> <p>1: Overrun error detected</p> <p>This bit is cleared by setting CSIGNSTCR0.CSIGNOVEC.</p> <p>This bit can be written to when CSIGNCTL0.CSIGNPWR = 0.</p> <p>This bit is initialized when CSIGNCTL0.CSIGNPWR changes from 0 to 1 or from 1 to 0.</p> <p>This bit is fixed to 0 in the dual buffer mode.</p> <p>If this bit is set due to an overrun error being detected and cleared by CSIGNSTCR0.CSIGNOVEC at the same time, setting the bit is prioritized.</p>

(5) CSIGNSTCR0 - CSIG status clear register 0

This register clears the status flags of the CSIGNSTR0 status register.

Access This register can be written in 16-bit units.

When read, the value 0000_H is always returned.

Address <CSIGN_base_USER> + 0008_H

Initial Value 0000_H. This register is initialized by any reset.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	0	0	0	0	0	0	0	CSIGN DCEC	0	CSIGN PEC	CSIGN OVEC
R	R	R	R	R	R	R	R	R	R	R	R	W	R	W	W

Table 21-15 CSIGNSTCR0 register contents

Bit position	Bit name	Function
3	CSIGNDCEC	Controls the data consistency error flag clear command. 0: No operation. Read value is always 0. 1: Clear data consistency error flag (CSIGNSTR0.CSIGNDCE)
1	CSIGNPEC	Controls the parity error flag clear command. 0: No operation. Read value is always 0. 1: Clear parity error flag (CSIGNSTR0.CSIGNPE)
0	CSIGNOVEC	Controls the overrun error flag clear command. 0: No operation. Read value is always 0. 1: Clear overrun error flag (CSIGNSTR0.CSIGNOVE)

(6) CSIGNBCTL0 - CSIG reception mode control register 0

This register enables/disables the data transfer in reception mode.

Access This register can be read/written in 8-bit or 1-bit units.

Address <CSIGN_base_USER> + 0080_H

Initial Value 01_H. This register is initialized by any reset.

7	6	5	4	3	2	1	0
0	0	0	0	0	0	0	CSIGNsCE
R	R	R	R	R	R	R	R/W

Table 21-16 CSIGNBCTL0 register contents

Bit position	Bit name	Function
0	CSIGNsCE	Disables/enables next data reception start by reading CSIGNRX0. 0: Next reception disabled 1: Next reception enabled For details, refer to (2) "Reception mode" on page 1101 and 21.3.7 "Communication in slave mode" on page 1105 .

- Cautions**
1. Writing the CSIGNsCE bit must be executed one clock before a CSIGNTIR interrupt is generated.
 2. The CSIGNsCE bits must be fixed to 1 when the operating mode is transmission or transmission/reception mode.

(7) CSIGNCFG0 - CSIG configuration register 0

This register configures the communication protocol – data length, parity, transfer direction, clock phase, and data phase.

Access This register can be read/written in 32-bit units.

Address <CSIGN_base_OS> + 1010_H

Initial Value 0000 0000_H. This register is initialized by any reset.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0	0	CSIGNPS[1:0]		CSIGNDLS[3:0]				0	0	0	0	0	CSIGNDIR	0	CSIGNDAP
R	R	R/W	R/W	R/W	R/W	R/W	R/W	R	R	R	R	R	R/W	R	R/W
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

- Cautions**
1. Writing is only possible when CSIGNCTL0.CSIGNPWR = 0 (except when writing the same value, which is possible even when CSIGNCTL0.CSIGNPWR = 1).
 2. Be sure to clear bits 31, 30, 23 to 19, 17, and 15 to 0.

Table 21-17 CSIGNCFG0 register contents (1/2)

Bit position	Bit name	Function			
29 and 28	CSIGNPS [1:0]	Specifies the parity.			
		CSIGNPS1	CSIGNPS0	Transmission	Reception
		0	0	No parity transmitted	Parity reception is not expected.
		0	1	Add parity bit fixed at 0	Parity bit reception is expected, but parity judgment is not performed.
		1	0	Add odd parity	Odd parity bit reception is expected.
1	1	Add even parity	Even parity bit reception is expected.

(8) CSIGNTX0W - Transmission data register 0 for word access

This register stores the transmission data. It has to be used when the extended data length function is enabled (CSIGNCTL1.SIGNEDLE = 1).

Access This register can be read/written in 32-bit units.

Address <CSIGN_base_USER> + 0084_H

Initial Value Undefined

Caution Writing to this register is prohibited when CSIGNCTL0.SIGNTXE and CSIGNCTL0.SIGNRXE = 0.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0	0	CSIGN EDL	0	0	0	0	0	0	0	0	0	0	0	0	0

Table 21-18 CSIGNTX0W register contents

Bit position	Bit name	Function
29	CSIGNEDL	Specifies whether the associated data requires the extended data length (EDL) option. 0: Normal operation 1: Extended data length activated The associated data is transmitted as of 16 bits. The inter-data delay time and idle time are not inserted after data transmission. When CSIGNCTL1.SIGNEDLE = 1 and CSIGNTX0W.SIGNEDL = 1, the same slave must also be selected for the second data. If the slave for the second data is changed, the correct operation is not guaranteed. Caution This bit can only be used when CSIGNCTL1.SIGNEDLE = 1.
15 to 0	CSIGN TX[15:0]	Stores the transmission data.

(9) CSIGNTX0H - Transmission data register 0 for half word access

This register stores the transmission data. It can be used when the Extended Data Length function is disabled (CSIGNCTL1.CSIGNEDLE = 0).

Access This register can be read/written in 16-bit units.

Address <CSIGN_base_USER> + 0088_H

Initial Value 0000_H. This register is initialized by any reset.

Caution Writing to this register is prohibited when CSIGNCTL0.CSIGNTXE and CSIGNCTL0.CSIGNRXE = 0.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 21-19 CSIGNTX0H register contents

Bit position	Bit name	Function
15 to 0	CSIGN TX[15:0]	Stores the transmission data.

(10) CSIGNRX0 - Reception data register 0

This register stores the received data.

Access This register can be read in 16-bit units.

Address <CSIGN_base_USER> + 008C_H

Initial Value 0000_H. This register is initialized by any reset.

- Cautions**
1. This register can be read when CSIGNCTL0.CSIGNPWR = 1, and can be written to when CSIGNCTL0.CSIGNPWR = 0.
 2. This register is initialized when the value of CSIGNCTL0.CSIGNPWR changes.
 3. Reading this register is prohibited when CSIGNCTL0.CSIGNTXE and CSIGNCTL0.CSIGNRXE = 0.

Table 21-20 CSIGNRX0 register contents

Bit position	Bit name	Function
15 to 0	CSIGNRX[15:0]	Stores the reception data.

21.5 Operating Procedure Example

(1) For transmission/reception in the master mode

The following conditions are assumed for the procedure shown here:

- Transmission data length: 8 bits (CSIGNCFG0.CSIGNDLS[3:0] = 1000_B)
- Transmission direction: MSB first (CSIGNCFG0.CSIGNDIR = 0)
- Normal clock phase and data phase (CSIGNCTL1.CSIGNCKR = 0, CSIGNCFG0.CSIGNDAP = 0)
- No delay for any interrupt (CSIGNCTL1.CSIGNSIT = 0)
- A CSIGNTIC interrupt is generated when transferring starts. (CSIGNCTL1.CSIGNCLIT = 1)

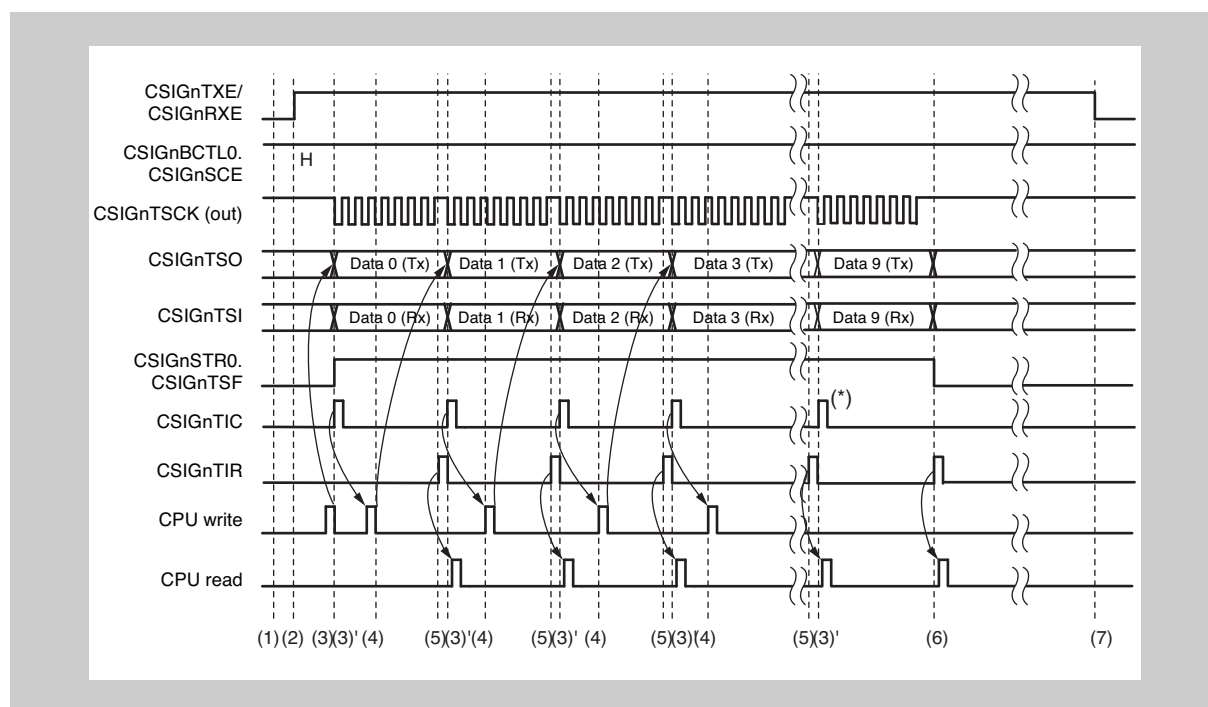

Figure 21-26 For transmission/reception in the master mode

- Procedure:**
1. Set up the following registers before setting CSIGNCTL0.CSIGNPWR to 1: CSIGNCTL1, CSIGNCTL2, CSIGNBCTL0, CSIGNCFG0
 2. CSIGNCTL0.CSIGNPWR = 1 (clock enabled)
CSIGNCTL0.CSIGNTXE = 1 (transmission enabled)
CSIGNCTL0.CSIGNRXE = 1 (reception enabled)
Bit 0 of CSIGNCTL0 = 1
 3. Write the first data to the transmission data register CSIGNTX0W. Transmission automatically starts.
 - 3'. When CSIGNCTL1.CSIGNSLIT is set to 1, CSIGNTIC is generated at the start edge of CSIGNTSCK. CSIGNTIC indicates that the second data can be written to CSIGNTX0W.
 4. Write the second data to CSIGNTX0W. By writing the second data immediately after writing the first data, the unnecessary inter-data delay can be avoided.

5. Each time data is received, a CSIGNTIR interrupt is generated.
 - CSIGNTIR indicates that the reception data register CSIGNRX0 must be read.
6. If the CSIGNTIC interrupt indicated by “*” in the figure is the last one, it is not necessary to write to the transmission data register CSIGNTX0W based on the corresponding CSIGNTIC interrupt.
7. Finally, clear CSIGNCTL0.CSIGNTXE and CSIGNCTL0.CSIGNRXE to disable transmission/reception operations. In addition, clear CSIGNCTL0.CSIGNPWR to reduce the power consumption of CSIG.

(2) For reception in the master mode

The following conditions are assumed for the procedure shown here:

- Transmission data length: 8 bits (CSIGNCFG0.CSIGNDLS[3:0] = 1000_B)
- Transmission direction: MSB first (CSIGNCFG0.CSIGNDIR = 0)
- Normal clock phase and data phase (CSIGNCTL1.CSIGNCKR = 0, CSIGNCFG0.CSIGNDAP = 0)
- No delay for any interrupt (CSIGNCTL1.CSIGNSIT = 0)
- A CSIGNTIC interrupt is generated when transferring starts. (CSIGNCTL1.CSIGNCLIT = 1)

Figure 21-27 For reception in the master mode

- Procedure:**
1. Set up the following registers before setting CSIGNCTL0.CSIGNPWR to 1: CSIGNCTL1, CSIGNCTL2, CSIGNBCTL0, CSIGNCFG0
 2. CSIGNCTL0.CSIGNPWR = 1 (clock enabled)
CSIGNCTL0.CSIGNTXE = 0 (transmission disabled)
CSIGNCTL0.CSIGNRXE = 1 (reception enabled)
Bit 0 of CSIGNCTL0 = 1
 3. Read the dummy data from the reception data register CSIGNRX0. Reception automatically starts.
 - 3'. When CSIGNCTL1.CSIGNSLIT is set to 1, CSIGNTIC is generated at the start edge of CSIGNTSCK.
 4. Each time data is received, a CSIGNTIR interrupt is generated.
 - CSIGNTIR indicates that the reception data register CSIGNRX0 must be read.
 5. To finish the consecutive reception with the data currently received, clear the CSIGNBCTL0.CSIGNSCE bit.
 6. Reception does not start even if reception data is read.

7. Finally, clear CSIGNCTL0.CSIGNRXE to disable reception operations. In addition, clear CSIGNCTL0.CSIGNPWR to reduce the power consumption of CSIG.

(3) For transmission/reception in the slave mode

The following conditions are assumed for the procedure shown here:

- Transmission data length: 8 bits (CSIGNCFG0.CSIGNDLS[3:0] = 1000_B)
- Transmission direction: MSB first (CSIGNCFG0.CSIGNDIR = 0)
- Normal clock phase and data phase (CSIGNCTL1.CSIGNCKR = 0, CSIGNCFG0.CSIGNDAP = 0)
- No delay for any interrupt (CSIGNCTL1.CSIGNSIT = 0)
- A CSIGNTIC interrupt is generated when transferring starts. (CSIGNCTL1.CSIGNCLIT = 1)

Figure 21-28 For transmission/reception in the slave mode

- Procedure:**
1. Set up the following registers before setting CSIGNCTL0.CSIGNPWR to 1: CSIGNCTL1, CSIGNCTL2, CSIGNBCTL0, CSIGNCFG0
 2. CSIGNCTL0.CSIGNPWR = 1 (clock enabled)
CSIGNCTL0.CSIGNTXE = 1 (transmission enabled)
CSIGNCTL0.CSIGNRXE = 1 (reception enabled)
Bit 0 of CSIGNCTL0 = 1
 3. Write the first data to the transmission data register CSIGNTX0W.
 4. When a serial clock is supplied from the master, transmission automatically starts.
When CSIGNCTL1.CSIGNSLIT is set to 1, CSIGNTIC is generated at the start edge of CSIGNTSCK. CSIGNTIC indicates that the second data can be written to CSIGNTX0W.
 5. Write the second data to CSIGNTX0W. By writing the second data immediately after writing the first data, the unnecessary inter-data delay can be avoided.

6. Each time data is received, a CSIGNTIR interrupt is generated.
 - CSIGNTIR indicates that the reception data register CSIGNRX0 must be read.
7. If the CSIGNTIC interrupt indicated by “*” in the figure is the last one, it is not necessary to write to the transmission data register CSIGNTX0W based on the corresponding CSIGNTIC interrupt.
8. Finally, clear CSIGNCTL0.CSIGNTXE and CSIGNCTL0.CSIGNRXE to disable transmission/reception operations. In addition, clear CSIGNCTL0.CSIGNPWR to reduce the power consumption of CSIG.

(4) For reception in the slave mode

The following conditions are assumed for the procedure shown here:

- Transmission data length: 8 bits (CSIGNCFG0.CSIGNDLS[3:0] = 1000_B)
- Transmission direction: MSB first (CSIGNCFG0.CSIGNDIR = 0)
- Normal clock phase and data phase (CSIGNCTL1.CSIGNCKR = 0, CSIGNCFG0.CSIGNDAP = 0)
- No delay for any interrupt (CSIGNCTL1.CSIGNSIT = 0)
- A CSIGNTIC interrupt is generated when transferring starts. (CSIGNCTL1.CSIGNCLIT = 1)

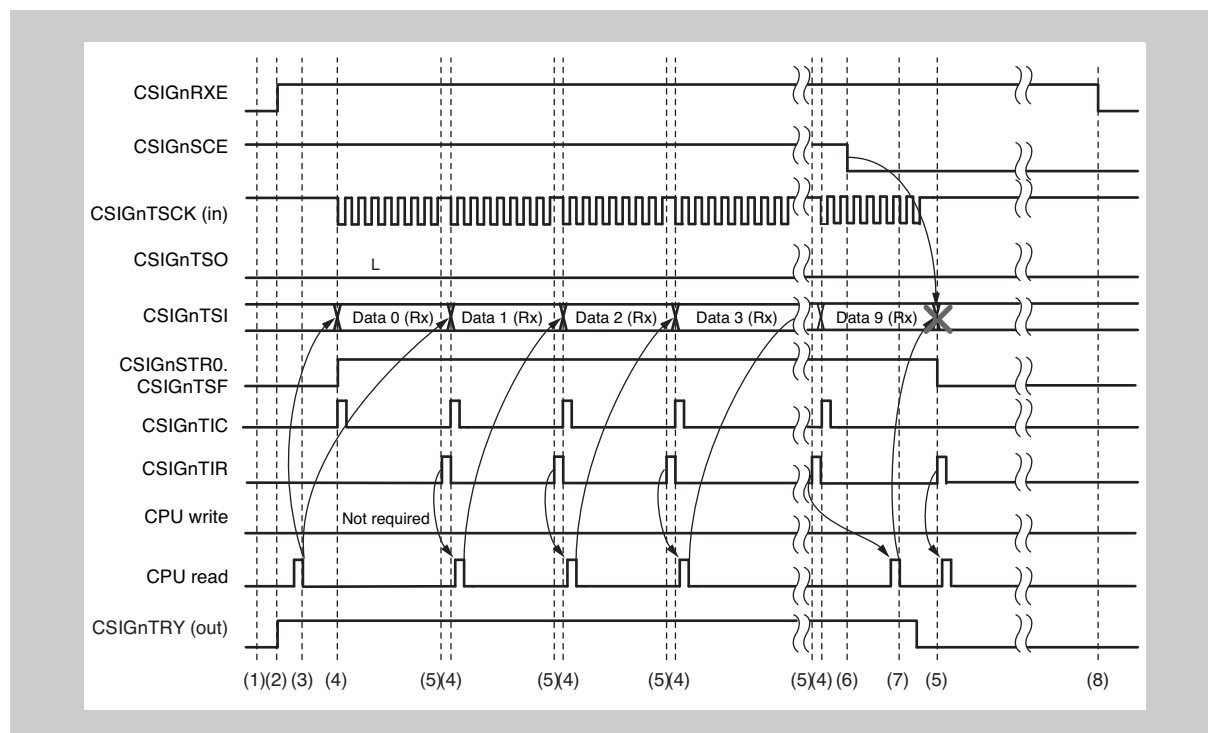

Figure 21-29 For reception in the slave mode

- Procedure:**
1. Set up the following registers before setting CSIGNCTL0.CSIGNPWR to 1: CSIGNCTL1, CSIGNCTL2, CSIGNBCTL0, CSIGNCFG0
 2. CSIGNCTL0.CSIGNPWR = 1 (clock enabled)
CSIGNCTL0.CSIGNTXE = 0 (transmission disabled)
CSIGNCTL0.CSIGNRXE = 1 (reception enabled)
Bit 0 of CSIGNCTL0 = 1
 3. Read the dummy data from the reception data register CSIGNRX0. Reception automatically starts.
 4. When a serial clock is supplied from the master, transmission automatically starts.
When CSIGNCTL1.CSIGNSLIT is set to 1, CSIGNTIC is generated at the start edge of CSIGNTSCK.
 5. Each time data is received, a CSIGNTIR interrupt is generated.
 - CSIGNTIR indicates that the reception data register CSIGNRX0 must be read.

6. To finish the consecutive reception with the data currently received, clear the CSIGNBCTL0.CSIGNSCE bit.
7. Reception does not start even if reception data is read.
8. Finally, clear CSIGNCTL0.CSIGNRXE to disable reception operations. In addition, clear CSIGNCTL0.CSIGNPWR to reduce the power consumption of CSIG.

Chapter 22 Clocked Serial Interface H (CSIH)

This chapter contains a generic description of clocked serial interface H (CSIH).

The first section describes all V850E2/ML4 specific properties, such as instances, register base addresses, and input/output signal names. The subsequent sections describe the features that apply to all implementations.

22.1 V850E2/ML4 CSIH Features

Instances This microcontroller has the following number of instances of CSIH.

Table 22-1 Instances of CSIH

Clocked serial interface H	
Instance	2
Name	CSIH0, CSIH1

Instances index n Throughout this chapter, the individual instances of CSIH is identified by the index "n" (n = 0, 1), for example, CSIHnCTL0 for CSIHn control register 0.

Chip select index x CSIH has up to 8 chip select signals. Throughout this chapter, the individual chip select signals are identified by the index "x" (x = 0 to 7), thus a certain chip select signal is denoted as CSx.
The number of chip selects for each instance of CSIH is given in the following table:

Table 22-2 Number of chip select signals of CSIH

CSIHn instance	Chip select signal numbers
CSIH0	CS0 to CS7
CSIH1	CS0 to CS7

Register addresses All CSIHn register addresses are given as addresses offset from the individual base address <CSIHn_base_USER> or <CSIHn_base_OS>. The base addresses <CSIHn_base_USER> and <CSIHn_base_OS> of each CSIHn are listed in the following table:

Table 22-3 Register base addresses

CSIHn instance	Base address	<CSIHn_base> address
CSIH0	<CSIHn_base_USER>	FFFF E000 _H
	<CSIHn_base_OS>	FF6C 0000 _H
CSIH1	<CSIHn_base_USER>	FFFF E100 _H
	<CSIHn_base_OS>	FF6D 0000 _H

Clock supply All CSIH provide one clock input:

Table 22-4 CSIHn clock supply

CSIHn instance	CSIHn clock	Connected to
CSIH0, CSIH1	PCLK	f _{PCLK}

Maximum transfer speed (baud rate) For CSIH, communication is possible at the maximum transfer speeds (baud rates) listed in the following table.

Table 22-5 Maximum CSIHn transfer speeds (baud rates)

Mode	Maximum transfer speed (baud rate)
Master mode	5.625 Mbps (Max.)
Slave mode	5.625 Mbps (Max.)

Interrupts and DMA/DTS CSIH can generate the following interrupt and DMA/DTS requests:

Table 22-6 CSIHn interrupt and DMA/DTS requests

CSIHn signals	Function	Connected to
CSIH0		
CSIH0TIC	Communication status interrupt	<ul style="list-style-type: none"> Interrupt controller 145 (INTCSIH0IC) DTS controller trigger 84
CSIH0TIR	Reception status interrupt	<ul style="list-style-type: none"> Interrupt controller 144 (INTCSIH0IR) DTS controller trigger 83
CSIH0TIRE	Communication error interrupt	<ul style="list-style-type: none"> Interrupt controller 143 (INTCSIH0IRE)
CSIH0TIJC	Job completion interrupt	<ul style="list-style-type: none"> Interrupt controller 146 (INTCSIH0IJC)
CSIH1		
CSIH1TIC	Communication status interrupt	<ul style="list-style-type: none"> Interrupt controller 149 (INTCSIH1IC) DTS controller trigger 87
CSIH1TIR	Reception status interrupt	<ul style="list-style-type: none"> Interrupt controller 148 (INTCSIH1IR) DTS controller trigger 86
CSIH1TIRE	Communication error interrupt	<ul style="list-style-type: none"> Interrupt controller 147 (INTCSIH1IRE)
CSIH1TIJC	Job completion interrupt	<ul style="list-style-type: none"> Interrupt controller 150 (INTCSIH1IJC)

I/O signals The I/O signals of CSIH are listed in the following table.

Table 22-7 CSIHn I/O signals

CSIHn signal	Function	Connected to
CSIH0		
CSIH0TCK	Serial clock signal	Port SCK0F
CSIH0TSI	Serial data input signal	Port SI0F
CSIH0TSO	Serial data output signal	Port SO0F
$\overline{\text{CSIH0TSSI}}$	Slave select input signal	Port CSI0F_SSI
CSIH0TRYO	Ready/busy output signal	Port CSI0F_RYO
CSIH0TRYI	Ready/busy input signal	Port CSI0F_RYI
CSIH0TCSSn[7:0]	Chip select signals	Port CSI0F_CS[7:0]
CSIH1		
CSIH1TCK	Serial clock signal	Port SCK1F
CSIH1TSI	Serial data input signal	Port SI1F
CSIH1TSO	Serial data output signal	Port SO1F
$\overline{\text{CSIH1TSSI}}$	Slave select input signal	Port CSI1F_SSI
CSIH1TRYO	Ready/busy output signal	Port CSI1F_RYO
CSIH1TRYI	Ready/busy input signal	Port CSI1F_RYI
CSIH1TCSSn[7:0]	Chip select signals	Port CSI1F_CS[7:0]

22.2 Functional Overview

- Features summary**
- Three-wire serial synchronous data transfer
 - Master mode and slave mode selectable
 - Multiple slaves configuration plus RCB (Recessive Configuration for Broadcasting) thanks to eight configurable chip select output signals
 - Slave select input signal ($\overline{\text{CSIHnTSSI}}$)
 - Built-in baud rate generator
 - Baud rate adjustable; in slave mode determined by input clock
 - Maximum transmission speed:
 - in master mode: PCLK/4
 - in slave mode: PCLK/6

Caution There might be restrictions on the maximum baud rate that can actually be used depending on the product. Specify the baud rate so as not to exceed the maximum rate for each product.

- Phase of clock and data selectable
- Data transfer with MSB or LSB first selectable
- Transfer data length selectable from 7 to 16 bits in 1-bit units
- Extended data length (EDL) function for transferring data with more than 16 bits
- Three selectable transfer modes:
 - transmit-only mode
 - receive-only mode
 - transmit/receive mode
- Built-in handshake function
- Error detection (data consistency check, parity, timeout, overflow, overrun)
- Full support of job concept
- 128 words I/O buffer memory
- Memory mode selectable (FIFO, dual buffer, Tx-only buffer, direct access)
- Four different interrupt request signals (CSIHnTIC, CSIHnTIR, CSIHnTIRE, CSIHnTIJC)
- Loop back mode (LBM) function for self test

The block diagram shows the main components of the CSIH.

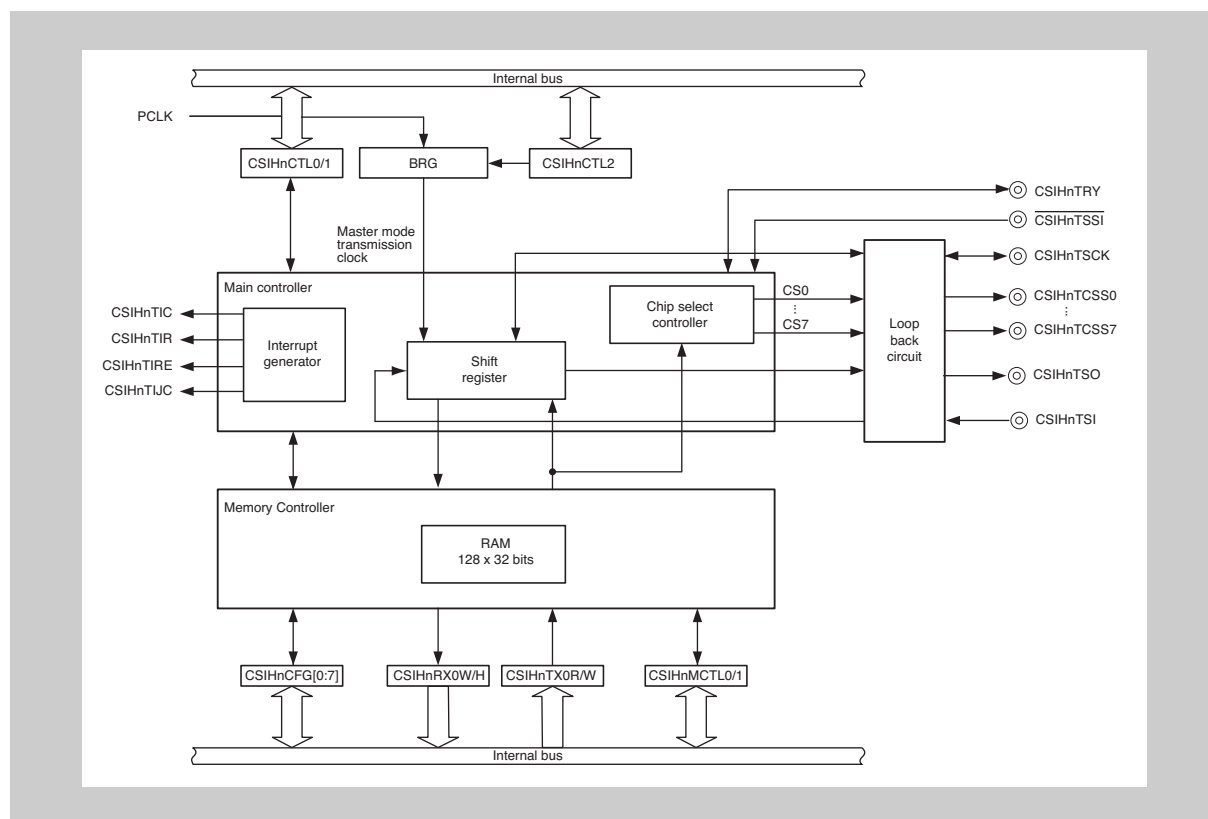

Figure 22-1 CSIH block diagram

In the master mode, the serial clock CSIHnTSCK is generated by the internal baud rate generator (BRG). In the slave mode, the serial clock is supplied from an external source.

The built-in memory can be configured as FIFO, dual buffer (separate transmit and receive buffers), or transmit-only buffer. It can also be bypassed for data transmission and reception without buffering.

The loop back circuit disconnects the CSIH completely from the ports and supports internal self test.

Note This chapter describes the following modes:

- The “operating mode” separates between master and slave mode. In this context, only a master can control and communicate with several slaves (for details, see 22.3.1 “Operating modes (master/slave)” on page 1144).
- The “job mode” is related to the Autosar job concept (for details, see 22.3.4 “Chip select timing details” on page 1150).
- The “memory mode” takes the various configurations of the associated buffer memory into account (for details, see 22.3.7 “CSIH buffer memory” on page 1155).
- The “data transfer mode” specifies the kind of the communication – transmit-only, receive only, or both (for details, see 22.3.8 “Data transfer modes” on page 1157).

22.3 Functional Description

The Clocked Serial Interface H uses three signals for communication:

- Serial clock CSIHnTSCK (output for the master mode or input for the slave mode)
- Data output signal CSIHnTSO
- Data input signal CSIHnTSI

Additional signals are available for external control and monitoring.

- $\overline{\text{CSIHnTSSI}}$: Slave select input signal
- CSIHnTRY: Handshake signal (input for the master mode or output for the slave mode)
- CSIHnTCSS[7:0]: Chip select signal

Data transmission is bit-wise and serial and synchronous to the serial clock.

The most important registers for setting up the CSIH are:

Register	Function
CSIHnCTL0	Enables or disables the operation clock (PCLK) and enables or disables data transmission and reception. Defines end-of-job behavior and enables/disables buffering (bypass of the buffer).
CSIHnCTL1	Controls options like interrupt timing, extended data length, job feature, data consistency check, loop-back mode, handshake, etc.
CSIHnCTL2	Selects master/slave mode and – effective in master mode – the baud rate of the Internal baud rate generator (BRG)
CSIHnMCTL0	Selects memory mode and specifies timeout
CSIHnMCTL1	Controls the memory in FIFO mode
CSIHnMCTL2	Controls the memory in the dual buffer mode or transmit-only buffer mode
CSIHnCFGx	Registers to configure the communication protocol for each chip select signal

22.3.1 Operating modes (master/slave)

Master/slave selection is performed by using the CSIHnCTL2.CSIHnPRS[2:0] bits, and, when the master is selected, the source clock of the transmission clock must also be selected.

(1) Master mode

In the master mode, the serial clock is generated by the internal baud rate generator (BRG) and provided to the slave(s) by signal CSIHnTSCK.

Master mode is enabled by setting CSIHnCTL2.CSIHnPRS[2:0] to anything but 111_B. In the master mode, the BRG frequency can be specified by specifying values for the CSIHnCTL2.CSIHnPRS[2:0] and CSIHnCTL2.CSIHnBRS[11:0] bits in combination.

Chip select signals In master mode, one or several chip select signals can be used. If several slaves are connected to the master, the chip select signals can be used to address one or several of the slaves. Only a selected slave is then enabled for communication.

The communication protocol as well as additional parameters are stored separately for each chip select signal. This makes it possible to adapt the data transfer individually to the requirements of each slave. For details, see 22.3.3 “Chip selection (CS) features” on page 1148.

Clock defaults The default level of CSIHnTSCK depends on the clock phase selection bit: It is high when CSIHnCFGx.CSIHnCKPx = 0, and is low when CSIHnCFGx.CSIHnCKPx = 1.

The example below shows the communication in master mode for 8 data bits, CSIHnCFGx.CSIHnCKPx = 0, CSIHnCFGx.CSIHnDAPx = 0, and MSB first:

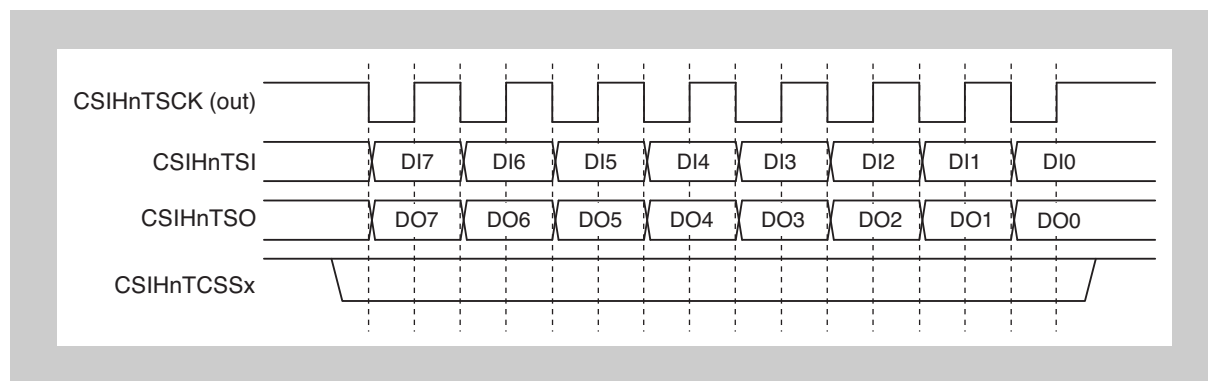

Figure 22-2 Transmit/receive in master mode

(2) Slave mode

In the slave mode, another device is the communication master. The serial clock is supplied through the CSIHnTSCK signal. When the serial clock signal is detected, a transmission or reception operation immediately starts.

Slave mode is selected by setting CSIHnCTL2.CSIHnPRS[2:0] to 111_B.

In slave mode, the transmission protocol setting of the CSIHnCFG0 register are relevant (The CSIHnCFG1 to CSIHnCFG7 register settings become invalid.):

- CSIHnPS0: Parity usage
- CSIHnDLS0: Data length selection
- CSIHnDIR0: Data direction
- CSIHnCKP0, CSIHnDAP0: Clock phase and data phase

Note When using the slave mode, the baud rate generator (BRG) can be disabled by clearing the CSIHnCTL2.CSIHnBRS[11:0] bits, reducing power consumption. However, when using the timeout error function, the BRG must be set to a value other than 0.

The example below shows the communication in the save mode for eight data bits when CSIHnCTL1.CSIHnCKR = 0, CSIHnCFGx.CSIHnDAPx = 0, and the MSB is first.

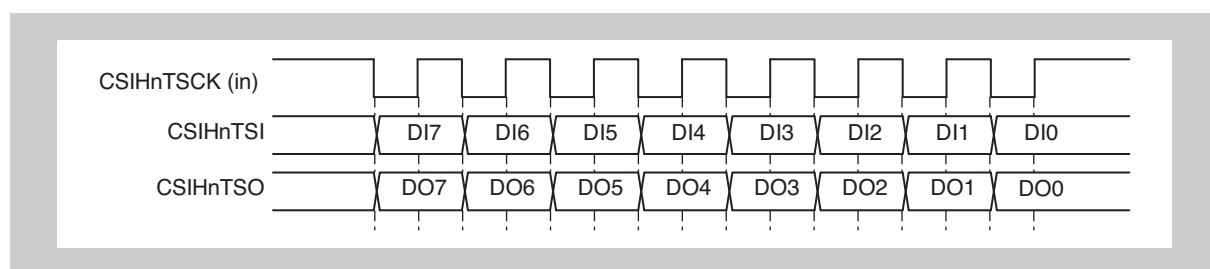

Figure 22-3 Transmission/reception in the slave mode

22.3.2 Master/slave connections

(1) One master and one slave

The following figure illustrates the connections between one master and one slave.

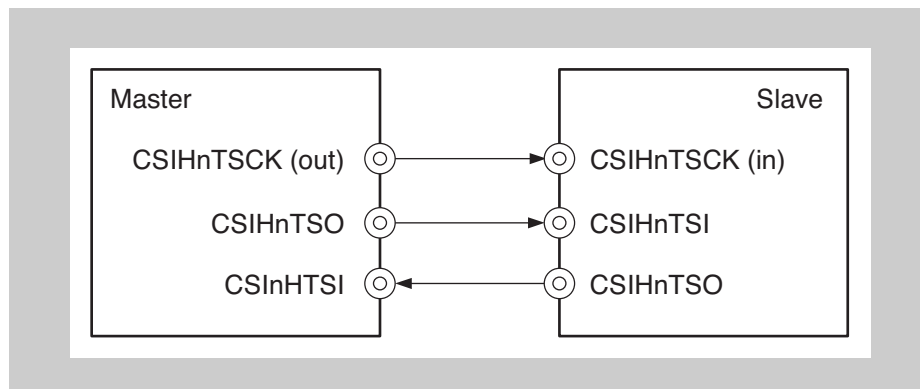

Figure 22-4 Direct master/slave connection

(2) One master and multiple slaves

The following figure illustrates the connections between one master and multiple slaves. In this example, a configuration in which the master supplies one chip select (CS) signal to each slave is possible. This signal is connected to the slave select input $\overline{\text{CSIHnTSSI}}$ of the slave.

The $\overline{\text{CSIHnTSSI}}$ signal recognition function can be enabled/disabled by bit CSIHnCTL1.CSIHnSSE.

Figure 22-5 Master to multiple slaves connection

The default chip select level is active low. In other words, when the slave select input signal ($\overline{\text{CSIHnTSSI}}$) of a slave is at the low level, that slave is selected as a CSIH slave (and enabled). However, to use a chip select signal (CS) for another device, programming that sets the chip select signal output level to active high is possible.

If a slave is not selected, it will neither receive nor transmit data. In addition, its output CSIHnTSO is set to input mode in order to avoid interference with the output of another slave that was selected.

(3) CSIHnTSO output control

The CSIH can output CSIHnTSO when all of the following conditions are satisfied:

- The CSIH is enabled (CSIHnCTL0.CSIHnPWR = 1).
- The CSIH is operated in transmit-only or transmit/receive mode (CSIHnCTL0.CSIHnTXE = 1).
- The CSIH is operated with slave select enabled (CSIHnCTL1.CSIHnSSE = 1).
- The slave mode selection signal $\overline{\text{CSIHnTSSI}}$ is inactive, i.e. on high level.

By this signal congestions on the external CSIHnTSO signal line are avoided.

22.3.3 Chip selection (CS) features

The chip select signals CSIHnTCSSx can be used by the master to select one or several slaves for communication.

(1) Configuration registers

The parameters for each chip select signal CSIHnTCSSx are defined in the corresponding configuration register CSIHnCFGx. The parameters include the communication protocol and additional CS parameters.

The communication protocol specifies:

- Data length: The number of bits to be sent or received.
- Transfer direction: MSB or LSB first.
- Parity usage: Odd, even, 0 parity, or none.
- Clock phase and data phase.

Additional parameters for each chip select and only available in master mode are:

- Prescaler selection of the baudrate generator separately for each chip select
- Chip select priority: Separates between “dominant” and “recessive” chip select signals. The priority applies if two or more chip selects with different configurations are simultaneously activated for message broadcasting. In this case, the configuration that is set as dominant is used.

The principle is also called “Recessive Configuration for Broadcasting” (RCB).

Caution It is forbidden to specify several chip select signals as dominant with different configurations unless all dominant chip selects have the same configuration.

- Chip select timing:
 - Setup time T_{setup} : The time from setting the CS signal active to starting data output.
 - Inter-data time T_{inter} : The time between data while the same CS signal is active.
 - Hold time T_{hold} : Hold time of CS active level before changing the CS.
 - Idle time T_{idle} : Inactive time after terminating a CS signal or after every data transfer to the same CSx.

The figure below shows the timing of the chip select (CSx) signal setup time, inter-data time, hold time, and idle time. No matter which CSIHnCFGx.CSIHnIDLx bit is set (to 1), idle time is added to all CS segments.

Figure 22-6 “Chip select timings” shows an example in which the default active low setting is specified for the CS1 and CS2 signals (CSIHnCTL1.CSIHnCSL1 = 0, CSIHnCTL1.CSIHnCSL2 = 0). The active level can be separately specified for each CS.

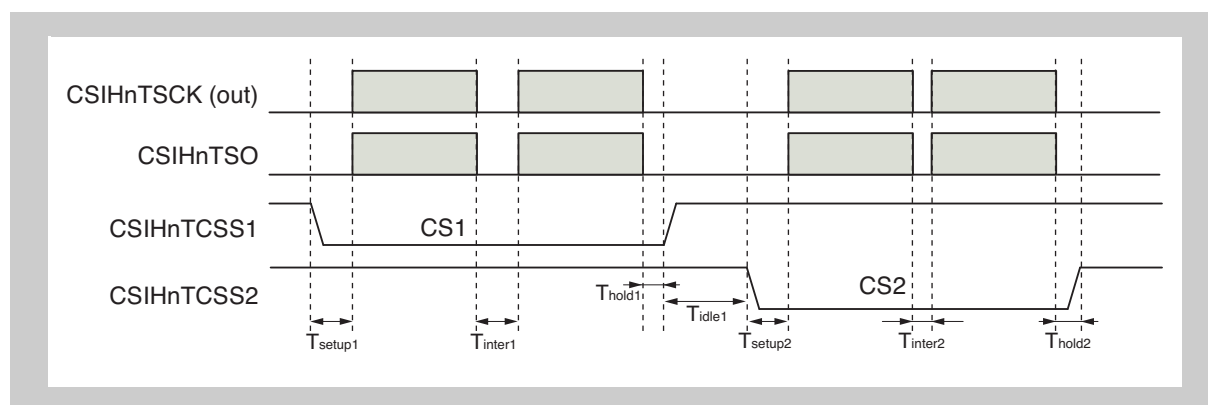

Figure 22-6 Chip select timings

Note that each CS can have a different value for setup, inter-data gap, hold and idle periods

A particular chip select signal is activated by setting the appropriate bit in the transmission data register CSIHnTX0W.CSIHnCS[7:0].

The reception data register indicates in CSIHnRX0W.CSIHnCS[7:0] the chip select signal associated with the received data.

(2) CS example

The following figure shows an example of two consecutive transmissions.

The first communication uses CS0 to address one single slave. The second (for which communication is performed using the dominant-side communication settings) enables CS0 and CS1 to broadcast a message to two slaves. The priority of CS0 is set to “recessive: low priority”, the priority of CS1 to “dominant: high priority”.

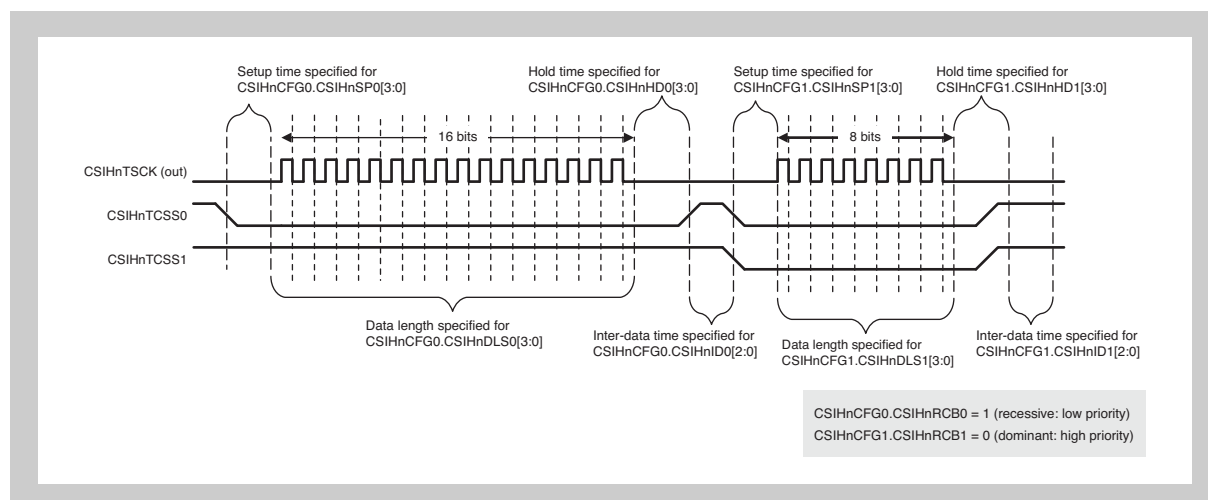

Figure 22-7 Chip select and RCB example

22.3.4 Chip select timing details

(1) Changing the clock phase

The serial clock level is specified for each chip select according to $\text{CSIHnCFGx.CSIHnCKPx}$. The chip select or serial clock level is switched during the idle time. The minimum idle time is 1/2 of a serial clock (CSIHnTSCK) cycle (0.5 SCK).

If the idle time is set to 0.5 transmission clock cycles (in $\text{CSIHnCFGx.CSIHnIDx}[2:0]$) and two consecutive data are sent with different $\text{CSIHnCFGx.CSIHnCKPx}$ configuration, the idle time is automatically extended to one cycle of CSIHnTSCK .

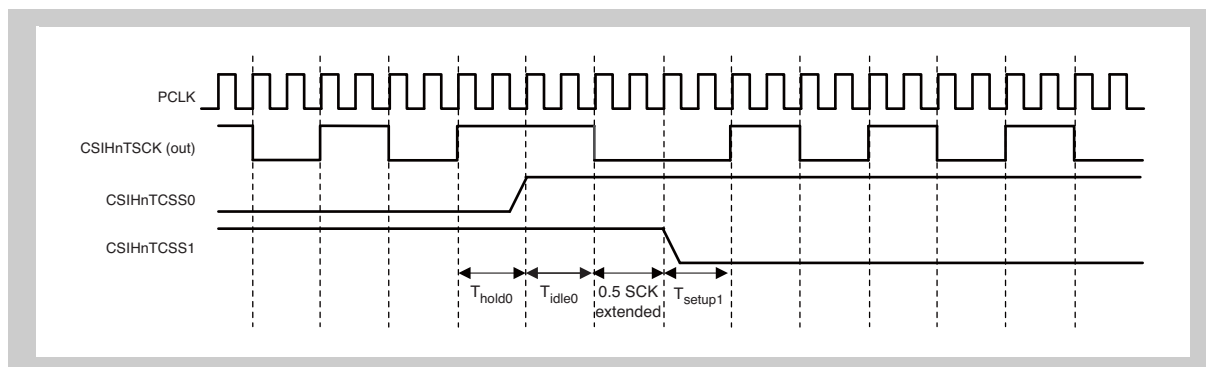

Figure 22-8 Clock phase timing (in the case of $\text{PCLK}/4$, $T_{\text{hold}0} = T_{\text{setup}1} = 0.5 \text{ SCK}$, $T_{\text{idle}0} = 0.5 \text{ SCK}$, $\text{CKP}0 = 0$ ($\text{CSIHnTCSS}0$) \rightarrow $\text{CKP}1 = 1$ ($\text{CSIHnTCSS}1$))

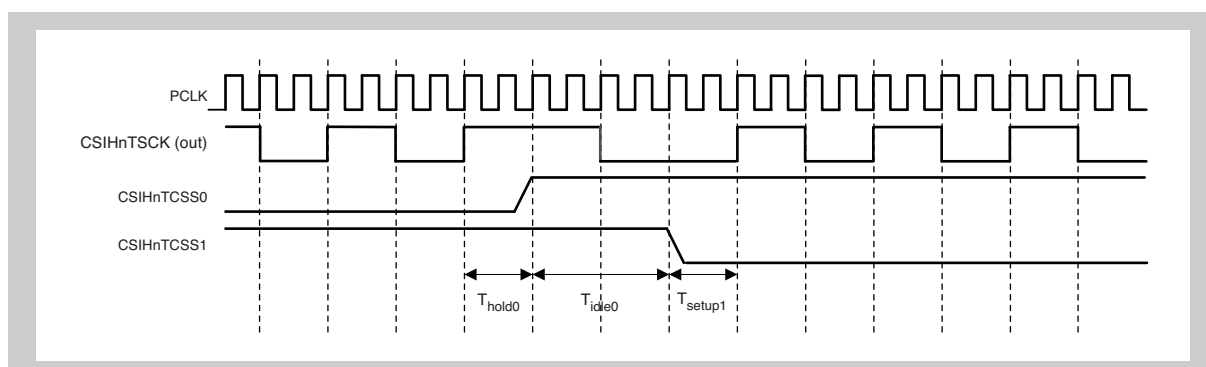

Figure 22-9 Clock phase timing (in the case of $\text{PCLK}/4$, $T_{\text{hold}0} = T_{\text{setup}1} = 0.5 \text{ SCK}$, $T_{\text{idle}0} = 1.0 \text{ SCK}$, $\text{CKP}0 = 0$ ($\text{CSIHnTCSS}0$) \rightarrow $\text{CKP}1 = 1$ ($\text{CSIHnTCSS}1$))

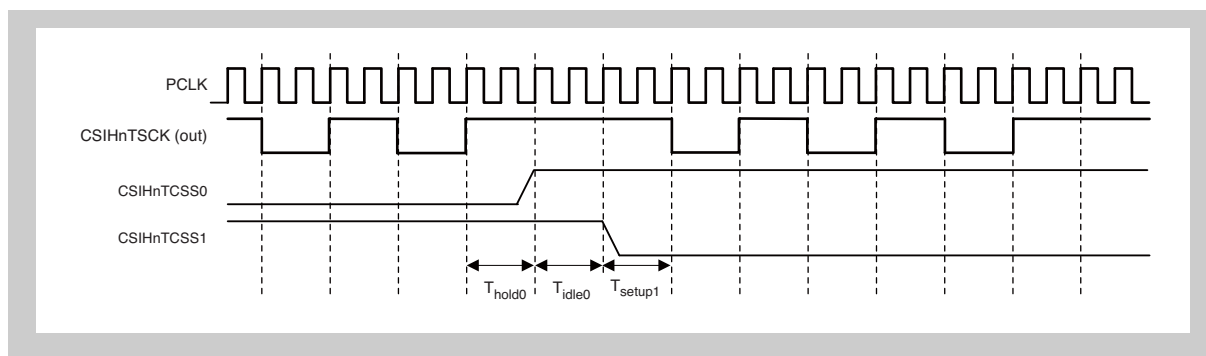

Figure 22-10 Clock phase timing (in the case of $\text{PCLK}/4$, $T_{\text{hold}0} = T_{\text{setup}1} = 0.5 \text{ SCK}$, $T_{\text{idle}0} = 0.5 \text{ SCK}$, $\text{CKP}0 = 0$ ($\text{CSIHnTCSS}0$) \rightarrow $\text{CKP}1 = 0$ ($\text{CSIHnTCSS}1$))

(2) Changing the data phase

The bit CSIHnCFGx.CSIHnDAPx defines the phase of the data bits relative to the clock.

If CSIHnCFGx.CSIHnDAPx = 0, the transmission clock CSIHnTSCK holds its level after the last bit of a data is transferred.

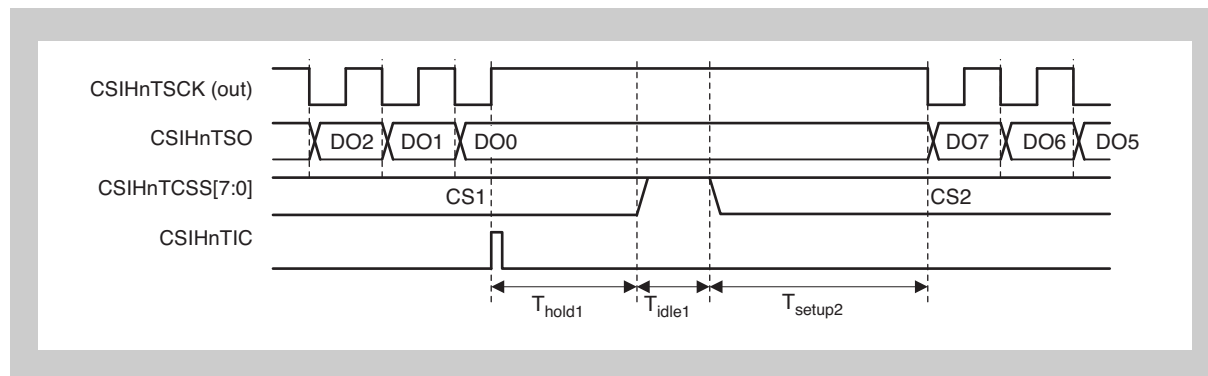

Figure 22-11 Data phase timing with
 CSIHnCFG1.CSIHnCKP1 = 0, CSIHnCFG1.CSIHnDAP1 = 0 and
 CSIHnCFG2.CSIHnCKP2 = 0, CSIHnCFG2.CSIHnDAP2 = 0

If the default clock phase changes between two consecutive chip selects, the transmission clock CSIHnTSCK changes its level after the last bit of the first data is transferred:

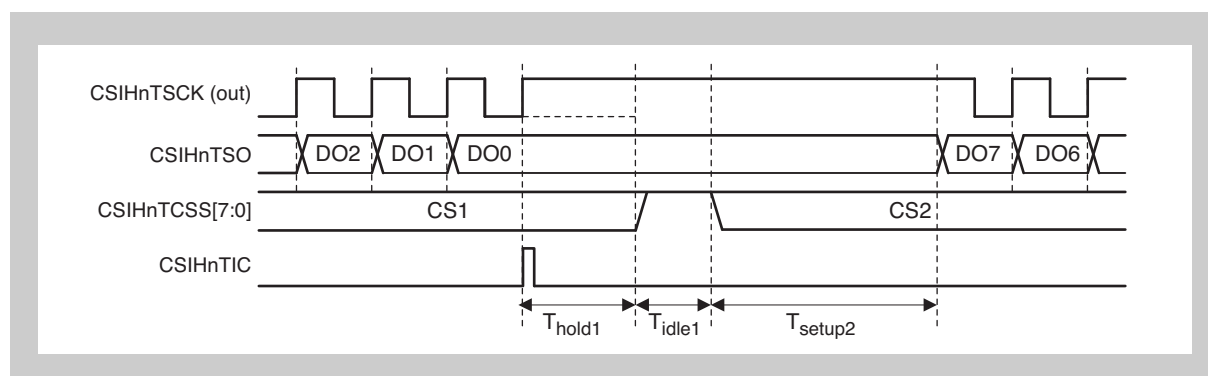

Figure 22-12 Data phase timing with
 CSIHnCFG1.CSIHnCKP1 = 1, CSIHnCFG1.CSIHnDAP1 = 0 and
 CSIHnCFG2.CSIHnCKP2 = 0, CSIHnCFG2.CSIHnDAP2 = 1

Note that the minimum idle time of one CSIHnTSCK cycle is automatically inserted, if CSIHnCFGx.CSIHnIDX[2:0] = 0 ($T_{idle1} = 0.5$ CSIHnTSCK cycles).

22.3.5 Job concept

In terms of CSIH, a job consists of a number of data that are transferred.

Note The job mode can only be used in master mode (CSIHnCTL2.CSIHnPRS[2:0] = 111_B).

Job mode enabled The job mode is enabled and disabled by CSIHnCTL1.CSIHnJE, while the CSIH is disabled by CSIHnCTL0.CSIHnPWR = 0.

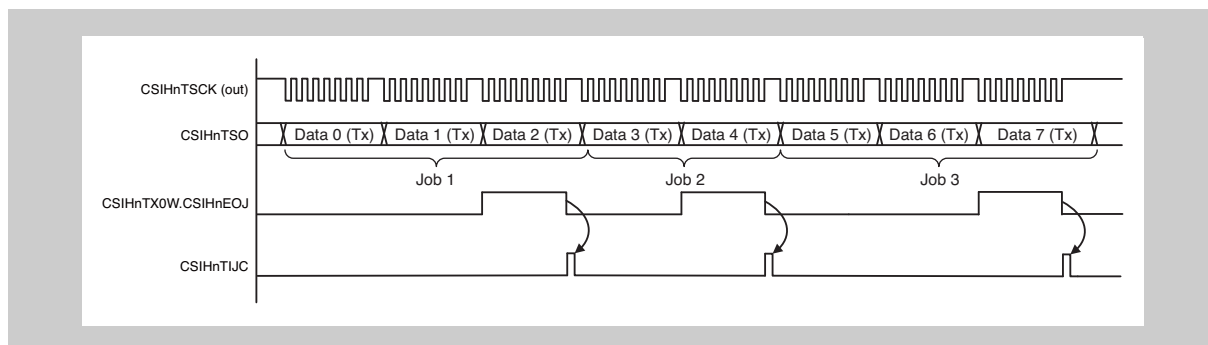

Figure 22-13 Job examples

A job ends when a data with the end-of-job bit set, i.e. with CSIHnTX0W.CSIHnEOJ = 1.

A communication stop can be specified to occur after a job has finished. This is done by setting CSIHnCTL0.CSIHnJOBE. When CSIHnJOBE is set, the communication continues until a data is sent, for which the CSIHnEOJ bit was set. After this data is sent, the communication is stopped and the end-of-job-interrupt CSIHnTIJC is generated.

22.3.6 Serial clock selection

In master mode, the transmission baudrate is selectable using

- CSIHnCTL2.CSIHnPRS[2:0]
- CSIHnCTL2.CSIHnBRS[11:0]
- CSIHnCFGx.CSIHn.CSIHnPSCLx

While the settings in the CSIHnCTL2 register determine the transmission base clock CSIHnBPCLK, a chip select dedicated prescaler, controlled by CSIHnCFGx.CSIHn.CSIHnPSCLx, allows to generated different baudrates for different chip selects.

The following figure shows a block diagram of the baudrate generator.

Figure 22-14 Baud rate generator block diagram

Clearing CSIHnCTL2.CSIHnBRS[11:0] disables the baudrate generator, and thus all CSIHnTSCKx are stopped.

Baud rate calculation The baudrate is calculated as:

$$\text{CSIHnTSCKx} = \text{PCLK} / (2^m \times k \times 2 \times 2^j)$$

where

$$m = \text{CSIHnCTL2.CSIHnPRS}[2:0] = 0 \text{ to } 6$$

$$k = \text{CSIHnCTL2.CSIHnBRS}[11:0] = 1 \text{ to } 4095$$

$$j = \text{CSIHnCFGx.CSIHnPSCLx}[1:0]$$

Baud rate limits When setting the baud rate, please note:

- Maximum acceptable baud rate in master mode is $\text{PCLK} / 4$.
- Maximum acceptable baud rate in slave mode is $\text{PCLK} / 6$ (must be ensured by the external master).
- Minimum baud rate in both modes is $\text{PCLK} / 524160$.

Caution There might be restrictions on the maximum baud rate that can actually be used depending on the product. Specify the baud rate so as not to exceed the maximum rate for each product.

Example If PCLK = 66.667 MHz, the maximum baud rate is

- 16.667 Mbps (PCLK / 4) in master mode
- 11.111 Mbps (PCLK / 6) in slave mode

The slowest baud rate is 127.188 bps (PCLK / 524160).

22.3.7 CSIH buffer memory

The CSIH has a configurable RAM that can be used for buffered I/O. The size is 128 words. One word consists of 32 bits of data.

The following configurations are available:

Mode	CSIHnCTL0. CSIHnMBS	CSIHnMCTL0. CSIHnMMS[1:0]
FIFO mode	0	00 _B
Dual buffer mode		01 _B
Transmit-only buffer mode		10 _B
Direct access mode	1	X

(1) FIFO mode

In FIFO mode, data can be written to the CSIHnTX0W register without waiting for completion of the transmission, and data can be received without reading the CSIHnRX0W register immediately, provided the FIFO is not full.

Data to be transmitted is stored to the FIFO memory. Transmission and reception occur simultaneously – one bit is sent, one bit is received. That means, received data overwrites the transmitted data in the FIFO.

CSIH automatically updates the respective FIFO memory pointers when a data package is committed, sent or received:

Pointer description	Control bits	Range
Number of words that have not been transmitted	CSIHnSTR0.CSIHnSPF[7:0]	0 to 128
Number of words stored in the reception FIFO buffer	CSIHnSTR0.CSIHnSRP[7:0]	0 to 128
Address of data to be sent	CSIHnMRWP0.CSIHnTRWA[6:0]	0000 _H to 01FC _H
Address of received data	CSIHnMRWP0.CSIHnRRA[6:0]	0000 _H to 01FC _H

The CSIH status register contains also two FIFO status flags:

- CSIHnSTR0.CSIHnFLF: FIFO full
- CSIHnSTR0.CSIHnEMF: FIFO empty

When this mode is started, bit CSIHnSTCR0.CSIHnPCT must be set. This resets all FIFO pointers and flags.

(2) Dual buffer mode

In this mode, the memory is divided into two parts of equal size – this means 64 words for transmit data and 64 words for received data. In dual buffer mode, the respective buffer pointers indicate:

Pointer description	Pointers ^a	Range
Destination address for data written to or read from CSIHnTX0W/H	CSIHnMRWP0.CSIHnTRWA[6:0]	0000 _H to 00FC _H
Address of data read from CSIHnRX0W/H	CSIHnMRWP0.CSIHnRRA[6:0]	0000 _H to 00FC _H
Transmission pointer	CSIHnMCTL2.CSIHnSOP[6:0]	0000 _H to 00FC _H

a) Each pointer is automatically incremented after each read or write.

(3) Transmit-only buffer mode

In this mode the entire memory is used to save transmission data.

Received data must be read directly from CSIHnRX0W/H.

In transmit-only buffer mode, the respective buffer pointer is:

Pointer description	Pointer ^a	Range
Destination address for data written to or read from CSIHnTX0W/H	CSIHnMRWP0.CSIHnTRWA[6:0]	0000 _H to 01FC _H
Transmission pointer	CSIHnMCTL2.CSIHnSOP[6:0]	0000 _H to 01FC _H

a) Each pointer is automatically incremented after each read or write.

(4) Direct access mode

In direct access mode, the CSIH memory is completely bypassed:

- Transmission data provided by the CPU to the transmission data register CSIHnTX0W or CSIHnTX0H is directly copied to the shift register.
- Reception data is directly copied from the shift register to the reception data register CSIHnRX0W or CSIHnRX0H.

22.3.8 Data transfer modes

(1) Transmit-only mode

Setting CSIHnCTL0.CSIHnTXE = 1 and CSIHnCTL0.CSIHnRXE = 0 puts the CSIH in transmit-only mode. Start of transmission depends on the memory mode:

- In case of FIFO or direct access mode, transmission starts when transmit data is written to the CSIHnTX0W or CSIHnTX0H register.
- In case of dual buffer or transmit-only buffer mode, transmission starts when bit CSIHnMCTL2.CSIHnBTST is set.

(2) Receive-only mode

Setting CSIHnCTL0.CSIHnTXE = 0 and CSIHnCTL0.CSIHnRXE = 1 puts the CSIH in receive-only mode.

In master mode, the start of reception depends on the memory mode:

- In case of FIFO, transmit-only buffer or direct access mode, reception starts when dummy data is written in the CSIHnTX0W or CSIHnTX0H register.
- In the dual buffer or transmit-only buffer mode, transmission starts when the CSIHnMCTL2.CSIHnBTST bit is set.

In slave mode, reception starts as soon as the transmission clock CSIHnTSCK from the master is received. It is not necessary to write data to the CSIHnTX0W or CSIHnTX0H register of the slave.

(3) Transmit & receive mode

Setting CSIHnCTL0.CSIHnTXE = 1 and CSIHnCTL0.CSIHnRXE = 1 puts the CSIH in transmit/receive mode.

The start of the communication (transmission and reception) depends on the memory mode:

- In case of FIFO or direct access mode, communication starts when transmit data is written to the CSIHnTX0W or CSIHnTX0H register.
- In case of dual buffer or transmit-only buffer mode, communication starts when bit CSIHnMCTL2.CSIHnBTST is set.

(4) Summary

The following table provides a summary. It shows how the data transfer is started in the various memory, operating, and transfer modes.

Table 22-8 Start of data transfer

Memory modes	Transfer modes	Operating modes	Condition for starting a data transfer
FIFO mode, direct access mode	Transmission mode	Master, slave	When transmission data is written to the CSIHnTX0W or CSIHnTX0H register
	Transmission/reception mode		
	Reception mode	Master	When dummy data is written to the CSIHnTX0W or CSIHnTX0H register
		Slave	When the serial clock CSIHnTSCK is received from the master
Transmit-only buffer mode, dual buffer mode	Transmission mode Transmission/reception mode Reception mode	Master, slave	When 1 is written to CSIHnMCTL2.CSIHnBTST

22.3.9 Data length selection

(1) Data length between 7 and 16 bits

CSIHnCFGx.CSIHnDLSx[3:0] can be used to select the data packet length for each chip select signal in the range from seven to 16 bits. The examples below show the communication with MSB first (CSIHnCFGx.CSIHnDIRx = 0).

Data length = 16 bits (CSIHnCFGx.CSIHnDLSx[3:0] = 0000_B):

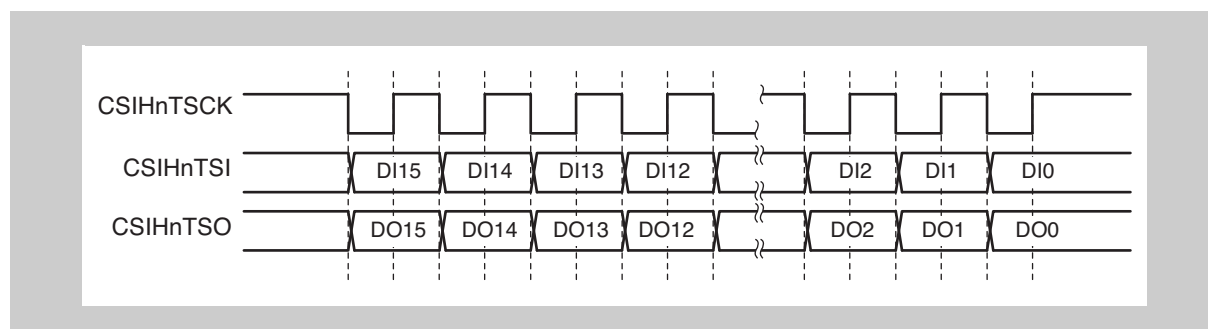

Figure 22-15 16-bit data, MSB first

Data length = 14 bits (CSIHnCFGx.CSIHnDLSx[3:0] = 1110_B):

Figure 22-16 14 bit-data, MSB first

(2) Data length greater than 16 bits

If the length of the data to be sent/received exceeds 16 bits, the extended data length (EDL) feature can be used.

The EDL function is enabled by setting CSIHnCTL1.CSIHnEDLE.

The operation and setup procedure of the EDL function are described below:

- Data is divided into 16-bit blocks and a remainder. For example, a 42-bit character string is divided into two 16-bit blocks and a 10-bit remainder.
- For the remainder, the data length is specified for the CSIHnCFGx.CSIHnDLSx[3:0] bits.
- When transmitting 16-bit blocks, set the CSIHnTX0W.CSIHnEDL bit. In this case, the data written to CSIHnTX0W is sent as a 16-bit data length regardless of the CSIHnCFGx.CSIHnDLSx[3:0] bits.
- When the specified length of data (the remainder when CSIHnTX0W.CSIHnEDL = 0) is transmitted, the transfer ends.

Example Example of transmitting the 40-bit data 123456789A_H to CS0

The 40-bit data is divided into two 16-bit blocks of data and one 8-bit block of data.

- Initialize CSIHnCFGx.CSIHnDLSx[3:0] = 8_D.
- To send the string 123456789A_H with MSB first, write the following sequence to CSIHnTX0W:
 - 2000 1234_H (CSIHnTX0W.CSIHnEDL = 1)
 - 2000 5678_H (CSIHnTX0W.CSIHnEDL = 1)
 - 0000 009A_H (CSIHnTX0W.CSIHnEDL = 0)

The following figure illustrates the timing.

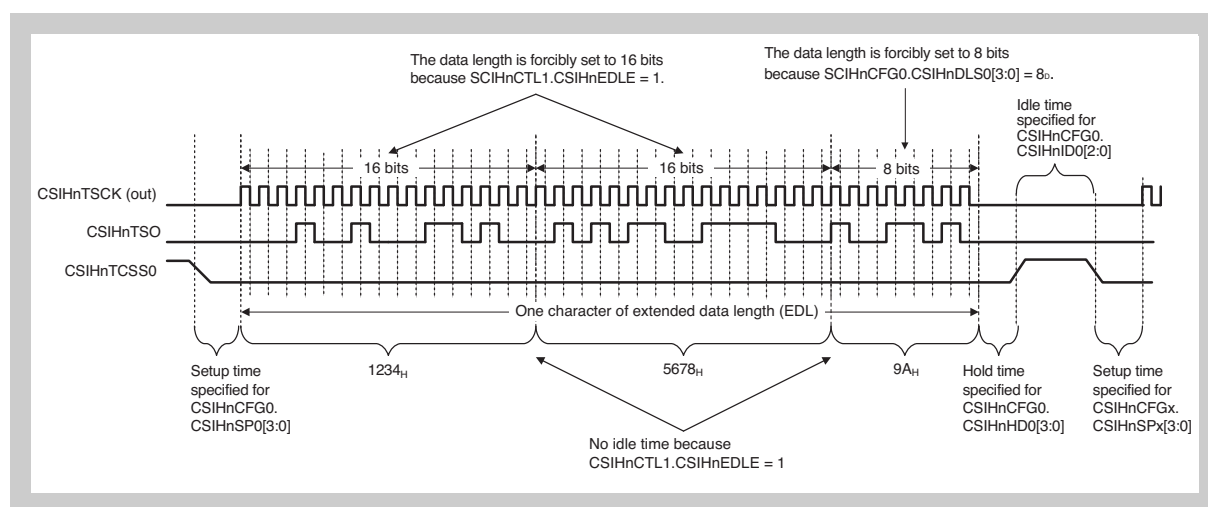

Figure 22-17 EDL timing chart

- Notes**
1. A data length less than 7 bits can be specified only when the EDL function is used.
 2. It is not possible to send two consecutive data with a data length of less than 7 bits.
 3. If parity is enabled, the parity bit is added after the last bit.
 4. The following describes an example where the transmitted data is 123456_H.
 - CSIHnCFGx.CSIHnDIR is cleared to 0 (MSB first).
2000 1234_H is written to CSIHnTX0W (CSIHnTX0W.CSIHnEDL = 1).
0000 0056_H is written to CSIHnTX0W (CSIHnTX0W.CSIHnEDL = 0).
 - CSIHnCFGx.CSIHnDIR is set to 1 (LSB first).
2000 3456_H is written to CSIHnTX0W (CSIHnTX0W.CSIHnEDL = 1).
0000 0012_H is written to CSIHnTX0W (CSIHnTX0W.CSIHnEDL = 0).
 5. The EDL function cannot be used in the slave mode (CSIHnCTL1.CSIHnPRS[2:0] = 1, 1, 1) and reception mode (CSIHnCTL0.CSIHnTXE = 0, CSIHnCTL0.CSIHnRXE = 1).

22.3.10 Serial data direction selection

The serial data direction is selectable for each chip select signal using the CSIHnDIRx bit in the CSIHnCFGx register.

The examples below show the communication for a data length of 8 bit (CSIHnCFGx.CSIHnDLSx[3:0] = 1000_B):

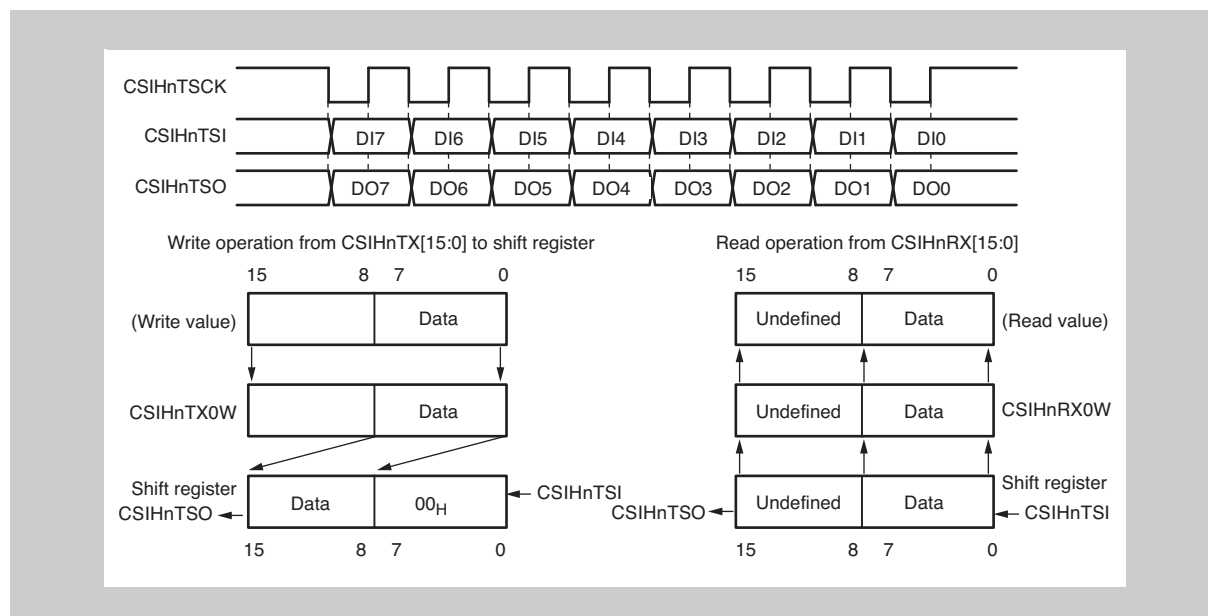

Figure 22-18 Serial data direction select function - MSB first (CSIHnDIR = 0)

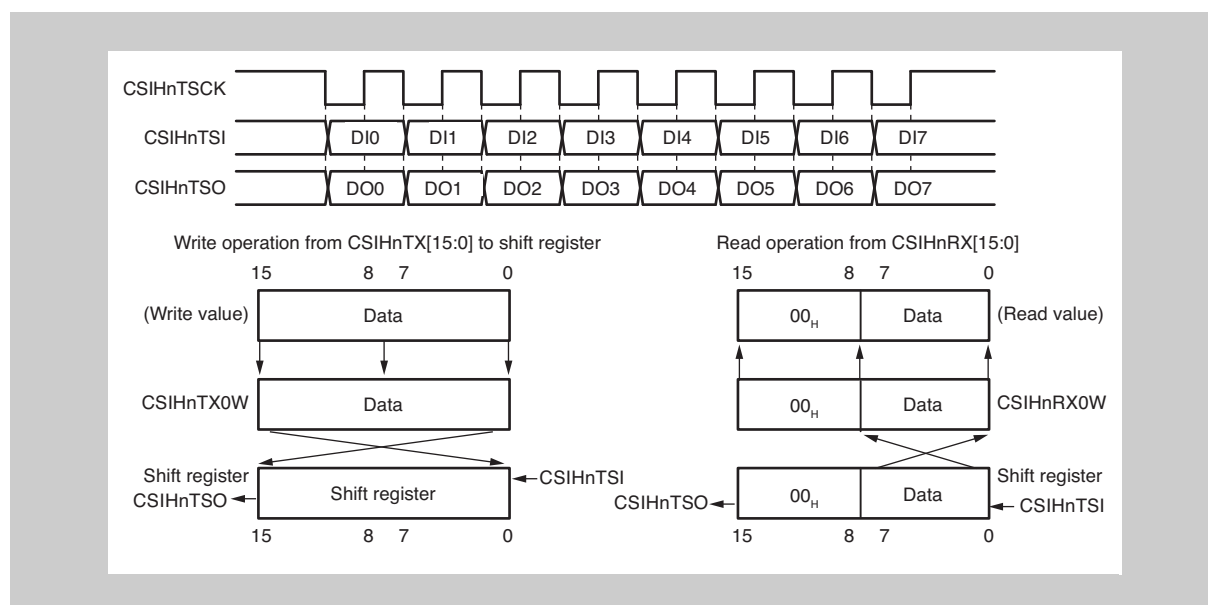

Figure 22-19 Serial data direction select function - LSB first (CSIHnDIR = 1)

22.3.11 Communication in slave mode

The following figure illustrates the communication signals and timings in slave mode.

In slave mode, the data transfer configuration is determined by the CSIHnCFG0 register.

Figure 22-20 Transmit/receive communication timing in slave mode

1. CSIH is placed in the slave mode by setting CSIHnCTL2.CSIHnPRS[2:0] to 111_B. The $\overline{\text{CSIHnTSSI}}$ signal is enabled (CSIHnCTL1.CSIHnSSE = 1).
2. CSIHnCTL1.CSIHnCKR and CSIHnCFG0.CSIHnDAP0 are 0, the data length is 8 bits (CSIHnCFG0.CSIHnDLS0[3:0] = 1000_B), and the data direction is MSB first (CSIHnCFG0.CSIHnDIR0 = 0).
3. CSIH is set to the transmission/reception mode (CSIHnCTL0.CSIHnPWR = 1, CSIHnCTL0.CSIHnTXE = 1, and CSIHnCTL0.CSIHnRXE = 1). Communication is enabled to start.
4. If transfer data is written to the transmission data register CSIHnTX0W or CSIHnTX0H, the transfer status flag CSIHnSTR0.CSIHnTSF is automatically set, and the system waits for the $\overline{\text{CSIHnTSSI}}$ signal to become low.
5. Data transmission/reception does not start while the $\overline{\text{CSIHnTSSI}}$ signal is high, even if the external serial clock CSIHnTSCK is input. CSIHnTSO retains the value, and input to CSIHnTSI is ignored.
6. When the $\overline{\text{CSIHnTSSI}}$ signal becomes low, it indicates that CSIHnTSO is enabled and data transmission is possible.
7. If a serial clock is input while $\overline{\text{CSIHnTSSI}}$ is low, the transfer data is transmitted from CSIHnTSO in synchronization with the serial clock, and data is received from CSIHnTSI at the same time.
8. The CSIHnRX0W or CSIHnRX0H register is read.

Note For details about the operating procedure in the slave mode for each operation mode, see 22.5 "Operating Procedures".

22.3.12 CSIH interrupt requests

CSIH can generate the following interrupt requests:

- CSIHnTIC (communication interrupt)
- CSIHnTIR (reception interrupt)
- CSIHnTIRE (error interrupt)
- CSIHnTIJC (job completion interrupt)

(1) CSIHnTIC (communication interrupt)

The conditions for generating CSIHnTIC differ depending on the memory mode and whether the job mode is enabled.

The following table gives an overview.

Table 22-9 CSIHnTIC generation

Memory modes	Interrupt source	
	Job mode disabled CSIHnCTL1.CSIHnJE = 0	Job mode enabled CSIHnCTL1.CSIHnJE = 1
FIFO	CSIHnTIC is generated immediately before the transmission data in the FIFO buffer disappears to inform the application that new data must be added. CSIHnTIC is generated when the number of transmission data items remaining in the FIFO buffer, CSIHnSTR0.CSIHnSPF[7:0], becomes equal to CSIHnMCTL1.CSIHnFES[6:0].	
	However, CSIHnTIC is not generated if the job is interrupted ^a .	–
Transmit-only buffer, dual buffer	CSIHnTIC is generated when communication ends (as specified by the CSIHnMCTL2.CSIHnND[7:0] bits).	CSIHnTIC is generated when data is transmitted while CSIHnTX0W.CSIHnCIRE is "1". However, when the data and a job interrupt request ^a are transmitted while CSIHnTX0W.CSIHnCIRE is "1", CSIHnTIJC is generated instead of CSIHnTIC.
Direct access	CSIHnTIC is generated each time a data transfer is performed. However, CSIHnTIC is not generated if the job is interrupted ^a .	Except when communication is interrupted, CSIHnTIC is generated each time a data transfer is performed. However, when the data and a job interrupt request ^a are transmitted while CSIHnTX0W.CSIHnCIRE is "1", CSIHnTIJC is generated instead of CSIHnTIC.

a) Job abortion condition: CSIHnTX0W.CSIHnEOJ = 1 and CSIHnCTL0.CSIHnJOBE = 1

CSIHnTIC in direct access mode

The following example shows the CSIHnTIC behavior in direct access mode.

The following example assumes:

- Master mode
- Direct access memory mode
- No delay for any interrupt (CSIHnCTL1.CSIHnSIT = 0)
- Normal clock phase and data phase (CSIHnCFGx.CSIHnCKPx = 0, CSIHnCFGx.CSIHnDAPx = 0)
- Data length 8 bits (CSIHnCFGx.CSIHnDLSx[3:0] = 1000_B)
- Normal CSIHnTIC interrupt timing (CSIHnCTL1.CSIHnSLIT = 0)

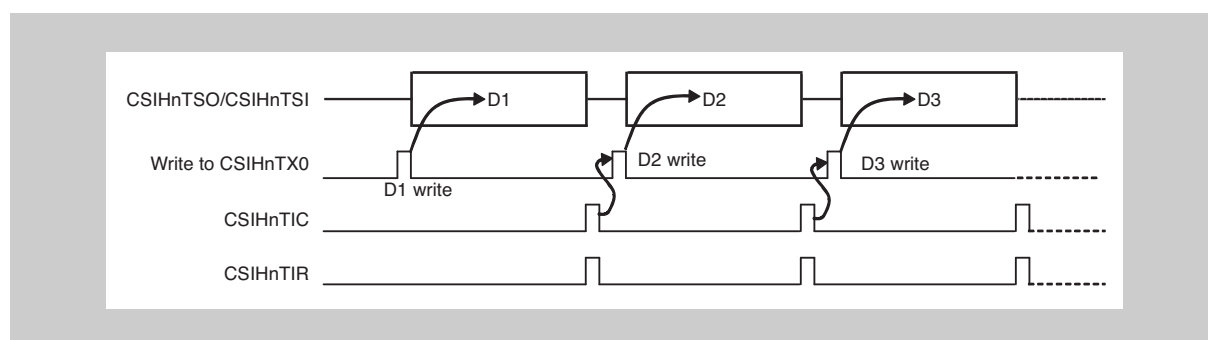

Figure 22-21 Generation of CSIHnTIC after transfer (CSIHnCTL1.CSIHnSLIT = 0)

If job mode is enabled (CSIHnCTL1.CSIHnJE = 1) and a job ends because data is sent with CSIHnTX0W.CSIHnEOJ = 1 and communication stop is requested (CSIHnCTL0.CSIHnJOBE = 1), then CSIHnTIC is replaced by the job completion interrupt CSIHnTIJC.

CSIHnTIC can also be set up to occur as soon as the CSIHnTX0 register is free for the next data. This is specified by setting CSIHnCTL1.CSIHnSLIT = 1.

Note This mode allows faster data transfer but is only available in direct access memory mode.

The effect is illustrated in the figure below.

Figure 22-22 Immediate generation of CSIHnTIC (CSIHnCTL1.CSIHnSLIT = 1)

Thus, the new data can be written in advance.

- CSIHnTIC in FIFO mode** The following example shows the CSIHnTIC behavior in FIFO mode. The following example assumes:
- Master mode
 - FIFO memory mode
 - No delay for any interrupt (CSIHnCTL1.CSIHnSIT = 0)
 - Normal clock phase and data phase (CSIHnCFGx.CSIHnCKPx = 0, CSIHnCFGx.CSIHnDAPx = 0)
 - Data length 8 bits (CSIHnCFGx.CSIHnDLSx[3:0] = 1000_B)

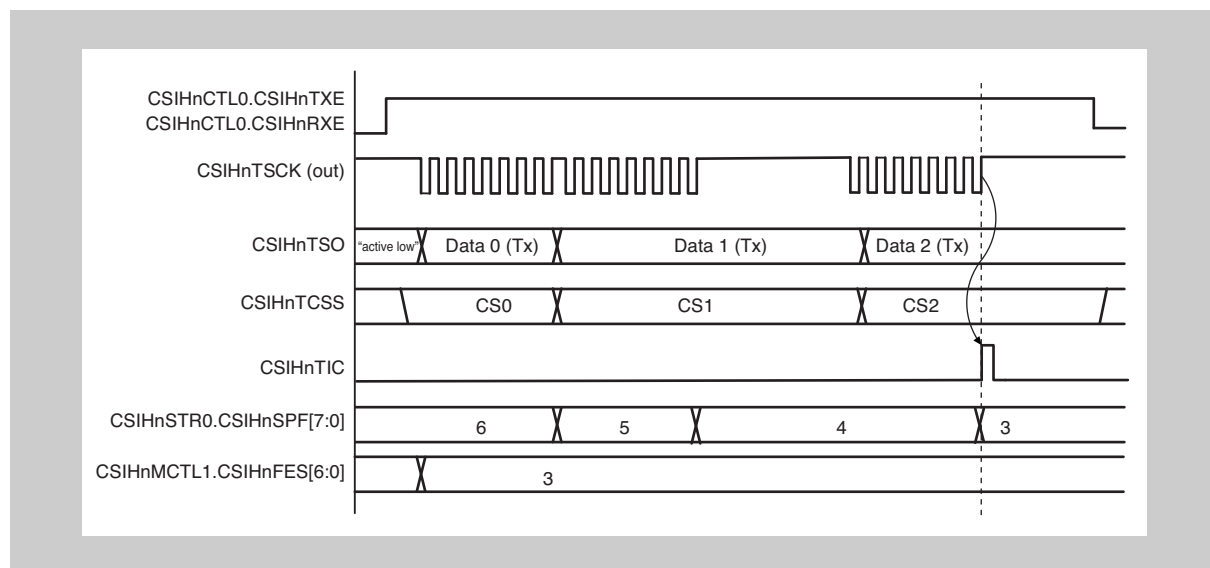

Figure 22-23 Generation of CSIHnTIC in FIFO memory mode

The condition for generating CSIHnTIC in the FIFO mode (an empty reception buffer) is specified for CSIHnMCTL1.CSIHnFES[6:0]. For the example in the above figure, three data items are specified as the condition. The CSIHnSTR0.CSIHnSPF[7:0] bits indicate the number of data items that remain in the FIFO buffer and have not been transmitted. When the number of remaining items matches the condition, the interrupt CSIHnTIC is generated.

CSIHnTIC in job mode

The following example shows the CSHnTIC behavior in job mode.

The following example assumes:

- Master mode
- Job mode enabled (CSIHnCTL1.CSIHnJE = 1)
- No delay for any interrupt (CSIHnCTL1.CSIHnSIT = 0)
- Normal clock phase and data phase (CSIHnCFGx.CSIHnCKPx = 0, CSHnCFGx.CSIHnDAPx = 0)
- Data length 8 bits (CSIHnCFGx.CSIHnDLSx[3:0] = 1000_B)
- Normal CSHnTIC interrupt timing (CSIHnCTL1.CSIHnSLIT = 0)
- Dual buffer mode (CSIHnCTL0.CSIHnMBS = 0, CSHnMCTL0.CSIHnMMS[1:0] = 01H)

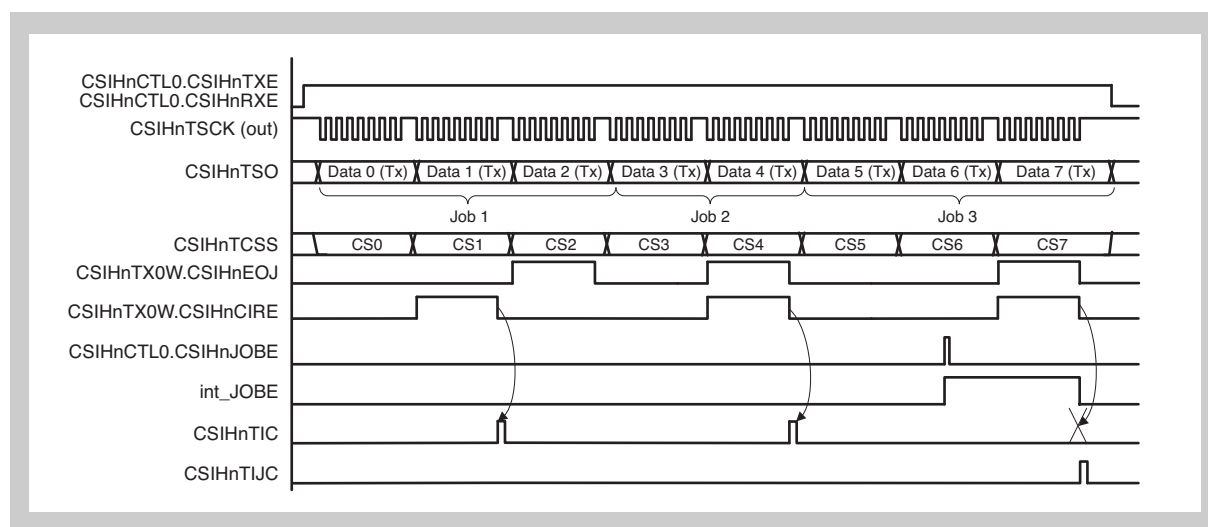

Figure 22-24 Generation of CSHnTIC in job mode

Note The int_JOBE signal in the above timing chart is the internal signal of the CSHnJOBE bit.

The rules for generating CSHnTIC in job mode are:

Table 22-10 Generation of CSIHnTIC in job mode

Memory modes	CSIHnTX0W. CSIHnCIRE	CSIHnTX0W. CSIHnEOJ	CSIHnTIC
FIFO mode (CSIHnCTL1. CSIHnJE = 1)	0 (FIFO empty ^a)	0	Generated
		1	CSIHnCTL0.CSIHnJOBE = 0: Generated CSIHnCTL0.CSIHnJOBE = 1: CSIHnTIJC is generated instead of CSIHnTIC.
	1 (FIFO empty ^a)	0	Generated
		1	CSIHnCTL0.CSIHnJOBE = 0: Generated CSIHnCTL0.CSIHnJOBE = 1: CSIHnTIJC is generated instead of CSIHnTIC.
	0 (Data in FIFO)	0	Not generated
		1	Not generated CSIHnCTL0.CSIHnJOBE = 1: CSIHnTIJC is generated instead of CSIHnTIC.
1 (Data in FIFO)	0	Not generated	
	1	CSIHnTIJC is generated instead of CSIHnTIC.	
Dual buffer mode, transmit-only buffer mode (CSIHnCTL1. CSIHnJE = 1)	0	0	Not generated
		1	Not generated CSIHnCTL0.CSIHnJOBE = 1: CSIHnTIJC is generated instead of CSIHnTIC.
	1	0	Generated
		1	CSIHnCTL0.CSIHnJOBE = 0: Generated CSIHnCTL0.CSIHnJOBE = 1: CSIHnTIJC is generated instead of CSIHnTIC.
Direct access mode (CSIHnCTL1. CSIHnJE = 1)	-	0	Generated
		1	
	-	0	Generated
		1	CSIHnCTL0.CSIHnJOBE = 1: CSIHnTIJC is generated instead of CSIHnTIC.

a) The value of CSIHnSTR0.CSIHnSPF7-0 is the same as that of CSIHnMCTL1.CSIHnFE6-0.

(2) CSIHnTIR reception interrupt

Depending on the memory mode and the job mode, this interrupt is generated according to the following conditions:

Table 22-11 CSIHnTIR interrupt generation

Memory mode	Master and slave	
	Job mode disabled CSIHnCTL1.CSIHnJE = 0	Job mode enabled CSIHnCTL1.CSIHnJE = 1
FIFO	This interrupt occurs when the FIFO buffer is almost full with received data, indicating to the application that the FIFO must be emptied. CSIHnTIR is generated, if the number of received data in the FIFO CSIHnSTR0.CSIHnSRP[7:0] equals CSIHnMCTL1.CSIHnFFS[6:0].	
Dual buffer	The interrupt is generated when communication ends (as specified by the CSIHnMCTL2.CSIHnND[7:0] bits) and CSIHnCTL0.CSIHnRXE = 1.	The interrupt is generated each time data is received if CSIHnCTL0.CSIHnRXE = 1.
Transmit-only buffer, direct access	The interrupt is generated each time data is received if CSIHnCTL0.CSIHnRXE = 1.	

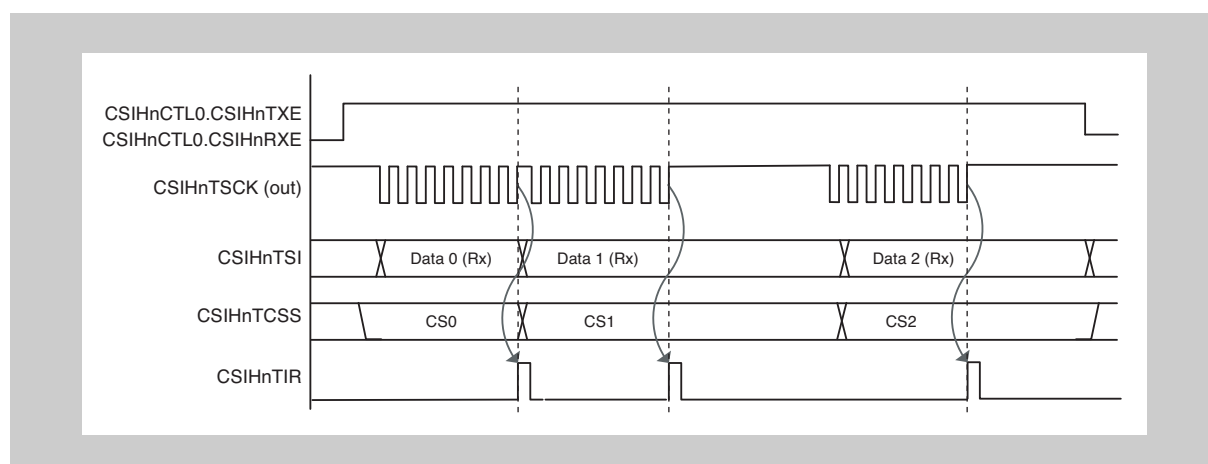

In transmit-only or dual buffer mode, this interrupt is generated in receive-only and transmit/receive mode after each data has been received.

CSIHnTIR in direct access mode

The following example shows the CSIHnTIR behavior in direct access mode.

The following example assumes:

- Master mode
- Direct access mode
- No delay for any interrupt (CSIHnCTL1.CSIHnSIT = 0)
- Normal clock phase and data phase (CSIHnCFGx.CSIHnCKPx = 0, CSIHnCFGx.CSIHnDAPx = 0)
- Data length 8 bits (CSIHnCFGx.CSIHnDLSx[3:0] = 1000_B)

**Figure 22-25 Generation of CSIHnTIR in direct access memory mode**

CSIHnTIR in the dual buffer mode

The following example shows the CSIHnTIR behavior in buffer mode.

The following example assumes:

- Master mode
- Transmit-only or dual buffer mode
- No delay for any interrupt (CSIHnCTL1.CSIHnSIT = 0)
- Default clock phase and data phase (CSIHnCFGx.CSIHnCKPx = 0, CSIHnCFGx.CSIHnDAPx = 0)
- 8-bit data length (CSIHnCFGx.CSIHnDLSx[3:0] = 1000_B)
- Three data items transmitted (CSIHnMCTL2.CSIHnND[7:0] = 03_H)
- Job mode disabled (CSIHnCTL1.CSIHnJE = 0)

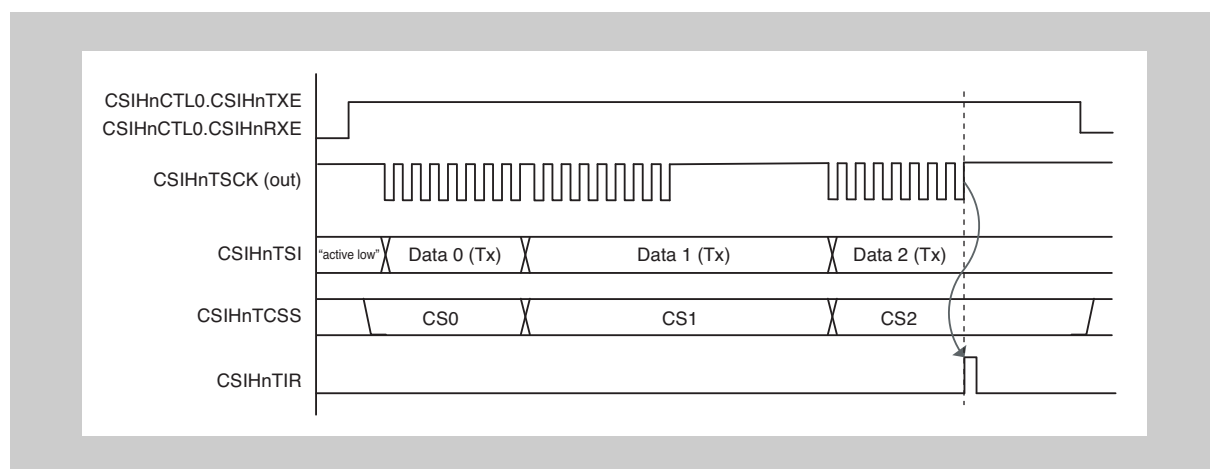

Figure 22-26 CSIHnTIR generation in the dual buffer mode

(3) CSIHnTIRE reception error interrupt

This interrupt is generated whenever an error is detected.

Table 22-12 Data error types

Error type	Communication status after error interrupt	Comment
FIFO overflow error	Interrupt is generated and communication continues	The data written to the FIFO is lost, but previously started communications are continued.
Parity error	Interrupt is generated and communication continues	–
Data consistency error	Interrupt is generated and communication continues	–
Timeout error	Interrupt is generated and communication continues	–
Overrun error	If CSIHnCTL1.CSIHnHSE = 0 (no handshake), communication continues after the interrupt is generated. (Communication does not stop.)	This error occurs (but only for the FIFO mode) if the CPU reads reception data after the number of reception data items reaches 0.
	If CSIHnCTL1.CSIHnHSE = 1 (handshake exists), communication is stopped according to the handshake. No interrupt is generated, and no overrun error occurs.	This error occurs when data reception finishes in one of the following statuses: <ul style="list-style-type: none"> • FIFO mode: The FIFO is full. (Overwriting is performed but the pointer is not incremented.) • Transmit-only buffer mode or direct access mode: Reception data remains in the CSIHnRX0 register.

The type of error that caused the generation of CSIHnTIRE is flagged in register CSIHnSTR0.

Additionally a parity and data consistency error flag is attached to the reception data in CSIHnRX0W.

For details about the various error types, refer to 22.3.14 “Error detection” on page 1176.

(4) CSIHnTIJC job completion interrupt

This interrupt supports the handling of jobs – refer to 22.3.4 “Chip select timing details” on page 1150. This interrupt is only available in master mode.

Job mode is enabled by setting CSIHnCTL1.CSIHnJE = 1. When CSIHnCTL1.CSIHnJE = 0, CSIHnTIJC is not generated.

Depending on the memory mode, this interrupt is generated according to the following conditions:

Table 22-13 CSIHnTIJC interrupt generation

Memory mode	Interrupt source	
	Job mode disabled CSIHnCTL1.CSIHnJE = 0	Job mode enabled CSIHnCTL1.CSIHnJE = 1
FIFO mode	Not applicable	After job abortion ^a is triggered, communication stops on job completion.
Transmit-only buffer mode		
Dual buffer mode		
Direct access mode		

a) Job abortion condition: CSIHnTX0W.CSIHnEOJ = 1 and CSIHnCTL0.CSIHnJOBE = 1

(5) Delay for all interrupts

In the master mode, all interrupts generated by the master can be delayed one half cycle of the serial clock CSIHnTSCK. This function cannot be used in the slave mode.

To specify this delay, set the CSIHnCTL1.CSIHnSIT bit to 1.

The figure below shows an example of using the interrupt delay function with the following settings: CSIHnCTL1.CSIHnSIT = 1 (interrupt delay enabled), CSIHnCFGx.CSIHnCKPx = 0, CSIHnCFGx.CSIHnDAPx = 0 (normal clock phase and data phase), and CSIHnCFGx.CSIHnDLSx[3:0] = 1000_B (8-bit data length).

Figure 22-27 Interrupt delay function (CSIHnCTL1.CSIHnSIT = 1)

When CSIHnCTL1.CSIHnSIT is set to 1, a delay of half a serial clock cycle is added. This also delays the end of the current chip select signal (CSIHnTCSSx).

22.3.13 Handshake function

CSIH features a handshake function to synchronize the master and the slave devices. This function can be enabled/disabled by bit CSIHnCTL1.CSIHnHSE. For handshake, the CSIHnTRY signal is used. In addition, when the handshake function is disabled (CSIHnCTL1.CSIHnHSE = 0), the CSIHnTRY signal is output at the low level.

The timing depends on the data phase selection bit CSIHnCFGx.CSIHnDAPx.

(1) Slave mode

When CSIHnCTL1.CSIHnHSE = 1 and the slave is busy, the CSIHnTRY signal is output at the low level. The busy state refers to the following two cases:

- When the slave is not ready for transmission
- When the transmission data cannot be transferred from the shift register to the CSIHnRXW/H register because received data remains in the CSIHnRXW/H register

Also, the state differs according to the memory mode. Table 22-14 “When the slave is not read for transmission” and Table 22-15 “When the transmission data cannot be transferred from the shift register” describe the state for each memory mode.

Table 22-14 When the slave is not read for transmission

Memory mode	State
	CSIHnCTL0.CSIHnRXE = 1
FIFO mode	The next transmission data buffer is empty. (CSIHnSTR0.CSIHnEMF = 1)
Direct access mode	The next transmission data buffer is empty.
Dual buffer mode	CSIHnMCTL2.CSIHnBTST is not set to 1.
Transmit-only buffer mode	

Table 22-15 When the transmission data cannot be transferred from the shift register

Memory mode	State
	CSIHnCTL0.CSIHnRXE = 1
FIFO mode	The FIFO buffer is full. (CSIHnSTR0.CSIHnFLF = 1)
Direct access mode	The CSIHnRX0W/H register is full.
Dual buffer mode	–
Transmit-only buffer mode	The CSIHnRX0W/H register is full.

Note When the master mode is specified and the CSIHnTRY (in) signal is detected to be at the low level, the following transmission is put on hold and the system waits. While the system waits, the CSIHnTRY (in) signal level is checked every one-half clock cycle of CSIHnTCSS0. However, the chip select signal CSIHnTCSSx is output before the system starts waiting, and is held during the wait.

- Cautions**
1. For the master, specify settings so that only the CSIHnTRY pin is detected from the slave selected by CSIHnTCSSx.
 2. Even if an active level signal from the slave to the master is detected during transmission, the next transmission is not performed until the current transmission operation ends.

Two descriptions are provided below, one for the FIFO mode and one for the direct access mode.

When the memory mode is FIFO mode

The slave is in transmit-only or transmit/receive mode but has no transmission data in its buffer. This status is indicated by the flag CSIHnSTR0.CSIHnEMF.

The following examples assume a data length of 8 bits.

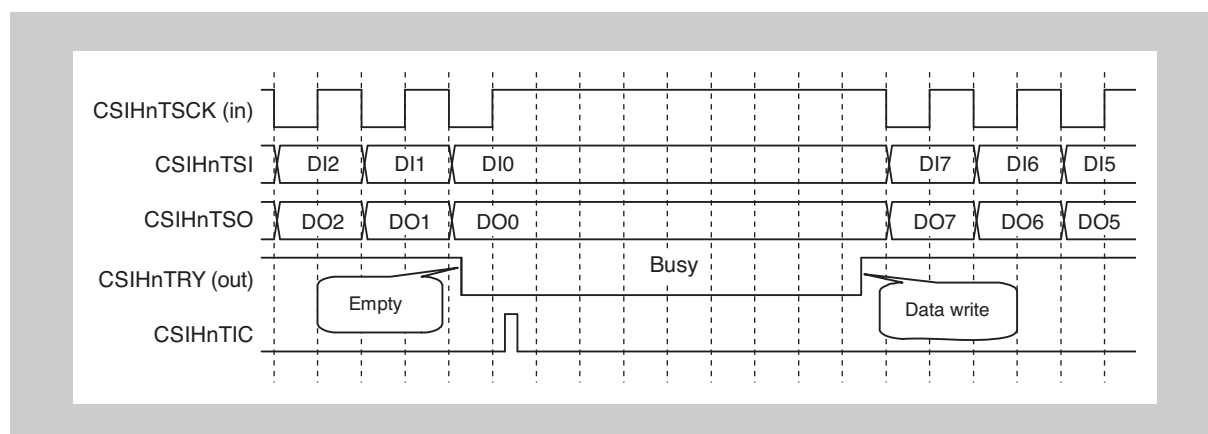

Figure 22-28 Busy signal from the slave (FIFO mode, CSIHnCFGx.CSIHnDAPx = 0)

The slave sets CSIHnTRY to high ("ready") as soon as new transmission data is written to the FIFO.

Figure 22-29 Busy signal from the slave (FIFO mode, CSIHnCFGx.CSIHnDAPx = 1)

When the memory mode is direct access mode

The slave is in receive-only or transmit/receive mode but previously received data is still in the CSIHnRX0 register, and new data cannot be copied from the shift register to CSIHnRX0 (CSIHnRX0 full condition).

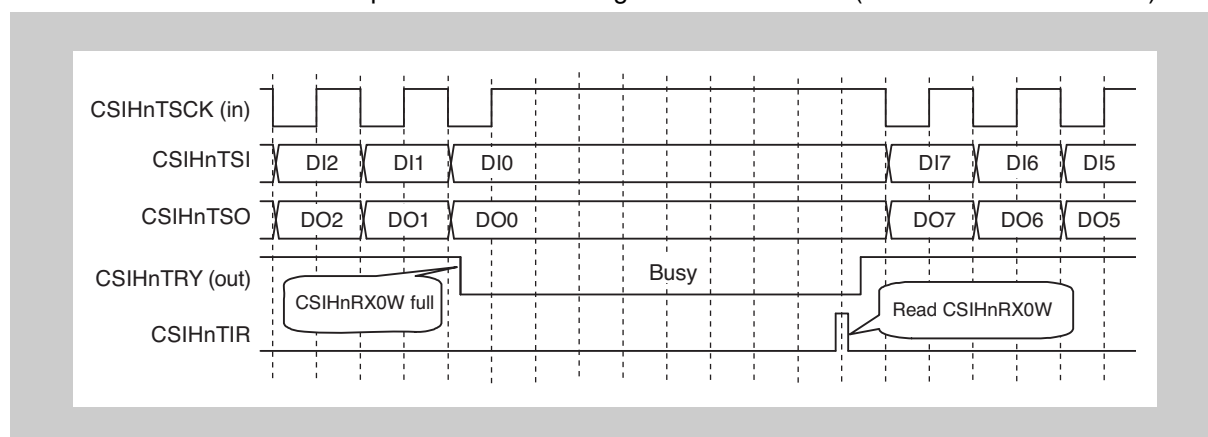

Figure 22-30 Busy signal from the slave (direct access mode, CSIHnCFGx.CSIHnDAPx = 0)

The slave sets CSIHnTRY to high ("ready") as soon as the reception data register CSIHnRX0 has been read.

Figure 22-31 Busy signal from the slave (direct access mode, CSIHnCFGx.CSIHnDAPx = 1)

(2) Master mode

When the master detects that CSIHnTRY is at the low level, the following transfer is put on hold, and the master goes on stand by. It suspends the clock CSIHnTSCK.

The CSIHnTRY level is checked at each half clock cycle of CSIHnTSCK.

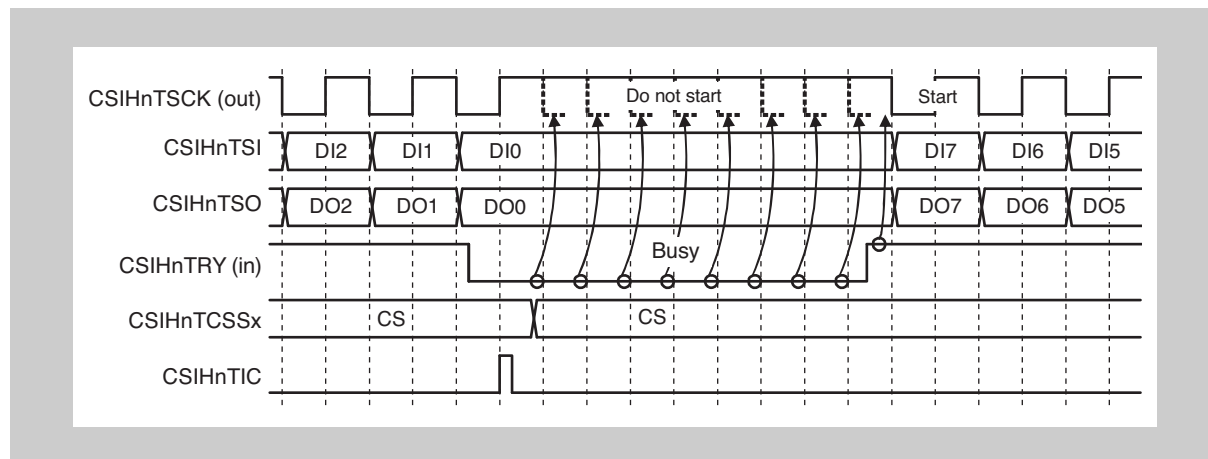

Figure 22-32 Master's reaction on CSIHnTRY (CSIHnCFGx.CSIHnDAPx = 0)

If the CSIHnTRY signal is pulled down while a data transfer is in progress, the serial clock is suspended after the transfer is complete.

The master resumes the communication as soon as CSIHnTRY becomes high (slave is "ready").

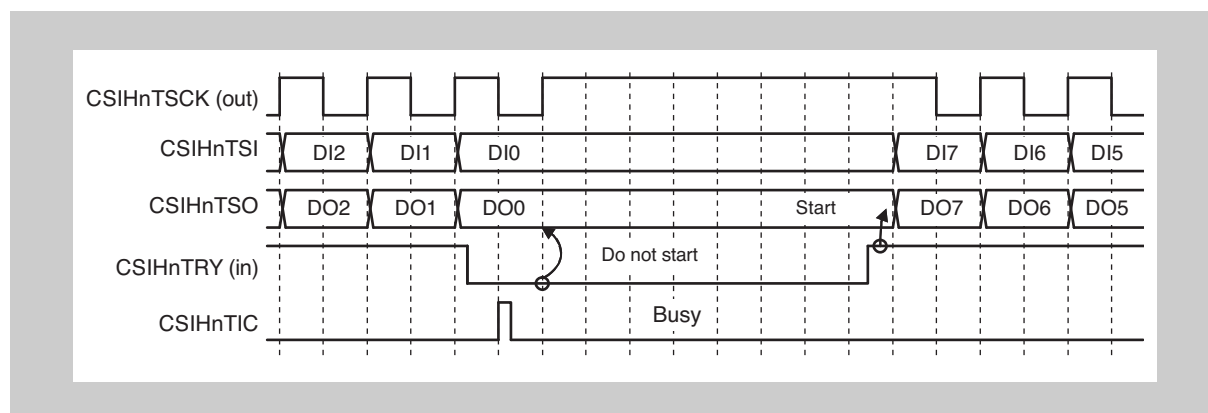

Figure 22-33 Master's reaction on CSIHnTRY (CSIHnCFGx.CSIHnDAPx = 1)

Caution If multiple slaves are connected, the master must only detect the CSIHnTRY signal of the slave it has selected for communication.

The slave must set the CSIHnTRY signal to low before the next data transfer starts. If the CSIHnTRY signal is set to low during a data transfer, the data transfer continues to the end.

22.3.14 Error detection

CSIH can detect five error types:

- Data consistency error (transmission data)
- Parity error (received data)
- Overrun error (received data)
- Timeout error (in FIFO mode)
- Overflow error (in FIFO mode)

Check for parity, data consistency and timeout errors can be enabled/disabled individually.

If one of these errors is detected, the interrupt request CSIHnTIRE is generated and the corresponding flag is set.

(1) Data consistency check

The purpose of the data consistency check is to ensure that the data physically sent as output signal is identical with the original data that was copied to the shift register.

The data consistency check can be enabled/disabled by bit CSIHnCTL1.CSIHnDCS. It is not active if data transmission is disabled (CSIHnCTL0.CSIHnTXE = 0).

When the data consistency check is active, the data transferred from CSIHnTX0W or CSIHnTX0H to the shift register is copied to a separate register. In addition, the physical levels at CSIHnTSO are read back via the CSIHnTDCS signal into an own shift register.

After completion of the transmission, the sent data is compared with the original transmission data.

Mismatch is considered as a data consistency error.

When a data consistency error occurs:

- Interrupt CSIHnTIRE is generated.
- Bit CSIHnSTR0.CSIHnDCE is set.

Additionally, CSIHnRX0W.CSIHnTDCE is set with the corresponding data.

The function is illustrated in the following block diagram.

Figure 22-34 Data consistency check functional block diagram

(2) Parity check

Parity checks are often used to detect single bit errors during data transmission. CSIH can append a parity bit to the last data bit (even if extended data length is used).

The use and type of parity is specified in `CSIHnCFGx.CSIHnPSx[1:0]`.

Parity check is enabled if `CSIHnCFGx.CSIHnPSx[1] = 1`.

The parity bit is checked after a reception is complete.

When a parity error occurs:

- Interrupt `CSIHnTIRE` is generated.
- Bit `CSIHnSTR0.CSIHnPE` is set.

Additionally, `CISHnRX0W.CSIHnRPE` is set with the corresponding data.

The following figure shows an example.

- Data length is 8 bits.
- The data transmitted is `05H` and `35H`.
- Data direction is LSB first.
- Parity type is odd.

Figure 22-35 Parity check example

The parity bit of the first data is 1. There is no parity error, because the total number of ones (including the parity bit) is odd.

The parity bit of the second data is 0. This is detected as a parity error, because the total number of ones (including the parity bit) is even.

If using the extended data length (EDL) function, the parity bit is added after the last data bit.

(3) Timeout error

Timeout error checks are only possible in slave FIFO mode.

A timeout error occurs if neither of the following occurs within a specific time:

- Reading reception data in the FIFO buffer
- Reception of data by the FIFO buffer from CSIHnTSl

The time is defined in CSIHnMCTL0.CSIHnTO[4:0] in multiples of 8 times the transmission clock CSIHnSCK. Timeout error occurs when the specified time is exceeded (When CSIHnMCTL0.CSIHnTO[4:0] is cleared to 00000_B, the timeout time is not detected.).

A dedicated timeout counter measures the time between the last and the next read operation.

Figure 22-36 Timeout error check functional timing chart

The timeout counter starts when:

- Reception ends.
- Reading data from the CPU ends. (If the buffer is empty, the counter does not start.)
- A timeout error is detected.

After a timeout error is detected, if the system is left as is, the timeout counter restarts.

If the time specified for the CSIHnMCTL0.CSIHnTO[4:0] bits is reached again, another CSIHnTIR interrupt is output.

The timeout counter continues counting as long as reception data is not read. To stop the timeout counter, read all the reception data, or set CSIHnSTCR0.CSIHnPCT (to 1). However, the pointer is cleared in this case.

The timeout counter is reset when:

- Data is read.
- One new data item is received.
- A timeout error is detected.
- The CSIHnSTCR0.CSIHnPCT bit is set.

When a timeout error occurs:

- Interrupt CSIHnTIRE is generated.
- Bit CSIHnSTR0.CSIHnTMOE is set.

(4) Overflow error

Overflow errors can occur in the FIFO mode. An overflow error occurs when transmission data is written to the CSIHnTX0W or CSIHnTX0H register while the FIFO buffer is full of transmission data and reception data.

Example 100 data have been transmitted. That means, the FIFO contains 100 received data. The application starts to read the received data.

While the read operation is in progress, the application begins to write another set of 50 transmission data to the FIFO. However, only 10 received data have been read up to now, 90 are still in the FIFO.

In this case, only 38 cells are available for new transmission data. When the CPU tries to write the 39th data, an overflow error happens.

This is illustrated in the following figure:

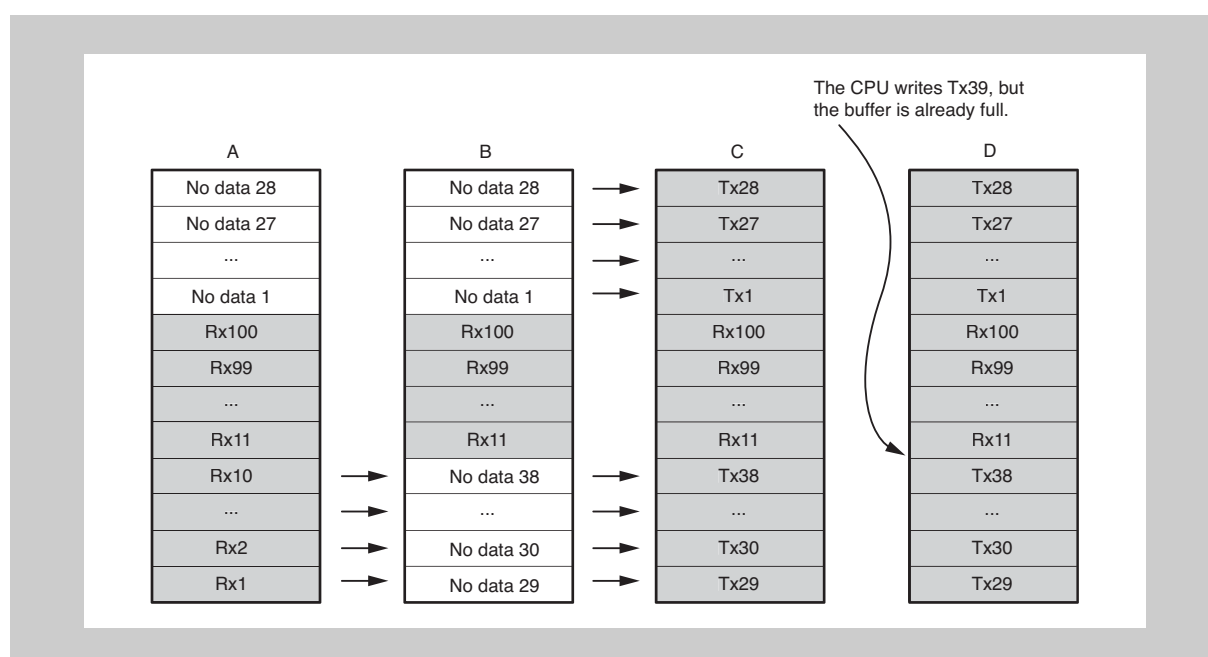

Figure 22-37 FIFO overflow

The data after 39 are discarded. The following figure shows the associated timing.

Figure 22-38 FIFO overflow timing

When an overflow error occurs:

- Interrupt CSIHnTIRE is generated.
- Bit CSIHnSTR0.CSIHnOFE is set.

(5) Overrun error

Overrun errors can occur in the direct access mode, transmit-only buffer mode, and FIFO mode. They cannot occur in the dual buffer mode.

**Direct access/
transmit-only buffer**

In direct access and transmit-only buffer mode, this error occurs when newly received data cannot be transferred from the shift register to the reception data register CSIHnRX0. This happens when CSIHnRX0 was not read and therefore contains previous reception data.

In the master mode, because the serial clock is stopped until the CPU reads reception data, overrun errors do not occur. In the slave mode, the handshake function can be used to avoid this problem.

The following figure illustrates the function.

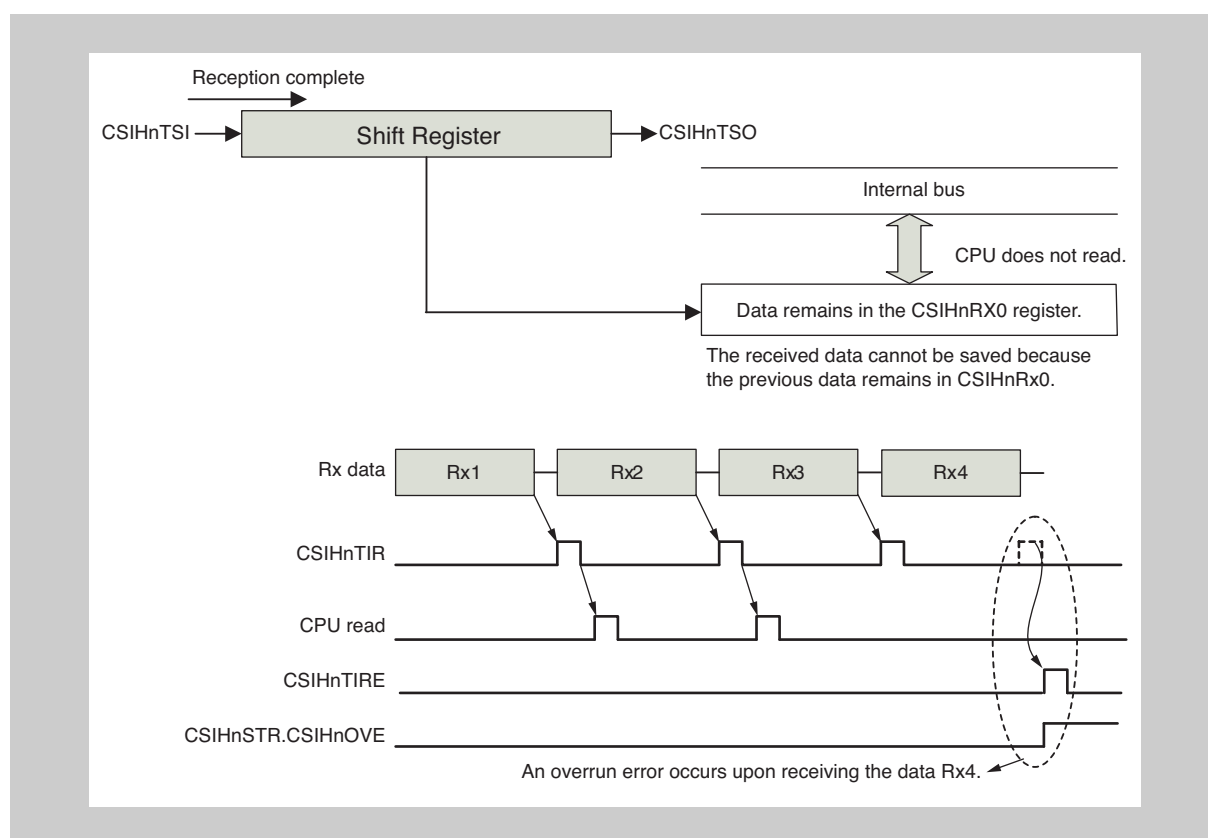

Figure 22-39 Overrun error detection in direct access and transmit-only buffer mode

FIFO mode In FIFO mode, an overrun error occurs if:

1. FIFO buffer full
Because the FIFO buffer is full, new received data cannot be transferred from the shift register to the FIFO buffer.
2. No data
The CPU attempts to read reception data that does not exist.

Note If the CPU attempts to read reception data that does not exist in the FIFO mode, an overrun error occurs even if data reception is disabled (CSIHnCTL0.CSIHnRXE = 0).

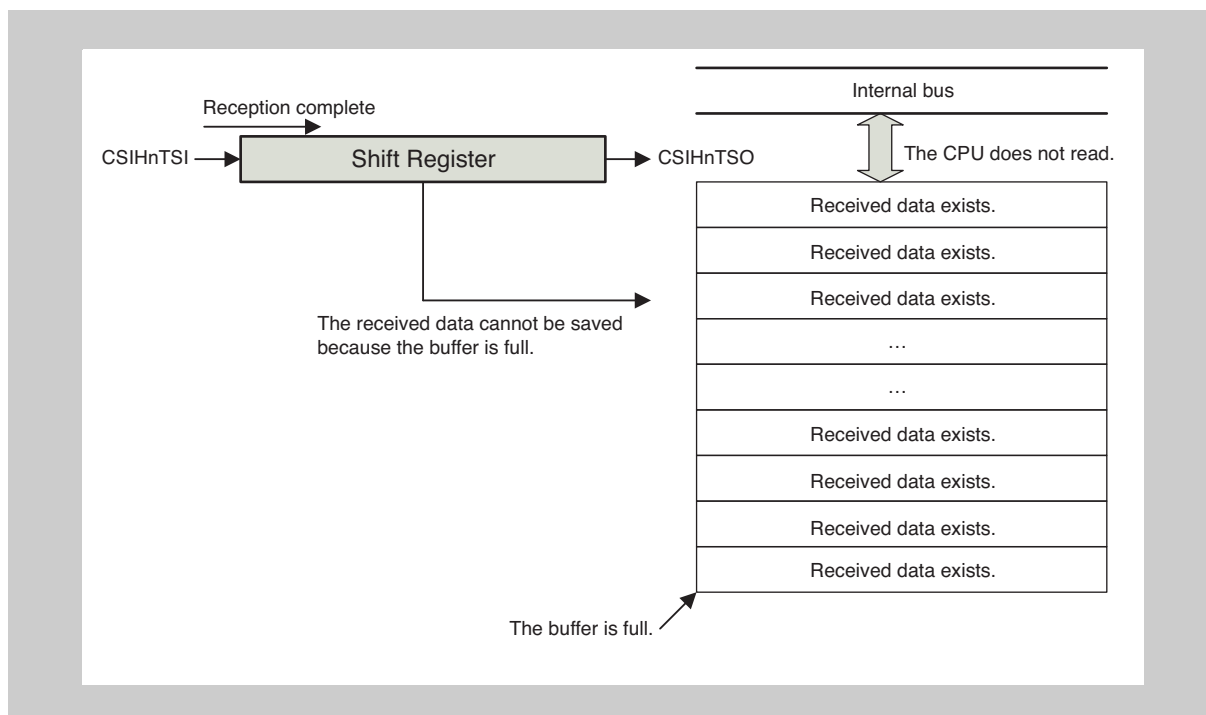

Figure 22-40 Overrun error detection in FIFO mode (FIFO full)

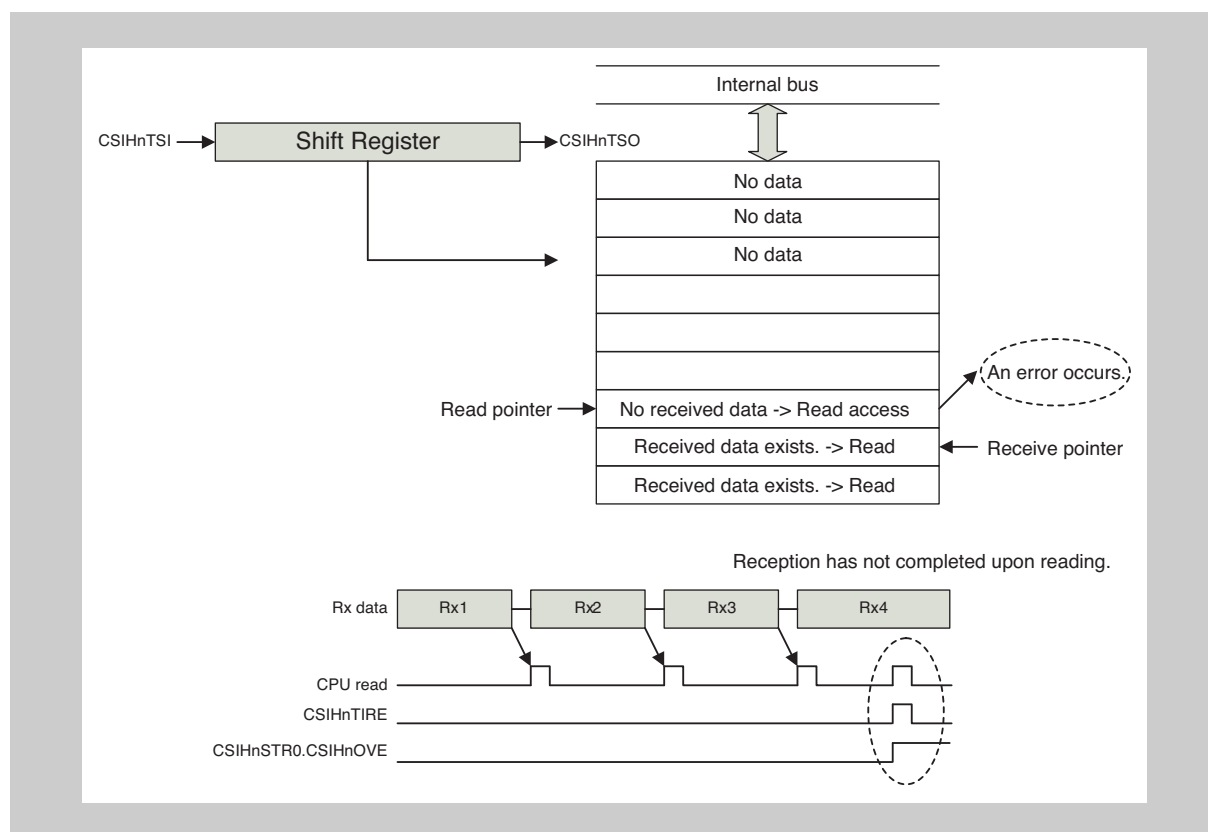

Figure 22-41 Overrun error detection in FIFO mode (no data)

When an overrun error occurs:

- Interrupt CSIHnTIRE is generated.
- Bit CSIHnSTR0.CSIHnOVE is set.
- Communication is stopped (except if the CPU tried to read non existing data).
- Communication continues (unless the CPU attempted to read data that did not exist).

Note An overrun error can be avoided in slave mode by using the handshake. When handshake is used in slave mode, the receiver (slave) signals to the transmitter (master) that it is busy. The transmitter then waits until the receiver has read its reception data register and is ready again.

For details, see 22.3.13 “Handshake function” on page 1172 .

22.3.15 Loop-back mode

Loop-back mode is a special mode for self-test. This feature is only available in master mode.

When this mode is active, the transmit and receive signals are internally connected, as shown in the figures below. The signals CSIHnTSCk, CSIHnTSo, and CSIHnTSl are disconnected from the ports. In addition, the CSIHnTSo output level is fixed to low, and CSIHnTSCk becomes inactive according to the setting of CSIHnCFGx.CSIHnCKPx. The handshake function cannot be used at this time. The rest of CSIH works as in normal operation.

The CSIHnTSCk, CSIHnTSo, CSIHnTSl, and CSIHnTCSSn[7:0] signals are disconnected from ports. The CSIHnTSo signal is fixed to the low output level, and the CSIHnTSCk and CSIHnTCSSn[7:0] signals are set to the inactive level (the level specified for the CSIHnCFGx.CSIHnCKPx bit in the case of the CSIHnTSCk signal, and the level specified for the CSIHnCTL1.CSIHnCLS[7:0] bits in the case of the CSIHnTCSSn[7:0] signal).

To perform a self-test of the CSIH, CSIHnCTL1.CSIHnLBM is set to 1, and a normal transfer operation is executed. Next, whether the reception data and transmission data are the same is checked.

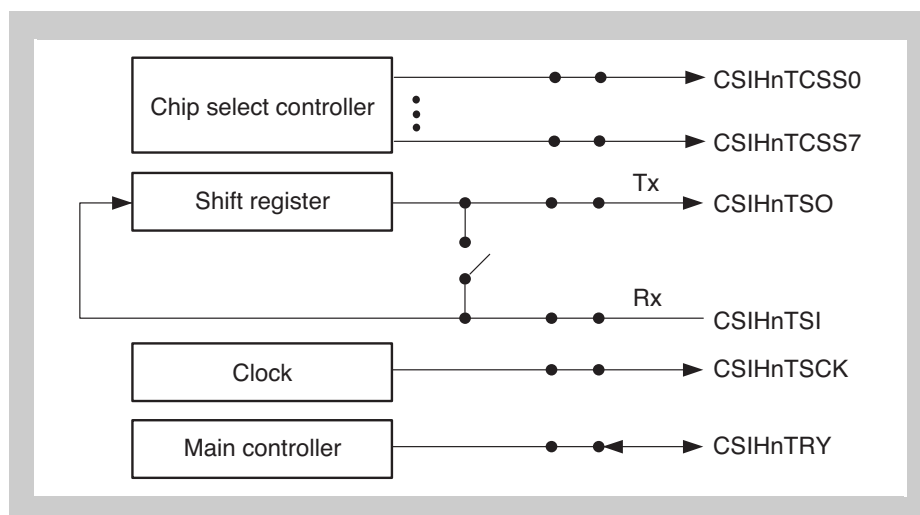

Figure 22-42 Normal operation

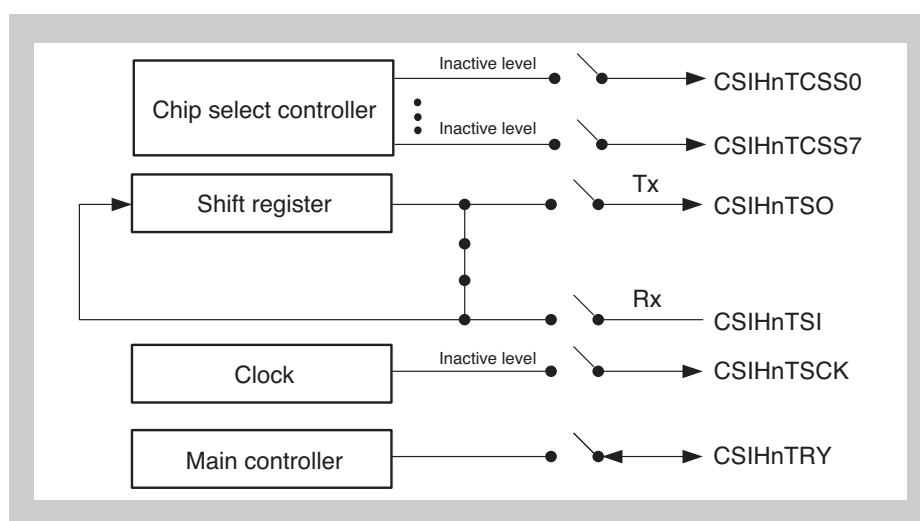

Figure 22-43 Loop-back operation

22.4 CSIH Control Registers

CSIHn is controlled and operated by means of the following registers:

Table 22-16 CSIH register overview

Register name	Shortcut	Address
Control register 0	CSIHnCTL0	<CSIHn_base_USER> + 0000 _H
Control register 1	CSIHnCTL1	<CSIHn_base_OS> + 0010 _H
Control register 2	CSIHnCTL2	<CSIHn_base_OS> + 0014 _H
Status register 0	CSIHnSTR0	<CSIHn_base_USER> + 0004 _H
Status clear register 0	CSIHnSTCR0	<CSIHn_base_USER> + 0008 _H
Memory control register 0	CSIHnMCTL0	<CSIHn_base_OS> + 1040 _H
Memory control register 1	CSIHnMCTL1	<CSIHn_base_USER> + 0080 _H
Memory control register 2	CSIHnMCTL2	<CSIHn_base_USER> + 0084 _H
Transmit data register 0 for word access	CSIHnTX0W	<CSIHn_base_USER> + 0088 _H
Transmit data register 0 for half word access	CSIHnTX0H	<CSIHn_base_USER> + 008C _H
Receive data register 0 for word access	CSIHnRX0W	<CSIHn_base_USER> + 0090 _H
Receive data register 0 for half word access	CSIHnRX0H	<CSIHn_base_USER> + 0094 _H
Memory read/write pointer register 0	CSIHnMRWP0	<CSIHn_base_USER> + 0098 _H
Configuration register 0	CSIHnCFG0	<CSIHn_base_OS> + 1044 _H

Configuration register 2	CSIHnCFG2	<CSIHn_base_OS> + 104C _H
Configuration register 3	CSIHnCFG3	<CSIHn_base_OS> + 1050 _H
Configuration register 4	CSIHnCFG4	<CSIHn_base_OS> + 1054 _H
Configuration register 5	CSIHnCFG5	<CSIHn_base_OS> + 1058 _H
Configuration register 6	CSIHnCFG6	<CSIHn_base_OS> + 105C _H
Configuration register 7	CSIHnCFG7	<CSIHn_base_OS> + 1060 _H

<CSIHn_base> The base addresses <CSIHn_base> of the CSIHn is defined in the first section of this chapter under the key word "Register addresses".

22.4.1 CSIH register details

(1) CSIHnCTL0 - CSIH control register 0

This register controls CSIHn. It mainly enables or disables the operation clock, transmission/reception, and the memory assigned to transmission/reception. It forces the stop of communication at the end of the current job.

Access This register can be read/written in 8-bit or 1-bit units.

Address <CSIHn_base_USER> + 0000_H

Initial Value 00_H. This register is initialized by any reset.

7	6	5	4	3	2	1	0
CSIHn PWR	CSIHn TXE	CSIHn RXE	0	0	0	CSIHn JOB	CSIHn MBS
R/W	R/W	R/W	R	R	R	R/W	R/W

Table 22-17 CSIHnCTL0 register contents (1/2)

Bit position	Bit name	Function
7	CSIHnPWR	Controls the operation clock. 0: Stops operation clock 1: Provides operation clock Clearing CSIHnPWR to 0 resets the internal circuits, stops operation, and sets the CSIH to standby state. No clock is provided to internal circuits, thus the power consumption of the CSIHn is minimized. If CSIHnPWR is cleared during communication, ongoing communication is immediately aborted. In this case, it is necessary to restart communication from the beginning.
6	CSIHnTXE	Enables/disables transmission. 0: Transmission disabled 1: Transmission enabled
5	CSIHnRXE	Enables/disables reception. 0: Receive disabled 1: Receive enabled

Table 22-17 CSIHnCTL0 register contents (2/2)

Bit position	Bit name	Function
1	CSIHnJOBE	<p>Stops the communication at the end of the current job (Communication ends when data is written to the transmission buffer while CSIHnTX0W.CSIHnEOJ = 1 (indicating that the job has ended)).</p> <p>0: Communication stop is not required 1: Communication stop</p> <p>This bit can be used to abort an ongoing job. It is automatically cleared. Even if this bit is set, 0 is always returned when it is read.</p> <p>In FIFO mode, the next communication should then be started after clearing the pointers by setting CSIHnSTCR0.CSIHnPCT = 1.</p> <p>Caution CSIHnJOBE is only valid when CSIHnCTL1.CSIHnJE = 1. Setting this bit is prohibited in the slave mode. When this bit is read, 0 is always returned.</p>
0	CSIHnMBS	<p>Bypasses the memory for transmission and/or reception data.</p> <p>0: Memory mode CSIH memory is used for transmission and/or reception data 1: Direct access mode CSIH memory is bypassed</p> <p>Caution This bit is only valid during a transfer operation when CSIHnCTL0.CSIHnPWR = 1 and CSIHnCTL1.CSIHnJE = 1. The bit is automatically cleared to 0 when the transfer finishes. Setting this bit is prohibited in the slave mode. When this bit is read, 0 is always returned.</p>

- Cautions**
1. When CSIHnPWR = 0, do not change the CSIHnTXE, CSIHnRXE, CSIHnJOBE, or CSIHnMBS bit. However, the CSIHnTXE, CSIHnRXE, or CSIHnMBS bit can be changed at the same time that the CSIHnPWR bit changes from 0 to 1.
 2. Do not modify CSIHnTXE or CSIHnRXE or CSIHnMBS while a data transmission is pending or going on, i.e. if CSIHnSTR0.CSIHnTSF = 1.

(2) CSIHnCTL1 - CSIH control register 1

This register controls CSIHn. It mainly specifies the clock phase, interrupt timing, and interrupt delay mode, controls the extended data length, and enables or disables the data consistency check, loopback mode, handshake function, and job mode. This register also selects the active output level of each chip select signal and the chip select signal operation to perform after the last data is transferred.

Access This register can be read/written in 32-bit units.

Address <CSIHn_base_OS> + 0010_H

Initial Value 0000 0000_H. This register is initialized by any reset.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Caution Changing the contents of this register is only permitted when CSIHnCTL0.CSIHnPWR = 0.

Table 22-18 CSIHnCTL1 register contents (1/2)

Bit position	Bit name	Function
17	CSIHnCKR	Selects the CSIHnTSCK clock phase. 0: The default CSIHnTSCK level is the high level. 1: The default CSIHnTSCK level is the low level. Caution When using this bit without using the chip select function, clear CSIHnCFGx.CSIHnCKPx to 0.
16	CSIHnSLIT	Selects the timing of interrupt CSIHnTIC. 0: Normal interrupt timing (interrupt is generated after the transfer) 1: When the contents of the CSIHnTX0W or CSIHnTX0H register are transferred to the shift register, an interrupt is immediately generated. (This only functions in the direct access mode.) For details, refer to “CSIHnTIC in direct access mode” on page 1164 .
15 to 8	CSIHnCSLx	Selects the active output level of chip select signal x (CSIHnTCSSx). 0: Chip select is active low 1: Chip select is active high For details, refer to 22.3.3 “Chip selection (CS) features” on page 1148 .
7	CSIHnEDLE	Enables/disables extended data length (EDL) mode. 0: Extended data length mode disabled 1: Extended data length mode enabled For details, refer to 2 “Data length greater than 16 bits” on page 1159 .

Table 22-18 CSIHnCTL1 register contents (2/2)

Bit position	Bit name	Function
6	CSIHnJE	Enables/disables job mode. 0: Job mode disabled 1: Job mode enabled For details, refer to 22.3.4 “Chip select timing details” on page 1150 . The CSIHnCTL0.CSIHnJOBE, CSIHnTX0W.CSIHnEOJ, and CSIHnTX0W.CSIHnCIRE bits are only valid when this bit is 1. Setting this bit is prohibited in the slave mode.
5	CSIHnDCS	Enables/disables data consistency check. 0: Data consistency check disabled 1: Data consistency check enabled For details, refer to 1 “Data consistency check” on page 1176 .
4	CSIHnCSRI	Defines chip select behavior after last data transfer. 0: Chip select holds active level 1: Chip select returns to inactive level The last data is identified at the interrupt timing while in the direct access mode or FIFO mode. The direct access mode is used while CSIHnCTL1.CSIHnSLIT = 1.
3	CSIHnLBM	Controls loop-back mode (LBM). 0: Loop-back mode deactivated 1: Loop-back mode activated For details, refer to 22.3.15 “Loop-back mode” on page 1186 . Setting this bit is prohibited in the slave mode.
2	CSIHnSIT	Selects interrupt delay mode. 0: No delay 1: Half clock delay for all interrupts This bit is only valid in master mode. In slave mode, no delay is generated. For details, refer to “CSIHnTIC in direct access mode” on page 1164 .
1	CSIHnHSE	Enables/disables handshake mode. 0: Handshake function disabled 1: Handshake function enabled For details, refer to 22.3.13 “Handshake function” on page 1172 .
0	CSIHnSSE	Enables/disables slave select function. 0: Input signal $\overline{\text{CSIHnTSSI}}$ is ignored 1: Input signal $\overline{\text{CSIHnTSSI}}$ is recognized If the slave select function is not used, this bit must be set to 0 (see also 22.3.2 “Master/slave connections” on page 1146).

Details about CSIHnCTL1.CSIHnSSE:

Table 22-19 Operation of the slave select function during reception

CSIHnCTL0. CSIHnRXE	CSIHnCTL1. CSIHnSSE	$\overline{\text{CSIHnTSSI}}$	Receive operation
0	–	–	Reception disabled
1	0	–	Possible
1	1	0	Possible
1	1	1	Disabled

0	–	–	Transmission disabled
1	0	–	Possible
1	1	0	Possible
1	1	1	Disabled

(3) CSIHnCTL2 - CSIH control register 2

This register controls CSIHn. It selects the operating mode, prescaler, and baud rate.

For details, refer to 22.3.6 “Serial clock selection” on page 1153.

Access This register can be read/written in 16-bit units.

Address <CSIHn_base_OS> + 0014_H

Initial Value E000_H. This register is initialized by any reset.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Table 22-22 CSIHnSTR0 register contents (3/3)

Bit position	Bit name	Function
5	CSIHnFLF	<p>Indicates whether the buffer is full while in the FIFO mode.</p> <p>0: FIFO buffer is not full 1: FIFO buffer is full</p> <p>This bit is set when the sum of the CSIHnSTR0.CSIHnSRP[7:0] bit value and CSIHnSTR0.CSIHnSPF[7:0] bit value matches 80_H, and is cleared when this sum does not match 80_H.</p> <p>This bit is cleared by CSIHnSTCR0.CSIHnPCT.</p> <p>The FIFO buffer sometimes fills up with data that has not been transmitted and reception data.</p>
4	CSIHnEMF	<p>Indicates whether the buffer is empty while in the FIFO mode.</p> <p>0: FIFO buffer is not empty 1: FIFO buffer is empty</p> <p>This bit is set by CSIHnSTCR0.CSIHnPCT.</p> <p>This bit is set when the sum of the CSIHnSTR0.CSIHnSRP[7:0] bit value and CSIHnSTR0.CSIHnSPF[7:0] bit value matches 00_H, and is cleared when this sum does not match 00_H.</p> <p>The FIFO buffer sometimes does not contain any data that has not been transmitted or reception data.</p>
3	CSIHnDCE	<p>Data consistency error flag</p> <p>0: No data consistency error detected 1: Data consistency error detected</p> <p>This bit is cleared by setting CSIHnSTCR0.CSIHnDCEC.</p> <p>This bit can be written to when CSIHnCTL0.CSIHnPWR = 0.</p> <p>This bit is initialized when CSIHnCTL0.CSIHnPWR changes from 0 to 1 or from 1 to 0.</p> <p>If this bit is set due to a data consistency error being detected and cleared by CSIHnSTCR0.CSIHnDCEC at the same time, setting the bit is prioritized.</p>
1	CSIHnPE	<p>Parity error flag</p> <p>0: No parity error detected 1: Parity error detected</p> <p>This bit is cleared by setting CSIHnSTCR0.CSIHnPEC.</p> <p>This bit can be written to when CSIHnCTL0.CSIHnPWR = 0.</p> <p>This bit is initialized when CSIHnCTL0.CSIHnPWR changes from 0 to 1 or from 1 to 0.</p> <p>If this bit is set due to a parity error being detected and cleared by CSIHnSTCR0.CSIHnPEC at the same time, setting the bit is prioritized.</p>
0	CSIHnOVE	<p>Overrun error flag</p> <p>0: No overrun error detected 1: Overrun error detected</p> <p>This bit is cleared by setting CSIHnSTCR0.CSIHnOVEC.</p> <p>This bit can be written to when CSIHnCTL0.CSIHnPWR = 0.</p> <p>This bit is initialized when CSIHnCTL0.CSIHnPWR changes from 0 to 1 or from 1 to 0.</p> <p>This bit is fixed to 0 in the dual buffer mode.</p> <p>If this bit is set due to an overrun error being detected and cleared by CSIHnSTCR0.CSIHnOVEC at the same time, setting the bit is prioritized.</p>

Table 22-23 Memory mode operation

Bit name	Bit position	Direct access mode	FIFO mode	Transmit-only buffer mode	Dual buffer mode
CSIHnSRP[7:0]	31 to 24	Fixed to 0	Number of received data items	Fixed to 0	Fixed to 0
CSIHnSPF[7:0]	23 to 16	Fixed to 0	Number of data items that have not been transmitted	Fixed to 0	Fixed to 0
CSIHnTMOE	15	Fixed to 0	0: No error has been detected. 1: An error has been detected.	Fixed to 0	Fixed to 0
CSIHnOFE	14	Fixed to 0	0: No error has been detected. 1: An error has been detected.	Fixed to 0	Fixed to 0
CSIHnTSF	7	0: Idle state 1: Transmitting or preparing to transmit			
CSIHnFLF	5	Fixed to 0	0: Not full 1: Full	Fixed to 0	Fixed to 0
CSIHnEMF	4	Fixed to 1	0: Not empty 1: Empty	Fixed to 1	Fixed to 1
CSIHnDCE	3	0: No error has been detected. 1: An error has been detected.			
CSIHnPE	1	0: No error has been detected. 1: An error has been detected.			
CSIHnOVE	0	0: No error has been detected. 1: An error has been detected.			Fixed to 0

(5) CSIHnSTCR0 - CSIH status clear register 0

This register clears the status flags of the CSIHnSTR0 status register.

Access This register can be written in 16-bit units.

When read, the value 0000_H is always returned.

Address <CSIHn_base_USER> + 0008_H

Initial Value 0000_H. This register is initialized by any reset.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CSIHn TMOEC	CSIHn OFEC	0	0	0	0	0	CSIHn PCT	0	0	0	0	CSIHn DCEC	0	CSIHn PEC	CSIHn OVEC
W	W	R	R	R	R	R	W	R	R	R	R	W	R	W	W

Table 22-24 CSIHnSTCR0 register contents

Bit position	Bit name	Function
15	CSIHnTMOEC	Timeout error flag clear command 0: No operation. Read value is always 0. 1: Clear time out error flag (CSIHnSTR0.CSIHnTMOE)
14	CSIHnOFEC	Overflow error flag clear command 0: No operation. Read value is always 0. 1: Clear overflow error flag (CSIHnSTR0.CSIHnOFE)
8	CSIHnPCT	Controls the FIFO buffer pointers. 0: No operation. Read value is always 0. 1: In the dual buffer mode, transmit-only buffer mode, or FIFO mode, clear all the following FIFO buffer pointers: - CSIHnMRWP0.CSIHnTRWA[6:0] - CSIHnMRWP0.CSIHnRRA[6:0] - CSIHnMCTL2.CSIHnSOP[6:0] In only the FIFO mode, also clear all the following status bits: - CSIHnSTR0.CSIHnSPF[7:0] - CSIHnSTR0.CSIHnSRP[7:0] - CSIHnSTR0.CSIHnFLF - CSIHnSTR0.CSIHnTSF Note that CSIHnSTR0.CSIHnEMF is set (indicating an empty FIFO buffer). Caution When this bit is set during communication, the communication stops.
3	CSIHnDCEC	Data consistency error flag clear command 0: No operation. Read value is always 0. 1: Clear data consistency error flag (CSIHnSTR0.CSIHnDCE)
1	CSIHnPEC	Parity error flag clear command 0: No operation. Read value is always 0. 1: Clear parity error flag (CSIHnSTR0.CSIHnPE)
0	CSIHnOVEC	Overrun error flag clear command 0: No operation. Read value is always 0. 1: Clear overrun error flag (CSIHnSTR0.CSIHnOVE)

(6) CSIHnMCTL0 - CSIH Memory control register 0

This register selects the memory mode and the timeout setting.

Access This register can be read/written in 16-bit units.

Address <CSIHn_base_OS> + 1040_H

Initial Value 001F_H. This register is initialized by any reset.

Clear these bits to 00000_B when in the master mode or a memory mode other than the FIFO mode (the direct access mode, dual buffer mode, or transmission mode). For details about timeout detection, see also 3 "Timeout error" on page 1179.</p>	CSIHnTO[4:0]	Description	00000 _B	No timeout detection	00001 _B	Timeout is (1 x 8 x BRG output clocks)	00010 _B	Timeout is (2 x 8 x BRG output clocks)	11111 _B	Timeout is (31 x 8 x BRG output clocks)			
CSIHnTO[4:0]	Description																
00000 _B	No timeout detection																
00001 _B	Timeout is (1 x 8 x BRG output clocks)																
00010 _B	Timeout is (2 x 8 x BRG output clocks)																
...	...																
11111 _B	Timeout is (31 x 8 x BRG output clocks)																

(7) CSIHnMCTL1 - CSIH Memory control register 1

This register selects the conditions to generate the interrupt requests CSIHnTIC and CSIHnTIR in FIFO mode.

Access This register can be read/written in 32-bit units.

Address <CSIHn_base_USER> + 0080_H

Initial Value 0000 007F_H. This register is initialized by any reset.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0	0	0	0	0	0	0	0	0	CSIHnFES[6:0]

R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Note This register can be written to during communication.

Table 22-26 CSIHnMCTL1 register contents

Bit position	Bit name	Function
22 to 16	CSIHnFES[6:0]	Select the condition for generating the CSIHnTIC interrupt (no transmission data). When the number of transmission data items in the FIFO buffer that have not been transmitted (checked by using the CSIHnSTR0.CSIHnSPF[7:0] bits) matches CSIHnMCTL1.CSIHnFES[6:0], a CSIHnTIC interrupt request is generated.
6 to 0	CSIHnFFS[6:0]	Select the condition for generating the CSIHnTIR interrupt (a full reception buffer). When the number of received data items in the FIFO buffer (checked by using the CSIHnSTR0.CSIHnSRP[7:0] bits) matches (128 – CSIHnMCTL1.CSIHnFFS[6:0]), a CSIHnTIR interrupt request is generated.

(8) CSIHnMCTL2 - CSIH Memory control register 2

This register controls memory operations while in the dual buffer mode or transmit-only buffer mode and generates triggers to start communication.

Access This register can be read/written in 32-bit units.

Address <CSIHn_base_USER> + 0084_H

Initial Value 0000 0000_H. This register is initialized by any reset.

- Cautions**
1. Writing to this register is prohibited when CSIHnSTR0.CSIHnTSF = 1 (during a transfer).
 2. Writing to the CSIHnMCTL2 register is prohibited in the following cases:
 - When CSIHnCTL0.CSIHnPWR = 0
 - When CSIHnCTL0.CSIHnTXE = CSIHnCTL0.CSIHnRXE = 0
 - When in the direct access mode or FIFO mode

(9) CSIHnMRWP0 - CSIH memory read/write pointer register 0

This register sets the pointers for reading from and writing to the dual or transmit-only buffer.

Access This register can be read/written in 32-bit units.

Address <CSIHn_base_USER> + 0098_H

Initial Value 0000 0000_H. This register is initialized by any reset.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

		<p>When transmission data is read or written from the CPU, these bits are automatically incremented.</p> <p>These bits are cleared when CSIHnSTCR0.CSIHnPCT is set.</p> <p>In the direct access mode, these bits are not incremented.</p> <p>In the FIFO mode, these bits indicate the read/write address of the transmission data.</p>				

(10) CSIHnCFGx - CSIH configuration register x

These eight registers specify for each chip select signal CSIHnTCSSx prescaler, parity, data length, recessive configuration for broadcasting, serial data direction, clock phase and data phase, idle enforcement configuration, idle timing, hold timing, inter-data time, and setup timing.

Slave mode In slave mode the transmission protocol setting of the CSIHnCFG0 register are relevant:

- CSIHnPS0: Parity usage
- CSIHnDLS0: Data length selection
- CSIHnDIR0: Data direction
- CSIHnCKP0, CSIHnDAP0: Clock phase and data phase

In the slave mode, clear the CSIHnCFG0 register bits other than the above and the CSIHnCFG1 to CSIHnCFG7 registers to 0.

Access This register can be read/written in 32-bit units.

Address CSIHnCFG0: <CSIHn_base_OS> + 1044_H
 CSIHnCFG1: <CSIHn_base_OS> + 1048_H
 CSIHnCFG2: <CSIHn_base_OS> + 104C_H
 CSIHnCFG3: <CSIHn_base_OS> + 1050_H
 CSIHnCFG4: <CSIHn_base_OS> + 1054_H
 CSIHnCFG5: <CSIHn_base_OS> + 1058_H
 CSIHnCFG6: <CSIHn_base_OS> + 105C_H
 CSIHnCFG7: <CSIHn_base_OS> + 1060_H

Initial Value 0000 0000_H. This register is initialized by any reset.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

(11) CSIHnTX0W - CSIH transmit data register 0 for word access

This register stores the transmission data. In addition, it specifies the communication interrupt request, the end-of-job, the extended data length, and the chip select activation.

Access This register can be read/written in 32-bit units.

Address <CSIHn_base_USER> + 0088_H

Initial Value Undefined

- Cautions**
1. Reading this register is prohibited during communication in the FIFO mode.
 2. Reading from and writing to this register are prohibited in the FIFO mode when CSIHnCTL0.CSIHnPWR = 0.
 3. Writing to this register is prohibited in the direct access mode when CSIHnCTL0.CSIHnTXE = CSIHnCTL0.CSIHnRXE = 0.

Table 22-30 CSIHnTX0W register contents (1/2)

Bit position	Bit name	Function
31	CSIHnCIRE	Enables the communication interrupt request CSIHnTIC in dual or transmit-only buffer mode or the job completion interrupt CSIHnTJC request in FIFO mode. 0: No interrupt requested 1: Interrupt requested. Generates interrupt CSIHnTIC or CSIHnTJC after transmission. For details, see “CSIHnTIC in direct access mode” on page 1164 and 4 “CSIHnTJC job completion interrupt” on page 1171. Caution This bit is only valid when the job mode is enabled (CSIHnCTL1.CSIHnJE = 1).
30	CSIHnEOJ	Specifies the end of a job. 0: No end-of-job data 1: End-of-job data Caution This bit is only valid when the job mode is enabled (CSIHnCTL1.CSIHnJE = 1). For use in the slave mode, clear this bit.

Table 22-30 CSIHnTX0W register contents (2/2)

Bit position	Bit name	Function
29	CSIHnEDL	<p>Specifies whether the associated data requires the extended data length (EDL) option.</p> <p>0: Normal operation 1: Extended data length activated</p> <p>The associated data is transmitted as of 16 bits. The inter-data delay time and idle time are not inserted after data transmission.</p> <p>When CSIHnCTL1.CSIHnEDLE = 1 and CSIHnTX0W.CSIHnEDL = 1, the same CS must also be selected for the second data. If the CS for the second data is changed, the correct operation is not guaranteed.</p> <p>Caution This bit can only be used when CSIHnCTL1.CSIHnEDLE = 1.</p>
23 to 16	CSIHnCSx	<p>Activates one or several chip select signals.</p> <p>0: Chip select x is activated for the associated transmission 1: Chip select x is deactivated for the associated transmission</p> <p>Setting CSIHnTX0W.CSIHnCS[7:0] to FF_H is prohibited.</p> <p>Caution If several chip select signals are enabled for broadcasting, the configuration of one with CSIHnCFGx.CSIHnRCBx = 0 (dominant) is used. In this case, all dominant chip selects must be set to precisely the same configuration. For use in the slave mode, set the CSIHnCS[7:0] bits to FE_H.</p>
15 to 0	CSIHnTX[15:0]	Stores the transmission data.

(12) CSIHnTX0H - CSIH transmit data register 0 for half word access

This register stores the transmission data. This register is the same as bits 15 to 0 of register CSIHnTX0W.

Access This register can be read/written in 16-bit units.

Address <CSIHn_base_USER> + 008C_H

Initial Value Undefined

-
- Cautions**
1. Reading this register is prohibited during communication in the FIFO mode.
 2. Reading from and writing to this register are prohibited in the FIFO mode when CSIHnCTL0.CSIHnPWR = 0.
 3. Writing to this register is prohibited in the direct access mode when CSIHnCTL0.CSIHnTXE = CSIHnCTL0.CSIHnRXE = 0.
-

Table 22-31 CSIHnTX0H register contents

Bit position	Bit name	Function
15 to 0	CSIHnTX[15:0]	Stores the transmission data.

(13) CSIHnRX0W - CSIH receive data register 0 for word access

This register stores the received data.

Access This register is read-only, in 32-bit units.

Address <CSIHn_base_USER> + 0090_H

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CSIHnRX[15:0]															
R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

- Cautions**
1. This register can be read when CSIHnCTL0.CSIHnPWR = 1, and can be written to when CSIHnCTL0.CSIHnPWR = 0.
 2. This register is Initialized when CSIHnCTL0.CSIHnPWR changes from 0 to 1 or from 1 to 0.
 3. Reading from and writing to this register are prohibited in the FIFO mode when CSIHnCTL0.CSIHnPWR = 0.

Table 22-32 CSIHnRX0W register contents

Bit position	Bit name	Function
25	CSIHnRPE	Indicates whether a reception data parity error was detected. 0: No parity error has been detected in the received data. 1: A parity error has been detected in the received data.
24	CSIHnTDCE	Indicates whether a transmission data consistency error was detected. A data consistency check is performed on transmission data. The result of the check performed on the data transmitted at the same time as saving received data to CSIHnRX0W.CSIHnRX[15:0] is applied to this bit. 0: No data consistency error has been detected in the transmitted data. 1: A data consistency error has been detected in the transmitted data.
23 to 16	CSIHnCSx	Indicate whether the chip select signal is active. When in the master mode, the status of the chip select signal upon receiving the data saved to CSIHnRX0W.CSIHnRX[15:0] (that is, which CS to perform communication for) is stored in these bits. 0: Chip select signal x was active upon receiving the data. 1: Chip select signal x was inactive upon receiving the data. When in the slave mode, because it is necessary to specify CS0 (CSIHnTX0W.CSIHnCS[7:0] = FE _H) as the communication partner when transmission is enabled, FE _H is saved in the transmission mode or transmission/reception mode. The value is always 00 _H when in the reception mode.
15 to 0	CSIHnRX[15:0]	Store the reception data. Read the value of the CSIHnRX0W or CSIHnRX0H register at least one serial clock cycle before the interrupt is generated.

(14) CSIHnRX0H - CSIH receive data register 0 for half word access

This register stores the reception data. This register is the same as bits 15 to 0 of register CSIHnTX0W.

Access This register is read-only, in 16-bit units.

Address <CSIHn_base_USER> + 0094_H

Initial Value Undefined

-
- Cautions**
1. This register can be read when CSIHnCTL0.CSIHnPWR = 1, and can be written to when CSIHnCTL0.CSIHnPWR = 0.
 2. This register is initialized when CSIHnCTL0.CSIHnPWR is changed from 0 to 1 or 1 to 0.
 3. Reading from and writing to this register are prohibited in the FIFO mode when CSIHnCTL0.CSIHnPWR = 0.
-

Table 22-33 CSIHnRX0H register contents

Bit position	Bit name	Function
15 to 0	CSIHnRX[15:0]	Stores the reception data.

22.5 Operating Procedures

The following examples and instructions are sorted according to the memory mode:

- Direct access
- Transmit-only buffer
- Dual buffer
- FIFO

22.5.1 Procedures in direct access mode

(1) For transmission/reception in the master mode, and when the job mode is disabled

The following conditions are assumed for the procedure shown here:

- Transmission data length: 8 bits (CSIHnCFGx.CSIHnDLSx[3:0] = 1000_B)
- Transmission direction: MSB first (CSIHnCFGx.CSIHnDIRx = 0)
- Normal clock phase and data phase (CSIHnCFGx.CSIHnCKPx = 0, CSIHnCFGx.CSIHnDAPx = 0)
- No delay for any interrupt (CSIHnCTL1.CSIHnSIT = 0)
- Job mode disabled (CSIHnCTL1.CSIHnJE = 0)
- A CSIHnTIC interrupt is generated when transferring starts. (CSIHnCTL1.CSIHnCLIT = 1)
- Direct access mode (CSIHnCTL0.CSIHnMBS = 0)

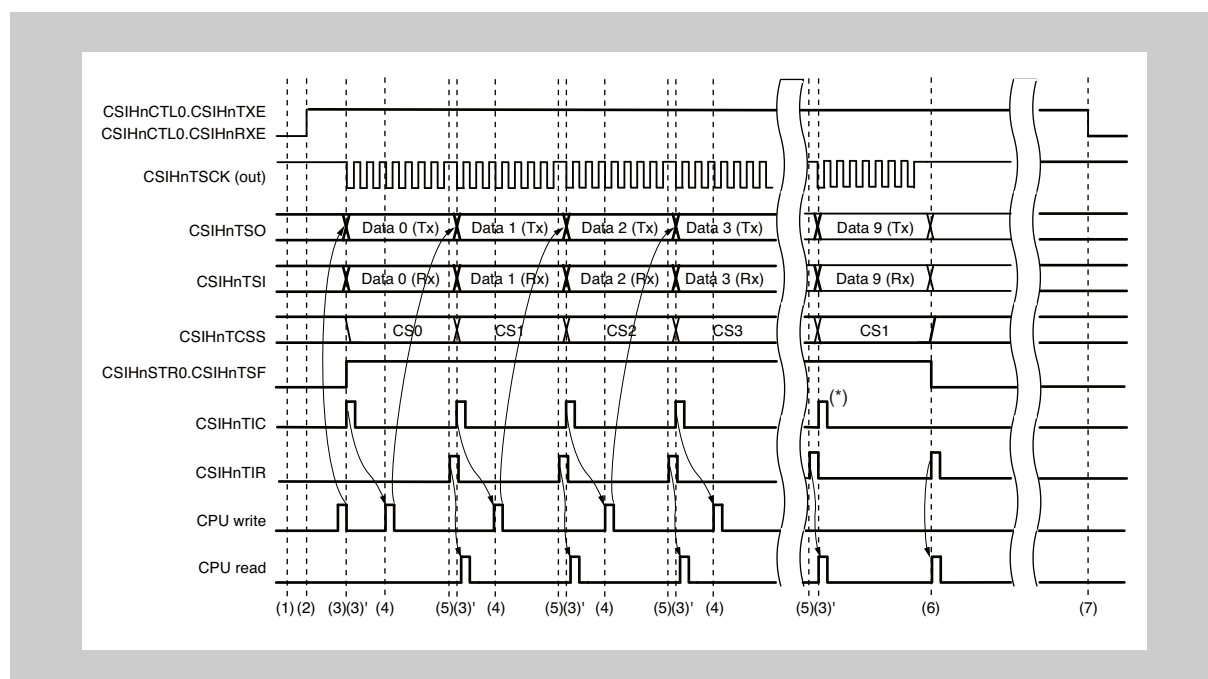

Figure 22-44 Direct access mode (for transmission/reception in the master mode, and when the job mode is disabled)

- Procedure:**
1. Set up the following registers before setting CSIHnCTL0.CSIHnPWR to 1: CSIHnCTL1, CSIHnCTL2 (transfer mode, operating mode) CSIHnCFGx (communication protocol)
(For this example, the chip select signals CS0 to CS3 are used.)
 2. CSIHnCTL0.CSIHnPWR = 1 (clock enabled)
CSIHnCTL0.CSIHnTXE = 1 (transmission enabled)
CSIHnCTL0.CSIHnRXE = 1 (reception enabled)
CSIHnCTL0.CSIHnMBS = 1 (direct access mode selected)
 3. Write the first data to the transmission data register CSIHnTX0W. This write operation activates CS0, and transmission automatically starts.
 - 3'. When CSIHnCTL1.CSIHnSLIT is set to 1, CSIHnTIC is generated at the start edge of CSIHnTSCK. CSIHnTIC indicates that the second data can be written to CSIHnTX0W.

4. Write the second data to CSIHnTX0W. If necessary, it is possible to change the CS and make a different device the communication partner. By writing the second data immediately after writing the first data, the unnecessary inter-data delay can be avoided.
5. Each time data is received, a CSIHnTIR interrupt is generated.
 - CSIHnTIR indicates that the reception data register CSIHnRX0 must be read.
6. If the CSIHnTIC interrupt indicated by “*” in the figure is the last one, it is not necessary to write to the transmission data register CSIHnTX0W based on the corresponding CSIHnTIC interrupt.
7. Finally, clear CSIHnCTL0.CSIHnTXE and CSIHnCTL0.CSIHnRXE to disable transmission/reception operations. In addition, clear CSIHnCTL0.CSIHnPWR to reduce the power consumption of the CSIH.

(2) For reception in the master mode, and when the job mode is disabled

The following conditions are assumed for the procedure shown here:

- Transmission data length: 8 bits (CSIHnCFGx.CSIHnDLSx[3:0] = 1000_B)
- Transmission direction: MSB first (CSIHnCFGx.CSIHnDIRx = 0)
- Normal clock phase and data phase (CSIHnCFGx.CSIHnCKPx = 0, CSIHnCFGx.CSIHnDAPx = 0)
- No delay for any interrupt (CSIHnCTL1.CSIHnSIT = 0)
- Job mode enabled (CSIHnCTL1.CSIHnJE = 1)
- A CSIHnTIC interrupt is generated when transferring starts. (CSHICTL1.CSIHnSLIT = 1)
- Direct access mode (CSHICTL0.CSIHnMBS = 1)

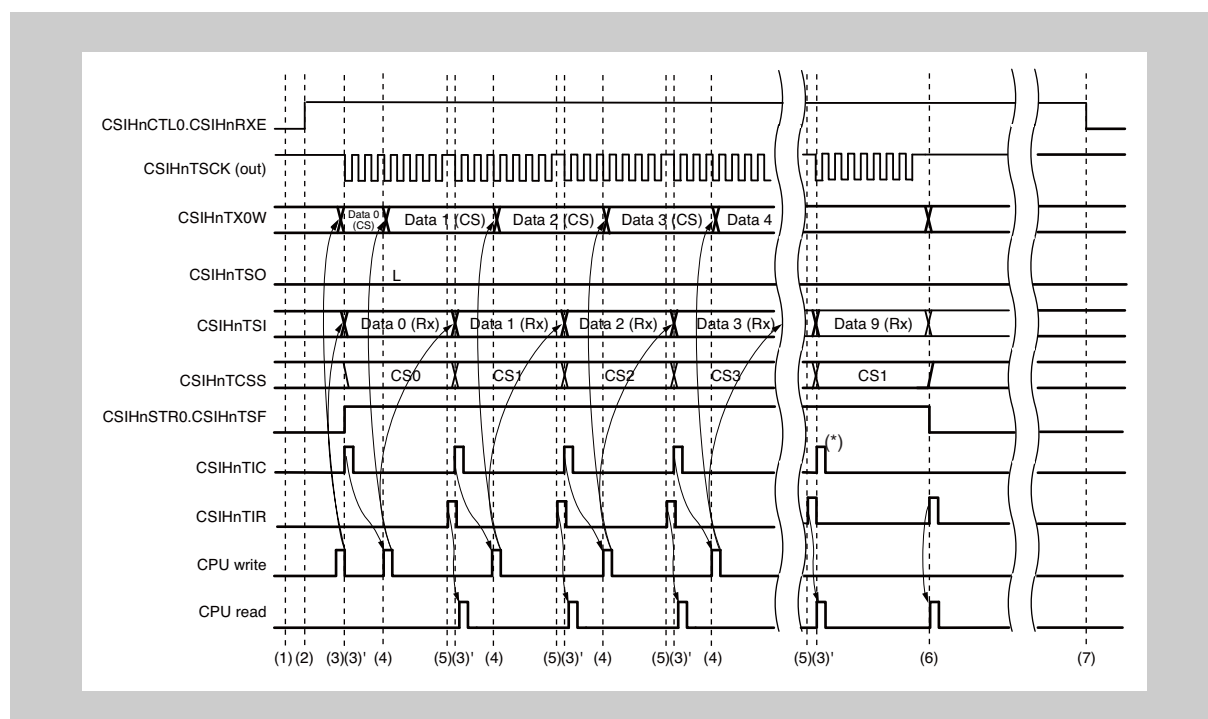

Figure 22-45 Direct access mode (for reception in the master mode, and when the job mode is disabled)

- Procedure:**
1. Set up the following registers before setting CSIHnCTL0.CSIHnPWR to 1: CSIHnCTL1, CSIHnCTL2 (transfer mode, operating mode) CSIHnCFGx (communication protocol)
(For this example, the chip select signals CS0 to CS3 are used.)
 2. CSIHnCTL0.CSIHnPWR = 1 (clock enabled)
CSIHnCTL0.CSIHnTXE = 0 (transmission disabled)
CSIHnCTL0.CSIHnRXE = 1 (reception enabled)
CSIHnCTL0.CSIHnMBS = 1 (direct access mode selected)
 3. Write the transmission data^a to the transmission data register CSIHnTX0W for the CS data. This write operation activates CS0, and reception automatically starts.

a). The transmission data is not used, but the chip select signal is enabled.

- 3'. When CSIHnCTL1.CSIHnSLIT is set to 1, CSIHnTIC is generated at the start edge of CSIHnTSCK. CSIHnTIC indicates that the second data can be written to CSIHnTX0W.
4. Write the second data to CSIHnTX0W. If necessary, it is possible to change the CS and make a different device the communication partner. By writing the second data immediately after writing the first data, the unnecessary inter-data delay can be avoided.
5. Each time data is received, a CSIHnTIR interrupt is generated.
 - CSIHnTIR indicates that the reception data register CSIHnRX0W must be read.
6. If the CSIHnTIC interrupt indicated by “*” in the figure is the last one, it is not necessary to write to the transmission data register CSIHnTX0W based on the corresponding CSIHnTIC interrupt.
7. Finally, clear CSIHnCTL0.CSIHnTXE and CSIHnCTL0.CSIHnRXE to disable transmission/reception operations. In addition, clear CSIHnCTL0.CSIHnPWR to reduce the power consumption of the CSIH.

(3) For transmission/reception in the slave mode, and when the job mode is disabled

The following conditions are assumed for the procedure shown here:

- Transmission data length: 8 bits (CSIHnCFG0.CSIHnDLS0[3:0] = 1000_B)
- Transmission direction: MSB first (CSIHnCFG0.CSIHnDIR0 = 0)
- Normal clock phase and data phase (CSIHnCFG0.CSIHnCKP0 = 0, CSIHnCFG0.CSIHnDAP0 = 0)
- Job mode disabled (CSIHnCTL1.CSIHnJE = 0)
- Handshake enabled (CSIHnCTL1.CSIHnHSE = 1)
- CSIHnTIC interrupt generated at the transfer start timing (CSIHnCTL1.CSIHnSLIT = 1)
- Direct access mode (CSIHnCTL0.CSIHnMBS = 1)

Figure 22-46 Direct access mode (for transmission/reception in the slave mode, and when the job mode is disabled)

- Procedure:**
1. Set up the following registers before setting CSIHnCTL0.CSIHnPWR to 1: CSIHnCTL1, CSIHnCTL2 (transfer mode, operating mode) CSIHnCFG0 (communication protocol)
 2. CSIHnCTL0.CSIHnPWR = 1 (clock enabled)
CSIHnCTL0.CSIHnTXE = 1 (transmission enabled)
CSIHnCTL0.CSIHnRXE = 1 (reception enabled)
CSIHnCTL0.CSIHnMBS = 1 (direct access mode selected)
 3. Write the first data to the transmission data register CSIHnTX0W. The CSIHnTRY signal is switched from BUSY (low level) to READY (high level) by writing data. When a serial clock is supplied from the master, communication automatically starts.
 4. When CSIHnCTL1.CSIHnSLIT is set to 1, CSIHnTIC is generated at the start edge of CSIHnTSCK. CSIHnTIC indicates that the second data can be written to CSIHnTX0W.

5. Write the second data to CSIHnTX0W. By writing the second data immediately after writing the first data, the unnecessary inter-data delay can be avoided.
6. Each time data is received, a CSIHnTIR interrupt is generated.
 - CSIHnTIR indicates that the reception data register CSIHnRX0W must be read.
7. If the CSIHnTIC interrupt indicated by "*" in the figure is the last one, it is not necessary to write to the transmission data register CSIHnTX0W based on the corresponding CSIHnTIC interrupt.
8. Finally, clear CSIHnCTL0.CSIHnTXE and CSIHnCTL0.CSIHnRXE to disable transmission/reception operations. In addition, clear CSIHnCTL0.CSIHnPWR to reduce the power consumption of the CSIH.

(4) For reception in the slave mode, and when the job mode is disabled

The following conditions are assumed for the procedure shown here:

- Transmission data length: 8 bits (CSIHnCFG0.CSIHnDLS0[3:0] = 1000_B)
- Transmission direction: MSB first (CSIHnCFG0.CSIHnDIR0 = 0)
- Normal clock phase and data phase (CSIHnCFG0.CSIHnCKP0 = 0, CSIHnCFG0.CSIHnDAP0 = 0)
- Job mode disabled (CSIHnCTL1.CSIHnJE = 0)
- Handshake enabled (CSIHnCTL1.CSIHnHSE = 1)
- CSIHnTIC interrupt generated at the transfer start timing (CSIHnCTL1.CSIHnSLIT = 1)
- Direct access mode (CSIHnCTL0.CSIHnMBS = 1)

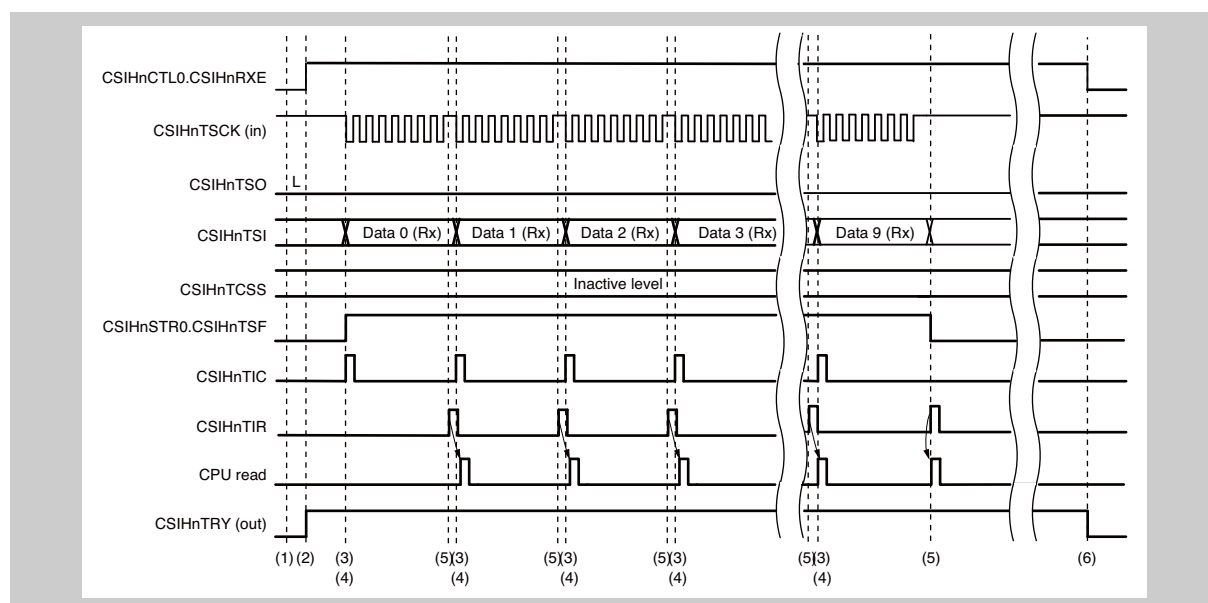

Figure 22-47 Direct access mode (for reception in the slave mode, and when the job mode is disabled)

- Procedure:**
1. Set up the following registers before setting CSIHnCTL0.CSIHnPWR to 1: CSIHnCTL1, CSIHnCTL2 (transfer mode, operating mode) CSIHnCFG0 (communication protocol)
 2. CSIHnCTL0.CSIHnPWR = 1 (clock enabled)
CSIHnCTL0.CSIHnTXE = 0 (transmission disabled)
CSIHnCTL0.CSIHnRXE = 1 (reception enabled)
CSIHnCTL0.CSIHnMBS = 1 (direct access mode selected)
 3. When a serial clock is supplied from the master, reception automatically starts.
 4. When CSIHnCTL1.CSIHnSLIT is set to 1, CSIHnTIC is generated at the start edge of CSIHnTSCK.
 5. Each time data is received, a CSIHnTIR interrupt is generated.
 - CSIHnTIR indicates that the reception data register CSIHnRX0W must be read.
 6. Finally, clear CSIHnCTL0.CSIHnRXE to disable reception operations. In addition, clear CSIHnCTL0.CSIHnPWR to reduce the power consumption of the CSIH.

(5) For transmission/reception in the master mode, and when the job mode is enabled

The following conditions are assumed for the procedure shown here:

- Transmission data length: 8 bits (CSIHnCFGx.CSIHnDLSx[3:0] = 1000_B)
- Transmission direction: MSB first (CSIHnCFGx.CSIHnDIRx = 0)
- Normal clock phase and data phase (CSIHnCFGx.CSIHnCKPx = 0, CSIHnCFGx.CSIHnDAPx = 0)
- No delay for any interrupt (CSIHnCTL1.CSIHnSIT = 0)
- Job mode enabled (CSIHnCTL1.CSIHnJE = 1)
- CSIHnTIC interrupt generated at the transfer start timing (CSIHnCTL1.CSIHnSLIT = 1)
- Direct access mode (CSIHnCTL0.CSIHnMBS = 1)
- Two jobs that each transmit three data packets

Figure 22-48 Direct access mode (for transmission/reception in the master mode, and when the job mode is enabled)

Note The int_JOBE signal in the above timing chart is the internal signal of the CSIHnJOBE bit.

- Procedure:**
1. Set up the following registers before setting CSIHnCTL0.CSIHnPWR to 1: CSIHnCTL1, CSIHnCTL2 (transfer mode, operating mode) CSIHnCFGx (communication protocol)
(For this example, the chip select signals CS1 and CS3 are used.)
 2. CSIHnCTL0.CSIHnPWR = 1 (clock enabled)
CSIHnCTL0.CSIHnTXE = 1 (transmission enabled)
CSIHnCTL0.CSIHnRXE = 1 (reception enabled)
CSIHnCTL0.CSIHnMBS = 1 (direct access mode selected)
 3. Write the first transmission data packet to the transmission data register CSIHnTX0W. Transmission automatically starts when the first data can be used.

The CSIHnSTR0.CSIHnTSF flag indicates that communication is being performed.
 - 3'. When CSIHnCTL1.CSIHnSLIT is set to 1, CSIHnTIC is generated at the start edge of CSIHnTSCK. CSIHnTIC indicates that the second data can be written to CSIHnTX0W.
 4. Write the second data to CSIHnTX0W. By writing the second data immediately after writing the first data, the unnecessary inter-data delay can be avoided.
 5. Each time data is received, a CSIHnTIR interrupt request is generated.
 - CSIHnTIR indicates that the reception data register CSIHnRX0W must be read.
 6. If the CSIHnTX0W register transfer data is the last job data, CSIHnTX0W.CSIHnEOJ is set to 1.
 7. By setting CSIHnCTL0.CSIHnJOB to 1, communication is forcibly stopped when the current job (job 2) ends.
 8. After communication is forcibly stopped, the interrupt request CSIHnTIC is replaced with CSIHnTIJC. CSIHnTIR is generated as usual.

The interrupt request CSIHnTIJC indicates that communication was forcibly stopped when the current job ended.
The interrupt request CSIHnTIC is not generated. Note that the usable transmission data in the CSIHnTX0 register (indicated by “*” in the figure) is not transmitted.
 9. Finally, clear CSIHnCTL0.CSIHnTXE and CSIHnCTL0.CSIHnRXE to disable transmission/reception operations. In addition, clear CSIHnCTL0.CSIHnPWR to reduce the power consumption of CSIH.

(6) For reception in the master mode, and when the job mode is enabled

The following conditions are assumed for the procedure shown here:

- Transmission data length: 8 bits (CSIHnCFGx.CSIHnDLSx[3:0] = 1000_B)
- Transmission direction: MSB first (CSIHnCFGx.CSIHnDIRx = 0)
- Normal clock phase and data phase (CSIHnCFGx.CSIHnCKPx = 0, CSIHnCFGx.CSIHnDAPx = 0)
- No delay for any interrupt (CSIHnCTL1.CSIHnSIT = 0)
- Job mode enabled (CSIHnCTL1.CSIHnJE = 1)
- CSIHnTIC interrupt generated at the transfer start timing (CSIHnCTL1.CSIHnSLIT = 1)
- Direct access mode (CSIHnCTL0.CSIHnMBS = 1)
- Two jobs that each transmit three data packets

Figure 22-49 Direct access mode (for reception in the master mode, and when the job mode is enabled)

Note The int_JOBE signal in the above timing chart is the internal signal of the CSIHnJOBE bit.

- Procedure:**
1. Set up the following registers before setting CSIHnCTL0.CSIHnPWR to 1:
CSIHnCTL1, CSIHnCTL2 (transfer mode, operating mode)
CSIHnCFGx (communication protocol)
(For this example, the chip select signals CS1 and CS3 are used.)
 2. CSIHnCTL0.CSIHnPWR = 1 (clock enabled)
CSIHnCTL0.CSIHnTXE = 0 (transmission disabled)
CSIHnCTL0.CSIHnRXE = 1 (reception enabled)
CSIHnMBS = 1 (direct access mode selected)
 3. Write the transmission data to the transmission data register CSIHnTX0W for reception.
Reception automatically starts. In addition, the CSIHnSTR0.CSIHnTSF bit is set.
 - 3'. When CSIHnCTL1.CSIHnSLIT is set to 1, CSIHnTIC is generated at the start edge of CSIHnTSCK. CSIHnTIC indicates that the second data can be written to CSIHnTX0W.
 4. Write the second data to CSIHnTX0H. By writing the second data immediately after writing the first data, the unnecessary inter-data delay can be avoided.
 5. Each time data is received, a CSIHnTIR interrupt request is generated.
 - CSIHnTIR indicates that the reception data register CSIHnRX0 must be read.
 6. If the CSIHnTX0W register transfer data is the last job data, CSIHnTX0W.CSIHnEOJ is set to 1.
 7. By setting CSIHnCTL0.CSIHnJOB2 to 1, communication is forcibly stopped when the current job (job 2) ends.
 8. When int_JOB2 is set and the last job 2 data is received, the interrupt request CSIHnTIJC is generated instead of CSIHnTIC.
CSIHnTIR is generated as usual.
The interrupt request CSIHnTIJC indicates that reception was forcibly stopped when the current job ended.
The interrupt request CSIHnTIC is not generated. Note that the data indicated by “*” in the figure is not transferred.
 9. Finally, clear CSIHnCTL0.CSIHnRXE to disable reception operations. In addition, clear CSIHnCTL0.CSIHnPWR to reduce the power consumption of CSIH.

22.5.2 Procedures in transmit-only buffer mode

This section provides examples where the job mode is enabled or disabled.

(1) For transmission/reception in the master mode, and when the job mode is disabled

The following conditions are assumed for the procedure shown here:

- Transmission data length: 8 bits (CSIHnCFGx.CSIHnDLSx[3:0] = 1000_B)
- Transmission direction: MSB first (CSIHnCFGx.CSIHnDIRx = 0)
- Normal clock phase and data phase (CSIHnCFGx.CSIHnCKPx = 0, CSIHnCFGx.CSIHnDAPx = 0)
- No delay for any interrupt (CSIHnCTL1.CSIHnSIT = 0)
- Job mode disabled (CSIHnCTL1.CSIHnJE = 0)
- Transmit-only buffer mode (CSIHnCTL0.CSIHnMBS = 0, CSIHnMCTL0.CSIHnMMS[1:0] = 10_B)
- Number of transmitted data items: 9 (CSIHnMCTL2.CSIHnND[7:0] = 09_H)
- Transfer start address: 10_H (CSIHnMCTL2.CSIHnSOP[6:0] = 10_H)
- Normal CSIHnTIC interrupt timing (CSIHnCTL1.CSIHnSLIT = 0)

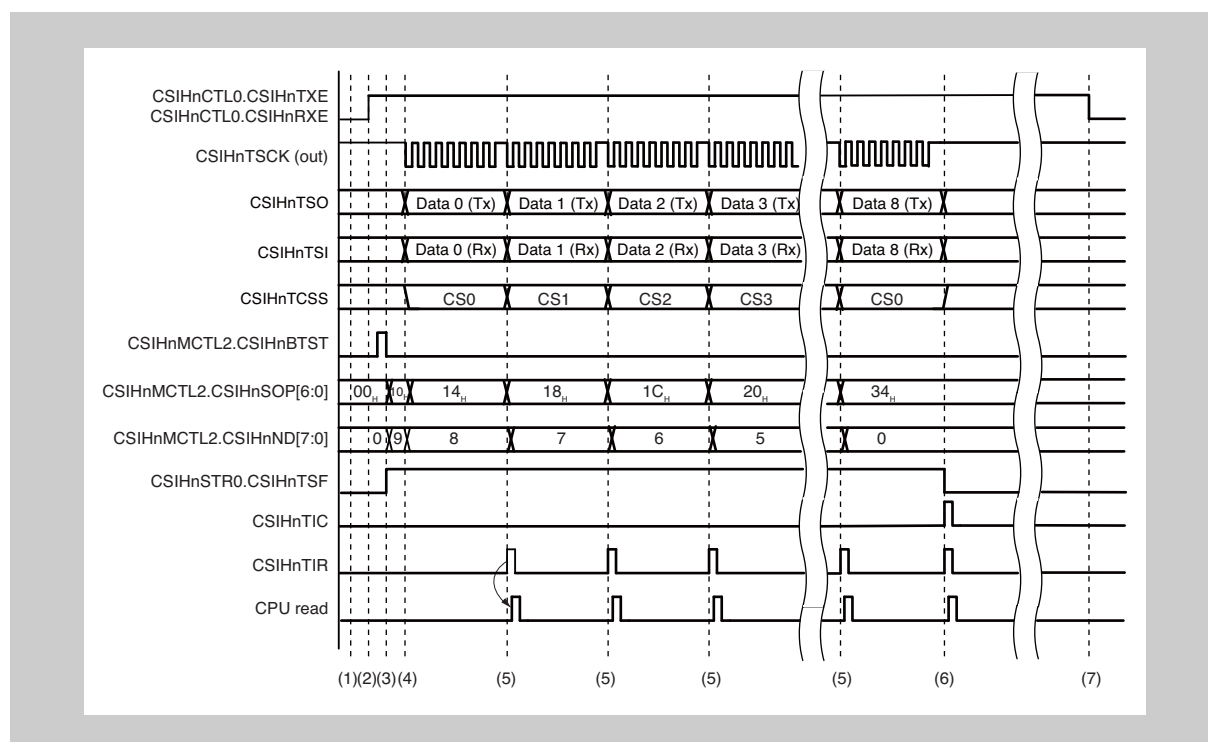

Figure 22-50 Transmit-only buffer mode (for transmission/reception in the master mode, and when the job mode is disabled)

Note The procedure for writing data to the buffer is not described here. The first data address is specified for CSIHnMRWP0.CSIHnTRWA[6:0], and the transfer data is written to CSIHnTX0W. Each time transfer data is written, the value of CSIHnMRWP0.CSIHnTRWA[6:0] is incremented.

- Procedure:**
1. Set up the following registers before setting CSIHnCTL0.CSIHnPWR to 1:
CSIHnCTL1, CSIHnCTL2 (transfer mode, operating mode)
CSIHnMCTL0.CSIHnMMS[1:0] = 10_B (memory mode)
CSIHnCFGx (communication protocol)
(For this example, the chip select signals CS0 to CS3 are used.)
 2. CSIHnCTL0.CSIHnPWR = 1 (clock enabled)
CSIHnCTL0.CSIHnTXE = 1 (transmission enabled)
CSIHnCTL0.CSIHnRXE = 1 (reception enabled)
CSIHnCTL0.CSIHnMBS = 0 (memory mode)
 3. The transmission pointer and number of data items are specified using the CSIHnMCTL2.CSIHnSOP[6:0] and CSIHnMCTL2.CSIHnND[7:0] bits. Communication is started by setting CSIHnMCTL2.CSIHnBTST.
 4. Transmission/reception starts. The CSIHnMCTL2.CSIHnSOP[6:0] bits are automatically incremented, and the CSIHnMCTL2.CSIHnND[7:0] bits are decremented each time a data item is transmitted.
 5. When all the data is received, CSIHnTIR is generated. The CSIHnTIR interrupt indicates that the reception data register CSIHnRX0W must be read.
 6. When all the data is transmitted, a CSIHnTIC interrupt request is generated.
 7. Finally, clear CSIHnCTL0.CSIHnTXE and CSIHnCTL0.CSIHnRXE to disable transmission/reception operations. In addition, clear CSIHnCTL0.CSIHnPWR to reduce the power consumption while not using CSIH.

(2) For reception in the master mode, and when the job mode is disabled

The following conditions are assumed for the procedure shown here:

- Transmission data length: 8 bits (CSIHnCFGx.CSIHnDLSx[3:0] = 1000_B)
- Transmission direction: MSB first (CSIHnCFGx.CSIHnDIRx = 0)
- Normal clock phase and data phase (CSIHnCFGx.CSIHnCKPx = 0, CSIHnCFGx.CSIHnDAPx = 0)
- No delay for any interrupt (CSIHnCTL1.CSIHnSIT = 0)
- Job mode enabled (CSIHnCTL1.CSIHnJE = 1)
- Transmit-only buffer mode (CSIHnCTL0.CSIHnMBS = 0, CSIHnMCTL0.CSIHnMMS[1:0] = 10_B)
- Number of transmitted data items: 9 (CSIHnMCTL2.CSIHnND[7:0] = 09_H)
- Transfer start address: 10_H (CSIHnMCTL2.CSIHnSOP[6:0] = 10_H)
- Normal CSIHnTIC interrupt timing (CSIHnCTL1.CSIHnSLIT = 0)

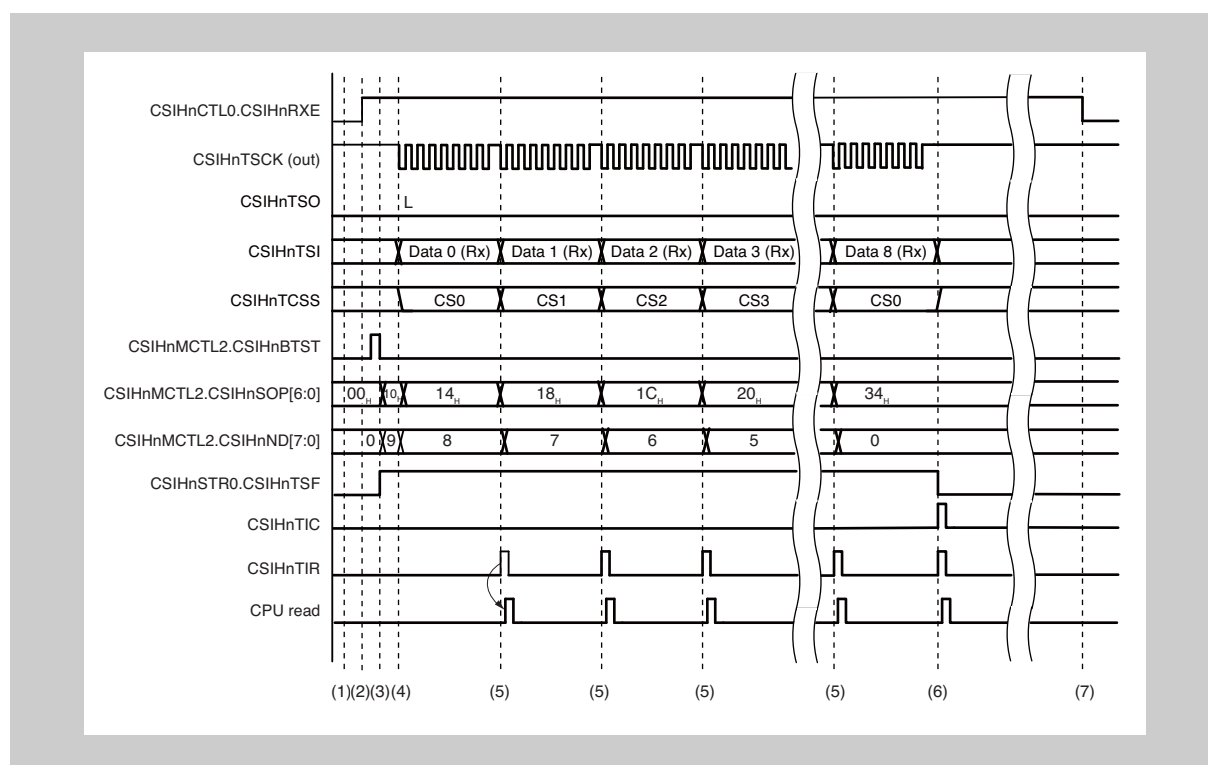

Figure 22-51 Transmit-only buffer mode (for reception in the master mode, and when the job mode is disabled)

Note The procedure for writing data to the buffer is not described here. The first data address is specified for CSIHnMRWP0.CSIHnTRWA[6:0], and the transfer data is written to CSIHnTX0W. Each time transfer data is written, the value of CSIHnMRWP0.CSIHnTRWA[6:0] is incremented.

- Procedure:**
1. Set up the following registers before setting CSIHnCTL0.CSIHnPWR to 1:
CSIHnCTL1, CSIHnCTL2 (transfer mode, operating mode)
CSIHnMCTL0.CSIHnMMS[1:0] = 10_B (memory mode)
CSIHnCFGx (communication protocol)
(For this example, the chip select signals CS0 to CS3 are used.)
 2. CSIHnCTL0.CSIHnPWR = 1 (clock enabled)
CSIHnCTL0.CSIHnTXE = 0 (transmission disabled)
CSIHnCTL0.CSIHnRXE = 1 (reception enabled)
CSIHnCTL0.CSIHnMBS = 0 (memory mode)
 3. The transmission pointer and number of data items are specified using the CSIHnMCTL2.CSIHnSOP[6:0] and CSIHnMCTL2.CSIHnND[7:0] bits. Communication is started by setting CSIHnMCTL2.CSIHnBTST.
 4. Reception starts. The CSIHnMCTL2.CSIHnSOP[6:0] bits are automatically incremented, and the CSIHnMCTL2.CSIHnND[7:0] bits are decremented each time a data packet is transmitted.
 5. When all the data is received, CSIHnTIR is generated. The CSIHnTIR interrupt indicates that the reception data register CSIHnRX0W must be read.
 6. When all the data is received, a CSIHnTIC interrupt request is generated.
 7. Finally, clear CSIHnCTL0.CSIHnRXE to disable reception operations. In addition, clear CSIHnCTL0.CSIHnPWR to reduce the power consumption while not using CSIH.

(3) For transmission/reception in the slave mode, and when the job mode is disabled

The following conditions are assumed for the procedure shown here:

- Transmission data length: 8 bits (CSIHnCFG0.CSIHnDLS0[3:0] = 1000_B)
- Transmission direction: MSB first (CSIHnCFG0.CSIHnDIR0 = 0)
- Normal clock phase and data phase (CSIHnCFG0.CSIHnCKP0 = 0, CSIHnCFG0.CSIHnDAP0 = 0)
- Job mode disabled (CSIHnCTL1.CSIHnJE = 0)
- Handshake enabled (CSIHnCTL1.CSIHnHSE = 1)
- Transmit-only buffer mode (CSIHnCTL0.CSIHnMBS = 0, CSIHnMCTL0.CSIHnMMS[1:0] = 10_B)
- Number of transmitted data items: 9 (CSIHnMCTL2.CSIHnND[7:0] = 09_H)
- Transfer start address: 10_H (CSIHnMCTL2.CSIHnSOP[6:0] = 10_H)
- Normal CSIHnTIC interrupt timing (CSIHnCTL1.CSIHnSLIT = 0)

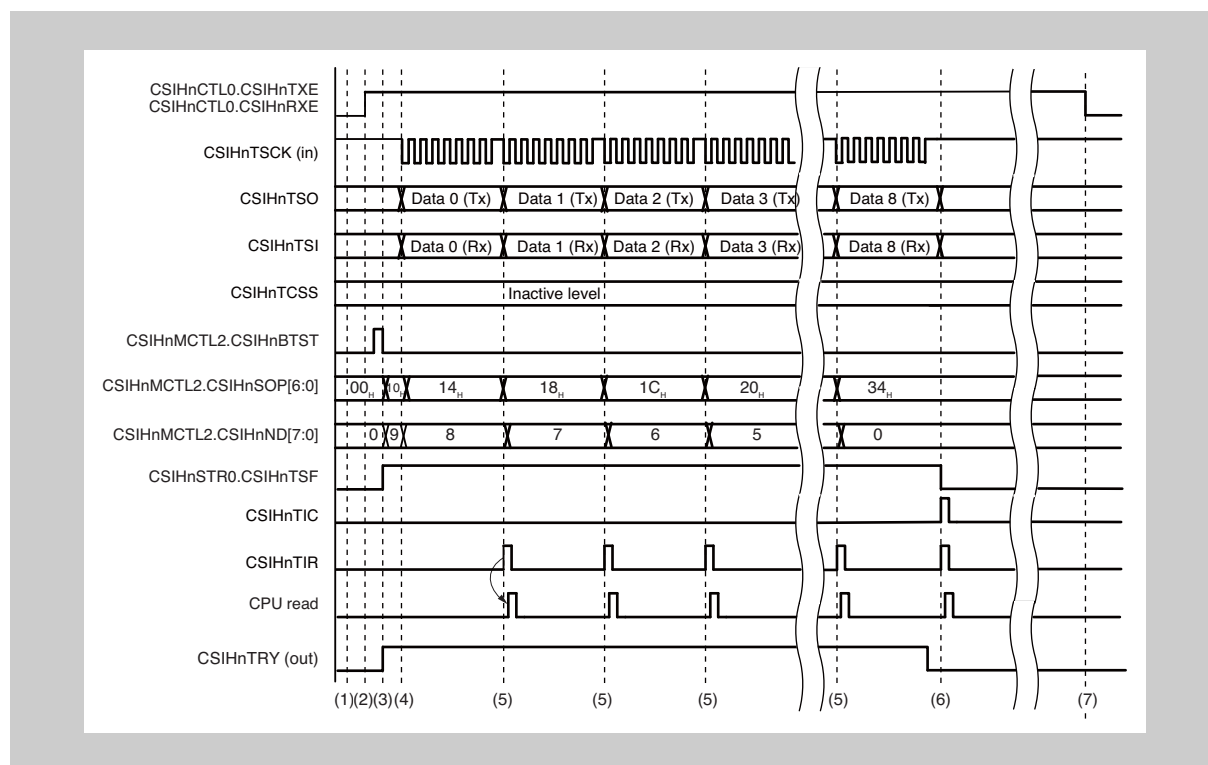

Figure 22-52 Transmit-only buffer mode (for transmission/reception in the slave mode, and when the job mode is disabled)

Note The procedure for writing data to the buffer is not described here. The first data address is specified for CSIHnMRWP0.CSIHnTRWA[6:0], and the transfer data is written to CSIHnTX0W. Each time transfer data is written, the value of CSIHnMRWP0.CSIHnTRWA[6:0] is incremented.

- Procedure:**
1. Set up the following registers before setting CSIHnCTL0.CSIHnPWR to 1:
CSIHnCTL1, CSIHnCTL2 (transfer mode, operating mode)
CSIHnMCTL0.CSIHnMMS[1:0] = 10_B (memory mode)
CSIHnCFG0 (communication protocol)
 2. CSIHnCTL0.CSIHnPWR = 1 (clock enabled)
CSIHnCTL0.CSIHnTXE = 1 (transmission enabled)
CSIHnCTL0.CSIHnRXE = 1 (reception enabled)
CSIHnCTL0.CSIHnMBS = 0 (memory mode)
 3. The transmission pointer and number of data items are specified using the CSIHnMCTL2.CSIHnSOP[6:0] and CSIHnMCTL2.CSIHnND[7:0] bits. Communication is started by setting CSIHnMCTL2.CSIHnBTST.
 4. When a serial clock is supplied from the master, communication starts. The CSIHnMCTL2.CSIHnSOP[6:0] bits are automatically incremented, and the CSIHnMCTL2.CSIHnND[7:0] bits are decremented each time a data packet is transmitted.
 5. Each time data is received, CSIHnTIR is generated. The CSIHnTIR interrupt indicates that the reception data register CSIHnRX0W must be read.
 6. When all the data is received, a CSIHnTIC interrupt request is generated.
 7. Finally, clear CSIHnCTL0.CSIHnTXE and CSIHnCTL0.CSIHnRXE to disable transmission/reception operations. In addition, clear CSIHnCTL0.CSIHnPWR to reduce the power consumption while not using CSIH.

(4) For reception in the slave mode, and when the job mode is disabled

The following conditions are assumed for the procedure shown here:

- Transmission data length: 8 bits (CSIHnCFG0.CSIHnDLS0[3:0] = 1000_B)
- Transmission direction: MSB first (CSIHnCFG0.CSIHnDIR0 = 0)
- Normal clock phase and data phase (CSIHnCFG0.CSIHnCKP0 = 0, CSIHnCFG0.CSIHnDAP0 = 0)
- Job mode disabled (CSIHnCTL1.CSIHnJE = 0)
- Handshake enabled (CSIHnCTL1.CSIHnHSE = 1)
- Transmit-only buffer mode (CSIHnCTL0.CSIHnMBS = 0, CSIHnMCTL0.CSIHnMMS[1:0] = 10_B)
- Number of transmitted data items: 9 (CSIHnMCTL2.CSIHnND[7:0] = 09_H)
- Transfer start address: 10_H (CSIHnMCTL2.CSIHnSOP[6:0] = 10_H)
- Normal CSIHnTIC interrupt timing (CSIHnCTL1.CSIHnSLIT = 0)

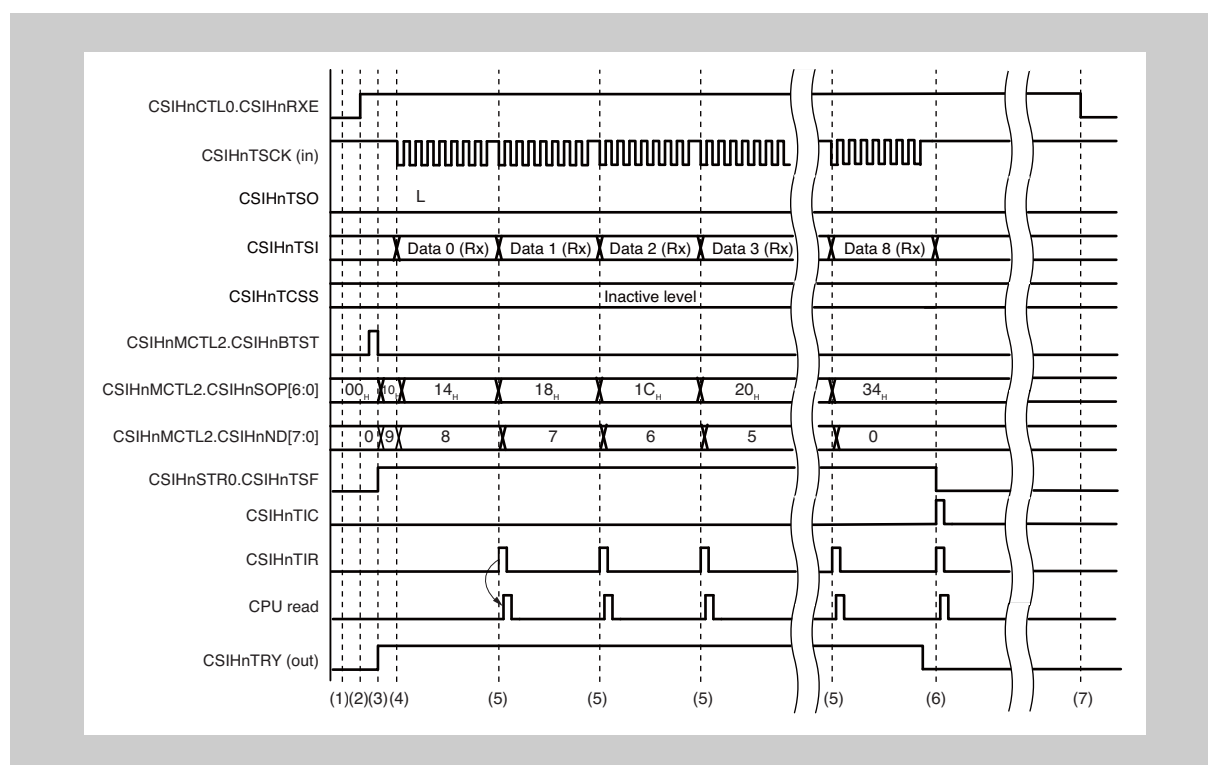

Figure 22-53 Transmit-only buffer mode (for reception in the slave mode, and when the job mode is disabled)

- Procedure:**
1. Set up the following registers before setting CSIHnCTL0.CSIHnPWR to 1:
CSIHnCTL1, CSIHnCTL2 (transfer mode, operating mode)
CSIHnMCTL0.CSIHnMMS[1:0] = 10_B (memory mode)
CSIHnCFG0 (communication protocol)
 2. CSIHnCTL0.CSIHnPWR = 1 (clock enabled)
CSIHnCTL0.CSIHnTXE = 0 (transmission disabled)
CSIHnCTL0.CSIHnRXE = 1 (reception enabled)
CSIHnCTL0.CSIHnMBS = 0 (memory mode)
 3. The transmission pointer and number of data items are specified using the CSIHnMCTL2.CSIHnSOP[6:0] and CSIHnMCTL2.CSIHnND[7:0] bits. Reception is started by setting CSIHnMCTL2.CSIHnBTST.
 4. When a serial clock is supplied from the master, reception starts. The CSIHnMCTL2.CSIHnSOP[6:0] bits are automatically incremented, and the CSIHnMCTL2.CSIHnND[7:0] bits are decremented each time a data packet is transmitted.
 5. Each time data is received, CSIHnTIR is generated. The CSIHnTIR interrupt indicates that the reception data register CSIHnRX0W must be read.
 6. When all the data is received, a CSIHnTIC interrupt request is generated.
 7. Finally, clear CSIHnCTL0.CSIHnRXE to disable reception operations. In addition, clear CSIHnCTL0.CSIHnPWR to reduce the power consumption while not using CSIH.

(5) For transmission/reception in the master mode, and when the job mode is enabled

The following conditions are assumed for the procedure shown here:

- Transmission data length: 8 bits (CSIHnCFGx.CSIHnDLSx[3:0] = 1000_B)
- Transmission direction: MSB first (CSIHnCFGx.CSIHnDIRx = 0)
- Normal clock phase and data phase (CSIHnCFGx.CSIHnCKPx = 0, CSIHnCFGx.CSIHnDAPx = 0)
- No delay for any interrupt (CSIHnCTL1.CSIHnSIT = 0)
- Job mode enabled (CSIHnCTL1.CSIHnJE = 1)
- Transmit-only buffer mode (CSIHnCTL0.CSIHnMBS = 0, CSIHnMCTL0.CSIHnMMS[1:0] = 10_B)
- Number of transmitted data items: 9 (CSIHnMCTL2.CSIHnND[7:0] = 09_H)
- Transfer start address: 10_H (CSIHnMCTL2.CSIHnSOP[6:0] = 10_H)
- Normal CSIHnTIC interrupt timing (CSIHnCTL1.CSIHnSLIT = 0)

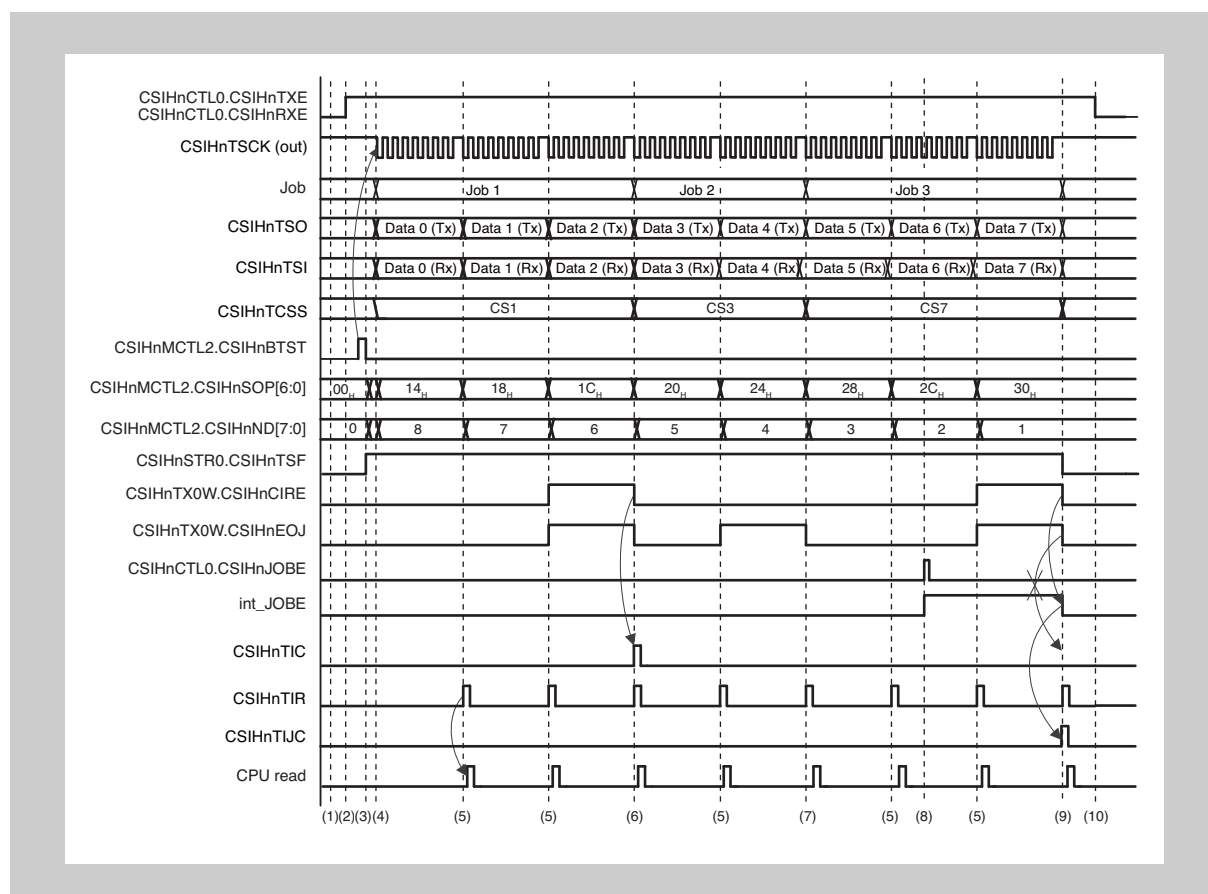

Figure 22-54 Transmit-only buffer mode (for transmission/reception in the master mode, and when the job mode is enabled)

- Notes**
1. The procedure for writing data to the buffer is not described here. The first data address is specified for CSIHnMRWP0.CSIHnTRWA[6:0], and the transfer data is written to CSIHnTX0W. Each time transfer data is written, the value of CSIHnMRWP0.CSIHnTRWA[6:0] is incremented.
 2. The int_JOBE signal in the above timing chart is the internal signal of the CSIHnJOBE bit.

- Procedure:**
1. Set up the following registers before setting CSIHnCTL0.CSIHnPWR to 1:
CSIHnCTL1, CSIHnCTL2 (transfer mode, operating mode)
CSIHnMCTL0.CSIHnMMS[1:0] = 10_B (memory mode)
CSIHnCFGx (communication protocol)
(For this example, the chip select signals CS1, CS3, and CS7 are used.)
 2. CSIHnCTL0.CSIHnPWR = 1 (clock enabled)
CSIHnCTL0.CSIHnTXE = 1 (transmission enabled)
CSIHnCTL0.CSIHnRXE = 1 (reception enabled)
CSIHnCTL0.CSIHnMBS = 0 (memory mode)
 3. The transmission pointer and number of data items are specified using the CSIHnMCTL2.CSIHnSOP[6:0] and CSIHnMCTL2.CSIHnND[7:0] bits.
Communication is started by setting CSIHnMCTL2.CSIHnBTST.
 4. Transmission starts. The CSIHnMCTL2.CSIHnSOP[6:0] bits are automatically incremented, and the CSIHnMCTL2.CSIHnND[7:0] bits are decremented each time a data item is transmitted.
 5. Each time a data item is received, a CSIHnTIR interrupt request is generated.
CSIHnTIR indicates that the reception data register CSIHnRX0W must be read.
 6. CSIHnTIC is generated by setting CSIHnTX0W.CSIHnCIRE to 1.
CSIHnTIC indicates that the last data (CSIHnTX0W.CSIHnEOJ = 1) of the current job was transmitted.
 7. Because the last data (CSIHnTX0W.CSIHnEOJ = 1) of the current job was transmitted by clearing CSIHnTX0W.CSIHnCIRE, the interrupt request CSIHnTIC is not generated.
 8. By setting CSIHnCTL0.CSIHnJOB3, communication is forcibly stopped when job 3 ends.
 9. After communication is forcibly stopped, the interrupt requests CSIHnTIJC and CSIHnTIR are generated when job 3 ends.

The interrupt request CSIHnTIJC indicates that communication was forcibly stopped when the current job ended.
Because the interrupt request CSIHnTIJC is generated instead of the interrupt request CSIHnTIC, the interrupt request CSIHnTIC is not generated.
 10. Finally, clear CSIHnCTL0.CSIHnTXE and CSIHnCTL0.CSIHnRXE to disable transmission/reception operations. In addition, clear CSIHnCTL0.CSIHnPWR to reduce the power consumption while not using the CSIH.

(6) For reception in the master mode, and when the job mode is enabled

The following conditions are assumed for the procedure shown here:

- Transmission data length: 8 bits (CSIHnCFGx.CSIHnDLSx[3:0] = 1000_B)
- Transmission direction: MSB first (CSIHnCFGx.CSIHnDIRx = 0)
- Normal clock phase and data phase (CSIHnCFGx.CSIHnCKPx = 0, CSIHnCFGx.CSIHnDAPx = 0)
- No delay for any interrupt (CSIHnCTL1.CSIHnSIT = 0)
- Job mode enabled (CSIHnCTL1.CSIHnJE = 1)
- Transmit-only buffer mode (CSIHnCTL0.CSIHnMBS = 0, CSIHnMCTL0.CSIHnMMS[1:0] = 10_B)
- Number of transmitted data items: 9 (CSIHnMCTL2.CSIHnND[7:0] = 09_H)
- Transfer start address: 10_H (CSIHnMCTL2.CSIHnSOP[6:0] = 10_H)
- Normal CSIHnTIC interrupt timing (CSIHnCTL1.CSIHnSLIT = 0)

Figure 22-55 Transmit-only buffer mode (for reception in the master mode, and when the job mode is enabled)

- Notes**
1. The procedure for writing data to the buffer is not described here. The first data address is specified for CSIHnMRWP0.CSIHnTRWA[6:0], and the transfer data is written to CSIHnTX0W. Each time transfer data is written, the value of CSIHnMRWP0.CSIHnTRWA[6:0] is incremented.
 2. The int_JOBE signal in the above timing chart is the internal signal of the CSIHnJOBE bit.

- Procedure:**
1. Set up the following registers before setting CSIHnCTL0.CSIHnPWR to 1:
 - CSIHnCTL1, CSIHnCTL2 (transfer mode, operating mode)
 - CSIHnMCTL0.CSIHnMMS[1:0] = 10_B (memory mode)
 - CSIHnCFGx (communication protocol)
 (For this example, the chip select signals CS1, CS3, and CS7 are used.)
 2. CSIHnCTL0.CSIHnPWR = 1 (clock enabled)
 CSIHnCTL0.CSIHnTXE = 0 (transmission disabled)
 CSIHnCTL0.CSIHnRXE = 1 (reception enabled)
 CSIHnCTL0.CSIHnMBS = 0 (memory mode)
 3. The transmission pointer and number of data items are specified using the CSIHnMCTL2.CSIHnSOP[6:0] and CSIHnMCTL2.CSIHnND[7:0] bits. Communication is started by setting CSIHnMCTL2.CSIHnBTST.
 4. Reception starts. The CSIHnMCTL2.CSIHnSOP[6:0] bits are automatically incremented, and the CSIHnMCTL2.CSIHnND[7:0] bits are decremented each time a data item is transmitted.
 5. Each time a data item is received, a CSIHnTIR interrupt request is generated.
 CSIHnTIR indicates that the reception data register CSIHnRX0W must be read.
 6. CSIHnTIC is generated by setting CSIHnTX0W.CSIHnCIRE to 1.
 CSIHnTIC indicates that the last data (CSIHnTX0W.CSIHnEOJ = 1) of the current job was transmitted.
 7. Because the last data (CSIHnTX0W.CSIHnEOJ = 1) of the current job was transmitted by clearing CSIHnTX0W.CSIHnCIRE, the interrupt request CSIHnTIC is not generated.
 8. By setting CSIHnCTL0.CSIHnJOB3, reception is forcibly stopped when job 3 ends.
 9. After communication is forcibly stopped, the interrupt requests CSIHnTIJC and CSIHnTIR are generated when job 3 ends.

 The interrupt request CSIHnTIJC indicates that reception was forcibly stopped when the current job ended.
 Because the interrupt request CSIHnTIJC is generated instead of the interrupt request CSIHnTIC, the interrupt request CSIHnTIC is not generated.
 10. Finally, clear CSIHnCTL0.CSIHnRXE to disable reception operations. In addition, clear CSIHnCTL0.CSIHnPWR to reduce the power consumption while not using the CSIH.

22.5.3 Procedures in dual buffer mode

(1) For transmission/reception in the master mode, and when the job mode is disabled

The following conditions are assumed for the procedure shown here:

- Transmission data length: 8 bits (CSIHnCFGx.CSIHnDLSx[3:0] = 1000_B)
- Transmission direction: MSB first (CSIHnCFGx.CSIHnDIRx = 0)
- Normal clock phase and data phase (CSIHnCFGx.CSIHnCKPx = 0, CSIHnCFGx.CSIHnDAPx = 0)
- No delay for any interrupt (CSIHnCTL1.CSIHnSIT = 0)
- Job mode disabled (CSIHnCTL1.CSIHnJE = 0)
- Dual buffer mode (CSIHnCTL0.CSIHnMBS = 0, CSIHnMCTL0.CSIHnMMS[1:0] = 01_B)
- Number of data packets: 9 (CSIHnMCTL2.CSIHnND[7:0] = 09_H)
- Transfer start address: 10_H (CSIHnMCTL2.CSIHnSOP[6:0] = 10_H)
- Normal CSIHnTIC interrupt timing (CSIHnCTL1.CSIHnSLIT = 0)

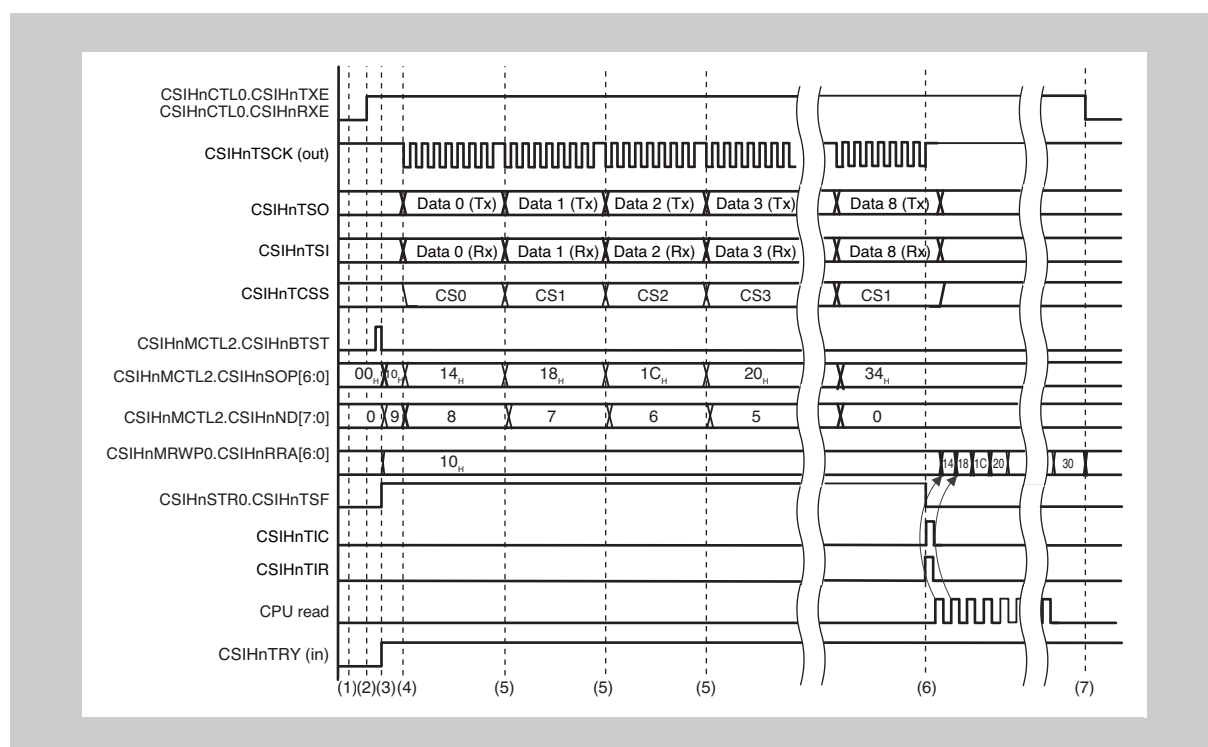

Figure 22-56 Dual buffer mode (for transmission/reception in the master mode, and when the job mode is disabled)

Note The procedure for writing data to the buffer is not described here. The first data address is specified for CSIHnMRWP0.CSIHnTRWA[6:0], and the transfer data is written to CSIHnTX0W. Each time transfer data is written, the value of CSIHnMRWP0.CSIHnTRWA[6:0] is incremented.

- Procedure:**
1. Set up the following registers before setting CSIHnCTL0.CSIHnPWR to 1:
CSIHnCTL1, CSIHnCTL2 (transfer mode, operating mode)
CSIHnMCTL0.CSIHnMMS[1:0] = 01_B (memory mode)
CSIHnCFGx (communication protocol)
(For this example, the chip select signals CS0 to CS3 are used.)
CSIHnSTCR0.CSIHnPCT = 1 (buffer pointers cleared)
 2. CSIHnCTL0.CSIHnPWR = 1 (clock enabled)
CSIHnCTL0.CSIHnTXE = 1 (transmission enabled)
CSIHnCTL0.CSIHnRXE = 1 (reception enabled)
CSIHnCTL0.CSIHnMBS = 0 (memory mode)
 3. The transmission pointer and number of data items are specified using the CSIHnMCTL2.CSIHnSOP[6:0] and CSIHnMCTL2.CSIHnND[7:0] bits. Communication is started by setting CSIHnMCTL2.CSIHnBTST.
 4. Transmission starts. Each time a data item is transmitted, the CSIHnMCTL2.CSIHnSOP[6:0] bits are automatically incremented, and the CSIHnMCTL2.CSIHnND[7:0] bits are decremented.
 5. (4) is repeated until the last data is transmitted/received. The interrupt requests CSIHnTIC and CSIHnTIR are not generated.
 6. When all the communication ends, the interrupt requests CSIHnTIC and CSIHnTIR are generated. The CPU starts reading the received data from the reception buffer. The read start address is specified by the CSIHnMRWP0.CSIHnRRA[6:0] bits. The CSIHnMRWP0.CSIHnRRA[6:0] bits are incremented each time a data item is read.
 7. Finally, clear CSIHnCTL0.CSIHnTXE and CSIHnCTL0.CSIHnRXE to disable transmission/reception operations. In addition, clear CSIHnCTL0.CSIHnPWR to reduce the power consumption while not using the CSIH.

(2) For reception in the master mode, and when the job mode is disabled

The following conditions are assumed for the procedure shown here:

- Transmission data length: 8 bits (CSIHnCFGx.CSIHnDLSx[3:0] = 1000_B)
- Transmission direction: MSB first (CSIHnCFGx.CSIHnDIRx = 0)
- Normal clock phase and data phase (CSIHnCFGx.CSIHnCKPx = 0, CSIHnCFGx.CSIHnDAPx = 0)
- No delay for any interrupt (CSIHnCTL1.CSIHnSIT = 0)
- Job mode disabled (CSIHnCTL1.CSIHnJE = 0)
- Dual buffer mode (CSIHnCTL0.CSIHnMBS = 0, CSIHnMCTL0.CSIHnMMS[1:0] = 01_B)
- Number of data packets: 9 (CSIHnMCTL2.CSIHnND[7:0] = 09_H)
- Transfer start address: 10_H (CSIHnMCTL2.CSIHnSOP[6:0] = 10_H)
- Normal CSIHnTIC interrupt timing (CSIHnCTL1.CSIHnSLIT = 0)

Figure 22-57 Dual buffer mode (for reception in the master mode, and when the job mode is disabled)

Note The procedure for writing data to the buffer is not described here. The first data address is specified for CSIHnMRWP0.CSIHnTRWA[6:0], and the transfer data is written to CSIHnTX0W. Each time transfer data is written, the value of CSIHnMRWP0.CSIHnTRWA[6:0] is incremented.

- Procedure:**
1. Set up the following registers before setting CSIHnCTL0.CSIHnPWR to 1:
CSIHnCTL1, CSIHnCTL2 (transfer mode, operating mode)
CSIHnMCTL0.CSIHnMMS[1:0] = 01_B (memory mode)
CSIHnCFGx (communication protocol)
(For this example, the chip select signals CS0 to CS3 are used.)
CSIHnSTCR0.CSIHnPCT = 1 (buffer pointers cleared)
 2. CSIHnCTL0.CSIHnPWR = 1 (clock enabled)
CSIHnCTL0.CSIHnTXE = 0 (transmission disabled)
CSIHnCTL0.CSIHnRXE = 1 (reception enabled)
CSIHnCTL0.CSIHnMBS = 0 (memory mode)
 3. The transmission pointer and number of data items are specified using the CSIHnMCTL2.CSIHnSOP[6:0] and CSIHnMCTL2.CSIHnND[7:0] bits.
Reception is started by setting CSIHnMCTL2.CSIHnBTST.
 4. Reception starts. Each time a data item is received, the CSIHnMCTL2.CSIHnSOP[6:0] bits are automatically incremented, and the CSIHnMCTL2.CSIHnND[7:0] bits are decremented.
 5. (4) is repeated until the last data is received.
The interrupt requests CSIHnTIC and CSIHnTIR are not generated.
 6. When all the reception ends, the interrupt requests CSIHnTIC and CSIHnTIR are generated.
The CPU starts reading the received data from the reception buffer. The read start address is specified by the CSIHnMRWP0.CSIHnRRA[6:0] bits. The CSIHnMRWP0.CSIHnRRA[6:0] bits are incremented each time a data item is read.
 7. Finally, clear CSIHnCTL0.CSIHnRXE to disable reception operations.
In addition, clear CSIHnCTL0.CSIHnPWR to reduce the power consumption while not using the CSIH.

(3) For transmission/reception in the slave mode, and when the job mode is disabled

The following conditions are assumed for the procedure shown here:

- Transmission data length: 8 bits (CSIHnCFGx.CSIHnDLSx[3:0] = 1000_B)
- Transmission direction: MSB first (CSIHnCFGx.CSIHnDIRx = 0)
- Normal clock phase and data phase (CSIHnCFG0.CSIHnCKP0 = 0, CSIHnCFG0.CSIHnDAP0 = 0)
- No delay for any interrupt (CSIHnCTL1.CSIHnSIT = 0)
- Job mode disabled (CSIHnCTL1.CSIHnJE = 0)
- Handshake enabled (CSIHnCTL1.CSIHnHSE = 1)
- Dual buffer mode (CSIHnCTL0.CSIHnMBS = 0, CSIHnMCTL0.CSIHnMMS[1:0] = 01_B)
- Number of data packets: 9 (CSIHnMCTL2.CSIHnND[7:0] = 09_H)
- Transfer start address: 10_H (CSIHnMCTL2.CSIHnSOP[6:0] = 10_H)
- Normal CSIHnTIC interrupt timing (CSIHnCTL1.CSIHnSLIT = 0)

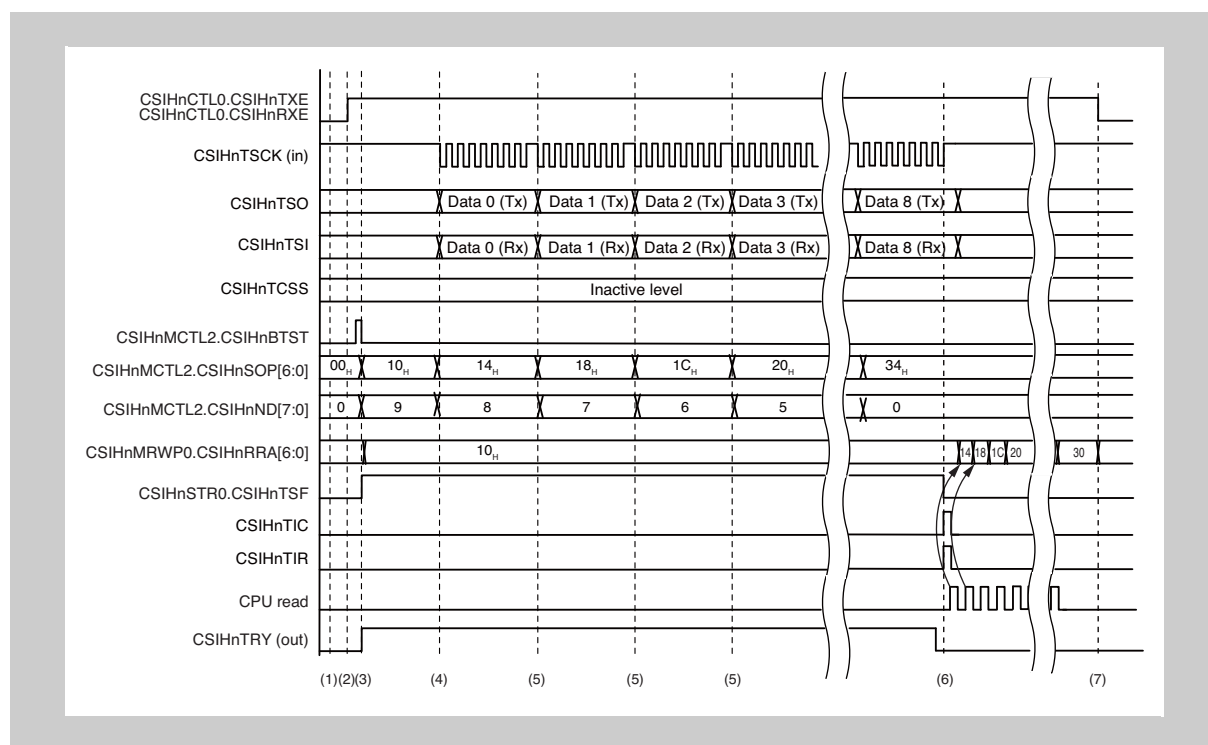

Figure 22-58 Dual buffer mode (for transmission/reception in the slave mode, and when the job mode is disabled)

Note The procedure for writing data to the buffer is not described here. The first data address is specified for CSIHnMRWP0.CSIHnTRWA[6:0], and the transfer data is written to CSIHnTX0W. Each time transfer data is written, the value of CSIHnMRWP0.CSIHnTRWA[6:0] is incremented.

- Procedure:**
1. Set up the following registers before setting CSIHnCTL0.CSIHnPWR to 1:
CSIHnCTL1, CSIHnCTL2 (transfer mode, operating mode)
CSIHnMCTL0.CSIHnMMS[1:0] = 01_B (memory mode)
CSIHnCFG0 (communication protocol)
CSIHnSTCR0.CSIHnPCT = 1 (buffer pointers cleared)
 2. CSIHnCTL0.CSIHnPWR = 1 (clock enabled)
CSIHnCTL0.CSIHnTXE = 1 (transmission enabled)
CSIHnCTL0.CSIHnRXE = 1 (reception enabled)
CSIHnCTL0.CSIHnMBS = 0 (memory mode)
 3. The transmission pointer and number of data items are specified using the CSIHnMCTL2.CSIHnSOP[6:0] and CSIHnMCTL2.CSIHnND[7:0] bits. Communication is started by setting CSIHnMCTL2.CSIHnBTST.
 4. Transmission starts. Each time a data item is transmitted, the CSIHnMCTL2.CSIHnSOP[6:0] bits are automatically incremented, and the CSIHnMCTL2.CSIHnND[7:0] bits are decremented.
 5. (4) is repeated until the last data is transmitted/received. The interrupt requests CSIHnTIC and CSIHnTIR are not generated.
 6. When all the communication ends, the interrupt requests CSIHnTIC and CSIHnTIR are generated. The CPU starts reading the received data from the reception buffer. The read start address is specified by the CSIHnMRWP0.CSIHnRRA[6:0] bits. The CSIHnMRWP0.CSIHnRRA[6:0] bits are incremented each time a data item is read.
 7. Finally, clear CSIHnCTL0.CSIHnTXE and CSIHnCTL0.CSIHnRXE to disable transmission/reception operations. In addition, clear CSIHnCTL0.CSIHnPWR to reduce the power consumption while not using the CSIH.

(4) For reception in the slave mode, and when the job mode is disabled

The following conditions are assumed for the procedure shown here:

- Transmission data length: 8 bits (CSIHnCFGx.CSIHnDLSx[3:0] = 1000_B)
- Transmission direction: MSB first (CSIHnCFGx.CSIHnDIRx = 0)
- Normal clock phase and data phase (CSIHnCFG0.CSIHnCKP0 = 0, CSIHnCFG0.CSIHnDAP0 = 0)
- No delay for any interrupt (CSIHnCTL1.CSIHnSIT = 0)
- Job mode disabled (CSIHnCTL1.CSIHnJE = 0)
- Handshake enabled (CSIHnCTL1.CSIHnHSE = 1)
- Dual buffer mode (CSIHnCTL0.CSIHnMBS = 0, CSIHnMCTL0.CSIHnMMS[1:0] = 01_B)
- Number of data packets: 9 (CSIHnMCTL2.CSIHnND[7:0] = 09_H)
- Transfer start address: 10_H (CSIHnMCTL2.CSIHnSOP[6:0] = 10_H)
- Normal CSIHnTIC interrupt timing (CSIHnCTL1.CSIHnSLIT = 0)

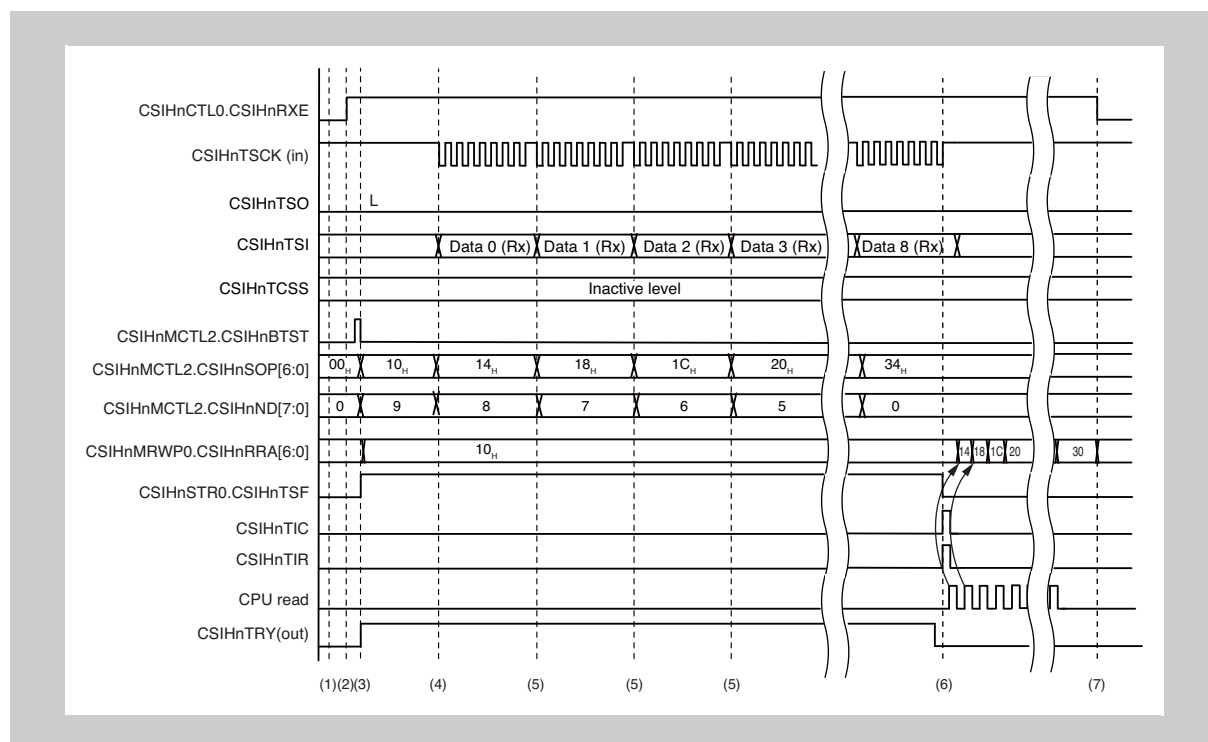

Figure 22-59 Dual buffer mode (for reception in the slave mode, and when the job mode is disabled)

Note The procedure for writing data to the buffer is not described here. The first data address is specified for CSIHnMRWP0.CSIHnTRWA[6:0], and the transfer data is written to CSIHnTX0W. Each time transfer data is written, the value of CSIHnMRWP0.CSIHnTRWA[6:0] is incremented.

- Procedure:**
1. Set up the following registers before setting CSIHnCTL0.CSIHnPWR to 1:
CSIHnCTL1, CSIHnCTL2 (transfer mode, operating mode)
CSIHnMCTL0.CSIHnMMS[1:0] = 01_B (memory mode)
CSIHnCFG0 (communication protocol)
CSIHnSTCR0.CSIHnPCT = 1 (buffer pointers cleared)
 2. CSIHnCTL0.CSIHnPWR = 1 (clock enabled)
CSIHnCTL0.CSIHnTXE = 0 (transmission disabled)
CSIHnCTL0.CSIHnRXE = 1 (reception enabled)
CSIHnCTL0.CSIHnMBS = 0 (memory mode)
 3. The transmission pointer and number of data items are specified using the CSIHnMCTL2.CSIHnSOP[6:0] and CSIHnMCTL2.CSIHnND[7:0] bits. Reception is started by setting CSIHnMCTL2.CSIHnBTST.
 4. Reception starts. Each time a data item is received, the CSIHnMCTL2.CSIHnSOP[6:0] bits are automatically incremented, and the CSIHnMCTL2.CSIHnND[7:0] bits are decremented.
 5. (4) is repeated until the last data is received.
The interrupt requests CSIHnTIC and CSIHnTIR are not generated.
 6. When all the reception ends, the interrupt requests CSIHnTIC and CSIHnTIR are generated.
The CPU starts reading the received data from the reception buffer. The read start address is specified by the CSIHnMRWP0.CSIHnRRA[6:0] bits. The CSIHnMRWP0.CSIHnRRA[6:0] bits are incremented each time a data item is read.
 7. Finally, clear CSIHnCTL0.CSIHnRXE to disable reception operations. In addition, clear CSIHnCTL0.CSIHnPWR to reduce the power consumption while not using the CSIH.

(5) For transmission/reception in the master mode, and when the job mode is enabled

The following conditions are assumed for the procedure shown here:

- Transmission data length: 8 bits (CSIHnCFGx.CSIHnDLSx[3:0] = 1000_B)
- Transmission direction: MSB first (CSIHnCFGx.CSIHnDIRx = 0)
- Normal clock phase and data phase (CSIHnCFGx.CSIHnCKPx = 0, CSIHnCFGx.CSIHnDAPx = 0)
- No delay for any interrupt (CSIHnCTL1.CSIHnSIT = 0)
- Job mode enabled (CSIHnCTL1.CSIHnJE = 1)
- Dual buffer mode (CSIHnCTL0.CSIHnMBS = 0, CSIHnMCTL0.CSIHnMMS[1:0] = 01_B)
- Number of data packets: 12 (CSIHnMCTL2.CSIHnND[7:0] = 12_H)
- Transfer start address: 00_H (CSIHnMCTL2.CSIHnSOP[6:0] = 00_H)
- Normal CSIHnTIC interrupt timing (CSIHnCTL1.CSIHnSLIT = 0)

Figure 22-60 Dual buffer mode (for transmission/reception in the master mode, and when the job mode is enabled)

- Notes**
1. The procedure for writing data to the buffer is not described here. The first data address is specified for CSIHnMRWP0.CSIHnTRWA[6:0], and the transfer data is written to CSIHnTX0W. Each time transfer data is written, the value of CSIHnMRWP0.CSIHnTRWA[6:0] is incremented.
 2. The int_JOBE signal in the above timing chart is the internal signal of the CSIHnCTL0.CSIHnJOBE bit.

- Procedure:**
1. Set up the following registers before setting CSIHnCTL0.CSIHnPWR to 1:
CSIHnCTL1, CSIHnCTL2 (transfer mode, operating mode)
CSIHnMCTL0.CSIHnMMS[1:0] = 01_B (memory mode)
CSIHnCFGx (communication protocol)
(For this example, the chip select signals CS0 to CS7 are used.)
CSIHnSTCR0.CSIHnPCT = 1 (buffer pointers cleared)
 2. CSIHnCTL0.CSIHnPWR = 1 (clock enabled)
CSIHnCTL0.CSIHnTXE = 1 (transmission enabled)
CSIHnCTL0.CSIHnRXE = 1 (reception enabled)
CSIHnCTL0.CSIHnMBS = 0 (memory mode)
 3. The transmission pointer and number of data items are specified using the CSIHnMCTL2.CSIHnSOP[6:0] and CSIHnMCTL2.CSIHnND[7:0] bits. Communication is started by setting CSIHnMCTL2.CSIHnBTST.
 4. Transmission starts. Each time a data item is transmitted, the CSIHnMCTL2.CSIHnSOP[6:0] bits are automatically incremented, and the CSIHnMCTL2.CSIHnND[7:0] bits are decremented.
 5. When all the data is received, CSIHnTIR is generated. The CSIHnTIR interrupt indicates that the reception data register CSIHnRX0W must be read.
 6. CSIHnTIC is generated by setting CSIHnTX0W.CSIHnCIRE to 1. CSIHnTIC indicates that the last data (CSIHnTX0W.CSIHnEOJ = 1) of the current job was transmitted.
 7. By setting CSIHnCTL0.CSIHnJOBE to 1, communication is forcibly stopped when job 3 ends.
 8. After communication is forcibly stopped, the interrupt requests CSIHnTIJC and CSIHnTIR are generated when job 3 ends. The interrupt request CSIHnTIJC indicates that communication was forcibly stopped when the current job ended. Because the interrupt request CSIHnTIJC is generated instead of the interrupt request CSIHnTIC, the interrupt request CSIHnTIC is not generated. Note that transfer data is not transmitted by the CSIHnTX0W register.
 9. Finally, clear CSIHnCTL0.CSIHnTXE and CSIHnCTL0.CSIHnRXE to disable transmission/reception operations. In addition, clear CSIHnCTL0.CSIHnPWR to reduce the power consumption while not using the CSIH.

(6) For reception in the master mode, and when the job mode is enabled

The following conditions are assumed for the procedure shown here:

- Transmission data length: 8 bits (CSIHnCFGx.CSIHnDLSx[3:0] = 1000_B)
- Transmission direction: MSB first (CSIHnCFGx.CSIHnDIRx = 0)
- Normal clock phase and data phase (CSIHnCFGx.CSIHnCKPx = 0, CSIHnCFGx.CSIHnDAPx = 0)
- No delay for any interrupt (CSIHnCTL1.CSIHnSIT = 0)
- Job mode enabled (CSIHnCTL1.CSIHnJE = 1)
- Dual buffer mode (CSIHnCTL0.CSIHnMBS = 0, CSIHnMCTL0.CSIHnMMS[1:0] = 01_B)
- Number of data packets: 12 (CSIHnMCTL2.CSIHnND[7:0] = 12_H)
- Transfer start address: 00_H (CSIHnMCTL2.CSIHnSOP[6:0] = 00_H)
- Normal CSIHnTIC interrupt timing (CSIHnCTL1.CSIHnSLIT = 0)

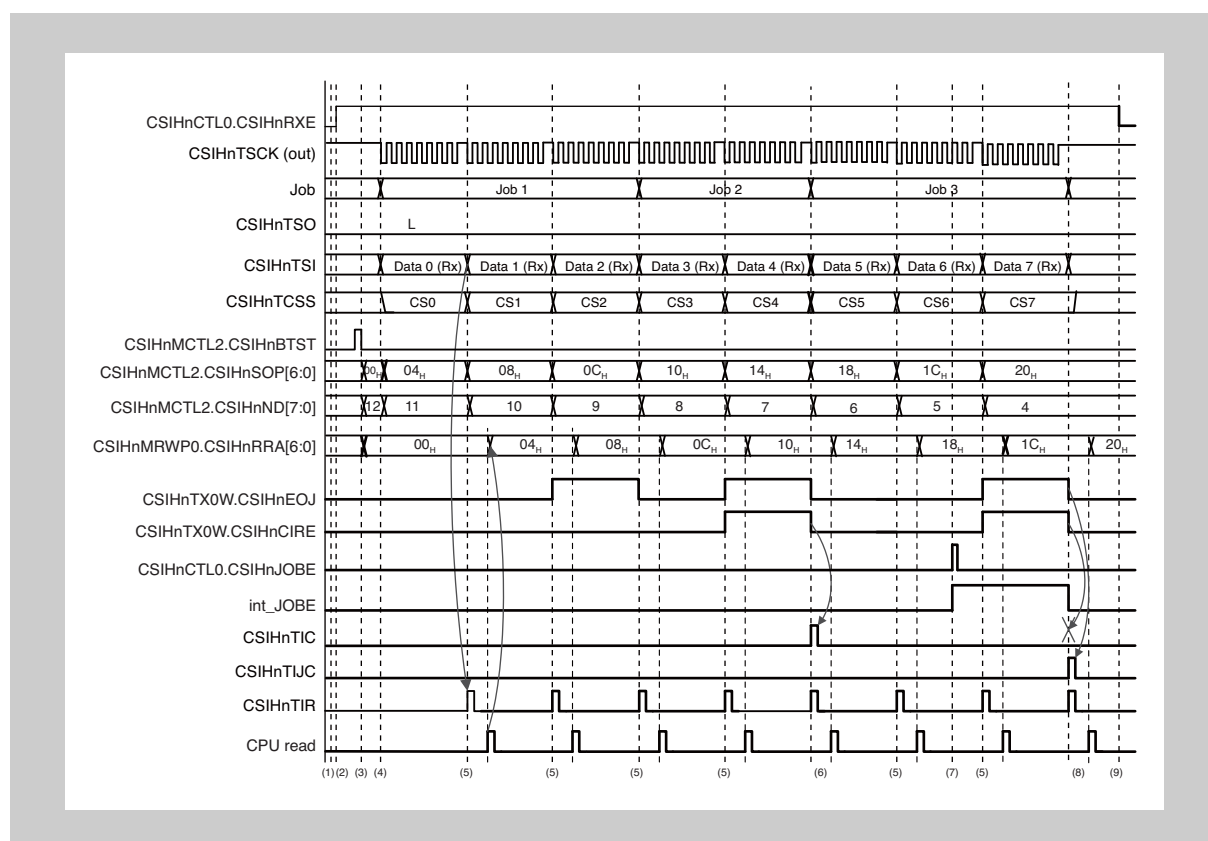

Figure 22-61 Dual buffer mode (for reception in the master mode, and when the job mode is enabled)

- Notes**
1. The procedure for writing data to the buffer is not described here. The first data address is specified for CSIHnMRWP0.CSIHnTRWA[6:0], and the transfer data is written to CSIHnTX0W. Each time transfer data is written, the value of CSIHnMRWP0.CSIHnTRWA[6:0] is incremented.
 2. The int_JOBE signal in the above timing chart is the internal signal of the CSIHnCTL0.CSIHnJOBE bit.

- Procedure:**
1. Set up the following registers before setting CSIHnCTL0.CSIHnPWR to 1:
CSIHnCTL1, CSIHnCTL2 (transfer mode, operating mode)
CSIHnMCTL0.CSIHnMMS[1:0] = 01_B (memory mode)
CSIHnCFGx (communication protocol)
(For this example, the chip select signals CS0 to CS7 are used.)
CSIHnSTCR0.CSIHnPCT = 1 (buffer pointers cleared)
 2. CSIHnCTL0.CSIHnPWR = 1 (clock enabled)
CSIHnCTL0.CSIHnTXE = 0 (transmission disabled)
CSIHnCTL0.CSIHnRXE = 1 (reception enabled)
CSIHnCTL0.CSIHnMBS = 0 (memory mode)
 3. The transmission pointer and number of data items are specified using the CSIHnMCTL2.CSIHnSOP[6:0] and CSIHnMCTL2.CSIHnND[7:0] bits. Communication is started by setting CSIHnMCTL2.CSIHnBTST.
 4. Reception starts. Each time a data item is received, the CSIHnMCTL2.CSIHnSOP[6:0] bits are automatically incremented, and the CSIHnMCTL2.CSIHnND[7:0] bits are decremented.
 5. Each time data is received, CSIHnTIR is generated. The CSIHnTIR interrupt indicates that the reception data register CSIHnRX0W must be read.
 6. CSIHnTIC is generated by setting CSIHnTX0W.CSIHnCIRE to 1. CSIHnTIC indicates that the last data (CSIHnTX0W.CSIHnEOJ = 1) of the current job was transmitted.
 7. By setting CSIHnCTL0.CSIHnJOBE to 1, reception is forcibly stopped when job 3 ends.
 8. After reception is forcibly stopped, the interrupt requests CSIHnTIJC and CSIHnTIR are generated when job 3 ends. The interrupt request CSIHnTIJC indicates that reception was forcibly stopped when the current job ended. Because the interrupt request CSIHnTIJC is generated instead of the interrupt request CSIHnTIC, the interrupt request CSIHnTIC is not generated. Note that transfer data is not transmitted by the CSIHnTX0W register.
 9. Finally, clear CSIHnCTL0.CSIHnRXE to disable reception operations. In addition, clear CSIHnCTL0.CSIHnPWR to reduce the power consumption while not using the CSIH.

22.5.4 Procedures in FIFO mode

(1) For transmission/reception in the master mode, and when the job mode is disabled

The following conditions are assumed for the procedure shown here:

- Transmission data length: 8 bits (CSIHnCFGx.CSIHnDLSx[3:0] = 1000_B)
- Transmission direction: MSB first (CSIHnCFGx.CSIHnDIRx = 0)
- Normal clock phase and data phase (CSIHnCFGx.CSIHnCKPx = 0, CSIHnCFGx.CSIHnDAPx = 0)
- No delay for any interrupt (CSIHnCTL1.CSIHnSIT = 0)
- Job mode disabled (CSIHnCTL1.CSIHnJE = 0)
- FIFO mode (CSIHnCTL0.CSIHnMBS = 0, CSIHnMCTL0.CSIHnMMS[1:0] = 00_B)
- Normal CSIHnTIC interrupt timing (CSIHnCTL1.CSIHnSLIT = 0)

Figure 22-62 FIFO mode (for transmission/reception in the master mode, and when the job mode is disabled)

- Procedure:**
1. Set up the following registers before setting CSIHnCTL0.CSIHnPWR to 1:
CSIHnCTL1, CSIHnCTL2 (transfer mode, operating mode)
CSIHnMCTL0.CSIHnMMS[1:0] = 00_B (memory mode)
CSIHnCFGx (communication protocol)
(For this example, the chip select signals CS0 to CS3 are used.)
 2. Set CSIHnSTCR0.CSIHnPCT to 1 to clear all the buffer pointers.
 3. Make sure that CSIHnSTR0.CSIHnFLF = 0, CSIHnSTR0.CSIHnEMF = 1, and CSIHnSTR0.CSIHnSPF[7:0] = 00_H.
 4. Specify the CSIHnTIC interrupt condition for CSIHnMCTL1.CSIHnFES[6:0].
Specify the CSIHnTIR interrupt condition for CSIHnMCTL1.CSIHnFFS[6:0].
 5. CSIHnCTL0.CSIHnPWR = 1 (clock enabled)
CSIHnCTL0.CSIHnTXE = 1 (transmission enabled)
CSIHnCTL0.CSIHnRXE = 1 (reception enabled)
CSIHnCTL0.CSIHnMBS = 0 (memory mode)
 6. When transmission data is written to the transmission data register CSIHnTX0W, communication starts.
 7. Some of the communication finishes, but CSIHnTIC is not generated because the values of CSIHnSTR0.CSIHnSPF[7:0] and CSIHnMCTL1.CSIHnFES[6:0] do not match.
 8. CSIHnTIC is generated because the values of CSIHnSTR0.CSIHnSPF[7:0] and CSIHnMCTL1.CSIHnFES[6:0] match.
 9. The interrupt request CSIHnTIR is generated because the values of CSIHnMCTL1.CSIHnFFS[6:0] and (128 – CSIHnSTR0.CSIHnSRP[7:0]) match.
The interrupt request CSIHnTIC is generated because the values of CSIHnSTR0.CSIHnSPF[7:0] and CSIHnMCTL1.CSIHnFES[6:0] match.
The CPU starts reading the received data stored in the reception buffer.
 10. The CPU finishes reading the received data. The CSIHnSTR0.CSIHnEMF bit is set because the FIFO buffer is empty.
 11. Finally, clear CSIHnCTL0.CSIHnTXE and CSIHnCTL0.CSIHnRXE to disable transmission/reception operations. In addition, clear CSIHnCTL0.CSIHnPWR to reduce the power consumption while not using the CSIH.

(2) For reception in the master mode, and when the job mode is disabled

The following conditions are assumed for the procedure shown here:

- Transmission data length: 8 bits (CSIHnCFGx.CSIHnDLSx[3:0] = 1000_B)
- Transmission direction: MSB first (CSIHnCFGx.CSIHnDIRx = 0)
- Normal clock phase and data phase (CSIHnCFGx.CSIHnCKPx = 0, CSIHnCFGx.CSIHnDAPx = 0)
- No delay for any interrupt (CSIHnCTL1.CSIHnSIT = 0)
- Job mode disabled (CSIHnCTL1.CSIHnJE = 0)
- FIFO mode (CSIHnCTL0.CSIHnMBS = 0, CSIHnMCTL0.CSIHnMMS[1:0] = 00_B)
- Normal CSIHnTIC interrupt timing (CSIHnCTL1.CSIHnSLIT = 0)

Figure 22-63 FIFO mode (for reception in the master mode, and when the job mode is disabled)

- Procedure:**
1. Set up the following registers before setting CSIHnCTL0.CSIHnPWR to 1:
CSIHnCTL1, CSIHnCTL2 (transfer mode, operating mode)
CSIHnMCTL0.CSIHnMMS[1:0] = 00_B (memory mode)
CSIHnCFGx (communication protocol)
(For this example, the chip select signals CS0 to CS3 are used.)
 2. Set CSIHnSTCR0.CSIHnPCT to 1 to clear all the buffer pointers.
 3. Make sure that CSIHnSTR0.CSIHnFLF = 0, CSIHnSTR0.CSIHnEMF = 1, and CSIHnSTR0.CSIHnSPF[7:0] = 00_H.
 4. Specify the CSIHnTIC interrupt condition for CSIHnMCTL1.CSIHnFES[6:0].
Specify the CSIHnTIR interrupt condition for CSIHnMCTL1.CSIHnFFS[6:0].
 5. CSIHnCTL0.CSIHnPWR = 1 (clock enabled)
CSIHnCTL0.CSIHnTXE = 0 (transmission disabled)
CSIHnCTL0.CSIHnRXE = 1 (reception enabled)
CSIHnCTL0.CSIHnMBS = 0 (memory mode)
 6. When transmission data is written to the transmission data register CSIHnTX0W, communication starts. (The transmission data is not used, but the chip select signal is enabled.)
 7. Some of the communication finishes, but CSIHnTIC is not generated because the values of CSIHnSTR0.CSIHnSPF[7:0] and CSIHnMCTL1.CSIHnFES[6:0] do not match.
 8. CSIHnTIC is generated because the values of CSIHnSTR0.CSIHnSPF[7:0] and CSIHnMCTL1.CSIHnFES[6:0] match.
 9. The interrupt request CSIHnTIR is generated because the values of CSIHnMCTL1.CSIHnFFS[6:0] and (128 – CSIHnSTR0.CSIHnSRP[7:0]) match.
The interrupt request CSIHnTIC is generated because the values of CSIHnSTR0.CSIHnSPF[7:0] and CSIHnMCTL1.CSIHnFES[6:0] match.
The CPU starts reading the received data stored in the reception buffer.
 10. The CPU finishes reading the received data. The CSIHnSTR0.CSIHnEMF bit is set because the FIFO buffer is empty.
 11. Finally, clear CSIHnCTL0.CSIHnRXE to disable reception operations.
In addition, clear CSIHnCTL0.CSIHnPWR to reduce the power consumption while not using the CSIH.

(3) For transmission/reception in the slave mode, and when the job mode is disabled

The following conditions are assumed for the procedure shown here:

- Transmission data length: 8 bits (CSIHnCFG0.CSIHnDLS0[3:0] = 1000_B)
- Transmission direction: MSB first (CSIHnCFG0.CSIHnDIR0 = 0)
- Normal clock phase and data phase (CSIHnCFG0.CSIHnCKP0 = 0, CSIHnCFG0.CSIHnDAP0 = 0)
- No delay for any interrupt (CSIHnCTL1.CSIHnSIT = 0)
- Job mode disabled (CSIHnCTL1.CSIHnJE = 0)
- Handshake enabled (CSIHnCTL1.CSIHnHSE = 1)
- FIFO mode (CSIHnCTL0.CSIHnMBS = 0, CSIHnMCTL0.CSIHnMMS[1:0] = 00_B)
- Normal CSIHnTIC interrupt timing (CSIHnCTL1.CSIHnSLIT = 0)

Figure 22-64 FIFO mode (for transmission/reception in the slave mode, and when the job mode is disabled)

- Procedure:**
1. Set up the following registers before setting CSIHnCTL0.CSIHnPWR to 1:
CSIHnCTL1, CSIHnCTL2 (transfer mode, operating mode)
CSIHnMCTL0.CSIHnMMS[1:0] = 00_B (memory mode)
CSIHnCFG0 (communication protocol)
 2. Set CSIHnSTCR0.CSIHnPCT to 1 to clear all the buffer pointers.
Make sure that CSIHnSTR0.CSIHnFLF = 0, CSIHnSTR0.CSIHnEMF = 1,
and CSIHnSTR0.CSIHnSPF[7:0] = 00_H.
 3. Specify the CSIHnTIC interrupt condition for
CSIHnMCTL1.CSIHnFES[6:0].
Specify the CSIHnTIR interrupt condition for
CSIHnMCTL1.CSIHnFFS[6:0].
 4. CSIHnCTL0.CSIHnPWR = 1 (clock enabled)
CSIHnCTL0.CSIHnTXE = 1 (transmission enabled)
CSIHnCTL0.CSIHnRXE = 1 (reception enabled)
CSIHnCTL0.CSIHnMBS = 0 (memory mode)
 5. Write the transfer data to the transmission data register CSIHnTX0W. The
CSIHnTRY signal is switched from BUSY (low level) to READY (high level)
when data is written.
 6. When a serial clock is supplied from the master, communication
automatically starts.
 7. Some of the communication finishes, but CSIHnTIC is not generated
because the values of CSIHnSTR0.CSIHnSPF[7:0] and
CSIHnMCTL1.CSIHnFES[6:0] do not match.
 8. CSIHnTIC is generated because the values of
CSIHnSTR0.CSIHnSPF[7:0] and CSIHnMCTL1.CSIHnFES[6:0] match.
 9. The interrupt request CSIHnTIR is generated because the values of
CSIHnMCTL1.CSIHnFFS[6:0] and (128 – CSIHnSTR0.CSIHnSRP[7:0])
match.
The interrupt request CSIHnTIC is generated because the values of
CSIHnSTR0.CSIHnSPF[7:0] and CSIHnMCTL1.CSIHnFES[6:0] match.
The CPU starts reading the received data stored in the reception buffer.
 10. The CPU finishes reading the received data. The CSIHnSTR0.CSIHnEMF
bit is set because the FIFO buffer is empty.
 11. Finally, clear CSIHnCTL0.CSIHnTXE and CSIHnCTL0.CSIHnRXE to
disable transmission/reception operations. In addition, clear
CSIHnCTL0.CSIHnPWR to reduce the power consumption while not using
the CSIH.

(4) For reception in the slave mode, and when the job mode is disabled

The following conditions are assumed for the procedure shown here:

- Transmission data length: 8 bits (CSIHnCFG0.CSIHnDLS0[3:0] = 1000_B)
- Transmission direction: MSB first (CSIHnCFG0.CSIHnDIR0 = 0)
- Normal clock phase and data phase (CSIHnCFG0.CSIHnCKP0 = 0, CSIHnCFG0.CSIHnDAP0 = 0)
- No delay for any interrupt (CSIHnCTL1.CSIHnSIT = 0)
- Job mode disabled (CSIHnCTL1.CSIHnJE = 0)
- Handshake enabled (CSIHnCTL1.CSIHnHSE = 1)
- FIFO mode (CSIHnCTL0.CSIHnMBS = 0, CSIHnMCTL0.CSIHnMMS[1:0] = 00_B)
- Normal CSIHnTIC interrupt timing (CSIHnCTL1.CSIHnSLIT = 0)

Figure 22-65 FIFO mode (for reception in the slave mode, and when the job mode is disabled)

- Procedure:**
1. Set up the following registers before setting CSIHnCTL0.CSIHnPWR to 1:
CSIHnCTL1, CSIHnCTL2 (transfer mode, operating mode)
CSIHnMCTL0.CSIHnMMS[1:0] = 00_B (memory mode)
CSIHnCFG0 (communication protocol)
 2. Set CSIHnSTCR0.CSIHnPCT to 1 to clear all the buffer pointers.
 3. Make sure that CSIHnSTR0.CSIHnFLF = 0, CSIHnSTR0.CSIHnEMF = 1, and CSIHnSTR0.CSIHnSPF[7:0] = 00_H.
 4. Specify the CSIHnTIR interrupt condition for CSIHnMCTL1.CSIHnFFS[6:0].
 5. CSIHnCTL0.CSIHnPWR = 1 (clock enabled)
CSIHnCTL0.CSIHnTXE = 0 (transmission disabled)
CSIHnCTL0.CSIHnRXE = 1 (reception enabled)
CSIHnCTL0.CSIHnMBS = 0 (memory mode)
The CSIHnTRY signal is switched from BUSY (low level) to READY (high level) by clearing CSIHnCTL0.CSIHnPWR to 0 and setting CSIHnCTL0.CSIHnRXE to 1.
 6. When a serial clock is supplied from the master, reception automatically starts.
 7. Some of the communication finishes, but CSIHnTIC is not generated because the system is in the reception mode.
 8. The interrupt request CSIHnTIR is generated because the values of CSIHnMCTL1.CSIHnFFS[6:0] and (128 – CSIHnSTR0.CSIHnSRP[7:0]) match.
The CPU starts reading the received data stored in the reception buffer.
 9. The CPU finishes reading the received data. The CSIHnSTR0.CSIHnEMF bit is set because the FIFO buffer is empty.
 10. Finally, clear CSIHnCTL0.CSIHnRXE to disable reception operations.
In addition, clear CSIHnCTL0.CSIHnPWR to reduce the power consumption while not using the CSIH.

(5) For transmission/reception in the master mode, and when the job mode is enabled

The following conditions are assumed for the procedure shown here:

- Transmission data length: 8 bits (CSIHnCFGx.CSIHnDLSx[3:0] = 1000_B)
- Transmission direction: MSB first (CSIHnCFGx.CSIHnDIRx = 0)
- Normal clock phase and data phase (CSIHnCFGx.CSIHnCKPx = 0, CSIHnCFGx.CSIHnDAPx = 0)
- No delay for any interrupt (CSIHnCTL1.CSIHnSIT = 0)
- Job mode is enabled (CSIHnCTL1.CSIHnJE = 1)
- FIFO mode (CSIHnCTL0.CSIHnMBS = 0, CSIHnMCTL0.CSIHnMMS[1:0] = 00_B)
- Normal CSIHnTIC interrupt timing (CSIHnCTL1.CSIHnSLIT = 0)
- Job 1 = four data items, job 2 = three data items, and job 3 = five data items

Figure 22-66 FIFO mode (for transmission/reception in the master mode, and when the job mode is enabled)

Note The int_JOBx signal in the above timing chart is the internal signal of the CSIHnCTL0.CSIHnJOBx bit.

- Procedure:**
1. Set up the following registers before setting CSIHnCTL0.CSIHnPWR to 1:
CSIHnCTL1, CSIHnCTL2 (transfer mode, operating mode)
CSIHnMCTL0.CSIHnMMS[1:0] = 00_B (memory mode)
CSIHnCFGx (communication protocol)
(For this example, the chip select signals CS0 to CS7 are used.)
 2. Set CSIHnSTCR0.CSIHnPCT to 1 to clear all the buffer pointers.
 3. Make sure that CSIHnSTR0.CSIHnFLF = 0, CSIHnSTR0.CSIHnEMF = 1, and CSIHnSTR0.CSIHnSPF[7:0] = 00_H.
 4. Specify the CSIHnTIC interrupt condition for CSIHnMCTL1.CSIHnFES[6:0].
Specify the CSIHnTIR interrupt condition for CSIHnMCTL1.CSIHnFFS[6:0].
 5. CSIHnCTL0.CSIHnPWR = 1 (clock enabled)
CSIHnCTL0.CSIHnTXE = 1 (transmission enabled)
CSIHnCTL0.CSIHnRXE = 1 (reception enabled)
CSIHnCTL0.CSIHnMBS = 0 (memory mode)
 6. When transmission data is written to the transmission data register CSIHnTX0W, communication starts.
 7. Some of the communication finishes, but CSIHnTIC is not generated because the values of CSIHnSTR0.CSIHnSPF[7:0] and CSIHnMCTL1.CSIHnFES[6:0] do not match.
 8. Because the last data (CSIHnTX0W.CSIHnEOJ = 1) of the current job was transmitted by clearing CSIHnTX0W.CSIHnCIRE, the interrupt request CSIHnTIC is not generated.
 9. Because the last data (CSIHnTX0W.CSIHnEOJ = 1) of the current job was transmitted by setting CSIHnTX0W.CSIHnCIRE, the interrupt request CSIHnTIC is generated.
 10. CSIHnTIC is generated because the values of CSIHnSTR0.CSIHnSPF[7:0] and CSIHnMCTL1.CSIHnFES[6:0] match. Because CSIHnTIC was generated, CSIHnTIJC is not generated. The interrupt request CSIHnTIR is generated because the values of CSIHnMCTL1.CSIHnFFS[6:0] and (128 – CSIHnSTR0.CSIHnSRP[7:0]) match. The CPU starts reading the received data stored in the reception buffer.
 11. Finally, clear CSIHnCTL0.CSIHnTXE and CSIHnCTL0.CSIHnRXE to disable transmission/reception operations. In addition, clear CSIHnCTL0.CSIHnPWR to reduce the power consumption while not using the CSIH.

(6) For reception in the master mode, and when the job mode is enabled

The following conditions are assumed for the procedure shown here:

- Transmission data length: 8 bits (CSIHnCFGx.CSIHnDLSx[3:0] = 1000_B)
- Transmission direction: MSB first (CSIHnCFGx.CSIHnDIRx = 0)
- Normal clock phase and data phase (CSIHnCFGx.CSIHnCKPx = 0, CSIHnCFGx.CSIHnDAPx = 0)
- No delay for any interrupt (CSIHnCTL1.CSIHnSIT = 0)
- Job mode enabled (CSIHnCTL1.CSIHnJE = 1)
- FIFO mode (CSIHnCTL0.CSIHnMBS = 0, CSIHnMCTL0.CSIHnMMS[1:0] = 00_B)
- Normal CSIHnTIC interrupt timing (CSIHnCTL1.CSIHnSLIT = 0)
- Job 1 = four data items, job 2 = three data items, and job 3 = five data items

Figure 22-67 FIFO mode (for reception in the master mode, and when the job mode is enabled)

Note The int_JOBx signal in the above timing chart is the internal signal of the CSIHnCTL0.CSIHnJOBx bit.

- Procedure:**
1. Set up the following registers before setting CSIHnCTL0.CSIHnPWR to 1:
 - CSIHnCTL1, CSIHnCTL2 (transfer mode, operating mode)
 - CSIHnMCTL0.CSIHnMMS[1:0] = 00_B (memory mode)
 - CSIHnCFGx (communication protocol)
 - (For this example, the chip select signals CS0 to CS7 are used.)
 2. Set CSIHnSTCR0.CSIHnPCT to 1 to clear all the buffer pointers.
 3. Make sure that CSIHnSTR0.CSIHnFLF = 0, CSIHnSTR0.CSIHnEMF = 1, and CSIHnSTR0.CSIHnSPF[7:0] = 00_H.
 4. Specify the CSIHnTIC interrupt condition for CSIHnMCTL1.CSIHnFES[6:0].
Specify the CSIHnTIR interrupt condition for CSIHnMCTL1.CSIHnFFS[6:0].
 5. CSIHnCTL0.CSIHnPWR = 1 (clock enabled)
CSIHnCTL0.CSIHnTXE = 1 (transmission enabled)
CSIHnCTL0.CSIHnRXE = 1 (reception enabled)
CSIHnCTL0.CSIHnMBS = 0 (memory mode)
 6. When transmission data is written to the transmission data register CSIHnTX0W, communication starts. (The transmission data is not used, but the chip select signal is enabled.)
 7. Some of the reception finishes, but CSIHnTIC is not generated because the values of CSIHnSTR0.CSIHnSPF[7:0] and CSIHnMCTL1.CSIHnFES[6:0] do not match.
 8. Because the last data (CSIHnTX0W.CSIHnEOJ = 1) of the current job was transmitted by clearing CSIHnTX0W.CSIHnCIRE, the interrupt request CSIHnTIC is not generated.
 9. Because the last data (CSIHnTX0W.CSIHnEOJ = 1) of the current job was transmitted by setting CSIHnTX0W.CSIHnCIRE, the interrupt request CSIHnTIC is generated.
 10. CSIHnTIC is generated because the values of CSIHnSTR0.CSIHnSPF[7:0] and CSIHnMCTL1.CSIHnFES[6:0] match. Because CSIHnTIC was generated, CSIHnTIJC is not generated. The interrupt request CSIHnTIR is generated because the values of CSIHnMCTL1.CSIHnFFS[6:0] and (128 – CSIHnSTR0.CSIHnSRP[7:0]) match. The CPU starts reading the received data stored in the reception buffer.
 11. Finally, clear CSIHnCTL0.CSIHnRXE to disable reception operations. In addition, clear CSIHnCTL0.CSIHnPWR to reduce the power consumption while not using the CSIH.

Chapter 23 I²C BUS (IICB)

Caution To use the IIC bus function, use the SCLn and SDAn pins, and set them to N-ch open drain.

This chapter describes the I²C bus (IICB).

The first section describes all properties specific to the V850E2/ML4, such as instances, register base addresses, input/output signal names.

The subsequent sections describe the features that apply to all implementations.

23.1 V850E2/ML4 IICB Features

Instances This microcontroller has the following number of instances of the IICB.

Table 23-1 Instances of IICB

IICB	
Instances	2
Names	IICB, IICB1

Instances index n Throughout this chapter, the individual instances of the IICB are identified by the index “n” (n = 0, 1), for example, IICBnDAT for the IICBn data register.

Register addresses All IICBn register addresses are given as address offsets from the individual base addresses <IICBn_base>. The base address <IICBn_base> of each IICBn is listed in the following table:

Table 23-2 Register base addresses <IICBn_base>

IICBn	IICBn instance	<IICBn_base>
IICB0	<IICBn_base_OS>	FF82 0000 _H
	<IICBn_base_USER>	FFFF F400 _H
IICB1	<IICBn_base_OS>	FF82 1000 _H
	<IICBn_base_USER>	FFFF F500 _H

Clock supply The IICBn uses PCLK as the clock input. PCLK is connected to the clock generator.

Table 23-3 IICBn clock supply

IICBn instance	Clock	Connected to:
IICB0, IICB1	PCLK	f _{PCLK}

Interrupt request signal The IICBn uses a data transmit/receive interrupt request signal (IICBTIA_n) and a status interrupt request signal (IICBTIS_n).

Table 23-4 IICBn interrupt request signals

Interrupt request signal	Function	Connected to
IICB0		
IICBTIA	Data transmit/receive interrupt request signal	<ul style="list-style-type: none"> • Interrupt controller 158 (INTUARTJ0IR) • DMA controller trigger 91 • DTS controller trigger 89
IICBTIS	Status interrupt request signal	<ul style="list-style-type: none"> • Interrupt controller 157 (INTCSIH0RE)
IICB1		
IICBTIA	Data transmit/receive interrupt request signal	<ul style="list-style-type: none"> • Interrupt controller 172 (INTFCN0REC) • DMA controller trigger 96
IICBTIS	Status interrupt request signal	<ul style="list-style-type: none"> • Interrupt controller 171 (INTFCN0IERR)

23.2 Functional Overview

Operating mode	Standard mode (SCL clock frequency: 100 kHz max.) Fast mode (SCL clock frequency: 400 kHz max.)
Transfer mode	Single transfer mode Continuous transfer mode
Pin configuration	SCLn: Serial clock pin SDAn: Serial transmit/receive data pin
Interrupt request signal	Data transmit/receive interrupt request signal (IICBTIA _n) Status interrupt request signal (IICBTIS _n)
Communication data length	8 bits
Multimaster support	Multiple masters can control the bus simultaneously.
SCLn level width	The high-level width and low-level width of the serial clock signal (SCLn) can be changed.
Automatic detection	The start and stop conditions can be detected automatically.

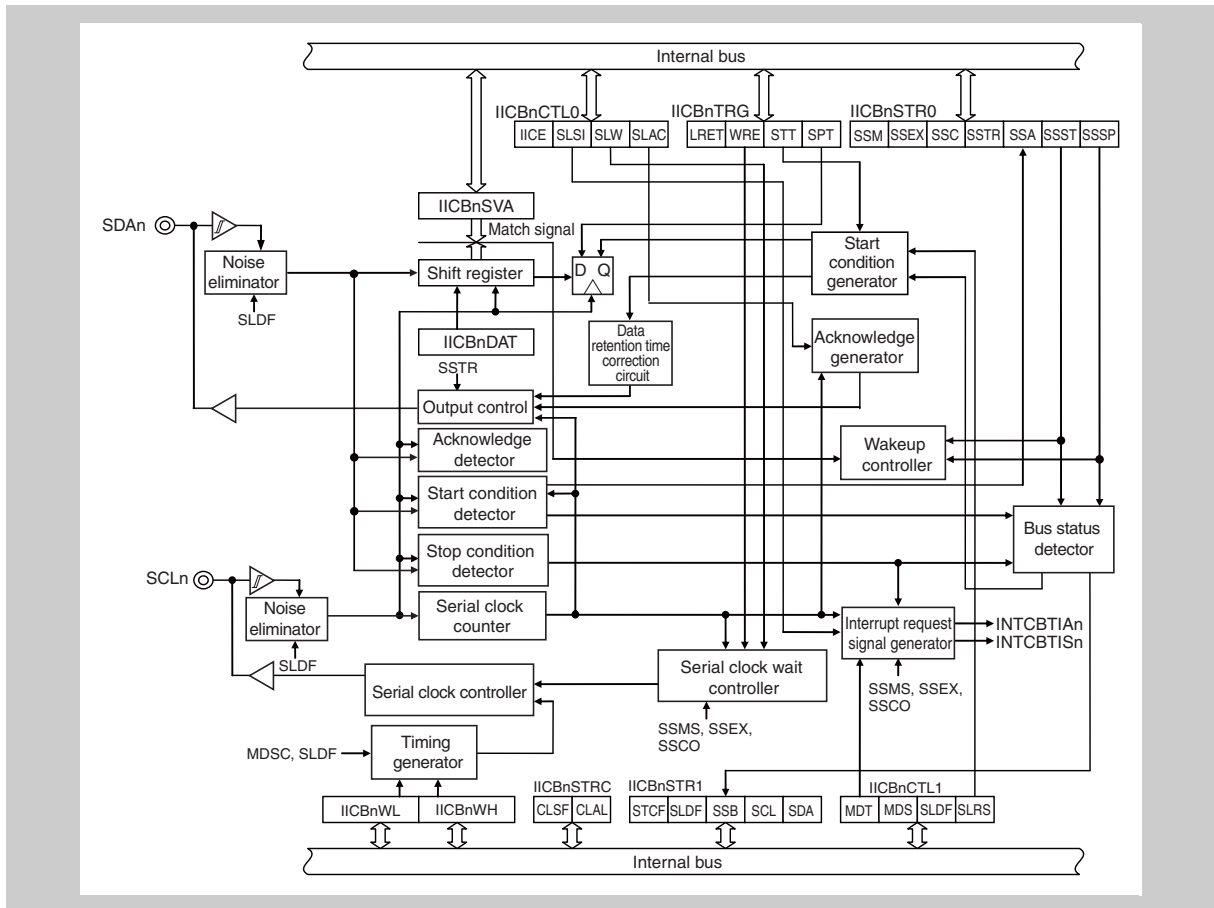

Figure 23-1 Block diagram of IICBn

23.3 IIC Bus Mode Functions

23.3.1 Pin configuration

The serial clock pin (SCLn) and serial data bus pin (SDAn) are configured as follows.

SCLn... This pin is used for serial clock input and output.
This pin is an N-ch open-drain output for both master and slave devices. Input is Schmitt input.

SDAn... This pin is used for serial data input and output.
This pin is an N-ch open-drain output for both master and slave devices. Input is Schmitt input.

Because the outputs of the serial clock line and serial data bus line are N-ch open-drain outputs, an external pull-up resistor must be connected to these lines.

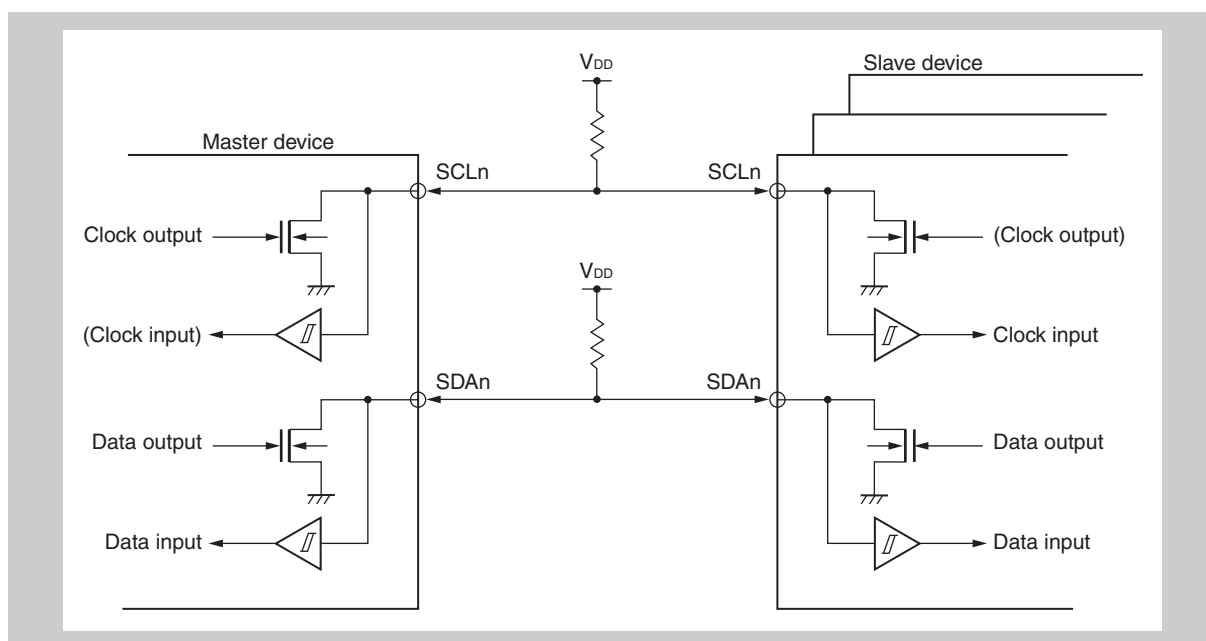

Figure 23-2 Pin configuration diagram

23.4 IIC Bus Definition

This section describes the IIC bus's serial data communication format and the signals used by the IIC bus.

Figure 23-3 "IIC bus serial data transfer timing" shows the transfer timing for the "start condition", "address", "transfer direction specification", "data", and "stop condition", which are output onto the IIC bus's serial data bus.

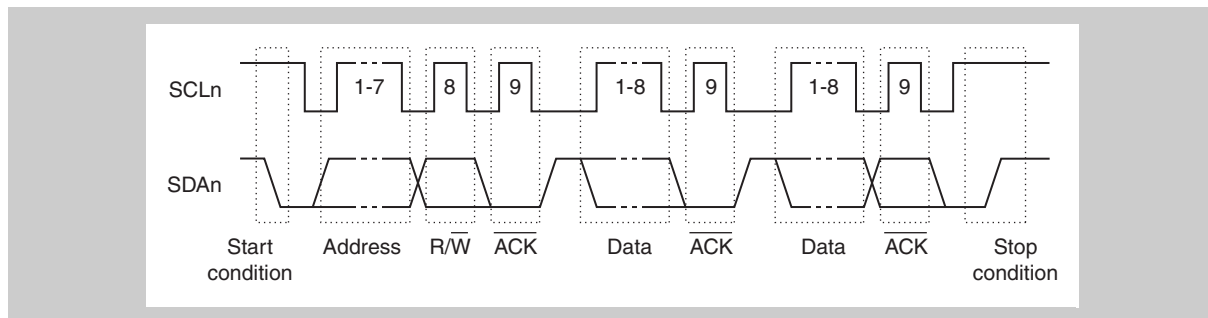

Figure 23-3 IIC bus serial data transfer timing

The start condition, slave address, and stop condition are output by the master device.

$\overline{\text{ACK}}$ can be output by either the master or slave device. (Normally, it is output by the device that receives 8-bit data.)

The serial clock signal (SCLn) is continuously output by the master device. In the slave device, the low-level period of the SCLn signal can be extended to insert a wait.

23.4.1 Start Condition

The start condition is met if the SDA_n signal level changes from high to low while the SCL_n signal is high. The start condition is output when the master device starts serial data transfer to a slave device. When the IICB_n is in the slave mode, it detects the start condition.

Figure 23-4 Start condition

23.4.2 Addresses

The 7 bits of data following the start condition are defined as an address.

An address is a 7-bit data segment that is output in order to select one of the slave devices that are connected to the master device via the bus lines. Therefore, each slave device connected via the bus lines must have a unique address.

The slave device checks whether the 7-bit data matches its own address. If they match, that slave device is selected as the communication destination and communicates with the master device until the master device outputs another start condition or a stop condition.

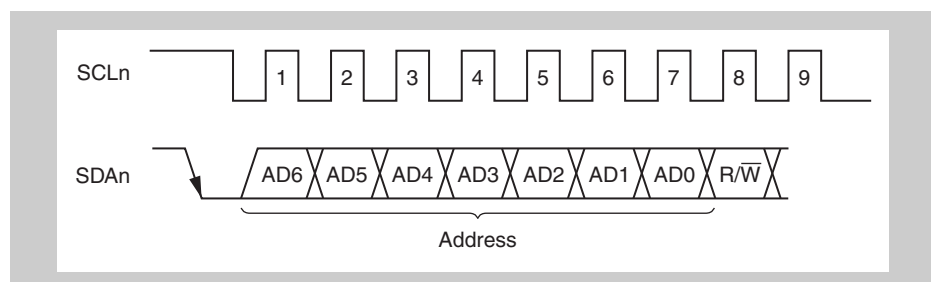

Figure 23-5 Addresses

23.4.3 Extension Code

When the higher 4 bits of the address are 0000 or 1111, these bits are called extension code. Table 23-5 “Extension code bit definitions” lists the bit definitions of extension code.

Table 23-5 Extension code bit definitions

Slave address	R/W bit	Description
0000 000	0	General call address
0000 000	1	Start byte
0000 001	x	CBUS address
0000 010	x	Address reserved for different bus format
0000 011	x	Reserved for future use
0000 1xx	x	HS mode master code ^a
1111 0xx	x	10-bit slave address specification
1111 1xx	x	Reserved for future use

a) The HS mode cannot be used for IICB.

23.4.4 Transfer direction specification

After the 7-bit address data, the master device transmits 1 bit that specifies the transfer direction.

If this transfer direction specification bit is 0, it indicates that the master device transmits data to a slave device. If this bit is 1, it indicates that the master device receives data from a slave device.

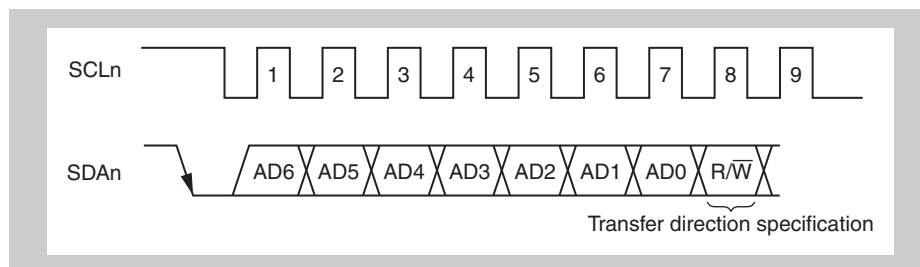

Figure 23-6 Transfer direction specification

23.4.5 Acknowledge ($\overline{\text{ACK}}$)

The 1-bit data after the transfer direction bit ($\overline{\text{R/W}}$) and the 1-bit data after the 8-bit data during address transfer are defined as an acknowledge signal ($\overline{\text{ACK}}$). $\overline{\text{ACK}}$ is used to check the serial data status of the transmitting and receiving devices.

The receiving device returns $\overline{\text{ACK}}$ after receiving 8-bit data.

The transmitting device normally receives $\overline{\text{ACK}}$ after transmitting 8-bit data. If the transmitting device receives $\overline{\text{ACK}}$ from the receiving device, it continues processing assuming that the transmitted data is normally received.

If the master device is the receiving device and receives the final data, it does not return $\overline{\text{ACK}}$ and outputs a stop condition. If the slave device is the receiving device and does not return $\overline{\text{ACK}}$, the master device outputs either a stop condition or a restart condition and then stops the current transmission. Failure to return $\overline{\text{ACK}}$ may be caused by the following factors.

- (1) The transmitted data has not been received normally.
- (2) The final data has been received.
- (3) The receiving device (slave) does not exist for the specified address.

$\overline{\text{ACK}}$ is output when the SDA_n line of the receiving device changes to low level at the 9th clock (normal reception).

Figure 23-7 Acknowledge ($\overline{\text{ACK}}$)

23.4.6 Data

The bits other than the nine bits following the start condition (seven address bits, an $\overline{R/\overline{W}}$ bit, and an acknowledge (\overline{ACK}) bit) and the acknowledge bits are defined as data.

If a 10-bit address is specified using an extension code, the 8-bit data that is transferred after the address is used as the second address.

23.4.7 Stop condition

A stop condition is met if the SDA_n signal level changes from low to high while the SCL_n signal is high.

The stop condition is output when serial data transfer from the master device to the slave device has been completed.

Figure 23-8 Stop condition

23.4.8 Wait state

A wait state is used to report to the communication destination that the IICBn (master or slave) is preparing to transmit or receive data.

The wait state is reported to the communication destination by setting the SCLn signal to low. The next data transfer cannot start until both the master and slave devices exit the wait state.

(a) When a wait at the 9th clock is specified for the master and a wait at the 8th clock for the slave (master: transmission, slave: reception)

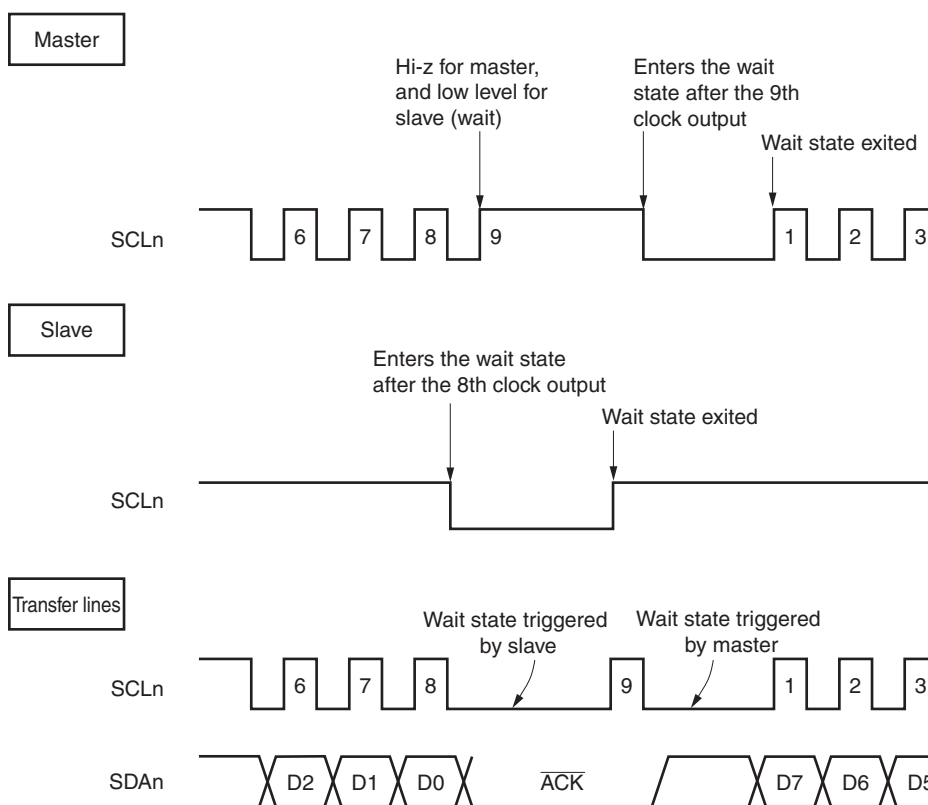

Figure 23-9 Wait state (1/2)

(b) When a wait at the 9th clock is specified for both the master and slave
(master: transmission, slave: reception)

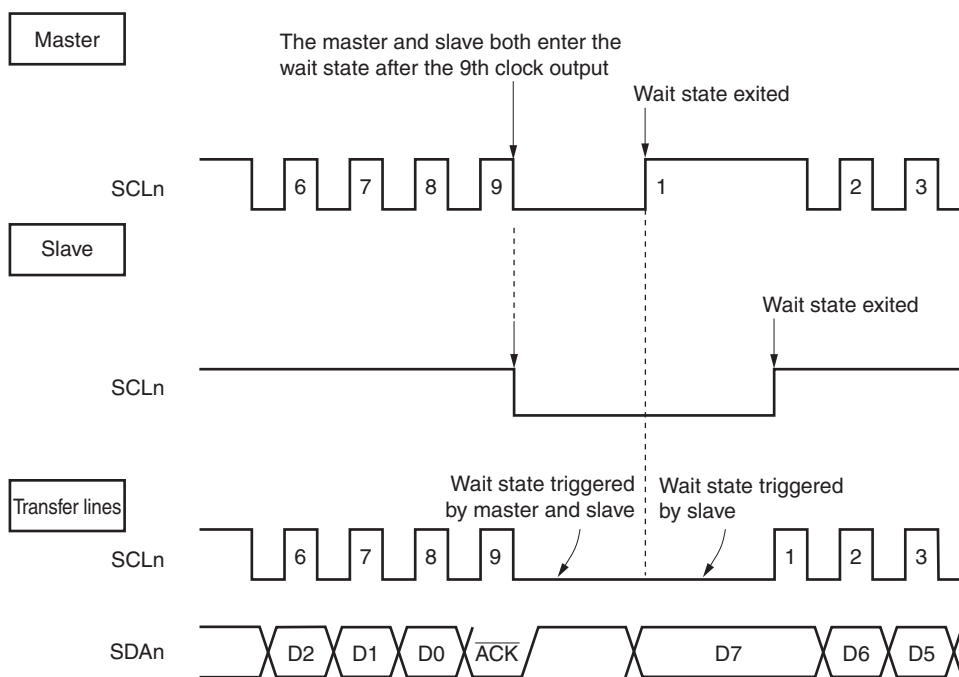

Figure 23-9 Wait state (2/2)

23.4.9 Arbitration

When several master devices simultaneously output a start condition, communication with the master devices continues until the data differs, while adjusting the clocks. An example where two masters simultaneously output a start condition and arbitration is conducted is described below.

This example assumes that one master outputs the SDA_n line high (master 1) and the other master outputs the SDA_n line low (master 2) while the SCL_n line is low.

In this case, the communication with master 2 is prioritized, and communication is not authorized for master 1.

This kind of operation is called arbitration, and the state in which communication is not authorized is called arbitration loss. The master that lost arbitration releases the bus by setting both the SCL_n and SDA_n line to high impedance.

Figure 23-10 Arbitration timing example

23.5 Registers

Caution In this section, the operation when an extension code is received is omitted. For details about the extension code, refer to 23.6.5 “Extension code”.

(1) IICBnDAT – IICBn data register

This register is used to transmit and receive transfer data.

Access This register can be read/written in 8-bit units.

Address <IICBn_base_USER> + 0000_H

Initial Value 00_H. This register is initialized by any reset. This register is also initialized by changing the value of the IICBnCTL0.IICBnIICE bit from 1 to 0 or from 0 to 1.

- Cautions**
1. When the IICBn becomes a master in the single transfer mode or continuous transfer mode, after the IICBnTRG.IICBnSTT bit has been set to 1, writing to the IICBnDAT register is allowed only once to transfer the address and communication direction.
 2. When transferring data in the single transfer mode, writing to the IICBnDAT register in communication state other than the wait state is prohibited.
 3. When transferring data in the continuous transfer mode, writing to the IICBnDAT register in response to an INTIICBTIA interrupt request signal is only allowed once.
 4. When executing transmission operations in the continuous transfer mode, do not read the IICBnDAT register. Similarly, when performing reception operations in the continuous transfer mode, do not write to the IICBnDAT register.

7	6	5	4	3	2	1	0
IICBnDAT7	IICBnDAT6	IICBnDAT5	IICBnDAT4	IICBnDAT3	IICBnDAT2	IICBnDAT1	IICBnDAT0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 23-6 IICBnDAT register contents

Bit position	Bit name	Function
7 to 0	IICBnDAT[7:0]	<p>During reception, these bits hold the received data. During transmission, these bits write the transmit data.</p> <p>The prescribed procedure must be followed during access (read, write) to the IICBnDAT register. For the setting sequence, refer to 23.9 “Setting Sequence”. The IICBn exits the wait state by performing access to the IICBnDAT register.</p> <ul style="list-style-type: none"> • In single transfer mode <ul style="list-style-type: none"> - When write access to the IICBnDAT register is performed • In continuous transfer mode <ul style="list-style-type: none"> - When write access to the IICBnDAT register is performed - When read access to the IICBnDAT register is performed during a wait state for data transfer that is not triggered by NACK signal reception

(2) IICBnSVA – IICBn slave address register

This register stores the slave address of the IICBn bus.

Access This register can be read/written in 8-bit units.

Address <IICBn_base_USER> + 0004_H

Initial Value 00_H. This register is initialized by any reset.

Caution Write access to the IICBnSVA register is prohibited when the value of the IICBnCTL0.IICBnIICE bit is 1.

7	6	5	4	3	2	1	0
IICBnSVA7	IICBnSVA6	IICBnSVA5	IICBnSVA4	IICBnSVA3	IICBnSVA2	IICBnSVA1	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R

Table 23-7 IICBnSVA register contents

Bit position	Bit name	Function
7 to 1	IICBnSVA[7:1]	Store the slave address of the IICBn bus. Address match/address mismatch is judged by comparing the received address and the IICBnSVA register. If the received address matches the IICBnSVA register, the IICBnSTR0.IICBnSSCO bit is set to 1.

(3) IICBnCTL0 – IICBn control register 0

This register is used to control the operations of the IICBn.

Access This register can be read/written in 8- or 1-bit units.

Address <IICBn_base_USER> + 0008_H

Initial Value 00_H. This register is initialized by any reset.

(4) IICBnCTL1 – IICBn control register 1

This register controls the operation of the IICBn.

Access This register can be read/written in 8-bit units.

Address <IICBn_base_OS> + 0020_H

Initial Value 00_H. This register is initialized by any reset.

Caution Write access to the IICBnCTL1 register is prohibited when the value of the IICBnCTL0.IICBnIICE is 1.

The IICBnCTL1.IICBnSLSE bit is automatically cleared to 0 upon detection of a start condition (even without a 0 write operation).</p> <p>Caution Clear the IICBnCTL1.IICBnSLSE bit to 0 when participating in communications after other communications have started. When other communications are being performed, if the IICBnTRG.IICBnSTT bit has been set to 1 with the IICBnCTL1.IICBnSLSE bit set to 1, the other communications may be damaged.</p>
0	IICBnSLRS	<p>Enables/disables the communication reserve function.</p> <p>0: Enables communication reserve function. 1: Disables communication reserve function.</p> <p>Communication reserve function enabled state: If the IICBnCTL1.IICBnSLRS bit is cleared to 0 while the IICBn is not operating as a master, the communication reserve state can be set by setting the IICBnTRG.IICBnSTT bit to 1 while the bus is being used. Whether the communication reserve state is set can be confirmed by checking the IICBnSTR0.IICBnSSRS bit.</p> <p>Communication reserve function disabled state: If the IICBnTRG.IICBnSTT bit is set to 1 while the IICBn is not participating in communications as a master and the bus is being used, the value of the IICBnSTR0.IICBnSTCF becomes 1 and communication reservation is not done.</p>

(5) IICBnWL – IICBn low level width setting register

This register is used to set the low level width of the serial clock register (SCLn).

Access This register can be read/written in 16-bit units.

Address <IICBn_base_OS> + 0024_H

Initial Value 03FF_H. This register is initialized by any reset.

Caution Write access to the IICBnWL register is prohibited when the value of the IICBnCTL0.IICBnIICE bit is 1.

Bit position	Bit name	Function
9 to 0	IICBnWH[9:0]	Specify the t_{HIGH} period (high level width of the SCLn clock) of the I ² C bus specification. The value of the IICBnWH register is used to determine the serial output timing of other I ² C bus specifications. For the serial output timing setting conditions, refer to <i>Table 23-12 “Conditions for generating serial output timing” on page 1285</i> .

Table 23-12 Conditions for generating serial output timing

Symbol	Description	Standard mode	Fast mode
$t_{HD:STA}$	Start condition hold time	$\frac{IICB0WH}{PCLK}$	$\frac{IICB0WH}{PCLK}$
t_{LOW}	SCL low-level width period	$\frac{IICB0WL}{PCLK}$	$\frac{IICB0WL}{PCLK}$
t_{HIGH}	SCL high-level width period	$\frac{IICB0WH}{PCLK}$	$\frac{IICB0WH}{PCLK}$
$t_{SU:STA}$	Start condition setup time	$\frac{IICB0WL}{PCLK}$	$\frac{IICB0WL}{PCLK}$
$t_{SU:STO}$	Stop condition setup time	$\frac{IICB0WH}{PCLK}$	$\frac{IICB0WH}{PCLK}$
t_{BUF}	Bus free time (interval between stop condition and start condition)	$\frac{IICB0WL}{PCLK}$	$\frac{IICB0WL}{PCLK}$
$t_{HD:DAT}$	Data hold time	$\frac{IICB0WL[9:2]}{PCLK}$	$\frac{IICB0WL[9:2]}{PCLK}$

(a) Setting transfer clock by using IICBnWL and IICBnWH registers

The various timings in compliance with the I²C bus specifications can be set by setting the IICBnWL register and IICBnWH register.

- Setting transfer clock on master side

$$\text{Transfer clock (Hz)} = \frac{\text{PCLK}}{(\text{IICBnWL} + \text{IICBnWH} + \text{PCLK} (t_R + t_F))}$$

At this time, the optimal setting values of IICBnWL and IICBnWH are as follows.

(The fractional parts of all setting values are rounded up.)

- In the fast mode

$$\text{IICBnWL} = \frac{0.52}{\text{Transfer clock}} \times \text{PCLK}$$

$$\text{IICBnWH} = \left(\frac{0.48}{\text{Transfer clock}} - t_R - t_F \right) \times \text{PCLK}$$

- In the standard mode

$$\text{IICBnWL} = \frac{0.47}{\text{Transfer clock}} \times \text{PCLK}$$

$$\text{IICBnWH} = \left(\frac{0.53}{\text{Transfer clock}} - t_R - t_F \right) \times \text{PCLK}$$

Caution The data hold time must be 0.9 μs or less in the fast mode and 3.45 μs or less in the standard mode.

Note The data hold time is determined by the IICBWL register setting as follows:

$$\text{Data hold time} = \text{IICBnWL.IICBnWL}[9:2] / \text{PCLK}$$

- Setting IICBnWL and IICBnWH on slave side
(The fractional parts of all setting values are rounded up.)
 - In the fast mode
$$\text{IICBnWL} = 1.3 \mu\text{s} \times \text{PCLK}$$
$$\text{IICBnWH} = (1.2 \mu\text{s} - t_{\text{R}} - t_{\text{F}}) \times \text{PCLK}$$
 - In the standard mode
$$\text{IICBnWL} = 4.7 \mu\text{s} \times \text{PCLK}$$
$$\text{IICBnWH} = (5.3 \mu\text{s} - t_{\text{R}} - t_{\text{F}}) \times \text{PCLK}$$

Note IICBnWL: IICBn low-level width setting register
IICBnWH: IICBn high-level width setting register
t_F: SDA_n and SCL_n signal falling times
t_R: SDA_n and SCL_n signal rising times
PCLK: Frequency of the clock supplied to the IICBn
f_{CLK}: SCL clock frequency

(7) IICBnTRG – IICBn trigger register

This register is used to set the IICBn trigger.

Access This register can be read/written in 8- or 1-bit units.

Address <IICBn_base_USER> + 000C_H

Initial Value 00_H. This register is initialized by any reset.

7	6	5	4	3	2	1	0
0	0	0	0	IICBn LRET	IICBn WRET	IICBn STT	IICBn SPT
R	R	R	R	R/W	R/W	R/W	R/W

Table 23-13 IICBnTRG register contents (1/4)

Bit position	Bit name	Function
3	IICBnLRET	<p>Communication exit trigger bit</p> <p>0: The read value is always 0, and writing 0 is ignored.</p> <p>1: The IICBn exits the current communication and enters the wait state. This bit is automatically cleared to 0 following execution.</p> <p>The following occurs when IICBnTRG.IICBnLRET is 1.</p> <ul style="list-style-type: none"> - SCLn and SDAn each go into high impedance (communication wait state). - Bits IICBnSSMS, IICBnSSDR, IICBnSSWT, IICBnSSEX, IICBnSSC0, IICBnSSTR, IICBnSSAC, IICBnSSRS, and IICBnSSST of the IICBnSTR0 register are cleared to 0. - When IICBnTRG.IICBnSTT = 1 (start condition output preparation) or IICBnTRG.IICBnSPT = 1 (stop condition output preparation) has been set, output of a start condition or stop condition is stopped. <p>The communication reserved state is released if the IICBn exits the communication in the communication reserved state. If it is necessary for the IICBn to operate a master again after this, the IICBnTRG.IICBnSTT bit must be set to 1 again.</p> <p>Caution If IICBnTRG.IICBnLRET is set to 1 during master operation (IICBnSTR0.IICBnSSMS = 1), the bus is released. Since serial clock output stops, problems occur during communication on the slave side.</p>
2	IICBnWRET	<p>This is the trigger bit for exiting the wait state.</p> <p>0: Does not exit the wait state.</p> <p>1: Exits the wait state and resumes communication. This bit is automatically cleared following execution.</p> <p>If the IICBn have exited the wait state by setting the IICBnTRG.IICBnWRET bit to 1 during the wait state triggered by the falling edge of the 9th clock, the IICBnSTR0.IICBnSSTR bit is cleared to 0 and SDAn goes into high impedance (this enables the external master to output a stop condition or start condition.)</p> <p>If the IICBn is not in the wait state (IICBnSTR0.IICBnSSWT = 0), setting this bit to 1 has no meaning.</p> <p>There are other conditions for exiting the wait state in addition to the setting of this bit. For details, refer to 23.6.4 “Entering and exiting wait state”.</p>

Table 23-13 IICBnTRG register contents (2/4)

Bit position	Bit name	Function
1	IICBnSTT	<p>Start condition trigger bit</p> <p>0: Does not output a start condition. 1: Outputs a start condition (This bit is automatically cleared to 0 after it has been set to 1).</p> <p>The IICBnTRG.IICBnSTT bit can be set to 1 under the following conditions: [1] IICBnSTR0.IICBnSSMS bit = Master state (1)</p> <ul style="list-style-type: none"> • Single transfer mode <ul style="list-style-type: none"> - During wait state triggered by the falling edge of the 9th clock (both address transfer and data transfer) - During data reception, only after clearing the IICBnCTL0.IICBnSLAC bit to 0 to report the end of reception to the slave • Continuous transfer mode <ul style="list-style-type: none"> - During wait state triggered by the falling edge of the 9th clock of address transfer - During data transfer - During data reception, only after clearing the IICBnCTL0.IICBnSLAC bit to 0 to report the end of reception to the slave <p>In the case of the wait period during the 9th clock, following wait cancellation, and in all other cases, upon detecting the falling edge of the 9th clock, SDAn and SCLn are set to the high level after the low-level width period of the SCLn clock, and then, when SDAn is set to the low level after waiting for the start condition setup time to elapse, a start condition is output. Next, SCLn is set to the low level after the start condition hold time has elapsed. For each time, see <i>Table 23-12 “Conditions for generating serial output timing” on page 1285</i>.</p> <p>[2] Slave state or communication wait state (IICBnSTR0.IICBnSSMS = 0)</p> <ul style="list-style-type: none"> • IICBnSTR0.IICBnSSBS bit = 0 (bus release state) <p>After the bus free time elapses, a start condition is output when SDAn is changed from the high level to the low level while SCLn is high level. (At this time, SCLn outputs a high level signal.) Next, SCLn is set to the low level after the start condition hold time has elapsed. For each time, see <i>Table 23-12 “Conditions for generating serial output timing” on page 1285</i>.</p> • IICBnSTR0.IICBnSSBS bit = 1 (bus communication state) <p>This status indicates that communication is performed on the bus while the IICBn is not operating as a master.</p> <ul style="list-style-type: none"> - When communication reserve function is enabled (IICBnCTL1.IICBnSLRS bit = 0): A start condition is output after the bus has been released (the stop condition has been detected) and the bus free time has elapsed. However, even if the bus free time has not elapsed, upon detecting a start condition, SDAn is immediately set to the low level without waiting for the bus free time to elapse. For each time, see <i>Table 23-12 “Conditions for generating serial output timing” on page 1285</i>. - When communication reserve function is disabled (IICBnCTL1.IICBnSLRS bit = 1): The IICBnSTR0.IICBnSTCF bit is set to 1 and a start condition is not output.

Table 23-13 IICBnTRG register contents (3/4)

Bit position	Bit name	Function
1	IICBnSTT	<p>Caution [2] shows the operations according to the value of the IICBnSTR0.IICBnSSBS bit when the IICBnTRG.IICBnSTT bit is 0. Even if the IICBnTRG.IICBnSTT bit is set to 1 after checking the value of the IICBnSTR0.IICBnSSBS bit through register read, the value of IICBnSTR0.IICBnSSBS may differ from its value when it was checked.</p> <p>The output processing of the start condition is started by setting the IICBnTRG.IICBnSTT bit to 1, but upon detection of the following states, output processing of the start condition is stopped and the start condition is not output.</p> <ul style="list-style-type: none"> - When 0 is written to the IICBnCTL0.IICBnIICE bit - When 1 is written to the IICBnTRG.IICBnLRET bit - Upon detection of arbitration loss - When 1 is written to the IICBnTRG.IICBnSPT bit after 1 is written to the IICBnTRG.IICBnSTT bit while the IICBn is operating as a master in the continuous transfer mode - When 1 is written to the IICBnTRG.IICBnSTT and IICBnTRG.IICBnSPT bits during the same data transfer period while the IICBn is operating as a master in the continuous transfer mode (In this case, writing 1 to the IICBnTRG.IICBnSTT bit is enabled.) <p>Cautions 1. When start in the initial communication state is enabled (IICBnCTL1.IICBnSLSE bit = 1), the start condition is output regardless of the bus status when the IICBnTRG.IICBnSTT bit is set to 1. If other communications are performed at that time, they may be damaged.</p> <p>2. Setting the IICBnTRG.IICBnSTT bit at the same time as the IICBnTRG.IICBnSPT bit is prohibited.</p>
0	IICBnSPT	<p>Stop condition trigger bit</p> <p>0: Does not output a stop condition. 1: Outputs a stop condition (This bit is automatically cleared after it has been set to 1).</p> <p>The IICBnTRG.IICBnSPT bit can be set to 1 under the following conditions while the IICBn is performing communication as a master.</p> <ul style="list-style-type: none"> • Single transfer mode <ul style="list-style-type: none"> - Wait state triggered by the falling edge of the 9th clock (both address transfer and data transfer) - During data reception, only after clearing the IICBnCTL0.IICBnSLAC bit to 0 to report the end of reception to the slave • Continuous transfer mode <p>The IICBnTRG.IICBnSPT bit can be set to 1 in the following states.</p> <ul style="list-style-type: none"> - During the wait state triggered by the falling edge of the 9th clock of address transfer - During data transfer - Detection of a NACK signal (IICBnSTR0.IICBnSSAC bit = 0) during the wait state triggered by the falling edge of the 9th clock for during data reception <p>A stop condition can be output with the following procedure. (If the IICBn is in the wait state, after exiting the wait state) SCLn is released when SDAn has output a low level, and SCLn = high level, SDAn is low level are waited for. Then, following the lapse of the $t_{SU:STO}$ time, a stop condition is output by setting SDAn to high level.</p>

Table 23-13 IICBnTRG register contents (4/4)

Upon detection of arbitration loss, the IICBnSTR0.IICBnSSMS and IICBnSTR0.IICBnSSTR bits are cleared to 0. (SCLn and SDA_n become high level and the bus is released.)</p> <p>Caution When the IICBnSTR0.IICBnALDF bit is set to 1 due to arbitration loss, the INTIICBTIA or INTIICBTISn interrupt request signal is output. After confirming that the IICBnSTR0.IICBnALDF bit has been set to 1 with an interrupt request signal, clear the IICBnSTR0.IICBnALDF bit with the IICBnSTRC.IICBnCLAF bit. If the value of the IICBnSTR0.IICBnALDF is not cleared and remains 1, the INTIICBTISn interrupt request signal will be output at the interrupt timing, even during unrelated communication.</p>

(9) IICBnSTR1 – IICBn status register 1

This register indicates the status of the serial bus.

Access This register is read-only, in 8-bit units.

Address <IICBn_base_USER> + 0014_H

Initial Value 00_H. This register is initialized by any reset.

Caution The serial clock (SCLn) and serial transmit/receive data (SDAn) are also read from an external source in the loopback mode (IICBnCTL1.IICBnMDLB = 1).

Bit position	Bit name	Function
1	IICBnCLSF	<p>Clears the IICBnSTR0.IICBnSTCF bit. 1: Clears the IICBnSTR0.IICBnSTCF bit.</p> <p>Note If the IICBnSTRC.IICBnCLSF bit is read after setting data, 0 is returned.</p>
0	IICBnCLAF	<p>Clears the IICBnSTR0.IICBnALDF bit. 1: Clears the IICBnSTR0.IICBnALDF bit.</p> <p>Caution If writing 1 to the IICBnSTRC.IICBnCLAF bit and the setting condition of the IICBnSTR0.IICBnALDF bit occur at the same time, the setting condition of the IICBnSTR0.IICBnALDF takes priority.</p> <p>Note If the IICBnSTRC.IICBnCLAF bit is read after data setting, 0 is returned.</p>

23.6 Operation

The IICBn supports two transfer modes, single transfer mode and continuous transfer mode.

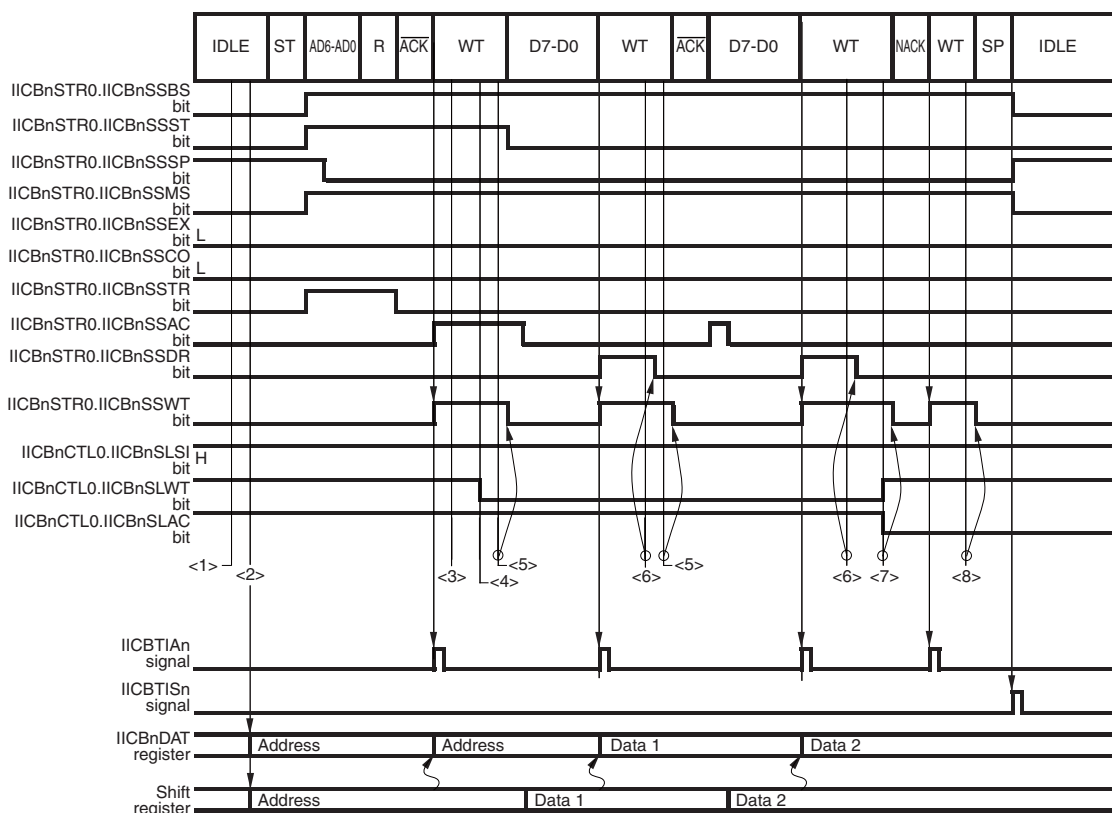

The transfer mode when the addresses of the master device and the slave device match is selected with the IICBnCTL0.IICBnMDTX0 bit, and the transfer mode when the extension code is detected by the slave device is selected with the IICBnCTL0.IICBnMDTX1 bit.

23.6.1 Single transfer mode

In the single transfer mode, a data transmit/receive interrupt request signal is output at the timing specified using the IICBnCTL0.IICBnSLW bit to make the IICBn enter the wait state, and transmit/receive data processing is performed during this wait state.

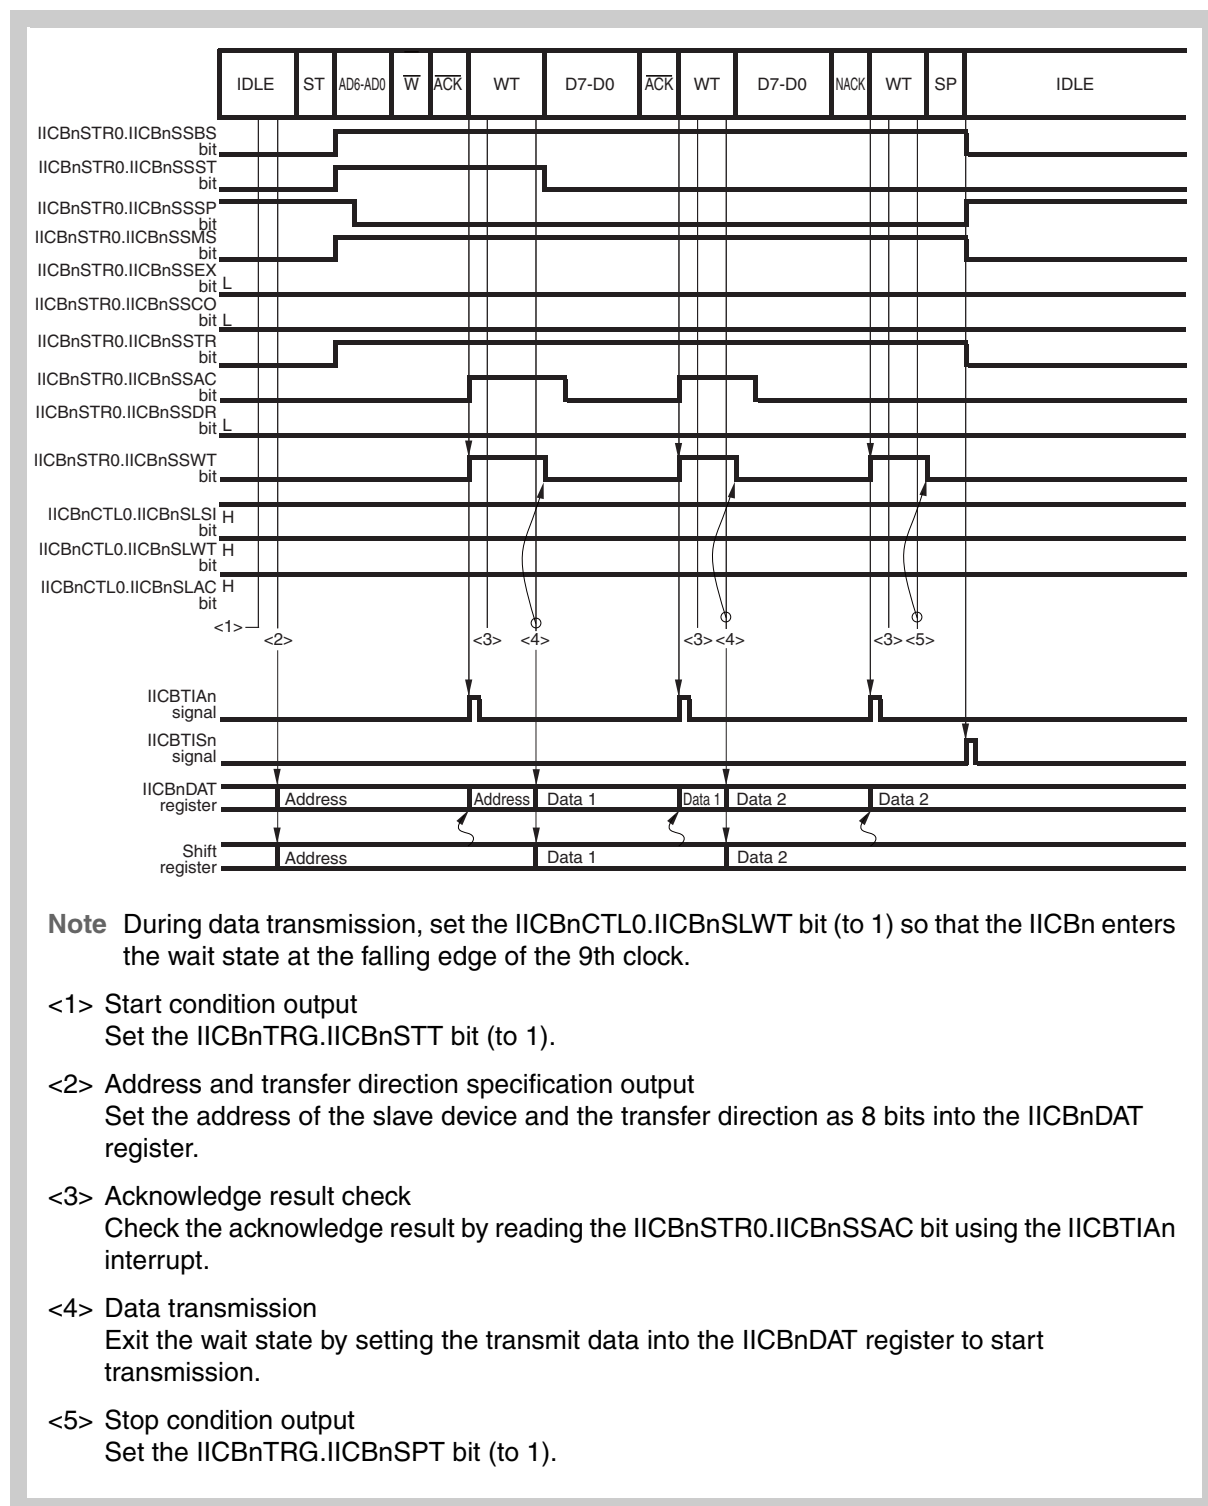

The various processing operations are described below.

(1) Example of communication in single transfer mode (master reception)

- <1> Start condition output
Set the IICBnTRG.IICBnSTT bit (to 1).
- <2> Address and transfer direction specification output
Set the address of the slave device and the transfer direction as 8 bits into the IICBnDAT register.
- <3> Acknowledge result check
Check the acknowledge result by reading the IICBnSTR0.IICBnSSAC bit using the IICBTIAN interrupt.
- <4> Wait timing setting
During data reception, clear the IICBnCTL0.IICBnSLWT bit (to 0) so that the IICBn enters the wait state at the falling edge of the 8th clock.
- <5> Data reception
Exit the wait state by setting the IICBnTRG.IICBnWRET bit (to 1) to start reception.
- <6> Receive data load
Read the receive data from the IICBnDAT register using the IICBTIAN interrupt.
- <7> Data reception completion processing
- Set the IICBnCTL0.IICBnSLWT bit to 1 and the IICBnCTL0.IICBnSLAC bit to 0.
 - Next, exit the wait state by setting the IICBnTRG.IICBnWRET bit (to 1). The end of the data is notified to the transmitting device without outputting ACK.
- <8> Stop condition output
Set the IICBnTRG.IICBnSPT bit (to 1).

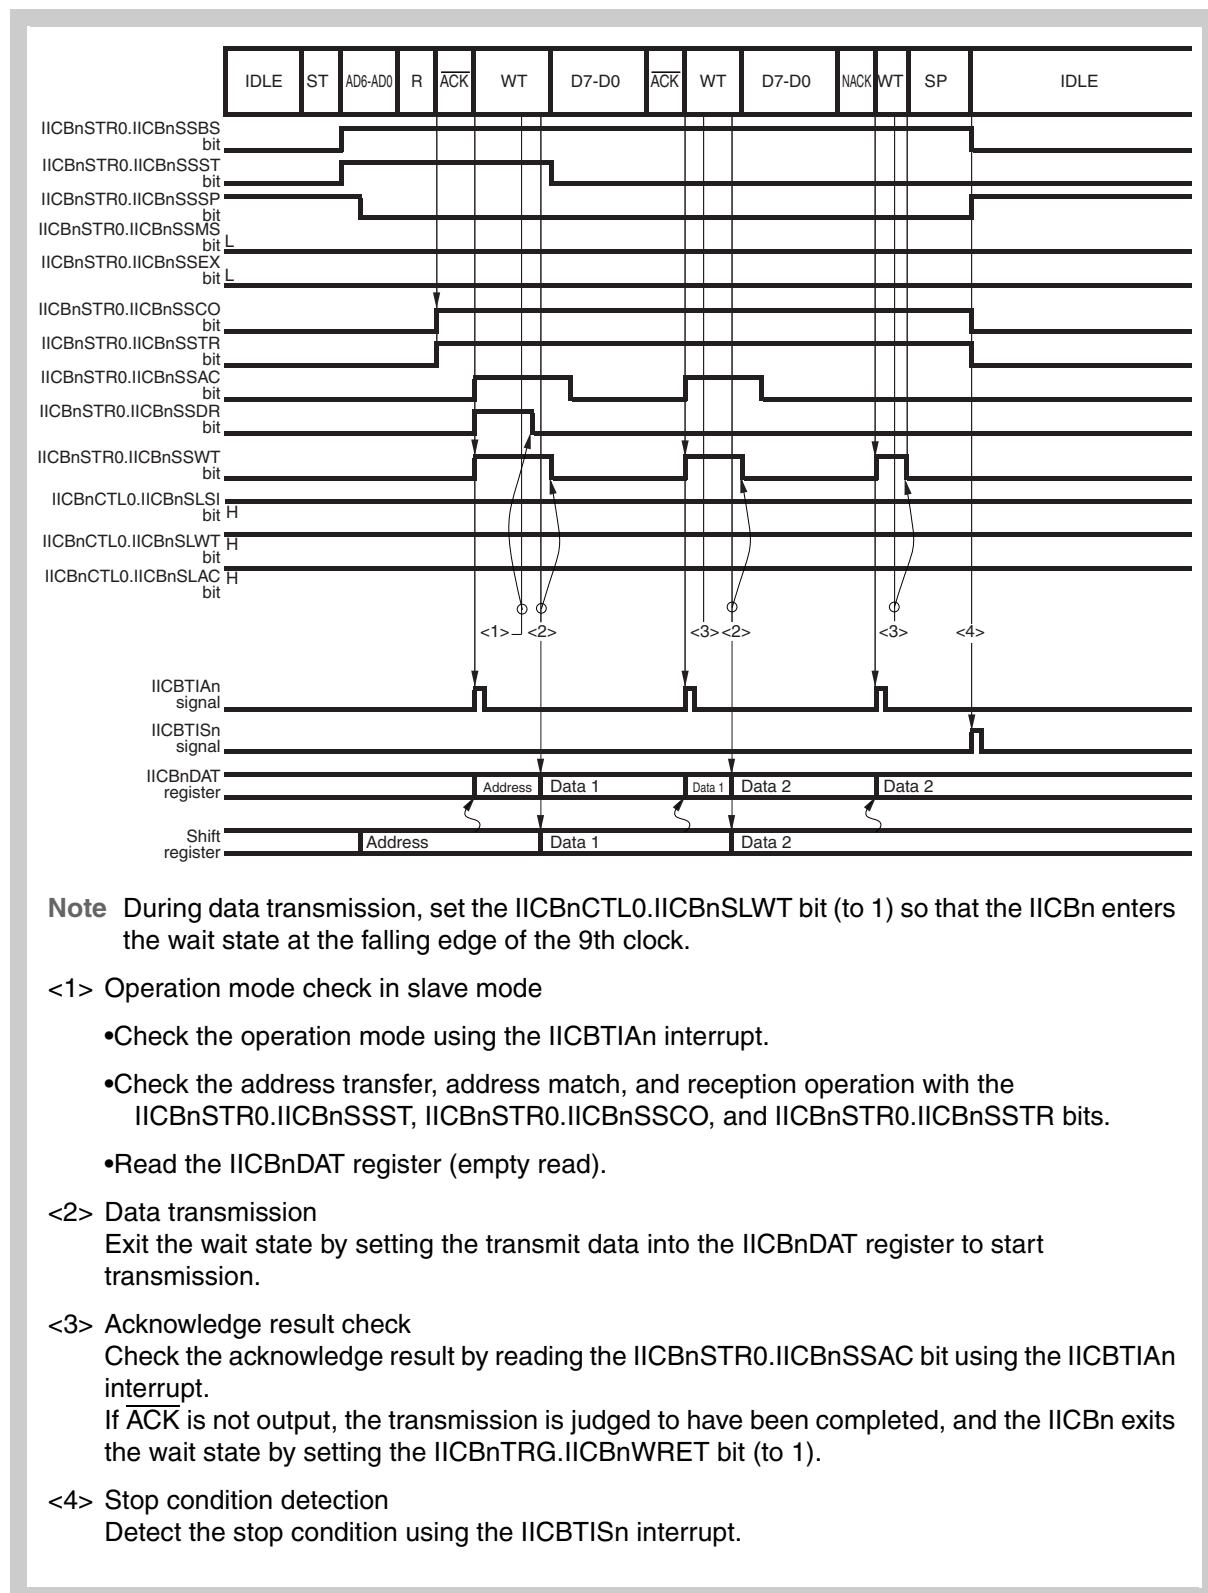

(2) Example of communication in single transfer mode (master transmission)

(3) Example of communication in single transfer mode (slave reception)

(4) Example of communication in single transfer mode (slave transmission)

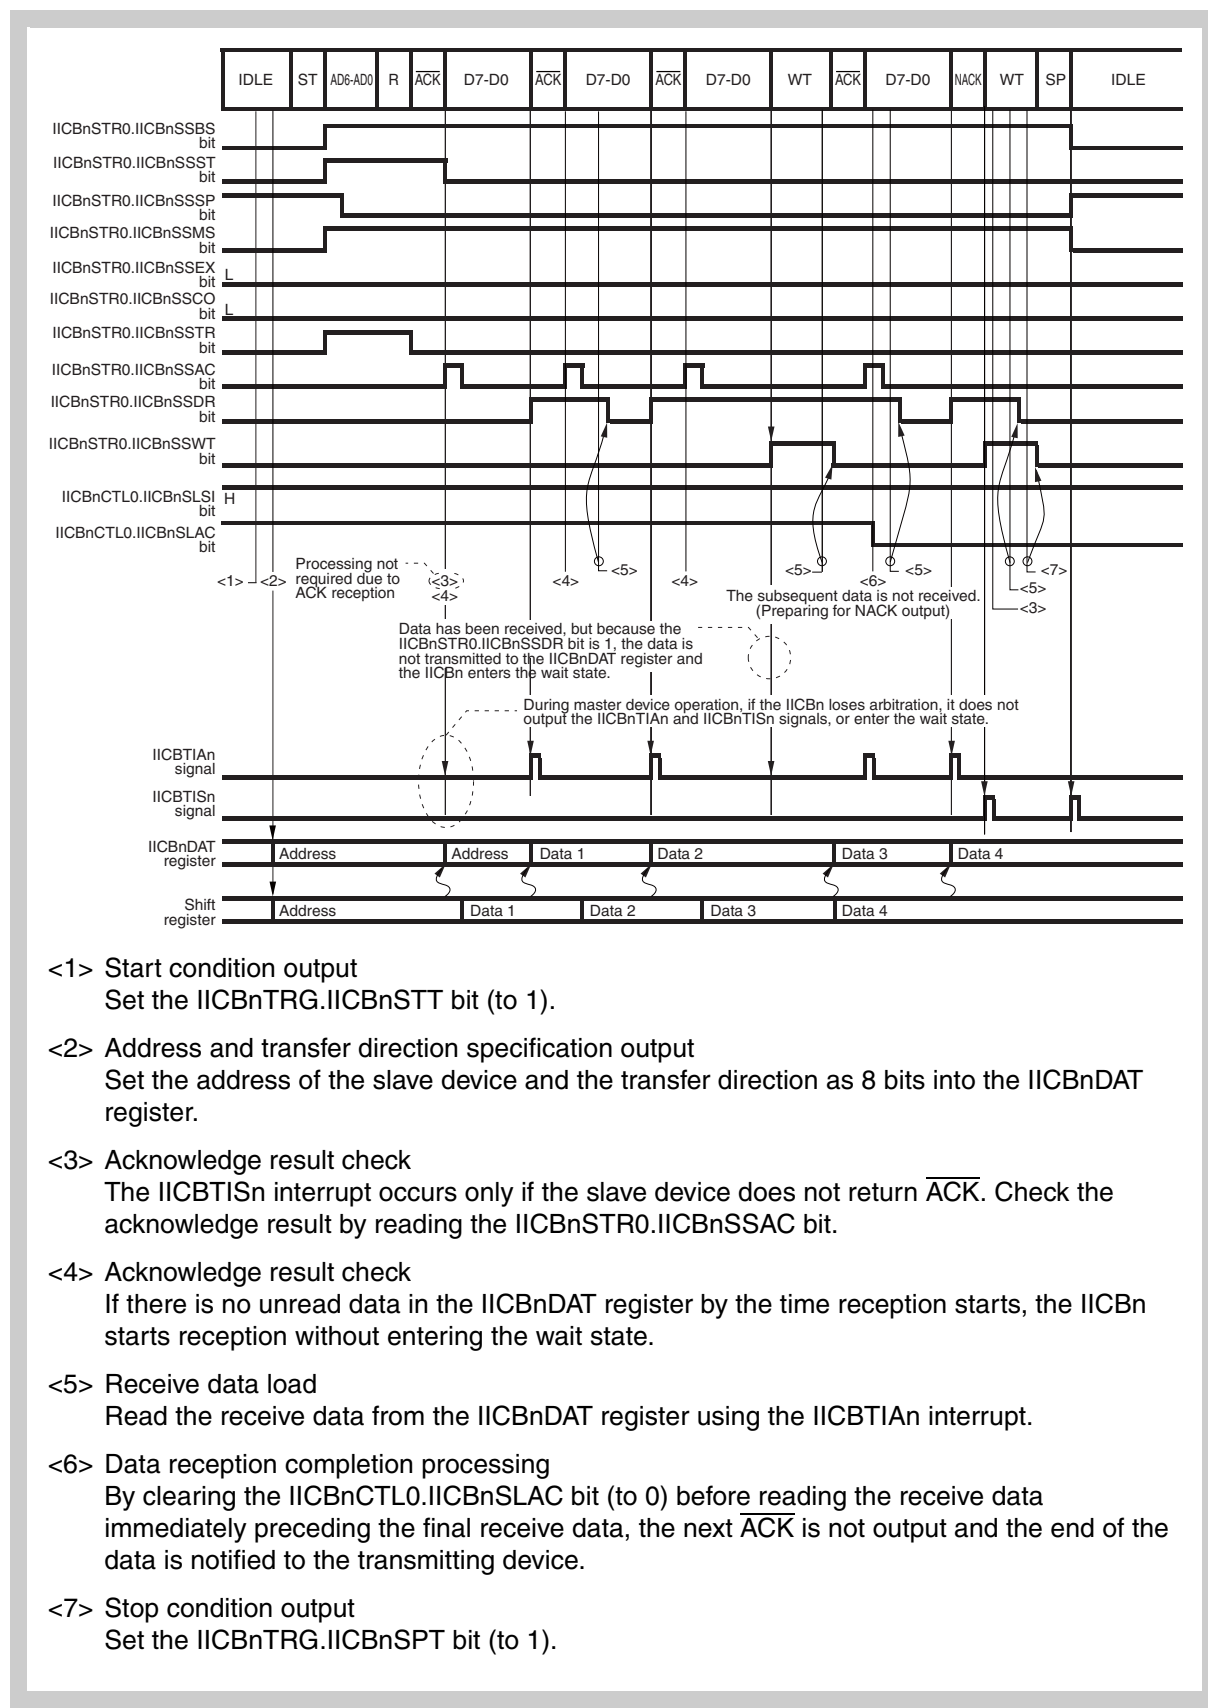

23.6.2 Continuous transfer mode

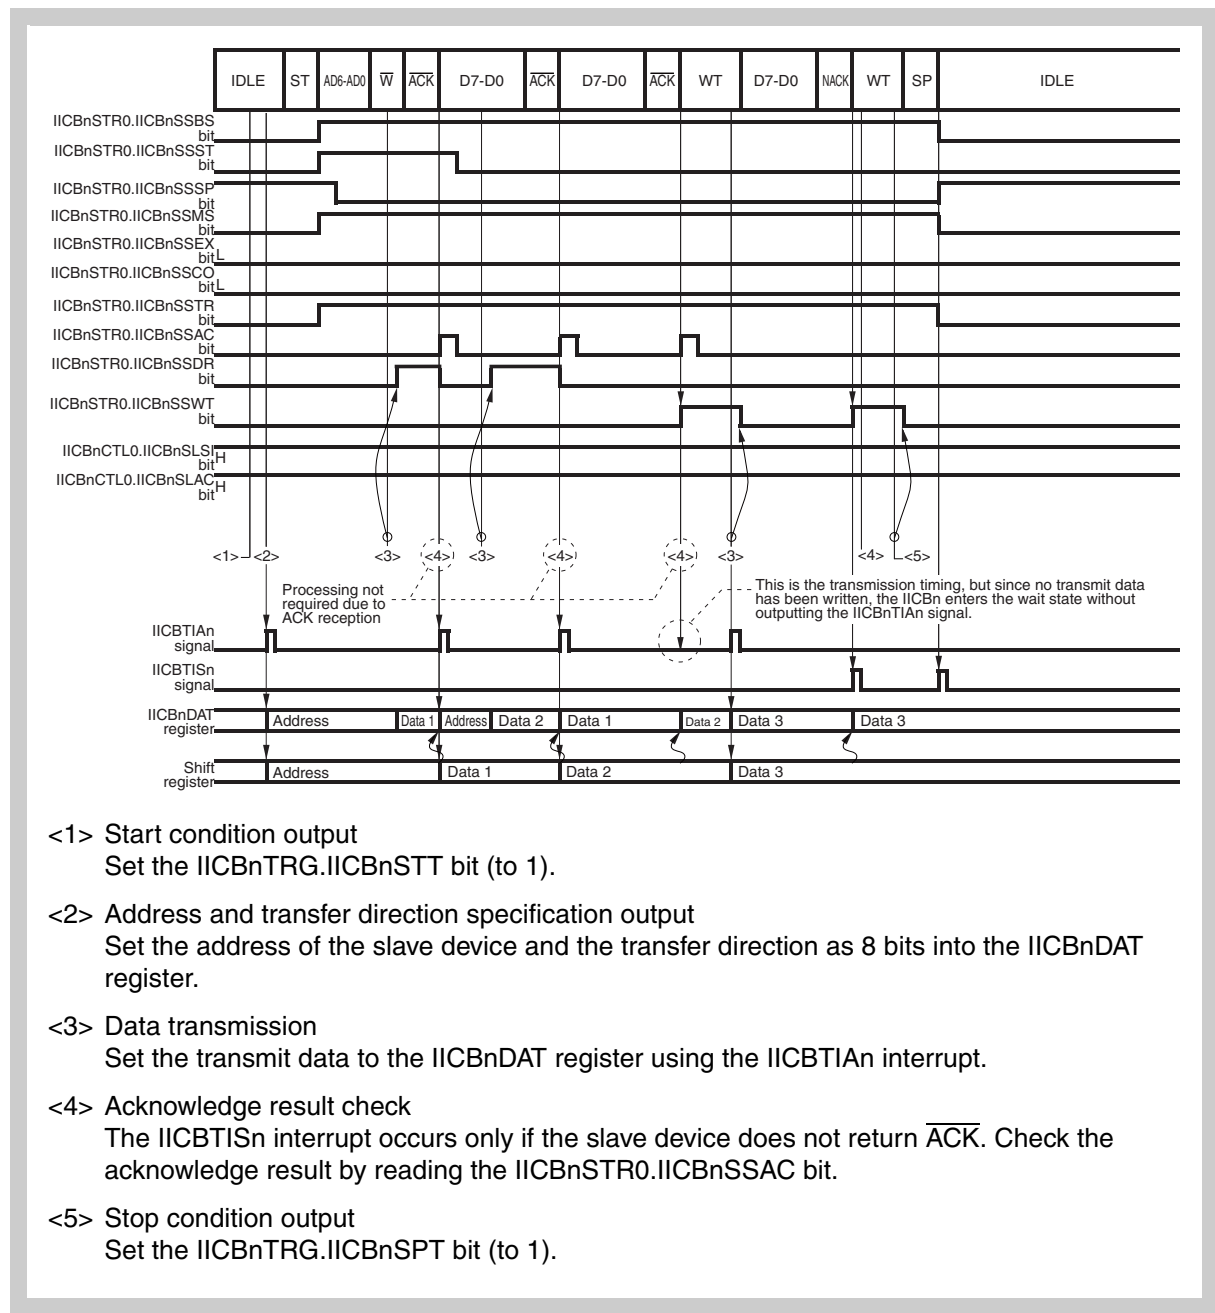

The continuous transfer mode allows continuous communication without entering the wait state by reading/writing data to/from the IICBnDAT register each time the data transmit/receive interrupt request signal (IICBTIA_n) is output.

The processing operations are described below.

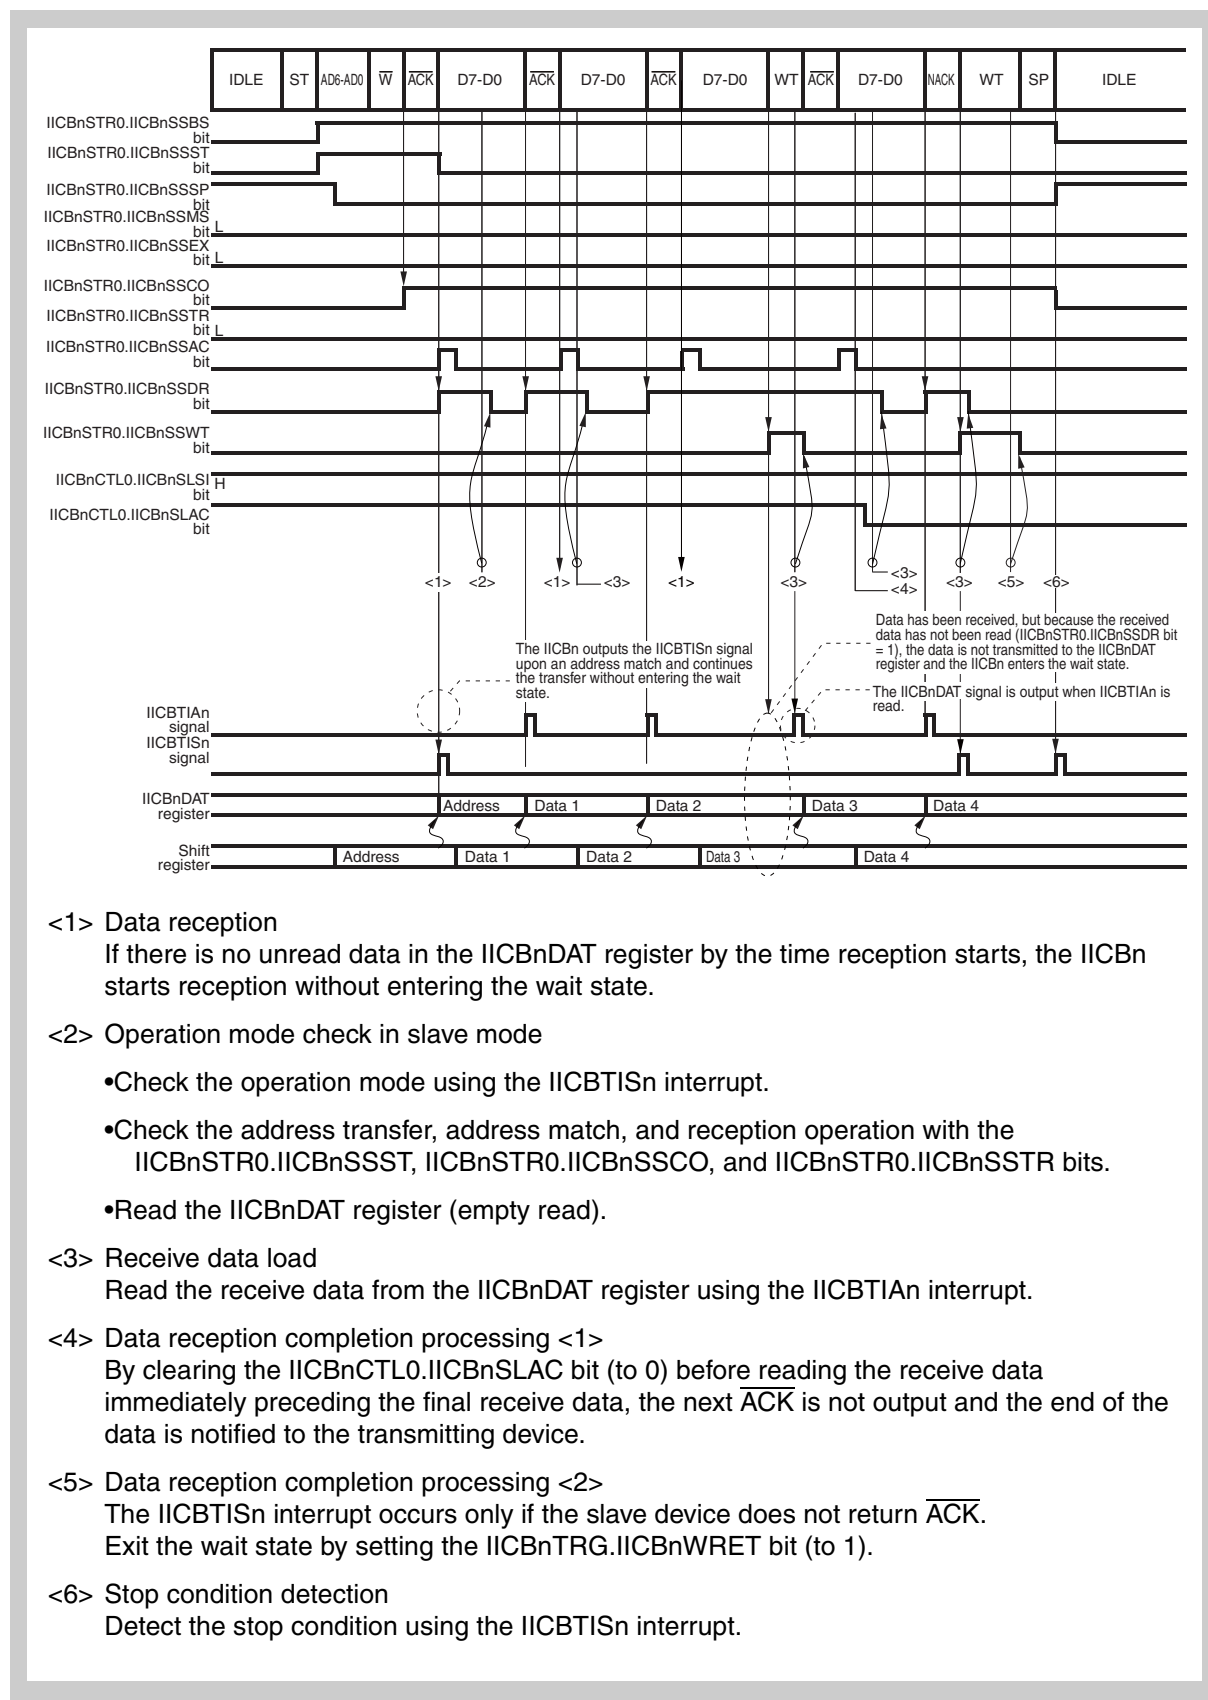

(1) Example of communication in continuous transfer mode (master reception)

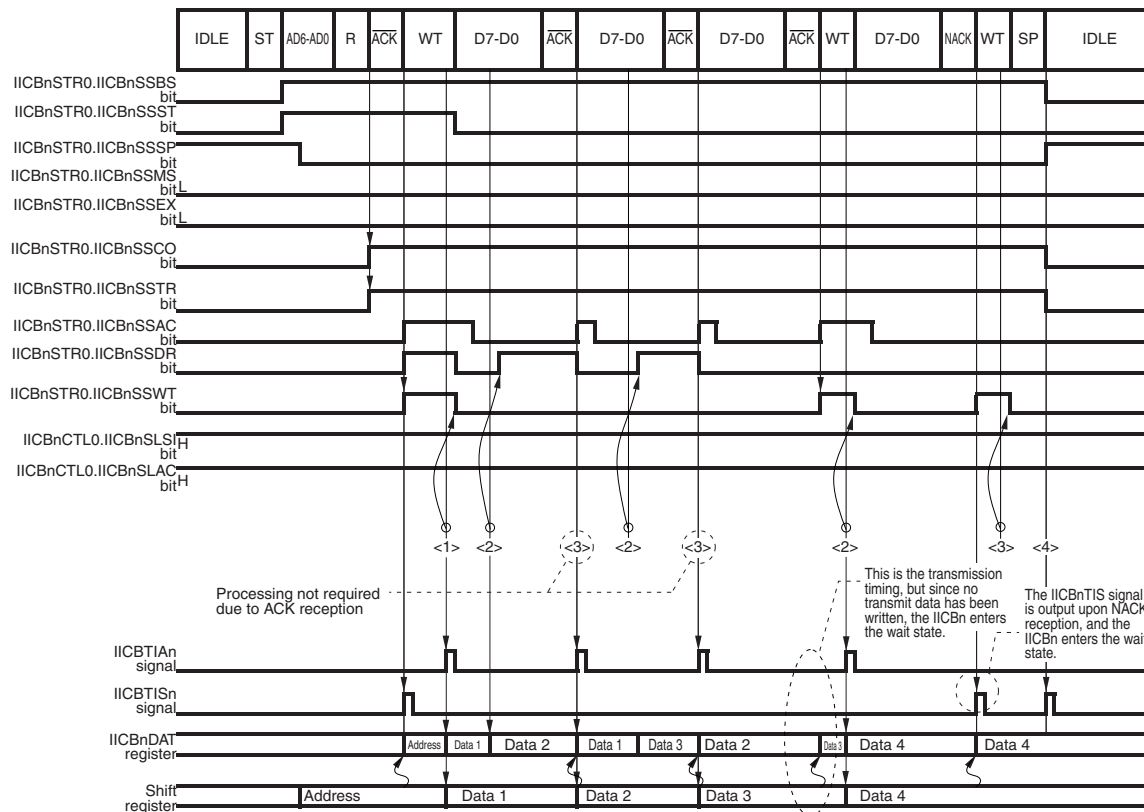

(2) Example of communication in continuous transfer mode (master transmission)

(3) Example of communication in continuous transfer mode (slave reception)

(4) Slave transmission in continuous transfer mode

<1> Operation mode check in slave mode

- Check the operation mode using the IICBTISn interrupt.
- Check the address transfer, address match, and reception operation with the IICBnSTR0.IICBnSSST, IICBnSTR0.IICBnSSCO, and IICBnSTR0.IICBnSSTR bits.
- After reading (empty read) the IICBnDAT register, set the first transmit data to the IICBnDAT register.

<2> Data transmission

Set the transmit data to the IICBnDAT register using the IICBTIA interrupt.

<3> Acknowledge result check

The IICBTISn interrupt occurs only if the slave device does not return $\overline{\text{ACK}}$. Check the acknowledge result by reading the IICBnSTR0.IICBnSSAC bit. If $\overline{\text{ACK}}$ is not output, the transmission is judged to have been completed, and the IICBn exits the wait state by setting the IICBnTRG.IICBnWRET bit (to 1).

<4> Stop condition detection

Detect the stop condition using the IICBTISn interrupt.

23.6.3 Arbitration

When the IICBn operates as the master device and loses arbitration, it enters the slave standby state by setting both SCLn and SDAn to high level upon detection of the arbitration loss, and then the IICBnSTR0.IICBnALDF bit is set (to 1) each time the status interrupt request signal (IICBTISn) is output.

(1) Status upon occurrence of arbitration

The statuses upon occurrence of arbitration during master device operation (IICBnSTR0.IICBnSSMS bit = 1) are listed below.

- [1] Address transmission
- [2] $\overline{R/W}$ bit transmission of address transfer
- [3] Extension code transmission
- [4] $\overline{R/W}$ bit transmission of extension code transfer
- [5] Data transmission
- [6] \overline{ACK} bit transmission after data reception
- [7] Start condition detection during address transfer or data transfer
- [8] Stop condition detection during address transfer or data transfer
- [9] The SDAn signal is low when the IICBn is attempting to output a restart condition
- [10] The SDAn signal is low when the IICBn is attempting to output a stop condition
- [11] The falling edge of the SCLn signal is detected when the IICBn is attempting to output a restart condition

23.6.4 Entering and exiting wait state

The IICBn enters the wait state at the following timings.

Table 23-17 Wait state transit timings

Timing	Description	Refer to:
$\Delta 0$	Upon detection of the first falling edge of the SCLn, following detection of start condition as the master device	1 "Wait state at falling edge of first SCLn after IICBn became master" on page 1312
$\Delta 1$	Upon detection of the falling edge of the 9th SCLn during address transfer after the start condition	2 "Wait state upon detection of the falling edge of the 9th SCLn during address transfer after the start condition" on page 1313
$\Delta 2$	Upon detection of the falling edge of the 8th SCLn during data transfer	3 "Wait state upon detection of the falling edge of the 8th SCLn during data transfer" on page 1314
$\Delta 3$	Upon detection of the falling edge of the 9th SCLn during data transfer	4 "Wait state upon detection of the falling edge of the 9th SCLn during data transfer" on page 1314

Note ST: Start condition
 AD6 to AD0: Address
 R/W: Transfer direction specification
 ACK: Acknowledge
 D7 to D0: Data
 SP: Stop condition

The method to exit the wait state differs according to the wait state.

Exit the wait state by applying the appropriate method for each of the four wait states as described below.

(1) Wait state at falling edge of first SCLn after IICBn became master

$\Delta 0$ indicates the wait state when the data to be transferred has not been written (to the IICBnDAT register) when the falling edge of the first SCLn after the IICBn became the master is detected, after 1 was written to the IICBnTRG.IICBnSTT bit.

(a) Wait state transit condition

The IICBn enters the wait state if data is not written to the IICBnDAT register in the period from when the IICBnTRG.IICBnSTT bit becomes 1 until the $\Delta 0$ timing, upon detection of the first falling edge of SCLn after the IICBn became master, after 1 was written to the IICBnTRG.IICBnSTT bit.

However, the valid times to write data to the IICBnDAT register (without entering the wait state) after 1 was written to the IICBnTRG.IICBnSTT bit differ depending on whether the communication reservation function is enabled. The valid times to write to the IICBnDAT register for each of these cases are shown in Figure 23-11 “Valid times to write to IICBnDAT register”.

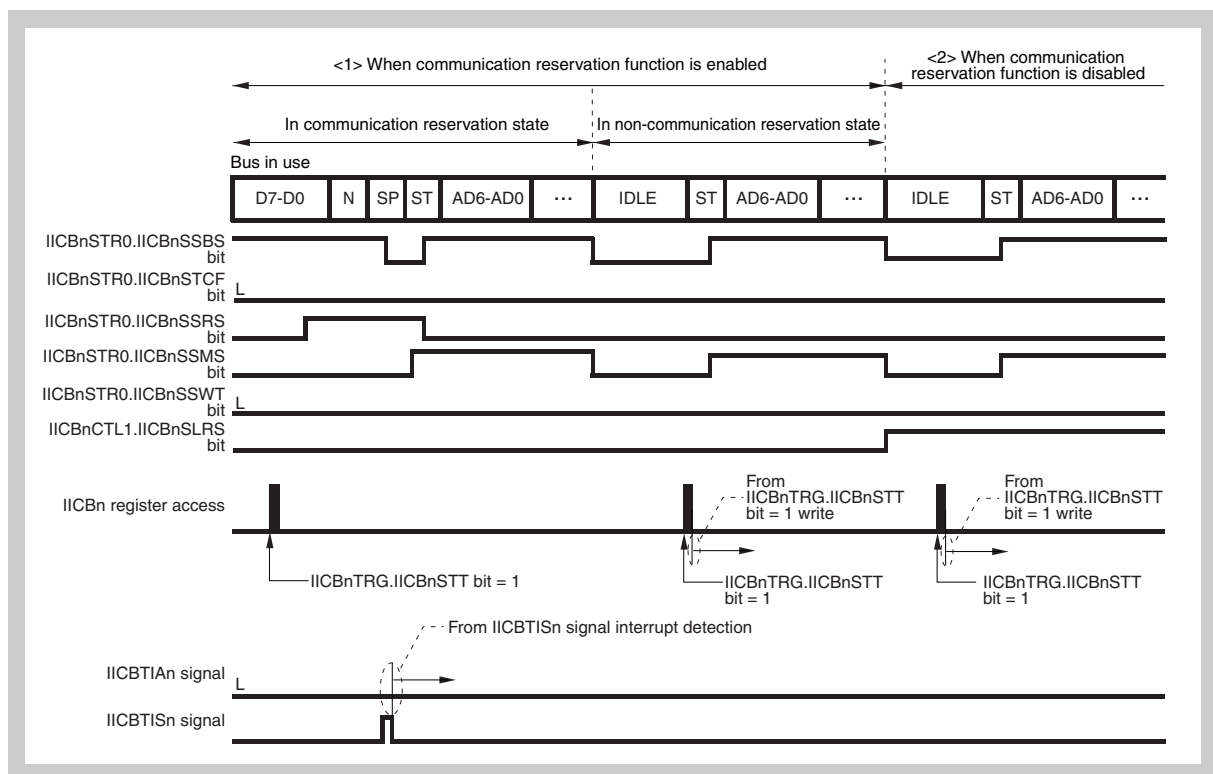

Figure 23-11 Valid times to write to IICBnDAT register

Caution The communication reservation function is disabled (<2> in the above figure) while the IICBnSTR0.IICBnSTCF bit is 0. When the IICBnSTR0.IICBnSTCF bit becomes 1, setting from IICBnSTR0.IICBnSTCF bit = 1 write is required again.

(b) Wait state exit conditions

Exit the wait state by writing to the IICBnDAT register.

(2) Wait state upon detection of the falling edge of the 9th SCLn during address transfer after the start condition

$\Delta 1$ indicates the wait state entered upon completion of address transfer.

(a) Wait state transit condition

<Single transfer mode>

In the single transfer mode, the IICBn always enters the wait state while it operates as the master.

While the IICBn operates as a slave, it enters the wait state upon an address match, or upon extension code detection while the IICBnCTL0.IICBnSLWT bit is 1.

<Continuous transfer mode>

In the continuous transfer mode, the IICBn enters the wait state in the following cases.

- Upon detection of NACK
- When the IICBn operates as the master and transmits data, if the data to be transferred next has not been written
- When the IICBn operates as a slave, if the received data has not been read, or during transmission

(b) Wait state exit conditions

<Single transfer mode>

Exit the wait state by writing to the IICBnDAT register during transmission, or by writing 1 to the IICBnTRG.IICBnWRET bit during reception. When the IICBn operates as the master and the IICBnSTR0.IICBnSSAC bit is 0 or the IICBn is at the transmission side, the wait state can be exited by writing 1 to the IICBnTRG.IICBnSTT or the IICBnTRG.IICBnSPT bit.

<Continuous transfer mode>

Exit the wait state by writing to the IICBnDAT register during transmission, or by reading the IICBnDAT register during reception. When the IICBn operates as the master and the IICBnSTR0.IICBnSSAC bit is 0, the wait state can be exited by writing 1 to the IICBnTRG.IICBnSTT or IICBnTRG.IICBnSPT bit.

(3) Wait state upon detection of the falling edge of the 8th SCLn during data transfer

$\Delta 2$ indicates the wait state entered upon detection of the falling edge of the 8th SCLn during data transfer.

(a) Wait state transit condition

<Single transfer mode>

When the IICBn participates in communications and the IICBnCTL0.IICBnSLWT bit is 0, the IICBn enters the wait state if the falling edge of the 8th SCLn is detected.

<Continuous transfer mode>

When the IICBn participates in communications and the IICBnSTR0.IICBnSSTR bit is 0, the IICBn enters the wait state if processing of the previous data (read from the IICBnDAT register) has not completed and 1 has not been written to the IICBnTRG.IICBnSTT and IICBnTRG.IICBnSPT bits before the falling edge of the 8th SCLn.

(b) Wait state exit conditions

<Single transfer mode>

Exit the wait state by writing to the IICBnDAT register during transmission, or by writing 1 to the IICBnTRG.IICBnWRET bit during reception.

<Continuous transfer mode>

Exit the wait state by reading the IICBnDAT register.

(4) Wait state upon detection of the falling edge of the 9th SCLn during data transfer

$\Delta 3$ indicates the wait state entered upon detection of the falling edge of the 9th SCLn during data transfer.

During the continuous transfer mode, the IICBn enters the wait state upon NACK reception.

(a) Wait state transit condition

<Single transfer mode>

When the IICBn participates in communications and the IICBnCTL0.IICBnSLWT bit is 1, the IICBn enters the wait state if the falling edge of the 9th SCLn is detected.

<Continuous transfer mode>

When the IICBn participates in communications, it enters the wait state in the following three cases during data transmission:

- Upon reception of NACK by ACK bit while the IICBnCTL0.IICBnSLWT bit is 1
- When transmit data is not written to the data register
- When the previous received data is not read

(b) Wait state exit conditions

The wait state exit conditions are listed for each transfer mode in *Table 23-18* "Wait state exit conditions".

Table 23-18 Wait state exit conditions

Master/ slave	Transfer mode	Transfer direction	IICBnSTR0. IICBnSSAC bit	Exit conditions
Master	Single transfer mode	Reception	0	IICBnTRG.IICBnSTT bit = 1 or IICBnTRG.IICBnSPT bit = 1
			1	IICBnTRG.IICBnWRET bit = 1
		Transmission	0	IICBnTRG.IICBnSTT bit = 1 or IICBnTRG.IICBnSPT bit = 1
			1	Write to IICBnDAT register or IICBnTRG.IICBnSTT bit = 1 or IICBnTRG.IICBnSPT bit = 1
	Continuous transfer mode	Reception	0	IICBnTRG.IICBnSTT bit = 1 or IICBnTRG.IICBnSPT bit = 1
			1	Read from IICBnDAT register ^a
		Transmission	0	IICBnTRG.IICBnSTT bit = 1 or IICBnTRG.IICBnSPT bit = 1
			1	Write to IICBnDAT register ^b
Slave	Single transfer mode	Reception	-	IICBnTRG.IICBnWRET bit = 1
		Transmission	0	IICBnTRG.IICBnWRET bit = 1
			1	Write to IICBnDAT register ^a
	Continuous transfer mode	Reception	0	IICBnTRG.IICBnWRET bit = 1
		Transmission	0	IICBnTRG.IICBnWRET bit = 1
			1	Write to IICBnDAT register

- a) Condition for exiting the wait state that was entered when no transmit data has been written to the data register
b) Condition for exiting the wait state that was entered when the received data has not been read

23.6.5 Extension code

The processing when the extension code is received differs according to the data after the extension code and thus must be executed through the user's software.

Therefore, the operation differs from that during normal slave address reception. These differences are described below.

- (1) When the upper 4 bits of the received address are 0000 or 1111, the extension code reception flag (IICBnSTR0.IICBnSSEX bit) is set to 1 to indicate that an extension code has been received. The status interrupt request signal (IICBTISn) is output at the falling edge of the 8th clock, and the IICBn enters the wait state (IICBnTRG.IICBnSSWT = 1). The IICBnSTR0.IICBnSSDR bit is then set (to 1).
- (2) During address transfer, the acknowledge output can be controlled by setting the IICBnCTL0.IICBnSLAC bit. (Note that an acknowledge is always output upon an address match, regardless of the setting of this bit, during address transfer for normal slave address reception.)
- (3) The method for exiting the wait state entered upon extension code detection depends on the setting of the IICBnCTL0.IICBnMDTX1 bit as follows.
<When IICBnCTL0.IICBnMDTX1 bit is 0>
During transmission while the IICBnCTL0.IICBnSLWT bit is 0, exit the wait state by writing to the IICBnDAT register. During transmission while the IICBnCTL0.IICBnSLWT bit is 1, or during reception, exit the wait state by writing 1 to the IICBnTRG.IICBnWRET bit.
<When IICBnCTL0.IICBnMDTX1 bit is 1>
During transmission, exit the wait state by writing to the IICBnDAT register, and, during reception, exit the wait state by reading from the IICBnDAT register.
- (4) At the falling edge of the 9th clock, if the IICBnCTL0.IICBnSLWT bit is 1, the interrupt request signal (IICBTIAN) is output and the IICBn enters the wait state (IICBnTRG.IICBnSSWT = 1). If the IICBnCTL0.IICBnSLWT bit is 0, the interrupt request signal (IICBTIAN) is not output and the IICBn does not enter the wait state.
- (5) If the IICBn receives an extension code, it participates in communications even if the addresses do not match.

For example, to avoid operating the IICBn as a slave device after receiving an extension code, set the IICBnTRG.IICBnLRET bit to 1. The IICBn enters the standby state for the next communication.

23.7 Interrupt Request Signals

Caution In this section, the operation when an extension code is received is omitted. For details about the extension code, refer to 23.6.5 “*Extension code*”.

The IICBn has two interrupt request signals, the data transmit/receive interrupt request signal (IICBTIA_n) and the status interrupt request signal (IICBTIS_n). Both signals are pulses of one PCLK clock width. The interrupt request signal output timing differs according to the transfer mode set using the IICBnCTL0.IICBnMDTX1 and IICBnCTL0.IICBnMDTX0 bits. The interrupt request signals are explained below for each transfer mode.

To perform transfer with an address match between the master device and the slave device, select the single transfer mode or continuous transfer mode with the IICBnCTL0.IICBnMDTX0 bit, and to perform transfer with extension code detection by the slave, select the single transfer mode or continuous transfer mode using the IICBnCTL0.IICBnMDTX1 bit.

23.7.1 Single transfer mode

The interrupt request signal timing in the single transfer mode is described in *Table 23-19 "Interrupt request signal output timing (single transfer mode)"* below.

During the single transfer mode, for the IICBTIA_n and IICBTIS_n interrupt request signals, whether to output an interrupt is judged based on the IICB_n state when the falling edge of SCL_n is detected during the bus cycle. Note, however, that whether to output an interrupt is judged based on the IICB_n state when a stop condition is detected at the $\Delta 4$ timing.

Table 23-19 Interrupt request signal output timing (single transfer mode)

Output timing	Description	Refer to:
$\Delta 1$	Upon detection of the falling edge of the 9th SCL _n during address transfer	1 "Interrupt request signal output conditions and output interrupt request signals during address transfer" on page 1319
$\Delta 2$	Upon detection of the falling edge of the 8th SCL _n during data transfer	2 "Interrupt request signal output conditions and interrupt request signals output during data transfer" on page 1320
$\Delta 3$	Upon detection of the falling edge of the 9th SCL _n during data transfer	2 "Interrupt request signal output conditions and interrupt request signals output during data transfer" on page 1320
$\Delta 4$	Upon detection of a stop condition	3 "Interrupt request signal output upon stop condition detection" on page 1320

Note

- ST: Start condition
- AD6 to AD0: Address
- R/W: Transfer direction specification
- $\overline{\text{ACK}}$: Acknowledge
- D7 to D0: Data
- SP: Stop condition

(1) Interrupt request signal output conditions and output interrupt request signals during address transfer

$\Delta 1$ in Table 23-19 “Interrupt request signal output timing (single transfer mode)” indicates the interrupt request signal output timing during an address transfer. Table 23-20 “Interrupt request signal output conditions and interrupt request signals output during address transfer (single transfer mode)” indicates the interrupt request signal output condition and the interrupt request signal that is output (IICBTIA_n or IICBTIS_n) at the timing of $\Delta 1$.

Table 23-20 Interrupt request signal output conditions and interrupt request signals output during address transfer (single transfer mode)

IICB _n SSMS	IICB _n ALDF	IICB _n SLWT	IICB _n SSCO	$\Delta 1$		Remark
				Interrupt	Wait	
1	0	x	x	IICBTIA _n	Wait	-
1	1	x	x	This state does not exist.		-
0	0	x	0	IICBTIS _n ^a	-	After restart, non-participation in communications
0	0	x	1	IICBTIA _n	Wait	-
0	1	x	0	IICBTIS _n	-	After arbitration loss, non-participation in communications
0	1	x	1	IICBTIA _n	Wait	-

a) In case of an address match or extension code detection, before the restart condition

Note x: don't care

(2) Interrupt request signal output conditions and interrupt request signals output during data transfer

$\Delta 2$ and $\Delta 3$ in Table 23-19 “Interrupt request signal output timing (single transfer mode)” indicate the interrupt request signal output timing during a data transfer. The interrupt request signal output timing of $\Delta 2$ or $\Delta 3$ is determined according to the setting of the IICBnCTL0.IICBnSLWT bit. Table 23-21 “Interrupt request signal output conditions and interrupt request signals output during address transfer (single transfer mode)” indicates the interrupt request signal output condition and the interrupt request signal that is output (IICBTIA_n or IICBTIS_n) at the timing of $\Delta 2$ and $\Delta 3$.

Table 23-21 Interrupt request signal output conditions and interrupt request signals output during address transfer (single transfer mode)

IICBn SSMS	IICBn ALDF	IICBn SLWT	IICBn SSCO	$\Delta 2$		$\Delta 3$		Remark
				Interrupt	Wait	Interrupt	Wait	
1	0	0	x	IICBTIA _n	Wait	-	-	-
1	0	1	x	-	-	IICBTIA _n	Wait	-
1	1	x	x	This state does not exist.				-
0	0	x	0	-	-	-	-	Non-participation in communications
0	0	0	1	IICBTIA _n	Wait	-	-	-
0	0	1	1	-	-	IICBTIA _n	Wait	-
0	1	0	0	IICBTIS _n	-	-	-	Non-participation in communications after arbitration loss
0	1	1	0	-	-	IICBTIS _n	-	Non-participation in communications after arbitration loss
0	1	0	1	IICBTIA _n	Wait	-	-	-
0	1	1	1	-	-	IICBTIA _n	Wait	-

Note x: don't care

(3) Interrupt request signal output upon stop condition detection

$\Delta 4$ in Table 23-19 “Interrupt request signal output timing (single transfer mode)” indicates the interrupt request signal output timing upon detection of a stop condition.

Interrupt request signal output is controlled according to the IICBnCTL0.IICBnSLSI bit. If a stop condition is detected while the IICBnCTL0.IICBnSLSI bit is 1, the status interrupt request signal (IICBTIS_n) is output.

23.7.2 Continuous transfer mode

(1) Data transmit/receive interrupt request signal (IICBTIAN)

The conditions for outputting an IICBTIAN signal in the continuous transfer mode are described below.

- Interrupt request signal output condition during reception

When receive data is saved from the shift register to the IICBnDAT register (timing <1> in Figure 23-12 "IICBTIAN signal output timing (reception in continuous transfer mode)")

Figure 23-12 IICBTIAN signal output timing (reception in continuous transfer mode)

- Interrupt request signal output condition during transmission

When data is written to the IICBnDAT register while there is no transmit data in the shift register and IICBnDAT register (timing <2> in Figure 23-13 “IICBTIA_n signal output timing (transmission in continuous transfer mode)”).

When data is saved from the IICBnDAT register to the shift register (timing <1> in Figure 23-13 “IICBTIA_n signal output timing (transmission in continuous transfer mode)”).

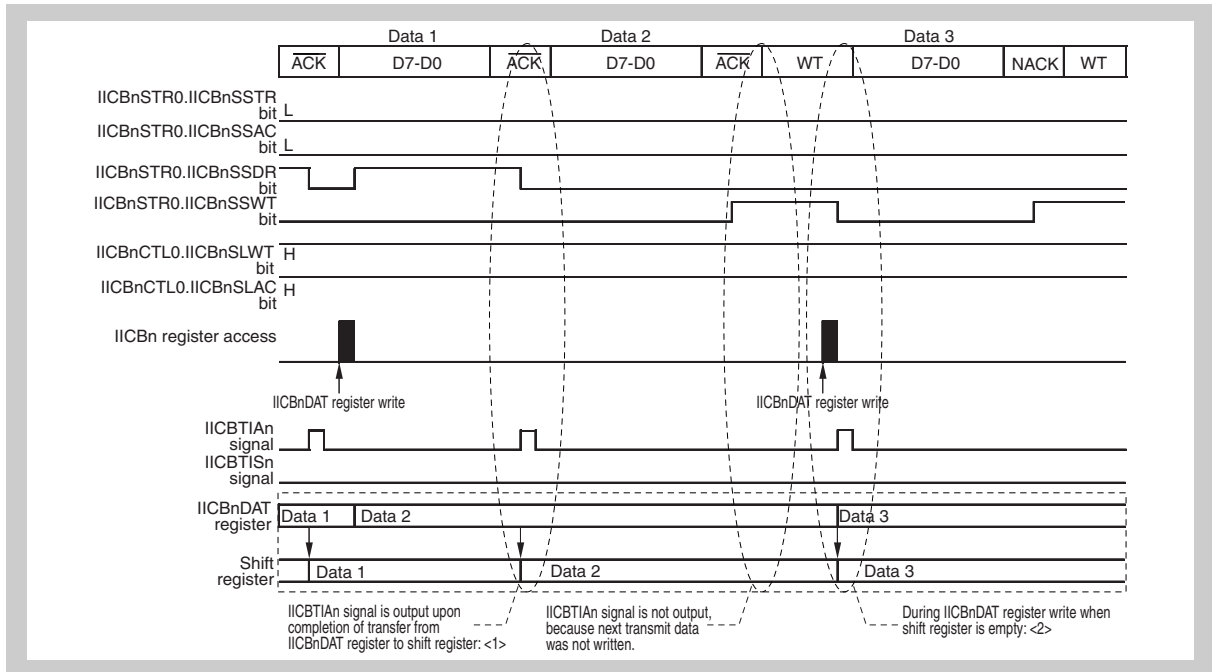

Figure 23-13 IICBTIA_n signal output timing (transmission in continuous transfer mode)

(2) Status interrupt request signal (IICBTISn)

The IICBTISn signal output timing in the continuous transfer mode is the same as that in the single transfer mode.

Table 23-22 IICBTISn signal output timing

Output timing	Description	Refer to:
$\Delta 1$	Upon detection of the falling edge of the 9th SCLn during address transfer after the start condition	<i>a "IICBTISn signal output conditions during address transfer" on page 1324</i>
$\Delta 2$	Upon detection of the falling edge of the 8th SCLn during data transfer	<i>b "IICBTISn signal output conditions during data transfer" on page 1325</i>
$\Delta 3$	Upon detection of the falling edge of the 9th SCLn during data transfer	<i>b "IICBTISn signal output conditions during data transfer" on page 1325</i>
$\Delta 4$	Upon detection of a stop condition	<i>c "IICBTISn signal output upon detection of stop condition" on page 1326</i>

Note

ST: Start condition
 AD6 to AD0: Address
 R/W: Transfer direction specification
 $\overline{\text{ACK}}$: Acknowledge
 D7 to D0: Data
 SP: Stop condition

(a) IICBTISn signal output conditions during address transfer

$\Delta 1$ in Table 23-22 “IICBTISn signal output timing” indicates the IICBTISn signal output timing during address transfer. Table 23-23 “IICBTISn signal output conditions during address transfer (continuous transfer mode)” indicates the IICBTISn signal output conditions at the $\Delta 1$ timing.

Table 23-23 IICBTISn signal output conditions during address transfer (continuous transfer mode)

IICBn SSMS	IICBn SSCO	IICBn ALDF	Transfer direction	IICBn SSDR	IICBn SSAC	$\Delta 1$	
						Interrupt	Wait
1	x	0	Transmission	0	1	-	Wait
1	x	0	Transmission	0	0	IICBTISn	Wait
1	x	0	Transmission	1	1	-	-
1	x	0	Transmission	1	0	IICBTISn	Wait
1	x	0	Reception	0	1	-	-
1	x	0	Reception	0	0	IICBTISn	Wait
1	x	0	Reception	1	1	IICBTISn during IICBnDAT read ^a	Wait
1	x	0	Reception	1	0	IICBTISn during IICBnDAT read	Wait
1	x	1	x	x	x	This state does not exist.	
0	0	0	x	x	x	IICBTISn ^b	-
0	0	1	x	x	x	IICBTISn	-
0	1	x	Transmission	x	1	IICBTISn	Wait
0	1	x	Reception	0	1	IICBTISn	-
0	1	x	Reception	1	1	IICBTISn during IICBnDAT read	Wait

a) Upon restarting without reading IICBnDAT after the reception ends

b) Upon an address match before restart condition

Caution For $\Delta 1$, the IICBnSTR0.IICBnSSAC bit is always 0.

Note x: don't care

(b) IICBTISn signal output conditions during data transfer

$\Delta 2$ and $\Delta 3$ in Table 23-22 "IICBTISn signal output timing" indicate the IICBTISn signal output timings during data transfer. Table 23-24 "IICBTISn signal output conditions during data transfer (continuous transfer mode)" indicates the IICBTISn signal output conditions at the $\Delta 2$ and $\Delta 3$ timings.

Table 23-24 IICBTISn signal output conditions during data transfer (continuous transfer mode)

IICBn SSMS	IICBn SSCO	IICBn SLWT	IICBn ALDF	Transfer direction	IICBn SSDR	IICBn SSAC	IICBnSTT or IICBnSPT	$\Delta 2$		$\Delta 3$	
								Interrupt	Wait	Interrupt	Wait
1	x	0	x	Transmission	0	1	a	-	-	-	Wait
1	x	0	x	Transmission	0	0	a	-	-	IICBTISn	Wait
1	x	0	x	Transmission	1	1	a	-	-	-	-
1	x	0	x	Transmission	1	0	a	-	-	IICBTISn	Wait
1	x	0	x	Reception	0	1	a	-	-	-	-
1	x	0	x	Reception	0	0	a	-	-	IICBTISn	Wait
1	x	0	x	Reception	1	1	a	-	-	-	-
1	x	0	x	Reception	1	0	a	-	-	IICBnDAT after IICBTISn read	Wait
1	x	x	x	x	x	0	b	-	-	IICBTISn	-
1	x	x	x	x	x	1	b	-	-	-	-
0	0	x	0	x	x	x	x	-	-	-	-
0	0	0	1	Reception	x	x	x	IICBTIS	-	-	-
0	0	1	1	Transmission	x	x	x	-	-	IICBTISn	-
0	1	0	x	Transmission	0	1	a	-	-	-	Wait
0	1	0	x	Transmission	0	0	a	-	-	IICBTISn	Wait
0	1	0	x	Transmission	1	1	a	-	-	-	-
0	1	0	x	Transmission	1	0	a	-	-	IICBTISn	Wait
0	1	0	x	Reception	0	1	a	-	-	-	-
0	1	0	x	Reception	0	0	a	-	-	IICBTISn	Wait
0	1	0	x	Reception	1	1	a	-	-	-	-
0	1	0	x	Reception	1	0	a	-	-	IICBnDAT during IICBTISn read	Wait

a) When 1 has not been written to the IICBnTRG.IICBnSTT or IICBnTRG.IICBnSPT bit

b) When 1 has been written to the IICBnTRG.IICBnSTT or IICBnTRG.IICBnSPT bit

Note x: don't care

(c) IICBTISn signal output upon detection of stop condition

$\Delta 4$ in *Table 23-22 "IICBTISn signal output timing"* indicates the IICBTISn signal output timing upon detection of a stop condition.

IICBTISn signal output is controlled according to the IICBnCTL0.IICBnSLSI bit. If a stop condition is detected while the IICBnCTL0.IICBnSLSI bit is 1, the IICBTISn signal is output.

23.8 Interrupt Outputs and Statuses

This section describes the statuses of the IICBnSTR0 register during interrupt output by communication flow.

The meanings of the symbols used in the figures are as follows.

ST:	Start condition
AD6-AD0:	Address
R, \bar{W} , R/ \bar{W} :	Transfer direction specification
\bar{ACK} :	Acknowledge
NACK:	Not acknowledge
D7-D0:	Data
SP:	Stop condition

23.8.1 Single transfer mode (master device operation)

(1) Start ~ Address ~ Data ~ Data ~ Stop (normal transmission/reception)

<1> When IICBnCTL0.IICBnSLWT bit is 0

 - Undefined

23.8.16 Continuous transfer mode (arbitration loss operation (IICBnSTR0.IICBnALDF bit = 1) (when address was transferred during reception): non-participation in communications after arbitration loss)

When using IICBn as the master in a multi-master system, read the IICBnSTR0.IICBnALDF bit for each IICBTISn interrupt occurrence to confirm the arbitration result.

(1) Arbitration loss during slave address transmission

<1> During reception, when IICBnCTL0.IICBnSLWT bit is 0

▲1: IICBnSTR0 register = 0-000001 0110--01B (IICBnSTRC.IICBnCLAF bit = 1)

△2: IICBnSTR0 register = 0-000000 0001--00B

Note

- ▲ Always output
- △ Output only when IICBnCTL0.IICBnSLSI = 1
- Undefined

(2) Arbitration loss during data transfer

<1> During reception, when IICBnCTL0.IICBnSLWT bit is 1

[▲1: IICBnSTR0 register = 0-000000 0100--01B]

IICBnSTRC.IICBnCLAF bit = 1

△2: IICBnSTR0 register = 0-000000 0001--00B

- Note**
- ▲ Always output
 - △ Output only when IICBnCTL0.IICBnSLSI = 1
 - Undefined

(3) Arbitration loss for the restart condition during data transfer

<1> During reception, when IICBnCTL0.IICBnSLWT bit is 1 (extension code mismatch, address mismatch)

[▲1: IICBnSTR0 register = 0-000001 0100--01B]

IICBnSTRC.IICBnCLAF bit = 1

△2: IICBnSTR0 register = 0-000000 0001--00B

Note ▲ Always output
 △ Output only when IICBnCTL0.IICBnSLSI = 1
 - Undefined

(4) Arbitration loss for the stop condition during data transfer

<1> During reception, when IICBnCTL0.IICBnSLWT bit is 1

△1: IICBnSTR0 register = 0-000000 0001--01B

IICBnSTRC.IICBnCLAF bit = 1

Note △ Output only when IICBnCTL0.IICBnSLSI = 1
 - Undefined

(5) Arbitration loss because the SDA_n signal is low level when attempting to output restart condition

<1> When IICBnCTL0.IICBnSLWT bit is 1

[▲1: IICBnSTR0 register = 1-1000XX 0100--00B]

IICBnDAT register read

IICBnTRG.IICBnSTT bit = 1

▲2: IICBnSTR0 register = 0-000000 0100--01B

IICBnSTRC.IICBnCLAF bit = 1

▲3: IICBnSTR0 register = 0-000000 0001--00B

Note

- ▲ Always output
- △ Output only when IICBnCTL0.IICBnSLSI = 1
- Undefined
- X don't care

(6) Arbitration loss for the stop condition when attempting to output restart condition

<1> When IICBnCTL0.IICBnSLWT bit is 1

[▲1: IICBnSTR0 register = 1-000001 0100--00B]

IICBnDAT register read

IICBnTRG.IICBnSTT bit = 1

△2: IICBnSTR0 register = 0-000000 0001--01B

Note ▲ Always output
 △ Output only when IICBnCTL0.IICBnSLSI = 1
 - Undefined

(7) Arbitration loss because the SDA_n signal is low level when attempting to output stop condition

<1> When IICBnCTL0.IICBnSLWT bit is 1

[▲1: IICBnSTR0 register = 1-1000XX 0100--00B]

IICBnDAT register read

IICBnTRG.IICBnSPT bit = 1

[▲2: IICBnSTR0 register = 0-0000XX 0100--01B (IICBnSTRC.IICBnCLAF bit = 1)]

△3: IICBnSTR0 register = 0-000000 0001--01B

Note ▲ Always output
 △ Output only when IICBnCTL0.IICBnSLSI = 1
 - Undefined
 X don't care

23.8.17 Continuous transfer mode (arbitration loss operation (IICBnSTR0.IICBnALDF bit = 1) (when address was transferred during reception): non-participation in communications after arbitration loss (during extension code transfer))

When using IICBn as the master in a multi-master system, read the IICBnSTR0.IICBnALDF bit for each IICBTISn interrupt occurrence to confirm the arbitration result.

(1) Arbitration loss during extension code transfer

[▲1: IICBnSTR0 register = 0-1000X0 0110--01B]

IICBnSTRC.IICBnCLAF bit = 1

IICBnTRG.IICBnLRET bit = 1

△2: IICBnSTR0 register = 0-000000 0001--01B

Note

- ▲ Always output
- △ Output only when IICBnCTL0.IICBnSLSI = 1
- Undefined
- X don't care

(2) Arbitration loss for the restart condition during data transfer (extension code match)

23.9 Setting Sequence

23.9.1 Single master environment

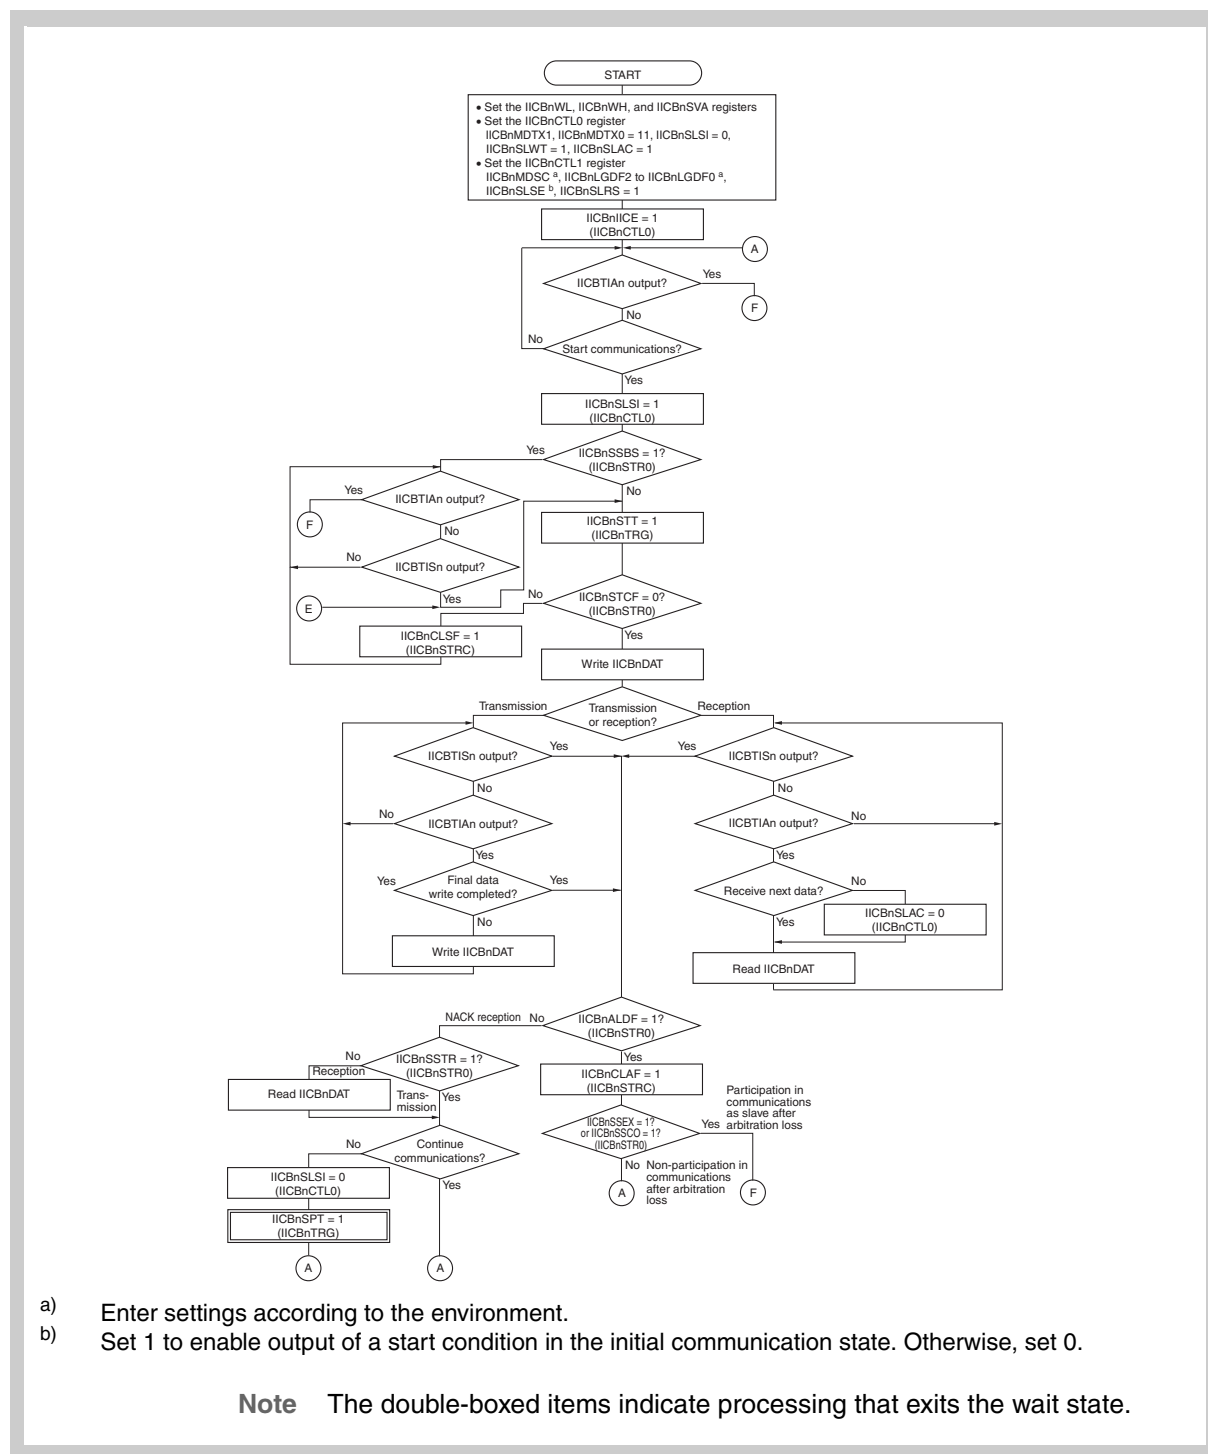

Figure 23-21 Continuous transfer mode setting sequence when communication reserve function is disabled (IICBnCTL1.IICBnSLRS bit = 1) (multi-master environment) (1/2)

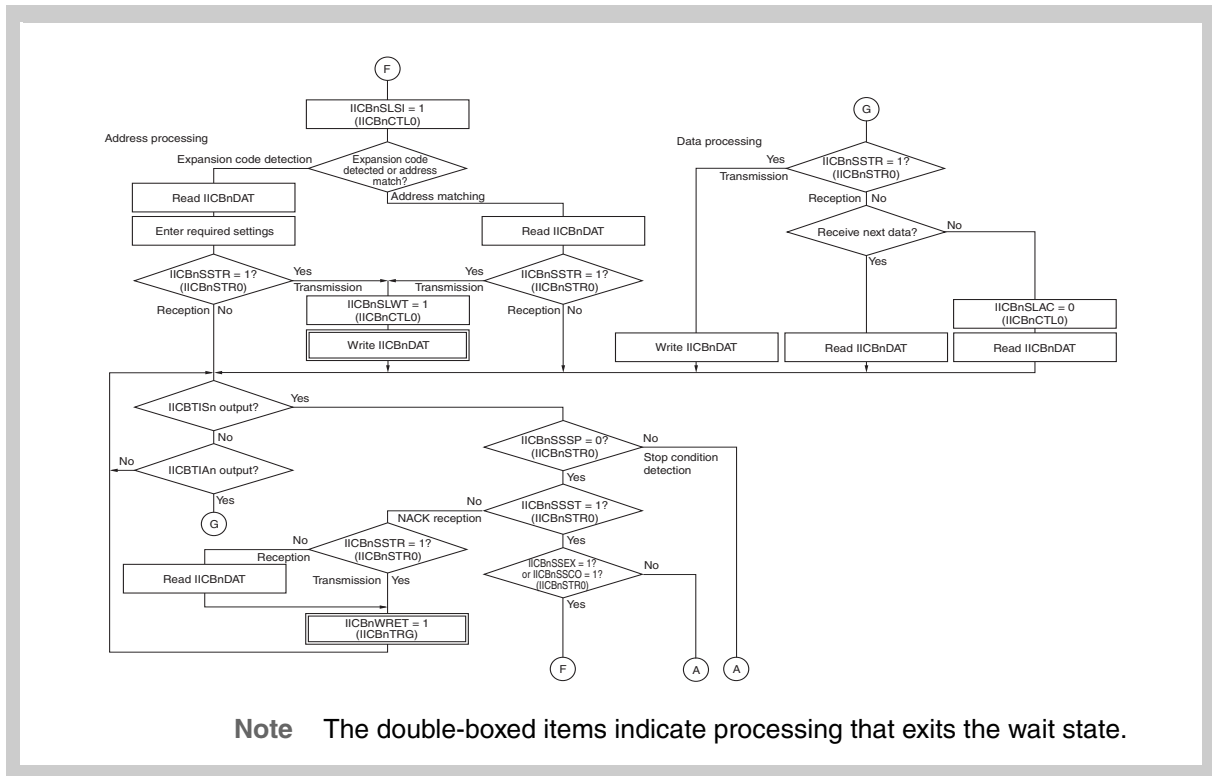

Figure 23-21 Continuous transfer mode setting sequence when communication reserve function is disabled (IICBnCTL1.IICBnSLRS bit = 1) (multi-master environment) (2/2)

Chapter 24 CAN Controller (FCN)

The product features on-chip CAN (Controller Area Network) controllers that comply with the CAN protocol as standardized in ISO 11898.

This chapter contains a generic description of the CAN Controller (FCN).

The first section describes all V850E2/ML4 devices specific properties, such as instances, register base addresses, input/output signal names, etc. The subsequent sections describe the features that apply to all implementations.

24.1 FCN Features of V850E2/ML4

Instances This microcontroller has the following number of instances of the CAN Controller.

Table 24-1 Instances of FCN

CAN Controller	
Instances	1
Name	FCN0

Instances index n Throughout this chapter, the instance of a CAN Controller is identified by the index “n” (n = 0), for example, FCN0GMCLCTL for the FCN0 control register.

Table 24-2 Message buffers of FCN

FCNn instance	Number m of message buffers
FCN0	64

Caution This products do not include the FCN0DNBMRX2 and the FCN0DNBMRX3 register.

Message buffers index m Throughout this chapter, the FCN message buffer registers are identified by “m” (m = 000 to 063), for example FCNnMmDAT4B for FCN instance n, message data byte 4 of message buffer register m.

Register addresses All CAN Controller register addresses are given as address offsets to the individual base address <FCNn_base>. *Table 24-3 “Register base addresses <FCNn_base>”* shows the <FCNn_base> addresses of FCNn.

Table 24-3 Register base addresses <FCNn_base>

FCNn instance	<FCNn_base> address
FCN0	FF48 0000 _H

Clock supply All CAN Controllers provide one clock input. The CAN Controllers are connected to P bus clock f_{PCLK} .

Table 24-4 CAN Controller clock supply

FCNn instance	Clock input signal CANCLK (f_{CAN})
FCN0	PCLK

Interrupts Table 24-5 “FCNn interrupt requests” shows the interrupts of the CAN Controllers.

Table 24-5 FCNn interrupt requests

FCNn Interrupt	Function	Connected to
FCN0		
<R> INTC0ERR	FCN0 error detected	<ul style="list-style-type: none"> Interrupt controller INTFCN0IERR
INTC0REC	FCN0 reception completion	<ul style="list-style-type: none"> Interrupt controller INTFCN0REC DTS controller trigger 96
INTC0TRX	FCN0 transmission completion	<ul style="list-style-type: none"> Interrupt controller INTFCN0TRX DTS controller trigger 97
INTC0WUP	FCN0 sleep wake-up / transmission abortion	<ul style="list-style-type: none"> Interrupt controller INTFCNWUP

I/O signals The I/O signals of the CAN Controllers are listed in the table below.

Table 24-6 CAN Controllers I/O signals

FCNn signals	Function	Connected to
FCN0		
CRXD0	FCN0 CAN bus receive input	CAN0RXD
CTXD0	FCN0 CAN bus transmit output	CAN0TXD

24.2 Features

- Compliant with ISO 11898
- Standard frame and extended frame transmission/reception enabled
- Transfer rate: 1 Mbps max. (If FCN clock input is ≥ 16 MHz)
- 64 message buffers per channel
- Receive/transmit history list function (can be set individually for each message buffer)
- Automatic block transmission function
- Multi-buffer receive block function
- Mask setting of 8 patterns is possible for each channel, applicable for data and remote frames
- Data bit time, communication baud rate and sample point can be controlled by FCN module bit-rate prescaler register (FCNnCMBRPRS) and bit rate register (FCNnCMBTCTL)
 - As an example the following sample-point configurations can be configured:
66.7%, 70.0%, 75.0%, 80.0%, 81.3%, 85.0%, 87.5%
 - Baud rates in the range of 10 kbps up to 1 Mbps can be configured
- Enhanced features:
 - Each message buffer can be configured to operate as a transmit or a receive message buffer
 - A transmission request can be aborted by clearing the Transmit-Request flag of the concerned message buffer. Supported by Transmission Abort Interrupt, on successful abortion.
 - Automatic block transmission operation mode (ABT)
 - Time stamp function for FCN channels 0 to 2 in collaboration with timers capture channels
 - A centralized global data update bit monitor register makes it possible to check all data update bits from one location

24.2.1 Overview of functions

Table 24-7 “Overview of functions” presents an overview of the CAN Controller functions.

Table 24-7 Overview of functions

Function	Details
Protocol	CAN protocol ISO 11898 (standard and extended frame transmission/reception)
Baud rate	Maximum 1 Mbps (minimum FCN clock input = 16 MHz)
Data storage	Storing messages in the FCN RAM
Number of messages	<ul style="list-style-type: none"> • 64/128 message buffers per channel • Each message buffer can be set to be either a transmit message buffer or a receive message buffer.
Message reception	<ul style="list-style-type: none"> • Unique ID can be set to each message buffer. • Mask setting of 8 patterns is possible for each channel, applicable for data and remote frames • A receive completion interrupt is generated each time a message is received and stored in a message buffer (receive completion interrupts can be enabled/disabled for each message buffer) • Two or more receive message buffers can be used as a FIFO receive buffer (multi-buffer receive block function). • Receive history list function (can be set individually for each message buffer) • Centralized global data update bit monitor register
Message transmission	<ul style="list-style-type: none"> • Unique ID can be set to each message buffer. • Receive completion interrupts can be enabled/disabled for each message buffer • Transmit Abort interrupt and Transmit Completion flag for each message buffer (only one transmission of any buffer can be aborted at a time) • Message buffer numbers 0 to 15/31 specified as the transmit message buffers can be used for automatic block transfer. The message transmission interval is programmable (using the automatic block transmission (“ABT”) function). • Transmission history list function (can be set individually for each message buffer)
Remote frame processing	<ul style="list-style-type: none"> • Remote frame processing by transmit message buffer • Remote frame processing by receive message buffer, when applying one of the 8 masks
Time stamp function	<ul style="list-style-type: none"> • The time stamp function can be set for a message reception when a 32-bit timer is used in combination. • Time stamp capture trigger can be selected (SOF or EOF in a CAN message frame can be detected.).
Diagnostic function	<ul style="list-style-type: none"> • Readable error counters • “Valid protocol operation flag” for verification of bus connections • Receive-only mode • Single-shot mode • CAN protocol error identification • Self-test mode
Release from bus-off state	<ul style="list-style-type: none"> • Forced release from bus-off possible by software. • No automatic release from bus-off (software must send recovery request).
Power save mode	<ul style="list-style-type: none"> • CAN sleep mode (can be woken up by CAN bus) • CAN stop mode (cannot be woken up by CAN bus)

24.2.2 Configuration

The CAN Controller is composed of the following four blocks.

- **Internal bus interface**
This functional block provides an internal bus interface and a means of transmitting and receiving messages between the FCN module and the host CPU.
- **MCM (Message Control Module)**
This functional block controls access to the CAN protocol layer and to the FCN RAM within the FCN module.
- **CAN protocol layer**
This functional block is involved in the operation of the CAN protocol and its related settings.
- **CAN RAM**
This is the CAN memory functional block, which is used to store message IDs, message data, etc.

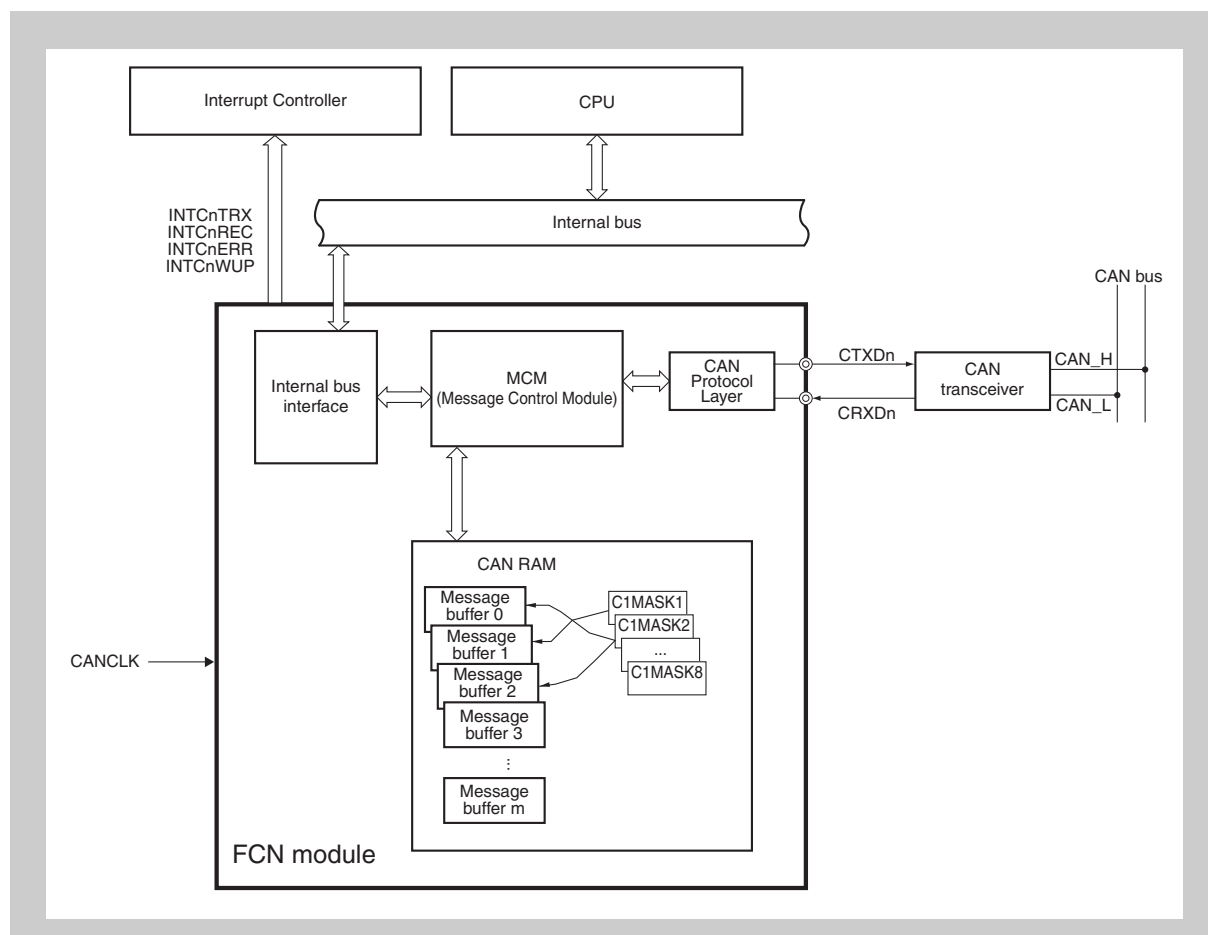

Figure 24-1 Block diagram of the CAN Controller

Caution The CAN RAM includes a memory reference module. If a CAN RAM error occurs during a software reset, the message buffer RAM read error detection bit (FCNnGMCLCTL.FCNnGMCLECCF) will be set. If this bit is set, be sure to check the FCN function for errors.

24.3 Internal Registers of FCN

24.3.1 CAN Controller configuration

Table 24-8 List of FCN registers (1/2)

Item	Register Name
FCNn global registers	FCNn global control register (FCNnGMCLCTL)
	FCNn global clock selection register (FCNnGMCSPRE)
	FCNn global automatic block transmission control register (FCNnGMABCTL)
	FCNn global automatic block transmission delay setting register (FCNnGMADCTL)
	FCNn global Data New bit monitor registers (FCNnDNBMRX0 - FCNnDNBMRX3)
FCNn module registers	FCNn module mask 1 registers (FCNnCMMKCTL01H, FCNnCMMKCTL02H, FCNnCMMKCTL01W)
	FCNn module mask 2 registers (FCNnCMMKCTL03H, FCNnCMMKCTL04H, FCNnCMMKCTL03W)
	FCNn module mask3 registers (FCNnCMMKCTL05H, FCNnCMMKCTL06H, FCNnCMMKCTL05W)
	FCNn module mask 4 registers (FCNnCMMKCTL07H, FCNnCMMKCTL08H, FCNnCMMKCTL07W)
	FCNn module mask 5 registers (FCNnCMMKCTL09H, FCNnCMMKCTL10H, FCNnCMMKCTL09W)
	FCNn module mask 6 registers (FCNnCMMKCTL11H, FCNnCMMKCTL12H, FCNnCMMKCTL11W)
	FCNn module mask 7 registers (FCNnCMMKCTL13H, FCNnCMMKCTL14H, FCNnCMMKCTL13W)
	FCNn module mask 8 registers (FCNnCMMKCTL15H, FCNnCMMKCTL16H, FCNnCMMKCTL15W)
	FCNn module control register (FCNnCMCLCTL)
	FCNn module last error information register (FCNnCMLCSTR)
	FCNn module information register (FCNnCMINCSTR)
	FCNn module error counter register (FCNnCMERCNT)
	FCNn module interrupt enable register (FCNnCMIECTL)
	FCNn module interrupt status register (FCNnCMISCTL)
	FCNn module bit rate prescaler and FCN clock selector register (FCNnCMBRPRS)
	FCNn module bit rate register (FCNnCMBTCTL)
	FCNn module last in-pointer register (FCNnCMLISTR)
	FCNn module receive history list register (FCNnCMRGRX)
	FCNn module last out-pointer register (FCNnCMLOSTR)
	FCNn module transmit history list register (FCNnCMTGTX)
FCNn module time stamp register (FCNnCMTSCTL)	

Table 24-8 List of FCN registers (2/2)

Item	Register Name
FCNn message buffer registers	FCNn message data byte 0 to 3 registers m (FCNnMmDAT0W, FCNnMmDAT0H, FCNnMmDAT2H, FCNnMmDAT0B, FCNnMmDAT1B, FCNnMmDAT2B, FCNnMmDAT3B)
	FCNn message data byte 4 to 7 registers m (FCNnMmDAT4W, FCNnMmDAT4H, FCNnMmDAT6H, FCNnMmDAT4B, FCNnMmDAT5B, FCNnMmDAT6B, FCNnMmDAT7B)
	FCNn message data length register m (FCNnMmDTLGB)
	FCNn message configuration register m (FCNnMmSTRB)
	FCNn message ID registers m (FCNnMmMID0H, FCNnMmMID1H, FCNnMmMID0W)
	FCNn message control register m (FCNnMmCTL)

24.3.2 CAN Controller Registers Overview

Address offset All register addresses are given as offsets to the base address <FCNn_base>. The <FCNn_base> addresses of the registers are defined in the first section of this chapter under the keyword “Register addresses”.

(1) FCNn global and module registers

Table 24-9 FCNn global and module registers (1/2)

Address offset	Register name	Symbol	R/W	Access bit	After reset
0 0008 _H	FCNn global clock selection register	FCNnGMCSPRE	R/W	8	0F _H
0 0020 _H	FCNn global automatic block transmission delay setting register	FCNnGMADCTL	R/W	8	00 _H
0 8000 _H	FCNn global control register	FCNnGMCLCTL	R/W	16	00x0 _H ^a
0 8018 _H	FCNn global automatic block transmission control register	FCNnGMABCTL	R/W	16	0000 _H

24.4 Bit Set/Clear Function

The FCN control registers include registers whose bits can be set or cleared via the CPU and via the CAN Controller. These register bits can not be changed directly by the CPU by any bit manipulation instructions, such as SET1, CLR1, and NOT1. Instead a special bit-set/bit-clear mechanism is used.

All registers where bit manipulation operations are prohibited are organised in such a way that all bits allowed for changing by the CPU are located in the lower byte (RWx in the register layout below), while in the upper byte either no or read-only information is located (ROx in the register layout below).

The registers can be read in the usual way getting all 16 data bits in their current setting and as described in the register description.

For setting or clearing any of the lower 8 bits the following mechanism is implemented:

When writing 16-bit data to the register address

- Bit clear**
- each of the lower 8 data bits (CLx in the register layout below) indicates whether the corresponding register bit RWx should be
 - cleared, i.e. set to 0: if CLx = 1, the corresponding RWx is cleared to 0
 - remain unchanged: if CLx = 0, the corresponding RWx does not change
- Bit set**
- each of the upper 8 data bits (SEx in the register layout below) indicate whether the corresponding register bit should be
 - set, i.e. set to 1: if SEx = 1, the corresponding RWx is set to 1
 - remain unchanged: if SEx = 0, the corresponding RWx does not change

Register layout for read access:

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RO7	RO6	RO5	RO4	RO3	RO2	RO1	RO0	RW7	RW6	RW5	RW4	RW3	RW2	RW1	RW0
changing by the CPU not possible								bits for CPU manipulation via SE7-SE0 and CL7-CL0							

Register layout for write access:

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SE7	SE6	SE5	SE4	SE3	SE2	SE1	SE0	CL7	CL6	CL5	CL4	CL3	CL2	CL1	CL0
SEx = 1 sets the corresponding RW7-RW0								CLx = 1 clears the corresponding RW7-RW0							

The following table denotes the operations applied to the RWx bits:

Table 24-15 Bit set/clear operation

CLx	SEx	Operation on RWx
0	0	Not changed
0	1	Set
1	0	Cleared
1	1	Not changed

Example The following shows an example.

Changing the register with the content 1883_H as follows:

- Bit 3 shall be set: SE3 = 1
- Bit 1 shall be cleared: CL1 = 1

Register read before bit manipulations:

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	1	1	0	0	0	1	0	0	0	0	0	1	1
may hold any value, here 18 _H								RW7-RW0: 83 _H							

Register write access:

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	1	0	0	0	0	0	0	0	0	0	1	0
SE3 = 1: 08 _H								CL1 = 1: 02 _H							

Register read after bit manipulations:

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	1	1	0	0	0	1	0	0	0	1	0	0	1
may hold any value, here 18 _H								RW7-RW0: 89 _H							

24.5 Control Registers

24.5.1 FCN global registers

(1) FCNnGMCLCTL - FCNn global control register

This register is used to control the operation of the FCN module.

Access This register can be read/written in 16-bit units.

Address <FCNn_base> + 0 8000_H

Initial Value 00x0_H.^{a)} The register is initialized by any reset.

- a) Soft reset starts automatically after hard reset.
So initial value is:
--- If error is not detected after soft reset, then it is 0000_H.
--- If error is not detected on soft reset, then it is 0010_H.
--- If error is detected after soft reset, then it is 0020_H.
--- If error is detected on soft reset, then it is 0030_H.

(a) FCNnGMCLCTL read

	15	14	13	12	11	10	9	8
FCNnGM CLSSMO	0	0	0	0	0	0	0	0
	7	6	5	4	3	2	1	0
	0	0	FCNnGM CLECCF	FCNnGM CLSORF	0	0	FCNnGM CLESDE	FCNnGM CLPWOM

FCNnGMCLSSMO	Bit enabling access to message buffer register, transmit/receive history registers
0	Write access and read access to the message buffer register and the transmit/receive history list registers is disabled.
1	Write access and read access to the message buffer register and the transmit/receive history list registers is enabled.

- Cautions**
1. While the FCNnGMCLCTL.FCNnGMCLSSMO is cleared (to 0), software access to FCN message buffer registers (i.e. all FCNnMm registers) and registers related to transmit history or receive history (FCNnCMLOSTR, FCNnCMTGTX, FCNnCMLISTR, and FCNnCMRGRX) is disabled.
 2. FCNnGMCLCTL.FCNnGMCLSSMO is read-only. Even if 1 is written while it is 0, its value does not change, and access to the message buffer registers, or registers related to transmit history or receive history remains disabled.

Note FCNnGMCLCTL.FCNnGMCLSSMO is cleared to (0) when the FCN module enters FCN sleep mode/FCN stop mode, or when the FCNnGMCLCTL.FCNnGMCLPWOM is cleared to (0).
FCNnGMCLSSMO is set to (1) when the FCN sleep mode/FCN stop mode is released, or when the FCNnGMCLCTL.FCNnGMCLPWOM is set to (1).

FCNnGMCLECCF	Message buffer RAM read error detect bit
0	Not detect error for reading from message buffer RAM.
1	Detect error for reading from message buffer RAM.

- Notes**
1. FCNnGMCLCTL.FCNnGMCLECCF is set (1) in case of detecting a memory error when reading from the message buffer RAM during the soft reset process. Once FCNnGMCLECCF is set (1), it keeps the level until it is cleared (0).
 2. Only use this bit to check for memory errors after executing a soft reset.
 3. It is impossible to clear FCNnGMCLECCF (0) during FCNnGMCLCTL.FCNnGMCLSORF is set (1) (soft reset is ongoing).

FCNnGMCLSORF	Soft reset execution status bit
0	No soft reset
1	Soft reset is ongoing

- Notes**
1. While a soft reset is ongoing (FCNnGMCLCTL.FCNnGMCLSORF is set (1)), it is impossible to set FCNnGMCLCTL.FCNnGMCLPWOM and FCNnGMCLCTL.EFSD.
It is possible to set start a software reset by FCNnGMCLCTL.FCNnGMCLSESR = 1 during FCNnGMCLCTL.FCNnGMCLPWOM bit is clear (0).
 2. When FCNnGMCLCTL.FCNnGMCLSORF is set (1), the initialization of message buffer RAM starts. It is possible to detect error during initializing message buffer RAM, if FCNnGMCLCTL.FCNnGMCLECCF is cleared before setting FCNnGMCLSORF.
 3. When FCNnGMCLCTL.FCNnGMCLSORF is set (1) again in the condition that is already set (1), the soft reset procedure does not restart, but continues.
 4. After releasing hardware reset FCNnGMCLCTL.FCNnGMCLSORF is set (1) automatically and initialization of message buffer RAM starts.
 5. It is impossible that clearing FCNnGMCLCTL.FCNnGMCLPWOM (0) and setting FCNnGMCLCTL.FCNnGMCLSORF (1) are done at the same time.
 6. If a hardware RESET occurs during FCNnGMCLCTL.FCNnGMCLSORF = 1, then the soft reset procedure is stopped (aborted), and the hardware RESET starts.

FCNnGMCLESEDE	Bit enabling forced shut down
0	Forced shutdown by setting FCNnGMCLCTL.FCNnGMCLPWOM = 0 is disabled.
1	Forced shutdown by setting FCNnGMCLCTL.FCNnGMCLPWOM = 0 is enabled.

Caution To request a forced shut down, FCNnGMCLCTL.FCNnGMCLPWOM must be cleared to 0 in a subsequent, immediately following access after FCNnGMCLCTL.FCNnGMCLSEDE has been set to 1. If any access to another register (including reading the FCNnGMCLCTL register) is executed without clearing FCNnGMCLPWOM immediately after FCNnGMCLSEDE has been set to 1, FCNnGMCLSEDE is forcibly cleared to 0, and the forced shut down request is invalid.

FCNnGMCLPWOM	Global operation mode bit
0	FCN module is disabled.
1	FCN module is enabled to operate.

Caution FCNnGMCLCTL.FCNnGMCLPWOM can be cleared only in the initialization mode or immediately after FCNnGMCLCTL.FCNnGMCLSEDE is set (forced shutdown).

(b) FCNnGMCLCTL write

15	14	13	12	11	10	9	8
0	0	0	FCNnGM CLSESR	0	0	FCNnGM CLSESD	FCNnGM CLSEOM
7	6	5	4	3	2	1	0
0	0	FCNnGM CLCLMB	0	0	0	0	FCNnGM CLCLOM

FCNnGMCLSESR	Software reset start
0	No changes.
1	Start soft reset.

FCNnGMCLSESD	FCNnGMCLSEDE bit setting
0	No change in FCNnGMCLSEDE bit.
1	FCNnGMCLSEDE bit set to 1.

FCNnGMCLSEOM	FCNnGMCLCLOM	FCNnGMCLPWOM bit setting
0	1	FCNnGMCLCTL.FCNnGMCLPWOM bit cleared to 0.
1	0	FCNnGMCLCTL.FCNnGMCLPWOM bit set to 1.
Other than above		No change of FCNnGMCLCTL.FCNnGMCLPWOM bit.

Caution Set FCNnGMCLCTL.FCNnGMCLPWOM and FCNnGMCLCTL.FCNnGMCLESDE bit always separately.

FCNnGMCLCLMB	FCNnGMCLCTL.FCNnGMCLECCF bit clear
0	No change in FCNnGMCLCTL.FCNnGMCLECCF bit.
1	FCNnGMCLCTL.FCNnGMCLECCF bit cleared to 0.

(2) FCNnGMCSPRE - FCNn global clock selection register

This register is used to select the FCN module system clock.

Access This register can be read/written in 8-bit units.

Address <FCNn_base> + 0008_H

Initial Value 0F_H. The register is initialized by any reset.

7	6	5	4	3	2	1	0
0	0	0	0	FCNnGMCSPRSC[3:0]			

FCNnGMCSPRSC[3:0]	Pre-CAN protocol layer basic system clock (f _{CANPRE})
0000 _B	f _{CAN} /1
0001 _B	f _{CAN} /2
0010 _B	f _{CAN} /3
0011 _B	f _{CAN} /4
0100 _B	f _{CAN} /5
0101 _B	f _{CAN} /6
0110 _B	f _{CAN} /7
0111 _B	f _{CAN} /8
1000 _B	f _{CAN} /9
1001 _B	f _{CAN} /10
1010 _B	f _{CAN} /11
1011 _B	f _{CAN} /12
1100 _B	f _{CAN} /13
1101 _B	f _{CAN} /14
1110 _B	f _{CAN} /15
1111 _B	f _{CAN} /16 (default value)

Note f_{CAN} = clock supplied to FCN on system level (clock generation, distribution and selection).

(3) FCNnGMABCTL - FCNn global automatic block transmission control register

This register is used to control the automatic block transmission (ABT) operation.

Access This register can be read/written in 16-bit units.

Address <FCNn_base> + 0 8018_H

Initial Value 0000_H. The register is initialized by any reset.

(a) FCNnGMABCTL read

15	14	13	12	11	10	9	8
0	0	0	0	0	0	0	0
7	6	5	4	3	2	1	0
0	0	0	0	0	0	FCNnGM ABCLRF	FCNnGM ABABTT

FCNnGMABCLRF	Automatic block transmission engine clear status bit
0	Clearing the automatic transmission engine is completed.
1	The automatic transmission engine is being cleared.

Note Start automatic transmission engine clearance by FCNnGMABCTL.FCNnGMABCLAT = 1 while FCNnGMABCTL.FCNnGMABCLRF = 0. The operation is not guaranteed if FCNnGMABCLRF is set to 1 while FCNnGMABCLRF = 1.

FCNnGMABABTT	Automatic block transmission status bit
0	Automatic block transmission is stopped.
1	Automatic block transmission is under execution.

(b) FCNnGMABCTL write

15	14	13	12	11	10	9	8
0	0	0	0	0	0	FCNnGM ABSEAC	FCNnGM ABSEAT
7	6	5	4	3	2	1	0
0	0	0	0	0	0	0	FCNnGM ABCLAT

Note When the automatic block transmission engine is cleared by setting FCNnGMABCTL.FCNnGMABSEAC to 1, FCNnGMABCLRF is automatically set, and cleared to 0 as soon as the requested clearing processing is completed.

- Cautions**
1. Before changing the normal operation mode with ABT to the initialization mode, be sure to set the FCNnGMABCTL register to the default value (0000_H) and confirm the FCNnGMABCTL register is surely initialized to the default value (0000_H).
 2. Do not start automatic block transmission in the initialization mode. If automatic block transmission is started in the initialization mode, the operation is not guaranteed after the CAN Controller has entered the normal operation mode with ABT.
 3. Do not start automatic block transmission while FCNnCMCLCTL.FCNnCMCLSSTS is set to 1 (transmission in progress). Confirm FCNnCMCLSSTS = 0 directly in advance before starting automatic block transmission.

FCNnGMABSEAC	Automatic block transmission engine clear request bit
0	The automatic block transmission engine is in idle status or under operation.
1	Request to clear the automatic block transmission engine. After the automatic block transmission engine has been cleared, automatic block transmission is started from message buffer 0 by setting the FCNnGMABCTL.FCNnGMABABTT = 1.

FCNnGMABSEAT	FCNnGMABCLAT	Automatic block transmission start bit
0	1	Request to stop automatic block transmission.
1	0	Request to start automatic block transmission.
Other than above		No change of FCNnGMABCTL.FCNnGMABABTT.

(4) FCNnGMADCTL - FCNn global automatic block transmission delay register

This register is used to set the interval at which the data of the message buffer assigned to ABT is to be transmitted in the normal operation mode with ABT.

Access This register can be read/written in 8-bit units.

Address <FCNn_base> + 0020_H

Initial Value 00_H. The register is initialized by any reset.

7	6	5	4	3	2	1	0
0	0	0	0	FCNnGMADSSAD[3:0]			

FCNnGMADSSAD[3:0]	Data frame interval during automatic block transmission in DBT ^a
0000 _B	0 DBT (default value)
0001 _B	2 ⁵ DBT
0010 _B	2 ⁶ DBT
0011 _B	2 ⁷ DBT
0100 _B	2 ⁸ DBT
0101 _B	2 ⁹ DBT
0110 _B	2 ¹⁰ DBT
0111 _B	2 ¹¹ DBT
1000 _B	2 ¹² DBT
Other than above	Setting prohibited

a) Unit: Data bit time (DBT)

- Cautions**
1. Do not change the contents of the FCNnGMADCTL register while FCNnGMABCTL.FCNnGMABCLRF = 1 (clearing of ABT in progress).
 2. The timing at which the ABT message is actually transmitted onto the CAN bus differs depending on the status of transmission from the other station or how a request to transmit a message other than an ABT message is made.

(5) FCNnDNBMRXk – FCNn global data update bit monitor register (k = 0 to 3)

These registers are used to read the data update bits of several message buffers at a time, globally.

Access These registers can be read in 32-bit units.

Address FCNnDNBMRX0: <FCNn_base> + 1 00C0_H

FCNnDNBMRX1: <FCNn_base> + 1 00D0_H

Following registers are available only with m = 128 message buffers:

FCNnDNBMRX2: <FCNn_base> + 1 00E0_H

FCNnDNBMRX3: <FCNn_base> + 1 00F0_H

Initial Value 0000_H. This register is initialized by any reset.

FCNnDNBMSSDN[31:0]	Message buffer data update bit
0	No remote or data frame has been stored into the message buffer.
1	A remote or data frame has been stored into the message buffer.

24.5.2 FCN module registers

(1) FCNnCMMKCTLaH - FCNn module mask control register

These registers are used to extend the number of receivable messages into the same message buffer by masking part of the identifier (ID) comparison of a message and invalidating the ID of the masked part.

Two 16-bit registers FCNnCMMKCTLaH (a = 01 to 16) can also be accessed via a single 32-bit access to the registers FCNnCMMKCTLaW (a = 01, 03, 05, 07, 09, 11, 13, 15).

Access The FCNnCMMKCTLaH registers can be read/written in 16-bit units.
The FCNnCMMKCTLaW registers can be read/written in 32-bit units.

Address FCNnCMMKCTL01H: <FCNn_base> + 0 8300_H
 FCNnCMMKCTL02H: <FCNn_base> + 0 8308_H
 FCNnCMMKCTL03H: <FCNn_base> + 0 8310_H
 FCNnCMMKCTL04H: <FCNn_base> + 0 8318_H
 FCNnCMMKCTL05H: <FCNn_base> + 0 8320_H
 FCNnCMMKCTL06H: <FCNn_base> + 0 8328_H
 FCNnCMMKCTL07H: <FCNn_base> + 0 8330_H
 FCNnCMMKCTL08H: <FCNn_base> + 0 8338_H
 FCNnCMMKCTL09H: <FCNn_base> + 0 8340_H
 FCNnCMMKCTL10H: <FCNn_base> + 0 8348_H
 FCNnCMMKCTL11H: <FCNn_base> + 0 8350_H
 FCNnCMMKCTL12H: <FCNn_base> + 0 8358_H
 FCNnCMMKCTL13H: <FCNn_base> + 0 8360_H
 FCNnCMMKCTL14H: <FCNn_base> + 0 8368_H
 FCNnCMMKCTL15H: <FCNn_base> + 0 8370_H
 FCNnCMMKCTL16H: <FCNn_base> + 0 8378_H

FCNnCMMKCTL01W: <FCNn_base> + 1 0300_H
 FCNnCMMKCTL03W: <FCNn_base> + 1 0310_H
 FCNnCMMKCTL05W: <FCNn_base> + 1 0320_H
 FCNnCMMKCTL07W: <FCNn_base> + 1 0330_H
 FCNnCMMKCTL09W: <FCNn_base> + 1 0340_H
 FCNnCMMKCTL11W: <FCNn_base> + 1 0350_H
 FCNnCMMKCTL13W: <FCNn_base> + 1 0360_H
 FCNnCMMKCTL15W: <FCNn_base> + 1 0370_H

Initial Value 0000_H for FCNnCMMKCTLaH. This register is initialized by any reset.
0000 0000_H for FCNnCMMKCTLaW. This register is initialized by any reset.

(a) FCNnCMMKCTLaH (a = 01, 03, 05, 07, 09, 11, 13, 15)**(b) FCNnCMMKCTLaH (a = 02, 04, 06, 08, 10, 12, 14, 16)****(c) FCNnCMMKCTLaW (a = 01, 03, 05, 07, 09, 11, 13, 15)**

FCNnCMMKSSID[i] ^a	Mask pattern setting of ID bit
0	The ID bit <i>i</i> of the message buffer <i>m</i> set by FCNnMmSSID[<i>i</i>] are compared with the ID bits of the received message frame.
1	The ID bit <i>i</i> of the message buffer <i>m</i> set by FCNnMmSSID[<i>i</i>] are not compared with the ID bits of the received message frame (they are masked).

a) $i = [28:0]$

Note Masking is always defined by an ID length of 29 bits. If a mask is assigned to a message with a standard ID, FCNnCMMKSSID[17:0] are ignored. Therefore, only FCNnCMMKSSID[28:18] of the received ID are masked. The same mask can be used for both the standard and extended IDs.

(2) FCNnCMCLCTL - FCNn module control register

This register is used to control the operation mode of the FCN module.

Access This register can be read/written in 16-bit units.

Address <FCNn_base> + 0 8240_H

Initial Value 0000_H. The register is initialized by any reset.

(a) FCNnCMCLCTL read

15	14	13	12	11	10	9	8
0	0	0	0	0	0	FCNnCM CLSSRS	FCNnCM CLSSTS
7	6	5	4	3	2	1	0
FCNnCM CLERCF	FCNnCM CLALBF	FCNnCM CLVALF	FCNnCM CLMDPF[1:0]		FCNnCM CLMDOF[2:0]		

FCNnCMCLSSRS	Reception status bit
0	Reception is stopped.
1	Reception is in progress.

- Notes**
1. FCNnCMCLSSRS is set to 1 under the following conditions (timing)
 - The SOF bit of a receive frame is detected
 - On occurrence of arbitration loss during a transmit frame
 2. FCNnCMCLSSRS is cleared to 0 under the following conditions (timing)
 - When a recessive level is detected at the second bit of the interframe space
 - On transition to the initialization mode at the first bit of the interframe space

FCNnCMCLSSTS	Transmission status bit
0	Transmission is stopped.
1	Transmission is in progress.

- Notes**
1. FCNnCMCLSSTS is set to 1 under the following conditions (timing)
 - The SOF bit of a transmit frame is detected
 2. FCNnCMCLSSTS is cleared to 0 under the following conditions (timing)
 - During transition to bus-off state
 - On occurrence of arbitration loss in transmit frame
 - On detection of recessive level at the second bit of the interframe space
 - On transition to the initialization mode at the first bit of the interframe space

FCNnCMCLERCF	Error counter clear bit
0	The FCNnCMERCNT and FCNnCMINSTR registers are not cleared in the initialization mode.
1	The FCNnCMERCNT and FCNnCMINSTR registers are cleared in the initialization mode.

Caution FCNnCMCLERCF is used to clear the error counter FCNnCMERCNT and information register FCNnCMINSTR for re-initialization or forced recovery from the bus-off state. The error counter and the information register can be cleared under the following conditions (by setting FCNnCMCLERCF):

- In the initialization mode during the bus-off period
- In the initialization mode after the FCN module starts up (by changing FCNnGMCLPWOM from 0 to 1)
- In the initialization mode entered after all the transmission requests have been cleared in accordance with the transmission abort processing shown in Table 24-24 “Transmission abort processing (except normal operation mode with ABT)” in an operation mode. (In normal operation mode with ABT, clear all the transmission requests in accordance with the transmission abort processing shown in Table 24-25 “Transmission abort processing (normal operation mode with ABT) - Repeat option for aborted message”.)

- Notes**
1. When the FCNnCMERCNT and FCNnCMINSTR registers have been cleared, FCNnCMCLERCF is also cleared to 0 automatically.
 2. FCNnCMCLERCF can be set to 1 at the same time as a request to change the initialization mode to an operation mode is made.
 3. FCNnCMCLERCF is read-only in the FCN sleep mode or FCN stop mode.
 4. The error counter can also be cleared by a normal shutdown or forced shutdown of the CAN controller.

FCNnCMCLALBF	Bit to set operation in case of arbitration loss
0	Re-transmission is not executed in case of an arbitration loss in the single-shot mode.
1	Re-transmission is executed in case of an arbitration loss in the single-shot mode.

Note FCNnCMCLALBF is valid only in the single-shot mode.

FCNnCMCLVALF	Valid receive message frame detection bit
0	A valid message frame has not been received since FCNnCMCLVALF was last cleared to 0.
1	A valid message frame has been received since FCNnCMCLVALF was last cleared to 0.

- Notes**
1. Detection of a valid receive message frame is not dependent upon storage in the receive message buffer (data frame/remote frame) or transmit message buffer (remote frame).
 2. If only two CAN nodes are connected to the CAN bus with one transmitting a message frame in the normal mode and the other in the receive-only mode, FCNnCMCLVALF is not set to 1 before the transmitting node enters the error passive state, because in receive-only mode no acknowledge is generated.
 3. To clear FCNnCMCLVALF, set FCNnCMCLLVL to 1 first and confirm that FCNnCMCLVALF is cleared. If it is not cleared, perform clearing processing again.

FCNnCMCLMDPF[1:0]	Power save mode
00 _B	No power save mode is selected.
01 _B	FCN sleep mode
10 _B	Setting prohibited
11 _B	FCN stop mode

- Cautions**
1. Transition to and from the FCN stop mode must be made via FCN sleep mode. A request for direct transition to and from the FCN stop mode is ignored.
 2. The FCNnGMCLSSMO flag of FCNnGMCLCTL must be checked after releasing a power save mode, prior to access the message buffers again.
 3. FCN sleep mode requests are kept pending, until cancelled by software or entered on appropriate bus condition (bus idle). Software can check the actual status by reading FCNnCMCLMDPF[1:0].
 4. Power save mode cannot be set in combination with the change of operation mode. Be sure to perform these operations in different steps.

Note When the system transitions from initialization mode to a communication mode, the FCN module participates in communication after first confirming the CAN bus idle period. Although it is possible to transition to sleep mode before the idle period has been confirmed, in this case, the wakeup condition will always change from recessive level to dominant level.

FCNnCMCLMDOF[2:0]	Operation mode
000 _B	No operation mode is selected (FCN module is in the initialization mode).
001 _B	Normal operation mode
010 _B	Normal operation mode with automatic block transmission function (normal operation mode with ABT)
011 _B	Receive-only mode
100 _B	Single-shot mode
101 _B	Self-test mode
Other than above	Setting prohibited

- Cautions**
1. Transit to initialization mode or power saving modes may take some time. Be sure to verify the success of mode change by reading the values, before proceeding.
 2. If initialization mode is set while receiving data in operation mode, data in the message buffer that sets the FCNnMmDTNF flag might be received last. However, the receive history list is cleared upon transition to operation mode. It is therefore necessary to confirm that initialization mode was set by reading the operation mode. Before restarting operation mode, make sure to clear all FCNnMmDTNF flags in every valid reception message buffer.

Note FCNnCM.FCNnCMCLMDOF[2:0] are read-only in the FCN sleep mode or FCN stop mode.

(b) FCNnCMCLCTL write

15	14	13	12	11	10	9	8
FCNnCM CLSERC	FCNnCM CLSEAL	0	FCNnCM CLSEPS[1:0]		FCNnCM CLSEOP[2:0]		
7	6	5	4	3	2	1	0
0	FCNnCM CLCLAL	FCNnCM CLCLVL	FCNnCM CLCLPS[1:0]		FCNnCM CLCLOP[2:0]		

FCNnCMCLSERC	Setting of FCNnCMCLERCF bit
1	FCNnCMCLERCF is set to 1.
Other than above	FCNnCMCLERCF is not changed.

FCNnCMCLSEAL	FCNnCMCLCLAL	Setting of FCNnCMCLALBF bit
0	1	FCNnCMCLALBF is cleared to 0.
1	0	FCNnCMCLALBF is set to 1.
Other than above		FCNnCMCLALBF is not changed.

FCNnCMCLCLVL	Setting of FCNnCMCLVALF bit
0	FCNnCMCLVALF is not changed.
1	FCNnCMCLVALF is cleared to 0.

FCNnCMSESEPS0	FCNnCMCLCLPS0	Setting of FCNnCMCLMDPF0 bit
0	1	FCNnCMCLMDPF0 is cleared to 0.
1	0	FCNnCMCLMDPF0 is set to 1.
Other than above		FCNnCMCLMDPF0 is not changed.

FCNnCMSESEPS1	FCNnCMCLCLPS1	Setting of FCNnCMCLMDPF1 bit
0	1	FCNnCMCLMDPF1 is cleared to 0.
1	0	FCNnCMCLMDPF1 is set to 1.
Other than above		FCNnCMCLMDPF1 is not changed.

FCNnCMCLSEOP0	FCNnCMCLCLOP0	Setting of FCNnCMCLMDOF0 bit
0	1	FCNnCMCLMDOF0 is cleared to 0.
1	0	FCNnCMCLMDOF0 is set to 1.
Other than above		FCNnCMCLMDOF0 is not changed.

FCNnCMCLSEOP1	FCNnCMCLCLOP1	Setting of FCNnCMCLMDOF1 bit
0	1	FCNnCMCLMDOF1 is cleared to 0.
1	0	FCNnCMCLMDOF1 is set to 1.
Other than above		FCNnCMCLMDOF1 is not changed.

FCNnCMCLSEOP2	FCNnCMCLCLOP2	Setting of FCNnCMCLMDOF2 bit
0	1	FCNnCMCLMDOF2 is cleared to 0.
1	0	FCNnCMCLMDOF2 is set to 1.
Other than above		FCNnCMCLMDOF2 is not changed.

(3) FCNnCMLCSTR - FCNn module last error information register

This register provides the error information of the CAN protocol.

Access This register can be read/written in 8-bit units.

Address <FCNn_base> + 0 0248_H

Initial Value 00_H. The register is initialized by any reset.

7	6	5	4	3	2	1	0
0	0	0	0	0	FCNnCMLCSSL[2:0]		

- Notes**
1. The contents of the FCNnCMLCSTR register are not cleared when the FCN module changes from an operation mode to the initialization mode.
 2. If an attempt is made to write a value other than 00_H to the FCNnCMLCSTR register by software, the access is ignored.

FCNnCMLCSSL[2:0]	Last CAN protocol error information
000 _B	No error
001 _B	Stuff error
010 _B	Form error
011 _B	ACK error
100 _B	Bit error. (The FCN module tried to transmit a recessive-level bit as part of a transmit message (except the arbitration field), but the value on the CAN bus is a dominant-level bit.)
101 _B	Bit error. (The FCN module tried to transmit a dominant-level bit as part of a transmit message, ACK bit, error frame, or overload frame, but the value on the CAN bus is a recessive-level bit.)
110 _B	CRC error
111 _B	Undefined

(4) FCNnCMINSTR - FCNn module information register

This register indicates the status of the FCN module.

Access This register is read-only in 8-bit units.

Address <FCNn_base> + 0 024C_H

Initial Value 00_H. The register is initialized by any reset.

7	6	5	4	3	2	1	0
0	0	0	FCNnCM INBOFF	FCNnCM INSSTE[1:0]	FCNnCM INSSRE[1:0]		

FCNnCMINBOFF	Bus-off state bit
0	Not bus-off state (transmit error counter ≤ 255). (The value of the transmit counter is less than 256.)
1	Bus-off state (transmit error counter > 255). (The value of the transmit counter is 256 or more.)

FCNnCMINSSTE[1:0]	Transmission error counter status bit
00 _B	The value of the transmission error counter is less than that of the warning level (< 96).
01 _B	The value of the transmission error counter is in the range of the warning level (96 to 127).
10 _B	Undefined
11 _B	The value of the transmission error counter is in the range of the error passive or bus-off status (≥ 128).

FCNnCMINSSRE[1:0]	Reception error counter status bit
00 _B	The value of the reception error counter is less than that of the warning level (< 96).
01 _B	The value of the reception error counter is in the range of the warning level (96 to 127).
10 _B	Undefined
11 _B	The value of the reception error counter is in the error passive range (≥ 128).

(5) FCNnCMERCNT - FCNn module error counter register

This register indicates the count value of the transmission/reception error counter.

Access This register is read-only in 16-bit units.

Address <FCNn_base> + 0 8250_H

Initial Value 0000_H. The register is initialized by any reset.

FCNnCMERRPSF	Reception error passive status bit
0	The reception error counter is not in the error passive range (< 128)
1	The reception error counter is in the error passive range (≥ 128)

FCNnCMERRECF[6:0]	Reception error counter bit
0 to 127	The reception error count. These bits reflect the status of the reception error counter. The error count is defined by the CAN protocol.

Note FCNnCMERRECF[6:0] are invalid in the reception error passive state (FCNnCMINSTR.FCNnCMINSSRE[1:0] = 11_B).

FCNnCMERTECF[7:0]	Transmission error counter bit
0 to 255	Number of transmission errors. These bits reflect the status of the transmission error counter. The number of errors is defined by the CAN protocol.

Note FCNnCMERTECF[7:0] are invalid in the bus-off state (FCNnCMINSTR.FCNnCMINBOFF = 1).

(6) FCNnCMIECTL - FCNn module interrupt enable register

This register is used to enable or disable the interrupts of the FCN module.

Access This register can be read/written in 16-bit units.

Address <FCNn_base> + 0 8258_H

Initial Value 0000_H. The register is initialized by any reset.

(a) FCNnCMIECTL read

15	14	13	12	11	10	9	8
0	0	0	0	0	0	0	0
7	6	5	4	3	2	1	0
0	FCNnCMIEINTF[6:0]						

FCNnCMIEINTF[6:0]	FCN module interrupt enable bit
0	Output of the interrupt corresponding to interrupt status register FCNnCMISCTL is disabled.
1	Output of the interrupt corresponding to interrupt status register FCNnCMISCTL is enabled.

(b) FCNnCMIECTL write

15	14	13	12	11	10	9	8
0	FCNnCMIESEIE[6:0]						
7	6	5	4	3	2	1	0
0	FCNnCMIECLIE[6:0]						

FCNnCMIESEIE[6:0]	FCNnCMIECLIE[6:0]	Setting of FCNnCMIEINTF[6:0] bit
0	1	FCNnCMIEINTF[6:0] bit is cleared to 0.
1	0	FCNnCMIEINTF[6:0] bit is set to 1.
Other than above		FCNnCMIEINTF[6:0] bit is not changed.

(7) FCNnCMISCTL - FCNn module interrupt status register

This register indicates the interrupt status of the FCN module.

Access This register can be read/written in 16-bit units.

Address <FCNn_base> + 0 8260_H

Initial Value 0000_H. The register is initialized by any reset.

(a) FCNnCMISCTL read

15	14	13	12	11	10	9	8
0	0	0	0	0	0	0	0
7	6	5	4	3	2	1	0
0	FCNnCMISITSF[6:0]						

FCNnCMISITSF[6:0]	FCN interrupt status bit
0	No related interrupt source event is pending
1	A related interrupt source event is pending

Interrupt status bit	Related interrupt source event
FCNnCMISITSF6	FCN module transmission abort interrupt status bit
FCNnCMISITSF5	Wakeup interrupt from FCN sleep mode ^a
FCNnCMISITSF4	Arbitration loss interrupt
FCNnCMISITSF3	CAN protocol error interrupt
FCNnCMISITSF2	CAN error status interrupt
FCNnCMISITSF1	Interrupt on completion of reception of valid message frame to message buffer m
FCNnCMISITSF0	Interrupt on normal completion of transmission of message frame from message buffer m

a) FCNnCMISITSF5 is set only when the FCN module is woken up from the FCN sleep mode by a CAN bus operation. It is not set when the FCN sleep mode has been released by software.

(b) FCNnCMISCTL write

15	14	13	12	11	10	9	8
0	0	0	0	0	0	0	0
7	6	5	4	3	2	1	0
0	FCNnCMISITSF[6:0]						

FCNnCMISCLTS[6:0]	Clearing of FCNnCMISITSF[6:0]
0	FCNnCMISITSF[6:0] bits are not changed.
1	FCNnCMISITSF[6:0] bits are cleared to 0.

Caution Clear the status bit of this register by software, when the confirmation of each status is necessary in the interrupt processing, because these bits are not cleared automatically.

(8) FCNnCMBRPRS - FCNn module bit rate prescaler register

This register is used to select the CAN protocol layer basic system clock (f_{TQ}). The communication baud rate is set to the FCNnCMBTCTL register.

Access This register can be read/written in 8-bit units.

Address <FCNn_base> + 0 0268_H

Initial Value FF_H. The register is initialized by any reset.

FCNnCMBRPRS[7:0]	CAN protocol layer basic system clock (f_{TQ})
0	$f_{CANPRE}/1$
1	$f_{CANPRE}/2$
n	$f_{CANPRE}/(n+1)$
:	:
255	$f_{CANPRE}/256$ (default value)

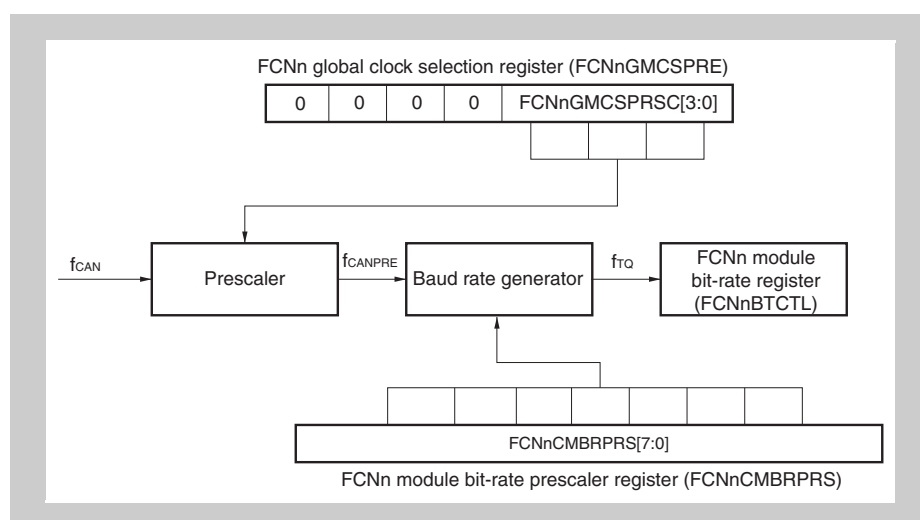

Figure 24-2 FCN module clock

Note f_{CAN} : Clock supplied to FCN
 f_{CANPRE} : PRE-CAN protocol layer basic system clock
 f_{TQ} : CAN protocol layer basic system clock

Caution FCNnCMBRPRS can be write-accessed only in the initialization mode.

(9) FCNnCMBTCTL - FCNn module bit rate register

This register is used to control the data bit time of the communication baud rate.

Access This register can be read/written in 16-bit units.

Address <FCNn_base> + 0 8270_H

Initial Value 370F_H. The register is initialized by any reset.

15	14	13	12	11	10	9	8
0	0	FCNnCM BTJWLG[1:0]		0	FCNnCM BTS2LG[2:0]		
7	6	5	4	3	2	1	0
0	0	0	0	FCNnCMBTS1LG[3:0]			

Figure 24-3 Data bit time

FCNnCMBTJWLG[1:0]	Length of synchronization jump width (SJW)
00 _B	1T _Q
01 _B	2T _Q
10 _B	3T _Q
11 _B	4T _Q (default value)

FCNnCMBTS2LG[2:0]	Length of time segment 2 (TSEG2)
000 _B	1T _Q
001 _B	2T _Q
010 _B	3T _Q
011 _B	4T _Q
100 _B	5T _Q
101 _B	6T _Q
110 _B	7T _Q
111 _B	8T _Q (default value)

FCNnCMBTS1LG[3:0]	Length of time segment 1 (TSEG1)
0000 _B	Setting prohibited
0001 _B	2T _Q ^a
0010 _B	3T _Q ^a
0011 _B	4T _Q
0100 _B	5T _Q
0101 _B	6T _Q
0110 _B	7T _Q
0111 _B	8T _Q
1000 _B	9T _Q
1001 _B	10T _Q
1010 _B	11T _Q
1011 _B	12T _Q
1100 _B	13T _Q
1101 _B	14T _Q
1110 _B	15T _Q
1111 _B	16T _Q (default value)

a) This setting must not be made when the FCNnCMBRPRS register = 00_H

Note T_Q = 1/f_{TQ} (f_{TQ}: CAN protocol layer basic system clock)

(10) FCNnCMLISTR - FCNn module last in-pointer register

This register indicates the number of the message buffer in which a data frame or a remote frame was last stored.

Access This register is read-only in 8-bit units.

Address <FCNn_base> + 0 0278_H

Initial Value Undefined.

FCNnCMLISSLR[7:0]	Last in-pointer register of receive history list
0 to 63 ^a 0 to 127 ^b	Reading the FCNnCMLISTR register obtains the number of the message buffer storing the last data frame or remote frame to be received.

a) On 64 message buffer FCN.

b) On 128 message buffer FCN.

Note The read value of FCNnCMLISTR is undefined if a data frame or a remote frame has never been received and stored in the message buffer. If FCNnCMRGRX.FCNnCMRGSSPM is set to 1 after the FCN module has changed from the initialization mode to an operation mode, therefore, the read value of FCNnCMLISTR is undefined.

(11) FCNnCMRGRX - FCNn module receive history list register

This register is used to read the receive history list (RHL).

Access This register can be read/written in 16-bit units.

Address <FCNn_base> + 0 8280_H

Initial Value xx02_H. The register is initialized by any reset.

(a) FCNnCMRGRX read

15	14	13	12	11	10	9	8
FCNnCMRGSSPT[7:0]							
7	6	5	4	3	2	1	0
0	0	0	0	0	0	FCNnCMRGSSPM	FCNnCMRGRVFF

FCNnCMRGSSPT[7:0]	Receive history list read pointer
0 to 63 ^a 0 to 127 ^b	When FCNnCMRGRX is read, the contents of the element indexed by the receive history list get pointer (FCNnCMRGRX.FCNnCMRGSSPT) of the receive history list are read. These contents indicate the number of the message buffer in which a data frame or a remote frame has been stored.

- a) On 64 message buffer FCN.
b) On 128 message buffer FCN.

FCNnCMRGSSPM ^a	Receive history list pointer match
0	The receive history list has at least one message buffer number that has not been read.
1	The receive history list has no message buffer numbers that have not been read.

- a) The read value of FCNnCMRGSSPT[7:0] is invalid when FCNnCMRGSSPM = 1.

FCNnCMRGRVFF ^a	Receive history list overflow bit ^b
0	All the message buffer numbers that have not been read are preserved. All the numbers of the message buffers in which a new data frame or remote frame has been received and stored are recorded to the receive history list (the receive history list has a vacant element).
1	At least (i) entries have been stored since the host processor has serviced the RHL last time (i.e. read FCNnCMRGRX). The first (i-1) entries are sequentially stored while the last entry can have been overwritten whenever newly received message is stored, because all buffer numbers are stored at position (i) , when FCNnCMRGRVFF is set. Thus the sequence of receptions can not be recovered completely now.

- a) If all the receive history entries have been read by the FCNnCMRGRX register while FCNnCMRGRVFF is set (1), FCNnCMRGSSPM is not cleared even if a new message is received.
b) i = 47 on 64 message buffer FCN;
i = 95 on 128 message buffer FCN.

(b) FCNnCMRGRX write

15	14	13	12	11	10	9	8
0	0	0	0	0	0	0	0
7	6	5	4	3	2	1	0
0	0	0	0	0	0	0	FCNnCMRGCLR

FCNnCMRGCLR	Clearing of FCNnCMRGRVFF bit
0	FCNnCMRGRVFF bit is not changed.
1	FCNnCMRGRVFF bit is cleared to 0.

(12) FCNnCMLOSTR - FCNn module last out-pointer register

This register indicates the number of the message buffer, from which a data frame or a remote frame was transmitted last.

Access This register is read-only in 8-bit units.

Address <FCNn_base> + 0 0288_H

Initial Value Undefined

FCNnCMLOSSLT[7:0]	Last out-pointer of transmit history list
0 to 63 ^a 0 to 127 ^b	When the FCNnCMLOSTR register is read, the contents of the element indexed by the last out-pointer (FCNnCMLOSTR[7:0]) of the receive history list are read. These contents indicate the number of the message buffer to which a data frame or a remote frame was transmitted last.

- a) On 64 message buffer FCN.
 b) On 128 message buffer FCN.

Note The value read from the FCNnCMLOSTR register is undefined if a data frame or remote frame has never been transmitted from a message buffer.

(13) FCNnCMTGTX - FCNn module transmit history list register

This register is used to read the transmit history list (THL).

Access This register can be read/written in 16-bit units.

Address <FCNn_base> + 0 8290_H

Initial Value xx02_H. The register is initialized by any reset.

(a) FCNnCMTGTX read

15	14	13	12	11	10	9	8
FCNnCMTGSSPT[7:0]							
7	6	5	4	3	2	1	0
0	0	0	0	0	0	FCNnCM TGSSPM	FCNnCM TGVFF

FCNnCMTGSSPT[7:0]	Transmit history list read pointer
0 to 63 ^a 0 to 127 ^b	When the FCNnCMTGTX register is read, the contents of the element indexed by the read pointer (FCNnCMTGSSPT[7:0]) of the transmit history list are read. These contents indicate the number of the message buffer to which a data frame or a remote frame was transmitted last.

- a) On 64 message buffer FCN.
b) On 128 message buffer FCN.

FCNnCMTGSSPM ^a	Transmit history pointer match
0	The transmit history list has at least one message buffer number that has not been read.
1	The transmit history list has no message buffer numbers that have not been read.

- a) The read value of FCNnCMTGSSPT[7:0] is invalid when the FCNnCMTGSSPM = 1.

FCNnCMTGTVFF ^a	Transmit history list overflow bit ^b
0	All the message buffer numbers that have not been read are preserved. All the numbers of the message buffers to which a new data frame or remote frame has been transmitted are recorded to the transmit history list (the transmit history list has a vacant element).
1	At least (i) entries have been stored since the host processor has serviced the THL last time (i.e. read FCNnCMTGTX). The first (i-1) entries are sequentially stored while the last entry can have been overwritten whenever newly received message is stored, because all buffer numbers are stored at position (i) , when FCNnCMTGTVFF is set. Thus the sequence of receptions can not be recovered completely now.

- a) If FCNnCMTGTVFF is set, FCNnCMTGSSPM is no longer cleared on message transmission, but FCNnCMTGSSPM is still set, if all entries of FCNnCMTGTX are read by software.
b) i = 15 on 64 message buffer FCN;
i = 31 on 128 message buffer FCN.

Note Transmission from message buffers ...

- 0 to 16 (for 64 message buffer FCN)
- 0 to 32 (for 128 message buffer FCN)

... is not recorded to the transmit history list in the normal operation mode with ABT.

(b) FCNnCMTGTX write

15	14	13	12	11	10	9	8
0	0	0	0	0	0	0	0
7	6	5	4	3	2	1	0
0	0	0	0	0	0	0	FCNnCM TGCLTV

FCNnCMTGCLTV	Setting of FCNnCMTGTVFF bit
0	FCNnCMTGTVFF bit is not changed
1	FCNnCMTGTVFF bit is cleared to 0

(14) FCNnCMTSCTL - FCNn module time stamp register

This register is used to control the time stamp function.

Access This register can be read/written in 16-bit units.

Address <FCNn_base> + 0 8298_H

Initial Value 0000_H. The register is initialized by any reset.

(a) FCNnCMTSCTL read

15	14	13	12	11	10	9	8
0	0	0	0	0	0	0	0
7	6	5	4	3	2	1	0
0	0	0	0	0	FCNnCM TSLOKE	FCNnCM TSSELE	FCNnCM TSTSGE

Note The lock function of the time stamp function must not be used when the FCN module is in the normal operation mode with ABT.

FCNnCMTSLOKE	Time stamp lock function enable bit
0	Time stamp lock function stopped. The TSOUT signal is toggled each time the selected time stamp capture event occurs.
1	Time stamp lock function enabled. The TSOUT signal is toggled each time the selected time stamp capture event occurs. However, the TSOUT output signal is locked when a data frame has been correctly received to message buffer 0 ^a .

a) FCNnCMTTSGE is automatically cleared to 0.

FCNnCMTSSELE	Time stamp capture event selection bit
0	The timestamp capture event is SOF.
1	The time stamp capture event is the last bit of EOF.

FCNnCMTTSGE	TSOUT operation setting bit
0	TSOUT toggle operation is disabled.
1	TSOUT toggle operation is enabled.

(b) FCNnCMTSCTL write

15	14	13	12	11	10	9	8
0	0	0	0	0	FCNnCM TSSELK	FCNnCM TSSES	FCNnCM TSSETS
7	6	5	4	3	2	1	0
0	0	0	0	0	FCNnCM TSCLLK	FCNnCM TSCLSL	FCNnCM TSC LTS

FCNnCMTSSELK	FCNnCMTSCLK	Setting of FCNnCMTSLOKE bit
0	1	FCNnCMTSLOKE is cleared to 0.
1	0	FCNnCMTSLOKE is set to 1.
Other than above		FCNnCMTSLOKE is not changed.

FCNnCMTSSESL	FCNnCMTSCLSL	Setting of FCNnCMTSSELE bit
0	1	FCNnCMTSSELE is cleared to 0.
1	0	FCNnCMTSSELE is set to 1.
Other than above		FCNnCMTSSELE is not changed.

FCNnCMTSSETS	FCNnCMTSCLTS	Setting of FCNnCMTSTSGE bit
0	1	FCNnCMTSTSGE is cleared to 0.
1	0	FCNnCMTSTSGE is set to 1.
Other than above		FCNnCMTSTSGE is not changed.

24.5.3 FCN message buffer registers

(1) FCNnMmDATxB/H/W, FCNn message data byte registers

These registers are used to store the data of a transmit/receive message.

Access The FCNnMmDATxW registers can be read/written in 32-bit units.
The FCNnMmDATxH registers can be read/written in 16-bit units.
The FCNnMmDATxB registers can be read/written in 8-bit units.

Address FCNnMmDAT0B: $\langle \text{FCNn_base} \rangle + 0\ 1000_{\text{H}} + m \times 40_{\text{H}}$
FCNnMmDAT1B: $\langle \text{FCNn_base} \rangle + 0\ 1004_{\text{H}} + m \times 40_{\text{H}}$
FCNnMmDAT2B: $\langle \text{FCNn_base} \rangle + 0\ 1008_{\text{H}} + m \times 40_{\text{H}}$
FCNnMmDAT3B: $\langle \text{FCNn_base} \rangle + 0\ 100\text{C}_{\text{H}} + m \times 40_{\text{H}}$
FCNnMmDAT4B: $\langle \text{FCNn_base} \rangle + 0\ 1010_{\text{H}} + m \times 40_{\text{H}}$
FCNnMmDAT5B: $\langle \text{FCNn_base} \rangle + 0\ 1014_{\text{H}} + m \times 40_{\text{H}}$
FCNnMmDAT6B: $\langle \text{FCNn_base} \rangle + 0\ 1018_{\text{H}} + m \times 40_{\text{H}}$
FCNnMmDAT7B: $\langle \text{FCNn_base} \rangle + 0\ 101\text{C}_{\text{H}} + m \times 40_{\text{H}}$

FCNnMmDAT0H: $\langle \text{FCNn_base} \rangle + 0\ 9000_{\text{H}} + m \times 40_{\text{H}}$
FCNnMmDAT2H: $\langle \text{FCNn_base} \rangle + 0\ 9008_{\text{H}} + m \times 40_{\text{H}}$
FCNnMmDAT4H: $\langle \text{FCNn_base} \rangle + 0\ 9010_{\text{H}} + m \times 40_{\text{H}}$
FCNnMmDAT6H: $\langle \text{FCNn_base} \rangle + 0\ 9018_{\text{H}} + m \times 40_{\text{H}}$

FCNnMmDAT0W: $\langle \text{FCNn_base} \rangle + 1\ 1000_{\text{H}} + m \times 40_{\text{H}}$
FCNnMmDAT4W: $\langle \text{FCNn_base} \rangle + 1\ 1010_{\text{H}} + m \times 40_{\text{H}}$

Initial Value 0000 0000_H for FCNnMmDATxW. This register is initialized by any reset.
0000_H for FCNnMmDATxH. This register is initialized by any reset.
00_H for FCNnMmDATxB. This register is initialized by any reset.

(a) FCNnCMmDATxB (x = 0 to 7)

(b) FCNnCMmDATxH (x = 0, 2, 4, 6)

(c) FCNnCMmDATxW (x = 0, 4)

31	30	29	28	27	26	25	24
FCNnMmSSD0, FCNnMmSSD4							
23	22	21	20	19	18	17	16
FCNnMmSSD1, FCNnMmSSD5							
15	14	13	12	11	10	9	8
FCNnMmSSD2, FCNnMmSSD6							
7	6	5	4	3	2	1	0
FCNnMmSSD3, FCNnMmSSD7							

(2) FCNnMmDTLGB - FCNn message data length register m

This register is used to set the number of bytes of the data field of a message buffer (DLC).

Access This register can be read/written in 8-bit units.

Address <FCNn_base> + 0 1020_H + m x 40_H

Initial Value 00_H. This register is initialized by any reset.

7	6	5	4	3	2	1	0
0	0	0	0	FCNnMmDTLG[3:0]			

FCNnMmDTLG[3:0]	Data length of transmit/receive message
0000 _B	0 bytes
0001 _B	1 byte
0010 _B	2 bytes
0011 _B	3 bytes
0100 _B	4 bytes
0101 _B	5 bytes
0110 _B	6 bytes
0111 _B	7 bytes
1000 _B	8 bytes
1001 _B	Setting prohibited (If these bits are set during transmission, 8-byte data is transmitted regardless of the set FCNnMmDTLG[3:0] value when a data frame is transmitted. However, the DLC actually transmitted to the CAN bus is the DLC value set to this register.) ^{Note}
1010 _B	
1011 _B	
1100 _B	
1101 _B	
1110 _B	
1111 _B	

Note The data and DLC value actually transmitted to CAN bus are as follows.

Type of transmit frame	Length of transmit data	DLC transmitted
Data frame	Number of bits specified by FCNnMmDTLG[3:0] (However, 8 bytes if value ≥ 8)	FCNnMmDTLGB.FC NnMmDTLG[3:0] bits
Remote frame	0 bytes	

- Cautions**
1. Be sure to set bits 7 to 4 to 0000_B.
 2. Receive data is stored in as many FCNnMmDATxB register as the number of bytes (however, the upper limit is 8) corresponding to DLC of the received frame. The FCNnMmDATxB register in which no data is stored is undefined.
 3. On reception, FCNnMmDTLGB is updated according to the received frame.

(3) FCNnMmSTRB - FCNn message configuration register m

This register is used to specify the type of the message buffer and to set a mask.

Access This register can be read/written in 8-bit units.

Address <FCNn_base> + 0 1024_H + m x 40_H

Initial Value 00_H. This register is initialized by any reset.

7	6	5	4	3	2	1	0
FCNnMm SSOW	FCNnMm SSMT[3:0]			FCNnMm SSRT	0	FCNnMm SSAM	

FCNnMmSSOW	Overwrite control bit
0	The message buffer that has already received a data frame ^a is not overwritten by a newly received data frame. The newly received data frame is discarded.
1	The message buffer that has already received a data frame ^a is overwritten by a newly received data frame.

a) The “message buffer that has already received a data frame” is a receive message buffer whose FCNnMmCTL.FCNnMmDTNF bit has been set to 1.

Note A remote frame is received and stored, regardless of the setting of FCNnMmCTL.FCNnMmSSOW and FCNnMmCTL.FCNnMmDTNF. A remote frame that satisfies the other conditions is always received and stored in the corresponding message buffer (interrupt generated, FCNnMmDTNF flag set, FCNnMmDTLGB.FCNnMmDTLG[3:0] updated, and recorded to the receive history list).

FCNnMmSSRT	Remote frame request bit
0	Transmit / receive a data frame.
1	Transmit / receive a remote frame.

FCNnMmSTRB.FCNnMmSSRT specifies the type of message frame that is transmitted or received from/to a message buffer.

- Notes**
1. If the message buffer is defined as a transmit message buffer, and a remote frame shall be received into it, the FCNnMmSSRT bit must be cleared.
 2. Even if a valid remote frame has been received in a transmit message buffer, the FCNnMmSSRT bit of the transmit message buffer that has received the frame remains cleared to 0.
 3. Even if a remote frame whose ID matches has been received from the CAN bus, if the FCNnMmSSRT bit of a transmit message buffer is set to 1 (to transmit a remote frame), that remote frame is not stored in this transmit message buffer.
 4. If the message buffer is defined as a receive message buffer, the FCNnMmSSRT bit must be set, in order to receive remote frames instead of data frames.

FCNnMmSSMT[3:0]	Message buffer type setting bit
0000 _B	Transmit message buffer
0001 _B	Receive message buffer (no mask setting)
0010 _B	Receive message buffer (mask 1 set)
0011 _B	Receive message buffer (mask 2 set)
0100 _B	Receive message buffer (mask 3 set)
0101 _B	Receive message buffer (mask 4 set)
0110 _B	Receive message buffer (mask 5 set)
0111 _B	Receive message buffer (mask 6 set)
1000 _B	Receive message buffer (mask 7 set)
1001 _B	Receive message buffer (mask 8 set)
Other than above	Setting prohibited

Note The setting of FCNnMmSSMT is also valid to select masks in conjunction with remote frame reception. To receive remote frames in receive message buffers, the flag FCNnMmSSRT of the message buffer must be set.

FCNnMmSSAM	Message buffer assignment bit
0	Message buffer not used.
1	Message buffer used.

Caution Be sure to write 0 to bit 1.

(4) FCNnMmMID0H, FCNnMmMID1H, FCNnMmMID0W - FCNn message ID register m

These registers are used to set an identifier (ID).

Access FCNnMmMID0H, FCNnMmMID1H can be read/written in 16-bit units.
FCNnMmMID0W can be read/written in 32-bit units.

Address FCNnMmMID0H: $\langle \text{FCNn_base} \rangle + 0\ 9028_{\text{H}} + m \times 40_{\text{H}}$
FCNnMmMID1H: $\langle \text{FCNn_base} \rangle + 0\ 9030_{\text{H}} + m \times 40_{\text{H}}$

FCNnMmMID0W: $\langle \text{FCNn_base} \rangle + 1\ 1028_{\text{H}} + m \times 40_{\text{H}}$

Initial Value 0000_H for FCNnMmMID0H and FCNnMmMID1H. This register is initialized by any reset.
0000 0000_H for FCNnMmMID0W. This register is initialized by any reset.

(a) FCNnMmMID0H**(b) FCNnMmMID1H****(c) FCNnCMmMID0W**

FCNnMmSSIE	Format mode specification bit
0	Standard format mode (FCNnMmSSID[28:18]: 11 bits, FCNnMmSSID[17:0] are not used)
1	Extended format mode (FCNnMmSSID[28:0]: 29 bits)

FCNnMmSSID[28:0]	Message ID
FCNnMmSSID[28:18]	Standard ID value of 11 bits (when FCNnMmSSIE = 0)
FCNnMmSSID[28:0]	Extended ID value of 29 bits (when FCNnMmSSIE = 1)

- Cautions**
1. Be sure to write 0 to bits 14 and 13 of FCNnMmMID1H, respectively bits 30 and 29 of FCNnMmMID0W register.
 2. Be sure to align the ID value according to the given bit positions into this registers. Note that for standard ID, the ID value must be shifted to fit into FCNnMmSSID[28:18] bit positions.

(5) FCNnMmCTL - FCNn message control register m

This register is used to control the operation of the message buffer.

Access This register can be read/written in 16-bit units.

Address <FCNn_base> + 0 9038_H + m x 40_H

Initial Value 0000_H. This register is initialized by any reset.

(a) FCNnMmCTL read

15	14	13	12	11	10	9	8
0	0	FCNnMm MUCF	0	0	0	FCNnMm TCPF	0
7	6	5	4	3	2	1	0
0	FCNnMm NHMF	0	FCNnMm MOWF	FCNnMm IENF	FCNnMm DTNF	FCNnMm TRQF	FCNnMm RDYF

FCNnMmMUCF	Bit indicating that message buffer data is being updated
0	The FCN module is not updating the message buffer (no data is being received and stored).
1	The FCN module is updating the message buffer (data is being received and stored).

FCNnMmTCPF ^a	Transmission complete flag
0	Transmission failed. ^b
1	Transmission is complete.

- a) FCNnMmTCPF is cleared if FCNnMmRDYF is changed or FCNnMmTRQF is set.
 b) If transmission abort was requested by clearing the FCNnMmTRQF flag by the application, FCNnMmTCPF = 0 indicates a successful transmission abort.

FCNnMmNHMF	History mask flag ^a
0	Updating of the receive history list register FCNnCMRGRX and transmit history list register FCNnCMTGTX is not masked.
1	Updating of the receive history list register FCNnCMRGRX and transmit history list register FCNnCMTGTX is masked.

- a) If updating is masked, the transmit and receive history lists are not updated even when reception or transmission on the corresponding message buffer finishes.

FCNnMmMOWF	Message buffer overwrite status bit
0	The message buffer is not overwritten by a newly received data or remote frame.
1	The message buffer is overwritten by a newly received data or remote frame.

Note This bit will not be set (1) if a remote frame is received and stored in a transmit message buffer with FCNnMmDTNF = 1.

FCNnMmIENF	Message buffer interrupt request enable bit
0	Receive message buffer: Valid message reception completion interrupt disabled. Transmit message buffer: Normal message transmission completion interrupt and transmit abort interrupt disabled.
1	Receive message buffer: Valid message reception completion interrupt enabled. Transmit message buffer: Normal message transmission completion interrupt enabled.

Caution Set FCNnMmIENF and FCNnMmRDYF always separately.

FCNnMmDTNF	Message buffer data update bit
0	A new data frame or remote frame has been stored in the message buffer.
1	No new data frame or remote frame has been stored in the message buffer.

Caution Do not set FCNnMmDTNF to 1 by software. Be sure to write 0 to bit 10.

FCNnMmTRQF	Message buffer transmission request bit
0	No message frame transmitting request that is pending or being transmitted is in the message buffer.
1	The message buffer is holding transmission of a message frame pending or is transmitting a message frame.

- Cautions**
1. Do not set FCNnMmTRQF and FCNnMmRDYF to 1 at the same time. Set FCNnMmRDYF = 1 before setting FCNnMmTRQF = 1.
 2. Only set FCNnMmTRQF to 1 for transmit message buffers (not to buffers for which FCNnMmSSMT[3:0] ≠ 4'b0000 or FCNnMmSSAM = 0).

FCNnMmRDYF	Message buffer ready bit
0	The message buffer can be written by software. The FCN module cannot write to the message buffer.
1	Writing the message buffer by software is ignored (except a write access to the FCNnMmRDYF, FCNnMmTRQF, FCNnMmDTNF, and FCNnMmMOWF). The FCN module can write to the message buffer.

- Cautions**
1. Set FCNnMmIENF and FCNnMmRDYF always separately.
 2. Do not set FCNnMmTRQF and FCNnMmRDYF to 1 at the same time. Set FCNnMmRDYF = 1 before setting FCNnMmTRQF = 1.
 3. Do not clear FCNnMmRDYF to "0" during message transmission. Follow the transmission abort process about clearing FCNnMmRDYF for redefinition of the message buffer.
 4. Clearing of FCNnMmRDYF may take some time, depending on activity of the CAN Controller. Repeat the clearing access, until reading of FCNnMmRDYF confirms that the bit is cleared.
 5. Be sure that FCNnMmRDYF is cleared before writing to the other message buffer registers, by checking the status of FCNnMmRDYF.

(b) FCNnMmCTL write

15	14	13	12	11	10	9	8
0	FCNnMm SENH	0	0	FCNnMm SEIE	0	FCNnMm SETR	FCNnMm SERY
7	6	5	4	3	2	1	0
0	FCNnMm CLNH	0	FCNnMm CLMW	FCNnMm CLIE	FCNnMm CLDN	FCNnMm CLTR	FCNnMm CLRY

FCNnMmSENH	FCNnMmCLNH	Setting of FCNnMmNHMF bit
0	1	FCNnMmNHMF is cleared.
1	0	FCNnMmNHMF is set.
Other than above		FCNnMmNHMF is not changed.

FCNnMmCLMW	Setting of FCNnMmMOWF bit
0	FCNnMmMOWF is not changed.
1	FCNnMmMOWF is cleared.

FCNnMmSEIE	FCNnMmCLIE	Setting of FCNnMmIENF bit
0	1	FCNnMmIENF is cleared.
1	0	FCNnMmIENF is set.
Other than above		FCNnMmIENF is not changed.

FCNnMmCLDN	Setting of FCNnMmDTNF bit
1	FCNnMmDTNF is cleared.
0	FCNnMmDTNF is set.

Note If FCNnMmDTNF is cleared at the end of ID field reception, the frames being received will be saved into the corresponding message buffer.

FCNnMmSETR	FCNnMmCLTR	Setting of FCNnMmTRQF bit
0	1	FCNnMmTRQF is cleared.
1	0	FCNnMmTRQF is set.
Other than above		FCNnMmTRQF is not changed.

FCNnMmSERY	FCNnMmCLRY	Setting of FCNnMmRDYF bit
0	1	FCNnMmRDYF is cleared.
1	0	FCNnMmRDYF is set.
Other than above		FCNnMmRDYF is not changed.

24.6 CAN Controller Initialization

24.6.1 Initialization of FCN module

Before FCN module operation is enabled, the FCN module system clock needs to be determined by setting FCNnGMCSPRE.FCNnGMCSPRSC[3:0] by software. Do not change the setting of the FCN module system clock after FCN module operation is enabled.

The FCN module is enabled by setting FCNnGMCLCTL.FCNnGMCLPWOM.

For the procedure of initializing the FCN module, refer to 24.14 “Operation of the CAN Controller” on page 1493.

24.6.2 Initialization of message buffer

After the FCN module is enabled, the message buffers might contain an undefined value (except after a software reset). A minimum initialization for all the message buffers, even for those not used in the application, is necessary before switching the FCN module from the initialization mode to one of the operation modes.

- Clear FCNnMmRDYF, FCNnMmTRQF, and FCNnMmDTNF of the FCNnMmCTL registers to 0.
- Clear all FCNnMmSTRB.FCNnMmSSAM to 0.

24.6.3 Redefinition of message buffer

Redefining a message buffer means changing the ID and control information of the message buffer while a message is being received or transmitted, without affecting other transmission/reception operations.

(1) To redefine message buffer in initialization mode

Place the FCN module in the initialization mode once and then change the ID and control information of the message buffer in the initialization mode. After changing the ID and control information, set the FCN module to an operation mode.

(2) To redefine message buffer during reception

Perform redefinition as shown in Figure 24-17 “Message buffer redefinition during reception” on page 1497.

(3) To redefine message buffer during transmission

To rewrite the contents of a transmit message buffer to which a transmission request has been set, perform transmission abort processing (see (1) “Transmission abort process except for in normal operation mode with automatic block transmission (ABT)” and (2) “Transmission abort process for ABT transmission in normal operation mode with automatic block transmission (ABT)” on page 1471 for details). Confirm that transmission has been aborted or completed, and then redefine the message buffer. After redefining the transmit message buffer, set a transmission request using the procedure described below. When setting a transmission request to a message buffer that

has been redefined without aborting the transmission in progress, however, the 1-bit wait time is not necessary.

Figure 24-4 Setting transmission request (FCNnMmCTL.FCNnMmTRQF) to transmit message buffer after redefinition

- Cautions**
1. When a message is received, reception filtering is performed in accordance with the ID and mask set to each receive message buffer. If the procedure in *Figure 24-17 "Message buffer redefinition during reception" on page 1497* is not observed, the contents of the message buffer after it has been redefined may contradict the result of reception (result of reception filtering). If this happens, check that the ID and IDE received first and stored in the message buffer following redefinition are those stored after the message buffer has been redefined. If no ID and IDE are stored after redefinition, redefine the message buffer again.
 2. When a message is transmitted, the transmission priority is checked in accordance with the ID, IDE, and FCNnMmSTRB.FCNnMmSSRT set to each transmit message buffer to which a transmission request was set. The transmit message buffer having the highest priority is selected for transmission. If the procedure in *Figure 24-4 "Setting transmission request (FCNnMmCTL.FCNnMmTRQF) to transmit message buffer after redefinition" on page 1454* is not observed, a message with an ID not having the highest priority may be transmitted after redefinition.

24.6.4 Transition from initialization mode to operation mode

The FCN module can be switched to the following operation modes.

- Normal operation mode
- Normal operation mode with ABT
- Receive-only mode
- Single-shot mode
- Self-test mode

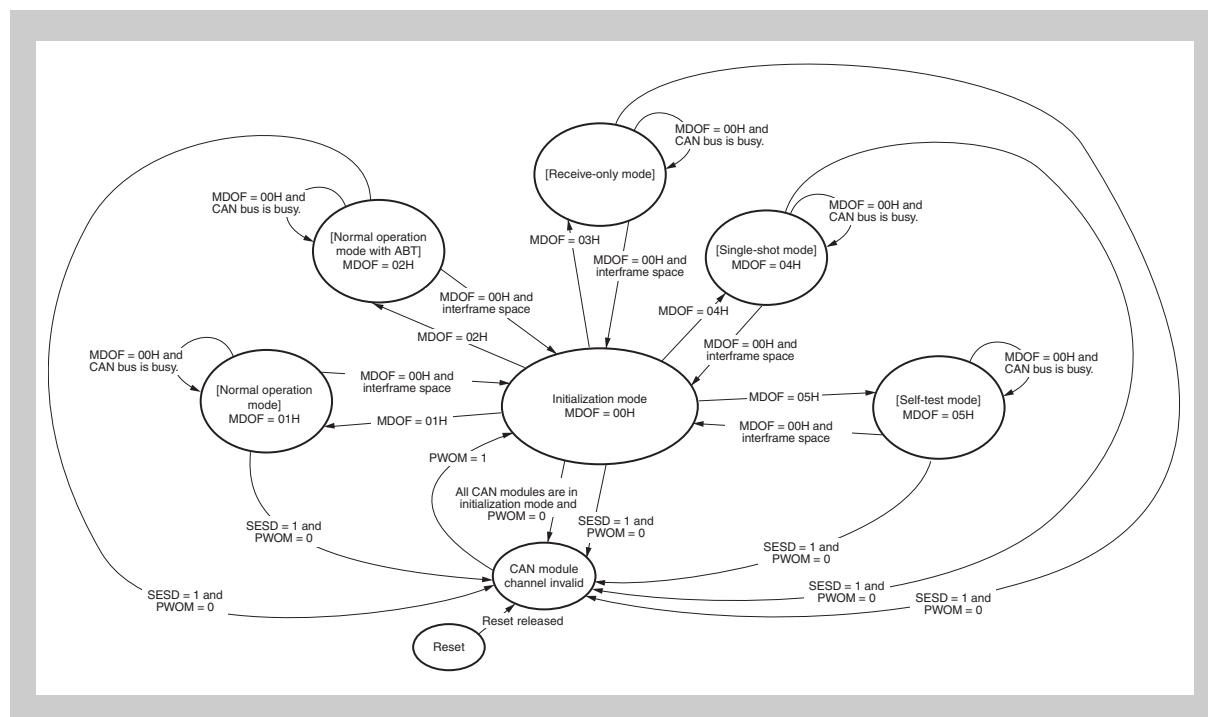

Figure 24-5 Transition to operation modes

Note In the figure above following abbreviations are used:

- MDOF = FCNnCMCLCTL.FCNnCMCLMDOF[2:0]
- PWOM = FCNnGMCLCTL.FCNnGMCLPWOM
- SESD = FCNnGMCLCTL.FCNnGMCLSESD

The transition from the initialization mode to an operation mode is controlled by the bit string FCNnCM.FCNnCMCLMDOF[2:0].

Changing from one operation mode into another requires shifting to the initialization mode in between. Do not change one operation mode to another directly; otherwise the operation will not be guaranteed.

Requests for transition from an operation mode to the initialization mode are held pending when the CAN bus is not in the interframe space (i.e., frame reception or transmission is in progress), and the FCN module enters the initialization mode at the first bit in the interframe space (the values of the FCNnCMCLCTL.FCNnCMCLMDOF[2:0] are changed to 000_B). After issuing a request to change the mode to the initialization mode, read FCNnCMCLCTL.FCNnCMCLMDOF[2:0] until their value becomes 000_B to confirm that the module has entered the initialization mode (see Figure 24-14 “Re-initialization without using the software reset function” on page 1494).

24.7 Message Reception

24.7.1 Message reception

In all the operation modes, the complete message buffer area is analyzed to find a suitable buffer to store a newly received message. All message buffers satisfying the following conditions are included in that evaluation (RX-search process).

- Used as a message buffer
(FCNnMmSTRB.FCNnMmSSAM = 1.)
- Set as a receive message buffer
(FCNnMmSTRB.FCNnMmSSMT[3:0] = 0001_B to 1001_B)
- Ready for reception
(FCNnMmCTL.FCNnMmRDYF = 1.)

When two or more message buffers of the FCN module are found to be able to receive a message, the message is stored according to the priority explained below. The message is always stored in the message buffer with the highest priority, not in a message buffer with a low priority. For example, when an unmasked receive message buffer and a receive message buffer linked to mask 1 have the same ID, the received message is not stored in the message buffer linked to mask 1, even if that message buffer has not received a message and a message has already been received in the unmasked receive message buffer. In other words, when a condition has been set in two or more message buffers with different priorities, the message buffer with the highest priority always stores the message; the message is not stored in message buffers with a lower priority. This also applies when the message buffer with the highest priority is unable to store a message (i.e., when FCNnMmCTL.FCNnMmDTNF = 1 indicating that a message has already been received, but rewriting is disabled because FCNnMmSTRB.FCNnMmSSOW = 0). In this case, the message is not actually stored in the candidate message buffer with the highest priority, but neither is it stored in a message buffer with a lower priority.

Table 24-16 MBRB priorities

Priority	Storing condition if same ID is set	
1 (high)	Unmasked message buffer	FCNnMmDTNF = 0
		FCNnMmDTNF = 1 and FCNnMmSSOW = 1
2	Message buffer linked to mask 1	FCNnMmDTNF = 0
		FCNnMmDTNF = 1 and FCNnMmSSOW = 1
3	Message buffer linked to mask 2	FCNnMmDTNF = 0
		FCNnMmDTNF = 1 and FCNnMmSSOW = 1
...	...	
9 (low)	Message buffer linked to mask 8	FCNnMmDTNF = 0
		FCNnMmDTNF = 1 and FCNnMmSSOWt = 1

24.7.2 Receive data read

To keep data consistency when reading FCN message buffers, perform the data reading according to *Figure 24-31 “Reception via interrupt (using FCNnCMLISTR register)”* on page 1512 to *Figure 24-34 “Reception via software polling”* on page 1516.

During message reception, the FCN module sets FCNnMmCTL.FCNnMmDTNF two times: at the beginning of the storage process of data to the message buffer, and again at the end of this storage process. During this storage process, FCNnMmCTL.FCNnMmMUCF of the message buffer is set (refer to *Figure 24-6 “Reception timing”*).

The receive history list is also updated just before the storage process. In addition, during storage process (FCNnMmCTL.FCNnMmMUCF = 1), FCNnMmCTL.FCNnMmRDYF of the message buffer is locked to avoid any coincidental data write by CPU. Note that the storage process may be disturbed (delayed) when the CPU accesses the message buffer.

Caution To reliably store a message in a message buffer, the DN bit for that buffer must be cleared before message search processing starts (after a frame ID is output on the bus). This might occur as early as the 15th CAN bit after EOF of the previous frame. To reliably receive successively sent CAN frames on the bus, using multiple message buffers for frame reception is recommended.

Figure 24-6 Reception timing

24.7.3 Receive history list function

The receive history list (RHL) function records in the receive history list the number of the receive message buffer in which each data frame or remote frame was received and stored. The RHL consists of storage elements equivalent to up to 47 messages (on 64 message buffer FCN) or up to 95 messages (on 128 message buffer FCN), the last in-message pointer FCNnCMLISSLR[7:0] with the corresponding FCNnCMLISTR register and the receive history list get pointer FCNnCMRGSSPT with the corresponding FCNnCMRGRX register.

The RHL is undefined immediately after the transition of the FCN module from the initialization mode to one of the operation modes.

The FCNnCMLISTR register holds the contents of the RHL element indicated by the value of the FCNnCMLISTR.FCNnCMLISSLR[7:0] pointer minus 1 (See *Figure 24-7 "Receive history list"*). It is consequently possible to check the number of the message buffer that received and stored the last data frame or remote frame by reading the FCNnCMLISTR register. The FCNnCMLISSLR[7:0] pointer is utilized as a write pointer that indicates to what part of the RHL a message buffer number is recorded. Any time a data frame or remote frame is received and stored, the corresponding message buffer number is recorded to the RHL element indicated by the FCNnCMLISSLR[7:0] pointer. Each time recording to the RHL has been completed, the FCNnCMLISSLR[7:0] pointer is automatically incremented. In this way, the number of the message buffer that has received and stored a frame will be recorded chronologically.

For message buffers, where the flag FCNnMmCTL.FCNnMmNHMF is set, no entry in the history lists is recorded.

The FCNnCMRGRX.FCNnCMRGSSPT pointer is utilized as a read pointer that reads a recorded message buffer number from the RHL. This pointer indicates the first RHL element that the CPU has not read yet. By reading the FCNnCMRGRX register by software, the number of a message buffer that has received and stored a data frame or remote frame can be read. Each time a message buffer number is read from the FCNnCMRGRX register, the FCNnCMRGSSPT pointer is automatically incremented.

If the value of the FCNnCMRGRX.FCNnCMRGSSPT pointer matches the value of the FCNnCMLISTR.FCNnCMLISSLR[7:0] pointer, FCNnCMRGRX.FCNnCMRGSSPM (receive history list pointer match) is set to 1. This indicates that no message buffer number that has not been read remains in the RHL. If a new message buffer number is recorded, the FCNnCMLISSLR[7:0] pointer is incremented and because its value no longer matches the value of the FCNnCMRGSSPT pointer, FCNnCMRGSSPM is cleared. In other words, the numbers of the unread message buffers exist in the RHL.

If the FCNnCMLISTR.FCNnCMLISSLR[7:0] pointer is incremented and matches the value of the FCNnCMRGRX.FCNnCMRGSSPT pointer minus 1, FCNnCMRGRX.FCNnCMRGRVFF (receive history list overflow) is set to 1. This indicates that the RHL is full of numbers of message buffers that have not been read. When further message reception and storing occur, the last recorded message buffer number is overwritten by the number of the message buffer that received and stored the newly received message. In this case, after FCNnCMRGRVFF has been set (1), the recorded message buffer numbers in the RHL do not completely reflect the chronological order. However messages itself are not lost and can be located by CPU search in message buffer memory with the help of FCNnMmCTL.FCNnMmDTNF, or by reading the global registers FCNnDNBMRX[3:0].

Caution If the history list is in the overflow condition (FCNnCMRGRX.FCNnCMRGRVFF is set), reading the history list contents is still possible, until the history list is empty (indicated by FCNnCMRGRX.FCNnCMRGSSPM flag set). Nevertheless, the history list remains in the overflow condition, until FCNnCMRGRVFF is cleared by software. If FCNnCMRGRVFF is not cleared, the FCNnCMRGSSPM flag will also not be updated (cleared) upon a message storage of newly received frame. This may lead to the situation, that FCNnCMRGSSPM indicates an empty history list, although a reception has taken place, while the history list is in the overflow state (FCNnCMRGRVFF and FCNnCMRGSSPM are set).

As long as the RHL still has free entries, the sequence of occurrence is maintained. If more receptions occur without reading the RHL by the host processor, complete sequence of receptions can not be recovered.

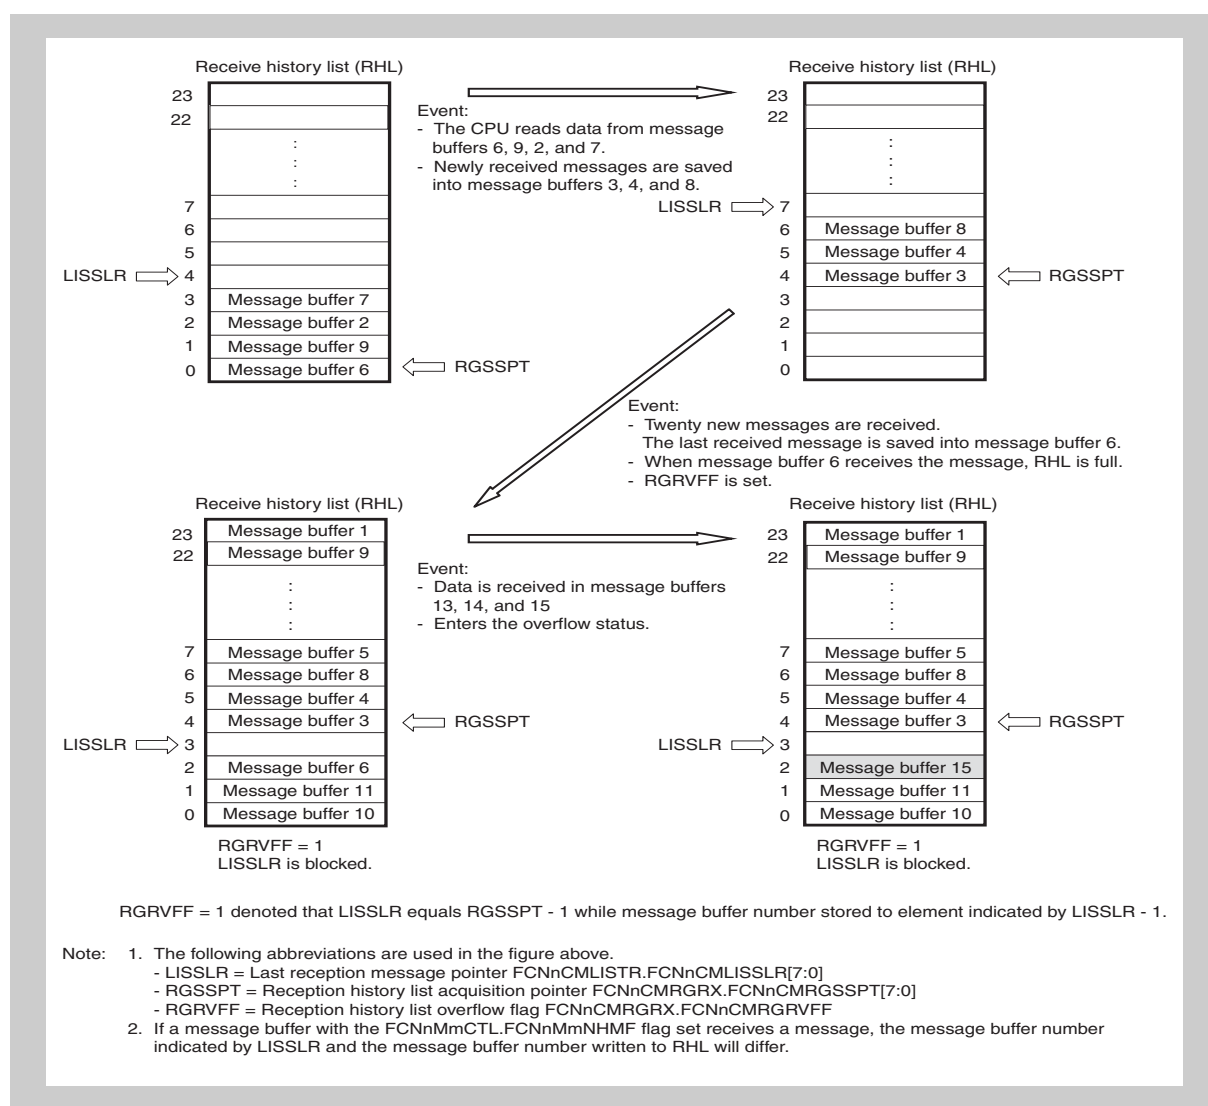

Figure 24-7 Receive history list

24.7.4 Mask function

For any message buffer, which is used for reception, the assignment to one of eight global reception masks (or no mask) can be selected.

By using the mask function, the message ID comparison can be reduced by masked bits, herewith allowing the reception of several different IDs into one buffer.

While the mask function is in effect, an identifier bit that is defined to be 1 by a mask in the received message is not compared with the corresponding identifier bit in the message buffer.

However, this comparison is performed for any bit whose value is defined as 0 by the mask.

For example, let us assume that all messages that have a standard-format ID, in which bits ID27 to ID25 are 0 and bits ID24 and ID22 are 1, are to be stored in message buffer 14. The procedure for this example is shown below.

(1) Identifier to be stored in message buffer

ID28	ID27	ID26	ID25	ID24	ID23	ID22	ID21	ID20	ID19	ID18
x	0	0	0	1	x	1	x	x	x	x

(2) Identifier to be configured in message buffer 14 (example) (using FCN1M014MID0W register)

ID28	ID27	ID26	ID25	ID24	ID23	ID22	ID21	ID20	ID19	ID18
x	0	0	0	1	x	1	x	x	x	x
ID17	ID16	ID15	ID14	ID13	ID12	ID11	ID10	ID9	ID8	ID7
x	x	x	x	x	x	x	x	x	x	x
ID6	ID5	ID4	ID3	ID2	ID1	ID0				
x	x	x	x	x	x	x				

- Notes**
1. ID with the ID27 to ID25 bits cleared to 0 and the ID24 and ID22 bits set to 1 is registered (initialized) to message buffer 14.
 2. Message buffer 14 is set as a standard format identifier that is linked to mask 1 (FCN1M014STRB.FCN1M014SSMT[3:0] = 0010_B).

**(3) Mask setting for FCN module 1 (mask 1) (example)
(using FCAN1 module mask 1 register FCN1CMMKCTL01W)**

FNCnCMMKSSID[..]

ID28	ID27	ID26	ID25	ID24	ID23	ID22	ID21	ID20	ID19	ID18
x	0	0	0	1	x	1	x	x	x	x
ID17	ID16	ID15	ID14	ID13	ID12	ID11	ID10	ID9	ID8	ID7
x	x	x	x	x	x	x	x	x	x	x
ID6	ID5	ID4	ID3	ID2	ID1	ID0				
x	x	x	x	x	x	x				

1: Not compared (masked)

0: Compared

FCN1CMMKSSID[27:24] and FCN1CMMKSSID[21] are cleared to 0, and FCN1CMMKSSID[28], FCN1CMMKSSID[23], and FCN1CMMKSSID[21:0] are set to 1.

24.7.5 Multi buffer receive block function

The multi buffer receive block (MBRB) function is used to store a block of data in two or more message buffers sequentially with no CPU interaction, by setting the same ID to two or more message buffers with the same message buffer type. These message buffers can be allocated anywhere in the message buffer memory, they do not even have to follow each other adjacently.

Suppose, for example, the same message buffer type is set to 10 message buffers, message buffers 10 to 19, and the same ID is set to each message buffer. If the first message whose ID matches an ID of the message buffers is received, it is stored in message buffer 10. At this point, FCNnMmCTL.FCNnMmDTNF of message buffer 10 is set, prohibiting overwriting the message buffer when subsequent messages are received.

When the next message with a matching ID is received, it is received and stored in message buffer 11. Each time a message with a matching ID is received, it is sequentially (in the ascending order) stored in message buffers 12, 13, and so on. Even when a data block consisting of multiple messages is received, the messages can be stored and received without overwriting the previously received matching-ID data.

Whether a data block has been received and stored can be checked by setting FCNnMmCTL.FCNnMmIENF of each message buffer. For example, if a data block consists of k messages, k message buffers are initialized for reception of the data block. FCNnMmIENF in message buffers 0 to $(k-2)$ is cleared to 0 (interrupts disabled), and FCNnMmIENF in message buffer $k-1$ is set to 1 (interrupts enabled). In this case, a reception completion interrupt occurs when a message has been received and stored in message buffer $k-1$, indicating that MBRB has become full. Alternatively, by clearing FCNnMmIENF of message buffers 0 to $(k-3)$ and setting FCNnMmIENF of message buffer $k-2$, a warning that MBRB is about to overflow can be issued.

The basic conditions of storing receive data in each message buffer for the MBRB are the same as the conditions of storing data in a single message buffer.

-
- Cautions**
1. MBRB can be configured for each of the same message buffer types. Therefore, even if a message buffer of another MBRB whose ID matches but whose message buffer type is different has a vacancy, the received message is not stored in that message buffer, but instead discarded.
 2. MBRB does not have a ring buffer structure. Therefore, after a message is stored in the message buffer having the highest number in the MBRB configuration, a newly received message will not be stored in the message buffer having the lowest message buffer number.
 3. MBRB operates based on the reception and storage conditions; there are no settings dedicated to MBRB, such as function enable bits. By setting the same message buffer type and ID to two or more message buffers, MBRB is automatically configured.
 4. With MBRB, “matching ID” means “matching ID after mask”. Even if the ID set to each message buffer is not the same, if the ID that is masked by the mask register matches, it is considered a matching ID and the buffer that has this ID is treated as the storage destination of a message.
 5. The priority between MBRBs is mentioned in the table *Table 24-16 “MBRB priorities”*.
-

24.7.6 Remote frame reception

In all the operation modes, when a remote frame is received, the message buffer that is to store the remote frame is searched from all the message buffers satisfying the following conditions (1 and 2, condition 1 has priority on reception acceptance). If condition 1 is not fulfilled, the remaining message buffers are scanned, whether condition 2 could be fulfilled.

- Condition 1:
 - Set as a transmit message buffer
(FCNnMmSTRB.FCNnMmSSMT[3:0] = 0000_B)
 - Used as a message buffer
(FCNnMmSTRB.FCNnMmSSAM = 1.)
 - Ready for reception
(FCNnMmCTL.FCNnMmRDYF = 1.)
 - Set to data frame message type
(FCNnMmSTRB.FCNnMmSSRT = 0.)
 - Transmission request is not set.
(FCNnMmCTL.FCNnMmTRQF = 0.)
- Condition 2:
 - Set as a receive message buffer
(FCNnMmSTRB.FCNnMmSSMT[3:0] = 0001_B ... 1001_B)
 - Used as a message buffer
(FCNnMmSTRB.FCNnMmSSAM = 1.)
 - Ready for reception
(FCNnMmCTL.FCNnMmRDYF = 1.)
 - Set to remote frame message type
(FCNnMmSTRB.FCNnMmSSRT = 1.)
 - Buffer is ready to store a message
(FCNnMmCTL.FCNnMmDTNF = 0, or FCNnMmSTRB.FCNnMmSSOW = 1 with FCNnMmCTL.FCNnMmDTNF = 1).

Upon acceptance of a remote frame, the following actions are executed if the ID of the received remote frame matches the ID of a message buffer that satisfies the above conditions.

- The FCNnMmDTLG[3:0] bit string in the FCNnMmDTLGB register store the received DLC value.
- When received in a transmit message buffer, registers FCNnMmDAT0B to FCNnMmDAT7B in the data area will not be updated (the data from before reception is stored).
- FCNnMmCTL.FCNnMmDTNF is set to 1.
- FCNnCMISCTL.FCNnCMISITSF1 is set to 1 (if FCNnMmCTL.FCNnMmIENF of the message buffer that receives and stores the frame is set to 1).
- The receive completion interrupt (INTCnREC) is output (if FCNnMmCTL.FCNnMmIENF of the message buffer that receives and stores the frame is set to 1 and if FCNnCMIECTL.FCNnCMIEINTF1 is set to 1).
- The message buffer number is recorded in the receive history list, if the flag FCNnMmCTL.FCNnMmNHMF is not set.

Caution When a transmit message buffer is found for receiving and storing a remote frame, overwrite control by FCNnMmSTRB.FCNnMmSSOW of the message buffer and FCNnMmCTL.FCNnMmDTNF are not checked. The setting of FCNnMmSSOW is ignored, and FCNnMmDTNF is set in any case.

- Notes**
1. If more than one transmit message buffer has the same ID and the ID of the received remote frame matches that ID, the remote frame is stored in the transmit message buffer with the lowest message buffer number.
 2. If transmit and receive message buffers are found, which could receive a remote frame matching with its ID, either masked or unmasked, the remote frame is stored in the transmit message buffer.
 3. If several receive message buffers would match for reception for a remote frame, the reception priority is identical as for a data frame.
 4. If a receive message buffer is found to match for a remote frame reception, and selected for storage, but this receive message buffer does not allow the storage, because FCNnMmDTNF is set, and FCNnMmSSOW is not set, the remote frame is not stored at all.

24.8 Message Transmission

24.8.1 Message transmission

A message buffer with its FCNnMmCTL.FCNnMmTRQF bit set to 1 participates in the search for the most high-prioritized message when the following conditions are fulfilled. This behavior is valid for all operational modes.

- Used as a message buffer
(FCNnMmSTRB.FCNnMmSSAM = 1)
- Set as a transmit message buffer
(FCNnMmSTRB.FCNnMmSSMT[3:0] = 0000_B)
- Ready for transmission
(FCNnMmCTL.FCNnMmRDYF = 1)

The CAN system is a multi-master communication system. In a system like this, the priority of message transmission is determined based on message identifiers (IDs). To facilitate transmission processing by software when there are several messages awaiting transmission, the FCN module uses hardware to check the ID of the message with the highest priority and automatically identifies that message. This eliminates the need for software-based priority control.

Transmission priority is controlled by the identifier (ID).

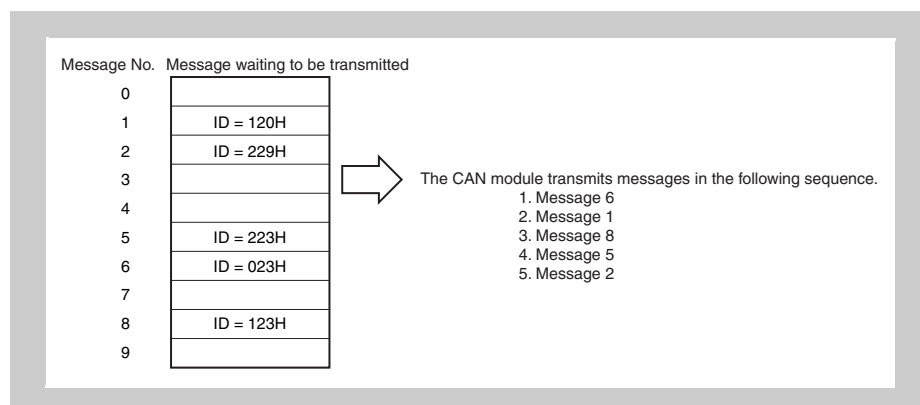

Figure 24-8 Message processing example

After the transmit message search, the transmit message with the highest priority of the transmit message buffers that have a pending transmission request (message buffers with the FCNnMmCTL.FCNnMmTRQF bit set to 1 in advance) is transmitted.

If a new transmission request is set, the transmit message buffer with the new transmission request is compared with the transmit message buffer with a pending transmission request. If the new transmission request has a higher priority, it is transmitted, unless transmission of a message with a low priority has already started. If transmission of a message with a low priority has already started, however, the new transmission request is transmitted later. To solve this priority inversion effect, the software can perform a transmission abort request for the lower priority message. The highest priority is determined according to the following rules.

Priority	Conditions	Description
1 (high)	Value of first 11 bits of ID [ID28 to ID18]:	The message frame with the lowest value represented by the first 11 bits of the ID is transmitted first. If the value of an 11-bit standard ID is equal to or smaller than the first 11 bits of a 29-bit extended ID, the 11-bit standard ID has a higher priority than a message frame with a 29-bit extended ID.
2	Frame type	A data frame with an 11-bit standard ID (FCNnMmSTRB.FCNnMmSSRT cleared to 0) has a higher priority than a remote frame with a standard ID and a message frame with an extended ID.
3	ID type	A message frame with a standard ID (message buffer identifier register FCNnMmMID... bit FCNnMmSSIE is cleared to 0) has a higher priority than a message frame with an extended ID.
4	Value of lower 18 bits of ID [ID17 to ID0]:	If one or more transmission-pending extended ID message frame has equal values in the first 11 bits of the ID and the same frame type (equal FCNnMmSTRB.FCNnMmSSRT bit values), the message frame with the lowest value in the lower 18 bits of its extended ID is transmitted first.
5 (low)	Message buffer number	If two or more message buffers request transmission of message frames with the same ID, the message from the message buffer with the lowest message buffer number is transmitted first.

- Notes**
1. If the automatic block transmission request bit FCNnGMABCTL.FCNnGMABABTT is set to 1 in the normal operation mode with ABT, FCNnMmCTL.FCNnMmTRQF is set to 1 only for one message buffer in the ABT message buffer group.

If ABT mode is triggered by setting FCNnGMABCTL.FCNnGMABSEAT = 1, then one of the FCNnMmCTL.FCNnMmTRQF in the ABT area (64 message buffers FCN:0 to 15, and 128 message buffers FCN:0 to 31) will be set to 1. Beyond this transmit request, the application can request transmissions (set FCNnMmTRQF to 1) for other TX-message buffers that do not belong to the ABT area. In that case an interval arbitration process (TX-search) evaluates all TX-message buffers with FCNnMmTRQF set to 1 and chooses the message buffer that contains the highest prioritized identifier for the next transmission. If there are 2 or more identifiers that have the highest priority (i.e. identical identifiers), the message located at the lowest message buffer number is transmitted at first.

Upon successful transmission of a message frame, the following operations are performed.

- The FCNnMmCTL.FCNnMmTRQF flag of the corresponding transmit message buffer is automatically cleared to 0.
 - The transmission completion status bit FCNnCMISCTL.FCNnCMISITSF0 is set to 1 (if the interrupt enable bit FCNnMmIENF of the corresponding transmit message buffer is set to 1).
 - An interrupt request signal INTcNTRX is output (if FCNnCMIECTL.FCNnCMIEINTF0 is set to 1 and if the interrupt enable bit FCNnMmIENF of the corresponding transmit message buffer is set to 1).
2. When changing the contents of a transmit buffer, the FCNnMmCTL.FCNnMmRDYF flag of this buffer must be cleared before updating the buffer contents. As during internal transfer actions, the FCNnMmRDYF flag may be locked temporarily, the status of FCNnMmRDYF must be checked by software, after changing it.

24.8.2 Transmit history list function

The transmit history list (THL) function records in the transmit history list the number of the transmit message buffer from which data or remote frames have been sent. The THL consists of storage elements equivalent to up to 15 messages (on 64 message buffer FCN) or up to 31 messages (on 128 message buffer FCN), the last out-message pointer FCNnCMLOSTR[7:0] with the corresponding FCNnCMLOSTR register, and the transmit history list get pointer FCNnCMTGSSPT[7:0] with the corresponding FCNnCMTGTX register.

The THL is undefined immediately after the transition of the FCN module from the initialization mode to one of the operation modes.

The FCNnCMLOSTR register holds the contents of the THL element indicated by the value of the FCNnCMLOSTR.FCNnCMLOSTR[7:0] pointer minus 1. By reading the FCNnCMLOSTR register, therefore, the number of the message buffer that transmitted a data frame or remote frame first can be checked. The FCNnCMLOSTR[7:0] pointer is utilized as a write pointer that indicates to what part of the THL a message buffer number is recorded. Any time a data frame or remote frame is transmitted, the corresponding message buffer number is recorded to the THL element indicated by the FCNnCMLOSTR[7:0] pointer. Each time recording to the THL has been completed, the FCNnCMLOSTR[7:0] pointer is automatically incremented. In this way, the number of the message buffer that has received and stored a frame will be recorded chronologically.

For message buffers, where the flag FCNnMmCTL.FCNnMmNHMF is set, no entry in the history lists is recorded.

The FCNnCMTGTX.FCNnCMTGSSPT[7:0] pointer is utilized as a read pointer that reads a recorded message buffer number from the THL. This pointer indicates the first THL element that the CPU has not yet read. By reading the FCNnCMTGTX register by software, the number of a message buffer that has completed transmission can be read. Each time a message buffer number is read from the FCNnCMTGTX register, the FCNnCMTGSSPT[7:0] pointer is automatically incremented.

If the value of the FCNnCMTGTX.FCNnCMTGSSPT[7:0] pointer matches the value of the FCNnCMLOSTR.FCNnCMLOSTR[7:0] pointer, FCNnCMTGTX.FCNnCMTGSSPM (transmit history list pointer match) is set to 1. This indicates that no message buffer numbers that have not been read remain in the THL. If a new message buffer number is recorded, the FCNnCMLOSTR[7:0] pointer is incremented and because its value no longer matches the value of the FCNnCMTGSSPT[7:0] pointer, FCNnCMTGSSPM is cleared. In other words, the numbers of the unread message buffers exist in the THL.

If the FCNnCMLOSTR.FCNnCMLOSTR[7:0] pointer is incremented and matches the value of the FCNnCMTGTX.FCNnCMTGSSPT[7:0] pointer minus 1, FCNnCMTGTX.FCNnCMTGTVFF (transmit history list overflow) is set to 1. This indicates that the THL is full of message buffer numbers that have not been read. If a new message is received and stored, the message buffer number recorded last is overwritten by the message buffer number that transmitted its message afterwards. In this case, after FCNnCMTGTVFF has been set (1), therefore, the recorded message buffer numbers in the THL do not completely reflect the chronological order. Even in this case, however, the CPU can identify the number of the message buffer that completed reception by searching all reception buffers (the CPU does this before resetting transmission). Regardless of the FCNnCMTGTX.FCNnCMTVFF setting, 14 (64 message buffers) or 30 (128 message buffer) transmit message buffer numbers are stored in THL.

Caution If the history list is in the overflow condition (FCNnCMTGTX.FCNnCMTGTVFF is set), reading the history list contents is still possible, until the history list is empty (indicated by FCNnCMTGTX.FCNnCMTGSSPM flag set). Nevertheless, the history list remains in the overflow condition, until FCNnCMTGTVFF is cleared by software. If FCNnCMTGTVFF is not cleared, the FCNnCMTGTX.FCNnCMTGSSPM flag will also not be updated (cleared) upon successful transmission of a new message. This may lead to the situation, that FCNnCMTGSSPM indicates an empty history list, although a successful transmission has taken place, while the history list is in the overflow state (FCNnCMTGTVFF and FCNnCMTGSSPM are set).

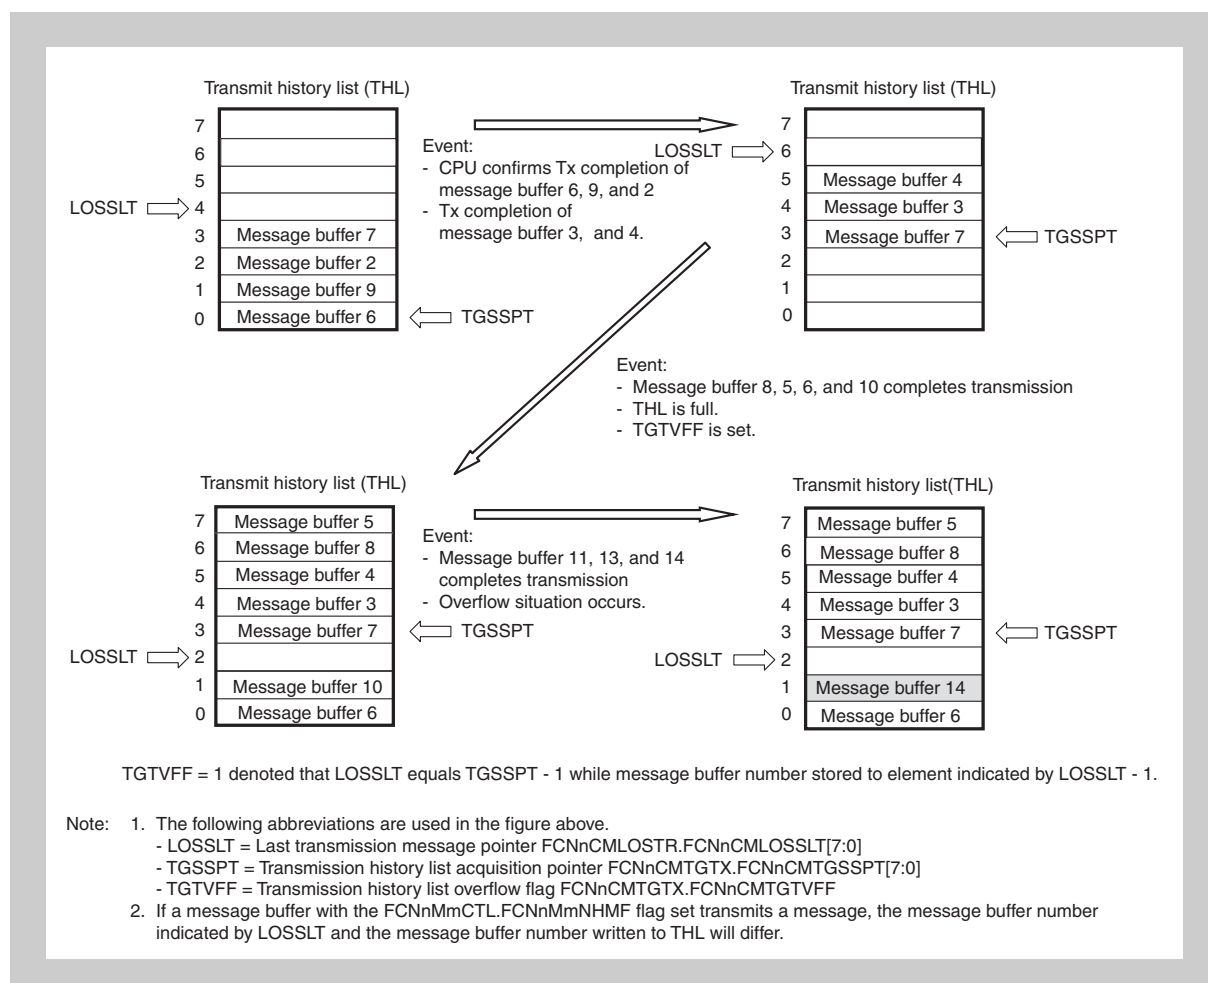

Figure 24-9 Transmit history list

24.8.3 Automatic block transmission (ABT)

The automatic block transmission (ABT) function is used to transmit two or more data frames successively with no CPU interaction. The maximum number of transmit message buffers assigned to the ABT function is 16 (for 64 message buffer FCN) or 32 (for 128 message buffer FCN), always located in the lowest message buffers.

By setting FCNnCMCLCTL.FCNnCMCLMDOF[2:0] to 010_B, “normal operation mode with automatic block transmission function” (hereafter referred to as ABT mode) can be selected.

To issue an ABT transmission request, define the message buffers by software first. Set FCNnMmSTRB.FCNnMmSSAM = 1 in all the message buffers used for ABT, and define all the buffers as transmit message buffers by setting the FCNnMmSTRB.FCNnMmSSMT[3:0] bits to 0000_B. Be sure to set the same ID for the message buffers for ABT even when that ID is being used for all the message buffers. To use two or more IDs, set the ID of each message buffer by using the FCNnMmMID0H and FCNnMmMID1H or FCNnMmMID0W registers. Set the FCN message data bytes registers before issuing a transmission request for the ABT function.

After initialization of message buffers for ABT is finished, FCNnMmCTL.FCNnMmRDYF needs to be set to 1. In the ABT mode, FCNnMmCTL.FCNnMmTRQF does not have to be manipulated by software.

After the data for the ABT message buffers has been prepared, set FCNnGMABCTL.FCNnGMABSEAT = 1. Automatic block transmission is then started. When ABT is started, FCNnMmCTL.FCNnMmTRQF in the first message buffer (message buffer 0) is automatically set to 1. After transmission of the data of message buffer 0 is finished, the FCNnMmTRQF of the next message buffer, message buffer 1, is set automatically. In this way, transmission is executed successively.

A delay time can be inserted by program in the interval in which the transmission request FCNnMmCTL.FCNnMmTRQF is automatically set while successive transmission is being executed. The delay time to be inserted is defined by the FCNnGMADCTL register. The unit of the delay time is DBT (data bit time). DBT depends on the setting of the FCNnCMBRPRS and FCNnCMBTCTL registers.

Among transmit objects within the ABT-area, the priority of the transmission ID is not evaluated. Messages are sent by order of message number, starting with message buffer 0. When the transmission of the data frame from the last message buffer is complete, FCNnGMABCTL.FCNnGMABABTT is automatically cleared to 0, and ABT operation completes.

If there is an ABT message buffer for which FCNnMmCTL.FCNnMmRDYF is cleared during ABT, no data frame is transmitted from that buffer, ABT is stopped, and FCNnGMABCTL.FCNnGMABABTT is cleared. After that, transmission can be resumed from the message buffer where ABT stopped, by setting FCNnMmRDYF and FCNnGMABABTT to 1 by software. To not resume transmission from the message buffer where ABT stopped, the internal ABT engine can be reset by setting the FCNnGMABCTL.FCNnGMABCLRFB bit to 1 while ABT mode is stopped and FCNnGMABABTT is cleared to 0. In this case, transmission is started from message buffer 0 if FCNnGMABCTL.FCNnGMABSEAC is cleared to 0 and then FCNnGMABABTT is set to 1.

An interrupt can be used to check if data frames have been transmitted from all the message buffers for ABT. To do so, FCNnMmCTL.FCNnMmIENF of each message buffer except the last message buffer needs to be cleared (0).

If a transmit message buffer other than those used by the ABT function is assigned to a transmit message buffer, the message to be transmitted next is determined by the priority of the transmission ID of the ABT message buffer whose transmission is currently held pending and the transmission ID of the message buffers other than those used by the ABT function.

Transmission of a data frame from an ABT message buffer is not recorded in the transmit history list (THL).

-
- Cautions**
1. Set FCNnGMABCTL.FCNnGMABSEAC = 1 while FCNnGMABCTL.FCNnGMABABTT is cleared to 0 in order to resume ABT operation at buffer No. 0. If FCNnGMABSEAC is set to 1 while FCNnGMABABTT is set to 1, the subsequent operation is not guaranteed.
 2. If the automatic block transmission engine is cleared by setting FCNnGMABCTL.FCNnGMABSEAC = 1, FCNnGMABSEAC is automatically cleared immediately after the processing of the clearing request is completed.
 3. Do not trigger automatic block transmission in the initialization mode. If FCNnGMABCTL.FCNnGMABSEAT is set in the initialization mode, the proper operation is not guaranteed after the mode is changed from the initialization mode to the ABT mode.
 4. Do not set FCNnMmCTL.FCNnMmTRQF of the ABT message buffers to 1 by software in the normal operation mode with ABT. Otherwise, the operation is not guaranteed.
 5. The FCNnGMADCTL register is used to set the delay time that is inserted in the period from completion of the preceding ABT message to setting of FCNnMmCTL.FCNnMmTRQF for the next ABT message when the transmission requests are set in the order of message numbers for each message for ABT that is successively transmitted in the ABT mode. The timing at which the messages are actually transmitted onto the CAN bus varies depending on the status of transmission from other stations and the status of the setting of the transmission request for messages other than the ABT messages.
 6. If a transmission request is made for a message other than an ABT message and if no delay time is inserted in the interval in which transmission requests for ABT are automatically set (FCNnGMADCTL = 00_H), messages other than ABT messages may be transmitted not depending on their priority compared to the priority of the ABT message.
 7. Do not clear FCNnMmCTL.FCNnMmRDYF to 0 when FCNnGMABCTL.FCNnGMABABTT = 1.
-

24.8.4 Transmission abort process

(1) Transmission abort process except for in normal operation mode with automatic block transmission (ABT)

The user can clear FCNnMmCTL.FCNnMmTRQF to 0 to abort a transmission request. FCNnMmTRQF will be cleared immediately if the abort was successful. Whether the transmission was successfully aborted or not can be checked using FCNnCMCLCTL.FCNnCMCLSSTS and the FCNnCMGTGX register, or the FCNnMmCTL.FCNnMmTCPF flag, which indicate the transmission status on the CAN bus (for details, refer to the processing in *Figure 24-24 "Transmission abort processing (except normal operation mode with ABT)" on page 1505*).

(2) Transmission abort process for ABT transmission in normal operation mode with automatic block transmission (ABT)

To abort ABT that is already started, clear FCNnGMABCTL.FCNnGMABABTT to 0. In this case, FCNnGMABCTL.FCNnGMABABTT remains 1 if an ABT message is currently being transmitted and until the transmission is completed (successfully or not), and is cleared to 0 as soon as transmission is finished. This aborts ABT.

If the last transmission (before ABT) was successful, the normal operation mode with ABT is left with the internal ABT pointer pointing to the next message buffer to be transmitted.

In the case of an erroneous transmission, the position of the internal ABT pointer depends on the status of FCNnMmCTL.FCNnMmTRQF in the last transmitted message buffer. If FCNnMmTRQF is cleared to 0 when clearing FCNnGMABCTL.FCNnGMABABTT is requested, the internal ABT pointer is incremented (+1) and points to the next message buffer in the ABT area (for details, refer to the process in *Figure 24-26 "ABT transmission request abort processing (in normal operation mode with ABT) (1)" on page 1507*).

Caution Be sure to abort ABT by clearing FCNnGMABCTL.FCNnGMABABTT to 0. The operation is not guaranteed if aborting transmission is requested by clearing FCNnMmCTL.FCNnMmRDYF.

When the normal operation mode with ABT is resumed after ABT has been aborted and FCNnGMABCTL.FCNnGMABSEAT is set to 1, the next ABT message buffer to be transmitted can be determined from the following table.

Status of FCNnMmCTL.FCNnMmTRQF of ABT message buffer	Abort after successful transmission	Abort after erroneous transmission
Set (1)	Next message buffer in the ABT area ^a	Same message buffer in the ABT area
Cleared (0)	Next message buffer in the ABT area ^a	Next message buffer in the ABT area ^a

- a) The above resumption operation can be performed only if a message buffer ready for ABT exists in the ABT area. For example, an abort request that is issued while ABT of highest ABT message buffer is in progress is regarded as completion of ABT, rather than abort, if transmission of this message buffer has been successfully completed, even if FCNnGMABCTL.FCNnGMABABTT is cleared to 0. If FCNnMmCTL.FCNnMmRDYF in the next message buffer in the ABT area is cleared to 0, the internal ABT pointer is retained, but the resumption operation is not performed even if FCNnGMABABTT is set to 1, and ABT ends immediately.

24.8.5 Remote frame transmission

Remote frames can be transmitted only from transmit message buffers. Set whether a data frame or remote frame is transmitted via FCNnMmSTRB.FCNnMmSSRT. Setting FCNnMmSSRT = 1 sets remote frame transmission.

24.9 Power Saving Modes

24.9.1 FCN sleep mode

The FCN sleep mode can be used to set the CAN Controller to stand-by mode in order to reduce power consumption. The FCN module can enter the FCN sleep mode from all operation modes. Release of the FCN sleep mode returns the FCN module to exactly the same operation mode from which the FCN sleep mode was entered.

In the FCN sleep mode, the FCN module does not transmit messages, even when transmission requests are issued or pending.

(1) Entering FCN sleep mode

The CPU issues a FCN sleep mode transition request by setting $\text{FCNnCMCLCTL.FCNnCMCLMDPF}[1:0] = 01_{\text{B}}$.

This transition request is acknowledged only under the following conditions.

1. The FCN module is already in one of the following operation modes
 - Normal operation mode
 - Normal operation mode with ABT
 - Receive-only mode
 - Single-shot mode
 - Self-test mode
 - FCN stop mode in all the above operation modes
2. The CAN bus state is bus idle (the 4th bit in the interframe space is recessive).
If the CAN bus is fixed to dominant, the request for transition to the FCN sleep mode is held pending. Also the transition from FCN stop mode to FCN sleep mode is independent of the CAN bus state.
3. No transmission request is pending.
4. Power save mode cannot be set in combination with the change of operation mode. Be sure to perform these operations in different steps.

Note If a sleep mode request is pending, and at the same time a message is received in a message box, the sleep mode request is not cancelled, but is executed right after message storage has been finished. This may result in FCN being in sleep mode, while the CPU would execute the RX interrupt routine. Therefore, the interrupt routine must check the access to the message buffers as well as reception history list registers by using the FCNnGMCLSSMO flag, if sleep mode is used.

If any one of the conditions mentioned above is not met, the FCN module will operate as follows.

- If the FCN sleep mode is requested from the initialization mode, the FCN sleep mode transition request is ignored and the FCN module remains in the initialization mode.
- If the CAN bus state is not bus idle (i.e., the CAN bus state is either transmitting or receiving) when the FCN sleep mode is requested in one of the operation modes, immediate transition to the FCN sleep mode is not possible. In this case, the FCN sleep mode transition request is held pending until the CAN bus state becomes bus idle (the 4th bit in the interframe space is recessive). In the time from the FCN sleep mode request to successful transition, $\text{FCNnCMCLCTL.FCNnCMCLMDPF}[1:0]$

remain 00_B. When the module has entered the FCN sleep mode, the FCNnCMCLMDPF[1:0] bits are set to 01_B.

- If a request for transition to the initialization mode and a request for transition to the FCN sleep mode are made at the same time while the FCN module is in one of the operation modes, the request for the initialization mode is enabled. The FCN module enters the initialization mode at a predetermined timing. At this time, the FCN sleep mode request is not held pending and is ignored.
- Even when initialization mode and sleep mode are not requested simultaneously (i.e the first request has not been granted while the second request is made), the request for initialization has priority over the sleep mode request. The sleep mode request is cancelled when the initialization mode is requested. When a pending request for initialization mode is present, a subsequent request for Sleep mode request is cancelled right at the point in time where it was submitted.

(2) Status in FCN sleep mode

The FCN module is in the following state after it enters the FCN sleep mode:

- The internal operating clock is stopped and the power consumption is minimized.
- The function to detect the falling edge of the FCN reception pin (CRXDn) remains in effect to wake up the FCN module from the CAN bus.
- To wake up the FCN module from the CPU, data can be set to FCNnCMCLCTL.FCNnCMCLMDPF[1:0], but nothing can be written to other FCN module registers or bits.
- The FCN module registers can be read, except for the FCNnCMLISTR, FCNnCMRGRX, FCNnCMLOSTR, and FCNnCMTGTX registers.
- The FCN message buffer registers cannot be written or read.
- FCNnGMCLCTL.FCNnGMCLSSMO is cleared.
- The registers FCNnDNBMRX cannot be read.
- A request for transition to the initialization mode is not acknowledged and is ignored.

(3) Releasing FCN sleep mode

The FCN sleep mode is released by the following events:

- When the CPU sets FCNnCMCLCTL.FCNnCMCLMDPF[1:0] to 00_B
- A falling edge at the FCN reception pin CRXDn (i.e. the CAN bus level shifts from recessive to dominant)

Caution Even if the falling edge belongs to the SOF of a receive message, this message will not be received and stored. If the CPU has turned off the clock supply to the FCN module while the FCN module was in sleep mode, even subsequently the FCN sleep mode will not be released and FCNnCMCLMDPF[1:0] will remain 01_B unless the clock to the FCN module is supplied again. In addition to this, the receive message will not be received after that.

After releasing the sleep mode, the FCN module returns to the operation mode from which the FCN sleep mode was requested and FCNnCMCLMDPF must be reset by software to 00_B. If the FCN sleep mode is released by a change in the CAN bus state, FCNnCMISCTL.FCNnCMISITSF5 is set to 1, regardless of FCNnCMIECTL.FCNnCMIEINTF[6:0]. After the FCN module is released from the FCN sleep mode, it participates in the CAN bus again by automatically detecting 11 consecutive recessive-level bits on the CAN bus. The user application has to wait until FCNnGMCLCTL.FCNnGMCLSSMO = 1, before accessing message buffers again.

When a request for transition to the initialization mode is made while the FCN module is in the FCN sleep mode, that request is ignored; the FCN module has to be released from sleep mode by software first before entering the initialization mode.

-
- Cautions**
1. Be aware that the release of FCN sleep mode by CAN bus event, and thus the wake up interrupt may happen at any time, even right after requesting sleep mode, if a CAN bus event occurs.
 2. Always reset the FCNnCMCLCTL.FCNnCMCLMDPF[1:0] bits to 00_B, when waking up from FCN sleep mode, before accessing any other registers of the FCN module.
 3. Always clear the interrupt flag FCNnCMISCTL.FCNnCMISITSF5, when waking up from FCN sleep mode.
-

24.9.2 FCN stop mode

The FCN stop mode can be used to set the CAN controller to stand-by mode to reduce power consumption. The FCN module can enter the FCN stop mode only from the FCN sleep mode. Release of the FCN stop mode puts the FCN module in the FCN sleep mode.

The FCN stop mode can only be released (entering FCN sleep mode) by setting 01_B to FCNnCMCLCTL.FCNnCMCLMDPF[1:0] and not by a change in the CAN bus state. No message is transmitted even when transmission requests are issued or pending.

(1) Entering FCN stop mode

A FCN stop mode transition request is issued by setting 11_B to FCNnCMCLCTL.FCNnCMCLMDPF[1:0].

A FCN stop mode request is only acknowledged when the FCN module is in the FCN sleep mode. In all other modes, the request is ignored.

Caution To set the FCN module to the FCN stop mode, the module must be in the FCN sleep mode. To confirm that the module is in the sleep mode, check that the FCNnCMCLCTL.FCNnCMCLMDPF[1:0] = 01_B , and then request the FCN stop mode. If a bus change occurs at the FCN reception pin CRXDn while this process is being performed, the FCN sleep mode is automatically released. In this case, the FCN stop mode transition request cannot be acknowledged.

(2) Status in FCN stop mode

The FCN module is in the following state after it enters the FCN stop mode.

- The internal operating clock is stopped and the power consumption is minimized.
- To wake up the FCN module from the CPU, data can be set to FCNnCMCLCTL.FCNnCMCLMDPF[1:0], but nothing can be written to other FCN module registers or bits.
- The FCN module registers can be read, except for the FCNnCMLISTR, FCNnCMRGRX, FCNnCMLOSTR, and FCNnCMTGTX registers.
- The FCN message buffer registers cannot be written or read.
- FCNnGMCLCTL.FCNnGMCLSSMO is cleared.
- The registers FCNnDNBMRX cannot be read.
- An initialization mode transition request is not acknowledged and is ignored.

(3) Releasing FCN stop mode

The FCN stop mode can only be released by writing 01_B to FCNnCMCLCTL.FCNnCMCLMDPF[1:0]. After releasing the FCN stop mode, the FCN module enters the FCN sleep mode.

When the initialization mode is requested while the FCN module is in the FCN stop mode, that request is ignored; the CPU has to release the stop mode and subsequently FCN sleep mode before entering the initialization mode. It is impossible to enter the other operation mode directly from the FCN stop mode not entering the FCN sleep mode, that request is ignored.

24.9.3 Example of using power saving modes

In some application systems, it may be necessary to place the CPU in a power saving mode to reduce the power consumption. By using the power saving mode specific to the FCN module and the power saving mode specific to the CPU in combination, the CPU can be woken up from the power saving status by the CAN bus.

Here is an example for using the power saving modes.

- First, put the FCN module in the FCN sleep mode (FCNnCMCLCTL.FCNnCMCLMDPF[1:0] = 01_B).
After successfully confirming this state by reading back the sleep mode status, put the CPU in the power saving mode. Disable interrupts for the CPU, while processing additional tasks after the FCN module is in sleep mode, to avoid that the FCN wakeup interrupt is acknowledged.
If a rising edge from recessive to dominant is detected on the CRXDn FCN reception pin in this state, FCNnCMISCTL.FCNnCMISITSF5 in the FCN module will be set to 1. If FCNnCNIECTL.FCNnCMIEINT5 is set to 1, a wakeup interrupt (INTCnWUP) is generated.
The FCN module is automatically released from FCN sleep mode (FCNnCMCLMDPF[1:0] = 00_B) and returns to normal operation mode.
- The CPU, in response to INTCnWUP, can release its own power saving mode and return to normal operation mode.

To further reduce the power consumption of the CPU, the internal clock - including that of the FCN module - may be stopped. In this case, the operating clock supplied to the FCN module is stopped after the FCN module has been put in FCN sleep mode. Then the CPU enters a power saving mode in which the clock supplied to the CPU is stopped.
- If an edge transition from recessive to dominant is detected at the FCN reception pin CRXDn in this status, the FCN module can set FCNnCMISCTL.FCNnCMISITSF5 to 1 and generate the wakeup interrupt INTCnWUP even if it is not supplied with the clock.
- The other functions, however, do not operate, because clock supply to the FCN module is stopped, and the module remains in FCN sleep mode.
- The CPU, in response to INTCnWUP,
 - releases its power saving mode,
 - resumes supply of the internal clocks - including the clock to the FCN module - after the oscillation stabilization time has elapsed, and
 - starts instruction execution.
- The FCN module is immediately released from the FCN sleep mode when clock supply is resumed, and returns to the normal operation mode (FCNnCMCLCTL.FCNnCMCLMDPF[1:0] = 00_B).

24.10 Interrupt Function

The FCN module provides 6 different interrupt sources.

The occurrence of these interrupt sources is stored in interrupt status registers. Four separate interrupt request signals are generated from the six interrupt sources. When an interrupt request signal that corresponds to two or more interrupt sources is generated, the interrupt sources can be identified by using an interrupt status register. After an interrupt source has occurred, the corresponding interrupt status bit must be cleared to 0 by software.

Table 24-17 List of FCN module interrupt sources

No.	Interrupt status bit FCNnCMISCTL.	Interrupt enable bit FCNnCMIESEIE. ^a	Interrupt request signal	Interrupt source description
1	FCNnCMISITSF0	FCNnCMIESEIE0	INTCnTRX	Message frame successfully transmitted from message buffer m
2	FCNnCMISITSF1	FCNnCMIESEIE1	INTCnREC	Valid message frame reception in message buffer m
3	FCNnCMISITSF2	FCNnCMIESEIE2	INTCnERR	FCN module error state interrupt <ul style="list-style-type: none"> This interrupt is generated when the transmission/reception error counter is at the warning level, or in the error passive or bus-off state.
4	FCNnCMISITSF3	FCNnCMIESEIE3		FCN module protocol error interrupt <ul style="list-style-type: none"> This interrupt is generated when a stuff error, form error, ACK error, bit error, or CRC error occurs.
5	FCNnCMISITSF4	FCNnCMIESEIE4		FCN module arbitration loss interrupt
6	FCNnCMISITSF5	FCNnCMIESEIE5	INTCnWUP	FCN module wakeup interrupt from FCN sleep mode <ul style="list-style-type: none"> This interrupt is generated when the FCN module wakes up from FCN sleep mode, due to detection of a rise on the FCN reception pin (change of CAN bus from recessive to dominant).
7	FCNnCMISITSF6	FCNnCMIESEIE6		FCN module transmit abort interrupt status <ul style="list-style-type: none"> This interrupt is generated when the abortion of a transmission was successful (aborted message was not sent).

- a) The message buffer interrupt enable bit FCNnMmCTL.FCNnMmIENF of the corresponding message buffer has to be set to 1 for that message buffer to participate in the interrupt generation process.

24.11 Diagnosis Functions and Special Operational Modes

The FCN module provides a receive-only mode, single-shot mode, and self-test mode to support CAN bus diagnosis functions or the operation of special CAN communication methods.

24.11.1 Receive-only mode

The receive-only mode is used to monitor receive messages without causing any interference on the CAN bus and can be used for CAN bus analysis nodes.

For example, this mode can be used for automatic baud-rate detection. The FCN module can change its baud rate during reception until “valid reception” is detected, so that the baud rate matches the baud rate on the transmission side (“valid reception” means a message frame has been received in the CAN protocol layer without occurrence of an error and with an appropriate ACK between nodes connected to the CAN bus). A valid reception does not require message frames to be stored in a receive message buffer (data frames) or transmit message buffer (remote frames). The event of valid reception is indicated by setting `FCNnCMCLCTL.FCNnCMCLVALF = 1`.

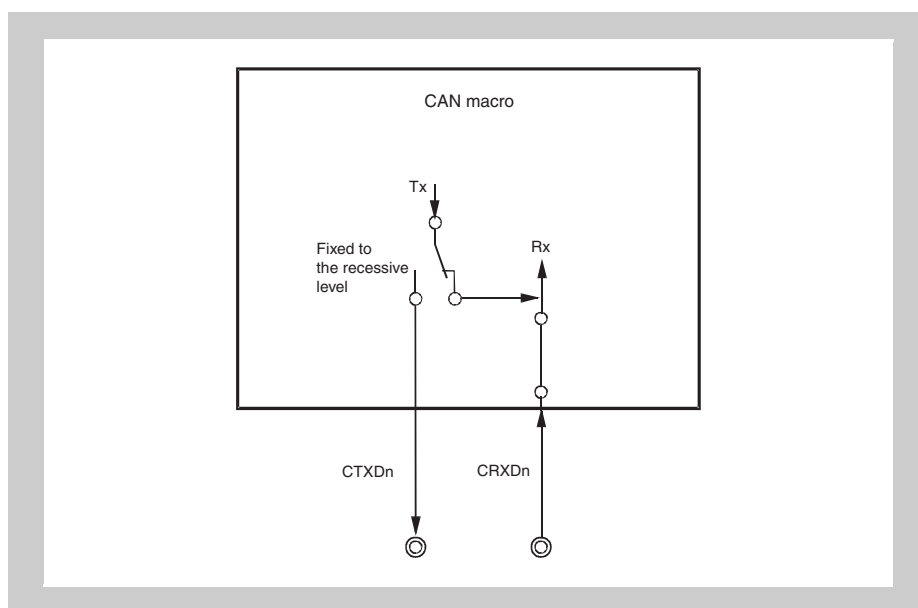

Figure 24-10 FCN module terminal connection in receive-only mode

In the receive-only mode, no message frames can be transmitted from the FCN module to the CAN bus. Transmit requests issued for message buffers defined as transmit message buffers are held pending.

In the receive-only mode, the FCN transmission pin CTXDn in the FCN module is fixed to the recessive level. Therefore, no active error flag can be transmitted from the FCN module to the CAN bus even when a CAN bus error is detected while receiving a message frame. Since no transmission can be issued from the FCN module, the transmission error counter the `FCNnCMERCNT.FCNnCMERTECF[7:0]` bits are never updated. Therefore, a FCN module in the receive-only mode does not enter the bus-off state.

Furthermore, in the receive-only mode ACK is not returned to the CAN bus in this mode upon the valid reception of a message frame. Internally, the local node recognizes that it has transmitted ACK. An overload frame cannot be transmitted to the CAN bus.

Caution If only two CAN nodes are connected to the CAN bus and one of them is operating in the receive-only mode, there is no ACK on the CAN bus. Due to the missing ACK, the transmitting node will transmit an active error flag, and repeat transmitting a message frame. The transmitting node becomes error passive after transmitting the message frame 16 times (assuming that the error counter was 0 in the beginning and no other errors have occurred). After the message frame for the 17th time is transmitted, the transmitting node generates a passive error flag. The receiving node in the receive-only mode detects the first valid message frame at this point, and the FCNnCMCLCTL.FCNnCMCLVALF bit is set to 1 for the first time.

24.11.2 Single-shot mode

In the single-shot mode, automatic re-transmission as defined in the CAN protocol is switched off. (According to the CAN protocol, a message frame transmission that has been aborted by either arbitration loss or error occurrence has to be repeated without control by software.) All other behavior of single shot mode is identical to normal operation mode. Features of single shot mode can not be used in combination with normal mode with ABT.

The single-shot mode disables the re-transmission of an aborted message frame transmission according to the setting of FCNnCMCLCTL.FCNnCMCLALBF. When FCNnCMCLALBF is cleared to 0, re-transmission upon arbitration loss and upon error occurrence is disabled. If FCNnCMCLALBF is set to 1, re-transmission upon error occurrence is disabled, but re-transmission upon arbitration loss is enabled. As a consequence, FCNnMmCTL.FCNnMmTRQF in a message buffer defined as a transmit message buffer is cleared to 0 by the following events:

- Successful transmission of the message frame
- Arbitration loss while sending the message frame
- Error occurrence while sending the message frame

The events arbitration loss and error occurrence can be distinguished by checking FCNnCMISCTL.FCNnCMISITSF4 and FCNnCMISCTL.FCNnCMISITSF3 respectively, and the type of the error can be identified by reading FCNnCMLCSTR.FCNnCMLCSSL[2:0].

Upon successful transmission of the message frame, the transmit completion interrupt bit FCNnCMISCTL.FCNnCMISITSF0 is set to 1. If FCNnCMIECTL.FCNnCMIEINTF0 is set to 1 at this time, an interrupt request signal is output.

The single-shot mode can be used when emulating time-triggered communication methods (e.g., TTCAN level 1).

Caution FCNnCMCLCTL.FCNnCMCLALBF is only valid in single-shot mode. It does not influence the operation of re-transmission upon arbitration loss in the other operation modes.

24.11.3 Self-test mode

In the self-test mode, message frame transmission and message frame reception can be tested without connecting the CAN node to the CAN bus or without affecting the CAN bus.

In the self-test mode, the FCN module is completely disconnected from the CAN bus, but transmission and reception are internally looped back. The FCN transmission pin CTXDn is fixed to the recessive level.

If the falling edge on the FCN reception pin CRXDn is detected after the FCN module has entered the FCN sleep mode from the self-test mode, however, the module is released from the FCN sleep mode in the same manner as the other operation modes. Use the CRXDn FCN reception pin as a port pin in order to keep the module in FCN sleep mode.

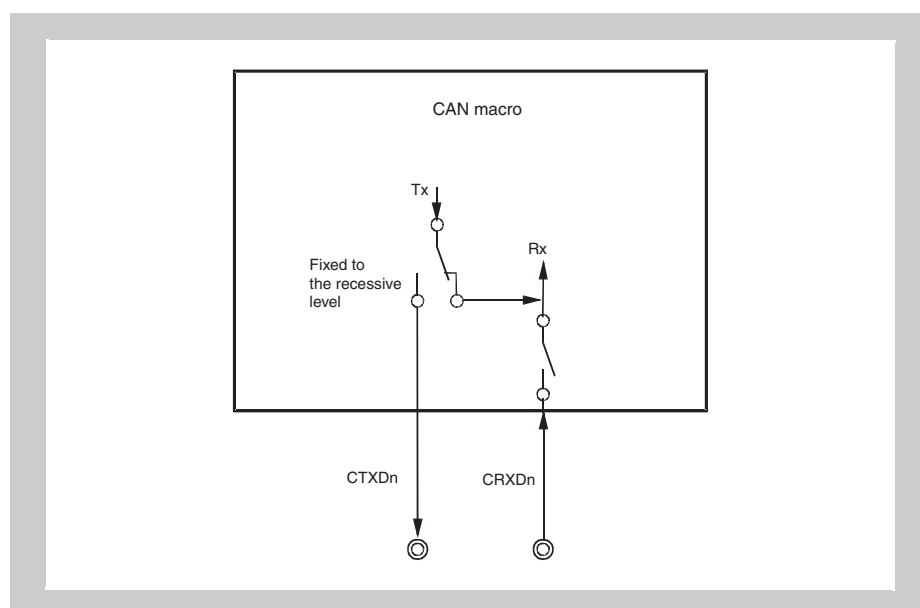

Figure 24-11 FCN module terminal connection in self-test mode

24.11.4 Receive/transmit operation in each operation mode

The following table shows outline of the receive/transmit operation in each operation mode.

Table 24-18 Outline of the receive/transmit in each operation mode

Operation mode	Transmission of data/remote frame	Transmission of ACK	Transmission of error/overload frame	Transmission on retry	Automatic block transmission (ABT)	Set of FCNnCM CLVALF bit	Store data to message buffer
Initialization mode	No	No	No	No	No	No	No
Normal operation mode	Yes	Yes	Yes	Yes	No	Yes	Yes
Normal operation mode with ABT	Yes	Yes	Yes	Yes	Yes	Yes	Yes
Receive only mode	No	No	No	No	No	Yes	Yes
Single-shot mode	Yes	Yes	Yes	No ^a	No	Yes	Yes
Self-test mode	Yes ^b	Yes ^b	Yes ^b	Yes ^b	No	Yes ^b	Yes ^b

- a) When the arbitration lost occurs, control of re-transmission is possible by FCNnCMCLCTL.FCNnCMCLALBF.
 b) Each signals are not generated to outside, but generated into the FCN module.

24.12 Time Stamp Function

CAN is an asynchronous serial communication protocol. All nodes connected to the CAN bus have a local, autonomous clock. As a consequence, the clocks of the nodes have no relation (i.e., the clocks are asynchronous and may have different frequencies).

In some applications, however, a common time base over the network (= global time base) is needed. In order to build up a global time base, a time stamp function is used. The essential mechanism of a time stamp function is the capture of timer values triggered by signals on the CAN bus.

24.12.1 Time stamp function

The CAN Controller supports the capturing of timer values triggered by a specific frame. An on-chip 16-bit capture timer unit in a microcontroller system is used in addition to the CAN Controller. The 16-bit capture timer unit captures the timer value according to a trigger signal (TSOUT) for capturing that is output when a data frame is received from the CAN Controller. The CPU can retrieve the time of occurrence of the capture event, i.e., the time stamp of the message received from the CAN bus, by reading the captured value. The TSOUT signal can be selected from the following two event sources and is specified by FCNnCMTSCTL.FCNnCMTSSELE.

- SOF event (start of frame)
(FCNnCMTSCTL.FCNnCMTSSELE = 0)
- EOF event (last bit of end of frame)
(FCNnCMTSCTL.FCNnCMTSSELE = 1)

The TSOUT signal is enabled by setting FCNnCMTSCTL.FCNnCMTSTSGE = 1.

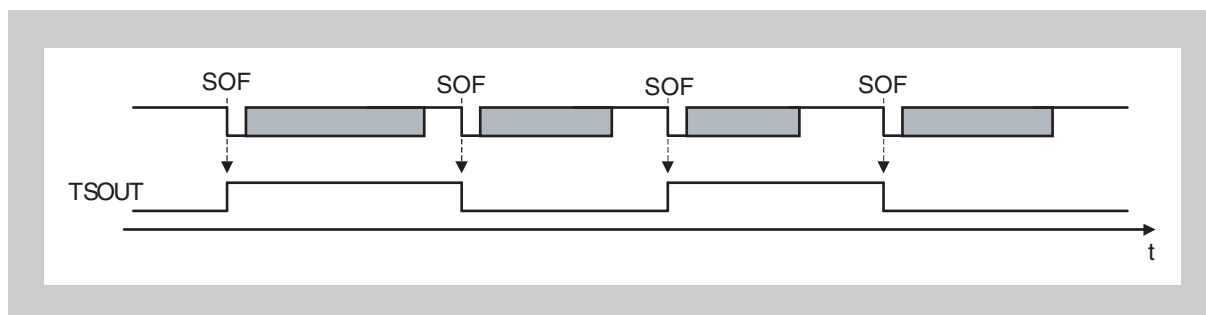

Figure 24-12 Timing diagram of capture signal TSOUT

The TSOUT signal toggles its level upon occurrence of the selected event during data frame reception (in Figure 24-12 "Timing diagram of capture signal TSOUT", the SOF is used as the trigger event source). To capture a timer value by using the TSOUT signal, the capture timer unit must detect the capture signal at both the rising edge and falling edge.

This time stamp function is controlled by the FCNnCMTSLOKE bit of the FCNnCMTSCTL register. When FCNnCMTSLOKE is cleared to 0, the TSOUT signal toggles upon occurrence of the selected event. If FCNnCMTSLOKE is set to 1, the TSOUT signal toggles upon occurrence of the selected event, but the toggle is stopped as FCNnCMTSCTL.FCNnCMTSTSGE is automatically cleared to 0 as soon as the message storing to the message buffer 0 starts. This suppresses the subsequent toggle occurrence by the TSOUT signal, so

that the time stamp value toggled last (= captured last) can be saved as the time stamp value of the time at which the data frame was received in message buffer 0.

Caution The time stamp function using the FCNnCMTSLOKE bit stops toggle of the TSOUT signal by receiving a data frame in message buffer 0. Toggle of the TSOUT signal does not stop when a data frame is received in a message buffer other than message buffer 0.

A data frame cannot be received in message buffer 0 when the FCN module is in the normal operation mode with ABT, because message buffer 0 must be set as a transmit message buffer.

In this operation mode, therefore, the function to stop toggle of the TSOUT signal by the FCNnCMTSLOKE bit cannot be used.

24.13 Baud Rate Settings

24.13.1 Baud rate setting conditions

Make sure that the settings are within the range of limit values for ensuring correct operation of the CAN Controller, as follows.

- $5 TQ \leq \text{SPT (sampling point)} \leq 17 TQ$
 $\text{SPT} = \text{TSEG1} + 1$
- $8 TQ \leq \text{DBT (data bit time)} \leq 25 TQ$
 $\text{DBT} = \text{TSEG1} + \text{TSEG2} + 1 TQ = \text{TSEG2} + \text{SPT}$
- $1 TQ \leq \text{SJW (synchronization jump width)} \leq 4 TQ$
 $\text{SJW} \leq \text{DBT} - \text{SPT}$
- $4TQ \leq \text{TSEG1} \leq 16TQ$ [$3 \leq \text{FCNnCMBTS1LG}[3:0] \leq 15$]
- $1 \leq \text{TSEG2} \leq 8$

<R>

- Notes**
1. $TQ = 1/f_{TQ}$ (f_{TQ} : CAN protocol layer basic system clock)
 2. The values of TSEG1, TSEG2, and SJW are defined by the bits of the FCNnCMBTCTL register as follows:
 $\text{TSEG1: FCNnCMBTCTL.FCNnCMBTS1LG}[3:0] + 1$
 $\text{TSEG2: FCNnCMBTCTL.FCNnCMBTS2LG}[2:0] + 1$
 $\text{SJW: FCNnCMBTCTL.FCNnCMBTJWLG}[1:0] + 1$

Table 24-19 "Settable bit rate combinations" shows the combinations of bit rates that satisfy the above conditions.

- Cautions**
1. The values in Table 24-20 "Representative examples of baud rate settings ($f_{CANPRE} = 8 \text{ MHz}$)" do not guarantee the operation of the network system. Thoroughly check the effect on the network system, taking into consideration oscillation errors and delays of the CAN bus and CAN transceiver.
 2. Baud rates higher than 500 kbit/s are not allowed with $f_{CANPRE} \leq 8 \text{ MHz}$.

33.3	60	00111011	8	1	3	2	2	0100	001	75.0
33.3	60	00111011	8	1	5	1	1	0101	000	87.5

Caution The values in Table 24-21 "Representative examples of baud rate settings ($f_{CANPRE} = 16 \text{ MHz}$)" do not guarantee the operation of the network system. Thoroughly check the effect on the network system, taking into consideration oscillation errors and delays of the CAN bus and CAN transceiver.

24.14 Operation of the CAN Controller

The processing procedure for showing in this chapter is recommended processing procedure to operate FCN.

Develop the program referring to recommended processing procedure in this chapter.

24.14.1 Initialization

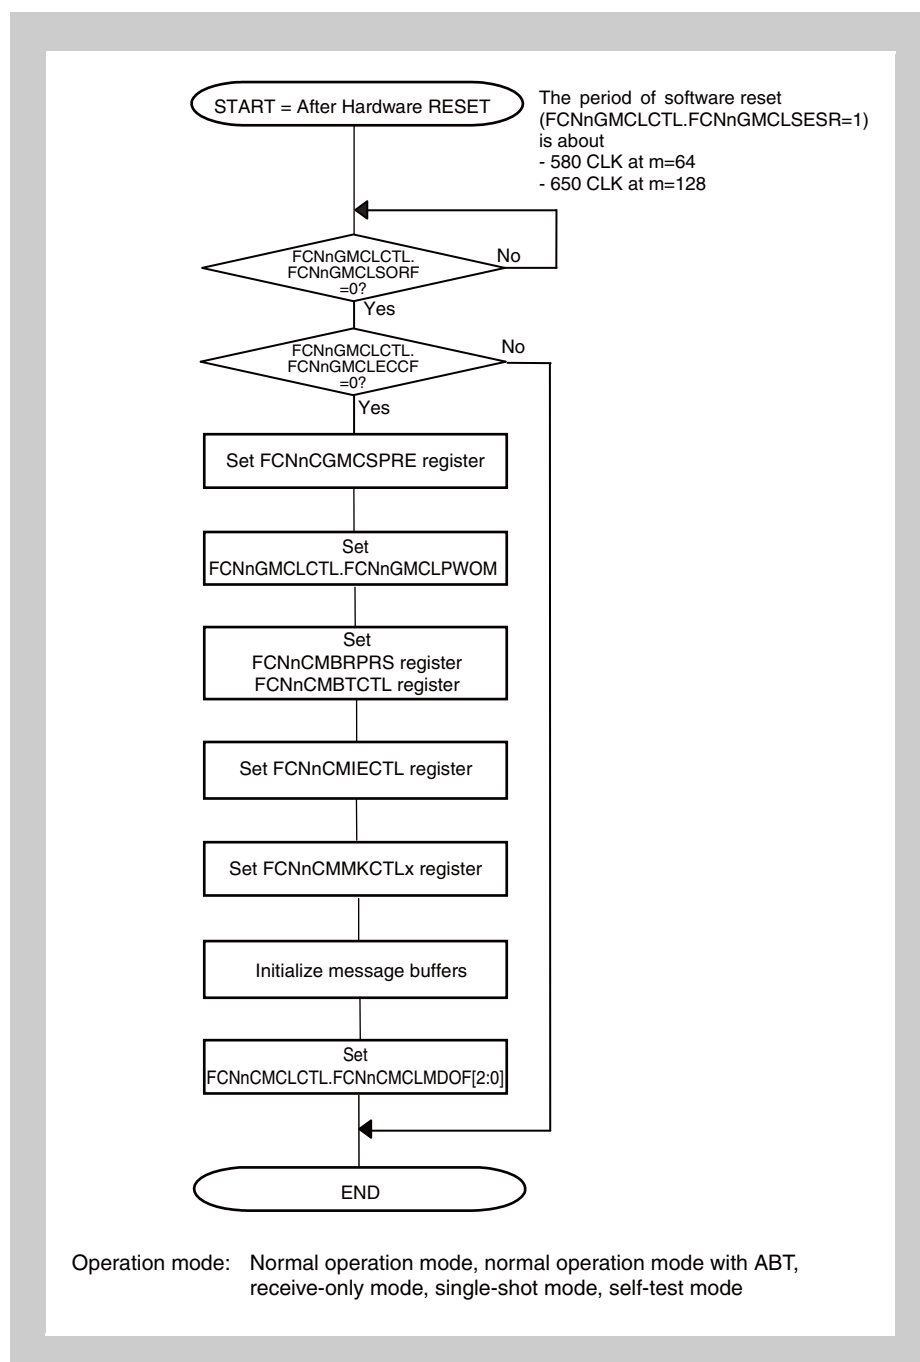

Figure 24-13 Initialization

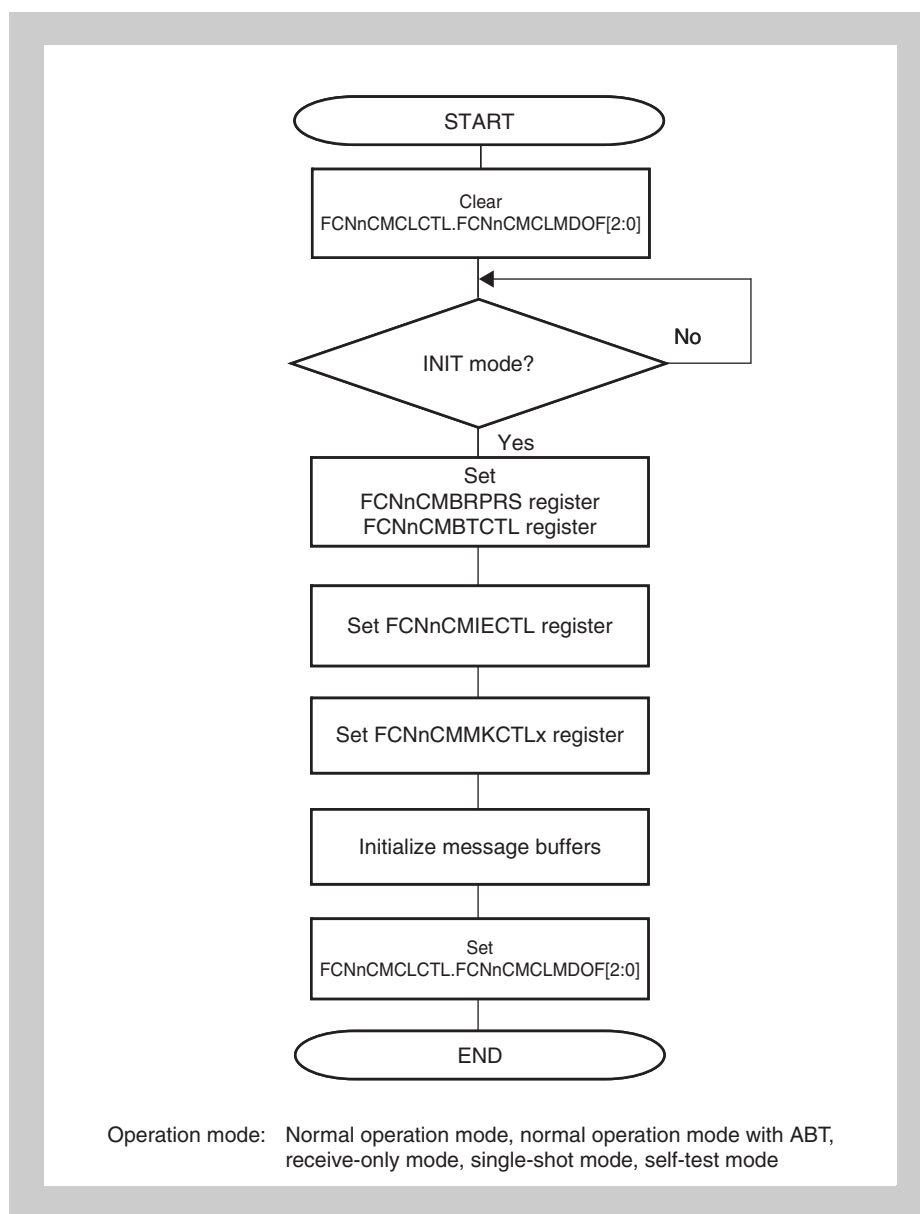

Figure 24-14 Re-initialization without using the software reset function

Caution To clear the error counter (by setting FCNnCMCLERCF) during re-initialization, do so in one of the following states.

- In the initialization mode state following FCN module start (by setting FCNnGMCLPWOM while FCNnGMCLPWOM = 0)
- In the initialization mode state following clearing of all transmission requests according to the transmission abort processing described in Figure 24-24 “Transmission abort processing (except normal operation mode with ABT)” during the operation mode (Clear all the transmission requests according to the transmission abort processing described in Figure 24-25 “Transmission abort processing (normal operation mode with ABT) - Repeat option for aborted message” in the normal operation mode with ABT.)

Figure 24-15 Re-initialization with Software Reset function

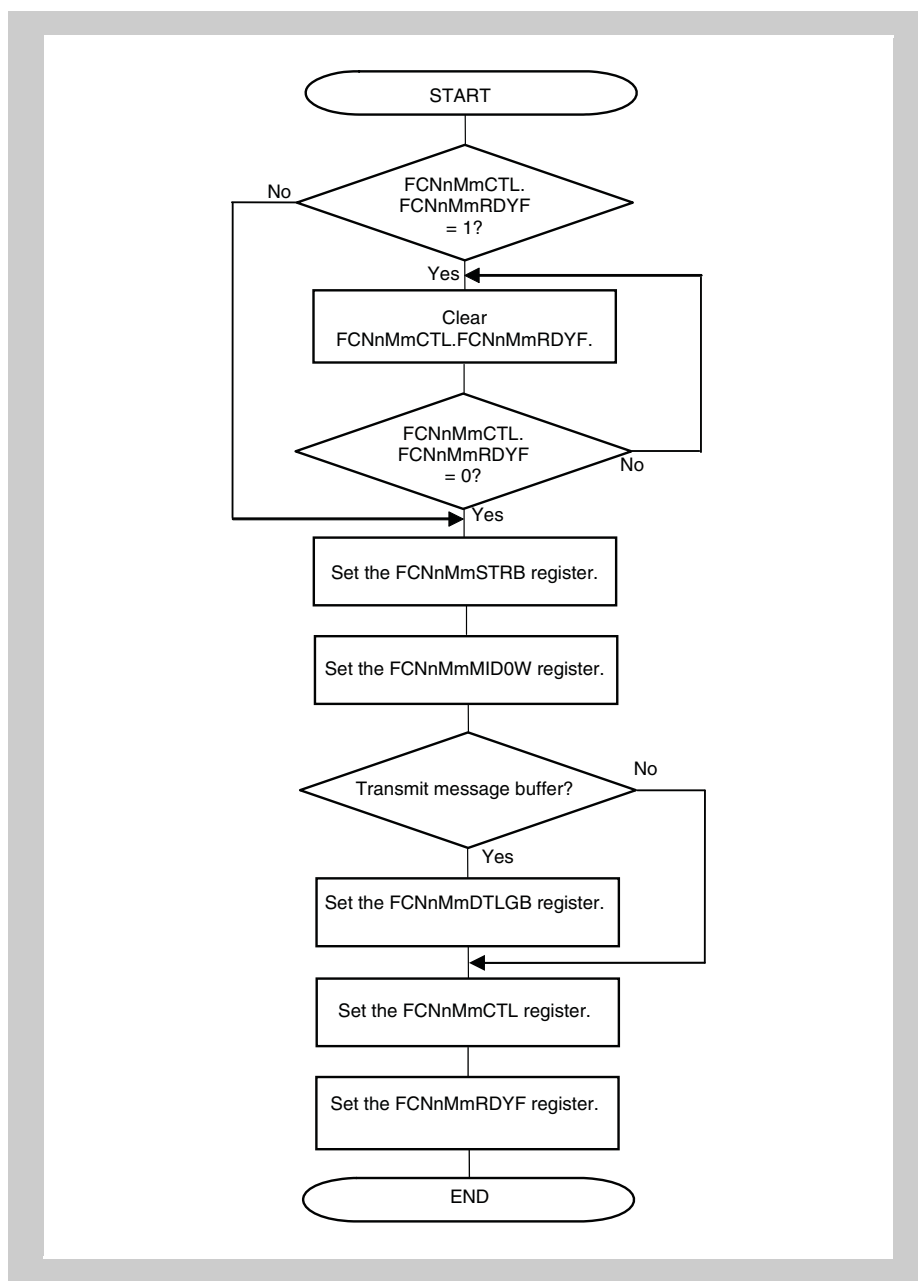

Figure 24-16 Message buffer initialization

- Cautions**
1. Before a message buffer is initialized, FCNnMmCTL.FCNnMmRDYF must be cleared.
 2. Make the following settings for message buffers not used by the application.
 - Clear FCNnMmRDYF, FCNnMmTRQF, and FCNnMmDTNF bits of the FCNnMmCTL register to 0.
 - Clear FCNnMmSTRB.FCNnMmSSAM to 0.

Figure 24-17 “Message buffer redefinition during reception” shows the processing for a receive message buffer (FCNnMmSTRB.FCNnMmSSMT[3:0] = 0001_B to 1000_B).

Figure 24-17 Message buffer redefinition during reception

Figure 24-18 “Message buffer redefinition during transmission” shows the processing for a transmit message buffer during transmission (FCNnMmSTRB.FCNnMmSSMT[3:0] = 0000_B).

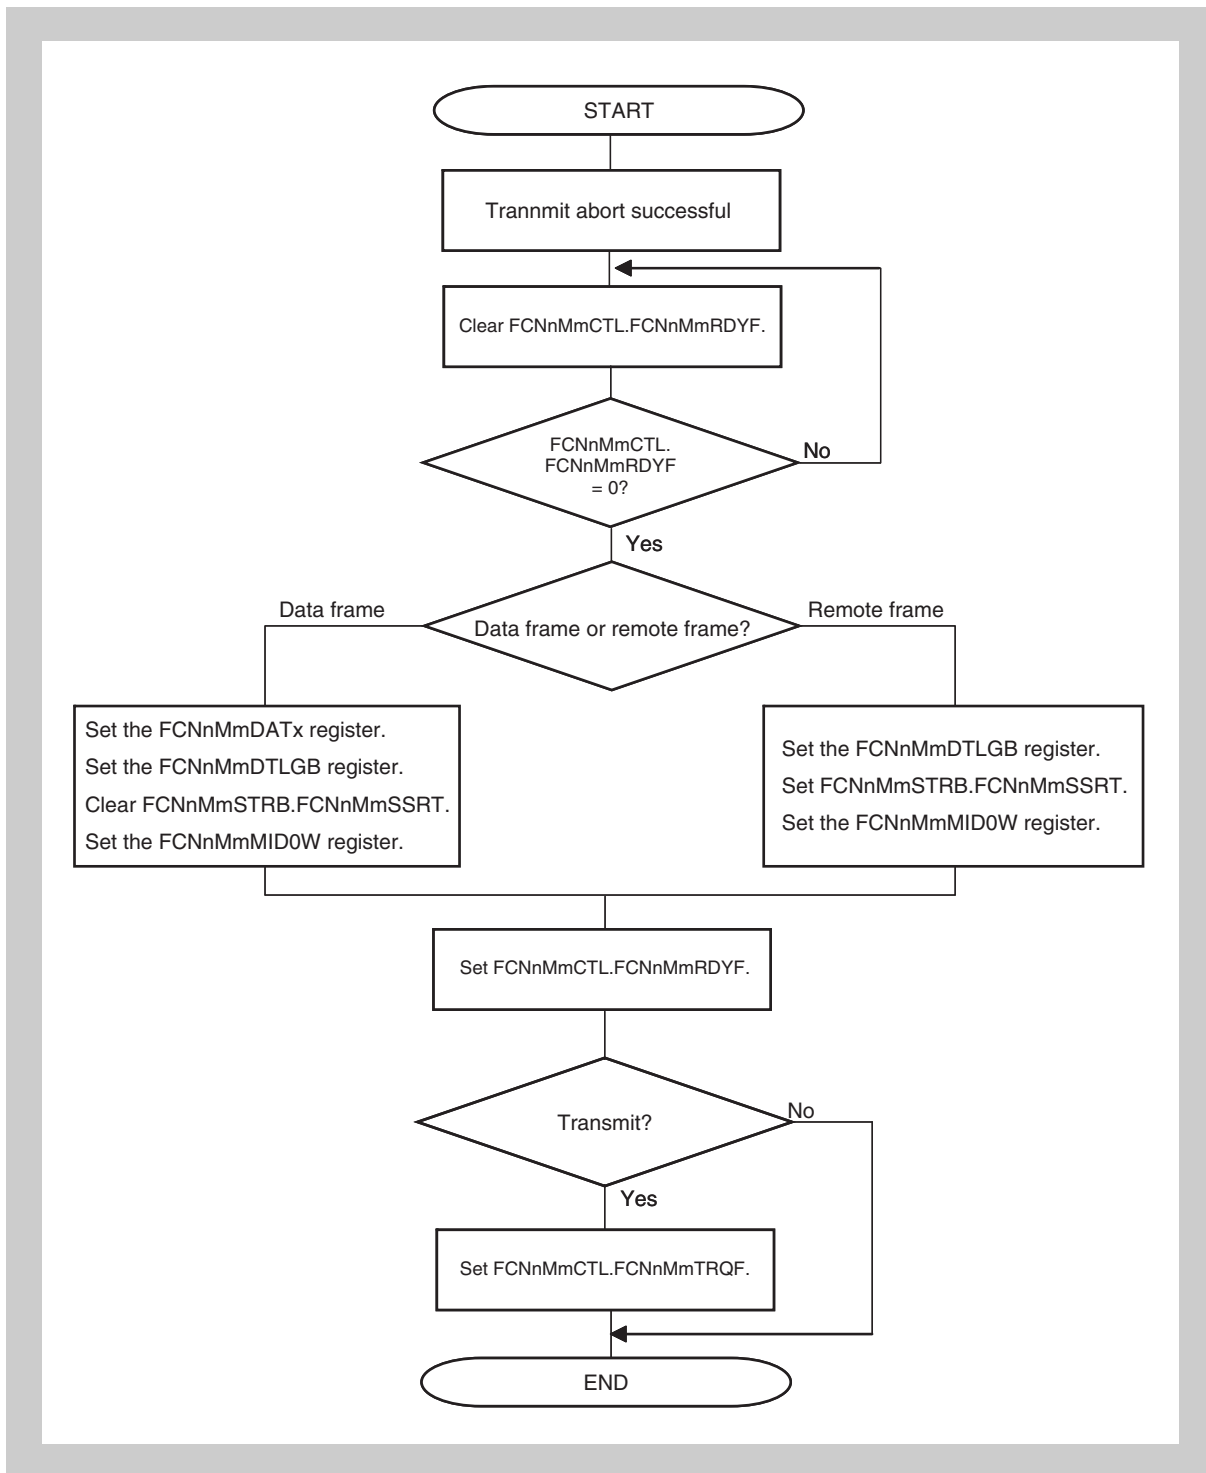

Figure 24-18 Message buffer redefinition during transmission

24.14.2 Message transmission

Figure 24-19 “Message transmit processing” shows the processing for a transmit message buffer (FCNnMmSTRB.FCNnMmSSMT[3:0] = 0000_B).

Figure 24-19 Message transmit processing

- Cautions**
1. FCNnMmCTL.FCNnMmTRQF should be set after FCNnMmCTL.FCNnMmRDYF is set.
 2. FCNnMmCTL.FCNnMmRDYF and FCNnMmCTL.FCNnMmTRQF should not be set at the same time.

Figure 24-20 “ABT message transmit processing” shows the processing for a transmit message buffer (FCNnMmSTRB.FCNnMmSSMT[3:0] = 0000_B)

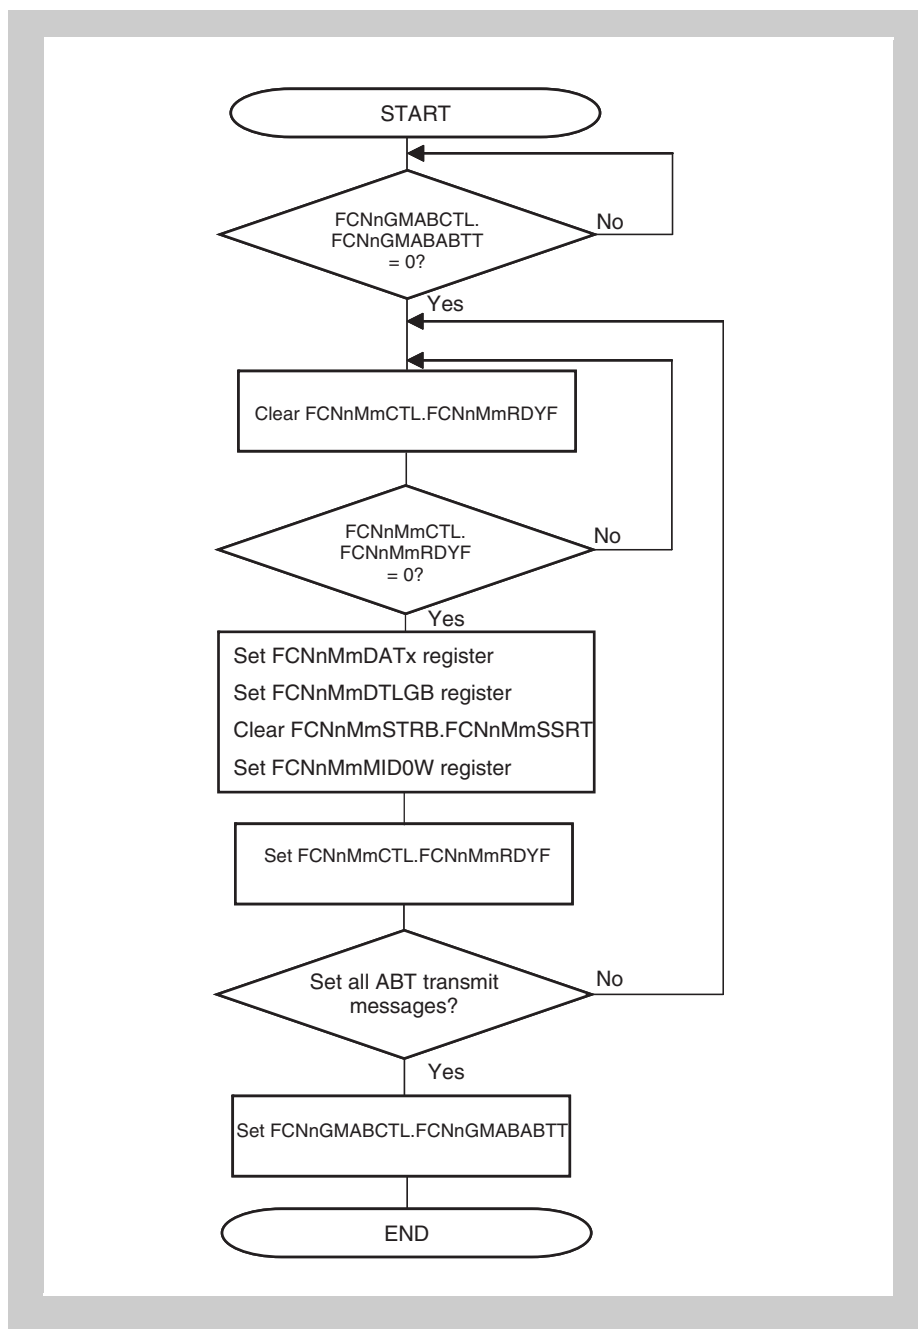

Figure 24-20 ABT message transmit processing

Note This processing (normal operation mode with ABT) can only be applied to message buffers usable with ABT mode. For message buffers other than the ABT message buffers, see Figure 24-19 “Message transmit processing” on page 1499.

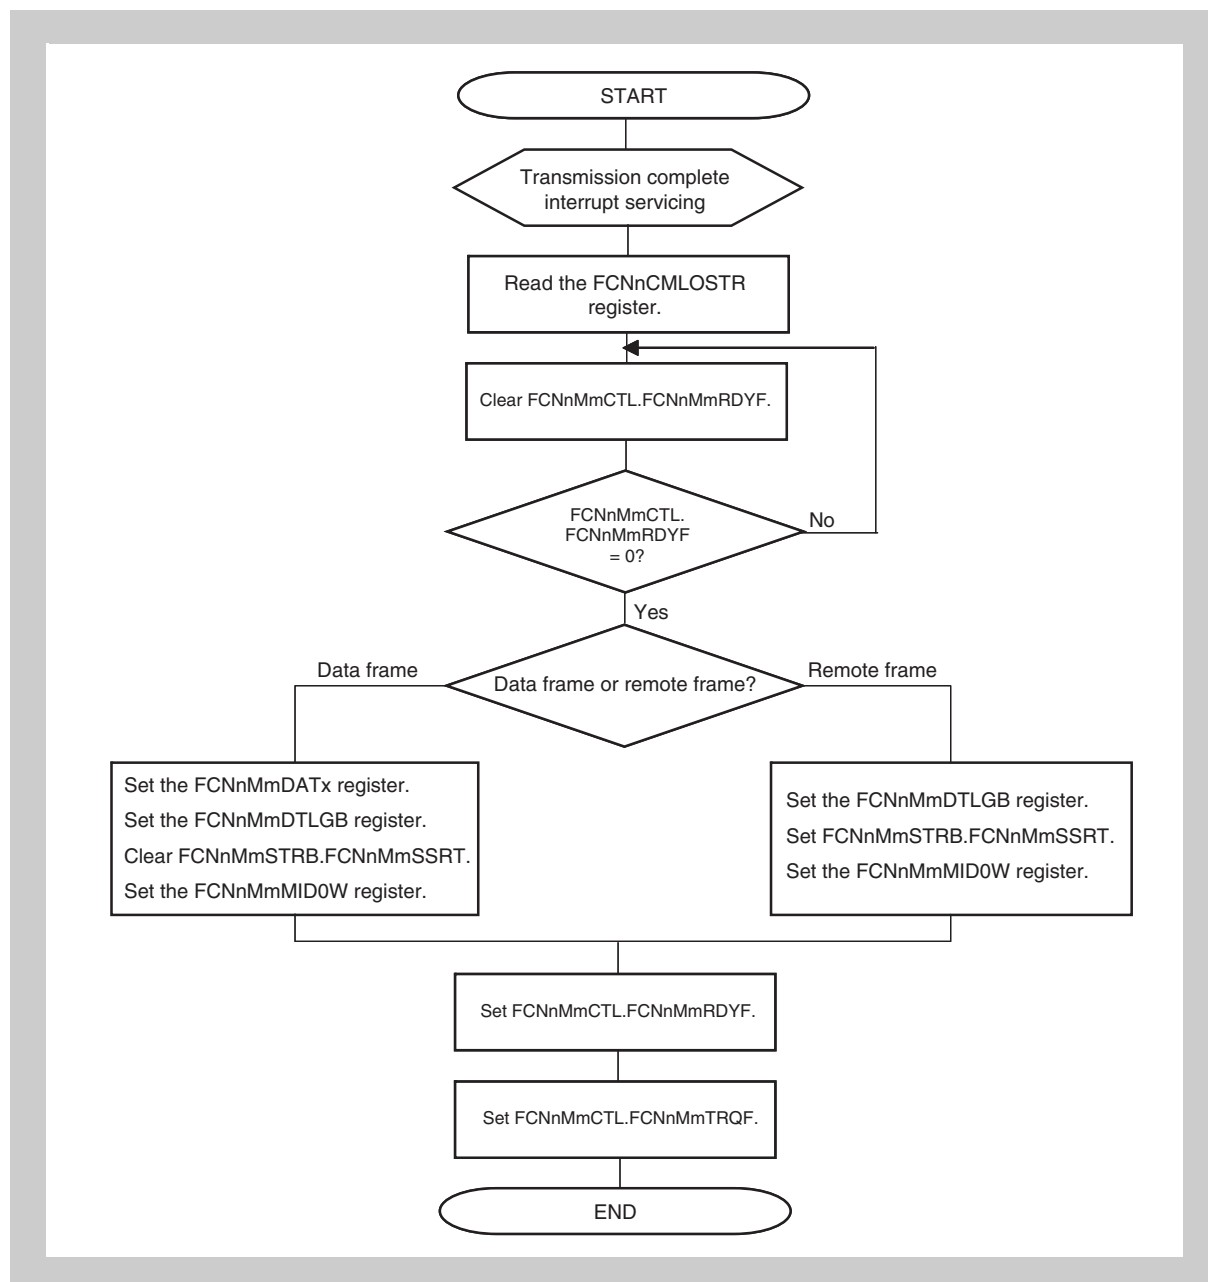

Figure 24-21 Transmission via interrupt (using FCNnCMLOSTR register)

- Cautions**
1. FCNnMmCTL.FCNnMmTRQF should be set after FCNnMmCTL.FCNnMmRDYF is set.
 2. FCNnMmCTL.FCNnMmRDYF and FCNnMmCTL.FCNnMmTRQF should not be set at the same time.

Note Also check the FCNnGMCLSSMO flag at the beginning and at the end of the interrupt routine, in order to check the access to the message buffers as well as TX history list registers, in case a pending sleep mode had been executed. If FCNnGMCLSSMO is detected to be cleared at any check, the actions and

results of the processing have to be discarded and processed again, after FCNnGMCLSSMO is set again.
It is recommended to cancel any sleep mode requests, before processing TX interrupts.

Figure 24-22 Transmission via interrupt (using FCNnCMTGTX register)

- Cautions**
1. FCNnMmCTL.FCNnMmTRQF should be set after FCNnMmCTL.FCNnMmRDYF is set.
 2. FCNnMmCTL.FCNnMmRDYF and FCNnMmCTL.FCNnMmTRQF should not be set at the same time.
-

- Notes**
1. Also check the FCNnGMCLSSMO flag at the beginning and at the end of the interrupt routine, in order to check the access to the message buffers as well as TX history list registers, in case a pending sleep mode had been executed. If FCNnGMCLSSMO is detected to be cleared at any check, the actions and results of the processing have to be discarded and processed again, after FCNnGMCLSSMO is set again.
It is recommended to cancel any sleep mode requests, before processing TX interrupts.
 2. If FCNnCMTGTX.FCNnCMTGTVFF was set once, the transmit history list is inconsistent. Consider to scan all configured transmit buffers for completed transmissions.

Figure 24-23 Transmission via software polling

- Cautions**
1. FCNnMmCTL.FCNnMmTRQF should be set after FCNnMmCTL.FCNnMmRDYF is set.
 2. FCNnMmCTL.FCNnMmRDYF and FCNnMmCTL.FCNnMmTRQF should not be set at the same time.

- Notes**
1. Also check the FCNnGMCLSSMO flag at the beginning and at the end of the polling routine, in order to check the access to the message buffers as well as TX history list registers, in case a pending sleep mode had been executed. If FCNnGMCLSSMO is detected to be cleared at any check, the actions and results of the processing have to be discarded and processed again, after FCNnGMCLSSMO is set again.
 2. If FCNnCMTGTX.FCNnCMTGTVFF was set once, the transmit history list is inconsistent. Consider to scan all configured transmit buffers for completed transmissions.

Figure 24-24 Transmission abort processing (except normal operation mode with ABT)

- Cautions**
1. Clear FCNnMmCTL.FCNnMmTRQF for aborting transmission request, not FCNnMmCTL.FCNnMmRDYF.
 2. Before making a sleep mode transition request, confirm that there is no transmission request left using this processing.
 3. FCNnCMCLCTL.FCNnCMCLSSTS can be periodically checked by a user application or can be checked after the transmit completion interrupt.
 4. Do not execute any new transmission request including in the other message buffers while transmission abort processing is in progress.

Figure 24-25 Transmission abort processing (normal operation mode with ABT) - Repeat option for aborted message

- Cautions**
1. Clear FCNnMmCTL.FCNnMmTRQF for aborting transmission request, not FCNnMmCTL.FCNnMmRDYF.
 2. Before making a sleep mode transition request, confirm that there is no transmission request left using this processing.
 3. FCNnCMCLCTL.FCNnCMCLSSTS can be periodically checked by a user application or can be checked after the transmit completion interrupt.
 4. Do not execute any new transmission request including in the other message buffers while transmission abort processing is in progress.

Figure 24-26 “ABT transmission request abort processing (in normal operation mode with ABT) (1)” shows the processing to not skip resumption of transmitting a message that was stopped when transmission of an ABT message buffer was aborted.

Figure 24-26 ABT transmission request abort processing (in normal operation mode with ABT) (1)

- Cautions**
1. Do not set any transmission requests while ABT transmission abort processing is in progress.
 2. Make a FCN sleep mode/FCN stop mode request after FCNnGMABCTL.FCNnGMABABTT is cleared (after ABT mode is stopped) following the procedure shown in Figure 24-26 “ABT transmission request abort processing (in normal operation mode with ABT) (1)”. When clearing a transmission request in an area other than the ABT area, follow the procedure shown in Figure 24-24 “Transmission abort processing (except normal operation mode with ABT)” on page 1505 .

Figure 24-27 “ABT transmission request abort processing (in normal operation mode with ABT) (2)” shows the processing to not skip resumption of transmitting a message that was stopped when transmission of an ABT message buffer was aborted.

Figure 24-27 ABT transmission request abort processing (in normal operation mode with ABT) (2)

- Cautions**
1. Do not set any transmission requests while ABT transmission abort processing is in progress.
 2. Make a FCN sleep mode/FCN stop mode request after FCNnGMABCTL.FCNnGMABABTT is cleared (after ABT mode is stopped) following the procedure shown in Figure 24-26 “ABT transmission request abort processing (in normal operation mode with ABT) (1)”. When clearing a transmission request in an area other than the ABT area, follow the procedure shown in Figure 24-24 “Transmission abort processing (except normal operation mode with ABT)” on page 1505 .

Figure 24-28 “ABT transmission request abort processing (normal operation mode with ABT) with transmission completely finished flag” shows the processing on ABT mode, when using the Transmit Abort functionality (transmit flag). The box “Transmission abort success” represents the checking of the transmission abort success by checking the FCNnMmTCPF flag within the ABT message buffers.

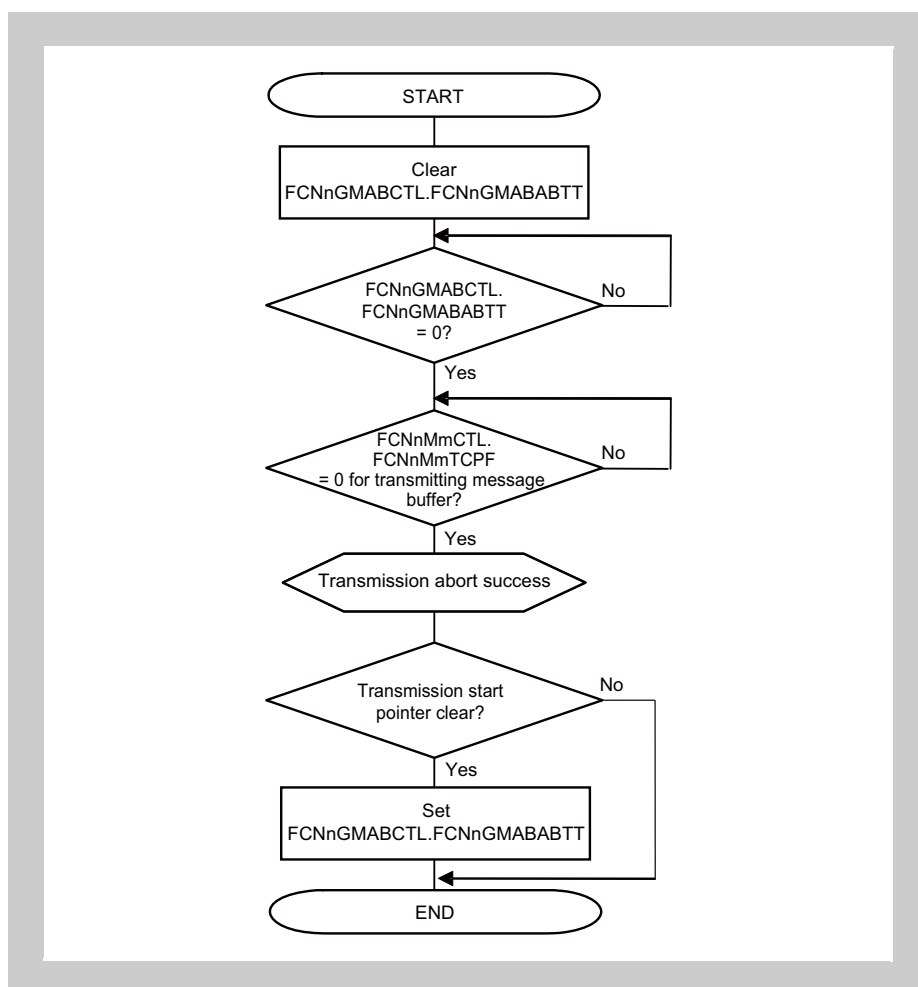

Figure 24-28 ABT transmission request abort processing (normal operation mode with ABT) with transmission completely finished flag

- Cautions**
1. Do not set any transmission requests while ABT transmission abort processing is in progress.
 2. Make a FCN sleep mode/FCN stop mode request after FCNnGMABCTL.FCNnGMABABTT is cleared (after ABT mode is stopped) following the procedure shown in *Figure 24-26 “ABT transmission request abort processing (in normal operation mode with ABT) (1)”*. When clearing a transmission request in an area other than the ABT area, follow the procedure shown in *Figure 24-24 “Transmission abort processing (except normal operation mode with ABT)” on page 1505*.

Note There is the case that all ABT is transmitted completely even if ABT transmission abort processing is performed successfully. Then it is possible to know which message is finished transmission.

Figure 24-29 “Transmission request abort processing with transmit abort interrupt and transmission completely finished flag” shows the processing when using the Transmit Abort functionality (Transmit Abort Interrupt).

Figure 24-29 Transmission request abort processing with transmit abort interrupt and transmission completely finished flag

Note The determination that FCNnMmRDYF=0 is made with consideration for the case when FCNnMmRDYF is cleared during transmission completion processing due to an interrupt.

- Cautions**
1. Abort transmissions by clearing FCNnMmTRQF rather than by clearing FCNnMmRDYF.
 2. Make sure that the transmission request made via this flow sequence has completely ended before sending a sleep request.
 3. Do not update messages subject to transmission abort processing (FCNnMmRDYF or FCNnMmTRQF is set), for example via transmission complete interrupt processing.
 4. Do not clear FCNnMmTRQF in other message buffers while performing transmission abort processing.
 5. If you change the ID to one with lower priority during transmission abort processing, then wait for at least one frame after clearing FCNnMmTRQF before sending a transmission request.
 6. Do not enable wake-up interrupts on RXONLY-CH if you use transmit abort interrupts. (DIAG version only)
 7. Always read FCNnMmTRQF and FCNnMmTCPF at least once.

Figure 24-30 “Transmission request abort processing with transmission completely finished flag” shows the processing when using the Transmit Abort functionality (Transmission Completely Finished Flag FCNnMmTCPF).

Figure 24-30 Transmission request abort processing with transmission completely finished flag

Note The determination that FCNnMmRDYF=0 is made with consideration for the case when FCNnMmRDYF is cleared during transmission completion processing due to an interrupt.

- Cautions**
1. Abort transmissions by clearing FCNnMmTRQF rather than by clearing FCNnMmRDYF.
 2. Make sure that the transmission request made via this flow sequence has completely ended before sending a sleep request.
 3. Do not update messages subject to transmission abort processing (FCNnMmRDYF or FCNnMmTRQF is set), for example via transmission complete interrupt processing.
 4. If you change the ID to one with lower priority during transmission abort processing, then wait for at least one frame after clearing FCNnMmTRQF before sending a transmission request.
 5. Always read FCNnMmTRQF and FCNnMmTCPF at least once.

24.14.3 Message reception

Figure 24-31 Reception via interrupt (using FCNnCMLISTR register)

- Notes**
1. Check FCNnMmCTL.FCNnMmMUCF and FCNnMmCTL.FCNnMmDTNF bits using one read access.
 2. Also check the FCNnGMCLSSMO flag at the beginning and at the end of the interrupt routine, in order to check the access to the message buffers as well as reception history list registers, in case a pending sleep mode had been executed. If FCNnGMCLSSMO is detected to be cleared at any check, the actions and results of the processing have to be discarded and processed again, after FCNnGMCLSSMO is set again. It is recommended to cancel any sleep mode requests, before processing RX interrupts.

Figure 24-32 Reception via interrupt (using FCNnCMRGRX register)

- Notes**
1. Check FCNnMmCTL.FCNnMmMUCF and FCNnMmCTL.FCNnMmDTNF bits using one read access.
 2. Depending of the processing target of the application, two ways are possible:
 - Way A: The message is not processed within this pass, but with the next pass, depending on the timing this can happen latest with the next Receive Interrupt.
Other messages will be processed earlier.
 - Way B: The message is processed within this pass, the loop waits on this message.
Other messages will be processed later.
 3. Also check the FCNnGMCLSSMO flag at the beginning and at the end of the interrupt routine, in order to check the access to the message buffers as well as reception history list registers, in case a pending sleep mode had been executed. If FCNnGMCLSSMO is detected to be cleared at any check, the actions and results of the processing have to be discarded and processed again, after FCNnGMCLSSMO is set again.
It is recommended to cancel any sleep mode requests, before processing RX interrupts.
 4. If FCNnCMRGRX.FCNnCMRGRVFF was set once, the receive history list is inconsistent. Consider to scan all configured receive buffers for receptions.
 5. For the processing shown in *Figure 24-32 “Reception via interrupt (using FCNnCMRGRX register)”*, the processing shown in *Figure 24-33 “Reception via interrupt (using FCNnCMRGRX register), alternative way”* can be used alternatively.

Figure 24-33 Reception via interrupt (using FCNnCMRGRX register), alternative way

- Notes**
1. Also check the FCNnGMCLSSMO flag at the beginning and at the end of the interrupt routine, in order to check the access to the message buffers as well as reception history list registers, in case a pending sleep mode had been executed. If FCNnGMCLSSMO is detected to be cleared at any check, the actions and results of the processing have to be discarded and processed again, after FCNnGMCLSSMO is set again. It is recommended to cancel any sleep mode requests, before processing RX interrupts.
 2. If FCNnCMRGRX.FCNnCMRGRVFF was set once, the receive history list is inconsistent. Consider to scan all configured receive buffers for receptions.
 3. This flow will not provide most recently received data for the application. However, due to less effort on processing, it reduces interrupt load.
 4. The overwrite function (FCNnMmSTRB.FCNnMmSSOW=1) must not be used with this flow - data inconsistency could occur.
 - 5.

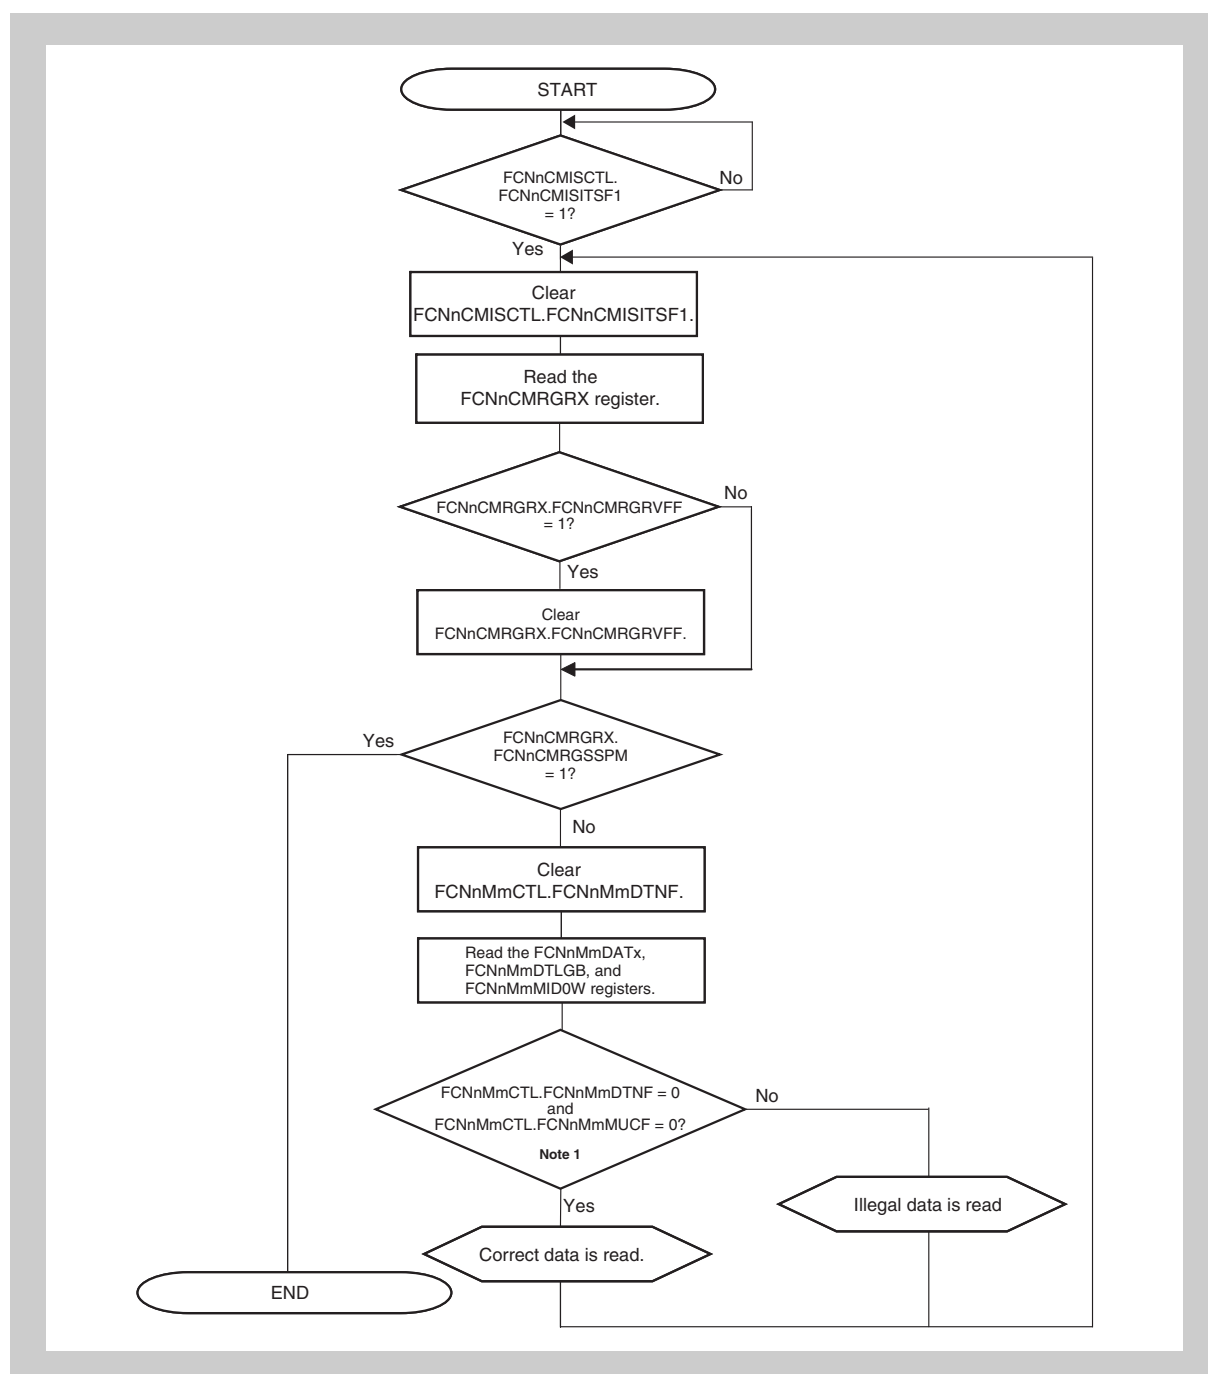

Figure 24-34 Reception via software polling

- Notes**
1. Check FCNnMmCTL.FCNnMmMUCF and FCNnMmCTL.FCNnMmDTNF bits using one read access.
 2. Also check the FCNnGMCLSSMO flag at the beginning and at the end of the polling routine, in order to check the access to the message buffers as well as reception history list registers, in case a pending sleep mode had been executed. If FCNnGMCLSSMO is detected to be cleared at any check, the actions and results of the processing have to be discarded and processed again, after FCNnGMCLSSMO is set again.
 3. If FCNnCMRGRX.FCNnCMRGRVFF was set once, the receive history list is inconsistent. Consider to scan all configured receive buffers for receptions.

24.14.4 Power save modes

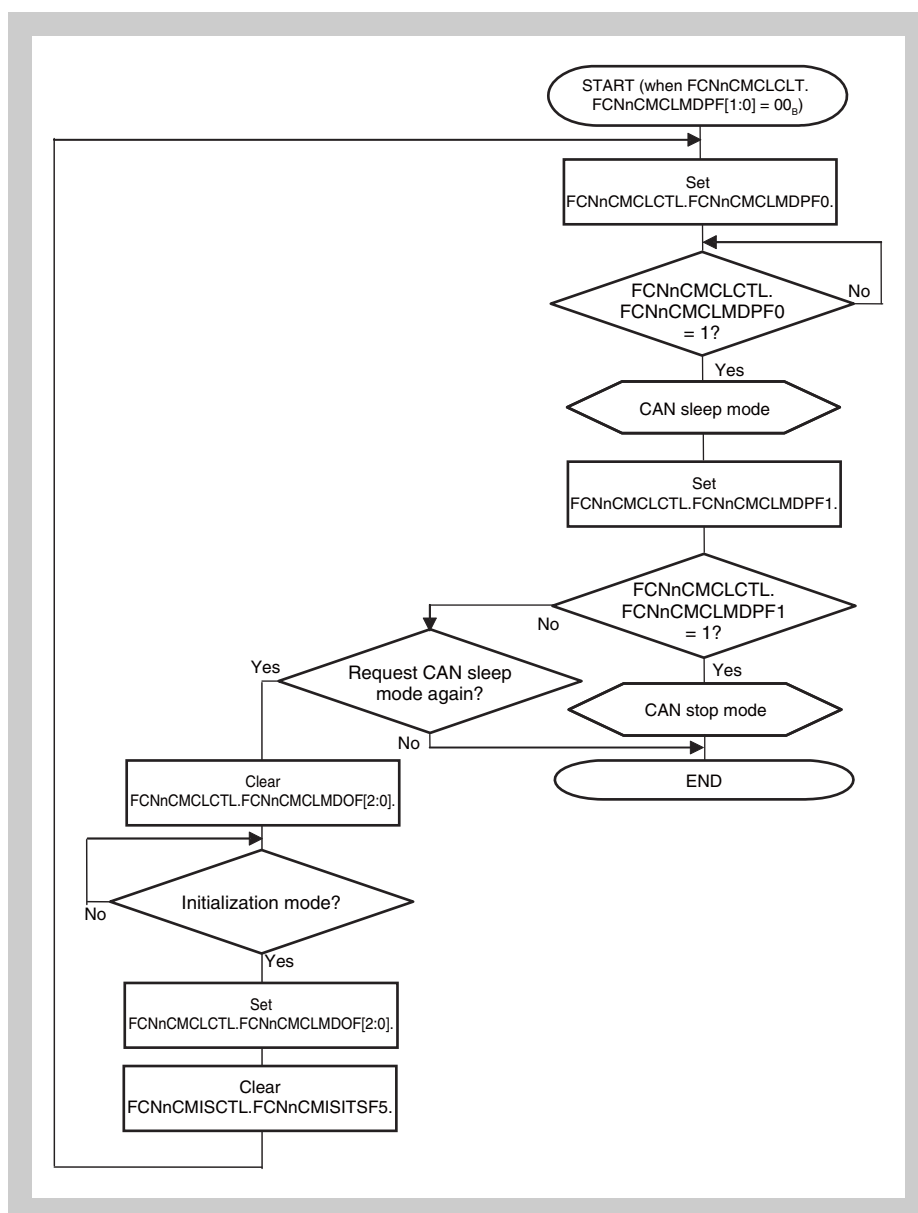

Figure 24-35 Setting FCN sleep mode/stop mode

Caution To abort transmission before making a request for the FCN sleep mode, perform processing according to previously given flowcharts.

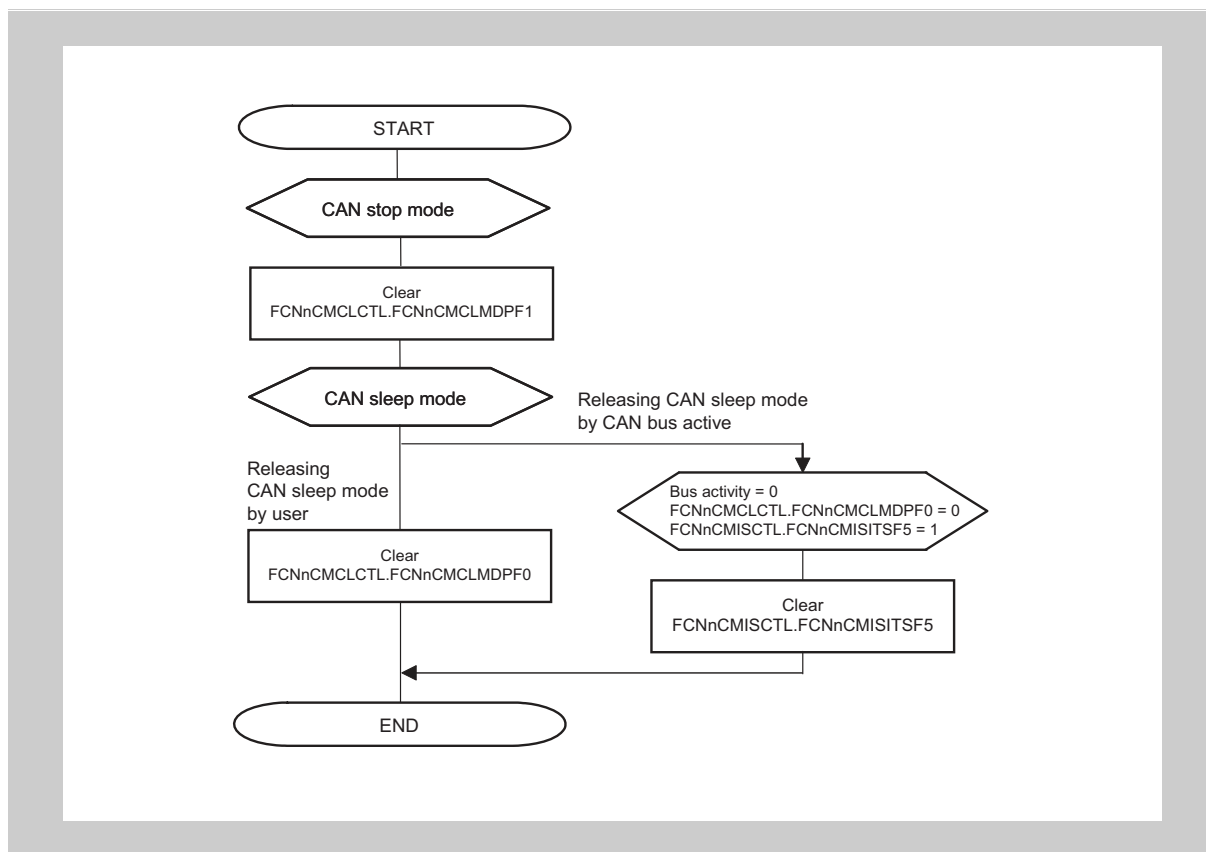

Figure 24-36 Clear FCN sleep/stop mode

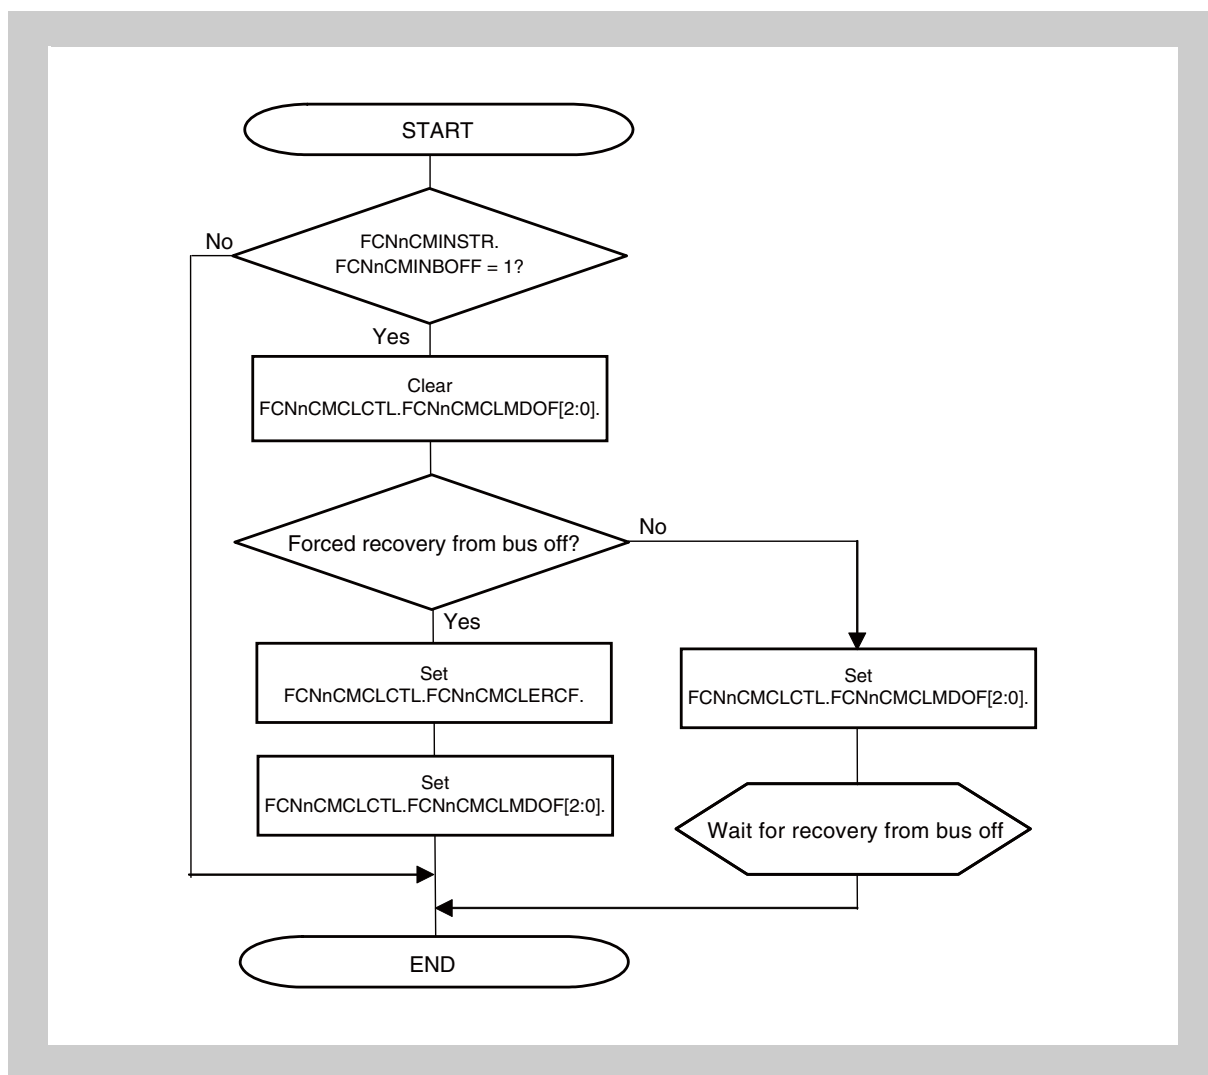

Figure 24-37 Bus-off recovery

Caution When the transmission from the initialization mode to any operation modes is requested to execute bus-off recovery sequence again in the bus-off recovery sequence, reception error counter is cleared. Therefore it is necessary to detect 11 consecutive recessive-level bits 128 times on the bus again.

Note Operation mode: Normal operation mode, normal operation mode with ABT, receive-only mode, singleshot mode, self-test mode.

Figure 24-38 Normal shutdown process

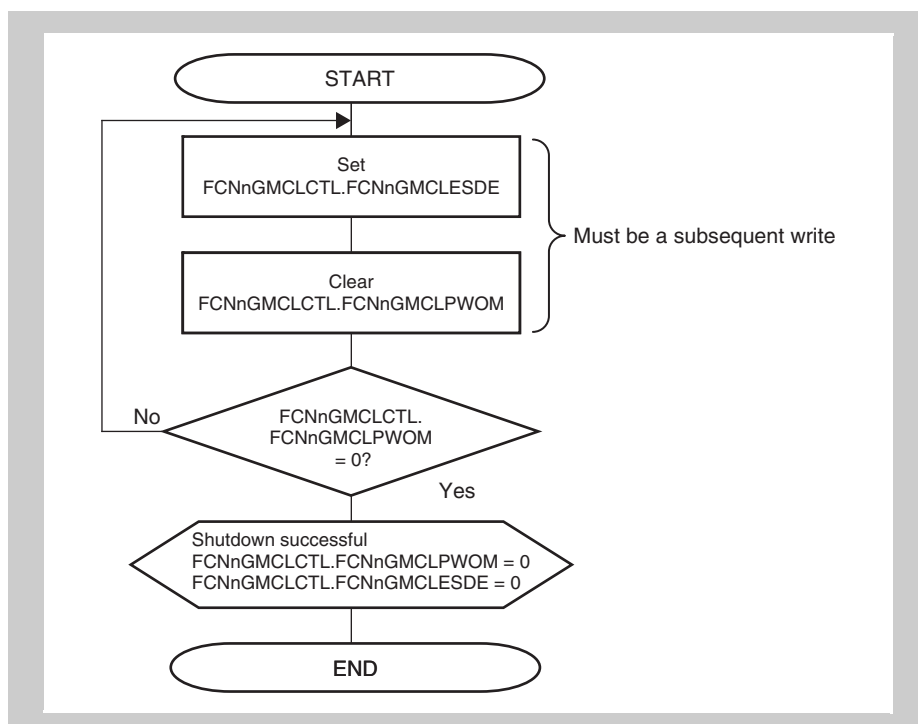

Figure 24-39 Forced shutdown process

Caution Do not read- or write-access any registers by software between setting the FCNnGMCLSEDE bit and clearing the FCNnGMCLPWOM bit.

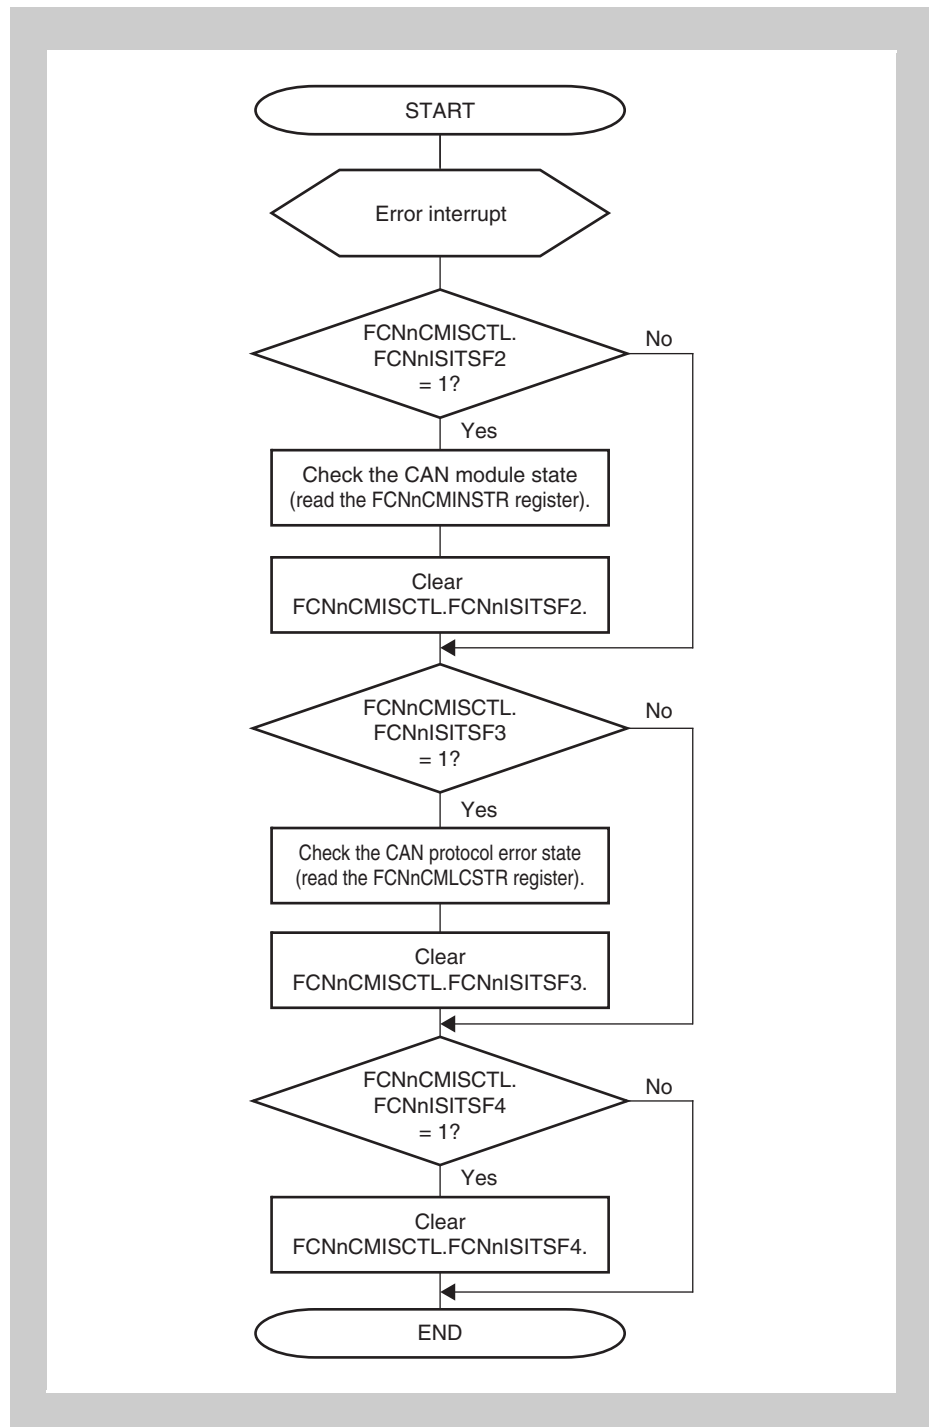

Figure 24-40 Error handling

Figure 24-41 Setting CPU stand-by (from FCN sleep mode)

- Notes**
1. Before the CPU is set in the CPU standby mode, please check if the FCN sleep mode has been reached. However, after check of the FCN sleep mode, until the CPU is set in the CPU standby mode, the FCN sleep mode may be cancelled by wakeup from CAN bus.
 2. There is a possibility, that between the check of FCNnGMCLSSMO = 0 and setting of the CPU standby mode a wake up condition on the CAN bus occurs. In that case the CAN module releases the SLEEP mode, the FCNnCMISITSF5 bit is set and if enabled the wake up interrupt will be generated.

Figure 24-42 Setting CPU stand-by (from FCN stop mode)

Caution The FCN stop mode can only be released by setting FCNnCMCLCTL.FCNnCMCLMDPF[1:0] to 01_B and not by a change in the FCN bus state.

Chapter 25 A/D Converter (ADCA)

This chapter provides a general description of the A/D converter (ADCA).

25.1 V850E2/ML4 Features describes the features specific to the V850E2/ML4, such as the number of channels, base addresses of registers, and I/O signal names.

25.2?Function Overview? and the sections that follow describe the features common to all products that have ADCA.

25.1 V850E2/ML4 Features

The V850E2/ML4 incorporates an A/D converter (ADCA).

The number of channels and other specifications vary depending on the product. The following table shows the specifications of the V850E2/ML4:

Product		V850E2/ML4
ADC		
ADC-equipped unit (indicated by n)		1 (n = 0)
Analog input pins (indicated by m)		12 (m = 0 to 11)
Channel groups (indicated by i)		3 (i = 0 to 2)
Register base address	<ADCA _n _base_OS> ^a	FF81 D000 _H
	<ADCA _n _base_USER> ^a	FFFF DC00 _H
Resolution		10/12 ^b bits
Discharge function		None
	ADCA _n CTL1.ADCA _n DISC	Not supported. Be sure to write "0" to this bit.
Hardware trigger expansion function		Available
Channel S/H functions (indicated by x) ^c		x = 0 to 5
Self-diagnosis functions		None
	ADCA _n CG0.ADCA _n DIAG	Not supported. Be sure to write "0" to this bit.
	ADCA _n IOC0.ADCA _n IDG	
	ADCA _n DGCTL0 ADCA _n DGCTL1 ADCA _n PDCTL0 ADCA _n DGCR	Access prohibited
Supply clock (PCLK)		f _{PCLK}
ADCA _n CNV _i signals		Available (i = 0 to 2)
Stand-by mode of product		Not supported.
ADCHALT modes		Not supported.
	ADCA _n STR2.ADCA _n RQ3	Fixed to 0.
	ADCA _n STR2.ADCA _n ST3	Fixed to 0.
	ADCA _n TRG3	Not supported.
	ADCA _n TRG7	Not supported.
Sampling and conversion times/sampling mode		A (see Table 25-3 "Sampling and Conversion Times")
ADCA _n CTL1 register ADCA _n TRM _i		Available
Stabilization time setting (ADCA _n CNT)		1 (μs) (target)

- a) All register addresses related to the A/D converter described in this chapter are defined as offsets from the above base addresses.
- b) To use 12-bit resolution for the V850E2/ML4, supply 5.0 V to the A/D converter power.
- c) Make sure to turn on the amplifier power when using the channel S/H circuit.

The following table shows what each signal is connected to:

Table 25-1 ADCA Interrupts and DMA Requests

Signal Name	Function	Connected to
INTADCA0T0	CG0 A/D conversion end interrupt	Interrupt controller 47 (INTADCA0I0) DMA controller trigger 28 DTS controller trigger 28
INTADCA0T1	CG1 A/D conversion end interrupt	Interrupt controller 48 (INTADCA0I1) DMA controller trigger 29 DTS controller trigger 29
INTADCA0T2	CG2 A/D conversion end interrupt	Interrupt controller 49 (INTADCA0I2) DMA controller trigger 30 DTS controller trigger 30
INTADCA0TLLT	Latest conversion latch timing signal	Not supported
INTADCA0TERR	Error interrupt	Interrupt controller 46 (INTADCA0ERR)

This microcontroller has a hardware trigger function. The following table shows what the CGi hardware trigger ADCA0TRGi is connected to:

Table 25-2 What the Hardware Trigger Is Connected to (1/2)

ADCAn Channel Group	Start Trigger Bit (ADCAnTSELi Register)	Trigger Input Signal			ADCAn Trigger Signal
		Name	Connected to		
			Unit	Signal	
CG0	ADCA0T0SEL00	ADCA0TTIN000	PIC	ADOPA0ADCATTIN00	ADCA0TTRG0

25.1.1 Conditions for transitioning to the stand-by mode

This microcontroller does not support the stand-by mode.

25.1.2 Operation while in the power saving mode

- HALT mode
A/D conversion operations continue.

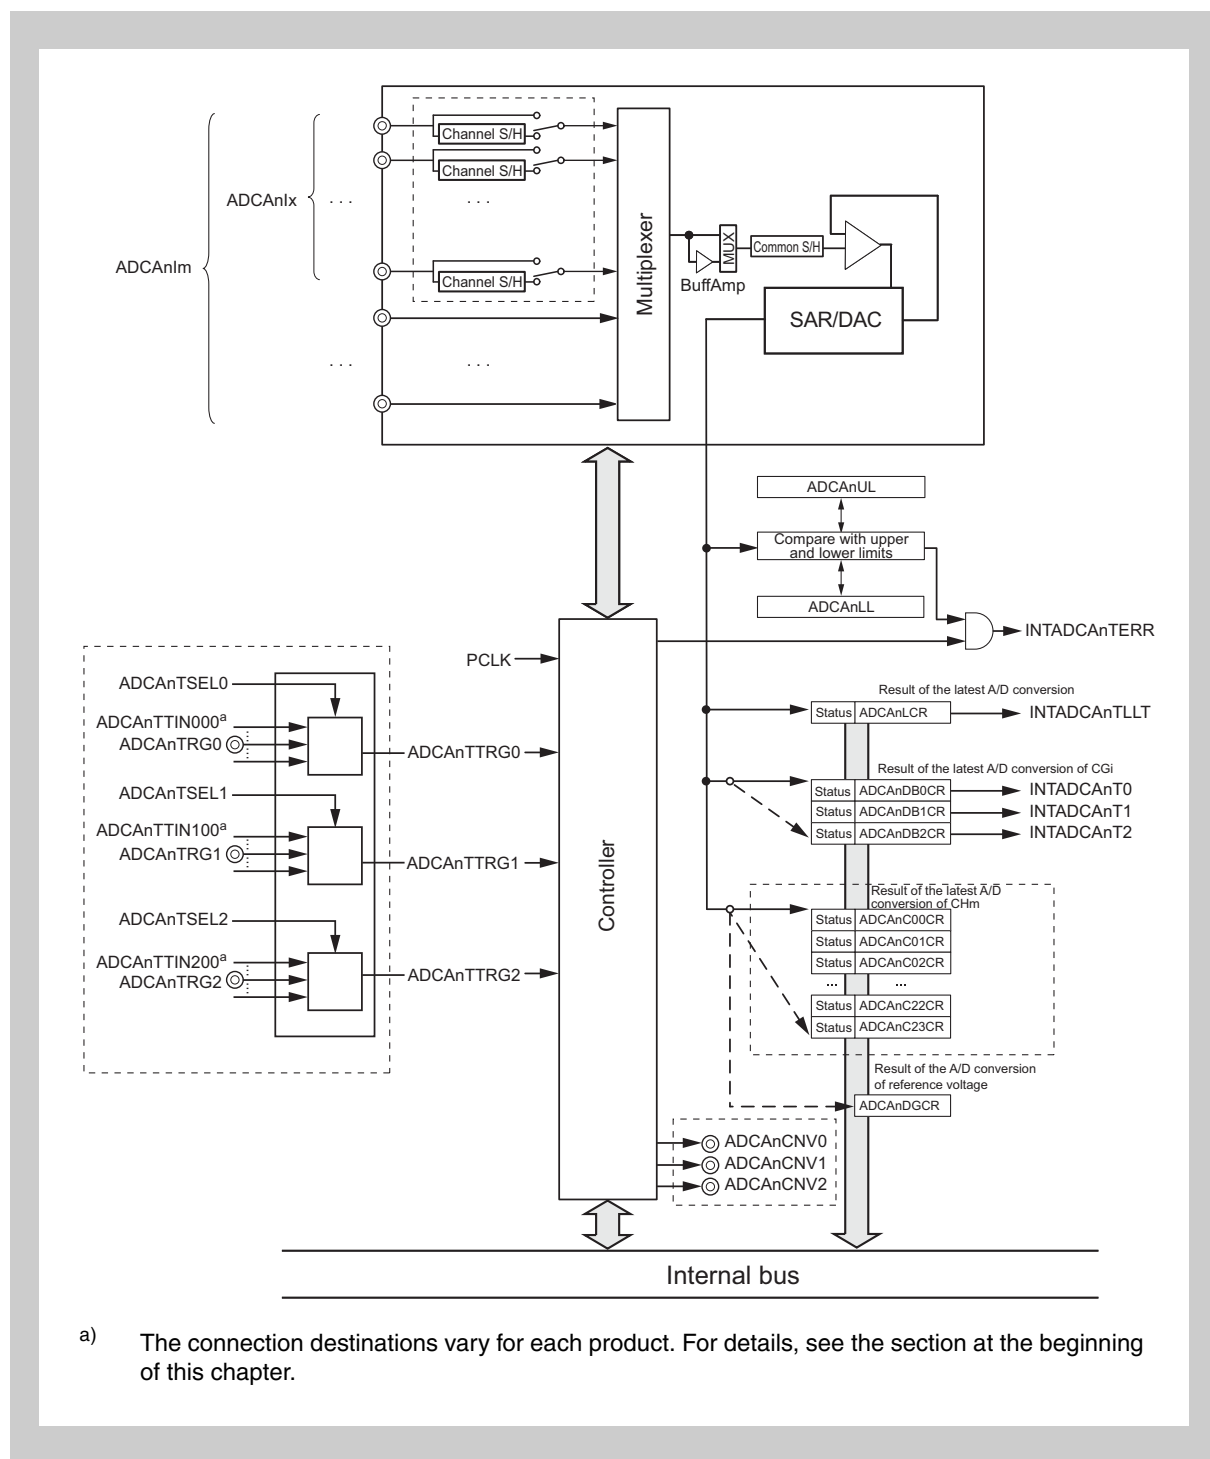

25.2 Function Overview

A/D converter A (ADCA) converts analog input signals to digital values.

Function overview ADCA has the following functions:

- Support for 10-bit and 12-bit resolution
- Successive approximation method
- Up to 24 analog input signals (depending on the product)
- Up to three differently-prioritized channel groups
- One-shot conversion mode, continuous conversion mode (only channel group 0)
- Auto-repeat function (one to four repeats for one shot mode)
- Software and hardware trigger modes
- The hardware trigger source can be selected from multiple input signals.
- The channel on which to generate the A/D conversion end interrupt when A/D conversion ends can be specified.
- Three conversion result check functions
- Discharge function to discharge the capacitor before a new sampling value is converted
- On/off switch function for the buffer amplifier
- Self-diagnosis functions

The following figure shows the main components of the ADCAn.

a) The connection destinations vary for each product. For details, see the section at the beginning of this chapter.

Figure 25-1 ADCAn Block Diagram

Note Portions enclosed in dashed lines are product dependent functions.

25.3 Description of Functions

A/D converter A (ADCAn) converts up to 24 analog input signals into digital values and supports 10-bit and 12-bit resolution (depending on the product).

Note The 10-bit/12-bit resolution setting is common to all the channels. The resolution cannot be changed on a channel basis.

Channels and channel groups Each input channel can be assigned to one of three channel groups (CGs). The list of input channels assigned to a CG is called a scan list (including the diagnostic A/D conversion of CG0). The scan list can be easily set up using one register. Note that it is also possible to set up a new scan list during operation. All A/D conversion for a scan list is called scan list conversion.

ADCAn supports up to three differently-prioritized channel groups and two conversion modes:

- One-shot conversion mode: Scan list conversion is performed only once. In the one-shot conversion mode, scan list conversion can be repeated a specified number of times (one to four times).
- Continuous conversion mode: Scan list conversion is performed repeatedly.

A/D conversion Conversion can be started by using the software or hardware as the start trigger.

A multiplexer selects the channel to be converted and the common sample & hold circuit holds the voltage input.

The successive approximation register (SAR) holds the D/A converter output voltage value to be compared to the analog input voltage value as a 10 or 12-bit digital value.

After each conversion the INTADCAnTLLT interrupt is generated.

A/D conversion result registers When the A/D conversion is complete, the contents of the SAR register are stored in three registers, making it possible to read the latest A/D conversion result, the latest A/D conversion result of CG_i, and the latest A/D conversion result of channel m.

Depending on the configuration, ADCAn generates a conversion end interrupt after the A/D conversion of certain channels or at the end of the A/D conversion of all channels of a channel group.

Conversion result check functions For ADCAn, the following functions can be used to check the A/D conversion result:

(product dependent)

- The conversion result overwrite check function
- The conversion result read flag function
- The conversion result limit comparison function

Discharge function (product dependent) If required, the internal capacitor of the common sample & hold circuit can be discharged before every conversion.

On/off switch function for the buffer amplifier	<p>To reduce the load of the external analog signal source, the signal can be connected to an internal buffer amplifier.</p> <p>The buffer amplifier accelerates the charge rate of the internal sampling capacitor during the A/D sampling period.</p>
Self-diagnosis functions	<p>Four (product dependent) self-diagnosis functions are provided to check that ADCAn works correctly and to detect analog input pins that are disconnected.</p> <ul style="list-style-type: none"> • A/D conversion circuit diagnosis • Channel multiplexer diagnosis • Open pin diagnosis • Channel sample & hold circuit diagnosis (product dependent)
Configurable stabilization time	<p>By specifying any value for the stabilization counter, the best possible stabilization time can be secured after turning the power on.</p>

25.3.1 Basic operation

This section describes the basic A/D conversion procedure. For details, see the following sections.

1. To optimize the start-up time after turning on the power or exiting the stand-by mode, you can increase or decrease the stabilization time by modifying the stabilization counter register ADCAnCNT.
2. Before enabling the A/D converter (ADCAnCTL0.ADCAnCE = 1 is required), specify the power on, resolution, ADCAn clock, trigger mode, conversion mode, interrupt generation, channel groups, and other settings for the following registers:
 - ADCAnCTL1 register
 - ADCAnCGi register
 - ADCAnIOCi register
 - ADCAnTSELi register (product dependent)
3. To check that the A/D conversion results are within a certain value range, enable the conversion result limit comparison function for the desired channels (ADCAnCTL2.ADCAnRCKm) and specify the lower and upper limits for the ADCAnLL and ADCAnUL registers.
4. To discharge the capacitor of the common sample & hold circuit before conversion, enable the discharge function by setting ADCAnCTL1.ADCAnDISC to 1.
5. Enable or disable the buffer amplifier by specifying a value for ADCAnCTL1.ADCAnBPC.
6. Enable the A/D converter by setting ADCAnCTL0.ADCAnCE to 1.
The A/D converter is ready for A/D conversion after the stabilization time has elapsed after turning the power on or exiting the stand-by mode.
7. Depending on the specified trigger mode, A/D conversion is started by using one of the following channel group related start triggers:
 - A software trigger (when ADCAnTRGi.ADCAnSTTi is set to 1)
 - A hardware trigger (input signal ADCATTRGi)

If the A/D conversion of multiple CGs is triggered, the order of A/D conversion depends on the priority of the CGs.

8. The A/D conversion end interrupt INTADCA_nT_i is generated when the conversion of the channel specified by the ADCA_nIO_C_i register ends.
9. Read the results from the A/D conversion result registers: ADCA_nLCR, ADCA_nDBiCR, and ADCA_nCmCR.
10. Monitor the following registers:
 - ADCA_nSTR1: Use this according to your purpose to check whether the A/D conversion results were overwritten before being read.
 - ADCA_nSTR0: Use this to check whether the A/D conversion results are outside the specified value range (only if the conversion result limit comparison function is enabled).
11. Disable the A/D converter if you want to reconfigure it. To do so, clear ADCA_nCTL0.ADCA_nCE.

Note The self-diagnosis functions are described in 25.3.13 “Self-diagnosis functions (product dependent)” on page 1552 .

25.3.2 Clock usage

The ADCA_n clock ADCA_nTCLK is generated from PCLK. The division ratio is specified for ADCA_nCTL1.ADCA_nFR[3:0].

25.3.3 Channels and channel groups

Each input channel is organized into a channel group (CG). The scan list for each CG can be created by specifying register settings, and this list can be set up again even during operation. The conversion settings of a CG are applied to all channels in the group.

ADCA_n supports up to three channel groups: CG_i (i = 0 to 2). The channels of CG_i are specified for the ADCA_nCG_i register.

Note ADCA_n processes A/D conversion requests for CGs only. By assigning only one input channel to a CG, it is possible to perform conversion for a single channel.

(1) Order of A/D conversion

If a CG start trigger occurs, conversion is performed for the channels specified in the scan list in ascending order (from CH00 to CH23 (product dependent)).

If A/D conversion requests for multiple CGs are pending, the CGs are converted in the following hierarchical order: CG2 (highest priority) > CG1 > CG0 (lowest priority)

The current A/D conversion is interrupted when a start trigger for a higher priority CG or an ADCHALT mode trigger is set. Depending on the ADCAnCTL1.ADCAnTRMi setting there are two options:

- The A/D conversion of CGs is interrupted immediately (when ADCAnCTL1.ADCAnTRMi is cleared).

The A/D conversion of the interrupted channel is resumed after all pending A/D conversions of higher priority CGs have finished.

- The A/D conversion of the current channel is completed before higher priority CGs are converted (when ADCAnCTL1.ADCAnTRMi is set).

The A/D conversion resumes starting with the next channel after all pending A/D conversions of higher priority CGs have finished.

ADCAnSTR2.ADCAnST[2:0] indicates the conversion status.

Example The figures below show an example of A/D conversion interruption. In this example, CH3, CH9, and CH20 are assigned to CG0, and CH5 and CH9 are assigned to CG2.

Figure 25-2 When the A/D Conversion of CG0 Is Interrupted Immediately (When ADCAnCTL1.ADCAnTRM0 Is Cleared to 0)

Figure 25-3 When the System Goes on Stand-By Until A/D Conversion of the Current Channel Ends (When ADCAnCTL1.ADCAnTRM0 Is Set to 1)

25.3.4 A/D conversion modes

The A/D converter has two A/D conversion modes:

Mode	Operation	Channel Group
One-shot conversion mode	Scan list conversion is performed only once. In the one-shot conversion mode, scan list conversion can be repeated a specified number of times (one to four times).	CG0, CG1, CG2
Continuous conversion mode	Scan list conversion is performed repeatedly.	CG0

- Notes**
1. If a running A/D conversion is interrupted by an A/D conversion request for a higher priority CG, it is automatically resumed after all requests of higher priority CGs have been finished. (For details, see (1) "Order of A/D conversion" on page 1534.)
 2. CG1 and CG2 are operated in the one-shot conversion mode regardless of the conversion mode setting. For CG0, the A/D conversion mode can be specified for ADCAnCTL1.ADCAnMD0.

(1) One-shot conversion mode

In the one-shot conversion mode, a start trigger causes CGi scan list conversion to be performed. The number of times to repeat scan list conversion can be specified for `ADCANCTL0.ADCANCTL0[1:0]` on a CG basis as a value from one to four.

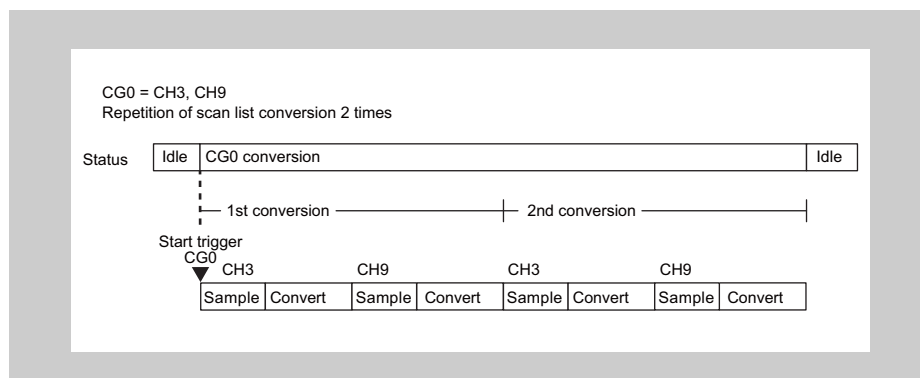

Figure 25-4 One-Shot Conversion Mode With Two Scan List Conversions

Operation when a start trigger is input before conversion ends

The A/D converter can hold up to one additional start trigger issued before conversion of a given CG ends. Therefore, if more than one additional start trigger is input before the A/D conversion of CGi caused by the first start trigger ends, A/D conversion is performed consecutively (but the second and subsequent additional start triggers are ignored).

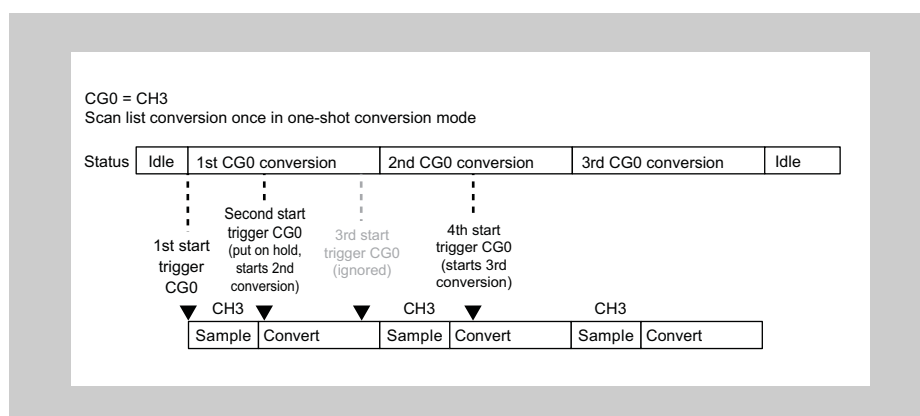

Figure 25-5 Operation When a Start Trigger Is Input Before Conversion Ends

Caution While a high priority CG is converted, any start triggers for lower priority CGs that occur before conversion completion are ignored. In contrast, if higher-priority CG conversion starts during the conversion for a lower-priority CG, the start trigger for the lower-priority CG conversion is held. Note that, if no start trigger has occurred, triggers are acknowledged even during the high-priority CG conversion period.

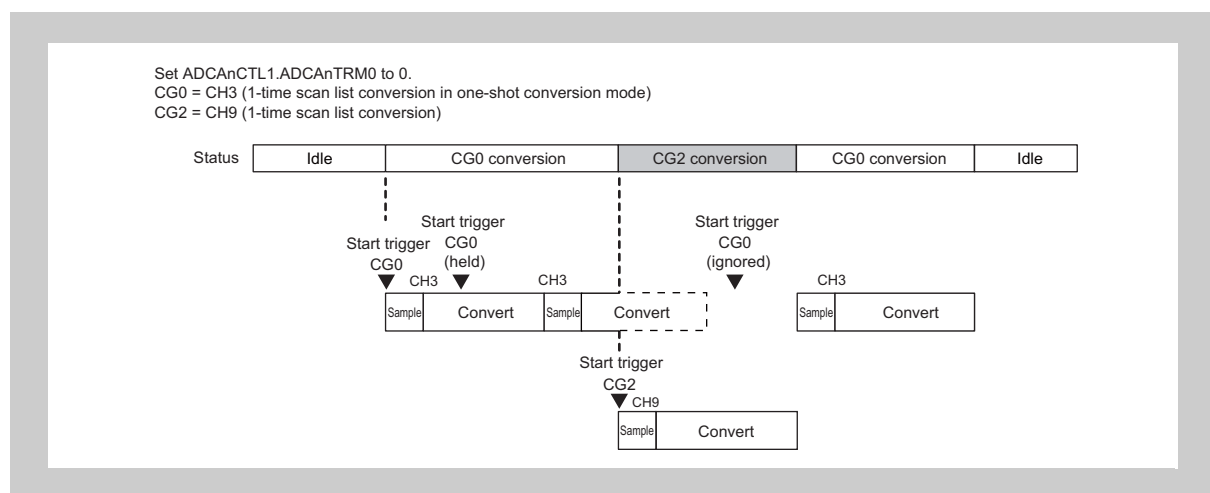

Figure 25-6 Operation When a High-Priority CG Start Trigger is Input Before Conversion of Low-Priority CG Ends

(2) Continuous conversion mode

The continuous conversion mode is available for CG0 only (and is enabled by setting ADCAnCTL1.ADCAn_MD0).

In the continuous conversion mode, a start trigger causes the channels of CG0 to be sampled and converted repeatedly until a stop trigger is generated or another stop condition occurs. (For details, see 25.3.6 “Stopping A/D conversion (stop triggers)” on page 1540 .)

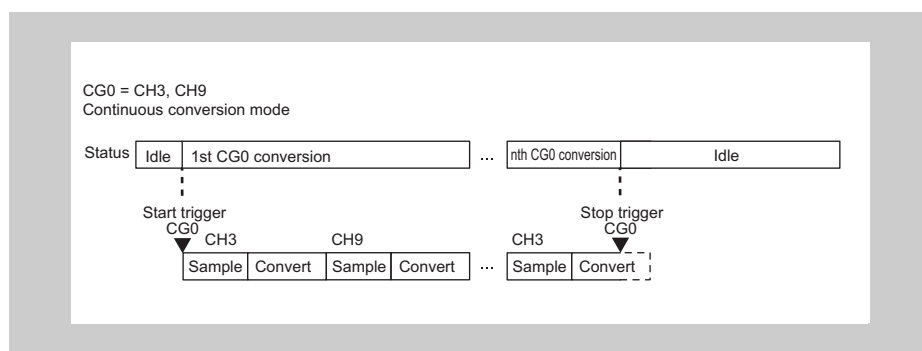

Figure 25-7 Continuous Conversion Mode

Caution After the stop trigger is generated, the system becomes idle, and sampling and conversion are not performed.

Note Start triggers for CG0 are ignored in the continuous conversion mode.

25.3.5 Starting A/D conversion (start triggers)

A/D conversion can be started by a software or hardware trigger specified for ADCAnCTL1.ADCAnMD1.

When A/D conversion is triggered for multiple CGs, the conversion order depends on the priority of the CGs. (For details, see (1) "Order of A/D conversion" on page 1534.)

- Notes**
1. ADCAn ignores start triggers for a CGi if there is no channel assigned to the scan list for the CGi. (ADCAnCGi register = 0000 0000_H).
 2. In the one-shot conversion mode, the A/D converter holds up to one start trigger.

Therefore, if more than one additional start trigger is input before the triggered A/D conversion of CGi ends, A/D conversion is performed consecutively (but the second and subsequent additional start triggers are ignored). (For details, see Figure 25-5 "Operation When a Start Trigger Is Input Before Conversion Ends" on page 1536 .)

3. In the continuous conversion mode, additional start triggers that are generated before a stop trigger has been generated are ignored.

(1) Software start trigger

The A/D conversion of CGi is triggered by setting ADCAnTRGi.ADCAnSTTi if the A/D converter is enabled (by setting ADCAnCTL0.ADCAnCE).

Software start trigger timing example

The following figure shows the timing of a software start trigger with the following conditions:

- ADCAnTCLK clock = PCLK / 2 (and ADCAnCTL1.ADCAnFR[3:0]=0000_B)

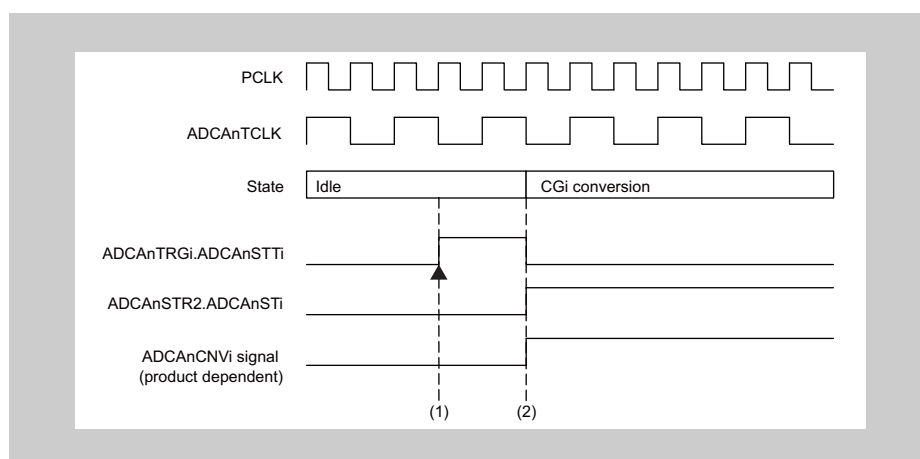

Figure 25-8 Software Start Trigger Timing Example

1. A software start trigger for CGi is written.
2. A/D conversion starts at the next falling edge of the ADCAnTCLK clock.
The status signal ADCAnTCNVi becomes active (product dependent) and ADCAnSTR2.ADCAnSTi is set, indicating that A/D conversion of CGi is running.

(2) Hardware start trigger

The A/D conversion of CGi is triggered by valid edge detection of the ADCAnTTRGi signal if the A/D converter is enabled (by setting ADCAnCTL0.ADCAnCE) and the hardware trigger mode is specified (by setting ADCAnCTL1.ADCAnMD1).

The valid edge is specified for ADCAnCTL1.ADCAnTiETS[1:0] on a CG basis.

Hardware trigger expansion (product dependent)

If hardware trigger expansion is supported, up to 16 hardware trigger sources can be specified for each ADCAnTTRGi signal input. The ADCAnTSELi register specifies the input signals to be used as the ADCAnTTRGi signal.

Note For details about the connection destinations of the hardware start trigger function, see *Table 25-2 “What the Hardware Trigger Is Connected to”*.

Hardware start trigger timing

The A/D converter starts A/D conversion when a valid edge of the ADCAnTTRGi signal is detected.

The figure below shows the timing of a hardware start trigger with the following conditions:

- ADCAnTCLK clock = PCLK / 2 (and ADCAnCTL1.ADCAnFR[3:0] = 0000_B)
- The valid edge of the ADCAnTTRGi signal is the rising edge (ADCAnCTL1.ADCAnTiETS[1:0] = 01_B)

Figure 25-9 Hardware Start Trigger Timing

1. The input signal ADCAnTTRGi rises.
2. A/D conversion starts at the next falling edge of the ADCAnTCLK clock.

The status signal ADCAnTCNVi becomes active (product dependent) and ADCAnSTR2.ADCAnSTi is set, indicating that A/D conversion of CGi is running.

25.3.6 Stopping A/D conversion (stop triggers)

(1) Stop trigger

Setting the stop trigger for CGi stops the A/D conversion of CGi (when ADCAnTRG4 + i.ADCAnSPi is set). If a stop trigger occurs before the end of A/D conversion, the A/D conversion end interrupt INTADCAnTi is not generated, and the A/D conversion result registers are not updated. If another start trigger is input after A/D conversion is stopped by a stop trigger, scan list conversion is performed from the beginning.

If using hardware start triggers, perform the following procedure:

1. Stop the generation of hardware start triggers.
2. Set the stop trigger bit (ADCAnTRG4 + i.ADCAnSPi).
3. Check the status of ADCAnSTR2.ADCAnSTi.

If the above procedure is not performed, there is a conflict between the hardware start trigger and stop trigger, and A/D conversion might not stop.

Stop trigger timing

1. A stop trigger for CGi is written.
2. A/D conversion of CGi stops at the next falling edge of the ADCAnTCLK clock.

ADCAnSTR2.ADCAnSTi is cleared, indicating that A/D conversion of CGi has stopped.

If the digital value of ADCAnIm is already available:

- All A/D conversion result registers are updated.
- The conversion end interrupt INTADCAnTi is generated as specified by the ADCAnIOCi register. (For details, see 25.3.10 “Interrupt generation” on page 1546 .)
- If specified by ADCAnCTL2, the A/D conversion result is checked to see whether it is in the specified value range. (For details, see 25.3.12 “Result check functions” on page 1550 .)

The A/D converter proceeds with any pending A/D conversion requests of other CGs.

The figures below show the timing of a stop trigger with the following conditions:

- ADCAnTCLK clock = PCLK / 2 (and ADCAnCTL1.ADCAnFR[3:0] = 0000_B)
- The A/D conversion end interrupt INTADCAnTi is generated at the end of the A/D conversion of CGi (ADCAnIOCi register = 0000 0000_H).

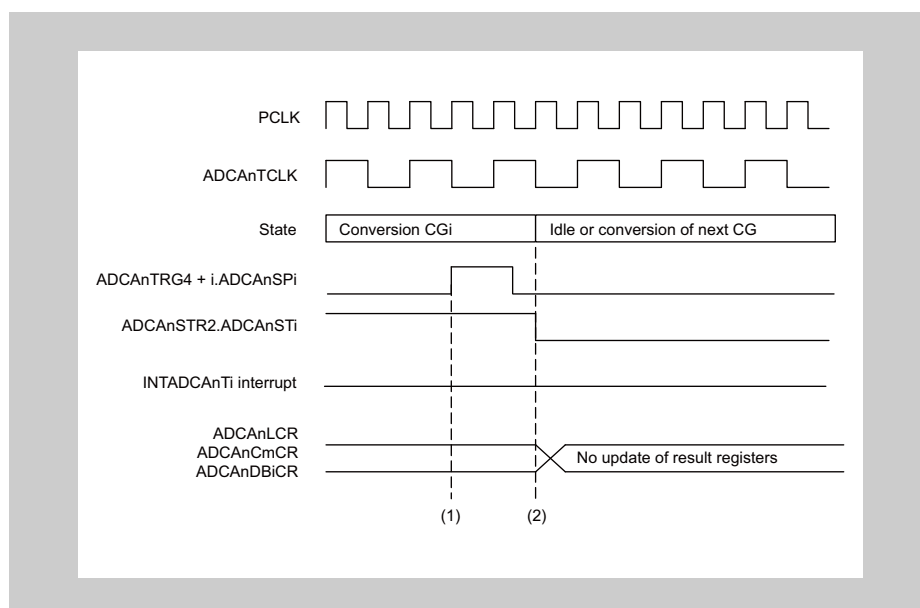

Figure 25-10 Stop Trigger Timing (When Generated Before A/D Conversion Completion)

1. The stop trigger bit (ADCAnTRG4 + i.ADCAnSPi) is set.
2. The status bit (ADCAnSTR2.ADCAnSTi) is cleared.

The A/D conversion end interrupt INTADCAnTi is not generated, and the A/D conversion result registers are not updated.

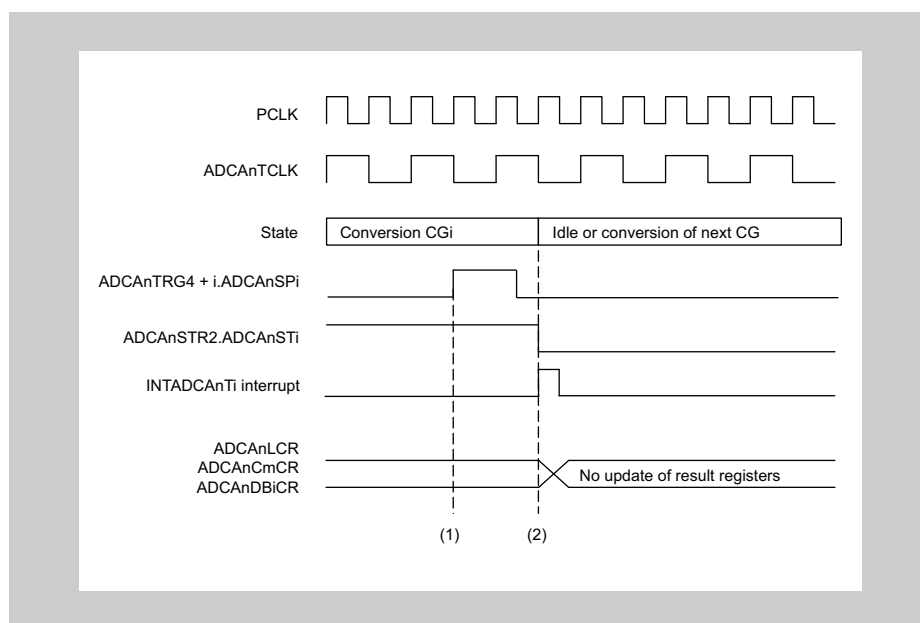

Figure 25-11 Stop Trigger Timing (When Generated After A/D Conversion Completion)

1. The stop trigger bit (ADCAnTRG4 + i.ADCAnSPi) is set.
2. The status bit (ADCAnSTR2.ADCAnSTi) is cleared.

The A/D conversion end interrupt INTADCAnTi is generated, and the A/D conversion result registers are updated.

(2) Other stop conditions

In addition to a software stop trigger, A/D conversion stops in the following condition:

- When the A/D converter is disabled (by clearing ADCAnCTL0.ADCAnCE)

25.3.7 Stand-by mode (product dependent)

The stand-by mode is entered as described in *25.1.1?Conditions for transitioning to the stand-by mode?*, which is at the beginning of this chapter.

The A/D converter is automatically disabled (by clearing ADCAnCTL0.ADCAnCE) while the system is in the stand-by mode.

To exit the stand-by mode:

1. Exit the related system stand-by mode.
2. Enable the A/D converter by setting ADCAnCTL1.ADCAnCE.

Note After exiting the stand-by mode, start triggers are acknowledged, but conversion will not start before the stabilization time has elapsed (stabilization counter ADCAnCNT = 00_H). For details, see *25.3.17 “Stabilization control” on page 1568*.

25.3.8 Pausing and resuming A/D conversion (ADCHALT mode) (product dependent)

The A/D converter allows the A/D conversion (of all CGs) to be paused or halted (the ADCHALT mode).

Procedure:

1. Change the system to the ADCHALT mode by setting ADCAnTRG3.ADCAnSTT3. (For details about the interrupt behavior, see (1) *“Order of A/D conversion” on page 1534*.)
 - Start triggers are ignored while in the ADCHALT mode.
 - The power consumption can be reduced by setting the sampling clock ADCAnTCLK to the low level and stopping the internal circuit.
 - While in the ADCHALT mode, the alternate functions of the analog input pin ADCAnIm can be used.
2. Exit the ADCHALT mode and resume the A/D conversion by setting ADCAnTRG7.ADCAnSP3.

Note The ADCHALT mode has the highest priority and overrules all CGi conversions.

25.3.9 Resolution, sampling, and conversion times

The total conversion time is the sum of the sampling time and A/D conversion time.

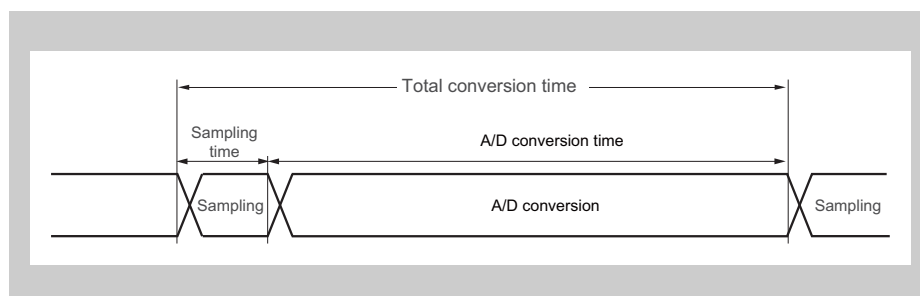

Figure 25-12 Total Conversion Time

- The sampling time is the time of connecting an analog input voltage to the common sample & hold circuit. The A/D conversion time is the time necessary to obtain one digital value from the analog input voltage. The A/D conversion time, and thus the total conversion time, depends on the conversion resolution as follows:

Table 25-3 Sampling and Conversion Times

Sampling Mode (Product Dependent)	Conversion Resolution	Sampling Time	Total Conversion Time
A	10 bit (when ADCAnCTL1.ADCAnCTYP is set)	6.5 clock cycles (ADCAnTCLK)	18 clock cycles (ADCAnTCLK)
	12 bit (when ADCAnCTL1.ADCAnCTYP is cleared)	6.5 clock cycles (ADCAnTCLK)	20 clock cycles (ADCAnTCLK)

- Notes**
- Enabling the discharge function (by setting ADCAnCTL1.ADCAnDISC) increases the total conversion time by one clock cycle (ADCAnTCLK).
For details, see 25.3.15 “Discharge function (product dependent)” on page 1567.
 - Enabling the buffer amplifier (by setting ADCAnCTL1.ADCAnBPC) increases the total conversion time by four clock cycles (ADCAnTCLK).
For details, see 25.3.16 “Buffer amplifier function” on page 1567.

Table 25-4 PCLK Settings When the Resolution is 12 Bits and the Specifiable Division Ratios and Conversion Times ($AV_{DD} = 4.5\text{ V}$)

1010B	1/12	4.000	4.500	Setting prohibited	5.550	Setting prohibited	5.556	3.240	Setting prohibited	3.960	Setting prohibited	Setting prohibited
1100B	1/14	Setting prohibited	Setting prohibited	Setting prohibited	Setting prohibited	Setting prohibited	4.762	3.780	Setting prohibited	4.620	Setting prohibited	Setting prohibited
1110B	1/16	Setting prohibited	Setting prohibited	Setting prohibited	Setting prohibited	Setting prohibited	4.167	4.320	Setting prohibited	5.280	Setting prohibited	Setting prohibited

Note The above conversion times do not include the overhead time due to A/D controller processing. The necessary overhead time is as follows:

- Conversion start request acknowledgment: One clock cycle (ADCA_nTCLK)
- Initialization before starting conversion: One clock cycle (ADCA_nTCLK)
- Conversion result storage processing: One clock cycle (ADCA_nTCLK)

When performing consecutive conversions, no conversion start request acknowledgment processing is necessary for the second or subsequent conversions.

25.3.10 Interrupt generation

(1) A/D conversion end interrupt INTADCA_nT_i

The interrupt INTADCA_nT_i reports that new A/D conversion results have been stored in the conversion result registers.

When the A/D conversion of any CG_i channel specified by the ADCAnIOC_i register ends, the A/D conversion end interrupt is generated.

If no specific channel or other relevant setting is specified (ADCAnIOC_i = 0000 0000_H), the interrupt INTADCA_nT_i is generated at the end of the A/D conversion of CG_i.

Figure 25-13 Generation of the A/D Conversion End Interrupt INTADCA_nT_i

- Notes**
1. The ADCAnIOC_i register can be written at any time even when the A/D converter is enabled (by setting ADCAnCTL0.ADCAnCE). The newly specified value takes effect after the current A/D conversion of CG_i has been completed.
 2. Because the ADCAnIOC_i register is associated with the ADCAnCG_i register, their buffer registers must be updated simultaneously. Because the update is performed when the ADCAnCG_i register is written to, always write to the ADCAnIOC_i register before the ADCAnCG_i register when changing the interrupt generation for a CG.

(2) Error interrupt INTADCA_nTERR

The interrupt INTADCA_nTERR is generated in the following cases:

- When the conversion result limit comparison function is enabled and an A/D conversion result of a specified channel is out of the specified range. For details, see (3) "Conversion result limit comparison function" on page 1551.
- The generation of the error interrupt INTADCA_nTERR when the A/D conversion results in the ADCAnLCR register, ADCAnDBiCR register, or ADCAnCmCR register are overwritten before they are read can be separately controlled for each register by setting ADCAnCTL0.ADCAnOEM[4:0]. For details, see (1) "Conversion result overwrite check function" on page 1550.

25.3.11 Storage of A/D conversion results

(1) A/D conversion result registers

The A/D conversion results are stored in the following registers:

- ADCAnLCR register
This register stores the latest A/D conversion results.
- ADCAnDBiCR register
This register stores the latest CGi A/D conversion results.
- ADCAnCmCR register
This register stores the latest A/D conversion results for channel m.

These registers store the digital value of the sampled analog input voltage in bits 15 to 00. Each register also stores A/D conversion result status flags. (For details, see 25.3.12 "Result check functions" on page 1550.)

Figure 25-14 Storage of A/D Conversion Results

(2) Settings related to storing conversion results**(a) Conversion result bit position specification function**

ADCA_nCTL1.ADCA_nCRAC specifies whether the 12-bit or 10-bit A/D conversion result is right aligned (ADCA_nCRAC bit = 0) or left aligned (ADCA_nCRAC bit = 1).

(b) Conversion result read and clear function

ADCA_nCTL1.ADCA_nRCL specifies whether the value of the A/D conversion result register ADCA_nCmCR is retained after reading it or cleared by reading it.

(3) Relationship between the analog input voltage and A/D conversion results

The following equation shows the relationship between the analog input voltage input to the analog input pin (ADCA_nIm) and the A/D conversion result value (the value of the ADCA_nLCR[15:00] bits, ADCA_nCmCR[15:00] bits, and ADCA_nDBiCR[15:00] bits):

$$\text{A/D conversion result value} = \text{INT} \left(\frac{V_{\text{IAN}} - AV_{\text{REFMn}}}{AV_{\text{REFPn}} - AV_{\text{REFMn}}} \times 2^k + 0.5 \right)$$

Or,

$$(\text{A/D conversion result value} - 0.5) \times \frac{AV_{\text{REFPn}} - AV_{\text{REFMn}}}{2^k} \leq V_{\text{IAN}} - AV_{\text{REFMn}} < (\text{A/D conversion result value} + 0.5) \times \frac{AV_{\text{REFPn}} - AV_{\text{REFMn}}}{2^k}$$

INT(): Function that returns the integer portion of the value in ()

V_{IAN}: Analog input voltage

AV_{REFPn}: AV_{REFPn} pin voltage

AV_{REFMn}: AV_{REFMn} pin voltage

A/D conversion result value:

Value of the ADCA_nLCR[15:00] bits, ADCA_nCmCR[15:00] bits, and ADCA_nDBiCR[15:00] bits

k: Resolution

Figure 25-15 shows the relationship between the analog input voltage and the A/D conversion results.

(i) 12-bit A/D converter conversion characteristics (when ADCAnCTL1.ADCAnCTYP is cleared)

(ii) 10-bit A/D converter conversion characteristics (when ADCAnCTL1.ADCAnCTYP is set)

Figure 25-15 Relationship Between the Analog Input Voltage and A/D Conversion Results

25.3.12 Result check functions

For ADCAn, the following functions can be used to check the A/D conversion result:

- The conversion result overwrite check function
- The conversion result read flag function
- The conversion result limit comparison function

(1) Conversion result overwrite check function

This function makes it possible to check whether an A/D conversion result was overwritten before it was read.

Error flags Each A/D conversion result register has the following overwrite error flags:

ADCAnLCR.ADCAnLER1

ADCAnDBiCR.ADCAnDBiER1

ADCAnCmCR.ADCAnCmER1

As an example, if the A/D conversion result stored in the ADCAnCmCR register is overwritten before it is read, ADCAnCmCR.ADCAnCmER1 is set.

The ADCAnLCR and ADCAnDBiCR registers function similarly.

Note that the value of ADCAnCmCR.ADCAnCmER1 is also applied to ADCAnSTR1.ADCAnOWEm.

Error interrupt The error interrupt INTADCAnTERR is generated if an A/D conversion result in the ADCAnLCR, ADCAnDBiCR, or ADCAnCmCR register is overwritten before it is read.

A conversion result register from which the conversion result is not read can be masked by specifying ADCAnCTL0.ADCAnOEM[4:0].

Example:

- CH7 is assigned to CG1.
- ADCAnCTL0.ADCAnOEM[4:0] is cleared to 00000B so that the error interrupt INTADCAnTERR is generated whenever an A/D conversion result is overwritten in the ADCAnLCR, ADCAnDBiCR, or ADCAnCmCR register before the result is read.

(2) Conversion result read flag function

This function makes it possible to check whether the A/D conversion result has been read before or is new and has not been read yet.

Status flags The A/D conversion result registers have the following update status flags:

ADCAnLCR.ADCAnLUR

ADCAnDBiCR.ADCAnDBiUR

ADCAnCmCR.ADCAnCmUR

If these flags are set to 1, the A/D conversion result is new.

The update status flags are cleared after being read.

(3) Conversion result limit comparison function

This function makes it possible to check whether the A/D conversion results are in the specifiable range.

This function can be enabled or disabled for individual channels by using the ADCAnCTL2 register.

The A/D conversion result of a channel for which this function is enabled is compared with the previously specified lower limit (the ADCAnLL register) and upper limit (the ADCAnUL register).

Error flags If the A/D conversion result of a specified channel is below the lower limit or above the upper limit, the error flag for that channel (ADCAnSTR0.ADCAnRCE) is set.

The ADCAnSTR0 register indicates the error status of the latest A/D conversion result limit comparison for every channel. This register makes it possible to check which A/D conversion results are outside the specified range.

Note that the value of the result check error flag ADCAnSTR0.ADCAnRCE is also applied to ADCAnCmCR.ADCAnCmER0.

Error interrupt The error interrupt INTADCAnTERR is generated if an A/D conversion result of a specified channel is outside the specified range.

25.3.13 Self-diagnosis functions (product dependent)

The following self-diagnosis functions can be used to check whether ADCAn is working:

- (1) A/D conversion circuit diagnosis
- (2) Channel multiplexer diagnosis
- (3) Open pin diagnosis
- (4) Channel sample & hold circuit diagnosis (product dependent)

The following figure provides an overview of the self-diagnosis functions, which are described in detail in the following chapters.

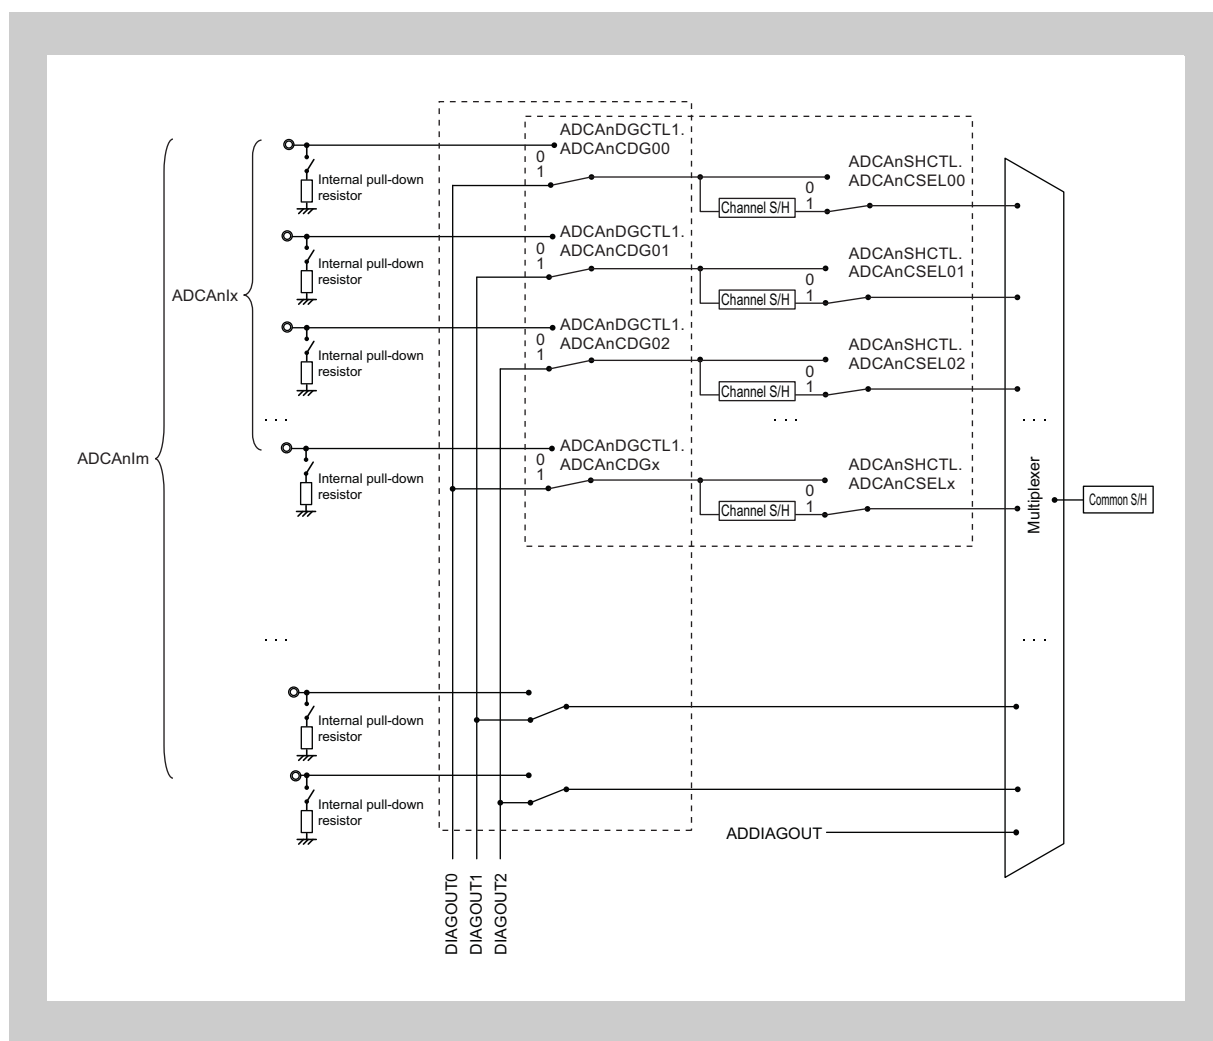

Figure 25-16 Overview of the Self-Diagnosis Functions

Note Portions enclosed in dashed lines are product dependent functions.

The following table shows when each diagnosis function can be specified:

Table 25-6 Self-Diagnosis Function Settings

Self-Diagnosis Function	ADCA _n CE Bit = 0	ADCA _n CE Bit = 1
A/D conversion circuit diagnosis	Specifiable	Specifiable
Channel multiplexer diagnosis	Specifiable	Not specifiable
Open pin diagnosis	Specifiable	Not specifiable
Channel sample & hold circuit diagnosis (product dependent)	Specifiable	Specifiable

(1) A/D conversion circuit diagnosis

This function makes it possible to diagnose the A/D conversion circuit operation.

The A/D conversion circuit can be diagnosed during normal A/D conversion operation. The reference voltage signal ADDIAGOUT is also converted at the end of the A/D conversion of CG0. If the result of this diagnostic A/D conversion differs significantly from the expected value, the hardware might be abnormal or operating incorrectly.

Diagnostic A/D conversion is enabled by setting ADCA_nCG0.ADCA_nDIAG.

Note A/D conversion circuit diagnosis is available only for CG0.

Diagnostic A/D conversion starts after the A/D conversion of the last channel of CG0 has been completed.

- The A/D conversion results of CG0 are stored in the normal A/D conversion result registers. (For details, see (1) "A/D conversion result registers" on page 1547.)
- The result of the diagnostic A/D conversion is stored in the ADCA_nDGCR register.

Self-diagnosis procedure

1. Turn on ADCA_n by setting ADCA_nCTL1.ADCA_nGPS.
2. Specify CG0 and the A/D conversion mode as follows:
 - Set ADCA_nCG0.ADCA_nDIAG to enable diagnostic A/D conversion of the reference voltage.
For example, specify 8000 000E_H to first convert the analog input voltages of CH1, CH2, and CH3, and then the reference voltage signal ADDIAGOUT for diagnostic purposes.
 - Set ADCA_nIOC0.ADCA_nCG0IDG to generate the A/D conversion end interrupt INTADCA_nT0 when diagnostic A/D conversion finishes.
3. Specify the reference voltage signal ADDIAGOUT for ADCA_nDGCTL0.ADCA_nPSEL[2:0].
For example, set ADCA_nDGCTL0.ADCA_nPSEL[2:0] to 010_B to apply the reference voltage 1/2 AV_{DD}.
4. Enable ADCA_n by setting ADCA_nCTL0.ADCA_nCE.
5. Generate a software or hardware start trigger to start A/D conversion.
6. When the A/D conversion end interrupt INTADCA_nT0 is generated, read the diagnostic A/D conversion results from the ADCA_nDGCR register.

ADCA_nDGCTL0.ADCA_nPSEL[2:0] can be written to even during A/D conversion. The following figure shows the operation when writing during A/D conversion:

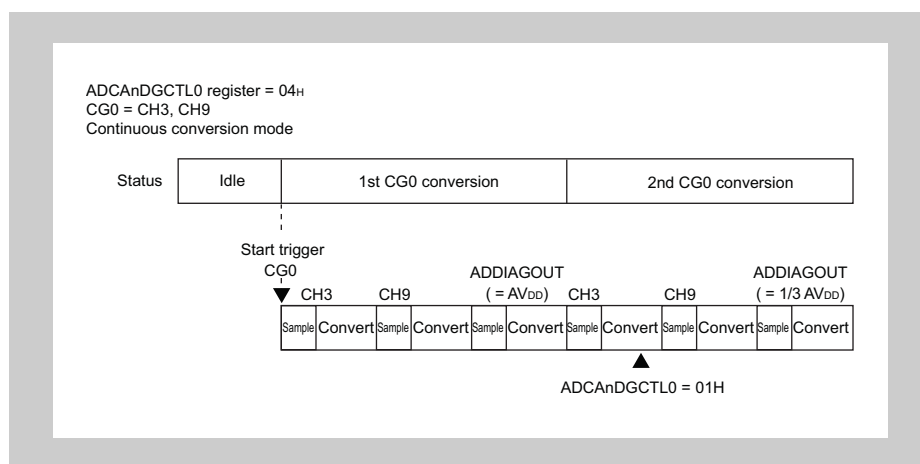

Figure 25-17 Writing During A/D Conversion

Note The value specified for ADCA_nDGCTL0.ADCA_nPSEL[2:0] is applied after conversion of the current channel finishes. Therefore, specify the reference voltage for the next diagnostic A/D conversion before that conversion starts.

(2) Channel multiplexer diagnosis

This function makes it possible to diagnose channel switching and selection.

Each channel is assigned one of three reference voltages. The values of the reference voltages can be changed using ADCA_nDGCTL0.ADCA_nPSEL[2:0].

Table 25-7 Channel assignment of reference voltages

Reference Voltage	Assigned Channels (Product Dependent)
DIAGOUT0	21, 18, 15, 12, 9, 6, 3, 0
DIAGOUT1	22, 19, 16, 13, 10, 7, 4, 1
DIAGOUT2	23, 20, 17, 14, 11, 8, 5, 2

To diagnose the channel multiplexer, different reference voltages can be input to each channel.

Self-diagnosis procedure

1. Turn on ADCA_n by setting ADCA_nCTL1.ADCA_nGPS.
2. Specify the channels of CG0 for the ADCA_nCG0 register.
For example, specify 0000 000E_H to use CH1, CH2, and CH3 for diagnosis.
3. Specify 0000 0000_H for the ADCA_nI0C0 register to generate the A/D conversion end interrupt INTADCA_nTi at the end of all A/D conversions for CG0.
4. Specify the other A/D conversion settings as necessary.

5. Specify the reference voltages for ADCAnDGCTL0.ADCAnPSEL[2:0].
For example, set ADCAnDGCTL0.ADCAnPSEL[2:0] to 010_B to use the following reference voltages:
 - DIAGOUT0 = 1/2 AV_{DD}
 - DIAGOUT1 = 2/3 AV_{DD}
 - DIAGOUT2 = 1/3 AV_{DD}
6. Specify which CG0 channels a reference voltage is applied to (instead of the analog input voltage ADCAnIm) for the ADCAnDGCTL1 register. For example, set the ADCAnDGCTL1 register to 0000 0006_H to use the following channels:
 - DIAGOUT1 (2/3 AV_{DD}) is applied to CH1.
 - DIAGOUT2 (1/3 AV_{DD}) is applied to CH2.
 - The analog input voltage is applied to CH3.
7. Enable ADCAn by setting ADCAnCTL0.ADCAnCE.
8. Generate a software or hardware start trigger to start A/D conversion.
9. When the A/D conversion end interrupt INTADCAnt0 is received, read the A/D conversion results of CG0.

Caution When ADCAnCTL0.ADCAnCE is set, changing the setting of the ADCAnDGCTL1 register is prohibited.

(3) Open pin diagnosis

When an input pin is open, the correct A/D conversion results cannot be obtained.

The internal pull-down resistor can be connected to diagnose the analog input ADCAnIm.

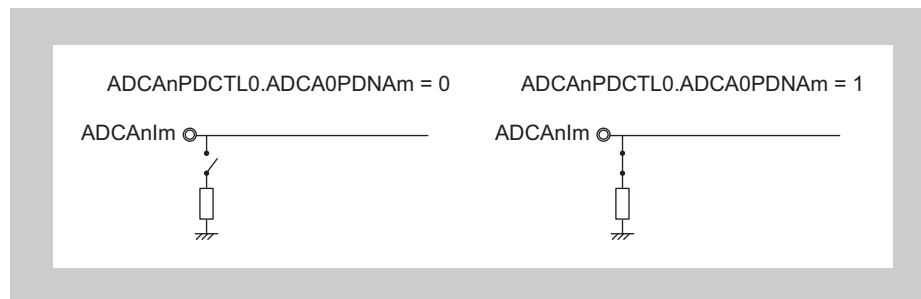

Figure 25-18 Internal Pull-Down Resistor

When the internal pull-down resistor is connected to the analog input ADCAnIm (by setting ADCAnPDCTL0.ADCAnPDNA_m) and ADCAnIm is open, the A/D conversion result is almost 0 V.

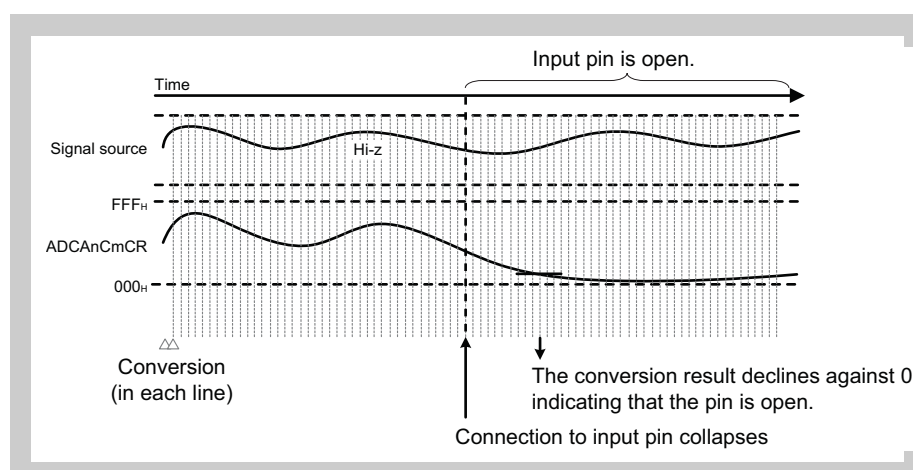

Figure 25-19 Detection of an Open Input Pin

- Notes**
1. If the analog input ADCAnIm is less than 0.2 V (target), an open pin cannot be detected. (For details, see *Chapter 34 Target Electrical Specifications*.)
 2. Do not connect the internal pull-down resistor during normal A/D conversion operation. Connecting this resistor might lead to a drop in the input voltage, and it might not be possible to obtain the correct A/D conversion results.

Self-diagnosis procedure

To diagnose open input pins:

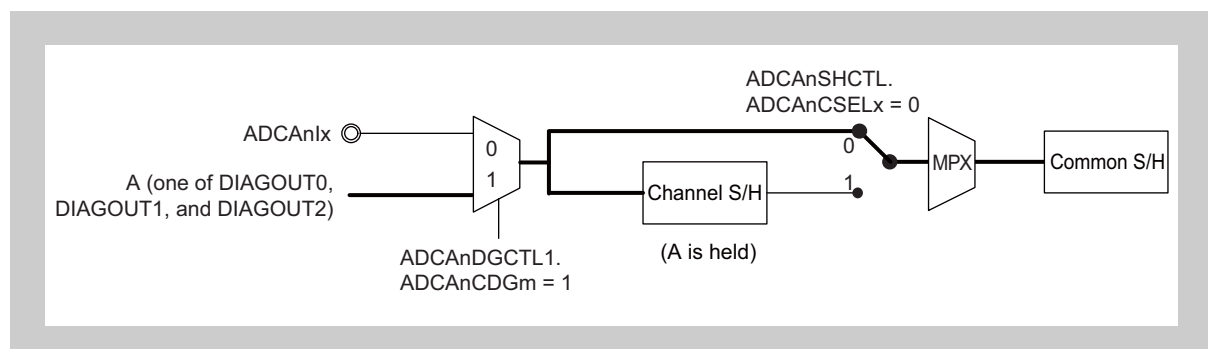

1. Specify the CG and A/D conversion settings as usual.
2. Set the ADCAnPDCTL0 register to connect the internal pull-down resistor.
3. Execute multiple A/D conversions (target).
4. Monitor the channel's A/D conversion results and check whether any result is near 0 V.

(4) Channel sample & hold circuit diagnosis (product dependent)

For details about the channel sample & hold function, see 25.3.14 “Channel sample & hold circuit function (product dependent)” on page 1560.

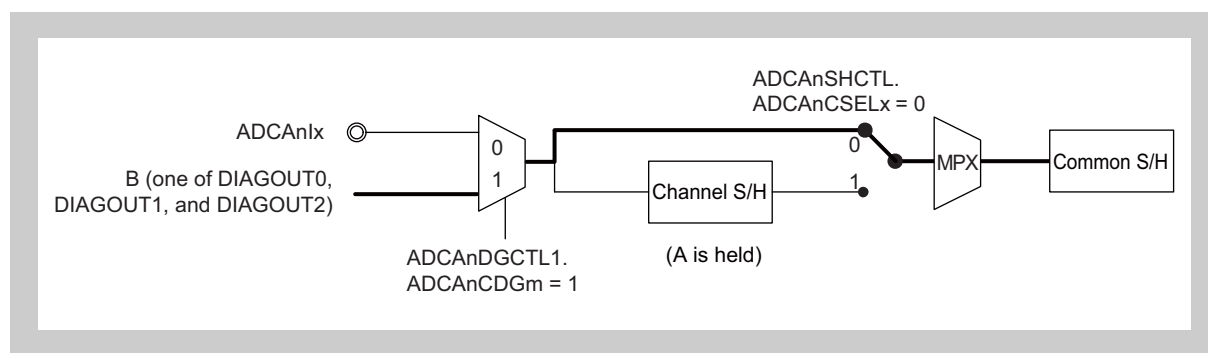

This function makes it possible to diagnose the channel sample & hold circuit. The following provides an overview.

1. One of the reference voltage signals from DIAGOUT0 to DIAGOUT2 is used.
2. The voltage “A” is specified for one of the reference voltage signals from DIAGOUT0 to DIAGOUT2. The channel sample & hold circuit holds “A”, and conversion is performed without using this circuit.

3. The voltage “B” is specified for one of the reference voltage signals from DIAGOUT0 to DIAGOUT2.

Conversion is performed without using the channel sample & hold circuit. The conversion result is “B”. The channel sample & hold circuit continues holding “A”.

4. Conversion is performed by using the channel sample & hold circuit.
The channel sample & hold circuit continues holding "A". The conversion result is "A".

5. The results are as follows:
 - The first conversion result (in (3)) is "B".
 - The second conversion result (in (4)) is "A".

The diagnostic flow for the channel sample & hold circuit is shown below.

Initial setup The following is an example for the ADCAn1 pin:

- Set ADCAnCTL1.ADCAnGPS.
- Specify a software trigger as the start trigger, and set the A/D conversion mode to the one-shot conversion mode (number of repetitions: 1).
- Set the ADCAnCG0 register to 0000 0002_H (to select ADCAn1, which has the channel sample & hold circuit).
- Set the ADCAnIOC0 register to 0000 0002_H to generate the A/D conversion end interrupt INTADCAnT0. (An interrupt must be generated when conversion ends.)
- Set ADCAnDGCTL0.ADCAnPSEL[2:0] to 001_B (to select 1/3 AV_{DD} for the reference voltage DIAGOUT1).
- Set ADCAnDGCTL1.ADCAnCDG01.
- Set ADCAnCTL0.ADCAnCE.

Operation flow Step 1

Input the first software start trigger for CG0. ($1/3 AV_{DD}$ is held by the channel sample & hold circuit.)

Next, change the ADCAnPSEL[2:0] bits to 010_B. (After the first A/D conversion ends, $2/3 AV_{DD}$ is selected for the reference voltage DIAGOUT1.)

Input the second software start trigger for CG0. (The start trigger is held.)

The procedure up to this point must be performed before the first A/D conversion ends.

Step 2

The first A/D conversion ends, and the A/D conversion end interrupt INTADCA_nT0 is generated.

Change the ADCAnCSEL01 bit to 1. (During the next A/D conversion, the voltage held by the channel sample & hold circuit is converted.)

Input the third software start trigger for CG0. (The start trigger is held.)

The procedure up to this point must be performed before the second A/D conversion ends.

Step 3

The second A/D conversion ends, and the A/D conversion end interrupt INTADCA_nT0 is generated.

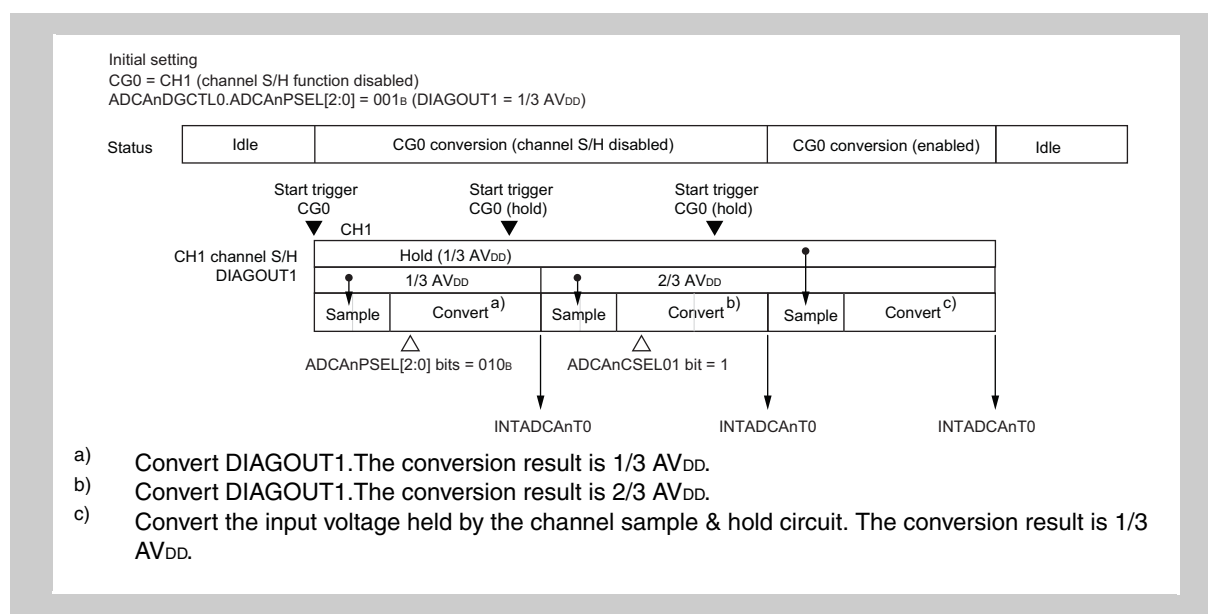

Read the ADCAnC01CR register, and make sure that the expected value ($2/3 AV_{DD}$) has been stored there.

Step 4

The third A/D conversion ends, and the A/D conversion end interrupt INTADCA_nT0 is generated.

Read the ADCAnC01CR register, and make sure that the expected value ($1/3 AV_{DD}$) has been stored there.

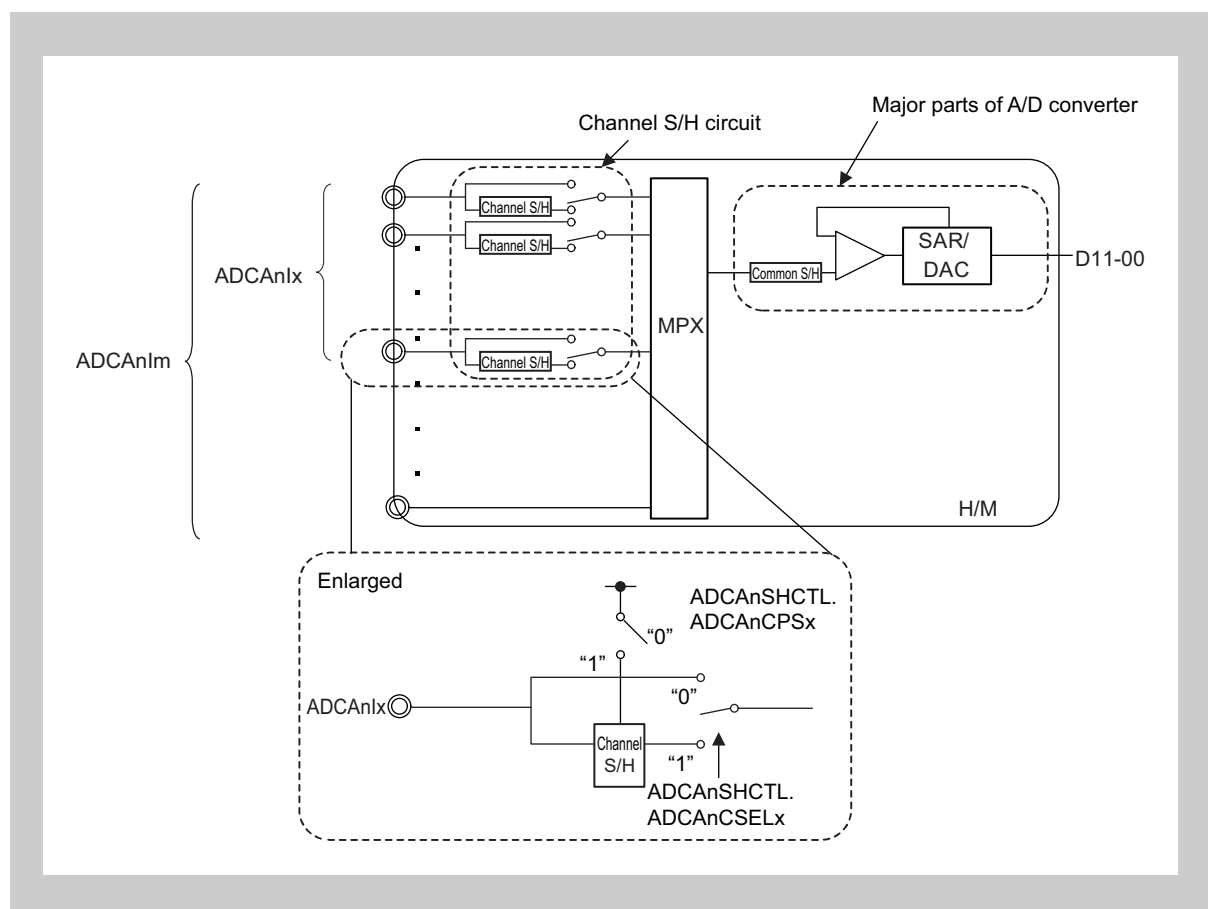

An example of timing for the channel sample & hold circuit is shown below.

25.3.14 Channel sample & hold circuit function (product dependent)

(1) Channel sample & hold circuit function

The channel sample & hold circuit is shown below.

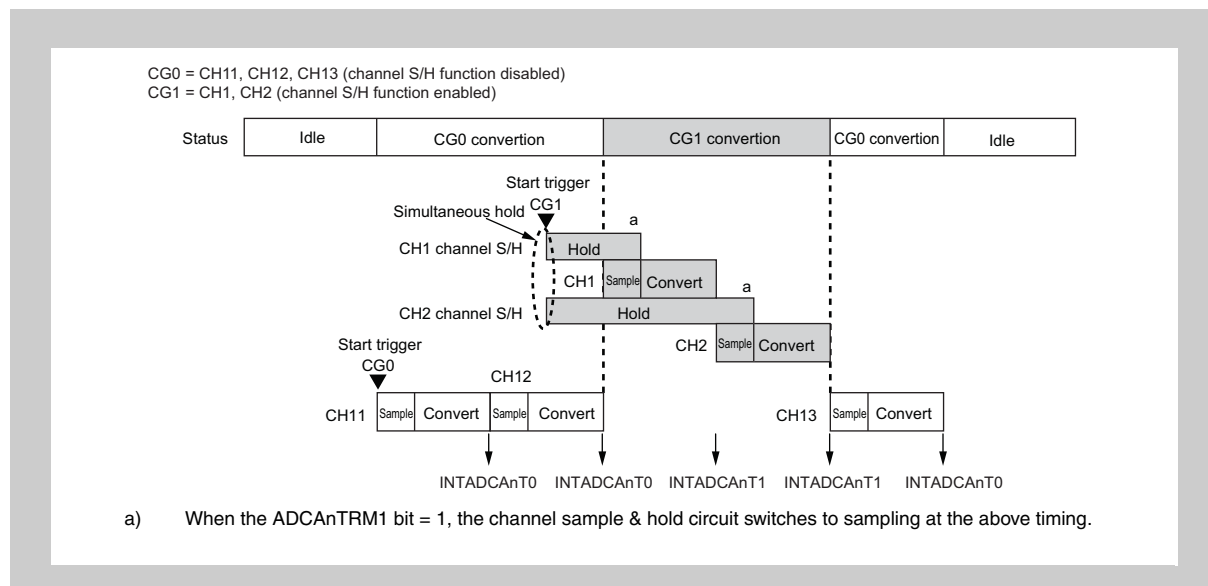

The channel sample & hold function can be used for CG0 in the one-shot conversion mode (no repetition), as well as for CG1 and CG2 (no repetition).

ADCAnSHCTL.ADCAnCPSx is used to control the supply of power to the channel sample & hold circuit, and ADCAnSHCTL.ADCAnCSELx is used to enable or disable the channel sample & hold function.

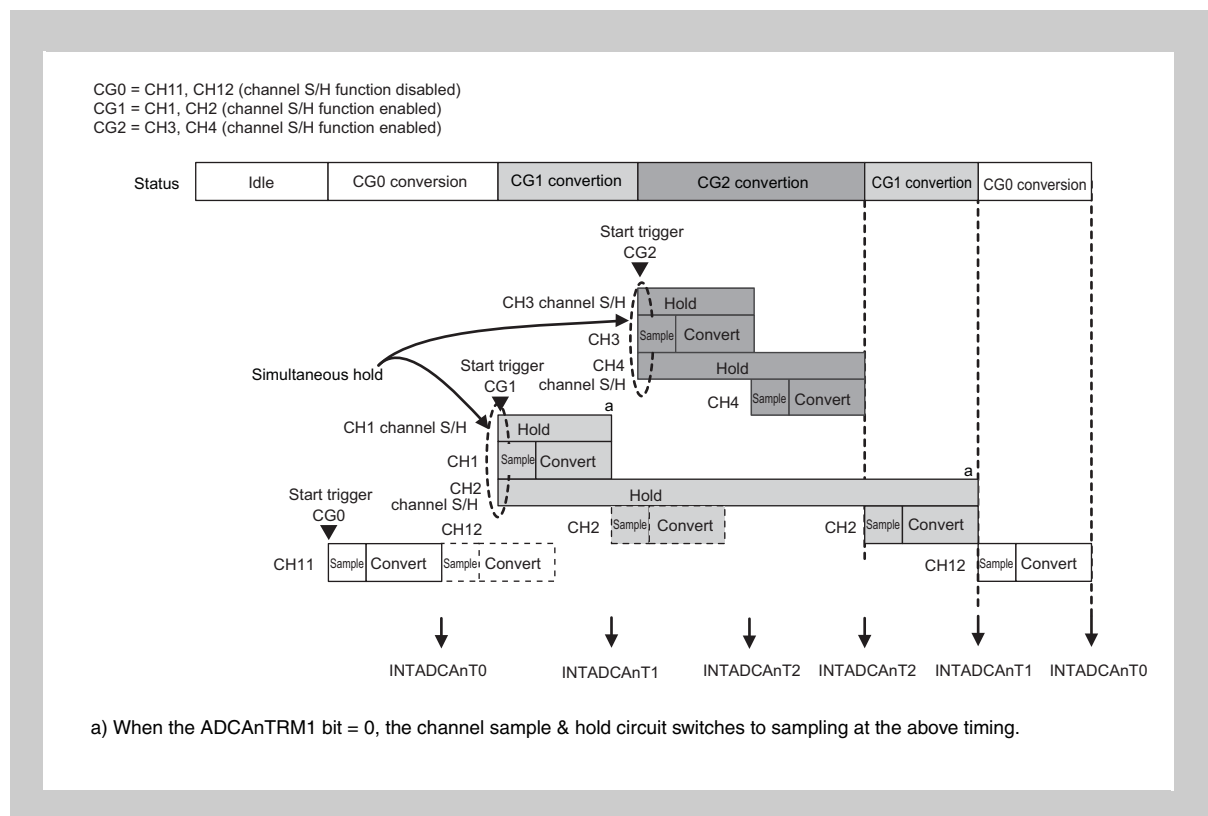

Caution Make sure to turn on the amplifier power when using the channel S/H circuit.

When a hardware or software start trigger is generated, the channel sample & hold circuit holds the analog input signal of the channel for which the channel sample & hold function was enabled by using ADCAnSHCTL.ADCAnCSELx. Next, scan list conversion is started according to the ADCAnCTL1.ADCAnTRMi setting.

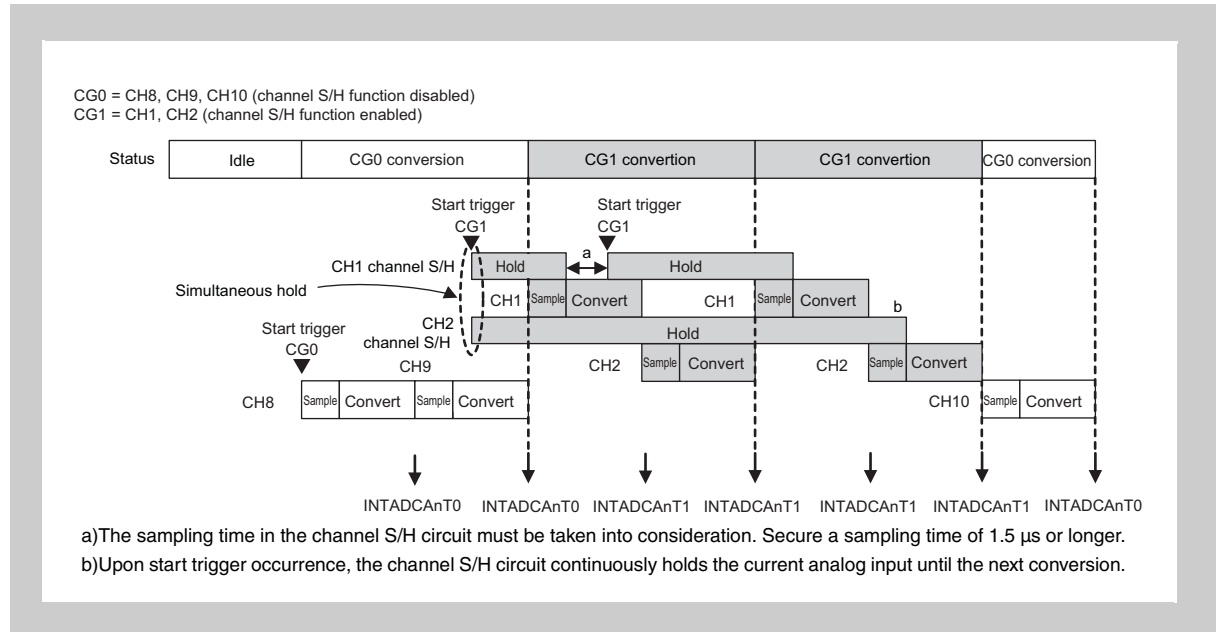

Example 1: When a high-priority start trigger is generated (the ADCAnTRM0 bit = 1 and the ADCAnTRM1 bit = 1)

Example 2: When a high-priority start trigger is generated (the ADCAnTRM0 bit = 0 and the ADCAnTRM1 bit = 0)

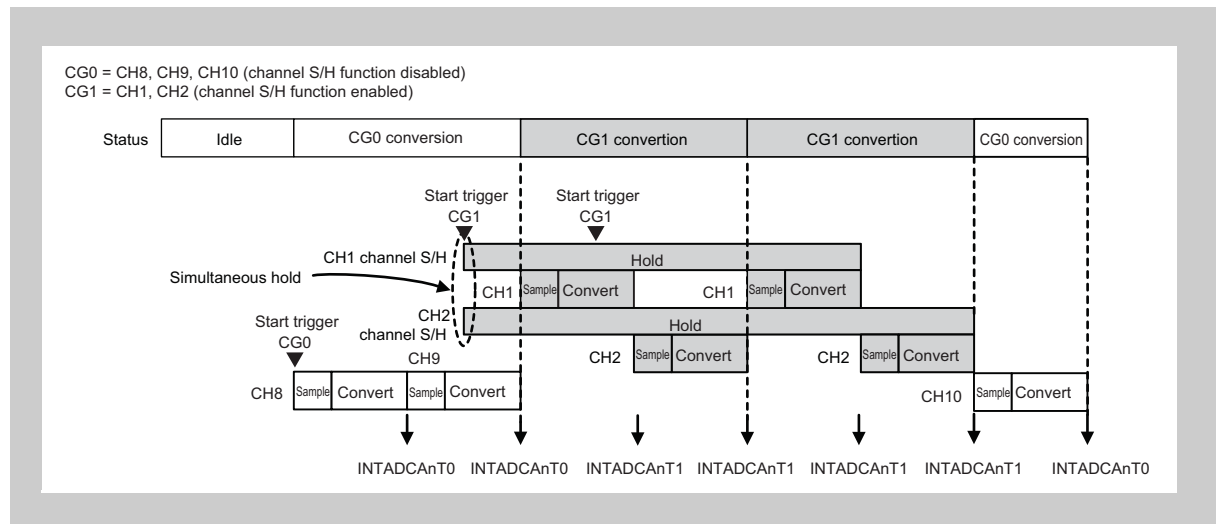

Example 3: When an additional start trigger is generated (the ADCAnTRM0 bit = 1 and the ADCAnTRM1 bit = 1)

Example 4: When an additional start trigger is generated (the ADCAnTRM0 bit = 1 and the ADCAnTRM1 bit = 0)

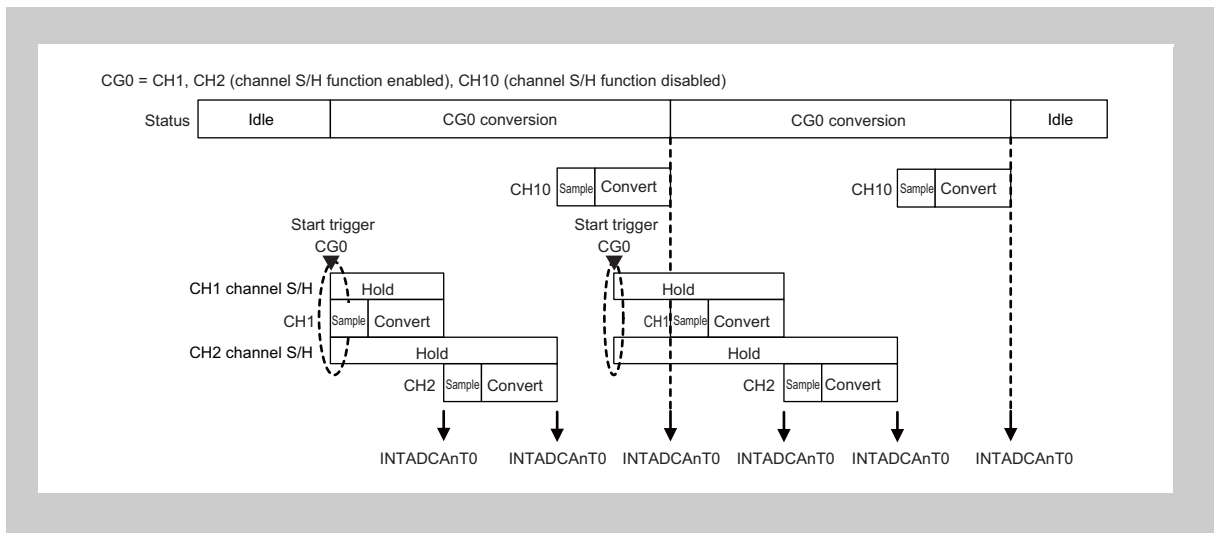

When an additional start trigger is generated during A/D conversion, the channel sample & hold circuit does not perform new sampling.

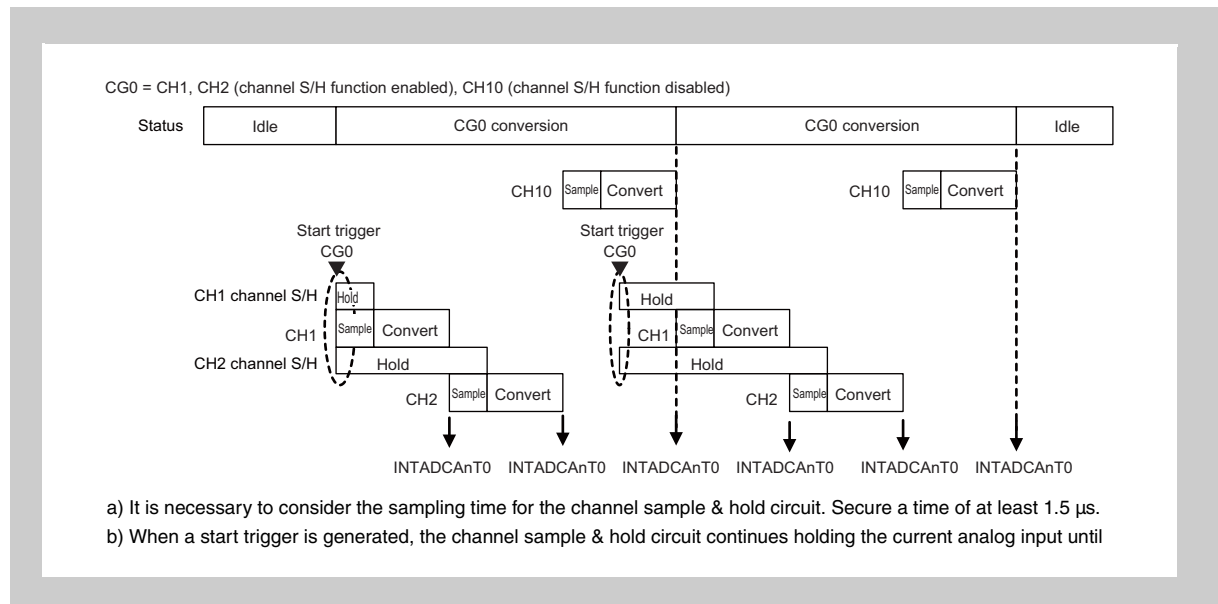

Example 5: When CG0 is in the one-shot conversion mode (no repetition) (the ADCAnTRM0 bit = 0)

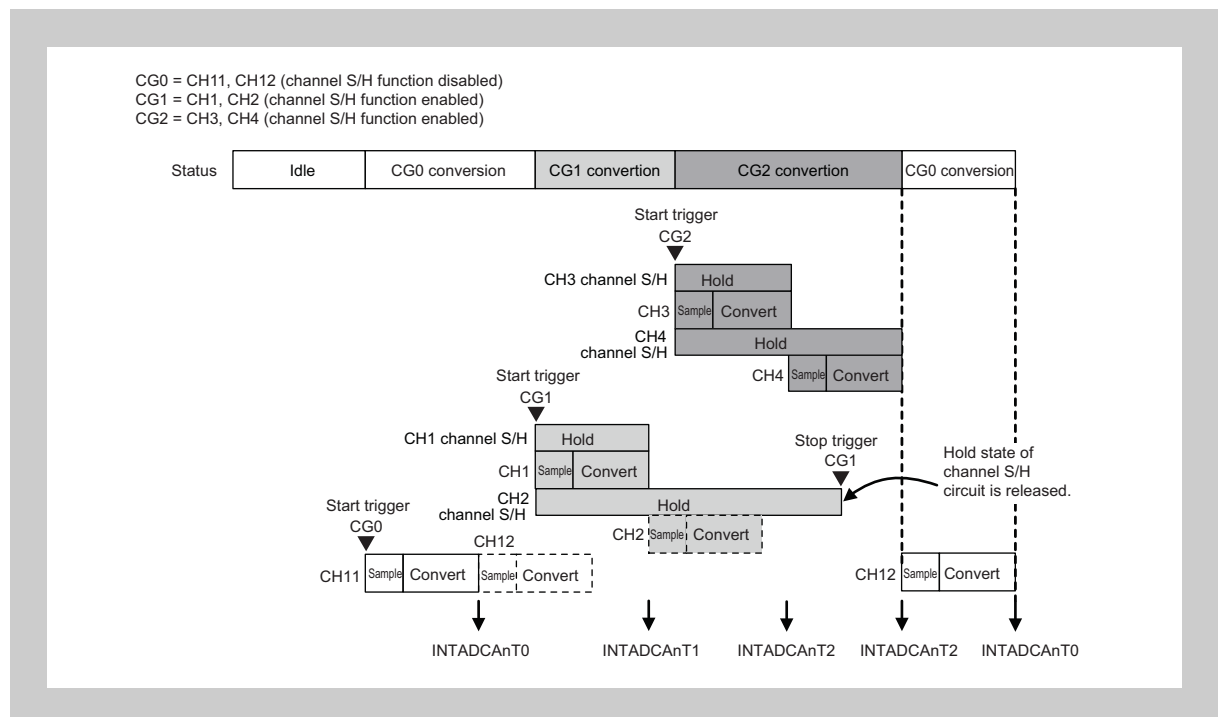

Example 6: When CG0 is in the one-shot conversion mode (no repetition), and an additional start trigger is generated (the ADCAnTRM0 bit = 0)

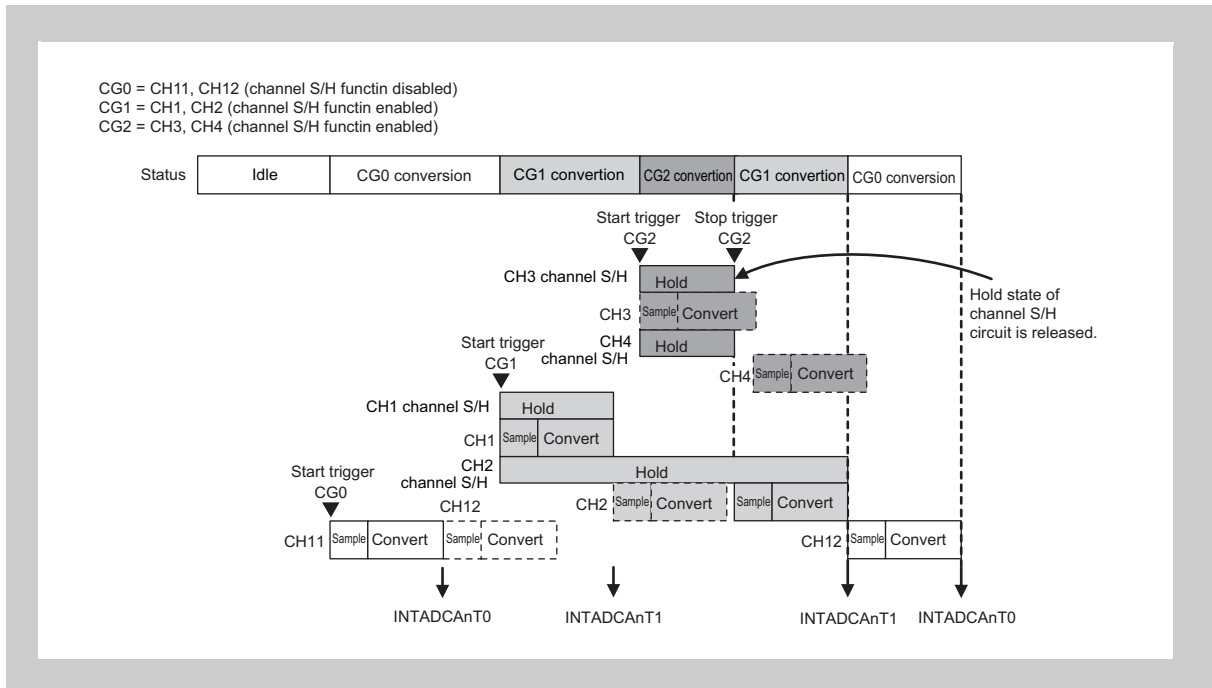

Example 7: When CG0 is in the one-shot conversion mode (no repetition), and an additional start trigger is generated (the ADCAnTRM0 bit = 1)

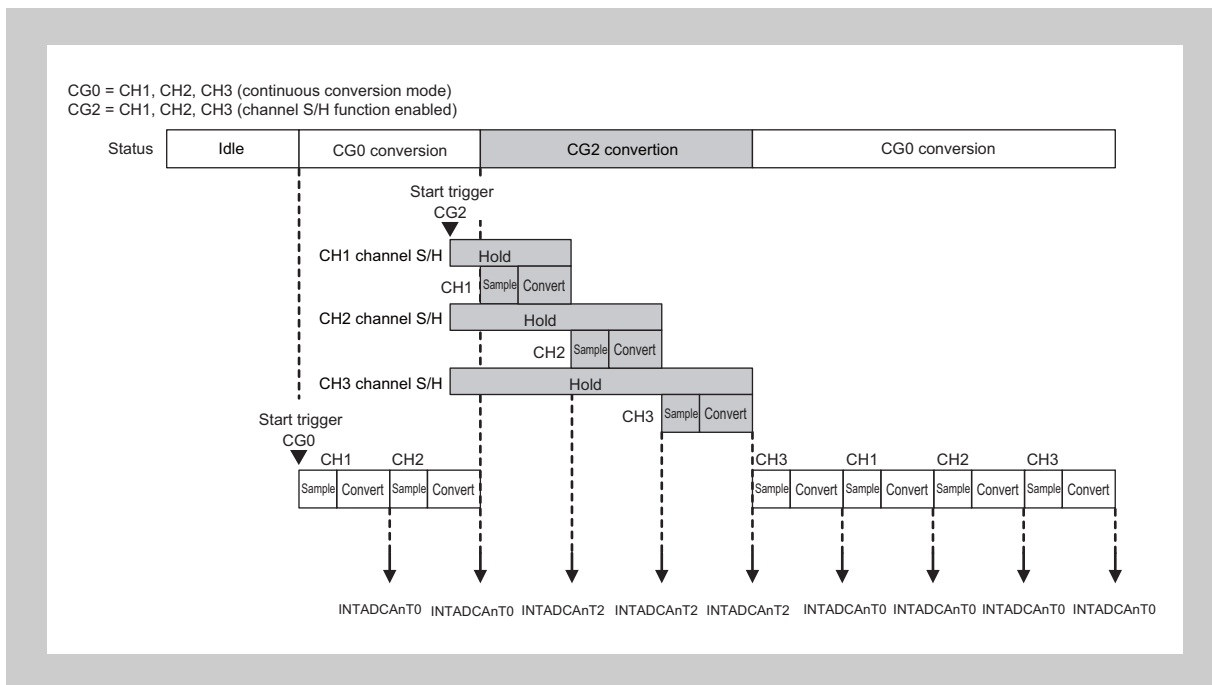

Example 8: When different channels are specified for CG1 and CG2, and a CG1 stop trigger is generated (the ADCAnTRM0 bit = 0 and the ADCAnTRM1 bit = 0)

Example 9: When different channels are specified for CG1 and CG2, and a CG2 stop trigger is generated (the ADCAnTRM0 bit = 0 and the ADCAnTRM1 bit = 0)

Example 10: When CG0 is in the continuous conversion mode, and the same channel is specified for CG0 and CG2 (the ADCAnTRM0 bit = 1 and the ADCAnTRM2 bit = 0)

(2) Restrictions when using the channel sample & hold function

The following describes the restrictions when using the channel sample & hold function.

1. Do not specify the channel used for the channel sample & hold function for multiple CGs at the same time.

Example 1: When using the channel sample & hold function for CG0, CG1, and CG2 (and CG0 is in the one-shot conversion mode)

The following combinations can be specified:

- CG0 (with CH1 selected), CG1 (with CH2 selected), and CG2 (with CH3 selected)

Specifying the following combinations is prohibited:

- CG0 (with CH1 selected), CG1 (with CH1 selected), and CG2 (with CH2 and CH3 selected)

Example 2: When using the channel sample & hold function for CG1 and CG2 (and CG0 is in the continuous conversion mode)

The following combinations can be specified:

- CG0 (with CH1 selected), CG1 (with CH1 and CH2 selected), and CG2 (with CH3 selected)
- CG0 (with CH1, CH2, and CH3 selected), CG1 (with CH1 selected), and CG2 (with CH2 and CH3 selected)

Specifying the following combinations is prohibited:

- CG0 (with CH1, CH2, and CH3 selected), CG1 (with CH1 and CH2 selected), and CG2 (with CH2 and CH3 selected)

2. When changing the scan list during operation for a CGi using the channel sample & hold function, do not change a channel subject to the function.

Example: When using the channel sample & hold function for CH1, CH2, and CH3

The following combinations can be specified:

- Changing CG0 (CH1, CH2, and CH3) to CG0 (CH1, CH2, CH3, CH10, and CH11)
- Changing CG0 (CH1, CH2, CH3, CH10, and CH11) to CG0 (CH1, CH2, and CH3)
- Changing CG0 (CH7, CH8, and CH9) to CG0 (CH10, CH11, and CH12)

Specifying the following combinations is prohibited:

- Changing CG0 (CH1, CH2, and CH3) to CG0 (CH1 and CH2)
- Changing CG0 (CH1) to CG0 (CH1, CH2, and CH3)
- Changing CG0 (CH7, CH8, and CH9) to CG0 (CH1, CH7, CH8, and CH9)
- Changing CG0 (CH1, CH2, and CH9) to CG0 (CH9, CH10, and CH11)

- Using repetition for CGs using the channel sample & hold function is prohibited. When using the channel sample & hold function for CGI, clear the bits that specify the number of repetitions for that CG (ADCA_nCTL0.ADCAnSCTi[1:0]) to 00_B.

25.3.15 Discharge function (product dependent)

If required, the internal capacitor of the common sample & hold circuit can be discharged before every conversion.

Note Enabling the discharge function increases the total conversion time by one clock cycle (ADCA_nTCLK). (For details, see 25.3.9 “Resolution, sampling, and conversion times” on page 1543.)

Setting To enable the discharge function, set ADCA_nCTL1.DCA_nDISC.

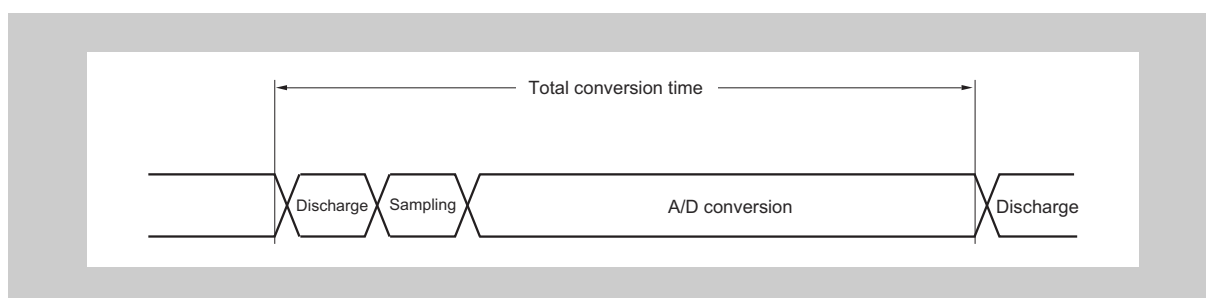

Figure 25-20 Conversion Timing When the Discharge Function Is Enabled

25.3.16 Buffer amplifier function

If required, the analog input signal can be connected to an internal buffer amplifier. The buffer amplifier accelerates the charge rate of the internal sampling capacitor during the A/D sampling period.

To enable the buffer amplifier function, set ADCA_nCTL1.ADCAnBPC.

Note Enabling the buffer amplifier function increases the total conversion time by four clock cycles (ADCA_nTCLK). (For details, see 25.3.9 “Resolution, sampling, and conversion times” on page 1543.)

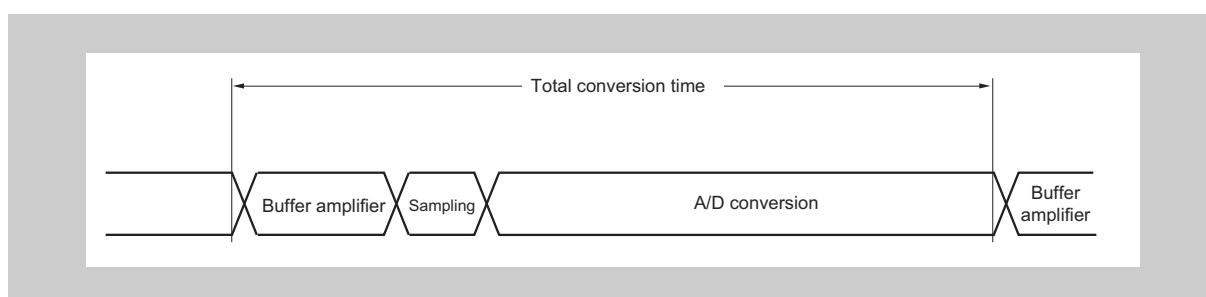

Figure 25-21 Conversion Timing When the Buffer Amplifier Function Is Enabled

25.3.17 Stabilization control

The A/D converter needs time for stabilization in the following cases:

- When the A/D converter is turned on (by setting ADCAnCTL1.ADCAnGPS)
- When the stand-by mode is exited

Start triggers are acknowledged even during the stabilization time, but conversion will not start until the stabilization time elapses.

To secure the minimum stabilization time, the stabilization time counter ADCAnCNT must be set.

25.4 Registers

This section describes all the registers of ADCAn.

25.4.1 Overview of the ADCAn registers

ADCAn is controlled and operated by the registers in the table below.

- If there is one register per channel, the channel number is indicated by an “m”.
- If there is one register per CG, the CG number is indicated by an “i” (where i = 0 to 2).

Table 25-8 ADCAn Registers (Product Dependent) (1/2)

Register Name	Symbol	Address
Control registers		
A/D converter mode control register 0	ADCAnCTL0	<ADCAn_base_OS> + 100 _H
A/D converter mode control register 1	ADCAnCTL1	<ADCAn_base_OS> + 104 _H
A/D converter CG register i	ADCAnCGi	<ADCAn_base_USER> + i×4 _H
A/D converter interrupt control register i	ADCAnIOCi	<ADCAn_base_USER> + C _H + i×4 _H
A/D converter trigger select control register i	ADCAnTSELi	<ADCAn_base_OS> + 108 _H + i×4 _H
A/D converter stabilization counter	ADCAnCNT	<ADCAn_base_OS> + 114 _H
Conversion status registers		
A/D converter overwrite error flag register	ADCAnSTR1	<ADCAn_base_USER> + 28 _H
ADCAnSTR1 flag clear register	ADCAnSTC1	<ADCAn_base_USER> + 34 _H
A/D converter status flag register 2	ADCAnSTR2	<ADCAn_base_USER> + 2C _H
ADCAnSTR2 flag clear register	ADCAnSTC2	<ADCAn_base_USER> + 38 _H
Software trigger registers		
A/D converter software trigger register i	ADCAnTRGi	<ADCAn_base_USER> + A4 _H + i×4 _H
A/D converter software trigger register 3	ADCAnTRG3	<ADCAn_base_USER> + B0 _H
A/D converter software trigger register 4+i	ADCAnTRG4+i	<ADCAn_base_USER> + B4 _H + i×4 _H
A/D converter software trigger register 7	ADCAnTRG7	<ADCAn_base_USER> + C0 _H
A/D conversion result registers		
A/D converter latest conversion result register	ADCAnLCR	<ADCAn_base_USER> + A0 _H
A/D converter conversion result register m	ADCAnCmCR	<ADCAn_base_USER> + 3C _H + m×4 _H
A/D converter CGi buffer result register i	ADCAnDBiCR	<ADCAn_base_USER> + C4 _H + i×4 _H
DMA Buffer register of CGi conversion register (product dependent)	ADCAnDBiCRL	<ADCAn_base_USER> + D0 _H + i×4 _H
A/D converter diagnostic conversion result register	ADCAnDGCR	<ADCAn_base_USER> + 9C _H
A/D conversion limit comparison registers		
A/D converter result check register	ADCAnCTL2	<ADCAn_base_USER> + 18 _H
A/D converter result check (upper limit)	ADCAnUL	<ADCAn_base_USER> + 1C _H
A/D converter result check (lower limit)	ADCAnLL	<ADCAn_base_USER> + 20 _H
A/D converter result check error flag	ADCAnSTR0	<ADCAn_base_USER> + 24 _H
ADCAnSTR0 flag clear register	ADCAnSTC0	<ADCAn_base_USER> + 30 _H

Table 25-8 ADCAn Registers (Product Dependent) (2/2)

Register Name	Symbol	Address
Diagnostic function control registers (product dependent)		
A/D converter self-diagnosis function control register 0	ADCAnDGCTL0	<ADCAn_base_USER> + DC _H
A/D converter self-diagnosis function control register 1	ADCAnDGCTL1	<ADCAn_base_OS> + 11C _H
A/D converter internal pull-down resistor control register 0	ADCAnPDCTL0	<ADCAn_base_OS> + 120 _H
Channel sample & hold function setup register (product dependent)		
A/D converter channel sample & hold control register (product dependent)	ADCAnSHCTL	<ADCAn_base_OS> + 118 _H

25.4.2 Control registers

(1) ADCAnCTL0 - A/D converter mode control register 0

This register enables or disables the A/D converter. In addition, it specifies the number of repetitions in the one-shot conversion mode and whether to generate error interrupt requests when an A/D conversion result is overwritten before it is read.

Access This register can be read or written in 16-bit units.

Address <ADCAn_base_OS> + 100_H

Initial value 0000_H. This register is initialized by any reset.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Table 25-9 ADCAnCTL0 Register Contents (1/2)

Bit Position	Bit Name	Description
12	ADCAn OEM4	This bit specifies whether the error interrupt INTADCAnTERR is generated when an A/D conversion result in the ADCAnLCR register is overwritten before it is read. 0: Generate the error interrupt INTADCAnTERR when an A/D conversion result is overwritten. 1: Do not generate the error interrupt INTADCAnTERR. For details, see (1) "Conversion result overwrite check function" on page 1550.
11 to 9	ADCAn OEM[3:1]	These bits specify whether the error interrupt INTADCAnTERR is generated when an A/D conversion result in an ADCAnDBiCR register is overwritten before it is read. 0: Generate the error interrupt INTADCAnTERR when an A/D conversion result is overwritten. 1: Do not generate the error interrupt INTADCAnTERR. CGI is controlled by the ADCAnOEM(i+1) bit. For details, see (1) "Conversion result overwrite check function" on page 1550.

Table 25-9 ADCAnCTL0 Register Contents (2/2)

Bit Position	Bit Name	Description															
8	ADCAnOEM0	<p>This bit specifies whether the error interrupt INTADCAnTERR is generated when an A/D conversion result in the ADCAnCmCR register is overwritten before it is read.</p> <p>0: Generate the error interrupt INTADCAnTERR when an A/D conversion result is overwritten.</p> <p>1: Do not generate the error interrupt INTADCAnTERR.</p> <p>For details, see (1) "Conversion result overwrite check function" on page 1550.</p>															
7	ADCAnCE	<p>This bit enables or disables the A/D converter.</p> <p>0: Disable the A/D converter.</p> <p>1: Enable the A/D converter.</p> <p>Note that A/D conversion only starts when there is a hardware or software trigger (ADCAnTRGi.ADCAnSTTi) if ADCAnCTL0.ADCAnCE is set to 1. Also note that the A/D converter needs time to stabilize after it has been enabled. Start triggers are acknowledged even immediately after turning the power on. A/D conversion starts after the stabilization counter ADCAnCNT reaches 00_H.</p>															
5 to 0	ADCAnSCTi[1:0]	<p>These bits specify the number of scan list conversions for CG1, CG2, and CG0 while it is in the one-shot conversion mode.</p> <table border="1"> <thead> <tr> <th>ADCAnSCTi1</th> <th>ADCAnSCTi0</th> <th>Number of CGi Scan List Conversions</th> </tr> </thead> <tbody> <tr> <td>0</td> <td>0</td> <td>1</td> </tr> <tr> <td>0</td> <td>1</td> <td>2</td> </tr> <tr> <td>1</td> <td>0</td> <td>3</td> </tr> <tr> <td>1</td> <td>1</td> <td>4</td> </tr> </tbody> </table>	ADCAnSCTi1	ADCAnSCTi0	Number of CGi Scan List Conversions	0	0	1	0	1	2	1	0	3	1	1	4

0	1	2															
1	0	3															
1	1	4															

(2) ADCAnCTL1 – A/D converter mode control register 1

This register specifies the conversion mode and controls the conversion operations.

Access This register can be read or written in 32-bit units.

Address <ADCAn_base_OS> + 104_H

Initial value 0100 0008_H. This register is initialized by any reset.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 25-10 ADCAnCTL1 Register Contents (1/3)

Bit Position	Bit Name	Description															
31 to 26	ADCAn TiETS[1:0]	These bits specify the valid edge of the hardware trigger signal ADCAnTTRGi. <table border="1"> <thead> <tr> <th>ADCAn TiETS1</th><th>ADCAn TiETS0</th><th>Valid Edge</th></tr> </thead> <tbody> <tr> <td>0</td><td>0</td><td>No valid edge detection (no acknowledgment)</td></tr> <tr> <td>0</td><td>1</td><td>Rising edge</td></tr> <tr> <td>1</td><td>0</td><td>Falling edge</td></tr> <tr> <td>1</td><td>1</td><td>Rising and falling edges</td></tr> </tbody> </table>	ADCAn TiETS1	ADCAn TiETS0	Valid Edge	0	0	No valid edge detection (no acknowledgment)	0	1	Rising edge	1	0	Falling edge	1	1	Rising and falling edges
ADCAn TiETS1	ADCAn TiETS0	Valid Edge															
0	0	No valid edge detection (no acknowledgment)															
0	1	Rising edge															
1	0	Falling edge															
1	1	Rising and falling edges															
24	ADCAn CRAC	This bit specifies the alignment of the A/D conversion and diagnostic conversion results. 0: Right-aligned 1: Left-aligned															
21	ADCAnMD1	This bit specifies the A/D conversion start trigger for all CGs. 0: Software trigger 1: Hardware trigger and software trigger This setting is valid for all CGs. Triggers are only detected when the A/D converter is enabled. For details, see 25.3.5 “Starting A/D conversion (start triggers)” on page 1538 .															
20	ADCAnMD0	This bit specifies the A/D conversion mode for CG0. 0: One-shot conversion mode The number of repetitions is specified by ADCAnCTL0.ADCAnSCT[1:0] for each CG. 1: Continuous conversion mode This setting applies to the A/D conversion of CG0 only. CG1 and CG2 are always operated in the one-shot conversion mode. For details, see 25.3.4 “A/D conversion modes” on page 1535 .															
17	ADCAnDISC	This bit enables or disables the discharge function. 0: Disable 1: Enable For details, see 25.3.15 “Discharge function (product dependent)” on page 1567 .															

Table 25-10 ADCAnCTL1 Register Contents (2/3)

Bit Position	Bit Name	Description																								
16	ADCAnRCL	This bit specifies whether the A/D conversion results in ADCAnCmCR and ADCAnDBiCR are retained after reading them. 0: Retain the A/D conversion result until it is overwritten by the next A/D conversion result. 1: Clear the A/D conversion result after reading it.																								
15	ADCAnCTYP	This bit specifies the resolution mode. 0: 12-bit resolution (product dependent) 1: 10-bit resolution																								
12	ADCAnSTL	This bit specifies the ADCAnCNVi signal level. 0: When ADCAnCNVi = L, CGi is not undergoing conversion. When ADCAnCNVi = H, CGi is undergoing conversion. 1: When ADCAnCNVi = H, CGi is not undergoing conversion. When ADCAnCNVi = L, CGi is undergoing conversion.																								
11 to 8	ADCAnFR [3:0]	These bits specify the ADCAn clock ADCAnTCLK. <table border="1" data-bbox="550 750 1385 1361"> <thead> <tr> <th>ADCAnFR[3:0]</th> <th>ADCAn Clock</th> </tr> </thead> <tbody> <tr> <td>0000</td> <td>PCLK/2</td> </tr> <tr> <td>0001</td> <td>PCLK/3</td> </tr> <tr> <td>0010</td> <td>PCLK/4</td> </tr> <tr> <td>0011</td> <td>PCLK/5</td> </tr> <tr> <td>0100</td> <td>PCLK/6</td> </tr> <tr> <td>0110</td> <td>PCLK/8</td> </tr> <tr> <td>1000</td> <td>PCLK/10</td> </tr> <tr> <td>1010</td> <td>PCLK/12</td> </tr> <tr> <td>1100</td> <td>PCLK/14</td> </tr> <tr> <td>1110</td> <td>PCLK/16</td> </tr> <tr> <td>Other than the above</td> <td>Setting prohibited</td> </tr> </tbody> </table>	ADCAnFR[3:0]	ADCAn Clock	0000	PCLK/2	0001	PCLK/3	0010	PCLK/4	0011	PCLK/5	0100	PCLK/6	0110	PCLK/8	1000	PCLK/10	1010	PCLK/12	1100	PCLK/14	1110	PCLK/16	Other than the above	Setting prohibited
ADCAnFR[3:0]	ADCAn Clock																									
0000	PCLK/2																									
0001	PCLK/3																									
0010	PCLK/4																									
0011	PCLK/5																									
0100	PCLK/6																									
0110	PCLK/8																									
1000	PCLK/10																									
1010	PCLK/12																									
1100	PCLK/14																									
1110	PCLK/16																									
Other than the above	Setting prohibited																									
6 to 4	ADCAnTRMi (product dependent)	These bits specify the interrupt behavior when the start trigger for the A/D conversion of a higher priority CG is input (or when transitioning to the ADCHALT mode is requested). 0: Interrupt the current A/D conversion of CGi, and start the A/D conversion of the higher priority CG (or enter the ADCHALT mode). 1: Finish the current CGi channel conversion, interrupt A/D conversion of the CG, and start the A/D conversion of the higher priority CG (or enter the ADCHALT mode). A/D conversion of CGi is continued as soon as all pending A/D conversions of higher priority CGs have been completed (or the ADCHALT mode has been exited). The priority is as follows: ADCHALT > CG2 > CG1 > CG0 For details, see (1) "Order of A/D conversion" on page 1534.																								
3	ADCAnBPC	This bit enables or disables the buffer amplifier function. 0: Disable 1: Enable For details, see 25.3.16 "Buffer amplifier function" on page 1567.																								

Table 25-10 ADCAnCTL1 Register Contents (3/3)

Bit Position	Bit Name	Description
0	ADCAnGPS	This bit turns ADCAn on or off. 0: Power off 1: Power on The A/D converter needs time to stabilize after being turned on. (For details, see 25.3.17 "Stabilization control" on page 1568).

(3) ADCAnCGi – A/D converter channel group register i

This register is used to create a scan list for the corresponding CG. The channels specified in the scan list are converted in ascending order. For details, see 25.3.3 “Channels and channel groups” on page 1533.

In addition, ADCAnCG0.ADCAnDIAG can be used to enable or disable the diagnosis of A/D conversion that uses the reference voltage signal ADDIAGOUT. For details, see (1) “A/D conversion circuit diagnosis” on page 1553.

Access This register can be read or written in 32-bit units. Because this register has a master/slave configuration, a new A/D conversion channel can be specified for the master register during A/D conversion. The timing at which the master register value is transferred to the slave register is as follows:

- If CGi is not undergoing A/D conversion, the value is transferred one clock cycle (PCLK) after writing to the master register.
- If CGi is undergoing A/D conversion, the value is transferred when the CGi scan list conversion currently being executed ends.
- If the CGi stop trigger bit (the ADCAnSPi bit) is set after a write to this register, the value is transferred when A/D conversion stops.

Address <ADCAn_base_USER> + i × 4_H

Initial value 0000 0000_H. This register is initialized by any reset.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 25-11 ADCAnCGi Register Contents

Bit Position	Bit Name	Description
31	ADCA _n DIAG	This bit enables or disables the diagnostic A/D conversion that uses the reference voltage signal ADDIAGOUT and is executed at the end of the A/D conversion of CG0. 0: Disable A/D conversion that uses the ADDIAGOUT signal. 1: Convert the ADDIAGOUT signal. This bit can only be specified for ADCAnCG0. Clear this bit for the ADCAnCG1 and ADCAnCG2 registers.
23 to 00	ADCA _n CGiS [23:00]	These bits specify the analog input signals to be converted for CGi. 0: Do not convert the analog input ADCAnIm. 1: Convert the analog input ADCAnIm. Note Clear bits corresponding to channels that are not provided by this microcontroller.

(4) ADCAnIOCi - A/D converter interrupt control register i

The A/D conversion end interrupt INTADCAnTi can be generated when the A/D conversion of a certain channel has been completed.

This register specifies the channels for which the interrupt INTADCAnTi is generated on A/D conversion completion.

If ADCAnIOCi is cleared to 0000 0000_H, the interrupt INTADCAnTi is automatically generated on the completion of A/D conversion of CGi.

Access This register can be read or written in 32-bit units. It can be written at any time, even when the A/D converter is enabled (by setting ADCAnCTL0.ADCAnCE to 1). The new value takes effect after the current A/D conversion of CGi has been completed.

Address <ADCAn_base_USER> + 0C_H + i × 4_H

Initial value 0000 0000_H. This register is initialized by any reset.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
ADCAnCG0IDG	0	0	0	0	0	0	0	ADCAnCGi[23:16]							
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

ADCAnCGi[15:00]															
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 25-12 ADCAnIOCi Register Contents

Bit Position	Bit Name	Description
31	ADCAnCG0IDG	This bit specifies whether the interrupt INTADCAnTi is generated on completion of the A/D conversion that uses the reference voltage when the diagnostic mode is enabled for CG0 (by setting ADCAnCG0.ADCAnDIAG to 1). 0: Do not generate the A/D conversion end interrupt INTADCAnTi. 1: Generate the A/D conversion end interrupt INTADCAnTi. This bit can only be specified for ADCAnIOC0. Clear this bit for the ADCAnIOC1 and ADCAnIOC2 registers. For details, see (1) "A/D conversion circuit diagnosis" on page 1553.
23 to 00	ADCAnCGi[23:00]	These bits specify whether the A/D conversion end interrupt INTADCAnTi is generated on A/D conversion completion of channel m. 0: Do not generate the A/D conversion end interrupt INTADCAnTi. 1: Generate the A/D conversion end interrupt INTADCAnTi. Note Clear bits corresponding to channels that are not provided by this microcontroller.

Note Because the ADCAnIOCi register is associated with the ADCAnCGi register, their buffer registers must be updated simultaneously. Because the update is performed when the ADCAnCGi register is written to, always write to the ADCAnIOCi register before the ADCAnCGi register when changing the interrupt generation for a CG.

(5) ADCAnCNT – A/D converter stabilization counter

This register specifies the stabilization time.

Access This register can be read or written in 8-bit units.

Address <ADCAn_base_OS> + 114_H

Initial value 00_H. This register is initialized by any reset.

Table 25-13 ADCAnCNT Register Contents

Bit Position	Bit Name	Description
7 to 0	ADCAnCNT[7:0]	These bits specify the stabilization counter value. Stabilization time = ADCAnCNT[7:0] × clock cycles (PCLK)

(6) ADCAnTSELi - A/D converter trigger select control register 0 (product dependent)

This register specifies the input signals to be used in combination with the hardware start trigger signal ADCAnTTRGi. Multiple trigger sources can be used simultaneously.

Access This register can be read or written in 16-bit units. It can only be written when the A/D converter is disabled (by clearing ADCAnCTL0.ADCAnCE).

Address <ADCAn_base_OS> + 108_H + i × 4_H

Initial value 0000_H. This register is initialized by any reset.

Table 25-14 ADCAnTSELi Register Contents

Bit Position	Bit Name	Description
15 to 0	ADCAnTiSEL[15:00]	These bits specify whether the corresponding input signal is to be used as a hardware start trigger. 0: Do not use the signal as a hardware start trigger. 1: Use the signal as a hardware start trigger. Note Clear bits corresponding to triggers that are not provided by this microcontroller.

Note For details about the connection destinations of hardware start triggers, see *Table 25-2 “What the Hardware Trigger Is Connected to”*.

25.4.3 Conversion status registers

(1) ADCAnSTR1 – A/D converter overwrite error flag

This register indicates whether the latest A/D conversion result in the ADCAnCmCR register was overwritten before it was read.

Access This register can be read in 32-bit units.

Address <ADCAn_base_USER> + 28_H

Initial value 0000 0000_H. This register is initialized by any reset.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0	0	0	0	0	0	0	0	ADCAnOWE[23:16]							
R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ADCAnOWE[15:00]															
R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 25-15 ADCAnSTR1 Register Contents

Bit Position	Bit Name	Description
23 to 0	ADCAnOWE[23:00]	<p>These bits indicate whether the A/D conversion result of channel m was overwritten before it was read.</p> <p>0: Not overwritten 1: Overwritten</p> <p>These error flags are cleared by setting ADCAnSTC1.ADCAnOWECm.</p> <p>Note Clear bits corresponding to channels that are not provided by this microcontroller.</p>

Note The value of ADCAnSTR1.ADCAnOWEm is applied to the following overwrite error flag:

- The error flag in the register that has the latest A/D conversion result of channel m (ADCAnCmCR.ADCAnCmER1)

(2) ADCAnSTC1 – ADCAnSTR1 flag clear register

This register clears the ADCAnSTR1 register.

Access This register can be written in 32-bit units.

When this register is read, 0000 0000_H is always returned.

Address <ADCAn_base_USER> + 34_H

Initial value 0000 0000_H. This register is initialized by any reset.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0	0	0	0	0	0	0	0	ADCAnOWEC[23:16]

W	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W

Table 25-16 ADCAnSTC1 Register Contents

Bit Position	Bit Name	Description
23 to 0	ADCAnOWEC[23:00]	0: No function 1: Clear the corresponding ADCAnSTR1.ADCAnOWEm. Note Clear bits corresponding to channels that are not provided by this microcontroller.

(3) ADCAnSTR2 – A/D converter status flag 2

This register indicates the current conversion status.

Access This register can be read in 16-bit units.

Address <ADCAn_base_USER> + 2C_H

Initial value 0000_H. This register is initialized by any reset.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	ADCAnRQ3	ADCAnRQ[2:0]	0	0	0	0	ADCAnST3	ADCAnST[2:0]				
R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 25-17 ADCAnSTR2 Register Contents

Bit Position	Bit Name	Description
11	ADCAnRQ3 (product dependent)	This bit indicates whether an ADCHALT request is pending: 0: No ADCHALT request is pending. 1: An ADCHALT request is pending.
10 to 8	ADCAnRQ[2:0]	These bits indicate whether an A/D conversion request for CGi is pending: 0: No A/D conversion request for CGi is pending. 1: An A/D conversion request for CGi is pending.
3	ADCAnST3 (product dependent)	This bit indicates whether A/D conversion is currently in the ADCHALT status due to a software trigger (ADCAnTRG3.ADCAnSTT3). 0: Conversion is not in the ADCHALT status. 1: Conversion is in the ADCHALT status. This bit is cleared when the A/D converter is disabled (by clearing ADCAnCTL0.ADCAnCE).
2 to 0	ADCAnST[2:0]	These bits indicate whether A/D conversion of CGi is currently being performed. 0: A/D conversion is not currently being performed (including when A/D conversion is interrupted due to A/D conversion of a higher priority CG). 1: A/D conversion is currently being performed. These bits are cleared when the A/D converter is disabled (by clearing ADCAnCTL0.ADCAnCE).

(4) ADCAnSTC2 – A/D converter status flag clear register 2

This register clears the overwrite and result check status flags of the ADCAnLCR and ADCAnDBiCR registers.

Access This register can be written in 8-bit units.

Address <ADCAn_base_USER> + 38_H

Initial value 00_H. This register is initialized by any reset.

7	6	5	4	3	2	1	0
ADCAn LERC1	ADCAn LERC0	ADCAn DB2ERC1	ADCAn DB2ERC0	ADCAn DB1ERC1	ADCAn DB1ERC0	ADCAn DB0ERC1	ADCAn DB0ERC0
W	W	W	W	W	W	W	W

Table 25-18 ADCAnSTC2 Register Contents

Bit Position	Bit Name	Description
7	ADCAn LERC1	This bit clears the overwrite flag ADCAnLCR.ADCAnLER1. 0: No function 1: Clear ADCAnLCR.ADCAnLER1.
6	ADCAn LERC0	This bit clears the result check error flag ADCAnLCR.ADCAnLER0. 0: No function 1: Clear ADCAnLCR.ADCAnLER0.
5, 3, 1	ADCAn DBiERC1	These bits clear the overwrite flag ADCAnDBiCR.ADCAnDBiER1. 0: No function 1: Clear ADCAnDBiCR.ADCAnDBiER1.
4, 2, 0	ADCAn DBiERC0	These bits clear the result check error flag ADCAnDBiCR.ADCAnDBiER0. 0: No function 1: Clear ADCAnDBiCR.ADCAnDBiER0.

25.4.4 Software trigger registers

(1) ADCAnTRGi – A/D converter software trigger register i

This register is the trigger register for starting the A/D conversion of CGi.

Access This register can be written in 8-bit units. When this register is read, 00_H is always returned.

Address <ADCAn_base_USER> + A4_H + i × 4_H

Initial value 00_H. This register is initialized by any reset.

7	6	5	4	3	2	1	0
0	0	0	0	0	0	0	ADCAn STTi
W	W	W	W	W	W	W	W

Table 25-19 ADCAnTRGi Register Contents

Bit Position	Bit Name	Description
0	ADCAnSTTi	This bit starts the A/D conversion of CGi. 0: No function 1: Start the A/D conversion of CGi.

For details, see 25.3.5 “Starting A/D conversion (start triggers)” on page 1538

(2) ADCAnTRG3 – A/D converter software trigger register 3 (product dependent)

This trigger register is used to transition to the ADCHALT mode.

Access This register can be written in 8-bit units. When this register is read, 00_H is always returned.

Address <ADCAn_base_USER> + B0_H

Initial value 00_H. This register is initialized by any reset.

7	6	5	4	3	2	1	0
0	0	0	0	0	0	0	ADCAn STT3
W	W	W	W	W	W	W	W

Table 25-20 ADCAnTRG3 Register Contents

Bit Position	Bit Name	Description
0	ADCAnSTT3	0: No function 1: Transition to the ADCHALT mode.

For details, see 25.3.8 “Pausing and resuming A/D conversion (ADCHALT mode) (product dependent)” on page 1542.

(3) ADCAnTRG4+i – A/D converter software trigger register 4+i

This software trigger register is used to stop the A/D conversion of CGi.

Access This register can be written in 8-bit units. When this register is read, 00_H is always returned.

Address <ADCAn_base_USER> + B4_H + i × 4_H

Initial value 00_H. This register is initialized by any reset.

7	6	5	4	3	2	1	0
0	0	0	0	0	0	0	ADCAnSPi
W	W	W	W	W	W	W	W

Table 25-21 ADCAnTRG4+i Register Contents

Bit Position	Bit Name	Description
0	ADCAnSPi	0: No function 1: Stop the A/D conversion of CGi.

For details, see 25.3.6 “Stopping A/D conversion (stop triggers)” on page 1540 .

(4) ADCAnTRG7 – A/D converter software trigger register 7 (product dependent)

This software trigger register is used to exit the ADCHALT mode and resume A/D conversion.

Access This register can be written in 8-bit units. When this register is read, 00_H is always returned.

Address <ADCAn_base_USER> + C0_H

Initial value 00_H. This register is initialized by any reset.

7	6	5	4	3	2	1	0
0	0	0	0	0	0	0	ADCAnSP3
W	W	W	W	W	W	W	W

Table 25-22 ADCAnTRG7 Register Contents

Bit Position	Bit Name	Description
0	ADCAnSP3	0: No function 1: Resume A/D conversion.

For details, see 25.3.8 “Pausing and resuming A/D conversion (ADCHALT mode) (product dependent)” on page 1542 .

25.4.5 A/D conversion result registers

(1) ADCAnLCR – A/D converter latest conversion result register

This register stores the result and status of the latest A/D conversion.

This register makes it possible to read the latest A/D conversion results.

Access This register can be read in 32-bit units.

- The upper 16 bits store the A/D conversion result status.
- The lower 16 bits store the A/D conversion result.

Address <ADCAn_base_USER> + A0_H

Initial value 0300 0000_H. This register is initialized by any reset.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 25-23 ADCAnLCR Register Contents (1/2)

Bit Position	Bit Name	Description															
25, 24	ADCAn LCG[1:0]	These bits indicate the CG to which the conversion result stored in ADCAnLCR[15:00] belongs. <table border="1" data-bbox="497 1205 1382 1480"> <thead> <tr> <th>ADCAn LCG1</th><th>ADCAn LCG0</th><th>Channel Group</th></tr> </thead> <tbody> <tr> <td>0</td><td>0</td><td>CG0</td></tr> <tr> <td>0</td><td>1</td><td>CG1</td></tr> <tr> <td>1</td><td>0</td><td>CG2</td></tr> <tr> <td>1</td><td>1</td><td>None</td></tr> </tbody> </table>	ADCAn LCG1	ADCAn LCG0	Channel Group	0	0	CG0	0	1	CG1	1	0	CG2	1	1	None
ADCAn LCG1	ADCAn LCG0	Channel Group															
0	0	CG0															
0	1	CG1															
1	0	CG2															
1	1	None															
23	ADCAn LER1	This bit indicates the overwrite error status. 0: Not overwritten 1: Overwritten This error flag is cleared by setting ADCAnSTC2.ADCAnLERC1.															
22	ADCAn LER0	This bit indicates the status of the A/D conversion result limit comparison. 0: The conversion results are within the specified range. 1: The conversion results are not within the specified range. This error flag is cleared by setting ADCAnSTC2.ADCAnLERC0.															
21	ADCAn LUR	This bit indicates the update status of the A/D conversion result. 0: The A/D conversion result has been read from the ADCAnLCR register. 1: The A/D conversion result is new and has not been read from the ADCAnLCR register. This bit is cleared by reading it.															
20 to 16	ADCAn LCN[4:0]	These bits indicate the channel number to which the conversion result stored in the ADCAnLCR[15:00] bits belongs. 00001 × m = CHm															

Table 25-23 ADCAnLCR Register Contents (2/2)

Bit Position	Bit Name	Description																				
15 to 0	ADCAnLCR [15:00]	<p>These bits indicate the A/D conversion result. The resolution and alignment depend on ADCAnCTL1.ADCAnCTYP and ADCAnCTL1.ADCAnCRAC as follows:</p> <table border="1"> <thead> <tr> <th>ADCAnCTL1.ADCAnCTYP</th> <th>ADCAnCTL1.ADCAnCRAC</th> <th>Resolution and Alignment</th> <th>A/D Conversion Result Value Bit Position</th> </tr> </thead> <tbody> <tr> <td>0</td> <td>0</td> <td>12-bit resolution, right-aligned</td> <td>[11:00] of ADCAnLCR[15:00]</td> </tr> <tr> <td>0</td> <td>1</td> <td>12-bit resolution, left-aligned</td> <td>[15:04] of ADCAnLCR[15:00]</td> </tr> <tr> <td>1</td> <td>0</td> <td>10-bit resolution, right-aligned</td> <td>[09:00] of ADCAnLCR[15:00]</td> </tr> <tr> <td>1</td> <td>1</td> <td>10-bit resolution, left-aligned</td> <td>[15:06] of ADCAnLCR[15:00]</td> </tr> </tbody> </table>	ADCAnCTL1.ADCAnCTYP	ADCAnCTL1.ADCAnCRAC	Resolution and Alignment	A/D Conversion Result Value Bit Position	0	0	12-bit resolution, right-aligned	[11:00] of ADCAnLCR[15:00]	0	1	12-bit resolution, left-aligned	[15:04] of ADCAnLCR[15:00]	1	0	10-bit resolution, right-aligned	[09:00] of ADCAnLCR[15:00]	1	1	10-bit resolution, left-aligned	[15:06] of ADCAnLCR[15:00]
ADCAnCTL1.ADCAnCTYP	ADCAnCTL1.ADCAnCRAC	Resolution and Alignment	A/D Conversion Result Value Bit Position																			
0	0	12-bit resolution, right-aligned	[11:00] of ADCAnLCR[15:00]																			
0	1	12-bit resolution, left-aligned	[15:04] of ADCAnLCR[15:00]																			
1	0	10-bit resolution, right-aligned	[09:00] of ADCAnLCR[15:00]																			
1	1	10-bit resolution, left-aligned	[15:06] of ADCAnLCR[15:00]																			

Note When A/D conversion is performed by using the internal reference voltage, the A/D conversion result is stored in the ADCAnDGCR register, not in the ADCAnLCR, ADCAnCmCR, and ADCAnDBiCR registers. (For details, see (4) “ADCAnDBiCRL – DMA buffer register of CGi (product dependent)” on page 1590.)

(2) ADCAnCmCR – A/D converter conversion result register for channel m

This register stores the result and status of the latest A/D conversion for channel m.

This makes it possible to read the A/D conversion results for a specified channel (m).

Access This register can be read in 32-bit units.

- The upper 16 bits store the A/D conversion result status.
- The lower 16 bits store the A/D conversion result.

Address <ADCAn_base_USER> + 3C_H + m × 4_H

Initial value 0300 0000_H + m × 0001 0000_H. This register is initialized by any reset.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0	0	0	0	0	0	ADCAn CmCG[1:0]	ADCAn CmER1	ADCAn CmER0	ADCAn CmUR	ADCAnCmCN[4:0]					
R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ADCAnCmCR[15:00]															
R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

- Notes**
1. The functions of each bit are the same as those of the ADCAnLCR register, except that here they affect the latest A/D conversion result for a specific channel instead of the latest A/D conversion results for all channels. (For details, see *Table 25-23 “ADCAnLCR Register Contents” on page 1584*.)
 2. After a reset, the ADCAnCmCG[1:0] bits are set to 11_B.
 3. If ADCAnCTL1.ADCAnRCL is cleared, the A/D conversion result in the ADCAnCmCR[15:00] bits is kept until it is overwritten by the next A/D conversion result.
If ADCAnCTL1.ADCAnRCL is set, the ADCAnCmCR[15:00] bits are cleared by reading them.

Table 25-24 ADCAnCmCR Register Contents (1/2)

Bit Position	Bit Name	Description															
25, 24	ADCAn CmCG [1:0]	These bits indicate the CG to which the conversion result stored in ADCAnCmCR[15:00] belongs. <table border="1" data-bbox="497 1639 1382 1917"> <thead> <tr> <th>ADCAn CmCG1</th><th>ADCAn CmCG0</th><th>Channel Group</th></tr> </thead> <tbody> <tr> <td>0</td><td>0</td><td>CG0</td></tr> <tr> <td>0</td><td>1</td><td>CG1</td></tr> <tr> <td>1</td><td>0</td><td>CG2</td></tr> <tr> <td>1</td><td>1</td><td>None</td></tr> </tbody> </table>	ADCAn CmCG1	ADCAn CmCG0	Channel Group	0	0	CG0	0	1	CG1	1	0	CG2	1	1	None

Table 25-24 ADCAnCmCR Register Contents (2/2)

Bit Position	Bit Name	Description																				
23	ADCAnCmER1	This bit indicates the overwrite error status. 0: Not overwritten 1: Overwritten This error flag reflects the value of ADCAnSTR1.ADCAnOWEm and is cleared by setting ADCAnSTC1.ADCAnQWECm.																				
22	ADCAnCmER0	This bit indicates the status of the A/D conversion result limit comparison. 0: The conversion results are within the specified range. 1: The conversion results are not within the specified range. This error flag reflects the value of ADCAnSTR0.ADCAnRCEm and is cleared by setting ADCAnSTC0.ADCAnRCECm.																				
21	ADCAnCmUR	This bit indicates the update status of the A/D conversion result. 0: The A/D conversion result has been read from the ADCAnCmCR register. 1: The A/D conversion result is new and has not been read from the ADCAnCmCR register. This bit is cleared by reading it.																				
20 to 16	ADCAnCmCN [4:0]	These bits indicate the channel number to which the conversion result stored in the ADCAnCmCR[15:00] bits belongs. 00001 × m = CHm																				
15 to 0	ADCAnCmCR [15:00]	These bits indicate the A/D conversion result. The resolution and alignment depend on ADCAnCTL1.ADCAnCTYP and ADCAnCTL1.ADCAnCRAC as follows: <table border="1" data-bbox="497 967 1383 1386"> <thead> <tr> <th>ADCAnCTL1.ADCAnCTYP</th> <th>ADCAnCTL1.ADCAnCRAC</th> <th>Resolution and Alignment</th> <th>A/D Conversion Result Value Bit Position</th> </tr> </thead> <tbody> <tr> <td>0</td> <td>0</td> <td>12-bit resolution, right-aligned</td> <td>[11:00] of ADCAnCmCR[15:00]</td> </tr> <tr> <td>0</td> <td>1</td> <td>12-bit resolution, left-aligned</td> <td>[15:04] of ADCAnCmCR[15:00]</td> </tr> <tr> <td>1</td> <td>0</td> <td>10-bit resolution, right-aligned</td> <td>[09:00] of ADCAnCmCR[15:00]</td> </tr> <tr> <td>1</td> <td>1</td> <td>10-bit resolution, left-aligned</td> <td>[15:06] of ADCAnCmCR[15:00]</td> </tr> </tbody> </table>	ADCAnCTL1.ADCAnCTYP	ADCAnCTL1.ADCAnCRAC	Resolution and Alignment	A/D Conversion Result Value Bit Position	0	0	12-bit resolution, right-aligned	[11:00] of ADCAnCmCR[15:00]	0	1	12-bit resolution, left-aligned	[15:04] of ADCAnCmCR[15:00]	1	0	10-bit resolution, right-aligned	[09:00] of ADCAnCmCR[15:00]	1	1	10-bit resolution, left-aligned	[15:06] of ADCAnCmCR[15:00]
ADCAnCTL1.ADCAnCTYP	ADCAnCTL1.ADCAnCRAC	Resolution and Alignment	A/D Conversion Result Value Bit Position																			
0	0	12-bit resolution, right-aligned	[11:00] of ADCAnCmCR[15:00]																			
0	1	12-bit resolution, left-aligned	[15:04] of ADCAnCmCR[15:00]																			
1	0	10-bit resolution, right-aligned	[09:00] of ADCAnCmCR[15:00]																			
1	1	10-bit resolution, left-aligned	[15:06] of ADCAnCmCR[15:00]																			

Note When A/D conversion is performed by using the internal reference voltage, the A/D conversion result is stored in the ADCAnDGCR register, not in the ADCAnLCR, ADCAnCmCR, and ADCAnDBiCR registers. (For details, see (4) “ADCAnDBiCRL – DMA buffer register of CGi (product dependent)” on page 1590.)

(3) ADCAnDBiCR – DMA buffer register of CGi

This register stores the result and status of the latest A/D conversion of CGi. This makes it possible to read the A/D conversion results for all channels of CGi.

Access This register can be read in 32-bit units.

- The upper 16 bits store the A/D conversion result status.
- The lower 16 bits store the A/D conversion result.

Address <ADCAn_base_USER> + C4_H + i × 4_H

Initial value 0000 0000_H + i × 0100 0000_H. This register is initialized by any reset.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 25-25 ADCAnDBiCR Register Contents (2/2)

Bit Position	Bit Name	Description																				
20 to 16	ADCAnDBiCN [4:0]	These bits indicate the channel number to which the conversion result stored in the ADCAnDBiCR[15:00] bits belongs. 00001 × m = CHm																				
15 to 0	ADCAnDBiCR [15:00]	These bits indicate the A/D conversion result. The resolution and alignment depend on ADCAnCTL1.ADCAnCTYP and ADCAnCTL1.ADCAnCRAC as follows: <table border="1" data-bbox="497 488 1383 909"> <thead> <tr> <th>ADCAnCTL1.ADCAnCTYP</th> <th>ADCAnCTL1.ADCAnCRAC</th> <th>Resolution and Alignment</th> <th>A/D Conversion Result Value Bit Position</th> </tr> </thead> <tbody> <tr> <td>0</td> <td>0</td> <td>12-bit resolution, right-aligned</td> <td>[11:00] of ADCAnDBiCR[15:00]</td> </tr> <tr> <td>0</td> <td>1</td> <td>12-bit resolution, left-aligned</td> <td>[15:04] of ADCAnDBiCR[15:00]</td> </tr> <tr> <td>1</td> <td>0</td> <td>10-bit resolution, right-aligned</td> <td>[09:00] of ADCAnDBiCR[15:00]</td> </tr> <tr> <td>1</td> <td>1</td> <td>10-bit resolution, left-aligned</td> <td>[15:06] of ADCAnDBiCR[15:00]</td> </tr> </tbody> </table>	ADCAnCTL1.ADCAnCTYP	ADCAnCTL1.ADCAnCRAC	Resolution and Alignment	A/D Conversion Result Value Bit Position	0	0	12-bit resolution, right-aligned	[11:00] of ADCAnDBiCR[15:00]	0	1	12-bit resolution, left-aligned	[15:04] of ADCAnDBiCR[15:00]	1	0	10-bit resolution, right-aligned	[09:00] of ADCAnDBiCR[15:00]	1	1	10-bit resolution, left-aligned	[15:06] of ADCAnDBiCR[15:00]
ADCAnCTL1.ADCAnCTYP	ADCAnCTL1.ADCAnCRAC	Resolution and Alignment	A/D Conversion Result Value Bit Position																			
0	0	12-bit resolution, right-aligned	[11:00] of ADCAnDBiCR[15:00]																			
0	1	12-bit resolution, left-aligned	[15:04] of ADCAnDBiCR[15:00]																			
1	0	10-bit resolution, right-aligned	[09:00] of ADCAnDBiCR[15:00]																			
1	1	10-bit resolution, left-aligned	[15:06] of ADCAnDBiCR[15:00]																			

Note When A/D conversion is performed by using the internal reference voltage, the A/D conversion result is stored in the ADCAnDGCR register, not in the ADCAnLCR, ADCAnCmCR, ADCAnDBiCR, and ADCAnDBiCRL registers. (For details, see (5) “ADCAnDGCR – Diagnostic conversion result register” on page 1591.)

(4) ADCAnDBiCRL – DMA buffer register of CGi (product dependent)

This register stores the result of the latest A/D conversion of CGi. This makes it possible to read the A/D conversion results for all channels of CGi. This register reflects the lower 16 bits of the DMA buffer register of CGi (ADCAnDBiCR).

Access This register can be read in 16-bit units.

Address <ADCAn_base_USER> + D0_H + i×4_H

Initial value 0000_H. This register is initialized by any reset.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ADCAnDBiCR[15:00]															
R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 25-26 ADCAnDBiCRL Register Contents

Bit Position	Bit Name	Description																				
15 to 0	ADCAnDBiCRL [15:00]	<p>These bits indicate the A/D conversion result. The resolution and alignment depend on ADCAnCTL1.ADCAnCTYP and ADCAnCTL1.ADCAnCRAC as follows:</p> <table border="1"> <thead> <tr> <th>ADCAnCTL1.ADCAnCTYP</th><th>ADCAnCTL1.ADCAnCRAC</th><th>Resolution and Alignment</th><th>A/D Conversion Result Value Bit Position</th></tr> </thead> <tbody> <tr> <td>0</td><td>0</td><td>12-bit resolution, right-aligned</td><td>[11:00] of ADCAnDBiCR[15:00]</td></tr> <tr> <td>0</td><td>1</td><td>12-bit resolution, left-aligned</td><td>[15:04] of ADCAnDBiCR[15:00]</td></tr> <tr> <td>1</td><td>0</td><td>10-bit resolution, right-aligned</td><td>[09:00] of ADCAnDBiCR[15:00]</td></tr> <tr> <td>1</td><td>1</td><td>10-bit resolution, left-aligned</td><td>[15:06] of ADCAnDBiCR[15:00]</td></tr> </tbody> </table>	ADCAnCTL1.ADCAnCTYP	ADCAnCTL1.ADCAnCRAC	Resolution and Alignment	A/D Conversion Result Value Bit Position	0	0	12-bit resolution, right-aligned	[11:00] of ADCAnDBiCR[15:00]	0	1	12-bit resolution, left-aligned	[15:04] of ADCAnDBiCR[15:00]	1	0	10-bit resolution, right-aligned	[09:00] of ADCAnDBiCR[15:00]	1	1	10-bit resolution, left-aligned	[15:06] of ADCAnDBiCR[15:00]
ADCAnCTL1.ADCAnCTYP	ADCAnCTL1.ADCAnCRAC	Resolution and Alignment	A/D Conversion Result Value Bit Position																			
0	0	12-bit resolution, right-aligned	[11:00] of ADCAnDBiCR[15:00]																			
0	1	12-bit resolution, left-aligned	[15:04] of ADCAnDBiCR[15:00]																			
1	0	10-bit resolution, right-aligned	[09:00] of ADCAnDBiCR[15:00]																			
1	1	10-bit resolution, left-aligned	[15:06] of ADCAnDBiCR[15:00]																			

Note When A/D conversion is performed by using the internal reference voltage, the A/D conversion result is stored in the ADCAnDGCR register, not in the ADCAnLCR, ADCAnCmCR, ADCAnDBiCR, and ADCAnDBiCRL registers. (For details, see (5) “ADCAnDGCR – Diagnostic conversion result register” on page 1591.)

(5) ADCAnDGCR – Diagnostic conversion result register

This register stores the result of the A/D conversion that uses the reference voltage signal ADDIAGOUT (when ADCAnCG0.ADCAnDIAG is set to 1).

Diagnostic conversion starts after the A/D conversion of the last channel of CG0 has been completed.

Access This register can be read in 16-bit units.

Address <ADCAn_base_USER> + 9C_H

Initial value 0000_H. This register is initialized by any reset.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ADCAnDGCR[15:00]															
R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 25-27 ADCAnDGCR Register Contents

Bit Position	Bit Name	Description
15 to 0	ADCAn DGCR[15:00]	These bits indicate the result of the diagnostic A/D conversion. The resolution and alignment depend on ADCAnCTL1.ADCAnCTYP and ADCAnCTL1.ADCAnCRAC (as for the normal A/D conversion result registers).

25.4.6 A/D conversion result limit comparison registers

(1) ADCAnCTL2 – A/D converter result check register

This register makes it possible to enable or disable the conversion result limit comparison function for individual channels.

For details, see 25.3.12 “Result check functions” on page 1550.

Access This register can be read or written in 32-bit units. It can only be written when the A/D converter is disabled (by clearing ADCAnCTL0.ADCAnCE).

Address <ADCAn_base_USER> + 18_H

Initial value 0000 0000_H. This register is initialized by any reset.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 25-28 ADCAnCTL2 Register Contents

Bit Position	Bit Name	Description
23 to 00	ADCAnRCK[23:00]	<p>These bits enable or disable result limit comparison for CH_m.</p> <p>0: Do not check whether the A/D conversion result of CH_m is within the specified range.</p> <p>1: Check whether the A/D conversion result of CH_m is within the specified range.</p> <p>Note Clear bits corresponding to channels that are not provided by this microcontroller.</p>

Note This setting is valid for A/D conversions of every CG.

(2) ADCAnUL – A/D converter result limit comparison (upper limit)

This register specifies the upper limit of the A/D conversion result.

For details, see 25.3.12 “Result check functions” on page 1550 .

Access This register can be read or written in 16-bit units. It can only be written when the A/D converter is disabled (by clearing ADCAnCTL0.ADCAnCE).

Address <ADCAn_base_USER> + 1C_H

Initial value 0000_H. This register is initialized by any reset.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ADCAnUL[11:00]												0	0	0	0

Table 25-29 ADCAnUL Register Contents

Bit Position	Bit Name	Description
15 to 4	ADCAn UL[11:00]	These bits specify the upper limit of the A/D conversion result. If using the 10-bit function, use ADCAnUL[11:02] for this specification.

(3) ADCAnLL – A/D converter result limit comparison (lower limit)

This register specifies the lower limit of the A/D conversion result.

For details, see 25.3.12 “Result check functions” on page 1550 .

Access This register can be read or written in 16-bit units. It can only be written when the A/D converter is disabled (by clearing ADCAnCTL0.ADCAnCE).

Address <ADCAn_base_USER> + 20_H

Initial value 0000_H. This register is initialized by any reset.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 25-30 ADCAnLL Register Contents

Bit Position	Bit Name	Description
15 to 4	ADCAn LL[11:00]	These bits specify the lower limit of the A/D conversion result. If using the 10-bit function, use ADCAnLL[11:02] for this specification.

(4) ADCAnSTR0 - A/D converter result limit comparison error flag

This register indicates the error status of the latest A/D conversion result limit comparison for the channels specified by the ADCAnCTL2 register. This

register makes it possible to check which A/D conversion results are outside the specified range.

For details, see 25.3.12 “Result check functions” on page 1550 .

Access This register can be read in 32-bit units.

Address <ADCA_n_base_USER> + 24_H

Initial value 0000 0000_H. This register is initialized by any reset.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 25-31 ADCA_nSTR0 Register Contents

Bit Position	Bit Name	Description
23 to 0	ADCA _n RCE[23:00]	<p>These bits indicate whether the A/D conversion results are within the specified value range.</p> <p>0: The conversion results are within the specified range.</p> <p>1: At least one conversion result is out of the specified range.</p> <p>This error flag is cleared by setting ADCA_nSTC0.ADCA_nRCEC_m.</p> <p>Note Clear bits corresponding to channels that are not provided by this microcontroller.</p>

Note The value of ADCA_nSTR0.ADCA_nRCEC_m is applied to the following A/D conversion result error flag:

- The error flag in the register that has the latest A/D conversion result of channel m (ADCA_nC_mCR.ADCA_nC_mER0)

(5) ADCAnSTC0 - ADCAnSTR0 flag clear register

This register clears ADCAnSTR0.

Access This register can be written in 32-bit units. When this register is read, 0000 0000_H is always returned.

Address <ADCAn_base_USER> + 30_H

Initial value 0000 0000_H. This register is initialized by any reset.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

25.4.7 Diagnostic function control registers (product dependent)

(1) ADCAnDGCTL0 – Self-diagnosis function control register 0

This register specifies the reference voltages to apply in order to diagnose the A/D conversion circuit.

This register can be written to even when ADCAnCTL0.ADCAnCE is set to 1.

Access This register can be read or written in 16-bit units.

Address <ADCAn_base_USER> + DC_H

Initial value 0000_H. This register is initialized by any reset.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	0	0	0	0	0	0	0	0	ADCAnPSEL[2:0]		
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

For details, see (1) "A/D conversion circuit diagnosis" on page 1553.

(2) ADCAnDGCTL1 – Self-diagnosis function control register 1

This register specifies the channels to which an internal reference voltage is applied (instead of the analog input signal ADCAnIm).

This register can only be written to when ADCAnCTL0.ADCAnCE is cleared to 0.

Access This register can be read or written in 32-bit units.

Address <ADCAn_base_OS> + 11C_H

Initial value 0000 0000_H. This register is initialized by any reset.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

(3) ADCAnPDCTL0 – Pull-down resistor control register 0

This register specifies the channels to which the ADCAnIm pin-internal pull-down resistor is connected. For details, see (3) “Open pin diagnosis” on page 1556.

This register can only be written to when ADCAnCTL0.ADCAnCE is cleared to 0.

Access This register can be read or written in 32-bit units.

Address <ADCAn_base_OS> + 120_H

Initial value 0000 0000_H. This register is initialized by any reset.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

25.4.8 Channel sample & hold function setup register (product dependent)

(1) ADCAnSHCTL – A/D converter channel sample & hold control register

This register controls whether power is supplied to the channel sample & hold circuit, as well as whether the circuit is enabled or disabled.

It can only be written when the A/D converter is disabled (by clearing ADCAnCTL0.ADCAnCE).

However, when performing channel sample & hold circuit diagnosis, the register can be written even when ADCAnCTL0.ADCAnCE is set to 1.

Access This register can be read or written in 32-bit units.

Address <ADCAn_base_OS> + 118_H

Initial value 0000 0000_H. This register is initialized by any reset.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

12 to 00	ADCAn CSEL[12:00]	<p>These bits enable or disable the channel sample & hold function.</p> <p>0: Disable the channel sample & hold function. 1: Enable the channel sample & hold function.</p> <p>When performing channel sample & hold circuit diagnosis, ADCAnSHCTL.ADCAnCSELx can be changed even if ADCAnCE = 1.</p> <p>Note Clear bits corresponding to channels that are not provided by this microcontroller.</p>

25.5 Precautions on Usage

25.5.1 Channel input voltage range

Caution Use input voltages to ADCAnIm that are within the range of the ratings. If a voltage higher than AV_{DD} or lower than AV_{SS} is input to a channel, the conversion value of the channel is saturated, and the electrical characteristics of the other channels may also be affected.

25.5.2 Stopping conversion operation

If "0" is written in ADCAnCTL0.ADCAnCE during conversion, the conversion stops and no conversion result is stored into ADCAnCmCR.

25.5.3 Restrictions when using the channel S/H function

For details, see (2) "Restrictions when using the channel sample & hold function" on page 1566.

25.5.4 Notes on application design

(1) Analog input pin (ADCAnIm)

1. Be sure to input a voltage within the rated range to the ADCAnIm pin. It is recommended to clamp this pin using a diode with a V_F of 0.3 V (target) or less to prevent a voltage higher than AV_{REFPn} or lower than AV_{REFMn} from being applied to the pin. If a voltage higher than AV_{REFPn} or a voltage lower than AV_{REFMn} is input to ADCAnIm, the conversion value of that channel becomes undefined and is not guaranteed. In addition, the conversion value of other channels may be also affected.
2. To eliminate noise, connect a resistor R_e between the ADCAnIm pin and the external analog signal input source, and a capacitor C_e between the ADCAnIm pin and AV_{SSn} pin.
3. Do not cross an analog signal line with a digital signal line or place an analog signal line in the vicinity of a digital signal line as this may degrade the A/D conversion characteristics due to noise induction.
4. It is recommended to avoid inputting and outputting a high driving current to or from a port close to the ADCAnIm pin and switching it by toggling.

(2) Wiring of power supply

To minimize the influence of switching noise of a digital circuit on the accuracy of the A/D converter, it is recommended to take the following measures.

1. Route the power line on a single side, or use as thick a pattern as possible and connect the power line in grid.

2. Insert a bypass capacitor close to the lead between a power supply pin (EV_{DD}, OSCV_{DD}, FV_{DD}, PLLV_{DD} (product dependent), CPUPLL_{DD} (product dependent), FRPLL_{DD} (some products only, product dependent), CV_{DD} (product dependent), V_{DDM} (product dependent), V_{DDC} (product dependent), AV_{DDn}) and a ground pin (EV_{SS}, OSCV_{SS}, FV_{SS}, PLLV_{SS} (product dependent), CPUPLL_{SS} (product dependent), FRPLL_{SS} (some products only, product dependent), CV_{SS} (product dependent), V_{SSM} (product dependent), V_{SSC} (product dependent), AV_{SSn}). A laminated ceramic capacitor of approx. 0.1 F (target) or a tantalum electrolytic capacitor of 4.7 F (target) or higher is recommended for use as this bypass capacitor.
3. It is recommended to separate the analog power line (AV_{DDn}) from the digital power lines (EV_{DD}, OSCV_{DD}, FV_{DD}, PLLV_{DD} (product dependent), CPUPLL_{DD} (product dependent), FRPLL_{DD} (some products only, product dependent), CV_{DD} (product dependent), V_{DDM} (product dependent), V_{DDC} (product dependent)) and to supply analog power from a series regulator. To share the analog power line with the digital power lines, short-circuit the analog power supply and digital power supply at one point with an electrolytic capacitor at the power source, and separately wire the patterns on the board.

In addition, insertion of a chip inductor at the inlet of the analog power is recommended. It is also recommended to ground the analog ground and digital ground at the ground source at one point with an electrolytic capacitor, and separate the wiring of the patterns on the board.

(3) Analog reference voltage input pins (AV_{REFPn}, AV_{REFMn})

Insert a bypass capacitor close to the pin lead between the AV_{REFPn} pin and AV_{REFMn} pin. A laminated ceramic capacitor of approx. 0.1 μF (target) or a tantalum electrolytic capacitor of 4.7 μF (target) or higher is recommended for use as this bypass capacitor.

(4) Variation of A/D conversion result

The result of A/D conversion may vary due to fluctuations in the supply voltage and noise. Noise at an analog input pin (ADCAn_m) or reference voltage input pin (AV_{REFPn}, AV_{REFMn}) may cause an invalid conversion result.

Mitigate these variations by software processing to protect the system from adverse influences due to these variations and illegal conversion results.

The following are examples of software processing.

- Use the average value of the results of multiple A/D conversions as the A/D conversion result.
- Perform multiple consecutive A/D conversions and use the conversion results, with the exception of any abnormal conversion results that are obtained.
- If an A/D conversion result is obtained, from which it is judged that an abnormality has occurred in the system, do not perform abnormality processing at once but perform it upon reconfirming the occurrence of an abnormality.

(5) Hysteresis characteristics of A/D conversion

The successive approximation A/D converter holds the analog input voltage on a capacitor for the internal common sample & hold, and then executes A/D conversion. Even after A/D conversion has been completed, the analog input voltage remains on the capacitor for the internal common sample & hold. Consequently, the following phenomena may occur.

1. If the voltage rises above or falls below the voltage for the A/D conversion immediately before when A/D conversion is to be executed with a single channel, hysteresis characteristics, in which the conversion result is affected by the value immediately before, may emerge, and the conversion results may differ even at the same voltage. The hysteresis characteristics tend to increase if the signal source impedance or resistor R_e of the external circuit of the analog input pin is high, or if the value of capacitor C_e is small.
2. When the analog input channel is changed, hysteresis characteristics, in which the conversion result is affected by the value of the channel immediately before, may emerge, and the conversion results may differ even at the same voltage, because A/D conversion is performed by using one A/D converter.

To obtain a more accurate conversion result, therefore, perform A/D conversion of the same channel two times in a row, and discard the first A/D conversion result.

25.6 How to Read A/D Converter Characteristics Table

This section describes the terms related to the A/D converter.

(1) Resolution

The minimum analog input voltage that can be identified, i.e. the ratio of the analog input voltage to 1 digital output is called 1 LSB (Least Significant Bit). The ratio of 1 LSB to the full scale is expressed as %FSR (full-scale range). %FSR is the ratio, in percentage, of the range in which an analog input voltage can be converted, and is expressed as follows regardless of the resolution.

$$\begin{aligned} 1\%FSR &= (\text{Maximum value of convertible analog input voltage} - \text{Minimum value of convertible analog input voltage})/100 \\ &= (AV_{REFP} - AV_{REFM})/100 \end{aligned}$$

1 LSB is as follows at a resolution of 10 bits:

$$\begin{aligned} 1 \text{ LSB} &= 1/2^{10} \\ &= 1/1024 \\ &= 0.098 \%FSR \end{aligned}$$

1 LSB is as follows at a resolution of 12 bits:

$$\begin{aligned} 1 \text{ LSB} &= 1/2^{12} \\ &= 1/4096 \\ &= 0.024 \%FSR \end{aligned}$$

The accuracy is determined by the total error, regardless of the resolution.

(2) Total error

This is the maximum value of the difference between the actually measured value and the theoretical value.

It is the total of the zero-scale error, full-scale error, linearity error, and a combination of these errors.

The total error shown in the characteristics table does not include the quantization error.

Figure 25-22 Total Error

(3) Quantization error

This is the error of $\pm 1/2$ LSB that always occurs when an analog value is converted into a digital value. Because the A/D converter converts an analog input voltage in a range of $\pm 1/2$ LSB into the same digital code, the quantization error is unavoidable.

Note that this error is not included in the total error, zero-scale error, full-scale error, integral linearity error, and differential linearity error in the characteristics table.

Figure 25-23 Quantization Error

(4) Zero-scale error

This is the difference between the actually measured value of the analog input voltage and the theoretical value (1/2 LSB) when the digital output changes from 0...000 to 0...001.

Figure 25-24 Zero-Scale Error

(5) Full-scale error

This is the difference between the actually measured value of the analog input voltage and the theoretical value (full scale – 3/2 LSB) when the digital output changes from 1...110 to 1...111.

Figure 25-25 Full-Scale Error

(6) Differential linearity error

Ideally, the width at which a specific code is output is 1 LSB. The differential linearity error is the difference between the actually measured value of the width at which a specific code is output and the ideal value.

Figure 25-26 Differential Linearity Error

(7) Integral linearity error

This error indicates the extent to which the conversion characteristics differ from the ideal linear relationship. It indicates the maximum value of the difference between the actually measured value and its theoretical value where the zero-scale error and full-scale error are 0.

Figure 25-27 Integral Linearity Error

(8) Conversion time

This is the time from when an analog voltage is input until digital output is produced.

The conversion time in the characteristics table includes sampling time.

(9) Sampling time

This is the time during which the analog switch is on to input the analog voltage to the sample & hold circuit.

(10) A/D start time

This is the time from the A/D conversion trigger to the start of A/D conversion.

Chapter 26 H-Bus-Shared Memory

26.1 Features

- 64 KB
- Bank configuration (32 KB x 2)
- The memory can be accessed from both the internal system bus and H bus.
- The memory can be read or written in 8, 16, or 32-bit units.

26.2 Configuration

The H-bus-shared memory is RAM that can be accessed from both the internal system bus and H bus. This memory can be read or written in 8, 16, or 32-bit units. The memory uses a bank configuration (32 KB x 2), and the bus master of the internal system bus and bus master of the H bus can access the different banks at the same time. Note that arbitration is performed if there is a conflict when trying to access the same bank.

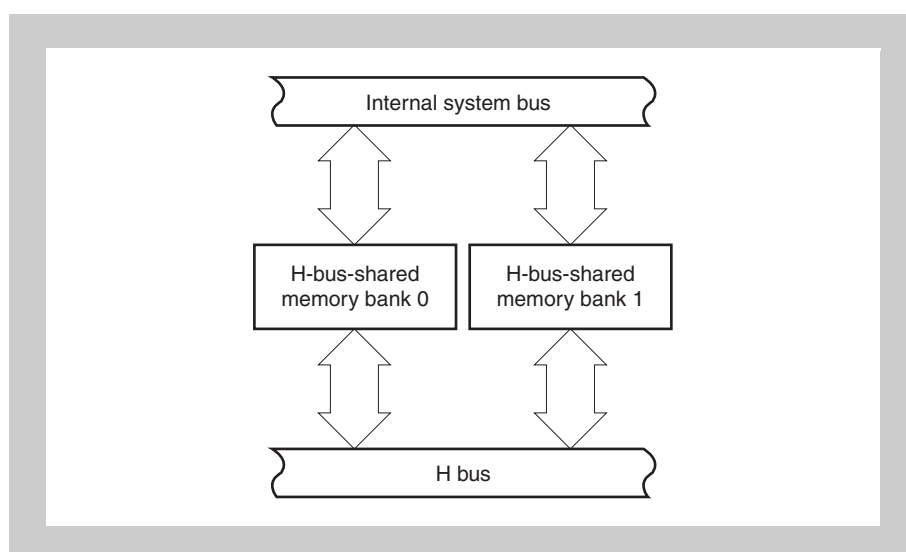

Figure 26-1 H-Bus-Shared Memory

The address spaces for each bank are shown below.

Table 26-1 H-Bus-Shared Memory

Bank	Size	Address
Bank 0	32 KB	F9800000 _H to F9807FFF _H
Bank 1	32 KB	F9808000 _H to F980FFFF _H

26.3 Operation

26.3.1 Parallel operation

The H-bus-shared memory is RAM that can be accessed from both the internal system bus and H bus. The memory uses a bank configuration (32 KB x 2), and the bus master of the internal system bus and bus master of the H bus can access the different banks at the same time.

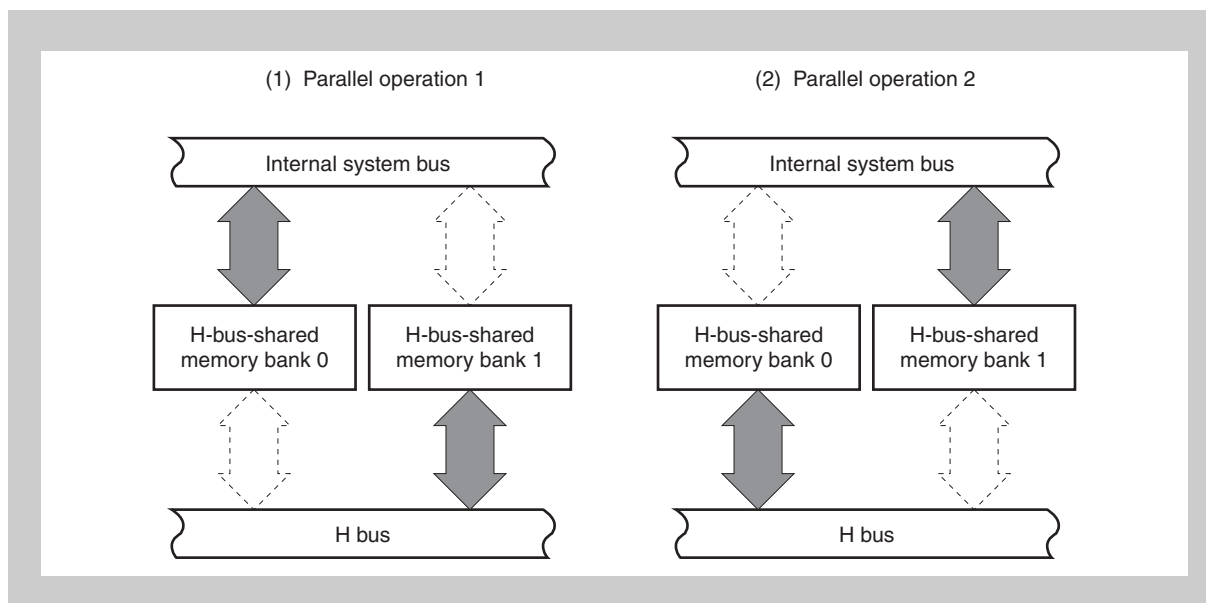

Figure 26-2 Parallel Operation Example

26.3.2 Arbitration

If there is a conflict when the bus master of the internal system bus and bus master of the H bus both attempt to access the same memory bank, round-robin access arbitration is performed to report only one of the access requests.

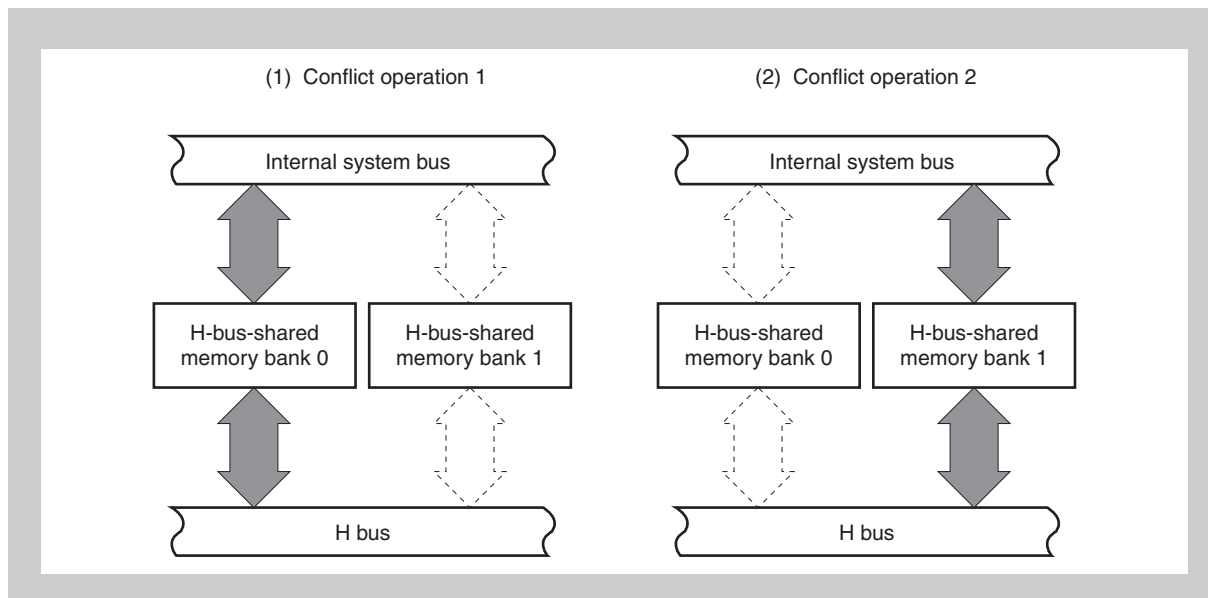

Figure 26-3 Conflict Operation Example

Chapter 27 USB Function Controller (USBF)

This microcontroller has an internal USB function controller (USBF) conforming to the Universal Serial Bus Specification. Data communication using the polling method is performed between the USB function controller and external host device by using a token-based protocol.

Caution Use the following procedure to read the USB Function controller registers.

- When connecting an external clock to the USBCLK pin

- (1) Set the EPC_RST bit of the EPC macro control register (USFA0EPCCTL) to 0 to cancel the reset.
- (2) Read the required USB function controller registers.

- When an external clock is not to be connected to the USBCLK pin

[1] When supplying an external clock is specified in the SFRCTL3 register (When the USBDIV1 and USBDIV0 bits of SFRCTL3 are 00b)

- (1) Set the USBDIV1 and USBDIV0 bits of the SFRCTL3 register to 11b to specify an internal clock of fxx/4.
- (2) Set the EPC_RST bit of the EPC macro control register (USFA0EPCCTL) to 0 to cancel the reset.
- (3) Read the required USB function controller registers.

[2] When supplying an internal clock is specified in the SFRCTL3 register (When the USBDIV1 and USBDIV0 bits of SFRCTL3 are 10b or 11b)

- (1) Set the EPC_RST bit of the EPC macro control register (USFA0EPCCTL) to 0 to cancel the reset.
 - (2) Read the required USB function controller registers.
-

27.1 V850E2/ML4 USBF Features

Register addresses All USBF register addresses are given as addresses offset from the base address <USBF_base>. Each <USBF_base> address of USBF is shown in the following table:

Table 27-1 Register base addresses <USBF_base>

USBF function	<USBF_base> address
EPC control registers	F993 1000 _H
EPC data hold registers	F993 1000 _H
EPC request data registers	F993 1000 _H
Bridge registers	F993 1000 _H

Clock supply The following clocks can be input to USBF:

Table 27-2 USBF clock supply

USBF clock (f_{USB})	
Internal	{7.2 MHz external clock × internal clock multiplied by 20}/3 = 48 MHz internal clock
External	External clock input from the UCLK pin ($f_{\text{USB}} = 48$ MHz)

Interrupts USBF can generate the following interrupt requests.

Table 27-3 USBF interrupt requests

USBF signal	Function	Connected to:
INTUSFA0I0	Bridge interrupt	• Interrupt controller 187 (INTUSFA0I0)
INTUSFA0I1	EPC interrupt	• Interrupt controller 188 (INTUSFA0I1)
INTUSFA0I2	USB Resume detection	• Interrupt controller 189 (INTUSFA0I2)

I/O signals The USBF I/O signals are shown in the following table.

Table 27-4 USBF I/O signals

USBF signal	Function	Connected to:
UDMF	USBF data I/O (-)	UDMF pin
UDPF	USBF data I/O (+)	UDPF pin

27.1.1 V850E2/ML4 USBF control register

Before using the USB function controller, set up the register below.

(1) USBF buffer control register (USFBC)

This register controls whether to enable or disable the input buffer for the USB function controller and whether to enable or disable the floating countermeasure.

Access This registers can be read or written in 32-bit units.

Address F990 1004_H

Initial value 0000 0000_H. This register is initialized by any reset.

	31	30	29	28	27	26	25	24
USFBC	0	0	0	0	0	0	0	0
	R	R	R	R	R	R	R	R
	23	22	21	20	19	18	17	16
	0	0	0	0	0	0	0	0
	R	R	R	R	R	R	R	R
	15	14	13	12	11	10	9	8
	0	0	0	0	0	0	0	0
	R	R	R	R	R	R	R	R
	7	6	5	4	3	2	1	0
	0	0	0	0	0	0	UBFIEN	UBFIOR
	R	R	R	R	R	R	R/W	R/W

Table 27-5 USFBC register contents

Bit position	Bit name	Function
1	UBFIEN	This bit controls whether to use the USB buffer. 0: Disable the buffer. 1: Enable the buffer. Caution: If not using USBF, be sure to clear the UBFIEN bit (to 0).
0	UBFIOR	This bit controls whether to use the floating countermeasure for the USB buffer. 0: Disable the floating countermeasure. 1: Enable the floating countermeasure. When the cable is not connected (when the data input is floating), this countermeasure prevents the incorrect recognition of Bus Reset, Suspend, Resume, and other signals due to undefined values. If this bit is set, control the floating countermeasure by using a VBUS or other signal to recognize the cable connection.

27.2 Overview

- Conforms to the Universal Serial Bus Specification
- Supports 12 Mbps (full-speed) transfers
- Endpoint for transfer incorporated

Endpoint name	FIFO size (bytes)	Transfer type	Remark
Endpoint0 Read	64	Control transfer	–
Endpoint0 Write	64	Control transfer	–
Endpoint1	64 × 2	Bulk 1 transfer (IN)	Two-buffer configuration
Endpoint2	64 × 2	Bulk 1 transfer (OUT)	Two-buffer configuration
Endpoint3	64 × 2	Bulk 2 transfer (IN)	Two-buffer configuration
Endpoint4	64 × 2	Bulk 2 transfer (OUT)	Two-buffer configuration
Endpoint7	64	Interrupt transfer	–
Endpoint8	64	Interrupt transfer	–

- A bulk transfer (IN/OUT) can be executed as a DMA transfer (2-cycle single-transfer mode).

Caution The registers in the USB function controller register list (in 27.7.1 “USB function controller registers” on page 1633) must be accessed after specifying that the internal clock or the external clock is to be used as the USB clock and enabling clock supply to the USB function controller.

27.3 Configuration

27.3.1 Block diagram

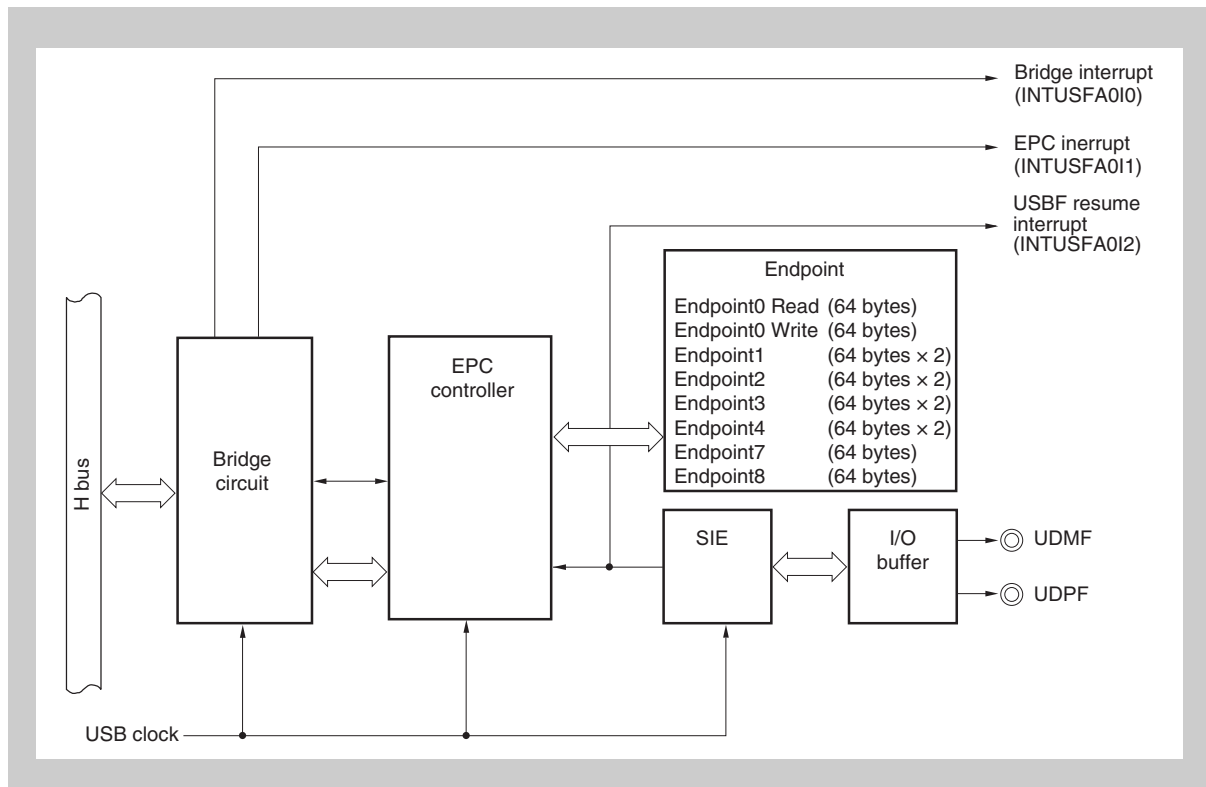

Figure 27-1 Block diagram for USB function controller

27.4 External Circuit Configuration

27.4.1 Overview

For USB transmission, when communication is performed with the host controller and function controller facing each other, pull-up/pull-down resistors must be connected to the USB signal (D+/D-) to identify the communication partner. For this microcontroller, series resistors must also be connected.

Because this microcontroller does not include these pull-up/pull-down resistors and series resistors, be sure to connect them externally.

The following shows the schematic configuration of the USB transmission line. For details about the external configuration, see the description provided in each section.

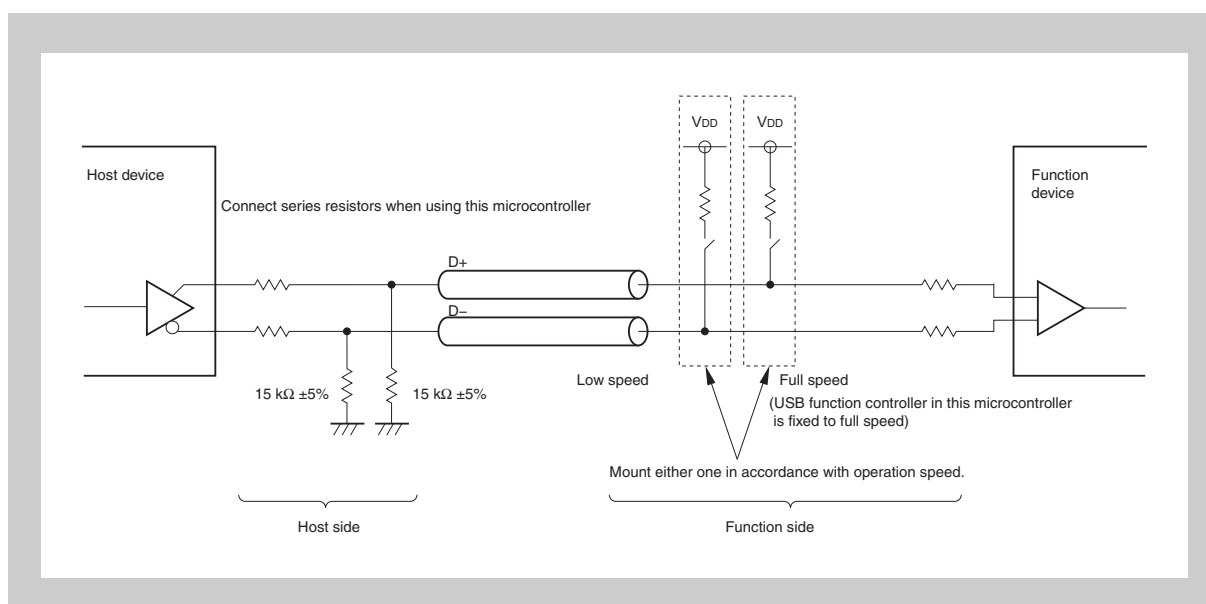

Figure 27-2 Schematic configuration of pull-up, pull-down, and series resistors in USB transmission line

27.4.2 Connection configuration

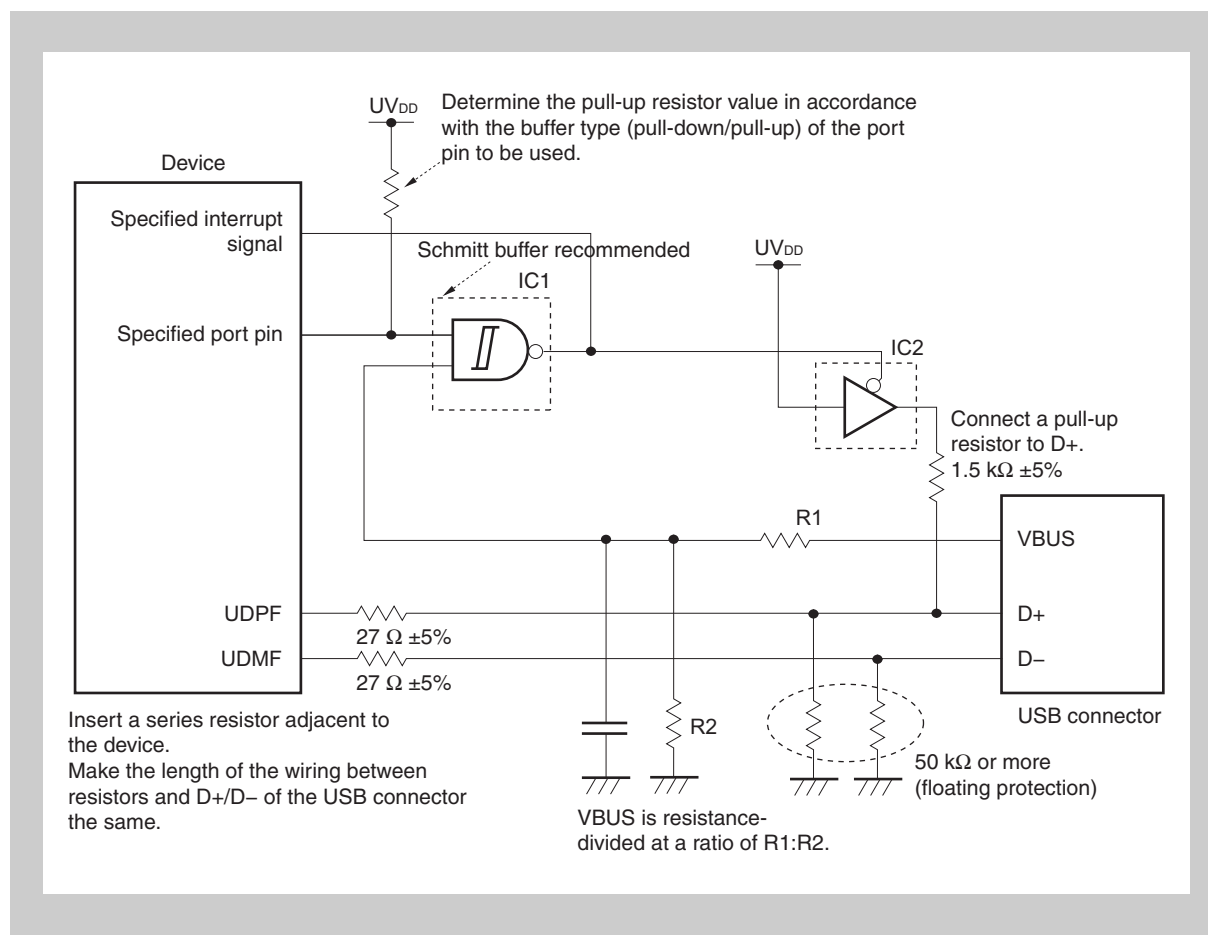

Figure 27-3 Example of USB function controller connections

(1) Series resistor connection to D+/D-

Connect series resistors of 27 Ω \pm 5% to the D+/D- pins (UDPF, UDMF) of the USB function controller in this microcontroller. If they are not connected, the impedance rating cannot be satisfied and the output waveform might be disturbed.

Place the series resistors adjacent to the microcontroller, and make the length of the wiring between the series resistors and the USB connectors the same, to make the impedance of D+ and D- equal. (A differential with 90 Ω \pm 5% is recommended.)

(2) Pull-up control of D+

Because the function controller of this microcontroller is fixed to full speed (FS), be sure to pull up the D+ pin (UFDP) by $1.5\text{ k}\Omega \pm 5\%$ to UV_{DD} .

To disable a connection report (D+ pull up) to the USB host controller/HUB (such as during high priority servicing or initialization), control the pull-up resistor of D+ via a general-purpose port in the system. For a circuit such as the one shown in *Figure 27-3 "Example of USB function controller connections"*, control the pull-up control signal and the VBUS input signal of the D+ pin by using a general-purpose port and the USB cable VBUS (AND circuit). In *Figure 27-3 "Example of USB function controller connections"*, if the general-purpose port is low level, pulling up D+ is prohibited. For the IC2 in *Figure 27-3 "Example of USB function controller connections"*, use an IC to which voltage can be applied when the system power is off.

(3) Detection of USB cable connection/disconnection

The USB function controller (USBF) requires a VBUS input signal to recognize whether the USB cable is connected or disconnected, because the state of the USBF is controlled by hardware. The voltage (5 V) from the USB host controller or HUB is applied as the VBUS input signal when the USB cable VBUS is connected to the USB host controller or HUB while the USBF power is off. For the IC2 in *Figure 27-3 "Example of USB function controller connections"*, use an IC to which voltage can be applied when the system power is off. When disconnecting the USB cable in the circuit in *Figure 27-3 "Example of USB function controller connections"*, the input signal to a specified interrupt might be unstable while the VBUS voltage is dropping. It is therefore recommended to use a Schmitt buffer for IC1 in *Figure 27-3 "Example of USB function controller connections"*.

(4) Floating protection during initialization or when USBF is unused

When the USB function controller is initialized or unused, to avoid a floating status, pull the D+/D- pins (UFDP, UFDN) down using a resistor of $50\text{ k}\Omega$ or higher.

27.5 Cautions

<R>

(1) Clock accuracy

When using the internal clock, use a resonator that satisfies the following accuracy:

When the system operates at 192 MHz: 9.6 MHz±500 ppm

When the system operates at 144 MHz: 7.2 MHz±100 ppm

Supply an external clock with an accuracy of 48 MHz±500 ppm or less to the UCLK pin. If the accuracy of the USB clock decreases, the transmitted data can no longer satisfy the USB Specification.

(2) Stopping the USB clock

The USB clock must be stopped when stopping the USB function controller. Stop the USB function controller, and then stop the clock supply (by clearing SFRCTL3.USBCKE2 to 0).

If the USB clock (f_{USB}) is stopped without stopping the USB function controller, malfunctions might occur due to clock noise (spike) when the clock is supplied again.

27.6 Requests

The USB standard has a request command that reports requests from the host device to the function device to execute response processing.

The requests are received in the SETUP stage of control transfer, and most can be automatically processed via the hardware of the USB function controller (USBF).

27.6.1 Automatic requests

(1) Decode

Table 27-6 “Request format” shows the request format and Table 27-7 “Correspondence between requests and decoded values” shows the correspondence between requests and decoded values.

Table 27-6 Request format

Offset	Field name	
0	bmRequestType	
1	bRequest	
2	wValue	Lower side
3		Higher side
4	wIndex	Lower side
5		Higher side
6	wLength	Lower side
7		Higher side

Table 27-7 Correspondence between requests and decoded values

Request	Offset	Decoded value							Response			Data stage

SET_ADDRESS	00 _H	05 _H	XX _H	XX _H	00 _H	00 _H	00 _H	00 _H	ACK NAK	ACK NAK	ACK NAK	–

- a) If the wLength value is less than the prepared value, the value up to wLength is returned. If the wLength value is the prepared value or greater, the value up to the prepared one is returned.
- b) The CLEAR_FEATURE request clears the device status register (USFA0DST) and EPn status register (USFA0EnS) (n = 0 to 4, 7) when ACK is received in the status stage.
- c) The SET_FEATURE request sets the device status register (USFA0DST) and EPn status register (USFA0EnS) (n = 0 to 4, 7) when ACK is received in the status stage.
If the E0HALT bit of the USFA0E0S register is set, a STALL response is returned in the status stage or data stage during control transfer for a request other than the GET_STATUS Endpoint0 request, SET_FEATURE Endpoint0 request, and a request generated by the CPUDEC interrupt request, until the CLEAR_FEATURE Endpoint0 request is received. A STALL response to an unsupported request does not set the E0HALT bit of the USFA0E0S register to 1, and the STALL response is cleared when the next SETUP token is received.
- d) A STALL response is automatically returned if the wValue value is not the value above.

-
- Notes**
1. The sequence of control transfer defined by the Universal Serial Bus Specification is not satisfied under the conditions below. The operation is not guaranteed under these conditions.
 - If an IN/OUT token is suddenly received without a SETUP stage
 - If DATA PID1 is sent in the data phase of the SETUP stage
 - If a token of 128 addresses or more is received
 - If the request data transmitted in the SETUP stage is of less than 8 bytes
 2. In the status stage, an ACK response is returned even when the host transmits data other than a Null packet.
 3. If the wLength value is 00_H during a control transfer (read) of FW processing, a Null packet is automatically transmitted for a control transfer (without data). No Null packet will be automatically transmitted for FW requests.
-

- Notes**
1. Df: Default state, Ad: Addressed state, Cf: Configured state
 2. ✓: Data stage
-: No data stage
 3. n = 0 to 4
For a request with interface number 1 to 4, whether the correct response or a STALL response is returned depends on the validity of the corresponding interface number specified by the active interface number register (USFA0AIFN).
 4. \$\$: Valid endpoint number including the transfer direction
Whether the target Endpoint is valid is determined by the currently specified Alternative Setting number. (For details, see (36) "Active alternative setting register (USFA0AAS)" on page 1693 and (38) "Endpoint1 interface mapping register (USFA0E1IM)" on page 1695 through (42) "Endpoint7 interface mapping register (USFA0E7IM)" on page 1699 in 27.7.2 "EPC control registers".)
 5. ? and #: Value transmitted from host (information on interface numbers 0 to 4)
For an alternate setting request corresponding to an interface number, whether the correct response or a STALL response is returned depends on the interface number and the validity of the alternate setting, which are specified by the active interface number register (USFA0AIFN) and active alternative setting register (USFA0AAS), respectively.

(2) Processing

The processing of an automatic request in the Default state, Addressed state, and Configured state is described below.

Note Default state: State in which an operation is performed with the Default address

Addressed state: State after an address has been allocated

Configured state: State after SET_CONFIGURATION wValue = 1 has been correctly received

(a) CLEAR_FEATURE() request

For the CLEAR_FEATURE() request, a STALL response is returned in the status stage if clearing has failed, the specified feature does not exist, or the request is for an interface or nonexistent endpoint. A STALL response is also returned if the wLength value is not 0.

- Default state:

When the CLEAR_FEATURE() request is received, the correct response is returned only if the request is for a device or Endpoint0. A STALL response is returned in the status stage in all other cases.

- Addressed state:

When the CLEAR_FEATURE() request is received, the correct response is returned only if the request is for a device or Endpoint0. A STALL response is returned in the status stage in all other cases.

- Configured state:

When the CLEAR_FEATURE() request is received, the correct response is returned only if the request is for a device or existent endpoint. A STALL response is returned in the status stage in all other cases.

When the CLEAR_FEATURE() request is correctly processed, the corresponding bit of the CLR request register (USFA0CLR) is set to 1, the EnHALT bit of the EPn status register (USFA0EnS) is cleared to 0, and an interrupt is issued (n = 0 to 4, 7, 8). If the CLEAR_FEATURE() request is received when the subject is an endpoint, the toggle bit (that controls switching between DATA0 and DATA1) of the corresponding endpoint is always re-set to DATA0.

(b) GET_CONFIGURATION() request

A STALL response is returned in the data stage if wValue, wIndex, or wLength is not the value shown in *Table 27-7?Correspondence between requests and decoded values?.*

- Default state:

The value stored in the configuration register (USFA0CNF) is returned when the GET_CONFIGURATION() request is received.

- Addressed state:

The value stored in the USFA0CNF register is returned when the GET_CONFIGURATION() request is received.

- Configured state:

The value stored in the USFA0CNF register is returned when the GET_CONFIGURATION() request is received.

(c) GET_DESCRIPTOR() request

If the subject descriptor has a length that is a multiple of wMaxPacketSize, a Null packet is returned to indicate the end of the data stage. If the length of the descriptor at this time is less than the wLength value, the entire descriptor is returned. If the length of the descriptor is the wLength value or greater, the descriptor up to the wLength value is returned.

- Default state:

The values stored in the device descriptor register n (USFA0DDn) and configuration/interface/endpoint descriptor register m (USFA0CIEm) are returned (n = 0 to 17, m = 0 to 255) when the GET_DESCRIPTOR() request is received.

- Addressed state:

The values stored in the USFA0DDn register and USFA0CIEm register are returned when the GET_DESCRIPTOR() request is received.

- Configured state:

The values stored in the USFA0DDn register and USFA0CIEm register are returned when the GET_DESCRIPTOR() request is received.

A descriptor of up to 256 bytes can be stored in the USFA0CIEm register. To transmit a descriptor of more than 256 bytes, set the CDCGDST bit of the USFA0MODC register and process the GET_DESCRIPTOR() request using FW.

Store the value of (the total number of bytes of the descriptor specified by the USFA0CIEm register 1) in the descriptor length register (USFA0DSCL). The transfer data is controlled by the value of this data + 1 and wLength.

(d) GET_INTERFACE() request

If wValue or wLength is not the value shown in *Table 27-7 “Correspondence between requests and decoded values”*, or if wIndex is not the value specified by the active interface number register (USFA0AIFN), a STALL response is returned in the data stage.

- Default state:

A STALL response is returned in the data stage when the GET_INTERFACE() request is received.

- Addressed state:

A STALL response is returned in the data stage when the GET_INTERFACE() request is received.

- Configured state:

The value stored in the interface n register (USFA0IFn, n = 0 to 4) corresponding to the wIndex value is returned when the GET_INTERFACE() request is received.

(e) GET_STATUS() request

A STALL response is returned in the data stage if wValue, wIndex, or wLength is not the value shown in *Table 27-7 “Correspondence between requests and decoded values”*. A STALL response is also returned in the data stage if the request is for an interface or nonexistent endpoint.

- Default state:

When the GET_STATUS() request is received, the value stored in the target status register^a is returned only if the request is for a device or Endpoint0. A STALL response is returned in the data stage in all other cases.

- Addressed state:

When the GET_STATUS() request is received, the value stored in the target status register^a is returned only if the request is for a device or Endpoint0. A STALL response is returned in the data stage in all other cases.

- Configured state:

When the GET_STATUS() request is received, the value stored in the target status register^a is returned only if the request is for a device or existent endpoint. A STALL response is returned in the data stage in all other cases.

a) The target status register is as follows.

- If the target is a device: Device status register (USFA0DST)
- If the target is Endpoint 0: EP0 status register (USFA0E0S)
- If the target is Endpoint n: EPn status register (USFA0EnS)
(n = 1 to 4, 7, 8)

(f) SET_ADDRESS() request

A STALL response is returned in the status stage if *wIndex* or *wLength* is not the value shown in *Table 27-7 "Correspondence between requests and decoded values"*. A STALL response is returned if the specified device address is greater than 127.

- Default state:

If the specified address is not 0 when the SET_ADDRESS() request is received, the device enters the Addressed state and the USB Address value to input to SIE is changed to a specified address value. If the specified address is 0, the device remains in the Default state.

- Addressed state:

If the specified address is 0 when the SET_ADDRESS() request is received, the device enters the Default state and the USB Address value to input to SIE is returned to the default address. If the specified address is not 0, the device remains in the Addressed state, and the USB Address value to input to SIE is changed to a specified new address value.

- Configured state:

The device remains in the Configured state and returns the USB Address value to be input to SIE to the default address if the specified address is 0 when the SET_ADDRESS() request has been received. In this case, the endpoints other than endpoint 0 remain valid, and control transfers (IN or OUT), bulk transfers, and interrupt transfers for an endpoint other than endpoint 0 are also acknowledged. If the specified address is not 0, the device remains in the Configured state and changes the USB Address value to be input to SIE to a specified new address value.

(g) SET_CONFIGURATION() request

A STALL response is made in the data stage if wValue, wIndex, or wLength is not the value shown in *Table 27-7 “Correspondence between requests and decoded values”*.

- Default state:

The CONF bit of the mode status register (USFA0MODS) and the configuration register (USFA0CNF) are set to 1 if the specified configuration value is 1 when the SET_CONFIGURATION() request has been received. If the specified configuration value is 0, the CONF bit of the USFA0MODS register and USFA0CNF register are cleared to 0. In other words, the device skips the Addressed state and moves to the Configured state in which it responds to the Default address.

- Addressed state:

The CONF bit of the USFA0MODS register and USFA0CNF register are set to 1 and the device enters the Configured state if the specified configuration value is 1 when the SET_CONFIGURATION() request has been received. If the specified configuration value is 0, the device remains in the Addressed state.

- Configured state:

The CONF bit of the USFA0MODS register and USFA0CNF register are set to 1 and the device returns to the Addressed state if the specified configuration value is 0 when the SET_CONFIGURATION() request has been received. If the specified configuration value is 1, the device remains in the Configured state.

If the SET_CONFIGURATION() request has been correctly processed, the target bit of the SET request register (USFA0SET) is set to 1, and an interrupt is issued. All Halt Features are cleared after the SET_CONFIGURATION() request has been completed even if the specified configuration value is the same as the current configuration value. If the SET_CONFIGURATION() request has been correctly processed, the data toggle of all endpoints is always initialized to DATA0 again (it is defined that the default status, Alternative Setting 0, is set from when the SET_CONFIGURATION request is received to when the SET_INTERFACE request is received).

(h) SET_FEATURE() request

A STALL response is returned in the status stage if setting has failed, the specified feature does not exist, or the request is for an interface or nonexistent endpoint. A STALL response is also returned if the wLength value is not 0.

- Default state:

When the SET_FEATURE() request is received, the correct response is returned only if the request is for a device or Endpoint0. A STALL response is returned in the status stage in all other cases.

- Addressed state:

When the SET_FEATURE() request is received, the correct response is returned only if the request is for a device or Endpoint0. A STALL response is returned in the status stage in all other cases.

- Configured state:

When the SET_FEATURE() request is received, the correct response is returned only if the request is for a device or existent endpoint. A STALL response is returned in the status stage in all other cases.

When the SET_FEATURE() request is correctly processed, the corresponding bit of the SET request register (USFA0SET) and the EnHALT bit of the EPn status register (USFA0EnS) are set to 0, and an interrupt is issued (n = 0 to 4, 7, 8).

(i) SET_INTERFACE() request

If *wLength* is not the value shown in *Table 27-7?Correspondence between requests and decoded values?*, *wIndex* is not the value specified by the active interface number register (USFA0AIFN), or *wValue* is not the value specified by the active alternative setting register (USFA0AAS), a STALL response is returned in the status stage.

- Default state:

A STALL response is returned in the status stage when the SET_INTERFACE() request is received.

- Addressed state:

A STALL response is returned in the status stage when the SET_INTERFACE() request is received.

- Configured state:

A Null packet is transmitted in the status stage when the SET_INTERFACE() request is received.

When the SET_INTERFACE() request is correctly processed, an interrupt is issued. All the Halt Features of the endpoint linked to the target interface are cleared after the SET_INTERFACE() request has been cleared. The data toggle of all the endpoints related to the target interface number is always reinitialized to DATA0. When the currently selected Alternative Setting is to be changed by correctly processing the SET_INTERFACE() request, the FIFO of the endpoint that is affected is completely cleared, and all the related interrupt sources are also initialized.

When the SET_INTERFACE() request is completed, the FIFO of all the endpoints linked to the target interface are cleared. At the same time, Halt Feature and Data PID are initialized, and the related INT status *n* register (USFA0IS_n) is cleared to 0 (*n* = 0 to 4). (Only Halt Feature and Data PID are initialized when the SET_CONFIGURATION request is completed.)

If the target endpoint is not supported by the SET_INTERFACE() request during a DMA transfer, the DMA request signal is immediately deasserted, and the FIFO of the endpoint that was linked when the SET_INTERFACE() request was completed is completely cleared. As a result of clearing the FIFO, transferring data by way of DMA is not correctly processed.

27.6.2 Other requests

(1) Response and processing

The following table shows how other requests are responded to and processed.

Table 27-8 Response and processing of other requests

Request	Response and processing
GET_DESCRIPTOR String	Generation of CPUDEC interrupt request
GET_STATUS Interface	Automatic STALL response
CLEAR_FEATURE Interface	Automatic STALL response
SET_FEATURE Interface	Automatic STALL response
all SET_DESCRIPTOR	Generation of CPUDEC interrupt request
All other requests	Generation of CPUDEC interrupt request

27.7.2 EPC control registers

(1) EP0NAK register (USFA0E0N)

This register controls NAK of Endpoint0 (except an automatically executed request).

It takes five USB clocks to apply the status to this register after the USFA0FIC0 and USFA0FIC1 registers have been set. If it is necessary to read the status correctly, therefore, separate a write signal that accesses the USFA0FIC0 and USFA0FIC1 registers from a read signal that accesses the USFA0EPS0, USFA0EPS1, USFA0EPS2, USFA0E0N, and USFA0EN registers by at least four USB clocks.

While NAK is being transmitted to Endpoint0 Read, Endpoint2, and Endpoint4, a write access to the EP0NKR bit is ignored.

Access This register can be read or written in 8-bit units. (However, bit 0 can only be read.)

Address 000_H

Initial value 00_H. This register is initialized by any reset.

	7	6	5	4	3	2	1	0
USFA0E0N	0	0	0	0	0	0	EP0NKR	EP0NKR
	R	R	R	R	R	R	R/W	R

Table 27-9 USFA0E0N register contents

Bit position	Bit name	Function
1	EP0NKR	<p>This bit controls NAK to the OUT token to Endpoint0 (except an automatically executed request). It is automatically set to 1 by hardware when Endpoint0 correctly receives data. It is automatically cleared to 0 by hardware when the data of the USFA0E0R register is read by FW (counter value = 0).</p> <p>1: Transmit NAK. 0: Do not transmit NAK. (Default)</p> <p>To not receive data from the USB bus for some reason even if USBF is ready to receive data, set this bit to 1 using FW. In this case, USBF continues transmitting NAK until this bit is cleared to 0 by FW. This bit is cleared to 0 at the same time when the USFA0E0R register is cleared.</p>
0	EP0NKR	<p>This bit indicates how NAK to the IN token to Endpoint0 is controlled (except an automatically executed request). It is automatically cleared to 0 by hardware when the data of Endpoint0 is transmitted and the host correctly receives the transmitted data. The data of the USFA0E0W register is retained until this bit is cleared. Therefore, it is not necessary to rewrite this bit even in the case of a retransmission request that is made if the host could not receive data correctly. To send a short packet, be sure to set the E0DED bit of the USFA0DEND register to 1. This bit is automatically set to 1 when the FIFO is full. This bit is automatically set to 1 at the same time when the E0DED bit of the USFA0DEND register is set to 1.</p> <p>1: Do not transmit NAK. 0: Transmit NAK. (Default)</p> <p>If a control transfer enters the status stage while ACK cannot be correctly received in the data stage, this bit is cleared to 0 at the same time when the USFA0E0W register is cleared. This bit is also cleared to 0 when USFA0E0W is cleared by FW.</p>

The procedure for a SETUP transaction that uses IN/OUT tokens is described below.

(a) When an IN token is used (except a request automatically executed by hardware)

Use FW to clear the PROT bit of the USFA0IS1 register to 0 after receiving the CPUDEC interrupt and before reading data from the USFA0E0ST register.

Next, perform processing in accordance with the request and, if it is necessary to return data by using an IN token, write data to the USFA0E0W register. After data has been written completely, confirm that the PROT bit of the USFA0IS1 register is 0, and then set the E0DED bit of the USFA0DEND register to 1. The hardware sends out data at the first IN token after the EP0NKW bit has been set to 1. If the PROT bit of the USFA0IS1 register is 1, it indicates that a SETUP transaction occurred again before the completion of the control transfer. In this case, clear the PROT bit of the USFA0IS1 register to 0 by clearing the PROTC bit of the USFA0IC1 register to 0, and then read data from the USFA0E0ST register again. A request received later can be read.

(b) When an OUT token is used (except a request automatically executed by hardware)

Use FW to clear the PROT bit of the USFA0IS1 register to 0 after receiving the CPUDEC interrupt and before reading data from the USFA0E0ST register.

Confirm that the PROT bit of the USFA0IS1 register is 0 before reading data from the USFA0E0R register. If the PROT bit is 1, it indicates that invalid data is retained. Clear the FIFO by using FW. (The EP0NKR bit is automatically cleared to 0.) If the PROT bit of the USFA0IS1 register is 0, read the data of the USFA0E0L register, and then read the set number of data items from the USFA0E0R register. When data has been read from the USFA0E0R register completely, (when the counter of the USFA0E0R register is cleared to 0), the hardware automatically clears the EP0NKR bit to 0.

(2) EP0NAKALL register (USFA0E0NA)

This register controls NAK to all the requests of Endpoint0. It is also valid for automatically executed requests.

Access This register can be read or written in 8-bit units.

Address 004_H

Initial value 00_H. This register is initialized by any reset.

	7	6	5	4	3	2	1	0
USFA0E0NA	0	0	0	0	0	0	0	EP0NKA
	R	R	R	R	R	R	R	R/W

Table 27-10 USFA0E0NA register contents

Bit position	Bit name	Function
0	EP0NKA	<p>This bit controls NAK to Endpoint0 of a transaction other than a SETUP transaction (including an automatically executed request). This bit is manipulated by FW.</p> <p>1: Transmit NAK. 0: Do not transmit NAK. (Default)</p> <p>This register is used to prevent a conflict between a write access by FW and a read access from SIE when the data used for an automatically executed request is to be changed. It postpones applying write access to this bit from FW during access from SIE. Before rewriting the request data register from FW, confirm that this bit has been correctly set to 1.</p> <p>Setting this bit to 1 is applied only in the following cases:</p> <ul style="list-style-type: none"> - Immediately after USBF is reset and no SETUP token has been received - Immediately after receiving Bus Reset and no SETUP token has been received - When a PID of a SETUP token is detected - When the stage is changed to the status stage <p>Clearing this bit to 0 is applied immediately, except while an IN token is being received and a NAK response is being sent.</p> <p>Setting the EP0NKA bit to 1 is applied only in the above four cases during an Endpoint0 transfer, but it is applied immediately after data has been written during a different transfer.</p>

(3) EPNAK register (USFA0EN)

This register controls NAK of endpoints other than Endpoint0.

The BKO2NK bit can be written only when the BKO2NKM bit of the USFA0ENM register is 1, and the BKO1NK bit can be written only when the BKO1NKM bit of the USFA0ENM register is 1.

The related bits are invalid if the corresponding endpoint is not supported according to the setting of the USFA0EnIM register (n = 1 to 4, 7, 8) and the current interface.

It takes five USB clocks to apply the status to this register after the USFA0FIC0 and USFA0FIC1 registers have been set. If it is necessary to read the status correctly, therefore, separate a write signal that accesses the USFA0FIC0 and USFA0FIC1 registers from a read signal that accesses the USFA0EPS0, USFA0EPS1, USFA0EPS2, USFA0E0N, and USFA0EN registers by at least four USB clocks.

While NAK is being transmitted to Endpoint0 Read, Endpoint2, and Endpoint4, writing to the BKO1NK and BKO2NK bits is ignored.

Access This register can be read or written in 8-bit units. (However, bits 5, 4, and 1 can only be read.)

Address 008_H

Initial value 00_H. This register is initialized by any reset.

Caution Be sure to clear bits 7 and 6 to "0".

	7	6	5	4	3	2	1	0
USFA0EN	0	0	IT2NK	IT1NK	BKO2NK	BKO1NK	BKI2NK	BKI1NK
	R	R	R	R	R/W	R/W	R	R

Table 27-11 USFA0EN register contents (1/3)

Bit position	Bit name	Function
5	IT2NK	This bit controls NAK to Endpoint8 (interrupt 2 transfer). It is automatically set to 1 and transmission is started when the USFA0INT2 register becomes full as a result of writing data to it. To send a short packet that does not make the FIFO full, set the IT2DEND bit of the USFA0DEND register to 1. When the IT2DEND bit is set to 1, this bit is automatically set to 1 at the same time. 1: Do not transmit NAK. 0: Transmit NAK. (Default) This bit is also cleared to 0 at the same time when the USFA0INT2 register is cleared.
4	IT1NK	This bit controls NAK to Endpoint7 (interrupt 1 transfer). It is automatically set to 1 and transmission is started when the USFA0INT1 register becomes full as a result of writing data to it. To send a short packet that does not make the FIFO full, set the IT1DEND bit of the USFA0DEND register to 1. When the IT1DEND bit is set to 1, this bit is automatically set to 1 at the same time. 1: Do not transmit NAK. 0: Transmit NAK. (Default) This bit is cleared to 0 at the same time when the USFA0INT1 register is cleared.

Table 27-11 USFA0EN register contents (2/3)

Bit position	Bit name	Function
3	BKO2NK	<p>This bit controls NAK to Endpoint4 (bulk 2 transfer (OUT)).</p> <p>1: Transmit NAK. 0: Do not transmit NAK. (Default)</p> <p>This bit is set to 1 only when the FIFO connected to the SIE side of the USFA0BO2 register (a 64-byte FIFO in a bank configuration) cannot receive data. It is cleared to 0 when a toggle operation is performed. The bank is changed (toggle operation) when the following conditions are satisfied:</p> <ul style="list-style-type: none"> - Correctly received data is stored in the FIFO connected to the SIE side. - The value of the FIFO counter connected to the CPU side is 0 (completion of reading). <p>Use FW to read data of the USFA0BO2L register when it has received the BLKO2DT interrupt request and read as many data items from the USFA0BO2 register as the value of that data. To not receive data from the USB bus for some reason even if USBF is ready to receive data, set this bit to 1 using FW. In this case, USBF keeps transmitting NAK until the FW clears this bit to 0. This bit is also cleared to 0 at the same time when the USFA0BO2 register is cleared.</p>
2	BKO1NK	<p>This bit controls NAK to Endpoint2 (bulk 1 transfer (OUT)).</p> <p>1: Transmit NAK. 0: Do not transmit NAK. (Default)</p> <p>This bit is set to 1 only when the FIFO connected to the SIE side of the USFA0BO1 register (a 64-byte FIFO in a bank configuration) cannot receive data. It is cleared to 0 when a toggle operation is performed. The bank is changed (toggle operation) when the following conditions are satisfied:</p> <ul style="list-style-type: none"> - Correctly received data is stored in the FIFO connected to the SIE side. - The value of the FIFO counter connected to the CPU side is 0 (completion of reading). <p>Use FW to read data of the USFA0BO1L register when it has received the BLKO1DT interrupt request and read as many data items from the USFA0BO1 register as the value of that data. To not receive data from the USB bus for some reason even if USBF is ready to receive data, set this bit to 1 using FW. In this case, USBF keeps transmitting NAK until the FW clears this bit to 0. This bit is also cleared to 0 at the same time when the USFA0BO1 register is cleared.</p>
1	BKI2NK	<p>This bit controls NAK to Endpoint3 (bulk 2 transfer (IN)).</p> <p>1: Do not transmit NAK. 0: Transmit NAK. (Default)</p> <p>This bit is cleared to 0 only when the FIFO that is connected to the SIE side and has transmitted the data of the USFA0BI2 register (a 64-byte FIFO in a bank configuration) cannot receive data. It is set to 1 when a toggle operation is performed. (The data of the USFA0BI2 register is retained until transmission has been correctly completed.) The bank is changed (toggle operation) when the following conditions are satisfied:</p> <ul style="list-style-type: none"> - Data is correctly written to the FIFO connected to the CPU bus side. (Writing has been completed and the FIFO is full or the USFA0DEND register is set.) - The value of the FIFO counter connected to the SIE side is 0. <p>This bit is automatically set to 1 and data transmission is started when the FIFO on the CPU side becomes full and a FIFO toggle operation is performed as a result of writing data to the FIFO. However, if the FIFO on the CPU side becomes full as a result of writing data to it by DMA while the BKI2T bit of the USFA0DEND register is cleared to 0, the toggle operation is not performed because the condition of the toggle operation is not satisfied until the BKI2DED bit of the USFA0DEND register is set to 1. To send a short packet that does not make the FIFO on the CPU side full, set the BKI2DED bit to 1 after completing writing data. When the BKI2DED bit is set to 1, a toggle operation is performed and, at the same time, this bit is automatically set to 1. This bit is also cleared to 0 at the same time when the USFA0BI2 register is cleared.</p>

Table 27-11 USFA0EN register contents (3/3)

Bit position	Bit name	Function
0	BKI1NK	<p>This bit controls NAK to Endpoint1 (bulk 1 transfer (IN)).</p> <p>1: Do not transmit NAK. 0: Transmit NAK. (Default)</p> <p>This bit is cleared to 0 only when the FIFO that is connected to the SIE side and has transmitted the data of the USFA0BI1 register (a 64-byte FIFO in a bank configuration) cannot receive data. It is set to 1 when a toggle operation is performed. (The data of the USFA0BI1 register is retained until transmission has been correctly completed.) The bank is changed (toggle operation) when the following conditions are satisfied:</p> <ul style="list-style-type: none"> - Data is correctly written to the FIFO connected to the CPU bus side. (Writing has been completed and the FIFO is full or the USFA0DEND register is set.) - The value of the FIFO counter connected to the SIE side is 0. <p>This bit is automatically set to 1 and data transmission is started when the FIFO on the CPU side becomes full and a FIFO toggle operation is performed as a result of writing data to the FIFO. However, if the FIFO on the CPU side becomes full as a result of writing data to it by DMA while the BKI1T bit of the USFA0DEND register is cleared to 0, the toggle operation is not performed because the condition of the toggle operation is not satisfied until the BKI1DED bit of the USFA0DEND register is set to 1. To send a short packet that does not make the FIFO on the CPU side full, set the BKI1DED bit to 1 after completing writing data. When the BKI1DED bit is set to 1, a toggle operation is performed and, at the same time, this bit is automatically set to 1. This bit is also cleared to 0 at the same time when the USFA0BI1 register is cleared.</p>

- Cautions**
1. If DMA is enabled while data is being read from the USFA0BO2 register in the PIO mode, a DMA request is immediately issued.
 2. If the last data of the FIFO on the CPU side is read in the DMA transfer mode, the DMA request signal becomes inactive.
 3. If the TC signal is received in the DMA transfer mode, the DMA request signal becomes inactive.
 4. If 64-byte data is written in the DMA transfer mode, the DMA request signal becomes inactive. If the BKI2NK bit is then set to 1, data is transmitted in synchronization with an IN token. The DMA request signal becomes active again when the FIFO is toggled, as long as the DMA request is not masked. If the BKI2NK bit is not set, data is not transmitted even if an IN token is received. In this case, set the BKI2DED bit of the USFA0DEND register to 1.
 5. If the TC signal is received in the DMA transfer mode, the DMA request signal becomes inactive. At the same time, the DMA request is masked. If the BKI2NK bit is not set to 1, data is not transmitted even if an IN token is received. When the BKI2DED bit of the USFA0DEND register is set to 1 by FW, data is transmitted in synchronization with an IN token. To execute another DMA transfer, unmask the DMA request.

(4) EPNAK mask register (USFA0ENM)

This register controls masking writing to the USFA0EN register.

Access This register can be read or written in 8-bit units.

Address 00C_H

Initial value 00_H. This register is initialized by any reset.

Caution Be sure to clear bits 7 to 4, 1, and 0 to "0".

	7	6	5	4	3	2	1	0
USFA0ENM	0	0	0	0	BKO2NKM	BKO1NKM1	0	0
	R	R	R	R	R/W	R/W	R	R

Table 27-12 USFA0ENM register contents

Bit position	Bit name	Function
3	BKO2NKM	Specify whether to mask writing to bit 3 (BKO2NK) of the USFA0EN register. 1: Do not mask writing. 0: Mask writing. (Default)
2	BKO1NKM	Specify whether to mask writing to bit 2 (BKO1NK) of the USFA0EN register. 1: Do not mask writing. 0: Mask writing. (Default)

(5) SNDSIE register (USFA0SDS)

This register performs manipulation such as no handshake. It can directly manipulate the SIE pins.

Be sure to clear bit 2 to "0". If it is set to 1, the operation is not guaranteed.

Access This register can be read or written in 8-bit units.

Address 010_H

Initial value 00_H. This register is initialized by any reset.

Caution Be sure to clear bits 7 to 4, 1, and 0 to "0".

	7	6	5	4	3	2	1	0
USFA0SDS	0	0	0	0	SNDSTL	0	0	RSUMIN
	R	R	R	R	R/W	R	R	R/W

Table 27-13 USFA0SDS register contents

Bit position	Bit name	Function
3	SNDSTL	<p>This bit makes Endpoint0 issue a STALL handshake. Setting this bit to 1 if a request for CPUDEC processing is not supported by the system results in a STALL handshake response. If an unsupported wValue is sent by the SET_CONFIGURATION or SET_INTERFACE request, the hardware sets this bit to 1. This bit is also set to 1 if a problem occurs in Endpoint0 due to overrun of an automatically executed request. However, the E0HALT bit of the USFA0E0S register is not set to 1.</p> <p>1: Respond with a STALL handshake. 0: Do not respond with a STALL handshake. (Default)</p> <p>This bit is cleared to 0 and the handshake response to the bus is not STALL when the next SETUP token is received. To set the SNDSTL bit to 1 by using FW, do not write data to the USFA0E0W register. Depending on the timing of setting this bit, the STALL response might not be made in time, and it might be sent to the next transfer after a NAK response has been sent.</p> <p>Setting this bit is valid only while an FW-executed request is under execution when this bit is set to 1. It is automatically cleared to 0 when the next SETUP token is received.</p> <p>Note The SNDSTL bit is valid only for an FW-executed request.</p>
0	RSUMIN	<p>This bit outputs the Resume signal to the USB bus. Writing this bit is invalid unless the RMWK bit of the USFA0DST register is set to 1.</p> <p>1: Generate the Resume signal. 0: Do not generate the Resume signal. (Default)</p> <p>While this bit is set to 1, the Resume signal continues to be generated. Clear this bit to 0 using FW after a specific time has elapsed. Because sampling is internally performed with the clock, the operation is guaranteed only when CLK is supplied. Care must be exercised when the system CLK is stopped.</p>

(6) CLR request register (USFA0CLR)

This register indicates the target of the received CLEAR_FEATURE request.

This register is meaningful only when an interrupt request is generated. Each bit is set to 1 after completion of the status stage, and automatically cleared to 0 when this register is read.

The related bits are invalid if the corresponding endpoint is not supported according to the setting of the USFA0EnIM register (n = 1 to 4, 7, 8) and the current interface.

Access This register is read-only, in 8-bit units.

Address 014_H

Initial value 00_H. This register is initialized by any reset.

	7	6	5	4	3	2	1	0
USFA0CLR	CLREP8	CLREP7	CLREP4	CLREP3	CLREP2	CLREP1	CLREP0	CLRDEV
	R	R	R	R	R	R	R	R

Table 27-14 USFA0CLR register contents

Bit position	Bit name	Function
7:1	CLREPN	These bits indicate that a CLEAR_FEATURE Endpoint n request was received and automatically processed. 1: A request was automatically processed. 0: No request was automatically processed. (Default)
0	CLRDEV	This bit indicates that a CLEAR_FEATURE Device request was received and automatically processed. 1: A request was automatically processed. 0: No request was automatically processed. (Default)

Note n = 0 to 4, 7, 8

(7) SET request register (USFA0SET)

This register indicates the target of an automatically processed SET_XXXX (except SET_INTERFACE) request.

This register is meaningful only when an interrupt request is generated. Each bit is set to 1 after completion of the status stage, and automatically cleared to 0 when this register is read.

Access This register is read-only, in 8-bit units.

Address 018_H

Initial value 00_H. This register is initialized by any reset.

	7	6	5	4	3	2	1	0
USFA0SET	SETCON	0	0	0	0	SETEP	0	SETDEV
	R	R	R	R	R	R	R	R

Table 27-15 USFA0SET register contents

Bit position	Bit name	Function
7	SETCON	This bit indicates that a SET_CONFIGURATION request was received and automatically processed. 1: A request was automatically processed. 0: No request was automatically processed. (Default)
2	SETEP	This bit indicates that a SET_FEATURE Endpoint n (n = 0 to 4, 7, 8) request was received and automatically processed. 1: A request was automatically processed. 0: No request was automatically processed. (Default)
0	SETDEV	This bit indicates that a SET_FEATURE Device request was received and automatically processed. 1: A request was automatically processed. 0: No request was automatically processed. (Default)

(8) EP status 0 register (USFA0EPS0)

This register indicates the USB bus status and whether there is register data.

The related bits are invalid if the corresponding endpoint is not supported according to the setting of the USFA0EnIM register ($n = 1$ to 4, 7, 8) and the current interface.

It takes five USB clocks to apply the status to this register after the USFA0FIC0 and USFA0FIC1 registers have been set. If it is necessary to read the status correctly, therefore, separate write access to the USFA0FIC0 and USFA0FIC1 registers from read access to the USFA0EPS0, USFA0EPS1, USFA0EPS2, USFA0E0N, and USFA0EN registers by at least four USB clocks.

Access This register is read-only, in 8-bit units.

Address 01C_H

Initial value 00_H. This register is initialized by any reset.

	7	6	5	4	3	2	1	0
USFA0EPS0	IT2	IT1	BKOUT2	BKOUT1	BKIN2	BKIN1	EP0W	EP0R
	R	R	R	R	R	R	R	R

Table 27-16 USFA0EPS0 register contents (1/2)

Bit position	Bit name	Function
7, 6	ITn	These bits indicate whether data is in the USFA0INTn register (FIFO). By setting the ITnDEND bit of the USFA0DEND register to 1, the status in which data is in the USFA0INTn register can be set even if data is not written to the register (Null data transmission). When the ITnDEND bit of the USFA0DEND register is set to 1, this bit is also set to 1 by hardware at the same time even if the counter of the USFA0INTn register is 0. This bit is cleared to 0 after successful transmission. 1: There is data in the register. 0: There is no data in the register. (Default)
5, 4	BKOUTn	These bits indicate whether data is in the USFA0BOn register (FIFO) connected to the CPU side. When the FIFO that makes up the USFA0BOn register is toggled, this bit is automatically set to 1 by hardware. It is automatically cleared to 0 by hardware when reading the USFA0BOn register (FIFO) connected to the CPU side has been completed (counter value = 0). It is not set to 1 when Null data is received (nor does toggling the FIFO does not take place). 1: There is data in the register. 0: There is no data in the register. (Default)
3, 2	BKINn	These bits indicate whether data is in the USFA0BIn register (FIFO) connected to the CPU side. By setting the BKInDED bit of the USFA0DEND register to 1, the status in which data is in the USFA0BIn register can be set even if data is not written to the register (Null data transmission). When the BKInDED bit of the USFA0DEND register is set to 1, this bit is also set to 1 by hardware at the same time even if the counter of the USFA0BIn register is 0. It is cleared to 0 when a toggle operation is performed. 1: There is data in the register. 0: There is no data in the register. (Default)

Table 27-16 USFA0EPS0 register contents (2/2)

Bit position	Bit name	Function
1	EP0W	<p>This bit indicates that data is in the USFA0E0W register (FIFO). By setting the E0DED bit of the USFA0DEND register to 1, the status in which data is in the USFA0E0W register can be set even if data is not written to the register (Null data transmission). When the E0DED bit of the USFA0DEND register is set to 1, this bit is also set to 1 by hardware at the same time even if the counter of the USFA0E0W register is 0. This bit is cleared to 0 after successful transmission.</p> <p>1: There is data in the register. 0: There is no data in the register. (Default)</p>
0	EP0R	<p>This bit indicates that data is in the USFA0E0R register (FIFO). It is automatically cleared to 0 by hardware when reading the USFA0E0R register (FIFO) has been completed (counter value = 0). It is not set to 1 if Null data is received.</p> <p>1: There is data in the register. 0: There is no data in the register. (Default)</p>

Note n = 1 or 2

(9) EP status 1 register (USFA0EPS1)

This register indicates the USB bus status and whether there is register data.

Access This register is read-only, in 8-bit units.

Address 020_H

Initial value 00_H. This register is initialized by any reset.

	7	6	5	4	3	2	1	0
USFA0EPS1	RSUM	0	0	0	0	0	0	0
	R	R	R	R	R	R	R	R

Table 27-17 USFA0EPS1 register contents

Bit position	Bit name	Function
7	RSUM	<p>This bit indicates that the USB bus is in the Resume status. This bit is meaningful only when an interrupt request is generated.</p> <p>1: The bus entered the Suspend status. 0: The bus entered the Resume status. (Default)</p> <p>Because sampling is internally performed with the clock, the operation is guaranteed only when CLK is supplied. Care must be exercised when the system CLK is stopped. The INTUSFA0I2 signal of SIE operates even when CLK is stopped. It can therefore be supported by making the interrupt control register (UFIC1) valid or lowering the frequency of CLK for the USBF.</p> <p>This bit is automatically cleared to 0 when it is read.</p>

(10) EP status 2 register (USFA0EPS2)

This register indicates the USB bus status and whether there is register data.

The related bits are invalid if the corresponding endpoint is not supported according to the setting of the USFA0EnIM register ($n = 1$ to 4, 7, 8) and the current interface.

Access This register is read-only, in 8-bit units.

Address 024_H

Initial value 00_H. This register is initialized by any reset.

	7	6	5	4	3	2	1	0
USFA0EPS2	0	HALT8	HALT7	HALT4	HALT3	HALT2	HALT1	HALT0
	R	R	R	R	R	R	R	R

Table 27-18 USFA0EPS2 register contents

Bit position	Bit name	Function
6:0	HALTn	<p>These bits indicate that Endpoint n is currently stalled. They are set to 1 when a stall condition, such as the occurrence of an overrun or reception of an undefined request, is satisfied. These bits are automatically set to 1 by hardware.</p> <p>1: The endpoint is stalled. 0: The endpoint is not stalled. (Default)</p> <p>The SNDSTL bit is set to 1 at the same time when the HALT0 bit is set to 1 as a result of the occurrence of an overrun or reception of an undefined request. If the next SETUP token is received in this status, the SNDSTL bit is cleared to 0 and, therefore, the HALT0 bit is also cleared to 0. If Endpoint0 is stalled by the SET_FEATURE Endpoint0 request, the HALT0 bit is not cleared to 0 until the CLEAR_FEATURE Endpoint0 request is received or Halt Feature is cleared by FW. If the GET_STATUS Endpoint0, CLEAR_FEATURE Endpoint0, or SET_FEATURE Endpoint0 request is received, or if a request to be processed by FW is received due to the CPUDEC interrupt request, the HALT0 bit is masked and cleared to 0 until the next SETUP token is received.</p> <p>The HALTn bit is not cleared to 0 until Endpoint n receives the CLEAR_FEATURE Endpoint request, Halt Feature is cleared by the SET_INTERFACE or SET_CONFIGURATION request to the interface to which the endpoint is linked, or Halt Feature is cleared by FW. When the SET_INTERFACE or SET_CONFIGURATION request is correctly processed, the Halt Features of all the target endpoints, except Endpoint0, are cleared after the request has been processed, even if the wValue is the same as the currently set value, and these bits are also cleared to 0. Halt Feature of Endpoint0 cannot be cleared if it is set because a STALL response is returned in response to the SET_INTERFACE and SET_CONFIGURATION requests.</p>

Note $n = 0$ to 4, 7, 8

(11) INT status 0 register (USFA0IS0)

This register indicates the interrupt source. If the contents of this register are changed, the USFA0EPCINT.EPC_INT0 bit is set to 1.

If an interrupt request (INTUSFA0I1) is generated from USBF, the FW must read this register to identify the interrupt source.

Each bit of this register is forcibly cleared to 0 when 0 is written to the corresponding bit of the USFA0IC0 register.

Access This register is read-only, in 8-bit units.

Address 040_H

Initial value 00_H. This register is initialized by any reset.

Caution In the USBF, multiple interrupt sources, such as Bus Reset, Resume, and Short, are ORed internally and issued as a single interrupt request (INTUSFA0I1). Therefore, even if multiple interrupt sources occur, they are ORed and issued as an INTUSFA0I1 interrupt request. For example, if a Bus Reset interrupt source and Resume interrupt source occur, the two sources are ORed and an INTUSFA0I1 interrupt request is issued. Under these conditions, if the Bus Reset interrupt source is cleared to 0 (USFA0IC0.BUSRSTC = 0), the INTUSFA0I1 interrupt request for this product might remain set to 1 because the Resume interrupt source will still remain. The new interrupt request flag (US0BIC.US0BIF), therefore, might not be set to 1. In this case, after performing clear processing for each interrupt request with the INTUSFA0I1 interrupt servicing routine, confirm the flag status for the USFA0IS0 and USFA0IS1 registers again, and, if there are any interrupt sources for which the flags are set to 1, clear the flags. (Clear only the applicable bits, not all the bits.)

	7	6	5	4	3	2	1	0
USFA0IS0	BUSRST	RSUSPD	0	SHORT	DMAED	SETRQ	CLRRQ	EPHALT
	R	R	R	R	R	R	R	R

Table 27-19 USFA0IS0 register contents (1/2)

Bit position	Bit name	Function
7	BUSRST	This bit indicates that Bus Reset has occurred. 1: Bus Reset has occurred. (An interrupt request has been generated.) 0: Bus Reset has not occurred. (Default)
6	RSUSPD	This bit indicates that the Resume or Suspend status has occurred. Reference bit 7 of the USFA0EPS1 register by using FW. 1: The Resume or Suspend status has occurred. (An interrupt request has been generated.) 0: The Resume or Suspend status has not occurred. (Default)
4	SHORT	This bit indicates that data is read from the FIFO of either the USFA0BO1 or USFA0BO2 register and that the USBSPnB signal (n = 2, 4) is active. It is valid only when the FIFO is not full in the DMA mode. 1: The USBSPnB signal has been activated. (An interrupt request has been generated.) 0: The USBSPnB signal has not been activated. (Default) Use the USFA0DMS1 register to determine which endpoint the operation is actually performed on. This bit is not automatically cleared to 0 even when the USFA0DMS1 register is read by FW.

Table 27-19 USFA0IS0 register contents (2/2)

Bit position	Bit name	Function
3	DMAED	<p>This bit indicates that the DMA end (TC) signal for Endpoint n (n = 1 to 4, 7) is active.</p> <p>1: The DMA end signal for Endpoint n has been input. (An interrupt request has been generated.)</p> <p>0: The DMA end signal for Endpoint n has not been input. (Default)</p> <p>When this bit is set to 1, the DMA request signal for Endpoint n becomes inactive. The DMA request signal for Endpoint n does not become active unless FW enables DMA transfers.</p> <p>Use the USFA0DMS0 register to determine which endpoint the operation is actually performed on. This bit is not automatically cleared to 0 even when the USFA0DMS0 register is read by FW.</p>
2	SETRQ	<p>This bit indicates that the SET_XXXX request to be automatically processed has been received and automatically processed (XXXX = CONFIGURATION or FEATURE).</p> <p>1: The SET_XXXX request to be automatically processed has been received. (An interrupt request has been generated.)</p> <p>0: The SET_XXXX request to be automatically processed has not been received. (Default)</p> <p>This bit is set to 1 upon completion of the status stage. Reference the USFA0SET register to identify the target of the request. This bit is not automatically cleared to 0 even if the USFA0SET register is read by FW.</p> <p>The EPHALT bit is also set to 1 when the SET_FEATURE Endpoint request is received.</p>
1	CLRRQ	<p>This bit indicates that the CLEAR_FEATURE request has been received and automatically processed.</p> <p>1: The CLEAR_FEATURE request has been received. (An interrupt request has been generated.)</p> <p>0: The CLEAR_FEATURE request has not been received. (Default)</p> <p>This bit is set to 1 upon completion of the status stage.</p> <p>Reference the USFA0CLR register to identify the target of the request. This bit is not automatically cleared to 0 even if the USFA0CLR register is read by FW.</p>
0	EPHALT	<p>This bit indicates that an endpoint has stalled.</p> <p>1: The endpoint has stalled. (An interrupt request has been generated.)</p> <p>0: The endpoint has not stalled. (Default)</p> <p>This bit is also set to 1 when an endpoint has been caused to stall by setting FW. Identify the endpoint that has stalled by referencing the USFA0EPS2 register. This bit is not automatically cleared to 0 even when a CLEAR_FEATURE Endpoint, SET_INTERFACE, or SET_CONFIGURATION request is received. In addition, it is not automatically cleared to 0 if the next SETUP token is received in the case of an Endpoint0 overrun.</p> <p>Caution Even if Halt Feature of Endpoint0 is set and an interrupt request is generated, bit 0 of the USFA0EPS2 register is masked and cleared to 0 between when a SET_FEATURE Endpoint0, CLEAR_FEATURE Endpoint0, GET_STATUS Endpoint0 request, or FW-processed request is received and when a SETUP token other than the above is received.</p>

(12) INT status 1 register (USFA0IS1)

This register indicates the interrupt source. If the contents of this register are changed, the USFA0EPCINT.EPC_INT0 bit is set to 1.

If an interrupt request (INTUSFA0I1) is generated from USBF, the FW must read this register to identify the interrupt source.

Each bit of this register is forcibly cleared to 0 when 0 is written to the corresponding bit of the USFA0IC1 register. However, the SUCES and STG bits of the USFA0IS1 register are automatically cleared to 0 when the next SETUP token is received.

Access This register is read-only, in 8-bit units.

Address 044_H

Initial value 00_H. This register is initialized by any reset.

Caution In the USBF, multiple interrupt sources, such as Bus Reset, Resume, and Short, are ORed internally and issued as a single interrupt request (INTUSFA0I1). Therefore, even if multiple interrupt sources occur, they are ORed and issued as an INTUSFA0I1 interrupt request. For example, if a Bus Reset interrupt source and Resume interrupt source occur, the two sources are ORed and an INTUSFA0I1 interrupt request is issued. Under these conditions, if the Bus Reset interrupt source is cleared to 0 (USFA0IC0.BUSRSTC = 0), the INTUSFA0I1 interrupt request for this product might remain set to 1 because the Resume interrupt source will still remain. The new interrupt request flag (US0BIC.US0BIF), therefore, might not be set to 1. In this case, after performing clear processing for each interrupt request with the INTUSFA0I1 interrupt servicing routine, confirm the flag status for the USFA0IS0 and USFA0IS1 registers again, and, if there are any interrupt sources for which the flags are set to 1, clear the flags. (Clear only the applicable bits, not all the bits.)

In addition, if an interrupt from the USBF is detected, the value of the interrupt request is stored in the EICn.EIRFn bit (n = 187 to 189). Therefore, even if the CPU acknowledges the interrupt and the EIRFn bit of the interrupt control register (EIC187 to EIC189) is cleared to 0, the EICn.EIRFn bit is immediately set to 0 and an interrupt is continuously generated. To prevent this from happening, execute the following processing in the interrupt service routine, and forcibly clear the EICn.EIRFn bit to 0.

- For EIC187 (when a bridge interrupt is detected)
 - (1) Clear the interrupt source flag in the H-bus bridge interrupt status register (USFA0BRGINT) to 0.
 - (2) Clear the EIC187.EIRF187 bit to 0.
- For EIC188 (when an EPC interrupt is detected)
 - (1) Clear the interrupt source flag in the INT status x register (USFA0ISx; x = 0 to 4) to 0.
 - (2) Clear the interrupt source flag in the EPC interrupt status register (USFA0EPCINT) to 0.
 - (3) Clear the EIC188.EIRF188 bit to 0.
- For EIC189 (when USB resume is detected)
 - (1) Clear the EIC189.EIRF189 bit to 0.

	7	6	5	4	3	2	1	0
USFA0IS1	0	E0IN	E0INDT	E0ODT	SUCES	STG	PROT	CPUDEC
	R	R	R	R	R	R	R	R

Table 27-20 USFA0IS1 register contents (1/2)

Bit position	Bit name	Function
6	E0IN	This bit indicates that an IN token for Endpoint0 has been received and the hardware has automatically transmitted NAK. 1: An IN token has been received and NAK has been transmitted. (An interrupt request has been generated.) 0: No IN token has been received. (Default)
5	E0INDT	This bit indicates that data has been correctly transmitted from the USFA0E0W register. 1: Transmission from the USFA0E0W register is complete. (An interrupt request has been generated.) 0: Transmission from the USFA0E0W register is not complete. (Default) Data is transmitted in synchronization with the IN token next to the one that set the EP0NKW bit of the USFA0E0N register to 1. This bit is automatically set to 1 by hardware when the host correctly receives that data. This bit is set to 1 even when the data is a Null packet. This bit is automatically cleared to 0 by hardware when the USFA0E0W register is written to the first time.
4	E0ODT	This bit indicates that data has been correctly received in the USFA0E0R register. 1: There is data in the USFA0E0R register. (An interrupt request has been generated.) 0: There is no data in the USFA0E0R register. (Default) This bit is automatically set to 1 by hardware when data has been correctly received. At the same time, the EP0R bit of the USFA0EPS0 register is set to 1. If a Null packet has been received, this bit is not set to 1. It is automatically cleared to 0 by hardware when the FW reads the USFA0E0R register and the value of the USFA0E0L register becomes 0.
3	SUCES	This bit indicates that either an FW-processed or hardware-processed request has been received and the status stage has been correctly completed. 1: A control transfer has been correctly processed. (An interrupt request has been generated.) 0: Control transfer processing has not ended correctly. (Default) This bit is set to 1 upon completion of the status stage. It is automatically cleared to 0 by hardware when the next SETUP token is received. This bit is also set to 1 when data with Data PID of 0 (Null data) is received in the status stage of a control transfer.
2	STG	This bit is set to 1 when the stage of a control transfer changes to the status stage. It is valid for both FW-processed and hardware-processed requests. This bit is also set to 1 when the stage of a control transfer (without data) changes to the status stage. 1: The system entered the status stage. (An interrupt request has been generated.) 0: The system has not entered the status stage. (Default) This bit is automatically cleared to 0 by hardware when the next SETUP token is received. It is also set to 1 when the stage of a control transfer changes to the status stage while ACK cannot be correctly received in the data stage. In this case, the EP0NKW bit of the USFA0E0N register is also cleared to 0 at the same time when the USFA0E0W register is cleared, if the FW is processing a control transfer (read).

Table 27-20 USFA0IS1 register contents (2/2)

Bit position	Bit name	Function
1	PROT	<p>This bit indicates that a SETUP token has been received. It is valid for both FW-processed and hardware-processed requests.</p> <p>1: A SETUP token has been correctly received. (An interrupt request has been generated.)</p> <p>0: No SETUP token has been received. (Default)</p> <p>This bit is set to 1 when data has been correctly received in the USFA0E0ST register. Clear this bit to 0 by using FW when the USFA0E0ST register is read the first time. If it is not cleared to 0 by FW, reception of the next SETUP token cannot be correctly recognized.</p> <p>This bit is used to accurately recognize that a SETUP transaction has been executed again during a control transfer. If the SETUP transaction is re-executed during a control transfer and a second request is executed by hardware, the CPUDEC bit is not set to 1, but the PROT bit can be used to recognize the re-execution.</p>
0	CPUDEC	<p>This bit indicates that the USFA0E0ST register has a request that is to be decoded by FW.</p> <p>1: There is data in the USFA0E0ST register. (An interrupt request has been generated.)</p> <p>0: There is no data in the USFA0E0ST register. (Default)</p> <p>This bit is automatically cleared to 0 by hardware when all the data of the USFA0E0ST register is read.</p>

(13) INT status 2 register (USFA0IS2)

This register indicates the interrupt source. If the contents of this register are changed, the USFA0EPCINT.EPC_INT1 bit is set to 1.

If an interrupt request (INTUSFA0I1) is generated from USBF, the FW must read this register to identify the interrupt source.

Each bit of this register is forcibly cleared to 0 when 0 is written to the corresponding bit of the USFA0IC2 register.

The related bits are invalid if the corresponding endpoint is not supported according to the setting of the USFA0EnIM register ($n = 1, 3, 7, 8$) and the current interface.

Access This register is read-only, in 8-bit units.

Address 048_H

Initial value 00_H. This register is initialized by any reset.

	7	6	5	4	3	2	1	0
USFA0IS2	BKI2IN	BKI2DT	BKI1IN	BKI1DT	0	0	IT2DT	IT1DT
	R	R	R	R	R	R	R	R

Table 27-21 USFA0IS2 register contents

Bit position	Bit name	Function
7, 5	BKInIN	These bits indicate that an IN token has been received in the USFA0BIn register (Endpoint m) and that NAK has been returned. 1: An IN token has been received and NAK has been transmitted. (An interrupt request has been generated.) 0: No IN token has been received. (Default)
6, 4	BKInDT	These bits indicate that the FIFO of the USFA0BIn register (Endpoint m) has been toggled. This means that data can be written to Endpoint m. 1: The FIFO has been toggled. (An interrupt request has been generated.) 0: The FIFO has not been toggled. (Default) The data written to Endpoint m is transmitted in synchronization with the IN token next to the one that set the BKInNK bit of the USFA0EN register to 1. When the FIFO has been toggled and then data can be written from the CPU, this bit is automatically set to 1 by hardware. It is also set to 1 when the FIFO has been toggled, even if the data is a Null packet. This bit is automatically cleared to 0 by hardware when the USFA0BIn register is written to the first time.
1, 0	ITnDT	These bits indicate that data has been correctly received from the USFA0INTn register (Endpoint x). 1: Transmission is complete. (An interrupt request has been generated.) 0: Transmission is not complete. (Default) Data is transmitted in synchronization with the IN token next to the one that set the ITnNK bit of the USFA0EN register to 1. These bits are automatically set to 1 by hardware when the host has correctly received the data. These bits are automatically cleared to 0 by hardware when the USFA0INTn register is written to the first time. They are set to 1 even when the data is a Null packet.

Note $n = 1$ or 2

$m = 1$ and $x = 7$ when $n = 1$

$m = 3$ and $x = 8$ when $n = 2$

(14) INT status 3 register (USFA0IS3)

This register indicates the interrupt source. If the contents of this register are changed, the USFA0EPCINT.EPC_INT1 bit is set to 1.

If an interrupt request (INTUSFA0I1) is generated from USBF, the FW must read this register to identify the interrupt source.

Each bit of this register is forcibly cleared to 0 when 0 is written to the corresponding bit of the USFA0IC3 register.

The related bits are invalid if the corresponding endpoint is not supported according to the setting of the USFA0EnIM register ($n = 2$ or 4) and the current interface.

Access This register is read-only, in 8-bit units.

Address $04C_H$

Initial value 00_H . This register is initialized by any reset.

	7	6	5	4	3	2	1	0
USFA0IS3	BKO2FL	BKO2NL	BKO2NAK	BKO2DT	BKO1FL	BKO1NL	BKO1NAK	BKO1DT
	R	R	R	R	R	R	R	R

Table 27-22 USFA0IS3 register contents (1/2)

Bit position	Bit name	Function
7, 3	BKOnFL	These bits indicate that data has been correctly received in the USFA0BOn register (Endpoint m) and the FIFOs of both the CPU and SIE hold the data. 1: Received data is in both FIFOs of the USFA0BOn register. (An interrupt request has been generated.) 0: Received data is not in the FIFO on the SIE side of the USFA0BOn register. (Default). If data is held in the FIFOs of both the CPU and SIE, these bits are automatically set to 1 by hardware. They are automatically cleared to 0 by hardware when the FIFO is toggled.
6, 2	BKOnNL	These bits indicate that a Null packet (a packet with a length of 0) has been received in the USFA0BOn register (Endpoint m). 1: A Null packet has been received. (An interrupt request has been generated.) 0: No Null packet has been received. (Default) These bits are set to 1 immediately after the reception of a Null packet when the FIFO is empty. They are set to 1 when the FIFO on the CPU side has been completely read if data is in that FIFO.
5, 1	BKOnNAK	These bits indicate that an OUT token has been received in the USFA0BOn register (Endpoint m) and NAK has been returned. 1: An OUT token has been received and NAK has been transmitted. (An interrupt request has been generated.) 0: No OUT token has been received. (Default)

Table 27-22 USFA0IS3 register contents (2/2)

Bit position	Bit name	Function
4, 0	BKOnDT	<p>These bits indicate that data has been correctly received in the USFA0BOn register (Endpoint m).</p> <p>1: Reception finished correctly. (An interrupt request has been generated.) 0: Reception is not complete. (Default)</p> <p>These bits are automatically set to 1 by hardware when data has been correctly received and the FIFO has been toggled. At the same time, the corresponding bits of the USFA0EPS0 register are set to 1. They are not set to 1 when the data is a Null packet. These bits are automatically cleared to 0 by hardware when the value of the USFA0BOnL register becomes 0 as a result of reading the USFA0BOn register using FW.</p> <p>These bits are automatically cleared to 0 when all the contents of the FIFO on the CPU side have been read. However, the interrupt request is not cleared if data is in the FIFO on the SIE side at this time, and the INTUSFA0I2 signal does not become inactive. The signal is kept active if data is successively received.</p>

Note n = 1 or 2
m = 2 when n = 1
m = 4 when n = 2

(15) INT status 4 register (USFA0IS4)

This register indicates the interrupt source. If the contents of this register are changed, USFA0EPCINT.EPC_INT2 is set to 1.

If an interrupt request (INTUSFA0I1) is generated from USBF, the FW must read this register to identify the interrupt source.

Each bit of this register is forcibly cleared to 0 when 0 is written to the corresponding bit of the USFA0IC4 register.

The related bits are invalid if the corresponding endpoint is not supported according to the setting of the USFA0EnIM register (n = 1 to 4, 7, 8) and the current interface.

Access This register is read-only, in 8-bit units.

Address 050_H

Initial value 00_H. This register is initialized by any reset.

	7	6	5	4	3	2	1	0
USFA0IS4	0	0	SETINT	0	0	0	0	0
	R	R	R	R	R	R	R	R

Table 27-23 USFA0IS4 register contents

Bit position	Bit name	Function
5	SETINT	<p>This bit indicates that the SET_INTERFACE request has been received and automatically processed.</p> <p>1: The request was automatically processed. (An interrupt request has been generated.)</p> <p>0: No request was automatically processed. (Default)</p> <p>The current setting of this bit can be identified by reading the USFA0ASS or USFA0IFn register (n = 0 to 4).</p>

(16) INT mask 0 register (USFA0IM0)

This register controls the masking of the interrupt sources indicated by the USFA0IS0 register.

FW can mask the occurrence of an interrupt request from USBF (INTUSFA011) by writing 1 to the corresponding bit of this register. The status is applied even when interrupt requests are masked.

Access This register can be read or written in 8-bit units.

Address 05C_H

Initial value 00_H. This register is initialized by any reset.

	7	6	5	4	3	2	1	0

Table 27-24 USFA0IM0 register contents

Bit position	Bit name	Function
7	BUSRSTM	This bit masks the Bus Reset interrupt. 1: Mask the interrupt. 0: Do not mask the interrupt. (Default)
6	RSUSPDM	This bit masks the Resume/Suspend interrupt. 1: Mask the interrupt. 0: Do not mask the interrupt. (Default)
4	SHORTM	This bit masks the Short interrupt 1: Mask the interrupt. 0: Do not mask the interrupt. (Default)
3	DMAEDM	This bit masks the DMA_END interrupt. 1: Mask the interrupt. 0: Do not mask the interrupt. (Default)
2	SETRQM	This bit masks the SET_RQ interrupt. 1: Mask the interrupt. 0: Do not mask the interrupt. (Default)
1	CLRRQM	This bit masks the CLR_RQ interrupt. 1: Mask the interrupt. 0: Do not mask the interrupt. (Default)
0	EPHALTM	This bit masks the EP_Halt interrupt. 1: Mask the interrupt. 0: Do not mask the interrupt. (Default)

(17) INT mask 1 register (USFA0IM1)

This register controls the masking of the interrupt sources indicated by the USFA0IS1 register.

FW can mask the occurrence of an interrupt request from USBF (INTUSFA011) by writing 1 to the corresponding bit of this register. The status is applied even when interrupt requests are masked.

Access This register can be read or written in 8-bit units.

Address 060_H

Initial value 00_H. This register is initialized by any reset.

	7	6	5	4	3	2	1	0

2	STGM	This bit masks the Stg interrupt. 1: Mask the interrupt. 0: Do not mask the interrupt. (Default)
1	PROTM	This bit masks the Protect interrupt. 1: Mask the interrupt. 0: Do not mask the interrupt. (Default)
0	CPUDECM	This bit masks the CPUDEC interrupt. 1: Mask the interrupt. 0: Do not mask the interrupt. (Default)

(18) INT mask 2 register (USFA0IM2)

This register controls the masking of the interrupt sources indicated by the USFA0IS2 register.

FW can mask the occurrence of an interrupt request from USBF (INTUSFA011) by writing 1 to the corresponding bit of this register. The status is applied even when interrupt requests are masked.

The related bits are invalid if the corresponding endpoint is not supported according to the setting of the USFA0EnIM register ($n = 1, 3, 7, 8$) and the current interface.

Access This register can be read or written in 8-bit units.

Address 064_H

Initial value 00_H. This register is initialized by any reset.

Note $n = 1$ or 2

(20) INT mask 4 register (USFA0IM4)

This register controls the masking of the interrupt sources indicated by the USFA0IS4 register.

FW can mask the occurrence of an interrupt request from USBF (INTUSFA011) by writing 1 to the corresponding bit of this register. The status is applied even when interrupt requests are masked.

The related bits are invalid if the corresponding endpoint is not supported according to the setting of the USFA0EnIM register (n = 1 to 4, 7, 8) and the current interface.

Access This register can be read or written in 8-bit units.

Address 06C_H

Initial value 00_H. This register is initialized by any reset.

	7	6	5	4	3	2	1	0
USFA0IM4	0	0	SETINTM	0	0	0	0	0
	R	R	R/W	R	R	R	R	R

Table 27-28 USFA0IM4 register contents

Bit position	Bit name	Function
5	SETINTM	This bit masks the SET_INT interrupt. 1: Mask 0: Do not mask the interrupt. (Default)

(21) INT clear 0 register (USFA0IC0)

This register controls clearing the interrupt sources indicated by the USFA0IS0 register.

FW can clear an interrupt source by writing 0 to the corresponding bit of this register. Even a bit that is automatically cleared to 0 by hardware can be cleared by FW before it is cleared by hardware. Writing 0 to a bit of this register automatically sets the bit to 1. Writing 1 to the bit is invalid.

Access This register is write-only, in 8-bit units. If this register is read, FF_H is read.

Address 078_H

Initial value FF_H. This register is initialized by any reset.

Bit position	Bit name	Function
7	BUSRSTC	This bit clears the Bus Reset interrupt. 0: Clear the interrupt.
6	RSUSPDC	This bit clears the Resume/Suspend interrupt. 0: Clear the interrupt.
4	SHORTC	This bit clears the Short interrupt. 0: Clear the interrupt.
3	DMAEDC	This bit clears the DMA_END interrupt. 0: Clear the interrupt.
2	SETRQC	This bit clears the SET_RQ interrupt. 0: Clear the interrupt.
1	CLRRQC	This bit clears the CLR_RQ interrupt. 0: Clear the interrupt.
0	EPHALTC	This bit clears the EP_Halt interrupt. 0: Clear the interrupt.

(22) INT clear 1 register (USFA0IC1)

This register controls clearing the interrupt sources indicated by the USFA0IS1 register.

FW can clear an interrupt source by writing 0 to the corresponding bit of this register. Even a bit that is automatically cleared to 0 by hardware can be cleared by FW before it is cleared by hardware. Writing 0 to a bit of this register automatically sets the bit to 1. Writing 1 to the bit is invalid.

Access This register is write-only, in 8-bit units. If this register is read, FF_H is read.

Address 07C_H

Initial value FF_H. This register is initialized by any reset.

6	E0INC	This bit clears the EP0IN interrupt. 0: Clear the interrupt.
5	E0INDTC	This bit clears the EP0INDT interrupt. 0: Clear the interrupt.
4	E0ODTC	This bit clears the EP0OUTDT interrupt. 0: Clear the interrupt.
3	SUCESC	This bit clears the Success interrupt. 0: Clear the interrupt.
2	STGC	This bit clears the Stg interrupt. 0: Clear the interrupt.
1	PROTC	This bit clears the Protect interrupt. 0: Clear the interrupt.
0	CPUDECC	This bit clears the CPUDEC interrupt. 0: Clear the interrupt.

(23) INT clear 2 register (USFA0IC2)

This register controls clearing the interrupt sources indicated by the USFA0IS2 register.

FW can clear an interrupt source by writing 0 to the corresponding bit of this register. Even a bit that is automatically cleared to 0 by hardware can be cleared by FW before it is cleared by hardware. Writing 0 to a bit of this register automatically sets the bit to 1. Writing 1 to the bit is invalid.

The related bits are invalid if the corresponding endpoint is not supported according to the setting of the USFA0EnIM register ($n = 1, 3, 7, 8$) and the current interface.

Access This register is write-only, in 8-bit units. If this register is read, FF_H is read.

Address 080_H

Initial value FF_H. This register is initialized by any reset.

	7	6	5	4	3	2	1	0

Table 27-31 USFA0IC2 register contents

Bit position	Bit name	Function
7, 5	BKInINC	These bits clear the BLKInIN interrupt. 0: Clear the interrupt.
6, 4	BKInDTC	These bits clear the BLKInDT interrupt. 0: Clear the interrupt.
1, 0	ITnDTC	These bits clear the INTnDT interrupt. 0: Clear the interrupt.

Note $n = 1$ or 2

(24) INT clear 3 register (USFA0IC3)

This register controls clearing the interrupt sources indicated by the USFA0IS3 register.

FW can clear an interrupt source by writing 0 to the corresponding bit of this register. Even a bit that is automatically cleared to 0 by hardware can be cleared by FW before it is cleared by hardware. Writing 0 to a bit of this register automatically sets the bit to 1. Writing 1 to the bit is invalid.

The related bits are invalid if the corresponding endpoint is not supported according to the setting of the USFA0EnIM register ($n = 2$ or 4) and the current interface.

Access This register is write-only, in 8-bit units. If this register is read, FF_H is read.

Address 084_H

Initial value FF_H. This register is initialized by any reset.

Table 27-32 USFA0IC3 register contents

Bit position	Bit name	Function
7, 3	BKOnFLC	These bits clear the BLKOnFL interrupt. 0: Clear the interrupt.
6, 2	BKOnNLC	These bits clear the BLKOnNL interrupt. 0: Clear the interrupt.
5, 1	BKOnNAKC	These bits clear the BLKOnNK interrupt. 0: Clear the interrupt.
4, 0	BKOnDTC	These bits clear the BLKOnDT interrupt. 0: Clear the interrupt.

Note $n = 1$ or 2

(25) INT clear 4 register (USFA0IC4)

This register controls clearing the interrupt sources indicated by the USFA0IS4 register.

FW can clear an interrupt source by writing 0 to the corresponding bit of this register. Even a bit that is automatically cleared to 0 by hardware can be cleared by FW before it is cleared by hardware. Writing 0 to a bit of this register automatically sets the bit to 1. Writing 1 to the bit is invalid.

The related bits are invalid if the corresponding endpoint is not supported according to the setting of the USFA0EnIM register ($n = 1$ to 4, 7, 8) and the current interface.

Access This register is write-only, in 8-bit units. If this register is read, FF_H is read.

Address 088_H

Initial value FF_H. This register is initialized by any reset.

	7	6	5	4	3	2	1	0
USFA0IC4	1	1	SETINTC	1	1	1	1	1
	W	W	W	W	W	W	W	W

Table 27-33 USFA0IC4 register contents

Bit position	Bit name	Function
5	SETINTC	This bit clears the SET_INT interrupt. 0: Clear the interrupt.

(26) INT & DMARQ register (USFA0IDR)

This register selects reporting by way of an interrupt request or starting DMA.

If data exists in either the USFA0BO1 or USFA0BO2 register, or if data can be written to the USFA0BI1 or USFA0BI2 register, this register selects whether it is reported to the FW by an interrupt request, or whether starting DMA is requested. If starting DMA is requested, the DMA transfer mode can be selected according to the setting of bits 0 and 1.

The related bits are invalid if the corresponding endpoint is not supported according to the setting of the USFA0EnIM register (n = 1 to 4) and the current interface.

Be sure to clear bits 3 and 2 to "0". If they are set to 1, the operation is not guaranteed.

Access This register can be read or written in 8-bit units.

Address 098_H

Initial value 00_H. This register is initialized by any reset.

Caution If the target endpoint is not supported by the SET_INTERFACE request during a DMA transfer, the DMA request signal becomes inactive immediately, and the corresponding bit is automatically cleared to 0 by hardware.

	7	6	5	4	3	2	1	0

Other than the above		Setting prohibited												

Note n = 1 or 2

m = 1 and x = 2 when n = 1

m = 3 and x = 4 when n = 2

(27) DMA status 0 register (USFA0DMS0)

This register indicates the DMA status of Endpoint1 to Endpoint4.

The related bits are invalid if the corresponding endpoint is not supported according to the setting of the USFA0EnIM register (n = 1 to 4) and the current interface.

Access This register is read-only, in 8-bit units.

Address 09C_H

Initial value 00_H. This register is initialized by any reset.

	7	6	5	4	3	2	1	0
USFA0DMS0	0	0	DQE4	DQE3	DQE2	DQE1	0	0
	R	R	R	R	R	R	R	R

Table 27-35 USFA0DMS0 register contents

Bit position	Bit name	Function
5	DQE4	This bit indicates that a DMA read request is being issued from Endpoint4 to memory. 1: A DMA read request from Endpoint4 is being issued. 0: No DMA read request from Endpoint4 is being issued. (Default)
4	DQE3	This bit indicates that a DMA write request is being issued from memory to Endpoint3. Note that, even if data is in Endpoint3 (when the FIFO is not full and after the BKI2DED bit has been set to 1), the DMA request signal becomes active immediately and the DMA transfer is started when the DQBI2MS bit of the USFA0IDR register is set to 1. 1: A DMA write request for Endpoint3 is being issued. 0: No DMA write request for Endpoint3 is being issued. (Default)
3	DQE2	This bit indicates that a DMA read request is being issued from Endpoint2 to memory. 1: A DMA read request from Endpoint2 is being issued. 0: No DMA read request from Endpoint2 is being issued. (Default)
2	DQE1	This bit indicates that a DMA write request is being issued from memory to Endpoint1. Note that, even if data is in Endpoint1 (when the FIFO is not full and after the BKI1DED bit has been set to 1), the DMA request signal becomes active immediately and the DMA transfer is started when the DQBI1MS bit of the USFA0IDR register is set to 1. 1: A DMA write request for Endpoint1 is being issued. 0: No DMA write request for Endpoint1 is being issued. (Default)

(28) DMA status 1 register (USFA0DMS1)

This register indicates the DMA status of Endpoint1 to Endpoint4.

The related bits are invalid if the corresponding endpoint is not supported according to the setting of the USFA0EnIM register ($n = 1$ to 4) and the current interface.

Each bit is automatically cleared to 0 when this register is read. Even when this register is read, however, bits 4 and 3 of the USFA0IS0 register are not cleared to 0. If the target endpoint is no longer supported by the SET_INTERFACE request, each bit is automatically cleared to 0 by hardware. (However, the DMA_END interrupt request and Short interrupt request are not cleared.)

Access This register is read-only, in 8-bit units.

Address 0A0_H

Initial value 00_H. This register is initialized by any reset.

	7	6	5	4	3	2	1	0
USFA0DMS1	DEDE4	DSPE4	DEDE3	DEDE2	DSPE2	DEDE1	0	0
	R	R	R	R	R	R	R	R

Table 27-36 USFA0DMS1 register contents

Bit position	Bit name	Function
7, 5, 4, 2	DEDE _n	These bits indicate that the DMA end (TC) signal for Endpoint n becomes active and DMA is stopped while a DMA read request is being issued from Endpoint n to memory. 1: The DMA end signal for Endpoint n is active. 0: The DMA end signal for Endpoint n is inactive. (Default)
6, 3	DSPE _m	These bits indicate that, although a DMA read request was being issued from Endpoint m to memory, DMA has been stopped because the received data is a short packet and there is no more data to be transferred. 1: The DMASTOP_EP _m signal is active. 0: The DMASTOP_EP _m signal is inactive. (Default)

Note $n = 1$ to 4

$m = 2$ or 4

(29) FIFO clear 0 register (USFA0FIC0)

This register clears each FIFO.

FW can clear the target FIFO by writing 1 to the corresponding bit of this register. A bit to which 1 has been written is automatically cleared to 0. Writing 0 to the bit is invalid.

The related bits are invalid if the corresponding endpoint is not supported according to the setting of the USFA0EnIM register ($n = 1, 3, 7, 8$) and the current interface.

Access This register is write-only, in 8-bit units. If this register is read, 00_H is read.

Address 0C0_H

Initial value 00_H. This register is initialized by any reset.

	7	6	5	4	3	2	1	0
USFA0FIC0	BKI2SC	BKI2CC	BKI1SC	BKI1CC	0	ITR1C	EP0WC	EP0RC
	W	W	W	W	W	W	W	W

Table 27-37 USFA0FIC0 register contents

Bit position	Bit name	Function
7, 5	BKInSC	These bits clear only the FIFO on the SIE side of the USFA0BIn register (reset the counter). 1: Clear the FIFO. Writing to these bits is invalid while an IN token for Endpoint m is being processed with the BKInNK bit set to 1. The BKInNK bit is automatically cleared to 0 by clearing the FIFO. Make sure that the FIFO on the CPU side is empty when these bits are used.
6, 4	BKInCC	These bits clear only the FIFO on the CPU side of the USFA0BIn register (reset the counter). 1: Clear the FIFO.
2	ITR1C	This bit clears the USFA0INT1 register (resets the counter). 1: Clear the register. Writing to these bits is invalid while an IN token for Endpoint 7 is being processed with the IT1NK bit set to 1. The IT1NK bit is automatically cleared to 0 by clearing the FIFO.
1	EP0WC	This bit clears the USFA0E0W register (resets the counter). 1: Clear the register. Writing to this bit is invalid while an IN token for Endpoint0 is being processed with the EP0NKW bit set to 1. The EP0NKW bit is automatically cleared to 0 by clearing the FIFO.
0	EP0RC	This bit clears the USFA0E0R register (resets the counter). 1: Clear the register. When the EP0NKR bit is set to 1 (except when it has been set by FW), the EP0NKR bit is automatically cleared to 0 by clearing the FIFO.

Note $n = 1$ or 2

$m = 1$ and $x = 7$ when $n = 1$

$m = 3$ and $x = 8$ when $n = 2$

(30) FIFO clear 1 register (USFA0FIC1)

This register clears each FIFO.

FW can clear the target FIFO by writing 1 to the corresponding bit of this register. A bit to which 1 has been written is automatically cleared to 0. Writing 0 to the bit is invalid.

The related bits are invalid if the corresponding endpoint is not supported according to the setting of the USFA0EnIM register ($n = 2$ or 4) and the current interface.

Access This register is write-only, in 8-bit units. If this register is read, 00_H is read.

Address $0C4_H$

Initial value 00_H . This register is initialized by any reset.

	7	6	5	4	3	2	1	0
USFA0FIC1	0	0	0	0	BK02C	BK02CC	BK01C	BK01CC
	R	R	R	R	W	W	W	W

Table 27-38 USFA0FIC1 register contents

Bit position	Bit name	Function
3, 1	BKOnC	These bits clear the FIFOs on both the SIE and CPU sides of the USFA0BOn register (reset the counter). 1: Clear the FIFOs. When the BKOnNK bit is set to 1 (except when it has been set by FW), the BKOnNK bit is automatically cleared to 0 by clearing the FIFO.
2, 0	BKOnCC	These bits clear only the FIFO on the CPU side of the USFA0BOn register (reset the counter). 1: Clear the FIFO. When the BKOnNK bit is set to 1 (except when it has been set by FW), the BKOnNK bit is automatically cleared to 0 by clearing the FIFO.

Note $n = 1$ or 2

(31) Data end register (USFA0DEND)

This register specifies the toggle setting for the transmission system FIFO and reports the end of writing.

By writing 1 to each BKInT (n = 0 or 1) bit, the FIFO can automatically be toggled when the target endpoint FIFO becomes full.

By writing 1 to the ITnDEND (n = 0 or 1), BKInDEND (n = 0 or 1), and E0DDED bits, a target endpoint data transfer can be started. A bit to which 1 has been written is automatically cleared to 0. Writing 0 to the bit is invalid.

The related bits are invalid if the corresponding endpoint is not supported according to the setting of the USFA0EnIM register (n = 1, 3, 7, 8) and the current interface.

Access This register can be read or written in 8-bit units. (However, bits 4 to 0 are write-only and return 0 when read.)

Address 0D4_H

Initial value 00_H. This register is initialized by any reset.

	7	6	5	4	3	2	1	0
USFA0DEND	BKI2T	BKI1T	0	IT2DEND	IT1DEND	BKI2DED	BKI1DED	E0DED
	R/W	R/W	R	W	W	W	W	W

Table 27-39 USFA0DEND register contents (1/2)

Bit position	Bit name	Function
7, 6	BKInT	These bits specify whether toggling the FIFO is automatically executed if the FIFO on the CPU side of the USFA0Bin register becomes full as a result of DMA. 1: Automatically toggle the FIFO as soon as the FIFO has become full. 0: Do not automatically toggle the FIFO even if the FIFO becomes full. (Default)
4, 3	ITnDEND	Set these bits to 1 to transmit the data of the USFA0INTn register. When these bits are set to 1, the ITnNK bit is set to 1 and data is transferred. 1: Transmit a short packet. 0: Do not transmit a short packet. (Default) If the ITRnC bit of the USFA0FIC0 register is set to 1 and then these bits are set to 1 (the counter of the USFA0INTn register = 0 and the corresponding bit of the USFA0EPS0 register = 1), a Null packet (with a data length of 0) is transmitted. If data exists in the USFA0INTn register and these bits are set to 1 (the counter of the USFA0INTn register is not 0 and the corresponding bit of the USFA0EPS0 register = 1), a short packet is transmitted. These bits are automatically controlled by hardware when the FIFO is full.

Table 27-39 USFA0DEND register contents (2/2)

Bit position	Bit name	Function
2, 1	BKInDED	<p>Set these bits to 1 when writing transmitted data to the USFA0BIn register has been completed. When these bits are set to 1, the FIFO is toggled as soon as possible, the BKInNK bit is set to 1, and data is transferred.</p> <p>1: Transmit a short packet. 0: Do not transmit a short packet. (Default)</p> <p>These bits control the FIFO on the CPU side.</p> <p>If the BKInCC bit of the USFA0FIC0 register is set to 1 and then these bits are set to 1 (the counter of the USFA0BIn register = 0), a Null packet (with a data length of 0) is transmitted.</p> <p>If data exists in the USFA0BIn register and these bits are set to 1 (the counter of the USFA0BIn register is not 0), and if the FIFO is not full, a short packet is transmitted.</p> <p>If the FIFO on the CPU side of the USFA0BIn register becomes full as a result of DMA, with the PIO or BKInT bit set to 1, the hardware starts data transmission even if these bits are not set to 1.</p> <p>If the FIFO on the CPU side of the USFA0BIn register becomes full as a result of DMA, with the BKInT bit cleared to 0, be sure to set these bits to 1. (For details, see (3) "EPNAK register (USFA0EN)" in 27.7.2 "EPC control registers".)</p>
0	E0DED	<p>Set this bit to 1 to transmit the data of the USFA0E0W register. When this bit is set to 1, the EP0NKW bit is set to 1 and data is transferred.</p> <p>1: Transmit a short packet. 0: Do not transmit a short packet. (Default)</p> <p>If the EP0WC bit of the USFA0FIC0 register is set to 1 and if this bit is set to 1 (the counter of the USFA0E0W register = 0 and bit 1 of the USFA0EPS0 register = 1), a Null packet (with a data length of 0) is transmitted.</p> <p>If data exists in the USFA0E0W register and this bit is set to 1 (the counter of the USFA0E0W register is not 0 and bit 1 of the USFA0EPS0 register = 1), and if the FIFO is not full, a short packet is transmitted.</p>

Note n = 1 or 2

(32) GPR register (USFA0GPR)

This register controls the USBF and USB interface.

FW can reset the USBF by writing 1 to bit 0 of this register. A bit to which 1 has been written is automatically cleared to 0. Writing 0 to the bit is invalid.

Access This register is write-only, in 8-bit units. If this register is read, 00_H is read.

Address 0DC_H

Initial value 00_H. This register is initialized by any reset.

Caution Be sure to clear bits 7 to 1 to "0".

	7	6	5	4	3	2	1	0
USFA0GPR	0	0	0	0	0	0	0	MRST
	R	R	R	R	R	R	R	W

Table 27-40 USFA0GPR register contents

Bit position	Bit name	Function
0	MRST	Set this bit to 1 to reset the USBF. 1: Reset the USBF. Actually, USBF is reset two USB clocks after this bit has been set to 1 by FW and the write signal has become inactive. Resetting the USBF by using the MRST bit while the system clock is operating has the same result as resetting by using the $\overline{\text{RESET}}$ pin (hardware reset) (and the register value returns to the default value).

(33) Mode control register (USFA0MODC)

This register controls CPUDEC processing.

By setting each bit of this register, the setting of the USFA0MODS register can be changed. The bit of this register is automatically cleared to 0 only upon a hardware reset and when the MRST bit of the USFA0GRP register has been set to 1.

Even if the bit of this register has automatically been set to 1 by hardware, the setting by FW takes precedence.

Access This register can be read or written in 8-bit units.

Address 0E8_H

Initial value 00_H. This register is initialized by any reset.

- Notes**
1. This register is provided for debugging purposes. Usually, do not set this register except for verifying the operation or when a special mode is used.
 2. Be sure to clear bits 7 and 5 to 0 to "0". If they are set to 1, the operation is not guaranteed.

	7	6	5	4	3	2	1	0
USFA0MODC	0	CDCGDST	0	0	0	0	0	0
	R	R/W	R	R	R	R	R	R

Table 27-41 USFA0MODC register contents

Bit position	Bit name	Function
6	CDCGDST	Set this bit to 1 to switch the GET_DESCRIPTOR Configuration request to CPUDEC processing. By setting this bit to 1, the CDCGD bit of the USFA0MODS register can be forcibly set to 1. 1: Forcibly change the GET_DESCRIPTOR Configuration request to CPUDEC processing (set the CDCGD bit of the USFA0MODS register to 1). 0: Automatically process the GET_DESCRIPTOR Configuration request. (Default)

(34) Mode status register (USFA0MODS)

This register indicates the configuration status.

Access This register is read-only, in 8-bit units.

Address 0F0_H

Initial value 00_H. This register is initialized by any reset.

	7	6	5	4	3	2	1	0
USFA0MODS	0	CDCGD	0	MPACK	DFLT	CONF	0	0
	R	R	R	R	R	R	R	R

Table 27-42 USFA0MODS register contents

Bit position	Bit name	Function
6	CDCGD	This bit specifies whether CPUDEC processing is performed for the GET_DESCRIPTOR Configuration request. 1: Forcibly change the GET_DESCRIPTOR Configuration request to CPUDEC processing. 0: Automatically process the GET_DESCRIPTOR Configuration request. (Default)
4	MPACK	This bit indicates the transmitted packet size of Endpoint0. 1: Transmit a packet of a size other than 8 bytes. 0: Transmit an 8-byte packet. (Default). This bit is automatically set to 1 by hardware after the GET_DESCRIPTOR Device request has been processed (on normal completion of the status stage). It is not cleared to 0 until the USBF has been reset (and is not cleared to 0 by Bus Reset). If this bit is not set to 1, the hardware transfers only the automatically-executed request in 8-byte units. Therefore, even if data of more than 8 bytes is sent by using the OUT token to be processed by FW before completion of the GET_DESCRIPTOR Device request, the data is correctly received. This bit is ignored if the size of Endpoint0 is 8 bytes.
3	DFLT	This bit indicates the default status (DFLT bit = 1). 1: Responses are enabled. 0: Responses are disabled (never a response). (Default) This bit is automatically set to 1 by Bus Reset. No transaction for an endpoint is responded to until this bit is set to 1.
2	CONF	This bit indicates whether the SET_CONFIGURATION request has been completed. 1: The SET_CONFIGURATION request has been completed. 0: The SET_CONFIGURATION request has not been completed. (Default) This bit is set to 1 when Configuration value = 1 is received by the SET_CONFIGURATION request. Unless this bit is set to 1, access to an endpoint other than Endpoint0 is ignored. This bit is cleared to 0 when Configuration value = 0 is received by the SET_CONFIGURATION request. It is also cleared to 0 when Bus Reset is detected.

(35) Active interface number register (USFA0AIFN)

This register specifies the valid Interface number that correctly responds to the GET/SET_INTERFACE request. Because Interface 0 is always valid, Interfaces 1 to 4 can be selected.

Access This register can be read or written in 8-bit units.

Address 100_H

Initial value 00_H. This register is initialized by any reset.

	7	6	5	4	3	2	1	0
USFA0AIFN	ADDIF	0	0	0	0	0	IFNO1	IFNO0
	R/W	R	R	R	R	R	R/W	R/W

Table 27-43 USFA0AIFN register contents

Bit position	Bit name	Function															
7	ADDIF	This bit allows the use of Interfaces with numbers other than 0. 1: Support up to the Interface number specified by the IFNO1 and IFNO0 bits. 0: Support only Interface 0. (Default) Setting bits 1 and 0 of this register is invalid when this bit is not set to 1.															
1, 0	IFNO1, IFNO0	These bits specify the range of Interface numbers to be supported. <table border="1" data-bbox="552 987 1345 1205"> <thead> <tr> <th>IFNO1</th> <th>FNO0</th> <th>Valid Interface No.</th> </tr> </thead> <tbody> <tr> <td>1</td> <td>1</td> <td>0, 1, 2, 3, 4</td> </tr> <tr> <td>1</td> <td>0</td> <td>0, 1, 2, 3</td> </tr> <tr> <td>0</td> <td>1</td> <td>0, 1, 2</td> </tr> <tr> <td>0</td> <td>0</td> <td>0, 1</td> </tr> </tbody> </table>	IFNO1	FNO0	Valid Interface No.	1	1	0, 1, 2, 3, 4	1	0	0, 1, 2, 3	0	1	0, 1, 2	0	0	0, 1
IFNO1	FNO0	Valid Interface No.															
1	1	0, 1, 2, 3, 4															
1	0	0, 1, 2, 3															
0	1	0, 1, 2															
0	0	0, 1															

(36) Active alternative setting register (USFA0AAS)

This register specifies a link between the Interface number and Alternative Setting.

For the USBF of this microcontroller, a five-series Alternative Setting (for which Alternate Setting 0, 1, 2, 3, and 4 can be defined) and a two-series Alternative Setting (for which Alternative Setting 0 and 1 can be defined) can be specified for one Interface each.

Access This register can be read or written in 8-bit units.

Address 104_H

Initial value 00_H. This register is initialized by any reset.

	7	6	5	4	3	2	1	0
USFA0AAS	ALT2	IFAL21	IFAL20	ALT2EN	ALT5	IFAL51	IFAL50	ALT5EN
	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 27-44 USFA0AAS register contents

Bit position	Bit name	Function															
7, 3	ALT _n	These bits specify whether an n-series Alternative Setting is linked with Interface 0. When these bits are set to 1, the setting of the IFAL _n 1 and IFAL _n 0 bits is invalid. 1: Link an n-series Alternative Setting with Interface 0. 0: Do not link an n-series Alternative Setting with Interface 0. (Default)															
6, 5, 2, 1	IFAL _n 1, IFAL _n 0	These bits specify the Interface number to be linked with the n-series Alternative Setting. If the linked Interface number is outside the range specified by the USFA0AIFN register, the n-series Alternative Setting is invalid (ALT _n EN bit = 0). <table border="1" data-bbox="550 1160 1343 1373"> <thead> <tr> <th>IFAL_n1</th> <th>IFAL_n0</th> <th>Interface Number to Link</th> </tr> </thead> <tbody> <tr> <td>1</td> <td>1</td> <td>Link Interface 4.</td> </tr> <tr> <td>1</td> <td>0</td> <td>Link Interface 3.</td> </tr> <tr> <td>0</td> <td>1</td> <td>Link Interface 2.</td> </tr> <tr> <td>0</td> <td>0</td> <td>Link Interface 1.</td> </tr> </tbody> </table> Do not link a five-series Alternative Setting and a two-series Alternative Setting with the same Interface number.	IFAL _n 1	IFAL _n 0	Interface Number to Link	1	1	Link Interface 4.	1	0	Link Interface 3.	0	1	Link Interface 2.	0	0	Link Interface 1.
IFAL _n 1	IFAL _n 0	Interface Number to Link															
1	1	Link Interface 4.															
1	0	Link Interface 3.															
0	1	Link Interface 2.															
0	0	Link Interface 1.															
4, 0	ALT _n EN	These bits validate the n-series Alternative Setting. Unless these bits are set to 1, the setting of the ALT _n , IFAL _n 1, and IFAL _n 0 bits is invalid. 1: Validate the n-series Alternative Setting. 0: Do not validate the n-series Alternative Setting. (Default)															

Note n = 2 or 5

For example, when the USFA0AIFN register is set to 82_H and the USFA0AAS register is set to 15_H, Interfaces 0, 1, 2, and 3 are valid. Interfaces 0 and 2 support only Alternative Setting 0, Interface 1 supports Alternative Setting 0 and 1, and Interface 3 supports Alternative Setting 0, 1, 2, 3, and 4. With this setting, the requests GET_INTERFACE wIndex = 0/1/2/3, SET_INTERFACE wValue = 0 & wIndex = 0/2, SET_INTERFACE wValue = 0/1 & wIndex = 1, and SET_INTERFACE wValue = 0/1/2/3/4 & wIndex = 3 are automatically responded to, and a STALL response is made to the other GET/SET_INTERFACE requests.

(37) Alternative setting status register (USFA0ASS)

This register indicates the current status of the Alternative Setting.

Check this register when the SET_INT interrupt request has been issued. The value received by the SET_INTERFACE request is applied to the USFA0IFn register (n = 0 to 4) as well as to this register.

Access This register is read-only, in 8-bit units.

Address 108_H

Initial value 00_H. This register is initialized by any reset.

	7	6	5	4	3	2	1	0

(38) Endpoint1 interface mapping register (USFA0E1IM)

This register specifies the Interface and Alternative Setting for which Endpoint1 is valid.

The setting of this register and the Alternative Setting selected by the SET_INTERFACE request indicate whether Endpoint1 is currently valid, and the hardware determines how the GET_STATUS/CLEAR_FEATURE/SET_FEATURE Endpoint1 request and the IN transaction to Endpoint1 are responded to, and whether the related bits are valid or invalid.

Access This register can be read or written in 8-bit units.

Address 10C_H

Initial value 00_H. This register is initialized by any reset.

(Default)</p>																																			

Note n = 1 to 4

(39) Endpoint2 interface mapping register (USFA0E2IM)

This register specifies the Interface and Alternative Setting for which Endpoint2 is valid.

The setting of this register and the Alternative Setting selected by the SET_INTERFACE request indicate whether Endpoint2 is currently valid, and the hardware determines how the GET_STATUS/CLEAR_FEATURE/SET_FEATURE Endpoint2 request and the OUT transaction to Endpoint2 are responded to, and whether the related bits are valid or invalid.

Access This register can be read or written in 8-bit units.

Address 110_H

Initial value 00_H. This register is initialized by any reset.

27.7.3 Data hold registers

(1) EP0 read register (USFA0E0R)

The USFA0E0R register is a 64-byte FIFO that stores the OUT data sent from the host during the data stage of a control transfer to/from Endpoint0.

The hardware automatically transfers data to the USFA0E0R register when it has received the data from the host. When the data has been correctly received, the E0ODT bit of the USFA0IS1 register is set to 1, the USFA0E0L register holds the quantity of the received data, and an interrupt request (INTUSFA0I1) is issued. The USFA0E0L register always updates the received data length while it is receiving data. If the final transfer is correct reception, the interrupt request is generated. If the reception is abnormal, the USFA0E0L register is cleared to 0 and the interrupt request is not generated.

Use FW to read the data held by the USFA0E0R register, up to the value of the amount of data read by the USFA0E0L register. Make sure that all data has been read by using the EP0R bit of the USFA0EPS0 register. (The EP0R bit = 0 when all data has been read.) If the value of the USFA0E0L register is 0, the EP0NKR bit of the USFA0E0N register is cleared to 0, and the USFA0E0R register is ready for reception. The USFA0E0R register is cleared when the next SETUP token has been received.

Access This register is read-only, in 8-bit units. Writing to this register is ignored.

Address 200_H

Initial value Undefined.

Caution Be sure to read all the stored data. Clear the FIFO to discard some data.

	7	6	5	4	3	2	1	0

Table 27-52 USFA0E0R register contents

Bit position	Bit name	Function
7:0	E0R[7:0]	These bits store the OUT data sent from the host during the data stage of a control transfer to/from Endpoint0.

The operation of the USFA0E0R register is shown below.

Figure 27-4 USFA0E0R register operation

(2) EP0 length register (USFA0E0L)

The USFA0E0L register stores the length of the data held by the USFA0E0R register.

The USFA0E0L register always updates the received data length while it is receiving data. If the final transfer is abnormal reception, the USFA0E0L register is cleared to 0 and the interrupt request is not generated. If the reception is normal, the interrupt request is generated, and FW can read as much data from the USFA0E0R register as the value read from the USFA0E0L register. The value of the USFA0E0L register is decremented each time the USFA0E0R register has been read.

Access This register is read-only, in 8-bit units. Writing to this register is ignored.

Address 204_H

Default value 00_H. This register is initialized by any reset.

	7	6	5	4	3	2	1	0
USFA0E0L	E0L7	E0L6	E0L5	E0L4	E0L3	E0L2	E0L1	E0L0
	R	R	R	R	R	R	R	R

Table 27-53 USFA0E0L register contents

Bit position	Bit name	Function
7:0	E0L[7:0]	These bits store the length of the data held by the USFA0E0R register.

(3) EP0 setup register (USFA0E0ST)

The USFA0E0ST register holds the SETUP data sent from the host.

The USFA0E0ST register always writes data when a SETUP transaction has been received. The hardware sets the PROT bit of the USFA0IS1 register when it has correctly received the SETUP transaction. It sets the CPUDEC bit of the USFA0IS1 register in the case of an FW-processed request. Next, an interrupt request (INTUSFA0I1) is issued. In the case of an FW-processed request, be sure to read the request in 8-byte units. If it is not read in 8-byte units, the subsequent requests cannot be correctly decoded. The read counter of the USFA0E0ST register is not cleared even when Bus Reset is received.

Always read this counter in 8-byte units regardless of whether Bus Reset is received. Because the USFA0E0ST register always enables writing, the hardware overwrites data to this register even if a SETUP transaction is received while the data of the register is being read. Even if the SETUP transaction cannot be correctly received, the CPUDEC interrupt request and Protect interrupt request are not generated, but the previous data is discarded. If a SETUP token of less than 8 bytes is received, however, the received SETUP token is discarded, and the previously received SETUP data is retained. If the SETUP token is received more than once when one control transfer is executed, be sure to check the PROT bit of the USFA0IS1 register under the conditions below. If PROT bit = 1, read the USFA0E0ST register again because the SETUP transaction has been received more than once.

Access This register is read-only, in 8-bit units. Writing to this register is ignored.

Address 208_H

Initial value 00_H. This register is initialized by any reset.

(1) If a request is decoded by FW and the USFA0E0R register is read or the USFA0E0W register is written

(2) When preparing for a STALL response for a request to which the decode result does not correspond

Caution Be sure to read all the stored data. The USFA0E0ST register is always updated by the request in the SETUP transaction.

Bit position	Bit name	Function
7:0	E0S[7:0]	These bits hold the SETUP data sent from the host.

The operation of the USFA0E0ST register is shown below.

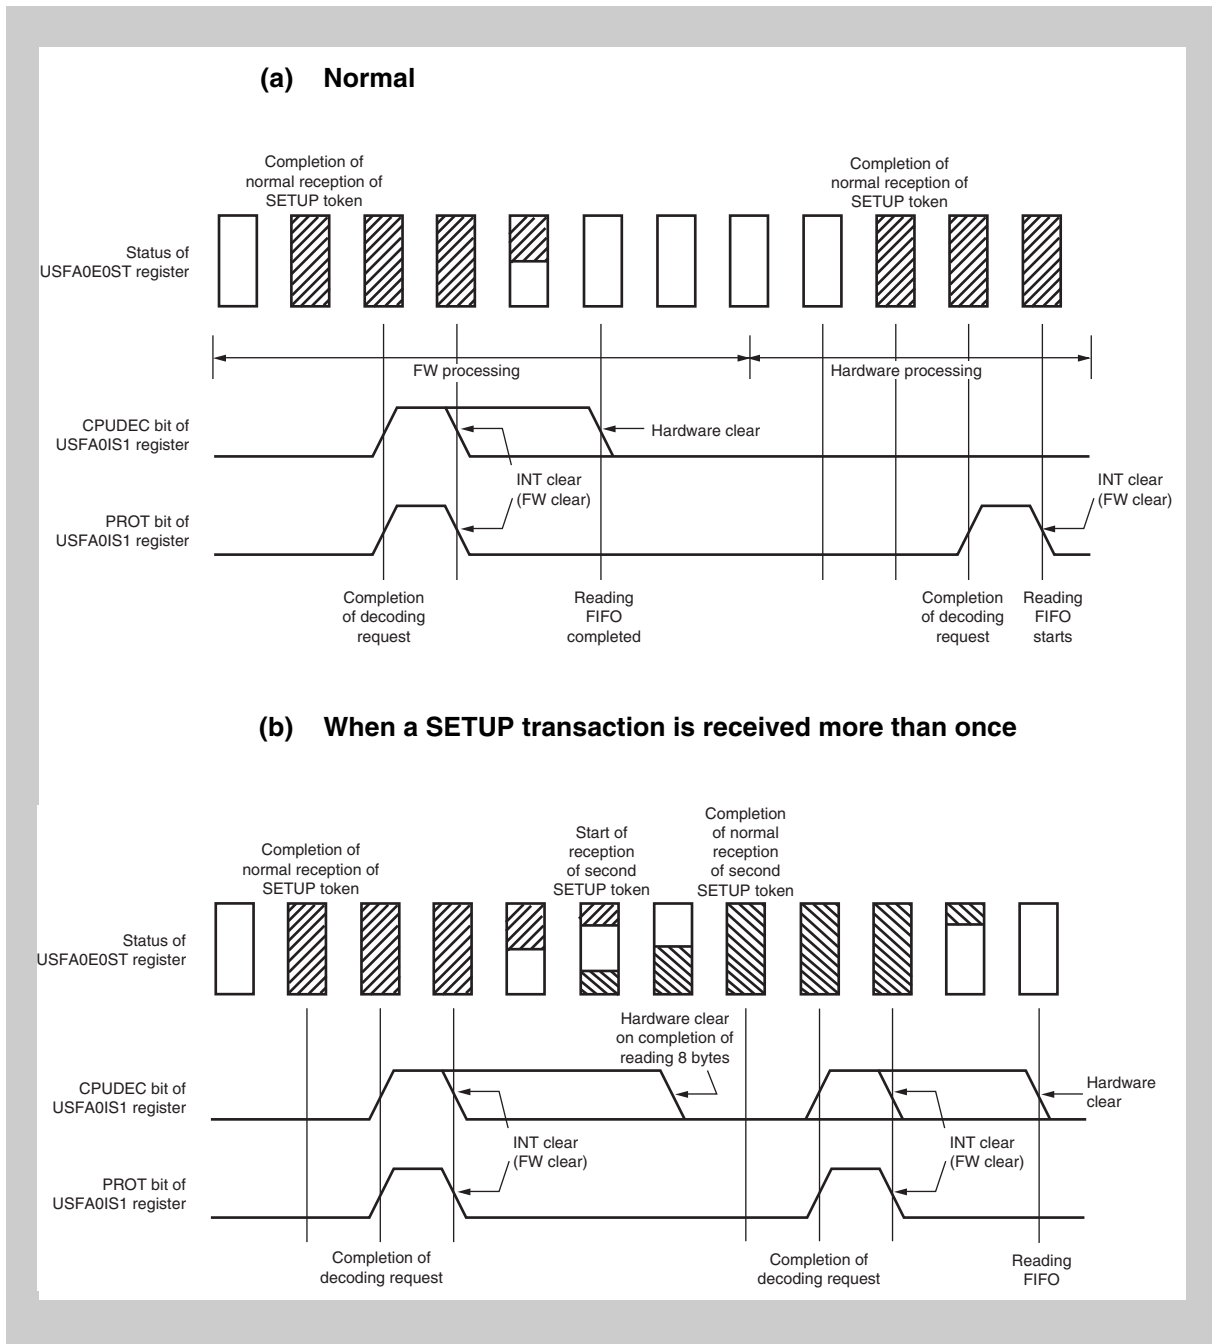

Figure 27-5 USFA0E0ST register operation

(4) EP0 write register (USFA0E0W)

The USFA0E0W register is a 64-byte FIFO that stores the IN data (passes it to SIE) sent to the host during the data stage to Endpoint0.

The hardware transmits data to the USB bus in synchronization with an IN token only when the EP0NKW bit of the USFA0E0N register is set to 1 (when NAK is not transmitted). When data is transmitted and when the host correctly receives the data, the EP0NKW bit of the USFA0E0N register is automatically cleared to 0 by hardware. A short packet is transmitted when data is written to the USFA0E0W register and the E0DED bit of the USFA0DEND register is set to 1 (EP0W bit of the USFA0EPS0 register = 1 (data exists)). A Null packet is transmitted when the USFA0E0W register is cleared and the E0DED bit of the USFA0DEND register is set to 1 (EP0W bit of the USFA0EPS0 register = 1 (data exists)).

The USFA0E0W register is cleared to 0 when the next SETUP token is received before transmission has been completed. If the stage of a control transfer (read) changes to the status stage while ACK has not been correctly received in the data stage, the USFA0E0W register is automatically cleared to 0. It is also cleared to 0 if the EP0NKW bit of the USFA0E0N register is 1 at the same time.

If the USFA0E0W register is read while no data is in it, 00_H is read.

Access This register is write-only, in 8-bit units. If this register is read, 00_H is read.

Address 20C_H

Initial value Undefined.

Bit position	Bit name	Function
7:0	E0W[7:0]	These bits store the IN data sent to the host during the data stage to Endpoint0.

The operation of the USFA0E0W register is shown below.

Figure 27-6 USFA0E0W register operation

(5) Bulk-out 1 register (USFA0BO1)

The USFA0BO1 register is a pair of 64-byte FIFOs that store data for Endpoint2. The USFA0BO1 register consists of two 64-byte FIFOs in a bank configuration, each of which performs a toggle operation and repeatedly connects the buses on the SIE and CPU sides. The toggle operation takes place when there is data in the FIFO on the SIE side but not in the FIFO on the CPU side (counter value = 0).

When the hardware receives data for Endpoint2 from the host, it automatically transfers the data to the USFA0BO1 register. When the register correctly receives the data, a FIFO toggle operation occurs. As a result, the BKO1DT bit of the USFA0IS3 register is set to 1, the amount of received data is held by the USFA0BO1L register, and an interrupt request or DMA request is issued to the CPU. Whether the interrupt request or DMA request is issued can be selected by using the DQBO1MS bit of the USFA0IDR register.

Use FW to read the data held by the USFA0BO1 register, up to the amount of data read by the USFA0BO1L register. When the correct received data is held by the FIFO connected to the SIE side and the value of the USFA0BO1L register reaches 0, the FIFO toggle operation occurs, and the BKO1NK bit of the USFA0EN register is automatically cleared to 0. If data greater than the value of the USFA0BO1L register is read and the FIFO toggle condition is satisfied, the FIFO toggle operation occurs. As a result, the next packet might be read by mistake. Note that, if the toggle condition is not satisfied, the first data is repeatedly read.

If overrun data is received while data is held by the FIFO connected to the CPU side, Endpoint2 stalls, and the FIFO on the CPU side is cleared.

If the USFA0BO1 register is read while no data is in it, an undefined value is read.

Access This register is read-only, in 8-bit units. Writing to this register is ignored.

Address 210_H

Initial value Undefined.

Caution Be sure to read all the stored data.

7:0	BKO[17:10]	These bits store data for Endpoint2.

The operation of the USFA0BO1 register is shown below.

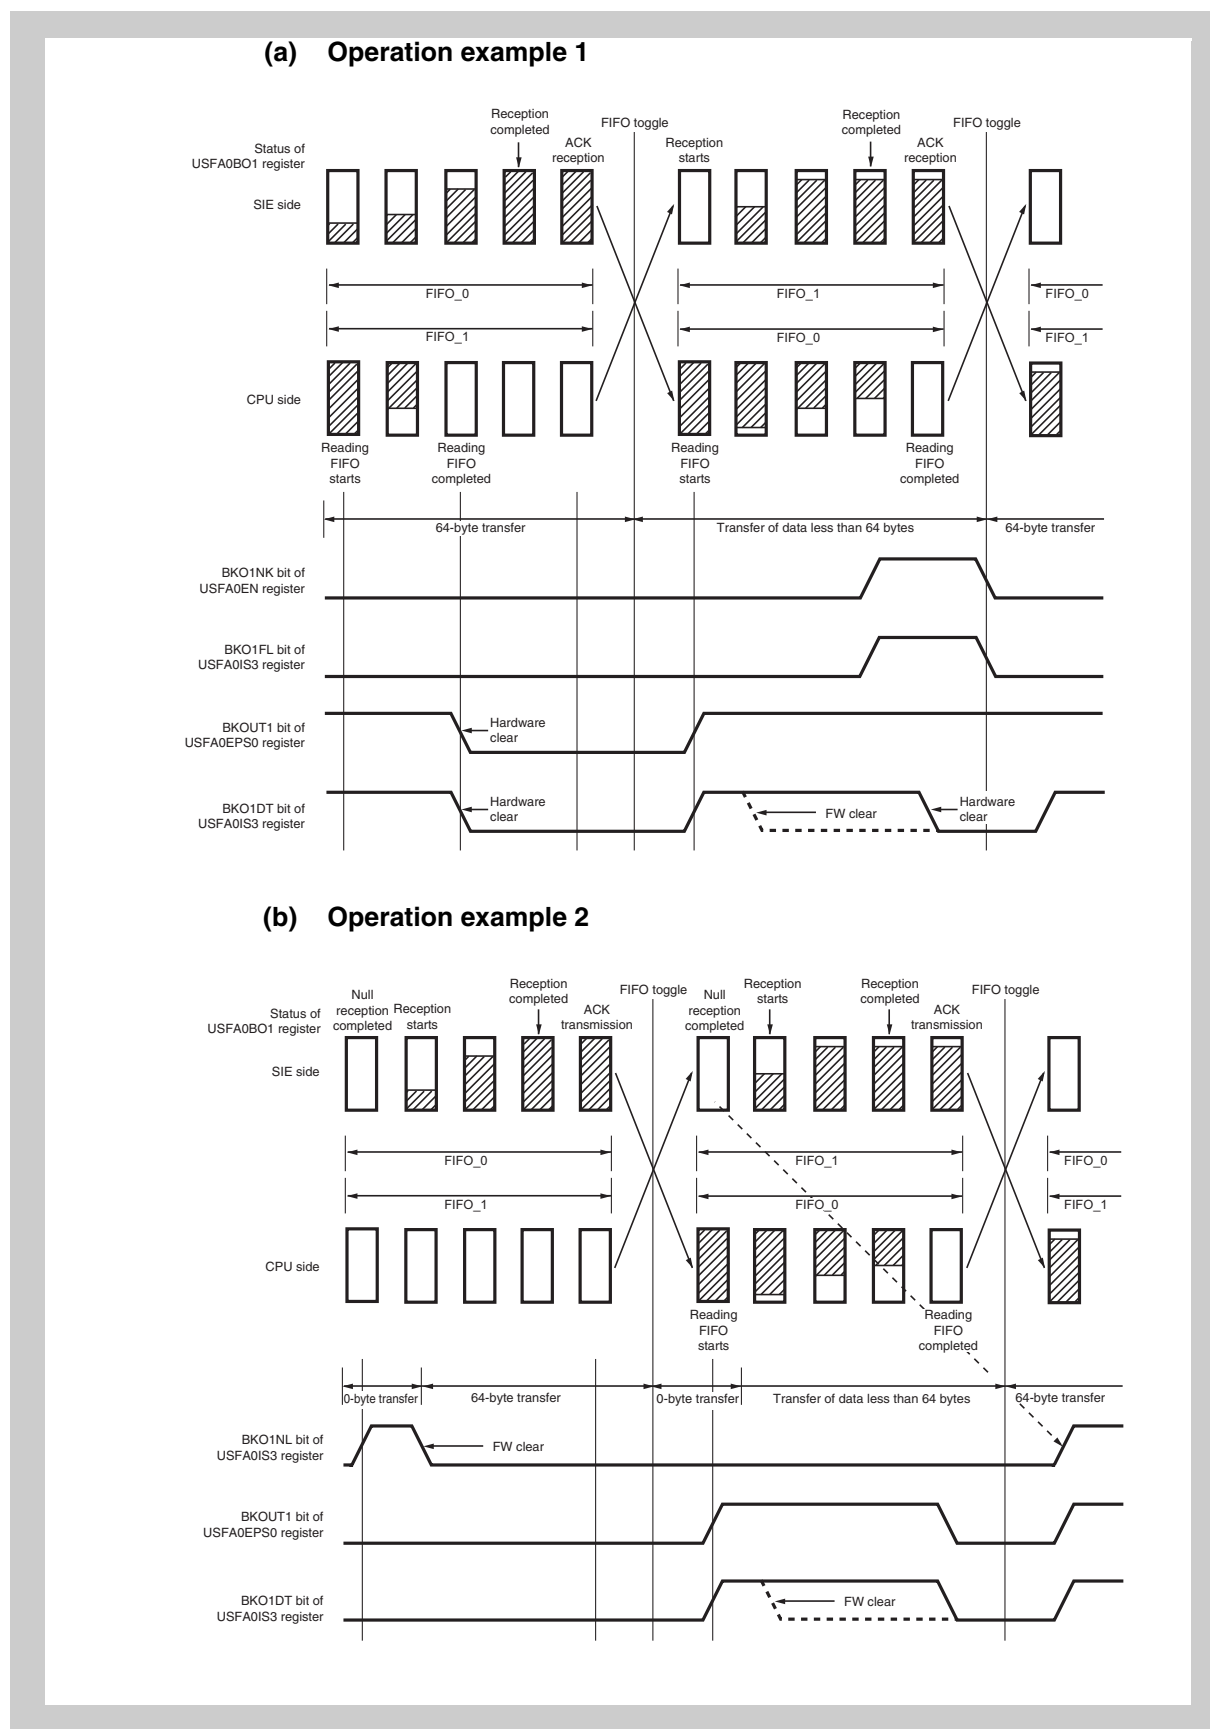

Figure 27-7 USFA0BO1 register operation

(6) Bulk-out 1 length register (USFA0BO1L)

The USFA0BO1L register stores the length of the data held by the USFA0BO1 register.

The USFA0BO1L register always updates the received data length while it is receiving data. If the final transfer results in abnormal reception, the USFA0BO1L register is cleared to 00_H, and an interrupt request is not generated. If the reception is normal, the interrupt request is generated, and FW can read as much data from the USFA0BO1 register as the value read from the USFA0BO1L register. The value of the USFA0BO1L register is decremented each time the USFA0BO1 register has been read.

Access This register is read-only, in 8-bit units. Writing to this register is ignored.

Address 214_H

Initial value 00_H. This register is initialized by any reset.

7:0	BKO1L[7:0]	These bits store the length of the data held by the USFA0BO1 register.

(7) Bulk-out 2 register (USFA0BO2)

The USFA0BO2 register is a pair of 64-bit FIFOs that store data for Endpoint4. The USFA0BO2 register consists of two 64-byte FIFOs in a bank configuration, each of which performs a toggle operation and repeatedly connects the buses on the SIE and CPU sides. The toggle operation takes place when there is data in the FIFO on the SIE side but not in the FIFO on the CPU side (counter value = 0).

When the hardware receives data for Endpoint4 from the host, it automatically transfers the data to the USFA0BO2 register. When the register correctly receives the data, a FIFO toggle operation occurs. As a result, the BKO2DT bit of the USFA0IS3 register is set to 1, the amount of received data is held by the USFA0BO2L register, and an interrupt request or DMA request is issued to the CPU. Whether the interrupt request or DMA request is issued can be selected by using the DQBO2MS bit of the USFA0IDR register.

Use FW to read the data held by the USFA0BO2 register, up to the amount of data read by the USFA0BO2L register. When the correct received data is held by the FIFO connected to the SIE side and the value of the USFA0BO2L register reaches 0, the FIFO toggle operation occurs, and the BKO2NK bit of the USFA0EN register is automatically cleared to 0. If data greater than the value of the USFA0BO2L register is read and the FIFO toggle condition is satisfied, the FIFO toggle operation occurs. As a result, the next packet might be read by mistake. Note that, if the toggle condition is not satisfied, the first data is repeatedly read.

If overrun data is received while data is held by the FIFO connected to the CPU side, Endpoint4 stalls, and the FIFO on the CPU side is cleared.

If the USFA0BO2 register is read while no data is in it, an undefined value is read.

Access This register is read-only, in 8-bit units. Writing to this register is ignored.

Address 218_H

Initial value Undefined.

Caution Be sure to read all the stored data.

Bit position	Bit name	Function
7:0	BKO2L[7:0]	These bits store the length of the data held by the USFA0BO2 register.

(9) Bulk-in 1 register (USFA0BI1)

The USFA0BI1 register is a pair of 64-byte FIFOs that store data for Endpoint1. The USFA0BI1 register consists of two 64-byte FIFOs in a bank configuration, each of which performs a toggle operation and repeatedly connects the buses on the SIE and CPU sides. The toggle operation takes place when there is no data in the FIFO on the SIE side (counter value = 0) and when the FIFO on the CPU side is correctly written (FIFO full or BKI1DED bit = 1).

The hardware transmits data to the USB bus in synchronization with the IN token for Endpoint1 only when the BKI1NK bit of the USFA0EN register is set to 1 (when NAK is not transmitted). The address at which data is to be written or read is managed by the hardware. Therefore, FW can transmit data to the host only by writing the data to the USFA0BI1 register sequentially. A short packet is transmitted when data is written to the USFA0BI1 register and the BKI1DED bit of the USFA0DEND register is set to 1 (BKIN1 bit of USFA0EPS0 register = 1 (data exists)). A Null packet is transmitted when the USFA0BI1 register is cleared and the BKI1DED bit of the USFA0DEND register is set to 1 (BKIN1 bit of the USFA0EPS0 register = 1 (data exists)). When the data is transmitted correctly, a FIFO toggle operation occurs, the BKI1DT bit of the USFA0IS2 register is set to 1, and an interrupt request is generated for the CPU. An interrupt request or DMA request can be selected by using the DQB11MS bit of the USFA0IDR register.

Access This register is write-only, in 8-bit units. If this register is read, 00_H is read.

Address 220_H

Initial value Undefined.

(10) Bulk-in 2 register (USFA0BI2)

The USFA0BI2 register is a pair of 64-byte FIFOs that store data for Endpoint3. The USFA0BI2 register consists of two 64-byte FIFOs in a bank configuration, each of which performs a toggle operation and repeatedly connects the buses on the SIE and CPU sides. The toggle operation takes place when there is no data in the FIFO on the SIE side (counter value = 0) and when the FIFO on the CPU side is correctly written (FIFO full or BKI2DED bit = 1).

The hardware transmits data to the USB bus in synchronization with the IN token for Endpoint3 only when the BKI2NK bit of the USFA0EN register is set to 1 (when NAK is not transmitted). The address at which data is to be written or read is managed by the hardware. Therefore, FW can transmit data to the host only by writing the data to the USFA0BI2 register sequentially. A short packet is transmitted when data is written to the USFA0BI2 register and the BKI1DED bit of the USFA0DEND register is set to 1 (BKIN2 bit of USFA0EPS0 register = 1 (data exists)). A Null packet is transmitted when the USFA0BI2 register is cleared and the BKI2DED bit of the USFA0DEND register is set to 1 (BKIN2 bit of the USFA0EPS0 register = 1 (data exists)). When the data is transmitted correctly, a FIFO toggle operation occurs, the BKI2DT bit of the USFA0IS2 register is set to 1, and an interrupt request is generated for the CPU. An interrupt request or DMA request can be selected by using the DQB12MS bit of the USFA0IDR register.

Access This register is write-only, in 8-bit units. If this register is read, 00_H is read.

(11) Interrupt 1 register (USFA0INT1)

The USFA0INT1 register is a 64-byte FIFO that stores data for Endpoint7 (to be passed to SIE).

The hardware transmits data to the USB bus in synchronization with the IN token for Endpoint7 only when the IT1NK bit of the USFA0EN register is set to 1 (when NAK is not transmitted). When the data is transmitted and the host correctly receives it, the IT1NK bit of the USFA0EN register is automatically cleared to 0 by hardware. A short packet is transmitted when data is written to the USFA0INT1 register and the IT1DEND bit of the USFA0DEND register is set to 1 (IT1 bit of the USFA0EPS0 register = 1 (data exists)). A Null packet is transmitted when the USFA0INT1 register is cleared and the IT1DEND bit of the USFA0DEND register is set to 1 (IT1 bit of the USFA0EPS0 register = 1 (data exists)).

Access This register is write-only, in 8-bit units. If this register is read, 00_H is read.

Address 228_H

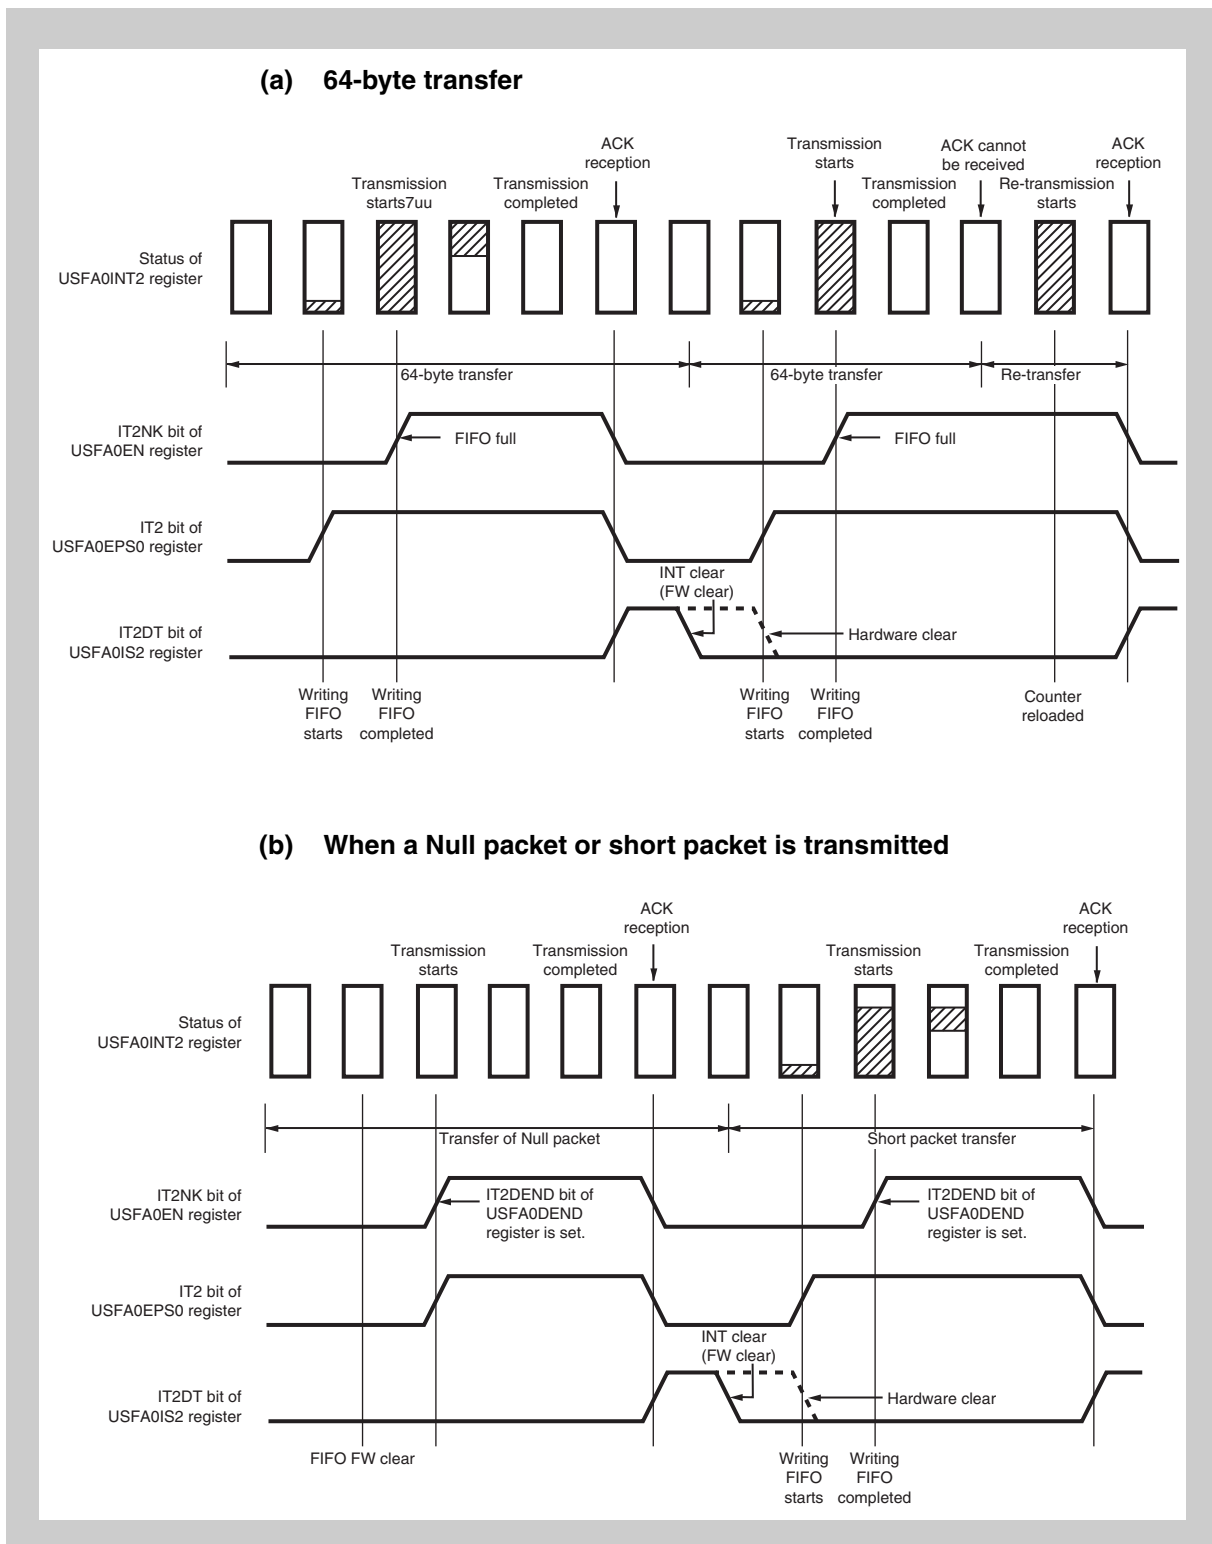

Figure 27-16 USFA0INT2 register operation

27.7.4 EPC request data registers

(1) Device status register (USFA0DST)

This register stores the value that is to be returned in response to the GET_STATUS Device request.

The hardware automatically transmits the contents of this register to the host when it has received the GET_STATUS Device request.

Access These registers can be read or written in 8-bit units.

Address 288_H

Initial value 00_H. This register is initialized by any reset.

Caution To rewrite this register, set the EP0NKA bit to 1 before reading the register contents, and then rewrite the register contents after confirming that the bit has been set, in order to prevent a conflict between reading and writing.

	7	6	5	4	3	2	1	0
USFA0DST	0	0	0	0	0	0	RMWK	SFPW
	R	R	R	R	R	R	R/W	R/W

Table 27-64 USFA0DST register contents

Bit position	Bit name	Function
1	RMWK	This bit specifies whether the remote wakeup function of the device is used. 1: Enabled 0: Disabled If the device supports the remote wakeup function, this bit is set to 1 by hardware when the SET_FEATURE Device request has been received, and is cleared to 0 by hardware when the CLEAR_FEATURE Device request has been received. If the device does not support the remote wakeup function, make sure that the SET_FEATURE Device request is not issued from the host.
0	SFPW	This bit indicates whether the device is self-powered or bus-powered. 1: Self-powered 0: Bus-powered

(2) EP0 status register (USFA0E0S)

This register stores the value that is to be returned in response to the GET_STATUS Endpoint0 request.

If an error occurs in USBF, the E0HALT bit is set to 1 by FW. Writing to this register is ignored while a USB-side access to Endpoint0 is being received.

When the E0HALT bit is set to 1 by FW, it is not applied until the next SETUP token is received if the control transfer immediately before is for SET_FEATURE Endpoint0, CLEAR_FEATURE Endpoint0, a GET_STATUS Endpoint0 request, or an FW-processed request.

The hardware automatically transmits the contents of this register to the host when it has received the GET_STATUS Endpoint0 request. If Endpoint0 has stalled, the USFA0E0W and USFA0E0R registers are cleared, and the EP0NKW and EP0NKR bits of the USFA0E0N register are cleared to 0.

Access This register can be read or written in 8-bit units. However, data can be written to this register only when the EP0NKA bit is set to 1.

Address 298_H

Initial value 00_H. This register is initialized by any reset.

Caution To rewrite this register, set the EP0NKA bit to 1 before reading the register contents, and then rewrite the register contents after confirming that the bit has been set, in order to prevent a conflict between reading and writing.

	7	6	5	4	3	2	1	0
USFA0E0S	0	0	0	0	0	0	0	E0HALT
	R	R	R	R	R	R	R	R/W

Table 27-65 USFA0E0S register contents

Bit position	Bit name	Function
0	E0HALT	This bit indicates the status of Endpoint0. 1: Endpoint0 has stalled. 0: Endpoint0 has not stalled. This bit is set to 1 by hardware when the SET_FEATURE Endpoint0 request has been received, and cleared to 0 by hardware when the CLEAR_FEATURE Endpoint0 request has been received. DATA PID is initialized to DATA0.

(3) EP1 status register (USFA0E1S)

This register stores the value that is to be returned in response to the GET_STATUS Endpoint1 request.

If an error occurs in Endpoint1, the E1HALT bit is set to 1. Writing to this register is ignored while a USB-side access to Endpoint1 is being received.

The hardware automatically transmits the contents of this register to the host when it has received the GET_STATUS Endpoint1 request. If Endpoint1 has stalled, the USFA0BI1 register is cleared and the BK11NK bit is cleared to 0.

Because writing to this register is always masked when a transfer to Endpoint1, rather than a control transfer, is executed, be sure to check whether data has been correctly written to this register.

Access This register can be read or written in 8-bit units. However, data can be written to this register only when the EP0NKA bit is set to 1.

Address 2A0_H

Initial value 00_H. This register is initialized by any reset.

Caution To rewrite this register, set the EP0NKA bit to 1 before reading the register contents, and then rewrite the register contents after confirming that the bit has been set, in order to prevent a conflict between reading and writing.

	7	6	5	4	3	2	1	0
USFA0E1S	0	0	0	0	0	0	0	E1HALT
	R	R	R	R	R	R	R	R/W

Bit position	Bit name	Function
0	E1HALT	<p>This bit indicates the status of Endpoint1.</p> <p>1: Endpoint1 has stalled.</p> <p>0: Endpoint1 has not stalled.</p> <p>This bit is set to 1 by hardware when the SET_FEATURE Endpoint1 request has been received. It is cleared to 0 by hardware when the CLEAR_FEATURE Endpoint1 request, SET_CONFIGURATION request, or SET_INTERFACE request for the interface to which Endpoint1 is linked has correctly been received. DATA PID is initialized to DATA0.</p>

(4) EP2 status register (USFA0E2S)

This register stores the value that is to be returned in response to the GET_STATUS Endpoint2 request.

If an error occurs in Endpoint2, the E2HALT bit is set to 1. Writing to this register is ignored while a USB-side access to Endpoint2 is being received.

The hardware automatically transmits the contents of this register to the host when it has received the GET_STATUS Endpoint2 request. If Endpoint2 has stalled, the USFA0BO1 register is cleared and the BKO1NK bit is cleared to 0.

Because writing to this register is always masked when a transfer to Endpoint2, rather than a control transfer, is executed, be sure to check whether data has been correctly written to this register.

Access This register can be read or written in 8-bit units. However, data can be written to this register only when the EP0NKA bit is set to 1.

Address 2A8_H

Initial value 00_H. This register is initialized by any reset.

Caution To rewrite this register, set the EP0NKA bit to 1 before reading the register contents, and then rewrite the register contents after confirming that the bit has been set, in order to prevent a conflict between reading and writing.

	7	6	5	4	3	2	1	0

It is cleared to 0 by hardware when the CLEAR_FEATURE Endpoint2 request, SET_CONFIGURATION request, or SET_INTERFACE request for the interface to which Endpoint2 is linked has correctly been received. DATA PID is initialized to DATA0.</p>

(5) EP3 status register (USFA0E3S)

This register stores the value that is to be returned in response to the GET_STATUS Endpoint3 request.

If an error occurs in Endpoint3, the E3HALT bit is set to 1. Writing to this register is ignored while a USB-side access to Endpoint3 is being received.

The hardware automatically transmits the contents of this register to the host when it has received the GET_STATUS Endpoint3 request. If Endpoint3 has stalled, the USFA0BI2 register is cleared and the BKI2NK bit is cleared to 0.

Because writing to this register is always masked when a transfer to Endpoint3, rather than a control transfer, is executed, be sure to check whether data has been correctly written to this register.

Access This register can be read or written in 8-bit units. However, data can be written to this register only when the EP0NKA bit is set to 1.

Address 2B0_H

Initial value 00_H. This register is initialized by any reset.

Caution To rewrite this register, set the EP0NKA bit to 1 before reading the register contents, and then rewrite the register contents after confirming that the bit has been set, in order to prevent a conflict between reading and writing.

0	E3HALT	<p>This bit indicates the status of Endpoint3.</p> <p>1: Endpoint3 has stalled.</p> <p>0: Endpoint3 has not stalled.</p> <p>This bit is set to 1 by hardware when the SET_FEATURE Endpoint3 request has been received. It is cleared to 0 by hardware when the CLEAR_FEATURE Endpoint3 request, SET_CONFIGURATION request, or SET_INTERFACE request for the interface to which Endpoint3 is linked has correctly been received. DATA PID is initialized to DATA0.</p>

(6) EP4 status register (USFA0E4S)

This register stores the value that is to be returned in response to the GET_STATUS Endpoint4 request.

If an error occurs in Endpoint4, the E4HALT bit is set to 1. Writing to this register is ignored while a USB-side access to Endpoint4 is being received.

The hardware automatically transmits the contents of this register to the host when it has received the GET_STATUS Endpoint4 request. If Endpoint4 has stalled, the USFA0BO2 register is cleared and the BKO2NK bit is cleared to 0.

Because writing to this register is always masked when a transfer to Endpoint4, rather than a control transfer, is executed, be sure to check whether data has been correctly written to this register.

Access This register can be read or written in 8-bit units. However, data can be written to this register only when the EP0NKA bit is set to 1.

Address 2B8_H

Initial value 00_H. This register is initialized by any reset.

Caution To rewrite this register, set the EP0NKA bit to 1 before reading the register contents, and then rewrite the register contents after confirming that the bit has been set, in order to prevent a conflict between reading and writing.

Bit position	Bit name	Function
0	E4HALT	<p>This bit indicates the status of Endpoint4.</p> <p>1: Endpoint4 has stalled.</p> <p>0: Endpoint4 has not stalled.</p> <p>This bit is set to 1 by hardware when the SET_FEATURE Endpoint4 request has been received. It is cleared to 0 by hardware when the CLEAR_FEATURE Endpoint4 request, SET_CONFIGURATION request, or SET_INTERFACE request for the interface to which Endpoint4 is linked has correctly been received. DATA PID is initialized to DATA0.</p>

(7) EP7 status register (USFA0E7S)

This register stores the value that is to be returned in response to the GET_STATUS Endpoint7 request.

If an error occurs in Endpoint7, the E7HALT bit is set to 1. Writing to this register is ignored while a USB-side access to Endpoint7 is being received.

The hardware automatically transmits the contents of this register to the host when it has received the GET_STATUS Endpoint7 request. If Endpoint7 has stalled, the USFA0INT1 register is cleared and the IT1NK bit is cleared to 0.

Because writing to this register is always masked when a transfer to Endpoint7, rather than a control transfer, is executed, be sure to check whether data has been correctly written to this register.

Access This register can be read or written in 8-bit units. However, data can be written to this register only when the EP0NKA bit is set to 1.

Address 2D0_H

Initial value 00_H. This register is initialized by any reset.

Caution To rewrite this register, set the EP0NKA bit to 1 before reading the register contents, and then rewrite the register contents after confirming that the bit has been set, in order to prevent a conflict between reading and writing.

	7	6	5	4	3	2	1	0
USFA0E7S	0	0	0	0	0	0	0	E7HALT
	R	R	R	R	R	R	R	R/W

Table 27-70 USFA0E7S register contents

Bit position	Bit name	Function
0	E7HALT	<p>This bit indicates the status of Endpoint7.</p> <p>1: Endpoint7 has stalled.</p> <p>0: Endpoin7 has not stalled.</p> <p>This bit is set to 1 by hardware when the SET_FEATURE Endpoint7 request has been received. It is cleared to 0 by hardware when the CLEAR_FEATURE Endpoint7 request, SET_CONFIGURATION request, or SET_INTERFACE request for the interface to which Endpoint7 is linked has correctly been received. DATA PID is initialized to DATA0.</p>

(8) EP8 status register (USFA0E8S)

This register stores the value that is to be returned in response to the GET_STATUS Endpoint8 request.

If an error occurs in Endpoint8, the E8HALT bit is set to 1. Writing to this register is ignored while a USB-side access to Endpoint8 is being received.

The hardware automatically transmits the contents of this register to the host when it has received the GET_STATUS Endpoint8 request. If Endpoint8 has stalled, the USFA0INT2 register is cleared and the IT2NK bit is cleared to 0.

Because writing to this register is always masked when a transfer to Endpoint8, rather than a control transfer, is executed, be sure to check whether data has been correctly written to this register.

Access This register can be read or written in 8-bit units. However, data can be written to this register only when the EP0NKA bit is set to 1.

Address 2D8_H

Initial value 00_H. This register is initialized by any reset.

Caution To rewrite this register, set the EP0NKA bit to 1 before reading the register contents, and then rewrite the register contents after confirming that the bit has been set, in order to prevent a conflict between reading and writing.

	7	6	5	4	3	2	1	0
USFA0E8S	0	0	0	0	0	0	0	E8HALT
	R	R	R	R	R	R	R	R/W

Table 27-71 USFA0E8S register contents

Bit position	Bit name	Function
0	E8HALT	<p>This bit indicates the status of Endpoint8.</p> <p>1: Endpoint8 has stalled.</p> <p>0: Endpoint8 has not stalled.</p> <p>This bit is set to 1 by hardware when the SET_FEATURE Endpoint8 request has been received. It is cleared to 0 by hardware when the CLEAR_FEATURE Endpoint8 request, SET_CONFIGURATION request, or SET_INTERFACE request for the interface to which Endpoint8 is linked has correctly been received. DATA PID is initialized to DATA0.</p>

(9) Address register (USFA0ADRS)

This register stores the device address.

The device address sent by the SET_ADDRESS request is analyzed and the resulting value is automatically written to this register. If the SET_ADDRESS request is processed by FW, the value of this register is applied as the device address when the SUCCESS signal is received in the status stage.

Access This register is read-only, in 8-bit units.

Address 300_H

Initial value 00_H. This register is initialized by any reset.

Caution Do not write to this register. If the register is written to, the operation is not guaranteed.

	7	6	5	4	3	2	1	0
USFA0ADRS	0	ADRS6	ADRS5	ADRS4	ADRS3	ADRS2	ADRS1	ADRS0
	R	R	R	R	R	R	R	R

Table 27-72 USFA0ADRS register contents

Bit position	Bit name	Function
6:0	ADRS[6:0]	These bits hold the SIE device address.

(10) Configuration register (USFA0CNF)

This register stores the value that is to be returned in response to the GET_CONFIGURATION request.

When the SET_CONFIGURATION request is received, its wValue is automatically written to this register.

When a change of the value of this register from 00_H to other than 00_H is detected, the CONF bit of the USFA0MODS register is set to 1. If the SET_CONFIGURATION request is processed by FW, the status of this register is immediately applied to the USFA0MODS register as soon as data has been written to this register (CONF bit = 1 before completion of the status stage).

Access This register is read-only, in 8-bit units.

Address 304_H

Initial value 00_H. This register is initialized by any reset.

Caution Do not write to this register. If the register is written to, the operation is not guaranteed.

	7	6	5	4	3	2	1	0
USFA0CNF	0	0	0	0	0	0	CONF1	CONF0
	R	R	R	R	R	R	R	R

Table 27-73 USFA0CNF register contents

Bit position	Bit name	Function
1, 0	CONF1, CONF0	These bits hold the data to be returned in response to the GET_CONFIGURATION request.

(11) Interface 0 register (USFA0IF0)

This register stores the value that is to be returned in response to the GET_INTERFACE wIndex = 0 request.

When the SET_INTERFACE request is received, its wValue is automatically written to this register.

If the SET_INTERFACE request is processed by FW, wIndex and wValue are decoded, and the endpoint setting is automatically changed. At this time, the status bit of the target endpoint and DPID are automatically cleared to 0, depending on the setting. The FIFO is not cleared automatically.

Access This register is read-only, in 8-bit units.

Address 308_H

Initial value 00_H. This register is initialized by any reset.

Caution Do not write to this register. If the register is written to, the operation is not guaranteed.

	7	6	5	4	3	2	1	0
USFA0IF0	0	0	0	0	0	IF02	IF01	IF00
	R	R	R	R	R	R	R	R

Table 27-74 USFA0IF0 register contents

Bit position	Bit name	Function
2:0	IF0[2:0]	These bits hold the data to be returned in response to the GET_INTERFACE wIndex = 0 request.

(12) Interface 1 to 4 registers (USFA0IF1 to USFA0IF4)

These registers store the value that is to be returned in response to the GET_INTERFACE wIndex = n request (n = 1 to 4).

When the SET_INTERFACE request is received, its wValue is automatically written to these registers.

These registers are disabled according to the setting of the USFA0AIFN and USFA0AAS registers.

If the SET_INTERFACE request is processed by FW, wIndex and wValue are decoded, and the endpoint setting is automatically changed. At this time, the status bit of the target endpoint and DPID are automatically cleared to 0, depending on the setting. The FIFO is not cleared automatically.

Access These registers are read-only, in 8-bit units.

Address 30C_H: USFA0IF1

310_H: USFA0IF2

314_H: USFA0IF3

318_H: USFA0IF4

Initial value 00H. These registers are initialized by any reset.

Caution Do not write to these registers. If the registers are written to, the operation is not guaranteed.

	7	6	5	4	3	2	1	0
USFA0IF1	0	0	0	0	0	IF12	IF11	IF10
	R	R	R	R	R	R	R	R
USFA0IF2	0	0	0	0	0	IF22	IF21	IF20
	R	R	R	R	R	R	R	R
USFA0IF3	0	0	0	0	0	IF32	IF31	IF30
	R	R	R	R	R	R	R	R
USFA0IF4	0	0	0	0	0	IF42	IF41	IF40
	R	R	R	R	R	R	R	R

Table 27-75 USFA0IF1 to USFA0IF4 register contents

Bit position	Bit name	Function
2:0	IFn[2:0]	These bits hold the data to be returned in response to the GET_INTERFACE wIndex = n request.

Note n = 1 to 4

(13) Descriptor length register (USFA0DSCL)

This register stores the length of the value that is to be returned in response to the GET_DESCRIPTOR Configuration request. The value of this register is the number of bytes of all the descriptors set by the USFA0CIEn register minus 1 ($n = 0$ to 255). The total descriptor length that is to be returned in response to the GET_DESCRIPTOR Configuration request is determined according to the value of this register.

wLength processing is automatically controlled. If this register is set to 00_H, it means the descriptor to be returned is 1 byte long. If the register is set to FF_H, a descriptor length of 256 bytes is returned. When a descriptor exceeding 256 bytes in length is used, set the CDCGDST bit of the USFA0MODC register to 1 and process the GET_DESCRIPTOR request by using FW. (At this time, the CDCGD bit of the USFA0MODS register is also set to 1.)

Access This register can be read or written in 8-bit units. However, data can be written to this register only when the EP0NKA bit is set to 1.

Address 340_H

Initial value 00_H. This register is initialized by any reset.

Caution To rewrite this register, set the EP0NKA bit to 1 before reading the register contents, and then rewrite the register contents after confirming that the bit has been set, in order to prevent a conflict between reading and writing.

	7	6	5	4	3	2	1	0
USFA0DSCL	DPL7	DPL6	DPL5	DPL4	DPL3	DPL2	DPL1	DPL0
	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 27-76 USFA0DSCL register contents

Bit position	Bit name	Function
7:0	DPL[7:0]	These bits specify the value of the number of bytes of all the descriptors to be returned in response to the GET_DESCRIPTOR Configuration request minus 1.

(14) Device descriptor registers 0 to 17 (USFA0DD0 to USFA0DD17)

These registers store the value to be returned in response to the GET_DESCRIPTOR Device request.

Access These registers can be read or written in 8-bit units. However, data can be written to these registers only when the EP0NKA bit is set to 1.

Address For details, see Table 27-77 “Mapping and data of device descriptor registers”.

Initial value Undefined.

- Notes**
1. To rewrite these registers, set the EP0NKA bit to 1 before reading the register contents, and then rewrite the register contents after confirming that the bit has been set, in order to prevent a conflict between reading and writing.
 2. Use the value defined by USB Specification Ver. 2.0 and the latest Class Specification as the setting.

Table 27-77 Mapping and data of device descriptor registers

Symbol	Address	Field Name	Description
USFA0DD0	344 _H	bLength	Size of this descriptor
USFA0DD1	348 _H	bDescriptorType	Device descriptor type
USFA0DD2	34C _H	bcdUSB	Value after the decimal point of the revision number in the USB specifications
USFA0DD3	350 _H		Value before the decimal point of the revision number in the USB specifications
USFA0DD4	354 _H	bDeviceClass	Class code
USFA0DD5	358 _H	bDeviceSubClass	Subclass code
USFA0DD6	35C _H	bDeviceProtocol	Protocol code
USFA0DD7	360 _H	bMaxPacketSize0	Maximum packet size of Endpoint0
USFA0DD8	364 _H	idVendor	Lower value of the vendor ID
USFA0DD9	368 _H		Higher value of the vendor ID
USFA0DD10	36C _H	idProduct	Lower value of the product ID
USFA0DD11	370 _H		Higher value of the product ID
USFA0DD12	374 _H	bcdDevice	Lower value of the device release number
USFA0DD13	378 _H		Higher value of the device release number
USFA0DD14	37C _H	iManufacturer	Index of the string descriptor describing the manufacturer
USFA0DD15	380 _H	iProduct	Index of the string descriptor describing the product
USFA0DD16	384 _H	iSerialNumber	Index of the string descriptor describing the device serial number
USFA0DD17	388 _H	BNumConfigurations	Number of settable configurations

(15) Configuration/interface/endpoint descriptor registers 0 to 255 (USFA0CIE0 to USFA0CIE255)

These registers store the value to be returned in response to the GET_DESCRIPTOR Configuration request.

Up to 256 bytes of descriptor information can be stored in these registers. Store each descriptor in the order of Configuration, Interface, and Endpoint (see Table 27-78 "Mapping of USFA0CIE_n Registers"). If there are multiple Interfaces, repeatedly store the data following the Interface descriptor.

Access These registers can be read or written in 8-bit units. However, data can be written to these registers only when the EPONKA bit is set to 1.

Address 38C_H to 788_H

Initial value Undefined.

Table 27-78 Mapping of USFA0CIE_n Registers

Address	Register	Stored Descriptor
38C _H	USFA0CIE0	Configuration descriptor 0
...
3AC _H	USFA0CIE8	Configuration descriptor 8
3B0 _H	USFA0CIE9	Interface0 descriptor 0
...
3D0 _H	USFA0CIE17	Interface0 descriptor 0
3D4 _H	USFA0CIE18	Endpoint1 descriptor 0
...
3EC _H	USFA0CIE24	Endpoint1 descriptor 6
3F0 _H	USFA0CIE25	Endpoint2 descriptor 0
...
408 _H	USFA0CIE31	Endpoint2 descriptor 6
40C _H	USFA0CIE32	Endpoint3 descriptor 0
...
XXX _H	USFA0CIE _{xxx}	Interfacex descriptor 0 (Create the descriptor according to the endpoints supported by the interface.)
...
XXX _H + 20 _H	USFA0CIE _{xxx} + 8	Interfacex descriptor 8
XXX _H + 24 _H	USFA0CIE _{xxx} + 9	Endpoint1 descriptor 0
...
XXX _H + 3C _H	USFA0CIE _{xxx} + 15	Endpoint1 descriptor 6
XXX _H + 40 _H	USFA0CIE _{xxx} + 16	Endpoint2 descriptor 0
...
XXX _H + 58 _H	USFA0CIE _{xxx} + 22	Endpoint2 descriptor 6
XXX _H + 5C _H	USFA0CIE _{xxx} + 23	Interfacex descriptor 0
...

The range of the valid data that can be specified for these registers varies according to the setting of the USFA0DSCL register. In addition to the descriptors listed in *Table 27-78 “Mapping of USFA0CIEn Registers”*, descriptors specific to classes and vendors can also be stored.

If all the values are fixed, they can be stored in ROM.

- Notes**
1. To rewrite these registers, set the EP0NKA bit to 1 before reading the register contents, and then rewrite the register contents after confirming that the bit has been set, in order to prevent a conflict between reading and writing.
 2. Use the value defined by USB Specification Ver. 2.0 and the latest Class Specification as the setting.

Table 27-79 USFA0CIEn register data

(a) Configuration descriptor (9 bytes)

Offset	Field Name	Description
0	bLength	Size of this descriptor
1	bDescriptorType	Descriptor type
2	wTotalLength	Lower value of the total number of bytes of the Configuration descriptor, all Interface descriptors, and all Endpoint descriptors
3		Higher value of the total number of bytes of the Configuration descriptor, all interface descriptors, and all endpoint descriptors
4	bNumInterface	Number of interfaces
5	bConfigurationValue	Value to select this Configuration
6	iConfiguration	Index of the string descriptor describing this Configuration
7	bmAttributes	Configuration features (self-powered, no remote wakeup)
8	MaxPower	Maximum power consumption of this Configuration (unit: mA) ^a

a) The power consumption is shown in 2 mA units. (Example: 50 = 100 mA)

(b) Interface descriptor (9 bytes)

Offset	Field Name	Description
0	bLength	Size of this descriptor
1	bDescriptorType	Descriptor type
2	bInterfaceNumber	Value of this interface
3	bAlternateSetting	Value to select the alternative interface setting
4	bNumEndpoints	Number of usable endpoints
5	bInterfaceClass	Class code
6	bInterfaceSubClass	Subclass code
7	bInterfaceProtocol	Protocol code
8	Interface	Index of the string descriptor describing this interface

(c) Endpoint descriptor (7 bytes)

Offset	Field Name	Description
0	bLength	Size of this descriptor
1	bDescriptorType	Descriptor type
2	bEndpointAddress	Address/transfer direction of this endpoint
3	bmAttributes	Transfer type
4	wMaxPaketSize	Lower value of the maximum data transfer number
5		Higher value of the maximum data transfer number
6	bInterval	Transfer interval

27.7.5 Bridge registers

(1) H-bus bridge interrupt status register (USFA0BRGINT)

This register indicates the status of the interrupts generated by the H-bus bridge.

Access This register can be read or written in 32-bit units.

Address 808_H

Initial value 0000 0000_H. This register is initialized by any reset.

	31	30	29	28	27	26	25	24
USFA0BRGINT	0	0	0	DMA_ERRINT[4:1]			0	
	R	R	R	R/W	R/W	R/W	R/W	R
	23	22	21	20	19	18	17	16
	0	0	0	DMA_ENDINT[4:1]			0	
	R	R	R	R/W	R/W	R/W	R/W	R
	15	14	13	12	11	10	9	8
	0	0	0	0	0	0	0	0
	R	R	R	R	R	R	R	R
	7	6	5	4	3	2	1	0
	0	MBUS_ERRINT	SBUS_ERRINT1	SBUS_ERRINT0	ERR_MASTER[3:0]			
	R	R/W	R/W	R/W	R	R	R	R

Table 27-80 USFA0BRGINT register contents

Bit position	Bit name	Function
28:25	DMA_ERRINT [4:1]	These bits are set to 1 when, during a DMA transfer with EPC, the epc_drqb signal becomes inactive faster than the maximum packet size in bursts specified for EPn_MPKT[8:0]. Writing 1 to the DMA_ERRINT[4:1] bits clears them to 0.
20:17	DMA_ENDINT [4:1]	These bits are set to 1 when a DMA transfer finishes successfully or such a transfer terminates with an error. Writing 1 to the DMA_ENDINT[4:1] bits clears them to 0.
6	MBUS_ERRINT	This bit is set to 1 if an error response is received when attempting to access the H bus during master operation. Writing 1 to the MBUS_ERRINT bit clears it to 0.
5	SBUS_ERRINT1	When there is access from the master specified by NOT_RETRY_MASTER, an error response is generated and this bit is set to 1. Writing 1 to the SBUS_ERRINT1 bit clears it to 0.
4	SBUS_ERRINT0	When there is access that uses a bus width of 32 bits or more, an error response is generated and this bit is set to 1. Writing 1 to the SBUS_ERRINT0 bit clears it to 0.
3:0	ERR_MASTER [3:0]	These bits store the master number in the error response generated when the SBUS_ERRINT1 or SBUS_ERRINT0 bit is set to 1. The ERR_MASTER[3:0] bits retain their current value until SBUS_ERRINT[1:0] is cleared to 00, even if another source is generated.

(2) H-bus bridge interrupt enable register (USFA0BRGINTE)

This register controls the interrupts generated by the H-bus bridge.

Access This register can be read or written in 32-bit units.

Address 80C_H

Initial value 0000 0000_H. This register is initialized by any reset.

	31	30	29	28	27	26	25	24
USFA0BRGINTE	0	0	0	DMA_ERRINTEN[4:1]				0
	R	R	R	R/W	R/W	R/W	R/W	R
	23	22	21	20	19	18	17	16
	0	0	0	DMA_ENDINTEN[4:1]				0
	R	R	R	R/W	R/W	R/W	R/W	R
	15	14	13	12	11	10	9	8
	0	0	0	VBUS_	0	0	0	0
	R	R	R	INTEN	R	R	R	R
	7	6	5	4	3	2	1	0
	0	MBUS_	SBUS_	SBUS_	0	0	0	0
	R	ERRINTEN	ERRINT1EN	ERRINT0EN	R	R	R	R
		R/W	R/W	R/W				

Table 27-81 USFA0BRGINTE register contents

Bit position	Bit name	Function
28:25	DMA_ERRINTEN [4:1]	These bits control whether to output an interrupt when the DMA_ERRINT[4:1] bits are set to 1. 0: Do not output the interrupt. 1: Output the interrupt.
20:17	DMA_ENDINTEN [4:1]	These bits control whether to output an interrupt when the DMA_ENDINT[4:1] bits are set to 1. 0: Do not output the interrupt. 1: Output the interrupt.
12	VBUS_INTEN	This bit controls whether to output an interrupt when the VBUS_INT bit is set to 1. 0: Do not output the interrupt. 1: Output the interrupt.
6	MBUS_ERRINT	This bit controls whether to output an interrupt when the MBUS_ERRINT bit is set to 1. 0: Do not output the interrupt. 1: Output the interrupt.
5	SBUS_ERRINT1EN	This bit controls whether to output an interrupt when the SBUS_ERRINT1 bit is set to 1. 0: Do not output the interrupt. 1: Output the interrupt.
4	SBUS_ERRINT0EN	This bit controls whether to output an interrupt when the SBUS_ERRINT0 bit is set to 1. 0: Do not output the interrupt. 1: Output the interrupt.

(3) EPC interrupt status register (USFA0EPCINT)

This register indicates the status of the interrupts generated by EPC.

Access This register is read-only, in 32-bit units.

Address 810_H

Initial value 0000 0000_H. This register is initialized by any reset.

	31	30	29	28	27	26	25	24
USFA0EPCINT	0	0	0	0	0	0	0	0
	R	R	R	R	R	R	R	R
	23	22	21	20	19	18	17	16
	0	0	0	0	0	0	0	0
	R	R	R	R	R	R	R	R
	15	14	13	12	11	10	9	8
	0	0	0	0	0	0	0	0
	R	R	R	R	R	R	R	R
	7	6	5	4	3	2	1	0
	0	0	0	0	0	EPC_INT2	EPC_INT1	EPC_INT0
	R	R	R	R	R	R	R	R

Table 27-82 USFA0EPCINT register contents

Bit position	Bit name	Function
2	EPC_INT2	This bit indicates the interrupt source of the INT status 4 register (USFA0IS4). If the USFA0IS4 register has changed, 1 is set.
1	EPC_INT1	This bit indicates the interrupt source of the INT status 2 register (USFA0IS2). If the USFA0IS2 register has changed, 1 is set. The bit also indicates the interrupt source of the INT status 3 register. Like USFA0IS3, if the USFA0IS3 register has changed, 1 is set.
0	EPC_INT0	This bit indicates the interrupt source of the INT status 0 register (USFA0IS0). If the USFA0IS0 register has changed, 1 is set. The bit also indicates the interrupt source of the INT status 1 register. Like USFA0IS0, if the USFA0IS register has changed, 1 is set.

(4) EPC interrupt enable register (USFA0EPCINTE)

This register controls the interrupts generated by EPC.

Access This register can be read or written in 32-bit units.

Address 814_H

Initial value 0000 0000_H. This register is initialized by any reset.

	31	30	29	28	27	26	25	24
USFA0EPCINTE	0	0	0	0	0	0	0	0
	R	R	R	R	R	R	R	R
	23	22	21	20	19	18	17	16
	0	0	0	0	0	0	0	0
	R	R	R	R	R	R	R	R
	15	14	13	12	11	10	9	8
	0	0	0	0	0	0	0	0
	R	R	R	R	R	R	R	R
	7	6	5	4	3	2	1	0
	0	0	0	0	0	EPC_ INT2EN	EPC_ INT1EN	EPC_ INT0EN
	R	R	R	R	R	R/W	R/W	R/W

Table 27-83 USFA0EPCINTE register contents

Bit position	Bit name	Function
2	EPC_ INT2EN	This bit controls whether to output an interrupt when the EPC_INT2 bit is set to 1. 0: Do not output the interrupt. 1: Output the interrupt.
1	EPC_ INT1EN	This bit controls whether to output an interrupt when the EPC_INT1 bit is set to 1. 0: Do not output the interrupt. 1: Output the interrupt.
0	EPC_ INT0EN	This bit controls whether to output an interrupt when the EPC_INT0 bit is set to 1. 0: Do not output the interrupt. 1: Output the interrupt.

(5) EPC macro control register (USFA0EPCCTL)

This register controls the reset signal to the EPC circuit.

Access This register can be read or written in 32-bit units.

Address 818_H

Initial value 00000001_H. This register is initialized by any reset.

	31	30	29	28	27	26	25	24
USFA0EPCCTL	0	0	0	0	0	0	0	0
	R	R	R	R	R	R	R	R
	23	22	21	20	19	18	17	16
	0	0	0	0	0	0	0	0
	R	R	R	R	R	R	R	R
	15	14	13	12	11	10	9	8
	0	0	0	0	0	0	0	0
	R	R	R	R	R	R	R	R
	7	6	5	4	3	2	1	0
	0	0	0	0	0	0	0	EPC_RST
	R	R	R	R	R	R	R	R/W

Table 27-84 USFA0EPCCTL register contents

Bit position	Bit name	Function
0	EPC_RST	This bit controls the reset signal to EPC. The initial value is 1 (the reset status). 0: Cancel the reset. 1: Reset EPC.

(6) Endpoint n DMA control register 1 (USFA0EnDC1)

This register sets up DMA transfer control.

Access This register can be read or written in 32-bit units.

Address 910_H (USFA0E1DC1)

920_H (USFA0E2DC1)

930_H (USFA0E3DC1)

940_H (USFA0E4DC1)

Initial value 0000 0000_H. This register is initialized by any reset.

Table 27-87 USFA0EnTAD register contents

Bit position	Bit name	Function
31:0	HBn_TADR[31:0]	<p>These bits specify the starting address for performing a transfer to the H bus side. Except for when the end packet is a short packet, transfers are performed in 32-bit units for the H bus, so the lower two bits are fixed to 00.</p> <p>The value of the USFA0EnTAD register is incremented each time a DMA transfer is performed.</p> <p>In addition, even when transferring short packets for which the number of bytes is not divisible by 4, the value of the USFA0EnTAD register is incremented in 4-byte units. For example, when 63 bytes are transferred, the value is incremented by 64 (40_H).</p> <p>Specify values for the HBnSTATADR[31:0] bits only when the EPnREQEN bit is 0.</p>

The following flowcharts show the program execution when the host is disconnected and then reconnected, as well as the program execution when power is supplied.

Figure 27-17 Flowchart of program when host is disconnected and then reconnected

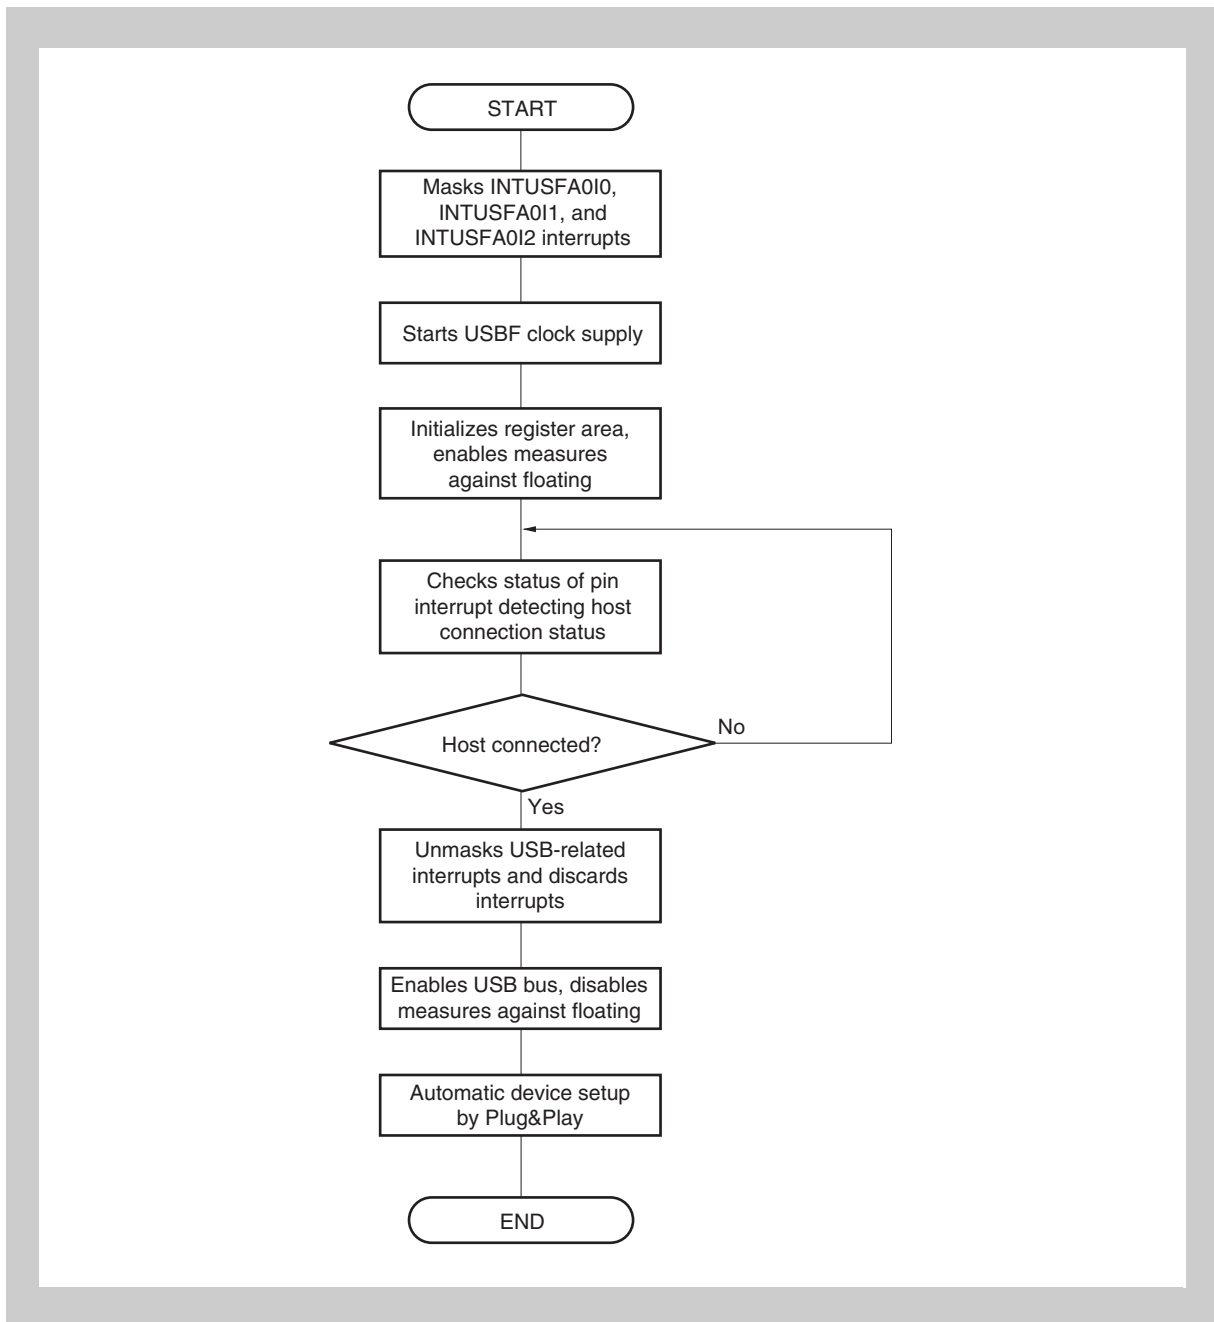

Figure 27-18 Flowchart of program when power is supplied

27.8 STALL Handshake or No Handshake

USBF error handling is defined as follows:

Transfer type	Transaction	Target packet	Error type	Function response	Processing
Control transfer, bulk transfer, interrupt transfer	IN/OUT/SETUP	Token	Endpoint not supported	No response	None
			Endpoint transfer direction mismatch	No response	
			CRC error	No response	
			Bit stuffing error	No response	
Control transfer, bulk transfer	OUT/SETUP	Data	Timeout	No response	None
			PID check error	No response	
			Unsupported PID (other than data PID)	No response	
			CRC error	No response	
	Bit stuffing error	No response			
OUT	Data	Data PID mismatch	ACK		
Control transfer (SETUP stage)	SETUP	Data	Overrun	No response	Received data is discarded.
Control transfer (data stage)	OUT	Data	Overrun	No response ^a	The SNDSTL bit of USFA0SDS register is set to 1 and the received data is discarded.
Control transfer (status stage)	OUT	Data	Overrun	ACK or no response ^b	
Bulk transfer	OUT	Data	Overrun	No response ^a	The EnHALT bit of the USFA0EnS register (n = 0 to 4, 7) is set to 1.
Control transfer, bulk transfer, interrupt transfer	IN	Handshake	PID check error	–	Transferred data is held and re-transferred. ^c
			Unsupported PID (other than ACK PID)	–	
			Timeout	–	

- a) A STALL is returned in response to re-transfer by the host.
b) An ACK response is returned if the transfer data is of MaxPacketSize or less and the data received in the status stage is discarded. If MaxPacketSize is exceeded, no response is returned, the SNDSTL bit of the USFA0SDS register is set to 1, and the received data is discarded.
c) If an OUT transaction indicating a change from the data stage to the status stage is received during a control transfer, an error is not handled and it is assumed that reception has been correctly completed.

-
- Notes**
1. The currently specified Alternative Setting number is used to judge whether the target endpoint is valid or invalid.
 2. For details about the response to the request included in a control transfer to or from Endpoint0, see *27.6?Requests?*.
-

27.9 Register Values in Specific Status

Table 27-88 Register values in a specific status (1/2)

Register name	After a CPU reset ($\overline{\text{RESET}}$)	After a bus reset

USFA0IF2 register	0000 0000 _H	0000 0000 _H
USFA0IF3 register	0000 0000 _H	0000 0000 _H
USFA0IF4 register	0000 0000 _H	0000 0000 _H
USFA0DSCL register	0000 0000 _H	The value is held.
USFA0DDn registers (n = 0 to 17)	b	b
USFA0CIEn registers (n = 0 to 255)	b	b

- a) This register is cleared to 0 when the $\overline{\text{RESET}}$ signal is asserted because the data in this register, including the write pointer, counter, and read pointer, is controlled by using a FIFO, in the same manner as when the USFA0FICn register is cleared.
- b) These registers cannot be cleared to 0. Because data can be written to them by using FW, however, any value can be written to the registers. (Before doing so, however, be sure to set the EPONKA bit of the USFA0E0NA register to 1.)

27.10 FW Processing

The following FW processing is performed:

- Setup processing on the device side for the SET_CONFIGURATION, SET_INTERFACE, SET_FEATURE, and CLEAR_FEATURE requests during enumeration processing
- Analysis and processing of XXXXStandard, XXXXClass, and XXXXVendor requests not subject to automatic processing
- Reading data following a bulk-transferred OUT token from the Rx buffer
- Writing data to be returned in response to a bulk-transferred IN token
- Writing data to be returned in response to an interrupt-transferred token

The following table lists the requests supported by FW:

Table 27-89 FW-supported standard requests

Request	Reception side	Processing /frequency	Description
CLEAR_FEATURE	Interface	Automatic STALL response	Though this request is reserved for bmRequestType, it is assumed that this request does not come to the interface because no function selector value is specified. When this request is received, the hardware makes an automatic STALL response.
SET_FEATURE	Interface	Automatic STALL response	Though it the request is reserved for bmRequestType, it is assumed that this request does not come to the interface because no function selector value is specified. When this request is received, the hardware makes an automatic STALL response.
GET_DESCRIPTOR	String	FW	FW returns the string descriptor. When this request is received by using the SETUP token, the hardware generates the CPUDEC interrupt request for FW. FW decodes the contents of the received request, and then writes the data to be returned to the host to the USFA0E0W register.
SET_DESCRIPTOR	Device	FW	FW rewrites the device descriptor. When this request is received by using the SETUP token, the hardware generates the CPUDEC interrupt request for FW. FW decodes the contents of the received request, and then writes the data for the next control transfer (OUT) to the USFA0DDn register (n = 0 to 17).
SET_DESCRIPTOR	Configuration	FW	FW rewrites the configuration descriptor. When this request is received by using the SETUP token, the hardware generates the CPUDEC interrupt request for FW. FW decodes the contents of the received request, and then writes the data for the next control transfer (OUT) to the USFA0CIEn register (n = 0 to 255).
SET_DESCRIPTOR	String	FW	FW rewrites the string descriptor. When this request is received by using the SETUP token, the hardware generates the CPUDEC interrupt request for FW. FW decodes the contents of the received request, and then loads the data for the next control transfer (OUT).
Other	NA	FW	When a request other than the above is received by using the SETUP token, the hardware generates the CPUDEC interrupt request for FW. FW decodes the contents of the received request, and then performs the necessary processing.

27.10.1 Initialization

Initialization is executed in the following two ways:

- Initializing the request data register
- Setting up interrupts

During initialization of request data registers, data for the GET_XXXX request to which a response is automatically returned is written, and an endpoint is assigned to the corresponding interface. In the interrupt settings, the interrupt sources that do not have to be checked can be masked by using the USFA0IMn register (n = 0 to 4).

The following flowcharts show the related processing.

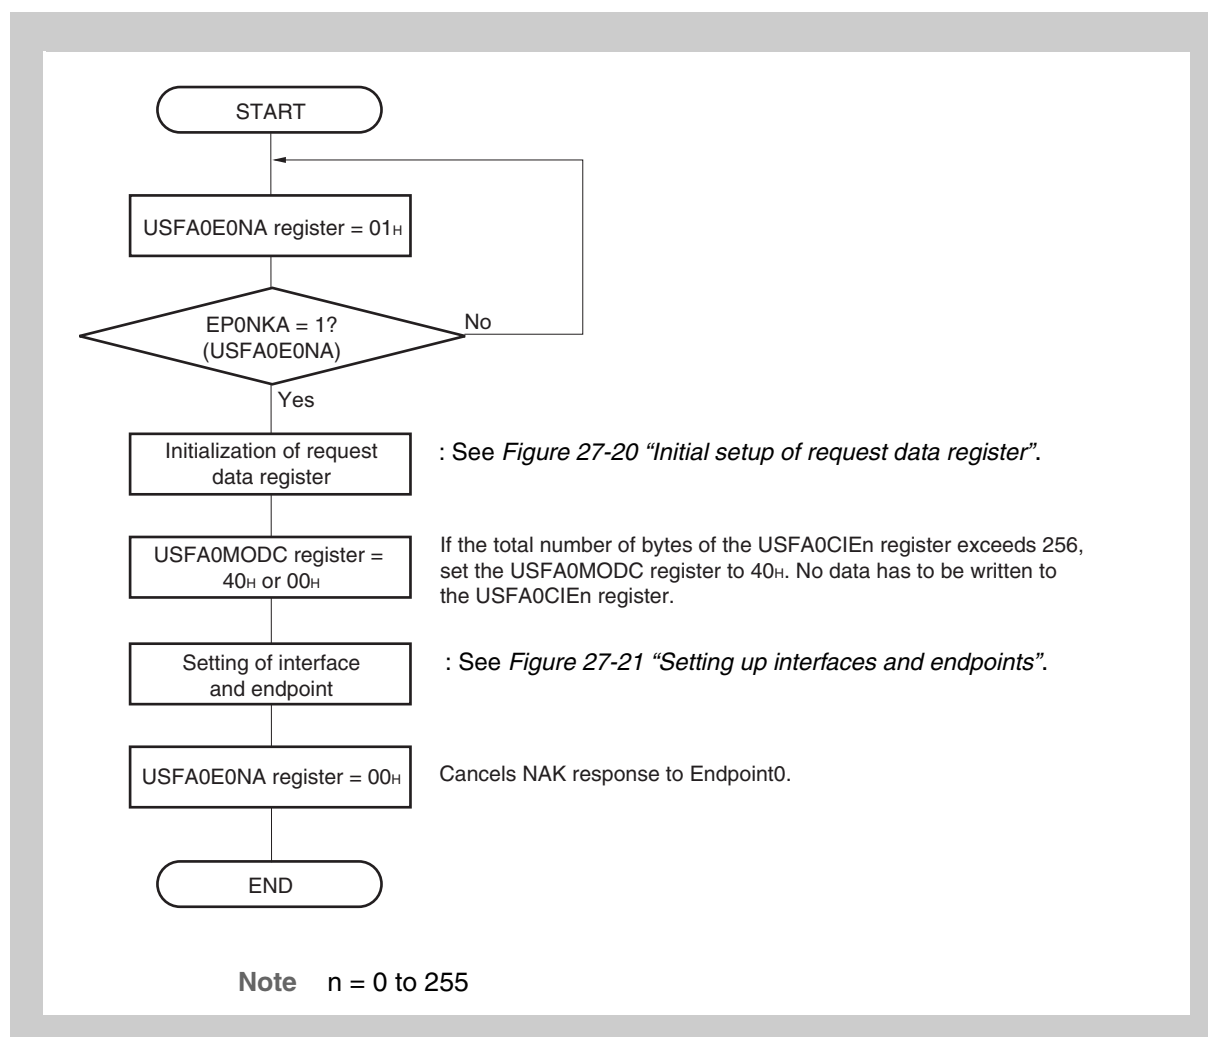

Figure 27-19 Initializing request data registers

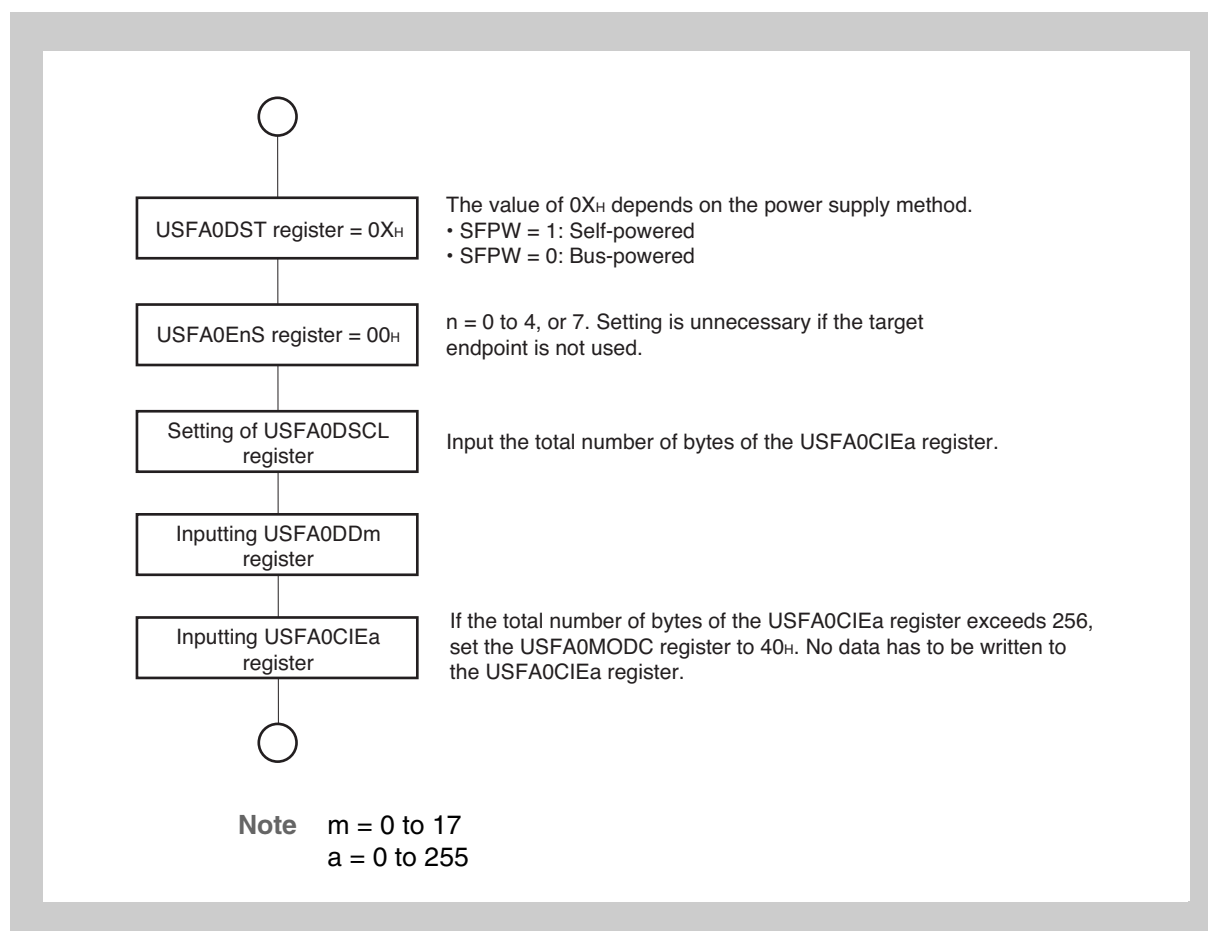

Figure 27-20 Initial setup of request data register

Figure 27-21 Setting up interfaces and endpoints

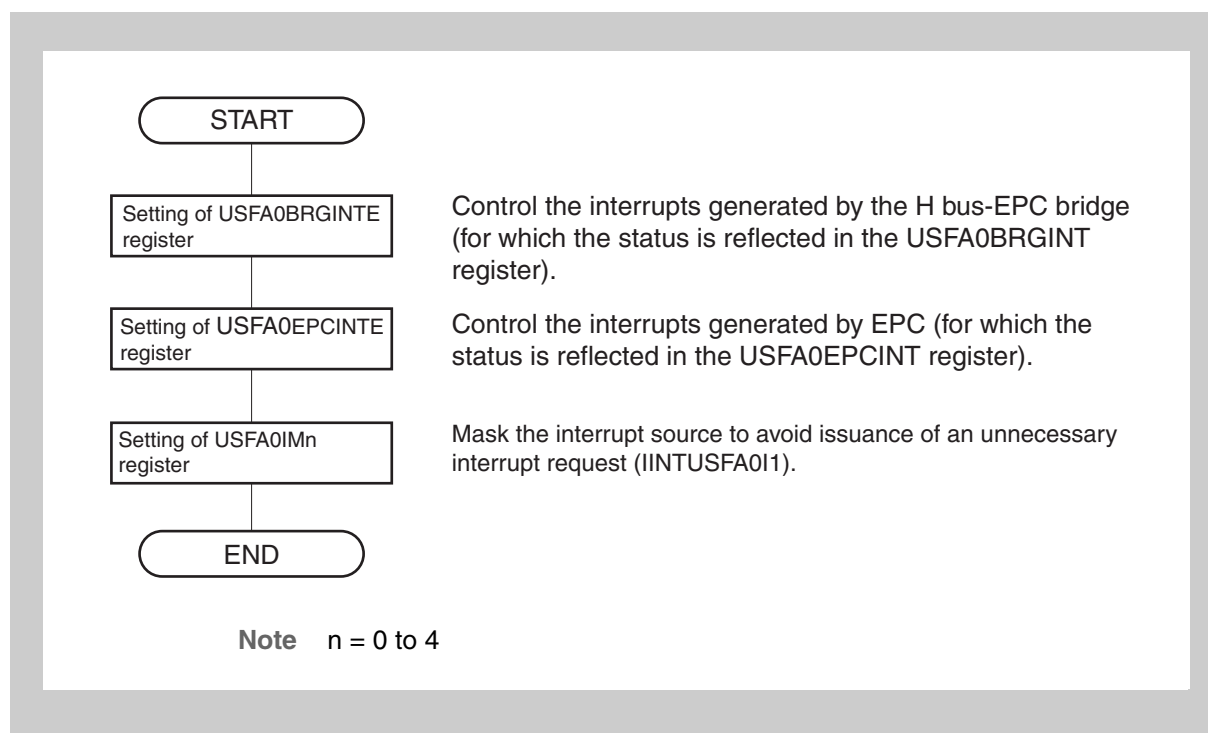

Figure 27-22 Setting up interrupts

27.10.2 Interrupt servicing

The following flowcharts show the related processing.

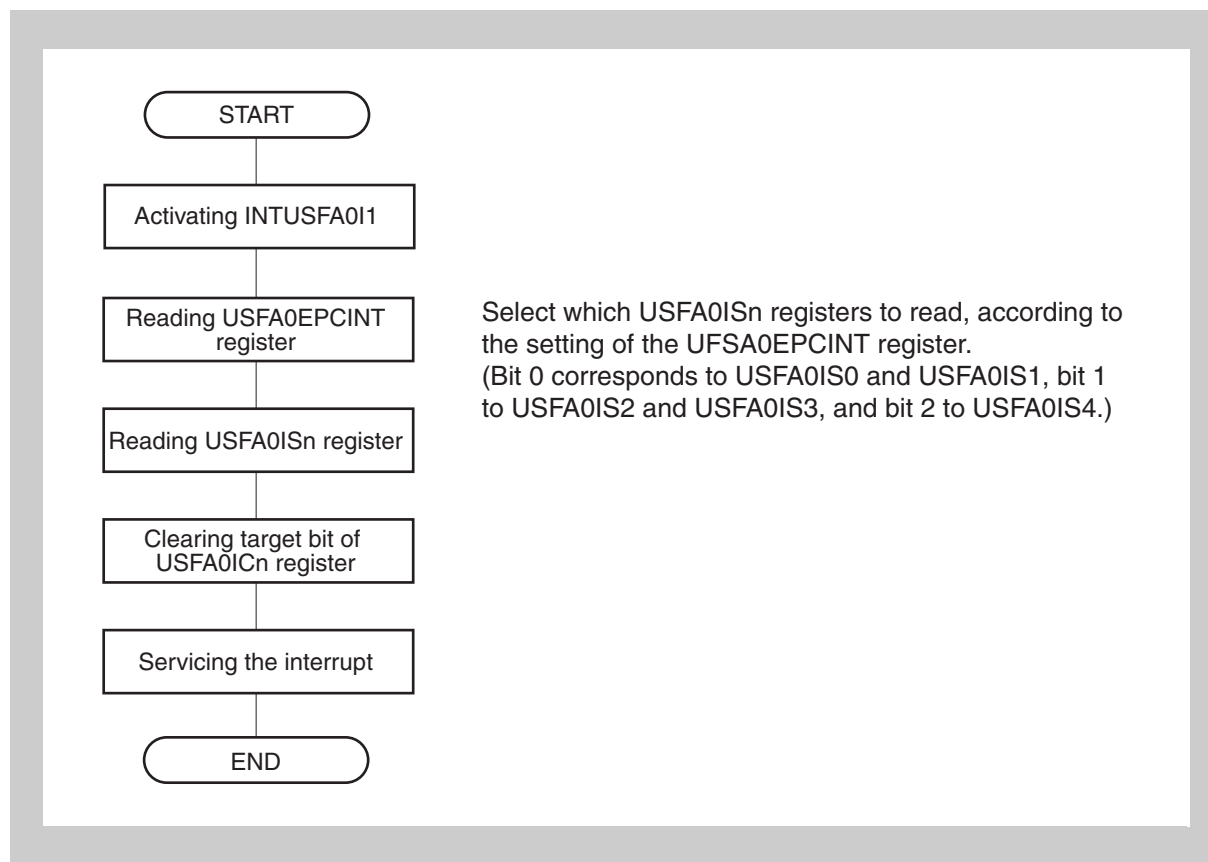

Figure 27-23 EPC interrupt detection

The following bits of the USFA0ISn register are cleared by hardware when a given condition is satisfied (n = 0 to 4):

- The E0INDT, E0ODT, SUCES, STG, and CPUDEC bits of the USFA0IS1 register
- The BKI2DT, BKI1DT, and IT1DT bits of USFA0IS2 register
- The BKO2FL, BKO2DT, BKO1FL, and BKO1DT bits of USFA0IS3 register

Because clearing an interrupt source by using the USFA0ICn register is given a lower priority than setting an interrupt source by hardware, the interrupt source might not be cleared depending on the timing (n = 0 to 4).

27.10.3 Main USB processing

The main USB processing involves processing USB transactions. The types of transactions to be processed are as follows:

- Fully automatically processed requests for control transfers
- Automatically processed requests for control transfers (SET_CONFIGURATION, SET_INTERFACE, SET_FEATURE, and CLEAR_FEATURE)
- CPUDEC requests for control transfers
- Processing for bulk transfers (IN)
- Processing for bulk transfers (OUT)
- Processing for interrupt transfers (IN)

The processing for endpoint n involves reading or writing data for transfers. The flowchart shown below is for PIO.

(1) Fully automatically processed requests for control transfers

Because a fully automatically processed request for a control transfer is executed by hardware, FW cannot reference it. Therefore, FW does not have to perform any special processing for this request.

(2) Automatically processed requests for control transfers

(SET_CONFIGURATION, SET_INTERFACE, SET_FEATURE, and CLEAR_FEATURE)

Processing to write a register for automatically processed requests for control transfers, such as SET_CONFIGURATION, SET_INTERFACE, SET_FEATURE, and CLEAR_FEATURE requests, is automatically executed by hardware, but an interrupt request is issued for recognition on the device side. This processing might be ignored if there is no special processing to execute.

The following flowcharts show the related processing.

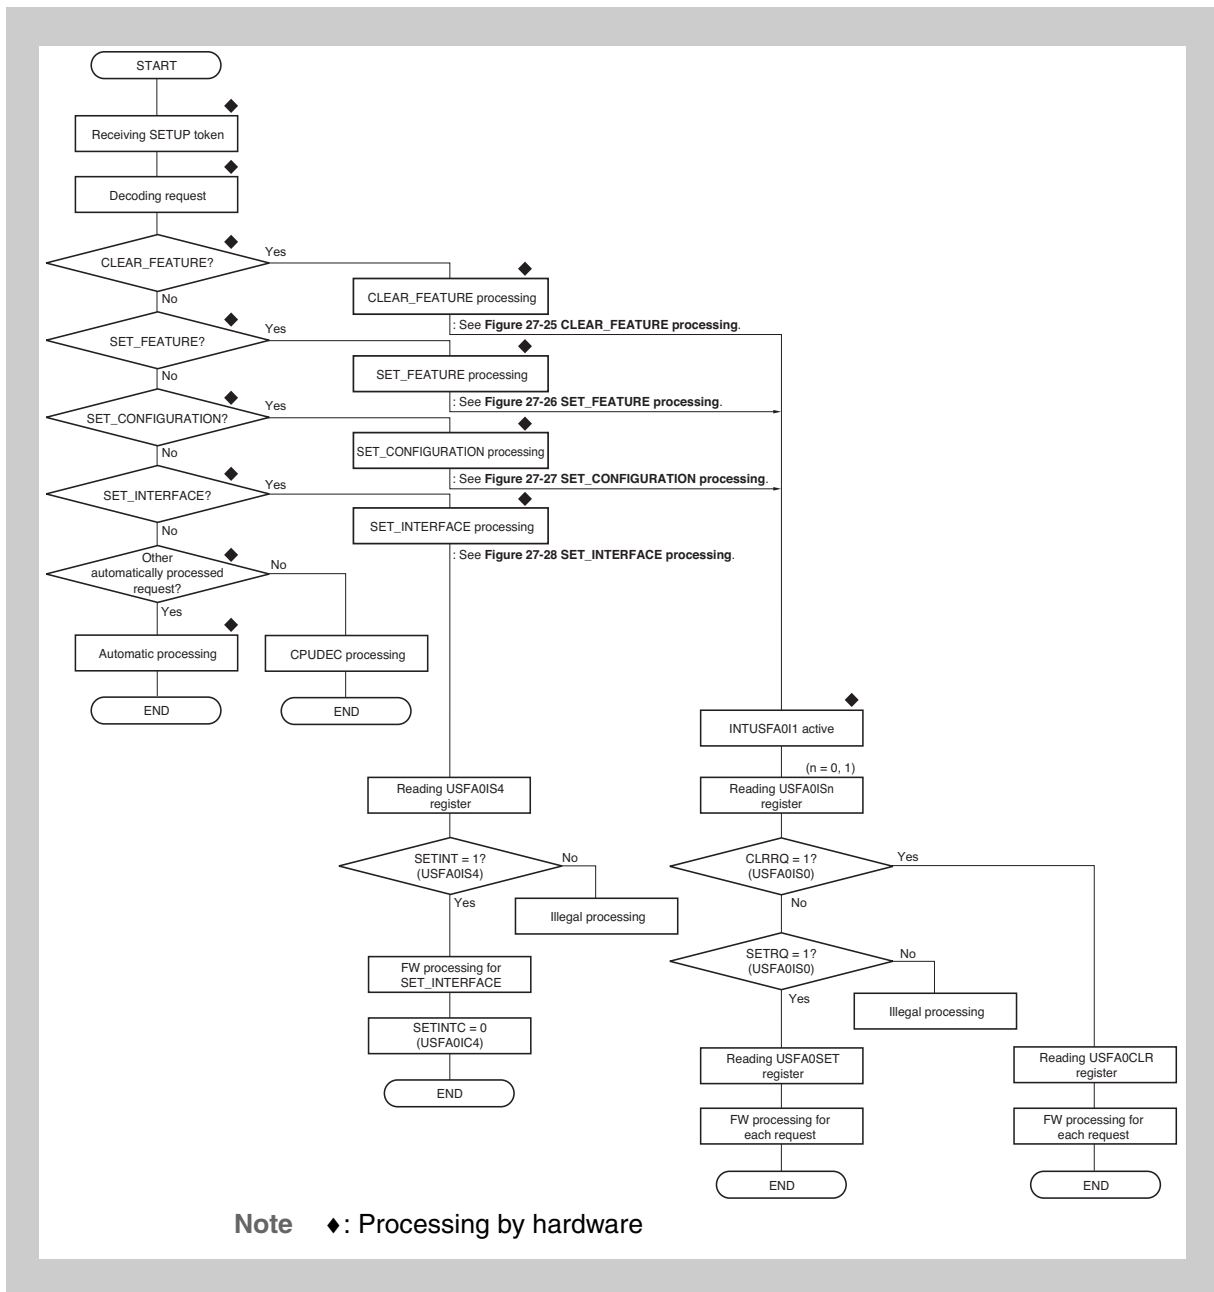

Figure 27-24 Automatically processed requests for control transfers

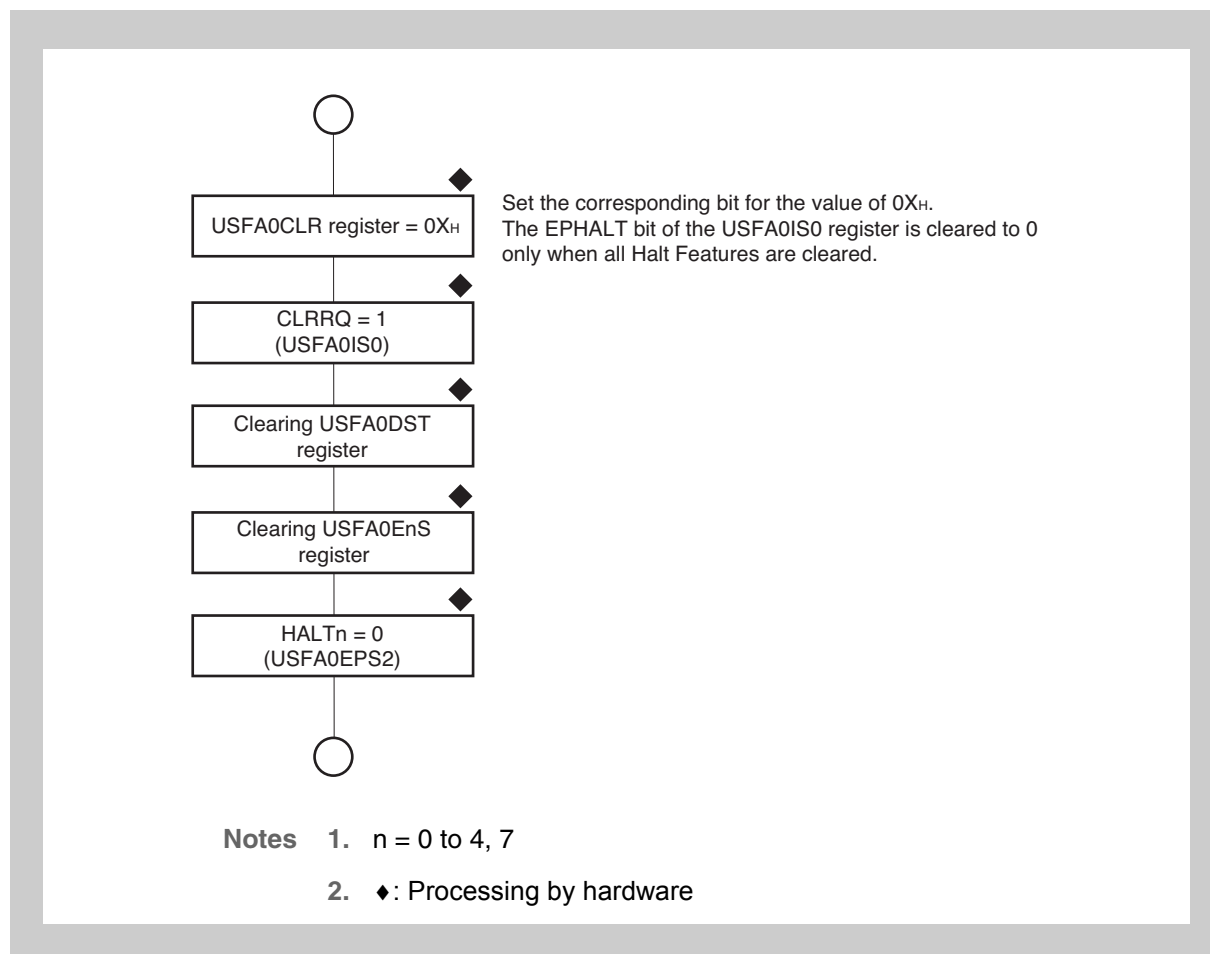

Figure 27-25 CLEAR_FEATURE processing

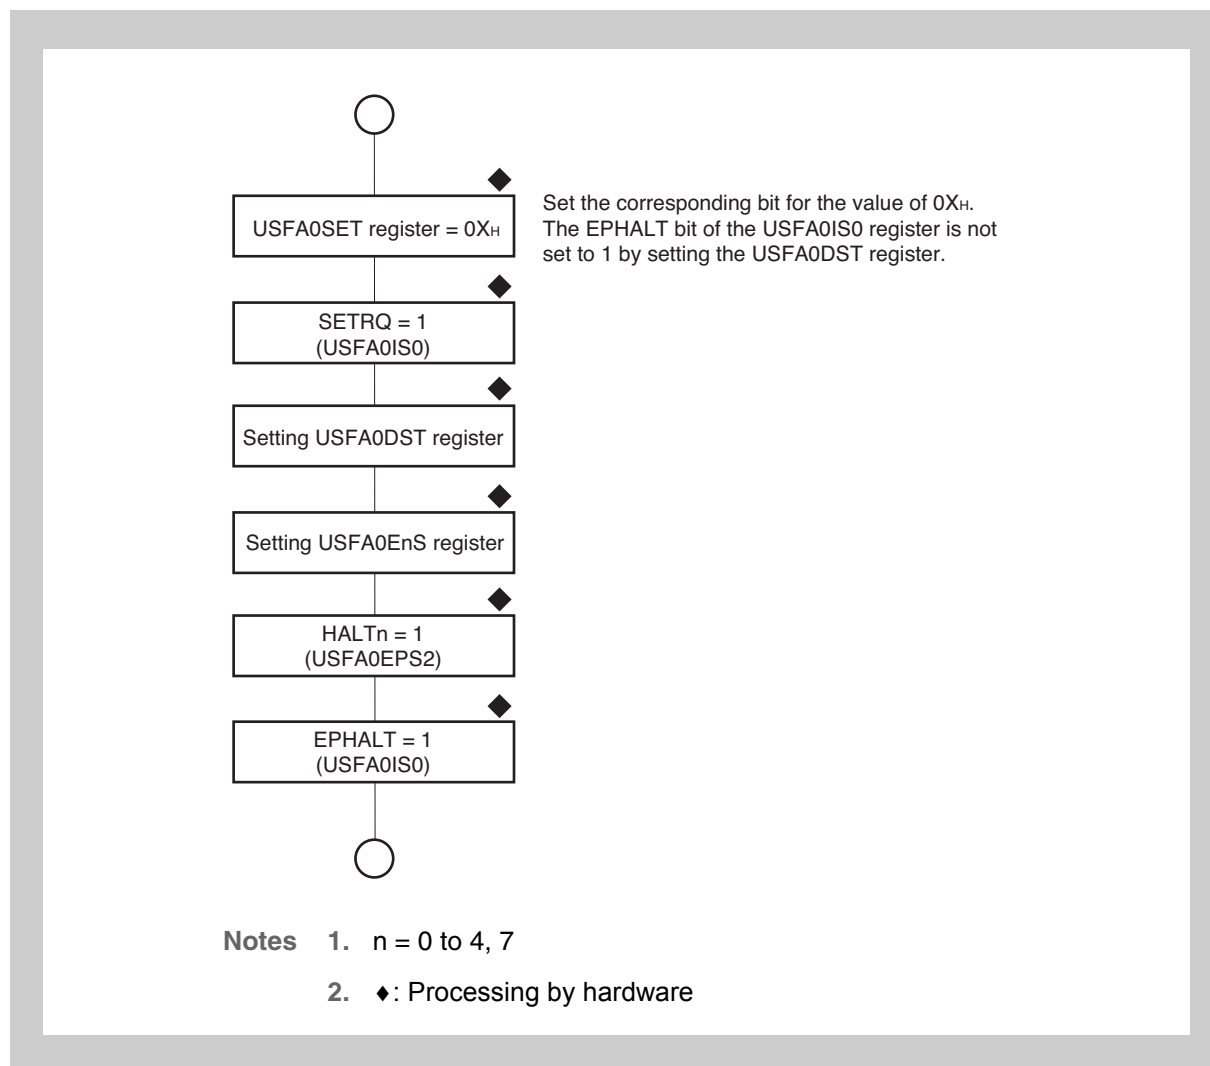

Figure 27-26 SET_FEATURE processing

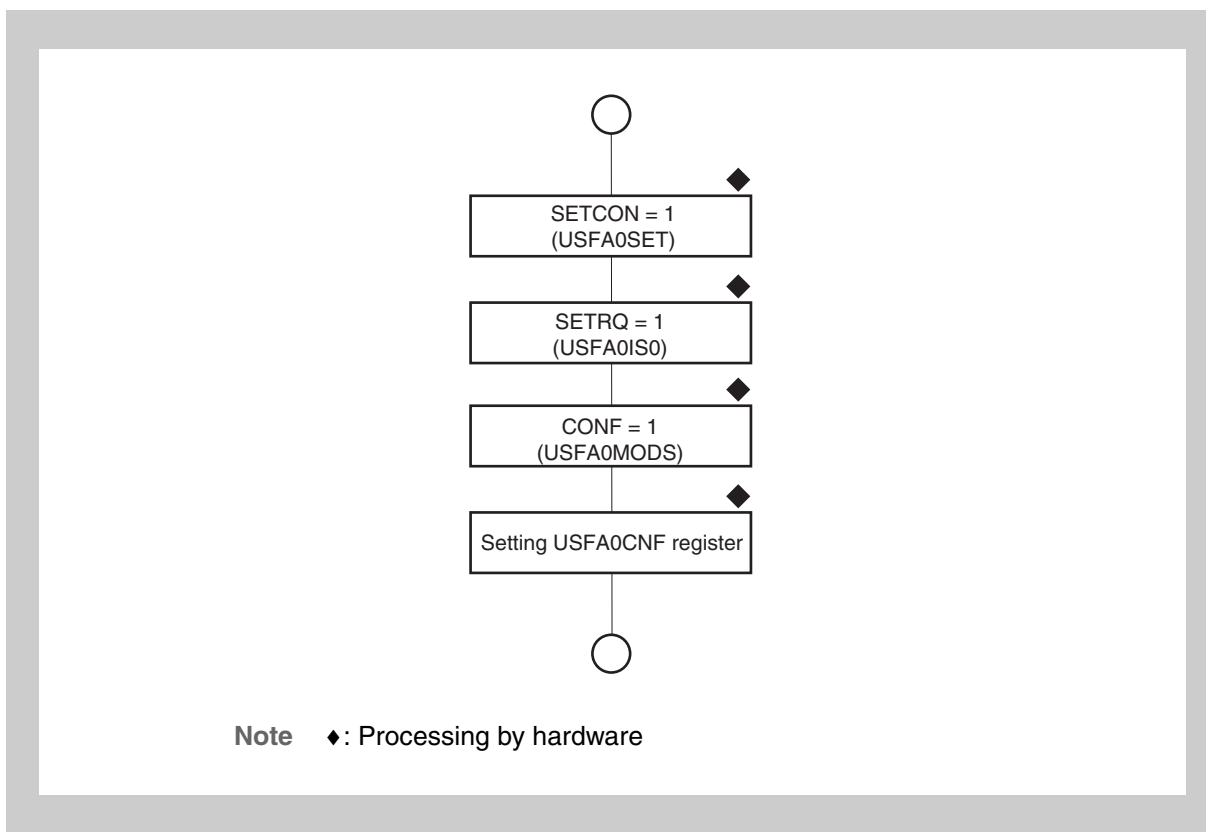

Figure 27-27 SET_CONFIGURATION processing

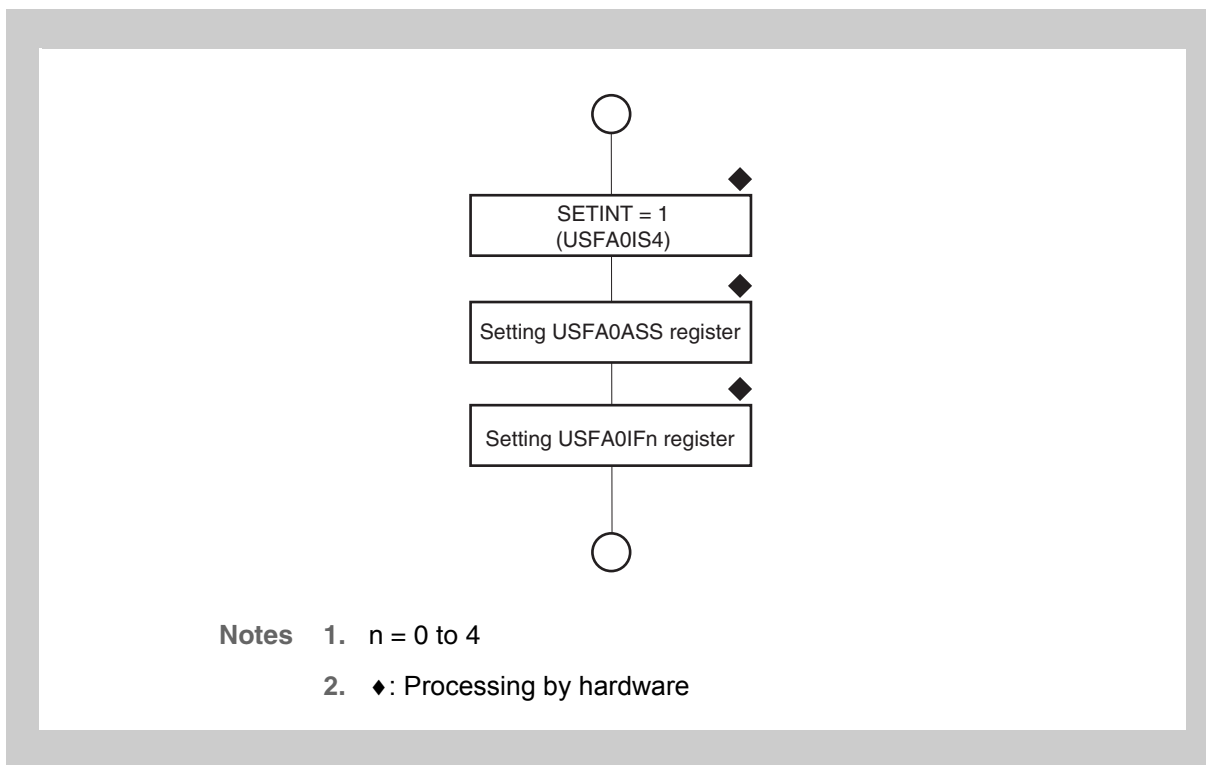

Figure 27-28 SET_INTERFACE processing

(3) CPUDEC requests for control transfers

There are three types of CPUDEC requests: requests for control transfer (write), control transfer (read), and control transfer (without data). Control transfer (write) is a request that uses the OUT transaction in the data stage (such as SET_DESCRIPTOR), control transfer (read) is a request that uses the IN transaction in the data stage (such as GET_DESCRIPTOR), and control transfer (without data) is a request that has no data stage (such as SET_CONFIGURATION).

The following flowcharts show the related processing.

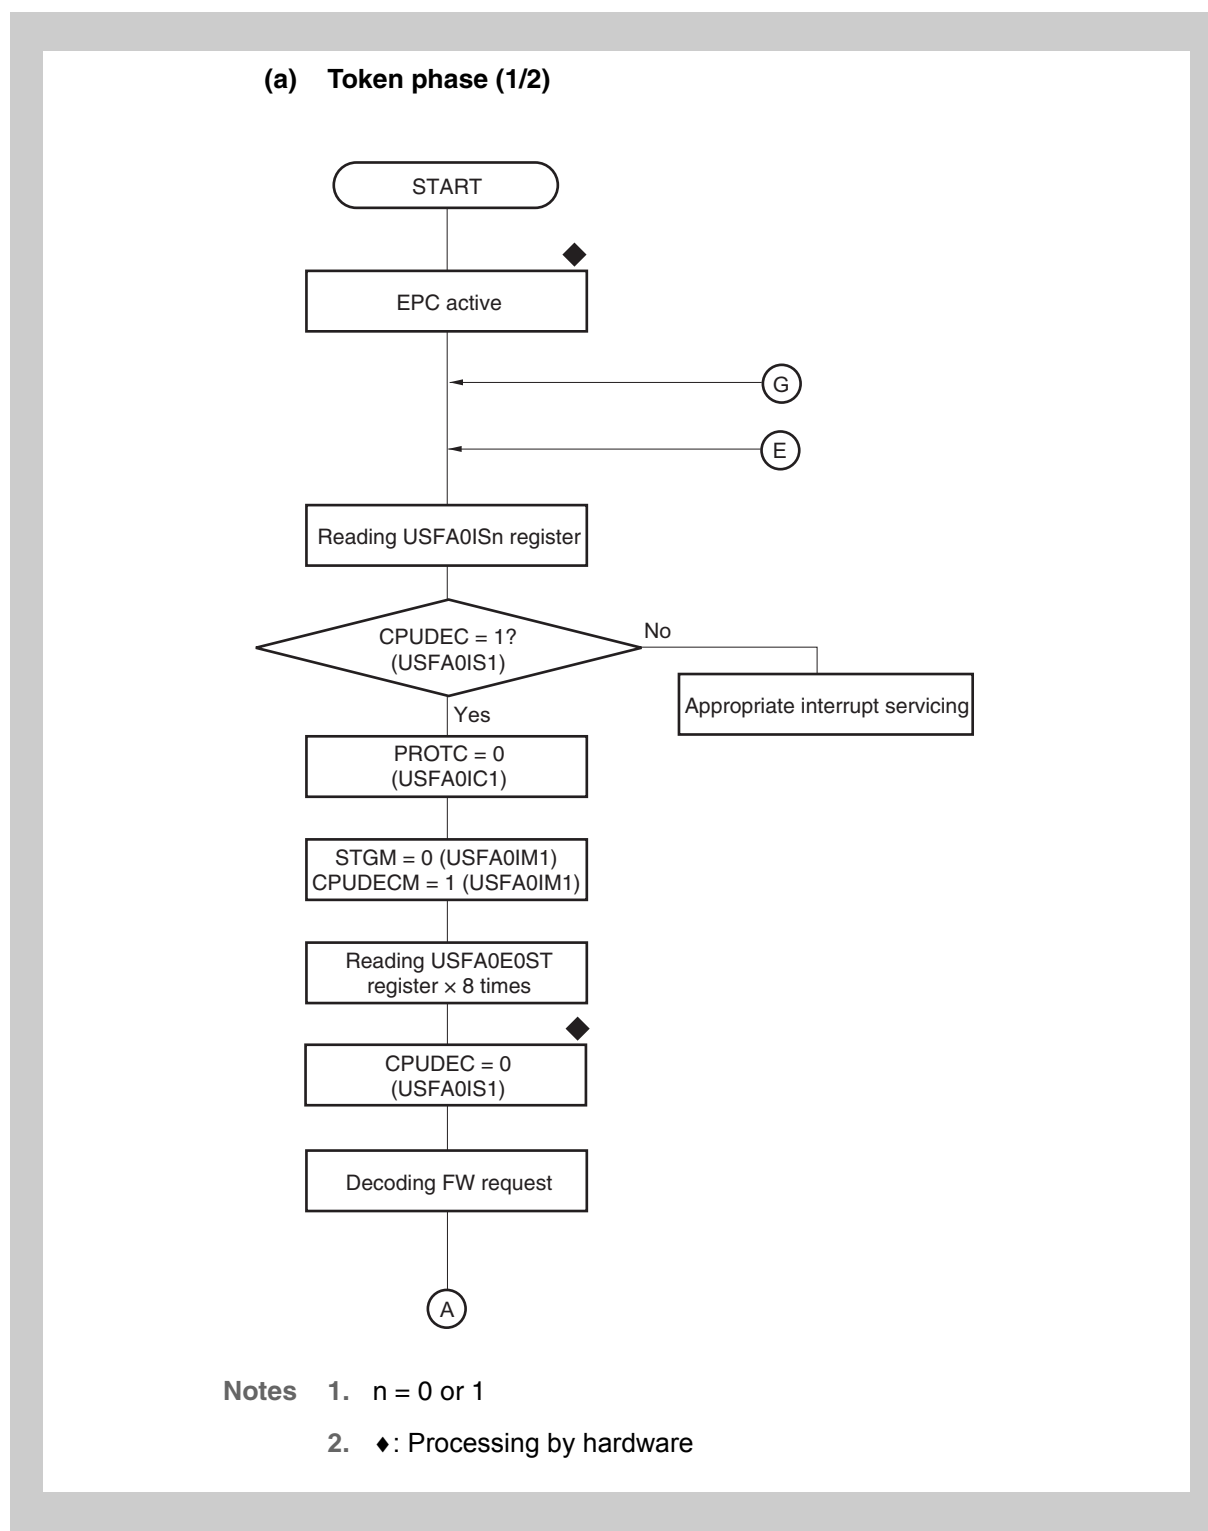

Figure 27-29 CPUDEC requests for control transfers (1/12)

- Notes
1. n = 0 or 1
 2. ♦: Processing by hardware

Figure 27-40 CPUDEC requests for control transfers (12/12)

(4) Processing for bulk transfers (IN)

A bulk transfer (IN) is assigned to Endpoints1 and 3. The flowchart below shows how Endpoint1 is controlled. Endpoint3 can also be controlled using the same sequence. To use this flowchart as the control flow of Endpoint3, therefore, read the bit names of Endpoint1 in the flowchart as those of Endpoint3.

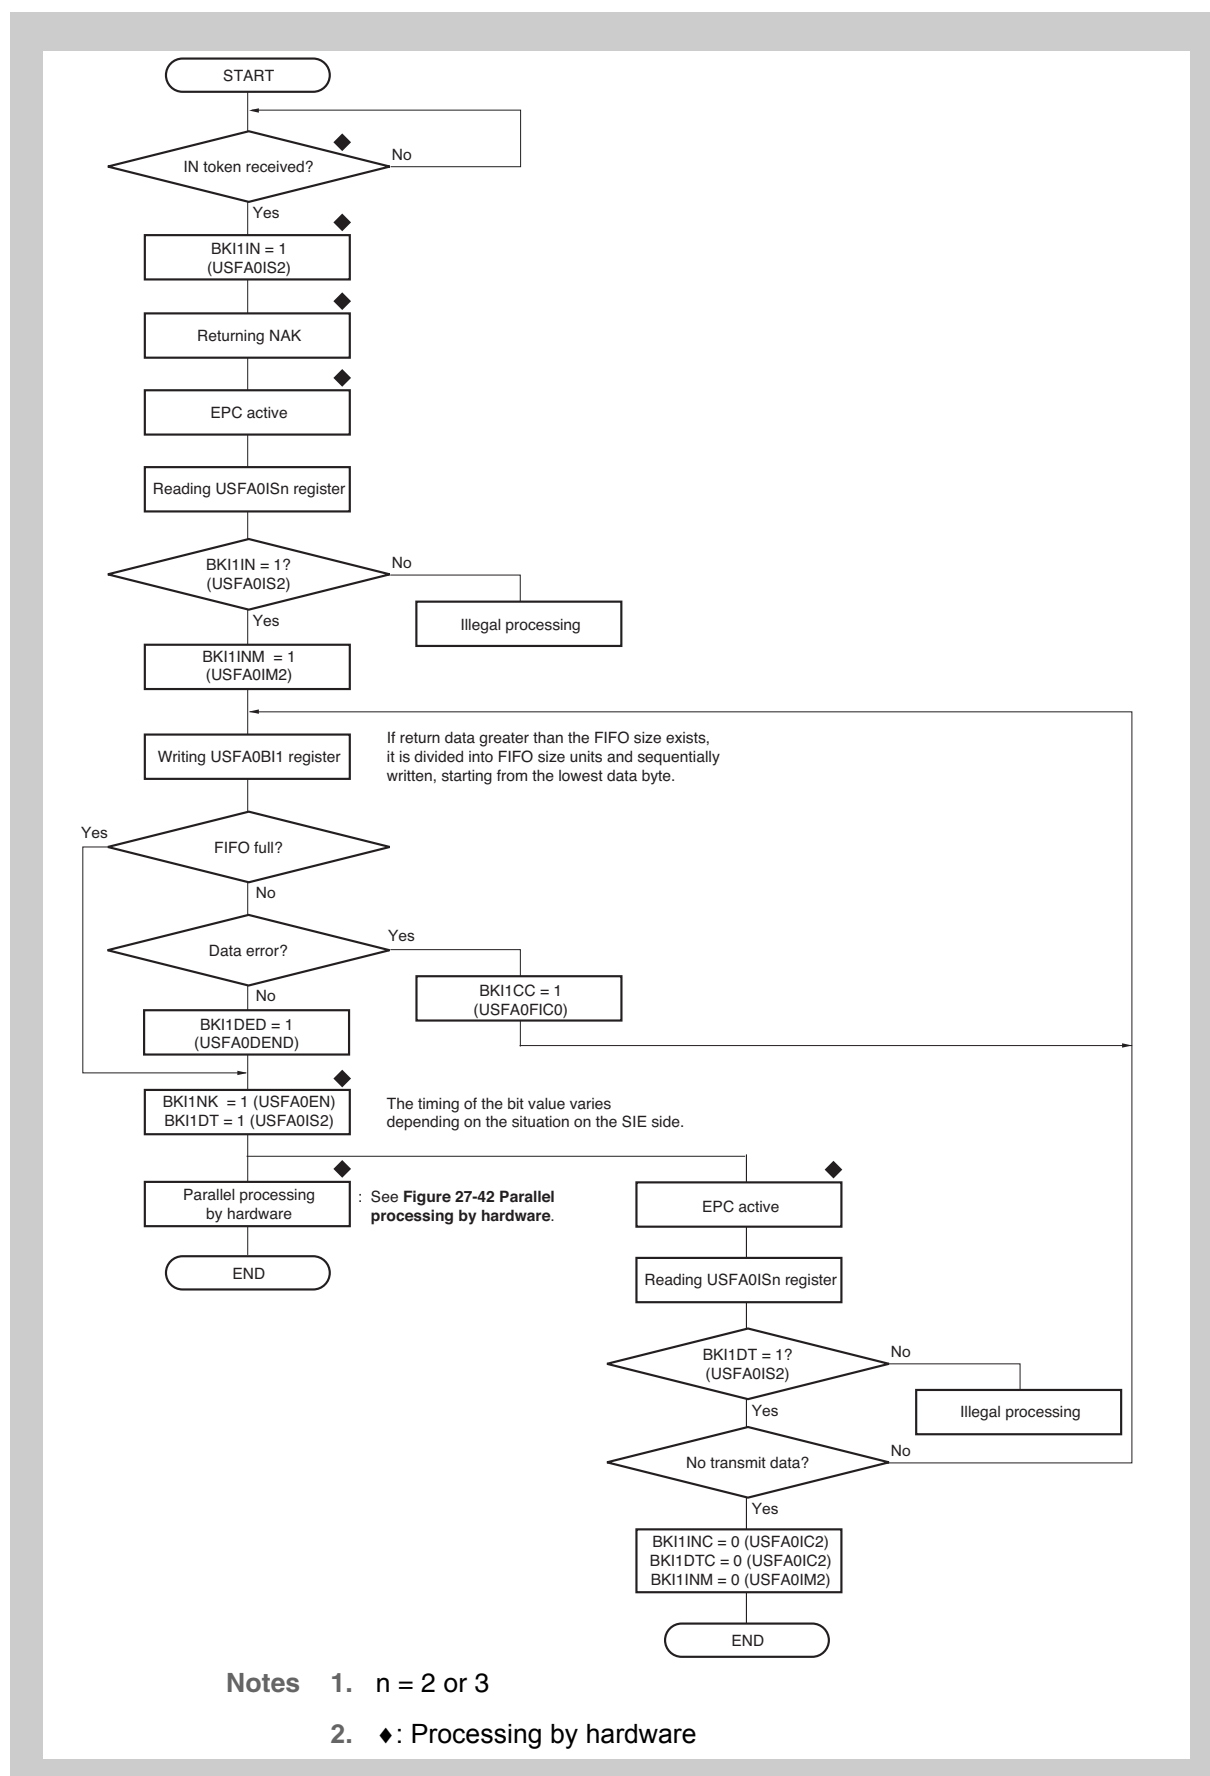

Figure 27-41 Processing for Bulk transfers (IN) (Endpoint1)

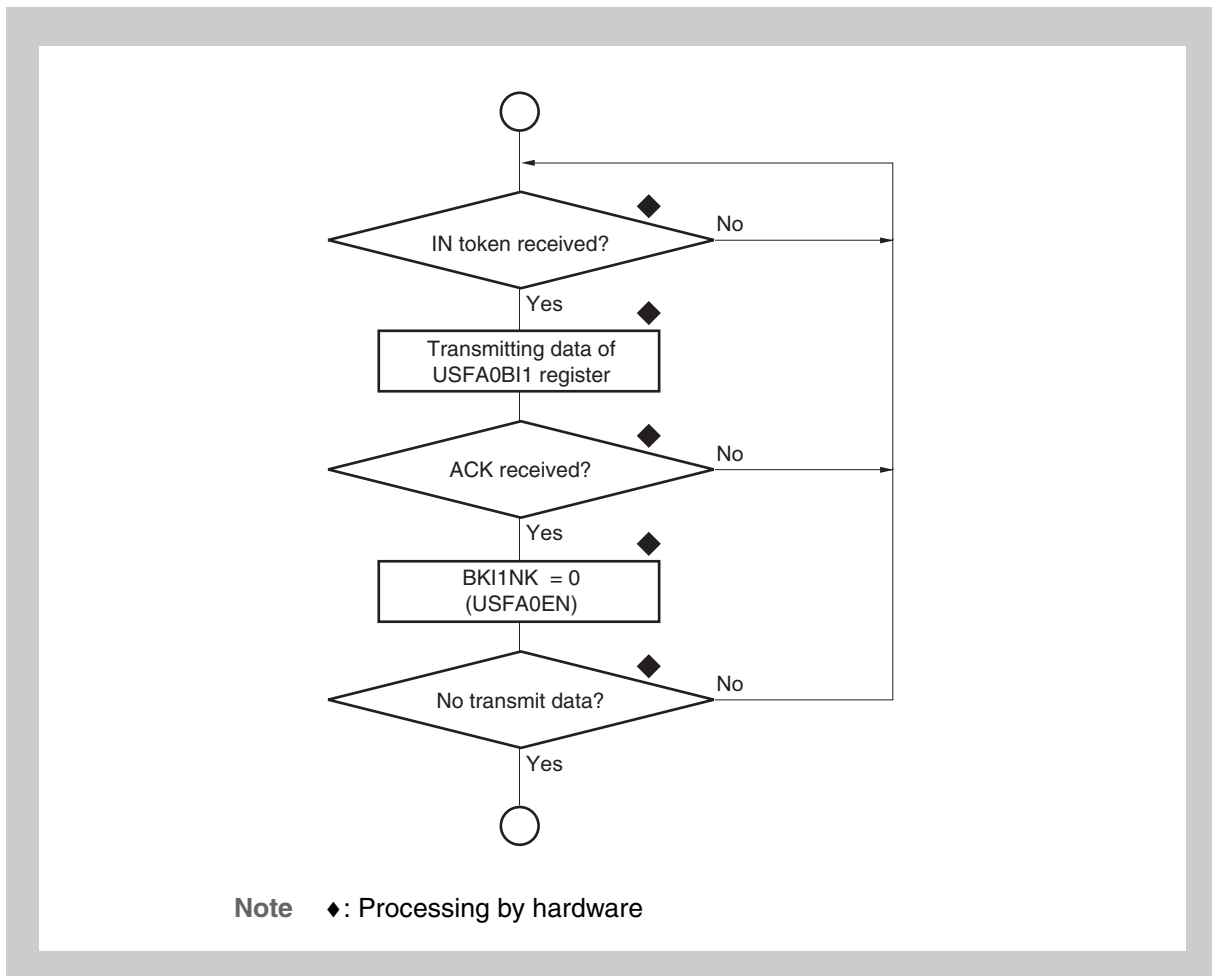

Figure 27-42 Parallel processing by hardware

(5) Processing for bulk transfers (OUT)

A bulk transfer (OUT) is assigned to Endpoints2 and 4. The flowchart below shows Endpoint2 is controlled. Endpoint4 can also be controlled using the same sequence. To use this flowchart as the control flow of Endpoint4, therefore, read the bit names of Endpoint2 in the flowchart as those of Endpoint4.

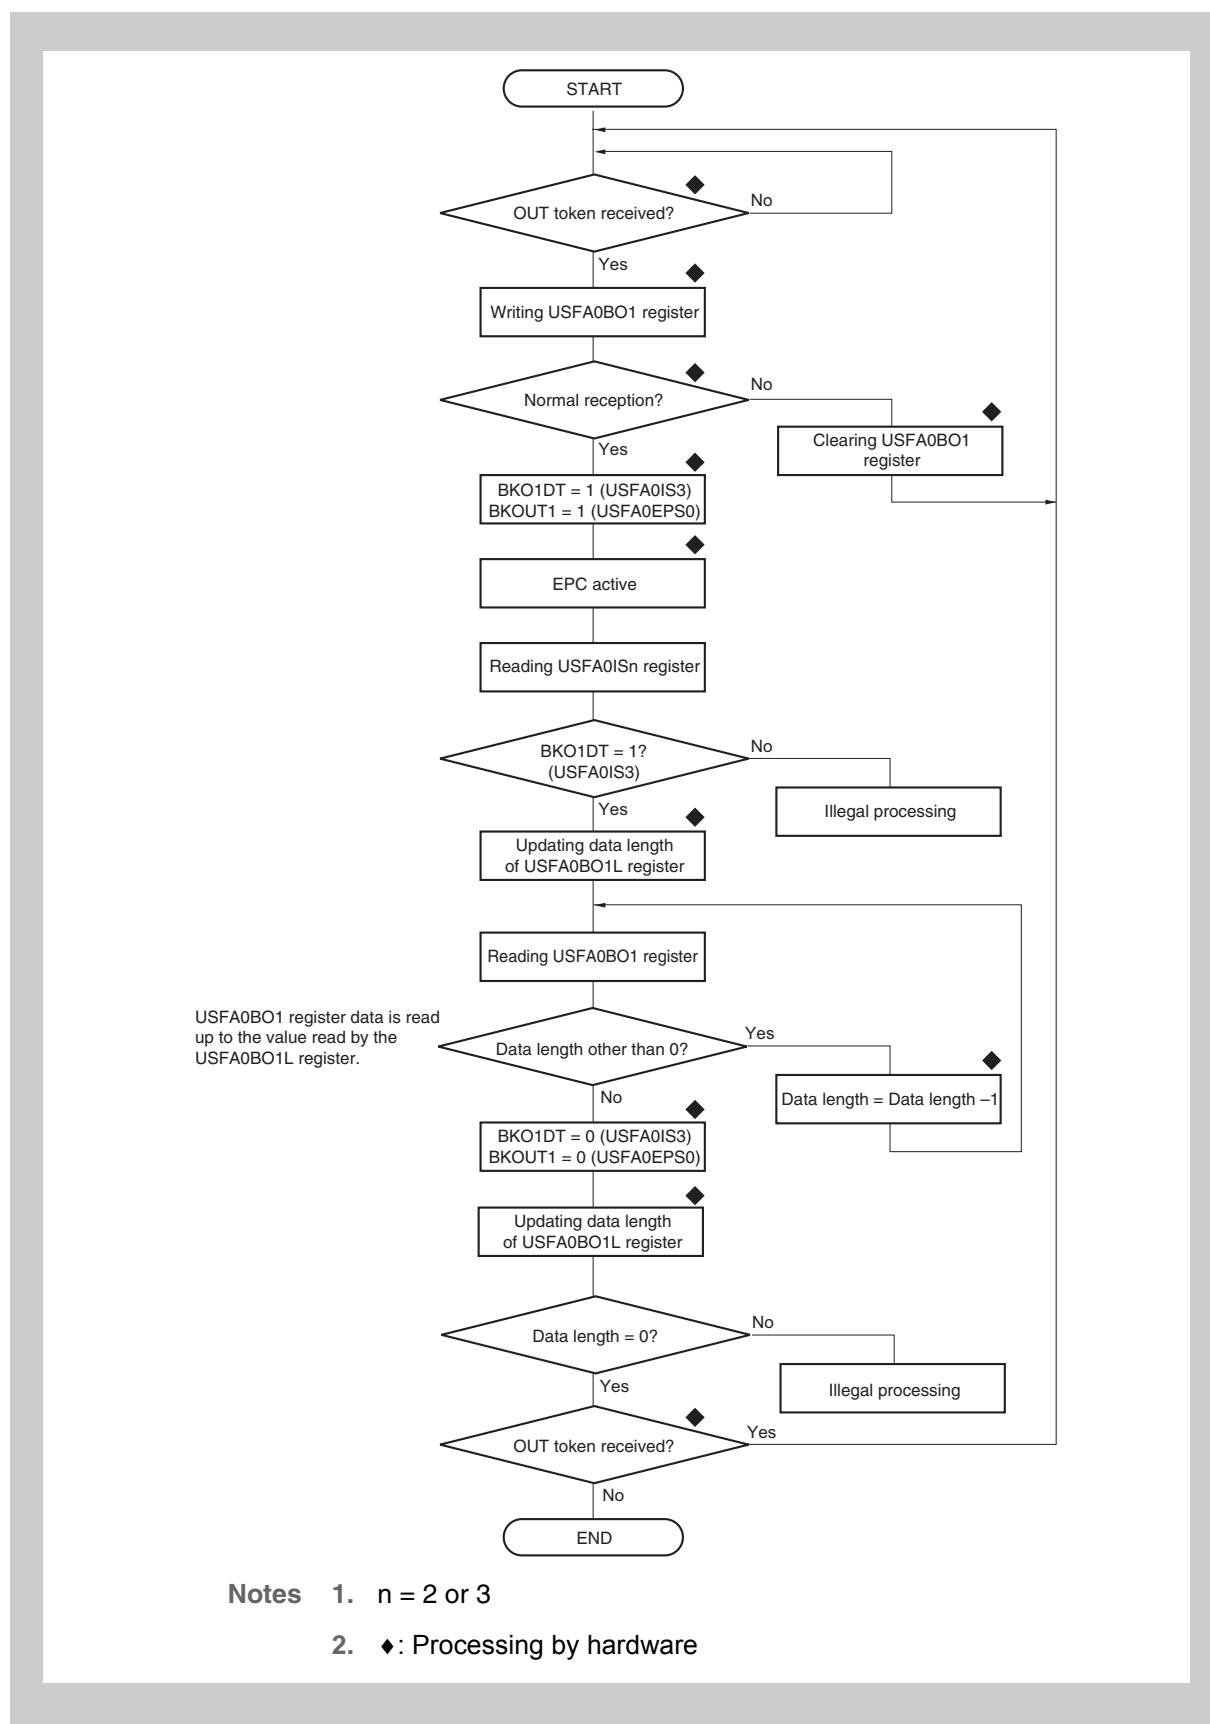

Figure 27-43 Normal processing for bulk transfers (OUT) (Endpoint2)

During a bulk transfer (OUT), more data than is expected by the system might be transmitted from the host. To allow for this, endpoints 2 and 4 for bulk transfers (OUT) in this product consist of two 64-byte buffers so data can be read from the CPU side even while the bus side is being accessed, preventing excessive NAK responses and improving the transfer rate of the USB bus. If the host sends more data than is expected by the system, up to 128 bytes of extra data might be received in the worst case. In this case, change the control flow from that of normal processing of endpoints 2 and 4 to the flow shown below when the system is expecting to receive only two more packets of data. This flowchart shows how Endpoint2 is controlled. Endpoint4 can also be controlled using the same sequence. To use this flowchart as the control flow of Endpoint4, therefore, read the bit names of Endpoint2 in the flowchart as those of Endpoint4.

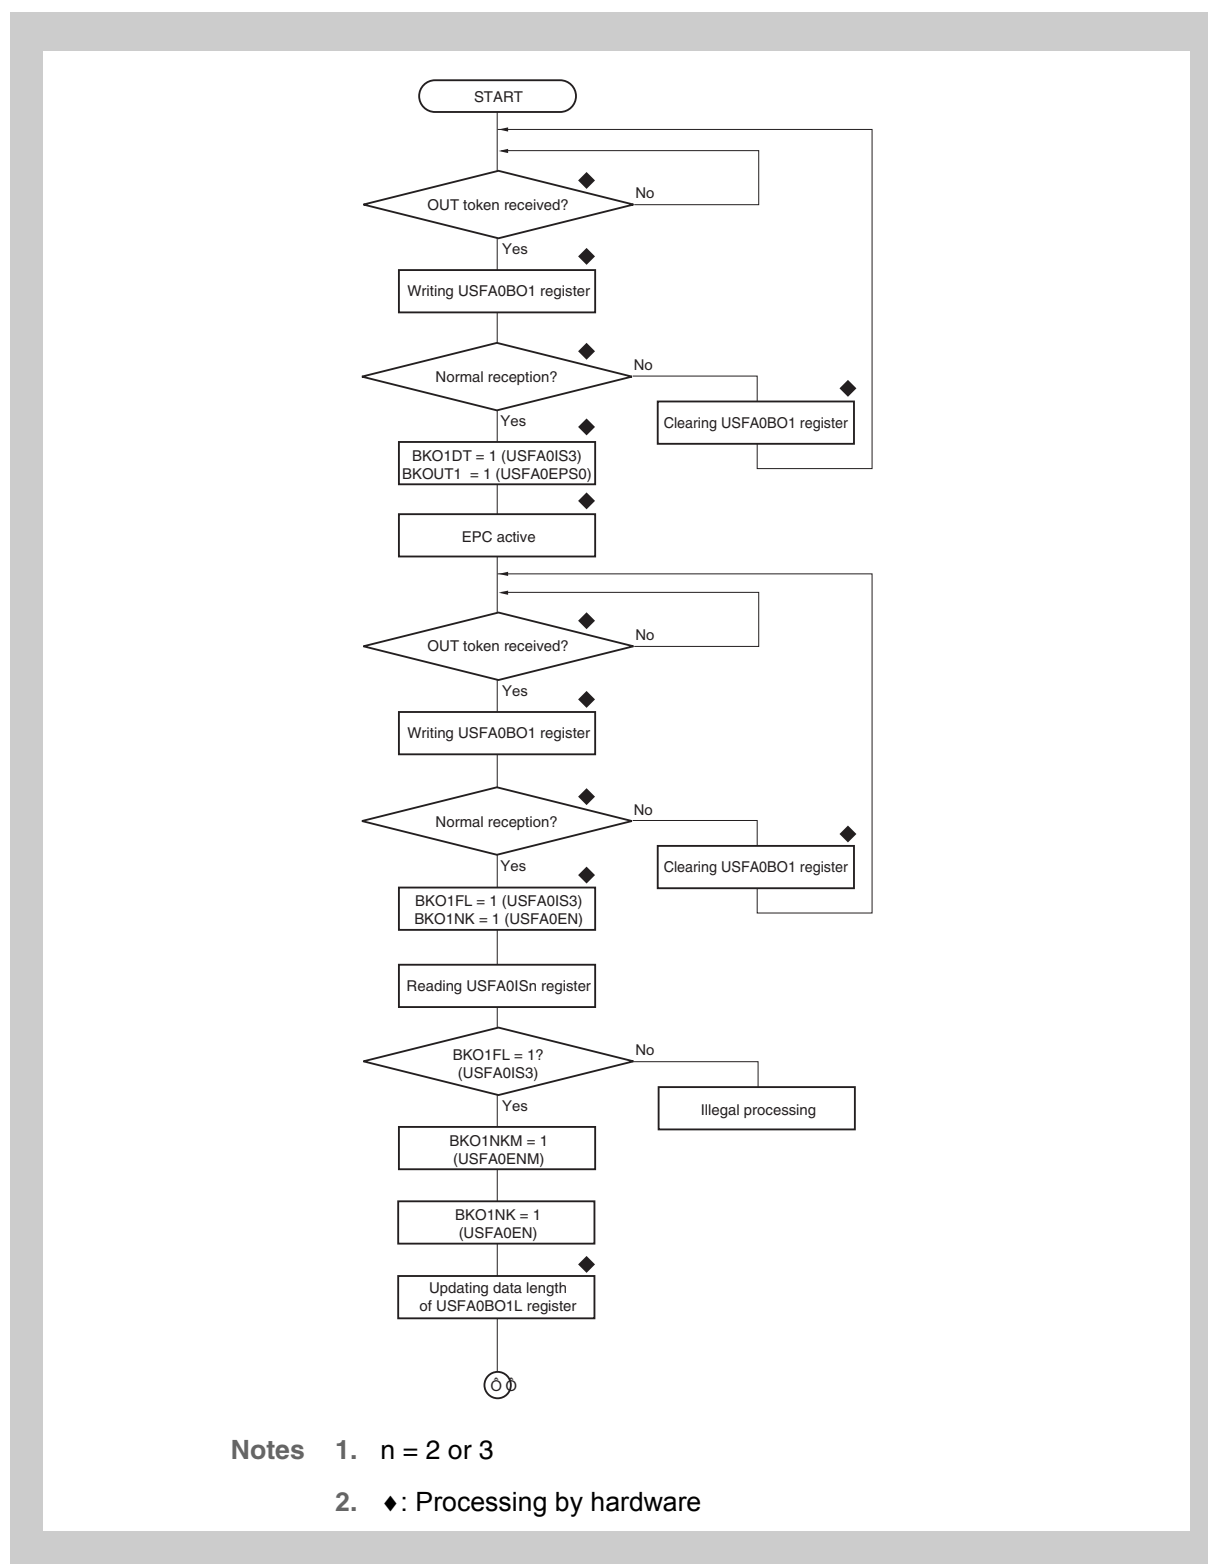

Figure 27-44 Processing if more data than is expected by system is transmitted (Endpoint2) (1/2)

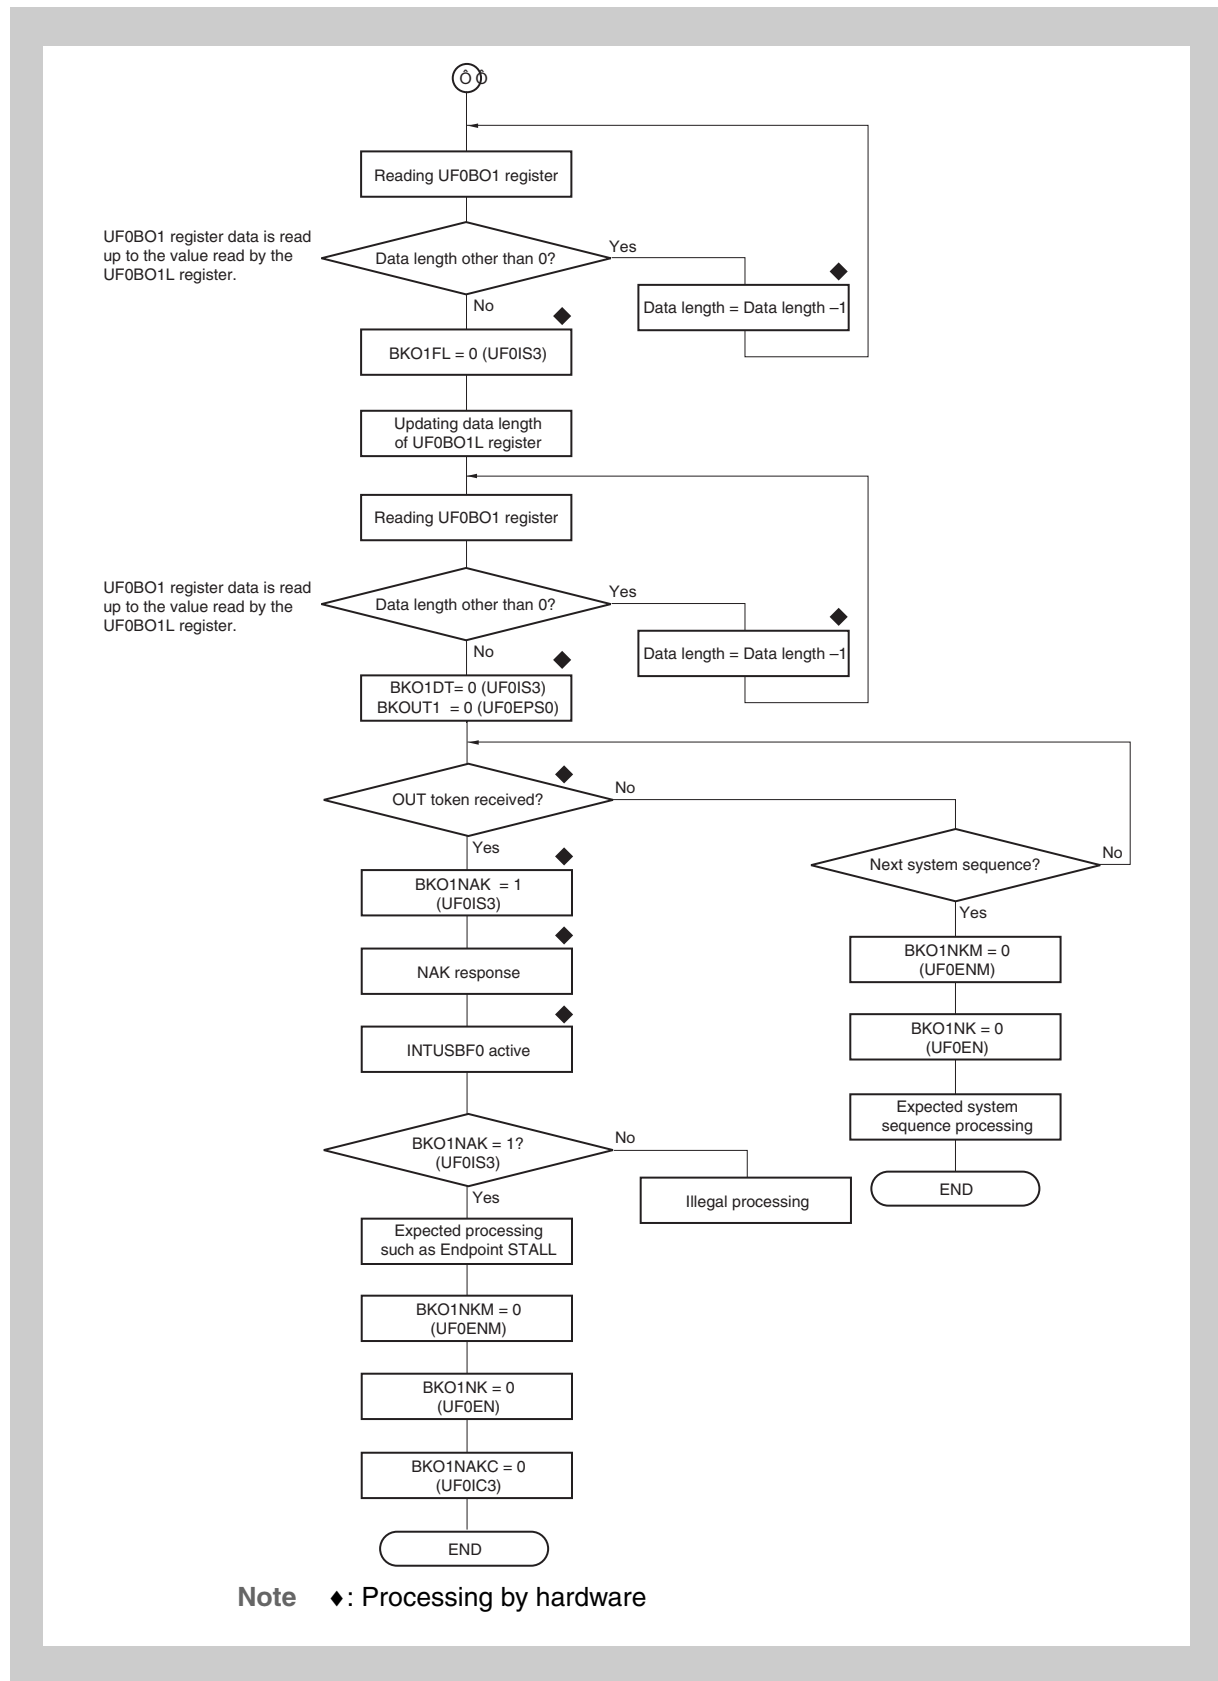

Figure 27-45 Processing if more data than is expected by system is transmitted (Endpoint2) (2/2)

(6) Processing for interrupt transfers (IN)

An interrupt transfer (IN) is assigned to Endpoint7. The flowchart in *Figure 27-46 "Processing for interrupt transfers (IN) (Endpoint7)"* shows the related processing.

Figure 27-46 Processing for interrupt transfers (IN) (Endpoint7)

27.10.4 Suspend/Resume processing

How Suspend/Resume processing is performed depends on the system configuration. One example is given below.

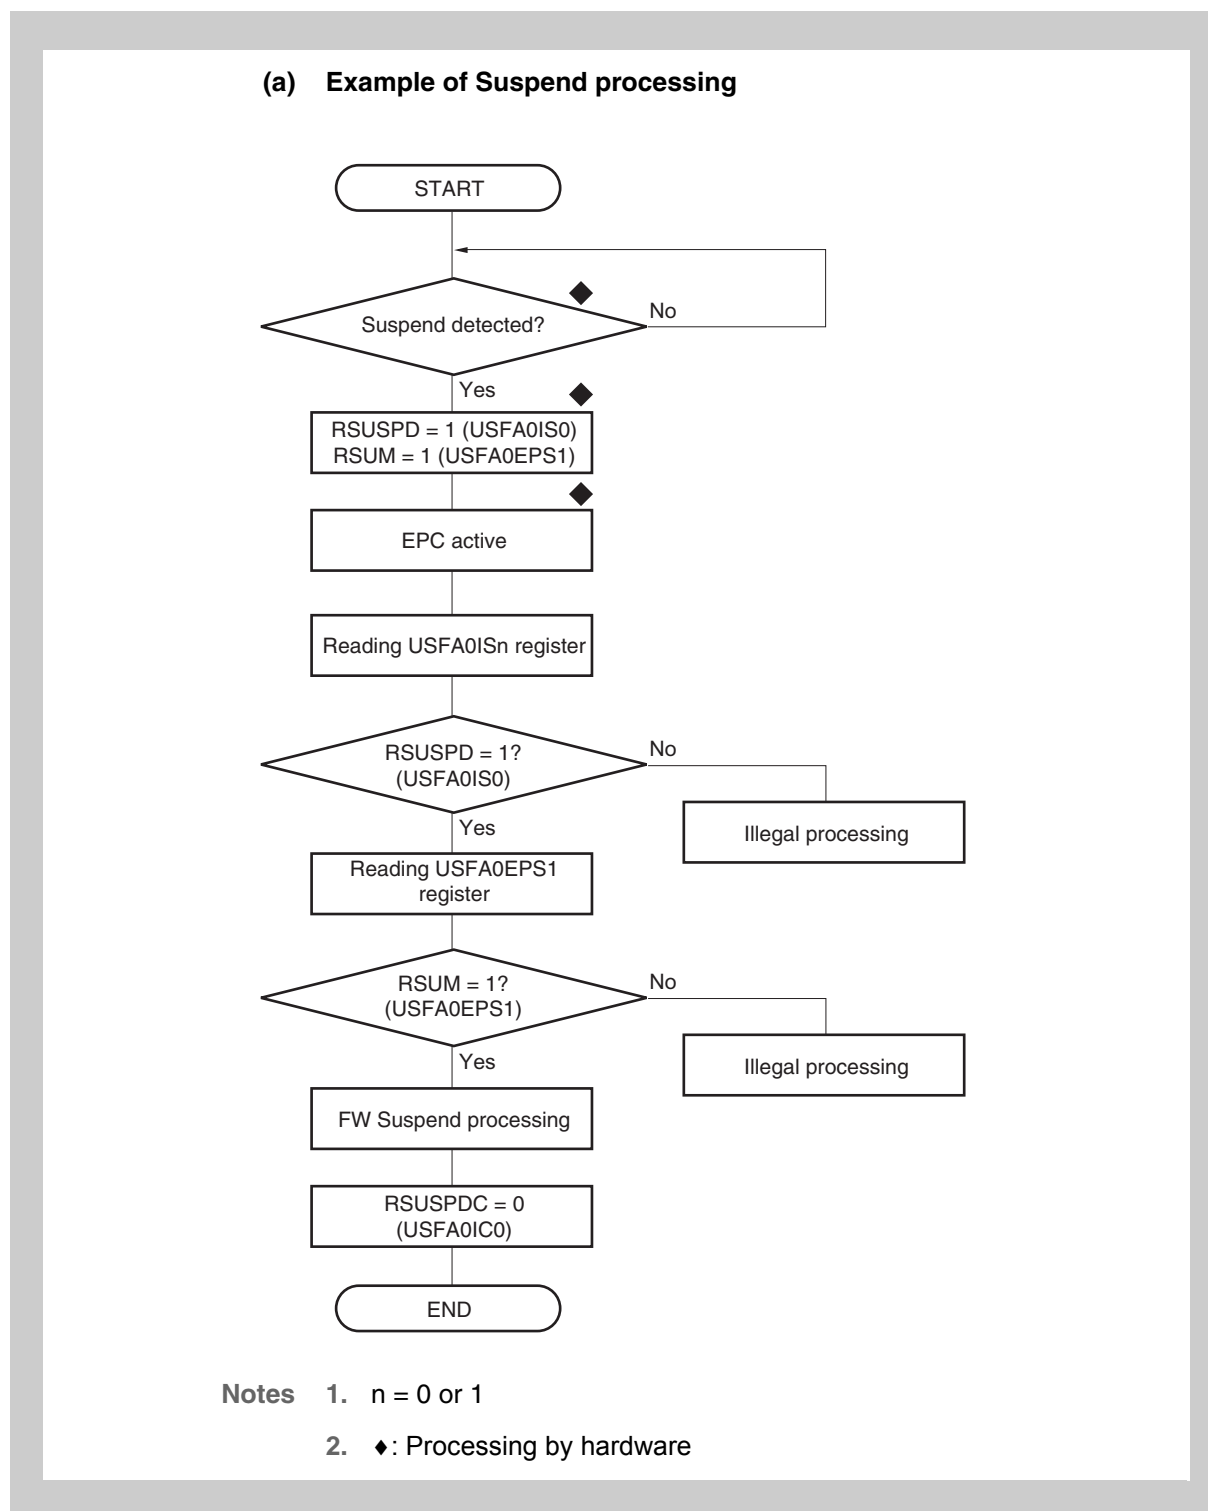

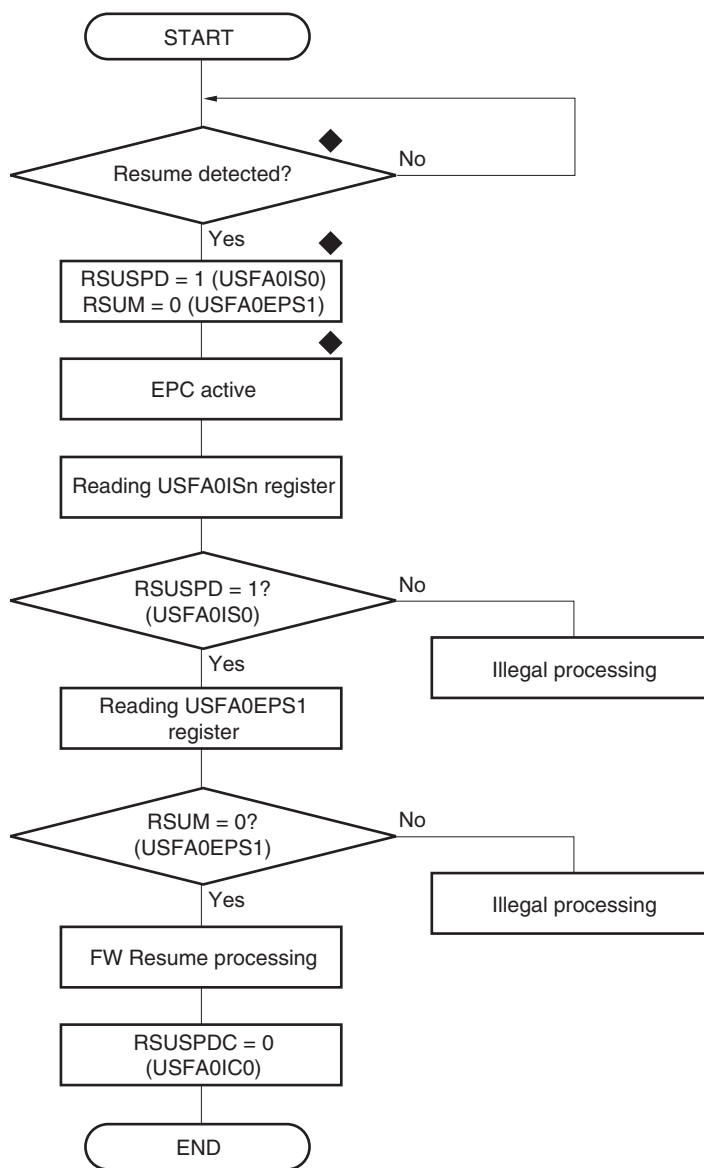

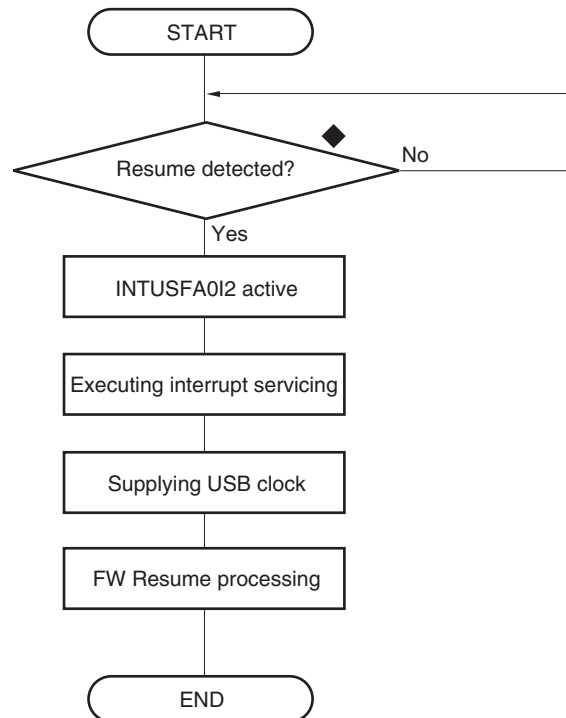

Figure 27-47 Example of Suspend/Resume processing (1/3)

(b) Example of Resume processing

- Notes**
1. $n = 0$ or 1
 2. ◆: Processing by hardware

- Notes**
1. $m = 0$ to 4
 2. ◆: Processing by hardware

Figure 27-51 Example of processing after power application and shutdown (2/3)

(b) Processing on power shutdown

- a) INTPxx refers to the external interrupt pins (INTP00 to INTP27) for this product. Assign one external interrupt pin for the following applications.

Detect disconnection of the connector in the case of self-powered mode (SFPW bit of USFA0DST register = 1). The VDD line of the USB connector is monitored, and if disconnection of the connector is detected, a signal is input to the external interrupt pin at the signal edge. Note that the noise elimination time of the interrupt input pin differs depending on the timer.

Detecting turning off the power from the hub when the device is mounted on the same board as a hub chip.

Note ◆: Processing by hardware

Figure 27-52 Example of processing after power application and shutdown (3/3)

Chapter 28 USB Host Controller (USBH)

This microcontroller has an internal USB host controller (USBH) conforming to the Universal Serial Bus Specification. Data communication using the polling method is performed between the USB host controller and external host device by using a token-based protocol.

Caution Use the following procedure to read the USB host controller registers.

- When connecting an external clock to the USBCLK pin

- (1) Set the PCICRST bit of the PCI control register_H (USHA0PCICTRL_H) to 0, and then cancel the reset.
- (2) Set the BMASEN bit of the PCI command register (USHA0PCICMD) to 1 to enable the bus master.
- (3) Read the required USB host controller registers.

- When an external clock is not to be connected to the USBCLK pin

[1] When supplying an external clock is specified in the SFRCTL3 register (When the USBDIV1 and USBDIV0 bits of SFRCTL3 are 00b)

- (1) Set the USBDIV1 and USBDIV0 bits of the SFRCTL3 register to 11b to specify an internal clock of $fx/4$.
- (2) Set the PCICRST bit of the PCI control register-H (USHA0PCICTRL_H) to 0 to cancel the reset.
- (3) Set the BMASEN bit of the PCI command register (USHA0PCICMD) to 1 to enable the bus master.
- (4) Read the required USB host controller registers.

[2] When supplying an internal clock is specified in the SFRCTL3 register (When the USBDIV1 and USBDIV0 bits of SFRCTL3 are 10b or 11b)

- (1) Set the PCICRST bit of the PCI control register-H (USHA0PCICTRL_H) to 0 to cancel the reset.
 - (2) Set the BMASEN bit of the PCI command register (USHA0PCICMD) to 1 to enable the bus master.
 - (3) Read the required USB host controller registers.
-

28.1 V850E2/ML4 USBH Features

Instances This microcontroller has the following number of instances of the USB host controller.

Table 28-1 Instances of USBH

USB host controller	V850E2/ML4
Instance	1

Register addresses All USBH register addresses are given as addresses offset from the individual base address <USHA0_base_OHCI> or <USHA0_base_PCI> for USBH. The <USHA0_base_OHCI> and <USHA0_base_PCI> addresses of USBH are given in the following table:

Table 28-2 Register base addresses <USHA0_base>

USBH registers	USBH features	<USHA0_base> addresses
OHCI Operational registers	USAH0_base_OHCI	F993 0000 _H
PCI bridge registers	USAH0_base_PCI	F993 0800 _H

Clock supply The following clocks can be input to USBH:

Table 28-3 USBH clock supply

Clock	Internal/external	Description
USBH clock	Internal	{7.2 MHz external clock × internal clock multiplied by 20}/3 = 48 MHz internal clock
	External	External clock input from the USBCLK pin (f _{USB} = 48 MHz)
PCI clock	Internal	The frequency from 25 to 33.33 MHz can be specified by using the SFRCTL3.PCIDIV[2:0] bits.

Interrupts USBH can generate the following interrupt requests:

Table 28-4 USBH interrupt requests

USBH signals	Description
INTUSHA0I0	Bridge error interrupt
INTUSHA0I1	USBH core interrupt
INTUSHA0PME	USBH wakeup interrupt

I/O signals The USBH I/O signals are given in the following table:

Table 28-5 USBH I/O signals

USBH signals	Description	Connected to
UDMH	USBH data I/O (-)	Port UDMH
UDPH	USBH data I/O (+)	Port UDPH
\overline{OCI}	Overcurrent detection input	Port \overline{OCI}
PPON	USB power supply output	Port PPON

Host controller communication area (HCCA) The following memory can be used as shared memory called the *host controller communication area (HCCA)*:

- H-bus shared memory

28.1.1 USB host controller memory map

The registers of the USB host controller are allocated to the following memory spaces:

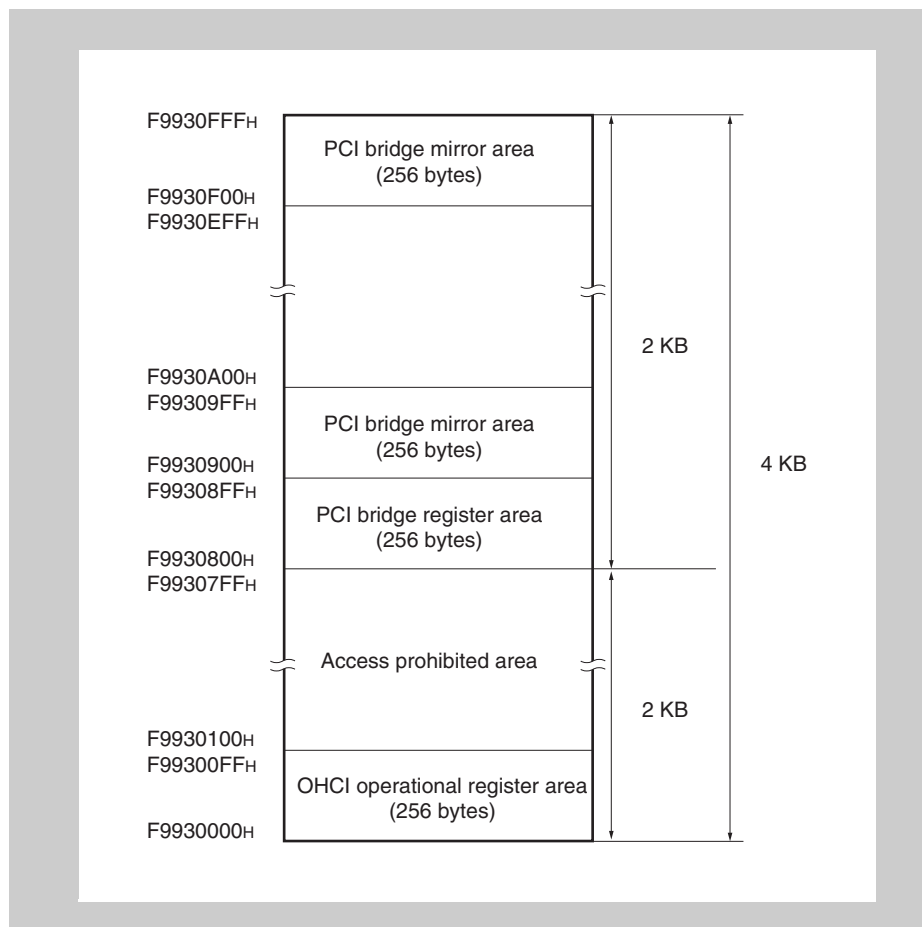

Figure 28-1 USB host controller memory map

28.1.2 V850E2/ML4 USB control register

Before using the USB host controller, set up the register below:

(1) USBH buffer control register (USHBC)

The USHBC register enables and disables the USB function controller input buffers and controls the input buffer floating state.

Access This register can be read or written in 32-bit units.

Address F990 1000_H

Initial value 0000 0000_H. This register is initialized by any reset.

	31	30	29	28	27	26	25	24
USHBC	0	0	0	0	0	0	0	0
	R	R	R	R	R	R	R	R
	23	22	21	20	19	18	17	16
	0	0	0	0	0	0	0	0
	R	R	R	R	R	R	R	R
	15	14	13	12	11	10	9	8
	0	0	0	0	0	0	0	0
	R	R	R	R	R	R	R	R
	7	6	5	4	3	2	1	0
	0	0	0	0	0	0	UBHIEN	UBHIOR
	R	R	R	R	R	R	R/W	R/W

Table 28-6 USHBC register contents

Bit position	Bit name	Function
1	UBHIEN	Specifies whether to enable the USB buffers. 0: Disable buffers. 1: Enable buffers. Caution: When not using the USB, clear the UBHIEN bit to 0.
0	UBHIOR	Specifies whether to enable the use of a measure to prevent the USB buffer inputs from floating. 0: Disable the use of a floating prevention measure. 1: Enable the use of a floating prevention measure. When no cable is connected (data input is in the floating state), it is necessary to take measures to prevent a signal that has an undefined value from being recognized as a bus reset, suspend, or resume signal. By setting this bit to 1, floating can be prevented by using a signal such as VBUS (for recognizing cable connection).

28.2 Overview

- Conforms to the Universal Serial Bus Specification Revision xx
- Supports 12 Mbps (full-speed) transfer
(Not supports low-speed transfer)
- Supports the open host controller interface (OHCI) 1.0a (with a restriction on changing USB ports from disabled to enabled)
- Supports control transfer, bulk transfer, interrupt transfer, and isochronous transfer^a
- Has a built-in root hub function and is equipped with 1 downstream port channel

- a) Isochronous transfer puts a heavy load on the system performance, so be sure to sufficiently evaluate performance with the target system in advance.

28.3 Configuration

28.3.1 Block diagram

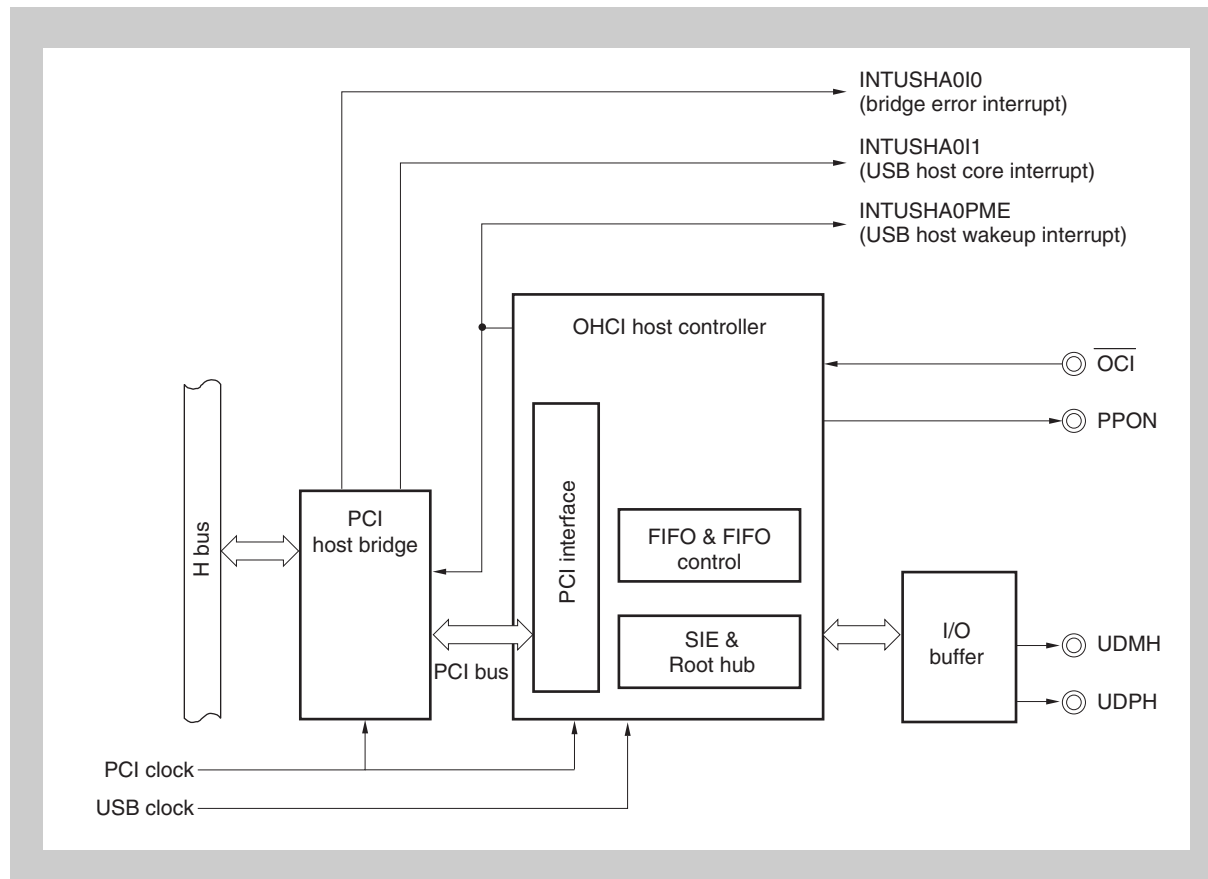

Figure 28-2 Block diagram of USB host controller

28.4 External circuit configuration

28.4.1 Overview

In USB transmission, when communication is performed with the host controller and function controller facing each other, pull-up/pull-down resistors must be connected to the USB signal pins (D+ and D-) to identify the communication partner. Moreover, in this microcontroller, series resistors must also be connected.

Because this microcontroller does not include pull-up, pull-down, or series resistors, be sure to connect them externally.

Figure 28-3 “Schematic configuration of pull-up, pull-down, and series resistors in USB transmission line” shows the outline configuration of the USB transmission line. For details about the external circuit configuration, see 28.4.2?Connection configuration?.

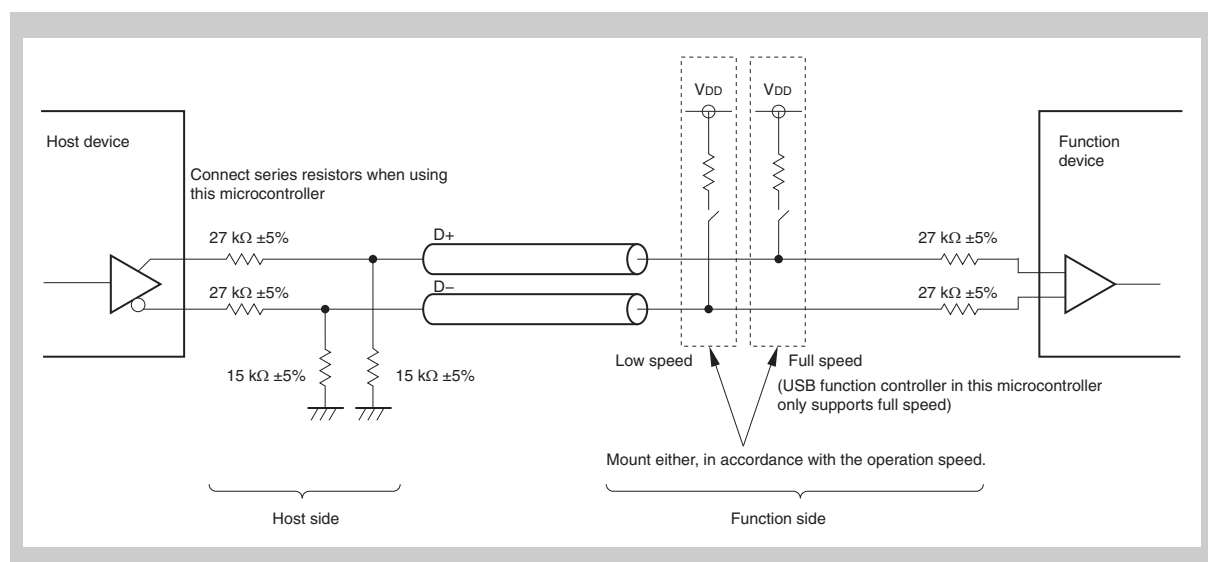

Figure 28-3 Schematic configuration of pull-up, pull-down, and series resistors in USB transmission line

28.4.2 Connection configuration

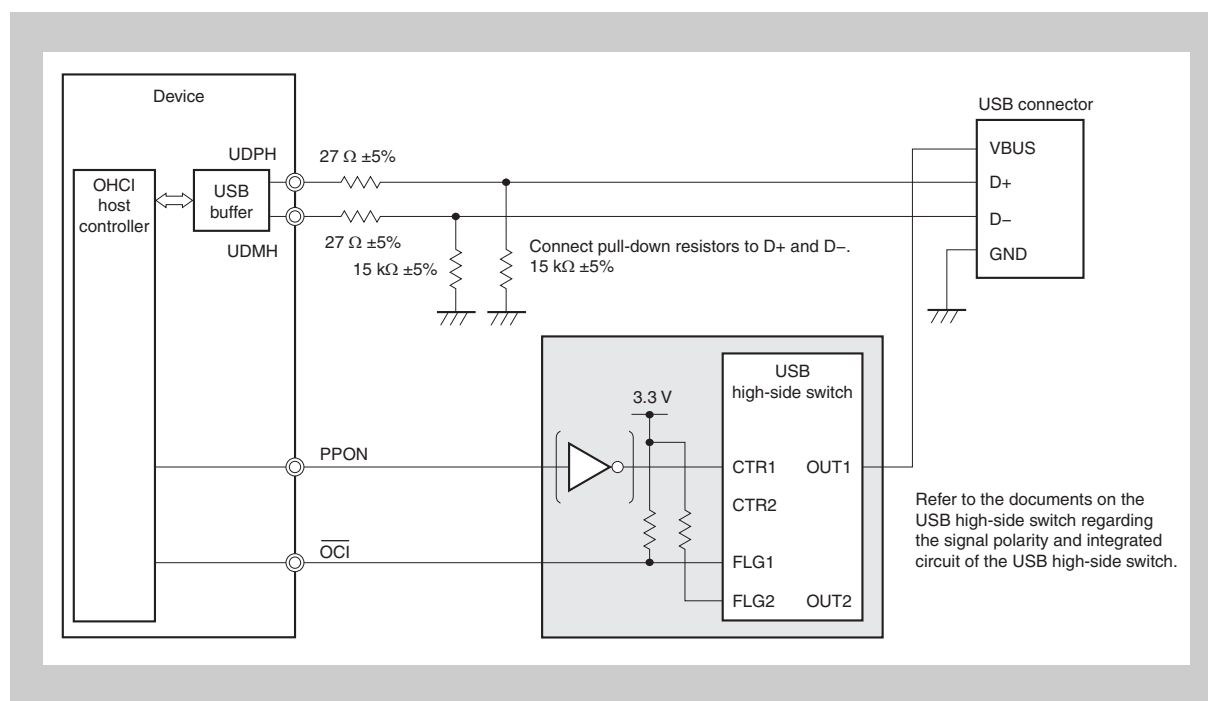

Figure 28-4 Example of USB host controller connection

(1) Series resistor connection to D+ and D-

Connect series resistors of $27\ \Omega \pm 5\%$ to the D+ and D- pins (UDPH, UDMH) of the USB host controller in this microcontroller. If they are not connected, the impedance specification cannot be satisfied and the output waveform might be disturbed.

Allocate the series resistors adjacent to this microcontroller as much as possible, and make the length of the wiring between the series resistors and the USB connectors the same, to make the impedance of D+ and D- equal (a differential with $90\ \Omega \pm 5\%$ is recommended).

(2) Pull-down resistor connection to D+ and D-

Be sure to pull down the D+ and D- pins (UDPH and UDMH) to GND using a resistance of $15\ \text{k}\Omega \pm 5\%$.

In this case, the configuration is the same as when no function device is connected.

28.4.3 USB power supply

(1) Overcurrent detection and power control

This microcontroller does not have a circuit for detecting overcurrent at USB ports or controlling the USB port power supply. To support these functions in the system, use an external circuit such as a USB high-side switch to configure these functions and connect it with the \overline{OCI} and PPON pins.

The following table shows the operations related to the \overline{OCI} and PPON pins used for controlling the external circuit for detecting overcurrent on USB ports or controlling the USB port power.

Table 28-7 OCI and PPON Signals

Pin	I/O	Level	Description
\overline{OCI}	Input	1	Overcurrent not detected
		0	Overcurrent detected
PPON	Output	1	Power supply to VBUS is on
		0	Power supply to VBUS is off

Figure 28-4 “Example of USB host controller connection” shows an example of connecting a circuit to detect overcurrent and control the power (VBUS). When the USB bus is not used, power consumption can be reduced by stopping VBUS supply to the port, though its availability depends on the connection to the USB connector. If the connected USB function device is bus-powered, using a high-side switch as shown in the connection example is recommended.

(2) VBUS control specification according to root hub register settings

Control of the PPS bit for controlling VBUS varies depending on the settings of the root hub control registers HcRhDescriptorA and HcRhDescriptorB.

To control VBUS for each port, the HcRhDescriptorA.NPS and HcRhDescriptorA.PSM bits must be set to 1.

28.5 Cautions

(1) Clock accuracy

To operate the USB host controller, a 48 MHz internal clock ($\{9.6 \text{ MHz external clock} \times \text{internal clock multiplied by } 20\}/4$ or $\{7.2 \text{ MHz external clock} \times \text{internal clock multiplied by } 20\}/3$) or a 48 MHz external clock (f_{USB}) (input to the USBCLK pin) must be used as the USB clock. When the external clock is used as the USB clock, supply a clock with an accuracy of 48 MHz ± 500 ppm max. (target) to the USBCLK pin. If the USB clock accuracy drops, the transmission data cannot satisfy the USB specifications.

The clock accuracy defined in the USB specifications is not guaranteed if an internal clock is used. Make sure to use an external clock to satisfy the USB specifications.

(2) Hub connection

Use of the external clock (crystal resonator) is recommended when connecting a device via the hub. When the internal clock is used, the USB specifications might not be satisfied because of the effects of clock jitter in the microcontroller's internal circuits. One-to-one connection with the host device is recommended when the internal clock is used.

28.6 PCI host bridge

28.6.1 PCI bridge registers

The table below lists the PCI bridge registers. For details about the base address, see *Table 28-2 “Register base addresses <USHA0_base>”*.

Address	Register name	Symbol	R/W	Manipulatable bit unit		Initial value
				16	32	
<USHA0_base_PCI> + 04 _H	PCI command register	USHA0PCICMD	R/W	✓		0006 _H
<USHA0_base_PCI> + 06 _H	PCI status register	USHA0PCISTS	R/W	✓		0280 _H
<USHA0_base_PCI> + 10 _H	PCI base address register 0	USHA0BAR0	R/W		✓	0000 0000 _H
<USHA0_base_PCI> + A0 _H	PCI address control register 0	USHA0ACR0	R/W		✓	0000 0000 _H
<USHA0_base_PCI> + C0 _H	Error register 1	USHA0ERR1	R/W		✓	0000 0000 _H
<USHA0_base_PCI> + CC _H	Read burst type register	USHA0RBTYPE	R/W		✓	0500 0000 _H
<USHA0_base_PCI> + E4 _H	PCI control register	USHA0PCICTRL_H	R/W		✓	0000 0000 _H
<USHA0_base_PCI> + EC _H	PCI BAR enable register	USHA0PCIBARE	R/W		✓	0000 DFFF _H
<USHA0_base_PCI> + F8 _H	PCI configuration address register	USHA0CNFIGADDR	R/W		✓	0000 0000 _H
<USHA0_base_PCI> + FC _H	PCI configuration data register	USHA0CNFIGDATA	R/W		✓	0000 0000 _H

(1) PCI command register (USHA0PCICMD)

The USHA0PCICMD register is used to specify the operating conditions of USBH on the PCI bus.

Access This register can be read or written in 16-bit units.

Address <USHA0_base_PCI> + 04_H

Initial value 0006_H. This register is initialized by any reset.

Caution Be sure to clear bits 15 to 3 and 0 to “0”.

15	14	13	12	11	10	9	8
0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
7	6	5	4	3	2	1	0
0	0	0	0	0	BMASEN	MEMEN	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 28-8 USHA0PCICMD register contents

Bit position	Bit name	Description
2	BMASEN	BUS Master Enable Specifies whether USBH operates as the PCI bus master. 0: USBH operates as the PCI bus master. 1: USBH does not operate as the PCI bus master.
1	MEMEN	Memory Space Enable Specifies whether USBH can access the memory space. 0: USBH cannot access the memory space. 1: USBH can access the memory space.

(2) PCI status register (USHA0PCISTS)

The USHA0PCISTS register is the PCI status register.

Access This register can be read or written in 16-bit units.

Address <USHA0_base_PCI> + 06_H

Initial value 0280_H. This register is initialized by any reset.

Caution Be sure to clear bits 15, 14, 11 to 0 to "0".

15	14	13	12	11	10	9	8
0	0	RMA	RTA	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
7	6	5	4	3	2	1	0
0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 28-9 USHA0PCISTS register contents

Bit position	Bit name	Description
13	RMA	Received Master-Abort This bit indicates whether master abort is received as the PCI master. This bit is cleared if 1 is written to. Writing 0 to this bit is ignored. 1: Master abort is received. 0: Master abort is cleared (default).
12	RTA	Received Target-Abort This bit indicates whether target abort is received as the PCI master. This bit is cleared if 1 is written to. Writing 0 to this bit is ignored. 1: Target abort is received. 0: Target abort is cleared (default).

(3) PCI base address register 0 (USHA0BAR0)

The USHA0BAR0 register is used to set up address window 0 when USBH operates as the PCI slave.

Access This register can be read or written in 32-bit units.

Address <USHA0_base_PCI> + 10_H

Initial value 0000 0000_H. This register is initialized by any reset.

- Notes**
1. Before specifying a value for the USHA0BAR0 register, specify the address space size by using PCI address control register 0 (USHA0ACR0).
 2. This register is cleared to 0 after a reset, so the value must be specified again when next using this register.
 3. If no space is used, set the USHA0ACR0.BARMASK bits to 0000b.
 4. If the USHA0BAR0 register setting is changed while the USB host controller is accessing the specified memory space via the PCI bus, the operation is undefined. Set up the USHA0BAR0 register during system initialization.

31	30	29	28	27	26	25	24

R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 28-10 USHA0BAR0 register contents

Bit position	Bit name	Function
31:4	BASEADD [31:4]	Specify the PCI slave start address (reset value: 0000000 _H).

(4) PCI address control register 0 (USHA0ACR0)

The USHA0ACR0 register is used to specify the size of the address space starting at the address specified by the USHA0BAR0 register and the address to be translated and passed to the AHB side.

Specify 64 KB as the address space size. If no space is used, set the BARMASK bits to 0000_B.

Access This register can be read or written in 32-bit units.

Address <USHA0_base_PCI> + A0_H

Initial value 0000 0000_H. This register is initialized by any reset.

- Notes**
1. Set the USHA0ACR0 register to 0000 0100_H.
 2. Before specifying a value for the USHA0BAR0 register, specify the address space size by using the USHA0ACR0 register.
 3. If the USHA0ACR0 register setting is changed while the USB host controller is accessing the specified memory space via the PCI bus, the operation is undefined. Set up the USHA0ACR0 register during system initialization.

Table 28-11 USHA0ACR0 register contents

Bit position	Bit name	Function
8:4	BARMASK [4:0]	Base Address Mask Specify the valid size of address window 0. Specify 10000 _B (64 KB).

(5) Error register 1 (USHA0ERR1)

This bit indicates the error generation status when an error response is returned to the USB host controller from the H-bus shared memory. This bit also possesses a control signal for asserting a bridge error interrupt (INTUSHA0I0) when an error is generated.

Access This register can be read or written in 32-bit units.

Address <USHA0_base_PCI> + C0_H

Initial value 0000 0000_H. This register is initialized by any reset.

Caution Be sure to clear bits 31 to 10, 8 to 6, and 4 to 0 to "0".

31	30	29	28	27	26	25	24
0	0	0	0	0	1	0	1

7	6	5	4	3	2	1	0
0	0	AMEr	0	0	0	0	0/1
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 28-12 USHA0ERR1 register contents

Bit position	Bit name	Function
9	AMEn	This bit enables notification using the bridge error interrupt (INTUSHA0I0) when the H-bus master unit in the PCI host bridge acknowledges an error response (when the H-bus shared memory returns an error response). 0: Do not assert the bridge error interrupt (INTUSHA0I0), even if the H-bus master unit in the PCI host bridge acknowledges an error response. 1: Assert the bridge error interrupt (INTUSHA0I0) when the H-bus master unit in the PCI host bridge acknowledges an error response.
5	AMEr	This bit is asserted when the H-bus master unit in the PCI host bridge acknowledges an error response. The bit is cleared to 0 when 1 is written to the AMEr bit. 0: The H-bus master unit in the PCI host bridge has not acknowledged an error response. 1: The H-bus master unit in the PCI host bridge has acknowledged an error response.

(6) Read burst type register (USHA0RBTYPE)

The USHA0RBTYPE register is used to specify the format of the access burst to be issued to the external bus during read transfers. Set up the USHA0RBTYPE register during initialization and do not change the setting while executing a transfer.

Access This register can be read or written in 32-bit units.

Address <USHA0_base_PCI> + CC_H

Initial value 0500 0000_H. This register is initialized by any reset.

Caution Be sure to specify 0500 0001_H.

31	30	29	28	27	26	25	24
0	0	0	0	0	1	0	1
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
23	22	21	20	19	18	17	16
0	0	0	0	0	0	0	0

15	14	13	12	11	10	9	8
0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
7	6	5	4	3	2	1	0
0	0	0	0	0	0	0	0/1
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

(7) PCI control register 1 (USHA0PCICTL_H)

The USHA0PCICTL_H register is used to specify the operating conditions of the PCI bus.

Access This register can be read or written in 32-bit units.

Address <USHA0_base_PCI> + E4_H

Initial value 0000 0000_H. This register is initialized by any reset.

- Cautions**
1. If the PCI master on the OHCI host controller is reset when the PCI host bridge sets the read data (data written from the CPU) by using a read request from the PCI master, accessing the PCI host bridge is not retried and the PCI bus might lock up. Therefore, if you are changing the settings of PCICRST from 0 to 1, you must first confirm that access to the PCI unit on the OHCI host controller has finished and stop access to the PCI unit on the OHCI host controller, or, change PCICRST by using the configuration register via the PCI in order to prevent the PCI host bridge from being reset during read data processing. In addition, when writing to the PCI unit on the OHCI host controller, use the PCI configuration address register (USHA0CNFIGADDR) and the PCI configuration data register (USHA0CNFIGDATA) to issue a configuration access to the PCI unit on the OHCI host controller. After writing to the PCICRST bit, read the register to confirm that the PCICRST bit has been set. Even if 1 is written to the PCICRST bit, the PCI host bridge is not reset.
 2. Be sure to clear bits 30, 29, 27 to 0 to "0".

31	30	29	28	27	26	25	24
PCICRST	0	0	CNFG DONE	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
23	22	21	20	19	18	17	16
0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
15	14	13	12	11	10	9	8
0	0	0	0	0	0	AMEn	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
7	6	5	4	3	2	1	0
0	0	AMEr	0	0	0	0	0/1
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 28-13 USHA0PCICTL_H register contents

Bit position	Bit name	Function
31	PCICRST	This bit controls the PCI interface on the OHCI host controller. Setting 1 resets the PCI interface on the OHCI host controller.
28	CNFGDON E	Specify the response for the access from the PCI on the OHCI host controller. 0: Issue a retry continuously for all accesses as the PCI on the OHCI host controller. 1: Acknowledge access as the PCI on the OHCI host controller.

(8) PCI BAR enable register (USHA0PCIBARE)

The USHA0PCIBARE register is used to enable or disable a PCI window. This register can be used to disable the window specified by using PCI address control register 0 (USHA0ACR0). If the window is disabled, even if an attempt is made to access the specified USHA0BAR0 space, the access is ignored .

Access This register can be read or written in 32-bit units.

Address <USHA0_base_PCI> + EC_H

Initial value 0000 DFFF_H. This register is initialized by any reset.

- Notes**
1. Be sure to clear bits 31 to 16 to “0”. Although the initial value of bits 11 to 1 is 1, be sure to clear these bits to 0.
 2. The USHA0PCIBARE register cannot be used to enable a USHA0BAR0 space disabled by using the USHA0ACR0 register.
 3. If the USHA0PCIBARE register setting is changed while the USB host controller is accessing the specified memory space via the PCI bus, the operation is undefined. Set up the USHA0PCIBARE register during system initialization.
 4. Be sure to set bits 15 to 12 to “1101”.
 5. Be sure to clear bits 11 to 1 to “0”.

Table 28-14 USHA0PCIBARE register contents

Bit position	Bit name	Function
0	BAR0En	USHA0BAR0 Enable Specifies whether to enable window 0 specified by using the USHA0BAR0 register. Be sure to set this bit to 1 to use the window. 0: Disable 1: Enable

(9) PCI configuration address register (USHA0CNFIGADDR)

The USHA0CNFIGADDR register is used to specify the address used to access the configuration of the PCI slaves on the OHCI host controller.

Set the CNFEN bit of the USHA0CNFIGADDR register to 1, and then access the USHA0CNFIGDATA register to perform a PCI configuration space access.

The USHA0CNFIGADDR and USHA0CNFIGDATA registers can only be accessed by using the AHB bus. Accessing these registers by using the PCI bus is prohibited.

Access This register can be read or written in 32-bit units.

Address <USHA0_base_PCI> + F8_H

Initial value 0000 0000_H. This register is initialized by any reset.

31	30	29	28	27	26	25	24

Table 28-15 USHA0CNFIGADDR register contents

Bit position	Bit name	Function
31	CNFEN	Config Enable Specifies whether to enable a PCI configuration space access. Before attempting a configuration space access by using the USHA0CNFIGDATA register, set this bit to 1. 0: Disable a configuration space access to a PCI device even if the USHA0CNFIGDATA register is accessed. 1: Enable a configuration space access to a PCI device if the USHA0CNFIGDATA register is accessed.
23:16	BUSNUM [23:16]	Bus Number Specify the number of the bus used for configuration space access. Set these bits to 0000 0000 _b . Type 0 configuration space access is specified.
15:11	DEVNUM [4:0]	Device Number Specify the device number. 00000: USB host configuration 00001: PCI host bridge internal registers Other than the above: Setting prohibited Accessing an PCI host bridge internal register by using these bits is required only when executing a PCI reset by using the PCICRST bit of the USHA0PCICTRL-H register.
10:8	FNCNUM [2:0]	Function Number Specify the function number. Set these bits to 000.
7:2	REGNUM [5:0]	Register Number Specify the OHCI configuration register number.

(10) PCI configuration data register (USHA0CNFIGDATA)

The USHA0CNFIGDATA register stores data used to access the configuration space of an external PCI slave.

Set the CNFEN bit of the USHA0CNFIGADDR register to 1, and then access the USHA0CNFIGDATA register to perform a PCI configuration space access.

When writing data to the configuration space of a PCI device, the data stored in the USHA0CNFIGDATA register is written. When reading data from the configuration space of a PCI device, the data read from the corresponding external PCI configuration register is stored in USHA0CNFIGDATA register.

The USHA0CNFIGADDR and USHA0CNFIGDATA registers can only be accessed by using the AHB bus. Accessing these registers by using the PCI bus is prohibited.

Access This register can be read or written in 32-bit units.

Address <USHA0_base_PCI> + FC_H

Initial value 0000 0000_H. This register is initialized by any reset.

28.7 OHCI host controller

28.7.1 OHCI host controller features

The OHCI host controller has the following features:

- Conforms to OpenHCI Specification Release 1.0a
- Conforms to Universal Serial Bus Specification Revision 1.1
 - Supports transfer at full-speed (12 Mbps)
- Incorporates 1 channel root hub and supports one downstream port
- USB clock: 48 MHz, PCI clock: 25 to 33 MHz
- Memory space
 - 4 KB PCI memory area (OHCI operational registers) allocated
 - 256-byte host controller communication area (HCCA) allocated
- Communication with CPU
 - Performs communication via operational registers in the OHCI host controller and the host controller communication area (HCCA).

Two communication channels are connected between the CPU and the OHCI host controller. The communication channel consists of OHCI operational registers, and the OHCI host controller serves as a target (slave) for this communication. The Base Address register (10_H) in the OHCI host configuration registers functions as a pointer to the OHCI operational registers.

The second communication channel is the host controller communication area (HCCA) in the OHCI operational registers, which functions as a pointer to the shared memory. The OHCI host controller serves as a master for this communication.

Descriptor information used for communication is managed by the OHCI operational registers and the HCCA area.

28.7.2 OHCI host configuration registers

The OHCI host configuration registers configure a 256-byte register space, and are incorporated in the OHCI host controller. These registers are accessed from the CPU system via PCI host bridge registers (USHA0CNFIGDATA and USHA0CNFIGADDR). For details about the base address, see 28.1.1?USB host controller memory map?.

Table 28-17 OHCI host configuration registers

Address	Bit 31	24	23	16	15	8	7	0	
00 _H	Reserved				Reserved

R	R/W	R	R	R	R/W	R/W	R

Table 28-18 Command and Status register contents (1/2)

Bit position	Bit name	Function
31	Detected Parity Error	Indicates the parity error status. This bit is set when an address or data parity error is detected. This bit is cleared to 0 when 1 is written via the PCI bus.
30	Signaled System Error	Indicates the SERR status. This bit is set when a system error occurs. This bit is cleared to 0 when 1 is written via the PCI bus.
29	Received Master Abort	Indicates the master's master abort status. This bit is set when master operation is terminated by master abort. This bit is cleared to 0 when 1 is written via the PCI bus.
28	Received Target Abort	Indicates the master's target abort status. This bit is set when master operation is terminated by target abort. This bit is cleared to 0 when 1 is written via the PCI bus.
27	Signaled Target Abort	Indicates the slave's target abort status. This bit is set when slave operation is terminated by target abort. This bit is cleared to 0 when 1 is written via the PCI bus.
26:25	Devsel Timing[1:0]	Indicates the DEVSEL response speed. This field is fixed to 01 because only the medium mode is supported. These bits are read-only.
24	Data Parity Detected	This bit is set when a parity error is detected during master operation. This bit is cleared to 0 when 1 is written via the PCI bus. This bit is fixed to 0 when the parity error response is disabled by using the Parity Error Response bit (Command register).
23	Fast Back to Back Capable	Indicates whether Fast Back-to-Back is supported. This bit is fixed to 0 because Fast Back-to-Back is not supported. This bit is read-only.
22:21	–	Reserved (Be sure to write 0 to these bits.)

Table 28-18 Command and Status register contents (2/2)

Bit position	Bit name	Function
20	Capabilities	Indicates that the power management mode is supported. This bit is fixed to 1. This bit is read-only.
19:10	–	Reserved (Be sure to write 0 to these bits.)
9	Fast Back to Back Enable	This bit is used to enable Fast Back-to-Back. This bit is fixed to 0 because the USB host controller does not support Fast Back to Back. This bit is read-only.
8	SERR Enable	This bit is used to enable SERR. Set this bit to 1 when reporting system errors by using the SERR signal.
7	Wait Cycle Control	This bit is used to enable wait cycle control. This bit is fixed to 0 because the USB host controller does not support address/data stepping. This bit is read-only.
6	Parity Error Response	This bit is used to enable parity error responses. Set this bit to 1 when checking parity errors.
5	VGA Palette Snoop	This bit is used to enable VGA palette snoop. This bit is fixed to 0 because the USB host controller does not support VGA palette snoop. This bit is read-only.
4	Memory Write and Invalidate	This bit is used to enable Memory Write and Invalidate. This bit is fixed to 0 because the USB host controller does not support Memory Write and Invalidate. This bit is read-only.
3	Special Cycle	This bit is used to enable special cycles. This bit is fixed to 0 because the USB host controller does not support Special Cycle. This bit is read-only.
2	Bus Master	This bit is used to enable bus master operation. This bit enables bus master accesses for the PCI bus and must be set to 1 before accessing SRAM via the system bus. Set this bit to 1 during host controller initialization.
1	Memory Space	This bit is used to enable memory space access. This bit enables memory accesses as defined in the PCI Specification, and must be set to 1 before accessing registers. Set this bit to 1 during host controller initialization.
0	I/O Space	This bit is used to enable I/O space access. This bit enables I/O accesses as defined in the PCI Specification, but this bit is fixed to 0 because the USB host controller does not use I/O accesses. This bit is read-only.

(2) Revision ID and Class Code registers (Offset: 08_H)

Access These registers are read-only, in 32-bit units.

Address 08_H

Initial value 0C03 1042_H. These registers are initialized by any reset.

31	30	29	28	27	26	25	24

R	R	R	R	R	R	R	R

Table 28-19 Revision ID and Class Code register contents

Bit position	Bit name	Function
31:24	Base Class [7:0]	Indicates the base class defined in the PCI Specification (Class Code). This field is fixed to 0C _H , which indicates the serial peripheral interface bus controller.
23:16	Sub Class [7:0]	Indicates the subclass defined in the PCI Specification (Class Code). This field is fixed to 03 _H , which indicates the USB device.
15:8	Program-ming I/F [7:0]	Indicates the program interface defined in the PCI Specification (Class Code). This field is fixed to 10 _H , which indicates an OHCI-specification USB.
7:0	Revision ID [7:0]	Indicates the revision of the USB host controller (Class Code). These bits are fixed to 42 _H .

(3) Cache Line Size, Latency Timer, Header Type, and BIST registers (Offset: 0C_H)

Access These registers can be read or written in 32-bit units.

Address 0C_H

Initial value 00000800_H. These registers are initialized by any reset.

31	30	29	28	27	26	25	24
BIST7	BIST6	BIST5	BIST4	BIST3	BIST2	BIST1	BIST0

Table 28-20 Cache Line Size, Latency Timer, Header Type, and BIST register contents

Bit position	Bit name	Function
31:24	BIST[7:0]	Field for self-testing. These bits are fixed to 00 _H . These bits are read-only.
23:16	Header Type[7:0]	Field for reporting the header type to the system This field is fixed to 00 _H because the device is a PCI device. Particularly, bit 23 is fixed to 0 because multifunction is not supported. These bits are read-only.
15:8	Latency Timer[7:0]	Field for reporting the latency timer to the system The lower 2 bits are fixed to 00. These bits are read-only.
7:0	Cache Line Size[7:0]	Field for reporting the cache line size to the system These bits are fixed to 00 _H . These bits are read-only.

(4) OHCI Base Address register (Offset: 10_H)

Access This register can be read or written in 32-bit units.

Address 10_H

Initial value 0000 0000_H. This register is initialized by any reset.

31	30	29	28	27	26	25	24

Table 28-21 OHCI Base Address register contents

Bit position	Bit name	Function
31:4	OHCI Base Address [27:0]	Specify the OHCI operational register address by using bits 31 to 12. Specify the OHCI operational register base address defined by the system during initialization. Bits 11 to 4 are fixed to 00 _H . These bits are read-only.
3	Prefetchable	Field indicating that the field specified by using the OHCI Base Address bits is a memory space. This bit is fixed to 0. This bit is fixed to 0, which indicates that prefetching from the field is prohibited. This bit is read-only.
2:1	Type[1:0]	Field that indicates the base address type. This field is fixed to 00. Indicates that the address specified by using the OHCI Base Address bits is a specific position in a 32-bit space. These bits are read-only.
0	Memory Space Indicator	Field indicating that the field specified by using the OHCI Base Address bits is a memory space. This bit is fixed to 0. This bit is read-only.

(5) Capability Pointer register (Offset: 34_H)

Access This register is read-only, in 32-bit units.

Address 34_H

Initial value 0000 0040_H. This register is initialized by any reset.

Table 28-24 Capability Identifier, Next Item Pointer, and Power Management Capabilities register contents

Bit position	Bit name	Function
31	PME Support [4:0]	Indicates whether the D3 Cold state is supported (Power Management Capabilities). This bit is fixed to 0 because the D3 Cold state is not supported.
30:27		Indicates that PME (Power Management Capabilities) is supported in all PCI power states (D0 to D3). These bits are fixed to 1111.
26	D2 Support	Indicates that D2 of the PCI power states is supported (Power Management Capabilities). This bit is fixed to 1.
25	D1 Support	Indicates that D1 of the PCI power states is supported (Power Management Capabilities). This bit is fixed to 1.
24:22	Aux Current [2:0]	Indicates that asserting PME interrupts in the D3 Cold state is not supported (Power Management Capabilities). These bits are fixed to 000.
21	DSI	Indicates that no special initialization is required when using Power Management (Power Management Capabilities). This bit is fixed to 0.
19	PME CLK	Indicates that PCLK is not required for generating PME interrupts (Power Management Capabilities). This bit is fixed to 0.
18:16	Version[2:0]	Indicates the power management version (Power Management Capabilities). These bits are fixed to 010 according to the circuit configuration implemented in the OHCI host controller.
15:8	Next Item Pointer[7:0]	Indicates that the next item does not exist. These bits are fixed to 00 _H .
7:0	Capability Identifier [7:0]	Indicates the Power Management register ID. These bits are fixed to 01 _H .

(8) Power Management Control/Status and PMCSR Bridge Support Extensions registers (Offset: 44_H)

Access These registers can be read or written in 32-bit units.

Address 44_H

Initial value 0000 0000_H. These registers are initialized by any reset.

Table 28-25 Power Management Control/Status and PMCSR Bridge Support Extensions register contents

Bit position	Bit name	Function															
31:24	Data[7:0]	This field is optional in the PCI Specification, and is not supported by the OHCI host controller (Data). These bits are fixed to 00. These bits are read-only.															
23	BPCC Enable	Bit for PCI bridges, which is not supported by the OHCI host controller (PMCSR Bridge Support Extensions). This bit is fixed to 0. This bit is read-only.															
22	B2_B3	Bit for bridges, which is not supported by the OHCI host controller (PMCSR Bridge Support Extensions). This bit is fixed to 0. This bit is read-only.															
15	PME Status	Indicates the PME interrupt status (Power Management Control/Status). This bit is set to 1 when conditions for asserting PME are satisfied. This bit is cleared to 0 when 1 is written to it via the PCI bus.															
14:13	Data Scale [1:0]	This field is optional in the PCI Specification, and is not supported by the OHCI host controller (Power Management Control/Status). These bits are fixed to 00. These bits are read-only.															
12:9	Data Select [3:0]	This field is optional in the PCI Specification, and is not supported by the OHCI host controller (Power Management Control/Status). These bits are fixed to 0000. These bits are read-only.															
8	PME Enable	Bit for setting whether to use external pin PME (Power Management Control/Status). If this bit is set to 1, a PME interrupt occurs when returning from power management mode.															
1:0	Power State[1:0]	Indicates the PCI power status (Power Management Control/Status). The status varies as follows depending on the setting of these bits: <table border="1" data-bbox="507 1272 1390 1487"> <thead> <tr> <th>Power State1</th> <th>Power State0</th> <th>Field status</th> </tr> </thead> <tbody> <tr> <td>0</td> <td>0</td> <td>D0 State</td> </tr> <tr> <td>0</td> <td>1</td> <td>D1 State</td> </tr> <tr> <td>1</td> <td>0</td> <td>D2 State</td> </tr> <tr> <td>1</td> <td>1</td> <td>D3 hot State</td> </tr> </tbody> </table>	Power State1	Power State0	Field status	0	0	D0 State	0	1	D1 State	1	0	D2 State	1	1	D3 hot State
Power State1	Power State0	Field status															
0	0	D0 State															
0	1	D1 State															
1	0	D2 State															
1	1	D3 hot State															

28.7.3 OHCI operational registers

The OHCI operational registers are incorporated in the OHCI host controller, and consist of the registers listed in *Table 28-26 "OHCI operational registers"*. For details, see OpenHCI Specification Release 1.0a.

Because OpenHCI Specification Release 1.0a defines the port number as [1: number of ports], this section observes this rule. For example, port 1 corresponds to host channel 0 and port 2 corresponds to host channel 1. For details about the base address, see *Table 28-2?Register base addresses <USAHO_base>?*.

Table 28-26 OHCI operational registers

Address	Bit	31	24	23	16	15	8	7	0
00 _H	HcRevision								
04 _H	HcControl								
08 _H	HcCommandStatus								
0C _H	HcInterruptStatus								
10 _H	HcInterruptEnable								
14 _H	HcInterruptDisable								
18 _H	HcHCCA								
1C _H	HcPeriodCurrentED								
20 _H	HcControlHeadED								
24 _H	HcControlCurrentED								
28 _H	HcBulkHeadED								
2C _H	HcBulkCurrentED								
30 _H	HcDoneHead								
34 _H	HcFmInterval								
38 _H	HcFmRemaining								
3C _H	HcFmNumber								
40 _H	HcPeriodicStart								
44 _H	HcLSThreshold								
48 _H	HcRhDescriptorA								
4C _H	HcRhDescriptorB								
50 _H	HcRhStatus								
54 _H	HcRhPortStatus1								
58 _H	HcRhPortStatus2								
5C _H to FF _H	Reserved								

Note HC: OHCI host controller
HCD: OHCI host controller driver
ED: Endpoint descriptor
TD: Transfer descriptor
EOP: End of packet
SOF: Start of frame

(1) HcRevision register (Offset: 00_H)

Access This register is read-only, in 32-bit units.

Address <USHA0_base_OHCI> + 00_H

Initial value 0000 0010_H. This register is initialized by any reset.

31	30	29	28	27	26	25	24
0	0	0	0	0	0	0	0

Revision							
R	R	R	R	R	R	R	R

Table 28-27 HcRevision register contents

Bit position	Bit name	Function
31:9	–	Reserved (Be sure to write 0 to these bits.)
8	Legacy	Indicates whether legacy-support registers are implemented in the OHCI host controller. This bit is fixed to 0 because the OHCI host controller does not support the legacy function.
7:0	Revision	Indicates the version of the OHCI Specification implemented in the OHCI host controller These bits are fixed to 10 _H because the OHCI host controller is compliant with OHCI Specification 1.0a.

(2) HcControl register (Offset: 04_H)

Access This register can be read or written in 32-bit units.

Address <USHA0_base_OHCI> + 04_H

Initial value 0000 0000_H. This register is initialized by any reset.

31	30	29	28	27	26	25	24
0	0	0	0	0	0	0	0

Table 28-28 HcControl register contents (1/2)

Bit position	Bit name	Function										
31:11	–	Reserved (Be sure to write 0 to these bits.)										
10	RWE	Remote WakeUp Enable Specifies how to detect an upstream resume signal. 1: Detect the resume signal as Remote Wakeup. 0: Do not detect the resume signal as Remote Wakeup.										
9	RWC	Remote WakeUp Connect Indicates whether the OHCI host controller supports Remote Wakeup. This bit must be set during initialization if remote wakeup is supported in the system. 1: Remote Wakeup is supported. 0: Remote Wakeup is not supported.										
8	IR	Interrupt Routing Indicates the method by which the OHCI host controller outputs interrupts. Specify how to report to the HcInterruptStatus register the source of an interrupt that has occurred. 1: Report the interrupt by using SMMI. 0: Report the interrupt by using INTA.										
7:6	HCFS[1:0]	Host Controller Functional State Indicates the OHCI host controller operating status. <table border="1"> <thead> <tr> <th>HCFS</th><th>USB status</th></tr> </thead> <tbody> <tr> <td>00</td><td>USB Reset</td></tr> <tr> <td>01</td><td>USB Resume</td></tr> <tr> <td>10</td><td>USB Operational</td></tr> <tr> <td>11</td><td>USB Suspend</td></tr> </tbody> </table> When the OHCI host controller transitions the USB Operational state, it starts management of frames in 1 ms units. This status is always controlled by the host controller driver (HCD) except for when the status transitions to USB Resume by remote wakeup during USB Suspend. This field is set to 00 after a hardware reset, or 11 after a software reset.	HCFS	USB status	00	USB Reset	01	USB Resume	10	USB Operational	11	USB Suspend
HCFS	USB status											
00	USB Reset											
01	USB Resume											
10	USB Operational											
11	USB Suspend											

Table 28-28 HcControl register contents (2/2)

Bit position	Bit name	Function										
5	BLE	<p>Bulk List Enable Specify whether to perform bulk list processing. 1: Perform bulk list processing. 0: Do not perform bulk list processing. The setting of this bit becomes valid from the next frame of bulk list processing. This bit must be 0 when modifying a bulk list.</p>										
4	CLE	<p>Control List Enable Specify whether to perform control list processing. 1: Perform control list processing. 0: Do not perform control list processing. The setting of this bit becomes valid from the next frame of control list processing. This bit must be 0 when modifying a control list.</p>										
3	IE	<p>Isochronous Enable Specify whether to perform isochronous ED processing. This bit is checked when an isochronous ED is detected during list processing to determine whether to perform isochronous ED processing. 1: Perform isochronous transfer processing. 0: Do not perform isochronous transfer processing. The setting of this bit becomes valid from the next frame of isochronous transfer processing.</p>										
2	PLE	<p>Periodic List Enable Specify whether to perform periodic list processing. 1: Perform periodic list processing. 0: Do not perform periodic list processing. The setting of this bit becomes valid from the next frame of periodic list processing.</p>										
1:0	CBSR[1:0]	<p>Control Bulk Service Ratio Specify the ratio of control transfer and bulk transfer services. The ratio specified in this field is retained and transfer is performed using this ratio during periodic list processing.</p> <table border="1"> <thead> <tr> <th>CBSR</th> <th>ED Service ratio (Bulk ED:Control ED)</th> </tr> </thead> <tbody> <tr> <td>00</td> <td>1:1</td> </tr> <tr> <td>01</td> <td>2:1</td> </tr> <tr> <td>10</td> <td>3:1</td> </tr> <tr> <td>11</td> <td>4:1</td> </tr> </tbody> </table>	CBSR	ED Service ratio (Bulk ED:Control ED)	00	1:1	01	2:1	10	3:1	11	4:1

0	0	0	0	0	0	0	0
R	R	R	R	R	R	R	R
7	6	5	4	3	2	1	0
0	0	0	0	OCR	BLF	CLF	HCR
R	R	R	R	R/W	R/W	R/W	R/W

Table 28-29 HcCommandStatus register contents (1/2)

Bit position	Bit name	Function
31:18	–	Reserved (Be sure to write 0 to these bits.)
17:16	SOC[1:0]	Scheduling Overrun Count This field is used to count the number of schedule overruns. This counter is incremented each time a schedule overrun occurs. This counter continues to be incremented even if the SO bit of the HcInterruptStatus register is set to 1. These bits are read-only.
15:4	–	Reserved (Be sure to write 0 to these bits.)
3	OCR	Ownership Change Request This bit is used to request to change the ownership of the OHCI host controller.
2	BLF	Bulk List Filled Indicates whether a TD exists in a bulk list. The host controller driver (HCD) sets this bit to 1 each time a TD is added to the ED of a bulk list. The OHCI host controller checks this bit when starting bulk list head processing. Bulk list processing is not started if this bit is 0. If this bit is 1, the OHCI host controller clears it to 0 and bulk list processing starts. If a TD is detected in a bulk list, this bit is set to 1 to continue bulk list processing. The host controller driver must set this bit before reconfiguring the list, setting the BLE bit of the HcCommand register, and starting list processing.
1	CLF	Control List Filled Indicates whether a control list exists. The host controller driver (HCD) sets this bit to 1 each time a TD is added to the ED of a control list. The OHCI host controller checks this bit when starting control list head processing. Control list processing is not started if this bit is 0. If this bit is 1, the OHCI host controller clears it to 0 and control list processing starts. If a TD is detected in a control list, this bit is set to 1 to continue control list processing. The host controller driver must set this bit before reconfiguring the list, setting the CLE bit of the HcCommand register, and starting list processing.

Table 28-29 HcCommandStatus register contents (2/2)

Bit position	Bit name	Function
0	HCR	Host Controller Reset This bit is used to execute a software reset for the OHCI host controller. When this bit is set, the USB Suspend state is entered regardless of the OHCI host controller function state. The OHCI host controller clears this bit to 0 when the reset operation finishes.

(4) HcInterruptStatus register (Offset: 0C_H)

Access This register can be read or written in 32-bit units.

Address <USHA0_base_OHCI> + 0C_H

Initial value 0000 0000_H. This register is initialized by any reset.

Caution In addition, if an interrupt from the USBF is detected, the value of the interrupt request is stored in the EICn.EIRFn bit (n = 190 to 192). Therefore, even if the CPU acknowledges the interrupt and the EICn.EIRFn bit of the interrupt control register (INTUSHA0xxx) is automatically cleared to 0, the EICn.EIRFn bit is immediately set to 1 and an interrupt is continuously generated. To prevent this from happening, clear the status flag of each interrupt request in the interrupt service routine, and then forcibly clear the EICn.EIRFn bit to 0.

31	30	29	28	27	26	25	24

Table 28-30 HcInterruptStatus register contents (1/2)

Bit position	Bit name	Function
31	–	Reserved (Be sure to write 0 to these bits.)
30	OC	Ownership Change Indicates that an Ownership Change interrupt has occurred. This bit is set to 1 when the OCR field of the HcCommandStatus register is set to 1. An SMMI interrupt occurs if the interrupt source is not masked. 1: An OC interrupt has occurred. 0: No OC interrupt has occurred. Writing 1 to this bit clears the interrupt source.
29:7	–	Reserved (Be sure to write 0 to these bits.)
6	RHSC	Root Hub Status Change Indicates that the HcRhPortStatus register setting has been changed. This bit is set to 1 when the status of the HcRhPortStatus register has been changed due to a hardware interrupt. 1: An RHSC interrupt has occurred. 0: No RHSC interrupt has occurred. Writing 1 to this bit clears the interrupt source.

Table 28-30 HcInterruptStatus register contents (2/2)

Bit position	Bit name	Function
5	FNO	<p>Frame Number Overflow</p> <p>Indicates that the MSB of a frame number has been changed. This bit is set to 1 after HccaFrameNumber is updated in a frame whose frame number MSB changes from 0 to 1, or 1 to 0.</p> <p>1: An FNO interrupt has occurred. 0: No FNO interrupt has occurred.</p> <p>Writing 1 to this bit clears the interrupt source.</p>
4	UE	<p>Unrecoverable Error</p> <p>Indicates that a system error has been detected on the PCI bus not related to the USB.</p> <p>1: A UE interrupt has occurred. 0: No UE interrupt has occurred.</p> <p>Writing 1 to this bit clears the interrupt source.</p>
3	RD	<p>Resume Detected</p> <p>Indicates that a resume signal has been detected. This bit is set to 1 when asserting the resume signal by a device on the USB bus is detected. This bit is not set if USB Resume is issued by the host controller driver (HCD).</p> <p>1: An RD interrupt has occurred. 0: No RD interrupt has occurred.</p> <p>Writing 1 to this bit clears the interrupt source.</p>
2	SF	<p>StartOfFrame</p> <p>Indicates that HccaFrameNumber was updated at the beginning of a frame. The OHCI host controller transmits the SOF packet and updates HccaFrameNumber.</p> <p>1: An SF interrupt has occurred. 0: No SF interrupt has occurred.</p> <p>Writing 1 to this bit clears the interrupt source.</p>
1	WDH	<p>Writeback Done Head</p> <p>Indicates that the OHCD host controller updated HccaDoneHead. The OHCI host controller sets this bit to 1 immediately after updating HccaDoneHead, and does not update HccaDoneHead until this bit is cleared to 0.</p> <p>1: A WDH interrupt has occurred. 0: No WDH interrupt has occurred.</p> <p>Writing 1 to this bit clears the interrupt source.</p>
0	SO	<p>Scheduling Overrun</p> <p>Indicates that the USB scheduling in a frame has overrun. This bit is set to 1 after updating of FrameNumberUpdate of the frame following the frame in which the USB scheduling overruns. When this bit is set to 1, the SOC field of the HcCommandStatus register is incremented.</p> <p>1: An SO interrupt has occurred. 0: No SO interrupt has occurred.</p> <p>Writing 1 to this bit clears the interrupt source.</p>

(5) HcInterruptEnable register (Offset: 10_H)

Access This register can be read or written in 32-bit units.

Address <USHA0_base_OHCI> + 10_H

Initial value 0000 0000_H. This register is initialized by any reset.

Table 28-31 HcInterruptEnable register contents (1/2)

Bit position	Bit name	Function
31	MIE	Master Interrupt Enable Specify whether to enable interrupt sources specified by using bits 30 and 6 to 0. 1: Enable all the specified interrupt sources. 0: Invalid (writing 0 is ignored). To disable the interrupt, write 1 to the corresponding bit of the HcInterruptDisable register.
30	OCE	Ownership Change Enable Specifies whether to enable OC as an interrupt source. 1: Enable OC as an interrupt source. 0: Invalid (writing 0 is ignored). Writing 1 to this bit specifies OC as an interrupt source. To disable the interrupt, write 1 to the corresponding bit of the HcInterruptDisable register.
29:7	–	Reserved (Be sure to write 0 to these bits.)
6	RHSCE	Root Hub Status Change Enable Specify whether to enable RHSC as an interrupt source. 1: Enable RHSC as an interrupt source. 0: Invalid (writing 0 is ignored). Writing 1 to this bit specifies RHSC as an interrupt source. To disable the interrupt, write 1 to the corresponding bit of the HcInterruptDisable register.
5	FNOE	Frame Number Overflow Enable Specify whether to enable FNO as an interrupt source. 1: Enable FNO as an interrupt source. 0: Invalid (writing 0 is ignored). Writing 1 to this bit specifies FNO as an interrupt source. To disable the interrupt, write 1 to the corresponding bit of the HcInterruptDisable register.

Table 28-31 HcInterruptEnable register contents (2/2)

Bit position	Bit name	Function
4	UEE	<p>Unrecoverable Error Enable Specify whether to enable UE as an interrupt source. 1: Enable UE as an interrupt source. 0: Invalid (writing 0 is ignored). Writing 1 to this bit specifies UE as an interrupt source. To disable the interrupt, write 1 to the corresponding bit of the HcInterruptDisable register.</p>
3	RDE	<p>Resume Detected Enable Specify whether to enable RD as an interrupt source. 1: Enable RD as an interrupt source. 0: Invalid (writing 0 is ignored). Writing 1 to this bit specifies RD as an interrupt source. To disable the interrupt, write 1 to the corresponding bit of the HcInterruptDisable register.</p>
2	SFE	<p>State Of Frame Enable Specify whether to enable SF as an interrupt source. 1: Enable SF as an interrupt source. 0: Invalid (writing 0 is ignored). Writing 1 to this bit specifies SF as an interrupt source. To disable the interrupt, write 1 to the corresponding bit of the HcInterruptDisable register.</p>
1	WDHE	<p>Writeback Done Head Enable Specify whether to enable WDH as an interrupt source. 1: Enable WDH as an interrupt source. 0: Invalid (writing 0 is ignored). Writing 1 to this bit specifies WDH as an interrupt source. To disable the interrupt, write 1 to the corresponding bit of the HcInterruptDisable register.</p>
0	SOE	<p>Scheduling Overrun Enable Specify whether to enable SO as an interrupt source. 1: Enable SO as an interrupt source. 0: Invalid (writing 0 is ignored). Writing 1 to this bit specifies SOE as an interrupt source. To disable the interrupt, write 1 to the corresponding bit of the HcInterruptDisable register.</p>

(6) HcInterruptDisable register (Offset: 14_H)

Access This register can be read or written in 32-bit units.

Address <USHA0_base_OHCI> + 14_H

Initial value 0000 0000_H. This register is initialized by any reset.

Table 28-36 HcControlCurrentED register contents

Bit position	Bit name	Function
31:4	Control CurrentED [27:0]	Indicates the processing address included in a control list. The OHCI host controller updates the value of this field each time a control ED processing sequence ends. When configuring a new list, set this field 0000 0000 _H , which indicates the end of the list. When suspending or resuming a transfer, it must be guaranteed that the ED indicated by this field exists.

(11) HcBulkHeadED register (Offset: 28_H)

Access This register can be read or written in 32-bit units.

Address <USHA0_base_OHCI> + 28_H

Initial value 0000 0000_H. This register is initialized by any reset.

31	30	29	28	27	26	25	24

R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 28-40 HcFmInterval register contents

Bit position	Bit name	Function
31	FIT	Frame Interval Toggle This bit is used to synchronize the frame setting values of the host controller driver (HCD) and OHCI host controller. Toggle the setting of this bit when writing to the FI field by using the HCD. The OHCI host controller applies the FIT value to the FRT bit of the HcFmRemaining register when loading the FI field. The HCD can check whether the new FI field value has been applied by comparing the FIT bit value that was specified when it was written to the FI field and the FRT bit value that was read.
30:16	FSMPS [14:0]	FSLargest Data Packet Specify the maximum data amount that can be transmitted or received without causing a schedule overrun. The current frame position and the specified value are compared, and judged up to which position of a frame can be transferred. The result depends on the system bus performance, so this value is specified by the host controller driver (HCD).
15:14	–	Reserved (Be sure to write 0 to these bits.)
13:0	FI[13:0]	FrameInterval Specify the bit time for the interval of two successive SOFs in Full-Speed mode. This field must be set to 2EDF _H to satisfy the length of one frame (= 1 ms) prescribed by the USB Specification.

(15) HcFmRemaining register (Offset: 38_H)

Access This register is read-only, in 32-bit units.

Address <USHA0_base_OHCI> + 38_H

Initial value 00002EDF_H. This register is initialized by any reset.

31	30	29	28	27	26	25	24

7	6	5	4	3	2	1	0
FR7	FR6	FR5	FR4	FR3	FR2	FR1	FR0
R	R	R	R	R	R	R	R

Table 28-41 HcFmRemaining register contents

Bit position	Bit name	Function
31	FRT	Frame Remaining Toggle This bit is used to synchronize the frame setting values of the host controller driver (HCD) and OHCI host controller. The OHCI host controller copies the FIT field value to this bit when the FR field is set to 0 _H and the FI field value is reloaded. The HCD can check whether the value set to the FI field has been applied to the FR field by comparing the FIT bit and FRT bit values.
13:0	FR [13:0]	Frame Remaining Indicates the current frame value. The value of this field is decremented as time elapses. Because the frame value is reloaded when the value of FI field becomes 0 _H , the FR field value is copied to this field and decrementing starts again.

(16) HcFmNumber register (Offset: 3C_H)

Access This register is read-only, in 32-bit units.

Address <USHA0_base_OHCI> + 3C_H

Initial value 0000 0000_H. This register is initialized by any reset.

31	30	29	28	27	26	25	24

Table 28-43 HcPeriodicStart register contents

Bit position	Bit name	Function
31:14	–	Reserved (Be sure to write 0 to these bits.)
13:0	Periodic Start[13:0]	These bits are used to determine the transfer ratio of periodic and async lists in a PeriodicStart field frame. This field must be set by the host controller driver (HCD) during initialization of the OHCI host controller. If the value of the FR field is larger than the value set to this field, the non-periodic list takes precedence over the periodic list. The OHCI Specification recommends setting this value to about 10% of the FI field value, and the relevant value is 3E67 _H .

(18) HcLSThreshold register (Offset: 44_H)

Access This register can be read or written in 32-bit units.

Address <USHA0_base_OHCI> + 44_H

Initial value 00000628_H. This register is initialized by any reset.

31	30	29	28	27	26	25	24

Table 28-44 HcLSThreshold register contents

Bit position	Bit name	Function
31:12	–	Reserved (Be sure to write 0 to these bits.)
11:0	HcLSThres- -hold[11:0]	Specify the threshold value for whether another transfer can be made before the remaining frame time elapses during an LS transfer. If the FR field value is larger than the value set to this field, an LS transfer can be started.

(19) HRDA (HcRhDescriptorA) register (Offset: 48_H)

Access This register can be read or written in 32-bit units.

Address <USHA0_base_OHCI> + 48_H

Initial value FF00 0902_H. This register is initialized by any reset.

	31	30	29	28	27	26	25	24

	NDP7	NDP6	NDP5	NDP4	NDP3	NDP2	NDP1	NDP0
	R	R	R	R	R	R	R	R

Table 28-45 HRDA (HcRhDescriptorA) register contents

Bit position	Bit name	Function
31:24	POTPGT [7:0]	Power On To Power Good Time Specify the wait time until the host controller driver (HCD) accesses a root hub powered on (unit: 2 ms). The wait time is calculated by POTPGT field value × 2 ms.
23:13	–	Reserved (Be sure to write 0 to these bits.)
12	NOCP	No Over Current Protection Specify whether to support root hub overcurrent protection. 1: Do not support overcurrent protection. 0: Support overcurrent protection.
11	OCPM	Over Current Protection Mode Specifies how to report the overcurrent state of the root hub. The mode specified for this bit must be the same as the mode specified for the PSM bit. 1: Report the overcurrent state in port units. 0: Report the overcurrent state at all ports simultaneously. The setting of this bit becomes valid only when the NOCP bit is 0.
10	DT	Device Type Indicates that the root hub is not a combined device. This field always returns 0 because the root hub must not be a combined device. This bit is read-only.
9	NPS	No Power Switching Specifies whether to support power switching or whether the power for the ports is constantly on. 1: Power is constantly on while the OHCI host controller is running. 0: Power for ports can be switched.
8	PSM	Power Switching Mode Specifies how to control root hub port power switching. 1: Control the power for ports individually. 0: Control the power for all ports simultaneously. Ports are only controlled by the SPP and CPP bits of the HcRhPortStatus register if the PPCM field of the HcRhDescriptorB register is 1. If this field is cleared, ports are controlled by the SGP and CGP bits. The setting of this bit becomes valid only when the NPS bit is 0.
7:0	NDP[7:0]	Number Downstream Port Specify the number of downstream ports supported by the root hub of the OHCI host controller. This field is fixed to 02 _H because the OHCI host controller incorporates two downstream ports. These bits are read-only.

(20) HcRhDescriptorB register (Offset: 4C_H)

Access This register can be read or written in 32-bit units.

Address <USHA0_base_OHCI> + 4C_H

Initial value 0006 0000_H. This register is initialized by any reset.

Table 28-46 HcRhDescriptorB register contents

0	0	0	0	0	0	OCI	CGP
W	W	W	W	W	W	W	W

Table 28-47 HcRhStatus register contents

Bit position	R/W	Bit name	Function
31	–	CRWE	Clear Remote Wakeup Enable Use this bit to clear the DRWE bit to 0. Writing 1 to this bit clears the DRWE bit to 0. Writing 0 to this bit is ignored. Value 0 is always read from this bit. This bit is write-only.
30:18	–	–	Reserved (Be sure to write 0 to these bits.)
17	–	OCIC	Over Current Indicate Change This bit is used to report a change in the OCI bit. It is set to 1 when the overcurrent state has changed. This bit is cleared to 0 when 1 is written while the OCIC bit is set (1). 1: The overcurrent state has changed. 0: The overcurrent state has not changed.
16	R	LPSC	Local Power Status Change This bit is fixed to 0 because the local power status is not supported.
	W	SGP	Set Global Power Use this bit to turn on the power to all ports in the global power mode. Setting this bit to 1 turns the power on to all ports. When the PSM bit of the HcRhDescriptorA register is set to 1, power is turned on to ports whose PPCM field is cleared (0).
15	R	DRWE	Device Remote Wakeup Enable Indicates whether a connection status change is included in the remote wakeup events. 1: A connection status change is a remote wakeup source. 0: A connection status change is not a remote wakeup source. If a connection status change event occurs while this bit is 1, the state changes from USB Suspend to USB Resume, and a Resume Detected interrupt occurs.
	W	SRWE	Set Remote Wakeup Enable Use this bit to set the DRWE bit to 1. Writing 1 to this bit sets the DRWE bit to 1. Writing 0 to this bit is ignored.
14:2	–	–	Reserved (Be sure to write 0 to these bits.)
1	–	OCI	Over Current Indicator This bit is used to report the overcurrent state in the global overcurrent detection mode. 1: The port is in the overcurrent state. 0: Ports are in the normal state. This bit is fixed to 0 when overcurrent is reported in port units. This bit is read-only.
0	R	LPS	Local Power Status This bit is fixed to 0 because the local power status is not supported.
	W	CGP	Clear Global Power Use this bit to turn off the power for all ports in the global power mode. Setting this bit to 1 turns off the power to all ports. When the PSM bit of the HcRhDescriptorA register is set to 1, the power is turned off to ports whose PPCM field is cleared (0).

(22) HcRhPortStatus register 1 (Offset: 54_H)

Access These registers can be read or written in 32-bit units.

Address <USHA0_base_OHCI> + 54_H

Initial value 0000 0000_H. These registers are initialized by any reset.

Table 28-48 HcRhPortStatus register 1 contents (1/3)

Bit position	R/W	Bit name	Function
30:21	–	–	Reserved (Be sure to write 0 to these bits.)
20	–	PRSC	Port Reset Status Change Indicates the completion of a port reset. 1: The port reset is complete. 0: The port reset status has not changed. This bit is set to 1 when a 10 ms hardware reset ends. This bit is cleared to 0 when 1 is written by the host controller driver (HCD).
19	–	OCIC	Over Current Indicate Change This bit is set to 1 when the overcurrent status is detected at a port. 1: The overcurrent state has changed. 0: The overcurrent state has not changed. This bit is cleared to 0 when 1 is written by the host controller driver (HCD).
18	–	PSSC	Port Suspend Status Change Indicates that the resume sequence has completed. 1: The resume sequence has completed. 0: Port Suspend Status has not changed. This bit is set when all of resume processing is completed by hardware. This bit is cleared to 0 when 1 is written by the host controller driver (HCD).
17	–	PESC	Port Enable Status Change Indicates that the PES bit has been cleared to 0. 1: The PES bit status has changed. (PES cleared) 0: The PES bit status has not changed. This bit is set to 1 when the PES bit is cleared to 0 because the port state is changed from Enable to Disable due to a hardware event such as an overcurrent state, device disconnection, power-off, or bubble error. This bit is cleared (0) when 1 is written by the host controller driver (HCD).
16	–	CSC	Connect Status Change Indicates that the CCS bit status has changed. 1: The CCS bit status has changed. 0: The CCS bit status has not changed. This bit is set to 1 when the CCS bit status is changed due to connection or disconnection of a USB device. This bit is set to 1 when a request for port reset, port suspend, or port enable is issued while a USB device is disconnected, so that the driver can re-evaluate the device connection. This bit is cleared to 0 when 1 is written by the host controller driver (HCD).
15:10	–	–	Reserved (Be sure to write 0 to these bits.)
9	R	LSDA	Low Speed Device Attached Indicates the speed of the device connected to the USB port. 1: A low-speed device is connected. 0: A full-speed device is connected. The bit is enabled only when the CCS bit is set.
	W	CPP	Clear Port Power Use this bit to turn off the power to the ports. Writing 1 to this bit turns the port power off. Writing 0 to this bit is ignored.

Table 28-48 HcRhPortStatus register 1 contents (2/3)

Bit position	R/W	Bit name	Function
8	R	PPS	Port Power Status Indicates the port power status. 1: Port power on 0: Port power off The control method depends on the power switch time.
	W	SPP	Set Port Power Use this bit to turn on the power to a port when the power is controlled in port units. Writing 1 to this bit turns the port power on. Writing 0 to this bit is ignored.
7:5	–	–	Reserved (Be sure to write 0 to these bits.)
4	R	PRS	Port Reset Status Indicates whether a downstream port is being reset or not. 1: The port is being reset. 0: The port is not being reset. This bit is cleared to 0 together with setting of the PRSC bit when a 10 ms port reset ends. This bit cannot be set when the CSC bit has been cleared to 0 (no device connected).
	W	SPR	Set Port Reset Use this bit to issue a port reset request to a downstream port. Writing 1 to this bit starts a 10 ms port reset. When 1 is written to this bit while the CCS bit is 0, the CSC bit is set and it is reported to the host controller driver that an attempt was made to reset the disconnected port. Writing 0 to this bit is ignored.
3	R	POCI	Port Over Current Indicator Indicates the overcurrent status at a downstream port. 1: The port is in the overcurrent state. 0: The port is in the normal state.
	W	CPS	Clear Port Suspend Use this bit to exit the suspend mode and start the resume sequence. Writing 1 to this bit starts the resume sequence. Writing 0 to this bit is ignored. The resume sequence starts only when the PSS bit has been set.
2	R	PSS	Port Suspend Status Indicates that ports are in the suspend state or the resume sequence is being executed. 1: Ports are in the suspend state. 0: Ports are in the normal transfer state. This bit cannot be set when the CCS bit has been cleared to 0 (no device connected). Writing to the SPS bit sets ports to the suspend state. This bit is cleared to 0 when the resume sequence ends, port reset ends, or when the state shifts to USB Resume.
	W	SPS	Set Port Suspend Use this bit to shift the port status to the suspend state. When 1 is written to this bit, ports enter the suspend state. Writing 0 to this bit is ignored. Writing to the SPS bit sets ports to the suspend state. If this bit is written when the CCS bit has been cleared to 0, the CSC bit is set and it is reported to the host controller driver that an attempt was made to suspend the disconnected port.

Table 28-48 HcRhPortStatus register 1 contents (3/3)

Bit position	R/W	Bit name	Function
1	R	PES	<p>Port Enable Status</p> <p>Indicates whether ports are enabled or disabled.</p> <p>1: Ports are enabled.</p> <p>0: Ports are disabled.</p> <p>This bit cannot be set when the CSC bit has been cleared to 0 (no device connected).</p> <p>Ports are enabled after a port reset ends.</p> <p>This bit is cleared to 0 by hardware when an event such as an overcurrent state, device disconnection, power-off, or bubble error is detected.</p>
	W	SPE	<p>Set Port Enable</p> <p>Use this bit to set the PES bit to 1.</p> <p>Writing 0 to this bit is ignored.</p> <p>Change the port status by setting the SPR bit. In this USB host controller, ports cannot be enabled by using this bit because the USB Specification does not support this feature, even though the OHCI Specification does.</p>
0	R	CCS	<p>Current Connect Status</p> <p>Indicates the current connection status at a downstream port.</p> <p>1: A device is connected.</p> <p>0: No device is connected.</p>
	W	CPE	<p>Clear Port Enable</p> <p>Use this bit to clear the CPE bit.</p> <p>When 1 is written to this bit, ports are disabled. Writing 0 to this bit is ignored.</p>

28.7.4 Interruption from USB host controller

The USB host controller collects and sorts interrupts sent from the OHCI host controller and reports them to the system as one of the following three types of interrupts:

Table 28-49 Interruption from USB host controller

Signals that report interrupts to the system	Interrupt report signal generated by OHCI host controller
INTUSBH0	USBH status interrupt (INTA, SMMI, or PME)
INTUSBH1	USBH PCI cycle error
INTUSBH2	USBH PME interrupt

The details of each interrupt are described below.

(1) USB status interrupt (INTUSBH0)

(a) Interrupt routing

The OHCI host controller reports an occurrence of the INTA or SMMI interrupt to the system, according to the setting of the IR bit of the OHCI operational register HcControl. After a reset, INTA is routed to report the interrupt by the initial setting of the IR bit.

INTA and SMMI are used as the interrupt sources, except for Ownership Change requests.

Table 28-50 Routing of interrupts INTA and SMMI

IR bit of HcControl register	Interrupt report signal
0	INTA (initial value)
1	SMMI

To use the INTA and SMMI interrupt, the `inta_en` and `int_smmi_en` bits of the PCI interrupt control register of PCI host bridge registers must be set to 1.

(b) Interrupt sources

Interrupts defined in the OHCI Specification are supported.

Use the HcInterruptEnable register to specify interrupt sources reported to the system. Interrupts are reported via the route specified by using the IR bit.

The interrupt sources are shown below.

Table 28-51 Sources of interrupts INTA and SMMI

Interrupt source	Function										
Scheduling Overrun	Indicates that USB scheduling has overrun in a frame.										
Writeback DoneHead	Indicates that the USB host controller has received the TD and written it back.										
Start Of Frame	Indicates the update of HccaFmNumber upon a start of a frame.										
Resume Detected	Indicates that a resume signal sent from a USB device was detected.										
Unrecoverable Error	Indicates that an error not related to the USB (PCI abort) was detected.										
Frame Number Overflow	Indicates that the FrameNumber15 bit of the HcFmNumber register has changed (from 0 to 1 or 1 to 0).										
Root Hub Status Change	Indicates that the HcRhStatus or HcRhPortStatus status has changed. This interrupt source is classified based on the following event details: <table border="1" data-bbox="507 891 1394 1249"> <thead> <tr> <th>OverCurrentIndicateChange</th> <th>Indicates that an overcurrent occurred.</th> </tr> </thead> <tbody> <tr> <td>Connect Status Change</td> <td>Indicates that a device has been connected to or disconnected from the USB bus.</td> </tr> <tr> <td>Port EnableStatusChange</td> <td>Indicates that the port is disabled due to a USB error.</td> </tr> <tr> <td>Port Suspend Status Change</td> <td>Indicates that the resume sequence has finished.</td> </tr> <tr> <td>Port Reset Status Change</td> <td>Indicates that a USB reset has finished.</td> </tr> </tbody> </table>	OverCurrentIndicateChange	Indicates that an overcurrent occurred.	Connect Status Change	Indicates that a device has been connected to or disconnected from the USB bus.	Port EnableStatusChange	Indicates that the port is disabled due to a USB error.	Port Suspend Status Change	Indicates that the resume sequence has finished.	Port Reset Status Change	Indicates that a USB reset has finished.
OverCurrentIndicateChange	Indicates that an overcurrent occurred.										
Connect Status Change	Indicates that a device has been connected to or disconnected from the USB bus.										
Port EnableStatusChange	Indicates that the port is disabled due to a USB error.										
Port Suspend Status Change	Indicates that the resume sequence has finished.										
Port Reset Status Change	Indicates that a USB reset has finished.										
Ownership Change	Indicates that an ownership request has been issued. This interrupt is reported to SMMI only.										

(2) PCI cycle error interrupt (INTUSBH1)

The PCI cycle error interrupt (INTUSBH1) occurs when a data access that causes an error is performed for the OHCI or PCI bus bridge register area (in 32-bit access). This interrupt is used during debugging; it is not used during normal operation.

(3) PME interrupt (INTUSBH2)

The PME interrupt is an interrupt signal for power management, which can be used to report the USB bus status change to the system when PCLK is not supplied.

The following lists the events that might occur on the USB bus and whether each interrupt is supported:

Table 28-52 PME interrupt sources

Event	Occurrence of interrupts
Over Current Indicate	Does not occur.
Connect	Occurs.
Disconnect	Occurs.
Resume (RemoteWakeUp)	Occurs.

To use the PME interrupt, the PME Enable bit of the Power Management Control/Status register in OHCI host configuration registers and the int_pme_en bit of the PCI interrupt control register in PCI host bridge registers must be set to 1 in advance.

Chapter 29 Ethernet Controller

29.1 General

The Ethernet controller includes a 10/100 Mbps Ethernet Media Access Controller (MAC) conforming to IEEE802.3, a FIFO controller for flow control, and a checksum calculation unit (only for received packets) conforming to RFC1071.

29.1.1 V850E2/ML4 Ethernet controller features

Instances This microcontroller has the following number of instances of the Ethernet controllers.

Table 29-1 Instances of Ethernet controller

Ethernet controller	V850E2/ML4
Number of instances	1

Register addresses All Ethernet controller register addresses are given as addresses offset from the individual base address <ETHA0_base_USER> or <ETHA0C_base>. The base addresses <ETHA0_base> and <ETHA0C_base> of each Ethernet controller are listed in the following table:

Table 29-2 Register base addresses

Ethernet function	Base address	Address
MAC control register	ETHA0_base	F993 2000 _H
Statistics counter	ETHA0_base	F993 2000 _H
FIFO controller control register	ETHA0_base	F993 2000 _H
Ethernet controller dedicated DMAC control register	ETHA0_base	F993 2000 _H
Transmission checksum dedicated DMAC control register	ETHA0C_base	F993 3000 _H

Interrupts The Ethernet controller can generate the following interrupt requests:

Table 29-3 Ethernet controller interrupt requests

Ethernet controller signals	Function	Connected to
INTETMRQ	Ethernet receive data ready interrupt	Interrupt controller INTETHA0SRX
INTETMRX	Ethernet packet reception interrupt	Interrupt controller INTETHA0SCRX DTS controller trigger 120
INTETMTX	Ethernet packet transmission interrupt	Interrupt controller INTETHA0SCTX DTS controller trigger 121
INTETMFS	Ethernet FIFO status interrupt	Interrupt controller INTETHA0FS
INTETMTS	Ethernet transmission status interrupt	Interrupt controller INTETHA0TS
INTETMRS	Ethernet reception status interrupt	Interrupt controller INTETHA0RS
INTETMOV	Ethernet MAC interrupt	Interrupt controller INTETHA0MAC
IRQSCTX_TCH	Ethernet transmit data calculation completion interrupt	Interrupt controller INTETHA0SCRXTCH
IRQSCRX_TCH	Ethernet transmit checksum interrupt	Interrupt controller INTETHA0SCTXTCH

Caution If an interrupt from the the Ethernet controller is detected, the value of the interrupt request is stored in the EICn.EIRFn bit (n = 178 to 186). Therefore, even if the CPU acknowledges the interrupt and the EIRFn bit of the interrupt control register (EICn) is automatically cleared to 0, the EICn.EIRFn bit is immediately set to 1 and an interrupt is continuously generated. To prevent this from happening, clear the status flag of each interrupt request in the interrupt service routine, and then forcibly clear the EICn.EIRFn bit to 0. For Ethernet reception data ready interrupts, after the received packet is read, forcibly clear the EIC178.EIRF178 bit to 0.

Assignment of descriptor and data buffer Descriptors and data buffers can be assigned to the following area:

- H-bus shared memory

29.1.2 Functions

(1) MAC

- 10/100 Mbps full-duplex communication, half-duplex communication, and flow control conforming to IEEE802.3 supported
- MII supported as physical layer device (PHY) interface
- Accessing PHY registers via serial management interface supported
- Statistics counter to support RMON/SNMP (RFC2665, RFC2819)
- Packet filtering based on address types
- VLAN frame detection

(2) FIFO

- Transmit/receive FIFO size: Transmit FIFO = 2 KB, receive FIFO = 2 KB
- FIFO status register
- Interrupts generated according to transmission/reception status and FIFO status

(3) DMAC for Ethernet controller

- Data transfer (DMA)
- Reception status DMA transfer
- Reading (in pointer chain format), analyzing, and writing back buffer descriptors
- Controlling interrupts in packet transfers

(4) Checksum calculation

- Transmit checksum calculation function conforming to RFC1071
DMAC for transmit checksum can calculate multiple checksums successively and save the result to any address.
- Receive checksum calculation conforming to RFC1071

The MAC header and FCS of a received packet are automatically identified and the checksum for verifying the received packet (excluding the dummy header) is generated.

29.2 Configuration

29.2.1 System configuration

The Ethernet controller transmits and receives data by using a dedicated direct memory access controller (DMAC). The Ethernet controller supports the MII (Media Independent Interface) of IEEE802.3 and can create a 10 Mbps or 100 Mbps Ethernet environment when it is connected to a PHY device conforming to MII. In addition, data can be communicated in full-duplex or half-duplex mode, which can be selected.

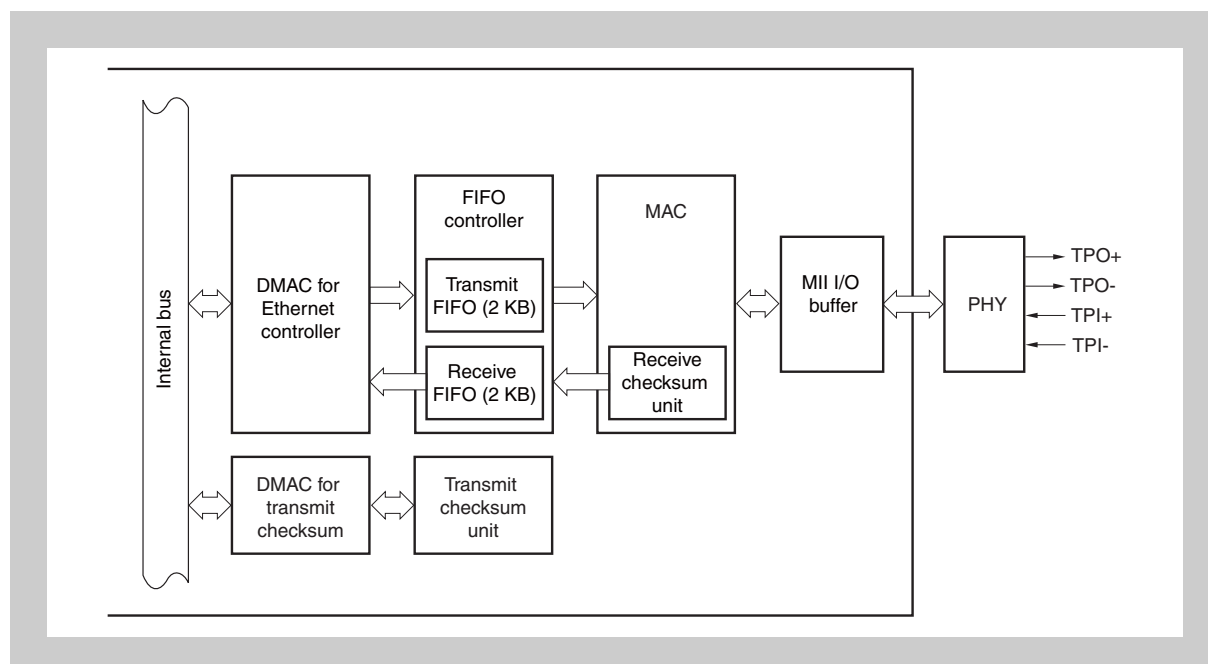

Figure 29-1 Configuration of Ethernet controller

(1) MAC

This unit has MAC functions and supports MII-based interfacing with an external PHY device.

- Receive checksum unit
This unit calculates the receive checksum.

(2) FIFO controller

This unit controls the transmit/receive FIFO buffers.

2 KB FIFO buffers are separately available for transmission and reception.

(3) DMAC for Ethernet controller

This DMA controller controls data transmission and reception with the internal bus.

Caution The DMAC for the Ethernet controller processes all the data the Ethernet controller transmits and receives. Data cannot be transmitted or received in packet units by reading or writing a register.

(4) Transmit Checksum DMAC

This DMA controller that interfaces with the internal bus is dedicated to the transmit checksum function.

(5) Transmit checksum unit

This unit can only calculate the transmit checksum. Independent of the data transmission/reception interface, the transmit checksum unit calculates and transfers transmit data by using the transmit checksum DMA function and descriptor.

29.2.2 Interrupt Requests and Sources

The Ethernet controller interrupt requests and their sources are listed below.

Table 29-4 Interrupt requests

Interrupt request		Interrupt source
INTETHA0SRX	Ethernet receive data ready interrupt	Received packet read request
INTETHA0SCRX	Ethernet packet reception interrupt	Packet reception (DMA) completion interrupt (RXI)
		Reception (DMA) end of chain interrupt (RECI)
		Receive data buffer access error interrupt (RBEI)
INTETHA0SCTX	Ethernet packet transmission interrupt	Packet transmission (DMA) completion interrupt (TXI)
		Transmission (DMA) end of chain interrupt (TECI)
		Transmit data buffer access error interrupt (TBEI)
INTETHA0FS	Ethernet FIFO status interrupt	FIFO status (ETHA0FSTATUS) interrupt
INTETHA0TS	Ethernet transmission status interrupt	Transmission status (ETHA0FTXSTATUS) interrupt
INTETHA0RS	Ethernet reception status interrupt	Reception status (ETHA0RXSTATUS) interrupt
INTETHA0MAC	Ethernet MAC interrupt	Statistics counter overflow (CARRY status)
INTETHA0SCT XTCH	Ethernet transmit data calculation completion interrupt	1 transmit checksum calculation completion interrupt (TCH_TXI)
		All transmit checksums calculation completion interrupt (TCH_TECI)
		Transmit checksum buffer access error interrupt (TCH_TBEI)
		Transmit checksum calculation pause interrupt (TCH_RUPI)
INTETHA0SCR XTCH	Ethernet transmit checksum interrupt	1 transmit checksum writing completion interrupt (TCH_RXI)
		All transmit checksums calculation writing completion interrupt (TCH_RECI)
		Data write error interrupt (TCH_RBEI)

- Each interrupt source can be masked. If an interrupt source is generated while the interrupt is masked, the corresponding bit in the status register is set but the interrupt request is not generated.
- It is recommended to read the interrupt register if multiple sources have been generated concurrently.

29.3 Initialization

Use the following procedure to perform initialization before using the V850E2/ML4 Ethernet controller:

1. Accessing a PHY device
2. Enable Ethernet controller operation.
3. Initialize the media access controller (MAC).
4. Initialize the FIFO controller.
5. Initialize the DMA controller.
6. Set up interrupts.

Use any port pin (including P7_0 and P7_1) to control a PHY device. Also use a port register (Pn) and port pin read register (PPRn) to directly write data to and read data from the PHY device.

(a) Example procedure for accessing a PHY device (when writing 1-bit data)

- (1) ETH_MDC substitute
PM70 = 0 (Output) P70 = 0
ETH_MDIO substitute
PM71 = 0 (Output)
- (2) ETH_MDC substitute
PM70 = 0 (Output), P70 = 1
ETH_MDIO substitute
PM71 = 0 (Output)
- (3) ETH_MDC substitute
PM70 = 0 (Output), P70 = 0
ETH_MDIO substitute
PM71 = 0 (Output)

a) By executing actions (1) and (2) by using different instructions, 10 ns can be secured even if the instructions are executed successively.

Figure 29-2 Timing of writing 1-bit data

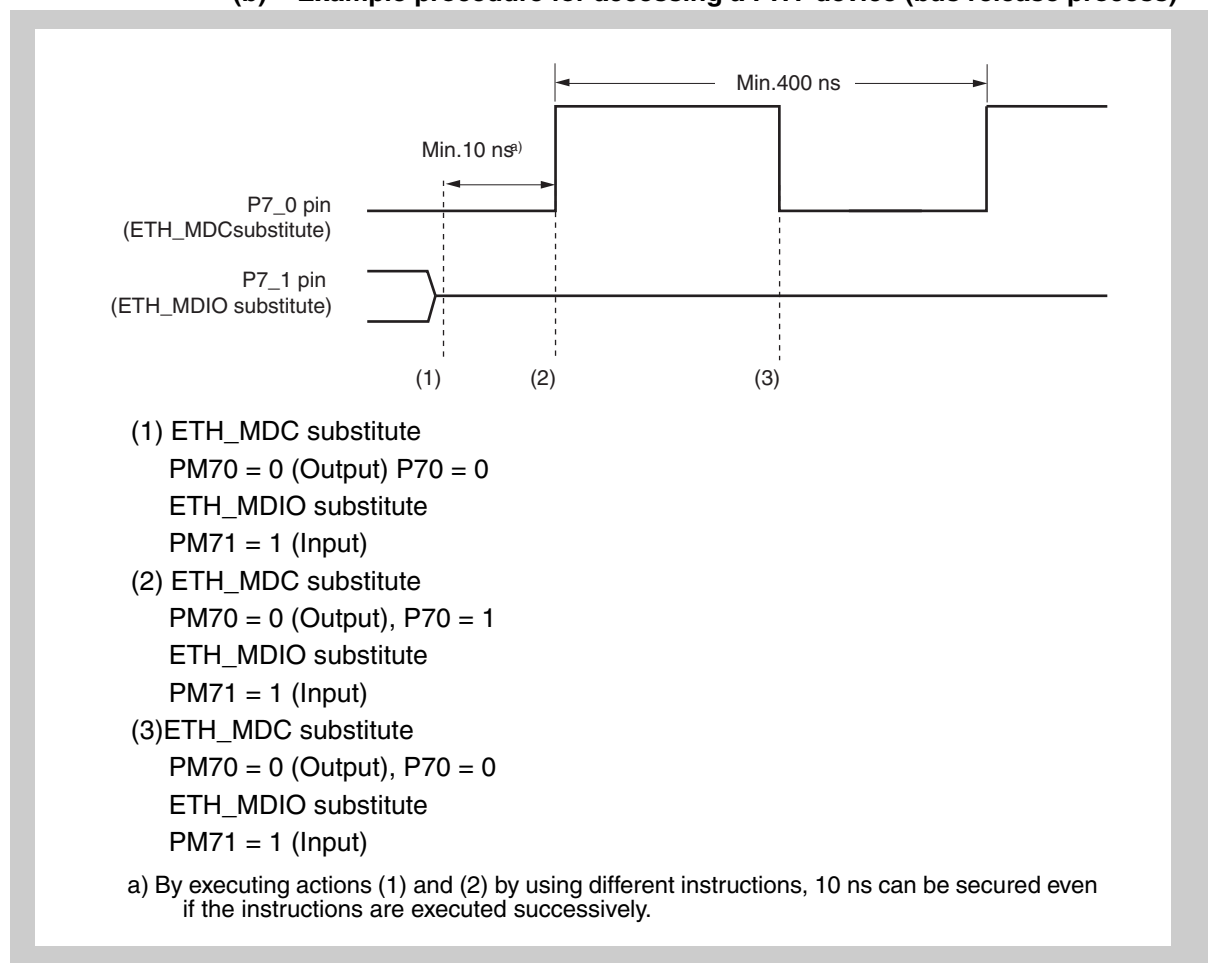

(b) Example procedure for accessing a PHY device (bus release process)

Figure 29-3 Timing of releasing the bus

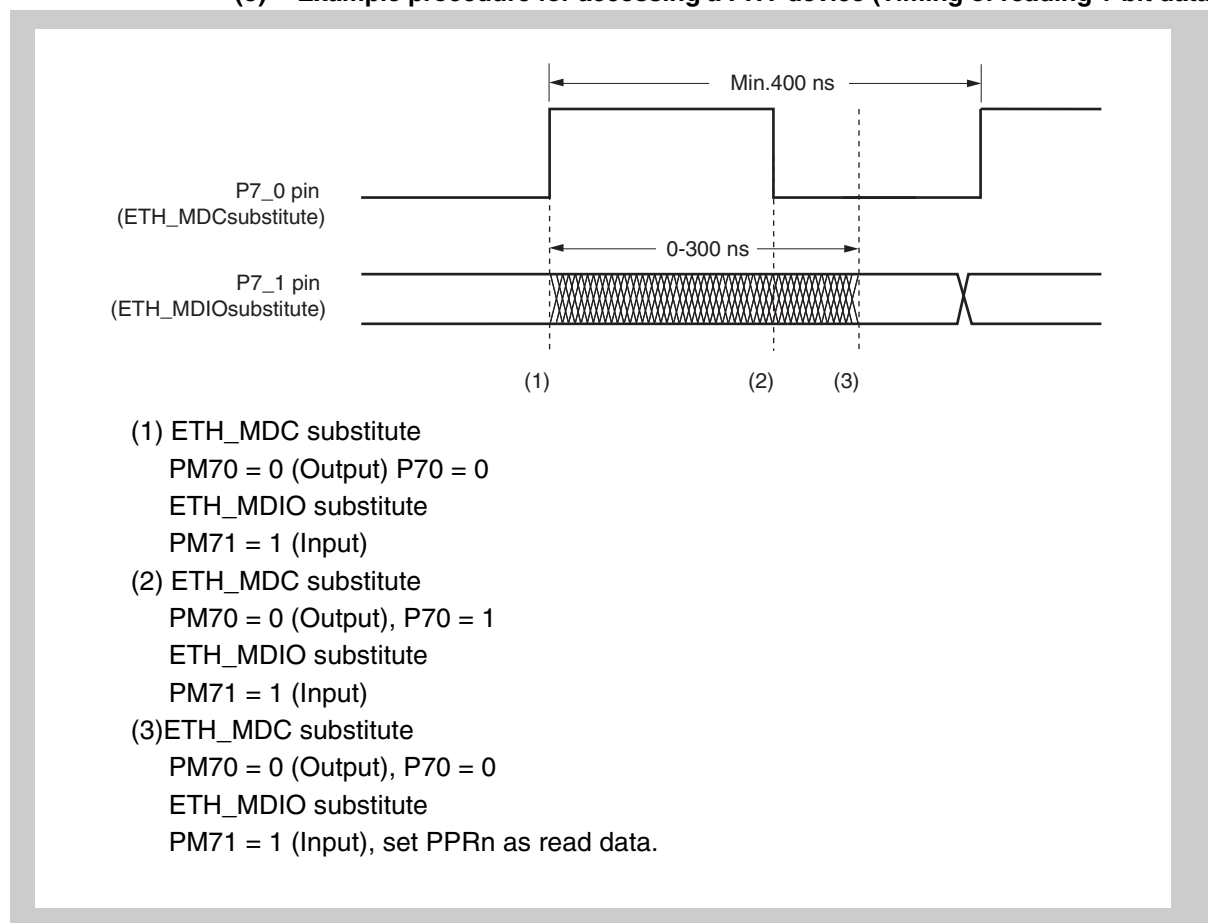

(c) Example procedure for accessing a PHY device (Timing of reading 1-bit data)

Figure 29-4 Timing of reading 1-bit data

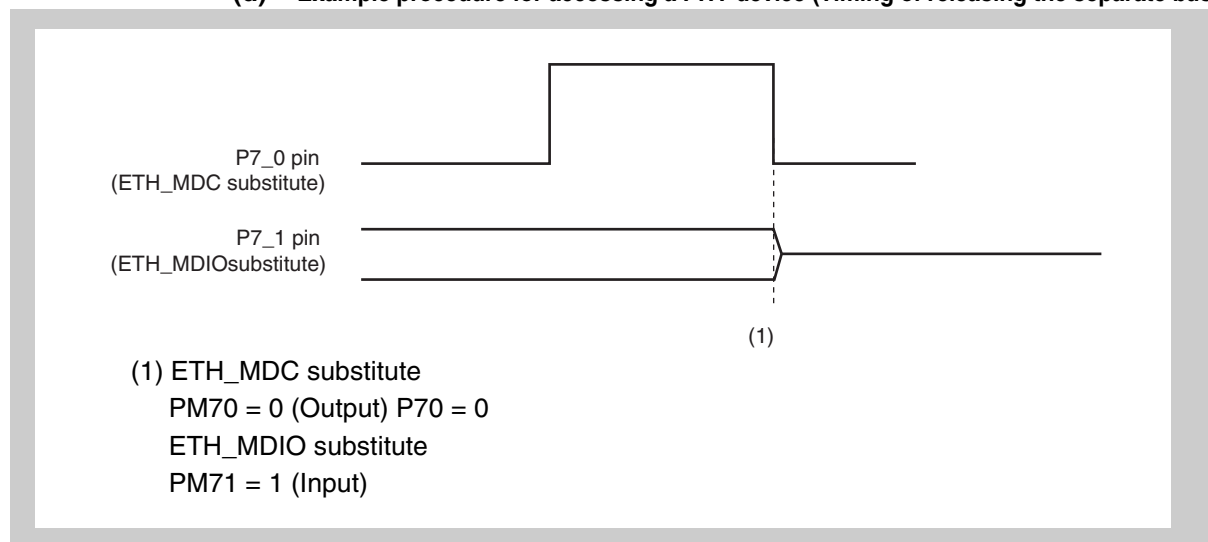

(d) Example procedure for accessing a PHY device (Timing of releasing the separate bus)

Figure 29-5 Timing of releasing the separate bus

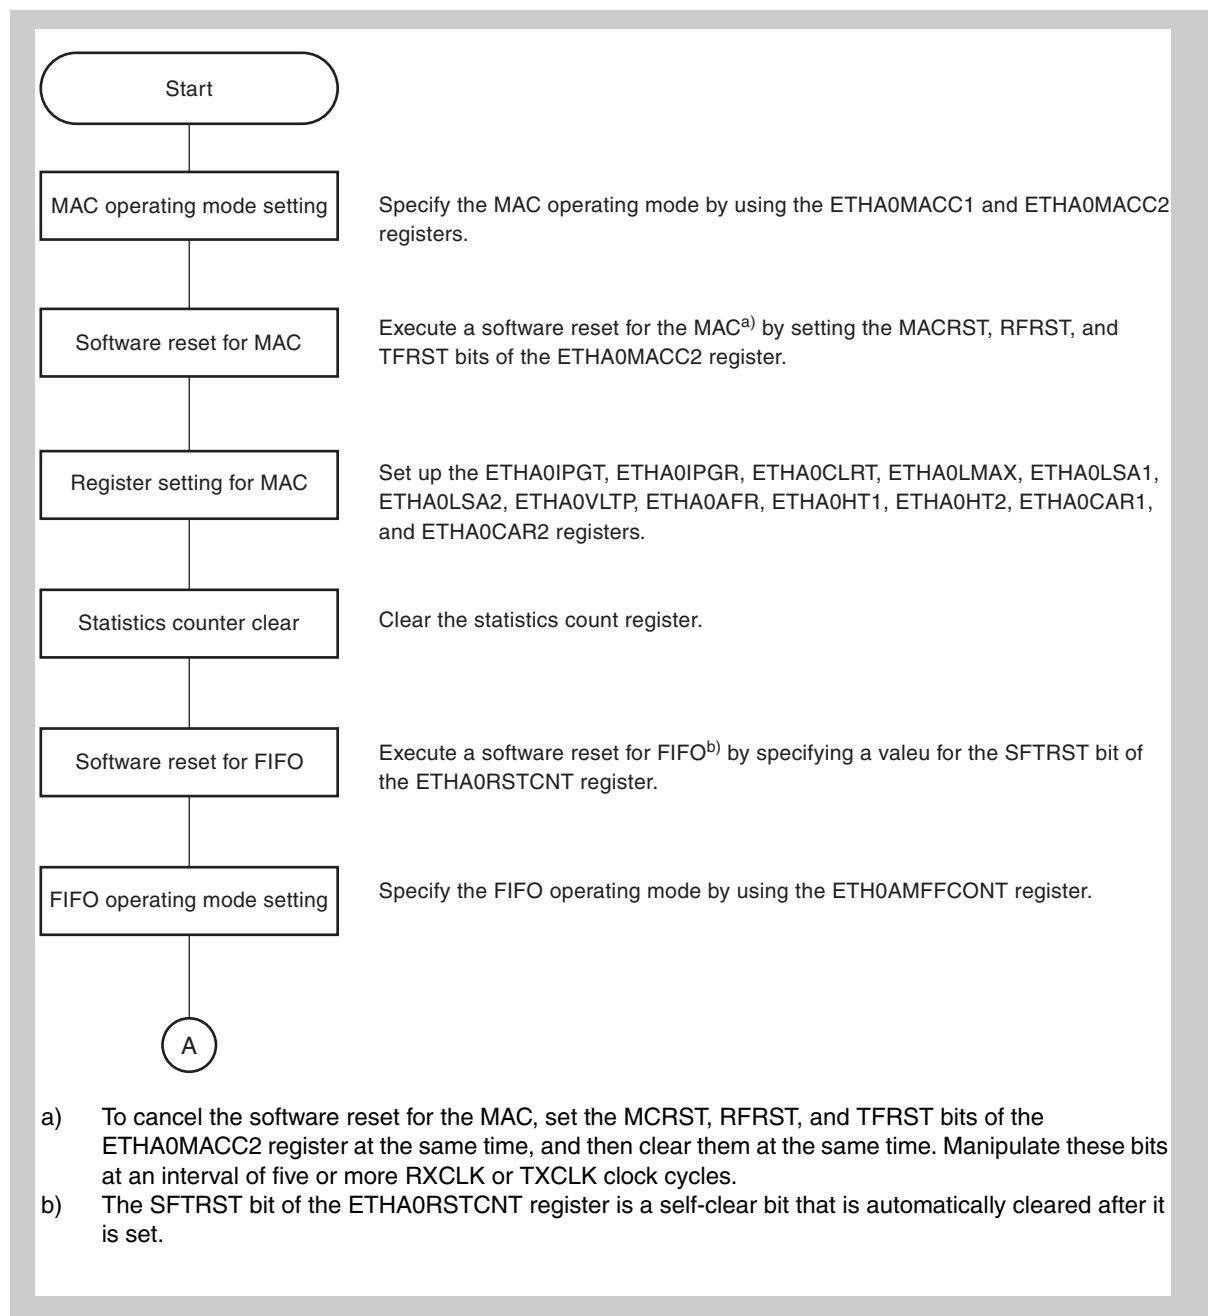

Figure 29-6 Initializing Ethernet controller (1/2)

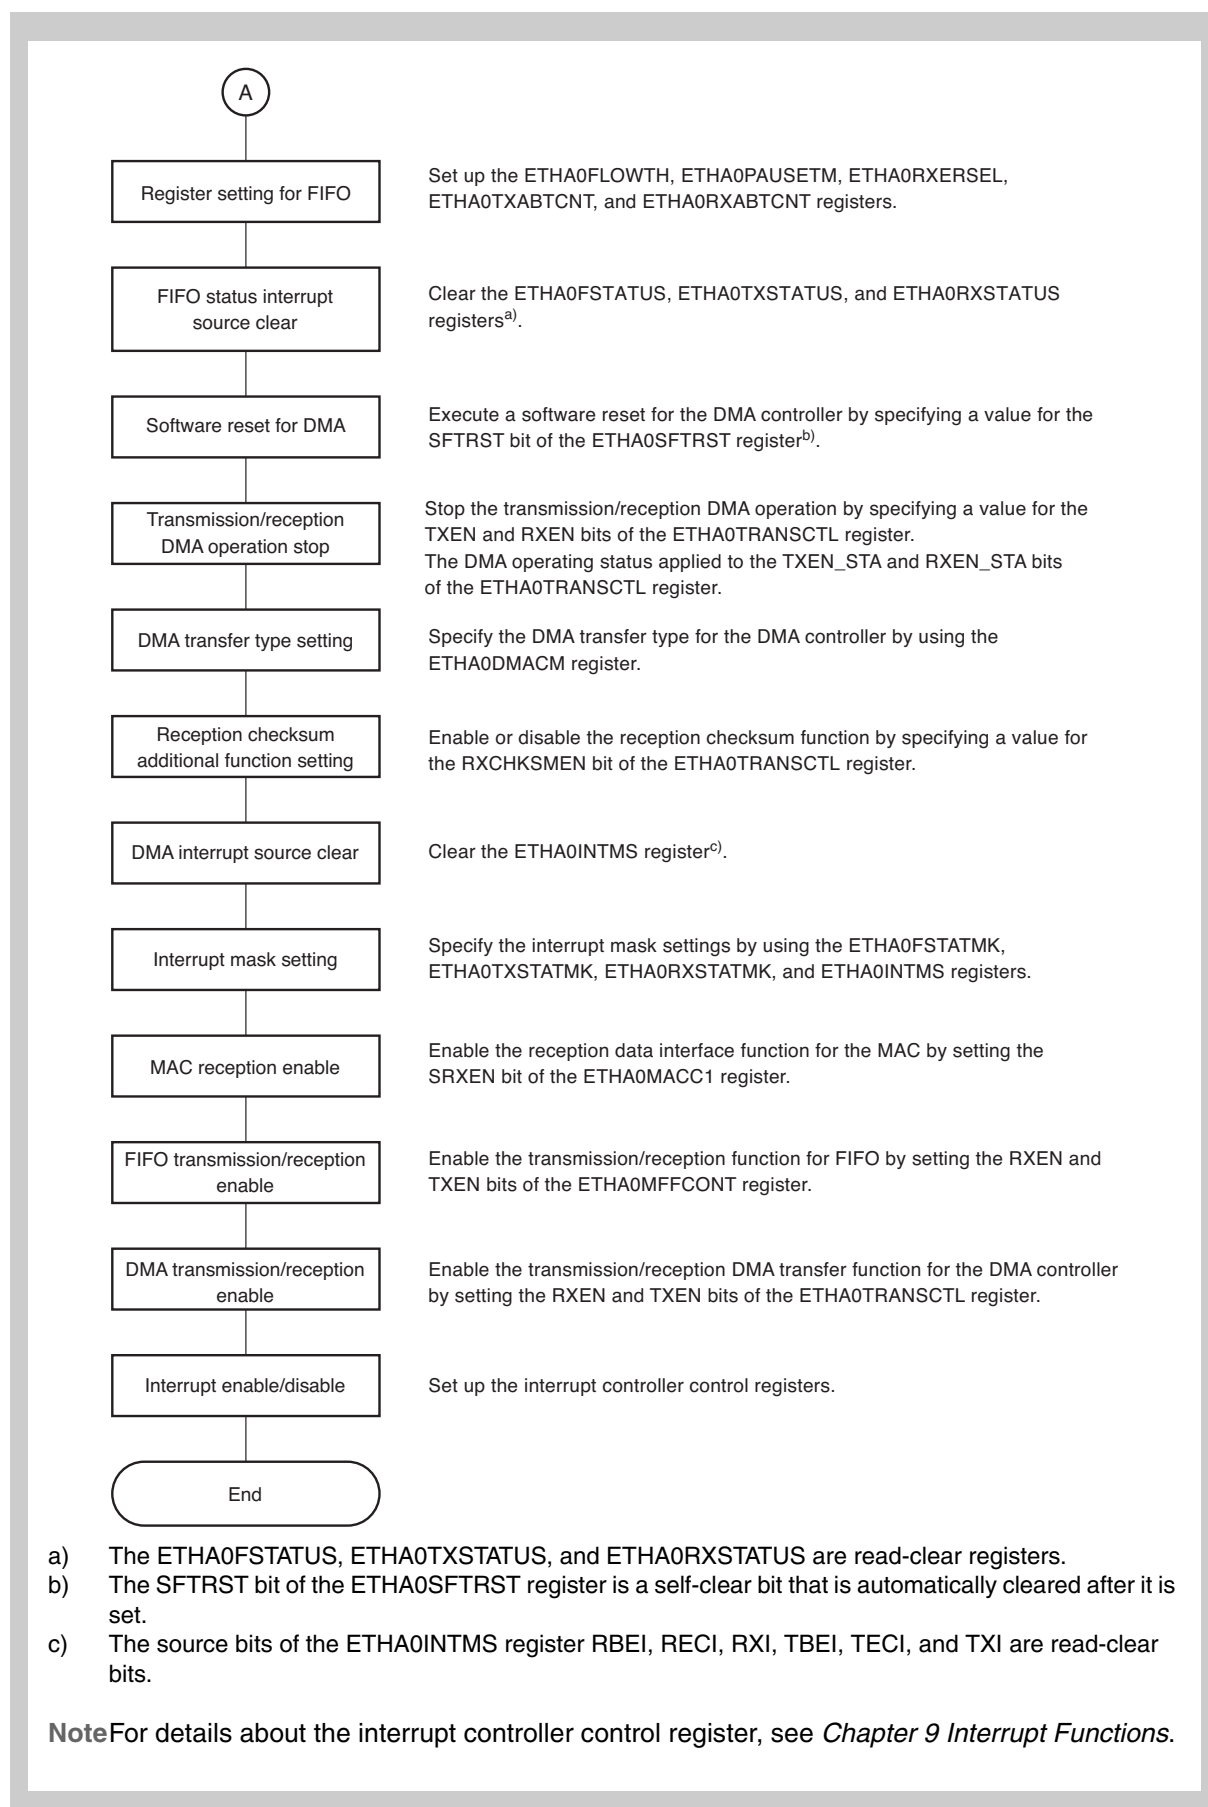

Figure 29-7 Initializing Ethernet controller (2/2)

29.3.1 Software reset

The Ethernet controller can be initialized by using a software reset if the system has become unstable or to protect against being effects from the previous mode when the operating mode has changed.

When executing a software reset, the MAC control registers are not initialized, but the DMAC registers for the FIFO controller and Ethernet controller are initialized, requiring the operating mode and interrupt mask to be specified again.

Discard packets being used with FIFO when executing a software reset.

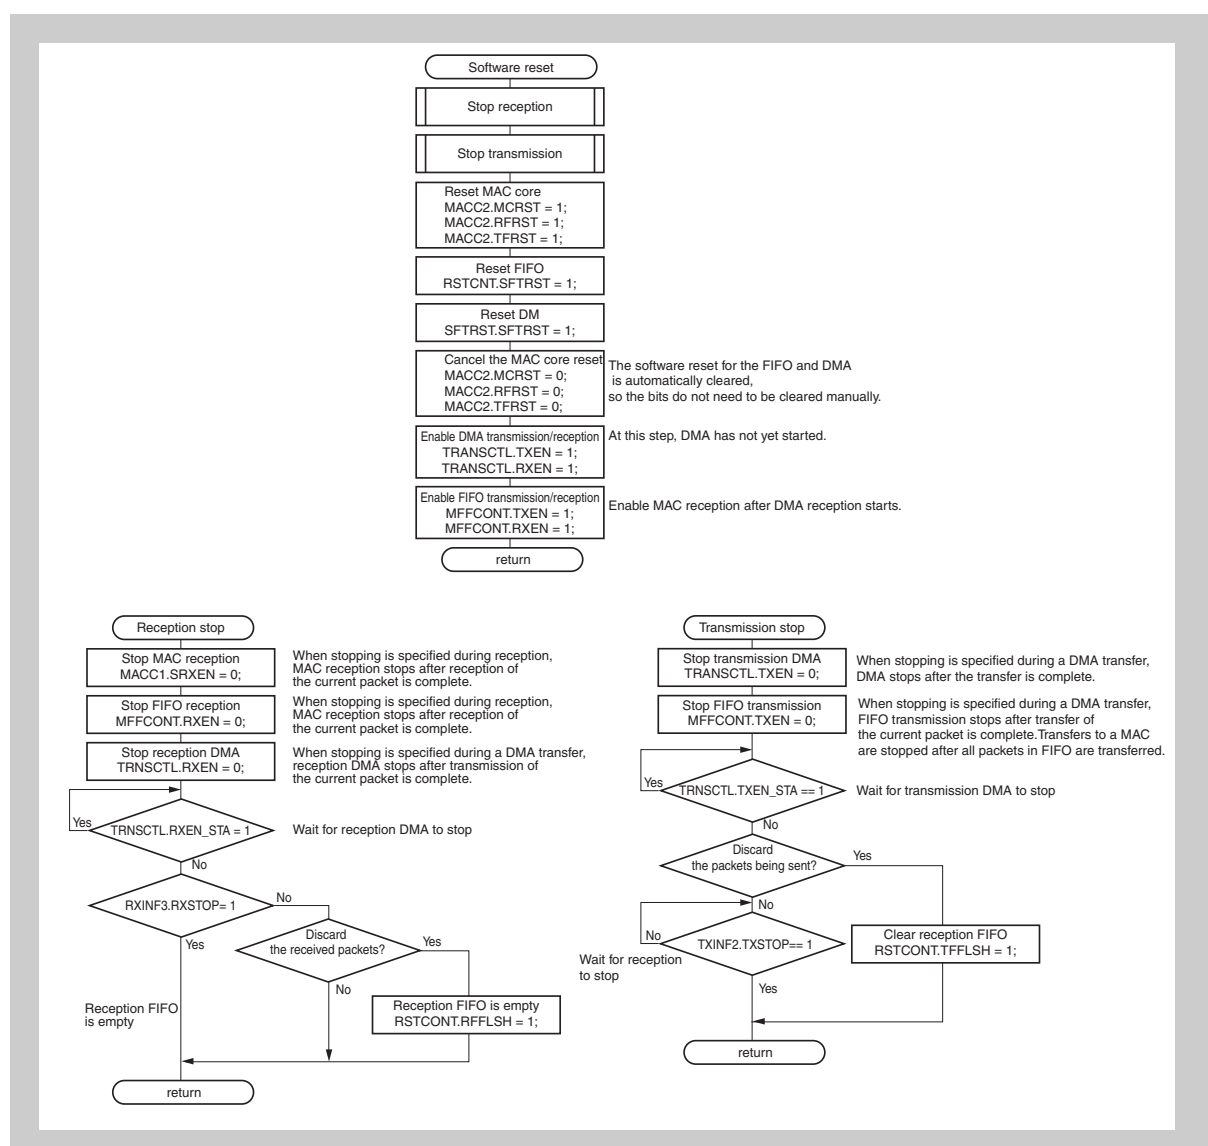

Figure 29-8 Software reset and restart process

29.4 Registers for Controlling the Ethernet Controller

(1) Register setting procedure

To update the values of the control registers, make sure that transmission and reception of frames and DMA are stopped.

If these registers are updated while frames are being transmitted or received, or while DMA is in progress, the operation is not guaranteed.

Caution When using the Ethernet controller, the FIFO controller control register (ETHA0MFFCONT) must be set up first. For details, refer to (1) “ETHA0MFFCONT - FIFO controller control register” on page 1943 in 29.4.3 “FIFO controller control registers”.

(2) Register list

Table 29-5 MAC control register list

Offset address	Symbol	Register name	R/W	Bit manipulation unit			Default value
				8	16	32	
0000 _H	ETHA0MACC1	MAC setting register 1	R/W			✓	Undefined

29.4.1 MAC control registers

(1) ETHA0MACC1 - MAC setting register

Access This register can be read/written in 32-bit units.

Address <ETHA0_base> + 0000_H

Initial value Undefined

- Cautions**
1. Be sure to execute a software reset after setting the operation mode. To execute a software reset, set the MCRST, RFRST, and TFRST bits of the ETHA0MACC2 register at the same time. Cancel the software reset by clearing these bits at the same time.
 2. Be sure to set bits 31 to 15, 13, 12, and 4 to "0".

31	30	29	28	27	26	25	24
–	–	–	–	–	–	–	–
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
23	22	21	20	19	18	17	16
–	–	–	–	–	–	–	–
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
15	14	13	12	11	10	9	8
–	MACLB	–	–	TXFC	RXFC	SRXEN	PARF
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
7	6	5	4	3	2	1	0
PUREP	FLCHT	NOBO	–	CRCEN	PADEN	FULLD	HUGEN
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 29-10 ETHA0MACC1 register contents (1/2)

Bit position	Bit name	Function
14	MACLB	MAC loopback 0: Disables loopback operation. 1: Operation loops back from transmission block to reception block in MAC. To execute the loopback operation, set the FULLD bit to enable full-duplex operation.
11	TXFC	Transmission flow control enable 0: Disables transmission of a pause control frame executed by inputting the TPCF signal. 1: Enables transmission of a pause control frame executed by inputting the TPCF signal.
10	RXFC	Reception flow control enable 0: A pause operation is not executed. 1: A pause operation is executed for the pause period set to the pause timer. The value of the pause timer is updated, regardless of the setting of this bit, when a valid pause control frame is received.

Table 29-10 ETHA0MACC1 register contents (2/2)

Bit position	Bit name	Function
9	SRXEN	Reception enable 0: Reception is disabled. 1: The function of the reception data interface is enabled. If the setting of this bit is changed while the CRS signal is asserted, the new setting becomes valid after the CRS signal has been deasserted, regardless of the setting of the FULLD bit.
8	PARF	Control packet pass 0: A control frame is judged as a control frame. 1: No received packet, including a control frame, is judged as a control frame. The value of the pause timer is not updated even if a valid pause control frame is received, regardless of the setting of the RXFC bit.
7	PUREP	Pure preamble 0: The data of a preamble is not checked. 1: A reception status interrupt is generated if an illegal preamble is detected.
6	FLCHT	Length field check 0: The length field is not checked. 1: The value of the length field and data field length are checked, and a status interrupt is generated.
5	NOBO	No backoff 0: Packets are transmitted by using the backoff algorithm. 1: Packets are always transmitted without using the backoff algorithm.
3	CRCEN	CRC appending 0: CRC is not appended. The end of the transmitted packet must be a valid frame check sequence (FCS). The MAC checks the FCS, and, if the FCS value is not correct, the MAC generates a transmission status interrupt (ETHA0TXSTATUS) to report an error. 1: CRC is automatically appended to the end of a packet. An internally generated frame check sequence (FCS) is appended to the end of the transmit packet.
2	PADEN	PAD appending 0: PAD is not appended. 1: PAD is appended to packets that are less than 64 bytes long. At this time, CRC is automatically appended to the end of the packet regardless of the setting of the CRCEN bit.
1	FULLD	Full-duplex enable 0: Half-duplex operation 1: Full-duplex operation
0	HUGEN	Huge packet enable 0: Transmission/reception of a packet that exceeds the value of the maximum packet length register (ETHA0LMAX) is stopped. 1: Transmission/reception of a packet that exceeds the value of the maximum packet length register (ETHA0LMAX) is not stopped.

(2) ETHA0MACC2 - MAC setting register

Access This register can be read/written in 32-bit units.

Address <ETHA0_base> + 0004_H

Initial value Undefined

- Cautions**
1. Be sure to execute a software reset after setting the operation mode. To execute a software reset, set the MCRST, RFRST, and TFRST bits of the ETHA0MACC2 register at the same time. Cancel the software reset by clearing these bits at the same time.
Manipulate these reset bits at an interval of five or more RXCLK or TXCLK cycles.
 2. Be sure to set bits 31 to 11, 7, and 3 to 0 to "0".

31	30	29	28	27	26	25	24
–	–	–	–	–	–	–	–
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
23	22	21	20	19	18	17	16
–	–	–	–	–	–	–	–
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
15	14	13	12	11	10	9	8
–	–	–	–	–	MCRST	RFRST	TFRST
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
7	6	5	4	3	2	1	0
–	BPNB	APD	VPD	–	–	–	–
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 29-11 ETHA0MACC2 register contents

Bit position	Bit name	Function
10	MCRST	MAC control block software reset 0: Cancels a software reset for the MAC control block. 1: Executes a software reset for the MAC control block.
9	RFRST	Reception block software reset 0: Cancels a software reset for the reception block. 1: Executes a software reset for the reception block.
8	TFRST	Transmission block software reset 0: Cancels a software reset for the transmission block. 1: Executes a software reset for the transmission block.
6	BPNB	No backoff after back pressure When this bit is set, backoff is not performed for a transmission after back pressure.
5	APD	Auto VLAN PAD If a packet that matches the VLAN type registered to the ETHA0VLTP register is transmitted, it is treated as a VLAN packet and PAD is appended.
4	VPD	VLAN pad mode The packet to be transmitted is always treated as a VLAN packet and PAD is appended.

(3) ETHA0IPGT - Back-to-back IPG register

Access This register can be read/written in 32-bit units.

Address <ETHA0_base> + 0008_H

Initial value Undefined

Caution Be sure to set bits 31 to 7 to "0".

31	30	29	28	27	26	25	24
–	–	–	–	–	–	–	–
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

–	IPGT						
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 29-12 ETHA0IPGT register contents

Bit position	Bit name	Function
6 to 0	IPGT	<p>IPG in back-to-back transmission</p> <p>These bits specify the gap between packets (inter-packet gap (IPG)) in back-to-back transmission. The expression used to calculate the IPG is as follows.</p> <ul style="list-style-type: none"> IPG = (5 + IPGT) x time required to transmit 4 bits (Time required to transmit 1 bit = 100 ns when the data rate is 10 Mbps or 10 ns when the data rate is 100 Mbps) <p>Set the IPG to the time required to transmit at least 96 bits to satisfy the specification of IEEE802.3 (refer to (5) "Inter-packet gap (IPG)" on page 1996 in 29.5.2 "Frame transmission").</p>

(4) ETHA0IPGR - Non back-to-back IPG register

Access This register can be read/written in 32-bit units.

Address <ETHA0_base> + 000C_H

Initial value Undefined

Caution Be sure to set bits 31 to 15 and 7 to “0”.

31	30	29	28	27	26	25	24
–	–	–	–	–	–	–	–
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
23	22	21	20	19	18	17	16

7	6	5	4	3	2	1	0
–	IPGR2						
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 29-13 ETHA0IPGR register contents

Bit position	Bit name	Function
14 to 8	IPGR1	Carrier sense period These bits specify the carrier sense period of the first half of the IPG in transmission other than back-to-back transmission. The calculation expression used to calculate the carrier sense period is as follows. <ul style="list-style-type: none"> Carrier sense period = (2 + IPGR1) x time required to transmit 4 bits Set the carrier sense period to 2/3IPG to satisfy the specification of IEEE802.3 (refer to (5) “Inter-packet gap (IPG)” on page 1996 in 29.5.2 “Frame transmission”).
6 to 0	IPGR2	IPG in transmission other than back-to-back transmission These bits specify the IPG in transmission other than back-to-back transmission. The expression used to calculate the IPG is as follows. <ul style="list-style-type: none"> IPG = (5 + IPGR2) x time required to transmit 4 bits The carrier sense period specified by the IPGR1 bits is included in the IPG specified by the IPGR2 bits. Set the IPG to the time required to transmit at least 96 bits to satisfy the specification of IEEE802.3 (refer to (5) “Inter-packet gap (IPG)” on page 1996 in 29.5.2 “Frame transmission”).

(5) ETHA0CLRT - Collision register

Access This register can be read/written in 32-bit units.

Address <ETHA0_base> + 0010_H

Initial value Undefined

Caution Be sure to set bits 31 to 14 and 7 to 4 to "0".

31	30	29	28	27	26	25	24
–	–	–	–	–	–	–	–
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
23	22	21	20	19	18	17	16

R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
7	6	5	4	3	2	1	0
–	–	–	–	RETRY			
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 29-14 ETHA0CLRT register contents

Bit position	Bit name	Function
13 to 8	LCOL	Collision window These bits specify the collision window width. The width of the collision window to be set is calculated by the following expression. <ul style="list-style-type: none"> Collision window width = (LCOL + 8) x time required to transmit 8 bits The IEEE802.3 defines the collision window width as the time required to transmit 512 bits.
3 to 0	RETRY	Maximum number of times of retransmission in case of collision These bits specify the maximum number of times to attempt retransmission when a collision occurs. If retransmission does not finish within the value specified by these bits, transmission is aborted. This value indicates the maximum number of collisions. The IEEE802.3 defines the maximum number of collisions as 15.

(6) ETHA0LMAX - Maximum packet length register

Access This register can be read/written in 32-bit units.

Address <ETHA0_base> + 0014_H

Initial value Undefined

Caution Be sure to set bits 31 to 16 to "0".

31	30	29	28	27	26	25	24
–	–	–	–	–	–	–	–
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 29-15 ETHA0LMAX register contents

Bit position	Bit name	Function
15:0	MAXF[15:0]	<p>Maximum packet length (bytes)</p> <p>When the ETHA0MACC1.HUGEN bit is 0, the transmit and receive packet length is limited by the value specified by these bits.</p> <p>During reception: Reception is terminated immediately when the receive frame length exceeds the value specified by the MAXF bits.</p> <p>During transmission: Transmission is aborted immediately when the transmit frame length exceeds the value specified by the MAXF bits.</p>

(7) ETHA0LSA1 - Station address register 1

This register is used to compare a source address when a pause control frame is assembled and a destination address when address filtering is used. This register is used in combination with the ETHA0LSA2 register as a 48-bit register.

Access This register can be read/written in 32-bit units.

Address <ETHA0_base> + 0054_H

Initial value Undefined

Caution Be sure to set bits 31 to 16 to "0".

31	30	29	28	27	26	25	24

R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 29-16 ETHA0LSA1 register contents

Bit position	Bit name	Function
15:0	LSA1[15:0]	Station address (SA) (47:32) The SA bits (47:0) are used to compare a source address when a pause control frame is assembled and a destination address when address filtering is used (refer to (a) "Filtering of unicast addresses" on page 2008 in (1) Overview of address filtering of 29.5.6 "Address filtering").

(8) ETHA0LSA2 - Station address register 2

This register is used to compare a source address when a pause control frame is assembled and a destination address when address filtering is used. This register is used in combination with the ETHA0LSA1 register as a 48-bit register.

Access This register can be read/written in 32-bit units.

Address <ETHA0_base> + 0058_H

Initial value 0000 0000_H. This register is initialized by any reset.

Table 29-17 ETHA0LSA2 register contents

Bit position	Bit name	Function
31:0	LSA2[31:0]	Station address (SA) (31:0) The SA bits (47:0) are used to compare a source address when a pause control frame is assembled and a destination address when address filtering is used (refer to (a) "Filtering of unicast addresses" on page 2008 in (1) Overview of address filtering of 29.5.6 "Address filtering").

(9) ETHA0PTVR - Pause timer value read register

This register is used to read the value of the pause timer counter.

Access This register is read-only, in 32-bit units.

Address <ETHA0_base> + 005C_H

Initial value Undefined

Table 29-18 ETHA0PTVR register contents

Bit position	Bit name	Function
15:0	PTCT[15:0]	Pause timer counter These bits indicate the value currently set in the pause timer. The value of this register is valid only when reception flow control is enabled (the ETHA0MACC1.RXFC bit is 1) (refer to (1) "Flow control" on page 2002 in 29.5.4 "MAC control function").

(10) ETHA0VLTP - VLAN type register

This register is used to specify the operation to be performed on a VLAN frame.

Access This register can be read/written in 32-bit units.

Address <ETHA0_base> + 0064_H

Initial value Undefined

Caution Be sure to set bits 31 to 16 to "0".

Table 29-19 ETHA0VLTP register contents

Bit position	Bit name	Function
15:0	VLTP[15:0]	<p>VLAN frame operation</p> <p>These bits specify the operation to be performed on a VLAN frame (refer to (3) "Operations related to VLAN frame" on page 2005 in 29.5.4 "MAC control function").</p> <p>During reception: The value of VLTP[15:0] is compared with the value of the TPID field (2 bytes following the source address) of a frame to detect a VLAN frame.</p> <p>During transmission: If the value of the VLAN field matches the value of VLTP[15:0] when the ETHA0MACC2.APD bit is 1, PAD is appended to the VLAN frame.</p>

(11) ETHA0AFR - Address filter register

This register is used to set the conditions under which a receive packet is received.

Access This register can be read/written in 32-bit units.

Address <ETHA0_base> + 00C8_H

Initial value Undefined

Caution Be sure to set bits 31 to 4 to “0”.

Table 29-20 ETHA0AFR register contents

Bit position	Bit name	Function
3	PRO	Promiscuous mode All packets are valid in this mode.
2	PRM	Multicast reception In this mode, all multicast packets are valid and other packets are discarded.
1	AMC	Conditional multicast reception In this mode, multicast packets that satisfy the conditions are valid and other packets are discarded. Only multicast packets whose multicast address matches the values of the hash table specified by the ETHA0HT1 and ETHA0HT2 registers are received. The hash table is specified by the ETHA0HT1 and ETHA0HT2 registers.
0	ABC	Broadcast reception In this mode, broadcast packets are valid and other packets are discarded.

For details of the settings of the ETHA0AFR register and the packets to be filtered, refer to *Table 29-107 “Settings of ETHA0AFR register and packets to be filtered” on page 2011*.

(12) ETHA0HT1 - Hash table register 1

This register is used to specify the hash table used for conditional multicast packet detection.

Access This register can be read/written in 32-bit units.

Address <ETHA0_base> + 00CC_H

Initial value 0000 0000_H. This register is initialized by any reset.

Table 29-22 ETHA0HT2 register contents

Bit position	Bit name	Function
31:0	HT2[31:0]	Hash table 2 The hash table is used for conditional multicast packet detection. These bits indicate the lower 32 bits of the hash table. HT (31:0)

(14) ETHA0CAR1 - Carry register 1

This register indicates that a statistics counter has overflowed. Each bit of this register corresponds to a statistics counter. When a statistics counter overflows, the corresponding bit in this register is set.

Each bit is cleared when it is read.

Access This register can be read/written in 32-bit units.

Address <ETHA0_base> + 00DC_H

Initial value Undefined

Caution Be sure to set bits 31 to 16 to "0".

8	M2UN	ETHA0RUND counter overflow interrupt mask bit 0: Interrupt generation is enabled (not masked). 1: Interrupt generation is disabled (masked).
7	M2FC	ETHA0RFCR counter overflow interrupt mask bit 0: Interrupt generation is enabled (not masked). 1: Interrupt generation is disabled (masked).
6	M2CD	ETHA0RCDE counter overflow interrupt mask bit 0: Interrupt generation is enabled (not masked). 1: Interrupt generation is disabled (masked).
5	M2FO	ETHA0RFLR counter carry mask bit 0: Interrupt generation is enabled (not masked). 1: Interrupt generation is disabled (masked).
4	M2AL	ETHA0RALN counter carry mask bit 0: Interrupt generation is enabled (not masked). 1: Interrupt generation is disabled (masked).
3	M2UO	ETHA0RXUO counter carry mask bit 0: Interrupt generation is enabled (not masked). 1: Interrupt generation is disabled (masked).
2	M2PF	ETHA0RXPf counter carry mask bit 0: Interrupt generation is enabled (not masked). 1: Interrupt generation is disabled (masked).
1	M2CF	ETHA0RXCF counter carry mask bit 0: Interrupt generation is enabled (not masked). 1: Interrupt generation is disabled (masked).
0	M2RE	ETHA0RFCS counter carry mask bit 0: Interrupt generation is enabled (not masked). 1: Interrupt generation is disabled (masked).

29.4.2 Statistics counters

(1) ETHA0RBYT - Reception byte counter

Access This register can be read/written in 32-bit units.

Address <ETHA0_base> + 0140_H

Initial value 0000 0000_H. This register is initialized by any reset.

31	30	29	28	27	26	25	24
RBYT31	RBYT30	RBYT29	RBYT28	RBYT27	RBYT26	RBYT25	RBYT24
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
23	22	21	20	19	18	17	16
RBYT23	RBYT22	RBYT21	RBYT20	RBYT19	RBYT18	RBYT17	RBYT16
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
15	14	13	12	11	10	9	8
RBYT15	RBYT14	RBYT13	RBYT12	RBYT11	RBYT10	RBYT9	RBYT8
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
7	6	5	4	3	2	1	0
RBYT7	RBYT6	RBYT5	RBYT4	RBYT3	RBYT2	RBYT1	RBYT0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 29-27 ETHA0RBYT register contents

Bit position	Bit name	Function
31:0	RBYT[31:0]	This counter indicates the number of bytes in a received packet. It counts from the destination address byte to the FCS byte. It continues counting bytes even if an error occurs. If a packet longer than the value specified by the ETHA0LMAX register is received when the ETHA0MACC1.HUGEN bit is 0, this counter is incremented because the packet length is assumed to be that specified by the ETHA0LMAX register.

(2) ETHA0RPKT - Reception packet counter

Access This register can be read/written in 32-bit units.

Address <ETHA0_base> + 0144_H

Initial value 0000 0000_H. This register is initialized by any reset.

31	30	29	28	27	26	25	24
RPKT31	RPKT30	RPKT29	RPKT28	RPKT27	RPKT26	RPKT25	RPKT24
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

RPKT7	RPKT6	RPKT5	RPKT4	RPKT3	RPKT2	RPKT1	RPKT0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 29-28 ETHA0RPKT register contents

Bit position	Bit name	Function
31:0	RPKT[31:0]	This counter is incremented when any packet, including packets in which an error has occurred, all unicast packets, all multicast packets, and broadcast packets, is received.

(3) ETHA0RFCS - Reception FCS error frame counter

Access This register can be read/written in 32-bit units.

Address <ETHA0_base> + 0148_H

Initial value 0000 0000_H. This register is initialized by any reset.

31	30	29	28	27	26	25	24
RFCS31	RFCS30	RFCS29	RFCS28	RFCS27	RFCS26	RFCS25	RFCS24
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
23	22	21	20	19	18	17	16

15	14	13	12	11	10	9	8
RFCS15	RFCS14	RFCS13	RFCS12	RFCS11	RFCS10	RFCS9	RFCS8
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
7	6	5	4	3	2	1	0
RFCS7	RFCS6	RFCS5	RFCS4	RFCS3	RFCS2	RFCS1	RFCS0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 29-29 ETHA0RFCS register contents

Bit position	Bit name	Function
31:0	RFCS[31:0]	This counter is incremented if a CRC error occurs in a receive packet. If a packet longer than the value specified by the ETHA0LMAX register is received when the ETHA0MACC1.HUGEN bit is 0, a CRC check is executed when the packet length reaches the value specified by the ETHA0LMAX register, so this counter might be incremented because the received packet is assumed to contain a CRC error.

(4) ETHA0RMCA - Reception multicast packet counter

Access This register can be read/written in 32-bit units.

Address <ETHA0_base> + 014C_H

Initial value 0000 0000_H. This register is initialized by any reset.

31	30	29	28	27	26	25	24
RMCA31	RMCA30	RMCA29	RMCA28	RMCA27	RMCA26	RMCA25	RMCA24
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
23	22	21	20	19	18	17	16
RMCA23	RMCA22	RMCA21	RMCA20	RMCA19	RMCA18	RMCA17	RMCA16
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
15	14	13	12	11	10	9	8
RMCA15	RMCA14	RMCA13	RMCA12	RMCA11	RMCA10	RMCA9	RMCA8
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
7	6	5	4	3	2	1	0
RMCA7	RMCA6	RMCA5	RMCA4	RMCA3	RMCA2	RMCA1	RMCA0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 29-30 ETHA0RMCA register contents

Bit position	Bit name	Function
31:0	RMCA[31:0]	This counter is incremented when a multicast packet whose length is 64 to 1,518 bytes (64 to 1,522 bytes for a VLAN frame) is received. It is not incremented when a multicast packet in which a CRC error has occurred or a broadcast packet is received.

(5) ETHA0RBCA - Reception broadcast packet counter

Access This register can be read/written in 32-bit units.

Address <ETHA0_base> + 0150_H

Initial value 0000 0000_H. This register is initialized by any reset.

31	30	29	28	27	26	25	24
RBCA31	RBCA30	RBCA29	RBCA28	RBCA27	RBCA26	RBCA25	RBCA24
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
23	22	21	20	19	18	17	16
RBCA23	RBCA22	RBCA21	RBCA20	RBCA19	RBCA18	RBCA17	RBCA16
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
15	14	13	12	11	10	9	8
RBCA15	RBCA14	RBCA13	RBCA12	RBCA11	RBCA10	RBCA9	RBCA8
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
7	6	5	4	3	2	1	0
RBCA7	RBCA6	RBCA5	RBCA4	RBCA3	RBCA2	RBCA1	RBCA0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 29-31 ETHA0RBCA register contents

Bit position	Bit name	Function
31:0	RBCA[31:0]	This counter is incremented when a broadcast packet whose length is 64 to 1,518 bytes (64 to 1,522 bytes for a VLAN frame) is received. It is not incremented when a broadcast packet in which a CRC error has occurred or a multicast packet is received.

(6) ETHA0RXCF - Reception control frame packet counter

Access This register can be read/written in 32-bit units.

Address <ETHA0_base> + 0154_H

Initial value 0000 0000_H. This register is initialized by any reset.

31	30	29	28	27	26	25	24
RXCF31	RXCF30	RXCF29	RXCF28	RXCF27	RXCF26	RXCF25	RXCF24
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
23	22	21	20	19	18	17	16

R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
15	14	13	12	11	10	9	8
RXCF15	RXCF14	RXCF13	RXCF12	RXCF11	RXCF10	RXCF9	RXCF8
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
7	6	5	4	3	2	1	0
RXCF7	RXCF6	RXCF5	RXCF4	RXCF3	RXCF2	RXCF1	RXCF0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 29-32 ETHA0RXCF register contents

Bit position	Bit name	Function
31:0	RXCF[31:0]	This counter is incremented when any control frame, including pause control frames and unsupported control frames is received. It is not incremented when a control frame in which a CRC error has been detected is received.

(7) ETHA0RXPf - Reception pause frame packet counter

Access This register can be read/written in 32-bit units.

Address <ETHA0_base> + 0158_H

Initial value 0000 0000_H. This register is initialized by any reset.

31	30	29	28	27	26	25	24
RXPF31	RXPF30	RXPF29	RXPF28	RXPF27	RXPF26	RXPF25	RXPF24
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
23	22	21	20	19	18	17	16
RXPF23	RXPF22	RXPF21	RXPF20	RXPF19	RXPF18	RXPF17	RXPF16
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
15	14	13	12	11	10	9	8
RXPF15	RXPF14	RXPF13	RXPF12	RXPF11	RXPF10	RXPF9	RXPF8
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
7	6	5	4	3	2	1	0
RXPF7	RXPF6	RXPF5	RXPF4	RXPF3	RXPF2	RXPF1	RXPF0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 29-33 ETHA0RXPf register contents

Bit position	Bit name	Function
31:0	RXPF[31:0]	This counter is incremented when a valid pause control frame is received.

(8) ETHA0RXUO - Reception undefined control packet counter

Access This register can be read/written in 32-bit units.

Address <ETHA0_base> + 015C_H

Initial value 0000 0000_H. This register is initialized by any reset.

31	30	29	28	27	26	25	24
RXUO31	RXUO30	RXUO29	RXUO28	RXUO27	RXUO26	RXUO25	RXUO24
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
23	22	21	20	19	18	17	16
RXUO23	RXUO22	RXUO21	RXUO20	RXUO19	RXUO18	RXUO17	RXUO16
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
15	14	13	12	11	10	9	8
RXUO15	RXUO14	RXUO13	RXUO12	RXUO11	RXUO10	RXUO9	RXUO8
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
7	6	5	4	3	2	1	0
RXUO7	RXUO6	RXUO5	RXUO4	RXUO3	RXUO2	RXUO1	RXUO0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 29-34 ETHA0RXUO register contents

Bit position	Bit name	Function
31:0	RXUO[31:0]	This counter is incremented when a control frame that has an opcode other than PAUSE or a pause control frame that has an invalid destination address is received. It is not incremented when a pause control frame in which a CRC error has been detected is received.

(9) ETHA0RALN - Reception alignment error counter

Access This register can be read/written in 32-bit units.

Address <ETHA0_base> + 0160_H

Initial value 0000 0000_H. This register is initialized by any reset.

31	30	29	28	27	26	25	24
RALN31	RALN30	RALN29	RALN28	RALN27	RALN26	RALN25	RALN24
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
23	22	21	20	19	18	17	16
RALN23	RALN22	RALN21	RALN20	RALN19	RALN18	RALN17	RALN16
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
15	14	13	12	11	10	9	8
RALN15	RALN14	RALN13	RALN12	RALN11	RALN10	RALN9	RALN8
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
7	6	5	4	3	2	1	0
RALN7	RALN6	RALN5	RALN4	RALN3	RALN2	RALN1	RALN0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 29-35 ETHA0RALN register contents

Bit position	Bit name	Function
31:0	RALN[31:0]	This counter is incremented if a CRC error and a dribble nibble occur in a received packet. If a packet longer than the value specified by the ETHA0LMAX register is received when the ETHA0MACC1.HUGEN bit is 0, an alignment error check is executed when the packet length reaches the length (in bytes) specified by the ETHA0LMAX register, so this counter is not incremented.

(10) ETHA0RFLR - Reception frame length error counter

Access This register can be read/written in 32-bit units.

Address <ETHA0_base> + 0164_H

Initial value 0000 0000_H. This register is initialized by any reset.

31	30	29	28	27	26	25	24
RFLR31	RFLR30	RFLR29	RFLR28	RFLR27	RFLR26	RFLR25	RFLR24
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
23	22	21	20	19	18	17	16
RFLR23	RFLR22	RFLR21	RFLR20	RFLR19	RFLR18	RFLR17	RFLR16
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
15	14	13	12	11	10	9	8
RFLR15	RFLR14	RFLR13	RFLR12	RFLR11	RFLR10	RFLR9	RFLR8
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
7	6	5	4	3	2	1	0
RFLR7	RFLR6	RFLR5	RFLR4	RFLR3	RFLR2	RFLR1	RFLR0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 29-36 ETHA0RFLR register contents

Bit position	Bit name	Function
31:0	RFLR[31:0]	This counter is incremented if the value of the length field of a receive packet does not match the data field length of a packet actually received. If the value of the length field is 1,501 or more (for example, when the bytes equivalent to the length field are used as the Ethernet type field), this counter is not incremented.

(11) ETHA0RCDE - Reception code error counter

Access This register can be read/written in 32-bit units.

Address <ETHA0_base> + 0168_H

Initial value 0000 0000_H. This register is initialized by any reset.

31	30	29	28	27	26	25	24
RCDE31	RCDE30	RCDE29	RCDE28	RCDE27	RCDE26	RCDE25	RCDE24
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
23	22	21	20	19	18	17	16
RCDE23	RCDE22	RCDE21	RCDE20	RCDE19	RCDE18	RCDE17	RCDE16
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
15	14	13	12	11	10	9	8
RCDE15	RCDE14	RCDE13	RCDE12	RCDE11	RCDE10	RCDE9	RCDE8
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
7	6	5	4	3	2	1	0
RCDE7	RCDE6	RCDE5	RCDE4	RCDE3	RCDE2	RCDE1	RCDE0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 29-37 ETHA0RCDE register contents

Bit position	Bit name	Function
31:0	RCDE[31:0]	This counter is incremented if an illegal data symbol has been detected at least once while a carrier is being detected.

(12) ETHA0RFCR - Reception false carrier counter

Access This register can be read/written in 32-bit units.

Address <ETHA0_base> + 016C_H

Initial value 0000 0000_H. This register is initialized by any reset.

31	30	29	28	27	26	25	24
RFCR31	RFCR30	RFCR29	RFCR28	RFCR27	RFCR26	RFCR25	RFCR24
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
23	22	21	20	19	18	17	16
RFCR23	RFCR22	RFCR21	RFCR20	RFCR19	RFCR18	RFCR17	RFCR16
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
15	14	13	12	11	10	9	8
RFCR15	RFCR14	RFCR13	RFCR12	RFCR11	RFCR10	RFCR9	RFCR8
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
7	6	5	4	3	2	1	0
RFCR7	RFCR6	RFCR5	RFCR4	RFCR3	RFCR2	RFCR1	RFCR0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 29-38 ETHA0RFCR register contents

Bit position	Bit name	Function
31:0	RFCR[31:0]	If a false carrier is generated in the idle status, this counter is incremented after the next packet is received. It is assumed that a false carrier has occurred if 1110 _B is input as nibble data from RXD while RXER is high. This counter is incremented only once even if multiple false carriers are generated in the idle status.

(13) ETHA0RUND - Reception undersize packet counter

Access This register can be read/written in 32-bit units.

Address <ETHA0_base> + 0170_H

Initial value 0000 0000_H. This register is initialized by any reset.

31	30	29	28	27	26	25	24
RUND31	RUND30	RUND29	RUND28	RUND27	RUND26	RUND25	RUND24
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
23	22	21	20	19	18	17	16
RUND23	RUND22	RUND21	RUND20	RUND19	RUND18	RUND17	RUND16
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
15	14	13	12	11	10	9	8
RUND15	RUND14	RUND13	RUND12	RUND11	RUND10	RUND9	RUND8
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
7	6	5	4	3	2	1	0
RUND7	RUND6	RUND5	RUND4	RUND3	RUND2	RUND1	RUND0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 29-39 ETHA0RUND register contents

Bit position	Bit name	Function
31:0	RUND[31:0]	This counter is incremented if the receive packet length is less than 64 bytes and the packet contains a valid FCS field.

(14) ETHA0ROVR - Reception oversize packet counter

Access This register can be read/written in 32-bit units.

Address <ETHA0_base> + 0174_H

Initial value 0000 0000_H. This register is initialized by any reset.

31	30	29	28	27	26	25	24

R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 29-40 ETHA0ROVR register contents

Bit position	Bit name	Function
31:0	ROVR[31:0]	This counter is incremented if the receive packet length exceeds 1,518 bytes (1,522 bytes for a VLAN frame) and the packet contains a valid FCS field. If a packet longer than the value specified by the ETHA0LMAX register is received when the ETHA0MACC1.HUGEN bit is 0, a CRC check is executed when the packet length reaches the value specified by the ETHA0LMAX register. Therefore, a CRC error might be detected and this counter might not be incremented.

(15) ETHA0FRG - Reception fragment counter

Access This register can be read/written in 32-bit units.

Address <ETHA0_base> + 0178_H

Initial value 0000 0000_H. This register is initialized by any reset.

31	30	29	28	27	26	25	24

Table 29-41 ETHA0FRG register contents

Bit position	Bit name	Function
31:0	RFRG[31:0]	This counter is incremented if the receive packet length is less than 64 bytes and the packet contains a CRC error or an alignment error.

(16) ETHA0RJBR - Reception jabber counter

Access This register can be read/written in 32-bit units.

Address <ETHA0_base> + 017C_H

Initial value 0000 0000_H. This register is initialized by any reset.

31	30	29	28	27	26	25	24
RJBR31	RJBR30	RJBR29	RJBR28	RJBR27	RJBR26	RJBR25	RJBR24

R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 29-42 ETHA0RJBR register contents

Bit position	Bit name	Function
31:0	RJBR[31:0]	This counter is incremented if the receive packet length exceeds 1,518 bytes (1,522 bytes for a VLAN frame) and the packet contains a CRC error or an alignment error. If a packet longer than the value specified by the ETHA0LMAX register is received when the ETHA0MACC1.HUGEN bit is 0, a CRC check is executed when the packet length reaches the value specified by the ETHA0LMAX register. Therefore, a CRC error might be detected and this counter might be incremented.

(17) ETHA0R64 - Receive 64-byte frame counter

Access This register can be read/written in 32-bit units.

Address <ETHA0_base> + 0180_H

Initial value 0000 0000_H. This register is initialized by any reset.

31	30	29	28	27	26	25	24

Table 29-43 ETHA0R64 register contents

Bit position	Bit name	Function
31:0	R64[31:0]	This counter is incremented if the receive packet length is 64 bytes. It is incremented even if the receive packet contains a CRC error, symbol error, or length/type error.

(18) ETHA0R127 - Receive 65- to 127-byte frame counter

Access This register can be read/written in 32-bit units.

Address <ETHA0_base> + 0184_H

Initial value 0000 0000_H. This register is initialized by any reset.

31	30	29	28	27	26	25	24

R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 29-46 ETHA0R511 register contents

Bit position	Bit name	Function
31:0	R511[31:0]	This counter is incremented if the receive packet length is 256 to 511 bytes. It is incremented even if the receive packet contains a CRC error, symbol error, or length/type error.

(21) ETHA0R1K - Receive 512- to 1023-byte frame counter

Access This register can be read/written in 32-bit units.

Address <ETHA0_base> + 0190_H

Initial value 0000 0000_H. This register is initialized by any reset.

31	30	29	28	27	26	25	24
R1K31	R1K30	R1K29	R1K28	R1K27	R1K26	R1K25	R1K24

R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 29-47 ETHA0R1K register contents

Bit position	Bit name	Function
31:0	R1K[31:0]	This counter is incremented if the receive packet length is 512 to 1,023 bytes. It is incremented even if the receive packet contains a CRC error, symbol error, or length/type error.

(22) ETHA0RMAX - Receive 1024- to RMAX-byte frame counter

Access This register can be read/written in 32-bit units.

Address <ETHA0_base> + 0194_H

Initial value 0000 0000_H. This register is initialized by any reset.

31	30	29	28	27	26	25	24
RMAX31	RMAX30	RMAX29	RMAX28	RMAX27	RMAX26	RMAX25	RMAX24
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
23	22	21	20	19	18	17	16

RMAX15	RMAX14	RMAX13	RMAX12	RMAX11	RMAX10	RMAX9	RMAX8
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
7	6	5	4	3	2	1	0
RMAX7	RMAX6	RMAX5	RMAX4	RMAX3	RMAX2	RMAX1	RMAX0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 29-48 ETHA0RMAX register contents

Bit position	Bit name	Function
31:0	RMAX[31:0]	This counter is incremented if the receive packet length is 1,024 to 1,518 bytes (1,024 to 1,522 bytes for a VLAN frame). It is incremented even if the receive packet contains a CRC error, symbol error, or length/type error.

(23) ETHA0RVBT - Receive valid byte counter

Access This register can be read/written in 32-bit units.

Address <ETHA0_base> + 0198_H

Initial value 0000 0000_H. This register is initialized by any reset.

31	30	29	28	27	26	25	24
RVBT31	RVBT30	RVBT29	RVBT28	RVBT27	RVBT26	RVBT25	RVBT24

TBYT7	TBYT6	TBYT5	TBYT4	TBYT3	TBYT2	TBYT1	TBYT0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 29-50 ETHA0TBYT register contents

Bit position	Bit name	Function
31:0	TBYT[31:0]	This counter indicates the number of bytes in a transmit packet. When a collision occurs before transmission is finished or aborted, the transmission byte at which the collision occurred is also counted. The preamble and SFD are not included in the byte count indication.

(25) ETHA0TPKT - Transmission packet counter

Access This register can be read/written in 32-bit units.

Address <ETHA0_base> + 01C4_H

Initial value 0000 0000_H. This register is initialized by any reset.

31	30	29	28	27	26	25	24
TPKT31	TPKT30	TPKT29	TPKT28	TPKT27	TPKT26	TPKT25	TPKT24

Table 29-54 ETHA0TBCA register contents

Bit position	Bit name	Function
31:0	TBCA[31:0]	This counter is incremented when a broadcast packet is transmitted. It is not incremented when a multicast packet is transmitted. Nor is it incremented if transmission is aborted or if a CRC error is detected.

(29) ETHA0TUCA - Transmit unicast packet counter

Access This register can be read/written in 32-bit units.

Address <ETHA0_base> + 01D4_H

Initial value 0000 0000_H. This register is initialized by any reset.

31	30	29	28	27	26	25	24
TUCA31	TUCA30	TUCA29	TUCA28	TUCA27	TUCA26	TUCA25	TUCA24
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
23	22	21	20	19	18	17	16
TUCA23	TUCA22	TUCA21	TUCA20	TUCA19	TUCA18	TUCA17	TUCA16
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
15	14	13	12	11	10	9	8
TUCA15	TUCA14	TUCA13	TUCA12	TUCA11	TUCA10	TUCA9	TUCA8
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
7	6	5	4	3	2	1	0
TUCA7	TUCA6	TUCA5	TUCA4	TUCA3	TUCA2	TUCA1	TUCA0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 29-55 ETHA0TUCA register contents

Bit position	Bit name	Function
31:0	TUCA[31:0]	This counter is incremented when a unicast packet is transmitted. It is not incremented if transmission is aborted or if a CRC error is detected.

(30) ETHA0TXPF - Transmission pause control frame counter

Access This register can be read/written in 32-bit units.

Address <ETHA0_base> + 01D8_H

Initial value 0000 0000_H. This register is initialized by any reset.

31	30	29	28	27	26	25	24
TXPF31	TXPF30	TXPF29	TXPF28	TXPF27	TXPF26	TXPF25	TXPF24
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
23	22	21	20	19	18	17	16
TXPF23	TXPF22	TXPF21	TXPF20	TXPF19	TXPF18	TXPF17	TXPF16
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
15	14	13	12	11	10	9	8
TXPF15	TXPF14	TXPF13	TXPF12	TXPF11	TXPF10	TXPF9	TXPF8
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
7	6	5	4	3	2	1	0
TXPF7	TXPF6	TXPF5	TXPF4	TXPF3	TXPF2	TXPF1	TXPF0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 29-56 ETHA0TXPF register contents

Bit position	Bit name	Function
31:0	TXPF[31:0]	This counter is incremented each time a pause control frame is transmitted when the maximum amount of data has been stored in the receive FIFO.

(31) ETHA0TDFR - Transmission delay packet counter

Access This register can be read/written in 32-bit units.

Address <ETHA0_base> + 01DC_H

Initial value 0000 0000_H. This register is initialized by any reset.

31	30	29	28	27	26	25	24
TDFR31	TDFR30	TDFR29	TDFR28	TDFR27	TDFR26	TDFR25	TDFR24
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
23	22	21	20	19	18	17	16
TDFR23	TDFR22	TDFR21	TDFR20	TDFR19	TDFR18	TDFR17	TDFR16
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
15	14	13	12	11	10	9	8
TDFR15	TDFR14	TDFR13	TDFR12	TDFR11	TDFR10	TDFR9	TDFR8
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
7	6	5	4	3	2	1	0
TDFR7	TDFR6	TDFR5	TDFR4	TDFR3	TDFR2	TDFR1	TDFR0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 29-57 ETHA0TDFR register contents

Bit position	Bit name	Function
31:0	TDFR[31:0]	This counter is incremented if a transmit delay occurs because of carrier detection when transmission is about to start. It is not incremented if a collision occurs during transmission that was started after the delay occurred.

(32) ETHA0TXDF - Transmission excessive delay packet counter

Access This register can be read/written in 32-bit units.

Address <ETHA0_base> + 01E0_H

Initial value 0000 0000_H. This register is initialized by any reset.

31	30	29	28	27	26	25	24
TXDF31	TXDF30	TXDF29	TXDF28	TXDF27	TXDF26	TXDF25	TXDF24
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
23	22	21	20	19	18	17	16
TXDF23	TXDF22	TXDF21	TXDF20	TXDF19	TXDF18	TXDF17	TXDF16
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
15	14	13	12	11	10	9	8
TXDF15	TXDF14	TXDF13	TXDF12	TXDF11	TXDF10	TXDF9	TXDF8
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
7	6	5	4	3	2	1	0
TXDF7	TXDF6	TXDF5	TXDF4	TXDF3	TXDF2	TXDF1	TXDF0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 29-58 ETHA0TXDF register contents

Bit position	Bit name	Function
31:0	TXDF[31:0]	This counter is incremented if transmission is aborted by an excessive delay.

(33) ETHA0TSCL - Transmission single collision packet counter

Access This register can be read/written in 32-bit units.

Address <ETHA0_base> + 01E4_H

Initial value 0000 0000_H. This register is initialized by any reset.

31	30	29	28	27	26	25	24
TSCL31	TSCL30	TSCL29	TSCL28	TSCL27	TSCL26	TSCL25	TSCL24
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

15	14	13	12	11	10	9	8
TSCL15	TSCL14	TSCL13	TSCL12	TSCL11	TSCL10	TSCL9	TSCL8
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
7	6	5	4	3	2	1	0
TSCL7	TSCL6	TSCL5	TSCL4	TSCL3	TSCL2	TSCL1	TSCL0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 29-59 ETHA0TSCL register contents

Bit position	Bit name	Function
31:0	TSCL[31:0]	This counter is incremented if a transmission finishes successfully after a single collision occurred during the transmission.

(34) ETHA0TMCL - Transmission multiple collision packet counter

Access This register can be read/written in 32-bit units.

Address <ETHA0_base> + 01E8_H

Initial value 0000 0000_H. This register is initialized by any reset.

31	30	29	28	27	26	25	24
TMCL31	TMCL30	TMCL29	TMCL28	TMCL27	TMCL26	TMCL25	TMCL24
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
23	22	21	20	19	18	17	16
TMCL23	TMCL22	TMCL21	TMCL20	TMCL19	TMCL18	TMCL17	TMCL16
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
15	14	13	12	11	10	9	8
TMCL15	TMCL14	TMCL13	TMCL12	TMCL11	TMCL10	TMCL9	TMCL8
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
7	6	5	4	3	2	1	0
TMCL7	TMCL6	TMCL5	TMCL4	TMCL3	TMCL2	TMCL1	TMCL0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 29-60 ETHA0TMCL register contents

Bit position	Bit name	Function
31:0	TMCL[31:0]	This counter is incremented if a transmission finishes successfully after a collision occurred multiple times (but less times than the value specified by ETHA0CLRT.RETRY) during the transmission.

(35) ETHA0TLCL - Transmission late collision packet counter

Access This register can be read/written in 32-bit units.

Address <ETHA0_base> + 01EC_H

Initial value 0000 0000_H. This register is initialized by any reset.

31	30	29	28	27	26	25	24
TLCL31	TLCL30	TLCL29	TLCL28	TLCL27	TLCL26	TLCL25	TLCL24
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
23	22	21	20	19	18	17	16

R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
15	14	13	12	11	10	9	8
TXCL15	TXCL14	TXCL13	TXCL12	TXCL11	TXCL10	TXCL9	TXCL8
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
7	6	5	4	3	2	1	0
TXCL7	TXCL6	TXCL5	TXCL4	TXCL3	TXCL2	TXCL1	TXCL0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 29-62 ETHA0TXCL register contents

Bit position	Bit name	Function
31:0	TXCL[31:0]	This counter is incremented if collision occurs more than the times specified by ETHA0CLRT.RETRY in a single transmission.

(37) ETHA0TNCL - Transmission total collision counter

Access This register can be read/written in 32-bit units.

Address <ETHA0_base> + 01F4_H

Initial value 0000 0000_H. This register is initialized by any reset.

31	30	29	28	27	26	25	24
TNCL31	TNCL30	TNCL29	TNCL28	TNCL27	TNCL26	TNCL25	TNCL24
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
23	22	21	20	19	18	17	16
TNCL23	TNCL22	TNCL21	TNCL20	TNCL19	TNCL18	TNCL17	TNCL16
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
15	14	13	12	11	10	9	8
TNCL15	TNCL14	TNCL13	TNCL12	TNCL11	TNCL10	TNCL9	TNCL8
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
7	6	5	4	3	2	1	0
TNCL7	TNCL6	TNCL5	TNCL4	TNCL3	TNCL2	TNCL1	TNCL0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 29-63 ETHA0TNCL register contents

Bit position	Bit name	Function
31:0	TNCL[31:0]	This counter counts the number of collisions after which transmission finishes successfully.

(38) ETHA0TCSE - Transmission carrier sense error counter

Access This register can be read/written in 32-bit units.

Address <ETHA0_base> + 01F8_H

Initial value 0000 0000_H. This register is initialized by any reset.

31	30	29	28	27	26	25	24
TCSE31	TCSE30	TCSE29	TCSE28	TCSE27	TCSE26	TCSE25	TCSE24
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
23	22	21	20	19	18	17	16
TCSE23	TCSE22	TCSE21	TCSE20	TCSE19	TCSE18	TCSE17	TCSE16
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
15	14	13	12	11	10	9	8
TCSE15	TCSE14	TCSE13	TCSE12	TCSE11	TCSE10	TCSE9	TCSE8
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
7	6	5	4	3	2	1	0
TCSE7	TCSE6	TCSE5	TCSE4	TCSE3	TCSE2	TCSE1	TCSE0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 29-64 ETHA0TCSE register contents

Bit position	Bit name	Function
31:0	TCSE[31:0]	This counter is incremented if a carrier sense error occurs during transmission.

(39) ETHA0TIME - MAC internal error counter

Access This register can be read/written in 32-bit units.

Address <ETHA0_base> + 01FC_H

Initial value 0000 0000_H. This register is initialized by any reset.

31	30	29	28	27	26	25	24
TIME31	TIME30	TIME29	TIME28	TIME27	TIME26	TIME25	TIME24
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
23	22	21	20	19	18	17	16
TIME23	TIME22	TIME21	TIME20	TIME19	TIME18	TIME17	TIME16
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
15	14	13	12	11	10	9	8
TIME15	TIME14	TIME13	TIME12	TIME11	TIME10	TIME9	TIME8
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
7	6	5	4	3	2	1	0
TIME7	TIME6	TIME5	TIME4	TIME3	TIME2	TIME1	TIME0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 29-65 ETHA0TIME register contents

Bit position	Bit name	Function
31:0	TIME[31:0]	This counter is incremented if an error occurs in MAC during transmission or if a packet longer than the value specified by the ETHA0LMAX register is transmitted.

29.4.3 FIFO controller control registers

(1) ETHA0MFFCONT - FIFO controller control register

Access This register can be read/written in 32-bit units.

Address <ETHA0_base> + 0200_H

Initial value Undefined

- Cautions**
- Be sure to set the following bits to the values specified below (fixed values). If other values are set, the correct operation cannot be guaranteed.
 - RXSDMA[1:0] = 10
 - ASOE = 0
 - APS = 1
 - APL = 1
 - RXTHRC = 0
 - TXTHRC = 0
 - Be sure to set bits 29, 28, 23 to 19, 13, and 7 to 3 to "0".

31	30	29	28	27	26	25	24
LOOPBACK	RCSEL	–	–	IMLP3	IMLP2	IMLP1	IMLP0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
23	22	21	20	19	18	17	16
–	–	–	–	–	FLOWCNT	IVPAUSE	ZEROPAUSE
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
15	14	13	12	11	10	9	8
RXSDMA1	RXSDMA0	–	ASOE	APS	APL	RXTHRC	RXEN
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
7	6	5	4	3	2	1	0
–	–	–	–	–	TABT	TXTHRC	TXEN
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 29-66 ETHA0MFFCONT register contents

Bit position	Bit name	Function
31	LOOPBACK	Loopback mode Loopback between the transmit FIFO and receive FIFO is performed. 0: Normal mode 1: Loopback mode
30	RCSEL	RXCLK selection TXCLK is selected to be internally connected, instead of RXCLK. Specify a value for this bit if it is necessary to switch RXCLK to TXCLK when the MAC or the FIFO controller is in the loopback mode. 0: Normal mode 1: Clock switch mode (RXCLK switched to TXCLK)
27 to 24	IMLP[3:0]	Set these bits to 0000.
18	FLOWCNT	Flow control enable/disable 0: Flow control is disabled. 1: Flow control is enabled.
17	IVPAUSE	Interval pause packet transmission control This bit specifies the method of retransmitting a pause packet. 0: Retransmission by threshold value of FIFO Internal pause timer (ETHA0PAUSETM.IPTIME) is not used. 1: Retransmission by internal pause timer Internal pause timer (ETHA0PAUSETM.IPTIME) is used.
16	ZEROPAUSE	Zero pause packet output enable/disable 0: Zero pause packet output is disabled. 1: Zero pause packet output is enabled.
15, 14	RXSDMA[1:0]	Fix these bits to 10.
12	ASOE	Fix this bit to 0.
11	APS	Fix this bit to 1.
10	APL	Fix this bit to 1.
9	RXTHRC	Fix this bit to 0.
8	RXEN	Reception enable 0: Disables reception. 1: Enables reception. [Timing for disabling reception] If this bit is cleared to disable reception while a packet is being written from the MAC to the receive FIFO, the receive FIFO write circuit is stopped after the packet has been written. The receive FIFO of the system stops after all the packets written in the receive FIFO have been read. The flow control circuit is not stopped by this bit.
2	TABT	Transmission abort control This bit retransmits a packet that has been aborted by the MAC. 0: Discards the packet. 1: Retransmits the packet.
1	TXTHRC	Fix this bit to 0.
0	TXEN	Transmission enable 0: Disables transmission. 1: Enables transmission. [Timing for disabling transmission] If this bit is cleared to disable transmission while a packet is being written to the transmit FIFO, the transmit FIFO write circuit is stopped after the packet has been written (after the END flag has been set), cancelling a request to write the next packet. Packet transfer to the MAC is stopped after all the packets in the transmit FIFO have been transferred (after the empty status is indicated).

(2) ETHA0RSTCNT - Software reset control register

This register is used to control software reset.

Access This register can be read/written in 32-bit units.

Address <ETHA0_base> + 0204_H

Initial value Undefined

Caution Be sure to set bits 31 to 17, 15 to 9, and 7 to 1 to “0”.

31	30	29	28	27	26	25	24
–	–	–	–	–	–	–	–
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
23	22	21	20	19	18	17	16

–	–	–	–	–	–	–	SFTRST
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 29-67 ETHA0RSTCNT register contents

Bit position	Bit name	Function
16	RFFLSH	Receive FIFO clear (flush) This bit clears the receive FIFO, reception control circuit, flow control circuit, reception status register, and interrupt registers related to reception. Writing 1 to this bit starts the reset operation, and then this bit is automatically cleared. This bit is always read as 0.
8	TFFLSH	Transmit FIFO clear (flush) This bit clears the transmit FIFO, transmission control circuit, transmission status register, and interrupt registers related to transmission. Writing 1 to this bit starts the reset operation, and then this bit is automatically cleared.
0	SFTRST	Software reset This bit resets all the circuits of the FIFO controller (MFF). Writing 1 to this bit starts the reset operation, and then this bit is automatically cleared.

(3) ETHA0FLOWTH - Flow control threshold value register

This register is used to specify a threshold value for the receive FIFO to start flow control, and a threshold value to transmit a zero pause control frame.

Access This register can be read/written in 32-bit units.

Address <ETHA0_base> + 0218_H

Initial value Undefined

Caution Be sure to set bits 31 to 27 and 15 to 11 to "0".

31	30	29	28	27	26	25	24

Table 29-68 ETHA0FLOWTH register contents

Bit position	Bit name	Function
26:16	FLOWTHR[10:0]	<p>These bits specify the threshold value in bytes for the receive FIFO to start flow control.</p> <p>Flow control starts when the amount of data in the receive FIFO reaches the value specified by these bits.</p> <p>Back pressure transmission is executed in the half-duplex mode and pause control packets are transmitted in the full-duplex mode.</p> <p>Writing bit 17 or 16 is ignored because the receive FIFO can only be written in 32-bit (4-byte) units.</p> <p>Bits 17 and 16 are always read as 0.</p>
10:0	ZPTHR[10:0]	<p>These bits specify the threshold value in bytes for transmitting a zero pause control packet.</p> <p>When zero pause packet transmission is enabled by setting the MFFCNT.ZEROPAUSE bit to 1 (high level) and flow is controlled by pause control packets, a zero pause packet is transmitted if the amount of data in the receive FIFO falls below the threshold value specified by these bits.</p> <p>Writing bit 1 or 0 is ignored because the receive FIFO can only be written in 32-bit (4-byte) units.</p> <p>Bits 1 and 0 are always read as 0.</p>

(4) ETHA0PAUSETM - Pause timer value register

This register is used to set the pause time.

Access This register can be read/written in 32-bit units.

Address <ETHA0_base> + 021C_H

Initial value 7FFF FFFF_H. This register is initialized by any reset.

31	30	29	28	27	26	25	24

Table 29-69 ETHA0PAUSETM register contents

Bit position	Bit name	Function
31:16	IPTIME[15:0]	Interval pause packet timer value These bits specify the interval for transmitting a pause packet when interval pause packet transmission is enabled by setting the MFFCNT.IVPAUSE bit. Time required to transmit one packet = Time required to transmit 512 bits (circuit size) = 128 TXCLK cycles Default value: About 168 ms when the data rate is 100 Mbps, or about 1.68 seconds when the data rate is 10 Mbps
15:0	PAUSETM_MAX[15:0]	Pause control timer value of MAX pause packet These bits specify the value of TPTV[15:0] when a pause control request is issued to the MAC. Time required to transmit one packet = Time required to transmit 512 bits (circuit size) = 128 TXCLK cycles Default value: About 336 ms when the data rate is 100 Mbps, or about 3.36 seconds when the data rate is 10 Mbps

(5) ETHA0RXERSEL - Receive error selection register

This register is used to specify whether to accept or discard the packet if a reception error occurs.

Access This register can be read/written in 32-bit units.

Address <ETHA0_base> + 0220_H

Initial value Undefined

Caution Be sure to set bits 25 to 23 and 15 to 2 to "0".

Table 29-70 ETHA0RXERSEL register contents (1/2)

Bit position	Bit name	Function
31	RLENE	Specifies whether to accept a packet that contains a packet length error. 0: Accepts the packet. 1: Discards the packet.
30	VLAN	Specifies whether to accept a VLAN packet. 0: Accepts the packet. 1: Discards the packet.
29	USOP	Specifies whether to accept an undefined opcode control packet. 0: Accepts the packet. 1: Discards the packet.
28	RPCF	Specifies whether to accept a pause control packet. 0: Accepts the packet. 1: Discards the packet.
27	RCFR	Specifies whether to accept a control packet. 0: Accepts the packet. 1: Discards the packet.
26	DBNB	Specifies whether to accept a packet that contains dribble nibble. 0: Accepts the packet. 1: Discards the packet.
22	RLOR	Specifies whether to accept a packet that has a length field exceeding 1,500 bytes. 0: Accepts the packet. 1: Discards the packet.

Table 29-70 ETHA0RXERSEL register contents (2/2)

Bit position	Bit name	Function
21	RLER	Specifies whether to accept a packet whose length field does not match the data field length. 0: Accepts the packet. 1: Discards the packet.
20	RCRCE	Specifies whether to accept a packet in which a CRC error has occurred. 0: Accepts the packet. 1: Discards the packet.
19	RXER	Specifies whether to accept a packet in which RXER has been detected. 0: Accepts the packet. 1: Discards the packet.
18	CEPS	Specifies whether to accept a packet in which a false carrier has been detected. 0: Accepts the packet. 1: Discards the packet.
17	REPS	Specifies whether to accept a packet in which the total size of the preamble and SFD or the data field size is one nibble. 0: Accepts the packet. 1: Discards the packet.
16	PAIG	Specifies whether to accept a packet for which one of the following events occurred after the previous packet was received. <ul style="list-style-type: none"> A carrier longer than 6,072 nibbles (3,036 bytes) has been detected. The next packet with IFG + preamble + SFD has been received before the time required to transmit 80 bits has elapsed after a packet has been received. An illegal preamble or SFD has been received while the pure preamble data check is enabled (the ETHA0MACC1.PUREP bit is set). 0: Accepts the packet. 1: Discards the packet.
1	TXRX	Specifies whether to accept a packet in which a collision has been detected by the MAC. 0: Accepts the packet. 1: Discards the packet.
0	DVCF	Specifies whether to accept a packet received by the MAC that is judged to be a valid control packet. 0: Accepts the packet. 1: Discards the packet.

(6) ETHA0TXSTMON1 - Transmission status monitor 1 register

Access This register is read-only, in 32-bit units.

Address <ETHA0_base> + 0230_H

Initial value Undefined

31	30	29	28	27	26	25	24
–	–	–	–	–	–	–	–
R	R	R	R	R	R	R	R

Table 29-71 ETHA0TXSTMON1 register contents

Bit position	Bit name	Function
20	CSE	Detection of carrier loss during transmission
19	TBP	Occurrence of a collision due to the back pressure function after the previous transmission ^a
18	TPP	End of transmission of a transmit packet requested during pausing ^b
17	TPCF	Transmission of a pause control packet
16	TCFR	Transmission of a control packet
15:0	TTBC[15:0]	Number of bytes of transmitted data, including packets in which collisions occurred

- a) This bit is set if a collision has occurred between when the transmission status was previously updated and when the status is updated this time.
- b) This bit is not set if the packet requested during pausing is a control frame.

(7) ETHA0TXSTMONI2 - Transmission status monitor 2 register

Access This register is read-only, in 32-bit units.

Address <ETHA0_base> + 0234_H

Initial value 0000 0000_H. This register is initialized by any reset.

31	30	29	28	27	26	25	24
TUDR	TGNT	LCOL	ECOL	TEDFR	TDFR	TBRO	TMUL
R	R	R	R	R	R	R	R

R	R	R	R	R	R	R	R

Table 29-72 ETHA0TXSTMONI2 register contents

Bit position	Bit name	Function
31	TUDR	Detection of a transmit packet underrun ^a
30	TGNT	Transmission of a packet longer than the value specified by ETHA0LMAX ^b
29	LCOL	Occurrence of a late collision
28	ECOL	Occurrence of collisions exceeding the specified maximum number
27	TEDFR	Detection of an excessive transmission delay
26	TDFR	Occurrence of a transmission delay
25	TBRO	Transmission of a broadcast packet
24	TMUL	Transmission of a multicast packet
23	TDONE	End of transmission ^c
22	TFLOR	Detection of a length field greater than 1,500 bytes ^d
21	TFLER	Detection of a packet whose length field does not match the data field length ^{d, e}
20	TCRCE	Occurrence of a CRC error when CRC automatic appending mode was disabled
19:16	TCBC[3:0]	Number of times retransmission occurred due to collisions ^f
15:0	TBYT[15:0]	Transmit packet length (number of bytes) when transmission finished normally ^f

- a) This bit is set only if no collision has occurred.
 b) This bit is set only if ETHA0MACC1.HUGEN is 0.
 c) This bit is not set if transmission has been aborted.
 d) This bit is not set if ETHA0MACC1.FLCHT is 0.
 e) If the length field exceeds 1,500 bytes, TFLOR is set and TFLER is not.
 f) This value is not correct if transmission has been aborted.

(8) ETHA0TXFINF1 - Transmission status 1 register

Access This register is read-only, in 32-bit units.

Address <ETHA0_base> + 0238_H

Initial value Undefined

31	30	29	28	27	26	25	24

R	R	R	R	R	R	R	R

Table 29-73 ETHA0TXFINF1 register contents

Bit position	Bit name	Function
24:16	TPCNT[8:0]	Number of packets in the transmit FIFO These bits indicate the number of packets (start flag to end flag) that exist in the transmit FIFO. The value is incremented when one packet has been written by the system. The value is decremented when one packet has been read by the MAC (upon completion or halting of transmission).
11:0	TREMAIN[11:0]	These bits indicate the remaining capacity of the transmit FIFO (in bytes). Bits 1 and 0 are always 00 because the data in the transmit FIFO are aligned in 32-bit (4-byte) units.

(9) ETHA0TXFINF2 - Transmission status 2 register

Access This register is read-only, in 32-bit units.

Address <ETHA0_base> + 023C_H

Initial value Undefined

Caution Before rewriting a mode register related to transmission, be sure to confirm that the ETHA0TXFINF2.TXSTOP bit is 1.

R	R	R	R	R	R	R	R

Table 29-75 ETHA0RXSTMONI register contents

Bit position	Bit name	Function
31	RLENE	Occurrence of a receive packet length error This bit is set if the received packet size is less than 64 bytes or greater than 1,518 bytes (or less than 64 bytes or greater than 1,522 bytes for a VLAN packet).
30	VLAN	Reception of a VLAN packet This bit is set if a packet whose TPID field matches ETHA0VLTP is received. ^a
29	USOP	Reception of an undefined opcode control packet ^b
28	RPCF	Reception of a pause control packet ^b
27	RCFR	Reception of a control packet ^b
26	DBNB	Reception of a packet containing dribble nibble
25	RBRO	Reception of a broadcast packet
24	RMUL	Reception of a multicast packet
23	RXOK	End of reception ^a
22	RLOR	Reception of a packet that has a length field exceeding 1,500 bytes ^c
21	RLER	Detection of a packet whose length field does not match the data field length ^{c, d}
20	RCRCE	Occurrence of a CRC error
19	RXER	Detection of RXER
18	CEPS	Detection of a false carrier ^e
17	REPS	Reception of a packet in which the total size of the preamble and SFD or the data field size is one nibble ^{e, f}
16	PAIG	This bit is set if one of the following events occurred after the previous packet was received. ^e <ul style="list-style-type: none"> • A carrier longer than 6,072 nibbles (3,036 bytes) has been detected. • The next packet with IFG + preamble + SFD has been received before the time required to transmit 80 bits has elapsed after a packet has been received.^f • An illegal preamble or SFD has been received while the pure preamble data check is enabled (the ETHA0MACC1.PUREP bit is set).^f
15:0	RBYT[15:0]	Number of received bytes

- a) This bit is not set if a CRC error or RXER has occurred.
- b) This bit is not set if a CRC error has occurred.
- c) This bit is not set if ETHA0MACC1.FLCHT is 0.
- d) If the length field exceeds 1,500 bytes, RLOR is set and RLER is not.
- e) The bit is set if a false carrier is detected between when the reception status was updated previously and when it is updated this time.
- f) A packet in which this event has occurred is ignored and not transferred to the upstream system. The ETHA0RXSTMONI register is updated when a DMA transfer of the receive packet has finished. (This register indicates the status of the packet transferred by DMA.) The ETHA0RXFINF1 register is also updated at the same time.

The ETHA0RXSTATUS register is updated when a DMA transfer of the receive packet has finished. The reception status register 1 (ETHA0RXFINF1) is also updated at the same time.

(11) ETHA0RXFINF1 - Reception status 1 register

Access This register is read-only, in 32-bit units.

Address <ETHA0_base> + 0244_H

Initial value Undefined

R	R	R	R	R	R	R	R

Table 29-77 ETHA0RXFINF2 register contents

Bit position	Bit name	Function
24:16	RPCNT[8:0]	Number of packets in the receive FIFO These bits indicate the number of packets (start flag to end flag) that exist in the receive FIFO. The value is incremented when one packet has been written by the MAC. (A packet that is discarded upon being received does not increment this value.) If a packet has been read from the DMAC for the Ethernet controller or if the packet is discarded, this value is decremented after the internal operation to discard the packet finishes.
11:0	RREMAIN[11:0]	These bits indicates the remaining receive FIFO capacity (in bytes). Bits 1 and 0 are always 00 because the data in the receive FIFO is aligned in 32-bit (4-byte) units.

(13) ETHA0RXFINF3 - Reception status 3 register

This register indicates the status of the receive FIFO while reception is stopped.

Access This register is read-only, in 32-bit units.

Address <ETHA0_base> + 024C_H

Initial value Undefined

Caution Before rewriting a mode setting register related to reception or flow control, be sure to confirm that the ETHA0RXFINF3.RXSTOP bit is 1.

31	30	29	28	27	26	25	24

Table 29-78 ETHA0RXFINF3 register contents

Bit position	Bit name	Function
0	RXSTOP	This bit is set if no data is in the receive FIFO while reception is stopped (by clearing ETHA0MFFCONT.RXEN). Before rewriting a mode setting register related to reception or flow control, confirm that the RXSTOP bit is 1. 0: Receive FIFO is operating. 1: Receive FIFO is stopped.

(14) ETHA0FSTATUS - FIFO status interrupt register

If an interrupt source that is not masked by the ETHA0FSTATMK register is generated, the INTETMFS interrupt (FIFO status interrupt) is generated. The INTETMFS interrupt signal is asserted until all bits in this register are cleared.

If an interrupt source masked by the ETHA0FSTATMK register is generated, the corresponding bit in this register is set. All the bits of the ETHA0FSTATUS register are cleared when the register is read.

Access This register is read-only, in 32-bit units.

Address <ETHA0_base> + 0250_H

Initial value Undefined

Caution The FIFO status interrupt status register is cleared when it is read. It is recommended to copy interrupt sources to variables so that multiple interrupt sources generated concurrently can be detected.

31	30	29	28	27	26	25	24
–	–	–	–	–	–	–	TACOF

7	6	5	4	3	2	1	0
RFFE	RSUP	–	RFWE	RFOF	–	RFFLW	RFZP
R	R	R	R	R	R	R	R

Table 29-79 ETHA0FSTATUS register contents

Bit position	Bit name	Function
24	TACOF	This bit is set when the ETHA0TXABTCNT register (TX abort counter) overflows.
16	RACOF	This bit is set when the ETHA0RXABTCNT register (RX abort counter) overflows.
12	TSUP	TX status update This bit is set when the transmission status is updated in the ETHA0TXSTMONI1 or ETHA0TXSTMONI2 register.
11	TFNRTY	Transmit FIFO abort (transmit FIFO no retry) This bit is set if transmission fails and the data in the transmit FIFO is discarded. In this case, ETHA0TXABTCNT is incremented.
10	TFWE	This bit is set if a transmit FIFO write error has occurred.
7	RFFE	Receive FIFO flag error This bit is set if handshaking is not correctly performed when receive data is written from the MAC to the receive FIFO. The receive packet and reception status are invalid but reception is not canceled. <ul style="list-style-type: none"> • If the reception status is updated before all receive data is stored in the receive FIFO, the end of the packet is assumed as soon as the reception status has been updated. • If the reception status is not updated after all receive data has been stored in the receive FIFO, the reception status is assumed to be all 0.
6	RSUP	This bit is set when the reception status monitor register (ETHA0RXSTMONI) is updated. A valid value can be read from the ETHA0RXSTMONI or ETHA0RXFINF1 register when this bit is 1.
4	RFFE	Receive FIFO write error This bit is set if a packet whose size is less than 32 bits (4 bytes) has been received and could not be written to the receive FIFO.
3	RFOF	This bit is set if the receive FIFO overflows.
1	RFFLW	This bit is set if the data in the receive FIFO reaches or exceeds the value specified by the ETHA0FLOWTH.FLOWTHR bits.
0	RFZP	This bit is set if the data in the receive FIFO reaches or exceeds the value specified by the ETHA0FLOWTH.ZPTHR bits.

(15) ETHA0FSTATMK - FIFO status interrupt mask register

Access This register can be read/written in 32-bit units.

Address <ETHA0_base> + 0254_H

Initial value Undefined

Caution Be sure to set bits 31 to 25, 23 to 17, 15 to 13, 9, 8, 5, and 2 to “1”.

(16) ETHA0TXSTATUS - Transmission status interrupt register

This register stores the cumulative result of the transmission status. If an interrupt that is not masked by the ETHA0TXSTATMK register is generated, the INTETMTS interrupt (transmission status interrupt) is generated. The INTETMTS interrupt signal is asserted until all bits in this register are cleared.

If an interrupt source masked by the ETHA0TXSTATMK register is generated, the corresponding bit in this register is set. All the bits of the ETHA0TXSTATUS register are cleared when the register is read.

Access This register is read-only, in 32-bit units.

Address <ETHA0_base> + 0258_H

Initial value Undefined

Caution The transmission status interrupt register is cleared when it is read. It is recommended to copy interrupt sources to variables so that multiple interrupt sources generated concurrently can be detected.

R	R	R	R	R	R	R	R

Table 29-81 ETHA0TXSTATUS register contents

Bit position	Bit name	Function
16	TAB	This bit is set if transmission has been aborted.
7	TGNT	This bit is set if a packet longer than the value specified by ETHA0LMAX has been transmitted (TAB source). This bit is not set if ETHA0MACC1.HUGEN is 1.
6	LCOL	This bit is set if a late collision has been detected (TAB source).
5	ECOL	This bit is set if collisions have occurred exceeding the specified maximum number (TAB source).
4	TEDFR	This bit is set if an excessive transmission delay has been detected (TAB source).
3	TDFR	This bit is set if a transmission delay has occurred.
2	TFLOR	This bit is set if a packet whose length field is greater than 1,500 bytes is detected. This bit is also set when a VLAN packet pause control frame is transmitted. This bit is not set if ETHA0MACC1.FLCHT is 0.
1	TFLER	This bit is set if a packet whose length field does not match the data field length is detected. This bit is not set if ETHA0MACC1.FLCHT is 0. If the length field exceeds 1,500 bytes, TFLOR is set and TFLER is not.
0	TCRCE	This bit is set if a CRC error occurred. This bit is set if transmission is performed with the CRC automatic appending mode disabled (the ETHA0MACC1.PADEN and ETHA0MACC1.CRCEN bits are 0).

(17) ETHA0TXSTATMK - Transmission status interrupt mask register

This register is used to mask the transmission status interrupt (INTCTS).

If an interrupt source that is not masked by this register is generated, the INTCTS interrupt is generated. The INTCTS interrupt signal is asserted until all the related interrupt sources are cleared. If an interrupt source masked by the ETHA0TXSTATMK register is generated, the corresponding bit in the ETHA0TXSTATUS register is set.

Access This register can be read/written in 32-bit units.

Address <ETHA0_base> + 025C_H

Initial value Undefined

Caution Be sure to set bits 31 to 17 and 15 to 8 to "1".

0	TCRCE	0: Does not mask interrupt. 1: Masks interrupt.

(18) ETHA0RXSTATUS - Reception status interrupt register

This register stores the cumulative result of the reception status. If an interrupt source that is not masked by the ETHA0RXSTATMK register is generated, the INTETMRS interrupt is generated. The INTETMRS interrupt signal is asserted until all bits in this register are cleared.

If an interrupt source masked by the ETHA0RXSTATMK register is generated, the corresponding bit in this register is set.

This register is not affected by the setting of ETHA0RXERSEL (receive error selection register).

All the bits of the ETHA0RXSTATUS register are cleared when the register is read.

Access This register is read-only, in 32-bit units.

Address <ETHA0_base> + 0260_H

Initial value Undefined

Caution The reception status interrupt status register is cleared when it is read. It is recommended to copy interrupt sources to variables so that multiple interrupt sources generated concurrently can be detected.

RLER	RCRCE	RXER	CEPS	REPS	PAIG	TXRX	DVCF
R	R	R	R	R	R	R	R

Table 29-83 ETHA0RXSTATUS register contents

Bit position	Bit name	Function
14	RLENE	Occurrence of a receive packet length error This bit is set if the received packet size is less than 64 bytes or greater than 1,518 bytes (or less than 64 bytes or greater than 1,522 bytes for a VLAN packet).
13	VLAN	Reception of a VLAN packet This bit is set if a packet whose TPID field matches ETHA0VLTP. ^a
12	USOP	Reception of an undefined opcode control packet ^b
11	RPCF	Reception of a pause control packet ^b
10	RCFR	Reception of a control packet ^b
9	DBNB	Reception of a packet containing dribble nibble
8	RLOR	Reception of a packet that has a length field exceeding 1,500 bytes ^c
7	RLER	Detection of a packet whose length field does not match the data field length ^{c, d}
6	RRCCE	Occurrence of a receive CRC error
5	RXER	Detection of RXER
4	CEPS	Detection of a false carrier ^e
3	REPS	Reception of a packet in which the total size of the preamble and SFD or the data field size is one nibble ^{e, f}
2	PAIG	This bit is set if one of the following events occurred after the previous packet was received. ^e <ul style="list-style-type: none"> • A carrier longer than 6,072 nibbles (3,036 bytes) has been detected. • The next packet with IFG + preamble + SFD has been received before the time required to transmit 80 bits has elapsed after a packet has been received. • An illegal preamble or SFD has been received while the pure preamble data check is enabled (the ETHA0MACC1.PUREP bit is set).
1	TXRX	This bit is set if transmission starts (a collision occurs) during half-duplex reception (immediately after starting reception).
0	DVCF	This bit is set if the received packet is a valid control packet (that does not contain an error).

- a) This bit is not set if a CRC error or RXER has occurred.
b) This bit is not set if a CRC error has occurred.
c) This bit is not set if ETHA0MACC1.FLCHT is 0.
d) If the length field exceeds 1,500 bytes, RLOR is set and RLER is not.
e) This bit indicates that this event occurred between when the reception status was updated previously and when it is updated this time.
f) A packet in which this event has occurred is ignored and not transferred to the upstream system.

(19) ETHA0RXSTATMK - Reception status interrupt mask register

This register is used to mask the reception status interrupt (INTETMRS).

If an interrupt source that is not masked by this register is generated, INTETMRS is generated. The INTETMRS interrupt signal is asserted until all the related interrupt sources are cleared. If an interrupt source masked by this register is generated, the corresponding bit in the ETHA0RXSTATUS register is set.

Access This register can be read/written in 32-bit units.

Address <ETHA0_base> + 0264_H

Initial value Undefined

Caution Be sure to set bits 31 to 15 to "1".

(20) ETHA0TXABTCNT - TX abort counter

This is a transmission abort counter. It counts the number of packets that have resulted in a MAC transmission error (including an underrun).

Access This register can be read/written in 32-bit units.

Address <ETHA0_base> + 0270_H

Initial value Undefined

Caution Be sure to set bits 31 to 16 to "0".

Table 29-85 ETHA0TXABTCNT register contents

Bit position	Bit name	Function
15:0	TABCNT[15:0]	<p>Transmission abort count</p> <p>These bits count the number of packets that have resulted in a MAC transmission error (including an underrun). This counter is not incremented when ETHA0MFFCONT.TABT is set to retransmit an aborted packet.</p> <p>Packets are counted after 68 bytes have been transferred because they are not retransmitted by a retry request (usually, the MAC does not issue a retry request after 64 bytes have been transferred).</p> <p>If the count value overflows, the value of these bits returns to 0 and the ETHA0FSTATUS.TACOF bit is set.</p> <p>These bits are not cleared by resetting the transmission circuit (by setting TFRST and TFFLSH).</p>

(21) ETHA0RXABTCNT - RX abort counter

This is a reception abort counter. These bits count the number of receive packets that have been discarded because of the status of the receive packet, the status of the receive FIFO, address filtering by the MAC, and reception of a control packet.

Access This register can be read/written in 32-bit units.

Address <ETHA0_base> + 0274_H

Initial value Undefined

Caution Be sure to set bits 31 to 16 to "0".

29.4.4 DMAC control registers for Ethernet controller

(1) ETHA0MODE - Core function control register

This register is used to analyze the reception start descriptor and transmission start descriptor.

Access This register can be read/written in 32-bit units.

Address <ETHA0_base> + 0300_H

Initial value Undefined

Caution Be sure to set bits 31 to 19 and 16 to 0 to "0".

31	30	29	28	27	26	25	24
–	–	–	–	–	–	–	–

R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 29-87 ETHA0MODE register contents

Bit position	Bit name	Function
18	RXS	Reception enable bit The RXS bit is used to start analyzing the reception start descriptor. This bit is automatically cleared after 1 is written to it.
17	TXS	Transmission enable bit The TXS bit is used to start analyzing the transmission start descriptor. This bit is automatically cleared after 1 is written to it.

(2) ETHA0INTMS - Interrupt control register

Access This register can be read/written in 32-bit units.

Address <ETHA0_base> + 0304_H

Initial value Undefined

Caution Be sure to set bits 31 to 28, 23 to 20, 15 to 11, and 7 to 3 to "0".

Note The RBEI, RECI, RXI, TBEI, TECI, and TXI bits of the ETHA0INTMS register are cleared when they are read.

31	30	29	28	27	26	25	24

Table 29-88 ETHA0INTMS register contents (1/2)

Bit position	Bit name	Function
27	RUSMSK	This bit specifies whether to mask the RUPI interrupt indicated by bit 19. 0: Does not mask interrupt. 1: Masks interrupt.
26	RBEMSK	This bit specifies whether to mask the RBEI interrupt indicated by bit 18. 0: Does not mask interrupt. 1: Masks interrupt.
25	RECMSK	This bit specifies whether to mask the RECI interrupt indicated by bit 17. 0: Does not mask interrupt. 1: Masks interrupt.
24	RXMSK	This bit specifies whether to mask the RXI interrupt indicated by bit 16. 0: Does not mask interrupt. 1: Masks interrupt.
19	RUPI	This bit indicates whether a pause interrupt specified by the "U" (used) bit of a receive descriptor has been generated. It is cleared when read. 0: No interrupt generated. 1: Interrupt generated.
18	RBEI	This bit indicates whether a receive data buffer access error interrupt has been generated. It is cleared when read. 0: No interrupt generated. 1: Interrupt generated.

Table 29-88 ETHA0INTMS register contents (2/2)

Bit position	Bit name	Function
17	RECI	This bit indicates whether a reception (DMA) end of chain interrupt has been generated. It is cleared when read. 0: No interrupt generated. 1: Interrupt generated.
16	RXI	This bit indicates whether a packet reception (DMA) completion interrupt has been generated. It is cleared when read. 0: No interrupt generated. 1: Interrupt generated.
11	TUSMSK	This bit specifies whether to mask the TUPI interrupt indicated by bit 3. 0: Does not mask interrupt. 1: Masks interrupt.
10	TBEMSK	This bit specifies whether to mask the TBEI interrupt indicated by bit 2. 0: Does not mask interrupt. 1: Masks interrupt.
9	TECMSK	This bit specifies whether to mask the TECI interrupt indicated by bit 1. 0: Does not mask interrupt. 1: Masks interrupt.
8	TXMSK	This bit specifies whether to mask the TXI interrupt indicated by bit 0. 0: Does not mask interrupt. 1: Masks interrupt.
3	TUPI	This bit indicates whether a pause interrupt specified by the “U” (used) bit of a transmit descriptor has been generated. It is cleared when read. 0: No interrupt generated. 1: Interrupt generated.
2	TBEI	This bit indicates whether a transmit data buffer access error interrupt has been generated. It is cleared when read. 0: No interrupt generated. 1: Interrupt generated.
1	TECI	This bit indicates whether a transmission (DMA) end of chain interrupt has been generated. It is cleared when read. 0: No interrupt generated. 1: Interrupt generated.
0	TXI	This bit indicates whether a packet transmission (DMA) completion interrupt has been generated. It is cleared when read. 0: No interrupt generated. 1: Interrupt generated.

(3) ETHA0TRANSCTL - Transfer control register

This register is used to control transfer by the DMAC for the Ethernet controller.

Access This register can be read/written in 32-bit units.

Address <ETHA0_base> + 0308_H

Initial value Undefined

Caution Be sure to set bits 31 to 26, 23 to 18, and 15 to 1 to "0".

31	30	29	28	27	26	25	24
–	–	–	–	–	–	RXEN_STA	TXEN_STA

Table 29-89 ETHA0TRANSCTL register contents

Bit position	Bit name	Function
25	RXEN_STA	This bit indicates the reception status. 0: Reception is not in progress (IDLE status). 1: Reception is in progress. Reception stops if an RBEL or RECI interrupt, which is controlled by the interrupt register (ETHA0INTMS), is generated. At this time, this bit is cleared.
24	TXEN_STA	This bit indicates the transmission status. 0: Transmission is not in progress (IDLE status). 1: Transmission is in progress. Transmission stops if a TBEL or TECI interrupt, which is controlled by the interrupt register (ETHA0INTMS), is generated. At this time, this bit is cleared.
17	RXEN	This bit specifies whether to enable reception. 0: Disables reception (DMA reception stops.) 1: Enables reception.
16	TXEN	This bit specifies whether to enable transmission. 0: Disables transmission (DMA transmission stops.) 1: Enables transmission.
0	RXCHKSMEN	This bit enables or disables the receive checksum appending function. 0: Disables the receive check sum appending function. 1: Enables the receive check sum appending function.

(4) ETHA0SFTRST - Software reset setting register

This register is used to execute a software reset for the DMAC for the Ethernet controller.

Access This register can be read/written in 32-bit units.

Address <ETHA0_base> + 030C_H

Initial value Undefined

Caution Be sure to set bits 31 to 1 to “0”.

31	30	29	28	27	26	25	24

Table 29-90 ETHA0SFTRST register contents

Bit position	Bit name	Function
0	SFTRST	Software reset When this bit is set, the DMAC for the Ethernet controller is reset. The receive checksum unit is also reset. This bit is automatically cleared after 1 is written to it.

(5) ETHA0DMACM - DMA mode control register

Access This register can be read/written in 32-bit units.

Address <ETHA0_base> + 0310_H

Initial value Undefined

Caution Be sure to set bits 31 to 11, 7 to 5, and 3 to 0 to “0”, and bit 4 to “1”.

31	30	29	28	27	26	25	24

(6) ETHA0RXDP - Receive descriptor pointer register

This register is used to specify the pointer position of the receive descriptor of the DMAC for the Ethernet controller.

Access This register can be read/written in 32-bit units.

Address <ETHA0_base> + 0320_H

Initial value FFFF FFFC_H. This register is initialized by any reset.

31	30	29	28	27	26	25	24
RXDP31	RXDP30	RXDP29	RXDP28	RXDP27	RXDP26	RXDP25	RXDP24

Table 29-95 ETHA0LSTTXDP register contents

Bit position	Bit name	Function
31:0	LSTTXDP[31:0]	These bits indicate the last transmit descriptor pointer address. They hold the address of the last accessed transmit descriptor. Bits 1 and 0 are fixed to 00.

29.4.5 Control registers of DMAC for transmit checksum

(1) ETHA0CMODE - Transmit checksum unit function setting register

This register is used to analyze the reception start descriptor and transmission start descriptor.

Access This register can be read/written in 32-bit units.

Address <ETHA0C_base> + 0300_H

Initial value Undefined

31	30	29	28	27	26	25	24
–	–	–	–	–	–	–	–
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
23	22	21	20	19	18	17	16
–	–	–	–	–	–	TCH_RXS	TCH_TXS
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
15	14	13	12	11	10	9	8
–	–	–	–	–	–	–	–
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
7	6	5	4	3	2	1	0
–	–	–	–	–	–	–	–
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 29-96 ETHA0CMODE register contents

Bit position	Bit name	Function
18	TCH_RXS	The TCH_RXS bit is used to start analyzing the reception start descriptor. This bit is cleared immediately after 1 is written to it.
17	TCH_TXS	The TCH_TXS bit is used to start analyzing the transmission start descriptor. This bit is cleared immediately after 1 is written to it.

(2) ETHA0CINTMS - Transmit checksum interrupt register

This register indicates the status of and masks the INTSCRXTCH and INTSCTXTCH interrupts of the DMAC for the transmit checksum.

Access This register can be read/written in 32-bit units. Bits 18 to 16 and 2 to 0 can only be read, however.

Address <ETHA0C_base> + 0304_H

Initial value Undefined

Caution The TCH_RBEI, TCH_RECI, TCH_RXI, TCH_TEBI, TCH_TECI, and TCH_TXI bits of the transmit checksum interrupt register are cleared when they are read. It is recommended to copy interrupt sources to variables so that multiple interrupt sources generated concurrently can be detected.

31	30	29	28	27	26	25	24
–	–	–	–	–	TCH_RBEMSK	TCH_RECMSK	TCH_RXMSK
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
23	22	21	20	19	18	17	16

R/W	R/W	R/W	R/W	R/W	R	R	R
15	14	13	12	11	10	9	8
–	–	–	–	–	TCH_TBEMSK	TCH_TECMSK	TCH_TXMSK
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
7	6	5	4	3	2	1	0
–	–	–	–	–	TCH_TBEI	TCH_TECI	TCH_TXI
R/W	R/W	R/W	R/W	R/W	R	R	R

Table 29-97 ETHA0CINTMS register contents

Bit position	Bit name	Function
26	TCH_RBEMSK	This bit specifies whether to mask the TCH_RBEI interrupt indicated by bit 18. 0: Does not mask interrupt. 1: Masks interrupt.
25	TCH_RECMSK	This bit specifies whether to mask the TCH_RECI interrupt indicated by bit 17. 0: Does not mask interrupt. 1: Masks interrupt.
24	TCH_RXMSK	This bit specifies whether to mask the TCH_RXI interrupt indicated by bit 16. 0: Does not mask interrupt. 1: Masks interrupt.
18	TCH_RBEI	This bit indicates whether a receive data buffer access error interrupt of INTSCRXTCH has been generated. It is cleared (0) when read. 0: No interrupt generated. 1: Interrupt generated.
17	TCH_RECI	This bit indicates whether a receive DMA end of chain interrupt of INTSCRXTCH has been generated. It is cleared (0) when read. 0: No interrupt generated. 1: Interrupt generated.
16	TCH_RXI	This bit indicates whether a packet reception DMA transfer completion interrupt of INTSCRXTCH has been generated. It is cleared (0) when read. 0: No interrupt generated. 1: Interrupt generated.
10	TCH_TBEMSK	This bit specifies whether to mask the TCH_TBEI interrupt indicated by bit 2. 0: Does not mask interrupt. 1: Masks interrupt.
9	TCH_TECMSK	This bit specifies whether to mask the TCH_TECI interrupt indicated by bit 1. 0: Does not mask interrupt. 1: Masks interrupt.
8	TCH_TXMSK	This bit specifies whether to mask the TCH_TXI interrupt indicated by bit 0. 0: Does not mask interrupt. 1: Masks interrupt.
2	TCH_TBEI	This bit indicates whether a transmit data buffer access error interrupt of INTSCTXTCH has been generated. It is cleared (0) when read. 0: No interrupt generated. 1: Interrupt generated.
1	TCH_TECI	This bit indicates whether a transmit DMA end of chain interrupt of INTSCTXTCH has been generated. It is cleared (0) when read. 0: No interrupt generated. 1: Interrupt generated.
0	TCH_TXI	This bit indicates whether a packet transmission DMA transfer completion interrupt of INTSCTXTCH has been generated. It is cleared (0) when read. 0: No interrupt generated. 1: Interrupt generated.

(3) ETHA0CTRANSCTL - Transmit checksum transfer control register

This register is used to control transmission/reception of the DMAC for the transmit checksum.

Access This register can be read/written in 32-bit units. Bits 25 and 24 can only be read, however.

Address <ETHA0C_base> + 0308_H

Initial value Undefined

31	30	29	28	27	26	25	24
–	–	–	–	–	–	TCH_RXEN_STA	TCH_TXEN_STA
R/W	R/W	R/W	R/W	R/W	R/W	R	R
23	22	21	20	19	18	17	16

–	–	–	–	–	–	–	–
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 29-98 ETHA0CTRANSCTL register contents

Bit position	Bit name	Function
25	TCH_RXEN_STA	This bit indicates the reception status. 0: Reception is not in progress (IDLE status). 1: Reception is in progress. Reception stops if a TCH_RBFI or TCH_RECI interrupt, which is controlled by the transmit checksum interrupt register (ETHA0CINTMS), is generated. At this time, this bit is cleared.
24	TCH_TXEN_STA	This bit indicates the transmission status. 0: Transmission is not in progress (IDLE status). 1: Transmission is in progress. Transmission stops if a TCH_TBFI or TCH_TECI interrupt, which is controlled by the transmit checksum interrupt register (ETHA0CINTMS), is generated. At this time, this bit is cleared.
17	TCH_RXEN	This bit specifies whether to enable reception. 0: Disables reception (DMA reception stops.) 1: Enables reception.
16	TCH_TXEN	This bit specifies whether to enable transmission. 0: Disables transmission (DMA transmission stops). 1: Enables transmission.

(4) ETHA0CSFTRST - Transmit checksum software reset register

This register is used to execute a software reset for the DMAC for the transmit checksum.

Access This register can be read/written in 32-bit units.

Address <ETHA0C_base> + 030C_H

Initial value Undefined

31	30	29	28	27	26	25	24
–	–	–	–	–	–	–	–
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

1	0	0	8-beat incremental burst transfer mode																							
1	1	1	16-beat incremental burst transfer mode																							
Other than above			Setting prohibited																							

(6) ETHA0CRXDP - Transmit checksum receive descriptor pointer register

This register is used to specify the pointer position of the receive descriptor of the DMAC for the transmit checksum. The lower 2 bits are fixed to 00_B.

Access This register can be read/written in 32-bit units.

Address <ETHA0C_base> + 0320_H

Initial value FFFF FFFC_H. This register is initialized by any reset.

Table 29-104 ETHA0CLSTTXDP register contents

Bit position	Bit name	Function
31:0	TCH_LSTTXDP[31:0]	These bits indicate the last transmit descriptor pointer address. They hold the address of the last accessed transmit descriptor. Bits 1 and 0 are fixed to 00.

29.5 MAC/FIFO/DMAC Function

29.5.1 Frame format

With Ethernet/IEEE802.3, data is transmitted and received as a packet or frame.

The Ethernet controller supports the following three types of frames.

- Basic frame
- VLAN frame
- Pause control frame

(1) Basic frame

The basic frame used with Ethernet consists of a preamble (PA), frame start delimiter (SFD), destination address (DA), source address (SA), type/length field (TYPE/LEN), data field (DATA), and frame check sequence (FCS).

The packet size is defined to be 64 bytes minimum and 1,518 bytes maximum, excluding the preamble (PA) and frame start delimiter (SFD).

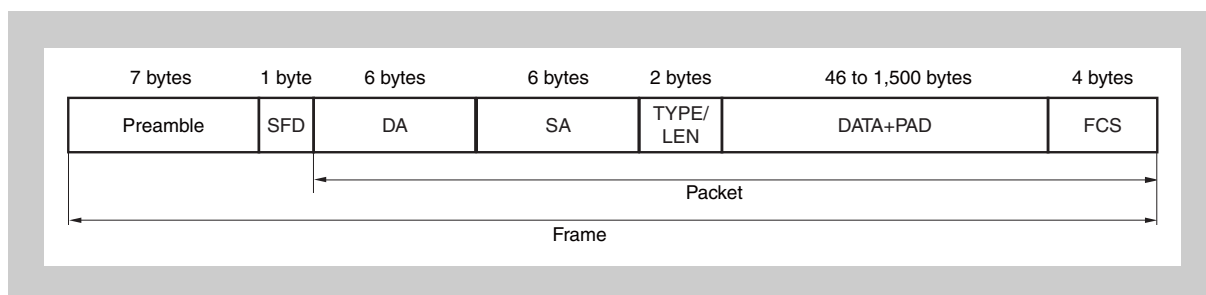

Figure 29-9 Basic frame structure

(a) Preamble and frame start delimiter (SFD)

The preamble and SFD consist of a repetition of 10 for 62 bits followed by 11 at the end, indicating the header of each frame.

(b) Destination address (DA)

The destination address field indicates the destination MAC address. A unicast address, multicast address, or broadcast address is written in this field.

(c) Source address (SA)

The source MAC address is written in this field.

(d) Type/length field

As an Ethernet frame, this field is a type field that indicates a protocol type. As an IEEE802.3 frame, this field is a length field that indicates the length of the data field.

(e) Data field

The data field size ranges from 46 bytes to 1,500 bytes.

Depending on the communication protocol, the data field might be divided to insert special header information. The Ethernet controller uses the data in this field only for calculating the CRC (Cycle Redundancy Check) for the FCS and does not check its contents.

(f) Frame check sequence (FCS)

The frame check sequence field is used to write a 32-bit CRC code to check the transfer data.

The Ethernet controller can automatically append a CRC to a transmit frame.

(2) VLAN frame

The structure of a VLAN frame (Qtag frame) is slightly different from that of a basic frame.

A 4-byte VLAN header is inserted immediately after the source address field. As a result, the minimum packet length of a VLAN frame is 64 bytes and the maximum packet length is 1,522 bytes.

The Ethernet controller has a VLAN frame detection function. If a transmit or receive packet is detected to be a VLAN frame, packet processing is performed based on the receive packet length.

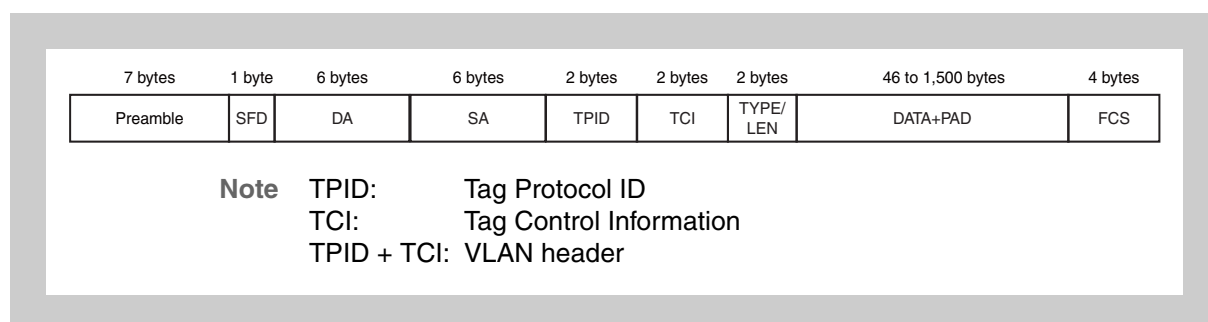

Figure 29-10 VLAN frame structure

Caution The Ethernet controller recognizes the value set to the ETHA0VLTP.VLTP[15:0] bits as a VLAN frame (TPID). The default value is 0000_H. For details, refer to (10) "ETHA0VLTP - VLAN type register" on page 1892 in 29.4.1 "MAC control registers".

(3) Pause control frame

The pause control frame is a 64-byte packet that has a dedicated format.

The destination address field has a fixed value of 01-80-C2-00-00-01_H.

The type/length field has a value of 8808_H, which indicates a control frame, and the opcode has a value of 0001_H, which indicates a pause control frame. The parameter field stores the value specified by the ETHA0PAUSETM register. The unused area following the parameter field is filled with PAD data consisting of zeros.

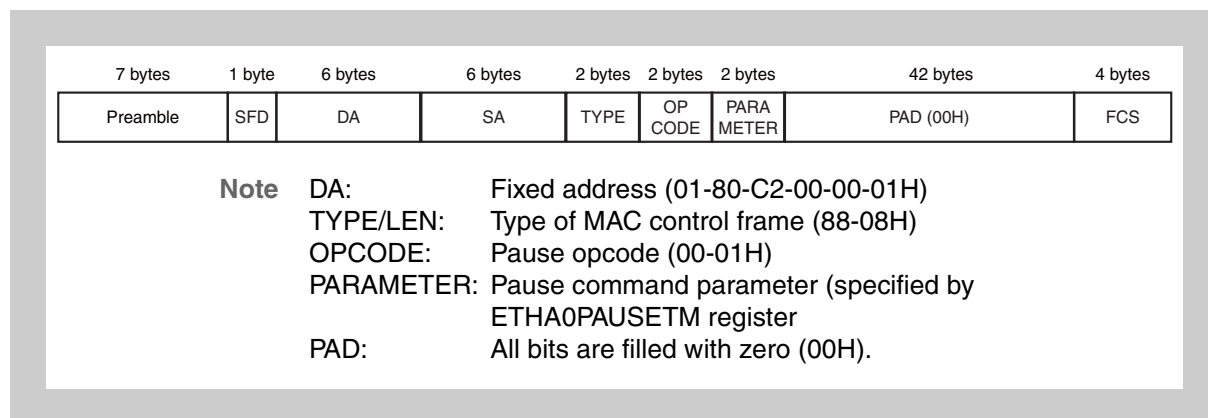

Figure 29-11 Pause control frame structure

The Ethernet controller can automatically transmit a pause control frame according to the amount of the remaining in the receive FIFO.

When a frame is received, the frame type is identified by the DA, TYPE, and OPCODE fields as shown in *Table 29-105 "Frame reception"*.

Table 29-105 Frame reception

DA	TYPE	OPCODE	Frame identified
01-80-C2-00-00-01	8808 _H	0001 _H	Pause frame
01-80-C2-00-00-01	8808 _H	Other than 0001 _H	Not supported
01-80-C2-00-00-01	Other than 8808 _H	xxxx	Data frame
Unicast (station address)	8808 _H	0001 _H	Pause frame
Unicast (station address)	8808 _H	Other than 0001 _H	Not supported
Unicast (station address)	Other than 8808 _H	xxxx	Data frame
Multicast	8808 _H	xxxx	Not supported
Multicast	Other than 8808 _H	xxxx	Data frame
Unicast (station address)	8808 _H	xxxx	Not supported
Unicast (station address)	Other than 8808 _H	xxxx	Data frame

(4) Pause control frame containing VLAN tag

The Ethernet controller does not support a pause control frame containing a VLAN tag.

It receives such a frame as an ordinary VLAN packet, but the RBRO and RLOR flags of the reception status monitor register (ETHA0RXSTMONI) are set (the RPCF and RCFR flags are not set).

(5) Envelope frame

The envelope frame format was added to IEEE802.3as (2005). Because it is a frame for 1,000 Mbps half-duplex communication, the Ethernet controller does not support this type of frame. If an envelope frame containing an EXTENSION field is received, a CRC error or length field mismatch occurs, or the receive FIFO overflows. Check the reception status and discard such a frame.

The Ethernet controller cannot transmit an envelope frame containing an EXTENSION field.

29.5.2 Frame transmission

The Ethernet controller generates a transmit frame as defined in IEEE802.3 from the transmit packet data stored in the transmit FIFO by the DMAC for the Ethernet controller via a DMA transfer, and then outputs that frame to a PHY device. If a collision is detected, the frame is retransmitted by using a random back-off algorithm. The status information of each transmit frame, such as excessive transmit delays and collisions exceeding the maximum number, is reflected in the ETHA0TXSTATUS register, and the number of times each event has occurred in all transmit frames is counted by statistics counters.

(1) Transmit frame

The transmit frame defined by IEEE802.3 consists of the following six fields (refer to *Figure 29-9 "Basic frame structure"*).

- Preamble (PA)
- Frame start delimiter (SFD)
- Destination address (DA)
- Source address (SA)
- Length field (LEN)
- Data and frame check sequence (FCS)

During transmission, the Ethernet controller generates a preamble, frame start delimiter, and FCS data.

(2) Transmission clock

The Ethernet controller operates in synchronization with the transmission clock (TXCLK) supplied by an external PHY device. Transmit packet data stored in the transmit FIFO via a DMA transfer is synchronized with TXCLK in the FIFO buffer, and then output to the PHY device. IEEE802.3 defines the frequency of TXCLK as $25\text{ MHz} \pm 100\text{ ppm}$ at a data transfer rate of 100 Mbps, or $2.5\text{ MHz} \pm 100\text{ ppm}$ at 10 Mbps.

(3) Carrier sense signal (CRS)

During half-duplex communication, if a carrier is detected (CRS = 1) after the Ethernet controller has stored transmit data in the FIFO buffer and transmission is enabled, the Ethernet controller postpones transmission until the end of the carrier (CRS = 0). After the carrier ends, transmission starts when the inter-packet gap (IPG) count specified by the ETHA0IPGT register has been reached.

If no carrier is detected (CRS = 0) when transmission is enabled and the IPG count is reached after the end of the previous carrier, transmission starts immediately.

When a frame is transmitted from the local side, the transmitted carrier sense signal is looped back from the external PHY device. If the transmitted carrier sense signal is masked by the external PHY device in the user-defined system,

the Ethernet controller detects a carrier sense error, but this does not affect the transmission.

(4) Collision detection (COL) and retransmission

If the Ethernet controller detects a collision during half-duplex communication, it transmits jam data (an error CRC) and then stops transmission.

If less than the maximum number of collisions (default value: 15) are detected in the collision window, transmission is kept waiting by a random back-off algorithm and data in the transmit FIFO is retransmitted. (In this case, no data is captured into the FIFO buffer again by DMA.)

If collisions exceeding the maximum number are detected or if a late collision (a collision detected outside the collision window) occurs, transmission is aborted and the transmit data is discarded.

(5) Inter-packet gap (IPG)

The IPG for successive data transmission from the local side is specified by the ETHA0IPGT register, and that for other cases is specified by the ETHA0IPGR register.

When transmission from the local side or the communicating device is finished, the Ethernet controller starts counting the IPG. If a request for the next transmission is issued from the FIFO buffer after transmission from the local side is finished and before the IPG count reaches the value of the ETHA0IPGT register, it is assumed that the data is to be transmitted successively (back to back), and transmission starts as soon as counting finishes.

If a packet is to be transmitted after transmission from the communicating device is finished, the IPG count is controlled by the ETHA0IPGR register. In the ETHA0IPGR register, the entire period of the IPG is specified for the IPGR2 bits and the interval time to detect a carrier in the first half of the IPG is specified for the IPGR1 bits. If a carrier is detected during the period specified for the IPGR1 bits, the Ethernet controller waits for the end of the carrier and then starts IPG counting from the beginning. If no carrier is detected during the period specified for the IPGR1 bits, transmission starts after the IPG period specified for the IPGR2 bits elapses.

If transmission does not start within the time required to transmit 24,288 bits (2.43 ms at 10 Mbps or 243.88 μ s at 100 Mbps) after the next transmission request is received from the FIFO buffer, an excessive transmission delay is assumed, transmission is aborted, and the transmit data is discarded.

The set value of the ETHA0IPGT and ETHA0IPGR registers and the actual IPG period are calculated by the following expression.

[At 100 Mbps]

Back-to-back transmission:

$$\text{IPG} = (5 + \text{IPGT}) \times 40 \text{ ns (default value: 960 ns)}$$

Non back-to-back transmission:

$$\text{IPG} = (5 + \text{IPGT}) \times 40 \text{ ns (default value: 960 ns)}$$

Carrier sense time:

$$(2 + \text{IPGR1}) \times 40 \text{ ns (default value: 640 ns)}$$

[At 10 Mbps]

Back-to-back transmission:

$$\text{IPG} = (5 + \text{IPGT}) \times 400 \text{ ns (default value: 9.6 } \mu\text{s)}$$

Non back-to-back transmission:

$$\text{IPG} = (5 + \text{IPGR2}) \times 400 \text{ ns (default value: 9.6 } \mu\text{s)}$$

Carrier sense time:

$$(2 + \text{IPGR1}) \times 400 \text{ ns (default value: 6.4 } \mu\text{s)}$$

Caution According to the specification of IEEE802.3, set the IPG to 960 ns or more at a data transfer rate of 100 Mbps, or 9.6 μ s or more at 10 Mbps. The default value of the ETHA0IPGT and ETHA0IPGR registers is the minimum rated value and may be used as is.

Figure 29-12 IPG during back-to-back transmission

Figure 29-13 IPG during non back-to-back transmission

(6) Appending preamble, CRC, and PAD

A 7-byte preamble and a 1-byte frame start delimiter (SFD) are appended to the beginning of the transmit packet supplied from the FIFO buffer.

ETHA0MACC1.CRCEN	Operation
0	The transmit packet must end with a valid frame check sequence (FCS). The MAC checks the FCS, and if the FCS value is not correct, the MAC generates a transmission status interrupt (INTETMTS) to report an error.
1	An internally generated frame check sequence (FCS) is appended to the end of the transmit packet.

If the ETHA0MACC1.CRCEN bit is set, a frame check sequence (FCS) that has been internally generated is appended to the end of the transmit packet.

If the ETHA0MACC1.CRCEN bit is cleared, the transmit packet must end with a valid FCS. The Ethernet controller can check the FCS. If the value of the FCS is not correct, the Ethernet controller generates an Ethernet transmission status interrupt.

If the ETHA0MACC1.PADEN bit is set, zeros (PAD) are appended to a transmit packet shorter than 64 bytes (this is known as padding). In this case, the Ethernet controller appends the correct FCS to the end of the frame, regardless of the setting of the CRCEN bit.

If the ETHA0MACC2.APD or ETHA0MACC2.VPD bit is set when the ETHA0MACC1.PADEN bit is 1, PAD is appended to a VLAN frame. If the APD bit is set, only a packet that matches the VLAN type specified by the ETHA0VLTP register is regarded as a VLAN frame and is padded. If the VPD bit is set, all frames are regarded as VLAN frames and padded. A packet regarded as a VLAN frame is padded to extend its length to 68 bytes. The data that is appended as a pad is all 0.

(7) Aborting transmission

The Ethernet controller aborts transmission under the following conditions.

It does not abort transmission if the transmit FIFO underruns within the normal operating range.

- If more than the maximum number of collisions (MAX collision) occur
- If collision occurs outside the collision window (late collision)
- If there is an excessive transmission delay
- If a packet exceeding the frame length specified by the ETHA0LMAX register is to be transmitted.

(If the ETHA0MACC1.HUGEN bit is 1, however, the transmit frame length is not limited.)

(8) Full-duplex operation

A full-duplex operation is enabled when the ETHA0MACC1.FULLD bit is set. The IPG is always the value specified by the ETHA0IPGT register. The FULLD signal is asserted if the ETHA0MACC1.FULLD bit is set, reporting to the external circuit that full-duplex operation is specified.

(9) Flow control and back pressure functions

The Ethernet controller has a flow control function (see (1) “Flow control” on page 2002 in 29.5.4 “MAC control function”) and a back pressure function (see (2) “Back pressure” on page 2004 in 29.5.4 “MAC control function”) associated with the receive FIFO. These functions are automatically activated to prevent the FIFO buffer from overflowing when the vacant capacity of the receive FIFO runs short.

(10) Transmission status update timing

The transmission status is updated in the timing shown below.

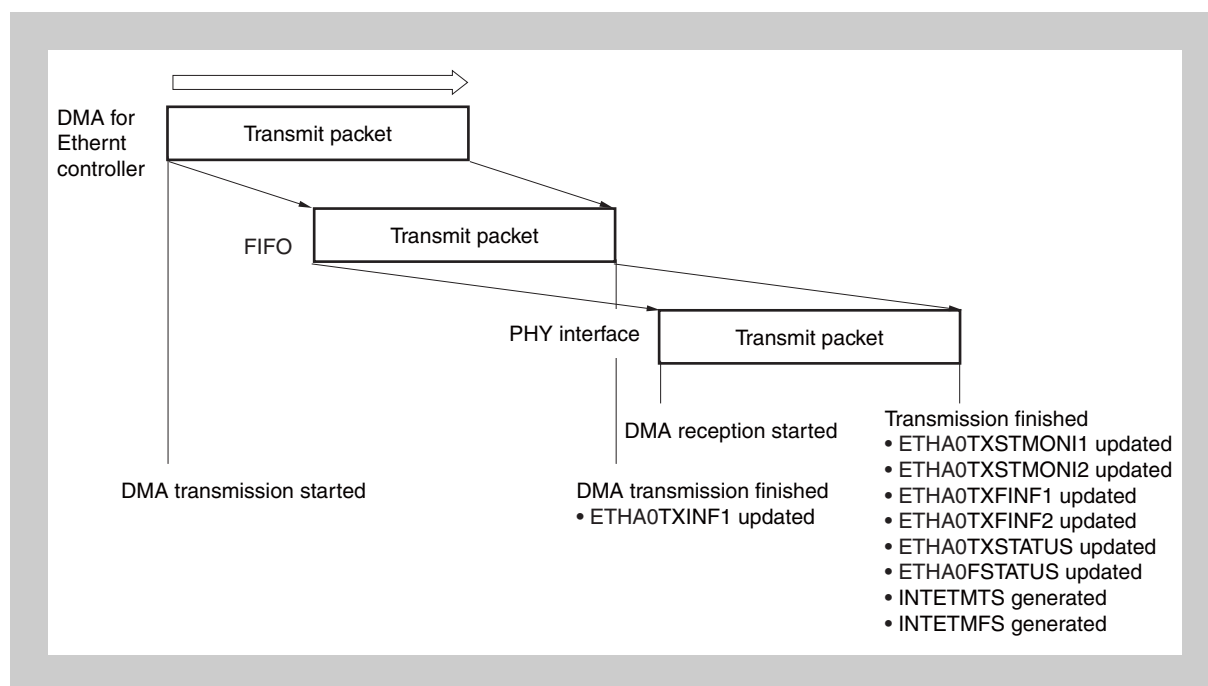

Figure 29-14 Transmission status update timing

29.5.3 Frame reception

The Ethernet controller generates a receive packet from a receive frame to be stored in the FIFO buffer, detects the SFD, checks the length field and FCS, and identifies whether the frame is a VLAN frame.

The status information of each receive packet is set to the reception status monitor register (ETHA0RXSTMONI) and the number of times each event has occurred in all receive frames is counted by statistics counters.

(1) Receive clock

The Ethernet controller receives data in synchronization with the reception clock (RXCLK) supplied by an external (PHY) device.

IEEE802.3 defines the frequency of RXCLK as 25 MHz±100 ppm at a data transfer rate of 100 Mbps, or 2.5 MHz±100 ppm at 10 Mbps.

(2) Reception of MII data

The Ethernet controller recognizes the RXD signal data as receive frames while the RXD[3:0] signal is asserted, and recognizes the end of the frames when the RXDV signal is deasserted.

(3) Detecting preamble and SFD

The Ethernet controller detects the preamble and SFD at the beginning of a receive frame and recognizes the data that follows as a receive packet.

(4) Checking length field

The Ethernet controller counts the length of a receive packet, and checks the length of the data field assuming the 2 bytes following the source address to be a length field. The result of this check can be read as the reception status from the ETHA0RXSTMONI register. An interrupt signal can be output to report a mismatch between the counted receive packet length and the length field value.

(5) CRC

The Ethernet controller calculates the 4-byte frame check sequence (FCS) from a receive packet and compares it with the FCS data appended to the end of the receive packet. The result of the comparison can be read from the ETHA0RXSTMONI register. An interrupt signal can be output to report a mismatch between the calculated 4-byte FCS and the FCS data at the end of the receive packet.

(6) Transmitting data to FIFO

The Ethernet controller assumes that a packet of 6 bytes or more is valid and discards a packet of less than 6 bytes.

(7) Detection of huge packet

If the ETHA0MACC1.HUGEN bit is cleared, the Ethernet controller receives only packets shorter than the maximum frame length specified by the ETHA0LMAX register (default value: 1,536 bytes), and stops receiving longer packets midway.

For details about the receivable packet length, refer to *Table 29-112 "Restrictions on receive FIFO"*.

(8) Detecting VLAN frame

The Ethernet controller checks whether received packets are VLAN frames.

If the value of the TPID field (the 2 bytes following the source address) of a received packet matches the value specified by the ETHA0VLTP register, the packet is recognized as a VLAN packet and the ETHA0RXSTMONI.VLAN flag is set. In a packet recognized as a VLAN frame, the 2 bytes immediately after the VLAN header (the 4 bytes following the source address) including the TPID field are regarded as the length field.

(9) Reception status update timing

The reception status is updated in the timing shown below.

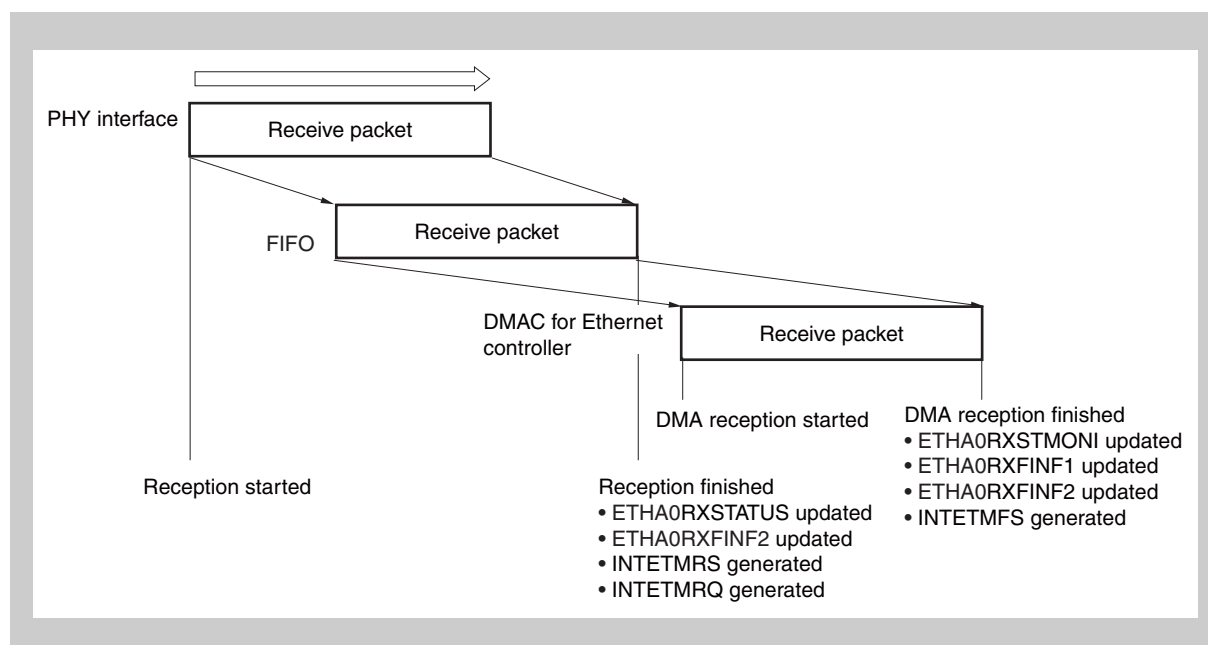

Figure 29-15 Reception status update timing

29.5.4 MAC control function

(1) Flow control

The Ethernet controller controls the flow by using the pause control frame defined in "IEEE802.3 Annex 31".

The purpose of flow control is to decrease the frequency of frame transmission executed by the communicating device (link partner) connected point-to-point during full-duplex operation. The amount of data a system can receive and process is limited. If frames are received too frequently, system processing cannot keep up, so the receive FIFO might overflow. Flow control is used to avoid this situation.

When the Ethernet controller receives a pause control frame, it loads the value of the parameter field in the control frame to the pause timer in the MAC. If the value of the pause timer is not 0, the next transmission starts after the time set to the pause timer has elapsed.

If the value of the parameter field in the received pause control frame is 0 (a zero pause control frame), the value of the pause timer is cleared to 0 and transmission is resumed after the packet interval specified by the ETHA0IPGR register has elapsed.

To suppress data transmission from the link partner, the reserved multicast address (01-80-C2-00-00-01), pause opcode (00-01), and the pause timer value of the ETHA0PAUSETM register (PAUSETM_MAX) are transmitted as a pause control frame.

Starting transmission of a pause frame takes precedence over starting transmission of a basic frame. If a condition for transmitting a pause frame is satisfied while a basic frame is being transmitted, however, the pause frame is transmitted after transmission of the basic frame has finished.

The Ethernet controller controls the flow by setting ETHA0MFFCONT.FLOWCNT.

The necessity of transmitting a pause control frame request is judged according to the amount of data in the receive FIFO.

If the ETHA0MFFCONT.IVPAUSE bit is 0 in the full-duplex communication mode, the Ethernet controller monitors the amount of data in the receive FIFO during reception (see (a) in Figure 29-16 "Flow control"). And if the amount of data in the receive FIFO exceeds the value specified by the ETHA0FLOWTH.FLOWTHR bits, a pause control frame is transmitted (see (b) in Figure 29-16 "Flow control").

If the ETHA0MFFCONT.IVPAUSE bit is 1, the pause control frame is continually transmitted at the interval specified by the ETHA0PAUSETM.IPTIME bits as long as the amount of data in the receive FIFO exceeds the value specified by the ETHA0FLOWTH.FLOWTHR bits.

The Ethernet controller monitors the quantity of data in the receive FIFO even while receive data is being transferred by DMA (see (c) in Figure 29-16 "Flow control").

If the ETHA0MFFCONT.ZEROPAUSE bit is 1, a zero pause control frame is transmitted if the amount of data in the receive FIFO falls below the value specified by the ETHA0FLOWTH.ZPTH bits (see (d) in Figure 29-16 "Flow control").

If the ETHA0MFFCONT.ZEROPAUSE bit is 0, a zero pause control frame is not transmitted.

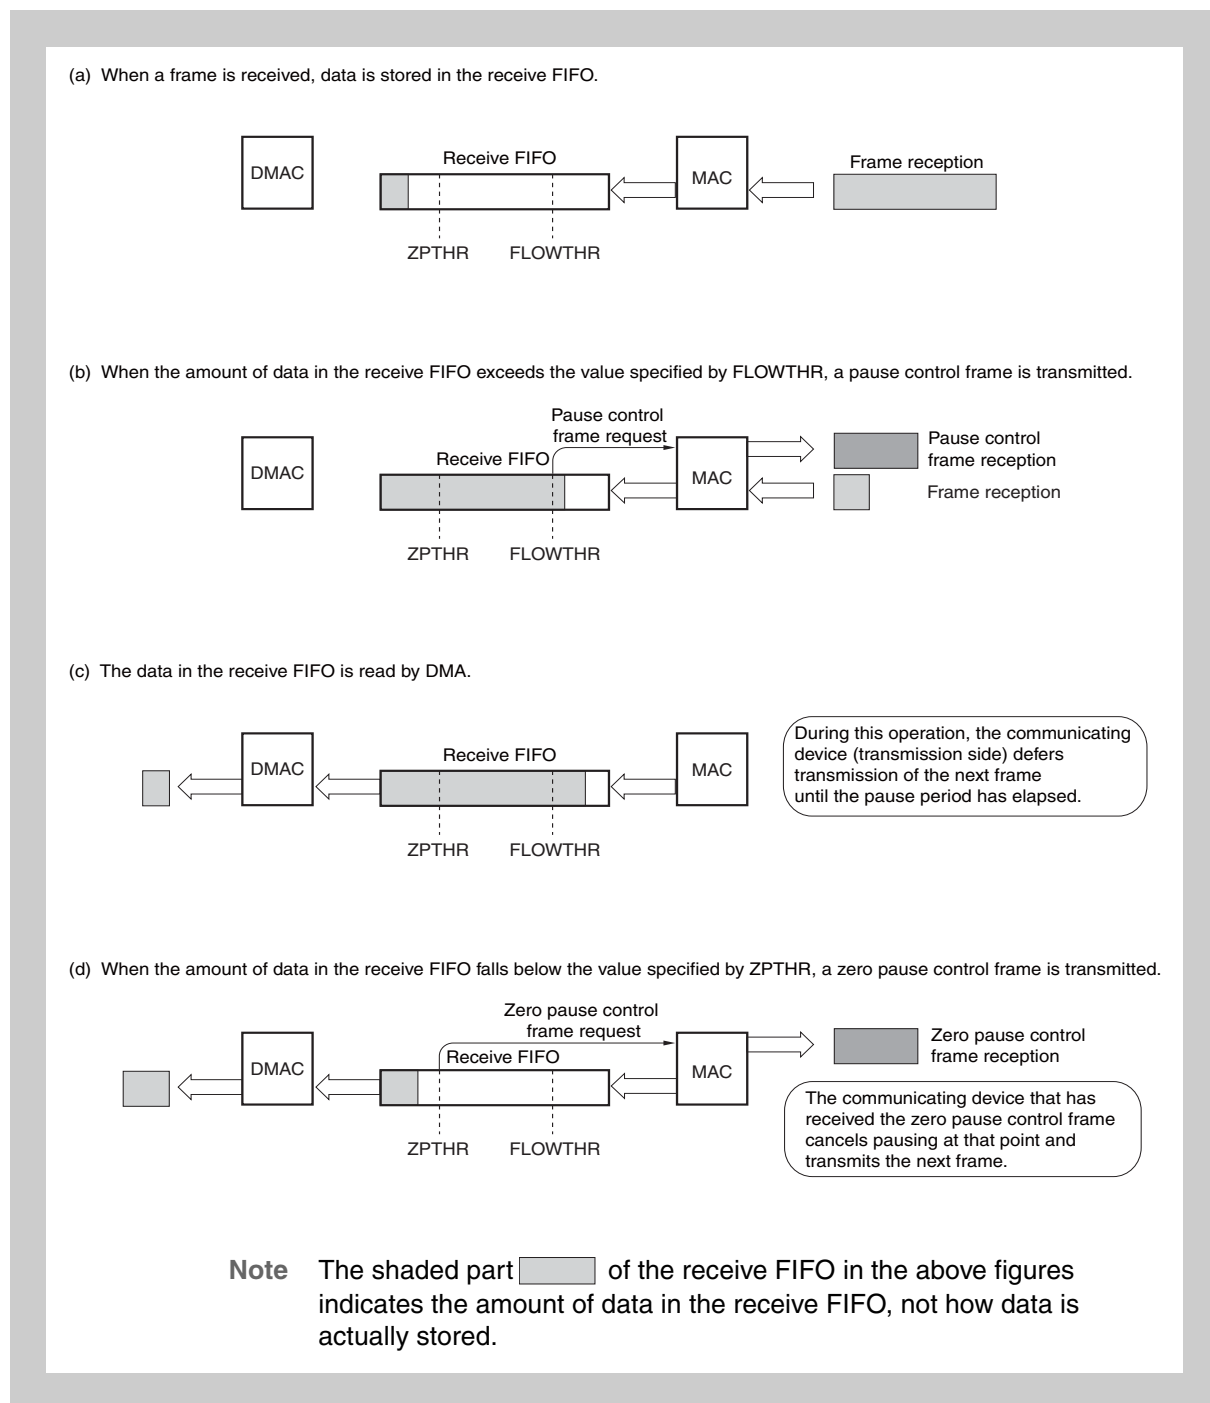

Figure 29-16 Flow control

(2) Back pressure

This function is available only during half-duplex operation.

If the amount of data in the receive FIFO exceeds the value specified by the ETHA0FLOWTH.FLOWTHR bits when the ETHA0MFFCONT.FLOWCNT bit is 1 and the ETHA0MACC1.FULLD bit is 0, the back pressure function is enabled (see (b) in Figure 29-17 “Back pressure control”).

If the next frame is received in this status, a collision is intentionally generated by transmitting a dummy packet, prompting the communicating device to retransmit the frame (see (c) in Figure 29-17 “Back pressure control”).

A collision that occurs in the back pressure status is not included in the number of collisions.

The back pressure status is released if the amount of data in the receive FIFO falls below the value specified by the FLOWTHR bits (see (d) in Figure 29-17 “Back pressure control”).

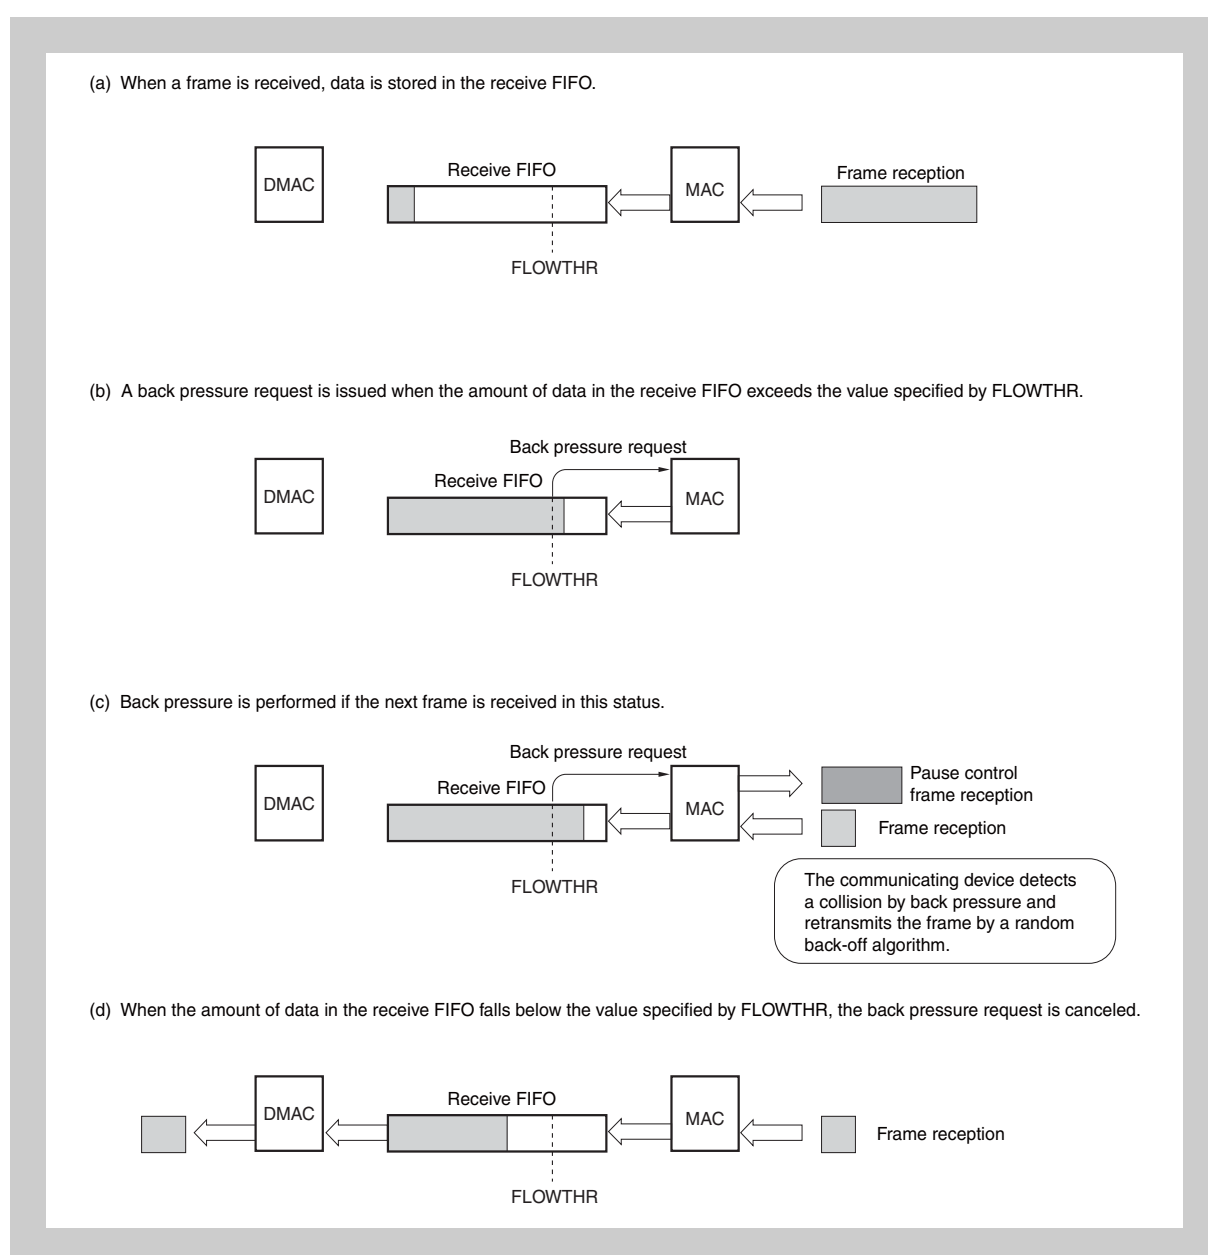

Figure 29-17 Back pressure control

(3) Operations related to VLAN frame

The Ethernet controller detects a VLAN frame by comparing the TPID field in a receive/transmit packet with the value of the VLAN type register (ETHA0VLTP). Operations related to the VLAN frame are described below.

(a) Detection of VLAN frame

The Ethernet controller constantly monitors the value of the 2-byte TPID field that follows the source address in a receive packet.

During transmission, the value of the TPID field is checked when the ETHA0MACC2.APD or ETHA0MACC2.VPD bit is 1.

The Ethernet controller recognizes a packet whose TPID field matches the value of the VLAN type register (ETHA0VLTP) as a VLAN frame.

(b) Reception of VLAN frame

If the value of the TPID field of a received packet matches the value of the VLAN type register (ETHA0VLTP), all judgments concerning the frame size are made based on the VLAN frame size (MAX: 1,522 bytes, MIN: 64 bytes).

(c) Transmission of VLAN frame

If a frame whose TPID field value matches the value of the VLAN type register (ETHA0VLTP) is transmitted from an upper layer when the ETHA0MACC2.APD bit is 1, the frame is recognized as a VLAN frame and is padded to extend its length to 68 bytes.

When the ETHA0MACC2.VPD bit is 1, all frames are recognized as VLAN frames and are padded with "0" to extend their lengths to 68 bytes.

29.5.5 DMAC

The dedicated DMAC for the Ethernet controller is a DMA function for the internal system bus of the Ethernet controller.

It is dedicated for the transmission/reception Ethernet controller.

All transmission and reception data is transferred by the dedicated DMAC for the Ethernet controller.

(1) DMA transfer mode

The following settings can be specified by using the ETHA0DMACM register.

Transfer mode

- Single transfer mode
- 4-beat incremental burst transfer mode
- 8-beat incremental burst transfer mode
- 16-beat incremental burst transfer mode

After the transfer mode has been specified by the ETHA0DMACM register, it will be applied starting with the next DMA transfer.

-
- Cautions**
1. Undefined length burst transfer mode cannot be specified using the register. Undefined length burst transfer is automatically used by the Ethernet controller to internally process fractional data during a DMA transfer. It is therefore not possible to transfer all transfer data in this mode intentionally.
 2. The register that specifies the transfer mode is not locked during a DMA transfer. If the setting of this register is changed during a DMA transfer, therefore, the current DMA cycle becomes illegal. Do not change the setting of the register during a DMA transfer (when RXEN_STA or TXEN_STA is 1).
-

(2) Areas accessible by DMA transfer

The following two areas are subject to DMA transfers:

- H-bus shared memory

(3) DMA address boundary

With the DMA for the Ethernet controller, the address boundary does not have to be considered when setting the start address of the data buffer and the number of transfer bytes.

If there is fractional data during a burst transfer, the fraction is automatically processed before the data is transferred.

For reception, however, because it is not possible to predict where the data to be received will end, the last transfer might be a dummy transfer when a burst transfer is used.

Note In the 4-, 8-, or 16-beat incremental burst transfer mode, if the last data is shorter than the fixed length, it is automatically transferred in undefined length burst transfer mode.

Byte access for byte alignment is always executed in the single transfer mode.

(4) DMA arbitration

Because the Ethernet controller supports full-duplex transfer, DMA transmission and DMA reception might be executed together. If DMA requests for transmission and reception are issued at the same time, the reception request takes precedence.

29.5.6 Address filtering

(1) Overview of address filtering

The Ethernet controller filters addresses by using the destination address of a received packet and, based on the filtering result, decides whether to accept or discard the received packet.

The filtering conditions can be specified by the ETHA0AFR register. Conditions can be individually specified for unicast addresses, multicast addresses, and broadcast addresses, or conditions can be combined.

(a) Filtering of unicast addresses

The address set to the ETHA0LSA1 and ETHA0LSA2 registers is compared with the destination address of a received packet as a unicast address. A received packet is accepted if its destination address matches the address specified for these registers, and is discarded if not. Each receive packet is checked to see if its destination address matches the set unicast address.

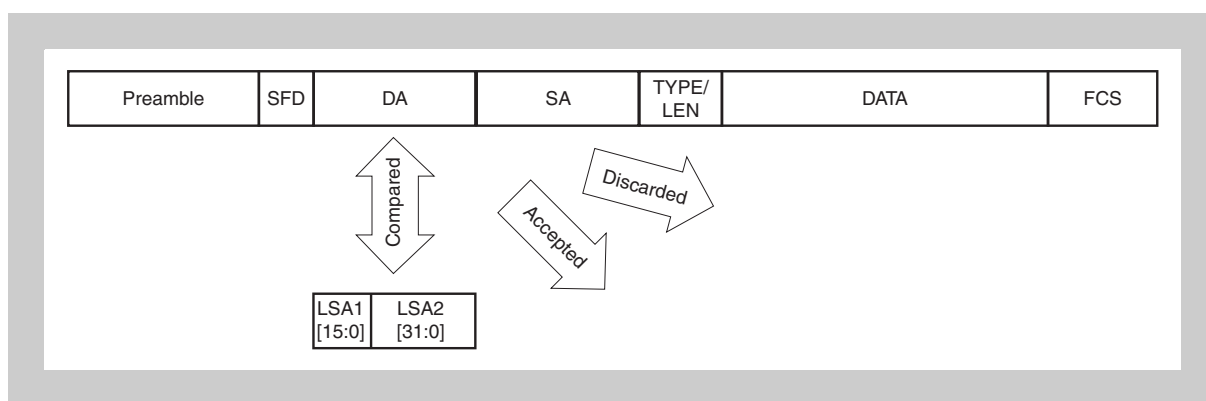

Figure 29-18 Image of filtering by unicast address during reception

(b) Filtering of multicast addresses

A multicast address is filtered in two ways. If the ETHA0AFR.PRM bit is set, all received packets that have a multicast address as the DA are accepted.

If the ETHA0AFR.AMC bit is set, only a received packet that has a multicast address that matches the hash table set up by the ETHA0HT1 and ETHA0HT2 registers is accepted, and a received packet whose multicast address does not match is discarded.

The hash table is used as follows for multicast address filtering.

The hash table is referenced by using bits [28:32] of the 32 bits of the CRC calculation result of the received multicast address. The following polynomial is used for calculating the CRC.

$$\text{CRC}(x) = X^{32} + X^{26} + X^{23} + X^{22} + X^{16} + X^{12} + X^{11} + X^{10} + X^8 + X^7 + X^5 + X^4 + X^2 + X + 1$$

If 1 is specified at the bit position indicated by the value resulting from decoding the above 6 bits in the ETHA0HT1 and ETHA0HT2 registers (shown in Table 29-106 “Correspondence between HT bits and hash values (ETHA0HT1 and ETHA0HT2)”), a receive packet that has that multicast address will be accepted. To set the hash table, it is necessary to execute a CRC calculation on a multicast address defined in advance, and set the corresponding bits.

Table 29-106 Correspondence between HT bits and hash values (ETHA0HT1 and ETHA0HT2)

CRC[28:26]	CRC[25:23]							
	111 _B	110 _B	101 _B	100 _B	011 _B	010 _B	001 _B	000 _B
111 _B	HT1[31]	HT1[30]	HT1[29]	HT1[28]	HT1[27]	HT1[26]	HT1[25]	HT1[24]
110 _B	HT1[23]	HT1[22]	HT1[21]	HT1[20]	HT1[19]	HT1[18]	HT1[17]	HT1[16]
101 _B	HT1[15]	HT1[14]	HT1[13]	HT1[12]	HT1[11]	HT1[10]	HT1[9]	HT1[8]
100 _B	HT1[7]	HT1[6]	HT1[5]	HT1[4]	HT1[3]	HT1[2]	HT1[1]	HT1[0]
011 _B	HT2[31]	HT2[30]	HT2[29]	HT2[28]	HT2[27]	HT2[26]	HT2[25]	HT2[24]
010 _B	HT2[23]	HT2[22]	HT2[21]	HT2[20]	HT2[19]	HT2[18]	HT2[17]	HT2[16]
001 _B	HT2[15]	HT2[14]	HT2[13]	HT2[12]	HT2[11]	HT2[10]	HT2[9]	HT2[8]
000 _B	HT2[7]	HT2[6]	HT2[5]	HT2[4]	HT2[3]	HT2[2]	HT2[1]	HT2[0]

An example of a program that executes hash table calculations is shown below.

If DA = 123456789ABC, for example, CRC = D4E88056, CRC[28:26] = 5, and CRC[25:23] = 1. If HT1[9] in Table 29-106 “Correspondence between HT bits and hash values (ETHA0HT1 and ETHA0HT2)” is set, a multicast packet with the target DA is received. If the value of both the ETHA0HT1 and ETHA0HT2 registers is 00000000H, all packets are discarded.

```

#include <stdio.h>

// Calculate CRC(Little endian)
unsigned long crc32( unsigned char *data, int size )
{
    const unsigned long poly = 0x04C11DB7ul; // MSB=X^31+X^30+X^29...
    unsigned long crc = 0xfffffffful;
    int i;
    unsigned char c;

    while( size-- != 0 ) {
        c = *data++;
        for ( i=0; i<8; i++, c >>= 1 ) {
            crc = (crc<<1)^(( (crc&0x80000000ul)?1:0)^(c&1)? poly : 0ul );
        }
    }
    return crc;
}

//=====
// Hash table value calculated by performing a CRC32 operation on the MAC address of ETHER-SS
//=====
int main( void )
{
    unsigned char temp[6] = { 0x12,0x34,0x56,0x78,0x9A,0xBC };
    unsigned long crc;
    unsigned int lp;

    printf("-----\n");
    printf(" MAC=%02X:%02X:%02X:%02X:%02X:%02X\n",
           temp[0],temp[1],temp[2],temp[3],temp[4],temp[5] );
    printf("-----\n");

    // CRC calculation method 1 for the MAC address
    crc = crc32( temp, sizeof(temp) );
    temp[5] = (char)(crc >> 26)&0x07;
    temp[4] = (char)(crc >> 23)&0x07;
    for( lp = 0; lp < 4; lp++, crc>>=8 ) temp[lp] = (char)(crc & 0xff);
    printf(" CRC=%02X, %02X, %02X, %02X \n", temp[3], temp[2], temp[1], temp[0] );
    if( temp[5] >4 ) printf(" HT1=%08X, HT2=00000000\n", (unsigned long)(1<<temp[4])<<(8*(temp[5]&0x03)) );
    else printf(" HT1=00000000, HT2=%08X\n", (unsigned long)(1<<temp[4])<<(8*(temp[5]&0x03)) );
    printf("-----\n");
    return 0;
}

```

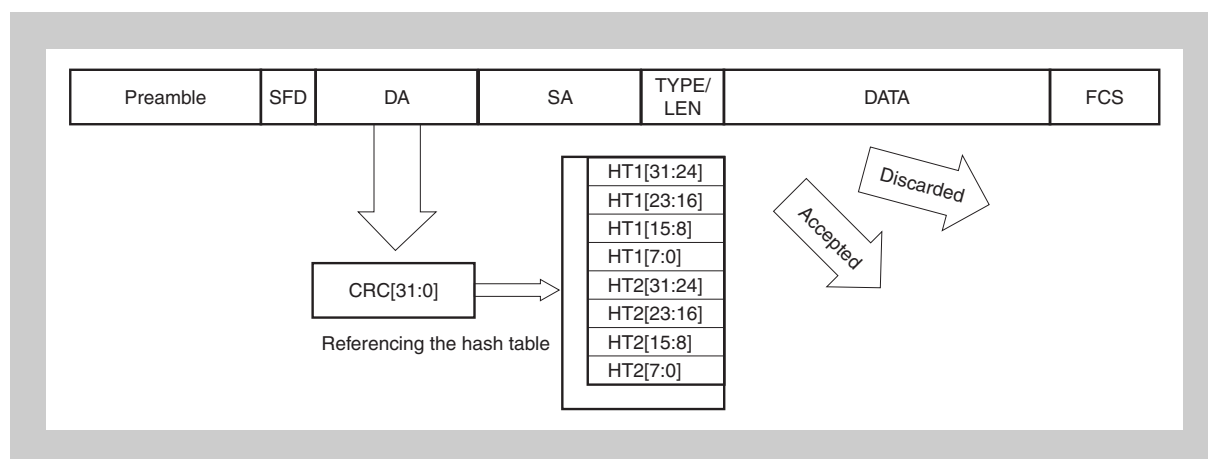

Figure 29-19 Image of filtering by referencing hash table

(c) Filtering of broadcast addresses

When the ETHA0AFR.ABC bit is set, a packet that has a broadcast address is received.

(d) Promiscuous mode

When the ETHA0AFR.PRO bit is set, the promiscuous mode is set and all packets are received.

If none of reception conditions (a) to (d) above is satisfied, the received packet is discarded.

For the combinations of the above conditions, refer to *Table 29-107 "Settings of ETHA0AFR register and packets to be filtered"*.

Table 29-107 Settings of ETHA0AFR register and packets to be filtered

Setting of ETHA0AFR register				Receive packet							
PRO	PRM	AMC	ABC	LSA mismatch, unicast	LSA match, unicast	HT mismatch, multicast	HT match, multicast	Broadcast packet			
1	–	–	–	Accepted	Accepted	Accepted	Accepted	Accepted			
0	1	–	–	Discarded					Discarded	Discarded	Discarded ^a
0	0	1	1			Discarded	Discarded	Accepted			
0	0	1	0								
0	0	0	1			Discarded	Discarded	Discarded			
0	0	0	0						Discarded	Discarded	Discarded
0	0	0	0	Discarded	Discarded	Discarded	Discarded				

a) The broadcast packet can be received if the corresponding bit in the hash table is set because the broadcast address is included in a multicast address.

Note –: Any

(2) Setting address filtering conditions

Set address filtering as follows.

First, clear the ETHA0MACC1.SRXEN bit. When the SRXEN bit is 0, the receive data interface is disabled. Next, set a station address to the ETHA0LSA1 and ETHA0LSA2 registers. Set a combination of the necessary filtering conditions to the ETHA0AFR register. To conditionally receive multicast packets, a hash table must be set up by using the ETHA0HT1 and ETHA0HT2 registers. After making the above settings, enable packet reception by setting the ETHA0MACC1.SRXEN bit.

29.5.7 Statistics counters

The Ethernet controller has 39 statistics counters to check the communication quality and other line statuses.

Each time communication of one frame has been finished (or aborted), the communication status is checked and the corresponding statistics counter is updated. The statistics counters cannot be stopped. To avoid using a statistics counter, set the corresponding bit in the ETHA0CAM1 or ETHA0CAM2 register to mask the interrupt from that counter.

The statistics counters can be read at any time even during communication.

If a counter overflows, the corresponding bit in the ETHA0CAR1 or ETHA0CAR2 register is set, and, if the relevant interrupt is not masked by the ETHA0CAM1 and ETHA0CAM2 registers, an Ethernet MAC interrupt is generated. The ETHA0CAM1 and ETHA0CAM2 registers can be used to specify whether to mask the overflow interrupt of each counter.

To clear a statistics counter, write 0 to it. At this time, the current communication does not have to be stopped. If updating a statistics counter and writing data to it occur at the same time and conflict, updating takes precedence, and the counter is written after it has been updated.

Note that the statistics counters cannot be stopped. To avoid using a statistics counter, mask the counter by setting the corresponding bit in carry mask register 1 or 2 (ETHA0CAM1 and ETHA0CAM2) to prevent the INTETMOV interrupt from being generated.

The statistics counters can be read/written in 32-bit units.

-
- Cautions**
1. The Ethernet controller updates the statistics counters based on the Ethernet controller clock (f_{EC}). If the Ethernet controller clock (f_{EC}) is considerably slower than the communication clock (TXCLK/RXCLK), the counters might miscount statistics information. If the statistics information is miscounted, a status vector overrun occurs, the C2DV bit in carry register 2 (ETHA0CAR2) is set, and an INTETMOV interrupt is generated.
 2. Carry registers 1 and 2 (ETHA0CAR1 and ETHA0CAR2) are cleared when they are read.
-

Note Aside from the statistics counters, a transmission abort counter (ETHA0TXABTCNT) and a reception abort counter (ETHA0RXABTCNT) are available for counting the number of times transmission/reception has been aborted.

29.6 Data Transfer

29.6.1 Buffer structure

The Ethernet controller buffer of the V850E2/ML4 consists of a buffer descriptor and data buffer.

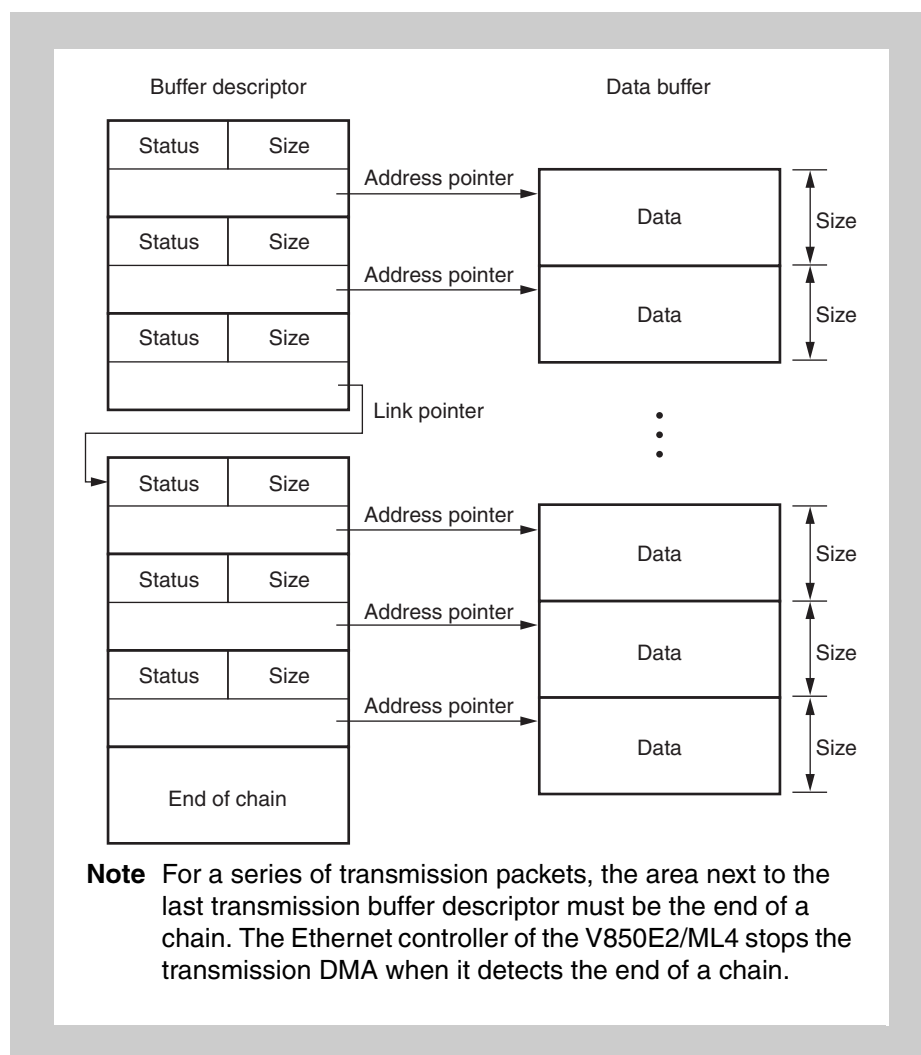

Figure 29-20 Ethernet controller buffer structure (transmission)

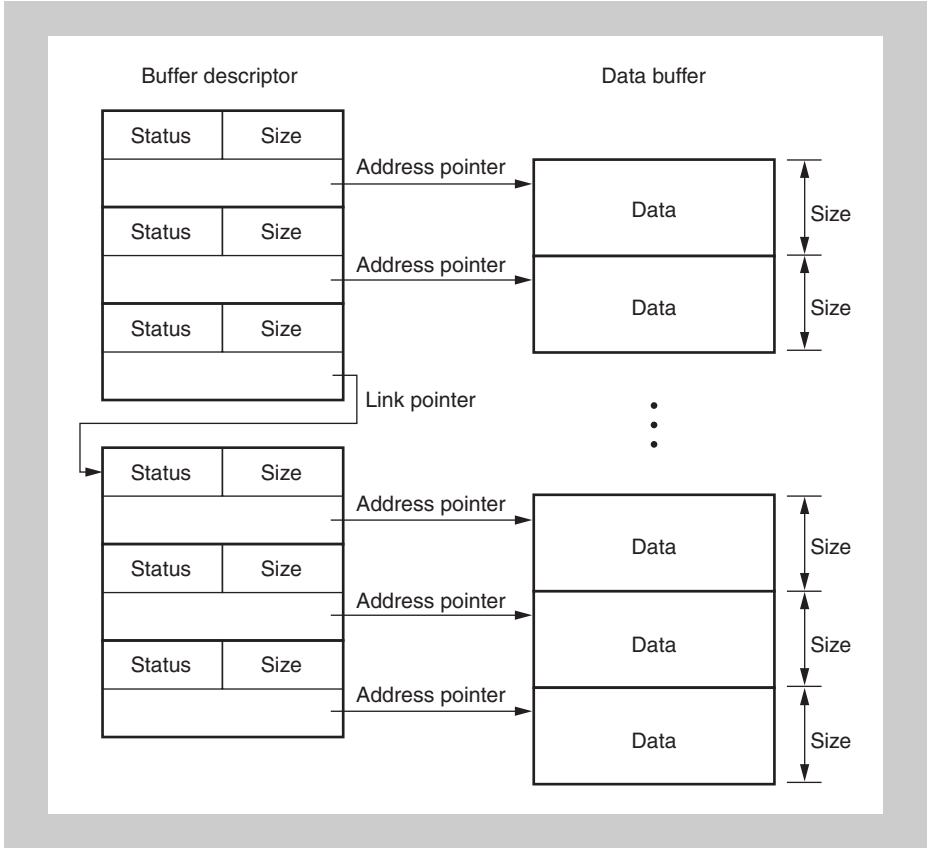

Figure 29-21 Ethernet controller buffer structure (reception)

29.6.2 Descriptor mechanism

The Ethernet controller supports a descriptor mechanism to support a situation where the memory space that stores transmit data and receive data is not contiguous.

The Ethernet controller uses the following three types of descriptors.

- Buffer descriptor
- Link pointer
- End of chain

Each descriptor consists of two word-aligned data (64 bits).

The Ethernet controller can consecutively process multiple descriptors in one DMA transfer (refer to (6) “Descriptor chain” on page 2022 in 29.6.2 “Descriptor mechanism”).

A reception DMA transfer or transmission DMA transfer is started by setting the first address of a receive descriptor chain to ETHA0RXDP or the first address of a transmit descriptor chain to ETHA0TXDP, and then setting the RXS or TXS bit of the ETHA0MODE register.

A descriptor chain must end with the descriptor of an end of chain.

(1) Format of buffer descriptor

A buffer descriptor is configured of 2 words (64 bits). The lower word consists of control bits. The higher word indicates the start address of the data buffer indicated by the descriptor.

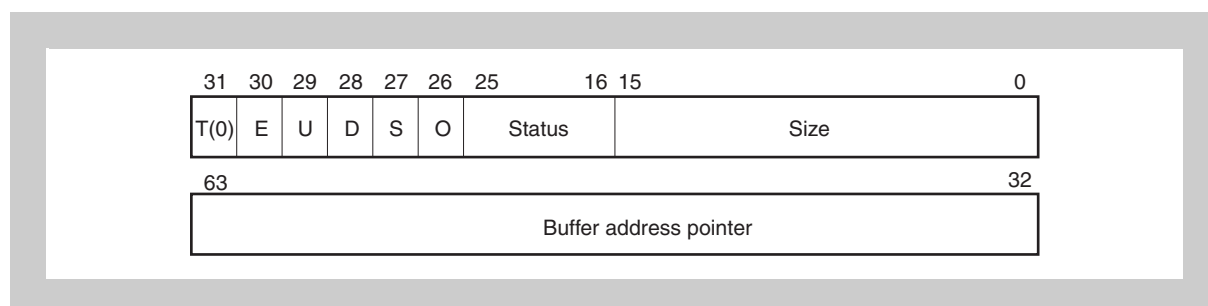

Figure 29-22 Buffer descriptor format

Table 29-108 Bit configuration of buffer descriptor (1/2)

Bit position	Bit name	Function
63 to 32	BAP	These bits specify an address pointer that indicates the start address of the data buffer. Byte alignment can be specified for BAP.
31	T	Descriptor type This bit indicates the type of the descriptor. Clear this bit for a buffer descriptor.
30	E	Last buffer flag This is a control bit that indicates the end of packet data. 0: Normal buffer data (not last data) 1: Last buffer data of the current packet If this bit is set for transmission, a TXI interrupt is generated when the data of the corresponding data buffer has been transferred, and then the next descriptor processing starts. Clear this bit for reception. When the last data of a frame has been written, this bit is set when the data is written back. Next, an RXI interrupt is generated, and then the next descriptor processing starts.
29	U	Used bit This bit indicates whether a DMA transfer has finished (including transfer in progress). 0: Transfer not finished (including transfer in progress) 1: Transfer finished The CPU clears this bit when it creates or obtains buffer data (a descriptor). When a DMA transfer to the buffer area indicated by this descriptor has finished, the Ethernet controller sets this bit. The Ethernet controller issues the TECI or RECI interrupt and stops DMA if it reads a descriptor whose U bit is set. If a bus error or overflow error occurs during reception, the U bit of either the first descriptor in the packet or the descriptor where the overflow occurred is set.
28	D	This bit indicates an access error in the data buffer. 0: No error 1: Access error in the data buffer The CPU clears this bit when it creates or obtains buffer data (a descriptor). If an access error occurs, the Ethernet controller sets control bit D of the first descriptor that indicates the current packet, and control bit D of the descriptor that was responsible for the access error.
27	S ^a	This bit indicates that reception status information has been written to the Status field (only control bit S in the first descriptor of a received packet is valid). 0: Status information is not included. 1: Status information of the received packet is included. The CPU clears this bit when it creates or obtains buffer data (a descriptor). When a received packet is transferred via DMA, the Ethernet controller writes a valid value to the Status field of the first descriptor of the current packet and sets control bit S each time one packet has been transferred.

Table 29-108 Bit configuration of buffer descriptor (2/2)

Bit position	Bit name	Function																								
26	O ^a	This bit indicates occurrence of an overflow error during reception. 0: No overflow 1: Overflow The CPU clears this bit when it creates or obtains buffer data (a descriptor). If an overflow error occurs during reception, the Ethernet controller writes back 1 to the control bit O of the first descriptor of the packet, and sets control bit E of the descriptor in which the overflow error occurred. No interrupt is generated.																								
25:16	Status ^a	These bits form a Status field that indicates status information during reception. If control bit S is 1, the value of the Status field is valid. The CPU clears this bit when it creates or obtains buffer data (a descriptor). During a DMA transfer of a receive packet, the Ethernet controller writes a valid value to the Status field of the first descriptor of the current packet and sets control bit S each time transfer of one packet has finished. <table border="1" data-bbox="552 692 1366 1240"> <thead> <tr> <th>Bit position</th> <th colspan="2">Bit name</th> </tr> </thead> <tbody> <tr> <td>16</td> <td colspan="2">CEPS</td> </tr> <tr> <td>17</td> <td colspan="2">RCV</td> </tr> <tr> <td>18</td> <td colspan="2">RCRCE</td> </tr> <tr> <td>19</td> <td colspan="2">RLOR</td> </tr> <tr> <td>20</td> <td colspan="2">DBNB</td> </tr> <tr> <td>21</td> <td colspan="2">RXOK</td> </tr> <tr> <td>23:25</td> <td>FYTP[0:2]</td> <td>000: RBRO 001: RMUL 010: USOP 011: VLAN 100: RPCF 101: RCFR 110: "Normal" 111: "Reserved"</td> </tr> </tbody> </table>	Bit position	Bit name		16	CEPS		17	RCV		18	RCRCE		19	RLOR		20	DBNB		21	RXOK		23:25	FYTP[0:2]	000: RBRO 001: RMUL 010: USOP 011: VLAN 100: RPCF 101: RCFR 110: "Normal" 111: "Reserved"
Bit position	Bit name																									
16	CEPS																									
17	RCV																									
18	RCRCE																									
19	RLOR																									
20	DBNB																									
21	RXOK																									
23:25	FYTP[0:2]	000: RBRO 001: RMUL 010: USOP 011: VLAN 100: RPCF 101: RCFR 110: "Normal" 111: "Reserved"																								
15:0	Size	These bits form a Size field that indicates the size (in bytes) of the buffer data indicated by this descriptor. During a DMA transfer of a receive packet, the Ethernet controller writes the length of one transferred packet to the Size field of the last descriptor of the current packet each time transfer of one packet has finished.																								

a) This bit is not used during transmission. Clear this bit.

Note The Size field is 16 bits. Setting 0 to this field is prohibited. If 0 is set, an error interrupt is generated.
If FFFFH is set to this field, transfer of 64K – 1 bytes is executed.

(2) Format of link pointer

A link pointer consists of 2 words. The lower word consists of control bits. The higher word indicates the address of the next descriptor.

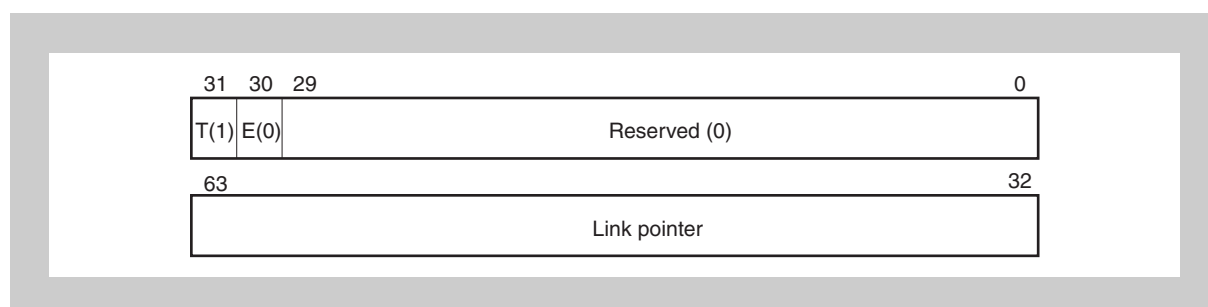

Figure 29-23 Link pointer format

Table 29-109 Bit configuration of link pointer

Bit position	Bit name	Function
63:32	Link Pointer	These bits indicate the address of the next descriptor. The lower 2 bits are ignored (word aligned).
31	T	Set this bit for a link pointer.
30	E	Clear this bit for a link pointer.
29:0	Reserved	These bits are reserved. Clear these bits.

(3) Format of end of chain

An end of chain consists of 2 words. The lower word consists of control bits. The higher word indicates 0.

When the Ethernet controller detects an end of chain, it finishes the DMA transfer and generates an RECI or TECI interrupt.

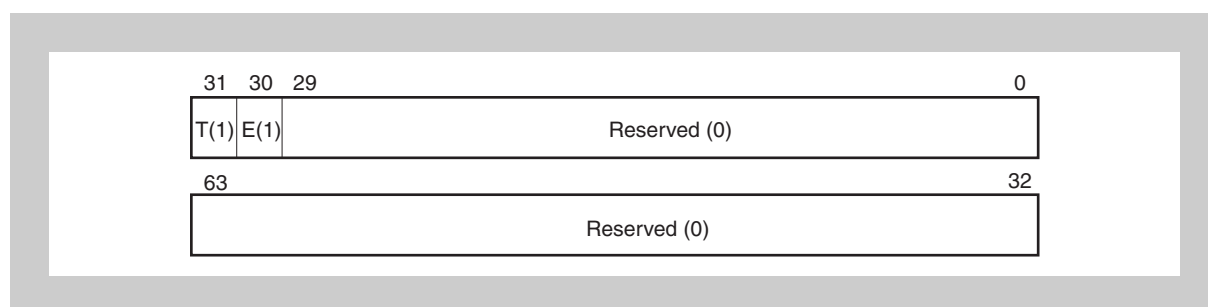

Figure 29-24 End of chain format

Table 29-110 Bit configuration of end of chain

Bit position	Bit name	Function
63:32	BAP	These bits are set to null (all zero) for an end of chain.
31	T	Set this bit for an end of chain.
30	E	Set this bit for an end of chain.
29:0	Reserved	These bits are reserved. Clear these bits.

(4) Writing back the status

When DMA reception is executed, the reception status is written back to the first descriptor of the packet, and the length of the packet transferred via DMA is written back to the last descriptor. The status is written back as described in the *Status* field in *Table 29-108 "Bit configuration of buffer descriptor"*.

(5) Reporting last descriptor

The current descriptor can be reported. Two registers, ETHA0LSTRXDP and ETHA0LSTTXDP, hold the address of the descriptors processed by the Ethernet controller. The address of the descriptor that was processed immediately before can be obtained by reading these two registers via software.

The timing to save the address of a descriptor to ETHA0LSTRXDP or ETHA0LSTTXDP is shown in *Figure 29-25 "Timing to copy last descriptor"* below.

When the link pointer is read, the address of the next descriptor can be read from the BAP bits. The address of the link pointer is then copied to ETHA0LSTRXDP or ETHA0LSTTXDP.

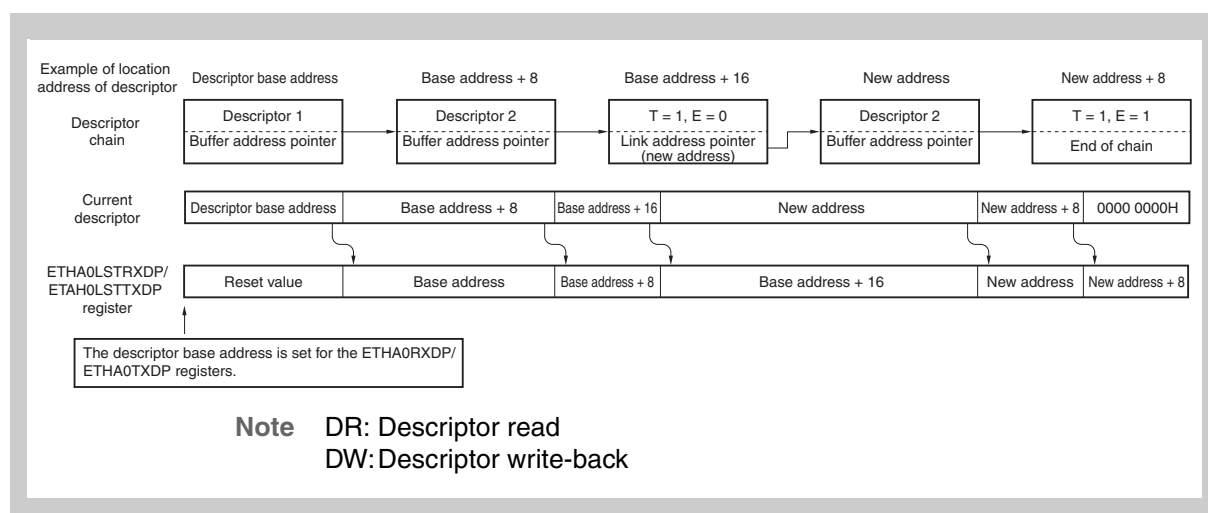

Figure 29-25 Timing to copy last descriptor

If a descriptor chain is configured in a ring buffer, the descriptor can be updated by reading ETHA0LSTRXDP or ETHA0LSTTXDP, using the TXI flag of the INTSCTX interrupt (the RXI flag of the INTSCRX interrupt) as a trigger.

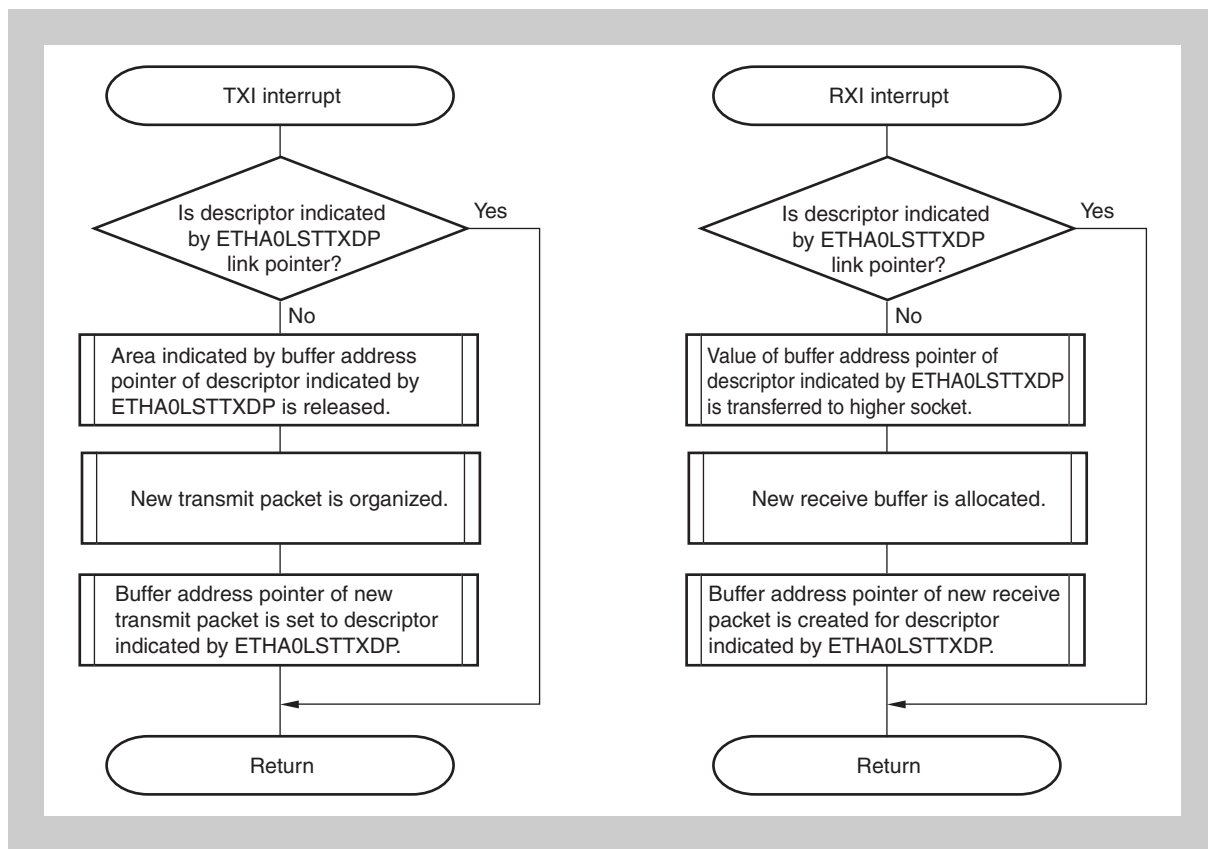

Figure 29-26 Updating descriptor chain by using ETHA0LSTRXDP or ETHA0LSTTXDP

(6) Descriptor chain

A descriptor uses a chain structure to indicate a data buffer (of an undefined length).

An image is as shown below.

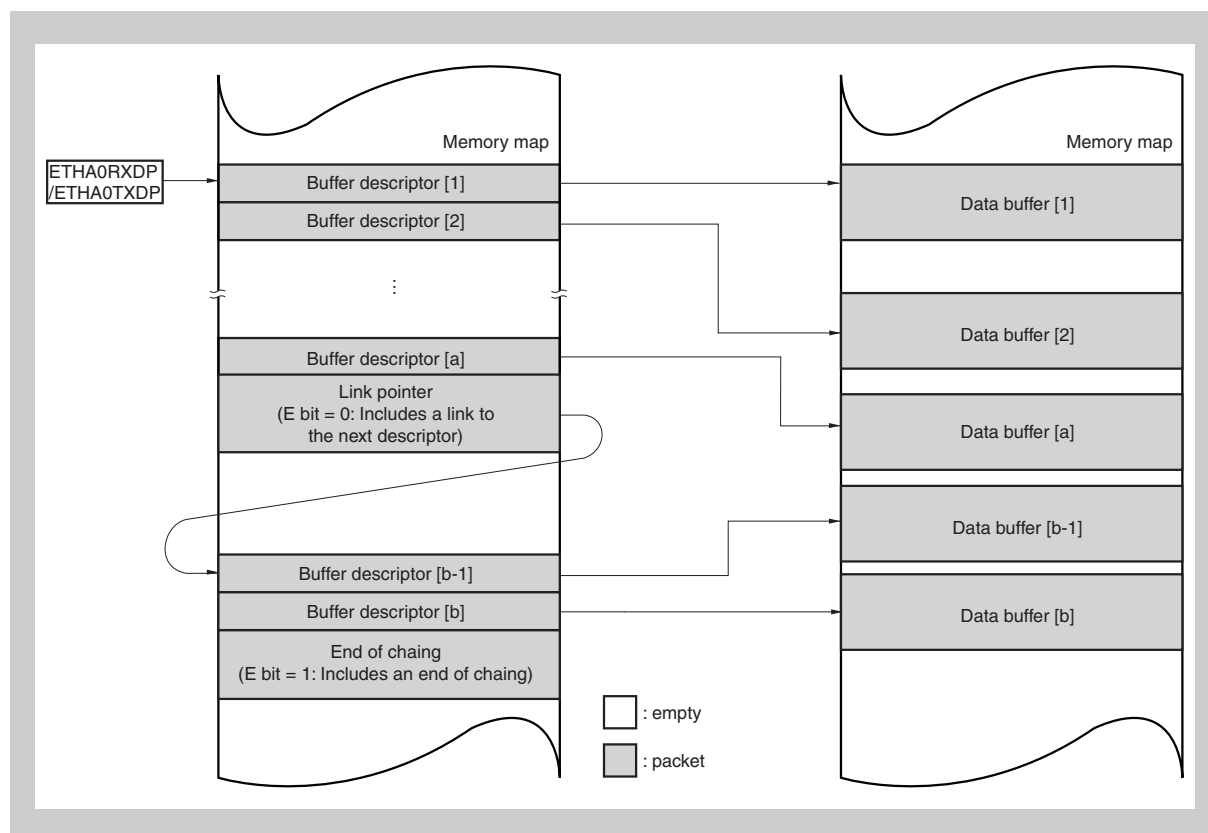

Figure 29-27 Overview of descriptor chain using ETHA0LSTRXDP or ETHA0LSTTXDP

Allocate a descriptor to a successive memory area. When a link pointer is used, a descriptor can also be allocated to a non-successive memory area by specifying the location address of the next buffer descriptor for the link pointer. The descriptor chain can be finished by specifying the end of a chain.

A ring descriptor chain may be configured by using the last link pointer to specify the memory address of the first buffer descriptor.

Figure 29-28 Overview of ring buffer formed by descriptor chain

A ring buffer is configured if the beginning of a descriptor chain is specified by a link pointer. In a ring buffer, if a descriptor whose U bit is set is read, the Ethernet controller generates a RECI or TECI interrupt in the same manner as when detecting the end of a chain, and then stops DMA.

Caution Handling of U bit

If the U bit of a transmit descriptor is set, it indicates that the processing for that descriptor has finished, so the CPU can specify a new descriptor by clearing the U bit.

For a receive descriptor that has the U bit set to 1, however, its content might be updated later due to status write back or error occurrence, so a new descriptor cannot be specified unless the completion of packet reception is confirmed. But if the E bit is set, it indicates that packet reception has finished, so the descriptor chain can be specified as a new descriptor.

(7) Byte alignment and word boundary

Although a descriptor must be word-aligned, the data buffer can be set at a byte-aligned address.

The Ethernet controller automatically identifies an address, executes a single transfer up to a word boundary and an undefined length word transfer up to the burst boundary, and then executes a burst transfer.

29.6.3 Frame transmission

When the CPU prepares the transmission descriptor and data for the transfer target of the DMAC for the Ethernet controller, the transmission descriptor register (ETHA0TXDP) is set up, and then the TXS bit of the ETHA0MODE register is set, the dedicated DMAC fetches the transmission buffer descriptor from the address specified for the descriptor register, reads the transmission data from the data buffer, and then transfers it to the transmission FIFO.

The data transferred to the FIFO buffer is then output to PHY in synchronization with TXCLK, in the order of the preamble, SFD, and then frame data.

If the CRCEN bit of the ETHA0MACC1 register is set, FCS is added to the end of the data.

If the PADEN bit of the ETHA0MACC1 register is set, short frames are automatically padded with 0s when they are transmitted.

If the current descriptor does not contain the end of the frame, the next descriptor is read and data is read from the data buffer indicated by the read descriptor.

When the transmission finishes, the transmission status is written to the last descriptor. Then, the next transmission buffer descriptor is fetched, and the transmission resumes in the same manner when the next data can be transmitted.

Each time DMA processing for a buffer descriptor finishes, an interrupt that indicates the end of transmission DMA (TXI) is generated.

If the next transmission buffer descriptor is the end of a chain descriptor, an interrupt that indicates this (TECI) is generated and transmission DMA stops.

To resume transmission DMA, set up the ETHA0TXDP register and buffer descriptors again.

The frame transmission procedure is described below.

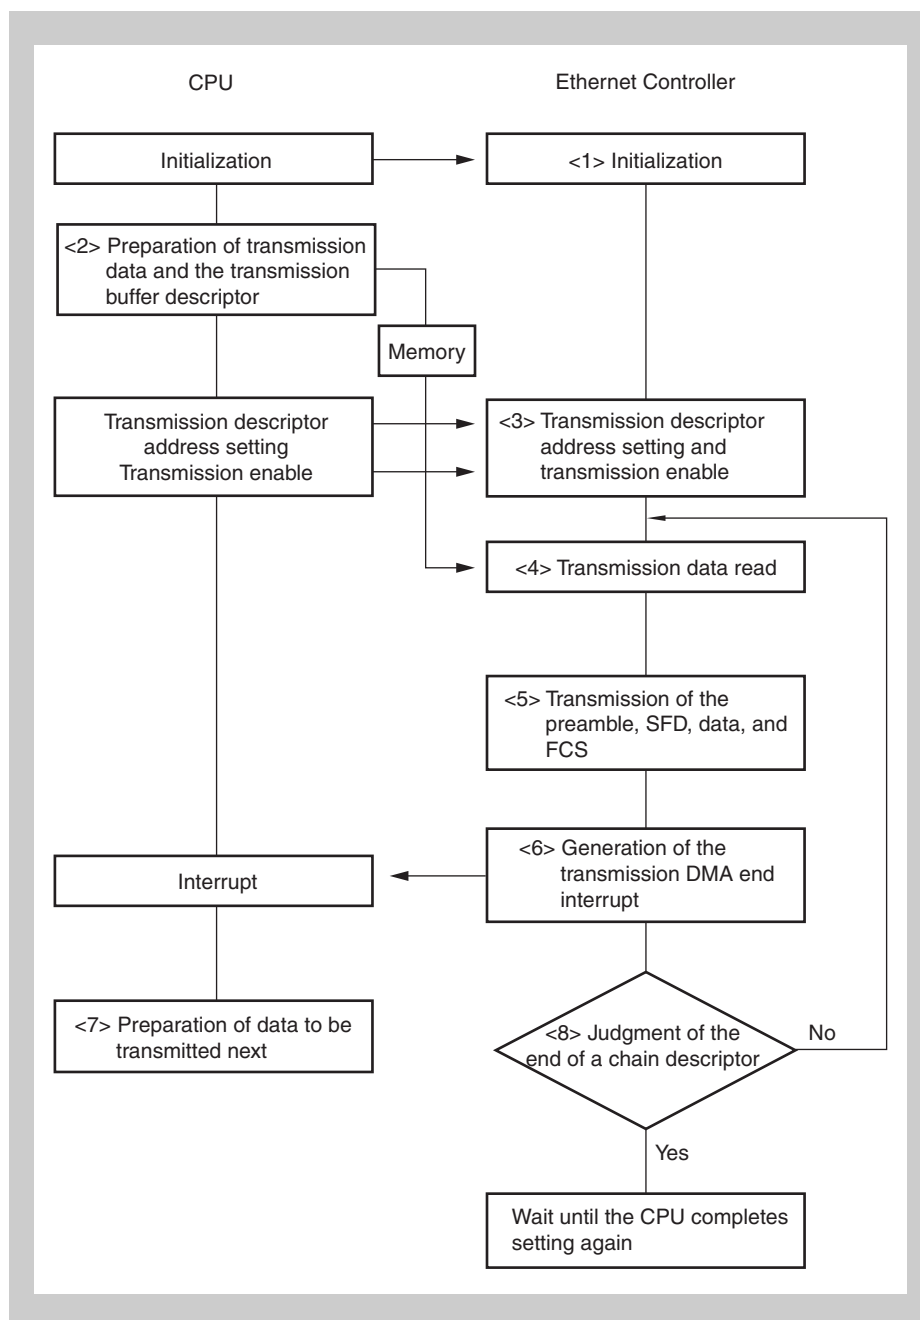

Figure 29-29 Frame transmission procedure example

1. Initialize the Ethernet controller.
For details about the initialization procedure, see 29.3 “Initialization” on page 1872 .
2. Create transmission data and the transmission buffer descriptor in the data RAM.

When creating the descriptor, specify values for the E bit (set to 1 if the last packet data needs to be kept), T bit (cleared to 0), U bit (cleared to 0), and Size bits of the transmission buffer descriptor.
3. Set up the transmission buffer descriptor register and enable transmission.

Specify the transmission descriptor address for the ETHA0TXDP register, and set the TXS bit of the ETHA0MODE register to enable transmission.
4. Read the transmission data.

The transmission data is read from memory by way of DMA.
The next descriptor is read if the E bit of the transmission buffer descriptor is 0.
5. Transmit a packet.

The preamble, SFD, data, and FCS are transmitted.
6. Report the end of DMA transmission.

A TXI interrupt request is generated to report the end of transmission to the CPU.
7. Prepare the next data.

The CPU checks the transmission status and prepares the data to be transmitted next.
8. Judge the end of a chain descriptor.

A TECI interrupt request is generated to report to the CPU that the end of the chain descriptor has been reached.

The frame transmission operation is described below, using a specific descriptor chain as an example.

When the TXS bit of the core function setting register ETHA0MODE is set by software, the first descriptor is read from the address (0028 0000_H) specified by the transmission descriptor pointer ETHA0TXDP, and transmission descriptor analysis starts. Specify the buffer address pointer (0028 1000_H) as the DMA transfer start address, and then transfer the data in the buffer to the transmission FIFO.

Because the E bit of the transmission descriptor is 0, which indicates that it is not the last data, the next buffer descriptor (0028 0008_H) is read, the buffer address pointer (0028 1800_H) is specified, and then the data in the buffer is transferred to the transmission FIFO.

If the data in the buffer indicated by the buffer descriptor whose E bit is 1 has been transferred completely, the U bit is set and the transmission processing finishes. At this time, an interrupt request TXI is generated.

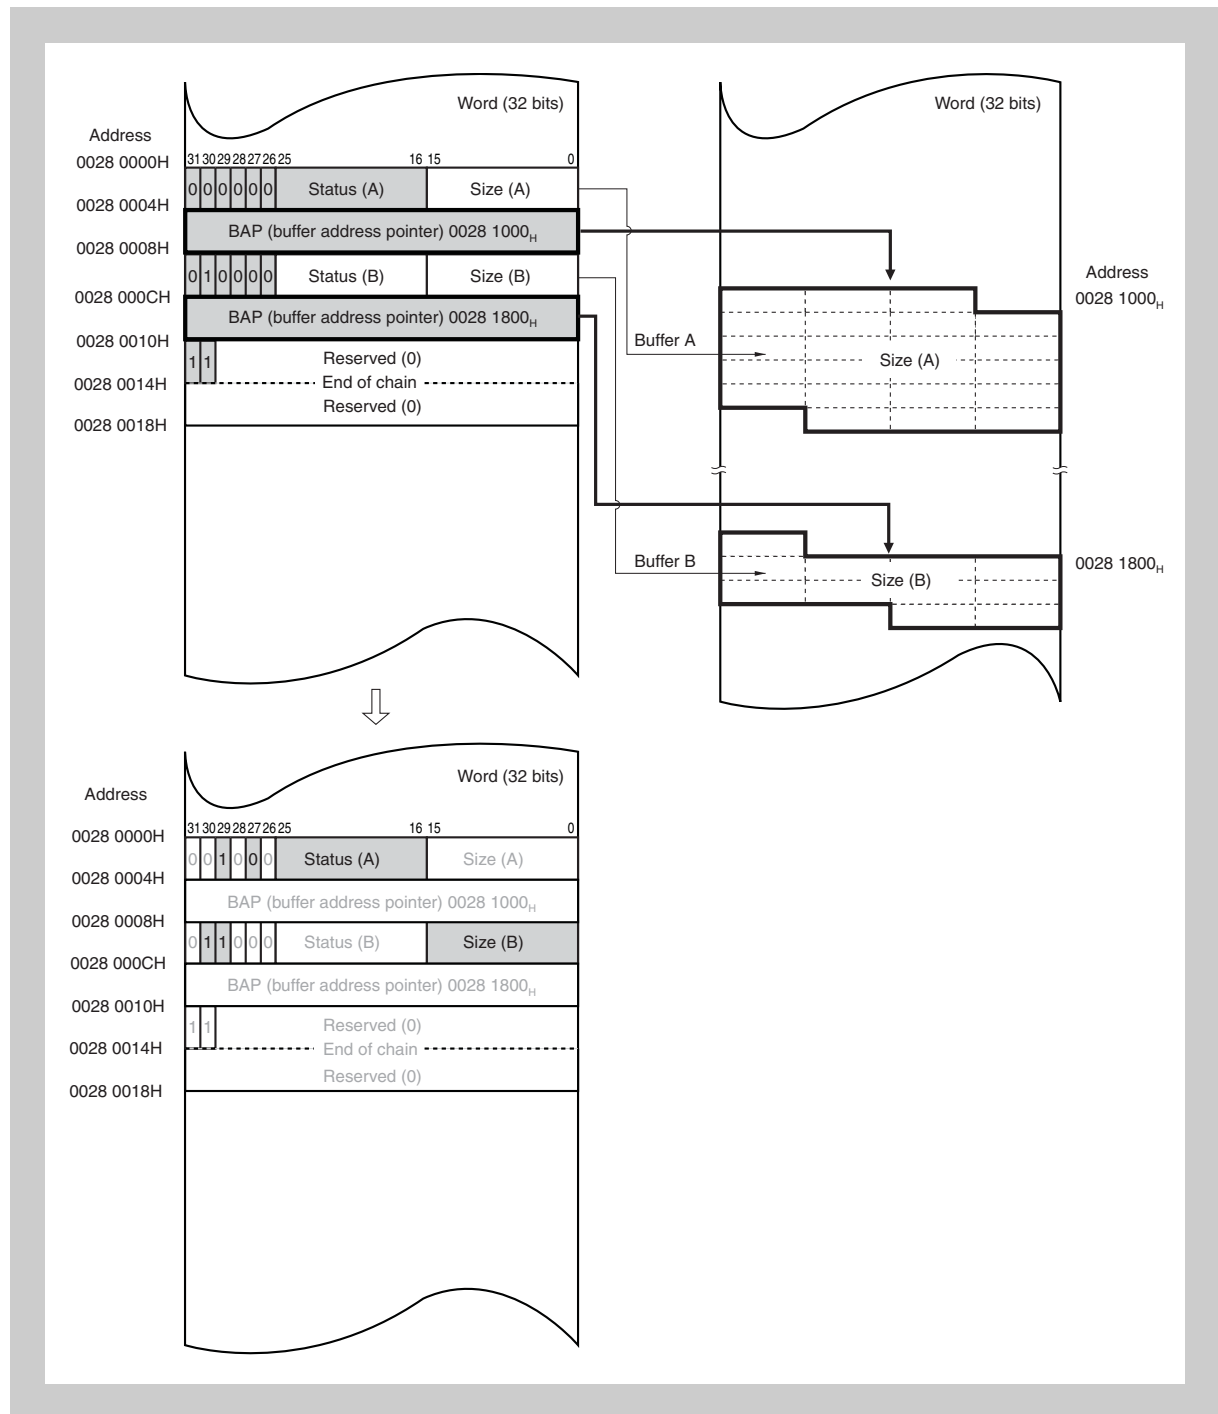

Figure 29-30 Descriptor chain configuration example (packet transmission)

29.6.4 Frame reception

When the SRXEN bit (reception enable) of the MAC configuration register (ETHA0MACC1) and the RXS bit (reception DMA enable) of the ETHA0MODE register are set and the descriptor pointer register ETHA0RXDP is set up, reception frame processing starts immediately when the MAC receives data.

When data is received, the preamble and frame start delimiter (SFD) are checked to determine whether they are valid.

If they are valid, processing of the received frame starts.

If either is invalid, the frame is ignored.

If a frame conflict occurs or a frame is corrupted due to address filtering, the data is not written to the reception buffer.

When the frame is normally received and not corrupted by address filtering, it is transferred to the data buffer specified by the reception buffer descriptor.

During reception, the Ethernet controller checks whether the frame length is correct.

At the end of the frame, the FCS is checked and written to the buffer descriptor.

A frame of 64 bytes or shorter (a short packet) is DMA transferred.

When the frame has been received completely, the E and U bits of the last descriptor are set and the number of data bytes transferred to the Size field is written back.

When the all packet data has been received, the U and S bits of the first descriptor are set and the reception status is written back to the Status field.

At this time, an interrupt request RXI is generated.

The frame reception procedure is described below.

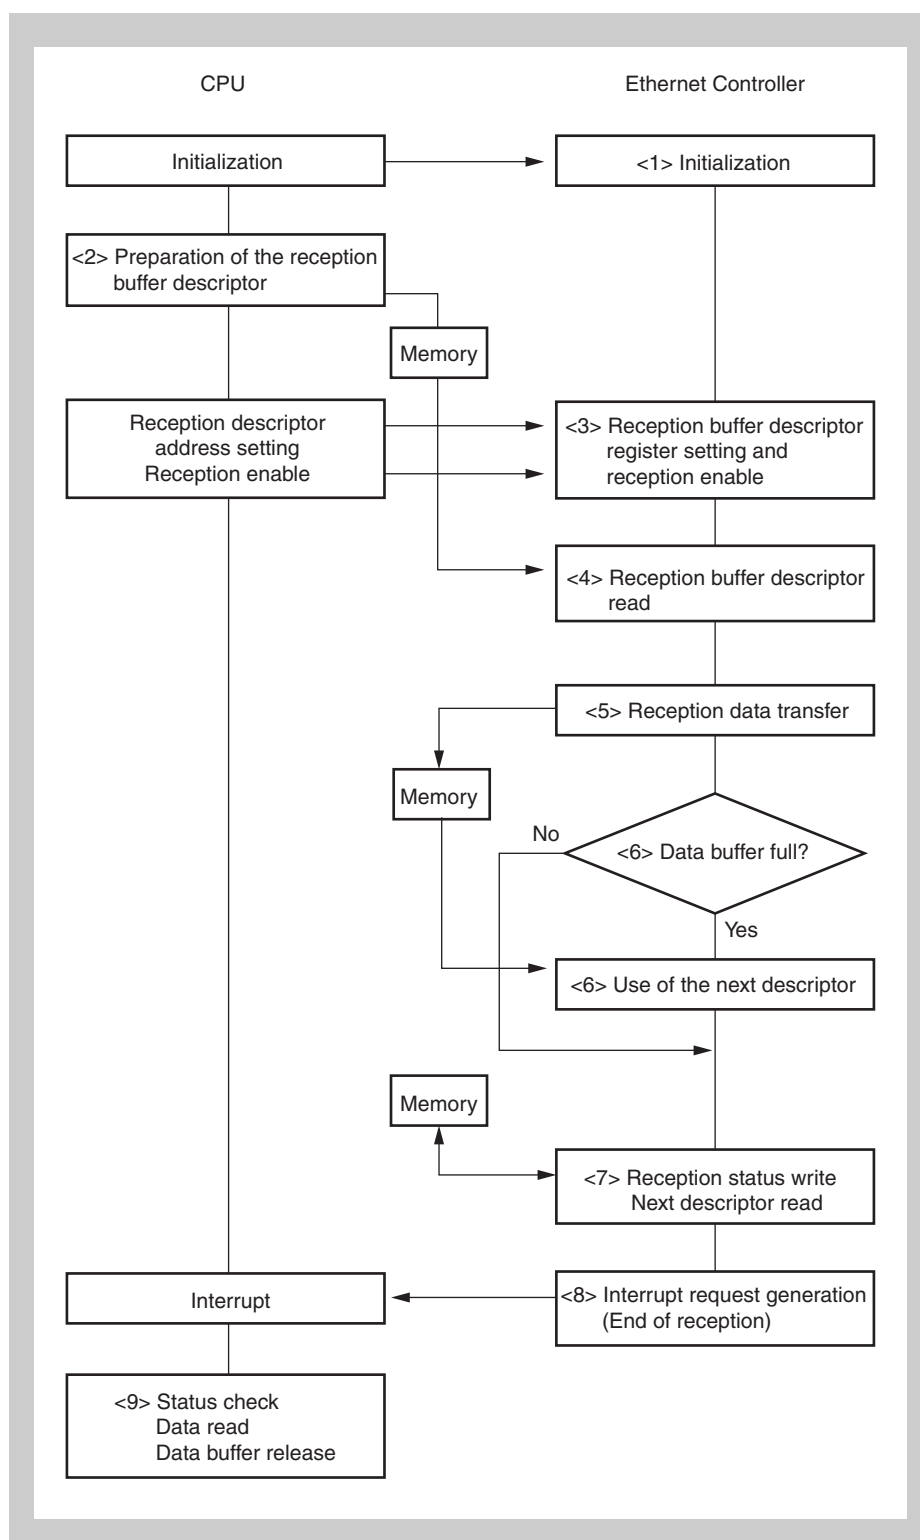

Figure 29-31 Frame reception procedure example

1. Initialize the Ethernet controller.
For details about the initialization procedure, see 29.3 "Initialization" on page 1872 .
2. Creating a reception buffer descriptor in memory.
When creating the descriptor, specify values for the T bit (cleared to 0), U bit (cleared to 0), and Size bits (data buffer size) of the reception buffer descriptor.
3. Set up the reception buffer descriptor register and enable reception.
Specify the reception descriptor address for the ETHA0RXDP register, and set the RXS bit of the ETHA0MODE register to enable reception.
4. Read the reception buffer descriptor.
The reception buffer descriptor is read by way of DMA.
5. Transfer reception data.
The data is transferred to the data RAM by way of DMA.
6. Judge whether the reception data buffer is full.
The next descriptor is read if the current data buffer is full.
7. Receive a packet.
Reading of the buffer descriptor and data transfers are repeatedly performed. When the end of the frame is received, 1 is written to the E bit of the last reception buffer descriptor and the number of bytes of transferred data is written to the Size field.
8. Report the end of reception.
An RXI interrupt request is generated to report the end of reception to the CPU (when the interrupt is not masked).
9. Prepare the next data.
The CPU checks the reception status, releases the data buffer, and then prepares the next data.

The frame reception operation is described below, using a specific descriptor chain as an example.

When the RXS bit of the core function setting register ETHA0MODE is set by software, the first descriptor is read from the address (0028 0000_H) specified by the reception descriptor pointer ETHA0RXDP, and reception descriptor analysis starts.

Specify the first buffer address pointer (0028 1000_H) as the DMA transfer start address, and then transfer the reception data in the FIFO buffer to buffer A.

When buffer A becomes full during the subsequent reception, the next descriptor (0028 0008_H) is read, the buffer address pointer (0028 1800_H) is specified as the DMA transfer start address, and then the reception data in the FIFO buffer is transferred to buffer C.

The E and U bits of the last descriptor are set and the number of bytes of data transferred to the Size field is written back.

When all packet data has been transferred, the U and S bits of the first descriptor are set and the reception status information is written back to the Status (A) field.

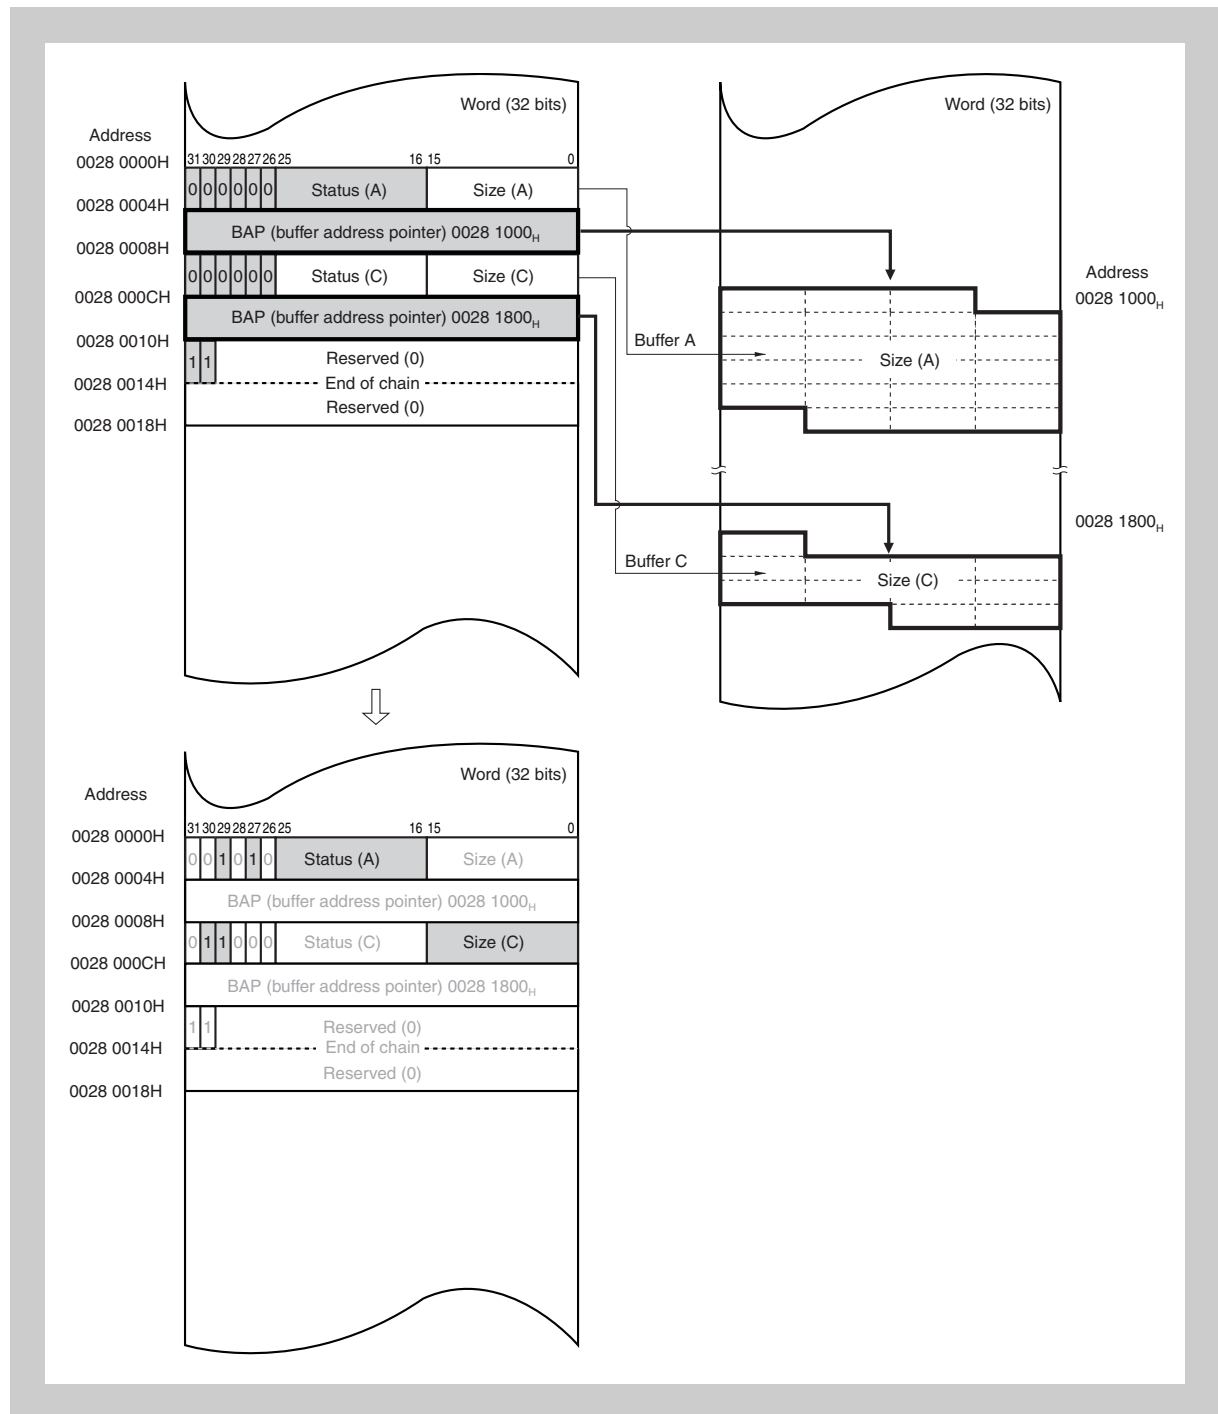

Figure 29-32 Descriptor chain configuration example (packet transmission)

29.6.5 Error processing

(1) Error write back

If a bus error occurs when accessing the data buffer during reception or transmission, an error interrupt is asserted and DMA is stopped. In addition, the U and D bits of the first descriptor in the packet are set (the U bit might already be set), and the U, D, and E bits of the descriptor where the error occurred are set.

If an overflow error occurs during reception, the U and O bits of the first descriptor in the packet are set (the U bit might already be set), and the U and E bits of the descriptor where the error occurred are set.

(2) Error interrupt

An error interrupt is not asserted only by a data buffer access error but also by a descriptor access error. Whether an error interrupt is generated can be checked using the ETHA0INTMS.RBEI and ETHA0INTMS.TBEI bits.

If a data buffer access error or descriptor access error has occurred, the descriptor chain that includes the descriptor where the error occurred must be set up again.

During transmission:

If a data buffer access error or descriptor access error has occurred, the TBEI bit is set and the DMA is stopped.

Transmission will not be performed until the TXS bit is set again.

During reception:

If a data buffer access error or descriptor access error has occurred, the RBEI bit is set and the DMA is stopped.

Reception will not be performed until the RXS bit is set again.

At this time, the packet being transferred from the FIFO buffer is canceled.

Packet cancellation is not executed if no packet is being transferred.

If a bus error occurred during write back due to a reception overflow, the processing is performed in the same way as when a descriptor access error occurs.

29.7 Receive Checksum

The Ethernet controller has a receive checksum unit that calculates the receive checksum.

Receive checksum calculation is enabled and disabled by setting the RXCHKSMEN bit of the ETHA0TRANSCTL register.

A checksum is appended to the end of receive data. Allocate enough memory for the amount of received data, which is the packet length plus 2 bytes.

When checksum calculation is enabled, all parts (payload) of a receive frame, except the MAC header (first 14 bytes) and CRC (last 4 bytes), are subject to checksum calculation. If the number of bytes subject to calculation is odd, 00H is added to the last byte for checksum calculation.

The minimum receive packet length subject to checksum calculation is 19 bytes (payload = 1 byte). If the receive packet length is 18 bytes (payload = 0 bytes) or less, 0 is output as the checksum. However, the length information increases by 2 bytes.

Before changing the value of the RXCHKSMEN bit, confirm that transfer of the receive frame is stopped.

29.7.1 Processing by software

The first 14 bytes of a packet are treated as the MAC header and are always excluded from checksum calculations. Therefore, calculation starts from the 15th byte. If the MAC header exceeds 14 bytes, such as in a VLAN and huge frame, correction by software is necessary.

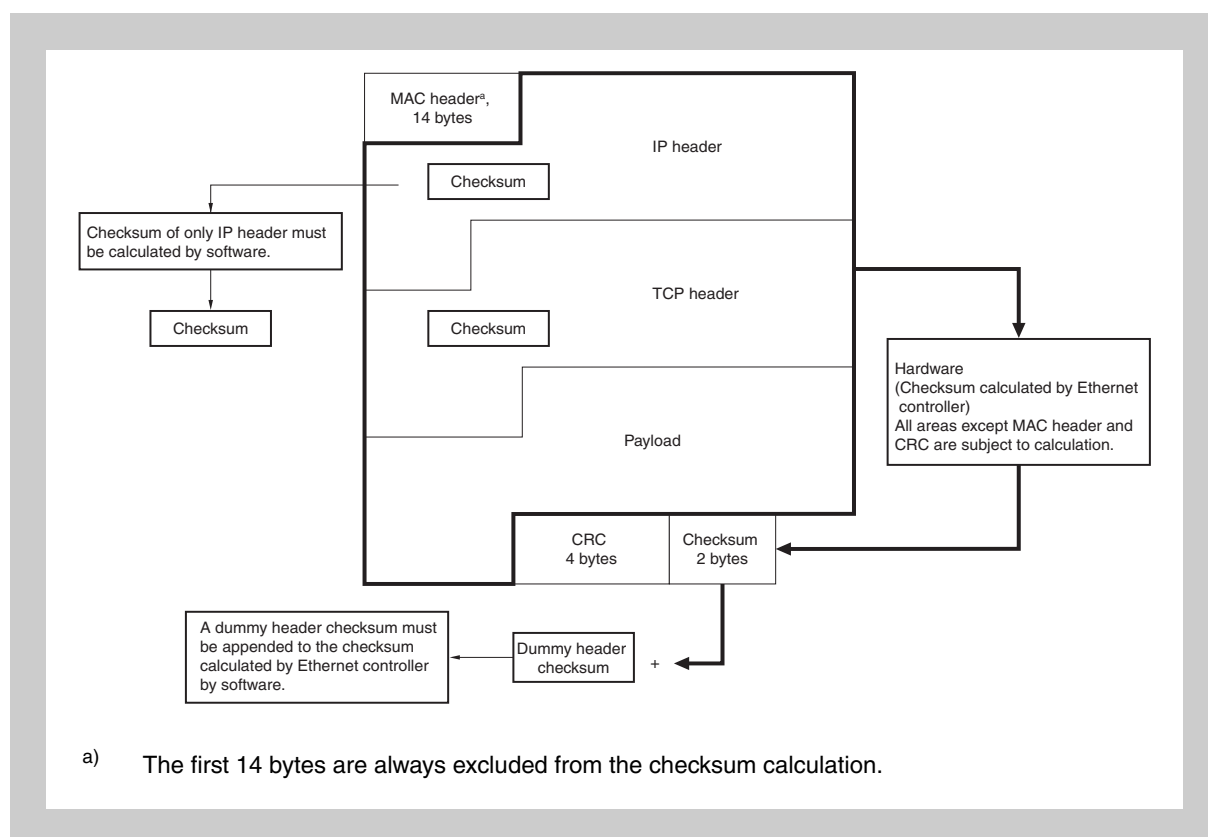

Figure 29-33 Checksum calculation

The minimum packet length is 64 bytes. When padding a short packet, many systems use 00_H, but some systems use a different code for padding. In this case, the checksum calculation is executed including the padding data, resulting in a mismatch between the calculation result and the checksum in the header. In this case, the checksum of the padding data must be corrected by software.

Caution According to RFC1071, the correct checksum comparison result can be obtained if the checksum result is compared using the same endian format (either big endian or little endian).

29.8 Transmit Checksum

The Ethernet controller has a transmit checksum function. This function has a dedicated DMAC (transmit checksum DMAC), which accesses the internal system bus independently of the internal Ethernet controller DMAC.

The algorithm for a transmit checksum complies with RFC1071, a payload is added in a 32-bit width, and a 2-byte checksum is output to the end of the data.

The minimum transmit payload subject to checksum calculations is 1 byte, and the maximum is 1,500 bytes as defined in IEEE802.3.

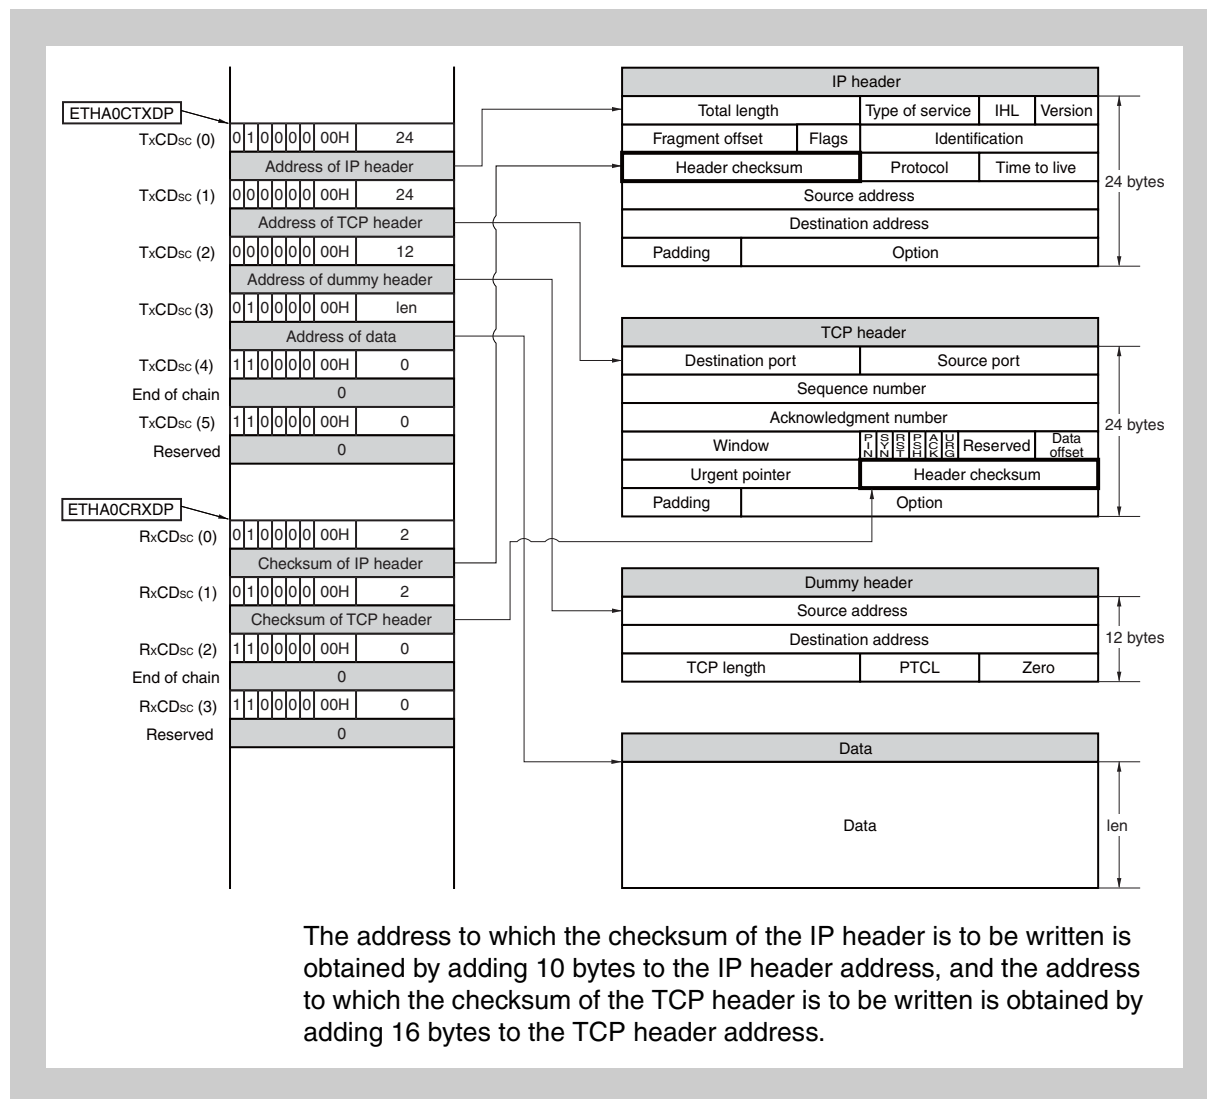

A checksum is calculated and the result is formatted in little endian format.

29.8.1 Configuration of transmit checksum descriptor

Calculation of a transmit checksum is controlled by a descriptor.

Depending on the configuration of the descriptor, the IP header and TCP header can be calculated separately or all at once.

The descriptor configuration for calculating the IP header and TCP header all at once is shown below.

The address to which the checksum of the IP header is to be written is obtained by adding 10 bytes to the IP header address, and the address to which the checksum of the TCP header is to be written is obtained by adding 16 bytes to the TCP header address.

Figure 29-34 Configuration of transmit checksum descriptor

29.9 Cautions

29.9.1 Cautions on FIFO

Note the following restrictions on the internal FIFO buffers of the Ethernet controller.

Table 29-111 Restrictions on transmit FIFO

Maximum FIFO capacity	DMA transfer condition	Retry/abort	Condition to transmit data to PHY	Feature	Note
2,044 bytes or less	Data in transmit FIFO is less than 1,536 bytes ^a .	Data is automatically retransmitted/ aborted when a collision is detected.	At least one packet is in the transmit FIFO.	Data can be retransmitted without underrun.	The transmit packet length must be 1,536 bytes or less.

- a) Multiple packets may be stored in the transmit FIFO as long as its capacity is not exceeded. However, if the data in the transmit FIFO reaches 1,536 bytes, DMA transmission stops, preventing the transmit FIFO from overflowing. However, because the Ethernet controller starts transmission after one packet of data has been stored in the transmit FIFO, the transmit FIFO is locked if the length of one packet is more than 1,536 bytes. Be sure to observe the rated size of one packet to use (1,518 bytes or less for non-VLAN frames or 1,522 bytes or less for VLAN frames).

Table 29-112 Restrictions on receive FIFO

Maximum FIFO capacity	DMA transfer condition	Condition to transmit pause control frame ^a	Feature	Note
2,036 bytes or less	At least one packet is in the receive FIFO.	<ul style="list-style-type: none"> Transmission of pause control frame: Data in the receive FIFO is greater than the size specified by the FLOWTHR bits. Transmission of 0 pause control frame: Data in the receive FIFO is less than the size specified by the ZPTHR bits. 	All error packets can be discarded.	The receive packet length must be 2,036 bytes or less.

- a) Control by a pause control frame does not completely prevent the receive FIFO from overflowing. If the receive FIFO overflows, receive packets that are not accepted are discarded.

Chapter 30 Standby Function

30.1 Features

This microcontroller has a HALT mode as a standby mode.

Table 30-1 Standby Mode

Mode	Function Overview
HALT mode	Only the CPU operation clock is stopped.

Figure 30-1 State Transition

30.2 HALT Mode

30.2.1 Setting and operation status

The HALT mode is set when a dedicated instruction (HALT) is executed in the normal operation mode.

In the HALT mode, the clock generator continues operating. Only supplying a clock to the CPU is stopped. Supplying a clock to the other on-chip peripheral functions continues.

As a result, program execution is stopped, and the internal RAM including the shared H-bus memory retains the contents before the HALT mode was set. The on-chip peripheral functions that are independent of instruction processing by the CPU continue operating.

The average current consumption of the system can be reduced by using the HALT mode in combination with the normal operation mode.

Table 30-2 Operation Status of Each Function in the HALT Mode

Function	Status
Main clock	Operates
PLL	Operates
Clock generator	Operates
CPU clock (f_{CPU})	Operates
P-bus clock (f_{PCLK})	Operates
H-bus clock (f_{HCLK})	Operates
Ethernet controller	Operates
USB function	Operates
CPU	Stops
I/O	Operates
P-bus peripheral function	Operates
WDT	Operates
A/D converter	Operates
H-bus peripheral function	Operates
Bus interface (MEMC)	Operates
Internal data	The internal data that will not be overwritten while the CPU stops, such as the CPU registers, statuses, data, and the contents of the internal RAM (including shared H-bus memory), retains the contents from before the HALT mode was set.

30.2.2 Exiting of the HALT mode

The state transition from the HALT mode to the normal operation mode is triggered by a reset input, interrupt, or occurrence of an exception.

If an interrupt or exception is acknowledged in the HALT mode, the PC indicated by the instruction following the HALT instruction is restored after the interrupt or exception is processed. (For details, see the description of the HALT instruction in the *V850E2M Architecture Users Manual*.)

The request to exit the HALT mode is input upon the occurrence of the next reset input, interrupt, or exception request.

(1) Reset inputs, interrupts, and exceptions that exit the HALT mode

The HALT mode is exited by the following sources:

- Reset input ($\overline{\text{RESET}}$)
- Occurrence of an internal reset (a software reset or WDT overflow)
- EI level maskable interrupt input (INT0 to INT255)
- FE level maskable interrupt input (FEINT)
- FE level non-maskable interrupt input (FENMI)
- Peripheral-device protection exception (PPI)
- Timing monitoring exception (TSI)
- System error exception (SYSERR)

Even if the conditions for acknowledging an exception above (the ID and NP values) are not satisfied, the HALT mode is exited if a request has been issued. For example, the HALT mode is exited upon the occurrence of INT0 even if ID is 1.

Note that the HALT mode exiting operation differs as follows if the HALT mode is set within an exception processing routine:

- If an exception request that has a priority level equal to or lower than that of the currently processed exception request is generated, the HALT mode is exited and this request is held.
- If an exception request that has a priority level higher than that of the currently processed exception request is generated, the HALT mode is exited and this request is acknowledged.

Note that the HALT mode will not be exited if servicing of the interrupt inputs including INT0 to INT255, FEINT, and FENMI is prohibited by the following interrupt control registers:

- EI level interrupt control registers (EIC0 to EIC255)
- EI level interrupt mask registers (IMR0 to IMR15)

Note For details about the interrupt and exception requests, see *Chapter 9 "Interrupt Functions" on page 223*. For details about the reset input types, see *Chapter 5 "Reset Function" on page 100*.

Chapter 31 Flash Memory

Type of flash memory The V850E2/ML4 microcontroller includes "Type05" flash memory. For details, see the descriptions of "Type05" flash memory in *Self Programming* and other documents.

This microcontroller has internal flash memory.

Table 31-1 Flash Memory

Product Name	Internal Flash Memory
μPD70F4021	768 KB
μPD70F4022	1 MB

The flash memory can be rewritten by using the following methods:

- Off-board programming: Mounting the device onto a dedicated program adapter (FA series) and rewriting with a dedicated flash memory programmer through communication with a serial interface
- On-board programming: Mounting the device onto a target system and rewriting with a dedicated flash memory programmer through communication with a serial interface
- Self programming: Rewriting the flash memory by using a user-created program (application)

31.1 Features

- Erasing individual blocks is possible (block: 4 KB).
- Communication with a dedicated flash memory programmer by way of a serial interface (on-board programming)
- On-board and off-board programming are possible.
- Programming the flash memory through self programming is possible.
- Erase/write prohibition (a security function): Supported
- Boot swapping: Supported

Table 31-2 Flash Memory Configuration

Block 255 (4 KB)	000F FFFF _H 000F F000 _H	Address
...	...	
Block 1 (4 KB)	0000 1FFF _H 0000 1000 _H	
Block 0 (4 KB)	0000 0FFF _H 0000 0000 _H	
1 MB	Flash memory size	
4/8/16/32/64/128/256 KB	Boot swap cluster size	

31.2 Rewriting by Using a Dedicated Flash Memory Programmer

The flash memory can be rewritten by using a dedicated flash memory programmer after the V850E2/ML4 is mounted on the target system (on-board programming). By using a dedicated program adapter (FA series), the flash memory can also be rewritten before the device is mounted on the target system (off-board programming).

Note The FA series is a product of Naito Densai Machida Mfg. Co., Ltd.

31.2.1 Communication methods

Communication between the dedicated flash memory programmer and the V850E2/ML4 is performed through serial communication by a one-wired UART or three-wired-HS CSI.

- One-wired UART

Pin No.	Pin Name	Function	Alternate Functions
118	FLRXD	Pin for the flash memory programmer	TDI/FLSI

Caution Communication cannot be performed at 2 Mbps.

- Three-wired-HS CSI

Pin No.	Pin Name	Function	Alternate Functions
117	FLSO	Pin for the flash memory programmer	TDO
118	FLSI	Pin for the flash memory programmer	TDI/FLRXD
121	FLSCK	Pin for the flash memory programmer	TCK

31.3 Rewriting by Self Programming

31.3.1 Overview

The V850E2/ML4 supports a flash macro service that allows a user-created program to rewrite the internal flash memory by itself. By using this interface and a self programming library that is used to rewrite the flash memory with a user-created application program, the flash memory can be rewritten by a user-created application transferred in advance to the internal RAM or external memory. Therefore, the user-created program can be upgraded and constant data can be rewritten in the field.

(1) Boot swapping

Boot swapping makes it possible to safely change flash memory programs and maintains a software version that can be run if changing a program fails (such as due to a power failure).

(2) Protection

During flash memory programming, a series of protection flags can be specified to prohibit reading, rewriting, erasing, or other types of access to the flash memory. This protects the flash memory contents from being read or rewritten by users without permission.

Note For details about boot swapping and protection, see 31.5.4 “Safe self programming (boot swap cluster)” on page 2057.

31.3.2 Erasing or rewriting the flash memory

Erase The flash memory can be erased by using the following two commands, depending on the block structure:

- Erasing all the blocks at once (erasing the chip, only in the serial programming mode)
All the blocks are erased at once.
- Erasing individual blocks
4 KB flash memory blocks are separately erased.
In the self programming mode, any number of sequential flash memory blocks can be erased at once.

Write In the self programming or serial programming mode, the flash memory can be written to in units smaller than one block. When all the blocks are erased, the flash memory can be written to in 16-byte units. After erasing all the blocks, data can be written once per 16-byte unit.

Erase/write The erase/write command can be used to erase a 32 KB block of flash memory and then write to a different 32 KB block.

31.4 Flash Memory Programming by Using a Flash Memory Programmer

The flash memory can be written to in the serial programming mode by using a dedicated flash memory programmer.

Serial programming During serial programming, the microcontroller is mounted onto a target board that has a connector, and the flash memory programmer is connected to the target microcontroller.

The microcontroller must provide a complete range of operations.

- All external power supplies must be activated.
- An external oscillator must be connected to the X1 and X2 pins.

All necessary microcontroller functions are set up and executed by using the on-board firmware.

Caution When connecting the flash memory programmer to the on-board microcontroller, conflicts with other signals might occur. For details, see the tips in (2) “Conflicts with on-board signals” on page 2050.

31.4.1 Programming environment

The recommended environment for writing data to the microcontroller’s flash memory is shown below.

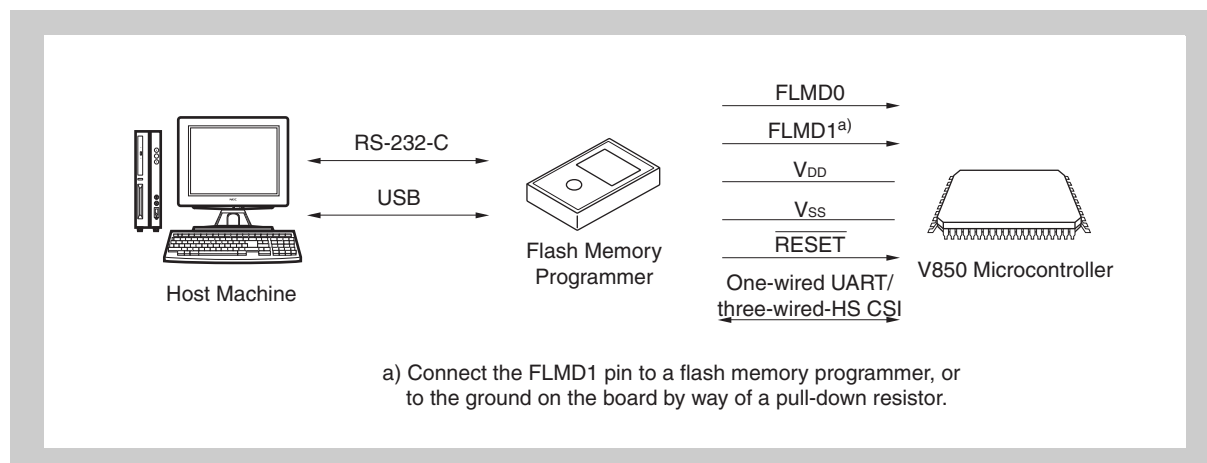

Figure 31-1 Environment for Writing Programs to the Flash Memory

A host machine is necessary for setting up the flash memory programmer. However, no host machine is necessary to use the flash memory programmer because the programmer can function in the standalone mode.

The dedicated microcontroller serial interfaces below can be used as an interface between the flash memory programmer and the microcontroller.

- Single-wire asynchronous serial programming interface: One-wired UART
- Synchronous serial programming interface: Three-wired-HS CSI

Note The one-wired UART and three-wired-HS CSI serial interfaces can only be used in the flash memory programming mode. They cannot be used in the normal operation mode.

31.4.2 Communication mode

(1) Single-wire asynchronous serial programming interface: One-wired UART

Connect the one-wired UART single-wire asynchronous serial programming interface to the flash memory programmer by using the following pin:

- Reception/transmission data: FLRXD

Various baud rates can be selected for the external flash memory programmer.

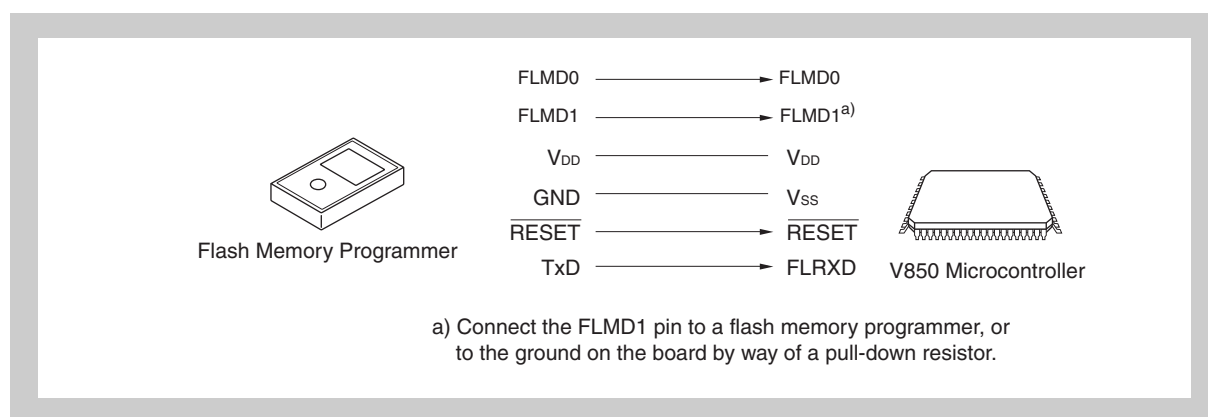

Figure 31-2 Communication with the Flash Memory Programmer by Using the One-Wired UART

Caution Communication cannot be performed at 2 Mbps.

(2) Synchronous serial programming interface: Three-wired-HS CSI

Connect the three-wired-HS CSI synchronous serial programming interface to the flash memory programmer by using the following pins:

- Serial data input: FLSI
- Serial data output: FLSO
- Serial data clock input: FLSCK

Various clock speeds can be selected for the external flash memory programmer.

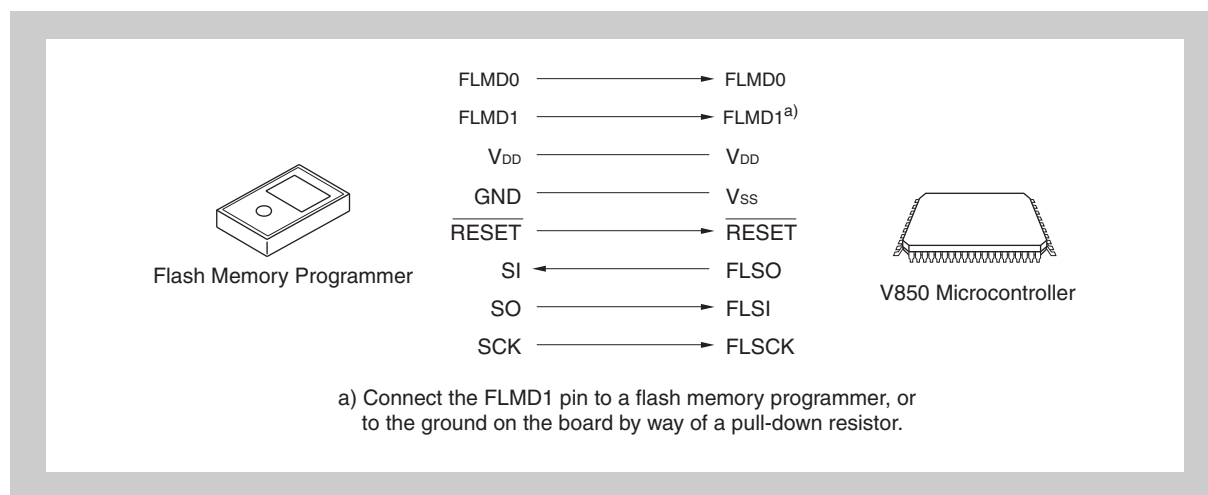

Figure 31-3 Communication with the Flash Memory Programmer by Way of the Three-Wired-HS CSI

The flash memory programmer outputs the serial data clock SCK, and the microcontroller runs as a slave.

31.4.3 Pin connections with the flash memory programmer PG-FP5

It is necessary to attach a connector to the target system and connect a flash memory programmer for serial programming. Functions for switching between the normal operation mode and flash memory programming mode, as well as for controlling the microcontroller's $\overline{\text{RESET}}$ pin, must also be provided on the board.

When the microcontroller flash memory programming mode is specified, all pins not used for flash memory programming have the same status as immediately after a reset.

If using PG-FP5 as the flash memory programmer, connect the PG-FP5 target interface connector to the microcontroller as shown below.

Table 31-3 Microcontroller Flash Memory Programmer PG-FP5 Connections

Flash Memory Programmer PG-FP5 Connection Pin			Microcontroller Signal (Alternate Function) Name			
Signal Name	I/O	Function	One-Wired UART		Three-Wired-HS CSI	
			Signal	Port	Signal	Port
SO/TxD	O	<ul style="list-style-type: none"> Transmission/reception data Transmission data 	FLRXD	TDI/FLSI	FLSI	TDI/FLRXD
SI/RxD	I	Reception data	Open		FLSO	TDO
SCK	O	Transfer clock	Open		FLSCK	TCK
CLK	O	Clock to the microcontroller	Open		Open	
			Open		Open	
$\overline{\text{RESET}}$	O	Reset signal	$\overline{\text{RESET}}$	–	$\overline{\text{RESET}}$	–
FLMD0	I	Mode selection	FLMD0	–	FLMD0	–
FLMD1	I	Mode selection	FLMD1 ^a	–	FLMD1 ^a	–
H/S	I	Handshake signal	Open		Open	
V _{DD}	O	Power supply	EV _{DD}		EV _{DD}	
V _{DD2}	O	Power supply	IV _{DD}		IV _{DD}	
V _{PP}	–	Flash memory programming voltage	Open		Open	
GND	–	Ground	VSS		VSS	
VDE	–	Reserved	Open		Open	
RFU-1	–	Reserved	Open		Open	

a) If FLMD1 is fixed to the low level on the target board, it is not necessary to connect the FLMD1 signal.

For details, see the PG-FP5 user's manual R20UT0008EJxxxx (where xxxx is the current version number).

31.4.4 Flash memory programming control

The flash memory programming procedure is shown below.

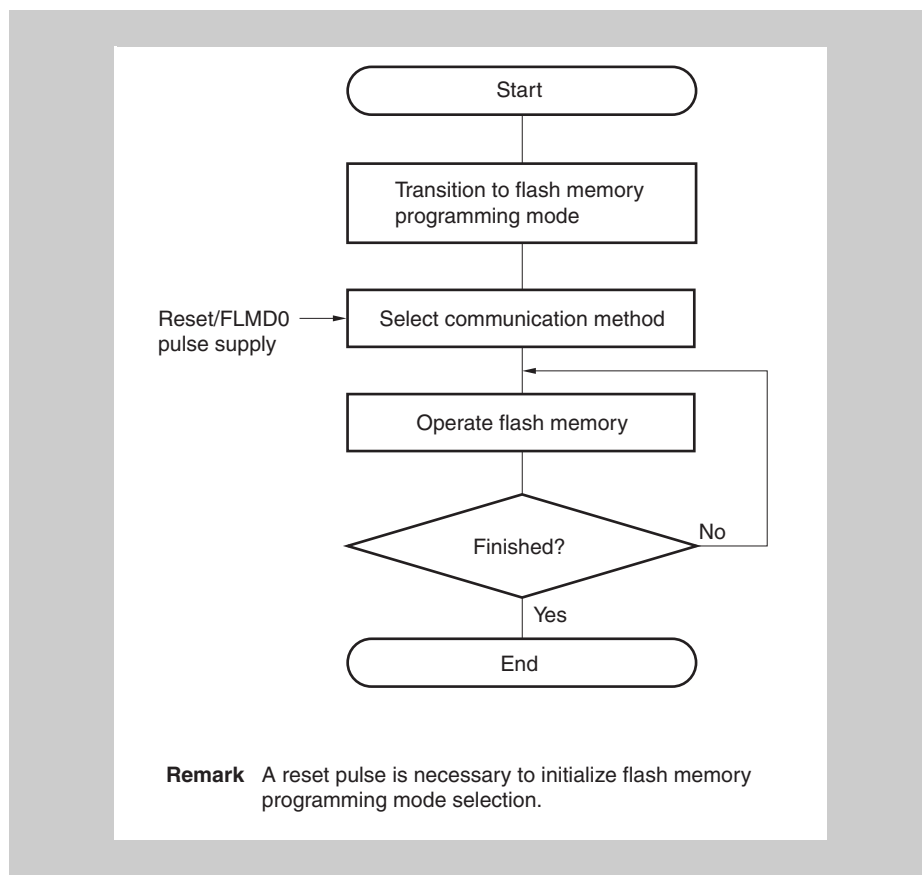

Figure 31-4 Flowchart of Flash Memory Programming Procedure

(1) Operation mode control

To use the flash memory programmer to rewrite the contents of flash memory, specify the flash memory programming mode for the microcontroller.

To specify this mode, set up the FLMD0 and FLMD1 pins as shown in *Table 31-4 “Operation Mode Selection” on page 2049* and cancel $\overline{\text{RESET}}$.

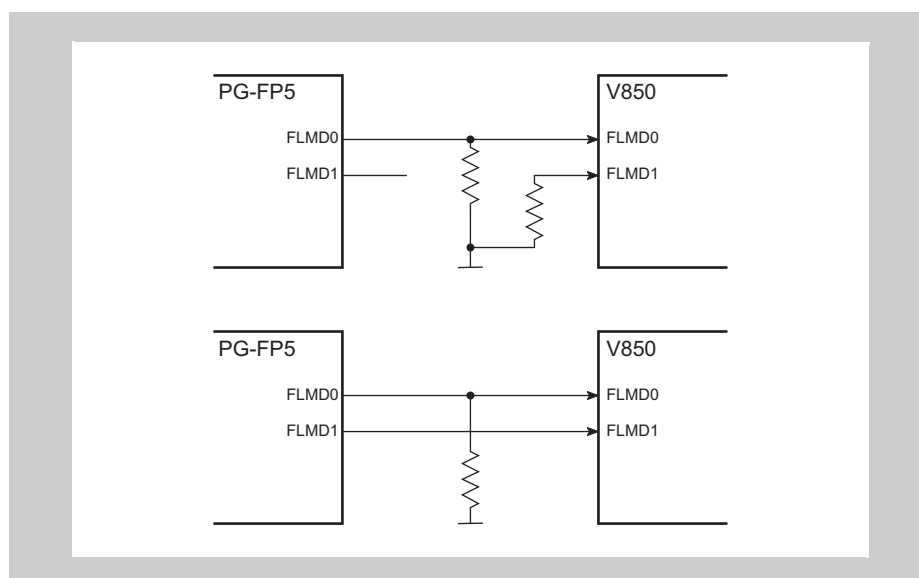

During the normal operation mode, VSS is input to the FLMD0 pin. When no flash memory programmer is connected, the operation in the normal operation mode is secured by the pull-down resistor connected to the FLMD0 pin.

To specify the serial flash memory programming mode (on-board programming using an external flash memory programmer), VDD and VSS are supplied to the FLMD0 and FLMD1 pins respectively when $\overline{\text{RESET}}$ is canceled.

Table 31-4 Operation Mode Selection

Pin				Operation Mode
FLMD0	FLMD1	MODE2	MODE3	
L	L	L	L	Normal operation mode
H	L	L	L	Flash memory programming mode
	H	L	L	Boundary scan mode
Other than above				Setting prohibited

An example of connecting the FLMD0 and FLMD1 pins is shown below. The FLMD1 pin can be connected to the ground by way of a resistor. The FLMD1 pin can also be connected directly to the FLMD1 pin of the flash memory programmer.

**Figure 31-5 Example of Flash Memory Programmer PG-FP5 Connection**

If the device is started in the normal operation mode (FLMD0 = 0), self programming can be enabled using the FLMD0 pin. For details, see *31.5 “Flash Memory Self Programming” on page 2053*.

(2) Conflicts with on-board signals

Serial I/O signals If another device is connected to the serial interface pin used for flash memory programming in the serial programming mode, take action to prevent relevant signals from conflicting with signals from the flash memory programmer or microcontroller. Isolate the output pins of the connected device, or make them high impedance. Such action is necessary to prevent the flash memory programmer signals from causing the connected device to malfunction.

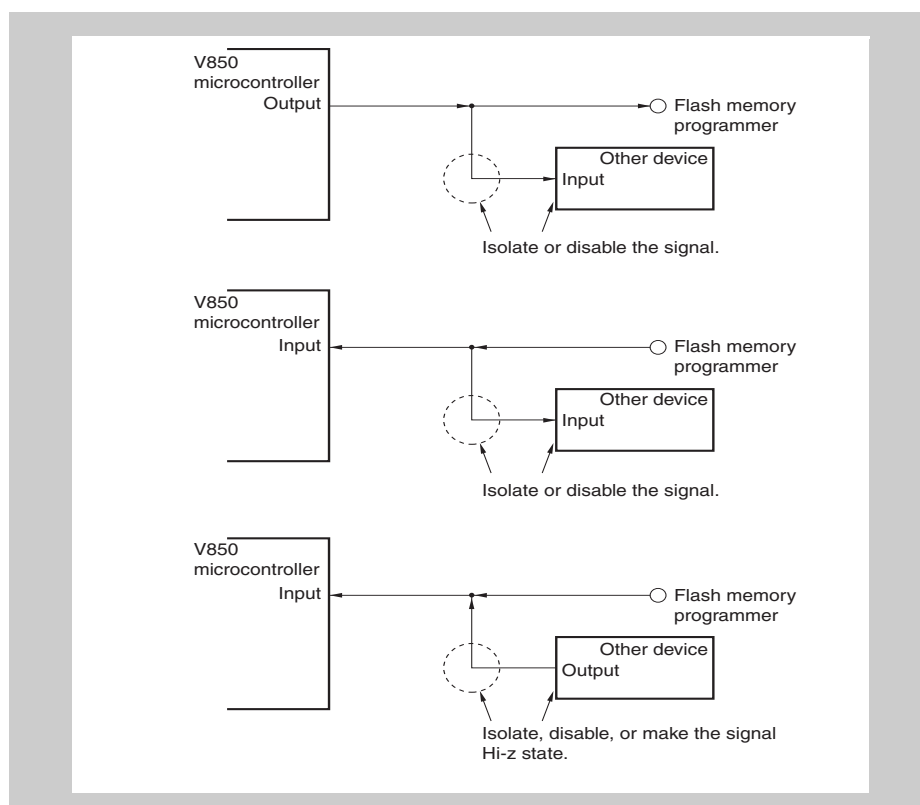

Figure 31-6 Conflict with Serial Interface Signals

$\overline{\text{RESET}}$ signal Special care is required when connecting the $\overline{\text{RESET}}$ signal of the flash memory programmer to the on-board reset generator. Isolate or disable the reset signal output from the reset generator because it might cancel the flash memory programming processing.

Figure 31-7 Conflict with $\overline{\text{RESET}}$ signal

Port signals During serial programming, the port pins of the V850 microcontrollers function as follows.

The pin used for programming is specified as the FLRXD or FLSO/FLSI/FLSCK pin.

The pins not used for programming are kept in their default state after a reset ends.

If the default state of a pin not used for programming is an input port or high-impedance output port, be careful of a device connected using this pin. If this device requires the level specified for the pin, connect this port to VDD or VSS by way of a resistor.

Oscillator Connect all oscillators in the same way during the normal operation mode.

Power supply Supply the same power as while in the normal operation mode to all power supply pins, including those for the reference voltage and voltage regulator.

(3) Communication mode selection

The communication interface is determined by applying the specified number of pulses to the FLMD0 pins after a reset ends. Note that this is processed using the flash memory programmer.

If a one-wired UART is selected after the FLMD0 pulses are received at 9,600 bps, the baud rate for the flash memory programmer is changed according to the user's selection specified by way of the flash memory programmer's user interface.

(4) Communication command

The flash memory programmer sends commands to the microcontroller. Upon receiving a command, the microcontroller returns the status information of required data.

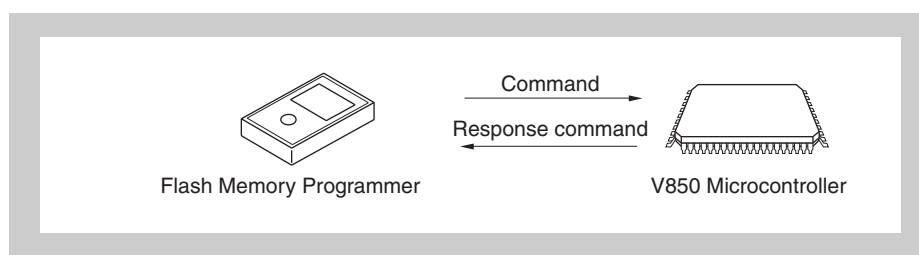

Figure 31-8 Communication command transfer

The table below lists the flash memory control commands for the microcontroller. These commands are all sent from the flash memory programmer, and the microcontroller performs the corresponding processing in response to them.

Table 31-5 Flash Memory Control Commands (1/2)

Type	Command Name	Supported Interface		Function
		One-Wired UART	Three-Wired-HS CSI	
Blank check	Chip blank check	Supported	Supported	Checks the data erase status of the flash option ^a and all areas of the code flash memory.
	Block blank check	Supported	Supported	Checks the data erase status of the specified block in the code flash memory.

Table 31-5 Flash Memory Control Commands (2/2)

Type	Command Name	Supported Interface		Function
		One-Wired UART	Three-Wired-HS CSI	
Erase	Chip erase	Supported	Supported	Erases the flash option ^a and data in all areas of code flash memory.
	Block erase	Supported	Supported	Erases the contents of the specified block in the code flash memory.
Write	Write	Supported	Supported	Writes data to the specified block in the code flash memory.
Erase/write	Block erase and write	Supported	Supported	Erases the contents of the specified block in the code flash memory and writes data to that block at the same time, enabling fast processing.
Read	Read	Supported	Supported	Reads the data of the specified block in the code flash memory.
Verify	Block verify	Supported	Supported	Compares the contents of the specified block in the code flash memory with the data transmitted by the programmer.
On-chip debug security ID specification	On-chip debug security ID specification	Supported	Supported	Sets an on-chip debug security ID to flash option ^a .
	On-chip debug security ID setting acquisition	Supported	Supported	Obtains the on-chip debug security ID from flash option ^a .
CRC	Chip CRC	Supported	Supported	Calculates the checksum of flash option ^a and all areas of the code flash memory.
	Block CRC	Supported	Supported	Calculates the checksum of the specified block in the code flash memory.
Option byte specification	Option byte specification	Supported	Supported	Sets the option byte setting to the flash option ^a .
	Option byte setting acquisition	Supported	Supported	Obtains the option byte setting from the flash option ^a .
Security specification	Security specification	Supported	Supported	Specifies the chip erase prohibit, block erase prohibit, write prohibit, read prohibit, boot area write prohibit, and flash memory shield window settings.
	Security setting acquisition	Supported	Supported	Obtains the security settings.
System setting and control	Reset	Supported	Supported	Used for communication synchronization.
	Oscillation frequency specification	Supported	Supported	Specifies an oscillation frequency.
	Baud rate specification	Not supported	Supported	Specifies a baud rate for using UART.
	Silicon signature	Supported	Supported	Obtains the signature information.

a) Flash option is a collective term indicating the security, write protection, reset vector handling function, option byte, and on-chip debug security ID settings.

Note For details about the on-chip debug ID, see the operation manual of the software tool used.

31.5 Flash Memory Self Programming

This V850 microcontroller supports a flash macro service that allows a user-created program to rewrite the internal flash memory by itself.

By using the flash macro service and self programming library (FSL) in a user-created application program, the flash memory can be rewritten by the data transferred in advance to the internal RAM or external memory.

This makes it possible to upgrade the user-created program and rewrite constant data fields.

Figure 31-9 Self Programming Schematic

Note that the flash memory cannot be accessed during self programming. Therefore, the program can be executed only by fetching an instruction from the internal RAM or external memory.

Before activating self programming, therefore, it is necessary to copy the instructions of the software routine that changes the user-created program while in the self programming procedure from the flash memory to the internal RAM or external memory. Because no interrupt can be serviced by an interrupt vector in the flash memory during self programming, a special function for acknowledging interrupts in the internal RAM is provided. (For details, see 31.5.5 “Interrupt service during flash memory self programming” on page 2061.)

Caution When using the flash self programming library, there are notes concerning data access using the gp and ep registers during interrupt processing. The notes regarding the gp register are not applicable to this product.

For general information about flash memory self programming, see the application notes that describe self programming.

31.5.1 Activating self programming

The self programming function can be activated from the normal user mode of the microcontroller.

- Set the external FLMD0 pin to high.
To do this, some external components must be set up, wiring is required (such as connecting an output port to the FLMD0 pin), and the FLMD0 must be pulled down (a 100 k Ω pull-down resistor is required).
- Specify the internal register bit FLMDCNT.FLMDPUP.
At this time, pull down the FLMD0 pin (a 100 k Ω pull-down resistor is recommended).

The following register is used to internally enable self programming by using software.

/

(1) FLMDCNT: FLMD control register

This register is used to control the on-chip pull-up and pull-down resistors that are connected to the FLMD0 pin and are used to enable and disable self programming, respectively.

Protection Writing to this register is protected by a special sequence of instructions by using the protection command register FLMDPCM

Access This register can be read/written in 8-bit units.

Address FF43 8000_H

Initial value 00_H

7	6	5	4	3	2	1	0
0	0	0	0	0	0	0	FLMDPUP
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 31-6 FLMDCNT register contents

Bit position	Bit name	Function
0	FLMDPUP	This bit controls pull-up and pull-down of the FLMD0 pin. 0: Activate the pull-down resistor connected to the FLMD0 pin (self programming mode disabled). 1: Activate the pull-up resistor connected to the FLMD0 pin (self programming mode enabled).

(2) FLMDPCMD: FLMD protection command register

This register is the protection command register for the FLMDCNT register.

Access This register can be written in 8-bit units.

Address FF438004_H

Initial value Undefined

Table 31-7 FLMDPCMD register contents

Bit position	Bit name	Function
7 to 0	FLMDPC[7:0]	These bits function as a protection command to enable writing to FLMDCNT.

(3) FLMDPS: FLMD protection error status register

This register indicates whether data was successfully written to the write-protected register FLMDCNT.

Access This register can be written in 8-bit units.

Address FF438008_H

Initial value 00_H

Table 31-8 FLMDPS register contents

Bit position	Bit name	Function
0	FLMDPRERR	These bits indicate whether data write to the write-protected register FLMDCNT was successful. 0: Successful 1: Failed

31.5.2 Self programming library functions

Flash memory self programming by the user-created program is supported by the self programming library.

This library provides a set of C function calls that execute the following basic features:

- Blank check, erase, rewrite, and verify for the flash memory
- Boot swap cluster (including boot cluster specification)
- Protection flag setting
- Acquisition of various types of information related to the flash memory

For details about how to use the library, see the application notes that describe self programming.

31.5.3 Occupation of internal RAM by self programming

During self programming, the upper 3.5 KB of the internal RAM (from FEDFF200_H to FEDFFFFF_H) are occupied to process the self programming. Therefore, the contents of the 2 KB RAM are changed during self programming, and it might be necessary to restore the contents using the user-created program.

Note In addition, it might be necessary to use the RAM as intermediate memory for storing user data and code when data is copied from the flash memory to the RAM during self programming.

31.5.4 Safe self programming (boot swap cluster)

The V850 flash microcontroller supports a mechanism that swaps the cluster in the flash memory block starting from $0000\ 0000_H$ with the upper adjacent cluster of the same size.

Boot swap cluster Because the cluster of the boot block to be swapped, which starts from the group address $0000\ 0000_H$, contains the entry point of the user-created program at the default reset vector $0000\ 0000_H$, it is called the *active boot swap cluster*.

Boot swapping flag Which of the two clusters is the boot swap cluster is specified using the self programming library during flash memory programming. *Figure 31-10 “Boot Swap Cluster Swapping” on page 2057* shows an example of the boot block swap function for a flash memory block of cluster size 4. When `boot_flag` is inverted, it becomes `not (boot_flag)` and blocks 4 to 7 become the active boot cluster. At this time, the user-created program starts from the new boot swap cluster the next time a reset ends.

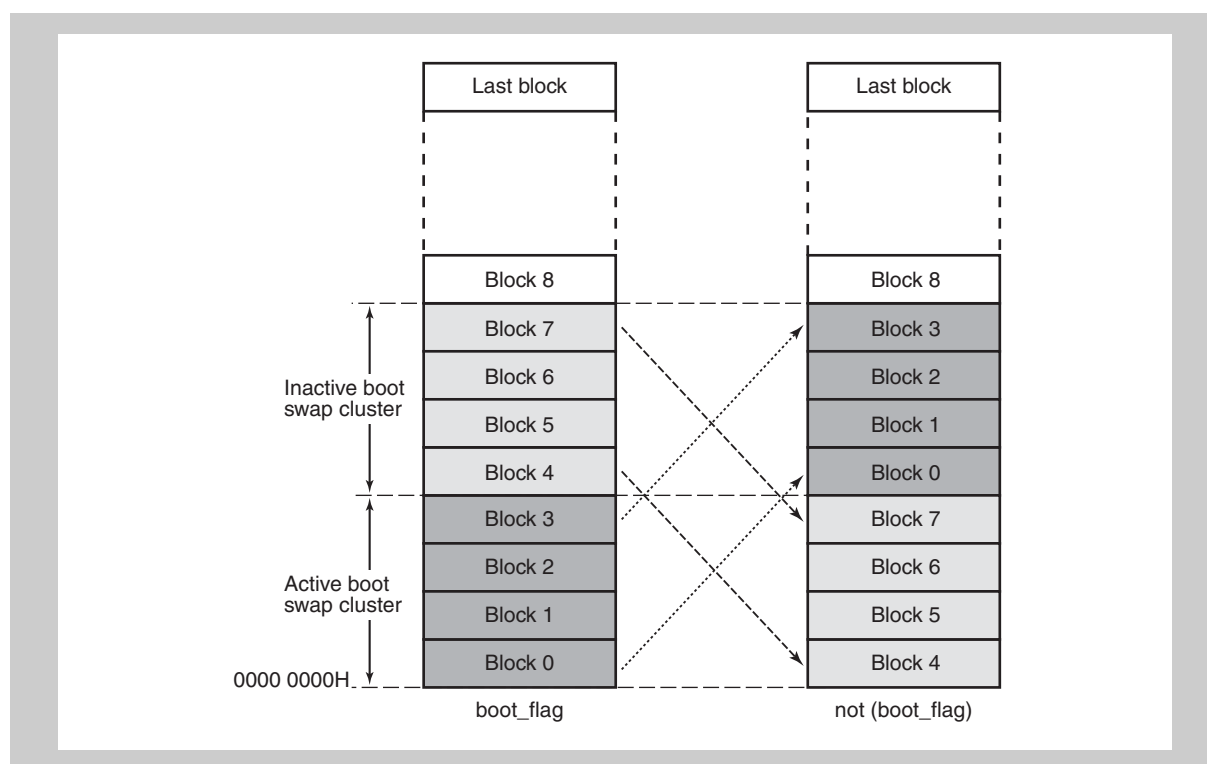

Figure 31-10 Boot Swap Cluster Swapping

Safe self programming The boot swap cluster function makes self programming safe. When a boot code is rewritten, the new code is written to the boot cluster, and `boot_flag` retains the previous contents. When the boot cluster is rewritten normally, `boot_flag` is inverted and the new boot code become active. Even if the new boot code failed to be rewritten due to a power failure, unexpected reset, or other error, rewriting can be executed again because the old boot code remains active.

Boot cluster The boot code might be smaller than that of the boot swap cluster.

A flash memory block, which is a part of the boot code, is called a *boot cluster*. The number of boot blocks that are cluster members can be specified by using the self programming library during self programming.

The size of the boot swap cluster is determined by that of the boot cluster. In other words, it is determined according to the number of boot blocks specified during self programming.

Table 31-9 “Correspondence between Boot Block and Boot Swap Cluster” on page 2059 shows the correspondence between the number of boot blocks, boot cluster size, and boot swap cluster.

Number of boot blocks The number of boot blocks must be specified by the user during self programming. The specified number of boot blocks determine the target boot block for boot cluster protection that protects the block from being erased or written.

Boot block protection To prohibit boot block rewriting, specify the boot cluster protection setting using the self programming library during flash memory programming. Once this setting is specified, the active boot cluster block is not erased or written, and is also protected from the boot swap cluster function. Note that only the active boot cluster block is protected. In *Figure 31-11 “Boot Swap Cluster Example” on page 2060*, for example, blocks 0 and 1 are protected from being erased or written while blocks 2 and 3 are not.

Caution Once boot cluster protection is activated, it cannot be inactivated.

Table 31-9 Correspondence between Boot Block and Boot Swap Cluster

Last address of boot block	Boot swap cluster		Cluster to be replaced with boot swap cluster	Boot block cluster	
	Size	Address	Address	Size	Address
00 _H	4 KB	0000 0000 _H to 0000 0FFF _H	0000 1000 _H to 0000 1FFF _H	4 KB	0000 0000 _H to 0000 0FFF _H
01 _H	8 KB	0000 0000 _H to 0000 1FFF _H	0000 2000 _H to 0000 3FFF _H	8 KB	0000 0000 _H to 0000 1FFF _H
02 _H	16 KB	0000 0000 _H to 0000 3FFF _H	0000 4000 _H to 0000 7FFF _H	12 KB	0000 0000 _H to 0000 2FFF _H
03 _H				16 KB	0000 0000 _H to 0000 3FFF _H
04 _H	32 KB	0000 0000 _H to 0000 7FFF _H	0000 8000 _H to 0000 FFFF _H	20 KB	0000 0000 _H to 0000 4FFF _H
...			
07 _H				32 KB	0000 0000 _H to 0000 7FFF _H
08 _H	64 KB	0000 0000 _H to 0000 FFFF _H	0001 0000 _H to 0001 FFFF _H	36 KB	0000 0000 _H to 0000 8FFF _H
...			
0F _H				64 KB	0000 0000 _H to 0000 FFFF _H
10 _H	128 KB	0000 0000 _H to 0001 FFFF _H	0002 0000 _H to 0003 FFFF _H	68 KB	0000 0000 _H to 0001 0FFF _H
...			
1F _H				128 KB	0000 0000 _H to 0001 FFFF _H
20 _H	256 KB	0000 0000 _H to 0003 FFFF _H	0004 0000 _H to 0007 FFFF _H	132 KB	0000 0000 _H to 0002 0FFF _H
...			
3F _H				256 KB	0000 0000 _H to 0003 FFFF _H
40 _H	Boot swap disabled			260 KB	0000 0000 _H to 0004 0FFF _H
...			
FF _H				1024 KB	0000 0000 _H to 000F FFFF _H

Maximum size of boot swap cluster The maximum size of the boot cluster is 256 KB. Therefore, a flash memory area whose size exceeds 512 KB cannot be used for boot swap cluster.

Figure 31-11 “Boot Swap Cluster Example” on page 2060 shows a boot swap example in which the cluster consists of four flash memory blocks. When `boot_flag` is inverted, it becomes `not (boot_flag)`, and blocks 4 to 7 make up an active boot block cluster. Therefore, the user-defined program starts from the replaced boot swap cluster after the next reset.

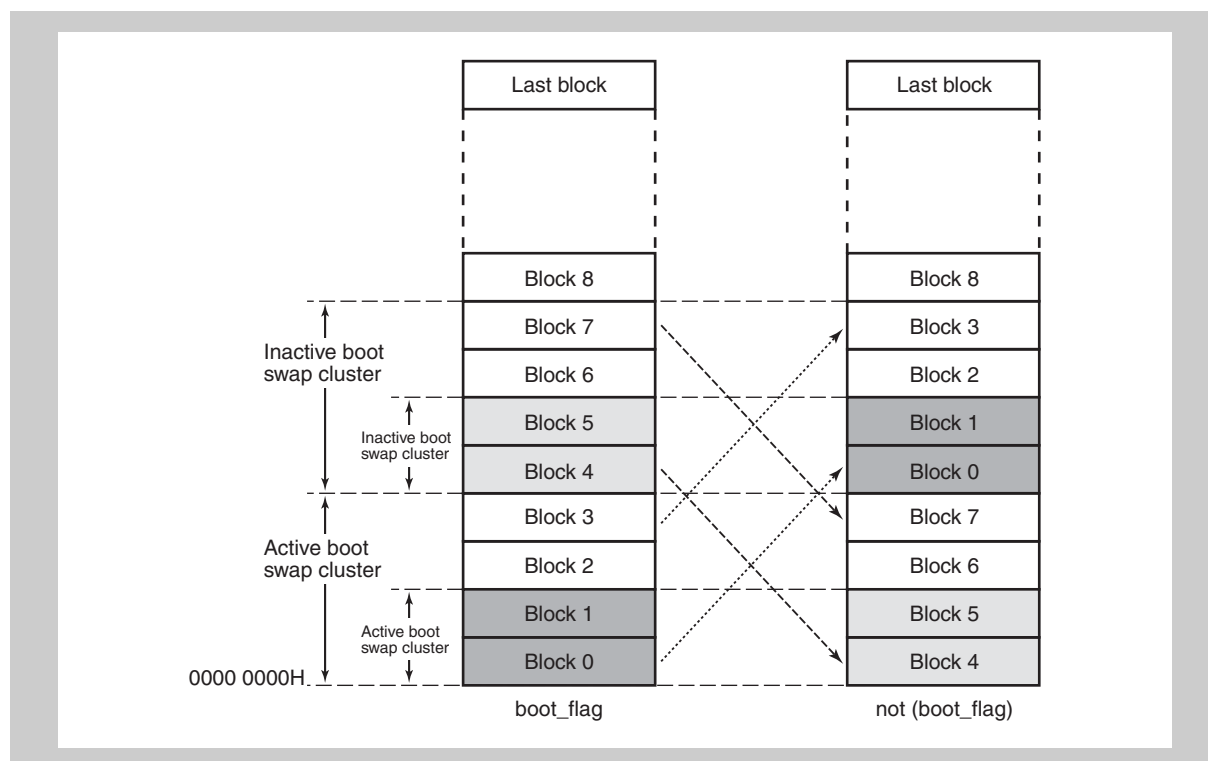

Figure 31-11 Boot Swap Cluster Example

Secure self programming

The boot swap function enables secure self programming. When rewriting a boot code, the new code is written into the inactive cluster (blocks 4 to 7) while `boot_flag` remains in its original state (the cluster of blocks 0 to 3 is active). Once the inactive cluster (blocks 4 to 7) is successfully rewritten, `boot_flag` is changed (boot swap) and the new boot code (the cluster of blocks 4 to 7) becomes active.

For example, even if the new boot code rewrite failed due to a blackout or unintentional reset, rewrite can be restarted because the original boot code remains active.

Boot block cluster

The boot block cluster is a boot area for the application program, and area selection is possible.

The security setting to disable rewriting can be specified for the boot block cluster.

Caution

Once boot cluster protection is activated, it cannot be inactivated.

31.5.5 Interrupt service during flash memory self programming

This microcontroller provides a function that maintains interrupt servicing during self programming.

When self programming is active, neither interrupt vector tables nor interrupt handler routines placed in the flash memory can be accessed. It is therefore necessary to acknowledge interrupts somewhere other than the flash memory, such as the internal RAM.

Interrupt handler addresses can be switched by using software.

For details, see 6.4 “*Exception handler address switching function*” in Volume 2 of the V850E2M Architecture User's Manual (R01US0001E).

For general information about flash memory self programming, see the application notes that describe self programming.

Chapter 32 Boundary Scan

32.1 Features

A boundary scan is a test method specified by IEEE 1149.1 that is used to sequentially test the external I/O pins of a device and then input or output the test data. This makes it possible to check the connections between devices mounted on an application system board.

32.2 Boundary Scan Environment

The host machine is communicated with by way of the JTAG test tool by using the TRST, TCK, TMS, TDI, and TDO signals.

Figure 32-1 Boundary Scan Block Diagram

32.3 Boundary Scan Mode

When performing a boundary scan, set the system to the boundary scan mode.

To switch to this mode, set up the FLMD0, FLMD1, MODE2, and MODE3 pins, and then cancel the reset.

Table 32-1 Boundary Scan Mode Settings

FLMD0	FLMD1	MODE2	MODE3	Operation Mode
L	L	L	L	Normal operation mode
H	L	L	L	Flash memory programming mode
H	H	L	L	Boundary scan mode
Other than the above				Setting prohibited

Note L: Low level H: High level

32.4 TAP (Test Access Port)

Use the following pins for boundary scan I/O.

(1) **$\overline{\text{TRST}}$**

This is the test reset input pin. This pin acknowledges asynchronous input and resets the boundary scan circuit when low-level input is received.

The $\overline{\text{TRST}}$ pin is pulled down on the chip by using a resistor.

(2) **TCK**

This is the test clock input pin. All input signals are captured at the rising edge of TCK, and output starts at the falling edge of TCK.

(3) **TMS**

This is the test mode selection pin. It inputs commands to the TAP controller.

(4) **TDI**

This is the test data input pin. It functions as the input for the serial registers placed between TDI and TDO.

The status of these registers is determined by the TAP controller status and instructions captured by the TAP controller.

(5) **TDO**

This is the test data output pin. It functions as the output for the serial registers lined up between TDI and TDO.

The output changes at the falling edge of TCK.

32.5 TAP Controller

32.5.1 Target pins

All pins are subject to boundary scans except those in *Table 32-2 “Pins Not Subject to Boundary Scans”*.

Table 32-2 Pins Not Subject to Boundary Scans

Type	Pin Name
JTAG I/F	$\overline{\text{TRST}}$, TCK, TMS, TDI, TDO, and RDY
MODE pins	FLMD0, FLMD1, MODE2, and MODE3
Analog input pins	ANI01 to ANI05
Clock pins	X1 and X2
Flash test pins	VPPTS2 and VPPTS3
Power supply pins	V _{DD} , EV _{DD} , DV _{DD} , OSCV _{DD} , PLLV _{DD} , UV _{DD} , AV _{DD} , and AV _{REFP}
GND pins	V _{SS} , EV _{SS} , DV _{SS} , OSCV _{SS} , PLLV _{SS} , UV _{SS} , AV _{SS} , and AV _{REFM}
USB pins	UDPF, UDMF, UDPH, and UDMH

32.5.2 Instructions

The V850E2/ML4 supports the BYPASS, EXTEST, SAMPLE, and PRELOAD instructions.

Table 32-3 Instruction Codes

Instructions	Instruction Codes		Remark
	20...16	15.....0	
BYPASS	1 1111	1111 1111 1111 1111	
EXTEST	1 1111	1111 1111 1110 1000	
SAMPLE	1 1111	1111 1111 1111 1000	Same code as PRELOAD
PRELOAD	1 1111	1111 1111 1111 1000	Same code as SAMPLE

(1) BYPASS

When the BYPASS instruction is captured by the instruction register, the TAP controller enters the shift-DR status and places the bypass register between TDI and TDO.

The board-level scan path for the BYPASS instruction makes it easy to test the scan paths of other devices by using the shortest possible route.

(2) EXTEST

The EXTEST instruction makes it possible to test an external circuit from a JTAG circuit.

The test vector is specified for the boundary scan register cell on the output pin side, and the test results are captured on the input pin side. Normally, the PRELOAD instruction is executed before the EXTEST instruction to specify the first test vector for the boundary scan register cell. The result of this is that, if the TAP controller enters the Update-IR status during EXTEST instruction execution, the output driver is enabled, and the PRELOAD data is output from the output pin.

(3) SAMPLE/PRELOAD

SAMPLE/PRELOAD is a general instruction for which the execution details are specified by IEEE 1149.1.

When the SAMPLE/PRELOAD instruction is captured by the instruction register, the TAP controller enters the capture-DR status, and the data input to the I/O pin is captured by the boundary scan register.

32.5.3 Scan registers**(1) Instruction register**

The instruction register is used to store instructions to be issued by the TAP controller.

When the instruction register is placed between TDI and TDO, instructions are captured by the register.

When the power supply is turned on, the instruction register captures an IDCODE instruction. At this time, the TAP controller is reset to the Test-Logic-Reset status.

(2) Bypass register

The bypass register is a 1-bit register placed between TDI and TDO.

The bypass register transfers sequential test data to other devices along the shortest possible route by way of the TAP controller.

(3) ID register

The ID register is a 32-bit register.

When the TAP controller enters the capture-DR status after the instruction register captures an IDCODE instruction, the ID register captures a 32-bit device code and manufacturer code.

When the TAP controller enters the shift-DR status, the ID register is placed between TDI and TDO.

Table 32-4 ID Register Codes

Device Name	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
μPD70F4021	0	0	0	0	1	0	0	0	0	0	0	1	0	0	1	0	1	1	1	0	0	1	0	0	0	1	0	0	0	1	1	1
μPD70F4022	0	0	0	0	1	0	0	0	0	0	0	1	0	0	1	0	1	1	0	1	0	1	0	0	0	1	0	0	0	1	1	1

(4) Boundary scan register

The boundary scan register is controlled by the TAP controller.

When the TAP controller enters the capture-DR status, the boundary scan register captures the contents of the RAM I/O ring. When the TAP controller enters the shift-DR status, the boundary scan register is placed between TDI and TDO. Several TAP instructions use the boundary scan register.

32.5.4 Status transitions

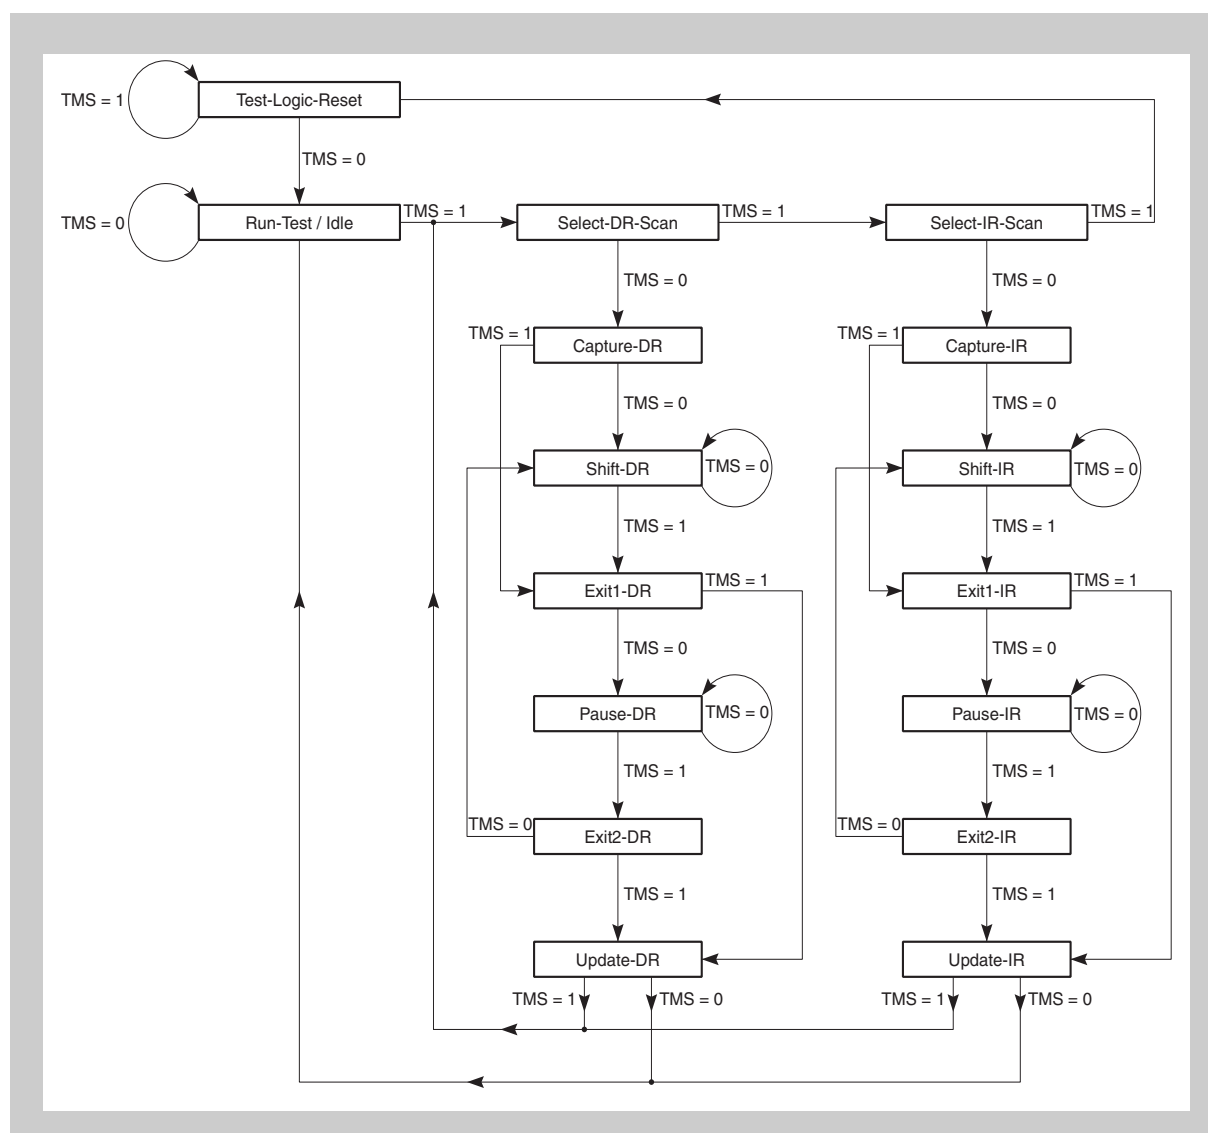

Figure 32-2 TAP Controller Status Transitions

Chapter 33 On-chip Debugging Unit (OCD)

This microcontroller has an on-chip debugging function. By using an on-chip debugging emulator, programs can be debugged on the microcontroller mounted on the target system.

The debugging function provided for this microcontroller complies with the Nexus debugging interface standards IEEE-ISTO 5001™2003 Class 1. This function also complies with Class 3 when trace pins are used.

Caution Although the debugging function described in this chapter is supported by this microcontroller, whether it can be used depends on the debugger. For details about the debugger, see its operation manual.

33.1 V850E2/ML4 On-chip Debugging Function

33.1.1 Peripheral break

The module performs one of the following operations when the debugger stops the microcontroller's operation during a peripheral break:

- Always stops (unconditional peripheral break)
- Optionally stops (peripheral break function)
- Continues operation

Peripheral break For peripheral break, the following points are referenced during a debugging session:

- Break point hit
- Manual break

(1) Module subject to unconditional peripheral break

The table below shows the module that always stops when a peripheral break occurs.

Table 33-1 Module That Stops upon a Peripheral Break (Unconditional Peripheral Break)

Module
Window Watchdog Timer A (WDTAn)

(2) Modules that continue operation upon a peripheral break

The table below shows the modules that continue operation when a peripheral break occurs.

Table 33-2 Modules That Continue Operation upon a Peripheral Break

Module
Timers (TAUA, TAUJ, OSTM, ENCA, and TAPA)
Serial interface modules (UARTE, CSIH, and I ² CB)
A/D converter (ADCA)

33.1.2 Signal mask

The external signals of the V850E2/ML4 below are not affected by on-chip debugging because they can be masked. This microcontroller is controlled by the on-chip debugging unit.

- $\overline{\text{RESET}}$
- $\overline{\text{HLDRQ}}$
- $\overline{\text{WAIT}}$

33.2 Description

The following provides an overview of the on-chip debugging function.

(1) Debugging interface

This interface is used to communicate with the host machine by way of an on-chip debugging emulator by using $\overline{\text{TRST}}$, TCK, TMS, TDI, TDO, and $\overline{\text{TRDY}}$ signals.

(2) Debug monitoring function

If the monitor program stored in the memory area is executed and debugging is performed while the user-created program is stopped, the following basic debugging functions can be monitored:

- Downloading user-created programs
- Reading and writing memory and registers
- Executing user-created programs started from any address

(3) Hardware break function

Up to four break points for an instruction or data can be specified. If a break point for an instruction is specified, execution can be interrupted at a specified address. If a break point for data is specified, execution can be interrupted when data at a specified address is accessed.

The break conditions can be combined by using up to two level sequences.

(4) Software break function

Execution of a user-created program stored in RAM can be interrupted at a specified address.

(5) Forced break function

Execution of a user-created program can be forcibly interrupted.

(6) Forced reset function

The microcontroller can be forcibly reset.

(7) Real-time RAM monitor (RRM)

The memory can be read during program execution. Because this read access uses the DMA dedicated to debugging, the effects on program execution can be minimized.

(8) Dynamic memory modification (DMM)

The memory can be written during program execution. Because this write access uses the DMA dedicated to debugging, the effects on program execution can be minimized.

(9) Timer function

A 32-bit counter is used to measure the time to execute the user-created program based on the clock that is obtained by dividing the DCUTCK signal frequency by two.

(10) Mask function

Some external dedicated signals are not affected by on-chip debugging because they can be masked. This microcontroller is controlled by the on-chip debugging unit.

For a list of these signals, see “*Signal mask*” at the beginning of this chapter.

(11) Selection of whether to continue or stop peripheral module operation upon a break

The microcontroller’s modules perform one of the following operations when a break point is reached:

- Always stop operation upon a break
- Operation upon a break can be specified by using user options and the module emulation registers.
- Always continue operation upon a break

The operations above only apply to the corresponding modules.

(12) Hot attach function

When an on-chip debugging emulator is connected, debugging can be started without resetting the running CPU.

(13) Security function

A 96-bit ID code can be written to the microcontroller to prevent the contents of the flash memory from being read by unauthorized users. The flash memory cannot be accessed until the code entered by the user when the debugger is started matches the ID code written to the microcontroller. If “0” is specified for the last bit (bit 95), however, the flash memory cannot be accessed regardless of whether the entered code matches the specified ID code.

For details about how to specify an ID code, see the operation manual of the software tool used.

33.3 Connection with on-chip debug emulator

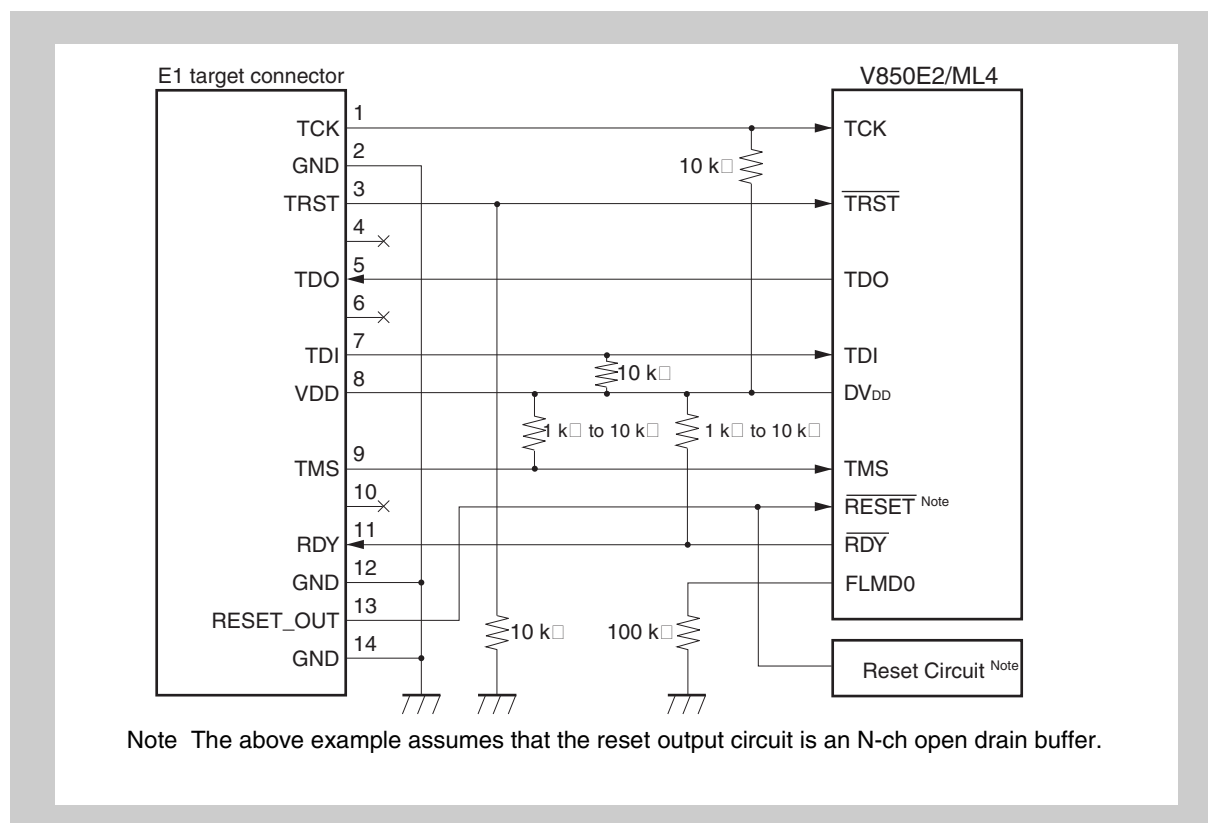

Figure 33-1 Connection with on-chip debug emulator

Table 33-3 Pins used for connection with on-chip debug emulator

Pin name	Description
VDD	Signal used to detect the power supply voltage of the target system and that of the buffer in the on-chip debug emulator
$\overline{\text{TRST}}$	Signal used to asynchronously reset the debugging function of the microcontroller
TCK	Clock signal used for debugging
TMS	Signal used to select data communication transfer mode
TDI	Data signal input to the microcontroller
TDO	Data signal output from the microcontroller
$\overline{\text{TRDY}}$	Synchronization signal for data communication
$\overline{\text{RESET}}$	Reset signal for the microcontroller. When this pin is connected, the microcontroller retains the reset status until the system is turned on and the debugger starts.
FLMD0	Mode signal used to rewrite the flash memory of the microcontroller

33.4 Cautions on Using On-chip Debugging

(1) Usage of devices used for debugging

Do not mount a device that was used for debugging onto a mass-produced product, because the flash memory was rewritten during debugging and the number of rewrites of the flash memory cannot be guaranteed.

Chapter 34 Target Electrical Specifications

34.1 Absolute Maximum Ratings

$T_A = 25^\circ\text{C}$

Item	Symbol	Conditions	Rating	Unit
Power supply	IV_{DD}	IV_{DD} pin	-0.5 to +1.6	V
	EV_{DD}	EV_{DD} pin	-0.5 to +4.1	V
	$OSCV_{DD}$	$OSCV_{DD}$ pin	-0.5 to +4.1	V
	$OSCV_{SS}$	$OSCV_{SS}$ pin	-0.5 to +0.5	V
	$PLLV_{DD}$	$PLLV_{DD}$ pin	-0.5 to +1.6	V
	$PLLV_{SS}$	$PLLV_{SS}$ pin	-0.5 to +0.5	V
	AV_{DD}	AV_{DD} pin	-0.5 to +6.0	V
	AV_{SS}	AV_{SS} pin	-0.5 to +0.5	V
	UV_{DD}	UV_{DD} pin	-0.5 to +4.1	V
	DV_{DD}	DV_{DD} pin	-0.5 to +4.1	V
Input voltage	V_I	The X1 pin, 5 V tolerant pin ^a , and analog input pin ^b are excluded.	-0.5 to +4.1 ^c	V
		5-V tolerant pin ^a (except during output)	-0.5 to +6.0	V
Clock input voltage	V_K	X1 pin	-0.5 to $OSCV_{DD} + 0.5^d$	V
Low-level output current	I_{OL}	Per pin	10.0	mA
		Total of all pins	100	mA
Output current, high	I_{OH}	Per pin	-10.0	mA
		Total of all pins	-100	mA
Output voltage	V_O		-0.5 to $EV_{DD} + 0.5$	V
Analog input voltage	V_{WASN}	Analog input pin ^b $AV_{REFP} \leq AV_{DD}$ AV_{DD} must not exceed +0.3 V.	-0.3 to $AV_{REFP} + 0.3$	V
A/D converter reference input voltage	AV_{REFP}	Do not exceed 6.0 V.	-0.3 to $AV_{DD} + 0.3$	V
	AV_{REFM}		-0.3 to +0.3	V
Package surface temperature	T_t	Normal operation	-40 to +100	$^\circ\text{C}$
		During flash memory rewriting	-40 to +100	$^\circ\text{C}$
Storage temperature	T_{stg}		-65 to +150	$^\circ\text{C}$

- a) The 5-V tolerant pin is assigned to one of the following pin numbers: 154 to 157.
 b) The analog input pin is assigned to one of the following pin numbers: 124 to 129, 134 to 139.
 c) Do not exceed the absolute maximum rating of EV_{DD} (the MAX value).
 d) Do not exceed the absolute maximum rating of the $OSCV_{DD}$ pin (the MAX value).

- Cautions**
1. Do not connect the output (an I/O pin in the output status) of an IC product to a different output pin (including an I/O pin in the output status), and do not directly connect power supply pins such as IV_{DD} and EV_{DD} or GND pins. However, direct connection of the I/O pins between an IC product and an external circuit is possible, if the I/O pins can be set to the high-impedance state and the output timing of the external circuit is designed to avoid output conflict.
 2. Product quality might suffer if the absolute maximum rating is exceeded even momentarily for any parameter. That is, the absolute maximum ratings are the rated values at which the product is on the verge of suffering physical damage. Use the product so as to stay away from these rated values as much as possible. The ratings and conditions indicated for DC characteristics and AC characteristics represent the quality assurance range during normal operation.

34.2 Capacitance

($T_t = -40$ to 100°C , $IV_{DD} = PLLV_{DD} = EV_{DD} = UV_{DD} = OSCV_{DD} = DV_{DD} = AV_{DD} = V_{SS} = AV_{SS} = 0$ V)

Item	Symbol	Conditions	MIN.	TYP	MAX.	Unit
Input capacitance	C_I	fc = 1 MHz Unmeasured pins returned to 0 V			15	pF
I/O capacitance	C_{IO}				15	pF
Output capacitance	C_O				15	pF

34.3 Operating Conditions

Internal Operating Frequency (f_{XX})	Package Surface Temperature (T_t)	Power Supply Voltage (IV_{DD} , $PLLV_{DD}$, EV_{DD} , UV_{DD} , DV_{DD} , $OSCV_{DD}$, AV_{DD})
144 MHz to 200 MHz	-40 to $+100^\circ\text{C}$	$IV_{DD} = PLLV_{DD} = 1.2$ V \pm 0.1 V $EV_{DD} = UV_{DD} = OSCV_{DD} = DV_{DD} = 3.3$ V \pm 0.3 V $AV_{DD} = 3.3$ V \pm 0.3 V or 5.0 V \pm 0.5 V

34.4 Oscillator Characteristics

Item	Symbol	Conditions	MIN.	TYP.	MAX.	Unit
Oscillation frequency	f_x		7.2		10	MHz

34.4.1 Recommended resonator

Schmitt trigger input hysteresis width	V_T^+ - V_T^-		d	0.3	0.6		V

a) This is determined by the used pin function. For details, see 2.6?Pin Input Circuit Types?.

b) The 5-V tolerant pin is assigned to one of the following pin numbers: 154 to 157.

c) The port 8 pin is assigned to one of the following pin numbers: 124 to 129.

d) NMI, INTP0/ADTRG00, ADTRG10, INTP1/ADTRG20, INTP2/SCK1F, INTP3/SI1F, INTP4/ $\overline{\text{OCI}}$, UCLK, RXD0F, ADTRG01, ADTRG11, ADTRG21, SIOF, SCK0F, ESO0, ESO2, ESO3, RXD1, RXD1F

($T_t = -40$ to 100°C , $I_{V_{DD}} = \text{PLL}_{V_{DD}} = 1.1$ to 1.3 V, $E_{V_{DD}} = U_{V_{DD}} = \text{OSCV}_{V_{DD}} = D_{V_{DD}} = 3.0$ to 3.6 V, $A_{V_{DD}} = 3.0$ to 3.6 V or $A_{V_{DD}} = 4.5$ to 5.5 V, $V_{SS} = A_{V_{SS}} = \text{OSCV}_{V_{SS}} = \text{PLL}_{V_{SS}} = D_{V_{SS}} = 0$ V)

Item	Symbol	Conditions	MIN.	TYP.	MAX.	Unit
Output voltage, high	V_{OH1}	$I_{OH} = -3$ mA	$E_{V_{DD}} - 1.0$			V
	V_{OH2}	$I_{OH} = -100$ mA	$E_{V_{DD}} - 0.5$			V
Output voltage, low	V_{OL}	$I_{OL} = 3$ mA			0.4	V
Input leakage current, high	I_{LIH}	$V_I = E_{V_{DD}} = U_{V_{DD}} = \text{OSCV}_{V_{DD}} = D_{V_{DD}} = A_{V_{DD}}$			10	μA
Input leakage current, low	I_{LIL}	$V_I = 0$ V			-10	μA
Analog pin input leakage current	I_{LIAN}				± 10	μA
Internal pull-down resistance	R_L		20	40	100	$\text{k}\Omega$
Internal pull-up resistance	R_H		20	40	100	$\text{k}\Omega$

34.5.2 Power supply current

($T_t = -40$ to 100°C , $I_{V_{DD}} = \text{PLL}_{V_{DD}} = 1.1$ to 1.3 V, $E_{V_{DD}} = U_{V_{DD}} = \text{OSCV}_{V_{DD}} = D_{V_{DD}} = 3.0$ to 3.6 V, $A_{V_{DD}} = 3.0$ to 3.6 V or $A_{V_{DD}} = 4.5$ to 5.5 V, $V_{SS} = A_{V_{SS}} = \text{OSCV}_{V_{SS}} = \text{PLL}_{V_{SS}} = D_{V_{SS}} = 0$ V)

Item	Symbol	Conditions	MIN.	TYP.	MAX.	Unit
Power supply current	I_{DD}	Normal operation	$I_{V_{DD}} + \text{PLL}_{V_{DD}}$ pin		530	mA
	$E_{I_{DD}}$		$E_{V_{DD}} + \text{OSCV}_{V_{DD}} + U_{V_{DD}} + D_{V_{DD}}$ pin		a	mA
	I_{DDH}	While in the HALT status	$I_{V_{DD}} + \text{PLL}_{V_{DD}}$ pin		340	mA

- a) Keep the external power supply current ($E_{V_{DD}}$) at 100 mA or less, including the $E_{V_{DD}}$ current consumed internally.
The external power supply current ($E_{V_{DD}}$) includes the current running through internal flash memory.
- Current when internal flash memory is read: 24 mA max.
 - Current when internal flash memory is written or erased: 45 mA max.

Note Leave sufficient margins during power supply design.

34.6 AC Characteristics

34.6.1 AC measurement points

Figure 34-1 AC Test Input Measurement Points

Figure 34-2 AC Test Output Measurement Points

Figure 34-3 External Bus Access AC Test I/O Measurement Points

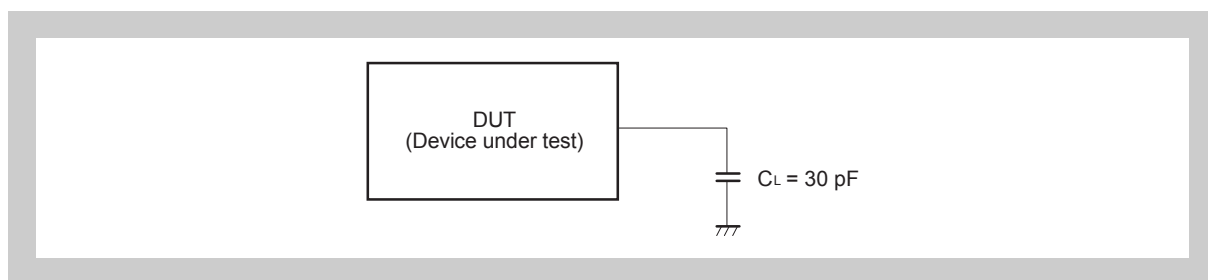

Figure 34-4 Load Condition

Caution If the load capacitance exceeds 30 pF due to the circuit configuration, bring the load condition of the device to 30 pF or less by inserting a buffer or by some other means.

34.6.2 External bus interface

(1) Memory controller, SRAM read access timing

H $\overline{\text{LDAK}}\downarrow$ delay time from H $\overline{\text{LDRQ}}\uparrow$	t_{DHQHA2}	$1.5f_{\text{CLK}}$		ns

Note f_{CLK} : Internal system clock

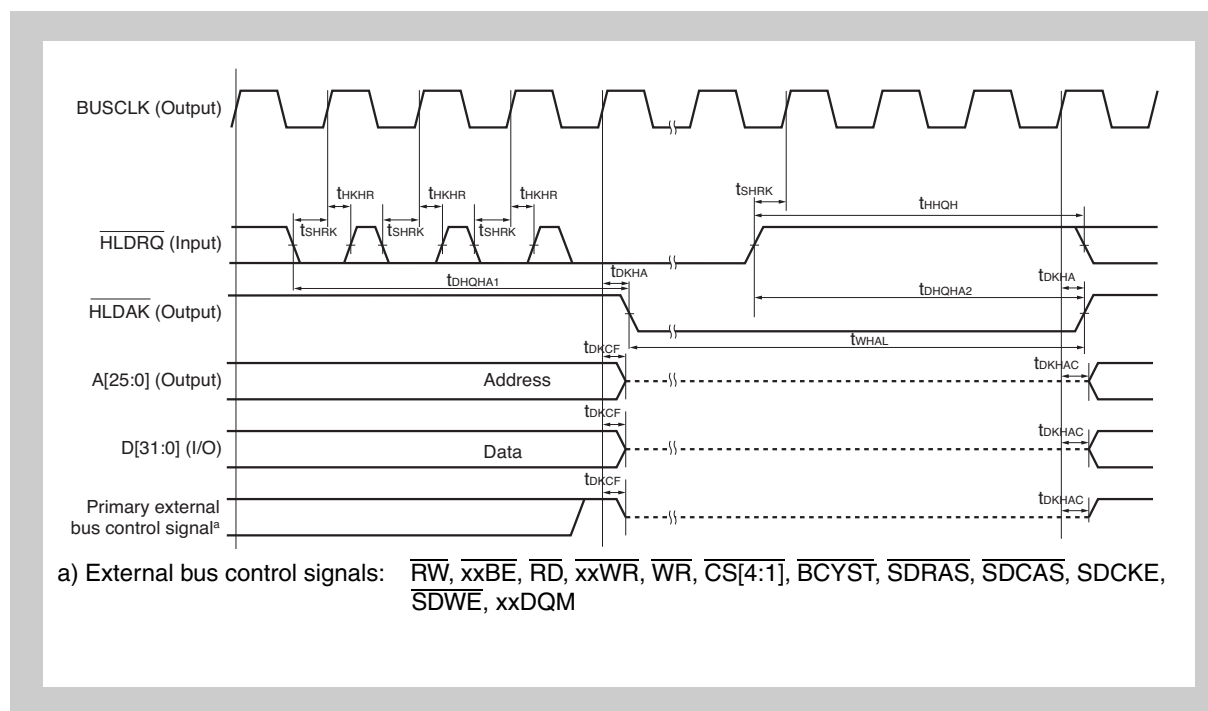

Figure 34-12 Memory Controller, Bus Hold Timing

34.6.3 Clock timing

($T_t = -40$ to 100°C , $IV_{DD} = PLLV_{DD} = 1.1$ to 1.3 V, $EV_{DD} = UV_{DD} = OSCV_{DD} = DV_{DD} = 3.0$ to 3.6 V, $AV_{DD} = 3.0$ to 3.6 V or $AV_{DD} = 4.5$ to 5.5 V, $V_{SS} = AV_{SS} = OSCV_{SS} = PLLV_{SS} = DV_{SS} = 0$ V)

Item	Symbol	Conditions	MIN.	MAX.	Unit
CPU operating frequency			144	200	MHz
BUSCLK output cycle	t_{BCYK}	SRAM mode	15		ns
		SDRAM mode	20		ns
BUSCLK high-level width	t_{BWKH}	During PLL operation when $m = 3, 4,$ or 6^a	$m \times 1000 \times 0.4/200$	$m \times 1000 \times 0.6/144$	ns
BUSCLK low-level width	t_{BWKL}	During PLL operation when $m = 3, 4,$ or 6^a	$m \times 1000 \times 0.4/200$	$m \times 1000 \times 0.6/144$	ns
BUSCLK rising edge width	t_{BKR}			5	ns
BUSCLK falling edge width	t_{BKF}			5	ns

- a) During the reset period, the main clock oscillator output is output from the BUSCLK pin. During the reset period, be careful of the duty factor for the BUSCLK pin.

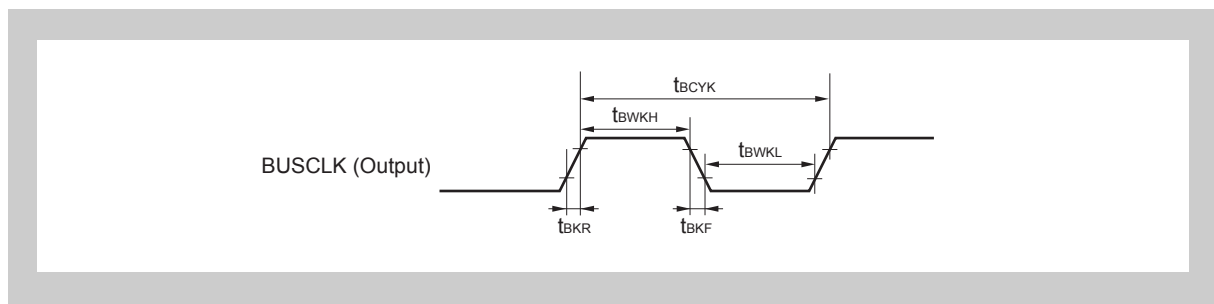

Figure 34-13 Clock Timing

34.6.4 Reset timing

($T_t = -40$ to 100°C , $IV_{DD} = PLLV_{DD} = 1.1$ to 1.3 V, $EV_{DD} = UV_{DD} = OSCV_{DD} = DV_{DD} = 3.0$ to 3.6 V, $AV_{DD} = 3.0$ to 3.6 V or $AV_{DD} = 4.5$ to 5.5 V, $V_{SS} = AV_{SS} = OSCV_{SS} = PLLV_{SS} = DV_{SS} = 0$ V)

Item	Symbol	Conditions	MIN.	MAX.	Unit
$\overline{\text{RESET}}$ high-level width	t_{WRSH}		500		ns
$\overline{\text{RESET}}$ low-level width	t_{WRSL}	When the power is on	$500 + t_{\text{OSC}}$		ns
		When the power is not on	500		ns

Note t_{OSC} : Main clock oscillation stabilization time (differs depending on the used oscillator)

b) This is the conversion time for only the analog portion. The conversion time specified for the ADCAnCTL1.ADCAnFR[3:0] bits is the value that results when the time it takes to transfer to the A/D controller is added.

Caution Make sure to turn on the amplifier power when using the channel S/H circuit.

34.7 Sequences for Turning the Power Supply On or Off

There are recommended procedures for turning the power supply on or off.

($T_t = -40$ to 100°C , $IV_{DD} = PLLV_{DD} = 1.1$ to 1.3 V, $EV_{DD} = UV_{DD} = OSCV_{DD} = DV_{DD} = 3.0$ to 3.6 V, $AV_{DD} = 3.0$ to 3.6 V or $AV_{DD} = 4.5$ to 5.5 V, $V_{SS} = AV_{SS} = OSCV_{SS} = PLLV_{SS} = DV_{SS} = 0$ V)

Item	Symbol	Conditions	MIN.	TYP.	MAX.	Unit
Delay from when the internal power supply rises until the external power supply rises Rising delay time	t_{DVIE}		0			s
Delay from when the external power supply rises until the ADC power supply rises Rising delay time	t_{DVEA}		0			s
Delay from when the ADC power supply rises until $\overline{\text{RESET}}\uparrow$ Delay time	t_{DVAR}		$t_{OSC} + 500$			ns
Delay from when $\overline{\text{RESET}}\downarrow$ until the ADC power supply falls Delay time	t_{DVRA}		500			ns
Delay from when the ADC power supply falls until the external power supply falls Falling delay time	t_{DVAE}		0			ns
Delay from when the external power supply falls until the internal power supply falls Falling delay time	t_{DVEI}		0			ns

Note t_{OSC} : Main clock oscillation stabilization time (differs depending on the used oscillator)

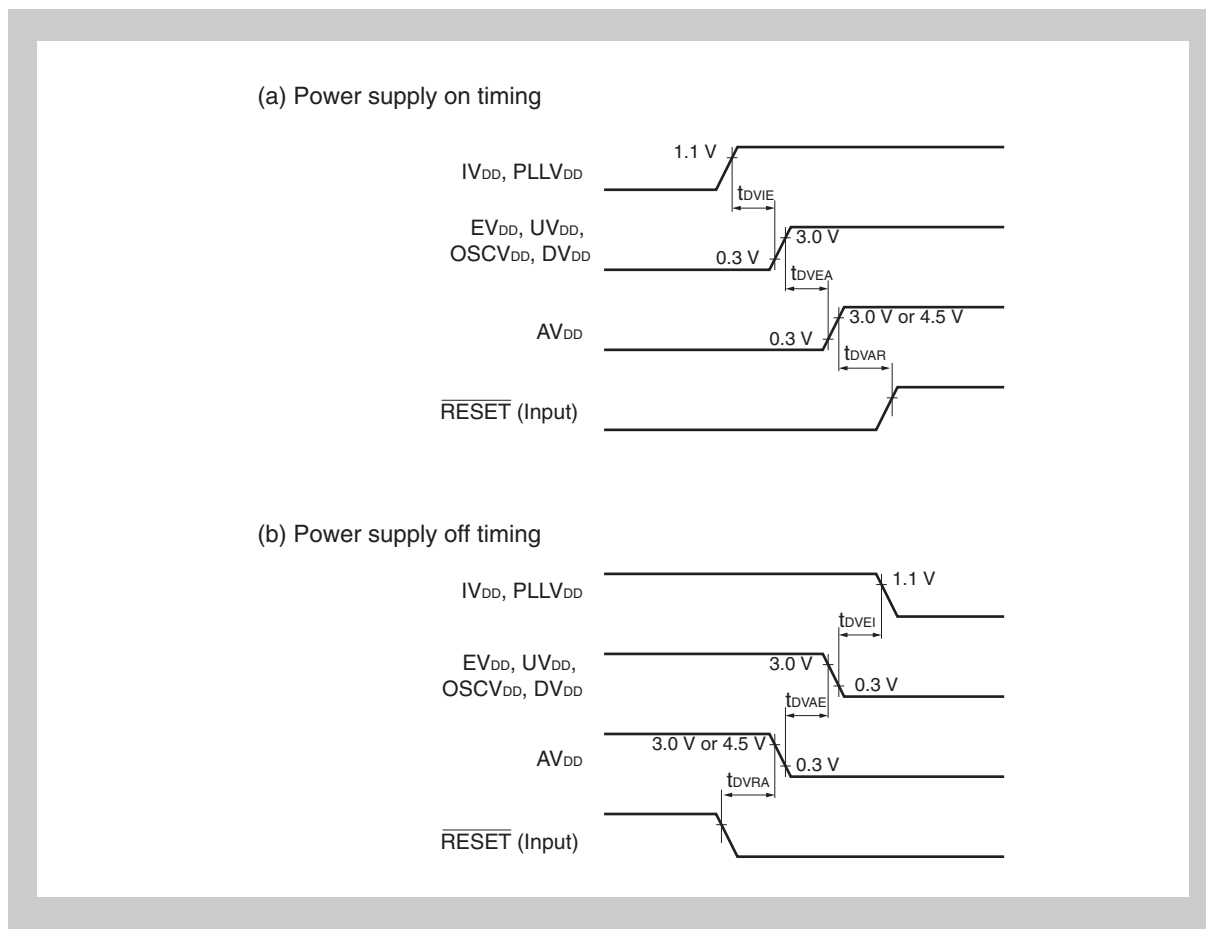

Figure 34-24 Timing of the Sequences for Turning the Power Supply On and Off

Caution The V850E2/ML4 has two power supply pins: IV_{DD} for internal units and EV_{DD} for external pins. The I/O status of the pins might be undefined outside the guaranteed operation range.

34.8 Flash Memory Programming Mode

(1) Basic characteristics

($T_t = -40$ to 100°C , $IV_{DD} = PLLV_{DD} = 1.1$ to 1.3 V, $EV_{DD} = UV_{DD} = OSCV_{DD} = DV_{DD} = 3.0$ to 3.6 V, $AV_{DD} = 3.0$ to 3.6 V or $AV_{DD} = 4.5$ to 5.5 V, $V_{SS} = AV_{SS} = OSCV_{SS} = PLLV_{SS} = DV_{SS} = 0$ V)

Item	Symbol	Conditions	MIN.	TYP.	MAX.	Unit
Number of rewrites	C_{ERWR}	One erasure + one post-erasure write = one rewrite ^a	100	100	100	Times/block

- a) When initially writing to a shipped product, both erasures followed by writes and writes alone are counted as rewrites. Example P: Write, E: Erasure
 Shipped product → E → P → E → P → E → P: Three rewrites
 Shipped product → E → P → E → P → E → P: Three rewrites

Chapter 36 Recommended Soldering Conditions

The V850E2/ML4 should be soldered and mounted under the following recommended conditions.

For technical information, see the following website.

Semiconductor Device Mount Manual (<http://www.renesas.com/products/package/manual/index.jsp>)

Table 36-1. Surface Mounting Type Soldering Conditions

- (1) μ PD70F4021GM-GBY-AX
 μ PD70F4022GM-GBY-AX

Soldering Method	Soldering Conditions	Recommended Condition Symbol
Infrared reflow	Package peak temperature: 250°C, Time: 60 seconds max. (at 220°C or higher), Count: Three times or less, Exposure limit: 7 days ^a (after that, prebake at 125°C for 10 to 72 hours)	IR50-107-3
Partial heating	Pin temperature: 350°C max., Time: 3 seconds max. (per pin row)	-

a) After opening the dry pack, store it at 25°C or less and 65% RH or less for the allowable storage period.

Caution Do not use different soldering methods together (except for partial heating).

- Notes**
1. The V850E2/ML4 is a lead-free product.
 2. For soldering methods and conditions other than those recommended above, please contact a Renesas Electronics sales representative.

		p.1871	Modification of Initial value, Attribute to 29.4.1 (5) ETHA0CLRT - Collision register.
		p.1872	Modification of Initial value, Attribute to 29.4.1 (6) ETHA0LMAX - Maximum packet length register.
p.1873	Modification of Initial value, Attribute to 29.4.1 (7) ETHA0LSA1 - Station address register 1		
p.1875	Modification of Initial value, Attribute to 29.4.1 (9) ETHA0PTVR - Pause timer value read register.		
p.1876	Modification of Initial value, Attribute to 29.4.1 (10) ETHA0VLTP - VLAN type register.		
p.1877	Modification of Initial value, Attribute to 29.4.1 (11) ETHA0AFR - Address filter register.		

Rev.	Date	Description	
		Page	Summary
0.02	Mar 26, 2012	p.1880	Modification of Initial value, Attribute to 29.4.1(14) ETHA0CAR1 - Carry register 1.
		p.1882	Modification of Initial value, Attribute to 29.4.1 (15) ETHA0CAR2 - Carry register 2.
		p.1884	Modification of Initial value, Attribute to 29.4.1 (16) ETHA0CAM1 - Carry mask register 1.
		p.1886	Modification of Initial value, Attribute to 29.4.1 (17) ETHA0CAM2 - Carry mask register 2.
		p.1927	Modification of Initial value, Attribute to 29.4.3 (1) ETHA0MFFCONT - FIFO controller control register.
		p.1929	Modification of Initial value, Attribute to 29.4.3 (2) ETHA0RSTCNT - Software reset control register.
		p.1930	Modification of Initial value, Attribute to 29.4.3 (3) ETHA0FLOWTH - Flow control threshold value register.
		p.1932	Modification of Initial value, Attribute to 29.4.3 (5) ETHA0RXERSEL - Receive error selection register.
		p.1934	Modification of Initial value, Attribute to 29.4.3 (6) ETHA0TXSTMONI1 - Transmission status monitor 1 register.
		p.1936	Modification of Initial value, Attribute to 29.4.3 (8) ETHA0TXFINF1 - Transmission status 1 register.
		p.1937	Modification of Initial value, Attribute to 29.4.3 (9) ETHA0TXFINF2 - Transmission status 2 register.
		p.1940	Modification of Initial value, Attribute to 29.4.3 (11) ETHA0RXFINF1 - Reception status 1 register.
		p.1941	Modification of Initial value, Attribute to 29.4.3 (12) ETHA0RXFINF2 - Reception status 2 register
		p.1942	Modification of Initial value, Attribute to 29.4.3 (13) ETHA0RXFINF3 - Reception status 3 register.
		p.1943	Modification of Initial value, Attribute to 29.4.3 (14) ETHA0FSTATUS - FIFO status interrupt register.
		p.1945	Modification of Caution, Initial value, Attribute to 29.4.3 (15) ETHA0FSTATMK - FIFO status interrupt mask register.
		p.1946	Modification of Initial value, Attribute to 29.4.3 (16) ETHA0TXSTATUS - Transmission status interrupt register.
		p.1948	Modification of Initial value, Attribute to 29.4.3 (17) ETHA0TXSTATMK - Transmission status interrupt mask register.
		p.1949	Modification of Initial value, Attribute to 29.4.3 (18) ETHA0RXSTATUS - Reception status interrupt register.
		p.1951	Modification of Initial value, Attribute to 29.4.3 (19) ETHA0RXSTATMK - Reception status interrupt mask register.
p.1953	Modification of Initial value, Attribute to 29.4.3 (20) ETHA0TXABTCNT - TX abort counter.		
p.1954	Modification of Initial value, Attribute to 29.4.3 (21) ETHA0RXABTCNT - RX abort counter.		
p.1955	Modification of Initial value, Attribute to 29.4.4 (1) ETHA0MODE - Core function control register.		
p.1956	Modification of Initial value, Attribute to 29.4.4 (2) ETHA0INTMS - Interrupt control register.		

Rev.	Date	Description	
		Page	Summary
0.02	Mar 26, 2012	p.1958	Modification of Initial value, Attribute to 29.4.4 (3) ETHA0TRANSCTL - Transfer control register.
		p.1959	Modification of Initial value, Attribute to 29.4.4 (4) ETHA0SFTRST - Software reset setting register.
		p.1960	Modification of Initial value, Attribute to 29.4.4 (5) ETHA0DMACM - DMA mode control register.
		p.1965	Modification of Initial value, Attribute to 29.4.5 (1) ETHA0CMODE - Transmit checksum unit function setting register.
		p.1966	Modification of Initial value, Attribute to 29.4.5 (2) ETHA0CINTMS - Transmit checksum interrupt register
		p.1968	Modification of Initial value, Attribute to 29.4.5 (3) ETHA0CTRANSCTL - Transmit checksum transfer control register
		p.1969	Modification of Initial value, Attribute to 29.4.5 (4) ETHA0CSFTRST - Transmit checksum software reset register.
		p.1970	Modification of Initial value, Attribute to 29.4.5 (5) ETHA0CDMACM - Transmit checksum DMAC control mode setting register.
		p.1993	Modification of Initial value, Attribute to 29.5.6 (1) (b) Filtering of multicast addresses.
		p.2026	Addition of Caution to 31.2.1 Communication method.
		p.2029	Addition of Caution to 31.4.2 (1) Single-wire asynchronous serial programming interface: One-wired UART.
		p.2037	Addition of Caution to 31.5 Flash Memory Self Programming.
		p.2059	Modification of 34.5.1 Pin characteristics.
		p.2060	Modification of 34.5.2 Power supply current.
		p.2075	Modification of 34.6.3 Clock timing.
		p.2080	Modification of 34.6.9 (1) CSIH0 (8.33 Mbps ($f_{XX} = 200$ MHz): While in the master mode).
		p.2082	Modification of 34.6.9 (3) CSIH1 (8.33 Mbps ($f_{XX} = 200$ MHz): While in the master mode).
		p.2084	Modification of Figure 34-18 CSIH Timing.
		p.2090	Modification of 34.6.13 (2) Reception interface.
		p.2092	Modification of 34.6.14 (1) Normal operation (ANI00 to ANI11).
p.2093	Modification of 34.6.14 (2) When using the channel sample & hold circuit (ANI00 to ANI05)		
p.2094	Modification of 34.6.15 (1) Normal operation (ANI00 to ANI11).		
p.2095	Modification of 34.6.15 (2) When using the channel sample & hold circuit (ANI00 to ANI05)		
p.2099	Modification of Chapter 35 Package Drawing		
1.00	Aug 24, 2012	p.76	Modification of Table 2-6 Default States and Recommended Connection of Unused Pins.
		p.160	Modification of Table 8-32 List of port pins and alternative functions for port groups 0 to 7.
		pp.183, 184, 191, 192, 195	Modification of Table 8-37 Register setting for each pin function.
		p.214	Modification of Figure 8-8 Digital filter block diagram.

Rev.	Date	Description	
		Page	Summary
1.00	Aug 24, 2012	pp.215, 216	Modification of 8.5.2 (2) (a) Digital filter function.
		p.221	Modification of Table 8-48 DNFACTL register contents.
		p.431	Modification of Table 11-19 Data flow during halfword access (little endian).
		p.432	Modification of Table 11-20 Data flow during halfword access (big endian).
		p.1379	Addition of Caution to 24.2.2 Configuration.
		p.1404	Modification of Caution, Note to 24.5.2 (2) (a) FCNnCMCLCTL read.
		p.1490	Addition of Figure 24-27 ABT transmission request abort processing (in normal operation mode with ABT) (2).
		p.1491	Modification of Figure 24-28 ABT transmission request abort processing (normal operation mode with ABT) with transmission completely finished flag.
		p.2053	Modification of Figure 32-1 Connection with on-chip debug emulator.
		p.2057	Modification of 34.4.1 Recommended resonator.
		p.2091	Modification of 34.6.14 (1) Normal operation (ANI00 to ANI11).
		p.2092	Modification of 34.6.14 (2) When using the channel sample & hold circuit (ANI00 to ANI05).
		p.2093	Modification of 34.6.15 (1) Normal operation (ANI00 to ANI11).
		p.2094	Modification of 34.6.15 (2) When using the channel sample & hold circuit (ANI00 to ANI05).
p.2099	Addition of Chapter 36 Recommended Soldering Conditions		
2.00	Feb 28, 2013	Through out	Change of the following function names <ul style="list-style-type: none"> • $\overline{\text{DRST}} \rightarrow \overline{\text{TRST}}$ • DCK \rightarrow TCK • DDI \rightarrow TDI • DDO \rightarrow TDO • DMS \rightarrow TMS
		p.214	Modification of Figure 8-8 Digital filter block diagram.
		p.219	Modification of Control for digital filters to 8.5.1(3) (a) FCLAnCTLm – Filter control register.
		p.219	Modification of Table 8-46 FCLAnCTLm register contents for digital filters.
		p.2092	Modification of 34.6.14 (2) When using the channel sample & hold circuit (ANI00 to ANI05).
		p.2093	Modification of 34.6.15 (1) Normal operation (ANI00 to ANI11).
		p.2094	Modification of 34.6.15 (2) When using the channel sample & hold circuit (ANI00 to ANI05).

Rev.	Date	Description	
		Page	Summary
3.00	Sep 15, 2014	p.82	Modification of 4.4.1 CPU address space.
		p.83	Modification of 4.4.2 (1) Program space.
		p.83	Modification of Figure 4-3 Program space wraparound.
		pp.231, 232	Modification of Table 9-5 EI level maskable interrupt requests.
		p.375	Addition of Caution to 10.13.3 DTSSELM (m = 0 to 11): DTS transfer end interrupt select register.
		p.523	Addition of Caution to 12.16.4 (2) Equations.
		p.588	Addition of Caution to 12.20.3 (2) Equations.
		p.825	Addition of Caution to 13.15.4 (2) Equations.
		p.835	Addition of Caution to 13.16.1 (2) Equations.
		p.1068	Modification of Figure 20-4 Processing flow after interrupt generation.
		p.1394	Modification of Table 24-5 FCNn interrupt requests.
		p.1485	Modification of 24.13.1 Baud rate setting conditions.
p.1621	Modification of 27.5 (1) Clock accuracy.
