Pin Name	Input / Output	Voltage (V)	I/O Power Group	Initial Value*7	I/O Type	Pin State when not in Use
VDD1218_I3C	—	1.2/1.8	—	—	—	Open*6
VDD18_PWC	—	1.8	—	—	—	Always in use
V_{SS}	—	—	—	—	—	Always in use

Note 1. This voltage is the IO buffer voltage. The amplitude is different between LP (low power) mode and HS (high speed) mode. For details, refer to the *MIPI Alliance Specification for D-PHY Version 1.2*.

Note 2. Pull-up or pull-down resistors are integrated in the IO buffers. For the resistance values, refer to the DC characteristics in **Section 3, Electrical Characteristics**.

Note 3. This pin is compliant with the JTAG specification.

Note 4. See **Figure 2.3-1** for how to connect the USBVBUS.

Note 5. VDD09_CA55 and PLDVDD09_PLLCA55 should be at the same voltage.

Note 6. When these power supplies are open, the corresponding signal pins should be open. When supplying power, follow the instructions in the table.

Note 7. The initial value indicates the status during a reset (QRESN = 0) and immediately after release from the reset state (QRESN = 1).

Note 8. When using these pins at 1.1 V, DDRx_VDDQLP should be connected to DDRx_VDDQ. (x = 0)

Note 9. All unconnected lanes must be terminated during compliance test.

Note 10. Connect an external resistor (6.2kΩ). For details, refer to the *RZ/V2N Group PCB Design Guidelines*.

Note 11. A load switch or similar component should be added so that voltage is applied to the USB20_VUBUSIN pin after power is supplied for USB20.

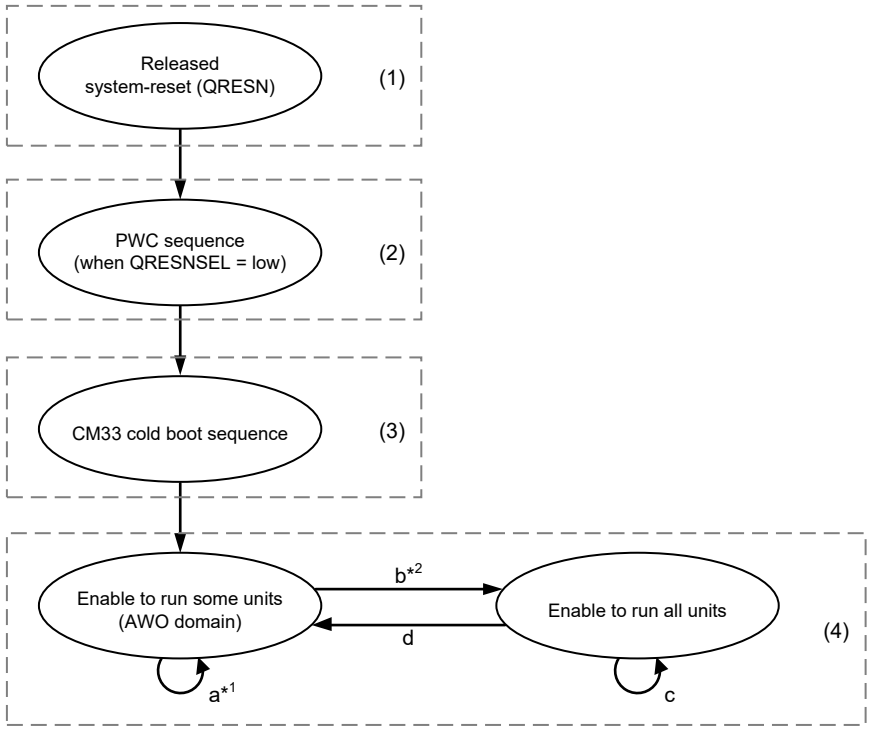
3.3 Power-On/Off Sequence

3.3.1 CM33 Boot Mode (PWC Enabled)

The state diagram of CM33 cold boot is shown in **Figure 3.3-1**. The boot mode states (1) to (4) refer to the sequence of (1) to (4) in **Figure 3.3-2**.



Note 1. CM33 operates the system managements.

Note 2. When the power mode switches from AWO to ALL_ON depending on the user system, CM33 sets the LSI registers and PMIC registers to supply power to the OTHERS domain.

Software control: RIIC or PFC (GPIO) control

Note: The clock stabilization time depends on the board design. Make the setting according to the results of evaluation. In addition, ensure that each clock is applied only after the corresponding I/O power supply has been enabled.

Note: Refer to the notes in **Section 3.3.3** and **Section 3.3.4** for details on the restrictions on the rise time and fall time of each power supply.

Note: When the QRESN pin becomes low, the PWEN0 to PWEN2 pins become low simultaneously.

Note: When using the PWC, set QRESN to the low level at the same time as or after the 1st Grp power off.

Note: The clock stabilization time depends on the board design. Make the setting according to the results of evaluation. In addition, ensure that each clock is applied only after the corresponding I/O power supply has been enabled.

Note: Refer to the notes in **Section 3.3.5** and **Section 3.3.6** for details on the restrictions on the rise time and fall time of each power supply.

Note: When the QRESN pin becomes low, the PWEN0 to PWEN2 pins become low simultaneously.

Note: When using the PWC, set QRESN to the low level at the same time as or after the 1st Grp power off.

Note 1. Specification at 133 MHz / Specification at 100 MHz

Note 2. These are values when the OEN assertion is extended in the Output Enable Asserting extension bit (COMCFG.OEASTEX = 1b).

Note 3. These are the values when the CS assertion is extended in the CS asserting extension bit (LIOCFGCSn.CSASTEX = 1b).

Note 4. The standard value for xSPI266 is 0.8 ns.

Note 5. If the DS is high during the command & modifier phase when using JESD251 Profile 2.0 memory, the time from CS low to DS high must also meet this specification.

Note 6. When using JESD251 Profile 1.0 memory or JESD251 Profile 2.0 memory with LIOCFGCSn.LATEMD set to 0, this constraint does not apply if the internal pull-down resistor of the DS pin is enabled.

Note 7. These are the values when the t_{CLKDSL} constraint is satisfied.

Note 8. This constraint is necessary only to satisfy the t_{DSLCSH} requirement specified in JESD251, which specifies that t_{DSLCSH} must be at least 80% of t_{PERIOD}. Set LIOCFGCSn.CSNEGEX to the appropriate value to ensure the memory specification complies with this constraint.

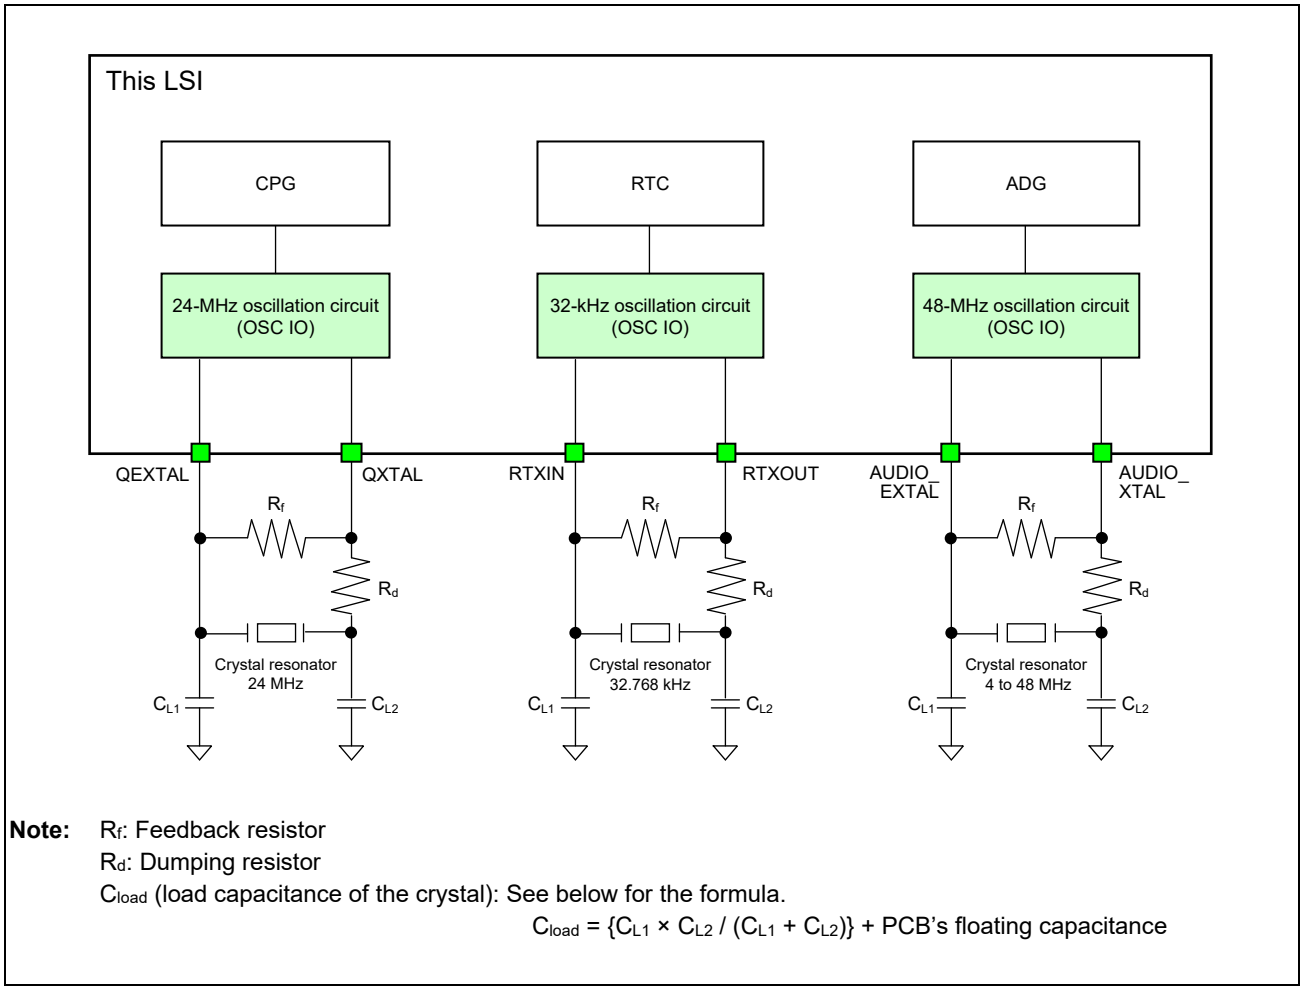
3.7 Oscillation Circuits for Connecting Crystal Resonators (OSC)

This LSI chip includes three oscillation circuits (OSC) for connection to crystal resonators, specifically a 24-MHz crystal resonator for the system clock, a crystal resonator with a frequency range of 4 to 48 MHz for the audio clock, and a 32.768-kHz crystal resonator for the real-time clock. **Table 3.7-1** lists the pins for connecting the crystal resonators and the clock frequencies. **Figure 3.7-1** shows an example of the connections with crystal resonators.

Table 3.7-1 Pins for Connecting Crystal Resonators and Clock Frequency

External Pin Name	I/O	Clock Frequency
For the system clock		
QEXTAL	Input	24 MHz (frequency deviation: ±50 ppm)
QXTAL	Output	24 MHz
For the real-time clock		
RTXIN	Input	32.768 kHz (frequency deviation: ±50 ppm)
RTXOUT	Output	32.768 kHz
For the audio clocks		
AUDIO_EXTAL	Input	4 to 48 MHz
AUDIO_XTAL	Output	4 to 48 MHz



Note: R_f: Feedback resistor
R_d: Dumping resistor
C_{load} (load capacitance of the crystal): See below for the formula.

$$C_{load} = \{C_{L1} \times C_{L2} / (C_{L1} + C_{L2})\} + \text{PCB's floating capacitance}$$

Figure 3.7-1 Example of Connections with Crystal Resonators

Place the crystal resonators and the capacitors C_{L1} and C_{L2} as close as possible to the pins to connect crystal resonators. To avoid interference and to ensure correct oscillation, the grounding points of the capacitors appended to the crystal resonators should be shared, and no wiring patterns should be placed near these components.

The characteristics of the crystal resonators are closely related to the design of the user board. Therefore, the user should sufficiently evaluate them with reference to the example of connection of crystal resonators in **Figure 3.7-1**.

The circuit rating of a crystal resonator depends on the crystal resonator and the stray capacitance of the mounting circuit. Therefore, contact the manufacturer of the crystal resonator before deciding upon the circuit rating. The user should thoroughly evaluate and then set the parameters (resistor and capacitor values).

Table 3.7-2 is a list of recommended values for the crystal resonators.

Table 3.7-2 Recommended Model Values for the Crystal Resonators

	Model Values for the Crystal Resonators			
Clock Frequency	Max. ESR*1	Max. C_L*2	Max. C_0*3	Max. Drive Level
32.768 kHz	70 kΩ	12.5 pF	1.4 pF	1 µW
24 MHz	60 Ω	12 pF	7 pF	100 µW
48 MHz	50 Ω	10 pF	7 pF	100 µW

Note 1. ESR means the equivalent series resistor of the crystal resonator.

Note 2. C_L is the load capacitance of the crystal resonator.

Note 3. C_0 is the parallel capacitance of the crystal resonator.

General Precautions in the Handling of Microprocessing Unit and Microcontroller Unit Products

The following usage notes are applicable to all Microprocessing unit and Microcontroller unit products from Renesas. For detailed usage notes on the products covered by this document, refer to the relevant sections of the document as well as any technical updates that have been issued for the products.

1. Precaution against Electrostatic Discharge (ESD)
   A strong electrical field, when exposed to a CMOS device, can cause destruction of the gate oxide and ultimately degrade the device operation. Steps must be taken to stop the generation of static electricity as much as possible, and quickly dissipate it when it occurs. Environmental control must be adequate. When it is dry, a humidifier should be used. This is recommended to avoid using insulators that can easily build up static electricity. Semiconductor devices must be stored and transported in an anti-static container, static shielding bag or conductive material. All test and measurement tools including work benches and floors must be grounded. The operator must also be grounded using a wrist strap. Semiconductor devices must not be touched with bare hands. Similar precautions must be taken for printed circuit boards with mounted semiconductor devices.
2. Processing at power-on
   The state of the product is undefined at the time when power is supplied. The states of internal circuits in the LSI are indeterminate and the states of register settings and pins are undefined at the time when power is supplied. In a finished product where the reset signal is applied to the external reset pin, the states of pins are not guaranteed from the time when power is supplied until the reset process is completed. In a similar way, the states of pins in a product that is reset by an on-chip power-on reset function are not guaranteed from the time when power is supplied until the power reaches the level at which resetting is specified.
3. Input of signal during power-off state
   Do not input signals or an I/O pull-up power supply while the device is powered off. The current injection that results from input of such a signal or I/O pull-up power supply may cause malfunction and the abnormal current that passes in the device at this time may cause degradation of internal elements. Follow the guideline for input signal during power-off state as described in your product documentation.
4. Handling of unused pins
   Handle unused pins in accordance with the directions given under handling of unused pins in the manual. The input pins of CMOS products are generally in the high-impedance state. In operation with an unused pin in the open-circuit state, extra electromagnetic noise is induced in the vicinity of the LSI, an associated shoot-through current flows internally, and malfunctions occur due to the false recognition of the pin state as an input signal become possible.
5. Clock signals
   After applying a reset, only release the reset line after the operating clock signal becomes stable. When switching the clock signal during program execution, wait until the target clock signal is stabilized. When the clock signal is generated with an external resonator or from an external oscillator during a reset, ensure that the reset line is only released after full stabilization of the clock signal. Additionally, when switching to a clock signal produced with an external resonator or by an external oscillator while program execution is in progress, wait until the target clock signal is stable.
6. Voltage application waveform at input pin
   Waveform distortion due to input noise or a reflected wave may cause malfunction. If the input of the CMOS device stays in the area between V_{IL} (Max.) and V_{IH} (Min.) due to noise, for example, the device may malfunction. Take care to prevent chattering noise from entering the device when the input level is fixed, and also in the transition period when the input level passes through the area between V_{IL} (Max.) and V_{IH} (Min.).
7. Prohibition of access to reserved addresses
   Access to reserved addresses is prohibited. The reserved addresses are provided for possible future expansion of functions. Do not access these addresses as the correct operation of the LSI is not guaranteed.
8. Differences between products
   Before changing from one product to another, for example to a product with a different part number, confirm that the change will not lead to problems. The characteristics of a microprocessing unit or microcontroller unit products in the same group but having a different part number might differ in terms of internal memory capacity, layout pattern, and other factors, which can affect the ranges of electrical characteristics, such as characteristic values, operating margins, immunity to noise, and amount of radiated noise. When changing to a product with a different part number, implement a system-evaluation test for the given product.
