

## µPD6464, 6465 On-Screen Character Display

Application Note	December 1997
Introduction	This application note describes how to use the $\mu$ PD6464 or $\mu$ PD6465 on-screen display with a $\mu$ PD784026 8/16-bit microcontroller. (In this document, $\mu$ PD646x means $\mu$ PD6464 or $\mu$ PD6465.)
	<b>Note:</b> If there are any questions regarding this application note, please contact Technical Support at (800) 366-9782 for help.
	NEC builds CMOS LSIs that create character displays to accompany pictures on televisions, VCRs, and camera monitors. An on-screen character display device consists of a clock oscillator circuit that generates clocks in synchronization with TV signals, a character ROM that stores character data, a video RAM, and a circuit that controls the output of display data and backgrounds.
	These CMOS LSI devices can overlay video information on top of an incoming video signal (from a VCR, for example), or they can generate the needed horizontal (Hsync) and vertical (Vsync) synchronizing pulses from an internal clock source.
	The $\mu$ PD6464 displays 128 different characters including lower-case and upper-case alphanumeric characters and character patterns such as Kanji, Hiragana, and Katakana. The $\mu$ PD6465 contains 256 different characters, which vary by mask code option.
	Each character consists of 12 horizontal dots by 18 vertical dots. Pictograms are made possible by combining two or more characters. The 12-line by 24-column display area can hold up to 288 characters. Four different character attributes can be selected with three blinking frequencies. If no external signal exists, the user can program the internal mode to generate the needed video signals with a blue, black, green, or white screen background.
	Video RAM data is cleared by a video RAM clear command and the power-on clear functions. Both capabilities have been included in the device to mitigate the workload of the host microcontroller. The device also has a separation circuit for composite signal synchronization and a x4 multiplier. This circuit eliminates the need to connect an external separator IC and a crystal resonator, reducing the mounting area and total cost. Although the IC has an internal sync separation circuit, the user must strip Hsync and Vsync and combine them into a composite sync signal (C-sync).
Using the µPD646x	The on-screen display has a three-line serial interface to receive commands and data from a microcontroller. The $\mu$ PD646x uses 8-bit and 16-bit instructions to perform all of its functions.
	Figure 1 is a schematic of the $\mu$ PD646x configured in the internal mode. The color background is generated internally, overlaid with on-screen character data and then driven out of the $\mu$ PD646x at the Video Out jack. The NRE pin (pin 20) performs noise reduction.
	Figure 2 is a schematic of the $\mu$ PD646x configured in the external mode. The top left portion of the schematic shows the video input circuit that clamps the composite video input signal to the proper level. The input signal consists of the negative synchronization signals (Hsync/Vsync) and positive video signals. In the external

mode, the user must strip Hsync and Vsync from the external source using the sync separation circuit shown on the top middle portion of the schematic in Figure 2. These two signals must be combined into a composite sync signal (C-sync) that drives pin 17.

A sync separator chip such as the EL4581C from Elantec can also be used instead of the discrete sync separation circuit. The EL4581C chip extracts timing information from the standard video sync signals found in NTSC, PAL, and SECAM broadcast systems. Figure 3 shows how the EL4581C could be combined with the circuit in Figure 2. Please be advised that this circuit was not tested during the making of this application note.

The LC oscillator shown on the lower middle side of the schematic (pins 5 and 6) generates the character dot clock. When no character is displayed, LC oscillation can be stopped with the display control command to reduce power consumption. Remember that data cannot be written to the video RAM with the oscillation stopped. To write data to the video RAM, be sure to turn ON the LC oscillation.

The lower-right side of the schematic contains the crystal oscillator (pins 11 and 12) for sync pulse generation. The  $\mu$ PD646x uses this oscillator to generate internal NTSC or PAL dot clocks. If the user is operating in external mode and an external sync source generates the needed video input signal, this crystal oscillator is not required. In this application note, the NTSC protocol was fixed by connecting the crystal oscillator on pins 11 and 12. For demonstration purposes, our software initialized the  $\mu$ PD646x for NTSC. If your application requires the ability to switch between NTSC/PAL/SECAM, you must use the external oscillator circuitry shown in Figure 8.

Note that all the PNP transistors shown in Figures 1, 2, and 3 are 2N3906s and all the NPN transistors are 2N3904s.

### Programming the µPD646x

The  $\mu$ PD646x is programmed with commands sent serially from a PC or microcontroller to the serial data input. Commands must be transmitted with the most significant bit first. The command bit stream is not RS-232-compatible because it requires a companion clock. Serial transfer is begun by making the chip select input low. The data presented to the  $\mu$ PD646x through the serial data input is shifted into its buffer each time the CLK input transitions from a low to a high level (see Figure 4). After eight clocks, the CLK input must go high and remain there for the minimum highlevel width of 400 ns. Afterward, the clock pattern can start again to input another command or character.

Transferring a two-byte command is similar to a one-byte command except that when

transferring a two-byte command, you must keep the chip select input  $\overline{(CS)}$  low during the transmission of both bytes.

Figure 4. µPD646x One-Byte Command (MSB-first)

Figure 5. µPD646x Programming Flow Chart

97YL-0269C (10/97)

## Internal Mode of the µPD646x

The  $\mu$ PD646x can be programmed for internal mode as well as external mode. In the internal mode, characters are output in sync with the video signal internally created by the IC. When programming the  $\mu$ PD646x, the first instruction should be a video RAM batch clear command (see Figure 5). This command clears all the character data in the video RAM buffer.

The next command in the flow chart is the display position control command that defines the vertical and horizontal starting positions on the screen. This position is relative to the first pixel on the TV and it defines the point where the block of data in video RAM will start to be displayed on the TV or monitor. For example, start location 0,0 would locate the screen display in the upper-left corner of the TV screen. Row and

	column positions greater than 0,0 will move the displayed block of characters toward the lower-right side of the screen.
	The character size, a two-byte command, is the next command to be sent serially. Select the video signal, NTSCor PAL, depending on the video protocol of your country. Select internal mode and turn ON the XOSC oscillation. Set the OSC crystal oscillation to quadruple oscillation, and choose the color of the internal video generated by the $\mu$ PD646x.
	Define the character attributes and the output level that controls the luminance of both the character and background. Using the display control command, turn ON both the display and the LC oscillation and, if you want blinking characters, choose the blinking frequency with this command.
	Use the write address control command to send the starting line and column addresses that define where the character data will begin display within the 12 line by 24 column display area. This command differs from the previous display position command that defined the starting vertical and horizontal positions on the screen. If a new line and column address is not sent with each character, the µPD646x will automatically write new characters into sequential locations in the video buffer. For a sample internal mode program, please see the Appendix.
External Mode of the µPD646x	In external mode, character data is overlaid on a video signal created from an external source such as a VCR. When programming the $\mu$ PD646x, it is recommended that the user follow the same four beginning steps as in the internal mode. (See Figure 5.) Afterward, set the video signal to external mode and turn on the crystal oscillation.
	Next, define the character attributes and the output level that controls the luminance of both the character and background. Using the display control command, turn ON both the display and the LC oscillation and if you want blinking characters, choose the blinking frequency with this command.
	Use the write address control command to send the starting line and column addresses that define where the character data will begin to display within the 12-line by 24-column display area. If a new line and column address is not sent with each character, the $\mu$ PD646x will automatically write new characters into sequential locations in the video buffer. For a sample external mode program, please see the Appendix.
Contiguous Command of the µPD646x	The µPD646x is programmable to display characters on the screen using the contiguous command instead of a single two-byte transfer command. The contiguous command is a successive command that is used when characters are to be displayed sequentially on the display area of the screen using the same character attributes. If the characters are not in succession or if the character attributes change, then the two-byte display character control command must be used instead of the contiguous command.
	The display character control command is a two-byte command that specifies the character data and character attributes to be written to the video RAM. If character data is sequentially written without a change in character attributes, the second character and those that follow can be abbreviated to the lower 8 bits (D7 to D0). Then only the lower byte needs to be transferred to display the character. In this case, the write column address is automatically incremented.
	To use the contiguous command, transfer the first byte (the display character control command) once and then transfer data bytes of the subsequent characters to be displayed. After the last byte is transferred, send an end code command or terminate

the two-byte contiguous command by making the chip select ( $\overline{CS}$ ) go high. Although only one of these two is necessary to terminate the contiguous command, both are recommended as a countermeasure against noise. Observe that the  $\mu$ PD6464 and  $\mu$ PD6465 have different end code commands. For a sample program using the contiguous command, please see the Appendix.

FAQs

Q Is the C-sync signal a combination of the horizontal and vertical sync pulses?

- A. Yes. The µPD646x has a sync separator that gives Hsync and Vsync out of the C-sync input.
- Q. What is the fsc signal input?
- A. Through an on-chip x4 multiplier, the fsc signal generates the 4fsc signal used in the sync signal separation circuit for external mode and in the sync signal generator for internal video signals. The x4 multiplier eliminates the need for crystal resonator, and in turn reduces the mounting area and the total cost. However, if you don't use the multiplier, you can use the crystal resonator set on quadruple oscillation in the crystal select control command. The crystal resonator application circuit. (Figure 6) can generate a fixed NTSCor PAL dot clock (4fsc) without the fsc input data pin 9.

### Figure 6. Crystal Resonator Circuit

97YL-0270C (10/97)

### Q. What configuration should be used if fsc is input from an external source?

A. The fsc is required to sync up the LC oscillator (VCO) phase (See Figure 7). It connects 4fsc from the VCO through a phase detector. Varactor diode VD is used for phase-locking between fsc, the color carrier signal, and 4fsc generated by the VCO. In NTSC mode, fsc is 3.579545 MHz and 300 mVp-p. The 100k-ohm resistor is used to control the capacitance of VD. If the device is used for NTSC application only, you can combine the two capacitors on the XOSI input for a total of65 pF.

Figure 7. Phase-Locking 4fsc to fsc

With a transistor to switch ON/OFF the 47-pF capacitor on XOSI, then the circuit shown in Figure 8 can be used to switch between NTSC and PAL with fsc for sync. (This circuit is the same as shown in the application circuit diagram of the  $\mu$ PD646x data sheet, document no. IC-3567.)

Figure 8. Switching Between NTSC and PAL

- Q. Why does NEC claim that µPD646x has a built-in sync separator if the design engineer must strip off the C-sync signal with an external circuit?
- A. The internal sync separator gives you Hsync and Vsync out of C-sync. The design engineer still needs to use an external sync separation circuit as shown on the top middle portion of the schematic in Figure 2 of this application note to get C-sync from the composite input.
- Q. If you do not use SECAM, how do you connect the SECAM pin?
- A. SECAM method can be selected using the video signal method control command. If you are not using SECAM, you can connect the pin to V<sub>DD</sub>, GND, or leave it open.

### APPENDIX

This Appendix contains three program examples written in assembly language to demonstrate the µPD646x software commands. In the setup, the µPD646x is controlled by a 78K4 microcontroller evaluation board (DDB-K4026) connected to a PC via the parallel port.

Figure A-1. This internal mode example fills the screen with the letters NEC and then displays blinking NECs in the corners and the middle of the screen.

Figure A-2. This external mode example executes a scrolling effect at the bottom of the screen while displaying NEC CORP.

Figure A-3. This external mode example shows how to use the contiguous commands of the  $\mu$ PD646x.

RET

## 

;This routine executes 24 times for the 24 columns of the display area.

;Each "NEC CORP." message, will be printed starting at every consecutive column. However the current ;letter "N" will be erased before repeating the message starting at the next consecutive column. This ;procedure mimics the scrolling effect. When the characters disappear at the end of line 11, the ;following character in the message is displayed at the beginning of line 11 obtaining a wrap around ;effect.

#### SCROLL\_ADD:

Some of the information contained in this document may vary from country tocountry. Before using any NEC product in your application, please contact a representative from the NEC office in your country to obtain a list of authorized representatives and distributors who can verify the following:

- Device availability
- Ordering information
- Product release schedule
- Availability of related technical literature
- Development environment specifications (for example, specifications for third-party tools and components, host computers, power plugs, AC supply voltages, and so forth)
- Network requirements

In addition, trademarks, export restrictions, and other legal issues may also vary from country to country.

No part of this document may be copied or reproduced in any form or by any means without the prior written consent of NEC Corporation. NEC Corporation assumes no responsibility for any errors which may appear in this document. NEC Corporation does not assume any liability for infringement of patents, copyrights or other intellectual property rights of third parties by or arising from use of a device described herein or any other liability arising from use of such device. No license, either express, implied or otherwise, is granted under any patents, copyrights or other intellectual property rights of NEC Corporation or others. While NEC Corporation has been making continuous effort to enhance the reliability of its semiconductor devices, the possibility of defects cannot be eliminated entirely. To minimize risks of damage or injury to persons or property arising from a defect in an NEC semiconductor device, customers must incorporate sufficient safety measures in its design, such as redundancy, fire-containment, and anti-failure features. NEC devices are classified into the following three quality grades: "Standard," "Special," and "Specific." The Specific quality grade applies only to devices developed based on a customer-designated "quality assurance program" for a specific application. The recommended applications of a device depend on its quality grade, as indicated below. Customers may check the quality grade of each device before using it in a particular application. Standard: Computers, office equipment, communications equipment, test and measurement equipment, audio and visual equipment, home electronic appliances, machine tools, personal electronic equipment and industrial robots. Special: Transportation equipment (automobiles, trains, ships, etc.), traffic control systems, anti-disaster systems, anticrime systems, safety equipment (not specifically designed for life support). Specific: Aircraft, aerospace equipment, submersible repeaters, nuclear reactor control systems, life support systems or medical equipment for life support, etc. The quality grade of NEC devices is "Standard" unless otherwise specified in NEC's data sheets or data books. If customers intend to use NEC devices for applications other than those specified for Standard quality grade, they should contact an NEC sales representative in advance.

In North America: No part of this document may be copied or reproduced in any form or by any means without the prior written consent of NEC Electronics Inc. (NECEL). The information in this document is subject to change without notice. All devices sold by NECEL are covered by the provisions appearing in NECEL Terms and Conditions of Sales only. Including the limitation of liability, warranty, and patent provisions. NECEL makes no warranty, express, statutory, implied or by description, regarding information set forth herein or regarding the freedom of the described devices from patent infringement. NECEL assumes no responsibility for any errors that may appear in this document. NECEL makes no commitments to update or to keep current information contained in this document. The devices listed in this document are not suitable for use in applications such as, but not limited to, aircraft control systems, aerospace equipment, submarine cables, nuclear reactor control systems and life support systems. "Standard" quality grade devices are recommended for computers, office equipment, communication equipment, test and measurement equipment, machine tools, industrial robots, audio and visual equipment, and other consumer products. For automotive and transportation equipment, traffic control systems, anti-disaster and anti-crime systems, it is recommended that the customer contact the responsible NECEL salesperson to determine the reliability requirements for any such application and any cost adder. NECEL does not recommend or approve use of any of its products in life support devices or systems or in any application where failure could result in injury or death. If customers wish to use NECEL devices in applications not intended by NECEL, customer must contact the responsible NECEL sales people to determine NECEL's willingness to support a given application.
