Figure 26.17 shows an example flow of serial transmission in asynchronous mode with FIFO selected.

[ 1 ] SCI initialization:
Set data transmission.
After the SCR.TE bit is set to 1, 1 is output for a frame, and transmission is enabled.

[ 2 ] Transmit data write to FTDRL*1 by an SCIn_TXI interrupt request:
When transmit data is transferred from FTDRL to TSR, when the quantity of transmit data written in FTDRL is equal to or less than the specified transmit triggering number, a transmit data FIFO empty interrupt (SCIn_TXI) request is generated. Write transmit data to FTDRL*1 *2 once in the SCIn_TXI interrupt handling routine.

[ 3 ] Serial transmission continuation procedure:
To continue serial transmission, write all transmit data to FTDRL using an SCIn_TXI interrupt request and clear the SSR_FIFO.TDFE flag to 0. The number of transmission data it is possible to write in is 16 - (the number of stored transmit FIFO data). Transmit data can also be written to FTDRL by activating the DTC or DMAC. When writing the data to FTDRL by DTC or DMAC, the TDFE flag is cleared automatically, so do not write to the TDFE flag.
When SCIn_TEI interrupt requests are in use, set the SCR.TIE bit to 0 and the SCR.TEIE bit to 1 after the last of the data to be transmitted is written to FTDRL.

[ 4 ] Break output at the end of serial transmission:
To output a break in serial transmission, after setting the output state (LOW level output) of TXD pin by SPTR.SPB2IO and SPTR.SPB2DT bits, set the SCR.TE bit to 0.

Note 1. When data length is 9 bits, this refers to FTDRH and FTDRL registers.
Note 2. When data length is 9 bits, write in order from FTDRH to FTDRL.

**Figure 26.17 Example flow of serial transmission in asynchronous mode with FIFO selected**

## 26.3.9 Serial Data Reception in Asynchronous Mode

(1) Non-FIFO selected

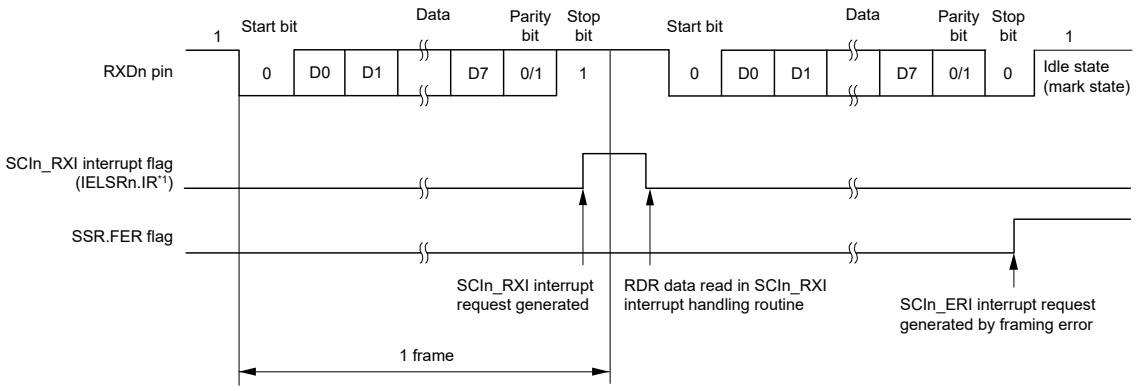

Figure 26.18 and Figure 26.19 show an example of the operation for serial data reception in asynchronous mode.

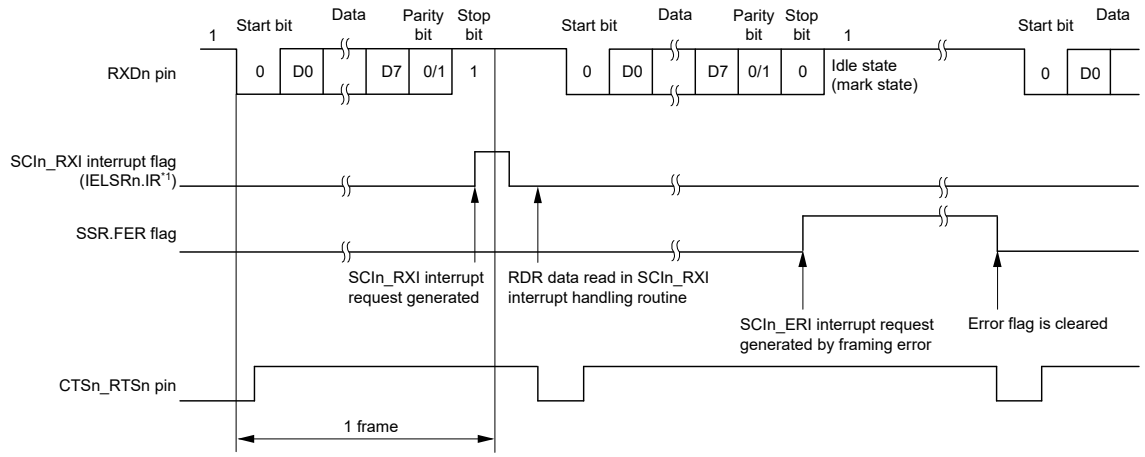
In serial data reception, the SCI operates as follows:

1. When the value of the SCR.RE bit becomes 1, the output signal on the CTSn_RTSn pin goes low.
2. The SCI monitors the communications line and when it detects a start bit, the SCI performs internal synchronization, stores receive data in RSR.
3. If the multi-processor communication function is enabled (SMR.MP = 1), see section 26.4.2. Multi-Processor Serial Data Reception. If the address match function (data compare match function) is enabled (DCCR.DCME = 1), the SCI cannot detect a parity or framing error as receive data are skipped (discarded) until the SCI detects a match between the receive data and comparison data (CDR.CMPD*1).



4. If the SCI detects an address match, the DCCR.DCME bit is automatically cleared, the DCCR.DCMF flag becomes 1, and an SCIn_AM interrupt[*2] request is generated. To enable the generation of an SCIn_RXI interrupt request, set the SCR.RIE bit to 1. The compared receive data are not stored in the RDR register[*3]. The SSR.RDRF flag remains 0.
5. If the SCI detects a framing error in the receive data for which an address match is detected, the DCCR.DFER flag is set to 1, and if the SCI detects a parity error in that frame, the DCCR.DPER flag becomes 1. To enable the generation of an SCIn_ERI interrupt request, set the SCR.RIE bit to 1.
6. If a framing or a parity error is detected (the DCCR.DFER flag or DCCR.DPER flag is 1) in the SCIn_AM interrupt handling routine, set the DCCR.DFER and DCCR.DPER flags to 0 and set the DCCR.DCME bit to 1 to enable the address match function again. If neither a framing nor a parity error has been detected (the DCCR.DFER and DCCR.DPER flags are both 0), set the DCCR.DCMF flag to 0. See Figure 26.9.
7. If an overrun error occurs, the SSR.ORER flag is set to 1. If the SCR.RIE bit is 1, an SCIn_ERI interrupt request is generated. Receive data is not transferred to the RDR[*3] register.
8. If a parity error is detected, the SSR.PER flag is set to 1 and receive data is transferred to the RDR[*3] register. If the SCR.RIE bit is 1, an SCIn_ERI interrupt request is generated.
9. If a framing error is detected, the SSR.FER flag is set to 1 and receive data is transferred to the RDR[*3] register. If the SCR.RIE bit is 1, an SCIn_ERI interrupt request is generated.
10. When reception finishes successfully, receive data is transferred to the RDR[*3] register. If the SCR.RIE bit is 1, an SCIn_RXI interrupt request is generated. Continuous reception is enabled by reading the receive data transferred to the RDR register in the SCIn_RXI interrupt handling routine before reception of the next receive data is complete. Reading the received data that was transferred to the RDR register causes the CTSn_RTSn pin to output low.

Note 1. This scope of comparison is selectable as one of three lengths: CMPD[6:0] is for 7-bit length, CMPD[7:0] is for 8-bit length, and CMPD[8:0] is for 9-bit length.
Note 2. As no interrupt enable bit is assigned to the SCIn_AM interrupt, an interrupt request is generated by setting the DCCR.DCMF to 1.
Note 3. Only read data in the RDRHL register when 9-bit data length is selected.

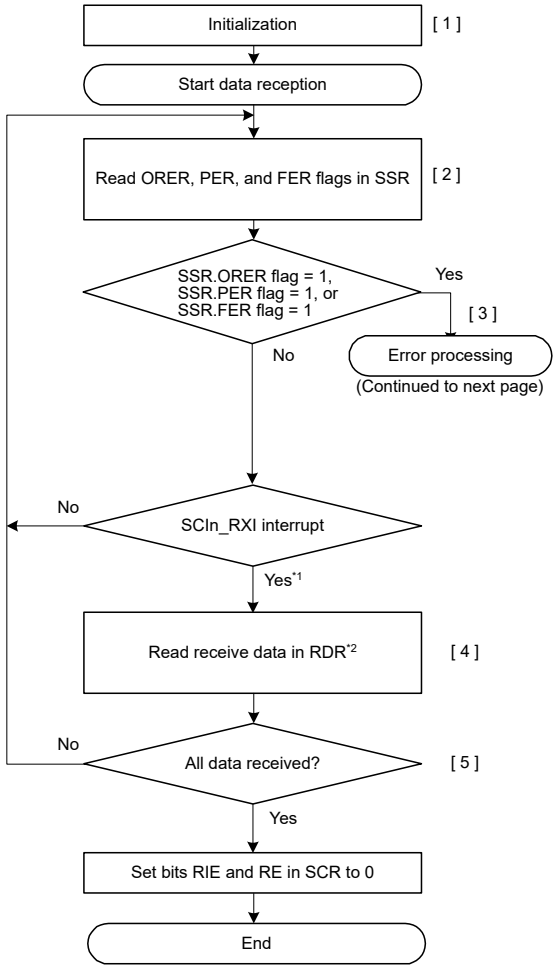
Note 1. See section 12, Interrupt Controller Unit (ICU) for information on the corresponding interrupt event number.

**Figure 26.18 Example of SCI operation for serial reception in asynchronous mode (1) when the RTS function is not used, and with 8-bit data, parity bit, and 1 stop bit**

Note 1. See section 12, Interrupt Controller Unit (ICU) for information on the corresponding interrupt event number.

**Figure 26.19 Example of SCI operation for serial reception in asynchronous mode (2) when RTS function is used, and with 8-bit data, parity bit, and 1 stop bit**

Table 26.30 lists the states of the flags in the SSR register and receive data handling when a receive error is detected.



If a receive error is detected, an SCIn_ERI interrupt request is generated but an SCIn_RXI interrupt request is not generated. Data reception cannot be resumed while the receive error flag is 1. Accordingly, set the ORER, FER, and PER bits to 0 before resuming reception. In addition, be sure to read the RDR or RDRHL register during overrun error processing. When a reception is forced to terminate by setting the SCR.RE bit to 0 during operation, read the RDR or RDRHL register because received data that is not yet read might be left in the RDR or RDRHL.

Figure 26.20 and Figure 26.21 show example flows of serial data reception.

**Table 26.30 Flags in SSR Status Register and receive data handling**

| Flags in the SSR Status Register | | | Receive data | Receive error type |
|---|---|---|---|---|
| ORER | FER | PER | | |
| 1 | 0 | 0 | Lost | Overrun error |
| 0 | 1 | 0 | Transferred to RDR*1 | Framing error |
| 0 | 0 | 1 | Transferred to RDR*1 | Parity error |
| 1 | 1 | 0 | Lost | Overrun error + framing error |
| 1 | 0 | 1 | Lost | Overrun error + parity error |
| 0 | 1 | 1 | Transferred to RDR*1 | Framing error + parity error |
| 1 | 1 | 1 | Lost | Overrun error + framing error + parity error |

Note 1. Only read data in the RDRHL register when 9-bit data length is selected.

[ 1 ] SCI initialization:
Set data reception.

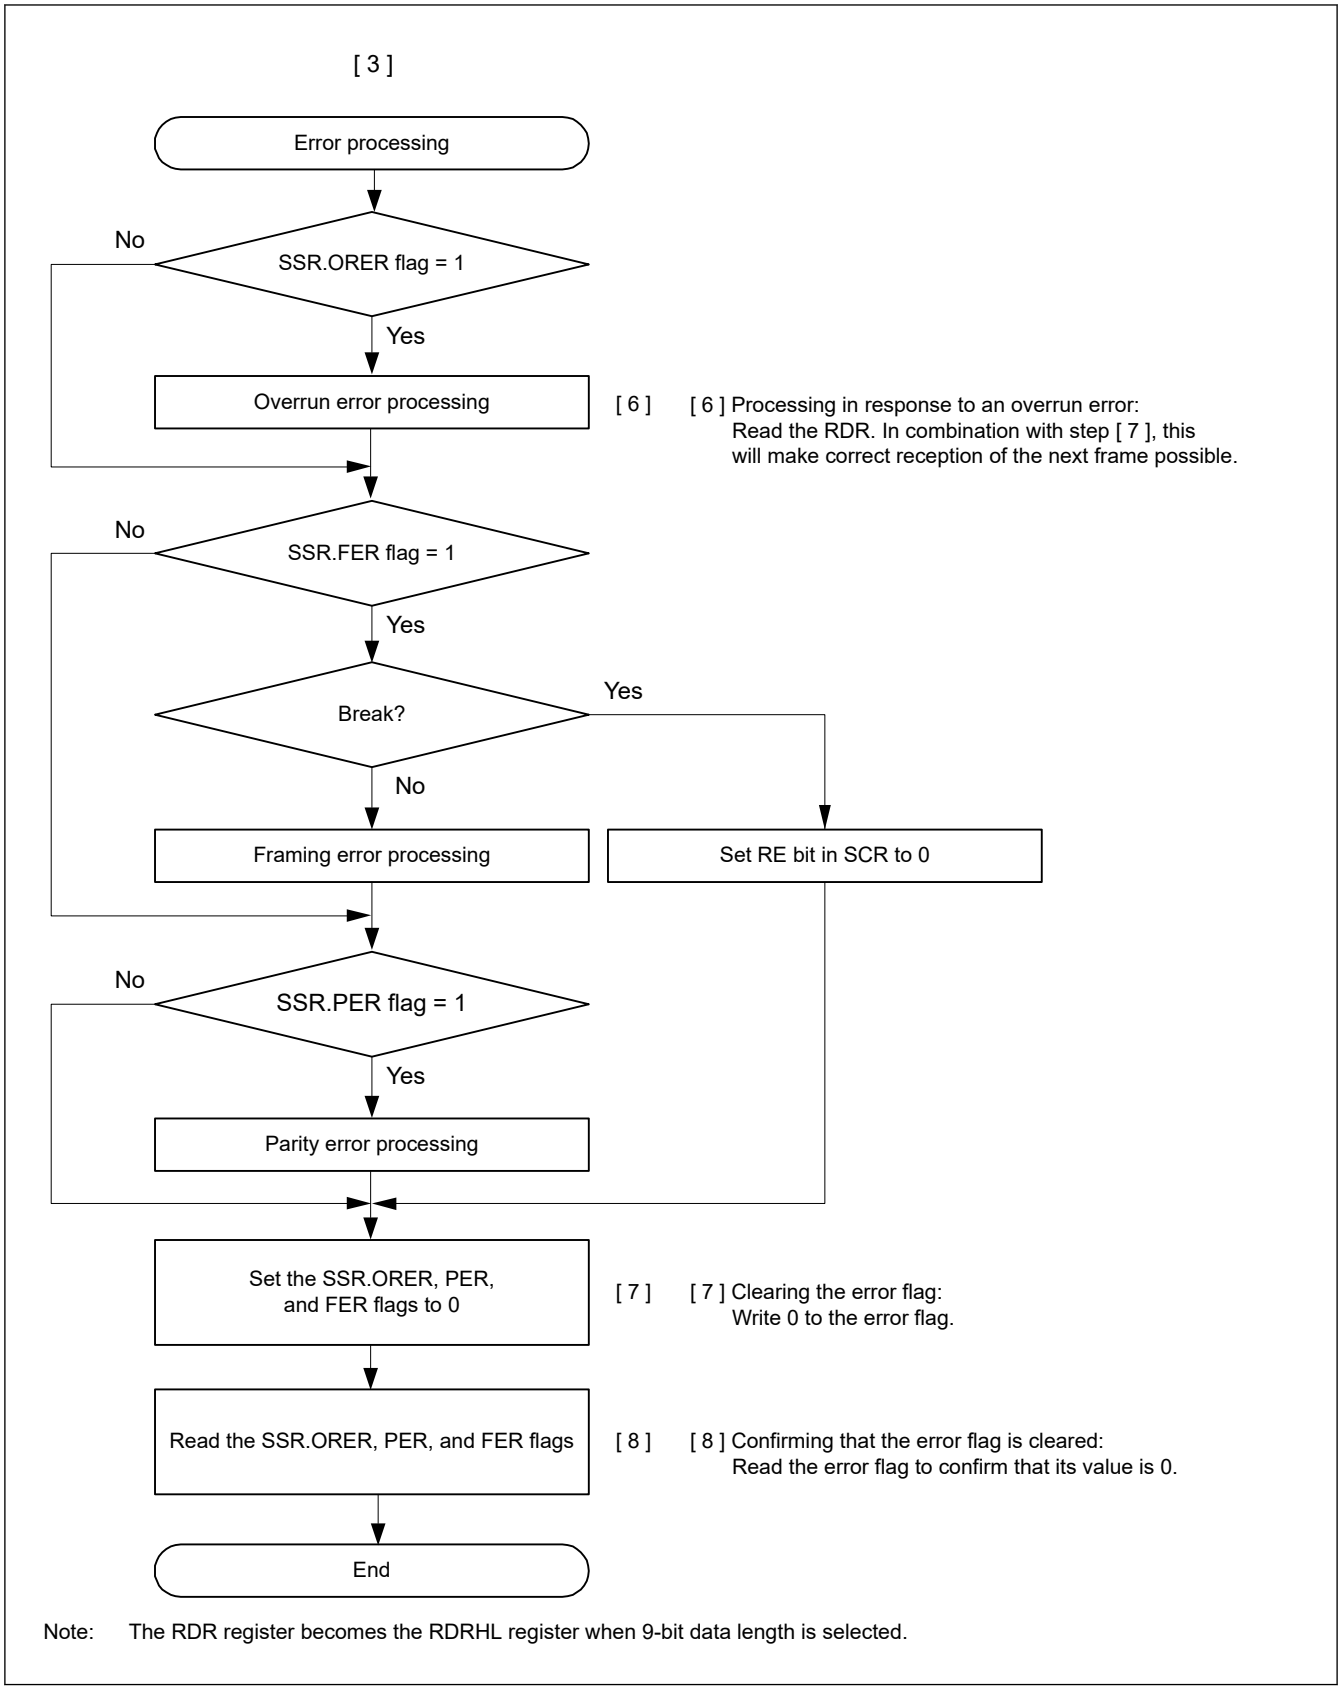
[ 2 ][ 3 ] Receive error processing and break detection:
If a receive error occurs, an SCIn_ERI interrupt is generated. The error type is identified by reading the ORER, PER, and FER flags in SSR. After performing the appropriate error processing, be sure to set the ORER, PER, and FER flags to 0. Reception cannot be resumed if any of these flags is set to 1. For a framing error, a break can be detected by reading the value of the input port associated with the RXDn pin.

[ 4 ] Read the receive data in RDR once inthe SCIn_RXI interrupt handling routine.

[ 5 ] To continue serial reception, before the stop bit of the current frame is received, read data from RDR in the SCIn_RXI interrupt processing routine. The RDR data can also be read by activating the DMAC or DTC.

Note 1. Do not set RE to 0 before reading RDR.
Note 2. The RDR register becomes the RDRHL register when 9-bit data length is selected.

**Figure 26.20 Example flow of serial reception in asynchronous mode with non-FIFO selected and Address Matching Disabled (1)**



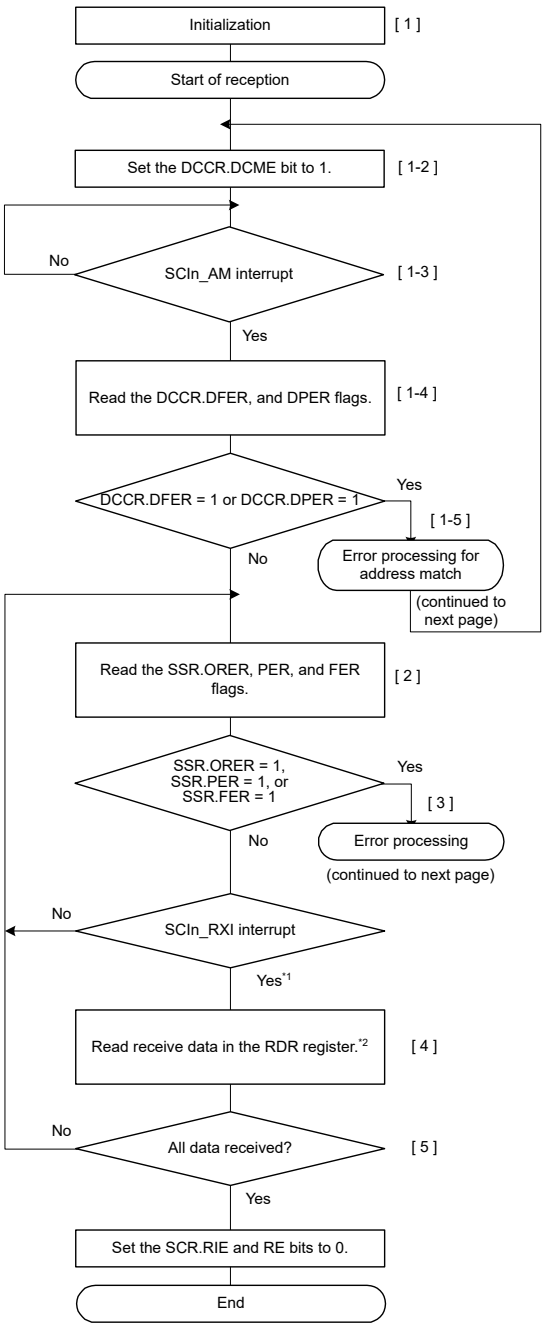


**Figure 26.21 Example flow of serial reception in asynchronous mode with non-FIFO selected and Address Matching Disabled (2)**

[ 1 ] SCI initialization:
Set data reception.

[ 1-2 ] Address match cycle:
Set the DCCR.DCME bit to 1 to enable address matching.

[ 1-3 ] Comparing receive data and data for comparison (CDR.CMPD):
Compare receive data and data for comparison (CDR.CMPD).
The SCI cannot detect a parity or framing error as receive data are skipped (discarded) until the SCI detects a match between the receive data and data for comparison.
If the SCI detects an address match, the DCCR.DCME bit is cleared, the DCCR.DCMF flag becomes 1, and an SCIn_AM interrupt request is issued.

[ 1-4 ] [ 1-5 ] Reception error processing:
An error is identified by reading the DFER or DPER flag in DCCR in the SCIn_AM interrupt handling routine.
After appropriate handling of the error, set both the DFER and DPER flags to 0.
If either of these flags is set to 1, address matching cannot be resumed.

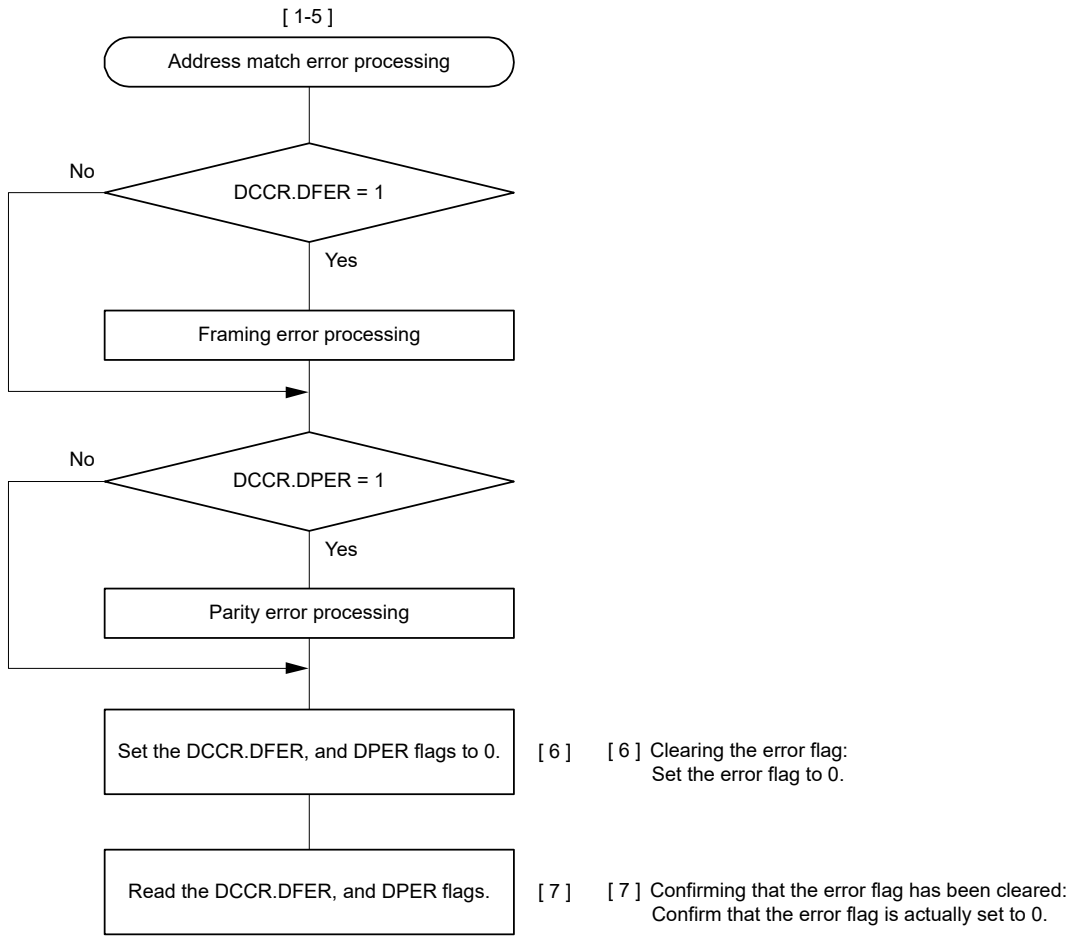
[ 2 ] [ 3 ] Reception error processing and break detection:
When a reception error occurs, the SCIn_ERI interrupt is generated.
The error is identified by reading the ORER, PER, and FER flags in the SSR.
After appropriate handling of the error, set all of the ORER, PER, and FER flags to 0. If any of these flags is set to 1, reception cannot be resumed.
If a framing error occurs, a break can be detected by reading the value of the input port bit corresponding to the RXDn pin.

[ 4 ] Read the receive data in the RDR register from within the SCIn_RXI interrupt handling routine.

[ 5 ] Procedure for continuing serial reception:
To continue serial reception, read the value of the RDR register in the SCIn_RXI interrupt handling routine before the stop bit is received.
The value of the RDR register can also be read by activating the DMAC or DTC.

Note 1. Be sure to set the RE bit to 0 before reading the RDR register.
Note 2. The RDRHL register is used instead of the RDR register when the 9-bit data length is selected.

**Figure 26.22 Example Flowchart of Serial Reception in Asynchronous Mode (FIFO not Selected and Address Matching Enabled) (1)**



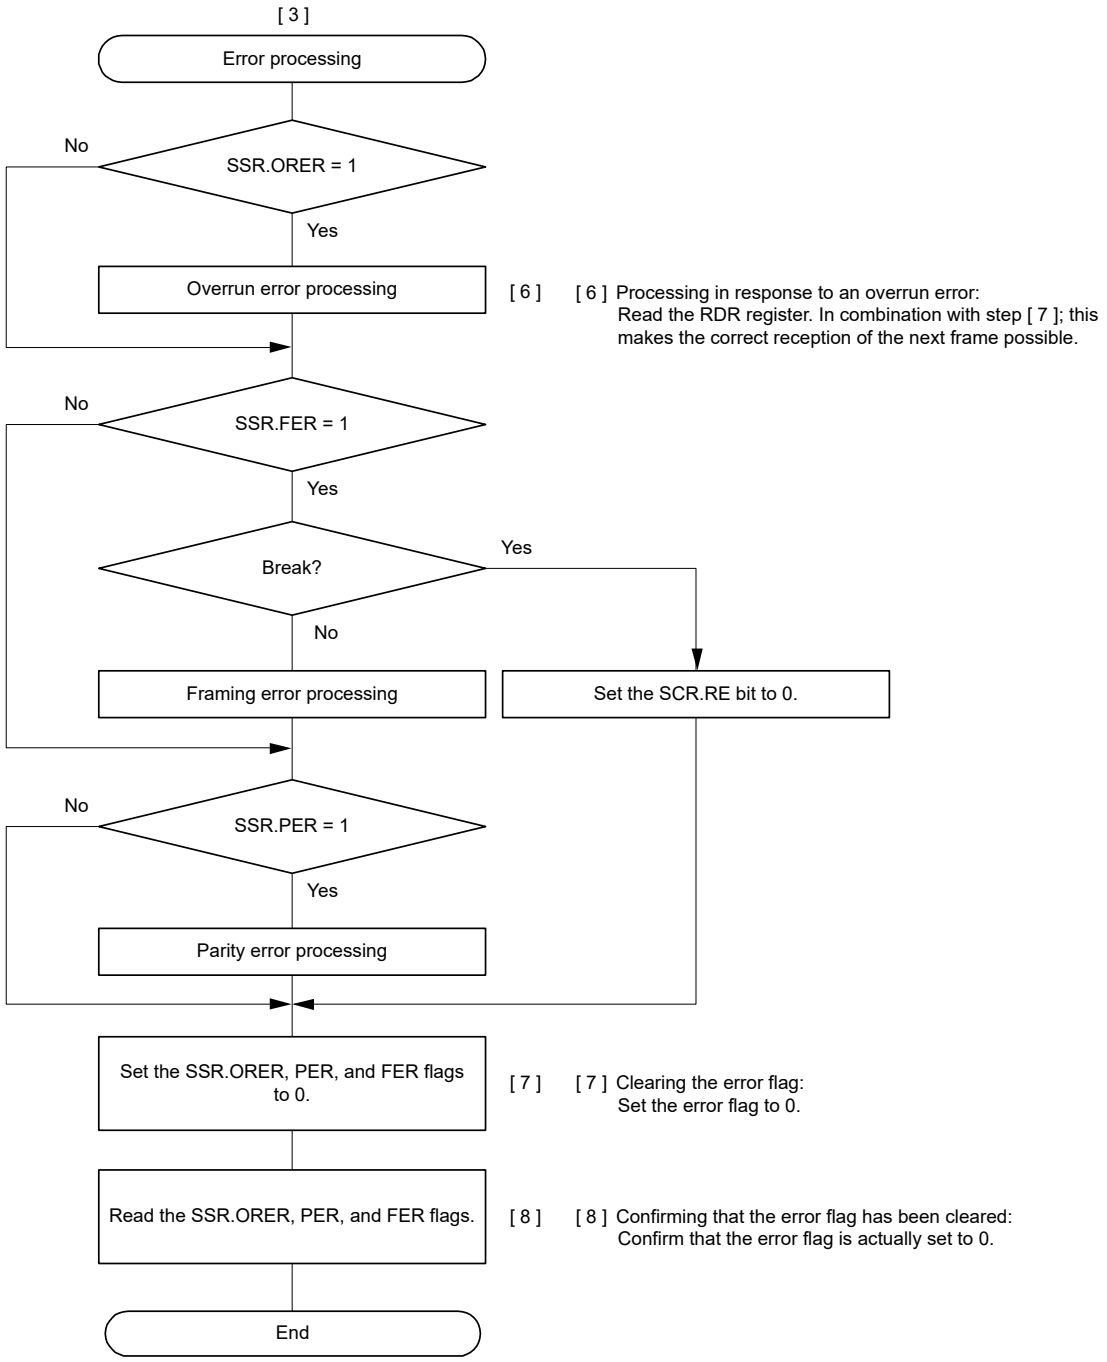


**Figure 26.23 Example Flowchart of Serial Reception in Asynchronous Mode (FIFO not Selected and Address Matching Enabled) (2)**

Note: The RDRHL register is used instead of the RDR register when the 9-bit data length is selected.

**Figure 26.24 Example Flowchart of Serial Reception in Asynchronous Mode (FIFO not Selected and Address Matching Enabled) (3)**

(2) FIFO selected

Figure 26.25 shows an example of a data format that is written to FRDRH register and FRDRL register in asynchronous mode.

In asynchronous mode, 0 is written to the MPB bit in the FRDRH register. Data that corresponds to the data length is written to FRDRH and FRDRL. Unused bits are written as 0. Read in order from FRDRH to FRDRL. If software reads FRDRL, the

SCI updates FER, PER, and receive data (RDAT[8:0]) in the FRDRL register with the next data. The flags RDF, ORER, and DR in the FRDRH register always reflect the associated flags in the SSR_FIFO register.

| Data Length | Register Setting | | Receive data in FRDRH, FRDRL | | | | | | | | | | | | | | | |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | | | FRDRHL | | | | | | | | | | | | | | | |
| | | | FRDRH | | | | | | | | FRDRL | | | | | | | |
| | SCMR.CHR1 | SMR.CHR | b15 | b14 | b13 | b12 | b11 | b10 | b9 | b8 | b7 | b6 | b5 | b4 | b3 | b2 | b1 | b0 |
| 7 bits | 1 | 0 | - | RDF | ORER | FER | PER | DR | 0 | 0 | 0 | 7-bit receive data | | | | | | |
| 8 bits | 1 | 1 | - | RDF | ORER | FER | PER | DR | 0 | 0 | 8-bit receive data | | | | | | | |
| 9 bits | 0 | Don't care | - | RDF | ORER | FER | PER | DR | 0 | 9-bit receive data | | | | | | | | |

Note: 0 is always read for MPB bit (FRDRH[1])
When data length is 7 bits, 0 is always read for FRDRH[0] and FRDRL[7]
When data length is 8 bits, 0 is always read for FRDRH[0]
FRDRH[7] bit is read as an indefinite value

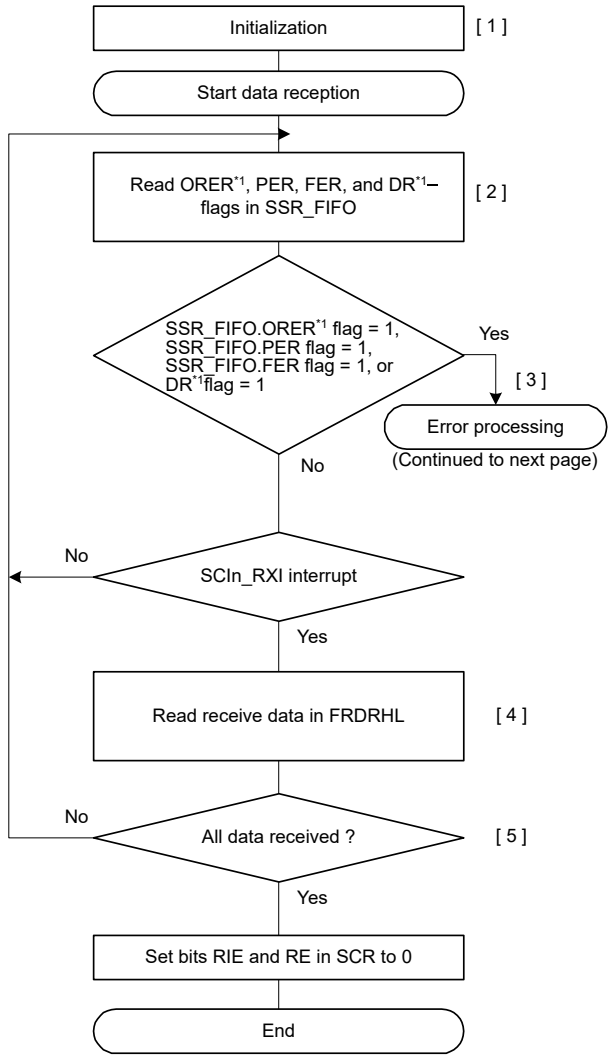

**Figure 26.25 Data format stored in FRDRH and FRDRL with FIFO selected**

In serial data reception, the SCI operates as follows:

1. When the value of the SCR.RE bit becomes 1, the output signal on the CTSn_RTSn pin goes low.
2. The SCI monitors the communications line and, when it detects a start bit, the SCI performs internal synchronization, stores receive data in the RSR register.
3. If the multi-processor communications function is enabled (SMR.MP = 1), see section 26.4.2. Multi-Processor Serial Data Reception. If the address match function (data compare match function) is enabled (DCCR.DCME = 1), the SCI cannot detect a parity or framing error as receive data are skipped (discarded) until the SCI detects a match between the receive data and the data for comparison (CDR.CMPD[*1]).
4. If the SCI detects an address match, the DCCR.DCME bit is automatically cleared, the DCCR.DCMF flag becomes 1, and an SCIn_AM interrupt[*2] request is generated. To enable the generation of an SCIn_RXI interrupt request, set the SCR.RIE bit to 1. The compared receive data are not stored in the RDR register[*3]. The SSR.RDRF flag remains 0.
5. If the SCI detects a framing error in the receive data for which an address match was detected, the DCCR.DFER flag is set to 1, and if the SCI detects a parity error in that frame, the DCCR.DPER flag becomes 1. To enable the generation of an SCIn_ERI interrupt request, set the SCR.RIE bit to 1.
6. If a framing or a parity error is detected (the DCCR.DFER flag or DCCR.DPER flag is 1) in the SCIn_AM interrupt handling routine, set the DCCR.DFER and DCCR.DPER flags to 0 and set the DCCR.DCME bit to 1 to enable the address match function again. If neither a framing nor a parity error has been detected (the DCCR.DFER and DCCR.DPER flags are 0), set the DCCR.DCMF flag to 0. See Figure 26.9.
7. If an overrun error occurs during normal communications, the SSR_FIFO.ORER flag is set to 1. If the SCR.RIE bit in SCR is 1, an SCIn_ERI interrupt request is generated. Receive data is not transferred to the FRDRL[*3] register.
8. If a parity error is detected, the PER flag and receive data are transferred to the FRDRL[*3] register. If the SCR.RIE bit is set to 1, an SCIn_ERI interrupt request is generated.
9. If a framing error is detected, the FER flag and receive data are transferred to the FRDRL[*3] register. If the SCR.RIE bit is set to 1, an SCIn_ERI interrupt request is generated.
10. After a framing error is detected and when SCI detects that the continuous receive data is zero for one frame, reception stops.
11. When the amount of data stored in the FRDRL register falls below the specified receive triggering number, and the next data is not received after 15 etus from the last stop bit in asynchronous mode, the SSR_FIFO.DR flag is set to 1. When the SCR.RIE bit is 1 and the FCR.DRES bit is 0, the SCI generates an SCIn_RXI interrupt request. When the FCR.DRES bit is 1, SCI generates an SCIn_ERI interrupt request.

12. When reception finishes successfully, receive data is transferred to the FRDRL[*3] register. The RDF bit is set to 1 when the amount of receive data written to FRDRHL is equal to or greater than the specified receive triggering number. If the SCR.RIE bit in SCR is 1, an SCIn_RXI interrupt request is generated. Continuous reception is enabled by reading the receive data transferred to the FRDRL[*4] register in the SCIn_RXI interrupt handling routine, before an overrun error occurs. If the received data that is transferred to FRDRL[*5] is less than the RTS trigger number, the CTSn_RTSn pin outputs low.

Note 1. One of three lengths is selected for the target for comparison: CMPD[6:0] is for 7-bit length, CMPD[7:0] is for 8-bit length, and CMPD[8:0] is for 9-bit length.
Note 2. As no interrupt enable bit is assigned to the SCIn_AM interrupt, an interrupt request is generated by setting the DCCR.DCMF to 1.
Note 3. Only read data in the FRDRH and FRDRL registers when 9-bit data length is selected.
Note 4. Read data in order from FRDRH to FRDRL when 9-bit data length is selected.
Note 5. The SCI only checks for update to the FRDRL register and not to the FRDRH register when 9-bit data length is selected.

[ 1 ] SCI initialization:
Set data reception.

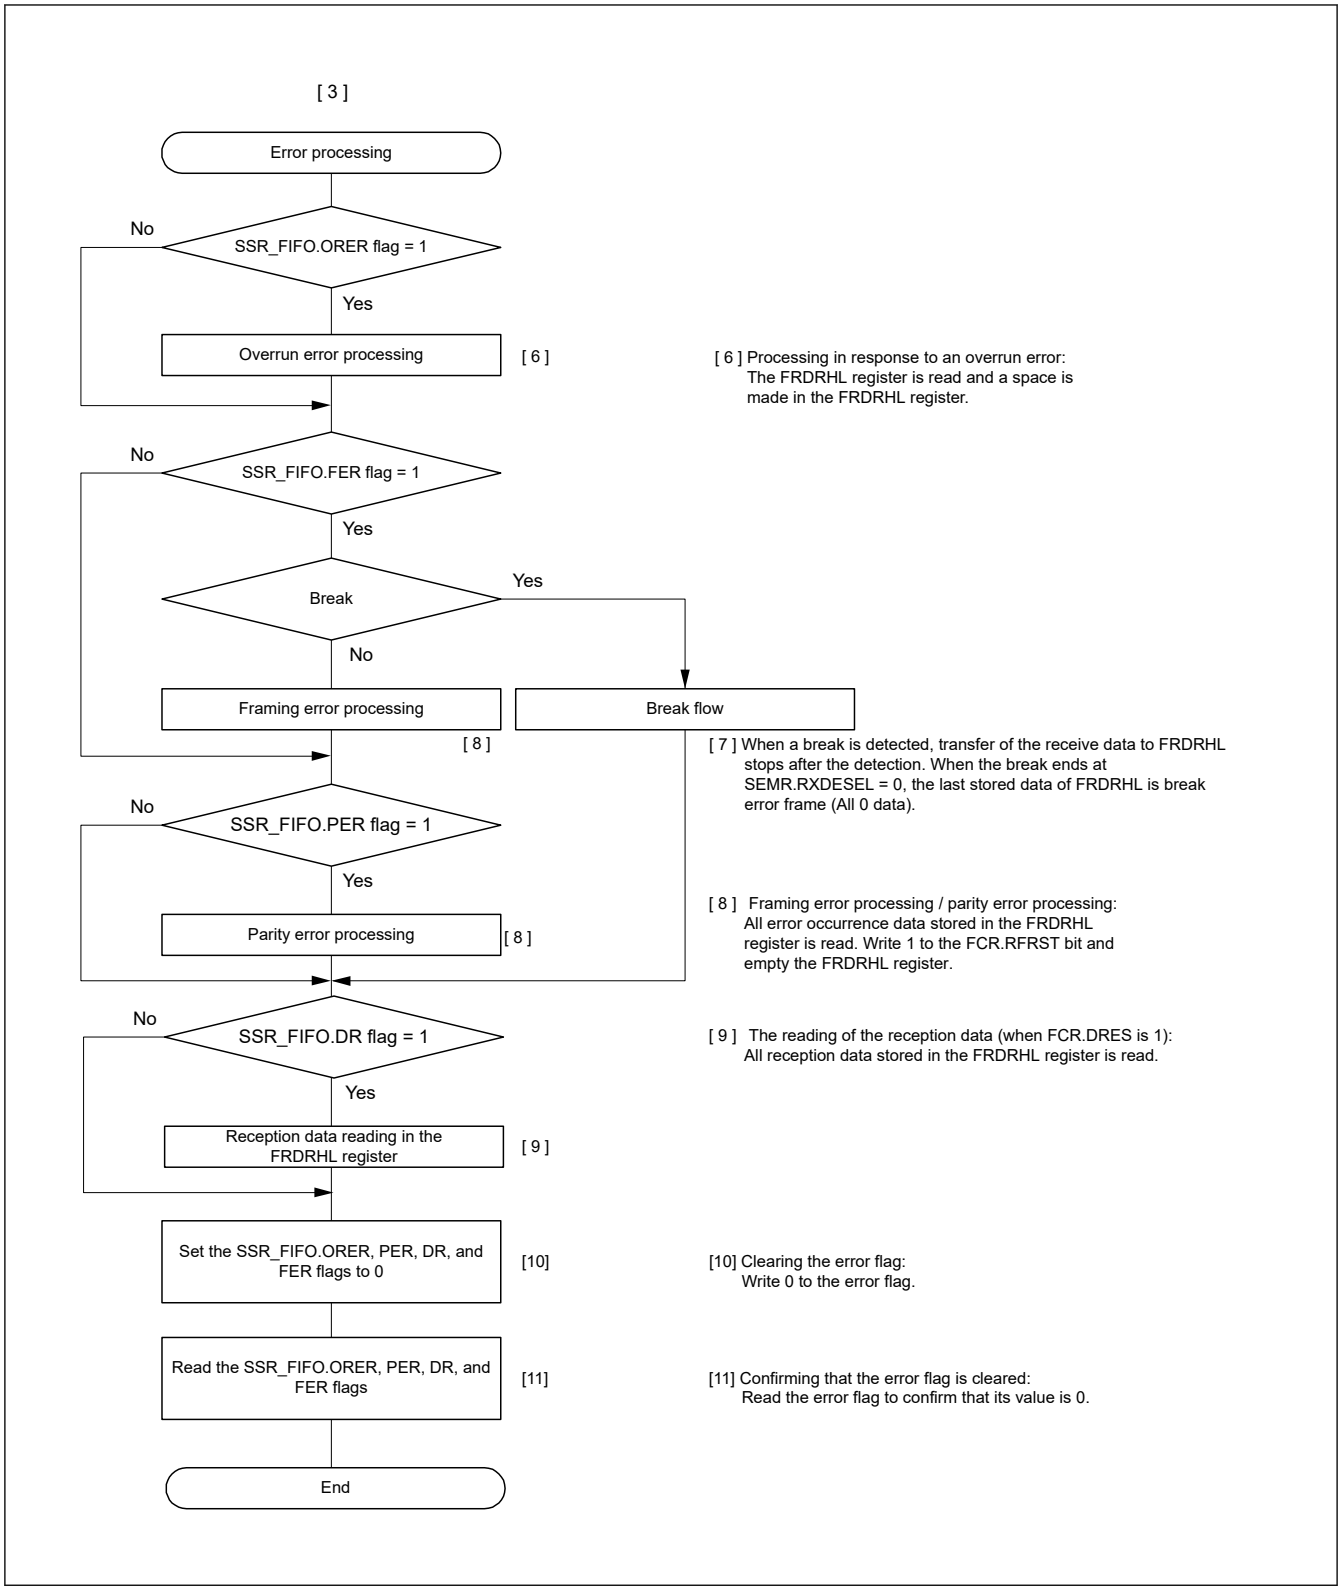
[ 2 ] [ 3 ] Receive error processing and break detection:
If a receive error occurs, an SCIn_ERI interrupt is generated. A break can be detected by reading the SPTR.RXDMON flag. An error is identified by reading the ORER*1, PER, DR*1, and FER flags in SSR_FIFO. After performing the appropriate error processing, be sure to set the ORER*1 flag to 0. Reception cannot be resumed if ORER*1 flag is set to 1. The reception operation is continuous, even if the FER = 1 or PER = 1 or DR*1 = 1.

[ 4 ] Read the receive data in FRDRHL in the SCIn_RXI interrupt handling routine. The receive data stored in the FRDRHL register is read until the number of stored data is below the FCR.RTRG value. Confirm the number of the reception data in the FIFO by reading FDR.R.

[ 5 ] Serial reception continuation procedure:
To continue serial reception, before an overrun error occurs, read data from FRDRHL in the SCIn_RXI interrupt handling routine and clear RDF flag and DR flag to 0.
The FRDRHL data can also be read by activating the DMA or DTC. The RDF flag is cleared automatically in this case, so do not write to the RDF flag.

Note 1. Can be read in the FRDRHL.ORER and DR flags.

**Figure 26.26 Example flow of serial reception in asynchronous mode with FIFO selected and Address Matching Enabled (1)**



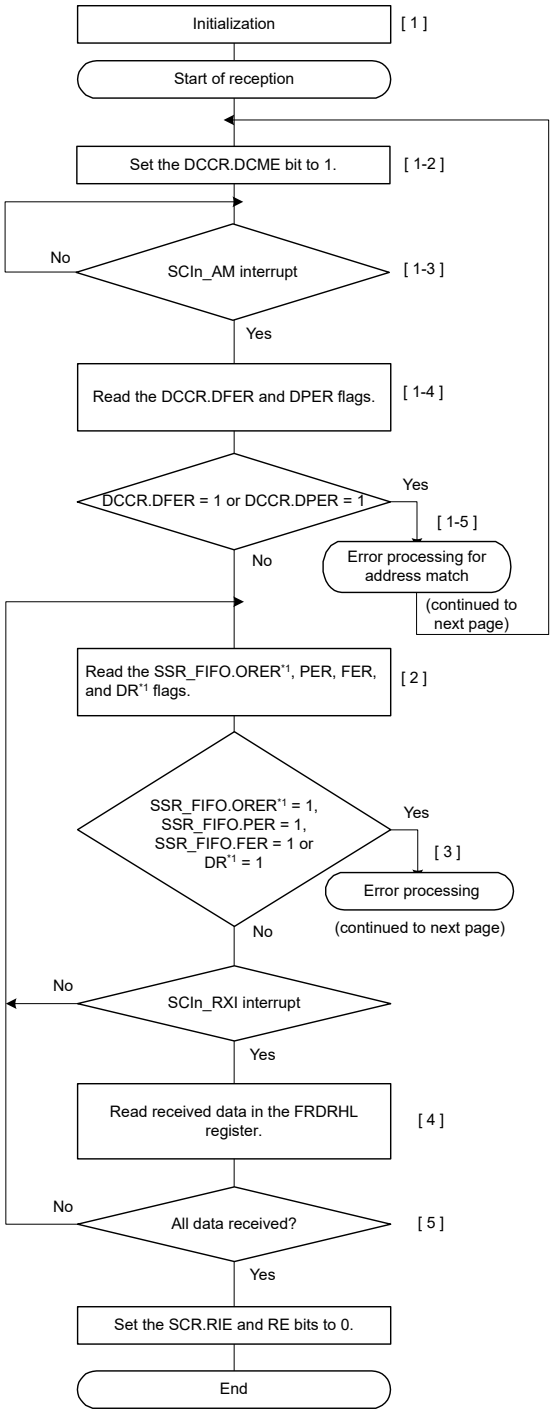


**Figure 26.27 Example flow of serial reception in asynchronous mode with FIFO selected Address Matching Disabled (2)**

[ 1 ] SCI initialization:
Set data reception.

[ 1-2 ] Address match cycle:
Set the DCCR.DCME bit to 1 to enable address matching.

[ 1-3 ] Comparing received data and data for comparison (CDR.CMPD):
Compare receive data and comparison data.
The SCI cannot detect a parity or framing error as received data are skipped (discarded) until the SCI detects a match between the received data and data for comparison.
If the SCI detects an address match, the DCCR.DCME bit is cleared, the DCCR.DCMF flag becomes 1, and an SCIn_AM interrupt request is issued.

[ 1-4 ] [ 1-5 ] Reception error processing:
An error is identified by reading the DFER or DPER flag in DCCR from within the SCIn_AM interrupt handling routine.
After appropriate handling of the error, set both the DFER and DPER flags to 0.
If either of these flags is set to 1, address matching cannot be resumed.

[ 2 ] [ 3 ] Reception error processing and break detection:
When a reception error occurs, an SCIn_ERI interrupt is generated.
A break is identified by reading SPTR.RXDMON.
The error is identified by reading each among the SSR_FIFO.ORER*1, PER, FER, and DR*1 flags.
After appropriate handling of the error, set the ORER*1 flag to 0.
If the ORER*1 flag remains 1, reception cannot be resumed.
The reception operation is continuous, even if the FER = 1, PER = 1 or DR*1 = 1.

[ 4 ] Reading the received data in the FRDRHL register from within the SCIn_RXI interrupt handling routine:
The received data stored in the FRDRHL register are read until the amount of stored data is less than the value of the FCR.RTRG[3:0] bits.
Confirm the number of received data in the FIFO with the value of the FDR.R[4:0] bits.

[ 5 ] Serial reception continuation procedure:
To continue with serial reception, read data from the FRDRHL register from within the SCIn_RXI interrupt handling routine before an overrun error occurs, and set the RDF and DR flags to 0. The data in the FRDRHL register can also be read by activating the DMAC or DTC. In this case, do not write to the RDF flag because the flag is automatically cleared.

Note 1. The FRDRHL.ORER and DR flags can also be read.

**Figure 26.28 Example Flowchart of Serial Reception in Asynchronous Mode (FIFO Selected and Address Matching Enabled) (1)**

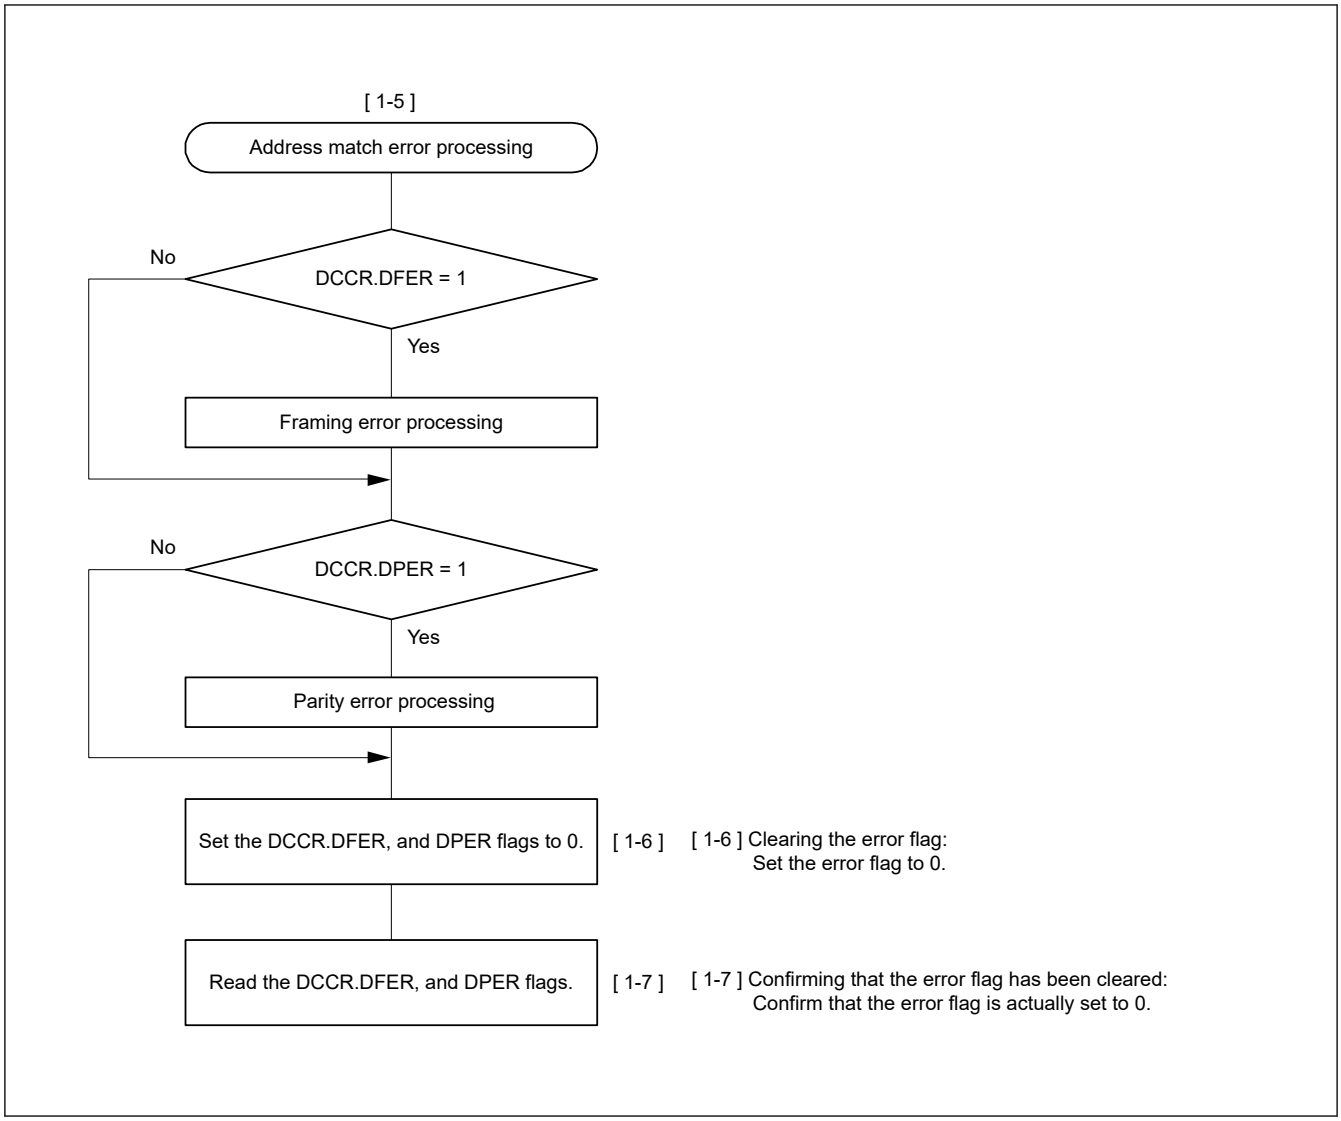

**Figure 26.29 Example Flowchart of Serial Reception in Asynchronous Mode (FIFO Selected and Address Matching Enabled) (2)**

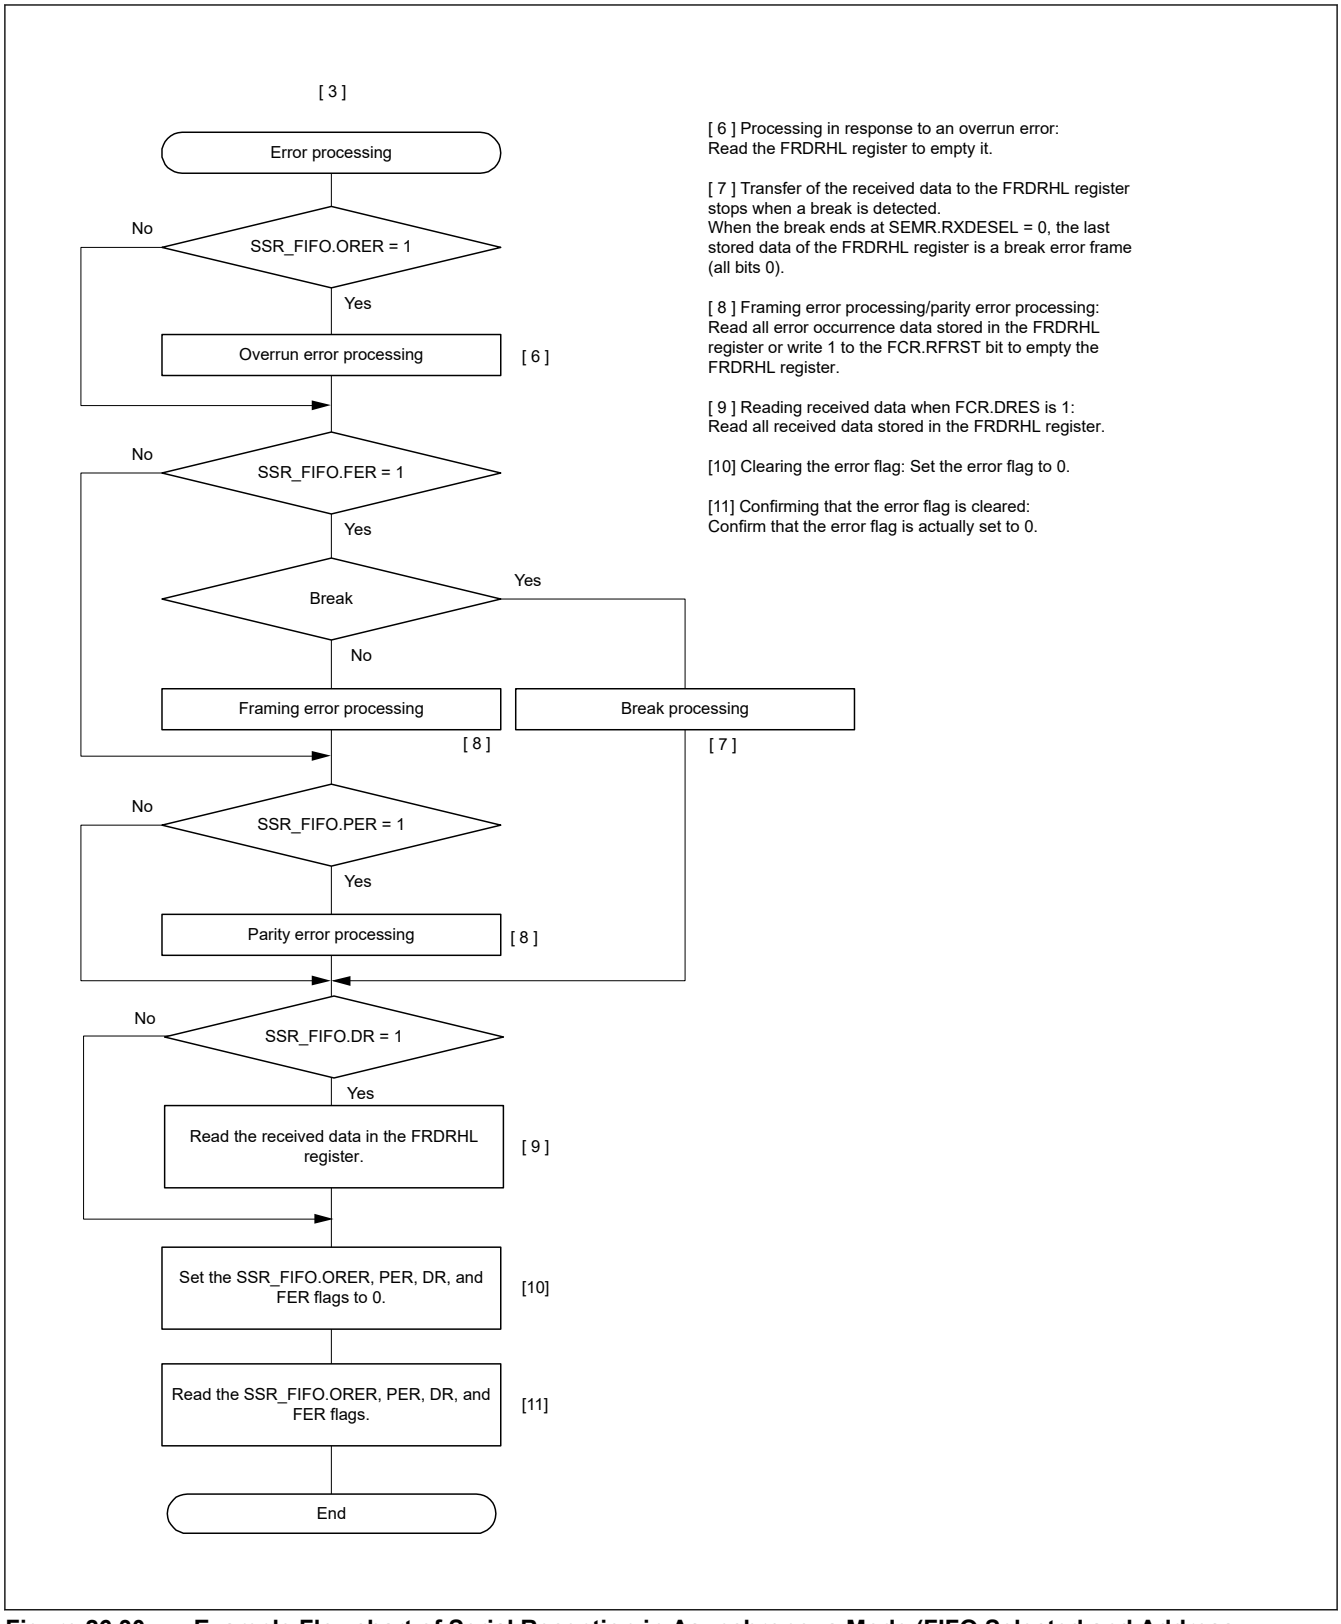

**Figure 26.30 Example Flowchart of Serial Reception in Asynchronous Mode (FIFO Selected and Address Matching Enabled) (3)**

## 26.3.10 The function of adjust receive sampling timing (Asynchronous Mode)

When there is the difference between the rising transfer time and the falling transfer time through a photo coupler, the receive sampling timing at middle of bit affects the reception margin. In this case, the receive sampling timing is able to adjust from the middle of bit to the optimum timing by using this function.

The receive sampling timing is adjusted from the middle of bit by following formula. The adjustable direction is set by ACTR.AJD. When adjusting backward (ACTR.AJD = 0), substitute AJD = +1 and substitute AJD = −1 when adjusting forward (ACTR.AJD = 1).

Adjusted sampling timing = the middle of bit + AJD × (base clock × the setting value of ACTR.AST[2:0])

The setting timing is limited by base clock cycles per 1 bit. For details, see Table 26.31.

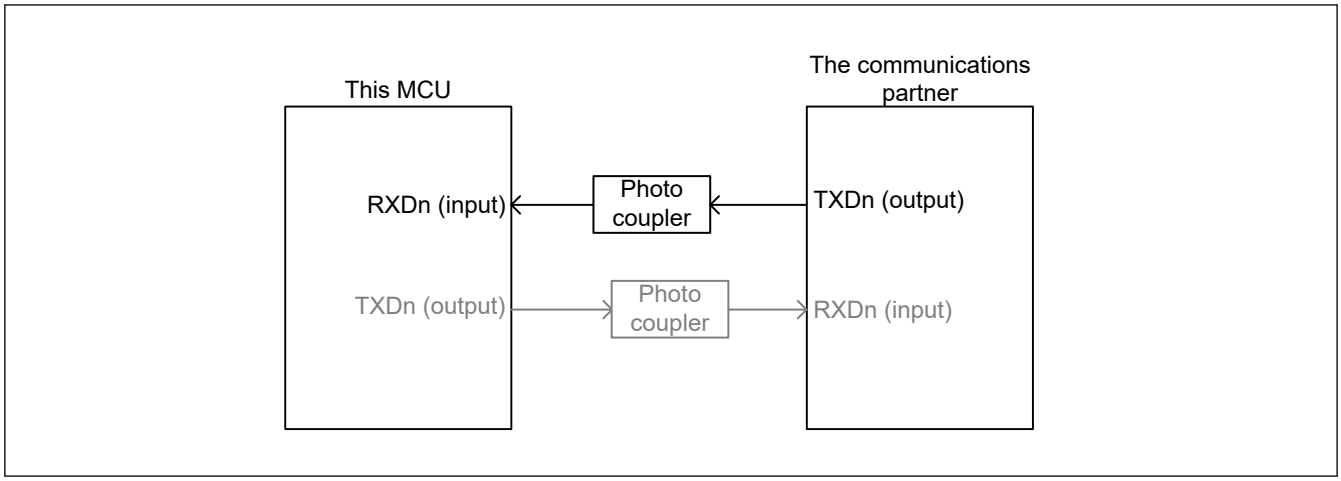
An overview of reception operation of the communication through a photo coupler with this function is shown in Figure 26.31, Figure 26.32 and Figure 26.33, the explanation of operation with this function is shown in Figure 26.34.

Do not use this function when there is no difference between the rising transfer time and the falling transfer time, because there is a possibility of deteriorating the reception margin.

**Table 26.31 The acceptable value of ACTR register (asynchronous mode using internal clock)**

| SEMR.ABCSE | SEMR.ABCS | The number of base clock cycles/1bit | The acceptable value of ACTR | |
|---|---|---|---|---|
| | | | ACTR.AJD | ACTR.AST |
| 1 | x | 6 | 0 | 000b – 010b*1 |
| | | | 1 | |
| 0 | 1 | 8 | 0 | 000b – 011b*1 |
| | | | 1 | |
| 0 | 0 | 16 | 0 | 000b – 111b |
| | | | 1 | |

Note: x: Don't care
Note 1. When the value of ACTR.AST exceeds the acceptable value, sampling is done at default timing. (Adjustment of sampling is not done.)



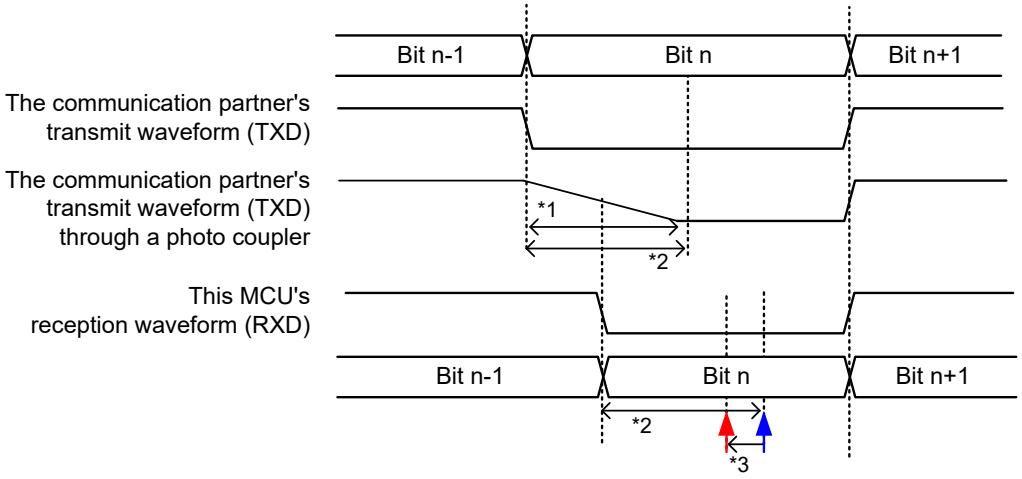


**Figure 26.31 Block diagram image of the reception through a photo coupler**

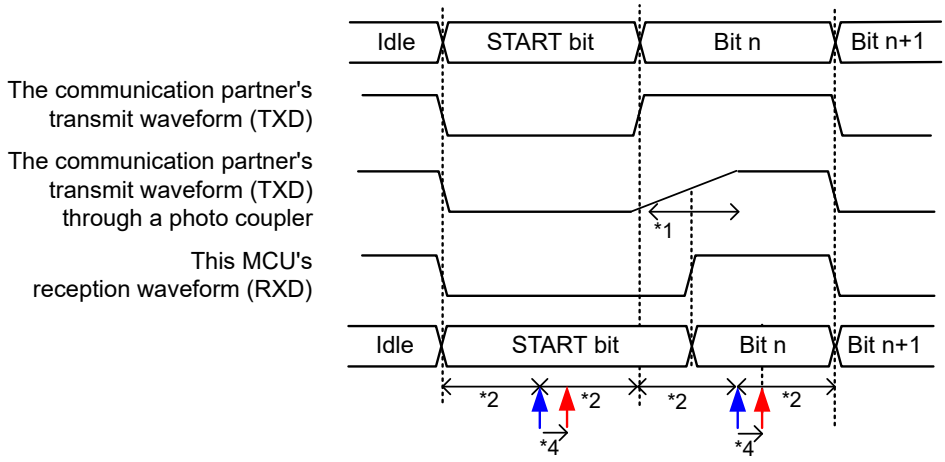

(a) In the case of the falling transfer time >> rising transfer time

The falling edge of reception waveform is made dull like following chart.
In this case, you can sampling at the middle of bit if you adjust the receive sampling timing to forward (AJD = 1).

(b) In the case of the falling transfer time << rising transfer time

The rising edge of reception waveform is made dull like following chart.
Thus, the reception margin of communications partner will be bad. In this case, you can improve the reception margin if you adjust the receive sampling timing to back.

The receive sampling timing when unadjusted (middle of bit)

The adjusted receive sampling timing

Note: This waveform shows the operation image of adjustment in reception sampling timing.
Note 1. The dull period by a photo coupler
Note 2. Bit center timing at set communication rate
Note 3. When ACTR.AJD is 1, the receive sampling timing is shifted to forward by the setting value of ACTR.AST[2:0].
Note 4. When ACTR.AJD is 0, the Receive sampling timing is shifted to backward by the setting value of ACTR.AST[2:0].

**Figure 26.32 Overview of reception operation of the communication through a photo coupler**

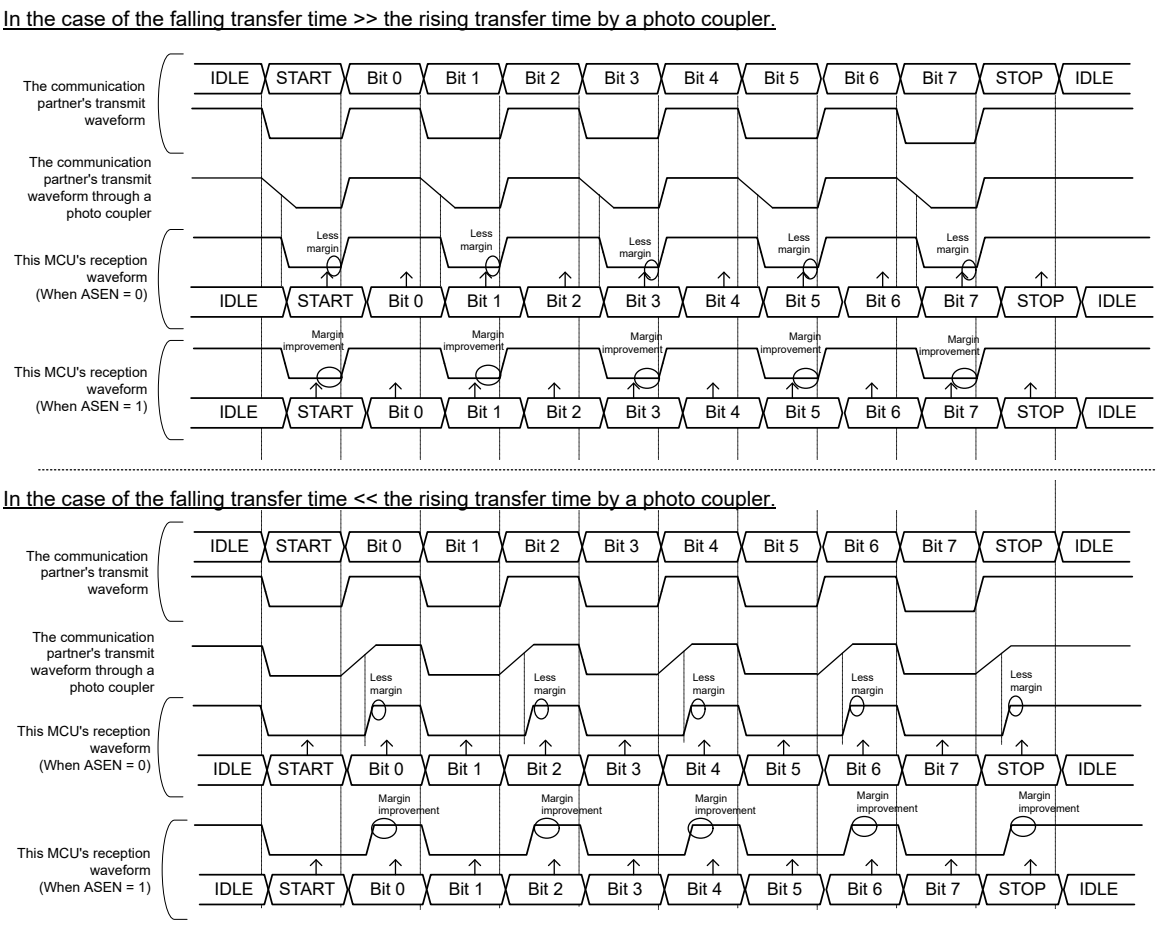

**Figure 26.33 Example of improvement in reception margin by the reception sampling timing adjustment function**

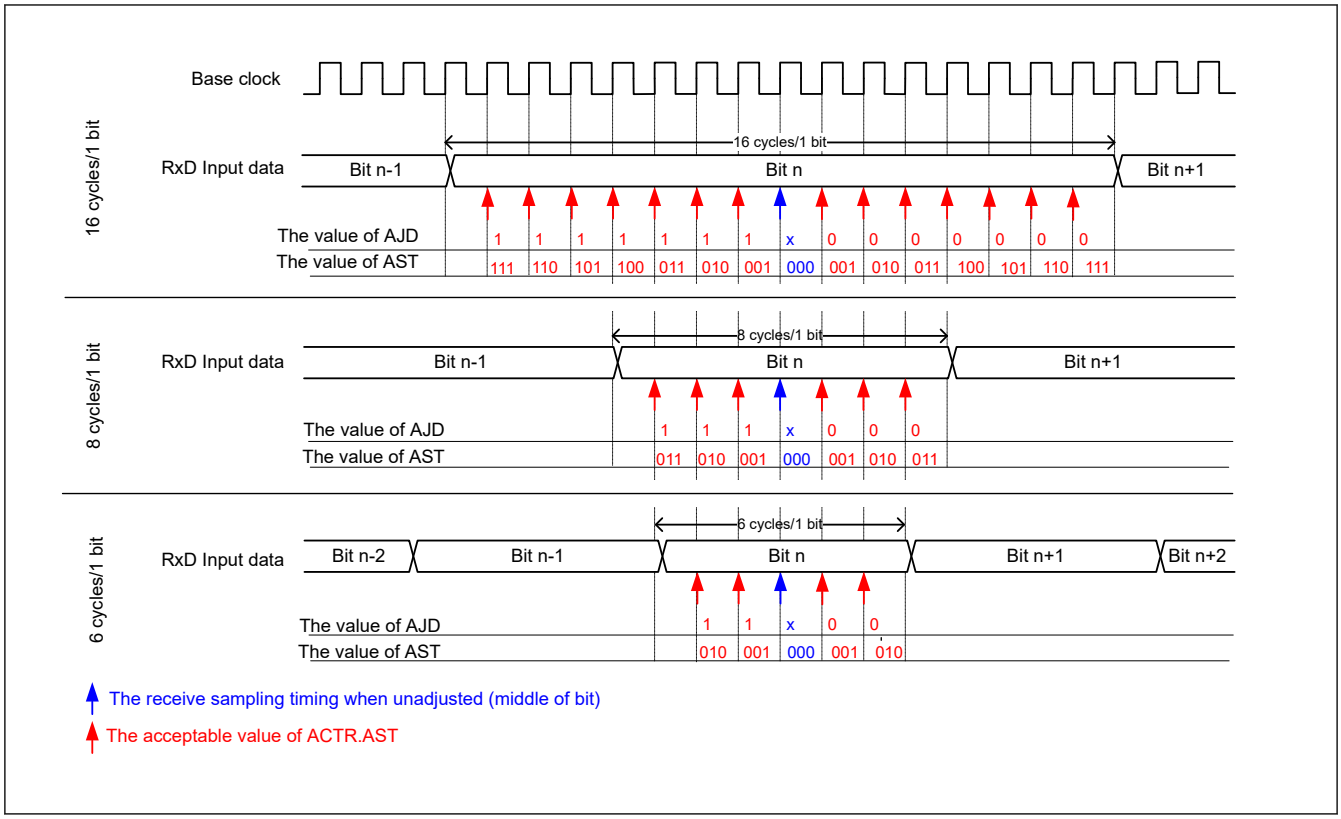

**Figure 26.34 Overview of the adjustment operation for the reception sampling timing (asynchronous mode using internal clock)**

## 26.3.11 The function of adjust transmit timing (Asynchronous Mode)

In communication via a photo coupler or the like, when either the rising or falling transition time of the TXDn output signal is long, then a communication partner receive dulled waveform. In this case, the reception margin may be affected.

In these cases, make a communication partner to be sampling at middle of bit using the function of adjust transmit timing.

When SPTR.ATEN is 1, this function can adjust the edge timing at the timing calculated by the following formula for the edge set with ACTR.AET.

The adjustment edge timing = the base clock × ACTR.ATT[2:0]

In addition, the upper limit of the adjustment edge timing is limited by setting the base clock cycles. For details, see Table 26.32.

A transmission movement image figure of the communication through a photo coupler with this function is shown in Figure 26.35, Figure 26.36 and Figure 26.37, the overview of operation with this function is shown in Figure 26.38 and Figure 26.39.

Do not use this function when there is not the difference between the rising transfer time and the falling transfer time, there is a possibility of deteriorating the reception margin of a communication partner.

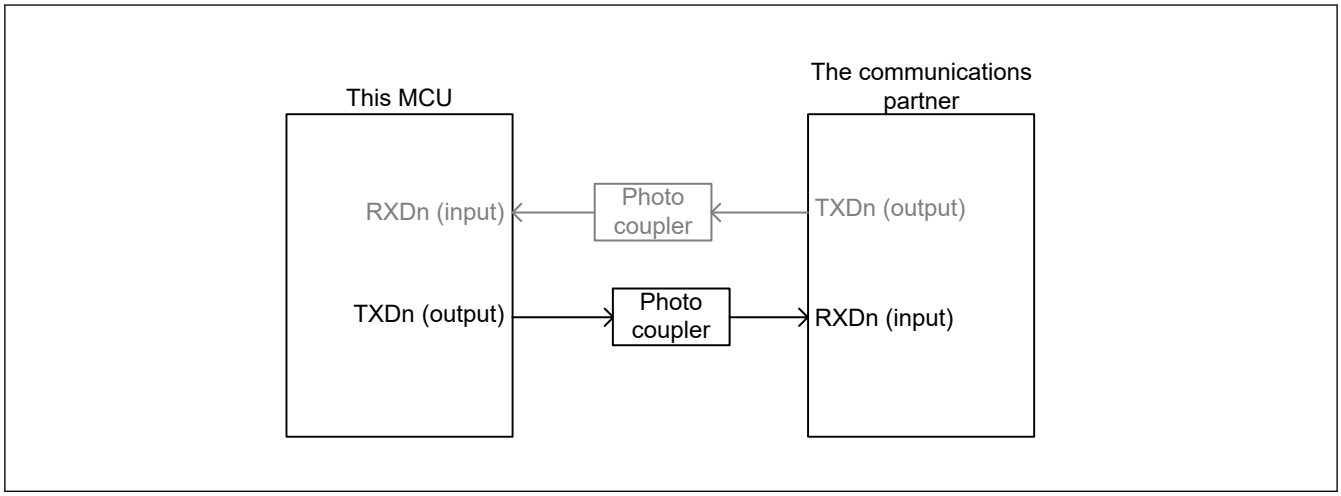
**Table 26.32 The acceptable value of ACTR.AET and ACTR.ATT (asynchronous mode using internal clock) (1 of 2)**

| ABCSE | ABCS | The number of base clock cycles/1bit | The acceptable value of ACTR | |
|---|---|---|---|---|
| | | | AET | ATT[2:0] |
| 1 | x | 6 | 0 | 000b – 101b |
| | | | 1 | |
| 0 | 1 | 8 | 0 | 000b – 111b |
| | | | 1 | |

**Table 26.32 The acceptable value of ACTR.AET and ACTR.ATT (asynchronous mode using internal clock) (2 of 2)**

| ABCSE | ABCS | The number of base clock cycles/1bit | The acceptable value of ACTR | |
|---|---|---|---|---|
| | | | AET | ATT[2:0] |
| 0 | 0 | 16 | 0 | 000b – 111b |
| | | | 1 | |

Note: x: Don't care
Note: When the value of ACTR.AET/ATT is out of the acceptable value, this SCI module doesn't adjust transmit timing.



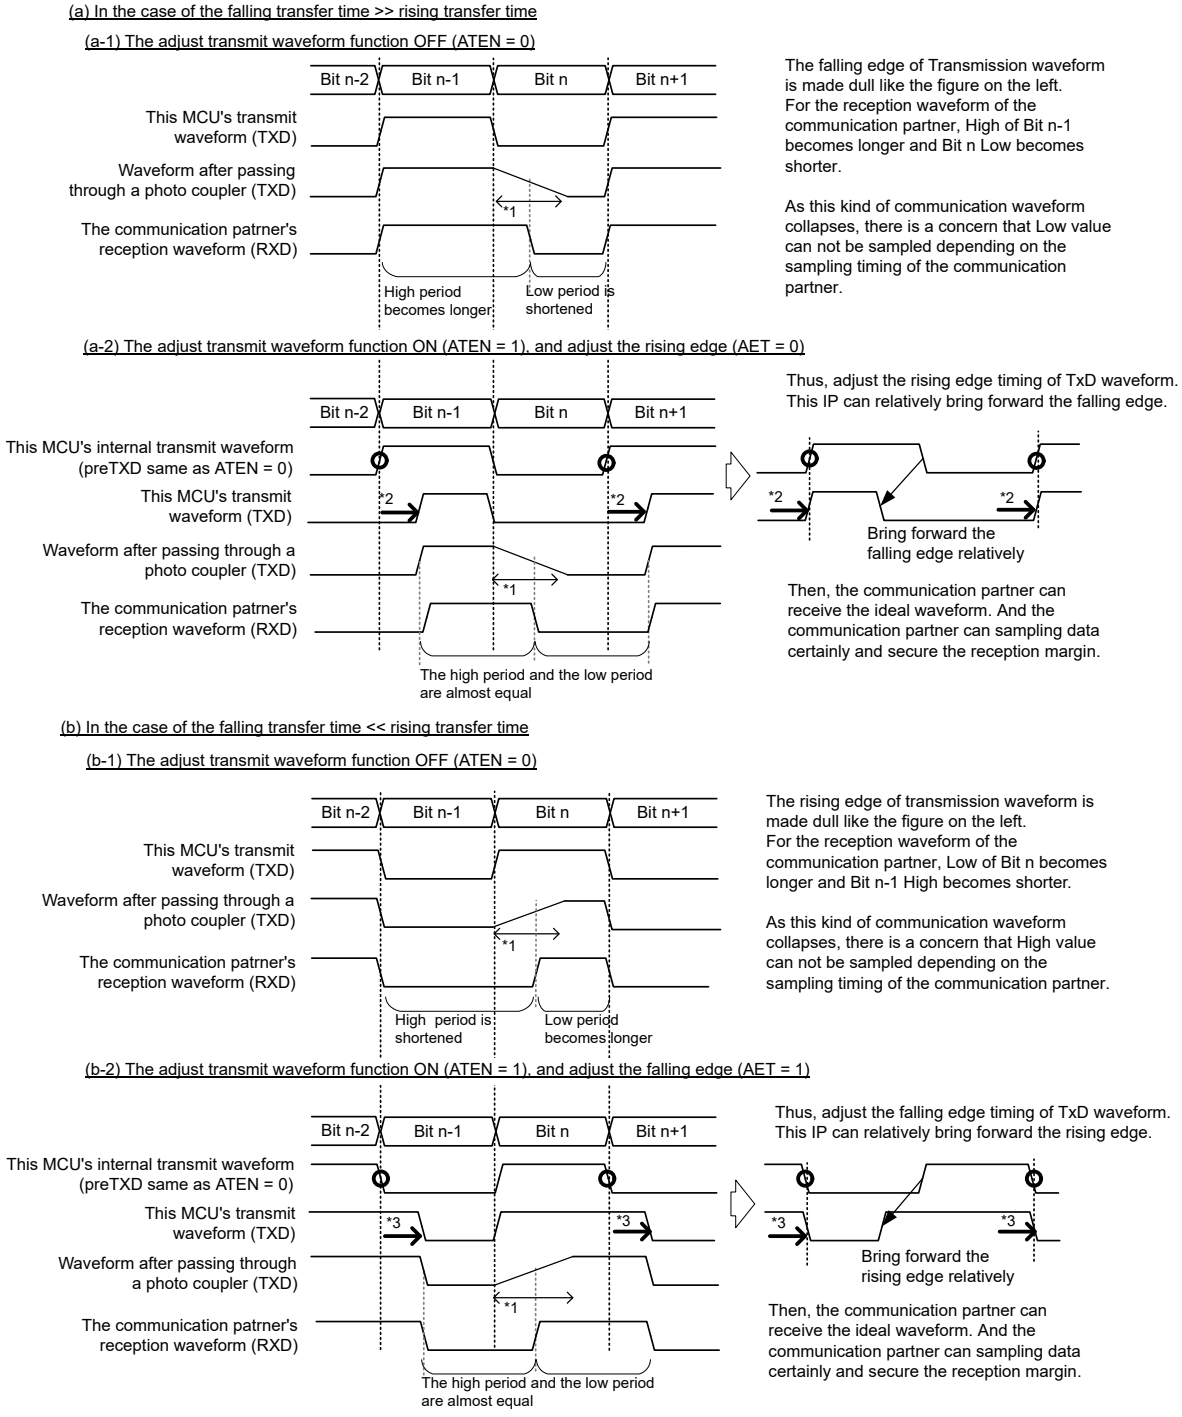


**Figure 26.35 block diagram image of the transmission through a photo coupler**

Note: This waveform shows the operation image of adjustment transmit waveform.
Note 1. The dull period by a photo coupler
Note 2. When ACTR.AET is 0, the rising edge of transmit waveform timing is shifted to back by the setting value of ACTR.ATT[2:0]. This IP transmit waveform bringing forward the falling edge relatively.
Note 3. When ACTR.AET is 1, the falling edge of transmit waveform timing is shifted to back by the setting value of ACTR.ATT[2:0]. This IP transmit waveform bringing forward the rising edge relatively.

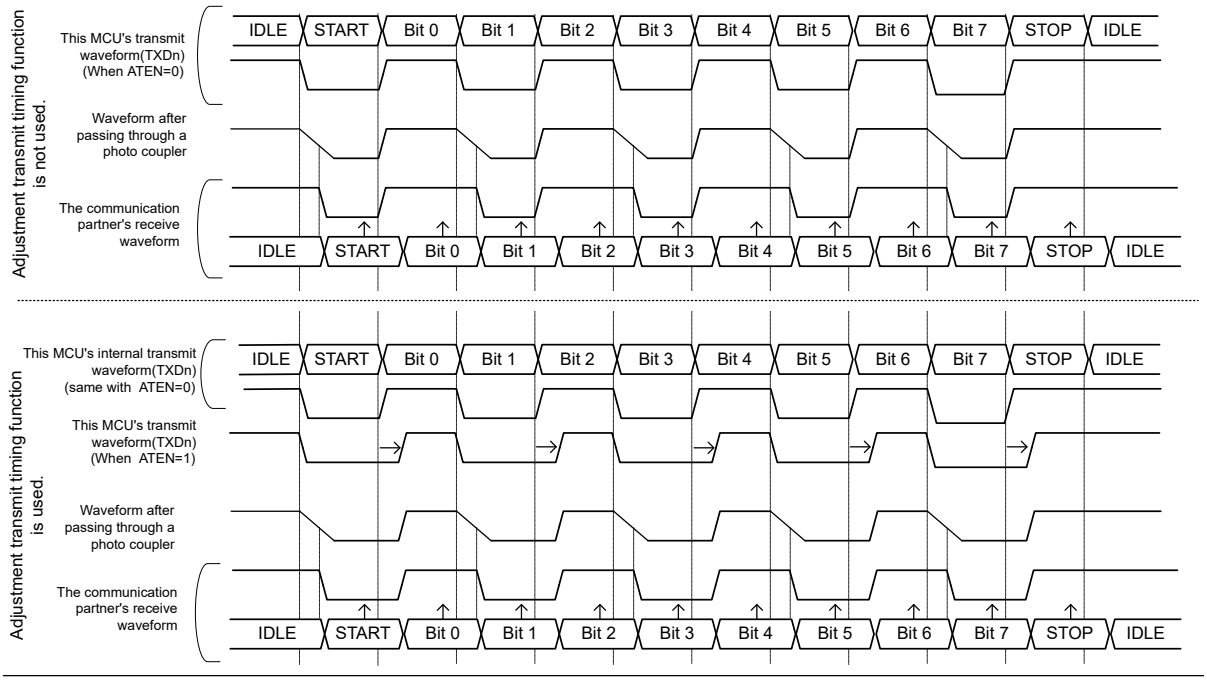

**Figure 26.36 The overview of transmission operation in the communication through a photo coupler**

The explanation of transmit waveforms of the communication through a photo coupler using adjust transmit timing function

When using the transmission timing adjustment function, adjust the edge timing of the transmission waveform and correct the reception waveform of the communication partner

The following example is 8 bit long data.

(a) In the case of the falling edge transfer time >> the rising transfer time

(b) In the case of the falling edge transfer time << the rising transfer time

Note 1. The falling edge of transmit timing is shifted to back by the setting value of ACTR.ATT[2:0].

**Figure 26.39 The adjustment operation explanation for the transmit timing when AET is 1**

## 26.4 Multi-Processor Communication Function

The multi-processor communication function enables the SCI to transmit and receive data between multiple processors by sharing an asynchronous serial communication line that has an added multi-processor bit. In multi-processor communication, a unique ID code is allocated to each receiving station. Serial communication cycles consist of an ID transmission cycle to specify the receiving station and a data transmission cycle to transmit data to the specified receiving station.

The multi-processor bit is used to distinguish between the ID transmission cycle and the data transmission cycle:

- When the multi-processor bit is set to 1, the transmission cycle is the ID transmission cycle
- When the multi-processor bit is set to 0, the transmission cycle is the data transmission cycle

Figure 26.40 shows an example of communication between processors using a multi-processor format. First, a transmitting station transmits communication data in which the multi-processor bit set to 1 is added to the ID code of the receiving station. Next, the transmitting station transmits communication data in which the multi-processor bit set to 0 is added to the transmit data. After receiving communication data with the multi-processor bit set to 1, the receiving station compares the received ID with the ID of the receiving station itself. If the two match, the receiving station receives communication data that is subsequently transmitted. If the received ID does not match with the ID of the receiving station, the receiving station skips the communication data until it receives data in which the multi-processor bit is set to 1.

(1) Non-FIFO selected

To support this function, the SCI provides the SCR.MPIE bit. When the MPIE bit is set to 1, the following operations are disabled until the reception of data in which the multi-processor bit is set to 1:

- Transfer of receive data from the RSR register to the RDR register (the RDRHL register when 9-bit data length is selected)
- Detection of a receive error
- Setting of the respective RDRF, ORER, and FER status flags in the SSR register

When the SCI receives a character in which the multi-processor bit is set to 1, the SSR.MPBT bit is set to 1 and the SCR.MPIE bit is automatically cleared, returning the SCI to normal reception operation. If the SCR.RIE bit is set to 1, an SCIn_RXI interrupt is generated.

When the multi-processor format is specified, the parity bit function is disabled. Apart from this, there is no difference from operation in normal asynchronous mode. The clock used for the multi-processor communication is the same as the clock used in normal asynchronous mode.

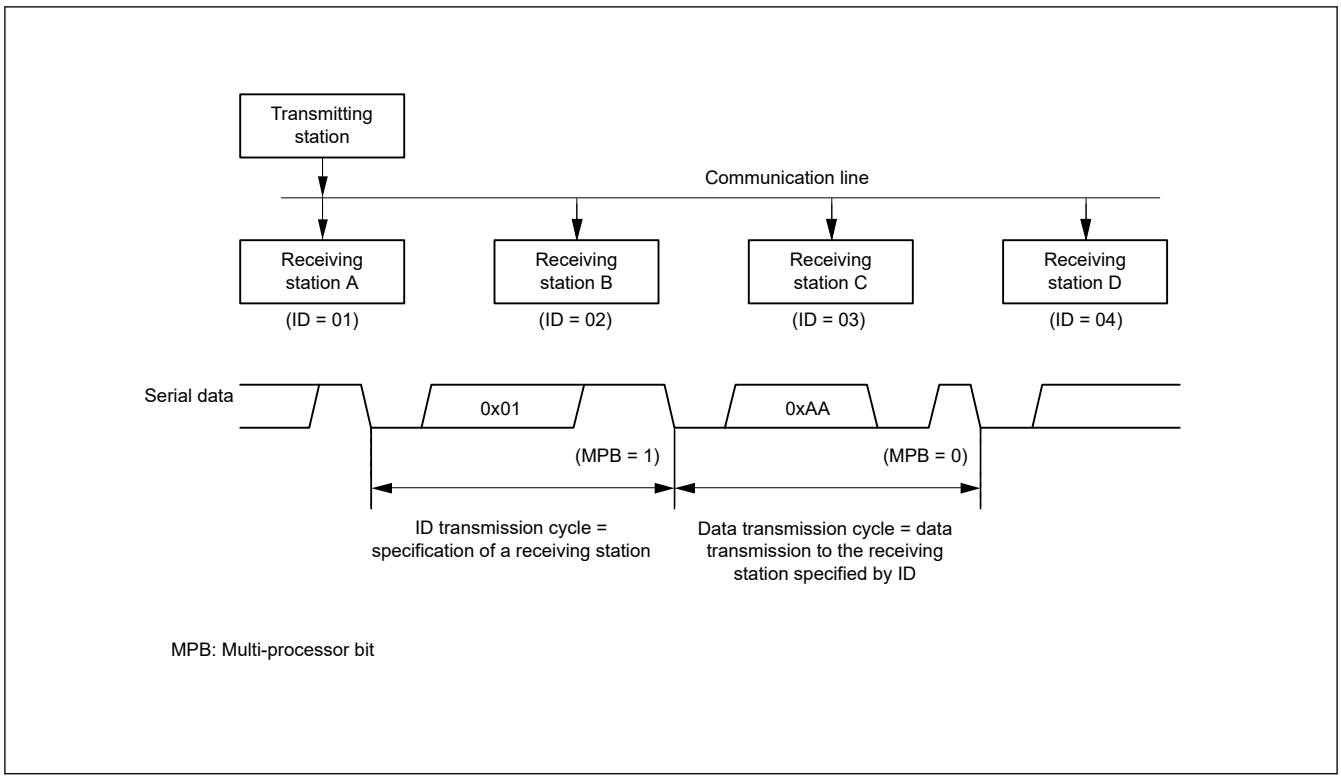

**Figure 26.40 Example of communication using multi-processor format with transmission of data 0xAA to receiving station A**

(2) FIFO selected

For data transmission, software must write data to FTDRHL.MPBT that corresponds to transmit data in FTDRHL.TDAT. For data reception, the multi-processor bit that is part of the receive data is written to FTDRHL.MPB and receive data is written to FRDRL.

When the MPIE bit is set to 1, the following operations are disabled until reception of data in which the multi-processor bit is set to 1:

- Transfer of receive data from the RSR register to the FRDRHL register
- Detection of a receive error
- Break
- Setting of the respective RDF, ORER, and FER status flags in the SSR_FIFO register

When the SCI receives an 8-bit character in which the multi-processor bit is set to 1, the FTDRHL.MPB bit is set to 1 and receive data is written to FRDRHL.RDAT. The SCR.MPIE bit is automatically cleared, returning the SCI to normal reception operation. If the SCR.RIE bit is set to 1, an SCIn_RXI interrupt is generated.

When the multi-processor format is specified, the parity bit function is disabled. Apart from this, there is no difference from operation in normal asynchronous mode with FIFO selected.

## 26.4.1 Multi-Processor Serial Data Transmission

**(1) Non-FIFO selected**

Figure 26.41 shows an example flow of multi-processor data transmission. In the ID transmission cycle, the ID must be transmitted with the SSR.MPBT bit set to 1. In the data transmission cycle, the data must be transmitted with the MPBT bit set to 0. The rest of the operations are the same as operations in asynchronous mode. Write the values in the order of the FTDRH register then the FTDRL register.

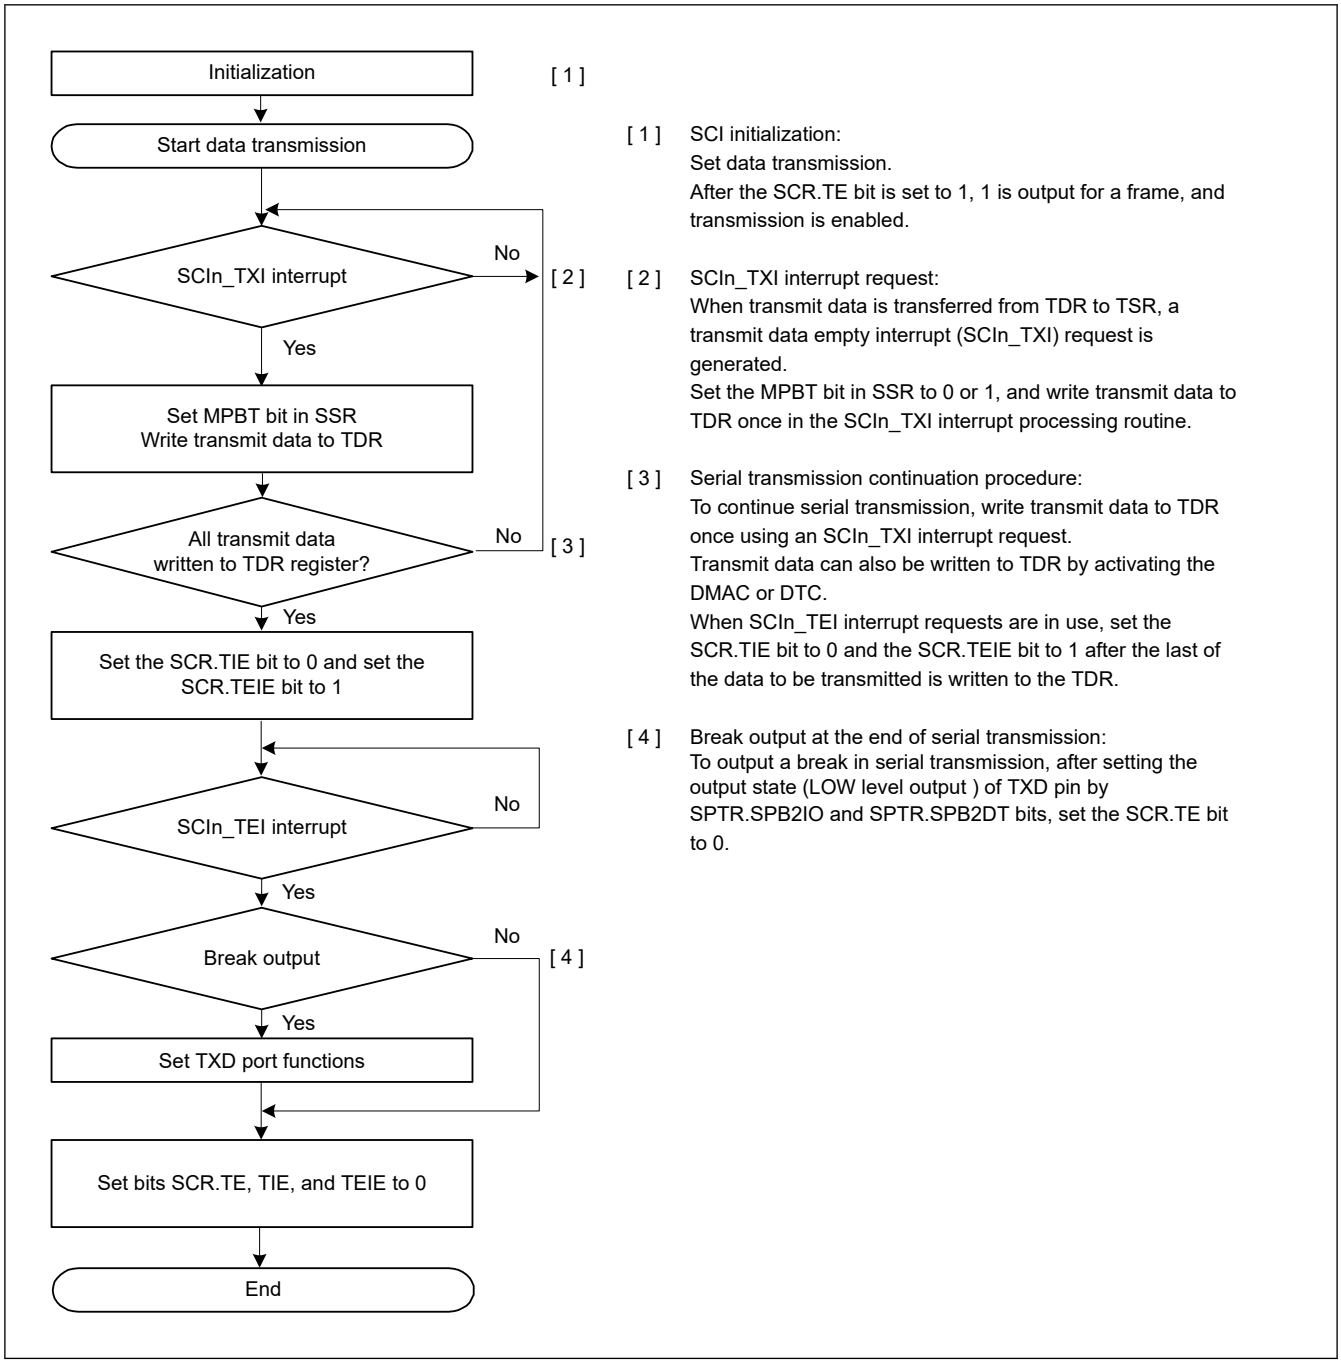

**Figure 26.41 Example flow of multi-processor serial transmission with non-FIFO selected**

### (2) FIFO selected

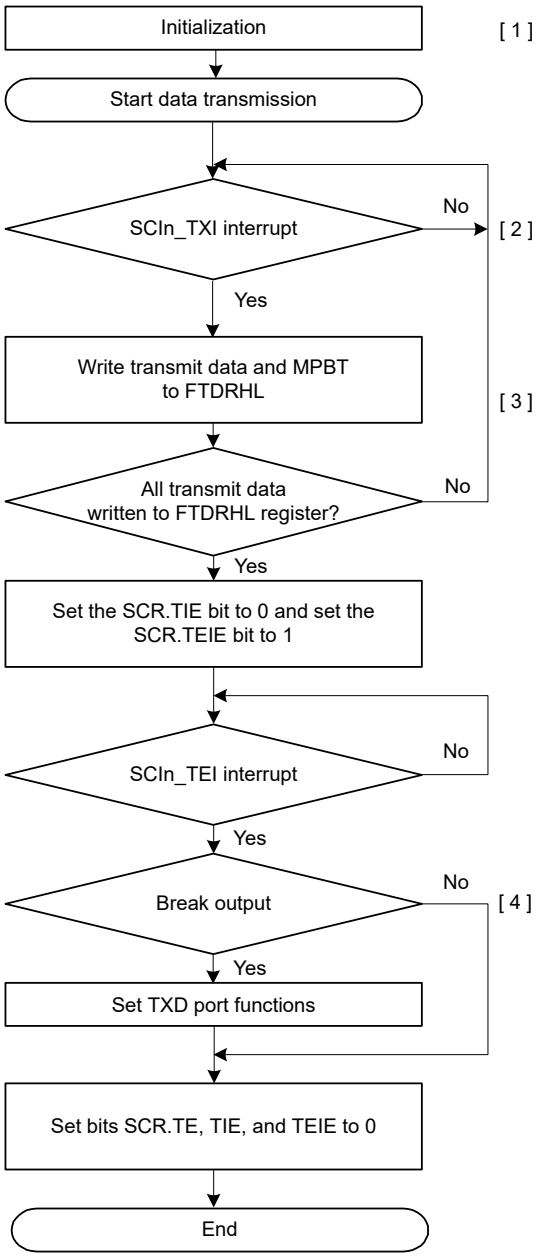

Figure 26.42 shows an example of data format that is written to FTDRH and FTDRL in multi-processor mode. The FTDRH.MPBT bit is set to 1. Data is set to FTDRH and FTDRL with the correct data length. Write 0 for unused bits. Write in order from FTDRH to FTDRL.

| Data Length | Register Setting | | Transmit data in FTDRH, FTDRL | | | | | | | | | | | | | | | |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | | | FTDRHL | | | | | | | | | | | | | | | |
| | | | FTDRH | | | | | | | | FTDRL | | | | | | | |
| | SCMR.CHR1 | SMR.CHR | b15 | b14 | b13 | b12 | b11 | b10 | b9 | b8 | b7 | b6 | b5 | b4 | b3 | b2 | b1 | b0 |
| 7 bits | 1 | 0 | – | – | – | – | – | – | MPBT | – | – | 7-bit transmit data | | | | | | |
| 8 bits | 1 | 1 | – | – | – | – | – | – | MPBT | – | 8-bit transmit data | | | | | | | |
| 9 bits | 0 | Don't care | – | – | – | – | – | – | MPBT | 9-bit transmit data | | | | | | | | |

Note: —: Invalid. The write value should be 0.

**Figure 26.42 Data format written to FTDRH and FTDRL in multi-processor mode with FIFO selected**

Figure 26.43 shows an example flow of multi-processor serial transmission with FIFO selected. In the ID transmission cycle, the ID must be transmitted with the FTDRH.MPBT bit set to 1. In the data transmission cycle, the data must be transmitted with the MPBT bit set to 0. The rest of the operations are the same as operations in asynchronous mode with FIFO selected.

[ 1 ] SCI initialization:
Set data transmission.
After the SCR.TE bit is set to 1, 1 is output for a frame, and transmission is enabled.

[ 2 ] Transmit data write to FTDRHL by an SCIn_TXI interrupt request:
When transmit data is transferred from FTDRHL to TSR, when the quantity of receive data written in FTDRHL is equal to or less than the specified transmit triggering number, a transmit data FIFO empty interrupt (SCIn_TXI) request is generated.

[ 3 ] Serial transmission continuation procedure:
To continue serial transmission, write transmit data and MPBT to FTDRHL once using an SCIn_TXI interrupt request.
Transmit data can also be written to FTDRHL by activating the DMAC or DTC.
When SCIn_TEI interrupt requests are in use, set the SCR.TIE bit to 0 and the SCR.TEIE bit to 1 after the last of the data to be transmitted is written to the FTDRHL.

[ 4 ] Break output at the end of serial transmission:
To output a break in serial transmission, after setting the output state (LOW level output) of TXD pin by SPTR.SPB2IO and SPTR.SPB2DT bits, set the SCR.TE bit to 0.

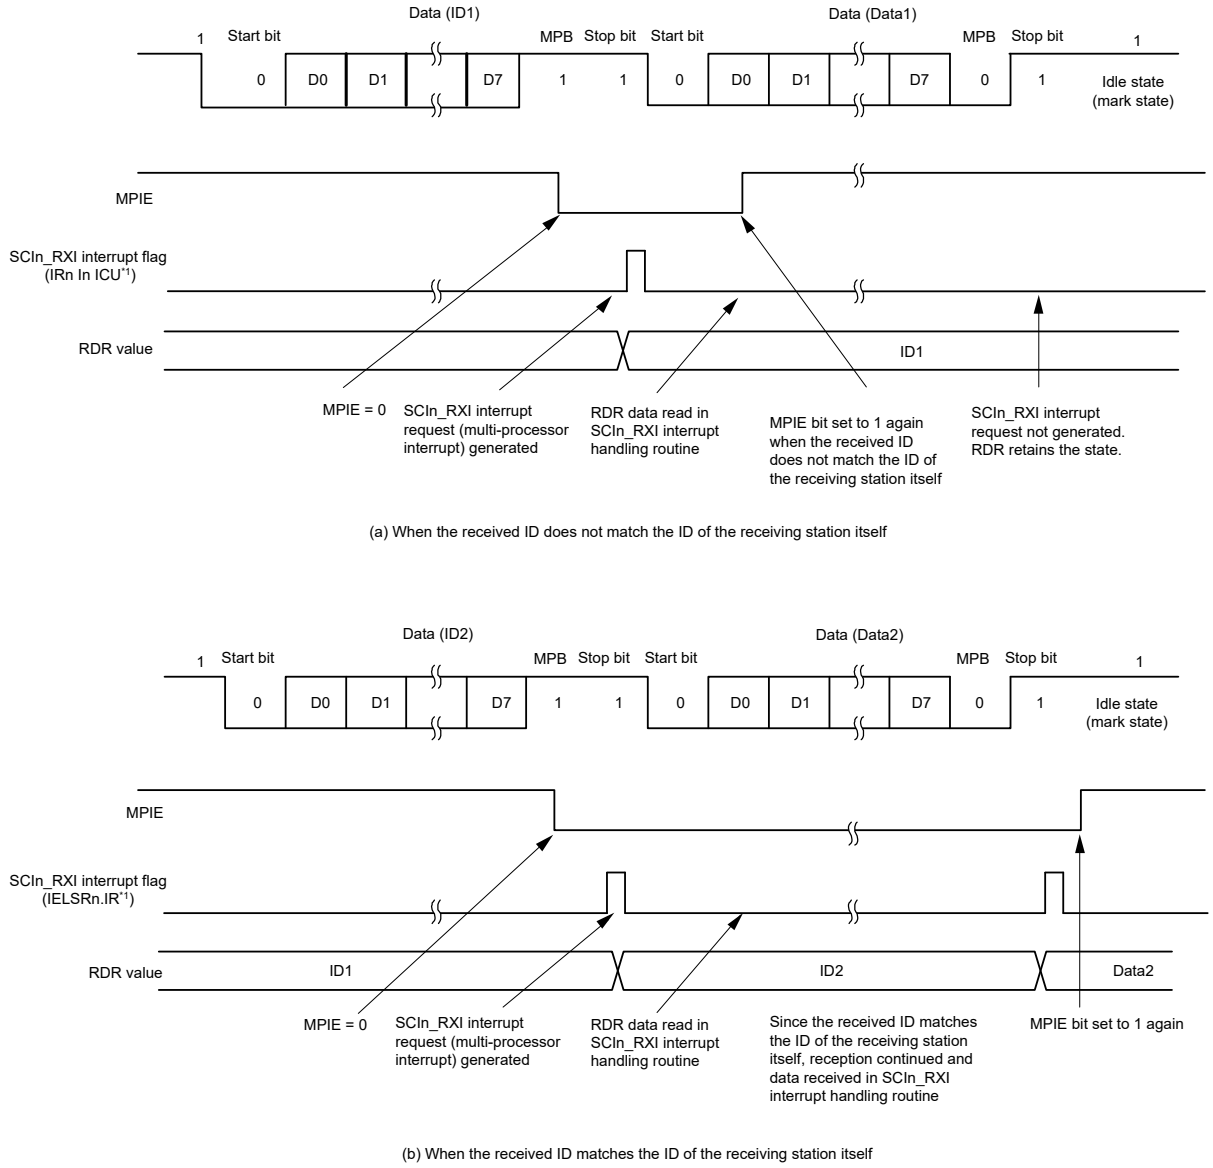

**Figure 26.43 Example flow of serial transmission in multi-processor mode with FIFO selected**

## 26.4.2 Multi-Processor Serial Data Reception

### (1) Non-FIFO selected

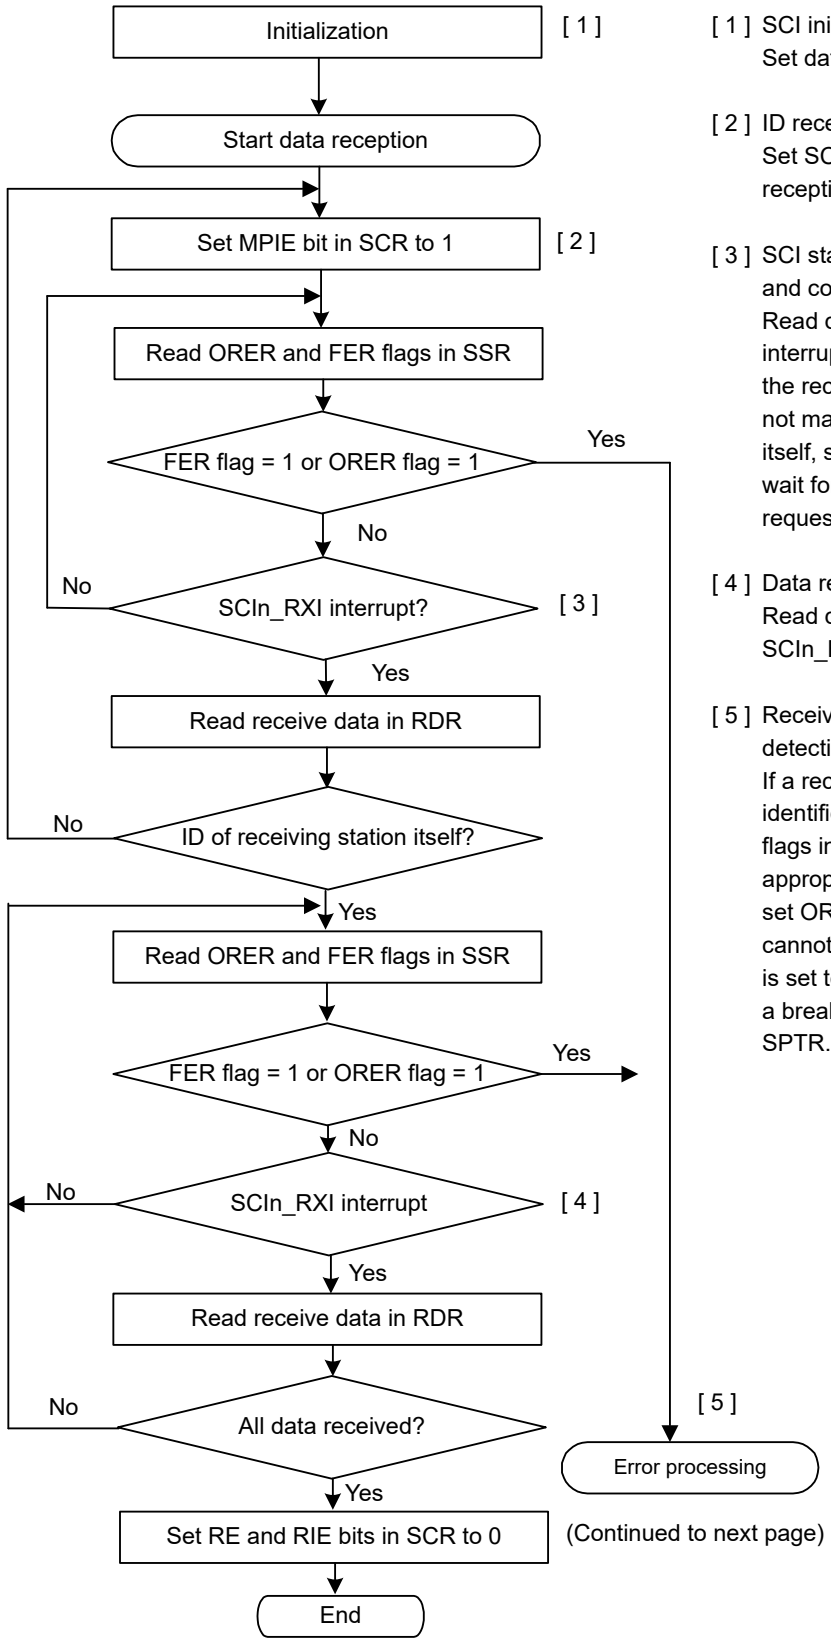

Figure 26.45 and Figure 26.46 are example flows of multi-processor serial reception. When the SCR.MPIE bit is set to 1, reading communication data is skipped until reception of communication data in which the multi-processor bit is set to 1. When communication data in which the multi-processor bit is set to 1 is received, the received data is transferred to the RDR register (the RDRHL register when 9-bit data length is selected), and the SCIn_RXI interrupt request is generated. The rest of the operations are the same as operations in asynchronous mode. Read the order from FRDRH to FRDRL.

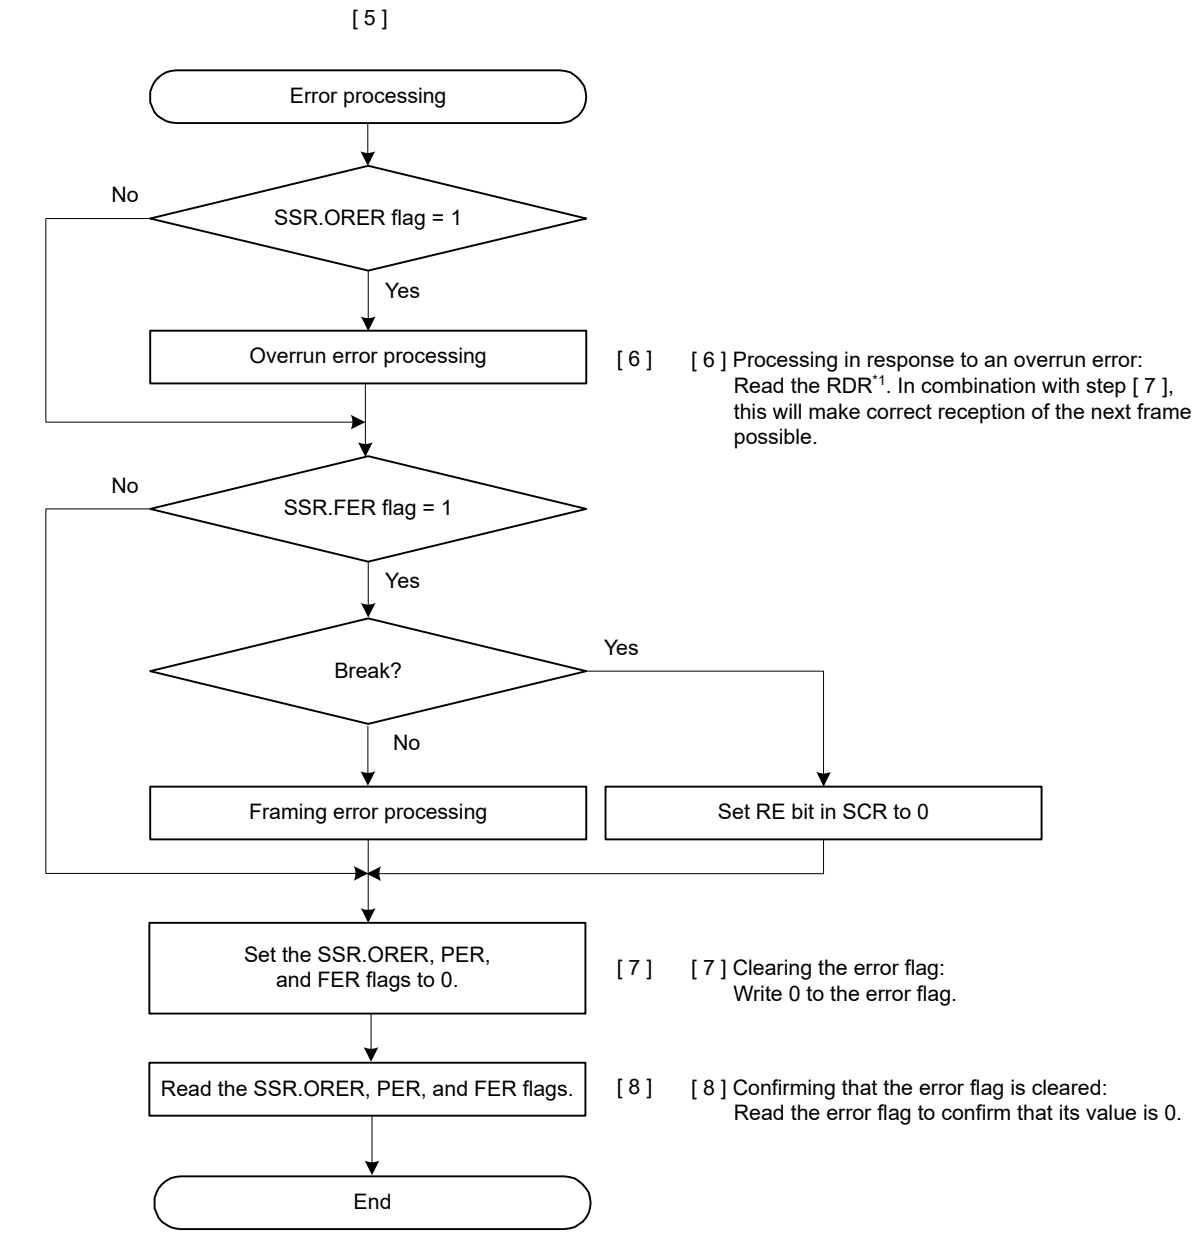
Figure 26.44 shows an example operation for data reception.

Note 1. See section 12, Interrupt Controller Unit (ICU) for information on the corresponding interrupt event number.

**Figure 26.44 Example of SCI reception with 8-bit data, multi-processor bit, and 1 stop bit**

[ 1 ] SCI initialization:
Set data reception.

[ 2 ] ID reception cycle:
Set SCR.MPIE bit to 1 and wait for ID reception.



[ 3 ] SCI status confirmation and reception and comparison of ID:
Read data in RDR*1 at the first SCIn_RXI interrupt and compare it with the ID of the receiving station itself. If the ID does not match the ID of the receiving station itself, set the MPIE bit to 1 again, and wait for another SCIn_RXI interrupt request.

[ 4 ] Data reception at an SCIn_RXI interrupt:
Read data in RDR*1 once in the SCIn_RXI interrupt routine.

[ 5 ] Receive error processing and break detection:
If a receive error occurs, an error is identified by reading ORER and FER flags in SSR. After performing the appropriate error processing, be sure to set ORER and FER flags to 0. Reception cannot be resumed if any of these flags is set to 1. In the case of a framing error, a break can be detected by reading SPTR.RXDMON flag.

Note 1. The RDR register becomes the RDRHL register when 9-bit data length is selected.

**Figure 26.45 Example flow of multi-processor serial reception with non-FIFO selected (1)**

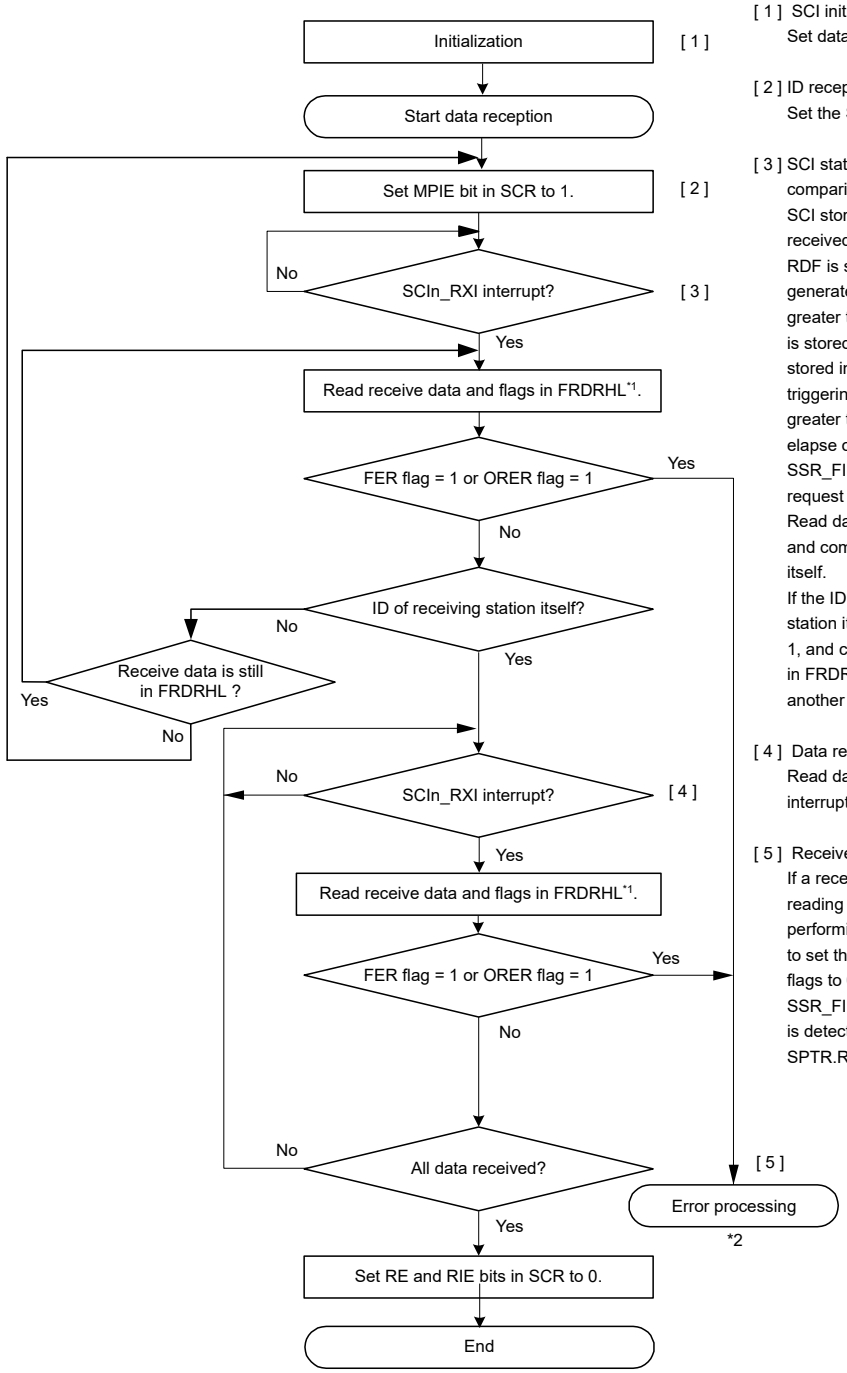
Note 1. The RDR register becomes the RDRHL register when 9-bit data length is selected.

**Figure 26.46 Example flow of multi-processor serial reception with non-FIFO selected (2)**

### (2) FIFO selected

Figure 26.47 shows an example of a data format that is written to FRDRH and FRDRL in multi-processor mode.

In multi-processor mode, the MPB value that is a part of the receive data is written to the FRDRH.MPB bit. A value of 0 is written to the FRDRH.PER flag. Data is written to FRDRH and FRDRL with the correct data length. Unused bits are written with 0. Read in order from FRDRH to FRDRL. When software reads the FRDRL register, the SCI updates FER, MPB, and receive data (RDAT[8:0]) in FRDRL with the next data. The RDF, ORER and DR flags in the FRDRH register always reflect the associated flags in the SSR_FIFO register.



| Data Length | Register Setting | | Receive data in FRDRH, FRDRL | | | | | | | | | | | | | | | |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | | | FRDRHL | | | | | | | | | | | | | | | |
| | | | FRDRH | | | | | | | | FRDRL | | | | | | | |
| | SCMR.CHR1 | SMR.CHR | b15 | b14 | b13 | b12 | b11 | b10 | b9 | b8 | b7 | b6 | b5 | b4 | b3 | b2 | b1 | b0 |
| 7 bits | 1 | 0 | – | RDF | ORER | FER | 0 | DR | MPB | 0 | 0 | 7-bit receive data | | | | | | |
| 8 bits | 1 | 1 | – | RDF | ORER | FER | 0 | DR | MPB | 0 | 8-bit receive data | | | | | | | |
| 9 bits | 0 | Don't care | – | RDF | ORER | FER | 0 | DR | MPB | 9-bit receive data | | | | | | | | |

Note: When data length is 7 bits, 0 is always read for FRDRH[0] and FRDRL[7]
When data length is 8 bits, 0 is always read for FRDRH[0]
FRDRHL[15] bit is read as an indefinite value

**Figure 26.47 Data format stored in FRDRH and FRDRL in multi-processor mode with FIFO selected**

Figure 26.48 shows an example flow of multi-processor data reception with FIFO selected. When the SCR.MPIE is set to 1, reading communication data is skipped until reception of communication data in which the multi-processor bit is set to 1. When communication data in which the multi-processor bit is set to 1 is received, the received data, MPB and associated errors are transferred to the FRDRHL register. The SCR.MPIE bit is automatically cleared and normal reception continues.

If a framing error occurs and the SSR_FIFO.FER flag is set to 1, the SCI continues data reception. The rest of the operations are the same as operations in asynchronous mode with FIFO selected.

[ 1 ] SCI initialization:
Set data reception.

[ 2 ] ID reception cycle:
Set the SCR.MPIE bit to 1 and wait for ID reception.

[ 3 ] SCI status confirmation and reception and comparison of ID:
SCI stores first data (MPB = 1) and subsequent received data in FRDRHL.
RDF is set to 1 and an SCIn_RXI interrupt request is generated when a quantity of receive data equal to or greater than the specified receive triggering number is stored in FRDRHL. When the quantity of data stored in FRDRHL falls the specified receive triggering number and received data is equal to or greater than 1, and no next data is received after the elapse of 15 etus from the last stop bit, SSR_FIFO.DR is set to 1. An SCIn_RXI interrupt request is generated when FCR.DRES bit is 0.
Read data in FRDRHL at the first SCIn_RXI interrupt, and compare it with the ID of the receiving station itself.
If the ID does not match the ID of the receiving station itself, the SCI reads until the data with MPB = 1, and compares next ID. If it is no data with MPB = 1 in FRDRHL, set the MPIE bit to 1 again and wait for another SCIn_RXI interrupt request.

[ 4 ] Data reception at an SCIn_RXI interrupt:
Read data in FRDRHL once in the SCIn_RXI interrupt routine.

[ 5 ] Receive error processing and break detection:
If a receive error occurs, an error is identified by reading the ORER and FER flags in SSR_FIFO. After performing the appropriate error processing, be sure to set the SSR_FIFO.ORER and SSR_FIFO.FER flags to 0. Reception cannot be resumed if the SSR_FIFO.ORER flag is set to 1. When framing error is detected, a break can be detected by reading the SPTR.RXDMON flag.

Note 1. If FRDRH and FRDRL are used instead of FRDRHL, read in order from FRDRH to FRDRL.
Note 2. Same as Figure 26.46

**Figure 26.48 Example flow of serial reception in multi-processor mode with FIFO selected**

## 26.5 Operation in Manchester mode

In Manchester mode, the transmit or receive serial data is coded in Manchester encoding.

Figure 26.49 shows the conceptual image of Manchester encoding.

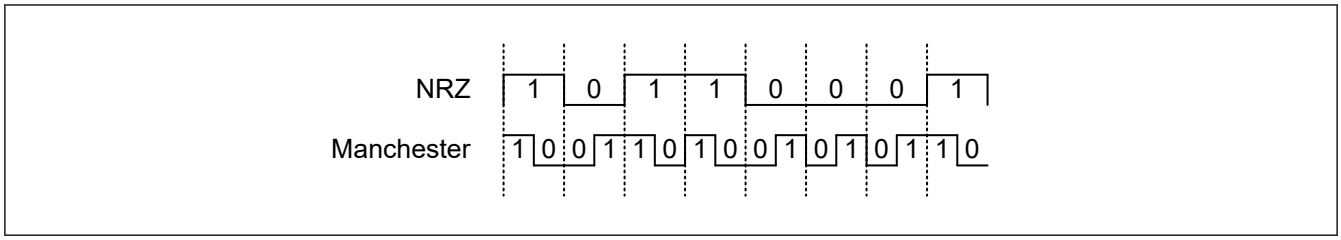


**Figure 26.49 Example of Manchester Encoding**

In Manchester mode, a preface and a start bit area are added to the transmit data in the register to configure a transmit frame. For transmission, data is encoded in Manchester encoding. When data is received, frames having the same format as transmitted frames are detected and Manchester decoding is performed.

For details on the frame format, see section 26.5.1. Frame Format.

## 26.5.1 Frame Format

Figure 26.50 shows the frame format in Manchester mode.

In the upper half of the figure, relevant setting registers are shown.

The preface area and the data area are encoded in Manchester encoding.

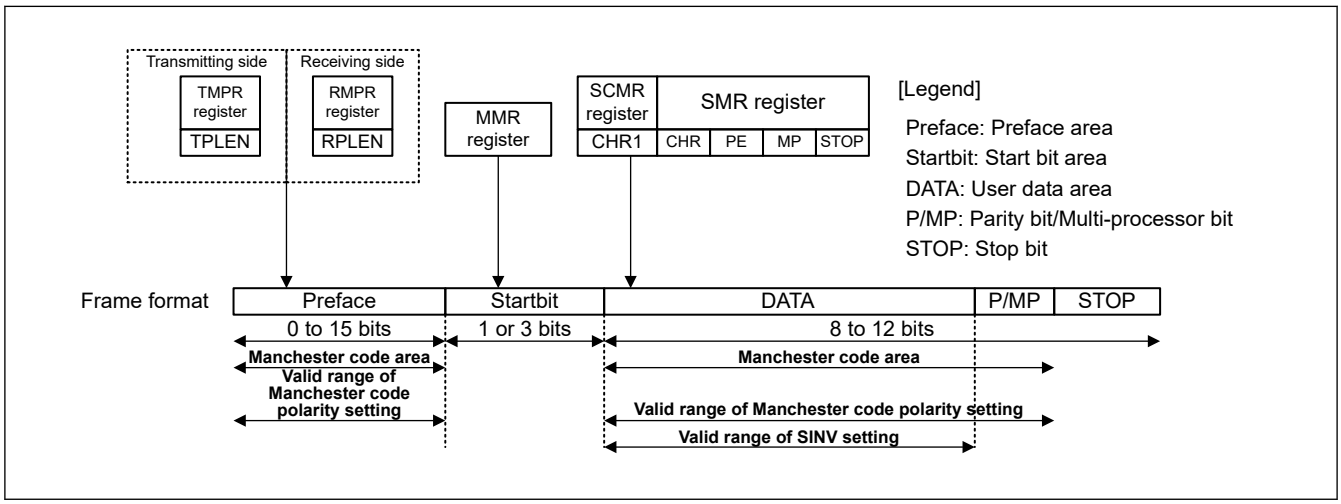

**Figure 26.50 Frame Format in Manchester Mode**

### (1) Preface area

This is a fixed pattern area located at the beginning of each frame.

Different registers are used to set the preface area for transmission and reception. The preface length is determined by setting TMPR.TPLEN[3:0] for transmission. It is determined by setting RMPR.RPLEN[3:0] for reception.

If it is set to 0, the transmit preface is disabled and is not added.

If it is set to 1d to 15d, a preface whose length is determined by this setting is added.

(For example, if it is set to 1d, a 1-bit preface is added. If it is set to 15d, a 15-bit preface is added.)

The preface pattern is set with TMPR.TPPAT[1:0] for transmission and RMPR.RPPAT[1:0] for reception, and is selected from four types of patterns.

Figure 26.51 shows how the preface pattern is set. The preface area and the start bit area are added for each communication frame.

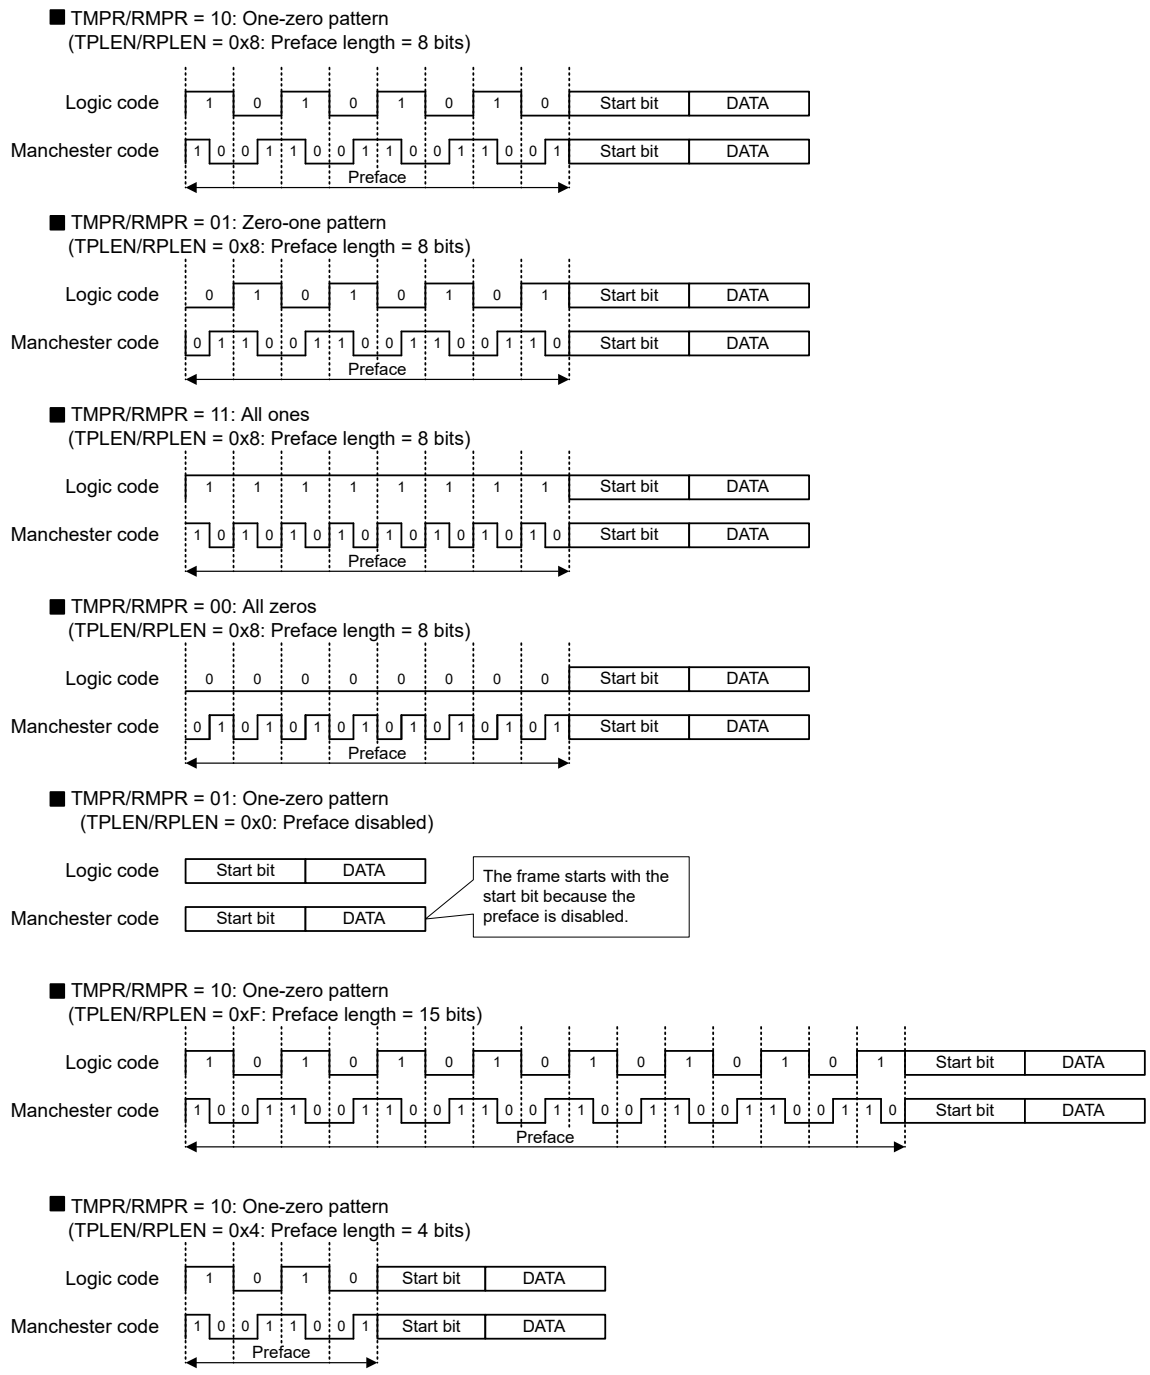

**Figure 26.51 Preface Pattern Setting Example**

## (2) Start bit area

This is an area indicating the start of valid data in a frame. It is added after the preface area.

The start bit length is determined by MMR.SBSEL setting. When MMR.SBSEL = 0, the start bit length is 1 bit.

When MMR.SBSEL = 1, the start bit length is 3 bits.

When MMR.SBSEL = 1, the SYNC type can be selected from command SYNC and data SYNC.

Command SYNC means the three start bits are added as a one-to-zero transition.

Data SYNC means the three start bits are added as a zero-to-one transition.

The SYNC type is determined by the MMR.SYNSEL, MMR.SYNVAL and TDRH_MAN.TSYNC settings.

(When receiving, the received result is applied to RDRH_MAN.RSYNC.)

When MMR.SBSEL = 0, the start bit is added as a zero-to-one or one-to-zero transition.

The selection is determined by the MMR.SYNVAL setting.

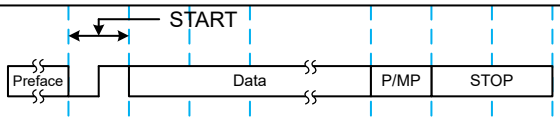
The MMR.SYNSEL bit specifies the destination to be referred to when setting for transmission.

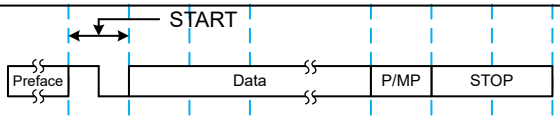
When the MMR.SYNSEL bit is set to 1, the MMR.SYNVAL setting is referred to. When the MMR.SYNSEL bit is set to 0, the TDRH_MAN.TSYNC setting is referred to.

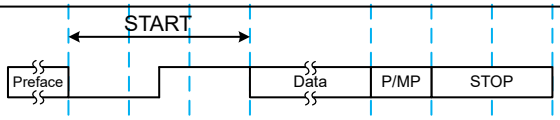
Figure 26.52 shows the state of the start bit area according to the settings in the MMR.SYNSEL, MMR.SYNVAL and TDRH_MAN.TSYNC registers in the case of transmission. Figure 26.53 shows that in the case of reception.

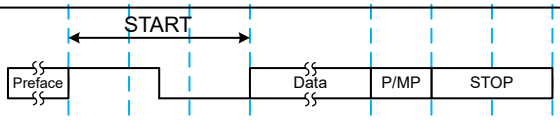
The start bit(s) is not affected by the MMR.TMPOL or MMR.RMPOL setting.

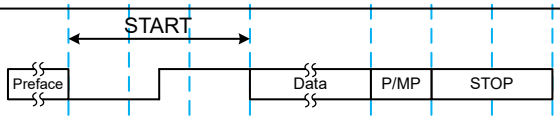
*d.c.=don't care, Preface=preface area, START=start bit area, Data=user data area,
P=parity bit, MP=multi-processor bit, STOP=stop bit

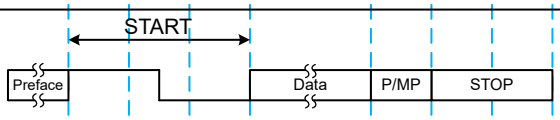


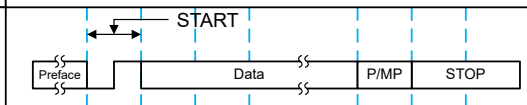


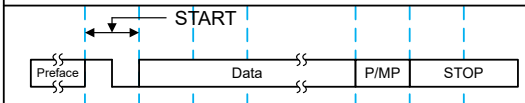


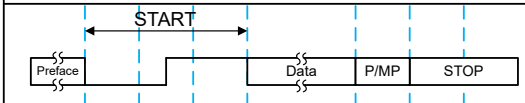


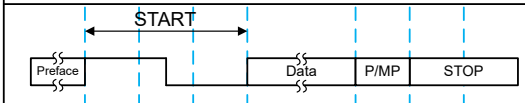


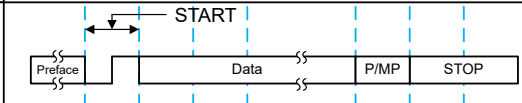


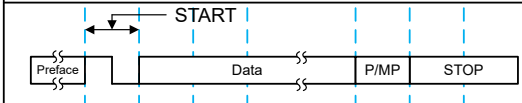


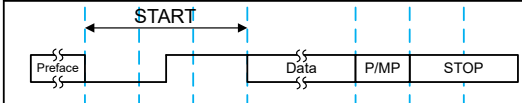


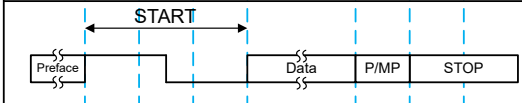


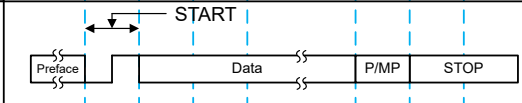


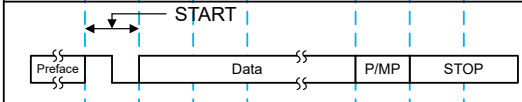


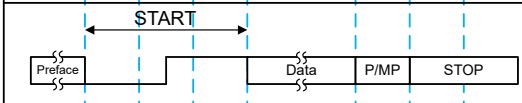


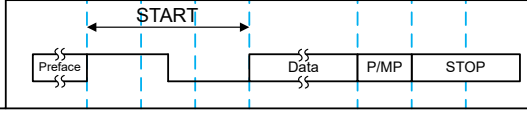












| Register setting | | | | Output signal | |
|---|---|---|---|---|---|
| MMR | | | TDRHL_MAN | Output TXDn waveform | Output start bit |
| SBSEL | SYNSEL | SYNVAL | TSYNC | | |
| 0 | d.c. | 0 | d.c. |  | 1bit<br>0 to 1 transition |
| 0 | d.c. | 1 | d.c. |  | 1bit<br>1->0transition |
| 1 | 0 | 0 | d.c. |  | 3bit<br>0to1 transition<br>(DATA SYNC) |
| 1 | 0 | 1 | d.c. |  | 3bit<br>1to0 transition<br>(COMMAND SYNC) |
| 1 | 1 | d.c. | 0 |  | 3bit<br>0to1 transition<br>(DATA SYNC) |
| 1 | 1 | d.c. | 1 |  | 3bit<br>1to0 transition<br>(COMMAND SYNC) |

**Figure 26.52 Settings Related to and Format of the Start Bit Area at Transmission**

When the start bit area is 3 bits long, SYNVAL is not referenced.

d.c. = don't care, Preface = Preface area, START = Start bit area, Data = Data area
P = Parity bit, MP = Multi-processor bit, STOP = Stop bit

| Register setting | | | | Input signal | Start bit detection result*1 | Register indication |
|---|---|---|---|---|---|---|
| MMR | | | TDRHL_MAN | RXDn input waveform | | RDRHL_MAN.RSYNC |
| SBSEL | SYNSEL | SYNVAL | TSYNC | | | |
| 0 | d.c. | 0 | d.c. |   | Normal start bit (1 bit: 0-to-1 transition) | 0 |
| | | | |   | Start bit error | 0 |
| | | | |   | Start bit error | 0 |
| | | | |   | Start bit error | 0 |
| 0 | d.c. | 1 | d.c. |   | Start bit error | 0 |
| | | | |   | Normal start bit (1 bit: 1-to-0 transition) | 0 |
| | | | |   | Start bit error | 0 |
| | | | |   | Start bit error | 0 |
| 1 | d.c. | d.c. | d.c. |   | Start bit error | 0 |
| | | | |   | Start bit error | 0 |
| | | | |   | Data SYNC | 0 |
| | | | |   | Command SYNC | 1 |

Note 1. Data other than the start bit is assumed to be normal.

**Figure 26.53 Settings Related to and Judgment of the Start Bit Area at Reception**

### (3) DATA

Since the format of the data area is the same as that of the asynchronous mode, see section 26.3.1. Serial Data Transfer Format.

As shown in Figure 26.49, Frame Format in Manchester Mode, the stop bit is not included in the Manchester encoding range.

## 26.5.2 Clock

As the transfer clock in Manchester mode, the clock generated by the on-chip baud rate generator is used by setting the SMR.CKS[1:0] bit.

Also it is possible to set the oversampling (transfer rate of one-bit period) by SEMR.ABCS bit.

When the SMER.ABCS bit is set to 0, oversampling x16 is selected with the one-bit period being 16 cycles of the base clock. When the SMER.ABCS bit is set to 1, oversampling x8 is selected with the one-bit period being 8 cycles of the base clock.

## 26.5.3 Initialization of the SCI in Manchester Mode

Before transferring data, write the initial value (0x00) to the SCR register and initialize the SCI following the example of flowchart shown in Figure 26.54.

Whenever the operating mode or transfer format is changed, the SCR register must be initialized before the change is made.

Note that setting the SCR.RE bit to 0 initializes none of the ORER, FER, PER, MER, and RDRF flags in the SSR_MANC register, the SYER, PFER and SBER flags in the MESR register, and the RDR, RDRHL_MAN registers.

Note also that switching the value of SCR.TE from 0 to 1 when SCR.TIE is 1 generates a SCIn_TXI interrupt request.

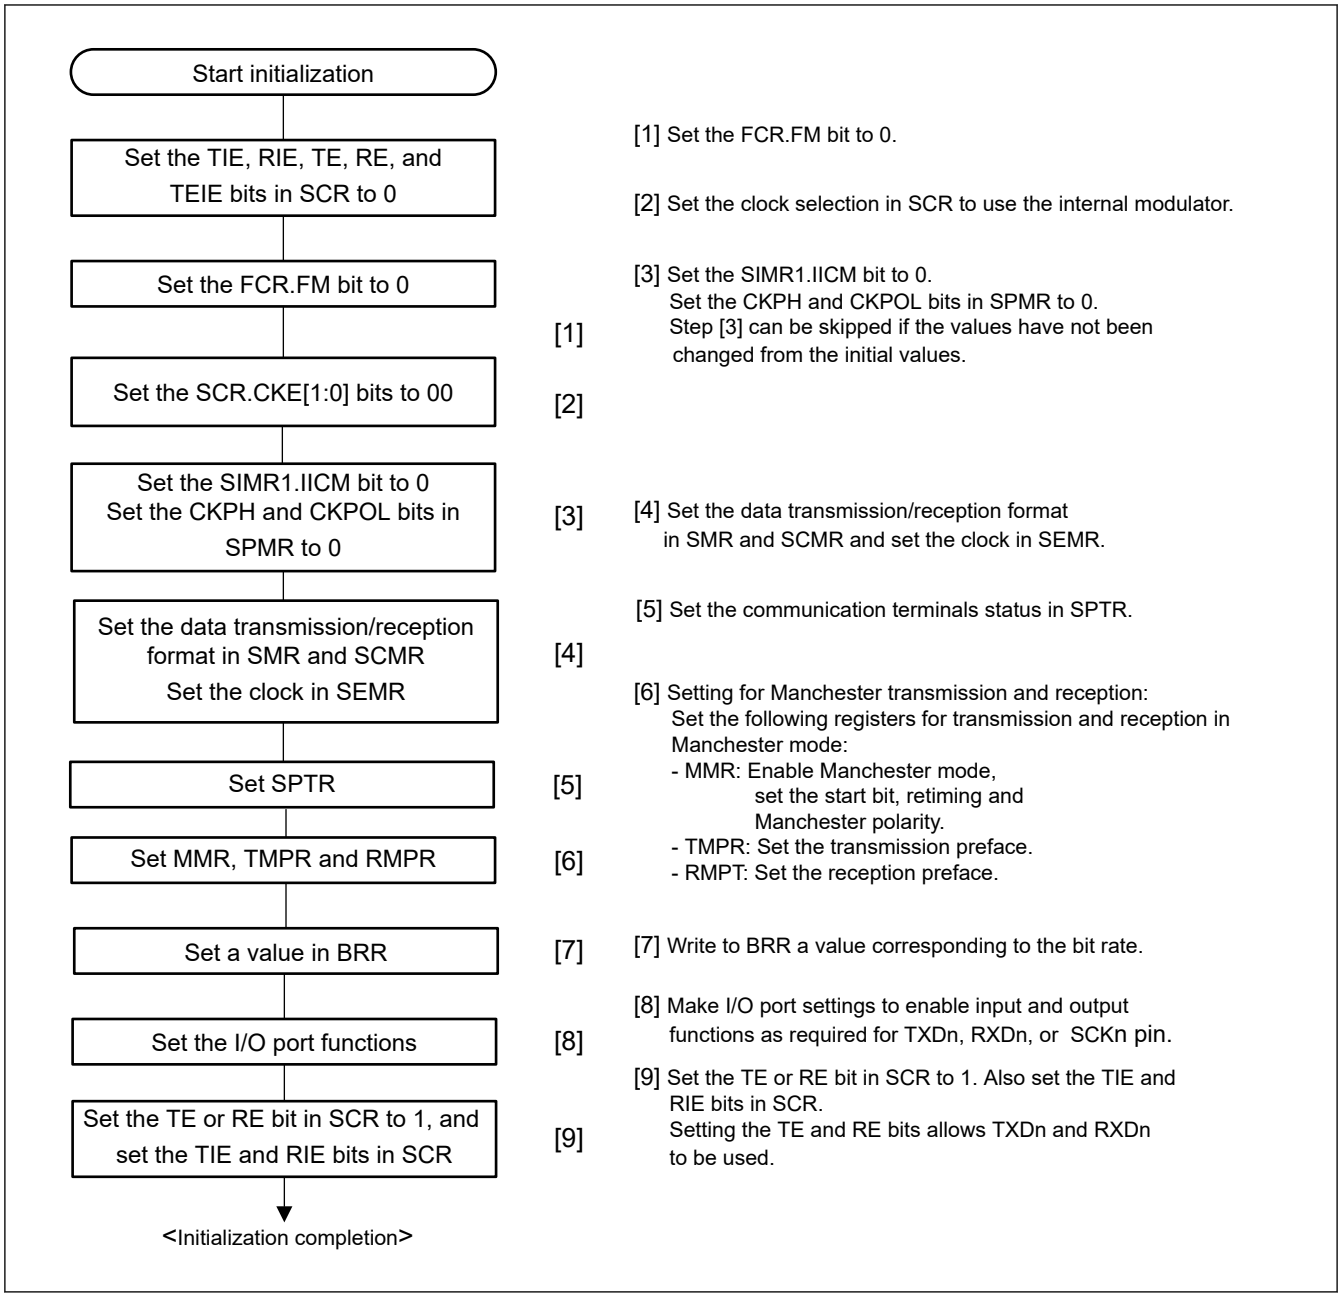


**Figure 26.54 SCI Initialization Flow in Manchester Mode**

## 26.5.4 Double-speed operation

When the ABCS bit in SEMR is set to 1 and eight pulses of the base clock for a 1-bit period is selected, the SCI operates on the bit rate twice that of when ABCS is set to 0.

When the BGDM bit in SEMR is set to 1, the cycle of the base clock is reduced to half and the SCI operates on the bit rate twice that of when ABCS is set to 0.

When the ABCS and the BGDM bits in SEMR are set to 1, the SCI operates on the bit rate four times that of when the ABCS and the BGDM bits in SEMR are set to 0.

## 26.5.5 CTS and RTS functions

The CTS function uses input on the CTSn_RTSn pin in transmission control. Setting the CTSE bit in SPMR to 1 enables the CTS function. The CTSn_RTSn pin can be set as a multiplexed pin which allows one pin to be used for either function, or as dedicated pins with each pin for a single function. Use the CTSPEN bit in SPMR for this setting.

When the CTS function is enabled, reception starts only when the CTSn_RTSn pin is at the low level.

Applying a high level to the CTSn_RTSn pin after transmission starts does not affect transmission of the current frame, which continues.

The RTS function uses output on the CTSn_RTSn pin to request transmission. When the SCI is ready to receive, it outputs a low level to the CTSn_RTSn pin, Conditions for output of the low level and high level are as follows:

[Conditions for low-level output]

When all conditions listed below are satisfied:

- The value of the RE bit in SCR is 1.
- The SCI is ready to receive.
- There is no received data yet to be read.
- All of the following flags are set to 0: SSR_MANC.ORER, FER, PER and MER flags, and MESR.SYER (when SYEREN = 1), PFER (when PFEREN = 1) and SBER flags (when SBEREN = 1).

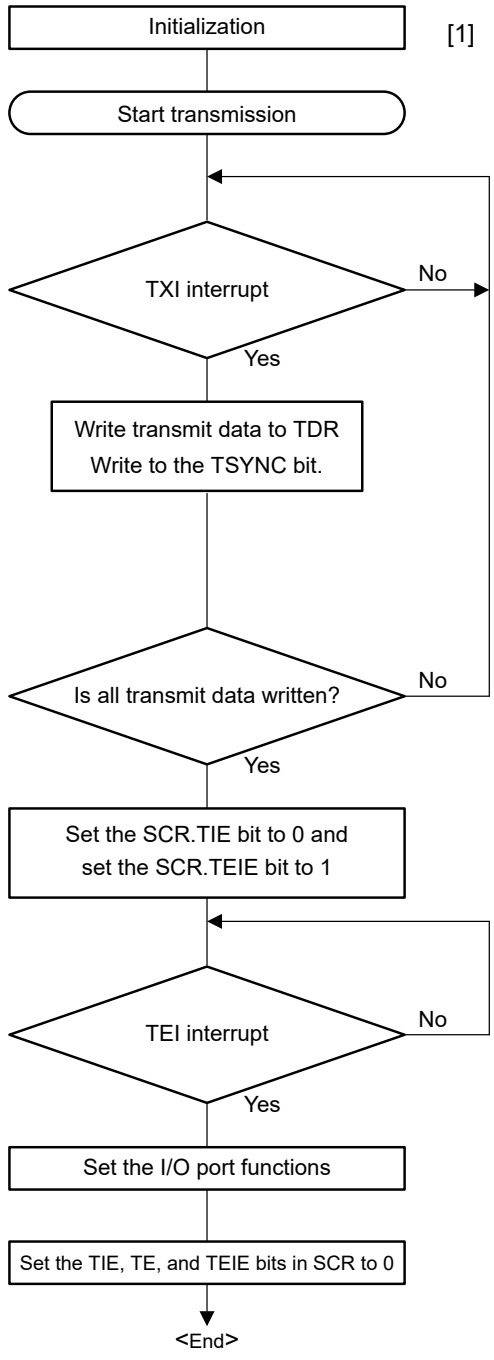
[Conditions for high-level output]

- When the conditions for low output are not satisfied

### 26.5.6 Serial data transmission in Manchester mode

The SCI encodes data in Manchester encoding and sends the resultant data in Manchester mode.

When the polarity setting (MMR.TMPOL) set to 0, logic 0 is coded as a zero-to-one transition in Manchester code and logic 1 is coded as a one-to-zero transition in Manchester code.



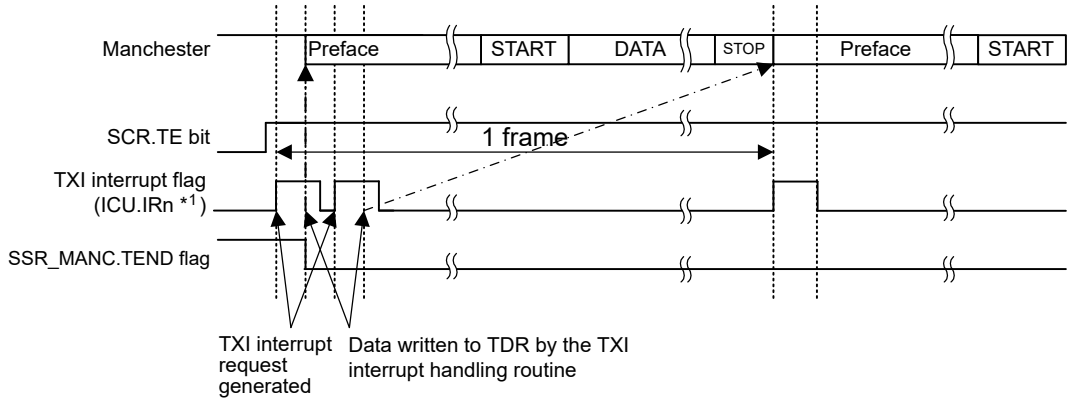
When the polarity setting (MMR.TMPOL) set to 1, logic 0 is coded as a one-to-zero transition in Manchester code and logic 1 is coded as a zero-to-one transition in Manchester code.

For this reason, a level transition occurs with the Manchester encoded data in the middle of individual logic data. (See Figure 26.49).

The transmitter constructs transmit frames in a specific format by adding a preface area to data and setting the start bit(s) according to the polarity setting and sends resultant serial data.

For details on the frame format, see section 26.5.1. Frame Format.

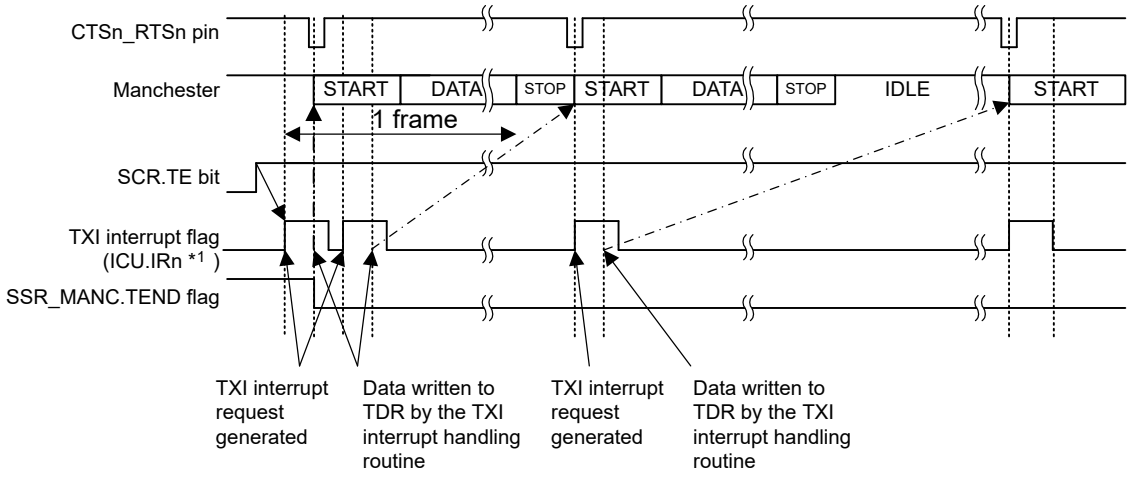
Figure 26.55 shows the flowchart in transmission. Figure 26.56, Figure 26.57, and Figure 26.58 show examples of the operation for serial transmission in Manchester mode.



[1] SCI Initialization:
Set data transmission.
Setting the SCR.TE bit to 1 enables transmission.

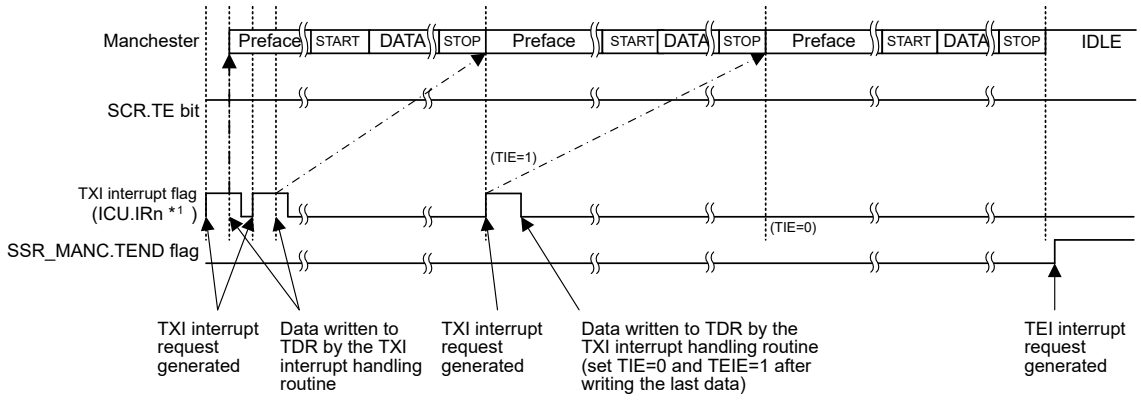
[2] TXI interrupt:
When transmit data is transferred from TDR to TSR, a transmit data empty interrupt (TXI) request is generated.

[3] TDR setting:
Write the transmit data to TDR.
When TSYNC is used, also set TDRHL_MAN.TYSNC.



[4] Serial transmission continuation procedure:
To continue serial transmission, write the transmit data to TDR once by using an TXI interrupt.
The transmit data can also be written to TDR by activating the DMAC or DTC in the TXI interrupt request.
When TEI interrupt requests are used, set the SCR.TIE bit to 0 and the SCR.TEIE bit to 1 after the last of the data to be transmitted is written to TDR.

**Figure 26.55 Example of Serial Transmission Flowchart in Manchester Mode**



Note 1. For corresponding interrupt numbers, see section 12, Interrupt Controller Unit (ICU)

**Figure 26.56 Example of Start-of-Transmission Operation for Serial Transmission in Manchester mode (with Preface but Without the CTS Function)**

Note 1. For corresponding interrupt numbers, see section 12, Interrupt Controller Unit (ICU)

**Figure 26.57 Example of Start-of-Transmission Operation for Serial Transmission in Manchester Mode (Without Preface but with the CTS Function)**

Note 1. For corresponding interrupt numbers, see section 12, Interrupt Controller Unit (ICU)

**Figure 26.58 Example of End-of-Transmission Operation for Serial Transmission in Manchester Mode (with Preface but Without the CTS Function)**

## 26.5.7 Serial Data Reception in Manchester Mode

In Manchester mode, the SCI operates on a base clock with a frequency of 16 times*1 the bit rate. Reception starts by sampling the falling edges of received data at the base clock. As shown in Figure 26.59, reception starts at a falling edge of the received data and it continues if the received data keeps low for the duration of 1/4 bit. If the received data goes high within the duration of 1/4 bit, the SCI judges it as an error and waits for a falling edge again.

If a high level is expected in the first half of a bit in the received data, the SCI judges a low level that continues for one base clock cycle as an error and ignores the change to the low level.

Note 1. This is the case when SEMR.ABCS = 0. When SEMR.ABCS = 1, the SCI operates on a base clock with a frequency of 8 times the bit rate.

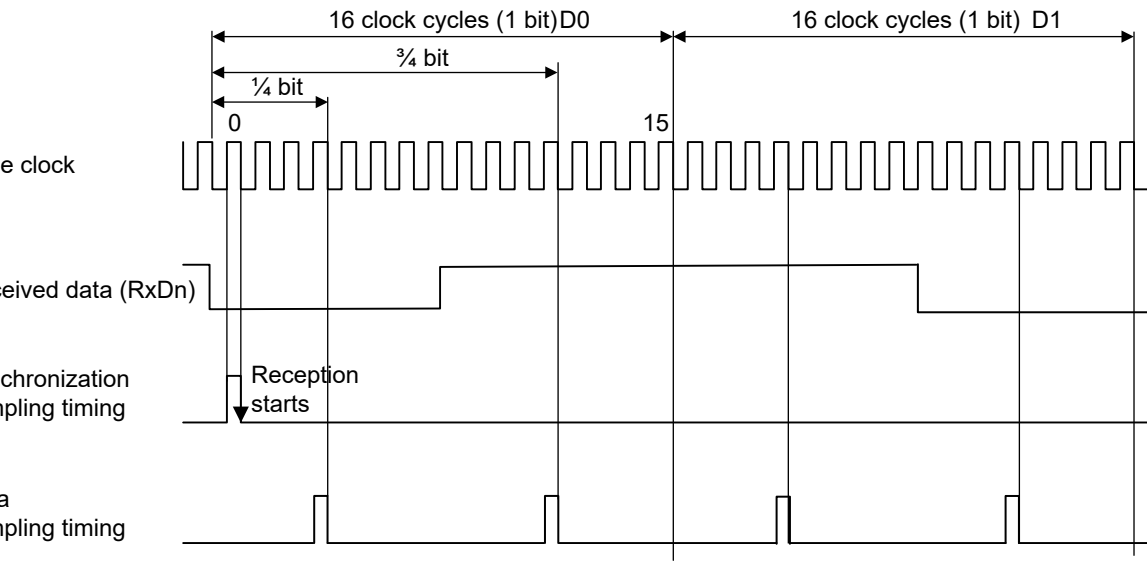


**Figure 26.59 Data Reception Sampling Timing in Manchester Mode**

In Manchester mode, data reception starts with detection of a preface and start bit area.

The SCI checks the input from the RXDn pin to see whether a preface is added based on the value of RMPR.RPLEN.

If the preface is disabled (RMPR.RPLEN = 0), it moves on to the detection of a start bit area without detecting a preface.

When a preface is enabled, it identifies a preface pattern setting according to the set value in RMPR.RPPAT, and compares it with the RXDn input for a pattern match to detect a preface pattern.

Upon detection of a preface pattern match, it judges it as a normal preface and moves on to the detection of a start bit area.

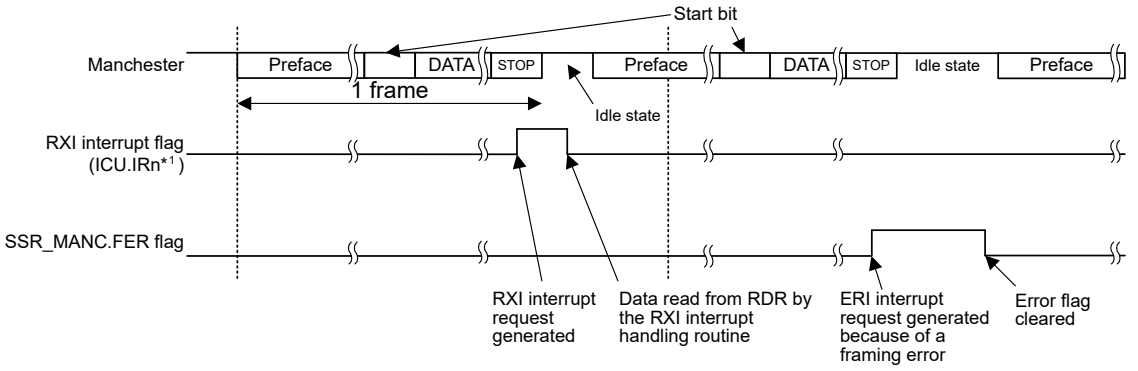
If detecting a preface pattern mismatch or a Manchester code error in the preface area, it judges it as a preface error and asserts a preface error (PFER).

For start bit detection, the SCI selects an expected value based on the register settings (MMR.SBSEL and SYNVAL), compares it with the RXDn input for a pattern match to detect a start bit area. Upon detection of a start bit pattern match, it judges it as a normal start bit area and moves on to the data processing.

Only when a preface and a start bit area are detected normally, it moves on to the next phase of data reception.

Upon detection of a start bit pattern mismatch, it asserts a start bit error flag (SBER).

In data processing, the SCI shifts the data by the expected received data length based on the register settings (SCMR.CHR1 and SMR.CHR) through the RSR register. If two sampling points in a bit of the received data are identical, the SCI judges this as a Manchester code error.



For details, see section 26.5.11. Errors in Manchester Mode (4).

When the parity function is disabled (SMR.PE = 0), the SCI moves on to the next phase of stop bit detection. When the parity function is enabled (SMR.PE = 1), the SCI performs parity checking. If detecting a parity error, it asserts a parity error flag (PER), and then moves on to stop bit detection.

In stop bit detection, the SCI checks the following in the stop bit area of the received frame:

It has two sampling points in a bit. If both points are at the high level, the bit is recognized as a normal stop bit and the data is stored in the RDR register. At least one low-level point is judged as an abnormal stop bit, causing a framing error flag (FER) to be set. Even when an error is detected, the received data is stored in the RDR register as abnormal data.

Figure 26.60 shows an example of the operation for serial data reception in Manchester mode.

Note 1. For corresponding interrupt numbers, see section 12, Interrupt Controller Unit (ICU).

**Figure 26.60 Example of Operation for Serial Data Reception in Manchester mode (with a Preface)**

For the state of each status flag in the SSR_MANC register and RXDn input processing when a receive error is detected, see section 26.5.11. Errors in Manchester Mode.

If a receive error is detected, an SCIn_ERI interrupt request is generated but an SCIn_RXI interrupt request is not generated.

Data reception cannot be resumed while the receive error flag is 1. Accordingly, set the ORER, FER, PER, MER, SYER*1, PFER*1, and SBER*1 flags to 0 before resuming reception. Also, be sure to read the RDR (or RDRHL_MAN) register during overrun error processing. When a reception is forcibly terminated by setting the SCR.RE bit to 0 during operation, read the RDR (or the RDRHL_MAN) register because received data which has not yet been read may be left in the RDR (or the RDRHL_MAN) register.

Figure 26.61 and Figure 26.62 show examples of serial data reception flowchart in Manchester mode.

Note 1. Effective when the corresponding bit is enabled.

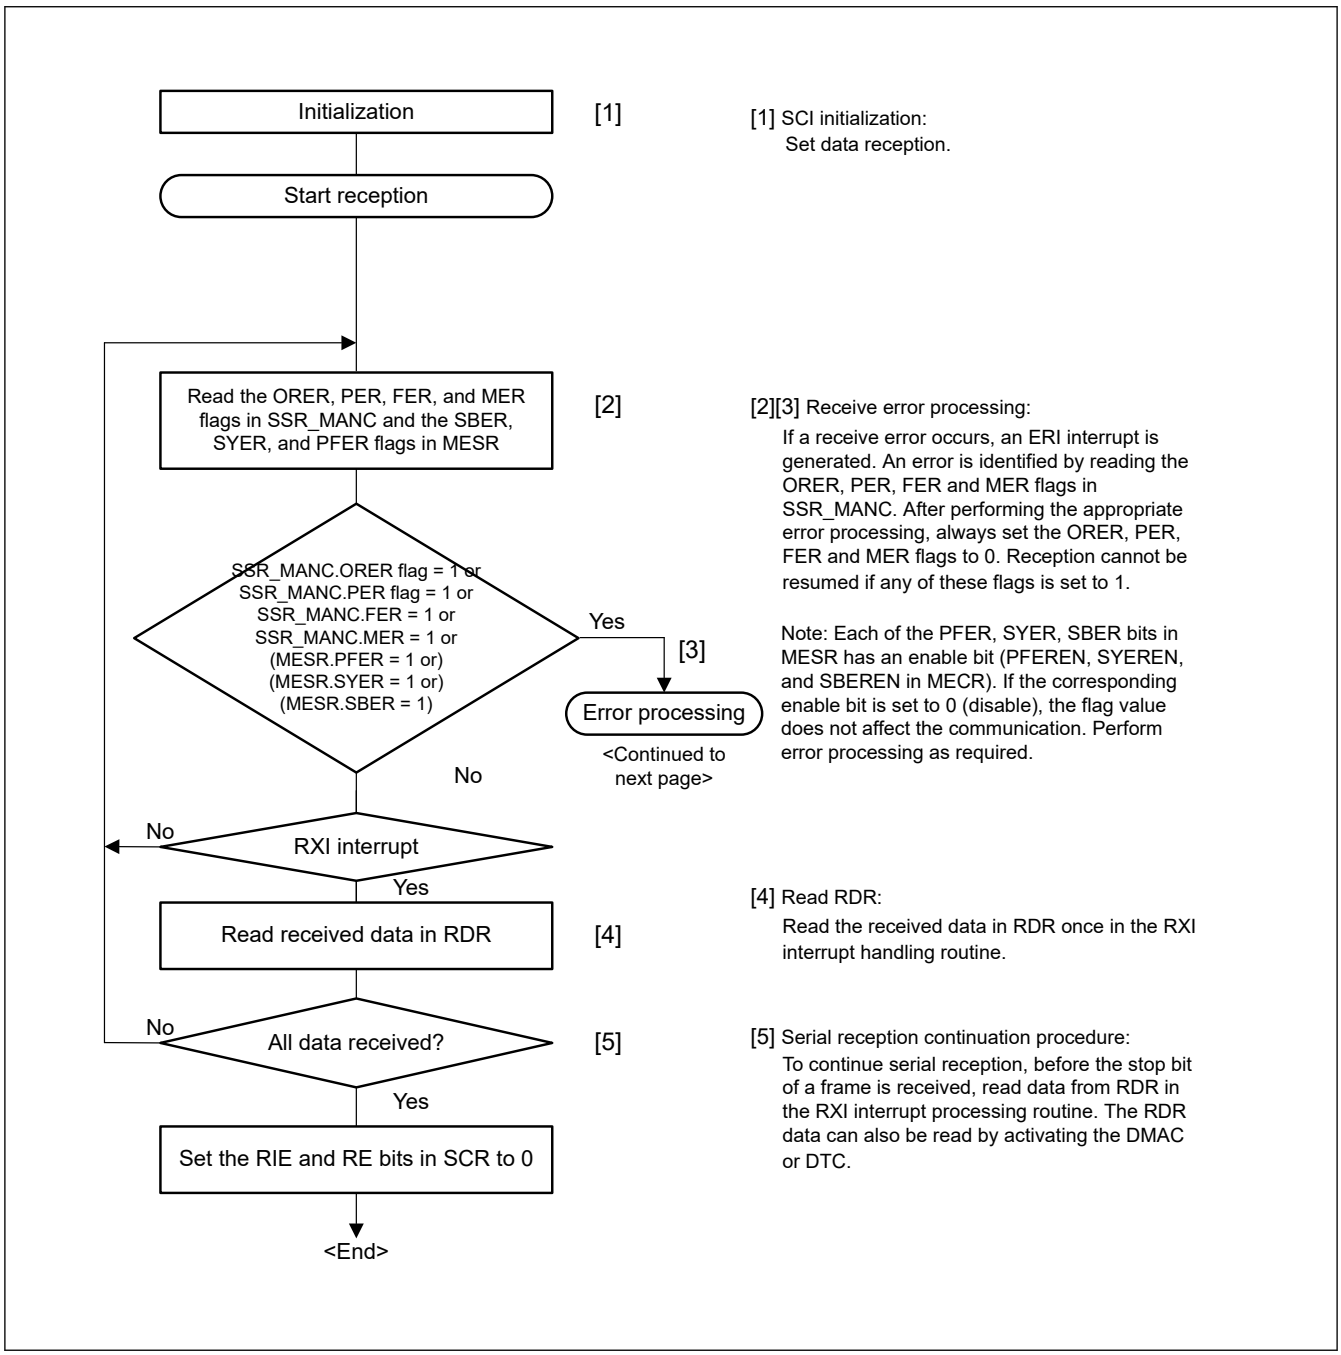


**Figure 26.61 Example of Serial Data Reception Flowchart in Manchester Mode (Normal Reception)**

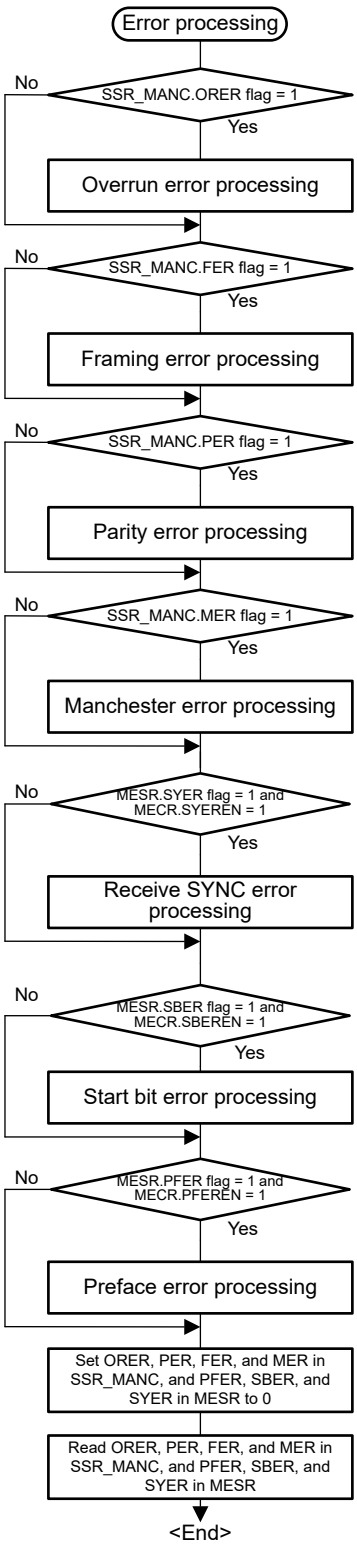

**Figure 26.62 Example of Serial Reception Flowchart in Manchester Mode (Error Processing)**

### 26.5.8 Operation When Multi-Processor Bit Is Used

See section 26.4. Multi-Processor Communication Function (1) for the operation in Manchester mode when using multi-processor mode because the operation is the same.

A preface and a start bit area are added to the frame format in Manchester mode. See Figure 26.62 for error processing in Manchester mode for the reception flowchart (Figure 26.46). See Table 26.35 for the operation status when detecting various errors.

### 26.5.9 Receive Retiming

This function corrects the timing for each central edge of the bit, taking advantage of the fact that each bit has an edge in the center in Manchester code.

The receive retiming function can be turned on or off by setting the ERTEN bit in the MMR register.

When the receive retiming function is turned off (MMR.ERTEN = 0), retiming is not performed, causing misalignment between the internal clock and the RXDn input to be accumulated and the receive margin to be reduced.

When the receive retiming function is turned on (MMR.ERTEN = 1), retiming is performed for the preface area, the start bit area*1, and the data area (excluding the stop bit).

Note 1. Retiming is not performed for the start bit area if the preface length is 0 and the start bit length is 3.

As an example, the receive retiming when oversampling x16 is selected is shown below.

When detecting an RXDn input edge two to four cycles before the expected receive cycle, the receive processing is shortened by one sampling CLK cycle.

When detecting a RXDn input edge two to three cycles after the expected receive cycle, the receive processing is extended by one sampling CLK cycle.

(Even if the clock is misaligned with the data by more than two cycles, one cycle is corrected for each bit.)

Figure 26.63 shows the conceptual image of receive retiming range.

When detecting an edge in the tolerance area in the figure, data is received as is without making correction.

When detecting an edge in the SyncJump area in the figure, data is corrected for reception.

When detecting an edge in the SyncError area in the figure, data is received as abnormal data with no correction made.

For a Manchester code error (data matches at the 1/4-phase and 3/4-phase sampling points), the SCI reports a code error.

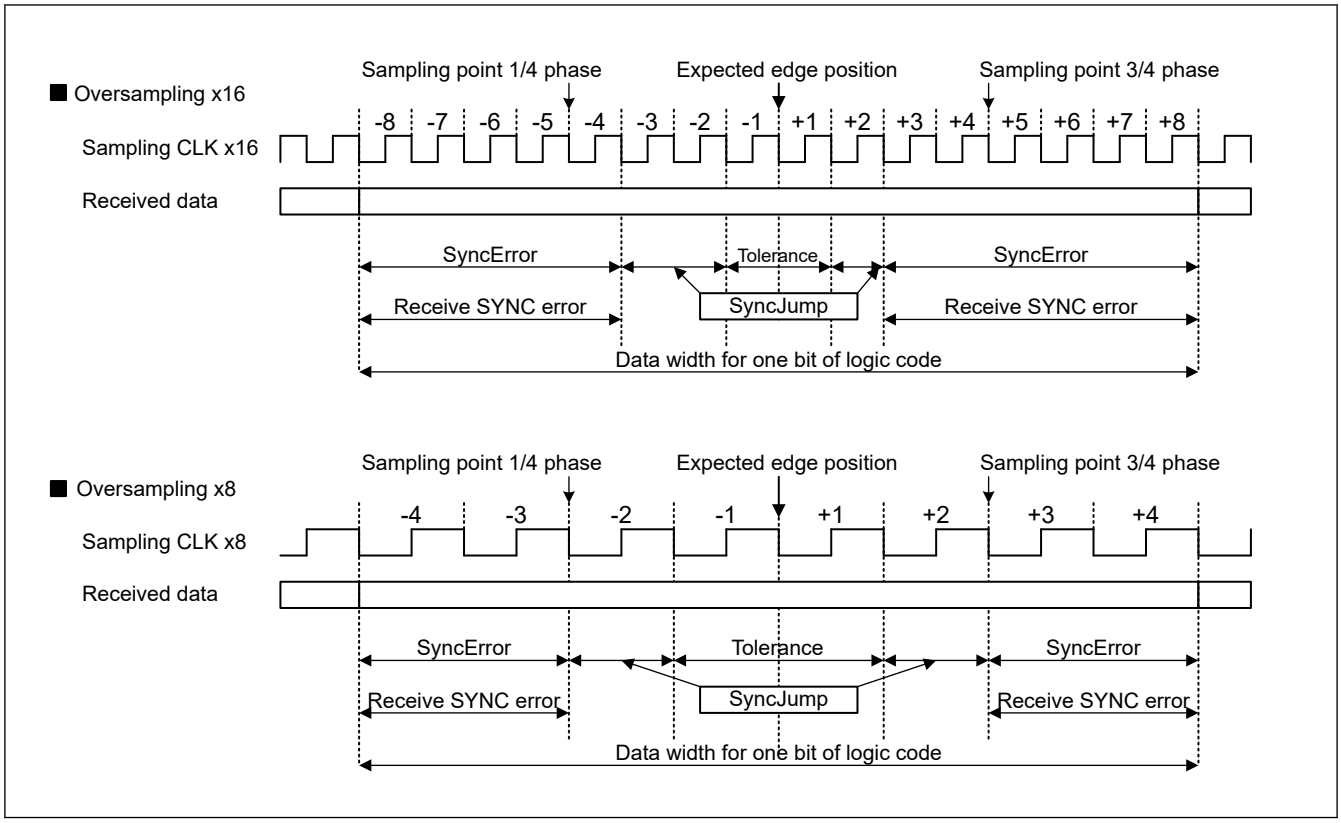

**Figure 26.63 Conceptual Image of Reception Retiming Range**

## 26.5.10 Polarity Setting for Manchester Code

The polarity of the Manchester code can be set with the Manchester Mode Register (MMR).

It can be set separately for transmission and reception. Use the MMR.TMPOL bit to set the polarity for transmission and the MMR.RMPOL bit to set the polarity for reception.

The Manchester code polarity setting is valid for the preface area, the data area, and the parity or multi-processor area.

When the initial settings (TMPOL/RMPOL = 0) are used for the polarity of Manchester code, logic 0 is encoded as a zero-to-one transition in Manchester code and logic 1 is encoded as a one-to-zero transition in Manchester code. If the settings are changed to TMPOL/RMPOL = 1, logic 0 is encoded as a one-to-zero transition in Manchester code and logic 1 is encoded as a zero-to-one transition in Manchester code. Figure 26.64 shows the conceptual image of the settings and operation.

Separately from the function above, the transmitted and received data in the data area can be inverted by the transmitted/received data inversion function (SCMR.SINV). Since the polarity of Manchester code (MMR.TMPOL/RMPOL) can be set separately from the transmitted/received data invert function (SCMR.SINV), if both are set to inversion (MMR.TMPOL/RMPOL = 1 and SCMR.SINV = 1), the transmitted and received data are set to initial state (inversion + inversion = normal).

The polarity of the start bit area can be set by a register different from the ones mentioned above.

Since a different register is used, the polarity of the start bit area is not affected by the polarity setting for Manchester code mentioned above.

For details on the setting for the start bit area, see section 26.5.1. Frame Format (2).

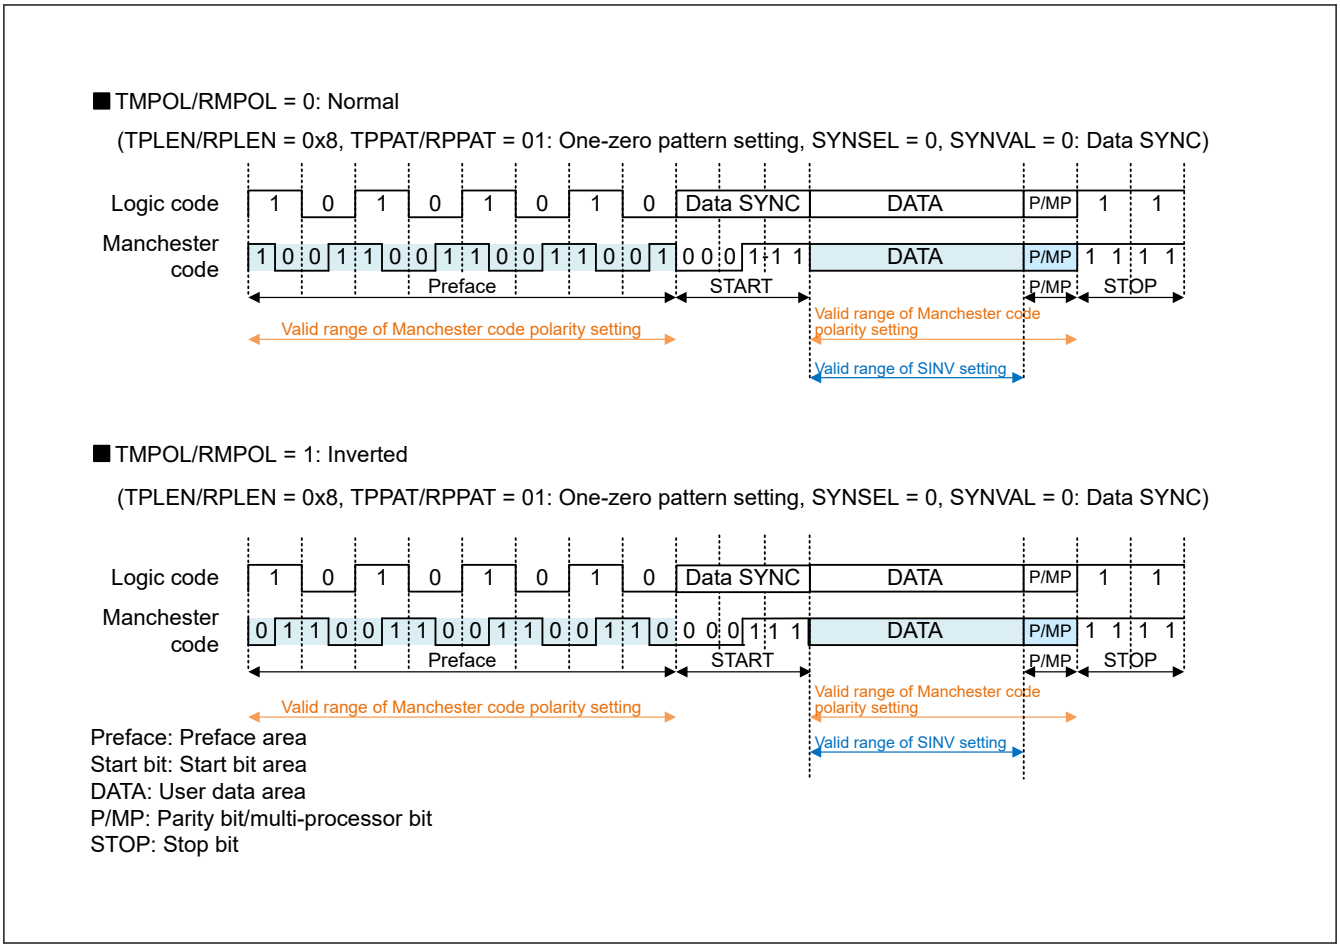

**Figure 26.64 Valid Range of the Manchester Code Polarity Setting**

## 26.5.11 Errors in Manchester Mode

There are the following errors in Manchester mode:

1. Parity error
2. Over run error
3. Framing error
4. Manchester error
5. Preface error
6. Start Bit error
7. Receive SYNC error

For errors (1) to (3), see section 26.3.9. Serial Data Reception in Asynchronous Mode (1) because they are the same as in asynchronous mode.

Each error is analyzed in each area, and it is reflected on flags and operations at the timing of 3/4-bit sampling of the STOP bit area. If a preface error or start bit error is detected, subsequent data will not be received. Therefore, no other error detection is performed, and the error flag holds the previous information.

Table 26.33 lists the states of the serial status register when detecting errors and judgment about whether to store data in the RDR.

Table 26.34 lists the errors that can be detected in each area of a Manchester frame.

If a preface error or start bit error is detected, subsequent data will not be received. Therefore, no other error detection is performed, and the error flag holds the result of the previous frame reception. Also, if an error is detected in the previous frame, data will not be received, but errors in the preface area and start bit area will update that flag. Table 26.35 shows the flags and actions in this case.

(4) Manchester error

A Manchester error is generated when a Manchester code error is detected.

In Manchester code, there must be an edge (transition) in the center of the bit.

In the data area of a received frame (including the parity/multi-processor bit), the values of the 1/4-bit and 3/4-bit sampling points are checked in each received 1-bit data, and a Manchester code error is determined if these two values match.

If a Manchester code error is detected, the Manchester error flag (SSR_MANC.MER) is asserted.

If a Manchester error occurs, it is handled as an interrupt source and event source. If a Manchester error is detected, the next reception is not performed until the corresponding error flag is cleared.

(5) Preface error

A preface error is generated when the preface pattern does not match or a Manchester code error is detected in the preface area. If a preface error is detected, the preface error flag (SSR_MANC.PFER) is asserted.

It is possible to set whether to use this error flag as an interrupt source with the setting of the MECR register.

When MECR.PFEREN = 1, a preface error is handled as an interrupt source or event source. If a preface error is detected, the next reception is not performed until the corresponding error flag is cleared.

When MECR.PFEREN = 0, a preface error is not handled as an interrupt source or event source, and the next reception is not halted. However, a preface error is notified to MESR.PFER.

(6) Start bit error

A start bit error is generated when a mismatch is detected between the start bit area in the received frame and the preset start bit pattern. Upon detection of a start bit error, a start bit error flag (MESR.SBER) is asserted.

It is possible to set whether to use the start bit error as an interrupt source with the setting of the MECR register.

When MECR.SBEREN = 1, a start bit error is handled as an interrupt source or event source. If a start bit error is detected, the next reception is not performed until the corresponding error flag is cleared.

When MECR.SBEREN = 0, a start bit error is not handled as an interrupt source or event source, and the next reception is not halted. However, a start bit error is notified to MESR.SBER.

(7) Receive SYNC error

When the receive retiming function described in section 26.5.9. Receive Retiming is enabled, the receive retiming operation is performed.

If no edges are detected within the receive retiming range (SyncError area in Figure 26.63) when receive timing operation is being performed, a receive SYNC error is generated. Upon detection of a receive SYNC error, a receive SYNC error flag (MESR.SYER) is asserted. In areas not subject to retiming, receive SYNC errors are not detected.

The preface area*1, the start bit area*1,*2, and the data area (excluding the stop bit) for which receive retiming operation is performed are checked.

It is possible to set whether to use the receive SYNC error as an interrupt source with the setting of the MECR register.

When MECR.SYEREN = 1, a receive SYNC error is handled as an interrupt source or event source. If a receive SYNC error is detected, the next reception is not performed until the corresponding error flag is cleared.

When MECR.SYEREN = 0, a receive SYNC error is not handled as an interrupt source or event source, and the next reception is not halted. However, a receive SYNC error is notified to MESR.SYER.

Note 1. For a frame that starts with a pattern that expects the first half of the bit to be high, it is excluded from retiming.
Note 2. In the start bit area, when there is no preface length and 3 bit start bit is set, it is not subject to retiming.
Also, the 1st bit and the 2nd bit in the start bit area when 3 bit start bit is set are not subject to retiming.

**Table 26.33 Flags in the SSR_MANC register and receive data handling in Manchester mode (1 of 2)**

| Flag in the SSR_MANC register | | | | Flag in the MESR register | | | received data | Received error status (ERI interrupt/event generation) |
|---|---|---|---|---|---|---|---|---|
| ORER | FER | PER | MER | SBER*1 | PFER*1 | SYER | | |
| 0 | 0 | 0 | 0 | 0 | 0 | 0 | transfer to RDR | No error |
| 0 | 1 | 0 | 0 | 0 | 0 | 0 | transfer to RDR | Framing error |

**Table 26.33 Flags in the SSR_MANC register and receive data handling in Manchester mode (2 of 2)**

| Flag in the SSR_MANC register | | | | Flag in the MESR register | | | received data | Received error status (ERI interrupt/event generation) |
|---|---|---|---|---|---|---|---|---|
| ORER | FER | PER | MER | SBER*1 | PFER*1 | SYER | | |
| 0 | 0 | 1 | 0 | 0 | 0 | 0 | transfer to RDR | Parity error |
| 0 | 1 | 1 | 0 | 0 | 0 | 0 | transfer to RDR | Framing error + Parity error |
| 0 | 0 | 0 | 1 | 0 | 0 | 0 | transfer to RDR | Manchester error |
| 0 | 1 | 0 | 1 | 0 | 0 | 0 | transfer to RDR | Framing error + Manchester error |
| 0 | 0 | 1 | 1 | 0 | 0 | 0 | transfer to RDR | Parity error + Manchester error |
| 0 | 1 | 1 | 1 | 0 | 0 | 0 | transfer to RDR | Framing error + Parity error + Manchester error |
| 1 | 0 | 0 | 0 | 0 | 0 | 0 | Lost | Overrun error |
| 1 | 1 | 0 | 0 | 0 | 0 | 0 | Lost | Overrun error + Framing error |
| 1 | 0 | 1 | 0 | 0 | 0 | 0 | Lost | Overrun error + Parity error |
| 1 | 1 | 1 | 0 | 0 | 0 | 0 | Lost | Overrun error + Framing error + Parity error |
| 1 | 0 | 0 | 1 | 0 | 0 | 0 | Lost | Overrun error + Manchester error |
| 1 | 1 | 0 | 1 | 0 | 0 | 0 | Lost | Overrun error + Framing error + Manchester error |
| 1 | 0 | 1 | 1 | 0 | 0 | 0 | Lost | Overrun error + Parity error + Manchester error |
| 1 | 1 | 1 | 1 | 0 | 0 | 0 | Lost | Overrun error + Framing error + Parity error + Manchester error |
| 0 | Combination of above | | | 0 | 0 | 0 | transfer to RDR | Errors above + Receive SYNC error*2 |
| 1 | | | | 0 | 0 | 0 | Lost | Errors above + Receive SYNC error*2 |
| hold | hold | hold | hold | 0 | 1 | 0 | Lost | Preface error*3 |
| hold | hold | hold | hold | 1 | 0 | 0 | Lost | Start bit error*3 |
| hold | hold | hold | hold | 0 | 1 | 1 | Lost | Preface error*3 + Receive SYNC error*2 |
| hold | hold | hold | hold | 1 | 0 | 1 | Lost | Start bit error*3 + Receive SYNC error*2 |

Note 1. Start bit error and preface error never become 1 at the same time.
Note 2. When MECR.SYEREN = 1, SCIn_ERI interrupt/event is generated by SYER factor.
Note 3. If MECR.PFEREN = 1 or MECR.SBEREN = 1, an SCIn_ERI interrupt/event is generated when the corresponding flag is set.

**Table 26.34 Errors detectable in each area**

| | Preface error (PFER) | Start Bit error (SBER) | Manchester error (MER) | Receive SYNC error (SYER) | Parity error (PER) | Framing error (FER) |
|---|---|---|---|---|---|---|
| Preface area | ✓ | — | —*1 | ✓*2 | — | — |
| Start Bit area | — | ✓ | — | ✓*2 | — | — |
| Data area | — | — | ✓ | ✓ | — | — |
| Parity area | — | — | ✓ | ✓ | ✓ | — |
| Multi-processor area | — | — | ✓ | ✓ | — | — |
| Stop Bit area | — | — | — | — | — | ✓ |

Note: ✓: Detected, —: Not detected
Note 1. When an Manchester code error occurs in the preface area, it is defined as a preface error.
Note 2. It may not be subject to receive SYNC error detection. For details see the text section 26.5.11. Errors in Manchester Mode (7)

**Table 26.35 Operation status due to presence/absence of error in previous frame and operation status list in multiprocessor mode (1 of 2)**

| Previous frame | Each area of the frame | | | | | PFEREN | SBEREN | SYEREN | received data | Error flag | Interrupt request | Event signal |

| | No Error | SBER<br>No SYER*1 | Don't Care | Don't Care | Don't Care | Don't Care | 0 | Don't Care | | Set SBER*1 | | |
| | | | | | | | 1 | | | | | |
| | SYER<br>No PFER | No Error | Don't Care | Don't Care | Don't Care | Don't Care | Don't Care | 0 | | Set SYER | | |
| | | | | | | | | 1 | | | | |
| | No Error | SYER<br>No SBER | Don't Care | Don't Care | Don't Care | Don't Care | Don't Care | 0 | | Set SYER | | |
| | | | | | | | | 1 | | | | |
| | No Error | No Error | SYER | | No Error | Don't Care | Don't Care | 0 | | Do not set any flags | | |
| | | | | | | | | 1 | | | | |
| | No Error | No Error | MER | | No Error | Don't Care | Don't Care | Don't Care | | | | |
| | No Error | No Error | Don't Care | PER | No Error | Don't Care | Don't Care | Don't Care | | | | |
| | No Error | No Error | Don't Care | Don't Care | FER | Don't Care | Don't Care | Don't Care | | | | |
| | There are some errors<br>ORER | | | | | Don't Care | Don't Care | Don't Care | | | | |
| | No Error | No Error | No Error | No Error | No Error<br>ORER | Don't Care | Don't Care | Don't Care | | | | |

Note 1. If SYER is detected, the SYER flag is also set. Other operations are as shown in this table.
Note 2. Other detected error flags including ORER are also set.
Note 3. If all the error flags are cleared before the STOP bit is determined, the operation is the same as the case where there is no error in the previous frame of this table.
Note 4. Since the SCIn_ERI interrupt request is level output, it remains active due to errors in the previous frame regardless of the presence or absence of error in the relevant frame.
Note 5. Since the error cause is continuously detected, the SCIn_ERI event is not newly output regardless of the presence or absence of errors in the relevant frame.
Note 6. For PFER, SBER, and SYER, when each enable bit is set to disable, it is treated as no error.

**Table 26.36 Operation when MPIE = 1 in multi-processor mode (MPIE = 0)**

| MPB*1 | Each area of the frame | | | | | PFERE N | SBERE N | SYERE N | Received data | Error flag | Interrupt request | Event signal |
|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | Preface | Start bit | Data | Parity | Stop | | | | | | | |
| 1 | No Error | No Error | Don't Care | Don't Care | Don't Care | Don't Care | Don't Care | Don't Care | Transfer to RDR | Set some flags | Output*2 | Output*2 |
| | No PFER | No SBER | Don't Care | Don't Care | Don't Care | Don't Care | Don't Care | 0 | | | | |
| | SYER*3 | SYER*3 | | | | | | 1 | Lost | Don't set any flags | Not output | Not output |
| | PFER | No Error | Don't Care | Don't Care | Don't Care | Don't Care | Don't Care | Don't Care | | | | |
| | No Error | SBER | Don't Care | Don't Care | Don't Care | Don't Care | Don't Care | | | | | |

Note 1. If the received MPB bit is 0, it does not receive the frame, and the operation is the same as lost of the reception data of this table.
Note 2. If no error is detected, SCIn_RXI interrupt request or event is output, and if it is detected, SCIn_ERI interrupt request or event is output.

Note 3. When SYER is detected in the preface area or the start bit area, the behavior of handling as an error depending on the SYEREN bit changes.

## 26.6 Operation in Clock Synchronous Mode

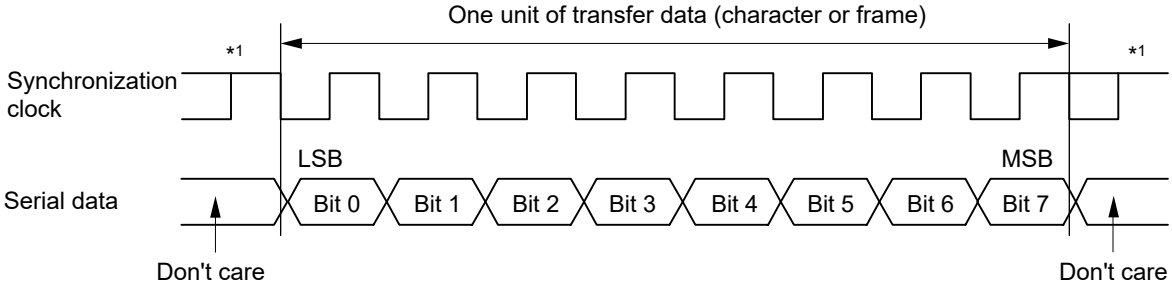

Figure 26.65 shows the data format for clock synchronous serial data communications.

In clock synchronous mode, data is transmitted or received in synchronization with clock pulses. For single-character data transfer, data consists of 8-bit. In clock synchronous mode, no parity bit can be added.

In data transmission, the SCI outputs data from one falling edge of the synchronization clock to the next falling edge. In data reception, the SCI receives data in synchronization with the rising edge of the synchronization clock. After 8-bit data is output, the transmission line holds the last bit as output state. When the SPMR.CKPH bit is 1 in slave mode, the transmission line holds the first bit output state.

Within the SCI, the transmitter and receiver are independent units, enabling full-duplex communications by using a shared clock. Both the transmitter and the receiver also have a double-buffered structure, so that the next transmit data can be written during transmission or the previous receive data can be read during reception, enabling continuous data transfer.

However, it is not possible to perform continuous transfer in the fastest bit rate setting (BRR[7:0] = 0x00 and SMR.CKS[1:0] = 00b). Therefore, when the FIFO is selected, this setting (BRR[7:0] = 0x00 and SMR.CKS[1:0] = 00b) is not available.

Note 1. Holds a high level except during continuous transfer.

**Figure 26.65 Data format in clock synchronous serial communications with LSB-first order**

### 26.6.1 Clock

Either an internal clock generated by the on-chip baud rate generator or an external synchronization clock input at the SCKn pin can be selected based on the SCR.CKE[1:0] setting.

When the SCI operates on an internal clock, the synchronization clock is output from the SCKn pin. Eight synchronization clock pulses are output in the transfer of one character. When no transfer is performed, the clock is held high. However, when only data reception is performed while the CTS function is disabled, the synchronization clock output starts when the SCR.RE bit set to 1. The synchronization clock stops when it goes high[*1] and an overrun error occurs or the SCR.RE bit is set to 0.

When only data reception is performed and the CTS function is enabled, the clock output does not start when the SCR.RE bit set to 1 and the CTSn_RTSn pin input is high. The synchronization clock output starts when the SCR.RE bit is set to 1 and the CTSn_RTSn pin input is low. Following that, when the CTSn_RTSn pin input is high on completion of the frame reception, the synchronization clock output stops when it goes high. If the CTSn_RTSn pin input continues to be low, the synchronization clock stops when it goes high[*1] and an overrun error occurs or the SCR.RE bit is set to 0.

Note 1. The signal is held high while (SPMR.CKPH = 0 and SPMR.CKPOL = 1) or (SPMR.CKPH = 1 and SPMR.CKPOL = 1). It is held low while (SPMR.CKPH = 0 and SPMR.CKPOL = 1) or (SPMR.CKPH = 1 and SPMR.CKPOL = 0).

### 26.6.2 CTS and RTS Functions

In the CTS function, the CTSn_RTSn pin input controls the start of data reception or transmission when the clock source is the internal clock. Setting the SPMR.CTSE bit to 1 enables the CTS function. When the CTS function is enabled, setting the CTSn_RTSn pin low causes data reception or transmission to start.

Setting the CTSn_RTSn pin high while the data transmission or reception is in progress does not affect transmission or reception of the current frame.

In the RTS function, the CTSn_RTSn pin output is used to request the start of data reception or transmission when the clock source is an external synchronizing clock. The CTSn_RTSn output goes low when serial communication is enabled. Conditions for output of the CTSn_RTSn low and high are shown as follows:

[Conditions for low output]

Satisfaction of all the following conditions:

**Non-FIFO selected when all of the following conditions are satisfied**

- The value of the SCR.RE bit or the SCR.TE bit is 1
- Neither transmission nor reception is in progress
- There is no received data available to be read when the SCR.RE bit is 1
- Transmit data is written when the SCR.TE bit is 1 and SCR.CKE[1] bit is 0
- Data is available for transmission in the TSR register when SCR.TE bit is 1 and SCR.CKE[1] bit is 1
- The SSR.ORER flag is 0

**FIFO selected when all of the following conditions are satisfied**

- The value of the SCR.RE bit or the SCR.TE bit is 1
- Neither transmission nor reception is in progress
- The amount of receive data written in FRDRHL is less than the setting value of FCRH.RSTRG[3:0] when SCR.RE = 1
- Data that has not been transmitted is available in FTDRHL when SCR.TE bit is 1 and SCR.CKE[1] bit is 0
- Data is available for transmission in the TSR register when SCR.TE bit is 1 and SCR.CKE[1] bit is 1
- The SSR_FIFO.ORER flag is 0

[Condition for high output]

- The conditions for low output are not satisfied

### 26.6.3 SCI Initialization in Clock Synchronous Mode

Before transmitting and receiving data, start by writing the initial value 0x00 to the SCR register, then continue through the SCI initialization procedure given in the sections describing non-FIFO and FIFO selection in section 26.6.2. CTS and RTS Functions. Anytime the operating mode or transfer format is to be changed, the SCR register must be initialized before the change can be made.

Note: Setting the SCR.RE bit to 0 initializes neither the ORER, FER, and PER flags in SSR/SSR_FIFO nor the RDR register. When the TE bit is set to 0, the TEND flag for the selected FIFO buffer is not initialized.

Note: In non-FIFO mode, switching the value of the SCR.TE bit from 1 to 0 or 0 to 1 when the SCR.TIE bit is 1 generates an SCIn_TXI interrupt request.

**Table 26.37 Example flow of SCI initialization in clock synchronous mode with non-FIFO selected (1 of 2)**

| No. | Step Name | Description |
|---|---|---|
| 1 | Start initialization | |
| 2 | Set the SCR.TIE, RIE, TE, RE, and TEIE bits to 0 | |
| 3 | Set the FCR.FM bit to 0 | Set the FCR.FM bit to 0. |
| 4 | Set the SCR.CKE[1:0] bits | Set the clock selection in SCR. |
| 5 | Set the SIMR1.IICM bit to 0. Set the SPMR.CKPH and CKPOL bits. | Set the SIMR1.IICM bit to 0.<br>Set the SPMR.CKPH and CKPOL bits.<br>Step 5 can be skipped if the values have not been changed from the initial values. |

**Table 26.37 Example flow of SCI initialization in clock synchronous mode with non-FIFO selected (2 of 2)**

| No. | Step Name | Description |
|---|---|---|
| 6 | Set the data transmission/ reception format in SMR, SCMR, and SEMR | Set data transmission/reception format in SMR, SCMR, and SEMR. |
| 7 | Set a value in SPTR | Set the communication terminals status in SPTR. |
| 8 | Set a value in BRR | Write a value corresponding to the bit rate to BRR.<br>This step is not necessary if an external clock is used. |
| 9 | Set a value in MDDR | Write the value obtained by correcting a bit rate error in MDDR. This step is not necessary if the BRME bit in SEMR is set to 0 or an external clock is used. |
| 10 | Set the I/O port functions | Make I/O port settings to enable input and output functions as required for TXDn, RXDn, and SCKn pins. |
| 11 | Set the SCR.TE or RE bit to 1, and set the SCR.TIE and RIE bits | Set the SCR.TE or RE bit to 1. Also set the SCR.TIE and RIE bits.<br>Setting the TE and RE bits allows TXDn and RXDn pins to be used. |
| 12 | Initialization completion | |

Note: In simultaneous transmit and receive operations, the TE and RE bits in SCR must both be set to 0 or set to 1 simultaneously

**Table 26.38 Example flow of SCI initialization in clock synchronous mode with FIFO selected**

| No. | Step Name | Description |
|---|---|---|
| 1 | Start initialization | |
| 2 | Set the SCR.TIE, RIE, TE, RE, and TEIE bits to 0 | |
| 3 | Set the FCR.FM, TFRST, and RFRST bits to 1.<br>Set the FCR.TTRG[3:0], RTRG [3:0], and RSTRG[3:0] bits. | Set the FCR.FM, TFRST, and RFRST bits to 1 (FIFO mode enabled, transmit/receive FIFOs empty).<br>Set the FCR.TTRG[3:0], RTRG[3:0], and RSTRG[3:0] bits. |
| 4 | Set the SCR.CKE[1:0] bits | Set the clock selection in SCR. |
| 5 | Set the SIMR1.IICM bit to 0.<br>Set the SPMR.CKPH and CKPOL bits. | Set the SIMR1.IICM bit to 0.<br>Set the SPMR.CKPH and CKPOL bits.<br>Step 5 can be skipped if the values have not been changed from the initial values. |
| 6 | Set the data transmission/ reception format in SMR, SCMR, and SEMR | Set data transmission/reception format in SMR, SCMR, and SEMR. |
| 7 | Set a value in SPTR | Set the communication terminals status in SPTR. |
| 8 | Set a value in BRR | Write a value corresponding to the bit rate to BRR.<br>This step is not necessary if an external clock is used. |
| 9 | Set a value in MDDR | Write the value obtained by correcting a bit rate error in MDDR. This step is not necessary if the BRME bit in SEMR is set to 0 or an external clock is used. |
| 10 | Set the FCR.TFRST and RFRST bits to 0 | Set the FCR.TFRST and RFRST bits to 0. |
| 11 | Set the I/O port functions | Make I/O port settings to enable input and output functions as required for TXDn, RXDn, and SCKn pins. |

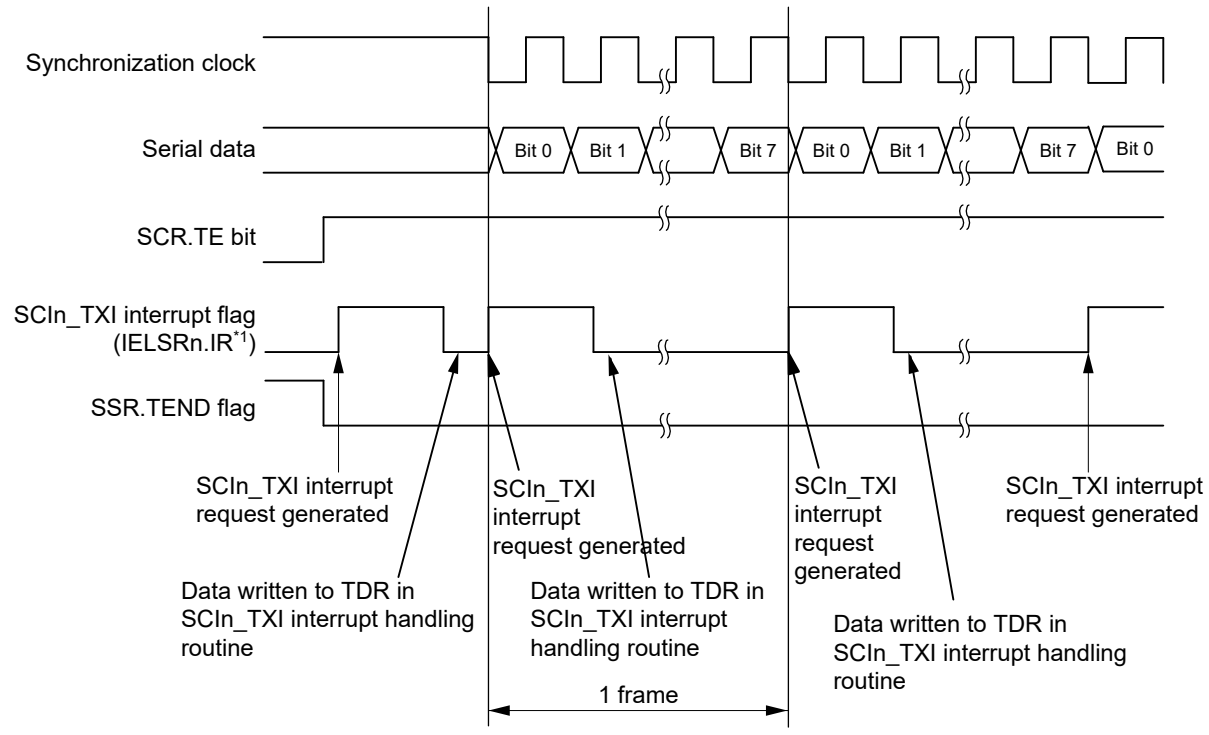
Note: In simultaneous transmit and receive operations, the TE and RE bits in SCR must both be set to 0 or set to 1 simultaneously.

## 26.6.4 Serial Data Transmission in Clock Synchronous Mode

(1) Non-FIFO selected

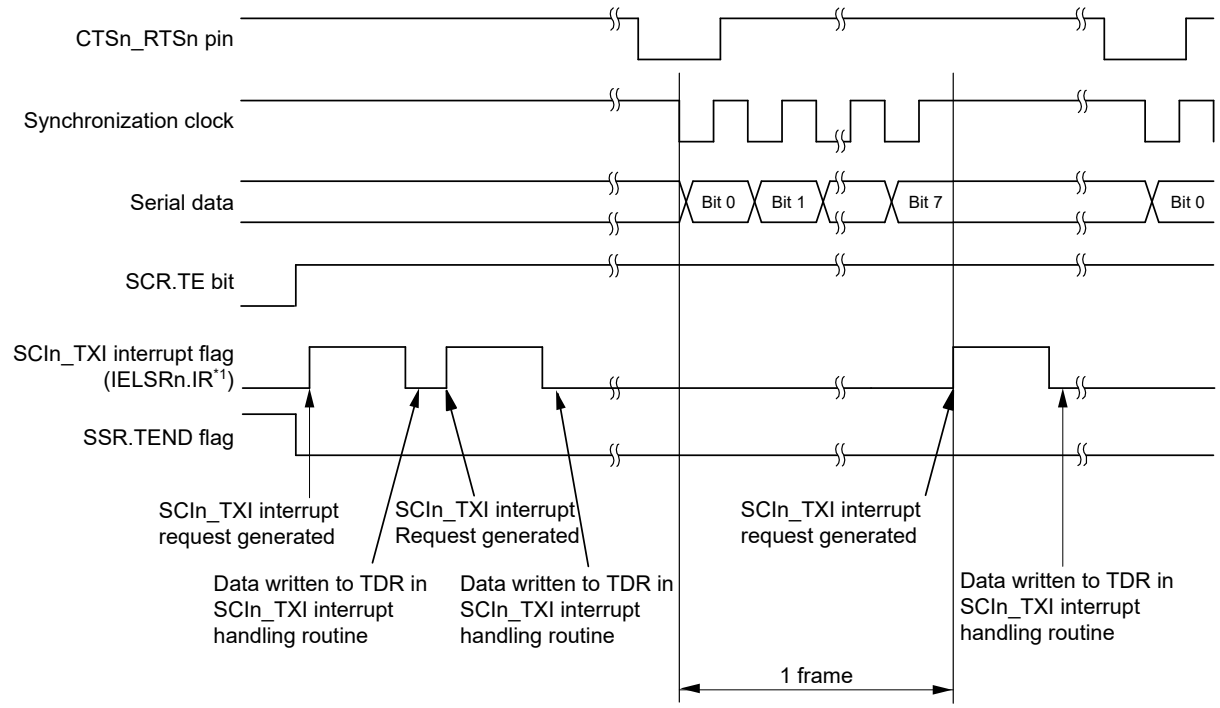
Figure 26.66, Figure 26.67, and Figure 26.68 show examples of serial transmission in clock synchronous mode.



In serial data transmission, the SCI operates as follows:

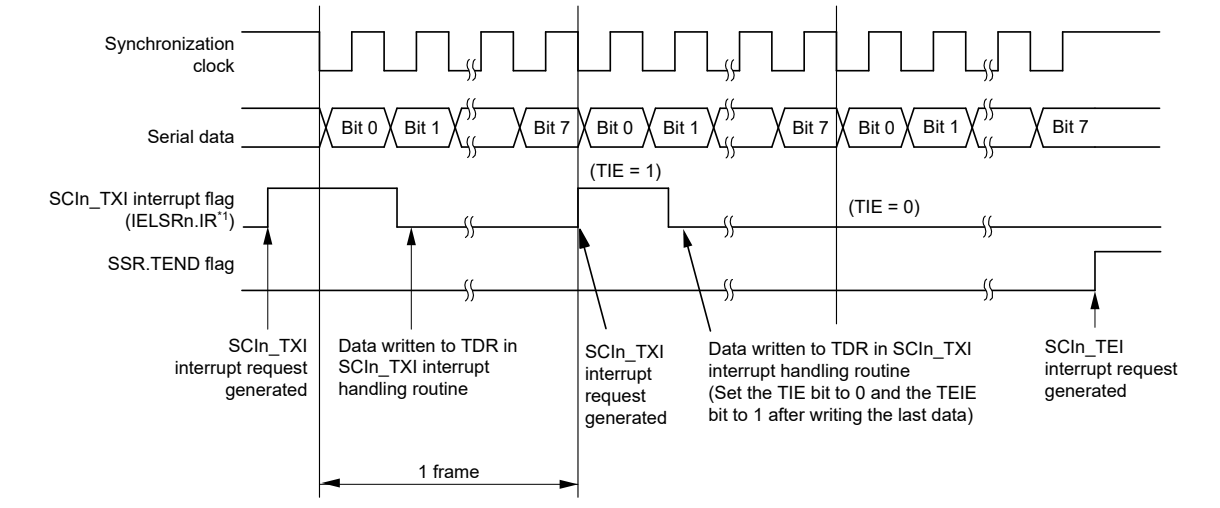
1. The SCI transfers data from the TDR register to the TSR register when data is written to TDR in the SCIn_TXI interrupt handling routine. The SCIn_TXI interrupt request at the beginning of transmission is generated when the TE bit is set to 1 but only after the TIE bit in the SCR is also set to 1 or when these two bits are set to 1 simultaneously by a single instruction.
2. After transferring data from TDR to TSR, the SCI starts transmission. When the SCR.TIE bit is set to 1, an SCIn_TXI interrupt request is generated. Continuous transmission is enabled by writing the next transmit data to TDR in the SCIn_TXI interrupt handling routine before transmission of the current transmit data finishes. When SCIn_TEI interrupt requests are in use, set the SCR.TIE bit to 0 and the SCR.TEIE bit to 1 after the last of the data to be transmitted is written to the TDR register from the handling routine for SCIn_TXI requests.
3. 8-bit data is sent from the TXDn pin in synchronization with the output clock when the clock output mode is specified and in synchronization with the input clock when the use of an external clock is specified. Output of the clock signal is suspended until the input CTS signal is low when the SPMR.CTSE bit is 1.
4. The SCI checks for update to the TDR register on output of the last bit.
5. When the TDR register is updated, the next transmit data is transferred from TDR to TSR, and serial transmission of the next frame starts.
6. If TDR is not updated, the SSR.TEND flag is set to 1. The TXDn pin retains the output state of the last bit. If the SCR.TEIE bit is 1, an SCIn_TEI interrupt request is generated and the SCKn pin is held high.

Figure 26.66, Figure 26.67, and Figure 26.68 show examples of serial data transmission.



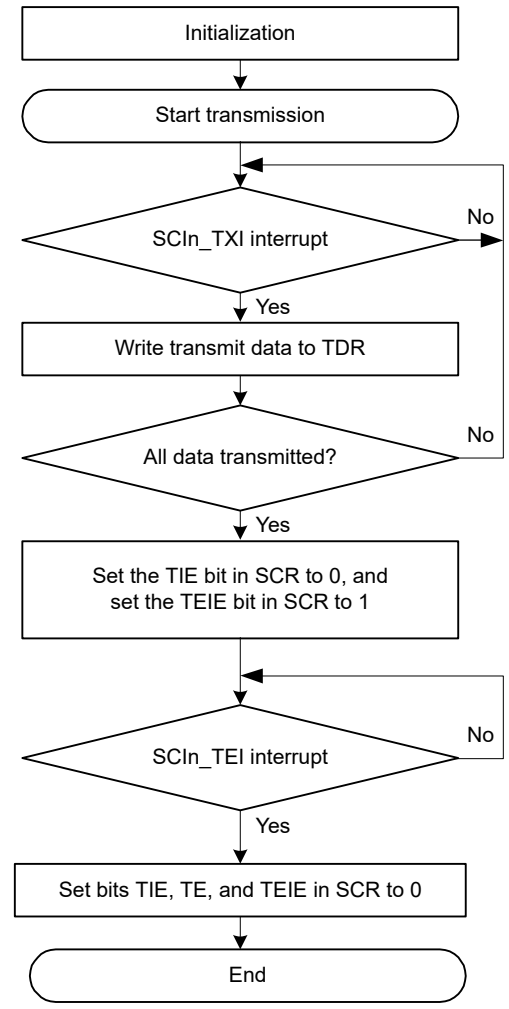
Transmission does not start while a receive error flag (ORER, FER, or PER in SSR) is set to 1. Always set the receive error flags to 0 before starting transmission.

Note: Setting the SCR.RE bit to 0 does not clear the receive error flags.



Note 1. See section 12, Interrupt Controller Unit (ICU) for information on the corresponding interrupt event number.

**Figure 26.66 Example of serial data transmission in clock synchronous mode when the CTS function is not used at the beginning of transmission**



Note 1. See section 12, Interrupt Controller Unit (ICU) for information on the corresponding interrupt event number.

**Figure 26.67 Example of serial data transmission in clock synchronous mode when the CTS function is used at the beginning of transmission**

Note 1. See section 12, Interrupt Controller Unit (ICU) for information on the corresponding interrupt event number.

**Figure 26.68 Example of serial data transmission in clock synchronous mode from the middle of transmission until transmission completion**

[ 1 ] [ 1 ]SCI initialization:
Set data transmission.

[ 2 ] [ 2 ]Writing transmit data write to TDR by an SCIn_TXI interrupt request:
When transmit data is transferred from TDR to TSR, a transmit data empty interrupt (SCIn_TXI) request is generated.
Transmit data is written to TDR once from the handling routine for SCIn_TXI requests.

[ 3 ] [ 3 ]Serial transmission continuation procedure:
To continue serial transmission, write transmit data to TDR upon accepting a transmit data empty interrupt (SCIn_TXI) request. Transmit data can also be written to TDR by activating the DMAC or DTC by theSCIn_TXI interrupt request.
When SCIn_TEI interrupt requests are in use, set the SCR.TIE bit to 0 and the SCR.TEIE bit to 1 after the last of the data to be transmitted is written to the TDR

Note: When the external clock is in use (the value of the SCR.CKE[1:0] bits is 10b or 11b), the rising edge on the SCKn pin for the last bit sets the SSR.TEND flag to 1. Setting the SCR.TE bit to 0 immediately after this might lead to insufficient received-data hold time on the receiver side.

**Figure 26.69 Example flow of serial transmission in clock synchronous mode with non-FIFO selected**

(2) FIFO selected

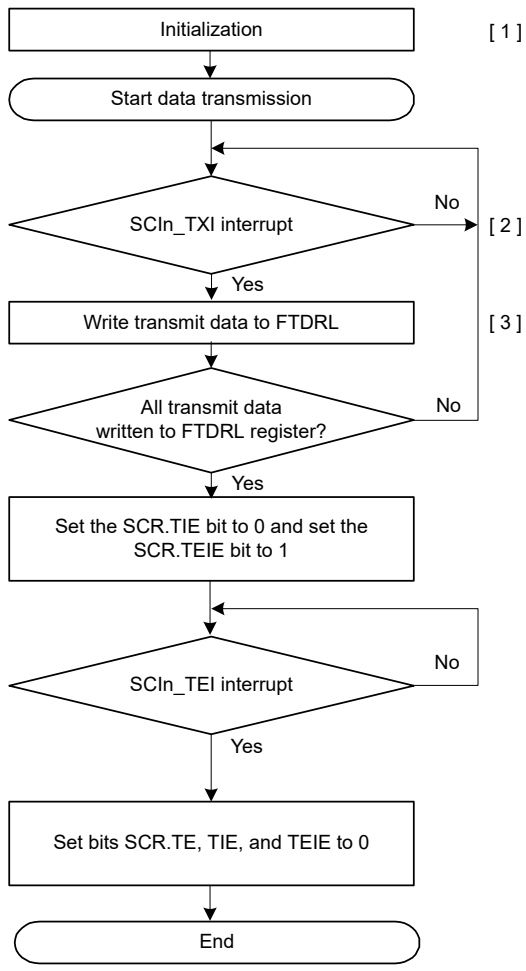


Figure 26.70 shows an example of serial transmission in clock synchronous mode with FIFO selected.

In serial data transmission, the SCI operates as follows:

1. The SCI transfers data from the FTDRL*1 register to the TSR register when data is written to FTDRL*1 in the SCIn_TXI interrupt handling routine. The amount of data that can be written to FTDRL is 16 minus FDR.T[4:0] bytes. The SCIn_TXI interrupt request at the beginning of transmission is generated when the SCR.TE bit is set to 1 but only after the SCR.TIE bit is also set to 1 or when these two bits are set to 1 simultaneously by a single instruction.
2. After transferring data from FTDRL to TSR, the SCI starts transmission. When the amount of transmit data written in FTDRL is equal to or less than the specified transmit triggering number, the SSR_FIFO.TDFE is set to 1. When the SCR.TIE bit is set to 1, an SCIn_TXI interrupt request is generated. Continuous transmission is enabled by writing the next transmit data to FTDRL in the SCIn_TXI interrupt handling routine before transmission of the current transmit data has finished. When SCIn_TEI interrupt requests are in use, set the SCR.TIE bit to 0 and the SCR.TEIE bit to 1 after the last of the data to be transmitted is written to the FTDRL from the handling routine for SCIn_TXI requests.
3. 8-bit data is sent from the TXDn pin in synchronization with the output clock when the clock output mode is specified and in synchronization with the input clock when the use of an external clock is specified. Output of the clock signal is suspended until the input CTS signal is low when the SPMR.CTSE bit is 1.
4. The SCI checks whether non-transmitted data remains in FTDRL on output of the stop bit.

5. When FTDRL is updated, the next transmit data is transferred from FTDRL to TSR and serial transmission of the next frame starts.
6. If FTDRL is not updated, the SSR_FIFO.TEND flag is set to 1. The TXDn pin retains the output state of the last bit. If the SCR.TEIE bit is 1, an SCIn_TEI interrupt request is generated and the SCKn pin is held high.

Note 1. In clock synchronous mode, FTDRH is not used.

[ 1 ]SCI initialization:
Set data transmission.
After the TE bit in SCR is set to 1, 1 is output for a frame, and transmission is enabled.

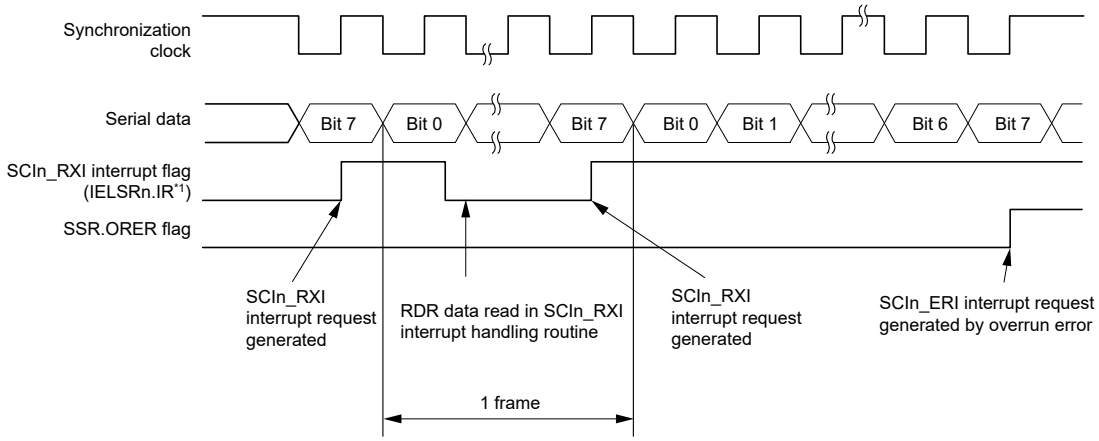
[ 2 ]Transmit data write to FTDRL by an SCIn_TXI interrupt request:
For transmission data from FTDRL to TSR, when the amount of transmit data written in FTDRL is equal to or less than the specified transmit triggering number, a transmit data FIFO empty interrupt (SCIn_TXI) request is generated. Write transmit data to FTDRL once in the SCIn_TXI interrupt handling routine.

[ 3 ]Serial transmission continuation procedure:
To continue serial transmission, write the next transmit data to FTDRL in this SCIn_TXI interrupt handling routine and clear the SSR_FIFO.TDFE flag to 0 before transmission of the current transmit data finishes.
Transmit data can also be written to FTDRL by activating the DMAC or DTC. The TDFE flag is cleared automatically in this case. Do not write to the TDFE flag.
When SCIn_TEI interrupt requests are in use, set the SCR.TIE bit to 0 and the SCR.TEIE bit to 1 after the last of the data to be transmitted is written to the FTDRL.

Note: When the external clock is in use (the value of the SCR.CKE[1:0] bits is 10b or 11b), the rising edge on the SCKn pin for the last bit sets the SSR_FIFO.TEND flag to 1. Setting the SCR.TE bit to 0 immediately after this might lead to insufficient received-data hold time on the receiver side.

**Figure 26.70 Example flow of serial transmission in clock synchronous mode with FIFO selected**

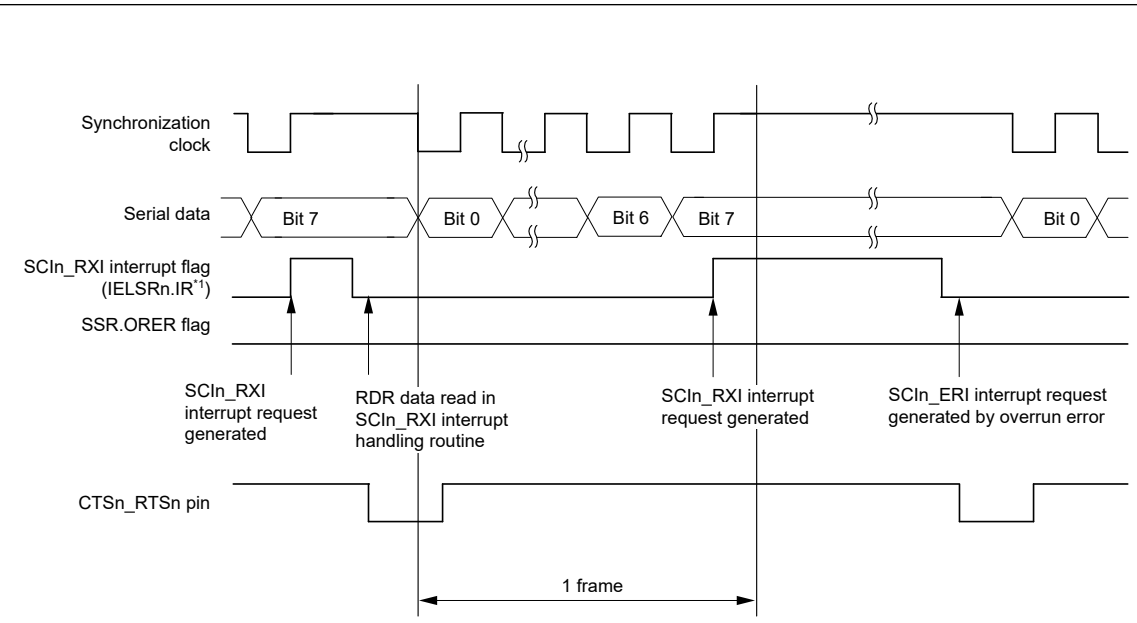
## 26.6.5 Serial Data Reception in Clock Synchronous Mode



(1) Non-FIFO selected

Figure 26.71 and Figure 26.72 show examples of SCI operation for serial reception in clock synchronous mode.

In serial data reception, the SCI operates as follows:



1. When the value of the SCR.RE bit becomes 1, the CTSn_RTSn pin goes low.
2. The SCI performs internal initialization and starts receiving data in synchronization with a synchronization clock input or output, and stores the receive data in the RSR register.
3. If an overrun error occurs, the SSR.ORER flag is set to 1. If the SCR.RIE bit is 1, an SCIn_ERI interrupt request is generated. Receive data is not transferred to the RDR register.

4. When reception completes successfully, receive data is transferred to the RDR register. If the SCR.RIE bit is 1, an SCIn_RXI interrupt request is generated. Continuous reception is enabled by reading the received data transferred to the RDR register in the SCIn_RXI interrupt handling routine before reception of the next receive data completes. Reading the received data that is transferred to RDR causes the CTSn_RTSn pin to output low.

Note 1. See section 12, Interrupt Controller Unit (ICU) for information on the corresponding interrupt event number.

**Figure 26.71 Example operation for serial reception in clock synchronous mode (1) when the RTS function is not used**

Note 1. See section 12, Interrupt Controller Unit (ICU) for information on the corresponding interrupt event number.

**Figure 26.72 Example operation for serial reception in clock synchronous mode (2) when RTS function is used**

Data transfer cannot resume while the receive error flag is 1. Therefore, clear the ORER, FER, and PER flags in the SSR register to 0 before resuming data reception. Additionally, always read the RDR register during overrun error processing. When a data reception is forced to terminate by a 0 write to the SCR.RE bit during operation, read the RDR register because received data that is not yet read might be left in the RDR register.

Figure 26.73 shows an example flow of serial data reception.

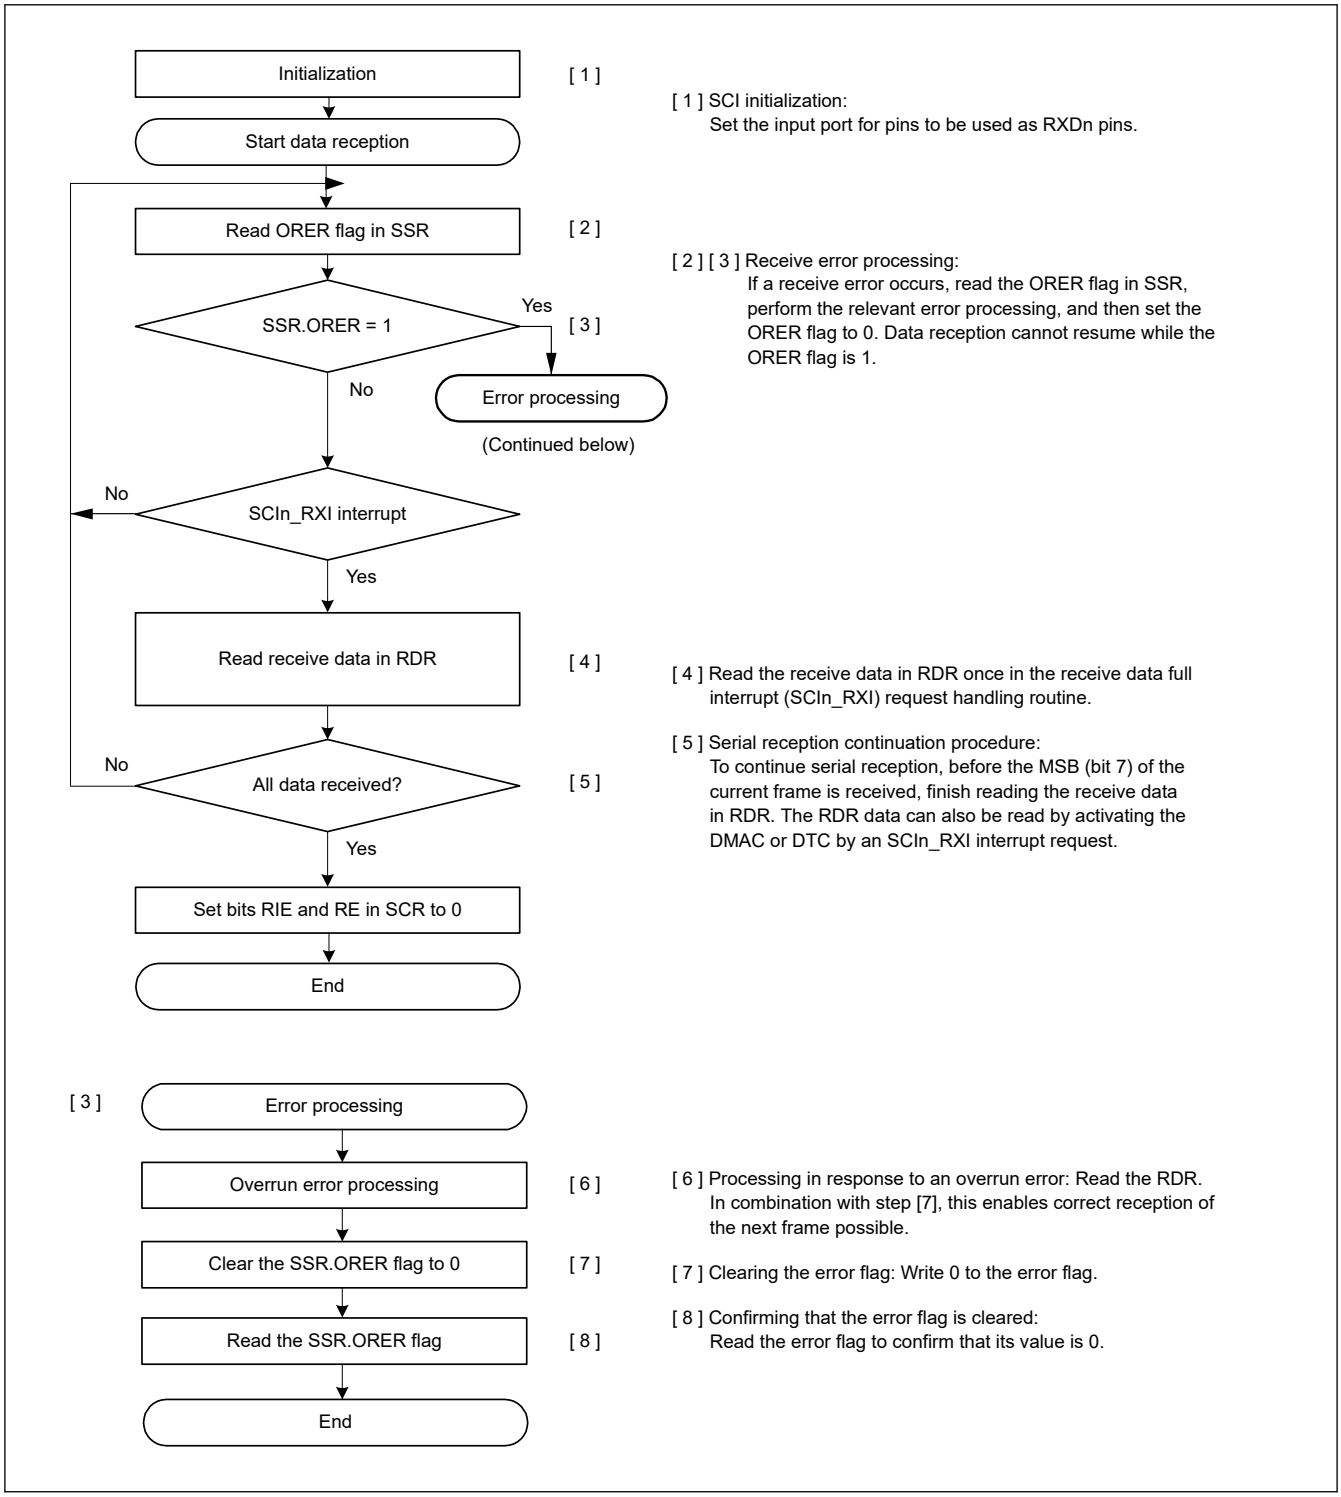


**Figure 26.73 Example flow of serial reception in clock synchronous mode with non-FIFO selected**

(2) FIFO selected

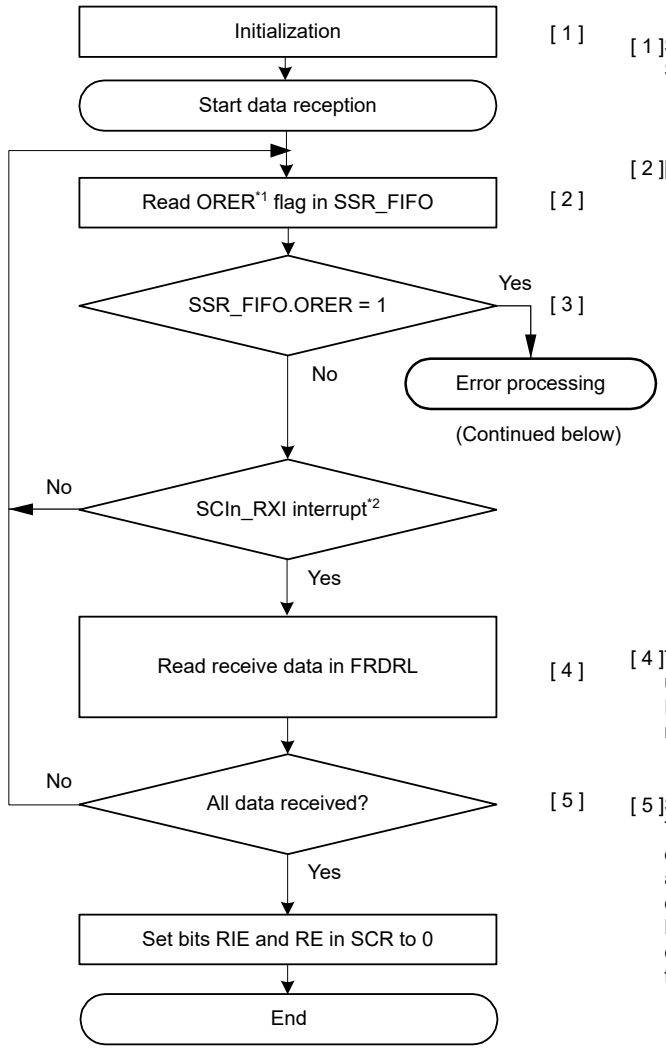

Figure 26.74 shows an example of serial reception in clock synchronous mode with FIFO selected.

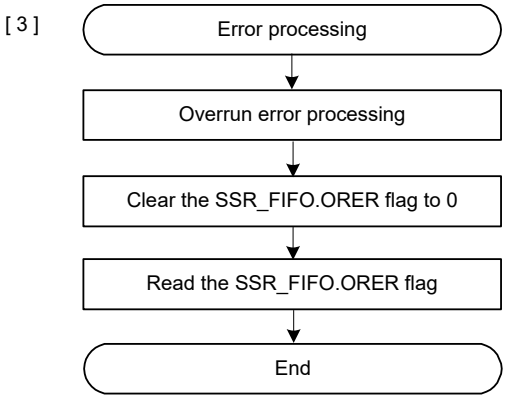

In serial data reception, the SCI operates as follows:

1. When the value of the SCR.RE bit becomes 1, the CTSn_RTSn pin goes low.
2. The SCI performs internal initialization and starts receiving data in synchronization with a synchronization clock input or output, and stores the receive data in the RSR register.

3. If an overrun error occurs, the SSR_FIFO.ORER flag is set to 1. If the SCR.RIE bit is 1, an SCIn_ERI interrupt request is generated. Received data is not transferred to the FRDRL[*1] register.
4. When data reception completes successfully, the receive data is transferred to the FRDRL[*1] register. The RDF flag is set to 1 when the amount of the receive data stored in FRDRL is equal to or greater than the specified receive triggering number. If the SCR.RIE bit is 1, an SCIn_RXI interrupt request is generated. Continuous data reception is enabled by reading the receive data transferred to FRDRL[*2] in the SCIn_RXI interrupt handling routine before an overrun error occurs. If the amount of received data that is transferred to FRDRL is less than the specified receive triggering number, the CTSn_RTSn pin goes low.

Note 1. In clock synchronous mode, FRDRH is not used.
Note 2. Read data in order from FRDRH to FRDRL when RDF and ORER are read with receive data.

[ 1 ]SCI initialization:
Set the input port for pins to be used as RXDn pins.

[ 2 ][ 3 ]Receive error processing:
If a receive error occurs, read the ORER flag in SSR_FIFO, perform the relevant error processing, then set the SSR_FIFO.ORER flag to 0. Data reception cannot resume while the ORER flag is 1.

[ 4 ]The receive data stored in FRDRL register is read until the amount of stored data is less than the FCR.RTRG[3:0] value. Software can check readable data in FDR.R[4:0].

[ 5 ]Serial reception continuation procedure:
To continue serial reception, before overrun error occurs, finish reading the receive data in FRDRL and clear the SSR_FIFO.RDF flag to 0.The FRDRL data can also be read by activating the DMAC or DTC by an SCIn_RXI interrupt request. The RDF flag is cleared automatically in this case. Do not write to the RDF flag.

[ 6 ]Processing in response to an overrun error:
Read the FRDRL. In combination with step [7], this enables correct reception of the next frame possible.

[ 7 ]Clearing the error flag:
Write 0 to the error flag.

[ 8 ]Confirming that the error flag is cleared:
Read the error flag to confirm that its value is 0.

Note 1. It can also be read from FRDRH.ORER. However, to clear the ORER flag, write 0 to the associated bit in the SSR_FIFO register.
Note 2. It should be all receive data and is an integer times the FIFO triggering number.

**Figure 26.74 Example flow of serial reception in clock synchronous mode with FIFO selected**

### 26.6.6 Simultaneous Serial Data Transmission and Reception in Clock Synchronous Mode

**(1) Non-FIFO selected**

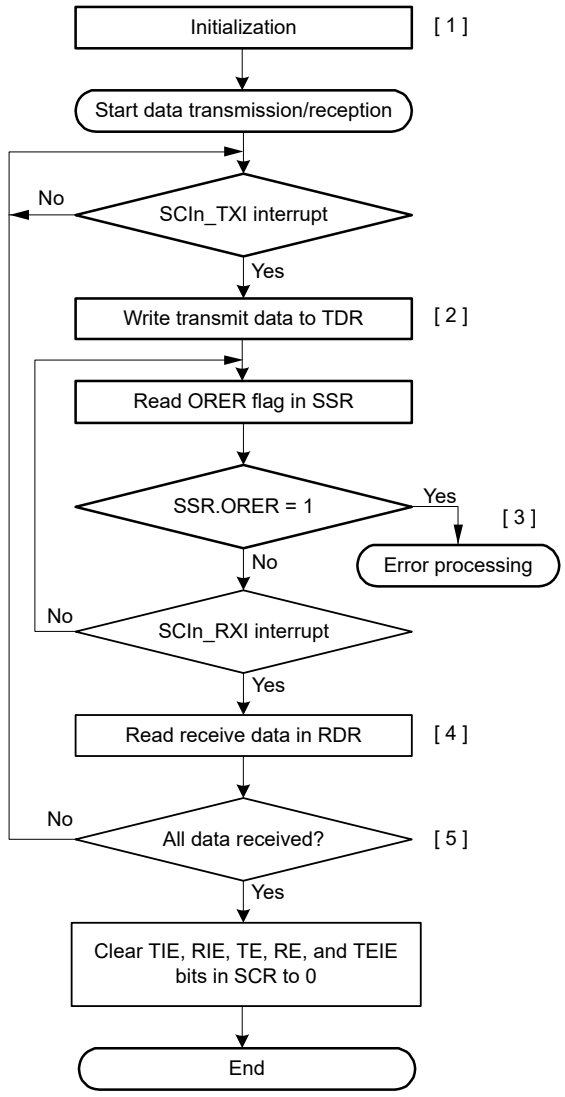

Figure 26.75 shows an example flow of simultaneous serial transmit and receive operations in clock synchronous mode. After initializing the SCI, use the following procedure for simultaneous serial data transmit and receive operations.

To switch from transmit mode to simultaneous transmit and receive mode:

1. Check that the SCI completes the data transmission by verifying that the SSR.TEND flag is set to 1.
2. Initialize the SCR register, and then set the TIE, RIE, TE, and RE bits in the SCR register to 1 simultaneously by a single instruction.

To switch from receive mode to simultaneous transmit and receive mode:

1. Check that the SCI completes the data reception.
2. Set the RIE and RE bits to 0, and then check that the receive error flag ORER in the SSR register is 0.
3. Set the TIE, RIE, TE, and RE bits in the SCR register to 1 simultaneously by a single instruction.

[ 1 ] SCI initialization:
The TXDn pin can act as the output pin for transmitted data and the RXDn pin can act as the input pin for received data at the same time.

[ 2 ] Transmit data write:
Write transmit data to TDR once in the SCIn_TXI interrupt request handling routine.

[ 3 ] Receive error processing:
If a receive error occurs, read the ORER flag in SSR, perform the relevant error processing, then set the ORER flag to 0. Data reception cannot resume while the ORER flag is 1.

[ 4 ] Reading receive data:
Read the receive data in RDR once in the SCIn_RXI interrupt request handling routine.

[ 5 ] Serial transmission/reception continuation procedure:
To continue serial transmission and reception, before the MSB bit 7 of the current frame is received, finish reading the receive data in RDR by the SCIn_RXI interrupt. Also, before the MSB bit 7 of the current frame is transmitted, write data to TDR by the SCIn_TXI interrupt.
Transmit data can also be written to TDR by activating the DMAC or DTC by a transmit data empty interrupt (SCIn_TXI) request. Similarly, the RDR data can also be read by activating the DMAC or DTC by a receive data full interrupt (SCIn_RXI) request.

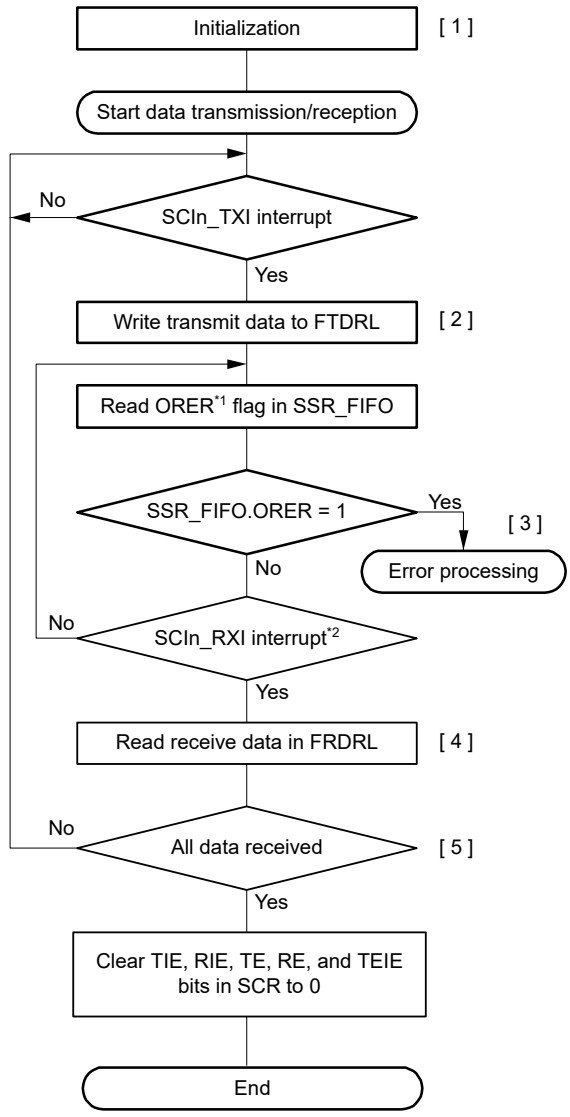
Note: When switching from transmit or receive operation to simultaneous transmit and receive operations, first set the TIE, RIE, TE, RE, and TEIE bits in SCR to 0, then set TIE, RIE, TE, and RE bits to 1 simultaneously.

**Figure 26.75 Example flow of simultaneous serial transmission and reception in clock synchronous mode with non-FIFO selected**

### (2) FIFO selected

Figure 26.76 shows an example flow of simultaneous serial transmit and receive operations in clock synchronous mode with FIFO selected.

After initializing the SCI, use the following procedure for simultaneous serial data transmit and receive operations.



To switch from transmit mode to simultaneous transmit and receive mode:

1. Check that the SCI completes the transmission by verifying that the SSR_FIFO.TEND flag is set to 1.
2. Initialize the SCR register, then set the TIE, RIE, TE, and RE bits in the SCR register to 1 simultaneously by a single instruction.

To switch from receive mode to simultaneous transmit and receive mode:

1. Check that the SCI completes the reception.

2. Set the RIE and RE bits to 0.
3. Check that the receive error flags ORER in the SSR_FIFO register are 0, and then set the TIE, RIE, TE, and RE bits in the SCR register to 1 simultaneously by a single instruction.

[ 1 ] SCI initialization:
The TXDn pin can act as the output pin for transmitted data and the RXDn pin can act as the input pin for received data at the same time.

[ 2 ] Transmit data write:
Write transmit data to FTDRL in the SCIn_TXI interrupt request handling routine. The number of transmission data that can be written is 16 bits, which is the number of stored transmit data in the FIFO.

[ 3 ] Receive error processing:
If a receive error occurs, read the ORER flag in SSR_FIFO, perform the relevant error processing, and then set the ORER flag to 0. Data reception cannot resume while the ORER flag is 1.

[ 4 ] Reading receive data:
The reception data stored in FRDRL register is read until the number of stored data is less than the FCR.RTRG value. Software can check readable data in FDR.R[4:0].

[ 5 ] Serial transmission/reception continuation procedure:
To continue serial reception, before overrun error occurs, finish reading the receive data in FRDRL and clear the SSR_FIFO.RDF flag to 0. To continue serial transmission, before transmission of the current transmit data is finished, write the next transmit data to FTDRL in the SCIn_TXI interrupt handling routine and clear the SSR_FIFO.TDFE flag to 0.
Transmit data can also be written to FTDRL by activating the DMAC or DTC by a transmit FIFO data empty interrupt (SCIn_TXI) request. Similarly, the FRDRL data can also be read by activating the DMAC or DTC by a receive FIFO data full interrupt (SCIn_RXI) request. The RDF and TDFE flags are cleared automatically in this case. Do not write to the RDF and TDFE flags.

Note 1. It can also be read from FRDRH.ORER. To clear the ORER flag, write 0 to the associated bit in the SSR_FIFO register.
Note 2. It should be all receive data with amount an integer times FIFO triggering number.

**Figure 26.76 Example flow of simultaneous serial transmission and reception in clock synchronous mode with FIFO selected**

## 26.7 Operation in Smart Card Interface Mode

The SCI supports smart card (IC card) interfaces conforming to ISO/IEC 7816-3 (standard for Identification Cards), as an extended function of the SCI.

Smart card interface mode can be selected using the appropriate register.

### 26.7.1 Example Connection

Figure 26.77 shows an example connection between a smart card (IC card) and the MCU. As shown in Figure 26.77, because the MCU communicates with an IC card using a single transmission line, interconnect the TXDn and RXDn pins and pull up the data transmission line to VCC using a resistor.

Setting the SCR_SMCI.TE and SCR_SMCI.RE bits to 1 with an IC card disconnected enables closed-loop transmission or reception, allowing self-diagnosis. To supply an IC card with the clock pulses generated by the SCI, input the SCKn pin output to the CLK pin of an IC card.

An output port of the MCU can be used to output a reset signal.

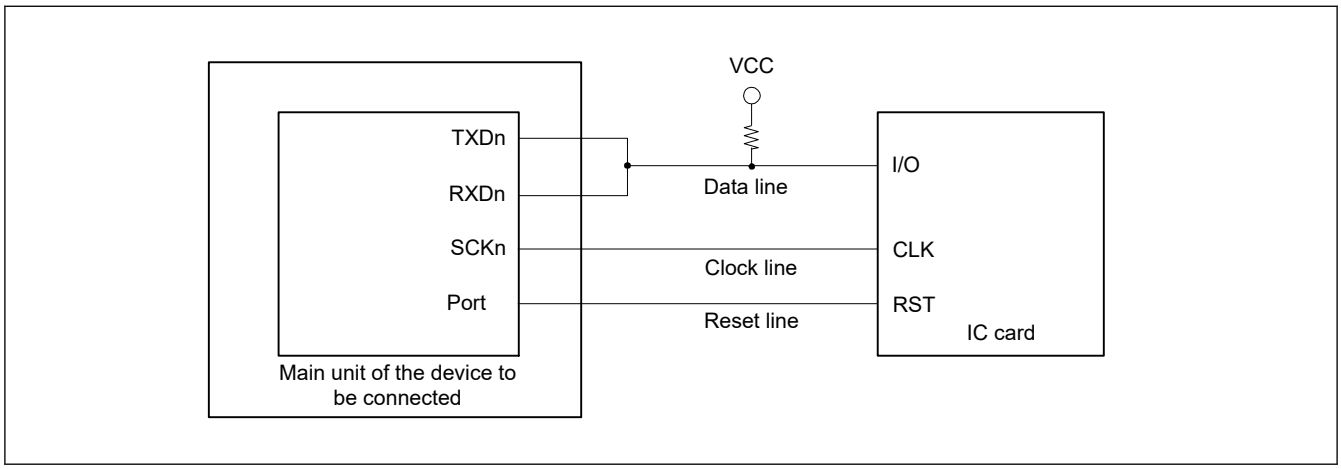


**Figure 26.77 Example connection with a smart card (IC card)**

### 26.7.2 Data Format (Except in Block Transfer Mode)

Figure 26.78 shows the data transfer formats in smart card interface mode:

- One frame consists of 8-bit data and a parity bit in asynchronous mode.
- During transmission, at least 2 etus (elementary time unit – the time required for transferring 1 bit) is set as a guard time from the end of the parity bit until the start of the next frame.
- If a parity error is detected during reception, a low error signal is output for 1 etu after 10.5 etus elapse from the start bit.
- If an error signal is sampled during transmission, the same data is automatically retransmitted after at least 2 etus.

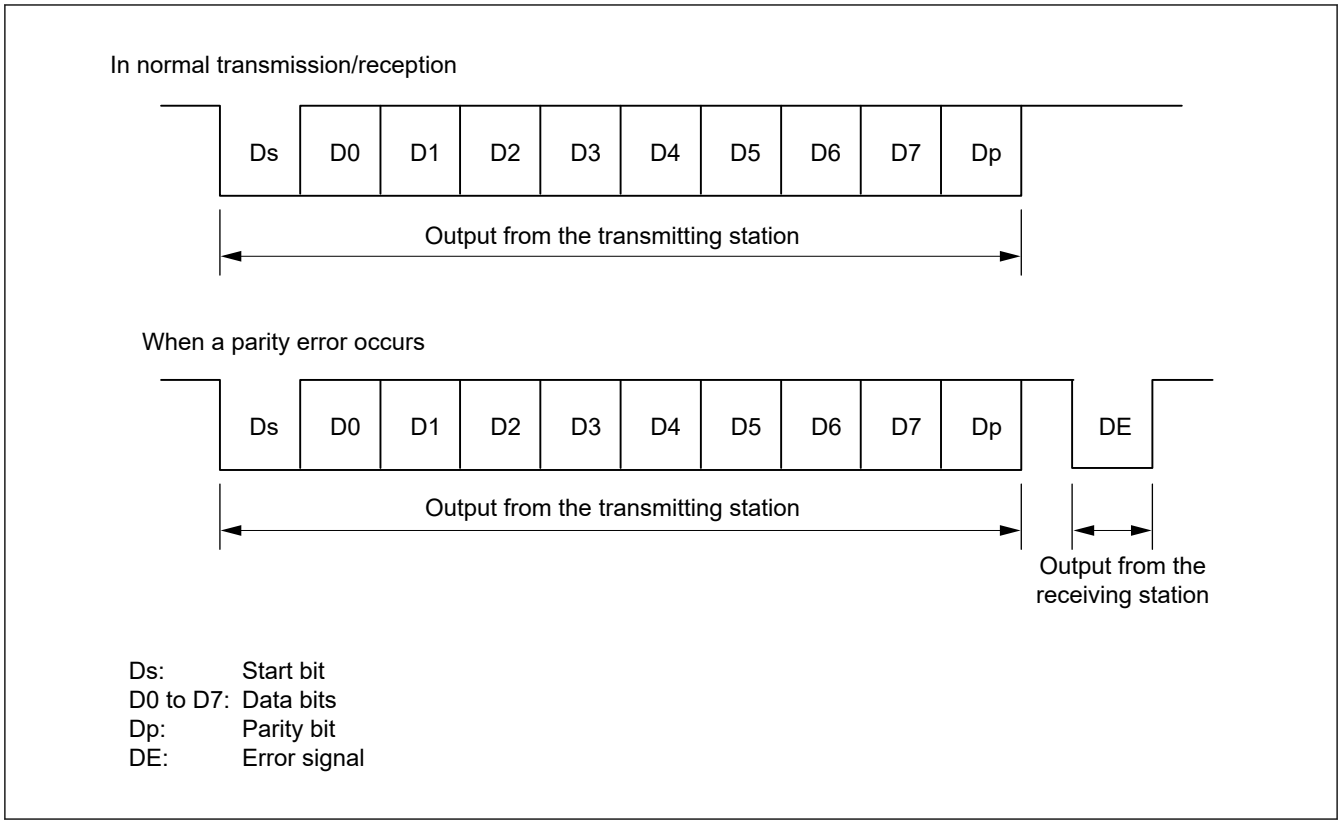

**Figure 26.78 Data formats in smart card interface mode**

For communications with IC cards of the direct convention type and inverse convention type, follow the procedures in this section.

## (1) Direct Convention Type

For the direct convention type, logic levels 1 and 0 indicate the Z and A states, respectively, and data is transferred with LSB-first for the start character, as shown in Figure 26.79. Therefore, data in the start character in the figure is 0x3B.

When using the direct convention type, write 0 to both the SCMR.SDIR and SCMR.SINV bits. Write 0 to the SMR_SMCI.PM bit to use even parity, which is prescribed by the smart card standard.

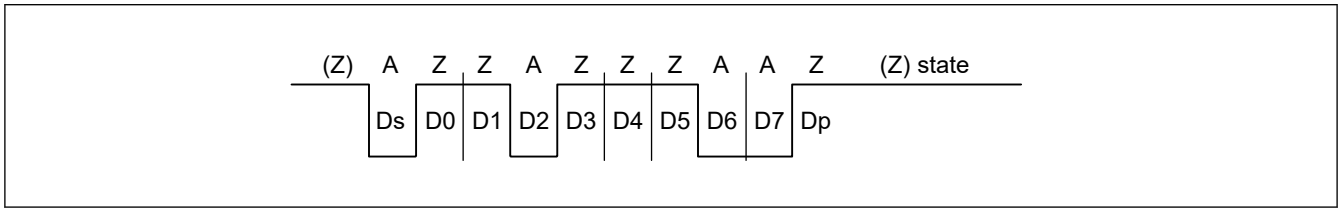

**Figure 26.79 Direct convention with SDIR in SCMR = 0, SINV in SCMR = 0, and PM in SMR_SMCI = 0**

## (2) Inverse Convention Type

For the inverse convention type, logic levels 1 and 0 indicate the A and Z states, respectively, and data is transferred with MSB-first for the start character, as shown in Figure 26.80. Therefore, data in the start character in the figure is 0x3F.

When using the inverse convention type, write 1 to both the SCMR.SDIR and SCMR.SINV bits. The parity bit is logic level 0 to produce even parity, which is prescribed by the smart card standard, and corresponds to the Z state. Because the SINV bit of the MCU only inverts data bits D7 to D0, write 1 to the PM bit in SMR_SMCI to invert the parity bit for both transmission and reception.

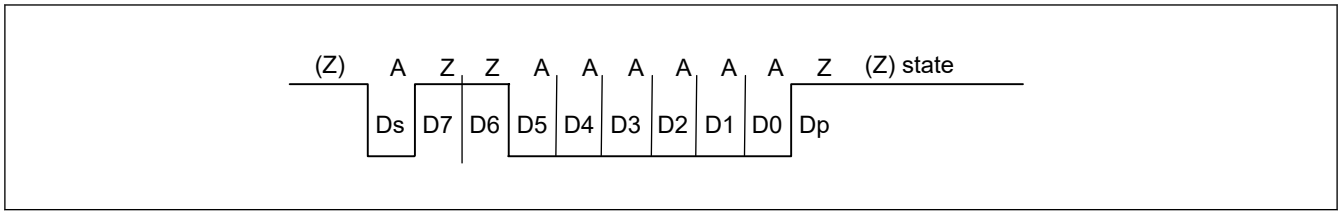

**Figure 26.80 Inverse convention with SDIR in SCMR = 1, SINV in SCMR = 1, and PM in SMR_SMCI = 1**

## 26.7.3 Block Transfer Mode

Block transfer mode differs from normal smart card interface mode as follows:

- Even if a parity error is detected during reception, no error signal is output. Because the PER flag in SSR_SMCI is set by error detection, clear the PER flag before receiving the parity bit of the next frame.
- During transmission, at least 1 etu is set as a guard time from the end of the parity bit until the start of the next frame
- Because the same data is not retransmitted, the TEND flag in SSR_SMCI is set to 11.5 etus after transmission starts
- In block transfer mode, the ERS flag in SSR_SMCI indicates the error signal status as in normal smart card interface mode, but the flag is read as 0 because no error signal is transferred

## 26.7.4 Receive Data Sampling Timing and Reception Margin

Only the internal clock generated by the on-chip baud rate generator can be used as a transfer clock in smart card interface mode.

In this mode, the SCI can operate on a base clock with a frequency of 32, 64, 372, 256, 93, 128, 186, or 512 times the bit rate set up in the SCMR.BCP2 and the SMR_SMCI.BCP[1:0] bits. The frequency is always 16 times the bit rate in normal asynchronous mode.

For data reception, the falling edge of the start bit is sampled with the base clock to perform internal synchronization.

Receive data is sampled on the 16th, 32nd, 186th, 128th, 46th, 64th, 93rd, and 256th rising edges of the base clock so that it can be latched at the middle of each bit as shown in Figure 26.81. The reception margin is determined by the following formula:

$$M = \left| \left(0.5 - \frac{1}{2N}\right) - (L - 0.5)F - \frac{|D - 0.5|}{N}(1 + F) \right| \times 100\ [\%]$$

M: Reception margin (%)

N: Ratio of bit rate to clock ($N = 32, 64, 372, 256$)

D: Duty cycle of clock ($D = 0$ to $1.0$)

L: Frame length ($L = 10$)

F: Absolute value of clock frequency deviation

Assuming values of F = 0, D = 0.5, and N = 372 in the specified formula, the reception margin is determined using the following formula:

$$M = \{0.5 - 1/(2 \times 372)\} \times 100\ [\%] = 49.866\ \%$$

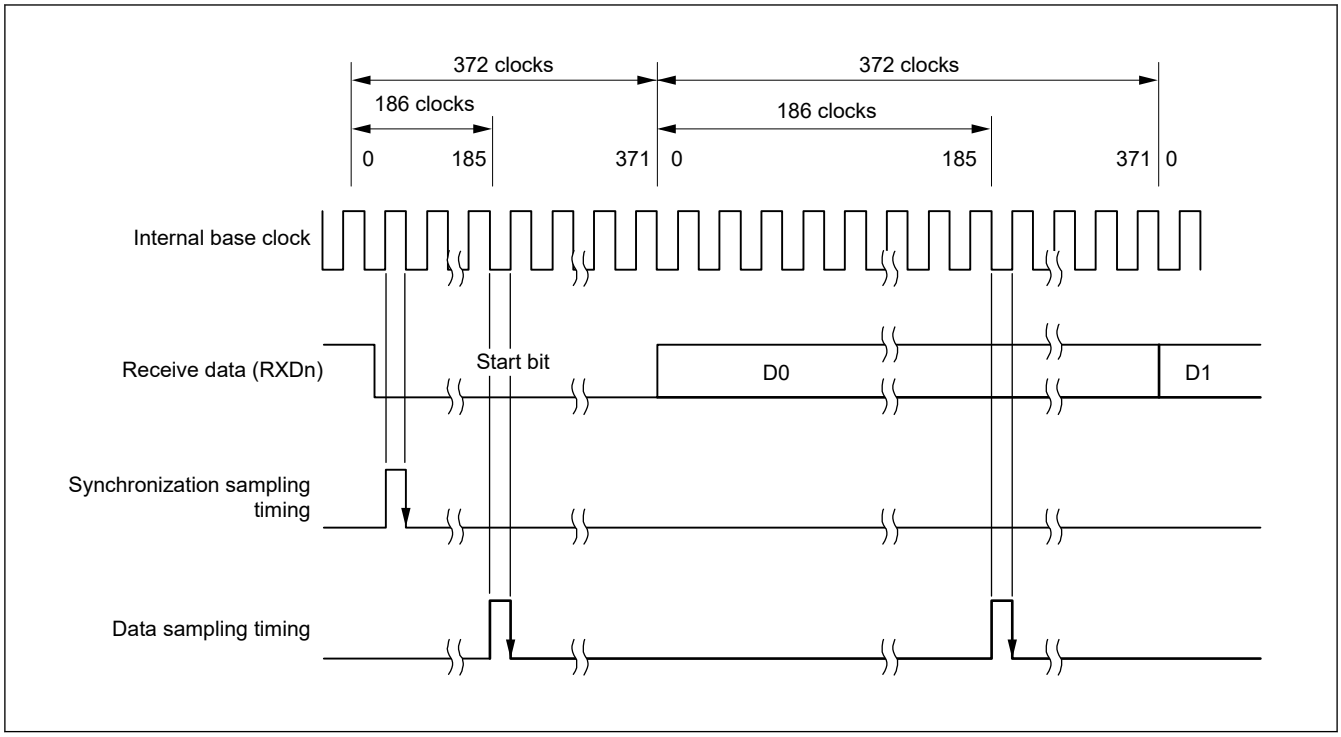

**Figure 26.81 Receive data sampling timing in smart card interface mode when the clock frequency is 372 times the bit rate**

## 26.7.5 SCI Initialization (Smart Card Interface Mode)

Before transmitting and receiving data, write the initial value 0x00 in the SCR_SMCI register and initialize the SCI following the example flow shown in Table 26.39.

Always set the initial value in the TIE, RIE, TE, RE, TEIE bits in the SCR_SMCI register before switching from transmission to reception mode or from reception to transmission mode. When SCR_SMCI.RE is set to 0, the RDR register is not initialized.

To change from reception mode to transmission mode, first check that reception has completed, then initialize the SCI. At the end of initialization, set SCR_SMCI.TE = 1 and SCR_SMCI.RE = 0. Reception completion can be verified by reading the SCIn_RXI request, ORER, or PER flag in SSR_SMCI.

To change transmission mode to reception mode, first check that transmission has completed, then initialize the SCI. At the end of initialization, set SCR_SMCI.TE = 0 and SCR_SMCI.RE = 1. Transmission completion can be verified by reading the TEND flag in SSR_SMCI.

**Table 26.39 Example flow of SCI initialization in smart card interface mode (1 of 2)**

| No. | Step Name | Description |
|---|---|---|
| 1 | Start initialization | |
| 2 | Set SCR_SMCI.TIE, RIE, TE, RE, TEIE, and CKE[1:0] to 0 | Stop the communication and initialize SKE[1:0]. |
| 3 | Set SIMR1.IICM bit to 0.<br>Set SCMR.SMIF to 1. | Set to smart card interface mode. |
| 4 | Set SSR_SMCI.ORER, ERS, PER to 0 | Write to SSR_SMCI after reading SSR_SMCI. |
| 5 | Set SPMR.CKPH, CKPOL | Set the transmission or reception format in SPMR. |
| 6 | Set SMR_SMCI.GM, BLK, PM, BCP[1:0], CKS[1:0], and set SMR_SMCI.PE to 1 | Set the operation mode and the transmission or reception format in SMR_SMCI. |
| 7 | Set SCMR.BCP2, SDIR, SINV | Set the transmission or reception format in SCMR. |
| 8 | Set SPTR to the initial value. | Set the Initial value to SPTR. |

**Table 26.39 Example flow of SCI initialization in smart card interface mode (2 of 2)**

| No. | Step Name | Description |
|---|---|---|
| 9 | Set SEMR.BRME and SEMR.RXDESEL to 0 | Set SEMR.BRME and SEMR.RXDESEL to 0. |
| 10 | Set a value in BRR | Write the value for the bit rate in BRR. |
| 11 | Set the I/O port functions | Set the I/O port functions for TXDn, RXDn, and SCKn. |
| 12 | Set a value in SCR_SMCI.CKE [1:0] | Set the SCR_SMCI.CKE[1:0]. Even though the function depends on SMR_SMCI.GM, when the CKE[0] bit is set to 1, the clock is output from the SCKn pin. |
| 13 | Set SCR_SMCI.TE or RE to 1, and set SCR_SMCI.TIE, RIE | Set the TE or RE bit in SCR_SMCI to 1, then set the TIE and RIE bits in SCR_SMCI. Do not simultaneously set the TE and RE bits to 1 if self-diagnosis is not used. |
| 14 | Initialization completed | |

## 26.7.6 Serial Data Transmission (Except in Block Transfer Mode)

Serial data transmission in smart card interface mode (except in block transfer mode) is different from that in non-smart card interface mode, in that an error signal is sampled and data can be re-transmitted in smart card mode. Figure 26.82 shows the data re-transfer operation during transmission.

1. When an error signal from the receiver end is sampled after 1-frame data is transmitted, the SSR_SMCI.ERS flag is set to 1. If the SCR_SMCI.RIE bit is 1, an SCIn_ERI interrupt request is generated. Clear the ERS flag to 0 before the next parity bit is sampled.
2. For a frame in which an error signal is received, the SSR_SMCI.TEND flag is not set. Data is re-transferred from TDR to TSR, allowing automatic data retransmission.
3. If no error signal is returned from the receiver, the ERS flag is not set to 1.
4. In this case, the SCI determines that transmission of 1-frame data, including the re-transfer, is complete, and the TEND flag is set. If the SCR_SMCI.TIE bit is 1, an SCIn_TXI interrupt request is generated. Write transmit data to the TDR to start transmission of the next data.

Figure 26.84 shows an example flow of serial transmission. All the processing steps are automatically performed using an SCIn_TXI interrupt request to activate the DTC or DMAC.

When the SSR_SMCI.TEND flag is set to 1 in transmission and when the SCR_SMCI.TIE bit is 1, an SCIn_TXI interrupt request is generated.

The DTC or DMAC is activated by an SCIn_TXI interrupt request if the SCIn_TXI interrupt request is previously specified as a source of DTC or DMAC activation, allowing the transfer of transmit data. The TEND flag is automatically set to 0 when the DTC or DMAC transfers the data.

If an error occurs, the SCI automatically retransmits the same data. During this retransmission, the TEND flag is kept at 0 and the DTC or DMAC is not activated. Therefore, the SCI and DTC or DMAC automatically transmit the specified number of bytes, including retransmission when an error occurs. Because the ERS flag is not automatically cleared, set the RIE bit to 1 before enabling an SCIn_ERI interrupt request to be generated if an error occurs, and clear the ERS flag to 0.

When transmitting or receiving data using the DTC or DMAC, always enable the DTC or DMAC before making the SCI settings.

For DTC or DMAC settings, see section 16, Data Transfer Controller (DTC), section 15, DMA Controller (DMAC).

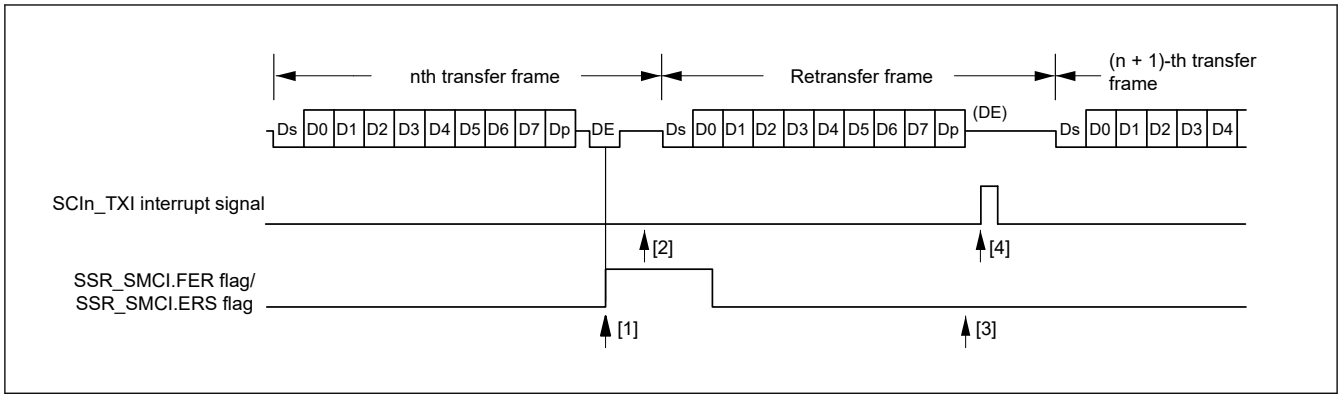

**Figure 26.82 Data re-transfer operation in smart card interface transmission mode**

The SSR_SMCI.TEND flag is set at different timings depending on the SMR_SMCI.GM bit setting. Figure 26.83 shows the TEND flag generation timing.

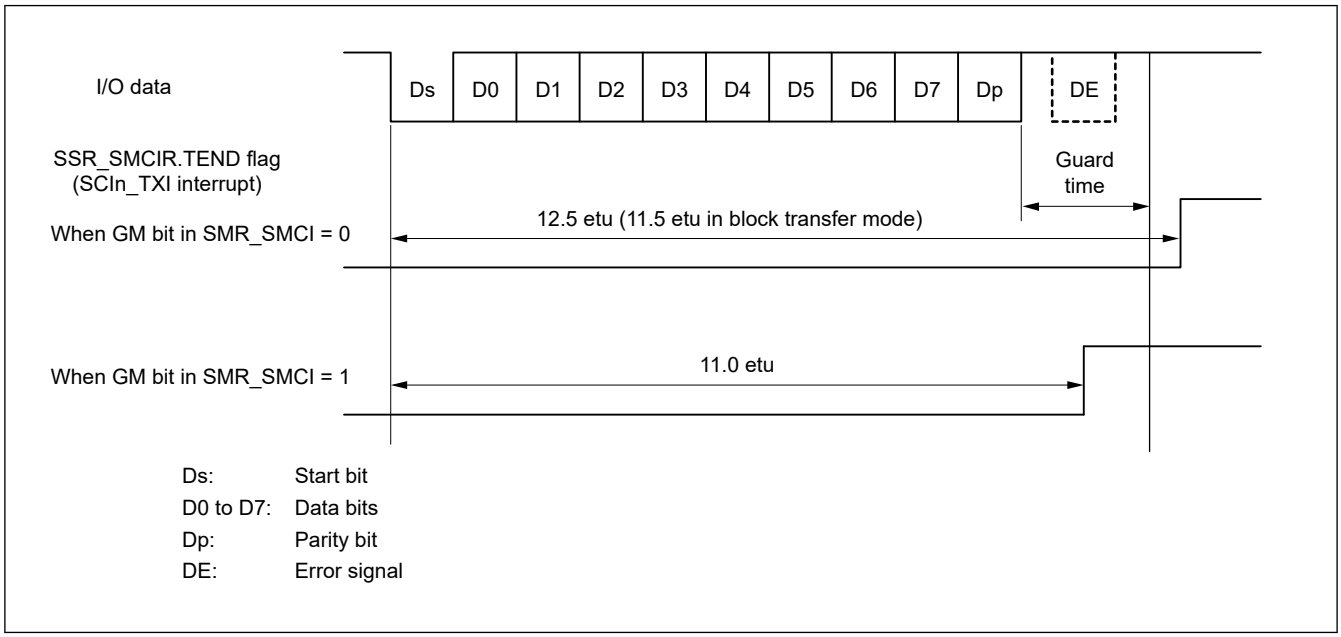

**Figure 26.83 SSR.TEND flag generation timing during transmission**

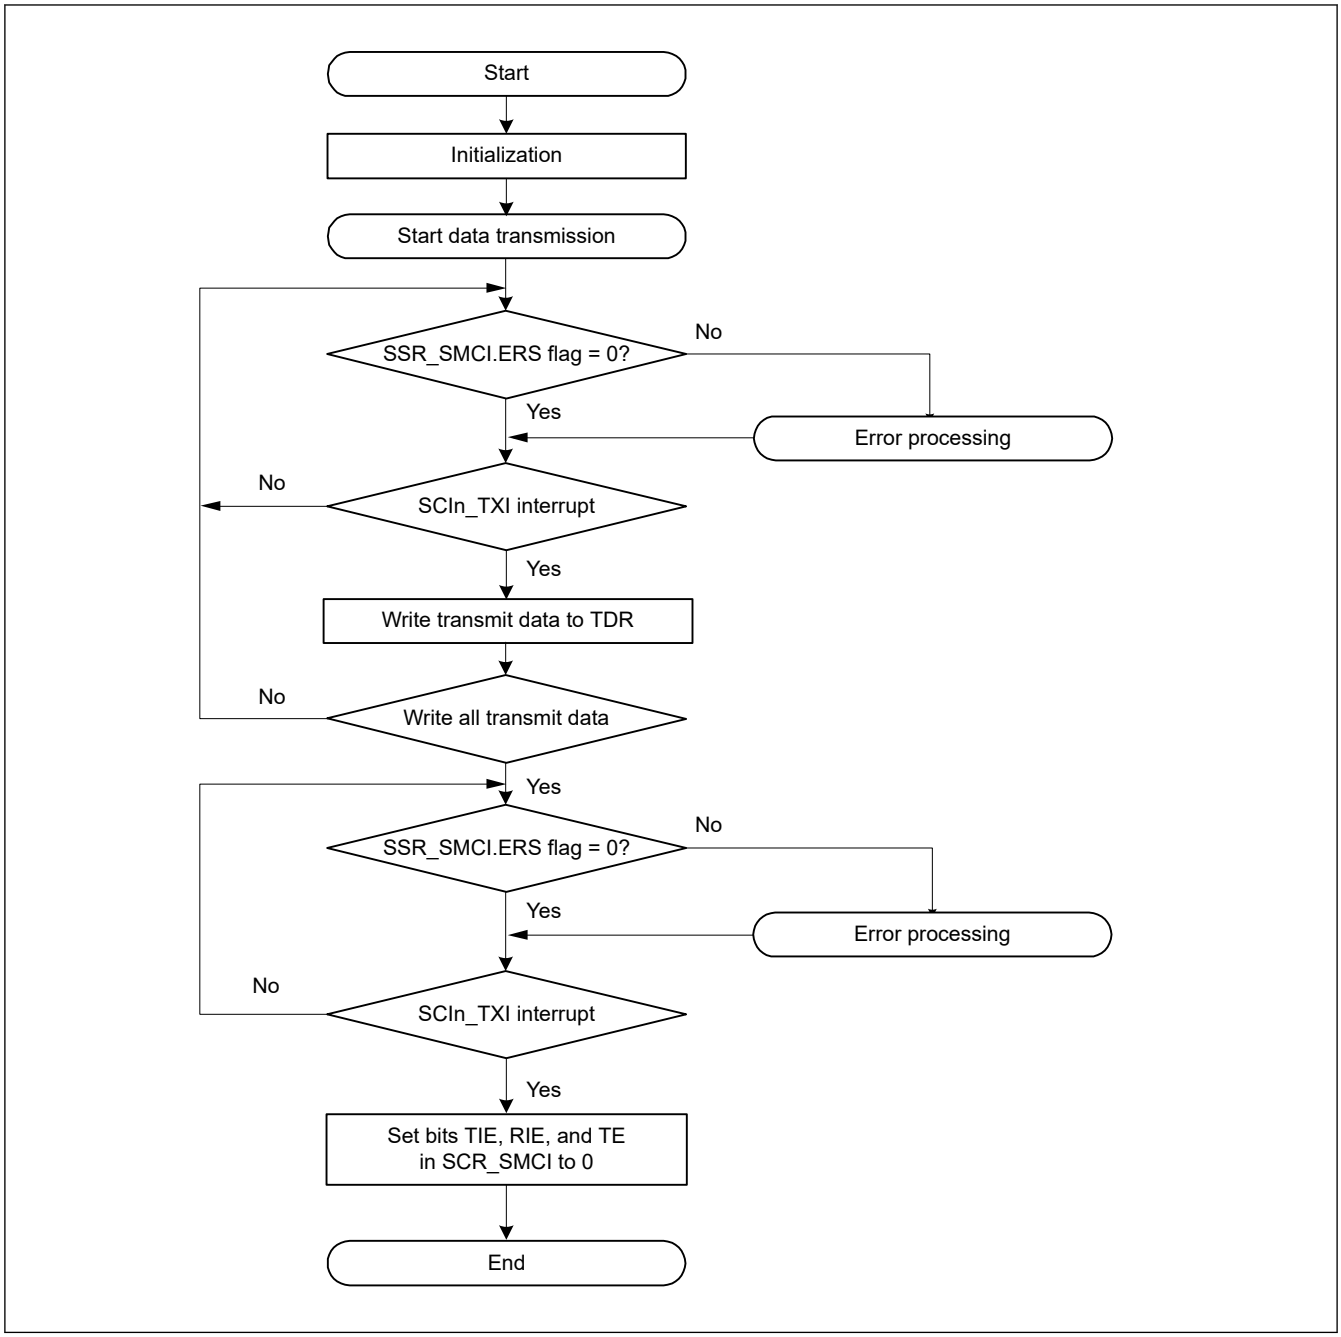

**Figure 26.84 Example flow of smart card interface transmission**

## 26.7.7 Serial Data Reception (Except in Block Transfer Mode)

Serial data reception in smart card interface mode is similar to that in non-smart card interface mode. Figure 26.85 shows the data re-transfer operation in reception mode.

1. If a parity error is detected in the receive data, the SSR_SMCI.PER flag is set to 1. When the SCR_SMCI.RIE bit is 1, an SCIn_ERI interrupt request is generated. Clear the PER flag to 0 before the next parity bit is sampled.
2. For a frame in which a parity error is detected, no SCIn_RXI interrupt is generated.
3. When no parity error is detected, the SCR_SMCI.PER flag is not set to 1.
4. In this case, data is determined to be received successfully. When the SCR_SMCI.RIE bit is 1, an SCIn_RXI interrupt request is generated.

Figure 26.86 shows an example flow of serial data reception. All the processing steps are automatically performed using an SCIn_RXI interrupt request to activate the DTC or DMAC.

In reception, setting the RIE bit to 1 allows an SCIn_RXI interrupt request to be generated. The DTC or DMAC is activated by an SCIn_RXI interrupt request if the SCIn_RXI interrupt request is previously specified as a source of DTC or DMAC activation, allowing the transfer of receive data.

If an error occurs during reception and either the ORER or PER flag in SSR_SMCI is set to 1, a receive error interrupt (SCIn_ERI) request is generated. Clear the error flag after the error occurrence. If an error occurs, the DTC or DMAC is not activated and receive data is skipped. Therefore, the number of bytes of receive data specified in the DTC or DMAC is transferred.

If a parity error occurs and the PER flag is set to 1 during reception, the receive data is transferred to RDR, allowing the data to be read.

When a reception is forced to terminate by setting SCR_SMCI.RE to 0 during operation, read the RDR register because the received data that is not yet read might be left in the RDR.

Note: For operations in block transfer mode, see section 26.3.9. Serial Data Reception in Asynchronous Mode.

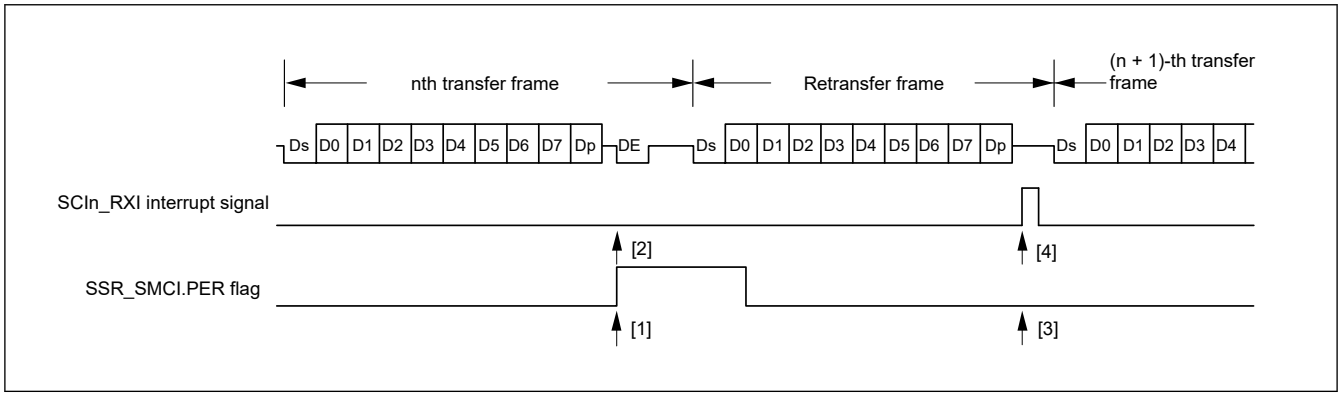

**Figure 26.85 Data re-transfer operation in smart card interface reception mode**

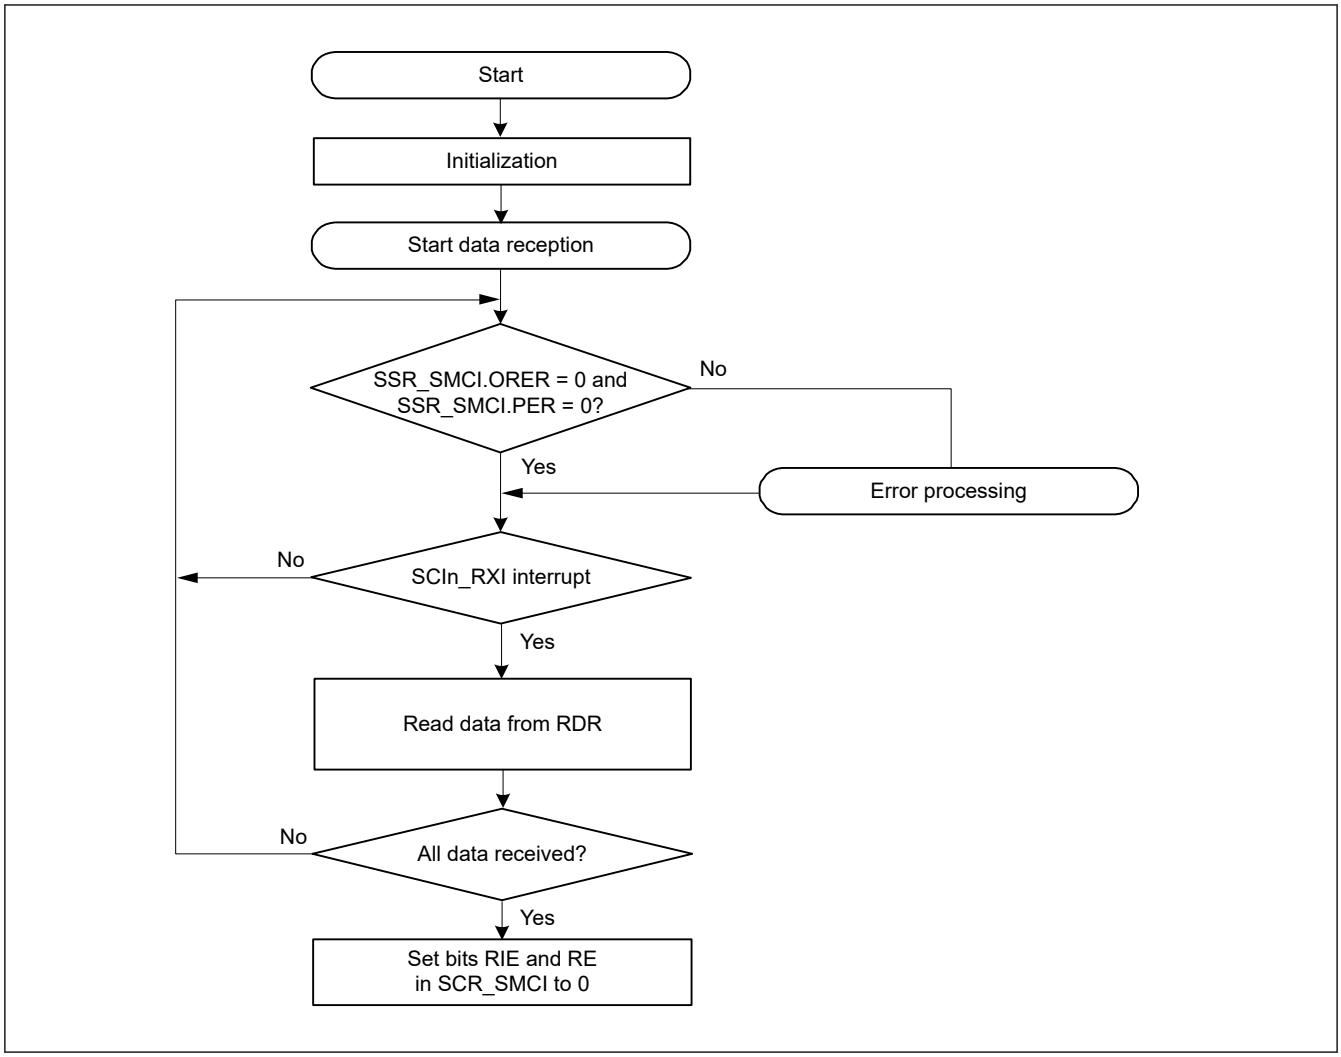

**Figure 26.86 Example flow of smart card interface reception**

## 26.7.8 Clock Output Control

When the GM bit in SMR_SMCI is set to 1, the clock output can be controlled by the CKE[1:0] bits in SCR_SMCI. For details on the CKE[1:0] bits, see section 26.2.14. SCR_SMCI : Serial Control Register for Smart Card Interface Mode (SCMR.SMIF = 1). When setting the clock output, the base clock described in section 26.7.4. Receive Data Sampling Timing and Reception Margin is applied.

Figure 26.87 shows an example timing for the clock output control when the CKE[1] bit in SCR_SMCI is set to 0 and the CKE[0] bit in SCR_SMCI is controlled.

When the GM bit in SMR_SMCI is 0, output control by the CKE[0] bit in SCR_SMCI is immediately reflected on the SCKn pin, so there is a possibility that pulses with an unintended width may be output from the SCKn pin.

When the GM bit in SMR_SMCI is 1, the clock with the same pulse width as the base clock is output even if the CKE[0] bit in SCR_SMCI is changed.

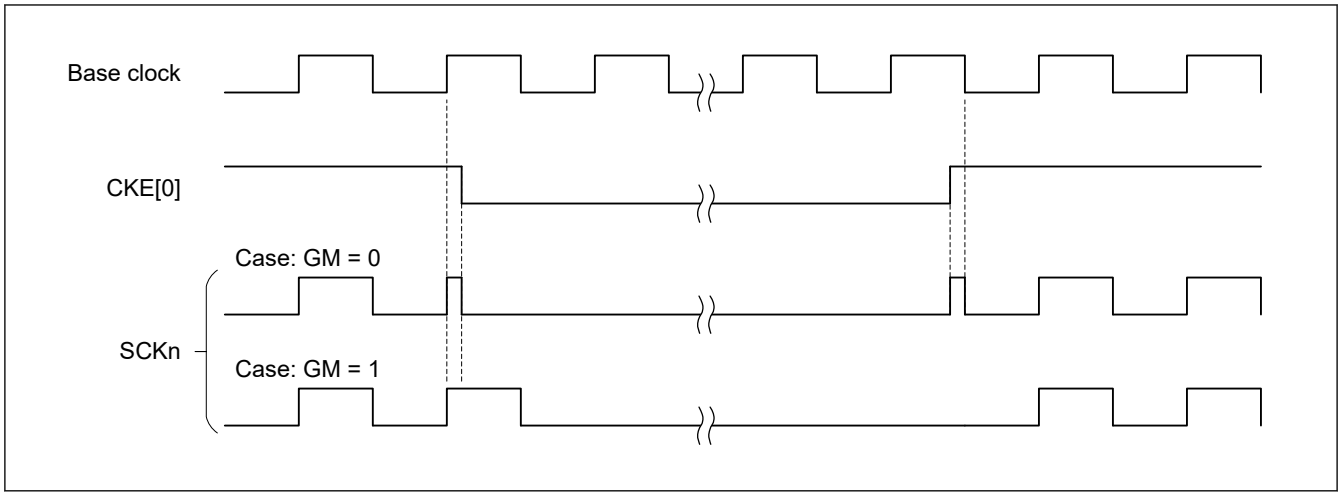

**Figure 26.87 Clock Output timing**

## 26.8 Operation in Simple IIC Mode

Simple IIC mode format is composed of 8 data bits and an acknowledge bit. By continuing into a slave-address frame after a start condition or restart condition, a master device can specify a slave device as the partner for communications. The currently specified slave device remains valid until a new slave device is specified or a stop condition is satisfied. The 8 data bits in all frames are transmitted in order from the MSB.

The $I^2C$ bus format and timing of the $I^2C$ bus are shown in Figure 26.88 and Figure 26.89.

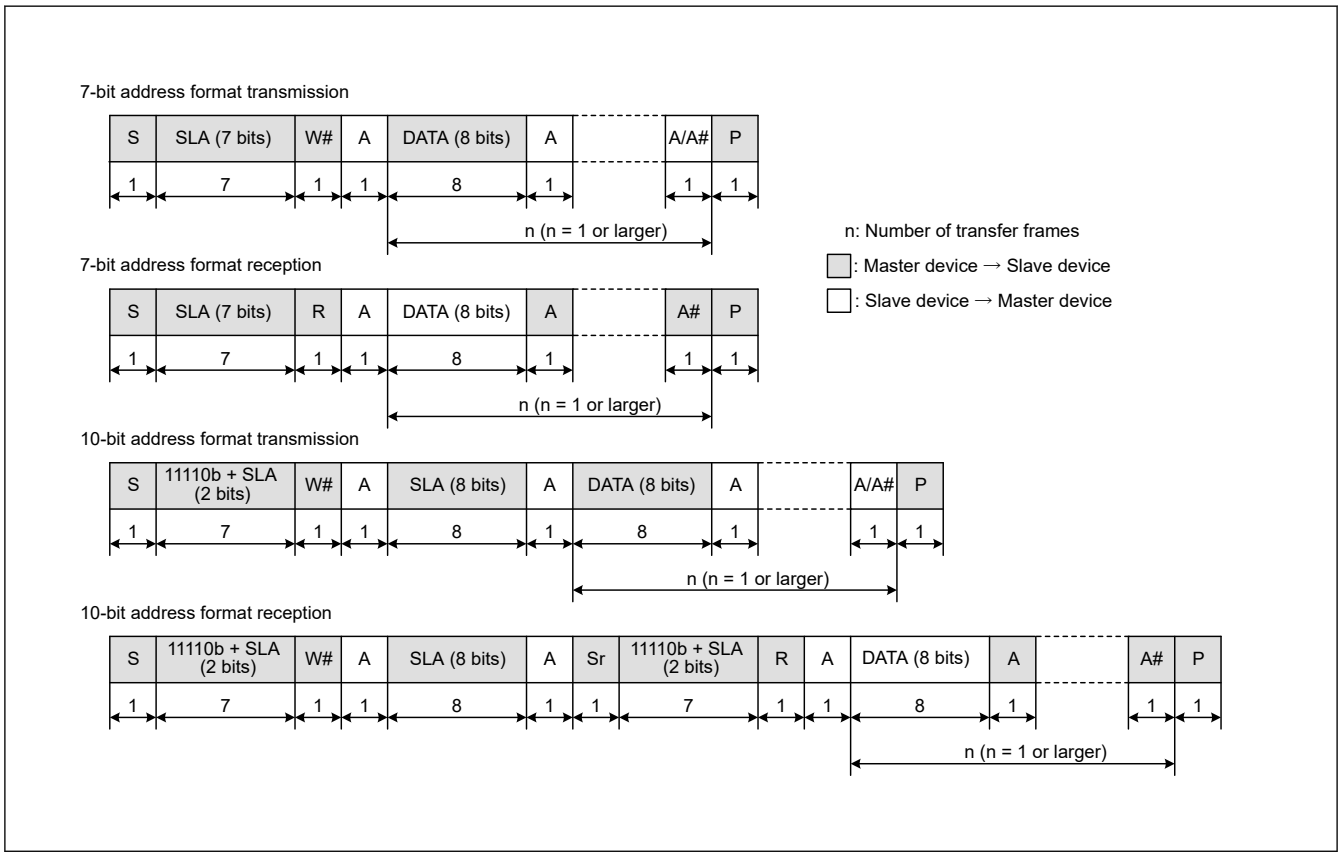

**Figure 26.88 $I^2C$ bus format**

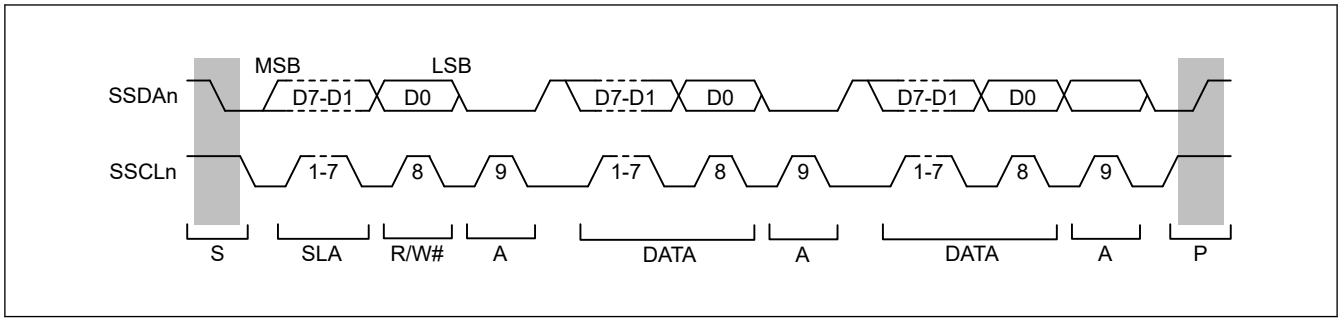

**Figure 26.89 I²C bus timing when SLA is 7 bits**

- S: Indicates a start condition, when the master device changes the level on the SDAn line from high to low while the SCLn line is high
- SLA: Indicates a slave address, by which the master device selects a slave device
- R/W#: Indicates the direction of transfer (reception or transmission). The value 1 indicates transfer from the slave device to the master device and 0 indicates transfer from the master device to the slave device.
- A/A#: Indicates an acknowledge bit. This is returned by the slave device for master transmission and by the master device for master reception. Return low indicates ACK and return high indicates NACK.
- Sr: Indicates a restart condition, when the master device changes the level on the SDAn line from high to low while the SCLn line is high and after the setup time elapses
- DATA: Indicates the data being received or transmitted
- P: Indicates a stop condition, when the master device changes the level on the SDAn line from low to high while the SCLn line is high

### 26.8.1 Generation of Start, Restart, and Stop Conditions

Writing 1 to the SIMR3.IICSTAREQ bit causes the generation of a start condition. The generation of a start condition proceeds through the following operations:

- The level on the SDAn line falls (from the high level to the low level) and the SCLn line is kept in the released state
- The hold time for the start condition is set as half of a bit period at the bit rate determined by the BRR setting
- The level on the SCLn line falls (from the high level to the low level), the IICSTAREQ bit in SIMR3 is set to 0, and a start-condition generated interrupt is output

Writing 1 to the IICRSTAREQ bit in SIMR3 causes the generation of a restart condition. The generation of a restart condition proceeds through the following operations:

- The SDAn line is released and the SCLn line is kept at the low level
- The period at low level for the SCLn line is set as half of a bit period at the bit rate determined by the BRR setting
- The SCLn line is released (transition from the low to the high level)
- When a high level is detected on the SCLn line, the setup time for the restart condition is set as half of a bit period at the bit rate determined by the BRR setting
- The level on the SDAn line falls (from the high level to the low level)
- The hold time for the restart condition is set as half of a bit period at the bit rate determined by the BRR setting
- The level on the SCLn line falls (from the high level to the low level), the SIMR3.IICRSTAREQ bit is set to 0, and a restart-condition generated interrupt is output

Writing 1 to the SIMR3.IICSTPREQ bit causes the generation of a stop condition. The generation of a stop condition proceeds through the following operations:

- The level on the SDAn line falls (from the high level to the low level) and the SCLn line is kept at the low level
- The period at low level for the SCLn line is set as half of a bit period at the bit rate determined by the BRR setting
- The SCLn line is released (transition from the low to the high level)

- When a high level is detected on the SCLn line, the setup time for the stop condition is set as half of a bit period at the bit rate determined by the BRR setting
- The SDAn line is released (transition from the low to the high level), the SIMR3.IICSTPREQ bit is set to 0, and a stop-condition generated interrupt is output

Figure 26.90 shows the timing of operations in the generation of start, restart, and stop conditions.

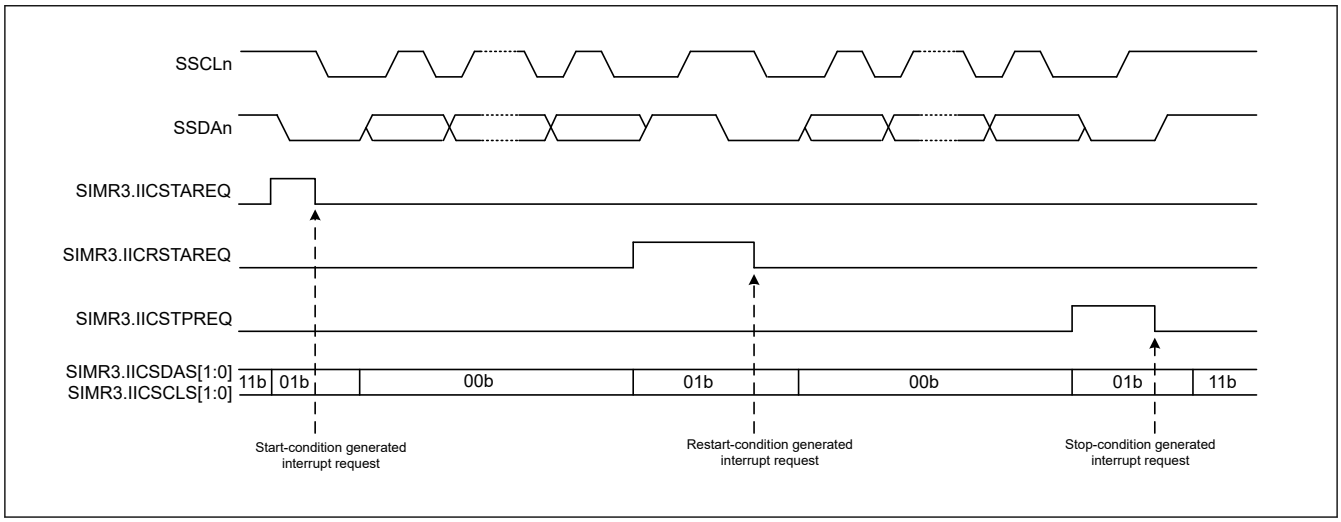

**Figure 26.90 Timing of operations in generation of start, restart, and stop conditions**

## 26.8.2 Clock Synchronization

The SCLn line can be driven low if a wait is inserted by a slave device at the other side of the transfer. Setting the SIMR2.IICCSC bit to 1 applies control to obtain synchronization when a difference arises between the levels of the internal SCLn clock signal and the level being input on the SCLn pin.

When the SIMR2.IICCSC bit is set to 1, the level of the internal SCLn clock signal changes from low to high. Counting to determine the period at a high level stops while the low level is being input on the SCLn pin. Counting to determine the period at a high level starts after the transition of the input on the SCLn pin to the high level.

The interval from this time until counting to determine the period at high level starts on the transition of the SCLn pin to the high level, is the total of the delay of SCLn output, delay for noise filtering of the input on the SCLn pin (2 or 3 cycles of sampling clock for the noise filter), and delay for internal processing (1 or 2 cycles of PCLK). The period at high level of the internal SCLn clock is extended even when other devices do not place the low level on the SCLn line.

If the SIMR2.IICCSC bit is 1, synchronization is obtained for the transmission and reception of data by taking the logical AND of the input on the SCLn pin and the internal SCLn clock. If the SIMR2.IICCSC bit is 0, synchronization with the internal SCLn clock is obtained for the transmission and reception of data.

If a slave device inserts a wait period into the interval until the transition of the internal SCLn clock signal from the low to the high level after a request for the generation of a start, restart, or stop condition is issued, the time until generation is prolonged by that period.

If a slave device inserts a wait period after the transition of the internal SCLn clock signal from the low to the high level, although the generation-completed interrupt is issued without stopping the waiting period, generation of the condition itself is not guaranteed.

Figure 26.91 shows an example operation for synchronizing the clocks.

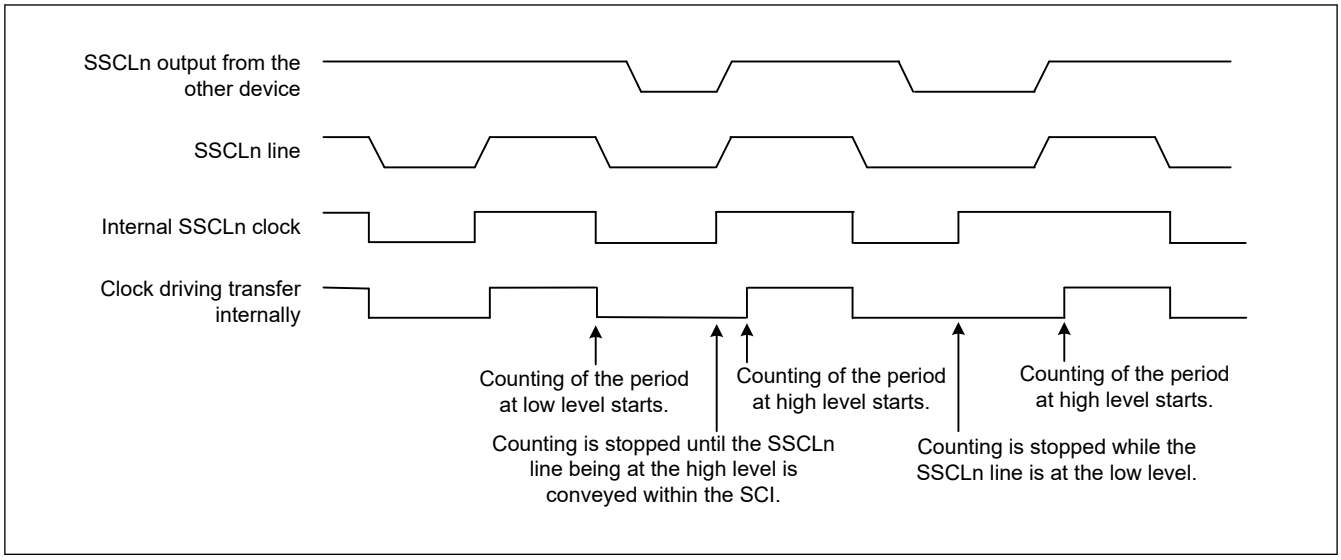

**Figure 26.91 Example operations for clock synchronization**

## 26.8.3 SDAn Output Delay

The SIMR1.IICDL[4:0] bits can be used to set a delay for output on the SDAn pin relative to falling edges of output on the SCLn pin. Delay settings from 0 to 31 are selectable, representing periods of the corresponding numbers of cycles of the clock signal from the on-chip baud rate generator (derived by frequency-dividing the base clock, PCLK, by the divisor selected in the SMR.CKS[1:0] bits). A delay for output on the SDAn pin applies to the start condition/restart condition/stop condition signal, 8-bit transmit data, and acknowledge bit.

If the SDAn output delay is shorter than the time for the level on the SCLn pin to fall, the change of the output on the SDAn pin starts while the output level on the SCLn pin is falling, creating a possibility of erroneous operation for slave devices. Ensure that settings for the delay of output on the SDAn pin specify times greater than the time output on the SCLn pin takes to fall (300 ns for IIC in normal mode and fast mode).

Figure 26.92 shows the timing of delays in SDAn output.

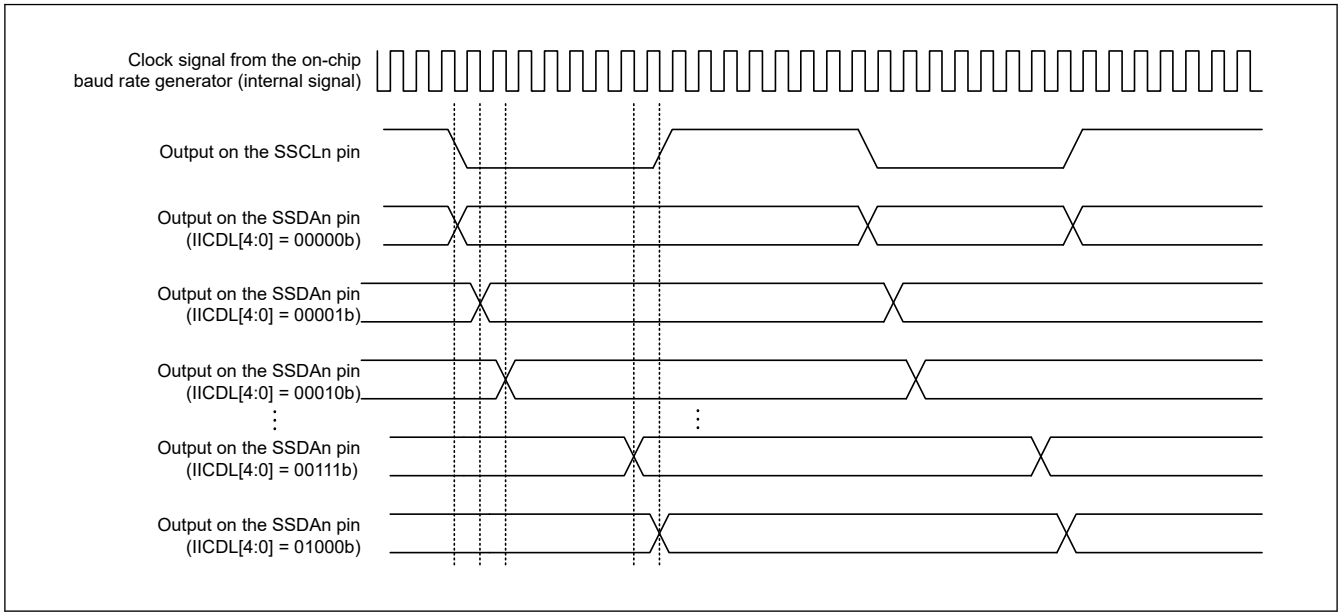

**Figure 26.92 Timing of delays in SDAn output**

## 26.8.4 SCI Initialization in Simple IIC Mode

Before transferring data, write the initial value 0x00 to SCR and initialize the interface following the example shown in Table 26.40.

Before making any changes to the operating mode or transfer format, be sure to set SCR to its initial value. In simple IIC mode, the open-drain setting for the communication ports should be made on the port side.

**Table 26.40 Example flow of SCI initialization in simple IIC mode**

| No. | Step Name | Description |
|---|---|---|
| 1 | Start of initialization | |
| 2 | Set the TIE, RIE, TE, RE, TEIE and CKE[1:0] bits in SCR to 0 | |
| 3 | Set the I/O port functions | Set the I/O port to allow use (on N-channel open-drain output pins) of the SSCLn and SSDAn pin functions. |
| 4 | Set the IICSDAS[1:0] and IICSCLS[1:0] bits in SIMR3 to 11b | Place the SSCLn and SSDAn pins in the high-impedance state until a start condition is to be generated. |
| 5 | Set up the transfer or reception format in SMR and SCMR | Set the format for transmission and reception in SMR and SCMR.<br>In SMR, set the CKS[1:0] bits to the target value and set the other bits to 0.<br>In SCMR, set the SDIR bit to 1 and the SINV and SMIF bits to 0. |
| 6 | Set the initial value to SPTR. | Set the Initial value to SPTR. |
| 7 | Set the value in BRR | Write the value for the targeted bit rate to BRR. |
| 8 | Set a value in MDDR | Write the value obtained by correcting a bit rate error in MDDR. This step is not required if the BRME bit in SEMR is set to 0. |
| 9 | Set the values in SEMR, SNFR, SIMR1, SIMR2, and SPMR | Set the values in SEMR, SNFR, SIMR1, SIMR2, and SPMR.<br>Set the NFEN and BRME bits in SEMR. In SNFR, set the NFCS[2:0] bits.<br>In SIMR1, set the IICM bit to 1 and the IICDL[4:0] bits as required.<br>In SIMR2, set the IICACKT and IICCSC bits to 1 and the IICINTM bits as required.<br>In SPMR, set all the bits to 0. |
| 10 | Set the SCR.RE and TE bit to 1 and set the SCR.TIE, RIE and TEIE bits | Set the RE and TE bits in the SCR to 1. Then, set the SCR.TIE, RIE, and TEIE bits (for transmission and when the SIMR2.IICINTM bit is 1, set the RIE bit to 0). Setting the TE and RE bits to 1 enables the SSCLn and SSDAn pin functions. |
| 11 | Start of transmission or reception | |

## 26.8.5 Operation in Master Transmission in Simple IIC Mode

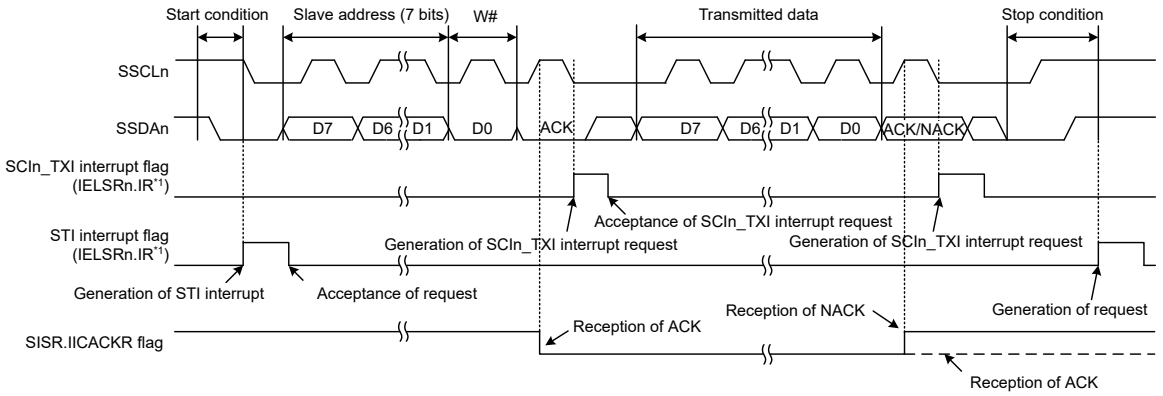

Figure 26.93 and Figure 26.94 show examples of master transmission and Figure 26.95 shows an example flow of data transmission.

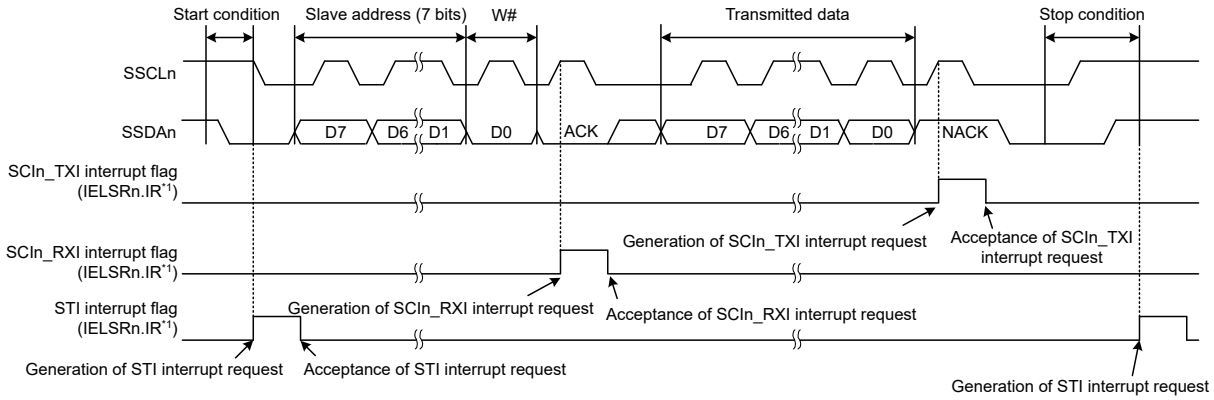
Figure 26.93 shows the operation example when SIMR2.IICINTM bit is 1 (use reception and transmission interrupts) and the value of the SCR.RIE bit is assumed to be 0 (SCIn_RXI and SCIn_ERI interrupt requests are disabled).

See Table 26.45 for more information on the STI interrupt.

Figure 26.95 shows a flow chart in the case of SIMR2.IICINTM is 1 and address transmission by CPU and data transmission by DTC or DMAC. When 10-bit slave addresses are in use, steps [3] and [4] are repeated twice.

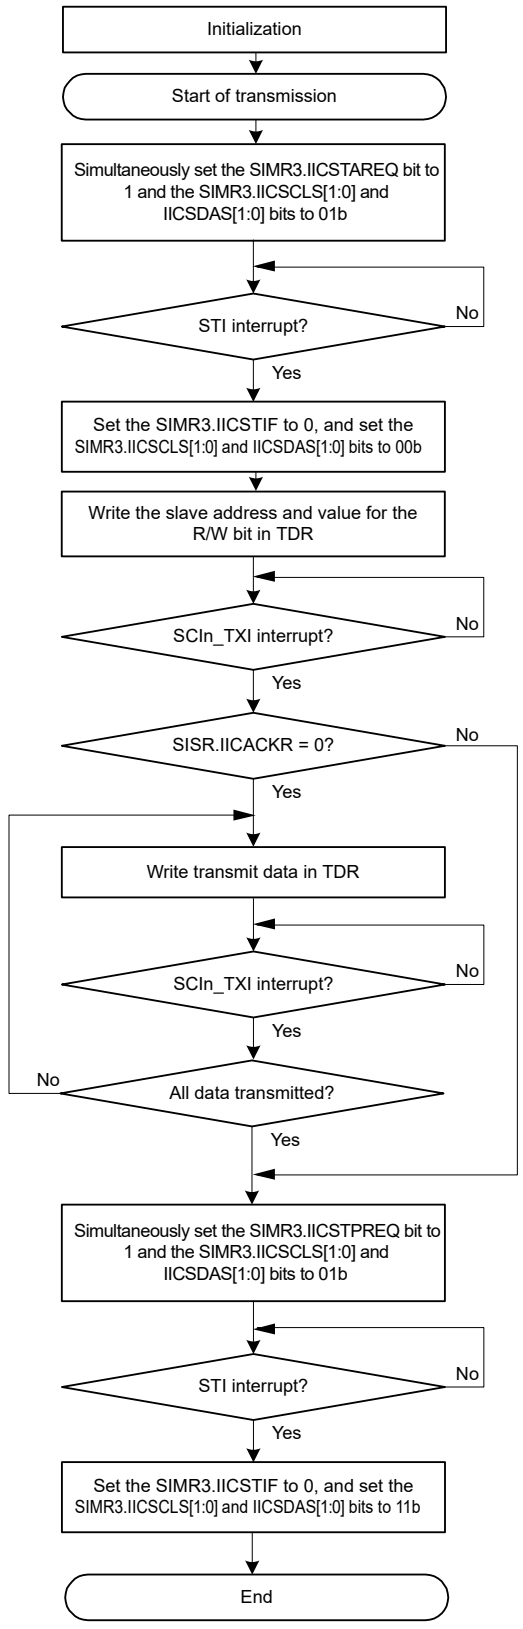
In simple IIC mode, the transmit data empty interrupt (SCIn_TXI) is generated when communication of one frame is complete, unlike the SCIn_TXI interrupt request generation timing during clock synchronous transmission.



Note 1. See section 12, Interrupt Controller Unit (ICU) for information on the corresponding interrupt event number.

**Figure 26.93 Example 1 of operations for master transmission in simple IIC mode with 7-bit slave addresses, transmission interrupts, and reception interrupts**

When the SIMR2.IICINTM bit is set to 0 (use ACK/NACK interrupts) during master transmission, the DTC or DMAC is activated by the ACK interrupt as the trigger and required number of data bytes are transmitted. When the NACK is received, error processing such as transmission stop and retransmission is performed using the NACK interrupt as the trigger.



To restart communication for some reason after writing data in the TDR register, use the following procedure:

1. Set the TE and RE bits in the SCR register to 0 to stop communication.
2. Set 0xF0 in the SIMR3 register, release the $I^2C$ bus, and clear the generation of a condition.
3. If the RDRF flag in the SSR register is set to 1, clear it.
4. Set the TE and RE bits in the SCR register to 1 and start the next communication.

Note 1. See section 12, Interrupt Controller Unit (ICU) for information on the corresponding interrupt event number.

**Figure 26.94 Example 2 of operations for master transmission in simple IIC mode with 7-bit slave addresses, ACK interrupts, and NACK interrupts**

[ 1 ] [ 1 ] Initialization in simple IIC mode:
For transmission, set the SCR.RIE to 0 to disable the SCIn_RXI and ERI interrupts.

[ 2 ] [ 2 ] Generate a start condition.

[ 3 ] [ 3 ] Writing to TDR:
Write the slave address and value for the R/W bit to TDR.

[ 4 ] [ 4 ] Confirming ACK response from the slave device:
Check the SISR.IICACKR bit. If SISR.IICACKR is 0, it indicates that the slave device responded with ACK and operations proceed. If SISR.IICACKR is 1, it indicates that there was no response from the slave device so the next transition is to generate a stop condition.

If 10-bit slave addresses are in use, processing of [ 3 ] and [ 4 ] is repeated twice.

[ 5 ] [ 5 ] Continuing with serial transmission:
When transmission is to continue, write additional transmit data to TDR. Except for the first data to be transmitted, a SCIn_TXI interrupt request can activate the DMAC or DTC to handle writing of data to TDR. But it cannot be confirmed status of ACK or NACK.

[ 6 ] [ 6 ] Generate a stop condition.

Note: In simple IIC mode, the SCIn_TXI interrupt is generated when communication completes.

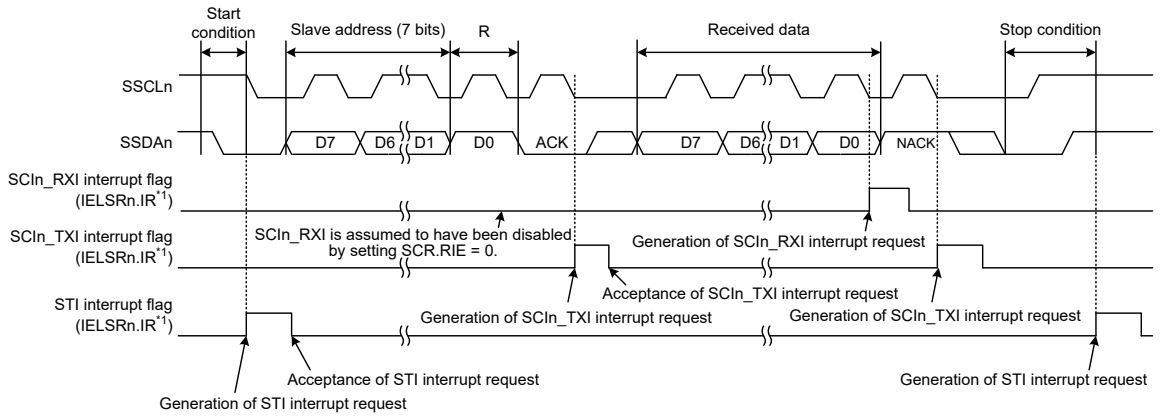


**Figure 26.95 Example flow of master transmission in simple IIC mode with transmission interrupts and reception interrupts**

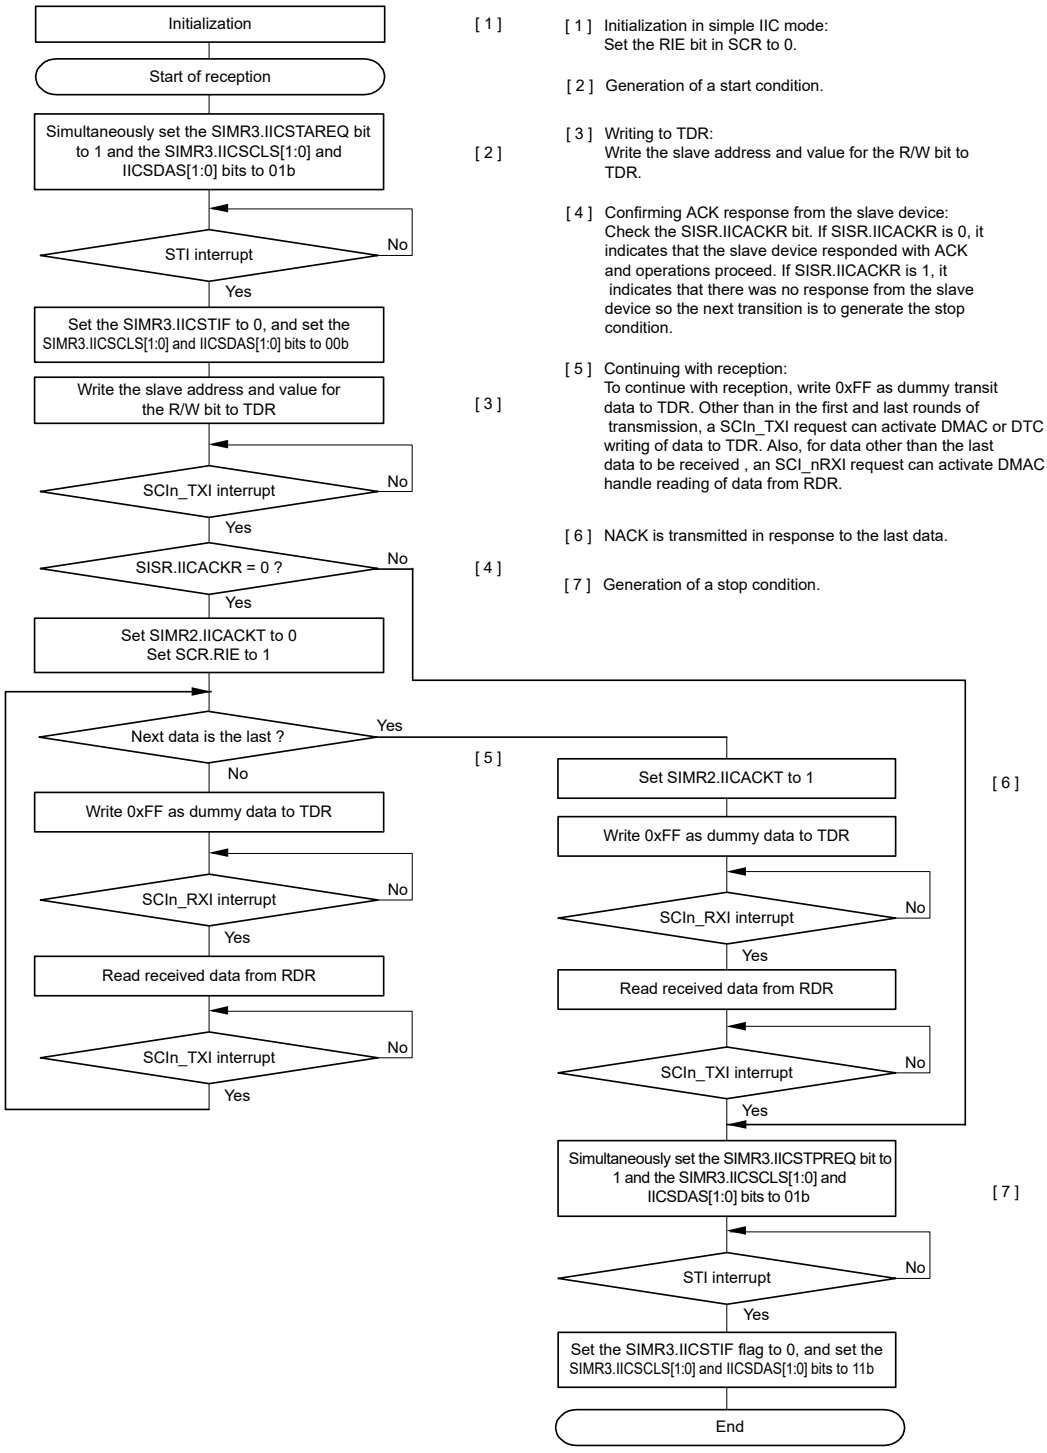
## 26.8.6 Master Reception in Simple IIC Mode

Figure 26.96 shows an example operation in simple IIC mode master reception and Figure 26.97 shows an example flow of master reception.



The value of the SIMR2.IICINTM bit is assumed to be 1 (use reception and transmission interrupts).

In simple IIC mode, the transmit data empty interrupt (SCIn_TXI) is generated when communication of one frame is complete, unlike the SCIn_TXI interrupt request generation timing during clock synchronous transmission.

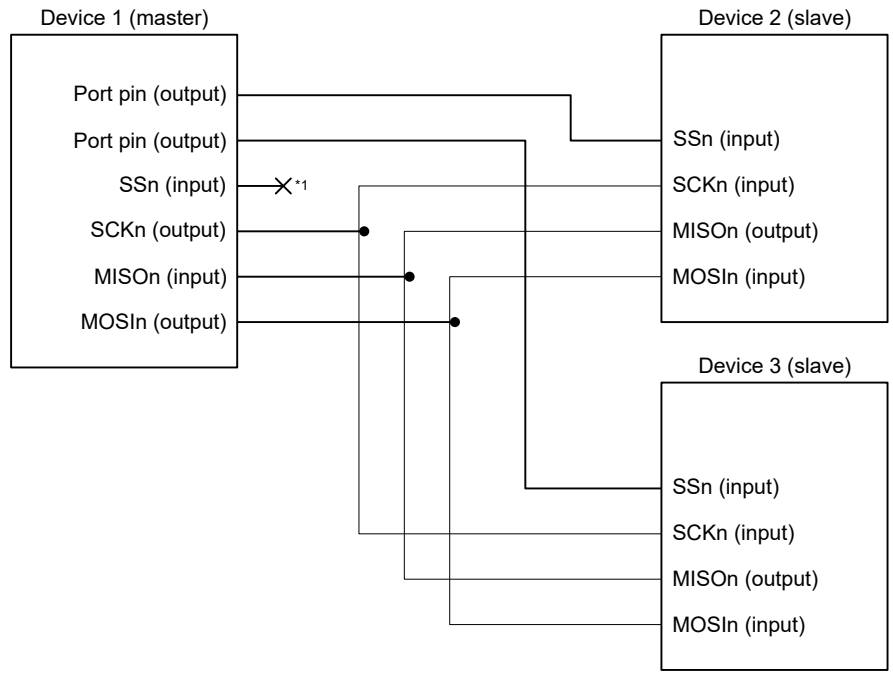
Note 1. See section 12, Interrupt Controller Unit (ICU) for information on the corresponding interrupt event number.

**Figure 26.96 Example operations for master reception in simple IIC mode with 7-bit slave addresses, transmission interrupts, and reception interrupts**

Note: In simple IIC mode, the SCIn_TXI interrupt request is generated when communication is complete.

**Figure 26.97 Example flow of master reception in simple IIC mode with transmission interrupts and reception interrupts**

## 26.9 Operation in Simple SPI Mode



As an extended function, the SCI supports a simple SPI mode that handles transfer among one or multiple master devices and multiple slave devices.

Using the settings for clock synchronous mode (SCMR.SMIF = 0, SIMR1.IICM = 0, SMR.CM = 1) and setting the SPMR.SSE bit to 1 place the SCI in simple SPI mode. However, the SSn pin function on the master side is not required for connection of the device used as the master in simple SPI mode when the configuration only has a single master. Therefore, set the SPMR.SSE bit to 0 in such cases.

Figure 26.98 shows an example of connections for simple SPI mode. Control a general port pin to produce the SSn output signal from the master.

In simple SPI mode, data is transferred in synchronization with clock pulses in the same way as in clock synchronous mode. One character of data for transfer consists of 8 bits of data, and parity bits cannot be appended. The data can be inverted by setting the SCMR.SINV bit to 1.

Because the receiver and transmitter are independent of each other within the SCI module, full-duplex communications are possible, with a shared clock signal. Additionally, because both the transmitter and receiver have a buffered structure, writing the next transmit data while transmission is in progress and reading previously received data while reception is in progress are both possible. This enables continuous transfer.

Note 1. The SSn pin input is not required in a single-master system (the interface is used with the setting SPMR.SSE = 0).

**Figure 26.98 Example connections using simple SPI mode in single master mode with SPMR.SSE bit = 0**

## 26.9.1 States of Pins in Master and Slave Modes

The direction (input or output) of pins for the simple SPI mode interface differs according to whether the device is a master (SCR.CKE[1:0] = 00b or 01b and SPMR.MSS = 0) or slave (SCR.CKE[1:0] = 10b or 11b and SPMR.MSS = 1).

Table 26.41 lists the relationship between the pin states, mode, and level on the SSn pin.

**Table 26.41 States of pins by mode and input level on SSn pin (1 of 2)**

| Mode | Input on SSn pin | State of MOSIn pin | State of MISOn pin | State of SCKn pin |
|---|---|---|---|---|
| Master mode*1 | High level (transfer can proceed) | Output for data transmission*2 | Input for received data | Clock output*3 |
| | Low level (transfer cannot proceed) | High-impedance | Input for received data (but disabled) | High-impedance |

**Table 26.41 States of pins by mode and input level on SSn pin (2 of 2)**

| Mode | Input on SSn pin | State of MOSIn pin | State of MISOn pin | State of SCKn pin |
|---|---|---|---|---|
| Slave mode | High level (transfer cannot proceed) | Input for received data (but disabled) | High-impedance | Clock input (but disabled) |
| | Low level (transfer can proceed) | Input for received data | Output for data transmission | Clock input |

Note 1. When there is only a single master (SPMR.SSE = 0), transfer is possible regardless of the input level on the SSn pin. This is equivalent to input of a high level on the SSn pin.
Note 2. The MOSIn pin output is in the high-impedance state when serial transmission is disabled (SCR.TE bit = 0).
Note 3. The SCKn pin output is in the high-impedance state when serial transmission is disabled (SCR.TE = 0 and SCR.RE = 0) in a multi-master configuration (SPMR.SSE = 1).

### 26.9.2 SS Function in Master Mode

Setting the CKE[1:0] bits in the SCR to 00b or 01b and the MSS bit in the SPMR to 0 selects master mode operation. The SSn pin is not used in single-master configurations (SPMR.SSE = 0), so transmission or reception can proceed regardless of the value of the SSn pin.

When the level on the SSn pin is high in a multi-master configuration (SPMR.SSE = 1), a master device outputs clock signals from the SCKn pin before starting transmission or reception to indicate that there are no other masters or another master is performing reception or transmission.

When the level on the SSn pin is low in a multi-master configuration (SPMR.SSE = 1), there are other masters, and a transmission or reception is in progress. The MOSIn output and SCKn pins are placed in the high-impedance state and starting transmission or reception is not possible. In addition, the value of the SPMR.MFF bit is 1, indicating a mode fault error. In a multi-master configuration, start error processing by reading SPMR.MFF flag. If a mode fault error occurs while transmission or reception is in progress, transmission or reception does not stop, but the MOSIn and SCKn outputs are in the high-impedance state after completion of the transfer.

Use a general port pin to produce the SS output signal from the master.

### 26.9.3 SS Function in Slave Mode

Setting the SCR.CKE[1:0] bits to 10b or 11b and the SPMR.MSS bit to 1 selects slave operation. When the SSn pin is high, the MISOn output pin is in the high-impedance state and clock input through the SCKn pin is ignored. When the SSn pin is low, clock input through the SCKn pin is valid and transmission or reception can proceed.

If the input on the SSn pin changes from low to high during transmission or reception, the MISOn output pin is placed in the high-impedance state. Meanwhile, the internal processing for transmission or reception continues at the rate of the clock input through the SCKn pin until processing for the character being transmitted or received is complete, after which it stops, and the appropriate interrupt (SCIn_TXI, SCIn_RXI, or SCIn_TEI) is generated.

### 26.9.4 Relationship between Clock and Transmit/Receive Data

The CKPOL and CKPH bits in the SPMR register can be used to set up the clock for use in transmission and reception in four different ways. The relation between the clock signal and the transmission and reception of data is shown in Figure 26.99. The relation is the same for both master and slave operation. This is the same as when the level on the SSn pin is high.

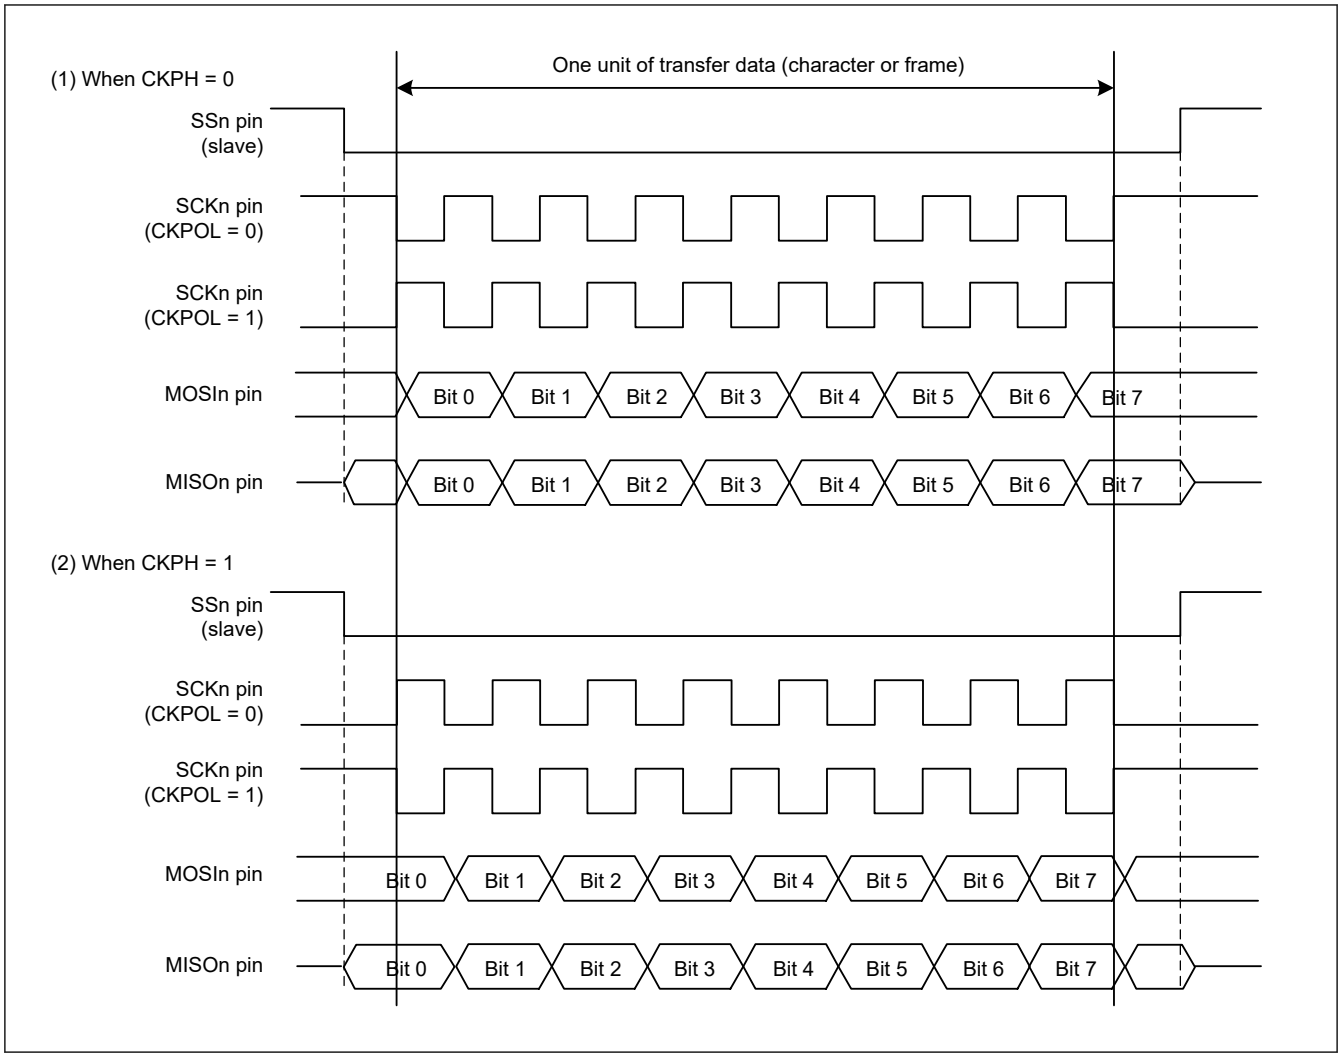


**Figure 26.99 Relation between clock signal and transmit or receive data in simple SPI mode**

## 26.9.5 SCI Initialization in Simple SPI Mode

Initialization in simple SPI mode is the same as in clock synchronous mode. See section 26.6.3. SCI Initialization in Clock Synchronous Mode for an example initialization flow. The CKPOL and CKPH bits in the SPMR register must be set to ensure that the clock signal is suitable for both master and slave devices.

Always initialize the SCR register before making any changes to the operating mode or transfer format.

Note: Only the RE bit is set to 0. The SSR.ORER, FER, PER, and RDR flags are not initialized.

Changing the value of the TE bit from 1 to 0 or from 0 to 1 when the TIE bit in the SCR register is 1 at the same time, leads to the generation of a transmit data empty interrupt (SCIn_TXI).

## 26.9.6 Transmission and Reception of Serial Data in Simple SPI Mode

In master operation, ensure that the SSn pin of the slave device on the other side of the transfer is at the low level before starting the transfer and at the high level on completion of the transfer. Otherwise, the procedures are the same as in clock synchronous mode.

## 26.10 Bit Rate Modulation Function

Using the bit rate modulation function, the bit rate can be evenly corrected using the number specified in the MDDR register among 256 clock cycles of internal clocks which is selected by the CKS[1:0] bits in SMR/SMR_SMCI.

Figure 26.100 shows an example where the PCLK is selected in the CKS[1:0] bits in SMR/SMR_SMCI, the BRR bit is set to 0, and the MDDR is set to 160 in asynchronous mode. In this example, the cycle of the base clock is evenly corrected (256/160) and the bit rate is also corrected (160/256).

Note: Enabling an internal clock causes bias, and expansion and contraction are generated in the pulse width of the internal base clock.

Do not use this function in clock synchronous mode and in the highest speed settings in simple SPI mode (SMR.CKS[1:0] = 00b, SCR.CKE[1] = 0, and BRR = 0).

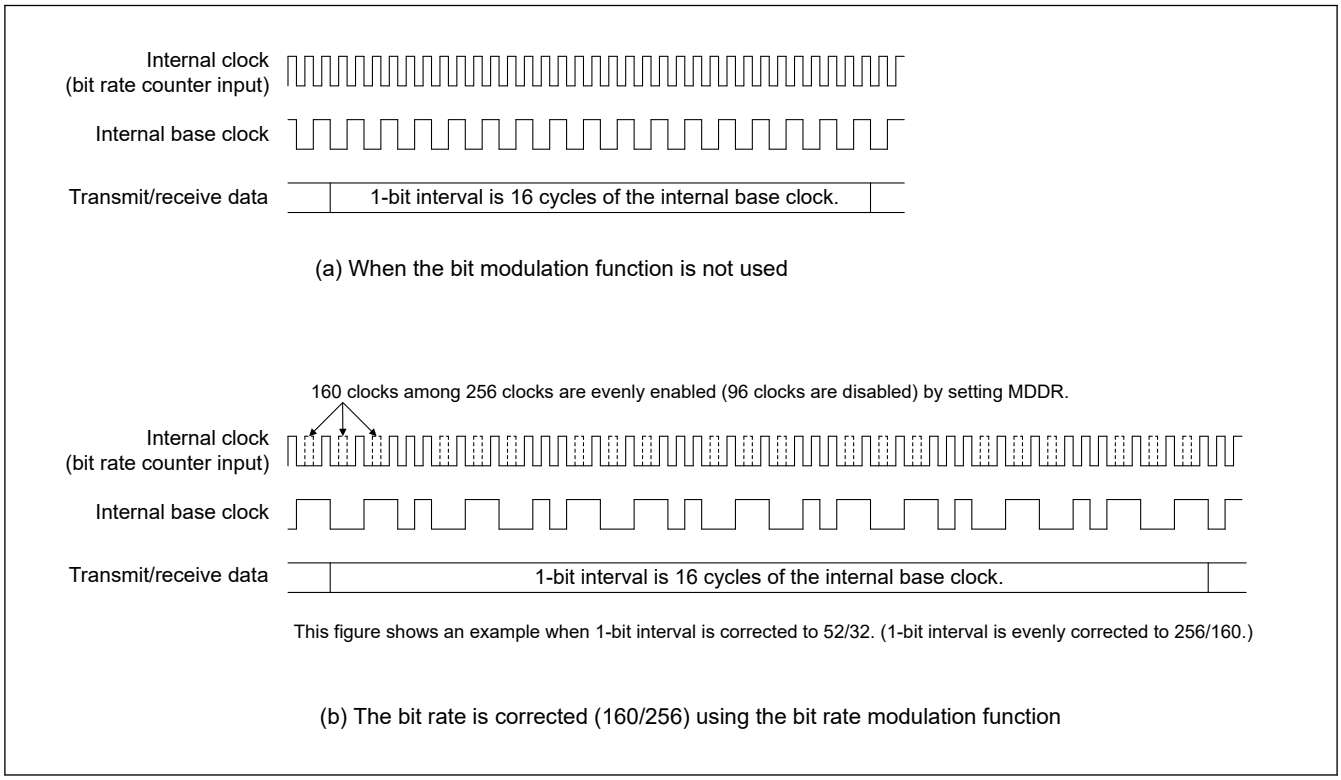

**Figure 26.100 Example internal base clock when bit rate modulation function is used**

## 26.11 Operation in Simple LIN Mode

### 26.11.1 Serial Transfer Protocol

The SCI supports the serial communication protocol (Figure 26.101) consisting of a Start Frame and an Information Frame as Simple LIN.

A Start Frame is composed of a Break Field, Control Field 0, and Control Field 1. An Information Frame is composed of a number of Data Fields, a CRC16 Upper Field, and a CRC16 Lower Field.

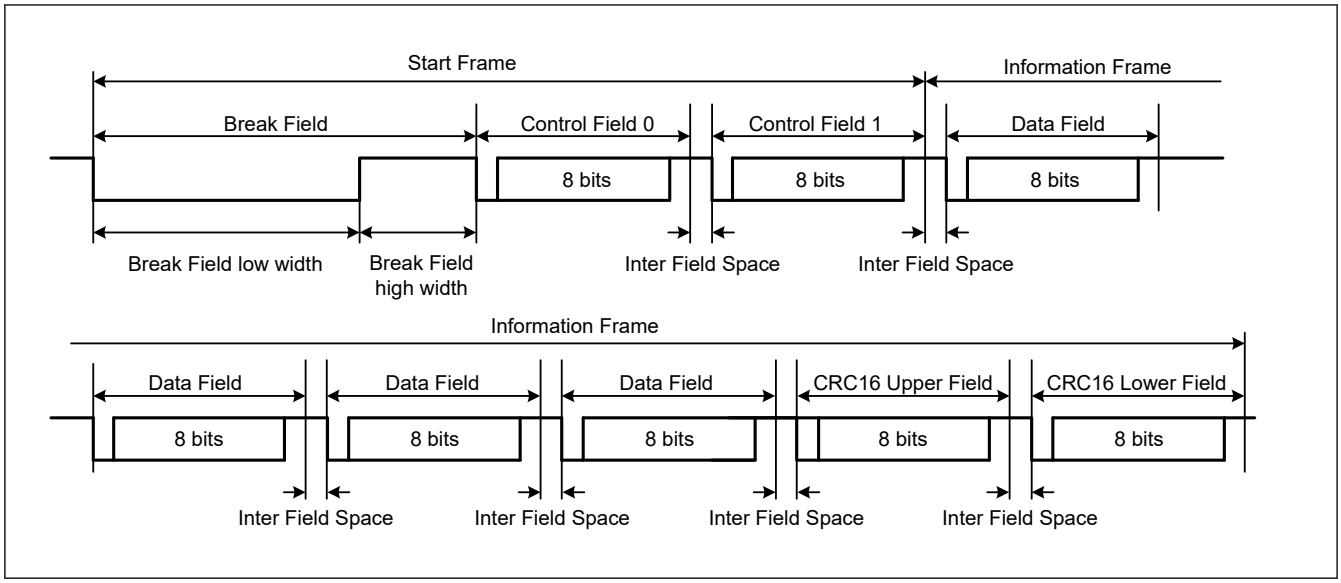

**Figure 26.101 Protocol for Serial Transfer by the Simple LIN Mode Control Section**

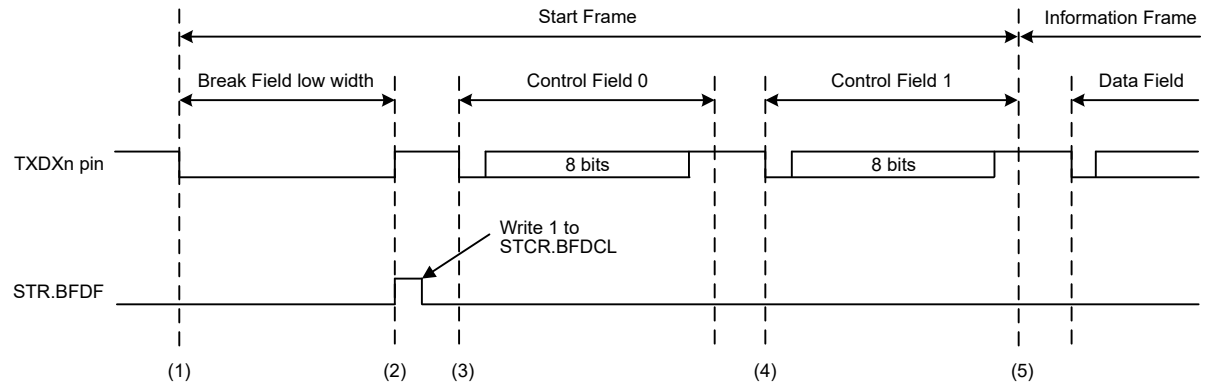

## 26.11.2 Transmitting a Start Frame

Figure 26.102 shows an example of operations to transmit a Start Frame, which is composed of the Break Field low width, Control Field 0, and Control Field 1. Figure 26.103 and Figure 26.104 are flowcharts for the transmission of a Start Frame.

Operations when the Simple LIN mode control section is to be used to transmit a Start Frame are as listed below. Be sure to use the SCIn (n = 1) in asynchronous mode.

1. With Break Field low width output mode as the operating mode for the timer, writing 1 to the TCR.TCST bit starts counting by the timer, and the low level is output from the TXDXn (n = 1) pin over the period corresponding to registers TCNT and TPRE settings.
2. The output on the TXDXn pin is inverted when the timer counter underflows, and the STR.BFDF flag is set to 1. An SCIX0 interrupt is also generated if the value of the ICR.BFDIE bit is 1.
3. Write 0 to the TCR.TCST bit to stop counting by the timer, and send the data for Control Field 0 by using SCIn. After the Break Field low width output, stop counting before the next underflow occurs.
4. When the data for Control Field 0 have been transmitted, send the data for Control Field 1.
5. When the data for Control Field 1 have been transmitted, send an Information Frame.

Omit the Break Field and Control Field 0 to suit the structure of the Start Frame.

The above diagram assumes the following:

ESMER: ESME = 1
PCR: TXDXPS = 0
ICR: BFDIE = 1
TMR: TOMS[1:0] = 10b

Note: n = 1

**Figure 26.102 Example of operations when transmitting a Start Frame**

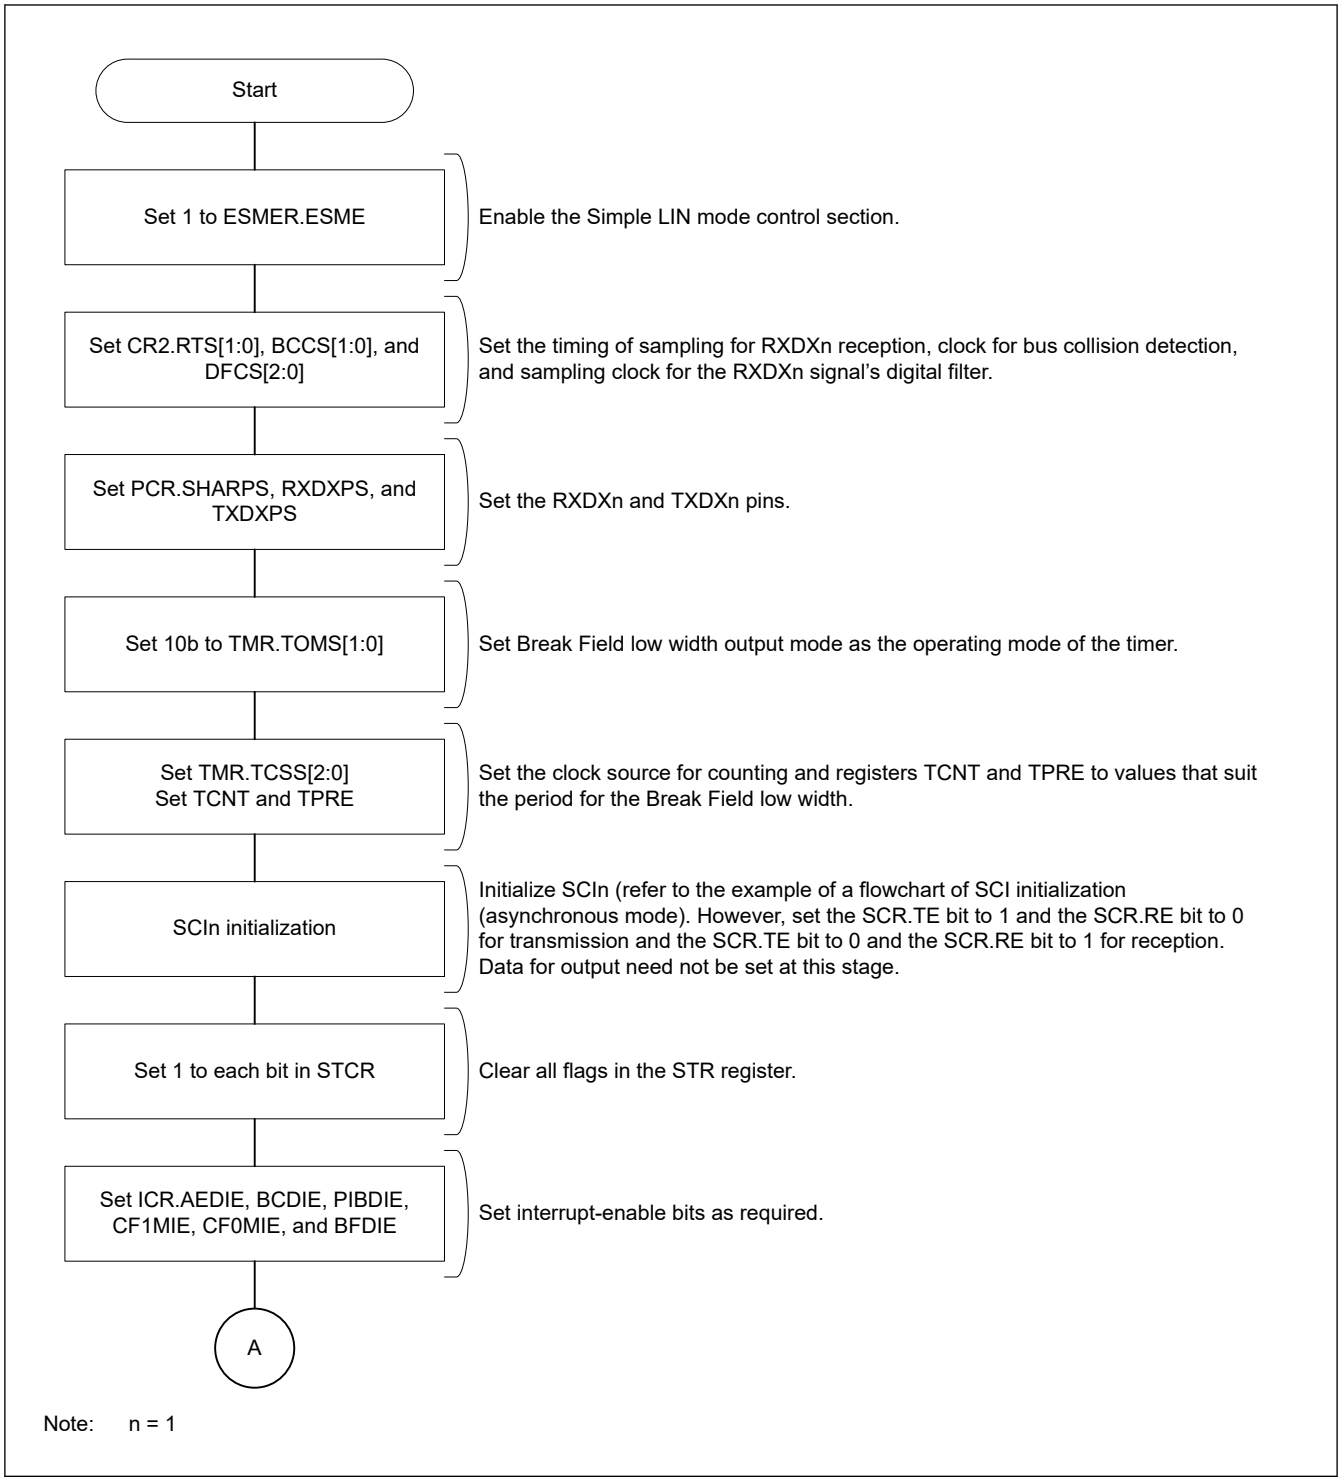

**Figure 26.103 Example of Start Frame transmission (1/2)**

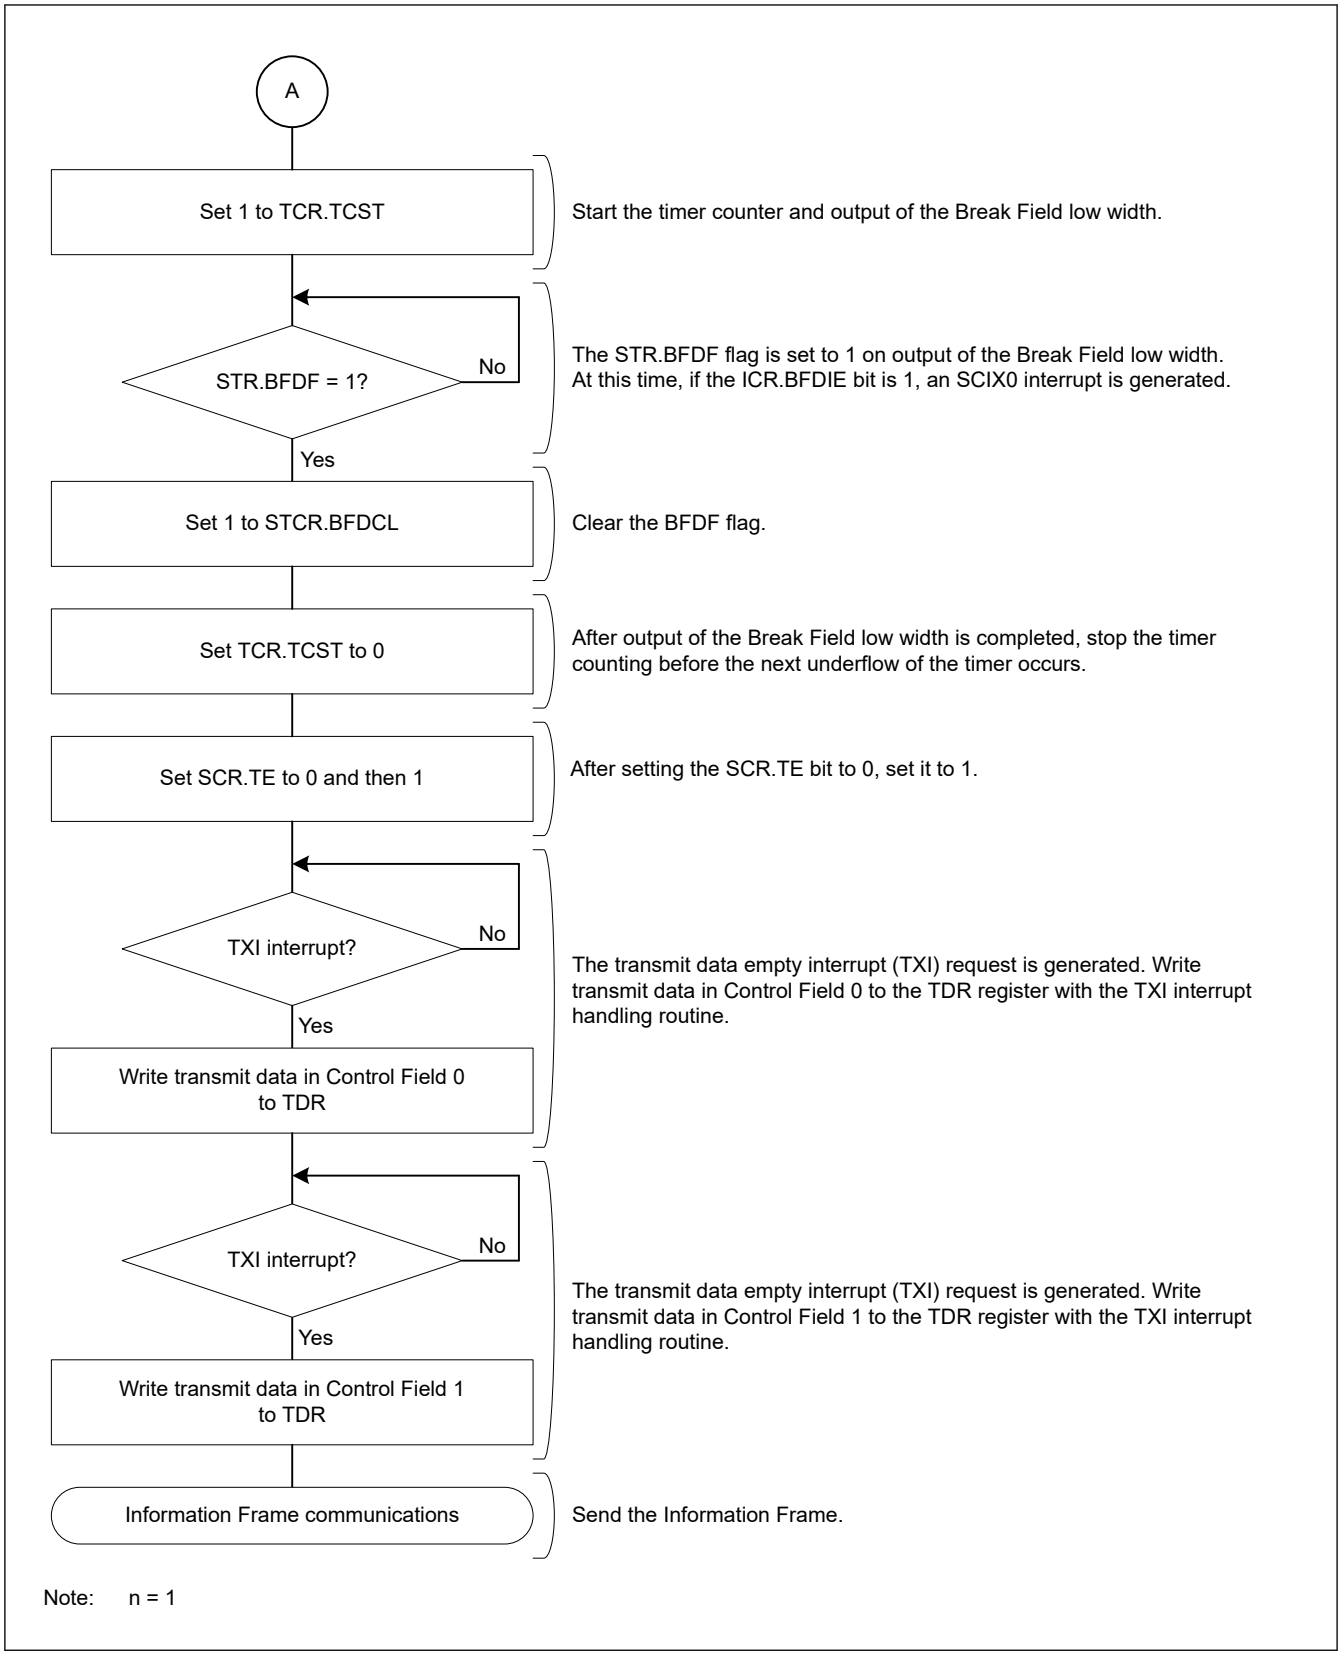

**Figure 26.104 Example of Start Frame transmission (2/2)**

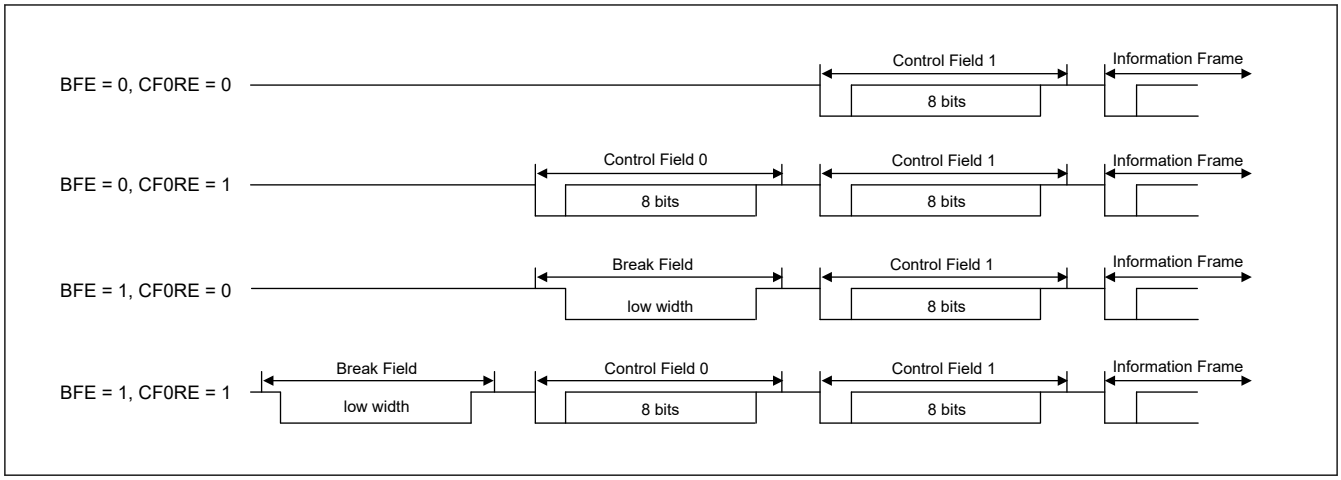
## 26.11.3 Receiving a Start Frame

The Simple LIN mode control section is capable of receiving Start Frames with the structures listed in Figure 26.105.



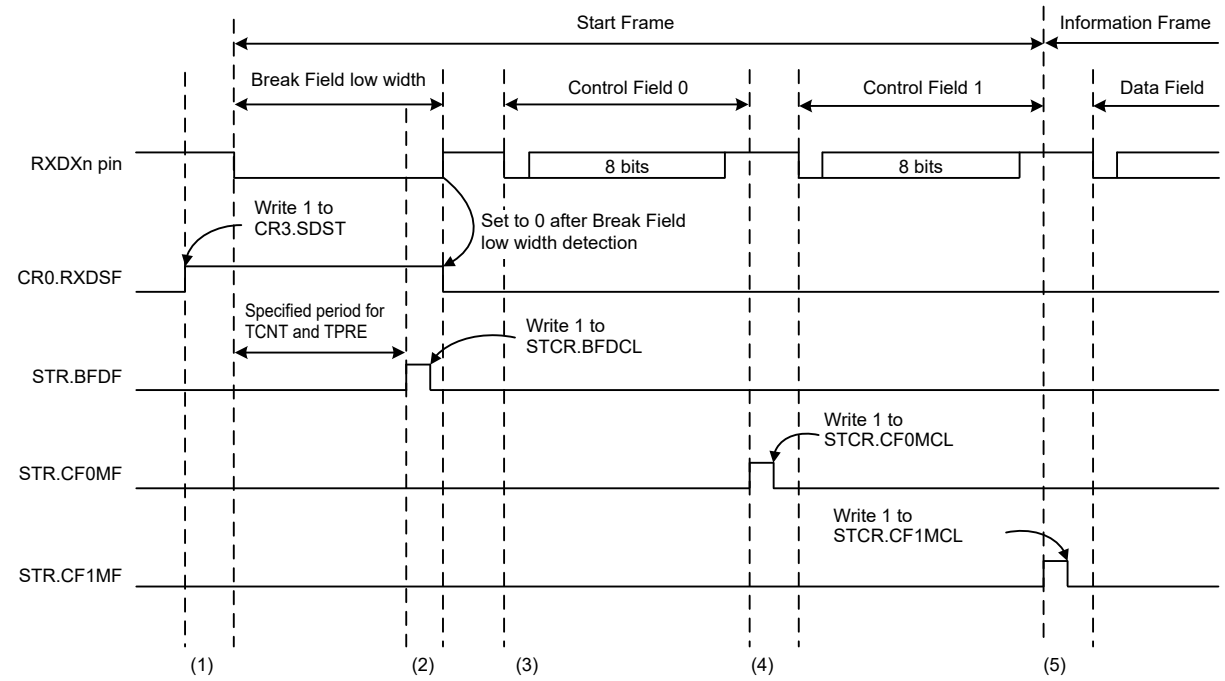


**Figure 26.105 Structures of Start Frames**

Figure 26.106 shows an example of operations to receive a Start Frame, which is composed of the Break Field low width, Control Field 0, and Control Field 1. Figure 26.107 and Figure 26.108 are flowcharts for the reception of a Start Frame, and Figure 26.109 is a state transition diagram for the Simple LIN mode control section.

Operations when the Simple LIN mode control section is to be used to receive a Start Frame are as listed below. Be sure to use the SCIn (n = 1) in asynchronous mode.

1. With Break Field low width detection mode as the operating mode for the timer, writing 1 to the CR3.SDST bit enables detection of the Break Field low width. RXDXn input to the SCIn is disabled at this time.
2. Low-level input on the RXDXn pin continuing over a period longer than that corresponding to the settings of registers TCNT and TPRE is detected as the Break Field low width. At this time, the STR.BFDF flag is set to 1. An SCIX0 interrupt is also generated if the value of the ICR.BFDIE bit is 1.
3. When the input from the RXDXn pin goes high after the Break Field low width, the CR0.RXDSF flag becomes 0 and reception of Control Field 0 by the SCIn starts.
4. If the data received in Control Field 0 match the data set in the CF0DR register, the STR.CF0MF flag is set to 1. An SCIX1 interrupt is also generated if the value of the ICR.CF0MIE bit is 1. Reception of Control Field 1 by the SCIn starts after that. If the data received in Control Field 0 do not match the data set in the CF0DR register, a transition to the state prior to Break Field low width detection proceeds.
5. If the data received in Control Field 1 match the data set in registers PCF1DR and SCF1DR, the STR.CF1MF flag is set to 1. An SCIX1 interrupt is also generated if the value of the ICR.CF1MIE bit is 1. Transfer of the Information Frame by the SCIn starts after that. If the data received in Control Field 1 do not match the data set in either or both of registers PCF1DR and SCF1DR, a transition to the state prior to Break Field low width detection proceeds.

Omit the Break Field and Control Field 0 to suit the structure of the Start Frame.

The above diagram assumes the following:

ESMER: ESME = 1

CR1: BFE = 1, CF0RE = 1, CF1DS[1:0] = 10b

PCR: RXDXPS = 0

ICR: BFDIE = 1, CF0MIE = 1, CF1MIE = 1

TMR: TOMS[1:0] = 01b

Note: n = 1

**Figure 26.106 Example of operations at the time of Start Frame reception**

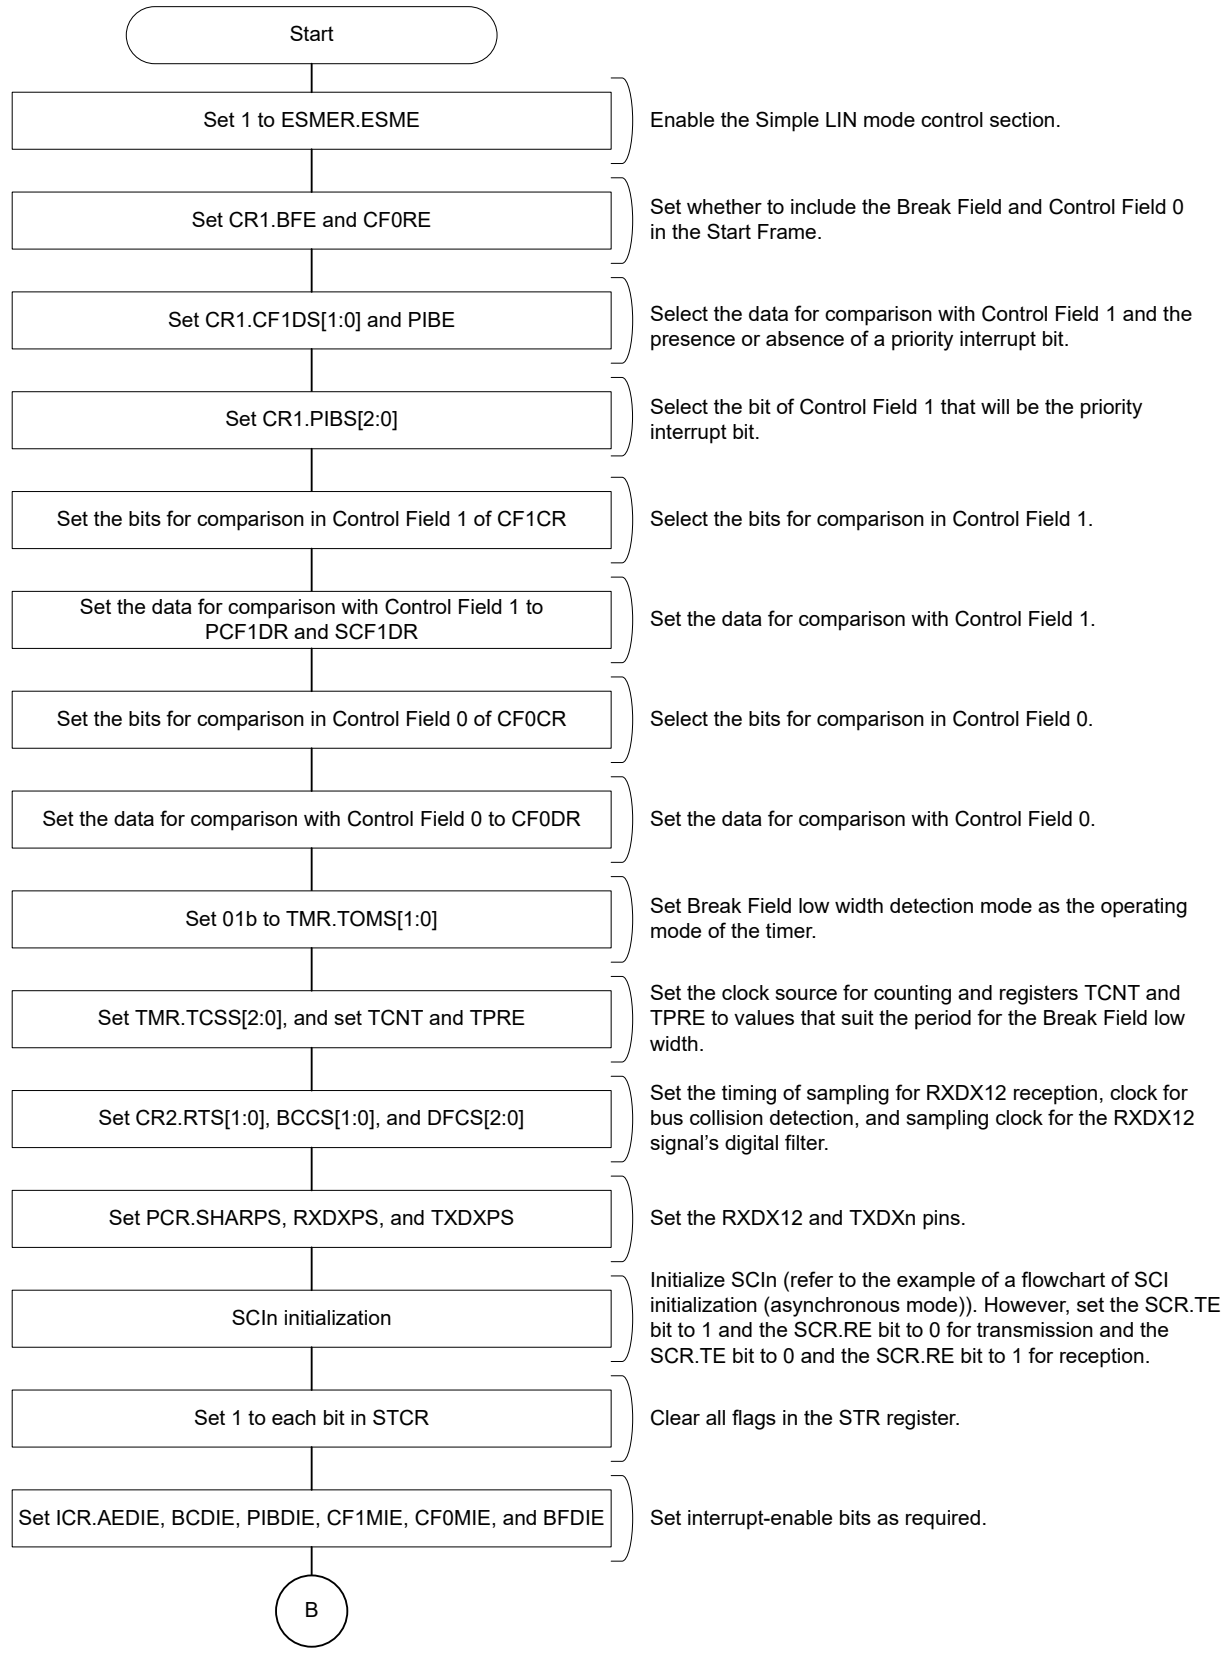

**Figure 26.107 Sample flowchart for reception of a Start Frame (1)**

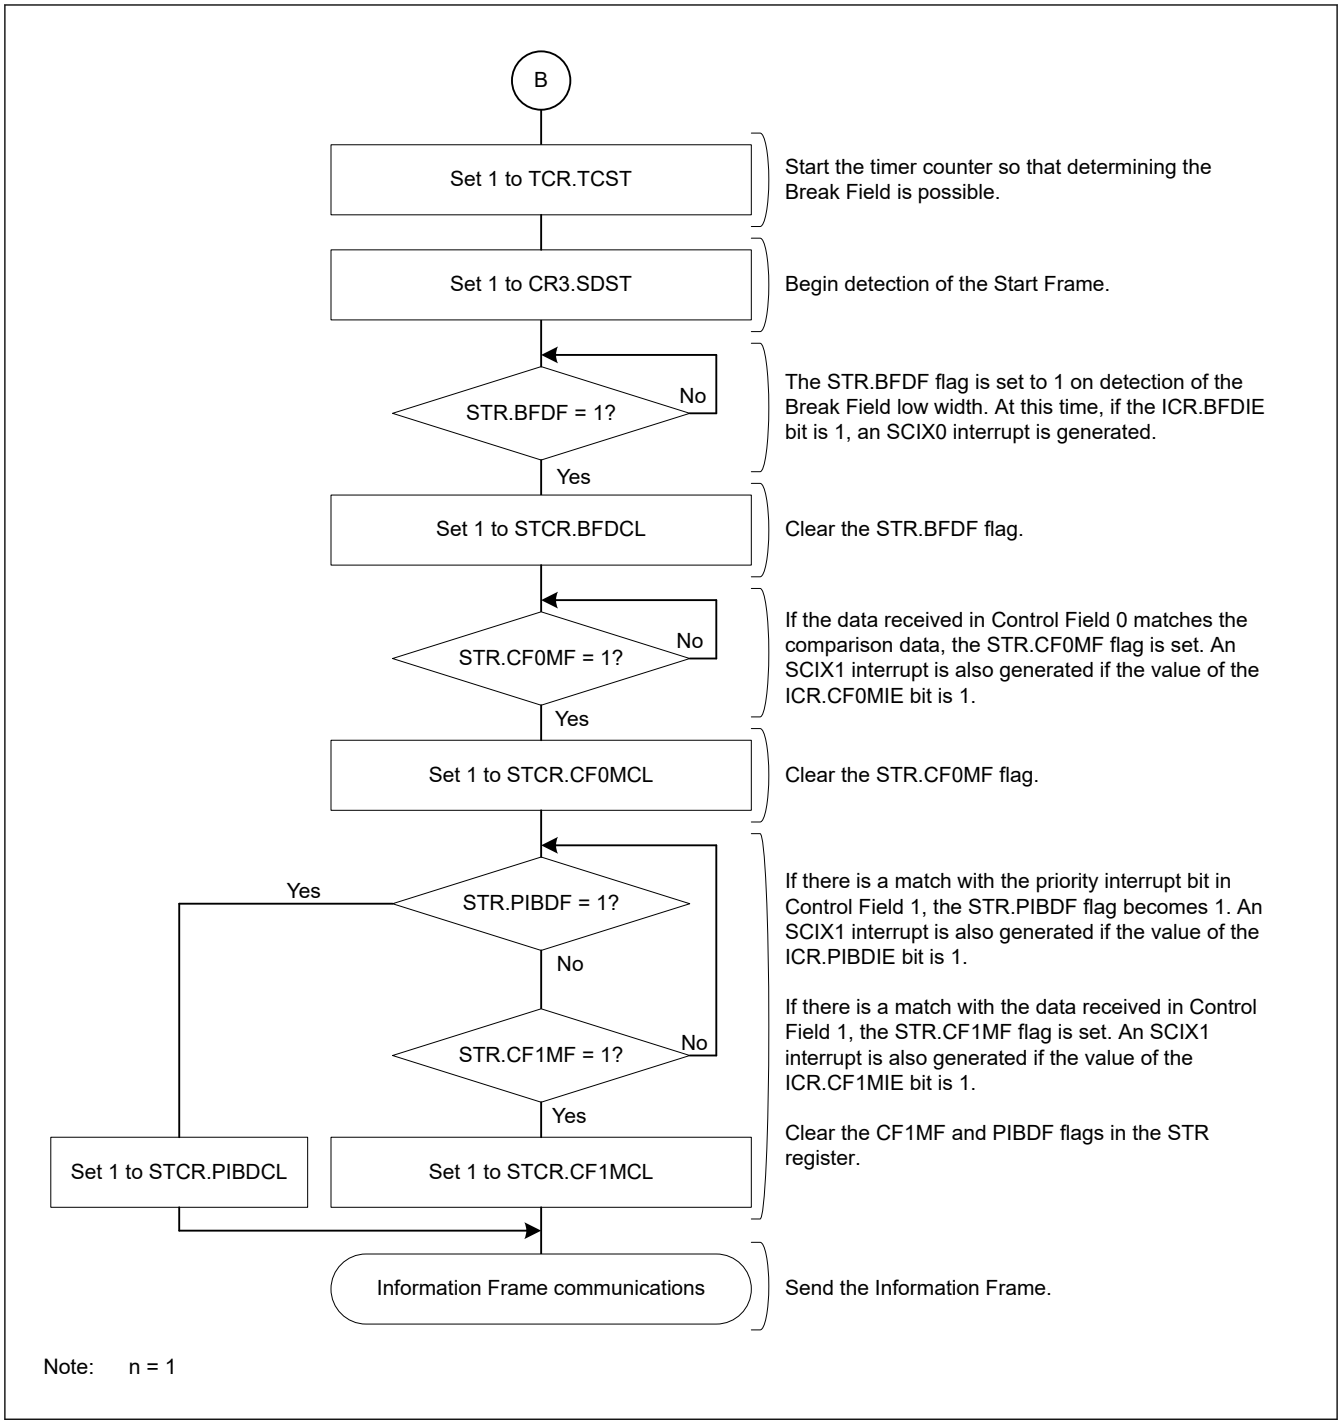

**Figure 26.108 Sample flowchart for reception of a Start Frame (2)**

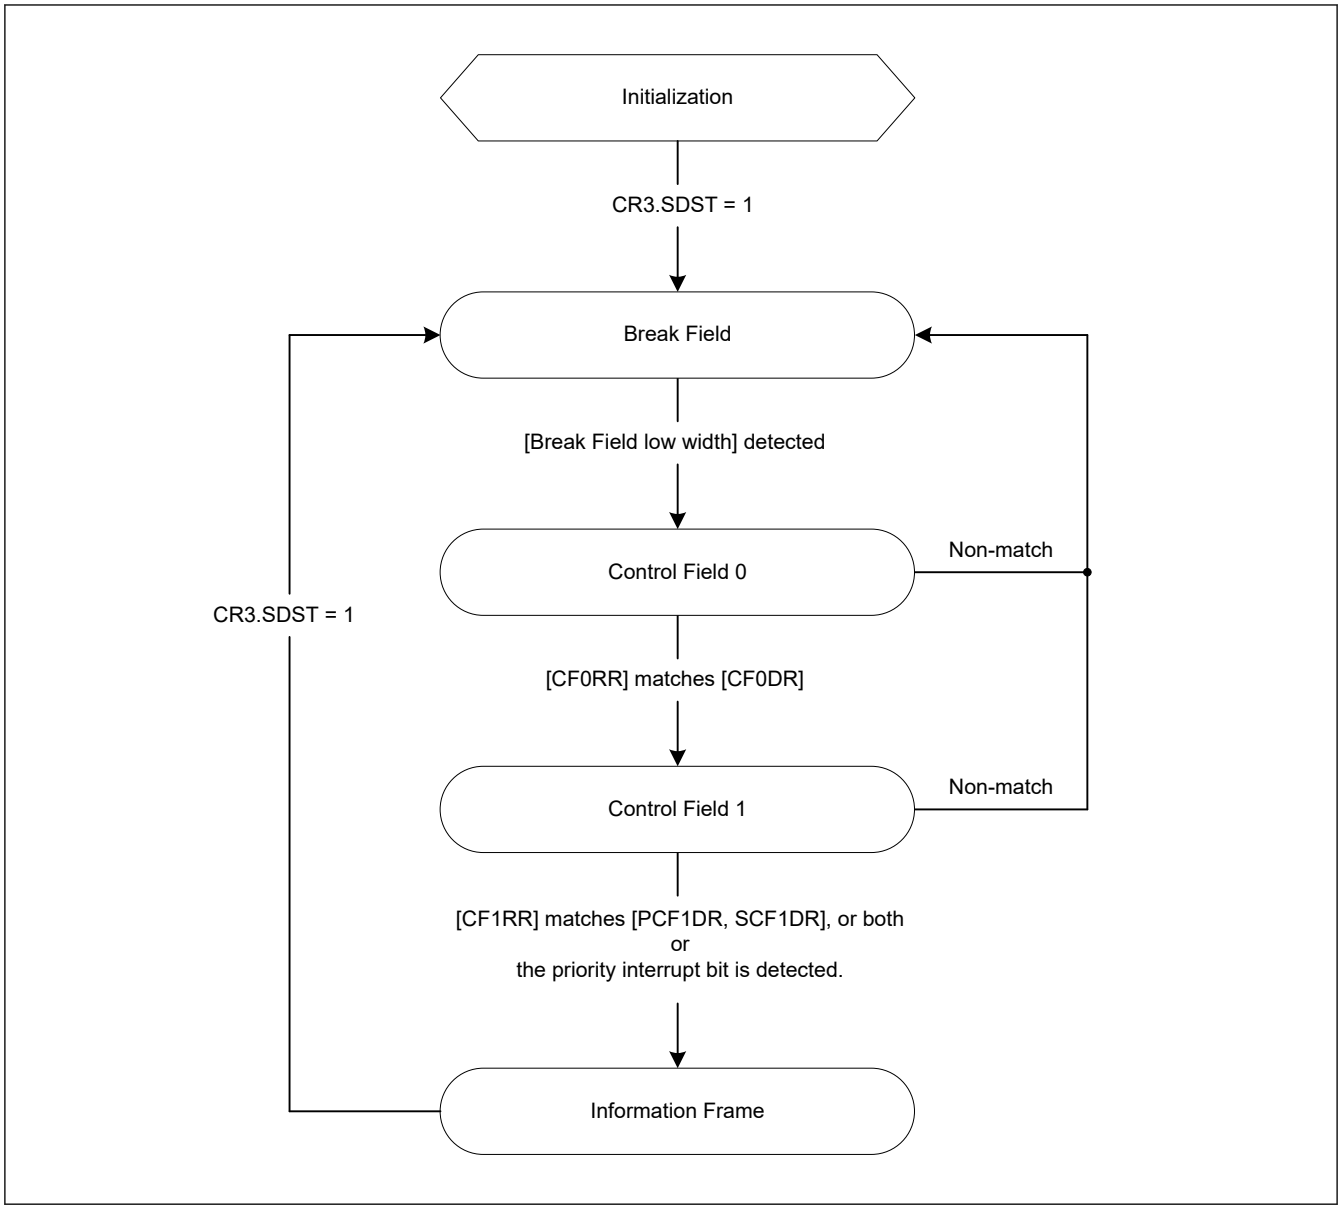

**Figure 26.109 State transitions when receiving a Start Frame**

### 26.11.3.1 Priority Interrupt Bit

Figure 26.110 shows an example of operation in Start Frame reception where a priority interrupt bit is in use. Setting the CR1.PIBE bit to 1 enables the use of a priority interrupt bit.

Operations of the Simple LIN mode control section in start Frame reception where a priority interrupt bit is in use are as described below.

Steps (1) to (4) are the same as in Figure 26.106, for Start Frame reception.

(5) If the value of the bit selected by the CR1.PIBS[2:0] bits matches the corresponding bit in the PCF1DR register, the STR.PIBDF flag is set to 1. An SCIX1 interrupt is also generated if the value of the ICR.PIBDIE bit is 1. Transfer of the Information Frame by the SCIn (n = 1) starts after that. If the data received in Control Field 1 do not match the data set in either or both of registers PCF1DR and SCF1DR and the priority interrupt bit is not detected, a transition to the state prior to Break Field low width detection proceeds.

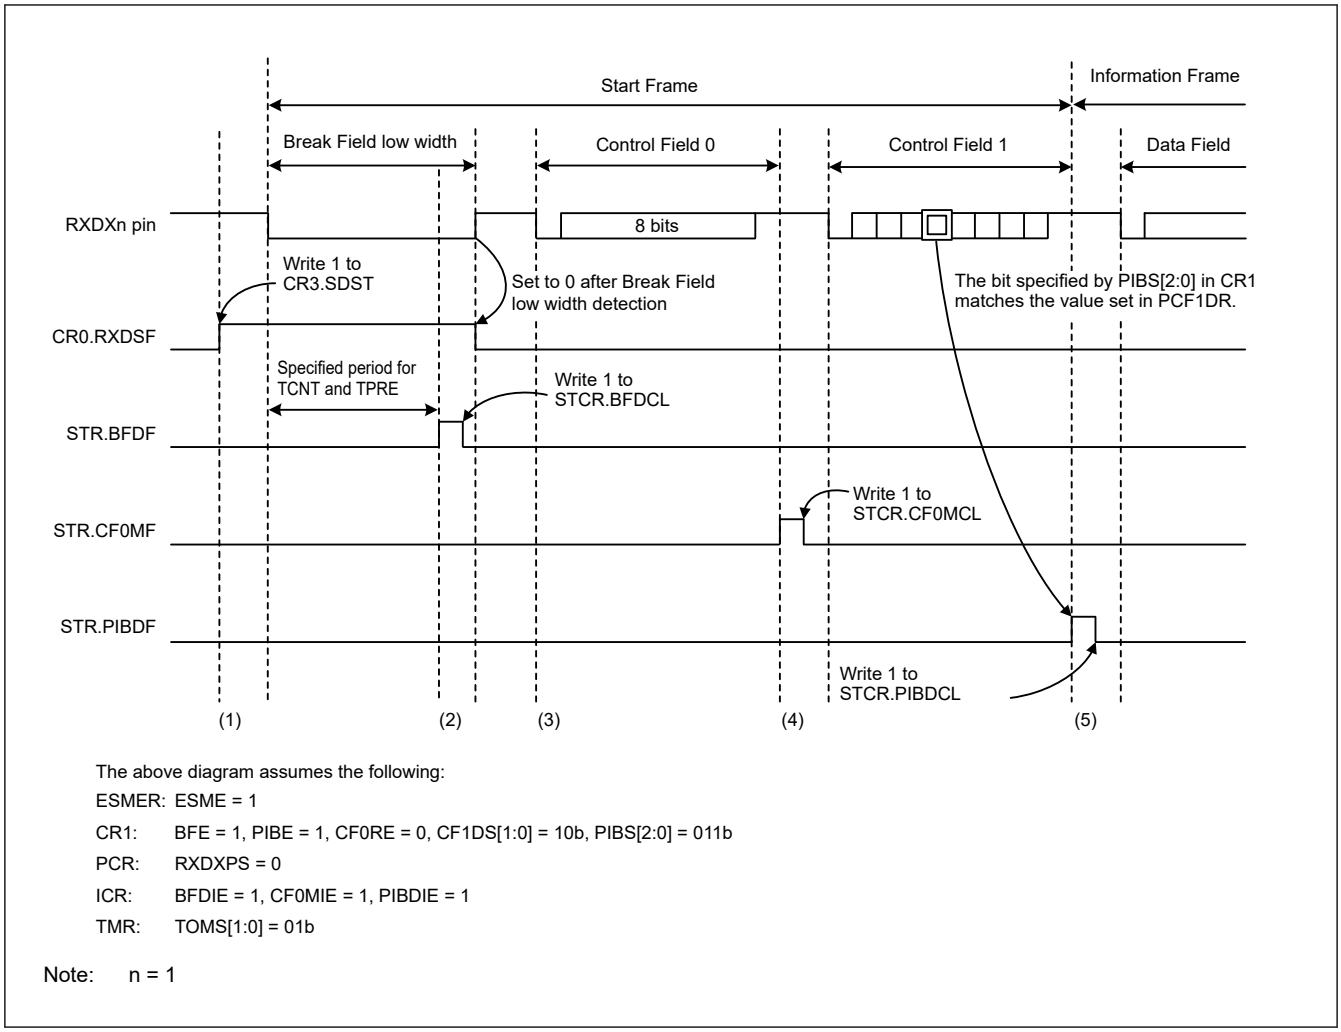

**Figure 26.110 Example of operations when receiving a Start Frame while the CR1.PIBE bit is 1**

## 26.11.4 Detection of Bus Collisions

Detection of bus collisions operate for cases where output of the Break Field low width and transmission of data by the SCIn (n = 1) are in progress when the ESMER.ESME bit and the SCIn.SCI.TE bit are set to 1.

Figure 26.111 shows an example of operations with bus collision detection. Signals output through TXDXn and input through RXDXn are sampled with the bus collision detection clock set with the CR2.BCCS[1:0] bits as the sampling clock, and the STR.BCDF flag is set to 1 if the signals fail to match three times in a row. An SCIX2 interrupt is also generated if the value of the ICR.BCDIE bit is 1.

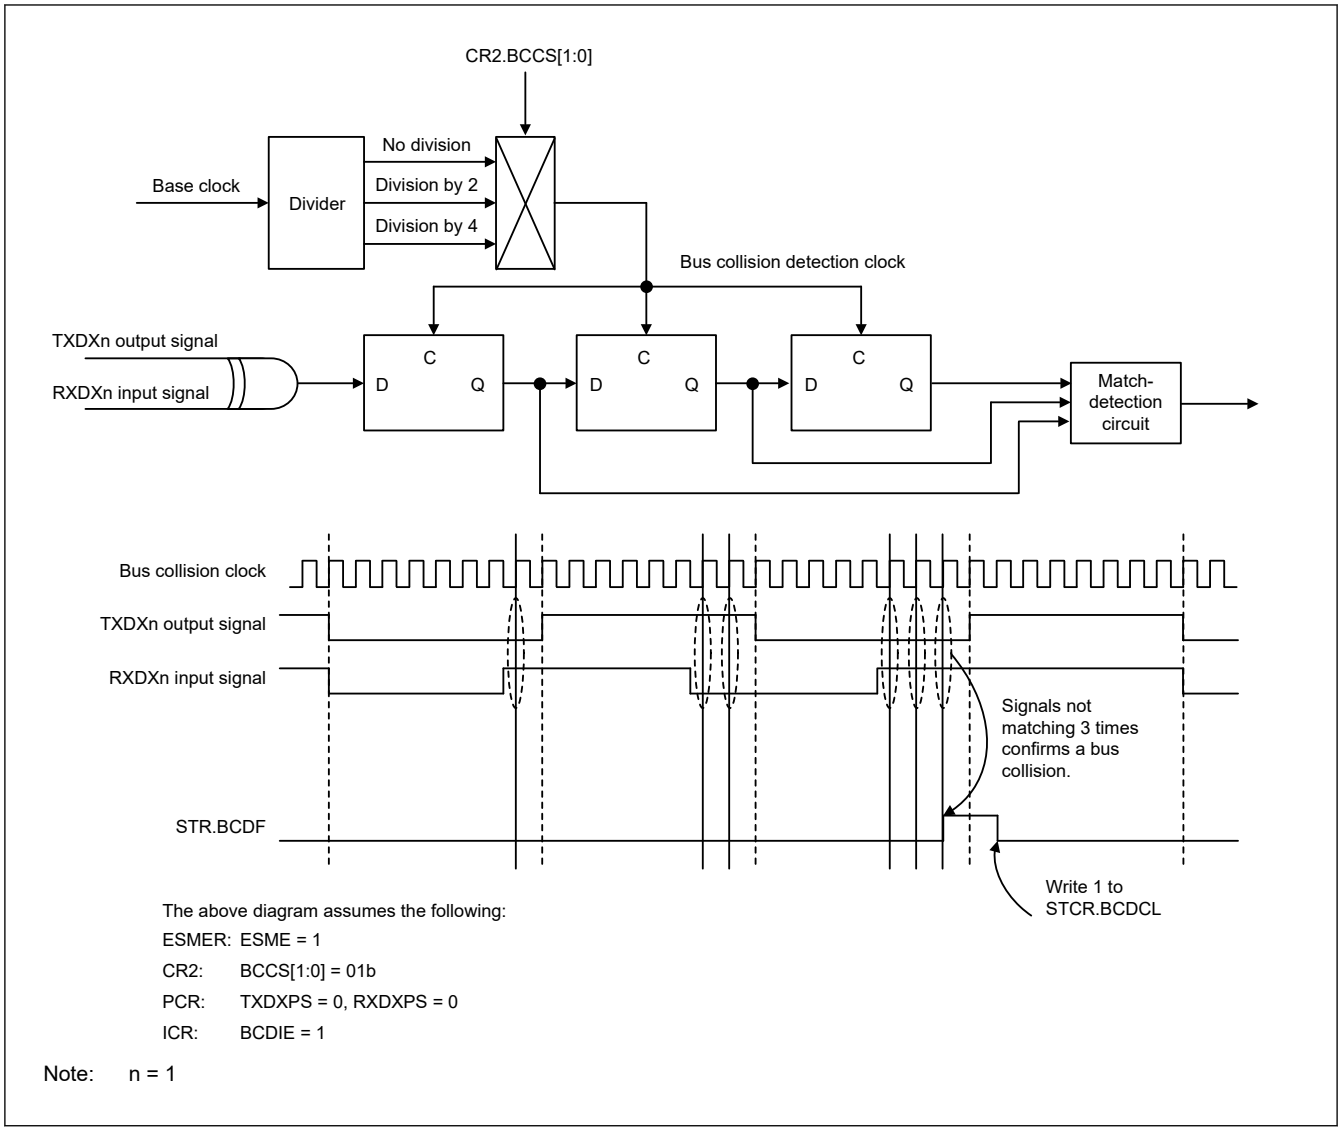

**Figure 26.111 Example of operations with bus collision detection**

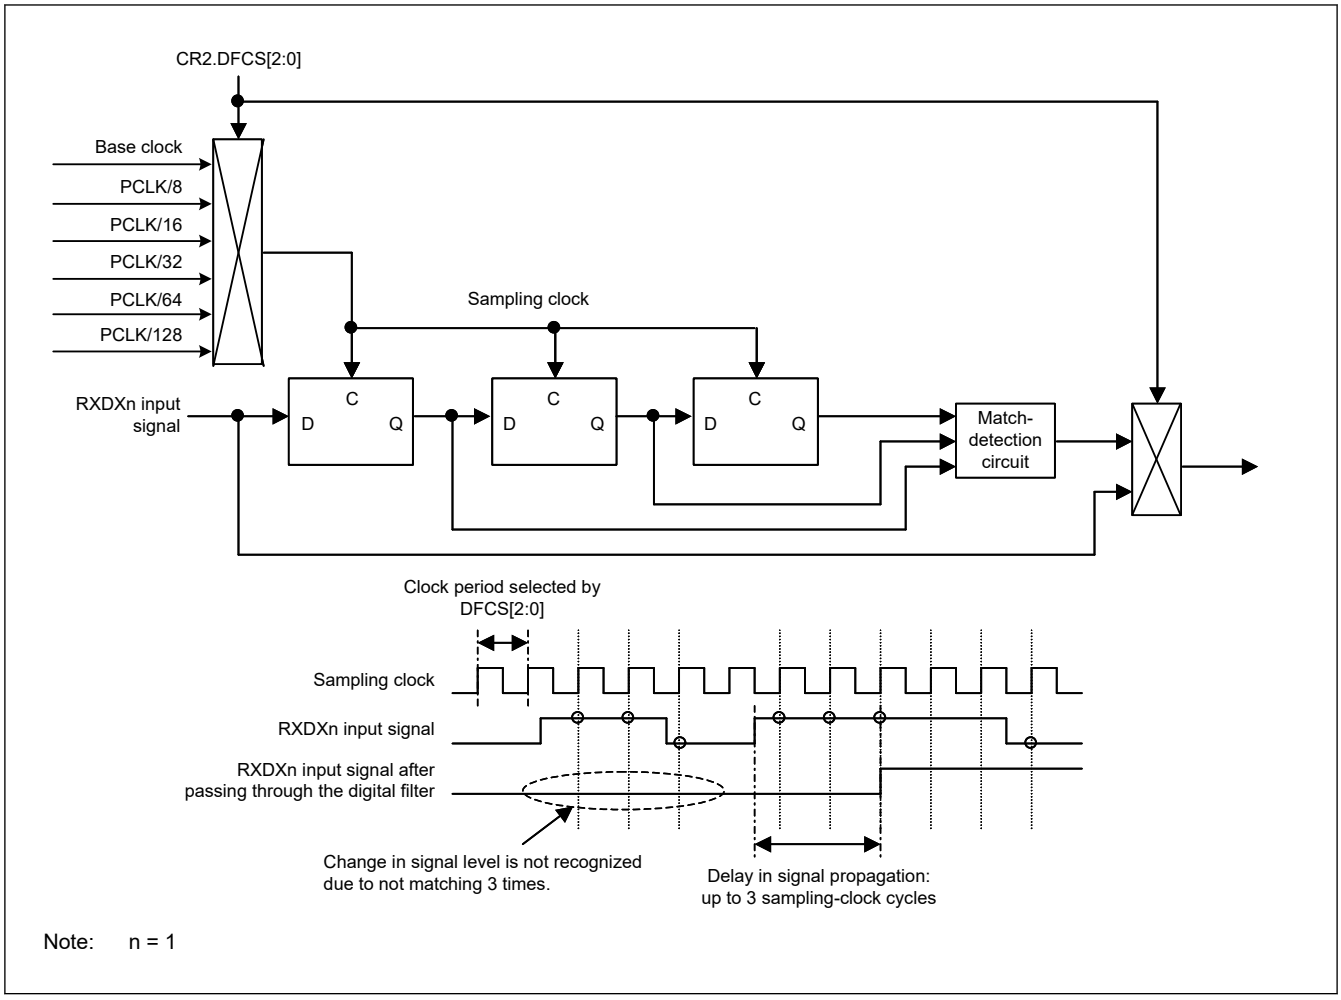
## 26.11.5 Digital Filter for Input on the RXDXn (n = 1) Pin

Signals input through the RXDXn pin can be passed through a digital filter before they are conveyed to the internal circuits. The digital filter consists of three flip-flop circuit stages connected in series and a match-detecting circuit. The CR2.DFCS[2:0] bits select the sampling clock for the RXDXn pin input signals. If the outputs of all three latches match, the given level is conveyed to subsequent circuits. If the levels do not match, the previous value is retained. In other words, levels are confirmed as being the signal if they are retained for at least three cycles of the sampling clock but judged to be noise rather than changes in the signal level if they change within three cycles of the sampling clock. Figure 26.112 shows an example of operations with the digital filter.



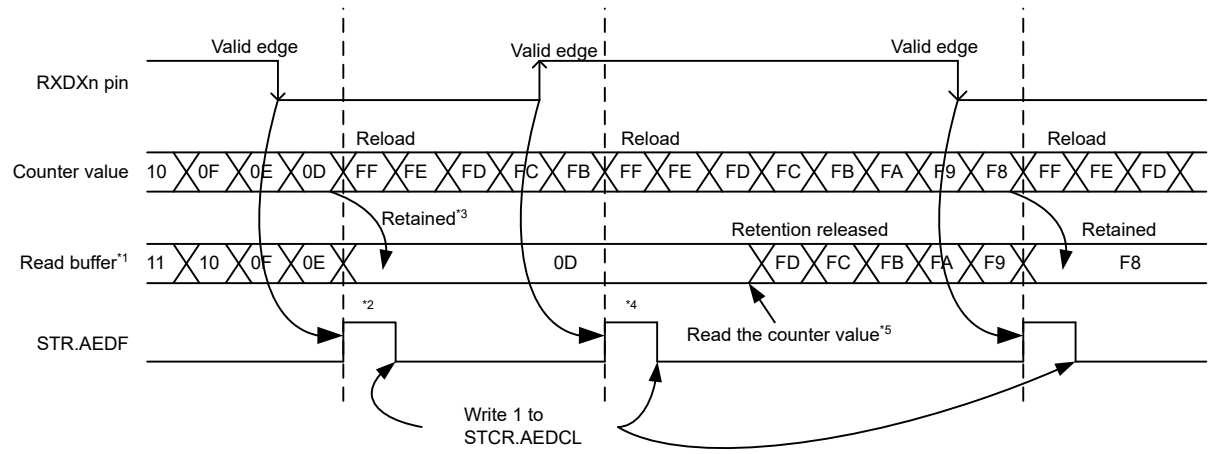


**Figure 26.112 Example of operations with the digital filter**

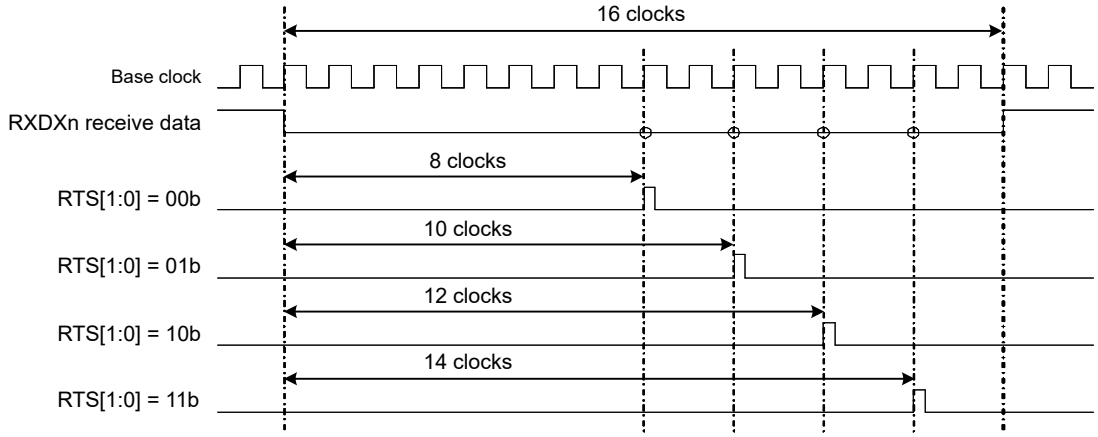
## 26.11.6 Bit Rate Measurement

The bit rate measurement function measures the intervals between rising and falling edges and between falling and rising edges of the signal input from the RXDXn (n = 1) pin. Figure 26.113 shows an example of operations for bit rate measurement.

1. Writing 1 to the CR0.BRME bit enables bit rate measurement. Only set the BRME bit to 1 when you wish to proceed with bit rate measurement. Furthermore, bit rate measurement will not proceed during a Break Field, even if the BRME bit is set to 1.
2. After detection of the Break Field low width, bit rate measurement starts when the level input on the RXDXn pin becomes high.
3. Once bit rate measurement has started, counter values from the timer are retained in the read buffers on the input of valid edges from the RXDXn pin (rising and falling edges) and the counter is reloaded. An SCIX3 interrupt is also generated if the value of the ICR.AEDIE bit is 1. Retention by registers TCNT and TPRE is released by reading these registers.
4. The bit rate as calculated from the values counted during intervals between valid edges can be used for adjusting the rate by changing the settings of the SCIn. To disable the bit rate measurement after a match with Control Field 1, write 0 to the CR0.BRME bit.



Note: n = 1
Note 1. The TCNT or TPRE register indicates the contents of the read buffers.
Note 2. The STR.AEDF flag becomes 1 on detection of a valid edge.
Note 3. When an effective edge is detected, the current value of the counter is stored in the read buffer.
Note 4. The value retained in the read buffers due to one valid edge is not updated to the new value even if a further valid edge is detected.
Note 5. Retention of a value in a read buffer due to a valid edge is released by reading the TCNT or TPRE register.

**Figure 26.113 Example of operations for bit rate measurement**

## 26.11.7 Selectable Timing for Sampling Data Received through RXDXn (n = 1)

The Simple LIN mode control section provides a way of adjusting the timing for the sampling of data received through the RXDXn pin of an SCIn by setting the CR2.RTS[1:0] bits to select the rising edges of 8th, 10th, 12th, or 14th cycle of the SCI base clock. If the value of the SEMR.ABCS bit is 1, the bits select the rising edges of 4th, 5th, 6th, or 7th cycle of the PCLK clock of the SCIn. Figure 26.114 shows timing for the sampling of data received through RXDXn.

The above diagram assumes the following:
SEMR.ABCS = 0

Note: n = 1

**Figure 26.114 Timing for sampling of data received through RXDXn**

## 26.11.8 Timer

The timer has the following operating modes.

### (1) Break Field Low Width Output Mode

This mode is for output through the TXDXn (n = 1) pin of the low level over the Break Field low width at the transmission of a Start Frame. Setting the TMR.TOMS[1:0] bits to 10b switches operation to Break Field low width output mode. The TMR.TCSS[2:0] bits select the clock source for the counter. When the TCR.TCST bit is set to 1, the output on the TXDXn pin goes to the low level and counting starts. When the timer underflows, the output on the TXDXn pin goes to the high level and the STR.BFDF flag is set to 1. An SCIX0 interrupt is also generated if the value of the ICR.BFDIE bit is 1. When 0 is written to the TCR.TCST bit, counting stops after reloading of registers TPRE and TCNT. After output of the Break Field low width is completed, stop the timer before it underflows again. Figure 26.115 shows an example of operations in Break Field low width output mode.

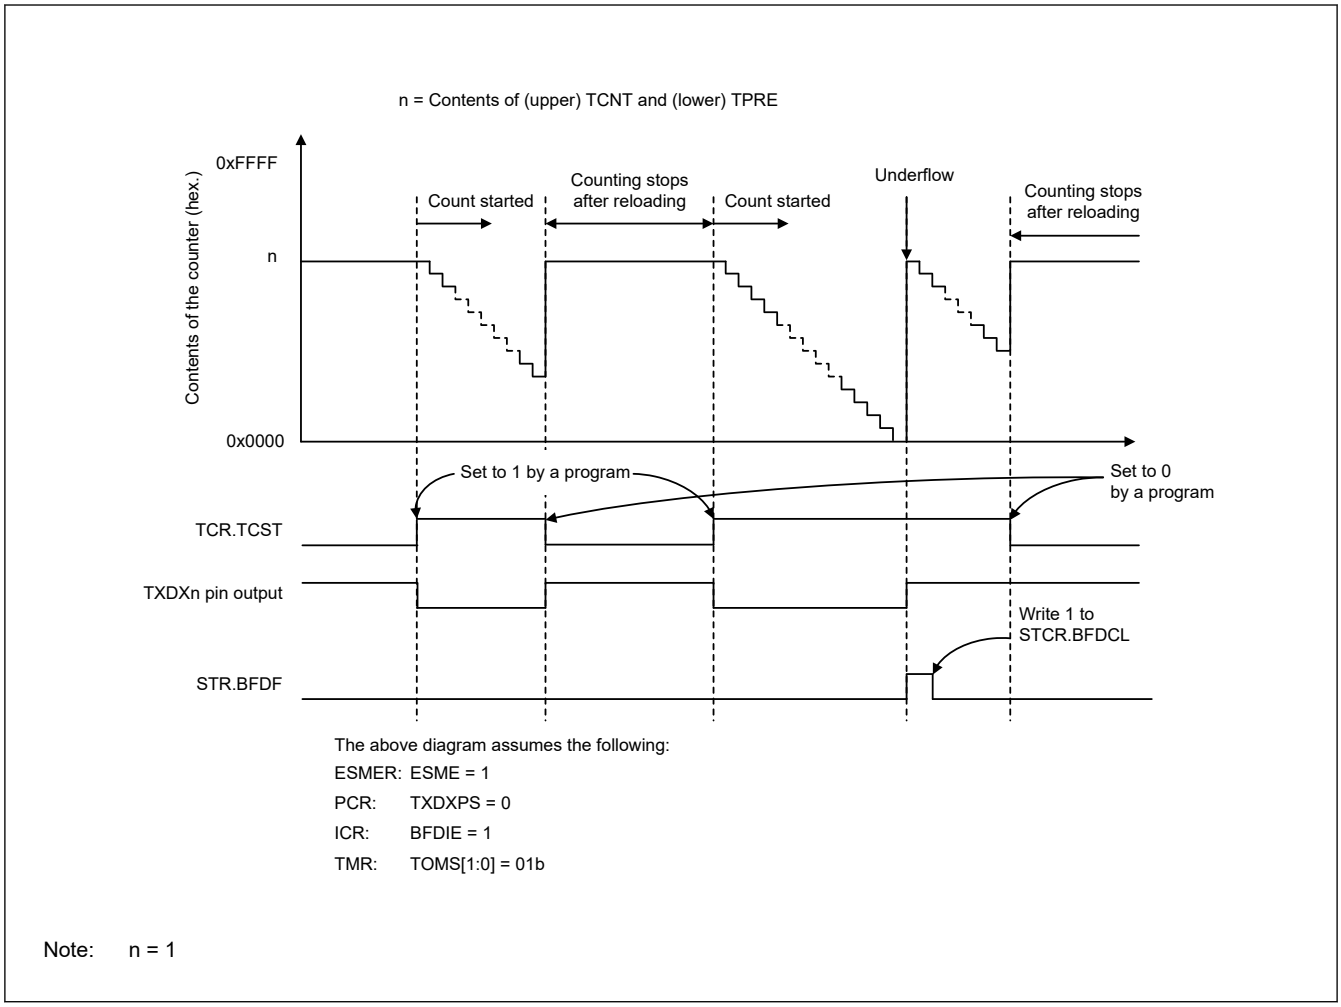


**Figure 26.115 Example of operations in Break Field low width output mode**

### (2) Break Field Low Width Determination Mode

This mode is for determining the Break Field low width in the input signal on the RXDXn (n = 1) pin at the reception of a Start Frame. Setting the TMR.TOMS[1:0] bits to 01b switches operation to Break Field low width determination mode. The TMR.TCSS[2:0] bits select the clock source for the counter. When the TCR.TCST bit is set to 1, the interface enters the Break Field low width determinable state. Determination starts when a low level is input from the RXDXn pin. When a high level is then input on the RXDXn pin, registers TPRE and TCNT are reloaded and the interface enters the Break Field low width determinable state. When the timer underflows during Break Field low width determination, the STR.BFDF flag is set to 1. An SCIX0 interrupt is also generated if the value of the ICR.BFDIE bit is 1. If an underflow of the timer during data transfer cause a problem in the form of interrupt generation, stop the timer after Break Field low width determination. Figure 26.116 shows an example of operations in Break Field low width determination mode.

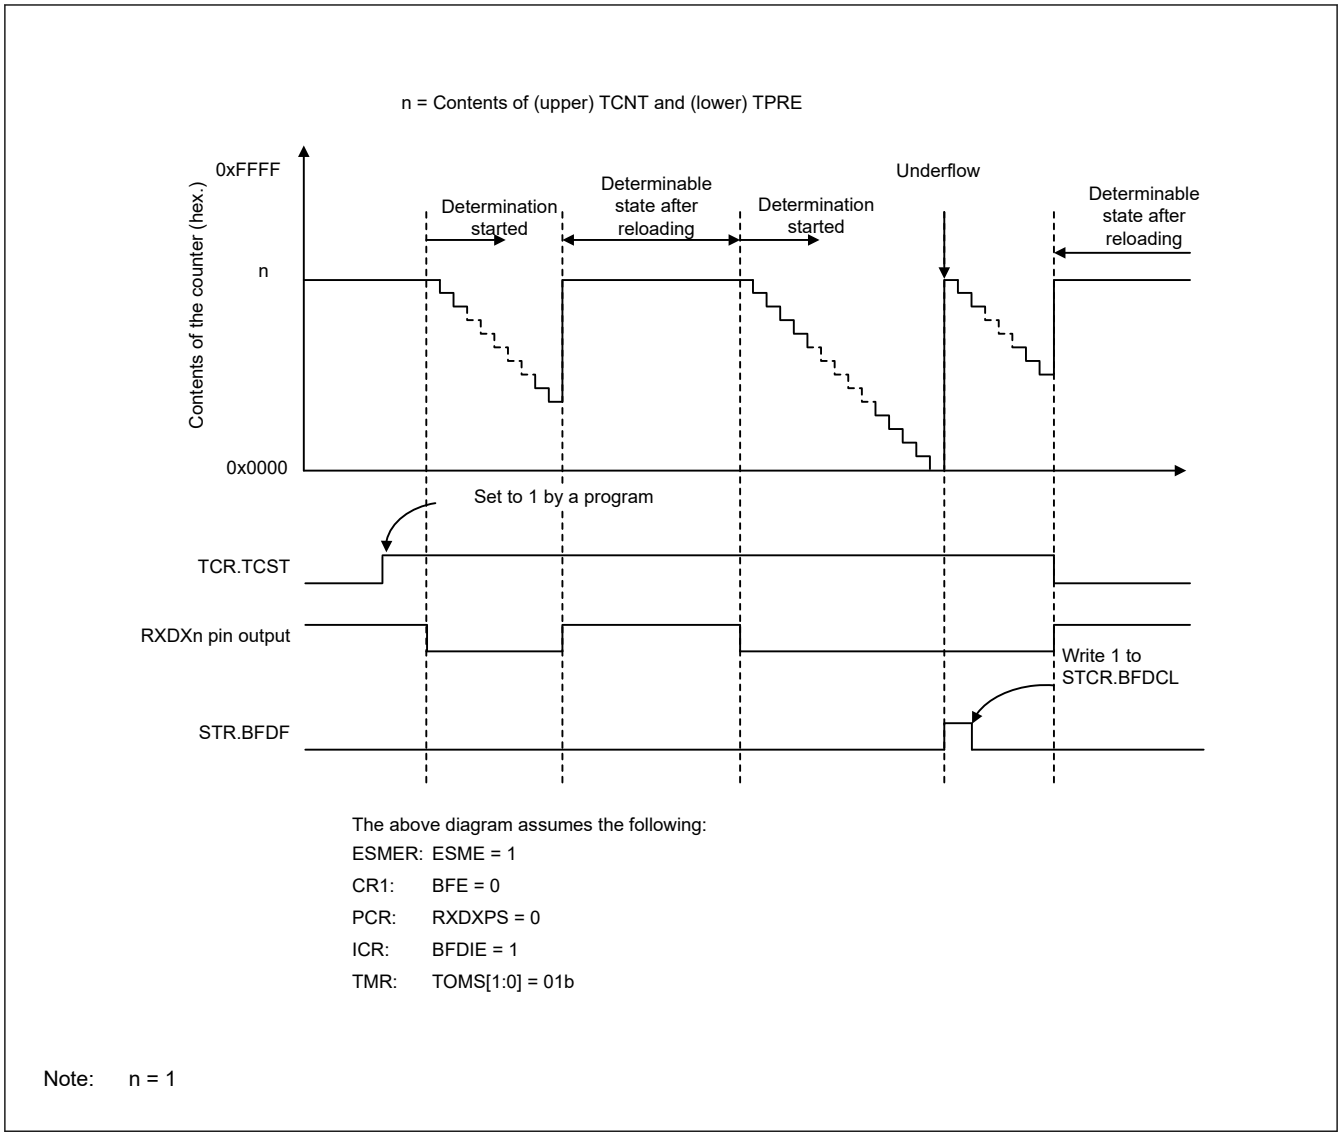

**Figure 26.116 Example of operations in Break Field low width determination mode**

### (3) Timer Mode

This mode is for counting cycles of the internal clock as the clock source. Setting the TMR.TOMS[1:0] bits to 00b switches operation to timer mode. The TMR.TCSS[2:0] bits select the clock source for the counter. Counting starts when 1 is written to the TCR.TCST bit and stops when 0 is written to the TCST bit. Registers TPRE and TCNT both count down. The TPRE register counts cycles of the clock source for counting, and underflows of the TPRE register provide the clock source for counting by the TCNT register. When the timer underflows, the STR.BFDF flag is set to 1. An SCIX0 interrupt is also generated if the value of the ICR.BFDIE bit is 1.

## 26.12 Interrupt Sources

### 26.12.1 Buffer Operation for SCIn_TXI and SCIn_RXI Interrupts (Non-FIFO Selected)

If the conditions for an SCIn_TXI and SCIn_RXI interrupt are satisfied while the interrupt status flag in the ICU is 1, the ICU does not output the interrupt request but saves it internally with a capacity for retention of one request per source.

When the interrupt status flag in the ICU is set to 0, the interrupt request retained within the ICU is output. The internally retained interrupt request is automatically discarded when the actual interrupt is output. Clearing of the associated interrupt enable bit (the TIE or RIE bit in the SCR/SCR_SMCI) can also be used to discard an internally retained interrupt request.

### 26.12.2 Buffer Operation for SCIn_TXI and SCIn_RXI Interrupts (FIFO Selected)

When an interrupt status flag in the ICU is set to 1, the SCIn_TXI and SCIn_RXI interrupts do not output interrupt requests to the ICU. When an interrupt status flag of the ICU is set to 0, and if the conditions for an SCIn_TXI and SCIn_RXI interrupts are satisfied, an interrupt request is generated.

### 26.12.3 Interrupts in Asynchronous, Manchester, Clock Synchronous, and Simple SPI Modes

**(1) Non-FIFO selected**

Table 26.42 lists interrupt sources in asynchronous mode, Manchester mode, clock synchronous mode, and simple SPI mode.

A different interrupt vector can be assigned to each interrupt source. Individual interrupt sources can be enabled or disabled with the enable bits in the SCR register.

If the SCR.TIE bit is 1, an SCIn_TXI interrupt request is generated when transmit data is transferred from the TDR or TDRHL register*1 to the TSR register. An SCIn_TXI interrupt request can also be generated by using a single instruction to set the SCR.TE and SCR.TIE bits to 1 at the same time. An SCIn_TXI interrupt request can activate the DTC or DMAC to handle data transfer.

An SCIn_TXI interrupt request is not generated by setting the SCR.TE bit to 1 when SCR.TIE is 0 or by setting the SCR.TIE bit to 1 when the SCR.TE is 1.*2

When new data is not written by the time of transmission of the last bit of the current transmit data and SCR.TEIE is 1, the SSR.TEND flag is set to 1 and an SCIn_TEI interrupt request is generated. Additionally, when SCR.TE is 1, the SSR.TEND flag retains the value 1 until more transmit data is written to the TDR or TDRHL register*1, and setting SCR.TEIE to 1 leads to the generation of an SCIn_TEI interrupt request.

Writing data to the TDR or TDRHL register*1 leads to clearing of the SSR.TEND flag and, after a certain time, discarding of the SCIn_TEI interrupt request.

If the SCR.RIE bit is 1, an SCIn_RXI interrupt request is generated when received data is stored in the RDR register. An SCIn_RXI interrupt request can activate the DTC or DMAC to handle data transfer.

Setting any of the SSR.ORER, FER, PER and MER*3 flags to 1 when the SCR.RIE bit is 1 leads to the generation of an SCIn_ERI interrupt request.

An SCIn_RXI interrupt request is not generated in this case. Clearing all these flags (ORER, FER, PER, MER*3, SYER*3, PFER*3 and SBER*3) leads to discarding of the SCIn_ERI interrupt request.

Note 1. When asynchronous mode and 9-bit data length are selected.
Note 2. To temporarily prohibit SCIn_TXI interrupts on transmission of the last of the data when a new round of transmission is to be started, after handling the transmission-completed interrupt, control activation of the interrupt by using the interrupt request enable bit in the ICU rather than using the SCR.TIE bit. This approach can prevent the suppression of SCIn_TXI interrupt requests in the transfer of new data.
Note 3. MER, SYER, PFER, and SBER work as a factor of SCIn_ERI interrupt only in Manchester mode. SYER, PFER, and SBER also only work if its enable bits (SYEREN, PFEREN, SBEREN in MECR) are set to 1.

**(2) FIFO selected**

Table 26.43 lists interrupt sources in FIFO selected mode.

If the SCR.TIE bit is 1, an SCIn_TXI interrupt request is generated when the stored amount of data in the FTDRL register becomes the threshold value indicated in FCR.TTRG or below. An SCIn_TXI interrupt request can also be generated by using a single instruction to set the SCR.TIE and SCR.TE bits to 1 simultaneously or by setting SCR.TIE to 1 when SCR.TE is 1.

An SCIn_TXI interrupt request is not generated by setting SCR.TE to 1 when SCR.TIE is 0.

If SCR.TEIE is 1 and if the next data is not written to the FTDRL register by the time the last bit of the transmit data is sent, the SSR_FIFO.TEND flag is set to 1 and the SCIn_TEI interrupt request is generated.

If SCR.RIE is 1, the SCIn_RXI interrupt request is generated when the stored amount of data in the FRDRL register is equal to or greater than the threshold value indicated in FCR.RTRG. When RTRG is 0, an SCIn_RXI interrupt does not occur even when the amount of data in the receive FIFO is equal to 0.

If the SCR.RIE bit is 1, when the SSR_FIFO.ORER flag is set to 1 or data with a framing error or a parity error is stored in the FRDRL register, the SCIn_ERI interrupt request is generated. When the amount of data stored in the FRDRL register is at the threshold value or above, the SCIn_RXI interrupt request is also generated. The SCIn_ERI interrupt request can be canceled, in which case SSR_FIFO.ORER, FER, and PER flags are all cleared.

**Table 26.42 SCI interrupt sources with non-FIFO selected**

| Name | | Interrupt source | Interrupt flag | Interrupt enable | DTC or DMAC activation |
|---|---|---|---|---|---|
| SCIn_ERI (n = 0, 1, 3 to 5, 9) | | Receive error*1 | SSR.ORER, SSR.FER, SSR.PER, DCCR.DFER, DCCR.DPER, (SSR.MER, MESR.SYER, MESR.PFER, MESR.SBER)*2 | SCR.RIE | Not possible |
| SCIn_RXI | (n = 0, 1, 3 to 5, 9) | Receive data full | SSR.RDRF | SCR.RIE | Possible |
| | (n = 0, 3 to 5, 9) | Address match | DCCR.DCMF | SCR.RIE | Possible |
| SCIn_AM (n = 0, 3 to 5, 9) | | Address match | DCCR.DCMF | — | Not possible |
| SCIn_TXI (n = 0, 1, 3 to 5, 9) | | Transmit data empty | SSR.TDRE | SCR.TIE | Possible |
| SCIn_TEI (n = 0, 1, 3 to 5, 9) | | Transmit end | SSR.TEND | SCR.TEIE | Not possible |

Note 1. The interrupt flag is only ORER when in clock synchronous and simple SPI mode.
Note 2. MER, SYER, PFER, and SBER work as a factor of ERI interrupt only in Manchester mode. SYER, PFER, and SBER also only work if its enable bits (SYEREN, PFEREN, SBEREN in MECR) are set to 1.

**Table 26.43 SCI interrupt sources with FIFO selected**

| Name | Interrupt source | Interrupt flag | Interrupt enable | DTC or DMAC activation |
|---|---|---|---|---|
| SCIn_ERI (n = 0, 3 to 5, 9) | Receive error*1 | SSR_FIFO.ORER, SSR_FIFO.FER, SSR_FIFO.PER, DCCR.DFER, DCCR.DPER | SCR.RIE | Not possible |
| | | SSR_FIFO.DR (when FCR.DRES = 1) | SCR.RIE | Not possible |
| SCIn_RXI (n = 0, 3 to 5, 9) | Receive data full | SSR_FIFO.RDF | SCR.RIE | Possible |
| | Receive data ready | SSR_FIFO.DR (when FCR.DRES = 0) | SCR.RIE | Possible |
| | Address match | DCCR.DCMF | SCR.RIE | Possible |
| SCIn_AM (n = 0, 3 to 5, 9) | Address match | DCCR.DCMF | — | Not possible |
| SCIn_TXI (n = 0, 3 to 5, 9) | Transmit data empty | SSR_FIFO.TDFE | SCR.TIE | Possible |
| SCIn_TEI (n = 0, 3 to 5, 9) | Transmit end | SSR_FIFO.TEND | SCR.TEIE | Not possible |

Note 1. The interrupt flag is only ORER when in clock synchronous and simple SPI mode.

## 26.12.4 Interrupts in Smart Card Interface Mode

Table 26.44 lists interrupt sources in smart card interface mode. A transmit end interrupt (SCIn_TEI) request and an address match (SCIn_AM) request cannot be used in this mode.

**Table 26.44 SCI interrupt sources**

| Name | Interrupt source | Interrupt flag | Interrupt enable | DTC or DMAC activation |
|---|---|---|---|---|
| SCIn_ERI (n = 0, 1, 3 to 5, 9) | Receive error or error signal detection | SSR_SMCI.ORER, SSR_SMCI.PER, SSR_SMCI.ERS | SCR_SMCI.RIE | Not possible |
| SCIn_RXI (n = 0, 1, 3 to 5, 9) | Receive data full | SSR_SMCI.RDRF | SCR_SMCI.RIE | Possible |
| SCIn_TXI (n = 0, 1, 3 to 5, 9) | Transmit data empty | SSR_SMCI.TEND | SCR_SMCI.TIE | Possible |

Data transmission or reception using the DTC or DMAC is also possible in smart card interface mode, similar to normal SCI mode. In transmission, when the SSR_SMCI.TEND flag is set to 1, an SCIn_TXI interrupt request is generated. This SCIn_TXI interrupt request activates the DTC or DMAC, allowing transfer of transmit data if the SCIn_TXI request is previously specified as a source of DTC or DMAC activation. The TEND flag is automatically set to 0 when the DTC or DMAC transfers the data.

If an error occurs, the SCI automatically retransmits the same data. During the retransmission, the TEND flag is kept at 0 and the DTC or DMAC is not activated. Therefore, the SCI and DTC or DMAC automatically transmit the specified number of bytes, including retransmission after an error occurrence. However, the SSR_SMCI.ERS flag is not automatically set to 0 at error occurrence. Therefore, the ERS flag must be cleared by previously setting the SCR_SMCI.RIE bit to 1 to enable an SCIn_ERI interrupt request to be generated at error occurrence.

When transmitting or receiving data using the DTC or DMAC, always enable the DTC or DMAC before making the SCI settings. For DTC or DMAC settings, see section 16, Data Transfer Controller (DTC), section 15, DMA Controller (DMAC).

In reception, an SCIn_RXI interrupt request is generated when receive data is set to the RDR register. This SCIn_RXI interrupt request activates the DTC or DMAC, allowing transfer of the receive data if the SCIn_RXI request is previously specified as a source of DTC or DMAC activation. If an error occurs, the error flag is set. Therefore, the DTC or DMAC is not activated and an SCIn_ERI interrupt request is issued to the CPU instead. The error flag must be cleared.

### 26.12.5 Interrupts in Simple IIC Mode

Table 26.45 lists the interrupt sources in simple IIC mode. The STI interrupt is allocated to the transmit end interrupt (SCIn_TEI) request. The receive error interrupt (SCIn_ERI) and the address match (SCIn_AM) request cannot be used.

The DTC or DMAC can also be used to handle transfer in simple IIC mode.

When the SIMR2.IICINTM bit is 1:

- An SCIn_RXI request is generated on the falling edge of the SCLn signal for the 8$^{th}$ bit. If SCIn_RXI is previously set up as an activation source for the DTC or DMAC, the SCIn_RXI request activates the DTC or DMAC to handle transfer of the received data.
- An SCIn_TXI request is generated on the falling edge of the SCLn signal for the 9$^{th}$ bit (acknowledge bit). If SCIn_TXI is previously set up as an activation source for the DTC or DMAC, the SCIn_TXI request activates the DTC or DMAC to handle transfer of the transmit data.

When the SIMR2.IICINTM bit is 0:

- An SCIn_RXI request (ACK detection) is generated if the input on the SDAn pin is low on the rising edge of the SCLn signal for the 9$^{th}$ bit (acknowledge bit)
- An SCIn_TXI request (NACK detection) is generated if the input on the SDAn pin is high on the rising edge of the SCLn signal for the 9$^{th}$ bit (acknowledge bit)
- If SCIn_RXI is previously set up as an activation source for the DTC or DMAC, the SCIn_RXI request activates the DTC or DMAC to handle transfer of the received data.

If the DTC or DMAC is used for data transfer in reception or transmission, always set up and enable the DTC or DMAC before setting up the SCI.

When the IICSTAREQ, IICRSTAREQ, and IICSTPREQ bits in SIMR3 are used to generate a start condition, restart condition, or stop condition, the STI request is issued when generation is complete.

**Table 26.45 SCI interrupt sources**

| Name | Interrupt source | Interrupt flag | Interrupt enable | DTC or DMAC activation |
|---|---|---|---|---|
| SCIn_RXI (n = 0, 1, 3 to 5, 9) | Reception, ACK detection | — | SCMR.RIE | Possible*1 |
| SCIn_TXI (n = 0, 1, 3 to 5, 9) | Transmission, NACK detection | — | SCMR.TIE | Possible |
| SCIn_TEI(STIn) (n = 0, 1, 3 to 5, 9) | Completion of generation of a start, restart, or stop condition | SIMR3.IICSTIF | SCMR.TEIE | Not possible |

Note 1. Activation of the DTC or DMAC is only possible when the SIMR2.IICINTM bit is 1 (use reception and transmission interrupts).

### 26.12.6 Interrupt Requests from the Simple LIN Mode Control Section

The Simple LIN Mode Control section has a total of six types of interrupt request for generating the SCIX0 interrupt (Break Field low width detected), SCIX1 interrupt (Control Field 0 match, Control Field 1 match, priority interrupt bit detected), SCIX2 interrupt (bus collision detected), and SCIX3 interrupt (valid edge detected). When any of the interrupt factors is generated, the corresponding status flag is set to 1. Details of all of the interrupt requests are listed in Table 26.46.

**Table 26.46 Interrupt sources of the Simple LIN Mode Control section**

| Interrupt request | Status flag | Interrupt factors |
|---|---|---|
| SCIX0 interrupt (Break Field low width detected) | BFDF | • Detection of a Break Field low width longer than the interval corresponding to the timer setting<br>• Completion of the output of a Break Field low width over the interval corresponding to the timer setting<br>• Underflow of the timer |
| SCIX1 interrupt (Control Field 0 match) | CF0MF | The data received in Control Field 0 matching the value set in CF0DR |
| SCIX1 interrupt (Control Field 1 match) | CF1MF | The data received in Control Field 1 matching the value set in PCF1DR or SCF1DR |
| SCIX1 interrupt (priority interrupt bit detected) | PIBDF | The value of the bit specified as the priority interrupt bit matching the value set in PCF1DR |
| SCIX2 interrupt (bus collision detected) | BCDF | The output level on the RXDXn (n = 1) pin and the input level on the RXDXn pin not matching on three consecutive cycles of the bus collision detection clock |
| SCIX3 interrupt (valid edge detected) | AEDF | Detection of a valid edge during bit rate measurement |

## 26.13 Event Linking

By using interrupt request signals as event signals, the SCIn can provide linked operation through the ELC for modules selected in advance.

Event signals can be output regardless of the values of the associated interrupt request enable bits.

### (1) Error event output (receive error or error signal detected) (SCIn_ERI, n = 0, 1, 3 to 5, 9)

- Indicates abnormal termination because of a parity error during reception in asynchronous mode
- Indicates abnormal termination because of a framing error during reception in asynchronous mode
- Indicates abnormal termination because of an overrun error during reception
- Indicates detection of the error signal during transmission in smart card interface mode
- The SSR_FIFO.FER and PER flags are 0, and receive data less than the receive FIFO data trigger number is set in a reception FIFO buffer, and it indicates that 15 etus elapse when FIFO is selected and the FCR.DRES bit is 1

### (2) Receive data full event output (SCIn_RXI, n = 0, 1, 3 to 5, 9)

- Indicates that ACK is detected if the SIMR2.IICINTM bit is 0 in simple IIC mode
- Indicates that the 8th-bit SCLn falling edge is detected if the SIMR2.IICINTM bit is 1 in simple IIC mode
- When the SIMR2.IICINTM bit is 1 during master transmission in simple IIC mode, set the ELC so that receive data full events are not used

**Non-FIFO selected**

- Indicates that received data is set in the Receive Data Register (RDR or RDRHL).

**FIFO selected**

- Using this event output is prohibited.

### (3) Transmit data empty event output (SCIn_TXI, n = 0, 1, 3 to 5, 9)

- Indicates that the SCR/SCR_SMCI.TE bit is changed from 0 to 1
- Indicates that transmission is complete in smart card interface mode
- Indicates that NACK is detected if the SIMR2.IICINTM bit is 0 in simple IIC mode
- Indicates that the 9th-bit SCLn falling edge is detected if the SIMR2.IICINTM bit is 1 in simple IIC mode

**Non-FIFO selected**

- Indicates that transmit data is transferred from the Transmit Data Register (TDR or TDRHL) to the Transmit Shift Register (TSR).

**FIFO selected**

- Using this event output is prohibited.

### (4) Transmit end event output (SCIn_TEI, n = 0, 1, 3 to 5, 9)

- Indicates the completion of transmission
- Indicates that the starting condition, resumption condition, or termination condition is generated in simple IIC mode

Note: When FIFO is selected, using this event output is prohibited.

### (5) Address match event output (SCIn_AM, n = 0, 3 to 5, 9)

- Indicates a match of the comparison data (CDR.CMPD) with one frame of receive data when DCCR.DCME is set to 1 in asynchronous mode, including multi-processor mode.

## 26.14 Address Non-match Event Output (SCI0_DCUF)

SCI0_DCUF indicates the non-match of comparison data (CDR.CMPD) with receive data that is one frame of the data that is received when DCCR.DCME is set to 1 in asynchronous mode, including multi-processor mode. This event can be used for Snooze end request only. For details, see section 10, Low Power Modes.

## 26.15 Noise Cancellation Function

Figure 26.117 shows the configuration of the noise filter used for noise cancellation. The noise filter consists of a 2-stage flip-flop circuit and a match detection circuit. When the input signals of the noise filter and the output signals of the 2-stage flip-flop circuits completely match, the matched level is conveyed as an internal signal. Unless otherwise matched, the previous value is retained. When the same level is retained for 3 cycles or longer on the sampling clock of the noise filter, it is considered as a valid receive signal. A change in pulse for 3 cycles or shorter is considered as noise, not as a receive signal.

In asynchronous mode, the noise cancellation function can be applied to the receive signal input to the RXDn pin. The receive level of the RXDn is taken in the flip-flop circuit of the noise filter on the base clock of asynchronous mode.

- When SEMR.ABCS = 0 and SEMR.ABCSE = 0, the cycle is 1/16 of a 1-bit period.
- When SEMR.ABCS = 1 and SEMR.ABCSE = 0, the cycle is 1/8 of a 1-bit period.
- When SEMR.ABCSE = 1, the cycle is 1/6 of a 1-bit period.

In simple IIC mode, this function can be used for each input on SDAn and SCLn. The sampling clock is selected from divided clock of baud rate generator settings SNFR.NFCS[2:0].

If the base clock is stopped once with the noise filter enabled and then the base clock input is restarted again, the noise filter operation resumes from the state where the clock was stopped. When SCR.TE and SCR.RE are set to 0 during base clock input, all of the noise filter flip-flop values are initialized to 1. Accordingly, if the input data is 1 when reception operation resumes, the function determines that a level match is detected and the result is conveyed as an internal signal. When the level being input corresponds to 0, the initial output of the noise filter is retained until the level matches in three consecutive sampling cycles.

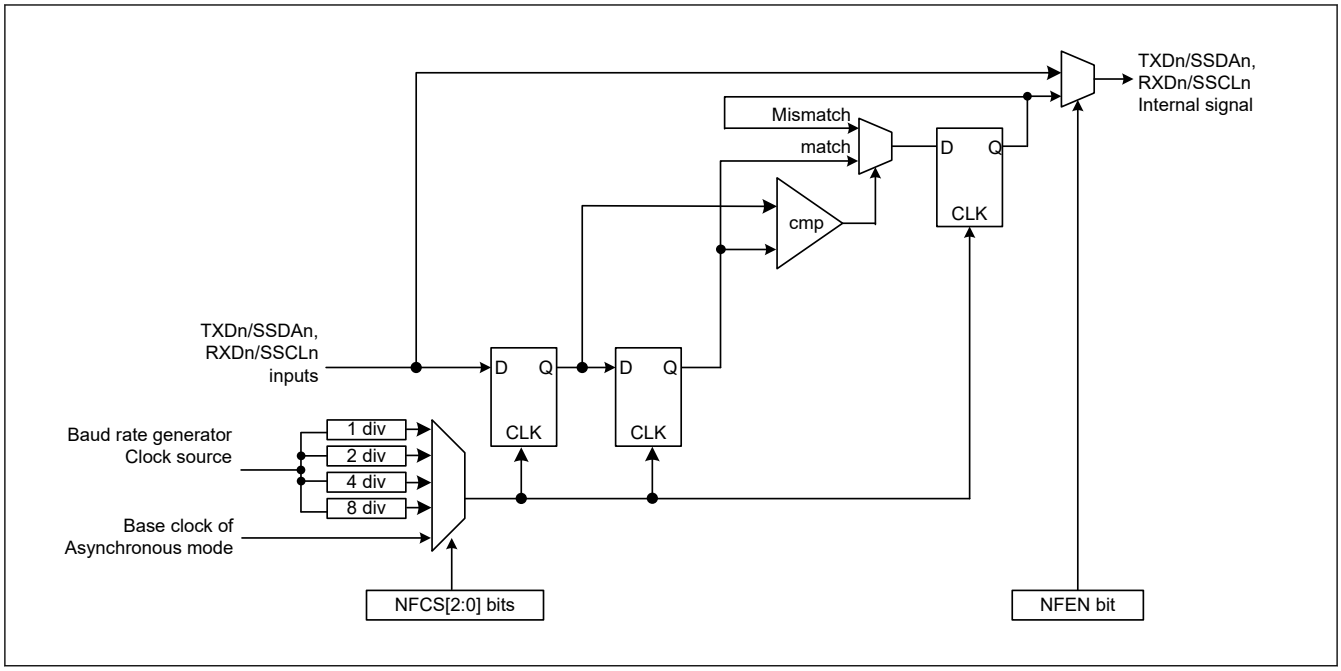

**Figure 26.117 Digital noise filter circuit block diagram**

## 26.16 Usage Notes

### 26.16.1 Settings for the Module-Stop Function

The Module Stop Control Register B (MSTPCRB) can enable or disable SCI operation. The SCI is initially stopped after reset. Releasing the module-stop state enables access to the registers. For details, see section 10, Low Power Modes.

### 26.16.2 SCI Operation during Low Power State

#### (1) Transmission

When setting the module to the stopped state or in transitions to Software Standby, stop operations (by setting the TIE, TE, and TEIE bits in the SCR/SCR_SMCI to 0) after switching the TXDn pin to the general I/O port pin function. When setting I/O port as an SCI connection, the SPTR register can control the state of the TXDn pin. Setting the TE bit to 0 initializes the TSR register and the TEND bit in the SSR/SSR_SMCI is initialized to 1 with non-FIFO selected, and the value is retained, with FIFO selected. Depending on the port settings and SPTR register settings, output pins might output the level before a transition to the low-power state is made after release from the module-stopped state or Software Standby mode. When transitions to these states are made during transmission, the transmitted data becomes indeterminate.

To transmit data in the same transmission mode after cancellation of the low-power state:

1. Set the TE bit to 1.
2. Read SSR/SSR_FIFO/SSR_SMCI.
3. Write data to TDR sequentially to start data transmission.

To transmit data with a different transmission mode, initialize the SCI first.

Figure 26.118 shows an example flow of transition to Software Standby mode during transmission. Figure 26.119 and Figure 26.120 show the port pin states during transition to Software Standby mode.

Before specifying the module-stop state or transitioning to Software Standby mode from the transmission mode using DTC or DMAC transfer, stop the transmit operations (TE = 0). To start transmission after cancellation using the DTC or DMAC, set the TE bit to 1. The SCIn_TXI interrupt flag is set to 1 and transmission starts using the DTC or DMAC.

### (2) Reception

#### When address match function is not used as wakeup condition

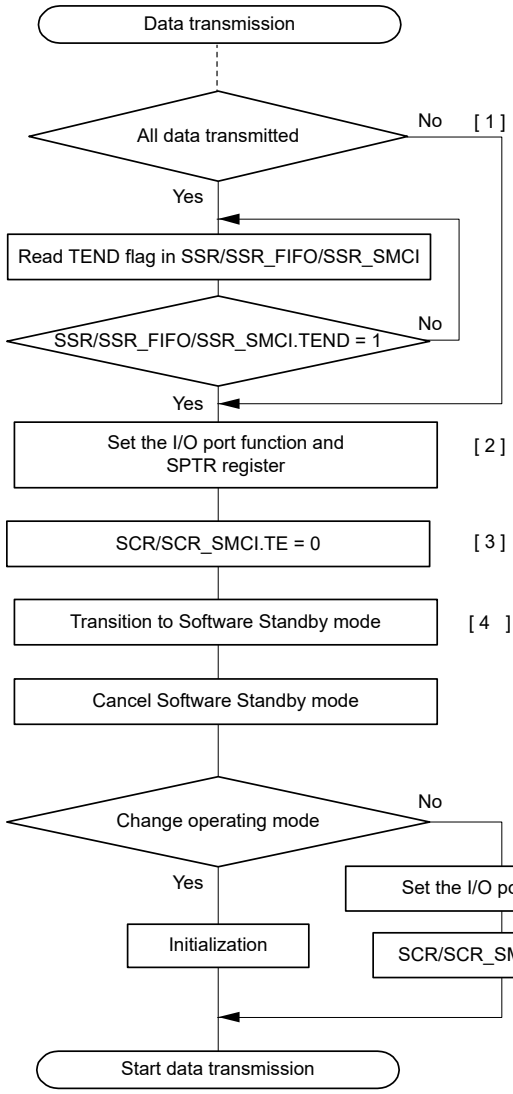
Before specifying the module-stop state or transitioning to Software Standby mode, stop the receive operations (RE = 0 in SCR/SCR_SMCI). If transition is made during data reception, the received data is invalid.

Figure 26.121 shows an example flow of transition to Software Standby mode during reception.

#### When address match function is used as wakeup condition

Before specifying the module-stop state or transitioning to Software Standby mode:

1. Set the operations after cancellation of the low power state.
2. Set CDR.CMPD and DCCR.DCME to 1.
3. Set the receive operations (RE = 1 in SCR/SCR_SMCI).
4. Set the module-stop state or Software Standby mode.



When SCI transfers to low power mode, if the receive data pin (RXD) is at the low level, set SEMR.RXDESEL = 0.

When setting SEMR.RXDESEL = 1, there is a possibility that a start bit (falling edge of RXD pin) cannot be detected on release of the low power mode.

Figure 26.122 shows an example flow of transition to Software Standby mode during reception with address match.

#### When using SCI0 in Snooze mode

When using SCI0 in Snooze mode, some restrictions apply, including maximum bit rates. For details, see section 10, Low Power Modes.

[ 1 ] Data being transmitted is lost. Data can be normally transmitted from the CPU by setting the TE bit in SCR/SCR_SMCI to 1, reading SSR/SSR_FIFO/ SSR_SMCI, and writing in Software Standby mode. However, if the DMAC or DTC is activated, the data remaining in the DMAC or DTC is transmitted when both the TE and TIE bits in SCR/SCR_SMCI are set to 1.

[ 2 ] Set the I/O port function and SPTR register settings to switch the TXDn pin to operate as a general I/O port.

[ 3 ] Set SCR/SCR_SMCI.TE bit to 0. If SCR/SCR_SMCI.TIE = 1 and SCR/SCR_SMCI.TEIE = 1, these are set to 0 simultaneously with the SCR.TE bit.

[ 4 ] This includes the setting for the module-stop state.

**Figure 26.118 Example flow of transition to Software Standby mode during transmission**

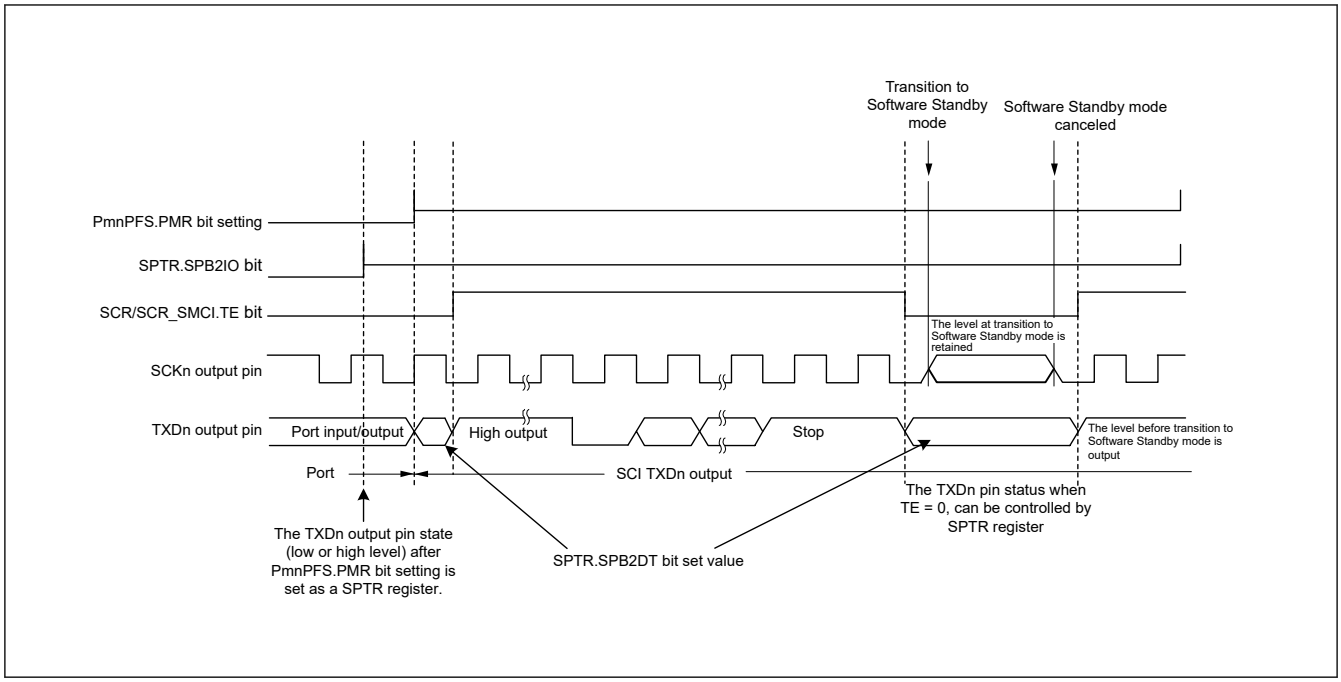


**Figure 26.119 Port pin states during transition to Software Standby mode with internal clock and asynchronous transmission**

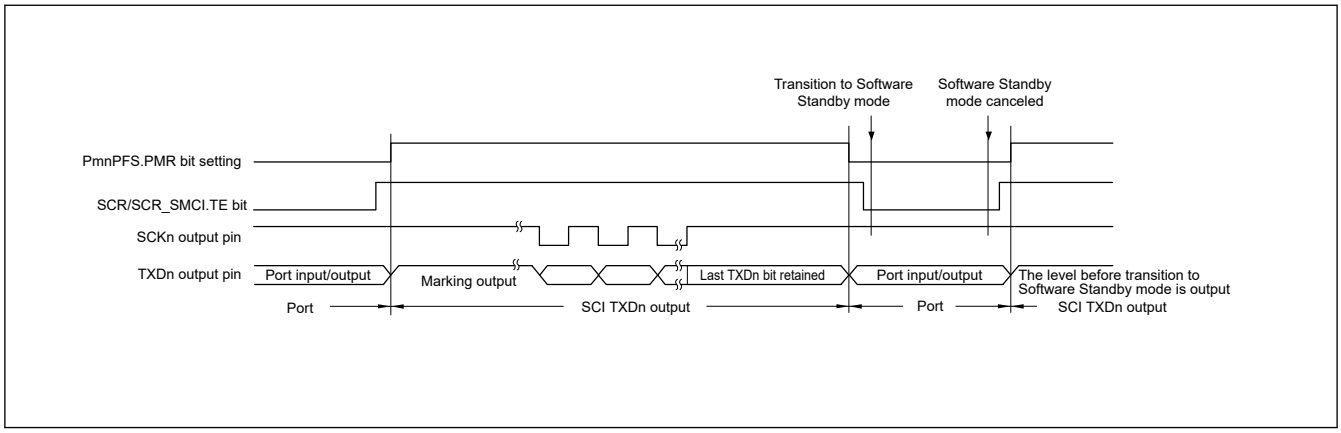

**Figure 26.120 Port pin states during transition to Software Standby mode with internal clock and clock synchronous transmission**

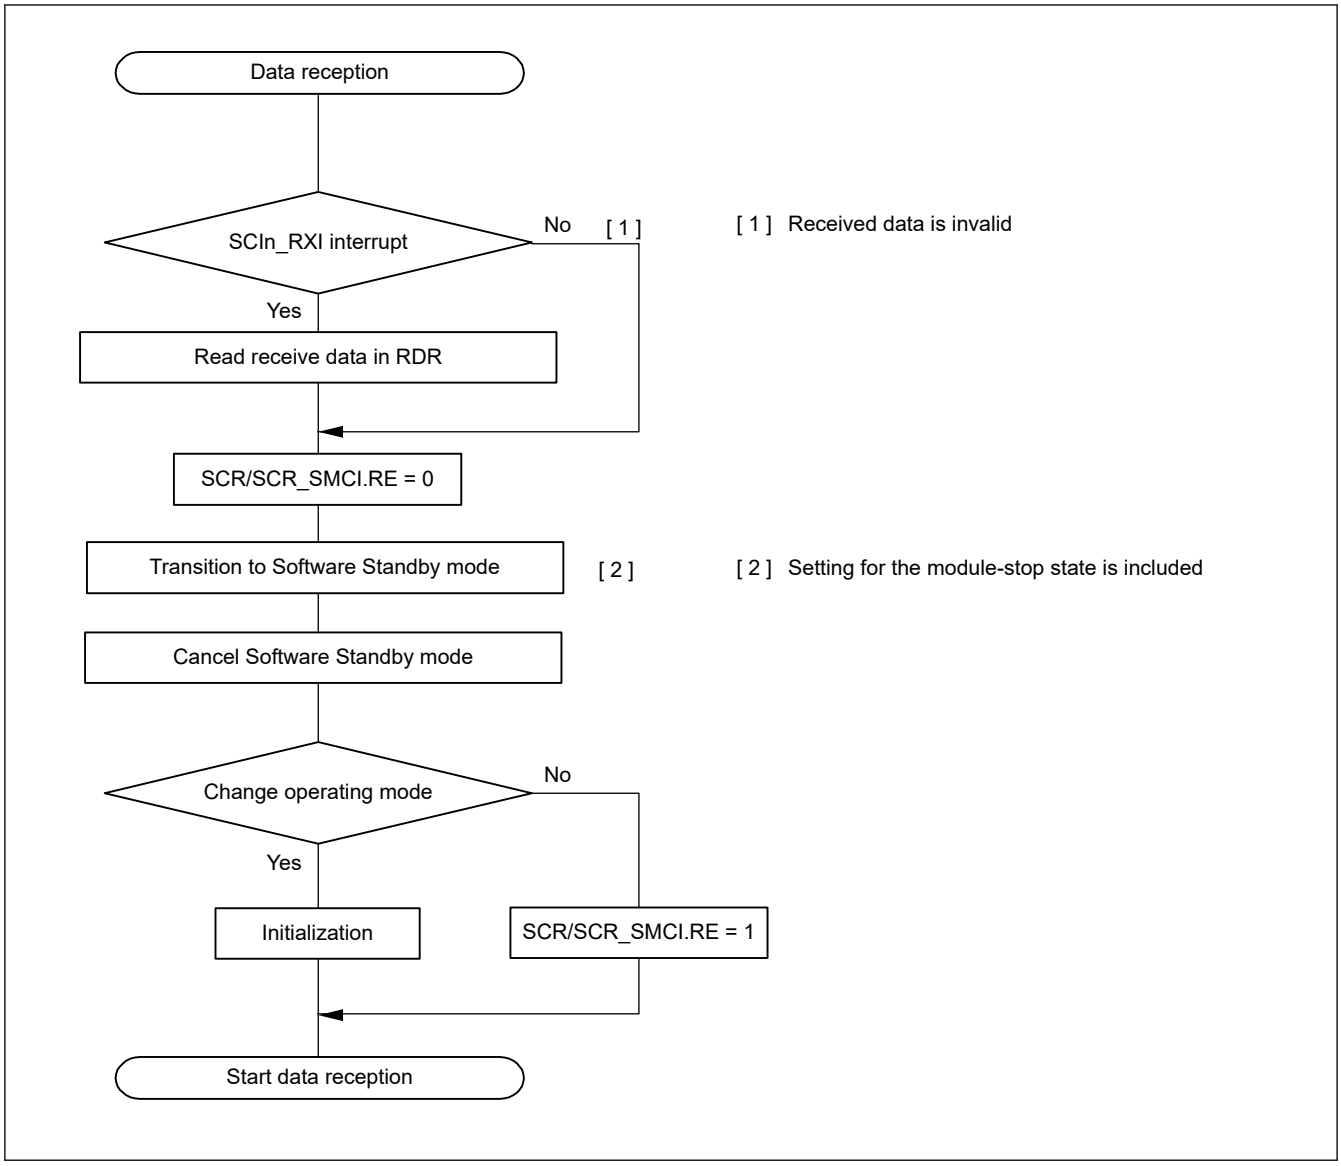

**Figure 26.121 Example flow of transition to Software Standby mode during reception**

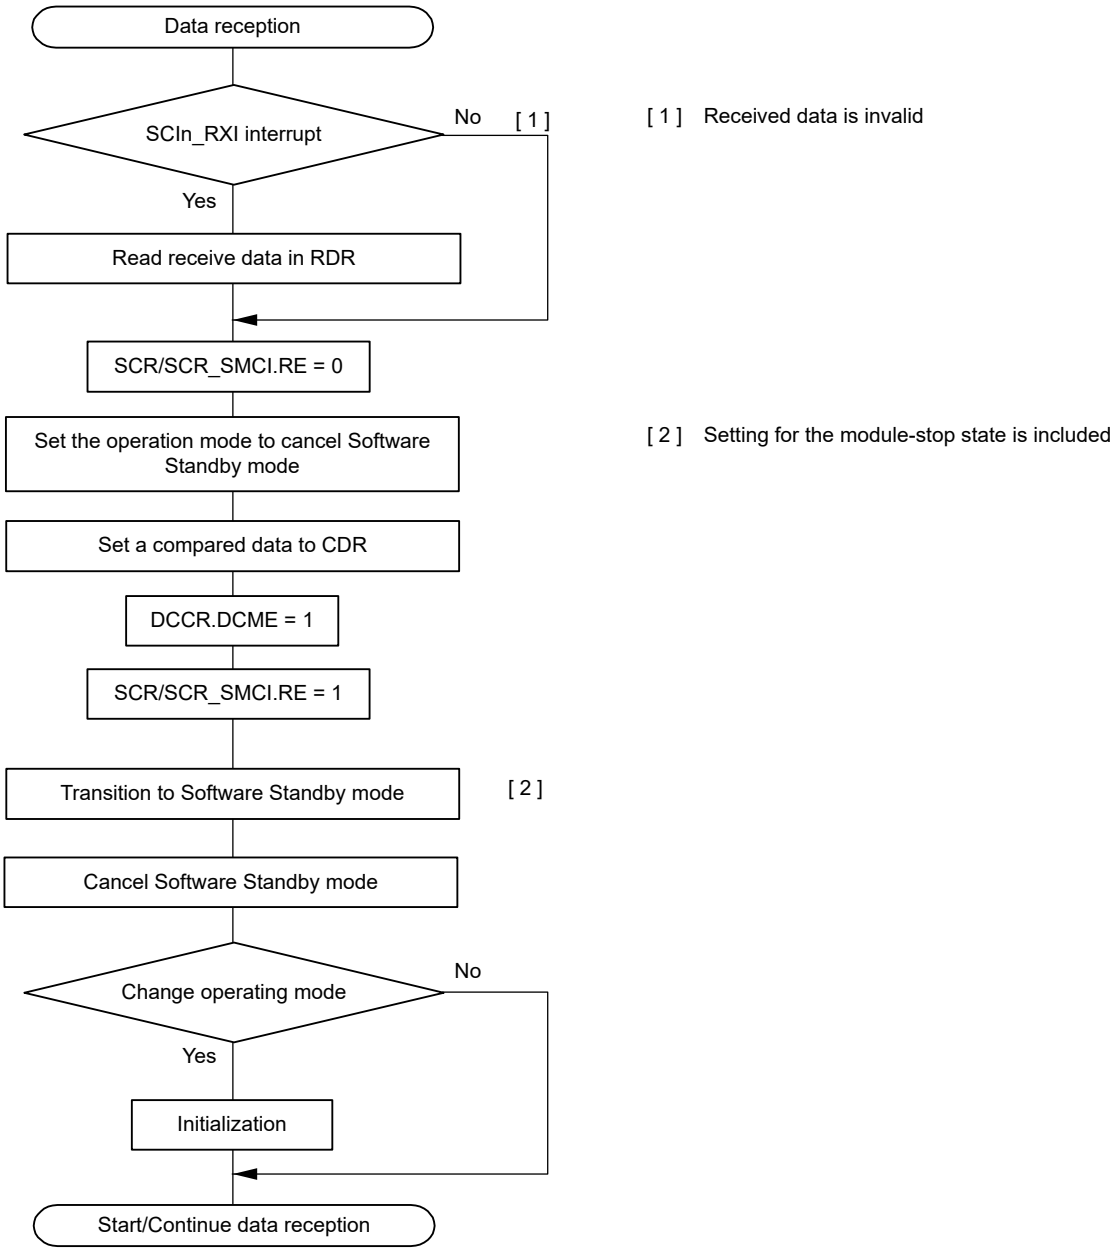

**Figure 26.122 Example flow of transition to Software Standby mode during reception with address match**

## 26.16.3 Break Detection and Processing

**(1) Non-FIFO selected**

When a framing error is detected, a break can be detected by reading the RXDn pin value directly. In a break, the input from the RXDn pin becomes all 0s, and the SSR.FER flag is set to 1 to indicate a framing error, and the SSR.PER flag might also be set to 1 to indicate a parity error. The SCI continues the receive operation even after a break is received. Therefore, even if the FER flag is 0, indicating that no framing error occurred, it is set to 1 again. When the SEMR.RXDESEL bit is 1, the SCI sets the SSR.FER flag to 1 and stops receiving operations until a start bit of the next data frame is detected. If the SSR.FER flag is set to 0, the SSR.FER flag retains 0 during the break.

When the RXDn pin is set to 1 and the break ends, detecting the beginning of the start bit on the first falling edge of the RXDn pin allows the SCI to start the receiving operation.

**(2) FIFO selected**

After a framing error is detected and when the SCI detects that continuous receive data is 0 for 1 frame, reception stops. When a framing error is detected, a break can be detected by reading the SPTR.RXDMON flag value. After the RXDn signal is in high and the break is finished, data reception to the FRDRHL register resumes.

### 26.16.4 Mark State and Production of Breaks

When the SCR/SCR_SMCI.TE bit is 0, disabling serial transmission, the state of the TXDn pin can be set using the SPTR.SPB2IO and SPTR.SPB2DT bits. With this approach, a TXDn pin can be placed in the mark state to transmit a break.

Before setting the SCR/SCR_SMCI.TE bit to 1, enabling serial transmission, set the SPB2IO and SPB2DT bits to put the communication line in the mark state (the state of 1), and change the TXDn pin using I/O port function. To output a break on data transmission, after setting the TXDn pin to output 0 by setting the SPB2IO and SPB2DT bits, change the TXDn pin using the I/O port function and set the SCR/SCR_SMCI.TE bit to 0. When the SCR/SCR_SMCI.TE bit is set to 0, the transmitter is initialized regardless of the current state of transmission.

### 26.16.5 Receive Error Flags and Transmit Operation in Clock Synchronous Mode and Simple SPI Mode

Transmission cannot start when a receive error flag (ORER) in SSR/SSR_FIFO is set to 1, even when data is written to TDR or FTDRL[*1]. Always set the receive error flags to 0 before starting transmission.

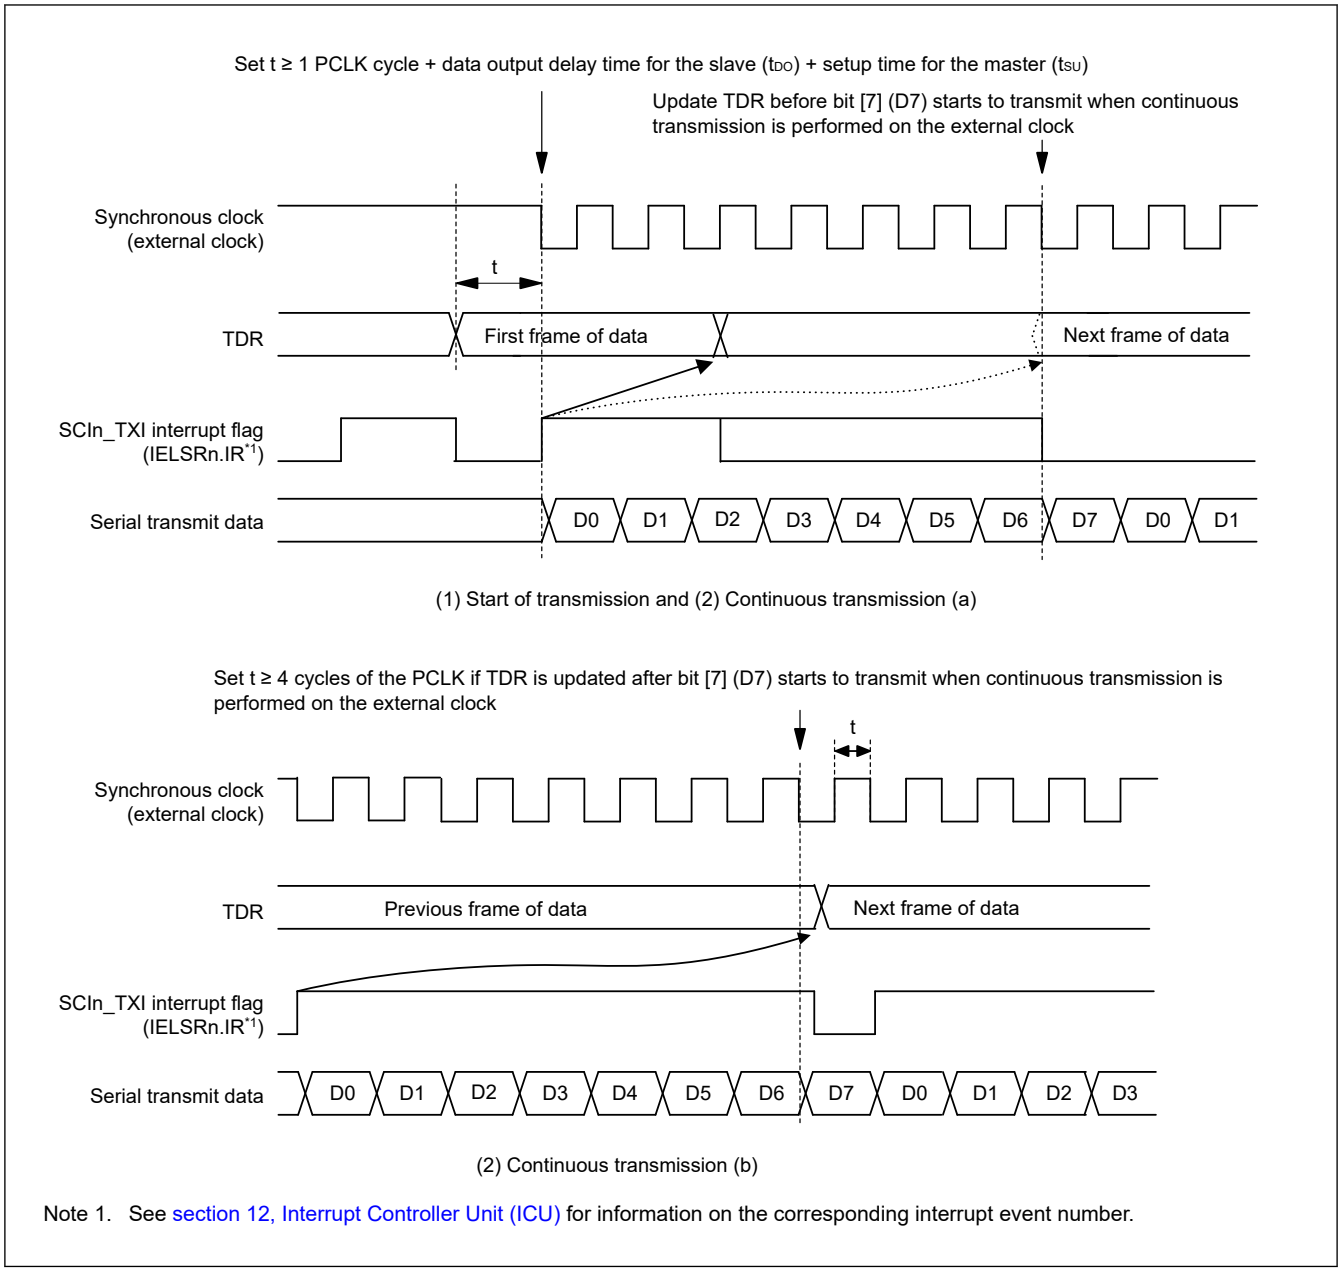
Note: The receive error flags cannot be set to 0 when the RE bit in SCR/SCR_SMCI is set to 0 (serial reception is disabled).

Note 1. Do not use the FTDRH register in simple SPI mode.

### 26.16.6 Restrictions on Clock Synchronous Transmission in Clock Synchronous Mode and Simple SPI Mode

When the external clock source is used as a synchronization clock, the following restrictions apply.

#### (1) Start of transmission



Wait at least the following time from writing transmit data to TDR to the start of the external clock input:

1 PCLK cycle + data output delay time for the slave ($t_{DO}$) + setup time for the master ($t_{SU}$). See Figure 26.123.

#### (2) Continuous transmission

Write the next transmit data to TDR or TDRHL before the falling edge of the transmit clock for bit [7] . See Figure 26.123.

When updating TDR after bit [7] has started to transmit, update TDR while the synchronization clock is in the low-level period, and set the high-level width of the transmit clock (bit [7]) to 4 PCLK cycles or longer. See Figure 26.123.

Note 1. See section 12, Interrupt Controller Unit (ICU) for information on the corresponding interrupt event number.

**Figure 26.123 Restraints on use of external clock in clock synchronous transmission**

## 26.16.7 Restrictions on Using DTC or DMAC

During transmission or reception operations using the DTC or DMAC, do not set transfer data for the DTC or DMAC.

### (1) Writing data to TDR (FTDRHL)

#### Non-FIFO selected

Data can be written to TDR and TDRHL. However, if new data is written to TDR or TDRHL when transmit data remains in TDR or TDRHL, the previous data in TDR and TDRHL is lost because it was not transferred to TSR yet. When using DTC or DMAC, always write transmit data to TDR or TDRHL in the SCIn_TXI interrupt request handling routine.

#### FIFO selected

It is possible to write data to the FTDRH and FTDRL registers when SCR.TE is 1. Confirm the amount of writable data using the FDR.T[4:0] bits.

### (2) Reading data from RDR (FRDRHL)

When using the DTC or DMAC to read RDR and RDRHL, always set the receive data full interrupt (SCIn_RXI) as the activation source of the relevant SCI.

## 26.16.8 Notes on Starting Transfer

At the point where transfer starts when the interrupt status flag (IELSRn.IR flag) in the ICU is 1, follow the procedure in this section to clear interrupt requests before permitting operations (by setting the SCR/SCR_SMCI.TE or SCR/SCR_SMCI.RE bit to 1). For details on the interrupt status flag, see section 12, Interrupt Controller Unit (ICU).

1. Confirm that transfer has stopped (the SCR/SCR_SMCI.TE or SCR/SCR_SMCI.RE bit is 0)
2. Set the associated interrupt enable bit (SCR/SCR_SMCI.TIE or SCR/SCR_SMCI.RIE bit) to 0
3. Read the associated interrupt enable bit (SCR/SCR_SMCI.TIE or SCR/SCR_SMCI.RIE bit) to check that it actually becomes 0
4. Set the interrupt status flag, IELSRn.IR, in the ICU to 0

## 26.16.9 External Clock Input in Clock Synchronous Mode and Simple SPI Mode

In clock synchronous mode and simple SPI mode, the external clock SCKn must be input as follows:

High-pulse period, low-pulse period = 2 PCLK cycles or more, period = 6 PCLK cycles or more.

## 26.16.10 Limitations on Simple SPI Mode

### (1) Master mode

- Use a resistor to pull up or pull down the clock line matching the initial settings for the transfer clock set in the SPMR.CKPH and CKPOL bits when the SPMR.SSE bit is 1.

  This prevents the clock line from being placed in the high-impedance state when the SCR.TE bit is set to 0 or unexpected edges from being generated on the clock line when the SCR.TE bit changes from 0 to 1. When the SPMR.SSE bit is 0 in single master mode, pulling up or pulling down the clock line is not required because the clock line is not placed in the high-impedance state even when the SCR.TE bit is set to 0.
- For the clock delay setting (SPMR.CKPH bit is 1), the receive data full interrupt (SCIn_RXI) is generated before the final clock edge on the SCKn pin as indicated in Figure 26.124. If the TE and RE bits in the SCR register become 0 before the final edge of the clock signal on the SCKn pin, the SCKn pin is placed in the high-impedance state, so the width of the last clock pulse of the transfer clock is shortened. Additionally, an SCIn_RXI interrupt might lead to the input signal on the SSn pin of a connected slave going to the high level before the final edge of the clock signal on the SCKn pin, leading to incorrect operation of the slave.
- In a multi-master configuration, the SCKn pin output goes to high-impedance while the input on the SSn pin is at the low level if a mode fault error occurs while a character is being transferred, stopping supply of the clock signal to the connected slave. Reset the connected slave to avoid misaligned bits when transfer is restarted.

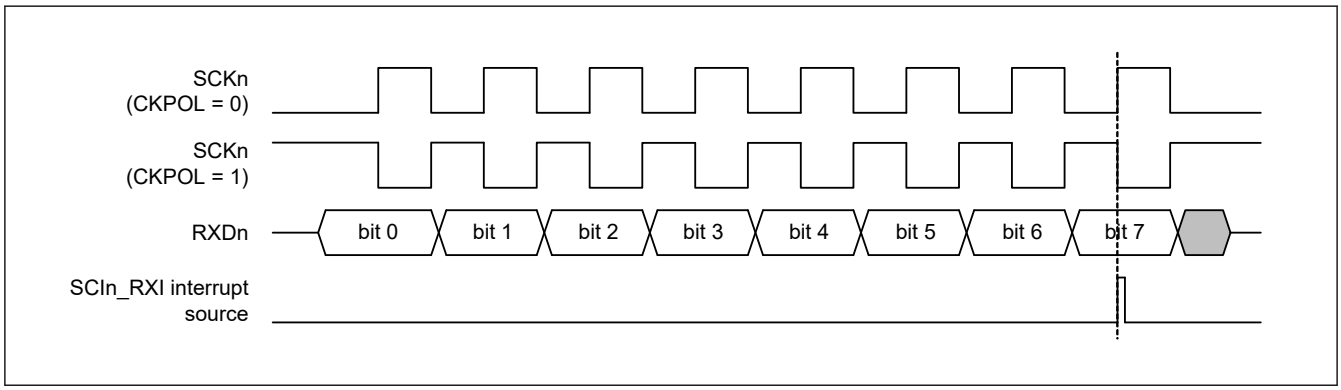


**Figure 26.124 Timing of SCIn_RXI interrupt in simple SPI mode with clock delay**

### (2) Slave mode

- Wait at least the following time from writing transmit data in the TDR register to the start of the external clock input.

  1 PCLK cycle + data output delay for the slave ($t_{DO}$) + setup time for the master ($t_{SU}$)

  Also wait at least 5 PCLK cycles from the input of the low level on the SSn pin to the start of the external clock input.
- Provide an external clock signal to the master the same as the data length for transfer
- Control the input on the SSn pin before the start and after the end of data transfer
- When the input level on the SSn pin is to be changed from low to high while a character is being transferred, set the TE and RE bits in the SCR register to 0 and, after restoring the settings, restart transfer of the first byte

## 26.16.11 Notes on Transmit Enable Bit (SCR.TE)

In initial register value, when SCR.TE = 0, the state of the TXDn pin is high impedance. The TXDn line should not be high impedance by the following one of ways.

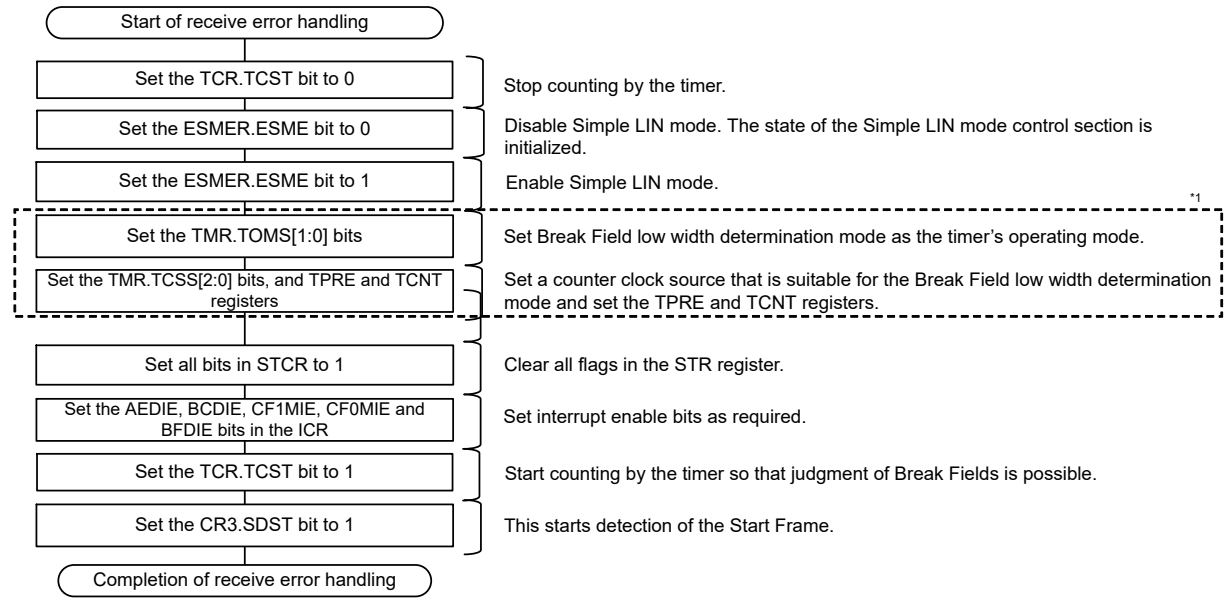
1. The pull-up resistance is connected to the TXDn line.
2. Before setting the SCR.TE bit to 0, the function of the pin should be changed to a general-purpose output port. After that, set the SCR.TE bit to 1, and then change the function of the pin to TXDn.
3. In asynchronous mode, set SPTR and decided level of TXDn pin during SCR.TE = 0.

In the Simple SPI mode slave operation, the MISOn pin operates in the same way as the above TXDn pin. The MISOn pin, the same as TXDn pin, should not be high impedance by the above list number 1 or list number 2.

## 26.16.12 Limitation 1 on Usage of the Simple LIN Mode Control Section

When the PCR.SHARPS bit is set to 1, output on the TXDXn/RXDXn (n = 1) pin is only possible when the following conditions apply.

- The timer of the SCIn module is in Break Field low width output mode and the value of the TCR.TCST bit is 1 (when the TCST bit is set to 1, the high level continues to be output for up to one cycle of the clock source for counting by the timer counter before output of the low level)
- The value of the SCIn.SCR.TE bit is 1.



## 26.16.13 Limitation 2 on Usage of the Simple LIN Mode Control Section

SCIn_ERI, SCIn_RXI, SCIn_TXI and SCIn_TEI (n = 1) are generated even if the Simple LIN mode is enabled. However, these interrupts should not be used during reception of a Start Frame.

The two ways of handling this limitation are described as follows.

1. Set the SCR.RIE bit of the SCIn to 0 to disable the output of interrupt requests. Check the error flags in the SSR register for SCIn on completion of the reception of a Start Frame, because an ERI interrupt is not generated if a receive error occurs. After reception of the Start Frame is completed, set the SCR.RIE bit of the SCIn to 1 by the time the first byte of the Information Frame is received.
2. Set the SCR.RIE bit of the SCIn to 1 to disable RXI interrupts and enable ERI interrupts for ICU.
   Clear the IRn.IR flag to enable the acceptance of RXI interrupts by ICU by the time the first byte of the Information Frame is received after the completion of Start Frame reception.

When a receive error is detected, clear the error flag of the SCIn and initialize the control section of the SCIn according to Figure 26.125.

Note 1. The setting in this step is not necessary if the setting conditions have not been changed.

**Figure 26.125 Example flowchart for receive error handling (during reception of the Start Frame)**

## 26.16.14 Note on Stopping Reception When Using the RTS Function in Asynchronous Mode

One clock cycle of PCLK is required for the time from setting the SCR.RE bit to 0 to stopping the RTS signal generator in asynchronous mode.

When reading the RDR (or RDRHL) register after setting the SCR.RE bit to 0, confirm that the SCR.RE bit has been set to 0 before reading the RDR (or RDRHL) register to prevent these two processes from being performed consecutively.

# 27. IrDA Interface (IrDA)

## 27.1 Overview

The IrDA (Infrared Data Association) interface sends and receives IrDA data communication waveforms in association with SCI5 based on the IrDA standard 1.0.

Enabling the IrDA function by setting the IRE bit in the IRCR register allows encoding and decoding the TXD5 and RXD5 signals of SCI5 to the waveforms conforming to the IrDA standard 1.0 (IRTXD5 and IRRXD5 pins). Connecting the waveforms to an infrared transmitter/receiver implements infrared data communication that conforms to the IrDA standard 1.0 system.

With the IrDA standard 1.0 system, data transfer can be started at 9600 bps and the transfer rate can be changed whenever necessary. Because the IrDA interface cannot change the transfer rate automatically, the transfer rate should be changed through software.

Figure 27.1 shows the association between the IrDA interface and SCI5.

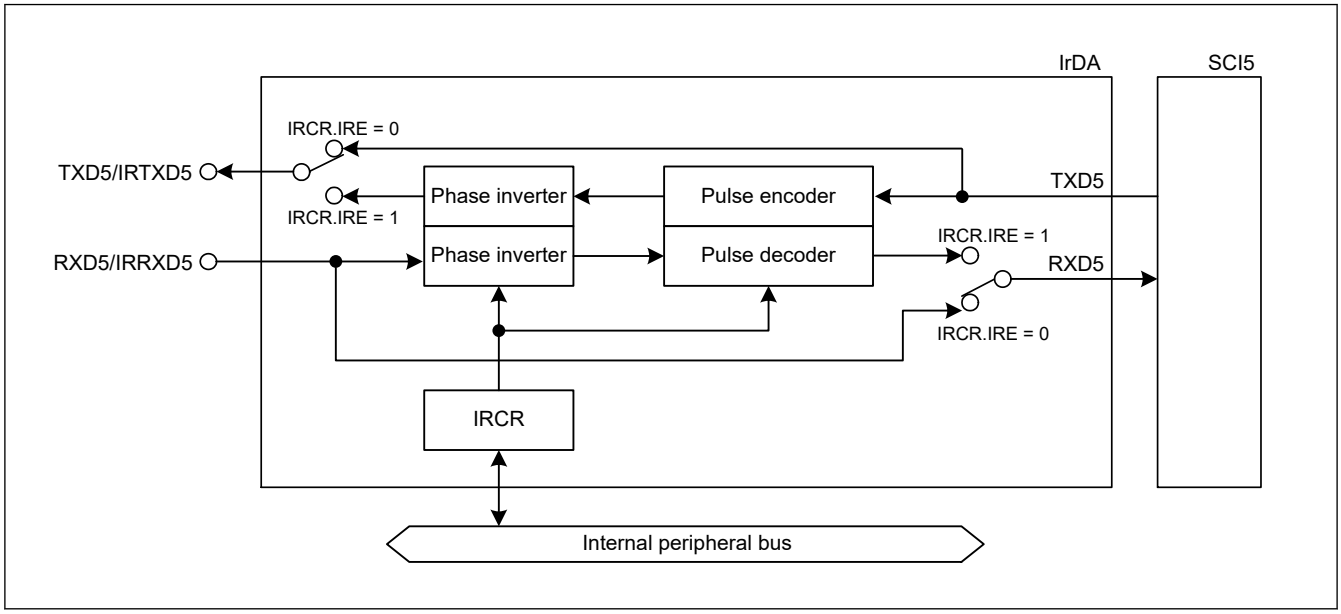


**Figure 27.1 Association between the IrDA interface and SCI5**

**Table 27.1 IrDA I/O pins**

| Pin name | I/O | Description |
|---|---|---|
| IRTXD5 | Output | Transmitted data |
| IRRXD5 | Input | Received data |

## 27.2 Register Descriptions

### 27.2.1 IRCR : IrDA Control Register

Base address: SCI5 = 0x4011_8500

Offset address: 0xA00

| Bit position: | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|
| Bit field: | IRE | — | — | — | IRTXINV | IRRXINV | — | — |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 1:0 | — | These bits are read as 0. The write value should be 0. | R/W |
| 2 | IRRXINV | IRRXD Polarity Switching<br>0: Use input from IRRXD pin as received data as is<br>1: Use input from IRRXD pin as received data after the polarity is inverted | R/W |
| 3 | IRTXINV | IRTXD Polarity Switching<br>0: Output transmitted data to IRTXD pin as is<br>1: Output transmitted data to IRTXD pin after the polarity is inverted | R/W |
| 6:4 | — | These bits are read as 0. The write value should be 0. | R/W |
| 7 | IRE | IrDA Enable<br>0: Use serial input/output pins for normal serial communication<br>1: Use serial input/output pins for IrDA data communication | R/W |

**IRRXINV bit (IRRXD Polarity Switching)**

The IRRXINV bit inverts the logic level of the input from IRRXD pin.

**IRTXINV bit (IRTXD Polarity Switching)**

The IRTXINV bit inverts the logic level of the output to IRTXD pin.

**IRE bit (IrDA Enable)**

The IRE bit configures the I/O pins for normal communication mode or IrDA data communication mode.

## 27.3 Operation

### 27.3.1 IrDA Interface Setup Procedure

Use the following procedure to set up the IrDA interface for operation:

1. Set the associated pins to IRTXD5 and IRRXD5 in the Port mn Pin Function Select Register (PmnPFS.PSEL[4:0] = 00101b) of the I/O port function.
2. Specify the peripheral function in the Port mn Pin Function Select Register (PmnPFS.PMR = 1) of the I/O port function.
3. Specify the IrDA function in the IRCR register.
4. Set the SCI5-related registers of the Serial Communications Interface (SCI).

### 27.3.2 Transmission

During transmission, the signals output from the SCI5 (UART frames) are converted to the IR frame data through the IrDA interface, see Figure 27.2. When the IRCR.IRTXINV bit is 0 and serial data is 0, high-level pulses with 3/16 the width of the bit cycle (1-bit width period) are output (initial setting). The IrDA standard requires that the minimum high-level pulse width must be 1.41 µs. When the serial data is 1, no pulses are output.

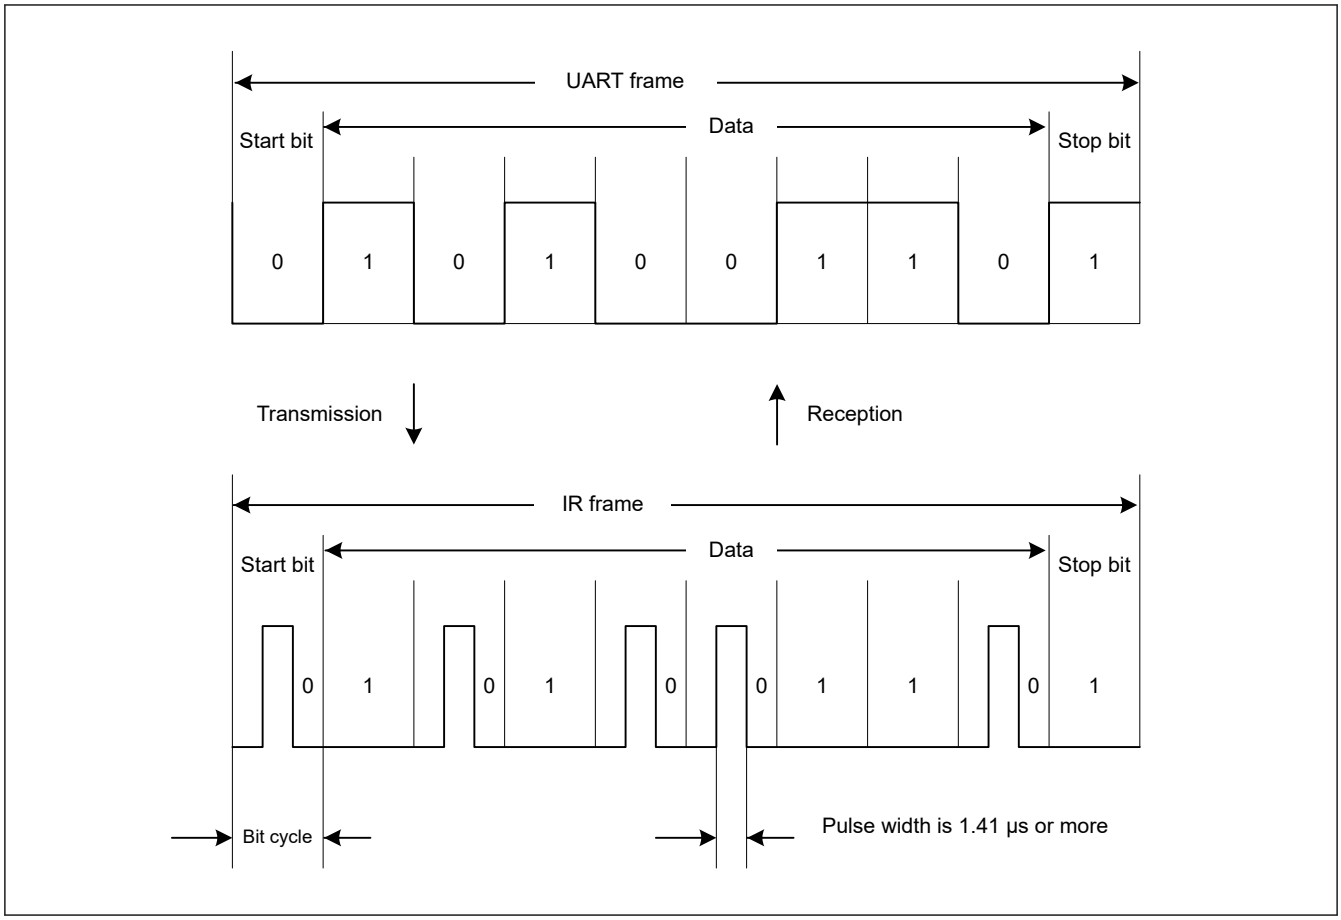

**Figure 27.2 Transmission and reception through the IrDA interface**

### 27.3.3 Reception

During reception, the IR frame data is converted to the UART frame data through the IrDA interface and is input to the SCI5. Low-level data is input to the SCI5 when the IRCR.IRRXINV bit is 0 and a high-level pulse is detected. High-level data is input to the SCI5 when no pulse is detected for a 1-bit period.

## 27.4 Usage Notes

### 27.4.1 Settings for the Module-Stop Function

The Module Stop Control Register B (MSTPCRB) can enable or disable IrDA operation. The IrDA is initially stopped after reset. Releasing the module-stop state enables access to the registers. For details, see section 10, Low Power Modes.

### 27.4.2 Asynchronous Reference Clock for SCI5

The IrDA receives a clock with frequency 16 times the bit rate from the SCI5 and operates in conjunction with the SCI5. When using the IrDA, set the SCI5.SEMR.ABCSE, SCI5.SEMR.ABCS, and SCI5.SEMR.BGDM bits to 0.

# 28. I²C Bus Interface (IIC)

## 28.1 Overview

The I²C bus interface (IIC) has 1 channel. The IIC module conforms with and provides a subset of the NXP I²C (Inter-Integrated Circuit) bus interface functions.

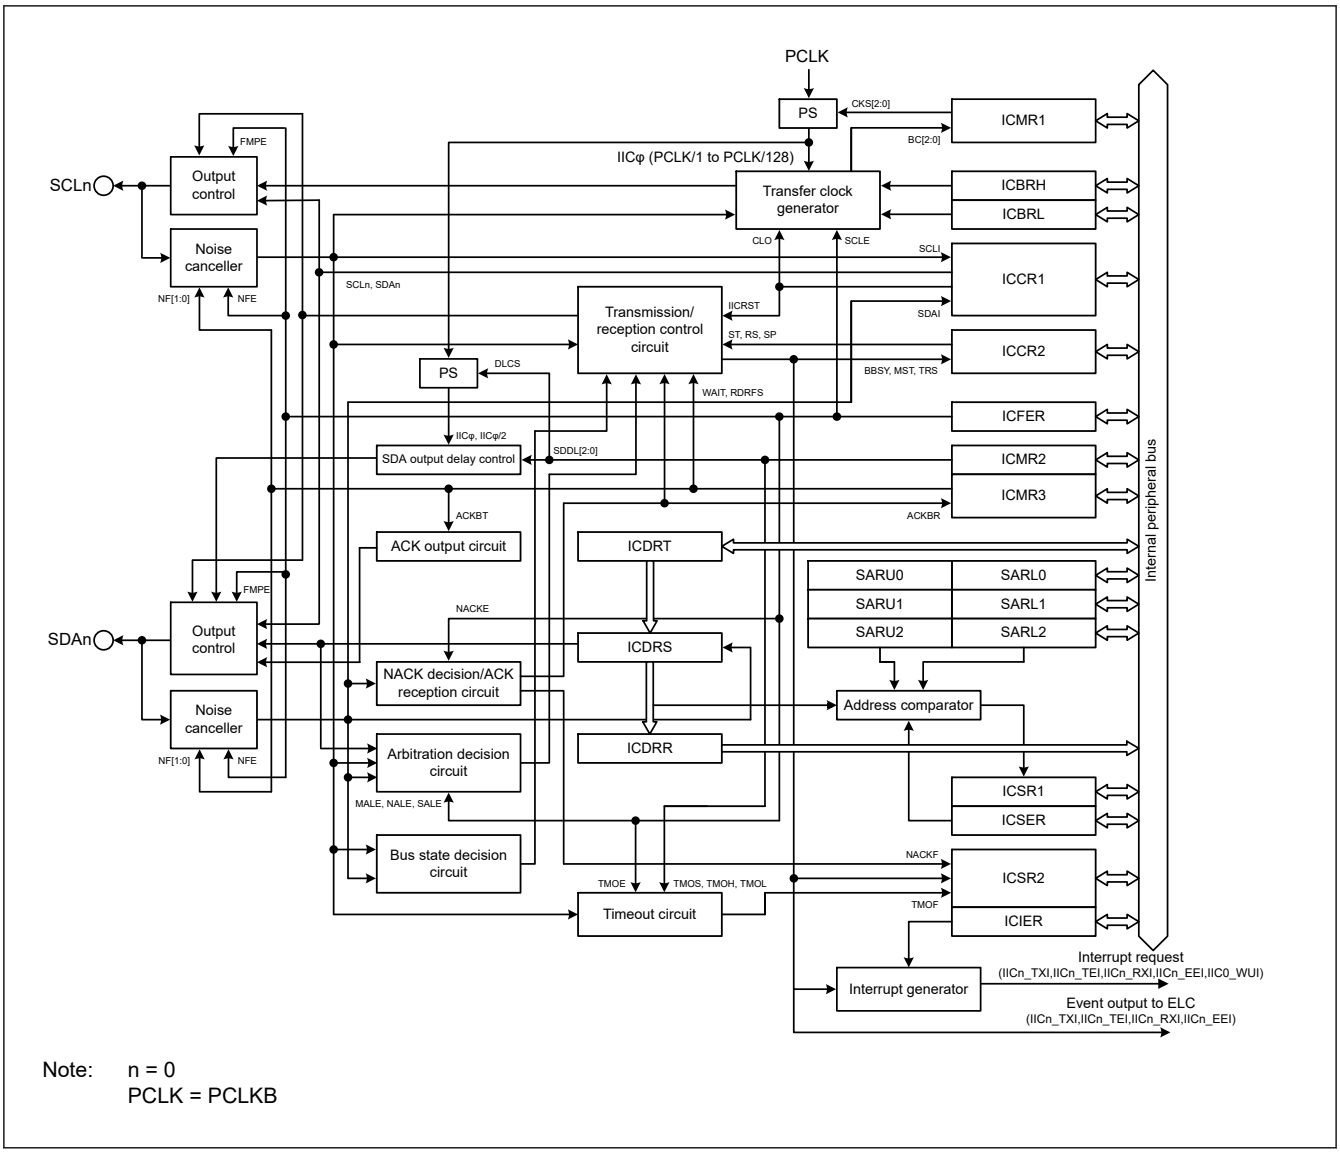

Table 28.1 lists the IIC specifications, Figure 28.1 shows a block diagram, and Figure 28.2 shows an example of I/O pin connections to external circuits, with an I²C bus configuration. Table 28.2 lists the I/O pins.

**Table 28.1 IIC specifications (1 of 2)**

| Parameter | Specifications |
|---|---|
| Communications format | • I²C-bus format or SMBus format<br>• Master or slave mode selectable<br>• Automatic securing of the setup times, hold times, and bus-free times for the transfer rate |
| Transfer rate | • Fast-mode Plus supported, up to 1 Mbps |
| SCL clock | For master operation, the duty cycle of the SCL clock is selectable in the range from 4% to 96% |
| Issuing and detecting conditions | • Start, restart, and stop conditions are automatically generated<br>• Start conditions (including restart conditions) and stop conditions are detectable |
| Slave address | • Configurable for up to three different slave addresses<br>• 7- and 10-bit address formats supported, including simultaneous use<br>• General call addresses, device ID addresses, and SMBus host addresses detectable |
| Acknowledgment | • For transmission, automatic loading of the acknowledge bit<br>Transfer of the next transmit data can be automatically suspended on detection of a not-acknowledge bit.<br>• For reception, automatic transmission of the acknowledge bit<br>If a wait between the 8th and 9th clock cycles is selected, the software can control the value in the acknowledge field in response to the received value. |
| Wait function | During reception, the following wait periods are available by holding the SCL clock low:<br>• Waiting between the 8th and 9th clock cycles<br>• Waiting between the ninth clock cycle and the 1st clock cycle of the next transfer |
| SDA output delay function | Output timing of transmitted data, including the acknowledge bit, can be delayed |
| Arbitration | • For multi-master operation:<br>– SCL clock synchronization is possible when conflict occurs with the SCL signal from another master<br>– When issuing the start condition creates conflict on the bus, loss of arbitration is detected by testing for a mismatch between the internal signal for the SDA line and the level on the SDA line<br>– In master operation, loss of arbitration is detected by testing for non-matching between the signal on the SDA line and the internal signal for the SDA line<br>• Loss of arbitration because the start condition occurs while the bus is busy is detectable, to prevent the issuing of double start conditions<br>• Loss of arbitration is detectable on transfer of a not-acknowledge bit because the internal signal for the SDA line and the level on the SDA line do not match<br>• Loss of arbitration because a mismatch of internal and line levels for data is detectable in slave transmission |
| Timeout function | Internal detection of long-interval stops of the SCL clock |
| Noise cancellation | • Digital noise filters for both the SCL and SDA signals<br>• Programmable window for noise cancellation by the filters |
| Interrupt sources | • Transfer error or event occurrence (arbitration-lost, NACK, timeout, start or restart condition, or stop condition)<br>• Receive data full, including matching with a slave address<br>• Transmit data empty, including matching with a slave address<br>• Transmit end |
| Module-stop function | Module-stop state can be set |
| IIC operating modes | • Master transmit<br>• Master receive<br>• Slave transmit<br>• Slave receive |

**Table 28.1 IIC specifications (2 of 2)**

| Parameter | Specifications |
|---|---|
| Event link function (output) | • Transfer error or event occurrence (arbitration-lost, NACK, timeout, start or restart condition, or stop condition)<br>• Receive data full, including matching with a slave address<br>• Transmit data empty, including matching with a slave address<br>• Transmit end |
| Wakeup function | CPU can return from Software Standby mode using a wakeup event |
| TrustZone Filter | Security attribution can be set for each channels |

Note: n = 0
PCLK = PCLKB

**Figure 28.1 IIC block diagram**

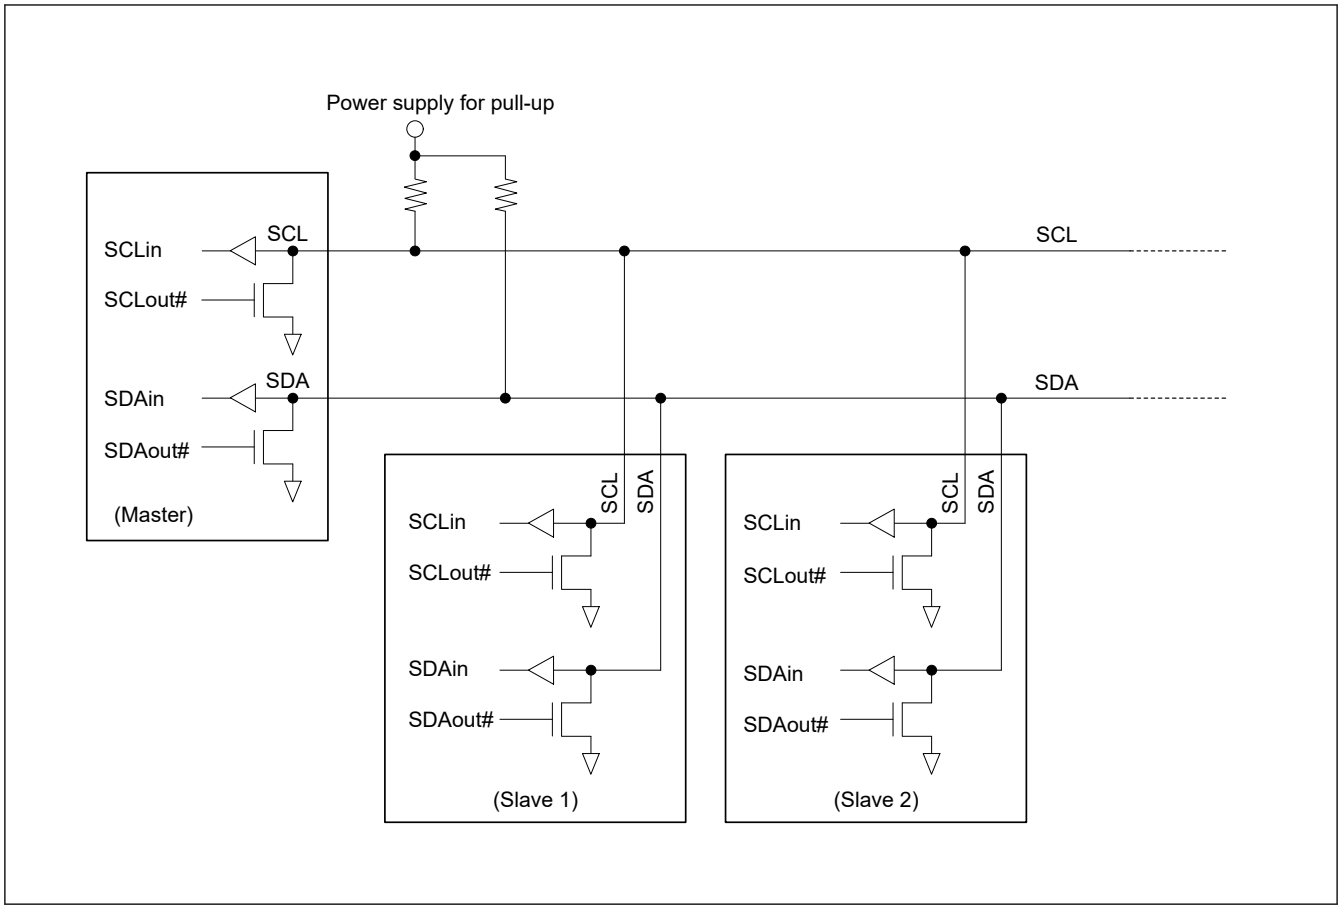

**Figure 28.2 I/O pin connection to an external circuit ($I^2C$ bus configuration example)**

The input level of the signals for IIC is CMOS when $I^2C$ bus is selected (ICMR3.SMBS = 0), or TTL when SMBus is selected (ICMR3.SMBS = 1).

**Table 28.2 IIC I/O pins**

| Channel | Pin name | I/O | Function |
|---|---|---|---|
| IIC0 | SCL0 | I/O | IIC0 serial clock I/O pin |
| | SDA0 | I/O | IIC0 serial data I/O pin |

## 28.2 Register Descriptions

### 28.2.1 ICCR1 : $I^2C$ Bus Control Register 1

Base address: IIC0 = 0x4009_F000

Offset address: 0x00

| Bit position: | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|
| Bit field: | ICE | IICRST | CLO | SOWP | SCLO | SDAO | SCLI | SDAI |
| Value after reset: | 0 | 0 | 0 | 1 | 1 | 1 | 1 | 1 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 0 | SDAI | SDA Line Monitor<br>0: SDA0 line is low<br>1: SDA0 line is high | R |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 1 | SCLI | SCL Line Monitor<br>0: SCL0 line is low<br>1: SCL0 line is high | R |
| 2 | SDAO | SDA Output Control/Monitor<br>0: Read: IIC drives SDA0 pin low<br>Write: IIC drives SDA0 pin low<br>1: Read: IIC releases SDA0 pin<br>Write: IIC releases SDA0 pin | R/W |
| 3 | SCLO | SCL Output Control/Monitor<br>Use an external pull-up resistor to drive the signal high.<br>0: Read: IIC drives SCL0 pin low<br>Write: IIC drives SCL0 pin low<br>1: Read: IIC releases SCL0 pin<br>Write: IIC releases SCL0 pin | R/W |
| 4 | SOWP | SCLO/SDAO Write Protect<br>This bit is read as 1.<br>0: Write enable SCLO and SDAO bits<br>1: Write protect SCLO and SDAO bits | W |
| 5 | CLO | Extra SCL Clock Cycle Output<br>This bit clears automatically after 1 clock cycle is output.<br>0: Do not output extra SCL clock cycle (default)<br>1: Output extra SCL clock cycle | R/W |
| 6 | IICRST | I2C Bus Interface Internal Reset<br>This setting clears the bit counter and the SCL0/SDA0 output latch.<br>0: Release IIC reset or internal reset<br>1: Initiate IIC reset or internal reset | R/W |
| 7 | ICE | I2C Bus Interface Enable<br>Used in combination with the IICRST bit to select either IIC or internal reset.<br>0: Disable (SCL0 and SDA0 pins in inactive state)<br>1: Enable (SCL0 and SDA0 pins in active state) | R/W |

### SDAO bit (SDA Output Control/Monitor) and SCLO bit (SCL Output Control/Monitor)

The SDAO and SCLO bits directly control the SDA0 and SCL0 signals output from the IIC. When writing to these bits, also write 0 to the SOWP bit. Setting these bits results in input to the IIC by the input buffer. When slave mode is selected, a start condition might be detected and the bus might be released, depending on the bit settings.

Do not rewrite these bits during a start condition, stop condition, restart condition, transmission, or reception. Operation after rewriting under these conditions is not guaranteed. When reading these bits, the state of signals output from the IIC can be read.

### CLO bit (Extra SCL Clock Cycle Output)

The CLO bit allows output of an extra SCL clock cycle for debugging or error processing. Normally, set this bit to 0. Setting the bit to 1 in a normal communication state causes a communication error. For details on this function, see section 28.12.2. Extra SCL Clock Cycle Output Function.

### IICRST bit (I2C Bus Interface Internal Reset)

The IICRST bit initiates an internal state reset of the IIC. Setting this bit to 1 initiates an IIC reset or internal reset. Whether an IIC reset or internal reset is initiated is determined by the settings of this bit in combination with the ICE bit. Table 28.3 lists the IIC resets.

The IIC reset initializes all registers except ICCR1.ICE and ICCR1.IICRST bits and internal states of the IIC. In addition to the internal states of the IIC, the internal reset initializes the following:

- Bit counter (ICMR1.BC[2:0] bits)
- I2C Bus Shift Register (ICDRS)
- I2C Bus Status Registers (ICSR1 and ICSR2)
- SDAO and SCLO Output Control/Monitor (ICCR1.SDAO and ICCR1.SCLO bits)

- I²C Bus Control Register 2 (except ICCR2.BBSY bit)

For the reset conditions for each register, see section 28.15. State of Registers When Issuing Each Condition.

An internal reset initiated with the IICRST bit set to 1 during operation (with the ICE bit set to 1) resets the internal states of the IIC without initializing the port settings and the control and setting registers of the IIC. If the IIC hangs in a low-level output state, resetting the internal states cancels the low-level output state and releases the bus with the SCL0 pin and SDA0 pin at high impedance.

Note: If an internal reset is initiated using the IICRST bit for a bus hang-up that occurs during communication with the master device in slave mode, the slave and master devices might enter different states, because the bit counter information differs. For this reason, do not initiate an internal reset in slave mode. Initiate recovery processing from the master device. If an internal reset is required because the IIC hangs with the SCL0 line in a low-level output state in slave mode, initiate an internal reset, then issue a restart condition from the master device, or issue a stop condition and resume communication from the start condition. If communication is restarted by initiating a reset solely in the slave device without issuing a start or restart condition from the master device, synchronization is lost because the master and slave devices operate asynchronously.

**Table 28.3 IIC resets**

| IICRST | ICE | State | Specifications |
|---|---|---|---|
| 1 | 0 | IIC reset | Resets all registers except ICCR1.IICRST and ICCR1.ICE bits, and the internal states of the IIC |
| | 1 | Internal reset | Reset the following:<br>• ICMR1.BC[2:0] bits<br>• ICSR1, ICSR2, ICDRS registers<br>• SDAO and SCLO Output Control/Monitor (ICCR1.SDAO and ICCR1.SCLO bits)<br>• I²C Bus Control Register 2 (except ICCR2.BBSY bit)<br>• Internal states of the IIC |

### ICE bit (I²C Bus Interface Enable)

The ICE bit selects the active or inactive state of the SCL0 and SDA0 pins. It can also be combined with the IICRST bit to initiate two types of resets. See Table 28.3 for the reset descriptions.

Set the ICE bit to 1 when using the IIC. The SCL0 and SDA0 pins are placed in the active state when the ICE bit is set to 1. Set the ICE bit to 0 when the IIC is not used. The SCL0 and SDA0 pins are placed in the inactive state when the ICE bit is set to 0. Do not assign the SCL0 or SDA0 pin to the IIC when setting up the pin function control. Slave address comparison is performed if the pins are assigned to the IIC.

## 28.2.2 ICCR2 : I²C Bus Control Register 2

Base address: IIC0 = 0x4009_F000

Offset address: 0x01

| Bit position: | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|
| Bit field: | BBSY | MST | TRS | — | SP | RS | ST | — |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 0 | — | This bit is read as 0. The write value should be 0. | R/W |
| 1 | ST | Start Condition Issuance Request<br>0: Do not issue a start condition request<br>1: Issue a start condition request | R/W |
| 2 | RS | Restart Condition Issuance Request<br>0: Do not issue a restart condition request<br>1: Issue a restart condition request | R/W |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 3 | SP | Stop Condition Issuance Request<br>0: Do not issue a stop condition request<br>1: Issue a stop condition request | R/W |
| 4 | — | This bit is read as 0. The write value should be 0. | R/W |
| 5 | TRS | Transmit/Receive Mode<br>0: Receive mode<br>1: Transmit mode | R/W*1 |
| 6 | MST | Master/Slave Mode<br>0: Slave mode<br>1: Master mode | R/W*1 |
| 7 | BBSY | Bus Busy Detection Flag<br>0: I2C bus released (bus free state)<br>1: I2C bus occupied (bus busy state) | R |

Note 1. The MST and TRS bits can be written to when the ICMR1.MTWP bit is set to 1.

### ST bit (Start Condition Issuance Request)

The ST bit requests transition to master mode and triggers a start condition. When this bit is set to 1, a start condition is issued when the BBSY flag is set to 0 (bus free state). For details on this function, see section 28.11. Start, Restart, and Stop Condition Issuing Function.

[Setting condition]

- When 1 is written to the ST bit.

[Clearing conditions]

- When 0 is written to the ST bit
- When a start condition is issued (a start condition is detected)
- When the AL (arbitration-lost) flag in ICSR2 is set to 1
- When 1 is written to the IICRST bit in ICCR1 to apply an IIC reset or an internal reset.

Note: Only set the ST bit to 1 (start condition request) when the BBSY flag is set to 0 (bus free state). Arbitration might be lost if the ST bit is set to 1 (start condition request) when the BBSY flag is 1 (bus busy state).

### RS bit (Restart Condition Issuance Request)

The RS bit requests that a restart condition be issued in master mode. When this bit is set to 1 to request a restart condition, a restart condition is issued when the BBSY flag is set to 1 (bus busy state) and the MST bit is set to 1 (master mode). For details on this function, see section 28.11. Start, Restart, and Stop Condition Issuing Function.

[Setting condition]

- When 1 is written to the RS bit with the BBSY flag in ICCR2 set to 1.

[Clearing conditions]

- When 0 is written to the RS bit
- When a restart condition is issued (a start condition is detected)
- When the AL (arbitration-lost) flag in ICSR2 is set to 1
- When 1 is written to the IICRST bit in ICCR1 to apply an IIC reset or an internal reset.

Note: Do not set the RS bit to 1 while issuing a stop condition.
Note: If 1 (restart condition request) is written to the RS bit in slave mode, the restart condition is not issued, but the RS bit remains set to 1. If the operating mode changes to master mode without the bit being cleared, a restart condition might be issued.

### SP bit (Stop Condition Issuance Request)

The SP bit requests that a stop condition be issued in master mode. When this bit is set to 1, a stop condition is issued when the BBSY flag is set to 1 (bus busy state) and the MST bit is set to 1 (master mode). For details on this function, see section 28.11. Start, Restart, and Stop Condition Issuing Function.

[Setting condition]

- When 1 is written to the SP bit with both the BBSY flag and the MST bit in ICCR2 set to 1.

[Clearing conditions]

- When 0 is written to the SP bit
- When a stop condition is issued (a stop condition is detected)
- When the AL (arbitration-lost) flag in ICSR2 is set to 1
- When a start condition and a restart condition are detected
- When 1 is written to the IICRST bit in ICCR1 to apply an IIC reset or an internal reset.

Note: Writing to the SP bit is not possible while the BBSY flag is 0 (bus free state).
Note: Do not set the SP bit to 1 while a restart condition is being issued.

### TRS bit (Transmit/Receive Mode)

The TRS bit indicates transmit or receive mode. The IIC is in receive mode when the TRS bit is 0 and in transmit mode when the bit is 1. The combination of this bit and the MST bit indicates the IIC operating mode.

The value of the TRS bit automatically changes to 1 for transmit mode or 0 for receive mode when a start condition is issued or detected and the R/W# bit is set. Although writing to the TRS bit is possible when the MTWP bit in ICMR1 is set to 1, writing to this bit is not required during normal usage.

[Setting conditions]

- When a start condition is issued normally because of a start condition request (when a start condition is detected with the ST bit set to 1)
- When a restart condition is issued normally because of a restart condition request (when a restart condition is detected with the RS bit set to 1)
- When the R/W# bit appended to the slave address is set to 0 in master mode
- When the address received in slave mode matches the address enabled in ICSER, with the R/W# bit set to 1
- When 1 is written to the TRS bit with the MTWP bit in ICMR1 set to 1.

[Clearing conditions]

- When a stop condition is detected
- When the AL (arbitration-lost) flag in ICSR2 is set to 1
- When the R/W# bit appended to the slave address is set to 1 in master mode
- In slave mode, on a match between the received address and the address enabled in ICSER when the value of the received R/W# bit is 0, including when the received address is the general call address
- In slave mode, when a restart condition is detected (a restart condition is detected with ICCR2.BBSY = 1 and ICCR2.MST = 0)
- When 0 is written to the TRS bit with the MTWP bit in ICMR1 set to 1
- When 1 is written to the IICRST bit in ICCR1 to apply an IIC reset or an internal reset.

### MST bit (Master/Slave Mode)

The MST bit indicates master or slave mode. The IIC is in slave mode when the MST bit is 0 and is in master mode when the bit is 1. The combination of this bit and the TRS bit indicates the IIC operating mode.

The value of the MST bit automatically changes to 1 for master mode or 0 for slave mode when a start condition is issued or a stop condition is issued or detected. Although writing to the MST bit is possible when the MTWP bit in ICMR1 is set to 1, writing to this bit is not required during normal usage.

[Setting conditions]

- When a start condition is issued normally because of a start condition request (when a start condition is detected with the ST bit set to 1)
- When 1 is written to the MST bit with the MTWP bit in ICMR1 set to 1.

[Clearing conditions]

- When a stop condition is detected
- When the AL (arbitration-lost) flag in ICSR2 is set to 1
- When 0 is written to the MST bit with the MTWP bit in ICMR1 set to 1
- When 1 is written to the IICRST bit in ICCR1 to apply an IIC reset or an internal reset.

### BBSY flag (Bus Busy Detection Flag)

The BBSY flag indicates whether the $I^2C$ bus is occupied (bus busy state) or released (bus free state). The flag is set to 1 when the SDA0 line changes from high to low when the SCL0 line is high, assuming that a start condition was issued. The flag is set to 0 if a start condition is not detected for the bus free time (ICBRL setting), assuming that a stop condition was issued.

[Setting condition]

- When a start condition is detected.

[Clearing conditions]

- When a start condition is not detected for the bus free time (ICBRL setting) after detecting a stop condition
- When 1 is written to the IICRST bit in ICCR1 with the ICE bit in ICCR1 set to 0 (IIC reset).

## 28.2.3 ICMR1 : $I^2C$ Bus Mode Register 1

Base address: IIC0 = 0x4009_F000

Offset address: 0x02

| Bit position: | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|
| Bit field: | MTWP | CKS[2:0] | | | BCWP | BC[2:0] | | |
| Value after reset: | 0 | 0 | 0 | 0 | 1 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 2:0 | BC[2:0] | Bit Counter<br>0 0 0: 9 bits<br>0 0 1: 2 bits<br>0 1 0: 3 bits<br>0 1 1: 4 bits<br>1 0 0: 5 bits<br>1 0 1: 6 bits<br>1 1 0: 7 bits<br>1 1 1: 8 bits | R/W*1 |
| 3 | BCWP | BC Write Protect<br>This bit is read as 1.<br>0: Write enable BC[2:0] bits<br>1: Write protect BC[2:0] bits | W*1 |
| 6:4 | CKS[2:0] | Internal Reference Clock Select<br>Select the internal reference clock source (IICφ) for the IIC.<br>IICφ = (PCLKB / $2^{CKS[2:0]}$) clock | R/W |
| 7 | MTWP | MST/TRS Write Protect<br>0: Write protect MST and TRS bits in ICCR2<br>1: Write enable MST and TRS bits in ICCR2 | R/W |

Note 1. Rewrite the BC[2:0] bits and set the BCWP bit to 0 at the same time.

### BC[2:0] bits (Bit Counter)

The BC[2:0] bits function as a counter indicating the number of bits remaining to be transferred on detection of a rising edge on the SCL0 line. Although BC[2:0] are read/write bits, it is not required to access these bits under normal conditions.

To write to these bits, specify the number of bits to be transferred plus one, for an additional acknowledge bit, between transferred frames when the SCL0 line is at a low level. The value in the BC[2:0] bits returns to 000b at the end of a data transfer, including the acknowledge bit, or when a start or restart condition is detected.

## 28.2.4 ICMR2 : I2C Bus Mode Register 2

Base address: IIC0 = 0x4009_F000

Offset address: 0x03

| Bit position: | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|
| Bit field: | DLCS | SDDL[2:0] | | | — | TMOH | TMOL | TMOS |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 1 | 1 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 0 | TMOS | Timeout Detection Time Select<br>0: Select long mode<br>1: Select short mode | R/W |
| 1 | TMOL | Timeout L Count Control<br>0: Disable count while SCL0 line is low<br>1: Enable count while SCL0 line is low | R/W |
| 2 | TMOH | Timeout H Count Control<br>0: Disable count while SCL0 line is high<br>1: Enable count while SCL0 line is high | R/W |
| 3 | — | This bit is read as 0. The write value should be 0. | R/W |
| 6:4 | SDDL[2:0] | SDA Output Delay Counter<br>0 0 0: No output delay<br>0 0 1: 1 IICφ cycle (When ICMR2.DLCS = 0 (IICφ))<br>1 or 2 IICφ cycles (When ICMR2.DLCS = 1 (IICφ/2))<br>0 1 0: 2 IICφ cycles (When ICMR2.DLCS = 0 (IICφ))<br>3 or 4 IICφ cycles (When ICMR2.DLCS = 1 (IICφ/2))<br>0 1 1: 3 IICφ cycles (When ICMR2.DLCS = 0 (IICφ))<br>5 or 6 IICφ cycles (When ICMR2.DLCS = 1 (IICφ/2))<br>1 0 0: 4 IICφ cycles (When ICMR2.DLCS = 0 (IICφ))<br>7 or 8 IICφ cycles (When ICMR2.DLCS = 1 (IICφ/2))<br>1 0 1: 5 IICφ cycles (When ICMR2.DLCS = 0 (IICφ))<br>9 or 10 IICφ cycles (When ICMR2.DLCS = 1 (IICφ/2))<br>1 1 0: 6 IICφ cycles (When ICMR2.DLCS = 0 (IICφ))<br>11 or 12 IICφ cycles (When ICMR2.DLCS = 1 (IICφ/2))<br>1 1 1: 7 IICφ cycles (When ICMR2.DLCS = 0 (IICφ))<br>13 or 14 IICφ cycles (When ICMR2.DLCS = 1 (IICφ/2)) | R/W |
| 7 | DLCS | SDA Output Delay Clock Source Select<br>0: Select internal reference clock (IICφ) as the clock source for SDA output delay counter<br>1: Select internal reference clock divided by 2 (IICφ/2) as the clock source for SDA output delay counter*1 | R/W |

Note 1. The setting DLCS = 1 (IICφ/2) is only valid when SCL is low. When SCL is high, the DLCS = 1 setting becomes invalid and the clock source becomes the internal reference clock (IICφ).

### TMOS bit (Timeout Detection Time Select)

The TMOS bit selects long or short mode for the timeout detection time when the timeout function is enabled (ICFER.TMOE = 1). When this bit is set to 0, long mode is selected. When it is set to 1, short mode is selected. In long mode, the timeout detection internal counter functions as a 16 bit-counter. In short mode, the counter functions as a 14- bit counter. While the SCL0 line is in the state that enables this counter as specified in the TMOH and TMOL bits, the counter counts up in synchronization with the internal reference clock (IICφ) as a count source. For details on this function, see section 28.12.1. Timeout Function.

### TMOL bit (Timeout L Count Control)

The TMOL bit enables or disables up-counting on the internal counter of the timeout function while the SCL0 line is held low and the timeout function is enabled (ICFER.TMOE = 1).

### TMOH bit (Timeout H Count Control)

The TMOH bit enables or disables up-counting on the internal counter of the timeout function while the SCL0 line is held high and the timeout function is enabled (ICFER.TMOE = 1).

### SDDL[2:0] bits (SDA Output Delay Counter)

The SDDL[2:0] bits can be used to delay the SDA output. This counter works with the clock source selected in the DLCS bit. This setting can be used for all types of SDA output, including transmission of the acknowledge bit.

Set the SDA output delay to meet the I2C bus standard for the data enable time/acknowledge enable time,*1 or the SMBus standard, within [data hold time (300 ns or more + the SCL clock low-level period) - the data setup time (250 ns)]. If a value outside the standard is set, communication between devices might malfunction or falsely indicate a start or stop condition, depending on the bus state.

For details on this function, see section 28.5. SDA Output Delay Function.

Note 1. Data enable time/acknowledge enable time.
3,450 ns for up to 100 kbps: Standard mode (Sm)
900 ns for up to 400 kbps: Fast mode (Fm)
450 ns for up to 1 Mbps: Fast-mode Plus (Fm+)

## 28.2.5 ICMR3 : I2C Bus Mode Register 3

Base address: IIC0 = 0x4009_F000

Offset address: 0x04

| Bit position: | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|
| Bit field: | SMBS | WAIT | RDRFS | ACKWP | ACKBT | ACKBR | NF[1:0] | |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 1:0 | NF[1:0] | Noise Filter Stage Select<br>0 0: Filter out noise of up to 1 IICφ cycle (single-stage filter)<br>0 1: Filter out noise of up to 2 IICφ cycles (2-stage filter)<br>1 0: Filter out noise of up to 3 IICφ cycles (3-stage filter)<br>1 1: Filter out noise of up to 4 IICφ cycles (4-stage filter) | R/W |
| 2 | ACKBR | Receive Acknowledge<br>0: 0 received as the acknowledge bit (ACK reception)<br>1: 1 received as the acknowledge bit (NACK reception) | R |
| 3 | ACKBT | Transmit Acknowledge<br>0: Send 0 as the acknowledge bit (ACK transmission)<br>1: Send 1 as the acknowledge bit (NACK transmission) | R/W*1 |
| 4 | ACKWP | ACKBT Write Protect<br>0: Write protect ACKBT bit<br>1: Write enable ACKBT bit | R/W |
| 5 | RDRFS | RDRF Flag Set Timing Select<br>Low-hold is released by writing to ACKBT.<br>0: Set the RDRF flag on the rising edge of the 9th SCL clock cycle. The SCL0 line is not held low on the falling edge of the 8th clock cycle.<br>1: Set the RDRF flag on the rising edge of the 8th SCL clock cycle. The SCL0 line is held low on the falling edge of the 8th clock cycle. | R/W*2 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 6 | WAIT | Low-hold is released by reading ICDRR.<br>0: No wait (the SCL0 line is not held low during the period between the 9th clock cycle and the 1st clock cycle.)<br>1: Wait (the SCL0 line is held low during the period between the 9th clock cycle and the 1st clock cycle.) | R/W*2 |
| 7 | SMBS | SMBus/I2C Bus Select<br>0: Select I2C Bus<br>1: Select SMBus | R/W |

Note 1. Write to the ACKBT bit only while the ACKWP bit is already 1. If the application writes 1 to the ACKWP and ACKBT bits at the same time, the ACKBT bit is not set to 1.
Note 2. The WAIT and RDRFS bits are only valid in receive mode (invalid in transmit mode).

### NF[1:0] bits (Noise Filter Stage Select)

The NF[1:0] bits select the number of stages in the digital noise filter. For details on this function, see section 28.6. Digital Noise Filter Circuits

Note: Set the noise range to be filtered within a range less than the SCL0 line high- or low-level period. If the noise range is set to a value of [SCL clock width: high- or low-level period, whichever is shorter] - [1.5 internal reference clock (IICφ) cycles + analog noise filter: 120 ns (reference values)] or more, the SCL clock is regarded as noise, which might prevent the IIC from operating normally.

### ACKBR bit (Receive Acknowledge)

The ACKBR bit stores the acknowledge bit information received from the receive device in transmit mode.

[Setting condition]

- When 1 is received as the acknowledge bit with the TRS bit in ICCR2 set to 1.

[Clearing conditions]

- When 0 is received as the acknowledge bit with the TRS bit in ICCR2 set to 1
- When 1 is written to the IICRST bit in ICCR1 while the ICE bit in ICCR1 is 0 (IIC reset).

### ACKBT bit (Transmit Acknowledge)

The ACKBT bit sets the acknowledge bit to be sent in receive mode

[Setting condition]

- When 1 is written to this bit with the ACKWP bit set to 1.

[Clearing conditions]

- When 0 is written to this bit with the ACKWP bit set to 1
- When stop condition request is detected with the SP bit in ICCR2 set to 1
- When 1 is written to the IICRST bit in ICCR1 while the ICE bit in ICCR1 is 0 (IIC reset).

### ACKWP bit (ACKBT Write Protect)

The ACKWP bit controls write enabling of the ACKBT bit.

### RDRFS bit (RDRF Flag Set Timing Select)

The RDRFS bit selects the RDRF flag set timing in receive mode and also selects whether to hold the SCL0 line low on the falling edge of the 8th SCL clock cycle.

When the RDRFS bit is 0, the SCL0 line is not held low on the falling edge of the 8th SCL clock cycle, and the RDRF flag is set to 1 on the rising edge of the 9th SCL clock cycle.

When the RDRFS bit is 1, the RDRF flag is set to 1 on the rising edge of the 8th SCL clock cycle, and the SCL0 line is held low on the falling edge of the 8th SCL clock cycle. The low-hold of the SCL0 line is released by a write to the ACKBT bit.

After data is received with this setting, the SCL0 line is automatically held low before the acknowledge bit is sent. This enables processing to send ACK (ACKBT = 0) or NACK (ACKBT = 1), based on the receive data.

### WAIT bit (WAIT)

The WAIT bit controls whether to force a low-hold between the ninth SCL clock cycle and the first SCL clock cycle, until the receive data buffer (ICDRR) is completely read each time single-byte data is received in receive mode.

When the WAIT bit is 0, the receive operation continues without a low-hold between the ninth and the first SCL clock cycle. When both the RDRFS and WAIT bits are 0, continuous receive operation is enabled with the double buffer.

When the WAIT bit is 1, the SCL0 line is held low from the falling edge of the ninth clock cycle until the ICDRR value is read each time single-byte data is received. This enables receive operation in byte units.

Note: When the value of the WAIT bit is to be read, always read ICDRR first.

### SMBS bit (SMBus/I2C Bus Select)

Setting the SMBS bit to 1 selects the SMBus and enables the HOAE bit in ICSER.

## 28.2.6 ICFER : I2C Bus Function Enable Register

Base address: IIC0 = 0x4009_F000

Offset address: 0x05

| Bit position: | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|
| Bit field: | FMPE | SCLE | NFE | NACKE | SALE | NALE | MALE | TMOE |
| Value after reset: | 0 | 1 | 1 | 1 | 0 | 0 | 1 | 0 |

|---|---|---|---|
| 0 | TMOE | Timeout Function Enable<br>0: Disable<br>1: Enable | R/W |
| 1 | MALE | Master Arbitration-Lost Detection Enable<br>0: Disable the arbitration-lost detection function and disable automatic clearing of the MST and TRS bits in ICCR2 when arbitration is lost<br>1: Enable the arbitration-lost detection function and enable automatic clearing of the MST and TRS bits in ICCR2 when arbitration is lost | R/W |
| 2 | NALE | NACK Transmission Arbitration-Lost Detection Enable<br>0: Disable<br>1: Enable | R/W |
| 3 | SALE | Slave Arbitration-Lost Detection Enable<br>0: Disable<br>1: Enable | R/W |
| 4 | NACKE | NACK Reception Transfer Suspension Enable<br>0: Do not suspend transfer operation during NACK reception (disable transfer suspension)<br>1: Suspend transfer operation during NACK reception (enable transfer suspension) | R/W |
| 5 | NFE | Digital Noise Filter Circuit Enable<br>0: Do not use the digital noise filter circuit<br>1: Use the digital noise filter circuit | R/W |
| 6 | SCLE | SCL Synchronous Circuit Enable<br>0: Do not use the SCL synchronous circuit<br>1: Use the SCL synchronous circuit | R/W |
| 7 | FMPE | Fast-Mode Plus Enable<br>0: Do not use the Fm+ slope control circuit for the SCL0 and SDA0 pins<br>1: Use the Fm+ slope control circuit for the SCL0 and SDA0 pins. | R/W |

### TMOE bit (Timeout Function Enable)

The TMOE bit enables or disables the timeout function. For details on this function, see section 28.12.1. Timeout Function.

### MALE bit (Master Arbitration-Lost Detection Enable)

The MALE bit specifies whether to use the arbitration-lost detection function in master mode. Normally, set this bit to 1.

### NALE bit (NACK Transmission Arbitration-Lost Detection Enable)

The NALE bit specifies whether to cause arbitration to be lost when ACK is detected during transmission of NACK in receive mode, for example when slaves with the same address exist on the bus or when two or more masters select the same slave device simultaneously with a different number of receive bytes.

### SALE bit (Slave Arbitration-Lost Detection Enable)

The SALE bit specifies whether to cause arbitration to be lost when a value different from the value being transmitted is detected on the bus in slave transmit mode, for example when slaves with the same address exist on the bus or when a mismatch with the transmit data occurs because of noise.

### NACKE bit (NACK Reception Transfer Suspension Enable)

The NACKE bit specifies whether to continue or discontinue the transfer operation when NACK is received in transmit mode. Normally, set this bit to 1.

When NACK is received with the NACKE bit set to 1, the next transfer operation is suspended. When the NACKE bit is 0, the next transfer operation continues regardless of the received acknowledge content.

For details, see section 28.9.2. NACK Reception Transfer Suspension Function.

### SCLE bit (SCL Synchronous Circuit Enable)

The SCLE bit specifies whether to synchronize the SCL clock with the SCL input clock. Normally, set this bit to 1.

When the SCLE bit is set to 0 (no SCL synchronous circuit used), the IIC does not synchronize the SCL clock with the SCL input clock. With this setting, the IIC outputs the SCL clock at the transfer rate set in ICBRH and ICBRL, regardless of the SCL0 line state. For this reason, if the bus load of the $I^2C$ bus line is much larger than the specification value, or if the SCL clock output overlaps in multiple masters, a short-cycle SCL clock that does not meet the specification might be output. When no SCL synchronous circuit is used, it also affects the issuing of the start, restart, and stop conditions, and the continuous output of extra SCL clock cycles.

Do not set this bit to 0 except when checking the output of the set transfer rate.

### FMPE bit (Fast-Mode Plus Enable)

The FMPE bit specifies whether to use a slope control circuit for Fast-mode Plus (Fm+).

When this bit is set to 1, a slope control circuit conforming to the $I^2C$ bus Fast-mode Plus (Fm+) standard (tof) is selected. When this bit is set to 0, a slope control circuit conforming to the $I^2C$ bus Standard-mode (Sm) and Fast-mode (Fm) standards (tof) is selected.

Set this bit to 1 when using transmission rates up to 1 Mbps (Fast-mode Plus (Fm+) standard). Set it to 0 when using other transmission rates (up to 100 kbps (Sm) or up to 400 kbps (Fm)) or for SMBus (10 to 100 kbps).

## 28.2.7 ICSER : $I^2C$ Bus Status Enable Register

Base address: IIC0 = 0x4009_F000

Offset address: 0x06

| 2 | SAR2E | Slave Address Register 2 Enable<br>0: Disable slave address in SARL2 and SARU2<br>1: Enable slave address in SARL2 and SARU2 | R/W |
| 3 | GCAE | General Call Address Enable<br>0: Disable general call address detection<br>1: Enable general call address detection | R/W |
| 4 | — | This bit is read as 0. The write value should be 0. | R/W |
| 5 | DIDE | Device-ID Address Detection Enable<br>0: Disable device-ID address detection<br>1: Enable device-ID address detection | R/W |
| 6 | — | This bit is read as 0. The write value should be 0. | R/W |
| 7 | HOAE | Host Address Enable<br>0: Disable host address detection<br>1: Enable host address detection | R/W |

### SARyE bit (Slave Address Register y Enable) (y = 0 to 2)

The SARyE bit enables or disables the received slave address and the slave address set in SARLy and SARUy.

When this bit is set to 1, the slave address set in SARLy and SARUy is enabled and is compared with the received slave address. When this bit is set to 0, the slave address set in SARLy and SARUy is disabled and is ignored even if it matches the received slave address.

### GCAE bit (General Call Address Enable)

The GCAE bit specifies whether to ignore the general call address (0000 000b + 0 [W]: All 0) when it is received.

When this bit is set to 1, if the received slave address matches the general call address, the IIC recognizes the received slave address as the general call address independently of the slave addresses set in SARLy and SARUy (y = 0 to 2) and performs the data receive operation. When this bit is set to 0, the received slave address is ignored even if it matches the general call address.

### DIDE bit (Device-ID Address Detection Enable)

The DIDE bit specifies whether to recognize and execute the device-ID address when a device ID (1111 100b) is received in the first frame after a start or restart condition is detected.

When this bit is set to 1, if the received first frame matches the device ID, the IIC recognizes that the device-ID address was received. When the next R/W# bit is 0 (W), the IIC recognizes the second and the subsequent frames as slave addresses and continues the receive operation. When this bit is set to 0, the IIC ignores the received first frame even if it matches the device-ID address, and it recognizes the first frame as a normal slave address.

For details on this function, see section 28.7.3. Device-ID Address Detection.

### HOAE bit (Host Address Enable)

The HOAE bit specifies whether to ignore the received host address (0001 000b) when the SMBS bit in ICMR3 is 1.

When this bit is set to 1 while the SMBS bit in ICMR3 is 1, if the received slave address matches the host address, the IIC recognizes the received slave address as the host address independently of the slave addresses set in SARLy and SARUy (y = 0 to 2) and performs the receive operation.

When the SMBS bit in ICMR3 or the HOAE bit is set to 0, the received slave address is ignored even if it matches the host address.

## 28.2.8 ICIER : I²C Bus Interrupt Enable Register

Base address: IIC0 = 0x4009_F000

Offset address: 0x07

| Bit position: | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|
| Bit field: | TIE | TEIE | RIE | NAKIE | SPIE | STIE | ALIE | TMOIE |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 0 | TMOIE | Timeout Interrupt Request Enable<br>0: Disable timeout interrupt (TMOI) request<br>1: Enable timeout interrupt (TMOI) request | R/W |
| 1 | ALIE | Arbitration-Lost Interrupt Request Enable<br>0: Disable arbitration-lost interrupt (ALI) request<br>1: Enable arbitration-lost interrupt (ALI) request | R/W |
| 2 | STIE | Start Condition Detection Interrupt Request Enable<br>0: Disable start condition detection interrupt (STI) request<br>1: Enable start condition detection interrupt (STI) request | R/W |
| 3 | SPIE | Stop Condition Detection Interrupt Request Enable<br>0: Disable stop condition detection interrupt (SPI) request<br>1: Enable stop condition detection interrupt (SPI) request | R/W |
| 4 | NAKIE | NACK Reception Interrupt Request Enable<br>0: Disable NACK reception interrupt (NAKI) request<br>1: Enable NACK reception interrupt (NAKI) request | R/W |
| 5 | RIE | Receive Data Full Interrupt Request Enable<br>0: Disable receive data full interrupt (IIC0_RXI) request<br>1: Enable receive data full interrupt (IIC0_RXI) request | R/W |
| 6 | TEIE | Transmit End Interrupt Request Enable<br>0: Disable transmit end interrupt (IIC0_TEI) request<br>1: Enable transmit end interrupt (IIC0_TEI) request | R/W |
| 7 | TIE | Transmit Data Empty Interrupt Request Enable<br>0: Disable transmit data empty interrupt (IIC0_TXI) request<br>1: Enable transmit data empty interrupt (IIC0_TXI) request | R/W |

### TMOIE bit (Timeout Interrupt Request Enable)

The TMOIE bit enables or disables timeout interrupt (TMOI) requests when the TMOF flag in ICSR2 is 1. To cancel a TMOI interrupt request, set the TMOF flag or the TMOIE bit to 0.

### ALIE bit (Arbitration-Lost Interrupt Request Enable)

The ALIE bit enables or disables arbitration-lost interrupt (ALI) requests when the AL flag in ICSR2 is 1. To cancel an ALI interrupt request, set the AL flag or the ALIE bit to 0.

### STIE bit (Start Condition Detection Interrupt Request Enable)

The STIE bit enables or disables start condition detection interrupt (STI) requests when the START flag in ICSR2 is 1. To cancel an STI interrupt request, set the START flag or the STIE bit to 0.

### SPIE bit (Stop Condition Detection Interrupt Request Enable)

The SPIE bit enables or disables stop condition detection interrupt (SPI) requests when the STOP flag in ICSR2 is 1. To cancel an SPI interrupt request, set the STOP flag or the SPIE bit to 0.

### NAKIE bit (NACK Reception Interrupt Request Enable)

The NAKIE bit enables or disables NACK reception interrupt (NAKI) requests when the NACKF flag in ICSR2 is 1. To cancel an NAKI interrupt request, set the NACKF flag or the NAKIE bit to 0.

### RIE bit (Receive Data Full Interrupt Request Enable)

The RIE bit enables or disables receive data full interrupt (IIC0_RXI) requests when the RDRF flag in ICSR2 is 1.

### TEIE bit (Transmit End Interrupt Request Enable)

The TEIE bit enables or disables transmit end interrupt (IIC0_TEI) requests when the TEND flag in ICSR2 is 1. To cancel an IIC0_TEI interrupt request, set the TEND flag or the TEIE bit to 0.

### TIE bit (Transmit Data Empty Interrupt Request Enable)

The TIE bit enables or disables transmit data empty interrupt (IIC0_TXI) requests when the TDRE flag in ICSR2 is 1.

## 28.2.9 ICSR1 : I2C Bus Status Register 1

Base address: IIC0 = 0x4009_F000

Offset address: 0x08

| Bit position: | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|
| Bit field: | HOA | — | DID | — | GCA | AAS2 | AAS1 | AAS0 |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 0 | AAS0 | Slave Address 0 Detection Flag<br>0: Slave address 0 not detected<br>1: Slave address 0 detected | R/(W)*1 |
| 1 | AAS1 | Slave Address 1 Detection Flag<br>0: Slave address 1 not detected<br>1: Slave address 1 detected | R/(W)*1 |
| 2 | AAS2 | Slave Address 2 Detection Flag<br>0: Slave address 2 not detected<br>1: Slave address 2 detected | R/(W)*1 |
| 3 | GCA | General Call Address Detection Flag<br>0: General call address not detected<br>1: General call address detected | R/(W)*1 |
| 4 | — | This bit is read as 0. The write value should be 0. | R/W |
| 5 | DID | Device-ID Address Detection Flag<br>This bit is set to 1 when the first frame received immediately after a start condition is detected matches a value of (device ID (1111 100b) + 0[W]).<br>0: Device-ID command not detected<br>1: Device-ID command detected | R/(W)*1 |
| 6 | — | This bit is read as 0. The write value should be 0. | R/W |
| 7 | HOA | Host Address Detection Flag<br>This bit is set to 1 when the received slave address matches the host address (0001 000b).<br>0: Host address not detected<br>1: Host address detected | R/(W)*1 |

Note 1. Only 0 can be written to clear the flag.

### AASy flag (Slave Address y Detection flag) (y = 0 to 2)

The AASy flag indicates whether slave address y was detected.

[Setting conditions]

For 7-bit address format (SARUy.FS = 0):

- When the received slave address matches the SVA[6:0] value in SARLy, with the SARyE bit in ICSER set to 1 (slave address y detection enabled).
  The AASy flag is set to 1 on the rising edge of the ninth SCL clock cycle in the frame.

For 10-bit address format: (SARUy.FS = 1):

- When the received slave address matches a value of (11110b + SVA[1:0] in SARUy), and the subsequent address matches the SARLy value, with the SARyE bit in ICSER set to 1 (slave address y detection enabled).
  The AASy flag is set to 1 on the rising edge of the ninth SCL clock cycle in the frame.

[Clearing conditions]

- When 0 is written to the AASy flag after reading AASy = 1
- When a stop condition is detected
- When 1 is written to the IICRST bit in ICCR1 to apply an IIC reset or an internal reset.

For 7-bit address format (SARUy.FS = 0):

- When the received slave address does not match the SVA[6:0] value in SARLy, with the SARyE bit in ICSER set to 1 (slave address y detection enabled).
  The AASy flag is set to 0 on the rising edge of the ninth SCL clock cycle in the frame.

For 10-bit address format (SARUy.FS = 1):

- When the received slave address does not match a value of (11110b + SVA[1:0] in SARUy), with the SARyE bit in ICSER set to 1 (slave address y detection enabled)
  The AASy flag is set to 0 on the rising edge of the ninth SCL clock cycle in the frame.
- When the received slave address matches a value of (11110b + SVA[1:0] in SARUy), and the subsequent address does not match the SARLy value, with the SARyE bit in ICSER set to 1 (slave address y detection enabled).
  The AASy flag is set to 0 on the rising edge of the ninth SCL clock cycle in the frame.

### GCA flag (General Call Address Detection Flag)

The GCA flag indicates whether the general call address was detected.

[Setting condition]

- When the received slave address matches the general call address (0000 000b + 0 [W]), with the GCAE bit in ICSER set to 1 (general call address detection enabled).
  The GCA flag is set to 1 on the rising edge of the ninth SCL clock cycle in the frame.

[Clearing conditions]

- When 0 is written to the GCA flag after reading GCA = 1
- When a stop condition is detected
- When the received slave address does not match the general call address (0000 000b + 0 [W]), with the GCAE bit in ICSER set to 1 (general call address detection enabled)
  The GCA flag is set to 0 on the rising edge of the ninth SCL clock cycle in the frame.
- When 1 is written to the IICRST bit in ICCR1 to apply an IIC reset or an internal reset.

### DID flag (Device-ID Address Detection Flag)

The DID flag indicates whether the device-ID address was detected.

[Setting condition]

- When the first frame received immediately after a start or restart condition is detected matches a value of (device ID (1111 100b) + 0 [W]), with the DIDE bit in ICSER set to 1 (device-ID address detection enabled).
  The DID flag is set to 1 on the rising edge of the ninth SCL clock cycle in the frame.

[Clearing conditions]

- When 0 is written to the DID flag after reading DID = 1
- When a stop condition is detected
- When the first frame received immediately after a start or restart condition is detected does not match a value of (device ID (1111 100b)), with the DIDE bit in ICSER set to 1 (device-ID address detection enabled)
  The DID flag is set to 0 on the rising edge of the ninth SCL clock cycle in the frame.

- When the first frame received immediately after a start or restart condition is detected matches a value of (device ID (1111 100b) + 0 [W]), and the second frame does not match any slave address from 0 to 2, with the DIDE bit in ICSER set to 1 (device-ID address detection enabled)
  The DID flag is set to 0 on the rising edge of the ninth SCL clock cycle in the frame.
- When 1 is written to the IICRST bit in ICCR1 to apply an IIC reset or an internal reset.

#### HOA flag (Host Address Detection Flag)

The HOA flag indicates whether the host address was detected.

[Setting condition]

- When the received slave address matches the host address (0001 000b), with the HOAE bit in ICSER set to 1 (host address detection enabled).
  The HOA flag is set to 1 on the rising edge of the ninth SCL clock cycle in the frame.

[Clearing conditions]

- When 0 is written to the HOA flag after reading HOA = 1
- When a stop condition is detected
- When the received slave address does not match the host address (0001 000b), with the HOAE bit in ICSER set to 1 (host address detection enabled)
  The HOA flag is set to 0 on the rising edge of the ninth SCL clock cycle in the frame.
- When 1 is written to the IICRST bit in ICCR1 to apply an IIC reset or an internal reset.

### 28.2.10 ICSR2 : I2C Bus Status Register 2

Base address: IIC0 = 0x4009_F000

Offset address: 0x09

| Bit position: | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|
| Bit field: | TDRE | TEND | RDRF | NACKF | STOP | START | AL | TMOF |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 0 | TMOF | Timeout Detection Flag<br>0: Timeout not detected<br>1: Timeout detected | R/(W)*1 |
| 1 | AL | Arbitration-Lost Flag<br>0: Arbitration not lost<br>1: Arbitration lost | R/(W)*1 |
| 2 | START | Start Condition Detection Flag<br>0: Start condition not detected<br>1: Start condition detected | R/(W)*1 |
| 3 | STOP | Stop Condition Detection Flag<br>0: Stop condition not detected<br>1: Stop condition detected | R/(W)*1 |
| 4 | NACKF | NACK Detection Flag<br>0: NACK not detected<br>1: NACK detected | R/(W)*1 |
| 5 | RDRF | Receive Data Full Flag<br>0: ICDRR contains no receive data<br>1: ICDRR contains receive data | R/(W)*1 |
| 6 | TEND | Transmit End Flag<br>0: Data being transmitted<br>1: Data transmit complete | R/(W)*1 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 7 | TDRE | Transmit Data Empty Flag<br>0: ICDRT contains transmit data<br>1: ICDRT contains no transmit data | R |

Note 1. Only 0 can be written, to clear the flag.

### TMOF flag (Timeout Detection Flag)

The TMOF flag is set to 1 when the IIC detects a timeout because the SCL0 line state remains unchanged for the set period.

[Setting condition]

- When the SCL0 line state remains unchanged for the period specified in the ICMR2.TMOH, TMOL, and TMOS bits while the ICFER.TMOE bit is 1 (timeout function enabled) in master or in slave mode and the received slave address matches.

[Clearing conditions]

- When 0 is written to the TMOF flag after reading TMOF = 1
- When 1 is written to the IICRST bit in ICCR1 to apply an IIC reset or an internal reset.

### AL flag (Arbitration-Lost Flag)

The AL flag indicates that bus mastership was lost in arbitration because of a bus conflict or some other reason when a start condition was issued or an address and data was transmitted. The IIC monitors the level on the SDA0 line during transmission and, if the level on the line does not match the value of the bit being output, is set the value of the AL flag to 1 to indicate that the bus is occupied by another device.

The IIC can also set the AL flag to indicate the detection of arbitration loss during NACK transmission or during data transmission.

[Setting conditions]

When master arbitration-lost detection is enabled (ICFER.MALE = 1):

- When the internal SDA output state does not match the SDA0 line level on the rising edge of the SCL clock except for the ACK period during data transmission in master transmit mode
- When a start condition is detected while the ST bit in ICCR2 is 1 (start condition requested) or the internal SDA output state does not match the SDA0 line level
- When the ST bit in ICCR2 is 1 (start condition requested), with the BBSY flag in ICCR2 set to 1.

When NACK arbitration-lost detection is enabled (ICFER.NALE = 1):

- When the internal SDA output state does not match the SDA0 line level on the rising edge of the SCL clock in the ACK period during NACK transmission in receive mode.

When slave arbitration-lost detection is enabled (ICFER.SALE = 1):

- When the internal SDA output state does not match the SDA0 line level on the rising edge of the SCL clock, except for the ACK period during data transmission in slave transmit mode.

[Clearing conditions]

- When 0 is written to the AL flag after reading AL = 1
- When 1 is written to the IICRST bit in ICCR1 to apply an IIC reset or an internal reset.

**Table 28.4 Relationship between arbitration-lost generation sources and arbitration-lost enable functions**

| ICFER | | | ICSR2 | | |
|---|---|---|---|---|---|
| MALE | NALE | SALE | AL | Error | Arbitration-lost generation source |
| 1 | x | x | 1 | Start condition issuance error | When internal SDA output state does not match SDA0 line level when a start condition is detected, while the ST bit in ICCR2 is 1 |
| | | | | | When ST in ICCR2 is set to 1 while BBSY in ICCR2 is 1 |
| | | | 1 | Transmit data mismatch | When transmit data (including slave address) does not match the bus state in master transmit mode |
| x | 1 | x | 1 | NACK transmission mismatch | When ACK is detected during transmission of NACK in master or slave receive mode |
| x | x | 1 | 1 | Transmit data mismatch | When transmit data does not match the bus state in slave transmit mode |

x: Don’t care

### START flag (Start Condition Detection Flag)

The START flag indicates whether a start or restart condition was detected.

[Setting condition]

- When a start or restart condition is detected.

[Clearing conditions]

- When 0 is written to the START flag after reading START = 1
- When a stop condition is detected
- When 1 is written to the IICRST bit in ICCR1 to apply an IIC reset or an internal reset.

### STOP flag (Stop Condition Detection Flag)

The STOP flag indicates whether a stop condition was detected.

[Setting condition]

- When a stop condition is detected.

[Clearing conditions]

- When 0 is written to the STOP flag after reading STOP = 1
- When 1 is written to the IICRST bit in ICCR1 to apply an IIC reset or an internal reset.

### NACKF flag (NACK Detection Flag)

The NACKF flag indicates whether a NACK was detected.

[Setting condition]

- When acknowledge is not received (NACK received) from the receive device in transmit mode, with the NACKE bit in ICFER set to 1 (transfer suspension enabled).

[Clearing conditions]

- When 0 is written to the NACKF flag after reading NACKF = 1
- When 1 is written to the IICRST bit in ICCR1 to apply an IIC reset or an internal reset.

Note: When the NACKF flag is set to 1, the IIC suspends data transmission and reception. Writing to ICDRT in transmit mode or reading from ICDRR in receive mode with the NACKF flag set to 1 does not enable data transmit or receive operation. To restart data transmission or reception, set the NACKF flag to 0.

### RDRF flag (Receive Data Full Flag)

The RDRF flag indicates whether the ICDRR contains receive data.

[Setting conditions]

- When receive data is transferred from ICDRS to ICDRR
  The RDRF flag is set to 1 on the rising edge of the eighth or ninth SCL clock cycle (selected in the RDRFS bit in ICMR3).
- When the received slave address matches after a start or restart condition is detected with the TRS bit in ICCR2 set to 0.

[Clearing conditions]

- When 0 is written to the RDRF flag after reading RDRF = 1
- When data is read from ICDRR
- When 1 is written to the IICRST bit in ICCR1 to apply an IIC reset or an internal reset.

#### TEND flag (Transmit End Flag)

The TEND flag indicates completion of transmission.

[Setting condition]

- On the rising edge of the ninth SCL clock cycle while the TDRE flag is 1.

[Clearing conditions]

- When 0 is written to the TEND flag after reading TEND = 1
- When data is written to ICDRT
- When a stop condition is detected
- When 1 is written to the IICRST bit in ICCR1 to apply an IIC reset or an internal reset.

#### TDRE flag (Transmit Data Empty Flag)

The TDRE flag indicates whether the ICDRT contains transmit data.

[Setting conditions]

- When data is transferred from ICDRT to ICDRS and ICDRT becomes empty
- When the TRS bit in ICCR2 is set to 1
- When the received slave address matches while the TRS bit is 1.

[Clearing conditions]

- When data is written to ICDRT
- When the TRS bit in ICCR2 is set to 0
- When 1 is written to the IICRST bit in ICCR1 to apply an IIC reset or an internal reset.

Note: When the NACKF flag is set to 1 while the NACKE bit in ICFER is 1, the IIC suspends data transmission and reception. In this case, if the TDRE flag is 0 (next transmit data written), data is transferred to the ICDRS register and the ICDRT register becomes empty on the rising edge of the 9th clock cycle, but the TDRE flag does not set to 1.

### 28.2.11 ICWUR : I2C Bus Wakeup Unit Register

Base address: IIC0WU = 0x4009_F014

Offset address: 0x02

| Bit position: | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|
| Bit field: | WUE | WUIE | WUF | WUACK | — | — | — | WUAFA |
| Value after reset: | 0 | 0 | 0 | 1 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 0 | WUAFA | Wakeup Analog Filter Additional Selection<br>0: Do not add the wakeup analog filter<br>1: Add the wakeup analog filter | R/W |
| 3:1 | — | These bits are read as 0. The write value should be 0. | R/W |
| 4 | WUACK | ACK Bit for Wakeup Mode<br>Choice of four response modes in combination with ICCR1.IICRST and WUACK. See Table 28.5. | R/W |
| 5 | WUF | Wakeup Event Occurrence Flag<br>0: Slave address not matching during wakeup<br>1: Slave address matching during wakeup | R/W |
| 6 | WUIE | Wakeup Interrupt Request Enable<br>0: Disable wakeup interrupt request (IIC0_WUI)<br>1: Enable wakeup interrupt request (IIC0_WUI) | R/W |
| 7 | WUE | Wakeup Function Enable<br>0: Disable wakeup function<br>1: Enable wakeup function | R/W |

**Table 28.5 Wakeup mode**

| IICRST | WUACK | Operation mode | Description |
|---|---|---|---|
| 0 | 0 | Normal wakeup mode 1 | ACK response on 9th SCL, and SCL low-hold after 9th SCL. |
| 0 | 1 | Normal wakeup mode 2 | No ACK response immediately and SCL low-hold between 8th and 9th SCL. SCL low-hold release and ACK response on 9th SCL. |
| 1 | 0 | Command recovery mode | ACK response on 9th SCL and no SCL low-hold. |
| 1 | 1 | EEP response mode | NACK response on 9th SCL and no SCL low-hold. |

### WUF flag (Wakeup Event Occurrence Flag)

The WUF flag indicates whether the slave address is matching during wakeup.

[Setting condition]

- When PCLKB is supplied after a slave-address match in the first 8th SCL low during wakeup mode.

[Clearing conditions]

- When 0 is written to the WUF flag after reading WUF = 1
- When ICE = 0 and IICRST = 1.

## 28.2.12 ICWUR2 : I2C Bus Wakeup Unit Register 2

Base address: IIC0WU = 0x4009_F014

Offset address: 0x03

| Bit position: | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | — | — | WUSYF | WUASYF | WUSEN |
| Value after reset: | 1 | 1 | 1 | 1 | 1 | 1 | 0 | 1 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 0 | WUSEN | Wakeup Function Synchronous Enable<br>0: IIC asynchronous circuit enable<br>1: IIC synchronous circuit enable | R/W |
| 1 | WUASYF | Wakeup Function Asynchronous Operation Status Flag<br>0: IIC synchronous circuit enable condition<br>1: IIC asynchronous circuit enable condition | R |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 2 | WUSYF | Wakeup Function Synchronous Operation Status Flag<br>0: IIC asynchronous circuit enable condition<br>1: IIC synchronous circuit enable condition | R |
| 7:3 | — | These bits are read as 1. The write value should be 1. | R/W |

### WUSEN bit (Wakeup Function Synchronous Enable)

The WUSEN bit is used in combination with the WUASYF flag (or WUSYF flag) to switch between the PCLKB synchronous and asynchronous operation, when the wakeup effective function is enabled (ICWUR.WUE = 1).

The PCLKB operation switches from synchronous to asynchronous operation:

When the ICCR2.BBSY flag is 0, if 0 is written to the WUSEN bit while the WUASYF flag is 0, the reception occurs independently of the operation of PCLKB (with PCLKB stopped) after it switches to the PCLKB asynchronous operation, on wakeup event detection.

The PCLKB operation switches from asynchronous to synchronous operation:

- When 1 is written to the WUSEN bit, with the WUASYF flag at 1, when a wakeup event is detected. After writing 1, the WUASYF flag immediately becomes 0.
- When the stop condition is detected with a wakeup event undetected.

### WUASYF flag (Wakeup Function Asynchronous Operation Status Flag)

The WUASYF flag can place the IIC in PCLKB asynchronous operation when the wakeup effective function is enabled (ICWUR.WUE = 1).

[Setting condition]

- When the ICCR2.BBSY flag is 0, and the WUSEN bit is set to 0 with the ICWUR.WUE bit set to 1.

[Clearing conditions]

- When 1 is written to the WUSEN bit after detecting the wakeup event with ICWUR.WUE bit set to 1.
- When a stop condition is detected with WUSEN bit set to 1 before detecting the wakeup event with WUASYF flag set to 1 with ICWUR.WUE bit set to 1.
- When you write 1 in the WUSEN bit with the WUASYF flag detected 1 and the wakeup event in the state of ICWUR.WUE = 1.
- ICCR1.ICE = 0 and ICCRST = 1 (ICC reset)
- ICWUR.WUE = 0.

### WUSYF flag (Wakeup Function Synchronous Operation Status Flag)

It is shown that IIC is in the PCLKB synchronous operation at wake-up effective function (ICWUR.WUE = 1). This flag is a value in which the WUASYF flag is always reserved.

[Setting conditions]

- When 1 is written to the WUSEN bit after detecting the wakeup event with ICWUR.WUE bit set to 1 with WUSYF flag set to 0 with ICWUR.WUE bit set to 1.
- When a stop condition is detected with WUSEN bit set to 1 before detecting the wakeup event with WUSYF flag set to 0 with ICWUR.WUE bit set to 1.
- ICCR1.ICE = 0 and ICCRST = 1 (ICC reset)
- ICWUR.WUE = 0.

[Clearing condition]

- When the ICCR2.BBSY flag is 0 with the ICWUR.WUE bit set to 1 after writing 0 to the WUSEN bit.

## 28.2.13 SARLy : Slave Address Register Ly (y = 0 to 2)

Base address: IIC0 = 0x4009_F000

Offset address: 0x0A + 0x02 × y

| Bit position: | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|
| Bit field: | SVA[6:0] | | | | | | | SVA0 |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 0 | SVA0 | 10-bit Address LSB<br>Slave address setting. | R/W |
| 7:1 | SVA[6:0] | 7-bit Address/10-bit Address Lower Bits<br>Slave address setting. | R/W |

### SVA0 bit (10-bit Address LSB)

When the 10-bit address format is selected (SARUy.FS = 1), the SVA0 bit functions as the LSB of a 10-bit address and is combined with the SVA[6:0] bits to form the lower 8 bits of a 10-bit address.

This bit is valid when the SARyE bit in ICSER is set to 1 (SARLy and SARUy enabled) and the SARUy.FS bit is 1. When the SARUy.FS or SARyE bit is 0, the setting in this bit is ignored.

### SVA[6:0] bits (7-bit Address/10-bit Address Lower Bits)

When the 7-bit address format is selected (SARUy.FS = 0), the SVA[6:0] bits function as a 7-bit address. When the 10-bit address format is selected (SARUy.FS = 1), these bits combine with the SVA0 bit to form the lower 8 bits of a 10-bit address.

When the SARyE bit in ICSER is 0, the setting in these bits is ignored.

## 28.2.14 SARUy : Slave Address Register Uy (y = 0 to 2)

Base address: IIC0 = 0x4009_F000

Offset address: 0x0B + 0x02 × y

| Bit position: | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | — | — | SVA[1:0] | | FS |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 0 | FS | 7-bit/10-bit Address Format Select<br>0: Select 7-bit address format<br>1: Select 10-bit address format | R/W |
| 2:1 | SVA[1:0] | 10-bit Address Upper Bits<br>Slave address setting. | R/W |
| 7:3 | — | These bits are read as 0. The write value should be 0. | R/W |

### FS bit (7-bit/10-bit Address Format Select)

The FS bit selects 7- or 10-bit format for slave address y (in SARLy and SARUy).

When the SARyE bit in ICSER is set to 1 (SARLy and SARUy enabled) and the SARUy.FS bit is 0, the 7-bit address format is selected for slave address y, the SVA[6:0] setting in SARLy is valid, and the SVA[1:0] and SVA0 settings in SARLy are ignored.

When the SARyE bit in ICSER is set to 1 (SARLy and SARUy enabled) and the SARUy.FS bit is 1, the 10-bit address format is selected for slave address y and the SVA[1:0] and SARLy settings are valid.

When the SARyE bit in ICSER is 0 (SARLy and SARUy disabled), the SARUy.FS setting is invalid.

### SVA[1:0] bits (10-bit Address Upper Bits)

When the 10-bit address format is selected (FS = 1), the SVA[1:0] bits function as the upper 2 bits of a 10-bit address.

These bits are valid when the SARyE bit in ICSER is set to 1 (SARLy and SARUy enabled) and the SARUy.FS bit is 1. When the SARUy.FS or SARyE bit is 0, the setting in these bits is ignored.

## 28.2.15 ICBRL : I2C Bus Bit Rate Low-Level Register

Base address: IIC0 = 0x4009_F000

Offset address: 0x10

| Bit position: | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | BRL[4:0] | | | | |
| Value after reset: | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 4:0 | BRL[4:0] | Bit Rate Low-Level Period<br>Low-level period of SCL clock. | R/W |
| 7:5 | — | These bits are read as 1. The write value should be 1. | R/W |

### BRL[4:0] bits (Bit Rate Low-Level Period)

The BRL[4:0] bits set the low-level period of the SCL clock. ICBRL counts the low-level period with the internal reference clock source (IICφ) specified by the CKS[2:0] bits in ICMR1. ICBRL also generates the data setup time for automatic SCL low-hold operation, see section 28.9. Automatic Low-Hold Function for SCL. When the IIC is used in slave mode, the BRL[4:0] bits must be set to a value longer than the data setup time*1.

If the digital noise filter is enabled (NFE bit in ICFER is 1), set the BRL[4:0] bits to a value at least one greater than the number of stages in the noise filter. For details on the number of stages, see the description of the NF[1:0] bits in section 28.2.5. ICMR3 : I2C Bus Mode Register 3.

Note 1. Data setup time ($t_{SU}$: DAT)

250 ns for up to 100 kbps: Standard-mode (Sm)

100 ns for up to 400 kbps: Fast-mode (Fm)

50 ns for up to 1 Mbps: Fast-mode Plus (Fm+)

## 28.2.16 ICBRH : I2C Bus Bit Rate High-Level Register

Base address: IIC0 = 0x4009_F000

Offset address: 0x11

| Bit position: | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | BRH[4:0] | | | | |
| Value after reset: | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 4:0 | BRH[4:0] | Bit Rate High-Level Period<br>High-level period of SCL clock. | R/W |
| 7:5 | — | These bits are read as 1. The write value should be 1. | R/W |

### BRH[4:0] bits (Bit Rate High-Level Period)

The BRH[4:0] bits set the high-level period of SCL clock. BRH[4:0] bits are valid in master mode. If the IIC is used only in slave mode, do not set the BRH[4:0] bits.

ICBRH counts the high-level period with the internal reference clock source (IICφ) specified in the CKS[2:0] bits in ICMR1.

If the digital noise filter is enabled (the NFE bit in ICFER is 1), set these bits to a value at least one greater than the number of stages in the noise filter. For the number of stages in the noise filter, see the description of the NF[1:0] bits in section 28.2.5. ICMR3 : I2C Bus Mode Register 3.

The IIC transfer rate and the SCL clock duty are calculated using the following expressions (1) to (5):

1. ICFER.SCLE = 0
   Transfer rate = 1/[{(BRH + 1) + (BRL + 1)}/IICφ*1 + tr*2 + tf*2]
   Duty cycle = [tr + {(BRH + 1)/IICφ}]/[tr + tf + {(BRH + 1) + (BRL + 1)}/IICφ]
2. ICFER.SCLE = 1 and ICFER.NFE = 0 and CKS[2:0] = 000b (IICφ = PCLKB)
   Transfer rate = 1/[{(BRH + 3) + (BRL+ 3)}/IICφ + tr + tf]
   Duty cycle = [tr + {(BRH + 3)/IICφ}]/[tr + tf + {(BRH + 3) + (BRL + 3)}/IICφ]
3. ICFER.SCLE = 1 and ICFER.NFE = 1 and CKS[2:0] = 000b (IICφ = PCLKB)
   Transfer rate = 1/[{(BRH + 3 + nf*3) + (BRL + 3 + nf)}/IICφ + tr + tf]
   Duty cycle = [tr + {(BRH + 3 + nf)/IICφ}]/[tr + tf + {(BRH + 3 + nf) + (BRL + 3 + nf)}/IICφ]
4. ICFER.SCLE = 1 and ICFER.NFE = 0 and CKS[2:0] ≠ 000b
   Transfer rate = 1/[{(BRH + 2) + (BRL + 2)}/IICφ + tr + tf]
   Duty cycle = [tr + {(BRH + 2)/IICφ}]/[tr + tf + {(BRH + 2) + (BRL + 2)}/IICφ]
5. ICFER.SCLE = 1 and ICFER.NFE = 1 and CKS[2:0] ≠ 000b
   Transfer rate = 1/[{(BRH + 2 + nf) + (BRL + 2 + nf)}/IICφ + tr + tf]
   Duty cycle = [tr + {(BRH + 2 + nf)/IICφ}]/[tr + tf + {(BRH + 2 + nf) + (BRL + 2 + nf)}/IICφ]

Note 1. IICφ = PCLKB × division ratio
Note 2. The SCL0 line rise time (tr) and SCL0 line fall time (tf) depend on the total bus line capacitance (Cb) and the pull-up resistor (Rp). For details, see the I2C bus standard from NXP Semiconductors.
Note 3. nf = Number of digital noise filters selected in the ICMR3.NF bit.

**Table 28.6 Example of ICBRH/ICBRL Settings for Transfer Rate IIC when SCLE = 0**

| Transfer rate (kbps) | CKS[2:0] (ICMR1) | BRH[4:0] (ICBRH) | BRL[4:0] (ICBRL) | PCLKB (MHz) | NF[1:0] | Computation expression |
|---|---|---|---|---|---|---|
| 100 | 011b | 19 (0xF3) | 23 (0xF7) | 40 | — | (1) |
| 400 | 010b | 6 (0xE6) | 11 (0xEB) | 40 | — | (1) |
| 1000 | 000b | 10 (0xEA) | 18 (0xF2) | 40 | — | (1) |

**Table 28.7 Example of ICBRH/ICBRL Settings for Transfer Rate when SCLE = 1 and NFE = 0**

| Transfer rate (kbps) | CKS[2:0] (ICMR1) | BRH[4:0] (ICBRH) | BRL[4:0] (ICBRL) | PCLKB (MHz) | NF[1:0] | Computation expression |
|---|---|---|---|---|---|---|
| 100 | 100b | 8 (0xE8) | 10 (0xEA) | 40 | — | (4) |

| 1000 | 000b | 7 (0xE7) | 17 (0xF1) | 40 | — | (2) |

**Table 28.8 Example of ICBRH/ICBRL Settings for Transfer Rate when SCLE = 1 and NFE = 1**

| Transfer rate (kbps) | CKS[2:0] (ICMR1) | BRH[4:0] (ICBRH) | BRL[4:0] (ICBRL) | PCLKB (MHz) | NF[1:0] | Computation expression |
|---|---|---|---|---|---|---|
| 100 | 011b | 16 (0xF0) | 20 (0xF4) | 40 | 01b | (5) |
| 400 | 001b | 8 (0xE8) | 22 (0xF6) | 40 | 01b | (5) |
| 1000 | 000b | 5 (0xE5) | 15 (0xEF) | 40 | 01b | (3) |

### 28.2.17 ICDRT : I2C Bus Transmit Data Register

Base address: IIC0 = 0x4009_F000

Offset address: 0x12

| Bit position: | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|
| Bit field: | | | | | | | | |
| Value after reset: | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 |

When ICDRT detects a space in the I2C Bus Shift Register (ICDRS), it transfers the transmit data that was written to ICDRT to ICDRS and starts transmitting data in transmit mode. The double-buffer structure of ICDRT and ICDRS allows continuous transmit operation if the next transmit data is written to ICDRT while the ICDRS data is being transmitted.

ICDRT can always be read and written to. Write transmit data to ICDRT once when a transmit data empty interrupt (IIC0_TXI) request is generated.

### 28.2.18 ICDRR : I2C Bus Receive Data Register

Base address: IIC0 = 0x4009_F000

Offset address: 0x13

| Bit position: | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|
| Bit field: | | | | | | | | |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

When 1 byte of data is received, the received data is transferred from the I2C Bus Shift Register (ICDRS) to ICDRR to enable the next data to be received. The double-buffer structure of ICDRS and ICDRR allows continuous receive operation if the received data is read from ICDRR while ICDRS is receiving data. ICDRR cannot be written to. Read data from ICDRR once when a receive data full interrupt (IIC0_RXI) request is generated.

If ICDRR receives the next receive data before the current data is read from ICDRR (while the RDRF flag in ICSR2 is 1), the IIC automatically holds the SCL clock low 1 cycle before the RDRF flag is set to 1 next.

### 28.2.19 ICDRS : I2C Bus Shift Register

Base address: n/a

Offset address: n/a

| Bit position: | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|
| Bit field: | | | | | | | | |
| Value after reset: | — | — | — | — | — | — | — | — |

ICDRS is an 8-bit shift register for data transmit and receive. During transmission, transmit data is transferred from ICDRT to ICDRS and is transmitted from the SDA0 pin. During reception, data is transferred from ICDRS to ICDRR after 1 byte of data is received. ICDRS cannot be accessed directly.

## 28.3 Operation

### 28.3.1 Communication Data Format

The I2C bus format consists of 8-bit data and 1-bit acknowledge. The frame following a start or restart condition is an address frame that specifies a slave device with which the master device communicates. The specified slave is valid until a new slave is specified or a stop condition is issued.

Figure 28.3 shows the I2C bus format, and Figure 28.4 shows the I2C bus timing.

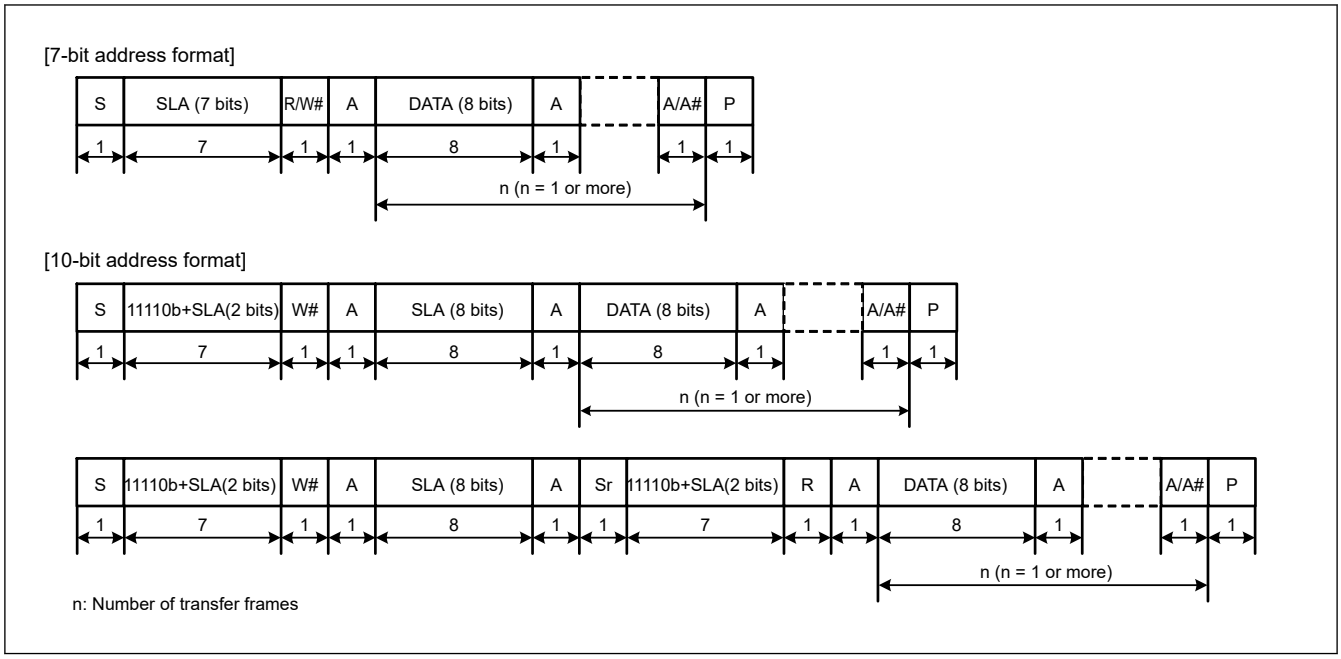

**Figure 28.3 I²C bus format**

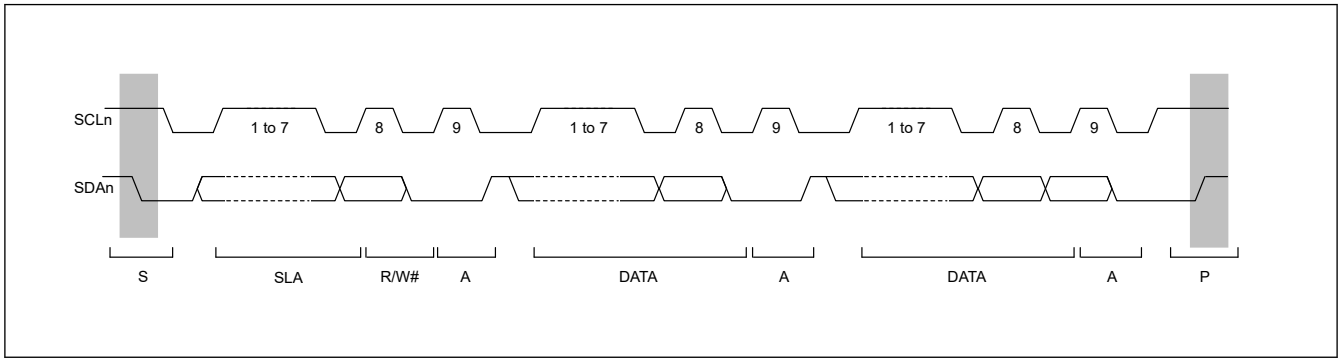

**Figure 28.4 I²C bus timing when the SLA setting = 7 bits**

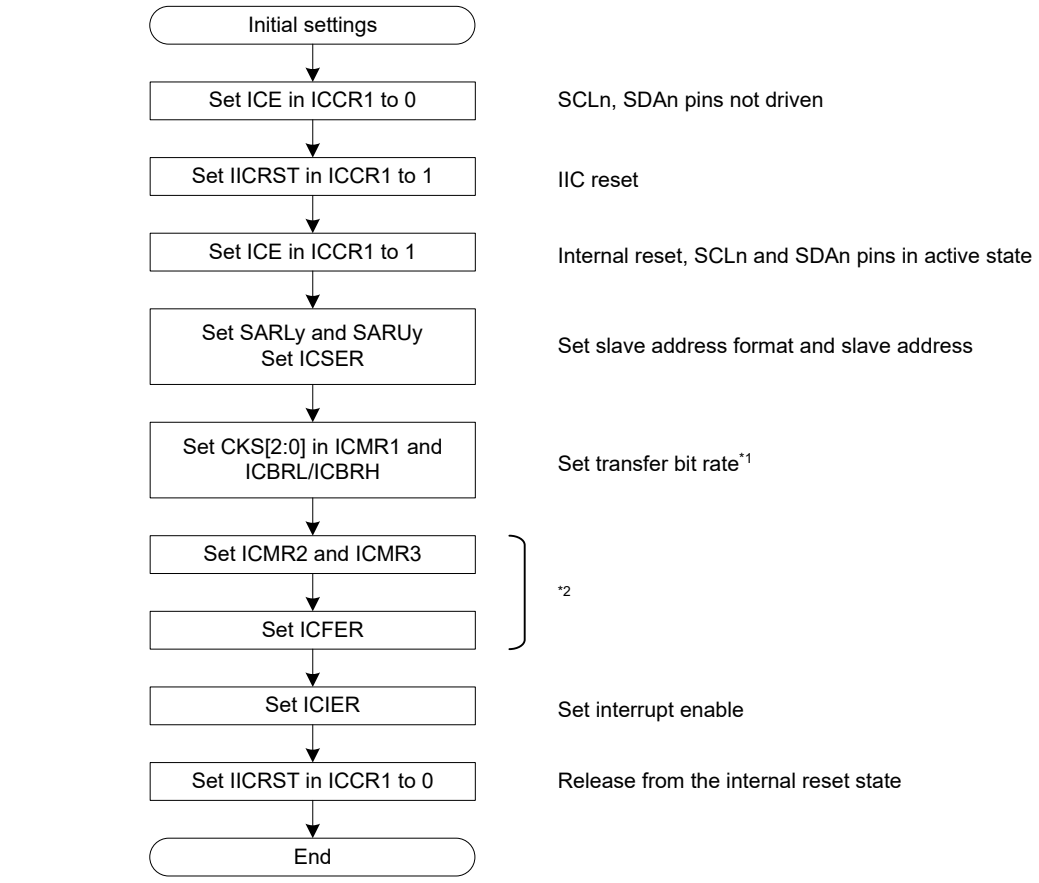
| | |
|---|---|
| S: | Start condition. The master device drives the SDAn line low from high while the SCLn line is high. |
| SLA: | Slave address, by which the master device selects a slave device. |
| R/W#: | Indicates the direction of data transfer: from the slave device to the master device when R/W# is 1, or from the master device to the slave device when R/W# is 0. |
| A: | Acknowledge. The receive device drives the SDAn line low. In master transmit mode, the slave device returns acknowledge. In master receive mode, the master device returns acknowledge. |
| A#: | Not Acknowledge. The receive device drives the SDAn line high. |
| Sr: | Restart condition. The master device drives the SDAn line low from the high level after the setup time has elapsed with the SCLn line high. |
| DATA: | Transmitted or received data. |
| P: | Stop condition. The master device drives the SDAn line high from low while the SCLn line is high. |



## 28.3.2 Initial Settings

Before starting data transmission or reception, initialize the IIC using the procedure shown in Figure 28.5.

1. Set the ICCR1.ICE bit to 0 to set the SCL0 and SDA0 pins to the inactive state.
2. Set the ICCR1.IICRST bit to 1 to initiate IIC reset.
3. Set the ICCR1.ICE bit to 1 to initiate internal reset.

4. Set the SARLy, SARUy, ICSER, ICMR1, ICBRH, and ICBRL registers (y = 0 to 2), and set the other registers as required. For initial settings of the IIC, see Figure 28.5.
5. When the required register settings are complete, set the ICCR1.IICRST bit to 0 to release the IIC reset.

This procedure is not required if the IIC initialization is already complete.

Note: n = 0
Note 1. When the IIC is used only in slave mode, set the ICBRL register to a value longer than the data setup time.
Note 2. Set these registers as required.

**Figure 28.5 Example IIC initialization flow**

## 28.3.3 Master Transmit Operation

In master transmit operation, the IIC outputs the SCL clock and transmitted data signals as the master device, and the slave device returns acknowledgments. Figure 28.6 shows an example of master transmission, and Figure 28.7 to Figure 28.9 show the operation timing in master transmission.

To set up and perform master transmission:

1. Process initial settings. For details, see section 28.3.2. Initial Settings.
2. Read the BBSY flag in ICCR2 to check that the bus is free, and then set the ST bit in ICCR2 to 1 (start condition request). On receiving the request, the IIC issues a start condition. At the same time, the BBSY and START flags in ICSR2 automatically set to 1 and the ST bit automatically is set to 0. At this time, if the start condition is detected and the internal levels for the SDA output state and the levels on the SDA0 line match while the ST bit is 1, the IIC recognizes that issuance of the start condition as requested by the ST bit is successfully complete, and the MST and

TRS bits in ICCR2 automatically set to 1, placing the IIC in master transmit mode. The TDRE flag in ICSR2 also automatically is set to 1 in response to the setting of the TRS bit to 1.

3. Check that the TDRE flag in ICSR2 is 1, and then write the value for transmission (the slave address and the R/W# bit) to ICDRT. When the transmit data is written to ICDRT, the TDRE flag automatically is set to 0, the data is transferred from ICDRT to ICDRS, and the TDRE flag again is set to 1. After the byte containing the slave address and R/W# bit is transmitted, the value of the TRS bit automatically updates to select master transmit or master receive mode based on the value of the transmitted R/W# bit. If the value of the R/W# bit was 0, the IIC continues in master transmit mode. Because the ICSR2.NACKF flag being 1 at this time indicates that no slave device recognized the address or there was an error in communications, write 1 to the ICCR2.SP bit to issue a stop condition.
   For data transmission with an address in the 10-bit format, start by writing 11110b, the 2 higher-order bits of the slave address, and W to ICDRT as the first address transmission. For the second address transmission, write the 8 lower-order bits of the slave address to ICDRT.
4. Check that the TDRE flag in ICSR2 is 1, and then write the transmit data to the ICDRT register. The IIC automatically holds the SCL0 line low until the transmit data is ready or a stop condition is issued.
5. After all bytes of transmit data are written to the ICDRT register, wait until the value in the TEND flag in ICSR2 returns to 1, and then set the SP bit in ICCR2 to 1 (stop condition requested). On receiving a stop condition request, the IIC issues the stop condition. Regarding issuing a stop condition, see section 28.11.3. Issuing a Stop Condition.
6. On detecting the stop condition, the IIC automatically sets the MST and TRS bits in ICCR2 to 00b and enters slave receive mode. Additionally, it automatically sets the TDRE and TEND flags to 0, and sets the STOP flag in ICSR2 to 1.
7. Check that the ICSR2.STOP flag is 1, and then set the ICSR2.NACKF and STOP flags to 0 for the next transfer operation.

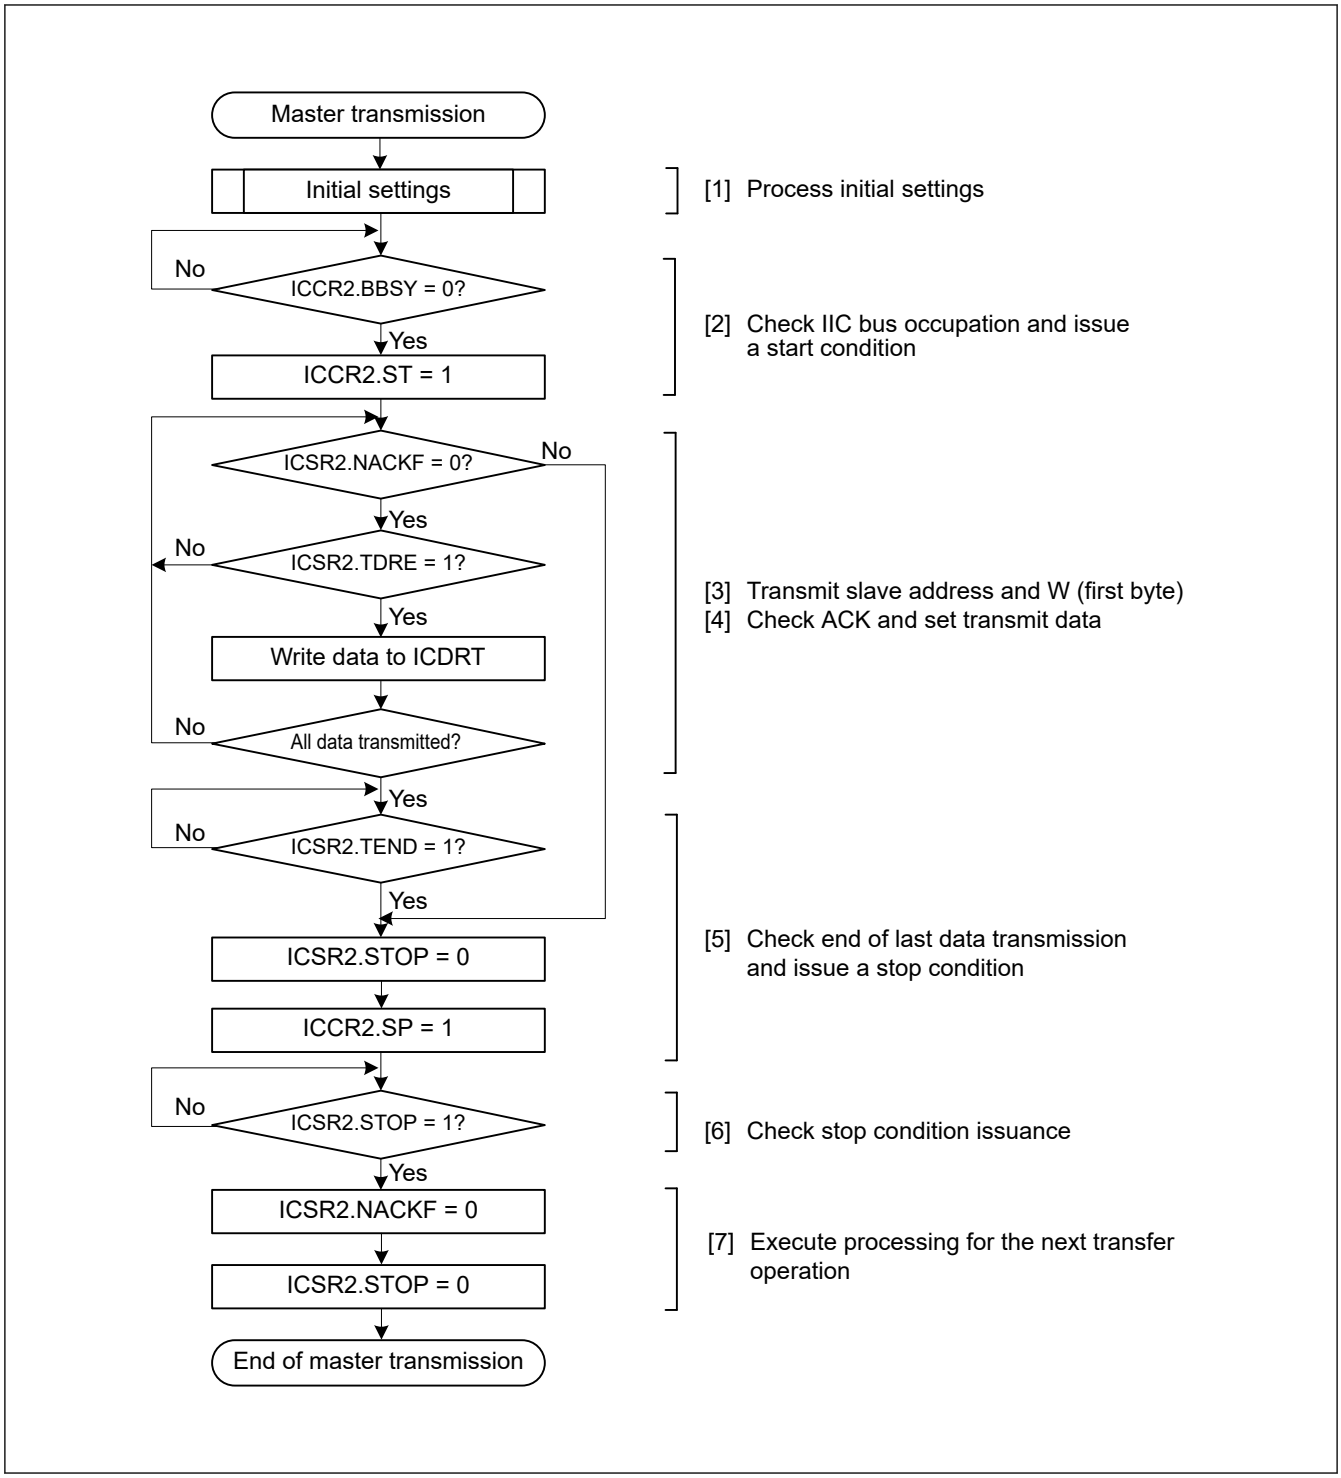


**Figure 28.6 Example master transmission flow**

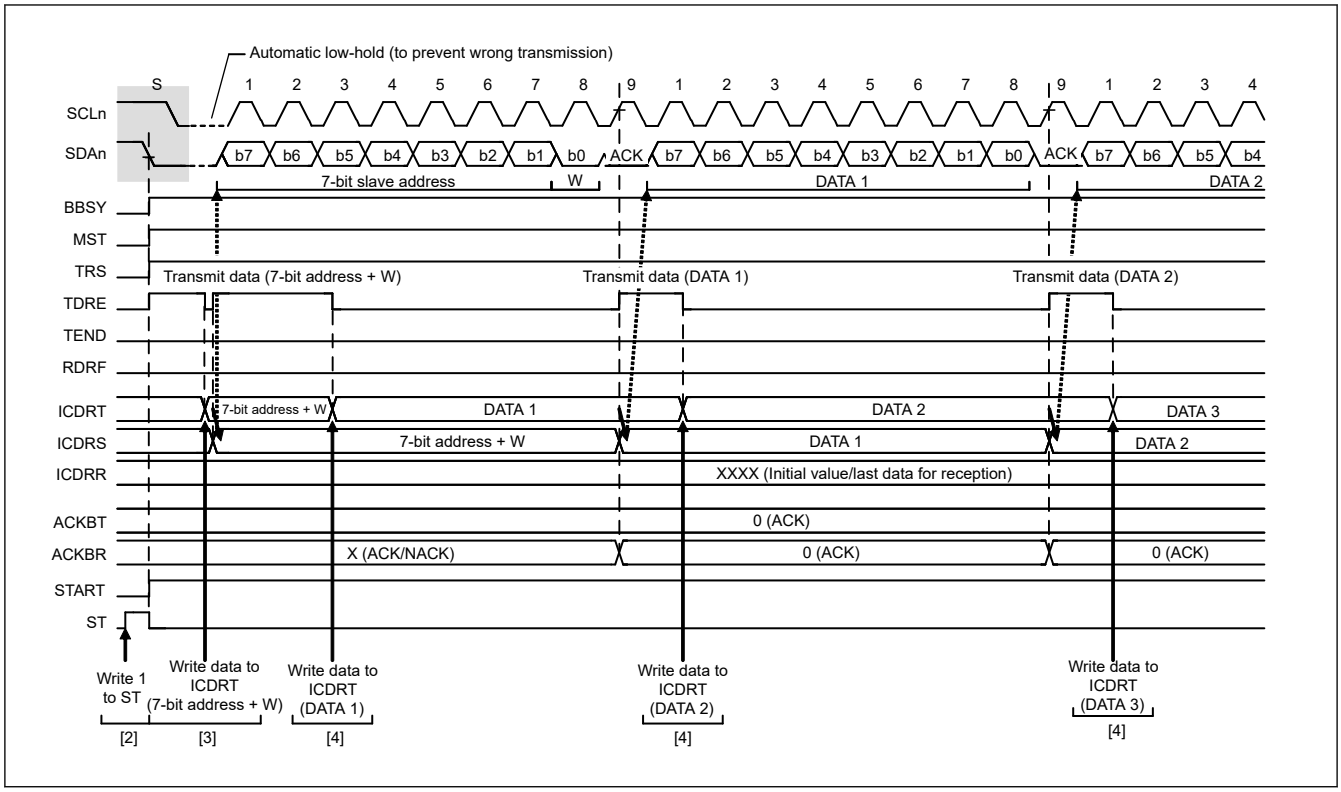

**Figure 28.7 Master transmit operation timing (1) with 7-bit address format**

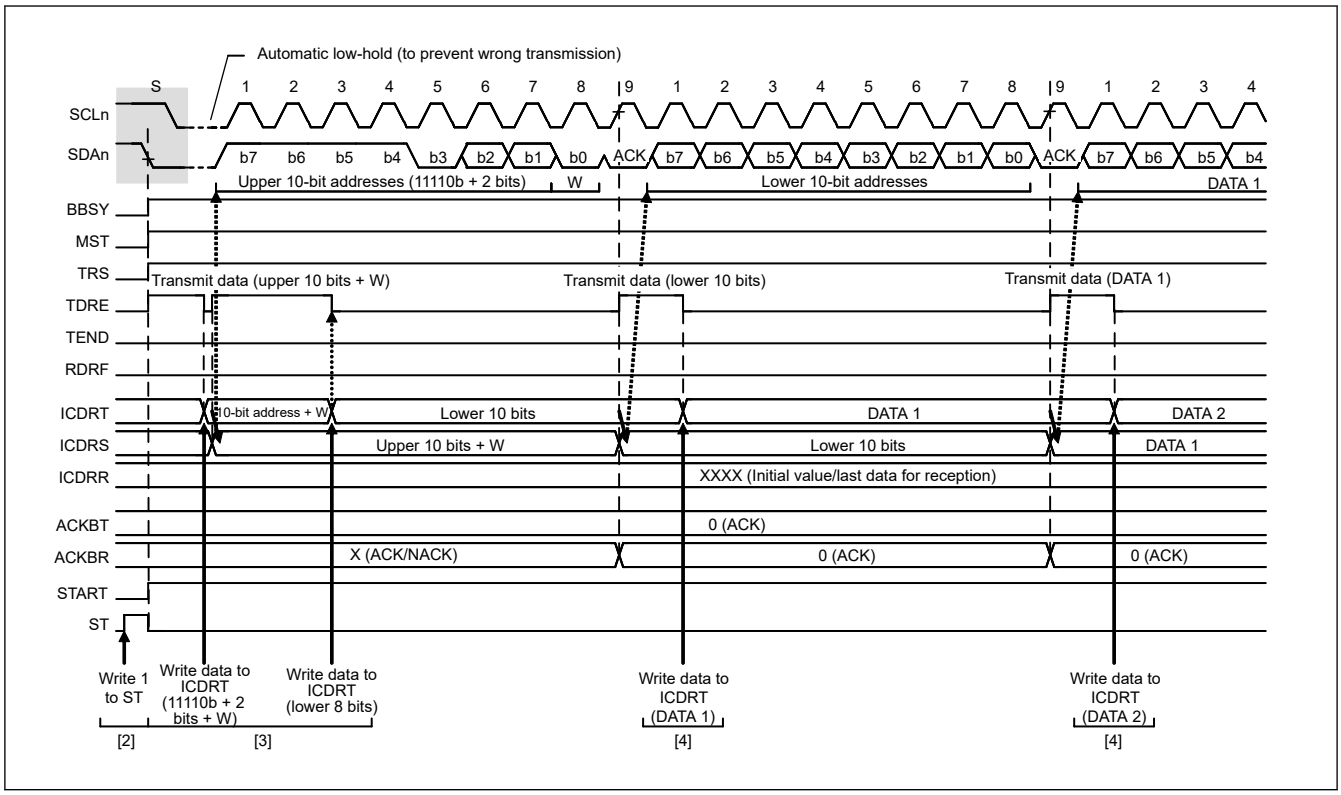

**Figure 28.8 Master transmit operation timing (2) with 10-bit address format**

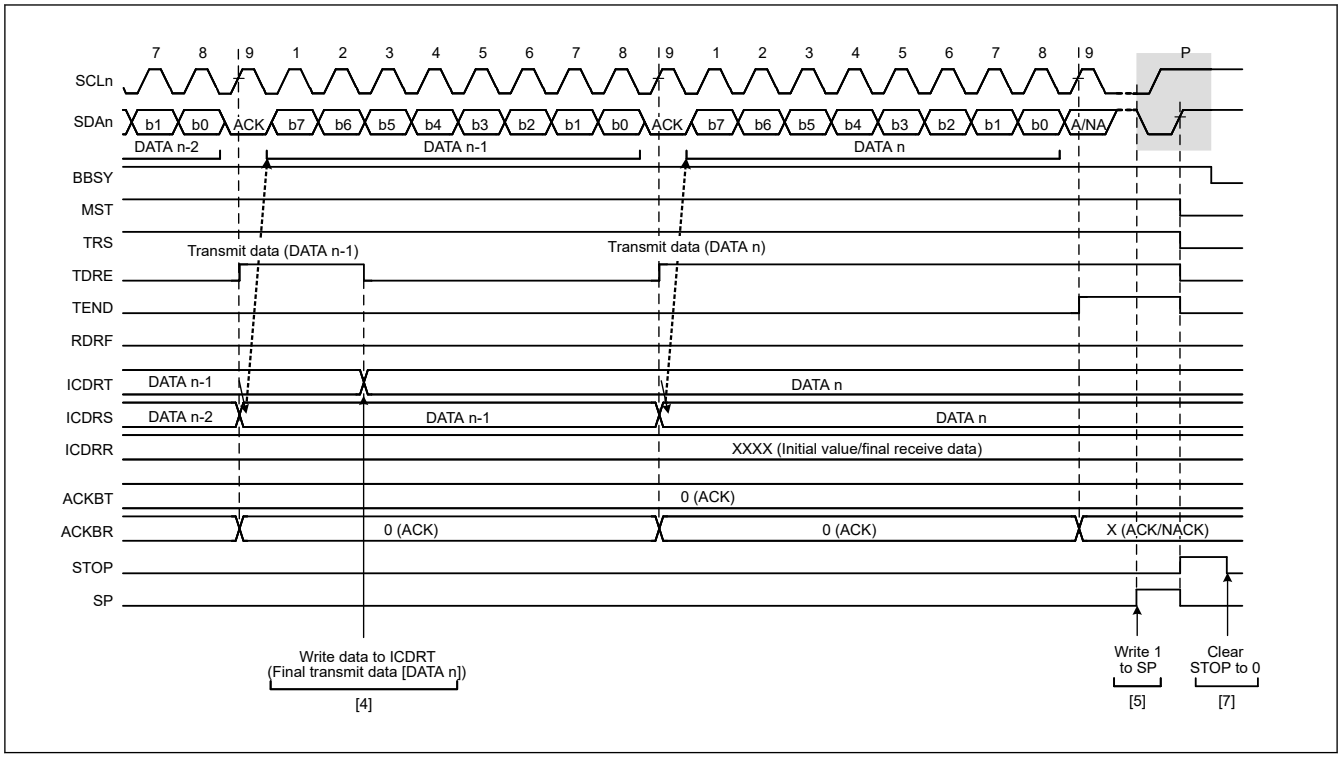

**Figure 28.9 Master transmit operation timing (3)**

## 28.3.4 Master Receive Operation

In master receive operation, the IIC as a master device outputs the SCL clock, receives data from the slave device, and returns acknowledgments. Because the IIC must start by sending a slave address to the associated slave device, this part of the procedure is performed in master transmit mode, but the subsequent steps are in master receive mode.

Figure 28.10 and Figure 28.11 show examples of master reception (7-bit address format), and Figure 28.12 to Figure 28.14 show the operation timing in master reception.

To set up and perform master reception:

1. Process initial settings. For details, see section 28.3.2. Initial Settings.
2. Read the BBSY flag in ICCR2 to check that the bus is free, and then set the ST bit in ICCR2 to 1 (start condition request). On receiving the request, the IIC issues a start condition. When the IIC detects the start condition, the BBSY and START flags in ICSR2 automatically set to 1, and the ST bit automatically is set to 0. At this time, if the start condition is detected and the levels for the SDA output and the levels on the SDA0 line match while the ST bit is 1, the IIC recognizes that issuance of the start condition as requested by the ST bit is successfully complete, and the MST and TRS bits in ICCR2 automatically set to 1, placing the IIC in master transmit mode. The TDRE flag in ICSR2 also automatically is set to 1 in response to the setting of the TRS bit to 1.
3. Check that the TDRE flag in ICSR2 is 1, and then write the value for transmission (the first byte indicates the slave address and value of the R/W# bit) to ICDRT. When the transmit data is written to ICDRT, the TDRE flag automatically is set to 0, the data is transferred from ICDRT to ICDRS, and the TDRE flag again is set to 1. When the byte containing the slave address and R/W# bit is transmitted, the value of the ICCR2.TRS bit automatically updates to select transmit or receive mode based on the value of the transmitted R/W# bit. If the value of the R/W# bit is 1, the TRS bit is set to 0 on the rising edge of the ninth cycle of the SCL clock, placing the IIC in master receive mode. At this time, the TDRE flag is set to 0 and the ICSR2.RDRF flag automatically is set to 1.
   Because the ICSR2.NACKF flag being 1 at this time indicates that no slave device recognized the address or there was an error in communications, write 1 to the ICCR2.SP bit to issue a stop condition.
   For master reception from a device with a 10-bit address, start by using master transmission to issue the 10-bit address, and then issue a restart condition. After that, transmitting 11110b, the two higher-order bits of the slave address, and the R bit places the IIC in master receive mode.
4. Dummy read ICDRR after confirming that the RDRF flag in ICSR2 is 1. This makes the IIC start output of the SCL clock and start data reception.

5. After 1 byte of data is received, the RDRF flag in ICSR2 is set to 1 on the rising edge of the 8th or 9th cycle of the SCL clock, as selected in the RDRFS bit in ICMR3. Reading ICDRR at this time produces the received data, and the RDRF flag is automatically set to 0 at the same time. Additionally, the value of the acknowledgment field received during the ninth cycle of the SCL clock is returned as the value set in the ICMR3.ACKBT bit. If the next byte to be received is the second-to-last byte, set the ICMR3.WAIT bit to 1 for wait insertion before reading ICDRR, containing the second-to-last byte. In addition to enabling NACK output, even when interrupts or other operations result in delays in setting the ICMR3.ACKBT bit to 1 (NACK) in step (6), this fixes the SCL0 line to the low level on the rising edge of the ninth clock cycle in reception of the last byte, which enables the issuing of a stop condition.
6. When the ICMR3.RDRFS bit is 0, and the slave device must be notified that it is to end transfer for data reception after transfer of the next and final byte, set the ICMR3.ACKBT bit to 1 (NACK).
7. After reading the second-to-last byte from the ICDRR register, if the value of the ICSR2.RDRF flag is 1, write 1 to the SP bit in ICCR2 (stop condition requested), and then read the last byte from ICDRR. When ICDRR is read, the IIC is released from the wait state and issues the stop condition after low-level output in the ninth clock cycle is complete or the SCL0 line is released from the low-hold state.
8. On detecting the stop condition, the IIC automatically sets the MST and TRS bits in ICCR2 to 00b and enters slave receive mode. Additionally, detection of the stop condition sets the ICSR2.STOP flag to 1.
9. Check that the ICSR2.STOP flag is 1, then set the ICSR2.NACKF and STOP flags to 0 for the next transfer operation.

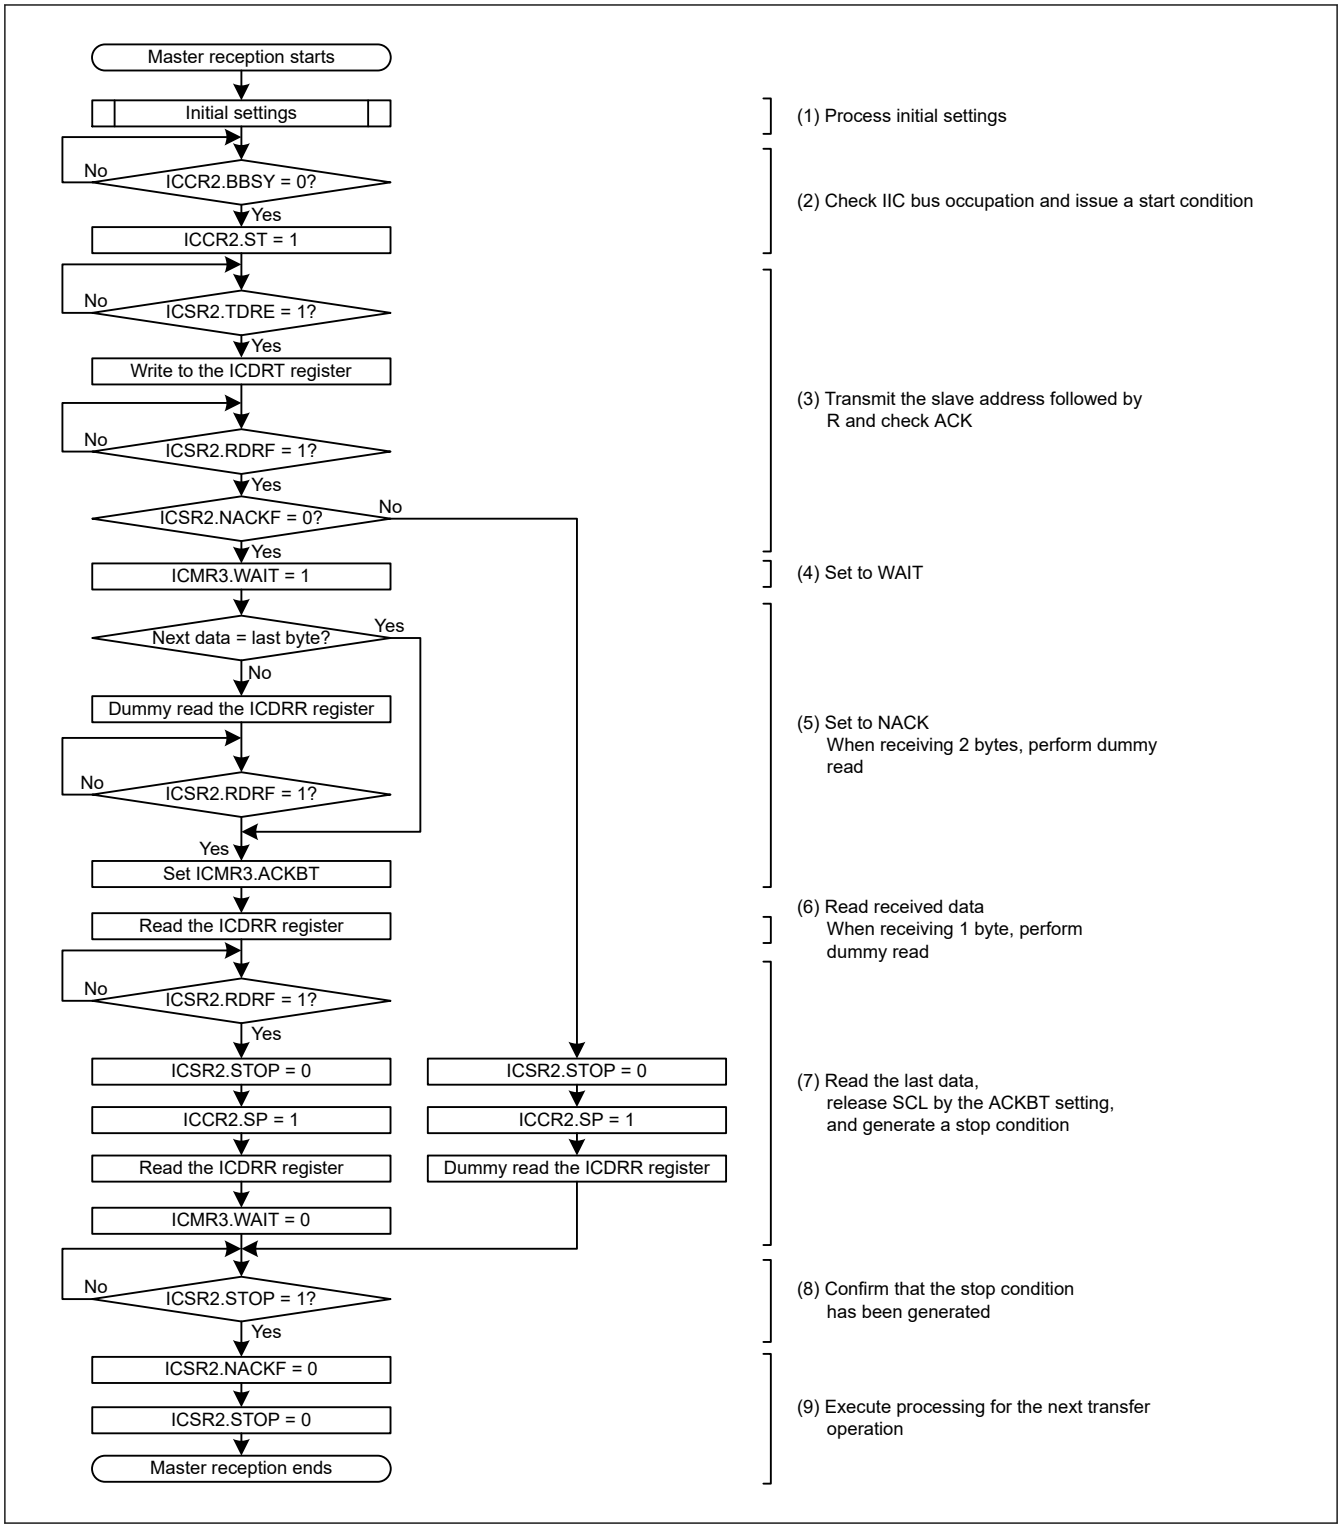

**Figure 28.10 Example master reception flow with 7-bit address format of 1 byte or 2 bytes**

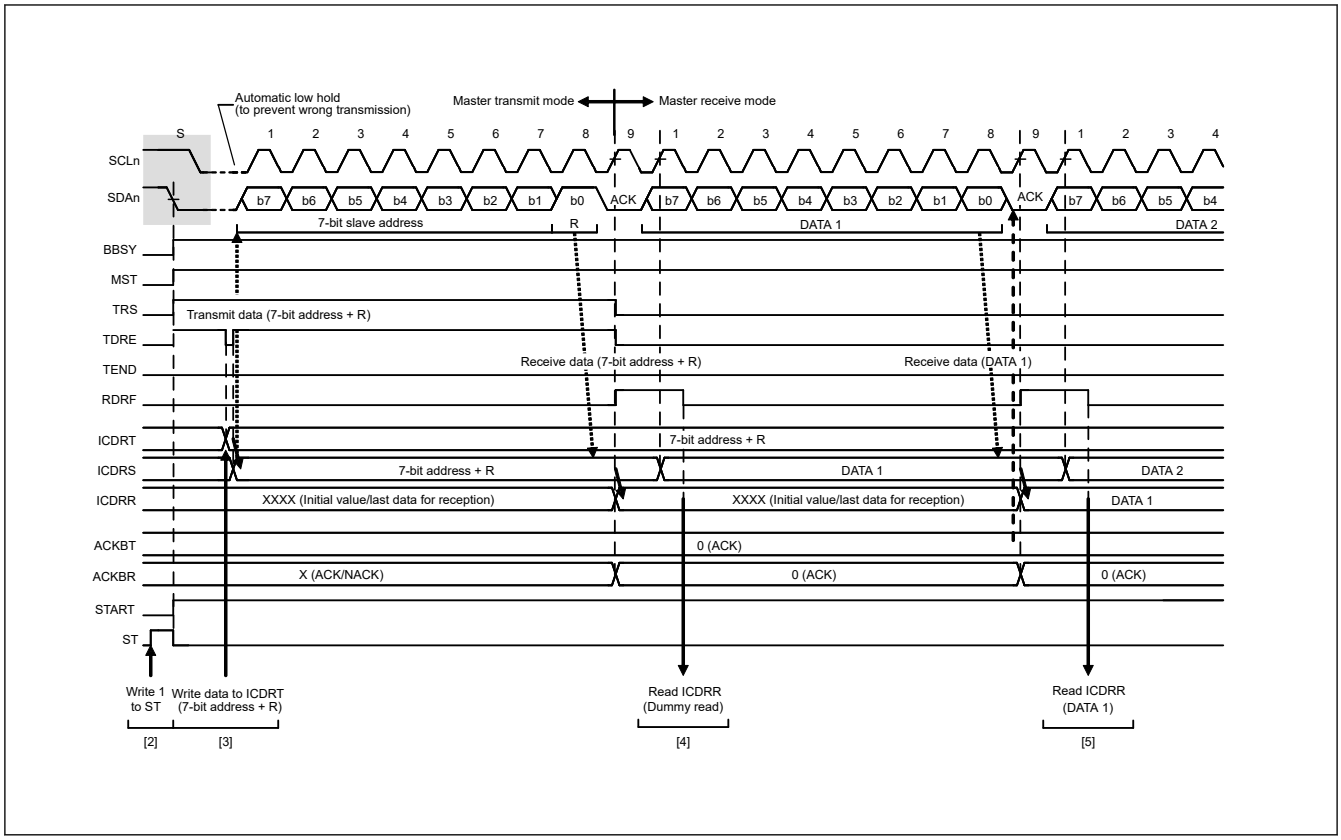

**Figure 28.12 Master receive operation timing (1) with 7-bit address format when RDRFS = 0**

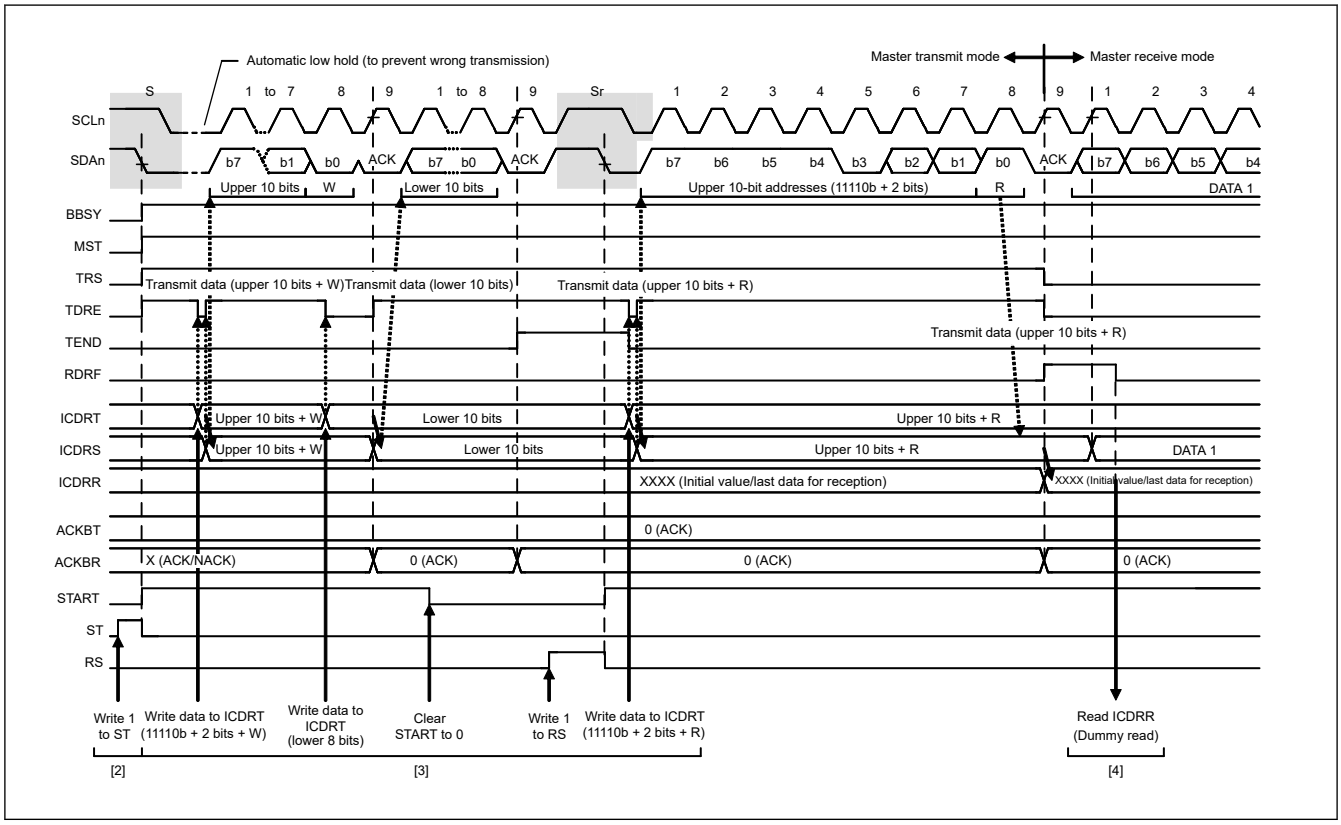

**Figure 28.13 Master receive operation timing (2) with 10-bit address format when RDRFS = 0**

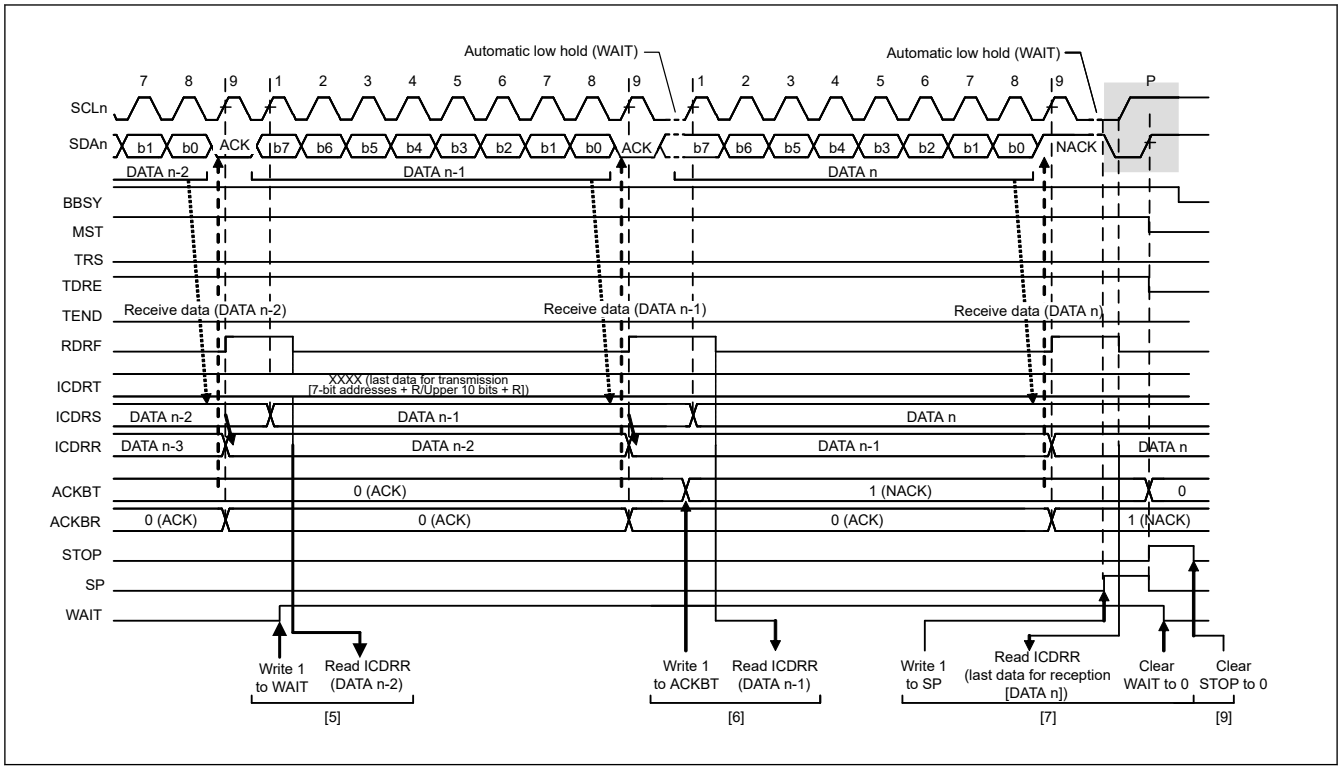

**Figure 28.14 Master receive operation timing (3) when RDRFS = 0**

## 28.3.5 Slave Transmit Operation

In slave transmit operation, the master device outputs the SCL clock, the IIC transmits data as a slave device, and the master device returns acknowledgments.

Figure 28.15 shows an example of slave transmission, Figure 28.16, and Figure 28.17 show the operation timing in slave transmission.

To set up and perform slave transmission:

1. Initialize the IIC using the procedure in section 28.3.2. Initial Settings.
   After initialization, the IIC stays in standby state until it receives a slave address that matches.
2. After receiving a matching slave address, the IIC sets one of the associated ICSR1.HOA, GCA, and AASy flags (y = 0 to 2) to 1 on the rising edge of the 9th cycle of the SCL clock and outputs the value set in the ICMR3.ACKBT bit to the acknowledge bit on the 9th cycle of the SCL clock. If the value of the R/W# bit is 1, the IIC automatically places itself in slave transmit mode by setting both the ICCR2.TRS bit and the ICSR2.TDRE flag to 1.
3. Check that the ICSR2.TDRE flag is 1, then write the transmit data to the ICDRT register. If the IIC receives no acknowledge from the master device (receives an NACK signal) while the ICFER.NACKE bit is 1, the IIC suspends transfer of the next data.
4. Wait until the ICSR2.TEND flag is set to 1 while the ICSR2.TDRE flag is 1, after the ICSR2.NACKF flag is set to 1 or the last byte for transmission is written to the ICDRT register. When the ICSR2.NACKF flag or the TEND flag is 1, the IIC drives the SCL0 line low on the 9th falling edge of the SCL clock.
5. When the ICSR2.NACKF or ICSR2.TEND flag is 1, dummy read ICDRR to complete the processing. This releases the SCL0 line.
6. On detecting the stop condition, the IIC automatically sets the ICSR1.HOA, GCA, and AASy flags (y = 0 to 2), the ICSR2.TDRE and TEND flags, and the ICCR2.TRS bit to 0, and enters slave receive mode.
7. Check that the ICSR2.STOP flag is 1, then set the ICSR2.NACKF and STOP flags to 0 for the next transfer operation.

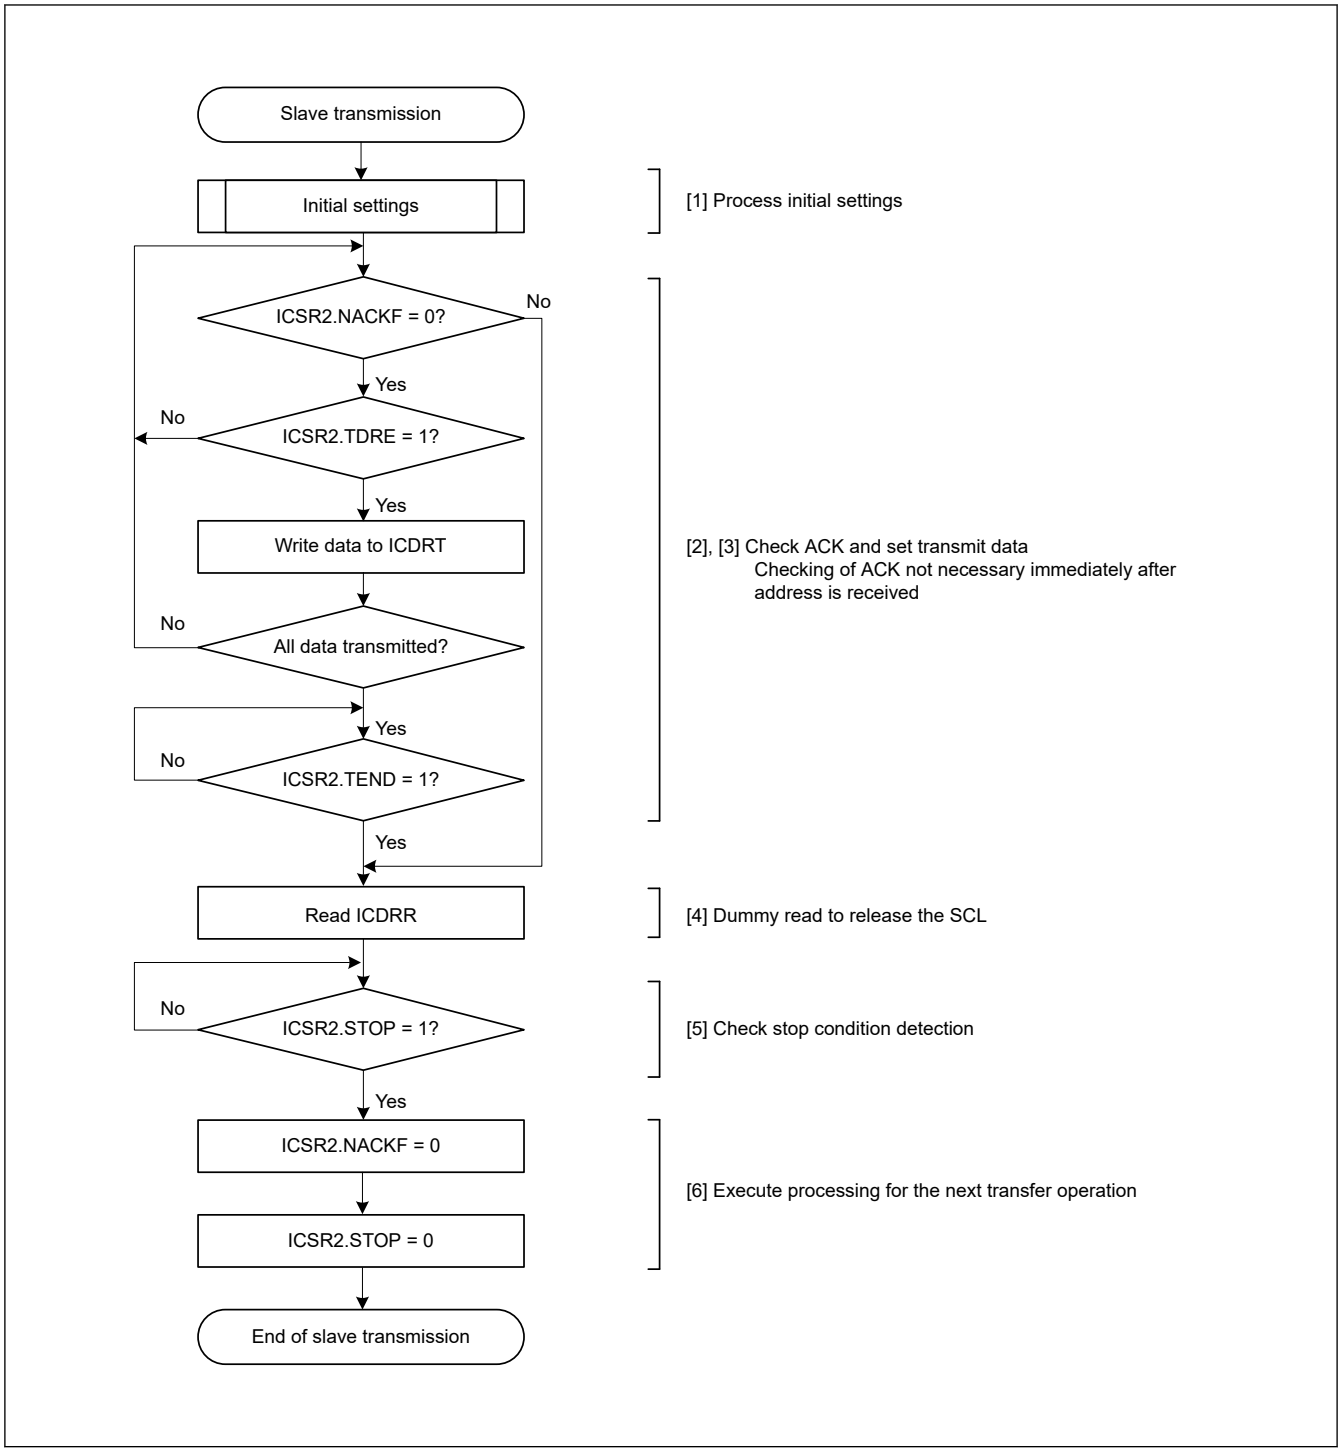

**Figure 28.15 Example slave transmission flow**

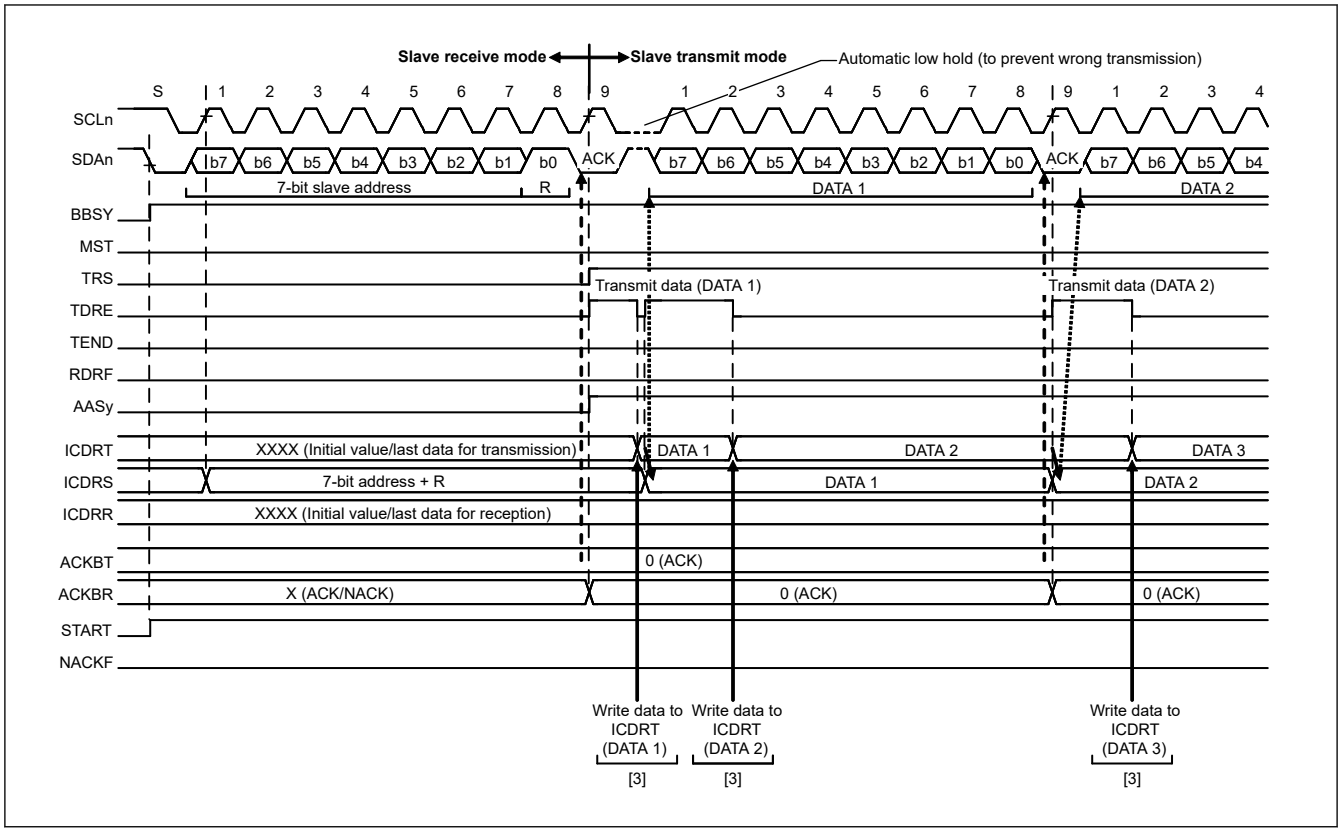

**Figure 28.16 Slave transmit operation timing (1) with 7-bit address format**

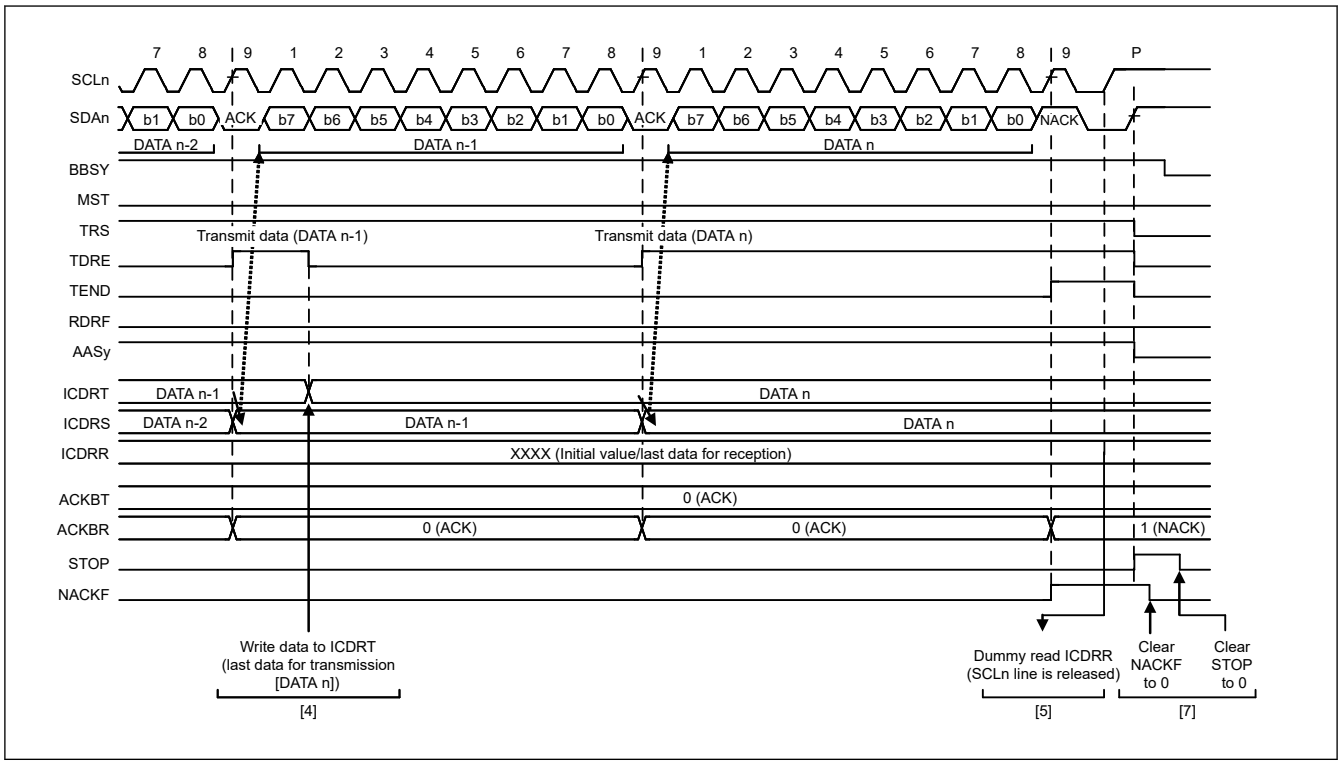

**Figure 28.17 Slave transmit operation timing (2)**

## 28.3.6 Slave Receive Operation

In slave receive operation, the master device outputs the SCL clock and transmit data, and the IIC returns acknowledgments as a slave device.

Figure 28.18 shows an example of slave reception, and Figure 28.19 and Figure 28.20 show the operation timing in slave reception.

To set up and perform slave reception:

1. Initialize the IIC using the procedure in section 28.3.2. Initial Settings.
   After initialization, the IIC stays in the standby state until it receives a slave address that matches.
2. After receiving a matching slave address, the IIC sets one of the associated ICSR1.HOA, GCA, and AASy flags (y = 0 to 2) to 1 on the rising edge of the ninth cycle of the SCL clock and outputs the value set in the ICMR3.ACKBT bit to the acknowledge bit on the ninth cycle of the SCL clock. If the value of the R/W# bit is 0, the IIC continues to place itself in slave receive mode and sets the RDRF flag in ICSR2 to 1.
3. Check that the ICSR2.STOP flag is 0 and the ICSR2.RDRF flag is 1, then dummy read ICDRR. The dummy value consists of the slave address and R/W# bit when the 7-bit address format is selected, or the lower 8 bits when the 10-bit address format is selected.
4. When ICDRR is read, the IIC automatically sets the ICSR2.RDRF flag to 0. If reading of ICDRR is delayed and a next byte is received while the RDRF flag is still set to 1, the IIC holds the SCL0 line low at the SCL clock one cycle before the point where the RDRF is set. In this case, reading ICDRR releases the SCL0 line from being held low.
   When the ICSR2.STOP flag is 1 and the ICSR2.RDRF flag is also 1, read ICDRR until all the data is completely received.
5. On detecting the stop condition, the IIC automatically clears the ICSR1.HOA, GCA, and AASy flags (y = 0 to 2) to 0.
6. Check that the ICSR2.STOP flag is 1, then set the ICSR2.STOP flag to 0 for the next transfer operation.

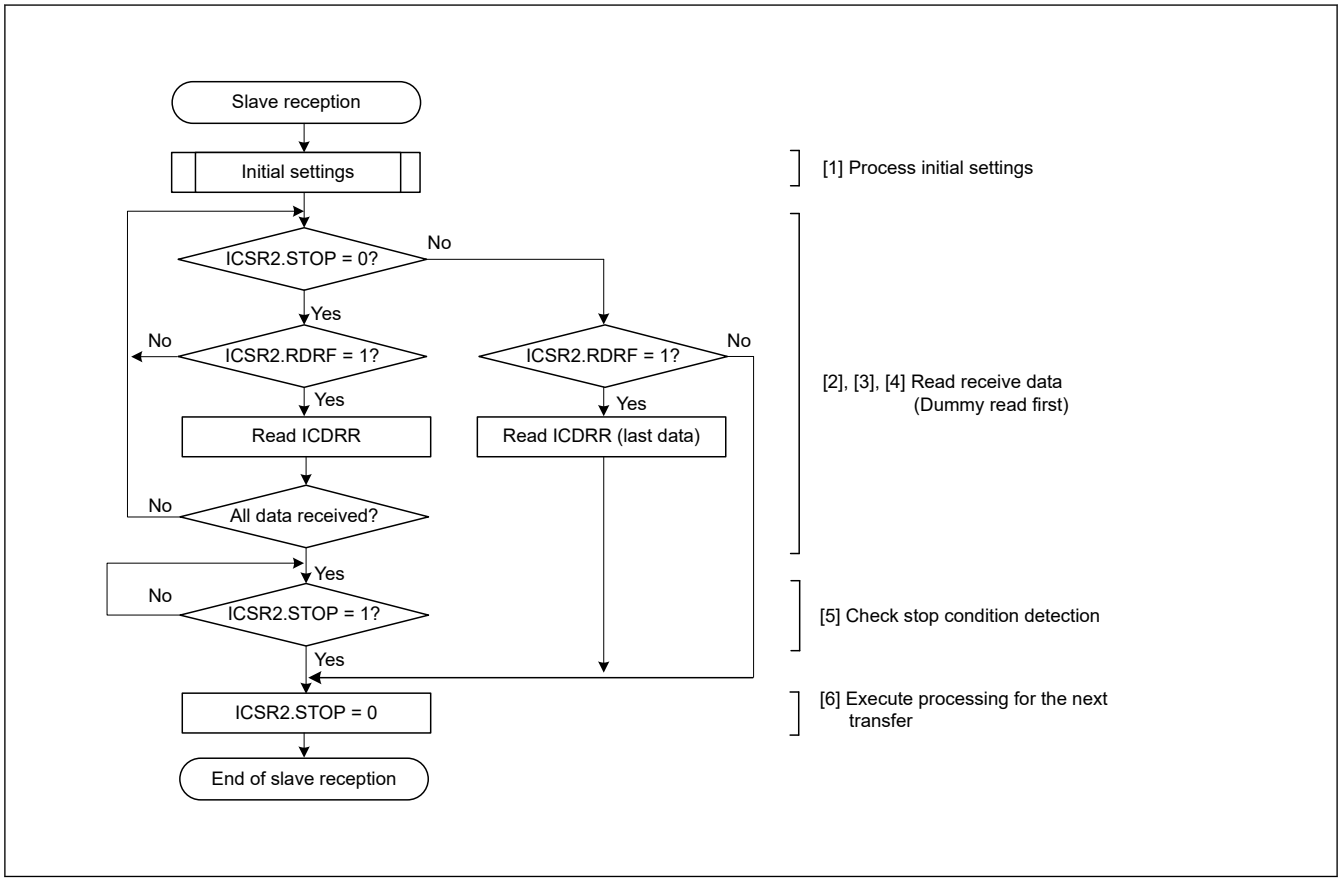

**Figure 28.18 Example slave reception flow**

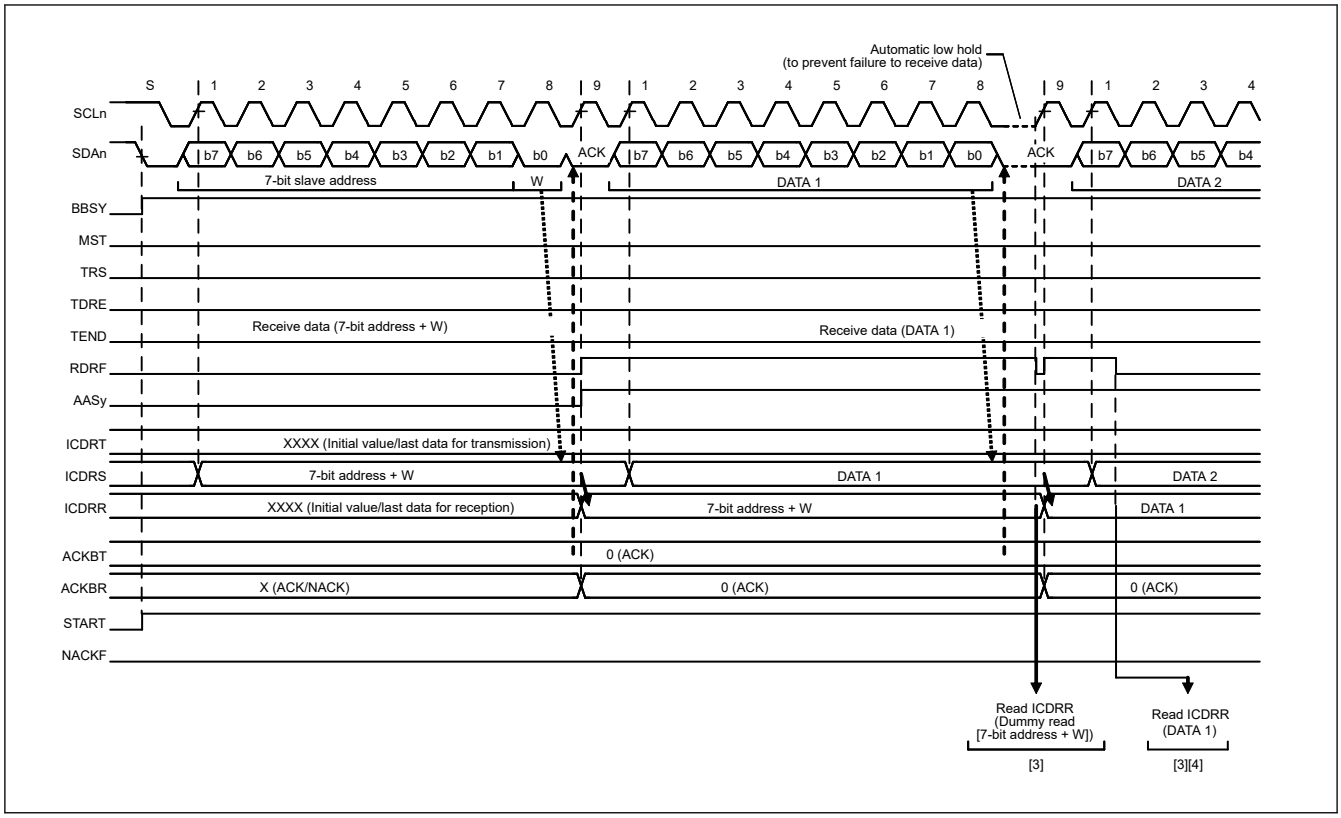

**Figure 28.19 Slave receive operation timing (1) with 7-bit address format when RDRFS = 0**

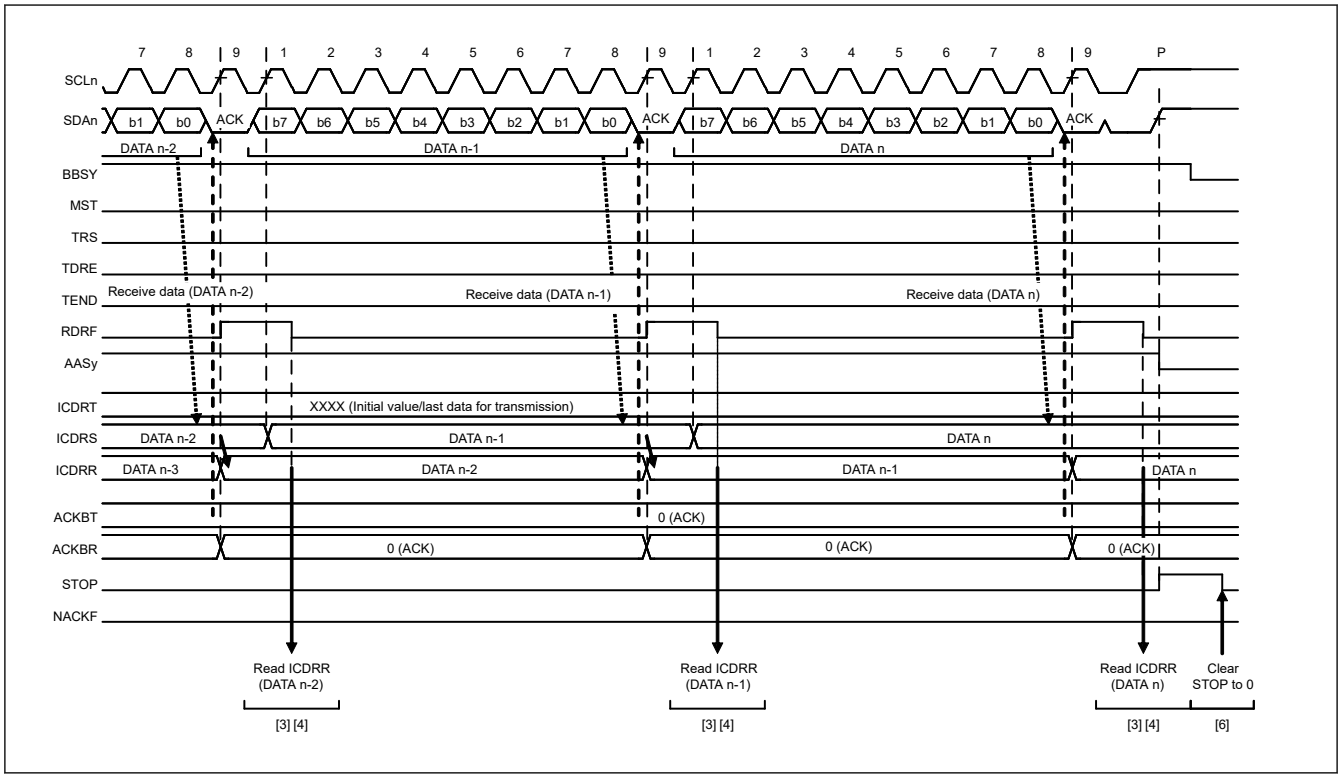

**Figure 28.20 Slave receive operation timing (2) when RDRFS = 0**

## 28.4 SCL Synchronization Circuit

For generation of the SCL clock, the IIC starts counting the value for the high-level period specified in ICBRH when it detects a rising edge on the SCL0 line, and it drives the SCL0 line low when it completes counting. When the IIC detects

the falling edge of the SCL0 line, it starts counting the value for the low-level period specified in ICBRL, and then it stops driving the SCL0 line, releasing the line, when it completes counting. The IIC repeats this process to generate the SCL clock.

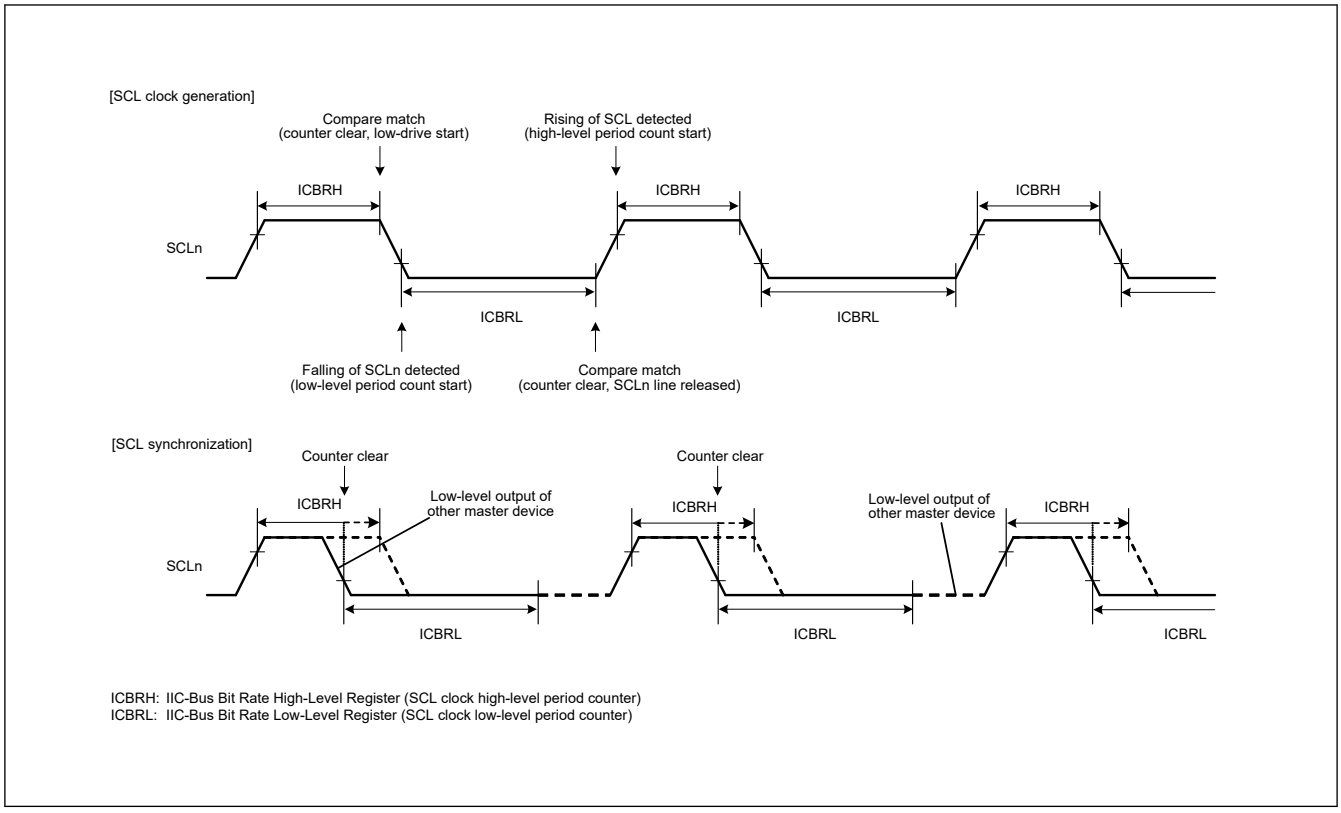
If multiple master devices are connected to the $I^2C$ bus, a collision of SCL signals might arise because of contention with another master device. In such cases, the master devices must synchronize their SCL signals. Because this synchronization of SCL signals must be bit-by-bit, the IIC is equipped with an SCL synchronization circuit to obtain bit-by-bit synchronization of the SCL clock signals by monitoring the SCL0 line while in master mode.

When the IIC detects a rising edge on the SCL0 line and starts counting the high-level period specified in ICBRH.BRH[4:0], and the level on the SCL0 line falls because an SCL signal is being generated by another master device, the IIC performs the following:

1. Stops counting when it detects the falling edge.
2. Drives the level on the SCL0 line low.
3. Starts counting the low-level period specified in ICBRL.BRL[4:0].

When the IIC finishes counting the low-level period, it stops driving the SCL0 line low to release the line. If the low-level period of the SCL clock signal from the other master device is longer than the low-level period set in the IIC, the low-level period of the SCL signal is extended. When the low-level period for the other master device ends, the SCL signal rises because the SCL0 line is released.

When the IIC finishes outputting the low-level period of the SCL clock, the SCL0 line is released and the SCL clock rises. That is, when SCL signals from more than one master are contending, the high-level period of the SCL signal is synchronized with that of the clock with the narrower period, and the low-level period of the SCL signal is synchronized with that of the clock with the broader period. However, such synchronization of the SCL signal is only enabled when the SCLE bit in ICFER is set to 1.



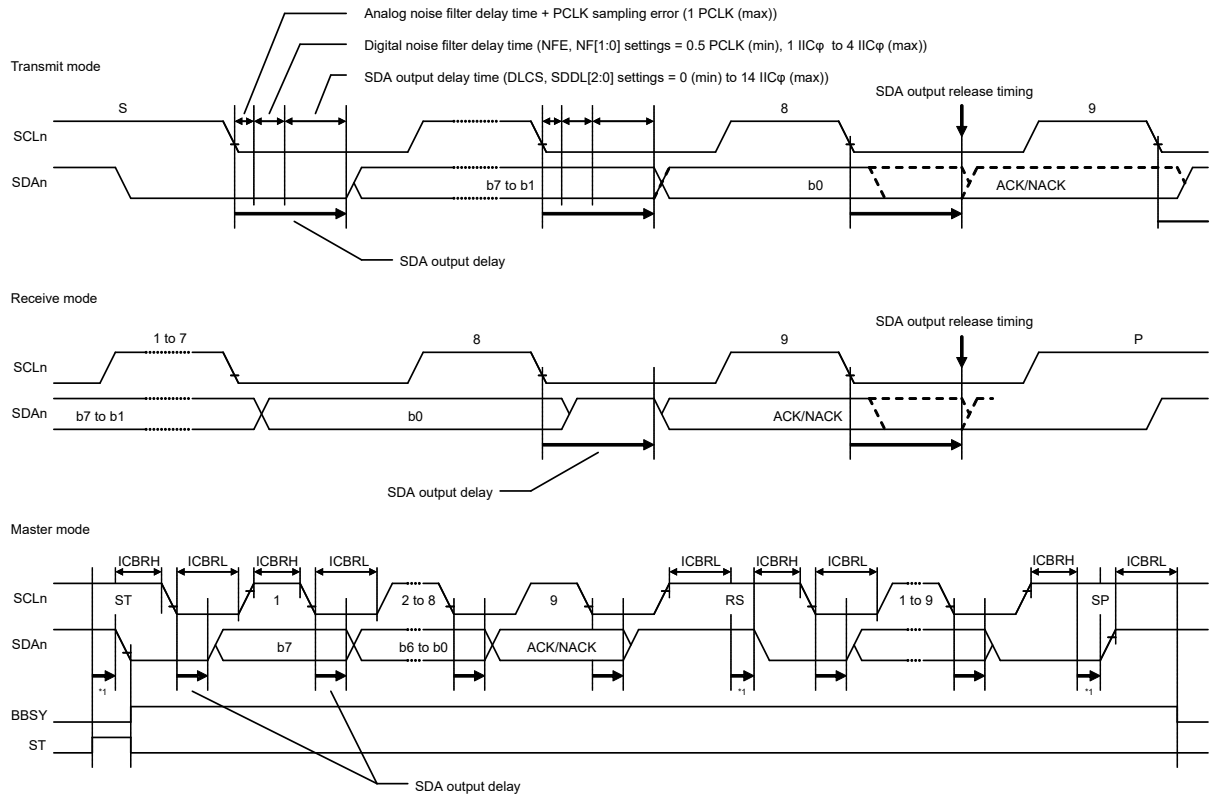


**Figure 28.21 Generation and synchronization of SCL signal from IIC**

## 28.5 SDA Output Delay Function

The IIC module incorporates a function for delaying output on the SDA line. The delay can be applied to all output on the SDA line, including issuing of the start, restart, and stop conditions, data, and the ACK and NACK signals.

With this function, SDA output is delayed from the detection of a falling edge of the SCL signal to ensure that the SDA signal is output within the interval during which the SCL clock is low. This approach helps prevent erroneous operation of communications devices, with the aim of satisfying the 300-ns minimum data-hold time requirement of the SMBus specification. The output delay function is enabled by setting the SDDL[2:0] bits in ICMR2 to a value other than 000b, and disabled by setting the same bits to 000b.

When the SDA output delay function is enabled, for example, the DLCS bit in ICMR2 selects the clock source for the SDA output delay counter, either as the internal base clock (IICφ) for the IIC module or as the internal base clock divided by 2 (IICφ/2). The counter counts the number of cycles set in the SDDL[2:0] bits in ICMR2. When the delay cycles count is reached, the IIC module places the required output (start, restart, or stop condition, data, or an ACK or NACK signal) on the SDA line.

Note: PCLK = PCLKB
Note 1. The output delay function is set by the DLCS and SDDL[2:0] bits when a start (ST), restart (RS), or stop (SP) condition is issued.

**Figure 28.22 SDA output delay function**

## 28.6 Digital Noise Filter Circuits

The internal circuitry sees the states of the SCL0 and SDA0 pins through analog and digital noise-filter circuits. Figure 28.23 shows a block diagram of the digital noise-filter circuit.

The on-chip digital noise-filter circuit of the IIC consists of four flip-flop circuit stages connected in series and a match-detection circuit. The number of valid stages in the digital noise filter is selected in the NF[1:0] bits in ICMR3. The selected number of valid stages determines the noise-filtering capability as a period from 1 to 4 IICφ cycles.

The input signal to the SCL0 pin (or SDA0 pin) is sampled on falling edges of the IICφ signal. When the input signal level matches the output level of the number of valid flip-flop circuit stages as selected in the NF[1:0] bits in ICMR3, the signal level is seen in the subsequent stage. If the signal levels do not match, the previous value is saved.

If the ratio between the frequency of the internal operating clock (PCLKB) and the transfer rate is small, for example, if data transfer is 400 kbps with PCLKB = 4 MHz, the characteristics of the digital noise filter might lead to the elimination of

required signals as noise. In such cases, it is possible to disable the digital noise-filter circuit by setting the ICFER.NFE bit to 0, and use only the analog noise filter circuit.

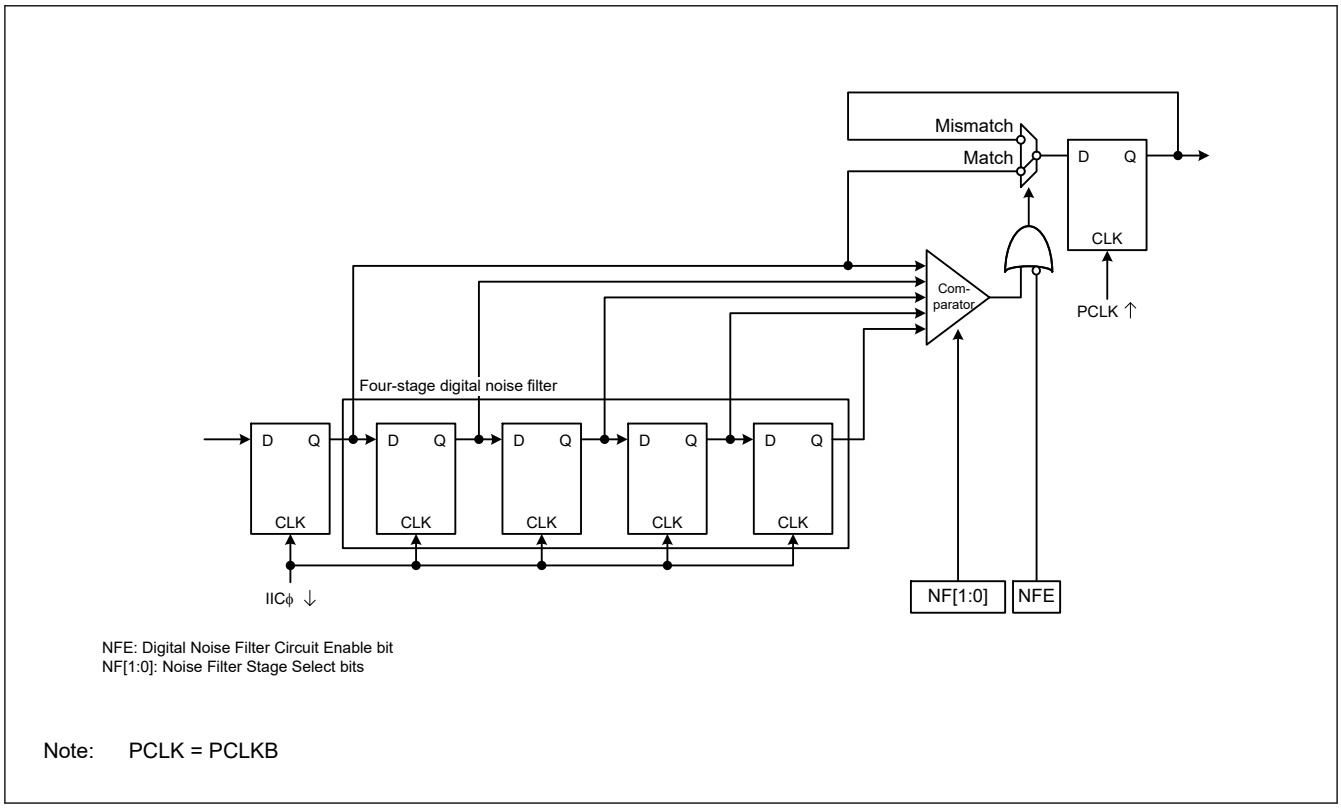

**Figure 28.23 Digital noise filter circuit block diagram**

## 28.7 Address Match Detection

The IIC can set three unique slave addresses in addition to the general call address and host address. The slave addresses can be 7-bit or 10-bit slave addresses.

### 28.7.1 Slave-Address Match Detection

The IIC can set three unique slave addresses and has a slave address detection function for each unique slave address. When the SARyE bit (y = 0 to 2) in ICSER is set to 1, the slave addresses set in SARUy and SARLy (y = 0 to 2) can be detected.

When the IIC detects a match of the set slave address, the associated AASy flag (y = 0 to 2) in ICSR1 is set to 1 on the rising edge of the ninth SCL clock cycle, and the RDRF flag in ICSR2 or the TDRE flag in ICSR2 is set to 1 by the subsequent R/W# bit. This causes a receive data full interrupt (IIC0_RXI) or transmit data empty interrupt (IIC0_TXI) to be generated. The AASy flag identifies which slave address is specified.

Figure 28.24 to Figure 28.26 show the AASy flag set timing in three cases.

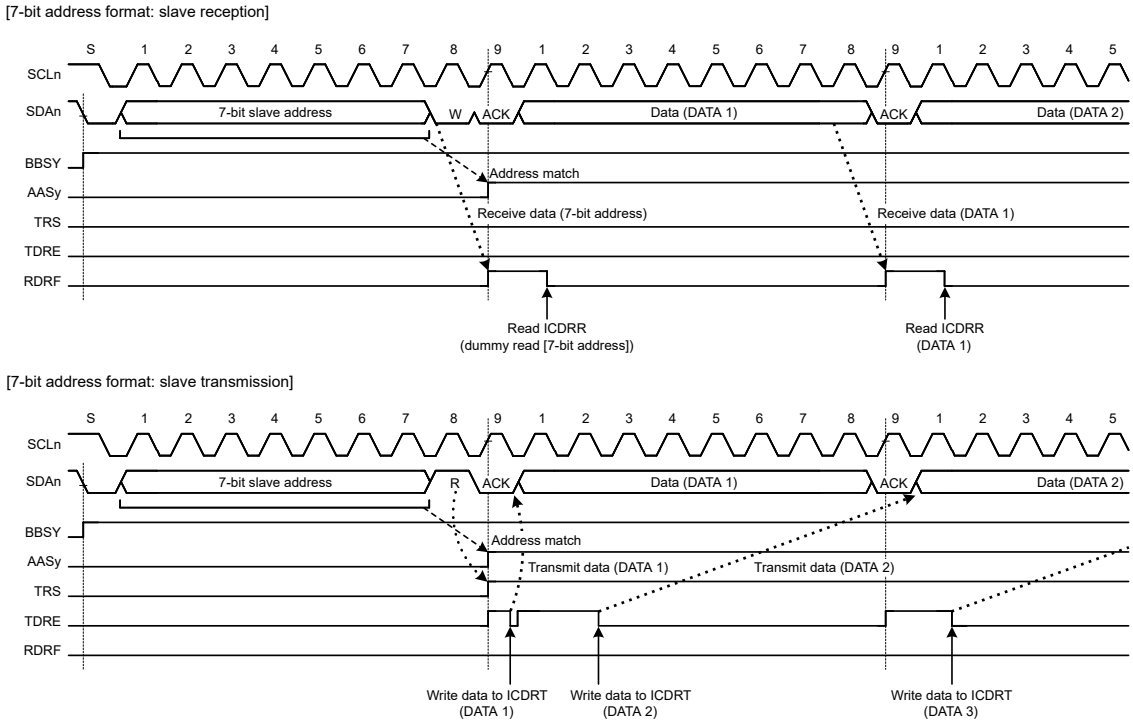

**Figure 28.24 AASy flag set timing with 7-bit address format**

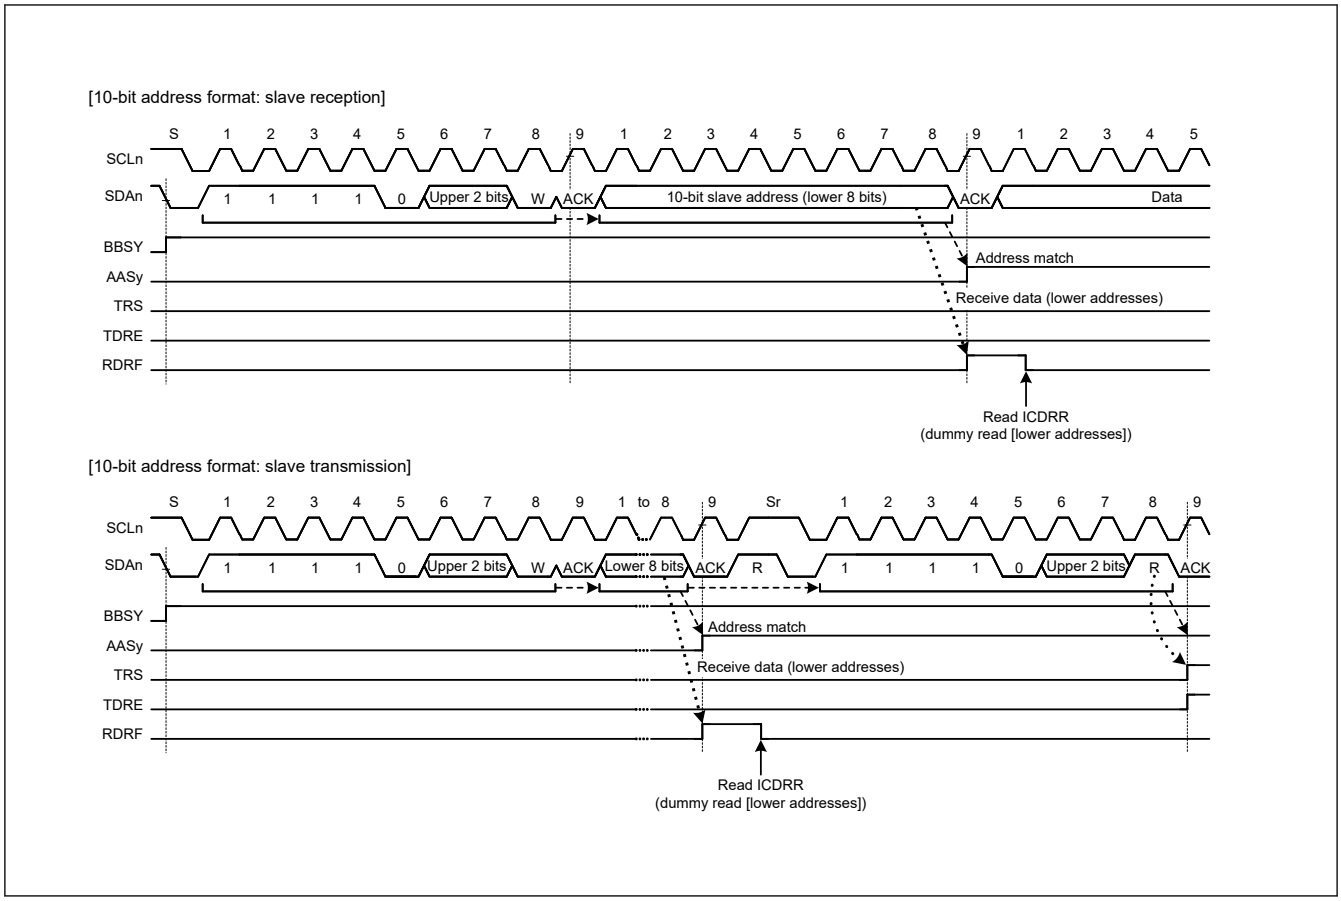

**Figure 28.25 AASy flag set timing with 10-bit address format**

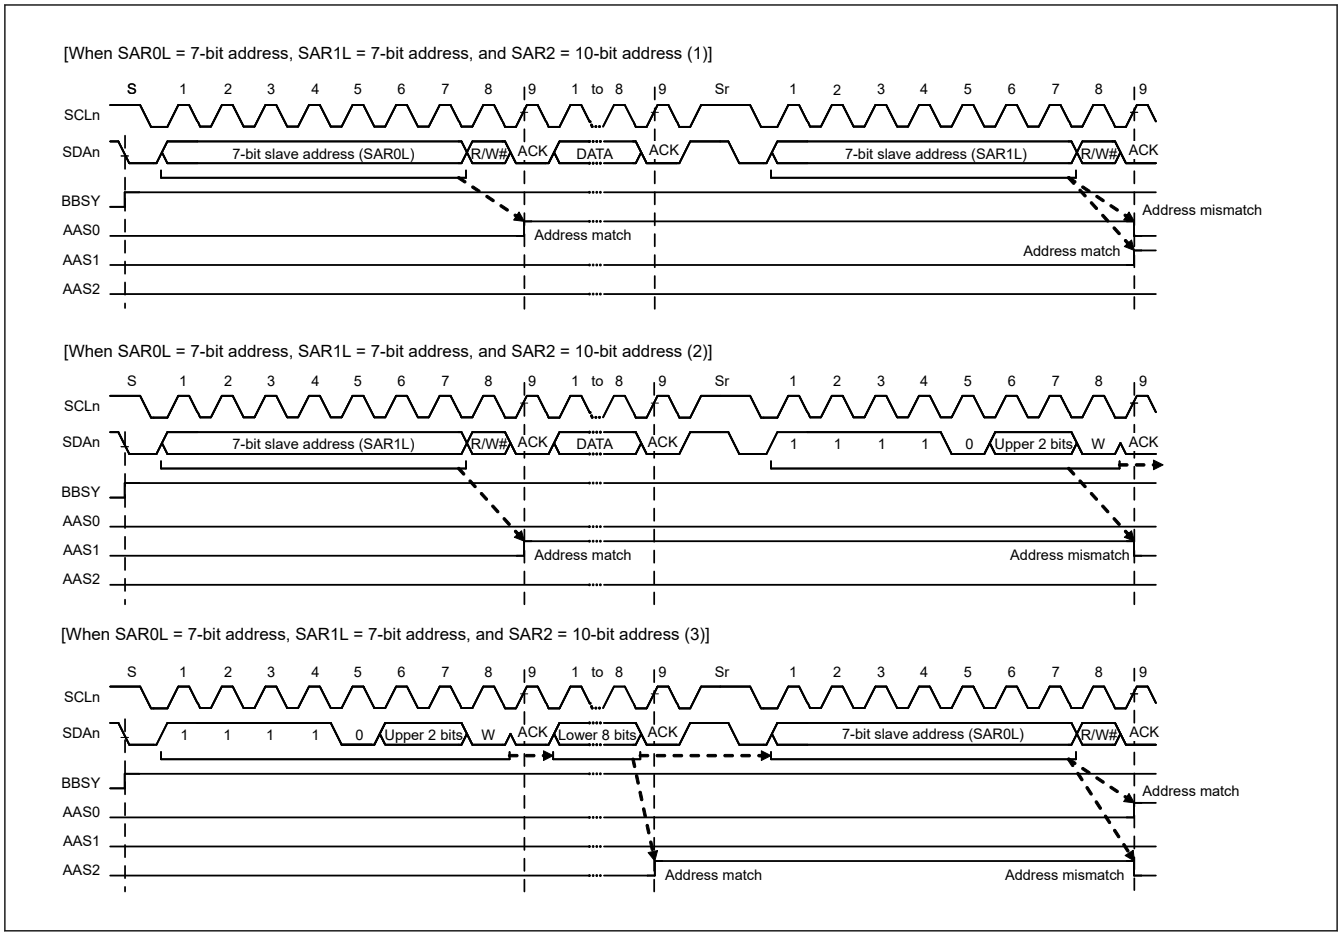

**Figure 28.26 AASy flag set and clear timing with mixed 7-bit and 10-bit address formats**

## 28.7.2 Detection of General Call Address

The IIC provides detection of the general call address (0000 000b + 0 [W]). This is enabled by setting the GCAE bit in ICSER to 1.

If the address received after a start or restart condition is issued is 0000 000b + 1[R] (start byte), the IIC recognizes this as the address of a slave device with an all-zero address, but not as the general call address.

When the IIC detects the general call address, both the GCA flag in ICSR1 and the RDRF flag in ICSR2 set to 1 on the rising edge of the ninth cycle of the SCL clock. This leads to the generation of a receive data full interrupt (IIC0_RXI). The value of the GCA flag can be checked to confirm that the general call address was transmitted.

Operation after detection of the general call address is the same as normal slave receive operation.

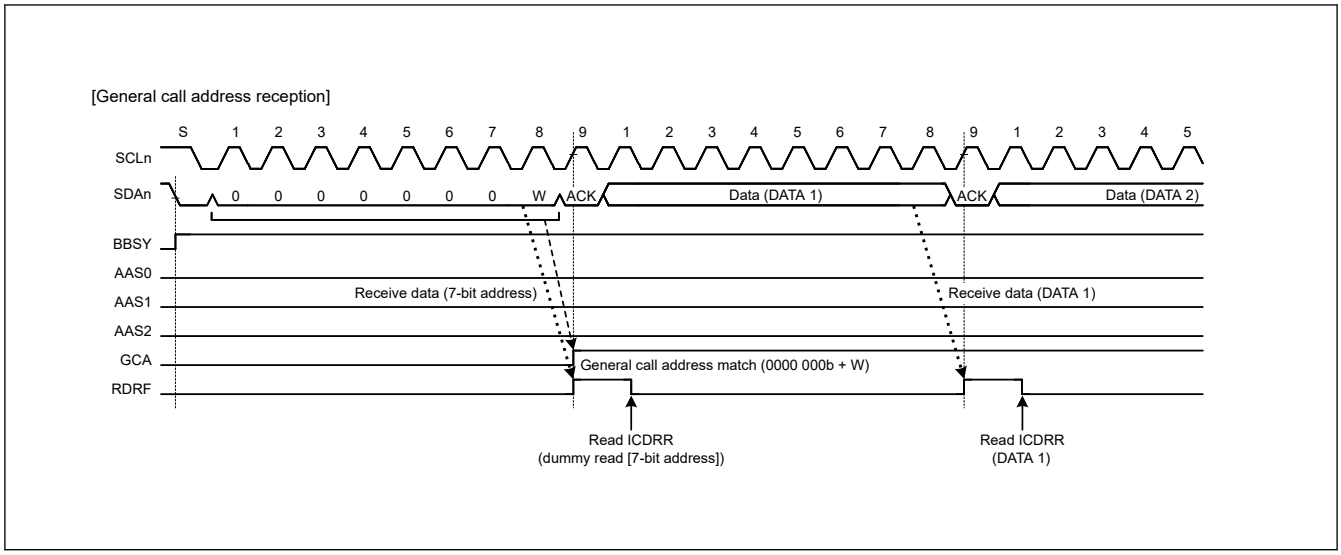

**Figure 28.27 Timing of GCA flag setting during reception of general call address**

## 28.7.3 Device-ID Address Detection

The IIC module provides detection of device-ID address compliant with the $I^2C$ bus specification (revision 03). When the IIC receives 1111 100b as the first byte after a start or restart condition is issued with the DIDE bit in ICSER set to 1, it recognizes the address as a device ID, sets the DID flag in ICSR1 to 1 on the rising edge of the ninth SCL clock cycle when the subsequent R/W# bit is 0, then compares the second and subsequent bytes with its own slave address. If the address matches the value in the slave address register, the IIC sets the associated AASy flag (y = 0 to 2) in ICSR1 to 1.

When the first byte received after the issue of a start or restart condition matches the device ID address (1111 100b) again and the subsequent R/W# bit is 1, the IIC does not compare the second and subsequent bytes and sets the ICSR2.TDRE flag to 1.

In the device ID address detection function, the IIC sets the DID flag to 0 if a match with the IIC slave address is not obtained or a match with the device ID address is not obtained after a match with the IIC slave address and a restart condition is not detected. If the first byte after detection of a start or restart condition matches the device ID address (1111 100b), and the R/W# bit is 0, the IIC sets the DID flag to 1 and compares the second and subsequent bytes with the slave address of the IIC. If the R/W# bit is 1, the DID flag holds the previous value and the IIC does not compare the second and subsequent bytes. Therefore, the reception of a device ID address can be checked by reading the DID flag after confirming that TDRE = 1.

Additionally, prepare the device ID fields (3 bytes: 12 bits indicating the manufacturer + 9 bits identifying the part + 3 bits indicating the revision) that must be sent to the host after reception of a continuous device-ID field as normal transmit data. For details on the information that must be included in device ID fields, contact NXP Semiconductors.

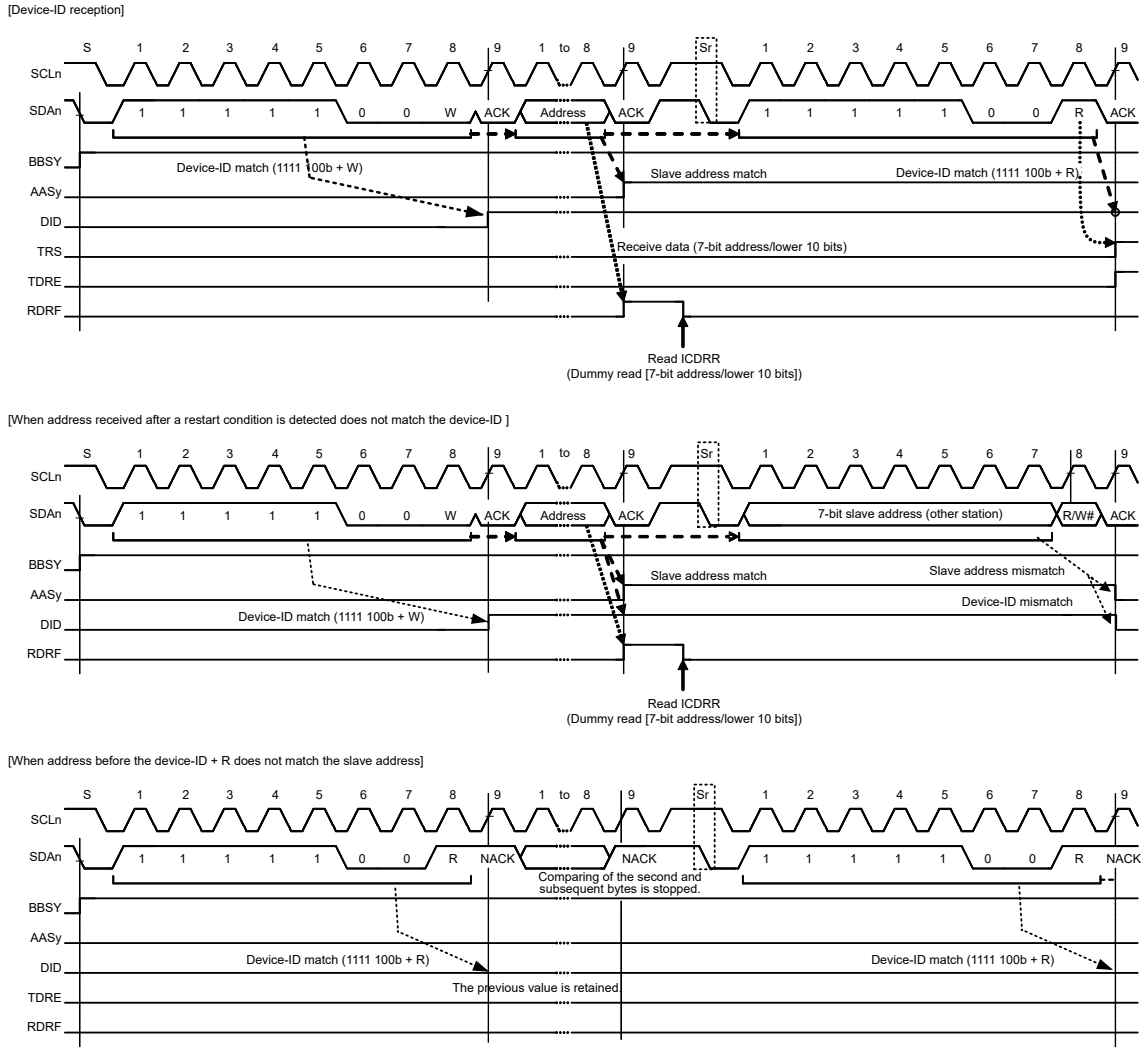

**Figure 28.28 AASy and DID flag set and clear timing during reception of device ID**

## 28.7.4 Host Address Detection

The IIC provides host address detection when operating in SMBus. When the HOAE bit in ICSER is set to 1 while the SMBS bit in ICMR3 is 1, the IIC can detect the host address (0001 000b) in slave receive mode (MST and TRS bits = 00b in ICCR2).

When the IIC detects the host address, the HOA flag in ICSR1 is set to 1 on the rising edge of the 9th SCL clock cycle, and at the same time, the RDRF flag in ICSR2 is set to 1 when the R/W# bit is 0 (Wr bit). This causes a receive data full interrupt (IIC0_RXI) to be generated. The HOA flag indicates that the host address was sent from another device.

If the bit following the host address (0001 000b) is an Rd bit (R/W# bit = 1), the IIC can also detect the host address. After the host address is detected, the IIC operates in the same manner as in normal slave operation.

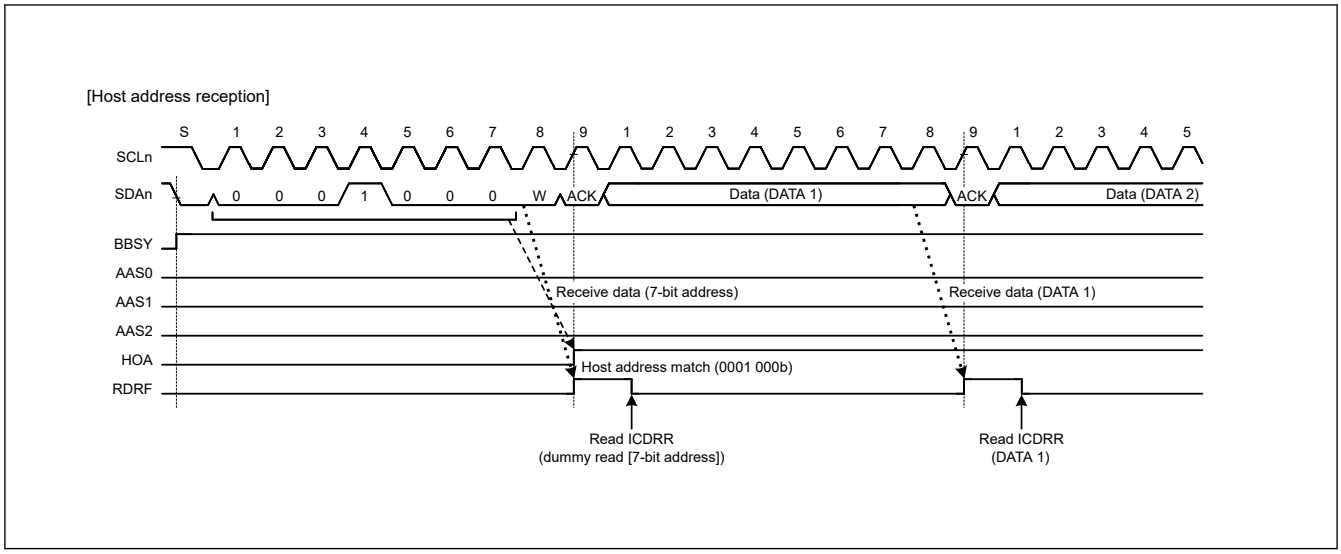

**Figure 28.29 HOA flag set timing during reception of host address**

## 28.8 Wakeup Function

The IIC provides a wakeup function that causes the MCU to transition from Software Standby mode or Snooze mode to normal operation. The wakeup function enables the reception of data when the system clock (PCLKB) is stopped, and generates a wakeup interrupt signal on a match of the slave address of the received data. This wakeup interrupt signal triggers the return to normal operation. After the wakeup interrupt occurs, switch the IIC to PCLKB synchronous operation so that communication can continue.

The wakeup function has four operation modes:

- Normal wakeup mode 1
- Normal wakeup mode 2
- Command recovery mode
- EEP response mode

Table 28.9 describes the behavior in these modes.

**Table 28.9 Wakeup operation modes**

| Operation mode | ACK response timing | ACK response before wakeup to PCLKB synchronous operation | SCL state during wakeup to PCLKB synchronous operation |
|---|---|---|---|
| Normal wakeup mode 1 | Before wakeup to PCLKB synchronous operation*1 | ACK | Fixed low |
| Normal wakeup mode 2 | After wakeup to PCLKB synchronous operation*2 | Before wakeup: no response (NACK level retained)<br>After wakeup: ACK response | Fixed low |
| Command recovery mode | Before wakeup to PCLKB synchronous operation*1 | ACK | Open |
| EEP response mode | Before recovery to PCLKB synchronous operation*1 | NACK | Open |

Note 1. Switching timing from PCLKB asynchronous operation to PCLKB synchronous operation is the falling edge of the 9th clock of the SCL.
Note 2. Switching timing from PCLKB asynchronous operation to PCLKB synchronous operation is the falling edge of the 8th clock of the SCL.

The following can be selected as wakeup interrupt sources:

- Host address detection (valid when ICSER.HOAE = 1)
- General call address detection (valid when ICSER.GCAE = 1)
- Slave address 0*1 detection (valid when ICSER.SAR0E = 1)

- Slave address 1[*1] detection (valid when ICSER.SAR1E = 1)
- Slave address 2[*1] detection (valid when ICSER.SAR2E = 1)

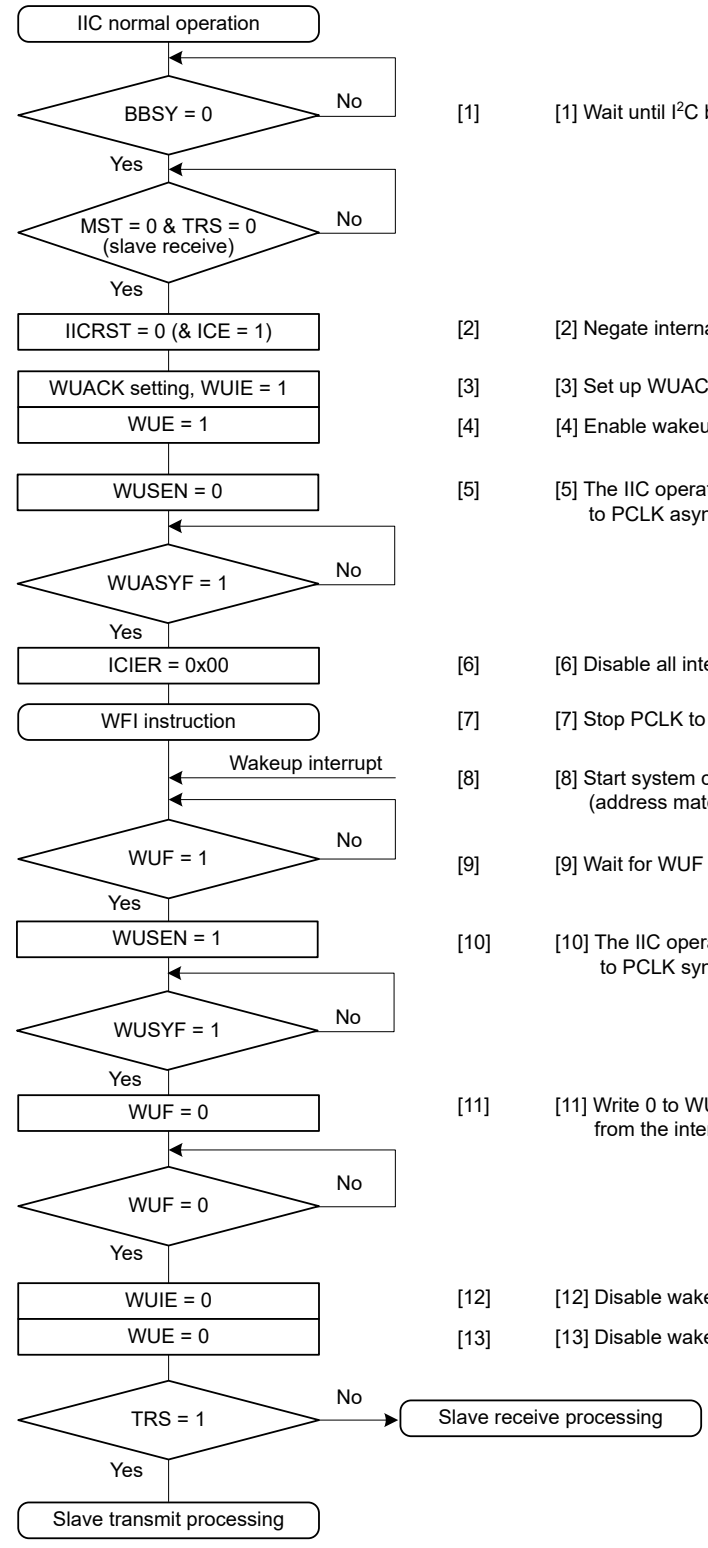
Note 1. Only 7-bit address can be set. Set the FS bit in SARUy (y = 0 to 2) to 0.

### Precautions on the use of the wakeup function

- Do not change the content of the IIC registers except the WUSEN bit in ICWUR2 while the WUASYF flag in ICWUR2 is 1 (during PCLKB asynchronous operation).
- Set ICWUR.WUE and ICWUR.WUIE to 1, and ICCR2.MST and ICCR2.TRS to 0 (slave reception mode) before switching to PCLKB asynchronous mode.
- The device ID and the 10-bit slave address cannot be selected for the wakeup interrupt source. Set the DIDE bit in ICSER and FS bit in SARUy (y = 0 to 2) to 0.
- Set bits TIE, TEIE, RIE, NAKIE, SPIE, STIE, ALIE, and TMOIE in the ICIER register to 0 (interrupt disabled) before switching to the asynchronous operation.
- When the wakeup function is enabled, do not use the timeout function (ICWUR.WUE = 1)
- Even when a wakeup interrupt is generated during PCLKB asynchronous operation (when ICWUR2.WUASYF = 1), if the slave addresses match in PCLKB synchronous mode (ICWUR2.WUASYF = 0), the wakeup interrupt does not occur and the WUF flag is not set.
- If the timing of writing 0 to the ICWUR2.WUSEN bit and the timing of detecting a start condition conflict, the IIC might start the next reception in PCLKB synchronous operation mode. In this case, ICWUR2.WUASYF flag becomes 1 (switch to PCLKB asynchronous mode) when data communication is complete, a stop condition is detected, and detection of a wakeup event starts.
- After writing 0 to the WUSEN bit in ICWUR2, do not change registers relate to the IIC operation mode setting (ICMR3, ICSER, and SARLy) until the mode is switched to PCLKB asynchronous operation from PCLKB synchronous operation (while the ICWUR2.WUASYF flag is 1). If the register value changes during this period by an interrupt handling or another factor, the IIC might malfunction before switching to the asynchronous operation.

## 28.8.1 Normal Wakeup Mode 1

This section describes the behavior, the timing, and an example operation of normal wakeup mode 1.



In normal wakeup mode 1, a wakeup interrupt triggered by the match of the slave address initiates the transition to normal operation as follows:

| | |
|---|---|
| Before wakeup: | ACK is sent in response to the data received with its own slave address of the IIC. |
| During wakeup: | ACK response is made on the 9th clock cycle of SCL, after which SCL is held low[*1]. |
| After wakeup: | Normal operation continues. |

Note 1. Between the 9th clock cycle and 1st clock cycle during wakeup, WAIT = 1 is invalid.

If the slave address does not match, the SCL line is not held low after the 9th clock cycle of SCL, and the slave operation continues. Figure 28.30 shows an operation example, and Figure 28.32 shows the detailed timing.

If the transition from Software Standby mode or Snooze mode is triggered by an interrupt other than a wakeup interrupt, for example the IRQn, the WUF flag is not set to 1. Figure 28.31 shows an operation example.

[1] [1] Wait until $I^2C$ bus is open and stay in standby state.

[2] [2] Negate internal reset (if asserted).

[3] [3] Set up WUACK for the desired wakeup mode. Enable wakeup interrupt.

[4] [4] Enable wakeup function.

[5] [5] The IIC operating state is changed from PCLK synchronous to PCLK asynchronous.

[6] [6] Disable all interrupt requests except WUI.

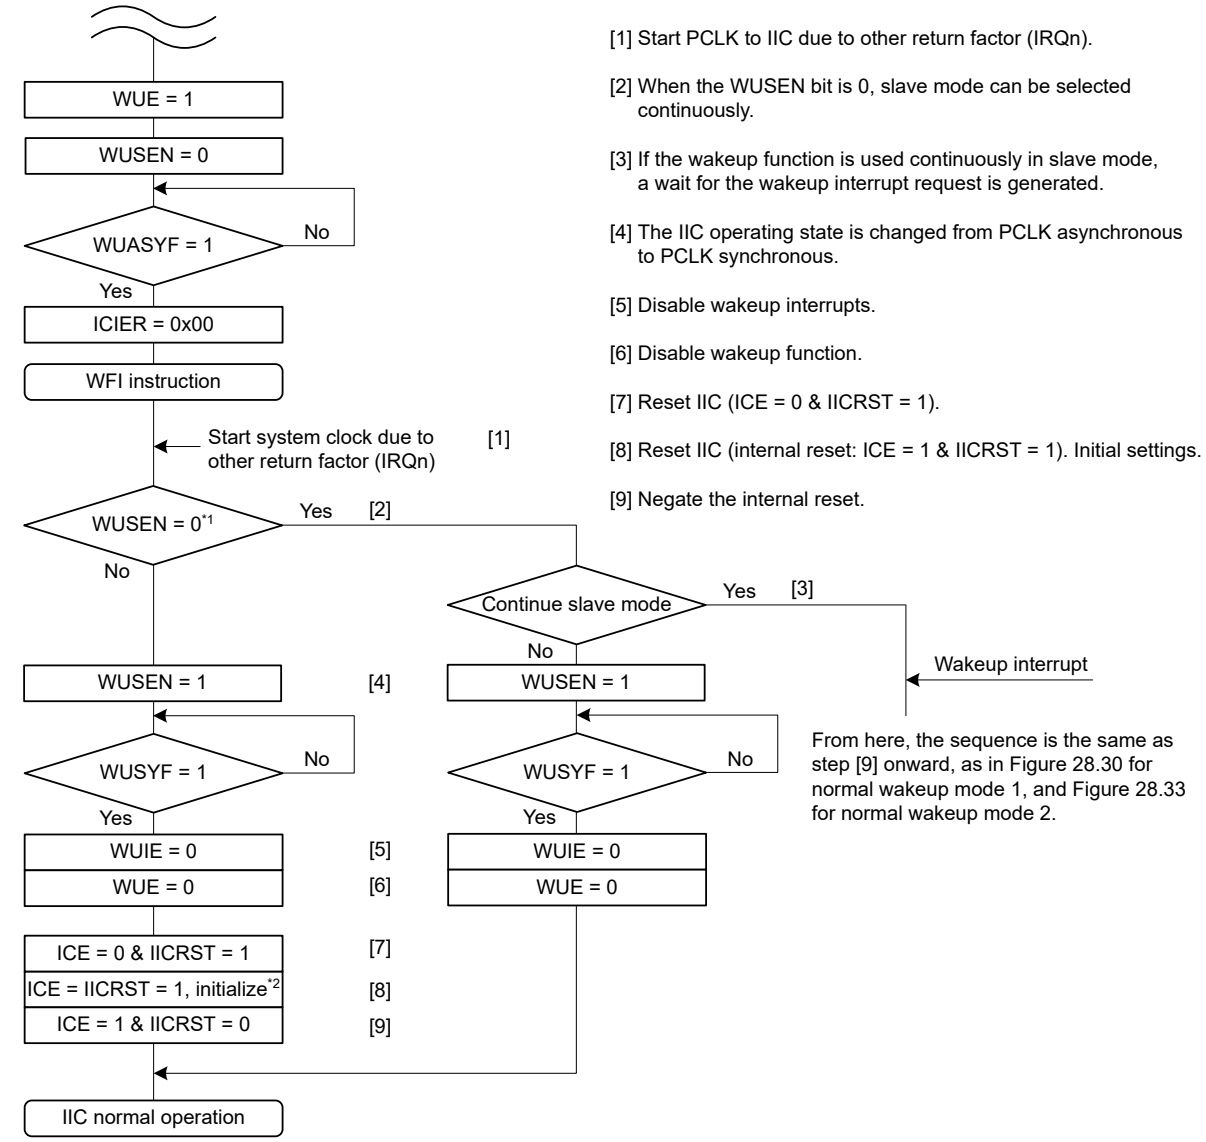
[7] [7] Stop PCLK to IIC. IIC continues to receive.

[8] [8] Start system clock and PCLK supply to IIC on wakeup interrupt (address match).

[9] [9] Wait for WUF = 1.

[10] [10] The IIC operating state is changed from PCLK asynchronous to PCLK synchronous.

[11] [11] Write 0 to WUF. Read and check that WUF = 0 before returning from the interrupt handling.

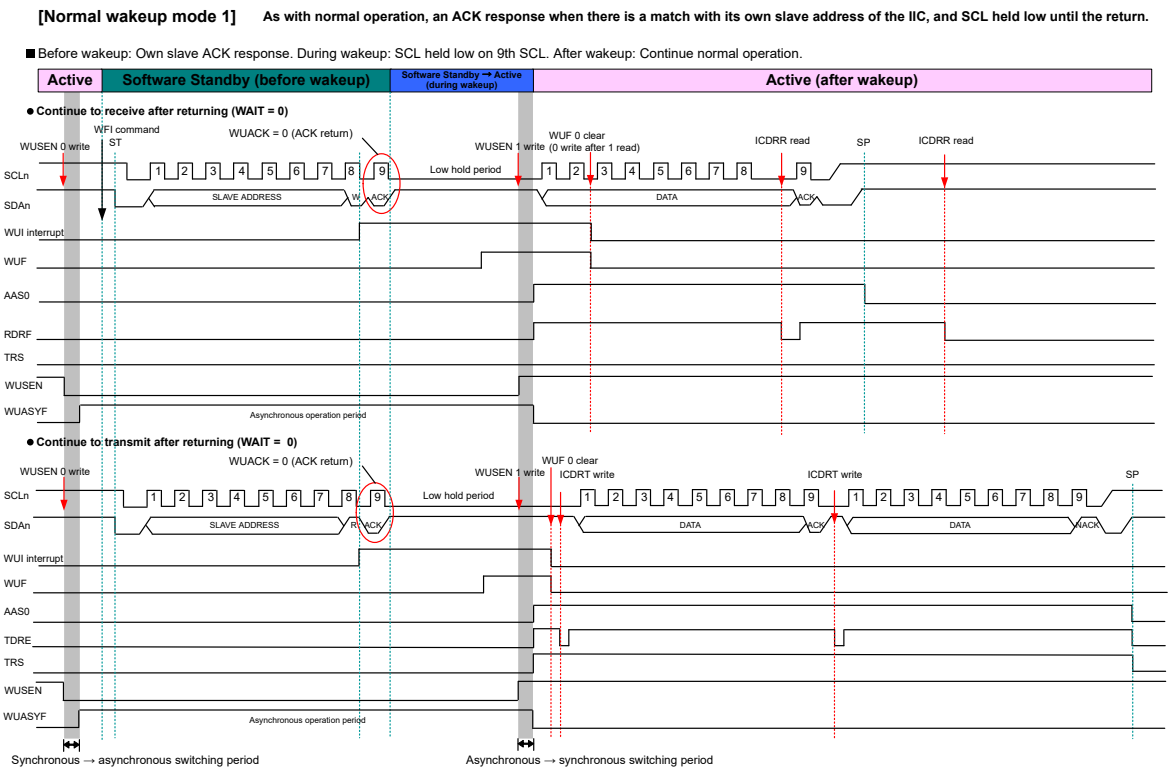


[12] [12] Disable wakeup Interrupt.

[13] [13] Disable wakeup function.

Note: PCLK = PCLKB

**Figure 28.30 Example operation of normal wakeup mode 1 when wakeup is triggered by a wakeup interrupt on match of the slave address**



Note: See Precautions on the use of the wakeup function.

Note: PCLK = PCLKB
Note 1. In the MCU, WUSEN bit is always 0 in the IIC.
Note 2. For details on the IIC initial settings, see section 28.3.2. Initial Settings.

**Figure 28.31 Example operation of normal wakeup modes 1 and 2 when wakeup is triggered by an interrupt other than IIC wakeup interrupt, for example, the IRQn**

Note: For details on the IIC initial settings, see section 28.3.2. Initial Settings.

Note: n = 0

**Figure 28.32 Timing of normal wakeup mode 1**

## 28.8.2 Normal Wakeup Mode 2

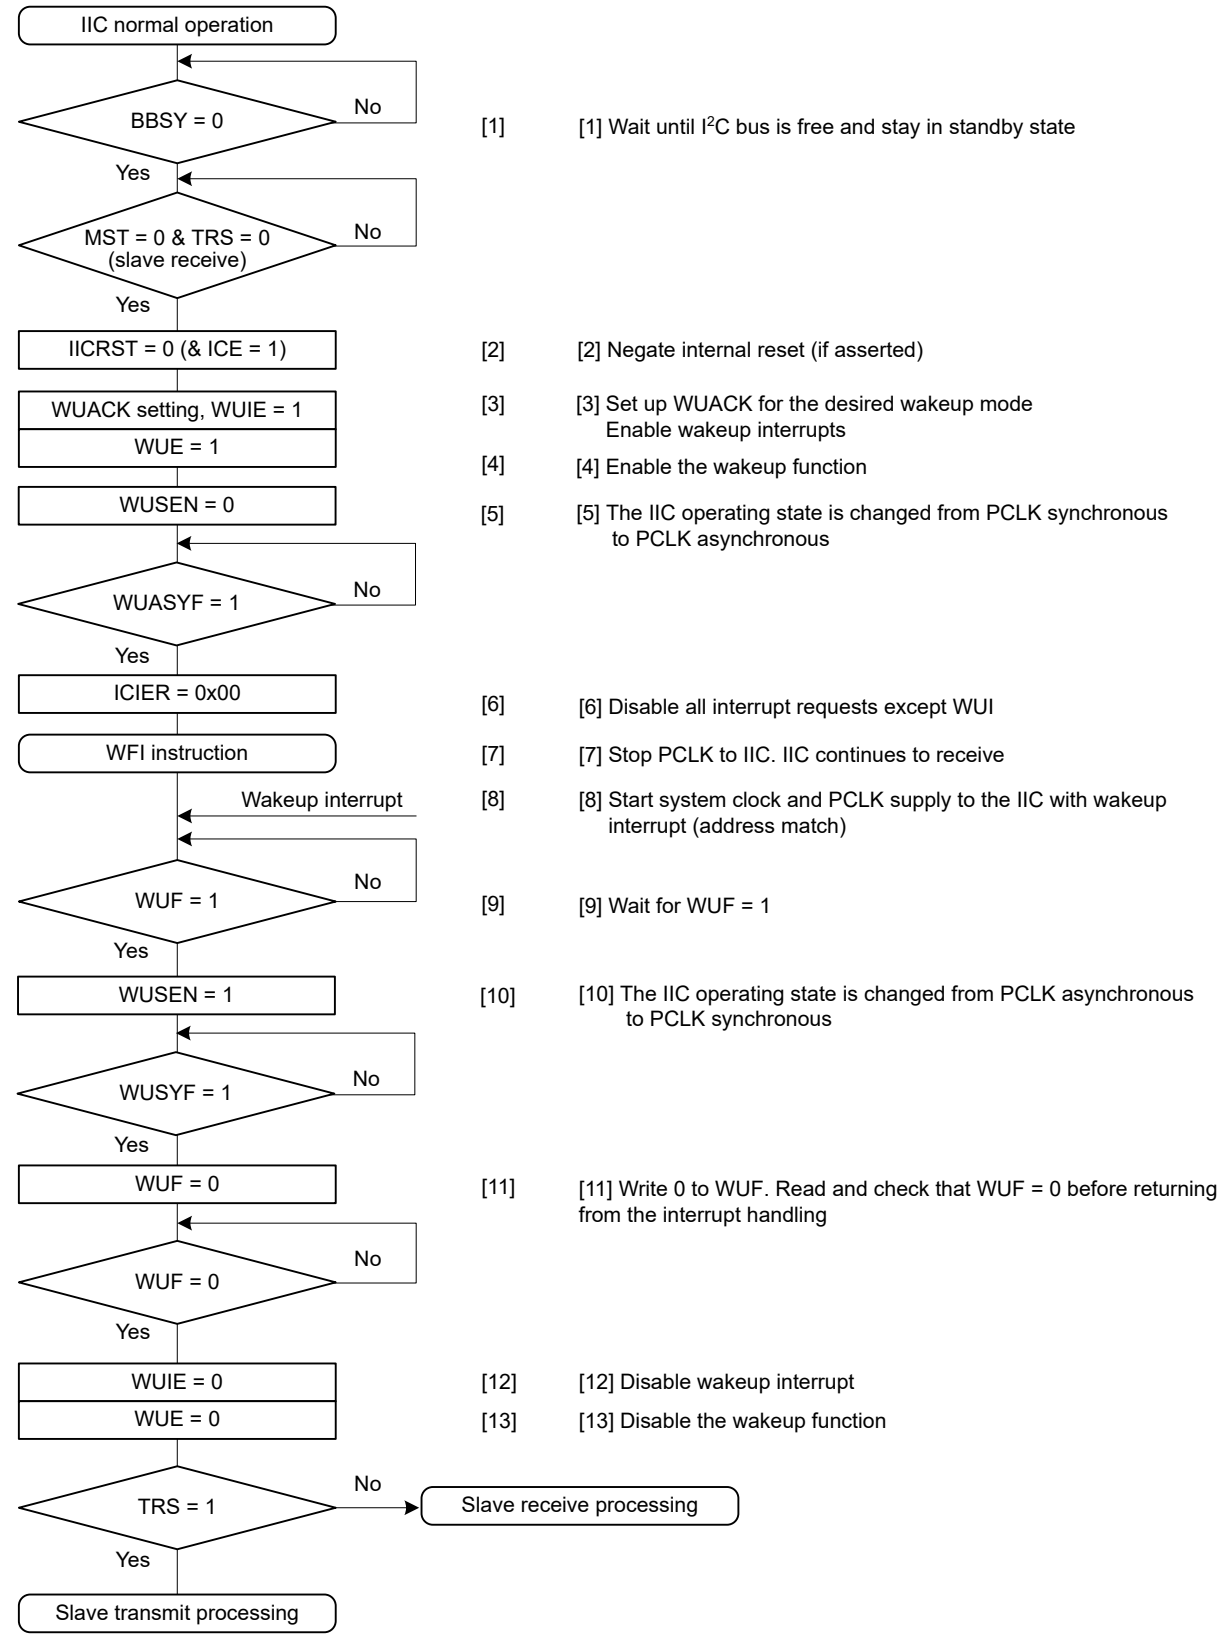
This section describes the behavior, the timing, and an example operation of normal wakeup mode 2.

In normal wakeup mode 2, a wakeup interrupt triggered by a match of the slave address initiates the transition to normal operation as follows:

| | |
|---|---|
| Before wakeup: | No response to data received with its own slave address until the end of the 8th SCL cycle. |
| During wakeup: | SCL line held low during the 8th and 9th clock cycles. |
| After wakeup: | ACK returns on the 9th clock cycle of SCL, and normal operation continues. |

If the slave address does not match, the SCL line is not held low after the 8th SCL clock cycle, and the slave operation continues. Figure 28.33 shows an example operation, and Figure 28.34 shows the detailed timing.

If the transition from Software Standby mode or Snooze mode is triggered by an interrupt other than a wakeup interrupt, such as the IRQn, for example, the WUF flag is not set to 1. Figure 28.31 shows an operation example.



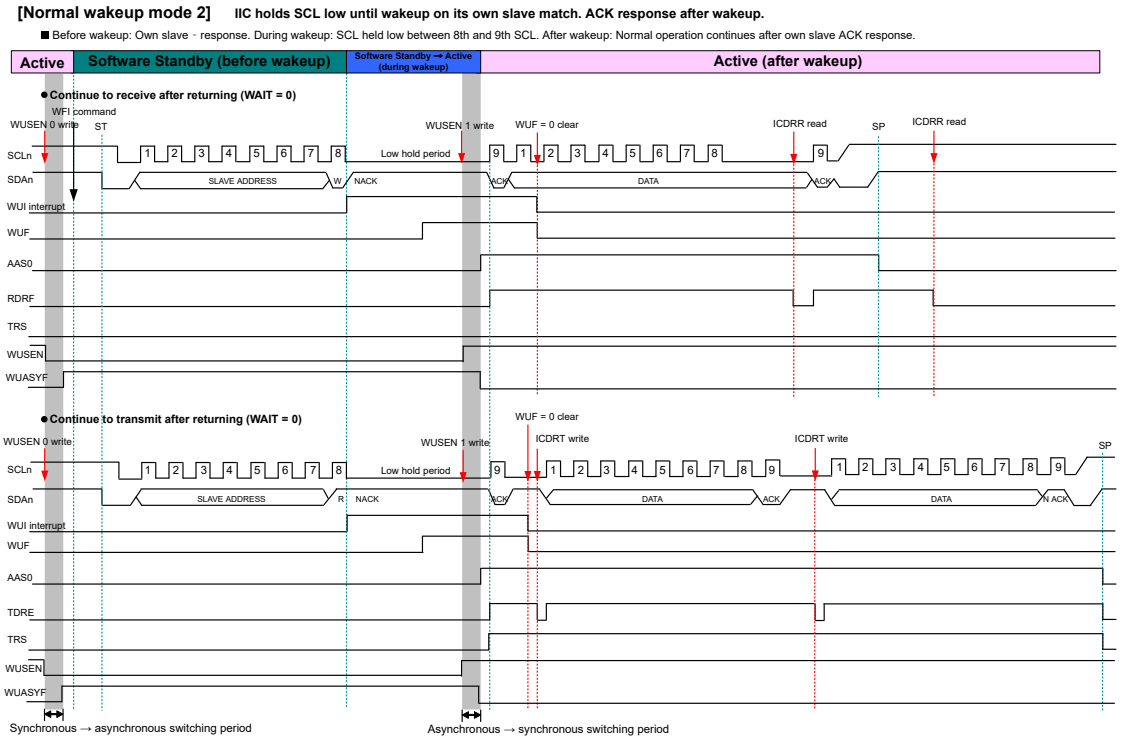


**Figure 28.33 Example operation of normal wakeup mode 2 when wakeup is triggered by a wakeup interrupt on match of the slave address**

Note: See Precautions on the use of the wakeup function.

Note: n = 0

**Figure 28.34 Timing of normal wakeup mode 2**

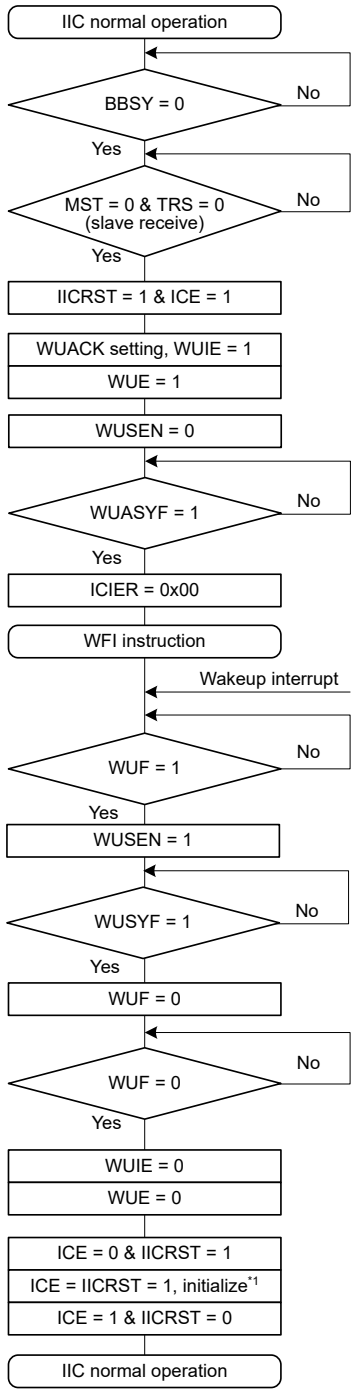
## 28.8.3 Command Recovery Mode and EEP Response Mode (Special Wakeup Modes)

This section describes the behavior, the timing, and example operations of the command recovery and EEP response modes.

In the command recovery and EEP response modes, the SCL line is not held low during the wakeup period (after the rise of the 9th clock cycle of SCL). Therefore, other IIC devices can use the $I^2C$ bus during this period.

A wakeup interrupt triggered by a match of the slave address initiates the transition to normal operation as follows:

| | |
|---|---|
| Before wakeup: | In response to the data received with its own slave address, the IIC returns ACK (command recovery mode) or NACK (EEP response mode). |
| During wakeup: | The SCL line is not held low. |
| After wakeup: | Normal operation continues after IIC initialization. |



If the slave address does not match, the slave operation continues.

Note: Because the SCL line is not held low during wakeup, transmission or reception of the data that follows the slave address is not possible.

Note: The command recovery and EEP response modes are internal reset states (ICE = IICRST = 1). Therefore, the match of the slave address does not set the flags, HOA, GCA, ASS0, ASS1, and ASS2 in the ICSR1 register.

Figure 28.35 shows an example operation in recovery and EEP response modes. Figure 28.37 shows the detailed timing.

If the transition from Software Standby mode or Snooze mode is triggered by an interrupt other than a wakeup interrupt, such as IRQn for example, the WUF flag is not set to 1. Follow the processing shown in Figure 28.36.

[1] [1] Wait until $I^2C$ bus is open and stay in standby state.

[2] [2] Internal reset is asserted.

[3] [3] Set up WUACK for the desired wakeup mode. Enable wakeup interrupt.

[4] [4] Enable wakeup function.

[5] [5] The IIC operating state is changed from PCLK synchronous to PCLK asynchronous.

[6] [6] Disable all interrupt requests except WUI.

[7] [7] Stop PCLK to IIC. IIC continues to receive.

[8] [8] Start system clock and PCLK supply to the IIC with wakeup interrupt (address match).

[9] [9] Wait for WUF = 1.

[10] [10] The IIC operating state is changed from PCLK asynchronous to PCLK synchronous.

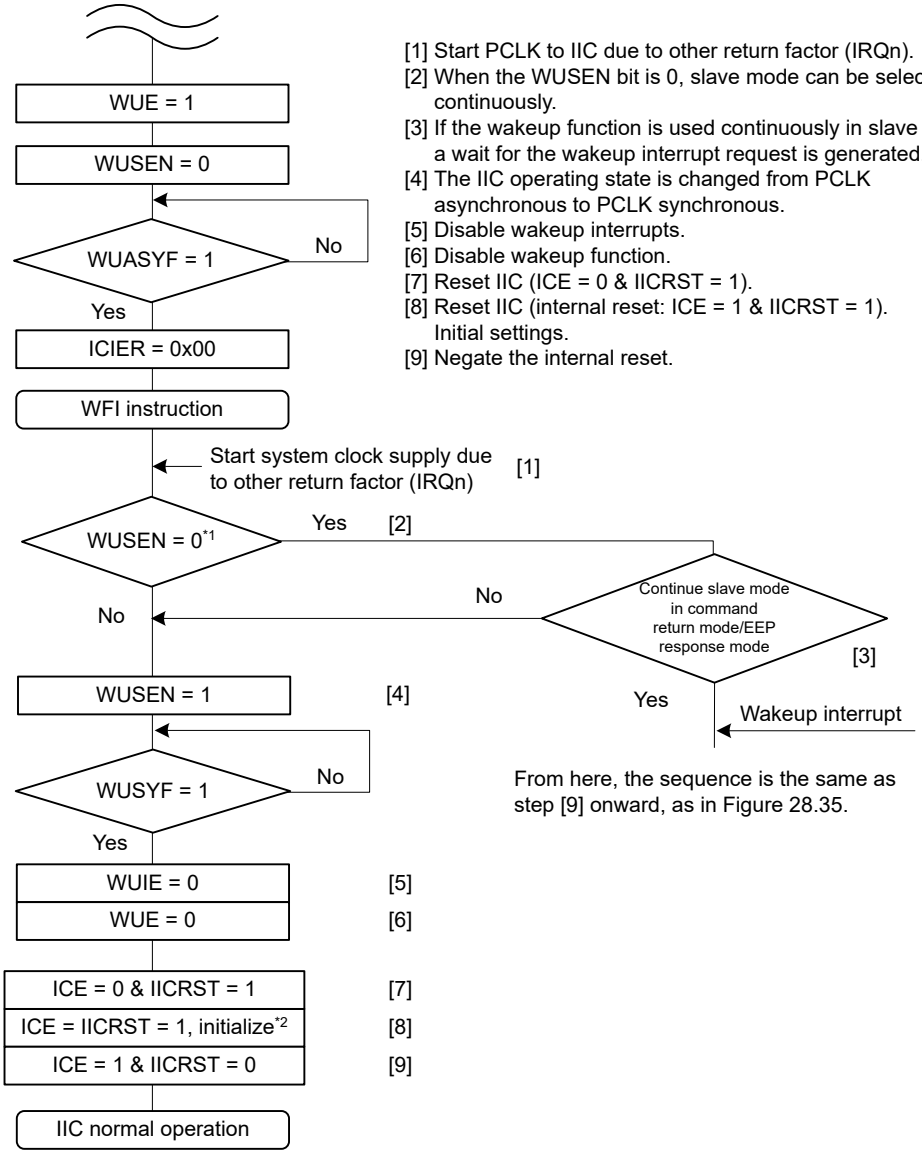
[11] [11] Write 0 to WUF. Read and check that WUF = 0 before returning from the interrupt handling.

[12] [12] Disable wakeup interrupt.

[13] [13] Disable wakeup function.

[14] [14] Reset IIC (ICE = 0 & IICRST = 1).

[15] [15] Reset IIC (internal reset: ICE = 1 & IICRST = 1). Initial settings.



[16] [16] Negate the internal reset.

Note: PCLK = PCLKB

Note 1. For details on IIC initialization, see section 28.3.2. Initial Settings.

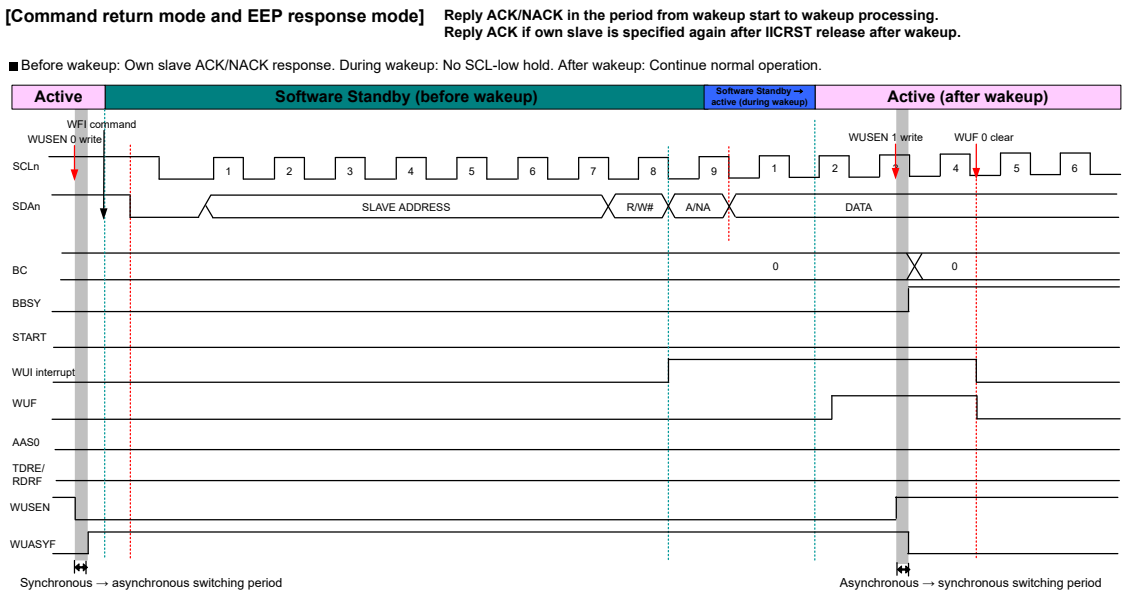


**Figure 28.35 Example operation of command recovery mode and EEP response mode when wakeup is triggered by a wakeup interrupt on match of the slave address**

Note: See Precautions on the use of the wakeup function.

Note: PCLK = PCLKB
Note 1. In the MCU, WUSEN bit is always 0 in the IIC.
Note 2. For details on IIC initialization, see section 28.3.2. Initial Settings.

**Figure 28.36 Example operation of command recovery and EEP response modes when wakeup is triggered by an interrupt other than IIC wakeup interrupt, for example, the IRQn**

Note: n = 0

**Figure 28.37 Timing of command recovery and EEP response modes**

## 28.9 Automatic Low-Hold Function for SCL

### 28.9.1 Function to Prevent Wrong Transmission of Transmit Data

If the $I^2C$ Bus Shift Register (ICDRS) is empty and data has not been written to the $I^2C$ Bus Transmit Data Register (ICDRT) with the IIC in transmission mode (TRS bit = 1 in ICCR2), the SCL0 line is automatically held low over the subsequent intervals. This low-hold period is extended until the transmit data is written, which prevents the unintended transmission of erroneous data.

Master transmit mode:

- Low-level interval after a start or restart condition is issued
- Low-level interval between the 9th clock cycle of one transfer and the 1st clock cycle of the next.

Slave transmit mode:

- Low-level interval between the 9th clock cycle of one transfer and the 1st clock cycle of the next.

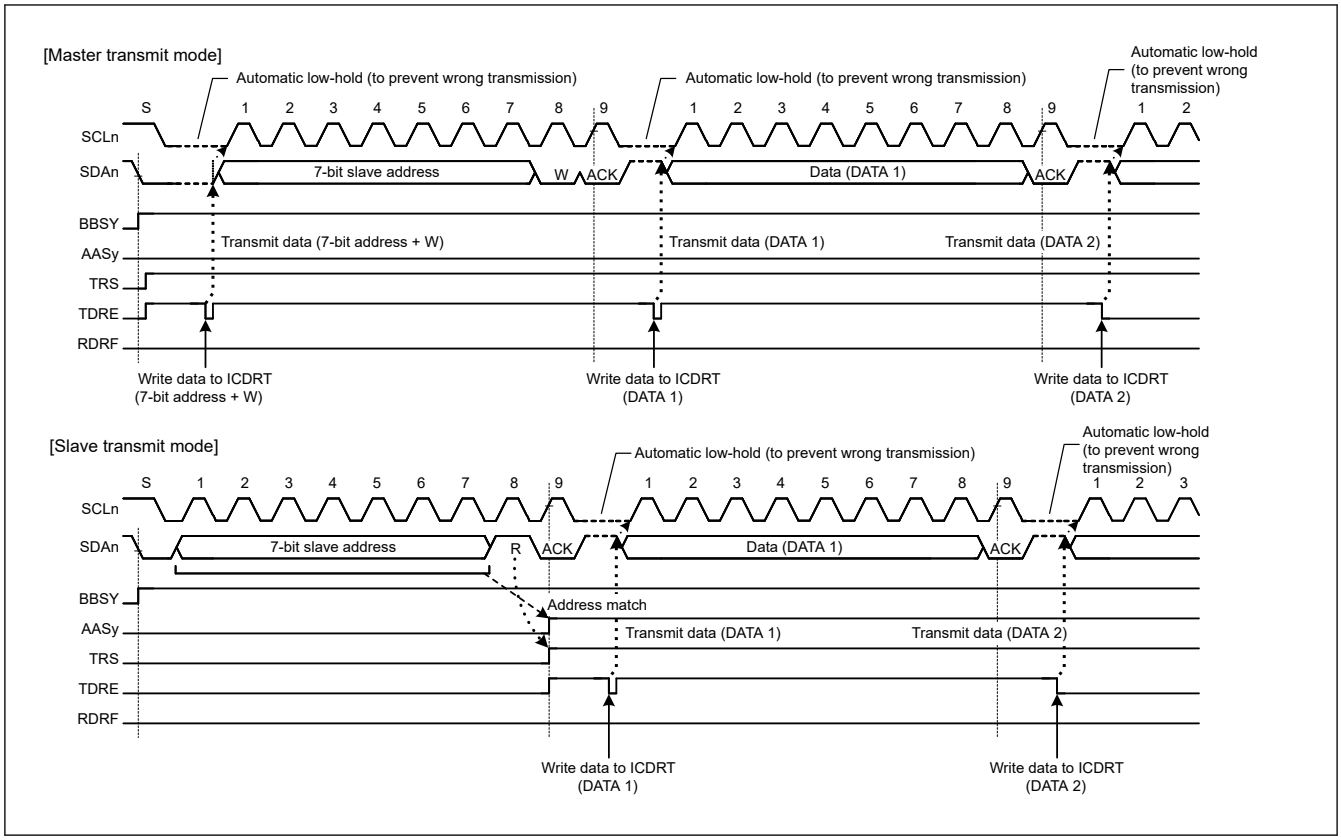

**Figure 28.38 Automatic low-hold operation in transmit mode**

## 28.9.2 NACK Reception Transfer Suspension Function

This function suspends transfer operation when NACK is received in transmit mode (TRS bit = 1 in ICCR2). This function is enabled when the NACKE bit in ICFER is set to 1. If the next transmit data is already written (TDRE flag = 0 in ICSR2) when NACK is received, the next data transmission on the falling edge of the 9th SCL clock cycle is automatically suspended. This prevents the SDA0 line output level from being held low when the MSB of the next transmit data is 0.

If the transfer operation is suspended by this function (NACKF flag = 1 in ICSR2), transmit and receive operations are discontinued. To restore transmit or receive operation, after issuing the restart condition, you need to set the NACKF flag to 0 and try again, or set the NACKF flag to 0 after issuing the stop condition and then start again from issuing the start condition.

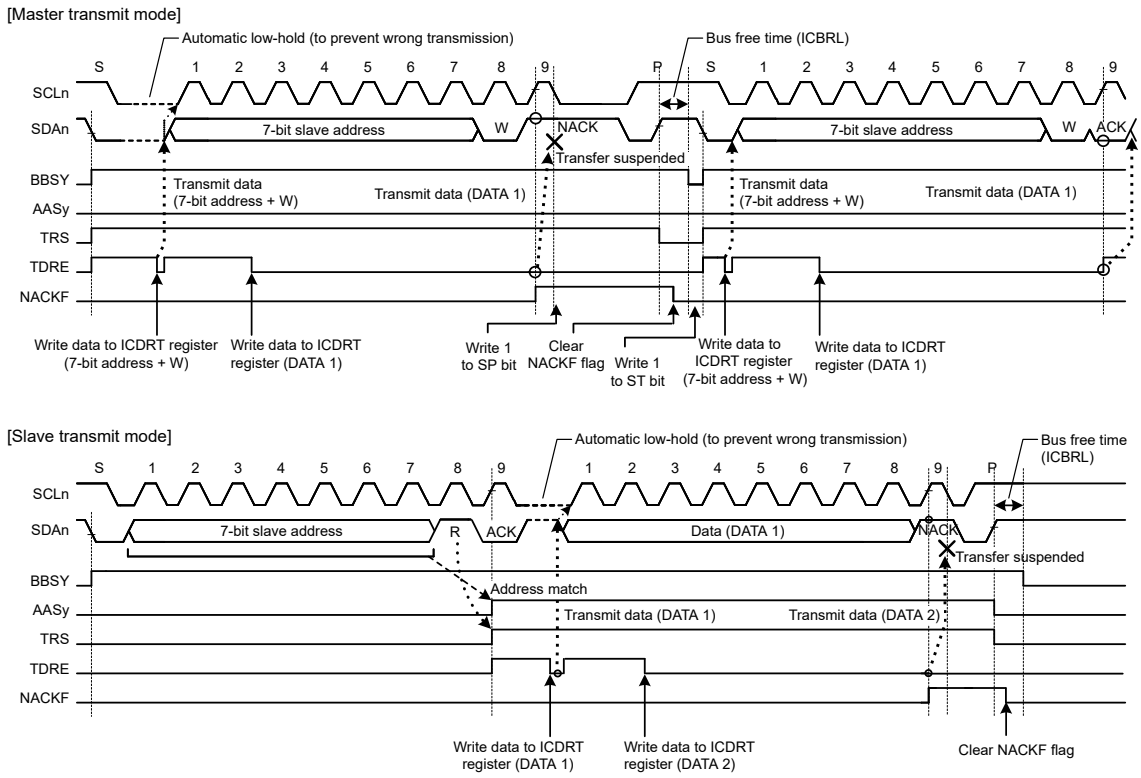

**Figure 28.39 Suspension of data transfer when NACK is received, when NACKE = 1**

## 28.9.3 Function to Prevent Failure to Receive Data

If response processing is delayed when receive data (ICDRR) read is delayed for a period of one transfer frame or more with receive data full (RDRF flag = 1 in ICSR2) in receive mode (TRS = 0 in ICCR2), the IIC holds the SCL0 line low automatically immediately before the next data is received to prevent a failure to receive data.

This function is enabled even if the read processing of the final receive data is delayed and, in the meantime, the IIC slave address is designated after a stop condition is issued. This function does not interfere with other communication because the IIC does not hold the SCL0 line low when a mismatch with its own slave address occurs after a stop condition is issued.

Periods in which the SCL0 line is held low can be selected with a combination of the WAIT and RDRFS bits in ICMR3.

### (1) 1-byte receive operation and automatic low-hold function using the WAIT bit

When the WAIT bit in ICMR3 is set to 1, the IIC performs a 1-byte receive operation using the WAIT bit function. Additionally, when the ICMR3.RDRFS bit is 0, the IIC automatically sends the ACKBT bit value in ICMR3 for the acknowledge bit in the period from the falling edge of the 8th SCL clock cycle to the falling edge of the 9th SCL clock cycle, and automatically holds the SCL0 line low on the falling edge of the 9th SCL clock cycle using the WAIT bit function. This low-hold is released by reading data from ICDRR, which enables byte-wise receive operation.

The WAIT bit function is enabled for receive frames after a match with the IIC slave address, including the general call address and host address, is obtained in master or slave receive mode.

### (2) 1-byte receive operation (ACK/NACK transmission control) and automatic low-hold function using the RDRFS bit

When the RDRFS bit in ICMR3 is set to 1, the IIC performs a 1-byte receive operation using the RDRFS bit function. When the RDRFS bit is set to 1, the RDRF flag in ICSR2 is set to 1 (receive data full) on the rising edge of the eighth SCL clock cycle, and the SCL0 line is automatically held low on the falling edge of the eighth SCL clock cycle. This low-hold is released by writing a value to the ACKBT bit in ICMR3, but cannot be released by reading data from ICDRR, which enables receive operation through the ACK or NACK transmission control based on the data received in byte units.

The RDRFS bit function is enabled for receive frames after a match with the IIC slave address, including the general call address and host address, is obtained in master or slave receive mode.

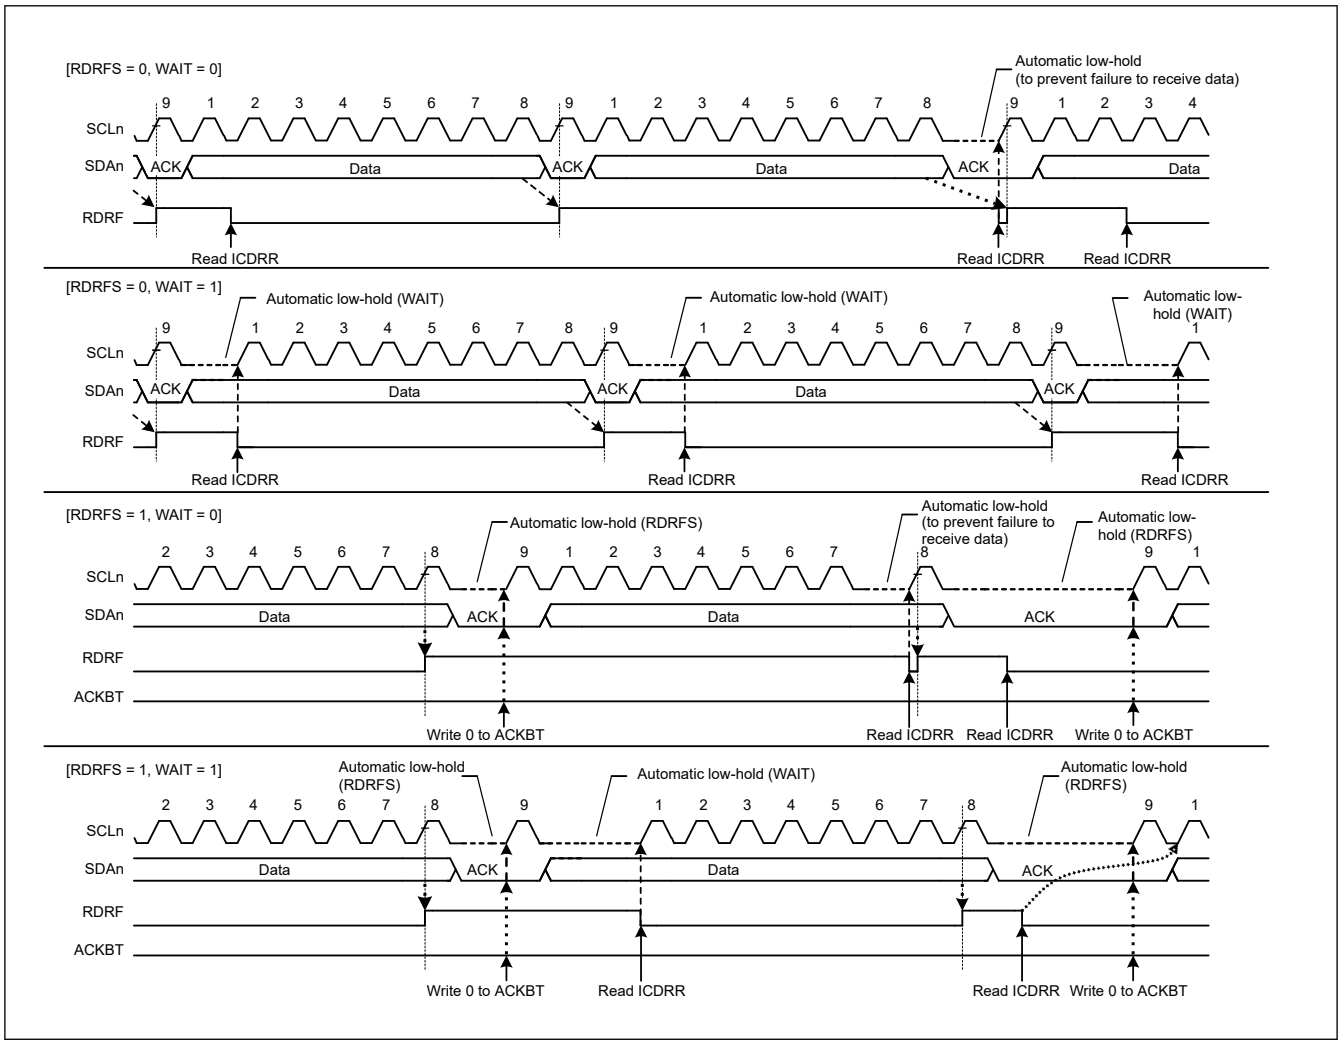

**Figure 28.40 Automatic low-hold operation in receive mode using the RDRFS and WAIT bits**

## 28.10 Arbitration-Lost Detection Functions

In addition to the normal arbitration-lost detection function defined by the $I^2C$ bus standard, the IIC provides functions to prevent double-issue of a start condition, detect arbitration-lost during transmission of NACK, and detect arbitration-lost in slave transmit mode.

### 28.10.1 Master Arbitration-Lost Detection (MALE Bit)

The IIC drives the SDA0 line low to issue a start condition. However, if the SDA0 line was already driven low by another master device issuing a start condition, the IIC regards its own start condition as an error and considers this a loss in arbitration. Priority is given to transfer by the other master device. Similarly, if a request to issue a start condition is made by setting the ST bit in ICCR2 to 1 while the bus is busy (BBSY flag = 1 in ICCR2), the IIC regards this as a double-issuing-of-start-condition error and considers itself to have lost in arbitration. This prevents a failure of transfer resulting from a start condition being issued while transfer is in progress.

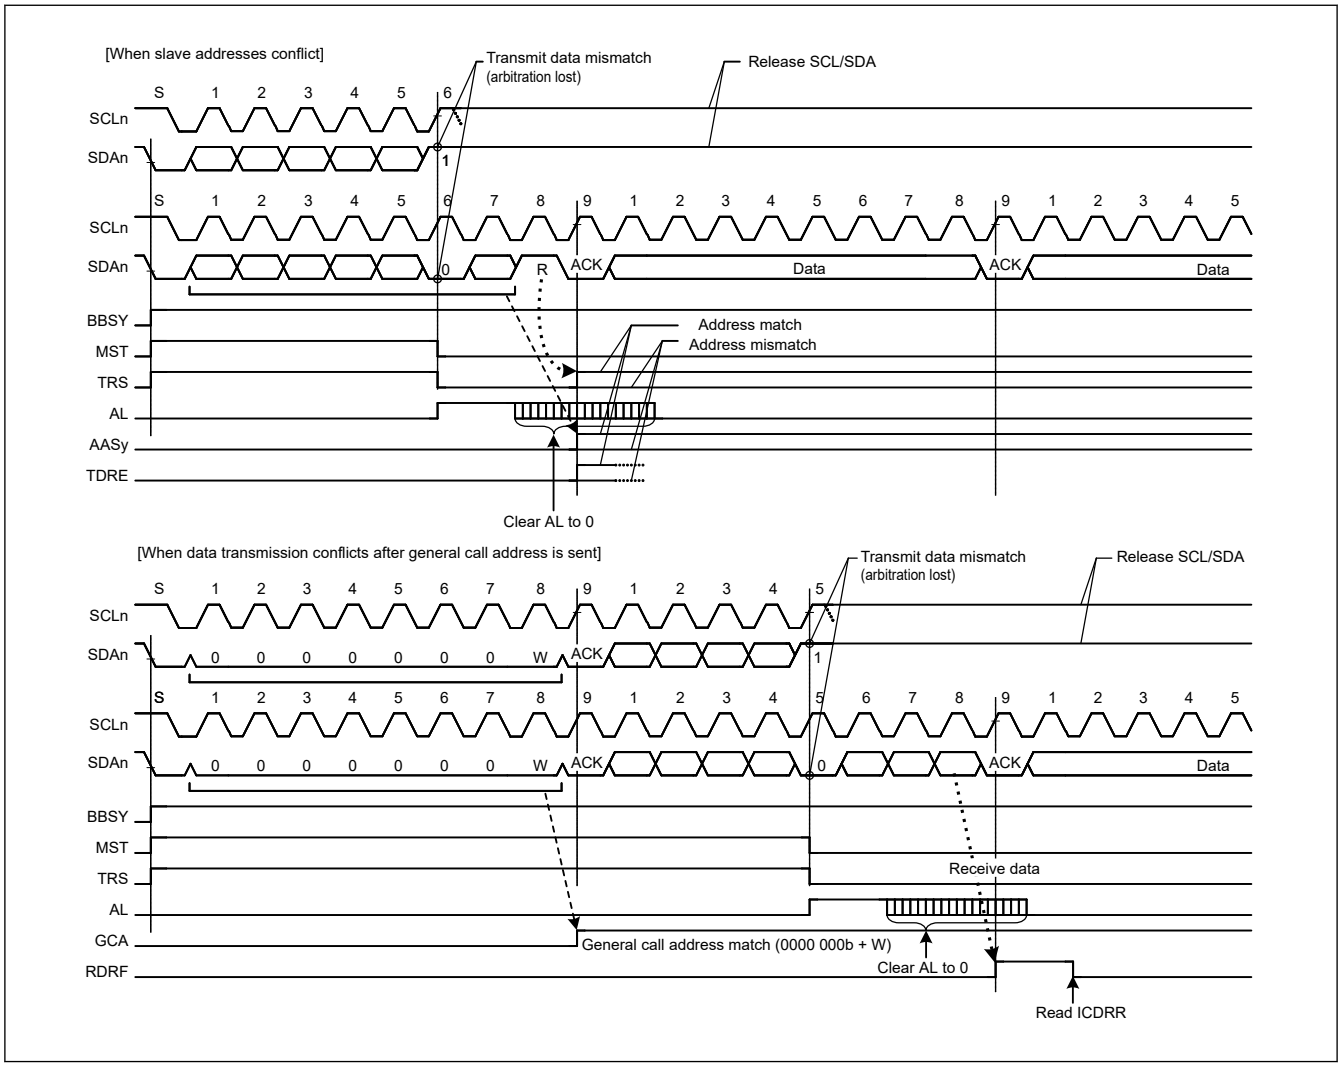
When a start condition is issued successfully, if the transmit data including the address bits (internal SDA output level) and the level on the SDA0 line do not match (high output as the internal SDA output, meaning the SDA0 pin is in the high-impedance state and a low level is detected on the SDA0 line), the IIC loses in arbitration.

After a loss in arbitration of mastership, the IIC immediately enters slave receive mode. If a slave address, including the general call address, matches its own address at this time, the IIC continues in slave operation.

A loss in arbitration of mastership is detected when the following conditions are met while the MALE bit in ICFER is 1 (master arbitration-lost detection enabled).

[Master arbitration-lost conditions]

- Mismatching of the internal level for output on SDA and the level on the SDA0 line after a start condition was issued by setting the ST bit in ICCR2 to 1 while the BBSY flag in ICCR2 is set to 0 (erroneous issuing of a start condition)
- Setting of the ST bit in ICCR2 to 1 (start condition double-issue error) while the BBSY flag is 1
- When the transmit data excluding acknowledge (internal SDA output level) does not match the level on the SDA0 line in master transmit mode (MST and TRS bits = 11b in ICCR2).



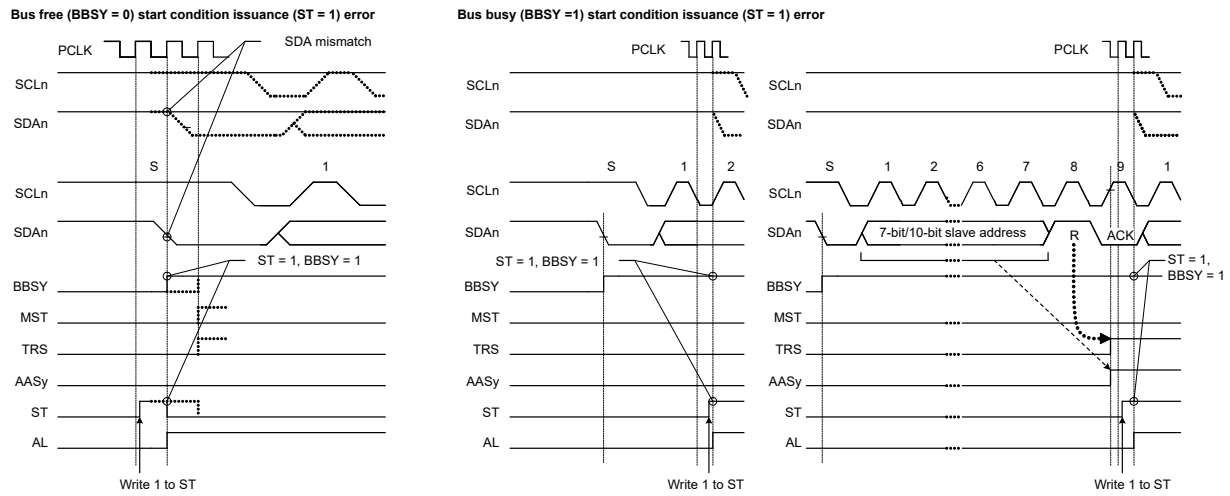


**Figure 28.41 Examples of master arbitration-lost detection when MALE = 1**

Note: PCLK = PCLKB

**Figure 28.42 Arbitration-lost when start condition is issued when MALE = 1**

## 28.10.2 Function to Detect Loss of Arbitration During NACK Transmission (NALE Bit)

This function causes arbitration to be lost if the internal SDA output level does not match the level on the SDA0 line (high output as the internal SDA output, meaning the SDA0 pin is in the high-impedance state and the low level is detected on the SDA0 line) during transmission of NACK in receive mode. Arbitration is lost because of a conflict between NACK and ACK transmissions when two or more master devices receive data from the same slave device simultaneously in a multi-master system. Such a conflict occurs when multiple master devices send or receive the same information through a single slave device. Figure 28.43 shows an example of arbitration-lost detection during transmission of NACK.

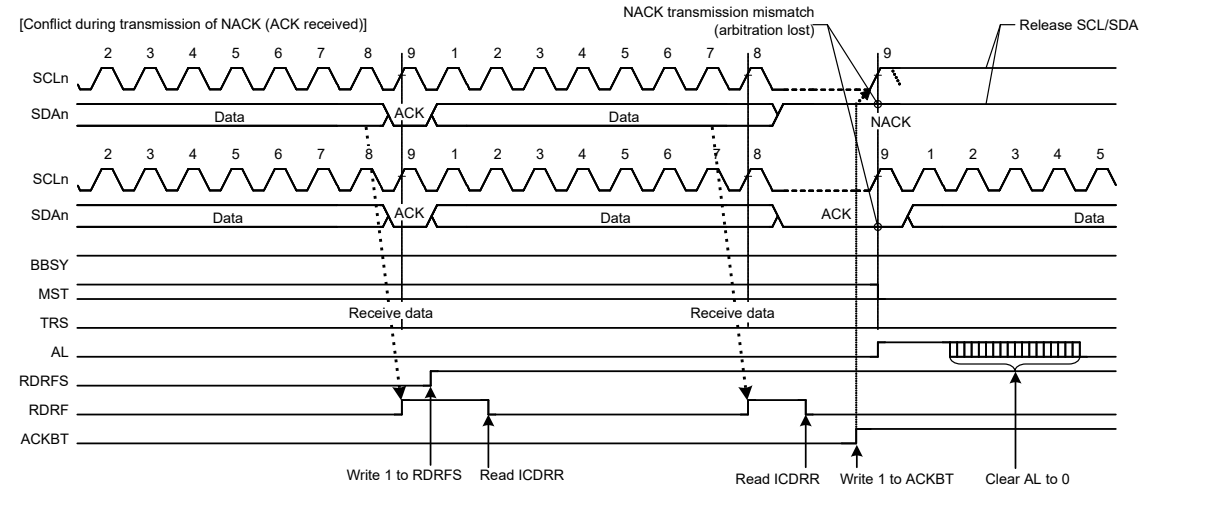

**Figure 28.43 Example of arbitration-lost detection during transmission of NACK when NALE = 1**

The following explains arbitration-lost detection using an example in which two master devices (master A and master B) and a single slave device are connected through the bus. In this example, master A receives 2 bytes of data from the slave device, and master B receives 4 bytes of data from the slave device.

If master A and master B access the slave device simultaneously, because the slave address is identical, arbitration is not lost in either master A or master B during access to the slave device. Therefore, both master A and master B recognize that they have obtained the bus mastership and operate as such. Master A sends NACK when it has received 2 final bytes of data from the slave device. Meanwhile, master B sends ACK because it has not received the required 4 bytes of data. At this time, the NACK transmission from master A and the ACK transmission from master B conflict. In general, if a conflict like

this occurs, master A cannot detect the ACK transmitted by master B and issues a stop condition. The stop condition issue conflicts with the SCL clock output of master B, which disrupts communication.

When the IIC receives ACK during transmission of NACK, it detects a defeat in conflict with other master devices and causes arbitration to be lost. If arbitration is lost during transmission of NACK, the IIC immediately cancels the slave match condition and enters slave receive mode. This prevents a stop condition from being issued, preventing a communication failure on the bus.

Similarly, in the ARP command processing of SMBus, the function to detect loss of arbitration during transmission of NACK is also available for eliminating the extra clock cycle processing, such as 0xFF transmission processing, which is required if the UDID (Unique Device Identifier) of the assigned address does not match in the Get UDID general processing after the Assign Address command.

The IIC detects arbitration-lost during transmission of NACK when the following condition is met with the NALE bit in ICFER set to 1 (arbitration-lost detection during NACK transmission enabled).

[Condition for arbitration-lost during NACK transmission]

- When the internal SDA output level does not match the SDA0 line (ACK is received) during transmission of NACK (ACKBT bit = 1 in ICMR3).

## 28.10.3 Slave Arbitration-Lost Detection (SALE Bit)

This function causes arbitration to be lost if the transmit data (internal SDA output level) and the level on the SDA0 line do not match (high output as the internal SDA output, meaning the SDA0 pin is in the high-impedance state and a low level is detected on the SDA0 line) in slave transmit mode. This arbitration-lost detection function is mainly used when transmitting a UDID (Unique Device Identifier) over an SMBus.

When the IIC loses slave arbitration, the IIC is immediately released from the slave-matched state and enters slave receive mode. This function can detect conflicts of data during transmission of UDIDs over an SMBus and eliminates subsequent redundant processing for the transmission of 0xFF.

The IIC detects slave arbitration-lost when the following condition is met with the SALE bit in ICFER set to 1 (slave arbitration-lost detection enabled).

[Condition for slave arbitration-lost]

- When transmit data excluding acknowledge (internal SDA output level) does not match the SDA0 line in slave transmit mode (MST and TRS bits = 01b in ICCR2).

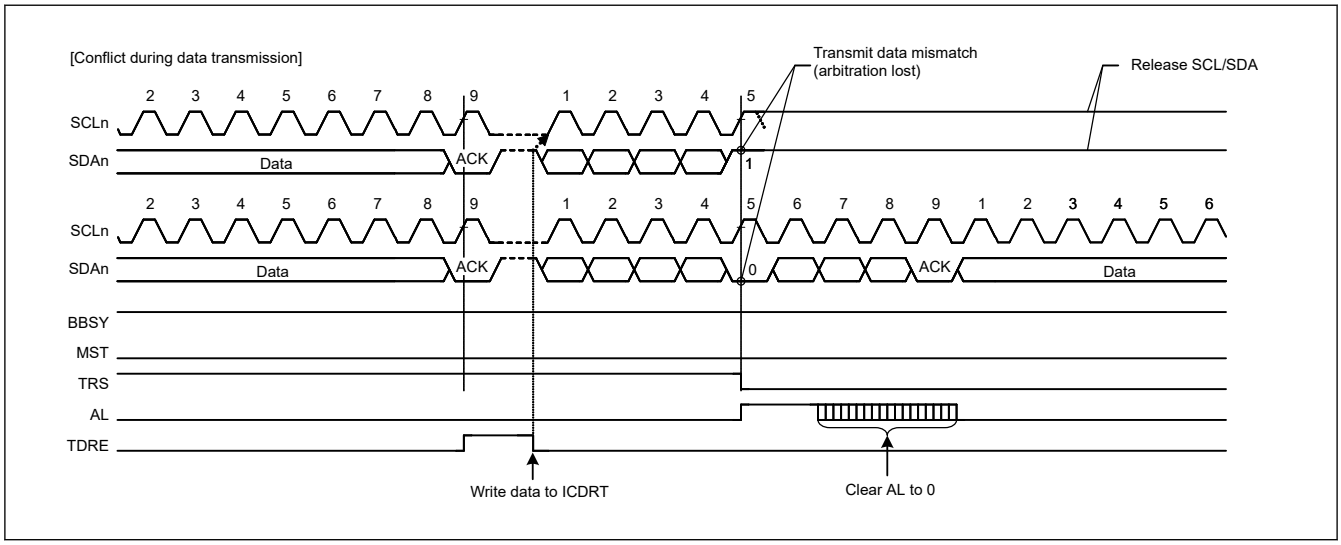

**Figure 28.44 Example of slave arbitration-lost detection when SALE = 1**

## 28.11 Start, Restart, and Stop Condition Issuing Function

### 28.11.1 Issuing a Start Condition

The IIC issues a start condition when the ST bit in ICCR2 is set to 1. When the ST bit is set to 1, a start condition request is made, and the IIC issues a start condition when the BBSY flag in ICCR2 is 0 (bus free state). When a start condition is issued normally, the IIC automatically shifts to the master transmit mode.

To issue a start condition:

1. Drive the SDA0 line low (high level to low level).
2. Ensure that the time set in ICBRH and the start condition hold time elapse.
3. Drive the SCL0 line low (high level to low level).
4. Detect low level on the SCL0 line and ensure the low-level period of the SCL0 line set in ICBRL elapses.

### 28.11.2 Issuing a Restart Condition

The IIC issues a restart condition when the RS bit in ICCR2 is set to 1. When the RS bit is set to 1, a restart condition request is made, and the IIC issues a restart condition when the BBSY flag in ICCR2 is 1 (bus busy state) and the MST bit in ICCR2 is 1 (master mode).

To issue a restart condition:

1. Release the SDA0 line.
2. Ensure the low-level period of the SCL0 line set in ICBRL elapses.
3. Release the SCL0 line (low level to high level).
4. Detect a high level on the SCL0 line and ensure the time set in ICBRL and the restart condition setup time elapse.
5. Drive the SDA0 line low (high level to low level).
6. Ensure the time set in ICBRH and the restart condition hold time elapse.
7. Drive the SCL0 line low (high level to low level).
8. Detect a low level on the SCL0 line and ensure the low-level period of the SCL0 line set in ICBRL elapses.

Note: When issuing restart condition requests, write the slave address to ICDRT after confirming that ICCR2.RS = 0. Data written while ICCR2.RS = 1 is not forwarded because of the retransmission condition before the occurrence.

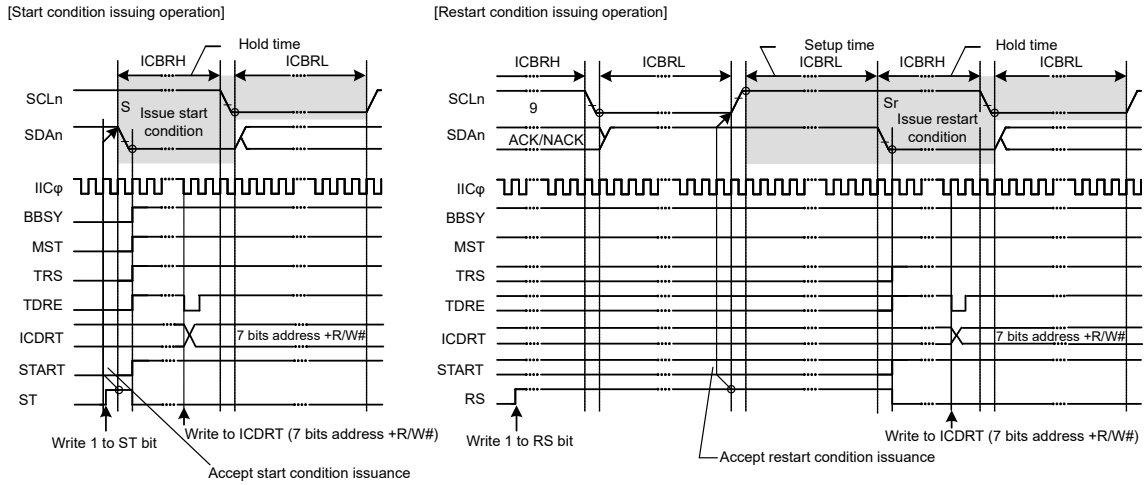

**Figure 28.45 Start and restart condition issue timing using the ST and RS bits**

Figure 28.46 shows the operation timing when a restart condition is issued after the master transmission.

[To issue a restart condition after the master transmission:]

1. Initialize the IIC using the procedure in section 28.3.2. Initial Settings.
2. Read the BBSY flag in ICCR2 to check that the bus is open, then set the ST bit in ICCR2 to 1 (start condition issuance request). On receiving the request, the IIC issues a start condition. At the same time, the BBSY and the START flags in ICSR2 are automatically set to 1 and the ST bit is automatically set to 0. If the start condition is detected and the internal levels for the SDA output state and the levels on the SDA0 line match while the ST bit is 1, the IIC recognizes that issuance of the start condition as requested by the ST bit has been successfully completed. The MST and TRS bits in ICCR2 are automatically set to 1, placing the IIC in master transmit mode. The TDRE flag in ICSR2 is also automatically set to 1 when the TRS bit is set to 1.
3. Check that the TDRE flag in ICSR2 is 1, and then write the value for transmission (the slave address and the R/W# bit) to ICDRT. After the data for transmission is written to ICDRT, the TDRE flag is automatically set to 0, data is transferred from ICDRT to ICDRS, and the TDRE flag is again set to 1. After the byte containing the slave address and R/W# bit has been transmitted, the value of the TRS bit is automatically updated to select master transmit or master receive mode according to the value of the transmitted R/W# bit. If the value of the R/W# bit is 0, the IIC continues in master transmit mode. If the ICSR2.NACKF flag is 1 at this time, indicating that no slave device recognized the address or that there was an error in communications, write 1 to ICCR2.SP bit to issue a stop condition. To transmit data with an address in the 10-bit format, start by writing 1111 0b, the 2 upper bits of the slave address, and W to ICDRT as the first address transmission. Then, as the second address transmission, write the 8 lower bits of the slave address to ICDRT.
4. After confirming that the TDRE flag in ICSR2 is 1, write data for transmission to the ICDRT register. The IIC automatically holds the SCL0 line low until data for transmission is ready, a restart condition is issued or a stop condition is issued.
5. After all bytes of data for transmission are written to the ICDRT register, wait until the value of the TEND flag in ICSR2 returns to 1. Then after checking that the START flag in ICSR2 is 1, set the START flag in ICSR2 to 0.
6. Set the RS bit in ICCR2 to 1 (restart condition issue request). On receiving the request, the IIC issues a restart condition.
7. After checking that the START flag in ICSR2 is 1, write the value for transmission (the slave address and the R/W# bit) to ICDRT.

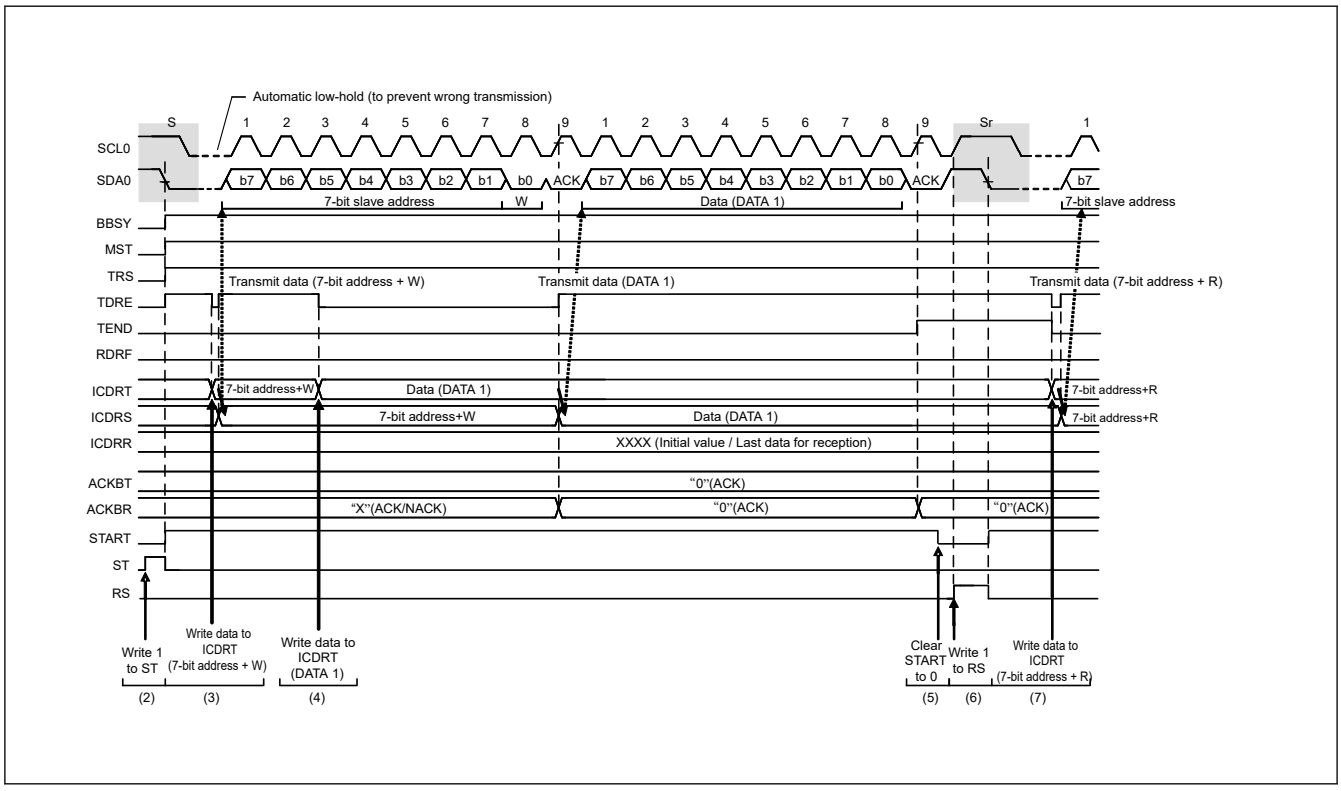

**Figure 28.46 Restart condition issue timing after master transmission.**

### 28.11.3 Issuing a Stop Condition

The IIC issues a stop condition when the SP bit in ICCR2 is set to 1. When the SP bit is set to 1, a stop condition request is made, and the IIC issues a stop condition when the BBSY flag in ICCR2 is 1 (bus busy state) and the MST bit in ICCR2 is 1 (master mode).

To issue a stop condition:

1. Drive the SDA0 line low (high level to low level).
2. Ensure the low-level period of the SCL0 line set in ICBRL elapses.
3. Release the SCL0 line (low level to high level).
4. Detect a high level on the SCL0 line and ensure the time set in ICBRH and the stop condition setup time elapse.
5. Release the SDA0 line (low level to high level).
6. Ensure the time set in ICBRL and the bus free time elapse.
7. Clear the BBSY flag to 0 to release the bus mastership.

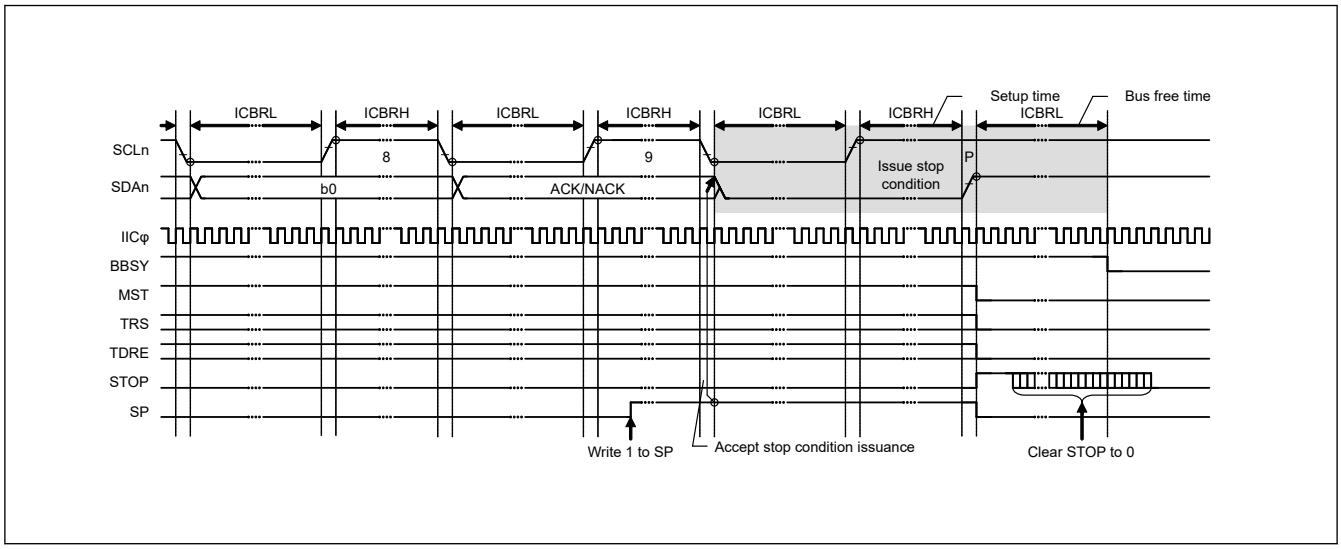

**Figure 28.47 Stop condition issue timing using the SP bit**

## 28.12 Bus Hanging

If the clock signals from the master and slave devices are out of synchronization because of noise or other factors, the $I^2C$ bus might hang with a fixed level on the SCL0 line or SDA0 line.

To manage bus hanging, the IIC has a timeout function to detect hanging by monitoring the SCL0 line, and a function for outputting an extra SCL clock cycle to release the bus from:

- A timeout function to detect hanging by monitoring the SCL0 line
- The IIC reset function
- An internal reset function.

By checking the SCLO, SDAO, SCLI, and SDAI bits in ICCR1, it is possible to see whether the IIC or its communicating partner is placing the low level on the SCL0 or SDA0 line.

### 28.12.1 Timeout Function

The timeout function can detect when the SCL0 line is stuck longer than the predetermined time. The IIC can detect an abnormal bus state by monitoring that the SCL0 line is stuck low or high for a predetermined time.

The timeout function monitors the SCL0 line state and counts the low- or high-level period using the internal counter. The timeout function resets the internal counter each time the SCL0 line changes (rises or falls), but continues to count unless the SCL0 line changes. If the internal counter overflows because no SCL0 line changes, the IIC can detect the timeout and report the bus hung state.

This timeout function is enabled when the ICFER.TMOE bit is 1. It detects a hung state when the SCL0 line is stuck low or high during the following conditions:

- The bus is busy (ICCR2.BBSY flag is 1) in master mode (ICCR2.MST bit is 1)
- The IIC slave address is detected (ICSR1 register is not 0x00) and the bus is busy (ICCR2.BBSY flag is 1) in slave mode (ICCR2.MST bit is 0)
- The bus is open (ICCR2.BBSY flag is 0) while a start condition is requested (ICCR2.ST bit is 1).

The internal counter of the timeout function uses the internal reference clock (IICφ) set in the CKS[2:0] bits in ICMR1 as a count source. It functions as a 16-bit counter when long mode is selected (TMOS bit = 0 in ICMR2) or a 14-bit counter when short mode is selected (TMOS bit = 1).

The SCL0 line level (low, high, or both levels) during which this counter is activated can be selected in the TMOH and TMOL bits in ICMR2. If both TMOL and TMOH bits are set to 0, the internal counter is disabled.

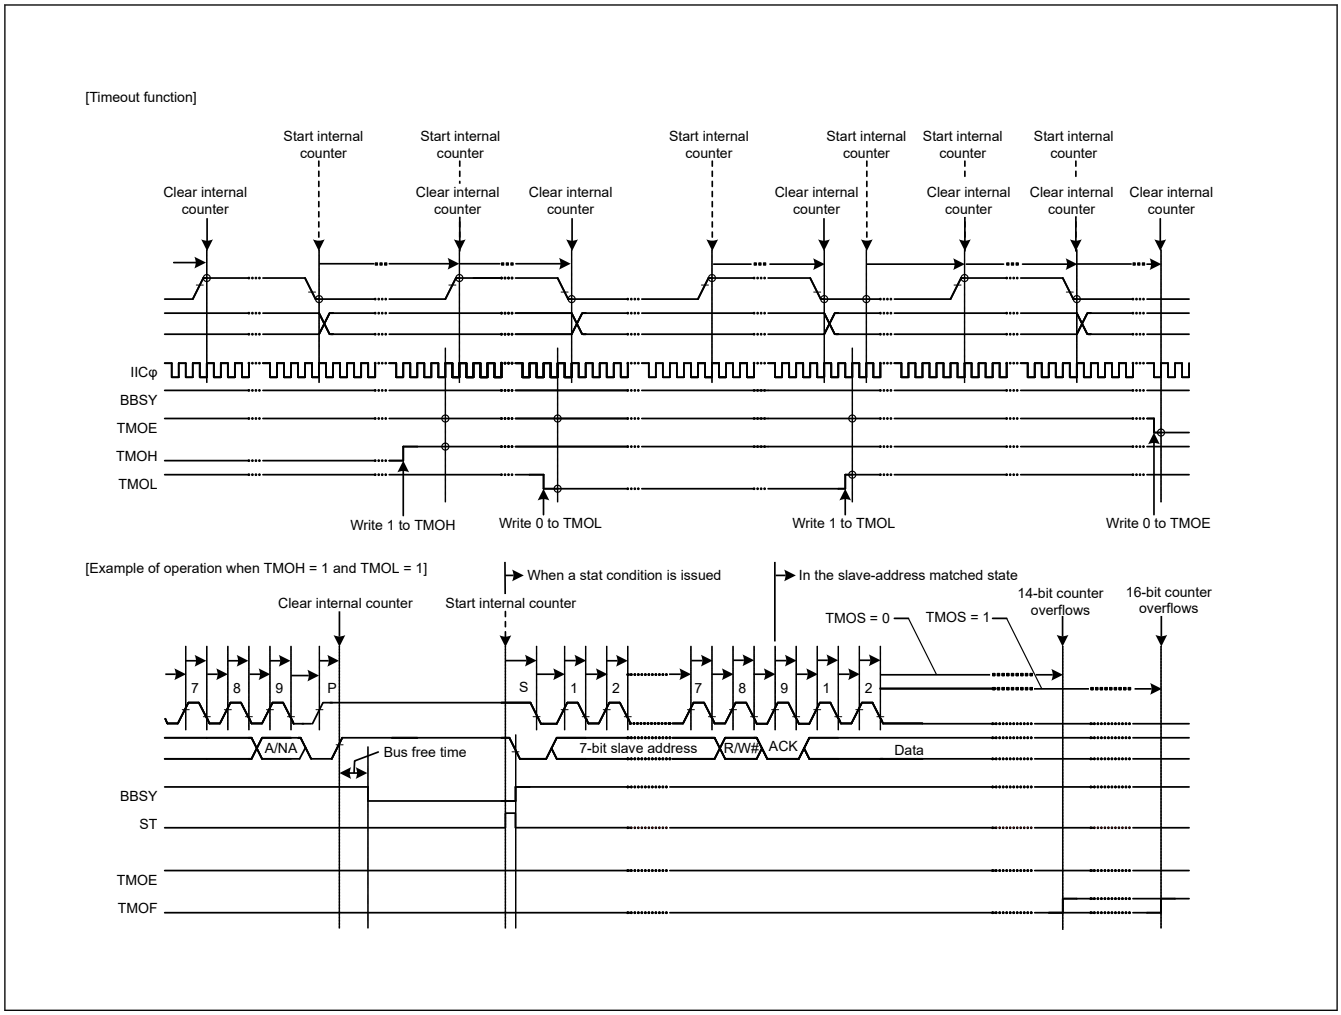

**Figure 28.48 Timeout function using the TMOE, TMOS, TMOH, and TMOL bits**

## 28.12.2 Extra SCL Clock Cycle Output Function

In master mode, this function outputs extra SCL clock cycles to release the SDA0 line of the slave device from being held low because the master is out of synchronization with the slave device. This function is mainly used in master mode to release the SDA0 line of the slave device from being fixed low by including extra cycles of SCL output from the IIC. It uses single cycles of the SCL clock for a bus error where the IIC cannot issue a stop condition because the slave device is holding the SDA0 line at the low level. Do not use this function in normal situations. Using it when communications are proceeding correctly leads to malfunctions.

When the CLO bit in ICCR1 is set to 1 in master mode, a single cycle of the SCL clock at the frequency specified in the CKS[2:0] bits in ICMR1, and in the ICBRH and ICBRL registers, is output as an extra clock cycle. After output of this

single cycle of the SCL clock, the CLO bit is automatically set to 0. At this time, if ICCR2.BBSY = 1, the SCL pin goes low, and when ICCR2.BBSY = 0, the SCL pin goes high. After confirming that the CLO bit is 0 by software, write 1 to the CLO bit to output the additional clock continuously.

When the IIC module is in master mode and the slave device is holding the SDA0 line low because synchronization with the slave device is lost because of effects like noise, the output of a stop condition is not possible. This function can be used to output extra cycles of SCL one by one to make the slave device release the SDA0 line from being held low, and so recover the bus from an unusable state. Release of the SDA0 line by the slave device can be monitored by reading the SDAI bit in ICCR1. After confirming the release of the SDA0 line by the slave device, complete communications by reissuing the stop condition.

[Output conditions for using the CLO bit in ICCR1]

- When the bus is open (BBSY flag in ICCR2 = 0) or in master mode (MST bit = 1 and BBSY flag = 1 in ICCR2)
- When the communication device does not hold the SCL0 line low.

Figure 28.49 shows the operation timing of the extra SCL clock cycle output function (CLO bit).

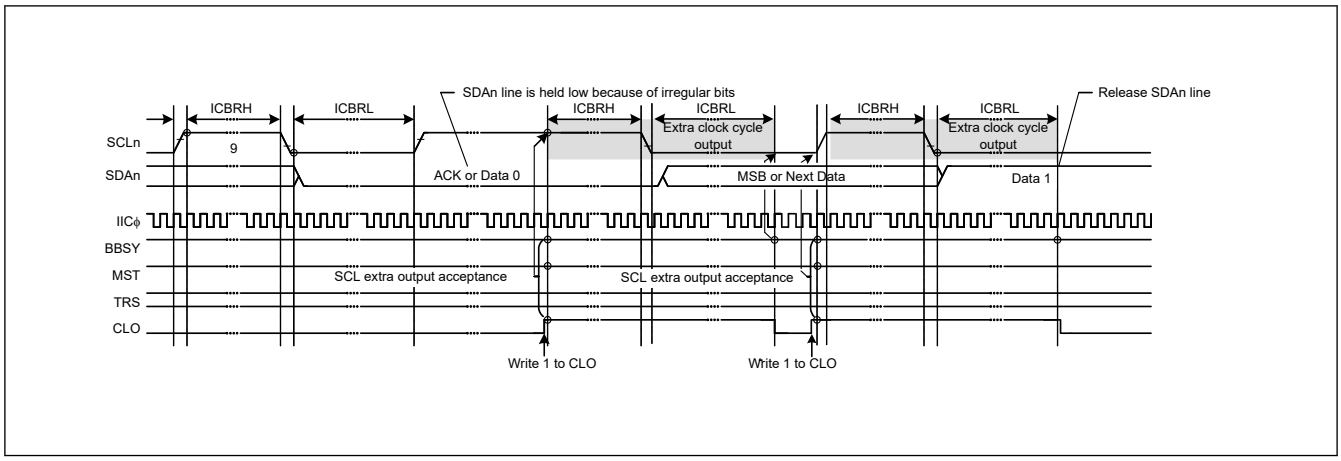

**Figure 28.49 Extra SCL clock cycle output function using the CLO bit**

## 28.12.3 IIC Reset and Internal Reset

The IIC module incorporates a function for resetting itself. It uses two types of resets:

- An IIC reset, which initializes all registers, including the BBSY flag in ICCR2.
- An internal reset, which releases the IIC from the slave-address matched state and initializes the internal counter while saving other settings.

After issuing a reset, always set the IICRST bit in ICCR1 to 0. Both types of resets are valid for release from bus-hung states, because both restore the output state of the SCL0 and SDA0 pins to the high-impedance state.

Issuing a reset during slave operation might lead to a loss of synchronization between the master device clock and the slave device clock, so avoid this when possible. In addition, monitoring of the bus state, such as for the presence of a start condition, is not possible during an IIC reset (ICE and IICRST bits = 01b in ICCR1).

For a detailed description of the IIC and internal resets, see section 28.15. State of Registers When Issuing Each Condition.

## 28.13 SMBus Operation

The IIC supports data communication conforming to the SMBus Specification (version 2.0). To perform SMBus communication, set the SMBS bit in ICMR3 to 1. To use the transfer rate within a range of 10 to 100 kbps of the SMBus standard, set the CKS[2:0] bits in ICMR1, the ICBRH, and ICBRL registers. In addition, specify the values in the DLCS bit in ICMR2 and the SDDL[2:0] bits in ICMR2 to meet the data hold time specification of 300 ns or more. When the IIC is used only as a slave device, the transfer rate setting is not required, but ICBRL must be set to a value longer than the data setup time (250 ns).

For the SMBus device default address (1100 001b), use one of the slave address registers L0 to L2 (SARL0, SARL1, and SARL2), and set the associated FS bit (7- or 10-bit address format select) in SARUy (y = 0 to 2) to 0 (7-bit address format).

When transmitting the UDID (Unique Device Identifier), set the SALE bit in ICFER to 1 to enable the slave arbitration-lost detection function.

### 28.13.1 SMBus Timeout Measurement

#### (1) Measuring slave device timeout

The following period (timeout interval: $T_{LOW:\ SEXT}$) must be measured for slave devices in SMBus communication:

- From start condition to stop condition.

To measure timeout for slave devices, measure the period from start condition detection to stop condition detection with the GPT using the IIC start condition detection interrupt (STI) and stop condition detection interrupt (SPI). The measured timeout period must be within the total clock low-level period [slave device] $T_{LOW:\ SEXT}$: 25 ms (maximum) of the SMBus standard.

If the time measured with the GPT exceeds the clock low-level detection timeout $T_{TIMEOUT}$: 25 ms (minimum) of the SMBus standard, the slave device must release the bus by writing 1 to the IICRST bit in ICCR1 to issue an internal reset of the IIC. When an internal reset is issued, the IIC stops driving the bus for the SCL0 and SDA0 pins, making them output high-impedance, which releases the bus.

#### (2) Measuring master device timeout

The following periods (timeout interval: $T_{LOW:\ MEXT}$) must be measured for master devices in SMBus communication:

- From start condition to acknowledge bit
- Between acknowledge bits
- From acknowledge bit to stop condition.

To measure timeout for master devices, measure these periods with the GPT using the IIC start condition detection interrupt (STI), stop condition detection interrupt (SPI), transmit end interrupt (IIC0_TEI), or receive data full interrupt (IIC0_RXI). The measured timeout period must be within the total clock low-level extended period (master device) $T_{LOW:\ MEXT}$: 10 ms (maximum) of the SMBus standard, and the total of all $T_{LOW:\ MEXT}$ values from start condition to stop condition must be within $T_{LOW:\ SEXT}$: 25 ms (maximum).

For the ACK receive timing (rising edge of the 9th SCL clock cycle), monitor the TEND flag in ICSR2 in master transmit mode (master transmitter) and the RDRF flag in ICSR2 in master receive mode (master receiver). Perform byte-wise transmit operations in master transmit mode, and hold the RDRFS bit in ICMR3 at 0 until the byte immediately before reception of the final byte in master receive mode. While the RDRFS bit is 0, the RDRF flag is set to 1 on the rising edge of the 9th SCL clock cycle.

If the period measured with the GPT exceeds the total clock low-level extended period (master device) $T_{LOW:\ MEXT}$: 10 ms (maximum) of the SMBus standard or the total of measured periods exceeds the clock low-level detection timeout $T_{TIMEOUT}$: 25 ms (minimum) of the SMBus standard, the master device must stop the transaction by issuing a stop condition. In master transmit mode, immediately stop the transmit operation (stop writing data to ICDRT).

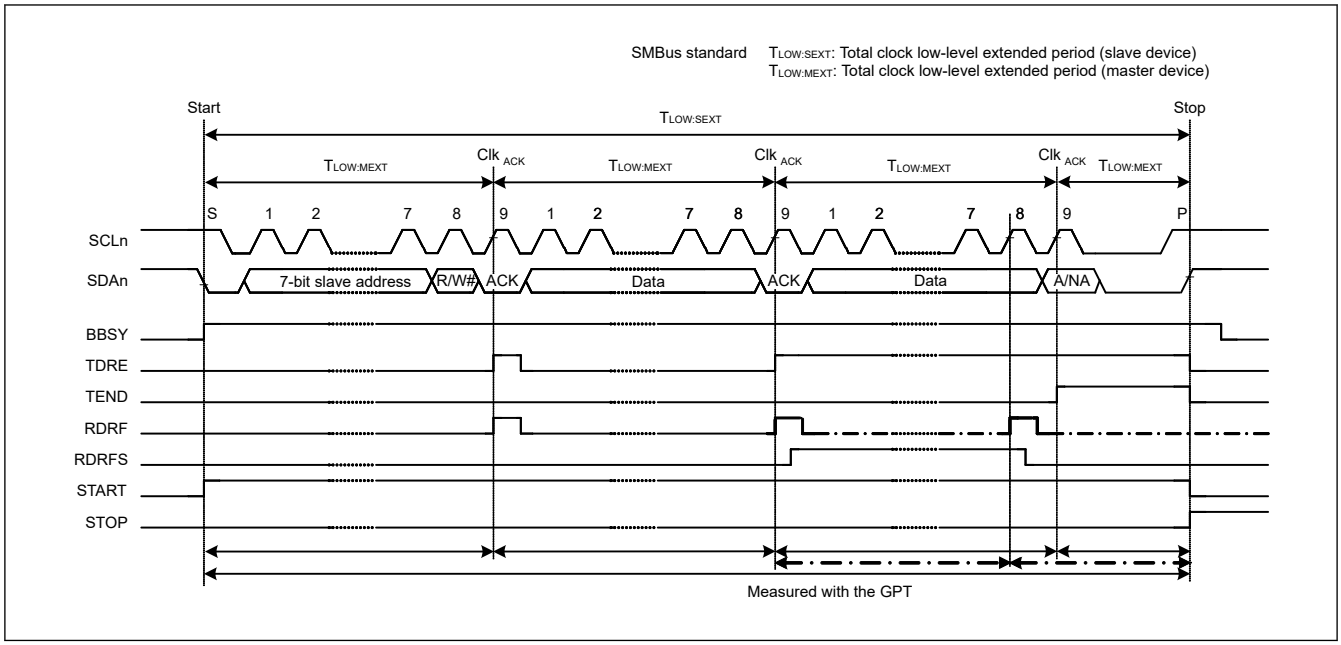

**Figure 28.50 SMBus timeout measurement**

## 28.13.2 Packet Error Code (PEC)

The MCU provides a CRC calculator that enables transmission of a Packet Error Code (PEC) or allows checking of the received data in SMBus data communication for the IIC. For the CRC-generating polynomials of the CRC calculator, see section 36, Cyclic Redundancy Check (CRC).

In master transmit mode, the PEC data can be generated by writing all transmit data to the CRC Data Input Register (CRCDIR) in the CRC calculator.

In master receive mode, the PEC data can be checked by writing all receive data to CRCDIR in the CRC calculator and comparing the obtained value in the CRC Data Output Register (CRCDOR) with the received PEC data.

To send ACK or NACK based on the match or mismatch result when the final byte is received as a result of the PEC code check, set the RDRFS bit in ICMR3 to 1 before the rising edge of the 8th SCL clock cycle during reception of the final byte, and hold the SCL0 line low on the falling edge of the 8th clock cycle.

## 28.13.3 SMBus Host Notification Protocol (Notify ARP Master Command)

In communicating over an SMBus, a slave device can temporarily act as a master device to notify the SMBus host (or ARP master) of its own slave address, or to request its own slave address from the SMBus host.

For a product using the MCU to operate as an SMBus host or ARP master, the host address (0001 000b) sent from the slave device must be detected as a slave address, and so the IIC provides a function for detecting the host address. To detect the host address as a slave address, set the SMBS bit in ICMR3 and the HOAE bit in ICSER to 1. Operation after the host address is detected is the same as normal slave operation.

## 28.14 Interrupt Sources

The IIC issues five types of interrupt requests:

- Transfer error or event generation (arbitration-lost, NACK detection, timeout detection, start condition detection, and stop condition detection)
- Receive data full
- Transmit data empty
- Transmit end
- Address match during wakeup function

Table 28.10 lists details about the interrupt requests. The receive data full and transmit data empty interrupts can activate data transfer by the DTC or DMAC.

**Table 28.10 Interrupt sources**

| Symbol | Interrupt source | Interrupt flag | DTC or DMAC activation | Interrupt condition |
|---|---|---|---|---|
| IIC0_EEI | Transfer error or event occurrence | AL | Not possible | AL = 1, ALIE = 1 |
| | | NACKF | | NACKF = 1, NAKIE = 1 |
| | | TMOF | | TMOF = 1, TMOIE = 1 |
| | | START | | START = 1, STIE = 1 |
| | | STOP | | STOP = 1, SPIE = 1 |
| IIC0_RXI*2 | Receive data full | RDRF | Possible | RDRF = 1, RIE = 1 |
| IIC0_TXI*1 | Transmit data empty | RDRF | Possible | TDRE = 1, TIE = 1 |
| IIC0_TEI*3 | Transmit end | TEND | Not possible | TEND = 1, TEIE = 1 |
| IIC0_WUI | Slave address match during wakeup function | WUF | Not possible | Slave address match<br>Slave receive complete<br>RWAK operation ASY0 = 1<br>WUIE = 1 |

Note: There is a delay between the execution of a write instruction for a peripheral module by the CPU and the actual writing to the module. When an interrupt flag is cleared or masked, read the relevant flag again to check whether clearing or masking is complete, then return from interrupt handling. Not doing so creates the possibility of repeated processing of the same interrupt.
Note 1. Because IIC0_TXI is edge-detected, it does not require clearing. Additionally, the TDRE flag in ICSR2 (condition for IIC0_TXI) is automatically set to 0 when transmit data is written to the ICDRT register or a stop condition is detected (STOP flag = 1 in ICSR2).
Note 2. Because IIC0_RXI is edge-detected, it does not require clearing. Additionally, the RDRF flag in ICSR2 (condition for IIC0_RXI) is automatically set to 0 when data is read from ICDRR.
Note 3. When using the IIC0_TEI interrupt, clear the TEND flag in ICSR2 in the IIC0_TEI interrupt handling. The TEND flag in ICSR2 automatically is set to 0 when transmit data is written to the ICDRT register or a stop condition is detected (STOP flag = 1 in ICSR2).

Clear or mask each flag during interrupt handling.

### 28.14.1 Buffer Operation for IIC0_TXI and IIC0_RXI Interrupts

If the conditions for generating an IIC0_TXI or IIC0_RXI interrupt are satisfied while the associated IR flag is 1, the interrupt request is not output for the ICU but is saved internally. One request per source can be saved internally.

An interrupt request that is saved in the ICU is output when the ICU.IELSRn.IR flag becomes 0. Internally saved interrupt requests are automatically cleared under normal conditions. They can also be cleared by writing 0 to the interrupt enable bit within the associated peripheral module.

## 28.15 State of Registers When Issuing Each Condition

The IIC has two dedicated resets, IIC reset and Internal reset. Table 28.11 lists the registers states when issuing each condition.

**Table 28.11 Register states when issuing each condition (1 of 2)**

| Registers | | Reset | IIC reset (ICE = 0, IICRST = 1) | Internal reset (ICE = 1, IICRST = 1) | Start or restart condition detection | Stop condition detection |
|---|---|---|---|---|---|---|
| ICCR1 | ICE, IICRST | In reset | Saved | Saved | Saved | Saved |
| | SCLO, SDAO | | In reset | In reset | | |
| | Others | | | Saved | | |
| ICCR2 | BBSY | In reset | In reset | Saved | Set | In reset |
| | ST, RS | | | In reset | In reset | Saved |
| | SP | | | | | In reset |
| | TRS | | | | Set or saved | |
| | MST | | | | | |
| ICMR1 | BC[2:0] | In reset | In reset | In reset | In reset | Saved |
| | Others | | | Saved | Saved | |

**Table 28.11 Register states when issuing each condition (2 of 2)**

| Registers | | Reset | IIC reset (ICE = 0, IICRST = 1) | Internal reset (ICE = 1, IICRST = 1) | Start or restart condition detection | Stop condition detection |
|---|---|---|---|---|---|---|
| ICMR2 | | In reset | In reset | Saved | Saved | Saved |
| ICMR3 | ACKBT | In reset | In reset | Saved | Saved | In reset |
| | Others | | | | | Saved |

## 28.16 Event Link Output

The IIC0 module handles the event output for the Event Link Controller (ELC) for the following sources:

### (1) Transfer error event

When a transfer error event occurs, the associated event signal can be output to another module by the ELC.

### (2) Receive data full

When a receive data register becomes full, the associated event signal can be output to another module by the ELC.

### (3) Transmit data empty

When a transmit data register becomes empty, the associated event signal can be output to another module by the ELC.

### (4) Transmit end

On completion of the transfer, the associated event signal can be output to another module by the ELC.

## 28.16.1 Interrupt Handling and Event Linking

Each of the IIC interrupt types (see Table 28.10) has an enable bit to control enabling and disabling of the associated interrupt signal. An interrupt request signal is output to the CPU when an interrupt source condition is satisfied while the associated enable bit is set.

The associated event link output signals are sent to other modules as event signals by the ELC when the interrupt source conditions are satisfied, regardless of the interrupt enable bit settings. For details on interrupt sources, see Table 28.10.

## 28.17 Usage Notes

### 28.17.1 Settings for the Module-Stop Function

The Module Stop Control Register B (MSTPCRB) can enable or disable IIC operation. The IIC is initially stopped after reset. Releasing the module-stop state enables access to the registers. For details, see section 10, Low Power Modes.

### 28.17.2 Notes on Starting Transfer

If the IR flag associated with the IIC interrupt is 1 when transfer is started (ICCR1.ICE bit = 1), follow the procedure in this section to clear the interrupts before enabling operations. Starting transfer with the IR flag set to 1 while the ICCR1.ICE bit is 1 leads to an interrupt request being internally saved after transfer starts, and this can lead to unexpected behavior of the IR flag.

To clear interrupts before starting transfer operation:

1. Confirm that the ICCR1.ICE bit is 0.
2. Set the relevant interrupt enable bits, such as ICIER.TIE to 0.
3. Read the relevant interrupt enable bits, such as ICIER.TIE, and confirm that the value is 0.
4. Set the IR flag to 0.

# 29. I3C Bus Interface (I3C)

Specific HDR modes are not covered by conformance test suite (CTS).

When CTS for HDR modes is available, Renesas will confirm CTS tests.

## 29.1 Overview

### 29.1.1 Functional Overview

The I3C bus interface (I3C) has one channel. The I3C module conforms with and provides a subset of the NXP $I^2C$ (Inter-Integrated Circuit) bus interface functions and a subset of the MIPI I3C.

In this section, PCLK refers to PCLKA, TCLK refers to I3CCLK.

Table 29.1 lists the $I^2C$ specifications and Table 29.2 lists the I3C specifications.

**Table 29.1 $I^2C$ specifications (1 of 2)**

| Parameter | Specifications |
|---|---|
| Operation mode | Master mode and slave mode selectable |
| Data handler | Single buffer transfer |
| Communication protocol | • $I^2C$ bus format<br>– Standard-mode (Sm) : 0 to 100 kbps<br>– Fast-mode (Fm) : 0 to 400 kbps<br>– Fast-mode Plus (Fm+) : 0 to 1 Mbps<br>– High-speed mode (Hs-mode) : 0 to 3 Mbps<br>• SMBus format : 10 to 100 kbps |

**Table 29.3 I3C I/O pins**

| Channel | Pin name | I/O | Function |
|---|---|---|---|
| I3C | I3C_SCL0 | I/O | I3C serial clock I/O pin |
| | I3C_SDA0 | I/O | I3C serial data I/O pin |

Note: In this section, I3C_SCL refers to I3C_SCL0, I3C_SDA refers to I3C_SDA0.

## 29.1.2 Block Diagram

Figure 29.1 shows the main components of this I3C.

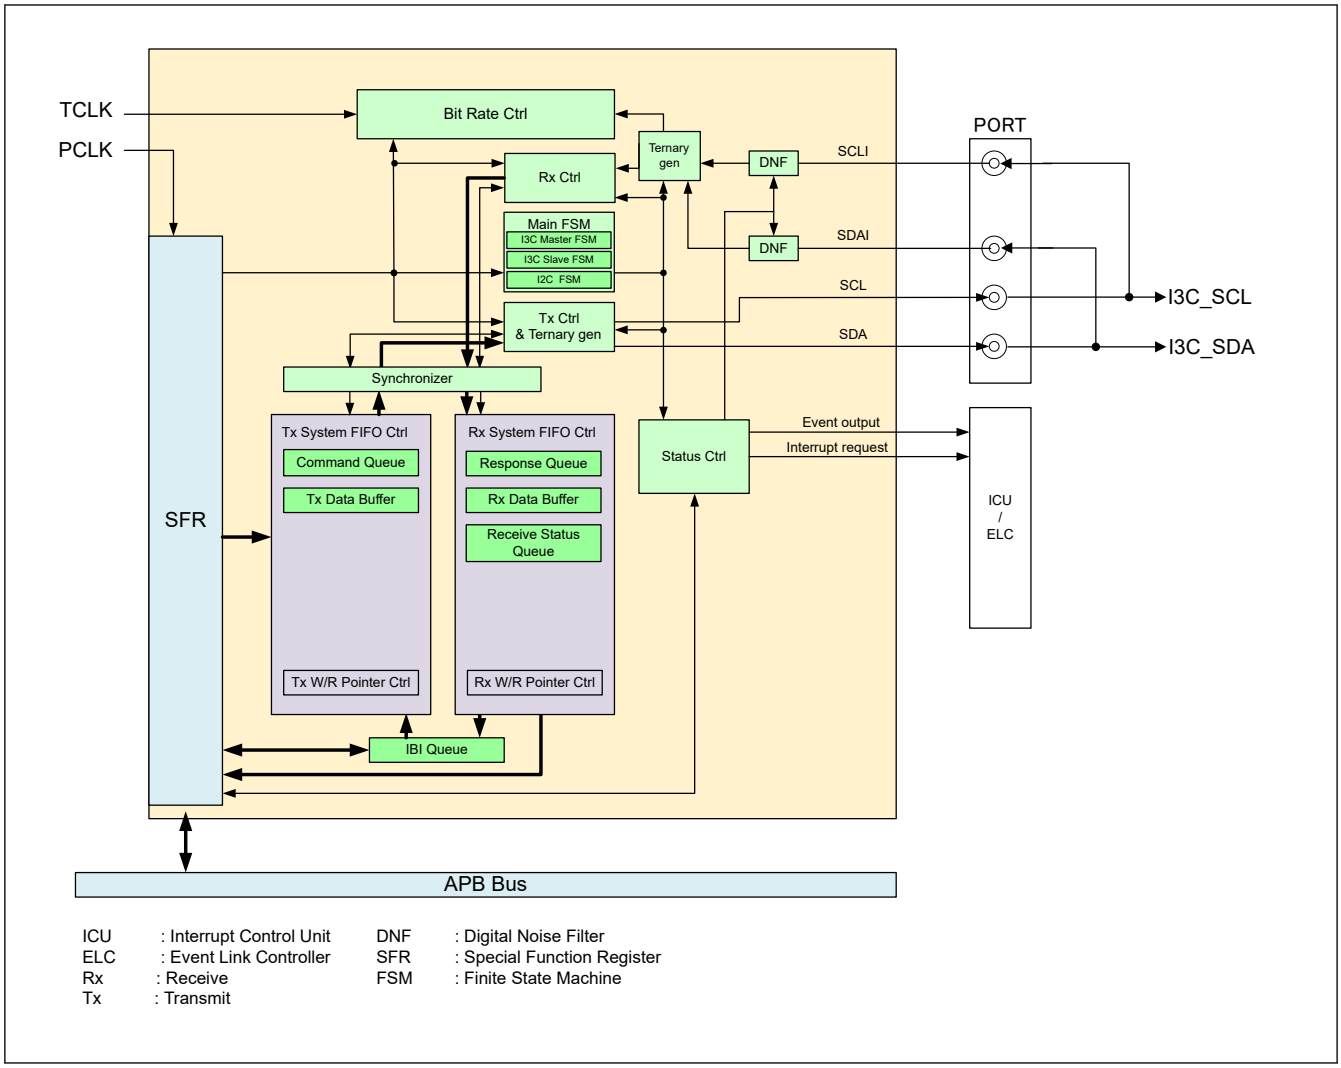

**Figure 29.1 I3C block diagram**

## 29.2 Registers

### 29.2.1 PRTS : Protocol Selection Register

Base address: I3C = 0x4011_F000

Offset address: 0x000

| Bit position: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit position: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | PRTMD |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 1 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 0 | PRTMD | Protocol Mode<br>0: I3C protocol mode<br>1: $I^2C$ protocol mode | R/W |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 31:1 | — | These bits are read as 0. The write value should be 0. | R/W |

Note: If the security attribution is configured as Secure:
- Secure access and Non-secure read access are allowed
- Non-secure write access is ignored, and TrustZone access error is not generated.

If the security attribution is configured as Non-secure:
- Secure and Non-secure access are allowed.

### PRTMD bit (Protocol Mode)

PRTMD = 0 : I3C FIFO buffer transfer (Equivalent to HCI)

PRTMD = 1 : $I^2C$ single buffer transfer

## 29.2.2 BCTL : Bus Control Register

Base address: I3C = 0x4011_F000

Offset address: 0x014

| Bit position: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | BUSE | RSM | ABT | — | — | — | — | — | — | — | — | — | — | — | — | — |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit position: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | — | — | — | — | HJACKCTL | — | — | — | — | — | — | — | INCBA |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 0 | INCBA | Include I3C Broadcast Address*1<br>0: Do not include I3C broadcast address for private transfers<br>1: Include I3C broadcast address for private transfers | R/W |
| 7:1 | — | These bits are read as 0. The write value should be 0. | R/W |
| 8 | HJACKCTL | Hot-Join Acknowledge Control*1<br>0: ACK the Hot-Join request<br>1: NACK and send broadcast CCC to disable Hot-Join | R/W |
| 28:9 | — | These bits are read as 0. The write value should be 0. | R/W |
| 29 | ABT | Abort*1<br>0: I3C is running<br>1: I3C has aborted a transfer | R/W |
| 30 | RSM | Resume*2<br>Values when read:<br>0: I3C is running<br>1: I3C is suspended | R/W |
| 31 | BUSE | Bus Enable<br>0: I3C bus operation is disabled<br>1: I3C bus operation is enabled | R/W |

Note: If the security attribution is configured as Secure:
- Secure access and Non-secure read access are allowed
- Non-secure write access is ignored, and TrustZone access error is not generated.

If the security attribution is configured as Non-secure:
- Secure and Non-secure access are allowed.

Note 1. This bit supports I3C master mode and I3C secondary master mode.
Note 2. This bit supports all I3C mode.

### INCBA bit (Include I3C Broadcast Address)

This bit controls whether the I3C broadcast address (0x7E) is included for private transfers.

If the I3C broadcast address is not included for private transfers, then IBIs driven from slaves might not win the arbitration, potentially delaying acceptance of the IBIs.

#### HJACKCTL bit (Hot-Join Acknowledge Control)

This bit acts as global control to either ACK (0) or NACK (1) all Hot-Join Requests arriving from the devices on the I3C Bus. If set to NACK (1), then the NACK is followed by the broadcast CCC to disable Hot-Join.

#### ABT bit (Abort)

When set to 1, this bit allows I3C to relinquish control of the I3C Bus before completing the currently issued transfer.

In response to an ABORT request, I3C issues the STOP condition on the I3C Bus after the complete data byte is transferred or received.

The Driver clears the ABT bit to allow operation on the Bus.

If BCTL.ABT is set and ABORT processing is performed, please ignore ERR_STATUS of Response Descriptor.

#### RSM bit (Resume)

This bit is used to resume I3C operation following the Halt state.

I3C enters the Halt state (as indicated in register PRSTDBG) as a result of any type of error occurring in a transfer.

The error type is indicated by the field ERR_STATUS in register NRSPQP, NRSQP and NIBIQP.

After I3C has entered the Halt state, the application must write the value 1 to the RSM bit to resume I3C operation. I3C auto-clears the RSM bit once it has resumed making transfers (it has initiated the next Command).

#### BUSE bit (Bus Enable)

Enables or disables the operation on the I3C Bus by I3C.

Set the BUSE bit to 1 when using I3C. The I3C_SCL and I3C_SDA pins are placed in the active state when the BUSE bit is set to 1. Set the BUSE bit to 0 when I3C is not to be used. The I3C_SCL and I3C_SDA pins are placed in the inactive state when the BUSE bit is set to 0.

If the software sets this bit, then it also confirms that initialization is done, and that I3C can use the programmed register values (for example, generation of SCL on IBI detection). If this bit is not set, then I3C does not generate SCL for incoming IBI.

Software may disable I3C bus operation while it is active, however:

- If a disable request occurs while receiving IBI, the actual disabling does not occur until reception of the IBI is complete.
- When the software reads the value 0 from this field, this indicates that I3C bus operation disable operation has completed.
  If commands remain in the command queue, do not set BUSE = 0.

### 29.2.3 MSDVAD : Master Device Address Register

Base address: I3C = 0x4011_F000

Offset address: 0x018

| Bit position: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | | | | | | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | MDYADV | — | — | — | — | — | — | — | — | MDYAD[6:0] | | | | | | |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit position: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 15:0 | — | These bits are read as 0. The write value should be 0. | R/W |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 22:16 | MDYAD[6:0] | Master Dynamic Address | R/W |
| 30:23 | — | These bits are read as 0. The write value should be 0. | R/W |
| 31 | MDYADV | Master Dynamic Address Valid<br>0: The master dynamic address field is not valid<br>1: The master dynamic address field is valid | R/W |

Note: If the security attribution is configured as Secure:
- Secure access and Non-secure read access are allowed
- Non-secure write access is ignored, and TrustZone access error is not generated.

If the security attribution is configured as Non-secure:
- Secure and Non-secure access are allowed.

Note: This register supports I3C master mode.

### MDYAD[6:0] bits (Master Dynamic Address)

This field is used to program I3C master dynamic address. I3C uses this address to respond to master transactions in I3C interface mode (slave or secondary master role).

In I3C main master mode, the software programs the dynamic address as it self-assigns its dynamic address.

### MDYADV bit (Master Dynamic Address Valid)

This bit indicates whether the value in the MDYAD field is valid.

In I3C main master mode, set this bit to 1 as it self-assigns its dynamic address.

Note: After setting MSDVAD and setting BCTL.BUSE = 1, the device acts as a main master.

Without setting MSDVAD, setting SVDCT.TBCR76[1:0] = 00b (Device Role Slave) and setting BCTL.BUSE = 1, the device acts as a slave.

Without setting MSDVAD, setting MSDCTm.RBCR76[1:0] = 01b (Device Role Master), and setting BCTL.BUSE = 1, the device acts as a slave.

## 29.2.4 RSTCTL : Reset Control Register

Base address: I3C = 0x4011_F000

Offset address: 0x020

| Bit position: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | INTLRST |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit position: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | — | — | — | — | — | — | RSQRST | IBIQRST | RDBRST | TDBRST | RSPQRST | CMDQRST | RI3CRST |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 0 | RI3CRST | I3C Software Reset<br>0: Release I3C reset.<br>1: Initiate I3C reset. | R/W |
| 1 | CMDQRST | Normal Command Queue Software Reset*1<br>0: The Normal Command Queues in I3C is not flushed.<br>1: The Normal Command Queues in I3C is flushed. | R/W |
| 2 | RSPQRST | Normal Response Queue Software Reset*1<br>0: The Normal Response Queues in I3C is not flushed.<br>1: The Normal Response Queues in I3C is flushed. | R/W |
| 3 | TDBRST | Normal Tx Data Buffer Software Reset*1<br>0: The Normal Tx Data buffers in I3C is not flushed.<br>1: The Normal Tx Data buffers in I3C is flushed. | R/W |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 4 | RDBRST | Normal Rx Data Buffer Software Reset*1<br>0: The Normal Rx Data buffers in I3C is not flushed.<br>1: The Normal Rx Data buffers in I3C is flushed. | R/W |
| 5 | IBIQRST | Normal IBI Queue Software Reset*1<br>0: The Normal IBI Queues in I3C is not flushed.<br>1: The Normal IBI Queues in I3C is flushed. | R/W |
| 6 | RSQRST | Normal Receive Status Queue Software Reset*2<br>0: The Normal Receive Status Queue in I3C is not flushed.<br>1: The Normal Receive Status Queue in I3C is flushed. | R/W |
| 15:7 | — | These bits are read as 0. The write value should be 0. | R/W |
| 16 | INTLRST | Internal Software Reset<br>0: Releases of some registers and internal state.<br>1: Resets of some registers and internal state. | R/W |
| 31:17 | — | These bits are read as 0. The write value should be 0. | R/W |

Note: If the security attribution is configured as Secure:
- Secure access and Non-secure read access are allowed
- Non-secure write access is ignored, and TrustZone access error is not generated.

If the security attribution is configured as Non-secure:
- Secure and Non-secure access are allowed.

Note 1. This bit supports all I3C mode.
Note 2. This bit supports I3C secondary master mode and I3C slave mode.

For details on reset for each register, see section 29.6. Reset Descriptions.

### RI3CRST bit (I3C Software Reset)

On Driver setting this bit to 1, I3C shall be reset and disabled.

All registers shall return to their reset values, and the software shall re-initialize I3C.

This field is cleared automatically upon I3C reset completion. This field also resets all Queues in I3C.

Note: Programming this field while it contains a value of 1 may result in undefined behavior.

### CMDQRST bit (Normal Command Queue Software Reset)

On software setting this bit to 1, the Normal Command Queues in I3C shall be flushed.

This field shall be cleared automatically upon Normal Command Queue reset completion.

### RSPQRST bit (Normal Response Queue Software Reset)

On software setting this bit to 1, the Normal Response Queues in I3C shall be flushed.

This field shall be cleared automatically upon Normal Response Queue reset completion.

### TDBRST bit (Normal Tx Data Buffer Software Reset)

On software setting this bit to 1, the Normal Tx Data Buffers in I3C shall be flushed.

This field shall be cleared automatically upon Normal Tx Data Buffer reset completion.

### RDBRST bit (Normal Rx Data Buffer Software Reset)

On software setting this bit to 1, the Normal Rx Data Buffers in I3C shall be flushed.

This field shall be cleared automatically upon completion of Normal Rx Data Buffer reset.

### IBIQRST bit (Normal IBI Queue Software Reset)

On software setting this bit to 1, the Normal IBI Queues in I3C shall be flushed.

This field shall be cleared automatically upon completion of Normal IBI Queue reset.

### RSQRST bit (Normal Receive Status Queue Software Reset)

On software setting this bit to 1, the Normal Receive Status Queues in I3C shall be flushed.

This field shall be cleared automatically upon Normal Receive Status Queue reset completion.

### INTLRST bit (Internal Software Reset)

When set to 1, some of the registers is reset. For details on the registers to be reset, see section 29.6. Reset Descriptions.

Note: When set internal software reset during bus operation enable, use DISEC CCC in advance to disable IBI transmission to I3C Slave in order to avoid conflict with IBI from I3C Slave connected to I3C Bus.

## 29.2.5 PRSST : Present State Register

Base address: I3C = 0x4011_F000

Offset address: 0x024

| Bit position: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit position: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | — | — | — | — | — | PRSSTWP | — | — | TRMD | — | CRMS | — | — |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 1:0 | — | These bits are read as 0. The write value should be 0. | R/W |
| 2 | CRMS | Current Master*2<br>0: The Master is not the Current Master, and must request and acquire bus ownership before initiating any transfer.<br>1: The Master is the Current Master, and as a result can initiate transfers. | R/W*1 |
| 3 | — | This bit is read as 0. The write value should be 0. | R/W |
| 4 | TRMD | Transmit/Receive Mode*3<br>0: Receive mode<br>1: Transmit mode | R |
| 6:5 | — | These bits are read as 0. The write value should be 0. | R/W |
| 7 | PRSSTWP | Present State Write Protect*2<br>0: CRMS bit is protected.<br>1: CRMS bit can be written when writing simultaneously with the value of the target bit. | W |
| 31:8 | — | These bits are read as 0. The write value should be 0. | R/W |

Note: If the security attribution is configured as Secure:
- Secure access and Non-secure read access are allowed
- Non-secure write access is ignored, and TrustZone access error is not generated.

If the security attribution is configured as Non-secure:
- Secure and Non-secure access are allowed.

Note 1. When the PRSSTWP bit is set to 1, the CRMS bit can be written to.
Note 2. This bit supports I2C, I3C master, and I3C secondary master mode.
Note 3. This bit supports I2C mode.

### CRMS bit (Current Master)

Indicates the set condition and reset condition of each operation mode.

Operation Mode [I2C/I3C common]

[Clearing conditions]

- When 0 written to the PRSST.CRMS by the software.

[Setting conditions]

- When 1 written to the PRSST.CRMS by the software.

Operation Mode [I2C]

[Clearing conditions]

- When STOP is issued.
- When Master Arbitration-Lost.

[Setting conditions]

- When START is issued.

Operation Mode [I3C Main Master]

[Clearing conditions]

- When 0 written to the MSDVAD.MDYADV by the software.
- When GETACCMST transmission is successfully completed by issuing STOP, after responding ACK to the Mastership-Request received from the Secondary Master.

[Setting conditions]

- When 1 written to the MSDVAD.MDYADV by the software.
- When GETACCMST reception is successfully completed by issuing STOP, after the ACK is responded to the Mastership-Request transmitted to the Secondary Master.

Operation Mode [I3C Secondary Master]

[Clearing condition]

- When GETACCMST transmission is successfully completed by issuing STOP, after responding ACK to the Mastership-Request received from the Non-Current Master.

[Setting condition]

- When GETACCMST reception is successfully completed by issuing STOP, after the ACK is responded to the Mastership-Request transmitted to the Current Master.

The PRSST register returns I3C current state.

State has two parts: this register which is mandatory, and an additional optional PRSST_DEBUG register intended for debug purposes (see the Debug Capability registers in the Extended Capabilities list).

### TRMD bit (Transmit/Receive Mode)

This bit indicates transmit or receive mode.

I3C is in receive mode when the TRMD bit is set to 0 and is in transmit mode when the bit is set to 1. Combination of this bit and the CRMS bit indicates the operating mode of I3C.

The value of TRMD bit is automatically changed to 1 for transmit mode or 0 for receive mode by issuing or detection of a START condition and setting of the R/W# bit.

[Setting conditions]

- When a START condition is issued normally according to the START condition issuance request (when a START condition is detected with the CNDCTL.STCND bit set to 1).
- When a Repeated START condition is issued normally according to the Repeated START condition issuance request (when a Repeated START condition is detected with the CNDCTL.SRCND bit set to 1).
- When the R/W# bit added to the slave address is set to 0 in master mode.
- When the address received in slave mode matches the address enabled in SVCTL, with the R/W# bit set to 1.

[Clearing conditions]

- When a STOP condition is detected.
- The ALF (arbitration-lost) flag in BST being set to 1.
- In master mode, reception of a slave address to which an R/W# bit with the value 1 is appended.

- In slave mode, a match between the received address and the address enabled in SVCTL when the value of the received R/W# bit is 0 (including cases where the received address is the general call address).
- In slave mode, a Repeated START condition is detected (a Repeated START condition is detected with BCST.BFREF = 0 and CRMS = 0).

#### PRSSTWP bit (Present State Write Protect)

PRSSTWP is always 0 when reading.

When writing to PRSST, writing 1 to this bit at the same time enables writing to CRMS bit.

### 29.2.6 INST : Internal Status Register

Base address: I3C = 0x4011_F000

Offset address: 0x030

| Bit position: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

|---|---|---|---|
| 9:0 | — | These bits are read as 0. The write value should be 0. | R/W |
| 10 | INEF | Internal Error Flag<br>0: I3C Internal Error has not detected.<br>1: I3C Internal Error has detected. | R/W*1 |
| 31:11 | — | These bits are read as 0. The write value should be 0. | R/W |

Note: If the security attribution is configured as Secure:
- Secure access and Non-secure read access are allowed
- Non-secure write access is ignored, and TrustZone access error is not generated.

If the security attribution is configured as Non-secure:
- Secure and Non-secure access are allowed.

Note: This register supports all I3C mode.

Note 1. Clearing (to 0) condition : Writing 0 after the 1 state is read.

The Interrupt Status register reflects the status of outstanding interrupts.

The status fields are either write 0 to clear, or else are cleared based on queue operations.

#### INEF bit (Internal Error Flag)

When this bit is 1, it indicates that I3C Internal Error has detected.

When this bit is 0, it indicates that I3C Internal Error has not detected.

[Setting conditions]

- The following 1 is satisfied and any of the following 2 to 9 are satisfied.
  1. The INSTE.INEE bit = 1
  2. When transmit data is written to the Tx Data Buffer that is completely full.
  3. When received data is read from the Rx Data Buffer that is completely empty.
  4. When Command Descriptor is written to the Command Queue that is completely full.
  5. When Response Descriptor is read from the Response Queue that is completely empty.
  6. When Receive Status Descriptor is read from the Receive Status Queue that is completely empty.

7. When IBI Status Descriptor is read from the IBI Queue under the condition that the IBI Queue is completely empty and PRSST.CRMS = 1.
8. When IBI Data is written to the IBI Queue under the condition that the IBI Queue is completely full and PRSST.CRMS = 0.
9. When the Response Queue, IBI Queue or Receive Status Queue overflows.

[Clearing condition]

- When 0 is written to the INEF bit after reading INEF bit = 1.

## 29.2.7 INSTE : Internal Status Enable Register

Base address: I3C = 0x4011_F000

Offset address: 0x034

| Bit position: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 9:0 | — | These bits are read as 0. The write value should be 0. | R/W |
| 10 | INEE | Internal Error Enable<br>0: Disable INST.INEF<br>1: Enable INST.INEF | R/W |
| 31:11 | — | These bits are read as 0. The write value should be 0. | R/W |

Note: If the security attribution is configured as Secure:
- Secure access and Non-secure read access are allowed
- Non-secure write access is ignored, and TrustZone access error is not generated.

If the security attribution is configured as Non-secure:
- Secure and Non-secure access are allowed.

Note: This register supports all I3C mode.

### INEE bit (Internal Error Enable)

When this bit set to 1, it enables detection of I3C Internal Error.

When this bit set to 0, it disables detection of I3C Internal Error.

## 29.2.8 INIE : Internal Interrupt Enable Register

Base address: I3C = 0x4011_F000

Offset address: 0x038

| Bit position: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — |

| 10 | INEIE | Internal Error Interrupt Enable<br>0: Disables Non-recoverable Internal Error Interrupt Signal.<br>1: Enables Non-recoverable Internal Error Interrupt Signal. | R/W |
| 31:11 | — | These bits are read as 0. The write value should be 0. | R/W |

Note: If the security attribution is configured as Secure:
- Secure access and Non-secure read access are allowed
- Non-secure write access is ignored, and TrustZone access error is not generated.

If the security attribution is configured as Non-secure:
- Secure and Non-secure access are allowed.

Note: This register supports all I3C mode.

### INEIE bit (Internal Error Interrupt Enable)

When set to 1 and register INEF is set, the hardware Controller asserts an interrupt to the Host.

## 29.2.9 INSTFC : Internal Status Force Register

Base address: I3C = 0x4011_F000

Offset address: 0x03C

| Bit position: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit position: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |

| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 9:0 | — | The write value should be 0. | W |
| 10 | INEFC | Internal Error Force<br>0: Not force a specific interrupt<br>1: Force a specific interrupt | W |
| 31:11 | — | The write value should be 0. | W |

Note: If the security attribution is configured as Secure:
- Secure access and Non-secure read access are allowed
- Non-secure write access is ignored, and TrustZone access error is not generated.

If the security attribution is configured as Non-secure:
- Secure and Non-secure access are allowed.

Note: This register supports all I3C mode.

### INEFC bit (Internal Error Force)

For debug, helps to force this interrupt.

## 29.2.10 DVCT : Device Characteristic Table Register

Base address: I3C = 0x4011_F000

Offset address: 0x044

| Bit position: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | — | — | — | — | — | IDX[4:0] | | | | | — | — | — |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit position: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 18:0 | — | These bits are read as 0. | R |
| 23:19 | IDX[4:0] | DCT Table Index<br>Current index of the DCT, which is used as the starting index for the I3C ENTDAA CCC. | R |
| 31:24 | — | These bits are read as 0. | R |

Note: If the security attribution is configured as Secure:
- Secure access and Non-secure read access are allowed
- Non-secure write access is ignored, and TrustZone access error is not generated.

If the security attribution is configured as Non-secure:
- Secure and Non-secure access are allowed.

Note: This register supports I3C master mode and I3C secondary master mode.

### IDX[4:0] bits (DCT Table Index)

Once the complete characteristics of device that won the arbitration are written to the DCT (during ENTDAA using Address Assignment Command) this index is incremented by 1.

Note: How to check the progress of ENTDAA using this bit:

1. Read the value of this bit before setting the Command Descriptor for issuing the ENTDAA command.
2. After starting the ENTDAA command, until the value of this bit is updated (that is, it changes from the value read in advance), it indicates that the Dynamic Address is being assigned to the device specified by the first index value (value set in DEV_INDEX[4:0] of Command Descriptor).
3. After the value of this bit is updated, it indicates that Dynamic Address is being assigned according to the value set in DEV_INDEX[4:0] and DEV_COUNT[3:0] of Command Descriptor to the device of the first index value or later.

## 29.2.11 IBINCTL : IBI Notify Control Register

Base address: I3C = 0x4011_F000

Offset address: 0x058

| Bit position: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit position: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | — | — | — | — | — | — | — | — | — | NRSIR CTL | — | NRMR CTL | NRHJ CTL |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 0 | NRHJCTL | Notify Rejected Hot-Join Control<br>0: Do not pass rejected IBI Status to IBI Queue, if the incoming HotJoin request is NACKed and is auto-disabled based on field HJACKCTL of BCTL.<br>1: Pass rejected IBI Status to the IBI Queue, if the incoming Hot Join request is NACKed and is auto-disabled based on field HJACKCTL of BCTL. | R/W |
| 1 | NRMRCTL | Notify Rejected Master Request Control<br>0: Do not pass rejected IBI Status to the Normal IBI Queue, if the incoming Master Request is NACKed and is auto-disabled based on DVMRRJ field in relevant DAT entry.<br>1: Pass rejected IBI Status to the Normal IBI Queue if the incoming Master Request is NACKed and is auto-disabled based on DVMRRJ field in relevant DAT entry. | R/W |
| 2 | — | This bit is read as 0. The write value should be 0. | R/W |
| 3 | NRSIRCTL | Notify Rejected Slave Interrupt Request Control<br>0: Do not pass rejected IBI Status to the Normal IBI Queue, if the incoming SIR is NACKed and is auto-disabled based on DVSIRRJ field in relevant DAT entry.<br>1: Pass rejected IBI Status to the Normal IBI Queue, if the incoming SIR is NACKed and is auto-disabled based on DVSIRRJ field in relevant DAT entry. | R/W |
| 31:4 | — | These bits are read as 0. The write value should be 0. | R/W |

Note: If the security attribution is configured as Secure:
- Secure access and Non-secure read access are allowed
- Non-secure write access is ignored, and TrustZone access error is not generated.

If the security attribution is configured as Non-secure:
- Secure and Non-secure access are allowed.

Note: This register supports I3C master mode and I3C secondary master mode.

### NRHJCTL bit (Notify Rejected Hot-Join Control)

Enables or disables reporting rejection of individual Hot Join requests.

### NRMRCTL bit (Notify Rejected Master Request Control)

Enables or disables reporting rejection of individual Master Requests.

### NRSIRCTL bit (Notify Rejected Slave Interrupt Request Control)

Enables or disables reporting rejection of individual Slave Interrupt Requests (SIR).

## 29.2.12 BFCTL : Bus Function Control Register

Base address: I3C = 0x4011_F000

Offset address: 0x060

| Bit position: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit position: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | HSME | FMPE | — | SMBS | — | — | — | SCSYNE | — | — | — | — | — | SALE | NALE | MALE |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 1 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 1 |

| 13 | — | This bit is read as 0. The write value should be 0. | R/W |
| 14 | FMPE | Fast-mode Plus Enable<br>0: No Fm+ slope control circuit uses for the I3C_SCL pin and I3C_SDA pin. (n = 0)<br>1: An Fm+ slope control circuit uses for the I3C_SCL pin and I3C_SDA pin. (n = 0) | R/W |
| 15 | HSME | High Speed Mode Enable<br>0: Disable High Speed Mode.<br>1: Enable High Speed Mode. | R/W |
| 31:16 | — | These bits are read as 0. The write value should be 0. | R/W |

Note: If the security attribution is configured as Secure:
- Secure access and Non-secure read access are allowed
- Non-secure write access is ignored, and TrustZone access error is not generated.

If the security attribution is configured as Non-secure:
- Secure and Non-secure access are allowed.

Note: This register supports for I2C mode.

### MALE bit (Master Arbitration-Lost Detection Enable)

This bit is used to specify whether to use the arbitration-lost detection function in master mode. Normally, set this bit to 1.

### NALE bit (NACK Transmission Arbitration-Lost Detection Enable)

This bit is used to specify whether to cause arbitration to be lost when ACK is detected during transmission of NACK in receive mode (such as when slaves with the same address exist on the bus or when two or more masters select the same slave device simultaneously with different number of receive bytes).

### SALE bit (Slave Arbitration-Lost Detection Enable)

This bit is used to specify whether to cause arbitration to be lost when a value different from the value being transmitted is detected on the bus in slave transmit mode (such as when slaves with the same address exist on the bus or when a mismatch with the transmit data occurs due to noise).

### SCSYNE bit (SCL Synchronous Circuit Enable)

This bit is used to specify whether to synchronize the SCL clock with the SCL input clock. Normally, set this bit to 1.

When the SCSYNE bit set to 0 (no SCL synchronous circuit used), I3C does not synchronize the SCL clock with the SCL input clock. In this setting, I3C outputs the SCL clock with the transfer rate set in STDBR and EXTBR regardless of the I3C_SCL line state. For this reason, if the bus load of the I$^2$C bus line is much larger than the specification value or if the SCL clock output overlaps in multiple masters, the short-cycle SCL clock that does not meet the specification may be output. When no SCL synchronous circuit uses, it also affects the issuance of a START condition, Repeated START condition, and STOP condition, and the continuous output of extra SCL clock cycles.

This bit must not be set to 0 except for checking the output of the set transfer rate.

### FMPE bit (Fast-mode Plus Enable)

This bit is used to specify whether to use a slope control circuit for Fast-mode Plus [Fm+].

When this bit is set to 1, a slope control circuit conforming to the Fast-mode Plus [Fm+] slope control specification (tof) of the I3C-bus is selected. When this bit is set to 0, a slope control circuit conforming to the Standard-mode [Sm] and Fast-mode [fm] slope control specification (tof) of the I3C-bus is selected.

Set this bit to 1 when using the transmission rate within a range up to 1 Mbps (Fast-mode Plus [Fm+]) of the I3C-bus specification. Set this bit to 0 when using the transmission rate at other rates (up to 100 kbps [Sm], up to 400 kbps [Fm]) or for SMBus (10 to 100 kbps).

Note: When communicating in Hs-mode, set as follows.
- Set FMPE to 0 when sending Hs-mode master code (0000 1XXXb) with Fast-mode.
- Set FMPE to 1 when sending Hs-mode master code (0000 1XXXb) with Fast-mode Plus.

**HSME bit (High Speed Mode Enable)**

This bit is used for communicating in Hs-mode.

When this bit is set to 1, the Hs-mode master code is recognized and Hs-mode communication is possible.

After the START condition is detected, if Hs-mode master code (0000 1XXXb) transmission is recognized, Hs-mode communication starts from Repeated START after receiving the NACK response.

It communicates at the bit rate set in STDBR until the NACK response, and automatically switches from Repeated START condition issuance after receiving the NACK response to the bit rate set in EXTBR.

Hs-mode continues until a STOP condition is detected.

When the STOP condition is detected, the bit rate is automatically switched to the bit rate set in STDBR.

Note: When this bit is set to 1, the BST.NACKDF bit will not be set even if a NACK response is received after sending the Hs-mode master code.

## 29.2.13 SVCTL : Slave Control Register

Base address: I3C = 0x4011_F000

Offset address: 0x064

| Bit position: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

| Bit field: | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | SVAE0 |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit position: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | HOAE | — | — | — | — | — | — | — | — | DVIDE | HSMCE | — | — | — | — | GCAE |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 0 | GCAE | General Call Address Enable*1<br>0: General call address detection disables.<br>1: General call address detection enables. | R/W |
| 4:1 | — | These bits are read as 0. The write value should be 0. | R/W |
| 5 | HSMCE | Hs-mode Master Code Enable*1<br>0: Hs-mode Master Code Detection disables.<br>1: Hs-mode Master Code Detection enables. | R/W |
| 6 | DVIDE | Device-ID Address Enable*1<br>0: Device-ID address detection disables.<br>1: Device-ID address detection enables. | R/W |
| 14:7 | — | These bits are read as 0. The write value should be 0. | R/W |
| 15 | HOAE | Host Address Enable*1<br>0: Host address detection disables.<br>1: Host address detection enables. | R/W |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 16 | SVAE0 | Slave Address Enable 0*2<br>0: Slave 0 disables<br>1: Slave 0 enables | R/W |
| 31:17 | — | These bits are read as 0. The write value should be 0. | R/W |

Note: If the security attribution is configured as Secure:
- Secure access and Non-secure read access are allowed
- Non-secure write access is ignored, and TrustZone access error is not generated.

If the security attribution is configured as Non-secure:
- Secure and Non-secure access are allowed.

Note 1. This bit supports $I^2C$ mode.
Note 2. These bits support $I^2C$, I3C secondary master, and I3C slave mode.

### GCAE bit (General Call Address Enable)

This bit is used to specify whether to ignore the general call address (0000 000 + 0 (write): All 0) when it is received. When this bit is set to 1, if the received slave address matches the general call address, I3C recognizes the received slave address as the general call address independently of the slave addresses set in the SVDVAD0.SVAD[9:0] bits and performs data receive operation.

When this bit is set to 0, the received slave address is ignored even if it matches the general call address.

### HSMCE bit (Hs-mode Master Code Enable)

This bit is used to specify whether to recognize and execute the Hs-mode master code (00001xxxb) is received in the first byte after a START condition is detected.

When this bit is set to 1, if the received first byte matches the Hs-mode master code, I3C recognizes that the Hs-mode master code has been received.

The first byte after Repeated START after NACK response to Hs-mode master code is recognized as a slave address and compared with the slave address set by SVDVAD0.SVAD[9:0] bits.

If the addresses match, the transmission / reception operation continues according to the R/W# bit value.

Hs-mode continues until a STOP condition is detected.

When this bit is set to 0, I3C will ignore the pattern until a STOP condition is detected, even if it matches the Hs-mode master code.

Note: When this bit is set to 1, SCSTRCTL.ACKTWE bit must be set to 0 and SCSTRCTL.RWE bit must be set to 1.

### DVIDE bit (Device-ID Address Enable)

This bit is used to specify whether to recognize and execute the Device-ID address when a device ID (1111 100) is received in the first byte after a START condition or Repeated START condition is detected.

When this bit is set to 1, if the received first byte matches the Device-ID, I3C recognizes that the Device-ID address has been received. When the following R/W# bit is 0 (write), I3C recognizes the second and the following bytes as slave addresses and continues the receive operation.

When this bit is set to 0, I3C ignores the received first byte even if it matches the Device ID address and recognizes the first byte as a normal slave address.

For details on the Device-ID address detection, see (3) Device-ID Address Detection [$I^2C$ mode].

### HOAE bit (Host Address Enable)

This bit is used to specify whether to ignore received host address (0001 000) when the BFCTL.SMBS bit = 1.

When this bit is set to 1 while the SMBS bit = 1, if the received slave address matches the host address, I3C recognizes the received slave address as the host address independently of the slave addresses set in the SVDVAD0.SVAD[9:0] bits and performs the receive operation.

When the SMBS bit or the HOAE bit is set to 0, the received slave address is ignored even if it matches the host address.

### SVAE0 bit (Slave Address Enable 0)

This bit is used to enable or disable the slave address set in the SVDVAD0.SVAD[9:0] bits.

When this bit is set to 1, the slave address set in the SVAD[9:0] bits is enabled and is compared with the received slave address.

When this bit is set to 0, the slave address set in the SVAD[9:0] bits is disabled and is ignored even if it matches the received slave address.

## 29.2.14 REFCKCTL : Reference Clock Control Register

Base address: I3C = 0x4011_F000

Offset address: 0x070

| Bit position: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — |

| 31:3 | — | These bits are read as 0. The write value should be 0. | R/W |

Note: If the security attribution is configured as Secure:
- Secure access and Non-secure read access are allowed
- Non-secure write access is ignored, and TrustZone access error is not generated.

If the security attribution is configured as Non-secure:
- Secure and Non-secure access are allowed.

Note 1. Set the IREFCKS[2:0] bit to 000 in I3C mode.

## 29.2.15 STDBR : Standard Bit Rate Register

Base address: I3C = 0x4011_F000

Offset address: 0x074

| Bit position: | 31 | 30 | 29 | | | | | 24 | 23 | 22 | 21 | | | | | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | DSBR PO | — | SBRHP[5:0] | | | | | | — | — | SBRLP[5:0] | | | | | |
| Value after reset: | 0 | 0 | 1 | 1 | 1 | 1 | 1 | 1 | 0 | 0 | 1 | 1 | 1 | 1 | 1 | 1 |

| Bit position: | 15 | | | | | | | 8 | 7 | | | | | | | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | SBRHO[7:0] | | | | | | | | SBRLO[7:0] | | | | | | | |
| Value after reset: | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 7:0 | SBRLO[7:0] | Standard Bit Rate Low-Level Period Open-Drain<br>Count value of the low-level period of SCL clock*1 | R/W |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 15:8 | SBRHO[7:0] | Standard Bit Rate High-Level Period Open-Drain<br>Count value of the high-level period of SCL clock*1 | R/W |
| 21:16 | SBRLP[5:0] | Standard Bit Rate Low-level Period Push-Pull*2<br>Count value of the low-level period of SCL clock | R/W |
| 23:22 | — | These bits are read as 0. The write value should be 0. | R/W |
| 29:24 | SBRHP[5:0] | Standard Bit Rate High-Level Period Push-Pull*3<br>Count value of the high-level period of SCL clock | R/W |
| 30 | — | This bit is read as 0. The write value should be 0. | R/W |
| 31 | DSBRPO | Double the Standard Bit Rate Period for Open-Drain*4<br>0: The time period set for SBRHO[7:0] and SBRLO[7:0] is not doubled.<br>1: The time period set for SBRHO[7:0] and SBRLO[7:0] is doubled. | R/W |

Note: If the security attribution is configured as Secure:
- Secure access and Non-secure read access are allowed
- Non-secure write access is ignored, and TrustZone access error is not generated.

If the security attribution is configured as Non-secure:
- Secure and Non-secure access are allowed.

Note 1. These bits support I2C, I3C master, and I3C secondary master mode.
Note 2. These bits support I3C master mode and I3C secondary master mode.
Note 3. These bits support all I3C mode.
Note 4. This bit supports I2C, I3C master, and I3C secondary master mode.

The STDBR register sets the bit rate according to the operating speed.

- I2C mode: Bit rate setting when communicating with Standard-mode / Fast-mode / Fast-mode plus
- I3C master mode: Bit rate setting selected by MODE bit of command descriptor
- I3C slave mode: I3C bit rate setting

The I2C transfer rate and the SCL clock duty are calculated using the following expression.

Transfer rate = 1 / {[(High-Level Period + α*1) + (Low-Level Period + α)] / I3Cφ*2 + I3C_SCL line rising time [tr]*3 + I3C_SCL line falling time [tf]*3}

Duty cycle = {I3C_SCL line rising time [tr] + (High-Level Period + α) / I3Cφ} / {I3C_SCL line falling time [tf] + (Low-Level Period + α) / I3Cφ}

Note 1. α depend on the number of stages in the noise filter.
Note 2. I3Cφ = TCLK × Division ratio
Note 3. The I3C_SCL line rising time [tr] and I3C_SCL line falling time [tf] depend on the total bus line capacitance [Cb] and the pull-up resistor [Rp]. For details, see the I2C-bus specification from NXP Semiconductors.

The I3C transfer rate and the SCL clock duty are calculated using the following expression.

Transfer rate = 1 / [(High-Level Period + Low-Level Period) / I3Cφ + I3C_SCL line rising time [tr] + I3C_SCL line falling time [tf]]

Duty cycle = [I3C_SCL line rising time [tr] + High-Level Period / I3Cφ] / [I3C_SCL line falling time [tf] + Low-Level Period / I3Cφ]

### SBRLO[7:0] bits (Standard Bit Rate Low-Level Period Open-Drain)

The SBRLO[7:0] bits are used to set the low-level period of SCL clock in Open-Drain mode.

I3C counts the low-level period with the internal reference clock source (I3Cφ) specified by the REFCKCTL.IREFCKS[2:0] bits. It also works to generate the data setup time for automatic SCL low-hold operation (see section 29.3.2.3.6. Clock Stretching [I2C mode]); when I3C is used in I2C slave mode, these bits need to be set to a value longer than the data setup time*1.

If the digital noise filter is enabled (INCTL.DNFE = 1), set the SBRLO[7:0] bits to a value at least one greater than the number of stages in the noise filter. Regarding the number of stages in the noise filter, see the description of the INCTL.DNFS[3:0] bits.

Note 1. Data setup time (tSU: DAT)

250 ns (up to 100 kbps: Standard-mode [Sm])

100 ns (up to 400 kbps: Fast-mode [Fm])

50 ns (up to 1 Mbps: Fast-mode plus [Fm+])

10 ns (up to 3 Mbps: Hs-mode [HS])

### SBRHO[7:0] bits (Standard Bit Rate High-Level Period Open-Drain)

The SBRHO[7:0] bits use to set the high-level period of SCL clock in Open-Drain mode. SBRHO[7:0] bits are valid in master mode. If I3C is used only in $I^2C$ slave mode, these bits need not to set the high-level period.

I3C counts the high-level period with the internal reference clock source (I3Cφ) specified by the REFCKCTL.IREFCKS[2:0] bits.

If the digital noise filter is enabled (the INCTL.DNFE bit = 1), set the SBRHO[7:0] bits to a value at least one greater than the number of stages in the noise filter. Regarding the number of stages in the noise filter, see the description of the INCTL.DNFS[3:0] bits.

### SBRLP[5:0] bits (Standard Bit Rate Low-level Period Push-Pull)

SBRLP[5:0] bits are used to set the low-level period of SCL clock in Push-Pull.

I3C counts the low-level period with the internal reference clock source (I3Cφ) specified by the REFCKCTL.IREFCKS[2:0] bits.

If the digital noise filter is enabled (the INCTL.DNFE bit = 1), set the SBRLP[5:0] bits to a value at least one greater than the number of stages in the noise filter. Regarding the number of stages in the noise filter, see the description of the INCTL.DNFS[3:0] bits.

### SBRHP[5:0] bits (Standard Bit Rate High-Level Period Push-Pull)

SBRHP[5:0] bits is used to set the high-level period of SCL clock in Push-Pull mode.

SBRHP[5:0] bits are valid in master mode. If I3C is used only in $I^2C$ slave mode, these bits need not to set the high-level period.

I3C counts the high-level period with the internal reference clock source (I3Cφ) specified by the REFCKCTL.IREFCKS[2:0] bits.

If the digital noise filter is enabled (the INCTL.DNFE bit = 1), set the SBRHP[5:0] bits to a value at least one greater than the number of stages in the noise filter. Regarding the number of stages in the noise filter, see the description of the INCTL.DNFS[3:0] bits.

### DSBRPO bit (Double the Standard Bit Rate Period for Open-Drain)

When DSBRPO = 1, double the high-level period that is set in SBRHO[7:0] and double the low-level period that is set in SBRLO[7:0].

**Table 29.4 Requirement and usage of setting in each mode**

| Bit name | Device mode | | | | |
|---|---|---|---|---|---|
| | $I^2C$ master | $I^2C$ slave | I3C Master | I3C Secondary Master | I3C Slave |
| SBRHP[5:0] | Do not use | Do not use | Setting required*3 | Setting required*4 | Do not use |
| SBRLP[5:0] | Do not use | Do not use | Setting required*3 | Setting required*5 | Do not use |
| SBRHO[7:0] | Setting required*1 | Do not use | Setting required*3 | Setting required*5 | Do not use |
| SBRLO[7:0] | Setting required*1 | Setting required*2 | Setting required*3 | Setting required*5 | Do not use |

Note 1. The setting value is used for the data rate of ST, FM, and FM+ mode.
Note 2. The setting value is used for the data setup time of automatic SCL low-hold operation.
Note 3. The setting value is used for the data rate of each communication.
Note 4. When operating with I3C Master, the setting value is used for the data rate of each communication.
Note 5. When operating with I3C Master, the setting value is used for the data rate of each communication.
When operating with I3C Slave, do not use.

## 29.2.16 EXTBR : Extended Bit Rate Register

Base address: I3C = 0x4011_F000

Offset address: 0x078

| Bit position: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | EBRHP[5:0] | | | | | | — | — | EBRLP[5:0] | | | | | | EBRHO[7:0] | | | | | | | | EBRLO[7:0] | | | | | | | |
| Value after reset: | 0 | 0 | 1 | 1 | 1 | 1 | 1 | 1 | 0 | 0 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 7:0 | EBRLO[7:0] | Extended Bit Rate Low-Level Period Open-Drain*1<br>Count value of the low-level period of SCL clock | R/W |
| 15:8 | EBRHO[7:0] | Extended Bit Rate High-Level Period Open-Drain*1<br>Count value of the high-level period of SCL clock | R/W |
| 21:16 | EBRLP[5:0] | Extended Bit Rate Low-Level Period Push-Pull*2<br>Count value of the low-level period of SCL clock | R/W |
| 23:22 | — | These bits are read as 0. The write value should be 0. | R/W |
| 29:24 | EBRHP[5:0] | Extended Bit Rate High-Level Period Push-Pull*2<br>Count value of the high-level period of SCL clock | R/W |
| 31:30 | — | These bits are read as 0. The write value should be 0. | R/W |

Note: If the security attribution is configured as Secure:
- Secure access and Non-secure read access are allowed
- Non-secure write access is ignored, and TrustZone access error is not generated.

If the security attribution is configured as Non-secure:
- Secure and Non-secure access are allowed.

Note 1. These bits support $I^2C$, I3C master, and I3C secondary master mode.
Note 2. These bits support I3C master mode and I3C secondary master mode.

The EXTBR register sets the bit rate according to the operating speed.

- $I^2C$ mode: Bit rate setting for communicating in high-speed mode
- I3C master mode: Bit rate setting selected by MODE bit of command descriptor
- I3C slave mode: Unused

### EBRLO[7:0] bits (Extended Bit Rate Low-Level Period Open-Drain)

See SBRLO[7:0] bits of section 29.2.15. STDBR : Standard Bit Rate Register for details. For the description of EBRHO[7:0] and EBRLO[7:0] bits, refer to SBRHO[7:0] and SBRLO[7:0] bits in the STDBR register.

### EBRHO[7:0] bits (Extended Bit Rate High-Level Period Open-Drain)

See SBRHO[7:0] bits of section 29.2.15. STDBR : Standard Bit Rate Register for details. For the description of EBRHO[7:0] and EBRLO[7:0] bits, refer to SBRHO[7:0] and SBRLO[7:0] bits in the STDBR register.

### EBRLP[5:0] bits (Extended Bit Rate Low-Level Period Push-Pull)

See SBRLP[5:0] bits of section 29.2.15. STDBR : Standard Bit Rate Register for details. For the description of EBRHP[5:0] and EBRLP[5:0] bits, refer to SBRHP[5:0] and SBRLP[5:0] bits in the STDBR register.

### EBRHP[5:0] bits (Extended Bit Rate High-Level Period Push-Pull)

See SBRHP[5:0] bits of section 29.2.15. STDBR : Standard Bit Rate Register for details. For the description of EBRHP[5:0] and EBRLP[5:0] bits, refer to SBRHP[5:0] and SBRLP[5:0] bits in the STDBR register.

**Table 29.5 Requirement and usage of setting in each mode (1 of 2)**

| Bit name | Device mode | | | | |
|---|---|---|---|---|---|
| | $I^2C$ master | $I^2C$ slave | I3C master | I3C Secondary master | I3C slave |
| EBRHP[5:0] | Do not use | Do not use | Setting required*3 | Setting required*4 | Do not use |

**Table 29.5 Requirement and usage of setting in each mode (2 of 2)**

| Bit name | Device mode | | | | |
|---|---|---|---|---|---|
| | I²C master | I²C slave | I3C master | I3C Secondary master | I3C slave |
| EBRLP[5:0] | Do not use | Do not use | Setting required*3 | Setting required*4 | Do not use |
| EBRHO[7:0] | Setting required*1 | Do not use | Setting required*3 | Setting required*4 | Do not use |
| EBRLO[7:0] | Setting required*1 | Setting required*2 | Setting required*3 | Setting required*4 | Do not use |

Note 1. The setting value is used for the data rate of High-Speed mode.
Note 2. The setting value is used for the data setup time of automatic SCL low-hold operation in HS-mode.
Note 3. The setting value is used for the data rate of each communication.
Note 4. When operating with I3C master, the setting value is used for the data rate of each communication.
When operating with I3C slave, do not use.

## 29.2.17 BFRECDT : Bus Free Condition Detection Time Register

Base address: I3C = 0x4011_F000

Offset address: 0x07C

| Bit position: | 31 | | | | | | | | | | | | | | | | | | | | | 9 | 8 | | | | | | | | | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | FRECYC[8:0] | | | | | | | | | |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 8:0 | FRECYC[8:0] | Bus Free Condition Detection Cycle<br>The count value is a period for detecting the Bus free condition. | R/W |
| 31:9 | — | These bits are read as 0. The write value should be 0. | R/W |

Note: If the security attribution is configured as Secure:
- Secure access and Non-secure read access are allowed
- Non-secure write access is ignored, and TrustZone access error is not generated.

If the security attribution is configured as Non-secure:
- Secure and Non-secure access are allowed.

### FRECYC[8:0] bits (Bus Free Condition Detection Cycle)

I3C counts the period for detecting the Bus free condition with the I3Cφ.

These bits set the Bus Free period. This Bus Free period is counted by the internal reference clock (I3Cφ) selected by the REFCKCTL.IREFCKS[2:0] bits. See the BCST.BFREF flag for Bus Free detection behavior.

## 29.2.18 BAVLCDT : Bus Available Condition Detection Time Register

Base address: I3C = 0x4011_F000

Offset address: 0x080

| Bit position: | 31 | | | | | | | | | | | | | | | | | | | | | 9 | 8 | | | | | | | | | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | AVLCYC[8:0] | | | | | | | | | |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 8:0 | AVLCYC[8:0] | Bus Available Condition Detection Cycle<br>The count value is a period for detecting the Bus available condition. | R/W |
| 31:9 | — | These bits are read as 0. The write value should be 0. | R/W |

Note: If the security attribution is configured as Secure:
- Secure access and Non-secure read access are allowed
- Non-secure write access is ignored, and TrustZone access error is not generated.

If the security attribution is configured as Non-secure:
- Secure and Non-secure access are allowed.

Note: This register supports all I3C mode.

### AVLCYC[8:0] bits (Bus Available Condition Detection Cycle)

I3C counts the period for detecting the Bus available condition with the I3Cφ.

These bits set the Bus Available period. This Bus Available period is counted by the internal reference clock (I3Cφ) selected by the REFCKCTL.IREFCKS[2:0] bits. See the BCST.BAVLF flag for Bus Available detection behavior.

## 29.2.19 BIDLCDT : Bus Idle Condition Detection Time Register

Base address: I3C = 0x4011_F000

Offset address: 0x084

| Bit position: | 31 | | | | | | | | | | | | | | 18 | 17 | | | | | | | | | | | | | | | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | — | — | — | — | — | — | — | — | — | — | — | IDLCYC[17:0] | | | | | | | | | | | | | | | | |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 17:0 | IDLCYC[17:0] | Bus Idle Condition Detection Cycle<br>The count value is a period for detecting the Bus idle condition. | R/W |
| 31:18 | — | These bits are read as 0. The write value should be 0. | R/W |

Note: If the security attribution is configured as Secure:
- Secure access and Non-secure read access are allowed
- Non-secure write access is ignored, and TrustZone access error is not generated.

If the security attribution is configured as Non-secure:
- Secure and Non-secure access are allowed.

Note: This register supports all I3C mode.

### IDLCYC[17:0] bits (Bus Idle Condition Detection Cycle)

I3C counts the period for detecting the Bus idle condition with the I3Cφ.

These bits set the Bus Idle period. This Bus Idle period is counted by the internal reference clock (I3Cφ) selected by the REFCKCTL.IREFCKS[2:0] bits. See the BCST.BIDLF flag for Bus Available detection behavior.

## 29.2.20 OUTCTL : Output Control Register

Base address: I3C = 0x4011_F000

Offset address: 0x088

| Bit position: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit position: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | SDODCS | — | — | — | — | SDOD[2:0] | | | — | — | — | EXCYC | — | SOCWP | SCOC | SDOC |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 1 | 1 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 0 | SDOC | SDA Output Control*1<br>0: I3C drives the I3C_SDA pin low.<br>1: I3C releases the I3C_SDA pin. | R/W |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 1 | SCOC | SCL Output Control[*1]<br>High level output is achieved through an external pull-up resistor.<br>0: I3C drives the I3C_SCL pin low.<br>1: I3C releases the I3C_SCL pin. | R/W |
| 2 | SOCWP | SCL/SDA Output Control Write Protect[*1]<br>0: Bits SCOC and SDOC are protected.<br>1: Bits SCOC and SDOC can be written (When writing simultaneously with the value of the target bit).<br>This bit is read as 0. | W |
| 3 | — | This bit is read as 0. The write value should be 0. | R/W |
| 4 | EXCYC | Extra SCL Clock Cycle Output[*3]<br>The EXCYC bit is cleared automatically after one clock cycle is output.<br>0: Does not output an extra SCL clock cycle (default).<br>1: Outputs an extra SCL clock cycle. | R/W |
| 7:5 | — | These bits are read as 0. The write value should be 0. | R/W |
| 10:8 | SDOD[2:0] | SDA Output Delay[*2]<br>0 0 0: No output delay<br>0 0 1: 1 I3Cφ cycle (When OUTCTL.SDODCS = 0 (I3Cφ))<br>1 or 2 I3Cφ cycles (When OUTCTL.SDODCS = 1 (I3Cφ/2))<br>0 1 0: 2 I3Cφ cycles (When OUTCTL.SDODCS = 0 (I3Cφ))<br>3 or 4 I3Cφ cycles (When OUTCTL.SDODCS = 1 (I3Cφ/2))<br>0 1 1: 3 I3Cφ cycles (When OUTCTL.SDODCS = 0 (I3Cφ))<br>5 or 6 I3Cφ cycles (When OUTCTL.SDODCS = 1 (I3Cφ/2))<br>1 0 0: 4 I3Cφ cycles (When OUTCTL.SDODCS = 0 (I3Cφ))<br>7 or 8 I3Cφ cycles (When OUTCTL.SDODCS = 1 (I3Cφ/2))<br>1 0 1: 5 I3Cφ cycles (When OUTCTL.SDODCS = 0 (I3Cφ))<br>9 or 10 I3Cφ cycles (When OUTCTL.SDODCS = 1 (I3Cφ/2))<br>1 1 0: 6 I3Cφ cycles (When OUTCTL.SDODCS = 0 (I3Cφ))<br>11 or 12 I3Cφ cycles (When OUTCTL.SDODCS = 1 (I3Cφ/2))<br>1 1 1: 7 I3Cφ cycles (When OUTCTL.SDODCS = 0 (I3Cφ))<br>13 or 14 I3Cφ cycles (When OUTCTL.SDODCS = 1 (I3Cφ/2)) | R/W |
| 14:11 | — | These bits are read as 0. The write value should be 0. | R/W |
| 15 | SDODCS | SDA Output Delay Clock Source Selection[*3]<br>0: The internal reference clock (I3Cφ) is selected as the clock source of the SDA output delay counter.<br>1: The internal reference clock divided by 2 (I3Cφ/2) is selected as the clock source of the SDA output delay counter.[*4] | R/W |
| 31:16 | — | These bits are read as 0. The write value should be 0. | R/W |

Note: If the security attribution is configured as Secure:
- Secure access and Non-secure read access are allowed
- Non-secure write access is ignored, and TrustZone access error is not generated.

If the security attribution is configured as Non-secure:
- Secure and Non-secure access are allowed.

Note 1. This bit supports $I^2C$, I3C master, and I3C secondary master mode.
Note 2. These bits support $I^2C$ mode.
Note 3. This bit supports $I^2C$ mode.
Note 4. The setting SDODCS = 1 (I3Cφ/2) only becomes valid when SCL is at the low level. When SCL is at the high level, the setting SDODCS = 1 becomes invalid and the clock source becomes the internal reference clock (I3Cφ).

### SDOC bit (SDA Output Control) and SCOC bit (SCL Output Control)

These bits are used to directly control the I3C_SDA and I3C_SCL signals output from this I3C.

When writing to these bits, also write 1 to the SOCWP bit at the same time.

The result of setting these bits is input to I3C via the input buffer. When slave mode is selected, a START condition may be detected and the bus may be released depending on the bit settings.

Do not rewrite these bits during a START condition, STOP condition, Repeated START condition, or during transmission or reception. Operation after rewriting under the above conditions is not guaranteed.

### EXCYC bit (Extra SCL Clock Cycle Output)

This bit is used to output an extra SCL clock cycle for debugging or error processing.

Normally, set the bit to 0. Setting the bit to 1 in a normal communication state causes a communication error.

For details on this function, see section 29.3.2.3.10. Port Control, (1) Extra SCL Clock Cycle Output Function.

## 29.2.21 INCTL : Input Control Register

Base address: I3C = 0x4011_F000

Offset address: 0x08C

| Bit position: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit position: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | | | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | — | — | — | — | — | — | — | — | DNFE | DNFS[3:0] | | | |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 1 | 1 | 0 | 1 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 3:0 | DNFS[3:0] | Digital Noise Filter Stage Selection<br>0x0: Noise of up to one I3Cφ cycle is filtered out (single-stage filter).<br>0x1: Noise of up to two I3Cφ cycles is filtered out (2-stage filter).<br>0x2: Noise of up to three I3Cφ cycles is filtered out (3-stage filter).<br>0x3: Noise of up to four I3Cφ cycles is filtered out (4-stage filter).<br>0x4: Noise of up to five I3Cφ cycles is filtered out (5-stage filter).<br>⋮<br>0xF: Noise of up to sixteen I3Cφ cycles is filtered out (16-stage filter). | R/W |
| 4 | DNFE | Digital Noise Filter Circuit Enable<br>0: No digital noise filter circuit is used.<br>1: A digital noise filter circuit is used. | R/W |
| 5 | — | This bit is read as 0. The write value should be 0. | R/W |
| 7:6 | — | These bits are read as 1. The write value should be 1. | R/W |
| 31:8 | — | These bits are read as 0. The write value should be 0. | R/W |

Note: If the security attribution is configured as Secure:
- Secure access and Non-secure read access are allowed
- Non-secure write access is ignored, and TrustZone access error is not generated.

If the security attribution is configured as Non-secure:
- Secure and Non-secure access are allowed.

Note: This register supports $I^2C$ mode.

### DNFS[3:0] bits (Digital Noise Filter Stage Selection)

These bits are used to select the number of stages in the digital noise filter.

For details on the digital noise filter function, see section 29.3.2.6.3. Digital Noise-Filter Circuits [$I^2C$ mode].

In $I^2C$ High Speed mode, I3C changes the number of noise filter stage to a quarter of the number of noise filter stage automatically.

Note:
- Set the noise range to be filtered out by the noise filter within a range less than the I3C_SCL line high-level period or low-level period. If the noise range is set to a value of (SCL clock width: high-level period or low-level period, whichever is shorter) - [1.5 internal reference clock (I3Cφ) cycles] or more, the SCL clock is regarded as noise by the noise filter function of I3C, which may prevent I3C from operating normally.
- In $I^2C$ High Speed mode, the lower 2 bits of the DNFS [3:0] bits are ignored, and the number of filter stages for 1 to 4 stages is selected by the upper 2 bits.

## 29.2.22 TMOCTL : Timeout Control Register

Base address: I3C = 0x4011_F000

Offset address: 0x090

| Bit position: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit position: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | — | — | — | — | — | TOMDS[1:0] | | TOHCTL | TOLCTL | — | — | TODTS[1:0] | |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 1 | 1 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 1:0 | TODTS[1:0] | Timeout Detection Time Selection<br>0 0: 16bit-timeout<br>0 1: 14bit-timeout<br>1 0: 8bit-timeout<br>1 1: 6bit-timeout | R/W |
| 3:2 | — | These bits are read as 0. The write value should be 0. | R/W |
| 4 | TOLCTL | Timeout L Count Control<br>0: Count is disabled while the I3C_SCL line is at a low level.<br>1: Count is enabled while the I3C_SCL line is at a low level. | R/W |
| 5 | TOHCTL | Timeout H Count Control<br>0: Count is disabled while the I3C_SCL line is at a high level.<br>1: Count is enabled while the I3C_SCL line is at a high level. | R/W |
| 7:6 | TOMDS[1:0] | Timeout Operation Mode Selection<br>0 0: Timeout is detected during the following conditions:<br>● The bus is busy (BCST.BFREF = 0) in master mode.<br>● I3C's own slave address is detected and the bus is busy in slave mode.<br>● The bus is free (BCST.BFREF = 1) while generation of a START condition is requested (CNDCTL.STCND = 1).<br>0 1: Timeout is detected while the bus is busy.<br>1 0: Timeout is detected while the bus is free.<br>1 1: Setting prohibited | R/W |
| 31:8 | — | These bits are read as 0. The write value should be 0. | R/W |

Note: If the security attribution is configured as Secure:
- Secure access and Non-secure read access are allowed
- Non-secure write access is ignored, and TrustZone access error is not generated.

If the security attribution is configured as Non-secure:
- Secure and Non-secure access are allowed.

### TODTS[1:0] bits (Timeout Detection Time Selection)

These bits are used to select for the timeout detection time when the timeout function is enabled (BSTE.TODE bit = 1).

When these bits are set to 00b, the timeout detection internal counter functions as a 16-bit counter.

When these bits are set to 01b, the counter functions as a 14-bit counter.

When these bits are set to 10b, the counter functions as an 8-bit counter.

When these bits are set to 11b, the counter functions as a 6-bit counter.

While the I3C_SCL line is in the state that enables this counter as specified by bits TOHCTL and TOLCTL, the counter counts up in synchronization with the internal reference clock (I3Cφ) as a count source.

For details on the timeout function, see section 29.3.2.4.4. Timeout Error Detection.

### TOLCTL bit (Timeout L Count Control)

This bit is used to enable or disable the internal counter of the timeout function to count up while the I3C_SCL line is held low when the timeout function is enabled (BSTE.TODE = 1).

### TOHCTL bit (Timeout H Count Control)

This bit is used to enable or disable the internal counter of the timeout function to count up while the I3C_SCL line is held high when the timeout function is enabled (BSTE.TODE = 1).

### TOMDS[1:0] bits (Timeout Operation Mode Selection)

These bits are used to select the detection condition for timeout when the timeout function is enabled.

Note: When working with I²C Slave, during 10-bit address communication, the timeout count starts when the upper address match is detected.

## 29.2.23 WUCTL : Wake-up Unit Control Register

Base address: I3C = 0x4011_F000

Offset address: 0x098

| Bit position: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit position: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | — | — | — | — | — | WUFE | WUFSYNE | — | WUANFS | — | — | — | WUACKS |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 1 | 0 | 0 | 0 | 0 | 0 | 1 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 0 | WUACKS | Wake-up Acknowledge Selection*1<br>Choice of four response modes with a combination of RSTCTL.INTLRST bit and WUACKS bit, shown in Table 29.6. | R/W |
| 3:1 | — | These bits are read as 0. The write value should be 0. | R/W |
| 4 | WUANFS | Wake-up Analog Noise Filter Selection*1<br>0: Do not add the Wake-up analog filter<br>1: Add the Wake-up analog filter | R/W |
| 5 | — | This bit is read as 0. The write value should be 0. | R/W |
| 6 | WUFSYNE | Wake-up Function PCLK Synchronous Enable<br>0: I3C asynchronous circuit enable<br>1: I3C synchronous circuit enable | R/W |
| 7 | WUFE | Wake-up Function Enable<br>Do not set WUFE = 0 during Wake-up operation.<br>0: Wake-up function disables<br>1: Wake-up function enables | R/W |
| 31:8 | — | These bits are read as 0. The write value should be 0. | R/W |

Note: If the security attribution is configured as Secure:
- Secure access and Non-secure read access are allowed
- Non-secure write access is ignored, and TrustZone access error is not generated.

If the security attribution is configured as Non-secure:
- Secure and Non-secure access are allowed.

Note 1. This bit supports I²C mode.

**Table 29.6 Wake-up mode (1 of 2)**

| INTLRST | WUACKS | Operation mode | Description |
|---|---|---|---|
| 0 | 0 | Normal Wake-up mode 1 | ACK response at 9th SCL and SCL low hold after at 9th SCL. |

**Table 29.6 Wake-up mode (2 of 2)**

| INTLRST | WUACKS | Operation mode | Description |
|---|---|---|---|
| 0 | 1 | Normal Wake-up mode 2 | No ACK response immediately and SCL low hold between 8th and 9th SCL. Release SCL low hold and ACK response at 9th SCL. |
| 1 | 0 | Command recovery mode | ACK response at 9th SCL and not SCL low hold. |
| 1 | 1 | EEP response mode | NACK response at 9th SCL and not SCL low hold. |

Note: In Wake-up mode 2, HS mode cannot be used.

### WUFSYNE bit (Wake-up Function PCLK Synchronous Enable)

This bit is used to switch between the PCLK synchronous operation and the PCLK asynchronous operation.

The bit is used in combination with the WUASYNF flag at Wake-up effective function (WUCTL.WUFE bit = 1).

[When switching from the PCLK synchronous operation to the PCLK asynchronous operation]

I3C operation changes into the PCLK asynchronous operation during BCST.BFREF flag = 1, when the WUASYNF flag set to 1 during WUFSYNE = 0.

The reception can operate without depending on the state of operation of PCLK (with PCLK stopped) after it switches to the PCLK asynchronous operation (Wake-up event detection operation).

[When switching from the PCLK asynchronous operation to the PCLK synchronous operation]

I3C operation changes into the PCLK synchronous operation at the following conditions (at the same timing when WUFSYNE flag becomes 0).

When wake-up event detects : right after WUFSYNE bit is set to 1.

When wake-up event does not detect : when STOP condition is detected after WUFSYNE bit is set to 1.

[Setting conditions]

- When 1 is written to the WUFSYNE bit
- WUCTL.WUFE = 0.

[Clearing condition]

- When 0 is written to the WUFSYNE bit.

## 29.2.24 ACKCTL : Acknowledge Control Register

Base address: I3C = 0x4011_F000

Offset address: 0x0A0

| Bit position: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit position: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | — | — | — | — | — | — | — | — | — | — | ACKTWP | ACKT | ACKR |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 0 | ACKR | Acknowledge Reception<br>0: A value 0 is received as the acknowledge bit (ACK reception)<br>1: A value 1 is received as the acknowledge bit (NACK reception) | R |
| 1 | ACKT | Acknowledge Transmission<br>0: A value 0 is sent as the acknowledge bit (ACK transmission)<br>1: A value 1 is sent as the acknowledge bit (NACK transmission) | R/W |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 2 | ACKTWP | ACKT Write Protect<br>0: The ACKT bit is protected<br>1: The ACKT bit can be written (when writing simultaneously with the value of the target bit)<br>This bit is read as 0. | W |
| 31:3 | — | These bits are read as 0. The write value should be 0. | R/W |

Note: If the security attribution is configured as Secure:
- Secure access and Non-secure read access are allowed
- Non-secure write access is ignored, and TrustZone access error is not generated.

If the security attribution is configured as Non-secure:
- Secure and Non-secure access are allowed.

Note: This register supports $I^2C$ mode.

### ACKR bit (Acknowledge Reception)

This bit is used to store the acknowledge bit information received from the receive device in transmit mode.

[Setting condition]

- When 1 is received as the acknowledge bit with the PRSST.TRMD bit set to 1.

[Clearing condition]

- When 0 is received as the acknowledge bit with the PRSST.TRMD bit set to 1.

### ACKT bit (Acknowledge Transmission)

[Setting condition]

- When 1 is written to the ACKT bit and 1 is written to the ACKTWP bit at the same time.

[Clearing conditions]

- When 0 is written to the ACKT bit and 1 is written to the ACKTWP bit at the same time
- When a STOP condition is detected (when a STOP condition is detected with the CNDCTL.SPCND bit set to 1).

Note: Set the ACKT bit to 0 in $I^2C$ Slave mode.

### ACKTWP bit (ACKT Write Protect)

This bit is used to control the modification of the ACKT bit.

When changing the ACKT bit, setting this bit to 1 at the same time can change the ACKT bit.

When this bit is read, 0 is always read.

## 29.2.25 SCSTRCTL : SCL Stretch Control Register

Base address: I3C = 0x4011_F000

Offset address: 0x0A4

| Bit position: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit position: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | — | — | — | — | — | — | — | — | — | — | — | RWE | ACKT WE |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 0 | ACKTWE | Acknowledge Transmission Wait Enable<br>0: NTST.RDBFF0 is set at the rising edge of the ninth SCL clock cycle. (The I3C_SCL line is not held low at the falling edge of the eighth clock cycle.)<br>1: NTST.RDBFF0 is set at the rising edge of the eighth SCL clock cycle. (The I3C_SCL line is held low at the falling edge of the eighth clock cycle.) Low-hold is released by writing a value to the ACKCTL.ACKT bit. | R/W |
| 1 | RWE | Receive Wait Enable<br>0: No WAIT (The period between ninth clock cycle and first clock cycle is not held low.)<br>1: WAIT (The period between ninth clock cycle and first clock cycle is held low.) Low-hold is released by reading NTDTBP0. | R/W |
| 31:2 | — | These bits are read as 0. The write value should be 0. | R/W |

Note: If the security attribution is configured as Secure:
- Secure access and Non-secure read access are allowed
- Non-secure write access is ignored, and TrustZone access error is not generated.

If the security attribution is configured as Non-secure:
- Secure and Non-secure access are allowed.

Note: This register supports $I^2C$ mode.

### ACKTWE bit (Acknowledge Transmission Wait Enable)

This bit is used to select the NTST.RDBFF0 flag set timing in receive mode and also to select whether to hold the I3C_SCL line low at the falling edge of the eighth SCL clock cycle.

When ACKTWE = 0, the I3C_SCL line is not held low at the falling edge of the eighth SCL clock cycle, and the NTST.RDBFF0 flag is set to 1 at the rising edge of the ninth SCL clock cycle.

When ACKTWE = 1, the NTST.RDBFF0 flag is set to 1 at the rising edge of the eighth SCL clock cycle and the I3C_SCL line is held low at the falling edge of the eighth SCL clock cycle. The low-hold of the I3C_SCL line is released by writing a value to the ACKCTL.ACKT bit.

After data is received with this setting, the I3C_SCL line is automatically held low before the acknowledge bit is sent. This enables processing to send ACK (ACKCTL.ACKT = 0) or NACK (ACKCTL.ACKT = 1) according to receive data.

### RWE bit (Receive Wait Enable)

This bit is used to control whether to hold the period between the ninth SCL clock cycle and the first SCL clock cycle low until the receive data buffer (NTDTBP0) is completely read each time single-byte data is received in receive mode.

When RWE = 0, the receive operation is continued without holding the period between the ninth and the first SCL clock cycle low. When both the ACKTWE and RWE bits = 0, continuous receive operation is enabled with the double buffer.

When RWE = 1, the I3C_SCL line is held low from the falling edge of the ninth clock cycle until the NTDTBP0 value is read each time single-byte data is received.

This enables receive operation in byte units.

Note: When the value of the RWE bit is to be read, be sure to read the NTDTBP0 beforehand.

## 29.2.26 SCSTLCTL : SCL Stalling Control Register

Base address: I3C = 0x4011_F000

Offset address: 0x0B0

| Bit position: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | ACKPE | PARPE | — | AAPE | — | — | — | — | — | — | — | — | — | — | — | — |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit position: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | STLCYC[15:0] | | | | | | | | | | | | | | | |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 15:0 | STLCYC[15:0] | Stalling Cycle<br>Counter setting of stall period (I3Cφ cycle). Common use for each phase. | R/W |
| 27:16 | — | These bits are read as 0. The write value should be 0. | R/W |
| 28 | AAPE | Assigned Address Phase Enable<br>Enable bit that allows stall by the first bit at address assignment<br>0: Does not stall the SCL clock during the address assignment phase.<br>1: Stall the SCL clock during address assignment phase. | R/W |
| 29 | — | This bit is read as 0. The write value should be 0. | R/W |
| 30 | PARPE | Parity Phase Enable<br>Stall enable bit in parity bit period<br>0: Does not stall the SCL clock during the parity bit period.<br>1: Stall the SCL clock during the parity bit period. | R/W |
| 31 | ACKPE | ACK phase Enable<br>Stall enable bit during ACK/NACK phase<br>0: Does not stall the SCL clock during the ACK/NACK phase.<br>1: Stall the SCL clock during the ACK/NACK phase. | R/W |

Note: If the security attribution is configured as Secure:
- Secure access and Non-secure read access are allowed
- Non-secure write access is ignored, and TrustZone access error is not generated.

If the security attribution is configured as Non-secure:
- Secure and Non-secure access are allowed.

Note: This register supports I3C master mode and I3C secondary master mode.

When setting this register, follow Chapter 5.1.2.5 Master Clock Stalling of MIPI I3C Spec V1.0, and use it only when necessary because of its negative impacts on bus performance.

### STLCYC[15:0] bits (Stalling Cycle)

These bits set the SCL stall period. The SCL stall period is counted by the internal reference clock (I3Cφ). This is a counter common to the enable bits of each phase.

### AAPE bit (Assigned Address Phase Enable)

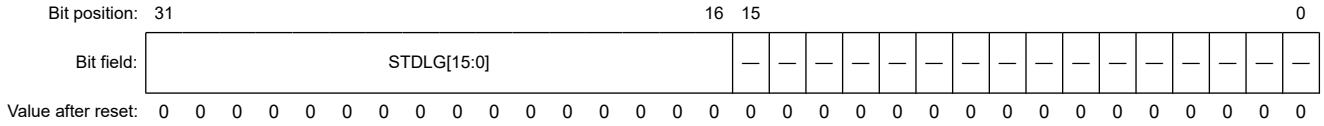
The master can stall SCL during the low period of the first bit of the assigned address phase of the Enter Dynamic Address Assignment CCC command. It can gain time in assigning dynamic address to the device based on the BCR and DCR of the slave. However, because the Dynamic Address Assignment procedure sends the dynamic address set in the DATBASm (m = 0 to 3) register in sequence, it is not necessary to set this bit and it is prohibited.

### PARPE bit (Parity Phase Enable)

The parity bit of the transmission data of I3C write transfer can be used for SCL stalling to avoid underrun of the transmission data FIFO. However, when the transmission data FIFO of the I3C master becomes empty, SCL stalling is performed regardless of the setting of this bit, it is not necessary to set this bit and it is prohibited. It is necessary to set this bit when the I3C slave requires preparation time to receive data.

### ACKPE bit (ACK phase Enable)

Determine the need to perform SCL stalling in the ACK/NACK phase based on the following criteria:



- It is necessary to set this bit when the I3C and I2C slaves connected to the bus require preparation time to receive or transmit data.
- In legacy $I^2C$ communication, if there is a possibility that the data FIFO of the I3C master might underrun or overflow, it is not necessary to set this bit because SCL Stalling is performed by FIFO Empty or Full regardless of the setting of this bit.
- Other than legacy $I^2C$ communication, the data FIFO of I3C master might underrun or overflow, and if SCL stalling is required in ACK phase, this bit can be set. However, it is necessary to build the software so that the FIFO does not underrun or overflow due to the interrupt generated according to the FIFO threshold setting (NQTHCTL, NTBTHCTL0, NRQTHCTL).
- When I3C master responds ACK/NACK to IBI, it is not necessary to set this bit because ACK/NACK response can be set in advance by BCTL.HJACK, DATBASm.DVMRRJ and DATBASm.DVS IRRJ (m = 0 to 3).

- It is necessary to set this bit when the I3C slave connected to the bus requires preparation time to transmit data for Direct GET CCC.

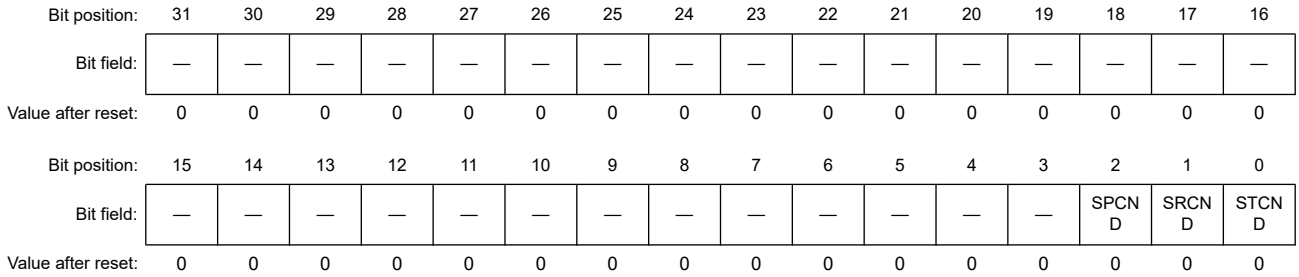
## 29.2.27 SVTDLG0 : Slave Transfer Data Length Register 0

Base address: I3C = 0x4011_F000

Offset address: 0x0C0

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 15:0 | — | These bits are read as 0. The write value should be 0. | R/W |
| 31:16 | STDLG[15:0] | Slave Transfer Data Length<br>Indicates the number of bytes to be transferred. | R/W |

Note: If the security attribution is configured as Secure:
- Secure access and Non-secure read access are allowed
- Non-secure write access is ignored, and TrustZone access error is not generated.



If the security attribution is configured as Non-secure:
- Secure and Non-secure access are allowed.

Note: This register supports I3C secondary master mode and I3C slave mode.

## 29.2.28 CNDCTL : Condition Control Register

Base address: I3C = 0x4011_F000

Offset address: 0x140

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 0 | STCND | START (S) Condition Issuance<br>0: Does not request to issue a START condition.<br>1: Requests to issue a START condition. | R/W |
| 1 | SRCND | Repeated START (Sr) Condition Issuance<br>0: Does not request to issue a Repeated START condition.<br>1: Requests to issue a Repeated START condition. | R/W |
| 2 | SPCND | STOP (P) Condition Issuance<br>0: Does not request to issue a STOP condition.<br>1: Requests to issue a STOP condition. | R/W |
| 31:3 | — | These bits are read as 0. The write value should be 0. | R/W |

Note: If the security attribution is configured as Secure:
- Secure access and Non-secure read access are allowed
- Non-secure write access is ignored, and TrustZone access error is not generated.

If the security attribution is configured as Non-secure:
- Secure and Non-secure access are allowed.

Note: This register supports $I^2C$ mode.

### STCND bit (START (S) Condition Issuance)

This bit is used to request transition to master mode and issuance of a START condition.

For details on the START condition issuance, see section 29.3.2.3.3. START Condition / Repeated START Condition / STOP Condition Issuing Function.

[Setting condition]

- When 1 is written to the STCND bit

[Clearing conditions]

- When 0 is written to the STCND bit
- When a START condition has been issued (A START condition is detected)
- When the BST.ALF (arbitration-lost) flag is set to 1

Note: Set the STCND bit to 1 (START condition issuance request) when the BCST.BFREF flag is set to 1 (bus free state).
Note that arbitration may be lost due to a START condition issuance error if the STCND bit is set to 1 (START condition issuance request) when the BFREF flag is set to 0 (bus busy state).

### SRCND bit (Repeated START (Sr) Condition Issuance)

This bit is used to request that a Repeated START condition be issued in master mode.

When this bit is set to 1 to request to issue a Repeated START condition, a Repeated START condition is issued when the BFREF flag is set to 0 (bus busy state) and the PRSST.CRMS bit is set to 1 (master mode).

For details on the Repeated START condition issuance, see section 29.3.2.3.3. START Condition / Repeated START Condition / STOP Condition Issuing Function.

[Setting condition]

- When 1 is written to the SRCND bit with the BCST.BFREF flag set to 0

[Clearing conditions]

- When 0 is written to the SRCND bit
- When a Repeated START condition has been issued (A Repeated START condition is detected)
- When the BST.ALF (arbitration-lost) flag is set to 1

Note: Do not set the SRCND bit to 1 while issuing a STOP condition.

Note: If 1 (requests to issue a Repeated START condition) is written to the SRCND bit in slave mode, the Repeated START condition is not issued, but the SRCND bit remains set to 1.
If the operating mode changes to master mode with the bit not being cleared, note that the Repeated START condition may be issued.

### SPCND bit (STOP (P) Condition Issuance)

This bit is used to request that a STOP condition be issued in master mode.

When this bit is set to 1 to request to issue a STOP condition, a STOP condition is issued when the BCST.BFREF flag is set to 0 (bus busy state) and the PRSST.CRMS bit is set to 1 (master mode).

For details on the STOP condition issuance, see section 29.3.2.3.3. START Condition / Repeated START Condition / STOP Condition Issuing Function.

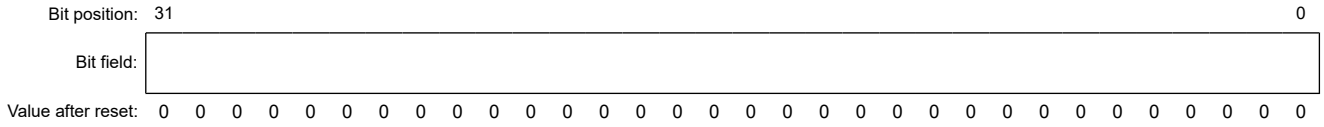
[Setting condition]

- When 1 is written to the SPCND bit with the BCST.BFREF flag set to 0 and the PRSST.CRMS bit set to 1

[Clearing conditions]

- When 0 is written to the SPCND bit
- When a STOP condition has been issued (A STOP condition is detected)
- When the BST.ALF (arbitration-lost) flag is set to 1

- When a START condition and a Repeated START condition are detected



Note: Writing to the SPCND bit is not possible while the setting of the BCST.BFREF flag = 1 (bus free state).

Note: Do not set the SPCND bit to 1 while a Repeated START condition is being issued.

## 29.2.29 NCMDQP : Normal Command Queue Port Register

Base address: I3C = 0x4011_F000

Offset address: 0x150

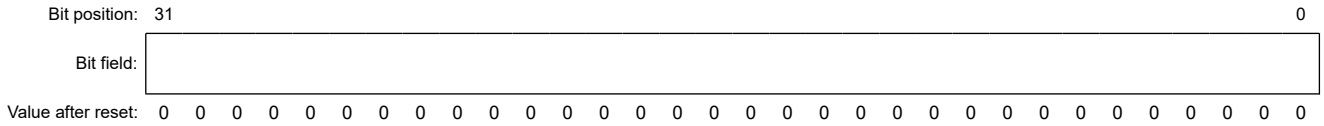
| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 31:0 | n/a | Normal Command Queue Port | W |

Note: If the security attribution is configured as Secure:
- Secure access and Non-secure read access are allowed
- Non-secure write access is ignored, and TrustZone access error is not generated.

If the security attribution is configured as Non-secure:
- Secure and Non-secure access are allowed.

Note: This register supports all I3C mode.

32-bit mailbox register NCMDQP contains a command descriptor structure that depends on the requested transfer type:



1. Address Assignment Command (see section 29.3.1.1.1. Address Assign Command)
2. Immediate Data Transfer (see section 29.3.1.1.2. Immediate Transfer Command)
3. Regular Data Transfer (see section 29.3.1.1.3. Regular Transfer Command)
4. Write + Write/Read Combo Transfer (see section 29.3.1.1.4. Combo Transfer Command)
5. Internal Control Command (see section 29.3.1.1.5. Internal Control Command)

Within the command descriptor, DWORDs appear starting with the Least Significant DWORD, in order until the Most Significant DWORD.

## 29.2.30 NRSPQP : Normal Response Queue Port Register

Base address: I3C = 0x4011_F000

Offset address: 0x154

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 31:0 | n/a | Normal Response Queue Port | R |

Note: If the security attribution is configured as Secure:
- Secure access and Non-secure read access are allowed
- Non-secure write access is ignored, and TrustZone access error is not generated.

If the security attribution is configured as Non-secure:
- Secure and Non-secure access are allowed.

Note: This register supports all I3C mode.

32-bit mailbox register NRSPQP contains a response structure (see section 29.3.1.4. Receive Status Descriptor).

## 29.2.31 NTDTBP0/NTDTBP0_BY : Normal Transfer Data Buffer Port Register 0

Base address: I3C = 0x4011_F000

Offset address: 0x158

| Bit position: | 31 | | | | | | | | | | | | | | | | | | | | | | | | | | | | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 31:0 | n/a | Normal Transfer Data Buffer Port<br>NTDTBP0 is a 32-bit read/write register.<br>NTDTBP0_BY (NTDTBP0[7:0]) is an 8-bit read/write register. | R/W |

Note: If the security attribution is configured as Secure:
- Secure access and Non-secure read access are allowed
- Non-secure write access is ignored, and TrustZone access error is not generated.

If the security attribution is configured as Non-secure:
- Secure and Non-secure access are allowed.

Note: NTDTBP0 is 32-bit access in I3C mode.

NTDTBP0_BY is 8-bit access in $I^2C$ mode.

32-bit mailbox register NTDTBP0 is a 32-bit bidirectional data transfer register which is used both to read from the Normal Rx Data Buffer, and to write to the Normal Tx Data Buffer.

In other words, the Normal Rx Data Buffer and the Normal Tx Data Buffer have the same offset, forming a single bidirectional port for transmitting or receiving I3C data.

### Read Operations:

[I3C protocol mode]

Data read from the Normal Rx Data Buffer. It should be read based on Normal Queue Status Level indications. The Rx data is always aligned to a 4-byte boundary, and stored in the Normal Rx Data Buffer. If the length of the data transfer is not aligned to a 4-byte boundary, then there are extra (unused) bytes at the end of the transferred data. The valid data must be identified using the DATA_LENGTH field in the Response Descriptor.

[I2C protocol mode]

When 1 byte of data is received, the received data is transferred from the internal shift register to NTDTBP0 to enable the next data to be received. The double-buffer structure of the internal shift register and NTDTBP0 allows continuous receive operation if the received data is read from NTDTBP0 while the internal shift register is receiving data. Read data from NTDTBP0 once when a Normal Rx Data buffer full interrupt (I3C_RX) request is generated. If NTDTBP0 receives the next Rx data before the current data is read from NTDTBP0 (while the RDBFF0 flag in NTST is 1), this module automatically holds the SCL clock low one cycle before the RDBFF0 flag is set to 1 next. The lower 8 bits of the read 32-bit data are valid as received data.

### Write Operations:

[I3C protocol mode]

Data written to the Normal Tx Data Buffer. Data DWORDs written to the Normal Tx Data Buffer are placed onto the I3C bus one byte at a time, with the DWORD LSB first. Within each byte, bits are placed onto the I3C bus in big-endian order, with bit 7 going out first on the bus. The Tx data always starts to align to a 4-byte boundary, and writes to the NTDTBP0 register. If the length of the transfer is not aligned to a 4-byte boundary, then there are extra (unused) bytes at the end of the transferred data. I3C only sends the valid number of bytes indicated in the DATA_LENGTH field of the Command Descriptor.

[I2C protocol mode]

When NTDTBP0 detects a space in the internal shift register, it transfers the Tx data that is written to NTDTBP0 to the internal shift register and starts transmitting data in transmit mode. The double-buffer structure of NTDTBP0 and the internal shift register allows continuous transmit operation if the next Tx data is written to NTDTBP0 while the internal

shift register data is being transmitted. Write Tx data to NTDTBP0 once when a Normal Tx Data buffer empty interrupt (I3C_TX) request is generated. The lower 8 bits of the written 32-bit data are valid as transmission data.

## 29.2.32 NIBIQP : Normal IBI Queue Port Register

Base address: I3C = 0x4011_F000

Offset address: 0x17C

| Bit position: | 31 | | | | | | | | | | | | | | | | | | | | | | | | | | | | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 31:0 | n/a | Normal IBI Queue Port | R/W |

Note: If the security attribution is configured as Secure:
- Secure access and Non-secure read access are allowed
- Non-secure write access is ignored, and TrustZone access error is not generated.

If the security attribution is configured as Non-secure:
- Secure and Non-secure access are allowed.

Note: This register supports all I3C mode.

When receiving an IBI, 32-bit mailbox register NIBIQP is used for both:

- Read the IBI status descriptor (see section 29.3.1.3. IBI Status Descriptor)
- Read the IBI data (which is raw/opaque data).

The IBI status descriptor is a read-only structure describing an IBI event received from a Slave device on the I3C bus.

Note: If the I3C HCI auto-read feature is used, then the IBI data includes the data received from the auto-generated private read operation.

Even if LAST_STATUS is set to 0, the driver software still evaluates the data payload length by examining the CHUNKS field.

## 29.2.33 NRSQP : Normal Receive Status Queue Port Register

Base address: I3C = 0x4011_F000

Offset address: 0x180

| Bit position: | 31 | | | | | | | | | | | | | | | | | | | | | | | | | | | | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 31:0 | n/a | Normal Receive Status Queue Port | R |

Note: If the security attribution is configured as Secure:
- Secure access and Non-secure read access are allowed
- Non-secure write access is ignored, and TrustZone access error is not generated.

If the security attribution is configured as Non-secure:
- Secure and Non-secure access are allowed.

Note: This register supports I3C secondary master mode and I3C slave mode.

32-bit mailbox register NRSQP contains a receive status structure (see section 29.3.1.4. Receive Status Descriptor).

## 29.2.34 NQTHCTL : Normal Queue Threshold Control Register

Base address: I3C = 0x4011_F000

Offset address: 0x190

| Bit position: | 31 | | | | | | | 24 | 23 | | | | | | | 16 | 15 | | | | | | | 8 | 7 | | | | | | | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | IBIQTH[7:0] | | | | | | | | IBIDSSZ[7:0] | | | | | | | | RSPQTH[7:0] | | | | | | | | CMDQTH[7:0] | | | | | | | |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 1 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 1 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 1 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 1 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 7:0 | CMDQTH[7:0] | Normal Command Queue Threshold*1<br>0x00: Interrupt is issued when Normal Command Queue is completely empty.<br>Others: Interrupt is issued when Normal Command Queue contains N empties. (N = CMDQTH[7:0]) | R/W |
| 15:8 | RSPQTH[7:0] | Normal Response Queue Threshold*1<br>0x00: Interrupt is issued when Normal Response Queue contains 1 entry (DWORD).<br>Others: Interrupt is triggered when Normal Response Queue contains N+1 entries (DWORD). (N = CMDQTH[7:0]) | R/W |
| 23:16 | IBIDSSZ[7:0] | Normal IBI Data Segment Size*2<br>Supported Values:<br>Minimum: 1 (4 bytes)<br>Maximum: 63 (252 bytes), provided that the configured IBI Queue depth is 64 or more. | R/W |
| 31:24 | IBIQTH[7:0] | Normal IBI Queue Threshold*1<br>0x00: I3C Protocol mode (Master):<br>Interrupt is generated when the Outstanding IBI Status count is 1 or more.<br>I3C Protocol mode (Slave):<br>Interrupt is issued when IBI Data Buffer is completely empty.<br>Others: I3C Protocol mode (Master):<br>Interrupt is generated when the Outstanding IBI Status count is N + 1 or more. (N = CMDQTH[7:0])<br>I3C Protocol mode (Slave):<br>Interrupt is issued when IBI Data Buffer contains N empties. | R/W |

Note: If the security attribution is configured as Secure:
- Secure access and Non-secure read access are allowed
- Non-secure write access is ignored, and TrustZone access error is not generated.

If the security attribution is configured as Non-secure:
- Secure and Non-secure access are allowed.

Note 1. These bits support all I3C mode.
Note 2. These bits support I3C master mode and I3C secondary master mode.

The Queue Threshold Control register controls the interrupt trigger thresholds for the Command Queue, the Response Queue, and the IBI Queue.

The specific reset values are indicative, and could be hardware implementation specific.

### CMDQTH[7:0] bits (Normal Command Queue Threshold)

Controls the minimum number of Normal Command Queue empties needed to trigger the I3C_CMD interrupt.

If this field is greater than (Normal Command Queue size*1 – 1), then only the number of bits required to address the full buffer depth will be considered.

### RSPQTH[7:0] bits (Normal Response Queue Threshold)

Controls the minimum number of Normal Response Queue entries needed to trigger the I3C_RESP interrupt.

If this field is greater than (Normal Response Queue size*2 – 1), then only the number of bits required to address the full buffer depth will be considered.

### IBIDSSZ[7:0] bits (Normal IBI Data Segment Size)

This is the IBI data segment size, in DWORDs (4 bytes).

In PIO mode, this field allows the incoming Normal IBI data to be sliced into multiple segments generating status individually, to support cut through readout of a long IBI payload data.

When Asynchronous Timing Control mode is supported, this field should be set to a value other than 1 or 3 to allow the single data segment to contain the entire Master time-stamp value (for example, both MREF and MC2).

**IBIQTH[7:0] bits (Normal IBI Queue Threshold)**

For I3C protocol mode (Master): PRTS.PRTMD = 0 and PRSST.CRMS = 1.

Controls generation of the I3C_IBI interrupt, based on the value of the Normal IBI Queue's Outstanding IBI status count.

Each IBI status entry can represent either the complete IBI payload (if the IBI payload byte size is 4×IBIDSSZ or less), or a segment of the IBI payload (if the IBI payload byte size is more than 4×IBIDSSZ).

For I3C protocol mode (Slave) : PRTS.PRTMD bit = 0, PRSST.CRMS bit = 0.

Controls the minimum number of IBI Data Buffer empties needed to trigger the I3C_IBI interrupt.

If this field is greater than (IBI Data Buffer size[*3] - 1), then only the number of bits required to address the full buffer depth will be considered.

Note 1. Normal Command Queue size is 2.
Note 2. Normal Response Queue size is 2.
Note 3. IBI Data Buffer size is 6.

Note: It is assumed that I3C has exactly one Command Queue, exactly one Response Queue, and exactly one IBI Queue.

## 29.2.35 NTBTHCTL0 : Normal Transfer Data Buffer Threshold Control Register 0

Base address: I3C = 0x4011_F000

Offset address: 0x194

| Bit position: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 26:24 | RXSTTH[2:0] | Normal Rx Start Threshold*2<br>0 0 0: Wait for 2 empty DWORDs<br>0 0 1: Reserved<br>Others: Setting prohibited | R/W |
| 31:27 | — | These bits are read as 0. The write value should be 0. | R/W |

Note: If the security attribution is configured as Secure:
- Secure access and Non-secure read access are allowed
- Non-secure write access is ignored, and TrustZone access error is not generated.

If the security attribution is configured as Non-secure:
- Secure and Non-secure access are allowed.

Note 1. These bits support all I3C mode.
Note 2. These bits support I3C master mode and I3C secondary master mode.

The Data Buffer Control register controls the interrupt trigger thresholds for the Rx Data Buffer Queue and the Tx Data Buffer Queue.

### TXDBTH[2:0] bits (Normal Tx Data Buffer Threshold)

Minimum number of Tx Data Buffer empties, in DWORDs, that will trigger the I3C_TX interrupt.

The software must program a value less than Tx Data Buffer size in this register.

### RXDBTH[2:0] bits (Normal Rx Data Buffer Threshold)

Minimum number of Rx Data Buffer entries in DWORDs that will trigger the I3C_RX interrupt.

The software must program a value less than Rx Data Buffer size in this register.

### TXSTTH[2:0] bits (Normal Tx Start Threshold)

When preparing to initiate a Write Transfer on the I3C Bus, I3C shall wait until the Transmit Buffer has at least the indicated number of locations available.

Two optional configurable Modes are available:

1. Store and Forward Mode
   If the TXSTTH[2:0] field is set to the Transmit Buffer size, then I3C shall delay initiation of the Write Command as follows:
   - If the data length to be transferred is more than the Transmit Buffer size, then this module shall wait until the Tx Data Buffer is completely full.
   - If the data length to be transferred is less than the Transmit Buffer size, then I3C shall wait until enough Tx Data Buffer locations are available to store the data to be transferred.
2. Threshold Mode
   If the TXSTTH[2:0] field value is less than the Transmit Buffer size, then I3C shall initiate the Write Command as soon as the indicated number of Tx Data Buffer locations are entries.

### RXSTTH[2:0] bits (Normal Rx Start Threshold)

When preparing to initiate a Read Transfer on the I3C bus, I3C shall wait until the Receive Buffer has at least the indicated number of empty locations in DWORDs.

Two optional configurable Modes are available:

1. Store and Forward Mode
   If the RXSTTH[2:0] field is set to the Receive Buffer size, then I3C shall delay initiation of the Read Command as follows:
   - If the data length to be transferred is more than the Receive Buffer size, then this module shall wait until the Rx Data Buffer is completely empty.
   - If the data length to be transferred is less than the Receive Buffer size, then I3C shall wait until enough Rx Data Buffer locations are available to store the data to be transferred.
2. Threshold Mode
   If the RXSTTH[2:0] field value is less than the Receive Buffer size, then I3C shall initiate the Read Command as soon as the indicated number of Rx Data Buffer locations are empty.

## 29.2.36 NRQTHCTL : Normal Receive Status Queue Threshold Control Register

Base address: I3C = 0x4011_F000

Offset address: 0x1C0

| Bit position: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | RSQTH[7:0] | | | | | | | |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 1 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 7:0 | RSQTH[7:0] | Normal Receive Status Queue Threshold<br>0x00: Interrupt is issued when Normal Receive Status Queue contains 1 entry (DWORD).<br>Others: Interrupt is triggered when Normal Receive Status Queue contains N+1 entries (DWORD). (N = RSQTH[7:0]) | R/W |
| 31:8 | — | These bits are read as 0. The write value should be 0. | R/W |

Note: If the security attribution is configured as Secure:
- Secure access and Non-secure read access are allowed
- Non-secure write access is ignored, and TrustZone access error is not generated.

If the security attribution is configured as Non-secure:
- Secure and Non-secure access are allowed.

Note: This register supports for I3C secondary master and I3C slave mode.

### RSQTH[7:0] bits (Normal Receive Status Queue Threshold)

Controls the minimum number of normal receive status queue entries needed to trigger the I3C_RCV interrupt.

If this field is greater than (Normal Receive Status Queue size[*1] – 1), then only the number of bits required to address the full buffer depth will be considered.

Note 1. Normal Receive Status Queue size is 2.

## 29.2.37 BST : Bus Status Register

Base address: I3C = 0x4011_F000

Offset address: 0x1D0

| Bit position: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 4 | NACKDF | NACK Detection Flag*2<br>0: NACK is not detected<br>1: NACK is detected | R/W*3 |
| 7:5 | — | These bits are read as 0. The write value should be 0. | R/W |
| 8 | TENDF | Transmit End Flag*2<br>0: Data is being transmitted<br>1: Data has been transmitted | R/W*3 |
| 15:9 | — | These bits are read as 0. The write value should be 0. | R/W |
| 16 | ALF | Arbitration Lost Flag*2<br>0: Arbitration is not lost<br>1: Arbitration is lost | R/W*3 |
| 19:17 | — | These bits are read as 0. The write value should be 0. | R/W |
| 20 | TODF | Timeout Detection Flag<br>0: Timeout is not detected<br>1: Timeout is detected | R/W*3 |
| 23:21 | — | These bits are read as 0. The write value should be 0. | R/W |
| 24 | WUCNDDF | Wake-up Condition Detection Flag<br>0: Wake-up is not detected<br>1: Wake-up is detected | R/W*3 |
| 31:25 | — | These bits are read as 0. The write value should be 0. | R/W |

Note: If the security attribution is configured as Secure:
- Secure access and Non-secure read access are allowed
- Non-secure write access is ignored, and TrustZone access error is not generated.

If the security attribution is configured as Non-secure:
- Secure and Non-secure access are allowed.

Note 1. This bit supports all I3C mode.
Note 2. This bit supports $I^2C$ mode.
Note 3. Clearing (to 0) condition : Writing 0 after 1 is read.

### STCNDDF bit (START Condition Detection Flag)

[Setting conditions]

- All the followings are satisfied:
  1. The BSTE.STCNDDE bit = 1.
  2. When a START condition (or a Repeated START condition) is detected.

[Clearing conditions]

- When 0 is written to the STCNDDF flag after reading STCNDDF flag = 1.
- When a STOP condition is detected.

### SPCNDDF bit (STOP Condition Detection Flag)

[Setting conditions]

- All the followings are satisfied:
  1. The BSTE.SPCNDDE bit = 1.
  2. When a STOP condition is detected.

[Clearing condition]

- When 0 is written to the SPCNDDF flag after reading SPCNDDF flag = 1.

### HDREXDF bit (HDR Exit Pattern Detection Flag)

[Setting conditions]

- All the followings are satisfied:

1. The BSTE.HDREXDE bit = 1.
2. When an HDR EXIT pattern is detected.

[Clearing condition]

- When 0 is written to the HDREXDF flag after reading HDREXDF flag = 1.

### NACKDF bit (NACK Detection Flag)

[Setting conditions]

- All the followings are satisfied:
  1. The PRTS.PRTMD bit = 1 ($I^2C$ protocol mode).
  2. The BSTE.NACKDE bit = 1 (enables NACK detection interrupt status logging).
  3. When acknowledge is not received (NACK is received) from the receive device in transmit mode.

[Clearing condition]

- When 0 is written to the NACKDF flag after reading NACKDF flag = 1.

### TENDF bit (Transmit End Flag)

[Setting conditions]

- All the followings are satisfied:
  1. The PRTS.PRTMD bit = 1 ($I^2C$ protocol mode).
  2. The BSTE.TENDE bit = 1 (enables transmit end interrupt status logging).
  3. At the rising edge of the 9th SCL clock cycle while the NTST.TDBEF0 flag = 1.
     Excluding when sending an address.

[Clearing conditions]

- When 0 is written to the TENDF flag after reading TENDF flag = 1.
- When data is written to the NTDTBP0 register.
- When a STOP condition is detected.

### ALF bit (Arbitration Lost Flag)

[Setting conditions]

When master arbitration-lost detection is enabled: BSTE.ALE bit = 1, BFCTL.MALE = 1.

- When the internal SDA output state does not match the I3C_SDA line level at the rising edge of the SCL clock except for the ACK period during data (including slave address) transmission in master transmit mode (when the I3C_SDA line is driven low while the internal SDA output is at a high level (the I3C_SDA pin is in the high impedance state)).
- All the followings are satisfied.
  1. When the START condition is detected while the CNDCTL.STCND bit = 1.
  2. When the internal SDA output state does not match the I3C_SDA line level.
- When the CNDCTL.STCND bit is set to 1 (START condition issuance request) while the BCST.BFREF flag = 0.

When NACK arbitration-lost detection is enabled: BSTE.ALE bit = 1, BFCTL.NALE = 1.

- When the internal SDA output state does not match the I3C_SDA line level at the rising edge of the SCL clock in the ACK period during NACK transmission in receive mode.

When slave arbitration-lost detection is enabled: BSTE.ALE bit = 1, BFCTL.SALE = 1.

- When the internal SDA output state does not match the I3C_SDA line level at the rising edge of the SCL clock except for the ACK period during data transmission in slave transmit mode.

[Clearing condition]

- When 0 is written to the ALF flag after reading ALF flag = 1.

### TODF bit (Timeout Detection Flag)

[Setting conditions]

- All the followings are satisfied.
  1. The BSTE.TODE bit = 1 (enables timeout detection interrupt status logging).
  2. When the master mode or the received slave address matches the slave address 0 in Slave mode.
  3. When the I3C_SCL line state remains unchanged for the period specified by TMOCTL register.

[Clearing condition]

- When 0 is written to the TODF flag after reading TODF flag = 1.

### WUCNDDF bit (Wake-up Condition Detection Flag)

[Setting condition]

For $I^2C$ protocol mode: PRTS.PRTMD bit = 1

- When PCLK and TCLK are supplied after all the followings are satisfied.
  1. The WUCTL.WUFE bit = 1 (wake-up function is enabled).
  2. The BSTE.WUCNDDE bit = 1 (enables wake-up condition detection status logging).
  3. The WUST.WUASYNF flag = 1.
  4. When the address received in slave mode matches the address of slave enabled in the SVCTL.SVAE0 bit (except for the Device-ID address).

For I3C Protocol mode (Master): PRTS.PRTMD bit = 0, PRSST.CRMS bit = 1.

- When PCLK and TCLK are supplied after all the followings are satisfied.
  1. The WUCTL.WUFE bit = 1 (wake-up function is enabled).
  2. The BSTE.WUCNDDE bit = 1 (enables wake-up condition detection status logging).
  3. The WUST.WUASYNF flag = 1.
  4. When a low level of the I3C_SDA line is detected (when the START condition is detected).

For I3C Protocol mode (Slave) : PRTS.PRTMD bit = 0, PRSST.CRMS bit = 0.

- When PCLK and TCLK are supplied after all the followings are satisfied.
  1. The WUCTL.WUFE bit = 1 (wake-up function is enabled).
  2. The BSTE.WUCNDDE bit = 1 (enables wake-up condition detection status logging).
  3. The WUST.WUASYNF flag = 1.
  4. When the broadcast address (0x7E) is detected after a START (or Repeated START) condition and the own dynamic address is detected after the Repeated START condition following the broadcast address.

[Clearing condition]

- When 0 is written to the WUCNDDF flag after reading WUCNDDF flag = 1 while the WUST.WUASYNF flag = 0.

## 29.2.38 BSTE : Bus Status Enable Register

Base address: I3C = 0x4011_F000

Offset address: 0x1D4

| Bit position: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

| 24 | WUCNDDE | Wake-up Condition Detection Enable<br>0: Disables Wake-up Condition Detection Status logging.<br>1: Enables Wake-up Condition Detection Status logging. | R/W |
| 31:25 | — | These bits are read as 0. The write value should be 0. | R/W |

Note: If the security attribution is configured as Secure:
- Secure access and Non-secure read access are allowed
- Non-secure write access is ignored, and TrustZone access error is not generated.

If the security attribution is configured as Non-secure:
- Secure and Non-secure access are allowed.

Note 1. This bit supports all I3C mode.

Note 2. This bit supports $I^2C$ mode.

### STCNDDE bit (START Condition Detection Enable)

When this bit is 1, operation of BST.STCNDDF is enabled. For the setting conditions and clearing conditions of the BST.STCNDDF flag, see the details of BST.STCNDDF.

### SPCNDDE bit (STOP Condition Detection Enable)

When this bit is 1, operation of BST.SPCNDDF is enabled. For the setting conditions and clearing conditions of the BST.SPCNDDF flag, see the details of BST.SPCNDDF.

### HDREXDE bit (HDR Exit Pattern Detection Enable)

When this bit is 1, the operation of BST.HDREXDF is enabled. For the setting conditions and clearing conditions of the BST.HDREXDF flag, see the details of BST.HDREXDF.

### NACKDE bit (NACK Detection Enable)

When this bit is 1, the operation of BST.NACKDF is enabled. This bit is used to specify whether to continue or discontinue the transfer operation when NACK is received from the slave device in transmit mode. Normally, set this bit to 1. For the setting conditions and clearing conditions of the BST.NACKDF flag, see the details of BST.NACKDF.

### TENDE bit (Transmit End Enable)

When this bit is 1, the operation of BST.TENDF is enabled. For the setting conditions and clearing conditions of the BST.TENDF flag, see the details of BST.TENDF.

### ALE bit (Arbitration Lost Enable)

When this bit is 1, the operation of BST.ALF is enabled. For the setting conditions and clearing conditions of the BST.ALF flag, see the details of BST.ALF.

### TODE bit (Timeout Detection Enable)

When this bit is 1, the operation of BST.TODF is enabled. For the setting conditions and clearing conditions of the BST.TODF flag, see the details of BST.TODF.

### WUCNDDE bit (Wake-up Condition Detection Enable)

When this bit is 1, the operation of BST.WUCNDDF is enabled. For the setting conditions and clearing conditions of the BST.WUCNDDF flag, see the details of BST.WUCNDDF.

| 4 | NACKDIE | NACK Detection Interrupt Enable*2<br>0: Disables NACK Detection Interrupt Signal.<br>1: Enables NACK Detection Interrupt Signal. | R/W |
| 7:5 | — | These bits are read as 0. The write value should be 0. | R/W |
| 8 | TENDIE | Transmit End Interrupt Enable*2<br>0: Disables Transmit End Interrupt Signal.<br>1: Enables Transmit End Interrupt Signal. | R/W |
| 15:9 | — | These bits are read as 0. The write value should be 0. | R/W |
| 16 | ALIE | Arbitration Lost Interrupt Enable*2<br>0: Disables Arbitration Lost Interrupt Signal.<br>1: Enables Arbitration Lost Interrupt Signal. | R/W |
| 19:17 | — | These bits are read as 0. The write value should be 0. | R/W |
| 20 | TODIE | Timeout Detection Interrupt Enable<br>0: Disables Timeout Detection Interrupt Signal.<br>1: Enables Timeout Detection Interrupt Signal. | R/W |
| 23:21 | — | These bits are read as 0. The write value should be 0. | R/W |
| 24 | WUCNDDIE | Wake-up Condition Detection Interrupt Enable<br>0: Disables Wake-up Condition Detection Interrupt Signal.<br>1: Enables Wake-up Condition Detection Interrupt Signal. | R/W |
| 31:25 | — | These bits are read as 0. The write value should be 0. | R/W |

Note: If the security attribution is configured as Secure:
- Secure access and Non-secure read access are allowed
- Non-secure write access is ignored, and TrustZone access error is not generated.

If the security attribution is configured as Non-secure:
- Secure and Non-secure access are allowed.

Note 1. This bit supports all I3C mode.
Note 2. This bit supports $I^2C$ mode.

The BIE register enables signaling of outstanding bus interrupts received by I3C.

### STCNDDIE bit (START Condition Detection Interrupt Enable)

This bit enables or disables the START Condition Detection interrupt requests when the BST.STCNDDF flag is set to 1.

### SPCNDDIE bit (STOP Condition Detection Interrupt Enable)

This bit enables or disables the STOP Condition Detection interrupt requests when the BST.SPCNDDF flag is set to 1.

### HDREXDIE bit (HDR Exit Pattern Detection Interrupt Enable)

This bit enables or disables the HDR Exit Pattern Detection interrupt requests when the BST.HDREXDF flag is set to 1.

### NACKDIE bit (NACK Detection Interrupt Enable)

This bit enables or disables the NACK Detection interrupt requests when the BST.NACKDF flag is set to 1.

### TENDIE bit (Transmit End Interrupt Enable)

This bit enables or disables the Transmit End interrupt (I3C_TEND) requests when the BST.TENDF flag is set to 1.

### ALIE bit (Arbitration Lost Interrupt Enable)

This bit enables or disables the Arbitration lost interrupt requests when the BST.ALF flag is set to 1.

### TODIE bit (Timeout Detection Interrupt Enable)

This bit enables or disables the Timeout Detection interrupt requests when the BST.TODF flag is set to 1.

**WUCNDDIE bit (Wake-up Condition Detection Interrupt Enable)**

This bit enables or disables the Wake-up Condition Detection interrupt (I3C_WU) requests when the BST.WUCNDDF flag is set to 1.

## 29.2.40 BSTFC : Bus Status Force Register

Base address: I3C = 0x4011_F000

Offset address: 0x1DC

| Bit position: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | — | — | — | — | WUCNDDFC | — | — | — | TODFC | — | — | — | ALFC |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| 31:21 | — | These bits are read as 0. The write value should be 0. | R/W |

Note: If the security attribution is configured as Secure:
- Secure access and Non-secure read access are allowed
- Non-secure write access is ignored, and TrustZone access error is not generated.

If the security attribution is configured as Non-secure:
- Secure and Non-secure access are allowed.

Note 1. This bit supports all I3C mode.
Note 2. This bit supports I3C secondary master mode and I3C slave mode.
Note 3. Clearing (to 0) condition : Writing 0 after the 1 state is read.

### TDBEF0 bit (Normal Tx Data Buffer Empty Flag 0)

[Setting conditions]

For $I^2C$ Protocol mode: PRTS.PRTMD bit = 1.

The following condition 1 is satisfied and any of the following conditions 2 to 4 are satisfied:

1. The NTSTE.TDBEE0 bit = 1 (enables Normal Tx Data Buffer Empty Interrupt Status logging).
2. When data has been transferred from the Normal Tx Data Buffer to the Shift Register and the Normal Tx Data Buffer becomes empty*1.
3. When the PRSST.TRMD bit is set to 1.
4. When the received slave address matches while the TRMD bit = 1.

For I3C Protocol mode: PRTS.PRTMD bit = 0.

The following conditions 1 and 2 are satisfied:

1. The NTSTE.TDBEE0 bit = 1 (enables Normal Tx Data Buffer Empty Interrupt Status logging).

2. When the number of empties in the Normal Tx Data Buffer is the NTBTHCTL0.TXDBTH[2:0] threshold or more (see NTBTHCTL0 register).

[Clearing conditions]

For $I^2C$ Protocol mode: PRTS.PRTMD bit = 1.

- When data is written to NTDTBP0.
- When the TRMD bit in PRSST is set to 0.

For I3C protocol mode: PRTS.PRTMD bit = 0.

- Write 0 to this bit after 1 is read.
- On completion of the last write access to Normal Tx Data by DMAC/DTC.

Note 1. When the BST.NACKDF flag is set to 1 while the BSTE.NACKDE bit = 1, I3C aborts data transmission/reception. If the TDBEF0 flag = 0 (next transmit data has been written), data is transferred to the Shift Register and the Normal Tx Data Buffer register becomes empty at the rising edge of the 9th clock cycle, but the TDBEF0 flag is not set to 1.

### RDBFF0 bit (Normal Rx Data Buffer Full Flag 0)

[Setting conditions]

For $I^2C$ Protocol mode: PRTS.PRTMD bit = 1.

The following condition 1 is satisfied and any of the following condition 2 or 3 is satisfied:

1. The NTSTE.RDBFE0 bit = 1 (enables Normal Rx Data Buffer Full Interrupt Status logging).
2. When Rx data is transferred from Shift Register to Normal Rx Data Buffer.
   The RDBFF0 flag is set to 1 on the rising edge of the 8th or 9th SCL clock cycle (selected in the ACKTWE bit in SCSTRCTL).
3. When the received slave address matches after a START (or Repeated START) condition is detected with the TRMD bit in PRSST set to 0.

For I3C Protocol mode: PRTS.PRTMD bit = 0.

The following conditions 1 and 2 are satisfied:

1. The NTSTE.RDBFE0 bit = 1 (enables Normal Rx Data Buffer Full Interrupt Status logging).
2. When the number of Normal Rx Data Buffer entries is the NTBTHCTL0.RXDBTH[2:0] threshold or more (see NTBTHCTL0 register).

[Clearing conditions]

For $I^2C$ Protocol mode: PRTS.PRTMD bit = 1.

- When data is read from NTDTBP0.

For I3C Protocol mode: PRTS.PRTMD bit = 0.

- Write 0 to this bit after 1 is read.
- On completion of the last read access to Normal Rx Data by DMAC/DTC.

### IBIQEFF bit (Normal IBI Queue Empty/Full Flag)

[Setting conditions]

The following 2 conditions are satisfied:

1. The NTSTE.IBIQEFE bit = 1 (enables Normal IBI Queue Empty/Full Interrupt Status logging)
2. For I3C protocol mode (master): PRTS.PRTMD bit = 0, PRSST.CRMS bit = 1.
   - When the number of Normal IBI Queue entries is more than the NQTHCTL.IBIQTH threshold (see NQTHCTL register).

   For I3C protocol mode (slave) : PRTS.PRTMD bit = 0, PRSST.CRMS bit = 0.

If the NQTHCTL.IBIQTH = 0:

- When IBI Data Buffer is completely empty.

If the NQTHCTL.IBIQTH is other than 0:

- When the number of IBI Data Buffer empties is the NQTHCTL.IBIQTH threshold or more (see NQTHCTL register).

[Clearing conditions]

For I3C protocol mode (master): PRTS.PRTMD bit = 0, PRSST.CRMS bit = 1.

- Write 0 to this bit after 1 is read.
- On completion of the last read access to IBI Status by DMAC/DTC.

For I3C protocol mode (slave): PRTS.PRTMD bit = 0, PRSST.CRMS bit = 0.

- Write 0 to this bit after 1 is read.
- On completion of the last write access to IBI Status by DMAC/DTC.

### CMDQEF bit (Normal Command Queue Empty Flag)

[Setting conditions]

The following 2 conditions are satisfied:

1. The NTSTE.CMDQEE bit = 1 (enables Normal Command Queue Empty Interrupt Status logging).
2. If the NQTHCTL.CMDQTH = 0:
   - When Normal Command Queue is completely empty.

   If the NQTHCTL.CMDQTH is other than 0:
   - When the number of Normal Command Queue empties is the NQTHCTL.CMDQTH threshold or more (see NQTHCTL register).

[Clearing conditions]

- Write 0 to this bit after 1 is read.
- On completion of the last write access to Normal Command by DMAC/DTC.

### RSPQFF bit (Normal Response Queue Full Flag)

[Setting conditions]

The following 2 conditions are satisfied:

1. The NTSTE.RSPQFE bit = 1 (enables Normal Response Queue Full Interrupt Status logging).
2. When the number of Normal Response Queue entries is more than the NQTHCTL.RSPQTH threshold (see NQTHCTL register).

[Clearing conditions]

- Write 0 to this bit after 1 is read.
- On completion of the last read access to Normal Receive Status by DMAC/DTC.

### TABTF bit (Normal Transfer Abort Flag)

[Setting conditions]

The following 2 conditions are satisfied:

1. The NTSTE.TABTE bit = 1 (enables Normal Transfer Abort Interrupt Status logging).
2. When any transfer is aborted.

[Clearing condition]

- Write 0 to this bit after 1 is read.

#### TEF bit (Normal Transfer Error Flag)

[Setting conditions]

The following 2 conditions are satisfied:

1. The NTSTE.TEE bit = 1 (enables Normal Transfer Error Interrupt Status logging).
2. When any transfer error occurs on the I3C bus. The Error type for this error is available in the Response or Receive Status structure corresponding to the Transfer command.

[Clearing condition]

- Write 0 to this bit after 1 is read.

#### RSQFF bit (Normal Receive Status Queue Full Flag)

[Setting conditions]

The following 2 conditions are satisfied:

1. The NTSTE.RSQFE bit = 1 (Normal Receive Status Queue Full Enable).
2. When the number of Normal Receive Status Queue entries is more than the NRQTHCTL.RSQTH threshold (see NRQTHCTL register).

[Clearing conditions]

- Write 0 to this bit after 1 is read.
- On completion of the last read access to Normal Receive Status by DMAC/DTC.

### 29.2.42 NTSTE : Normal Transfer Status Enable Register

Base address: I3C = 0x4011_F000

Offset address: 0x1E4

| Bit position: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

| 31:21 | — | These bits are read as 0. The write value should be 0. | R/W |

Note: If the security attribution is configured as Secure:
- Secure access and Non-secure read access are allowed
- Non-secure write access is ignored, and TrustZone access error is not generated.

If the security attribution is configured as Non-secure:
- Secure and Non-secure access are allowed.

Note 1. This bit supports all I3C mode.
Note 2. This bit supports I3C secondary master mode and I3C slave mode.

### TDBEE0 bit (Normal Tx Data Buffer Empty Enable 0)

When this bit is 1, the operation of NTST.TDBEF0 is enabled.

For the setting conditions and clearing conditions of the NTST.TDBEF0 flag, see the details of NTST.TDBEF0.

### RDBFE0 bit (Normal Rx Data Buffer Full Enable 0)

When this bit is 1, the operation of NTST.RDBFF0 is enabled.

For the setting conditions and clearing conditions of the NTST.RDBFF0 flag, see the details of NTST.RDBFF0.

### IBIQEFE bit (Normal IBI Queue Empty/Full Enable)

When this bit is 1, the operation of NTST.IBIQEFF is enabled.

For the setting conditions and clearing conditions of the NTST.IBIQEFF flag, see the details of NTST.IBIQEFF.

### CMDQEE bit (Normal Command Queue Empty Enable)

When this bit is 1, the operation of NTST.CMDQEF is enabled.

For the setting conditions and clearing conditions of the NTST.CMDQEF flag, see the details of NTST.CMDQEF.

### RSPQFE bit (Normal Response Queue Full Enable)

When this bit is 1, the operation of NTST.RSPQFF is enabled.

For the setting conditions and clearing conditions of the NTST.RSPQFF flag, see the details of NTST.RSPQFF.

### TABTE bit (Normal Transfer Abort Enable)

When this bit is 1, the operation of NTST.TABTF is enabled.

For the setting conditions and clearing conditions of the NTST.TABTF flag, see the details of NTST.TABTF.

### TEE bit (Normal Transfer Error Enable)

When this bit is 1, the operation of NTST.TEF is enabled.

For the setting conditions and clearing conditions of the NTST.TEF flag, see the details of NTST.TEF.

### RSQFE bit (Normal Receive Status Queue Full Enable)

When this bit is 1, the operation of NTST.RSQFF is enabled.

For the setting conditions and clearing conditions of the NTST.RSQFF flag, see the details of NTST.RSQFF.

## 29.2.43 NTIE : Normal Transfer Interrupt Enable Register

Base address: I3C = 0x4011_F000

Offset address: 0x1E8

| Bit position: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

| 31:21 | — | These bits are read as 0. The write value should be 0. | R/W |

Note: If the security attribution is configured as Secure:
- Secure access and Non-secure read access are allowed
- Non-secure write access is ignored, and TrustZone access error is not generated.

If the security attribution is configured as Non-secure:
- Secure and Non-secure access are allowed.

Note 1. This bit supports all I3C mode.
Note 2. This bit supports I3C secondary master mode and I3C slave mode.

The PIO Interrupt Signal Enable register enables signaling of outstanding interrupts received by I3C.

**TDBEIE0 bit (Normal Tx Data Buffer Empty Interrupt Enable 0)**

This bit is used to enable or disable the Normal Tx Data buffer empty interrupt (I3C_TX) requests when the NTST.TDBEF0 flag is set to 1.

### RDBFIE0 bit (Normal Rx Data Buffer Full Interrupt Enable 0)

This bit is used to enable or disable the Normal Rx Data buffer full interrupt (I3C_RX) requests when the NTST.RDBFF0 flag is set to 1.

### IBIQEFIE bit (Normal IBI Queue Empty/Full Interrupt Enable)

This bit is used to enable or disable the Normal IBI Queue Empty/Full interrupt (I3C_IBI) requests when the NTST.IBIQEFF flag is set to 1.

### CMDQEIE bit (Normal Command Queue Empty Interrupt Enable)

This bit is used to enable or disable the Normal Command queue empty interrupt (I3C_CMD) requests when the NTST.CMDQEF flag is set to 1.

### RSPQFIE bit (Normal Response Queue Full Interrupt Enable)

This bit is used to enable or disable the Normal Response queue full interrupt (I3C_RESP) requests when the NTST.RSPQFF flag is set to 1.

### TABTIE bit (Normal Transfer Abort Interrupt Enable)

This bit is used to enable or disable the Normal Transfer Abort interrupt (I3C_EEI) requests when the NTST.TABTF flag is set to 1.

### TEIE bit (Normal Transfer Error Interrupt Enable)

This bit is used to enable or disable the Normal Transfer Error interrupt (I3C_EEI) requests when the NTST.TEF flag is set to 1.

### RSQFIE bit (Normal Receive Status Queue Full Interrupt Enable)

This bit is used to enable or disable the Normal Receive Status queue full interrupt (I3C_RCV) requests when the NTST.RSQFF flag is set to 1.

## 29.2.44 NTSTFC : Normal Transfer Status Force Register

Base address: I3C = 0x4011_F000

Offset address: 0x1EC

| Bit position: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

| 31:21 | — | The write value should be 0. | W |

Note: If the security attribution is configured as Secure:
- Secure access and Non-secure read access are allowed
- Non-secure write access is ignored, and TrustZone access error is not generated.

If the security attribution is configured as Non-secure:
- Secure and Non-secure access are allowed.

Note 1. This bit supports all I3C mode.
Note 2. This bit supports I3C secondary master mode and I3C slave mode.

The PIO Interrupt Force register is used to force specific interrupt. It can be used for debug purposes.

### TDBEFC0 bit (Normal Tx Data Buffer Empty Force 0)

For software testing, when set to 1, forces the corresponding interrupt, subject to TDBEE0 and TDBEIE0 configuration.

### RDBFFC0 bit (Normal Rx Data Buffer Full Force 0)

For software testing, when set to 1, forces the corresponding interrupt, subject to RDBFE0 and RDBFIE0 configuration.

### IBIQEFFC bit (Normal IBI Queue Empty/Full Force)

For software testing, when set to 1, forces the corresponding interrupt, subject to IBIQEFE and IBIQEFIE configuration.

### CMDQEFC bit (Normal Command Queue Empty Force)

For software testing, when set to 1, forces the corresponding interrupt, subject to CMDQEE and CMDQEIE configuration.

### RSPQFFC bit (Normal Response Queue Full Force)

For software testing, when set to 1, forces the corresponding interrupt, subject to RSPQFE and RSPQFIE configuration.

### TABTFC bit (Normal Transfer Abort Force)

For software testing, forces the corresponding interrupt, subject to TABTE and TABTIE configuration.

### TEFC bit (Normal Transfer Error Force)

For software testing, when set to 1, forces the corresponding interrupt, subject to TEE and TEIE configuration.

### RSQFFC bit (Normal Receive Status Queue Full Force)

For software testing, when set to 1, forces the corresponding interrupt, subject to RSQFE and RSQFIE configuration.

## 29.2.45 BCST : Bus Condition Status Register

Base address: I3C = 0x4011_F000

Offset address: 0x210

| Bit position: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

| Bit field: | — | — | — | — | — | — | — | — | — | — | — | — | — | BIDLF | BAVLF | BFREF |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 0 | BFREF | Bus Free Detection Flag<br>0: Have not Detected Bus Free<br>1: Have Detected Bus Free | R |
| 1 | BAVLF | Bus Available Detection Flag*1<br>0: Have not Detected Bus Available<br>1: Have Detected Bus Available | R |
| 2 | BIDLF | Bus Idle Detection Flag*1<br>0: Have not Detected Bus Idle<br>1: Have Detected Bus Idle | R |
| 31:3 | — | These bits are read as 0. | R |

Note: If the security attribution is configured as Secure:
- Secure access and Non-secure read access are allowed
- Non-secure write access is ignored, and TrustZone access error is not generated.

If the security attribution is configured as Non-secure:
- Secure and Non-secure access are allowed.

Note 1. This bit supports all I3C mode.

### BFREF bit (Bus Free Detection Flag)

The Bus Free Condition is a period occurring after a STOP and before a START, and with the following duration:

- For Pure Bus: A duration of at least tCAS (see section 49, Electrical Characteristics)
- For Mixed Bus (at least one Legacy $I^2C$ is present on the I3C Bus): A duration of at least tBUF (see section 49, Electrical Characteristics)

[Setting conditions]

- After a STOP condition is detected, when the number of cycles (I3Cφ) that are set by BFRECDT.FRECYC[8:0] has passed in the state of SCL = SDA = 1.
- After setting BCTL.BUSE to 1, when the number of cycles (I3Cφ) that are set by BFRECDT.FRECYC[8:0] has passed in the state of SCL = SDA = 1.

[Clearing conditions]

- When SCL and SDA are other than high.
- When the BCTL.BUSE bit is set to 0.

### BAVLF bit (Bus Available Detection Flag)

The Bus Available Condition is a period during which the Bus Free Condition is sustained continuously for a duration of at least tAVAL (see section 49, Electrical Characteristics). A Slave can only issue a START Request (for an In-Band Interrupt, or for a Master Handoff Request) after a Bus Available Condition.

[Setting conditions]

- After a STOP condition is detected, when the number of cycles (I3Cφ) that are set by BAVLCDT.AVLCYC[8:0] has passed in the state of SCL = SDA = 1.
- After setting BCTL.BUSE to 1, when the number of cycles (I3Cφ) that are set by BAVLCDT.AVLCYC[8:0] has passed in the state of SCL = SDA = 1.

[Clearing conditions]

- When SCL and SDA are other than high.
- When the BCTL.BUSE bit is set to 0.

#### BIDLF bit (Bus Idle Detection Flag)

The I3C Bus Idle Condition is in order to help ensure Bus stability during Hot-Join events.

The Bus Idle Condition is a period during which the Bus Available Condition is sustained continuously for a duration of at least tIDLE (see section 49, Electrical Characteristics).

If a Hot-Join Device is powered up onto the I3C Bus at the same time as the Main Master, then the Hot-Join Device may pull SDA Low after 1 ms if (1) the Main Master has SCL and SDA pulled up, and (2) the Master does not act on the I3C Bus within the same Idle period.

[Setting conditions]

- After a STOP condition is detected, when the number of cycles (I3Cφ) that are set by BIDLCDT.IDLCYC[17:0] has passed in the state of SCL = SDA = 1.
- After setting BCTL.BUSE to 1, when the number of cycles (I3Cφ) that are set by BIDLCDT.IDLCYC[17:0] has passed in the state of SCL = SDA = 1.

[Clearing conditions]

- When SCL and SDA are other than high.
- When the BCTL.BUSE bit is set to 0.

## 29.2.46 SVST : Slave Status Register

Base address: I3C = 0x4011_F000

Offset address: 0x214

| Bit position: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

| 31:17 | — | These bits are read as 0. The write value should be 0. | R/W |

Note: If the security attribution is configured as Secure:
- Secure access and Non-secure read access are allowed
- Non-secure write access is ignored, and TrustZone access error is not generated.

If the security attribution is configured as Non-secure:
- Secure and Non-secure access are allowed.

Note: This register supports $I^2C$ mode.

Note 1. Clearing (to 0) condition : Writing 0 after the 1 state is read.

### GCAF flag (General Call Address Detection Flag)

$I^2C$ Normal Wake-up mode1/2 sets GCAF to 1 when switching from asynchronous operation to synchronous unit.

[Setting conditions]

- This flag is set to 1 at the rising edge of the 9th SCL clock cycle in the first byte when all the followings are satisfied.
  1. The SVCTL.GCAE bit = 1 (general call address detection is enabled).
  2. When the received slave address matches the general call address (0000 000 + 0 (write)).

[Clearing conditions]

- When 0 is written to the GCAF flag after reading GCAF flag to be 1
- When a STOP condition is detected
- When a Repeated START condition is detected.

### HSMCF flag (Hs-mode Master Code Detection Flag)

The $I^2C$ Normal Wake-up mode 1/2 sets 1 to HSMCF when switching from asynchronous operation to synchronous unit.

[Setting conditions]

- This flag is set to 1 at the rising edge of the 9th SCL clock cycle in the first byte when all the followings are satisfied.
  1. The SVCTL.HSMCE bit = 1 (Hs-mode master code detection is enabled).
  2. When the first byte received immediately after a START condition is detected matches a value of Hs-mode master code (0000 1XXX) + 1 (NACK).

[Clearing conditions]

- When 0 is written to the HSMCF flag after reading HSMCF flag to be 1
- When a STOP condition is detected.

### DVIDF flag (Device-ID Address Detection Flag)

[Setting conditions]

- This flag is set to 1 at the rising edge of the 9th SCL clock cycle in the first byte when all the followings are satisfied.
  1. The SVCTL.DVIDE bit = 1 (Device-ID address detection is enabled).
  2. When the first byte received immediately after a START condition or Repeated START condition is detected matches a value of Device ID (1111 100) + 0 (write).

[Clearing conditions]

- When 0 is written to the DVIDF flag after reading DVIDF flag to be 1
- When a STOP condition is detected
- This flag is set to 0 at the rising edge of the 9th SCL clock cycle in the first byte when the following 1 and 2 or 1 and 3 are satisfied.
  1. The SVCTL.DVIDE bit = 1 (Device-ID address detection is enabled).
  2. When the first byte received immediately after a START condition or Repeated START condition is detected does not match a value of Device ID (1111 100).
  3. When the first byte received immediately after a START condition or Repeated START condition is detected matches a value of (device ID (1111 100) + 0 [W]) and the second byte does not match any of slave addresses 0 to 2.

#### HOAF flag (Host Address Detection Flag)

I$^2$C Normal Wake-up Mode1/2 sets HOAF to 1 at the time of switching from asynchronous operation to synchronous unit.

[Setting conditions]

- This flag is set to 1 at the rising edge of the 9th SCL clock cycle in the first byte when all the followings are satisfied.
  1. The SVCTL.HOAE bit = 1 (Host address detection is enabled).
  2. When the received slave address matches the host address (0001 000).

[Clearing conditions]

- When 0 is written to the HOAF flag after reading HOAF flag to be 1
- When a STOP condition is detected
- When a Repeated START condition is detected.

#### SVAF0 flag (Slave Address Detection Flag 0)

I$^2$C Normal Wake-up Mode1/2 sets 1 to SVAF0 when switching from asynchronous operation to synchronous unit.

[Setting conditions]

For 7-bit address format: SVDVAD0.SADLG bit = 0.

- This flag is set to 1 at the rising edge of the 9th SCL clock cycle in the first byte when all the followings are satisfied.
  1. The SVCTL.SVAE0 bit = 1 (Slave 0 enabled).
  2. When the received slave address matches the SVDVAD0.SVAD[6:0] bits value.

For 10-bit address format: SVDVAD0.SADLG bit = 1.

- This flag is set to 1 at the rising edge of the 9th SCL clock cycle in the second byte when all the followings are satisfied.
  1. The SVCTL.SVAE0 bit = 1 (Slave 0 enabled).
  2. When the received slave address matches a value of 11110 + SVDVAD0.SVAD[9:8] bits and the following address matches the SVDVAD0.SVAD[7:0] value.

[Clearing conditions]

- When 0 is written to the SVAF0 flag after reading SVAF0 flag to be 1
- When a STOP condition is detected.

For 7-bit address format: SVDVAD0.SADLG bit = 0.

- This flag is set to 0 at the rising edge of the 9th SCL clock cycle in the first byte when all the followings are satisfied.
  1. The SVCTL.SVAE0 bit = 1 (Slave 0 enabled).
  2. When the received slave address does not match SVDVAD0.SVAD[6:0] bits value.

For 10-bit address format: SVDVAD0.SADLG bit = 1.

- This flag is set to 0 at the rising edge of the 9th SCL clock cycle in the first byte when all the followings are satisfied.
  1. The SVCTL.SVAE0 bit = 1 (Slave 0 enabled).

2. When the received slave address does not match a value of 11110b + SVDVAD0.SVAD[9:8] bits.

- This flag is set to 0 at the rising edge of the 9th SCL clock cycle in the second byte when all the followings are satisfied.
  1. The SVCTL.SVAE0 bit = 1 (Slave 0 enabled).
  2. When the received slave address matches a value of 11110b + SVDVAD0.SVAD[9:8] bits and the following address does not match the SVDVAD0.SVAD[7:0] value.

## 29.2.47 WUST : Wake-up Unit Operating Status Register

Base address: I3C = 0x4011_F000

Offset address: 0x218

| Bit position: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit position: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | WUASYNF |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 0 | WUASYNF | Wake-up function asynchronous operation status flag<br>0: I3C synchronous circuit enable condition<br>1: I3C asynchronous circuit enable condition | R |
| 31:1 | — | These bits are read as 0. | R |

Note: If the security attribution is configured as Secure:
- Secure access and Non-secure read access are allowed
- Non-secure write access is ignored, and TrustZone access error is not generated.

If the security attribution is configured as Non-secure:
- Secure and Non-secure access are allowed.

**WUASYNF flag (Wake-up function asynchronous operation status flag)**

This bit shows whether I3C is in the TCLK asynchronous operation (WUCTL.WUFE bit = 1).

[Setting condition]

- All the followings are satisfied.
  1. The WUCTL.WUFE bit = 1 (Wake-up function is enabled).
  2. When the BCST.BFREF flag = 1 after 0 is written to the WUCTL.WUFSYNE bit.

[Clearing conditions : $I^2C$ slave]

- The WUCTL.WUFE bit = 0 (wake-up function is disabled)
- All the followings are satisfied.
  1. The WUCTL.WUFE bit = 1 (wake-up function is enabled).
  2. Wake-up event is detected.
  3. When 1 is written to the WUCTL.WUFSYNE bit during WUASYNF flag = 1.

[Clearing conditions : I3C slave]

- The WUCTL.WUFE bit = 0 (wake-up function is disabled)
- All the followings are satisfied.
  1. The WUCTL.WUFE bit = 1 (wake-up function is enabled).
  2. Wake-up event is detected.
  3. When 1 is written to the WUCTL.WUFSYNE bit during WUASYNF flag = 1.

4. When a STOP condition is detected.

[Clearing condition : $I^2C$/I3C slave]

- All the followings are satisfied.
  1. The WUCTL.WUFE bit = 1 (wake-up function is enabled).
  2. Wake-up event is not detected.
  3. The WUASYNF flag = 1.
  4. The WUCTL.WUFSYNE bit = 1.
  5. When a STOP condition is detected.

[Clearing conditions : I3C master]

- The WUCTL.WUFE bit = 0 (wake-up function is disabled).
- All the followings are satisfied.
  1. The WUCTL.WUFE bit = 1 (wake-up function is enabled).
  2. Wake-up event is detected.
  3. The WUASYNF flag = 1.
  4. The WUCTL.WUFSYNE bit = 1.

## 29.2.48 DATBASm : Device Address Table Basic Register m (m = 0 to 3)

Base address: I3C = 0x4011_F000

Offset address: 0x224 + 0x08 × m

| Bit position: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | | | | | | | 16 |

| 23:16 | DVDYAD[7:0] | Device I3C Dynamic Address<br>Bit [23] is the parity bit, per the I3C specification, computed and updated by the software driver. | R/W |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 28:24 | — | These bits are read as 0. The write value should be 0. | R/W |
| 30:29 | DVNACK[1:0] | Device NACK Retry Count<br>Device-specific retry count | R/W |
| 31 | DVTYP | Device Type<br>0: I3C device<br>1: $I^2C$ device | R/W |

Note: If the security attribution is configured as Secure:
- Secure access and Non-secure read access are allowed
- Non-secure write access is ignored, and TrustZone access error is not generated.

If the security attribution is configured as Non-secure:
- Secure and Non-secure access are allowed.

Note: This register supports I3C master mode and I3C secondary master mode.

### DVIBIPL bit (Device IBI Payload)

Indicates whether IBIs from this device have a data payload. This field reflects the IBI Payload bit in the Device Bus Characteristics Register (BCR).

During IBI handling for this device, the master uses this field to determine whether to drive reception of the IBI data payload. Data continuation is indicated by the T-Bit.

### DVSIRRJ bit (Device In-Band Slave Interrupt Request Reject)

Controls whether this device, when operating in the master role, accepts or rejects slave interrupt requests from other devices.

### DVMRRJ bit (Device In-Band Master Request Reject)

Controls whether this device, when operating in the master role, accepts or rejects master requests from other devices.

This bit is only valid if I3C declares Non-Current Master Capability.

### DVIBITS bit (Device IBI Time-stamp)

Enables or disables IBI time-stamping for a specific device.

Note: The IBI Status Descriptor for each IBI event indicates whether the individual IBI event was actually time-stamped. Set to 0 except for Async mode 0 and Async mode 1 of timing control.

### DVNACK[1:0] bits (Device NACK Retry Count)

These bits set the number of retries when a NACK response is received from the slave for the transaction set in the Command Descriptor.

Note: When ENTDAA is executed by Address Assign Command, the setting of this bit is ignored and the transaction ends when NACK is received once.

Note: I3C retries according to the setting of DVNACK[1:0] bits, even if it receives a NACK for the broadcast address.

Note: If DVNACK[1:0] bits are 0x0, I3C does not retry even for Direct CCCs.

## 29.2.49 EXDATBAS : Extended Device Address Table Basic Register

Base address: I3C = 0x4011_F000

Offset address: 0x2A0

| Bit position: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | EDTYP | EDNACK[1:0] | | — | — | — | — | — | EDDYAD[7:0] | | | | | | | |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit position: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | — | — | — | — | — | — | EDSTAD[6:0] | | | | | | |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 6:0 | EDSTAD[6:0] | Extended Device Static Address<br>I3C/I$^2$C static address | R/W |
| 15:7 | — | These bits are read as 0. The write value should be 0. | R/W |
| 23:16 | EDDYAD[7:0] | Extended Device I3C Dynamic Address<br>Bit 23 is the parity bit, per the I3C specification, computed and updated by the software driver. | R/W |
| 28:24 | — | These bits are read as 0. The write value should be 0. | R/W |
| 30:29 | EDNACK[1:0] | Extended Device NACK Retry Count<br>Device-specific retry count | R/W |
| 31 | EDTYP | Extended Device Type<br>0: I3C Device<br>1: I$^2$C Device | R/W |

Note: If the security attribution is configured as Secure:
- Secure access and Non-secure read access are allowed
- Non-secure write access is ignored, and TrustZone access error is not generated.

If the security attribution is configured as Non-secure:
- Secure and Non-secure access are allowed.

Note: This register supports I3C master mode and I3C secondary master mode.

## 29.2.50 SDATBAS0 : Slave Device Address Table Basic Register 0

Base address: I3C = 0x4011_F000

Offset address: 0x2B0

| Bit position: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 9:0 | SDSTAD[9:0] | Slave Device Static Address*2<br>I3C Static Address | R/W |
| 10 | SDADLS | Slave Device Address Length Selection*3<br>0: Slave device address length 7 bits selected<br>1: Slave device address length 10 bits selected (I$^2$C device only) | R/W |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 11 | — | This bit is read as 0. The write value should be 0. | R/W |
| 12 | SDIBIPL[*1] | Slave Device IBI Payload[*4]<br>This bit is the mirror bit of the SVDCT.TBCR2.<br>0: IBIs from this device do not carry a data payload<br>1: IBIs from this device carry a data payload | R/W |
| 15:13 | — | These bits are read as 0. The write value should be 0. | R/W |
| 22:16 | SDDYAD[6:0][*1] | Slave Device I3C Dynamic Address[*5] | R/W |
| 31:23 | — | These bits are read as 0. The write value should be 0. | R/W |

Note: If the security attribution is configured as Secure:
- Secure access and Non-secure read access are allowed
- Non-secure write access is ignored, and TrustZone access error is not generated.

If the security attribution is configured as Non-secure:
- Secure and Non-secure access are allowed.

Note: Software write to the SDATBAS register of the main master is prohibited.
Note 1. This bit is valid only in SDATBAS0 register.
Note 2. These bits support $I^2C$, I3C secondary master, and I3C slave mode.
Note 3. This bit supports $I^2C$ mode.
Note 4. This bit supports I3C secondary master mode and I3C slave mode.
Note 5. These bits support I3C secondary master mode and I3C slave mode.

### SDSTAD[9:0] bits (Slave Device Static Address)

When the 7-bit address format is selected (SDADLS bit is 0), the lower 7 bits of SDSTAD[9:0] function as the 7-bit address.

When the 10-bit address format is selected (SDADLS bit is 1), the SDSTAD[9:0] function as the 10-bit address. While the SVCTL.SVAE0 bit is 0, the setting of this bit is ignored.

### SDIBIPL bit (Slave Device IBI Payload)

Indicates whether IBIs from this device have a data payload. This field reflects the IBI Payload bit in the Device Bus Characteristics Register (BCR).

During IBI handling for this device, the Master uses this field to determine whether to drive reception of the IBI Data Payload. Data continuation is indicated by the T-Bit.

### SDDYAD[6:0] bits (Slave Device I3C Dynamic Address)

[Update conditions]

- When writing dynamic address value.
- When slave address value is its own static address in receiving SETDASA CCC (Direct), these bits are updated to dynamic address value.[*1]
- When Dynamic Address Assignment procedure that starts by receiving ENTDAA CCC (Broadcast) is established.[*1]
- When receiving RSTDAA CCC (Broadcast), all bits are cleared to 0. [*1]
- When slave address value is its own dynamic address in receiving RSTDAA CCC (Direct), all bits are cleared to 0. [*1]
- When slave address value is its own dynamic address in receiving SETNEWDA CCC (Direct), these bits are updated to the dynamic address value. [*1]
- When receiving SETAASA CCC (Broadcast), these bits are updated to the value of SDSTAD[6:0] bits[*2].

Note 1. See the MIPI I3C Specification v1.0.
Note 2. See the MIPI I3C Basic Specification v1.0.

## 29.2.51 MSDCTm : Master Device Characteristic Table Register m (m = 0 to 3)

Base address: I3C = 0x4011_F000

Offset address: 0x2D0 + 0x04 × m

| Bit position: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit position: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | RBCR76[1:0] | | RBCR 5 | RBCR 4 | RBCR 3 | RBCR 2 | RBCR 1 | RBCR 0 | — | — | — | — | — | — | — | — |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 7:0 | — | These bits are read as 0. The write value should be 0. | R/W |
| 8 | RBCR0 | Max Data Speed Limitation*1<br>0: No Limitation<br>1: Limitation | R/W |
| 9 | RBCR1 | IBI Request Capable<br>0: Not Capable<br>1: Capable | R/W |
| 10 | RBCR2 | IBI Payload<br>0: No data byte follows the accepted IBI.<br>1: Mandatory one or more data bytes follow the accepted IBI. Data byte continuation is indicated by T-Bit. | R/W |
| 11 | RBCR3 | Offline Capable*2<br>0: Device will always respond to I3C bus commands.<br>1: Device will not always respond to I3C bus commands. | R/W |
| 12 | RBCR4 | Bridge Identifier*3<br>0: Not a Bridge Device<br>1: A Bridge Device | R/W |
| 13 | RBCR5 | SDR Only / SDR and HDR Capable<br>0: SDR only<br>1: HDR Capable | R/W |
| 15:14 | RBCR76[1:0] | Device Role<br>0 0: I3C Slave<br>0 1: I3C Master*4<br>Others: Setting prohibited | R/W |
| 31:16 | — | These bits are read as 0. The write value should be 0. | R/W |

Note: If the security attribution is configured as Secure:
- Secure access and Non-secure read access are allowed
- Non-secure write access is ignored, and TrustZone access error is not generated.

If the security attribution is configured as Non-secure:
- Secure and Non-secure access are allowed.

Note: This register supports I3C master mode and I3C secondary master mode.
Note 1. Master shall use the GETMXDS CCC to interrogate the Slave for specific limitation.
Note 2. Offline Capable Devices retain the Dynamic Address.
Note 3. Bridge Devices are required to comply with this MIPI Specification for I3C.
Note 4. For an I3C Device acting as I3C Main Master, the BCR Device Role bits will contain the value 01.

The DCT table captures the Device characteristics (PID, BCR, DCR) and assigned Dynamic Address of each Device on the I3C Bus that participates in the Dynamic Address Allocation (ENTDAA) procedure.

### RBCRn bits (Received Bus Characteristic Register)

Each I3C Device that is connected to the I3C Bus shall have an associated read-only Bus Characteristics Register (BCR). This read-only register describes the I3C compliant Device's role and capabilities for use in Dynamic Address assignment and Common Command Codes.

Note: When RBCR2 is 0 and when ACK response to Slave Interrupt Request from I3C Slave by DATBASm.DVSIRRJ = 0 (m = 0 to 3), STOP Condition is issued after ACK response. When RBCR2 is 1 and when ACK response to Slave Interrupt Request from I3C Slave by DATBASm.DVSIRRJ = 0 (m = 0 to 3), IBI Payload is received after ACK response. STOP Condition is issued after end of IBI Payload.

[Update condition]

- When receiving of Bus Characteristics Register (BCR) from Device in the Dynamic Address Assignment procedure starting by receiving ENTDAA CCC (Broadcast).*1

Note 1. See the MIPI I3C Specification v1.0

## 29.2.52 SVDCT : Slave Device Characteristic Table Register

Base address: I3C = 0x4011_F000

Offset address: 0x320

| Bit position: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit position: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | TBCR76[1:0] | | TBCR5 | TBCR4 | TBCR3 | TBCR2 | TBCR1 | TBCR0 | TDCR[7:0] | |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 7:0 | TDCR[7:0] | Transfer Device Characteristic Register<br>255 available codes for describing the type of sensor, or device.<br>Examples: Accelerometer, gyroscope, composite devices<br>Default value is 0x0: Generic Device | R/W |
| 8 | TBCR0 | Max Data Speed Limitation*1<br>0: No Limitation<br>1: Limitation | R/W |
| 9 | TBCR1 | IBI Request Capable<br>0: Not Capable<br>1: Capable | R/W |
| 10 | TBCR2 | IBI Payload<br>0: No data byte follows the accepted IBI.<br>1: Mandatory one or more data bytes follow the accepted IBI. Data byte continuation is indicated by T-Bit. | R/W |
| 11 | TBCR3 | Offline Capable*2<br>0: Device will always respond to I3C bus commands.<br>1: Device will not always respond to I3C bus commands. | R/W |
| 12 | TBCR4 | Bridge Identifier*3<br>0: Not a Bridge Device<br>1: A Bridge Device | R/W |
| 13 | TBCR5 | SDR Only / SDR and HDR Capable<br>0: SDR only<br>1: HDR Capable | R/W |
| 15:14 | TBCR76[1:0] | Device Role<br>0 0: I3C Slave<br>0 1: I3C Master*4<br>Others: Setting prohibited | R/W |
| 31:16 | — | These bits are read as 0. The write value should be 0. | R/W |

Note: If the security attribution is configured as Secure:
- Secure access and Non-secure read access are allowed
- Non-secure write access is ignored, and TrustZone access error is not generated.

If the security attribution is configured as Non-secure:
- Secure and Non-secure access are allowed.

Note: This register supports I3C secondary master mode and I3C slave mode.
Note 1. Master shall use the GETMXDS CCC to interrogate the Slave for specific limitation.
Note 2. Offline Capable Devices retain the Dynamic Address.
Note 3. Bridge Devices are required to comply with this MIPI Specification for I3C.
Note 4. For an I3C Device acting as I3C Main Master, the BCR Device Role bits will contain the value 01b.

The DCT table captures the Device characteristics (PID, BCR, DCR) and assigned Dynamic Address of each device on the I3C bus that participates in the Dynamic Address Allocation (ENTDAA) procedure.

### TDCR[7:0] bits (Transfer Device Characteristic Register)

Each I3C device that is connected to the I3C bus has an associated Device Characteristics Register (DCR). This register describes the I3C compliant device type such as accelerometer and gyroscope, for use in Dynamic Address assignment and Common Command Codes.

### TBCRn bits (Transfer Bus Characteristic Register)

Each I3C device that is connected to the I3C bus has an associated Bus Characteristics Register (BCR). This register describes the role and capabilities of the I3C compliant device for use in Dynamic Address assignment and Common Command Codes.

When I3C Slave issues IBI by Command Descriptor, the condition of TBCRn is described as follows:

[Slave Interrupt Request : No IBI Payload follow the accepted IBI]

- TBCR1 = 1
- TBCR2 = 0

Note: Set DATA_LENGTH[15:0] of Command Descriptor to 0.

[Slave Interrupt Request : IBI Payload follow the accepted IBI]

- TBCR1 = 1
- TBCR2 = 1

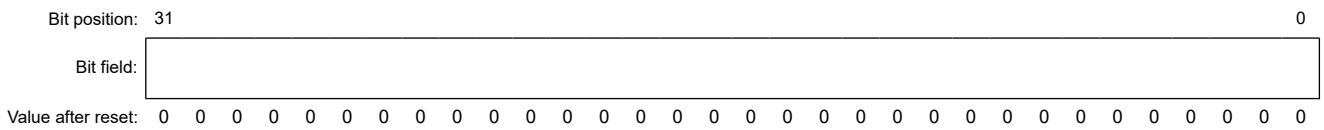
Note: Set DATA_LENGTH[15:0] of Command Descriptor to any value.

[Mastership Request]

- TBCR1 = 1
- TBCR76[1:0] = 01b

[Hot-join Event]

- TBCR1 = 1



When I3C Slave receives CCC from I3C Master, it performs the following operations according to the setting of TBCRn:

- When TBCR2 = 1, CMRLG.IBIPSZ[7:0] is sent as the 3rd byte data to GETMRL CCC from I3C Master
- When TBCR0 = 0, NACK responses to GETMXDS CCC from I3C Master
- When TBCR0 = 1, ACK responses to GETMXDS CCC from I3C Master and sends data from CMDSPW, CMDSPR, and CMDSPT registers

## 29.2.53 SDCTPIDL : Slave Device Characteristic Table Provisional ID Low Register

Base address: I3C = 0x4011_F000

Offset address: 0x324

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 31:0 | n/a | Transfer Device Provisional ID Low<br>Bits 31 to 16 are read as 0.<br>Bits 15 to 0 are bits [15:0] of device's I3C PID. | R/W |

Note: If the security attribution is configured as Secure:
- Secure access and Non-secure read access are allowed
- Non-secure write access is ignored, and TrustZone access error is not generated.

If the security attribution is configured as Non-secure:
- Secure and Non-secure access are allowed.

Note: This register supports I3C secondary master mode and I3C slave mode.

## 29.2.54 SDCTPIDH : Slave Device Characteristic Table Provisional ID High Register

Base address: I3C = 0x4011_F000

Offset address: 0x328

| Bit position: | 31 | | | | | | | | | | | | | | | | | | | | | | | | | | | | | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 31:0 | n/a | Transfer Device Provisional ID High<br>Bits [47:16] of device's I3C PID. | R/W |

Note: If the security attribution is configured as Secure:
- Secure access and Non-secure read access are allowed
- Non-secure write access is ignored, and TrustZone access error is not generated.

If the security attribution is configured as Non-secure:
- Secure and Non-secure access are allowed.

Note: This register supports I3C secondary master mode and I3C slave mode.

## 29.2.55 SVDVAD0 : Slave Device Address Register 0

Base address: I3C = 0x4011_F000

Offset address: 0x330

| Bit position: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | | | | | | | | | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | SDYADV | SSTADV | — | — | SADLG | — | SVAD[9:0] | | | | | | | | | |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit position: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 15:0 | — | These bits are read as 0. | R |
| 25:16 | SVAD[9:0] | Slave Address*1<br>A slave address is set.<br>When rewriting SVAD, change to SVAE0 = 0 and rewrite. | R |
| 26 | — | This bit is read as 0. | R |
| 27 | SADLG | Slave Address Length*2<br>0: The 7-bit address format is selected<br>1: The 10-bit address format is selected | R |
| 29:28 | — | These bits are read as 0. | R |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 30 | SSTADV | Slave Static Address Valid[*1]<br>0: Slave address is disabled<br>1: Slave address is enabled | R |
| 31 | SDYADV[*4] | Slave Dynamic Address Valid[*3]<br>0: Dynamic Address is disabled<br>1: Dynamic Address is enabled | R |

Note: If the security attribution is configured as Secure:
- Secure access and Non-secure read access are allowed
- Non-secure write access is ignored, and TrustZone access error is not generated.

If the security attribution is configured as Non-secure:
- Secure and Non-secure access are allowed.

Note 1. These bits support $I^2C$, I3C secondary master, and I3C slave mode.
Note 2. This bit supports $I^2C$ mode.
Note 3. This bit supports I3C secondary master mode and I3C slave mode.
Note 4. This bit is valid only in SVDVAD0 register.

### SVAD[9:0] bits (Slave Address)

The SVAD[9:0] bits indicate a valid slave address.

[The SVDVAD0.SDYADV bit = 1]

Note: This condition is only for SVDVAD0.SVAD[9:0].

- The SVAD[9:7] bits = 0
- The SVAD[6:0] bits = the SDATBAS0.SDDYAD[6:0] bits.

[The SVDVAD0.SSTADV bit = 1 and the SVDVAD0.SADLG bit = 0]

- The SVAD[9:7] bits = 0
- The SVAD[6:0] bits = the SDATBAS0.SDSTAD[6:0] bits

[The SVDVAD0.SSTADV bit = 1 and the SVDVAD0.SADLG bit = 1]

- The SVAD[9:0] bits = the SDATBAS0.SDSTAD[9:0] bits.

### SADLG bit (Slave Address Length)

[Setting conditions]

- All the followings are satisfied:

1. The PRTS.PRTMD bit = 1 ($I^2C$ Protocol mode).
2. The SVCTL.SVAE0 bit = 1 (slave 0 is enabled).
3. The SDATBAS0.SDADLS bit = 1 (the address length is 10 bits).

[Clearing condition]

- [Setting condition] is not satisfied.

### SSTADV bit (Slave Static Address Valid)

[Setting conditions]

- All the followings are satisfied:

1. The SVCTL.SVAE0 bit = 1 (slave 0 is enabled).
2. The SVDVAD0.SDYADV bit = 0 (dynamic address is disabled).

   Note: This condition is only for SVDVAD0.SSTADV.
3. If the SVDVAD0.SADLG bit = 0, the SDATBAS0.SDSTAD[6:0] bits are not all 0.
   If the SVDVAD0.SADLG bit = 1, the SDATBAS0.SDSTAD[9:0] bits are not all 0.

[Clearing condition]

- [Setting condition] is not satisfied.

**SDYADV bit (Slave Dynamic Address Valid)**

[Setting conditions]

- All the followings are satisfied:

1. The PRTS.PRTMD bit = 0 (I3C Protocol mode).
2. The SVCTL.SVAE0 bit = 1 (Slave 0 is enabled).
3. The SDATBAS0.SDDYAD[6:0] bits are not all 0.

Note: This condition is only for SVDVAD0.SDYADV.

[Clearing condition]

- [Setting condition] is not satisfied.

## 29.2.56 CSECMD : CCC Slave Events Command Register

Base address: I3C = 0x4011_F000

Offset address: 0x350

| Bit position: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit position: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | — | — | — | — | — | — | — | — | — | HJEVE | — | MSRQE | SVIRQE |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 0 | SVIRQE | Slave Interrupt Requests Enable<br>0: DISABLED: Slave-initiated Interrupts is Disabled by the Master to control.<br>1: ENABLED: Slave-initiated Interrupts is Enabled by the Master to control. | R/W |
| 1 | MSRQE | Mastership Requests Enable<br>0: DISABLED: Mastership requests from Secondary Masters is Disabled by the Current Master to control.<br>1: ENABLED: Mastership requests from Secondary Masters is Enabled by the Current Master to control. | R/W |
| 2 | — | This bit is read as 0. The write value should be 0. | R/W |
| 3 | HJEVE | Hot-Join Event Enable<br>0: DISABLED: Slave-initiated Hot-Join is Disabled by the Master to control.<br>1: ENABLED: Slave-initiated Hot-Join is Enabled by the Master to control. | R/W |
| 31:4 | — | These bits are read as 0. The write value should be 0. | R/W |

Note: If the security attribution is configured as Secure:
- Secure access and Non-secure read access are allowed
- Non-secure write access is ignored, and TrustZone access error is not generated.

If the security attribution is configured as Non-secure:
- Secure and Non-secure access are allowed.

Note: This register supports I3C secondary master mode and I3C slave mode.

**SVIRQE bit (Slave Interrupt Requests Enable)**

This bit allows the Master to control when Slave-initiated Interrupts are allowed on the I3C Bus.

These four Direct (ENEC/DISEC Format 1) or Broadcast (ENEC/DISEC Format 2) CCCs allows the Master to control when Slave-initiated traffic is (Enable) vs. is not (Disable) allowed on the I3C Bus. This control governs a Slave's attempts to request an Interrupt (ENI), to request Mastership (ENMR), or to signify a Hot-Join event (ENHJ).

[Setting conditions]

- When writing 1
- When receiving ENEC CCC (Broadcast) with ENINT bit = 1.*1
- When ENINT bit = 1 with own Slave Address in receiving ENEC CCC (Direct).*1

[Clearing conditions]

- When writing 0.
- When receiving DISEC CCC (Broadcast) with DISINT bit = 1.*1
- When DISINT bit = 1 with own Slave Address in receiving DISEC CCC (Direct).*1

#### MSRQE bit (Mastership Requests Enable)

This bit allows the Current Master to control when Mastership requests from Secondary Masters are allowed on the I3C Bus.

[Setting conditions]

- When writing 1.
- When receiving ENEC CCC (Broadcast) with ENMR bit = 1.*1
- When ENMR bit = 1 with own Slave Address in receiving ENEC CCC (Direct).*1

[Clearing conditions]

- When writing 0.
- When receiving DISEC CCC (Broadcast) with DISMR bit = 1.*1
- When DISMR bit = 1 with own Slave Address in receiving DISEC CCC (Direct).*1

#### HJEVE bit (Hot-Join Event Enable)

This bit allows the Master to control when Slave-initiated Hot-Join is allowed on the I3C Bus.

[Setting conditions]

- When writing 1.
- When receiving ENEC CCC (Broadcast) with ENHJ bit = 1.*1
- When ENHJ bit = 1 with own Slave Address in receiving ENEC CCC (Direct).*1

[Clearing conditions]

- When writing 0.
- When receiving DISEC CCC (Broadcast) with DISHJ bit = 1.*1
- When DISHJ bit = 1 with own Slave Address in receiving DISEC CCC (Direct)*1

Note 1. See the MIPI I3C Specification v1.0

## 29.2.57 CEACTST : CCC Enter Activity State Register

Base address: I3C = 0x4011_F000

Offset address: 0x354

| Bit position: | 31 | | | | | | | | | | | | | | | | | | | | | | | | | | 3 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | ACTST[3:0] | |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 3:0 | ACTST[3:0] | Activity State<br>0x1: ENTAS0 (1µs: Latency-free operation)<br>0x2: ENTAS1 (100 µs)<br>0x4: ENTAS2 (2 ms)<br>0x8: ENTAS3 (50 ms: Lowest-activity operation)<br>Others: Setting prohibited | R/W |
| 31:4 | — | These bits are read as 0. The write value should be 0. | R/W |

Note: If the security attribution is configured as Secure:
- Secure access and Non-secure read access are allowed
- Non-secure write access is ignored, and TrustZone access error is not generated.

If the security attribution is configured as Non-secure:
- Secure and Non-secure access are allowed.

Note: This register supports I3C secondary master mode and I3C slave mode.

### ACTST[3:0] bits (Activity State)

[Update conditions]

- When writing Activity State value.
- When receiving ENTAS0 CCC (Broadcast), these bits are updated to 0x1.*1
- When receiving ENTAS1 CCC (Broadcast), these bits are updated to 0x2.*1
- When receiving ENTAS2 CCC (Broadcast), these bits are updated to 0x4.*1
- When receiving ENTAS3 CCC (Broadcast), these bits are updated to 0x8.*1
- When Slave Address value is its own Slave Address in receiving ENTAS0 CCC (Direct), these bits are updated to 0x1.*1
- When Slave Address value is its own Slave Address in receiving ENTAS1 CCC (Direct), these bits are updated to 0x2.*1
- When Slave Address value is its own Slave Address in receiving ENTAS2 CCC (Direct), these bits are updated to 0x4.*1
- When Slave Address value is its own Slave Address in receiving ENTAS3 CCC (Direct), these bits are updated to 0x8.*1

Note 1. See the MIPI I3C Specification v1.0.

## 29.2.58 CMWLG : CCC Max Write Length Register

Base address: I3C = 0x4011_F000

Offset address: 0x358

| Bit position: | 31 | | | | | | | | | | | | | | | 15 | | | | | | | | | | | | | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | MWLG[15:0] | | | | | | | | | | | | | |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 15:0 | MWLG[15:0] | Max Write Length | R/W |
| 31:16 | — | These bits are read as 0. The write value should be 0. | R/W |

Note: If the security attribution is configured as Secure:
- Secure access and Non-secure read access are allowed
- Non-secure write access is ignored, and TrustZone access error is not generated.

If the security attribution is configured as Non-secure:
- Secure and Non-secure access are allowed.

Note: This register supports I3C secondary master mode and I3C slave mode.

### MWLG[15:0] bits (Max Write Length)

These bits use for the I3C Master to set or get a maximum data write length in bytes for one Slave Device.

This Max Write Length does not affect data write lengths for Broadcast CCCs. The Set/Get Max Write Length value is transmitted over two bytes, with the most significant byte (MSB) transmitted first. The minimum value that Max Write Length can be set to is 8.

[Update conditions]

- When writing Max Write Length value.
- When receiving SETMWL CCC (Broadcast), these bits are updated to MWL value.*1
- When Slave Address value is its own Slave Address in receiving SETMWL CCC (Direct), these bits are updated to MWL value.*1

Note 1. See the MIPI I3C Specification v1.0

## 29.2.59 CMRLG : CCC Max Read Length Register

Base address: I3C = 0x4011_F000

Offset address: 0x35C

| Bit position: | 31 | | | | | | | | 23 | | | | | | | | 16 | 15 | | | | | | | | | | | | | | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | — | — | — | — | — | IBIPSZ[7:0] | | | | | | | | | MRLG[15:0] | | | | | | | | | | | | | | |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 15:0 | MRLG[15:0] | Max Read Length | R/W |
| 23:16 | IBIPSZ[7:0] | IBI Payload Size | R/W |
| 31:24 | — | These bits are read as 0. The write value should be 0. | R/W |

Note: If the security attribution is configured as Secure:
- Secure access and Non-secure read access are allowed
- Non-secure write access is ignored, and TrustZone access error is not generated.

If the security attribution is configured as Non-secure:
- Secure and Non-secure access are allowed.

Note: This register supports I3C secondary master mode and I3C slave mode.

### MRLG[15:0] bits (Max Read Length)

These bits use for the I3C Master to set or get a maximum data read length for one Slave Device.

The Set/Get Max Read Length value is transmitted over the first two bytes, with most significant byte (MSB) transmitted first. The minimum value to which Max Read Length can be set is 16.

[Update conditions]

- When writing Max Read Length value.
- When receiving SETMRL CCC (Broadcast), these bits are updated to MRL value.*1
- When Slave Address value is its own Slave Address in receiving SETMRL CCC (Direct), these bits are updated to MRL value.*1

### IBIPSZ[7:0] bits (IBI Payload Size)

These bits use for the I3C Master to set or get optionally a maximum IBI payload size.

For devices with BCR bit 2 set to 1, the Max IBI payload size value is added as a third-byte, where a value of 0 indicates an unlimited payload size. If Timing Control is used, then the minimum IBI payload size is either four bytes or five bytes. If Timing Control is not used, then the minimum IBI payload size is 1 (one byte).

This CCC is optional for the Slave, with two exceptions:

1. This CCC is required if both (a) any private Read Request Message (s) and/or any extended Read Request CCC (s) implemented by the Slave support a variable limit on the maximum number of data bytes that the Slave may return per Message, and (b) this limit is greater than 16 bytes.
2. This CCC is required if the Slave both (a) supports an IBI Payload (as indicated with BCR bit 1), and (b) will transmit more than one byte of private payload (not counting Timing Control bytes, when Timing Control used).

[Update conditions]

- When writing Max IBI payload size value.
- When receiving SETMRL CCC (Broadcast), these bits are updated to IBI payload size value.*1
- When Slave Address value is its own Slave Address in receiving SETMRL CCC (Direct), these bits are updated to IBI payload size value.*1

Note 1. See the MIPI I3C Specification v1.0.

## 29.2.60 CETSTMD : CCC Enter Test Mode Register

Base address: I3C = 0x4011_F000

Offset address: 0x360

| Bit position: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | TSTMD[7:0] | |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 7:0 | TSTMD[7:0] | Test Mode<br>0x00: Exit Test Mode<br>This value removes all I3C devices from Test Mode.<br>0x01: Vendor Test Mode<br>This value indicates that I3C devices shall return a random 32bit value in the provisional ID during the Dynamic Address Assignment procedure.<br>Others: Setting prohibited | R |
| 31:8 | — | These bits are read as 0. | R |

Note: If the security attribution is configured as Secure:
- Secure access and Non-secure read access are allowed
- Non-secure write access is ignored, and TrustZone access error is not generated.

If the security attribution is configured as Non-secure:
- Secure and Non-secure access are allowed.

Note: This register supports I3C secondary master mode and I3C slave mode.

### TSTMD[7:0] bits (Test Mode)

When these bits set to 0x00, all I3C Devices remove from Test Mode.

When these bits set to 0x01, I3C Devices shall return a random 32bit value in the Provisional ID during the Dynamic Address Assignment procedure.

The Broadcast CCC informs all I3C Devices that the Master is entering a specified Test Mode during manufacturing or Device test. The Enter Test Mode command Frame format includes a byte that specifies which Test Mode to enter. Supporting I3C Devices shall enter the indicated Test Mode upon receipt of the Enter Test Mode CCC.

[Update condition]

- When receiving ENTTM CCC (Broadcast), these bits are updated to Test Mode Byte value.*1

Note 1. See the MIPI I3C Specification v1.0.

## 29.2.61 CGDVST : CCC Get Device Status Register

Base address: I3C = 0x4011_F000

Offset address: 0x364

| Bit position: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit position: | 15 | 8 | 7 | 6 | 5 | 4 | 3 | 0 |
|---|---|---|---|---|---|---|---|---|
| Bit field: | VDRSV[7:0] | | ACTMD[1:0] | | PRTE | — | PNDINT[3:0] | |
| Value after reset: | 0 0 0 0 0 0 0 0 | | 0 0 | | 0 | 0 | 0 0 0 0 | |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 3:0 | PNDINT[3:0] | Pending Interrupt<br>Contains the interrupt number of any pending interrupt, or 0 if no interrupts are pending. This encoding allows for up to 15 numbered interrupts. If more than one interrupt is set, then the highest priority interrupt shall be returned. | R/W |
| 4 | — | This bit is read as 0. The write value should be 0. | R/W |
| 5 | PRTE | Protocol Error<br>0: The Slave has not detected a protocol error since the last Status read.<br>1: The Slave has detected a protocol error since the last Status read. | R/W |
| 7:6 | ACTMD[1:0] | Slave Device's current Activity Mode<br>0 0: Activity Mode 0<br>0 1: Activity Mode 1<br>1 0: Activity Mode 2<br>1 1: Activity Mode 3 | R/W |
| 15:8 | VDRSV[7:0] | Vendor Reserved<br>Reserved for vendor-specific meaning | R/W |
| 31:16 | — | These bits are read as 0. The write value should be 0. | R/W |

Note: If the security attribution is configured as Secure:
- Secure access and Non-secure read access are allowed
- Non-secure write access is ignored, and TrustZone access error is not generated.

If the security attribution is configured as Non-secure:
- Secure and Non-secure access are allowed.

Note: This register supports I3C secondary master mode and I3C slave mode.

### PRTE bit (Protocol Error)

If this bit set to 1, then the Slave detects a protocol error since the last Status read.

The Slave checks for such errors. Note that this value self-clears by the hardware upon every successful completion of a Master read of the Slave's Status.

The Direct CCC is a Get request for one I3C Slave Device to return its current Status, in the two-byte format detailed. Note that byte 0 is the LSB, and byte 1 is the MSB.

[Setting condition]

- When the Slave detected a protocol error.*1

[Clearing condition]

- When transmission by own Slave Address is completed without error after receiving GETSTATUS CCC (Direct).*1

**ACTMD[1:0] bits (Slave Device's current Activity Mode)**

Contains the two-bit ID of the Slave Device's current Activity Mode (readiness to support data read of sensor or related information).

Note 1. See the MIPI I3C Specification v1.0.

## 29.2.62 CMDSPW : CCC Max Data Speed W (Write) Register

Base address: I3C = 0x4011_F000

Offset address: 0x368

| Bit position: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit position: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | — | — | — | — | — | — | — | — | — | — | MSWDR[2:0] | | |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 2:0 | MSWDR[2:0] | Maximum Sustained Write Data Rate<br>0 0 0: fscl Max (default value)<br>0 0 1: 8 MHz<br>0 1 0: 6 MHz<br>0 1 1: 4 MHz<br>1 0 0: 2 MHz<br>Others: Setting prohibited | R/W |
| 31:3 | — | These bits are read as 0. The write value should be 0. | R/W |

Note: If the security attribution is configured as Secure:
- Secure access and Non-secure read access are allowed
- Non-secure write access is ignored, and TrustZone access error is not generated.

If the security attribution is configured as Non-secure:
- Secure and Non-secure access are allowed.

Note: This register supports I3C secondary master mode and I3C slave mode.

## 29.2.63 CMDSPR : CCC Max Data Speed R (Read) Register

Base address: I3C = 0x4011_F000

Offset address: 0x36C

| Bit position: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit position: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | | 3 | 2 | | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | — | — | — | — | — | — | — | CDTTIM[2:0] | | | MSRDR[2:0] | | |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 2:0 | MSRDR[2:0] | Maximum Sustained Read Data Rate<br>0 0 0: fscl Max (default value)<br>0 0 1: 8 MHz<br>0 1 0: 6 MHz<br>0 1 1: 4 MHz<br>1 0 0: 2 MHz<br>Others: Setting prohibited | R/W |
| 5:3 | CDTTIM[2:0] | Clock to Data Turnaround Time (TSCO)<br>0 0 0: 8 ns or less (default value)<br>0 0 1: 9 ns or less<br>0 1 0: 10 ns or less<br>0 1 1: 11 ns or less<br>1 0 0: 12 ns or less<br>1 1 1: TSCO is more than 12 ns, and is reported by private agreement.<br>Others Setting prohibited | R/W |
| 31:6 | — | These bits are read as 0. The write value should be 0. | R/W |

Note: If the security attribution is configured as Secure:
- Secure access and Non-secure read access are allowed
- Non-secure write access is ignored, and TrustZone access error is not generated.

If the security attribution is configured as Non-secure:
- Secure and Non-secure access are allowed.

Note: This register supports I3C secondary master mode and I3C slave mode.

## 29.2.64 CMDSPT : CCC Max Data Speed T (Turnaround) Register

Base address: I3C = 0x4011_F000

Offset address: 0x370

| Bit position: | 31 | | | | | | | | 23 | | | | | | | | | | | | | | | | | | | | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | MRTE | — | — | — | — | — | — | — | MRTTIM[23:0] | | | | | | | | | | | | | | | | | | | | |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 23:0 | MRTTIM[23:0] | Maximum Read Turnaround Time<br>24-bit field can encode turnaround times from 0.0 seconds to 16 seconds.<br>0x000000: 0 µs (minimum value)<br>0x000001: 1 µs (resolution)<br>⋮<br>0xF42400: 16 seconds (maximum value)<br>Others: Setting prohibited | R/W |
| 30:24 | — | These bits are read as 0. The write value should be 0. | R/W |
| 31 | MRTE | Maximum Read Turnaround Time Enable<br>0: Disables transmission of the Maximum Read Turnaround Time. (GETMXDS Format 1: Without Turnaround)<br>1: Enables transmission of the Maximum Read Turnaround Time. (GETMXDS Format 2: With Turnaround) | R/W |

Note: If the security attribution is configured as Secure:
- Secure access and Non-secure read access are allowed
- Non-secure write access is ignored, and TrustZone access error is not generated.

If the security attribution is configured as Non-secure:
- Secure and Non-secure access are allowed.

Note: This register supports I3C secondary master mode and I3C slave mode.

## 29.2.65 CETSM : CCC Exchange Timing Support Information M (Mode) Register

Base address: I3C = 0x4011_F000

Offset address: 0x374

| Bit position: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | — | — | — | — | — | INAC[7:0] | | | | | | | | FREQ[7:0] | | | | | | | | — | — | — | — | — | — | — | — |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 7:0 | — | These bits are read as 0. The write value should be 0. | R/W |
| 15:8 | FREQ[7:0] | Frequency Byte<br>This byte represents the Slave's internal oscillator frequency in increments of 0.5 MHz (500 kHz), up to 127.5 MHz.<br>0x00: 32.0 kHz<br>0x01: 0.5 MHz<br>0x02: 1.0 MHz<br>⋮<br>0xFD: 126.5 MHz<br>0xFE: 127.0 MHz<br>0xFF: 127.5 MHz | R/W |
| 23:16 | INAC[7:0] | Inaccuracy Byte<br>This byte represents the maximum variation of the Slave's internal oscillator in 1/10th percent (0.1%) increments, up to 25.5%.<br>0x00: 0.0%<br>0x01: 0.1%<br>0x02: 0.2%<br>⋮<br>0xFD: 25.3%<br>0xFE: 25.4%<br>0xFF: 25.5% | R/W |
| 31:24 | — | These bits are read as 0. The write value should be 0. | R/W |

Note: If the security attribution is configured as Secure:
- Secure access and Non-secure read access are allowed
- Non-secure write access is ignored, and TrustZone access error is not generated.

If the security attribution is configured as Non-secure:
- Secure and Non-secure access are allowed.

Note: This register supports I3C secondary master mode and I3C slave mode.

## 29.2.66 CGHDRCAP : CCC Get HDR Capability Register

Base address: I3C = 0x4011_F000

Offset address: 0x37C

| Bit position: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | DDREN |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 0 | DDREN | HDR-DDR Operation Enable<br>0: HDR-DDR Operation is Disabled.<br>1: HDR-DDR Operation is Enabled. | R/W |
| 31:1 | — | These bits are read as 0. The write value should be 0. | R |

Note: If the security attribution is configured as Secure:
- Secure access and Non-secure read access are allowed
- Non-secure write access is ignored, and TrustZone access error is not generated.

If the security attribution is configured as Non-secure:

- Secure and Non-secure access are allowed.

Note: This register supports for I3C secondary master mode and I3C slave mode.

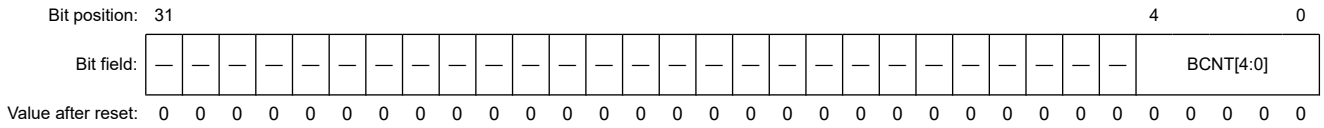
### DDREN bit (HDR-DDR Operation Enable)

This bit is used to enable or disable the HDR-DDR communication when used with I3C Slave.

HDR-DDR communication is permitted only when SVDCT.TBCR5 = 1 and DDREN = 1.

[Setting condition]

- When writing 1.



[Clearing condition]

- When writing 0.

## 29.2.67 BITCNT : Bit Count Register

Base address: I3C = 0x4011_F000

Offset address: 0x380

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 4:0 | BCNT[4:0] | Bit Counter<br>Indicates the number of bits remaining to be transferred.<br>For details on the values, see Table 29.7 and Table 29.8. | R |
| 31:5 | — | These bits are read as 0. | R |

Note: If the security attribution is configured as Secure:
- Secure access and Non-secure read access are allowed
- Non-secure write access is ignored, and TrustZone access error is not generated.

If the security attribution is configured as Non-secure:
- Secure and Non-secure access are allowed.

### BCNT[4:0] bits (Bit Counter)

These bits function as a counter that indicates the number of bits remaining to be transferred at the detection of a sampling edge on the I3C_SCL line.

**Table 29.7 I²C / Legacy I²C transfer**

| BCNT[4:0] | Master | | Slave | |
|---|---|---|---|---|
| | Address phase | Data phase | Address phase | Data phase |
| 0x00 | 2 to 1 bits | 2 to 1 bits | 3 to 1 bits | 2 to 1 bits |
| 0x01 | 3 bits | 3 bits | 4 bits | 3 bits |
| 0x02 | 4 bits | 4 bits | 5 bits | 4 bits |
| 0x03 | 5 bits | 5 bits | 6 bits | 5 bits |
| 0x04 | 6 bits | 6 bits | 7 bits | 6 bits |
| 0x05 | 7 bits | 7 bits | 8 bits | 7 bits |
| 0x06 | 8 bits | 8 bits | 9 bits | 8 bits |
| 0x07 | 9 bits | 9 bits | — | 9 bits |

**Table 29.8 I3C transfer**

| BCNT[4:0] | SDR*1 | | HDR-DDR | |
|---|---|---|---|---|
| | Transmission | Reception | Command/Data | CRC |
| 0x00 | 1 bit | 2 to 1 bits | 19, 1 bits | 11, 1 bits |
| 0x01 | 2 bits | 3 bits | 20, 2 bits | 12, 2 bits |
| 0x02 | 3 bits | 4 bits | 3 bits | 3 bits |
| 0x03 | 4 bits | 5 bits | 4 bits | 4 bits |
| 0x04 | 5 bits | 6 bits | 5 bits | 5 bits |
| 0x05 | 6 bits | 7 bits | 6 bits | 6 bits |
| 0x06 | 7 bits | 8 bits | 7 bits | 7 bits |
| 0x07 | 8 bits | 9 bits | 8 bits | 8 bits |
| 0x08 | 9 bits | — | 9 bits | 9 bits |
| 0x09 | — | — | 10 bits | 10 bits |
| 0x0A | — | — | 11 bits | — |
| 0x0B | — | — | 12 bits | — |
| 0x0C | — | — | 13 bits | — |
| 0x0D | — | — | 14 bits | — |
| 0x0E | — | — | 15 bits | — |
| 0x0F | — | — | 16 bits | — |
| 0x10 | — | — | 17 bits | — |
| 0x11 | — | — | 18 bits | — |

Note 1. The address phase is the same as in Table 29.7.

## 29.2.68 NQSTLV : Normal Queue Status Level Register

Base address: I3C = 0x4011_F000

Offset address: 0x394

| Bit position: | 31 | 30 | 29 | 28 | 24 | 23 | 16 | 15 | 8 | 7 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | IBISCNT[4:0] | | IBIQLV[7:0] | | RSPQLV[7:0] | | CMDQFLV[7:0] | |
| Value after reset: | 0 | 0 | 0 | 0 | 0 0 0 0 0 0 0 0 | | 0 0 0 0 0 0 0 0 | | 0 0 0 0 0 1 0 0 | | |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 7:0 | CMDQFLV[7:0] | Normal Command Queue Free Level*1<br>Number of free buffer entries currently in the Normal Command Queue.<br>Reset value is the depth of the Normal Command Queue. | R |
| 15:8 | RSPQLV[7:0] | Normal Response Queue Level*1<br>Number of buffer entries currently in the Normal Response Queue. | R |
| 23:16 | IBIQLV[7:0] | Normal IBI Queue Level*1<br>Number of buffer entries currently in the Normal IBI Queue. | R |
| 28:24 | IBISCNT[4:0] | Normal IBI Status Count*2<br>Number of IBI Status entries currently in the Normal IBI Queue. | R |
| 31:29 | — | These bits are read as 0. | R |

Note: If the security attribution is configured as Secure:
- Secure access and Non-secure read access are allowed
- Non-secure write access is ignored, and TrustZone access error is not generated.

If the security attribution is configured as Non-secure:
- Secure and Non-secure access are allowed.

Note 1. These bits support all I3C mode.
Note 2. These bits support I3C master mode and I3C secondary master mode.

## 29.2.69 NDBSTLV0 : Normal Data Buffer Status Level Register 0

Base address: I3C = 0x4011_F000

Offset address: 0x398

| Bit position: | 31 | | | | | | | | | | | | | | | | 15 | | | | | | | 8 | 7 | | | | | | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | RDBLV[7:0] | | | | | | | | TDBFLV[7:0] | | | | | | | |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 1 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 7:0 | TDBFLV[7:0] | Normal Tx Data Buffer Free Level<br>Indicates the number of free Tx Data Buffer entries in the Tx Data Queue.<br>Reset value is the depth of the Tx Data Queue. | R |
| 15:8 | RDBLV[7:0] | Normal Rx Data Buffer Level<br>Indicates the number of Rx Data Buffer entries in the Rx Data Queue. | R |
| 31:16 | — | These bits are read as 0. | R |

Note: If the security attribution is configured as Secure:
- Secure access and Non-secure read access are allowed
- Non-secure write access is ignored, and TrustZone access error is not generated.

If the security attribution is configured as Non-secure:
- Secure and Non-secure access are allowed.

Note: This register supports all I3C mode.

## 29.2.70 NRSQSTLV : Normal Receive Status Queue Status Level Register

Base address: I3C = 0x4011_F000

Offset address: 0x3C0

| Bit position: | 31 | | | | | | | | | | | | | | | | | | | | | | | | 7 | | | | | | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | RSQLV[7:0] | | | | | | | |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 7:0 | RSQLV[7:0] | Normal Receive Status Queue Level | R |
| 31:8 | — | These bits are read as 0. | R |

Note: If the security attribution is configured as Secure:
- Secure access and Non-secure read access are allowed
- Non-secure write access is ignored, and TrustZone access error is not generated.

If the security attribution is configured as Non-secure:
- Secure and Non-secure access are allowed.

Note: This register supports I3C secondary master mode and I3C slave mode.

## 29.2.71 PRSTDBG : Present State Debug Register

Base address: I3C = 0x4011_F000

Offset address: 0x3CC

| Bit position: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit position: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | — | — | — | — | — | — | — | — | — | SDOLV | SCOLV | SDILV | SCILV |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 1 | 1 | 1 | 1 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 0 | SCILV | I3C_SCL Line Signal Level<br>This bit is used to check the I3C_SCL Line level, in order to recover from errors and for debugging. | R |
| 1 | SDILV | I3C_SDA Line Signal Level<br>This bit is used to check the I3C_SDA Line level, in order to recover from errors and for debugging. | R |
| 2 | SCOLV | SCL Output Level<br>0: I3C has driven the I3C_SCL pin low.<br>1: I3C has released the I3C_SCL pin. | R |
| 3 | SDOLV | SDA Output Level<br>0: I3C has driven the I3C_SDA pin low.<br>1: I3C has released the I3C_SDA pin. | R |
| 31:4 | — | These bits are read as 0. | R |

Note: If the security attribution is configured as Secure:
- Secure access and Non-secure read access are allowed
- Non-secure write access is ignored, and TrustZone access error is not generated.

If the security attribution is configured as Non-secure:
- Secure and Non-secure access are allowed.

### SCILV bit (I3C_SCL Line Signal Level)

This bit is used to check the I3C_SCL Line level, in order to recover from errors and for debugging.

### SDILV bit (I3C_SDA Line Signal Level)

This bit is used to check the I3C_SDA Line level, in order to recover from errors and for debugging.

### SCOLV bit (SCL Output Level)

This bit is used to select the output level of I3C_SCL pin.

### SDOLV bit (SDA Output Level)

This bit is used to select the output level of I3C_SDA pin.

## 29.2.72 MSERRCNT : Master Error Counters Register

Base address: I3C = 0x4011_F000

Offset address: 0x3D0

| Bit position: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | M2ECNT[7:0] | | | | | | | |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 7:0 | M2ECNT[7:0] | M2 Error Counter<br>Counts I3C Type M2 errors on the I3C Bus.<br>Cleared upon read out. | R |
| 31:8 | — | These bits are read as 0. | R |

Note: If the security attribution is configured as Secure:
- Secure access and Non-secure read access are allowed
- Non-secure write access is ignored, and TrustZone access error is not generated.

If the security attribution is configured as Non-secure:
- Secure and Non-secure access are allowed.

Note: This register supports I3C master mode and I3C secondary master mode.

## 29.3 Operation

### 29.3.1 Data Structures

#### 29.3.1.1 Command Descriptor

The write-only Command Descriptor structure is 64 bits in length. The Command Descriptor is put to the Command Queue with writes to the Command Queue Port.

Write to the Command Queue Port in the following order:

1. First write : The least significant DWORD (Command Descriptor Structure Low).
2. Second write : The most significant DWORD (Command Descriptor Structure High).

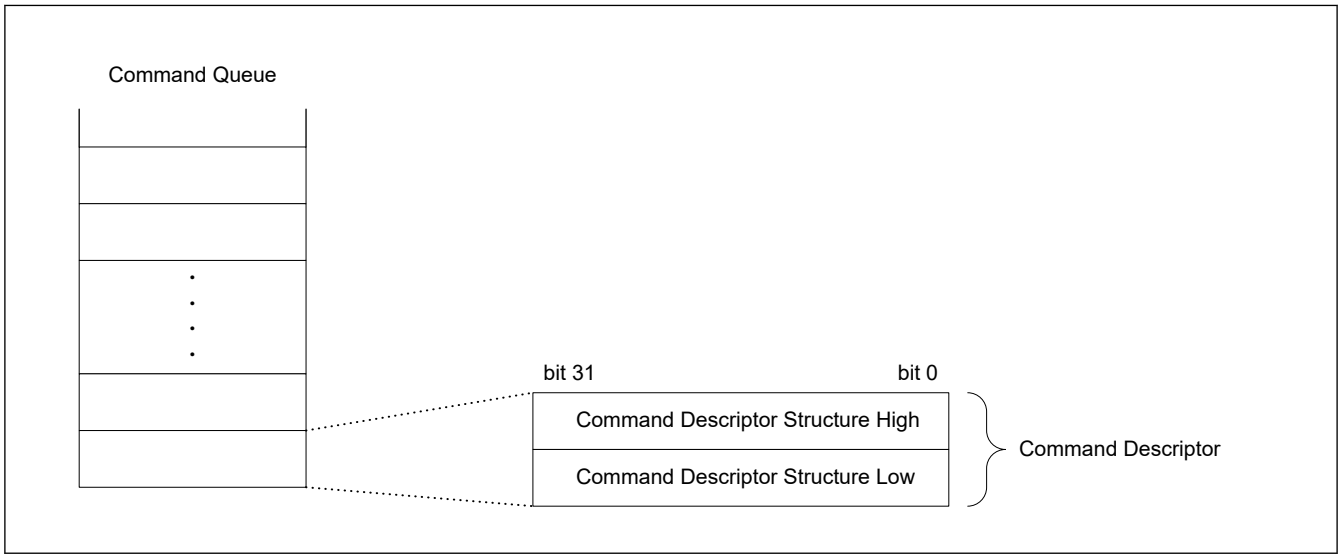


**Figure 29.2 Command descriptor data structure**

I3C provides a Command Descriptor structure for each command type as follows:

- Address Assign Command
- Immediate Transfer Command
- Regular Transfer Command
- Combo Transfer Command
- Internal Control Command

Details are explained in the following sections.

##### 29.3.1.1.1 Address Assign Command

This command is used for address assignment (ENTDAA, SETDASA).

Note: When issuing SETAASA CCC, use the Immediate Transfer command.

The I3C provides an address assign command for the following mode:

- I3C Master mode

Details of the Address Assign command structure are as follows.

| Bit position: | 63 | 62 | 61 | 60 | 59 | 58 | 57 | 56 | 55 | 54 | 53 | 52 | 51 | 50 | 49 | 48 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit position: | 47 | 46 | 45 | 44 | 43 | 42 | 41 | 40 | 39 | 38 | 37 | 36 | 35 | 34 | 33 | 32 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit position: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 2:0 | CMD_ATTR[2:0] | Command Attributes<br>0x0: XFER: Regular Transfer<br>0x1: IMMED_DATA_XFER: Immediate Data Transfer<br>0x2: ADDR_ASSGN_CMD: Address Assignment Command<br>0x3: WWR_COMBO_XFER: Write + Write/Read Combo Transfer<br>0x7: INTERNAL_CONTROL: Internal Control command<br>Others: Setting prohibited | W |
| 6:3 | TID[3:0] | Transaction ID | W |
| 14:7 | CMD[7:0] | Transfer Command CCC Value | W |
| 15 | — | The write value should be 0. | W |
| 20:16 | DEV_INDEX[4:0] | Device Index | W |
| 21 | EXT_DEVICE | Extended Device Index<br>0: Use the DATBASm table indicated by DEV_INDEX[4:0].<br>1: Use the EXDATBAS table. | W |
| 25:22 | — | The write value should be 0. | W |
| 29:26 | DEV_COUNT[3:0] | Device Count | W |
| 30 | ROC | Response on Completion<br>0: NOT_REQUIRED: Response Status is not required.<br>1: REQUIRED: Response Status is required. | W |
| 31 | TOC | Terminate on Completion<br>0: RESTART: Issue Repeated START (Sr) at end of transfer<br>1: STOP: Issue STOP (P) at end of transfer | W |
| 63:32 | — | The write value should be 0. | W |

### CMD_ATTR[2:0] bits (Command Attributes)

Command Type, defining the format of the other fields.

#### TID[3:0] bits (Transaction ID)

Used as an identification tag for this command. This field shall be populated by the software Driver, and the same value shall be reflected in the Response Descriptor.

#### CMD[7:0] bits (Transfer Command CCC Value)

Specifies CCC code indicating whether Address Assignment uses ENTDAA or SETDASA commands. The field comprises the entire command code (ENTDAA or SETDASA).

#### DEV_INDEX[4:0] bits (Device Index)

Indicates the DATBASm table index for the Slave device being addressed with the transfer. Static and device addressing related information are stored to this index in the DATBASm.

#### DEV_COUNT[3:0] bits (Device Count)

Indicates the number of devices that a dynamic address is assigned to.

#### ROC bit (Response on Completion)

Controls whether Response Status is sent after successful completion of the Transfer command. The successful completion is read from register NRSPQP. Upon unsuccessful transfer the Response Status is sent.

#### TOC bit (Terminate on Completion)

Controls what bus condition to issue after the Transfer command completes.

For ENTDAA, a STOP condition is issued regardless of the setting value of TOC. It is meaningful for SETDASA transfers.

When sending SETDASA CCC by TOC = 0 (RESTART), the next command must be set to SETDASA CCC with the Address Assign Command.

When the next command is not the same SETDASA CCC flame, it must be set to TOC = 1 (STOP).

### 29.3.1.1.2 Immediate Transfer Command

This structure directly contains data (max 4 bytes) to be transferred, and as a result is only useful for Transfers/CCCs that write data. This structure should not be used for read operations (for example, to Rx data).

When transmitting data of 4 bytes or less, use this Immediate Transfer Command to communicate.

When transmitting data of 5 bytes or more, use the Regular Transfer Command to communicate.

For the Regular Transfer Command, see section 29.3.1.1.3. Regular Transfer Command.

I3C provides an Immediate Transfer Command for the following mode:

- I3C Master mode

Details of the Immediate Transfer Command Structure of each mode are shown in this section.

| Bit position: | 63 | 62 | 61 | 60 | 59 | 58 | 57 | 56 | 55 | 54 | 53 | 52 | 51 | 50 | 49 | 48 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | DATA_BYTE_4[7:0] | | | | | | | | DATA_BYTE_3[7:0] | | | | | | | |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit position: | 47 | 46 | 45 | 44 | 43 | 42 | 41 | 40 | 39 | 38 | 37 | 36 | 35 | 34 | 33 | 32 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | DATA_BYTE_2[7:0] | | | | | | | | DATA_BYTE_1[7:0] | | | | | | | |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit position: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | TOC | ROC | RNW | MODE[2:0] | | | BYTE_CNT[2:0] | | | — | EXT_DEVICE | DEV_INDEX[4:0] | | | | |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit position: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | CP | CMD[7:0] | | | | | | | | TID[3:0] | | | | CMD_ATTR[2:0] | | |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| 31 | TOC | Immediate Data Transfer Terminate on Completion<br>0: RESTART: Issue Repeated START (Sr) at end of data transfer<br>1: STOP: Issue STOP (P) at end of data transfer | W |
| 39:32 | DATA_BYTE_1[7:0] | Immediate Data Transfer Data Byte 1 Direct argument | W |
| 47:40 | DATA_BYTE_2[7:0] | Immediate Data Transfer Data Byte 2 Direct argument | W |
| 55:48 | DATA_BYTE_3[7:0] | Immediate Data Transfer Data Byte 3 Direct argument | W |
| 63:56 | DATA_BYTE_4[7:0] | Immediate Data Transfer Data Byte 4 Direct argument | W |

#### CMD_ATTR[2:0] bits (Immediate Data Transfer Command Attribute)

Command Type, defining the format of the other fields.

#### TID[3:0] bits (Immediate Data Transfer Transaction ID)

Used as an identification tag for this command. This field should be populated by the software driver, and the same value should be reflected in the Response Descriptor.

#### CP bit (Immediate Data Transfer Command Present)

Indicates whether CMD field is valid for CCC or HDR Transfer.

#### DEV_INDEX[4:0] bits (Immediate Data Transfer Device Index)

Indicates the DATBASm Table index for the Slave Device being addressed with the transfer. Static and Device addressing related information are stored to this index in the DATBASm.

#### BYTE_CNT[2:0] bits (Immediate Data Transfer Byte Count)

Number of valid data bytes to use in this Immediate Data Transfer Descriptor.

This field must be set to non-zero value, except for CCCs that does not have payload defined.

This field must be set to even value, when specifying HDR mode (MODE[2:0] = 0x6).

#### MODE[2:0] bits (Immediate Data Transfer Mode and Speed Values)

Sets the mode and speed for the I3C or $I^2C$ transfer.

Interpretation of this field depends on whether the device is in I3C mode or $I^2C$ mode (see the DEVICE field in the DATBASm Table entry indexed by field DEV_INDEX).

#### RNW bit (Immediate Data Transfer R/W)

Identifies direction of the transfer.

This field should always be set to 0, because Immediate transfers are valid for Write transactions only.

#### ROC bit (Immediate Data Transfer Response on Completion)

Controls whether Response Status is required after successful completion of the data transfer command. The successful completion shall be read from NRSPQP register. Upon unsuccessful transfer, the Response Status should always be sent.

#### TOC bit (Immediate Data Transfer Terminate on Completion)

Controls what Bus condition is issued after completion of the data transfer.

When sending Direct CCC by TOC = 0 (RESTART), next command must be set to same Direct CCC.

When the next command is not the same Direct CCC, must be set to TOC = 1 (STOP).

### 29.3.1.1.3 Regular Transfer Command

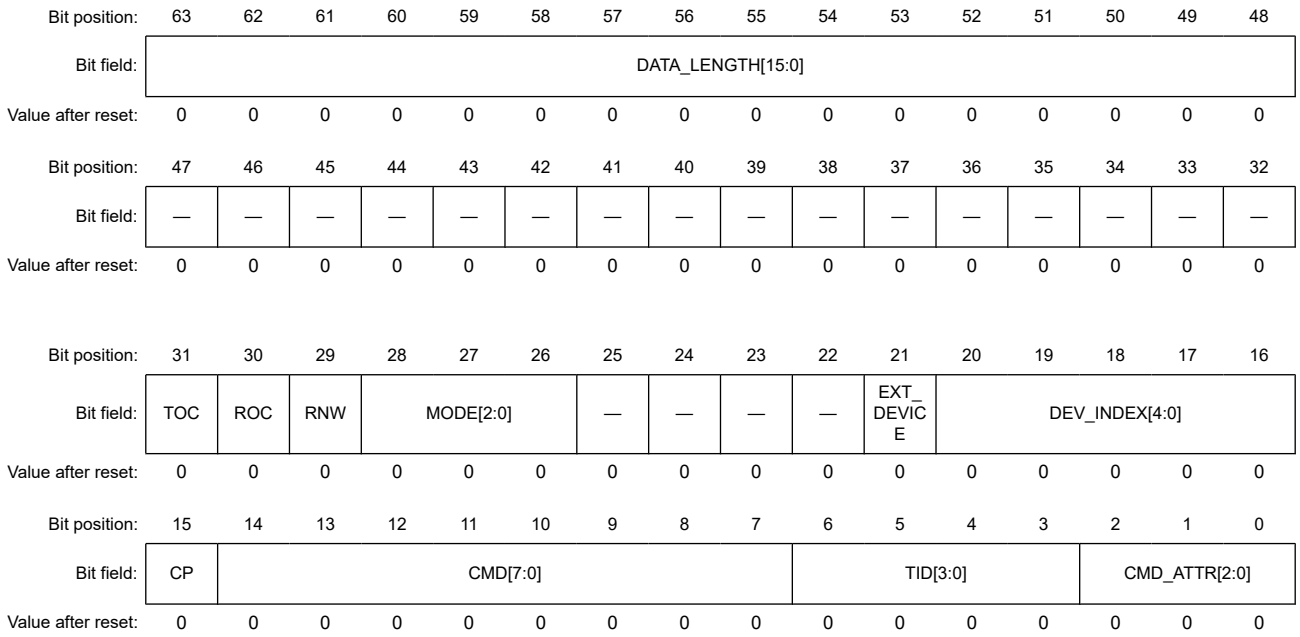
This structure does not contain data to be transferred.

For Master mode, the data buffer is available through Transfer Data Queue Port (Rx Data Queue Port and Tx Data Queue Port).

When transmitting data of 5 bytes or more, use this Regular Transfer Command to communicate.

When transmitting data of 4 bytes or less, use the Immediate Transfer Command to communicate.

For the Immediate Transfer Command, see section 29.3.1.1.2. Immediate Transfer Command.



For I3C Slave mode, the IBI Payload buffer is available through IBI Queue Port.

I3C provides a Regular Transfer Command for the following modes:

- I3C Master mode
- I3C Slave mode

Details of the regular transfer command structure of each mode are as follows.

### (1) I3C Master mode

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 2:0 | CMD_ATTR[2:0] | Data Transfer Command Attribute<br>Command Type, defining the format of the other fields.<br>Values:<br>0x0: XFER: Regular Transfer<br>0x1: IMMED_DATA_XFER: Immediate Data Transfer<br>0x2: ADDR_ASSGN_CMD: Address Assignment Command<br>0x3: WWR_COMBO_XFER: Write + Write/Read Combo Transfer<br>0x7: INTERNAL_CONTROL: Internal Control command<br>Others: Setting prohibited | W |
| 6:3 | TID[3:0] | Data Transfer Transaction ID<br>Identification tag for this command | W |
| 14:7 | CMD[7:0] | Data Transfer CCC / HDR Command Code Value<br>Specifies the I3C Command code<br>For CCC: 8 bits<br>For HDR: 7 bits | W |
| 15 | CP | Data Transfer Command Present<br>0: TRANSFER: This structure describes an SDR transfer, so the CMD field is not valid<br>1: CCC_HDR: This structure describes a CCC or HDR transfer, so the CMD field is valid | W |
| 20:16 | DEV_INDEX[4:0] | Data Transfer Device Index | W |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 21 | EXT_DEVICE | Data Transfer Extended Device Index<br>0: Use the DATBASm table indicated by DEV_INDEX[4:0]<br>1: Use the EXDATBAS table | W |
| 25:22 | — | The write value should be 0. | W |
| 28:26 | MODE[2:0] | Data Transfer Speed and Mode<br>0x0: I3C SDR0 / Data rate : STDBR (I3C mode)<br>Legacy $I^2C$ Message 0 / Data rate : STDBR ($I^2C$ mode)<br>0x1: I3C SDR1 / Data rate : EXTBR (I3C mode)<br>Legacy $I^2C$ Message 0 / Data rate : EXTBR (I2C mode)<br>0x2: I3C SDR2 / Data rate : STDBR × 2 (I3C mode)<br>Reserved ($I^2C$ mode)<br>0x3: I3C SDR3 / Data rate : EXTBR × 2 (I3C mode)<br>Reserved ($I^2C$ mode)<br>0x4: I3C SDR4 / Data rate : EXTBR × 4 (I3C mode)<br>Reserved ($I^2C$ mode)<br>0x6: I3C HDR-DDR / Data rate : STDBR (I3C mode)<br>Reserved ($I^2C$ mode)<br>Others: Setting prohibited | W |
| 29 | RNW | Data Transfer R/W<br>0: WRITE: Write transfer<br>1: READ: Read transfer | W |
| 30 | ROC | Data Transfer Response on Completion<br>0: NOT_REQUIRED: Response Status is not required<br>1: REQUIRED: Response Status is required | W |
| 31 | TOC | Data Transfer Terminate on Completion<br>0: RESTART: Issue Repeated START (Sr) at end of transfer<br>1: STOP: Issue STOP (P) at end of transfer | W |
| 47:32 | — | The write value should be 0. | W |
| 63:48 | DATA_LENGTH [15:0] | Data Transfer Data Length<br>Indicates the number of bytes to be transferred.<br>This field must be set to non-zero value, except for CCCs that does not have payload defined. | W |

### CMD_ATTR[2:0] bits (Data Transfer Command Attribute)

Command Type, defining the format of the other fields.

### TID[3:0] bits (Data Transfer Transaction ID)

Used as an identification tag for this command. This field is populated by the software driver, and the same value is reflected in the Response Descriptor.

### CP bit (Data Transfer Command Present)

Indicates whether the contents of the CMD field is valid for a CCC or HDR Transfer.

### DEV_INDEX[4:0] bits (Data Transfer Device Index)

Indicates the DATBASm Table index for the slave device being addressed with the transfer. Static and Device addressing related information are stored to this index in the DATBASm.

### MODE[2:0] bits (Data Transfer Speed and Mode)

Sets the mode and speed for the I3C or $I^2C$ transfer.

Interpretation of this field depends on whether the Device is in I3C mode vs. $I^2C$ mode (see the DEVICE field in the DATBASm Table entry indexed by field DEV_INDEX).

### RNW bit (Data Transfer R/W)

Identifies direction of the transfer.

### ROC bit (Data Transfer Response on Completion)

Controls whether Response Status is required after successful completion of the transfer command. The successful completion is read from NRSPQP register. Upon unsuccessful transfer the Response Status shall always be sent.

### TOC bit (Data Transfer Terminate on Completion)

Controls what Bus condition is issued after completion of the transfer.

When sending Direct CCC by TOC = 0 (RESTART), next command must be set to same Direct CCC.

When the next command is not the same Direct CCC, must be set to TOC = 1 (STOP).

### DATA_LENGTH[15:0] bits (Data Transfer Data Length)

Number of valid data bytes to use in this Regular Transfer Descriptor.

This field must be set to non-zero value, except for CCCs that does not have payload defined.

This field must be set to even value, when specifying HDR mode (MODE[2:0] = 0x6).

Length setting of GETMXDS command should be fixed to 5.

## (2) I3C Slave mode

| Bit position: | 63 | 62 | 61 | 60 | 59 | 58 | 57 | 56 | 55 | 54 | 53 | 52 | 51 | 50 | 49 | 48 |

| 47:31 | — | The write value should be 0. | W |
| 63:48 | DATA_LENGTH [15:0] | Data Transfer Data Length<br>Indicates the number of bytes to be transferred.<br>This field must be set to non-zero value, except for CCCs that does not have payload defined. | W |

#### CMD_ATTR[2:0] bits (Data Transfer Command Attribute)

Command Type, defining the format of the other fields.

#### TID[3:0] bits (Data Transfer Transaction ID)

Used as an identification tag for this command. This field is populated by the software driver, and the same value is reflected in the Response Descriptor.

#### HJ bit (Data Transfer Hot-Join Event)

Indicates whether Hot-Join Event is valid in this IBI Data transfer.

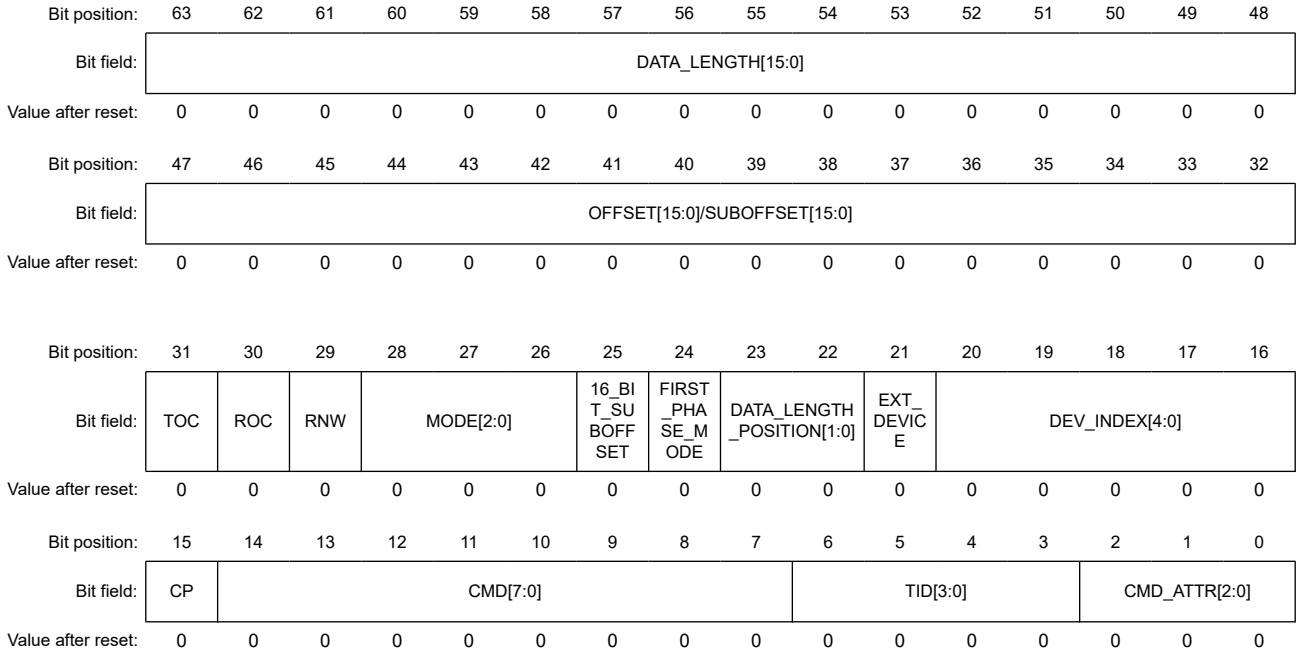
#### RNW bit (Data Transfer R/W)

Identifies direction of the transfer.

#### ROC bit (Data Transfer Response on Completion)

Controls whether Response Status is required after successful completion of the transfer command. The successful completion is read from NRSPQP register. Upon unsuccessful transfer, the Response Status is always sent.

### 29.3.1.1.4 Combo Transfer Command



This structure contains a combined Write + Read/Write operation.

The data buffer is available through Transfer Data Queue Port (Rx Data Queue Port and Tx Data Queue Port).

I3C provides a Combo Transfer Command for the following mode:

- I3C Master mode

Details of the Combo Transfer Command Structure of each mode are as follows.

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 2:0 | CMD_ATTR[2:0] | Combo Transfer Command Attribute<br>Command Type, defining the format of the other fields.<br>0x0: XFER: Regular Transfer<br>0x1: IMMED_DATA_XFER: Immediate Data Transfer<br>0x2: ADDR_ASSGN_CMD: Address Assignment Command<br>0x3: WWR_COMBO_XFER: Write + Write/Read Combo Transfer<br>0x7: INTERNAL_CONTROL: Internal Control command<br>Others: Setting prohibited | W |
| 6:3 | TID[3:0] | Combo Transfer Transaction ID<br>Identification tag for the command | W |
| 14:7 | CMD[7:0] | Combo Transfer HDR Command Code Value<br>Specifies the I3C Command code (7 bits). | W |
| 15 | CP | Combo Transfer Command Present<br>Indicates whether the CMD field is valid for an HDR Transfer<br>0: TRANSFER: This structure describes an SDR transfer, so the CMD field is not valid<br>1: CCC_HDR: This structure describes an HDR transfer, so the CMD field is valid | W |
| 20:16 | DEV_INDEX[4:0] | Combo Transfer Device Index | W |

| 47:32 | OFFSET[15:0]/ SUBOFFSET[15:0] | Combo Transfer Offset/Sub-Offset Offset of the target operation | W |
| 63:48 | DATA_LENGTH [15:0] | Combo Transfer Data Length<br>Number of bytes to be transferred. This field must be set to non-zero value. | W |

### CMD_ATTR[2:0] bits (Combo Transfer Command Attribute)

Command Type, defining the format of the other fields.

### TID[3:0] bits (Combo Transfer Transaction ID)

Used as an identification tag for this command. This field is populated by the software driver, and the same value is reflected in the Response Descriptor.

### CP bit (Combo Transfer Command Present)

Indicates whether the contents of the CMD field is valid for an HDR Transfer.

### DEV_INDEX[4:0] bits (Combo Transfer Device Index)

Indicates the DATBASm table index for the slave device being addressed with the transfer. Static and Device addressing related information are stored to this index in the DATBASm.

### DATA_LENGTH_POSITION[1:0] bits (Data Length Field Position)

Indicates whether and where to put Data Length (DATA_LENGTH) in the first phase of the transfer. This field is only applicable if First phase of the transfer is executed in HDR mode.

Whether 8-bit or 16-bit of Data Length field is used is indicated with 16_BIT_SUBOFFSET field. In case of 8-bit value, it is encoded in Lower Byte of DATA_LENGTH field.

### FIRST_PHASE_MODE bits (Combo Transfer First Phase Mode)

Indicates whether the first phase of the Combo Transfer is executed in SDR mode, vs. the mode indicated by the MODE field.

### MODE[2:0] bits (Combo Transfer Speed and Mode Values for I3C Mode)

Sets the mode and speed for the I3C or $I^2C$ transfer.

Interpretation of this field depends on whether the Device is in I3C mode vs. $I^2C$ mode (see the DEVICE field in the DATBASm Table entry indexed by field DEV_INDEX).

### RNW bit (Combo Transfer R/W Identifies direction of the transfer)

Identifies direction of the transfer.

### ROC bit (Combo Transfer Response on Completion)

Controls whether Response Status is required after successful completion of the data transfer command. The successful completion is read from NRSPQP register. Upon unsuccessful transfer, the Response Status is always sent.

### TOC bit (Combo Transfer Terminate on Completion)

Controls what Bus condition is issued after completion of the data transfer.

When sending 2nd frame by TOC = 0 (RESTART) and HDR mode (MODE[2:0] = 0x6), next command must be set to that 1st frame is the same as HDR mode (MODE[2:0] = 0x6).

When the next command is not the same HDR mode (MODE[2:0] = 0x6), must be set to TOC = 1 (STOP).

### DATA_LENGTH[15:0] bit (Combo Transfer Data Length)

Number of valid data bytes to use in this Combo Transfer Descriptor.

This field must be set to non-zero value.

This field must be set to even value, when specifying HDR mode (MODE[2:0] = 0x6).

## 29.3.1.1.5 Internal Control Command

This structure is used for controlling I3C itself (not for transfer commands).

I3C provides an Internal Control Command for the following mode:

- I3C Master mode

Details of the Internal Control Command Structure are as follows:

| Bit position: | 63 | 62 | 61 | 60 | 59 | 58 | 57 | 56 | 55 | 54 | 53 | 52 | 51 | 50 | 49 | 48 |

| 63:13 | — | The write value should be 0. | W |

Note 1. The IBA_INCLUDE on state set by MIPI_CMD [3:0] = 0x2 and ON_OFF = 1 is cleared by setting RSTCTL.INTLRST to 1.
Note 2. The Response descriptor is not stored when the Internal Control Command is executed.

### 29.3.1.2 Response Descriptor

The Response Descriptor is a read-only structure describing the success or failure of a command, and the amount of data transferred.

The Response Descriptor is read from Response Queue with reads from Response Queue Port.

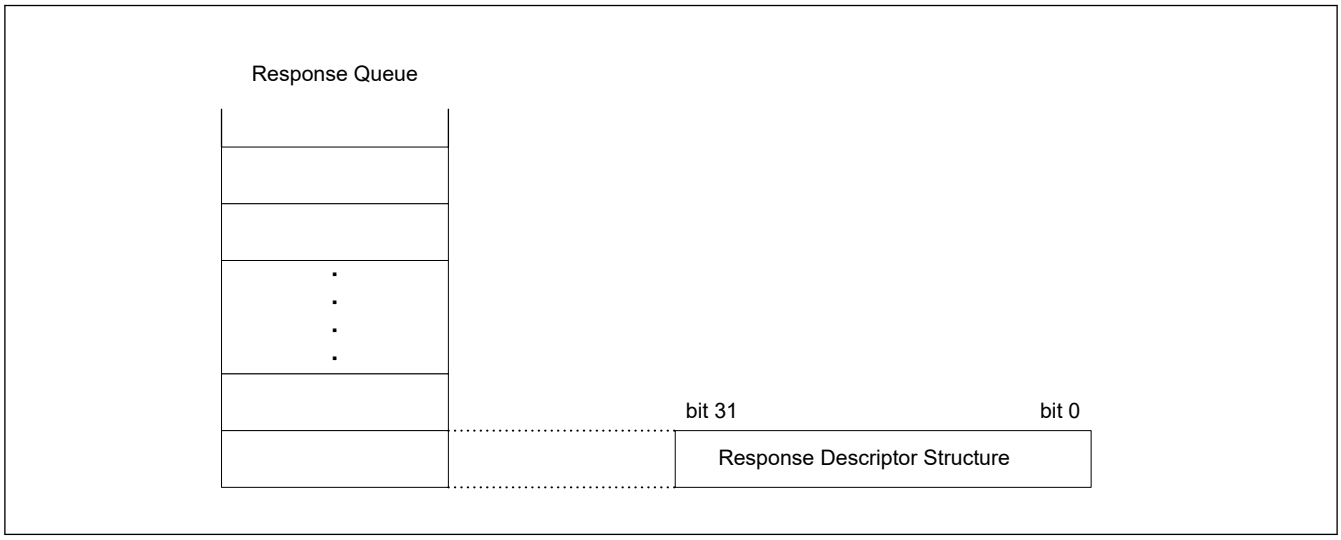

**Figure 29.3 Response descriptor data structure**

I3C provides a Response Descriptor for the following modes:

- I3C Master mode
- I3C Slave mode

Details of the Response Descriptor structure of each mode are shown in the following sections.

#### (1) I3C Master Mode

| Bit position: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | ERR_STATUS[3:0] | | | | TID[3:0] | | | | — | — | — | — | — | — | — | — |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit position: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | DATA_LENGTH[15:0] | | | | | | | | | | | | | | | |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 15:0 | DATA_LENGTH [15:0] | Data Length / Device Count<br>The meaning of this field depends on the context:<br>For Write Transfer: Remaining data length (in bytes)<br>For Read Transfer: Received data length (in bytes)<br>For Address Assignment: Remaining Device count | R |
| 23:16 | — | These bits are read as 0. | R |
| 27:24 | TID[3:0] | Command/Response Transaction ID<br>Identification tag for the command.<br>This value shall match one of commands sent on the Bus.<br>0x0-0x7: Valid Transaction IDs<br>Others: Reserved | R |
| 31:28 | ERR_STATUS[3:0] | Response Error Status<br>0x0: SUCCESS: Transfer successful, no error<br>0x1: CRC: CRC Error<br>0x2: PARITY: Parity Error<br>0x3: FRAME: Frame Error<br>0x4: ADDR_HEADER: Address Header Error<br>0x5: NACK: Address NACKed or Dynamic Address Assignment NACKed<br>0x6: OVL: Receive Overflow or Transfer Underflow Error<br>0x8: ABORTED: Aborted<br>0x9: $I^2C$_WR_DATA_NACK: NACK received for the $I^2C$ Write Data transfer<br>0xA: NOT_SUPPORTED: Command with specific parameters not supported by I3C implementation (for example, specific Internal Control codes may not be supported)<br>Others: Reserved | R |

Note: In I3C Master mode, when an abnormal command with a specific parameter that is not supported is stored in Command Descriptor, it is indicated as NOT_SUPPORTED (0xA) in ERR_STATUS [3:0].

## (2) I3C Slave Mode

| Bit position: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | ERR_STATUS[3:0] | | | | TID[3:0] | | | | — | — | — | — | — | — | — | — |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit position: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | DATA_LENGTH[15:0] | | | | | | | | | | | | | | | |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 15:0 | DATA_LENGTH [15:0] | Data Length<br>Remaining data length (in bytes) for Slave Interrupt Request | R |
| 23:16 | — | These bits are read as 0. | R |
| 27:24 | TID[3:0] | Command/Response Transaction ID<br>Identification tag for the command.<br>This value matches one of commands sent on the bus.<br>0x0-0x7: Valid Transaction IDs<br>Others: Reserved | R |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 31:28 | ERR_STATUS[3:0] | Response Error Status<br>0x0: SUCCESS: Transfer successful, no error.<br>0x3: FRAME: Frame Error<br>0x4: ADDR_HEADER: Address Header Error<br>0x5: NACK: Address NACK'ed or Dynamic Address Assignment NACK'ed<br>0x6: OVL: Receive Overflow or Transfer Underflow Error<br>0x8: ABORTED: Aborted<br>0xA: NOT_SUPPORTED: Command with specific parameters not supported by I3C implementation (for example, specific Internal Control codes may not be supported)<br>Others: Reserved | R |

Note: In I3C Slave mode, it is indicated as NOT_SUPPORTED (0xA) in ERR_STATUS[3:0] in the following cases:
- When an abnormal command with a specific parameter that is not supported is stored in the Command Descriptor.
- When the IBI to be transmitted is disabled in the CSECMD register.
- After the normal command for IBI transmission is prepared in the Command Queue, when that IBI is disabled in the CSECMD register by the DISEC CCC frame from the I3C Master.

### 29.3.1.3 IBI Status Descriptor

The IBI Status Descriptor is a read-only structure describing an IBI event received from a Slave device on the I3C Bus.

The IBI Status Descriptor is read from IBI Queue with reads from IBI Queue Port.

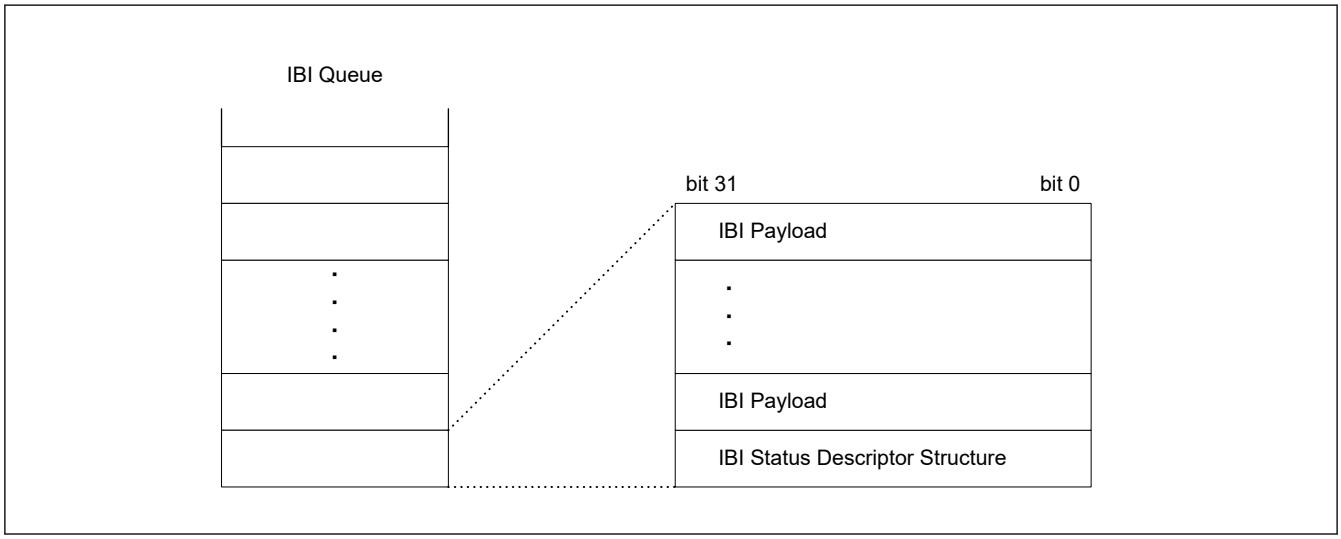

**Figure 29.4 IBI status descriptor data structure**

I3C provides a IBI Status Descriptor for the following mode:

- I3C Master mode

Details of the IBI Status Descriptor Structure are as follows.

| Bit position: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | IBI_ST | — | — | ERR_STATUS[2:0] | | | TS | LAST_STATUS | — | — | — | — | — | — | — | — |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit position: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | IBI_ID[7:0] | | | | | | | | DATA_LENGTH[7:0] | | | | | | | |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 7:0 | DATA_LENGTH[7:0] | IBI Data Length<br>Number of data bytes in IBI Data. | R |
| 15:8 | IBI_ID[7:0] | IBI Received ID<br>The meaning of this field depends on the context:<br>For Slave Interrupt or Master Request: Bits 15:9 contain the Slave's Device Address, and bit 8 contains the R/W bit.<br>For Hot-Join IBI: Bits 15:8 contain the Hot-Join ID for the IBI. | R |
| 23:16 | — | These bits are read as 0. The write value should be 0. | R |
| 24 | LAST_STATUS | Last IBI Status<br>Last IBI status for the IBI transaction. | R |
| 25 | TS | IBI Time-stamp Present<br>Indicates whether a time-stamp is available for the IBI.<br>0: OFF: IBI is not time-stamped.<br>1: ON: IBI is time-stamped. | R |
| 28:26 | ERR_STATUS[2:0] | IBI Error Status<br>0x0: SUCCESS<br>0x3: ERROR: FRAME (Frame Error)<br>0x4: ERROR: ADDR_HEADER (Address Header Error)<br>0x5: NACK: Address NACKed<br>0x7: ERROR: ABORT (Aborted to Master)<br>Others: Reserved | R |
| 30:29 | — | These bits are read as 0. | R |
| 31 | IBI_ST | IBI Received Status<br>Indicates how the received IBI was handled.<br>0: The IBI was handled with ACK.<br>1: NACK: The IBI was handled with NACK, and then Auto-Disabled. | R |

**LAST_STATUS bits (Last IBI Status)**

Even if LAST_STATUS is set to 0, the software driver still evaluates the data payload length by examining the DATA_LENGTH field.

### 29.3.1.4 Receive Status Descriptor

The Receive Status Descriptor is a read-only structure describing the success or failure of read/write operation from the master, and the amount of data transferred.

The Receive Status Descriptor is read from Receive Status Queue with reads from Receive Status Queue Port.

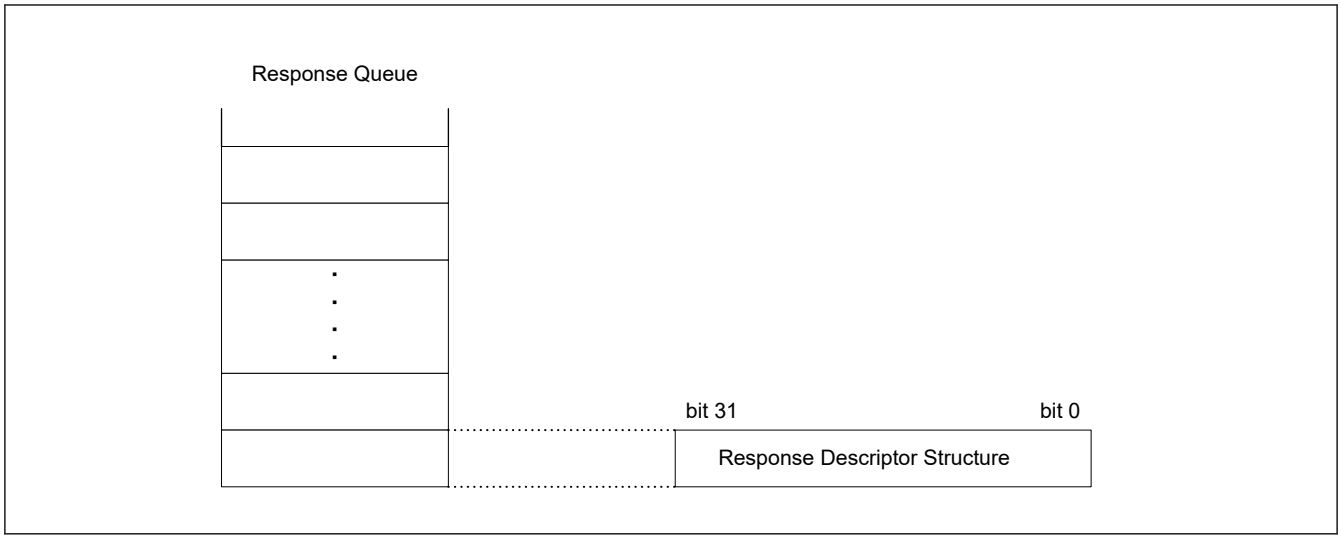

**Figure 29.5 Receive status descriptor data structure**

I3C provides a Receive Status Descriptor for the following mode:

- I3C Slave mode

Details of the Receive Status Descriptor structure of each mode are as follows.

| Bit position: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | DEV_INDEX[2:0] | | | TRANSFER_TYPE[1:0] | | ERR_STATUS[2:0] | | | CMD[7:0] | | | | | | | |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit position: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | DATA_LENGTH[15:0] | | | | | | | | | | | | | | | |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 15:0 | DATA_LENGTH [15:0] | Data Length<br>The meaning of this field depends on the context.<br>For Write Transfer: Received data length (in bytes)<br>For Read Transfer: Transmitted data length (in bytes) | R |
| 23:16 | CMD[7:0] | The contents are different depending on the operation mode. Details are follows:<br>[SDR Private Message Mode]<br>CMD[7]: R/W Type<br>CMD[6:4]: Reserved<br>CMD[3]: I3C_$I^2C$ Type<br>CMD[2:0]: Reserved<br>[SDR CCC Mode]<br>CCC code[7:0]<br>[HDR-DDR mode]<br>HDR CMD[7:0]<br>0x00 – 0x7F: Write Command<br>0x80 – 0xFF: Read Command | R |
| 26:24 | ERR_STATUS[2:0] | Error Status<br>0x0: SUCCESS<br>0x1: ERROR: CRC (CRC Error)<br>0x2: ERROR: PARITY (Parity Error)<br>0x3: ERROR: FRAME (Frame Error)<br>0x4: ERROR: ADDR_HEADER (Address Header Error)<br>0x5: ERROR: NACK (Slave NACKed)<br>0x6: ERROR: OVL (FIFO Overflow/Underflow)<br>0x7: ERROR: ABORT (Aborted to Master) | R |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 28:27 | TRANSFER_TYPE [1:0] | Transfer Type<br>0 0: I3C SDR/I2C Message<br>0 1: I3C CCC<br>1 0: I3C HDR-DDR<br>1 1: Setting prohibited | R |
| 31:29 | DEV_INDEX[2:0] | Device Index<br>Indicates the SVDVAD0 index for the response with the transfer. | R |

## 29.3.2 Details of Function

### 29.3.2.1 Operation Mode

The support relationship between the mode select (I3C mode / I2C mode) and operation mode (Master/Slave) on the I3C bus or the I2C bus is shown in Table 29.9.

**Table 29.9 Support of operating mode**

| I3C/I2C Bus | I3C mode | | I2C mode | |
|---|---|---|---|---|
| | Master | Slave | Master | Slave |
| I3C Bus | ✓ | ✓ | — | ✓ |
| I2C Bus | — | — | ✓ | ✓ |

Note: ✓: Supported
—: Unsupported

#### 29.3.2.1.1 Master Mode Operation

##### (1) I2C Master Operation

(a) Data Write Transfer (Single Buffer transfer)

In master transmit operation, I3C outputs the SCL clock and transmitted data signals as the master device, and the slave device returns acknowledgments. Figure 29.129 shows an example of usage of master transmission and Figure 29.6 to Figure 29.8 show the timing of operations in master transmission.

The following describes the procedure and operations for master transmission.

1. Initial settings. For details, see section 29.3.3.1. Initial Setting Flow.
2. Read the BCST.BFREF flag to check that the bus is open, and then set the CNDCTL.STCND bit to 1 (START condition issuance request). Upon receiving the request, I3C issues a START condition. At the same time, the BFREF flag bit is automatically set to 0, the BST.STCNDDF flag is automatically set to 1 and the STCND bit is automatically set to 0. At this time, if the START condition is detected and the internal levels for the SDA output state and the levels on the I3C_SDA line have matched while the STCND bit = 1, I3C recognizes that issuing of the START condition as requested by the STCND bit has been successfully completed, and bits CRMS and TRMD in the PRSST register are automatically set to 1, placing I3C in master transmit mode. The NTST.TDBEF0 flag is also automatically set to 1 in response to setting of the TRMD bit to 1.
3. Check that the NTST.TDBEF0 flag = 1, and then write the value for transmission (the slave address and the R/W# bit) to the NTDTBP0 register. Once the data for transmission are written to the NTDTBP0 register, the TDBEF0 flag is automatically set to 0, the data are transferred from the Normal Tx Data Buffer to the Shift Register, and the TDBEF0 flag is again set to 1. After the byte containing the slave address and R/W# bit has been transmitted, the value of the TRMD bit is automatically updated to select master transmit or master receive mode in accord with the value of the transmitted R/W# bit. If the value of the R/W# bit was 0, I3C continues in master transmit mode. Because the BST.NACKDF flag being 1 at this time indicates that no slave device recognized the address or there was an error in communications, write 1 to the CNDCTL.SPCND bit to issue a STOP condition. For data transmission with an address in the 10-bit format, start by writing 1111 0, the 2 higher-order bits of the slave address, and W to the NTDTBP0 register as the first address transmission. Then, as the second address transmission, write the 8 lower-order bits of the slave address to the NTDTBP0 register.

4. After confirming that the NTST.TDBEF0 flag = 1, write the data for transmission to the NTDTBP0 register. I3C automatically holds the I3C_SCL line low until the data for transmission are ready or a STOP condition is issued.
5. After all bytes of data for transmission have been written to the NTDTBP0 register, wait until the value of the BST.TENDF flag returns to 1, and then set the CNDCTL.SPCND bit to 1 (STOP condition issuance request). Upon receiving a STOP condition issuance request, I3C issues the STOP condition.
6. Upon detecting the STOP condition, I3C automatically sets bits CRMS and TRMD in the PRSST register to 00 and enters slave receive mode. Furthermore, it automatically sets the TDBEF0 and TENDF flags to 0, and sets the BST.SPCNDDF flag to 1.
7. After checking that the BST.SPCNDDF flag = 1, set the BST.NACKDF and SPCNDDF flags to 0 for the next transfer operation.

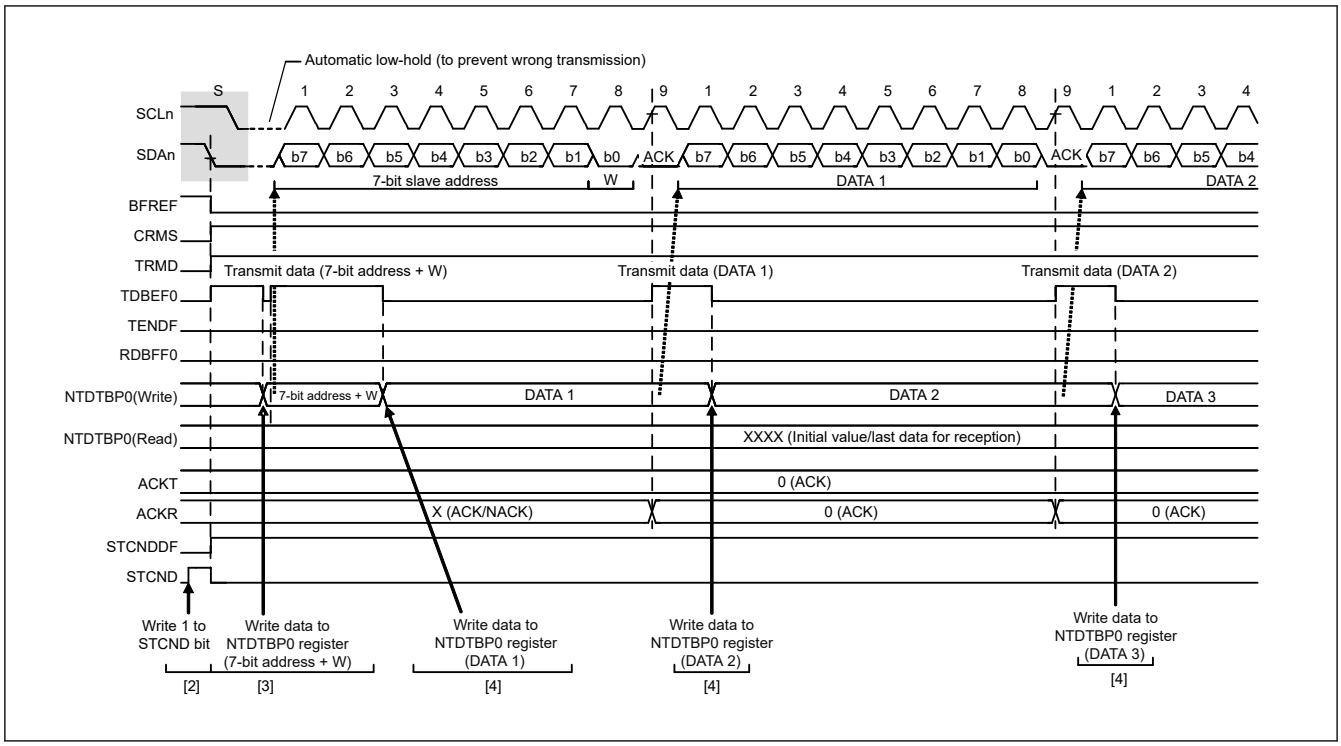

**Figure 29.6 Master transmit operation timing (1) (7-bit address format)**

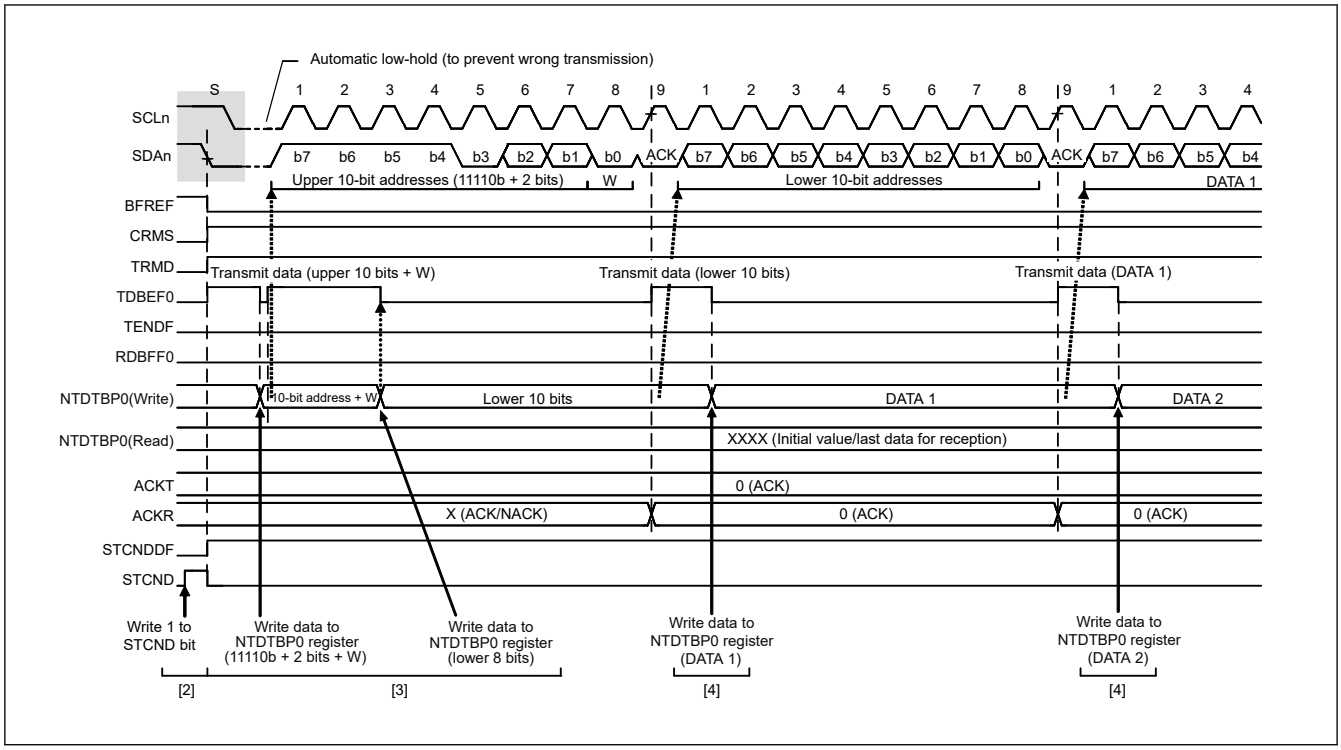

**Figure 29.7 Master transmit operation timing (2) (10-bit address format)**

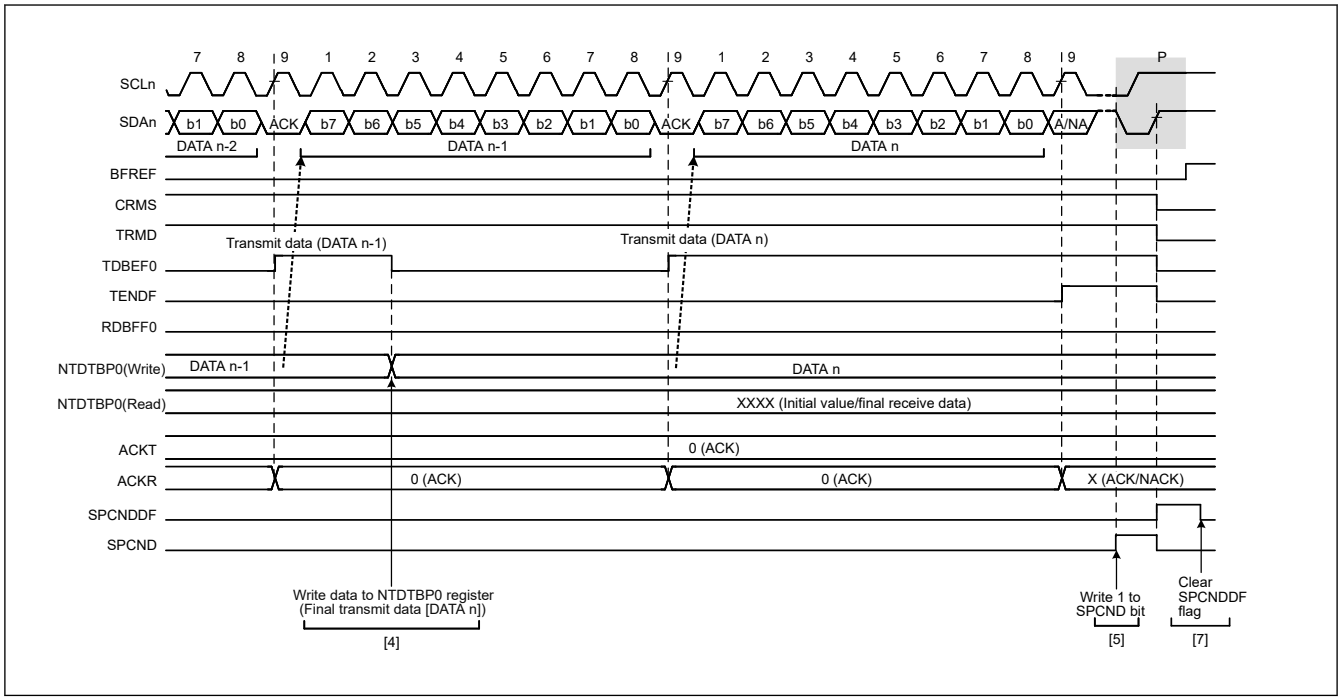

**Figure 29.8 Master transmit operation timing (3)**

(b) Data Read Transfer (Single Buffer transfer)

In master receive operation, I3C as a master device outputs the SCL clock, receives data from the slave device, and returns acknowledgments. Because I3C must start by sending a slave address to the corresponding slave device, this part of the procedure is performed in master transmit mode, but the subsequent steps are in master receive mode.

Figure 29.130 and Figure 29.131 show examples of usage of master reception (7-bit address format) and Figure 29.9 to Figure 29.11 show the timing of operations in master reception.

The following describes the procedure and operations for master reception.

1. Initial settings. For details, see section 29.3.3.1. Initial Setting Flow.

2. Read the BCST.BFREF flag to check that the bus is open, and then set the CNDCTL.STCND bit to 1 (START condition issuance request). Upon receiving the request, I3C issues a START condition. When I3C detects the START condition, the BFREF flag is automatically set to 0 and the BST.STCNDDF flag is automatically set to 1 and the STCND bit is automatically set to 0. At this time, if the START condition is detected and the levels for the SDA output and the levels on the I3C_SDA line have matched while the STCND bit = 1, I3C recognizes that issuing of the START condition as requested by the STCND bit has been successfully completed, and bits CRMS and TRMD in the PRSST register are automatically set to 1, placing I3C in master transmit mode. The NTST.TDBEF0 flag is also automatically set to 1 in response to setting of the TRMD bit to 1.
3. Check that the NTST.TDBEF0 flag = 1, and then write the value for transmission (the first byte indicates the slave address and value of the R/W# bit) to the NTDTBP0 register. Once the data for transmission are written to the NTDTBP0 register, the TDBEF0 flag is automatically set to 0, the data are transferred from the Normal Tx Data Buffer to the Shift Register, and the TDBEF0 flag is again set to 1. Once the byte containing the slave address and R/W# bit has been transmitted, the value of the PRSST.TRMD bit is automatically updated to select transmit or receive mode in accord with the value of the transmitted R/W# bit. If the value of the R/W# bit was 1, the TRMD bit is set to 0 on the rising edge of the ninth cycle of SCL clock, placing I3C in master receive mode. At this time, the TDBEF0 flag is set to 0. The NTST.RDBFF0 flag is automatically set to 1 when ACK response is received from the slave device. If the slave device is not recognized or a communication failure occurs, the BST.NACKDF flag will be set to 1. At this time, set 1 to the CNDCTL.SPCND bit to issue a STOP condition. For master reception from a device with a 10-bit address, start by using master transmission to issue the 10-bit address, and then issue a Repeated START condition. After that, transmitting 1111 0, the two higher-order bits of the slave address, and the R bit places I3C in master receive mode.
4. Dummy read the NTDTBP0 register after confirming that the NTST.RDBFF0 flag = 1; this makes I3C start output of the SCL clock and start data reception.
5. After 1 byte of data has been received, the NTST.RDBFF0 flag is set to 1 on the rising edge of the eighth or ninth cycle of SCL clock (the clock signal) as selected by the SCSTRCTL.ACKTWE bit. Reading the NTDTBP0 register at this time will produce the received data, and the RDBFF0 flag is automatically set to 0 at the same time. Furthermore, the value of the acknowledgment field received during the ninth cycle of SCL clock is returned as the value set in the ACKCTL.ACKT bit. Furthermore, if the next byte to be received is the next to last byte, set the SCSTRCTL.RWE bit to 1 (for wait insertion) before reading the NTDTBP0 register (containing the second byte from last). As well as enabling NACK output even in the case of delays in processing to set the ACKCTL.ACKT bit to 1 (NACK) in step 6, due to other interrupts, etc., this fixes the I3C_SCL line to the low level on the falling edge of the ninth clock cycle in reception of the last byte, so the state is such that issuing a STOP condition is possible.
6. When the SCSTRCTL.ACKTWE bit = 0 and the slave device must be notified that it is to end transfer for data reception after transfer of the next (final) byte, set the ACKCTL.ACKT bit to 1 (NACK).
7. After reading the byte before last from the NTDTBP0 register, if the value of the NTST.RDBFF0 flag is confirmed to be 1, write 1 to the CNDCTL.SPCND bit (STOP condition issuance request) and then read the last byte from the NTDTBP0 register. When 1 is written to the CNDCTL.SPCND bit, I3C is released from the wait state and issues the STOP condition after low-level output in the ninth clock cycle is completed or the I3C_SCL line is released from the low-hold state.
8. Upon detecting the STOP condition, I3C automatically sets bits CRMS and TRMD in the PRSST register to 00 and enters slave receive mode. Furthermore, detection of the STOP condition leads to setting of the BST.SPCNDDF flag to 1.
9. After checking that the BST.SPCNDDF flag = 1, set the BST.NACKDF and SPCNDDF flags to 0 for the next transfer operation.

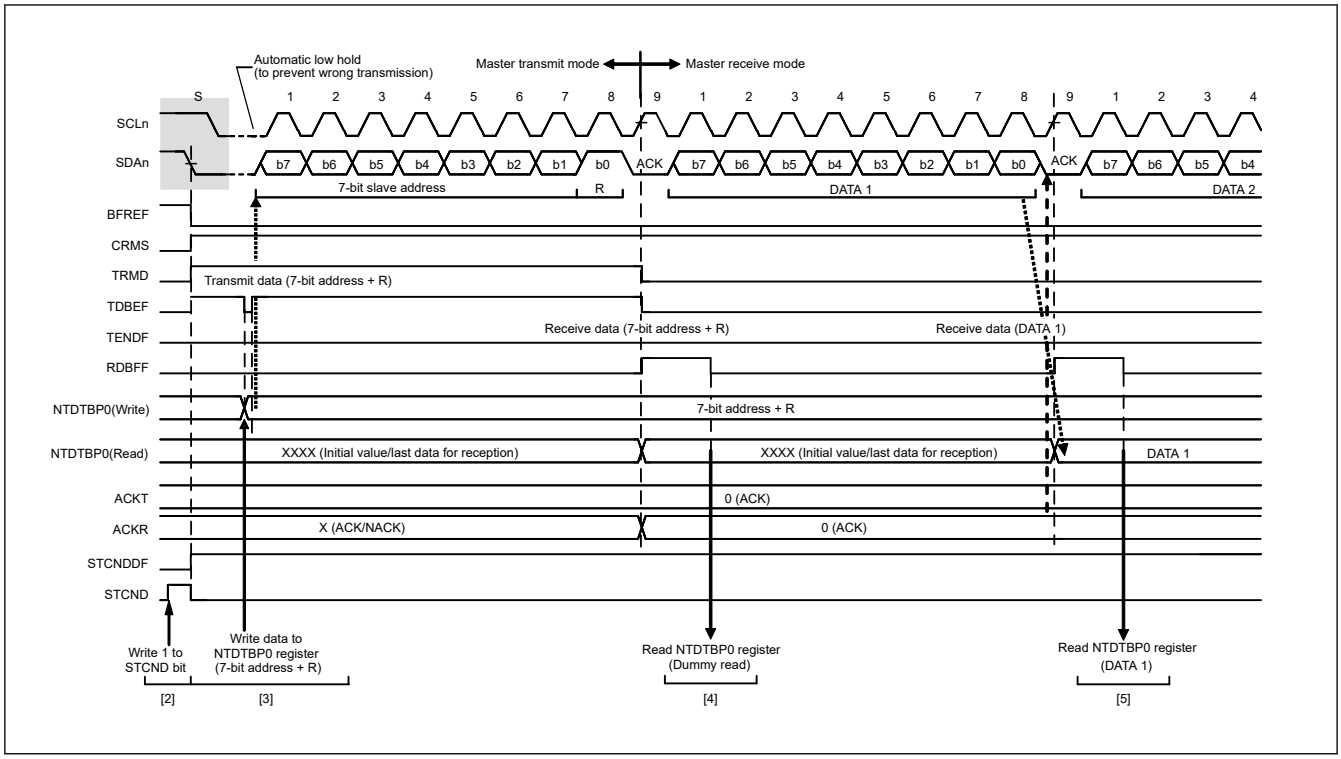

**Figure 29.9 Master receive operation timing (1) (7-bit address format, when ACKTWE = 0)**

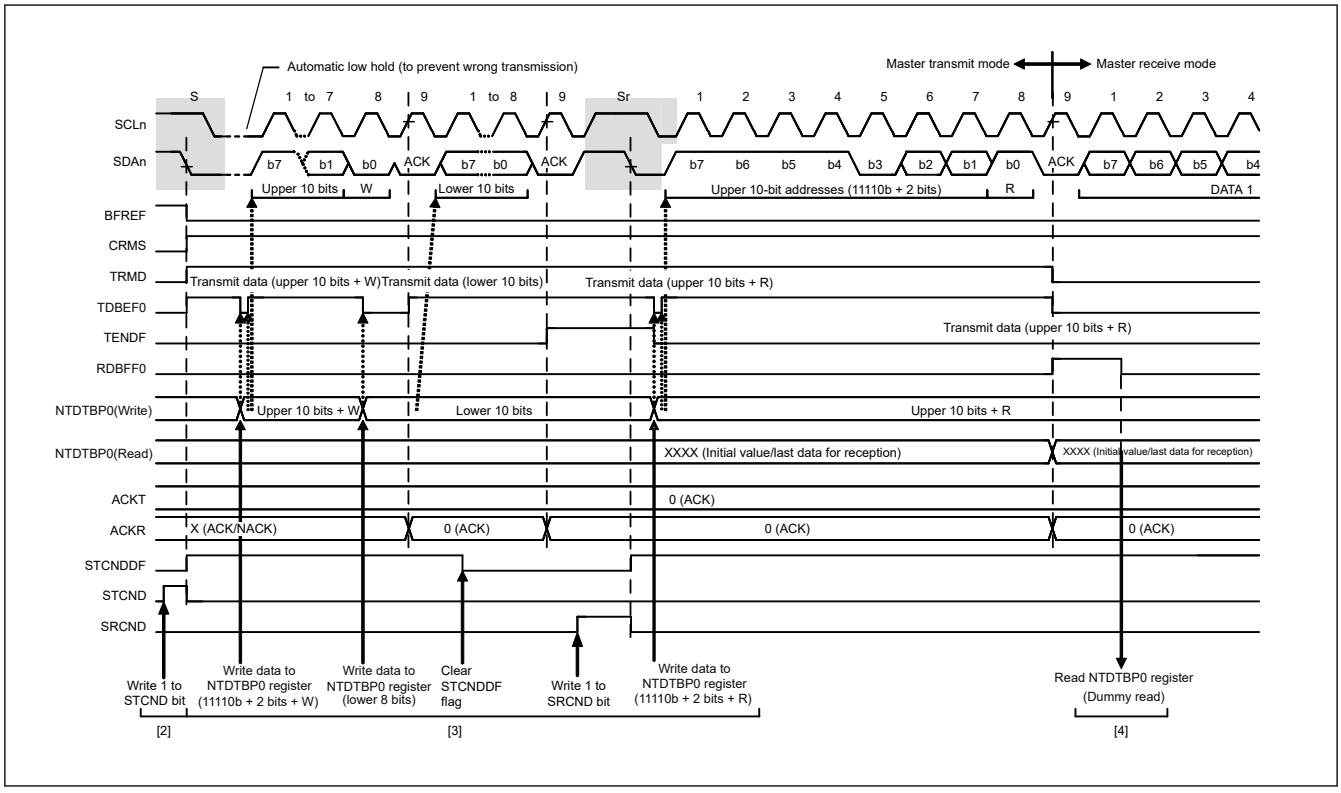

**Figure 29.10 Master receive operation timing (2) (10-bit address format, when ACKTWE = 0)**

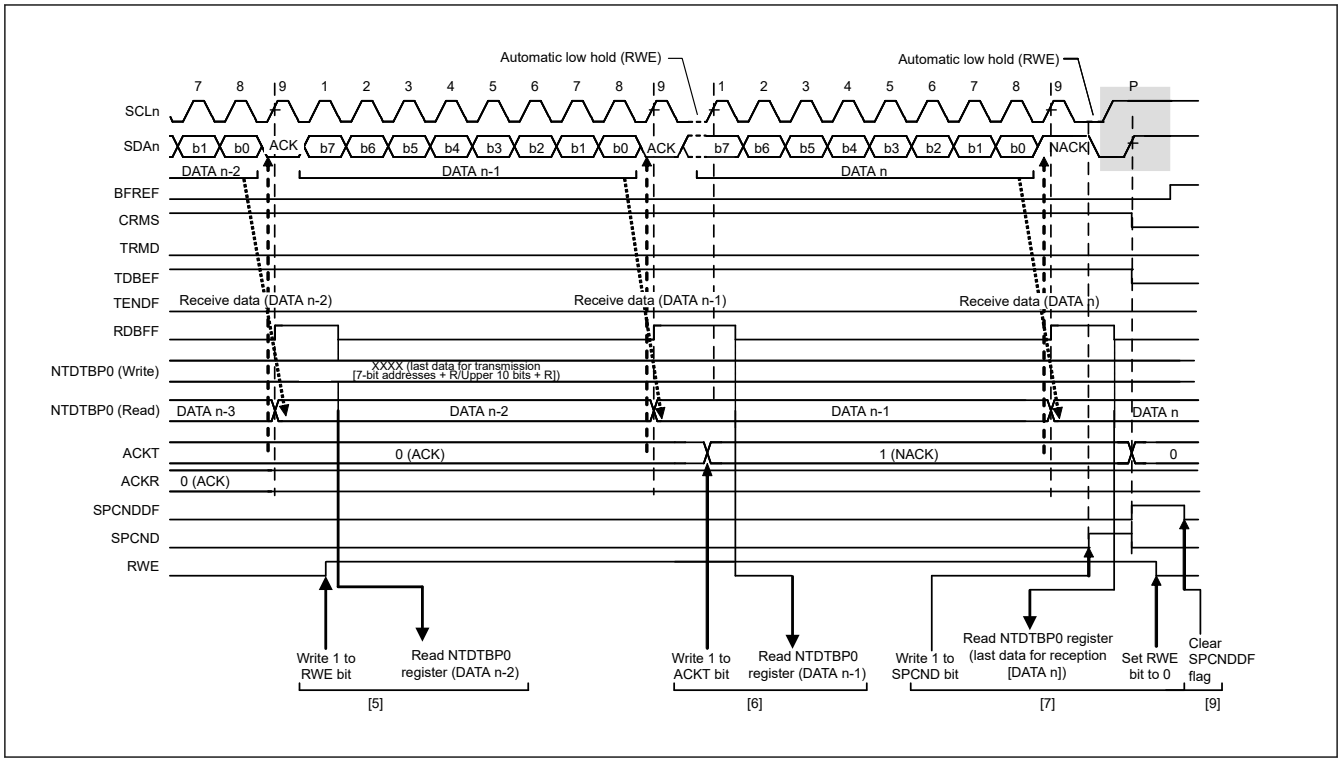

**Figure 29.11 Master receive operation timing (3) (when ACKTWE = 0)**

## (2) I3C Master Operation

(a) Dynamic Address Assign Procedure

After initializing I3C, first execute Dynamic Address Assign Procedure for I3C Slave connected on the I3C Bus. The following describes the procedure.

1. Initial setting (see section 29.3.3.1.2. I3C Initial Setting Flow for details)
2. Execute Dynamic Address Assign with ENTDAA or SETDASA Common Command Code (CCC) for I3C Slave set in DAT (DATBASm register).
   Write Command Descriptor (Address Assign Command) to Command Buffer via the NCMDQP register.
3. When Command Descriptor is written to Command Buffer, Transaction is issued on I3C Bus.
4. When ENTDAA is specified for CMD[7:0] of Address Assign Command:
   Execute Dynamic Address Assign for I3C Slave for the number of DATs specified by DEV_COUNT[3:0] starting with DAT specified by DEV_INDEX[4:0] of Address Assign Command.
   When SETDASA is specified for CMD[7:0] of Address Assign Command:
   Execute Dynamic Address Assign for I3C Slave indicated by DAT specified by DEV_INDEX[4:0] of Address Assign Command.
5. In case of ENTDAA, the Provisional ID, BCR, DCR transmitted from I3C Slave is stored in Receive Data Buffer (BCR is also automatically stored in the MSDCTm register).
   Read the Provisional ID, BCR, and DCR from the Receive Data Buffer via the NTDTBPn register with an interrupt by RDBFF0 = 1.
6. When execution of Dynamic Address Assign is completed, issue STOP condition and store the Response Descriptor into the Response Buffer.
7. Read the Response Descriptor via the NRSPQP register and check the status.
8. Check whether the value of the DATA_LENGTH[15:0] bits of the Response Descriptor matches the value of DEV_COUNT[3:0] of the Address Assign Command.

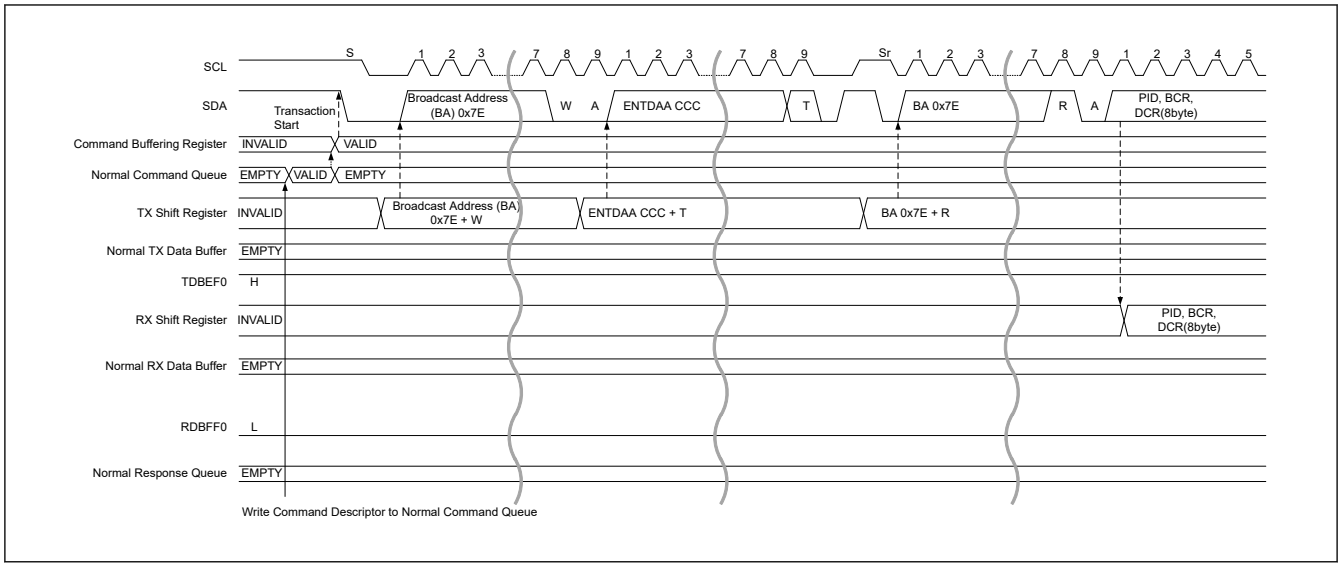

**Figure 29.12 Dynamic address assign procedure (ENTDAA CCC) timing (1/3)**

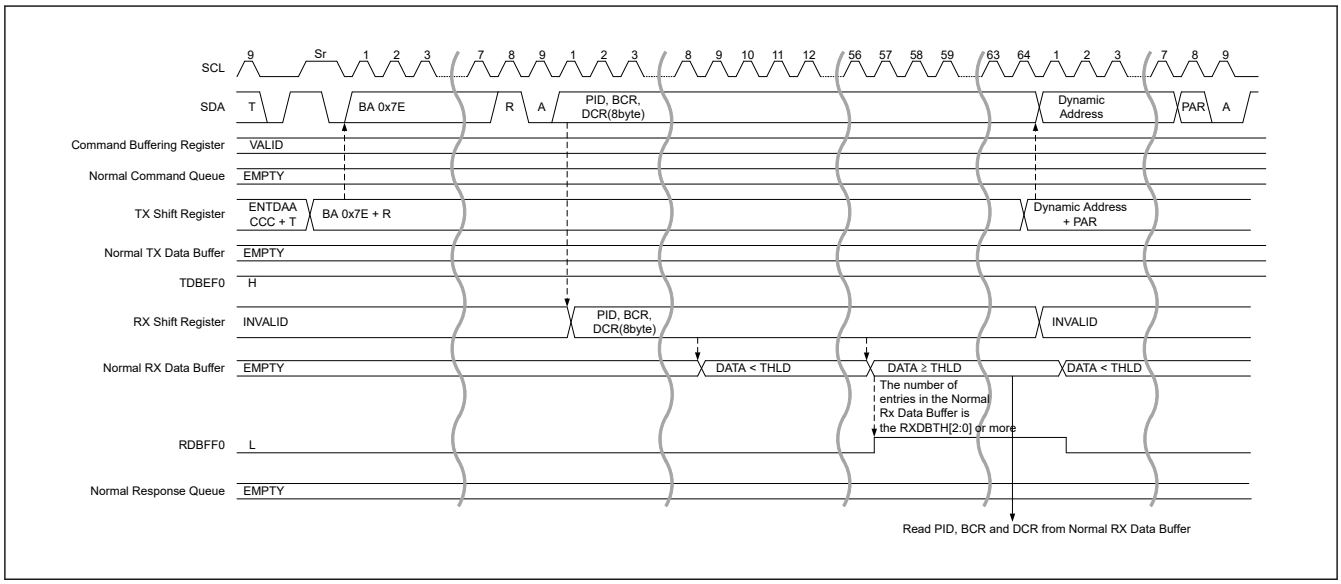

**Figure 29.13 Dynamic address assign procedure (ENTDAA CCC) timing (2/3)**

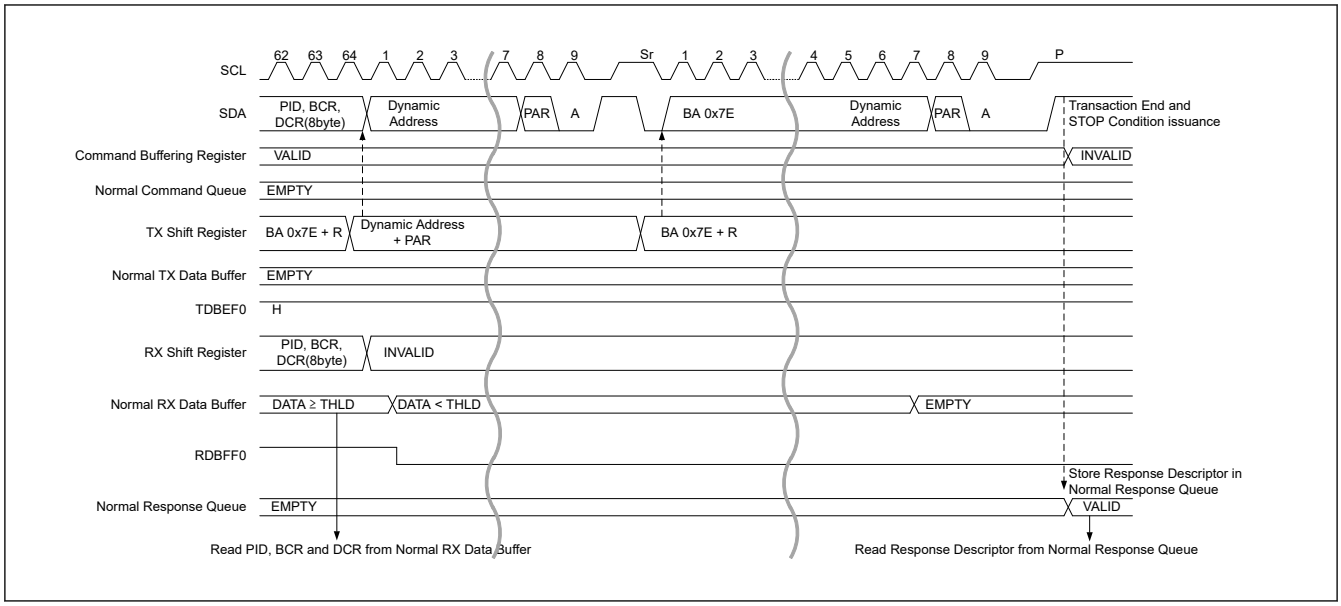

**Figure 29.14 Dynamic address assign procedure (ENTDAA CCC) timing (3/3)**

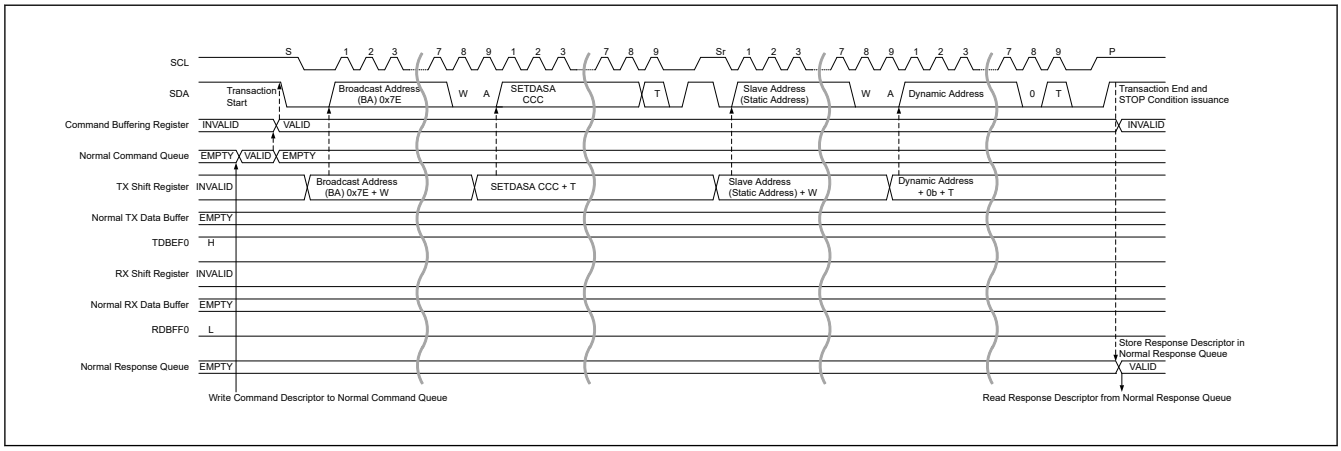

**Figure 29.15 Dynamic address assign procedure (SETDASA CCC) timing**

(b) SDR Data Write Transfer

1. Write data for transmission to the Tx Data Buffer via the NTDTBPn register.
2. Write a Command Descriptor (Immediate Transfer Command or Regular Transfer Command or Combo Transfer Command) for Data Transfer to the Command Buffer via the NCMDQP register.
3. When Command Descriptor is written to Command Buffer, transaction is issued on I3C Bus.
   When NACK is received with the Address Header, transaction of the same command is automatically issued according to the NACK Retry Count value (DATBASm.DVNACK) of DAT.
4. If data for transmission still remain, write data for transmission by an interrupt with TDBEF0 = 1 to the Tx Data Buffer via the NTDTBPn register.
5. When data transmission for the number of Data Length specified by the DATA_LENGTH[15:0] bits of the Command Descriptor is completed, the Repeated START condition or STOP condition is issued and the Response Descriptor is stored in the Response Buffer.
6. Read the Response Descriptor via the NRSPQP register and check the status.
7. Check that the value of the DATA_LENGTH[15:0] bits of the Response Descriptor is 0.

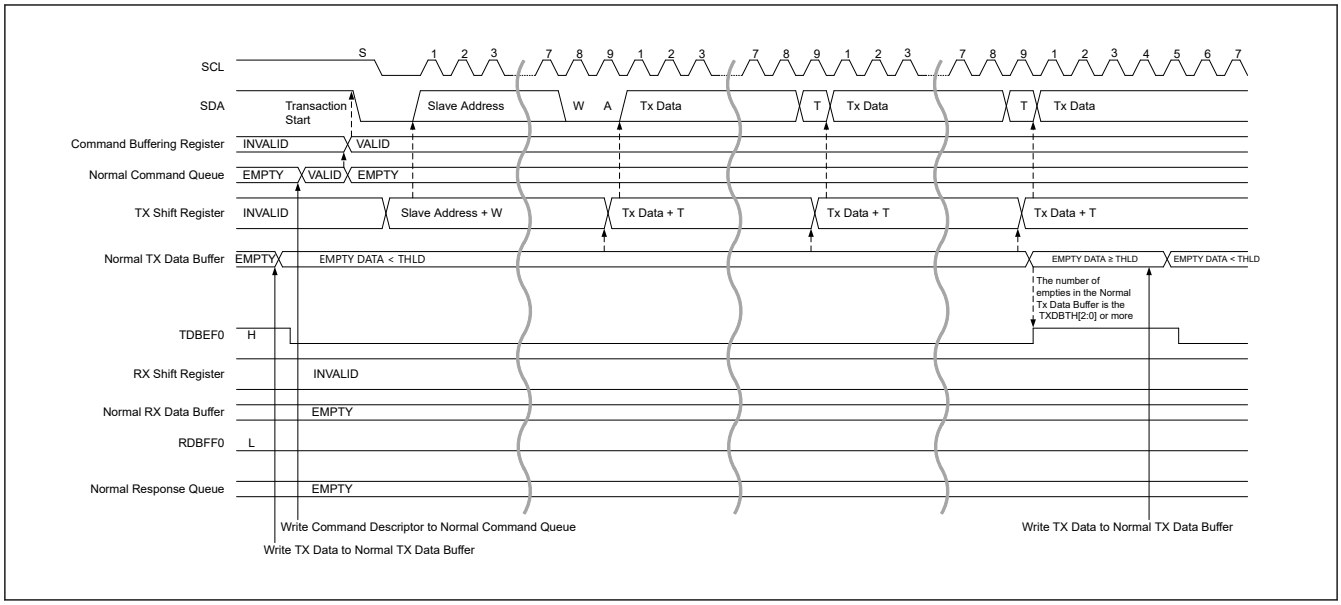

**Figure 29.16 SDR data write transfer timing (1/2)**

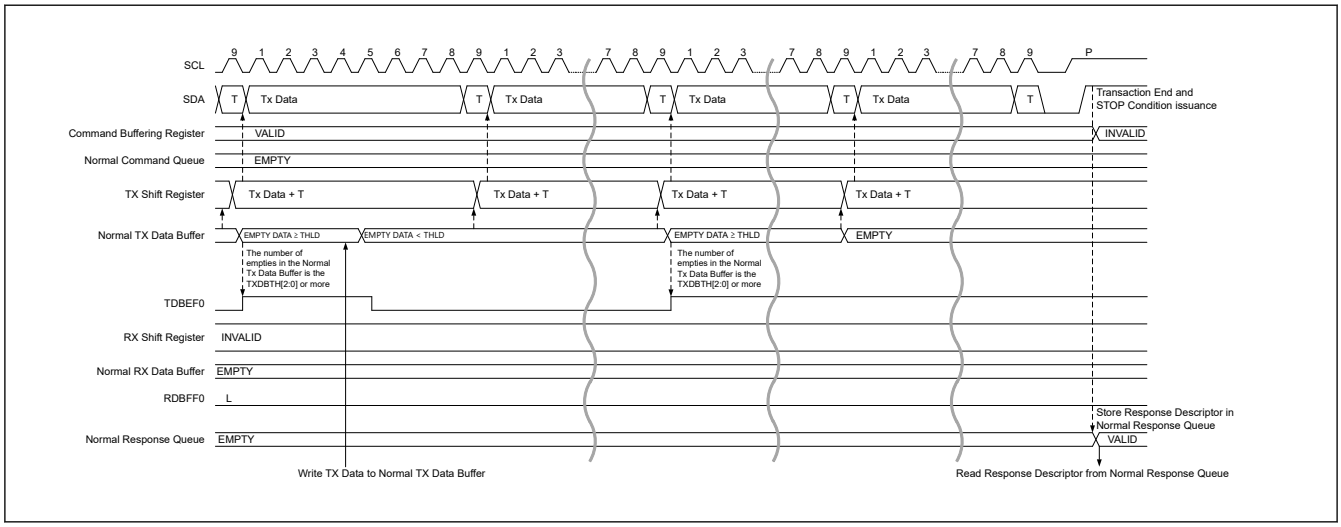

**Figure 29.17 SDR data write transfer timing (2/2)**

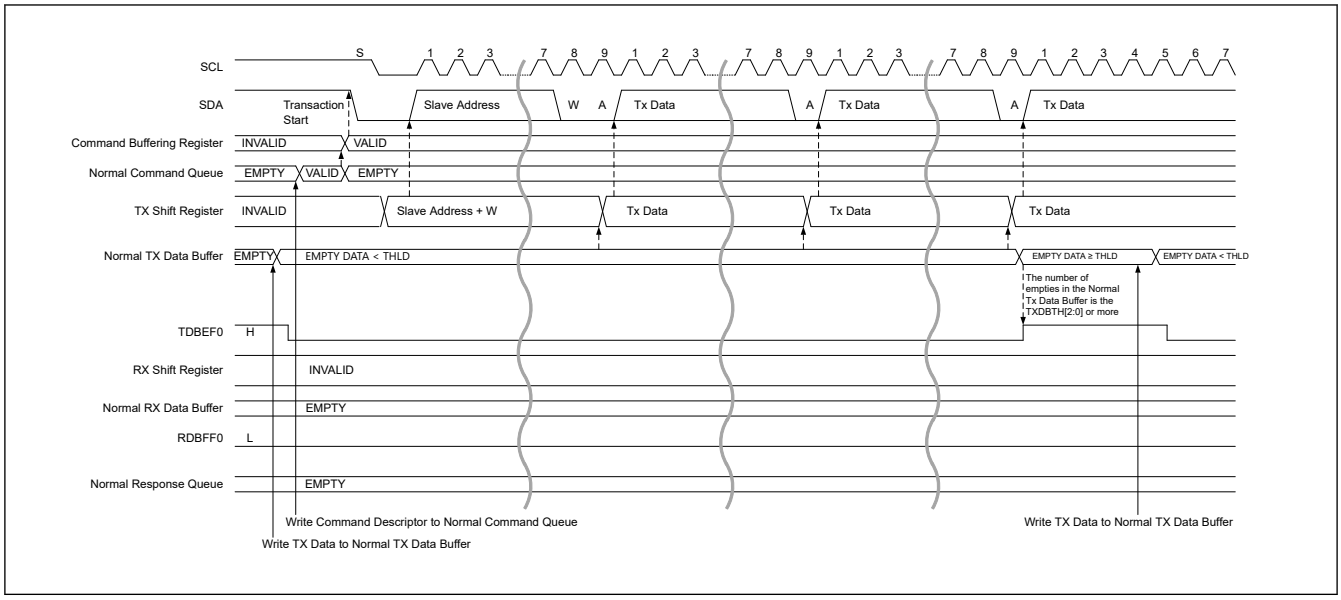

**Figure 29.18 Legacy I²C message data write timing (1/2)**

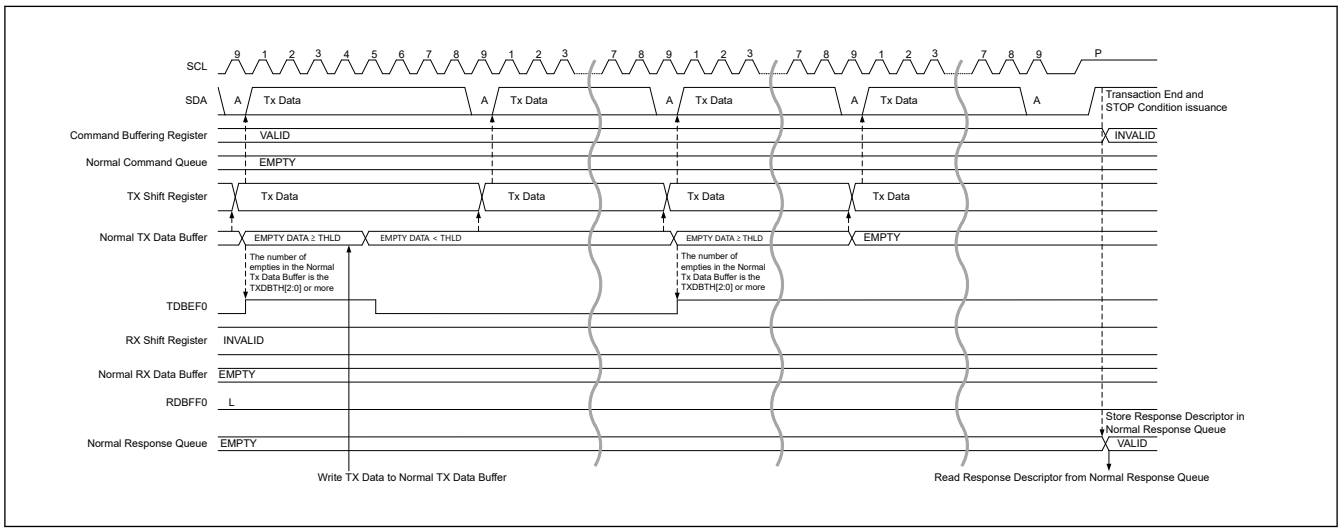

**Figure 29.19 Legacy I²C message data write timing (2/2)**

(c) SDR Data Read Transfer

1. Write a Command Descriptor (Immediate Transfer Command or Regular Transfer Command or Combo Transfer Command) for Data Transfer to the Command Buffer via the NCMDQP register.
2. When Command Descriptor is written to Command Buffer, transaction is issued on I3C Bus.
   When NACK is received with the Address Header, transaction of the same command is automatically issued according to the NACK Retry Count value (DATBASm.DVNACK) of DAT.
3. Data received from the I3C Slave is stored in the Receive Data Buffer.
4. With the RDBFF0 = 1 interrupt, the received data is read from the Receive Data Buffer via the NTDTBPn register.
5. SDR:
   Detecting Low in T-bit or receiving Data for the number of Data Length specified by the DATA_LENGTH[15:0] bits of Command Descriptor is completed, issue Repeated START condition or STOP condition and store the Response Descriptor into the Response Buffer.
   Legacy I²C Message:
   When data reception for the number of Data Length specified by the DATA_LENGTH[15:0] bits of Command Descriptor is completed, NACK is issued. After that, issue a Repeated START condition or STOP condition and store the Response Descriptor into the Response Buffer.
6. Read the Response Descriptor via the NRSPQP register and check the status.

7. Check whether the value of the DATA_LENGTH[15:0] bits of the Response Descriptor matches the data length setting value of the Command Descriptor.

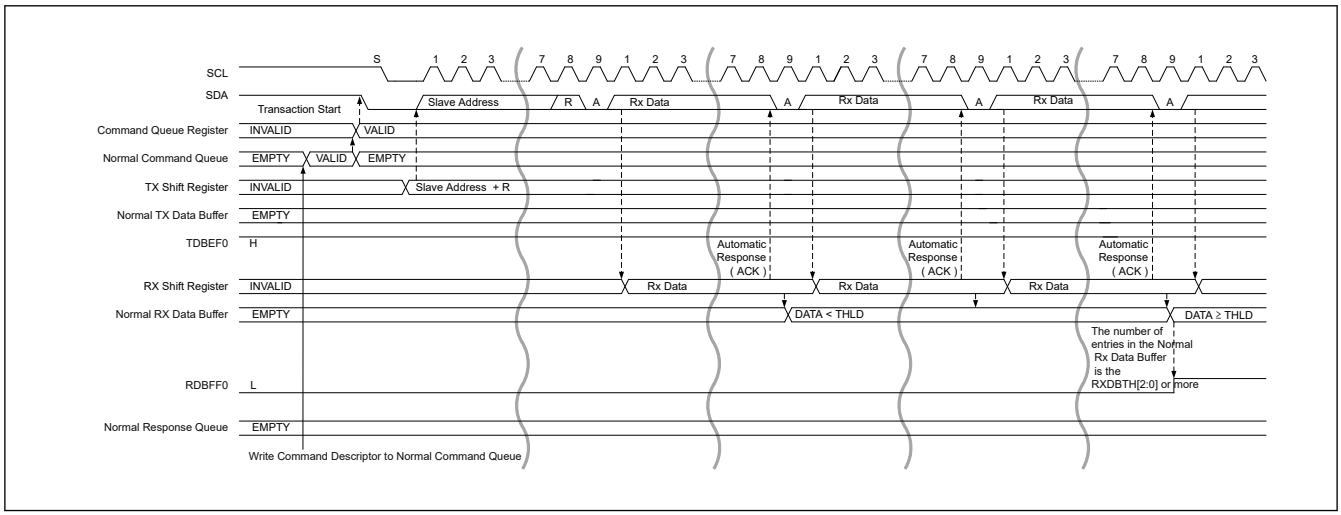

**Figure 29.20 SDR data read transfer timing (1/2)**

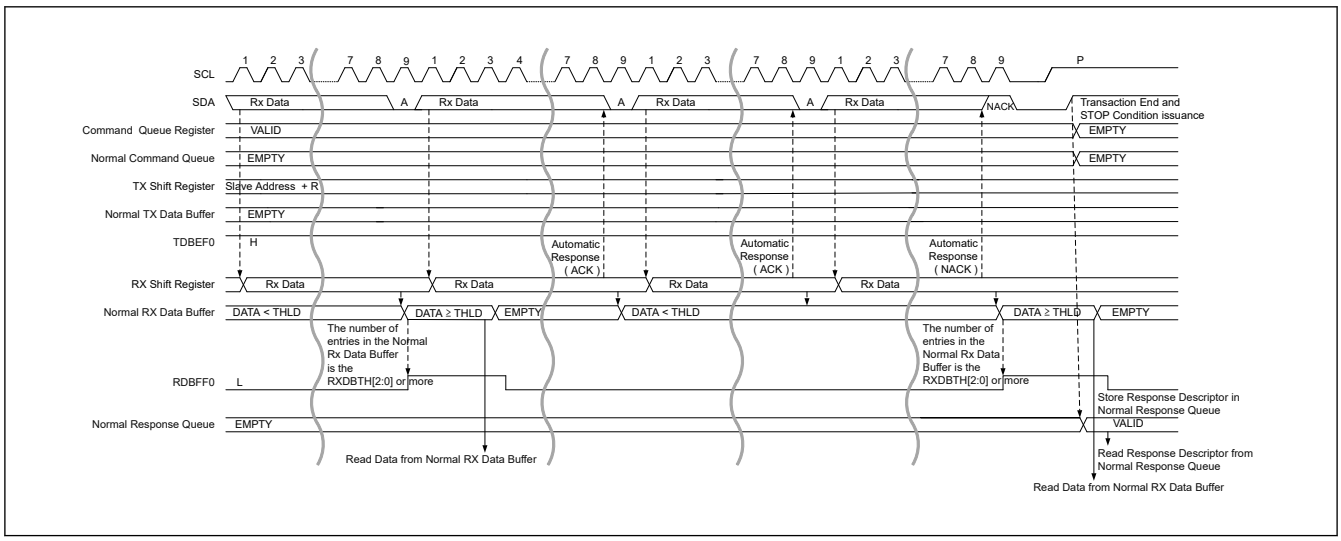

**Figure 29.21 SDR data read transfer timing (2/2)**

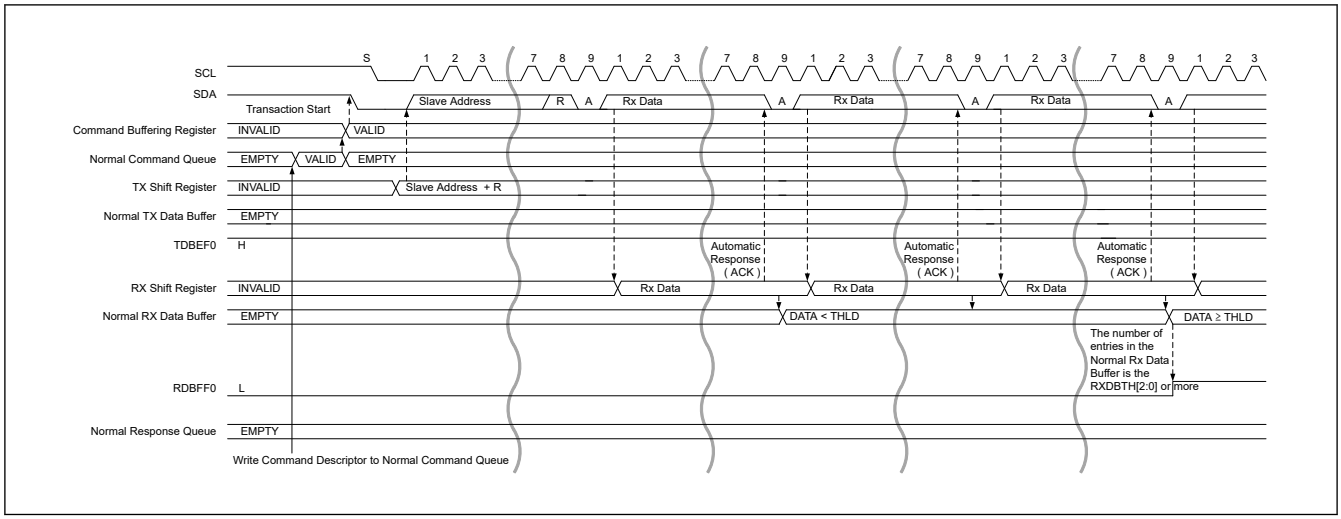

**Figure 29.22 Legacy I²C message data read transfer timing (1/2)**

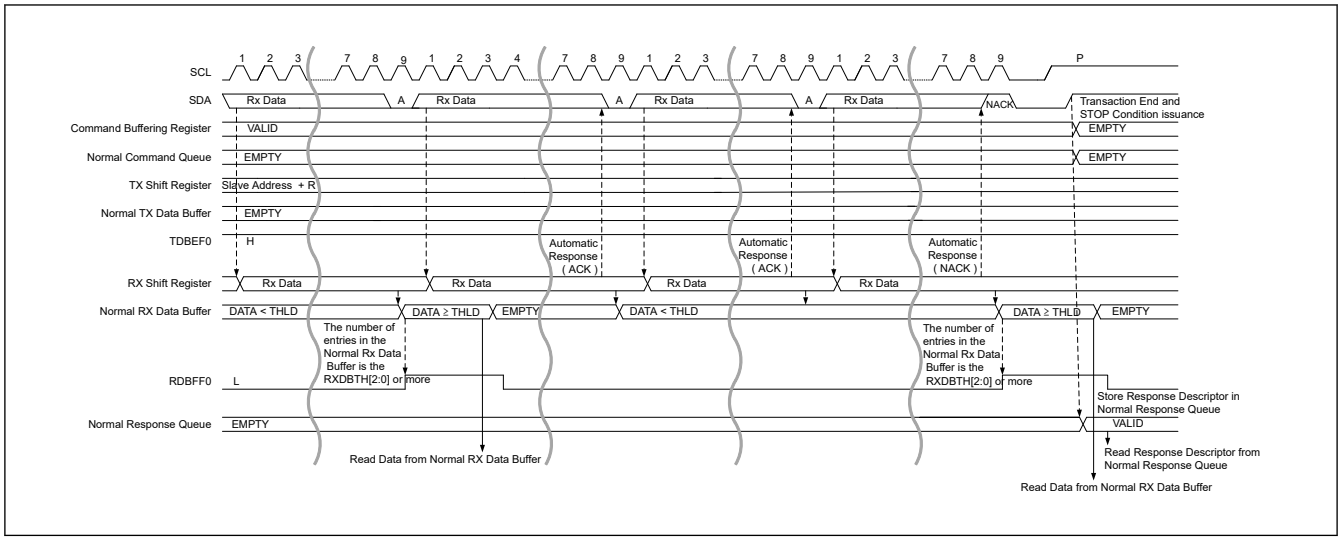

**Figure 29.23 Legacy I²C message data read transfer timing (2/2)**

(d) HDR Data Write Transfer

1. Write data for transmission to the Tx Data Buffer via the NTDTBPn register.
2. Write a Command Descriptor (Immediate Transfer Command or Regular Transfer Command or Combo Transfer Command) for Data Transfer to the Command Buffer via the NCMDQP register.
3. When Command Descriptor is written to Command Buffer, transaction is issued on I3C Bus.
   When NACK is received with the Address Header, transaction of the same command is automatically issued according to the NACK Retry Count value (DATBASm.DVNACK) of DAT.
4. If data for transmission still remains, write data for transmission by an interrupt with TDBEF0 = 1 to the Tx Data Buffer via the NTDTBPn register.
5. HDR-DDR:
   When the data transmission for the number of Data Length specified by the DATA_LENGTH[15:0] bits of the Command Descriptor is completed, CRC Word is transmitted. After that, issue HDR Restart Pattern or HDR Exit Pattern + STOP condition and store the Response Descriptor into Response Buffer.
6. Read the Response Descriptor via the NRSPQP register and check the status.
7. Check that the value of the DATA_LENGTH[15:0] bits of the Response Descriptor is 0.

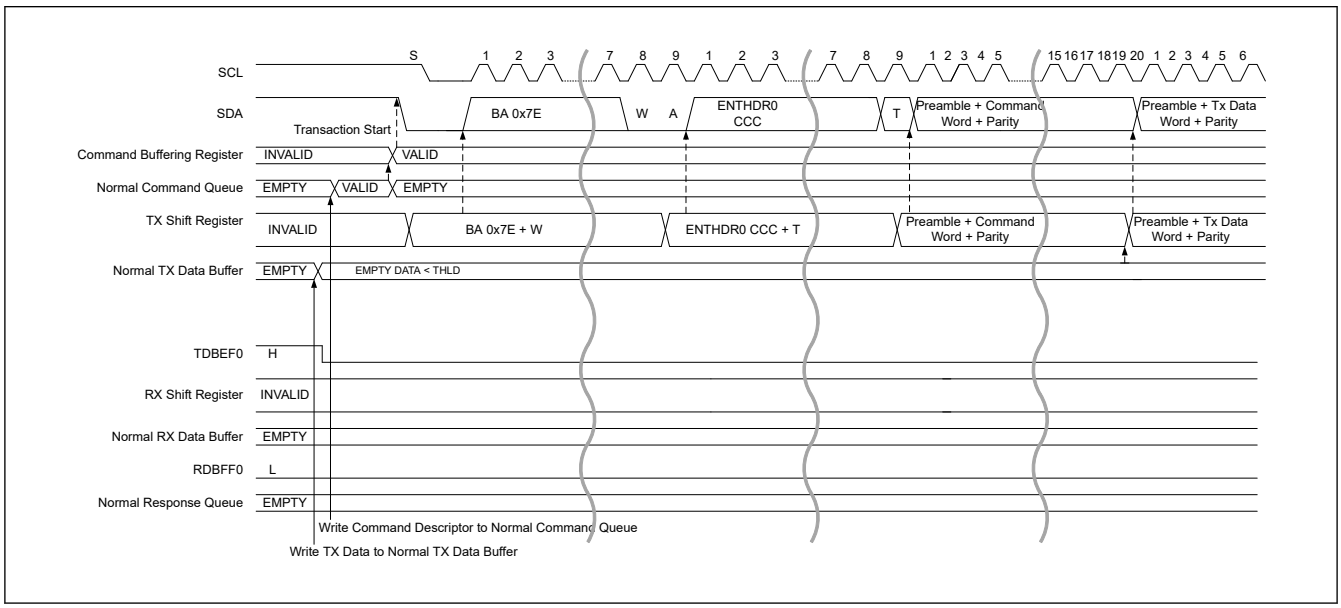

**Figure 29.24 HDR data write transfer (HDR-DDR) timing (1/4)**

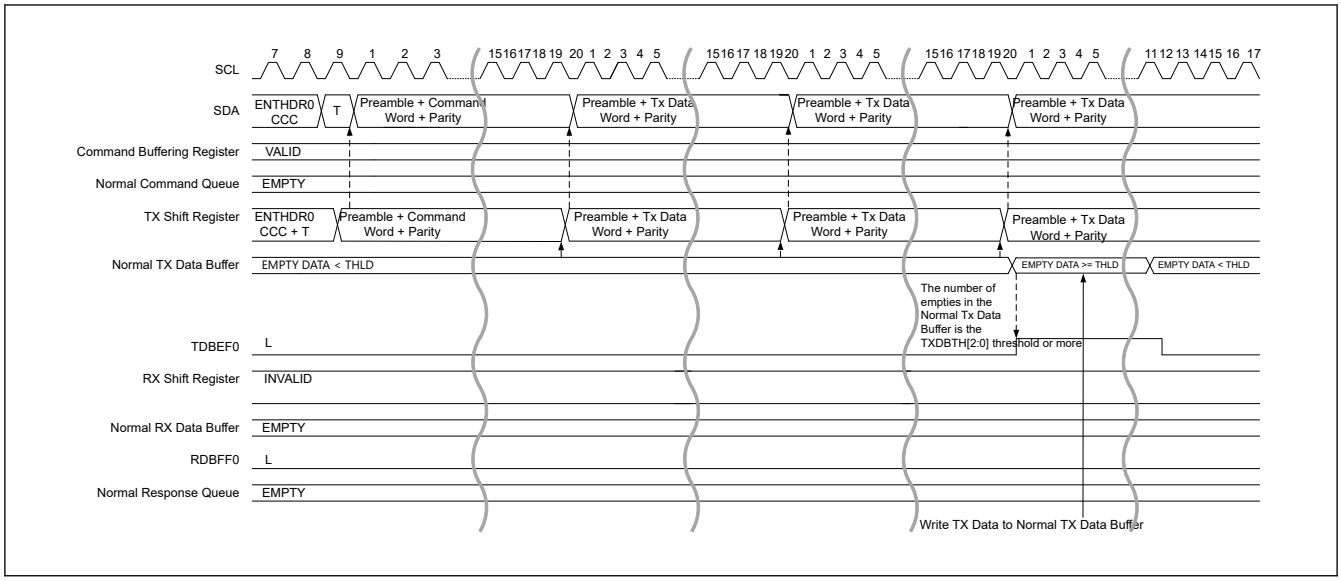

**Figure 29.25 HDR data write transfer (HDR-DDR) timing (2/4)**

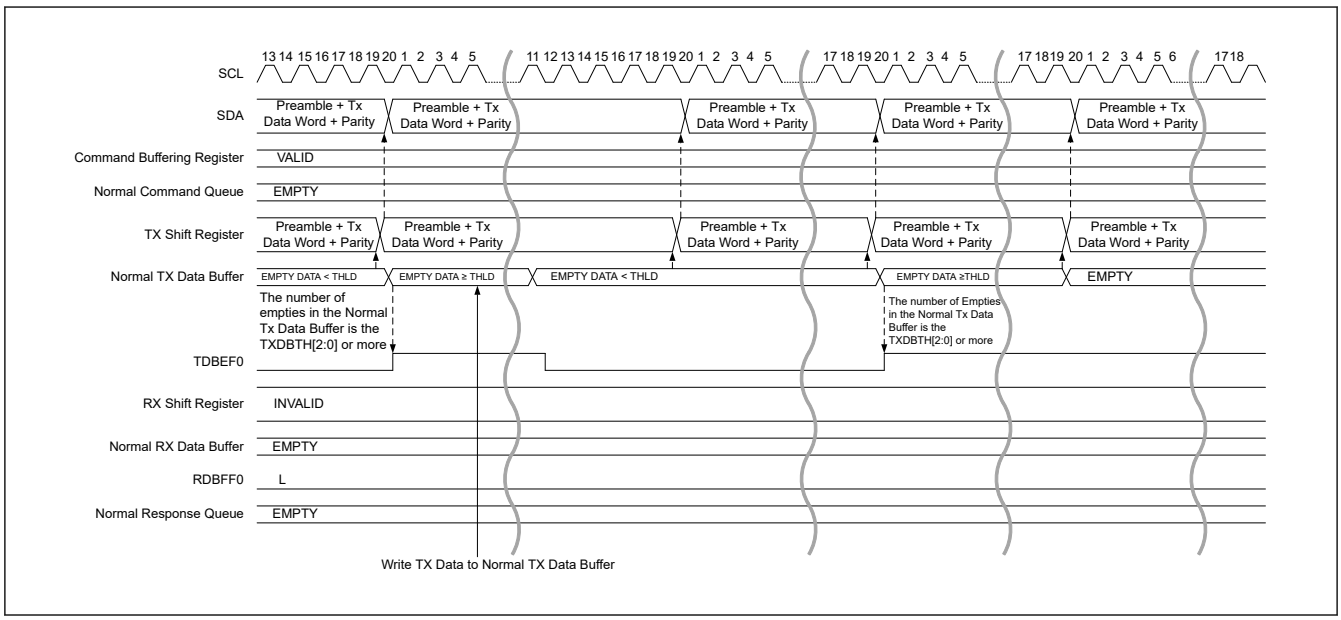

**Figure 29.26 HDR data write transfer (HDR-DDR) timing (3/4)**

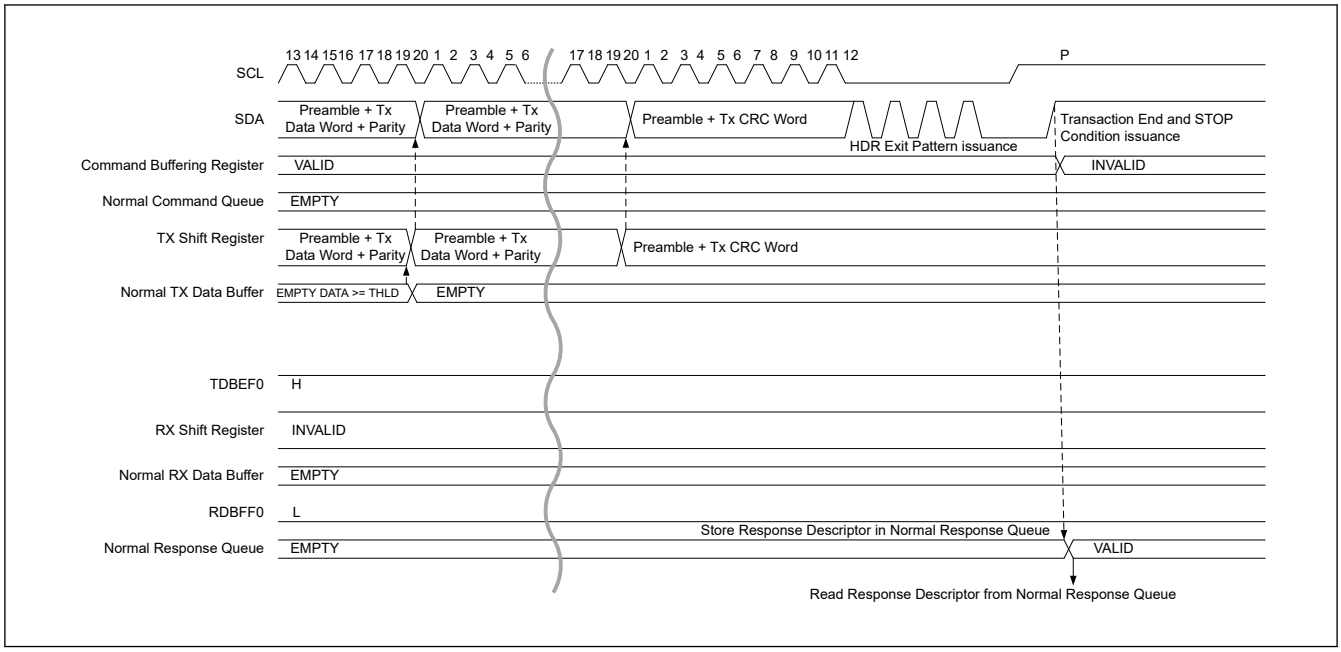

**Figure 29.27 HDR data write transfer (HDR-DDR) timing (4/4)**

(e) HDR Data Read Transfer

1. Write a Command Descriptor (Immediate Transfer Command or Regular Transfer Command or Combo Transfer Command) for Data Transfer to the Command Buffer via the NCMDQP register.
2. When Command Descriptor is written to Command Buffer, transaction is issued on I3C Bus.
   When NACK is received with the Address Header, transaction of the same command is automatically issued according to the NACK Retry Count value (DATBASm.DVNACK) of DAT.
3. Data received from the I3C Slave is stored in the Receive Data Buffer.
4. With the RDBFF0 = 1 interrupt, the received data is read from the Receive Data Buffer via the NTDTBPn register.
5. HDR-DDR:
   (a) When CRC Word is received, it issues HDR Restart Pattern or HDR Exit Pattern + STOP condition and stores the Response Descriptor into the Response Buffer.
   (b) When the preamble following the received data for the number of Data Length specified by the DATA_LENGTH[15:0] bits of Command Descriptor indicates Data Word (11), drive (Abort) low to the second bit of the preamble. After that, issue HDR Restart Pattern or HDR Exit Pattern + STOP condition and store the Response Descriptor into the Response Buffer.
6. Read the Response Descriptor via the NRSPQP register and check the status.
7. Check whether the value of the DATA_LENGTH[15:0] bits of the Response Descriptor matches the data length setting value of the Command Descriptor.

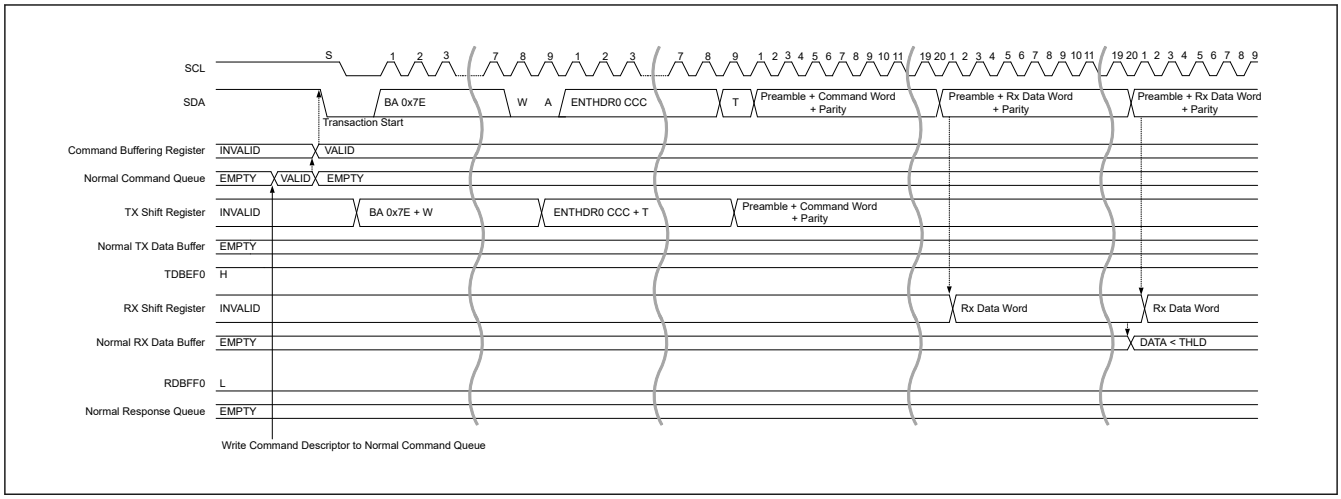

**Figure 29.28 HDR data read transfer (HDR-DDR) timing (1/2)**

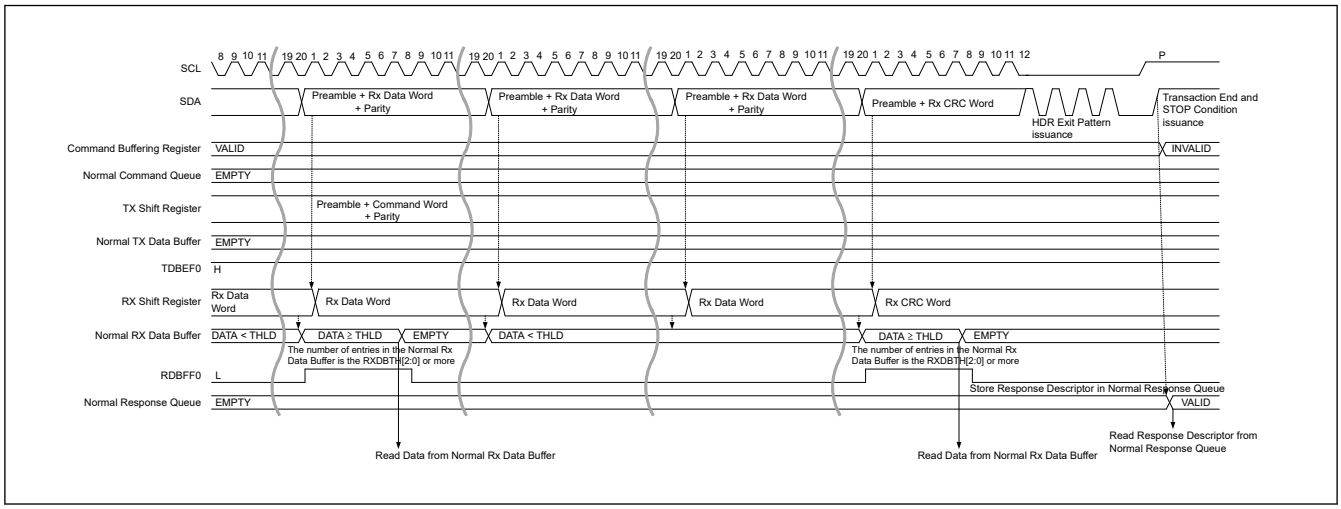

**Figure 29.29 HDR data read transfer (HDR-DDR) timing (2/2)**

(f) IBI Transfer

1. Write Command Descriptor to the Command Buffer and issue Transaction on I3C Bus.
   If START Request (SDA Low Drive) is issued from the slave device, I3C drives SCL to Low and completes START condition.
   Thereafter, the SCL is supplied and In-Band Interrupt Request is received.
2. In Slave Address with RnW of the Address Header, if losing Arbitration by issuing In-Band Interrupt from I3C Slave, stop issuing Transaction.
3. According to section 29.3.2.3.8. In-Band Interrupt [I3C mode], detect In-Band Interrupt and process.
4. In the interrupt with IBIQEFF = 1, read the IBI Status Descriptor from the IBI Queue via the NIBIQP register and check the status.
   When detected a Slave Interrupt Request and responded with ACK, Read the IBI Data for the Data Length indicated by the DATA_LENGTH[15:0] bits of the IBI Status Descriptor from the IBI Data Buffer via the NIBIQP register.
5. Restart issuing Transaction of Command of Step1.

An example of the processing procedure after detection of In-Band Interrupt is shown below.

Processing procedure for detecting Mastership Request and transferring master right to Secondary Master.

1. If the I3C Secondary Master wins the Arbitration, issue a DEFSLVS CCC and notify Slave information to Secondary Master.
2. Issue a GETACCMST CCC and complete CCC by a STOP condition.

The Mastership processing flow is shown in Figure 29.32.

Note:
- After transferring master right to Secondary Master, to get master right again, issue a Mastership Request according to (f) IBI Transfer of (2) I3C Slave Operation.
- After Mastership Request is accepted by the Current Master, to get master right again at receiving the GETACCMST CCC and complete CCC by a STOP condition.

Processing procedure when Hot-Join Event is detected.

1. Issue a Broadcast Command Code Enter Dynamic Address Assignment (ENTDAA) to start the Dynamic Address Assignment process.
2. Issue a DEFSLVS CCC and notify Slave information to Secondary Master.

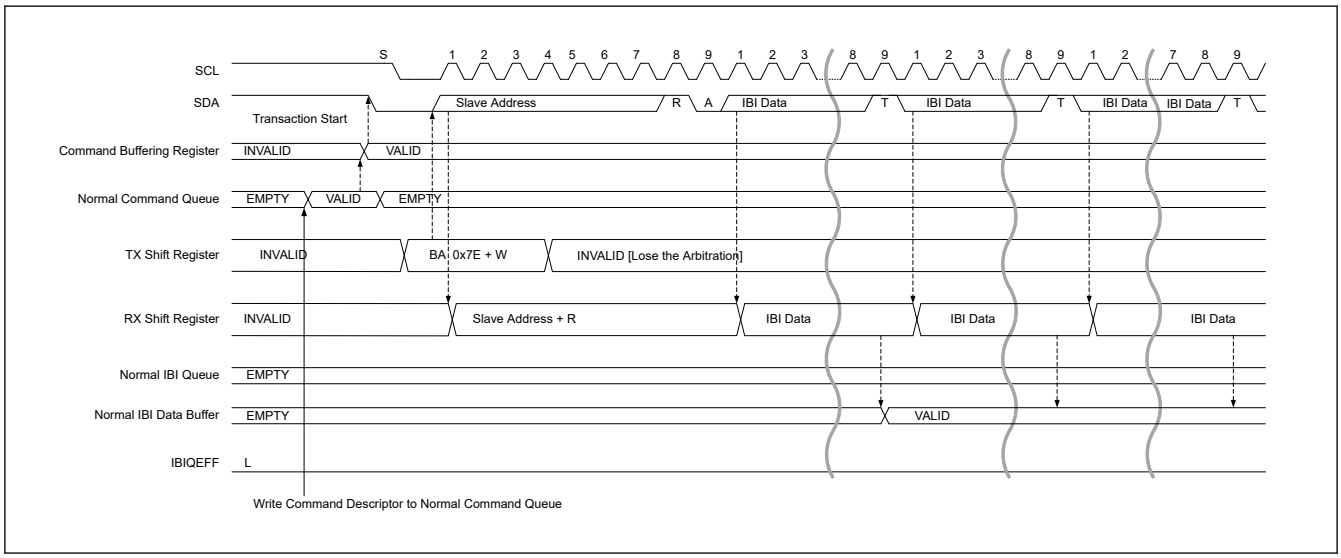

**Figure 29.30 I3C master IBI transfer timing (1/2)**

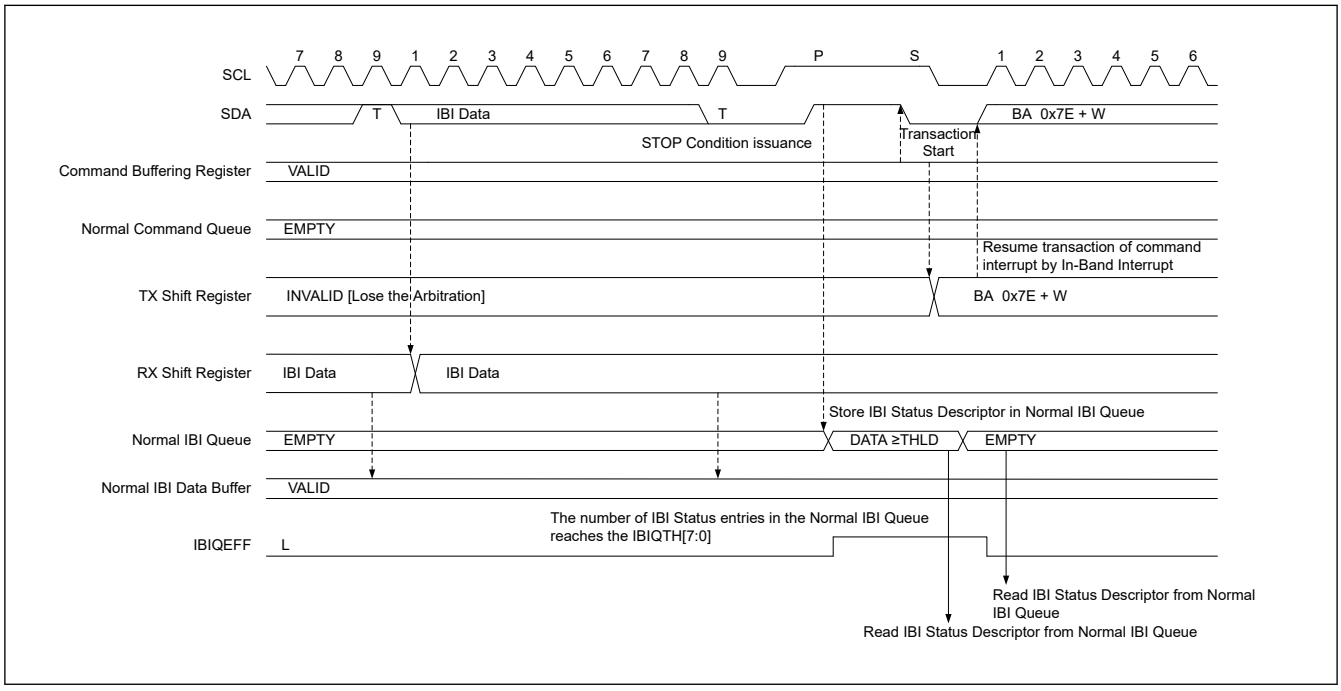

**Figure 29.31 I3C master IBI transfer timing (2/2)**

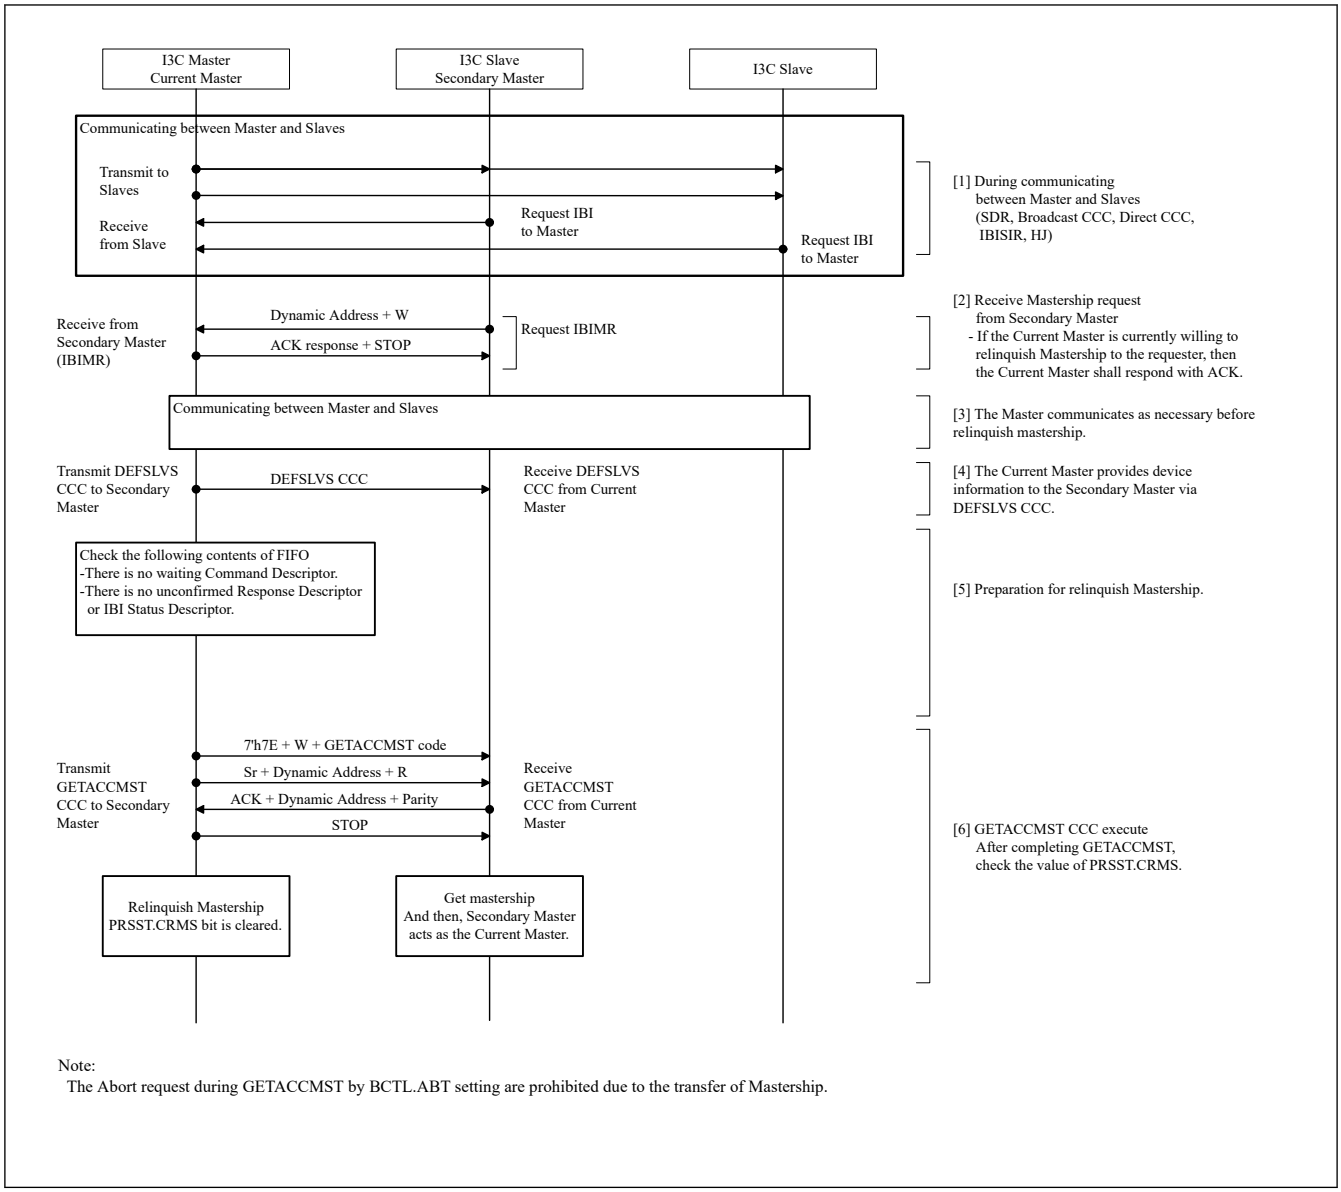

**Figure 29.32 I3C Master Mastership processing flow**

### 29.3.2.1.2 Slave Mode Operation

#### (1) I²C Slave Operation

(a) Data Write Transfer (Single Buffer transfer)

In slave receive operation, the master device outputs the SCL clock and transmit data, and I3C returns acknowledgments as a slave device.

Figure 29.137 shows an example of usage of slave reception and Figure 29.33 and Figure 29.34 show the timing of operations in slave reception.

The following procedure describes the operations for slave reception.

1. Initial settings. For details, see section 29.3.3.1. Initial Setting Flow. After initial settings, I3C stays in the standby state until it receives a slave address that it matches.
2. After receiving a matching slave address, I3C sets one of the corresponding bits SVST.HOAF, GCAF, and SVAF0 to 1 on the rising edge of the 9th cycle of SCL clock (the clock signal) and outputs the acknowledge bit (ACK) on the 9th cycle of SCL clock. If the value of the R/W# bit that was also received at this time is 0, I3C continues to place itself in slave receive mode and sets the NTST.RDBFF0 flag to 1.

3. After the BST.SPCNDDF flag is confirmed to be 0 and the NTST.RDBFF0 flag to be 1, dummy read the NTDTBP0 register (the dummy value consists of the slave address and R/W# bit when the 7-bit address format is selected, or the lower 8 bits when the 10-bit address format is selected).
4. When the NTDTBP0 register is read, I3C automatically sets the NTST.RDBFF0 flag to 0. If reading of the NTDTBP0 register is delayed and a next byte is received while the RDBFF0 flag is still set to 1, I3C holds the I3C_SCL line low from one SCL cycle before the timing with which RDBFF0 should be set. In this case, reading the NTDTBP0 register releases the I3C_SCL line from being held at the low level. When the BST.SPCNDDF flag = 1 and the NTST.RDBFF0 flag is also 1, read the NTDTBP0 register until all the data is completely received.
5. Upon detecting the STOP condition, I3C automatically clears bits SVST.HOAF, GCAF, and SVAF0 to 0.
6. After checking that the BST.SPCNDDF flag = 1, set the BST.SPCNDDF flag to 0 for the next transfer operation.

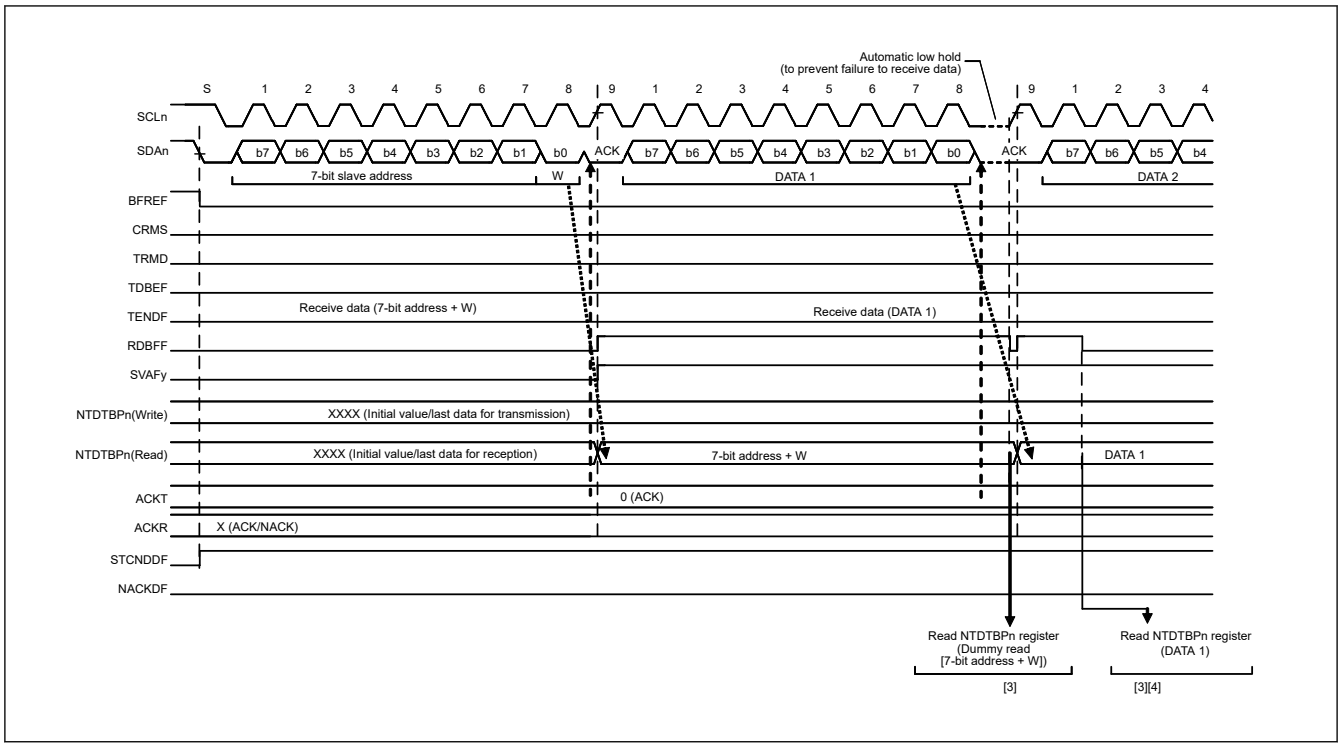

**Figure 29.33 Slave receive operation timing (1) (7-bit address format, when ACKTWE = 0)**

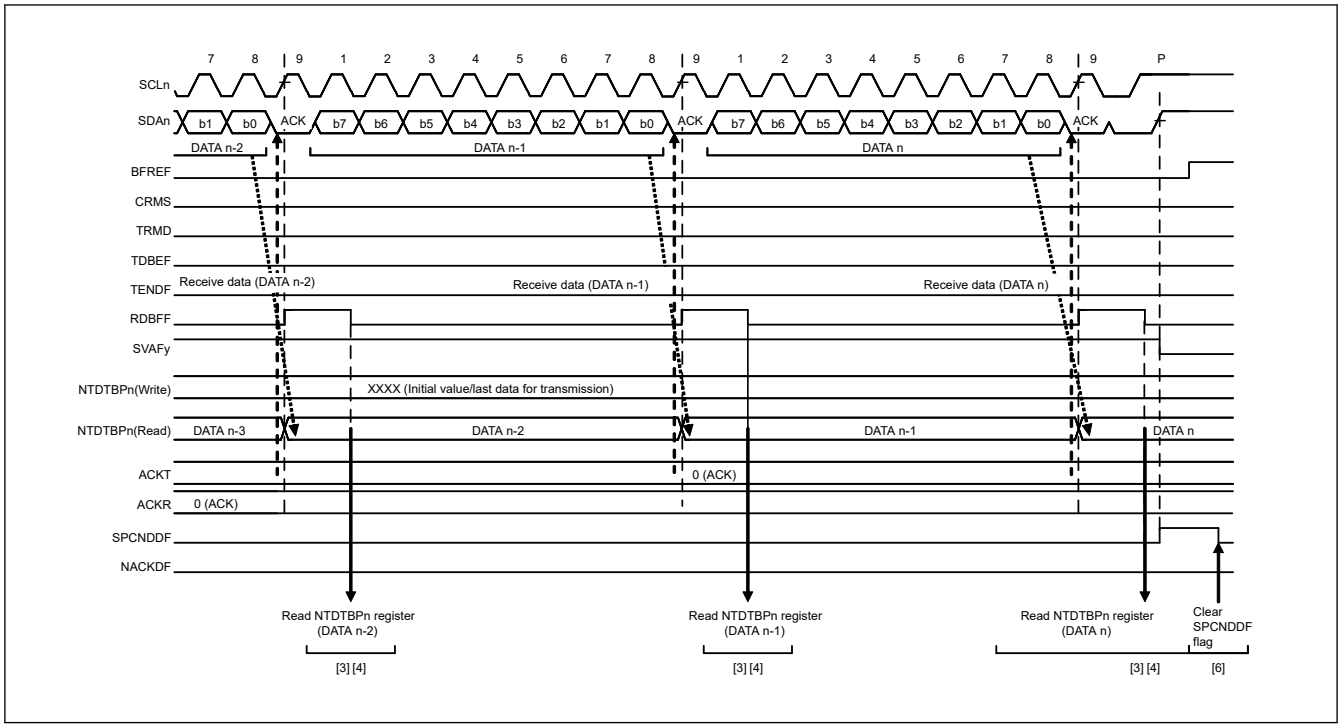

**Figure 29.34 Slave receive operation timing (2) (when ACKTWE = 0)**

(b) Data Read Transfer (Single Buffer transfer)

In slave transmit operation, the master device outputs the SCL clock, I3C transmits data as a slave device, and the master device returns acknowledgments.

Figure 29.136 shows an example of usage of slave transmission and Figure 29.35 and Figure 29.36 show the timing of operations in slave transmission.

The following procedure describes the operations for slave transmission.

1. Initial settings. For details, see section 29.3.3.1. Initial Setting Flow.
   After initial settings, I3C stays in the standby state until it receives a slave address that it matches.
2. After receiving a matching slave address, I3C sets one of the corresponding bits SVST.HOAF, GCAF, and SVAF0 to 1 on the rising edge of the 9th cycle of SCL clock (the clock signal) and outputs the acknowledge bit (ACK) on the 9th cycle of SCL clock. If the value of the R/W# bit that was also received at this time is 1, I3C automatically places itself in slave transmit mode by setting both the PRSST.TRMD bit and the NTST.TDBEF0 flag to 1.
3. After the NTST.TDBEF0 flag is confirmed to be 1, write the data for transmission to the NTDTBP0 register.
   At this time, if I3C does not receive acknowledge from the master device (receives an NACK signal) while the BSTE.NACKDE bit = 1, I3C aborts transfer of the next data.
4. Wait until the following (a) or (b) condition.
   (a) The BST.NACKDF flag is set to 1.
   (b) The BST.TENDF flag is set to 1 while the NTST.TDBEF0 flag = 1, after the last byte for transmission is written to the NTDTBP0 register.
5. When the BST.NACKDF flag or the BST.TENDF flag = 1, dummy read the NTDTBP0 register to complete the processing. This releases the I3C_SCL line.
6. Upon detecting the STOP condition, I3C automatically sets bits SVST.HOAF, GCAF, and SVAF0, flags NTST.TDBEF0 and BST.TENDF, and the PRSST.TRMD bit to 0, and enters slave receive mode.
7. After checking that the BST.SPCNDDF flag = 1, set the BST.NACKDF and SPCNDDF flags to 0 for the next transfer operation.

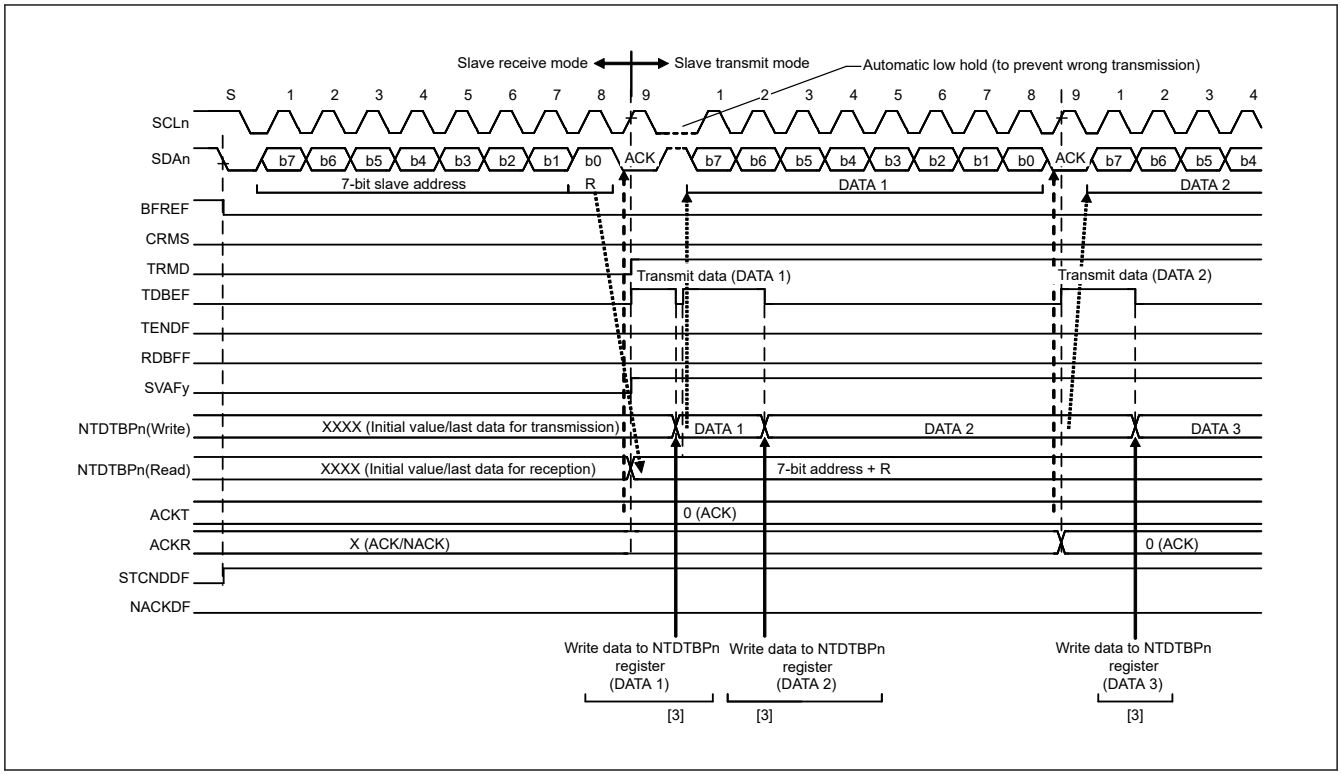

**Figure 29.35 Slave transmit operation timing (1) (7-bit address format)**

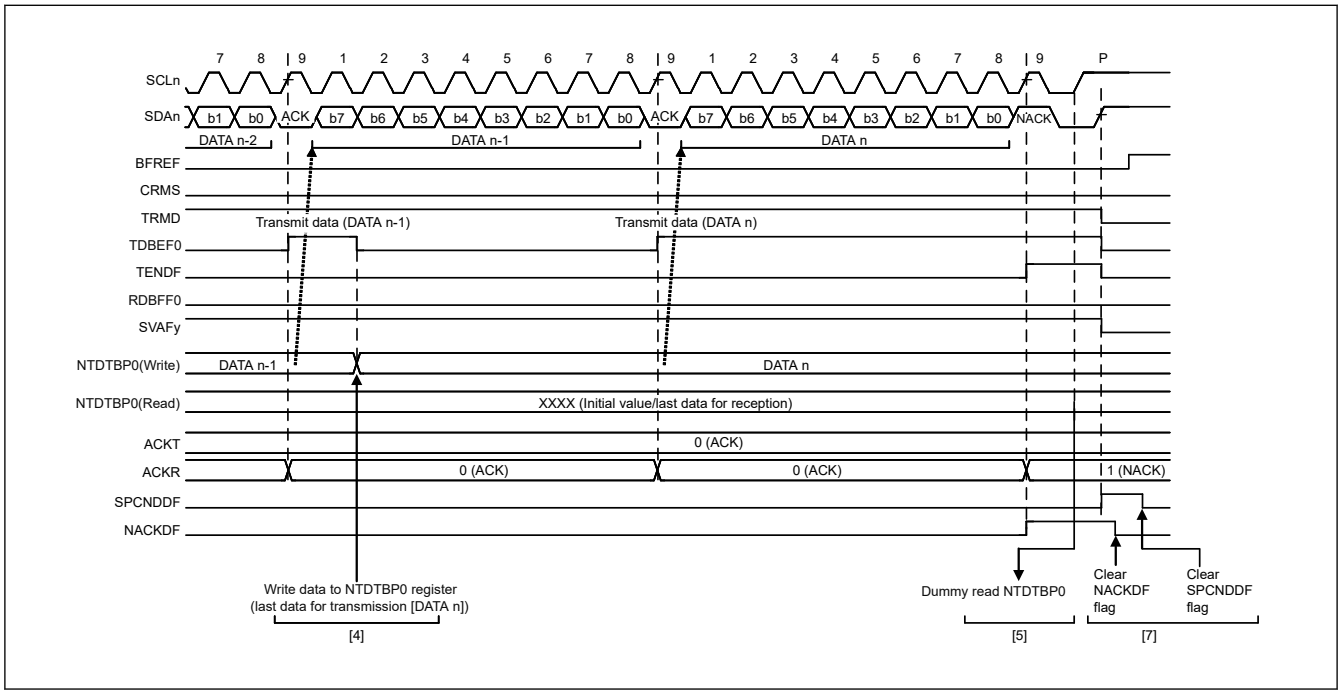

**Figure 29.36 Slave transmit operation timing (2)**

## (2) I3C Slave Operation

(a) Dynamic Address Assign Procedure

After initializing I3C, the I3C master first performs Dynamic Address Assign Procedure.

The operation of R-I3 during the Dynamic Address Assign Procedure by ENTDAA CCC is described below.

1. Initial setting (for details, see section 29.3.3.1.2. I3C Initial Setting Flow)

2. When ENTDAA CCC is received, I3C transmits Provisional ID (SDCTPIDH[31:0], SDCTPIDL[15:0]), BCR (SVDCT.TBCRn), DCR (SVDCT.TDCR[7:0]) until a dynamic address is assigned. (For details, see "In case of Broadcast CCC (ENTDAA)" of (6) CCC detection function [I3C mode].)
3. When ENTDAA CCC is completed and a STOP condition is detected, Receive Status Descriptor is stored in Receive Status Queue.
4. Read Receive Status Descriptor using the NRSQP register and check the status.
5. Read the data for the Data Length indicated by the DATA_LENGTH[15:0] bits of the Receive Status Descriptor from the Receive Data Buffer using the NTDTBP0 register.

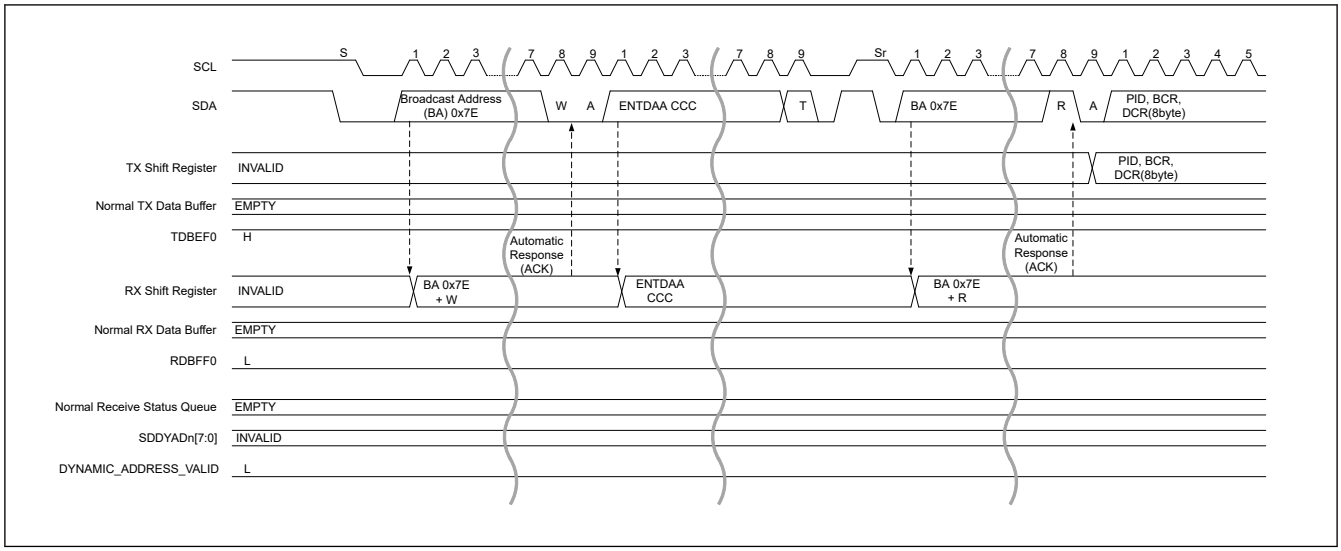

**Figure 29.37 Dynamic address assign procedure (ENTDAA CCC) timing (1/3)**

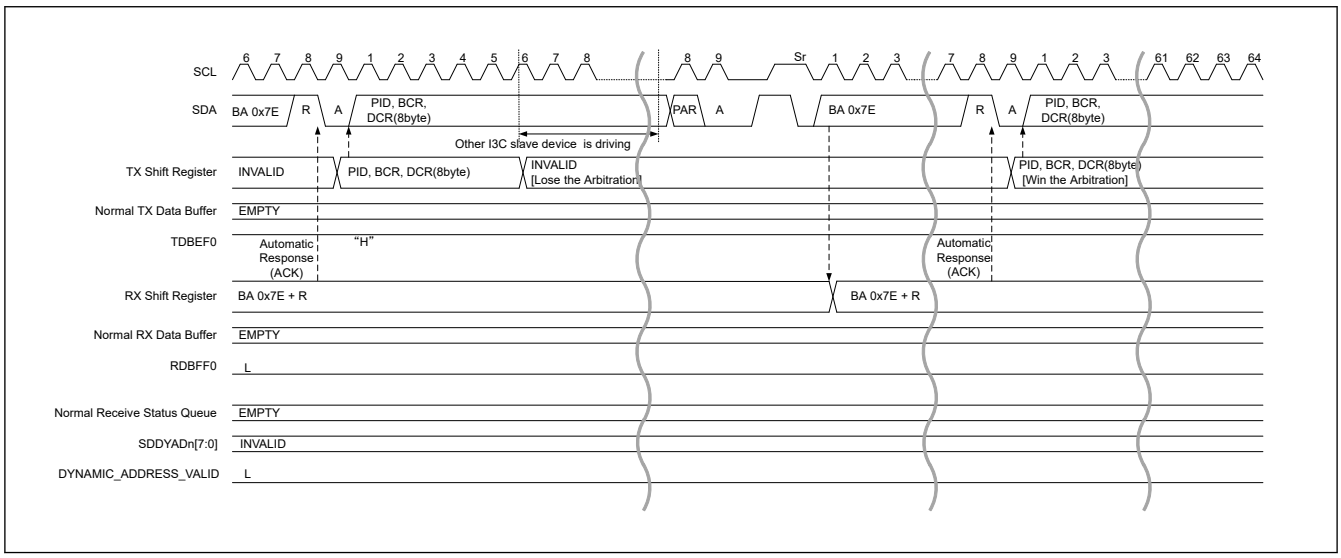

**Figure 29.38 Dynamic address assign procedure (ENTDAA CCC) timing (2/3)**

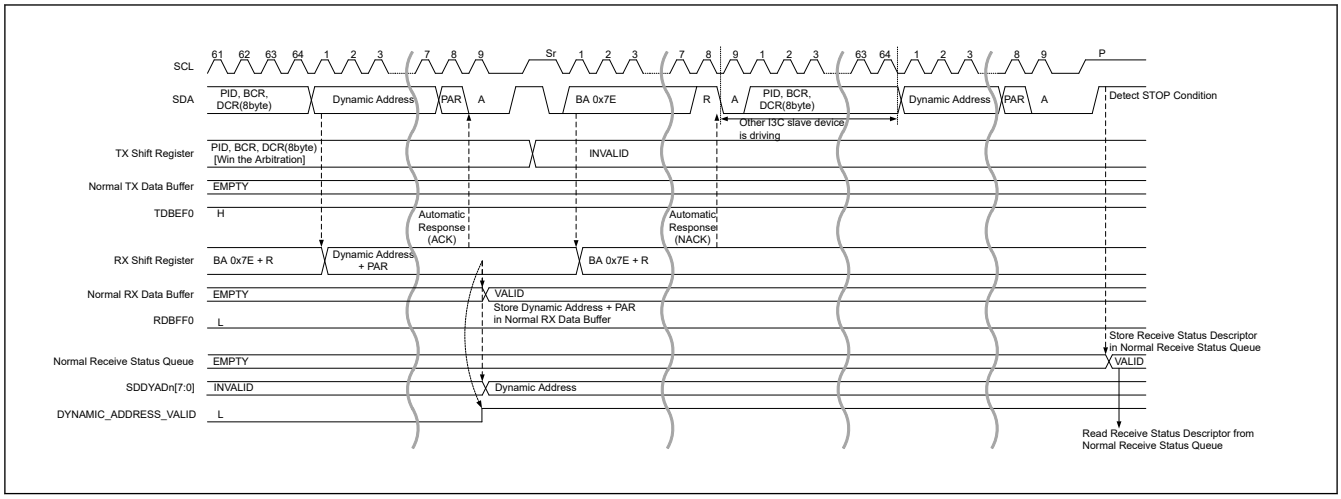

**Figure 29.39 Dynamic address assign procedure (ENTDAA CCC) timing (3/3)**

When communicating with a Static Address until the Dynamic Address is assigned from the I3C master, by setting to the DVSTAD[6:0] bit of DAT (SDATBAS0 register), the SSTADV bit of the SVDVAD0 register is set to 1 and the Static Address Will be effective.

If the I3C Slave has a Static Address and the I3C master executes the Dynamic Address Assign Procedure, it is possible to assign a Dynamic Address with SETDASA CCC.

The operation of I3C during SETDASA CCC Dynamic Address Assign Procedure is described below.

1. Initial setting (for details, see section 29.3.3.1.2. I3C Initial Setting Flow)
2. When SETDASA CCC which agrees with its own Static Address is received, the SDDYAD [7:0] bit of DAT (SDATBAS0 register) is renewed and SDYADV bit of SVDVAD0 register is set in 1. (For details, see "In case of Direct Write CCC" of (6) CCC detection function [I3C mode].)
3. When SETDASA CCC is completed and a STOP condition is detected, Receive Status Descriptor is stored in Receive Status Queue.
4. Read Receive Status Descriptor using the NRSQP register and check the status.

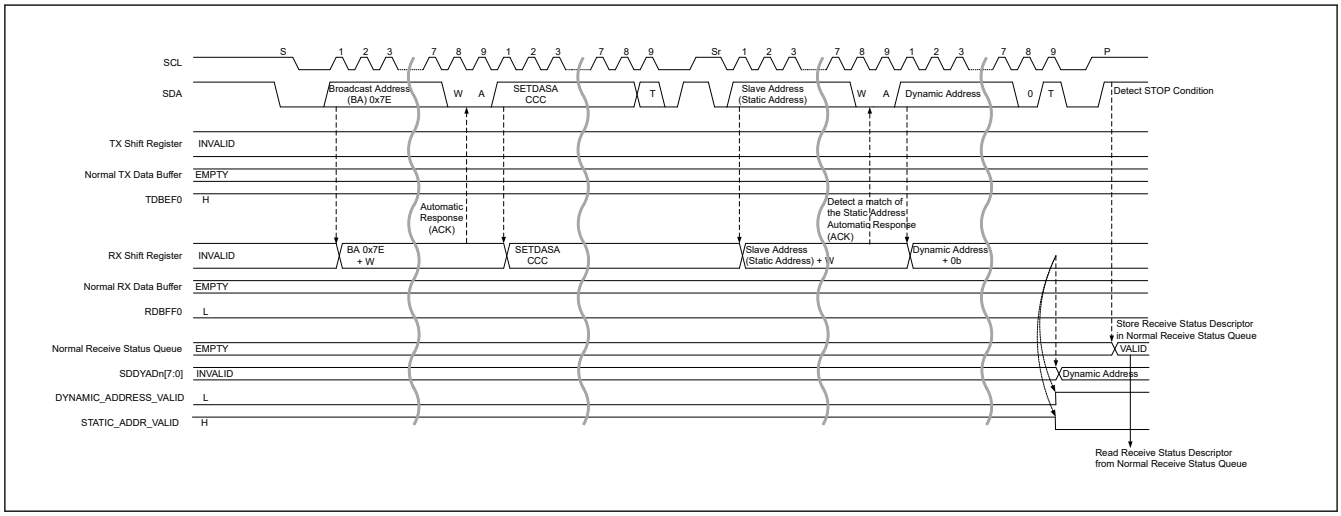

**Figure 29.40 Dynamic address assign procedure (SETDASA CCC) timing**

(b) SDR Data Write Transfer

1. When transaction is issued from the I3C master, it compares the Slave Address of Address Header with its own Slave Address, and if it matches, I3C responds with ACK.
   When a transaction is received, if the Receive Data Buffer is full, the I3C Slave responds with NACK in the Address Header.
   In preparation for retrying the I3C master, read the data from the Receive Data Buffer using the NTDTBPn register, and empty the Receive Data Buffer.

2. Data received from I3C master is stored in the Receive Data Buffer.
3. With the RDBFF0 = 1 interrupt, the received data is read from the Receive Data Buffer using the NTDTBPn register.
4. When Repeated START condition or STOP condition is detected, the Receive Status Descriptor is stored in the Receive Status Queue.
5. Read Receive Status Descriptor using NRSQP register and check the status.

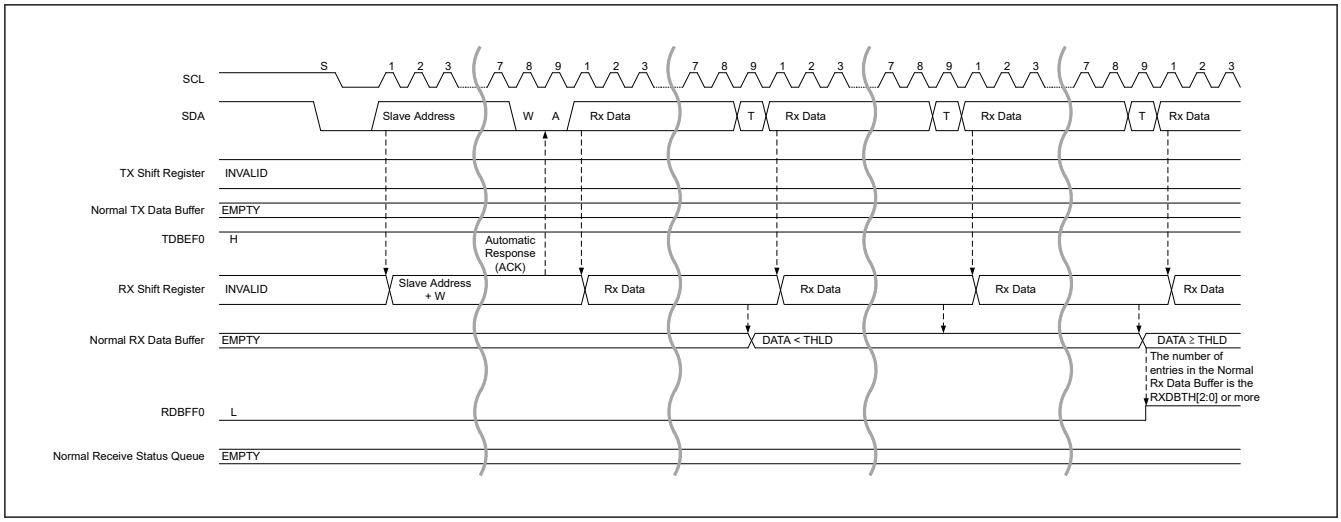

**Figure 29.41 SDR data write transfer timing (1/2)**

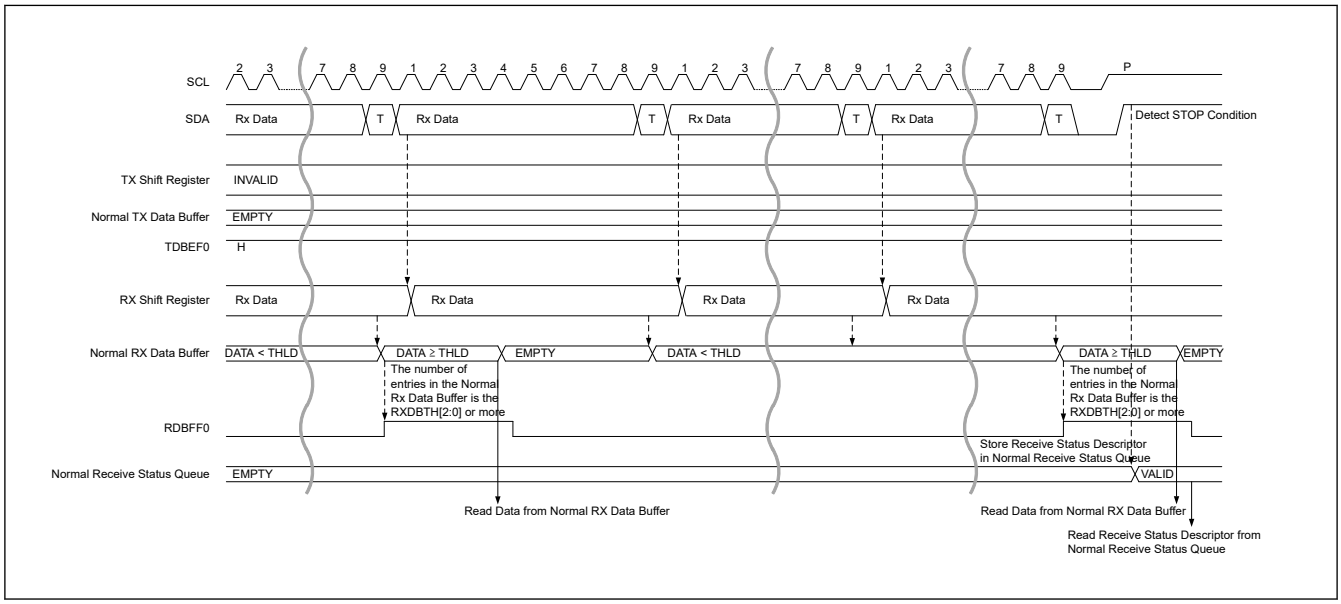

**Figure 29.42 SDR data write transfer timing (2/2)**

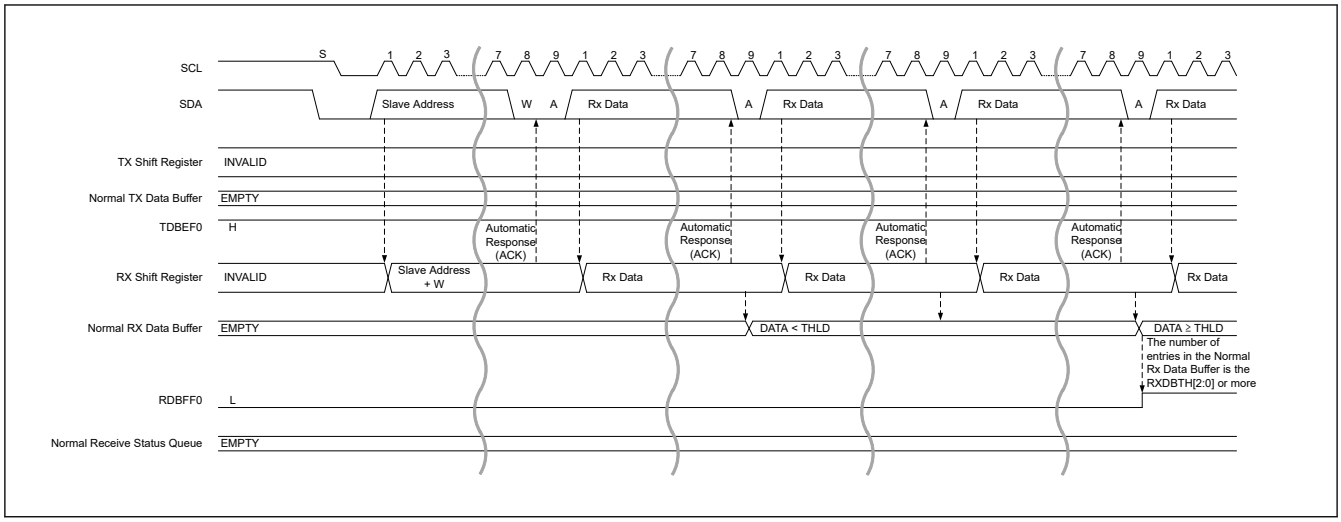

**Figure 29.43 Legacy I²C message data write transfer timing (1/2)**

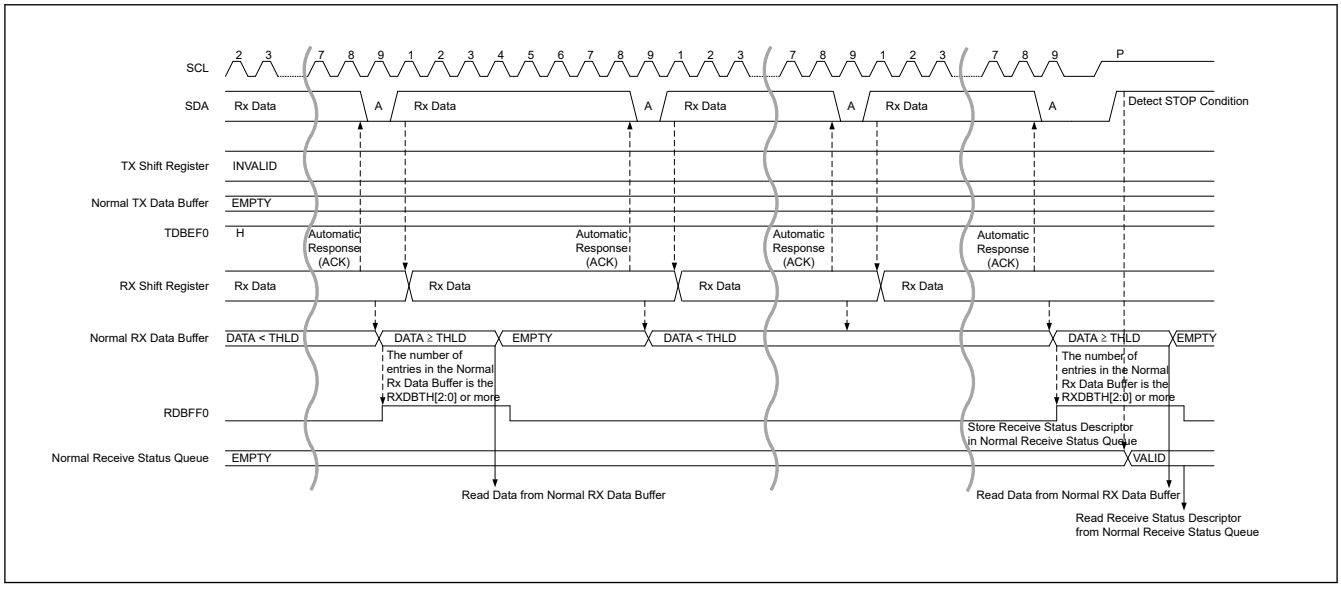

**Figure 29.44 Legacy I²C message data write transfer timing (2/2)**

(c) SDR Data Read Transfer

1. Write the data requested from the I3C master to the Tx Data Buffer using the NTDTBPn register.
2. When transaction is issued from the I3C master, it compares the Slave Address of Address Header with its own Slave Address, and if it matches, I3C responds with ACK.
   When a transaction is received, if the Tx Data Buffer is EMPTY, I3C Slave responds with NACK with the Address Header.
   In preparation for retrying the I3C master, write data to the Tx Data Buffer using the NTDTBPn register.
3. Transmit the data stored in the Tx Data Buffer.
4. If data to be transmitted still remains, write the data to be transmitted with an interrupt by TDBEF0 = 1 to the Tx Data Buffer using the NTDTBPn register.
5. SDR:
   When the transmission of the data stored in the Tx Data Buffer is completed, low is output to the T-bit following data, and it is notified to the I3C master that it is the final data.
   Legacy I²C Message:
   When NACK is detected, data transmission is terminated.
6. When a Repeated START condition or STOP condition is detected, the Receive Status Descriptor is stored in the Receive Status Queue.

7. Read the Receive Status Descriptor using NRSQP and check the status.

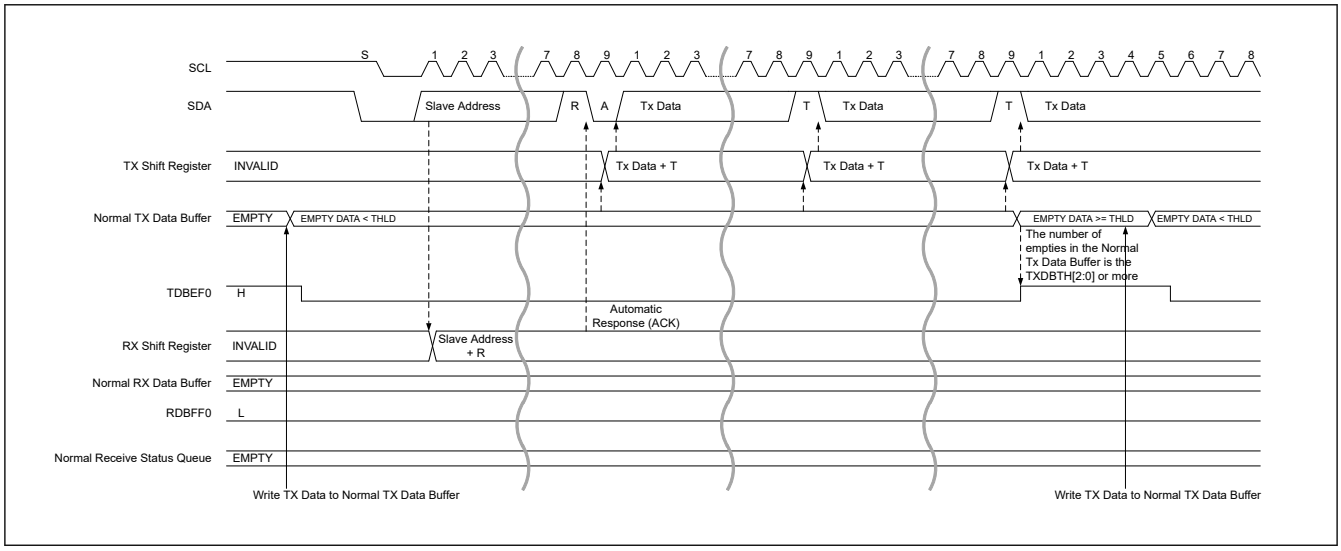

**Figure 29.45 SDR data read transfer timing (1/2)**

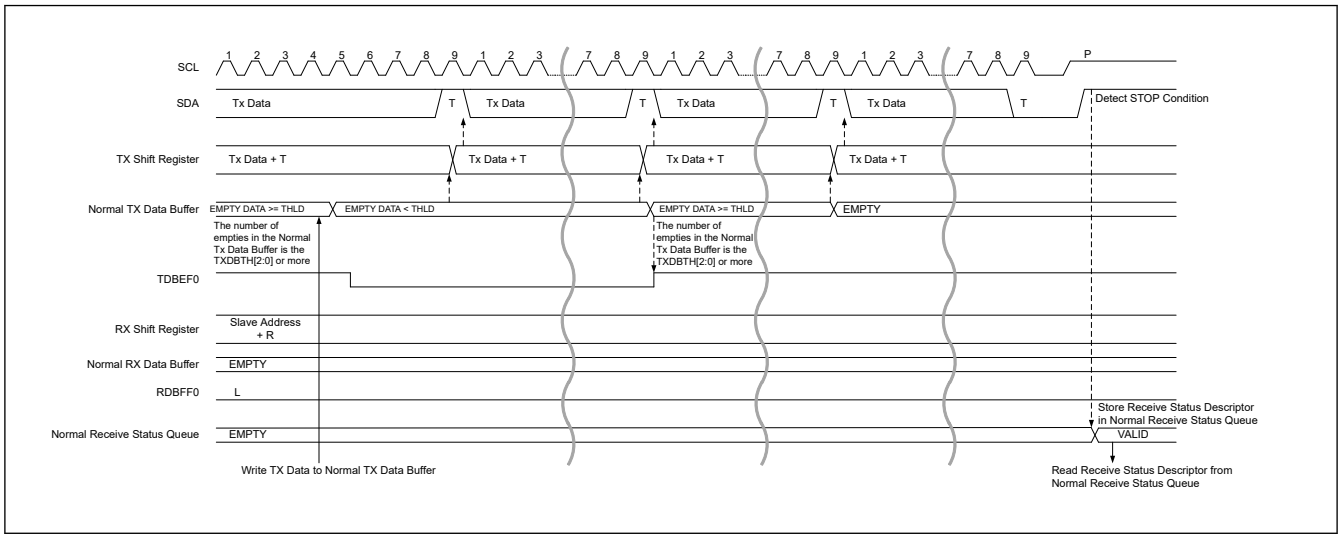

**Figure 29.46 SDR data read transfer timing (2/2)**

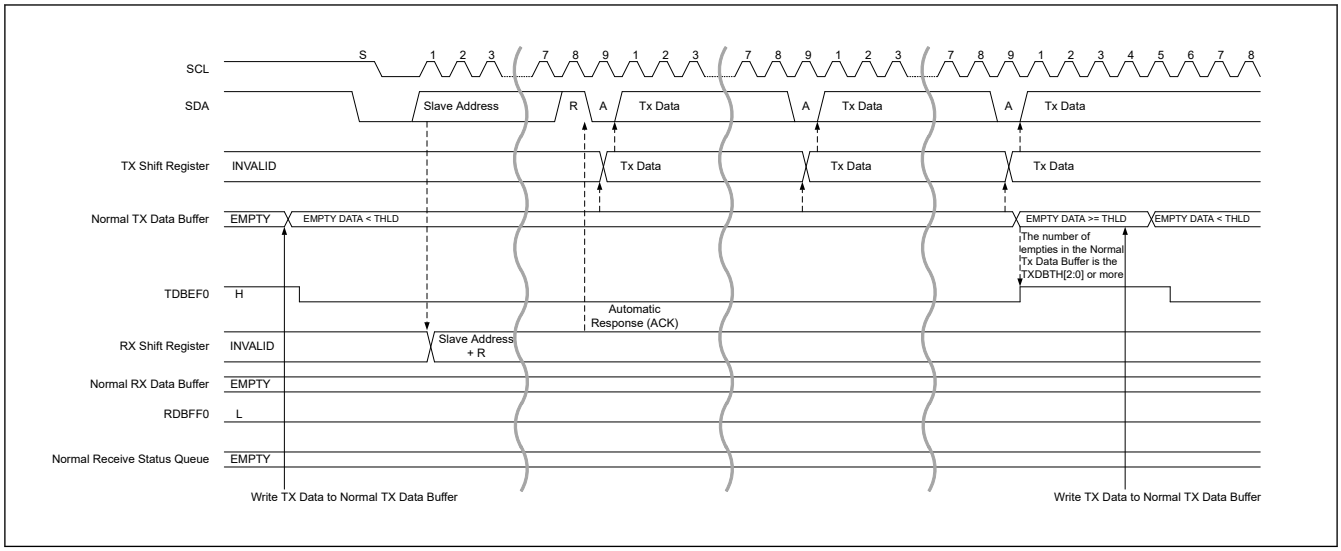

**Figure 29.47 Legacy I²C message data read transfer timing (1/2)**

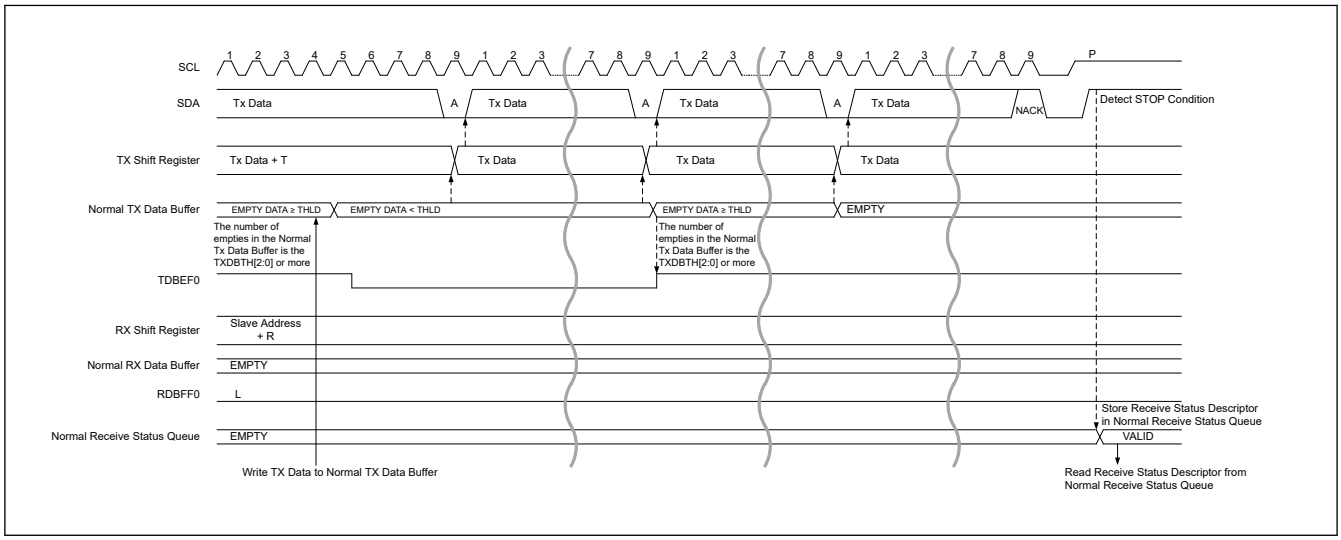

**Figure 29.48 Legacy I²C message data read transfer timing (2/2)**

(d) HDR Data Write Transfer

1. Upon receipt of ENTHDR * CCC from the I3C master, it transits to HDR mode (For details, see "In case of Broadcast CCC (ENTHDR *)" of (6) CCC detection function [I3C mode]).
2. Compare the Slave Address of the HDR Command Word issued from the I3C master with its own Slave Address, and if it matches, receive the following Data Word.
3. Data received from the I3C master is stored in the Receive Data Buffer.
4. With the RDBFF0 = 1 interrupt, the received data is read from the Receive Data Buffer using the NTDTBPn register.
5. When detecting HDR Restart Pattern or HDR Exit Pattern + STOP condition, it stores the Receive Status Descriptor into the Receive Status Queue.
6. Read the Receive Status Descriptor using NRSQP and check the status.

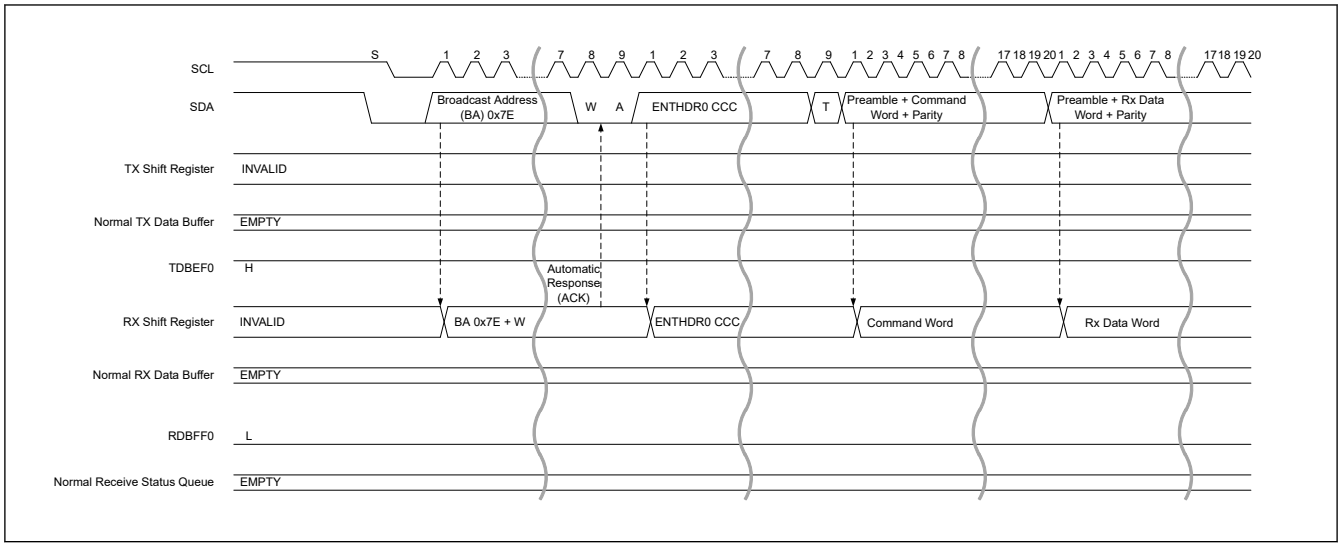

**Figure 29.49 HDR data write transfer (HDR-DDR) timing (1/3)**

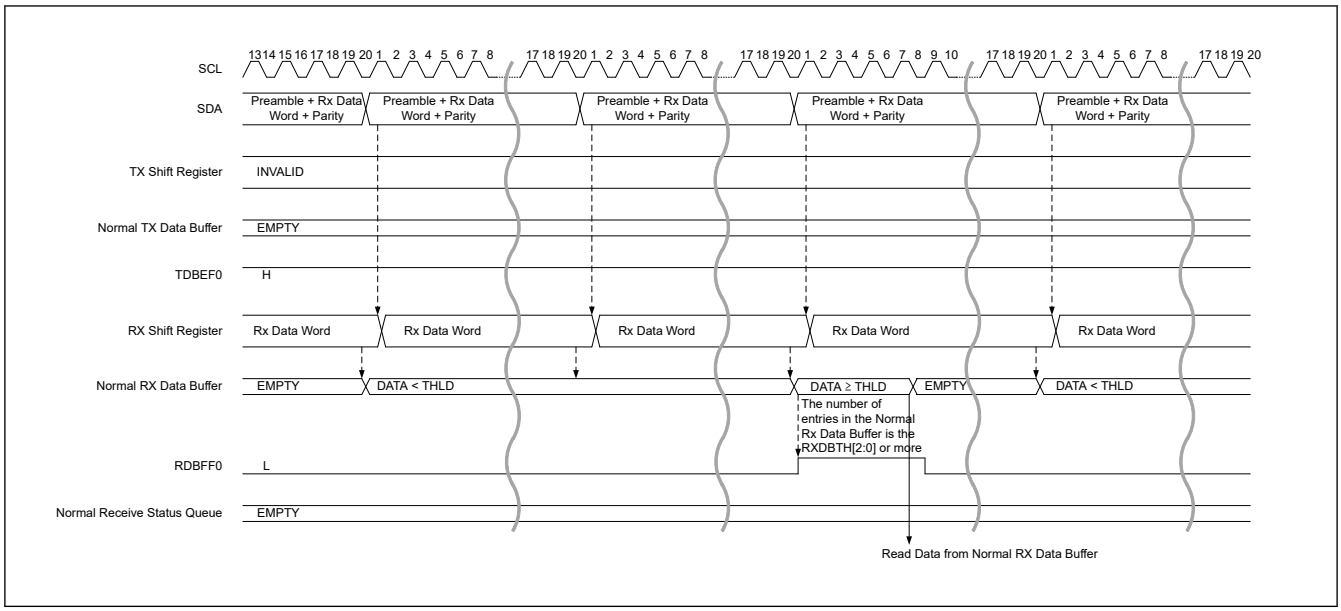

**Figure 29.50 HDR data write transfer (HDR-DDR) timing (2/3)**

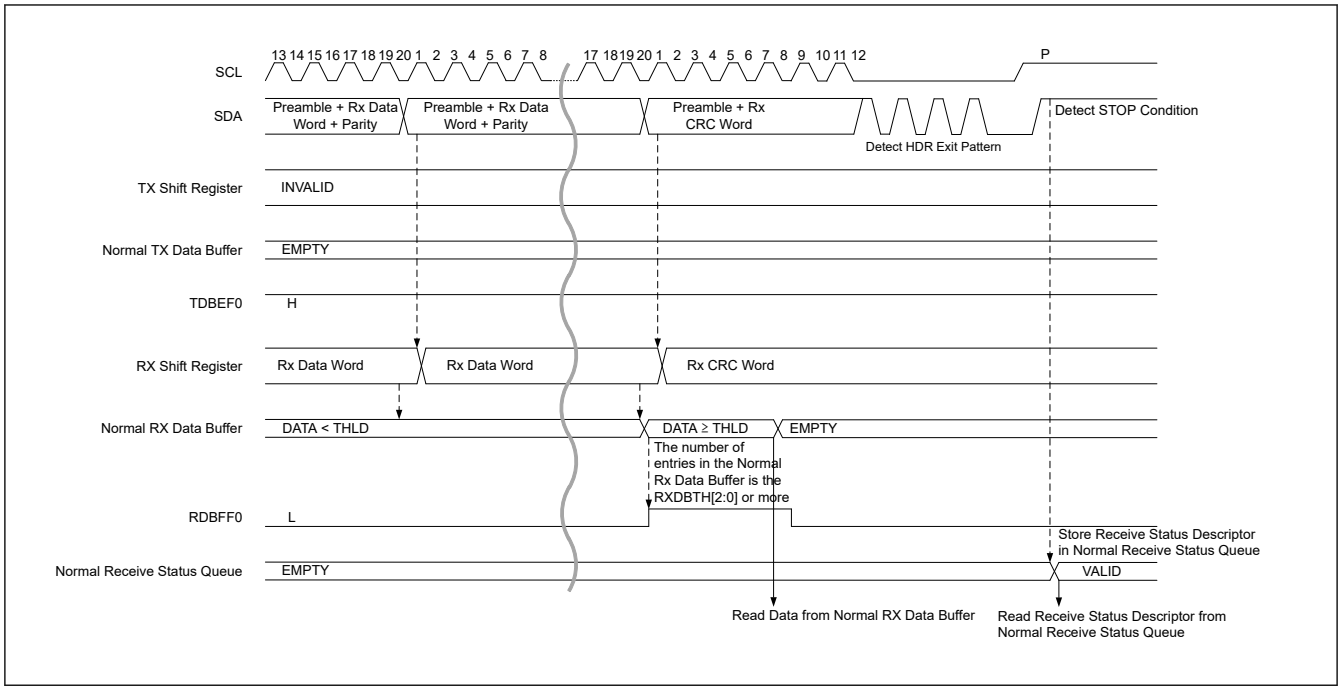

**Figure 29.51 HDR data write transfer (HDR-DDR) timing (3/3)**

(e) HDR Data Read Transfer

1. Write the data requested by the I3C master to the Tx Data Buffer using the NTDTBPn register.
2. Upon receipt of ENTHDR * CCC from the I3C master, it transits to HDR mode (for details, see "In case of Broadcast CCC (ENTHDR *)" of (6) CCC detection function [I3C mode]).
3. When comparing the Slave Address of the HDR Command Word issued from the I3C master with its own Slave Address, if it matches, the data stored in the Tx Data Buffer is transmitted.
   If the Tx Data Buffer is EMPTY when the Slave Address of the HDR Command Word matches its own Slave Address, a NACK response is sent.
   NACK response :
   - HDR-DDR :
     Send 11 followed by Command Word followed by Preamble.
4. If data to be transmitted still remains, Write the data to be transmitted with an interrupt by TDBEF0 = 1 to the Tx Data Buffer using the NTDTBPn register.
5. HDR-DDR:
   When the transmission of the data stored in the Tx Data Buffer is completed, the CRC Word is sent continuously to notify the I3C Master that it is the final data.
6. When detecting HDR Restart Pattern and HDR Exit Pattern + STOP condition, it stores the Receive Status Descriptor into the Receive Status Queue.
7. Read the Receive Status Descriptor using NRSQP and check the status.

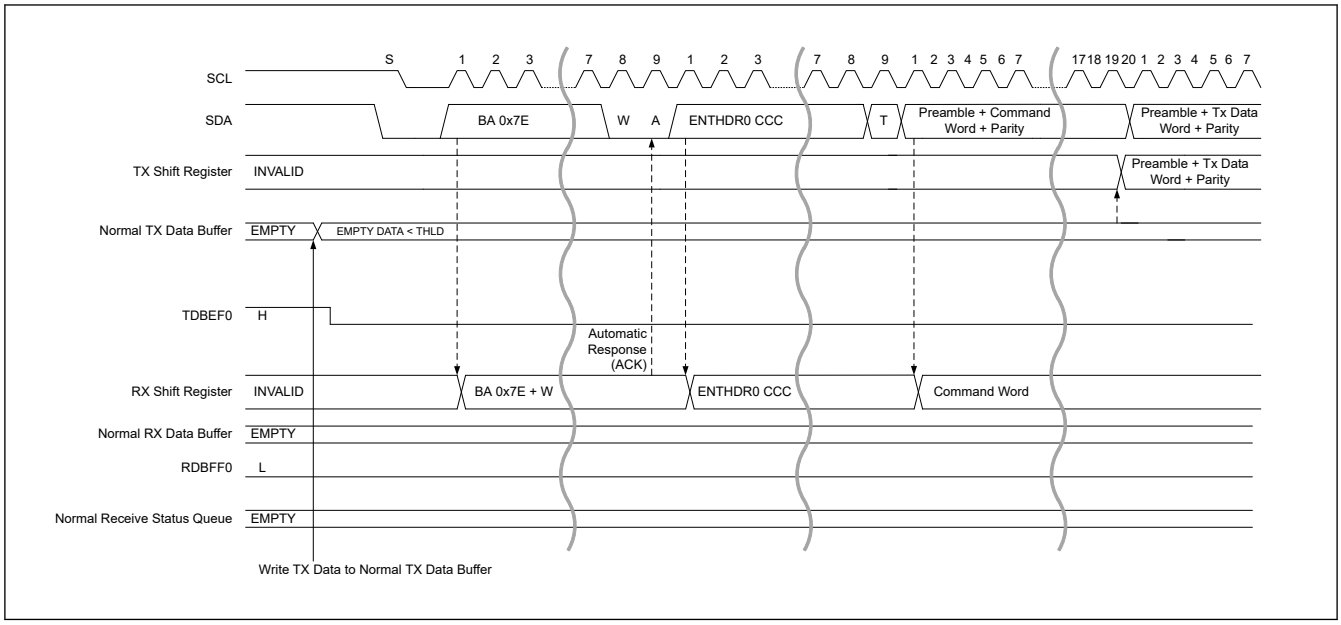

**Figure 29.52 HDR data read transfer (HDR-DDR) timing (1/3)**

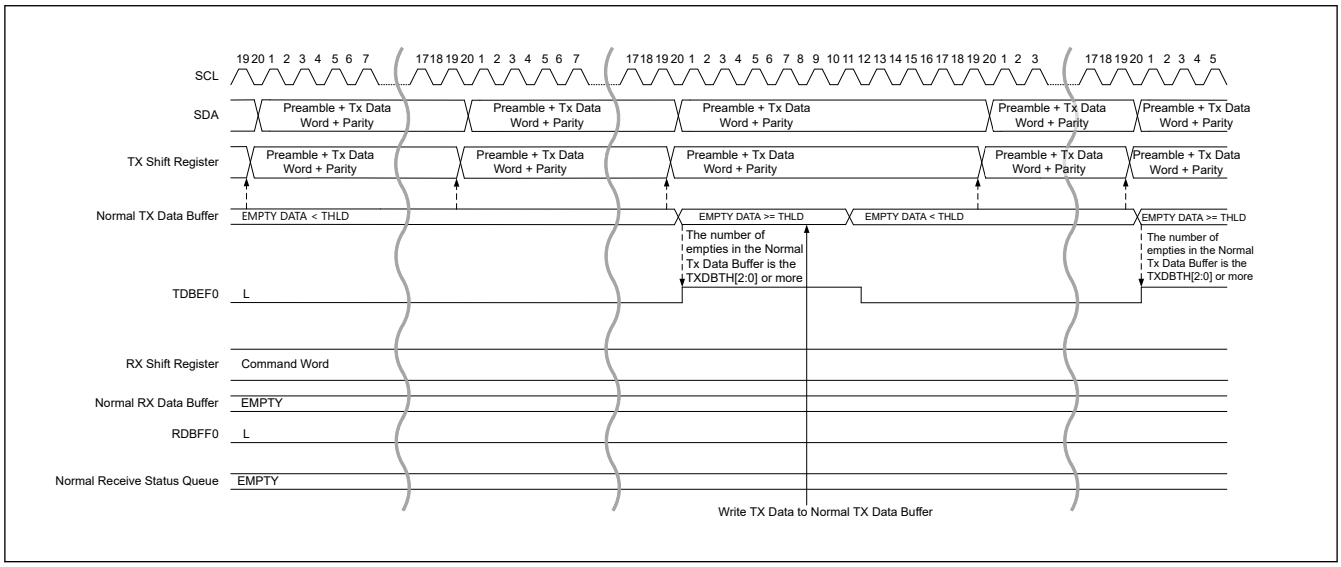

**Figure 29.53 HDR data read transfer (HDR-DDR) timing (2/3)**

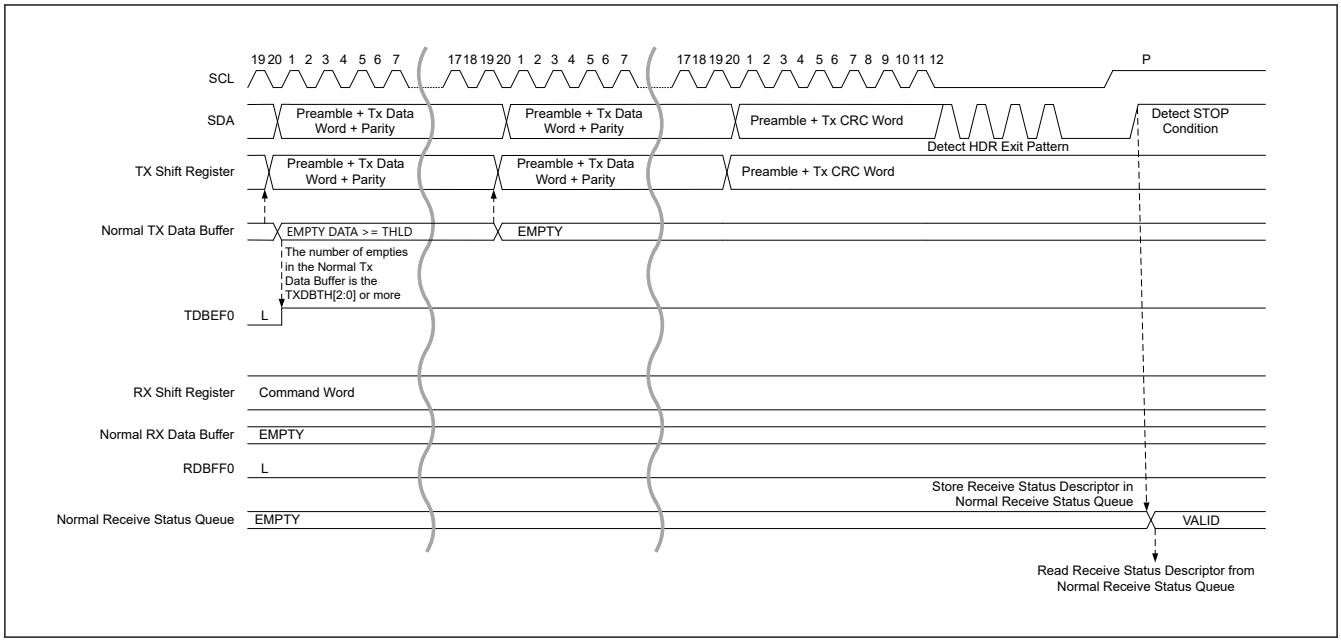

**Figure 29.54 HDR data read transfer (HDR-DDR) timing (3/3)**

(f) IBI Transfer

1. When sending Slave Interrupt Request.
   When transmitting IBI Data, write IBI Data to the IBI Data Buffer using the NIBIQP register.
2. Write Command Descriptor (Immediate Transfer Command or Regular Transfer Command) to the Command Buffer for IBI Transfer using the NCMDQP register.
3. When Command Descriptor is written to Command Buffer, IBI Transaction is issued under the following conditions.
   - When START condition is detected in Slave Interrupt Request or Mastership Request (does not apply a Repeated START condition).
   - If no START is forthcoming within the following Bus Condition, then this module issue a START Request by pulling the I3C_SDA line Low.
   - (a) Slave Interrupt Request, Mastership Request: Bus Available
     (b) Hot-Join Event: Bus Idle
4. In Slave Address with RnW of the Address Header, if losing arbitration by issuing a transaction from I3C master, stop issuing transaction.
   When detecting Repeated START condition or STOP condition, store the Response Descriptor into the Response Buffer.
5. When sending Slave Interrupt Request:
   - When IBI data for transmission still remains, write IBI data with an interrupt by IBIQEFF = 1 to the IBI Data Buffer using the NIBIQP register.
   - When the transmission of IBI data for the number of Data Length specified by the DATA_LENGTH[15:0] bits of the Command Descriptor is completed, output low to the T-bit following IBI data and notify the I3C master that it is the final IBI data.
6. When detecting Repeated START condition or STOP condition, store the Response Descriptor into the Response Buffer.
7. Read the Response Descriptor from the Response Buffer using the NRSPQP register and check the status. If NACK is responded, repeat steps 1 to 7.
8. When sending Slave Interrupt Request:
   Check that the value of the DATA_LENGTH[15:0] bit of the Response Descriptor is 0.

The Mastership processing flow is shown in Figure 29.57. When joining the I3C Bus by Hot-Join after the I3C Bus has already been configured, issue the Hot-Join according to the flow shown in Figure 29.141.

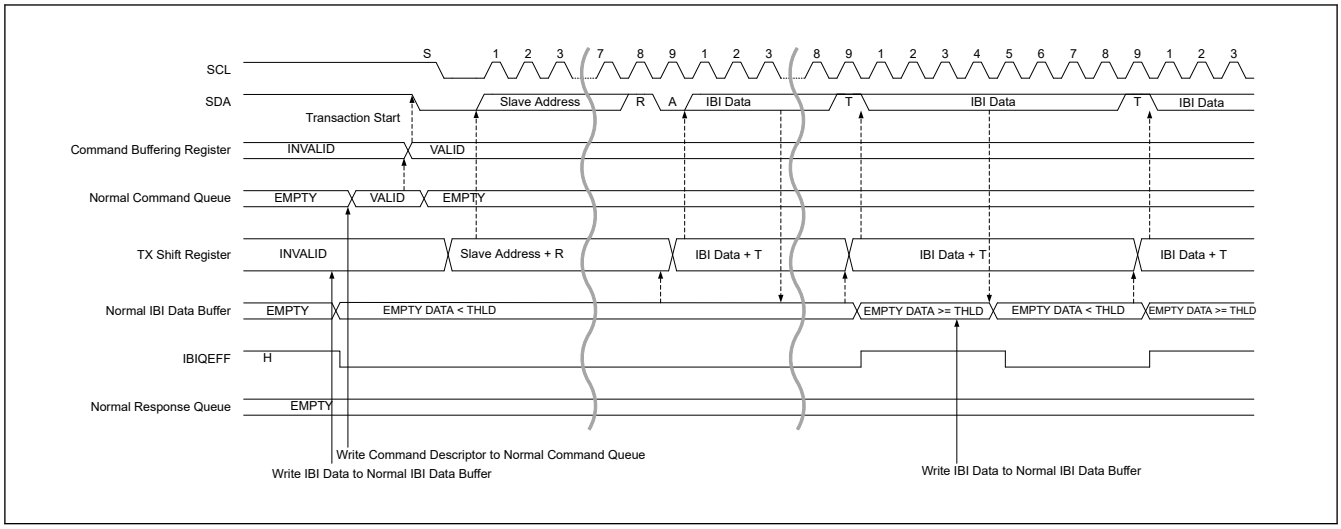

**Figure 29.55 I3C slave IBI transfer timing (1/2)**

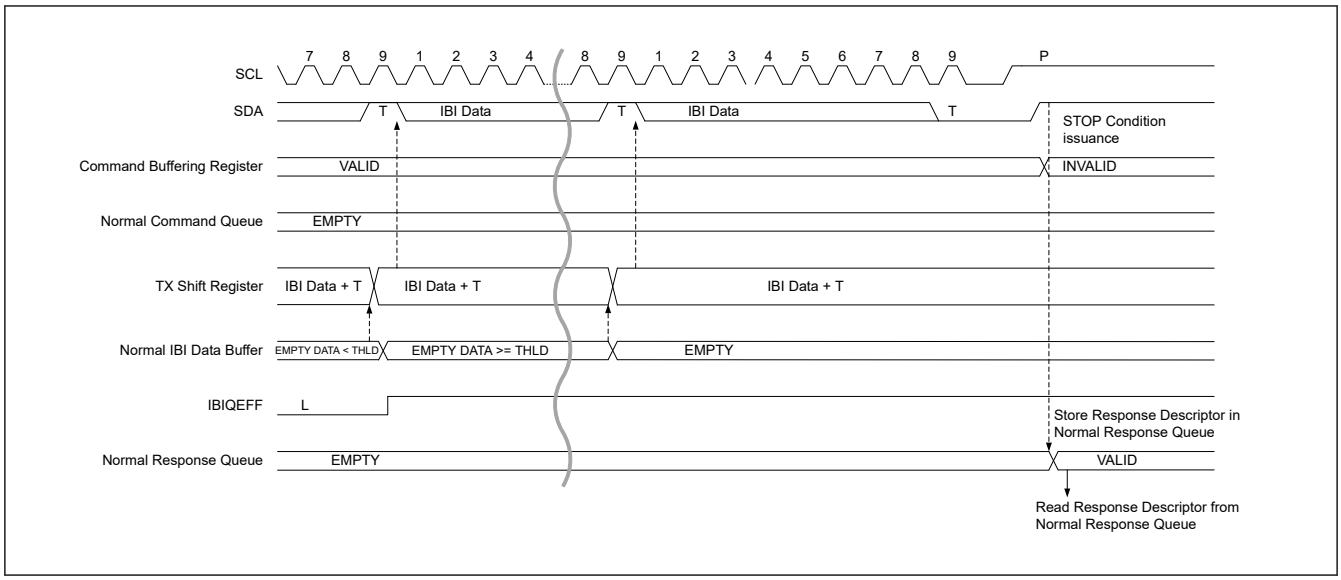

**Figure 29.56 I3C slave IBI transfer timing (2/2)**

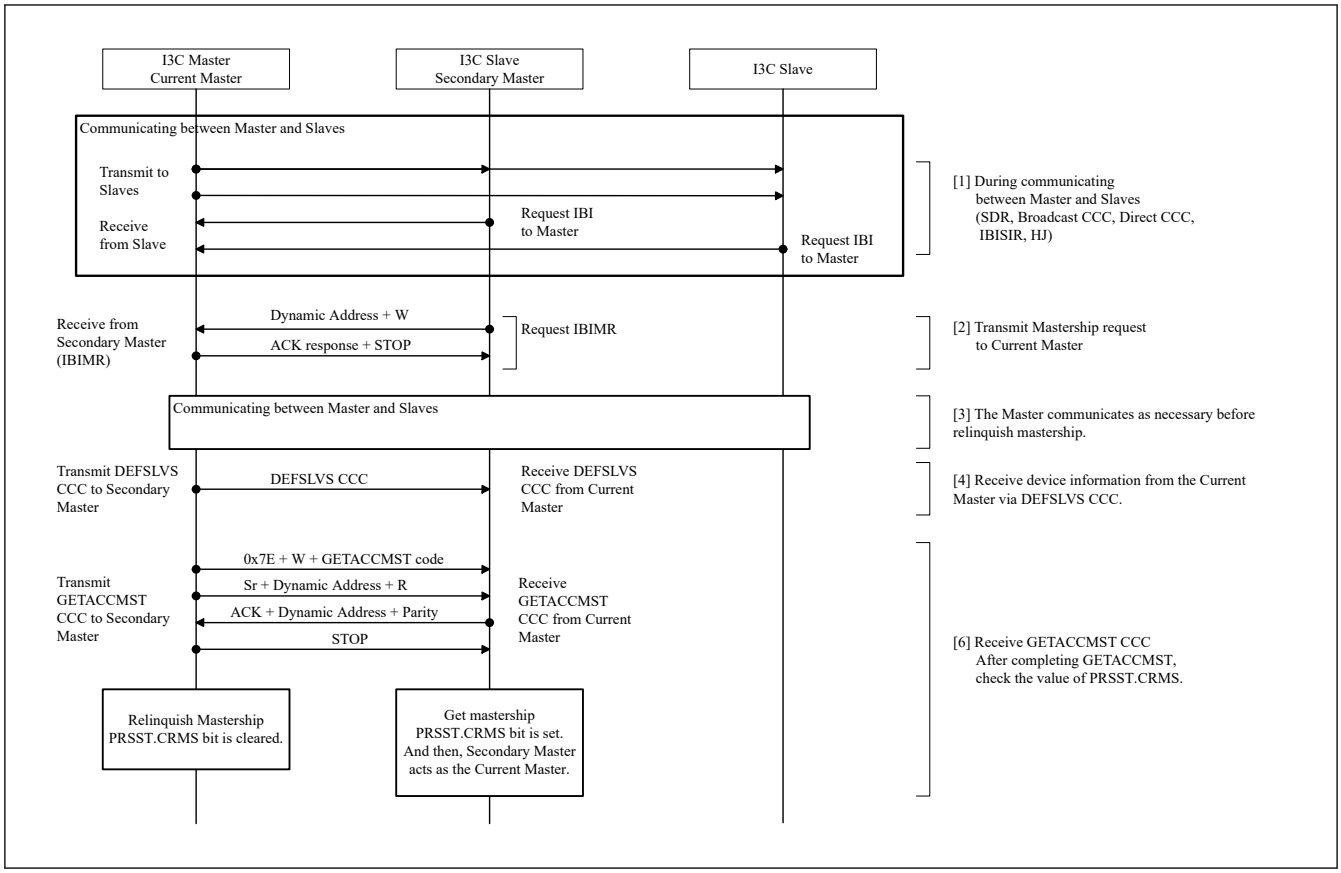

**Figure 29.57 I3C Slave Mastership processing flow**

### 29.3.2.2 Data Handler

The relationship between the transfer method and the queue is shown in Table 29.10.

**Table 29.10 Transfer method and queue**

| Protocol | Transfer method | Queue/Buffer | size | Master | Slave | Secondary Master |
|---|---|---|---|---|---|---|
| $I^2C$ Mode | Single buffer transfer | Normal Tx Data | 1 byte | ✓ | ✓ | — |
| | | Normal Rx Data | 1 byte | ✓ | ✓ | — |
| I3C Mode | Normal FIFO buffer transfer | Normal Command | 2 QUEUEs | ✓ | ✓ | ✓ |
| | | Normal Response | 2 QUEUEs | ✓ | ✓ | ✓ |
| | | Normal Tx Data | 2 DWORDs | ✓ | ✓ | ✓ |
| | | Normal Rx Data | 2 DWORDs | ✓ | ✓ | ✓ |
| | | Normal Receive Status | 2 QUEUEs | — | ✓ | ✓ |
| | | Normal IBI Status | 2 QUEUEs | ✓ | — | ✓ |
| | | Normal IBI Data | 6 DWORDs | ✓ | ✓ | ✓ |

#### 29.3.2.2.1 Transfer Method in $I^2C$ Mode

##### (1) Single Buffer transfer

Each process (condition issue, data transfer, ACK / NACK response) is controlled by software.

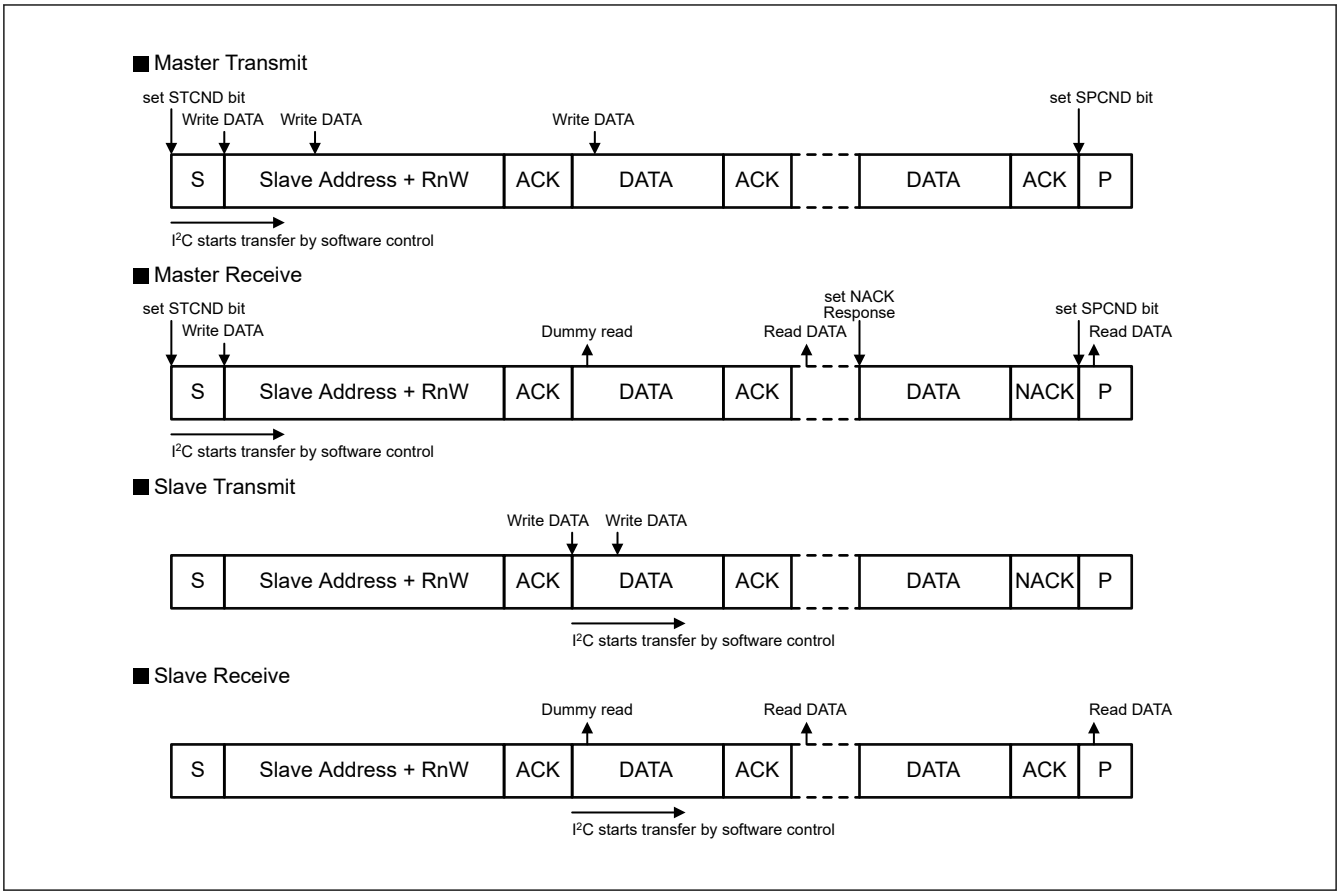

**Figure 29.58 Data handler with single buffer transfer**

### 29.3.2.2.2 Transfer Method in I3C Mode

#### (1) Normal FIFO Buffer Transfer

I3C autonomously starts transfer when data and command are written.

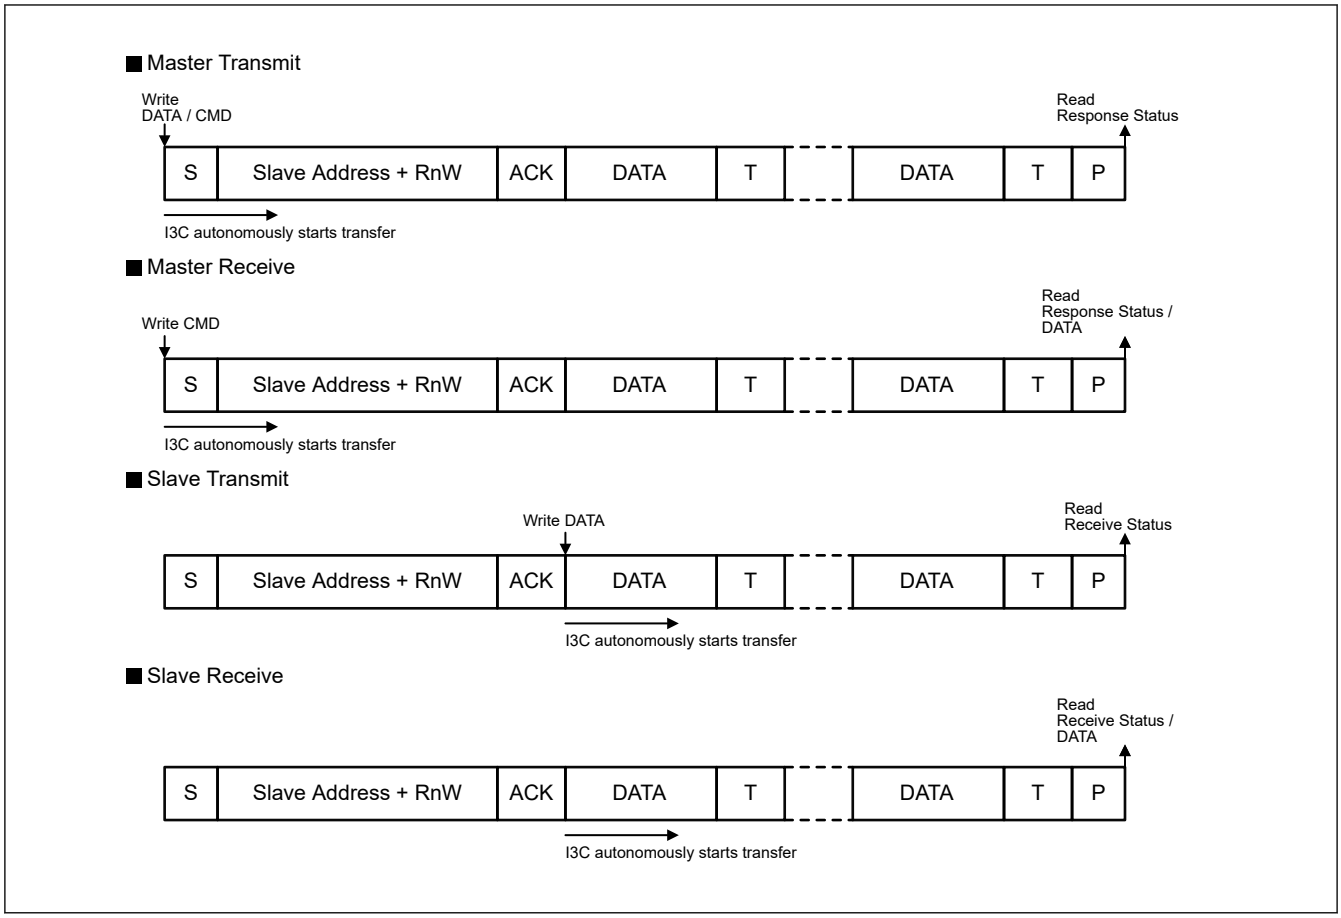

**Figure 29.59 Data handler with normal FIFO buffer transfer**

### 29.3.2.3 $I^2C$/I3C Protocol

#### 29.3.2.3.1 Communication Protocol

##### (1) $I^2C$ Communication Data Format

The $I^2C$ bus format consists of 8-bit data and 1-bit acknowledge. The frame following a START condition or Repeated START condition is an address frame used to specify a slave device with which the master device communicates. The specified slave is valid until a new slave is specified or a STOP condition is issued.

Figure 29.60 shows the $I^2C$ bus format, and Figure 29.61 shows the $I^2C$ bus timing.

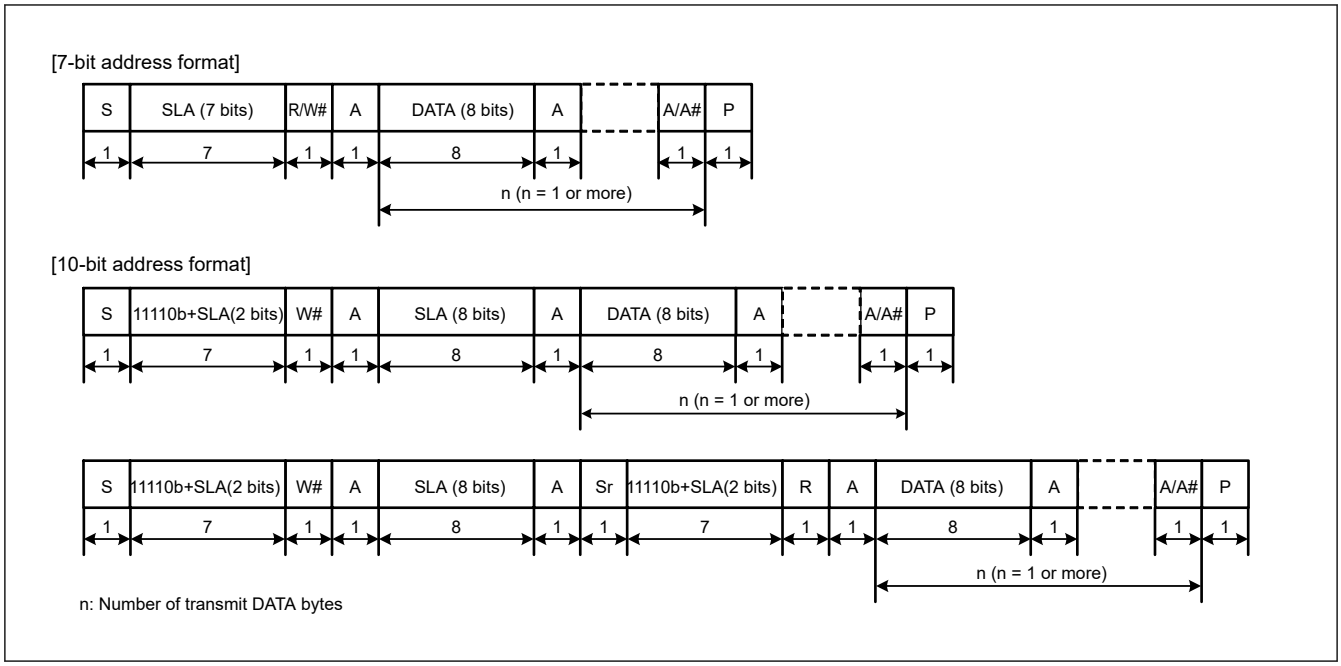

**Figure 29.60 I²C bus format**

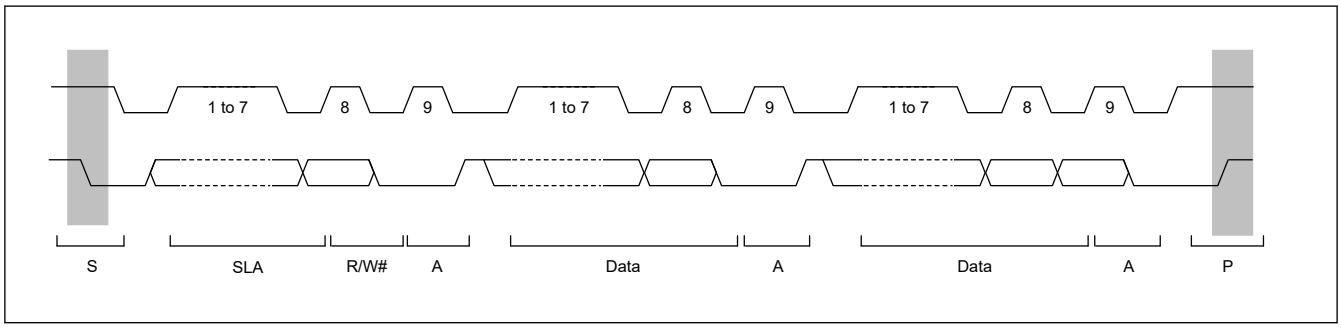

**Figure 29.61 I²C bus timing (SLA = 7 bits)**

| | |
|---|---|
| S: | START condition. The master device drives the I3C_SDA line low from high level while the I3C_SCL line is at a high level. |
| SLA: | Slave address, by which the master device selects a slave device. |
| R/W#: | Indicates the direction of data transfer: from the slave device to the master device when R/W = 1, or from the master device to the slave device when R/W = 0. |
| A: | Acknowledge. The receive device drives the I3C_SDA line low. (In Master transmit mode, the slave device returns acknowledge. In Master receive mode, the master device returns acknowledge.) |
| A#: | Not Acknowledge. The receive device drives the I3C_SDA line high. |
| Sr: | Repeated START condition. The master device drives the I3C_SDA line low from the high level after the setup time has elapsed with the I3C_SCL line at the high level. |
| DATA: | Transmitted or received data |
| P: | STOP condition. The master device drives the I3C_SDA line high from low level while the I3C_SCL line is at a high level. |

## (2) I3C Communication Data Format

Figure 29.62 through Figure 29.66 show a typical communication for each of the six I3C Protocols. While these diagrams do not exhaustively show all possible I3C communications, they do serve as useful introductions to the signaling and transmission formatting used in each I3C Protocol.

Figure 29.62 illustrates example communication using I3C Single Data Rate (SDR) coding with Broadcast (0x7E). It shows the Master reading a byte of data from the Slave at address 0x2B in SDR mode. From the Bus Free Condition, the Master issues a START by driving the I3C_SDA line Low while keeping the I3C_SCL line High. It then issues the Broadcast Address (0x7E) followed by RnW (0 for Write). Then the Master turns on a pull-up resistor and goes to Open Drain.

All Slaves ACK by pulling the I3C_SDA line Low (in the figures, pink fill means the Slave is in control of the I3C_SDA line at this time). The Master then issues a Repeated START, then the address of the Slave (0x2B) it wants to read followed by RnW (1 for Read). The Master then turns on a pull-up resistor and goes to Open Drain, allowing the Slave to acknowledge by pulling the I3C_SDA line Low. At this point, the Master continues to toggle the I3C_SCL line and release the I3C_SDA line, allowing the Slave to drive SDA to send one byte of data (0x4A) followed by T. T = 1 informs the Master that there is additional data, whereas T = 0 signals the end. Here there is additional data, so the Slave drives SDA High until SCL goes High, at which time it releases SDA. The Master has the option of holding SDA High with a weak pullup, which signals to the Slave that the Master allows another byte to be transmitted, or to pull SDA Low (while SCL is High – hence a Repeated START), which would signal to the Slave that the Master has terminated the Read and is taking over.

SDR mode is backwards compatible with Legacy I2C Devices, because the High time of an SCL pulse is always less than 50ns and therefore SCL will always appear to be Low because of the I2C 50ns Spike Filter.

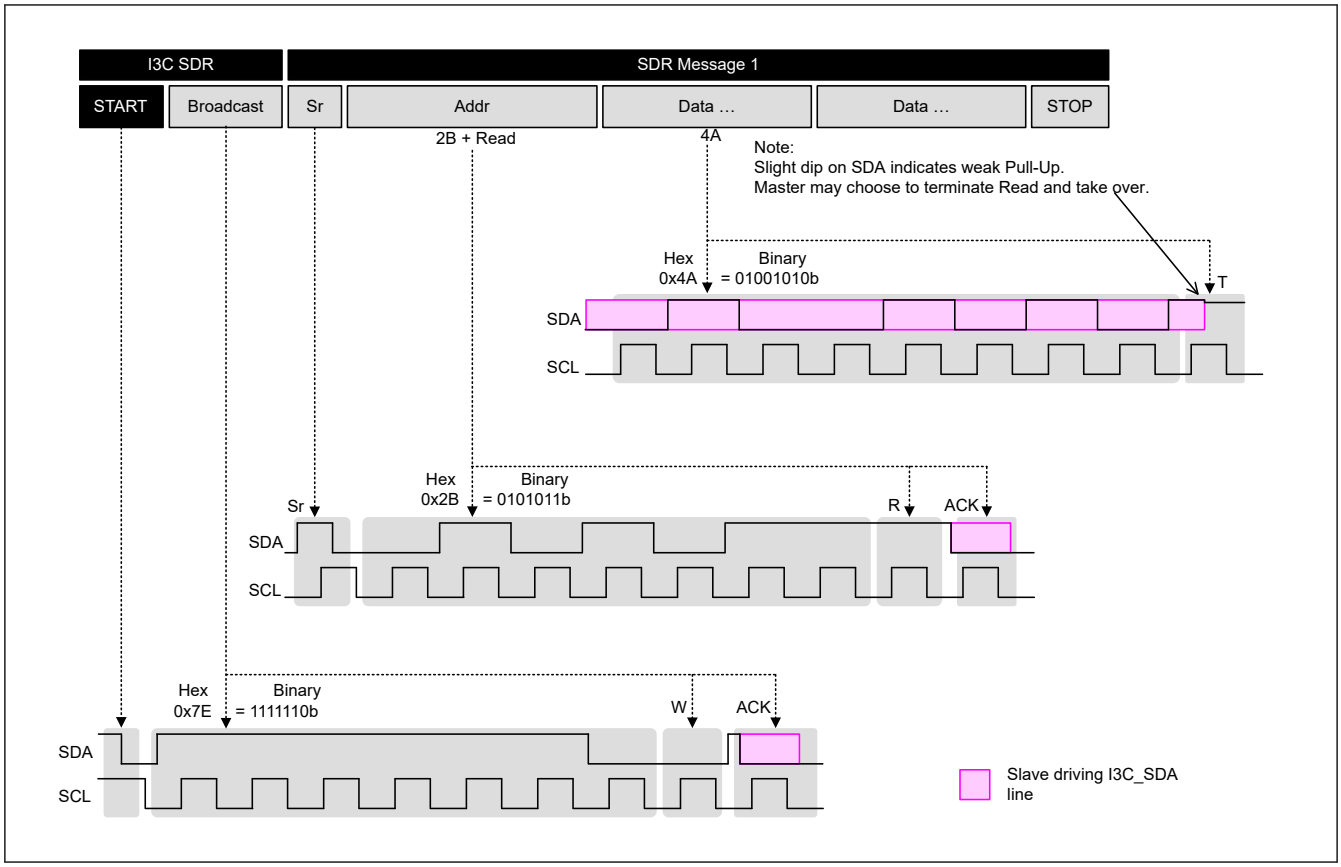

**Figure 29.62 Example communication using I3C coding SDR with broadcast (0x7E)**

Figure 29.63 illustrates example communication using I3C Single Data Rate (SDR) coding without Broadcast (0x7E). It shows the Master reading a byte of data from the Slave at address 0x2B in SDR mode. From the Bus Free Condition, The Master then issues a START, then the Address of the Slave (0x2B) it wants to read followed by RnW (1 for Read).

The Master then turns on a pull-up resistor and goes to Open Drain, allowing the Slave to acknowledge by pulling the I3C_SDA line Low. At this point, the Master continues to toggle the I3C_SCL line and release the I3C_SDA line, allowing the Slave to drive SDA to send one byte of data (0x4A) followed by T. T = 1 informs the Master that there is additional data, whereas T = 0 signals the end. Here there is additional data, so the Slave drives SDA High until SCL goes High, at which time it releases SDA. The Master has the option of holding SDA High with a weak pull-up, which signals to the Slave that the Master allows another byte to be transmitted, or to pull SDA Low (while SCL is High – hence a Repeated START), which would signal to the Slave that the Master has terminated the Read and is taking over.

SDR mode is backwards compatible with Legacy I2C Devices, because the High time of an SCL pulse is always less than 50ns and therefore SCL will always appear to be Low because of the I2C 50ns Spike Filter.

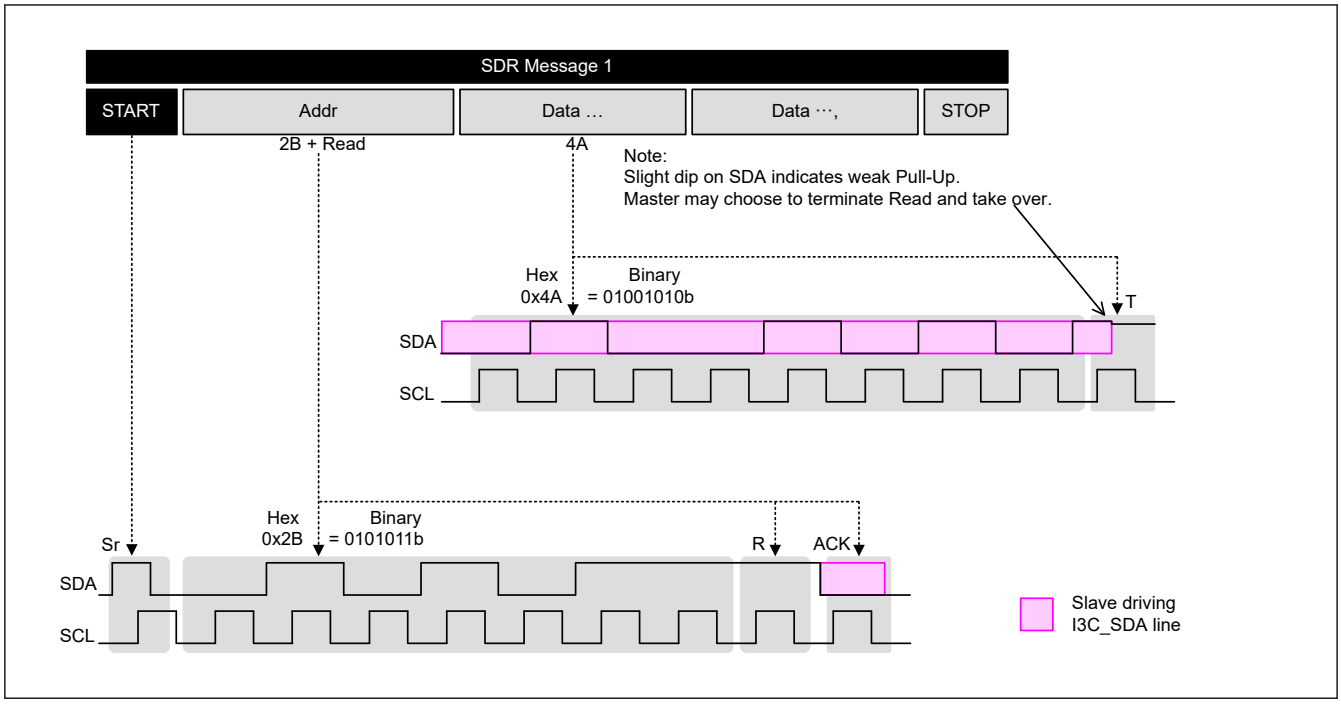

**Figure 29.63 Example communication using I3C coding SDR without broadcast (0x7E)**

Figure 29.64 shows the Master issuing a CCC Direct Command to a single Slave. This particular command (GETPID) reads the Provisional ID of a Slave.

From the Bus Free Condition, the Master issues a START by driving the I3C_SDA line Low while keeping the I3C_SCL line High. It then issues the Broadcast Address (0x7E) followed by RnW (0 for Write). Then the Master turns on a pull-up resistor and goes to Open Drain. All Slaves ACK by pulling SDA Low (in the figures, pink fill means the Slaves are in control of SDA at this time). The Master then issues the Direct Common Command Code for GETPID (0x8C) followed by parity bit T (odd parity = 0 for 0x8C) then the 7-bit Dynamic Address of the Slave (chosen arbitrarily here to be 0x2B) followed by a RnW bit (1 for Read). Then the Master turns on a pull-up resistor and goes to Open Drain, allowing the Slave at address 0x2B to ACK by pulling SDA Low, which tells the Master that the Slave Acknowledges the command and will comply. (Alternatively, the Slave may NACK by not pulling SDA Low, which would inform the Master that the Slave will not comply – in this case, that an error occurred.) Following the ACK the Slave outputs its 48-bit PID one byte at a time, and then the Master issues a Repeated START (this part of the waveform sequence is not shown in the figure).

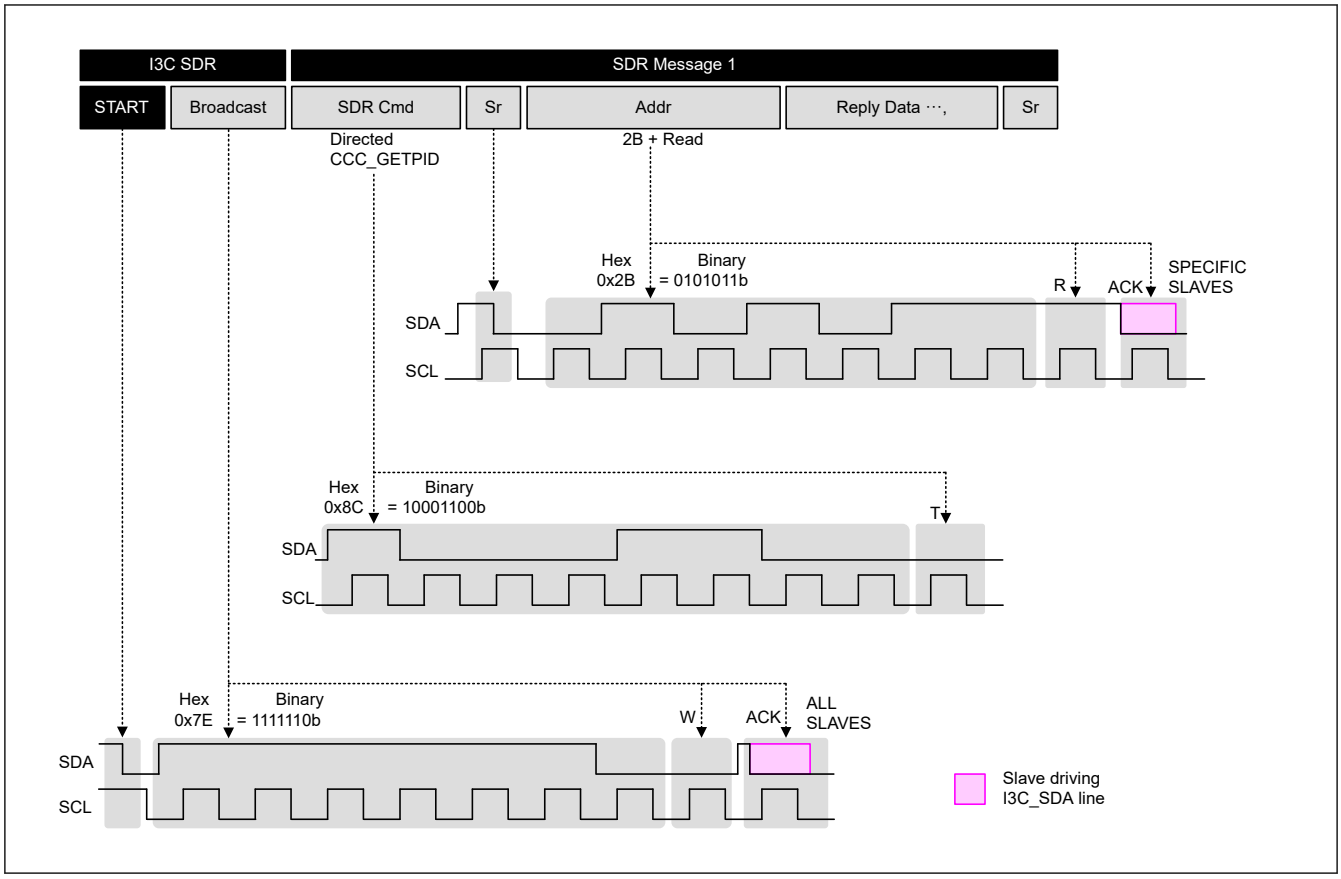

**Figure 29.64 Example communication using I3C coding SDR with CCC direct addressing**

Figure 29.65 illustrates example SDR communication with a CCC Broadcast command. The command used in this example sets the Maximum Read Length of all Slaves to 43 bytes (0x002B).

From the Bus Free Condition, the Master issues a START by driving the I3C_SDA line Low while keeping the I3C_SCL line High. It then issues the Broadcast Address (0x7E) followed by RnW (0 for Write). Then the Master turns on a pull-up resistor and goes to Open Drain. All Slaves ACK by pulling SDA Low (in the figures, pink fill means the Slaves are in control of SDA at this time). The Master then issues the Broadcast Common Command Code for SETMRL (0x09) followed by parity bit T (odd parity = 1 for 0x09), and then 2 data bytes (MSB first) to define the maximum number of bytes which can be read from a slave in a single read operation. Each data byte is followed by a T bit (parity bit – odd parity). After this, the Master issues a Repeated START.

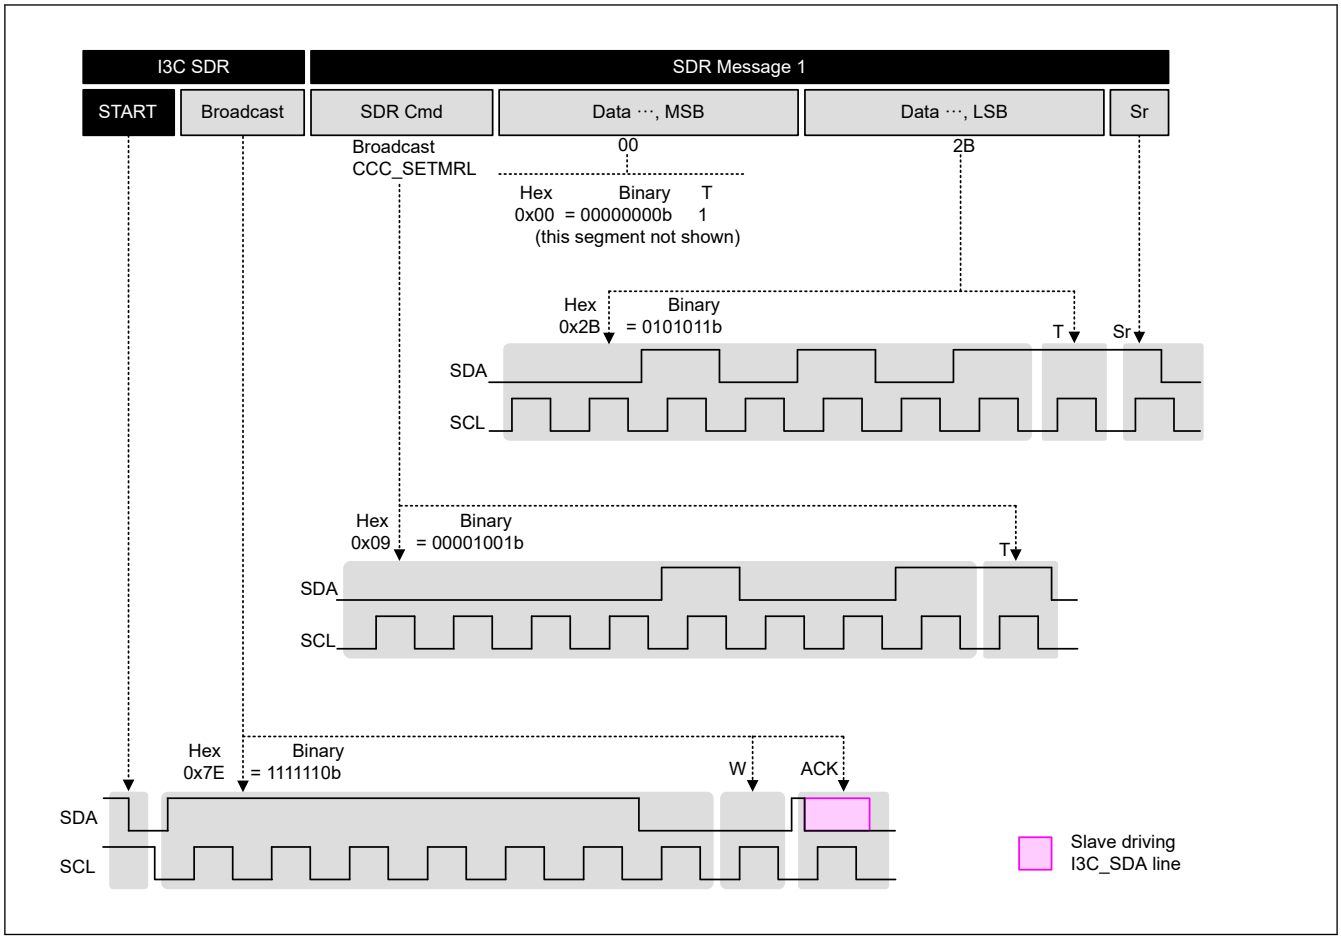

**Figure 29.65 Example communication using I3C coding SDR with CCC broadcast**

Figure 29.66 illustrates use of the HDR-DDR (Double Data Rate) mode. It shows how the Master can change the mode from SDR (Single Data Rate) mode to HDR-DDR mode, and a sample of the HDR-DDR data format.

From the Bus Free Condition, the Master issues a START by driving the I3C_SDA line Low while keeping the I3C_SCL line High. The Master then issues the Broadcast Address (0x7E) followed by RnW (0 for Write). Then the Master turns on a pull-up resistor and goes to Open Drain. All Slaves 'ACK' by pulling SDA Low (in the figures, pink fill means the Slaves are in control of SDA at this time). The Master then issues the Broadcast Common Command Code for ENTHDR0 (0x20), followed by parity bit T (odd parity = 0 for 0x20). At this point, the Bus is in HDR-DDR mode. In the HDR-DDR protocol, the I3C_SDA line is sampled on every SCL edge (both Low-to-High and High-to-Low transitions of SCL). The HDR-DDR Word consists of a 2-bit Preamble, followed by two bytes of data, followed by two parity bits. The waveform for the 5-bit CRC and following traffic is not shown in the figure.

HDR-DDR mode is backwards compatible with Legacy $I^2C$ Devices, because the High time of an SCL pulse is always less than 50ns and as a result SCL will always appear to be Low because of the $I^2C$ 50ns Spike Filter.

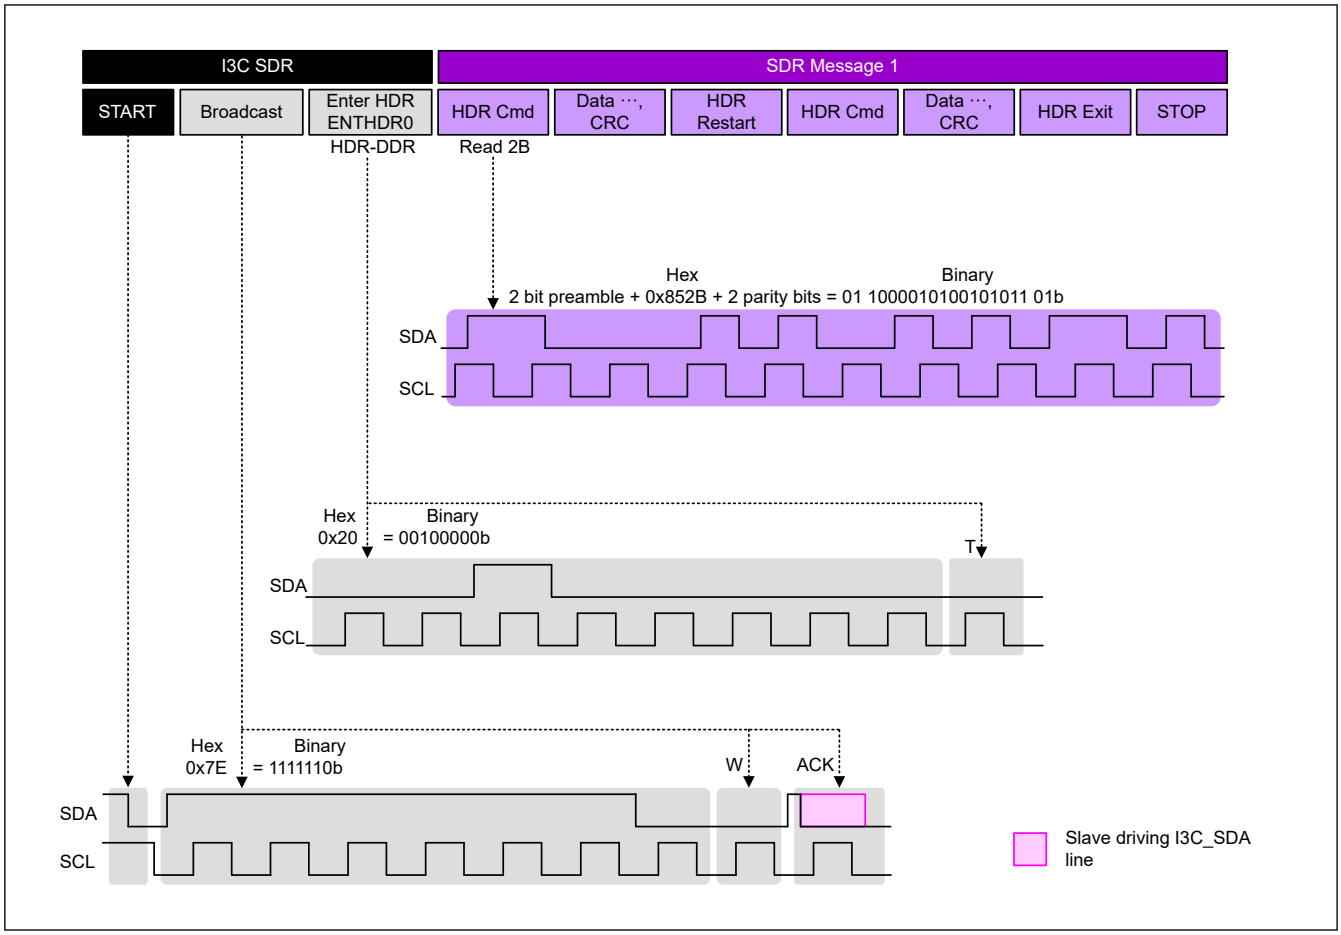

**Figure 29.66 Example communication using HDR-DDR protocol**

### 29.3.2.3.2 Bus Conditions

I3C defines three distinct conditions in which the I3C Bus shall be considered inactive: Bus Free, Bus Available, and Bus Idle (see Figure 29.67).

#### (1) Bus Free Condition

State on the I3C Bus where both the I3C_SCL line and the I3C_SDA line are High for at least the period set by BFRECDT.FRECYC[8:0] bit.

#### (2) Bus Available Condition [I3C mode]

State on the I3C Bus where both the I3C_SCL line and the I3C_SDA line are High for at least the period set by BAVLCDT.AVLCYC[8:0] bit.

A Slave may only issue a START Request (For example, for an In-Band Interrupt, or for a Master Handoff Request) after a Bus Available Condition.

#### (3) Bus Idle Condition [I3C mode]

State on the I3C Bus where both the I3C_SCL line and the I3C_SDA line are High for at least the period set by BIDLCDT.IDLCYC[17:0] bit.

A Slave may only issue a START Request (For example, for a Hot-Join) after a Bus Idle Condition.

Specifications are as follows. IDLE needs to be the largest.

BFRECDT.FRECYC[8:0] < BAVLCDT.AVLCYC[8:0] < BIDLCDT.IDLCYC[17:0]

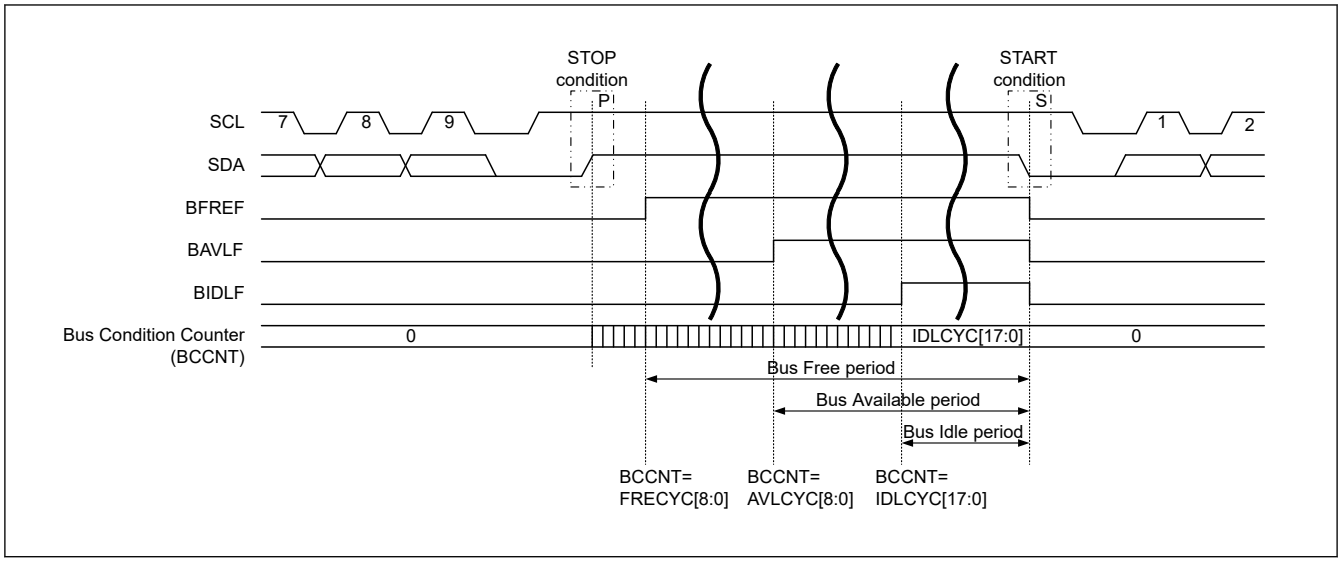

**Figure 29.67 Bus conditions**

### 29.3.2.3.3 START Condition / Repeated START Condition / STOP Condition Issuing Function

#### (1) Issuing a START Condition

I3C issues a START condition when the CNDCTL.STCND bit is set to 1.

Set the STCND bit to 1 (START condition issuance request) when the BCST.BFREF flag is set to 1 (bus free state).

I3C issues a START condition.

When a START condition is issued normally, I3C automatically shifts to the master transmit mode. A START condition is issued in the following sequence.

[START condition issuance]

- Drive the I3C_SDA line low (high level to low level).
- Ensure the time set in STDBR.SBRHO[7:0] and the START condition hold time.
- Drive the I3C_SCL line low (high level to low level).
- Detect low level of the I3C_SCL line and ensure the low-level period of I3C_SCL line set in STDBR.SBRLO[7:0].

#### (2) Issuing a Repeated START Condition

I3C issues a Repeated START condition when the CNDCTL.SRCND bit is set to 1.

When the SRCND bit is set to 1, a Repeated START condition issuance request is made and I3C issues a Repeated START condition when the BCST.BFREF flag = 0 (bus busy state) and the PRSST.CRMS bit = 1 (master mode).

A Repeated START condition is issued in the following sequence.

[Repeated START condition issuance]

- Release the I3C_SDA line.
- Ensure the low-level period of I3C_SCL line set in STDBR.SBRLO[7:0] or EXTBR.EBRLO[7:0].
- Release the I3C_SCL line (low level to high level).
- Detect a high level of the I3C_SCL line and ensure the time set in STDBR.SBRLO[7:0] or EXTBR.EBRLO[7:0] and the Repeated START condition setup time.
- Drive the I3C_SDA line low (high level to low level).
- Ensure the time set in STDBR.SBRHO[7:0] or EXTBR.EBRHO[7:0] or EXTBR.EBRHO[7:0] and the Repeated START condition hold time.
- Drive the I3C_SCL line low (high level to low level).

- Detect a low level of the I3C_SCL line and ensure the low-level period of I3C_SCL line set in STDBR.SBRLO[7:0] or EXTBR.EBRLO[7:0].

Note: When issuing Repeated START conditions request, write the slave address to NTDTBP0 after confirming CNDCTL.SRCND = 0. Data written in the period of CNDCTL.SRCND = 1 is not forwarded because retransmission condition before the occurrence.

To issue a Repeated START condition in Hs-mode, follow the steps below.

1. Wait for PRSTDBG.SCOLV=0.
2. Set EXTBR.EBRHO[7:0] to satisfy the hold time of the Repeated START condition.
3. Set the CNDCTL.SRCND bit to 1.
4. After confirming CNDCTL.SRCND=0, wait for PRSTDBG.SCOLV=0.
5. Set EXTBR.EBRHO [7: 0] according to the High period of the SCL clock in Hs-mode.
6. Write the slave address to NTDTBP0.

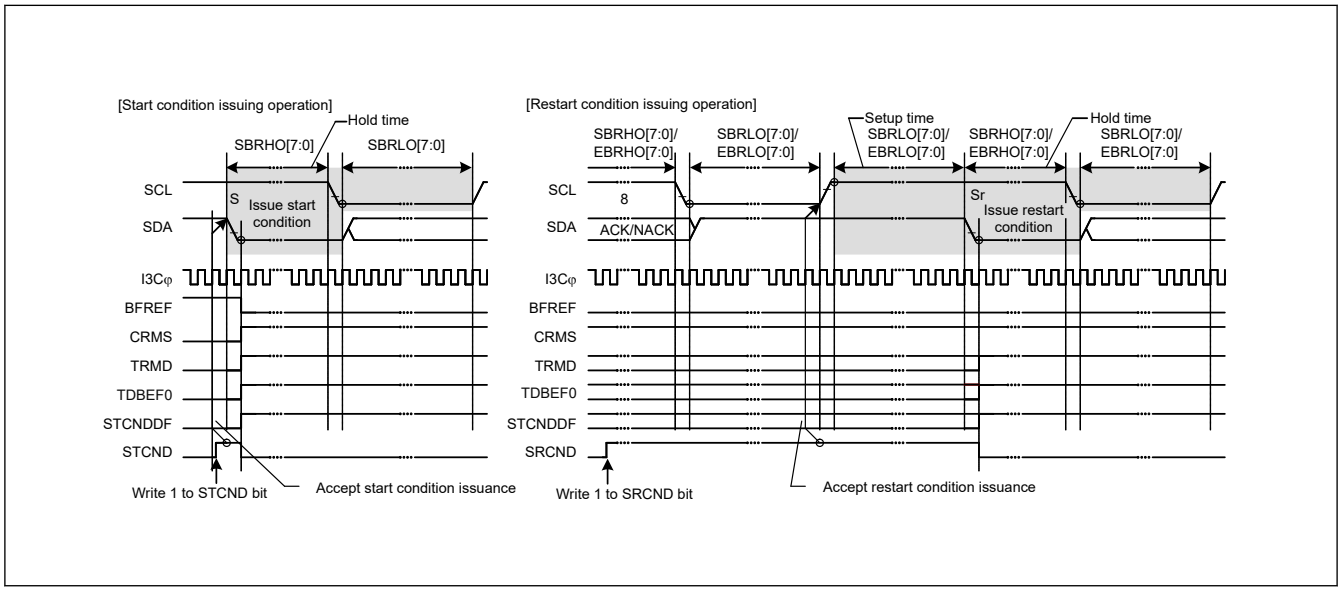

**Figure 29.68 START condition / repeated START condition issue timing (STCND and SRCND bits)**

Figure 29.69 shows the operation to issue a Repeated START condition after the master transmission.

[Repeated START condition issuance after the master transmission]

- Initial setting. For details, see section 29.3.3.1. Initial Setting Flow.
- Read the BFREF flag in BCST to check that the bus is open, and then set the STCND bit in CNDCTL to 1 (START condition issuance request). Upon receiving the request, I3C issues a START condition. At the same time, the BFREF flag is automatically set to 0 and the STCNDDF flag in BST is automatically set to 1 and the STCND bit is automatically set to 0. At this time, if the START condition is detected and the internal levels for the SDA output state and the levels on the I3C_SDA line have matched while the STCND bit = 1, I3C recognizes that issuing of the START condition as requested by the STCND bit has been successfully completed, and CRMS and TRMD bits in PRSST is automatically set to 1, placing I3C in master transmit mode. The NTST.TDBEF0 flag is also automatically set to 1 in response to setting of the TRMD bit to 1.
- Check that the NTST.TDBEF0 flag = 1, and then write the value for transmission (the slave address and the R/W# bit) to NTDTBP0. Once the data for transmission are written to NTDTBP0, the TDBEF0 flag is automatically set to 0, the data are transferred from NTDTBP0, and the TDBEF0 flag is again set to 1. After the byte containing the slave address and R/W# bit has been transmitted, the value of the TRMD bit is automatically updated to select master transmit or master receive mode in accord with the value of the transmitted R/W# bit. If the value of the R/W# bit was 0, I3C continues in master transmit mode. Since the BST.NACKDF flag being 1 at this time indicates that no slave device recognized the address or there was an error in communications, write 1 to CNDCTL.SPCND bit to issue a STOP condition. For data transmission with an address in the 10-bit format, start by writing 1111 0, the 2 higher-order bits of the slave address, and W to NTDTBP0 as the first address transmission. Then, as the second address transmission, write the 8 lower-order bits of the slave address to NTDTBP0.

- After confirming that the NTST.TDBEF0 flag = 1, write the data for transmission to the NTDTBP0 register. I3C automatically holds the I3C_SCL line low until the data for transmission are ready, a Repeated START condition is issued or a STOP condition is issued.
- After all bytes of data for transmission have been written to the NTDTBP0 register, wait until the value of the BST.TENDF flag returns to 1, and then, after check that the BST.STCNDDF flag = 1, set the BST.STCNDDF flag to 0.
- Set the SRCND bit in CNDCTL to 1 (Repeated START condition issuance request). Upon receiving the request, I3C issues a Repeated START condition.
- After check that the BST.STCNDDF flag = 1, write the value for transmission (the slave address and the R/W# bit) to NTDTBP0.

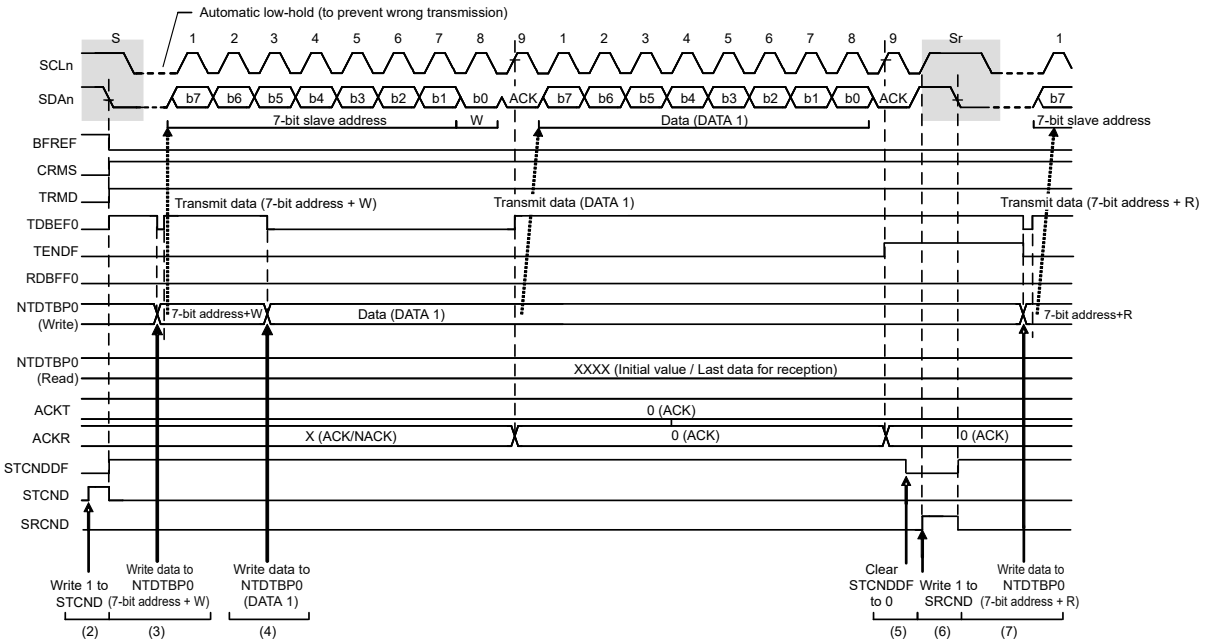

**Figure 29.69 Repeated START condition issuance after the master transmission timing**

## (3) Issuing a STOP Condition

I3C issues a STOP condition when the SPCND bit in CNDCTL is set to 1.

When the SPCND bit is set to 1, a STOP condition issuance request is made and I3C issues a STOP condition when the BCST.BFREF flag = 0 (bus busy state) and the PRSST.MST bit = 1 (master mode).

A STOP condition is issued in the following sequence.

[STOP condition issuance]

- Drive the I3C_SDA line low (high level to low level).
- Ensure the low-level period of I3C_SCL line set in STDBR.SBRLO[7:0] or EXTBR.EBRLO[7:0].
- Release the I3C_SCL line (low level to high level).
- Detect a high level of the I3C_SCL line and ensure the time set in STDBR.SBRHO[7:0] or EXTBR.EBRHO[7:0] and the STOP condition setup time.
- Release the I3C_SDA line (low level to high level).
- Ensure the time set in BFRECDT.FRECYC[8:0] and the bus free time.
- Set the BFREF flag to 1 (to release the bus mastership).

Note: To issue a STOP condition in Hs-mode, follow the steps below.

1. Wait for PRSTDBG.SCOLV=0.

2. Set EXTBR.EBRHO[7:0] to satisfy the setup time for the STOP condition.
3. Set the CNDCTL.SPCND bit to 1.
4. Wait for CNDCTL.SPCND=0.
5. Set EXTBR.EBRHO [7:0] according to the High period of the SCL clock in Hs-mode.

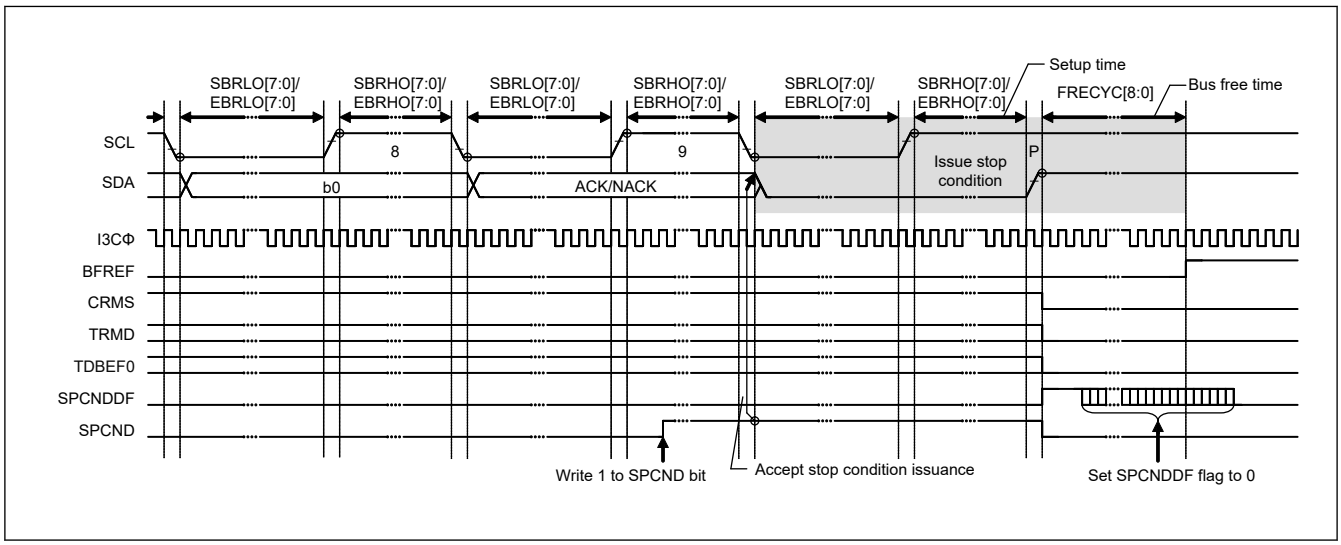

**Figure 29.70 STOP condition issue timing (SPCND bit)**

### 29.3.2.3.4 Address Match Detection

I3C can set three unique slave addresses in addition to the general call address and host address, and also can set 7- bit or 10- bit slave addresses.

#### (1) Slave-Address Match Detection [I2C mode]

I3C can set three unique slave addresses, and has a slave address detection function for each unique slave address.

When the SVCTL.SVAE0 bit is set to 1, the slave addresses set in the SVDVAD0 register can be detected.

When I3C detects a match of the set slave address, the corresponding SVST.SVAF0 flag is set to 1 at the rising edge of the ninth SCL clock cycle, and the NTST.RDBFF0 flag or the NTST.TDBEF0 flag is set to 1 by the following R/W# bit. This causes a Normal Rx Data buffer full interrupt (I3C_RX) or Normal Tx Data buffer empty interrupt (I3C_TX) to be generated. The SVAF0 flag is used to identify which slave address has been specified.

Figure 29.71 and Figure 29.72 show the SVAF0 flag set timing in two cases.

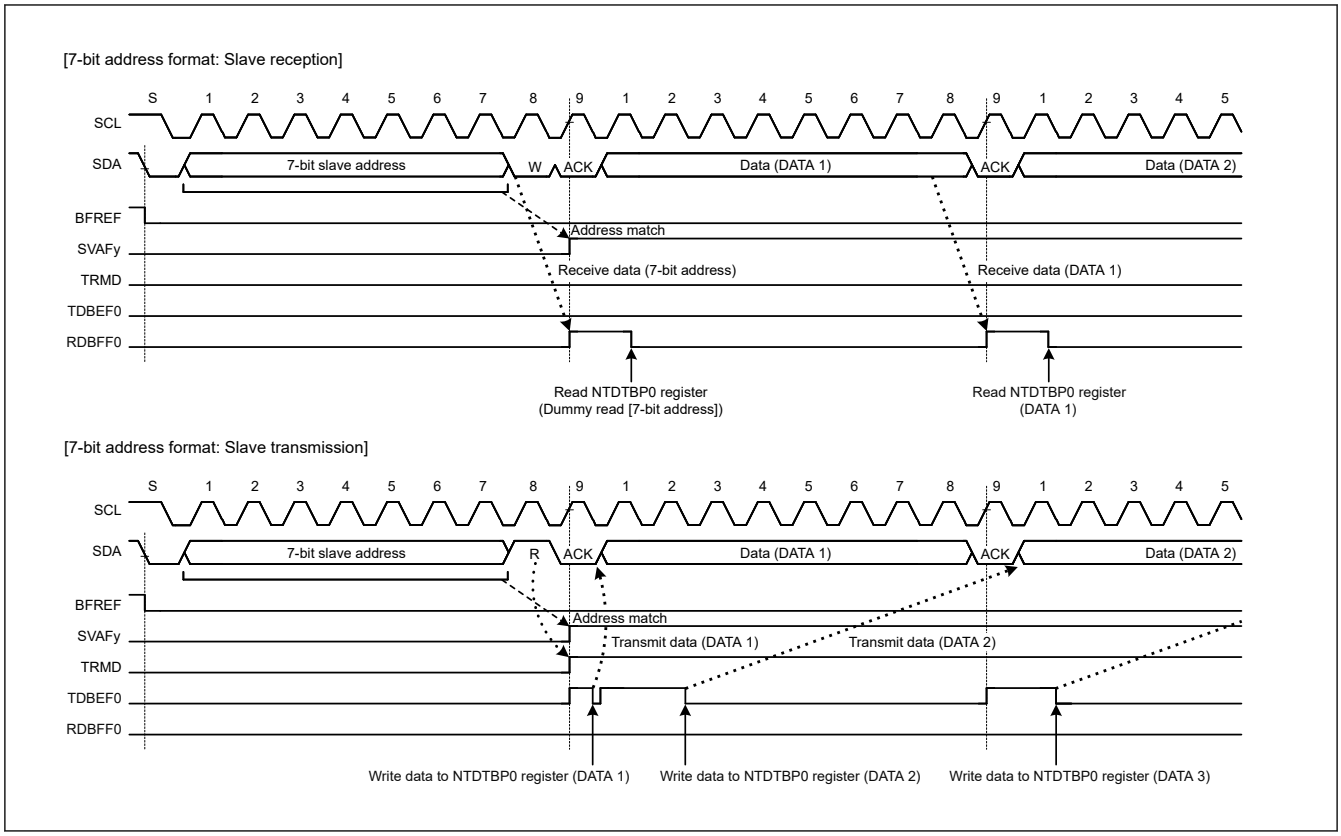

**Figure 29.71 SVAF0 flag set timing with 7-bit address format selected**

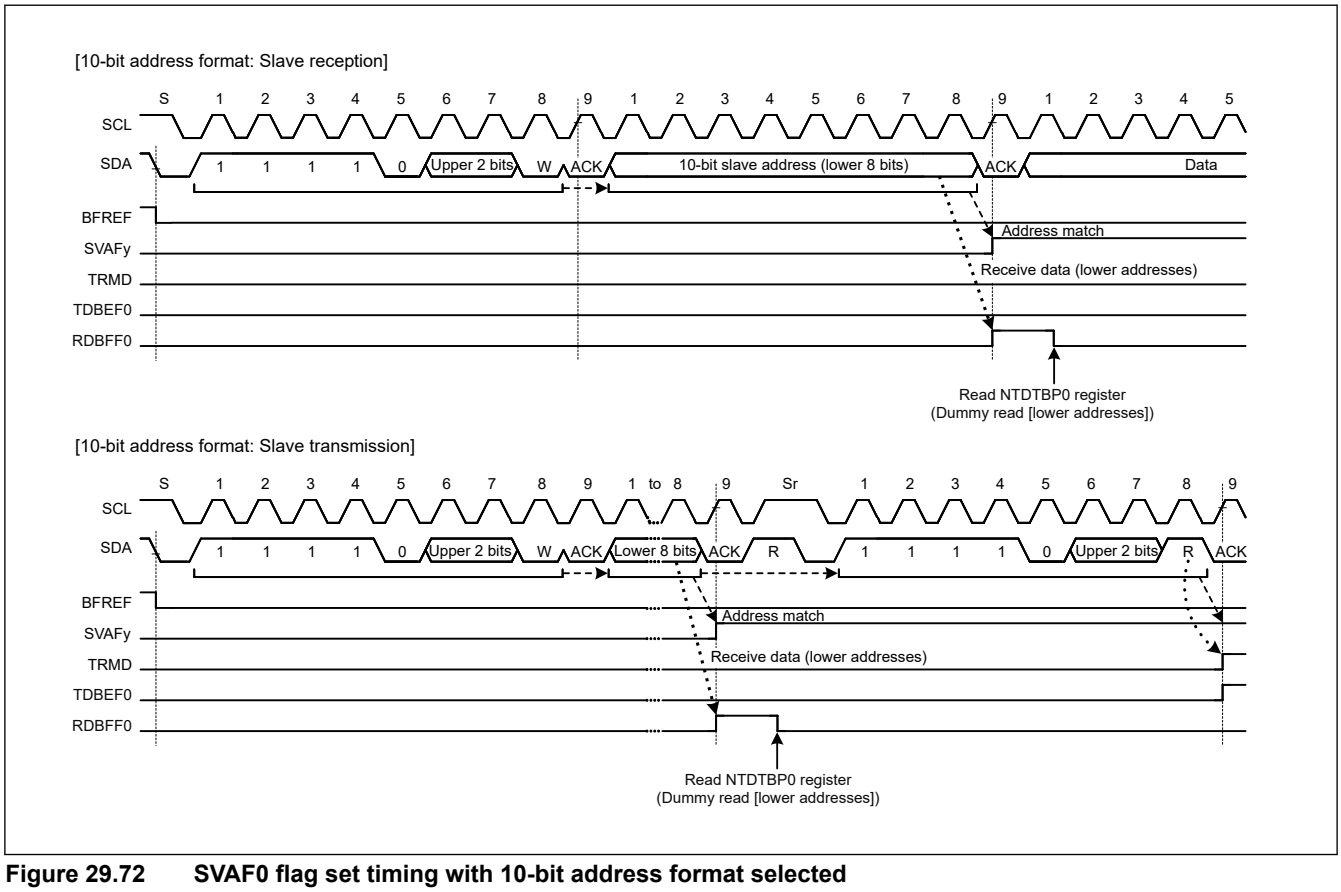

**Figure 29.72 SVAF0 flag set timing with 10-bit address format selected**

### (2) Detection of the General Call Address [I2C mode]

I3C has a facility for detecting the general call address (0000 000 + 0 (write)). This is enabled by setting the SVCTL.GCAE bit to 1.

If the address received after a START or Repeated START condition is issued is 0000 000 + 1 (read) (start byte), I3C recognizes this as the address of a slave device with an all-zero address but not as the general call address.

When I3C detects the general call address, both the SVST.GCAF flag and the NTST.RDBFF0 flag are set to 1 on the rising edge of the ninth cycle of SCL clock. This leads to the generation of a Normal Rx Data buffer full interrupt (I3C_RX). The value of the GCAF flag can be confirmed to recognize that the general call address has been transmitted.

Operation after detection of the general call address is the same as normal slave receive operation.

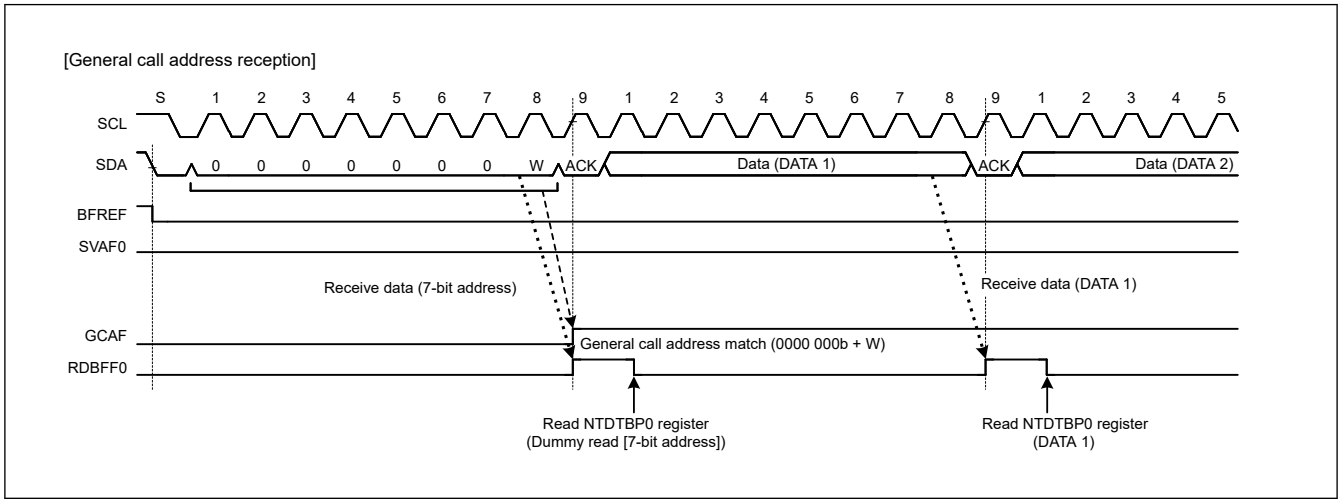

**Figure 29.73 Timing of GCAF flag setting during reception of general call address**

### (3) Device-ID Address Detection [I2C mode]

I3C module has a facility for detecting device-ID addresses conformant with the I2C-bus specification (Rev.03). When I3C receives 1111 100 as the first byte after a START condition or Repeated START condition was issued with the SVCTL.DVIDE bit set to 1, I3C recognizes the address as a device ID, sets the SVST.DVIDF flag to 1 on the rising edge of the ninth SCL clock cycle when the following R/W# bit = 0, and then compares the second and subsequent bytes with its own slave address. If the address matches the value in the slave address register, I3C sets the corresponding SVST.SVAF0 flag to 1.

After that, when the first byte received after a START or Repeated START condition is issued matches the device ID address (1111 100) again and the following R/W# bit = 1, I3C does not compare the second and subsequent bytes and sets the NTST.TDBEF0 flag to 1.

In the device-ID address detection function, I3C sets the DVIDF flag to 0 if a match with I3C's own slave address is not obtained or a match with the device ID address is not obtained after a match with I3C's own slave address and the detection of a Repeated START condition. If the first byte after detection of a START or Repeated START condition matches the device ID address (1111 100) and the R/W# bit = 0, I3C sets the DVIDF flag to 1 and compares the second and subsequent bytes with I3C's slave address. If the R/W# bit = 1, the DVIDF flag holds the previous value and I3C does not compare the second and subsequent bytes. Therefore, the reception of a device-ID address can be checked by reading the DVIDF flag after confirming that TDBEF0 flag = 1.

Furthermore, prepare the device-ID fields (3 bytes: 12 bits indicating the manufacturer + 9 bits identifying the part + 3 bits indicating the revision) that must be sent to the host after reception of a continuous device-ID field as normal data for transmission. For details of the information that must be included in device-ID fields, contact NXP Semiconductors.

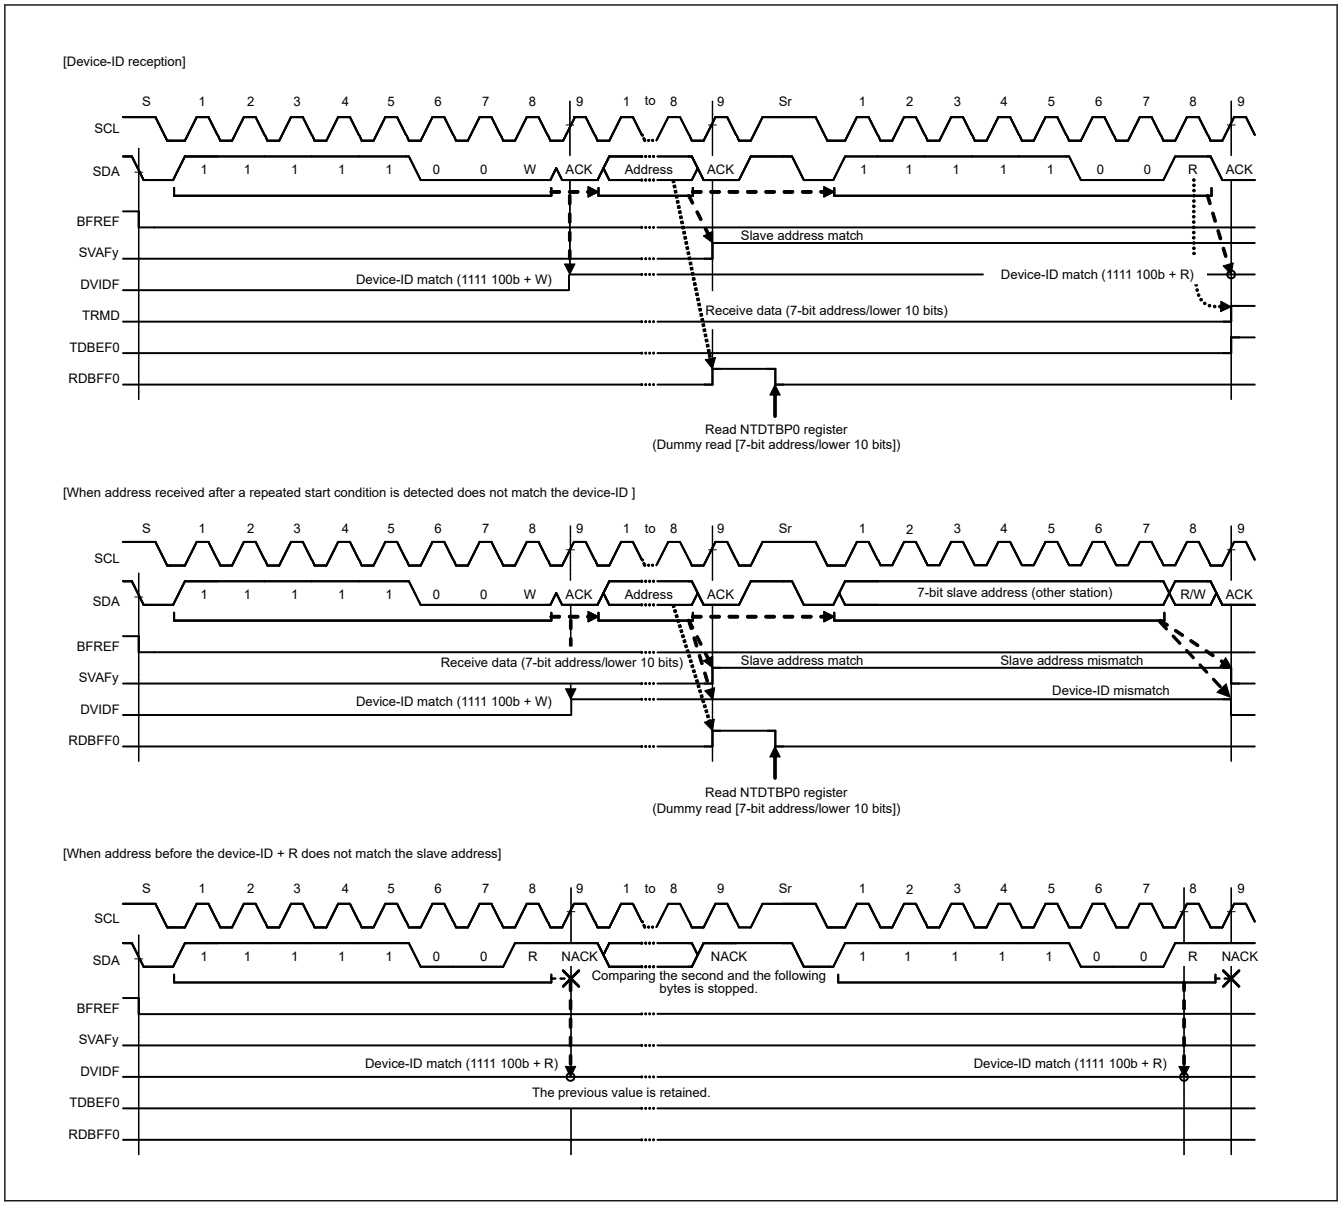

**Figure 29.74 SVAF0/DVIDF flag set/clear timing during reception of device-ID**

## (4) Host Address Detection [I2C mode]

I3C has a function to detect the host address while the SMBus is operating. When the SVCTL.HOAE bit is set to 1 while the BFCTL.SMBS bit = 1, I3C can detect the host address (0001 000) in slave receive mode (bits CRMS and TRMD in the PRSST register = 00).

When I3C detects the host address, the SVST.HOAF flag is set to 1 at the rising edge of the ninth SCL clock cycle, and at the same time, the NTST.RDBFF0 flag is set to 1 when the R/W# bit = 0 (Wr bit). This causes a Normal Rx Data buffer full interrupt (I3C_RX) to be generated. The HOAF flag is used to recognize that the host address was sent from the smart battery or other devices.

If the bit following the host address (0001 000) is an Rd bit (R/W# bit = 1), I3C can also detect the host address. After the host address is detected, I3C operates in the same manner as normal slave operation.

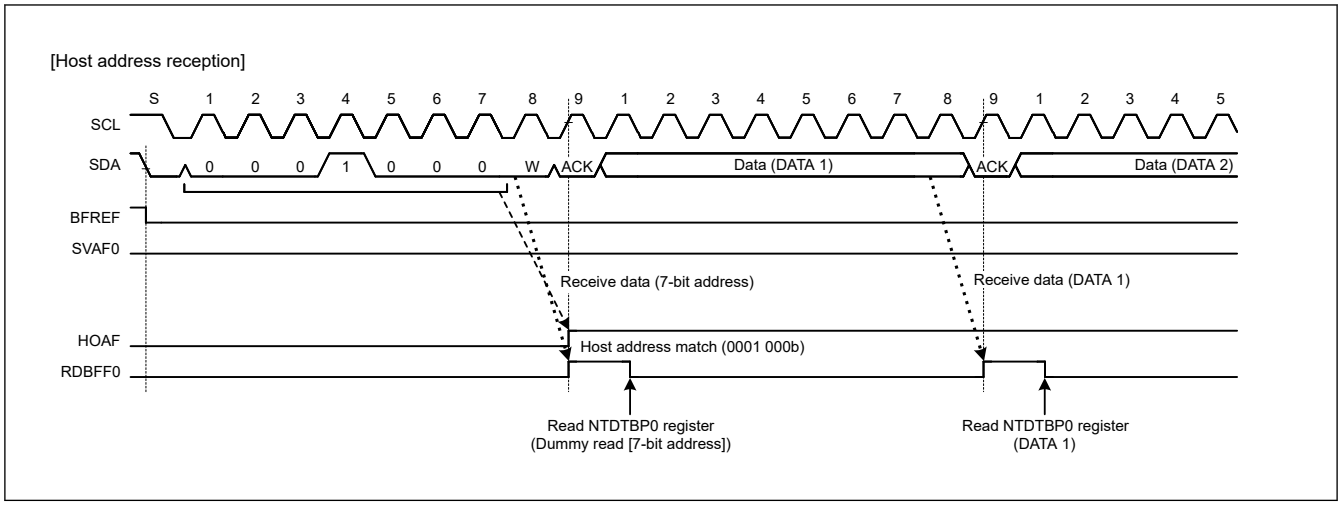

**Figure 29.75 HOAF flag set timing during reception of host address**

## (5) Hs-mode master code Detection [$I^2C$ mode]

IIC has a facility for detecting the Hs-mode master code (0000 1XXXb). When IIC receives the Hs-mode master code (0000 1XXXb) as the first byte after a START condition was issued with the SVCTL.HSMCE bit set to 1, this module recognizes the address as the Hs-mode master code, sets the SVST.HSMCF flag to 1 on the rising edge of the ninth SCL clock cycle. The first byte after Repeated START after NACK response to Hs-mode master code is recognized as a slave address and compared with the slave address set by SVDVAD0.SVAD[9:0]. When IIC detects a match of the set slave address, the corresponding SVST.SVAF0 flag is set to 1 at the rising edge of the ninth SCL clock cycle, and the NTST.RDBFF0 flag or the NTST.TDBEF0 flag is set to 1 by the following R/W# bit. This causes a Normal Rx Data buffer full interrupt (I3C_RX) or Normal Tx Data buffer empty interrupt (I3C_TX) to be generated. The SVAF0 flag is used to identify which slave address has been specified. The SVST.HSMCF flag is cleared to 0 when the STOP condition is detected.

Note: If the Hs-mode master code (0000 1XXXb) is received with the SVCTL.HSMCE bit set to 0, other patterns are ignored until the STOP condition is detected.

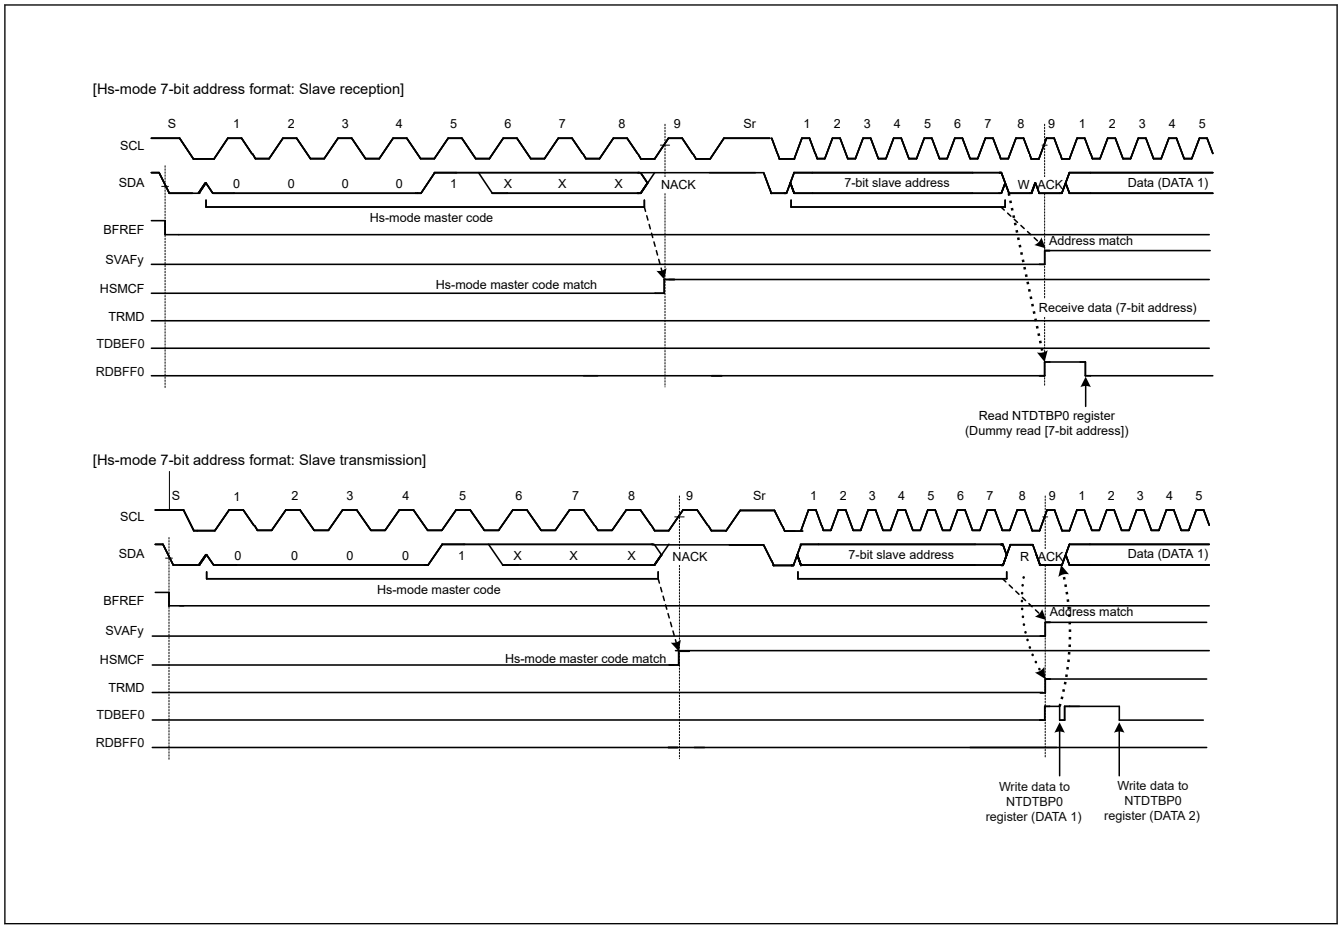

**Figure 29.76 SVAF0/HSMCF Flag Set Timing during Reception of Hs-mode master code**

## (6) CCC detection function [I3C mode]

- In case of Broadcast CCC
  1. It receives Broadcast Address (0x7E) and R/W# = 0 after START condition or Repeated START.
  2. Respond to ACK.
  3. Receive Common Command Code (CCC).
  4. In accordance with the CCC, the following data is stored. (Storage destination: see Table 29.11)
  5. Store the Receive Status Descriptor into the Receive Status Queue.
- In case of Broadcast CCC (ENTDAA)
  1. It receives Broadcast Address (0x7E) and R/W# = 0 after START condition.
  2. Respond to ACK.
  3. Receive ENTDAA.
  4. If receives Broadcast Address (0x7E) and R/W# = 1 after Repeated START.
  5. When the Dynamic Address is not assigned, ACK response is done.
  6. This Provisional ID (SDCTPIDH[31:0], SDCTPIDL[15:0]), BCR (SVDCT.TBCRn) and DCR (SVDCT.TDCR[7:0]) are transmitted.
  7. When winning the arbitration in a transmission of the above Step 6, the dynamic address following that is received. When losing arbitration in a transmission of the above Step 6, processing of Step 6 is repeated from Step 4.
  8. When parity of the Dynamic Address is valid, ACK response is done.
  9. When parity of the Dynamic Address is invalid, NACK replies, and repeat the process from Steps 4 to 7.
  10. SDATBAS0.SDDYAD[7:0] is renewed and the SVDVAD0.SDYADV bit is set to 1.

11. Upon detecting the STOP condition, Store the Receive Status Descriptor into the Receive Status Queue.

- In case of Broadcast CCC (ENTHDR*)
  1. It receives Broadcast Address (0x7E) and R/W# = 0 after START condition or Repeated START.
  2. Respond to ACK.
  3. Receive ENTHDR*.
  4. Transit to HDR mode according to ENTHDR*.
  5. Receives the HDR command word.
  6. Compare the Dynamic Address in the HDR command word with the assigned Dynamic Address, and if they match, transmit / receive according to the Read / Write bit.
     If they do not match, wait for HDR Restart Pattern or HDR Exit Pattern + STOP.
  7. When HDR Restart Pattern or HDR Exit Pattern + STOP is received, Receive Status Descriptor is stored in Receive Status Queue.
     For HDR Restart Pattern, repeat Steps 5 to 6.
- In case of Direct Write CCC
  1. It receives Broadcast Address (0x7E) and R/W# = 0 after START condition or Repeated START.
  2. Respond to ACK.
  3. Receive Common Command Code (CCC).
  4. Receive Dynamic Address and R/W# = 0 after Repeated START.
  5. Compare the received Dynamic Address with the assigned Dynamic Address, and if it matches, I3C responds with ACK.
     If they do not match, it responds with NACK and waits for Repeated START or STOP.
  6. In accordance with the CCC, the following data is stored. (Storage destination: see Table 29.11)
  7. Store the Receive Status Descriptor into the Receive Status Queue.
- In case of Direct Read CCC
  1. It receives Broadcast Address (0x7E) and R/W# = 1 after START condition or Repeated START.
  2. Respond to ACK.
  3. Receive Common Command Code (CCC).
  4. Receive Dynamic Address and R/W# = 1 after Repeated START.
  5. Compare the received Dynamic Address with the assigned Dynamic Address, and if it matches, I3C responds with ACK.
     If they do not match, it responds with NACK and waits for Repeated START or STOP.
  6. Respond from SFR according to CCC. (Responding CCC: see Table 29.11)
  7. Store the Receive Status Descriptor into the Receive Status Queue.

**Table 29.11 Common command code operation (1 of 2)**

| Command Code | CCC Type | Command Name | With Data | Auto Response | Storage |
|---|---|---|---|---|---|
| 0x00 | Broadcast | ENEC | Yes | — | SFR |
| 0x01 | Broadcast | DISEC | Yes | — | SFR |
| 0x02 | Broadcast | ENTAS0 | No | — | SFR |
| 0x03 | Broadcast | ENTAS1 | No | — | SFR |

### 29.3.2.3.5 Arbitration-Lost Detection [$I^2C$ mode]

In addition to the normal arbitration-lost detection function defined by the $I^2C$-bus specification, the I3C has functions to prevent double-issue of a start condition, to detect arbitration-lost during transmission of NACK, and to detect arbitration-lost in slave transmit mode.

#### (1) Master Arbitration-Lost Detection (MALE Bit)

The I3C drives the I3C_SDA line low to issue a start condition. However, if the I3C_SDA line has already been driven low by another master device issuing a start condition, this module causes arbitration to be lost, so priority is given to transfer by the other master device. Similarly, if the CNDCTL.STCND bit is set to 1 while the BCST.BFREF flag is 0 (bus busy state), arbitration is lost, so priority is given to transfer by the other master device. No start condition is issued in this case.

When a start condition is issued successfully, if the data for transmission including the address bits (the internal SDA output level) and the level on the I3C_SDA line do not match (the high output as the internal SDA output, that is, the I3C_SDA pin is in the high-impedance state) and the low level is detected on the I3C_SDA line, the I3C loses in arbitration.

I3C detects master arbitration-lost when the following conditions are met while the BSTE.ALE bit = 1 and the BFCTL.MALE bit = 1 (master arbitration-lost detection enabled).

If arbitration of mastership is lost, I3C immediately enters slave receive mode.

If a slave address (including the general call address) matches its own address at this time, I3C continues in slave operation.

[Conditions for master arbitration-lost]

- Non-matching of the internal level for output on SDA and the level on the I3C_SDA line after a START condition was issued by setting the CNDCTL.STCND bit to 1 while the BCST.BFREF flag was set to 1 (erroneous issuing of a START condition)
- Setting of the CNDCTL.STCND bit to 1 (START condition double-issue error) while the BFREF flag is set to 0

  Note: I3C does not issue a START condition.
- When the transmit data excluding acknowledge (internal SDA output level) does not match the level on the I3C_SDA line in master transmit mode (bits CRMS and TRMD in the PRSST register = 11b)

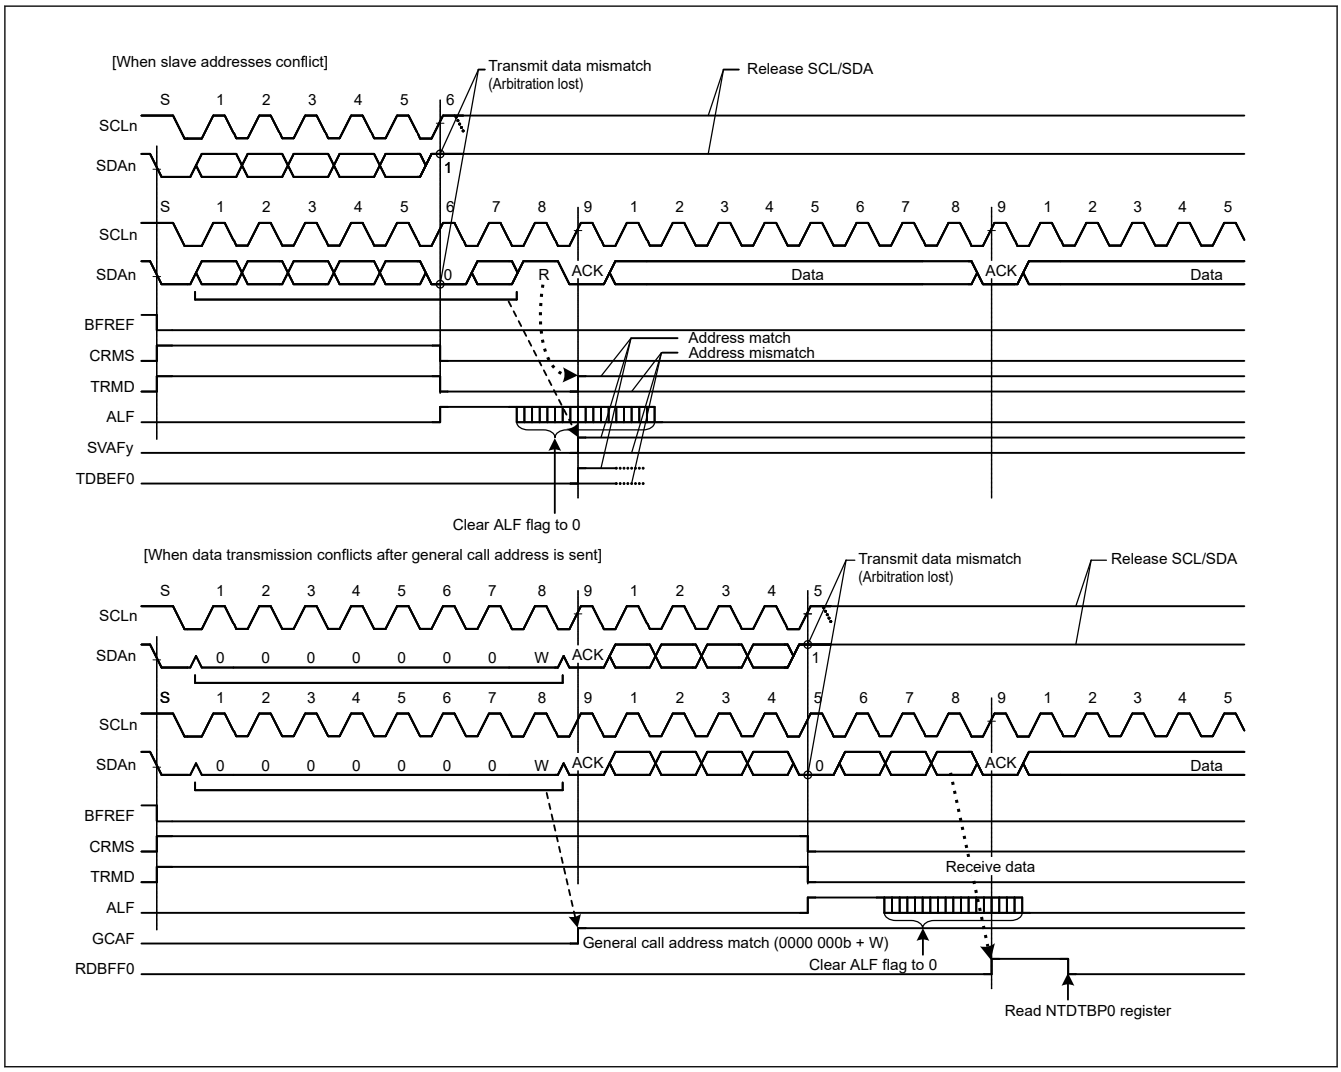

**Figure 29.77 Examples of master arbitration-lost detection (MALE = 1)**

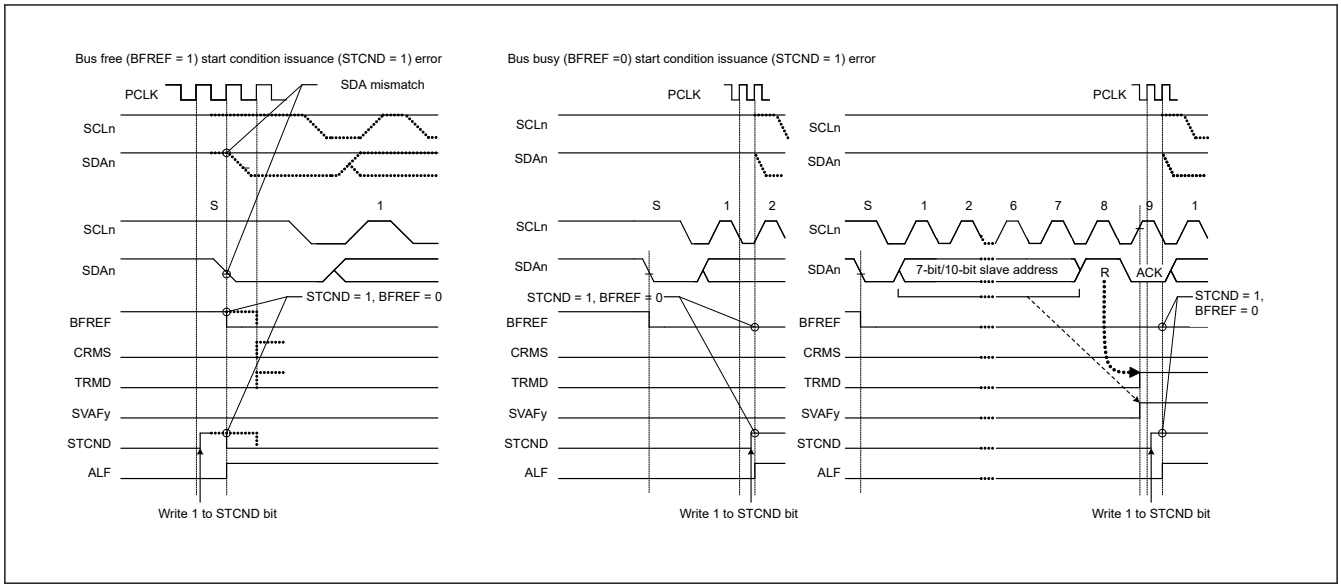

**Figure 29.78 Arbitration-lost detection when a START condition is issued (MALE = 1)**

## (2) Arbitration-Lost Detection during NACK Transmission (NALE Bit)

The I3C has a function to cause arbitration to be lost if the internal SDA output level does not match the level on the I3C_SDA line (the high output as the internal SDA output; i.e. the I3C_SDA pin is in the high-impedance state) and the low level is detected on the I3C_SDA line during transmission of NACK in receive mode. Arbitration is lost due to a conflict of NACK transmission and ACK transmission when two or more master devices receive data from the same slave device simultaneously in a multi-master system. Such conflict occurs when multiple master devices send/receive the same information through a single slave device.

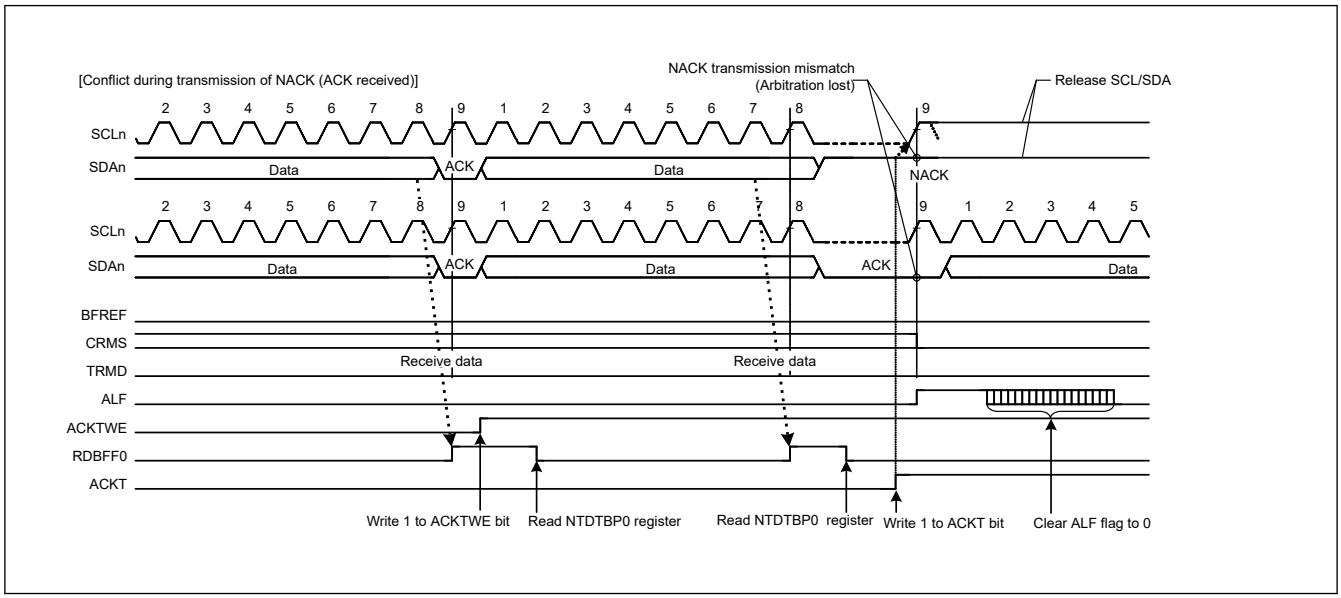

**Figure 29.79 Example of arbitration-lost detection during transmission of NACK (NALE = 1)**

The following section explains arbitration-lost detection using an example where two master devices (master A and master B) and a single slave device are connected through the bus. In this example, master A receives 2 bytes of data from the slave device, and master B receives 4 bytes of data from the slave device.

If master A and master B access the slave device simultaneously, because the slave address is identical, arbitration is not lost in both master A and master B during access to the slave device. Therefore, both master A and master B recognize that they have obtained the bus mastership and operate as such. In this example, master A sends NACK when it has received 2 final bytes of data from the slave device. Meanwhile, master B sends ACK because it has not received the necessary 4 bytes of data. At this time, the NACK transmission from master A and the ACK transmission from master B conflict. In general, if

a conflict like this occurs, master A cannot detect ACK transmitted by master B and issues a stop condition. Therefore, the issuance of the stop condition conflicts with the SCL clock output of master B, which disturbs communication.

When this module receives ACK during transmission of NACK, it detects a defeat in conflict with other master devices and causes arbitration to be lost.

If arbitration is lost during transmission of NACK, this module is immediately released from the slave-matched state and enters slave receive mode. This prevents a stop condition from being issued, preventing a communication failure on the bus.

Similarly, in the ARP command processing of SMBus, the function to detect loss of arbitration during transmission of NACK is also available for eliminating the extra clock cycle processing (such as 0xFF transmission processing) necessary if the UDID (Unique Device Identifier) of assign address does not match in the Get UDID (general) processing after the Assign Address command.

The I3C detects arbitration-lost during transmission of NACK when the following condition is met while the BSTE.ALE bit = 1 and the BFCTL.NALE bit = 1 (arbitration-lost detection during NACK transmission enabled).

[Condition for arbitration-lost during NACK transmission]

- When the internal SDA output level does not match the I3C_SDA line (ACK is received) during transmission of NACK (ACKCTL.ACKT bit = 1)

### (3) Slave Arbitration-Lost Detection (SALE Bit)

The I3C has a function to cause arbitration to be lost if the data for transmission (the internal SDA output level) and the level on the I3C_SDA line do not match (the high output as the internal SDA output, that is, the I3C_SDA pin is in the high impedance state) and the low level is detected on the I3C_SDA line in slave transmit mode. This arbitration-lost detection function is mainly used when transmitting a UDID (Unique Device Identifier) over an SMBus.

If arbitration is lost during transmission of DATA, this module is immediately released from the slave-matched state and enters slave receive mode. This function can detect conflicts of data during transmission of UDIDs over an SMBus and eliminate subsequent redundant processing (processing for the transmission of 0xFF).

The I3C detects slave arbitration-lost when the following condition is met while the BSTE.ALE bit = 1 and the BFCTL.SALE bit = 1 (slave arbitration-lost detection enabled).

[Condition for slave arbitration-lost]

- When the transmit data excluding acknowledge (internal SDA output level) does not match the level on the I3C_SDA line in slave transmit mode (bits CRMS and TRMD in the PRSST register = 01b).

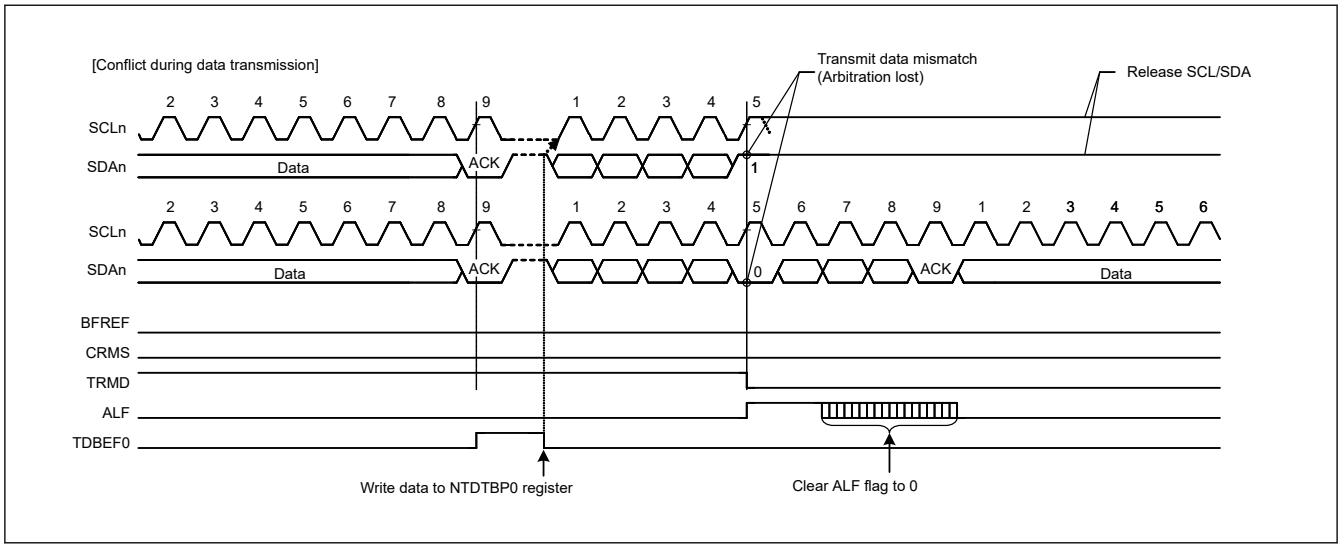

**Figure 29.80 Example of slave arbitration-lost detection (SALE = 1)**

### 29.3.2.3.6 Clock Stretching [$I^2C$ mode]

#### (1) Function to Prevent Wrong Transmission of Transmit Data

When data have not been written to the Normal Transfer Data Buffer Port Register 0 (NTDTBP0) with I3C in transmission mode (PRSST.TRMD = 1), the I3C_SCL line is automatically held at the low level over the intervals shown below. This low-hold period is extended until data for transmission have been written, which prevents the unintended transmission of erroneous data.

**Master transmit mode**

- Low-level interval after a START condition or Repeated START condition is issued
- Low-level interval between the ninth clock cycle of one transfer and the first clock cycle of the next

**Slave transmit mode**

- Low-level interval between the ninth clock cycle of one transfer and the first clock cycle of the next

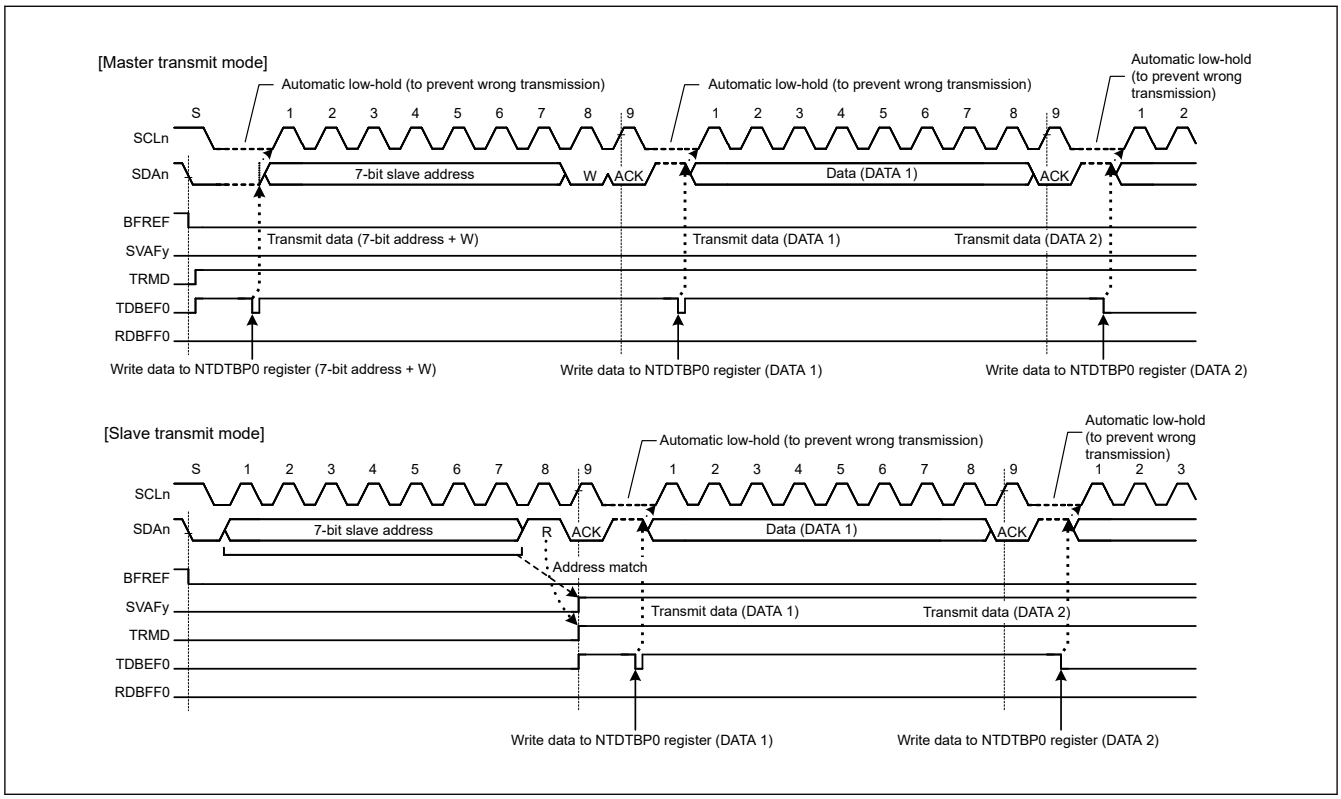

**Figure 29.81 Automatic low-hold operation in transmit mode**

#### (2) NACK Reception Transfer Abort Function

I3C has a function to abort transfer operation when NACK is received in transmit mode (PRSST.TRMD = 1). This function is enabled when the BSTE.NACKDE bit is set to 1 (transfer abort enabled). If the next transmit data has already been written (NTST.TDBEF0 = 0) when NACK is received, next data transmission at the falling edge of the ninth SCL clock cycle is automatically aborted. This prevents the I3C_SDA line output level from being held low when the MSB of the next transmit data is 0.

If the transfer operation is aborted by this function (BST.NACKDF = 1), transmit operation and receive operation are discontinued. To restore transmit/receive operation, be sure to set the NACKDF flag to 0. In master transmit mode, restore operation using either of the methods below:

- After issuing a Repeated START condition, set the NACKDF flag to 0
- After issuing a STOP condition, set the NACKDF flag to 0 and then issue a START condition

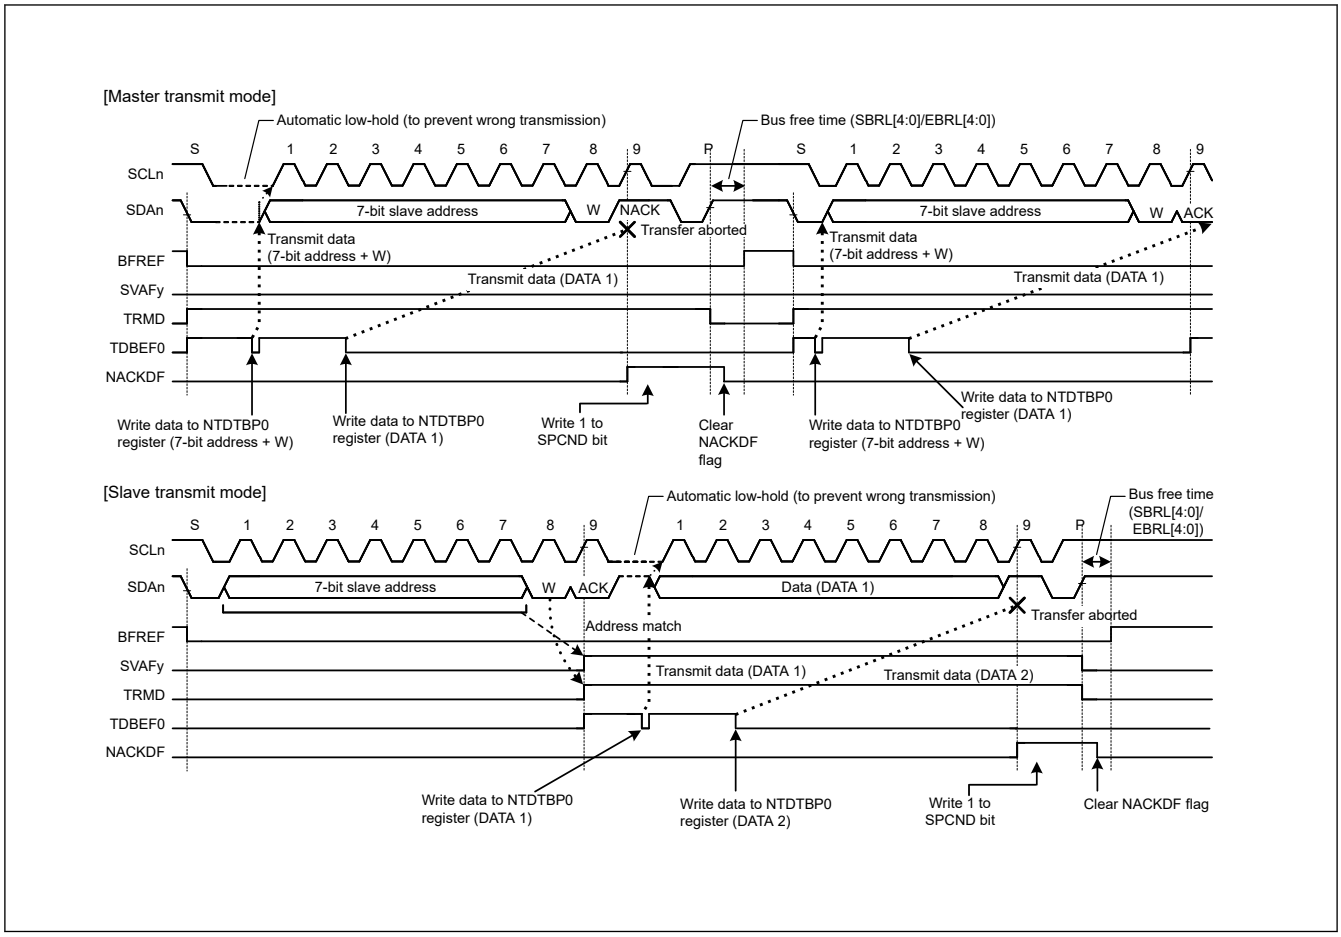

**Figure 29.82 Abort of data transfer when NACK is received (NACKE = 1)**

## (3) Function to Prevent Failure to Receive Data

If response processing is delayed when receive data (NTDTBP0) read is delayed for a period of one transfer frame or more with receive data full (NTST.RDBFF0 = 1) in receive mode (PRSST.TRMD = 0), I3C holds the I3C_SCL line low automatically immediately before the next data is received to prevent failure to receive data.

This function to prevent failure to receive data using the automatic low-hold function is also enabled even if the read processing of the final receive data is delayed and, in the meantime, I3C's own slave address or another slave address is received after a STOP condition is issued.

Sections in which the I3C_SCL line is held low can be selected with a combination of the RWE and ACKTWE bits in SCSTRCTL.

### (a) 1-Byte Receive Operation and Automatic Low-Hold Function Using the RWE Bit

When the SCSTRCTL.RWE bit is set to 1, I3C performs 1-byte receive operation using the RWE bit function.

Furthermore, when the SCSTRCTL.ACKTWE bit = 0, I3C automatically sends the ACKCTL.ACKT bit value for the acknowledge bit in the period from the falling edge of the eighth SCL clock cycle to the falling edge of the ninth SCL clock cycle, and automatically holds the I3C_SCL line low at the falling edge of the ninth SCL clock cycle using the RWE bit function. This low-hold is released by reading data from NTDTBP0, which enables bytewise receive operation.

The RWE bit function is enabled for receive frames after a match with I3C's own slave address (including the general call address and host address) is obtained in master receive mode or slave receive mode.

### (b) 1-Byte Receive Operation (ACK/NACK Transmission Control) and Automatic Low-Hold Function Using the ACKTWE Bit

When the SCSTRCTL.ACKTWE bit is set to 1, I3C performs 1-byte receive operation using the ACKTWE bit function.

When the ACKTWE bit is set to 1, the NTST.RDBFF0 flag (Normal Rx Data buffer full) is set to 1 at the rising edge of the eighth SCL clock cycle, and the I3C_SCL line is automatically held low at the falling edge of the eighth SCL clock

cycle. This low-hold is released by writing a value to the ACKCTL.ACKT bit, but cannot be released by reading data from NTDTBP0, which enables receive operation by the ACK/NACK transmission control according to the data received in byte units.

The ACKTWE bit function is enabled for receive frames after a match with I3C's own slave address (including the general call address and host address) is obtained in master receive mode or slave receive mode.

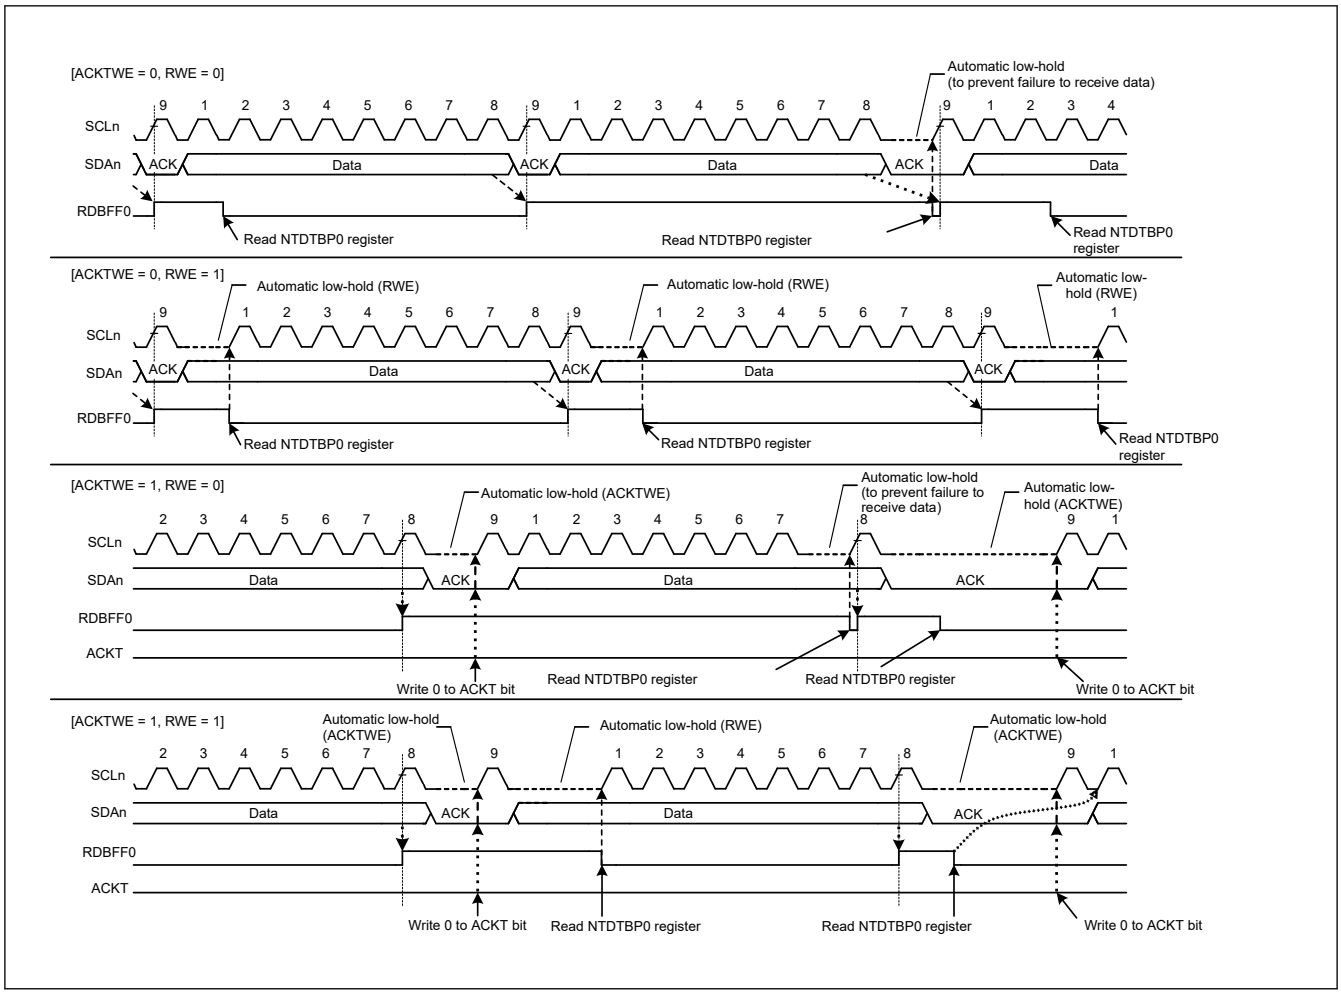

**Figure 29.83 Automatic low-hold operation in receive mode (using ACKTWE and RWE bits)**

## 29.3.2.3.7 Clock Stalling [I3C mode]

I3C has the function of stalling the SCL during the SCL Low period.

The SCL stall control is described in the table below.

**Table 29.12 I3C clock stalling (1 of 2)**

| Clock stalling condition | Clock stalling control | Clock stalling period |
|---|---|---|
| I3C Transfer, ACK/NACK Phase | SCSTLCTL.ACKPE bit setting | During the count period of SCSTLCTL.STLCYC [15:0] value |
| | Tx Data Buffer Empty | Until data is written to the Tx Data Buffer |
| | Rx Data Buffer Full | Until data is read from the Rx Data Buffer |
| I3C Write Data Transfer, Parity Bit | SCSTLCTL.PARPE bit setting | During the count period of SCSTLCTL.STLCYC [15:0] value |
| | Tx Data Buffer Empty | Until data is written to the Tx Data Buffer |
| I3C Read Transfer, Transition Bit | Rx Data Buffer Full | Until data is read from the Rx Data Buffer |

**Table 29.12 I3C clock stalling (2 of 2)**

| Clock stalling condition | Clock stalling control | Clock stalling period |
|---|---|---|
| Assigned Address Phase | SCSTLCTL.AAPE bit setting | During the count period of SCSTLCTL.STLCYC [15:0] value |

The following figure shows the stalling timing of each Condition.

(1) I3C Transfer, ACK/NACK Phase

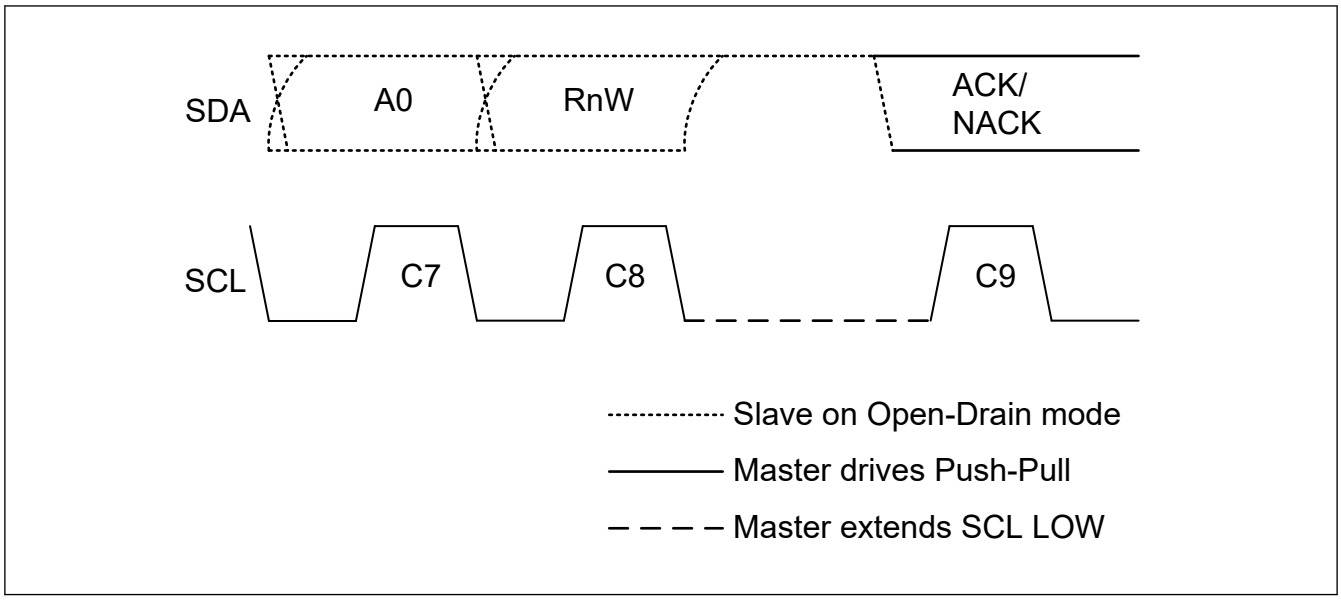

**Figure 29.84 Master clock stalling in ACK phase**

(2) I3C Write Data Transfer, Parity Bit

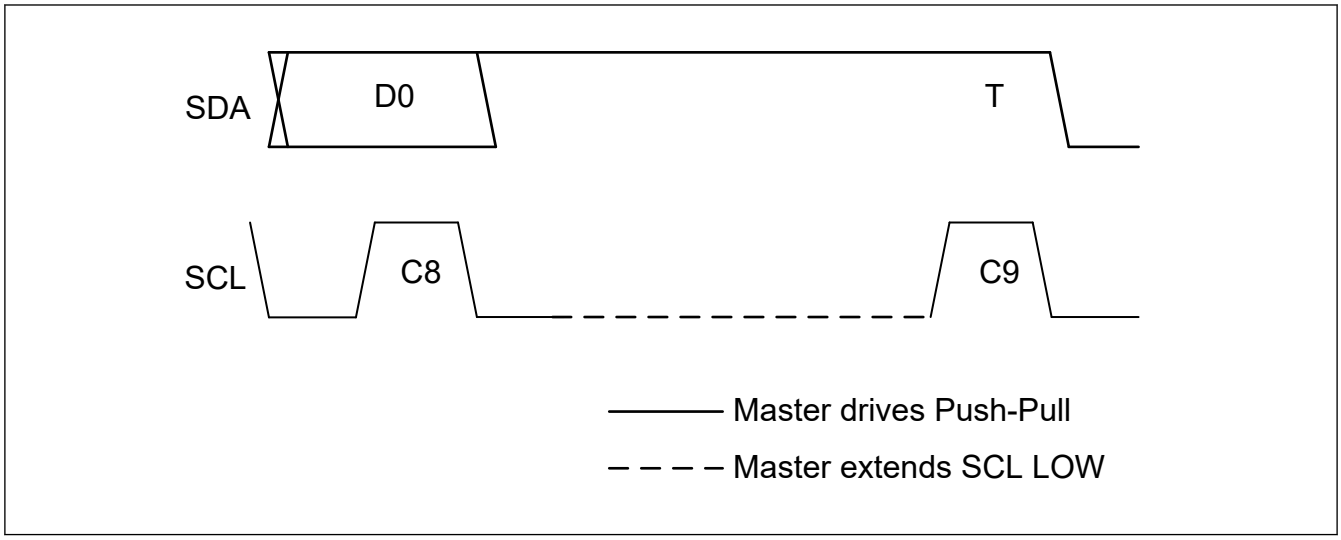

**Figure 29.85 Master clock stalling in write parity bit**

(3) I3C Read Transfer, Transition Bit

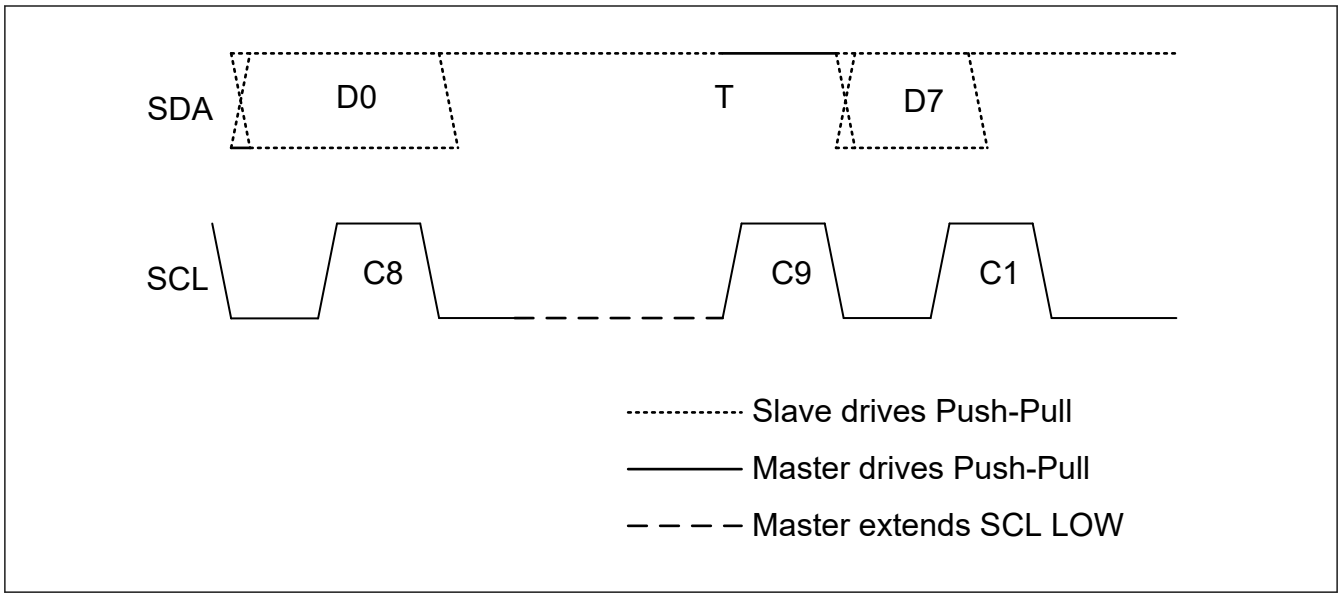

**Figure 29.86 Master clock stalling in T-bit before next read data**

(4) Dynamic Address Assignment, First Bit of Assigned Address

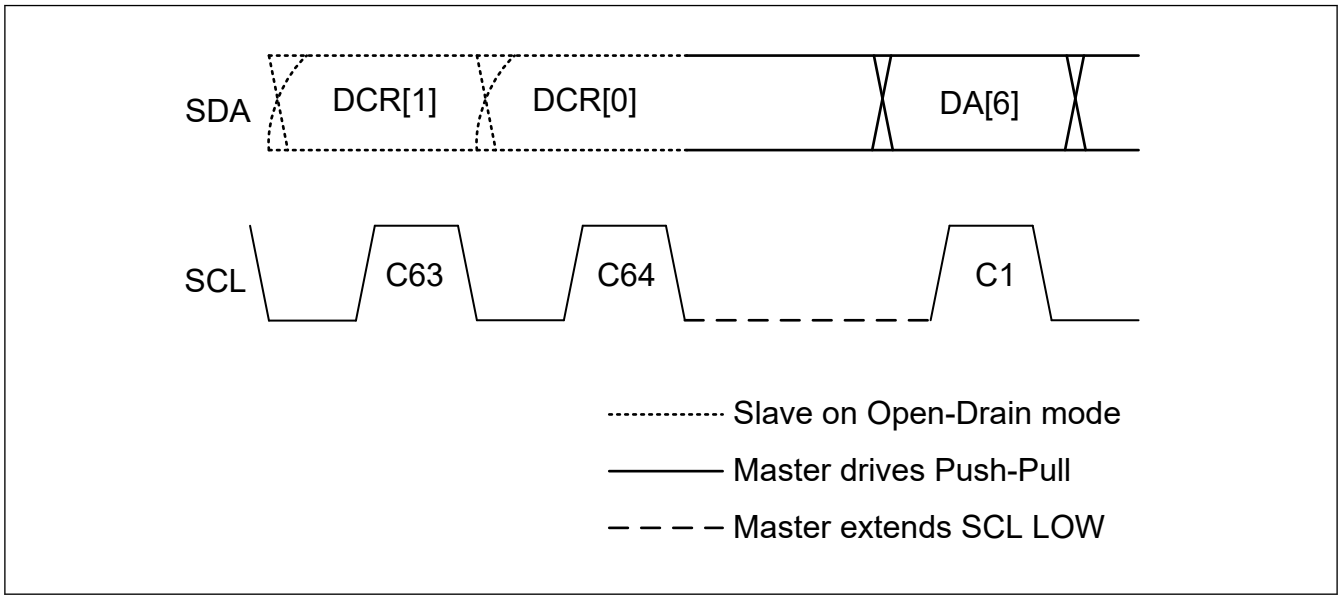

**Figure 29.87 Master clock stalling in dynamic address first bit**

### 29.3.2.3.8 In-Band Interrupt [I3C mode]

I3C detects In-Band Interrupt in the arbitrated Address Header following a START condition (but not following a Repeated START). If START Request (SDA Low Drive) is issued from Slave Device, I3C drives SCL low and completes START condition. After that, it supplies SCL and receives In-Band Interrupt Request.

The In-Band Interrupt to be detected is classified into the following three types.

- Slave Interrupt Request
- Mastership Request
- Hot-Join Event

The operation when detecting each In-Band Interrupt is described below.

### (1) Slave Interrupt Request

1. Detect Slave Address with RnW bit High in Address Header.
2. Compare the detected Slave Address with the DVDYAD[7:0] in each DAT (DATBASm register).
3. When it does not match DAT.DVDYAD[7:0]:
   Responds NACK, then issues the STOP condition.
   When it matches the DAT.DVDYAD[7:0] bits and the DAT.DVSIRRJ bit = 1:
   It operates in the following order:
   (a) Responds NACK.
   (b) Issues Repeated START condition, then automatically issues Direct DISEC CCC to the detected Slave.
   (c) Issues the STOP condition.

   When it matches the DAT.DVDYAD[7:0] bits and the DAT.DVSIRRJ bit = 0:
   Responds ACK.
4. When DAT.DVIBIPL = 0:
   Issues the STOP condition.
   When DAT.DVIBIPL = 1:
   Drives the SCL to receive the IBI Data from the Slave following the ACK response and receives IBI Data.
   It stores the received IBI Data into the IBI Data Queue.
   Each time IBI Data of the size set by the NQTHCTL.IBIDSSZ[7:0] bits is received, the IBI Status Descriptor is stored in the IBI Queue.
5. After detection of Low of T-bit following IBI Data, issues STOP condition.
6. After issues of STOP condition,
   NACK response:
   - If IBINCTL.NRSIRCTL = 0, the IBI Status Descriptor is not stored into the IBI Queue.
   - If IBINCTL.NRSIRCTL = 1, the IBI Status Descriptor is stored into the IBI Queue.

   ACK response:
   Stores the IBI Status Descriptor into the IBI Queue.

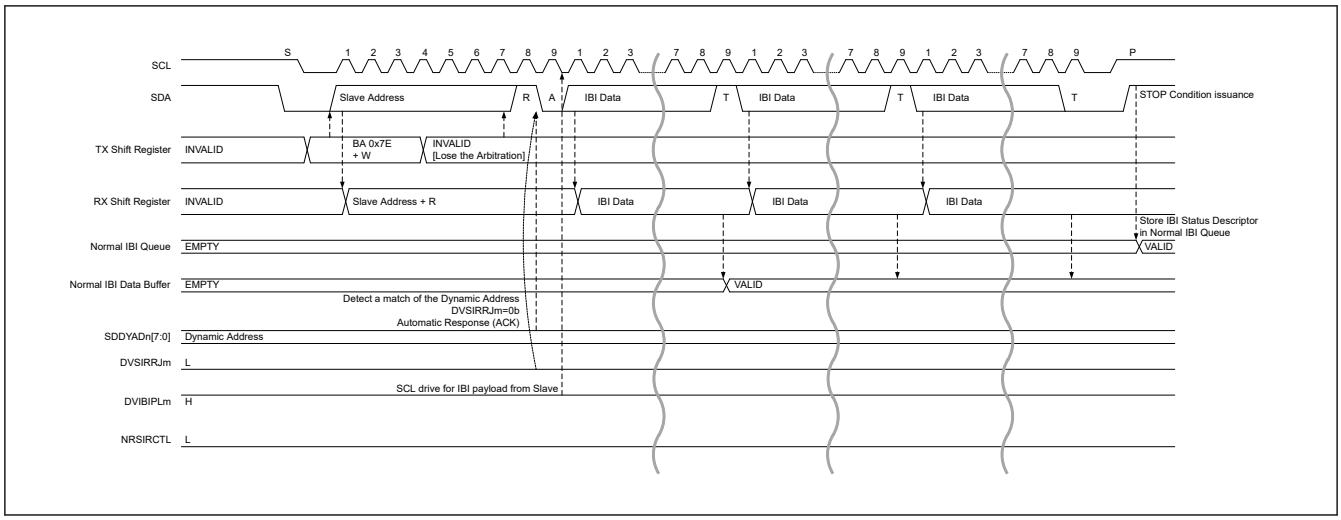

**Figure 29.88 Slave interrupt request : ACK and DVIBIPL = 1**

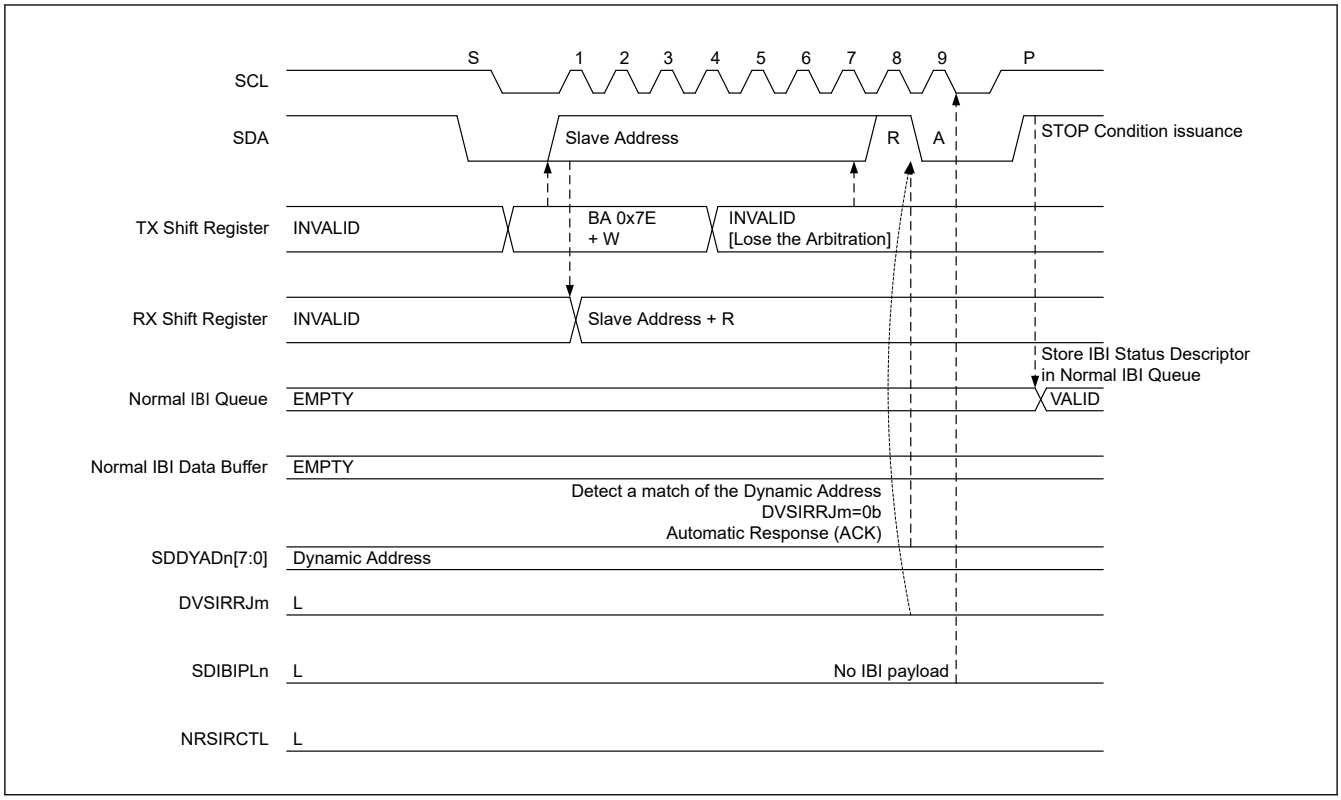

**Figure 29.89 Slave interrupt request : ACK and DVIBIPL = 0**

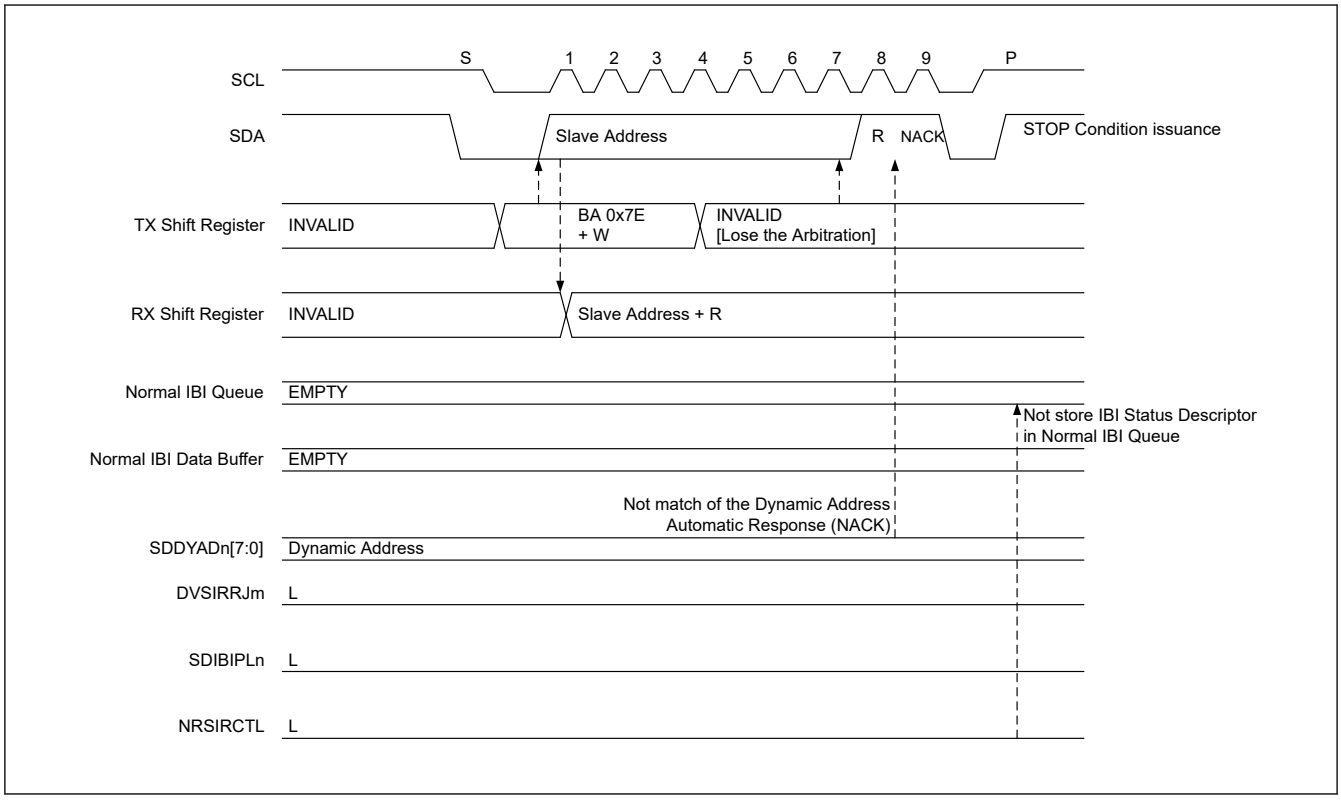

**Figure 29.90 Slave interrupt request : NACK (not match the SDDYAD[7:0] of DAT) and NRSIRCTL = 0**

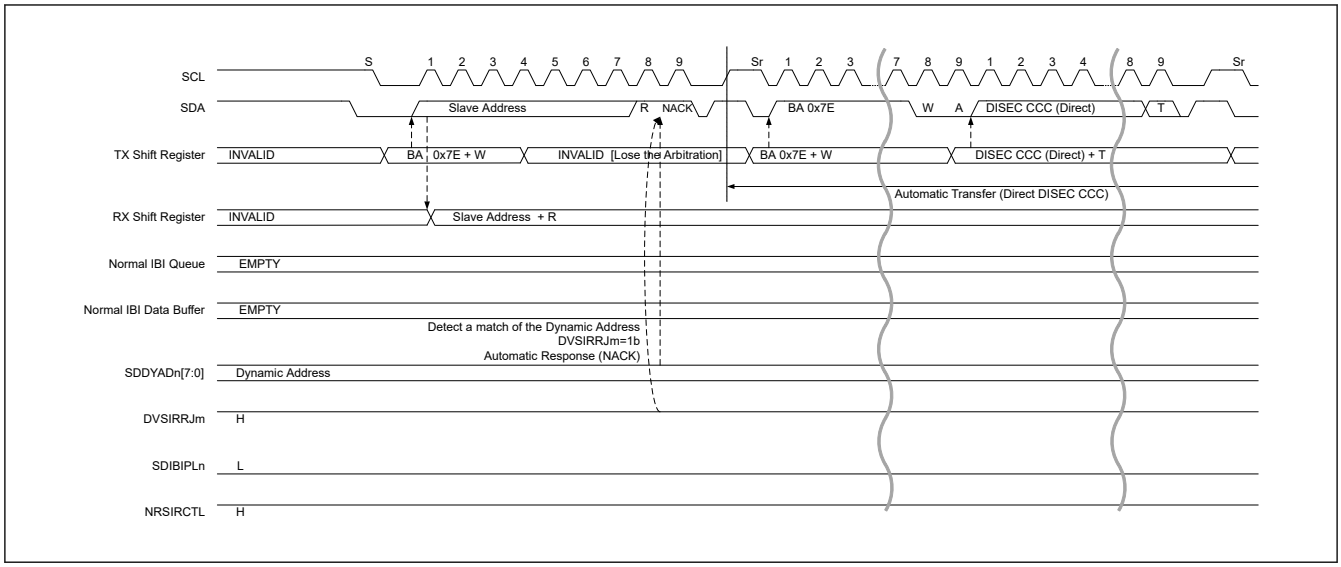

**Figure 29.91 Slave interrupt request : NACK (DVSIRRJ = 1) and NRSIRCTL = 1 (1/2)**

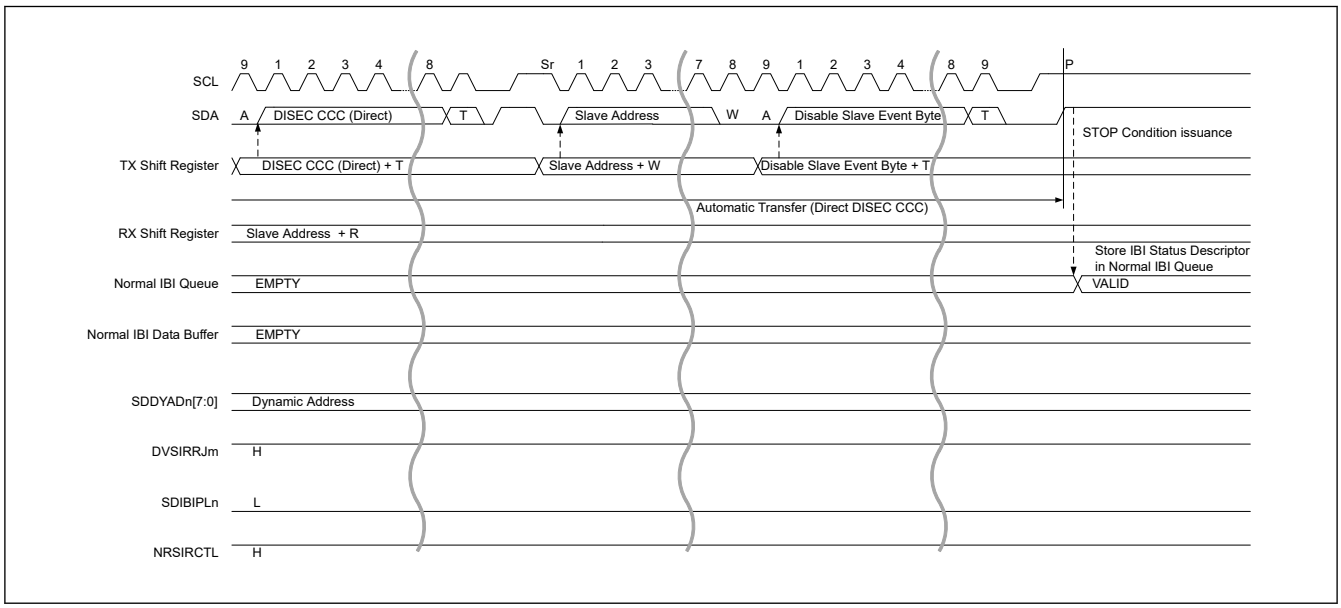

**Figure 29.92 Slave interrupt request : NACK (DVSIRRJ = 1) and NRSIRCTL = 1 (2/2)**

## (2) Mastership Request

1. Detect Slave Address with RnW bit Low in Address Header.
2. Compare the detected Slave Address with the DVDYAD[7:0] in each DAT (DATBAS register).
3. When it does not match DAT.DVDYAD[7:0]:
   Responds NACK, then issues the STOP condition.
   When it matches the DAT.DVDYAD[7:0] bits and Device Role[1:0] in RBCR (MSDCTm) is other than I3C Master (01b):
   Responds NACK, then issues the STOP condition.
   When it matches the DAT.DVDYAD[7:0] bits and Device Role[1:0] in RBCR (MSDCTm) is I3C Master (01b):
   - When DAT.DVMRRJ = 1
     It operates in the following order.
     (a) Responds NACK.
     (b) Issued Repeated START condition and automatically issues Direct DISEC CCC to the detected Slave.
     (c) Issues the STOP condition.

- When DAT.DVMRRJ = 0
  Responds ACK, then issues STOP condition.

4. After issues of STOP condition,
   NACK response:
   - If IBINCTL.NRMRCTL = 0, the IBI Status Descriptor is not stored into the IBI Queue.
   - If IBINCTL.NRMRCTL = 1, the IBI Status Descriptor is stored into the IBI Queue.

   ACK response:
   Stores the IBI Status Descriptor into the IBI Queue.

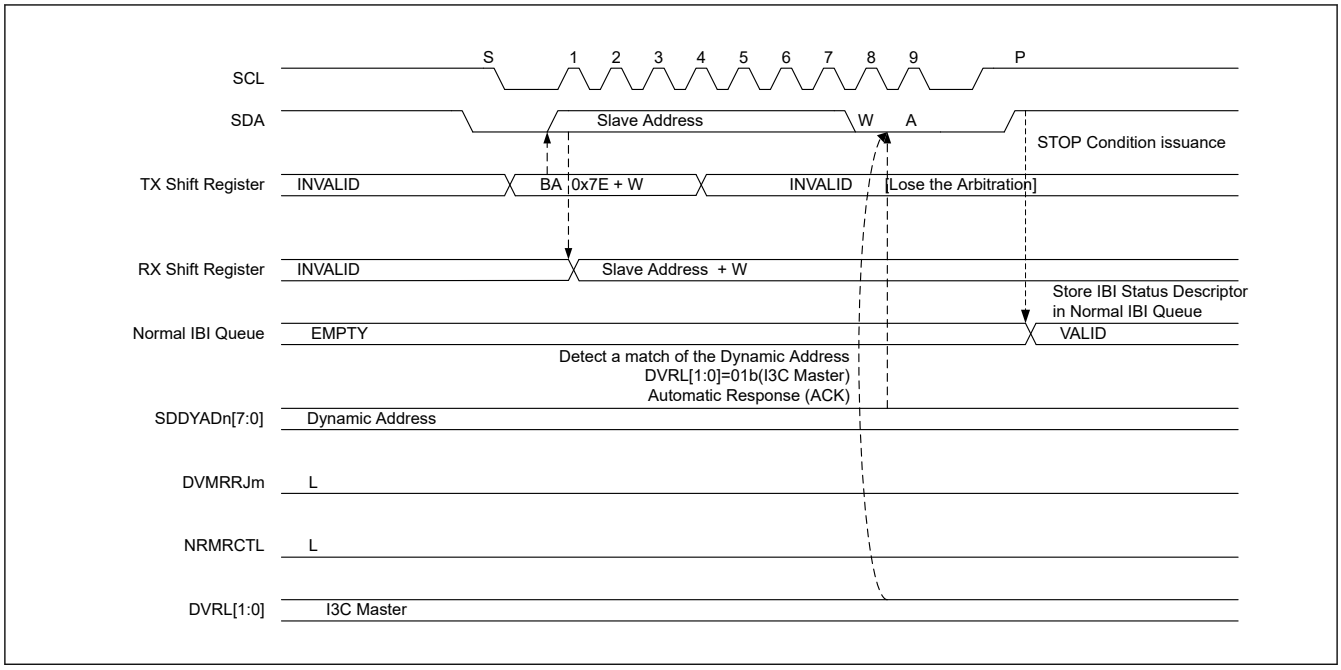

**Figure 29.93 Mastership request : ACK**

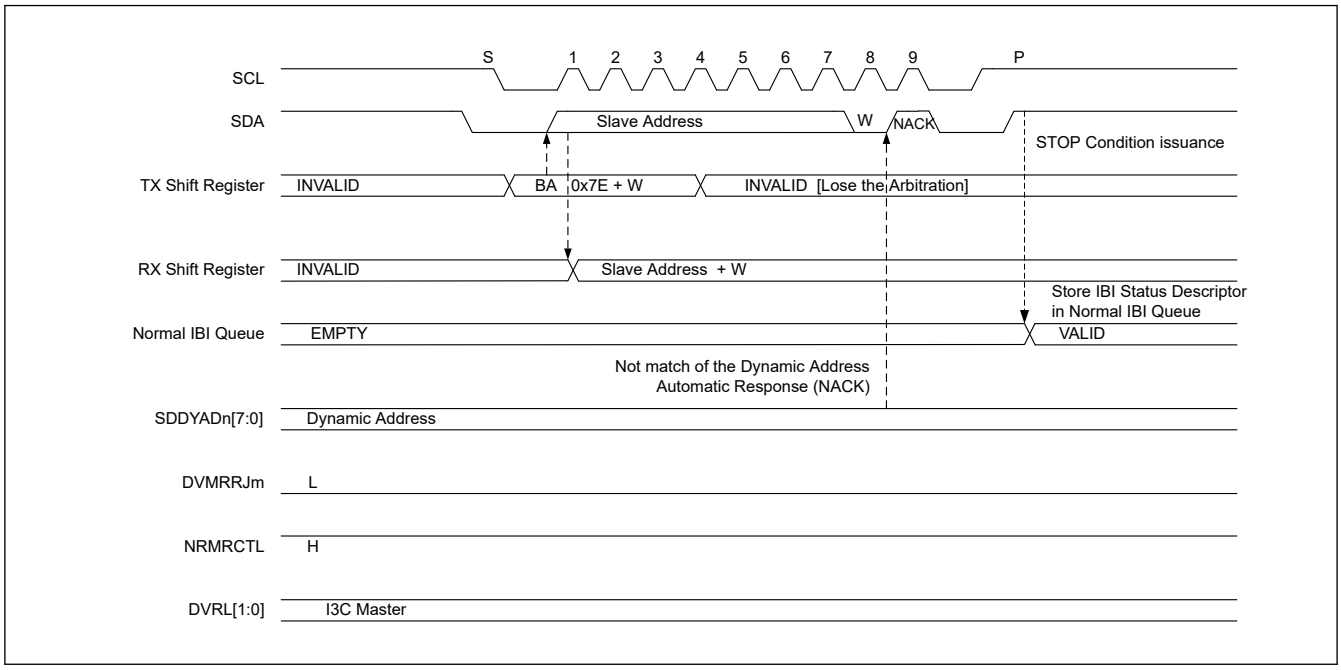

**Figure 29.94 Mastership request : NACK (not match the DVDYAD[7:0] of DAT) and NRMRCTL = 1**

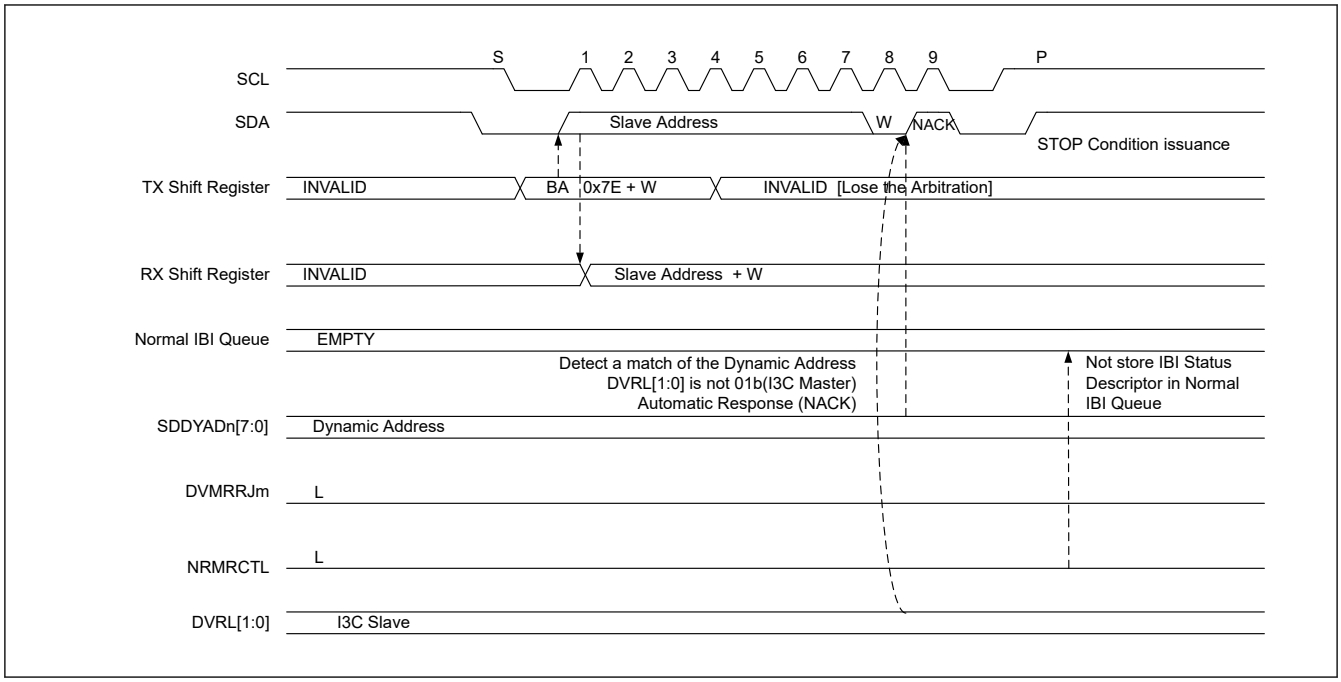

**Figure 29.95 Mastership request : NACK (Device Role[1:0] is not 01 (I3C master)) and NRMRCTL = 0**

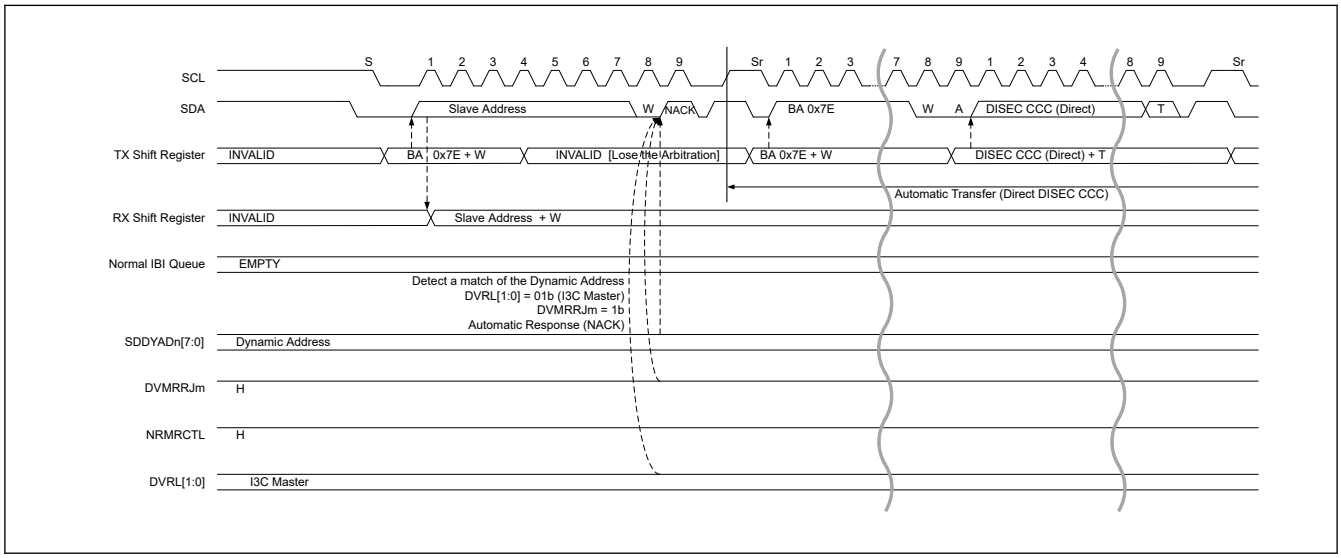

**Figure 29.96 Mastership request : NACK (DVMRRJ = 1) and NRMRCTL = 1 (1/2)**

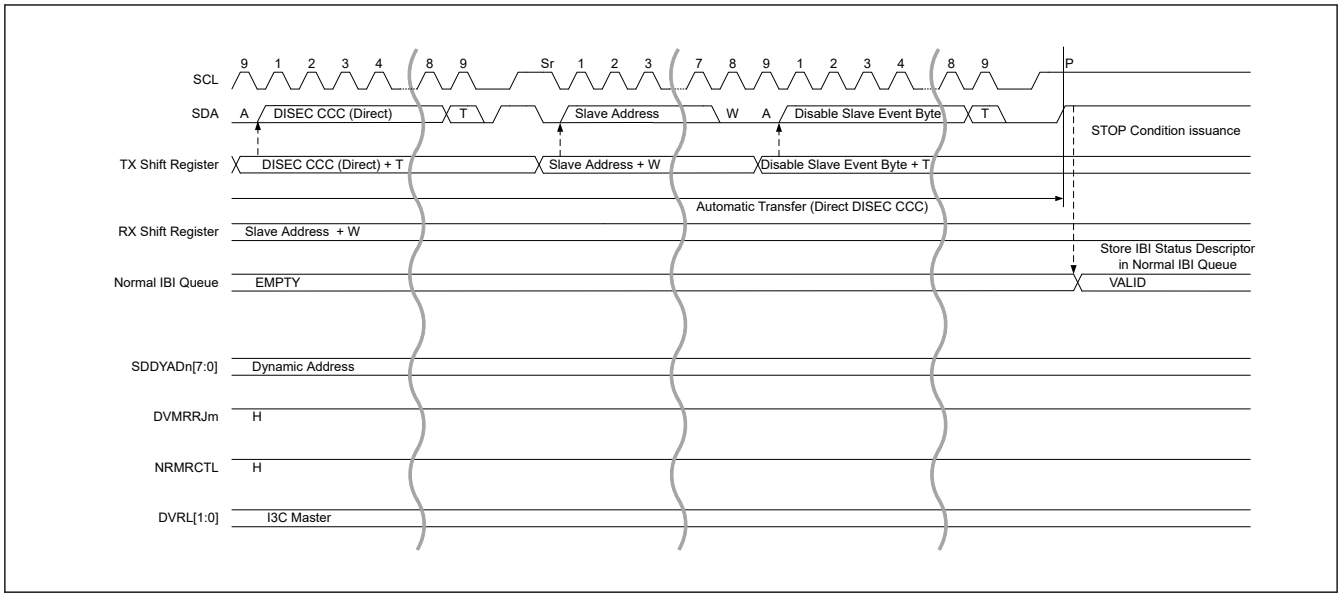

**Figure 29.97 Mastership request : NACK (DVMRRJ = 1) and NRMRCTL = 1 (2/2)**

## (3) Hot-Join Event

1. Detect the Hot-Join Address (0x02) with RnW bit Low in the Address Header.
2. When BCTL.HJACKCTL = 1:
   It operates in the following order.
   (a) Responds NACK.
   (b) Issues Repeated START condition and automatically issues Broadcast DISEC CCC.
   (c) Issues the STOP condition.

   When BCTL.HJACKCTL = 0:
   Responds ACK, then issues STOP condition.
3. After issues of STOP condition,
   NACK response:
   - If IBINCTL.NRHJCTL = 0, the IBI Status Descriptor is not stored into the IBI Status Queue.
   - If IBINCTL.NRHJCTL = 1, store the IBI Status Descriptor into the IBI Status Queue.

   ACK response:
   Stores the IBI Status Descriptor into the IBI Status Queue.

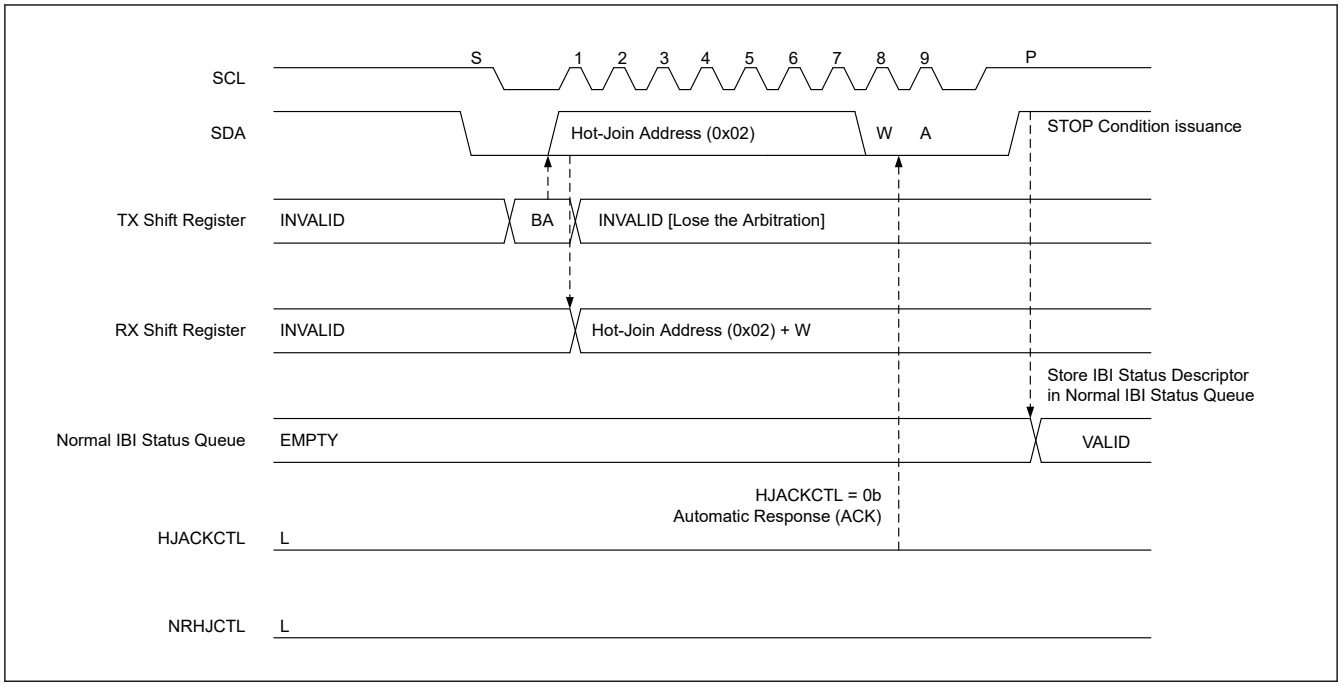

**Figure 29.98 Hot-join event: ACK**

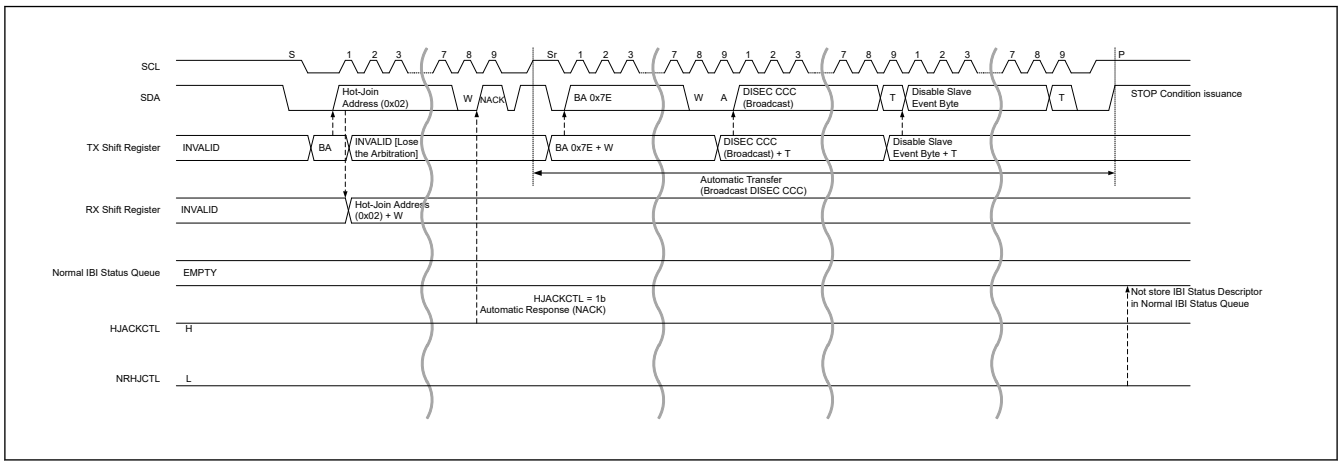

**Figure 29.99 Hot-join event: NACK (HJACKCTL = 1) and NRHJCTL = 0**

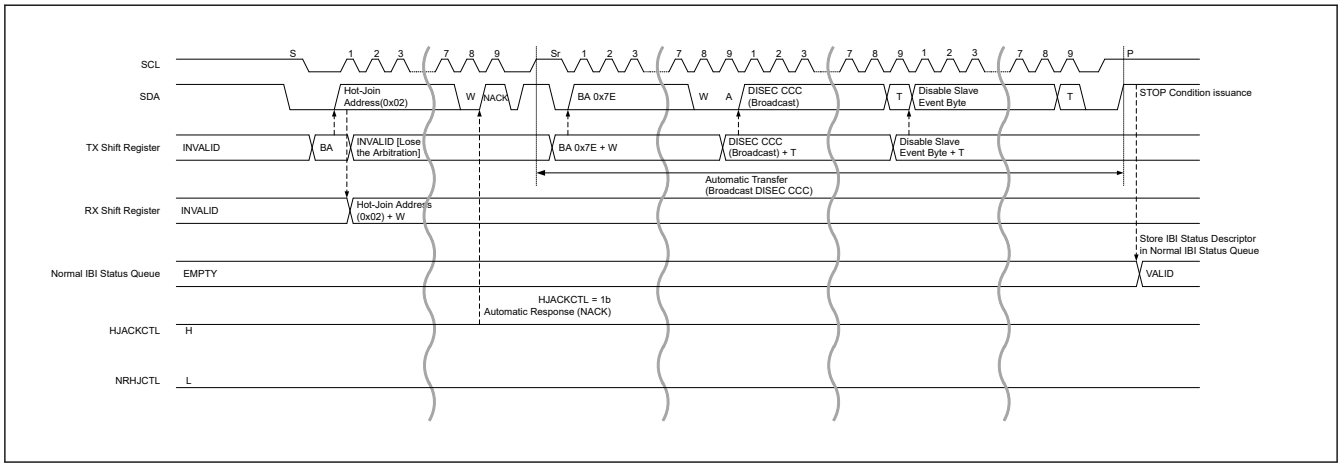

**Figure 29.100 Hot-join event: NACK (HJACKCTL = 1) and NRHJCTL = 1**

#### 29.3.2.3.9 HDR-DDR CRC5 Algorithm

The CRC5 value is computed on a complete message, including the Command Word and all Data Words.

For a Command Word, the CRC5 is computed based on the value of the 16-bit payload, including:

- The Read vs. Write bit
- The Command Value
- The Slave Address, and
- The lowest-order bit (Write Reserved and Read Parity adjustment).

For Data Words, the CRC5 is computed based on all Data 16-bit values transmitted for that Command.

The CRC5 value is initialized to 0x1F. The CRC5 polynomial is below.

$CRC5 = X^5 + X^2 + X^0$

#### 29.3.2.3.10 Port Control

##### (1) Extra SCL Clock Cycle Output Function

In master mode, I3C module has a facility for the output of extra SCL clock cycles to release the I3C_SDA line of the slave device from being held at the low level due to the master being out of synchronization with the slave device.

This function is mainly used in master mode to release the I3C_SDA line of the slave device from the state of being fixed to the low level by including extra cycles of SCL output from I3C with single cycles of the SCL clock as the unit in the case of a bus error where I3C cannot issue a Repeated START condition or a STOP condition because the slave device is holding the I3C_SDA line at the low level. Do not use this facility in normal situations. Using it when communications are proceeding correctly will lead to malfunctions.

When the OUTCTL.EXCYC bit is set to 1, an additional clock pulse at the frequency set by the REFCKCTL.IREFCKS[2:0] bits and the STDBR.SBRHO[7:0] and STDBR.SBRLO[7:0] registers is output from the I3C_SCL pin. After output of this clock pulse, the EXCYC bit automatically becomes 0. After confirming that the EXCYC bit is 0, wait for the setup time of the Repeated START condition or STOP condition, and then confirm the detection of the Repeated START condition or STOP condition. If the Repeated START condition or STOP condition is not detected, consecutive additional clock pulses can be output by writing 1 to the EXCYC bit again.

When I3C module is in master mode and the slave device is holding the I3C_SDA line at the low level because synchronization with the slave device has been lost due to the effects of noise, etc., the output of a Repeated START condition or a STOP condition is not possible. The facility for output of an extra cycle of the SCL clock can be used to output extra cycles of SCL one by one to make the slave device release the I3C_SDA line from being held at the low level, thus recovering the bus from an unusable state. Release of the I3C_SDA line by the slave device can be monitored by reading the SDILV bit in PRSTDBG. After the I3C_SDA line has been released by the slave device, the preset of a Repeated START condition or a STOP condition is issued.

Use this function with the BFCTL.MALE bit set to 0 (master arbitration-lost detection is disabled).

[Output conditions for using the EXCYC bit in OUTCTL]

- When the bus is free (BFREF flag in BCST = 1) or in master mode (CRMS bit = 1 in PRSST and BFREF flag = 0 in BCST)
- When the communication device does not hold the I3C_SCL line low

Figure 29.101 shows the operation timing of the extra SCL clock cycle output function (EXCYC bit).

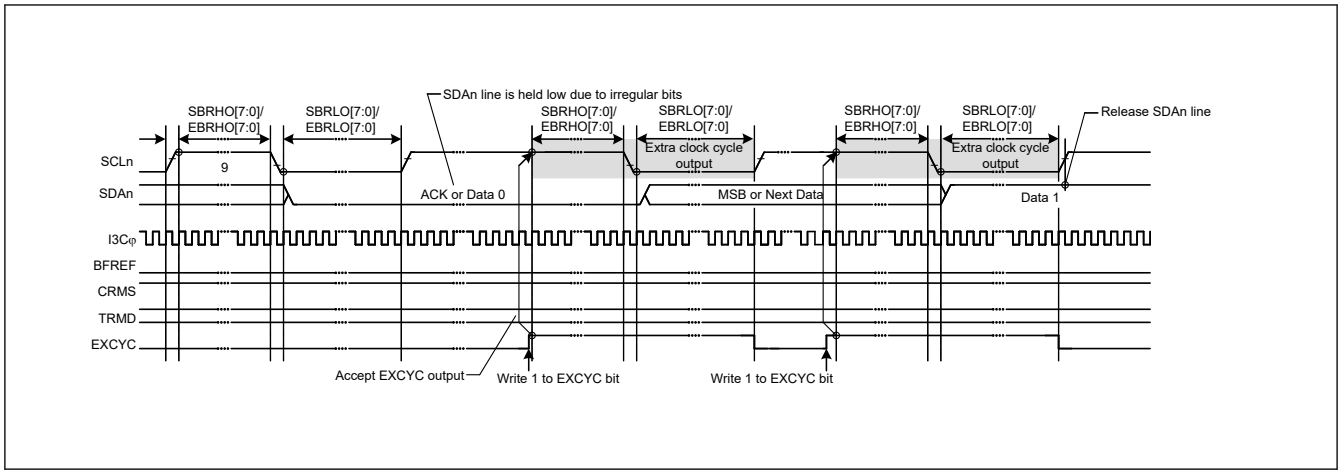

**Figure 29.101 Extra SCL clock cycle output function (EXCYC bit)**

### 29.3.2.3.11 SMBus Operation [I2C mode]

I3C is available for data communication conforming to the SMBus (Version 2.0). To perform SMBus communication, set the BFCTL.SMBS bit to 1. To use the transfer rate within a range of 10 kbps to 100 kbps of the SMBus specification, set the REFCKCTL.IREFCKS[2:0] bits, the STDBR.SBRHO[7:0] bits, and the STDBR.SBRLO[7:0] bits. In addition, determine the values of the OUTCTL.SDODCS bit and the OUTCTL.SDOD[2:0] bits to meet the data hold time specification of 300 ns or more. If I3C is used only as an I2C slave device, the transfer rate setting is not necessary, whereas the STDBR.SBRLO[7:0] bits needs to be set to a value longer than the data setup time (250 ns).

For the SMBus device default address (1100 001), use one of the slave device address table basic registers 0 (SDATBAS0.SDSTAD[6:0] bits), and set the corresponding SDATBAS0.SDADLS bit (7-bit/10-bit address format select) to 0 (7-bit address format).

When transmitting the UDID (Unique Device Identifier), set the BFCTL.SALE bit to 1 to enable the slave arbitration lost detection function.

#### (1) SMBus Timeout Measurement

(a) Measuring timeout of slave device

The following period (timeout interval: $T_{LOW:SEXT}$) must be measured for slave devices in SMBus communication.

- From START condition to STOP condition

To measure timeout for slave devices, measure the period from START condition detection to STOP condition detection with the GPT timer using a START condition detection interrupt (I3C_EEI) and STOP condition detection interrupt (I3C_EEI) of I3C. The measured timeout period must be within the total clock low-level period [slave device] $T_{LOW:SEXT}$: 25 ms (max.) of the SMBus specification.

If the time measured with the GPT exceeds the clock low-level detection timeout $T_{TIMEOUT}$: 25 ms (min.) of the SMBus specification, the slave device must release the bus by writing 1 to the RSTCTL.INTLRST bit to issue an internal reset of I3C. When an internal reset is issued, I3C stops driving the bus for the I3C_SCL pin and I3C_SDA pin and make the I3C_SCL/I3C_SDA pin outputs high-impedance, which releases the bus.

(b) Measuring timeout of master device

The following periods (timeout interval: $T_{LOW:MEXT}$) must be measured for master devices in SMBus communication.

- From START condition to acknowledge bit
- Between acknowledge bits
- From acknowledge bit to STOP condition

To measure timeout for master devices, measure these periods with the GPT timer using a START condition detection interrupt (I3C_EEI), STOP condition detection interrupt (I3C_EEI), and transmit end interrupt (I3C_TEND) or Normal Rx Data buffer full interrupt (I3C_RX) of I3C. The measured timeout period must be within the total clock low-level extended

period (master device) $T_{LOW:MEXT}$: 10 ms (max.) of the SMBus specification, and the total of all $T_{LOW:MEXT}$ from START condition to STOP condition must be within $T_{LOW:SEXT}$: 25 ms (max.).

For the ACK receive timing (rising edge of the ninth SCL clock cycle), monitor the BST.TENDF flag in master transmit mode (master transmitter) and the NTST.RDBFF0 flag in master receive mode (master receiver). For this reason, perform bytewise transmit operation in master transmit mode, and hold the SCSTRCTL.ACKTWE bit 0 until the byte just before reception of the final byte in master receive mode. While the ACKTWE bit = 0, the RDBFF0 flag is set to 1 at the rising edge of the ninth SCL clock cycle.

If the period measured with the GPT exceeds the total clock low-level extended period (master device) $T_{LOW:MEXT}$: 10 ms (max.) of the SMBus specification or the total of measured periods exceeds the clock low-level detection timeout $T_{TIMEOUT}$: 25 ms (min.) of the SMBus specification, the master device must stop the transaction by issuing a STOP condition. In master transmit mode, immediately stop the transmit operation (writing data to NTDTBP0).

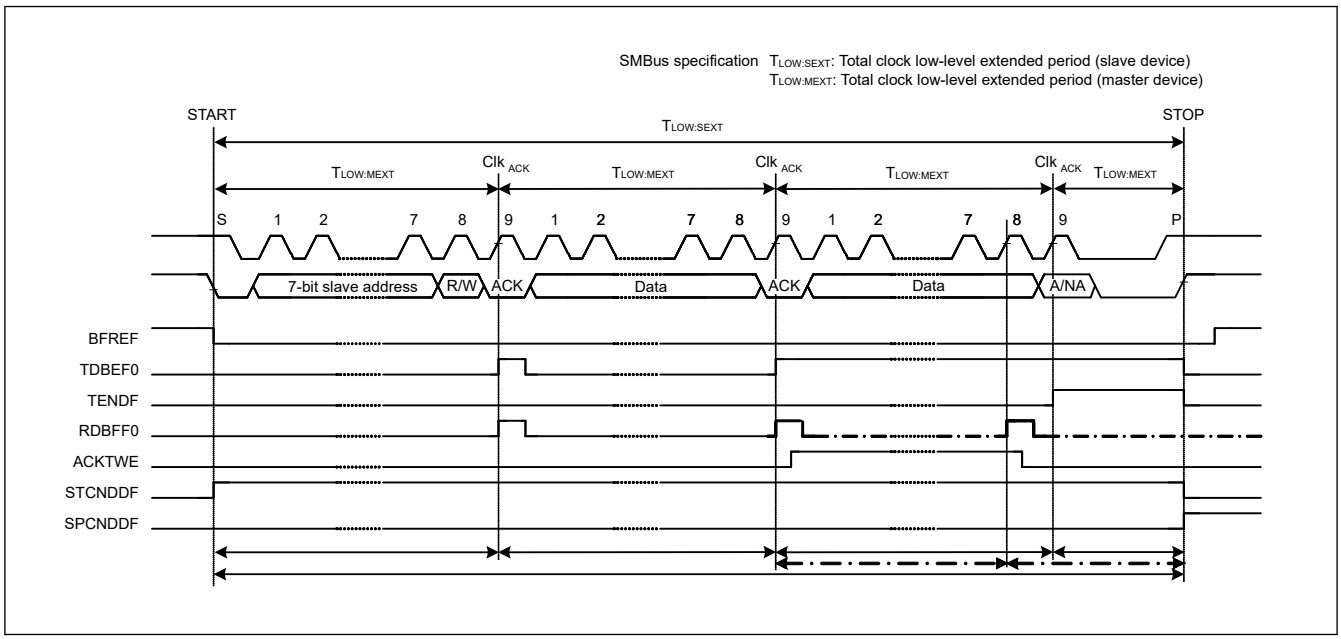

**Figure 29.102 SMBus timeout measurement**

## (2) Packet Error Code (PEC)

This MCU incorporates a CRC calculator. The CRC calculator enables transmission of a packet error code (PEC) or checking the received data of the SMBus in data communication of I3C. For the CRC generating polynomials of the CRC calculator, see section 36, Cyclic Redundancy Check (CRC).

The PEC data in master transmit mode can be generated by writing all transmit data to the CRC data input register (CRCDIR) in the CRC calculator.

The PEC data in master receive mode can be checked by writing all receive data to CRCDIR in the CRC calculator and comparing the obtained value in the CRC data output register (CRCDOR) with the received PEC data.

To send ACK or NACK according to the match or mismatch result when the final byte is received as a result of the PEC code check, set the SCSTRCTL.ACKTWE bit to 1 before the rising edge of the eighth SCL clock cycle during reception of the final byte, and hold the I3C_SCL line low at the falling edge of the eighth clock cycle.

## (3) SMBus Host Notification Protocol (Notify ARP Master Command)

In communications over an SMBus, a slave device can temporarily act as a master device to notify the SMBus host (or ARP master) of its own slave address or to request its own slave address from the SMBus host.

For a product of this MCU to operate as an SMBus host (or ARP master), the host address (0001 000) sent from the slave device must be detected as a slave address, so I3C has a function for detecting the host address. To detect the host address as a slave address, set the BFCTL.SMBS bit and the SVCTL.HOAE bit to 1. Operation after the host address has been detected is the same as normal slave operation.

#### 29.3.2.3.12 Common Command Codes (CCC) [I3C mode]

For the common command code (CCC), refer to 5.1.9 Common Command Codes (CCC) in MIPI I3C Specification v1.0. I3C is based on Table 15 I3C Common Command Codes in 5.1.9.3 Common Command Definitions of MIPI I3C Specification v1.0.

The MIPI Reserved area and Vendor Extension area of Command Code are described below.

I3C Master mode :

When sending CCCs in the MIPI Reserved area and Vendor Extension area from the I3C Master, only Broadcast/Direct SET CCCs using the Immediate Transfer Command can be sent.

Sending Direct GET CCC is not supported.

I3C Slave mode :

Only Broadcast/Direct SET CCC can be received for CCC in MIPI Reserved area and Vendor Extension area.

Receiving Direct GET CCC is not supported.

### 29.3.2.4 Error Detection

#### 29.3.2.4.1 SDR Error Detection and Recovery Methods for I3C Slave Devices [I3C mode]

The seven error types summarized in Table 29.13 are supported for all I3C slave devices. Each error type is further explained below the table.

**Table 29.13 SDR slave error types**

| Error type | Description | Error detection method | Error recovery method |
|---|---|---|---|
| S0 | Broadcast address/W (= 0x7E/W) or Dynamic address/RW | Detect any of the following:<br>0x3E / W<br>0x5E / W<br>0x6E / W<br>0x76 / W<br>0x7A / W<br>0x7C / W<br>0x7F / W<br>0x7E / R | Enable HDR EXIT Detector and ignore all other patterns |
| S1 | CCC code | Parity check, using T-Bit | Enable HDR EXIT detector and neglect other patterns |
| S2 | Write data | Parity check, using T-Bit | Enable STOP detector and neglect other patterns |
| S3 | Assigned address during Dynamic address arbitration | Parity check, using PAR Bit | Generate NACK (after PAR), then wait for another Repeated START and 7E/R to re-transmit the Provisional ID |
| S4 | 0x7E/R after Sr during Dynamic address arbitration | Detect any value other than 0x7E/R after Sr during Dynamic Address Arbitration | Generate NACK (after 0x7E/R), then enable STOP Detector and ignore all other patterns |
| S5 | Transaction after detecting CCC | Detect illegally formatted CCC | Generate NACK (after Slave Address), then enable STOP Detector and ignore all other patterns |
| S6 (optional) | Monitoring error | Slave detects (through monitoring) that transmitted Data differs from what it intended to transmit (Does not apply during Dynamic address arbitration) | Stop the transmission, then enable STOP Detector and ignore all other patterns |

#### 29.3.2.4.2 SDR Error Detection and Recovery Methods for I3C Master Devices [I3C mode]

The two error types summarized in Table 29.14 are supported for all I3C master devices. Each error type is further explained below the table.

**Table 29.14 SDR master error types**

| Error type | Description | Error detection method | Error recovery method |
|---|---|---|---|
| M0 | Transaction after sending CCC | Detect illegally formatted CCC | Stop the transmission, then send STOP and retry the transmission. |
| M1 (optional) | Monitoring error | Master detects (through monitoring) transmitted data different from what it intended to transmit (Does not apply during Dynamic address arbitration) | Stop the transmission, then send STOP and retry the transmission. |
| M2 | No response to Broadcast address (0x7E) | Master detects NACK after Broadcast address (0x7E) transmission | Upon detection of NACK, master transmits HDR exit pattern followed by STOP |

### 29.3.2.4.3 HDR-DDR Error Detection

Four error types are defined for HDR-DDR mode.

**Table 29.15 HDR-DDR error types**

| Error type | Description | Error detection method | Error recovery method |
|---|---|---|---|
| Framing | The Preamble 2-bits before command and data | The Slave detects that the Preamble 2-bits before command and data is not valid values.*1 | Master: Issue SCL clocks until 19 SCL clocks (38 bits) have been seen with SDA High. The Master shall then Park SCL Low, and emit an HDR Exit Pattern using SDA.<br>Slave: Wait for HDR EXIT Pattern |
| Parity checking | Parity error | The Master and the Slave detect mismatched parity.*2 | |
| CRC5 checking | CRC5 error | The Master and the Slave detect mismatched CRC.*3 | |
| NACK receiving | NACK by the Slave on a Read command | The Master detects a NACK by the Slave on a Read command.*4 | Issue SCL clocks until 19 SCL clocks (38 bits) have been seen with SDA high. The Master shall then Park SCL low, and emit either an HDR exit pattern or an HDR restart pattern using SDA. |
| Monitoring | Monitoring error | Both the Master and the Slave should always monitor the data that they each transmit, and they detect the monitored data differs from the data that the Master or Slave intended to send.*5 | Both the Master and the Slave can stop the transmission and then Master and Slave should each do the following.<br>Master: Issue SCL clocks until 19 SCL clocks (38 bits) have been seen with SDA High. The Master shall then Park SCL Low, and emit an HDR Exit Pattern using SDA. After the Master sends HDR EXIT, it can retry the transmission.<br>Slave: Wait for HDR Exit Pattern |

Note 1. This supports a positional error detection mechanism:
- A Command Word shall always follow the Enter HDR CCC and HDR Restart Pattern, and shall never appear in any other position. It is an error condition for a Command Word to appear in any other position, or to be missing where expected.
- A Data Word shall always follow either a Command Word or another Data Word, and shall never appear in any other position. It is an error condition for a Data Word to appear in any other position, or to be missing where expected.
- A single CRC Word shall always follow the last Data Word for a Command, such that it ends the Message. As a result, a CRC Word shall always be followed by either the HDR Restart Pattern or the HDR Exit Pattern. It is error condition for a CRC Word to appear in any other position, or to be missing where expected.
- The first nibble of a valid CRC shall contain the allowed value 0xC. Any other value in the first nibble should be considered a framing error.

Note 2. Parity encoding (for transmitters) parity checking (for receivers) shall be performed on all Command Words and Data Words. Mismatched parity is an error condition.

Note 3. CRC5 encoding (for transmitters) and CRC5 checking (for receivers) shall be performed on all payload bits for Command Words and Data Words. Mismatched CRC is an Error.

Note 4. NACK by the Slave on a Read command is not a normal behavior (ACK is normal). The Master may choose to treat a NACK on a Read command as a possible framing error. The Master can choose to treat the NACK of a Read command as a possible line error, and therefore use the same approach in order to ensure that the Slave is not driving the Bus.

Note 5. If the Master or Slave performs such monitoring, and if the monitored Data differs from the Data that the Master or Slave intended to send (except for Data transferred during a Dynamic Address Arbitration procedure), then this shall be considered an error.

### 29.3.2.4.4 Timeout Error Detection

I3C includes a timeout function for detecting when the I3C_SCL line has been stuck longer than the predetermined time. I3C can detect an abnormal bus state by monitoring that the I3C_SCL line is stuck low or high for a predetermined time.

The timeout function monitors the I3C_SCL line state and counts the low-level period or high-level period using the internal counter. The timeout function resets the internal counter each time the I3C_SCL line changes (rising or falling), but continues to count unless the I3C_SCL line changes. If the internal counter overflows due to no I3C_SCL line change, I3C can detect the timeout and report the bus hung state.

This timeout function is enabled when BSTE.TODE = 1. It detects a hung state that the I3C_SCL line is stuck low or high during the following conditions: (When TMOCTL.TOMDS[1:0] = 00b)

- The bus is busy (BCST.BFREF = 0) in master mode (PRSST.CRMS = 1).
- I3C's own slave address is detected (SVST register is not 0x0000) and the bus is busy (BCST.BFREF = 0) in slave mode (PRSST.CRMS = 0).
- The bus is free (BCST.BFREF = 1) while generation of a START condition is requested (CNDCTL.STCND = 1).

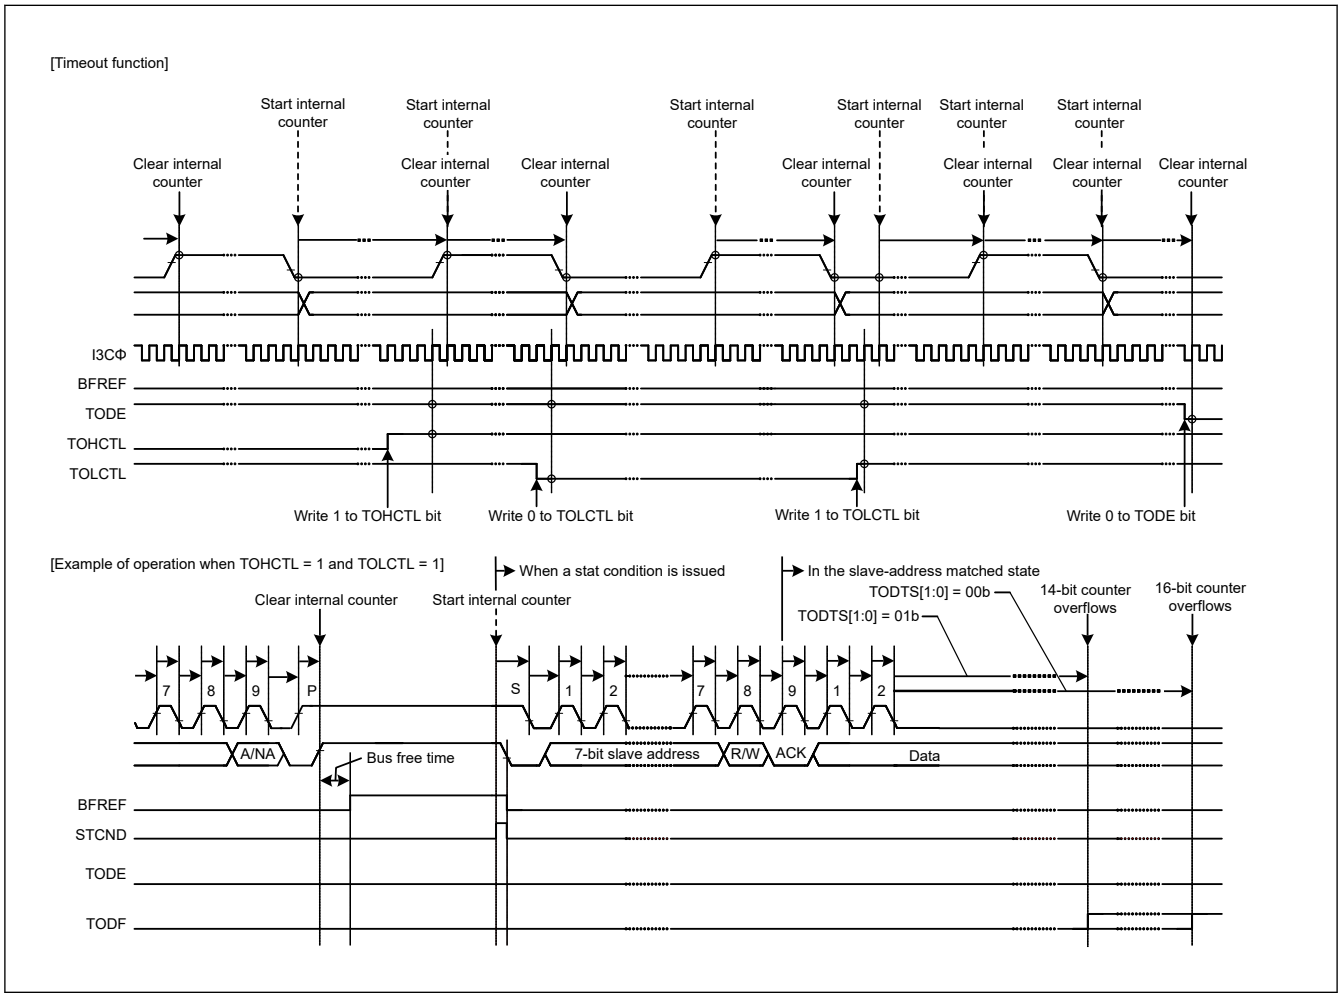

**Figure 29.103 Timeout error detection (TODE, TODTS[1:0], TOHCTL, and TOLCTL bits)**

### 29.3.2.4.5 Resume Operation [I3C mode]

I3C enters the Halt state as a result of any type of error occurring in a transfer.

The error type is indicated by the field ERR_STATUS in Response Descriptor or Receive Status Descriptor. After I3C has entered the Halt state, the user must write the value 1 to the RSM bit to resume operation. I3C shall auto-clear the RSM bit once it has initiated the next Command transfer or detected the START condition.

### 29.3.2.4.6 Abort Operation [I3C mode]

When the BCTL.ABT bit is set to 1, I3C relinquishes control of the bus before completing the currently issued transfer. In response to an abort request, I3C issues the STOP condition on the bus after the complete data byte is transferred or received. After I3C has aborted, clear the BCTL.ABT bit to allow operation on the bus.

Note: For read transaction, when BCTL.ABT is set to 1, the receive data is stored in Rx data buffer.

Abbreviations

Pa: Parity

Pr: Preamble

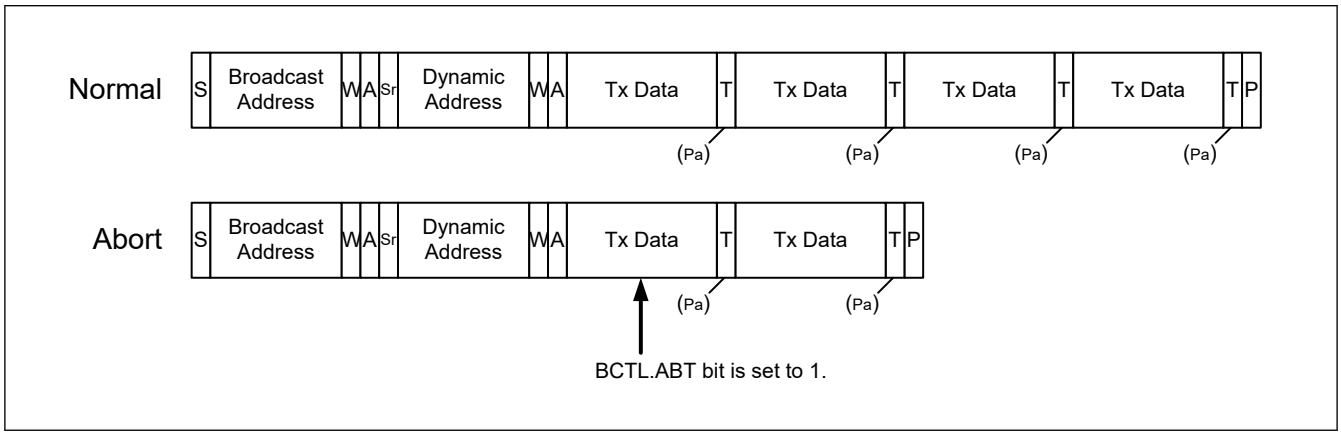

**Figure 29.104 Abort operation of SDR write transfer**

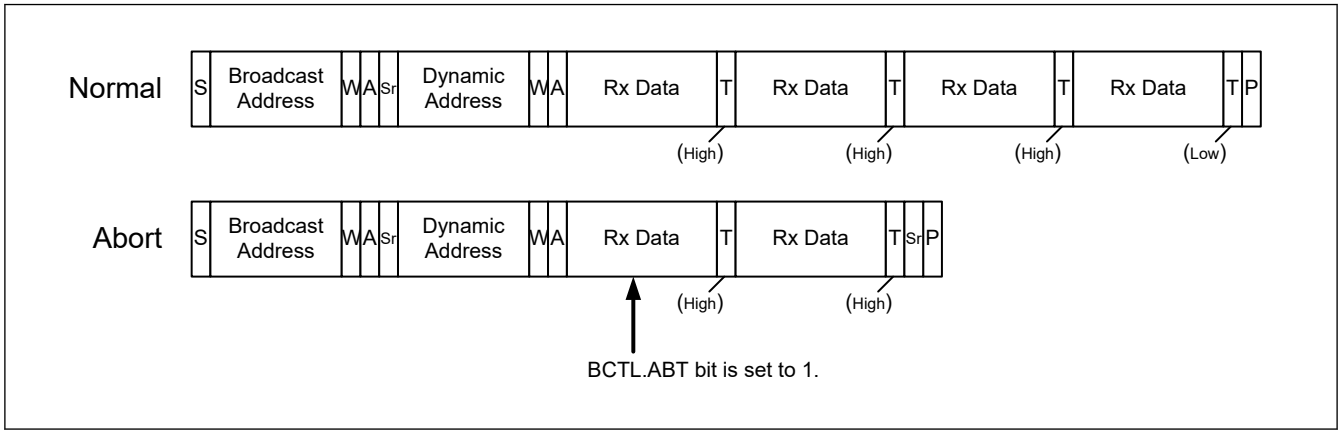

**Figure 29.105 Abort operation of SDR read transfer**

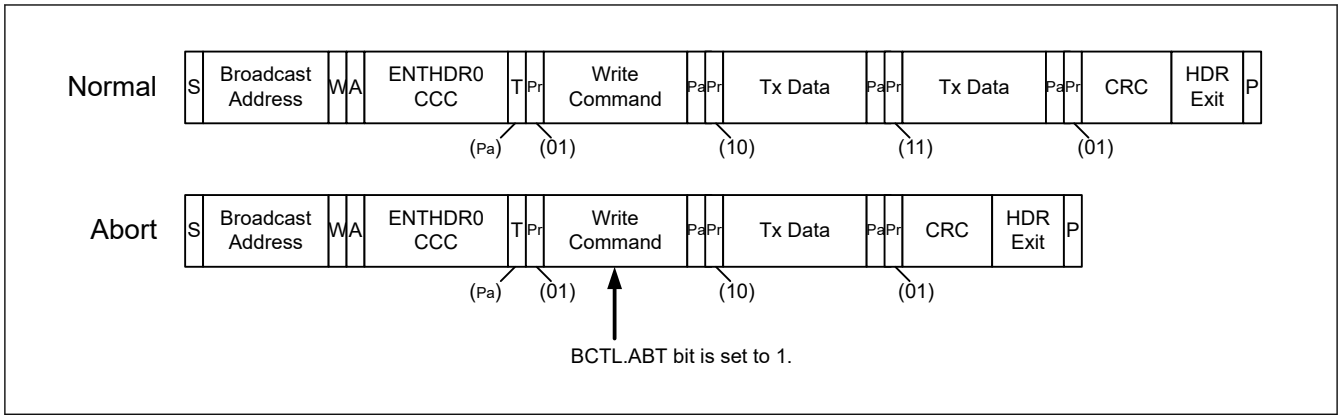

**Figure 29.106 Abort operation of HDR-DDR write transfer**

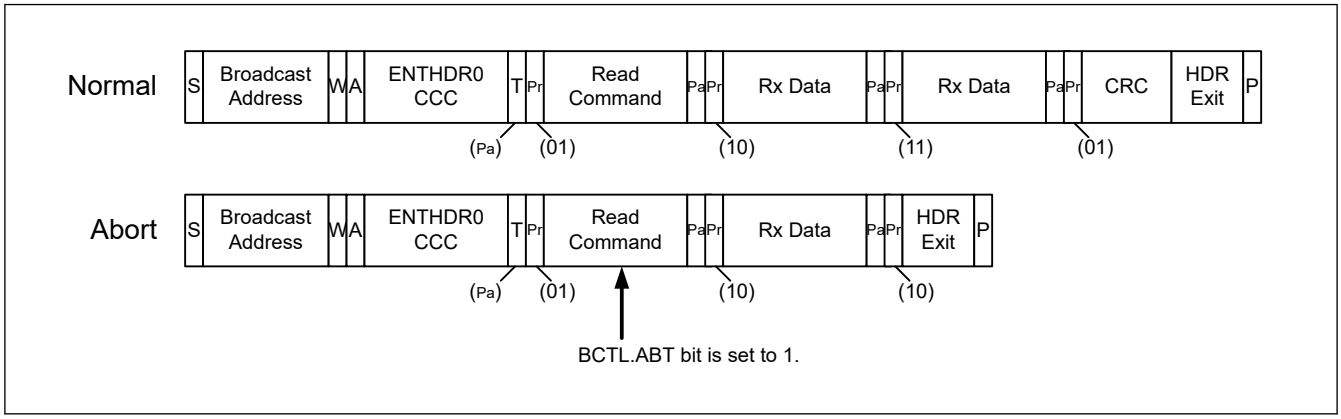

**Figure 29.107 Abort operation of HDR-DDR read transfer**

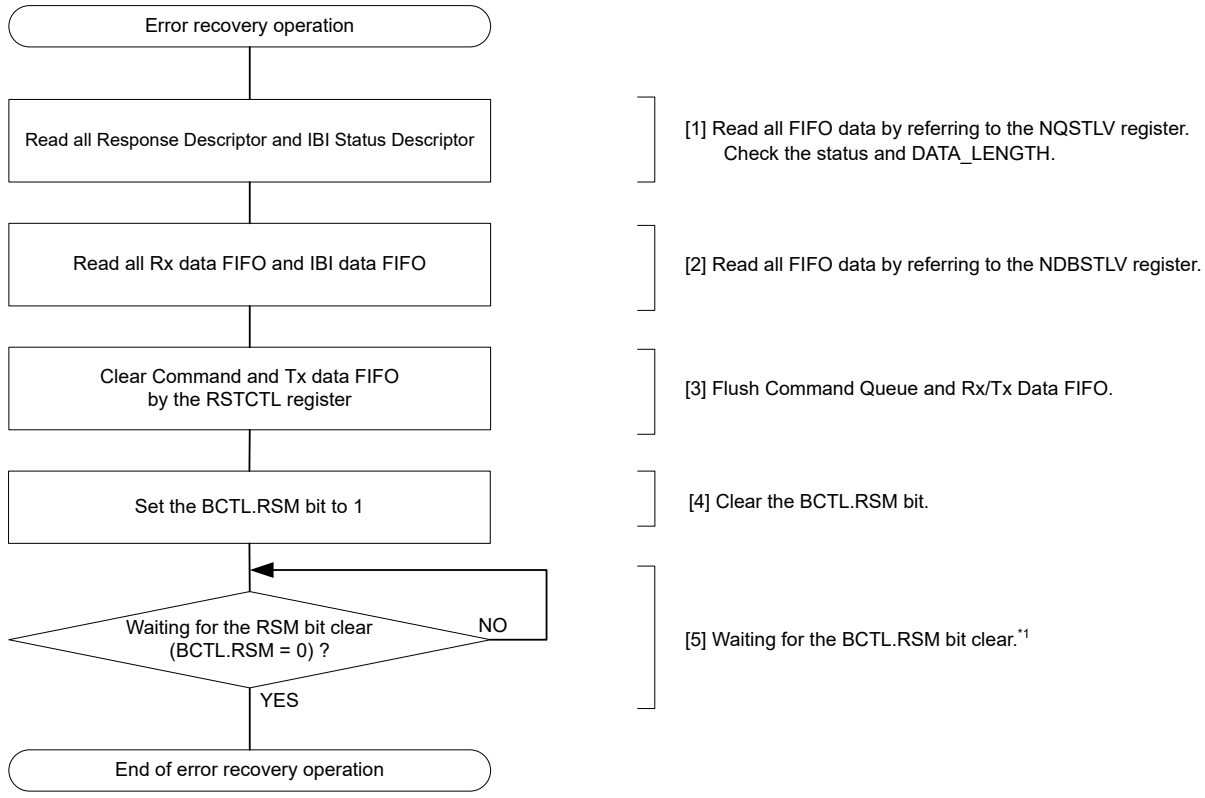
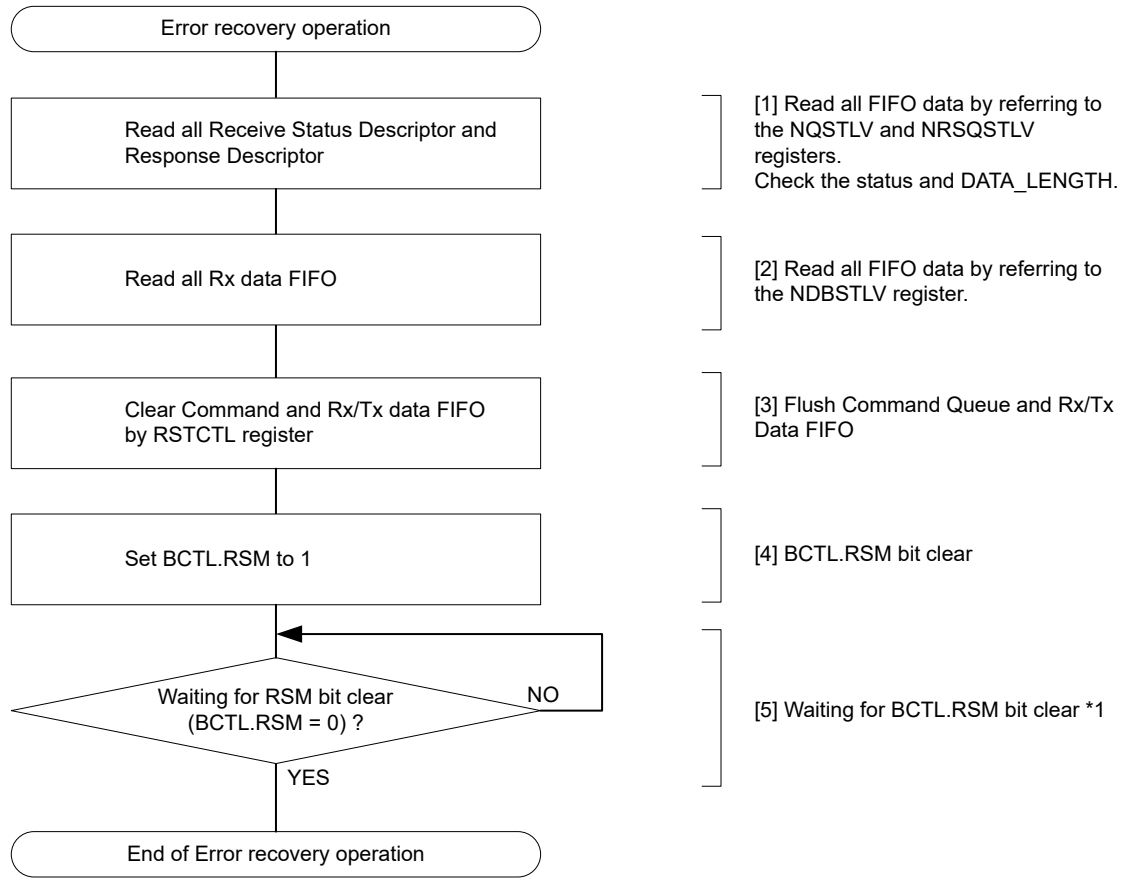
### 29.3.2.4.7 Error Recovery Operation



(1) Error Recovery Operation

When an error occurs, the INST.INEF, NTST.TEF, and NTST.TABTF flags are set to 1 according to the cause of the error, or the interrupts associated with each flag are asserted (when detection and interrupts are enabled.)

There is a possibility of communication error or internal module error.



Note: If an error occurs, I3C will be suspended (BCTL.RSM becomes 1). After I3C is suspended, the application must write the value 1 to the BCTL.RSM bit to resume I3C operation and recover from the suspended state.

Figure 29.108 and Figure 29.109 show the error recovery flow.

Note 1. The Command Descriptor can be written to the Command Queue via writing to the Command Queue Port (NCMDQP) before the RSM bit is cleared.

**Figure 29.108 Example of error recovery operation flowchart for I3C master**

Note 1. The Command Descriptor for issuing IBI can be written to the Command Queue via writing to the Command Queue Port (NCMDQP) before the RSM bit is cleared.

**Figure 29.109 Example of error recovery operation flowchart for I3C slave**

When I3C Slave recovers from an error according to the error recovery flow, after setting BCTL.RSM to 1, BCTL.RSM becomes 0 after detecting a state in which Bus Available period communication is not performed on I3C Bus.

If communication occurs on the I3C bus within the Bus Available period, BCTL.RSM will not be set to 0 and error recovery will not be completed, NACK response will be made to the communication.

(2) Master Error Detection and Escalation Handling

If the Master does not receive an ACK of a transmitted private Message to a Slave and Steps 1 and 2 described in Chapter 5.1.10.2.4 of MIPI I3C Spec v1.0 fail, the processing flow of Step 3 is shown in Figure 29.110 and Figure 29.111.

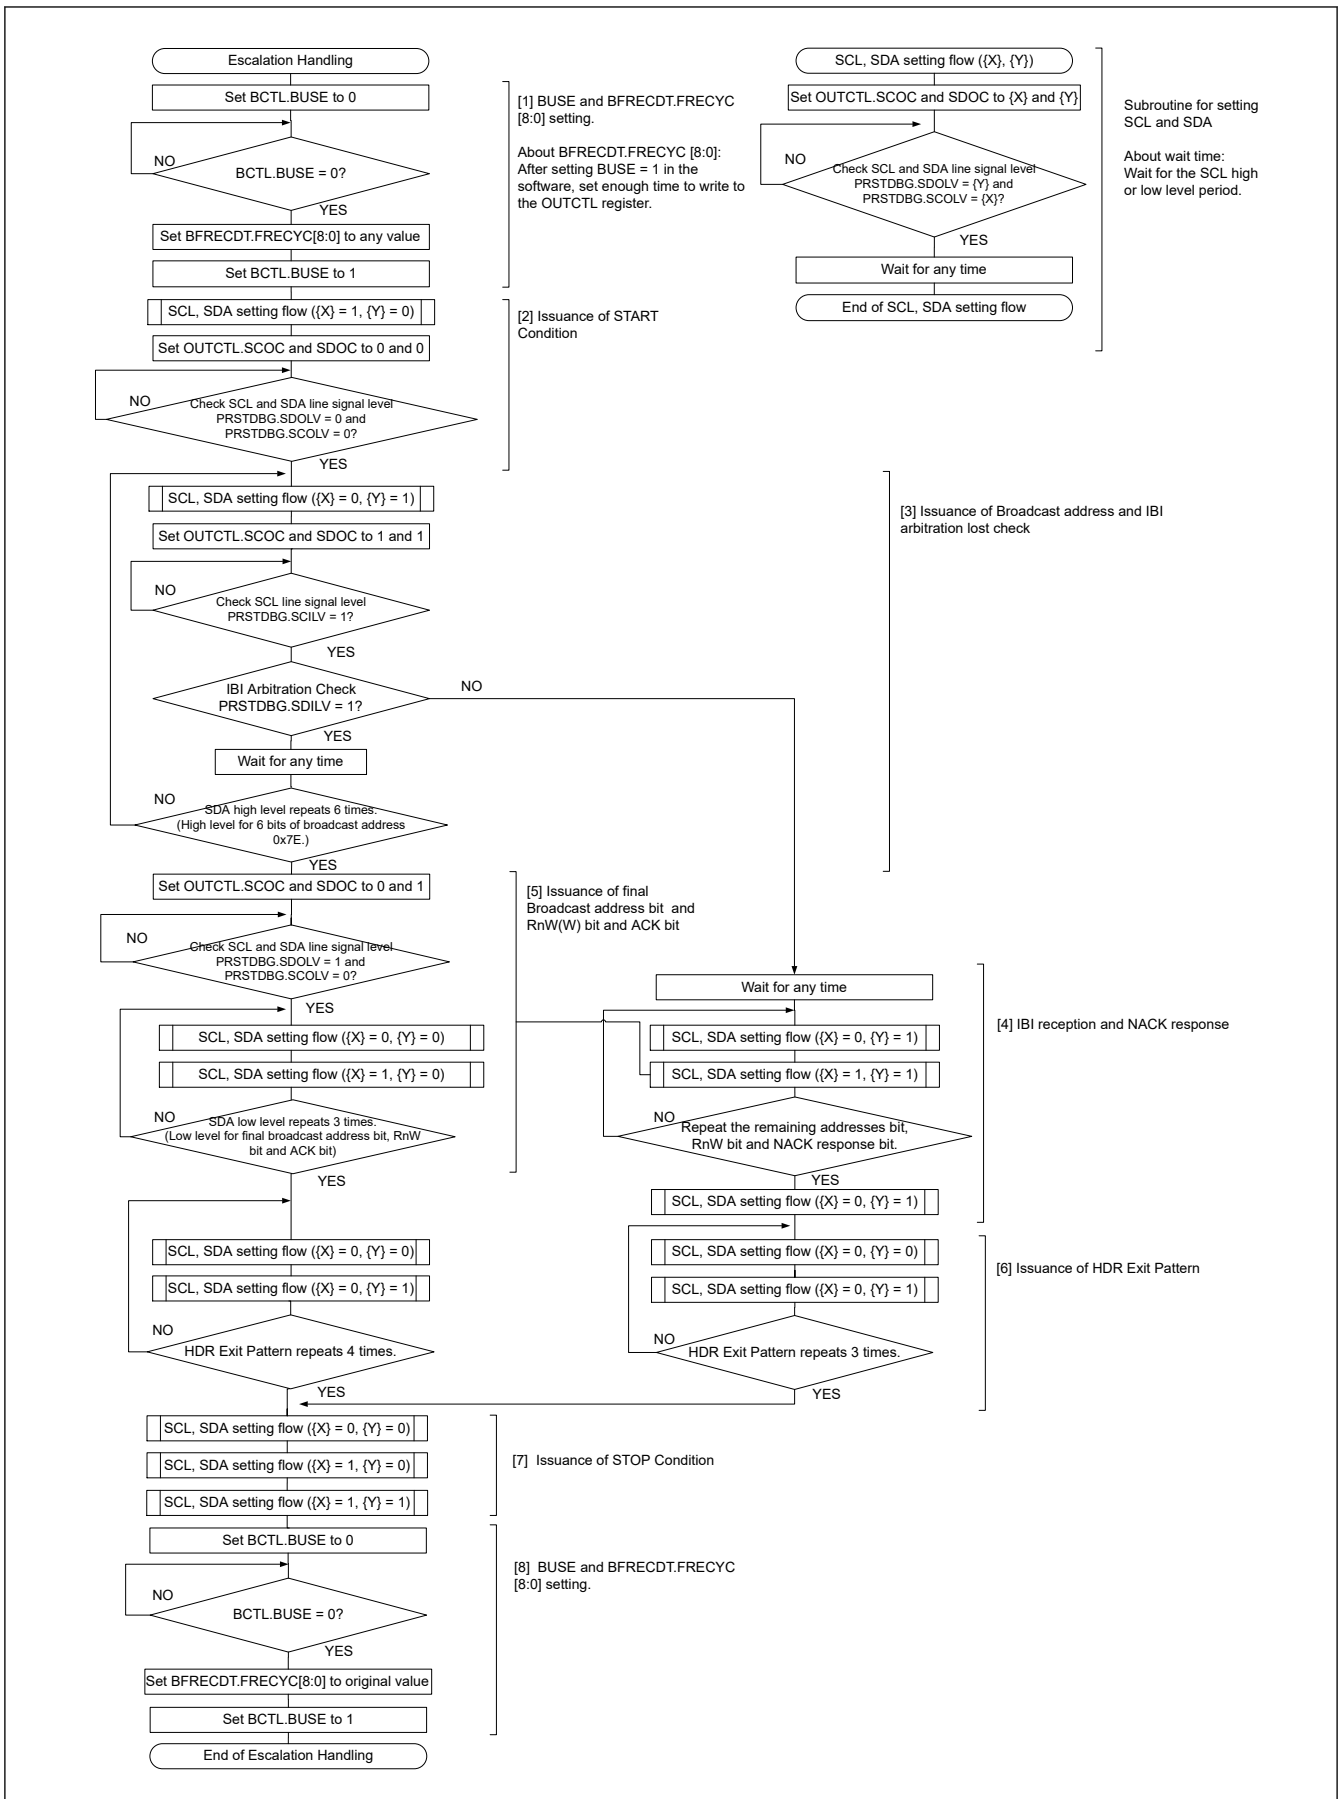


**Figure 29.110 Escalation handling flowchart for I3C master**

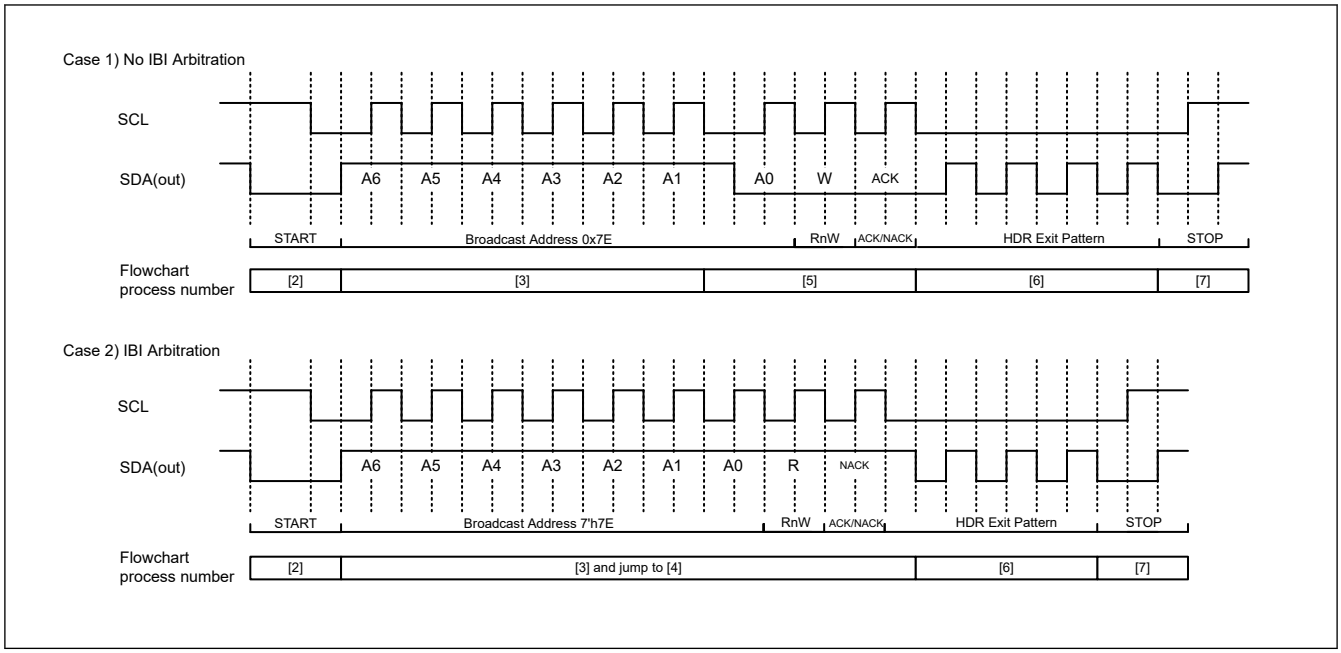

**Figure 29.111 I3C Escalation Handling timing chart for I3C Master**

## 29.3.2.5 Low Power Function

### 29.3.2.5.1 Wake-up function [I²C mode]

I3C is equipped with the Wake-up function that causes the microcomputer to transition from low power consumption mode with system clock (ICLK) is stopped (software standby mode, etc.) to the normal operation. The Wake-up function is used to generate a Wake-up interrupt signal when the received data matches the address set to Wake-up interrupt factor also receives data in a state where the operating clock (PCLK/TCLK) is stopped (PCLK/TCLK asynchronous operation). This Wake-up interrupt signal causes the microcomputer to transition to the normal operation. After Wake-up interrupt occurs, switch I3C to PCLK/TCLK synchronous operation, it will be able to continue the communication operation.

The Wake-up function has four Wake-up operation modes (normal WU mode 1, normal WU mode 2, command recovery mode, and EEP response mode). The table below describes the behavior in these four Wake-up operation modes.

**Table 29.16 Wake-up operation mode**

| | ACK response timing | ACK Type responded before recovery to PCLK/TCLK synchronous operation | SCL state before recovery to PCLK/TCLK synchronous operation |
|---|---|---|---|
| Normal WU mode 1 | Before recovery to PCLK/TCLK synchronous operation*1 | ACK | Fixed to L |
| Normal WU mode 2 | After recovery to PCLK/TCLK synchronous operation*2 | Before recovery: no response (NACK level retained)<br>After recovery: ACK response | Fixed to L |
| Command recovery mode | Before recovery to PCLK/TCLK synchronous operation*1 | ACK | Open |
| EEP response mode | Before recovery to PCLK/TCLK synchronous operation*1 | NACK | Open |

Note 1. Switching timing from PCLK/TCLK asynchronous operation to PCLK/TCLK synchronous operation is the fall of the 9th clock of SCL.
Note 2. Switching timing from PCLK/TCLK asynchronous operation to PCLK/TCLK synchronous operation is the fall of the 8th clock of SCL.

The following is able to select as Wake-up interrupt factor.

- Host address detection (valid when SVCTL.HOAE = 1)
- General call address detection (valid when SVCTL.GCAE = 1)
- Slave address 0*1 detection (valid when SVCTL.SVAE0 = 1)

Note 1. 7-bit address only can be set. Set SDADLS bit to 0 in SDATBAS0.

### (1) Normal Wake-up mode 1

This section describes the behavior, the timing, and a use case of normal WU mode 1.

A Wake-up interrupt triggered by the match of the slave address makes the transition to the normal operation in the manner described below. Also, the detailed timing is provided in Figure 29.114.

| | |
|---|---|
| Before Wake-up recovery: | ACK is sent in response to the data received with its own slave address. |
| During Wake-up recovery: | ACK response is made at the 9th clock cycle of SCL, and the SCL is held low afterward.*1 |
| After Wake-up recovery: | Normal operation continues. |

Note 1. Between ninth clock cycle and first clock cycle during Wake-up recovery, SCSTRCTL.RWE = 1 does not work.

If the slave address does not match, the I3C_SCL line is not held low after the fall of the 9th clock cycle of SCL, and the slave operation continues.

See Figure 29.112 below for a use case.

A Wake-up interrupt is not generated at the transition to the normal operation if the transition is triggered by a cause (other recovery causes (IRQ)) other than a Wake-up interrupt signal generated by a slave address match. BST.WUCNDDF is not set in this case. Carry out the following processing according to Figure 29.113.

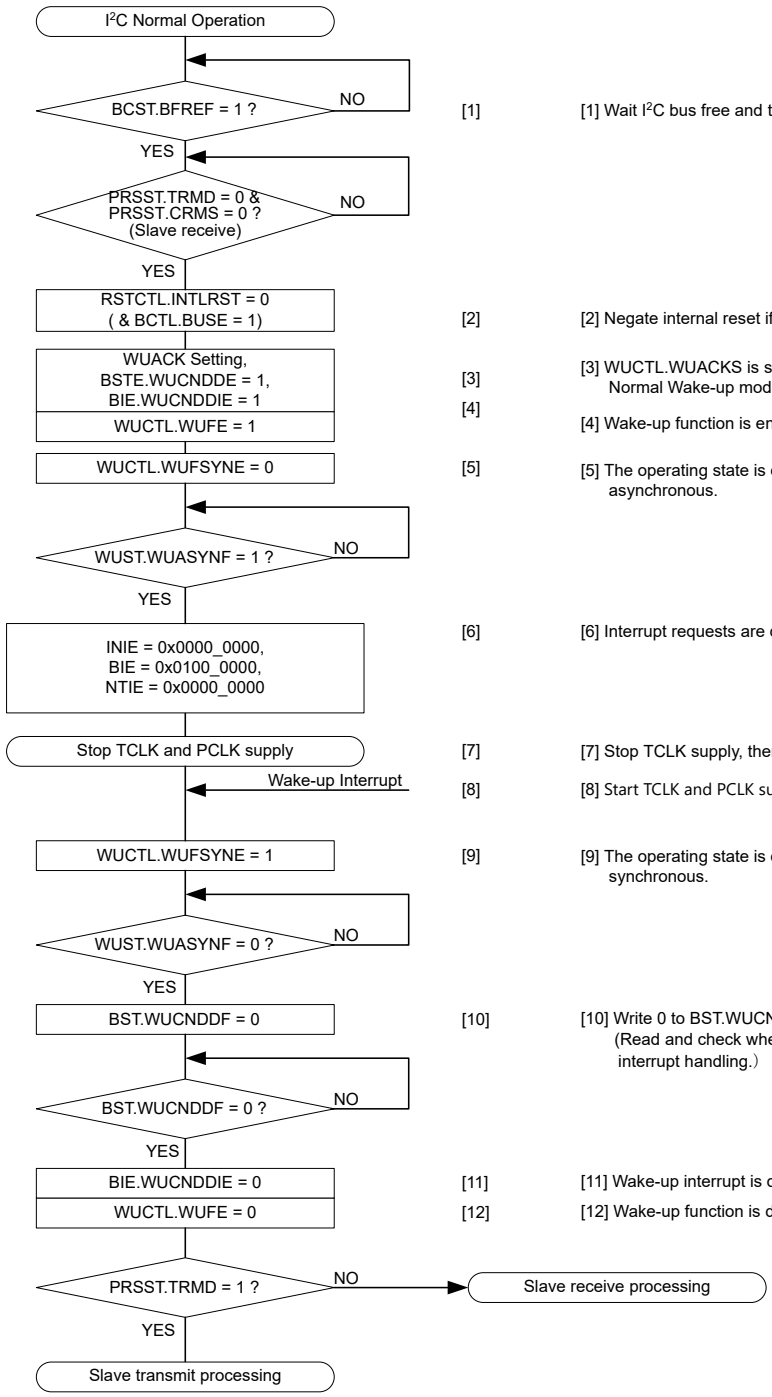

**Figure 29.112 Use case of normal WU mode 1 (Wake-up recovery by a Wake-up interrupt triggered by the match of the slave address)**

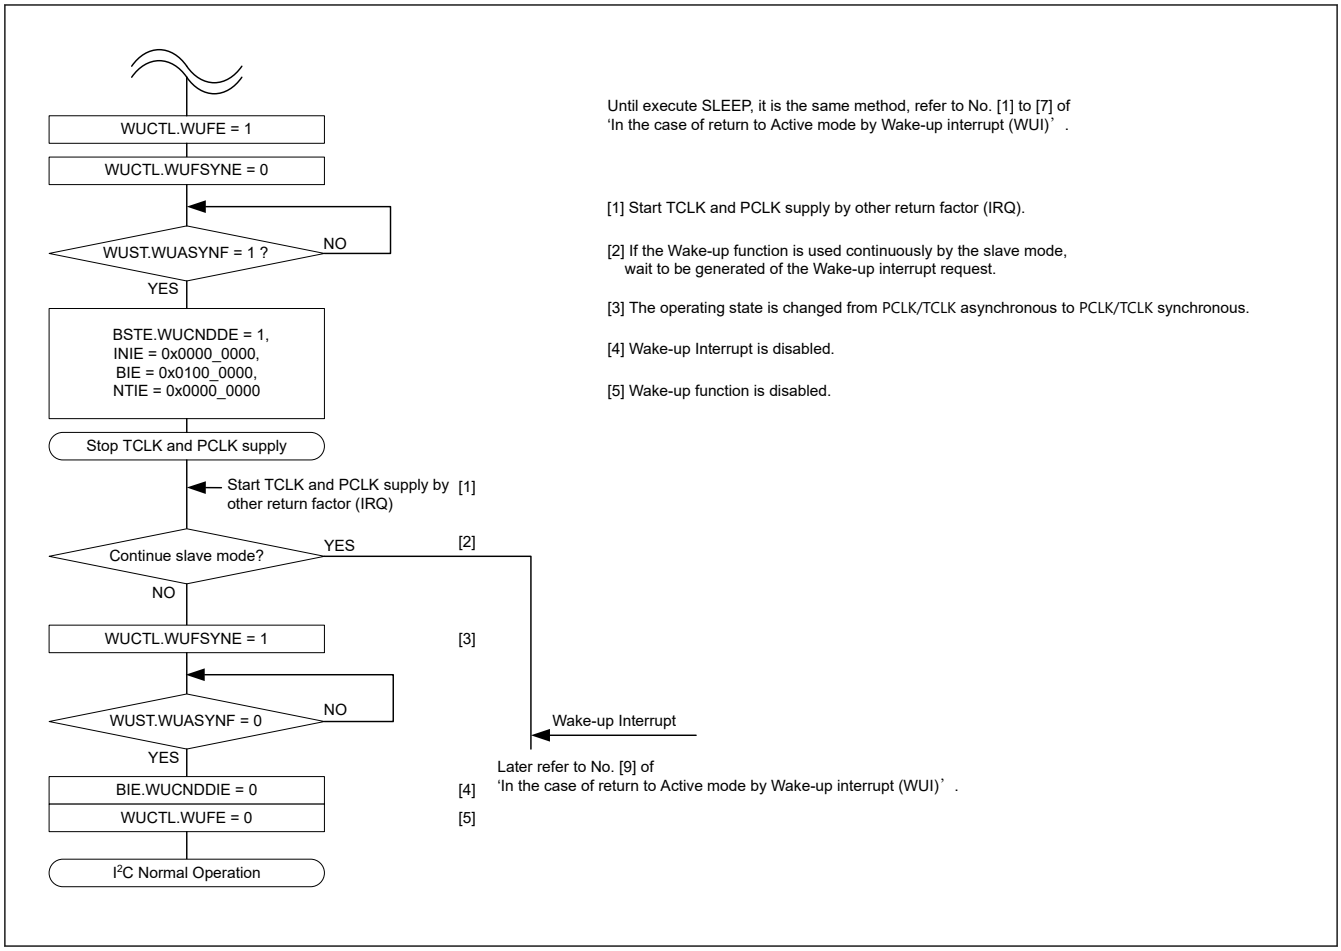

**Figure 29.113 Use case of normal WU modes 1 and 2 (Wake-up recovery by other recovery causes (IRQ))**

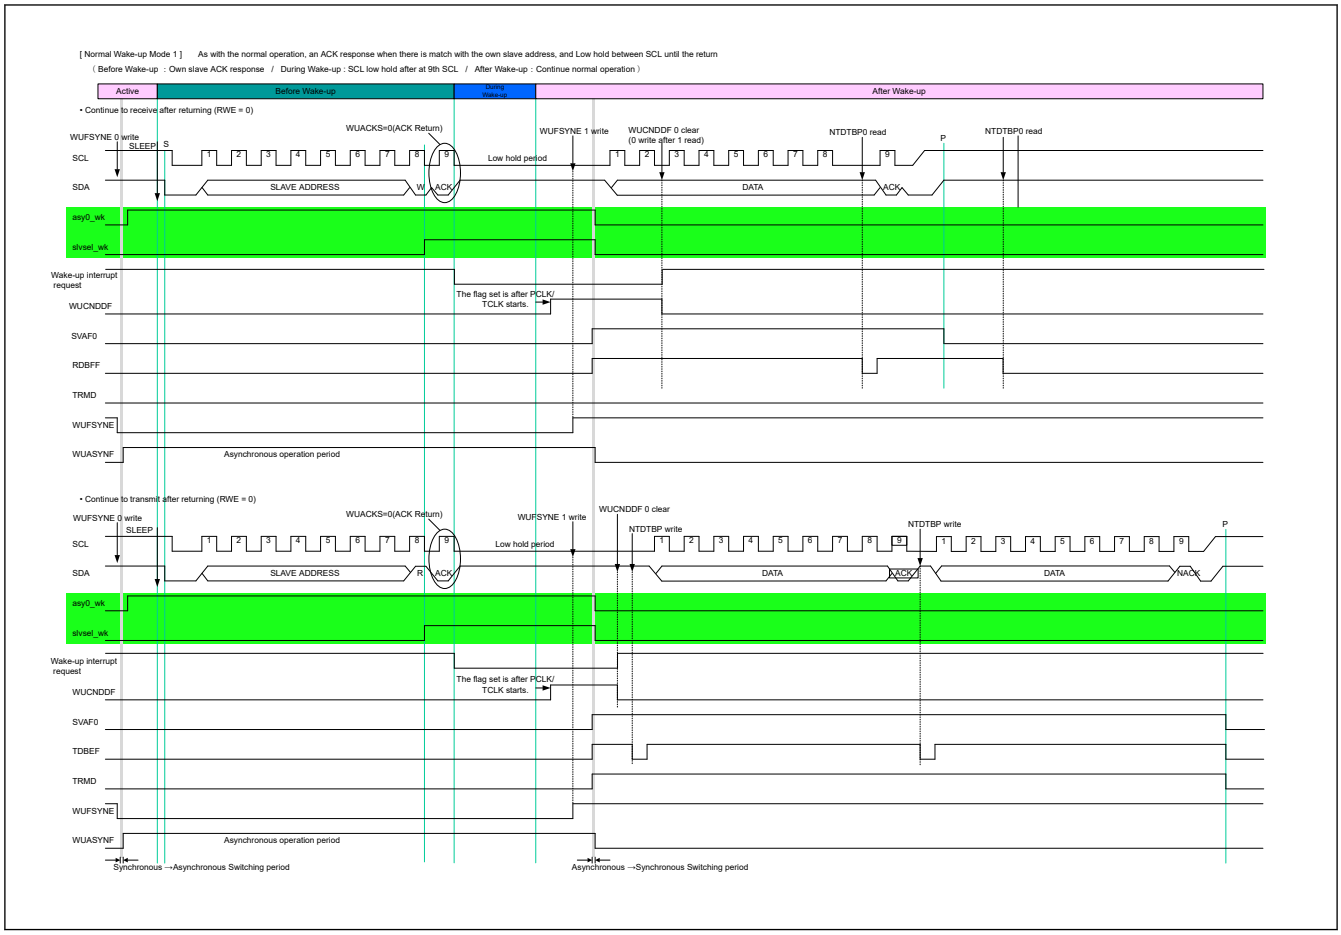

**Figure 29.114 Timing of normal Wake-up mode 1**

## (2) Normal Wake-up Mode 2

This section describes the behavior, the timing, and a use case of normal WU mode 2.

A Wake-up interrupt triggered by the match of the slave address makes the transition to the normal operation in the manner described below.

Also, the detailed timing is provided in Figure 29.116.

| | |
|---|---|
| Before Wake-up recovery: | No response to the data received with its own slave address (until 8th SCL cycle end) |
| During Wake-up recovery: | Holding the I3C_SCL line low during the 8th and 9th clock cycles |
| After Wake-up recovery: | Returning ACK at the 9th clock cycle of SCL, and continuing the normal operation |

If the slave address does not match, the I3C_SCL line is not held low after the fall of the 8th SCL v clock cycle. The slave operation continues.

See Figure 29.115 below for a use case.

A Wake-up interrupt is not generated at the transition to the normal operation if the transition is triggered by a cause (other recovery causes (IRQ)) other than a Wake-up interrupt signal generated by a slave address match. BST.WUCNDDF is not set in this case. Carry out the following processing according to Figure 29.113.

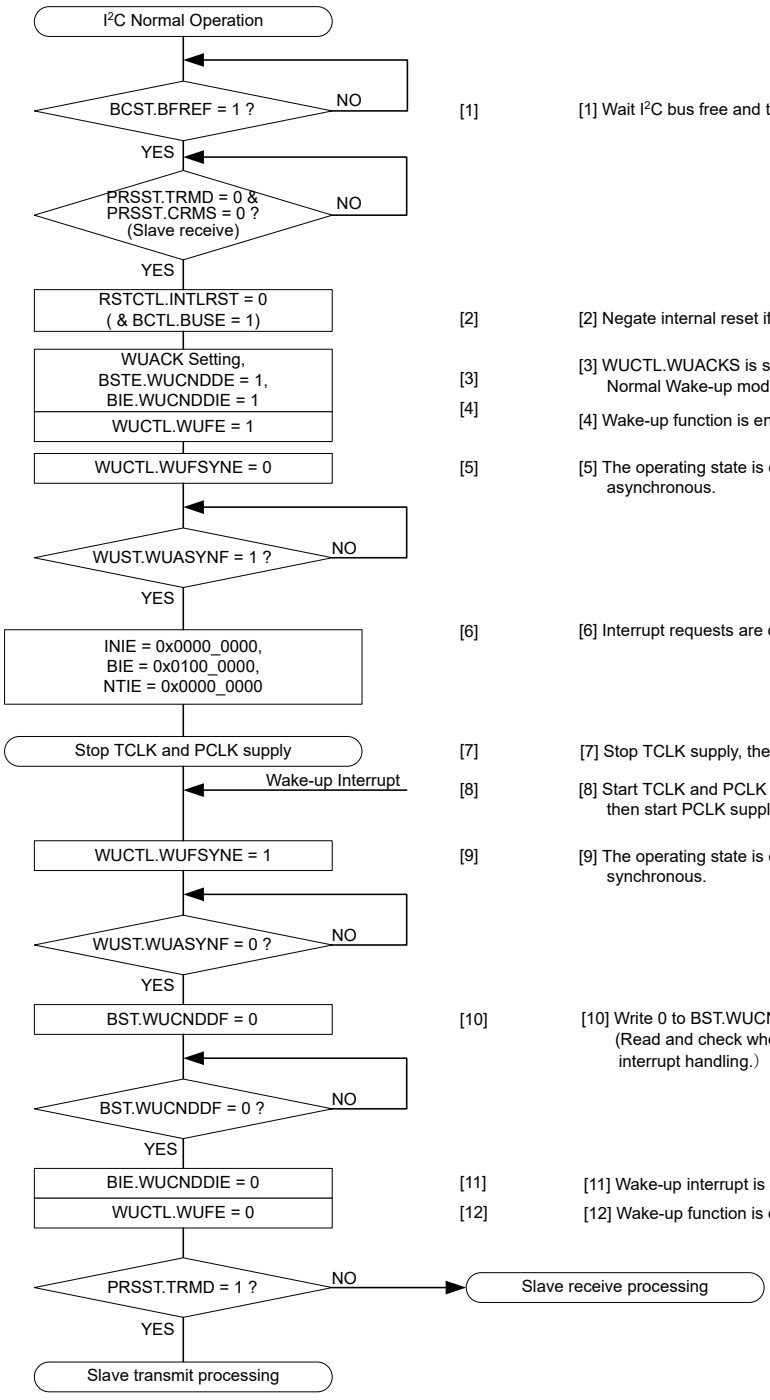

**Figure 29.115 Use case of normal WU mode 2 (Wake-up recovery by a Wake-up interrupt triggered by the match of the slave address)**

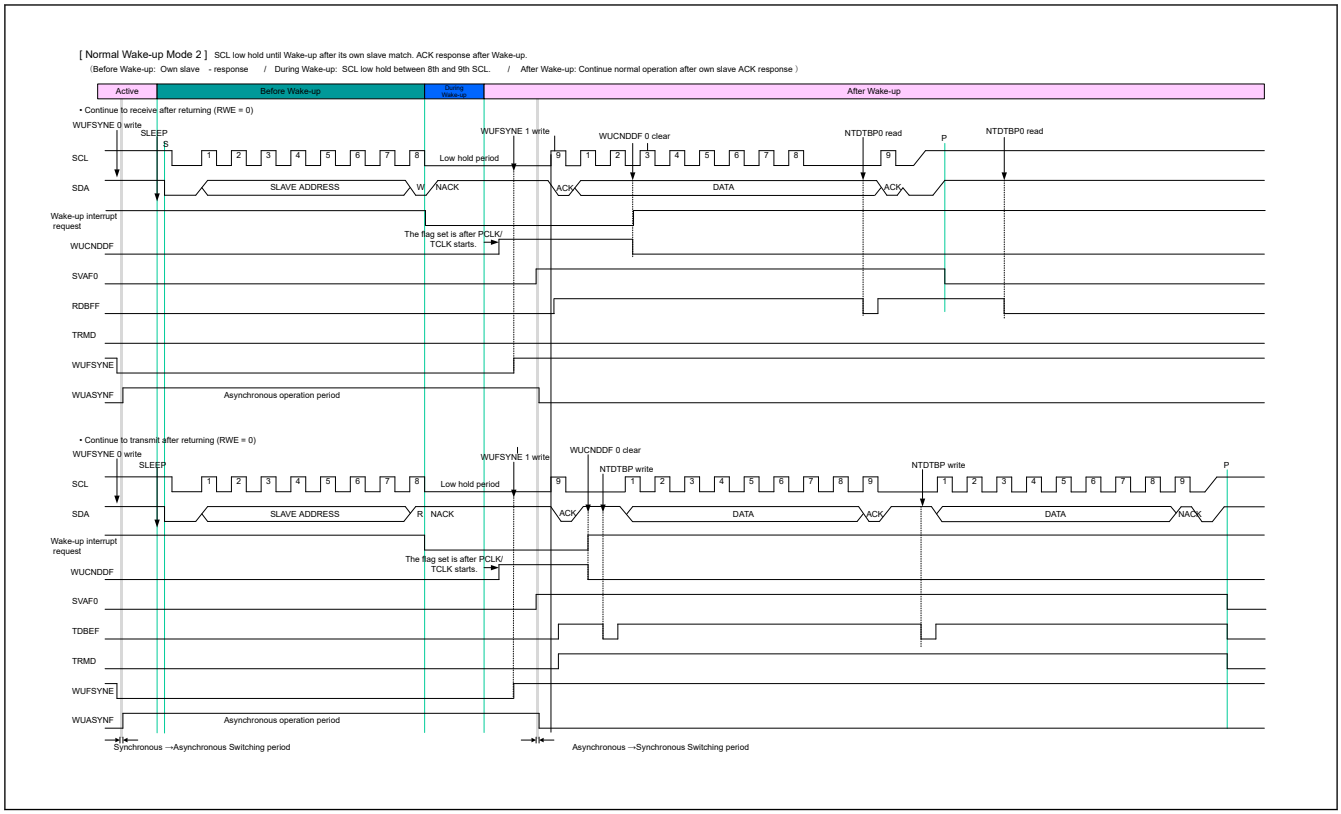

**Figure 29.116 Timing of normal Wake-up mode 2**

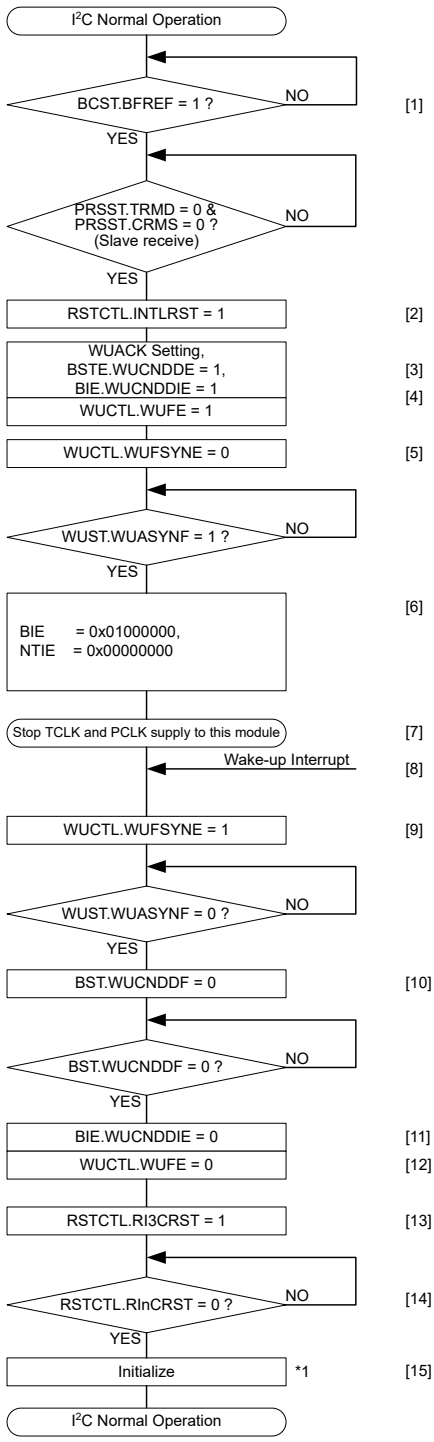
## (3) Command recovery mode/EEP response mode (Special Wake-up mode)

In the command recovery mode and EEP response mode, the I3C_SCL line is not held low during the Wake-up recovery period (after the rise of the 9th clock cycle of SCL), so other $I^2C$/I3C devices can use the $I^2C$ bus during this period. This section describes the behavior, the timing, and use cases of the command recovery mode and the EEP response mode.

A Wake-up interrupt triggered by the match of the slave address makes the transition to the normal operation in the manner described below. Also, the detailed timing is provided in Figure 29.119.

| | |
|---|---|
| Before Wake-up recovery: | In response to the data received with its own slave address, ACK (command recovery mode) or NACK (EEP response mode) is returned. |
| During Wake-up recovery: | The I3C_SCL line is not held low. |
| After Wake-up recovery: | Normal operation continues after I3C initial setting. |



Note: Because the I3C_SCL line is not held low during Wake-up recovery, the transmission/reception of the data that follows the slave address is not possible.

Note: The command recovery mode and the EEP response mode are internal reset (RSTCTL.INTLRST = 1) states. Therefore, the match of the slave address does not set the SVST flags (HOAF, GCAF, and SVAF0).

If the slave address does not match, the slave operation continues.

See Figure 29.118 below for a use case.

A Wake-up interrupt is not generated at the transition to the normal operation if the transition is triggered by a cause (other recovery causes (IRQ)) other than a Wake-up interrupt signal generated by a slave address match. BST.WUCNDDF is not set in this case. Carry out the following processing according to Figure 29.118.

[1] Wait I²C bus free and this module stay in the standby state.

[2] Assert the internal reset.

[3] WUCTL.WUACKS is set up according to each mode. (Command return mode/ EEP response mode) Wake-up Interrupt is enabled.

[4] Wake-up function is enabled.

[5] This module of operating state is changed from PCLK/TCLK synchronous to PCLK/TCLK asynchronous.

[6] Interrupt requests are disabled except WUI.

[7] Stop TCLK supply to this module, then stop PCLK supply to this module. (This module will continue to receive)

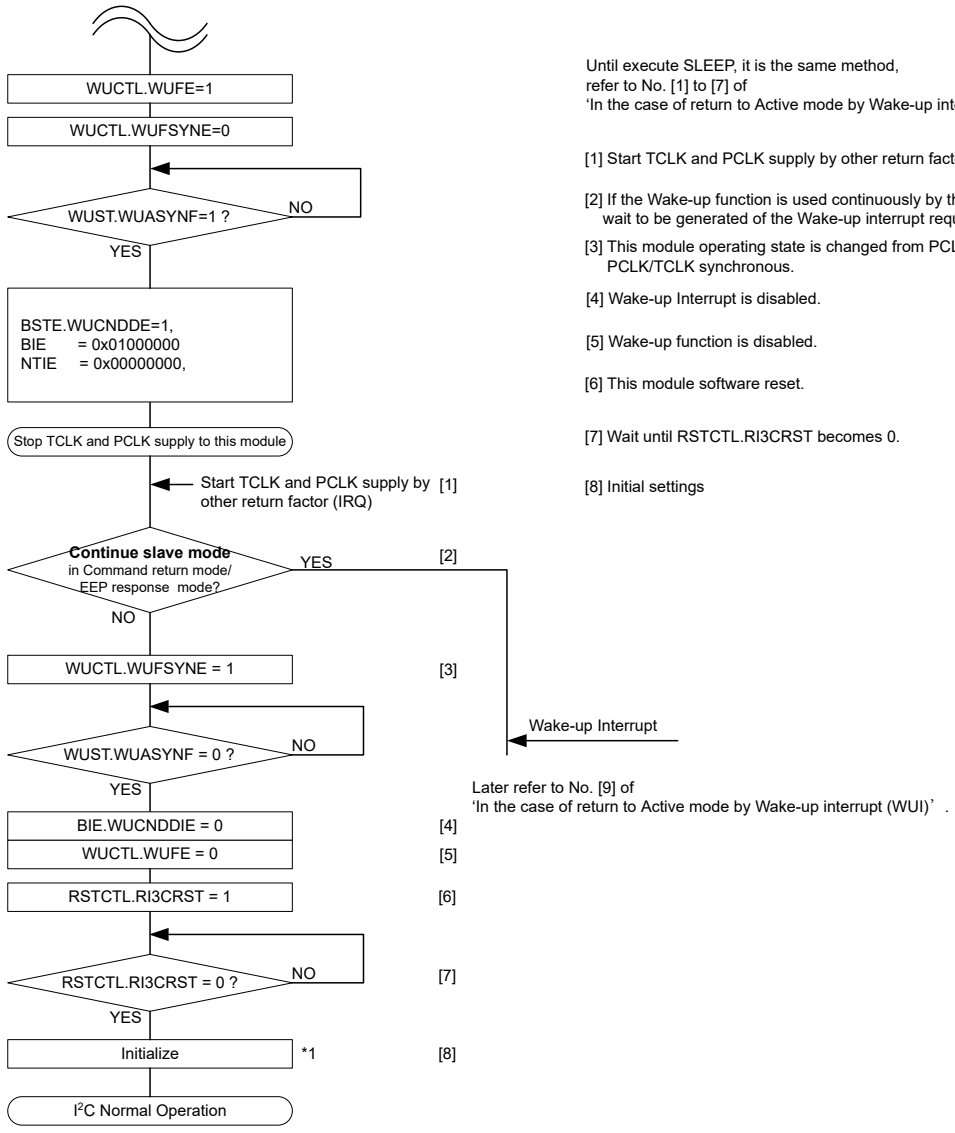
[8] Start TCLK and PCLK supply to this module by Wake-up interrupt (address match), then start PCLK supply to this module.

[9] This module of operating state is changed from PCLK/TCLK asynchronous to PCLK/TCLK synchronous.

[10] Write 0 to BST.WUCNDDF.
(Read and check whether clearing has been completed before return from interrupt handling.)

[11] Wake-up interrupt is disabled.

[12] Wake-up function is disabled.



[13] Software reset.

[14] Wait until RSTCTL.RI3CRST becomes 0.

[15] Initial settings

Note 1. See section 29.3.3.1. Initial Setting Flow for details of initialization.

**Figure 29.117 Use case of command recover mode and EEP response mode (Wake-up recovery by a Wake-up interrupt triggered by the match of the slave address)**

Note 1. See section 29.3.3.1. Initial Setting Flow for details of initialization.

**Figure 29.118 Use case of command recover mode and EEP response mode (Wake-up recovery by other recovery causes (IRQ))**

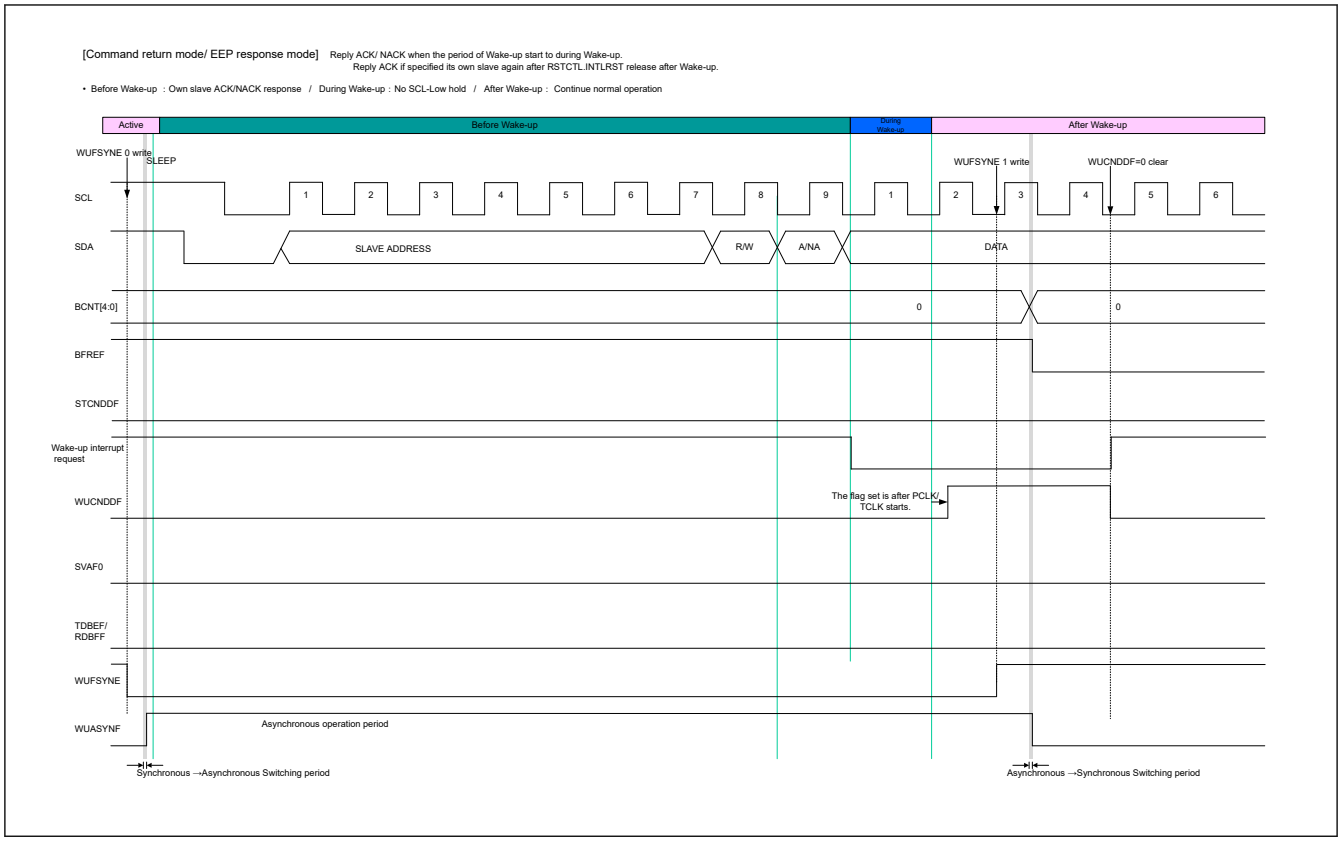


**Figure 29.119 Timing of command recovery mode/EEP response mode**

## (4) Precautions on the use of the Wake-up function

Precautions on the use of the Wake-up function is shown below.

- Do not change the registers in I3C except the WUCTL.WUFSYNE bit while the WUST.WUASYNF flag = 1 (while PCLK/TCLK asynchronous operation).
- Set WUCTL.WUFE = BSTE.WUCNDDE = BIE.WUCNDDIE = 1 and PRSST.CRMS = PRSST.TRMD = 0 (slave reception mode) before switching PCLK/TCLK asynchronous mode.
- Cannot select the device ID and the 10-bit slave address for Wake-up interrupt factor. Set the DVIDE bit in SVCTL and SDADLS bit in SDATBAS0 to 0.
- Sets all bits in BIE (TENDIE, NACKDIE, SPCNDDIE, STCNDDIE, ALIE, TODIE) and TDBEIE0 and RDBFIE0 bits in NTIE to 0 (Interrupt disabled) before switching the asynchronous operation.
- Do not use the timeout function while the Wake-up function is enabled (WUCTL.WUFE = 1).
- Wake-up interrupt is generated while PCLK/TCLK asynchronous operation (when WUST.WUASYNF = 1). In case of detecting slave address matching, The case of detect slave address match in PCLK/TCLK synchronous mode (WUST.WUASYNF = 0), does not occur Wake-up interrupt, and BST.WUCNDDF flag will be not set also.
- If WUCTL.WUFSYNE bit to 0 write timing and START condition of detecting a conflict, I3C might start the next reception in PCLK/TCLK synchronous operation mode. In this case, WUST.WUASYNF flag becomes 1 (switch to PCLK/TCLK asynchronous mode) when data communication is finished and detected STOP condition and starts the Wake-up event detection.
- If you want to switch from PCLK/TCLK asynchronous operation to PCLK/TCLK synchronous operation without address match detection, it will switch in the STOP condition detection. When the WUCTL.WUFSYNE bit was set to 1 in a bus free state, it is continued PCLK/TCLK asynchronous operation (Reception operation: waiting communication frame). WUST.WUASYNF flag becomes to 0 when I3C detect the STOP condition of the next communication frame, and I3C switches to PCLK/TCLK synchronous operation.
- After writing 0 to WUFSYNE bit in WUCTL, do not change I3C operation mode setting register (BFCTL, SCSTRCTL, ACKCTL, INCTL, SVCTL, SDATBAS0) until switched to the PCLK/TCLK asynchronous operation from PCLK/

TCLK synchronous operation (while WUST.WUASYNF flag = 1). If register value changes by the interrupt processing etc. in this period, I3C might malfunction without succeeding to the setting to the asynchronous operation.

- During PCLK/TCLK asynchronous operation (WUST.WUASYNF = 1), do not refer to each flag of SVST, BST, NTST register and BCST.BFREF flag.
- Do not set ACKCTL.ACKT = 1 in order to make an ACK response in the synchronization unit when Wake-up is performed by slave address match in Normal Wake-up mode 2.

### 29.3.2.5.2 Wake-up function

#### (1) I3C Master Wake-up

Wake-up interrupt causes of I3C master are shown below.

- SDA low detection (IBI request from I3C slave)

The operation when transitioning to active mode (normal operation) by Wake-up interrupt of SDA Low detection is shown below.

| | |
|---|---|
| Before Wake-up recovery: | SDA Low Drive is detected and the I3C_WU interrupt is asserted. |
| During Wake-up recovery: | Keep I3C_SCL Line High. |
| After Wake-up recovery: | Drive SCL Low and complete START condition.<br>SCL is supplied on the I3C bus and IBI from I3C slave is received. |

If transition to active mode (normal operation) due to other factors, disable the Wake-up function as necessary.

After confirming PRSTDBG.SDILV = 1, set WUCTL.WUFE = 0.

Do not use the timeout function while the Wake-up function is enabled (WUCTL.WUFE = 1).

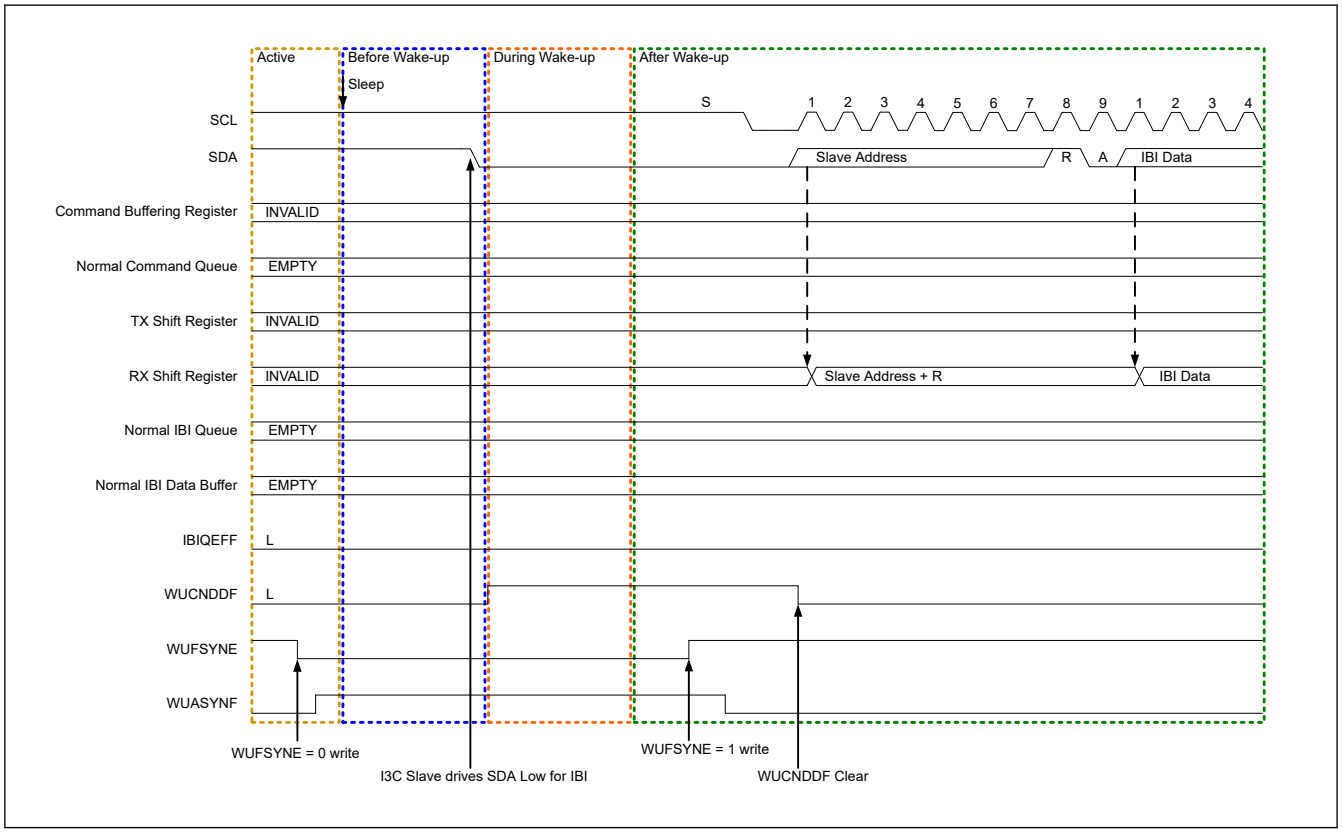

**Figure 29.120 I3C master Wake-up operation**

#### (2) I3C Slave Wake-up

Wake-up interrupt causes of I3C slave are shown below.

- Broadcast address (0x7E) and detects its own Slave address match

The operation when the Broadcast address (0x7E) and transition to active mode (normal operation) by Wake-up interrupt by detecting its own Slave address match is shown.

| | |
|---|---|
| Before Wake-up recovery: | 1. If I3C detects BA (0x7E/W) following a START (or Repeated START) Condition, then I3C generates ACK (after 0x7E/W).<br>2. If I3C detects its own Dynamic address after a Repeated START condition following Step1, then I3C generates NACK (after its own Dynamic address) and then issues a I3C_WU interrupt. |
| During Wake-up recovery: | I3C always generates NACK. |
| After Wake-up recovery: | Normal operation continues. |

If transition to active mode (normal operation) due to other factors, disable the Wake-up function as necessary. Do not use the timeout function while the Wake-up function is enabled (WUCTL.WUFE = 1).

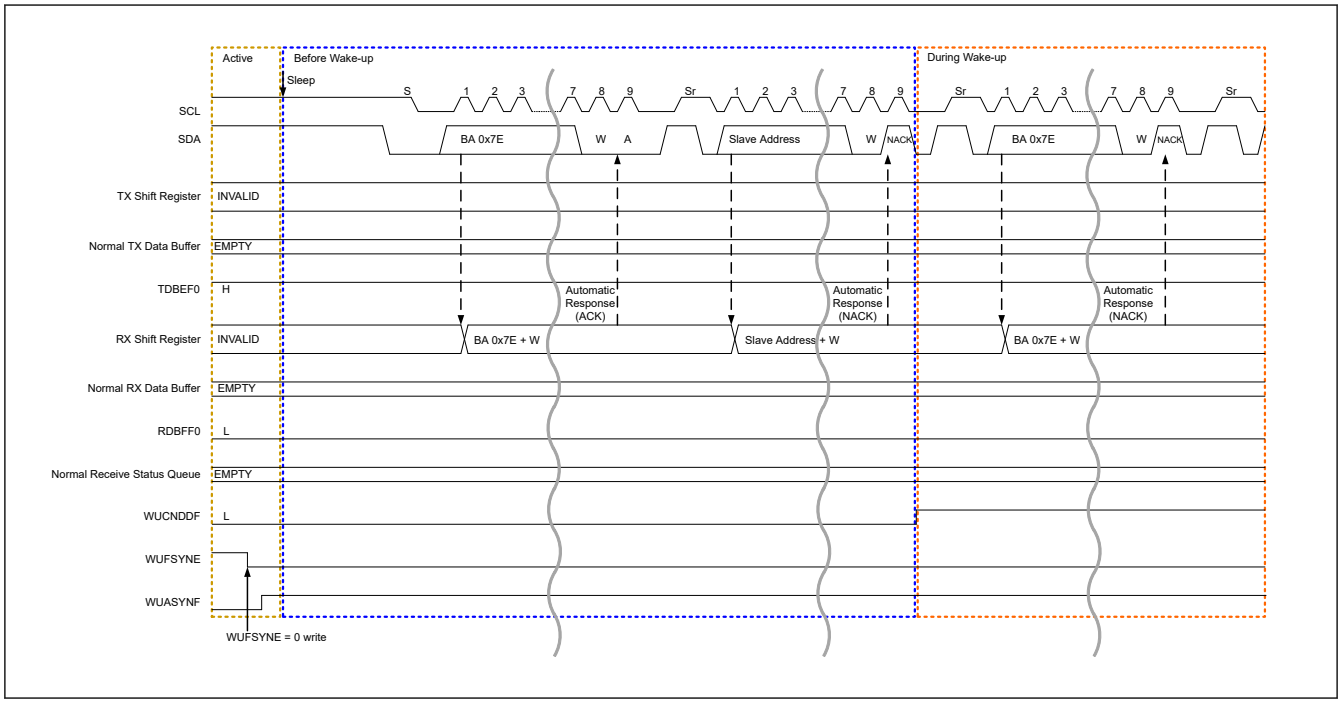

**Figure 29.121 I3C slave Wake-up operation (1/2)**

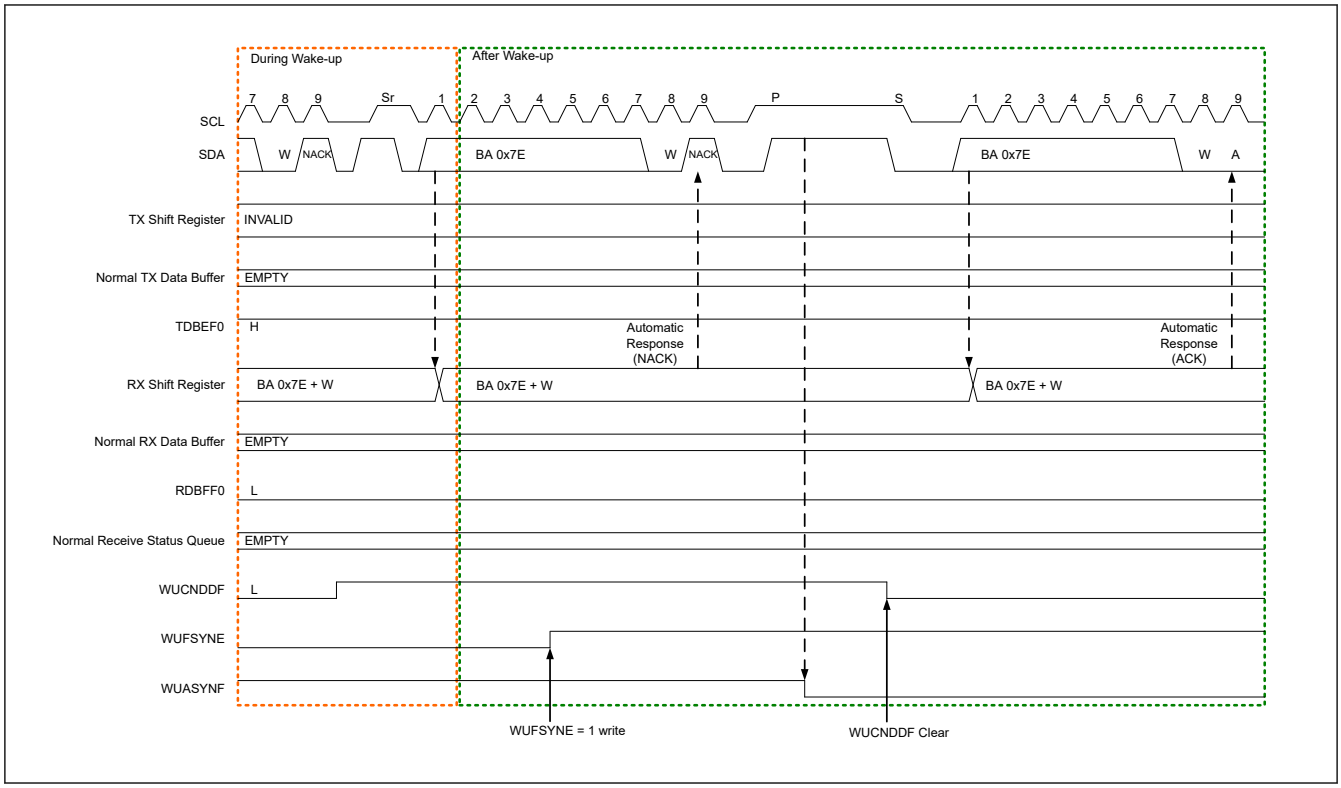

**Figure 29.122 I3C slave Wake-up operation (2/2)**

## 29.3.2.6 Other

### 29.3.2.6.1 SCL Synchronization Circuit [$I^2C$ mode]

This function is enabled while the PRTS.PRTMD bit is set to 1.

In generation of the SCL clock, I3C starts counting out the value for width at high level specified in STDBR.SBRHO[7:0] when it detects a rising edge on the I3C_SCL line and drives the I3C_SCL line low once counting of the width at high level is complete.

When I3C detects the falling edge of the I3C_SCL line, it starts counting out the width at low level period specified in STDBR.SBRLO[7:0], and then stops driving the I3C_SCL line (releases the line) once counting of the width at low level is complete. The SCL clock is thus generated.

If multiple master devices are connected to the $I^2C$ bus, a collision of SCL signals may arise due to contention with another master device. In such cases, the master devices have to synchronize their SCL signals. Since this synchronization of SCL signals must be bit by bit, I3C is equipped with a facility (the SCL synchronization circuit) to obtain bit-by-bit synchronization of the SCL clock signals by monitoring the I3C_SCL line while in master mode.

When I3C has detected a rising edge on the I3C_SCL line and thus started counting out the width at high level specified in STDBR.SBRHO[7:0], and the level on the I3C_SCL line falls because an SCL signal is being generated by another master device, I3C stops counting when it detects the falling edge, drives the level on the I3C_SCL line low, and starts counting out the width at low level specified in STDBR.SBRLO[7:0]. When I3C finishes counting out the width at low level, it stops driving the I3C_SCL line to the low level (releases the line). At this time, if the width at low level of the SCL clock signal from the other master device is longer than the width at low level set in this module, the width at low level of the SCL signal will be extended. Once the width at low level for the other master device has ended, the SCL signal rises because the I3C_SCL line has been released. When I3C finishes outputting the low-level period of the SCL clock, the I3C_SCL line is released and the SCL clock rises. That is, in cases of contention of SCL signals from more than one master, the width at high level of the SCL signal is synchronized with that of the clock having the narrower width, and the width at low level of the SCL signal is synchronized with that of the clock having the broader width. However, such synchronization of the SCL signal is only enabled when the SCSYNE bit in BFCTL is set to 1.

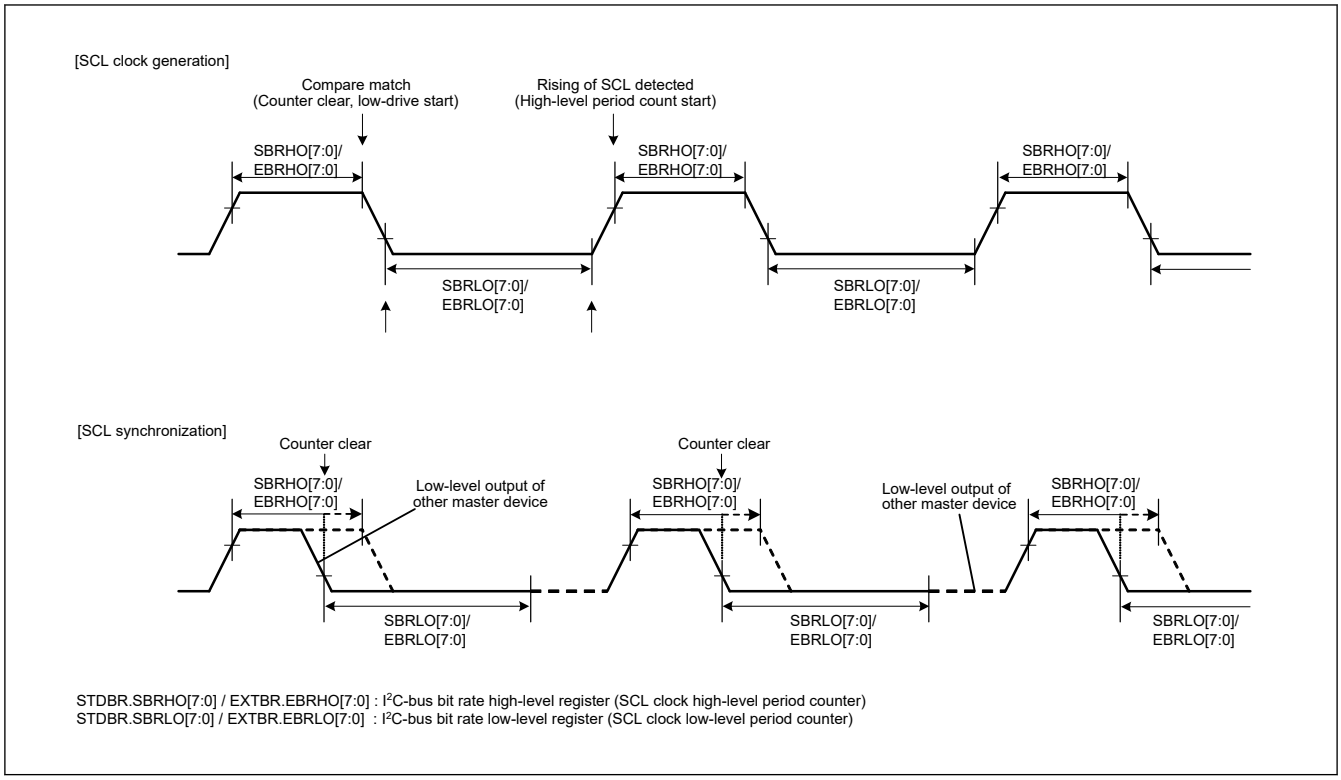

**Figure 29.123 Generation and synchronization of the SCL signal**

### 29.3.2.6.2 Facility for Delaying SDA Output [I²C mode]

I3C module incorporates a facility for delaying output on the I3C_SDA line. The delay can be applied to all output (issuing of the START, Repeated START, and STOP conditions, data, and the ACK and NACK signals) on the I3C_SDA line.

With the SDA output delay facility, SDA output is delayed from detection of a falling edge of the SCL signal to ensure that the SDA signal is output within the interval over which the SCL clock is at the low level. Doing this leads to usage with the aim of preventing erroneous operation of communications devices, with the aim of satisfying the 300 ns (minimum) data-hold time requirement of the SMBus specification.

The output delay facility is enabled by setting the SDOD[2:0] bits in OUTCTL to any value other than 000b, and disabled by setting the same bits to 000b.

While the SDA output delay facility is enabled (while the SDOD[2:0] bits in OUTCTL are set to any value other than 000b), the SDODCS bit in OUTCTL selects the clock source for counting by the SDA output delay counter as the internal base clock (I3Cφ) for I3C module or as a clock signal derived by dividing the frequency of the internal base clock by two (I3Cφ/2). The counter counts the number of cycles set in the SDOD[2:0] bits in OUTCTL. After counting of the set number of delay cycles is completed, I3C module places the required output (START, Repeated START, or STOP condition, data, or an ACK or NACK signal) on the I3C_SDA line.

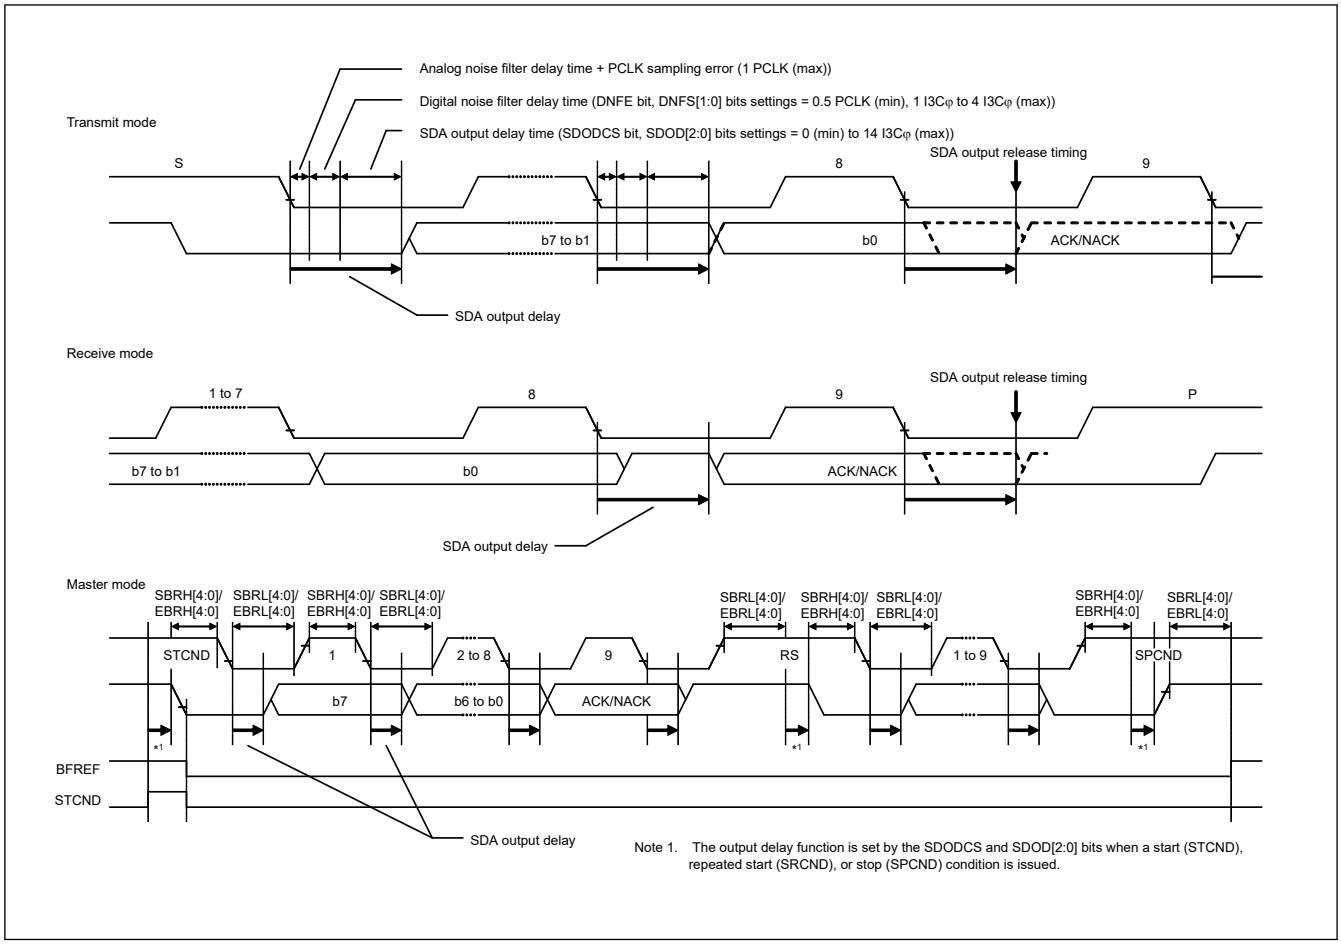

**Figure 29.124 SDA output delay facility**

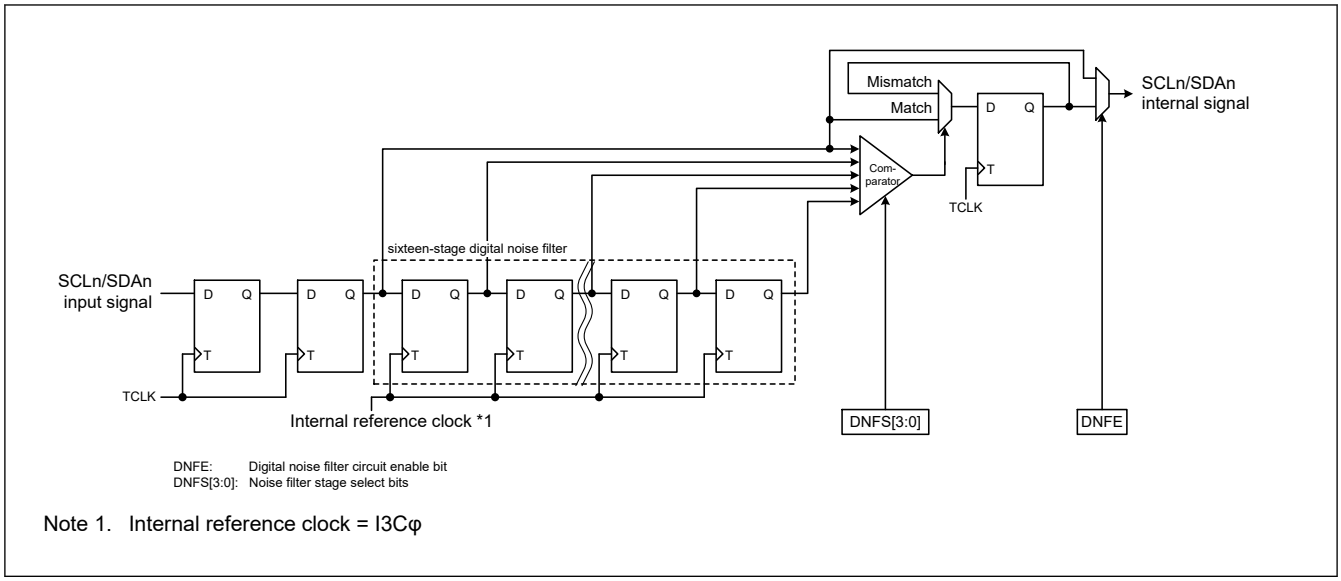
### 29.3.2.6.3 Digital Noise-Filter Circuits [$I^2C$ mode]



The states of the I3C_SCL and I3C_SDA pins are conveyed to the internal circuitry through digital noise-filter circuits. Figure 29.125 is a block diagram of the digital noise-filter circuit.

The on-chip digital noise-filter circuit of I3C consists of 16 flip-flop circuit stages connected in series and a match detection circuit. When HS mode is selected, only the first four flip-flop circuits stages are enabled.

The number of effective stages in the digital noise filter is selected by the INCTL.DNFS[3:0] bits. The selected number of effective stages determines the noise-filtering capability as a period from one to sixteen I3Cφ cycles.

The input signal to the I3C_SCL pin (or I3C_SDA pin) is sampled on rising edges of the I3Cφ signal. When the input signal level matches the output level of the number of effective flip-flop circuit stages as selected by the INCTL.DNFS[3:0] bits, the signal level is conveyed to the subsequent stage. If the signal levels do not match, the previous value is retained.

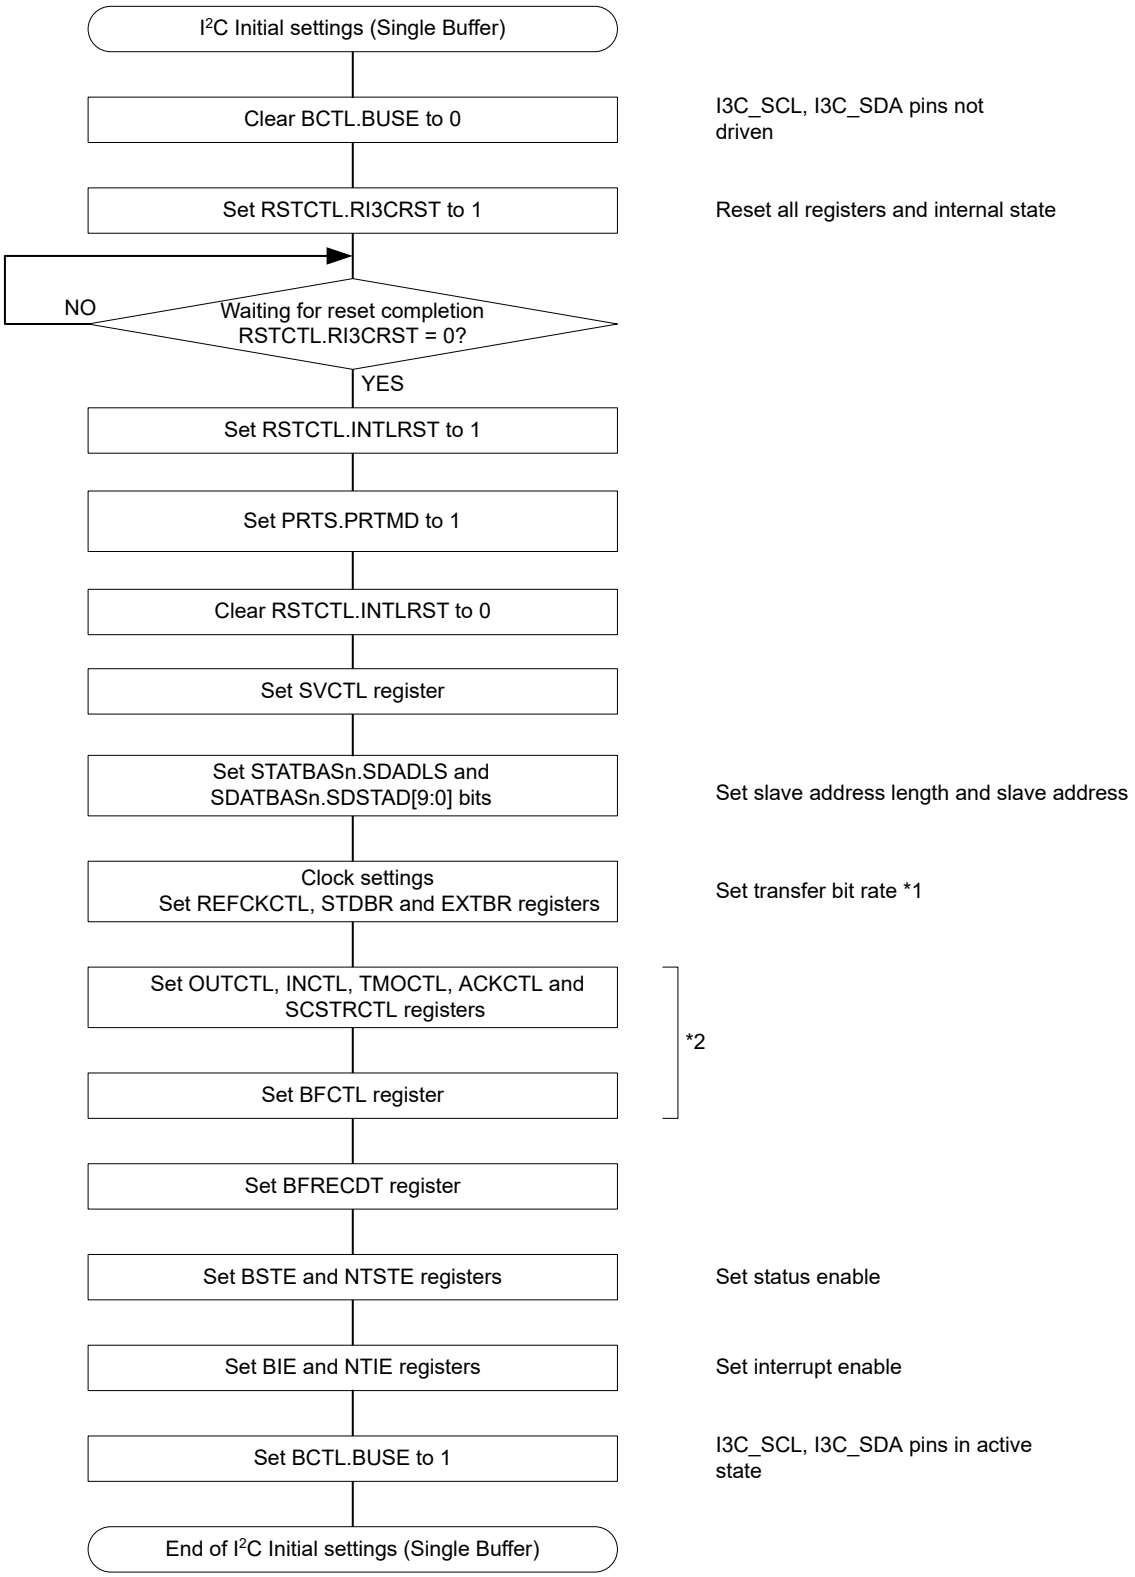
If the ratio between the frequency of the internal operating clock (TCLK) and the transfer rate is small (For example, data transfer at 400 kbps with TCLK = 4 MHz), the characteristics of the digital noise filter may lead to the elimination of needed signals as noise.

Note 1. Internal reference clock = I3Cφ

**Figure 29.125 Block diagram of digital noise filter circuit**

## 29.3.3 Operation

### 29.3.3.1 Initial Setting Flow



#### 29.3.3.1.1 I²C Initial Setting Flow (Single Buffer Transfer)

Before starting data transmission and reception in I²C protocol mode, initialize I3C module.

First, set the BCTL.BUSE bit to 0 (I3C_SCL, I3C_SDA pins not driven).

Next, set the RSTCTL.RI3CRST bit to 1. This initializes the registers and internal state of I3C module. Then, it waits for RI3CRST to become 0. For flags and registers to be initialized by this operation, see section 29.6. Reset Descriptions.

After that, set each register required for operation. For detail procedure, see Figure 29.126.

Note: n = 0
Note 1. When the I3C is used only in slave mode, set the STDBR register to a value longer than the data setup time.
Note 2. Set these registers as necessary.

**Figure 29.126 Example of I²C initialization flowchart (single buffer transfer)**

### 29.3.3.1.2 I3C Initial Setting Flow

Before starting data transmission and reception in I3C protocol mode, initialize I3C module.

Set the RSTCTL.RI3CRST bit to 1. This initializes the registers and internal state of I3C module. Then, it waits for RI3CRST to become 0. For flags and registers to be initialized by this operation, see section 29.6. Reset Descriptions.

After that, set each register required for operation. For detail procedure on each of the master mode and slave mode, see Figure 29.127.

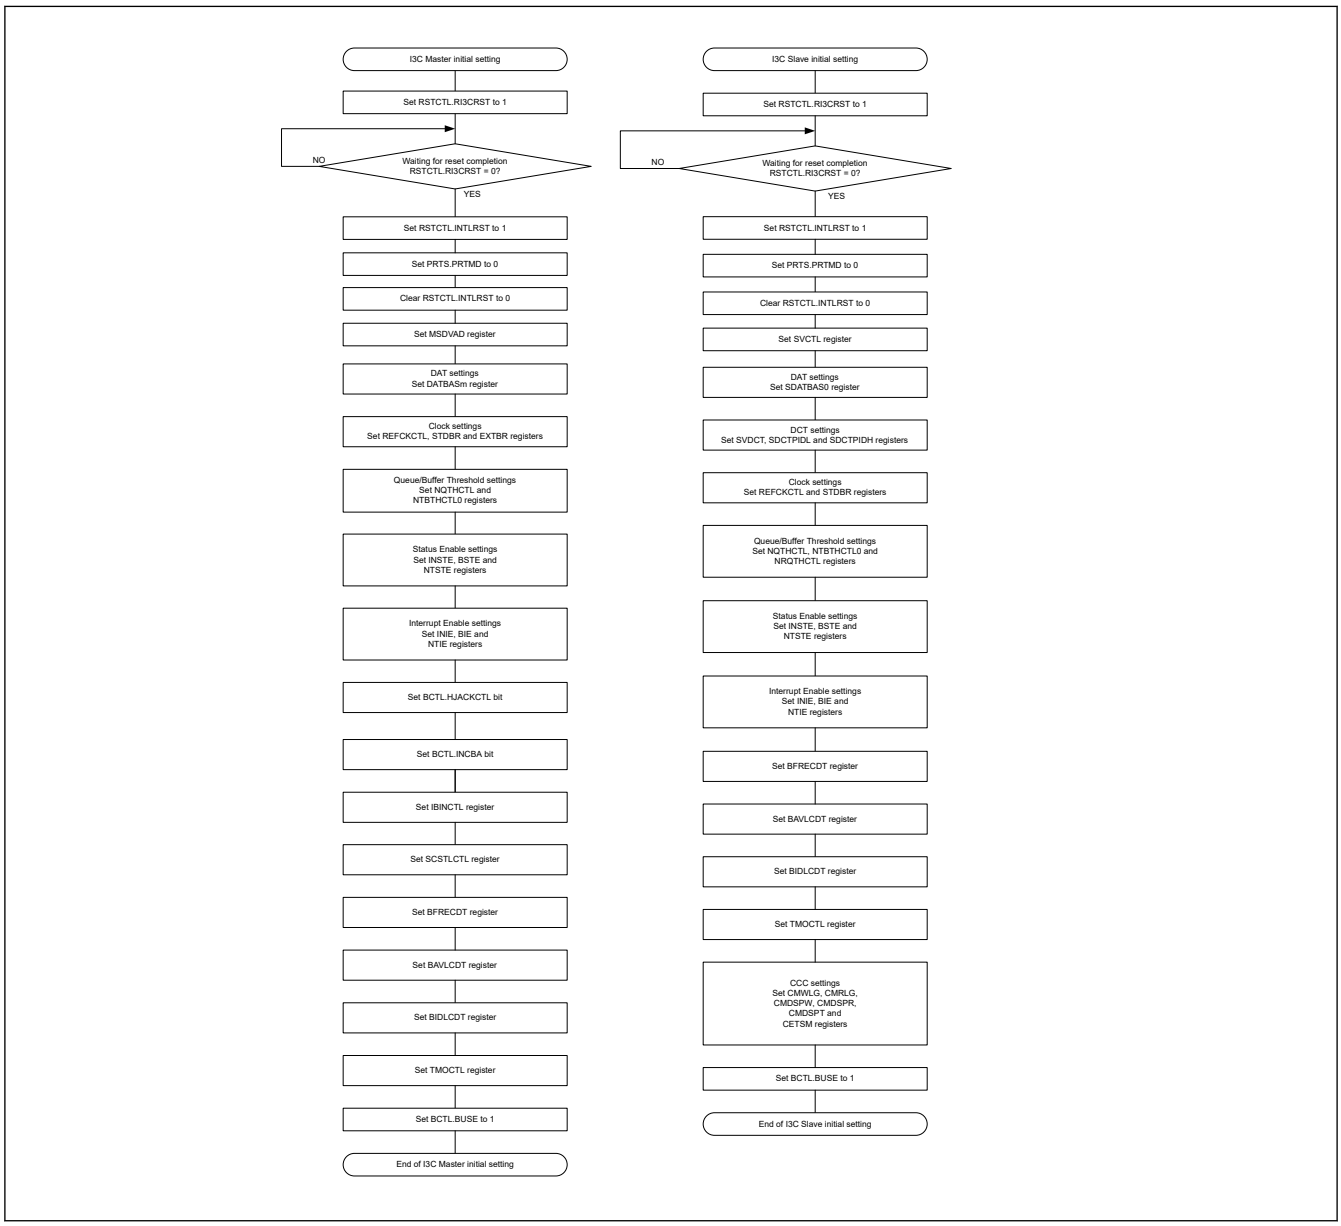


**Figure 29.127 Example of each initialization flowchart for I3C master mode and slave mode**

### 29.3.3.2 I3C Communication Flow

Figure 29.128 illustrates how I3C communication is initiated:

- All I3C communication occurs within a frame. The frame begins with a START, followed by one or more transfers, and a STOP.
- For the HDR modes:
  - First the dedicated Broadcast I3C address (0x7E) is issued to all Slaves on the I3C bus.

– Then one of the EnterHDR CCCs is issued, indicating that the Master is entering an HDR mode. Each HDR mode has its own EnterHDR CCC.
– This is followed by one or more HDR transfers.
– HDR mode is ended by using the HDR exit pattern protocol.

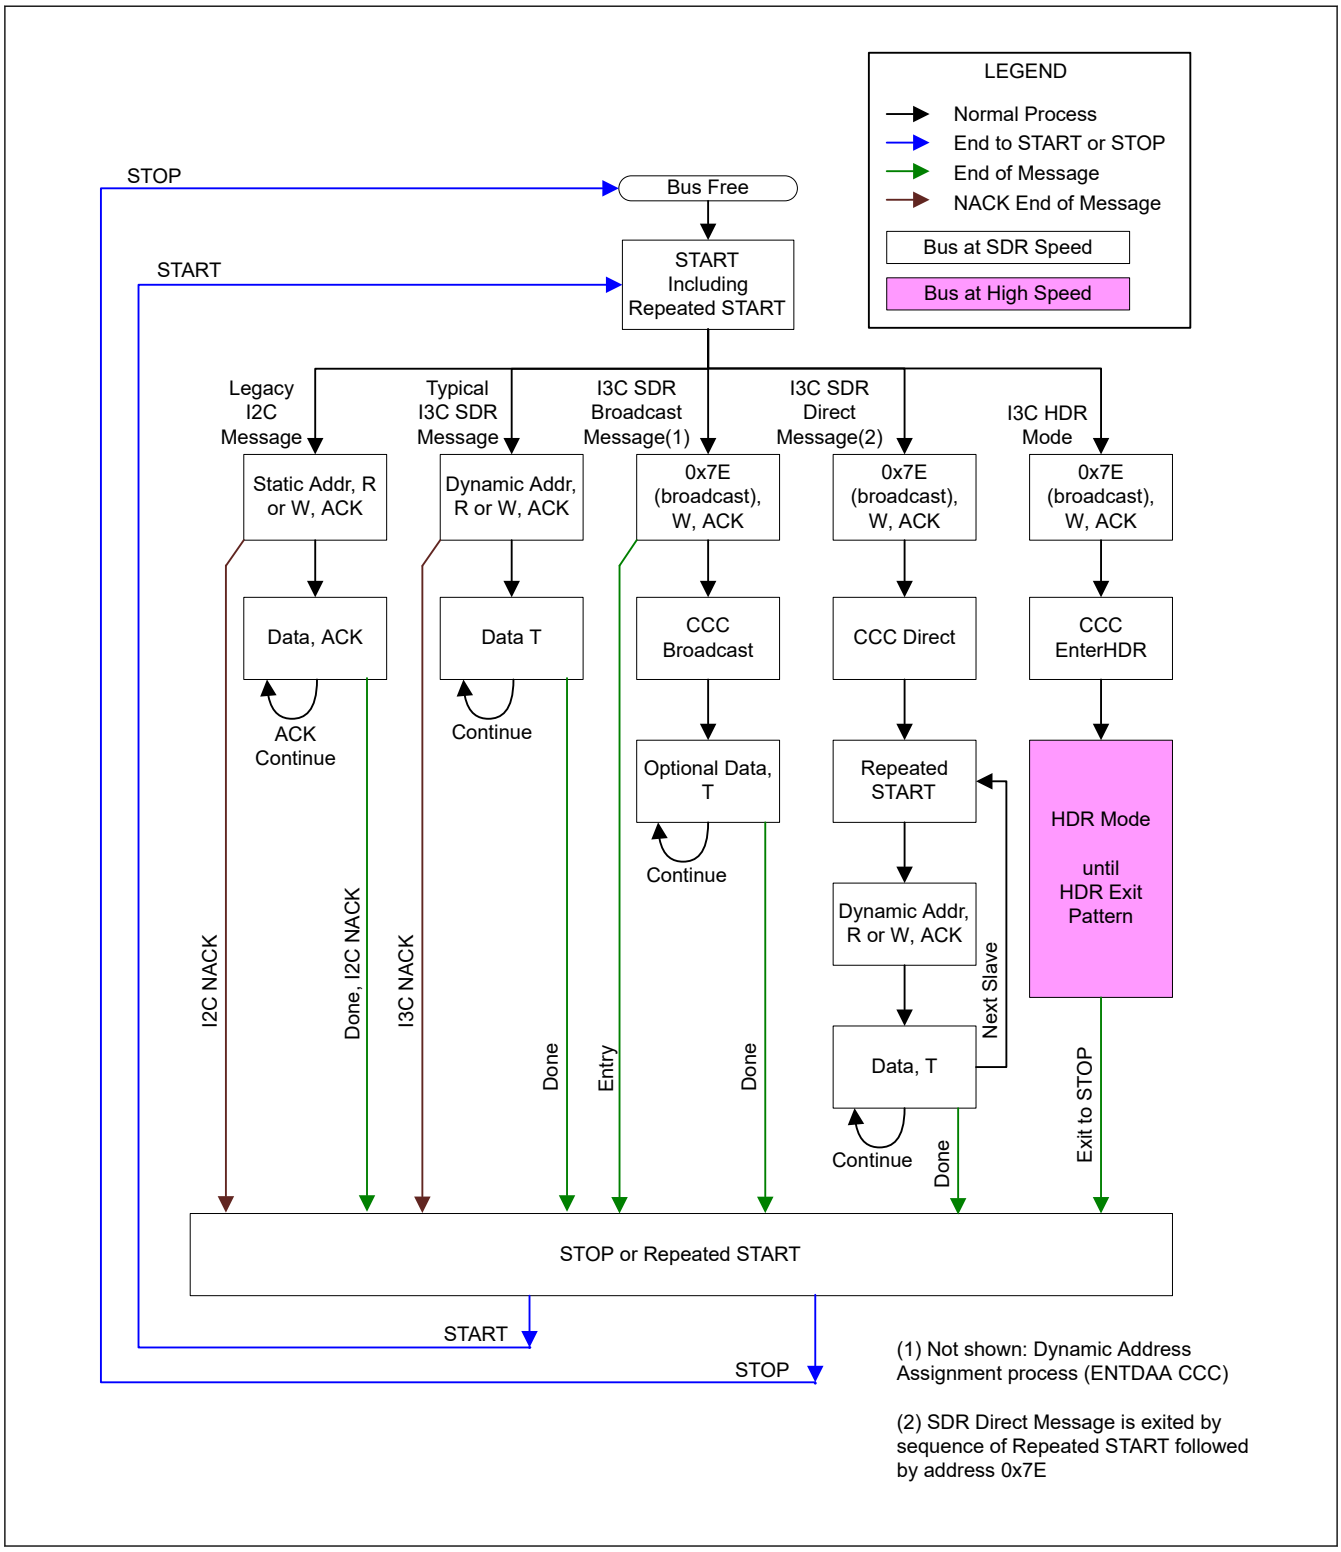

**Figure 29.128 I3C communication flow**

I3C is based on a frame encapsulation approach. A frame includes a data payload. The transfer protocol for the data payload is either SDR or HDR. Frames are bordered by $I^2C$-like bus management.

The I3C frame always includes at least the START, the Header, the Data, and the STOP. The Header following a START allows for Bus Arbitration. The Master uses the Header to address Slave device (s). Slave devices (s) may use the Header Arbitration for multiple purposes: for In-Band Interrupt, for Hot-Join, and for Secondary Master functionality.

Common Command Codes (CCCs) are used to enter the High Data Rate (HDR) modes. It is important to understand that I3C bus activity for the HDR Message does not follow the Legacy $I^2C$ format.

I3C allows only one Master to have control of the I3C bus at a time. Mechanisms for handoff of the Master role from one device to another device are provided.

### 29.3.3.3 Master Mode Communication Flow

#### 29.3.3.3.1 I²C Master Transmission Flow (Single Buffer Transfer)

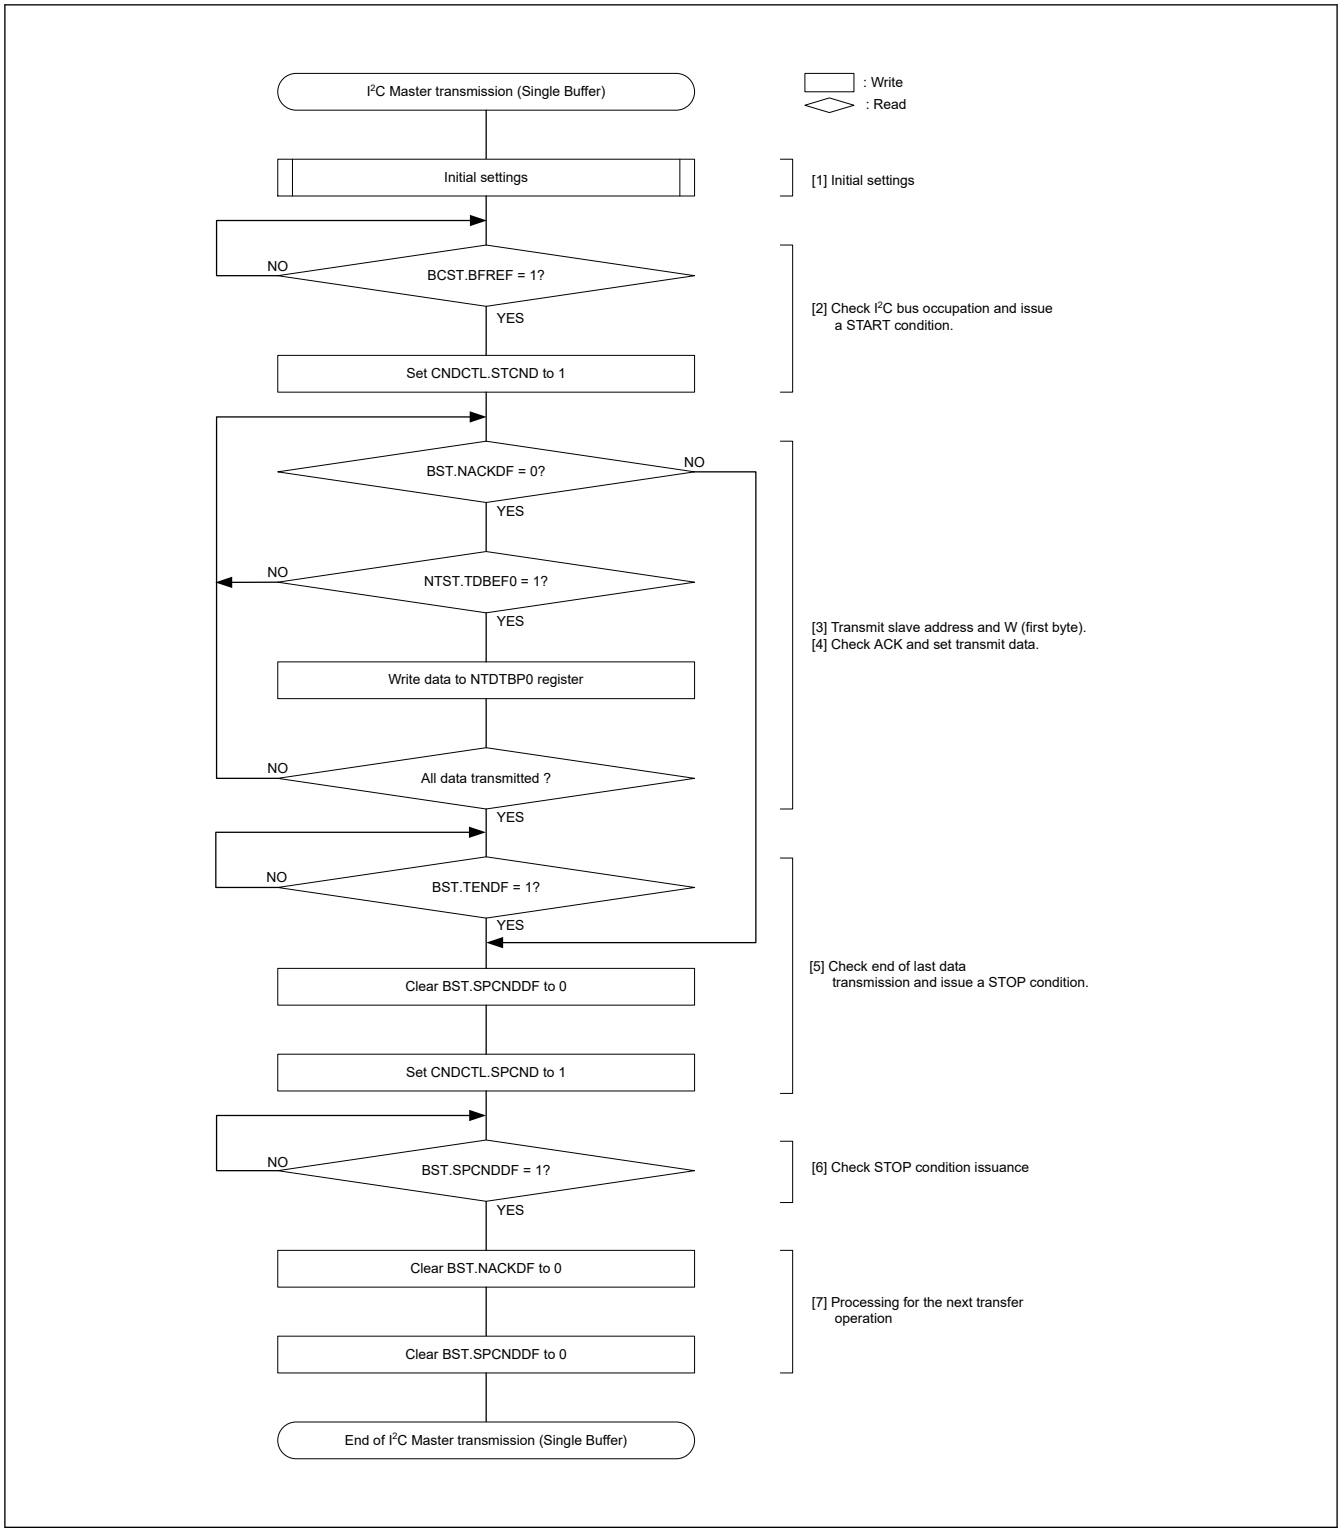

**Figure 29.129 Example of I²C master transmission flowchart (single buffer transfer)**

### 29.3.3.3.2 I²C Master Reception Flow (Single Buffer Transfer)

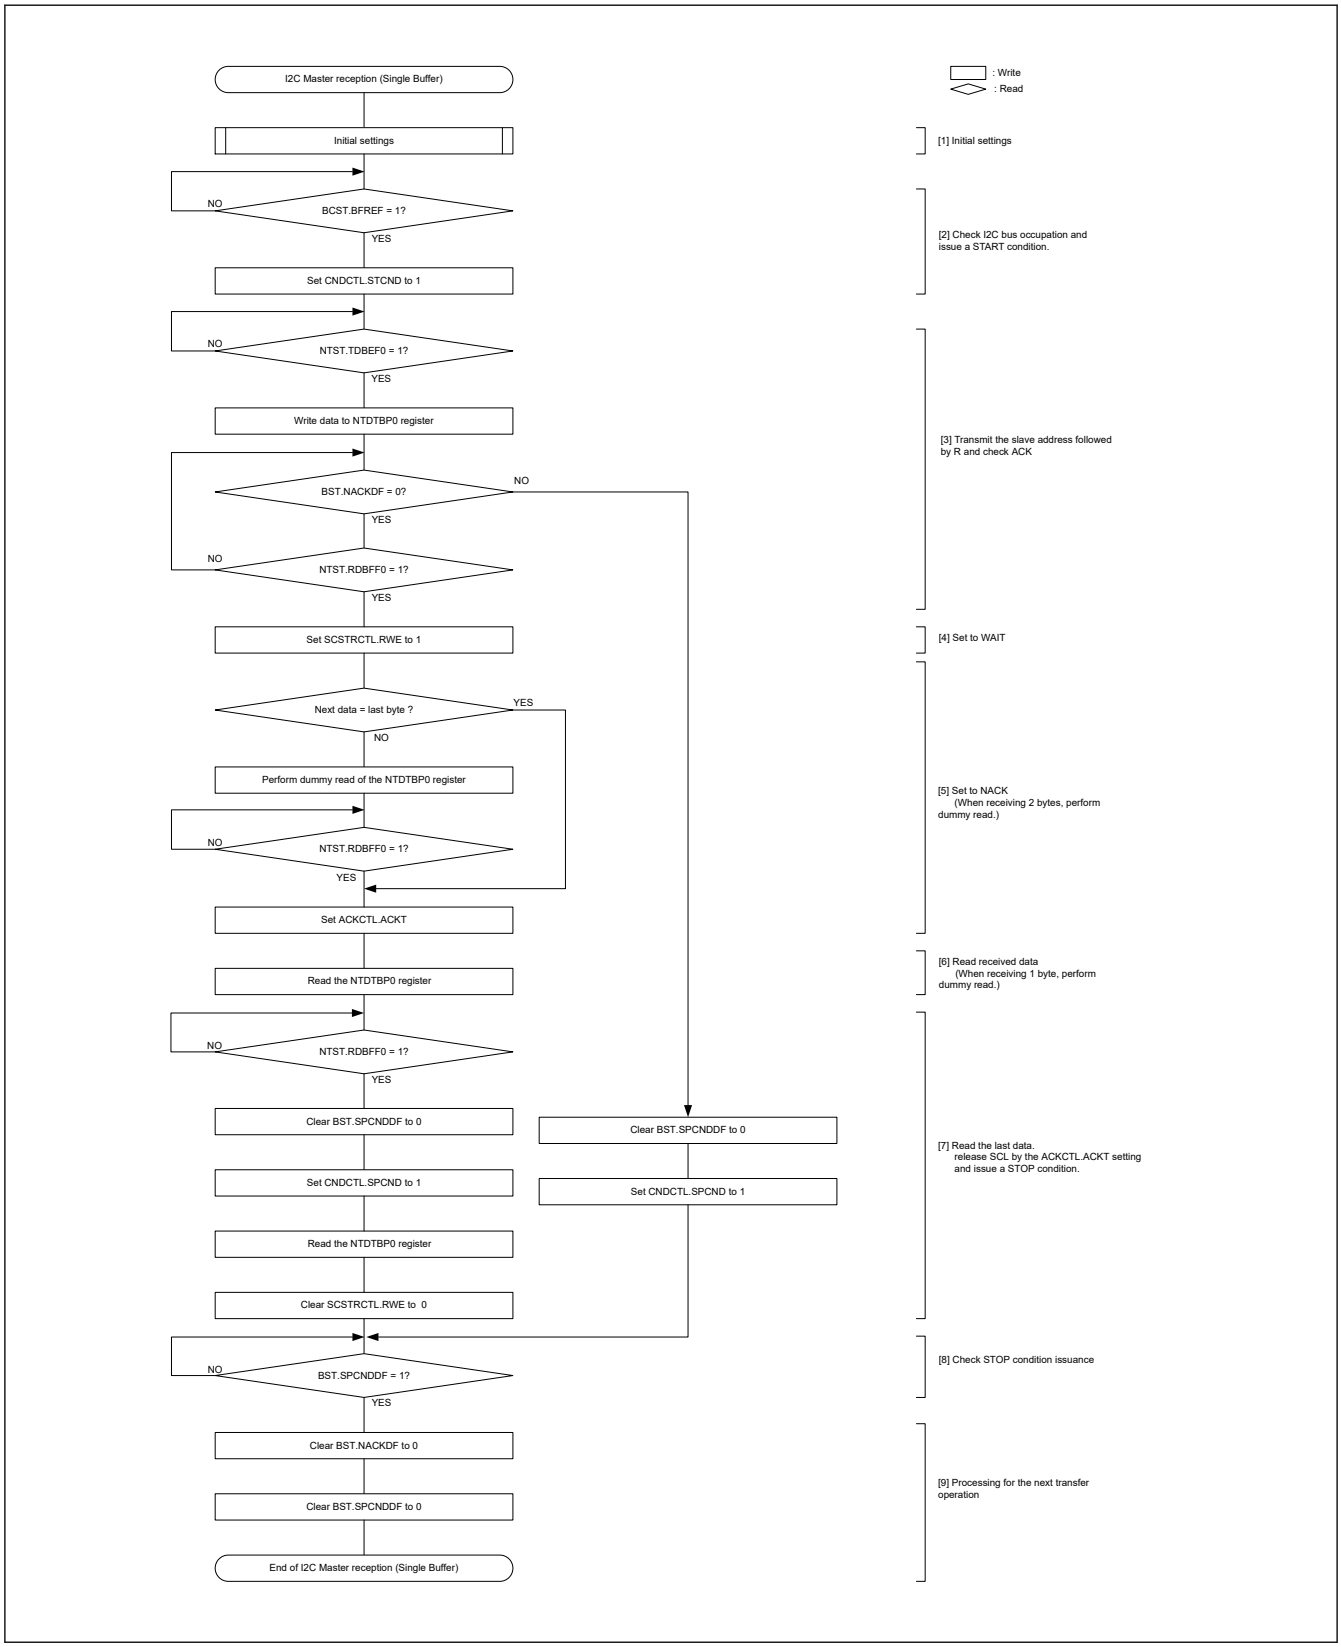

**Figure 29.130 Example of I²C master reception flowchart (7-bit address format, 1 or 2 bytes)**

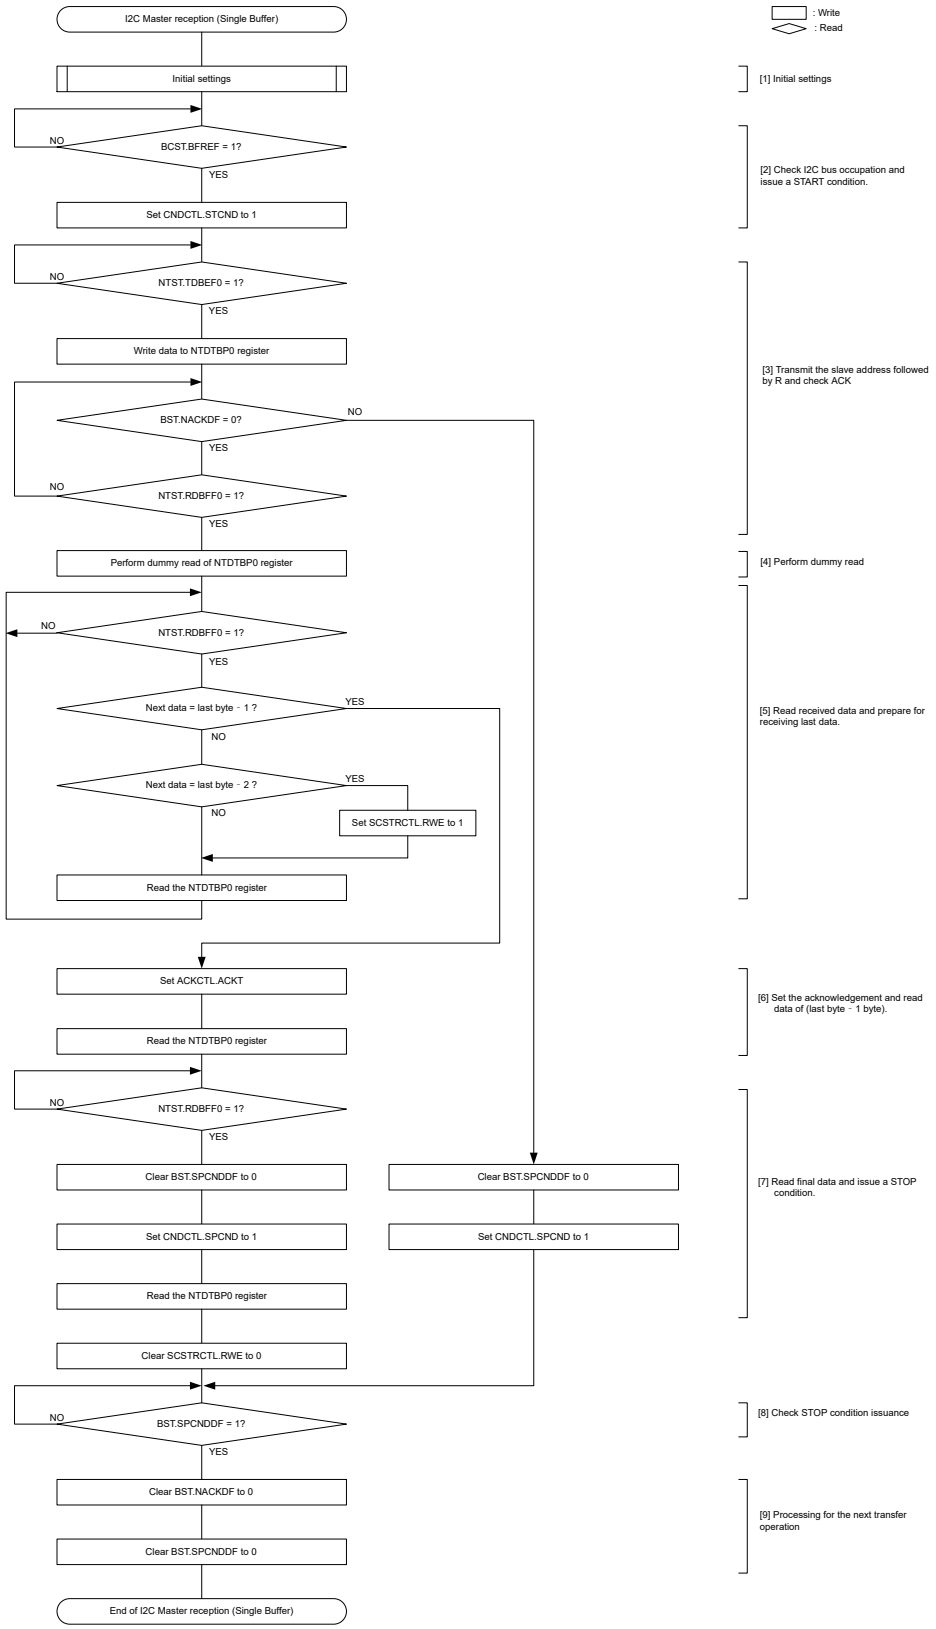

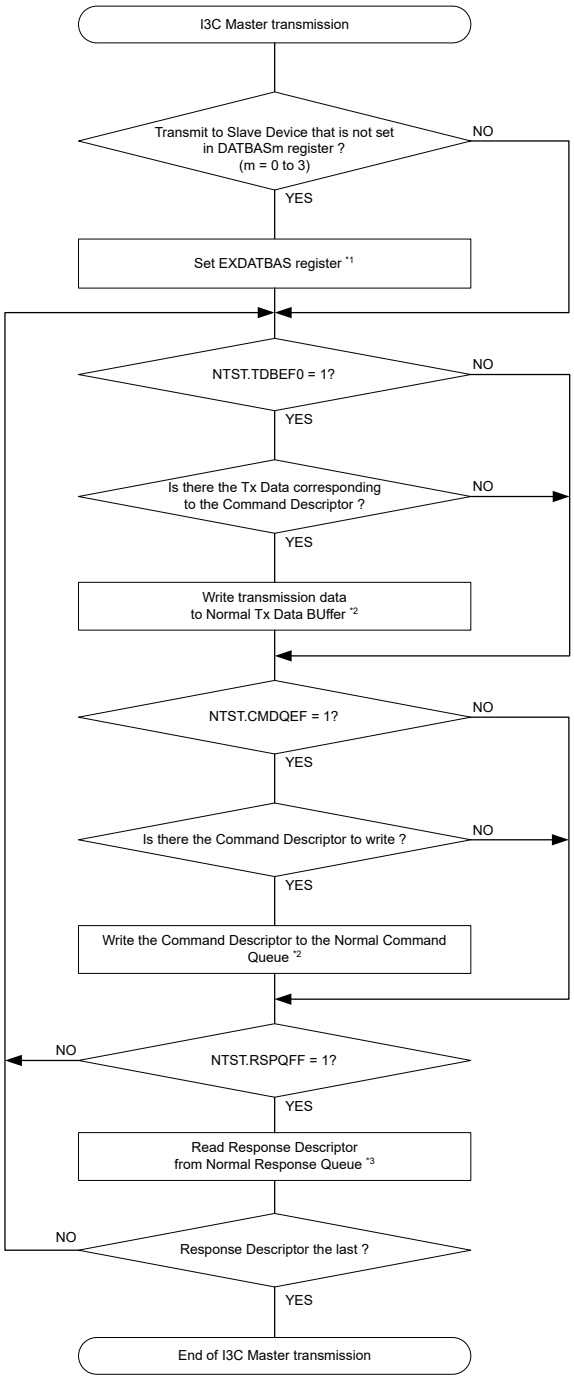

**Figure 29.131 Example of I²C master reception flowchart (7-bit address format, 3 bytes or more)**

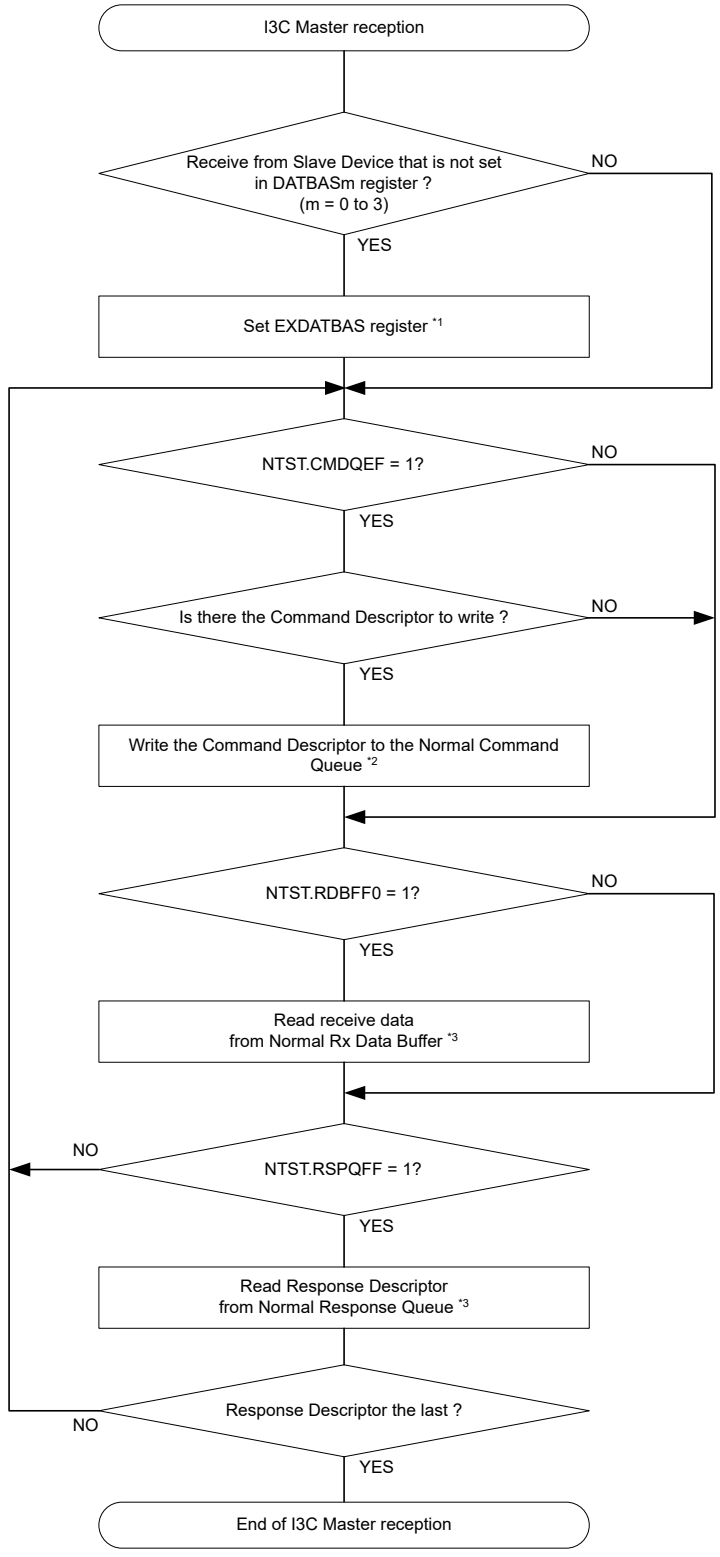
### 29.3.3.3.3 I3C Master Transmission Flow (Normal FIFO Buffer Transfer)

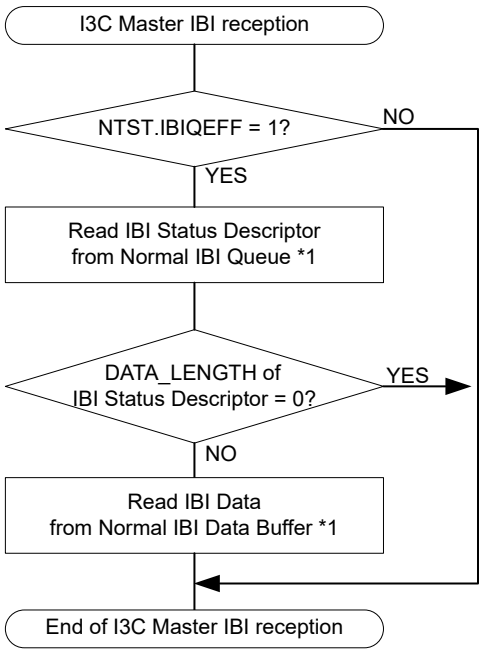
Master transmission flow in I3C normal FIFO buffer transfer is common to Legacy $I^2C$, SDR (Private Transfer, Broadcast CCC, Direct CCC), and HDR-DDR.



Note 1. Changing the EXDATBAS register is prohibited until all response descriptors of command for the Slave device set in the EXDATBAS register are stored.
Note 2. In the case the register is write by a way other than DMAC/DTC, clear corresponding flags after write access.
Note 3. In the case the register is read by a way other than DMAC/DTC, clear corresponding flags after read access.

**Figure 29.132 Example of I3C master transmission flowchart (normal FIFO buffer transfer)**

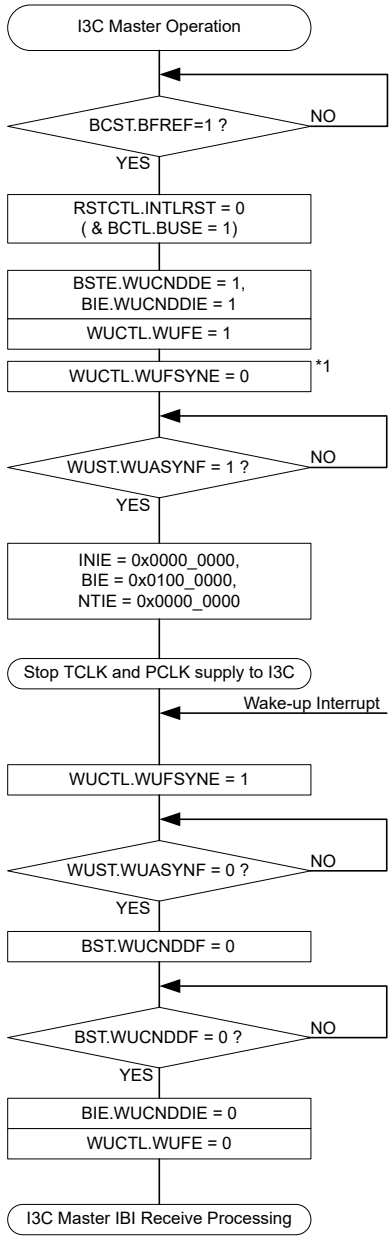
#### 29.3.3.3.4 I3C Master Reception Flow (Normal FIFO Buffer Transfer)



Master reception flow in I3C normal FIFO buffer transfer is common to Legacy $I^2C$, SDR (Private Transfer, Broadcast CCC, Direct CCC), and HDR-DDR.

Note 1. Changing the EXDATBAS register is prohibited until all response descriptors of command for the slave device set in the EXDATBAS register are stored.
Note 2. When the register is written by a way other than DMAC/DTC, clear the corresponding flags after write access.
Note 3. When the register is read by a way other than DMAC/DTC, clear the corresponding flags after read access.

**Figure 29.133 Example of I3C master reception flowchart (normal FIFO buffer transfer)**



### 29.3.3.3.5 I3C Master IBI Reception Flow

Note 1. In the case the register is read by a way other than DMAC/DTC, clear corresponding flags after read access.

**Figure 29.134 Example of I3C master IBI reception flowchart**

### 29.3.3.3.6 I3C Master Wake-up Flow

[1] Wait I3C bus free and I3C stay in the standby state.

[2] Negate internal reset if assert the internal reset.

[3] Wake-up Interrupt is enabled.

[4] Wake-up function is enabled.

[5] I3C of operating state is changed from PCLK/TCLK synchronous to PCLK/TCLK asynchronous.

[6] Interrupt requests are disabled except WUI.

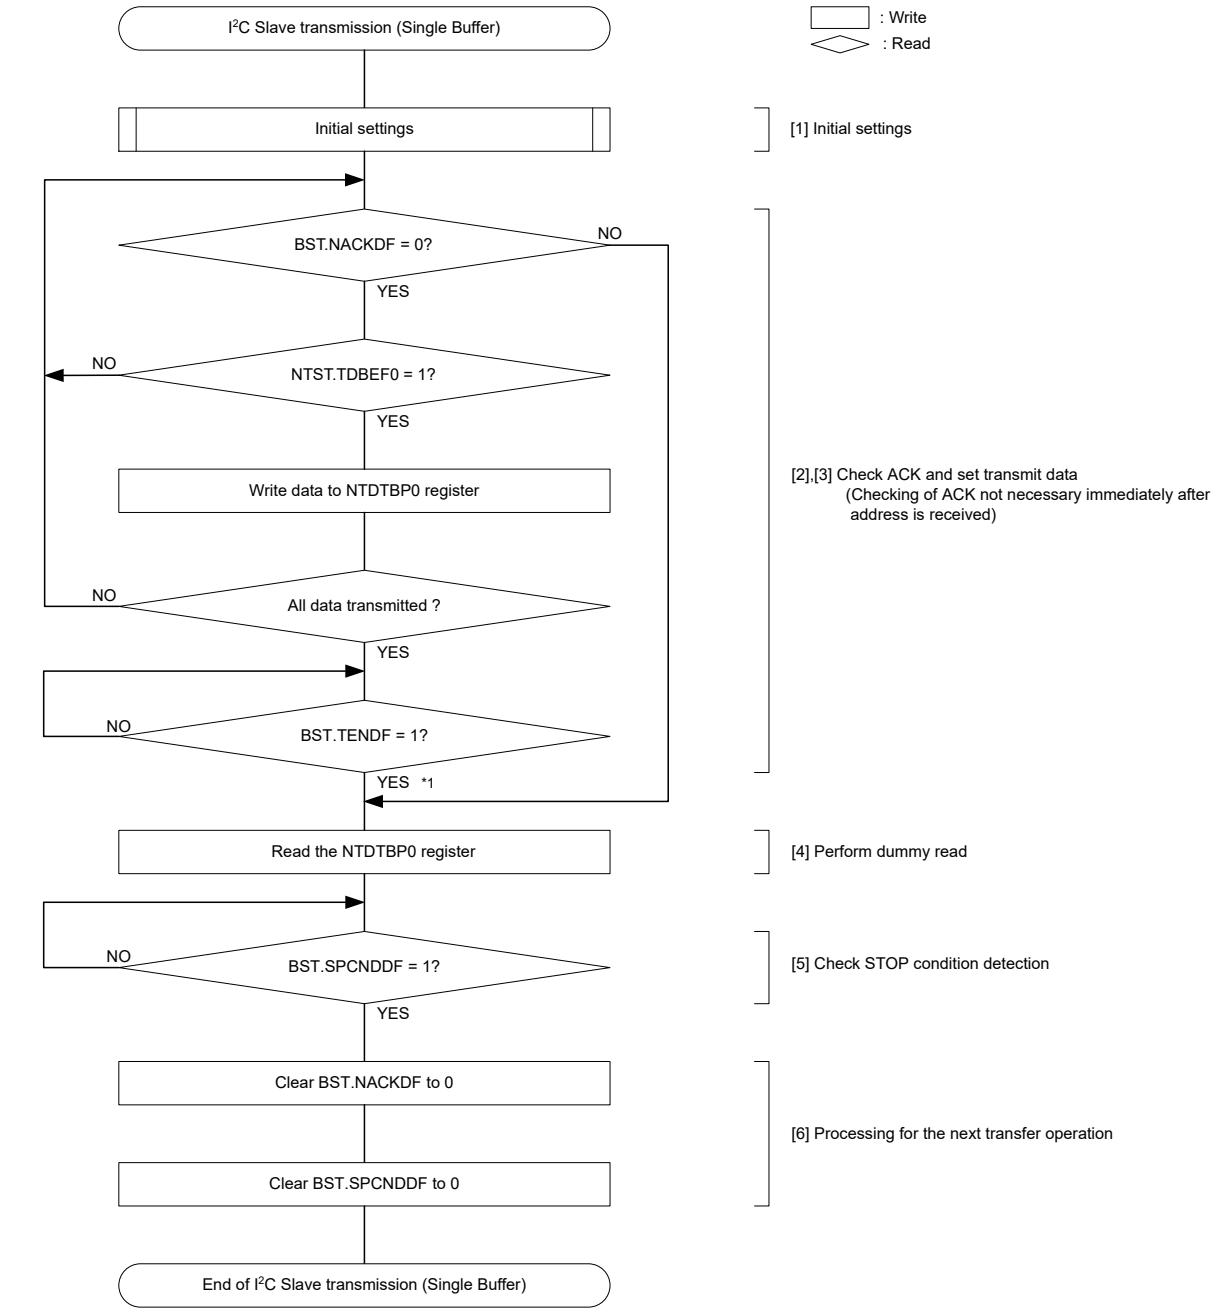
[7] Stop TCLK supply to I3C, then stop PCLK supply to I3C.
(I3C will continue to receive)

[8] Start TCLK and PCLK supply to I3C by Wake-up interrupt,
then start PCLK supply to I3C.

[9] I3C of operating state is changed from PCLK/TCLK asynchronous to PCLK/TCLK synchronous.

[10] Write 0 to BST.WUCNDDF.
(Read and check whether clearing has been completed before return from interrupt handling.)

[11] Wake-up interrupt is disabled.



[12] Wake-up function is disabled.

Note 1. After switching the I3C_SDA pin to the general I/O port (Input) in the I/O port function setting, set WUCTL.WUFSYNE to 1. Then wait until WUST.WUASYNF = 1, and switch the I3C_SDA pin to the peripheral function in the I/O port function setting.

**Figure 29.135 Use case of I3C master Wake-up**

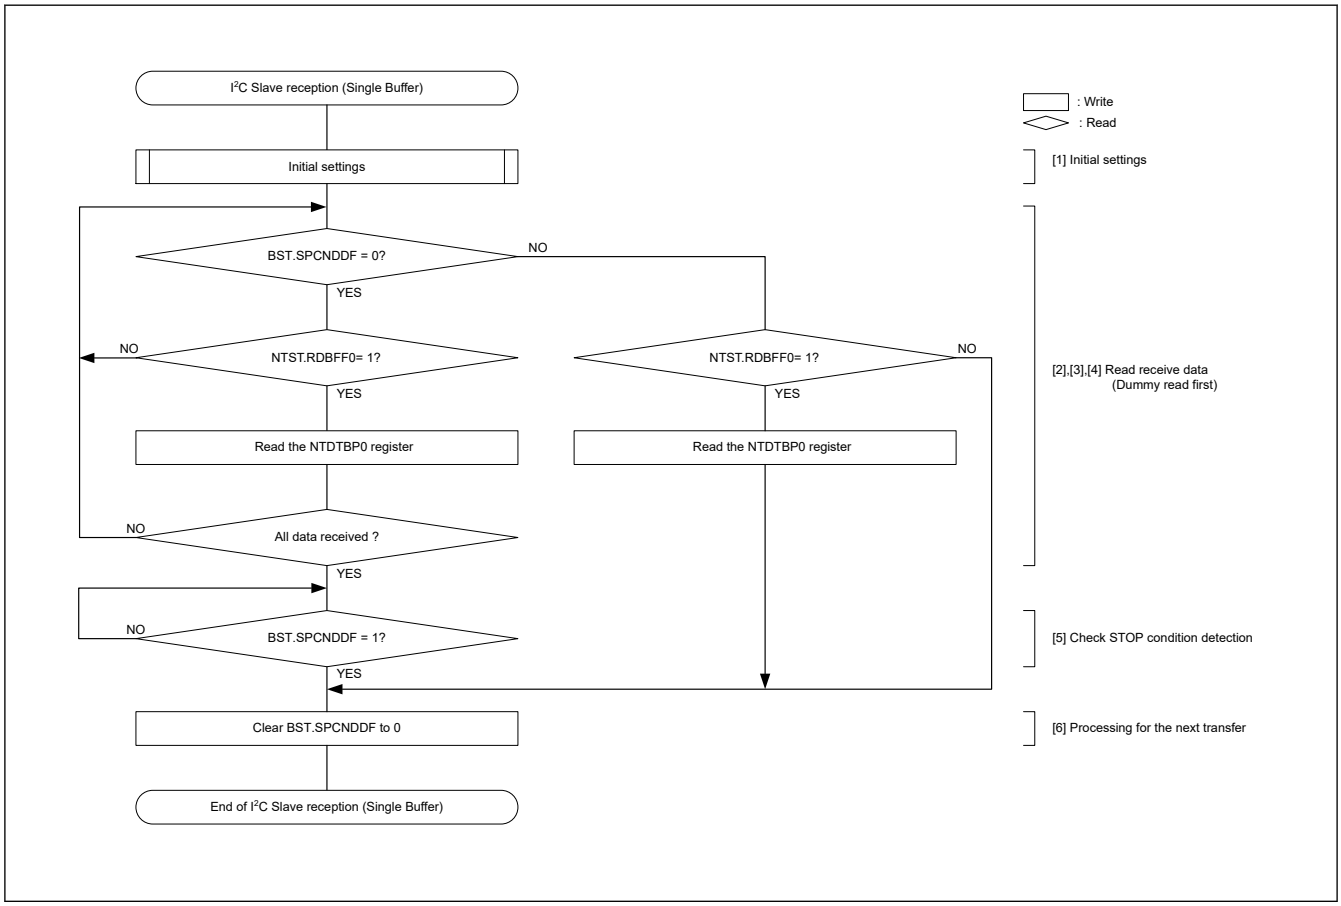
### 29.3.3.4 Slave Mode Communication Flow

#### 29.3.3.4.1 I²C Slave Transmission Flow (Single Buffer Transfer)

Note 1. Normally, Master responds to the last byte with NACK, so when BST.TENDF=1, BST.NACKDF will also 1. If BST.NACKDF is 0 after BST.TENDF=1, the master may hang up, so reset I3C with RSTCTL.INTLRST.

**Figure 29.136 Example of I²C slave transmission flowchart (single buffer transfer)**

### 29.3.3.4.2 I²C Slave Reception Flow (Single Buffer Transfer)



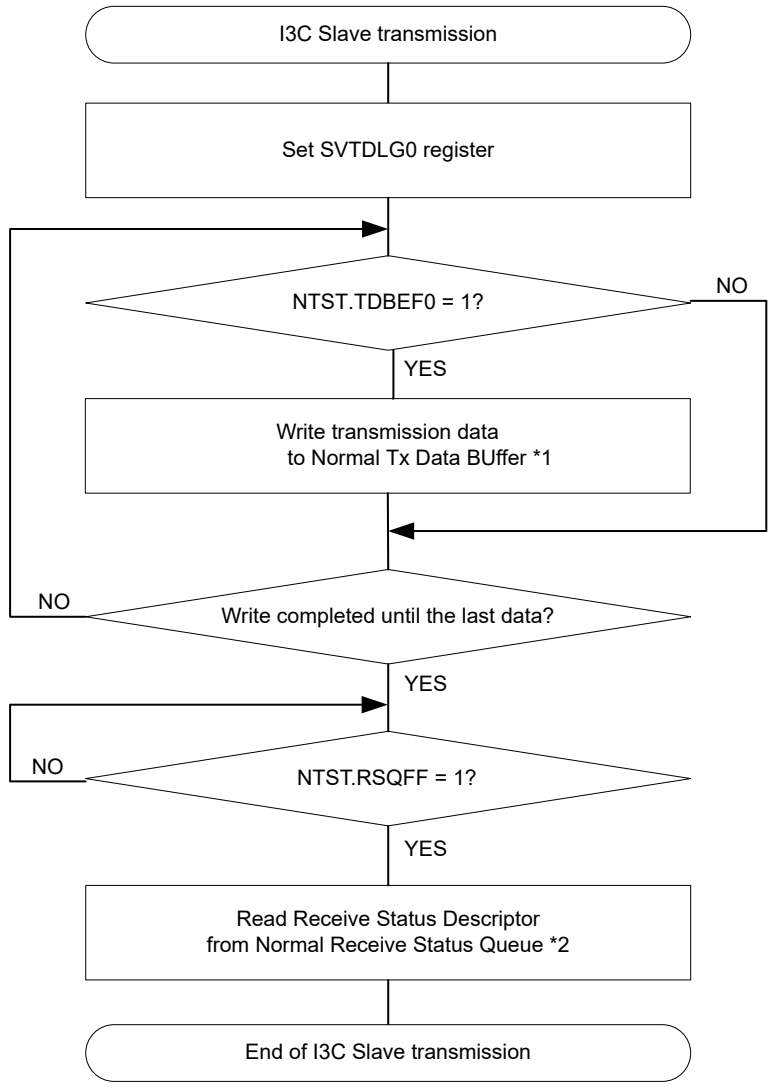


**Figure 29.137 Example of I²C slave reception flowchart (single buffer transfer)**

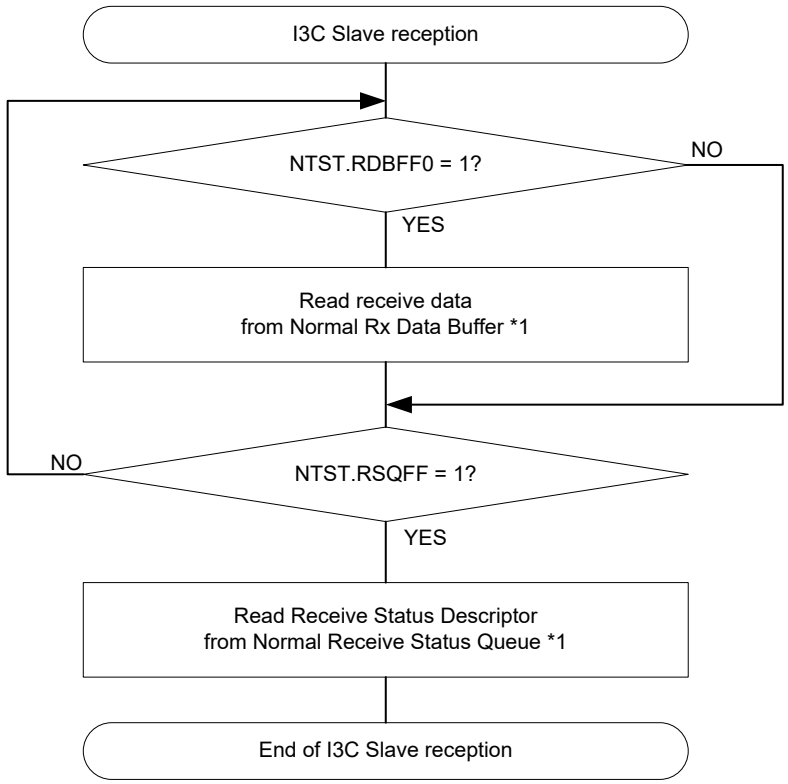
### 29.3.3.4.3 I3C Slave Transmission Flow (Normal FIFO Buffer Transfer)

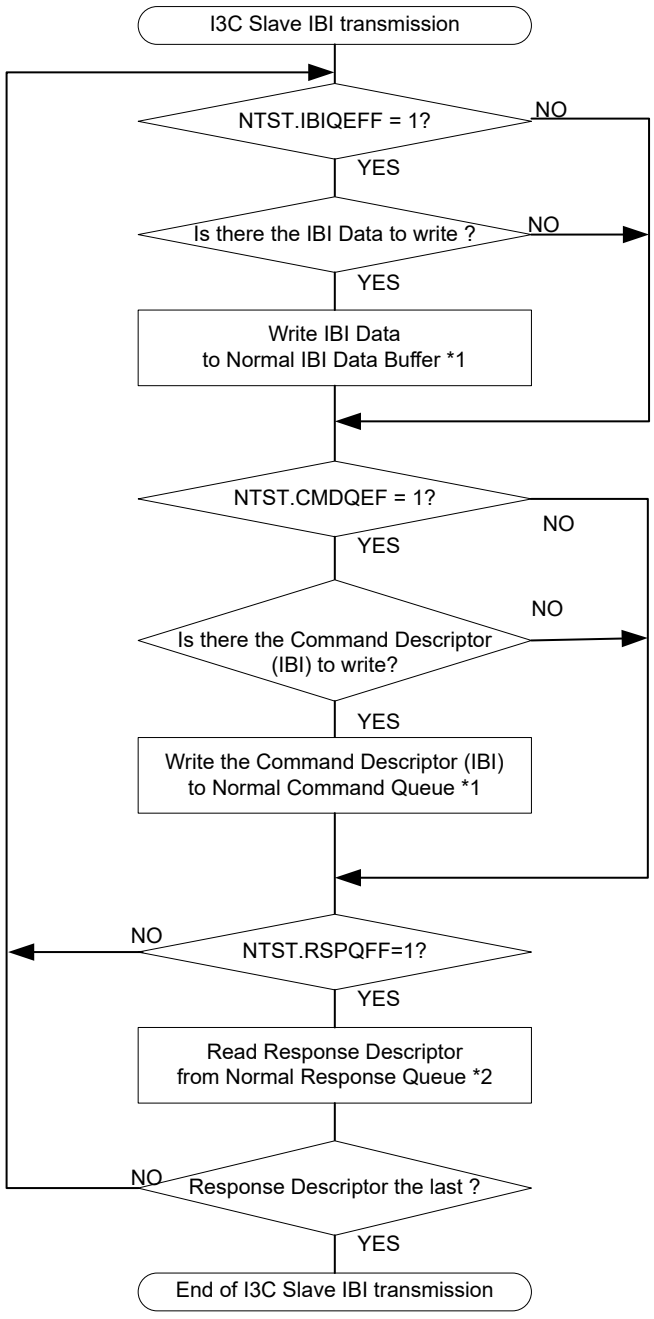
Slave Transmission Flow in I3C normal FIFO buffer transfer is common to Legacy I²C, SDR (Private Transfer, Broadcast CCC, Direct CCC), and HDR-DDR.



Note 1. In the case the register is write by a way other than DMAC/DTC, clear corresponding flags after write access.
Note 2. In the case the register is read by a way other than DMAC/DTC, clear corresponding flags after read access.

**Figure 29.138 Example of I3C slave transmission flowchart (normal FIFO buffer transfer)**

### 29.3.3.4.4 I3C Slave Reception Flow (Normal FIFO Buffer Transfer)



Slave Reception Flow in I3C normal FIFO buffer transfer is common to Legacy $I^2C$, SDR (Private Transfer, Broadcast CCC, Direct CCC), and HDR-DDR.

Note 1. In the case the register is read by a way other than DMAC/DTC, clear corresponding flags after read access.

**Figure 29.139 Example of I3C slave reception flowchart (normal FIFO buffer transfer)**

### 29.3.3.4.5 I3C Slave IBI Transmission Flow

Note 1. In the case the register is write by a way other than DMAC/DTC, clear corresponding flags after write access.
Note 2. In the case the register is read by a way other than DMAC/DTC, clear corresponding flags after read access.

**Figure 29.140 Example of I3C slave IBI transmission flowchart**

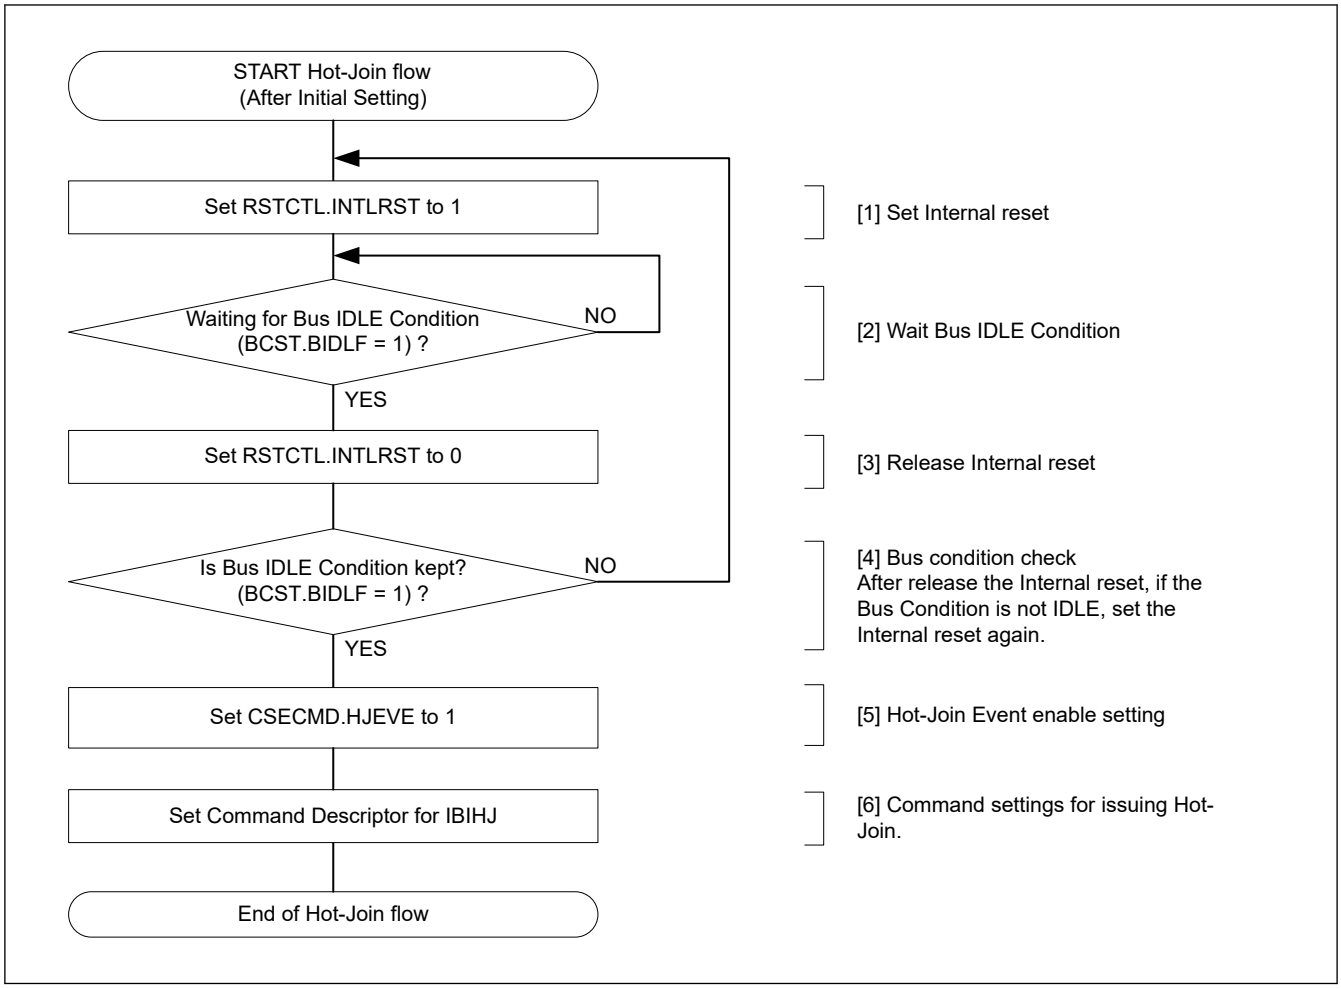


**Figure 29.141 Hot-join flowchart after the I3C bus has already been configured**

### 29.3.3.4.6 I3C Slave Wake-up Flow

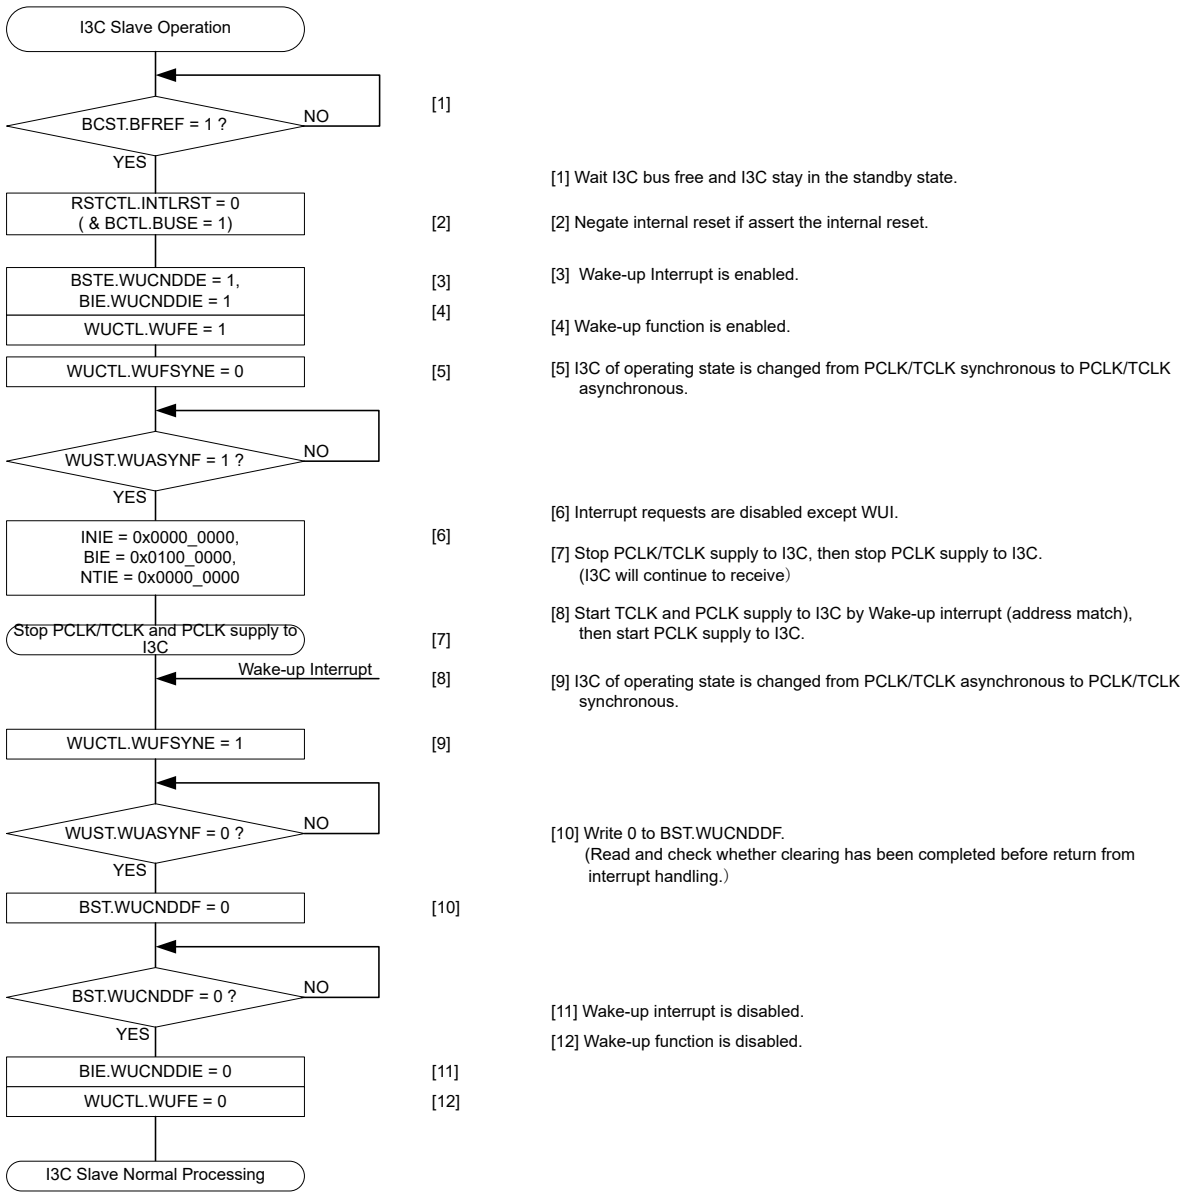

**Figure 29.142 Use case of I3C slave Wake-up (Wake-up recovery by a Wake-up interrupt triggered by the match of the slave address)**

## 29.4 Interrupt Sources

I3C can generate the following interrupt requests:

### 29.4.1 Overview

The I3C has the interrupt factors shown in Table 29.17.

**Table 29.17 Interrupt Generation (1 of 2)**

| Symbol | Interrupt source | Support | | | |
|---|---|---|---|---|---|
| | | I2C | I3CM | I3C2M | I3CS |
| I3C_RESP | Normal Response Queue full | — | ✓ | ✓ | ✓ |

**Table 29.17 Interrupt Generation (2 of 2)**

| Symbol | Interrupt source | Support | | | |
|---|---|---|---|---|---|
| | | I2C | I3CM | I3C2M | I3CS |
| I3C_CMD | Normal Command queue empty | — | ✓ | ✓ | ✓ |
| I3C_IBI | Normal IBI Queue Empty/Full | — | ✓ | ✓ | ✓ |
| I3C_RX | Normal Rx Data buffer full | ✓ | ✓ | ✓ | ✓ |
| I3C_TX | Normal Tx Data buffer empty | ✓ | ✓ | ✓ | ✓ |
| I3C_RCV | Normal Receive Status queue full | — | — | ✓ | ✓ |
| I3C_TEND | Transmit end | ✓ | — | — | — |
| I3C_EEI | Non-recoverable internal error | — | ✓ | ✓ | ✓ |
| | Normal Transfer Error | — | ✓ | ✓ | ✓ |
| | Normal Transfer Abort | — | ✓ | ✓ | ✓ |
| | START condition detection | ✓ | ✓ | ✓ | ✓ |
| | STOP condition detection | ✓ | ✓ | ✓ | ✓ |
| | HDR Exit Pattern detection | — | ✓ | ✓ | ✓ |
| | NACK detection | ✓ | — | — | — |
| | Arbitration lost | ✓ | — | — | — |
| | Timeout detection | ✓ | ✓ | ✓ | ✓ |
| I3C_WU | Wake-up condition detection | ✓ | ✓ | ✓ | ✓ |

Note: ✓ : Support
— : Not support

Note: $I^2C$: $I^2C$ Master/Slave (Single Buffer)
I3CM: I3C Master
I3C2M: I3C Secondary Master
I3CS: I3C Slave

Note: There is a delay time between the execution of a write instruction for a peripheral module by the CPU and actual writing to the module. Thus, when an interrupt flag has been cleared, read the relevant flag again to check whether clearing has been completed, and then return from interrupt handling. Returning from interrupt handling without checking that writing to the module has been completed creates a possibility of repeated processing of the same interrupt.

For I2C Protocol mode:

- Since I3C_TX is an edge-detected interrupted, it does not require clearing. Furthermore, the NTST.TDBEF0 flag (a condition for I3C_TX) is automatically set to 0 when data for transmission are written to NTDTBP0 or a STOP condition is detected (SPCNDDF flag = 1 in BST).

- Since I3C_RX is an edge-detected interrupted, it does not require clearing. Furthermore, the NTST.RDBFF0 flag (a condition for I3C_RX) is automatically set to 0 when data are read from NTDTBP0.

For I3C Protocol mode:

For details, refer to the detailed explanation of each flag bit.

- The I3C_CMD, I3C_TX, and I3C_IBI (I3C Slave) interrupts are cleared under the following conditions.
  On completion of the last write access by DMAC/DTC.
  Write 0 to this bit after 1 state is read by CPU.
- The I3C_RESP, I3C_IBI (I3C Master), I3C_RX, and I3C_RCV interrupts are cleared under the following conditions.
  On completion of the last read access by DMAC/DTC.
  Write 0 to this bit after 1 state is read by CPU.

## 29.4.2 Buffer Operation for Buffer Full/Empty Interrupts

If the conditions for generating each buffer full/empty interrupts are satisfied while the corresponding IR flag is 1, the interrupt request is not output for the ICU but retained internally (the capacity for internal retention is one request per source).

An interrupt request that was being retained within the ICU is output when the value of the IELSRn.IR flag becomes 0. Internally retained interrupt requests are automatically cleared under normal conditions of usage. Internally retained interrupt requests can also be cleared by writing 0 to the interrupt enable bit within the given peripheral module.

## 29.5 Event Link Output

I3C handles event output for the event link controller (ELC) corresponding to the following sources.

### (1) Communication event

When a Communication event (arbitration-lost detection, detection of NACK, detection of timeout, detection of a START condition, or detection of a STOP condition) occurs, the corresponding event signal can be output for another module via the ELC.

### (2) Rx Data buffer full

When a receive data register becomes full, the corresponding event signal can be output for another module via the ELC.

### (3) Tx Data buffer empty

When a transmit data register becomes empty, the corresponding event signal can be output for another module via the ELC.

### (4) Transmit end

On completion of transfer, the corresponding event signal can be output for another module via the ELC.

Other events are also available. For details, see section 17, Event Link Controller (ELC)18.2.3 ELSRn : Event Link Setting Register n.

### 29.5.1 Interrupt Handling and Event Linking

I3C module produces four kinds of interrupt: communication event (arbitration-lost detection, detection of NACK, detection of timeout, detection of a START condition, or detection of a STOP condition), Rx Data buffer full, Tx Data buffer empty, and transmit end interrupts. Each of these has an enable bit to control enabling and disabling of the interrupt signal. An interrupt request signal is output for the CPU when an interrupt source condition is satisfied while the setting of the corresponding enable bit is enabled.

The corresponding event link output signals are sent to other modules as event signals via the ELC when the interrupt source conditions are satisfied, regardless of the settings of the interrupt enable bits. For details on interrupt sources, see section 29.4.1. Overview.

## 29.6 Reset Descriptions

**Table 29.18 Register states when issuing each condition (1) (1 of 2)**

| Register symbol | Register bit name | System reset | RSTCTL Register | | | | | | | |

## 29.7 Usage Notes

### 29.7.1 Settings for the Operating Clock

The following relation is required between the frequencies of the bus clock (PCLK) and transfer clock(TCLK).

TCLK/2 ≤ PCLK ≤ TCLK

### 29.7.2 Settings for the SCL frequency Clock

As described in Chapter 5.1.2.4 of MIPI I3C Specification V1.0, the SCL frequency setting is required depending on the bus configuration.

In Mixed Bus with both I3C and legacy I2C devices are present on the bus, If the Legacy I2C device has a 50ns Spike Filter, I3C Master can change the frequency by setting the SCL High period to less than 50ns (tDIG_H_MIXED).

### 29.7.3 Module-stop function

I3C operation can be disabled or enabled using Module Stop Control Register B (MSTPCRB). The I3C module is initially stopped after reset. Releasing the module-stop state enables access to the registers. For details, see section 10, Low Power Modes.

# 30. Serial Interface UARTA (UARTA)

## 30.1 Overview

Table 30.1 lists specifications of the serial interface UARTA.

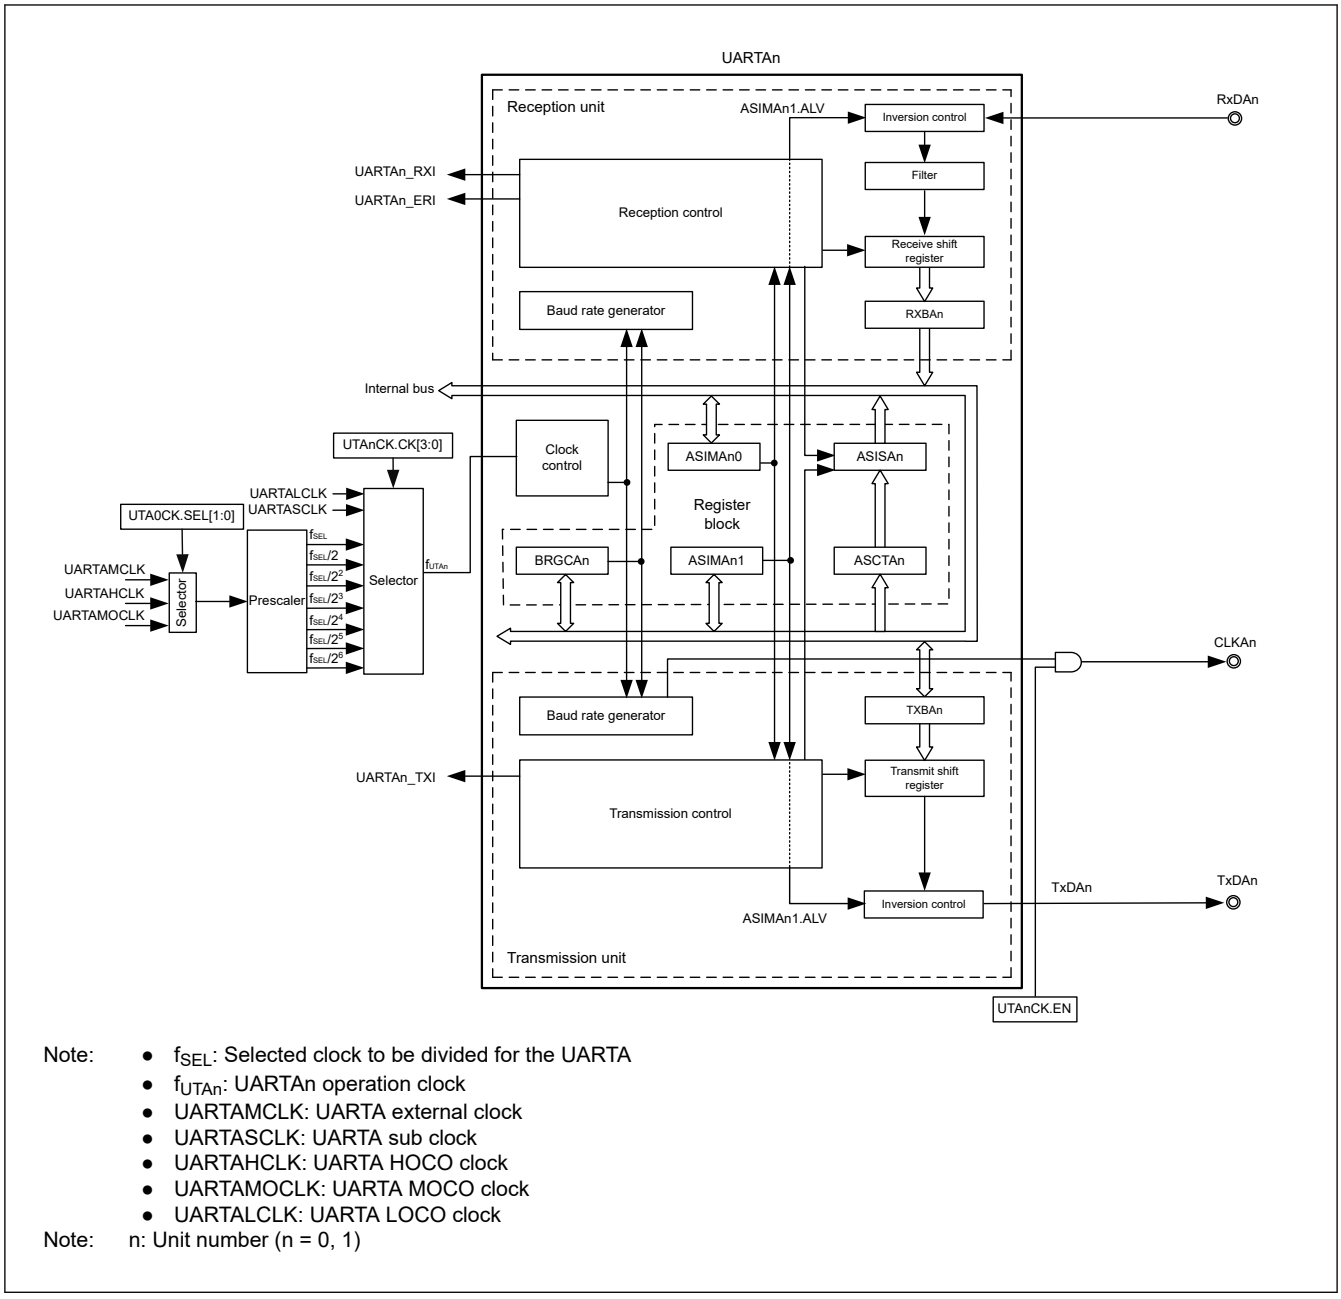

**Table 30.1 UARTA specifications**

| Item | Specifications |
|---|---|
| Serial interface modes | • Operation stop mode<br>• UART mode |
| Interfaces | • TxDAn: Transmit data output pin<br>• RxDAn: Receive data input pin<br>• CLKAn: Transmit clock output pin |
| Operation clock sources | Operating clock independent of the system/peripheral module clock selectable to UARTAMCLK, UARTALCLK, UARTASCLK, UARTAHCLK, and UARTAMOCLK |
| Transfer rate | Up to 153.6 kbps |
| Baud rate | Settable with the dedicated internal 8-bit baud rate generator |
| Data format | • MSB-first or LSB-first selectable<br>• Transfer bit length selectable to 5, 7, or 8 bits |
| Interrupt sources | • Transfer completion interrupt<br>• Reception transfer end<br>• Reception error interrupt |
| Other functions | • Transmission and reception independent of each other (full-duplex communication)<br>• Inversion control of communication logic level provided |
| Module-stop function | Module-stop state can be set to reduce power consumption |
| TrustZone Filter | Security attribution can be set |

Note: • UARTAMCLK: UARTA external clock
• UARTASCLK: UARTA sub clock
• UARTAHCLK: UARTA HOCO clock
• UARTAMOCLK: UARTA MOCO clock
• UARTALCLK: UARTA LOCO clock

Note: n: Unit number (n = 0, 1)

Figure 30.1 shows a block diagram of UARTAn and Table 30.2 shows the pin configuration of UARTAn.

Note: • $f_{SEL}$: Selected clock to be divided for the UARTA
- $f_{UTAn}$: UARTAn operation clock
- UARTAMCLK: UARTA external clock
- UARTASCLK: UARTA sub clock
- UARTAHCLK: UARTA HOCO clock
- UARTAMOCLK: UARTA MOCO clock
- UARTALCLK: UARTA LOCO clock

Note: n: Unit number (n = 0, 1)

**Figure 30.1 Block diagram of UARTAn**

**Table 30.2 UARTAn pin configuration**

| Name | I/O | Function |
|---|---|---|
| RxDAn | Input | Serial data input signal |
| TxDAn | Output | Serial data output signal |
| CLKAn | Output | Serial clock output signal |

Note: n: Unit number (n = 0, 1)

## 30.2 Register Descriptions

### 30.2.1 TXBAn : Transmit Buffer Register n (n = 0, 1)

Base address: UARTA = 0x4009_7000

Offset address: 0x00 + 0x8 × n

| Bit position: | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|
| Bit field: | | | | | | | | |
| Value after reset: | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 7:0 | n/a | Transmit data buffer | R/W |

TXBAn is a buffer register for setting transmit data.

Transmission starts by writing data for transmission to the TXBAn register.

When a character length of 8 bits is specified:

- Data in bits [7:0] of TXBAn are transferred.

When a character length of 7 bits is specified:

- Data in bits [6:0] of TXBAn are transferred in either MSB- or LSB-first mode. Bit 7 is invalid.

When a character length of 5 bits is specified:

- Data in bits [4:0] of TXBAn are transferred in either MSB- or LSB-first mode. Bits [7:5] are invalid.

Note: When the TXBFA bit of the ASISAn register is 1, do not write data for transmission to the TXBAn register.

Note: After setting the TXEA bit of the ASIMAn0 register to 1, wait for the period of at least one cycle of the UARTAn operation clock ($f_{UTAn}$) before setting the first data for transmission in the TXBAn register. If data for transmission is set within one cycle of the UARTAn operation clock after the ASIMAn0.TXEA bit is set to 1, the start of transmission is delayed by one cycle of the UARTAn operation clock.

Note: Data is transferred from the TXBAn register to this register, and is then transmitted as serial data through the TxDAn pin. In the first transmission, data is transferred from the TXBAn register to this register immediately after data is written to the TXBAn register. In continuous transmission, data is transferred after transmission of one frame and just before generation of the transfer completion interrupt.

The transmit shift register cannot be manipulated directly by software.

### 30.2.2 RXBAn : Receive Buffer Register n (n = 0, 1)

Base address: UARTA = 0x4009_7000

Offset address: 0x01 + 0x8 × n

| Bit position: | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|
| Bit field: | | | | | | | | |
| Value after reset: | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 7:0 | n/a | Receive data buffer | R |

The RXBAn register stores the parallel data converted by the receive shift register. Every time one byte of data is received, the next receive data is transferred from the receive shift register *1 to this register.

Note 1. The receive shift register converts the serial data that is input through the RxDAn pin to parallel data.

The receive shift register cannot be manipulated directly by software.

When a character length of 8 bits is specified:

- Receive data is transferred to bits [7:0] of this register.

When a character length of 7 bits is specified:

- Receive data is transferred to bits [6:0] of this register in either MSB- or LSB-first mode. Bit 7 is always 0.

When a character length of 5 bits is specified:

- Receive data is transferred to bits [4:0] of this register in either MSB- or LSB-first mode. Bits [7:5] are always 0.

Note: If an overrun error (ASISAn.OVEA) occurs, the data received at that time is not stored in the RXBAn register.

## 30.2.3 ASIMAn0 : Operation Mode Setting Register n0 (n = 0, 1)

Base address: UARTA = 0x4009_7000

Offset address: 0x02 + 0x8 × n

| Bit position: | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|
| Bit field: | EN | TXEA | RXEA | — | — | — | ISSMA | ISRMA |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 1 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 0 | ISRMA | Receive interrupt mode select<br>0: The UARTAn_ERI interrupt is generated when a reception error occurs (UARTAn_RXI is not generated)<br>1: The UARTAn_RXI interrupt is generated when a reception error occurs (UARTAn_ERI is not generated) | R/W |
| 1 | ISSMA | Transmit interrupt mode select<br>0: The UARTAn_TXI interrupt is generated on completion of transmission<br>1: The UARTAn_TXI interrupt is generated when the transmit buffer becomes empty (for continuous transmission) | R/W |
| 4:2 | — | These bits are read as 0. The write value should be 0.*1 | R/W |
| 5 | RXEA | Reception enable<br>0: Disables reception (reset the reception circuit)<br>1: Enables reception | R/W |
| 6 | TXEA | Transmission enable<br>0: Disables transmission (resets the transmission circuit)<br>1: Enables transmission | R/W |
| 7 | EN*2 | UART operation enable<br>0: Disables the UART operation clock (resets the internal circuits*3)<br>1: Enables the UART operation clock | R/W |

Note 1. Be sure to clear bits [4:2] to 0.

Note 2. When EN = 0, the level being output from the TxDAn pin and the level being input from the RxDAn pin are determined according to the setting of the ASIMAn1.ALV bit as follows:
- When ASIMAn1.ALV = 0, output from the TxDAn pin is high.
- When ASIMAn1.ALV = 1, output from the TxDAn pin is low.

Note 3. The ASISAn and RXBAn registers are reset by clearing the EN bit to 0.

The ASIMAn0 register controls serial communication of the serial interface UARTAn.

To start transmission, set the EN bit to 1 and then set the TXEA bit to 1. To stop transmission, clear the TXEA bit to 0 and then clear the EN bit to 0.

To start reception, set the EN bit to 1 and then set the RXEA bit to 1. To stop reception, clear the RXEA bit to 0 and then clear the EN bit to 0.

Use the following procedure when setting the EN bit to 1 and then setting the RXEA bit to 1.

- When ASIMAn1.ALV = 0

The setting must be made while the level being input to the RxDAn pin is high. Otherwise, reception starts at that point and a framing error may occur.

- When ASIMAn1.ALV = 1
  The setting must be made while the level being input to the RxDAn pin is low. Otherwise, reception starts at that point and a framing error may occur.

The TXEA and RXEA bits are synchronized with the UARTAn operation clock ($f_{UTAn}$).

To enable transmission or reception again, set the TXEA or RXEA bit to 1 at least two cycles of the UARTAn operation clock after clearing the TXEA or RXEA bit to 0. If the bit is set to 1 within two cycles of the UARTAn operation clock after the clearing, the transmission or reception circuit may not be able to initialize.

After setting TXEA bit to 1, wait for at least one cycle of the UARTAn operation clock ($f_{UTAn}$) before setting the transmit data in the TXBAn register.

Clear the RXEA bit to 0 before modifying the ISRMA bit.

## 30.2.4 ASIMAn1 : Operation Mode Setting Register n1 (n = 0, 1)

Base address: UARTA = 0x4009_7000

Offset address: 0x03 + 0x8 × n

| Bit position: | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|
| Bit field: | — | PS[1:0] | | CL[1:0] | | SL | DIR | ALV |
| Value after reset: | 0 | 0 | 0 | 1 | 1 | 0 | 1 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 0 | ALV | Transmission and reception level setting<br>0: Positive logic (wait state = high level, start bit = low level, stop bit = high level)<br>1: Negative logic (wait state = low level, start bit = high level, stop bit = low level) | R/W |
| 1 | DIR | Transmission and reception order setting<br>0: MSB-first<br>1: LSB-first | R/W |
| 2 | SL | Transmission stop bit length setting<br>0: Stop bit length = 1 bit<br>1: Stop bit length = 2 bits | R/W |
| 4:3 | CL[1:0] | Transmission and reception character length setting<br>0 0: Character length of data = 5 bits<br>0 1: Setting prohibited<br>1 0: Character length of data = 7 bits<br>1 1: Character length of data = 8 bits | R/W |
| 6:5 | PS[1:0] | Transmission and reception parity bit setting<br>0 0: Transmission: No parity bit is output.<br>Reception: Data is received without parity.<br>0 1: Transmission: 0 parity is output.<br>Reception: Data is received with 0 parity.*1<br>1 0: Transmission: Odd parity is output.<br>Reception: A check is made for odd parity.<br>1 1: Transmission: Even parity is output.<br>Reception: A check is made for even parity. | R/W |
| 7 | — | This bit is read as 0. The write value should be 0. | R/W |

Note 1. When “Data is received with 0 parity” is set, parity check is not performed. Accordingly, the PEA bit of the ASISAn register is not set (no reception error interrupts are generated).

The ASIMAn1 register controls serial communication of the serial interface UARTAn.

The ASIMAn1 register must be modified while ASIMAn0.TXEA = 0 and ASIMAn0.RXEA = 0.

Clear both the ASIMAn0.TXEA and RXEA bits to 0 before modifying the ASIMAn1 register. Reception is always handled as including a stop bit. The setting of the SL bit does not affect reception.

## 30.2.5 BRGCAn : Baud Rate Generator Control Register n (n = 0, 1)

Base address: UARTA = 0x4009_7000

Offset address: 0x04 + 0x8 × n

| Bit position: | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|
| Bit field: | | | | | | | | |
| Value after reset: | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 7:0 | n/a | Controls the UART baud rate (serial transfer speed)<br>Selection of 8-bit counter output clock ($f_{UTAn}$/BRGCAn)<br>0x02: $f_{UTAn}$/2<br>0x03: $f_{UTAn}$/3<br>⋮ ⋮<br>0xFC: $f_{UTAn}$/252<br>0xFD: $f_{UTAn}$/253<br>0xFE: $f_{UTAn}$/254<br>0xFF: $f_{UTAn}$/255<br>Others: Setting prohibited | R/W |

The BRGCAn register sets the frequency divisor for the 8-bit counter in the serial interface UARTAn.

Modify the BRG[7:0] bits while the ASIMAn0.TXEA and RXEA bits are 0 (in the transmission and reception stopped state). The baud rate is one half the frequency of the output clock signal from the 8-bit counter. For an example of the baud rate setting, see (c) Baud rate setting example.

## 30.2.6 ASISAn : Status Register n (n = 0, 1)

Base address: UARTA = 0x4009_7000

Offset address: 0x05 + 0x8 × n

| Bit position: | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | TXBFA | TXSFA | — | PEA | FEA | OVEA |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 0 | OVEA | Overrun error flag<br>0: No error has occurred<br>1: An error has occurred | R |
| 1 | FEA | Framing error flag<br>0: No error has occurred<br>1: An error has occurred | R |
| 2 | PEA | Parity error flag<br>0: No error has occurred<br>1: An error has occurred | R |
| 3 | — | This bit is read as 0. | R |
| 4 | TXSFA | Transmit shift register data flag<br>0: Data is not being transmitted<br>1: Data is being transmitted | R |
| 5 | TXBFA | Transmit buffer data flag<br>0: No valid data exists in the TXBAn register<br>1: Valid data exists in the TXBAn register | R |
| 7:6 | — | These bits are read as 0. | R |

The ASISAn register indicates the error status and the transmission status on completion of reception by the serial interface UARTAn. It consists of three error flag bits (PEA, FEA, and OVEA) and two transmission status flag bits (TXBFA and TXSFA).

The PEA, FEA, and OVEA bits are initialized by clearing the ASIMAn0.EN or RXEA bit to 0. These bits are also cleared by writing to the corresponding bit of the ASCTAn register. The TXBFA and TXSFA flags are initialized by clearing the ASIMAn0.EN or TXEA bit to 0.

For continuous transmission, be sure to check that the TXBFA flag is 0 after writing the first transmit data (the first byte) to the TXBAn register and then write the next transmit data (the second byte) to the TXBAn register. Otherwise, the transmit data becomes undefined. However, the TXBFA flag need not be checked when continuous transmission is performed using the buffer empty interrupt (ASIMAn0.ISSMA bit = 1).

When initializing the transmission unit (ASIMAn0.TXEA = 0) after completion of continuous transmission, be sure to check that the TXSFA flag is 0 after the transfer completion interrupt is generated, and then initialize the unit. Otherwise, the transmit data becomes undefined.

The operation of the PEA bit depends on the setting of the PS[1:0] bits of the ASIMAn1 register. For receive data, only the first one bit of the stop bits is checked regardless of the stop bit length. When an overrun error occurs, the next receive data is not written to the RXBAn register and is discarded.

#### OVEA flag (Overrun error flag)

[Clearing condition]

- The ASIMAn0.EN or RXEA bit is cleared to 0.
- 1 is written to the ASCTAn.OVECTA bit.

[Setting condition]

- The next reception is completed before the receive data in the RXBAn register is read.

#### FEA flag (Framing error flag)

[Clearing condition]

- The ASIMAn0.EN or RXEA bit is cleared to 0.
- 1 is written to the ASCTAn.FECTA bit.

[Setting condition]

- A stop bit is not detected when receiving data.

#### PEA flag (Parity error flag)

[Clearing condition]

- The ASIMAn0.EN or RXEA bit is cleared to 0.
- 1 is written to the ASCTAn.PECTA bit.

[Setting condition]

- The parity of the received data does not match the parity bit.

#### TXSFA flag (Transmit shift register data flag)

[Clearing condition]

- The ASIMAn0.EN or TXEA bit is cleared to 0.
- Data is transferred from the transmit shift register and then no subsequent data is transferred from the TXBAn register.

[Setting condition]

- Data is transferred from the TXBAn register. (Data is being transmitted.)

#### TXBFA flag (Transmit buffer data flag)

[Clearing condition]

- The ASIMAn0.EN or TXEA bit is cleared to 0.
- Data is transferred to the transmit shift register.

[Setting condition]

- Data is written to the TXBAn register. (Data exists in the TXBAn register.)

## 30.2.7 ASCTAn : Status Clear Trigger Register n (n = 0, 1)

Base address: UARTA = 0x4009_7000

Offset address: 0x06 + 0x8 × n

| Bit position: | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | — | — | PECTA | FECTA | OVECTA |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 0 | OVECTA*1 | Overrun error flag clear trigger<br>0: Does not clear the ASISAn.OVEA flag (the flag is retained)<br>1: Clears the ASISAn.OVEA flag | R/W |
| 1 | FECTA*1 | Framing error flag clear trigger<br>0: Does not clear the ASISAn.FEA flag (the flag is retained)<br>1: Clears the ASISAn.FEA flag | R/W |
| 2 | PECTA*1 | Parity error flag clear trigger<br>0: Does not clear the ASISAn.PEA flag (the flag is retained)<br>1: Clears the ASISAn.PEA flag | R/W |
| 7:3 | — | These bits are read as 0. The write value should be 0. | R/W |

Note 1. When reading the ASCTAn register, 0 is returned.

The ASCTAn register sets the trigger to clear the error status on completion of reception of the serial interface UARTAn. It contains 3 bits of the error clear trigger flags (PECTA, FECTA, and OVECTA).

When the ASCTAn register is read, 0x00 is always read.

Writing 1 to the PECTA, FECTA, and OVECTA bits clears the PEA, FEA, and OVEA flags of the ASISAn register, respectively. When writing 0, the corresponding error flags are not cleared.

After writing 1 to the trigger bit, the corresponding error flag is cleared on the next rising edge of the operating clock ($f_{UTAn}$). Accordingly, if reading the ASISAn register immediately after writing 1 to the trigger bit, the corresponding error flag may not have been cleared yet.

## 30.2.8 UTA0CK : UARTA Clock Select Register 0

Base address: UARTA = 0x4009_7000

Offset address: 0x10

| Bit position: | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|
| Bit field: | EN | — | SEL[1:0] | | CK[3:0] | | | |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 3:0 | CK[3:0] | UARTA0 operation clock select ($f_{UTA0}$)<br>0x0: $f_{SEL}$<br>0x1: $f_{SEL}/2$<br>0x2: $f_{SEL}/4$<br>0x3: $f_{SEL}/8$<br>0x4: $f_{SEL}/16$<br>0x5: $f_{SEL}/32$<br>0x6: $f_{SEL}/64$<br>0x8: UARTLCLK<br>0x9: UARTSCLK<br>Others: Setting prohibited | R/W |
| 5:4 | SEL[1:0] | $f_{SEL}$ clock select<br>0 0: Stop<br>0 1: UARTAMCLK<br>1 0: UARTAHCLK<br>1 1: UARTAMOCLK | R/W |
| 6 | — | This bit is read as 0. The write value should be 0. | R/W |
| 7 | EN | UARTA0 clock output function enable<br>0: Disables CLKA0 output<br>1: Enables CLKA0 output | R/W |

Note:
- $f_{SEL}$: Selected clock to be divided for the UARTA
- UARTAMCLK: UARTA external clock
- UARTASCLK: UARTA sub clock
- UARTAHCLK: UARTA HOCO clock
- UARTAMOCLK: UARTA MOCO clock
- UARTALCLK: UARTA LOCO clock
- PCLKB > $f_{UTA0}$

The UTA0CK register selects the operating clock of the UARTAn. The SEL[1:0] bits select the clock source, $f_{SEL}$, for UARTAn from UARTAMCLK, UARTAHCLK, and UARTAMOCLK. The CK[3:0] bits select the operating clock for UARTA0 from $f_{SEL}$ to $f_{SEL}/64$, UARTALCLK, and UARTASCLK.

Setting the EN bit to 1 selects the UARTA0 clock output mode, and the operating clock for UARTA0 is output from the CLKA0 pin.

This register should be read or written when the ASIMAn0.TXEA and RXEA bits are 0 (in the transmission and reception stopped state).

## 30.2.9 UTA1CK : UARTA Clock Select Register 1

Base address: UARTA = 0x4009_7000

Offset address: 0x11

| Bit position: | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|
| Bit field: | EN | — | — | — | CK[3:0] | | | |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 3:0 | CK[3:0] | UARTA1 operation clock select ($f_{UTA1}$)<br>0x0: $f_{SEL}$<br>0x1: $f_{SEL}/2$<br>0x2: $f_{SEL}/4$<br>0x3: $f_{SEL}/8$<br>0x4: $f_{SEL}/16$<br>0x5: $f_{SEL}/32$<br>0x6: $f_{SEL}/64$<br>0x8: UARTLCLK<br>0x9: UARTSCLK<br>Others: Setting prohibited | R/W |
| 6:4 | — | These bits are read as 0. The write value should be 0. | R/W |
| 7 | EN | UARTA1 clock output function enable<br>0: Disables CLKA1 output<br>1: Enables CLKA1 output | R/W |

Note:
- $f_{SEL}$: Selected clock to be divided for the UARTA
- UARTALCLK: UARTA LOCO clock
- UARTASCLK: UARTA sub clock
- PCLKB > $f_{UTA1}$

The UTA1CK register selects the operating clock of UARTA1. The CK[3:0] bits select the operating clock for UARTA1 from $f_{SEL}$ to $f_{SEL}/64$, UARTALCLK, and UARTASCLK.

Setting the EN bit to 1 selects the UARTA1 clock output mode, and the operating clock for UARTA1 is output from the CLKA1 pin.

This register should be read or written when the ASIMA10.TXEA and RXEA bits are 0 (in the transmission and reception stopped state).

## 30.3 Operation

UARTAn operates in the following two modes:

- Operation stop mode
- UART mode

### 30.3.1 Operation Stop Mode

In the operation stop mode, serial communication is not performed, and thus the power consumption can be reduced. In addition, in this mode, the pins can be used as ordinary port pins. To set the operation stop mode, clear the EX, TXEA, and RXEA bits of the ASIMAn0 register to 0.

### 30.3.2 UART Mode

In this mode, one byte of data is transmitted and one byte is received following the start bit. This means, operation is full duplex.

A dedicated UART baud rate generator is incorporated, so that communication can be executed at a wide range of baud rates.

#### (1) Communication procedure

Table 30.3 shows the step of communication procedure.

**Table 30.3 Step of communication procedure**

| Step | | Process | Detail |
|---|---|---|---|
| Step of communication procedure | <1> | Enable clock supply | Set bit 0 of the MSTPCRB register to 0. |
| | <2> | Baud rate setting | Set the BRGCAn register. |
| | <3> | Operation mode setting 1 | Set the ALV, DIR, SL, CL[1:0], and PS[1:0] bits of the ASIMAn1 register. |
| | <4> | Operation mode setting 2 | Set the ISSMA and ISRMA bits of the ASIMAn0 register. |
| | <5> | Enable operation | Set the EN bit of the ASIMAn0 register to 1. |
| | <6> | Enable communication | Set the TXEA bit of the ASIMAn0 register to 1 to enable transmission.<br>Set the RXEA bit of the ASIMAn0 register to 1 to enable reception. |
| | <7> | Write transmit data | Write transmit data to the TXBAn register. |
| | <8> | Start of transmission | — |

Note: Specify I/O port settings to enable input and output functions as required for TXDAn, RXDAn, and CLKAn pins in advance. For details, see section 18, I/O Ports.
Note: n: Unit number (n = 0, 1)

## (2) Format and waveform example of transmit and receive data

This section describes the communication data format of UARTAn.

Figure 30.2 shows the data format.

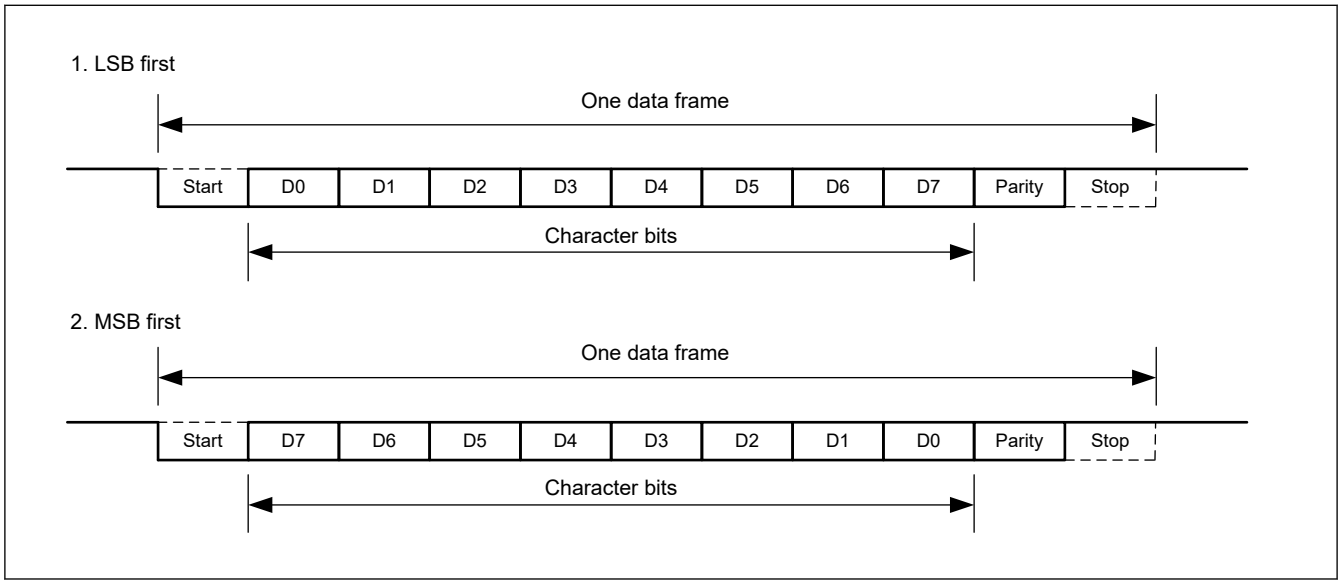

**Figure 30.2 Transmit and receive data format**

One data frame consists of the following bits.

- Start bit: 1 bit
- Character bits: 5, 7 or 8 bits
- Parity bit: Even parity, odd parity, 0 parity, or no parity
- Stop bit: 1 or 2 bits

The character bit length, the parity, the stop bit length, the transfer direction (LSB or MSB first), and the TxDAn pin output (direct or inverted) in one data frame are specified by the ASIMAn1 register.

Note: n: Unit number (n = 0, 1)

Figure 30.3 shows the examples of transmit and receive data waveforms.

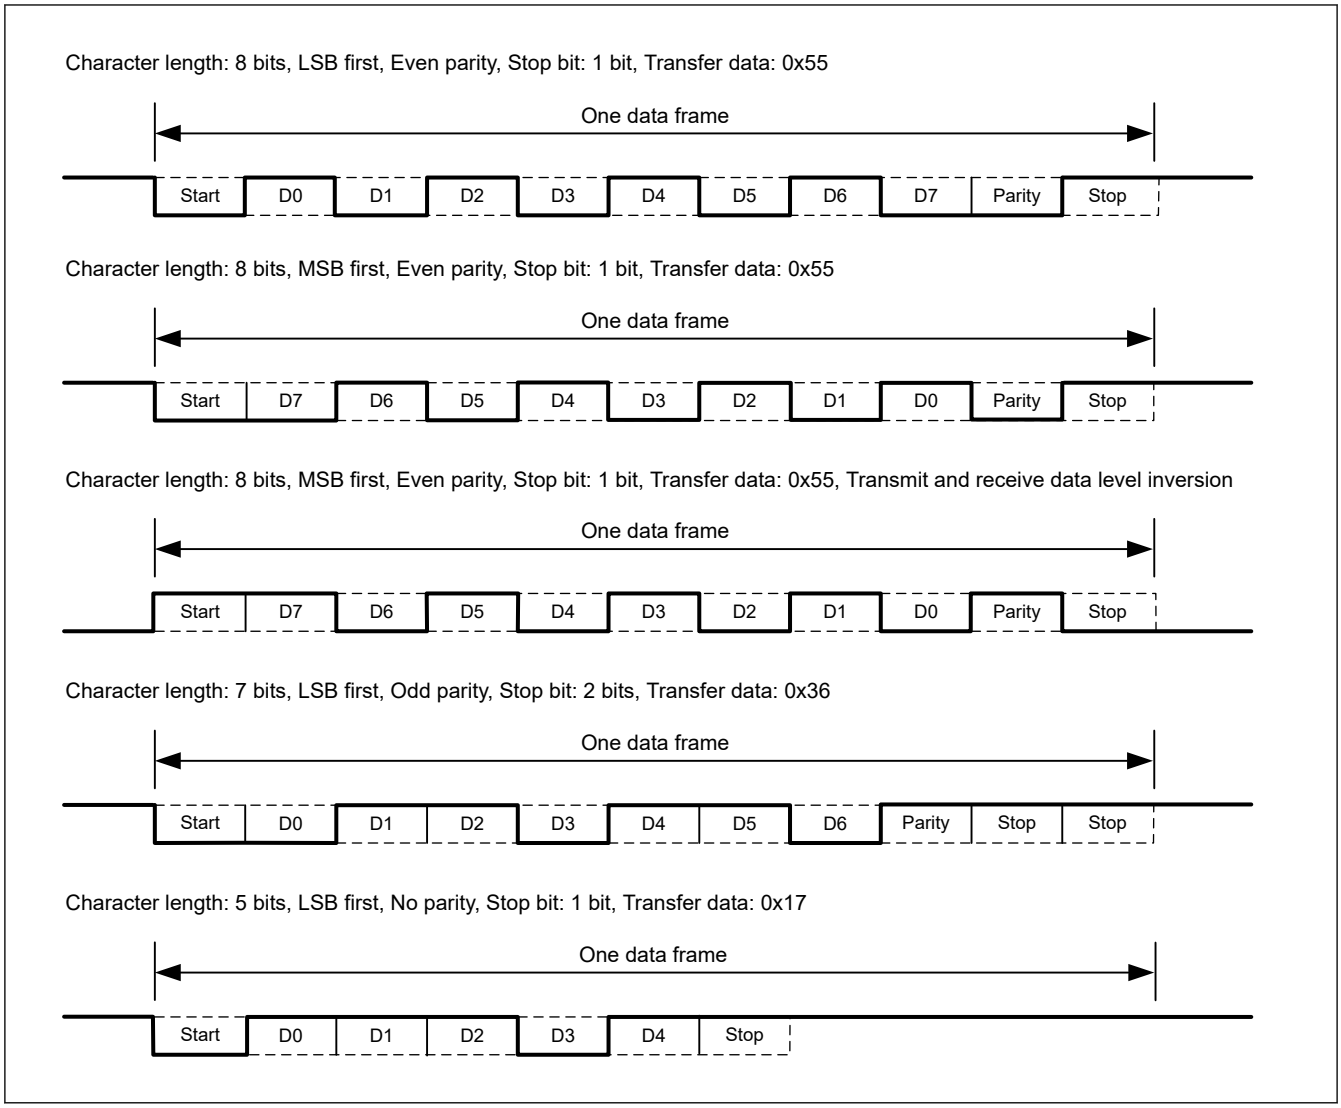

**Figure 30.3 Example of transmit and receive data waveform**

## (3) Parity types and operation

The parity bit is used to detect a bit error in communication data. Usually, the same type of parity bit is used on both the transmitting and reception sides. With even and odd parity, a 1-bit (odd number) error can be detected. With zero and no parity, an error cannot be detected.

(a) Even parity

- In transmission
  Data for transmission, including the parity bit, are controlled so that an even number of bits have the value 1. The value of the parity bit is set as follows.
  If the data for transmission have an odd number of bits with the value 1:1
  If the data for transmission have an even number of bits with the value 1:0
- In reception
  In the data for reception, including the parity bit, the number of bits with the value 1, is counted. If it is odd, a parity error occurs.

(b) Odd parity

- In transmission
  Unlike even parity, data for transmission, including the parity bit, are controlled so that an odd number of bits have the value 1.
  If the data for transmission have an odd number of bits with the value 1:0
  If the data for transmission have an even number of bits with the value 1:1

- In reception
  In the data for reception, including the parity bit, the number of bits with the value 1, is counted. If it is even, a parity error occurs.

(c) 0 parity

The parity bit is cleared to 0 when data is transmitted, regardless of the transmit data.

The parity bit is not detected when the data is received. Therefore, a parity error does not occur regardless of whether the parity bit is 0 or 1.

(d) No parity

No parity bit is appended to the transmit data.

Reception is performed assuming that there is no parity bit. A parity error does not occur, because there is no parity bit.

### (4) Normal transmission

Transmission is enabled by setting the EN bit of the operation mode setting register 0 (ASIMAn0) to 1 and then setting the TXEA bit of ASIMAn0 to 1. Transmission can be started by writing the data for transmission to the transmission buffer register (TXBAn). The start bit, parity bit, and stop bit are automatically appended to the data. When transmission is started, the data in the TXBAn register are transferred to the transmit shift register. After that, the transmit data are sequentially output from the transmit shift register to the TxDAn pin in the specified transfer direction. When transmission is completed, the parity and stop bits which are set by the ASIMAn0 register are appended and a transfer completion interrupt request signal (UARTAn_TXI) is generated.

Transmission is suspended until the next transmit data is written to the TXBAn register.

Figure 30.4 shows the timing of the transfer completion interrupt request signal (UARTAn_TXI). UARTAn_TXI is issued at the following timing.

a. When ASIMAn0.ISSMA = 0 (UARTAn_TXI functions as a transfer completion interrupt.)
   UARTAn_TXI is issued after the output of the last stop bit.
b. ASIMAn0.ISSMA = 1 (UARTAn_TXI functions as a buffer empty interrupt.)
   UARTAn_TXI is issued when the start bit is output.

Note: n: Unit number (n = 0, 1)

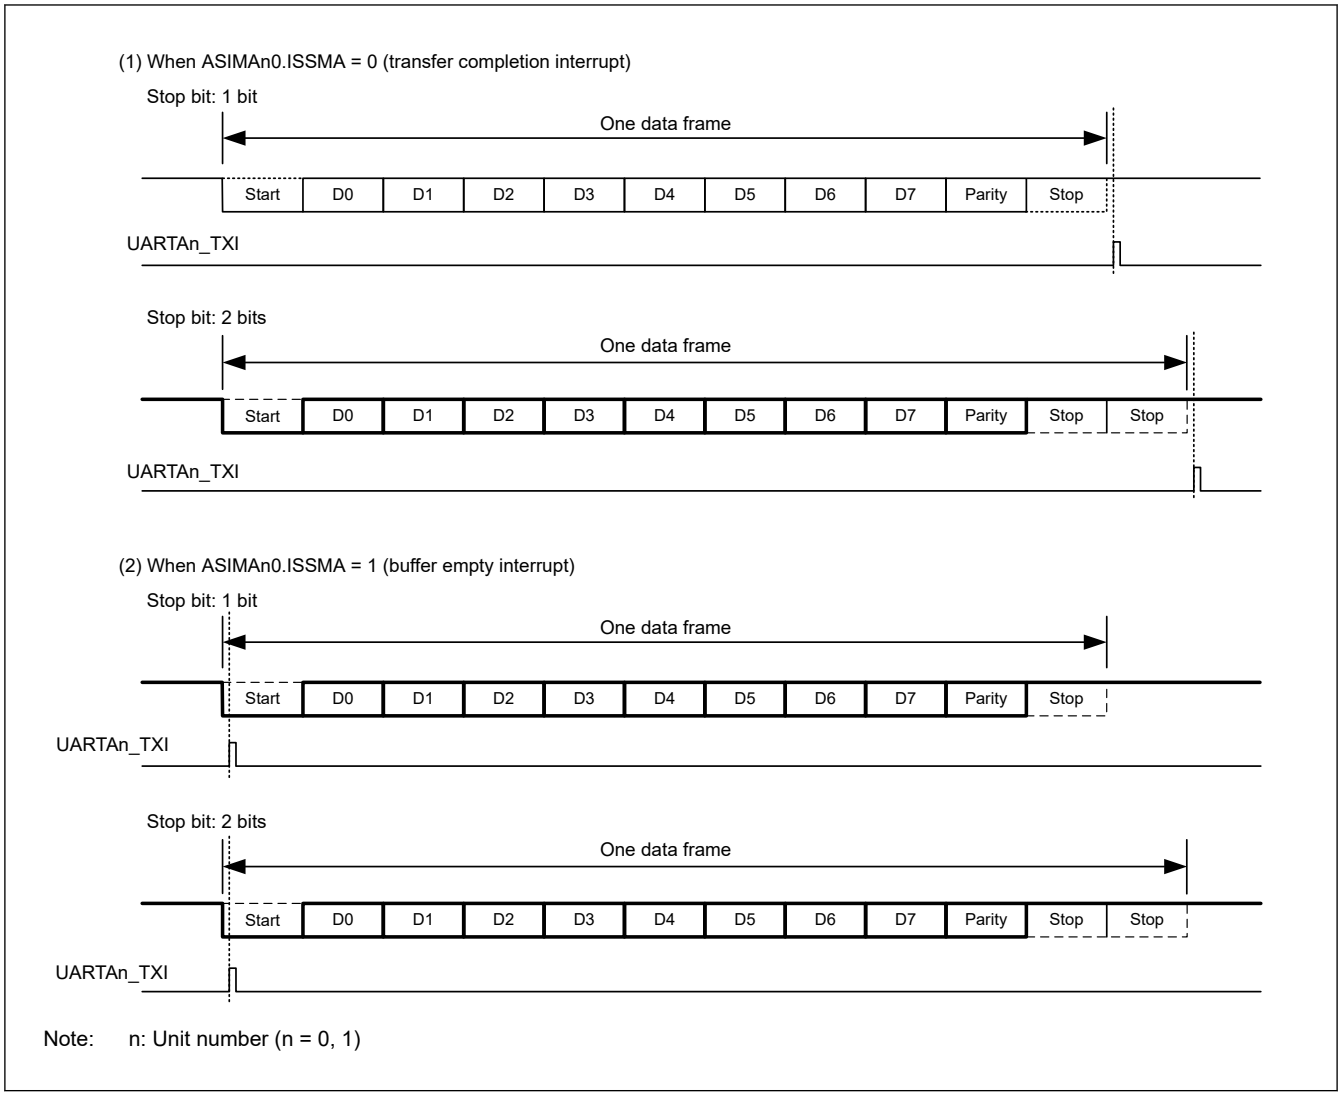

**Figure 30.4 Interrupt output timing**

## (5) Continuous transmission

UARTAn has two separate registers for continuous transmission: the transmit buffer register (TXBAn) and the transmit shift register.

At the moment the transmit shift register starts a shift operation, the next transmit data can be written to the transmit buffer register (TXBAn). This operation enables continuous transmission, thereby improving communication rate.

Note that continuous transmission is not achieved when writing to the TXBAn register is not completed within the maximum number of clock cycles defined below from generation of the buffer empty interrupt.

Maximum number of clock cycles = Data transfer length × 2k − (2k + 3)

k: the value set with the BRGCAn register (k = 2, 3, 4, 5, 6, …, 255)

An example of calculating the maximum number of clock cycles is described below. When the BRGCAn register = 0x02 (k = 2),

start bit = 1 bit, character length = 8 bits, parity used, and stop bit = 1 bit:

The maximum number of clock cycles = Transfer length × 2k − (2k + 3) = 11 × 2 × 2 − (2 × 2 + 3) = 37

(Writing must be completed within 37 cycles of the UARTAn operating clock ($f_{UTAn}$).)

Continuous transmission is achieved by the following two methods.

(a) Continuous transmission by polling

Continuous transmission is achieved by polling the TXBFA and TXSFA flags of the status register (ASISAn).

When using this method, clear the ISSMA bit of the operation mode setting register 0 (ASIMAn0) to 0.

### At the start of and during continuous transmission

At the start of continuous transmission, write the first byte of data to the TXBAn register, check that the transmit buffer data flag (ASISAn.TXBFA) is 0, and then write the second byte of data. Similarly, check that the ASISAn.TXBFA flag is 0 and then write the subsequent data to the TXBAn register.

Table 30.4 shows the determination flag indicating that writing to the TXBAn register is enabled or disabled at the start of continuous transmission.

**Table 30.4 Determination flag indicating that writing to the TXBAn register is enabled or disabled at the start of continuous transmission**

| ASISAn.TXBFA | Description |
|---|---|
| 0 | Writing is enabled. |
| 1 | Writing is disabled. |

Note: To determine if continuous transmission is enabled or disabled, only check the ASISAn.TXBFA flag. The ASISAn.TXSFA flag must not be used for the determination in combination with this flag.
Note: n: Unit number (n = 0, 1)

### Completion of continuous transmission

In continuous transmission, when data in the transmit shift register and the TXBAn register are transmitted after the required number of transmit data are written to the TXBAn register, the continuous transmission is completed. To confirm the completion, check the setting of the transmit shift register data flag (ASISAn.TXSFA).

Table 30.5 shows the confirmation flag indicating whether transmission is in progress or not.

**Table 30.5 Confirmation flag indicating whether transmission is in progress or not**

| ASISAn.TXSFA | Description |
|---|---|
| 0 | Transmission is completed. |
| 1 | Transmission is in progress. |

Note: When initializing the transmission unit after completion of continuous transmission, check that the ASISAn.TXSFA flag is 0 after the transfer completion interrupt is generated, and then initialize the unit.
Note: During continuous transmission, after transmission of one data frame, the subsequent transmission may be completed before execution of the UARTAn_TXI interrupt processing.
This can be detected by incorporating the program that counts the number of transmit data and by referencing the ASISAn.TXSFA flag.
Note: n: Unit number (n = 0, 1)

Table 30.6 shows a step example of continuous transmission processing by polling.

**Table 30.6 Step example of continuous transmission processing by polling**

| Step | | Process | Detail |
|---|---|---|---|
| Step example of continuous transmission processing by polling | <1> | Set registers | ASIMAn0.ISSMA = 0 |
| | <2> | Check if the required number of transmit data are written to the TXBAn register.<br>If yes, go to <5><br>If no, go to <3> | — |
| | <3> | Wait until the ASISAn.TXBFA flag is cleared. | Data is transferred to the transmit shift register. |
| | <4> | Write transmit data to the TXBAn register.<br>Go to <2> | — |
| | <5> | Wait until the ASISAn.TXSFA flag is cleared. | Data is transferred from the transmit shift register and then no subsequent data is transferred from the TXBAn register. |
| | <6> | End of transmission processing | — |

Note: n: Unit number (n = 0, 1)

(b) Continuous transmission by using an interrupt

Continuous transmission is achieved by using the interrupt (UARTAn_TXI).

An interrupt can be generated when data in the transmit buffer register (TXBAn) are transferred to the transmit shift register by setting the ISSMA bit to 1 in the operation mode setting register 0 (ASIMAn0).

With this setting, continuous transmission is enabled by writing data to the TXBAn register on occurrence of the buffer empty interrupt.

In addition, the transfer completion interrupt can be generated on completion of continuous transmission by clearing the ISSMA bit to 0 after writing the last transmit data to the TXBAn register.

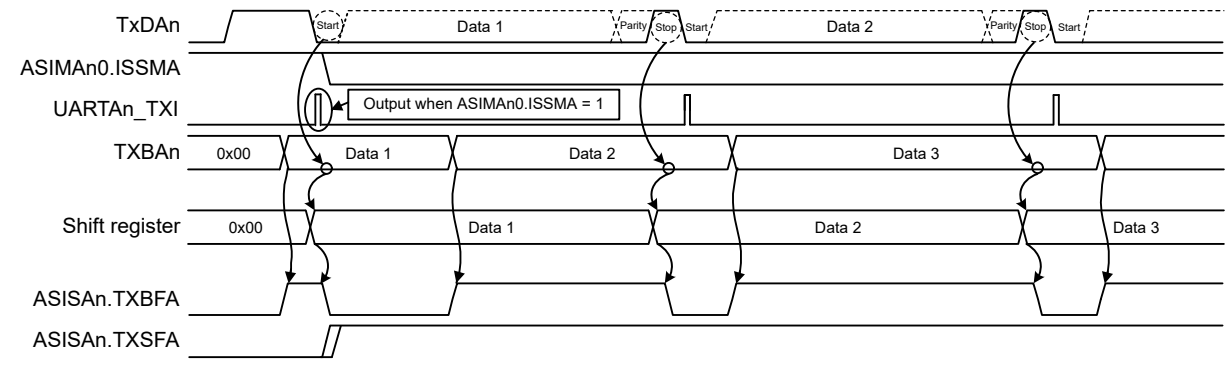

Table 30.7 shows a step example of continuous transmission using interrupt.

**Table 30.7 Step example of continuous transmission using interrupt**

| Step | | Process | Detail |
|---|---|---|---|
| Step example of continuous transmission using interrupt | <1> | Set registers | ASIMAn0.ISSMA = 1 |
| | <2> | Write to the TXBAn register | — |
| | <3> | Waiting for UARTAn_TXI | Buffer empty interrupt |
| | <4> | Generation of UARTAn_TXI | — |
| | <5> | Check if the required number of transmit data are written to the TXBAn register.<br>If yes, go to step <6>.<br>If no, go to step <2>. | — |
| | <6> | Set the ASIMAn0 register | ASIMAn0.ISSMA = 0 |
| | <7> | Waiting for UARTAn_TXI | Transfer completion interrupt |
| | <8> | Generation of UARTAn_TXI | — |
| | <9> | End of transmission processing | — |

Note: n: Unit number (n = 0, 1)

Figure 30.5 and Figure 30.6 show the timing when continuous transmission is started and completed, respectively.

Note: n: Unit number (n = 0, 1)

**Figure 30.5 Timing when continuous transmission is started**

Note: When the ASISAn register is read, both the ASISAn.TXBFA and TXSFA flags are read as 1 within this period. Accordingly, use only the ASISAn.TXBFA flag to determine if writing is enabled or disabled.

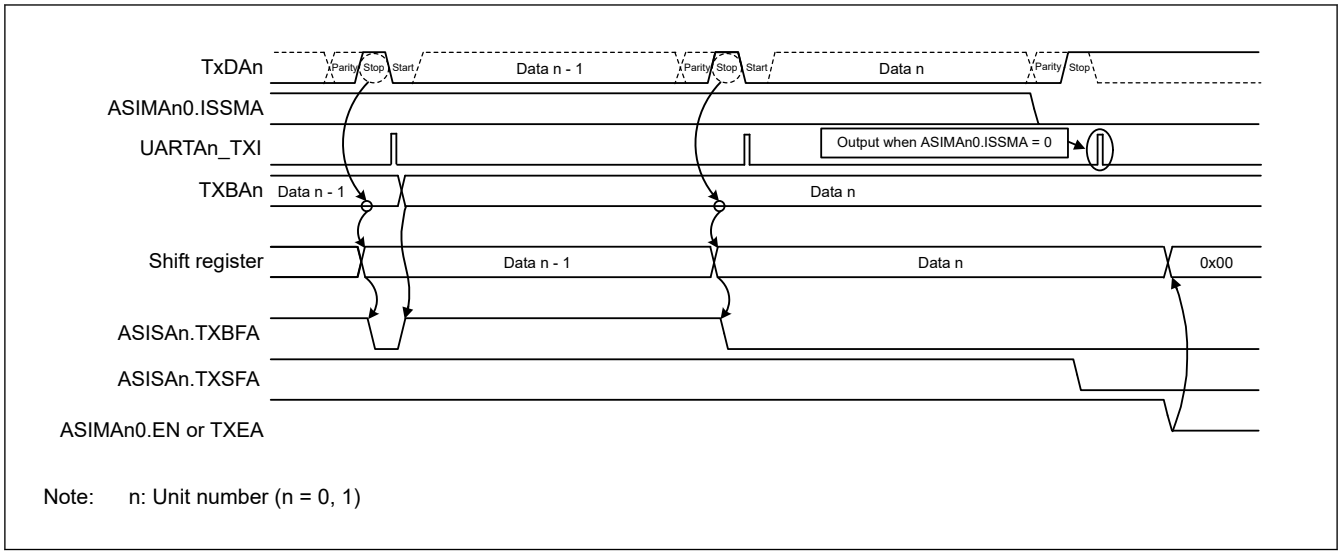

**Figure 30.6 Timing when continuous transmission is completed**

## (6) Normal reception

When setting the EN bit of the operation mode setting register 0 (ASIMAn0) to 1 and then setting the RXEA bit of the ASIMAn0 register to 1, reception is enabled, and sampling of the input to the RxDAn pin is performed.

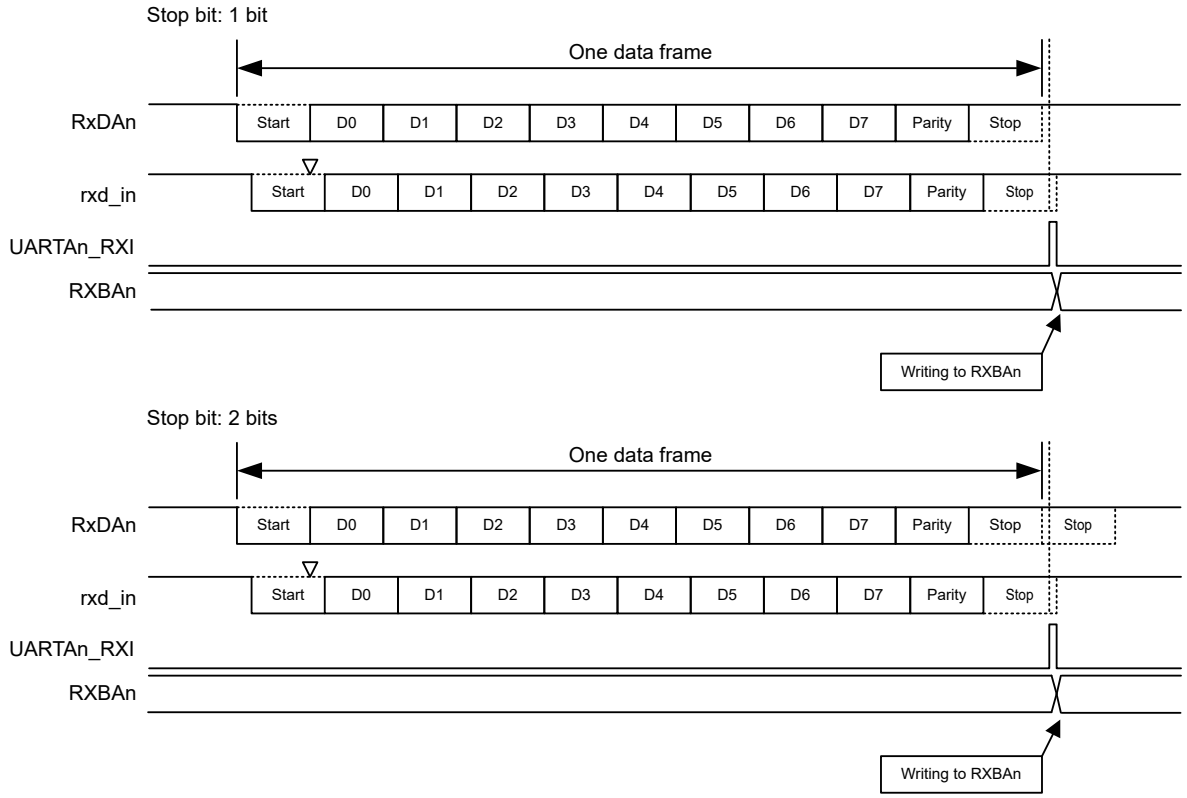
When the ASIMAn1.ALV bit is 0, the 8-bit counter of the baud rate generator starts counting on detection of the falling edge on the RxDAn pin. When the counter reaches the set value of the baud rate generator control register (BRGCAn), the input to the RxDAn pin is sampled again (at the point indicated with ∇ in Figure 30.7). If the RxDAn pin is low, it is regarded as a start bit.

When the ASIMAn1.ALV bit is 1, the 8-bit counter of the baud rate generator starts counting on detection of the rising edge on the RxDAn pin. When the counter reaches the set value of the baud rate generator control register (BRGCAn), the input to the RxDAn pin is sampled again (at the point indicated with ∇ in Figure 30.7). If the RxDAn pin is high, it is regarded as a start bit.

Figure 30.7 shows the timing chart of receive operation.

On detection of a start bit, receive operation is started: serial data is sequentially stored in the receive shift register at a specified baud rate. On reception of a stop bit, the transfer completion interrupt (UARTAn_RXI) is generated, and at the same time, the data in the receive shift register is written to the receive buffer register (RXBAn).

Note that when an overrun error (ASISAn.OVEA) occurs, the data received on occurrence of the error is not written to the RXBAn register.



When a parity error (ASISAn.PEA) or a framing error (ASISAn.FEA) occurs during reception, reception continues until a stop bit is received. After completion of the reception, the reception error interrupt (UARTAn_RXI or UARTAn_ERI) set in the ASIMAn0.ISRMA bit is generated.

When a reception error occurs, read the status register (ASISAn) and then read the receive buffer register (RXBAn) to clear the error flag.

If the receive buffer register (RXBAn) is not read, an overrun error will occur when the next data is received: the reception error state will continue.

Reception is always handled as including a stop bit. Accordingly, the second stop bit is ignored.

Note: n: Unit number (n = 0, 1)

Note: rxd_in: The internal signal generated by latching RxDAn with a noise filter
(rxd_in is delayed relative to RxDAn by maximum of 3 cycles of the UART operation clock.)
Note: The UARTAn_RXI output timing in the figure is just an example.
The timing relative to RxDAn varies according to the setting of the BRGCAn register.
Note: n: Unit number (n = 0, 1)

**Figure 30.7 Timing of UART receive operation**

## (7) Reception error

Three types of errors may occur during reception; parity error, framing error, and overrun error.

When these errors occur, the corresponding error flag in the status register (ASISAn) is set, and the reception error interrupt request signal (UARTAn_RXI or UARTAn_ERI) is generated.

The type of the reception error can be identified by the reception error interrupt processing routine, which reads and checks the contents of the status register (ASISAn).

The contents of the ASISAn register is cleared to 0 by setting the corresponding bit of the status clear trigger register (ASCTAn) to 1.

Table 30.8 shows the causes of the reception errors.

**Table 30.8 Causes of reception errors**

| Error flag | Reception error | Cause |
|---|---|---|
| ASISAn.PEA | Parity error | The parity specified for reception does not match the parity of receive data. |
| ASISAn.FEA | Framing error | No stop bit is detected. |
| ASISAn.OVEA | Overrun error | Before the receive data is read from the receive buffer, the next data reception is completed. |

Setting the ISRMA bit of the operation mode setting register 0 (ASIMAn0) to 0 allows the reception error interrupt to be separated from UARTAn_RXI and allows it to be generated as UARTAn_ERI.

Figure 30.8 shows the interrupt output waveform which varies depending on the setting of the ASIMAn0.ISRMA bit.

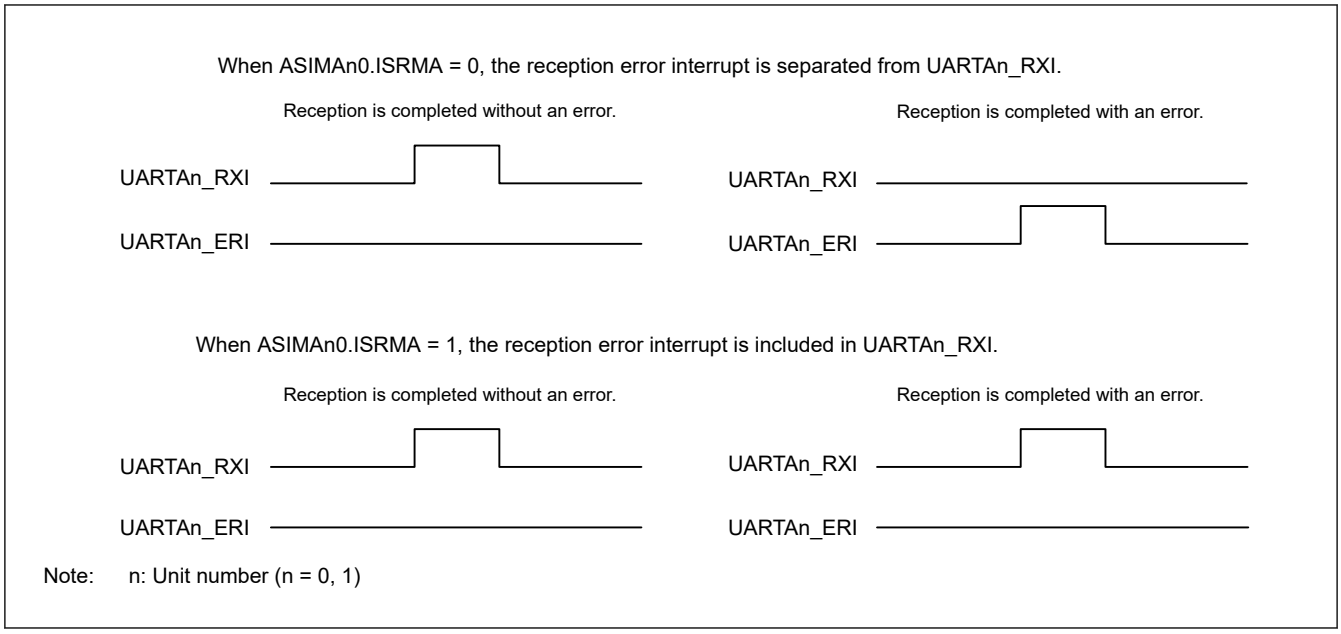


**Figure 30.8 Various interrupt output waveforms depending on ASIMAn0.ISRMA setting**

## 30.3.3 Receive Data Noise Filter

This filter samples the receive data (RxDAn), and determines the level when the same level is sampled twice.

The receive data is delayed by a maximum of 3 cycles of the operating clock because of the circuit configuration.

Figure 30.9 shows the noise filter circuit.

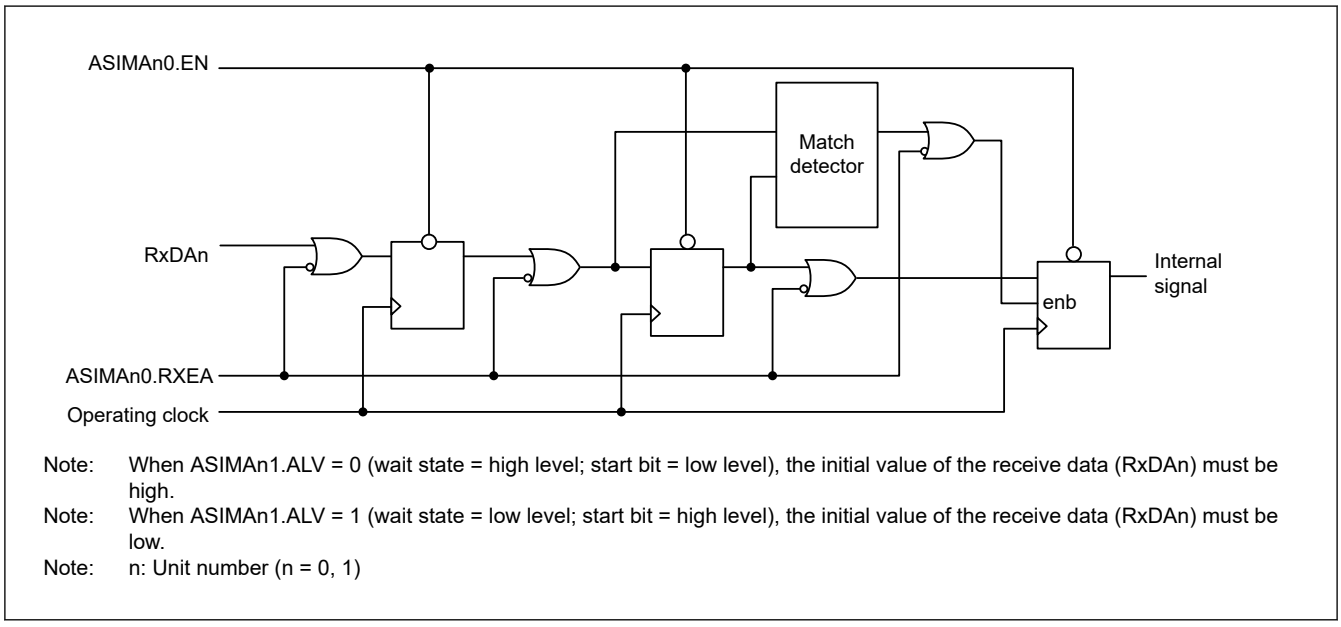

**Figure 30.9 Noise filter**

## 30.3.4 Baud Rate Generator

The baud rate generator consists of 8-bit programmable counters, and generates a serial clock for transmission and reception of UARTAn.

An 8-bit counter is provided each for transmission and reception.

### (1) Configuration of baud rate generator

(a) UARTAn operation clock

When ASIMAn0.EN = 1, the UARTAn operation clock ($f_{UTAn}$) is supplied to each module. When ASIMAn0.EN = 0, the UARTAn operation clock is fixed to low level.

(b) Transmission counter

This counter is cleared to 0 and stops when ASIMAn0.EN = 0 or ASIMAn0.TXEA = 0. It starts counting when ASIMAn0.EN = 1 and ASIMAn0.TXEA = 1.

The counter is cleared to 0 when the first transmit data is written to the transmit buffer register (TXBAn).

When continuous transmission is performed, the counter is cleared to 0 again when transmission of one frame of data has been completed. If there is no data to be transmitted next, the counter is not cleared to 0 and continues counting until the ASIMAn0.EN or TXEA bit is cleared to 0. When ASIMAn0.EN = 0 or ASIMAn0.TXEA = 0, the counter stops at 0x00.

(c) Reception counter

This counter is cleared to 0 and stops when ASIMAn0.EN = 0 or ASIMAn0.RXEA = 0. It starts counting when the start bit is detected.

The counter stops operation after one frame has been received, until the next start bit is detected. When ASIMAn0.EN = 0 or ASIMAn0.RXEA = 0, the counter stops at 0x00.

Note: n: Unit number (n = 0, 1)

Figure 30.10 shows the configuration of the baud rate generator.

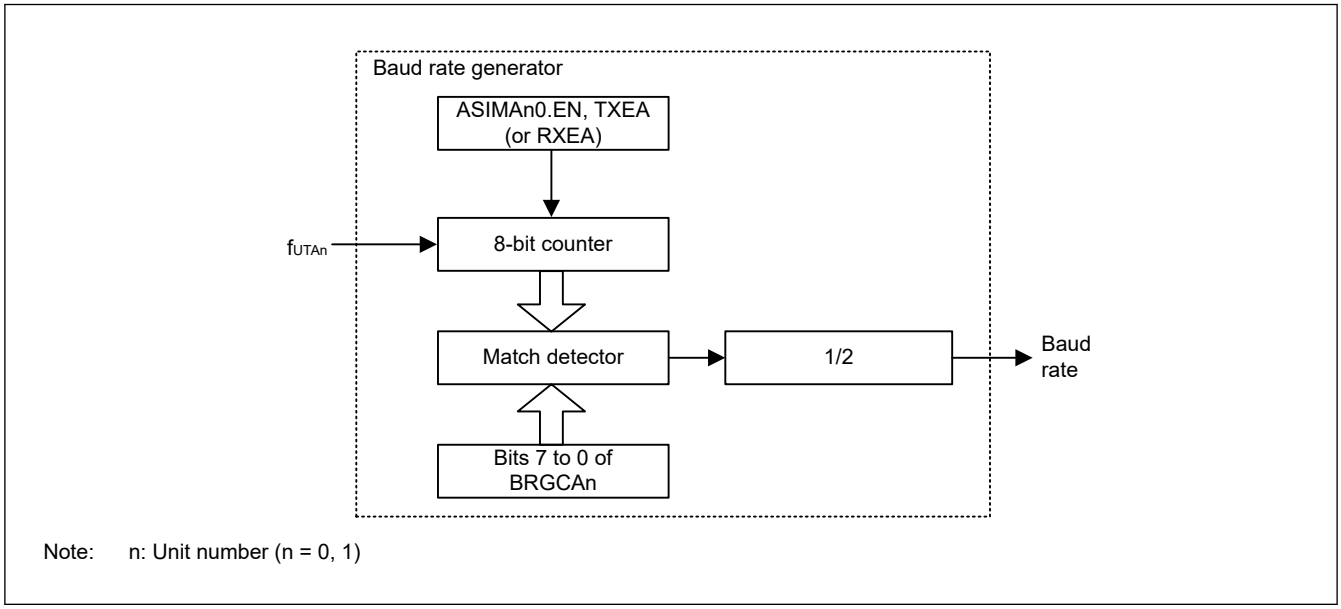

**Figure 30.10 Configuration of baud rate generator**

## (2) Generation of serial clock

A serial clock to be generated can be specified by using the baud rate generator control register (BRGCAn).

The baud rate generator divides the frequency of the input clock signal to the 8-bit counter ($f_{UTAn}$) by the divisor set by the BRGCAn register. The result of this division is further divided by 2 to produce the serial clock.

## (3) Baud rate calculation

(a) Baud rate calculation expression

The baud rate can be calculated by the following expression.

Baud rate = $f_{UTAn} \div (2 \times k)$ [bps]

$f_{UTAn}$: Frequency of operating clock

k: Value set by bits 7 to 0 of the BRGCAn register (k = 2, 3, 4, …, 255)

(b) Baud rate error

The baud rate error can be calculated by the following expression.

$$\text{Error} = \left[\frac{\text{Actual baud rate (baud rate with error)}}{\text{Desired baud rate (correct baud rate)}} - 1\right] \times 100[\%]$$

Note: Keep the baud rate error during transmission to within the permissible error range on the reception side.

Note: Make sure that the baud rate error during reception satisfies the permissible baud rate error range during reception. Permissible baud rate error during reception is described in (d) Permissible baud rate range during reception.

Note: n: Unit number (n = 0, 1)

(c) Baud rate setting example

Table 30.9 to Table 30.12 show the set data of the baud rate generator.

**Table 30.9 Set data of baud rate generator (1/4)**

| Desired baud rate | In operation with UARTAHCLK = 80 MHz (UTA0CK.SEL[1:0] = 10b) | | | | | | | | | | | | | |

| 300 bps | 55 | −0.70% |
| 600 bps | 27 | −1.14% |
| 1200 bps | 14 | −2.48% |

**Table 30.12 Set data of baud rate generator (4/4) (2 of 2)**

| Desired baud rate | In operation with UARTALCLK = 32.768 kHz (UTAnCK.CK[3:0] = 0x8) | |
|---|---|---|
| | k | Error from the desired baud rate |
| 2400 bps | 7 | −2.48% |
| 4800 bps | Disabled | |
| 9600 bps | Disabled | |
| 19200 bps | Disabled | |
| 38400 bps | Disabled | |
| 76800 bps | Disabled | |
| 115200 bps | Disabled | |
| 153600 bps | Disabled | |

Note:
- UARTAMCLK: UARTA external clock
- UARTASCLK: UARTA sub clock
- UARTAHCLK: UARTA HOCO clock
- UARTAMOCLK: UARTA MOCO clock
- UARTALCLK: UARTA LOCO clock

Note: k: Value set by bits 7 to 0 of the baud rate generator control register (BRGCAn) (k = 2, 3, 4, …, 255)
n: Unit number (n = 0, 1)

(d) Permissible baud rate range during reception

Figure 30.11 shows the permissible error from the baud rate on the transmitting side during reception.

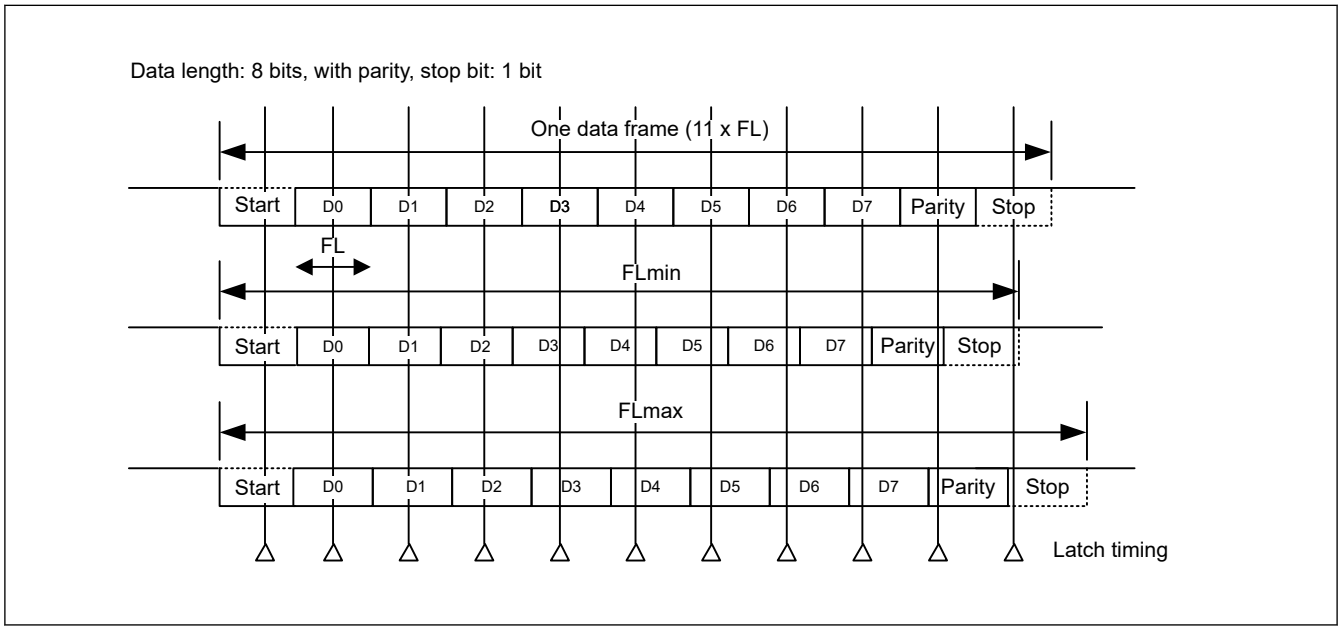

**Figure 30.11 Permissible baud rate range during reception**

Note: Be sure to make settings so that the baud rate error during reception is within the permissible error range. Use the calculation expression below to check if the error is within the permissible range.

After the start bit is detected, the latch timing of receive data is determined by the counter specified with the baud rate generator control register (BRGCAn). If the whole frame including the stop bit has been received before this latching, reception can proceed correctly.

Assuming that 11 bits of data are received, the theoretical values can be calculated as follows.

- The relation between 1-bit data length and baud rate
  FL = (Brate) - 1
  Brate: Baud rate of UART
  k: Set value of the BRGCAn register

FL: 1-bit data length
Margin of latch timing: 2 clock

- Minimum permissible data frame length (FLmin)
  $FLmin = 11 \times FL - \frac{k-2}{2k} \times FL = \frac{21k+2}{2k}FL$
- Maximum permissible baud rate for reception on the transmitting side (BRmax)
  $BRmax = \frac{22k+1}{22k}Brate \text{ (when } k = 2)$
  $BRmax = (FLmin/11)^{-1} = \frac{22k}{21k+2}Brate \text{ (when } k \geq 3)$
- Maximum permissible data frame length (FLmax)
  $FLmax = \frac{21k+2}{20k}FL \times 11$
- Minimum permissible baud rate for reception on the transmitting side (BRmin)
  $BRmin = \frac{22k-1}{22k}Brate \text{ (when } k = 2)$
  $BRmin = (FLmax/11)^{-1} = \frac{20k}{21k-2}Brate \text{ (when } k \geq 3)$

Table 30.13 shows the permissible baud rate error between UART and the transmitting side that can be calculated from the above minimum and maximum baud rate expressions.

**Table 30.13 Maximum and minimum permissible baud rate error**

| Division ratio (k) | Maximum permissible baud rate error | Minimum permissible baud rate error |
|---|---|---|
| 2 | +2.27% | −2.27% |
| 4 | +2.33% | −2.44% |
| 8 | +3.53% | −3.61% |
| 20 | +4.27% | −4.31% |
| 50 | +4.56% | −4.58% |
| 100 | +4.66% | −4.67% |
| 255 | +4.72% | −4.73% |

Note: The permissible error of reception depends on the number of bits in one frame, input clock frequency, and division ratio (k). The higher the input clock frequency and the division ratio (k), the higher the permissible error.
Note: k: Set value of the BRGCAn register
Note: n: Unit number (n = 0, 1)

## 30.4 Usage Notes

### 30.4.1 Port Setting for RxDAn Pin

When ASIMAn1.ALV = 0 (wait state = high level, start bit = low level), the initial value of receive data (RxDAn) must be high. When ASIMAn1.ALV = 1 (wait state = low level, start bit = high level), the initial value of receive data (RxDAn) must be low. Accordingly, port setting is required for the RxDAn pin before setting ASIMAn0.EN = 1.

### 30.4.2 Point for Caution when Selecting the UARTAn Operation Clock ($f_{UTAn}$)

When UARTAMOCLK is selected for $f_{UTAn}$, communication may not be executed correctly due to the oscillation frequency accuracy of the middle-speed on-chip oscillator. Adjust the accuracy, therefore, by using the MOCO user trimming control register (MOCOUTCR).

When the low-speed on-chip oscillator peripheral clock (UARTALCLK) is selected for $f_{UTAn}$, communication may not be executed correctly due to the oscillation frequency accuracy of the low-speed on-chip oscillator. Adjust the accuracy, therefore, by using the LOCO user trimming control register (LOCOUTCR).

# 31. CAN with Flexible Data-rate (CANFD)

## 31.1 Overview

The CAN with Flexible Data-rate (CANFD) supports the following functions:

- CAN with Flexible Data-rate.*1

Note 1. This feature is not available in the classical CAN function.

The CANFD module has a flexible message buffer and FIFO structure that meet the requirements of various applications. It also provides test modes to achieve high testability of the module that can be useful for power-on testing.

This specification describes of the CANFD module.

### 31.1.1 CANFD Module

**Table 31.1 CANFD module specifications (1 of 2)**

| Parameter | | Specifications |
|---|---|---|
| Communication | | CAN functionality conforms to CANFD ISO 11898-1 (2015) |
| Protocol engine version | | RS-CANFD_PE V3.0 |
| Data transfer rate | CANFD*1 | Up to 1 Mbps for arbitration phase and up to 8 Mbps for data phase |
| | Classical CAN | Up to 1 Mbps |
| Operation frequency of Peripheral module clock | | 40 MHz (PCLKB)<br>RAM clock: 80 MHz (PCLKA) |
| Data Link Layer (DLL) clock | | 8 MHz to 40 MHz<br>The following clocks can be selected.<br>● CANMCLK : External Oscillator Clock<br>● CANFDCLK : CANFD Core Clock |
| Input/Output pins | | CRXn/CTXn (n = 0) |
| CAN channels | | 1 channel |
| Selectable ID type | | 11-bit Standard ID |
| | | 11-bit Standard ID + 18-bit Extended ID |
| Selectable frame type | | Data frame (RTR = 0) (CAN and CANFD frames) |
| | | Remote frame (RTR = 1) (only CAN frames) |
| Variable data byte count for data frames | | DLC range: 0 to F |
| Message buffer | | Up to 16 reception message buffers |
| | | 4 transmit message buffers |
| | | 1 transmission queue<br>Automatic message transfer into transmission queues supported |
| FIFO number | | 2 reception FIFO buffers<br>1 COMMON FIFO individually configurable as:<br>● Reception FIFO<br>● Transmission FIFO |
| Automatic delay interval timer for transmission | | The delay timer can be applied to:<br>● Transmission FIFO |

**Table 31.1 CANFD module specifications (2 of 2)**

| Parameter | Specifications |
|---|---|
| Enhanced reception filtering | Support of 11 bits and 29 bits CAN identifier |
| | Programmable 29 bits CAN identifier acceptance filter mask for each entry |
| | Programmable routing capability for each FIFO and reception message buffers (up to 2 routing destinations) |
| | RTR and IDE masking |
| | Data Length Code (DLC) filter |
| | Message buffer payload overload protection |
| | Payload filter |
| | Updating Acceptance Filter List (AFL) entry during communication |
| General software support | Automatic label information added to receive message (for upper software layer support) |
| Timer | TX and RX Time Stamp function |
| Power down function | Module start stop function for CAN node (Channel and Global Sleep mode) |
| RAM | RAM ECC protected (2 bits error detection, 1-bit error correction) |
| Module-stop function | Module-stop state can be set to reduce power consumption. |
| TrustZone Filter | Security attribution can be set. |

Note 1. The maximum reliable communication bit-rate depends on board-design and environmental factors. Sufficient evaluation is recommended on actual target hardware.

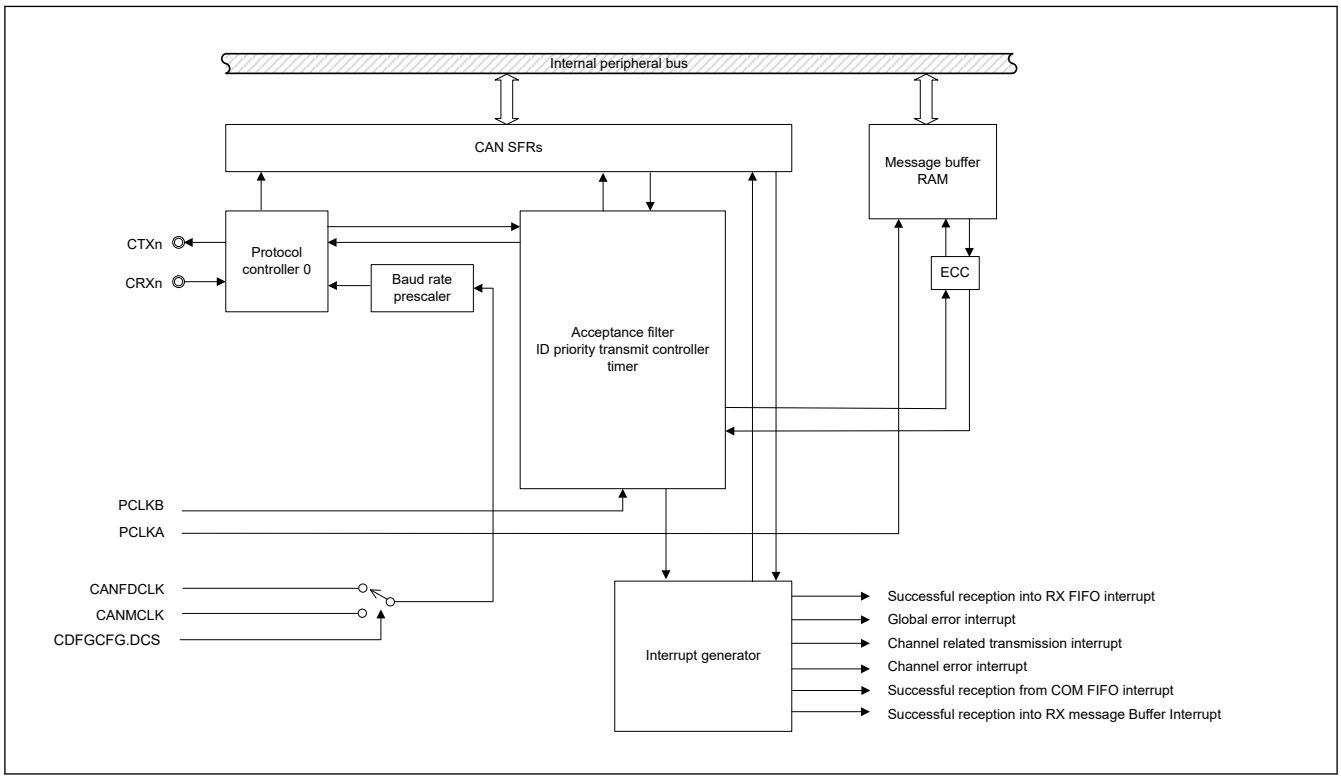

**Figure 31.1 Overview of the CANFD module**

- CRXn/CTXn:
  Input/Output pins of the CANFD module
- Protocol controller:
  Handles CAN protocol processing such as bus arbitration, bit timing at transmission and reception, stuffing, error handling

- Message buffer RAM (MBRAM):
  This RAM is used to store messages after reception or for transmission using a normal message buffer or a FIFO. Each message entry has an individual ID, data length code, data field, message pointer for upper layer application usage and a time stamp.
  This RAM is used to store the message acceptance filtering entries. Each acceptance filter entry has an individual ID, data length code, data field, message pointer for upper layer application usage and message direction pointer.
- Acceptance filter list RAM (AFLRAM):
  Performs filtering of received messages. The entries in the Acceptance filter list RAM are used for the filtering process.
- Two timers:
  - Reception Timestamp function
  - Transmission separation time for FIFO buffers
- Interrupt generator:
  Generates several types of global and channel interrupts
- CAN Special Function Registers (SFRs):
  Registers associated with CAN. See section 31.2. Register Descriptions.

### 31.1.2 Clock restriction

For the CAN communication the following restriction for the clocks should be satisfied:

- PCLKA/2 = PCLKB ≥ CANFDCLK
- PCLKA/2 = PCLKB ≥ CANMCLK

To avoid missing events the CAN engine clock (CANFDCLK or CANMCLK) frequency must be less than the PCLKB clock frequency.

To avoid loss of CAN message, the PCLKB should be set to a clock with a frequency depend on the CAN communication Baud Rate. The constraint of a baud rate and a PCLKB clock is shown in Table 31.2.

**Table 31.2 Clock restriction**

| | Baud rate | PCLKB |
|---|---|---|
| CANFD | 1 Mbps Nominal<br>8 Mbps Data*1 | PCLKB = 40 MHz |
| | 500 Kbps Nominal<br>5 Mbps Data | PCLKB ≥ 32 MHz |
| Classical CAN | 1 Mbps Data | PCLKB ≥ 32 MHz |

Note 1. The maximum reliable communication bit-rate depends on board-design and environmental factors. Sufficient evaluation is recommended on actual target hardware.

The frequency of CANFDCLK and CANMCLK depend on the required baud rate. For information how to configure the baud rate, see section 31.4.1.3. Baud Rate.

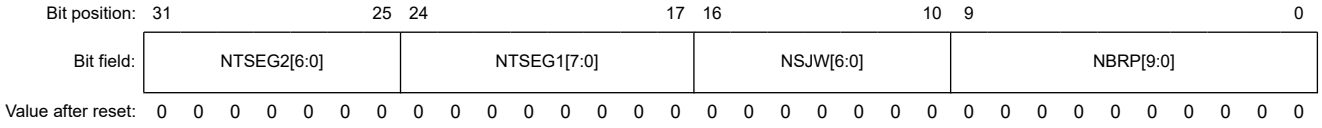
## 31.2 Register Descriptions

### 31.2.1 Register Table

The reset value shown for the RAM area, consisting of CFDGAFLIDr, CFDGAFLMr, CFDGAFLP0r, CFDGAFLP1r, CFDRMBCPb, CFDRFMBCPb, CFDCFMBCP0, CFDTMBCPb, CFDTHLACC0, CFDTHLACC1 and CFDRPGACCk is valid after initialization of a hardware reset. See section 31.4.2. CAN Module Configuration after Hardware Reset for details of the initialization process.

If a write access with a size of 8 or 16 bits is performed for the RAM area, then the CANFD module does a read-modify write-access to the RAM location, because the RAM requires a 32-bit access through the ECC module.

For single bit error, the correct data is written back. For multiple bit errors, unknown data is written back.



Do not access the space where the register is not assigned.

The read data from the space where the register is not assigned is unknown.

## 31.2.2 CFDC0NCFG : Nominal Baud Rate Configuration Register

Base address: CANFD = 0x400B_0000

Offset address: 0x0000

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 9:0 | NBRP[9:0] | Channel Nominal Baud Rate Prescaler<br>Nominal baud rate prescaler division ratio | R/W |
| 16:10 | NSJW[6:0] | Resynchronization Jump Width<br>0x00: 1 Tq<br>0x01: 2 Tq<br>⋮<br>0x7E: 127 Tq<br>0x7F: 128 Tq | R/W |
| 24:17 | NTSEG1[7:0] | Timing Segment 1<br>0x00: Reserved<br>0x01: 2 Tq<br>0x02: 3 Tq<br>0x03: 4 Tq<br>⋮<br>0xFE: 255 Tq<br>0xFF: 256 Tq | R/W |
| 31:25 | NTSEG2[6:0] | Timing Segment 2<br>0x00: Reserved<br>0x01: 2 Tq<br>⋮<br>0x7E: 127 Tq<br>0x7F: 128 Tq | R/W |

Note: Tq means time quantum.

This register configures the transmission/reception nominal baud rate parameters of the channels.

### NBRP[9:0] bits (Channel Nominal Baud Rate Prescaler)

The NBRP[9:0] bits are used to define the peripheral bus clock periods contained in a time quantum.

Do not write to these bits in CH_OPERATION or CH_SLEEP mode.

Only write to these bits when the CANFD channel is in CH_RESET or CH_HALT mode.

### NSJW[6:0] bits (Resynchronization Jump Width)

The NSJW[6:0] bits set the synchronization jump width. A value from 1 to 128 time quanta can be set.

Do not write to these bits in CH_OPERATION or CH_SLEEP mode.

Only write to these bits when the CANFD channel is in CH_RESET or CH_HALT mode.

### NTSEG1[7:0] bits (Timing Segment 1)

The NTSEG1[7:0] bits set the segment TSEG1 to compensate for edges on the CAN bus with a positive phase error. These bits contain the propagation segment.

Do not write to these bits in CH_OPERATION or CH_SLEEP mode.

Only write to these bits when the CANFD channel is in CH_RESET or CH_HALT mode.

Additionally, configure a Tq value only between 2 and 256, inclusive. See section 31.4.1.2. CAN Bit Timing for more details.

**NTSEG2[6:0] bits (Timing Segment 2)**

The NTSEG2[6:0] bits set the segment TSEG2 to compensate for edges on the CAN bus with a negative phase error.

Do not write to these bits in CH_OPERATION or CH_SLEEP mode.

Only write to these bits when the CANFD channel is in CH_RESET or CH_HALT mode.

Additionally, configure a Tq value only between 2 and 128, inclusive.

## 31.2.3 CFDC0CTR : Control Register

Base address: CANFD = 0x400B_0000

Offset address: 0x0004

| Bit position: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

| 31 | ROM*1 | Restricted Operation Mode<br>0: Restricted operation mode disabled<br>1: Restricted operation mode enabled | R/W |

Note 1. These bits are not available in the classical CAN function.

Channel Control register controls the modes of the related channel. It is used to enable generation of interrupts if errors are detected on the CAN bus connected to this channel. It is also used to configure the channel in test mode.

### CHMDC[1:0] bits (Channel Mode Control)

The CHMDC[1:0] bits can be used to configure modes of the CAN channel.

CAN mode transitions are described in more details in section 31.3.3. Channel Modes.

Setting CHMDC[1:0] bits to 11b has no effect. When the CANFD module is in GL_HALT mode, these bits can only be set to 10b or 01b. These bits cannot be set in CH_SLEEP mode.

These bits can change automatically when transitioning to Halt mode by the CFDC0CTR.BOM settings.

If CPU write access to CFDC0CTR.CHMDC occurs at the same time when the CAN channel enters Halt mode (at the start of bus-off when CFDC0CTR.BOM = 01b, or at the end of bus-off when CFDC0CTR.BOM = 10b), then the CPU write access has the highest priority.

The CAN channel changes the value of CFDC0CTR.CHMDC within the Channel Control Registers for the specified cases only if the CFDC0CTR.CHMDC value is 00b (Operation mode).

#### CSLPR bit (Channel Sleep Request)

When the CSLPR bit is 1, a Sleep mode request is generated for the corresponding CAN channel

When this bit is 0, a request to exit Sleep mode is generated for the related CANFD channel.

Only write to this bit when the related CANFD channel is in CH_RESET or CH_SLEEP mode.

#### RTBO bit (Return from Bus-Off)

When the protocol controller of the CAN channel enters bus-off state, you can force a recovery from bus-off state by setting the RTBO bit in the Channel Control Register to 1.

The error state changes from bus-off state to integrating with a maximum delay of 1 CAN bit time.

When the RTBO bit is set to 1, the REC and TEC registers are initialized and the Bus-Off Status bit (Channel Bus-off Status, CFDC0STS.BOSTS) is set to 0.

Registers other than the REC and TEC registers are not initialized by this command. Even if CFDC0CTR.BORIE is set, a bus-off recovery interrupt is not generated by this recovery from the bus-off state.

The RTBO bit cannot be set in CH_SLEEP mode. Setting this bit in any state other than bus-off state has no effect and the bit is cleared immediately. The read value is always 0.

Return from the Bus-Off command should be used only when CFDC0CTR.BOM is set to 00b.

Only write to this bit when the related CANFD channel is in CH_OPERATION mode. This bit is automatically cleared when set by software.

#### BEIE bit (Bus Error Interrupt Enable)

When the BEIE and the CFDC0ERFL.BEF bits are both 1, an error interrupt request is generated.

This bit cannot be set in CH_SLEEP mode. Only write to this bit when the related CANFD channel is in CH_RESET mode.

#### EWIE bit (Error Warning Interrupt Enable)

When the EWIE and the CFDC0ERFL.EWF bits are both 1, an error interrupt request is generated.

The EWIE bit cannot be set in CH_SLEEP mode. Only write to this bit when the related CANFD channel is in CH_RESET mode.

#### EPIE bit (Error Passive Interrupt Enable)

An error interrupt request is generated when the EPIE bit and the CFDC0ERFL.EPF are both 1.

The EPIE bit cannot be set in CH_SLEEP mode. Only write to this bit when the related CANFD channel is in CH_RESET mode.

#### BOEIE bit (Bus-Off Entry Interrupt Enable)

When the BOEIE and the CFDC0ERFL.BOEF bits are both 1, an error interrupt request is generated.

The BOEIE bit cannot be set in CH_SLEEP mode. Only write to this bit when the related CANFD channel is in CH_RESET mode.

#### BORIE bit (Bus-Off Recovery Interrupt Enable)

When the BORIE and the CFDC0ERFL.BORF bits are both 1, an error interrupt request is generated.

The BORIE bit cannot be set in CH_SLEEP mode. Only write to this bit when the related CANFD channel is in CH_RESET mode.

#### OLIE bit (Overload Interrupt Enable)

When the OLIE and the CFDC0ERFL.OVLF bits are both 1, an error interrupt request is generated.

Do not write to this bit in CH_SLEEP mode. Only write to this bit when the related CANFD channel is in CH_RESET mode.

#### BLIE bit (Bus Lock Interrupt Enable)

When the BLIE and the CFDC0ERFL.BLF bits are both 1, an error interrupt request is generated.

Do not write to this bit in CH_SLEEP mode. Only write to this bit when the related CANFD channel is in CH_RESET mode.

#### ALIE bit (Arbitration Lost Interrupt Enable)

When the ALIE and the CFDC0ERFL.ALF bits are both 1, an error interrupt request is generated.

Do not write to this bit in CH_SLEEP mode. Only write to this bit when the related CANFD channel is in CH_RESET mode.

#### TAIE bit (Transmission Abort Interrupt Enable)

When the TAIE bit is 1 and a transmission is successfully aborted from a TX MB belonging to the corresponding CAN channel, an interrupt request is generated.

Do not write to this bit in CH_SLEEP mode. Only write to this bit when the related CANFD channel is in CH_RESET mode.

#### EOCOIE bit (Error Occurrence Counter Overflow Interrupt Enable)

When the EOCOIE bit is 1 and the CFDC0FDSTS.EOCO bit belonging to the corresponding CAN channel is 1, an error interrupt request is generated.

The EOCOIE bit cannot be set in CH_SLEEP mode. Only write to this bit when the related CANFD channel is in CH_RESET mode.

#### SOCOIE bit (Successful Occurrence Counter Overflow Interrupt Enable)

When the SOCOIE bit is 1 and the CFDC0FDSTS.SOCO bit belonging to the corresponding CAN channel is 1, an error interrupt request is generated.

The SOCOIE bit cannot be set in CH_SLEEP mode. Only write to this bit when the related CANFD channel is in CH_RESET mode.

#### TDCVFIE bit (Transceiver Delay Compensation Violation Interrupt Enable)

When the TDCVFIE bit is 1 and the CFDC0FDSTS.TDCVF bit belonging to the corresponding CAN channel is 1, an error interrupt request is generated.

The TDCVFIE bit cannot be set in CH_SLEEP mode.

Only write to this bit when the related CANFD channel is in CH_RESET mode. Do not set this bit when in Classical CAN mode.

Note: This bit is not available in the classical CAN function.

#### BOM[1:0] bits (Channel Bus-Off Mode)

The BOM[1:0]bits control the timing of the recovery from Bus-Off mode of the CANFD Channel.

Do not write to these bits in CH_SLEEP mode. Only write to these bits when the related CANFD channel is in CH_RESET mode.

Only write to these bits when the related CANFD channel is in CH_RESET mode.

#### ERRD bit (Channel Error Display)

The ERRD bit controls the display mode of the error flag bits [14:8] in the Channel Error Flag Register (CFDC0ERFL).

If the ERRD bit is 0 and more than one error occur at the same time, the error flag bits are set for all the errors that occurred at the same time. No further errors are flagged until CFDC0ERFL[14:8] is cleared.

Do not write to the ERRD bit in CH_SLEEP mode. Only write to this bit when the related CANFD channel is in CH_RESET or CH_HALT mode.

#### CTME bit (Channel Test Mode Enable)

The CTME bit enables the channel test modes.

Do not write to this bit in CH_SLEEP mode. Only write to this bit when the related CANFD channel is in CH_HALT mode.

#### CTMS[1:0] bits (Channel Test Mode Select)

The CTMS[1:0] bits are used to select the required test mode.

Do not write to these bits in CH_SLEEP or CH_RESET mode. Only write to these bits when the related CANFD channel is in CH_HALT mode.

These bits are cleared automatically when the related CANFD channel is in CH_RESET mode.

#### BFT bit (Bit Flip Test)

The BFT bit checks the internal CRC generator logic of the protocol controller.

It inverts the first bit (ID bit) of the CAN message data stream being received, so that the internal generated CRC result will not match the received CRC value of the frame. Refer to the bit stuffing rule, when using this feature, as there is the possibility of receiving a stuff error (due to the inversion) rather than a CRC error.

The internal generated CRC value is always observed in the following registers:

- CFDC0ERFL.CRCREG (Classical CAN frames)
- CFDC0FDCRC.CRCREG (CANFD frames).*1

Note 1. This feature is not available in the classical CAN function.

Some restriction exist when using this bit:

Other CAN node will send a reference message and the receiver node(s) can invert one bit of incoming bit stream.

Note: The transmitter and receiver modes share the same CRC generator, therefore it is not necessary to consider the modes separately when testing.

The Bit Flip test mode is enabled if the BFT (new control signal that inverts the first bit of the bit stream) and CTME bits are both 1 and CFDC0CTR.CTMS is 0x00.

If this function is used by a transmitting node, a bit error or an arbitration lost will occur.

Do not write to the BFT bit in CH_SLEEP mode. Users should not use this function when the Self test mode 1 (Internal Loop back mode). Only write to this bit when the related CANFD channel is in CH_HALT mode.

This bit is cleared automatically when the related CANFD channel is in CH_RESET mode.

#### ROM bit (Restricted Operation Mode)

When the ROM and CTME bits are both 1, the restricted operation mode is enabled. This mode should only be used in basic test mode (CFDC0CTR.CTMS[1:0] = 00b).

The ROM bit cannot be set in CH_SLEEP mode. Only write to this bit when the related CANFD channel is in CH_HALT mode.

This bit is cleared automatically when the related CANFD channel is in CH_RESET mode. Do not set this bit when in Classical CAN mode.

Note: This bit is not available in the classical CAN function.

### 31.2.4 CFDC0STS : Status Register

Base address: CANFD = 0x400B_0000

Offset address: 0x0008

| Bit position: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

| 7 | COMSTS | Channel Communication Status<br>0: Channel is not ready for communication<br>1: Channel is ready for communication | R |
| 8 | ESIF*1 | Error State Indication Flag<br>0: No CANFD message has been received when the ESI flag was set<br>1: At least one CANFD message was received when the ESI flag was set | R/W |
| 15:9 | — | These bits are read as 0. The write value should be 0. | R/W |
| 23:16 | REC[7:0] | Reception Error Count<br>These bits increment or decrement the counter value according to error status of the CAN channel during reception. | R |
| 31:24 | TEC[7:0] | Transmission Error Count<br>These bits increment or decrement the counter value according to error status of the CAN channel during transmission. | R |

Note 1. This bit is not available in the classical CAN function.

Channel Status Register shows the mode, error and transmission or reception status of the related channel together with its reception and transmission error count values.

### CRSTSTS bit (Channel Reset Status)

The CRSTSTS bit indicates whether the related CAN channel is in Reset mode.

This bit is set automatically when the related CAN channel enters Channel Reset mode. When the mode is changed from Reset mode to Sleep mode, the CRSTSTS bit remains 1.

This bit is cleared automatically when the related CAN channel exits the Channel Reset mode, except when changing to Sleep mode.

### CHLTSTS bit (Channel Halt Status)

The CHLTSTS bit indicates whether the related CAN channel is in Halt mode.

This bit is set automatically when the related CAN module enters Halt mode, and is cleared automatically when the related CAN module exits Halt mode.

### CSLPSTS bit (Channel Sleep Status)

The CSLPSTS bit indicates whether the related CAN channel is in Sleep mode.

This bit is set automatically when the related CANFD channel enters Sleep mode, and is cleared automatically when the related CANFD channel exits Sleep mode.

#### EPSTS bit (Channel Error Passive Status)

The EPSTS bit indicates whether the related CANFD channel has entered the error passive state.

This bit is set automatically when the value of the CAN Transmission or Reception Counter Register exceeds the value of 0x7F.

This bit is cleared automatically when the related CANFD channel exits the error passive state or enters Reset mode.

#### BOSTS bit (Channel Bus-Off Status)

The BOSTS bit indicates whether the related CANFD channel has entered the error bus-off state.

This bit is set automatically when the value of the related CAN Transmission Error Count Register exceeds 0xFF and the related CANFD channel is in the bus-off state (CAN Transmission Error Count Register > 0xFF).

This bit is cleared automatically when the related CANFD channel exits bus-off state.

#### TRMSTS bit (Channel Transmit Status)

The TRMSTS bit indicates whether the related CANFD channel is transmitting a message.

This bit is set automatically when the related CANFD channel is operating as a transmitter node or is in the bus-off state.

This bit is cleared automatically when the related CANFD channel is in the bus-idle state or starts operating as a receiver node.

#### RECSTS bit (Channel Receive Status)

The RECSTS bit indicates whether the related CANFD channel is receiving a message.

This bit is set automatically when the related CANFD channel is operating as a receiver node.

This bit is cleared automatically when the related CANFD channel is in the bus-idle state or starts operating as a transmitter node.

#### COMSTS bit (Channel Communication Status)

The COMSTS bit indicates whether the related CANFD channel is ready for communication.

This bit is set automatically when the related CANFD channel is ready to perform communication following the detection of 11 consecutive recessive bits after exiting the Reset or Halt mode.

This bit is cleared automatically when the related CANFD channel is in CH_RESET or CD_HALT mode.

Note: This bit is 1 during bus-off state.

#### ESIF bit (Error State Indication Flag)

The ESIF bit is set when the ESI bit is sampled recessively for a reception CAN message without any error. When in Loopback or Mirror mode, the self-transmitted messages are considered reception messages.

If a set from the CANFD channel occurs simultaneously with a clear by a write access, then the bit is set.

This bit is cleared by writing 0 to it. This bit is cleared automatically when the related CANFD channel is in CH_RESET mode.

Only write to this bit when the related CANFD channel is in CH_HALT or CH_OPERATION mode.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1.

Note: This bit is not available in the classical CAN function.

#### REC[7:0] bits (Reception Error Count)

The REC[7:0] bits increment or decrement the counter value according to error status of the CANFD channel during reception, and display the value of the REC error counter.

The value in bus-off state is indeterminate.

These bits are cleared automatically when the CANFD module enters GL_RESET or the CANFD channel is in CH_RESET mode.

**TEC[7:0] bits (Transmission Error Count)**

The TEC[7:0] bits increment or decrement the counter value according to error status of the CANFD channel during transmission, and display the value of the TEC error counter.

Only write to these bits when in test mode and CANFD channel is in CH_HALT mode.

These bits are cleared automatically when CANFD module is in GL_RESET or CANFD channel is in CH_RESET mode.

## 31.2.5 CFDC0ERFL : Error Flag Register

Base address: CANFD = 0x400B_0000

Offset address: 0x000C

| Bit position: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

|---|---|---|---|
| 11 | CERR | CRC Error<br>0: Channel CRC error not detected<br>1: Channel CRC error detected | R/W |
| 12 | B1ERR | Bit 1 Error<br>0: Channel bit 1 error not detected<br>1: Channel bit 1 error detected | R/W |
| 13 | B0ERR | Bit 0 Error<br>0: Channel bit 0 error not detected<br>1: Channel bit 0 error detected | R/W |
| 14 | ADERR | Acknowledge Delimiter Error<br>0: Channel acknowledge delimiter error not detected<br>1: Channel acknowledge delimiter error detected | R/W |
| 15 | — | This bit is read as 0. The write value should be 0. | R/W |
| 30:16 | CRCREG[14:0] | CRC Register value<br>These bits show the CRC value calculated for the CAN2.0 CAN frame. | R |
| 31 | — | This bit is read as 0. The write value should be 0. | R/W |

Channel Error Flag register shows the status of various error conditions detectable regardless of the setting of the related CAN Channel Error Interrupt Enable Register. It also shows the status of the various bus errors detectable by the CAN channel. Refer to the CAN specification (ISO 11898-1) to check when each error condition occurs.

For this register, only a single bit can be cleared by software. Do not use the bit clear instruction to clear the bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1.

Example in assembler language to clear the CFDC0ERFL.BEF bit:

mov.b #0x0FE, CFDC0ERFL ;

### BEF bit (Bus Error Flag)

The BEF bit indicates a detection of a CAN channel bus error state, flagged by bits [14:8] in this register.

This bit is cleared by writing 0 to it, and can only be set by CANFD module logic. Writing 1 has no effect.

This bit is set automatically when a bus error is detected, and is cleared automatically when the related CANFD channel is in CH_RESET mode.

If a set from the CAN channel occurs simultaneously with a clear by a write access, then the bit is set.

Only write to this bit when the related CANFD channel is in CH_HALT or CH_OPERATION mode.

### EWF bit (Error Warning Flag)

The EWF bit indicates whether an error warning condition has been detected for the CAN channel.

This bit is cleared by writing 0 to it, and can only be set by CANFD module logic. Writing 1 has no effect.

This bit is set automatically when either TEC or REC exceeds 0x5F.

The setting of this bit only occurs when the TEC or REC initially exceeds 0x5F. Therefore, if the TEC or REC remains > 0x5F and the EWF bit is cleared by software, it is not set again until both the TEC and REC go below 0x60 and either TEC or REC crosses over again from a value 0x5F to a value > 0x5F.

If a set condition occurs simultaneously with a clear condition, then the bit is set. It is cleared automatically when the related CANFD channel is in CH_RESET mode.

Only write to this bit when the related CANFD channel is in CH_HALT or CH_OPERATION mode.

### EPF bit (Error Passive Flag)

The EPF bit indicates a detection of a CAN channel error passive state.

This bit is cleared by writing 0 to it, and can only be set by CANFD module logic. Writing 1 has no effect.

This bit is set automatically when the CAN error state becomes error passive state.

The setting of this bit only occurs when the TEC or REC initially exceeds 0x7F. Therefore, if the TEC or REC remains > 0x7F and the bit is cleared by software, it is not set again until both the TEC and REC go below 0x80 and either TEC or REC crosses over again from a value ≤ 0x7F to a value > 0x7F.

If a set condition occurs simultaneously with a clear condition, then the bit is set. It is cleared automatically when the related CANFD channel is in CH_RESET mode.

Only write to this bit when the related CANFD channel is in CH_HALT or CH_OPERATION mode.

#### BOEF bit (Bus-Off Entry Flag)

The BOEF bit indicates a detection of a CAN channel bus-off entry state.

This bit is cleared by writing 0 to it, and can only be set by CANFD module logic. Writing 1 has no effect.

This bit is set automatically when the CAN error state enters the bus-off state.

This bit is cleared automatically when the related CANFD channel is in CH_RESET mode. If a set condition occurs simultaneously with a clear condition, then the bit is set.

Only write to this bit when the related CANFD channel is in CH_HALT or CH_OPERATION mode.

#### BORF bit (Bus-Off Recovery Flag)

The BORF bit indicates a detection of a CAN channel bus-off recovery state.

This bit is cleared by writing 0 to it, and can only be set by CANFD module logic. Writing 1 has no effect.

This bit is set automatically if CAN channel recovers from bus-off state in the following conditions:

- When CFDC0CTR.BOM is 00b and normal recovery (11 consecutive recessive bits x 128 times detected) occurs
- When CFDC0CTR.BOM is 10b and normal recovery (11 consecutive recessive bits x 128 times detected) occurs
- When CFDC0CTR.BOM is 11b and normal recovery (11 consecutive recessive bits x 128 times detected) occurs.

The bit is not set if CAN channel recovers from bus-off state in the following conditions:

- When CAN Reset mode is requested
- When CFDC0CTR.RTBO is set to 1 (the CAN channel returns to error active)
- When CFDC0CTR.BOM is 01b
- When CFDC0CTR.BOM is 11b and a halt request is asserted before the CAN channel reaches the end of the bus-off state.

This bit is cleared automatically when the related CANFD channel is in CH_RESET mode. If a set condition occurs simultaneously with a clear condition, the flag is set.

Only write to this bit when the related CANFD channel is in CH_HALT or CH_OPERATION mode.

#### OVLF bit (Overload Flag)

The OVLF flag indicates a detection of a CAN channel overload state.

The OVLF bit is cleared by writing 0 to it, and can only be set by CANFD module logic. Writing 1 has no effect.

This bit is set automatically when an overload condition is detected. If a set condition occurs simultaneously with a clear condition, then the bit is set.

This bit is cleared automatically when the related CANFD channel is in CH_RESET mode.

Only write to this bit when the related CANFD channel is in CH_HALT or CH_OPERATION mode.

#### BLF bit (Bus Lock Flag)

The BLF bit indicates a detection of a CAN channel bus lock condition.

This bit is cleared by writing 0 to it, and can only be set by CANFD module logic. Writing 1 has no effect.

This bit is set automatically when 32 consecutive dominant bits are detected on the CAN bus while the CAN channel is in Operation mode.

If a set condition occurs simultaneously with a clear condition, then the bit is set. It is cleared automatically when the related CANFD channel is in CH_RESET mode.

Only write to this bit when the related CANFD channel is in CH_HALT or CH_OPERATION mode.

It is cleared automatically when the related CANFD channel is in CH_RESET mode.

#### ALF bit (Arbitration Lost Flag)

The ALF bit indicates a detection of a CAN channel bus arbitration lost condition.

This bit is cleared by writing 0 to it, and can only be set by CANFD module logic. Writing 1 has no effect.

The bit is set automatically when an arbitration lost condition is detected on the CAN bus while the CAN channel is in Operation mode.

If a set condition occurs simultaneously with a clear condition, then the bit is set. It is cleared automatically when the related CANFD channel is in CH_RESET mode.

Only write to this bit when the related CANFD channel is in CH_HALT or CH_OPERATION mode.

#### SERR bit (Stuff Error)

The SERR bit indicates a detection of a CAN stuff error.

This bit is cleared by writing 0 to it, and can only be set by CANFD module logic. Writing 1 has no effect.

To clear this bit, use the following sequence:

1. Clear the corresponding flag bit.
2. Read if the flag bit is cleared.
3. If yes, continue, else go back to step 1.

This bit is set automatically when a stuff error is detected. If CFDC0CTR.ERRD bit is 1 and if the set and clear conditions occur at the same time for this bit, then this bit is set.

This bit is cleared automatically when the related CANFD channel is in CH_RESET mode. If CFDC0CTR.ERRD bit is 0 and the set and clear conditions occur at the same time for this bit, then it is cleared if a bit at CFDC0ERFL[14:8] is already set. Otherwise, this bit is set if CFDC0ERFL[14:8] is 0000000b.

Only write to this bit when the related CANFD channel is in CH_HALT or CH_OPERATION mode.

#### FERR bit (Form Error)

The FERR bit indicates a detection of a CAN form error.

This bit is cleared by writing 0 to it, and can only be set by CANFD module logic. Writing 1 has no effect.

To clear this bit, use the following sequence:

1. Clear the corresponding flag bit.
2. Read if the flag bit is cleared.
3. If yes, continue, else go back to step 1.

This bit is set automatically when a form error is detected. If CFDC0CTR.ERRD bit is 1 and if the set and clear conditions occur at the same time for this bit, then this bit is set.

This bit is cleared automatically when the related CANFD channel is in CH_RESET mode. If CFDC0CTR.ERRD bit is 0 and the set and clear conditions occur at the same time for this bit, then it is cleared if a bit at CFDC0ERFL[14:8] is already set. Otherwise, this bit is set if CFDC0ERFL[14:8] is 0000000b.

Only write to this bit when the related CANFD channel is in CH_HALT or CH_OPERATION mode.

#### AERR bit (Acknowledge Error)

The AERR bit indicates a detection of a CAN acknowledge error.

This bit is cleared by writing 0 to it, and can only be set by CANFD module logic. Writing 1 has no effect.

To clear this bit, use the following sequence:

1. Clear the corresponding flag bit.
2. Read if the flag bit is cleared.
3. If yes, continue, else go back to step 1.

This bit is set automatically when an acknowledge error is detected. If CFDC0CTR.ERRD bit is 1 and if the set and clear conditions occur at the same time for this bit, then this bit is set.

This bit is cleared automatically when the related CANFD channel is in CH_RESET mode. If CFDC0CTR.ERRD bit is 0 and the set and clear conditions occur at the same time for this bit, then it is cleared if a bit at CFDC0ERFL[14:8] is already set. Otherwise, this bit is set if CFDC0ERFL[14:8] is 0000000b.

Only write to this bit when the related CANFD channel is in CH_HALT or CH_OPERATION.

#### CERR bit (CRC Error)

The CERR bit indicates a detection of a CAN CRC error.

This bit is cleared by writing 0 to it, and can only be set by CANFD module logic. Writing 1 has no effect.

To clear this bit, use the following sequence:

1. Clear the corresponding flag bit.
2. Read if the flag bit is cleared.
3. If yes, continue, else go back to step 1.

This bit is set automatically when a CRC error is detected. If CFDC0CTR.ERRD bit is 1 and if the set and clear conditions occur at the same time for this bit, then this bit is set.

This bit is cleared automatically when the related CANFD channel is in CH_RESET mode. If CFDC0CTR.ERRD bit is 0 and the set and clear conditions occur at the same time for this bit, then it is cleared if a bit at CFDC0ERFL[14:8] is already set. Otherwise, this bit is set if CFDC0ERFL[14:8] is 0000000b.

Only write to this bit when the related CANFD channel is in CH_HALT or CH_OPERATION mode.

#### B1ERR bit (Bit 1 Error)

The B1ERR bit indicates a detection of a recessive bit error.

This bit is cleared by writing 0 to it, and can only be set by CANFD module logic. Writing 1 has no effect.

To clear this bit, use the following sequence:

1. Clear the corresponding flag bit.
2. Read if the flag bit is cleared.
3. If yes, continue, else go back to step 1.

This bit is set automatically when a recessive bit error (expected recessive bit, sampled as dominant bit) is detected. If CFDC0CTR.ERRD bit is 1 and if the set and clear conditions occur at the same time for this bit, then this bit is set.

This bit is cleared automatically when the related CANFD channel is in CH_RESET mode. If CFDC0CTR.ERRD bit is 0 and the set and clear conditions occur at the same time for this bit, then it is cleared if a bit at CFDC0ERFL[14:8] is already set. Otherwise, this bit is set if CFDC0ERFL[14:8] is 0000000b.

Only write to this bit when the related CANFD channel is in CH_HALT or CH_OPERATION mode.

#### B0ERR bit (Bit 0 Error)

The B0ERR bit indicates a detection of a dominant bit error.

This bit is cleared by writing 0 to it, and can only be set by CANFD module logic. Writing 1 has no effect.

To clear this bit, use the following sequence:

1. Clear the corresponding flag bit.
2. Read if the flag bit is cleared.
3. If yes, continue, else go back to step 1.

This bit is set automatically when a dominant bit error (expected dominant bit, sampled as recessive bit) is detected. If CFDC0CTR.ERRD bit is 1 and if the set and clear conditions occur at the same time for this bit, then this bit is set.

This bit is cleared automatically when the related CANFD channel is in CH_RESET mode. If CFDC0CTR.ERRD bit is 0 and the set and clear conditions occur at the same time for this bit, then it is cleared if a bit at CFDC0ERFL[14:8] is already set. Otherwise, this bit is set if CFDC0ERFL[14:8] is 0000000b.

Only write to this bit when the related CANFD channel is in CH_HALT or CH_OPERATION mode.

#### ADERR bit (Acknowledge Delimiter Error)

The ADERR bit indicates a detection of an acknowledge delimiter bit error.

This bit is cleared by writing 0 to it, and can only be set by CANFD module logic. Writing 1 has no effect.

To clear this bit, use the following sequence:

1. Clear the corresponding flag bit.
2. Read if the flag bit is cleared.
3. If yes, continue, else go back to step 1.

This bit is set automatically when a form error is detected during the acknowledge delimiter state of frame transmission. If CFDC0CTR.ERRD bit is 1 and if the set and clear conditions occur at the same time for this bit, then this bit is set.

This bit is cleared automatically when the related CANFD channel is in CH_RESET mode. If CFDC0CTR.ERRD bit is 0 and the set and clear conditions occur at the same time for this bit, then it is cleared if a bit at CFDC0ERFL[14:8] is already set. Otherwise, this bit is set if CFDC0ERFL[14:8] is 0000000b.

Only write to this bit when the related CANFD channel is in CH_HALT or CH_OPERATION mode.

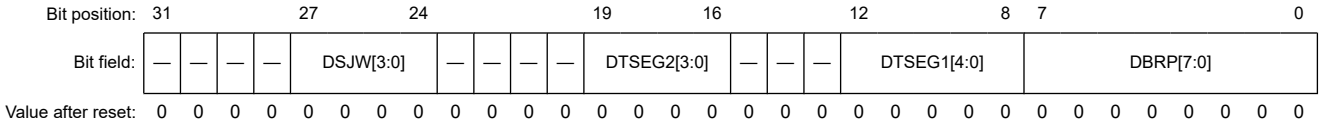
#### CRCREG[14:0] bits (CRC Register value)

The CRCREG[14:0] bits read the calculated CRC value when CFDC0CTR.CTME bit is 1 for the channel.

If CFDC0CTR.CTME bit is 0, then these bits are always read as 0.

These bits show the CAN2.0 CRC value calculated by the CANFD channel logic when the CTME bit is enabled.

The CFDC0ERFL.CRCREG value is updated in the first bit of the CRC field of the CAN frame (reception and transmission).



These bits are cleared automatically when the related CANFD channel is in CH_RESET mode.

### 31.2.6 CFDC0DCFG : Data Baud Rate Configuration Register

This register is not available in the classical CAN function.

Base address: CANFD = 0x400B_0000

Offset address: 0x0100

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 7:0 | DBRP[7:0] | Channel Data Baud Rate Prescaler<br>Data Baud Rate Prescaler division ratio | R/W |
| 12:8 | DTSEG1[4:0] | Timing Segment 1<br>0x00: Reserved<br>0x01: 2 Tq<br>0x02: 3 Tq<br>0x03: 4 Tq<br>⋮<br>0x1E: 31 Tq<br>0x1F: 32 Tq | R/W |
| 15:13 | — | These bits are read as 0. The write value should be 0. | R/W |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 19:16 | DTSEG2[3:0] | Timing Segment 2<br>0x0: Reserved<br>0x1: 2 Tq<br>⋮<br>0xE: 15 Tq<br>0xF: 16 Tq | R/W |
| 23:20 | — | These bits are read as 0. The write value should be 0. | R/W |
| 27:24 | DSJW[3:0] | Resynchronization Jump Width<br>0x0: 1 Tq<br>0x1: 2 Tq<br>⋮<br>0xF: 16 Tq | R/W |
| 31:28 | — | These bits are read as 0. The write value should be 0. | R/W |

Note: Tq means time quantum.

The Data Baud Rate Configuration Register configures the transmission/reception data baud rate parameters of the channels.

The channel of Classical CAN mode does not perform configuration of this register.

### DBRP[7:0] bits (Channel Data Baud Rate Prescaler)

The DBRP[7:0] bits define the peripheral bus clock periods contained in a time quantum.

Do not write to these bits in CH_OPERATION or CH_SLEEP mode.

Only write to these bits when the related CANFD channel is in CH_RESET or CH_HALT mode.

### DTSEG1[4:0] bits (Timing Segment 1)

The DTSEG1[4:0] bits set the segment TSEG1 to compensate for edges on the CAN bus with a positive phase error. A value from 2 to 32 time quanta can be set.

The DTSEG1[4:0] bits are also used to set the propagation segment.

Do not write to these bits in CH_OPERATION or CH_SLEEP mode.

Only write to these bits when the related CANFD channel is in CH_RESET or CH_HALT mode. Do not write any other value to these bits. See section 31.4.1.2. CAN Bit Timing for more details.

### DTSEG2[3:0] bits (Timing Segment 2)

The DTSEG2[3:0] bits set the segment TSEG2 to compensate for edges on the CAN bus with a negative phase error. A value from 2 to 16 time quanta can be set.

Do not write to these bits in CH_OPERATION or CH_SLEEP mode.

Only write to these bits when the related CANFD channel is in CH_RESET or CH_HALT mode. Do not write any other value to these bits.

### DSJW[3:0] bits (Resynchronization Jump Width)

The DSJW[3:0] bits set the synchronization jump width. A value from 1 to 16 time quanta can be set.

Do not write to these bits in CH_OPERATION or CH_SLEEP mode.

Only write to these bits when the related CANFD channel is in CH_RESET or CH_HALT mode.

## 31.2.7 CFDC0FDCFG : CANFD Configuration Register

Base address: CANFD = 0x400B_0000

Offset address: 0x0104

| Bit position: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

| 10 | ESIC*1 | Error State Indication Configuration<br>0: The ESI bit in the frame represents the error state of the node itself<br>1: The ESI bit in the frame represents the error state of the message buffer if the node itself is not in error passive. If the node is in error passive, then the ESI bit is driven by the node itself. | R/W |
| 11 | — | This bit is read as 0. The write value should be 0. | R/W |
| 15:12 | — | These bits are read as 0. The write value should be 0. | R/W |
| 23:16 | TDCO[7:0]*1 | Transceiver Delay Compensation Offset | R/W |
| 27:24 | — | These bits are read as 0. The write value should be 0. | R/W |
| 28 | FDOE*1 | FD-Only Enable<br>0: FD-only mode disabled<br>1: FD-only mode enabled | R/W |
| 29 | REFE | RX Edge Filter Enable<br>0: RX edge filter disabled<br>1: RX edge filter enabled | R/W |
| 30 | CLOE*1 | Classical CAN Enable<br>0: Classical CAN mode disabled<br>1: Classical CAN mode enabled | R/W |
| 31 | — | This bit is read as 0. The write value should be 0. | R/W |

Note 1. These bits are not available in the classical CAN function.

The CANFD Configuration Register configures which communication direction (transmitter/receiver) errors are counted.

**EOCCFG[2:0] bits (Error Occurrence Counter Configuration)**

The EOCCFG[2:0] bits select which type of CAN frame configuration and direction, including protocol errors are counted.

Do not write to these bits in CH_OPERATION or CH_SLEEP mode.

Only write to these bits when the related CANFD channel is in CH_RESET or CH_HALT mode.

#### TDCOC bit (Transceiver Delay Compensation Offset Configuration)*1

The TDCOC bit selects which offset is used when defining the position of the secondary sample point (SSP) for the CANFD channel. If the bit is set to 0, the position of the SSP is the measured transceiver delay plus the fixed offset. If the bit is 1, the position of the SSP is defined only by the offset.

Do not write to this bit in CH_OPERATION or CH_SLEEP mode.

Only write to this bit when the related CANFD channel is in CH_RESET or CH_HALT mode. Do not set this bit when in Classical CAN mode.

#### TDCE bit (Transceiver Delay Compensation Enable)*1

The TDCE bit enables the transceiver delay compensation for the CANFD channel.

Do not write to this bit in CH_OPERATION or CH_SLEEP mode.

Only write to this bit when the related CANFD channel is in CH_RESET or CH_HALT mode. Do not set this bit when in Classical CAN mode.

#### ESIC bit (Error State Indication Configuration)*1

The ESIC bit controls the transmission of either the ESI flag information or the message of ESI flag information (CFDCFFDCSTS.CFESI or CFDTMFDCTRb.TMESI).

Do not write to this bit in CH_OPERATION or CH_SLEEP mode.

Only write to this bit when the related CANFD channel is in CH_RESET or CH_HALT mode. Do not set this bit when in Classical CAN mode.

#### TDCO[7:0] bits (Transceiver Delay Compensation Offset)*1

The TDCO[7:0] bits set the secondary sample point offset. How this value is used, depends on the CFDC0FDCFG.TDCOC setting.

If CFDC0FDCFG.TDCOC = 0, the transceiver delay compensation result is equal to the Trv_Delay (measured delay) + the value in CFDC0FDCFG.TDCO, rounded down to the nearest integer number of time quanta. Otherwise, the result is equal to the value in CFDC0FDCFG.TDCO. See section 31.4.1.5. Transmitter Delay Compensation for details on how CFDC0FDCFG.TDCO is used.

The actual offset value is interpreted as TDCO + 1. For example, if 4 is set in TDCO, the offset is 5 clock cycles. Clock cycle is 1 cycle of CAN channel DLL clock.

Do not write to the TDCO[7:0] bits in CH_OPERATION or CH_SLEEP mode.

Only write to these bits when the related CANFD channel is in CH_RESET or CH_HALT mode. Do not set this bit when in Classical CAN mode.

#### FDOE bit (FD-Only Enable)*1

The FDOE bit enables the reception and transmission of CANFD-only frames. If enabled, communication in Classical CAN frame format is disabled. Transmission of Classical CAN frames is not possible because the FDF bit of the message buffer is a don’t care (CFDCFFDCSTS.CFFDF/CFDTMFDCTRb.TMFDF).

If messages with Classical CAN frame format are received, the protocol controller treats them as invalid frames and response with error frames. When a Classical CAN frame is configured for transmitting, the FDF bit is sent as recessive, therefore an FD frame is sent. If the data length code (DLC) is configured of greater than 8 bytes, the remaining data bytes are padded with 0xCC.

The FDOE bit cannot be written in CH_OPERATION, CH_HALT or CH_SLEEP mode.

Do not set CFDC0FDCFG.FDOE and CFDC0FDCFG.CLOE simultaneously.

#### REFE bit (RX Edge Filter Enable)

The REFE bit enables the RX edge filter during the IDLE detection (bus integration). When the bit is enabled, two consecutive dominant time quanta are required to detect a synchronization edge.

The REFE bit cannot be written in CH_OPERATION, CH_HALT and CH_SLEEP mode. Do not set this bit when in Classical CAN mode.

### CLOE bit (Classical CAN Enable)*1

The CLOE bit enables the Classical CAN mode. If this bit is 1, the protocol controller can only send classical frames and response with a form or CRC error on FD frames.

Do not set CFDC0FDCFG.CLOE and CFDC0FDCFG.FDOE simultaneously.

| CFDC0FDCFG.CLOE | CFDC0FDCFG.FDOE | Channel mode |
|---|---|---|
| 0 | 0 | CANFD mode |
| 0 | 1 | FD-only mode |
| 1 | 0 | Classical CAN mode |
| 1 | 1 | Reserved |

Do not write to this bit in CH_OPERATION, CH_HALT or CH_SLEEP mode.

Only write to these bits when the CANFD channel is in CH_RESET mode.

Note 1. These bits are not available in the classical CAN function.

## 31.2.8 CFDC0FDCTR : CANFD Control Register

Base address: CANFD = 0x400B_0000

Offset address: 0x0108

| Bit position: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit position: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | — | — | — | — | — | — | — | — | — | — | — | SOCCLR | EOCCLR |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 0 | EOCCLR | Error Occurrence Counter Clear<br>0: No error occurrence counter clear<br>1: Clear error occurrence counter | R/W |
| 1 | SOCCLR | Successful Occurrence Counter Clear<br>0: No successful occurrence counter clear<br>1: Clear successful occurrence counter | R/W |
| 31:2 | — | These bits are read as 0. The write value should be 0. | R/W |

The CANFD Control Register controls the error and successful occurrence counters.

### EOCCLR bit (Error Occurrence Counter Clear)

The EOCCLR bit is used to clear the error occurrence counter.

Do not write to this bit in CH_SLEEP or CH_RESET mode. The read value is always 0.

This bit is cleared automatically by the CANFD module logic and when the related CANFD channel is in CH_RESET mode.

### SOCCLR bit (Successful Occurrence Counter Clear)

The SOCCLR bit is used to clear the successful occurrence counter.

Do not write to this bit in CH_SLEEP or CH_RESET mode. The read value is always 0.

This bit is cleared automatically by the CANFD module logic and when the related CANFD channel is in CH_RESET mode.

## 31.2.9 CFDC0FDSTS : CANFD Status Register

Base address: CANFD = 0x400B_0000

Offset address: 0x010C

| Bit position: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | SOC[7:0] | | | | | | | | EOC[7:0] | | | | | | | |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit position: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | TDCVF | — | — | — | — | — | SOCO | EOCO | TDCR[7:0] | | | | | | | |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 7:0 | TDCR[7:0]*1 | Transceiver Delay Compensation Result | R |
| 8 | EOCO | Error Occurrence Counter Overflow<br>0: Error occurrence counter has not overflowed<br>1: Error occurrence counter has overflowed | R/W |
| 9 | SOCO | Successful Occurrence Counter Overflow<br>0: Successful occurrence counter has not overflowed<br>1: Successful occurrence counter has overflowed | R/W |
| 14:10 | — | These bits are read as 0. The write value should be 0. | R/W |
| 15 | TDCVF*1 | Transceiver Delay Compensation Violation Flag<br>0: Transceiver delay compensation violation has not occurred<br>1: Transceiver delay compensation violation has occurred | R/W |
| 23:16 | EOC[7:0] | Error Occurrence Counter<br>These bits show the error occurrence counter value. | R |
| 31:24 | SOC[7:0] | Successful occurrence counter<br>These bits show the successful occurrence counter value. | R |

Note 1. These bits are not available in the classical CAN function.

The CANFD Status Register indicates the transceiver compensation delay result and its related FIFO message lost status.

### TDCR[7:0] bits (Transceiver Delay Compensation Result)

The TDCR[7:0] bits are set when the transceiver delay has been measured.

The measured delay is a multiple of the CAN channel DLL clock. The result depends on the CFDC0FDCFG.TDCOC configuration and the offset value in CFDC0FDCFG.TDCO. See section 31.4.1.5. Transmitter Delay Compensation for details on how this value is derived.

The TDCR[7:0] bits are updated at the falling edge between FDF and the RES bit when CFDC0FDCFG.TDCOC = 0 and the transceiver delay compensation is enabled (CFDC0FDCFG.TDCE = 1).

These bits are cleared automatically when the related CANFD channel is in CH_RESET mode.

Note: These bits are not available in the classical CAN function.

### EOCO bit (Error Occurrence Counter Overflow)

The EOCO bit indicates whether the related CAN channel error occurrence counter has overflowed. This bit is cleared by writing 0 to it. Writing 1 has no effect.

This bit is set automatically when CFDC0FDSTS.EOC is 0xFF and a CAN bus error is detected based on the configuration defined in CFDC0FDCFG.EOCCFG.

If the set from the CAN channel occurs simultaneously with the clear by the write access, then the bit is set.

This bit is cleared automatically when the related CANFD channel is in CH_RESET mode.

Only write to this bit when the related CANFD channel is in CH_HALT or CH_OPERATION mode.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1.

#### SOCO bit (Successful Occurrence Counter Overflow)

The SOCO bit indicates whether the related CAN channel successful occurrence counter has overflowed. This bit is cleared by writing 0 to it. Writing 1 has no effect.

This bit is set automatically when CFDC0FDSTS.SOC is 0xFF and a successful message reception or successful message transmission occurs.

If the set from the CAN channel occurs simultaneously with the clear by the write access, then the bit is set.

This bit is cleared automatically when the related CANFD channel is in CH_RESET mode.

Write to this bit only when the related CANFD channel is in CH_HALT or CH_OPERATION mode.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1.

#### TDCVF bit (Transceiver Delay Compensation Violation Flag)

The CANFD module captures internally the transmitted data bit-by-bit. This data is then compared against the received CAN bus level which is delayed by the transceiver loop delay.

The transceiver delay has some variations depending on the physical parameters such as temperature. The result bit CFDC0FDSTS.TDCR is updated by each message. However, temporary maximum delay violation could be missed. Therefore, the TDCVF bit captures this violation.

This bit is cleared by writing 0 to it. Writing 1 has no effect.

This bit is set automatically when the transceiver delay compensation is greater than the maximum delay compensation (6 data bit times - 2 clk_dlc) and the internal bit is overrun.

If the set from the CAN channel occurs simultaneously with the clear by the write access, then the bit is set.

This bit is cleared automatically when the related CANFD channel is in CH_RESET mode.

Only write to this bit when the related CANFD channel is in CH_HALT or CH_OPERATION mode.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1.

Note: This bit is not available in the classical CAN function.

#### EOC[7:0] bits (Error Occurrence Counter)

The EOC[7:0] bits are used together with the SOC[7:0] bits to support an option for host-controlled fall-back to payload bit rate identical to arbitration bit rate when messages utilizing the reduced payload bit length have significant higher error rates compared to other messages.

This higher error rate can be detected depending on the configuration of the CFDC0FDCFG.EOCCFG bits.

The EOC[7:0] bits are set only by CANFD module logic. These bits are cleared by writing 1 to CFDC0FDCTR.EOCCLR. Writing any other value has no effect.

These bits are updated when an error occurs, according to the configuration of the CFDC0FDCFG.EOCCFG bits. When the counter reaches the value of 0xFF, the update stops.

These bits are cleared automatically when the related CANFD channel is in CH_RESET mode.

#### SOC[7:0] bits (Successful occurrence counter)

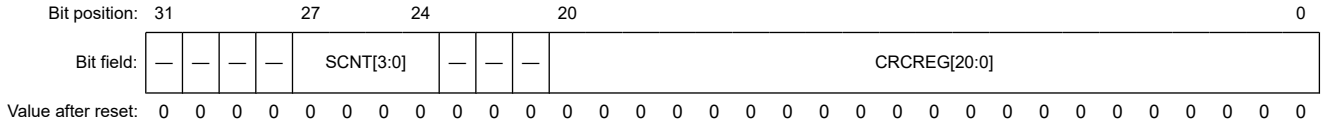
The SOC[7:0] bits are used together with the EOC[7:0] bits to support an option for host-controlled fall-back to payload bit rate identical to arbitration bit rate when messages utilizing the reduced payload bit length have significant higher error rates compared to other messages.

The SOC[7:0] bits are set only by CANFD module logic. Writing any other value has no effect.

These bits are updated when the occurrence of any error-free messages on the bus is detected through reception or transmission. When the counter reaches the value of 0xFF, the update stops.

Note: In Loopback mode, the counter is incremented twice.

These bits are cleared by writing 1 to CFDC0FDCTR.SOCCLR.



These bits are cleared automatically when the related CANFD channel is in CH_RESET mode.

## 31.2.10 CFDC0FDCRC : CANFD CRC Register

This register is not available in the classical CAN function.

Base address: CANFD = 0x400B_0000

Offset address: 0x0110

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 20:0 | CRCREG[20:0] | CRC Register value<br>These bits show the CRC value calculated for the CANFD frame. | R |
| 23:21 | — | These bits are read as 0. | R |
| 27:24 | SCNT[3:0] | Stuff bit count<br>These bits shows the stuff bit count (mod 8) for the CANFD frame. | R |
| 31:28 | — | These bits are read as 0. | R |

The CANFD CRC Register holds the CRC value calculated for the CANFD frame.

### CRCREG[20:0] bits (CRC Register value)

The CRCREG[20:0] bits contain the CRC value calculated by the CANFD channel logic when the CFDC0CTR.CTME bit is enabled.

The CFDC0FDCRC.CRCREG value is updated in the first bit of the CRC field of the CANFD frame (reception and transmission).

When the CFDC0CTR.CTME bit is 0, the CRCREG[20:0] bits are always read as 0.

When bit 17th of the CRC field is used, CRCREG[20:17] are always read as 0.

These bits are cleared automatically when the related CANFD channel is in CH_RESET mode.

### SCNT[3:0] bits (Stuff bit count)

The SCNT[3:0] bits contain the stuff count value of the CANFD frame. These bits indicate the number of inserted stuff bits (modulo 8, Graycoded) for a CANFD frame when the CFDC0CTR.CTME bit is enabled in CFDC0FDCRC.SCNT[3:1]. SCNT[0] is the parity bit.

When the CFDC0CTR.CTME bit is 0, the SCNT[3:0] bits are always read as 0.

The SCNT value is updated in the first bit of CRC field of the CANFD frame (reception and transmission).

These bits are cleared automatically when the related CANFD channel is in CH_RESET mode.

## 31.2.11 CFDGCFG : Global Configuration Register

Base address: CANFD = 0x400B_0000

Offset address: 0x0014

| Bit position: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | ITRCP[15:0] | | | | | | | | | | | | | | | |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit position: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | TSSS | TSP[3:0] | | | | — | — | CMPOC | DCS | MME | DRE | DCE | TPRI |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 0 | TPRI | Transmission Priority<br>0: ID priority<br>1: Message buffer number priority | R/W |
| 1 | DCE | DLC Check Enable<br>0: DLC check disabled<br>1: DLC check enabled | R/W |
| 2 | DRE | DLC Replacement Enable<br>0: DLC replacement disabled<br>1: DLC replacement enabled | R/W |
| 3 | MME | Mirror Mode Enable<br>0: Mirror mode disabled<br>1: Mirror mode enabled | R/W |
| 4 | DCS | Data Link Controller Clock Select<br>0: CANFD core clock (CANFDCLK)<br>1: External oscillator clock (CANMCLK) | R/W |
| 5 | CMPOC*1 | CANFD Message Payload Overflow Configuration<br>0: Message is rejected<br>1: Message payload is cut to fit to configured message size | R/W |
| 7:6 | — | These bits are read as 0. The write value should be 0. | R/W |
| 11:8 | TSP[3:0] | Timestamp Prescaler<br>0x0: Timestamp prescaler = 1<br>0x1: Timestamp prescaler = 2<br>0x2: Timestamp prescaler = 4<br>0x3: Timestamp prescaler = 8<br>⋮<br>0xD: Timestamp prescaler = 8192<br>0xE: Timestamp prescaler = 16384<br>0xF: Timestamp prescaler = 32768 | R/W |
| 12 | TSSS | Timestamp Source Select<br>0: Source clock for timestamp counter is peripheral clock<br>1: Source clock for timestamp counter is bit time clock | R/W |
| 15:13 | — | These bits are read as 0. The write value should be 0. | R/W |
| 31:16 | ITRCP[15:0] | Interval Timer Reference Clock Prescaler<br>FIFO interval timer prescaler value | R/W |

Note 1. This bit is not available in the classical CAN function.

The Global Configuration Register is used to select the transmission priority to be used for all the TX message buffers and the clock source for the CAN protocol engine of CAN channel. The CFDGCFG register is also used to select the source for the timestamp clock and to configure the frequency for the timestamp clock and interval timer reference clock.

### TPRI bit (Transmission Priority)

The TPRI bit selects the transmission priority for CAN channel.

Do not write to this bit in GL_SLEEP mode. Only write to this bit when CANFD module is in GL_RESET mode.

Message buffer number priority should not be used together with TX queue transmission.

#### DCE bit (DLC Check Enable)

The DCE bit enables data length code (DLC) check for CAN channel.

Do not write to this bit in GL_SLEEP mode. Only write to this bit when CANFD module is in GL_RESET mode.

#### DRE bit (DLC Replacement Enable)

When the DRE bit is 1 and the DCE is 1, the CANFD stores the configured value (CFDGAFLP0r.GAFLDLC) of the DLC in the destination RX message buffer or FIFO buffer if the DLC check passes. Otherwise, the DLC value in the destination RX message buffer or FIFO buffer is unchanged.

Do not write to this bit in GL_SLEEP mode. Only write to this bit when CANFD module is in GL_RESET mode.

#### MME bit (Mirror Mode Enable)

The MME bit enables the Mirror mode for CAN channel.

Do not write to this bit in GL_SLEEP mode. Only write to this bit when CANFD module is in GL_RESET mode.

#### DCS bit (Data Link Controller Clock Select)

The DCS bit selects CANFDCLK or CANMCLK as the clock source for CAN communication.

Do not write to this bit in GL_SLEEP or GL_OPERATION mode. Only write to this bit when CANFD module is in GL_RESET mode.

#### CMPOC bit (CANFD Message Payload Overflow Configuration)

The CMPOC bit controls the message payload acceptance mechanism when the received payload is higher than the message buffer payload size CFDRMNB.RMPLS, CFDRFCCa.RFPLS, and CFDCFCC.CFPLS. The received message payload is always compared with the available message payload size in the message buffer.

Do not write to this bit in GL_SLEEP or GL_OPERATION mode. Only write to this bit when CANFD module is in GL_RESET mode.

When this bit is set and payload overflow occurs, the DLC value is stored in the RX message buffer or FIFO buffer unchanged.

Note: This bit is not available in the classical CAN function.

#### TSP[3:0] bits (Timestamp Prescaler)

The value configured in the TSP[3:0] bits defines the period of the clock source used for the timestamp counter.

Do not write to this bit in GL_SLEEP mode. Only write to this bit when CANFD module is in GL_RESET mode.

#### TSSS bit (Timestamp Source Select)

The TSSS bit allows the selection of the clock source for the timestamp counter.

Do not write to this bit in GL_SLEEP mode. Only write to this bit when CANFD module is in GL_RESET mode. Additionally, do not set this bit to 1 when CANFD communication is used.*1

Note: The bit time clock varies depending on the nominal and data rate bit configuration.

Note 1. This feature is not available in the classical CAN function.

#### ITRCP[15:0] bits (Interval Timer Reference Clock Prescaler)

The ITRCP[15:0] bits allow the definition of a reference clock for the FIFO interval timer source clock.

When these bits are 0x0000, the timer is disabled.

Do not write to this bit in GL_SLEEP mode. Only write to this bit when CANFD module is in GL_RESET mode.

## 31.2.12 CFDGCTR : Global Control Register

Base address: CANFD = 0x400B_0000

Offset address: 0x0018

| Bit position: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | TSRST |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit position: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | — | CMPOFIE | THLEIE | MEIE | DEIE | — | — | — | — | — | GSLPR | GMDC[1:0] | |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 1 | 0 | 1 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 1:0 | GMDC[1:0] | Global Mode Control<br>0 0: Global operation mode request<br>0 1: Global reset mode request<br>1 0: Global halt mode request<br>1 1: Keep current value | R/W |
| 2 | GSLPR | Global Sleep Request<br>0: Global sleep request disabled<br>1: Global sleep request enabled | R/W |
| 7:3 | — | These bits are read as 0. The write value should be 0. | R/W |
| 8 | DEIE | DLC Check Interrupt Enable<br>0: DLC check interrupt disabled<br>1: DLC check interrupt enabled | R/W |
| 9 | MEIE | Message Lost Error Interrupt Enable<br>0: Message lost error interrupt disabled<br>1: Message lost error interrupt enabled | R/W |
| 10 | THLEIE | TX History List Entry Lost Interrupt Enable<br>0: TX history list entry lost interrupt disabled<br>1: TX history list entry lost interrupt enabled | R/W |
| 11 | CMPOFIE*1 | CANFD Message Payload Overflow Flag Interrupt Enable<br>0: CANFD message payload overflow flag interrupt disabled<br>1: CANFD message payload overflow flag interrupt enabled | R/W |
| 15:12 | — | These bits are read as 0. The write value should be 0. | R/W |
| 16 | TSRST | Timestamp Reset<br>0: Timestamp not reset<br>1: Timestamp reset | R/W |
| 31:17 | — | These bits are read as 0. The write value should be 0. | R/W |

Note 1. This bit is not available in the classical CAN function.

The Global Control Register controls the global mode of the CANFD module and the timestamp function. The register also enables and disables the global error interrupts.

### GMDC bits (Global Mode Control)

The GMDC bits can be used to configure the modes for the CANFD module. Additionally, if CFDGCTR.GSLPR bit is 1 when the CANFD module is in Reset mode, the CANFD module enters Global Sleep mode.

Setting the GMDC bits to 11b has no effect. Mode transition is described in detail in section 31.3.2. Global Modes.

Do not write to this bit when the CANFD module is in GL_SLEEP mode.

### GSLPR bit (Global Sleep Request)

The GSLPR bit globally selects the sleep request for CANFD module including CAN channels. Channel sleep request is set automatically for channels.

Only write to this bit when the CANFD module is in GL_RESET or GL_SLEEP mode.

**DEIE bit (DLC Check Interrupt Enable)**

When the DEIE bit is 1, an interrupt is generated if a DLC error is detected in the received frames.

Do not write to this bit when the CANFD module is in GL_SLEEP mode.

**MEIE bit (Message Lost Error Interrupt Enable)**

When the MEIE bit is 1, an interrupt is generated if a message lost condition occurs.

Do not write to this bit when the CANFD module is in GL_SLEEP mode.

**THLEIE bit (TX History List Entry Lost Interrupt Enable)**

When the THLEIE bit is 1, an interrupt is generated if a TX history list entry lost condition occurs.

Do not write to this bit when the CANFD module is in GL_SLEEP mode.

**CMPOFIE bit (CANFD Message Payload Overflow Flag Interrupt Enable)**

When the CMPOFIE bit is 1, an interrupt is generated when a CANFD message payload overflow condition occurs.

Do not write to this bit when the CANFD module is in GL_SLEEP mode.

Note: This bit is not available in the classical CAN function

**TSRST bit (Timestamp Reset)**

When the TSRST bit is 1, the Global Timestamp Register is reset to 0x0000.

Do not write to this bit when the CANFD module is in GL_SLEEP or GL_RESET mode.

Read value is always 0.

This bit is cleared automatically by the CANFD module logic.

## 31.2.13 CFDGSTS : Global Status Register

Base address: CANFD = 0x400B_0000

Offset address: 0x001C

| Bit position: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit position: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | — | — | — | — | — | — | — | — | — | GRAM INIT | GSLP STS | GHLT STS | GRST STS |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 1 | 1 | 0 | 1 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 0 | GRSTSTS | Global Reset Status<br>0: Not in Reset mode<br>1: In Reset mode | R |
| 1 | GHLTSTS | Global Halt Status<br>0: Not in Halt mode<br>1: In Halt mode | R |
| 2 | GSLPSTS | Global Sleep Status<br>0: Not in Sleep mode<br>1: In Sleep mode | R |
| 3 | GRAMINIT | Global RAM Initialization<br>0: RAM initialization is complete<br>1: RAM initialization is ongoing | R |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 31:4 | — | These bits are read as 0. | R |

The Global Status Register indicates the global status of the CANFD module.

**GRSTSTS bit (Global Reset Status)**

The GRSTSTS bit indicates the status of Global CANFD module Reset mode.

This bit is set automatically when the CANFD module enters GL_RESET mode. When the mode changes from GL_RESET mode to GL_SLEEP mode, this bit remains set.

This bit is cleared automatically when the CANFD module exits the GL_RESET mode.

**GHLTSTS bit (Global Halt Status)**

The GHLTSTS bit indicates the status of Global CANFD module Halt mode.

This bit is set automatically when the CANFD module enters GL_HALT mode.

This bit is cleared automatically when the CANFD module exits the GL_HALT mode.

**GSLPSTS bit (Global Sleep Status)**

The GSLPSTS bit indicates the status of Global CANFD module Sleep mode.

This bit is set automatically when the CANFD module enters GL_SLEEP mode.

This bit is cleared automatically when the CANFD module exits the GL_SLEEP mode.

**GRAMINIT bit (Global RAM Initialization)**

The GRAMINIT bit indicates the status of Global CANFD module RAM initialization.

This bit is set automatically when the CANFD module enters GL_SLEEP mode after a hardware reset.

This bit is cleared automatically when the CANFD module completed RAM initialization.

This bit is cleared when the test_mode input port is set to 1.

## 31.2.14 CFDGERFL : Global Error Flag Register

Base address: CANFD = 0x400B_0000

Offset address: 0x0020

| Bit position: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | — | — | — | — | — | — | — | — | — | — | — | | EEF0 |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit position: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | — | — | — | — | — | — | — | — | — | CMPOF | THLES | MES | DEF |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 0 | DEF | DLC Error Flag<br>0: DLC error not detected<br>1: DLC error detected | R/W |
| 1 | MES | Message Lost Error Status<br>0: Message lost error not detected<br>1: Message lost error detected | R |
| 2 | THLES | TX History List Entry Lost Error Status<br>0: TX history list entry lost error not detected<br>1: TX history list entry lost error detected | R |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 3 | CMPOF*1 | CANFD Message Payload Overflow Flag<br>0: CANFD message payload overflow not detected<br>1: CANFD message payload overflow detected | R/W |
| 15:4 | — | These bits are read as 0. The write value should be 0. | R/W |
| 16 | EEF0 | ECC Error Flag<br>0: ECC error not detected during TX-SCAN<br>1: ECC error detected during TX-SCAN | R/W |
| 31:17 | — | These bits are read as 0. The write value should be 0. | R/W |

Note 1. This bit is not available in the classical CAN function.

The Global Error Flag register indicates the detection of global errors.

### DEF bit (DLC Error Flag)

The DEF bit indicates the error status of the DLC.

Do not write to this bit when the CANFD module is in GL_SLEEP or GL_RESET mode. Writing 1 has no effect.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1.

This bit is set automatically when a DLC error is detected in a received frame.

If the set from the CAN channel occurs simultaneously with the clear by the write access, then the bit is set

The bit is cleared by writing 0 to it.

This bit is cleared automatically in GL_RESET mode.

### MES bit (Message Lost Error Status)

The MES bit indicates status of the message lost error.

This bit is set automatically when a FIFO message lost error is detected.

This bit is cleared automatically when:

- All FIFO message lost flags are cleared
- The CANFD module is in GL_RESET mode.

### THLES bit (TX History List Entry Lost Error Status)

The THLES bit indicates status of the TX history list entry lost error.

This bit is set automatically when a TX history list entry lost error is detected.

This bit is cleared automatically when:

- All TX history list entry lost flags are cleared
- The CANFD module is in GL_RESET mode.

### CMPOF bit (CANFD Message Payload Overflow Flag)

The CMPOF bit is set automatically when a CANFD message payload overflow is detected on at least one channel.

Do not write to this bit when the CANFD module is in GL_SLEEP or GL_RESET mode.

This bit is cleared by writing 0 to it. Writing 1 to this bit has no effect.

If the set from the CAN channel occurs simultaneously with the clear by the write access, then the bit is set.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1.

This bit is cleared automatically in GL_RESET mode.

Note: This bit is not available in the classical CAN function

### EEF0 bit (ECC Error Flag)

The EEF0 bit specifies whether an ECC error has occurred.

Do not write to this bit when the CANFD module is in GL_SLEEP or GL_RESET mode. Writing 1 to this bit has no effect.

If the set from the CAN channel occurs simultaneously with the clear by the write access, then the bit is set.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1.

The bit is cleared by writing 0 to it. This bit is cleared automatically in GL_RESET mode.

## 31.2.15 CFDGTINTSTS : Global TX Interrupt Status Register

Base address: CANFD = 0x400B_0000

Offset address: 0x00A4

| Bit position: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit position: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | — | — | — | — | — | — | — | — | THIF0 | CFTIF0 | TQIF0 | TAI0 | TSIF0 |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 0 | TSIF0 | TX Successful Interrupt Flag<br>0: Channel n TX Successful Interrupt flag not set<br>1: Channel n TX Successful Interrupt flag set | R |
| 1 | TAI0 | TX Abort Interrupt Flag<br>0: Channel n TX Abort Interrupt flag not set<br>1: Channel n TX Abort Interrupt flag set | R |
| 2 | TQIF0 | TX Queue Interrupt Flag<br>0: Channel n TX Queue Interrupt flag not set<br>1: Channel n TX Queue Interrupt flag set | R |
| 3 | CFTIF0 | COM FIFO TX Mode Interrupt Flag<br>0: Channel n COM FIFO TX Mode Interrupt flag not set<br>1: Channel n COM FIFO TX Mode Interrupt flag set | R |
| 4 | THIF0 | TX History List Interrupt<br>0: Channel n TX History List Interrupt flag not set<br>1: Channel n TX History List Interrupt flag set | R |
| 31:5 | — | These bits are read as 0. | R |

The Global TX Interrupt Status register indicates the detection of transmit specific interrupts.

### TSIF0 bit (TX Successful Interrupt Flag)

The TSIF0 bit is set to 1 when the TX Successful Interrupt flag of the related channel is set (when the interrupt is enabled). This bit is cleared automatically:

- When the related TX MB Result Status bits are cleared (when the interrupt enable is disabled)
- When in GL_RESET or CH_RESET mode.

### TAI0 bit (TX Abort Interrupt Flag)

The TAIF0 bit is set to 1 when the TX Abort Interrupt flag of the related channel is set (when the interrupt is enabled).

This bit is cleared automatically:

- When the related TX MB Result Status bits are cleared (when the interrupt enable is disabled)
- When in GL_RESET or CH_RESET mode.

#### TQIF0 bit (TX Queue Interrupt Flag)

The TQIF0 bit is set to 1 when the TX Queue Interrupt flag of the related channel is set (when the interrupt is enabled). This bit is cleared automatically:

- When the related TX Queue Interrupt flag is cleared (when the interrupt is enable disabled)
- When in GL_RESET or CH_RESET mode.

#### CFTIF0 bit (COM FIFO TX Mode Interrupt Flag)

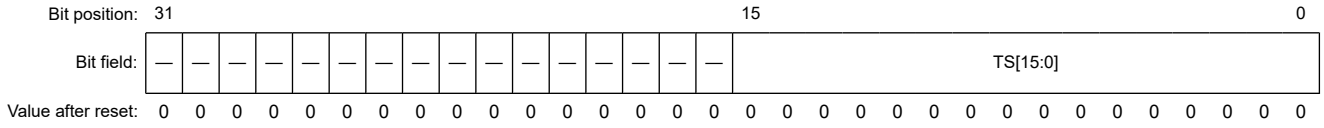
The CFTIF0 bit is set to 1 when the related COM TX FIFO Mode Interrupt flag (CFDCFSTS.CFTXIF) is set (when the interrupt is enabled).

This bit is cleared automatically:

- When the related COM TX FIFO Mode Interrupt flag (CFDCFSTS.CFTXIF) is cleared (when the interrupt enable is disabled)
- When in GL_RESET or CH_RESET mode.

#### THIF0 bit (TX History List Interrupt)

The THIF0 bit is set to 1 when the related TX History List Interrupt flag (CFDTHLSTS.THLIF) is set (when the interrupt is enabled).



This bit is cleared automatically:

- When the related TX History List Interrupt flag (CFDTHLSTS.THLIF) is cleared (when the interrupt enable is disabled)
- When in GL_RESET or CH_RESET mode.

### 31.2.16 CFDGTSC : Global Timestamp Counter Register

Base address: CANFD = 0x400B_0000

Offset address: 0x0024

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 15:0 | TS[15:0] | Timestamp value | R |
| 31:16 | — | These bits are read as 0. | R |

The Global Timestamp Counter register stores the timestamp based on the selected configuration.

#### TS[15:0] bits (Timestamp value)

The Timestamp value is stored in the Global Timestamp Counter register based on the configuration of TSSS, TSBTCS and TSP. The accuracy of the timestamp counter cannot be guaranteed when transitioning to halt state.

The Timestamp value is stored in this register based on the configuration of TSSS, TSBTCS and TSP.

Do not write to bits TS[15:0] when the CANFD module is in GL_RESET or GL_SLEEP mode.

The TS[15:0] bits are cleared automatically in GL_RESET mode.

## 31.2.17 CFDGAFLECTR : Global Acceptance Filter List Entry Control Register

Base address: CANFD = 0x400B_0000

Offset address: 0x0028

| Bit position: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit position: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | — | — | — | — | AFLDAE | — | — | — | — | — | — | — | — |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 7:0 | — | These bits are read as 0. The write value should be 0. | R/W |
| 8 | AFLDAE | Acceptance Filter List Data Access Enable<br>0: Acceptance Filter List data access disabled<br>1: Acceptance Filter List data access enabled | R/W |
| 31:9 | — | These bits are read as 0. The write value should be 0. | R/W |

The Global Acceptance Filter List Entry Control Register is used to select the Global Acceptance Filter List page for reading or writing entries into the Global Acceptance Filter List.

### AFLDAE bit (Acceptance Filter List Data Access Enable)

The AFLDAE bit prevents write access to the Acceptance Filter List when cleared after configuration of the Acceptance Filter List.

Data can be read from the Acceptance Filter List independent of the status of this bit.

Do not write to this bit when the CANFD module is in GL_SLEEP mode. Set this bit to enable write access for the Acceptance Filter List.

## 31.2.18 CFDGAFLCFG : Global Acceptance Filter List Configuration Register

Base address: CANFD = 0x400B_0000

Offset address: 0x002C

| Bit position: | 31 | 20 | 16 | 0 |
|---|---|---|---|---|
| Bit field: | — | RNC0[4:0] | — | — |
| Value after reset: | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 15:0 | — | These bits are read as 0. The write value should be 0. | R/W |
| 20:16 | RNC0[4:0] | Rule Number<br>Number of rules dedicated | R/W |
| 31:21 | — | These bits are read as 0. The write value should be 0. | R/W |

The Global Acceptance Filter List Configuration Register is used to define the number of rules for entries in the Acceptance Filter List.

The total number of available entries in the Acceptance Filter List is 16.

### RNC0[4:0] bits (Rule Number)

The RNC0[4:0] bits define the number of rules in the Acceptance Filter List.

Only write to these bits when the CANFD module is in GL_RESET mode. These bits can set to 5 bits for 16 rules.

## 31.2.19 CFDGAFLIDr : Global Acceptance Filter List ID Registers (r = 1 to 16)

Base address: CANFD = 0x400B_0000

Offset address: 0x0120 + 0x0010 × (r - 1)

| Bit position: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | GAFLIDE | GAFLRTR | GAFLLB | GAFLID[28:16] | | | | | | | | | | | | |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit position: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | GAFLID[15:0] | | | | | | | | | | | | | | | |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 28:0 | GAFLID[28:0] | Global Acceptance Filter List Entry ID Field<br>ID part of the Global Acceptance Filter List entry | R/W |
| 29 | GAFLLB | Global Acceptance Filter List Entry Loopback Configuration<br>0: Global Acceptance Filter List entry ID for acceptance filtering with attribute RX<br>1: Global Acceptance Filter List entry ID for acceptance filtering with attribute TX | R/W |
| 30 | GAFLRTR | Global Acceptance Filter List Entry RTR Field<br>0: Data frame<br>1: Remote frame | R/W |
| 31 | GAFLIDE | Global Acceptance Filter List Entry IDE Field<br>0: Standard identifier of rule entry ID is valid for acceptance filtering<br>1: Extended identifier of rule entry ID is valid for acceptance filtering | R/W |

The Global Acceptance Filter List ID Registers are used to configure the ID field for the rules of entries in the Global Acceptance Filter List.

### GAFLID[28:0] bits (Global Acceptance Filter List Entry ID Field)

The GAFLID[28:0] bits represent the CAN identifier (ID) field of each entry in the Global Acceptance Filter List.

Do not write to these bits when CFDGAFLECTR.AFLDAE bit is 0.

Only write to these bits when the related CANFD channel is in CH_RESET or CH_HALT mode.

### GAFLLB bit (Global Acceptance Filter List Entry Loopback Configuration)

The GAFLLB bit selects whether entry in the Global Acceptance Filter List gets the attribute RX or TX.

This attribute determines the validity of the entry in Mirror mode, Loopback test mode, and during standard (non-loopback) reception. See section 31.5.5. Loopback Modes for detailed description of the validity of the Global Acceptance Filter List entry depending on transmitter/receiver case, the type of loopback mode, and RX/TX attribute.

Do not write to this bit when CFDGAFLECTR.AFLDAE bit is 0.

Only write to this bit when the related CANFD channel is in CH_RESET or CH_HALT mode.

### GAFLRTR bit (Global Acceptance Filter List Entry RTR Field)

The GAFLRTR bit allows the configuration of the specified frame format (data frame or remote frame) for each entry of the Global Acceptance Filter List. For each rule entry in a CAN channel, the acceptance filter process compares this bit against the RTR bit of the received CAN message.

Do not write to this bit when CFDGAFLECTR.AFLDAE bit is 0.

Only write to this bit when the related CANFD channel is in CH_RESET or CH_HALT mode.

### GAFLIDE bit (Global Acceptance Filter List Entry IDE Field)

The GAFLIDE bit allows the configuration of the ID format (standard ID or extended ID) for each entry in the Global Acceptance Filter List. For each rule entry in a CAN channel, the acceptance filter process compares this bit against the IDE bit of the received CAN message.

Do not write to this bit when CFDGAFLECTR.AFLDAE bit is 0.

Only write to this bit when the related CANFD channel is in CH_RESET or CH_HALT mode.

## 31.2.20 CFDGAFLMr : Global Acceptance Filter List Mask Registers (r = 1 to 16)

Base address: CANFD = 0x400B_0000

Offset address: 0x0124 + 0x0010 × (r - 1)

| Bit position: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | GAFLIDEM | GAFLRTRM | GAFLIFL1 | GAFLIDM[28:16] | | | | | | | | | | | | |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit position: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | GAFLIDM[15:0] | | | | | | | | | | | | | | | |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 28:0 | GAFLIDM[28:0] | Global Acceptance Filter List ID Mask Field<br>Global Acceptance Filter List Mask field bits for ID field | R/W |
| 29 | GAFLIFL1 | Global Acceptance Filter List Information Label 1<br>Global Acceptance Filter List information label bit 1 | R/W |
| 30 | GAFLRTRM | Global Acceptance Filter List Entry RTR Mask<br>0: RTR bit is not used for ID matching<br>1: RTR bit is used for ID matching | R/W |
| 31 | GAFLIDEM | Global Acceptance Filter List IDE Mask<br>0: IDE bit is not used for ID matching<br>1: IDE bit is used for ID matching | R/W |

The Global Acceptance Filter List Mask Registers are used to configure the Mask field of each rule for entries in the Global Acceptance Filter List.

### GAFLIDM[28:0] bits (Global Acceptance Filter List ID Mask Field)

GAFLIDM[28:0] bits are the filter mask bits for the related bits in the CAN Identifier field of each Global Acceptance Filter List entry.

| | |
|---|---|
| 0 | Corresponding STD-ID/EXT-ID bit is not used for ID matching |
| 1 | Corresponding STD-ID/EXT-ID bit is used for ID matching |

Do not write to these bits when CFDGAFLECTR.AFLDAE bit is 0.

Only write to these bits when the related CANFD channel is in CH_RESET or CH_HALT mode.

### GAFLIFL1 bit (Global Acceptance Filter List Information Label 1)

The GAFLIFL1 bit allows the configuration of a 2-bit information label to be attached to a received message accepted by the associated entry in the Global Acceptance Filter List. This bit is a MSB bit of an information label.

Do not write to this bit when CFDGAFLECTR.AFLDAE bit is 0.

Only write to this bit when the related CANFD channel is in CH_RESET or CH_HALT mode.

This bit is stored in the Information Label Field [1] (CFDRMFDSTSb.RMIFL [1], CFDRFFDSTSb.RFIFL [1], CFDCFFDCSTS.CFIFL [1]) of the storage location of an incoming message.

### GAFLRTRM bit (Global Acceptance Filter List Entry RTR Mask)

The GAFLRTRM bit allows the configuration of the RTR mask bit for each entry in the Global Acceptance Filter List.

Do not write to this bit when CFDGAFLECTR.AFLDAE bit is 0.

Only write to this bit when the related CANFD channel is in CH_RESET or CH_HALT mode.

### GAFLIDEM bit (Global Acceptance Filter List IDE Mask)

The GAFLIDEM bit allows the configuration of the IDE mask bit for each entry in the Global Acceptance Filter List.

When the IDE mask bit is 0, the ID comparison depends on the received IDE bit.

If the received IDE bit is 0, the STD-ID comparison takes place.

If the received IDE bit is 1, the EXT-ID comparison takes place.

Do not write to this bit when CFDGAFLECTR.AFLDAE bit is 0.

Only write to this bit when the related CANFD channel is in CH_RESET or CH_HALT mode.

## 31.2.21 CFDGAFLP0r : Global Acceptance Filter List Pointer 0 Registers (r = 1 to 16)

Base address: CANFD = 0x400B_0000

Offset address: 0x0128 + 0x0010 × (r - 1)

| Bit position: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | GAFLPTR[15:0] | | | | | | | | | | | | | | | |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit position: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | GAFLRMV | — | — | GAFLRMDP[4:0] | | | | | GAFLIFL0 | — | — | — | GAFLDLC[3:0] | | | |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 3:0 | GAFLDLC[3:0] | Global Acceptance Filter List DLC Field<br>Minimum number of data bytes in a data frame required for acceptance | R/W |
| 6:4 | — | These bits are read as 0. The write value should be 0. | R/W |
| 7 | GAFLIFL0 | Global Acceptance Filter List Information Label 0 | R/W |
| 12:8 | GAFLRMDP[4:0] | Global Acceptance Filter List RX Message Buffer Direction Pointer<br>RX message buffer number for storage of received messages | R/W |
| 14:13 | — | These bits are read as 0. The write value should be 0. | R/W |
| 15 | GAFLRMV | Global Acceptance Filter List RX Message Buffer Valid<br>0: Single message buffer direction pointer is invalid<br>1: Single message buffer direction pointer is valid | R/W |
| 31:16 | GAFLPTR[15:0] | Global Acceptance Filter List Pointer | R/W |

The Global Acceptance Filter List Pointer 0 Registers are used to configure the data length code (DLC), software pointer, single message buffer select, and message buffer direction pointer for each rule entry in the Global Acceptance Filter List.

### GAFLDLC[3:0] bits (Global Acceptance Filter List DLC Field)

The GAFLDLC[3:0] bits allow the configuration of a minimum data length code (DLC) value for a message to be accepted by the associated entry in the Global Acceptance Filter List (automatic DLC filter function).

DLC filter process is only passed if the DLC value of the message accepted by an entry in the Global Acceptance Filter List is equal to or higher than the DLC value configured for this associated Global Acceptance Filter List entry. Automatic DLC filter function is disabled for the corresponding rule entry when this field is set to 0.

Table 31.3 shows DLC value that can be configured.

**Table 31.3 Configuration of DLC value**

| Format | DLC[3] | DLC[2] | DLC[1] | DLC[0] | Description |
|---|---|---|---|---|---|
| CAN and CANFD | 0 | 0 | 0 | 0 | DLC of received message = 0 or more (DLC filter check is disabled) |
| CAN and CANFD | 0 | 0 | 0 | 1 | DLC of received message = 1 or more |
| CAN and CANFD | 0 | 0 | 1 | 0 | DLC of received message = 2 or more |
| CAN and CANFD | 0 | 0 | 1 | 1 | DLC of received message = 3 or more |
| CAN and CANFD | 0 | 1 | 0 | 0 | DLC of received message = 4 or more |
| CAN and CANFD | 0 | 1 | 0 | 1 | DLC of received message = 5 or more |
| CAN and CANFD | 0 | 1 | 1 | 0 | DLC of received message = 6 or more |
| CAN and CANFD | 0 | 1 | 1 | 1 | DLC of received message = 7 or more |
| CAN | 1 | x | x | x | DLC of received message = 8 or more |
| CANFD | 1 | 0 | 0 | 0 | DLC of received message = 8 or more*1 |
| CANFD | 1 | 0 | 0 | 1 | DLC of received message = 12 or more*1 |
| CANFD | 1 | 0 | 1 | 0 | DLC of received message = 16 or more*1 |
| CANFD | 1 | 0 | 1 | 1 | DLC of received message = 20 or more*1 |
| CANFD | 1 | 1 | 0 | 0 | DLC of received message = 24 or more*1 |
| CANFD | 1 | 1 | 0 | 1 | DLC of received message = 32 or more*1 |
| CANFD | 1 | 1 | 1 | 0 | DLC of received message = 48 or more*1 |
| CANFD | 1 | 1 | 1 | 1 | DLC of received message = 64*1 |

Note 1. This setting is not available in the classical CAN function.

Do not write to these bits when CFDGAFLECTR.AFLDAE bit is 0.

Only write to these bits when the related CANFD channel is in CH_RESET or CH_HALT mode.

### GAFLIFL0 bit (Global Acceptance Filter List Information Label 0)

The GAFLIFL0 bit allows the configuration of a 2-bit information label that can be attached to a received message accepted by the related Global Acceptance Filter List entry. This bit is a LSB bit of an information label.

You cannot write to this bit when CFDGAFLECTR.AFLDAE bit is 0.

Only write to the bit when the related CANFD channel is in CH_RESET or CH_HALT mode.

This bit is stored in Information Label Field[0] (CFDRMFDSTSb.RMIFL[0], CFDRFFDSTSb.RFIFL[0], CFDCFFDCSTS.CFIFL[0]) of the storage location of an incoming message.

### GAFLRMDP[4:0] bits (Global Acceptance Filter List RX Message Buffer Direction Pointer)

The GAFLRMDP[4:0] bits allow the configuration of a single reception message buffer as the destination target for a received message that passes the acceptance check of the related Global Acceptance Filter List entry. The value entered is the single destination message buffer number.

Do not write to these bits when CFDGAFLECTR.AFLDAE bit is 0.

Only write to these bits when the related CANFD channel is in CH_RESET or CH_HALT mode.

CFDRMNB.NRXMB[4:0] is the value entered in the RX Message Buffer Number Register to configure the number of RX message buffers. The value to be entered in CFDGAFLP0r.GAFLRMDP[4:0] bits should only be between 0x00 and CFDMNB.NMB[4:0] to 1 less.

If CFDRMNB.NRXMB[4:0] = 0x00, the GAFLRMV bit should be configured as 0.

### GAFLRMV bit (Global Acceptance Filter List RX Message Buffer Valid)

The GAFLRMV bit allows the enabling or disabling of a single reception message buffer as the target for a received message that passes the acceptance check of the related Global Acceptance Filter List entry.

Do not write to these bits when CFDGAFLECTR.AFLDAE bit is 0.

Only write to these bits when the related CANFD channel is in CH_RESET or CH_HALT mode.

### GAFLPTR[15:0] bits (Global Acceptance Filter List Pointer)

The GAFLPTR[15:0] bits allow the configuration of a 16-bit pointer to be attached to a received message accepted by the related Global Acceptance Filter List entry. The pointer is added during message storage in the Message Buffer area and can be used by the application as a support function. The pointer information can be used for example, to support PDU Identifier allocation for the received message in AUTOSAR systems.

Do not write to these bits when CFDGAFLECTR.AFLDAE bit is 0.

Only write to these bits when the related CANFD channel is in CH_RESET or CH_HALT mode.

## 31.2.22 CFDGAFLP1r : Global Acceptance Filter List Pointer 1 Registers (r = 1 to 16)

Base address: CANFD = 0x400B_0000

Offset address: 0x012C + 0x0010 × (r - 1)

| Bit position: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit position: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | — | — | — | — | GAFL FDP8 | — | — | — | — | — | — | GAFL FDP1 | GAFL FDP0 |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 0 | GAFLFDP0 | Global Acceptance Filter List FIFO Direction Pointer<br>FIFO direction pointer bits for received message storage<br>0: Disable RX FIFO 0 as target for reception<br>1: Enable RX FIFO 0 as target for reception | R/W |
| 1 | GAFLFDP1 | Global Acceptance Filter List FIFO Direction Pointer<br>FIFO direction pointer bits for received message storage<br>0: Disable RX FIFO 1 as target for reception<br>1: Enable RX FIFO 1 as target for reception | R/W |
| 7:2 | — | These bits are read as 0. The write value should be 0. | R/W |
| 8 | GAFLFDP8 | Global Acceptance Filter List FIFO Direction Pointer<br>FIFO direction pointer bits for received message storage<br>0: Disable Common FIFO as target for reception<br>1: Enable Common FIFO as target for reception | R/W |
| 31:9 | — | These bits are read as 0. The write value should be 0. | R/W |

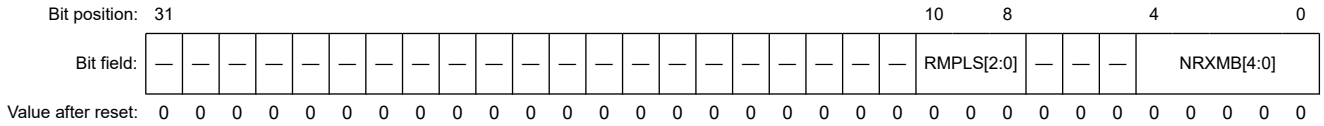
The Global Acceptance Filter List Pointer 1 registers are used to configure the FIFO direction pointer fields in each Rule Entry of the Global Acceptance Filter List.

### GAFLFDP8, GAFLFDP1, GAFLFDP0 bits (Global Acceptance Filter List FIFO Direction Pointer)

These bits allow the configuration of FIFO Buffers as the target for a received message passing the acceptance check of the related Global Acceptance Filter List entry. Each bit of the GAFLFDP8, GAFLFDP1, GAFLFDP0 is configuring a dedicated FIFO.

Users cannot write to these bits when CFDGAFLECTR.AFLDAE bit is 0.

For storage in Common FIFO, target for reception can only be those Common FIFO Buffers that are configured as RX FIFO.



Only write to these bits when the related CANFD channel is in CH_RESET or CH_HALT mode.

Users should only configure up to 2 destination FIFO Buffers or 1 destination FIFO Buffers plus one RX Message Buffer.

## 31.2.23 CFDRMNB : RX Message Buffer Number Register

Base address: CANFD = 0x400B_0000

Offset address: 0x0030

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 4:0 | NRXMB[4:0] | Number of RX Message Buffers | R/W |
| 7:5 | — | These bits are read as 0. The write value should be 0. | R/W |
| 10:8 | RMPLS[2:0] | Reception Message Buffer Payload Data Size<br>0 0 0: 8 bytes<br>0 0 1: 12 bytes<br>0 1 0: 16 bytes<br>0 1 1: 20 bytes<br>1 0 0: 24 bytes<br>1 0 1: 32 bytes<br>1 1 0: 48 bytes<br>1 1 1: 64 bytes | R/W |
| 31:11 | — | These bits are read as 0. The write value should be 0. | R/W |

The RX Message Buffer Number register is used to configure the total number of RX message buffers allocated to channels.

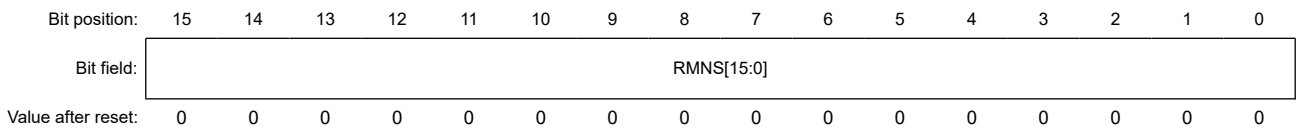
### NRXMB[4:0] bits (Number of RX Message Buffers)

The NRXMB[4:0] bits are used to configure the number of RX message buffers.

Only write to these bits when the CANFD module is in GL_RESET mode.

Enter only values between 0 and 16 inclusive, with 0x00 indicating that no RX message buffer is allocated.

### RMPLS[2:0] bits (Reception Message Buffer Payload Data Size)



The RMPLS[2:0] bits are used to configure the message buffer payload data size.

Only write to these bits when the CANFD module is in GL_RESET mode.

## 31.2.24 CFDRMND : RX Message Buffer New Data Register

Base address: CANFD = 0x400B_0000

Offset address: 0x0034

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 15:0 | RMNS[15:0] | RX Message Buffer New Data Status<br>0: New data not stored in corresponding RX message buffer<br>1: New data stored in corresponding RX message buffer | R/W |

The RX Message Buffer New Data Status Register specifies the new data storage status of the RX message buffers.

**RMNS[15:0] bits (RX Message Buffer New Data Status)**

The RMNS[15:0] bits indicate the status of new data for the corresponding RX message buffer. RMNS bit [0] corresponds to RX message buffer [0] and so on.

The bit position of CFDRMND corresponds to the buffer number of RXMB.

Do not write to these bits when the CANFD module is in GL_RESET or GL_SLEEP mode. Writing 1 has no effect.

These bits cannot be cleared when message storage in the corresponding RX message buffer is in progress.
Do not use the bit clear instruction to clear these bits. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1.

These bits are set automatically when storage of new messages are in the corresponding RX message buffer. These bits are cleared by writing 0. These bits are cleared automatically when the CANFD module is in GL_RESET mode.

When CFDRMNB.RMPLS = 000b (maximum 8 bytes payload), the duration of message storage is 6 PCLKB cycles.

When CFDRMNB.RMPLS > 000b, the duration of message storage is 6 PCLKB cycles + 1 for each 4 bytes (maximum of 20 PCLKB cycles for 64 bytes).

Note: This feature is not available in the classical CAN function.

## 31.2.25 CFDRFCCa : RX FIFO Configuration/Control Registers a (a = 0 to 1)

Base address: CANFD = 0x400B_0000

Offset address: 0x003C + 0x04 × a

| Bit position: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit position: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | RFIGCV[2:0] | | | RFIM | — | RFDC[2:0] | | | — | RFPLS[2:0] | | | — | — | RFIE | RFE |

| 11 | — | This bit is read as 0. The write value should be 0. | R/W |
| 12 | RFIM | RX FIFO Interrupt Mode<br>0: Interrupt generated when RX FIFO counter reaches RFIGCV value from values smaller than RFIGCV<br>1: Interrupt generated at the end of every received message storage | R/W |
| 15:13 | RFIGCV[2:0] | RX FIFO Interrupt Generation Counter Value<br>0 0 0: Interrupt generated when FIFO is 1/8th full<br>0 0 1: Interrupt generated when FIFO is 1/4th full<br>0 1 0: Interrupt generated when FIFO is 3/8th full<br>0 1 1: Interrupt generated when FIFO is 1/2 full<br>1 0 0: Interrupt generated when FIFO is 5/8th full<br>1 0 1: Interrupt generated when FIFO is 3/4th full<br>1 1 0: Interrupt generated when FIFO is 7/8th full<br>1 1 1: Interrupt generated when FIFO is full | R/W |
| 31:16 | — | These bits are read as 0. The write value should be 0. | R/W |

Note 1. These bits are not available in the classical CAN function.

The RX FIFO Configuration/Control Registers are used to configure and control the two RX FIFOs.

### RFE bit (RX FIFO Enable)

The RFE bit enables the FIFO. When this bit is set to 0, the RX FIFO is cleared to empty.

Only write to this bit when the CANFD module is in GL_HALT or GL_OPERATION mode.

This bit can only be set if the configured FIFO depth is greater than 0x000 (CFDRFCCa.RFDC > 0x000) and less than 0x110.

Set the RFE bit with a separate write access to the CFDRFCCa register, after all the other bits in the CFDRFCCa register are set.

This bit is cleared automatically when the CANFD module is in GL_RESET mode.

### RFIE bit (RX FIFO Interrupt Enable)

The RFIE bit enables generation of the FIFO interrupt.

Do not write to this bit when the CANFD module is in GL_SLEEP mode.

### RFPLS[2:0] bits (Rx FIFO Payload Data Size Configuration)

The RFPLS[2:0] bits define the message data payload allocation in the RAM.

This is the maximum number of bytes which can be received by this FIFO.

Only write to these bits when the CANFD module is in GL_RESET mode.

Note: These bits are not available in the classical CAN function.

### RFDC[2:0] bits (RX FIFO Depth Configuration)

The RFDC[2:0] bits select the depth of the FIFO in terms of the number of messages. If the FIFO depth is configured to 0 messages, the FIFO cannot be used.

Only write to these bits when the CANFD module is in GL_RESET mode.

### RFIM bit (RX FIFO Interrupt Mode)

The RFIM bit selects the interrupt generation condition for the FIFO.

Do not write to this bit when the CANFD module is in GL_SLEEP mode.

Only write to this bit when the CANFD module is in GL_RESET mode.

### RFIGCV[2:0] bits (RX FIFO Interrupt Generation Counter Value)

The RFIGCV[2:0] bits select the counter value of the FIFO for generation of FIFO interrupts. These values represent fractions of the FIFO depth for which an interrupt is generated.

Do not write to these bits when the CANFD module is in GL_SLEEP mode.

The setting of the RFIGCV[2:0] bits should be synchronized with the RFDC[2:0] bits.

Only write to these bits when the CANFD module is in GL_RESET mode.

## 31.2.26 CFDRFSTSa : RX FIFO Status Registers a (a = 0 to 1)

Base address: CANFD = 0x400B_0000

Offset address: 0x0044 + 0x04 × a

| Bit position: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit position: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | RFMC[5:0] | | | | | | — | — | — | — | RFIF | RFMLT | RFFLL | RFEMP |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 1 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 0 | RFEMP | RX FIFO Empty<br>0: FIFO not empty<br>1: FIFO empty | R |
| 1 | RFFLL | RX FIFO Full<br>0: FIFO not full<br>1: FIFO full | R |
| 2 | RFMLT | RX FIFO Message Lost<br>0: No message lost in FIFO<br>1: FIFO message lost | R/W |
| 3 | RFIF | RX FIFO Interrupt Flag<br>0: FIFO interrupt condition not satisfied<br>1: FIFO interrupt condition satisfied | R/W |
| 7:4 | — | These bits are read as 0. The write value should be 0. | R/W |
| 13:8 | RFMC[5:0] | RX FIFO Message Count<br>Number of messages stored in FIFO | R |
| 31:14 | — | These bits are read as 0. The write value should be 0. | R/W |

The RX FIFO Status Registers show the status of messages stored in the corresponding FIFO buffers.

### RFEMP bit (RX FIFO Empty)

The RFEMP bit is set automatically when:

- The RFMC bit is 0
- RX FIFO is disabled by setting the CFDRFCCa.RFE bit to 0
- The CANFD module is in GL_RESET mode.

The RFEMP bit is cleared automatically when the first message is stored in the RX FIFO buffer.

### RFFLL bit (RX FIFO Full)

The RFFLL bit is set automatically when the number of CAN messages stored in the FIFO buffer matches the configured FIFO depth.

The RFFLL is cleared automatically when:

- The number of CAN messages stored in the FIFO buffer is less than the configured FIFO depth
- RX FIFO is disabled by setting the CFDRFCCa.RFE bit to 0
- The CANFD module is in GL_RESET mode.

### RFMLT bit (RX FIFO Message Lost)

Only write to the RFMLT bit when CANFD module is in GL_HALT or GL_OPERATION mode. Writing 1 has no effect.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1.

This bit is set automatically whenever a message is lost due to attempted storage when the FIFO buffer is already full. If a set from the CAN channel occurs simultaneously with a clear by a write access, then the bit is set.

The bit is cleared:

- By writing 0 to it
- When the CANFD module is in GL_RESET mode.

### RFIF bit (RX FIFO Interrupt Flag)

The RFIF bit is set automatically when the configured interrupt condition is satisfied. This bit is not automatically cleared when the RX FIFO buffer is disabled.

Only write to this bit when the CANFD module is in GL_HALT or GL_OPERATION mode. Writing 1 has no effect.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1.

If a set from the CAN channel occurs simultaneously with a clear by a write access, then this bit is set.

The bit is cleared by writing 0 to it. The bit is also cleared when CANFD module is in GL_RESET mode.

### RFMC[5:0] bits (RX FIFO Message Count)

The RFMC[5:0] bits indicate the number of CAN messages stored in the RX FIFO buffer that can be read by the CPU.

These bits are cleared automatically when the FIFO is disabled and when the CANFD module is in GL_RESET mode.

## 31.2.27 CFDRFPCTRa : RX FIFO Pointer Control Registers a (a = 0 to 1)

Base address: CANFD = 0x400B_0000

Offset address: 0x004C + 0x04 × a

| Bit position: | 31 | | | | | | | | | | | | | | | | | | | | | | | | 7 | | | | | | | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | RFPC[7:0] | | | | | | | |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 7:0 | RFPC[7:0] | RX FIFO Pointer Control<br>Increments read pointer of the corresponding RX FIFO buffers | W |
| 31:8 | — | The write value should be 0. | W |

The RX FIFO Pointer Control Registers can be used to increment the read pointer of the corresponding RX FIFO buffers.

### RFPC bits (RX FIFO Pointer Control)

When the value 0xFF is written to the RFPC bits, the pointer of the corresponding RX FIFO buffer is moved to the next FIFO entry. Only write 0xFF to these registers when the corresponding RX FIFO buffer is enabled and not empty.

The read value from these bits is always 0x00.

Only write to these bits when the CANFD module is in GL_HALT or GL_OPERATION mode.

Do not write to the RX FIFO Pointer Control registers when DMA is enabled.

## 31.2.28 CFDCFCC : Common FIFO Configuration/Control Register

Base address: CANFD = 0x400B_0000

Offset address: 0x0054

| Bit position: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

| 17:16 | CFTML[1:0] | Common FIFO TX Message Buffer Link<br>Transmission scan link position of the corresponding channel | R/W |
| 20:18 | — | These bits are read as 0. The write value should be 0. | R/W |
| 23:21 | CFDC[2:0] | Common FIFO Depth Configuration<br>0 0 0: FIFO Depth = 0 message<br>0 0 1: FIFO Depth = 4 messages<br>0 1 0: FIFO Depth = 8 messages<br>0 1 1: FIFO Depth = 16 messages<br>1 0 0: FIFO Depth = 32 messages<br>1 0 1: FIFO Depth = 48 messages<br>1 1 0: FIFO Depth = Reserved<br>1 1 1: FIFO Depth = Reserved | R/W |
| 31:24 | CFITT[7:0] | Common FIFO Interval Transmission Time<br>Delay the start of transmission from the FIFO if configured in TX mode, delay is a multiple of basic Interval Timer Clock Source unit | R/W |

Note 1. These bits are not available in the classical CAN function.

### CFE bit (Common FIFO Enable)

The CFE bit enables the FIFO when set. FIFO is disabled when this bit is cleared.

This bit can also be used, by clearing it, to abort transmission from Common FIFO when configured in TX mode, or to stop reception into the Common FIFO in RX mode.

Only write to this bit when the CANFD module is in GL_HALT or GL_OPERATION mode and the related CANFD channel is not in CH_RESET mode for FIFOs configured as TX FIFO.

This bit can only be set if the configured FIFO depth is greater than 0x000 (CFDCFCC.CFDC > 0x000) and less than 0x110 (0x110 > CFDCFCC.CFDC > 0x000).

Set the CFE bit with a separate write access to the CFDCFCC register, after all the other bits in this register are set.

This bit is cleared automatically when the CANFD module is in GL_RESET mode.

This bit is also cleared automatically when the related channel is in CH_RESET mode if the FIFO is configured in TX mode.

### CFRXIE bit (Common FIFO RX Interrupt Enable)

The CFRXIE bit enables generation of FIFO interrupts when the interrupt flag is set after reception of a frame in the corresponding FIFO buffer.

Do not write to this bit when the CANFD module is in GL_SLEEP mode.

### CFTXIE bit (Common FIFO TX Interrupt Enable)

The CFTXIE bit enables generation of common FIFO interrupts when the interrupt flag is set after transmission of a frame from the corresponding FIFO buffer.

Do not write to this bit when the CANFD module is in GL_SLEEP mode.

#### CFPLS[2:0] bits (Common FIFO Payload Data Size Configuration)

The CFPLS[2:0] bits define the message data payload allocation in the RAM. This is the maximum number of bytes which can be received or transmitted by the FIFO buffer.

For details, see section 31.6. FIFO Buffers and Normal Message Buffer Configuration.

Only write to this bit when the CANFD module is in GL_RESET mode.

Note: These bits are not available in the classical CAN function.

#### CFM bit (Common FIFO Mode)

The CFM bit selects the mode of the FIFO. When a hardware reset is applied, all the Common FIFO buffers are configured in RX FIFO mode.

Do not write to these bits in GL_OPERATION or GL_SLEEP mode.

Only write to these bits when the CANFD module is in GL_RESET mode.

#### CFITSS bit (Common FIFO Interval Timer Source Select)

The CFITSS bit selects the basic clock source for the Interval Transmission Timer.

Do not write to this bit when the CANFD module is in GL_SLEEP mode. In addition, do not write to this bit when the CFE bit is set to 1.

Do not write 1 to this bit when CANFD communication is used.*1

Note: The bit time clock can vary depending on the nominal and data rate bit configuration.

Note 1. This feature is not available in the classical CAN function.

#### CFITR bit (Common FIFO Interval Timer Resolution)

The CFITR bit selects the resolution of the reference clock for the Interval Transmission Timer (peripheral clock is the source for the reference clock).

Do not write to this bit when the CANFD module is in GL_SLEEP mode. Also, do not write to this bit when the CFE bit is set to 1.

#### CFIM bit (Common FIFO Interrupt Mode)

The CFIM bit selects the interrupt generation condition for the FIFO buffer.

Do not write to this bit in GL_SLEEP mode.

Only write to this bit when the CANFD module is in GL_RESET mode.

#### CFIGCV[2:0] bits (Common FIFO Interrupt Generation Counter Value)

The CFIGCV[2:0] bits select the message counter value for the generation of FIFO interrupts. These values represent fractions of the FIFO depth at which the interrupt is to be generated.

Do not write to these bits when the CANFD module is in GL_SLEEP mode.

The setting of these bits should be synchronized with the CFDC[2:0] bits.

Only write to these bits when the CANFD module is in GL_RESET mode.

#### CFTML[1:0] bits (Common FIFO TX Message Buffer Link)

The CFTML[1:0] bits select the normal transmit message buffer position where the TX FIFO is linked to, for transmission scanning.

Do not write to these bits in GL_OPERATION or GL_SLEEP mode.

Only write to this bit when the CANFD module is in GL_RESET mode.

#### CFDC[2:0] bits (Common FIFO Depth Configuration)

The CFDC[2:0] bits select the depth of the common FIFO in terms of the number of messages. If the FIFO depth is configured to 0 message, the FIFO cannot be used.

Only write to these bits when the CANFD module is in GL_RESET mode.

### CFITT[7:0] bits (Common FIFO Interval Transmission Time)

The CFITT[7:0] bits select the delay in the start of transmission for all messages transmitted from this FIFO buffer when configured in TX mode. The delay is a multiple of the basic interval timer clock source period (reference clock × 1, reference clock × 10, or bit time clock of the related CAN channel).

Do not write to these bits when the CANFD module is in GL_SLEEP mode.

Do not write to these bits when the CFE bit is set to 1.

When CFDGCFG.ITRCP[15:0] = 0x0000, set the CFITT[7:0] bits to 0x0000.

## 31.2.29 CFDCFSTS : Common FIFO Status Register

Base address: CANFD = 0x400B_0000

Offset address: 0x0058

| Bit position: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

| 3 | CFRXIF | Common RX FIFO Interrupt Flag<br>0: FIFO interrupt condition not satisfied after frame reception<br>1: FIFO interrupt condition satisfied after frame reception | R/W |
| 4 | CFTXIF | Common TX FIFO Interrupt Flag<br>0: FIFO interrupt condition not satisfied after frame transmission<br>1: FIFO Interrupt condition satisfied after frame transmission | R/W |
| 7:5 | — | These bits are read as 0. The write value should be 0. | R/W |
| 13:8 | CFMC[5:0] | Common FIFO Message Count<br>Number of messages stored in FIFO | R |
| 31:14 | — | These bits are read as 0. The write value should be 0. | R/W |

### CFEMP bit (Common FIFO Empty)

The CFEMP bit is set automatically when:

- The CPU has read all messages from the FIFO configured in RX mode
- All messages have been transmitted from the FIFO configured in TX mode
- The FIFO is disabled by setting the CFE bit to 0
- The CANFD module is in GL_RESET mode
- The related CANFD channel is in CH_RESET when FIFO configured in TX mode.

The CFEMP bit is cleared automatically when:

- The first reception message is stored in the FIFO buffer when configured in RX mode
- The first message to be transmitted is stored in the FIFO buffer when configured in TX mode.

#### CFFLL bit (Common FIFO Full)

The CFFLL bit is set automatically when the number of CAN messages stored in the FIFO matches the configured FIFO depth.

The CFFLL bit is cleared automatically when:

- The number of CAN messages stored in the FIFO is less than the configured FIFO depth
- The FIFO is disabled by setting the CFE bit to 0
- The CANFD module is in GL_RESET mode
- The related CANFD channel is in CH_RESET mode when FIFO buffer is configured in TX mode.

#### CFMLT bit (Common FIFO Message Lost)

The CFMLT bit is set automatically whenever a message is lost due to attempted storage of a new message when FIFO is already full in RX mode.

If a set from the CAN channel occurs simultaneously with a clear by a write access, then this bit is set.

Only write to this bit when the CANFD module is in GL_HALT or GL_OPERATION mode and the related CANFD channel is not in CH_RESET mode for FIFO configured as TX FIFO. Writing 1 has no effect.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1.

The CFMLT bit is cleared:

- By writing 0 to it
- When the CANFD module is in GL_RESET mode
- When the related CANFD channel is in CH_RESET mode if the FIFO buffer is configured in TX mode.

#### CFRXIF bit (Common RX FIFO Interrupt Flag)

The CFRXIF bit is not cleared automatically if the Common FIFO buffer is disabled.

Only write to this bit when the CANFD module is in GL_HALT or GL_OPERATION mode and the related CANFD channel is not in CH_RESET mode for FIFO configured as TX FIFO. Writing 1 has no effect.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1.

This bit is set automatically when the configured interrupt condition is satisfied for Common FIFO buffers when configured in RX mode.

If the set from the CAN channel occurs simultaneously with the clear by the write access, then the bit is set.

The CFRXIF bit is cleared:

- By writing 0 to it
- When the CANFD module is in GL_RESET mode

#### CFTXIF bit (Common TX FIFO Interrupt Flag)

The CFTXIF bit is not cleared automatically if the Common FIFO buffer is disabled.

Only write to this bit when the CANFD module is in GL_HALT or GL_OPERATION mode and the related CANFD channel is not in CH_RESET mode for FIFO buffer configured as TX FIFO. Writing 1 has no effect.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1.

This bit is set automatically when the configured interrupt condition is satisfied for Common FIFO buffers configured in TX mode.

If the set from the CAN channel occurs simultaneously with the clear by the write access, then the bit is set.

The CFTXIF bit is cleared:

- By writing 0 to it
- When the CANFD module is in GL_RESET mode
- When the related CANFD channel is in CH_RESET mode if the FIFO buffer is configured in TX mode.

#### CFMC[5:0] bits (Common FIFO Message Count)

The CFMC[5:0] bits indicate the following:

- Number of CAN messages stored by the CPU in the FIFO buffer configured in TX mode pending for transmission
- Number of CAN messages stored in the FIFO buffer configured in RX mode by CANFD module to be read by the CPU

The CFMC[5:0] bits are cleared automatically when:

- The FIFO is disabled
- The CANFD module is in GL_RESET mode
- The related CANFD channel is in CH_RESET mode if the FIFO buffer is configured in TX mode.

## 31.2.30 CFDCFPCTR : Common FIFO Pointer Control Register

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 7:0 | CFPC[7:0] | Common FIFO Pointer Control<br>Increments read or write pointer of the corresponding Common FIFO buffers depending on the mode configuration. | W |
| 31:8 | — | The write value should be 0. | W |

The Common FIFO Pointer Control Registers can be used to increment the read or write pointer of the corresponding Common FIFO buffer.

#### CFPC[7:0] bits (Common FIFO Pointer Control)

When the value 0xFF is written into the CFPC[7:0] bits, the read pointer of the corresponding Common FIFO buffer (when configured in RX mode), or the write pointer of the corresponding Common FIFO buffer (when configured in TX mode) moves to the next FIFO entry.

The read value from these bits is always 0x00.

Only write to these bits when the CANFD module is in GL_HALT or GL_OPERATION mode.

Only write 0xFF to this register when:

- The Common FIFO buffer is enabled and is not empty if configured in RX mode
- The Common FIFO buffer is enabled and is not full if configured in TX mode

Do not write to the Common FIFO Pointer Control registers when DMA is enabled.

## 31.2.31 CFDFESTS : FIFO Empty Status Register

Base address: CANFD = 0x400B_0000

Offset address: 0x0060

| Bit position: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit position: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | — | — | — | — | CFEMP | — | — | — | — | — | — | RFXEMP[1:0] | |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 1 | 0 | 0 | 0 | 0 | 0 | 0 | 1 | 1 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 1:0 | RFXEMP[1:0] | RX FIFO Empty Status<br>0: Corresponding FIFO not empty<br>1: Corresponding FIFO empty | R |
| 7:2 | — | These bits are read as 0. | R |
| 8 | CFEMP | Common FIFO Empty Status<br>0: Corresponding FIFO not empty<br>1: Corresponding FIFO empty | R |
| 31:9 | — | These bits are read as 0. | R |

The FIFO Empty Status register shows status of the empty bits of the FIFO buffers.

### RFXEMP[1:0] bits (RX FIFO Empty Status)

The RFXEMP[1:0] bits are set when the CANFD module is in GL_RESET mode.

Each bit is set automatically when the corresponding bit is set in the RX FIFO Status Registers.

Each bit is cleared automatically when the corresponding bit is cleared in the RX FIFO Status Registers.

### CFEMP bit (Common FIFO Empty Status)

The CFEMP bits are set when the CANFD module is in GL_RESET mode.

Each bit is set automatically when the corresponding bit is set in the Common FIFO Status Registers.

Each bit is cleared automatically when the corresponding bit is cleared in the Common FIFO Status Registers.

## 31.2.32 CFDFFSTS : FIFO Full Status Register

Base address: CANFD = 0x400B_0000

Offset address: 0x0064

| Bit position: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit position: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | — | — | — | — | CFFLL | — | — | — | — | — | — | RFXFLL[1:0] | |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 1:0 | RFXFLL[1:0] | RX FIF0 Full Status<br>0: Corresponding FIFO not full<br>1: Corresponding FIFO full | R |
| 7:2 | — | These bits are read as 0. | R |
| 8 | CFFLL | Common FIF0 Full Status<br>0: Corresponding FIFO not full<br>1: Corresponding FIFO full | R |
| 31:9 | — | These bits are read as 0. | R |

The FIFO Full Status Register shows status of the full bits of the FIFO buffers.

**RFXFLL[1:0] bits (RX FIF0 Full Status)**

The RFXFLL[1:0] bits are cleared when CANFD module is in GL_RESET mode.

Each bit is set automatically when the corresponding bit is set in the RX FIFO Status Registers.

Each bit is cleared automatically when the corresponding bit is cleared in the RX FIFO Status Registers.

**CFFLL bits (Common FIF0 Full Status)**

The CFFLL bits are cleared when the CANFD module is in GL_RESET mode.

Each bit is set automatically when the corresponding bit is set in the Common FIFO Status Registers.

Each bit is cleared automatically when the corresponding bit is cleared in the Common FIFO Status Registers.

## 31.2.33 CFDFMSTS : FIFO Message Lost Status Register

Base address: CANFD = 0x400B_0000

Offset address: 0x0068

| Bit position: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit position: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | — | — | — | — | CFMLT | — | — | — | — | — | — | RFXMLT[1:0] | |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 1:0 | RFXMLT[1:0] | RX FIFO Message Lost Status<br>0: Corresponding FIFO Message Lost flag not set<br>1: Corresponding FIFO Message Lost flag set | R |
| 7:2 | — | These bits are read as 0. | R |
| 8 | CFMLT | Common FIFO Message Lost Status<br>0: Corresponding FIFO Message Lost flag not set<br>1: Corresponding FIFO Message Lost flag set | R |
| 31:9 | — | These bits are read as 0. | R |

The FIFO Message Lost Status Register shows status of the Msg Lost bits of the FIFO buffers.

**RFXMLT[1:0] bits (RX FIFO Message Lost Status)**

The RFXMLT[1:0] bits are cleared when the CANFD module is in GL_RESET mode.

Each bit is set automatically when the corresponding bit is set in the RX FIFO Status Registers.

Each bit is cleared automatically when the corresponding bit is cleared in the RX FIFO Status Registers.

**CFMLT bits (Common FIFO Message Lost Status)**

The CFMLT bits are cleared when the CANFD module is in GL_RESET mode.

Each bit is set automatically when the corresponding bit is set in the Common FIFO Status Registers.

Each bit is cleared automatically when the corresponding bit is cleared in the Common FIFO Status Registers.

## 31.2.34 CFDRFISTS : RX FIFO Interrupt Flag Status Register

Base address: CANFD = 0x400B_0000

Offset address: 0x006C

| Bit position: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit position: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | — | — | — | — | — | — | — | — | — | — | — | RFXIF[1:0] | |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 1:0 | RFXIF[1:0] | RX FIFO[x] Interrupt Flag Status<br>0: Corresponding RX FIFO Interrupt flag not set<br>1: Corresponding RX FIFO Interrupt flag set | R |
| 31:2 | — | These bits are read as 0. | R |

The FIFO Interrupt Flag Status Register shows status of the interrupt flag bits of the RX FIFO buffers.

**RFXIF[1:0] bits (RX FIFO[x] Interrupt Flag Status)**

Each bit is set automatically when the corresponding interrupt flag bit is set in the RX FIFO Status Registers.

The RFXIF[1:0] bits are cleared when the CANFD module is in GL_RESET mode.

Each bit is cleared automatically when the corresponding interrupt flag bit is cleared in the RX FIFO Status Registers.

## 31.2.35 CFDCDTCT : DMA Transfer Control Register

Base address: CANFD = 0x400B_0000

Offset address: 0x00C8

| Bit position: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit position: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | — | — | — | — | CFDMAE | — | — | — | — | — | — | RFDMAE1 | RFDMAE0 |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 0 | RFDMAE0 | DMA Transfer Enable for RXFIFO 0<br>0: DMA transfer request disabled<br>1: DMA transfer request enabled | R/W |
| 1 | RFDMAE1 | DMA Transfer Enable for RXFIFO 1<br>0: DMA transfer request disabled<br>1: DMA transfer request enabled | R/W |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 7:2 | — | These bits are read as 0. The write value should be 0. | R/W |
| 8 | CFDMAE | DMA Transfer Enable for Common FIFO 0<br>0: DMA transfer request disabled<br>1: DMA transfer request enabled | R/W |
| 31:9 | — | These bits are read as 0. The write value should be 0. | R/W |

The DMA Transfer Control Register controls the start and stop of DMA transfer operation.

**RFDMAEe (e = 0 to 1) bit (DMA Transfer Enable for RXFIFO e)**

The RFDMAEe bit cannot be set in GL_SLEEP or GL_RESET mode.

This bit is cleared when the CANFD module is in GL_RESET mode.

**CFDMAE bit (DMA Transfer Enable for Common FIFO)**

The CFDMAE bit enables or disables DMA transfer request for common FIFO

The CFDMAE bit cannot be set in GL_SLEEP or GL_RESET mode.

Do not enable a DMA transfer for a Common FIFO that is configured as TX FIFO.

This bit is cleared when the CANFD module is in GL_RESET mode.

## 31.2.36 CFDCDTSTS : DMA Transfer Status Register

Base address: CANFD = 0x400B_0000

Offset address: 0x00CC

| Bit position: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit position: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | — | — | — | — | CFDMASTS | — | — | — | — | — | — | RFDMASTS1 | RFDMASTS0 |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 0 | RFDMASTS0 | DMA Transfer Status for RX FIFO 0<br>0: DMA transfer stopped<br>1: DMA transfer on going | R |
| 1 | RFDMASTS1 | DMA Transfer Status for RX FIFO 1<br>0: DMA transfer stopped<br>1: DMA transfer on going | R |
| 7:2 | — | These bits are read as 0. | R |
| 8 | CFDMASTS | DMA Transfer Status only for Common FIFO<br>0: DMA transfer stopped<br>1: DMA transfer on going | R |
| 31:9 | — | These bits are read as 0. | R |

The DMA Transfer Status Register shows the status of the DMA transfer.

**RFDMASTSe (e = 0 to 1) bit (DMA Transfer Status for RX FIFO e)**

Each bit is set automatically when the corresponding DMA enable bit is set and the corresponding DMA FIFO is not empty.

Each bit is cleared automatically when the DMA transfer stops either because the DMA is disabled or the DMA FIFO is empty.

When CFDCDTCT.RFDMAEe (see CFDCDTCT.RFDMAEe bit in section 31.2.35. CFDCDTCT : DMA Transfer Control Register) is set to 0 while DMA transfer for the corresponding FIFO is on going, the RFDMASTSe bit becomes 0 when the DMA transfer is complete.

This bit is cleared when the CANFD module is in GL_RESET mode.

### CFDMASTS bit (DMA Transfer Status only for Common FIFO)

Each bit is set automatically when the corresponding DMA enable bit is set and the corresponding DMA FIFO is not empty.

Each bit is cleared automatically when the DMA transfer stops either because the DMA is disabled or the DMA FIFO is empty.

When CFDCDTCT.CFDMAE (see CFDCDTCT.CFDMAE bit in section 31.2.35. CFDCDTCT : DMA Transfer Control Register) is set to 0 while DMA transfer for the corresponding FIFO is on going, the CFDMASTS bit becomes 0 when the DMA transfer is complete.

This bit is cleared when the CANFD module is in GL_RESET mode.

## 31.2.37 CFDTMCi : TX Message Buffer Control Registers i (i = 0 to 3)

Base address: CANFD = 0x400B_0000

Offset address: 0x0070 + 0x01 × i

| Bit position: | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | — | — | TMOM | TMTAR | TMTR |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 0 | TMTR | TX Message Buffer Transmission Request<br>0: TX Message buffer transmission not requested<br>1: TX message buffer transmission requested | R/W |
| 1 | TMTAR | TX Message Buffer Transmission Abort Request<br>0: TX message buffer transmission request abort not requested<br>1: TX message buffer transmission request abort requested | R/W |
| 2 | TMOM | TX Message Buffer One-shot Mode<br>0: TX message buffer not configured in one-shot mode<br>1: TX message buffer configured in one-shot mode | R/W |
| 7:3 | — | These bits are read as 0. The write value should be 0. | R/W |

The TX Message Buffer Control Registers configure the TX message buffer functions.

### TMTR bit (TX Message Buffer Transmission Request)

When the TMTR bit is set, the CANFD module logic tries to transmit the message stored in the corresponding message buffer.

Only write to this bit when the related CANFD module is in CH_HALT or CH_OPERATION mode.

Do not set this bit if the corresponding TX message buffer is linked to a COM FIFO in TX mode or is a part of TX Queue.

This bit cannot be directly cleared by a CPU write access.

This bit can only be set when the Transmission Result flag bits (CFDTMSTSj.TMTRF) in the CFDTMSTSj register corresponding to the message buffer are cleared to 00b.

The TMTR bit is automatically cleared by the:

- CANFD module logic at the end of a successful transmission
- CANFD module logic at the end of a transmission abort, requested by the corresponding CFDTMCi.TMTAR bit
- CANFD module logic when there is a detection of a CAN bus error or arbitration loss if CFDTMCi.TMOM bit is set for the message buffer
- CANFD module logic when the CANFD module is in GL_RESET mode or the related channel is in CH_RESET mode.

**TMTAR bit (TX Message Buffer Transmission Abort Request)**

When the TMTAR bit is set, the CANFD module logic tries to abort the transmission of the frame stored in the corresponding message buffer.

In most cases, transmission cannot be aborted if the internal scan for transmission is complete and the message buffer has already been selected for transmission. In this case, frame may be transmitted successfully from the message buffer. The message buffer selection is released by entering CH_HALT mode.

However, message buffer selected for transmission can be aborted by an abort request when the CAN node detects a new message on the bus (RX pin) before it starts transmission from the selected message buffer.

Only write to the TMTAR bit when the related CANFD channel is in CH_HALT or CH_OPERATION mode. This bit can only be set when the related transmit request TMTR bit is set.

The TMTAR bit cannot be cleared by a CPU write access. Clearing of this bit by CANFD has priority over setting by a CPU write access.

The TMTAR bit is automatically cleared by:

- The CANFD module logic at the end of a successful transmission
- The CANFD module logic at the end of a transmission abort
- The CANFD module logic when there is detection of a CAN bus error or arbitration loss
- The CANFD module logic when the CANFD module is in GL_RESET mode or the related channel enters CH_RESET mode.

**TMOM bit (TX Message Buffer One-shot Mode)**

When the TMOM bit is set, the CANFD module logic tries to transmit the message only once.

If the transmission is successful, the CFDTMSTSj.TMTRF bits are set to 10b or 11b. Otherwise, the transmission is automatically aborted and CFDTMSTSj.TMTRF bits are set to 01b due to a bus error or a bus arbitration lost.

The TMOM bit remains set if the transmission has completed successfully or aborted due to an error or a loss of arbitration.

Only write to this bit when the related CANFD channel is in CH_HALT or CH_OPERATION mode.

Set this bit at the same time as the TMTR bit. Clear this bit with a write access.

If a message has already been requested for transmission, do not write to this bit until the message has been successfully transmitted or transmission has been aborted.

The TMOM bit is automatically cleared by the CANFD module logic when the CANFD module is in GL_RESET mode or the related channel is in CH_RESET mode.

## 31.2.38 CFDTMSTSj : TX Message Buffer Status Registers j (j = 0 to 3)

Base address: CANFD = 0x400B_0000

Offset address: 0x0074 + 0x01 × j

| Bit position: | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | TMTARM | TMTRM | TMTRF[1:0] | | TMTSTS |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 0 | TMTSTS | TX Message Buffer Transmission Status<br>0: No transmission in progress<br>1: Transmission in progress | R |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 2:1 | TMTRF[1:0] | TX Message Buffer Transmission Result Flag<br>0 0: No result<br>0 1: Transmission aborted from the TX message buffer<br>1 0: Transmission successful from the TX message buffer and transmission abort was not requested<br>1 1: Transmission successful from the TX message buffer and transmission abort was requested | R/W |
| 3 | TMTRM | TX Message Buffer Transmission Request Mirrored<br>0: TX message buffer transmission not requested<br>1: TX message buffer transmission requested | R |
| 4 | TMTARM | TX Message Buffer Transmission Abort Request Mirrored<br>0: TX message buffer transmission request abort not requested<br>1: TX message buffer transmission request abort requested | R |
| 7:5 | — | These bits are read as 0. The write value should be 0. | R/W |

The CFDTMSTSj registers j (j = 0 to 3) show status of the transmission and transmission abort for the corresponding message buffers.

### TMTSTS bit (TX Message Buffer Transmission Status)

The TMTSTS bit is set automatically at the start of the transmission from the corresponding TX message buffer.

This bit is cleared automatically when:

- Transmission stops
- The CANFD module is in GL_RESET mode
- The related CANFD channel is in CH_RESET mode.

### TMTRF[1:0] bits (TX Message Buffer Transmission Result Flag)

The TMTRF[1:0] bits show the result for the corresponding TX message buffer. The status is as follows:

- 00: Transmission in progress or has not been requested
- 01: Transmission has been aborted from the corresponding TX message buffer
- 10: Transmission was successful from the corresponding TX message buffer and the CFDTMCi.TMTAR bit was not set for this TX message buffer
- 11: Transmission was successful from the corresponding TX message buffer, but the CFDTMCi.TMTAR bit was set for this TX message buffer.

Only write to these bits when the related CANFD channel is in CH_HALT or CH_OPERATION mode.

The TMTRF[1:0] bits are cleared automatically when the CANFD module is in GL_RESET mode or the related channel is in CH_RESET mode.

If the set from the CAN channel occurs simultaneously with the clear by the write access, then the bit is set.

### TMTRM bit (TX Message Buffer Transmission Request Mirrored)

The TMTRM bit is set when the CFDTMCi.TMTR bit in the corresponding CFDTMCi register is set.

This bit is cleared when the CFDTMCi.TMTR bit in the corresponding CFDTMCi register is cleared.

### TMTARM bit (TX Message Buffer Transmission Abort Request Mirrored)

The TMTARM bit is set when the CFDTMCi.TMTAR bit in the corresponding CFDTMCi register is set.

This bit is cleared when the CFDTMCi.TMTAR bit in the corresponding CFDTMCi register is cleared.

## 31.2.39 CFDTMTRSTS : TX Message Buffer Transmission Request Status Register

Base address: CANFD = 0x400B_0000

Offset address: 0x0078

| Bit position: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit position: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | — | — | — | — | — | — | — | — | — | CFDTMTRSTS3 to CFDTMTRSTS0 | | | |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 3:0 | CFDTMTRSTS3 to CFDTMTRSTS0 | TX Message Buffer n Transmission Request Status (n = 0 to 3)<br>0: Transmission not requested<br>1: Transmission requested | R |
| 31:4 | — | These bits are read as 0. | R |

These bits show the TX Message Buffer Transmission Request Status for the corresponding TX Message Buffer.

**CFDTMTRSTSn bits (TX Message Buffer n Transmission Request Status (n = 0 to 3))**

The CFDTMTRSTSn bits show status of the CFDTMCi.TMTR bits of the TX Message Buffer Control Registers.

Each bit is set automatically when the corresponding bit is set in the TX Message Buffer Control Registers (CFDTMCi), and only when the message buffer does not belong to a TX Queue.

Each bit is cleared automatically when:

- The corresponding bit is cleared in the TX Message Buffer Control Registers
- The CANFD module is in GL_RESET mode
- The related CANFD channel is in CH_RESET mode.

## 31.2.40 CFDTMTARSTS : TX Message Buffer Transmission Abort Request Status Register

Base address: CANFD = 0x400B_0000

Offset address: 0x007C

| Bit position: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit position: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | — | — | — | — | — | — | — | — | — | CFDTMTARSTS3 to CFDTMTARSTS0 | | | |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 3:0 | CFDTMTARSTS3 to CFDTMTARSTS0 | TX Message Buffer n Transmission Abort Request Status (n = 0 to 3)<br>0: Transmission abort not requested<br>1: Transmission abort requested | R |
| 31:4 | — | These bits are read as 0. | R |

These bits show the TX Message Buffer Transmission Abort Request Status for the corresponding TX Message Buffer.

**CFDTMTARSTSn bits (TX Message Buffer n Transmission Abort Request Status (n = 0 to 3))**

The CFDTMTARSTSn bits show status of the CFDTMCi.TMTAR bits of the TX Message Buffer Control Registers.

Each bit is set automatically when the corresponding bit is set in the TX Message Buffer Control Registers, and when the message buffer belongs to a TX Queue.

Each bit is cleared automatically when:

- The corresponding bit is cleared in the TX Message Buffer Control Registers
- The CANFD module is in GL_RESET mode
- The related CANFD channel is in CH_RESET mode.

## 31.2.41 CFDTMTCSTS : TX Message Buffer Transmission Completion Status Register

Base address: CANFD = 0x400B_0000

Offset address: 0x0080

| Bit position: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit position: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | — | — | — | — | — | — | — | — | — | CFDTMTCSTS3 to CFDTMTCSTS0 | | | |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 3:0 | CFDTMTCSTS3 to CFDTMTCSTS0 | TX Message Buffer n Transmission Completion Status (n = 0 to 3)<br>0: Transmission not complete<br>1: Transmission completed | R |
| 31:4 | — | These bits are read as 0. | R |

These bits show the TX Message Buffer Transmission Completion Status for the corresponding TX Message Buffer.

**CFDTMTCSTSn bits (TX Message Buffer n Transmission Completion Status (n = 0 to 3))**

The CFDTMTCSTSn bits show status of successful completion of the TX Message Buffer Status Registers.

Each bit is set automatically when the corresponding bit is set in the TX Message Buffer Status Registers.

Each bit is cleared automatically when:

- The corresponding bit is cleared in the TX Message Buffer Status Registers
- The CANFD module is in GL_RESET mode
- The related CANFD channel is in CH_RESET mode.

If a CAN channel enters CH_RESET mode, then the bits related to that channel are cleared.

## 31.2.42 CFDTMTASTS : TX Message Buffer Transmission Abort Status Register

Base address: CANFD = 0x400B_0000

Offset address: 0x0084

| Bit position: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit position: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | — | — | — | — | — | — | — | — | — | CFDTMTASTS3 to CFDTMTASTS0 | | | |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 3:0 | CFDTMTASTS3 to CFDTMTASTS0 | TX Message Buffer n Transmission Abort Status (n = 0 to 3)<br>0: Transmission not aborted<br>1: Transmission aborted | R |
| 31:4 | — | These bits are read as 0. | R |

These bits show the TX Message Buffer Transmission abort Status for the corresponding TX Message Buffer.

**CFDTMTASTSn bits (TX Message Buffer n Transmission Abort Status (n = 0 to 3))**

The CFDTMTASTSn bits show status of the successful transmission abort of the corresponding TX message buffer.

Each bit is set automatically when the CFDTMSTSj.TMTRF bits are set to 01b in the corresponding TX Message Buffer Status Register.

Each bit is cleared automatically when:

- The CFDTMSTSj.TMTRF bits are cleared in the corresponding TX Message Buffer Status Register
- The CANFD module is in GL_RESET mode
- The related CANFD channel is in CH_RESET mode.

## 31.2.43 CFDTMIEC : TX Message Buffer Interrupt Enable Configuration Register

Base address: CANFD = 0x400B_0000

Offset address: 0x0088

| Bit position: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit position: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | — | — | — | — | — | — | — | — | — | TMIE3 to TMIE0 | | | |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 3:0 | TMIE3 to TMIE0 | TX Message Buffer n Interrupt Enable (n = 0 to 3)<br>0: TX message buffer interrupt disabled<br>1: TX message buffer interrupt enabled | R/W |
| 31:4 | — | These bits are read as 0. The write value should be 0. | R/W |

These bits show the TX Message Buffer Interrupt Enable for the corresponding TX Message Buffer.

### TMIEn bits (TX Message Buffer n Interrupt Enable (n = 0 to 3))

If the TMIEn bits are set, an interrupt is generated at the end of a successful transmission from the corresponding message buffer.

See section 31.7. Interrupts and DMA for TX Message Buffer Interrupt specification.

Do not write to the TMIEn bits when:

- The CANFD module is in GL_SLEEP mode
- The related CANFD channel is in CH_SLEEP mode
- The corresponding TX message buffer is linked to a Common FIFO with the CFDCFCC.CFTML bits.

## 31.2.44 CFDTXQCC : TX Queue Configuration/Control Register

Base address: CANFD = 0x400B_0000

Offset address: 0x008C

| Bit position: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit position: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | — | — | — | TXQDC[1:0] | | TXQIM | — | TXQTXIE | — | — | — | — | TXQE |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 0 | TXQE | TX Queue Enable<br>0: TX Queue disabled<br>1: TX Queue enabled | R/W |
| 4:1 | — | These bits are read as 0. The write value should be 0. | R/W |
| 5 | TXQTXIE | TX Queue TX Interrupt Enable<br>0: TX Queue TX interrupt disabled<br>1: TX Queue TX interrupt enabled | R/W |
| 6 | — | This bit is read as 0. The write value should be 0. | R/W |
| 7 | TXQIM | TX Queue Interrupt Mode<br>0: When the last message is successfully transmitted<br>1: At every successful transmission | R/W |
| 9:8 | TXQDC[1:0] | TX Queue Depth Configuration<br>0x00: 0 messages<br>0x01: Reserved<br>0x10: 3 messages<br>0x11: 4 messages | R/W |
| 31:10 | — | These bits are read as 0. The write value should be 0. | R/W |

The TX Queue Configuration/Control Registers are used to configure the TX Queue transmission.

TXQ is composed of TXMB0 to TXMB3 (at the maximum) when TXQE is enabled.

### TXQE bit (TX Queue Enable)

The TXQE bit cannot be set if the configured TX Queue depth is 0x00 (CFDTXQCC.TXQDC = 0x00).

You cannot write to this bit when the CANFD module is in GL_SLEEP mode.

Do not write to this bit when the related CANFD channel is in CH_RESET or CH_SLEEP mode.

The TXQE bit is cleared automatically when the related CANFD channel is in CH_RESET mode.

**TXQTXIE bit (TX Queue TX Interrupt Enable)**

When the TXQTXIE bit is set, an interrupt is generated based on the setting of the TXQIM bit.

You cannot write to this bit when the CANFD module is in GL_SLEEP mode.

Do not write to this bit when the related CANFD channel is in CH_SLEEP mode.

**TXQIM bit (TX Queue Interrupt Mode)**

The TXQIM bit selects the interrupt generation condition for the TX Queue.

You cannot write to this bit when the CANFD module is in GL_SLEEP mode.

Do not write to this bit when the related CANFD channel is in any of the following modes:

- CH_SLEEP
- CH_HALT
- CH_OPERATION.

**TXQDC[1:0] bits (TX Queue Depth Configuration)**

The TXQDC[1:0] bits select the depth of the transmission queue. The message buffer selection starts from MB[0] up to MB[3] depending on the configured depth.

You cannot write to this bit when the CANFD module is in GL_SLEEP mode.

Do not write to this bit when the related CANFD channel is in any of the following modes:

- CH_SLEEP
- CH_HALT
- CH_OPERATION.

## 31.2.45 CFDTXQSTS : TX Queue Status Register

Base address: CANFD = 0x400B_0000

Offset address: 0x0090

| Bit position: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit position: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | — | — | TXQMC[2:0] | | | — | — | — | — | — | TXQTXIF | TXQFLL | TXQEMP |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 1 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 0 | TXQEMP | TX Queue Empty<br>0: TX Queue not empty<br>1: TX Queue empty | R |
| 1 | TXQFLL | TX Queue Full<br>0: TX Queue not full<br>1: TX Queue full | R |
| 2 | TXQTXIF | TX Queue TX Interrupt Flag<br>0: TX Queue interrupt condition not satisfied after a frame TX<br>1: TX Queue interrupt condition satisfied after a frame TX | R/W |
| 7:3 | — | These bits are read as 0. The write value should be 0. | R/W |
| 10:8 | TXQMC[2:0] | TX Queue Message Count<br>Number of messages in the TX Queue. | R |
| 31:11 | — | These bits are read as 0. The write value should be 0. | R/W |

The TX Queue Status Registers show the status of the TX Queue of corresponding CAN channel.

#### TXQEMP bit (TX Queue Empty)

The TXQEMP bit is set automatically when the TX Queue is disabled or no messages are stored in the TX Queue.

This bit is set automatically when:

- The last message is transmitted from the TX Queue
- The related CANFD channel is in CH_RESET mode.

The bit is cleared automatically when the first message to be transmitted is stored in the TX Queue.

#### TXQFLL bit (TX Queue Full)

The TXQFLL bit is set automatically when the number of CAN messages stored in the TX Queue matches the configured TX Queue depth.

This bit is cleared automatically when:

- The number of CAN messages stored in the TX Queue is less than the configured TX Queue depth
- The related CANFD channel is in CH_RESET mode.

#### TXQTXIF bit (TX Queue TX Interrupt Flag)

The TXQTXIF bit is not cleared automatically if the TX Queue is disabled.

When stopping the TX Queue, this bit should be cleared, after disabling TXQE and checking an empty state of TX Queue.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1. Writing 1 has no effect.

This bit is set automatically when the configured interrupt condition is satisfied for the TX Queue.

If the set from the CAN channel occurs simultaneously with the clear by the write access, then the bit is set.

You cannot write to this bit when the related CANFD channel is in CH_SLEEP or CH_RESET mode.

The bit is cleared:

- By writing 0 to it
- When the related CANFD channel is in CH_RESET mode.

#### TXQMC[2:0][13:8] bits (TX Queue Message Count)

The TXQMC[2:0] bits show the number of CAN messages in the TX Queue.

These bits are cleared automatically when the related CANFD channel is in CH_RESET mode.

### 31.2.46 CFDTXQPCTR : TX Queue Pointer Control Register

Base address: CANFD = 0x400B_0000

Offset address: 0x0094

| Bit position: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | TXQPC[7:0] | | | | | | | |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 7:0 | TXQPC[7:0] | TX Queue Pointer Control<br>Increments the write pointer to the TX Queue buffer in the corresponding channel | W |
| 31:8 | — | The write value should be 0. | W |

The TX Queue Pointer Control Registers are used to confirm storage of a full message in the corresponding TX Queue buffers.

### TXQPC[7:0] bits (TX Queue Pointer Control)

When the value 0xFF is written to the TXQPC[7:0] bits, the write pointer of the corresponding TX Queue buffer is updated and a transmit request is initiated for this message.

The read value from these bits is always 0x00. Do not write to the FIFO control registers when DMA is enabled.

You cannot write to these bits when the related CANFD channel is in CH_SLEEP or CH_RESET mode.

Only write 0xFF to this register when:

- The corresponding TX Queue is enabled and not full
- The Common FIFO is enabled.

## 31.2.47 CFDTHLCC : TX History List Configuration/Control Register

Base address: CANFD = 0x400B_0000

Offset address: 0x0098

| Bit position: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit position: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | — | — | THLDTE | THLIM | THLIE | — | — | — | — | — | — | — | THLE |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 0 | THLE | TX History List Enable<br>0: TX History List disabled<br>1: TX History List enabled | R/W |
| 7:1 | — | These bits are read as 0. The write value should be 0. | R/W |
| 8 | THLIE | TX History List Interrupt Enable<br>0: TX History List Interrupt disabled<br>1: TX History List Interrupt enabled | R/W |
| 9 | THLIM | TX History List Interrupt Mode<br>0: Interrupt generated if TX History List level reaches ¾ of the TX History List depth<br>1: Interrupt generated for every successfully stored entry | R/W |
| 10 | THLDTE | TX History List Dedicated TX Enable<br>0: TX FIFO + TX Queue<br>1: Flat TX MB + TX FIFO + TX Queue | R/W |
| 31:11 | — | These bits are read as 0. The write value should be 0. | R/W |

The TX History List Configuration/Control Register configures the TX History List functions.

### THLE bit (TX History List Enable)

The THLE bit enables the TX History List buffer when it is set.

You cannot write to this bit when the related CANFD channel is in CH_RESET or CH_SLEEP mode.

This bit is cleared automatically when the related CANFD channel is in CH_RESET mode.

### THLIE bit (TX History List Interrupt Enable)

The THLIE bit enables the generation of the TX History List interrupt when it is set.

You cannot write to this bit when the CANFD module is in GL_SLEEP mode.

### THLIM bit (TX History List Interrupt Mode)

The THLIM bit selects the interrupt generation condition for the FIFO.

You cannot write to this bit when the CANFD module is in GL_SLEEP mode.

Do not write to this bit when the CANFD module is in GL_HALT or GL_OPERATION mode.

### THLDTE bit (TX History List Dedicated TX Enable)

The THLDTE bit selects the condition for storing an entry in the TX History List after successful transmission.

You cannot write to this bit when the CANFD module is in GL_SLEEP mode.

Do not write to this bit when the CANFD module is in GL_HALT or GL_OPERATION mode.

## 31.2.48 CFDTHLSTS : TX History List Status Register

Base address: CANFD = 0x400B_0000

Offset address: 0x009C

| Bit position: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit position: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | — | THLMC[3:0] | | | | — | — | — | — | THLIF | THLELT | THLFLL | THLEMP |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 1 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 0 | THLEMP | TX History List Empty<br>0: TX History List not empty<br>1: TX History List empty | R |
| 1 | THLFLL | TX History List Full<br>0: TX History List not full<br>1: TX History List full | R |
| 2 | THLELT | TX History List Entry Lost<br>0: No entry lost in TX History List<br>1: TX History List entry Lost | R/W |
| 3 | THLIF | TX History List Interrupt Flag<br>0: TX History List interrupt condition not satisfied<br>1: TX History List interrupt condition satisfied | R/W |
| 7:4 | — | These bits are read as 0. The write value should be 0. | R/W |
| 11:8 | THLMC[3:0] | TX History List Message Count<br>Number of messages stored in TX History List | R |
| 31:12 | — | These bits are read as 0. The write value should be 0. | R/W |

The TX History List Status register shows the status of data stored in the TX History List buffer.

### THLEMP bit (TX History List Empty)

The THLEMP bit is set automatically when the CPU has read all the entries from the TX History List buffer.

This bit is cleared automatically when the first entry is stored to the TX History List.

This bit is set automatically when:

- TX History List is disabled
- The related CANFD channel is in CH_RESET mode.

### THLFLL bit (TX History List Full)

The THLFLL bit is set automatically when the number of entries in the TX History List buffer matches the TX History List depth.

Each TX History List can store up to 8 entries.

This bit is cleared automatically when:

- The number of entries in the TX History List buffer is less than the TX History List depth
- The TX History List is disabled
- The related CANFD channel is in CH_RESET mode.

#### THLELT bit (TX History List Entry Lost)

The THLELT bit is set when a new entry cannot be stored because the related TX History List buffer is already full.

Only write to this bit when the related CANFD channel is in CH_HALT or CH_OPERATION mode. Writing 1 has no effect.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1.

If the set from the CAN channel occurs simultaneously with the clear by the write access, then the bit is set.

This bit is cleared:

- By writing 0 to it
- When the related CANFD channel is in CH_RESET mode.

#### THLIF bit (TX History List Interrupt Flag)

The THLIF bit is set when the configured interrupt condition is satisfied.

Only write to this bit when the related CANFD channel is in CH_HALT or CH_OPERATION mode. Writing 1 has no effect.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1.

If the set from the CAN channel occurs simultaneously with the clear by the write access, then the bit is set.

This bit is cleared:

- By writing 0 to it
- When the related CANFD channel is in CH_RESET mode.

The bit is cleared by writing 0 to it.

This bit is automatically cleared in CH_RESET mode.

#### THLMC[3:0] bits (TX History List Message Count)

The THLMC[3:0] bits show the number of transmitted messages stored in the TX History List.

These bits are cleared automatically when the related CANFD channel is in CH_RESET mode.

### 31.2.49 CFDTHLACC0 : TX History List Access Register 0

Base address: CANFD = 0x400B_0000

Offset address: 0x0740

| Bit position: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | TMTS[15:0] | | | | | | | | | | | | | | | |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit position: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | — | — | — | — | — | — | — | — | BN[1:0] | | BT[2:0] | | |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 2:0 | BT[2:0] | Buffer Type<br>0 0 1: Flat TX message buffer<br>0 1 0: TX FIFO message buffer number<br>1 0 0: TX Queue message buffer number | R |
| 4:3 | BN[1:0] | Buffer Number<br>Number of the message buffer | R |
| 15:5 | — | These bits are read as 0. | R |
| 31:16 | TMTS[15:0] | Transmit Timestamp<br>Transmit timestamp value for software drivers | R |

The TX History List Access Registers 0 provide access to the entry in the TX History List based on the read timestamp value.

### BT[2:0] bits (Buffer Type)

The BT[2:0] bits indicate whether data has been stored following a transmission from a FIFO buffer, a TX Queue or a TX message buffer.

### BN[1:0] bits (Buffer Number)

The BN[1:0] bits show the message buffer from which transmission was successfully completed. If a message from a Common FIFO is transmitted, then these bits show the message buffer that is linked to the Common FIFO for transmission.

### TMTS[15:0] bits (Transmit Timestamp)

The TMTS[15:0] bits indicate the timestamp for use by software drivers.

## 31.2.50 CFDTHLACC1 : TX History List Access Register 1

Base address: CANFD = 0x400B_0000

Offset address: 0x0744

| Bit position: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|

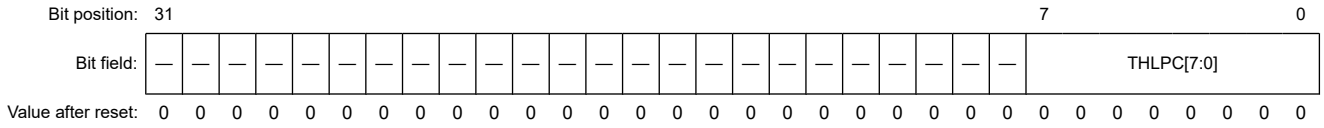
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | TID[15:0] | | | | | | | | | | | | | | | |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 15:0 | TID[15:0] | Transmit ID<br>These bits indicate that message buffer reference ID, TX FIFO reference ID, or AFL pointer field is stored for software drivers. | R |
| 17:16 | TIFL[1:0] | Transmit Information Label<br>These bits indicate that message buffer information label, TX FIFO information label, or AFL information label is stored for software drivers. | R |
| 31:18 | — | These bits are read as 0. | R |

The TX History List Access Registers 1 provide access to entry in the TX History List based on the read pointer value.

### TID[15:0] bits (Transmit ID)

The TID[15:0] bits indicate whether the message buffer reference ID (CFDTMFDCTRb.TMPTR) or the TX FIFO reference ID (CFDCFFDCSTS.CFPTR) is for use by software drivers.



### TIFL[1:0] bits (Transmit Information Label)

The TIFL[1:0] bits indicate whether the message buffer information label (CFDTMFDCTRb.TMIFL) or the TX FIFO information label (CFDCFFDCSTS.CFIFL) is for use by software drivers.

## 31.2.51 CFDTHLPCTR : TX History List Pointer Control Register

Base address: CANFD = 0x400B_0000

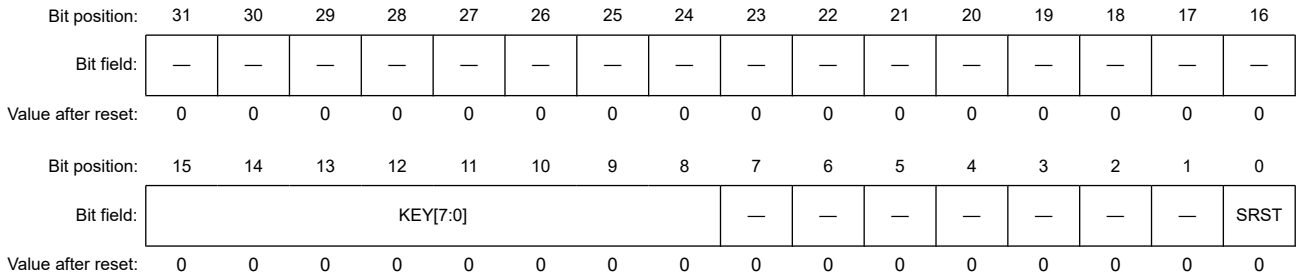
Offset address: 0x00A0

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 7:0 | THLPC[7:0] | TX History List Pointer Control<br>Increments the write pointer to the TX History List in the corresponding channel | W |
| 31:8 | — | The write value should be 0. | W |

The TX History List Pointer Control Registers are used to increment the read pointer of the TX History List.

### THLPC[7:0] bits (TX History List Pointer Control)

When 0xFF is written to the THLPC[7:0] bits, the read pointer of the TX History List is moved to the next TX History List entry address.



The read value from these bits is always 0x00. Only write to these bits when the related CANFD channel is in CH_HALT or CH_OPERATION mode.

Only write 0xFF to these registers when the corresponding TX History List is enabled and not empty.

## 31.2.52 CFDGRSTC : Global SW reset Register

Base address: CANFD = 0x400B_0000

Offset address: 0x00D8

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 0 | SRST | SW Reset<br>0: Normal state<br>1: SW reset state | R/W |
| 7:1 | — | These bits are read as 0. The write value should be 0. | R/W |
| 15:8 | KEY[7:0] | Key Code<br>These bits control the validity of rewriting of a SRST bit. | W |
| 31:16 | — | These bits are read as 0. The write value should be 0. | R/W |

### SRST bit (SW Reset)

When the SRST bit is set, the CANFD module is in the same state as hardware reset. When a reset is required, write 1 then write 0 to this bit.

This bit is cleared when the CANFD module is in GL_SLEEP mode.

When this bit is cleared, the RAM initialization sequence does not operate. The configuration of RAM is performed by software.

The RAM is not initialized when software reset is performed during the initialization of RAM. Software must perform the initialization of RAM.

#### KEY[7:0] bits (Key Code)

When 0xC4 is written in the KEY[15:8] bits, a write to the SRST bit is valid.

The read value from these bits is always 0x00.

CFDGRSTC.SRST bit and the CFDGRSTC.KEY bit should be written simultaneously.

### 31.2.53 CFDGTSTCFG : Global Test Configuration Register

Base address: CANFD = 0x400B_0000

Offset address: 0x00A8

| Bit position: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | — | — | — | — | — | — | — | — | — | RTMPS[3:0] | | | |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit position: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 15:0 | — | These bits are read as 0. The write value should be 0. | R/W |
| 19:16 | RTMPS[3:0] | RAM Test Mode Page Select<br>Select a RAM test mode page | R/W |
| 31:20 | — | These bits are read as 0. The write value should be 0. | R/W |

The Global Test Configuration Register is used to configure the RAM test mode page.

#### RTMPS[3:0] bits (RAM Test Mode Page Select)

The RTMPS[3:0] bits select the RAM page mode for CPU read/write access when the CANFD module is configured in RAM test mode.

See section 31.9.2.1. RAM Test Mode for the RAM test mode specification.

Do not write to these bits when the CANFD module is in GL_RESET or GL_SLEEP mode.

Only enter values from 0 to 8 (0x008) for the message buffer RAM.

Only write to these bits when the CANFD module is in GL_HALT mode.

These bits are cleared automatically when the related CANFD channel is in GL_RESET mode.

## 31.2.54 CFDGTSTCTR : Global Test Control Register

Base address: CANFD = 0x400B_0000

Offset address: 0x00AC

| Bit position: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit position: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | — | — | — | — | — | — | — | — | — | — | RTME | — | — |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 1:0 | — | These bits are read as 0. The write value should be 0. | R/W |
| 2 | RTME | RAM Test Mode Enable<br>0: RAM test mode disabled<br>1: RAM test mode enabled | R/W |
| 31:3 | — | These bits are read as 0. The write value should be 0. | R/W |

The Global Test Control register is used to control the global test modes of the CANFD module.

**RTME bit (RAM Test Mode Enable)**

When the RTME bit is set, the CANFD module is configured in RAM test mode. See section 31.9.2.1. RAM Test Mode for RAM test mode specification.

Only write to this bit when the CANFD module is in GL_HALT mode.

Clear this bit when the CANFD module is in GL_HALT mode.

This bit is cleared automatically when the CANFD module is in GL_RESET mode.

## 31.2.55 CFDGFDCFG : Global FD Configuration Register

Base address: CANFD = 0x400B_0000

Offset address: 0x00B0

| Bit position: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit position: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | — | — | — | TSCCFG[1:0] | | — | — | — | — | — | — | — | RPED |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 0 | RPED | RES Bit Protocol Exception Disable<br>0: Protocol exception event detection enabled<br>1: Protocol exception event detection disabled | R/W |
| 7:1 | — | These bits are read as 0. The write value should be 0. | R/W |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 9:8 | TSCCFG[1:0] | Timestamp Capture Configuration<br>0 0: Timestamp capture at the sample point of SOF (start of frame)<br>0 1: Timestamp capture at frame valid indication<br>1 0: Timestamp capture at the sample point of RES bit<br>1 1: Reserved | R/W |
| 31:10 | — | These bits are read as 0. The write value should be 0. | R/W |

### RPED bit (RES Bit Protocol Exception Disable)

The RPED bit configures the protocol exception event handling according to ISO 11898-1.

When this bit is enabled, the protocol exception event detection is disabled, and the protocol controller transmits an error frame when the protocol exception event is detected (RES bit is sampled recessive).

Only write to this bit when the CANFD module is in GL_RESET mode.

### TSCCFG[1:0] bits (Timestamp Capture Configuration)

The TSCCFG[1:0] bits configure the different capture points of the timestamp for transmission and reception.

When CFDGFDCFG.TSCCFG[1:0] = 10b, the timestamp capture is performed for CANFD frames at RES bit and for Classical frames at the start of frame.

Only write to these bits when the CANFD module is in GL_RESET mode.

## 31.2.56 CFDGLOCKK : Global Lock Key Register

Base address: CANFD = 0x400B_0000

Offset address: 0x00B8

| Bit position: | 31 | | | | | | | | | | | | | | | 15 | | | | | | | | | | | | | | | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | LOCK[15:0] | | | | | | | | | | | | | | | |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 15:0 | LOCK[15:0] | Lock Key<br>Key bits for unlocking the protection of test modes | W |
| 31:16 | — | The write value should be 0. | W |

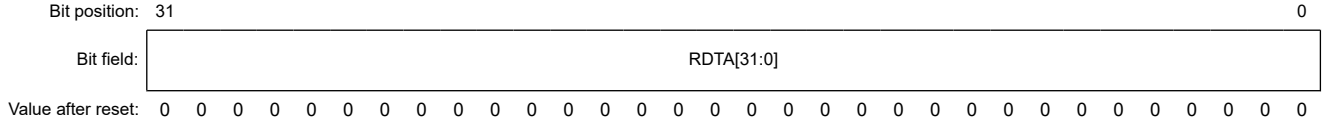
The Global Lock Key register is a write-only register that is used to unlock the protection for special test bits.

See section 31.9.2. Global Test Modes for Lock key specification.

### LOCK[15:0] bits (Lock Key)

The unlock key sequence must be written in the LOCK[15:0] bits to configure the CANFD module in FIFO OTB disable and RAM test modes.

The read value from these bits is always 0x0000.



You cannot write to these bits when the CANFD module is in GL_SLEEP or GL_RESET mode.

Do not write to these bits when the CANFD module is in GL_OPERATION mode.

## 31.2.57 CFDRPGACCk : RAM Test Page Access Registers k (k = 0 to 63)

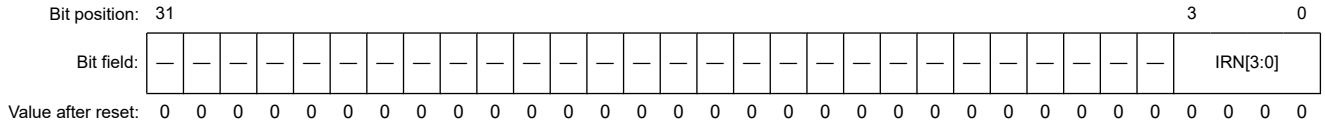
Base address: CANFD = 0x400B_0000

Offset address: 0x0280 + 0x0004 × k

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 31:0 | RDTA[31:0] | RAM Data Test Access<br>RAM data bytes | R/W |

**RDTA[31:0] bits (RAM Data Test Access)**

Data can be read from or written into the RDTA[31:0] bits when the CANFD module is configured in RAM test mode.



Only write to this bit when the CANFD module is in GL_HALT mode and RAM test mode is enabled.

Software data should be read/written in the RAM Test Page Access registers during RAM test mode.

## 31.2.58 CFDGAFLIGNENT : Global AFL Ignore Entry Register

Base address: CANFD = 0x400B_0000

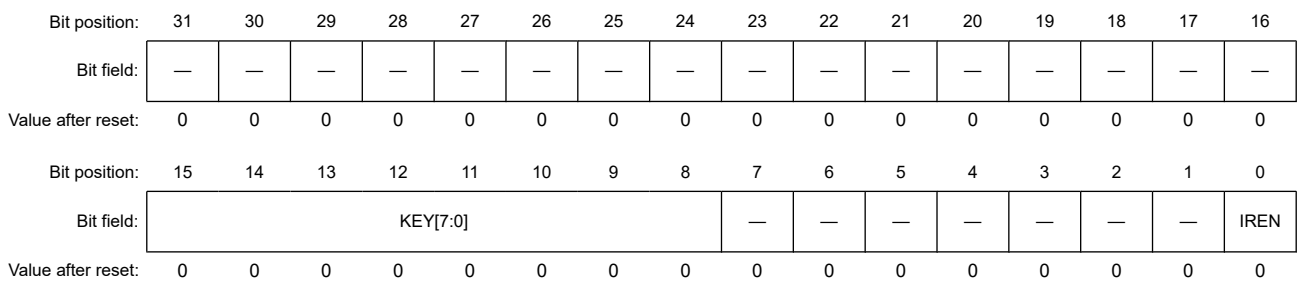
Offset address: 0x00C0

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 3:0 | IRN[3:0] | Ignore Rule Number<br>Define rule number which ignores an AFL entry. | R/W |
| 31:4 | — | These bits are read as 0. The write value should be 0. | R/W |

**IRN[3:0] bits (Ignore Rule Number)**

The IRN[3:0] bits define the rule number which updates an AFL entry.

Enter only values between 0 and 15 (0x0F) inclusive.



Only write to these bits when the CFDGAFLIGNCTR.IREN bit is 0.

You cannot write to these bits when the CANFD module is in GL_SLEEP mode.

## 31.2.59 CFDGAFLIGNCTR : Global AFL Ignore Control Register

Base address: CANFD = 0x400B_0000

Offset address: 0x00C4

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 0 | IREN | Ignore Rule Enable<br>0: AFL entry number is not ignored<br>1: AFL entry number is ignored | R/W |
| 7:1 | — | These bits are read as 0. The write value should be 0. | R/W |
| 15:8 | KEY[7:0] | Key Code<br>These bits control the validity of rewriting the IREN bit. | W |
| 31:16 | — | These bits are read as 0. The write value should be 0. | R/W |

**IREN bit (Ignore Rule Enable)**

When the IREN bit is set, the entry number (selected by CFDGAFLIGNENT register) is ignored.

This bit is cleared automatically when the CANFD module is in GL_RESET mode.

**KEY[7:0] bits (Key Code)**

When 0xC4 is written in the KEY[7:0] bits, a write to the IREN bit is valid.

The read value from these bits is always 0x00.

CFDGAFLIGNCTR.IREN bit and the CFDGAFLIGNCTR.KEY bit should be written simultaneously

## 31.2.60 CFDRMIEC : RX Message Buffer Interrupt Enable Configuration Register

Base address: CANFD = 0x400B_0000

Offset address: 0x0038

| Bit position: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | RMIE[15:0] | | | | | | | | | | | | | | | |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 15:0 | RMIE[15:0] | RX Message Buffer Interrupt Enable<br>0: RX Message Buffer Interrupt disabled for corresponding RX message buffer<br>1: RX Message Buffer Interrupt enabled for corresponding RX message buffer | R/W |

These bits show the RX Message Buffer Interrupt Enable for the corresponding RX Message Buffer. CFDRMIEC bit 0 corresponds to RX Message Buffer 0 and so on.

The bit position of CFDRMIEC corresponds to the buffer number of RXMB.

**RMIE[15:0] bits (RX Message Buffer Interrupt Enable)**

If this bit is set, then an interrupt will be generated at the end of a successful reception from the corresponding Message Buffer.

For details, see section 31.7.1. Interrupts.

Users cannot write to this bit when the CANFD module is in GL_SLEEP mode.

## 31.2.61 Identifier Bits Alignment

Standard Identifier (11 bits) format: ID28 – ID18 is aligned to b10 to b0, b11 to b28 should be 0.

Extended Identifier (29 bits) format: ID28 – ID0 is aligned to b28 – b0

**Table 31.4 Standard Identifier (11-bit format) (1 of 2)**

| b31 | b30 | b29 | b28 | b27 | b26 | b25 | b24 | b23 | b22 | b21 | b20 | b19 | b18 | b17 | b16 |

## 31.2.62 Message Buffer Component Structure

### 31.2.62.1 Start Addresses

The start address for each of the Message Buffer component is calculated using the number of related Message Buffer components.

The start addresses for each register in the Message Buffer component are depicted in Table 31.6.

**Table 31.6 Message Buffer Component Register Start Addresses**

| b = Message buffer component index | MBCP | p | Register | Start Address |
|---|---|---|---|---|
| [0…15]<br>b = [0…7] | RMBCPb[0] | x | RMID | 0x0920 + b × 0x004C |
| | | x | RMPTR | 0x0924 + b × 0x004C |
| | | x | RMFDSTSb | 0x0928 + b × 0x004C |
| | | [1…15] | RMDFbp | 0x092C + b × 0x004C + p × 0x0004 |
| [0…15]<br>b = [8…15] | RMBCPb[0] | x | RMIDb | 0x0D20 + (b-8) × 0x004C |
| | | x | RMPTRb | 0x0D24 + (b-8) × 0x004C |
| | | x | RMFDSTSb | 0x0D28 + (b-8) × 0x004C |
| | | [1…15] | RMDFbp | 0x0D2C + (b-8) × 0x004C + p × 0x0004 |
| [0…1] | RFMBCPb[0] | x | RFIDb | 0x0520 + b × 0x004C |
| | | x | RFPTRb | 0x0524 + b × 0x004C |
| | | x | RFFDSTSb | 0x0528 + b × 0x004C |
| | | [1…15] | RFDFbp | 0x052C + b × 0x004C + p × 0x0004 |
| [0] | CFMBCPb[0] | x | CFID | 0x05B8 |
| | | x | CFPTR0 | 0x05BC |
| | | x | CFFDCSTS0 | 0x05C0 |
| | | [1…15] | CFDFp0 | 0x05C4 + p × 0x0004 |
| [0…3] | TMBCPb[0] | x | TMIDb | 0x0604 + b × 0x004C |
| | | x | TMPTRb | 0x0608 + b × 0x004C |
| | | x | TMFDCTRb | 0x060C + b × 0x004C |
| | | [1…15] | TMDFbp | 0x0610 + b × 0x004C + p × 0x0004 |

The message buffer configuration consists of four types of Message Buffer components:

- RX Message Buffer Component (CFDRMBCPb[0])

- RX FIFO Access Message Buffer Component (CFDRFMBCPb[0])
- Common FIFO Access Message Buffer Component (CFDCFMBCP0[0])
- TX Message Buffer Component (CFDTMBCPb[0]).

Where b = the Message Buffer component index that has a range that varies based on the type of Message Buffer component.

For a summary of this configuration, see Figure 31.28. For a detailed description of the number of and the different types of message buffers, see section 31.6. FIFO Buffers and Normal Message Buffer Configuration.

As described in section 31.2. Register Descriptions, each Message Buffer component consists of the following registers:

- Identifier (ID)
- Pointer (PTR)
- Data Field (DFp).

Where p = the Data Field register index that has a range that varies based on the type of message buffer component.

Rc is the Message Buffer Component register where c = Message Buffer Component register index that has a range that varies based on the type of Message Buffer component.

A description of the registers, their associated bits and their accessibility are shown below the summary and detailed figures of each component.

In each of the figures, a cell that contains '-' means reserved and has the same behavior as reserved bits for registers in section 31.2.62. Message Buffer Component Structure.

### 31.2.62.2 CFDRMBCPb[0] : RX Message Buffer Component b (b = 0 to 15)

Base address: CANFD = 0x400B_0000

Offset address: See Table 31.6

| Bit position: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 15:0 | Rc[15:0] | RX Message Buffer Component c<br>Refer to Table 31.7, Table 31.8 and the descriptions that follow for a detailed description of each register and its related bits, contained within this message buffer component. | R/W |

Where the total number of CFDRMBCPb = 16 as shown in Figure 31.28 (c = RX Message Buffer Component Register index = [0…18])

#### Rc[15:0] bit (RX Message Buffer Component c)

The RX Message Buffer Component is made up of the following registers: CFDRMIDb, CFDRMPTRb, CFDRMFDSTSb, and CFDRMDFbp. Refer to Table 31.8 for details of how to interpret the structure of this buffer component and how to access the respective registers.

**Table 31.7 RX Message Buffer Component Summary (1 of 2)**

| RX Message Buffer Component (RMBCP) | |

## 31.2.62.3 CFDRMIDb : RX Message Buffer ID Registers (b = 0 to 15)

Base address: CANFD = 0x400B_0000

Offset address: 0x0920 + 0x004C × b (b = 0 to 7)
0x0D20 + 0x004C × (b - 8) (b = 8 to 15)

| Bit position: | 31 | 30 | 29 | 0 |
|---|---|---|---|---|
| Bit field: | RMIDE | RMRTR | — | RMID[28:0] |
| Value after reset: | 0 | 0 | 0 | 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 28:0 | RMID[28:0] | RX Message Buffer ID Field<br>STD-ID/EXT-ID fields | R |
| 29 | — | This bit is read as 0. | R |
| 30 | RMRTR | RX Message Buffer RTR Bit<br>0: Data frame<br>1: Remote frame | R |
| 31 | RMIDE | RX Message Buffer IDE Bit<br>0: STD-ID is stored<br>1: EXT-ID is stored | R |

The RX Message Buffer ID Register b (b = 0 to 15) store the ID field, IDE bit, and RTR bit of the received message.

#### RMID[28:0] bits (RX Message Buffer ID Field)

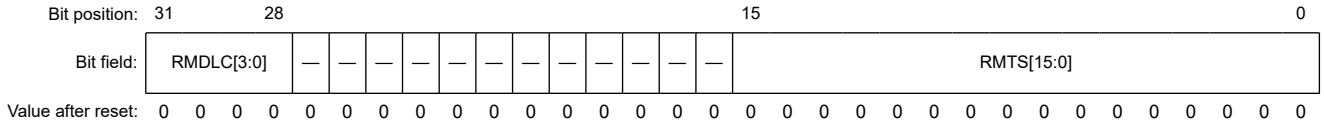
The RMID[28:0] are the bits of the STD-ID/EXT-ID fields of the message stored in the RX message buffer.

See section 31.2.62.1. Start Addresses for details on how to interpret the structure of this buffer component.

#### RMRTR bit (RX Message Buffer RTR Bit)

The RMRTR bit shows whether a data frame or a remote frame was stored in the RX message buffer.

Note: There are no remote frames in CANFD format. When a CANFD frame is received, the register reflects the state of the received value (the RRS bit in FD frame format).



#### RMIDE bit (RX Message Buffer IDE Bit)

The RMIDE bit shows whether message with Standard Identifier or Extended Identifier was stored in the RX message buffer.

### 31.2.62.4 CFDRMPTRb : RX Message Buffer Pointer Registers (b = 0 to 15)

Base address: CANFD = 0x400B_0000

Offset address: 0x0924 + 0x004C × b (b = 0 to 7)
0x0D24 + 0x004C × (b - 8) (b = 8 to 15)

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 15:0 | RMTS[15:0] | RX Message Buffer Timestamp Field<br>Timestamp value stored for the message in the RX message buffer | R |
| 27:16 | — | These bits are read as 0. | R |
| 31:28 | RMDLC[3:0] | RX Message Buffer DLC Field<br>Number of data bytes received in a CAN frame. | R |

The RX Message Buffer Pointer Register b (b = 0 to 15) store the DLC and Timestamp fields for the received message.

#### RMTS[15:0] bits (RX Message Buffer Timestamp Field)

The RMTS[15:0] bits store the timestamp value taken at the capture point as configured by CFDGFDCFG.TSCCFG of the received message.

#### RMDLC[3:0] bits (RX Message Buffer DLC Field)

The RMDLC[3:0] bits store the number of data bytes that were received in the RX message buffer.

See Table 5 in ISO 11898-1 (2015) Specification for details in defining the number of data bytes that were received.

Note: The maximum capacity of the buffer belongs to CFDRMNB.RMPLS and this is not available in the classical CAN function.

### 31.2.62.5 CFDRMFDSTSb : RX Message Buffer CANFD Status Registers (b = 0 to 15)

Base address: CANFD = 0x400B_0000

Offset address: 0x0928 + 0x004C × b (b = 0 to 7)
0x0D28 + 0x004C × (b - 8) (b = 8 to 15)

| Bit position: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | RMPTR[15:0] | | | | | | | | | | | | | | | |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit position: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | — | — | — | RMIFL[1:0] | | — | — | — | — | — | RMFDF | RMBRS | RMESI |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 0 | RMESI*1 | Error State Indicator bit<br>0: CANFD frame received from error active node<br>1: CANFD frame received from error passive node | R |
| 1 | RMBRS*1 | Bit Rate Switch bit<br>0: CANFD frame received with no bit rate switch<br>1: CANFD frame received with bit rate switch | R |
| 2 | RMFDF*1 | CAN FD Format bit<br>0: Non CANFD frame received<br>1: CANFD frame received | R |
| 7:3 | — | These bits are read as 0. | R |
| 9:8 | RMIFL[1:0] | RX Message Buffer Information Label Field | R |
| 15:10 | — | These bits are read as 0. | R |
| 31:16 | RMPTR[15:0] | RX Message Buffer Pointer Field | R |

Note 1. This bit is not available in the classical CAN function.

The CFDRMFDSTSb register (b = 0 to 15) shows the status of the FDF, BRS and ESI bits, and pointer of the received CANFD frame.

#### RMESI bit (Error State Indicator bit)

The RMESI bit has the same value as the ESI bit of the received CANFD frame.

When the received FDF bit is 0, this means a CAN2.0 frame is received and 0 is stored to this bit.

Note: This bit is not available in the classical CAN function.

#### RMBRS bit (Bit Rate Switch bit)

The RMBRS bit has the same value as the BRS bit of the received CANFD frame.

When the received FDF bit is 0, this means a CAN2.0 frame is received and 0 is stored to this bit.

Note: This bit is not available in the classical CAN function.

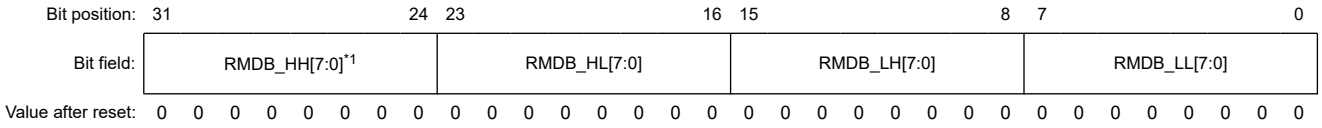
#### RMFDF bit (CAN FD Format bit)

The RMFDF bit has the same value as the FDF bit of the received CANFD frame.

Note: This bit is not available in the classical CAN function.

#### RMIFL[1:0] bits (RX Message Buffer Information Label Field)

The RMIFL[1:0] bits store the information label value from the related Global Acceptance Filter List entry.



**RMPTR[15:0] bits (RX Message Buffer Pointer Field)**

The RMPTR[15:0] bits store the pointer value from the related Global Acceptance Filter List entry.

## 31.2.62.6 CFDRMDFb_p : RX Message Buffer Data Field p Registers (p = 0 to 15, b = 0 to 15)

Base address: CANFD = 0x400B_0000

Offset address: 0x092C + 0x004C × b + 0x0004 × p (b = 0 to 7 , p = 0 to 15)
0x0D2C + 0x004C × (b - 8) + 0x0004 × p (b = 8 to 15 , p = 0 to 15)

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 7:0 | RMDB_LL[7:0] | RX Message Buffer Data Byte (p × 4) | R |
| 15:8 | RMDB_LH[7:0] | RX Message Buffer Data Byte ((p × 4) + 1) | R |
| 23:16 | RMDB_HL[7:0] | RX Message Buffer Data Byte ((p × 4) + 2) | R |
| 31:24 | RMDB_HH[7:0]*1 | RX Message Buffer Data Byte ((p × 4) + 3) | R |

Note 1. These bits are not available in the classical CAN function.

The RX Message Buffer Data Field p Register b (p = 0 to 15, b = 0 to 15) store the data bytes (p × 4) to data bytes ((p × 4) + 3) of the received message.

**RMDB_LL[7:0] bits (RX Message Buffer Data Byte (p × 4))**

The RMDB_LL[7:0] bits store data bytes (p × 4) of the message in the RX message buffer.

Unused data bytes are filled with 0x00.

**RMDB_LH[7:0] bits (RX Message Buffer Data Byte ((p × 4) + 1))**

The RMDB_LH[7:0] bits store data bytes ((p × 4) + 1) of the message in the RX message buffer.

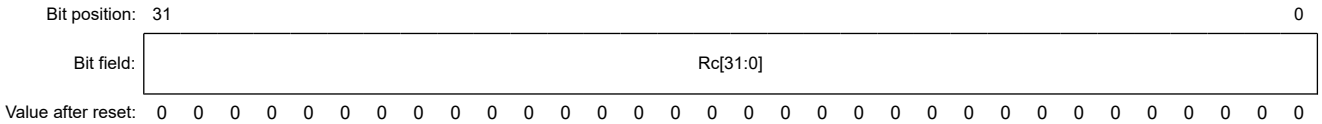
Unused data bytes are filled with 0x00.

**RMDB_HL[7:0] bits (RX Message Buffer Data Byte ((p × 4) + 2))**

The RMDB_HL[7:0] bits store data bytes ((p × 4) + 2) of the message in the RX message buffer.

Unused data bytes are filled with 0x00.

**RMDB_HH[7:0] bits (RX Message Buffer Data Byte ((p × 4) + 3))**



The RMDB_HH[7:0] bits store data bytes ((p × 4) + 3) of the message in the RX message buffer.

Unused data bytes are filled with 0x00.

## 31.2.62.7 CFDRFMBCPb[0] : RX FIFO Access Message Buffer Component b (b = 0 to 1)

Base address: CANFD = 0x400B_0000

Offset address: See Table 31.6.

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 31:0 | Rc[31:0] | RX FIFO Access Message Buffer Component c<br>See Table 31.9, Table 31.10 and the descriptions that follow for a detailed description of each register and its related bits, contained within this message buffer component. | R |

Where the total number of CFDRFMBCPb = 2 as shown in Figure 31.28 (c = RX FIFO Access Message Buffer Component Register index = [0…18])

### Rc[31:0] bits (RX FIFO Access Message Buffer Component c)

The RX FIFO Access Message Buffer component comprises of the following registers:

- CFDRFIDb
- CFDRFPTRb
- CFDRFFDSTSb
- CFDRFDFbp

See Table 31.10 for details on how to interpret the structure of this buffer component and how to access the respective registers.

**Table 31.9 RX FIFO Access Message Buffer component summary**

| Rc | |
|---|---|

## 31.2.62.8 CFDRFIDb : RX FIFO Access ID Register b (b = 0 to 1)

Base address: CANFD = 0x400B_0000

Offset address: 0x0520 + 0x004C × b

| Bit position: | 31 | 30 | 29 | 0 |
|---|---|---|---|---|
| Bit field: | RFIDE | RFRTR | — | RFID[28:0] |
| Value after reset: | 0 | 0 | 0 | 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 28:0 | RFID[28:0] | RX FIFO Buffer ID Field<br>STD-ID/EXT-ID fields | R |
| 29 | — | This bit is read as 0. | R |
| 30 | RFRTR | RX FIFO Buffer RTR bit<br>0: Data frame<br>1: Remote frame | R |
| 31 | RFIDE | RX FIFO Buffer IDE bit<br>0: STD-ID has been received<br>1: EXT-ID has been received | R |

The RX FIFO Access ID Registers b (b = 0 to 1) store the ID field, IDE bit and RTR bit of the message.

### RFID[28:0] bits (RX FIFO Buffer ID Field)

The RFID[28:0] bits are the bits of the STD-ID/EXT-ID fields of the message in the FIFO buffer.

For alignment of these bits in standard and extended frame format, see section 31.2.61. Identifier Bits Alignment.

### RFRTR bit (RX FIFO Buffer RTR bit)

The RFRTR bit shows whether a data frame or a remote frame was stored in the FIFO buffer.

Note: There are no remote frames in CANFD format. When a CANFD frame was received, the register reflects the state of the received value (RRS bit in FD frame format).

### RFIDE bit (RX FIFO Buffer IDE bit)

The RFIDE bit shows whether message with the Standard Identifier or Extended Identifier was received in the FIFO buffer.

## 31.2.62.9 CFDRFPTRb : RX FIFO Access Pointer Register b (b = 0 to 1)

Base address: CANFD = 0x400B_0000

Offset address: 0x0524 + 0x004C × b

| Bit position: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | RFDLC[3:0] | | | | — | — | — | — | — | — | — | — | — | — | — | — | RFTS[15:0] | | | | | | | | | | | | | | | |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 15:0 | RFTS[15:0] | RX FIFO Timestamp Value<br>Timestamp value of the received CAN frame | R |
| 27:16 | — | These bits are read as 0. | R |
| 31:28 | RFDLC[3:0] | RX FIFO Buffer DLC Field<br>Number of data bytes received in a CAN frame | R |

The FIFO Access Pointer Registers b (b = 0 to 1) store the DLC and Timestamp fields for the received message.

### RFTS[15:0] bits (RX FIFO Timestamp Value)

The RFTS[15:0] bits store the timestamp value taken at the capture point as configured by the CFDGFDCFG.TSCCFG bit of the received message.

### RFDLC[3:0] bits (RX FIFO Buffer DLC Field)

The RFDLC[3:0] bits store the number of data bytes that were received in the RX FIFO buffer.

See Table 5 in ISO 11898-1 (2015) Specification for details in defining the number of data bytes that were received.

## 31.2.62.10 CFDRFFDSTSb : RX FIFO Access CANFD Status Register b (b = 0 to 1)

Base address: CANFD = 0x400B_0000

Offset address: 0x0528 + 0x004C × b

| Bit position: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | CFDRFPTR[15:0] | | | | | | | | | | | | | | | |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit position: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | — | — | — | RFIFL[1:0] | | — | — | — | — | — | RFFDF | RFBRS | RFESI |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 0 | RFESI*1 | Error State Indicator bit<br>0: CANFD frame received from error active node<br>1: CANFD frame received from error passive node | R |
| 1 | RFBRS*1 | Bit Rate Switch bit<br>0: CANFD frame received with no bit rate switch<br>1: CANFD frame received with bit rate switch | R |
| 2 | RFFDF*1 | CAN FD Format bit<br>0: Non CANFD frame received<br>1: CANFD frame received | R |
| 7:3 | — | These bits are read as 0. | R |
| 9:8 | RFIFL[1:0] | RX FIFO Buffer Information Label Field | R |
| 15:10 | — | These bits are read as 0. | R |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 31:16 | CFDRFPTR[15:0] | RX FIFO Buffer Pointer Field | R |

Note 1. This bit is not available in the classical CAN function.

The RX FIFO Access CANFD Status Registers b (b = 0 to 1) show the status of the FDF, BRS, and ESI bits including the pointer of the received CANFD frame.

#### RFESI bit (Error State Indicator bit)

The RFESI bit has the same value as the ESI bit of the received CANFD frame.

When the received FDF bit is 0, this means a CAN2.0 frame is received and 0 is stored to this bit.

Note: This bit is not available in the classical CAN function.

#### RFBRS bit (Bit Rate Switch bit)

The RFBRS bit has the same value as the BRS bit of the received CANFD frame.

When the received FDF bit is 0, this means a CAN2.0 frame is received and 0 is stored to this bit.

Note: This bit is not available in the classical CAN function.

#### RFFDF bit (CAN FD Format bit)

The RFFDF bit has the same value as the FDF bit of the received CANFD frame.

Note: This bit is not available in the classical CAN function.

#### RFIFL[1:0] bits (RX FIFO Buffer Information Label Field)

The RFIFL[1:0] bits store the information label value from the related Global Acceptance Filter List entry.

#### CFDRFPTR[15:0] bits (RX FIFO Buffer Pointer Field)

The CFDRFPTR[15:0] bits store the pointer value from the related Global Acceptance Filter List entry.

### 31.2.62.11 CFDRFDFb_p : RX FIFO Access Data Field p Register b (p = 0 to 15, b = 0 to 1)

Base address: CANFD = 0x400B_0000

Offset address: 0x052C + 0x004 × p + 0x04C × b

| Bit position: | 31 | | | | | | | 24 | 23 | | | | | | | 16 | 15 | | | | | | | 8 | 7 | | | | | | | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | RFDB_HH[7:0] | | | | | | | | RFDB_HL[7:0] | | | | | | | | RFDB_LH[7:0] | | | | | | | | RFDB_LL[7:0] | | | | | | | |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 7:0 | RFDB_LL[7:0] | RX FIFO Buffer Data Byte (p × 4) | R |
| 15:8 | RFDB_LH[7:0] | RX FIFO Buffer Data Byte ((p × 4) + 1) | R |
| 23:16 | RFDB_HL[7:0] | RX FIFO Buffer Data Byte ((p × 4) + 2) | R |
| 31:24 | RFDB_HH[7:0] | RX FIFO Buffer Data Byte ((p × 4) + 3) | R |

The RX FIFO Access Data Field p Registers b (p = 0 to 15, b = 0 to 1) store data bytes (p × 4) to data byte ((p × 4) + 3) of the received message.

#### RFDB_LL[7:0] bits (RX FIFO Buffer Data Byte (p × 4))

The RFDB_LL[7:0] bits store data bytes (p × 4) of the message present in the FIFO buffer.

Unused data bytes are filled with 0x00 according to the configured data payload size CFDRFCCa.RFPLS.

### RFDB_LH[7:0] bits (RX FIFO Buffer Data Byte ((p × 4) + 1))

The RFDB_LH[7:0] bits store data bytes ((p × 4) + 1) of the message present in the FIFO buffer.

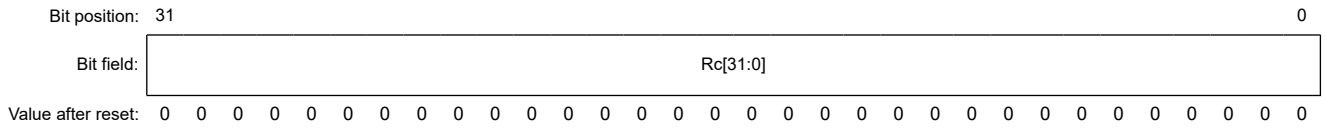
Unused data bytes are filled with 0x00.

### RFDB_HL[7:0] bits (RX FIFO Buffer Data Byte ((p × 4) + 2))

The RFDB_HL[7:0] bits store data bytes ((p × 4) + 2) of the message present in the FIFO buffer.

Unused data bytes are filled with 0x00.

### RFDB_HH[7:0] bits (RX FIFO Buffer Data Byte ((p × 4) + 3))



The RFDB_HH[7:0] bits store data bytes ((p × 4) + 3) of the message present in the FIFO buffer.

Unused data bytes are filled with 0x00.

## 31.2.62.12 CFDCFMBCP0[0] : Common FIFO Access Message Buffer Component

Base address: CANFD = 0x400B_0000

Offset address: See Table 31.6

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 31:0 | Rc[31:0] | Common FIFO Access Message Buffer Component c<br>See Table 31.11, Table 31.12 and the descriptions that follow for a detailed description of each register and its related bits, contained within this message buffer component. | R |

Where the total number of CFDCFMBCP0 = 1 as shown in Figure 31.28 (c = Common FIFO Message Buffer Component Register index = [0…18])

### Rc[31:0] bits (Common FIFO Access Message Buffer Component c)

The Common FIFO Access Message Buffer Component consists of the following registers: CFDCFID, CFDCFPTR, CFFDSTS0, and CFDCFDFp. See Table 31.12 for details of how to interpret the structure of this buffer component and how to access the respective registers.

**Table 31.11 Common FIFO access message buffer component summary (1 of 2)**

| Common FIFO access message buffer component (CFMBCP) | |

## 31.2.62.13 CFDCFID : Common FIFO Access ID Register

Base address: CANFD = 0x400B_0000

Offset address: 0x05B8

| Bit position: | 31 | 30 | 29 | 28 | … | 0 |
|---|---|---|---|---|---|---|
| Bit field: | CFIDE | CFRTR | THLEN | CFID[28:0] | | |
| Value after reset: | 0 | 0 | 0 | 0 | … | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 28:0 | CFID[28:0] | Common FIFO Buffer ID Field<br>STD-ID / EXT-ID fields | R/W |
| 29 | THLEN | THL Entry enable<br>TX FIFO Mode:<br>0: Entry will not be stored in THL after successful TX.<br>1: Entry will be stored in THL after successful TX.<br>RX FIFO Mode:<br>Reserved, this bit is read as 0 | R/W |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 30 | CFRTR | Common FIFO Buffer RTR Bit<br>0: Data Frame<br>1: Remote Frame | R/W |
| 31 | CFIDE | Common FIFO Buffer IDE Bit<br>0: STD-ID will be transmitted or has been received<br>1: EXT-ID will be transmitted or has been received | R/W |

The Common FIFO Access ID registers store the ID field, IDE bit and RTR bit of the message.

In TX mode, users can read data from the FIFO, only for the current entry based on the write pointer value, not for the other entries.

#### CFID[28:0] bit (Common FIFO Buffer ID Field)

These are the bits of the STD-ID / EXT-ID fields of the message in the FIFO Buffer.

In TX mode, users can write and read from FIFO buffers.

In RX mode, users can only read data from FIFO buffers.

#### THLEN bit (THL Entry enable)

This bit controls the storage of an entry corresponding to the transmitted message in the TX History list at the end of a successful transmission.

In TX mode, users can write and read from FIFO buffers.

In RX mode, users can only read data from FIFO buffers.

#### CFRTR bit (Common FIFO Buffer RTR Bit)

This bit selects whether a Data Frame or a Remote Frame will be transmitted from or was received in the FIFO Buffer.

Note: There are no remote frames in CANFD format. In case a CANFD frame was received (RX mode) the register reflects the state of the received value (RRS bit in FD frame format). In case of CANFD transmission (TX mode CFDCFID.CFFDF =1) the bit is always transmitted dominant (Data Frame).

In TX mode, users can write and read from FIFO buffers.

In RX mode, users can only read data from FIFO buffers.

#### CFIDE bit (Common FIFO Buffer IDE Bit)

This bit selects whether a message with EXT-ID or STD-ID will be transmitted from or was received in the FIFO Buffer.

In TX mode, users can write and read from FIFO buffers.

In RX mode, users can only read data from FIFO buffers.

### 31.2.62.14 CFDCFPTR : Common FIFO Access Pointer Register

Base address: CANFD = 0x400B_0000

Offset address: 0x05BC

| Bit position: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | CFDLC[3:0] | | | | — | — | — | — | — | — | — | — | — | — | — | — | CFTS[15:0] | | | | | | | | | | | | | | | |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 15:0 | CFTS[15:0] | Common FIFO Timestamp Value<br>Timestamp value of the received CAN frame (FIFO in RX mode). | R/W |
| 27:16 | — | These bits are read as 0. The write value should be 0. | R/W |
| 31:28 | CFDLC[3:0] | Common FIFO Buffer DLC Field<br>Number of data bytes received in a CAN frame, or to be transmitted in a CAN frame. | R/W |

The Common FIFO Access Pointer Registers store the DLC and Timestamp fields.

In TX mode, you can read data from the FIFO buffer, only for the current entry based on the write pointer value, and not for the other entries.

#### CFTS[15:0] bits (Common FIFO Timestamp Value)

The CFTS[15:0] bits store the timestamp value taken at the capture point as configured by the CFDGFDCFG.TSCCFG bit of the received message (if FIFO is configured in RX mode).

In TX mode, you can read and write from FIFO buffers.

In RX mode, you can only read data from FIFO buffers.

#### CFDLC[3:0] bits (Common FIFO Buffer DLC Field)

The CFDLC[3:0] bits store the number of data bytes that were received in the FIFO buffer or are to be transmitted.

See Table 5 in ISO 11898-1 (2015) Specification for details in defining the number of data bytes.

In TX mode, you can read and write from the FIFO buffers. Do not read data for the other entries in the FIFO when configured in TX mode.

In RX mode, you can only read data from the FIFO buffers.

### 31.2.62.15 CFDCFFDCSTS : Common FIFO Access CANFD Control/Status Register

Base address: CANFD = 0x400B_0000

Offset address: 0x05C0

| Bit position: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | CFPTR[15:0] | | | | | | | | | | | | | | | |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit position: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | — | — | — | CFIFL[1:0] | | — | — | — | — | — | CFFDF | CFBRS | CFESI |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 0 | CFESI*1 | Error State Indicator bit<br>0: CANFD frame received or to transmit by error active node<br>1: CANFD frame received or to transmit by error passive node | R/W |
| 1 | CFBRS*1 | Bit Rate Switch bit<br>0: CANFD frame received or to transmit with no bit rate switch<br>1: CANFD frame received or to transmit with bit rate switch | R/W |
| 2 | CFFDF*1 | CAN FD Format bit<br>0: Non CANFD frame received or to transmit<br>1: CANFD frame received or to transmit | R/W |
| 7:3 | — | These bits are read as 0. The write value should be 0. | R/W |
| 9:8 | CFIFL[1:0] | COMMON FIFO Buffer Information Label Field | R/W |
| 15:10 | — | These bits are read as 0. The write value should be 0. | R/W |
| 31:16 | CFPTR[15:0] | Common FIFO Buffer Pointer Field | R/W |

Note 1. This bit is not available in the classical CAN function.

The Common FIFO Access CANFD Control/Status Registers show the status of the FDF, BRS and ESI bits including the pointer of the received CANFD frame or the CANFD frame to transmit.

In TX mode, you can read data from the FIFO, only for the current entry based on the write pointer value, and not for the other entries.

#### CFESI bit (Error State Indicator bit)

In TX mode, you can read and write from FIFO buffers. In this mode, when the CANFD module is not in error passive, the CFESI bit equals the write value. Otherwise, it is a don't care and the bit is transmitted as 1 on the CAN bus, indicating this is an error passive node.

In RX mode, you can only read data from FIFO buffers.

In RX mode, the CFESI bit is updated with the ESI bit value of the CANFD frame when it has been received, indicating the error state of the transmitting node. In RX mode, 0 is stored to this bit when the received FDF bit is 0, this means a CAN 2.0 frame is received.

Note: This bit is not available in the classical CAN function.

#### CFBRS bit (Bit Rate Switch bit)

In TX mode, you can read and write from FIFO buffers. In this mode, the CANFD module either transmits a 0 to indicate no bit rate switch in the frame to be transmitted or a 1 to indicate a bit rate switch in the frame to be transmitted.

In RX mode, you can only read data from FIFO buffers.

In RX mode, the CFBRS bit is updated with the BRS bit value of the CANFD frame when it has been received, indicating whether there is a bit rate switch (1) or (0) on the CANFD frame.

In RX mode, 0 is stored to the CFBRS bit when the received FDF bit is 0, this means a CAN 2.0 frame is received.

Note: This bit is not available in the classical CAN function.

#### CFFDF bit (CAN FD Format bit)

In TX mode, you can read and write from FIFO buffers. In this mode, the CANFD module either transmits a 0 to indicate a CAN 2.0 frame is to be transmitted or a 1 to indicate a CANFD frame is to be transmitted.

In RX mode, you can only read data from FIFO buffers.

In RX mode, the CFFDF bit is updated with the FDF bit value of the CAN frame when it has been received, indicating whether it is a CAN 2.0 frame (0) or a CANFD frame (1).

Note: This bit is not available in the classical CAN function.

#### CFIFL[1:0] bits (COMMON FIFO Buffer Information Label Field)

If the Common FIFO is configured in TX mode, the value programmed in CFDCFFDCSTS.CFIFL[1:0] is stored together with additional message information, to the TX History List after successful transmission of the message.

The information label value from the related Global Acceptance Filter List entry is stored in these bits (if FIFO is configured in either RX mode).

In TX mode, you can read and write from FIFO buffers.

In RX mode, you can only read data from FIFO buffers.

#### CFPTR[15:0] bits (Common FIFO Buffer Pointer Field)

If the Common FIFO is configured in TX mode, the value programmed in CFDCFFDCSTS.CFPTR[15:0] is stored together with additional message information, to the TX History List after successful transmission of the message.

The pointer value from the related Global Acceptance Filter List entry is stored in these bits (if FIFO is configured in either RX mode).

In TX mode, you can read and write from FIFO buffers.

In RX mode, you can only read data from FIFO buffers.

### 31.2.62.16 CFDCFDFp : Common FIFO Access Data Field p Registers (p = 0 to 15)

Base address: CANFD = 0x400B_0000

Offset address: 0x05C4 + 0x004 × p

| Bit position: | 31 | | | | | | | 24 | 23 | | | | | | | 16 | 15 | | | | | | | 8 | 7 | | | | | | | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | CFDB_HH[7:0] | | | | | | | | CFDB_HL[7:0] | | | | | | | | CFDB_LH[7:0] | | | | | | | | CFDB_LL[7:0] | | | | | | | |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 7:0 | CFDB_LL[7:0] | Common FIFO Buffer Data Bytes (p × 4) | R/W |
| 15:8 | CFDB_LH[7:0] | Common FIFO Buffer Data Bytes ((p × 4) + 1) | R/W |
| 23:16 | CFDB_HL[7:0] | Common FIFO Buffer Data Bytes ((p × 4) + 2) | R/W |
| 31:24 | CFDB_HH[7:0] | Common FIFO Buffer Data Bytes ((p × 4) + 3) | R/W |

The FIFO Access Data Field p Registers (p = 0 to 15) store data bytes (p × 4) to data bytes ((p × 4) + 3) of the message.

In TX mode, you can read data from the FIFO, only for the current entry based on the write pointer value, and not for the other entries.

**CFDB_LL[7:0] bits (Common FIFO Buffer Data Bytes (p × 4))**

The CFDB_LL[7:0] bits store data bytes (p × 4) of the message present in the FIFO buffer.

In TX mode, you can read and write from the FIFO buffers.

In RX mode, you can only read data from the FIFO buffers.

In RX mode, unused data bytes are filled with 0x00, according to their configured data payload size CFDCFCC.CFPLS.*1

**CFDB_LH[7:0] bits (Common FIFO Buffer Data Bytes ((p × 4) + 1))**

The CFDB_LH[7:0] bits store data bytes ((p × 4) + 1) of the message present in the FIFO buffer.

In TX mode, you can read and write from the FIFO buffers.

In RX mode, you can only read data from the FIFO buffers.

In RX mode, unused data bytes are filled with 0x00, according to their configured data payload size CFDCFCC.CFPLS.*1

**CFDB_HL[7:0] bits (Common FIFO Buffer Data Bytes ((p × 4) + 2))**

The CFDB_HL[7:0] bits store data bytes ((p × 4) + 2) of the message present in the FIFO buffer.

In TX mode, you can read and write from the FIFO buffers.

In RX mode, you can only read data from the FIFO buffers.

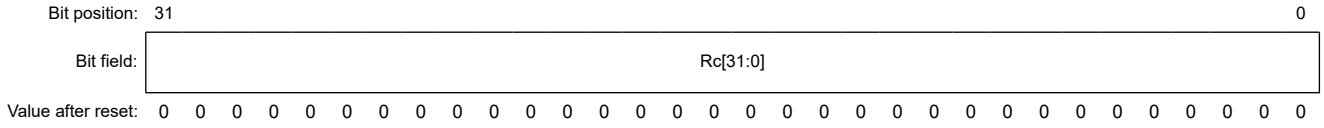
In RX mode, unused data bytes are filled with 0x00, according to their configured data payload size CFDCFCC.CFPLS.*1

**CFDB_HH[7:0] bits (Common FIFO Buffer Data Bytes ((p × 4) + 3))**

The CFDB_HH[7:0] bits store data bytes ((p × 4) + 3) of the message present in the FIFO buffer.

In TX mode, you can read and write from the FIFO buffers.

In RX mode, you can only read data from the FIFO buffers.



In RX mode, unused data bytes are filled with 0x00, according to their configured data payload size CFDCFCC.CFPLS.*1

Note 1. In RX mode, unused data bytes are filled with 0x00 according to the configured data payload size CFDCFCC.CFPLS, which is a CANFD feature not found in classical CAN.

## 31.2.62.17 CFDTMBCPb[0] : TX Message Buffer Component b (b = 0 to 3)

Base address: CANFD = 0x400B_0000

Offset address: See Table 31.6

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 31:0 | Rc[31:0] | TX Message Buffer Component c<br>Refer to Table 31.13, Table 31.14 and the descriptions that follow for a detailed description of each register and its related bits, contained within this message buffer component. | R |

Where the total number of CFDTMBCPn = 4 as shown in Figure 31.28 (c = TX Message Buffer Component Register index = [0…18])

### Rc[31:0] bit (TX Message Buffer Component c)

TX Message Buffer Component c

The TX Message Buffer Component is made up of the following registers: CFDTMIDb, CFDTMPTRb, CFDTMFDCTRb, and CFDTMDFbp. Refer to Table 31.14 for details of how to interpret the structure of this buffer component and how to access the respective registers.

**Table 31.13 TX Message Buffer Component Summary**

| TX Message Buffer Component (TMBCP) | |
|---|---|
| **Rc** | **CANFD mode (CAN_FD_MODE = 1b)** |

## 31.2.62.18 CFDTMIDb : TX Message Buffer ID Registers (b = 0 to 3)

Base address: CANFD = 0x400B_0000

Offset address: 0x0604 + 0x004C × b

| Bit position: | 31 | 30 | 29 | 28:0 |
|---|---|---|---|---|
| Bit field: | TMIDE | TMRTR | THLEN | TMID[28:0] |
| Value after reset: | 0 | 0 | 0 | 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 28:0 | TMID[28:0] | TX Message Buffer ID Field<br>STD-ID/EXT-ID fields | R/W |
| 29 | THLEN | Tx History List Entry<br>0: Entry not stored in THL after successful TX<br>1: Entry stored in THL after successful TX | R/W |
| 30 | TMRTR | TX Message Buffer RTR bit<br>0: Data frame<br>1: Remote frame | R/W |
| 31 | TMIDE | TX Message Buffer IDE bit<br>0: STD-ID is transmitted<br>1: EXT-ID is transmitted | R/W |

Each TX Message Buffer ID Register b (b = 0 to 3) are used to store the ID, IDE, RTR fields and history configuration of the message to be transmitted from the associated buffer.

### TMID[28:0] bits (TX Message Buffer ID Field)

The TMID[28:0] bits are bits of the STD-ID/EXT-ID fields of the message stored in this TX message buffer.

Do not write to these bits when the related CANFD channel is in CH_SLEEP mode.

### THLEN bit (Tx History List Entry)

The THLEN bit controls the storage of an entry corresponding to the transmitted message in the TX History list at the end of a successful transmission.

Do not write to these bits when the related CANFD channel is in CH_SLEEP mode.

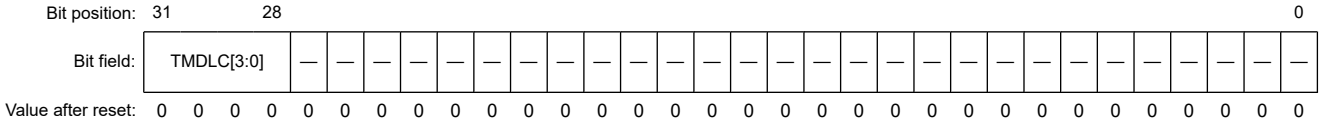
### TMRTR bit (TX Message Buffer RTR bit)

The TMRTR bit selects whether a data frame or remote frame is to be transmitted from this TX message buffer.

Note: There are no remote frames in CANFD format. For a CANFD transmission (CFDTMFDCTRb.CFFDF = 1), this bit is always transmitted dominant (data frame).

Do not write to these bits when the related CANFD channel is in CH_SLEEP mode.

**TMIDE bit (TX Message Buffer IDE bit)**



The TMIDE bit selects whether a message with EXT-ID or STD-ID is to be transmitted from this TX message buffer.

Do not write to these bits when the related CANFD channel is in CH_SLEEP mode.

## 31.2.62.19 CFDTMPTRb : TX Message Buffer Pointer Register (b = 0 to 3)

Base address: CANFD = 0x400B_0000

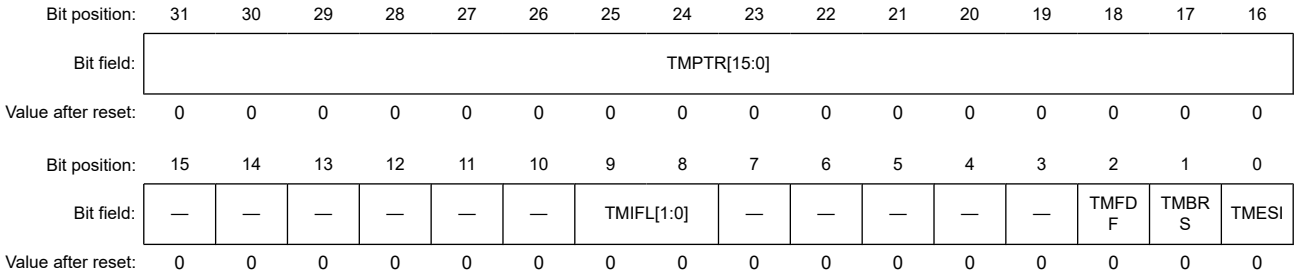
Offset address: 0x0608 + 0x004C × b

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 27:0 | — | The read values are undefined. The write value should be 0. | R/W |
| 31:28 | TMDLC[3:0] | TX Message Buffer DLC Field<br>Number of data bytes to be transmitted in a CAN frame. | R/W |

Each TX Message Buffer Pointer Register b (b = 0 to 3) is used to store the DLC fields of the message to transmit from the associated buffer.

**TMDLC[3:0] bits (TX Message Buffer DLC Field)**

The TMDLC[3:0] bits select the number of data bytes to be transmitted from this TX message buffer when the corresponding TMRTR bit is configured as 0.



See Table 5 in ISO 11898-1 (2015) Specification for details in defining the number of data bytes to be transmitted.

Do not write to these bits when the related CANFD channel is in CH_SLEEP mode.

## 31.2.62.20 CFDTMFDCTRb : TX Message Buffer CANFD Control Register (b = 0 to 3)

Base address: CANFD = 0x400B_0000

Offset address: 0x060C + 0x004C × b

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 0 | TMESI*1 | Error State Indicator bit<br>0: CANFD frame to transmit by error active node<br>1: CANFD frame to transmit by error passive node | R/W |
| 1 | TMBRS*1 | Bit Rate Switch bit<br>0: CANFD frame to transmit with no bit rate switch<br>1: CANFD frame to transmit with bit rate switch | R/W |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 2 | TMFDF*1 | CAN FD Format bit<br>0: Non CANFD frame to transmit<br>1: CANFD frame to transmit | R/W |
| 7:3 | — | The read values are undefined. The write value should be 0. | R/W |
| 9:8 | TMIFL[1:0] | TX Message Buffer Information Label Field | R/W |
| 15:10 | — | The read values are undefined. The write value should be 0. | R/W |
| 31:16 | TMPTR[15:0] | TX Message Buffer Pointer Field | R/W |

Note 1. This bit is not available in the classical CAN function.

The TX Message Buffer CANFD Control Registers b (b = 0 to 3) show the status of the FDF, BRS and ESI bits including the pointer fields of the CANFD frame to be transmitted.

#### TMESI bit (Error State Indicator bit)

If the channel is not in error passive, then the TMESI bit equals the write value, otherwise it is a don't care and the bit is transmitted as 1 on the CAN bus, indicating this is an error passive node.

Do not write to the TMESI bit when the related CANFD channel is in CH_SLEEP mode.

Note: This bit is not available in the classical CAN function.

#### TMBRS bit (Bit Rate Switch bit)

Do not write to the TMBRS bit when the related CANFD channel is in CH_SLEEP mode.

Note: This bit is not available in the classical CAN function.

#### TMFDF bit (CAN FD Format bit)

Do not write to the TMFDF bit when the related CANFD channel is in CH_SLEEP mode.

Note: This bit is not available in the classical CAN function.

#### TMIFL[1:0] bits (TX Message Buffer Information Label Field)

The TMIFL[1:0] bits store the information label value to be copied, together with additional message information, in the TX History List after successful transmission of the message.

Do not write to these bits when the related CANFD channel is in CH_SLEEP mode.

#### TMPTR[15:0] bits (TX Message Buffer Pointer Field)

The TMPTR[15:0] bits store the pointer value to be copied, together with additional message information in the TX History List after successful transmission of the message.

Do not write to these bits when the related CANFD channel is in CH_SLEEP mode.

### 31.2.62.21 CFDTMDFb_p : TX Message Buffer Data Field Register (p= 0 to 15 , b= 0 to 3)

Base address: CANFD = 0x400B_0000

Offset address: 0x0610 + 0x004 × p + 0x004C × b

| Bit position: | 31 to 24 | 23 to 16 | 15 to 8 | 7 to 0 |
|---|---|---|---|---|
| Bit field: | TMDB_HH[7:0] | TMDB_HL[7:0] | TMDB_LH[7:0] | TMDB_LL[7:0] |
| Value after reset: | 0 0 0 0 0 0 0 0 | 0 0 0 0 0 0 0 0 | 0 0 0 0 0 0 0 0 | 0 0 0 0 0 0 0 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 7:0 | TMDB_LL[7:0] | TX Message Buffer Data Byte (p × 4) | R/W |
| 15:8 | TMDB_LH[7:0] | TX Message Buffer Data Byte ((p × 4) + 1) | R/W |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 23:16 | TMDB_HL[7:0] | TX Message Buffer Data Byte ((p × 4) + 2) | R/W |
| 31:24 | TMDB_HH[7:0] | TX Message Buffer Data Byte ((p × 4) + 3) | R/W |

Each TX Message Buffer Data Field p Register b (p = 0 to 15, b = 0 to 3) is used to store data bytes (p × 4) to data bytes ((p × 4) + 3) of the message to transmit from the associated buffer.

**TMDB_LL[7:0] bits (TX Message Buffer Data Byte (p × 4))**

TMDB_LL[7:0] bits store data bytes (p × 4) of the message in the TX message buffer.

Do not write to these bits when the related CANFD channel is in CH_SLEEP mode.

**TMDB_LH[7:0] bits (TX Message Buffer Data Byte ((p × 4) + 1))**

TMDB_LH[7:0] bits store data bytes ((p × 4) + 1) of the message in the TX message buffer.

Do not write to these bits when the related CANFD channel is in CH_SLEEP mode.

**TMDB_HL[7:0] bits (TX Message Buffer Data Byte ((p × 4) + 2))**

TMDB_HL[7:0] bits store data bytes ((p × 4) + 2) of the message in the TX message buffer.

Do not write to these bits when the related CANFD channel is in CH_SLEEP mode.

**TMDB_HH[7:0] bits (TX Message Buffer Data Byte ((p × 4) + 3))**

TMDB_HH[7:0] bits store data bytes ((p × 4) + 3) of the message in the TX message buffer.

Do not write to these bits when the related CANFD channel is in CH_SLEEP mode.

## 31.3 Modes of Operation

### 31.3.1 Overview

The modes of the CANFD module can be classified into 2 groups:

- Global modes
- Channel modes

### 31.3.2 Global Modes

These modes are applicable for the complete CANFD module and therefore are called Global modes. The global modes of the CANFD module are:

- Global Sleep
- Global Reset
- Global Halt
- Global Operation.

Figure 31.2 shows the possible transitions between the Global modes.

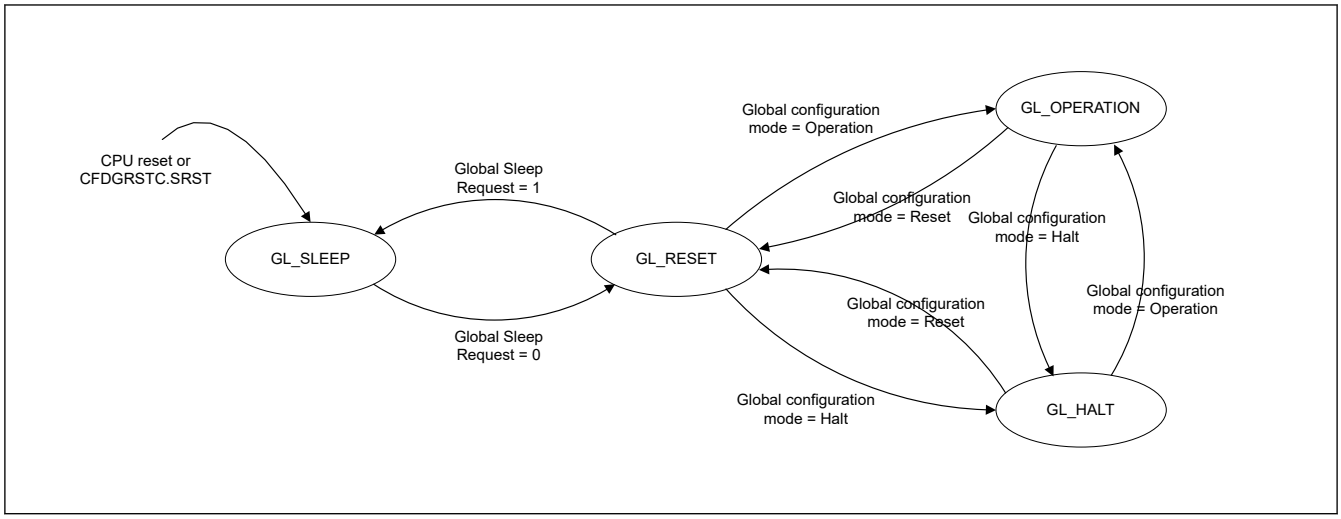


**Figure 31.2 Transition between CANFD Global modes**

Change in the Global mode can affect the Channel mode. Table 31.15 shows the effect of a Global mode transition on a Channel mode.

**Table 31.15 Possible CANFD Channel modes and Global modes**

| Current Global mode | Target Global mode | | | |
|---|---|---|---|---|
| | **Sleep** | **Reset** | **Halt** | **Operation** |
| **Sleep** | | Ch-Sleep: Keep<br>Ch-Reset: N/A<br>Ch-Halt: N/A<br>Ch-Oper: N/A | | |
| **Reset** | Ch-Sleep: Keep<br>Ch-Reset: → Ch-Sleep<br>Ch-Halt: N/A<br>Ch-Oper: N/A | | Ch-Sleep: Keep<br>Ch-Reset: Keep<br>Ch-Halt: N/A<br>Ch-Oper: N/A | Ch-Sleep: Keep<br>Ch-Reset: Keep<br>Ch-Halt: N/A<br>Ch-Oper: N/A |
| **Halt** | | Ch-Sleep: Keep<br>Ch-Reset: Keep<br>Ch-Halt: → Ch-Reset<br>Ch-Oper: N/A | | Ch-Sleep: Keep<br>Ch-Reset: Keep<br>Ch-Halt: Keep<br>Ch-Oper: N/A |
| **Operation** | | Ch-Sleep: Keep<br>Ch-Reset: Keep<br>Ch-Halt: → Ch-Reset<br>Ch-Oper: → Ch-Reset | Ch-Sleep: Keep<br>Ch-Reset: Keep<br>Ch-Halt: Keep<br>Ch-Oper: → Ch-Halt | |

### 31.3.2.1 Global Sleep Mode

After the release of a hardware reset or after setting and clearing a CFDGRSTC.SRST bit, the CANFD module automatically enters Global Sleep mode.

The CANFD module also enters the Global Sleep mode when the Global Sleep Request bit is set while it is in Global Reset mode. This control bit cannot be set in Global Halt mode or Global Operation mode.

Setting the Global Sleep Request bit sets Channel Sleep Request bit and forces the channel into the Channel Sleep mode.

Sleep mode is used for power saving purpose. When CANFD module is in Global Sleep mode, only the clock for CPU write access to the Global Sleep Mode Request bit is active. All other clocks are stopped and all other functions of the CANFD module are suspended.

Read access from all registers is still possible and all register values are preserved.

After setting the Global Sleep Request bit, it is necessary to confirm that the Global Sleep status has been updated, indicating successful transition to Global Sleep mode before the Global Sleep Request bit can be cleared again.

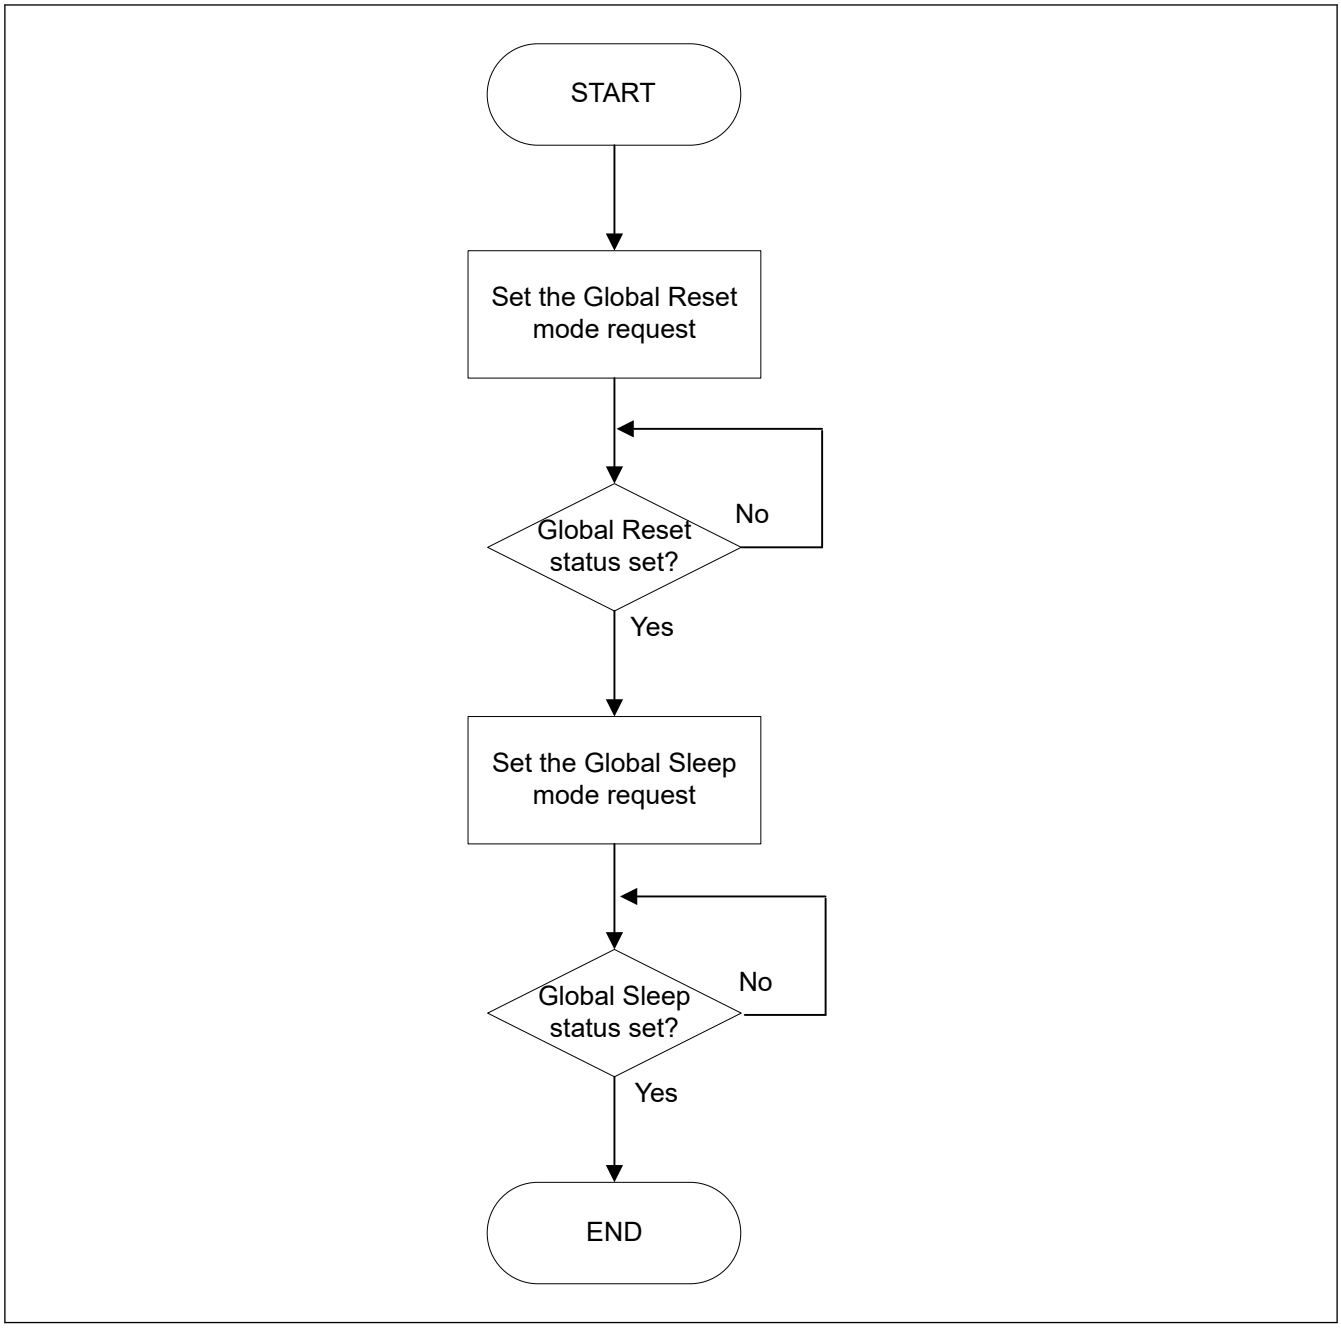

**Figure 31.3 Procedure for entering Global Sleep mode**

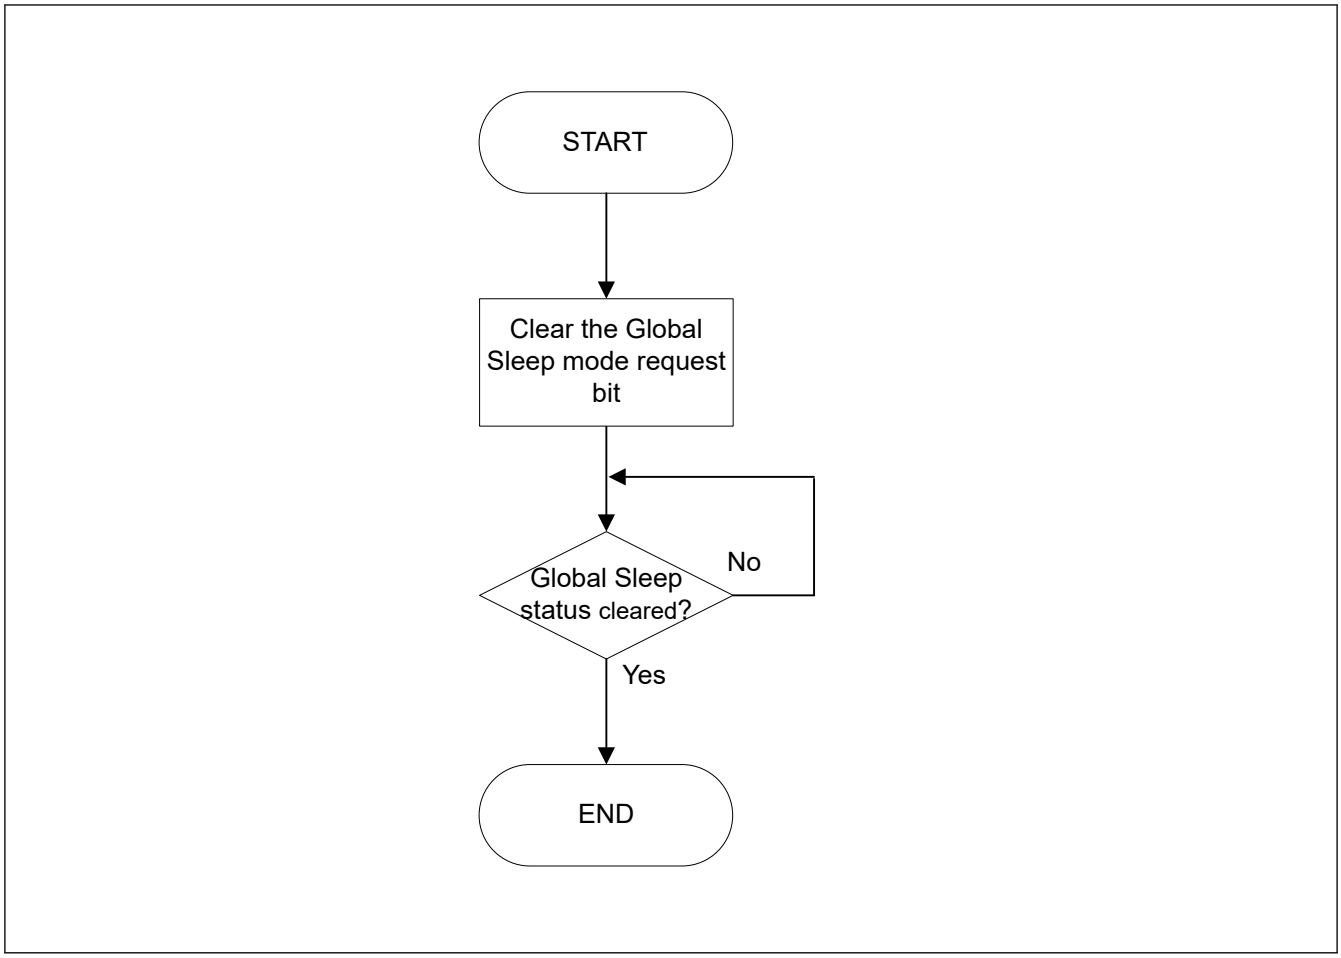

**Figure 31.4 Procedure for exiting Global Sleep mode**

### 31.3.2.2 Global Reset Mode

The CANFD module enters this mode in the following ways:

- Global Mode Control bit CFDGCTR.GMDC in the Global Control Register is configured for Global Reset mode while the CANFD module is in Global Halt or Global Operation mode
- Global Sleep Mode Request bit is cleared while CANFD module is in Global Sleep mode.

In Global Reset mode, all CANFD module functions are suspended and all status and flag registers are initialized.

Additionally all FIFOs and TX Queues are disabled and transmission control bits are cleared.

Configuration registers (except the test mode registers) are not initialized in this mode to their MCU reset values and the CANFD module can be configured.

See section 31.3.4. Global Mode and Channel Mode Transition Interactions for a detailed description of the behavior of all registers when transition to Global Reset mode is performed.

Setting the Global mode to Reset by setting the Global Mode Control bits CFDGCTR.GMDC in the Global Control Register to 01b sets Channel Mode Control bits CFDC0CTR.CHMDC in the Channel Control Registers to 01b and forces the channel into the Channel Reset mode.

For channels that are already in Channel Reset mode or Channel Sleep mode, this automatic transition is not performed (CFDC0CTR.CHMDC of related channel already set to 01b).

After setting Global Mode Control bit CFDGCTR.GMDC to Reset mode, it is necessary to confirm that the Reset Mode Status bit CFDGSTS.GRSTSTS in the Global Status Register has been updated, indicating successful transition to Global Reset mode before CFDGCTR.GMDC can be changed again.

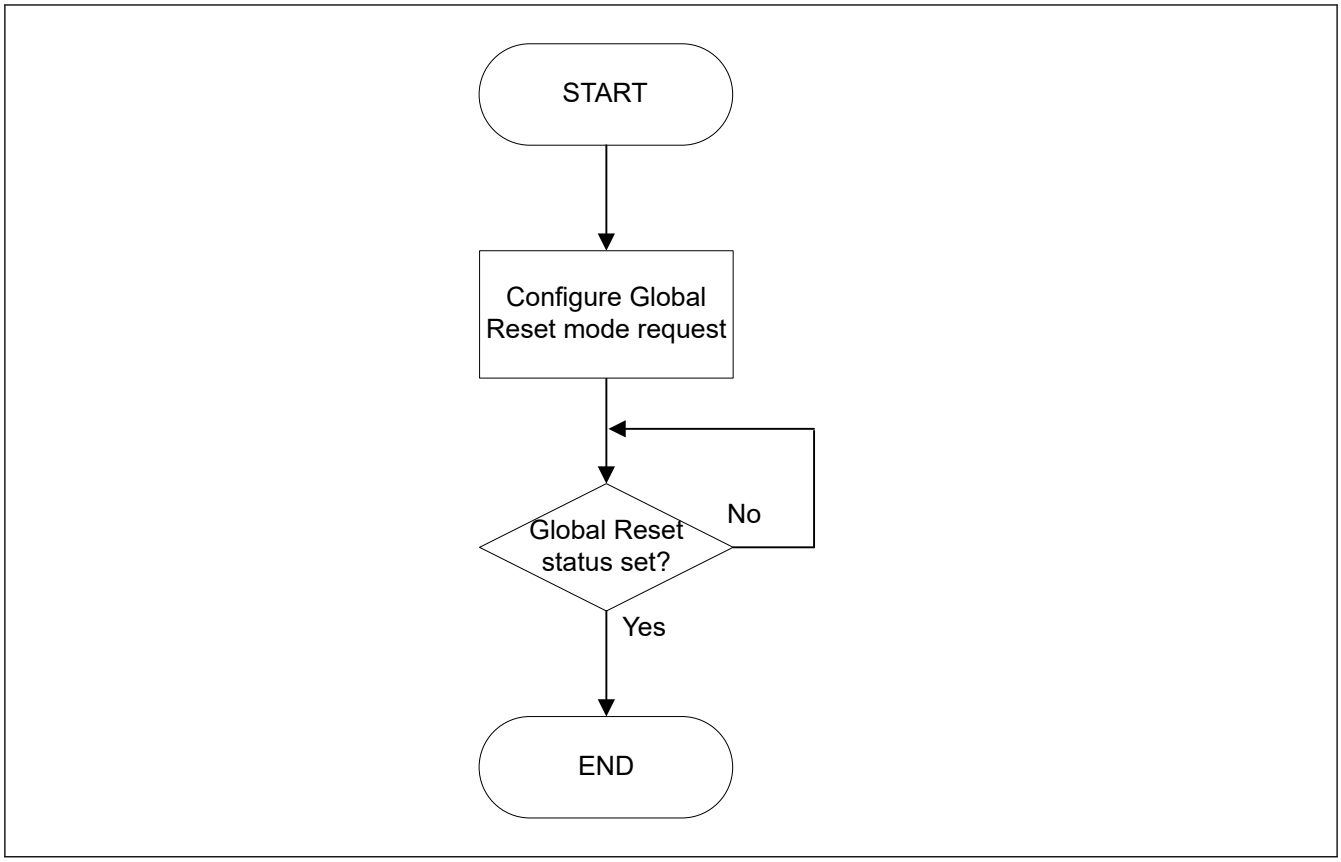

**Figure 31.5 Procedure for entering Global Reset mode**

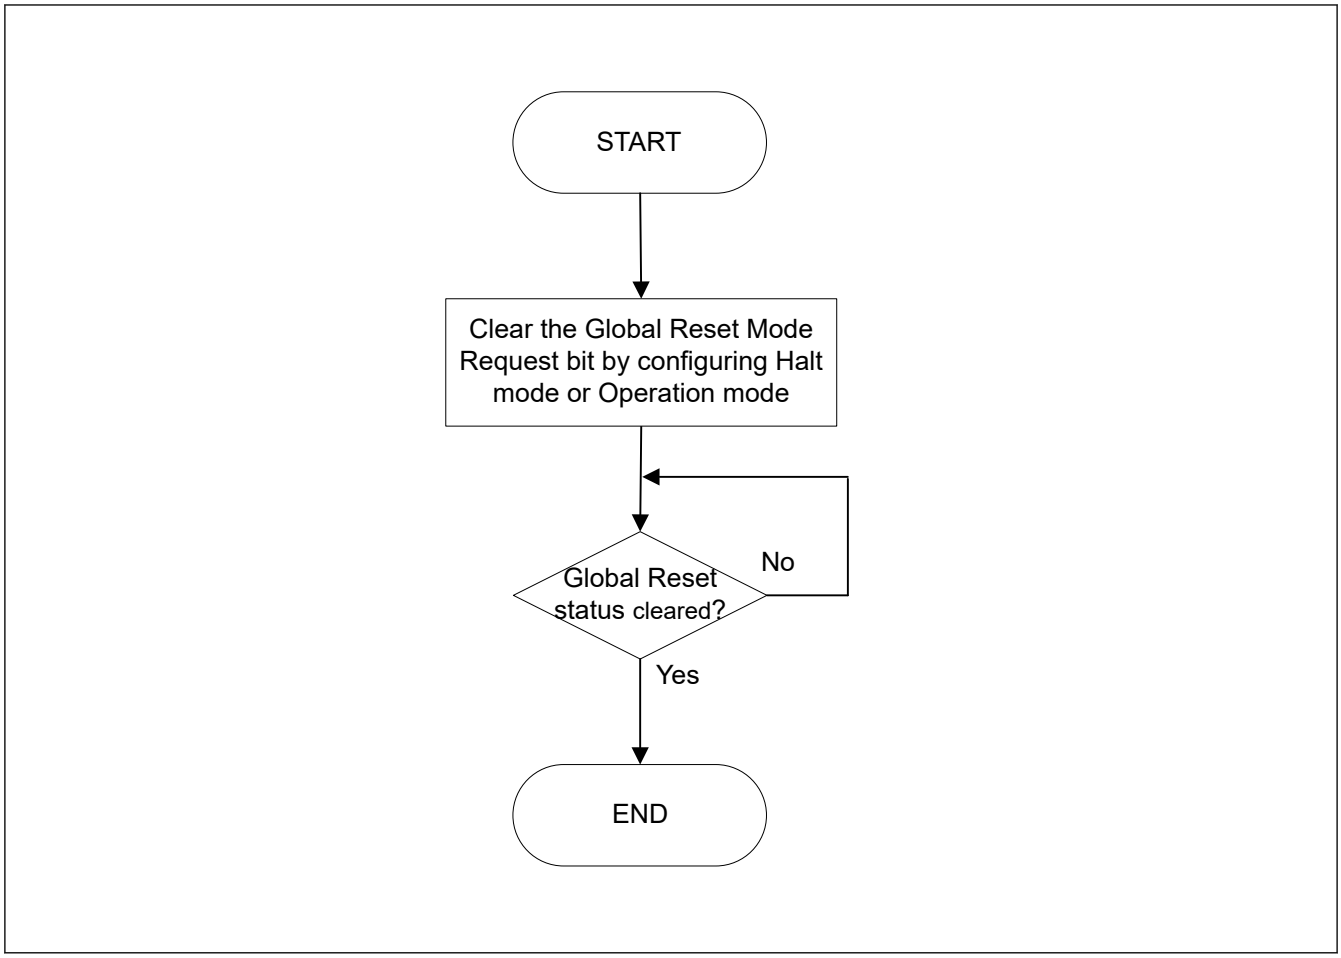

**Figure 31.6 Procedure for exiting Global Reset mode**

### 31.3.2.3 Global Halt Mode

The CANFD module enters this mode in the following ways:

- Global Mode Control bit CFDGCTR.GMDC in the Global Control Register is configured for Global Halt mode while the CANFD module is in Global Reset mode:
  - the channel in either Channel Reset or Channel Sleep mode remains in this mode
- Global Mode Control bit CFDGCTR.GMDC in the Global Control Register is configured for Global Halt mode while the CANFD module is in Global Operation mode:
  - the channel in Channel Reset, Channel Halt, or Channel Sleep mode remains in this mode
  - the channel in Channel Operation mode transitions to Channel Halt mode
  - Global Halt Mode Status bit is set when the channel has left Channel Operation mode.

If a transmission or reception is ongoing for a channel, the transition to Channel Halt mode is delayed until completion of the communication.

Similarly, if a channel is in bus-off, the full bus-off recovery sequence may be delayed depending on the channel configuration.

In Global Halt mode, all communications are suspended and CANFD logic does not cause any change to the Status and Flag registers (only when a channel is in the bus-off that its REC and TEC values are cleared). Additionally, the test mode configuration and control registers are not initialized in this mode.

The Global Halt mode should be used to configure global module test modes.

See section 31.3.4. Global Mode and Channel Mode Transition Interactions for a detailed description of the behavior of all registers when transition to Global Halt mode is performed.

Setting the Global mode to Halt by setting the Global Mode Control bit CFDGCTR.GMDC in the Global Control Register to 10b sets Channel Mode Control bits CFDC0CTR.CHMDC in the Channel Control Registers to 10b for the channel that are in Channel Operation mode and forces these channels into the Channel Halt mode.

For the channel that are already in Channel Reset, Channel Halt, or Channel Sleep mode, this automatic transition is not performed.

Therefore, the Global Halt mode request can be used to shut down all CANFD channel communications without loss of messages and disruption on the related CAN bus (no interruption of reception/transmission processes on the channels).

After setting the Global Mode Control bit CFDGCTR.GMDC to Halt mode, it is necessary to confirm that the Halt Mode Status bit CFDGSTS.GHLTSTS in the Global Status Register has been updated to indicate a successful transition to Global Halt mode. Do not specify any other SFR setting until confirming CFDGSTS.GHLTSTS is set.

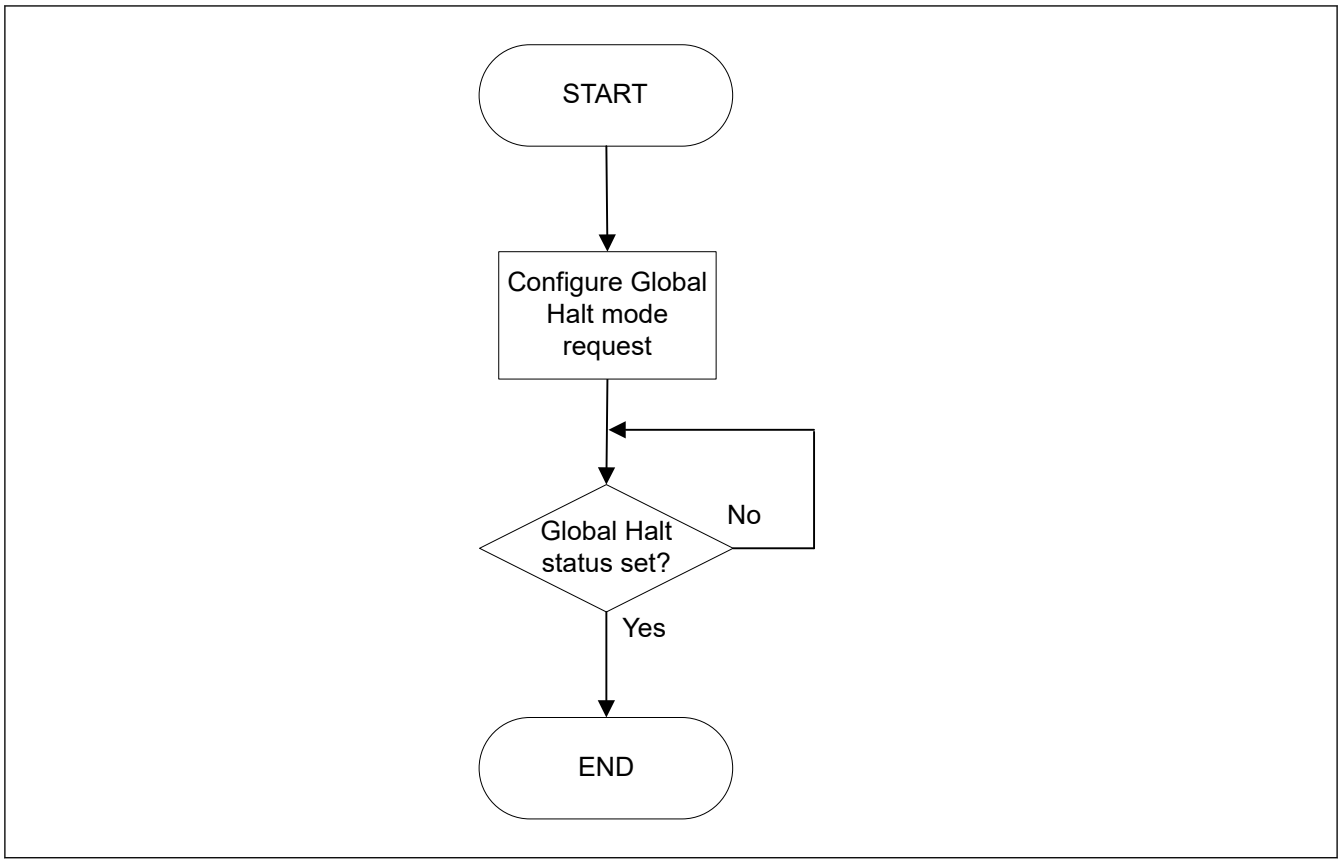

**Figure 31.7 Procedure for entering Global Halt mode**

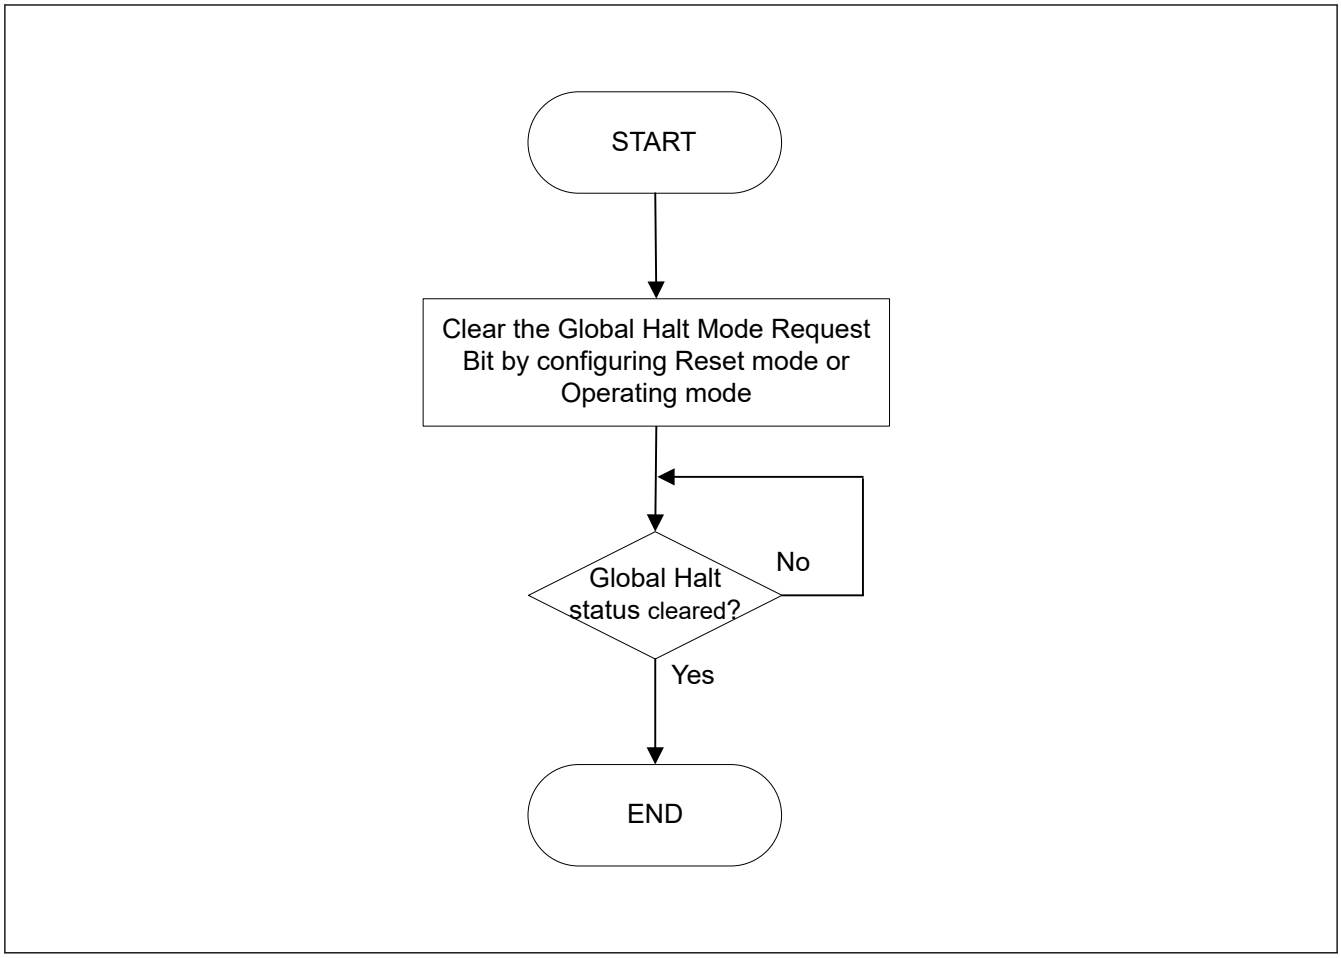

**Figure 31.8 Procedure for exiting Global Halt mode**

### 31.3.2.4 Global Operation Mode

The CANFD module enters this mode when the Global Mode Configuration bits are set to Global Operation mode.

The CANFD channel can only be set to Channel Operation mode and start CAN communication when CANFD is in Global Operation mode.

After setting the Global Mode Control bit CFDGCTR.GMDC to Global Operation mode, it is necessary to confirm that the Global Reset Mode Status bit CFDGSTS.GRSTSTS and the Global Halt Mode Status bit CFDGSTS.GHLTSTS in the Global Status Register have been cleared to indicate a successful transition to Global Operation mode before CFDGCTR.GMDC can be modified again.

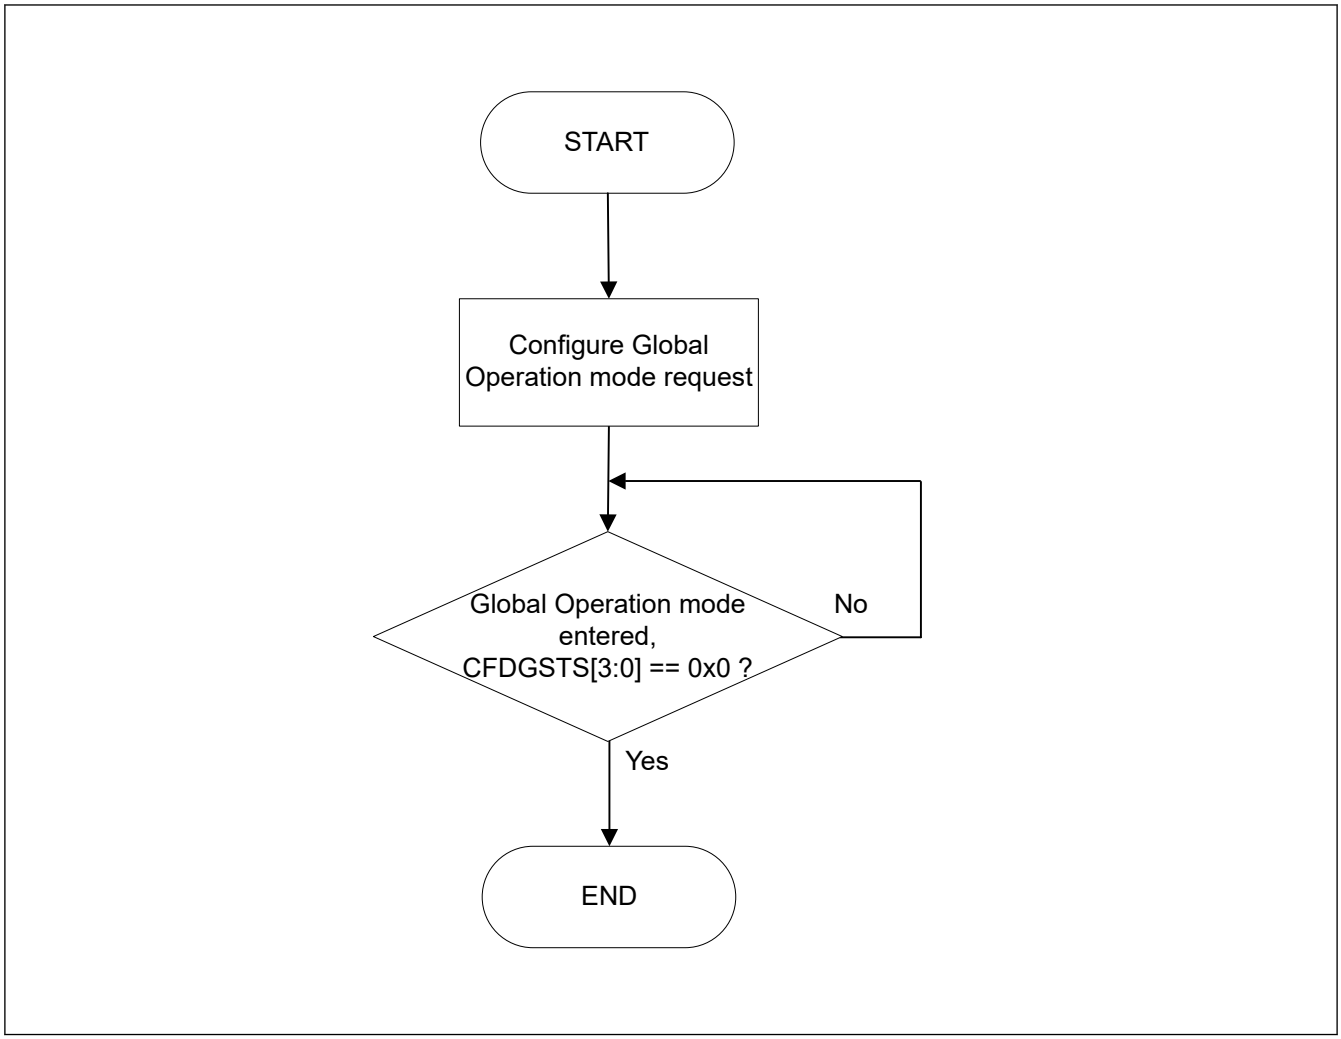

**Figure 31.9 Procedure for entering Global Operation mode**

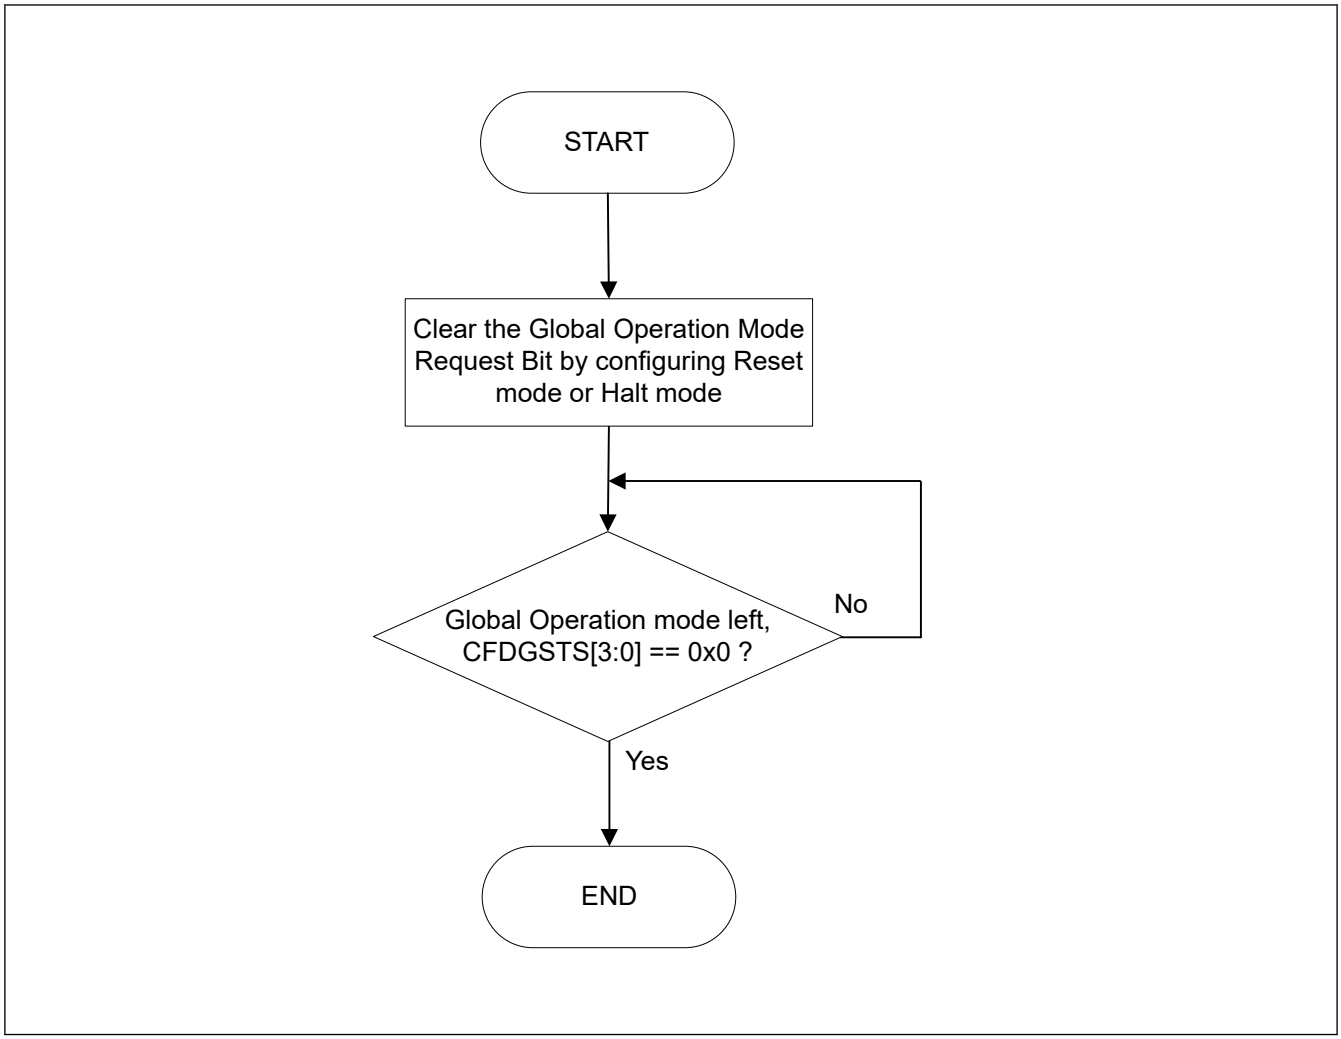

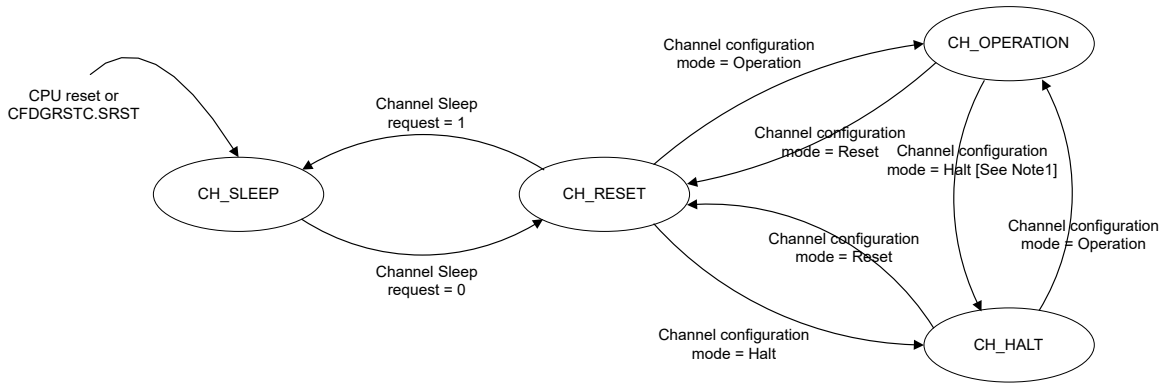

**Figure 31.10 Procedure for exiting Global Operation mode**

### 31.3.3 Channel Modes

A CAN channel can be in one of the following four channel modes:

- Reset
- Halt
- Operation
- Sleep.

Figure 31.11 shows the possible transitions between the channel modes.

Note 1. The transition timing depends on BOM setting in the Channel Configuration Register:
- when BOM = 01b, the state transition timing is immediate after entering bus-off state
- when BOM = 10b, the state transition timing is at the end of bus-off state
- when BOM = 11b, the state transition timing is matching with the setting of CHMDC to Halt mode.

**Figure 31.11 Transition between CAN channel modes**

### 31.3.3.1 CAN Channel Sleep Mode

After the release of a hardware reset or after setting and clearing the CFDGRSTC.SRST bit, a CAN channel of the CANFD module automatically enters Channel Sleep mode.

A CAN channel also enters Channel Sleep mode when the related Channel Sleep Mode Request bit is set while the CAN channel is in Channel Reset mode. Do not set this control bit in Channel Halt mode or Channel Operation mode.

Entering the CAN Channel Sleep mode instantly stops the clock supplied to the CAN channel unit and therefore reduces power consumption.

After setting the Channel Sleep Mode Request bit, it is necessary to confirm that the Channel Sleep mode status has been updated to indicate a successful transition to Channel Sleep mode before the Channel Sleep Mode Request bit can be cleared again.

During Channel Sleep mode, do not write to channel related registers. Read operation is still possible.

### 31.3.3.2 CAN Channel Reset Mode

A CANFD CAN channel enters this mode in the following ways:

- Channel Mode Control bit CFDC0CTR.CHMDC in the Channel Control Registers is configured for Channel Reset mode while the related CAN channel is in Channel Halt mode or Channel Operation mode
- Channel Sleep Mode Request bit is cleared while the related CAN channel is in Channel Sleep mode
- Global Mode Control bit CFDGCTR.GMDC is set to Global Reset mode and CAN channel is not in Channel Sleep mode or Channel Reset mode.

In Channel Reset mode, all CAN channel status and flag registers are initialized.

Additionally, all channel-related transmission control bits are cleared and the channel related TX Queue is disabled.

Configuration registers (except the Channel Test Mode registers) are not initialized in this mode and the CAN channel can be configured for communication.

See section 31.3.4. Global Mode and Channel Mode Transition Interactions for a detailed description of the behavior of all registers when transition to Channel Reset mode is performed.

After setting the Channel Mode Control bit CFDC0CTR.CHMDC to Channel Reset mode, it is necessary to confirm that the Reset Mode Status bit CFDC0STS.CRSTSTS in the related Channel Status Registers has been updated to indicate a successful transition to Channel Reset mode before the related CFDC0CTR.CHMDC bit can be modified again.

See Table 31.16 for the behavior of transitioning to Channel Reset mode while CAN communication is in progress.

### 31.3.3.3 CAN Channel Halt Mode

A CANFD CAN channel enters this mode in the following ways:

- Channel Mode Control bit CFDC0CTR.CHMDC in the Channel Control Registers is configured for Channel Halt mode while the related CAN channel is in Channel Reset mode or Channel Operation mode
- Global Mode Control bit CFDGCTR.GMDC is set to Global Halt mode and CAN channel is in Channel Operation mode.

In Channel Halt mode, all channel CAN communication is suspended but all status and flag registers remain unchanged during Channel Halt mode entry (except for the bus-off case where REC and TEC values are cleared for this channel).

In addition, the Channel Test Mode Configuration and Control registers are not initialized in this mode.

The Channel Halt mode should be used to configure channel test modes.

See section 31.3.4. Global Mode and Channel Mode Transition Interactions for a detailed description of the behavior of all registers when transition to Channel Halt mode is performed.

After setting the Channel Mode Control bit CFDC0CTR.CHMDC to Channel Halt mode, it is necessary to confirm that the Halt Mode Status bit CFDC0STS.CHLTSTS in the related Channel Status Register has been updated to indicate a successful transition to Channel Halt mode before the related CFDC0CTR.CHMDC can be modified again.

See Table 31.16 for the transition behavior to Channel Halt mode while CAN communication is ongoing.

**Table 31.16 Transition behavior in CAN Reset mode and Halt mode**

| Mode | State | | |
|---|---|---|---|
| | **Receiver** | **Transmitter** | **Bus-Off** |
| **CAN Channel Reset mode (CFDC0CTR.CHMDC = 01b)** | The CAN channel enters Channel Reset mode without waiting for the completion of the ongoing reception.*1 | The CAN channel enters Channel Reset mode without waiting for the completion of the ongoing transmission.*1 | The CAN channel enters Channel Reset mode without waiting for the completion of the bus-off recovery. |
| **CAN Channel Halt mode (CFDC0CTR.CHMDC = 10b)** | CAN channel enters Channel Halt mode at the end of the ongoing reception or error.*2 | CAN channel enters Channel Halt mode after completion of the ongoing transmission. | When CFDC0CTR.BOM is set to 00b, a Channel Halt mode request is accepted only after the completion of the full bus-off recovery sequence.<br>When CFDC0CTR.BOM is set to 10b, the CAN channel transits automatically to Channel Halt mode after waiting for the completion of the bus-off recovery.<br>When CFDC0CTR.BOM is set to 01b, the CAN channel transits automatically to Channel Halt mode without waiting for the completion of the bus-off recovery.<br>When CFDC0CTR.BOM is set to 11b, the CAN channel enters Channel Halt mode as soon as Channel Halt mode is requested (without waiting for the completion of the bus-off recovery). |

Note 1. If the entry to Channel Reset mode is required only at the end of an ongoing communication, then Channel Halt mode can be requested first to prevent interruption of CAN communication by direct transition to Channel Reset mode. After the CAN channel enters Channel Halt mode, the Channel Reset mode can be requested.

Note 2. If CAN communication is locked at dominant level after an error flag, software can detect this situation by monitoring the channel related BusLock flag and resolve lock condition by setting the CAN channel to Channel Reset mode.

### 31.3.3.4 CAN Channel Operation Mode

The Channel Operation mode is activated by setting the CFDC0CTR.CHMDC bits to 00b. If 11 consecutive recessive bits are detected after entering the CAN Operation mode, the CFDC0STS.COMSTS bit is set and the CAN channel:

- Enables the functions of the channel communication by allowing the channel to become an active node on the CAN network
- Releases the internal fault confinement logic including receive and transmit error counters.

At this point, the CAN channel can start transmission and reception of CAN messages.

Within the CAN Channel Operation mode, the channel may be in four different sub-modes, depending on which type of communication functions are performed (see Figure 31.12):

- Channel idle: The CAN channel is neither receiving nor transmitting
- Channel receives: The channel is receiving a CAN message sent by another CAN node
- Channel transmits: The channel is transmitting a CAN message

  Note: The channel may receive its own message simultaneously when Self-test mode is enabled.
- Channel is in bus-off state: The CAN channel is cut off from CAN bus communication.

After setting the Channel Mode Control bit CFDC0CTR.CHMDC to Channel Operation mode, it is necessary to confirm that the Channel Reset Mode Status bit CFDC0STS.CRSTSTS and the Channel Halt Mode Status bit CFDC0STS.CHLTSTS in the Channel Status Register have been updated to indicate a successful transition to Channel Operation mode before the related CFDC0CTR.CHMDC bit can be changed again.

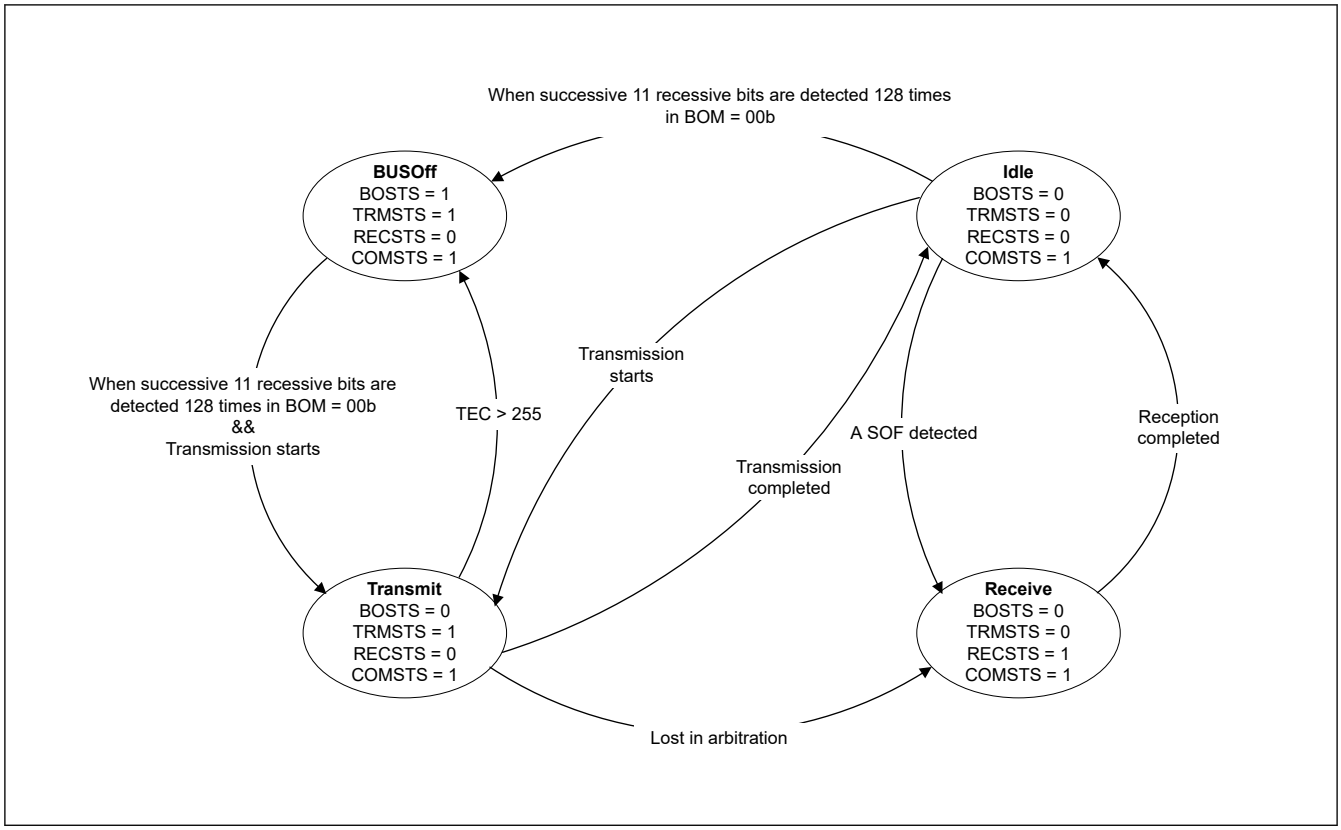

**Figure 31.12 Sub-modes of CAN Channel Operation mode (only when BOM = 00b)**

### 31.3.3.5 CAN Channel Bus-Off State

The CAN channel bus-off state is entered according to the fault confinement rules of the CAN specification. The following modes can be configured for returning to the CAN Channel Operation mode from the bus-off state:

- CFDC0CTR.BOM = 00b:
  Bus-Off recovery is compliant to ISO 11898-1, namely the CAN channel reenters CAN communication (error active state) after 11 consecutive recessive bits are detected 128 times. TEC and REC counters are initialized to 0. The Bus-Off Recovery Flag CFDC0ERFL.BORF is set in this case.
- CFDC0CTR.BOM = 01b:

The CAN channel changes the value of the CFDC0CTR.CHMDC bits within the CAN Channel Control Register to 10b and switches immediately to Channel Halt mode automatically after entering bus-off state. TEC and REC counters are initialized to 0 and the Bus-Off Recovery Flag CFDC0ERFL.BORF is not set in this case.

- CFDC0CTR.BOM = 10b:
  The CAN channel changes the value of the CFDC0CTR.CHMDC bits within the CAN Channel Control Register to 10b as soon as it reaches bus-off state and enters Channel Halt mode automatically after the CAN channel has completed the bus-off recovery sequence (after 11 consecutive recessive bits are detected 128 times). TEC and REC counters are initialized to 0 and the Bus-Off Recovery Flag CFDC0ERFL.BORF is set in this case.
- CFDC0CTR.BOM = 11b:
  Bus-off recovery is initiated but CAN channel can immediately enter Channel Halt mode when still in bus-off state if a request is made to enter Channel Halt mode.
  TEC and REC counters are initialized to 0 and the Bus-Off Recovery Flag CFDC0ERFL.BORF is not set.
  Without setting CFDC0CTR.CHMDC [1:0] = 10b and when 11 recessive bits are detected 128 times continuously, transition conditions become the same as CFDC0CTR.BOM = 00b.

Note: If the recovery from bus-off occurs normally in this mode (after waiting for 128 sequences of 11 consecutive recessive bits), and no halt request has been generated during this period, the Bus-Off Recovery flag CFDC0ERFL.BORF is set.

When software writes to the CFDC0CTR.CHMDC bit at the same time as the CAN channel enters Halt mode (at the start of bus-off when CFDC0CTR.BOM = 01b, or at the end of bus-off when CFDC0CTR.BOM = 10b), the software request has the highest priority.

Note: In the above case, the automatic setting of the CFDC0CTR.CHMDC bit to Channel Halt mode request is performed when the CFDC0CTR.CHMDC bit value is previously 00b (Channel Operation mode).

Additionally, it is possible to force the CAN channel to recover from the bus-off state by setting CFDC0CTR.RTBO to 1. The error state changes from bus-off state to integrating state with a maximum delay of 1 CAN bit time, and the CAN communication becomes possible again after 11 consecutive recessive bits are detected. The Bus-Off Recovery Flag is not set in this case, and the TEC and REC counters are initialized to 0.

Before setting CFDC0CTR.RTBO to 1, all pending transmissions from the TX message buffers, TX Queues and/or Common FIFO in TX mode should be disabled.

The disable of the pending transmission message buffer, TX Queue or FIFO must be confirmed by the corresponding acknowledge flags.

For the TX message buffer, the acknowledge flags are the Transmission Result Flags (CFDTMSTSj.TMTRF). For the TX Queue, it is the TX Queue Empty flag (CFDTXQSTS.TXQEMP). For the FIFO, it is the FIFO Empty flag (CFDCFSTS.CFEMP).

The CFDC0CTR.RTBO bit should be used for bus-off recovery only when CFDC0CTR.BOM is set to 00b.

Setting this bit in any state other than bus-off has no effect and the bit is cleared immediately.

Table 31.17 shows the settings for the Bus-Off Entry flag CFDC0ERFL.BOEF and the Bus-Off Recovery flag CFDC0ERFL.BORF for the different configurations of CFDC0CTR.BOM.

**Table 31.17 Behavior of Bus-off Entry and Recovery flags**

| BOM | BOEF bit set | BORF bit set |
|---|---|---|
| 00b | Always (on entry to bus-off) | Always (on exit from bus-off) |
| 00b<br>CFDC0CTR.RTBO set to 1 | Always (on entry to bus-off) | Only if normal bus-off recovery occurs before software sets CFDC0CTR.RTBO to 1 |
| 01b | Always (on entry to bus-off) | Never |
| 10b | Always (on entry to bus-off) | Always (on exit from bus-off) |
| 11b | Always (on entry to bus-off) | Only if normal bus-off recovery occurs before software issues a Halt request |

For an efficient software procedure, it is not necessary to wait for the bus-off recovery sequence to end.

It is possible to perform a transmission re-initialization during bus-off recovery. To do this, follow the recommended software flow in Figure 31.13.

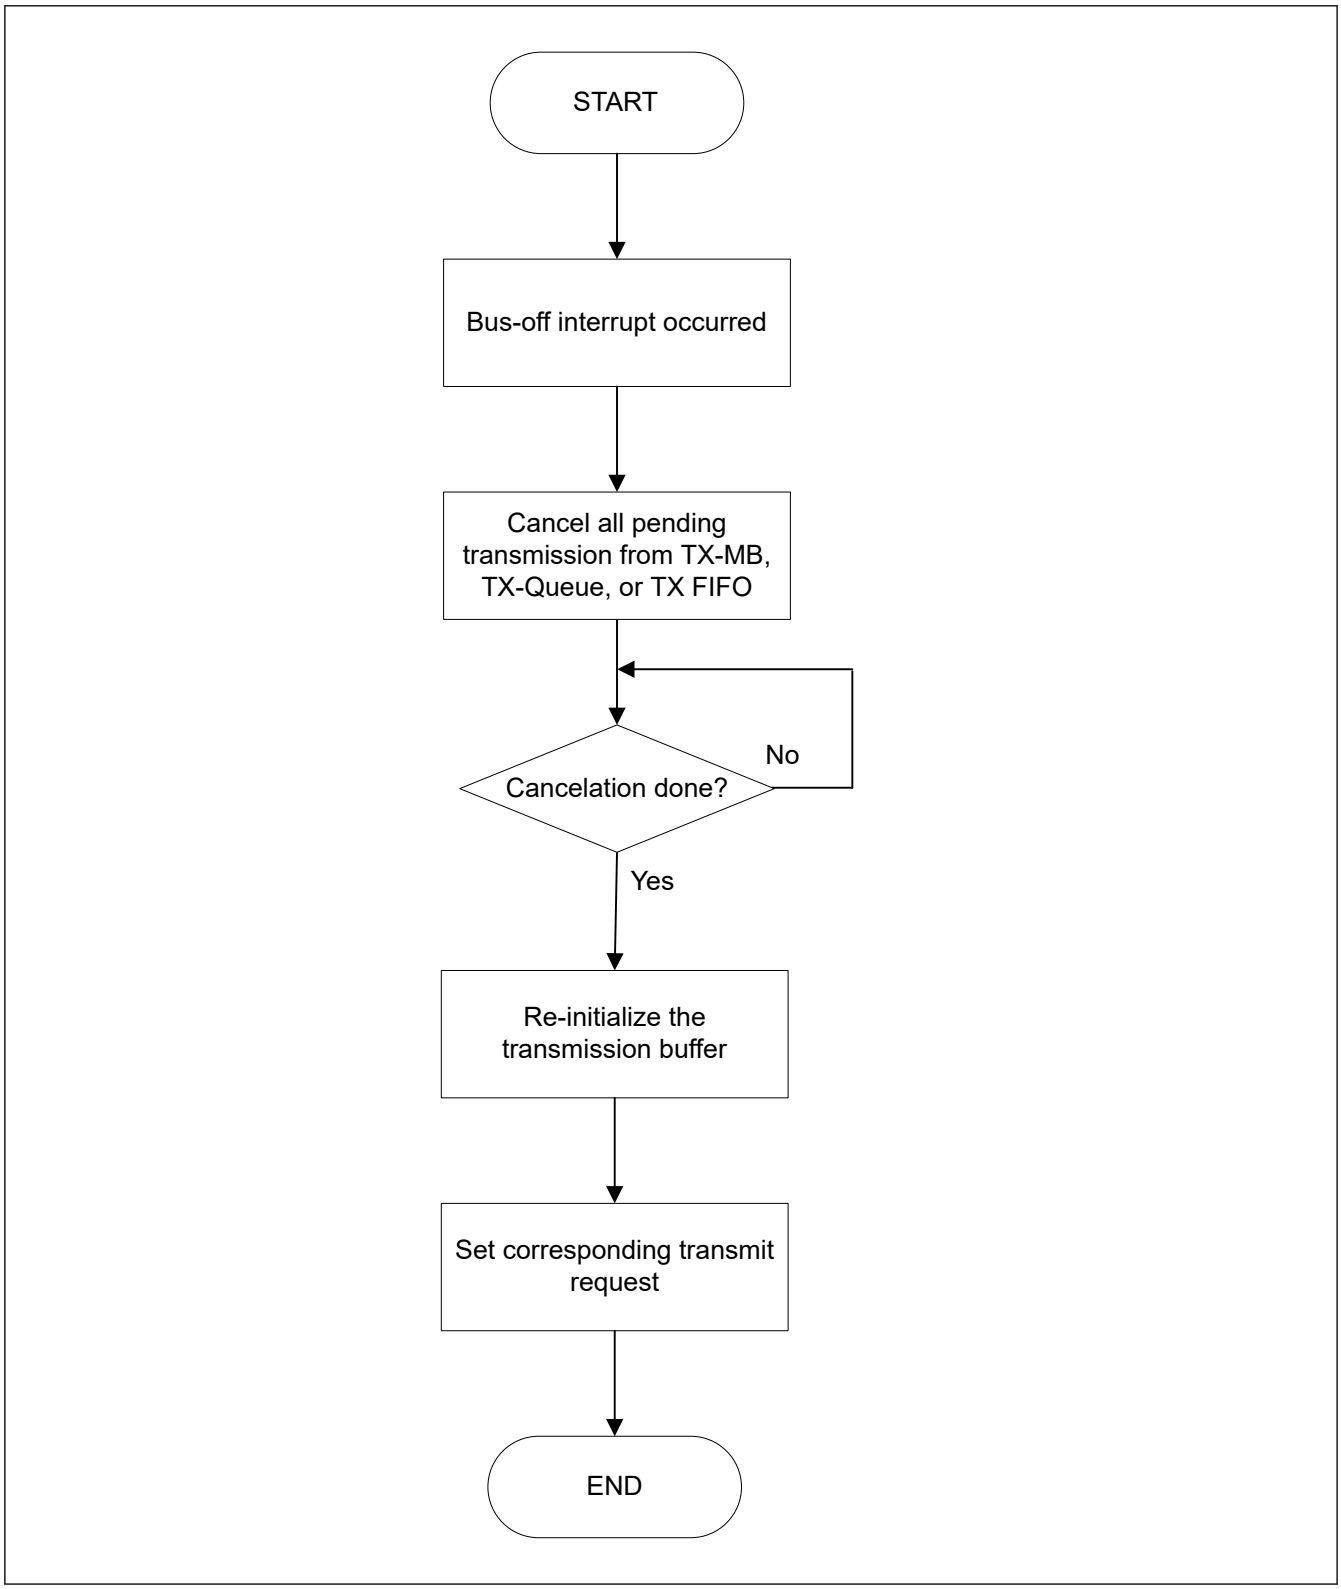

**Figure 31.13 Transmission reinitialization during bus-off**

## 31.3.4 Global Mode and Channel Mode Transition Interactions

The interaction between Global mode setting and Channel mode setting is as follows:

- Changing the Channel Mode Control bit CFDC0CTR.CHMDC in the Channel Control Registers does not affect the Global Mode Control bit CFDGCTR.GMDC.
- Changing the Global Mode Control bit CFDGCTR.GMDC affects the channel mode control as described in Table 31.18.

**Table 31.18 Interaction between Global and Channel mode transition**

| Global mode change | Channel mode | Channel mode transition action |
|---|---|---|
| Sleep → Reset | Sleep | Channel remains in Sleep mode |
| Sleep → Halt | — (Global mode change not possible) | |
| Sleep → Operation | — (Global mode change not possible) | |
| Reset → Sleep | Sleep | Channel remains in Sleep mode |
| | Reset | Channel Sleep request bit is set automatically, channel enters Sleep Mode |
| Reset → Halt | Sleep | Channel remains in Sleep mode |
| | Reset | Channel remains in Reset mode |
| Reset → Operation | Sleep | Channel remains in Sleep mode |
| | Reset | Channel remains in Reset mode |
| Halt → Sleep | — (Global mode change not possible) | |
| Halt → Reset | Sleep | Channel remains in Sleep mode |
| | Reset | Channel remains in Reset mode |
| | Halt | Channel mode control is set to Reset mode, channel enters Reset mode |
| Halt → Operation | Sleep | Channel remains in Sleep mode |
| | Reset | Channel remains in Reset mode |
| | Halt | Channel remains in Halt mode |
| Operation → Sleep | — (Global mode change not possible) | |
| Operation → Reset | Sleep | Channel remains in Sleep mode |
| | Reset | Channel remains in Reset mode |
| | Halt | Channel mode control is set to Reset mode, channel enters Reset mode |
| | Operation | Channel mode control is set to Reset mode, channel enters Reset mode |
| Operation → Halt | Sleep | Channel remains in Sleep mode |
| | Reset | Channel remains in Reset mode |
| | Halt | Channel remains in Halt mode |
| | Operation | Channel mode control is set to Halt mode, channel enters Halt mode after communication finished |

### 31.3.4.1 Timing of Global Mode Change

The transition time for the Global mode changes are shown in the following table.

**Table 31.19 Maximum transition time for the global mode (1 of 2)**

| From | To | Maximum transition time |
|---|---|---|
| GL_SLEEP | GL_RESET | 3 peripheral clock cycles*2 |
| GL_RESET | GL_SLEEP | 3 peripheral clock cycles |
| GL_RESET | GL_HALT | 10 peripheral clock cycles |
| GL_RESET | GL_OPERATION | 10 peripheral clock cycles |

**Table 31.19 Maximum transition time for the global mode (2 of 2)**

| From | To | Maximum transition time |
|---|---|---|
| GL_HALT | GL_RESET | 2 CAN bit times |
| GL_HALT | GL_OPERATION | 3 peripheral clock cycles |
| GL_OPERATION | GL_RESET | 2 CAN bit times |
| GL_OPERATION | GL_HALT | 3 CAN frames*1 *3 |

Note 1. The given transition time is the time without any errors on the bus. In case of an error condition, the transition time can lengthen to an uncalculated result. The transition time can also come to a stuck condition for locked RX lines or continued error conditions.
Note 2. Exit GL_SLEEP mode only when CFDGSTS.GRAMINIT is cleared.
Note 3. TQ, CAN frame and CAN bits are related to the individual channels. For the maximum transition time, the channel with the lowest baud rate must be used.

#### 31.3.4.2 Timing of Channel Mode Change

The transition time for the Channel mode changes are shown in the following table.

**Table 31.20 Maximum transition time for the channel mode**

| From | To | max. transition time |
|---|---|---|
| CH_SLEEP | CH_RESET | 3 peripheral clock cycles |
| CH_RESET | CH_SLEEP | 3 peripheral clock cycles |
| CH_RESET | CH_HALT | 3 CAN bit times |
| CH_RESET | CH_OPERATION | 4 CAN bit times |
| CH_HALT | CH_RESET | 2 CAN bit times |
| CH_HALT | CH_OPERATION | 4 CAN bit times*3 |
| CH_OPERATION | CH_RESET | 2 CAN bit times |
| CH_OPERATION | CH_HALT | 2 CAN frames*1 *2 |

Note 1. The time specified for this transition does not include the case where channel enters bus-off state. For bus-off, the timing depends on the configuration of the CFDC0CTR.BOM[1:0] bits.
Note 2. The given transition time is the time without any errors on the bus. In case of an error condition, the transition time can lengthen to an uncalculated result. The transition time can also come to a stuck condition for locked RX lines or continued error conditions.
Note 3. In general, if the baud rate prescaler value CFDC0NCFG.NBRP is changed in CH_HALT mode, the transition time can deviate. The internal prescaler is a free running down counter that creates the TQ clock, and new BRP value is captured when the counter reaches the value 0.

## 31.4 Initialization

Before joining CAN communications, configure the following settings:

- Clock setting
- Bit timing setting (nominal and data rate)
- Baud Rate setting (nominal and data rate)
- CANFD setting
- Acceptance Filter setting (configuration of Global Acceptance Filter List)
- Reception, Transmission and GW-FIFO setting
- CAN Operation mode setting

### 31.4.1 Initialization of CAN Clock, Bit Timing and Baud Rate

#### 31.4.1.1 Bit Timing Conditions

The following lines describe the composition of each segment and the restriction that apply to the segment setting.

1. Each segment setting
   SS = Fixed to 1 TQ

TSEG1 = See CFDC0NCFG and CFDC0DCFG[*1]
TSEG2 = See CFDC0NCFG and CFDC0DCFG[*1]
SJW = See CFDC0NCFG and CFDC0DCFG[*1]
SS + TSEG1 + TSEG2 = 5 to 49 TQs for Data Bit Rate and 8 to 385 for Nominal Bit Rate

2. Restriction on TSEG1, TSEG2 and SJW
TSEG1(N) > TSEG2(N) ≥ SJW(N)
TSEG1(D) ≥ TSEG2(D) ≥ SJW(D)[*1]
When only classical frames are used, configure the bit fields TSEG1 and TSEG2 of CFDC0DCFG to valid values.

Note 1. This feature is not available in the classical CAN function.

Table 31.21 shows an example of how to set the bit timing to achieve the required Sample Point settings.

**Table 31.21 Bit timing examples**

| 1 bit | Set value (TQ) | | | | Sample point (%) |
|---|---|---|---|---|---|
| | SS | TSEG1 | TSEG2 | SJW | |
| 5TQ | 1 | 2 | 2 | 1 | 60.00 |
| 8TQ | 1 | 4 | 3 | 1 | 62.50 |
| | 1 | 5 | 2 | 1 | 75.00 |
| 10TQ | 1 | 6 | 3 | 1 | 70.00 |
| | 1 | 7 | 2 | 1 | 80.00 |
| 12TQ | 1 | 8 | 3 | 1 | 75.00 |
| | 1 | 9 | 2 | 1 | 83.33 |
| 15TQ | 1 | 10 | 4 | 1 | 73.33 |
| | 1 | 11 | 3 | 1 | 80.00 |
| 16TQ | 1 | 10 | 5 | 1 | 68.75 |
| | 1 | 11 | 4 | 1 | 75.00 |

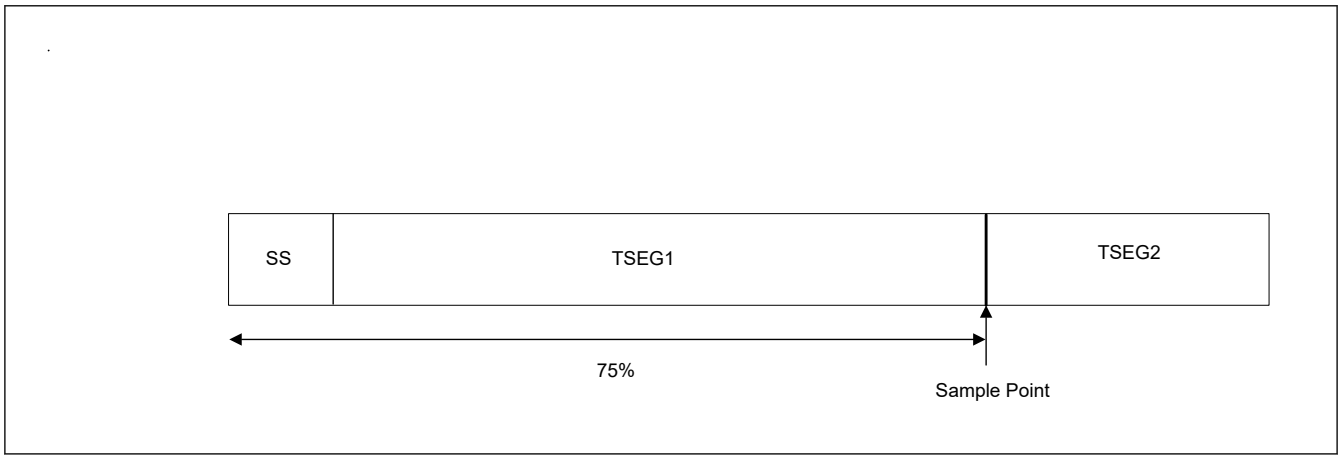

**Figure 31.14 Sample point (in case of 75%)**

### 31.4.1.2 CAN Bit Timing

In the CAN protocol, each bit in a communication frame is composed of three segments that can be configured individually for channel using the related CFDC0NCFG and CFDC0DCFG*1 registers.

Note 1. This register is not available in the classical CAN function.

Figure 31.15 shows the segment composition of a bit and the sample point in it.

Of these segments, the Time Segment 1 (TSEG1) and Time Segment 2 (TSEG2) are used to specify the position of the sample point, so that the timing at which each bit on the CAN bus is sampled can be altered by changing the values of these segments.

The minimum resolution for this timing is referred to as Time Quantum (TQ), which is determined by the clock frequency supplied to the CAN channel and the divide-by-N value of the baud rate prescaler (nominal and data rate).

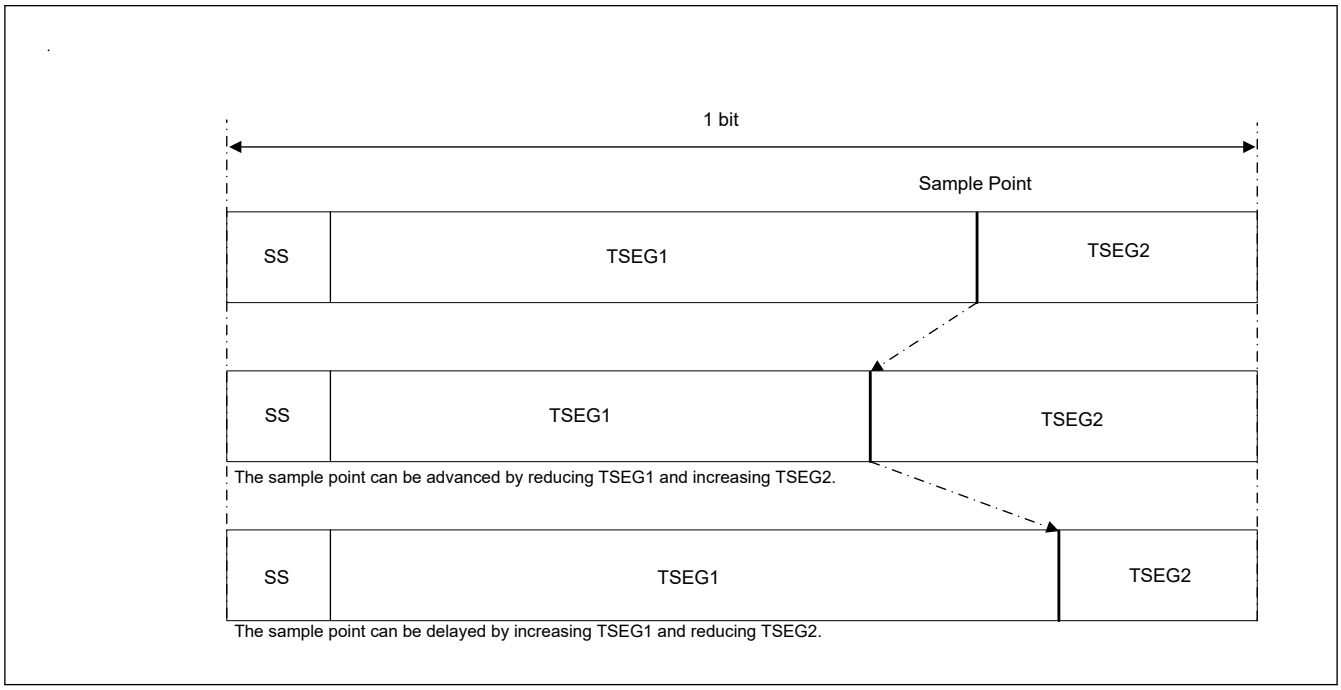

**Figure 31.15 Segment composition of a bit and the sample point**

1. SS: Synchronization Segment
   This segment is used to synchronize bits by monitoring a recessive-to-dominant edge during the interframe space. This comprises of intermission, suspend transmission, bus idle, during bus idle, and all nodes that can start transmission.
2. TSEG1: Time Segment 1
   This segment absorbs physical delays on the CAN network. A physical delay on the network is two times the total sum of a bus delay, input comparator delay, and output driver delay. It can be lengthened by SJW.
3. TSEG2: Time Segment 2
   This segment is used to correct a phase error by performing resynchronization. It can be shortened by SJW. While sending or receiving a message, communication frames between some nodes may get out of sync due to a drift in the oscillator frequency or a delay in the transmission path. This is referred to as a phase error.
4. SJW: Resynchronization Jump Width
   This is the maximum width by which bits that have become out of sync due to a phase error may be corrected.

Figure 31.15 shows only one symbolic sample point.

### 31.4.1.3 Baud Rate

Either the CANFD core clock (CANFDCLK) or the external oscillator clock (CANMCLK) can be selected globally as CAN communication clock.

The transfer speed is determined by the DLL clock, the divide-by-N value of the baud rate prescaler, and the number of TQs in one bit.

$$\text{baud rate} = \frac{\text{DLL_Clock}}{(\text{number_of_time_quanta_per_bit}) \times (\text{BRP} + 1)}$$

Figure 31.16 shows a block diagram of the circuit that generates the CAN channel communication clock and Table 31.22 shows a baud rate examples.

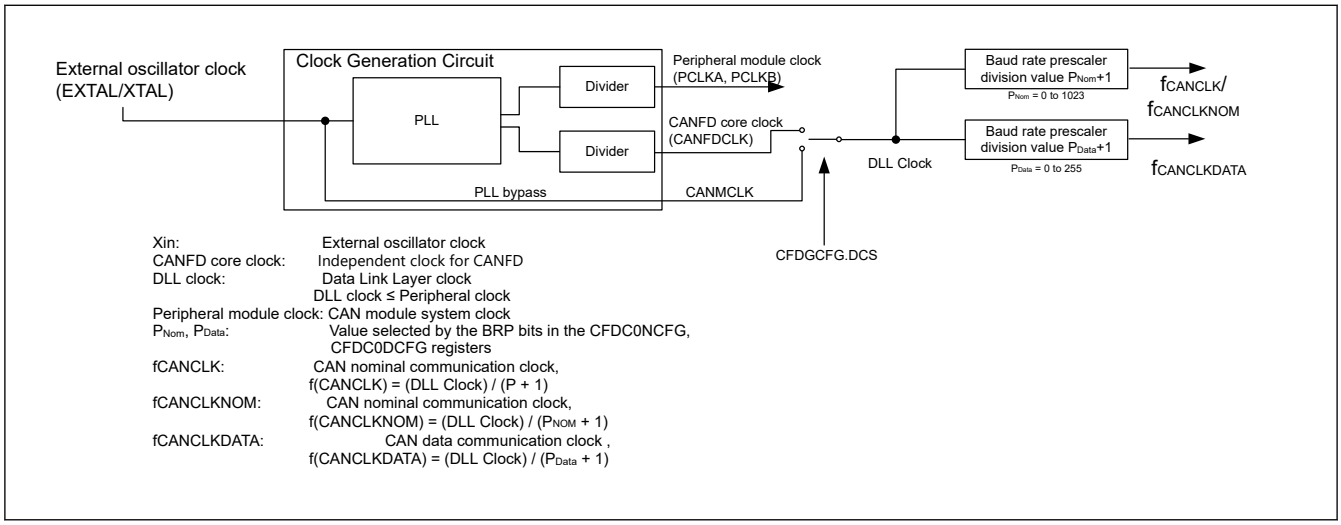

**Figure 31.16 Block diagram of the circuit that generates the CAN channel communication clock**

**Table 31.22 Nominal baud rate calculation formula and example CAN communication configurations**

| Baud rate calculation formula | (DLL clock) (baud rate prescaler divide-by-N value*1) × (number of TQs in one bit) | | | | | | | |
|---|---|---|---|---|---|---|---|---|
| | 40 MHz | 32 MHz | 30 MHz | 24 MHz | 20 MHz | 16 MHz | 10 MHz | 8 MHz*2 |

| 33.3 Kbps | 8TQ (150)<br>12TQ (100)<br>16TQ (75)<br>20TQ (60)<br>24TQ (50) | 8TQ (120)<br>10TQ (96)<br>12TQ (80)<br>15TQ (64)<br>16TQ (60)<br>20TQ (48)<br>24TQ (40) | 10TQ (90)<br>12TQ (75)<br>15TQ (60)<br>20TQ (45) | 8TQ (90)<br>10TQ (72)<br>12TQ (60)<br>15TQ (48)<br>16TQ (45)<br>20TQ (36)<br>24TQ (30) | 8TQ (75)<br>10TQ (60)<br>12TQ (50)<br>15TQ (40)<br>20TQ (30)<br>24TQ (25) | 8TQ (60)<br>10TQ (48)<br>12TQ (40)<br>15TQ (32)<br>16TQ (30)<br>20TQ (24)<br>24TQ (20) | 10TQ (30)<br>12TQ (25)<br>15TQ (20)<br>20TQ (15) | 8TQ (30) |

Note: Shown in ( ) are the baud rate prescaler divide-by-N value.
Note 1. Baud rate prescaler divide-by-N value = P + 1 (P = 0 - 1023) P: value selected by the BRP bits in the Channel Configuration Registers.
Note 2. Minimum frequency to achieve maximum nominal baud rate of 1 Mbps.

**Table 31.23 Baud rate calculation example for nominal and data bit rate CAN communication configurations**

| Baud rate calculation formula | (DLL clock) (baud rate prescaler divide-by-N value*1) × (number of TQs in one bit) | |
|---|---|---|
| | 40 MHz | 20 MHz |
| Nominal 1 Mbps Data 8 Mbps | 40TQ (1) | 20TQ (1) |
| | 5TQ (1) | Not possible |
| Nominal 1 Mbps Data 5 Mbps | 40TQ (1) | 20TQ (1) |
| | 8TQ (1) | Not possible |
| Nominal 500 Kbps Data 2 Mbps | 80TQ (1) | 40TQ (1) |
| | 20TQ (1) | 10TQ (1) |

Note: Shown in ( ) are the baud rate prescaler divide-by-N values and this table is not available in the classical CAN function.
Note 1. Baud rate prescaler divide-by-N value = P + 1 (P = 0 - 1023) P: value selected by the BRP bits in the Channel Configuration Registers.

For optimum clock tolerance in networks using the FD frame format, the length of the time quantum should be the same in nominal bit time and in data bit time. This means CFDC0NCFG.NBRP = CFDC0DCFG.DBRP.

Additionally, if transceiver delay compensation is used, do not program the CFDC0DCFG.DBRP bit to be greater than 1, as 1 means divide by 2.

### 31.4.1.4 Setting of CAN Clock, Bit Timing and Baud Rate

Figure 31.17 shows the procedure for setting the CAN clock and the baud rate for a channel.

These settings should be performed during Channel Reset mode (Configuration mode) for the CAN channels.

Before going to channel communication state, the baud rate must be configured, otherwise the mode does not switch correctly.

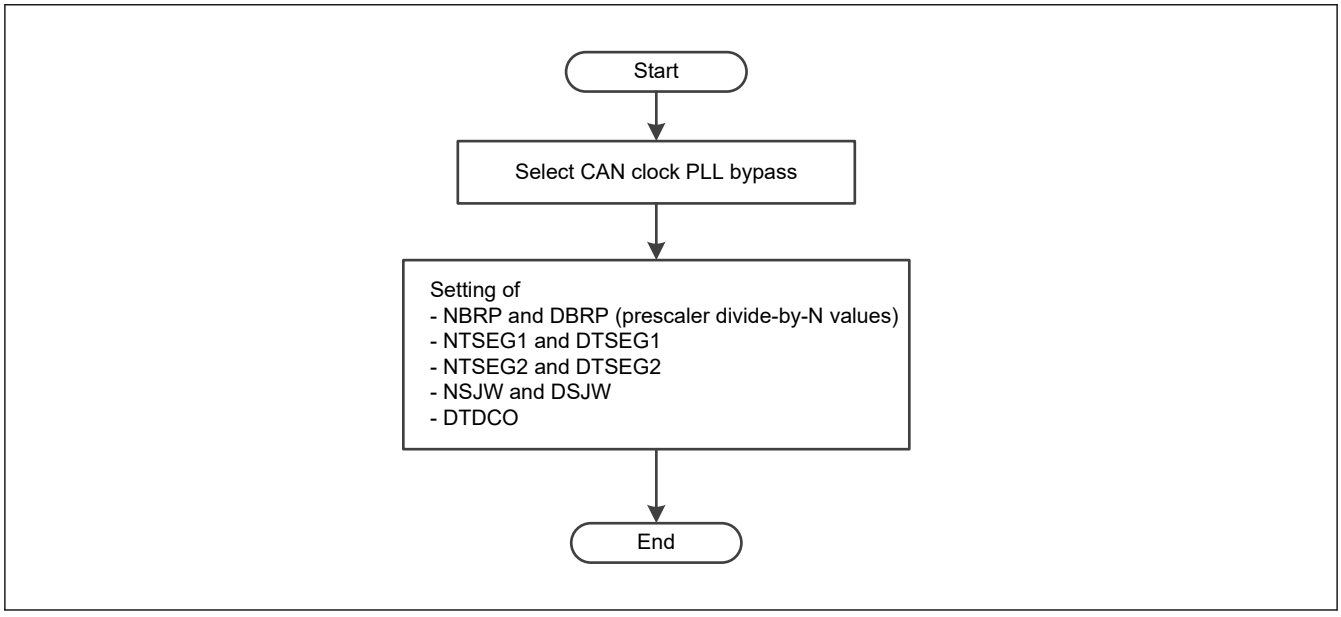

**Figure 31.17 Procedure for setting the CAN bit timing and baud rate**

### 31.4.1.5 Transmitter Delay Compensation

This chapter is not valid for classical CAN.

When a high baud rate is used such as 5 to 8 Mbps for the data phase, the transmitter delay can become greater than TSEG1. In this case, the transmitter always detects a bit-error in the data phase of the CANFD frame. The TDC compensates for the inability of the transmitter to receive its own transmitted bit at the sample point of that bit.

There is another symbolic sample point known as the Secondary Sample Point (SSP) that is used only during the data phase of CANFD frames. This is derived from the Transceiver Delay Compensation Result bit (CFDC0FDSTS.TDCR) as shown in Figure 31.18.

The resolution of the configuration, measured and offset values is based on the CAN channel DLL clock.

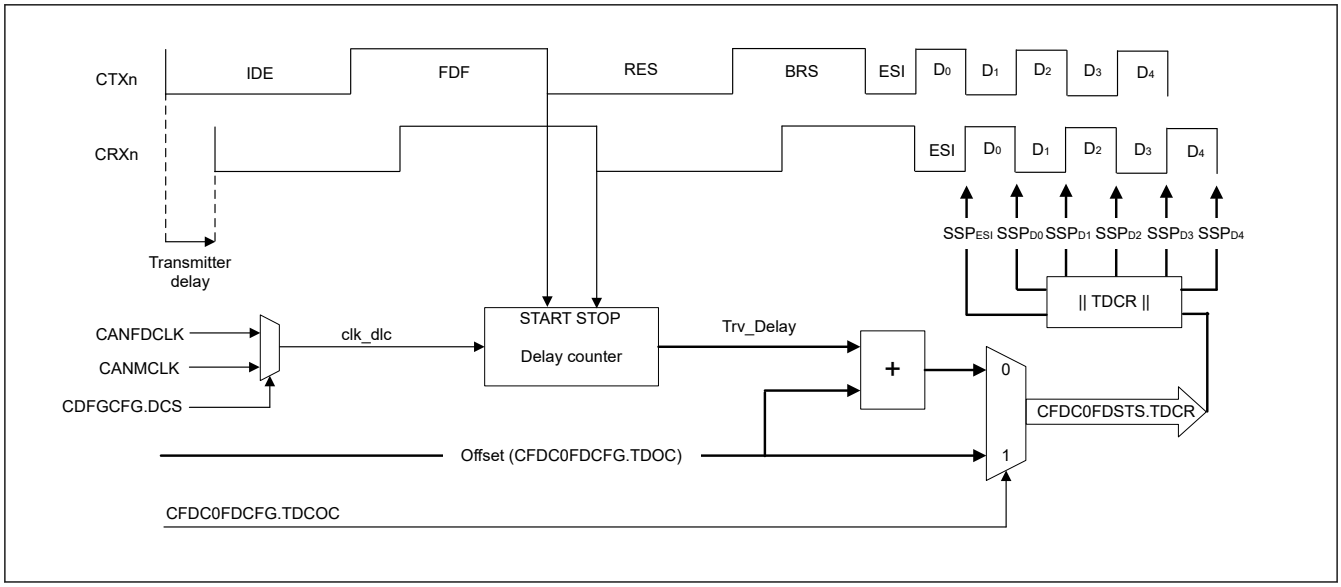

**Figure 31.18 Transmitter delay compensation**

The measured Trv_Delay is based on the number of clk_dlc clock cycles. The delay is counted up by one for each started clock until the dominant value is seen on CRXn. Figure 31.19 shows the measured result. Trv_Delay counted to maximum 127 with a clk_dlc clock.

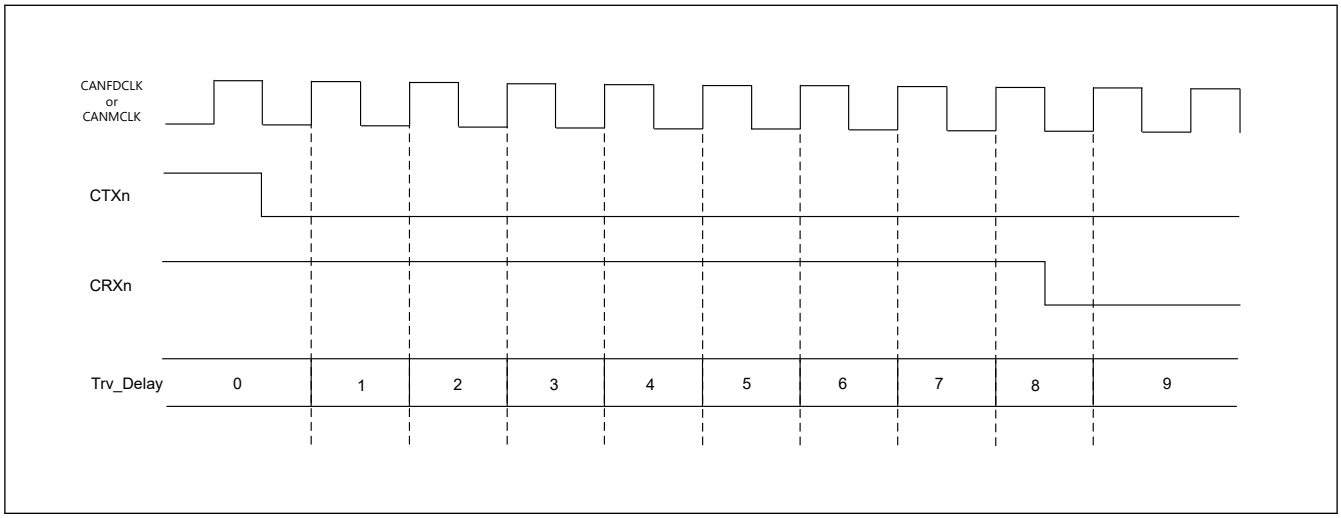

**Figure 31.19 Trv_Delay measurement example**

The SSP is calculated by taking the result from CFDC0FDSTS.TDCR and rounding the value down to the nearest integer number of data time quanta.

Figure 31.20 shows the positioning of the secondary sample point. When CFDC0FDCFG.TDCOC is equal to 0, the SSP is equal to the Trv_Delay (measured delay) + CFDC0FDCFG.TDCO, rounded down to the nearest integer number of time quanta. Usually, the TDCO value should have the size of (SyncSegmentdata + TSEG1data) to position the SSP to a theoretical location of the sample point.

If the CFDC0FDCFG.TDCOC is equal to 1, the SSP is defined by CFDC0FDCFG.TDCO. If CFDC0DCFG.DBRP is greater than 0, the value is also rounded down to the nearest integer number of time quanta.

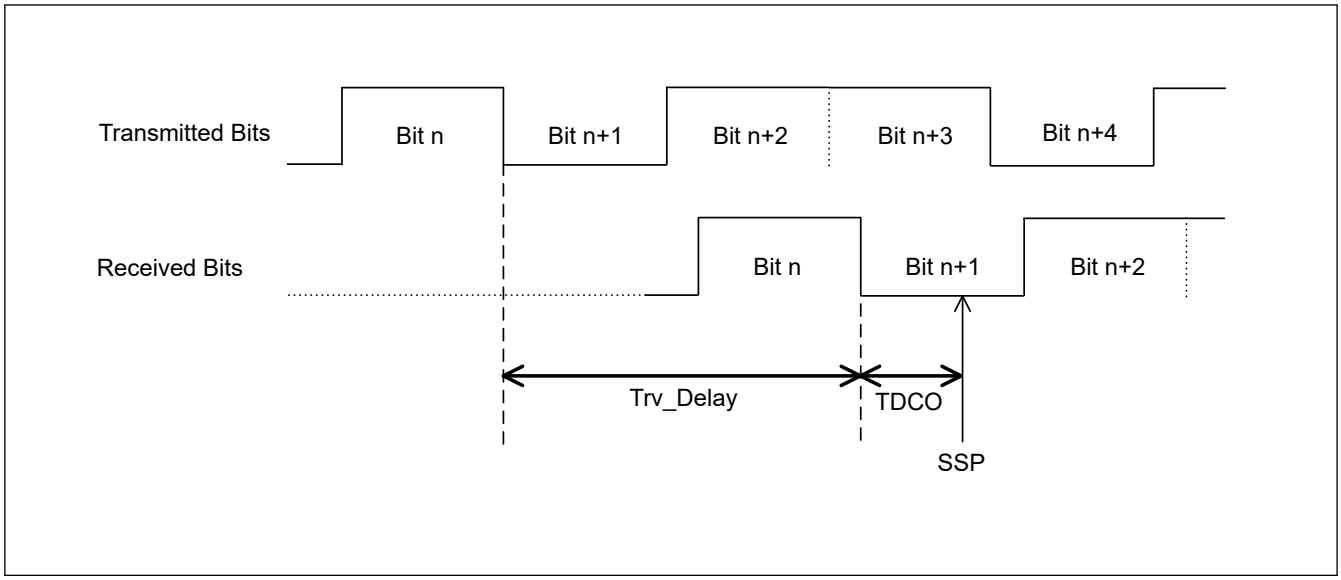

**Figure 31.20 Position of the secondary sample point**

The maximum delay (Trv_Delay + TDCO) which can be compensated by the CANFD module is (6 data bits - 2clk_dlc).

The ISO 11898-1 allows you to set different values for BRP_data and BRP_nom.

If different values are used for CFDC0NCFG.NBRP and CFDC0DCFG.DBRP, then two CAN nodes may be out of synchronization at the point when the bit rate changes from nominal bit rate to data bit rate after sample point of the BRS bit. This condition is shown in Figure 31.21.

The length of the time quantum should be the same in the nominal bit time and in the data bit time. This means CFDC0NCFG.NBRP = CFDC0DCFG.DBRP.

Different bit rates can be achieved by selecting different configuration values for the Time Segments. The nominal bit rate can be configured from 8 to 385 TQs and the data bit rate from 5 to 49 TQs.

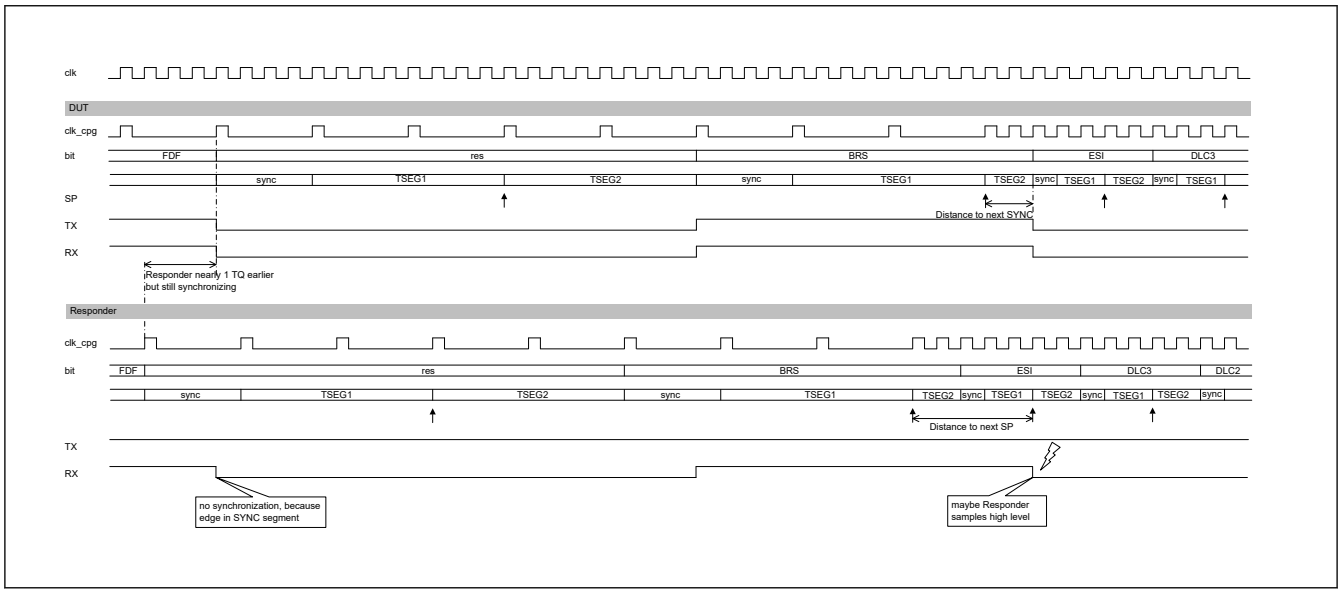

**Figure 31.21 Loss of synchronization between two CAN nodes**

The transmitter delay compensation measurement result is updated at the falling edge from FDF bit to RES bit when configured accordingly (CFDC0FDCFG.TDCE = 1, CFDC0FDCFG.TDCOC = 0).

Figure 31.22 shows the read flow to get the measured transmitter delay compensation result.

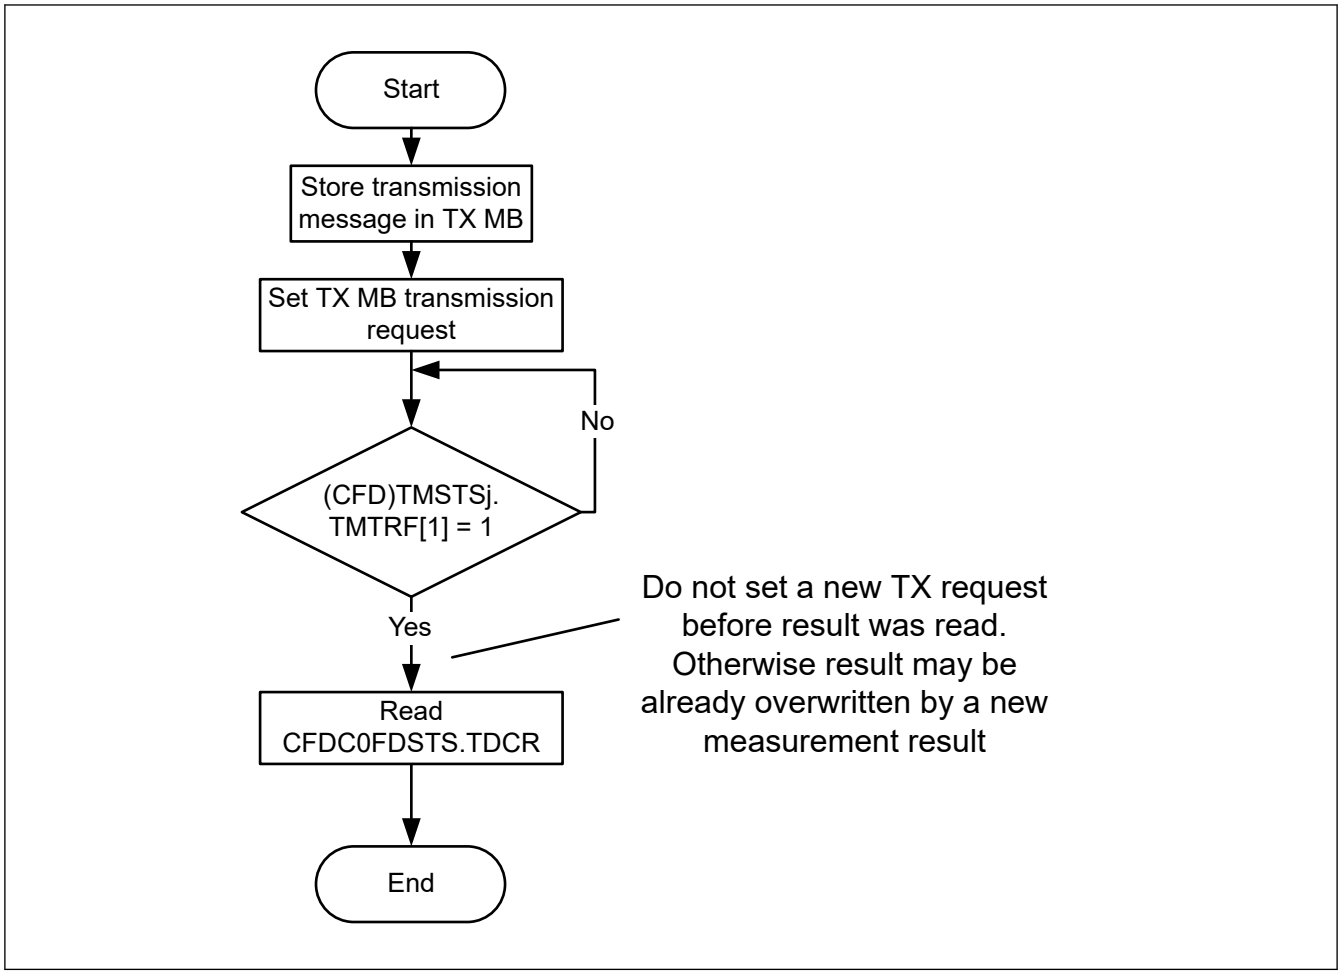

**Figure 31.22 TDC result read flow**

## 31.4.2 CAN Module Configuration after Hardware Reset

After a hardware reset (power on reset) or after setting and clearing a CFDGRSTC.SRST bit, the CANFD module enters Global Sleep mode automatically.

To enable configuration of the CANFD module, you must exit Sleep mode by clearing the Global Sleep Request bit CFDGCTR.GSLPR to 0.

After a hardware reset, the module starts RAM initialization, the CFDGSTS.GRAMINIT bit in the Global Status Register is set automatically to indicate that the CANFD logic is initializing the RAM.

After RAM initialization is complete, this bit is cleared automatically.

RAM initialization is necessary to avoid setting of false ECC error flag after HW reset the random data presented in the RAM.

Do not access registers of CANFD in either read or write until RAM initialization is complete and the CFDGSTS.GRAMINIT bit is cleared.

Before going to communication mode, the Global Acceptance Filter List and message FIFO buffers must be configured. In addition, CAN channel must be configured such as CAN bit timing. For this configuration, CAN channel must be released from Channel Sleep mode and must be configured for communication in Channel Reset mode (Configuration mode).

Figure 31.23 shows the configuration procedure. For details about each step, see section 31.5. Acceptance Filtering Function using Global Acceptance Filter List (AFL), section 31.6. FIFO Buffers and Normal Message Buffer Configuration, section 31.7. Interrupts and DMA and section 31.4.1.3. Baud Rate.

The CANFD module does not perform the RAM initialization sequence after executing a software reset by setting CFDGRSTC.SRST.

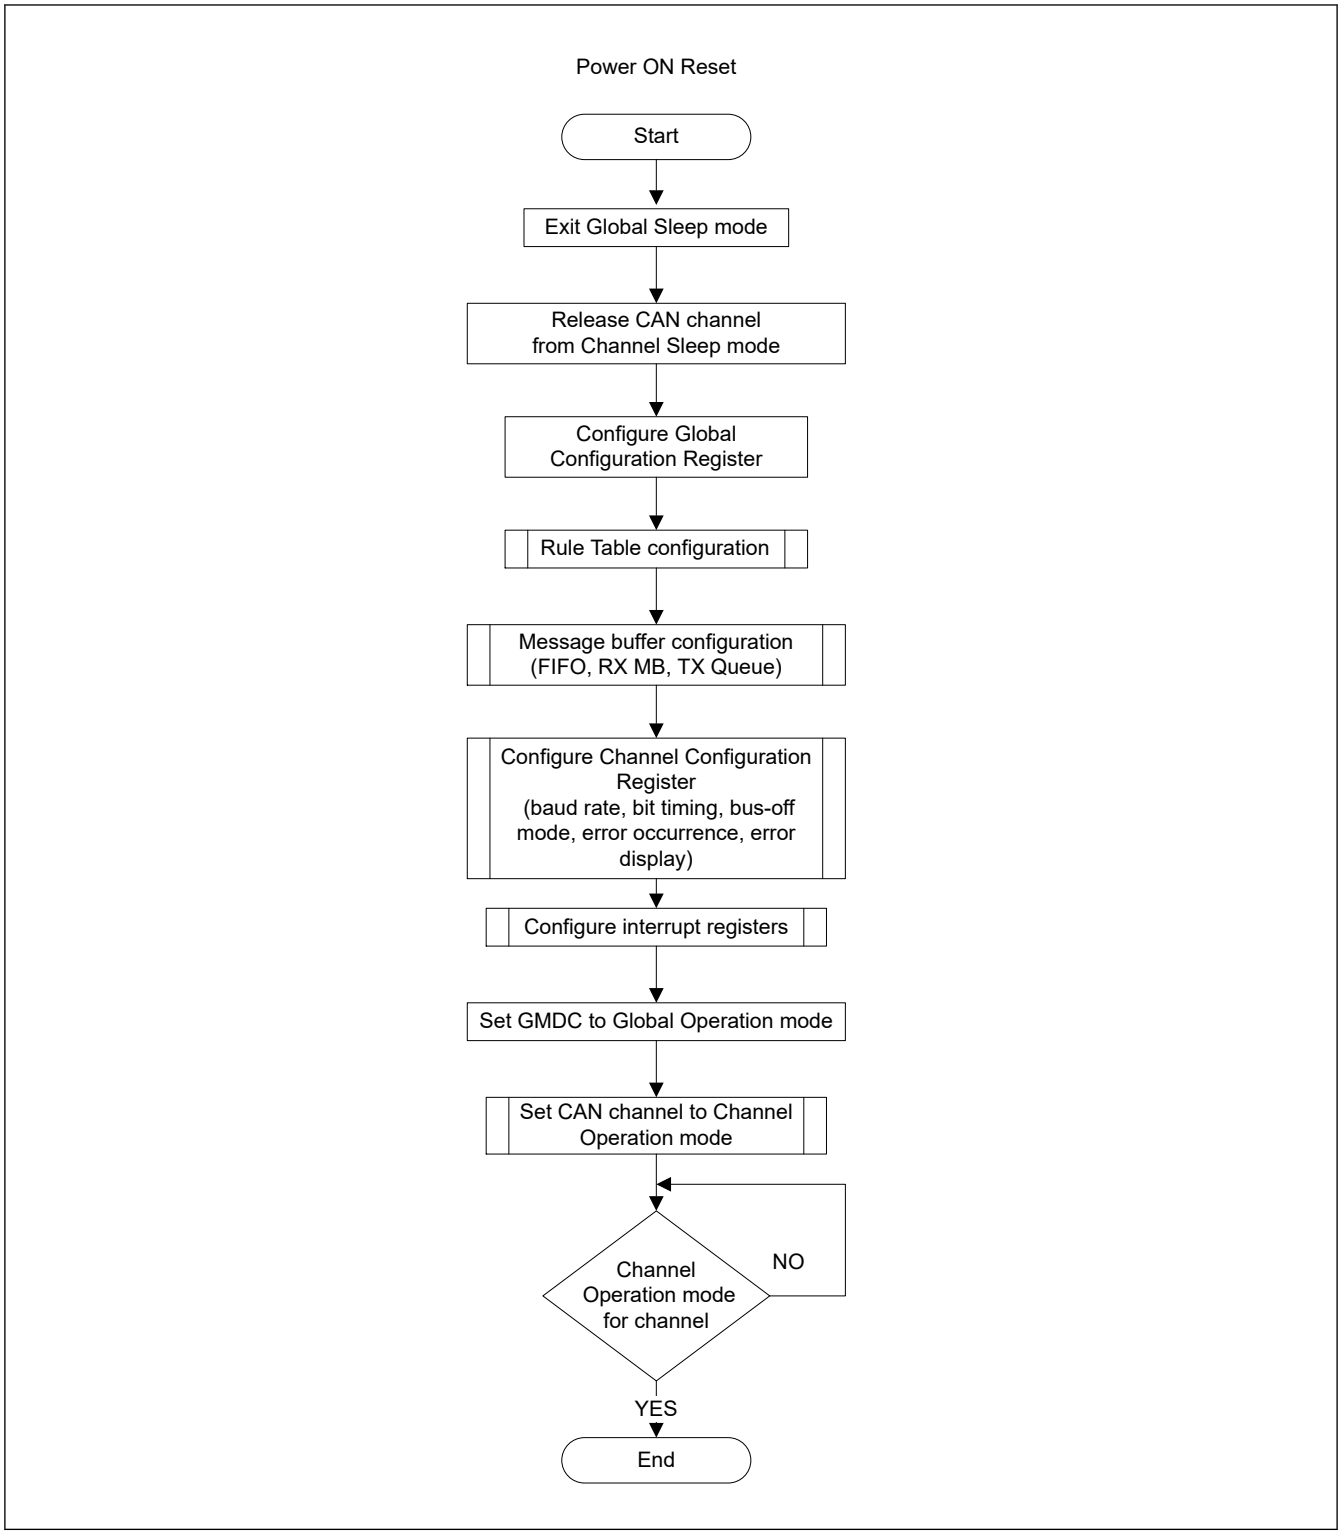

**Figure 31.23 Configuration procedure after a hardware reset**

## 31.5 Acceptance Filtering Function using Global Acceptance Filter List (AFL)

### 31.5.1 Overview

The CANFD module can handle message acceptance filtering with a global Acceptance Filter List (called AFL). Each element of the AFL defines a filter rule for messages received on a specific channel.

The following actions are performed based on the AFL entries:

- Acceptance filtering based on received CAN Identifier and masking
- DLC filtering based on received DLC value
- Message data payload according to the CFDGCFG.CMPOC bit*1
- Storage of accepted messages in the message buffer objects defined in the related AFL entry
- Attaching a 16-bit pointer to the stored messages defined in the related AFL entry, for example to support AUTOSAR applications
- Attaching a 2-bit information label to the stored messages defined in the related AFL entry

Note 1. This feature is not available in the classical CAN function.

The CANFD module allows a maximum of 16 AFL entries.

During acceptance filtering process, each AFL entry in a channel is checked against the received message by the acceptance filter unit. The check starts from the lowest AFL entry number for this channel.

AFL search stops when a match of the received identifier with a configured identifier/mask combination occurs or when the received identifier has been compared against all AFL entries defined for the related channel. If no match occurs, then the received message is rejected. No notification is given to the application in this case.

Additionally, an automatic DLC filtering is performed for each accepted message if DLC check is globally enabled. If the DLC value of the received message is equal to or higher than the configured DLC value in the matching AFL entry, the DLC check is passed.

If DLC replacement (CFDGCFG.DRE bit) is enabled, DLC value configured in the matching AFL entry is greater than 0x0 and DLC check passes, then the configured value of DLC in the matching AFL entry is stored in the destination RXMB or FIFO Buffer.

If the received value of DLC is greater than the configured DLC value in the matching AFL entry, then the additional data bytes received on the CAN Bus are not stored in the destination RXMB or FIFO Buffer. These additional data bytes are stored as 0x00 in the destination RXMB or FIFO Buffer.

If DLC replacement is enabled and DLC value of matching AFL entry is 0x0, then the received value of DLC is stored in the destination RX MB or FIFO Buffer.

If DLC replacement (the CFDGCFG.DRE bit) is disabled and DLC check passes, then the received value of DLC on the CAN bus is stored in the destination RXMB or FIFO buffer.

If the received value of DLC is greater than the configured DLC value in the matching AFL entry, then the additional data bytes received from the CAN bus are also stored in the destination RXMB or FIFO buffer.

If DLC value of the received message is less than the configured DLC value in the matching AFL entry, then DLC check fails. In this case, the received message is rejected and is not stored in any RXMB or FIFO buffer.

Additionally, DLC check failure is flagged by the DLC Error Flag in the Global Error Flag Register. If configured, an error interrupt is also generated. The DLC replacement configuration has no impact if the DLC check fails.

If a message has passed both acceptance filtering and DLC filtering, it is stored in a single reception message buffer and/or in FIFO buffers configured for reception function.

This message storage target information is also defined in the same AFL entry. Do not set a target at the AFL entry which is not configured.

Each accepted received message can be stored into a maximum of 2 different target destinations (single reception message buffer and/or FIFO buffers).

The programming of more than 2 target destinations is not allowed. If more destinations are programmed, then the internal timing might lead to a race condition that prevents the storage of received messages in the message RAM.. Correct configuration of the numbers of target destination is the responsibility of the application.

Additional protection mechanism is made for the case when a received message contains more data payload Bytes than possible to store in the target destination (CFDRMNB.RMPLS, CFDRFCCa.RFPLS or CFDCFCC.CFPLS).

If CFDGCFG.CMPOC = 0, the message is completely rejected and is stored in the target destination. When CFDGCFG.CMPOC = 0 and RX or Common FIFO full including the received message contains more data payload bytes than possible to store in the target destination (CFDRMNB.RMPLS, CFDRFCCa.RFPLS or CFDCFCC.CFPLS), the corresponding CFDFMSTS.RFxMLT or CFDFMSTS.CFxMLT bit is not set to 1, respectively.

When CFDGCFG.CMPOC = 1, the received data bytes greater than CFDRMNB.RMPLS is rejected. When CFDGCFG.CMPOC = 1 and RX or Common FIFO full including the received message contains more data payload bytes than possible to store in the target destination (CFDRMNB.RMPLS, CFDRFCCa.RFPLS or CFDCFCC.CFPLS), the corresponding CFDFMSTS.RFxMLT or CFDFMSTS.CFxMLT bit is set to 1, respectively.

Depending on the CFDGCFG.DRE bit, the original received DLC or the DLC value configured at the AFL entry is stored.

Regardless of the CFDGCFG.CMPOC bit setting, CFDGERFL.CMPOF is set to 1 if a payload overflow condition is detected.

The DLC filtering is performed before the payload overflow function. So for one reception frame, only one flag can be set at the same time with CFDGERFL.DEF or CFDGERFL.CMPOF*1.

Note 1. This bit is not available in the classical CAN function.

## 31.5.2 Allocation of AFL Entries

The number of AFL entries can be configured using the dedicated field in the related Global Acceptance Filter Configuration Registers (see Figure 31.24).

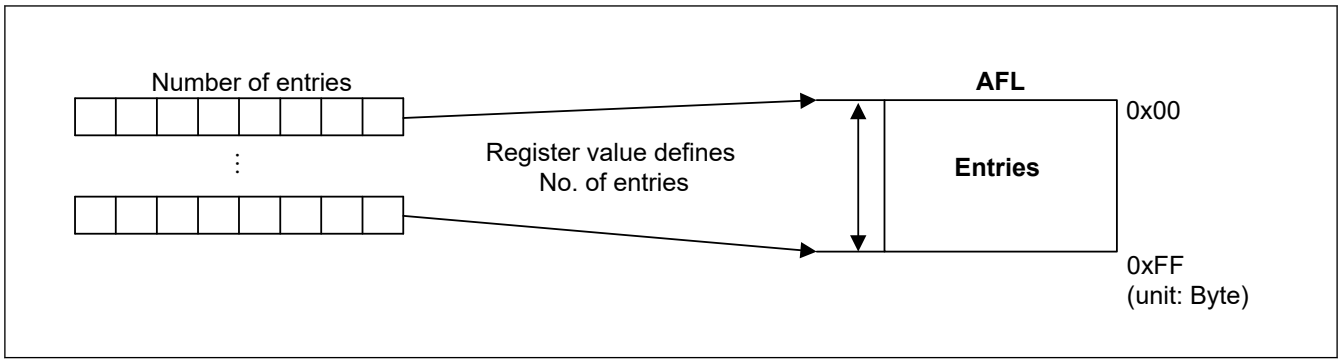

**Figure 31.24 Configuration of AFL for each channel**

The minimum number of entries for one channel is 0 (no entries defined for the channel) and the maximum number of entries is 16.

All entries are unique for a channel and overlapping or sharing of entries is not supported. Correct configuration of the AFL is the responsibility of the application.

The CANFD module does not flag errors related to the configuration of the AFL.

## 31.5.3 AFL Entry Description

Each AFL entry consists of 16 bytes. The fields in all entries are identical.

Each entry contains the following information for acceptance filtering and DLC filtering:

- Identifier (11 bits for Standard Frame format, 29 bits for Extended Frame format):
  Acceptance filter unit checks the identifier field of the received message against the identifier field of each AFL entry (full 29 bits masking of identifier bits is possible, see information that follows).
- IDE bit:
  Acceptance filter unit checks the IDE bit of the received message against this bit and selects the relevant part of the identifier field for acceptance filtering (masking of IDE bit is possible, see the information that follows).
- RTR bit:
  Acceptance filter unit only accepts data frames (RTR = 0) or remote frames (RTR = 1) according to the setting of this bit (masking of RTR bit is possible, see the information that follows).
- Loopback Configuration bit:
  This bit can enable or disable the AFL entry depending on the Loopback Configuration or Mirror mode condition.
- Mask for Identifier bits (29 bits):

Each bit in the identifier mask can mask the corresponding identifier bit in the AFL entry during acceptance filtering, see Figure 31.25.

- Mask for IDE bit:
  If this Mask bit masks the IDE bit of the AFL entry in both Standard Identifier and Extended Identifier format, messages can be accepted by this AFL entry. The identifier of the received message is compared against the Standard Identifier part of the AFL entry for Standard Identifier format messages and against the Extended Identifier part of the AFL entry for Extended Identifier format messages.

- Mask for RTR bit:
  If this Mask bit masks the RTR bit of the AFL entry in both frame formats, data frame and remote frame formats are accepted by this AFL entry.

- Pointer information (16 bits):
  This 16-bit pointer is attached to a received message accepted by the related AFL entry. The pointer is added during message storage in the message buffer area and can be used by application as support function. The pointer information can be used for example to support PDU identifier allocation for the received message in AUTOSAR systems.

- Information label (2 bits):
  This 2-bit label is attached to a received message accepted by the related AFL entry. The label is added during message storage in the message buffer area and can be used by application as support function.

- DLC value for automatic DLC filtering:
  If the DLC value of the received message is equal or higher than the configured DLC value, the DLC check is passed.

If the DLC value in this AFL entry is configured to 0, DLC filtering is effectively disabled for this entry (all accepted messages pass DLC filtering).

Each AFL entry contains the following information for the handling of received messages:

- Message buffer number of one single reception message buffer as target for received message storage
- Single reception message buffer enable bit to configure the single reception message buffer number to be valid or invalid, as target for received message storage
- FIFO direction pointer - each bit of the FIFO direction pointer configures a dedicated FIFO as possible target for a received message

There is no hardware protection against such storage of message. Therefore, the FIFO direction pointer must be configured carefully.

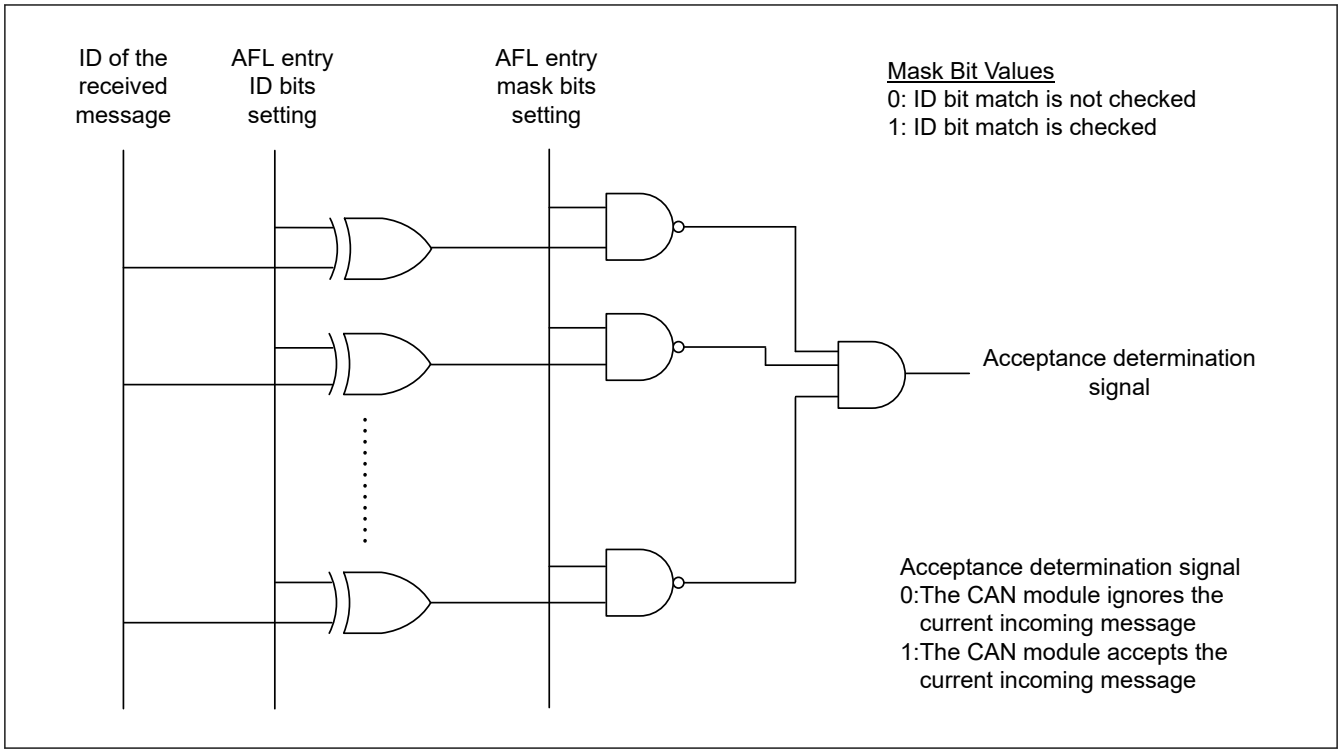

**Figure 31.25 Acceptance function**

## 31.5.4 Entering Entries in the AFL

Application software can enter one full entry into the AFL using the following registers:

- Global AFL ID Entry Register: Part 1 of the AFL entry
- Global AFL Mask Entry Register: Part 2 of the AFL entry
- Global AFL Pointer 0 Entry Register: Part 3 of the AFL entry
- Global AFL Pointer 1 Entry Register: Part 4 of the AFL entry.

16 sets of these registers form a group of AFL entries. The AFL should only be configured in CH_RESET or CH_HALT mode.

Follow the configuration shown in Figure 31.26 to program the AFL.

After entering all entries in Configuration mode, locking of the AFL access should be performed to protect unwanted write access to the AFL.

Write protection is active during all Global modes (GL_RESET, GL_HALT, and GL_OPERATION) if the lock bit is set.

Read access to AFL is still possible during all Global modes even when AFL data access is disabled (consistency check of AFL contents is possible during run time).

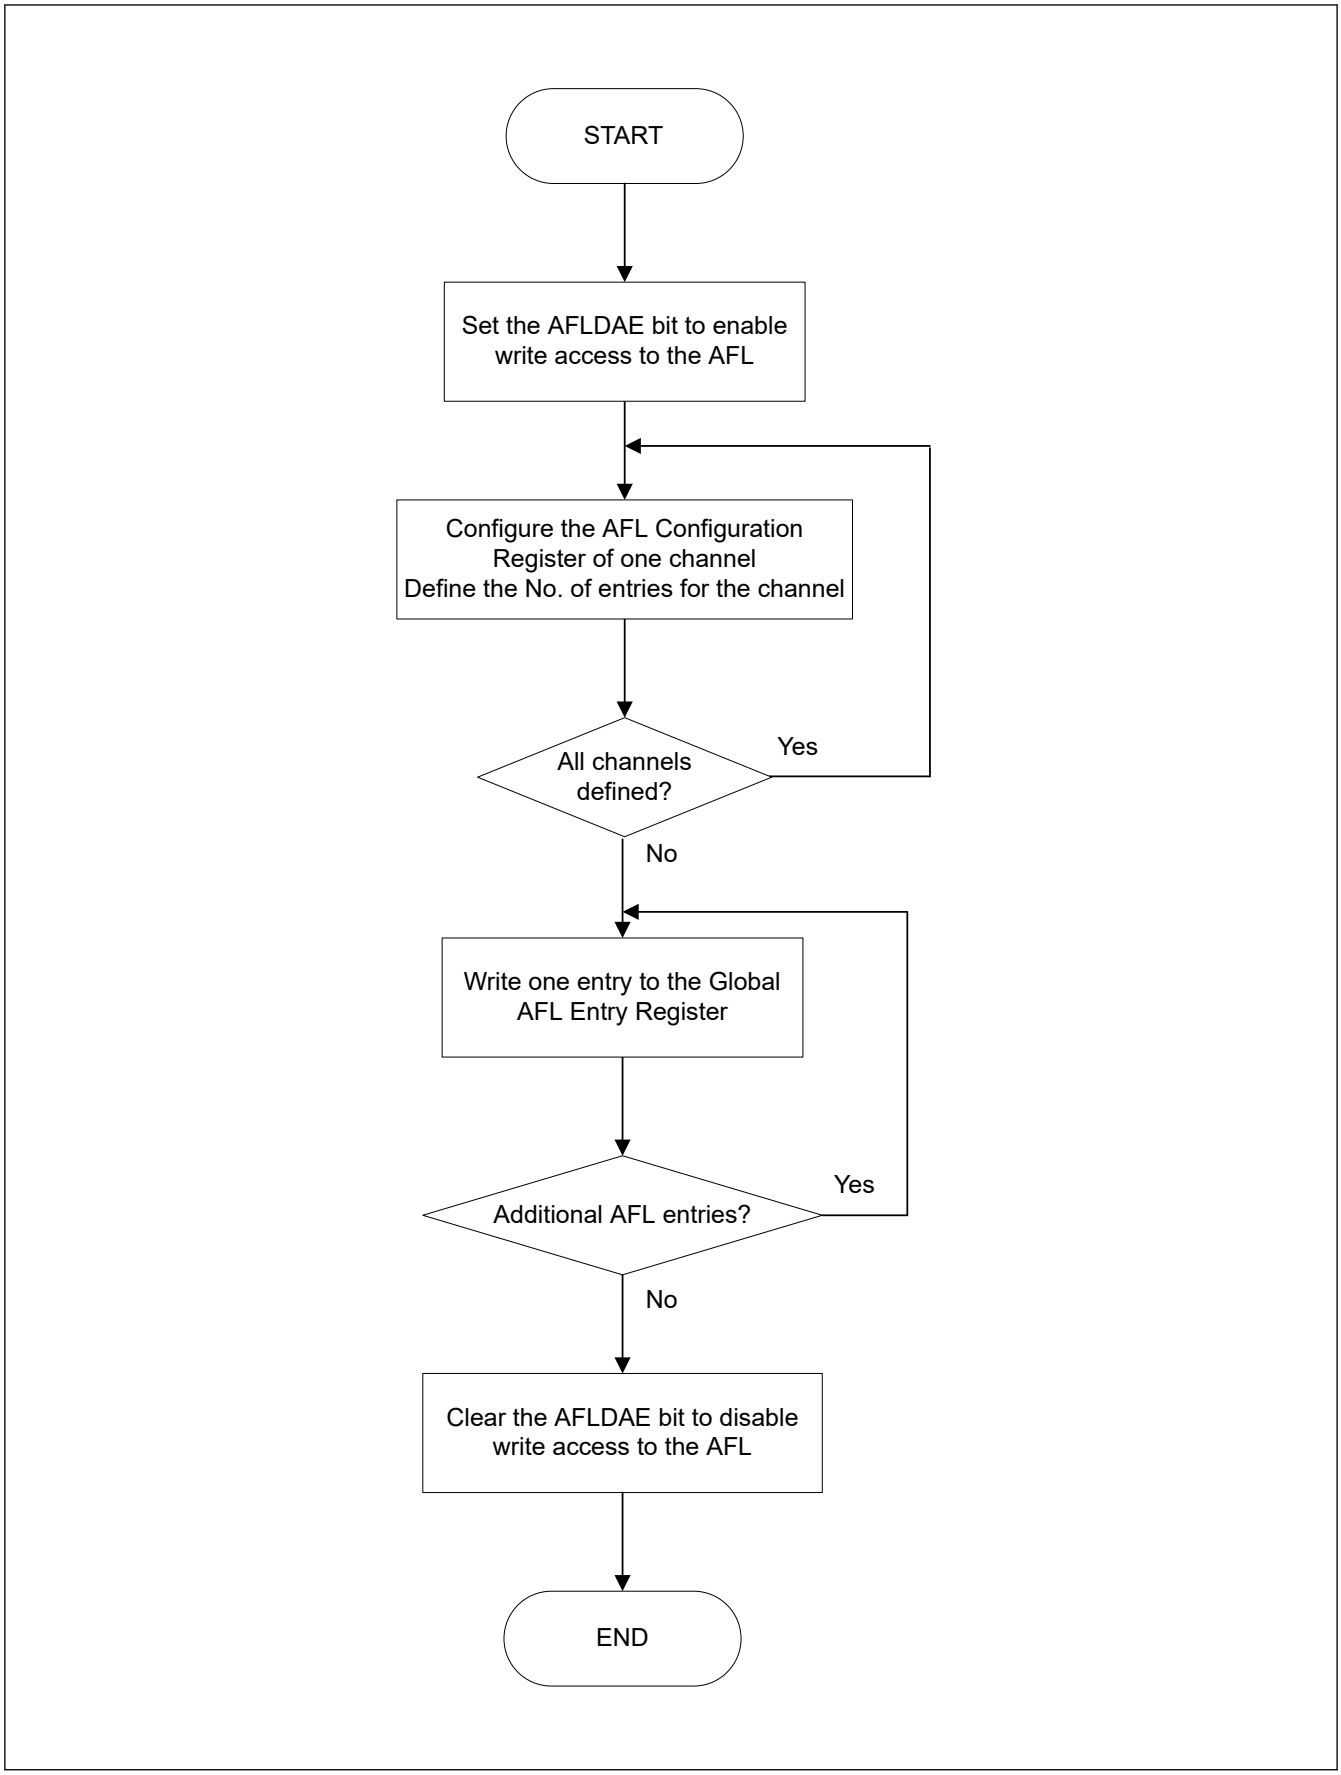

**Figure 31.26 AFL configuration flow**

### 31.5.5 Loopback Modes

If the Loopback Configuration bit is set, the AFL entry is only valid in Loopback test mode (Self-test mode 0 or Self-test mode 1) or in mirror mode when receiving messages that were transmitted by the respective CAN channel itself.

The AFL entry is not valid for received messages in loopback mode transmitted by other CAN nodes on the bus. The expression valid or invalid for the related entry means that this AFL entry is or is not compared against the received message ID respectively.

If the Loopback Configuration bit is 0, the AFL entry is only valid for:

- Received messages transmitted by other CAN nodes on the bus in normal (non-loopback mode) and mirror modes
- Received messages transmitted by other CAN nodes or the CAN channel itself in Loopback test mode.

The mirror mode can be enabled with the CFDGCFG.MME bit in the Global Configuration Register. If CFDGCFG.MME bit is set, then a successfully transmitted message can be stored back in an RX message buffer or FIFO buffer if a matching entry is configured in the AFL for that channel.

The Loopback Configuration bit in the matching AFL entry must be set to store this frame.

If Mirror mode and Loopback test mode are configured at the same time, the Loopback test mode behavior applies.

Table 31.24 shows the behavior of the acceptance filter unit depending on the setting of the related input signals.

**Table 31.24 Behavior of acceptance filter based on the loopback configuration setting in AFL entry**

| Mirror Mode Enable (MME Configuration bit) | Loopback in test mode (Self-test mode 0 or Self-test mode 1) | Channel mode | Loopback Configuration bit in AFL entry | AFL entry |
|---|---|---|---|---|
| 0 | 0 | Receiver | 0 | Valid |
| | | | 1 | Invalid |
| | | Transmitter | 0 | Invalid |
| | | | 1 | Invalid |
| | 1 | Receiver | 0 | Valid |
| | | | 1 | Invalid |
| | | Transmitter | 0 | Valid |
| | | | 1 | Valid |
| 1 | 0 | Receiver | 0 | Valid |
| | | | 1 | Invalid |
| | | Transmitter | 0 | Invalid |
| | | | 1 | Valid |
| | 1 | Receiver | 0 | Valid |
| | | | 1 | Invalid |
| | | Transmitter | 0 | Valid |
| | | | 1 | Valid |

Note: The expression valid or invalid for the related entry means that this AFL entry is or is not compared against the received message ID, respectively.

### 31.5.6 IDE Masking

When the GAFLIDEM bit is 0 in an AFL entry, the IDE bit configured in the AFL entry is not used for ID matching. In this case, the use of ID[10:0] or ID[28:0] matching is based on the received IDE bit.

Consider the following example:

- The ID and Mask fields of an AFL entry x is configured as follows:
  - CFDGAFLID [x] = 0xC0553A20 → IDE = 1, RTR = 1, LLB = 0, ID[10:0] = 0x220 / ID[28:0] = 0x00553A20
  - CFDGAFLMr = 0x0000FFFF → IDEM = 0. RTRM = 0, IDM[10:0] = 0x7FF / IDM[28:0] = 0x0000FFFF

- The comparison result for the four different received IDs with AFL entry x is described as follows:
  - If a frame with IDE = 0 and ID = 0x220 is received, this is considered as a match
  - If a frame with IDE = 0 and ID = 0x320 is received, this is not a match
  - If a frame with IDE = 1 and ID = 0x1FFF3A20 is received, this is considered as a match
  - If a frame with IDE = 1 and ID = 0x08803220 is received, this is not a match.

### 31.5.7 Updating AFL Entry during Communication

You can update the AFL entry without disabling all CAN communications. Choose the entry number to be updated by setting the AFL entry number, and ignore the enable bit.

This entry number is ignored from the AFL matching while the entry is being updated.

Figure 31.27 shows the update flow for an AFL entry.

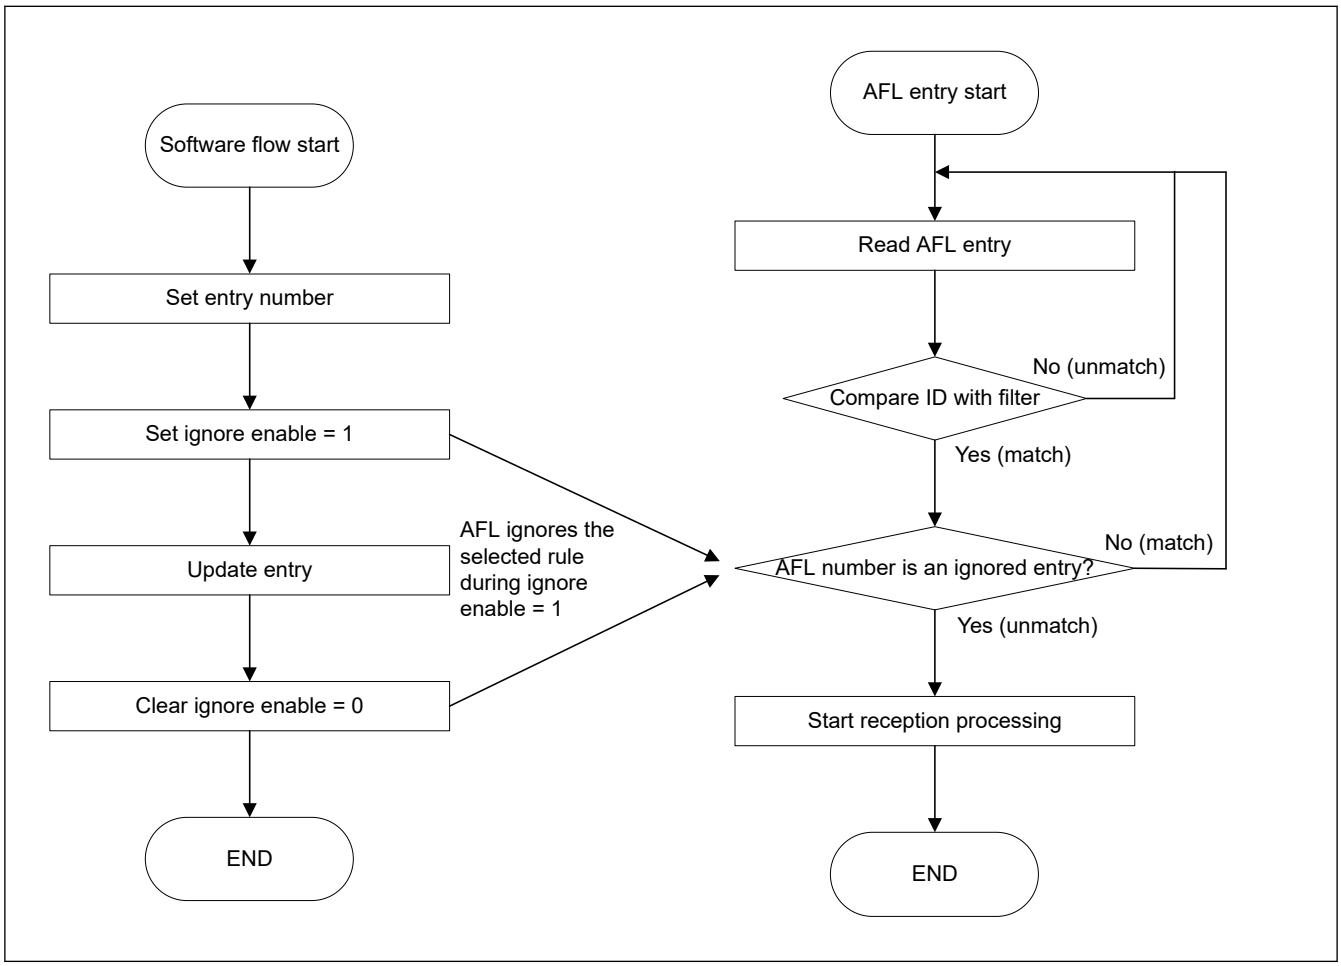

**Figure 31.27 Update flow for an AFL entry**

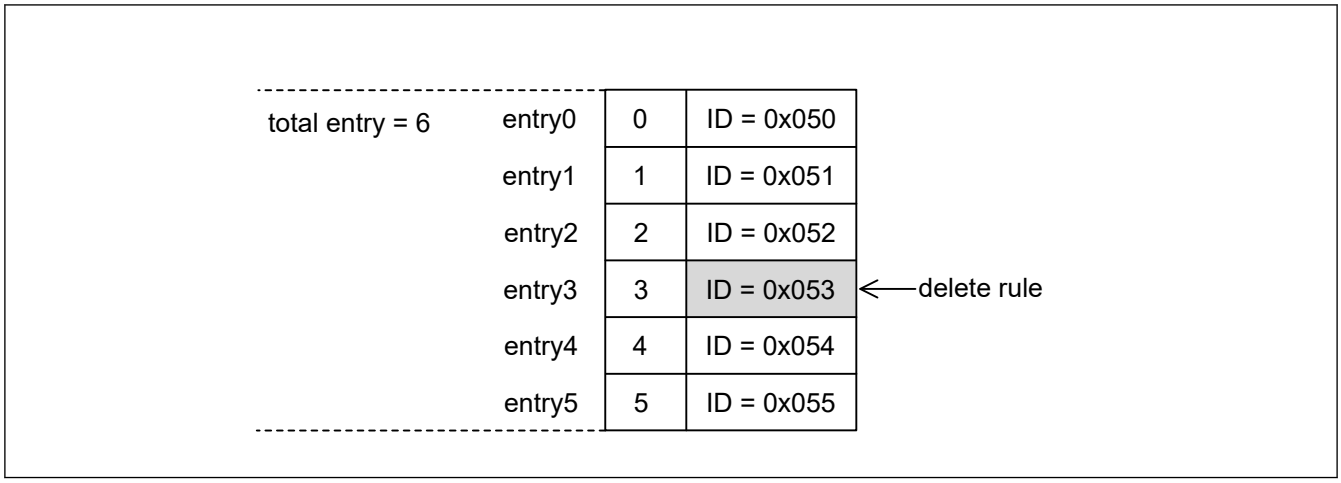
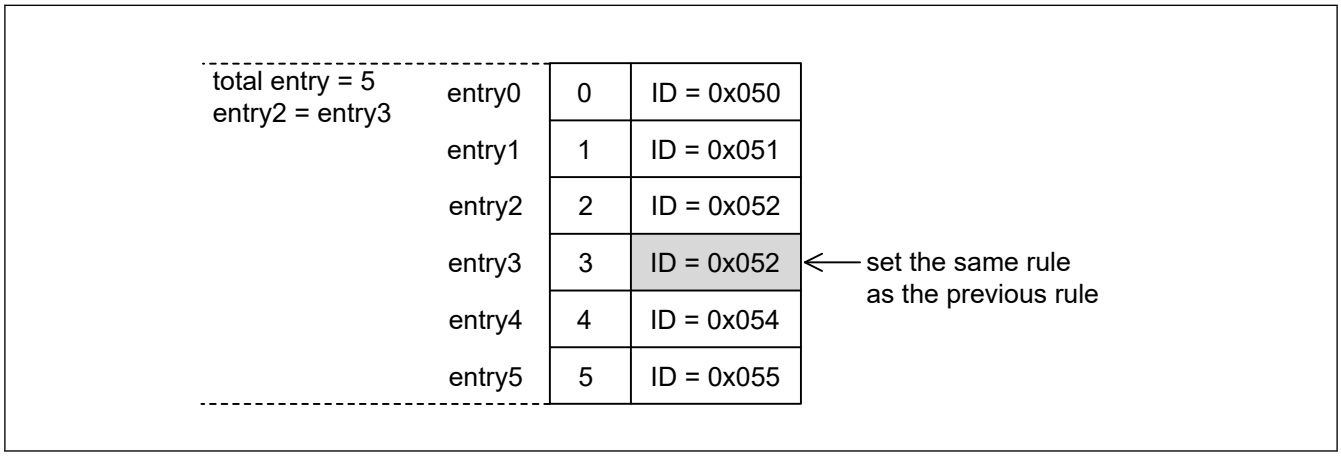


The method to update an AFL entry is as follows:

1. Set the entry number to CFDGAFLIGNENT register.
2. Set the value 0xC401 (key code and enable bit) to CFDGAFLIGNCTR register.
3. CFDGAFLECTR.AFLDAE is set to 1.
4. Set the new rule to CFDGAFLIDr, CFDGAFLMr, CFDGAFLP0r, CFDGAFLP1r registers.
5. CFDGAFLECTR.AFLDAE is cleared to 0.
6. Set the value 0xC400 (key code and clear enable bit) to CFDGAFLIGNCTR register.

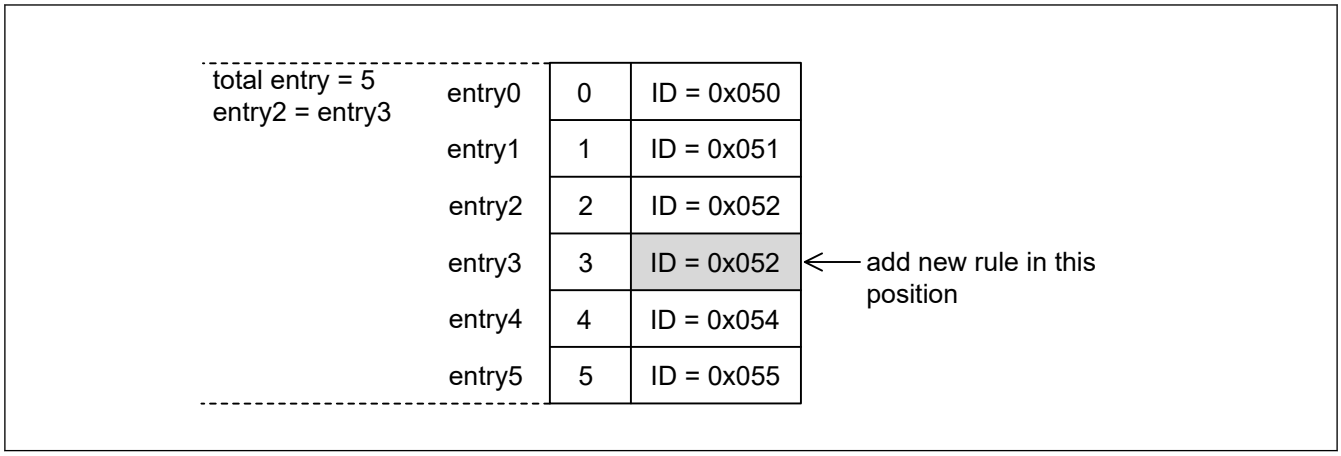
Note: This entry number is ignored during the periods from (2) to (5).

### (1) Example 1: Deleting an entry



Deleting entry3 when the total number of entries is 6 channel.

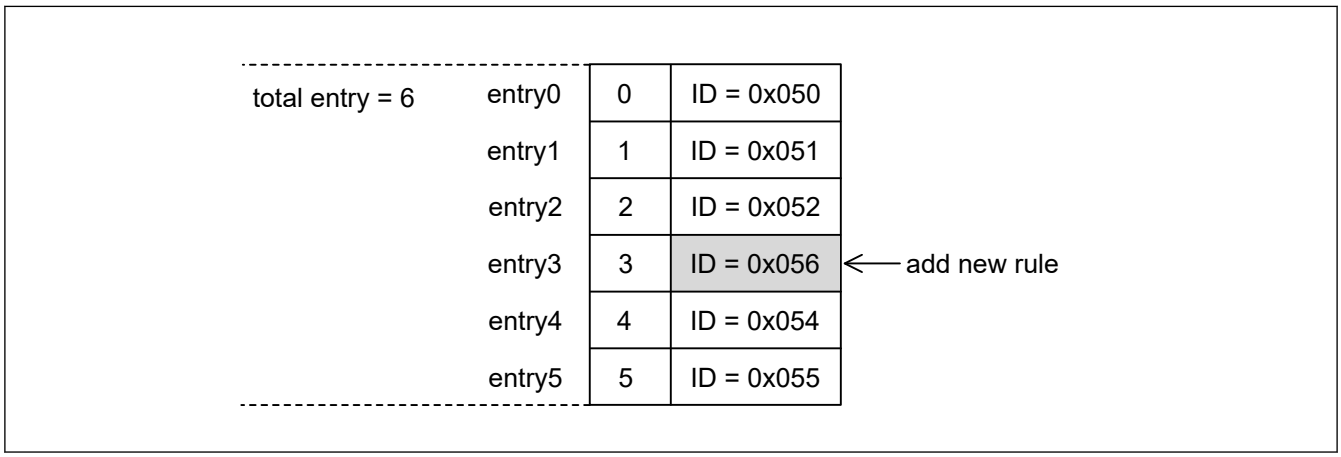
**How to delete an entry**



1. Set 0x00000003 to CFDGAFLIGNENT register.
2. Set 0x0000C401 to CFDGAFLIGNCTR register.
3. Set 0x00000100 to CFDGAFLECTR register.
4. Set the same rule as the previous rule by accessing CFDGAFLIDr, CFDGAFLMr, CFDGAFLP0r, CFDGAFLP1r (r = 3, this is entry3).
5. Set 0x00000000 to CFDGAFLECTR register.
6. Set 0x0000C400 to CFDGAFLIGNCTR register.

Entry3 is now deleted.

### (2) Example 2: Adding an entry



Adding a new entry to entry3 when the total number of entries is 6.

**How to add an entry**

1. Set 0x00000003 to CFDGAFLIGNENT register.
2. Set 0x0000C401 to CFDGAFLIGNCTR register.
3. Set 0x00000100 to CFDGAFLECTR register.
4. Set the new rule by accessing CFDGAFLIDr, CFDGAFLMr, CFDGAFLP0r, CFDGAFLP1r (r = 3, this is entry3).
5. Set 0x00000000 to CFDGAFLECTR register.
6. Set 0x0000C400 to CFDGAFLIGNCTR register.

The new entry is now added.

The AFL filter can be used to set CFDGAFLCFG, and addition/deletion of an entry is possible. Therefore, it is necessary to set the maximum number to be used to CFDGAFLCFG.

## 31.6 FIFO Buffers and Normal Message Buffer Configuration

This section describes the process for configuring the number of RX message buffers, the FIFO buffers, and the flat TX message buffers in the CANFD module. The message buffers are mapped as shown in Figure 31.28.

The RX message buffers can be accessed with the RX Message Buffer Registers.

The RX FIFO buffers and the common FIFO buffers configured in RX mode or TX mode can only be accessed with the FIFO Access Registers.

If the common FIFO is configured in TX mode, you can only write data into the FIFO buffer using the FIFO Access registers.

If the common FIFO is configured in RX mode, you can only read data from the FIFO Access Registers.

The TX message buffers can be accessed with the TX Message Buffer Registers.

If unused message buffer locations are read, the message buffer locations are read as unknown values.

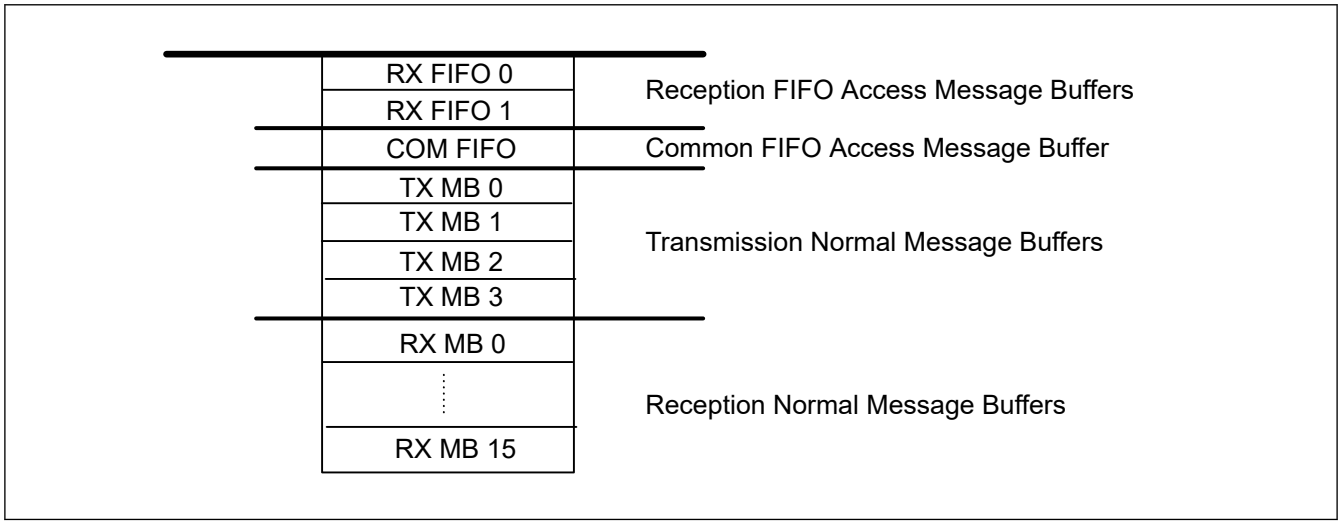


**Figure 31.28 Message buffer configuration**

## 31.6.1 Normal RX Message Buffers

In CANFD module, the frames received can be stored in normal RX message buffers based on the configuration of the AFL entries.

Additionally, the number of normal RX message buffers required in the system can be chosen up to a fixed maximum limit.

### 31.6.1.1 Normal RX Message Buffer Configuration

In CANFD module, the number of normal RX message buffers can be configured by writing to the RX Message Buffer Number Register.

The limiting values for the configuration of number of message buffers are:

- Minimum value = 0x00 (no normal RX MB)
- Maximum value = 0x10

Do not use values outside these limits.

The AFL entries for routing the received messages to normal RX message buffers must be configured to match the requirements of the system.

The AFL entries must also be configured properly, and an AFL entry for normal RX message buffers should not exceed the number of message buffers configured in the RX Message Buffer Number Register.

Note: There is no internal check procedure provided in CANFD module against wrong configuration of the AFL.

The data field size of the RX message buffer can be configured with the CFDRMNB.RMPLS bit. The default size is 8 bytes and the maximum data payload size is 64 bytes.

When the receiving frame exceeds the data field size, then the acceptance depends on the configuration of CFDGCFG.CMPOC (message rejecting or data payload cut).

Note: RMPLS and CMPOC bit is not available in the classical CAN function, so, these feature is not valid for classical CAN.

## 31.6.2 FIFO Buffers

The CANFD module provides a fixed number of FIFO buffers to support storage of frames for reception and transmission functions .

The number of reception-only FIFO buffers is fixed to 2. However, common FIFO buffer channel can be configured to store messages for transmission or reception function.

These FIFO buffers can be enabled or disabled, and the following parameters can be configured to match the system requirements:

- Size
- Interrupt structure
- Message lost mechanism
- Message overwrite mechanism of the FIFO buffers
- Location of the TX FIFO.

When the receiving frame exceeds the data field size, the acceptance depends on the configuration of the CFDGCFG.CMPOC bit (message rejecting or data payload cut).

#### 31.6.2.1 FIFO Buffers Configuration

In CANFD module, the FIFO buffers can be configured to match the system requirements.

The total number of FIFO buffers = 2 RX FIFO buffers + 1 common FIFO buffer = 3 FIFO buffers.

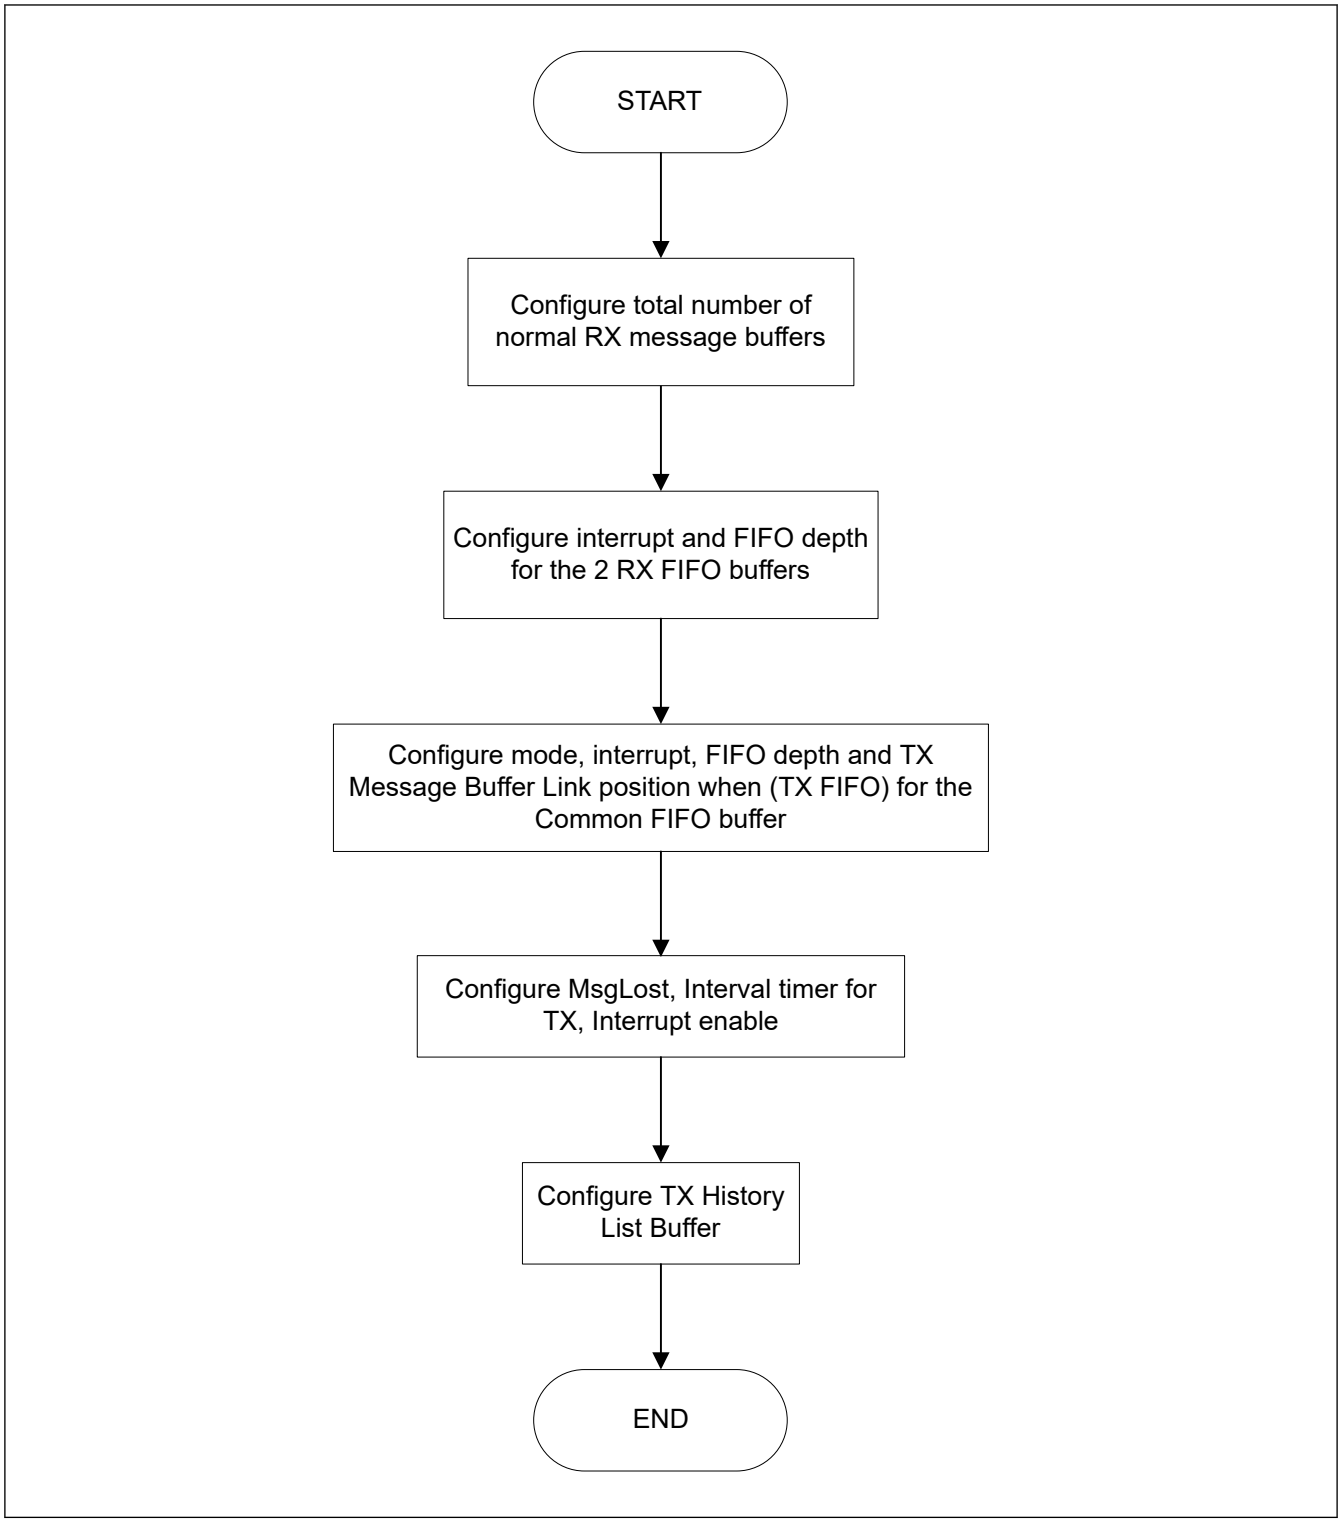

**Figure 31.29 FIFO buffer configuration flow in CANFD module**

As shown in Figure 31.29, the various FIFO buffers can be configured by writing to the RX FIFO Configuration/Control Registers and the Common FIFO Configuration/Control Registers.

For the 2 RX FIFO buffers, the following parameters can be configured:

- Interrupts
- FIFO depth
- FIFO payload data size.

For the common FIFO buffer, the following parameters can be configured:

- Mode
- Interrupts FIFO depth
- FIFO payload data size
- FIFO TX link position.

### (1) FIFO mode configuration of Common FIFO buffer

The mode of the common FIFO buffer can be configured by writing to the CFDCFCC.CFM[1:0] bits in the Common FIFO Configuration/Control Register. The possible modes of configuration for Common FIFO buffer are:

- 0b RX mode (default mode after hardware reset)
- 1b TX mode

Messages can only be read from the RX FIFO buffers and the Common FIFO buffer configured in RX mode. Messages are stored by the CAN module in these FIFO buffers based on the AFL entries.

Messages can be read and written into the Common FIFO buffer configured in TX mode. These messages are transmitted on the appropriate CAN channel.

The pointers can only be incremented when a new message is stored in the FIFO buffer and decremented when a message is transmitted on the corresponding CAN channel by the CANFD module.

After a hardware reset, the Common FIFO buffer is configured in RX mode by default. Only enable the FIFO buffers after configuring the Common FIFO buffer in the required modes.

### (2) FIFO TX message buffer link configuration

When the common FIFO is configured as TX FIFO, the FIFO buffer must be linked to a normal TX message buffer to participate in the transmission scan.

Do not write data into a TX message buffer that is linked to a Common FIFO buffer. Also, the TX message buffer linked to a Common FIFO buffer should not be a part of the TX Queue.

The TX message buffer link of each Common FIFO buffer can be configured by writing to the CFDCFCC.CFTML[1:0] bits in the Common FIFO Configuration/Control Registers. Available options for TX message buffer link configuration are:

- 0x00: TX Message Buffer 0
- 0x01: TX Message Buffer 1
- 0x10: TX Message Buffer 2
- 0x11: TX Message Buffer 3

### (3) FIFO depth configuration

The depth of each FIFO buffer can be configured by writing to the CFDRFCCa.RFDC[2:0] bits and CFDCFCC.CFDC[2:0] bits in the RX FIFO Configuration/Control Registers and the Common FIFO Configuration/Control Registers. The 6 available options for depth configuration are:

- 0x000: 0 Message (FIFO buffer cannot be enabled)
- 0x001: 4 Messages
- 0x010: 8 Messages
- 0x011: 16 Messages
- 0x100: 32 Messages
- 0x101: 48 Messages

The RAM allocation for RX message buffers along with FIFO buffers is limited to 16 messages with 64 data bytes. Configuration of the RX message buffers, along with FIFO buffers, that exceeds this maximum limit should not be done.

CANFD module logic does not check the validity of the configuration.

Note: If the FIFO depth of a common FIFO is 4 messages or more (CFDCFCC.CFDC[2:0] > 000b), then the Common FIFO TX message buffer link is valid when the FIFO is disabled or enabled.

If FIFO depth is 0 messages, then the Common FIFO TX message buffer link is not valid when the FIFO is disabled or enabled.

### (4) FIFO payload size configuration

The data size of each FIFO buffer can be configured by writing to the CFDRFCCa.RFPLS[2:0] bits and CFDCFCC.CFPLS[2:0] bits in the RX FIFO Configuration/Control Registers and the Common FIFO Configuration/Control Registers. The eight available options for depth configuration are:

- 000b: 8 bytes
- 001b: 12 bytes
- 010b: 16 bytes
- 011b: 20 bytes
- 100b: 24 bytes
- 101b: 32 bytes
- 110b: 48 bytes
- 111b: 64 bytes

The RAM allocation for RX message buffers along with FIFO buffers is limited to 16 messages with 64 data bytes. Configuration of the RX message buffers, along with FIFO buffers, that exceeds this maximum limit should not be done.

CANFD module logic does not check the validity of the configuration.

Note: This feature is not available in the classical CAN function.

### (5) FIFO interrupt configuration

The Interrupt generation conditions for the FIFO buffers can be configured by writing to the CFDRFCCa.RFIM and CFDCFCC.CFIM bit in the RX FIFO Configuration/Control Registers and the Common FIFO Configuration/Control Registers. The two available options are:

- 0:
  - RX FIFO mode: Interrupt generated when the Common FIFO counter reaches CFDRFCCa.RFIGCV/ CFDCFCC.CFIGCV value
  - TX FIFO mode: Interrupt generated when the Common FIFO transmits the last message successfully
- 1:
  - RX FIFO mode: Interrupt generated at the end of storage of every received message
  - TX FIFO mode: Interrupt generated for every successfully transmitted message

If the Interrupt Mode bit is 0 for a RX FIFO, then interrupt is generated based on the configuration of the CFDRFCCa.RFIGCV[2:0] bits.

Similarly, if the Interrupt Mode bit is 0 for a Common FIFO configured in RX mode, then interrupt is generated based on the configuration of CFDCFCC.CFIGCV[2:0] bits.

The eight available options for configuring the FIFO counter value for generation of an interrupt are:

- 000b: Interrupt generated when FIFO is 1/8th Full
- 001b: Interrupt generated when FIFO is 1/4th Full
- 010b: Interrupt generated when FIFO is 3/8th Full
- 011b: Interrupt generated when FIFO is 1/2 Full
- 100b: Interrupt generated when FIFO is 5/8th Full
- 101b: Interrupt generated when FIFO is 3/4th Full
- 110b: Interrupt generated when FIFO is 7/8th Full
- 111b: Interrupt generated when FIFO is Full.

In this case, an interrupt is generated when the message count matches the configured value.

However, there are some limitations on the configuration of the CFDRFCCa.RFIGCV[2:0] and CFDCFCC.CFIGCV[2:0] bits depending on the FDC[2:0] bits (FIFO Depth Configuration), see Table 31.25.

**Table 31.25 FIFO interrupt generation counter and FIFO depth configuration**

| RFDC[2:0] (CFDC[2:0]) | RFIGCV[2:0] (CFIGCV[2:0]) | | | | | | | |
|---|---|---|---|---|---|---|---|---|
| | 111b | 110b | 101b | 100b | 011b | 010b | 001b | 000b |
| 000b | Don't care (FIFO cannot be enabled) | | | | | | | |
| 001b | Allowed | Not allowed | Allowed | Not allowed | Allowed | Not allowed | Allowed | Not allowed |
| 010b | Allowed | | | | | | | |
| 011b | Allowed | | | | | | | |
| 100b | Allowed | | | | | | | |
| 101b | Allowed | | | | | | | |
| 110b | Allowed | | | | | | | |
| 111b | Allowed | | | | | | | |

### 31.6.2.2 FIFO Buffers Control

The FIFO interrupt must be enabled by setting any one of the following bits in the RX FIFO Configuration/Control Registers:

- CFDRFCCa.RFIE

In addition, the FIFO interrupt must be enabled by setting any one of the following bits in the Common FIFO Configuration/Control Register:

- CFDCFCC.CFRXIE
- CFDCFCC.CFTXIE

After configuration is complete, each FIFO can be enabled by setting the CFDRFCCa.RFE and CFDCFCC.CFE bits in the RX FIFO Configuration/Control Registers and the Common FIFO Configuration/Control Register to allow transmission and reception of messages.

## 31.7 Interrupts and DMA

### 31.7.1 Interrupts

The CANFD module generates several interrupts. The interrupt output, which is connected to the Interrupt Controller Unit (ICU), can be controlled by the corresponding interrupt enable bit.

The status flag is set independent of this enable bit.

The channel transmission interrupt has an additional status flag register. The status bits are set when the corresponding interrupt enables are set.

The status flag register supports the identification of the interrupt source for the channel transmission, as this interrupt is driven by several trigger sources.

The interrupts in the CANFD module can be classified into two groups, global interrupts and channel interrupts:

- Global interrupts:
  The CANFD module can generate 3 global interrupts:
  - Global interrupt for successful reception into the 2 RX FIFO buffers
  - Global error interrupt
  - Global Interrupt for successful reception into the 16 RX message buffers.
- Channel interrupts:
  Channel of the CANFD module can generate 3 channel interrupts:

1. Channel transmission
   - Transmission completion from channel
   - Transmission abort from channel
   - Transmission from TX Queue for a channel
   - Channel THL interrupt
   - Successful transmission from a Common FIFO in TX mode for a channel.
2. Channel error interrupt
3. Successful reception in a Common FIFO in RX mode for a channel

The interrupts are cleared when the corresponding flag bits are cleared or the interrupt enable bits are cleared.

Table 31.26 gives an overview of interrupt sources for the different interrupt outputs. The interrupt outputs are active-high.

**Table 31.26 Interrupt source overview**

| Parameter | Interrupt | Name | Interrupt source | Interrupt clearing |
|---|---|---|---|---|
| Global Interrupts | Successful reception into at least one RX FIFO | CAN_RXF | Interrupt flag of corresponding RX FIFO for which interrupt is enabled | Clear the interrupt flag of corresponding RX FIFO buffer for which interrupt is enabled |
| | Global Error | CAN_GLERR | Any of the following:<br>• DLC Error flag<br>• Message Lost Status bit<br>• TX History Entry Lost Status bit<br>• CANFD Message Payload overflow flag | Clear all of :<br>• DLC Error flag<br>• Message Lost flags in all the FIFO Status Registers<br>• TX History List Entry Lost flag<br>• CANFD Message Payload overflow flag |
| | Successful reception into at least one RXMB | CANn_RXMB (n = 0) | Interrupt flag of corresponding RXMB for which interrupt is enabled | Clear the interrupt flag of corresponding RXMB buffer for which interrupt is enabled |
| Channel Transmission Interrupts | Channel successful transmission | CANn_TX (n = 0) | Any channel related TXMB Successful flag when interrupt is enabled*1 | Clear all channel related TXMB Result status bits for which the interrupt is enabled |
| | Channel Abort | | Any channel related TXMB Abort flag when interrupt is enabled*1 | Clear all channel related TXMB Result Status bits for which the interrupt is enabled globally |
| | Channel transmission from TX Queue | | Related channel TX Queue Interrupt flag | Clear related channel TX Queue Interrupt flag |
| | Channel THL Interrupt | | Channel THL Interrupt status flag | Clear the relevant THL Interrupt status flag |
| | Channel COM FIFO TX Interrupt | | Interrupt Flag for Common FIFOs in TX mode belonging to the related channel | Clear the interrupt flags of Common FIFOs in TX mode belonging to the related channel |
| Channel Error Interrupt | Channel Error | CANn_CHERR (n = 0) | Any channel related error flag in the Channel Error Flag Register for which interrupt is enabled in the Channel Error Interrupt Enable Register | Clear all channel related error flags in the Channel Error Flag Register for which interrupt is enabled in the Channel Error Interrupt Enable Register |
| Channel COM RX FIFO Interrupt | Channel COM FIFO RX Interrupt | CANn_COMFRX (n = 0) | Interrupt flag for Common FIFOs in RX mode belonging to the related channel | Clear the interrupt flags of Common FIFOs in RX mode belonging to the related channel |

Note 1. These interrupts are only set for TX Message Buffers that do not belong to an enabled TX Queue and are not pointing to a common FIFO.
Separate interrupts are provided for common FIFO buffers and TX Queue.

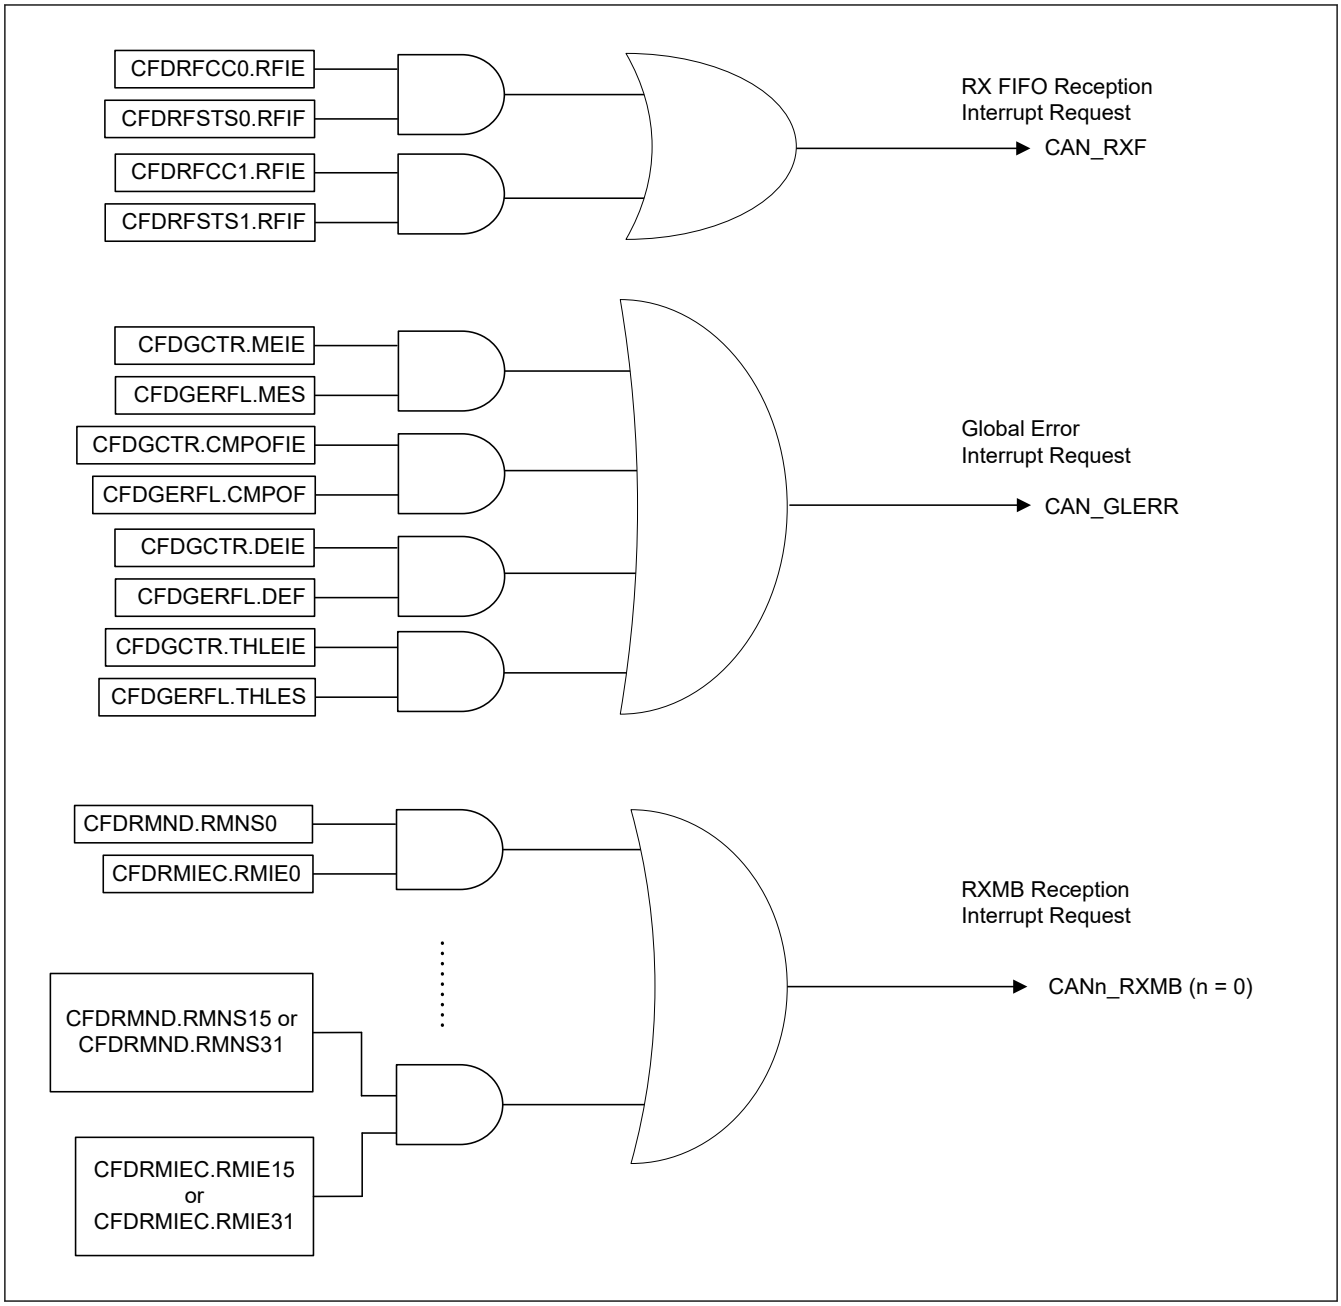

**Figure 31.30 Global interrupt block diagram**

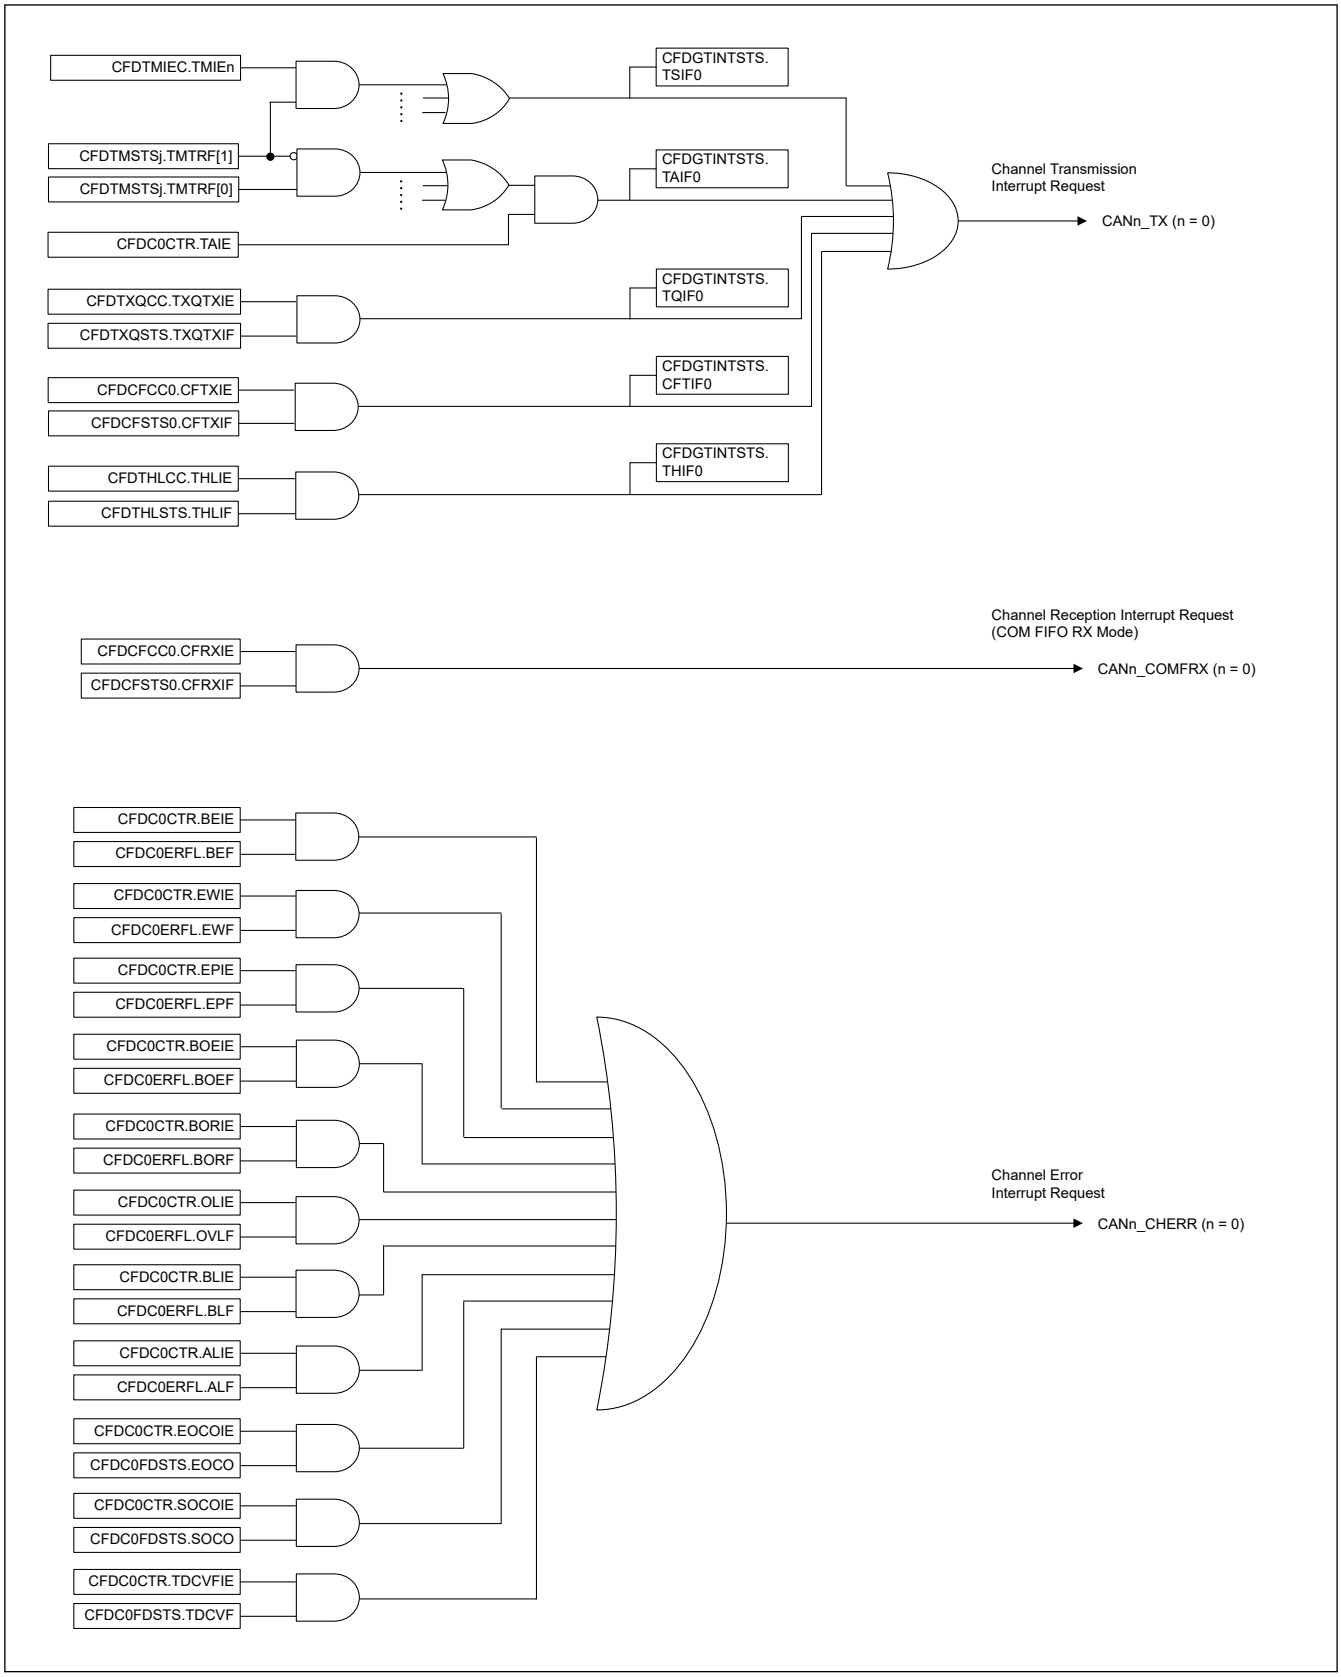

**Figure 31.31 Channel interrupt block diagram**

## 31.7.2 DMA Transfer

The CANFD module has message buffers that can be associated with a DMA channel:

- Reception DMA
  - 2 RX FIFO message buffers
  - Common FIFO Message Buffer

Figure 31.32 shows the potential DMA channels.

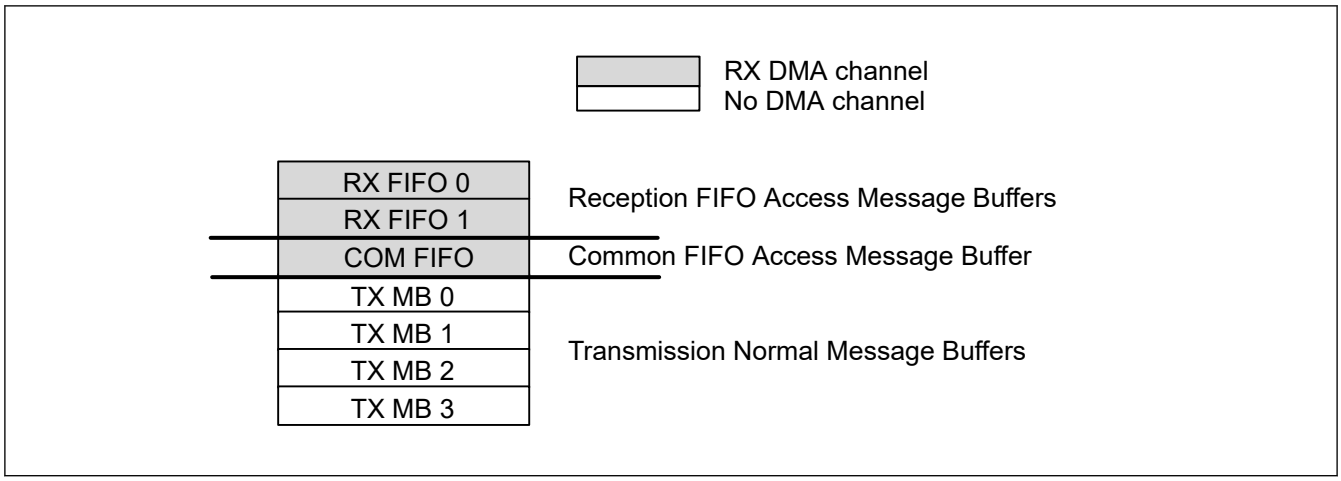

**Figure 31.32 Message buffer connectable to a DMA channel**

A DMA channel transfer request is generated for each FIFO entry to the DMAC when the related CFDCDTCT.RFDMAE or CFDCDTCT.CFDMAE is set to 1 and the belonging FIFO is not empty.

Reception FIFO Interrupt should be disabled for this particular FIFO (CFDRFCCa.RFIE or CFDCFCC.CFRXIE)

Use the regular start address for the DMA access window address. See Figure 31.33.

**Table 31.27 DMA channel access window address**

| b = Message buffer component index | Message Buffer Component | Register | P | Regular Start Address |
|---|---|---|---|---|
| b = [0…1] | RFMBCPb[0] | CFDRFIDb | x | 0x0520 + b × 0x004C |
| | | CFDRFPTRb | x | 0x0524 + b × 0x004C |
| | | CFDRFFDSTSb | x | 0x0528 + b × 0x004C |
| | | CFDRFDFbp | [0…15] | 0x052C + p × 0x0004 + b × 0x004C |
| — | CFMBCP0[0] | CFDCFID | x | 0x05B8 |
| | | CFDCFPTR | x | 0x05BC |
| | | CFDCFFDCSTS | x | 0x05C0 |
| | | CFDCFDFp | [0…15] | 0x05C4 + p × 0x0004 |

DMA FIFO pointer decrement is done automatically by reading the last configured data payload byte (CFDRFCCa.RFPLS or CFDCFCC.CFPLS).

Note: The DMA must read the exact length of the configured data payload size (CFDRFCCa.RFPLS or CFDCFCC.CFPLS).

Note: This feature is not available for classical CAN function because CFDRFCCa.RFPLS and CFDCFCC.CFPLS are not in classical CAN.

Do not write to the FIFO control registers when DMA is enabled. The DMA enable of the particular DMA FIFO (CFDCDTCT.RFDMAE or CFDCDTCT.CFDMAE) can be set at any time. Figure 31.33 shows a configuration flow for an initial setup.

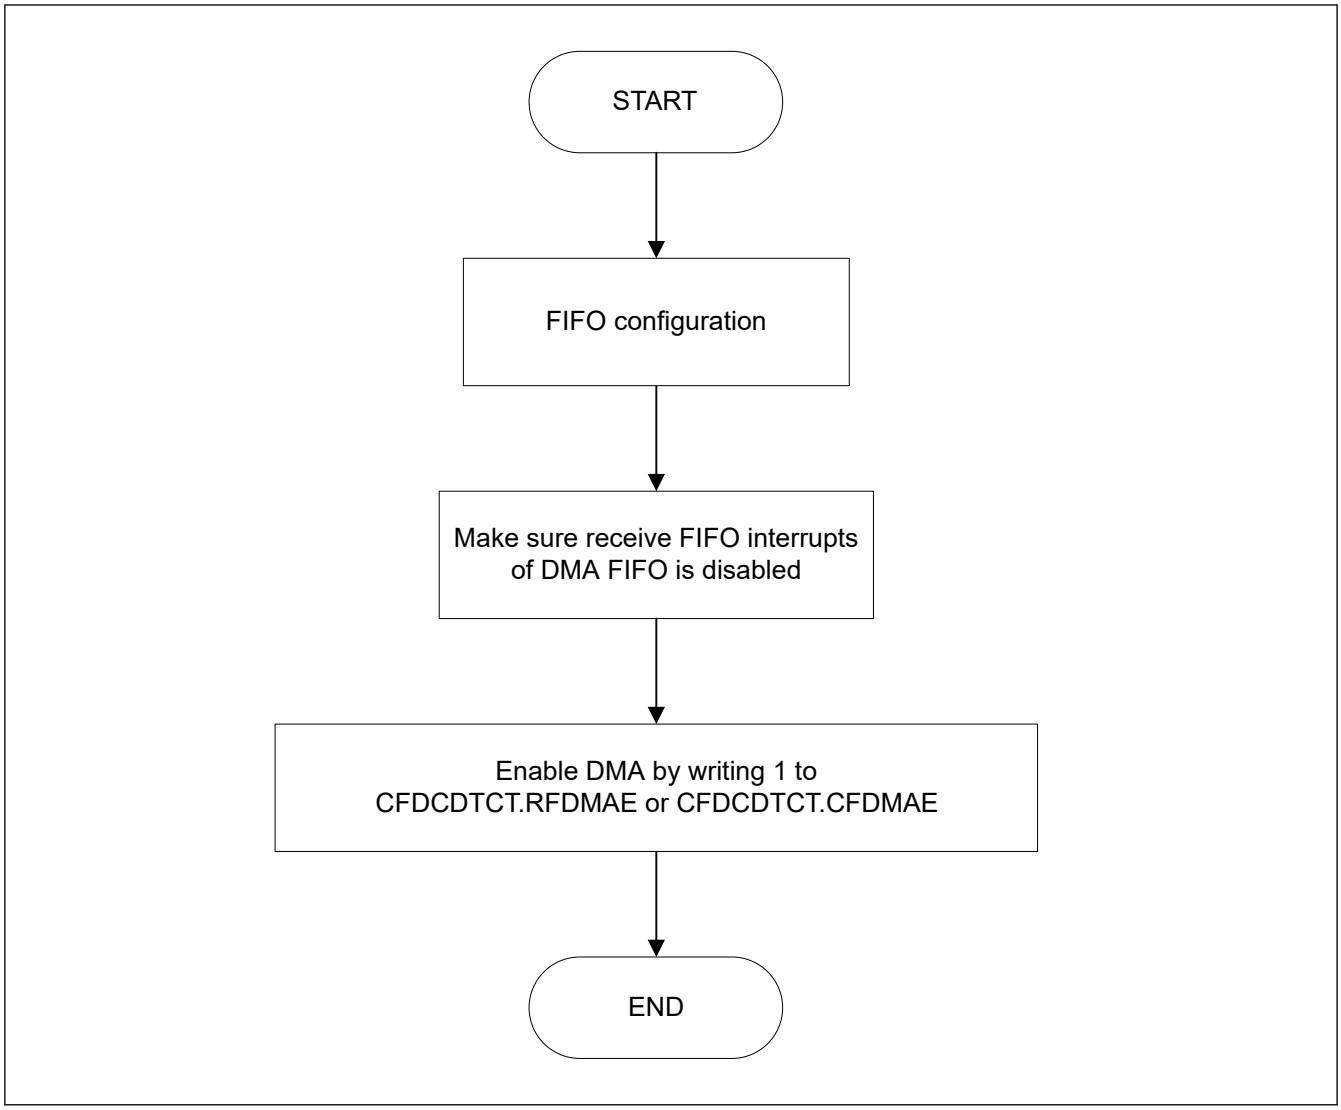

**Figure 31.33 DMA enable flow**

To disable a DMA transfer request, you must disable the particular DMA enable bit (CFDCDTCT.RFDMAE or CFDCDTCT.CFDMAE). If the disable is made during an ongoing transfer, then the transfer must be completed first before further action can be taken. The transfer status can be identified by the CFDCDTSTS.RFDMASTS or CFDCDTSTS.CFDMASTS bit. See Figure 31.34 for the DMA disable flow. When the DMA is disabled, consideration should be made for the remaining or new incoming messages to this particular reception FIFO.

When the FIFO is not disabled, reception to the FIFO continues.

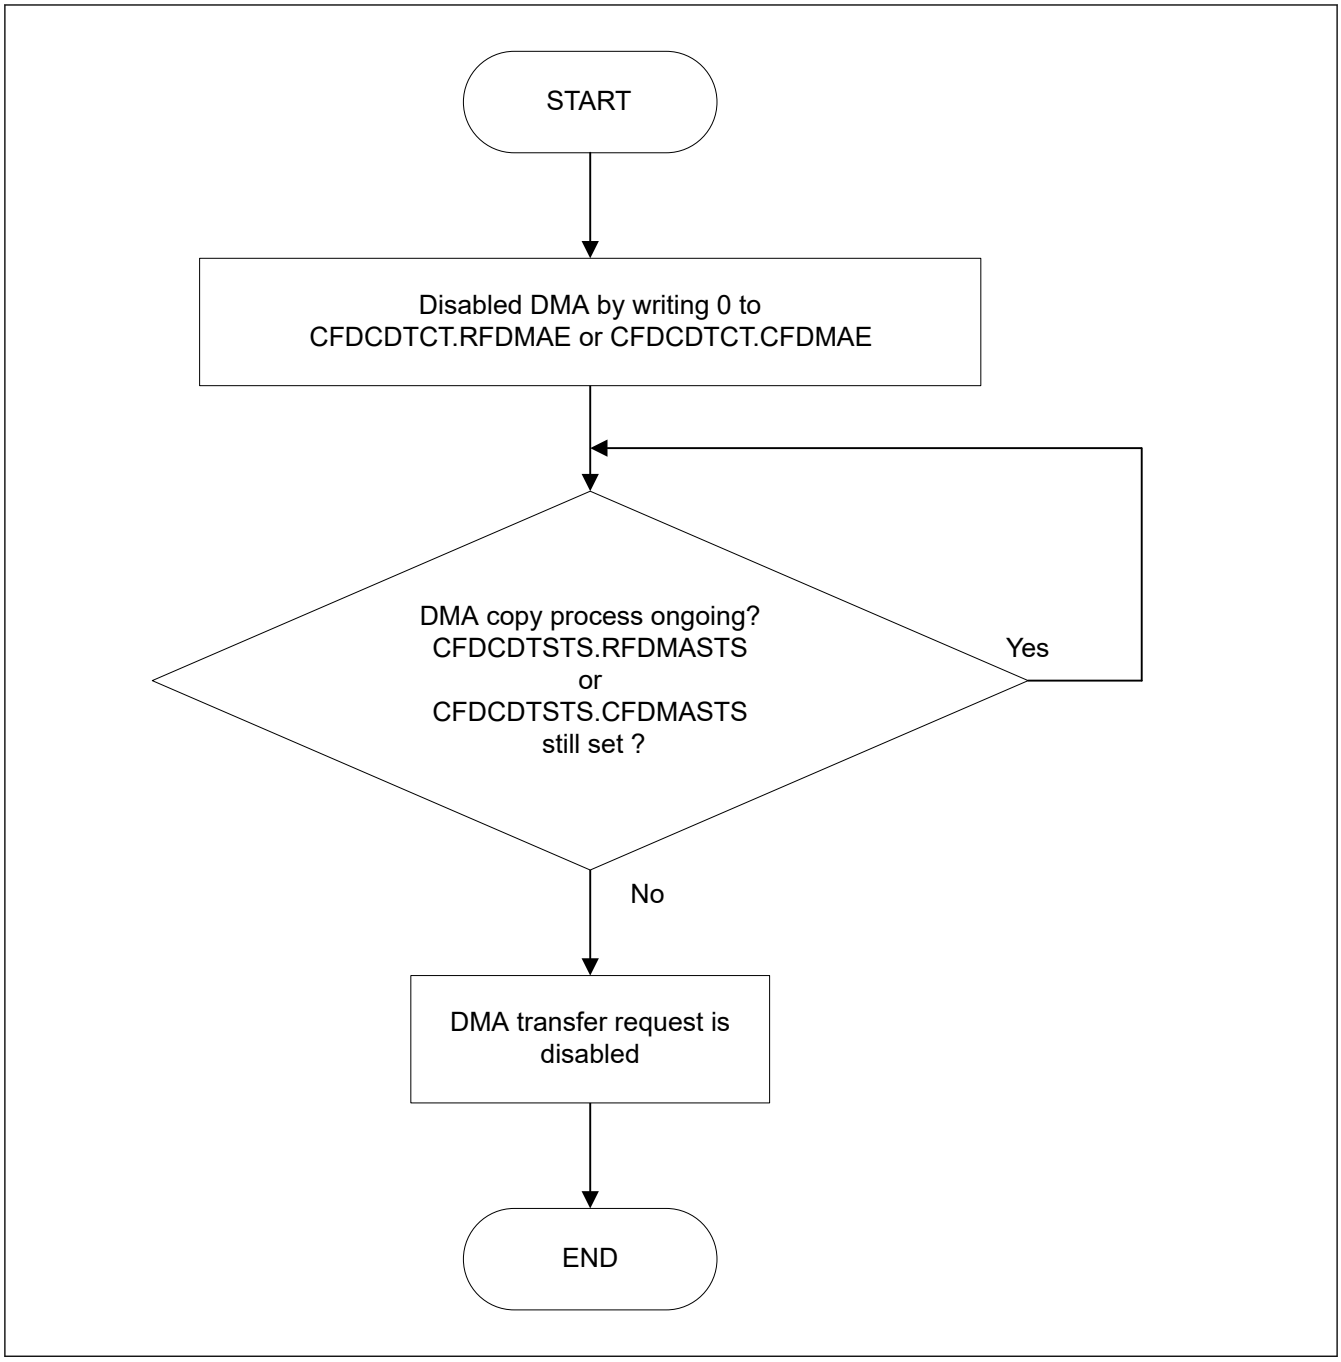

**Figure 31.34 DMA disable flow**

## 31.8 Reception and Transmission

### 31.8.1 Reception

In the CANFD module, CAN messages received on any of the channels are stored in RX message buffers, RX FIFO buffers, or Common FIFO buffers configured in RX mode depending on the Acceptance Filter List entries.

- Up to 16 RX message buffers can be configured
- 2 RX FIFO buffers available
- 1 Common FIFO Buffer can be configured in RX mode

### 31.8.1.1 Message Storage in RX Message Buffers

When a message is successfully received and stored in a RX message buffer, the corresponding New Data flag is set in the RX Message Buffer New Data Register.

The CAN message can be read from the corresponding RX message buffer.

If a new message is stored into a RX message buffer before the previous message in this message buffer can be read, then the original message is overwritten. There is no mechanism for preventing a new message from overwriting the current message in the RX message buffer. If such a loss of messages is not acceptable, then RX FIFO should be used for storing related messages.

Note: Users should do the same processing as the existing software flow also when using interrupt. (see Figure 31.36)

Note: Unused data bytes are filled with 0x00 depending on the DLC value.

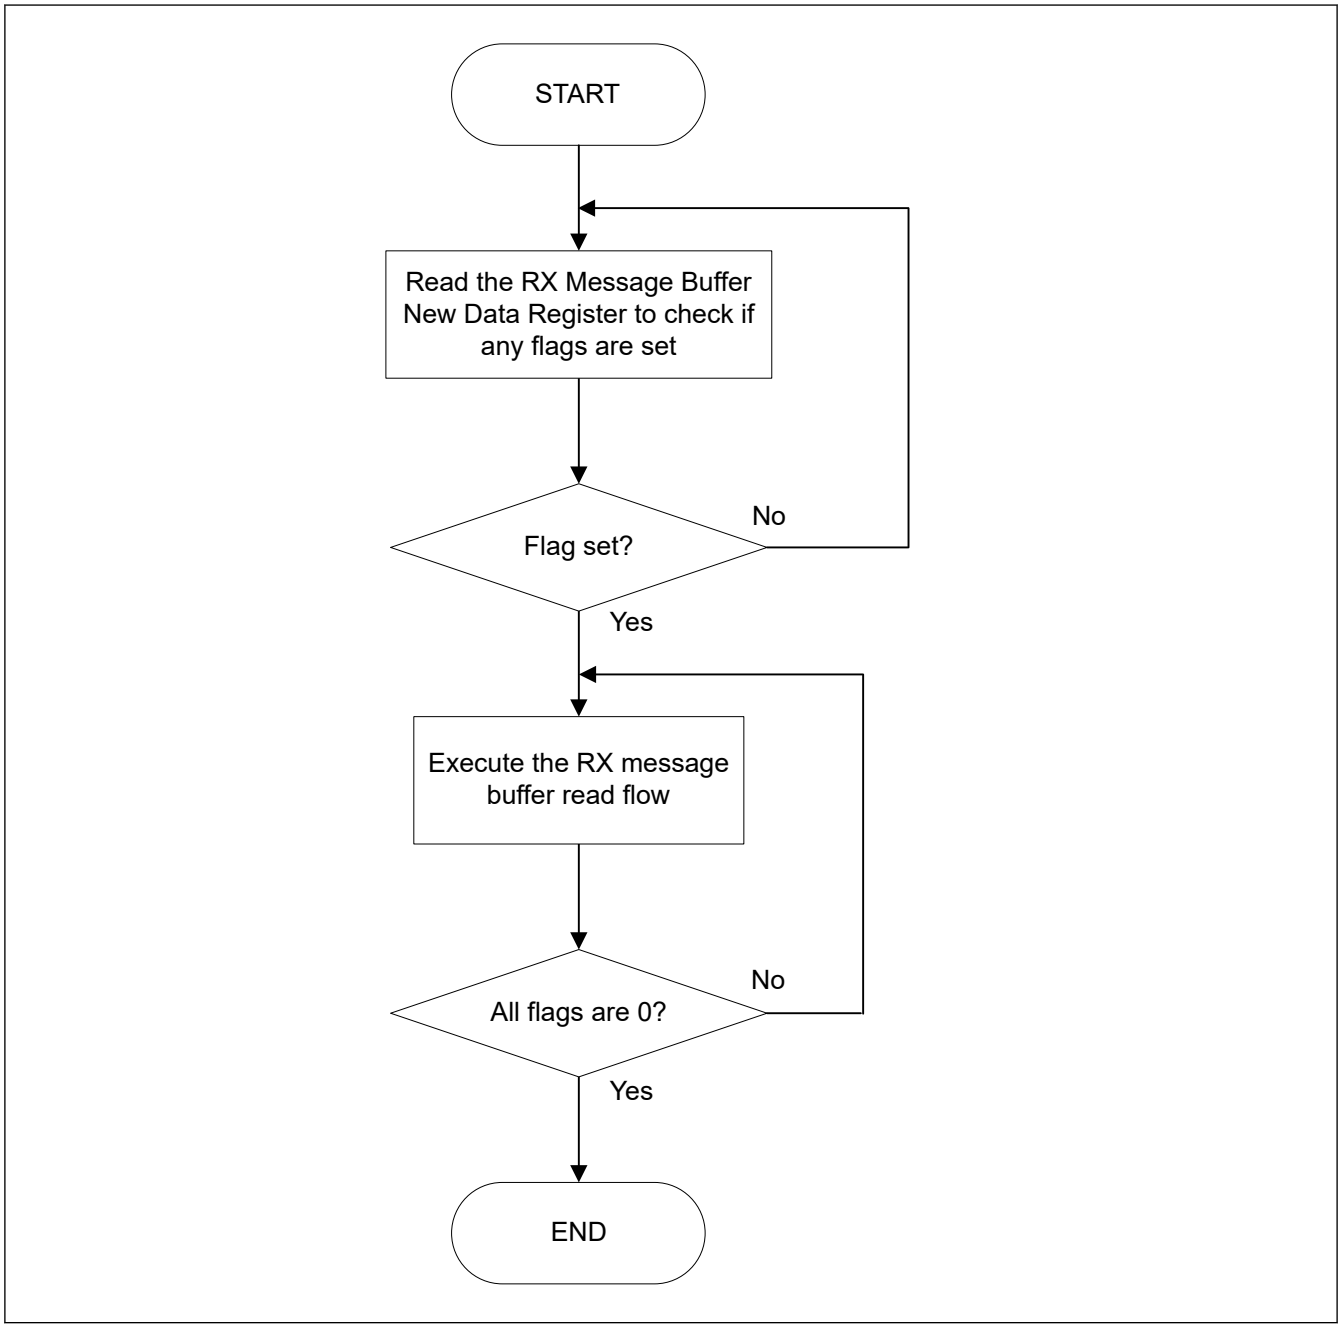

**Figure 31.35 Access flow of RX message buffer (Polling)**

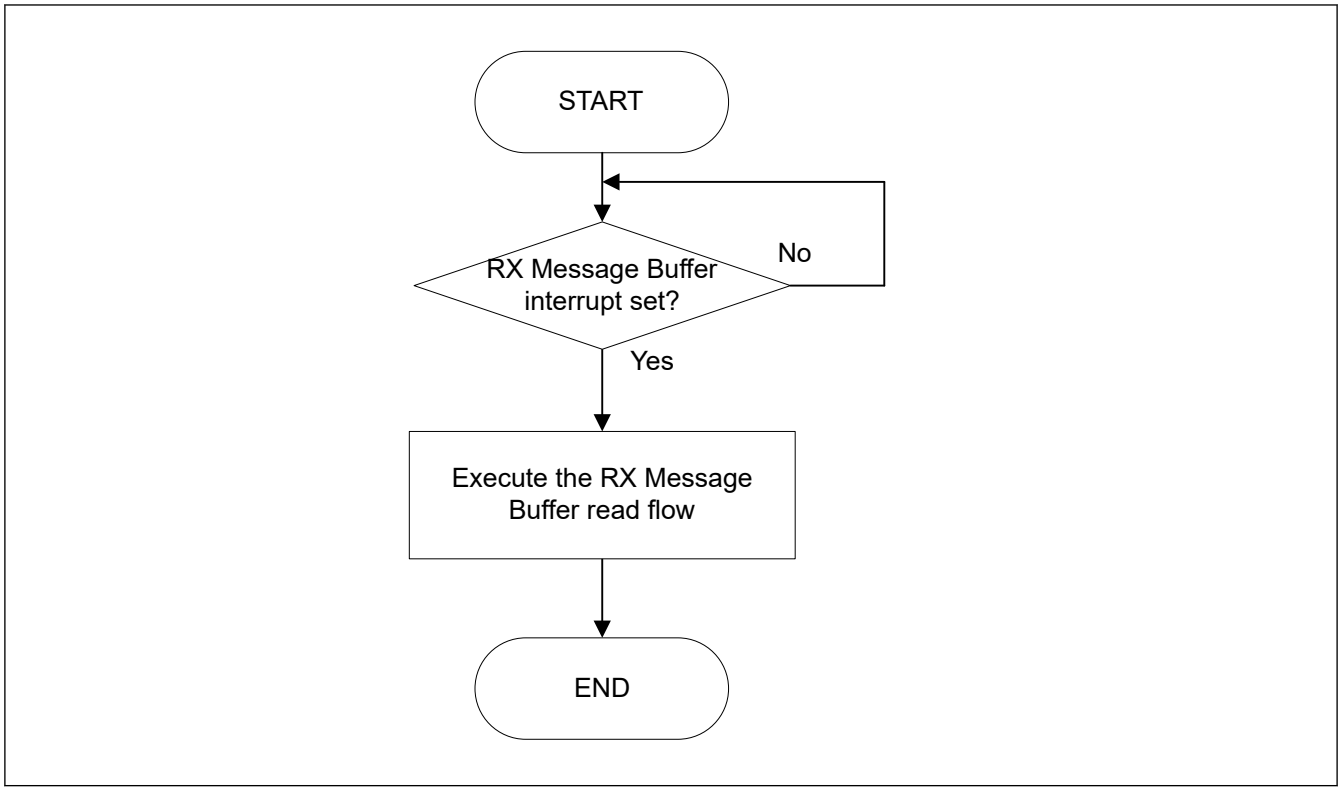

**Figure 31.36 RX Message Buffer Message Access Flow (interrupt)**

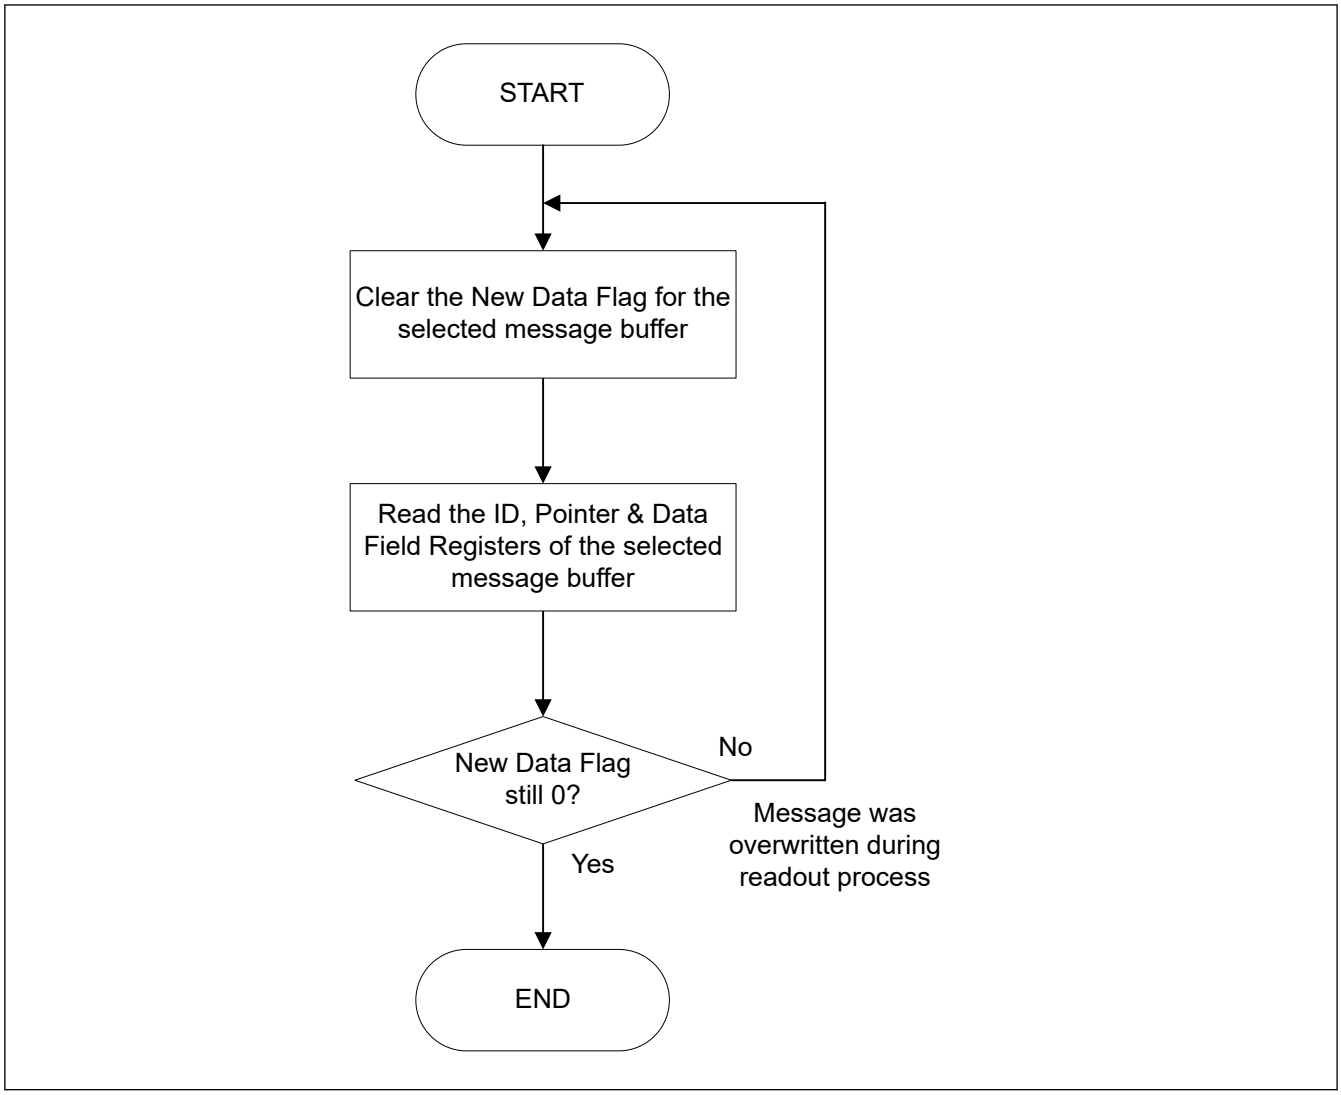

**Figure 31.37 Read flow of RX message buffer**

### 31.8.1.2 Message Storage in FIFO Buffers

The AFL entries for routing the received messages to RX FIFO buffers or Common FIFO buffer configured in RX mode should be configured based on system requirements.

The CFDGAFLP1r.GAFLFDP[8,1:0] field in the matching AFL entry selects the FIFO buffers to which the related reception message is stored.

When the received message is stored in one or more RX FIFO buffers or Common FIFO buffer configured in RX mode, the message counter value is incremented in the corresponding RX FIFO Status Registers or Common FIFO Status Register.

Depending on the configuration of the FIFO buffers, an interrupt might also be generated.

The message can be read from the corresponding FIFO Access registers.

Note: Because many messages can be stored in the FIFO buffers, reading more than one message may be required to read the latest message stored in a FIFO buffer.

If the message count value matches the FIFO depth, the FIFO Full flag is set.

When the value 0xFF is written to the corresponding FIFO Pointer Control Register, the message count is decremented by 1.

Only write 0xFF to the FIFO Pointer Control register after reading the complete message from the FIFO Access registers of the corresponding FIFO.

When all the messages stored in the FIFO are read, the FIFO Empty flag is set.

If a new message is stored into the FIFO when the FIFO message count matches the FIFO depth (FIFO full condition), the FIFO Message Lost flag is set and the new message is lost (no overwrite of already stored messages takes place).

An appropriate value can be configured as warning level to generate an interrupt before the FIFO full condition occurs to avoid loss of a message due to an overrun condition.

Note: The message lost can be set only in RX mode by CAN, and the flag is not set when the CPU is overloading the FIFO buffers.

The RX FIFO buffers and the Common FIFO buffers configured in RX mode can be disabled at any time by clearing the CFDRFCCa.RFE or CFDCFCC.CFE bit in the RX FIFO Configuration/Control Registers and the Common FIFO Configuration/Control Registers.

When the CFDRFCCa.RFE or CFDCFCC.CFE bit is cleared, the message read and write pointers of the FIFO are cleared and are no longer active. Therefore, all messages in the FIFO buffers are lost and no further messages can be stored into the FIFO.

When the RX FIFO buffers or Common FIFO buffer configured in RX mode is assigned as a DMA channel, software should not access the FIFO Access Register of this FIFO buffer or write 0xFF to the FIFO Pointer Control Register (CFDCFPCTR.CFPC or CFDRFPCTRa.RFPC). This can lead to unintended FIFO message decrement. The DMA channel controls the FIFO decrement automatically.

Note: If the interrupt flag is set for a FIFO buffer and then the FIFO is disabled, the interrupt flag is not cleared automatically. The interrupt flag should be cleared before disabling the FIFO.

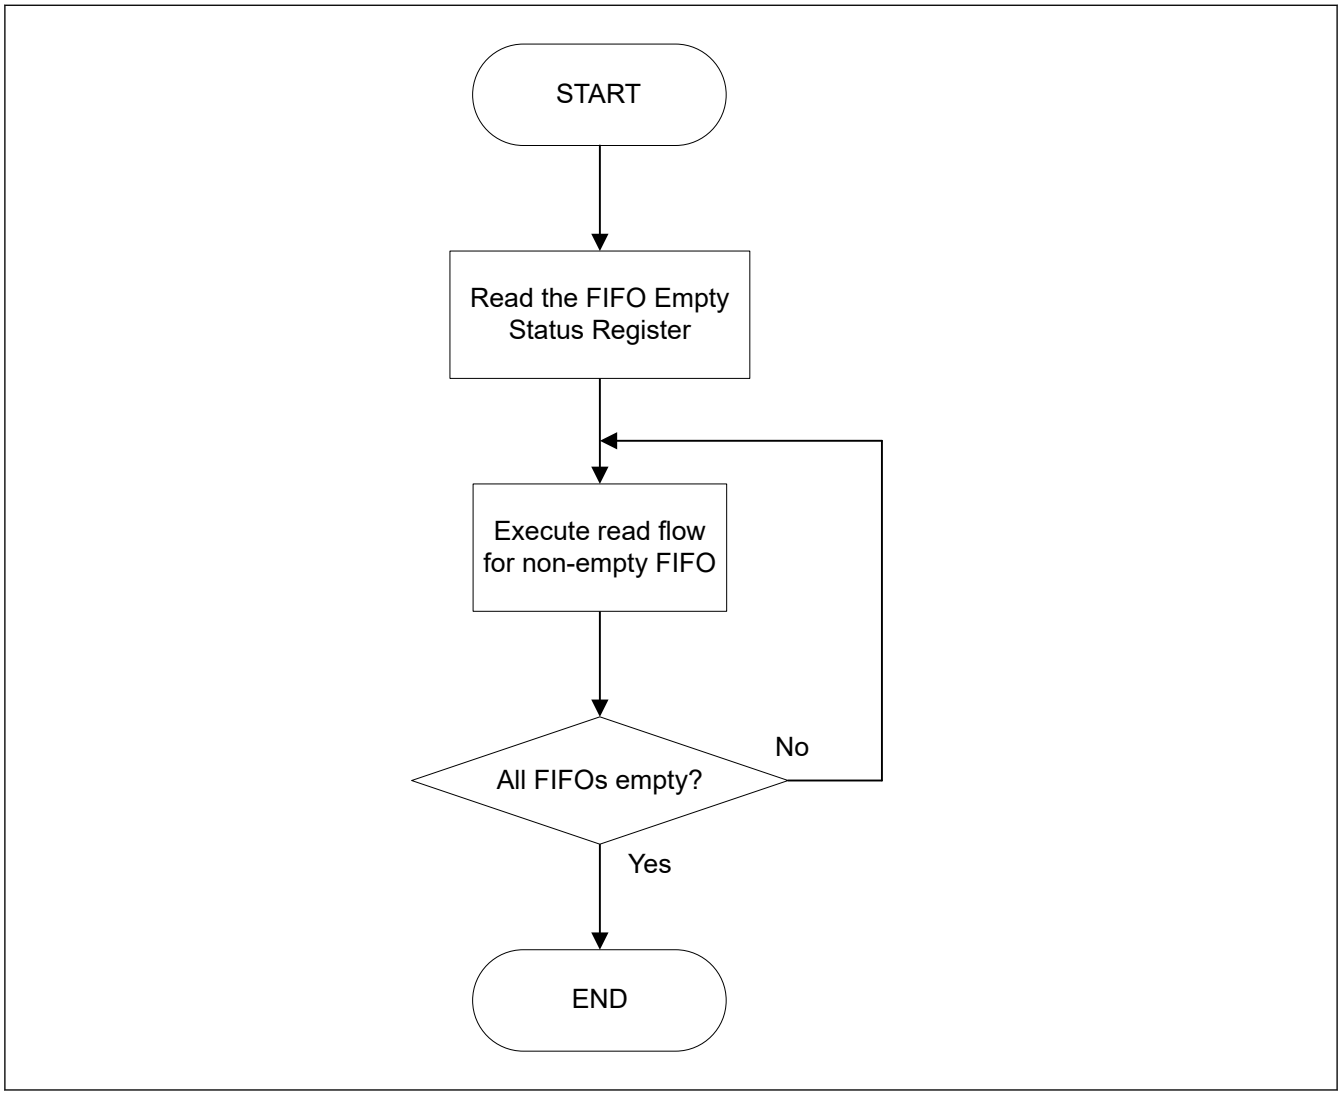

**Figure 31.38 Access flow of FIFO buffer message (example for polling case)**

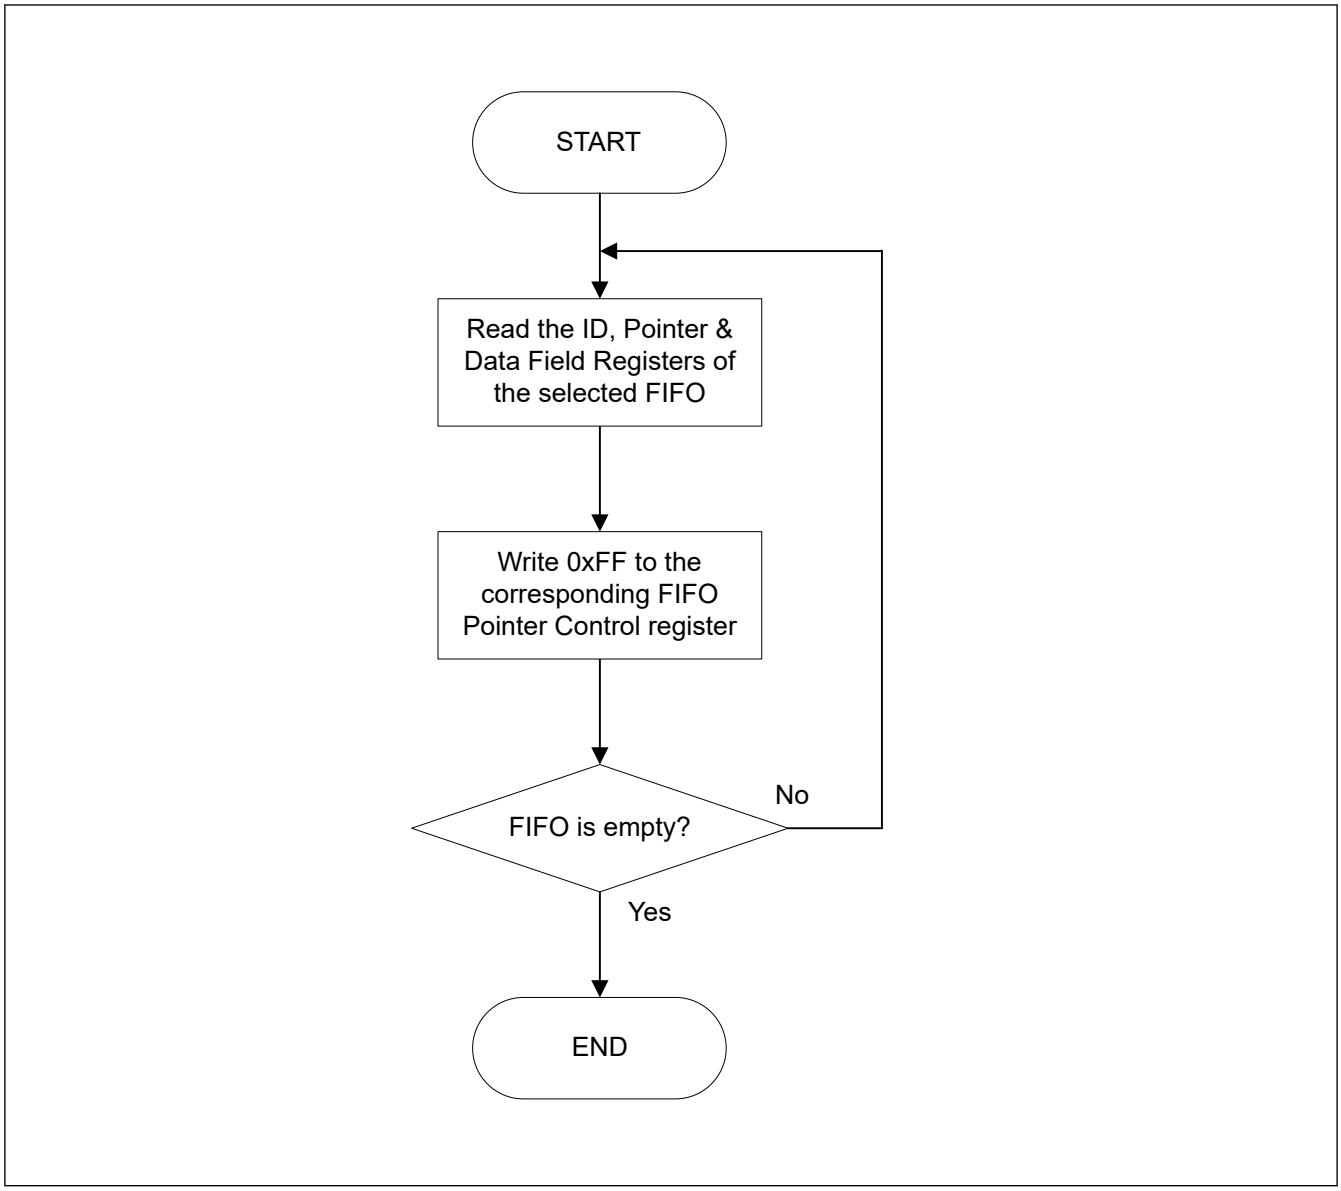

**Figure 31.39 Read flow of RX FIFO buffer message (example for polling case)**

Note: When the next frame is received before clearing the completion interrupt flag of reception, the completion interrupt of reception is not set again.

Even when an interruption flag is cleared after the completion processing of reception, the already received interrupt flag is not set.

It is necessary to perform the completion processing of reception even before the next completion of frame reception, and to clear an interruption flag.

When processing does not meet the condition, after checking that receiving data is empty, interrupt flag is cleared and it checks that receiving data is empty again.

### 31.8.1.3 Timestamp

The timestamp counter is a free-running counter that can be used to check reception time of an incoming message or transmission time of successful transmitted messages. The Timestamp counter value is captured based on the CFDGFDCFG.TSCCFG[1:0] configuration (at the sample point of start of frame, point in time when the frame is valid, or for CANFD frames also at the sample point of the RES bit). For reception, it is stored together with the message ID and data into the target RX message buffer or RX FIFO.

For transmit message, the timestamp counter value is stored as part of the TX History List entry.

The counter can be clocked with the peripheral clock or with the CAN channel bit timing clock. The counter source clock can be configured with the CFDGCFG.TSSS bit of the Global Configuration Register. If this bit is 0, the peripheral clock is used. If the bit is 1, the selected CAN channel bit time clock is used.

The channel selection is performed with the CFDGCFG.TSBTCS bit of the Global Configuration Register.

Care must be taken when using selected CAN channel bit time clock as the clock source. When entering Channel Halt mode or Channel Reset node, for this channel, the timestamp counter is stopped. For other CAN channels, the timestamp counter value is not updated.

If peripheral clock is selected as the timestamp counter clock source, Channel modes do not affect the timestamp counter function.

The source clock for the timestamp counter can be divided by a factor defined by the CFDGCFG.TSP bits (timestamp prescaler) in the Global Configuration Register.

The timestamp counter can be reset to 0x0000 with the CFDGCTR.TSRST bit (timestamp reset).

### 31.8.2 Transmission

There are several possible transmission configurations:

- Normal transmission
- FIFO transmission
- TX Queue transmission
  A fixed number of transmission message buffers (4 TX message buffers) are dedicated. These message buffers are only used for transmission and cannot be configured for reception.
  Additionally transmission from TX Queue or Common FIFO in TX mode can be configured in the following way (see Figure 31.40):
  – TX Queue: Up to four transmission message buffers can be grouped to form a TX Queue with a common access window.
    Upper transmission message buffers are used to form the TXQ.
    TXQ has an access window.
    • TXQ is transmission Message Buffer 0.
- Common FIFO (TX mode): Common FIFO in TX mode is linked to a dedicated channel.
  Channel has a fixed number of one Common FIFO assigned to it. Within the channel, a Common FIFO configured in TX mode, can be freely linked (assigned) between 0 and 3 transmission message buffers (only one FIFO to one transmission message buffer).
  The Common FIFO buffer then replaces the transmission message buffer linked to it.
  Transmission Control and Status registers of these transmission message buffers should not be used.

See Figure 31.28 for information about Common FIFO buffer assignment to related channel.

Note: Common FIFO buffer should not be linked to TX message buffers that are already part of a TX Queue.

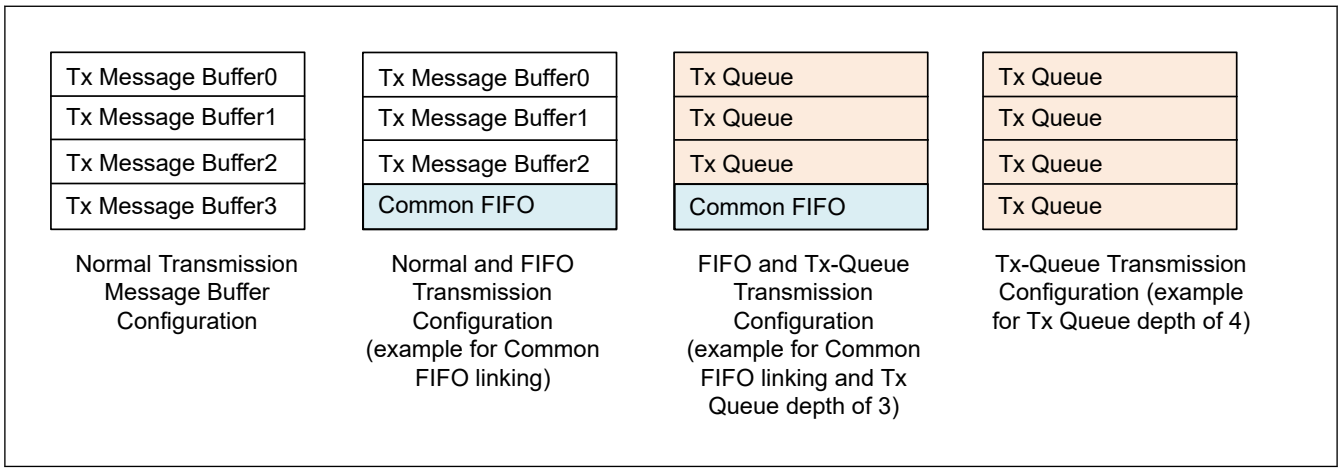

**Figure 31.40 Configuration of channel transmission message buffer**

#### 31.8.2.1 Transmission Priority

If two or more transmission message buffers of a channel are configured for transmission, then the transmission priority in the CANFD module can be selected from the following two modes:

- CAN ID priority
- Message buffer number priority.

The transmission priority mode is common for all message buffers. It can be configured with the CFDGCFG.TPRI bit in the Global Configuration Register.

For message buffer number priority transmission, the smallest message buffer number with transmission request has the highest priority for transmission. This also includes the TX message buffers linked to the Common FIFO buffer configured in TX mode.

However, message buffer number priority should not be used if TX Queue is enabled.

For CAN ID priority transmission, ID priority complies with the CAN bus arbitration rule (as specified in ISO 11898-1 specification). All TX message buffers can enter the ID priority comparison for message buffers configured for transmission. This also includes the TX message buffers linked to the Common FIFO buffer configured in TX mode and includes the TX Queue message buffers.

If the ID of two or more message buffers is the same, then the smaller message buffer number has higher priority for transmission.

Note: For Common FIFO buffer configured in TX mode, only the message currently being pointed to by the FIFO read pointer can be included in the transmission arbitration.

If the message is being transmitted from the FIFO, then the next pending message within the same FIFO is considered in the transmission arbitration.

In contrast to this, all transmission message buffers of a TX Queue participate in internal transmission arbitration.

Figure 31.41 shows the transmission configuration flow.

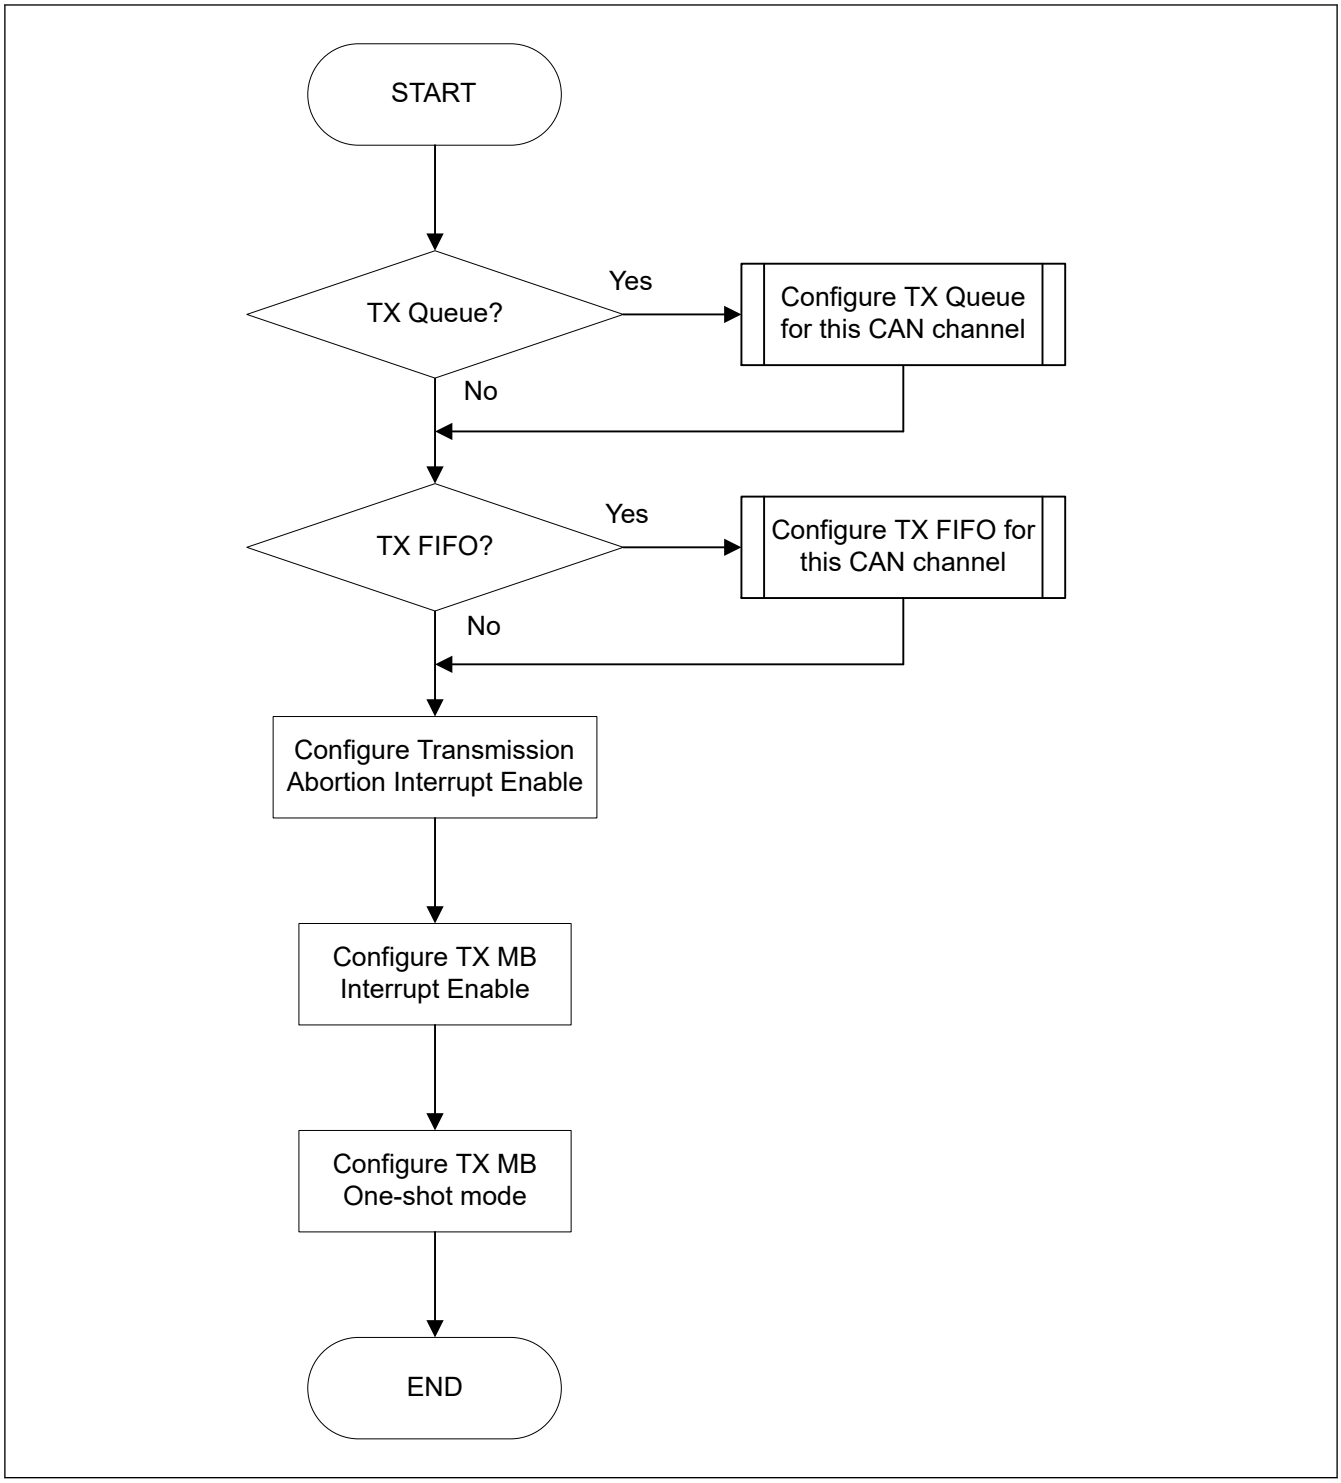

**Figure 31.41 Flow for transmission configuration**

### 31.8.2.2 Normal Transmission

Each transmission message buffer has two modes of message transmission:

1. Regular transmission mode
   If the message buffer is placed in regular transmission mode, the data frame or remote frame set in that message buffer can be transmitted.
   Completion of regular transmission can be checked through the related TX Message Buffer Transmission Result flag bits (CFDTMSTSj.TMTRF) in the TX Message Buffer Status Registers. These bits are set to 10b or 11b when the regular transmission is successful.

When arbitration is lost or an error occurs, message transmission is further attempted if no transmission abort request is set for this transmission message buffer.
New internal transmission arbitration for this channel is performed for all message buffers with transmission request.

2. One-shot transmission mode

When the CFDTMCi.TMOM bit of the TX Message Buffer Control Registers is set for a transmission message buffer, the message buffer is placed in One-shot transmission mode and attempts to transmit a message only once.

Completion of One shot transmission can be checked through the related TX Message Buffer Transmission Result Flag bits (CFDTMSTSj.TMTRF) in the TX Message Buffer Status Registers. The CFDTMSTSj.TMTRF bits are set to 10b or 11b when One-shot transmission is successful.

The CFDTMSTSj.TMTRF bits are set to 01b when arbitration is lost or an error occurs during transmission of the related message buffer.

Additional message transmission is not attempted in this case.

The regular transmission request procedure after a configuration is shown in Figure 31.42.

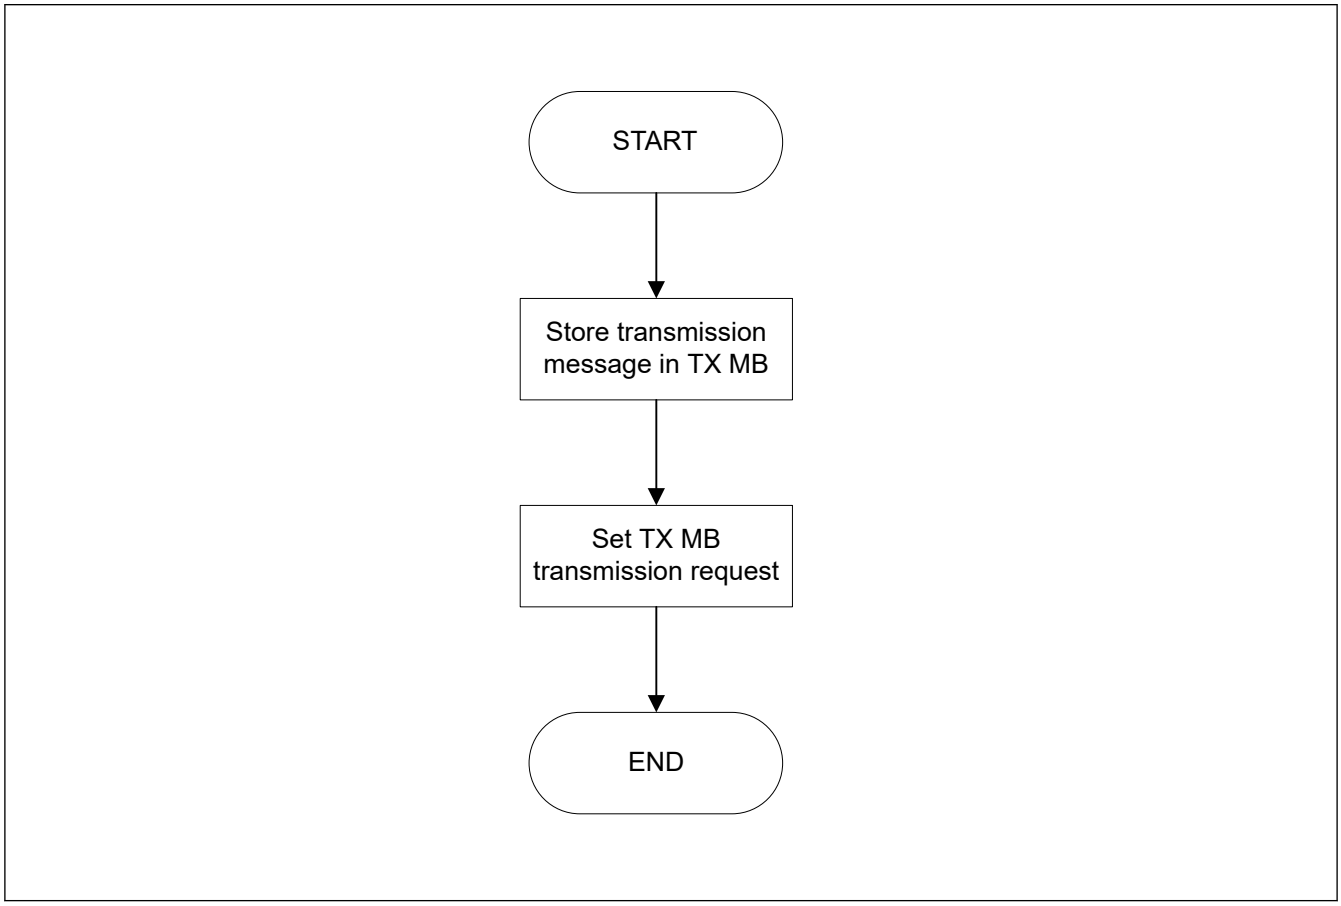

**Figure 31.42 Transmission request procedure using normal TX Message Buffer mode**

### (1) Setting for TX Message Buffer Control Register

Table 31.28 shows configuration of a normal CAN transmission mode.

**Table 31.28 Configuration of CAN transmission mode (1 of 2)**

| Transmission request CFDTMCi.TMTR | Transmission abort request CFDTMCi.TMTAR | One-shot enable CFDTMCi.TMOM | Communication activity |
|---|---|---|---|
| 0 | 0 | 0 | Message buffer disabled |
| 0 | 0 | 1 | Message buffer disabled |

**Table 31.28 Configuration of CAN transmission mode (2 of 2)**

| Transmission request CFDTMCi.TMTR | Transmission abort request CFDTMCi.TMTAR | One-shot enable CFDTMCi.TMOM | Communication activity |
|---|---|---|---|
| 1 | 0 | 0 | Configured as a transmission message buffer for a data frame or a remote frame |
| 1 | 0 | 1 | Configured as a one-shot transmission message buffer for a data frame or a remote frame |
| 1 | 1 | 0 | Transmission abort requested |
| 1 | 1 | 1 | One-shot transmission abort requested |

The configuration bits can be configured in the TX Message Buffer Control Registers.

Figure 31.43 shows timings for successful transmission for two message buffers.

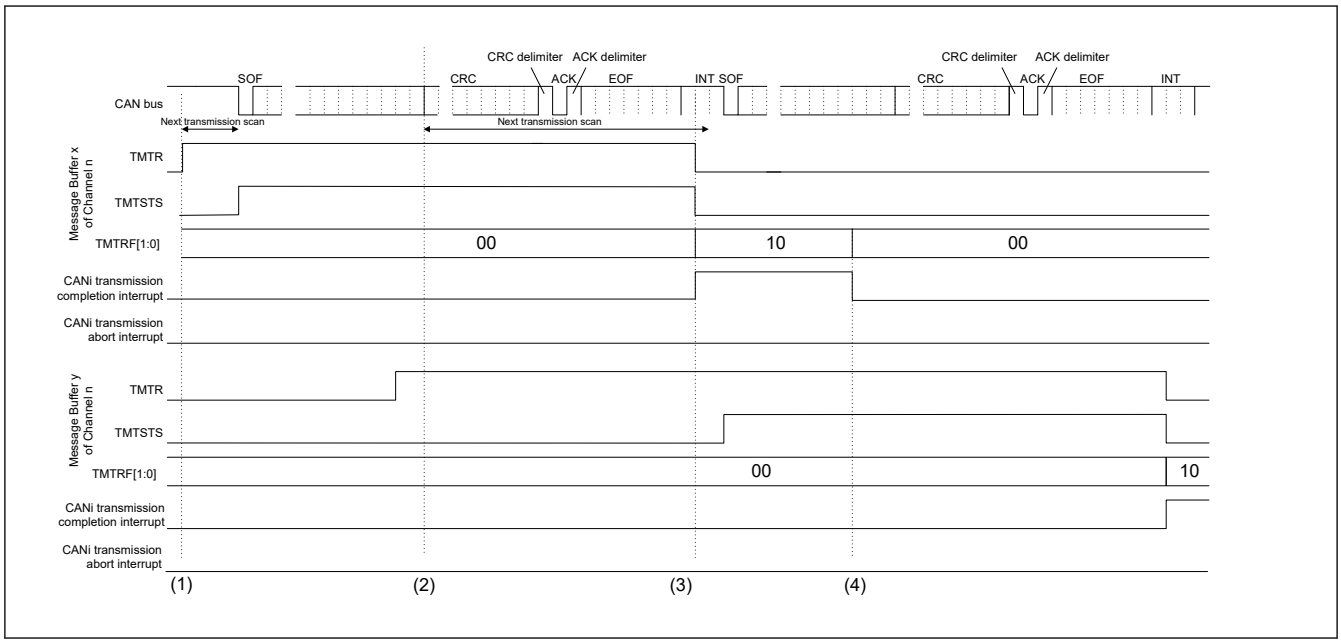

**Figure 31.43 Timing of request and flag bits for successful transmission**

1. If the CFDTMCi.TMTR bit in the TX Message Buffer Control Registers is set in the bus idle state, the message buffer scanning procedure determines the highest priority message buffer for transmission.
   When the transmission message buffer is determined, the CFDTMSTSj.TMTSTS bit in the related TX Message Buffer Status Registers is set (transmitting/transmitter), and CAN channel starts the transmission *1.
2. At the first bit of CRC, the transmission scanning procedure starts for the next possible transmission when pending transmission requests exist.
3. If the message has been successfully transmitted, the CFDTMSTSj.TMTRF[1:0] bits in the corresponding TX Message Buffer Status Registers are set to 10b and CFDTMSTSj.TMTSTS and the CFDTMCi.TMTR bits are cleared.
   When the TMIE bit in the TX Message Buffer Interrupt Enable Configuration Registers is set (interrupt enabled), the CAN successful transmission interrupt request is generated.
   To clear the related interrupt line, clear the CFDTMSTSj.TMTRF flag bits.
4. Before starting the next transmission, clear the CFDTMSTSj.TMTRF bits. Load the next message in the transmission message buffer and set the CFDTMCi.TMTR bit again.
   CFDTMCi.TMTR bit cannot be set again before CFDTMSTSj.TMTRF[1:0] bits are cleared.

Note 1. If arbitration is lost after the CAN channel starts the transmission, the CFDTMSTSj.TMTSTS bit is cleared.

The transmission scanning procedure is performed again to search for the highest priority transmission message buffer from the beginning of the first CRC bit.

If an error occurs either during transmission or following the loss of arbitration, then during the error frame, the transmission scanning procedure is performed again to search for the highest priority transmission message buffer.

Note: The setting point of CFDTMSTSj.TMTSTS is not always fixed at the start of the SOF. It may be delayed up to the start of the standard ID due to the synchronization logic implemented for the PLL bypass.

Figure 31.44 shows timings for transmission abort for two message buffers.

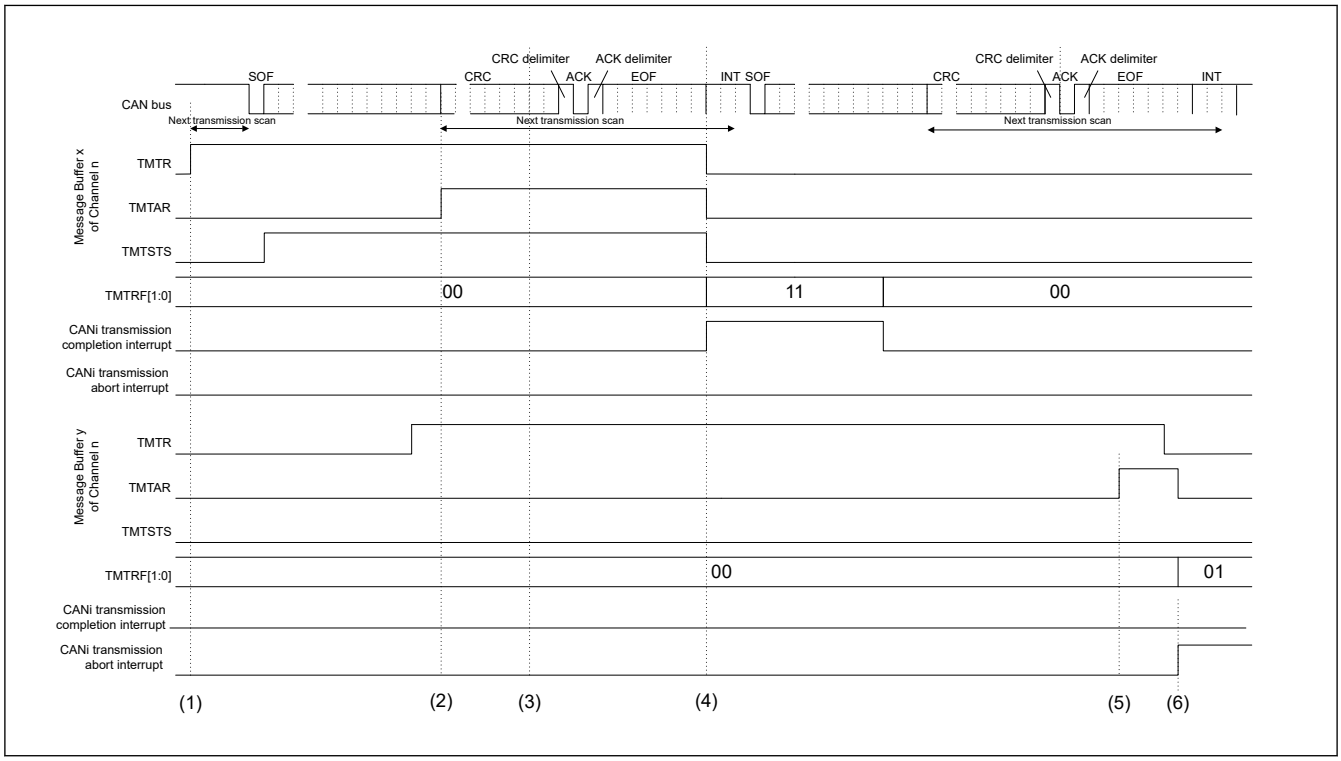

**Figure 31.44 Timing of request and flag bits for transmission abort**

1. If the CFDTMCi.TMTR bit in the TX Message Buffer Control Registers is set in the bus idle state, the message buffer scanning procedure determines the highest priority message buffer for transmission.
   When the transmission message buffer is determined, the CFDTMSTSj.TMTSTS bit in the TX Message Buffer Status Registers is set (transmitting/transmitter), and CAN channel starts the transmission*1.
2. If the CFDTMCi.TMTAR bit is set when the related message buffer is already selected for transmission or currently transmitting, the message is not aborted, if no error occurs or arbitration is lost.
3. At the first CRC bit, the transmission scanning procedure starts for the next transmission. In this example, timing chart message buffer y is not selected as the next transmission message buffer.
4. If the message has been successfully transmitted, the CFDTMSTSj.TMTRF[1:0] bits in the corresponding TX Message Buffer Status Registers are set to 11b and the CFDTMSTSj.TMTSTS and CFDTMCi.TMTR bits are cleared.
   When the TMIE bit in the TX Message Buffer Interrupt Enable Configuration Registers is set (interrupt enabled), the CAN successful transmission interrupt request is generated.
   To clear the related interrupt line, clear the CFDTMSTSj.TMTRF[1:0] bits.
5. Another CAN node is transmitting on the CAN bus (CFDTMSTSj.TMTSTS is not set). If the CFDTMCi.TMTAR bit is set when the related channel is under transmission scan, the transmission request cannot be cleared.
6. After internal processing time, the transmission is aborted and the CFDTMSTSj.TMTRF[1:0] bits are set to 01b.
   If the message buffer is not transmitting or selected as the next transmission message buffer or under transmit scan, then the abort is immediately accepted and the corresponding CFDTMSTSj.TMTRF[1:0] bits in the TX Message Buffer Status Registers are set to 01b.
   In addition, CFDTMCi.TMTR, and CFDTMCi.TMTAR bits are cleared automatically.
   When the transmission abort interrupt enable TAIE bit of the related Channel Control Register is set then an interrupt is generated for successful transmission abort.
   To clear the related interrupt line the CFDTMSTSj.TMTRF[1:0] bits have to be cleared.

Note 1. If arbitration is lost after the CAN channel starts the transmission, the CFDTMSTSj.TMTSTS bit is cleared.

The transmission scanning procedure is performed again to search for the highest priority transmission message buffer from the beginning of the first CRC bit.

If an error occurs, either during transmission, or following the loss of arbitration, then during the error frame, the transmission scanning procedure is performed again to search for the highest priority transmission message buffer.

#### 31.8.2.3 TX FIFO Transmission

One common FIFO buffer is assigned to the CANFD module. The FIFO buffer can be linked to any normal TX message buffer position for this channel with the CFDCFCC.CFTML bits in the Common FIFO Configuration/Control Register if configured in TX mode.

When the transmission scan starts and the FIFO buffer corresponding to this TX message buffer is enabled, the relevant message in the FIFO buffer participates in the transmission scan.

Configuration of a TX message buffer linked to a FIFO buffer configured in TX mode should not be done.

##### (1) TX FIFO Operation

CAN messages can be written into the TX FIFO by writing to the corresponding FIFO Access registers.

When the value 0xFF is written into the corresponding FIFO Pointer Control Register, the message count of the related FIFO is incremented by 1.

Only write to the FIFO Pointer Control register after writing the complete message to the corresponding FIFO Access registers. If the message count matches the FIFO depth, the FIFO Full flag is set.

The oldest message in the TX FIFO is included in the scan for transmission by the corresponding CANFD module channel logic.

When a message is successfully transmitted from the TX FIFO, the message count value is decremented by 1. When all the messages from the FIFO are transmitted, the FIFO Empty flag is set.

The interrupt generation conditions for the TX FIFO buffer can be configured by configuring the CFDCFCC.CFIM bit in the corresponding Common FIFO Configuration/Control Register.

If CFDCFCC.CFIM bit is 0, then an interrupt is generated when the last message is successfully transmitted from the TX FIFO buffer.

If CFDCFCC.CFIM bit is 1, then an interrupt is generated for every successfully transmitted message from the TX FIFO buffer.

The Common FIFO can set interrupt when CAN frame transmission is complete.

The Common FIFO buffer configured in TX Mode can be disabled by clearing the CFDCFCC.CFE bit in the Common FIFO Configuration/Control Register. If this bit is cleared to 0, the FIFO Empty flag is set as follows:

- Immediately if the message from the TX FIFO is neither scheduled for the next transmission nor in transmission
- Following the transmission completion, the detection of an error on the CAN bus, loss of arbitration or transition to Channel or Global Halt mode if the transmission from the TX FIFO is already scheduled for transmission or already in transmission.

Note: The Common FIFO buffer is considered as disabled after clearing the CFDCFCC.CFE bit only when the Empty flag is set for the corresponding Common FIFO buffer.

Other possible messages pending from the TX FIFO are lost and their transmission must be requested again. Before CFDCFCC.CFE is set again, ensure that CFDCFSTS.CFEMP bit is set and that there are no pending aborts from the TX FIFO.

When the CFDCFCC.CFE bit is cleared, the message read and write pointers of the FIFO are cleared and are no longer active. Therefore, all messages in the FIFO buffers are lost and no further message can be stored into the FIFO.

The FIFO transmission request procedure after configuration is shown in Figure 31.45.

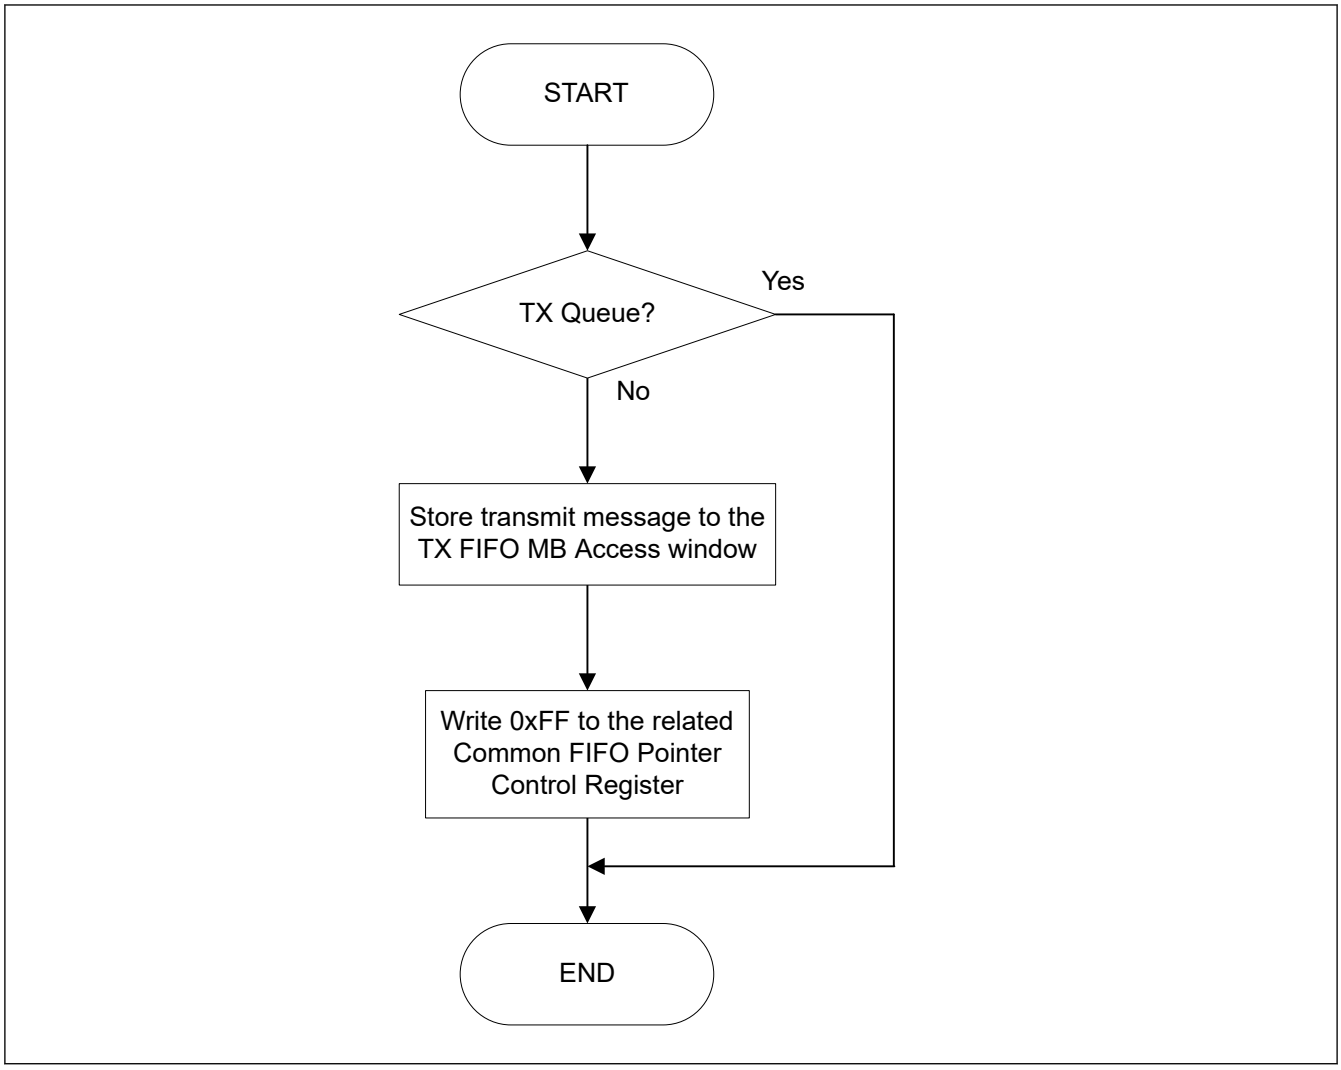

**Figure 31.45 Request procedure for TX FIFO transmission**

### (2) Interval Timer for FIFO Transmission

For each Common FIFO in TX mode, it is possible to specify a delay between two consecutive messages that are configured for transmission from the same FIFO buffer. This delay is called interval time. This interval time starts after the first message has been successfully transmitted from the FIFO buffer after the CFDCFCC.CFE bit is set.

When the Common FIFO in TX mode is enabled, the first message is transmitted without considering this interval time.

The interval timer stops counting when:

- FIFO is disabled by clearing the CFDCFCC.CFE bit.
- CAN channel is in CH_RESET mode.

The interval time is specified by the CFDCFCC.CFITT value from 0 to 255 timer units in the Common FIFO Configuration/Control Register.

The timer unit can be defined based on two different source clocks for the interval timer. To disable the interval timer for FIFO transmission, select a value of 0.

The timer source can be selected with the configuration bit CFITSS in the Common FIFO Configuration/Control Register.

If the CAN channel bit time clock is configured as the clock source, and the CAN channel enters CH_HALT, CH_RESET, or CH_SLEEP mode, the interval timer is stopped for that channel.

If a peripheral clock is selected as the interval timer clock source, the interval timer is stopped only when the CAN channel is in CH_RESET or CH_SLEEP mode.

The reference clock can be used to configure the interval time in fixed time units. It is based on the peripheral clock. The reference clock prescaler value CFDGCFG.ITRCP in the Global Configuration Register defines the relation between the peripheral clock frequency/period and the reference clock period.

See Table 31.29 for CFDGCFG.ITRCP configuration values to achieve different reference clock periods based on the peripheral clock frequency and period.

**Table 31.29 Configuration example for the reference clock of the FIFO interval timer**

| Reference clock/Peripheral clock | 1 µs | 100 µs | 500 µs |
|---|---|---|---|
| 16 MHz/62.5 ns | 16 | 1600 | 8000 |
| 20 MHz/50 ns | 20 | 2000 | 10000 |
| 32 MHz/31.25 ns | 32 | 3200 | 16000 |
| 50 MHz/20 ns | 50 | 5000 | 25000 |

The reference clock resolution can be specified by the interval timer reference clock resolution value CFDCFCC.CFITR in the Common FIFO Configuration/Control Register.

The interval time is based on the reference clock period multiplied by the configured value (x1 or x10). The reference clock based interval timer can be used to satisfy the requirements of the ISO 15765-2 Separation Time. The whole range for the separation time from 100 µs to 127 ms can be covered.

The specified interval time starts after successful transmission event (after EOF7 state of the CAN protocol).

When the interval time has elapsed, the next transmission request is raised by the related TX FIFO. Therefore, the interval time defines the minimum time between two messages transmitted from one FIFO.

The next message is sent at the earliest after this interval time. Figure 31.46 shows an example timing of the internal processing.

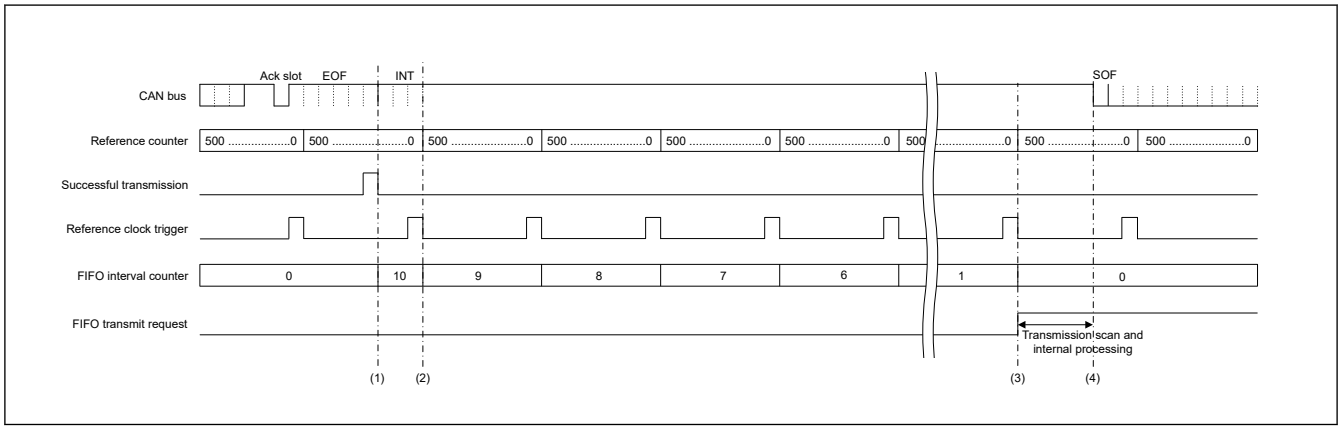

**Figure 31.46 Example for interval processing time**

The configuration for the timing in Figure 31.46 is as follows:

- Peripheral clock frequency = 50 MHz
- Interval timer reference clock (CFDGCFG.ITRCP) = 500 times
- Reference clock from the settings in Figure 31.46 = 10 µs
- Common FIFO interval timer source selection (CFDCFCC.CFITSS) = 0
- Common FIFO interval timer resolution (CFDCFCC.CFITR) = 0
- Common FIFO interval transmission time (CFDCFCC.CFITT) = 10 times
- Theoretical message separation interval = 100 µs

1. The internal FIFO interval timer is restarted with the occurrence of successful transmission result. This restart is not synchronized to the reference clock trigger. Therefore, the first interval is counting less or equal to 1 reference clock interval.
2. With the next reference clock trigger the FIFO interval timer is decremented.

3. When the FIFO interval timer reached the value 0, the FIFO transmit request is set.
4. When the FIFO is selected for transmission, the transmission starts. Due to internal processing, this usually takes less than 3 CAN bit time, between the internal FIFO transmit request set in step 3. and the actual transmission.

In the worst case when multiple events such as a reception scan, an internal message routing, a transmit scan on all channels occur, it can take up to 120 peripheral clock cycles.

As shown in Figure 31.46, it is not guaranteed that the minimum interval is always equal to the configured value. If a minimum time must never be breached, configure CFDCFCC.CFITT to the required minimum value plus 1.

If additional TX message buffers or TX FIFO are configured for transmission of the same channel, the real delay between two messages transmitted from a TX FIFO can be much longer than specified by the interval time. This is due to higher priority message transmission from these TX message buffers or TX FIFO.

Figure 31.47 shows a block diagram of the FIFO interval time generation circuit.

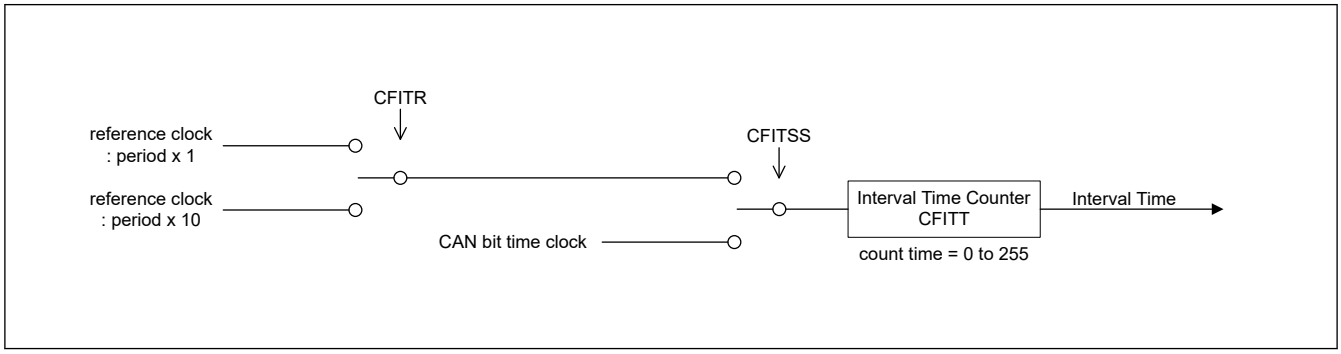

**Figure 31.47 Block diagram of FIFO interval timer**

### 31.8.2.4 TX Queue

Each enabled TX Queue for a specific channel consists of 3 to 4 TX message buffers, which are accessed through one access window.

- The first TX Queue can be configured with a depth of three up to four buffers and uses TX Message Buffer No. 0 as access window (referred to as TXQ)

All the TXQ messages enter the priority comparison for the transmission, which should be only ID Priority (CFDGCFG.TPRI = 0).

The registers for TXQ are:

- CFDTXQCC
- CFDTXQSTS
- CFDTXQPCTR

See related access registers TX Message Buffer ID Registers (TMID[m]), TX Message Buffer Pointer Registers (TMPTR[m]), TX Message Buffer Data Field 0 Registers, and TX Message Buffer Data Field 1 Registers (TMDF[0:1][m]) when access window TXQ0 is used.

The depth of each TXQ buffer can be configured by writing to the CFDTXQCC.TXQDC[1:0] bits of the TX Queue Configuration/Control Register. TXQ can be set from TXMB0 to TXMB3 as a queue buffer at the maximum.

The 4 available options for the depth configuration of TXQ buffer are:

- 0x00: TX Queue disabled
- 0x01: reserved
- 0x10: 3 Messages
- 0x11: 4 Messages

Do not access all the TX message buffers forming the TX Queue directly (except TX Message Buffer No. 0, which act as TX Queue access window).

When a system writes in TXQ, it writes in send data, after checking the state of TXQ.

Do not access or configure the related TX Message Buffer Control Registers.

The messages stored to the TX Queue access window are internally stored to a free buffer of the TX Queue.

When the buffer is full, no further access should be done to the queue, until it is no longer full. If access is a software write when the buffer of TXQ is full, send data is overwritten.

The TX Queue can be disabled by clearing the TXQE bit in the TX Queue Configuration/Control Register. If this bit is cleared, the TX Queue Empty flag is set as follows:

- Immediately if the message from the TX Queue is neither scheduled for the next transmission nor in transmission
- Following the transmission completion, the detection of an error on the CAN bus, loss of arbitration or transition to Channel or Global Halt mode if the transmission from the TX Queue is already scheduled for transmission or already in transmission.

Note: The TX Queue is disabled only when the Empty flag is set after clearing the TXQE bit for the corresponding TX Queue.

Other possible messages pending from the TX Queue are lost and their transmission must be requested again.

Before TXQE is set again, ensure that the CFDTXQSTS.TXQEMP bit is set and that there is no pending abort from the TX Queue.

When the TXQE bit is cleared, all messages in the TX Queue buffers are lost and no further message should be stored in the TX Queue.

When a message has been stored to the TX Queue, write 0xFF in the TX Queue Pointer Control Register. This sets the transmit request automatically and changes the internal message buffer pointer to the next free message buffer location of the TX Queue.

Note: If two messages with the same ID are stored in the TX Queue, the order of transmission of these messages can be different from the order in which they were stored in the TX Queue.

To avoid this condition, it is important to confirm that the previous message with the same ID was successfully transmitted before a new message with the same ID is stored in the TX Queue.

For the TX Queue, a dedicated interrupt can be enabled by setting the TXQIE bit of the TX Queue Configuration/Control Register.

The interrupt mode can be configured with the CFDTXQCC.TXQIM bit of the same register either to generate an interrupt for every transmitted message or for the last transmitted message.

The TX Queue transmission request procedure after configuration is shown in Figure 31.48.

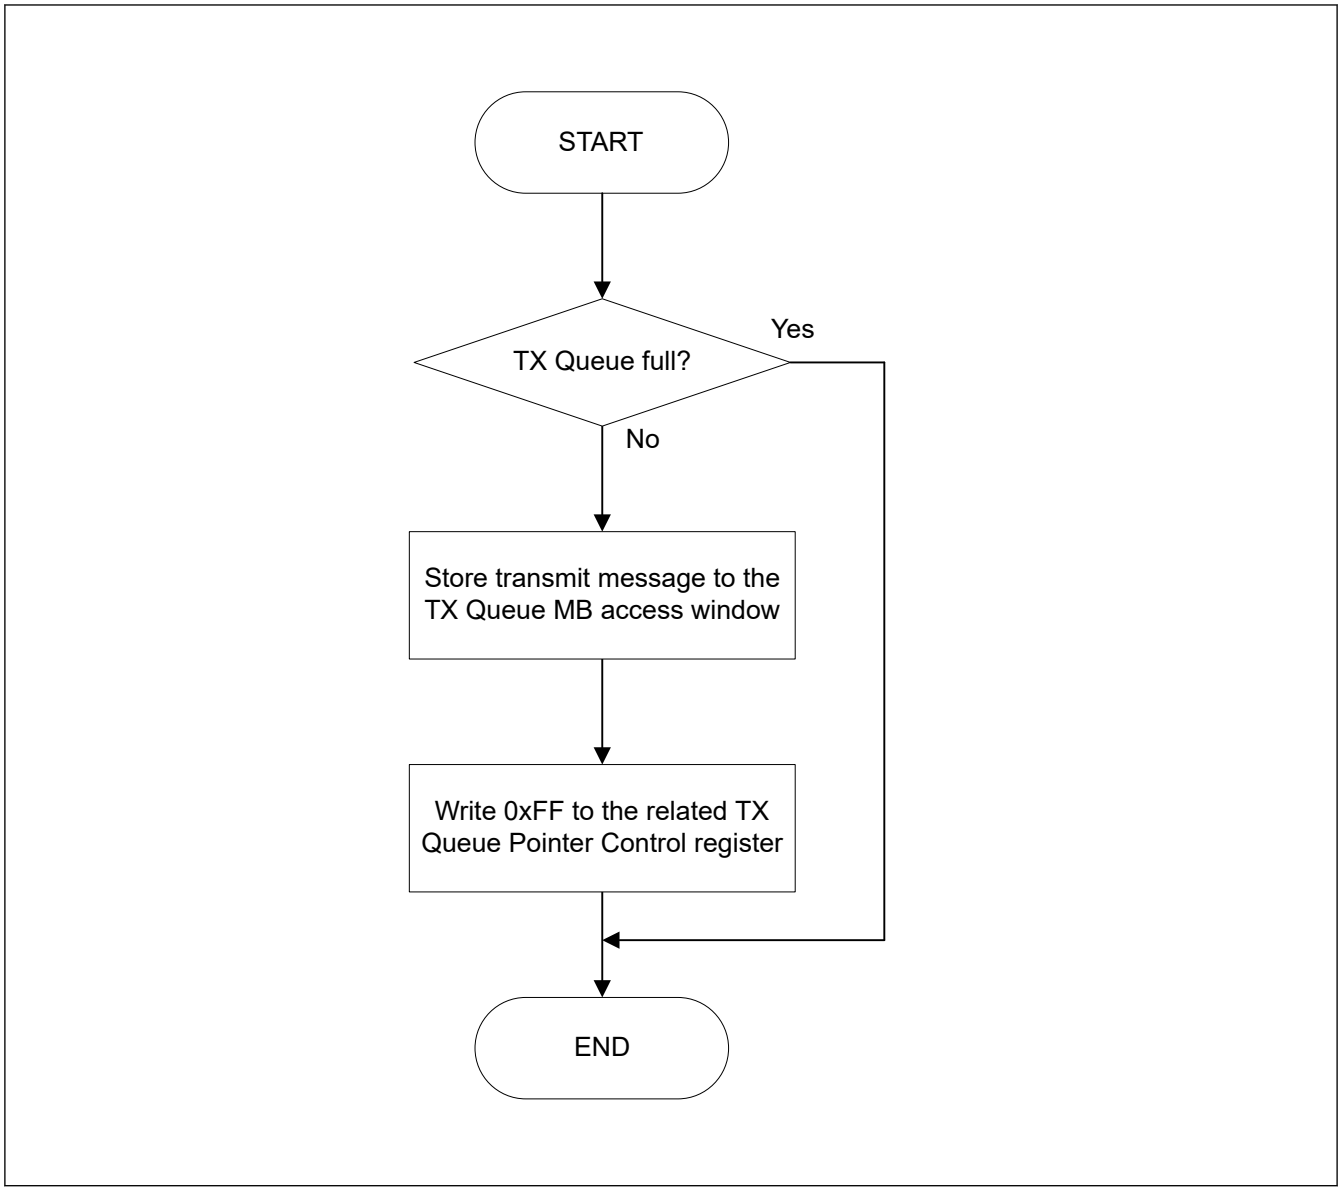

**Figure 31.48 TX Queue transmission request**

### 31.8.2.5 TX History List

The TX History List function records the information of the successfully transmitted message in the TX History List Buffers. Two TX History List buffers are provided and the THL buffer can store up to 8 TX History List entries.

The CFDTHLCC.THLDTE bit of the TX History List Configuration/Control Register can be used to configure if only message information from TX FIFO or TX Queue is stored, or if all transmit message information from TX Queue, TX FIFO, or normal TX message buffers is stored in the TX History List.

Each transmit message can be individually configured for acceptance to the TX History List with the CFDCFID.THLEN bit in the Message Buffer Pointer Register.

The message information is stored to the TX History List Buffer of a CAN channel after the message is successfully transmitted.

Storing to the list is not synchronized with the status of CFDTMSTSj.TMTRF[1:0] bits in the TX Message Buffer Status Register.

Due to internal processing, the storage to the list can occur with a delay after the successful transmission indication.

Storing the TX History List data can be recognized by the condition that the THLIF is set to 1 when the THLIE bit is configured to 1 or when the TX History List counter CFDTHLSTS.THLMC[5:0] is increased.

Under worst-case conditions, where multiple events such as reception scan and internal message routing are triggered, the delay from setting CFDTMSTSj.TMTRF to storing TX History List data can reach up to 70 peripheral bus clock cycles.

The History list records the following information of a transmitted message:

- Buffer type:
  - 001: TX Message Buffer
  - 010: TX FIFO
  - 100: TX Queue
- Buffer number:
  TX message buffer, TX Queue message buffer or TX message buffer link for the Common FIFO buffer from which transmission occurred. The number depends on the buffer type. See Table 31.30.
- Transmission ID:
  Transmission pointer stored in the transmission message
- Transmit timestamp:
  Message timestamp captured at the capture point as configured by CFDGFDCFG.TSCCFG.
- Transmission information label:
  Transmission information label stored in the transmission message.

**Table 31.30 TX History List Buffer number entry**

| Buffer Number | BT[2:0] Buffer Type | | |
|---|---|---|---|
| | 001b TX Message Buffer | 101b TX FIFO | 100b TX Queue |
| 00b | Message Buffer 0 | Number shown corresponds to the common FIFO. TX Message Buffer Link CFTML of the related Common FIFO configuration | Number shown corresponds to the Message Buffer belonging to the TX Queue which the frame was transmitted |
| 01b | Message Buffer 1 | | |
| 10b | Message Buffer 2 | | |
| 11b | Message Buffer 3 | | |

The Transmission ID entry is used to identify which message of a TX FIFO or TX Queue has been successfully transmitted because the TX FIFO or TX Queue number alone is not sufficient.

Therefore, a unique number can be attached to each transmission message stored in a TX FIFO or TX Queue. This unique identification number should be written to the CFDCFFDCSTS.CFPTR[15:0] part of the Common FIFO Access Pointer Register for a TX FIFO or to the CFDTMFDCTRb.TMPTR[15:0] part of the TX Message Buffer Pointer Register of the TX Queue access window message buffer.

When the message is successfully transmitted, this identification number is stored together with the other message-related information to the TX History List and can be read using the Transmission ID (TID) of the TX History List Access Register.

Also, for normal TX message buffers, the CFDTMFDCTRb.TMPTR[15:0] part of the TX Message Buffer Pointer Register is stored in the Transmission History List and the information label is the same.

Figure 31.49 shows a transmission preparation flow when TX History List is used.

Read access to the TX History List Access Register is done for every single entry.

After reading one entry, 0xFF must be written to the corresponding TX History List Pointer Control Register to be able to access the next entry until TX History List is empty.

Figure 31.50 shows an example flow for processing the TX History List information.

The TX History Lists have dedicated interrupts, which can be configured with the CFDTHLCC.THLIM bit of the corresponding TX History List Configuration/Control Register and enabled with the CFDTHLCC.THLIE bit of the same registers, either to generate an interrupt when the History List reached a filling level of 75% or for every new TX History List entry.

An entry lost indication is flagged by the CFDTHLSTS.THLELT bit in the TX History List Status Register. The status of this bit is also shown by the THLES bit in the Global Error Flag Register.

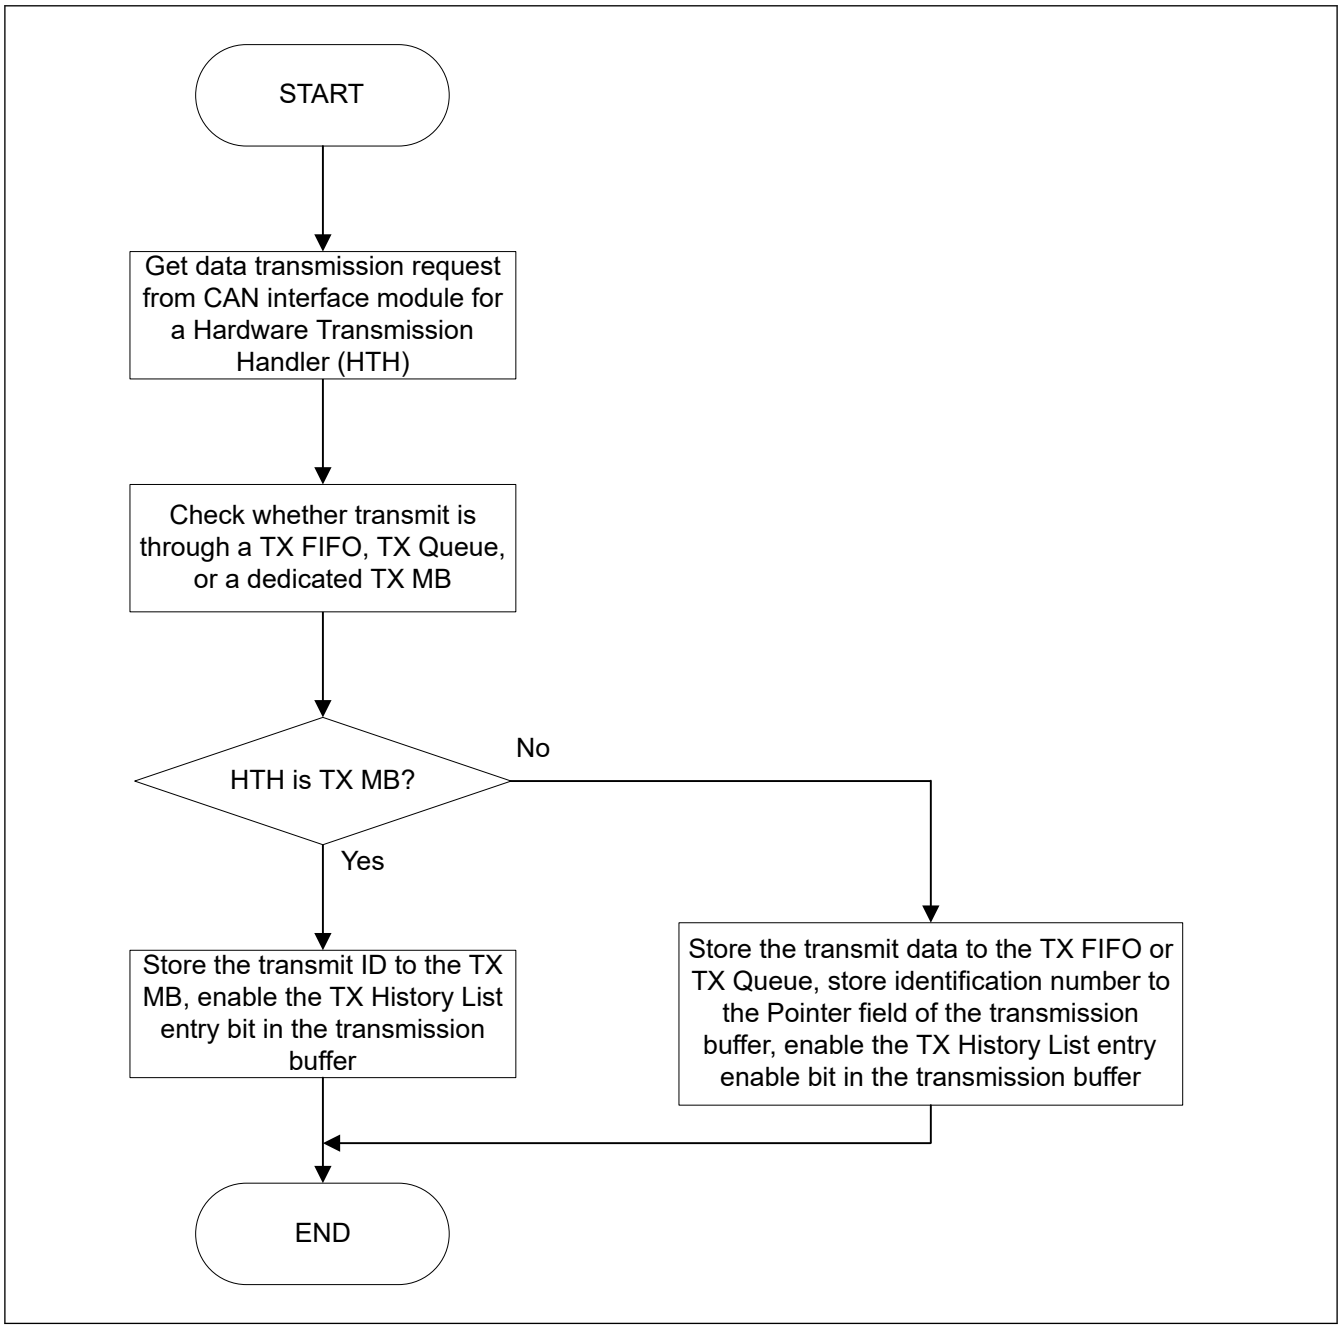

**Figure 31.49 TX History List preparation flow**

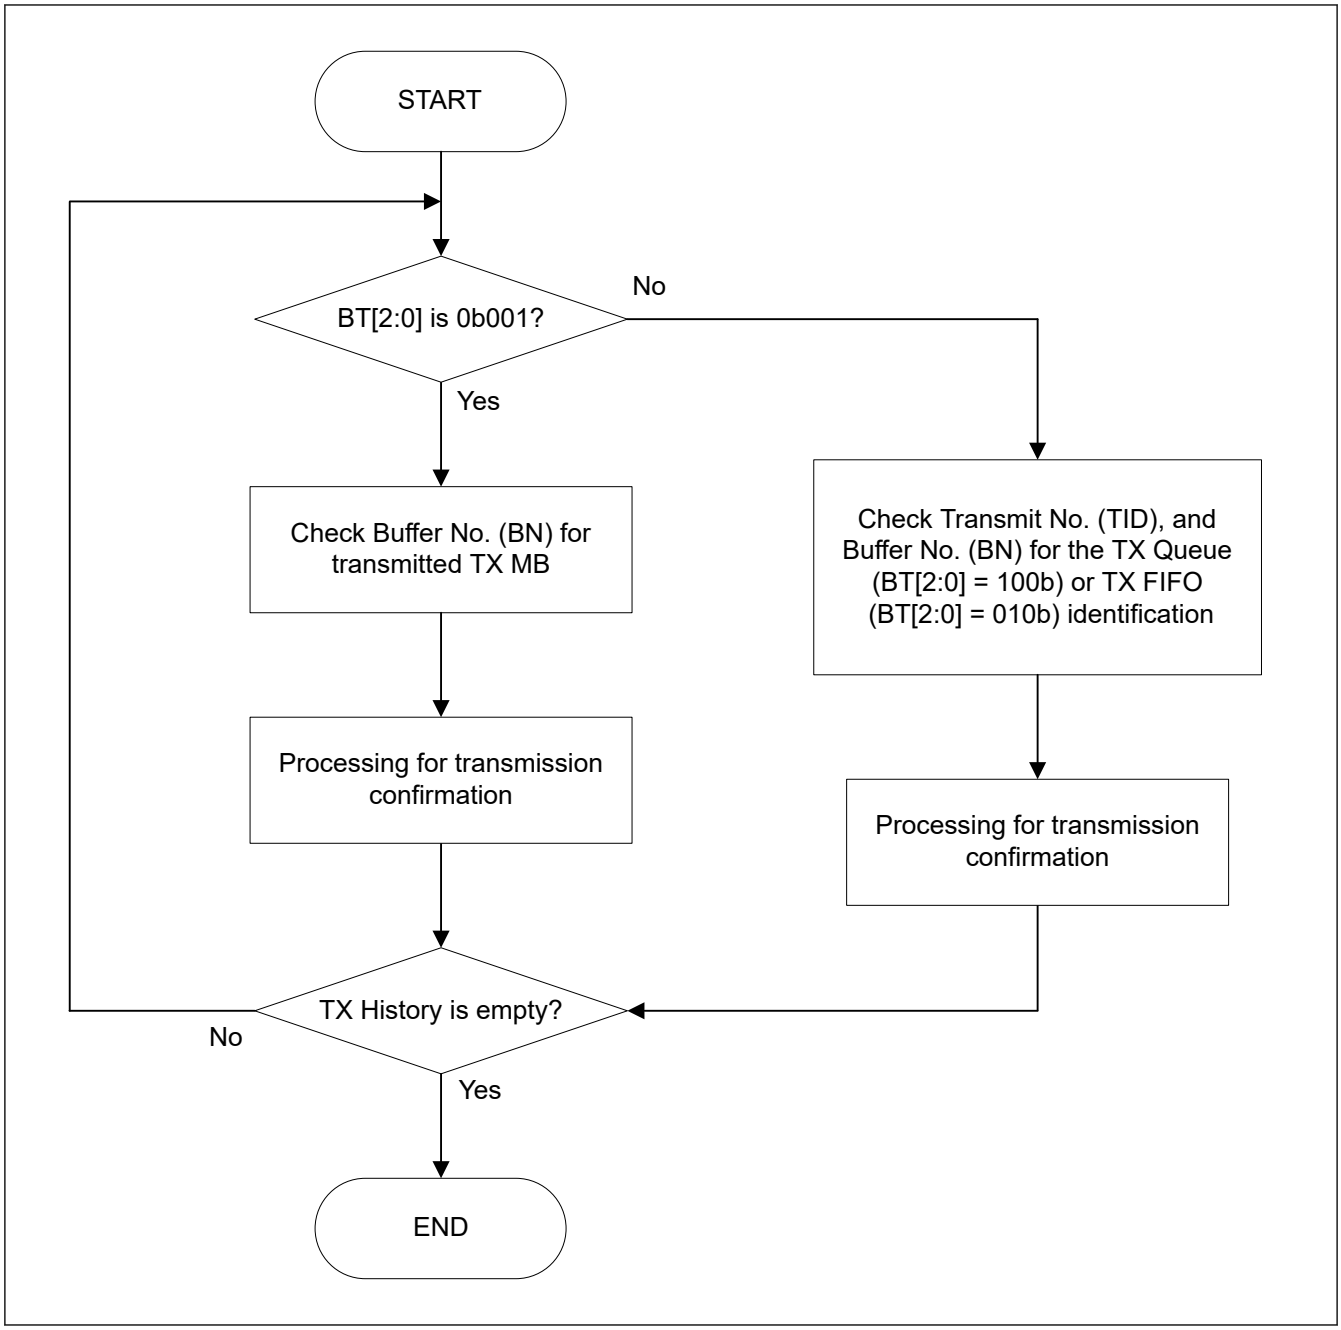

**Figure 31.50 TX History List processing flow**

### 31.8.2.6 TX Data Padding

This chapter is not valid for classical CAN.

If the data length code (DLC) of the transmitting message has a higher number of data bytes than the buffer size, the data bytes beyond the restricted range are replaced by bytes with the value of 0xCC.

This can happen for Common FIFO configured as (TX mode) when the transmit message DLC is higher than the CFDCFCC.CFPLS.

This can also happen in FD only mode, if a Classical frame is configured with a DLC bigger than 8.

## 31.9 Test Mode

The CANFD module can be configured into test modes to allow testing of certain features. These features are provided only for special purposes and care must be taken when configuring the CANFD module in test modes.

Note: All test modes are mutually exclusive unless it is explicitly stated that some functions can be enabled across other test modes.

Do not enable any combination of the various test modes specified in this section.

The test modes can be broadly split into 2 groups:

- Channel specific test modes
- Global test modes.

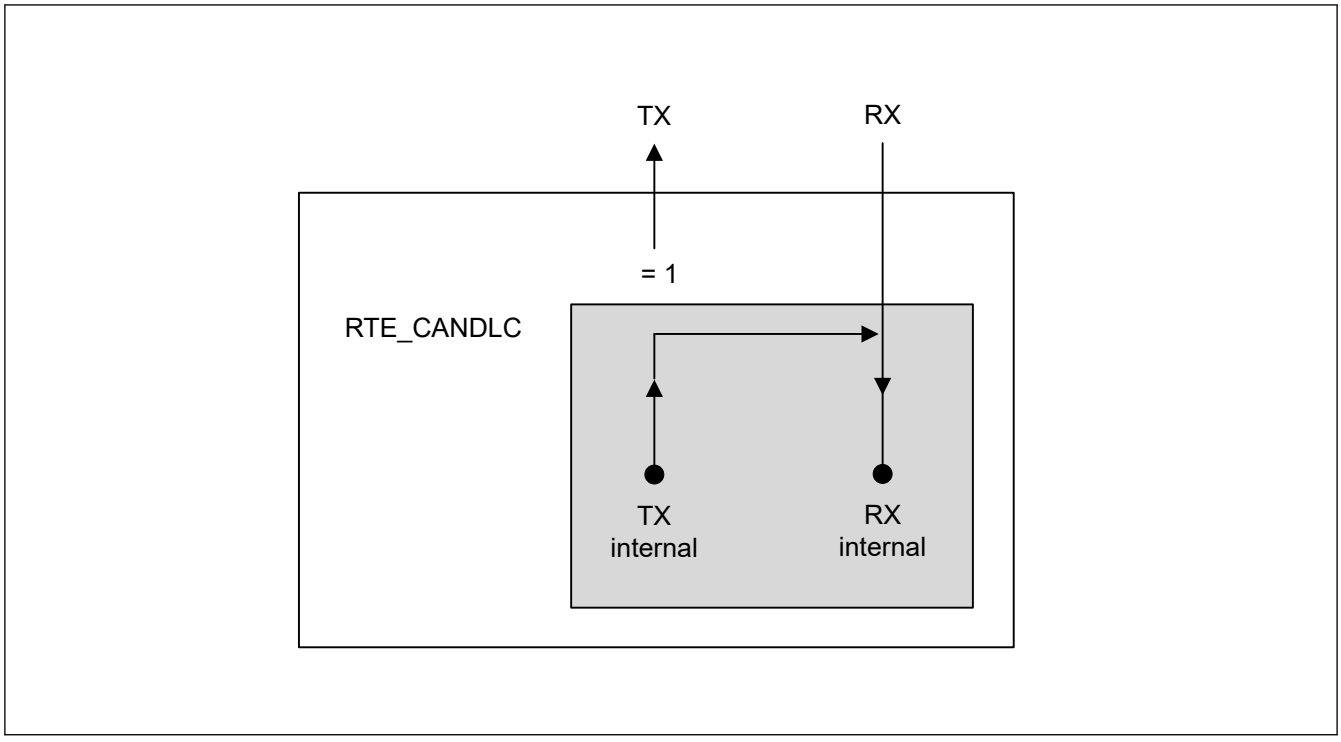
### 31.9.1 Channel Specific Test Modes

CAN channel can be configured into the following test modes:

- Basic test mode
- Listen-only mode
- Self-test mode 0 (External loop back mode)
- Self-test mode 1 (Internal loop back mode)
- Restricted operation mode.

#### 31.9.1.1 Basic Test Mode

The basic test mode should be used when there is requirement for a particular test setting to be enabled other than when in Listen-only and Self-test modes.



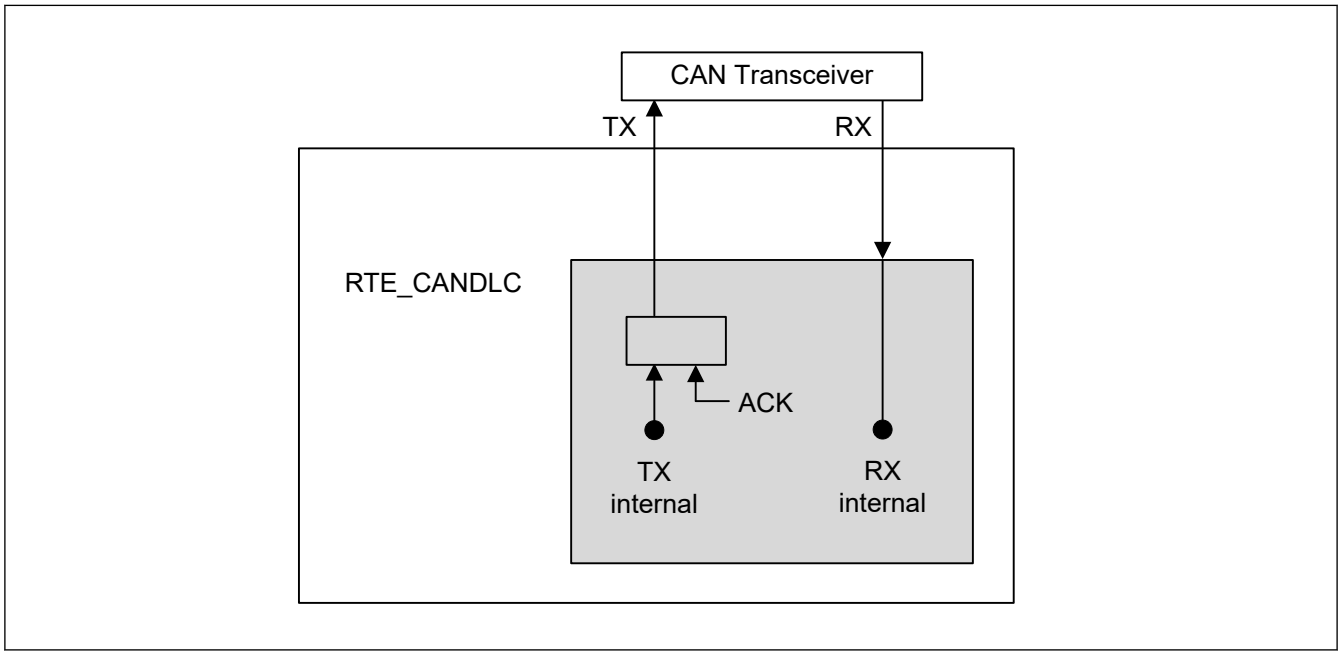
#### 31.9.1.2 Listen-only Mode

The ISO 11898-1 recommends an optional bus-monitoring mode. In this mode, the CAN channel is able to receive valid data frames and valid remote frames. However, it sends only recessive bits on the CAN bus and is not allowed to transmit.

If the CAN engine is required to send a dominant bit (ACK bit, overload flag, active error flag), the bit is routed internally so that the CAN engine monitors this as dominant. The external TX pin remains in recessive state.

This mode can be used for baud rate detection. In this mode, an error interrupt is generated if a bus error occurs and the interrupt is enabled.

In this mode, it is not permitted to request transmission from any normal TX message buffer or TX FIFO.

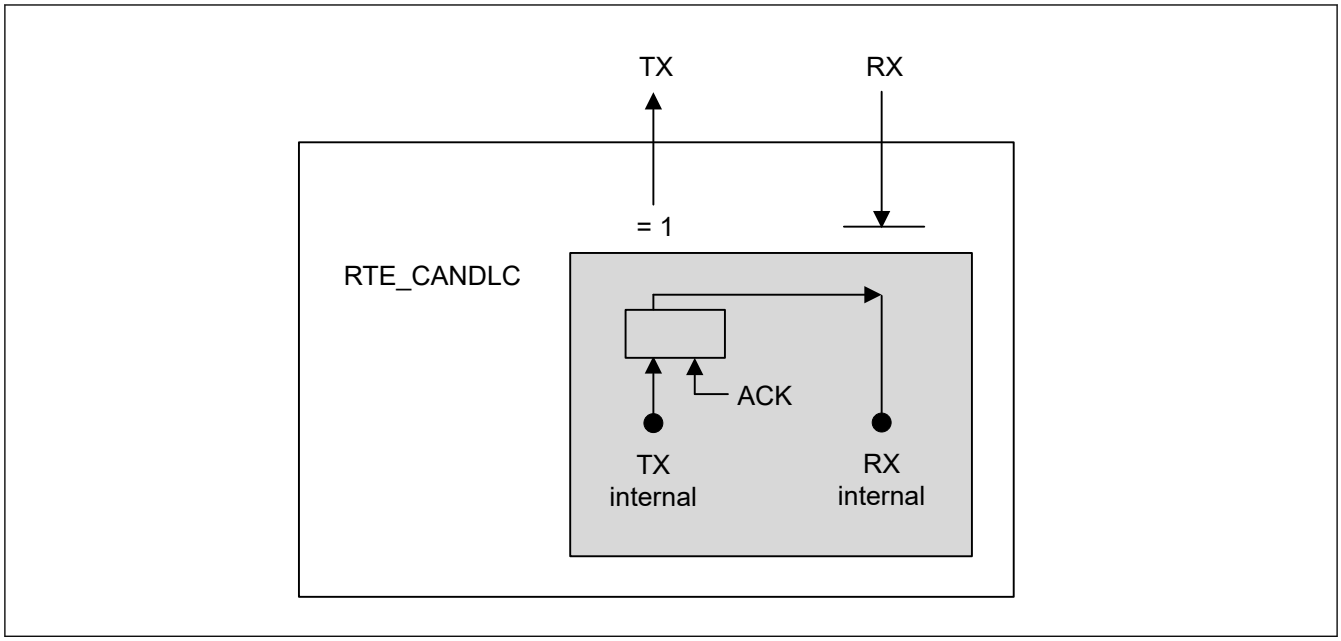


### 31.9.1.3 Self-test Mode 0 (External Loopback Mode)

In Self-test mode 0, the CAN engine treats its own transmitted messages as received messages through the CAN transceiver and stores them into its receive message buffers.

To be independent of external stimulation, the engine generates its own Acknowledge bit.

This test can be used for CAN transceiver tests and the RX/TX pins should be connected to the transceiver.



### 31.9.1.4 Self-test Mode 1 (Internal Loopback Mode)

In Self-test mode 1, the CAN engine treats its own transmitted messages as received messages and stores them into the receive buffer. This mode is provided for self-test functions. To be independent of external stimulation, the CAN engine generates its own Acknowledge bit. In this mode the CAN engine performs an internal feedback from TX internal to RX internal. The actual value of the external RX input is disregarded by the CAN engine.

The external TX pin outputs only recessive bits. The RX/TX pins do not need to be connected to the CAN bus or any external device.

Note: The channel pins are also disconnected from the internal CAN bus communication line.

#### 31.9.1.5 Restricted Operation Mode

This chapter is not valid for classical CAN.

In Restricted operation mode, the CAN node is able to receive valid data and remote frames generating the Acknowledge bit.

Active error or overload frames cannot be transmitted, instead it waits for the occurrence of bus idle condition to resynchronize itself to the CAN communication after an error or overload condition occurs.

Additionally, the Receive and Transmit Error Counter (REC and TEC) are frozen independently from the occurrence of errors. The mode is specified in ISO 11898-1 and the setting of transmit request is permitted.

### 31.9.2 Global Test Modes

The CANFD module can be configured into the following test modes:

- RAM test mode
- Bit Flip Test

The test modes in the following table are protected by a special software procedure to enable the mode. This software procedure enables write access to the test mode by a specific unlock key as shown in the table.

| Test mode | Unlock key 1 | Unlock key 2 |
|---|---|---|
| RAM test mode | 0x7575 | 0x8A8A |

If the software sequence of the two consecutive unlock key write accesses (half-word or word access) is interrupted by any other write access to the register or if incorrect data is written to the Global Unlock Key Register, the corresponding test mode cannot be set and the sequence must be restarted.

After the two unlock key write accesses, the next write access should be to set the corresponding test mode enable bit. If this is not followed, the unlock mechanism reset and the test mode enable bit cannot be set and the unlock sequence must be restarted.

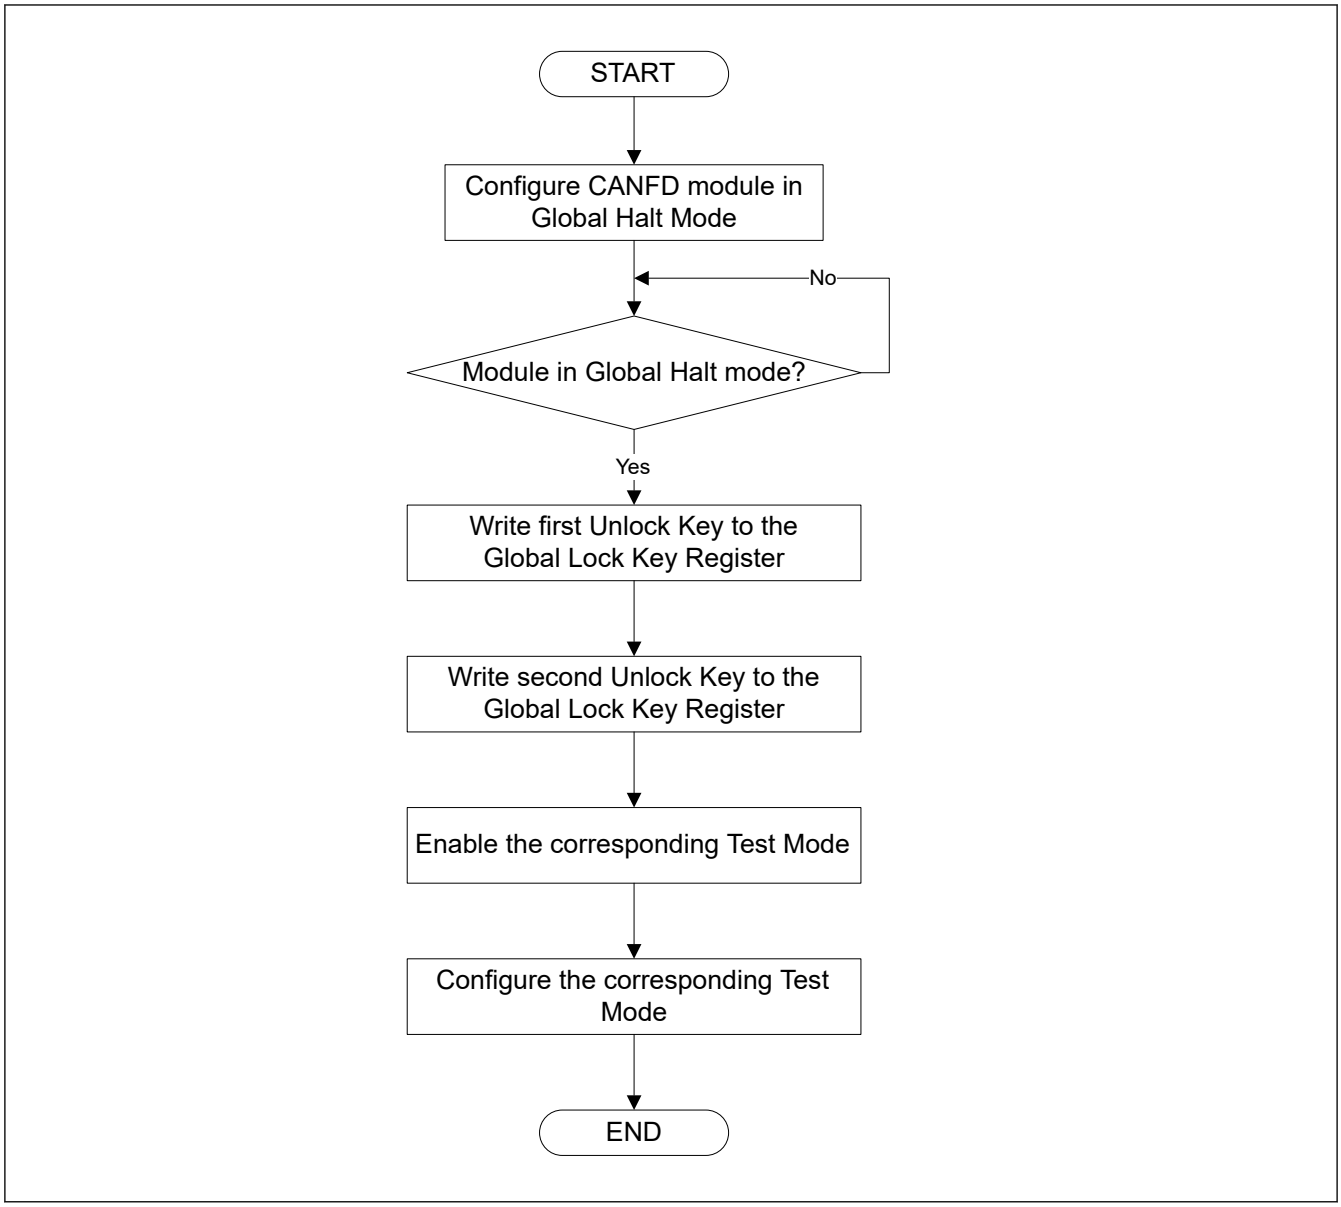


**Figure 31.51 Unlock software protection routine**

### 31.9.2.1 RAM Test Mode

The CANFD module can be configured in RAM test mode by setting the CFDGTSTCTR.RTME bit in the Global Test Control Register when the corresponding lock key is previously written. This is a special test mode, in which, the complete RAM area can be accessed.

Note: The actual RAM size is bigger than the RAM area initialized after a hardware reset. Therefore, ECC error flag (of the ECC macro) may be set if CPU reads data from this uninitialized RAM area while CANFD module is in RAM test mode.

In this mode, the RAM area is split into number of pages (pn) of 256 bytes, each which can be accessed with the CFDRPGACCk register.

The page should be selected for read/write access by writing to the CFDGTSTCFG.RTMPS[3:0] bits in the Global Test Control Register. Data can then be read from or written in to the RAM Test Page Access Registers.

Figure 31.52 shows the structure of the pages in the RAM when performing a RAM test mode.

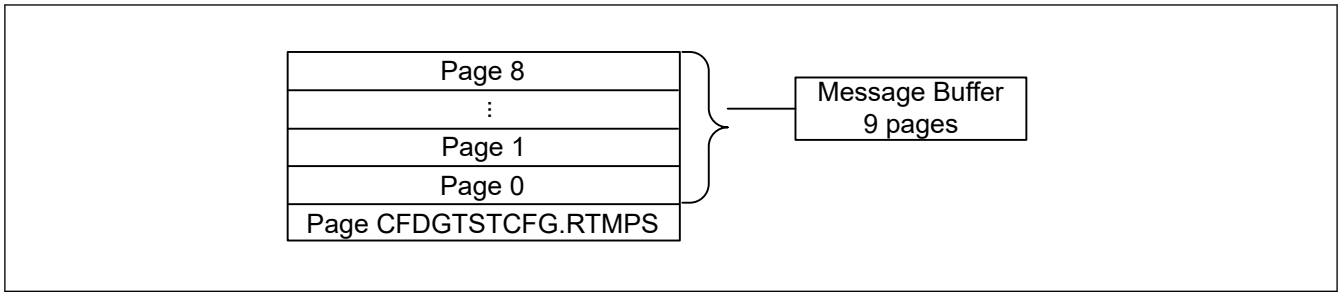

**Figure 31.52 RAM page structure**

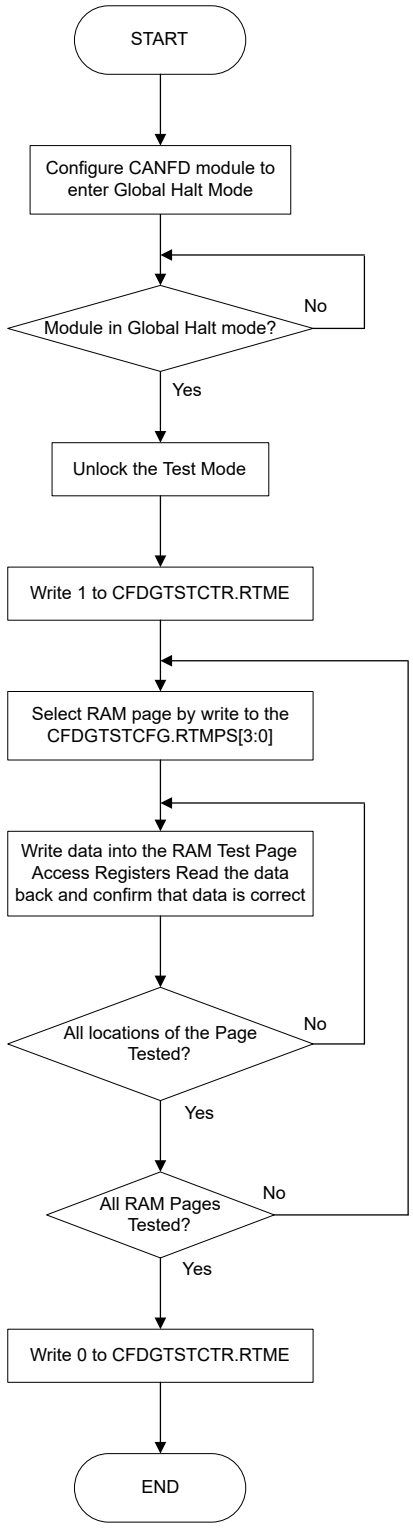

The total available RAM size is 2072 bytes for the Message Buffer RAM.

The pn and CFDGTSTCFG.RTMPS[3:0] values for the MB RAMs are calculated in the following way:

pn = ceil (total RAM size in bytes / number of bytes per page)

- MB RAM:
  pn = ceil (2072 / 256) = 9 pages
  CFDGTSTCFG.RTMPS[3:0] = 0 to 8 inclusive

Figure 31.53 shows the software flow for RAM test mode.

Note 1. Change into the following status before changing to RAMTEST.
- Cancel of a request for transmission.
- Disable of all the FIFO and TXQ.
- Clear of the receiving flag for a receiving buffer.

**Figure 31.53 Software flow for RAM test mode**

To exit this test mode, the CFDGTSTCTR.RTME bit must be cleared. The CFDGTSTCTR.RTME bit is cleared by writing 0 to it.

The CFDGTSTCTR.RTME bit is cleared automatically when the CANFD module enters Global Reset mode from the test mode.

#### 31.9.2.2 Bit Flip Test

Bit Flip Test can invert the bit (the 1st bit of ID) of the beginning of the bit stream to receive.

If this function is used by a transmitting node, a bit error or an arbitration lost will occur.

If this function is used by a receiving node, a CRC error or a stuff error will occur.

Users should refer to the bit stuffing rule when using this feature, as there is the possibility of receiving a stuff error (due to the inversion) rather than a CRC error.

The following sequence should be used to perform CRC Error testing. In the sequence below CANFD module is the receiver.

1. Set the CFDC0CTR.BFT bit to 1, in order to invert the first bit of the incoming bit stream from sending node
2. Wait for the CANn_CHERR (n = 0) output signal to set to 1
3. Read either the CFDC0ERFL.CRCREG or the CFDC0FDCRC.CRCREG (depending on the received frame type: Classical or FD). The value should be different from the received CRC value of the reference message from sending node.
4. Check that CFDC0ERFL.CERR is 1

As the CRC generator logic is shared for RX and TX there is no need to create a separate TX CRC Error test.

## 31.10 Usage notes

### 31.10.1 Module-stop function

CANFD operation can be disabled or enabled using Module Stop Control Register C (MSTPCRC). The CANFD module is initially stopped after reset. Releasing the module-stop state enables access to the registers. For details, see section 10, Low Power Modes.

# 32. CANFD ECC (CNECC)

## 32.1 Overview

The MBRAM has ECC function of 2-bit ECC error detection and 1-bit ECC error detection and correction*1. The ECC module adds 7-bit ECC data to 32-bit RAM data.

Note 1. The ECC module cannot detect 3 or more bit errors. It can, however, detect 1-bit or 2-bit error, but does not detect errors or correct erroneous bit to erroneous data by setting. When all RAM data is fixed to 0 or 1, it is detected as 2-bit ECC error.

## 32.2 Register Descriptions

### 32.2.1 EC710CTL : ECC Control Register

Base address: ECCMB = 0x4012_F000

Offset address: 0x00

| Bit position: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

| 31:18 | — | These bits are read as 0. The write value should be 0. | R/W |

### ECEMF bit (ECC Error Message Flag)

The ECEMF bit shows that there is error in the present read data bus. This bit is updated by every RAM output data.

When RAM output data is undefined and the ECERVF bit is set to 1, the value of this bit is undefined.

[Setting condition]

There is a bit error in the present RAM output data under the condition that error detection is enabled.

[Clearing conditions]

- Under the condition that there is no 1-bit error in input data to decode circuit
- When ECC error detection is disabled (ECERVF = 0).

### ECER1F bit (1-bit ECC Error Detection and Correction Flag)

The ECER1F bit shows that the bit errors are detected in one part of the RAM read data [38:0] at RAM read access when error detection is enabled.

When the 1-bit error interrupt output is enabled, error interrupt is generated by setting this flag.

This bit is read-only, so writing 1 or 0 has no effect.

To clear this bit, write 1 to the ECER1C bit.

When 1-bit error is detected again under the condition that this bit is set, the interrupt is not generated.

[Setting condition]

- When error detection is enabled and there is 1-bit error in the RAM output data (when not setting ECER1C = 1).

[Clearing conditions]

- Writing ECER1C = 1
- When ECC error detection is disabled (ECERVF = 0).

### ECER2F bit (2-bit ECC Error Detection Flag)

The ECER2F bit shows that the bit errors are detected in two parts of the RAM read data [38:0] at RAM read access when the error detection is enabled.

When the 2-bit error interrupt output is enabled, error interrupt is generated by setting this flag.

This bit is read-only, so writing 1 or 0 has no effect.

To clear this bit, write 1 to the ECER2C bit.

When 2-bit error is detected again under the condition that this bit is set, the interrupt is not generated.

[Setting condition]

- When error detection is enabled and there is 2-bit error in the RAM output data (when not setting ECER2C = 1).

[Clearing conditions]

- Writing ECER2C = 1
- When ECC error detection is disabled (ECERVF = 0).

### EC1EDIC bit (1-bit ECC Error Detection Interrupt Control)

The EC1EDIC controls the interrupt output at detecting 1-bit error. By setting 1 to this bit, the 1-bit error interrupt is outputted when 1-bit error detected.

### EC2EDIC bit (2-bit ECC Error Detection Interrupt Control)

The EC2EDIC controls the interrupt output at detecting 2-bit error. By setting 1 to this bit, the 2-bit error interrupt is output when 2-bit error is detected.

### EC1ECP bit (1-bit ECC Error Correction Permission)

The EC1ECP sets the permission to correct the 1-bit error when ECC error detection and correction is valid. By setting 1 to this bit, the non-corrected data is output if 1-bit error is detected.

### ECERVF bit (ECC Error Detection Enable)

Setting the ECERVF bit to 1 enables the detection of error. The correction of output data and the interrupt output depend on setting of the EC1ECP bit, EC2EDIC bit, and EC1EDIC bit.

The write access to this bit is valid when the write value of the EMCA[1:0] is 01b. So only the 16 bits or 32 bits operation command is valid for write access to this bit.

### ECER1C bit (Accumulating ECC Error Detection and Correction Flag Clear)

The ECER1C bit clears the status flag of the ECER1F bit.

The read value is always 0. By writing 0, the internal condition is not changed. When the competition between writing 1 to this bit and setting the ECER1F bit, the former has priority.

The ECER1F bit is cleared by writing 1 to this bit while the ECER1F bit is set. Additionally, the Overflow Detection flag (ECOVFF), ECC Dual Bit Error flag (ECDEDF0) and ECC Single Bit Error flag (ECSEDF0) are also cleared.

### ECER2C bit (2-bit ECC Error Detection Flag Clear)

The ECER2C bit clears the status flag of the ECER2F bit.

The read value is always 0. By writing 0, the internal condition is not changed. When the competition between writing 1 to this bit and setting the ECER2F bit, the former has priority.

The ECER2F bit is cleared by writing 1 to this bit while the ECER2F bit is set. Additionally, the Overflow Detection flag (ECOVFF), ECC Dual Bit Error flag (ECDEDF0), and ECC Single Bit Error flag (ECSEDF0) are also cleared.

### ECOVFF bit (ECC Overflow Detection Flag)

The ECOVFF bit is set and the overflow interruption is output by detecting the new error address under the condition that error address is already captured in the EC710EAD0 register. The overflow interrupt is output again when this bit is set and new error is detected.

This bit is read-only, so writing 1 or 0 has no effect.

To clear this bit, write 1 to the ECER2C bit and the ECER1C bit.

[Setting condition]

- When new error address is captured under the condition that error address is already captured in the EC710EAD0 register (when not setting ECER2C = 1 or ECER1C = 1).

[Clearing conditions]

- Writing ECER2C = 1 or ECER1C = 1
- When ECC error detection is disabled (ECERVF = 0).

### EMCA[1:0] bits (ECC Error Detection Enable Access Control)

The EMCA[1:0] bits are the write trigger reserved bits for the ECERVF bit. The read value is always 0. When the value of these bits is 01b, it is possible to have write access to the ECERVF bit. If these bits are not 01b, write access to the ECERVF bit is ignored and the value is not written.

### ECSEDF0 bit (1-bit ECC Error Address Detection Flag)

The ECSEDF0 bit shows that the error is captured in the error address register when error detection is valid. This bit is set by 1-bit error detection.

When 1-bit error is detected after the 2-bit error address is already captured in the EC710EAD0 register, this bit is not updated but the EC710EAD0 register is updated.

This bit is read-only, so writing 1 or 0 has no effect. To clear this bit, write 1 to the ECER1C bit.

[Setting condition]

- When there is 1-bit error in the RAM output data and error address is captured in EC710EAD0 under the condition that the error detection is permitted (when not setting ECER1C = 1).

[Clearing conditions]

- Writing ECER1C = 1
- When ECC error detection is disabled (ECERVF = 0).

### ECDEDF0 bit (2-bit ECC Error Address Detection Flag)

The ECDEDF0 bit shows that the error is captured in the error address register when error detection is valid. This bit is set by 2-bit error detection.

When 2-bit error is detected after the 1-bit error address is already captured in the EC710EAD0 register, this bit is not updated but the EC710EAD0 register is updated.

This bit is read-only, so writing 1 or 0 has no effect. To clear this bit, write 1 to the ECER2C bit.

[Setting condition]

- When there is 2-bit error in the RAM output data and error address is captured in EC710EAD0 under the condition that the error detection is permitted (when not setting ECER2C = 1).

[Clearing conditions]

- Writing ECER2C = 1
- When ECC error detection is disabled (ECERVF = 0).

## 32.2.2 EC710TMC : ECC Test Mode Control Register

Base address: ECCMB = 0x4012_F000

Offset address: 0x04

| Bit position: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | ETMA[1:0] | | — | — | — | — | — | — | ECTMCE | — | — | — | — | — | ECDCS | — |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 0 | — | This bit is read as 0. The write value should be 0. | R/W |
| 1 | ECDCS | ECC Decode Input Select<br>0: Input lower 32 bits of RAM output data to data area of decode circuit<br>1: Input ECEDB31-0 in EC710TED register to data area of decode circuit | R/W |
| 6:2 | — | These bits are read as 0. The write value should be 0. | R/W |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 7 | ECTMCE | ECC Test Mode Control Enable<br>0: The access to test mode register and bit is disabled<br>1: The access to test mode register and bit is enabled | R/W |
| 13:8 | — | These bits are read as 0. The write value should be 0. | R/W |
| 15:14 | ETMA[1:0] | ECC Test Mode Bit Access Control<br>These bits enable or disable write access to ECTMCE bit. | R/W |

### ECDCS bit (ECC Decode Input Select)

The ECDCS bit selects either the lower 32 bits data value from RAM or value from the internal test register (EDEDB[31:0] in EC710TED) as input signal to decoder.

The write access to this bit is valid under the condition of ECTMCE = 1 (it is possible to set them at the same time.)

This bit is cleared by setting ECTMCE = 0.

### ECTMCE bit (ECC Test Mode Control Enable)

The ECTMCE bit selects the access enable or disable to test register and test control bit.

The write access to this bit is valid under the condition that the value of the ETMA[1:0] bits is 10b.

### ETMA[1:0] bits (ECC Test Mode Bit Access Control)

The ETMA[1:0] bits are the write trigger reserved bits to the ECTMCE bit. The read value is always 0. When the value of these bits is 10b, it is possible to have write access to the ECTMCE bit. If these bits are not 10b, the write access to the ECTMCE bit is ignored and the value is not written.

## 32.2.3 EC710TED : ECC Test Substitute Data Register

Base address: ECCMB = 0x4012_F000

Offset address: 0x0C

| Bit position: | 31 | | | | | | | | | | | | | | | | | | | | | | | | | | | | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | ECEDB[31:0] | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 31:0 | ECEDB[31:0] | ECC Test Substitute Data<br>Substitute data in ECC test mode. | R/W |

This register is for the 32 bits data for ECC decode. It is possible to read and write using 32 bits operation command when ECTMCE = 1. When ECTMCE = 0, all bits are always 0.

### ECEDB[31:0] bits (ECC Test Substitute Data)

When ECDCS in EC710TMC register is 1, the value of this register is bits [31:0] of the input data to the decode circuit.

### 32.2.4 EC710EAD0 : ECC Error Address Register

Base address: ECCMB = 0x4012_F000

Offset address: 0x10

| Bit position: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit position: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | — | — | — | ECEAD[9:0] | | | | | | | | | |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 9:0 | ECEAD[9:0] | ECC Error Address | R |
| 31:10 | — | These bits are read as 0. | R |

This is a read-only register to hold the ECC error address.

**ECEAD[9:0] bits (ECC Error Address)**

When ECC error is detected, RAM address is captured by the detected signal as a trigger and is held as the error occurring address. The error address is not captured when the error occurred again to the one held by the same factor.

If 2-bit error occurred under the condition that 1-bit error address is already captured, the 2-bit error address is over-written and the ECDEDF0 bit is set to 1.

If 1-bit error occurred under the condition that 2-bit error address is already captured, the 1-bit error address is not overwritten and the ECSEDF0 bit is not set to 1.

## 32.3 Operation

### 32.3.1 ECC Function Setting

Figure 32.1 shows a procedure for ECC function setting.

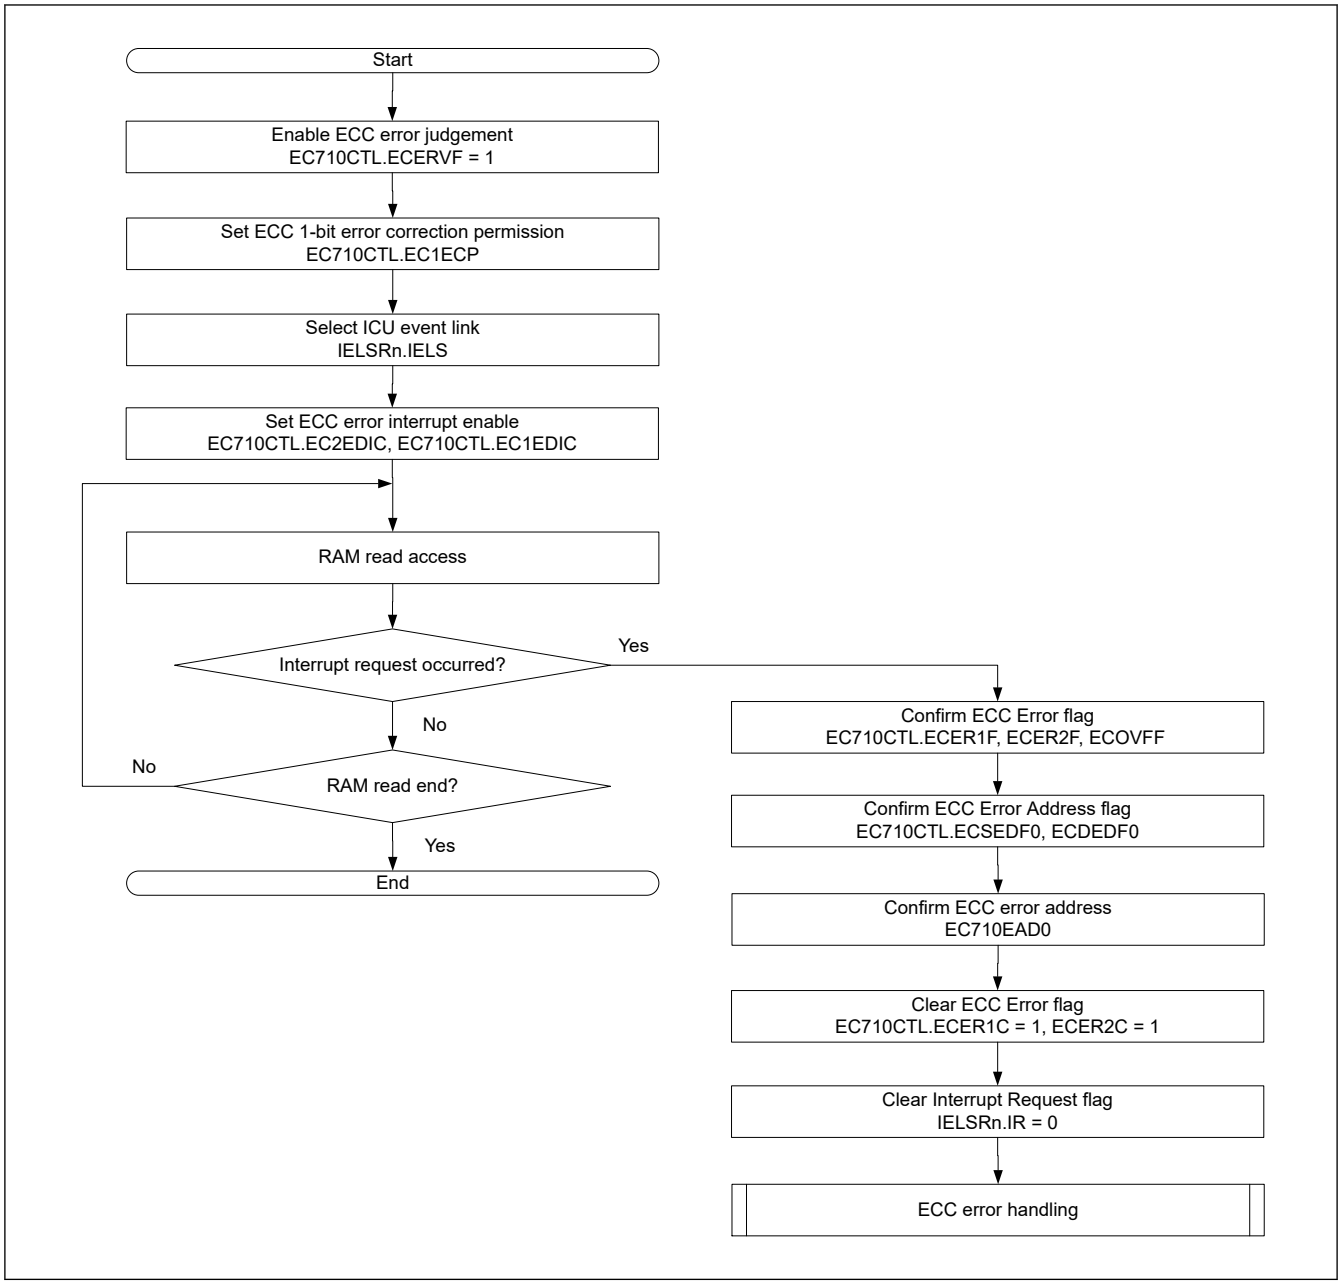

**Figure 32.1 Setting procedure for ECC function**

## 32.3.2 ECC Decoder Testing

ECC interrupts can be intentionally generated by ECC test mode. Figure 32.2 shows a procedure for ECC decoder testing.

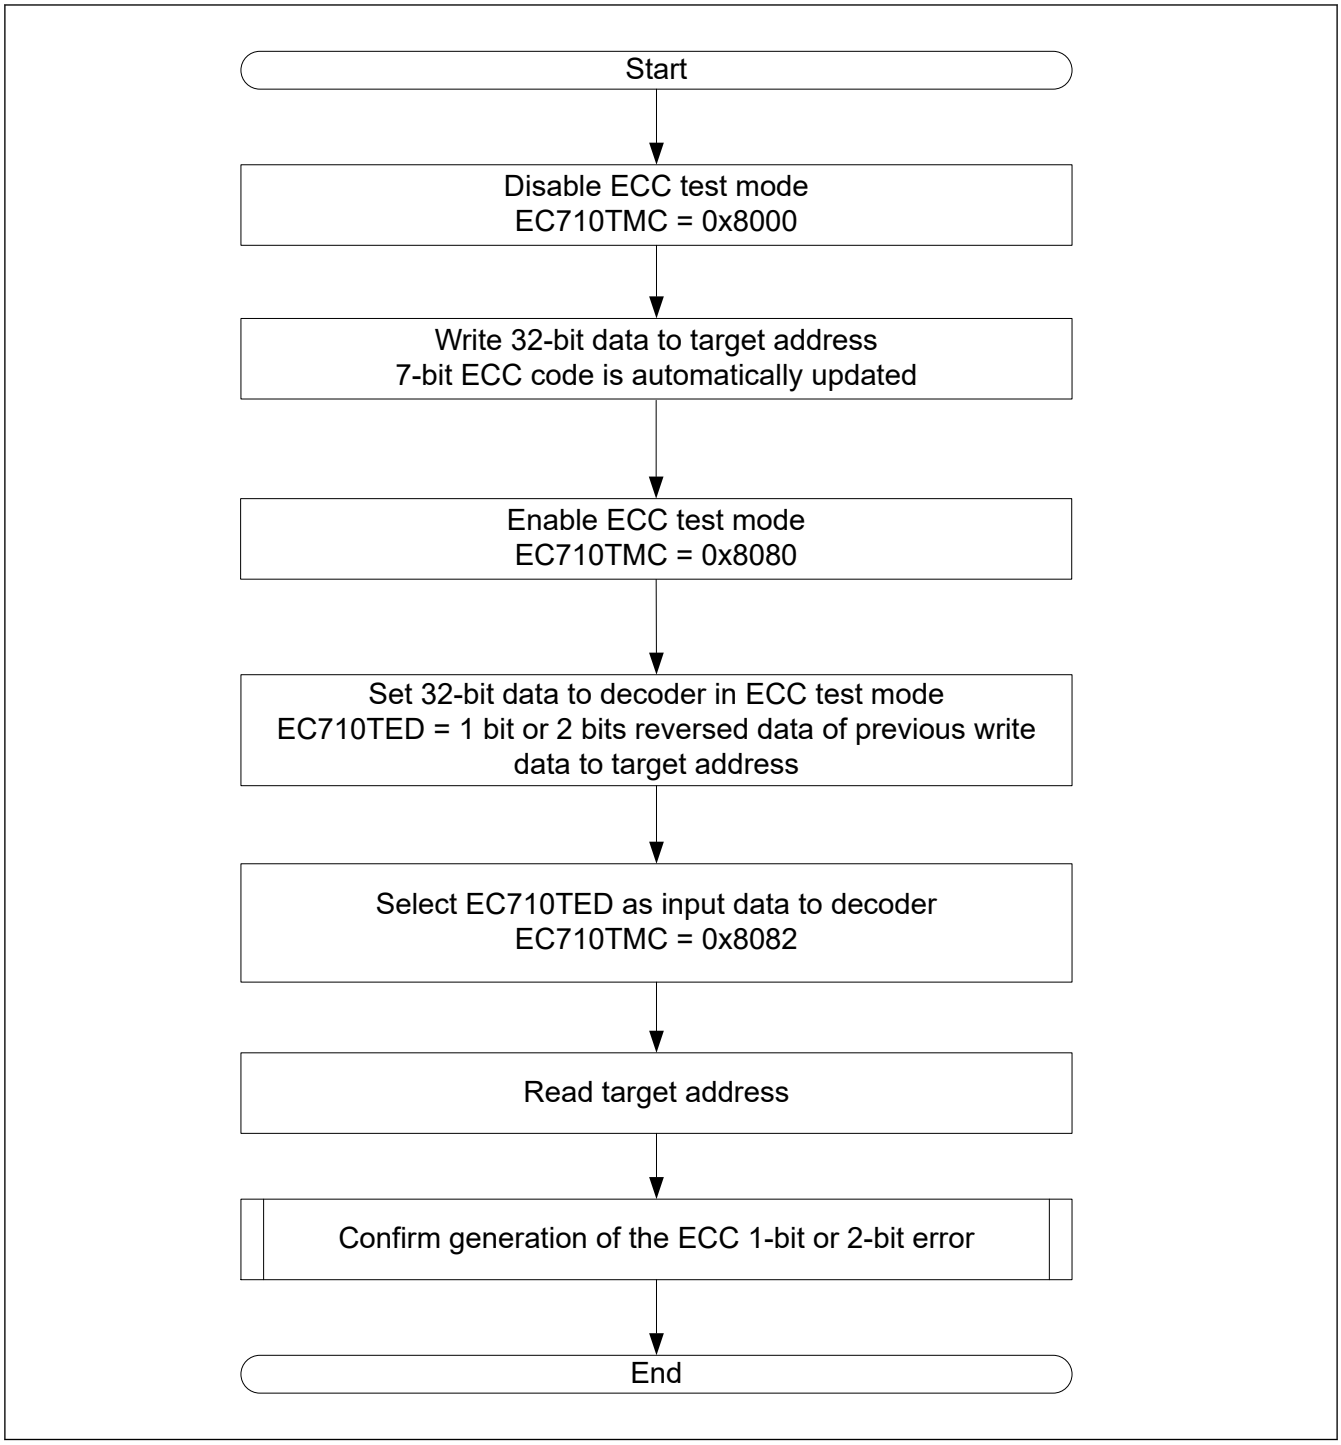

**Figure 32.2 Testing procedure for ECC decoder**

## 32.4 Interrupts

The ECC module issues one interrupt request:

- CANn_MRAM_ERI (n = 0)

Interrupt sources for the interrupt request include:

- 1-bit ECC error
- 2-bit ECC error
- ECC error overflow.

# 33. Serial Peripheral Interface (SPI)

## 33.1 Overview

The Serial Peripheral Interface (SPI) has one channel. The SPI provides high-speed full-duplex synchronous serial communications with multiple processors and peripheral devices. Table 33.1 lists the SPI specifications, Figure 33.1 shows a block diagram, and Table 33.2 lists the I/O pins.

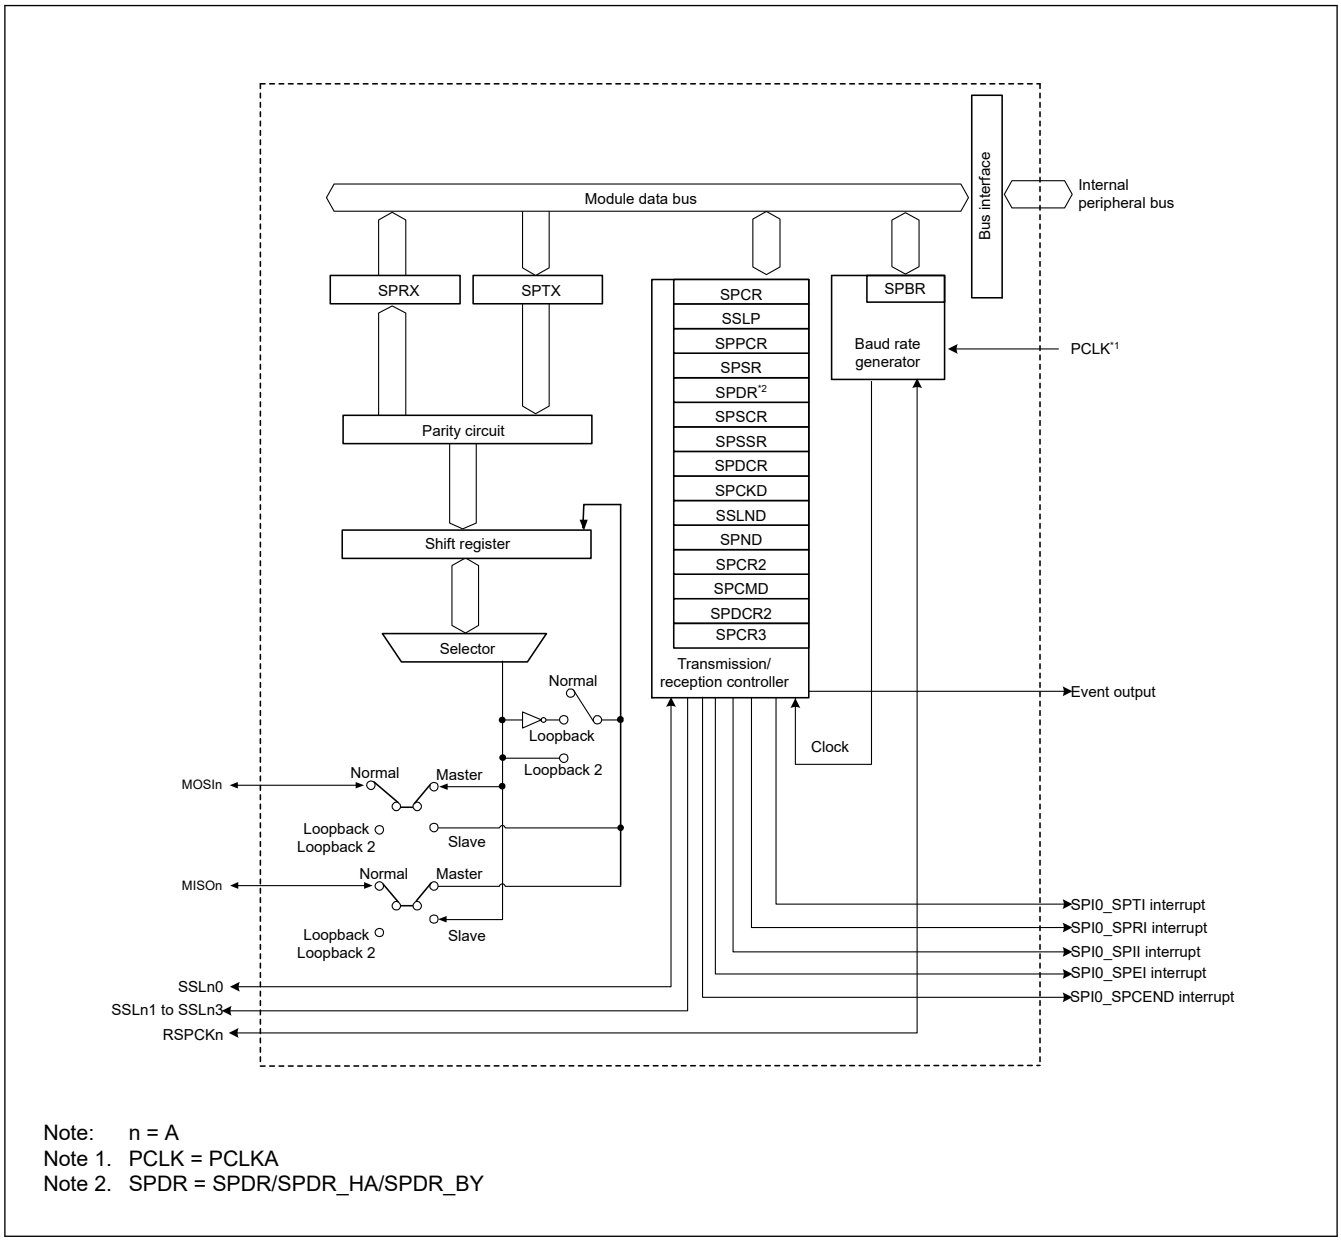

**Table 33.1 SPI specifications (1 of 2)**

| Parameter | Specifications |
|---|---|
| Number of channels | One channel |
| SPI transfer functions | • Use of MOSI (master out/slave in), MISO (master in/slave out), SSL (slave select), and RSPCK (SPI clock) signals allows serial communications through SPI operation (4-wire method) or clock synchronous operation (3-wire method)<br>• Transmit-only operation available<br>• Receive-only operation is available (Slave mode only)<br>• Communication mode selectable to full-duplex or transmit-only<br>• RSPCK polarity switching<br>• RSPCK phase switching |
| Data format | • MSB-first or LSB-first selectable<br>• Transfer bit length selectable to 8, 9, 10, 11, 12, 13, 14, 15, 16, 20, 24, or 32 bits<br>• 128-bit transmit and receive buffers<br>• Up to four frames transferable in one round of transmission or reception (each frame consisting of up to 32 bits)<br>• Byte swap operating function<br>• Transmit/receive data can be inverted. |
| Bit rate | • In master mode, the on-chip baud rate generator generates RSPCK by frequency-dividing PCLKA (the division ratio ranges from divided by 2 to divided by 4096)<br>• In slave mode, the minimum PCLKA clock divided by 4 can be input as RSPCK (PCLKA divided by 4 is the maximum RSPCK frequency)<br>Width at high level: 2 PCLKA cycles; width at low level: 2 PCLKA cycles |
| Buffer configuration | • Double buffer configuration for the transmit and receive buffers<br>• 128 bits for the transmit and receive buffers |
| Error detection | • Mode fault error detection<br>• Underrun error detection<br>• Overrun error detection*1<br>• Parity error detection |
| SSL control function | • Four SSL pins (SSLni: SSLn0 to SSLn3) (n = A) for each channel<br>• In single-master mode, SSLn0 to SSLn3 pins are output<br>• In multi-master mode, SSLn0 pin for input, and SSLn1 to SSLn3 pins either for output or unused<br>• In slave mode, SSLn0 pin for input and SSLn1 to SSLn3 pins unused<br>• Controllable delay from SSL output assertion to RSPCK operation (RSPCK delay)<br>Range: 1 to 8 RSPCK cycles (set in RSPCK-cycle units)<br>• Controllable delay from RSPCK stop to SSL output negation (SSL negation delay)<br>Range: 1 to 8 RSPCK cycles (set in RSPCK-cycle units)<br>• Controllable wait for next-access SSL output assertion (next-access delay)<br>Range: 1 to 8 RSPCK cycles (set in RSPCK-cycle units)<br>• Function for changing SSL polarity<br>• Delay between frames in burst transfer is settable |
| Control in master transfer | • Transfers of up to eight commands each can be executed sequentially in looped execution<br>• For each command, the following can be set:<br>SSL signal value, bit rate, RSPCK polarity and phase, transfer data length, MSB- or LSB-first, burst, RSPCK delay, SSL negation delay, and next-access delay<br>• Transfers can be initiated by writing to the transmit buffer<br>• MOSI signal value specifiable in SSL negation<br>• RSPCK auto-stop function |
| Interrupt sources | Interrupt sources:<br>• Receive buffer full interrupt<br>• Transmit buffer empty interrupt<br>• SPI error interrupt (mode fault error, overrun error, parity error)<br>• SPI idle interrupt (SPI idle)<br>• Transmission-complete interrupt |

**Table 33.1 SPI specifications (2 of 2)**

| Parameter | Specifications |
|---|---|
| Event link function | The following events can be output to the Event Link Controller (ELC):<br>● Receive buffer full signal<br>● Transmit buffer empty signal<br>● Mode fault, underrun, overrun, or parity error signal<br>● SPI idle signal<br>● Communication end signal |
| Other functions | ● Switching between CMOS output and open-drain output<br>● SPI initialization function<br>● Loopback mode |
| Module-stop function | Module-stop state can be set to reduce power consumption |
| TrustZone Filter | Security attribution can be set |

Note 1. In master reception and when the RSPCK auto-stop function is enabled, an overrun error does not occur because the transfer clock is stopped on overrun error detection.

Note: n = A
Note 1. PCLK = PCLKA
Note 2. SPDR = SPDR/SPDR_HA/SPDR_BY

**Figure 33.1 SPI block diagram**

The SPI automatically switches the I/O direction of the SSLn0 pin. SSLn0 is set as an output when the SPI is a single master, and as an input when the SPI is a multi-master or a slave. The RSPCKn, MOSIn, and MISOn pins are automatically set as inputs or outputs based on the master or slave setting and the level input on the SSLn0 pin. For details, see section 33.3.2. Controlling the SPI Pins.

**Table 33.2 SPI I/O pins**

| Channel | Pin name | I/O | Description |
|---|---|---|---|
| SPI0 | RSPCKA | I/O | Clock input/output pin |
| | SSLA0 | I/O | Slave selection input/output |
| | SSLA1 to SSLA3 | Output | Slave selection output |
| | MOSIA | I/O | Master transmit data input/output |
| | MISOA | I/O | Slave transmit data input/output |

## 33.2 Register Descriptions

### 33.2.1 SPCR : SPI Control Register

Base address: SPI0 = 0x4011_A000

Offset address: 0x00

| Bit position: | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|
| Bit field: | SPRIE | SPE | SPTIE | SPEIE | MSTR | MODFEN | TXMD | SPMS |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 0 | SPMS | SPI Mode Select<br>0: Select SPI operation (4-wire method)<br>1: Select clock synchronous operation (3-wire method) | R/W |
| 1 | TXMD | Communications Operating Mode Select<br>0: Select full-duplex synchronous serial communications<br>1: Select serial communications with transmit-only | R/W |
| 2 | MODFEN | Mode Fault Error Detection Enable<br>0: Disable detection of mode fault errors<br>1: Enable detection of mode fault errors | R/W |
| 3 | MSTR | SPI Master/Slave Mode Select<br>0: Select slave mode<br>1: Select master mode | R/W |
| 4 | SPEIE | SPI Error Interrupt Enable<br>0: Disable SPI error interrupt requests<br>1: Enable SPI error interrupt requests | R/W |
| 5 | SPTIE | Transmit Buffer Empty Interrupt Enable<br>0: Disable transmit buffer empty interrupt requests<br>1: Enable transmit buffer empty interrupt requests | R/W |
| 6 | SPE | SPI Function Enable<br>0: Disable SPI function<br>1: Enable SPI function | R/W |
| 7 | SPRIE | SPI Receive Buffer Full Interrupt Enable<br>0: Disable SPI receive buffer full interrupt requests<br>1: Enable SPI receive buffer full interrupt requests | R/W |

**SPMS bit (SPI Mode Select)**

The SPMS bit selects SPI operation (4-wire method) or clock synchronous operation (3-wire method).

The SSLn0 to SSLn3 pins are not used in clock synchronous operation. The RSPCKn, MOSIn, and MISOn pins handle communications. For clock synchronous operation in master mode (MSTR = 1), the SPCMDm.CPHA bit can be set to

either 0 or 1. For clock synchronous operation in slave mode (MSTR = 0), always set the CPHA bit to 1. Do not perform operations if the CPHA bit is set to 0 for clock synchronous operation in slave mode (MSTR = 0).

#### TXMD bit (Communications Operating Mode Select)

The TXMD bit selects full-duplex synchronous serial communications or transmit-only operations. When this bit is set to 1, the SPI only performs transmit operations and not receive operations (see section 33.3.6. Data Transfer Modes), and receive buffer full interrupt requests cannot be used.

TXMD setting is invalid in receive only slave mode.

#### MODFEN bit (Mode Fault Error Detection Enable)

The MODFEN bit enables or disables the detection of mode fault errors (see section 33.3.10. Error Detection). In addition, the SPI determines the I/O direction of the SSLni pins based on combination of the MODFEN and MSTR bits (see section 33.3.2. Controlling the SPI Pins).

#### MSTR bit (SPI Master/Slave Mode Select)

The MSTR bit selects master or slave mode for the SPI. Based on the MSTR bit settings, the SPI determines the direction of the RSPCKn, MOSIn, MISOn, and SSLni pins.

#### SPEIE bit (SPI Error Interrupt Enable)

The SPEIE bit enables or disables the generation of SPI error interrupt requests when one of the following occurs:

- The SPI detects a mode fault error or underrun error and sets the SPSR.MODF flag to 1
- The SPI detects an overrun error and sets the SPSR.OVRF flag to 1
- The SPI detects a parity error and sets the SPSR.PERF flag to 1

For details, see section 33.3.10. Error Detection.

#### SPTIE bit (Transmit Buffer Empty Interrupt Enable)

The SPTIE bit enables or disables the generation of transmit buffer empty interrupt requests when the SPI detects that the transmit buffer is empty. To generate a transmit buffer empty interrupt request when transmission starts, set the SPE and SPTIE bits to 1 at the same time or set the SPE bit to 1 after setting the SPTIE bit to 1.

When the SPTIE bit is 1, transmit buffer interrupts are generated even when the SPI function is disabled (when the SPE bit is changed to 0).

#### SPE bit (SPI Function Enable)

The SPE bit enables or disables the SPI function. The SPE bit cannot be set to 1 when the SPSR.MODF flag is 1. For details, see section 33.3.10. Error Detection.

Setting the SPE bit to 0 disables the SPI function and initializes a part of the module function. For details, see section 33.3.11. Initializing the SPI. In addition, a transmit buffer empty interrupt request is generated when the SPE bit is changed from 0 to 1 or from 1 to 0.

#### SPRIE bit (SPI Receive Buffer Full Interrupt Enable)

The SPRIE bit enables or disables the generation of an SPI receive buffer full interrupt request when the SPI detects a receive buffer full write after completion of a serial transfer.

### 33.2.2 SSLP : SPI Slave Select Polarity Register

Base address: SPI0 = 0x4011_A000

Offset address: 0x01

| Bit position: | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | — | SSL3P | SSL2P | SSL1P | SSL0P |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 0 | SSL0P | SSLn0 Signal Polarity Setting<br>0: Set SSLn0 signal to active-low<br>1: Set SSLn0 signal to active-high | R/W |
| 1 | SSL1P | SSLn1 Signal Polarity Setting<br>0: Set SSLn1 signal to active-low<br>1: Set SSLn1 signal to active-high | R/W |
| 2 | SSL2P | SSLn2 Signal Polarity Setting<br>0: Set SSLn2 signal to active-low<br>1: Set SSLn2 signal to active-high | R/W |
| 3 | SSL3P | SSLn3 Signal Polarity Setting<br>0: Set SSLn3 signal to active-low<br>1: Set SSLn3 signal to active-high | R/W |
| 7:4 | — | These bits are read as 0. The write value should be 0. | R/W |

### 33.2.3 SPPCR : SPI Pin Control Register

Base address: SPI0 = 0x4011_A000

Offset address: 0x02

| Bit position: | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | MOIFE | MOIFV | — | — | SPLP2 | SPLP |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 0 | SPLP | SPI Loopback<br>0: Normal mode<br>1: Loopback mode (receive data = inverted transmit data) | R/W |
| 1 | SPLP2 | SPI Loopback 2<br>0: Normal mode<br>1: Loopback mode (receive data = transmit data) | R/W |
| 3:2 | — | These bits are read as 0. The write value should be 0. | R/W |
| 4 | MOIFV | MOSI Idle Fixed Value<br>0: Set level output on MOSIn pin during MOSI idling to low<br>1: Set level output on MOSIn pin during MOSI idling to high | R/W |
| 5 | MOIFE | MOSI Idle Value Fixing Enable<br>0: Set MOSI output value to equal final data from previous transfer<br>1: Set MOSI output value to equal value set in the MOIFV bit | R/W |
| 7:6 | — | These bits are read as 0. The write value should be 0. | R/W |

**SPLP bit (SPI Loopback)**

The SPLP bit selects the mode of the SPI pins. When this bit is set to 1, the SPI shuts off the path between the MISOn pin and the shift register if the SPCR.MSTR bit is 1, and between the MOSIn pin and the shift register if the SPCR.MSTR bit is 0. The SPI then inverts the value of the input path for the shift register and connects it to the output path (loopback mode). For more information, see section 33.3.14. Loopback Mode.

**SPLP2 bit (SPI Loopback 2)**

The SPLP2 bit selects the mode of the SPI pins. When this bit is set to 1, the SPI shuts off the path between the MISOn pin and the shift register if the SPCR.MSTR bit is 1, and between the MOSIn pin and the shift register if the SPCR.MSTR bit is 0. The SPI then connects the value of the input path for the shift register to the output path (loopback mode) without inverting the value. For more information, see section 33.3.14. Loopback Mode.

### MOIFV bit (MOSI Idle Fixed Value)

The MOIFV bit determines the MOSIn pin output value during the SSL negation period (including the SSL retention period during a burst transfer) when the MOIFE bit is 1 in master mode.

### MOIFE bit (MOSI Idle Value Fixing Enable)

The MOIFE bit fixes the MOSIn output value when the SPI is in master mode and in an SSL negation period (including the SSL retention period during a burst transfer). When the MOIFE bit is 0, the SPI outputs the last data from the previous serial transfer during the SSL negation period to the MOSIn pin. When the MOIFE bit is 1, the SPI outputs the fixed value set in the MOIFV bit to the MOSIn pin.

## 33.2.4 SPSR : SPI Status Register

Base address: SPI0 = 0x4011_A000

Offset address: 0x03

| Bit position: | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|
| Bit field: | SPRF | CENDF | SPTEF | UDRF | PERF | MODF | IDLNF | OVRF |
| Value after reset: | 0 | 0 | 1 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 0 | OVRF | Overrun Error Flag<br>0: No overrun error occurred<br>1: Overrun error occurred | R/W*1 |
| 1 | IDLNF | SPI Idle Flag<br>0: SPI is in the idle state<br>1: SPI is in the transfer state | R |
| 2 | MODF | Mode Fault Error Flag<br>0: No mode fault or underrun error occurred<br>1: Mode fault error or underrun error occurred | R/W*1 |
| 3 | PERF | Parity Error Flag<br>0: No parity error occurred<br>1: Parity error occurred | R/W*1 |
| 4 | UDRF | Underrun Error Flag<br>The UDRF bit is valid when MODF flag is 1.<br>0: Mode fault error occurred (MODF = 1)<br>1: Underrun error occurred (MODF = 1) | R/W*1 *2 |
| 5 | SPTEF | SPI Transmit Buffer Empty Flag<br>0: Data is in the transmit buffer<br>1: No data is in the transmit buffer | R/W*3 |
| 6 | CENDF | Communication End Flag<br>0: Not communicating or communicating<br>1: Communication completed | R/W*1 |
| 7 | SPRF | SPI Receive Buffer Full Flag<br>0: No valid data is in SPDR/SPDR_HA<br>1: Valid data is in SPDR/SPDR_HA | R/W*3 |

Note 1. Only 0 can be written to clear the flag after reading 1.
Note 2. Clear the UDRF flag at the same time as the MODF flag.
Note 3. The write value should be 1.

### OVRF flag (Overrun Error Flag)

The OVRF flag indicates the occurrence of an overrun error. In master mode (SPCR.MSTR bit = 1) and when the RSPCK clock auto-stop function is enabled (SPCR1.SCKASE bit = 1), overrun errors do not occur. This flag does not set to 1. For details, see section 33.3.10.1. Overrun errors.

[Setting condition]

When the next serial transfer ends and the receive buffer is full, and satisfy one of following.

- The SPCR.TXMD bit = 0. (transmit-receive master mode or transmit-receive slave mode or receive only slave mode)
- The SPCR.MSTR bit = 0, and the SPCR3.ETXMD bit = 1. (receive only slave mode)

[Clearing condition]

- When 0 is written to the OVRF flag after the OVRF flag is confirmed to be 1 by a read of SPSR.

### IDLNF flag (SPI Idle Flag)

The IDLNF flag indicates the transfer status of the SPI.

[Setting conditions]

Master mode

- When none of the conditions in the master mode [Clearing condition] is met.

Slave mode

- When the SPE bit in SPCR is 1, enabling the SPI function.

[Clearing conditions]

Master mode

When condition 1 or all other conditions are satisfied.

Condition 1: The SPE bit in SPCR is 0, indicating that the SPI is initialized.

Condition 2: The transmit buffer (SPTX) is empty, indicating that data for the next transfer is not set.

Condition 3: The SPI internal sequencer is in the idle state, indicating that operation up to next-access delay is complete.

Condition 4: The SPCP[2:0] bits in SPSSR are 000 (at the beginning of sequence control)

Slave mode

- When condition 1 is satisfied.

### MODF flag (Mode Fault Error Flag)

The MODF flag indicates the occurrence of a mode fault error or an underrun error. The UDRF flag indicates which error occurred.

[Setting conditions]

Multi-master mode

- When the input level of the SSLni pin changes to the active level while the SPCR.MSTR bit is 1 (master mode) and the SPCR.MODFEN bit is 1 (mode fault error detection is enabled), triggering a mode fault error.

Slave mode

- When condition 1 or 2 is satisfied.

Condition 1: The SSLni pin is negated before the RSPCK cycle required for data transfer ends while the SPCR.MSTR bit is 0 (slave mode) and the SPCR.MODFEN bit is 1 (mode fault error detection is enabled), triggering a mode fault error.

Condition 2: The serial transfer begins with the SPCR.MSTR bit is set to 0 (slave mode), the SPCR.SPE bit is set to 1, and the transmission data not prepared, triggering an underrun error.

The active level of the SSLni signal is determined by the SSLP.SSLiP bit (SSLi signal polarity setting).

[Clearing condition]

- When SPSR is read while this flag is 1, and then 0 is written to this flag.

### PERF flag (Parity Error Flag)

The PERF flag indicates the occurrence of a parity error.

[Setting condition]

When a serial transfer ends while the SPCR2.SPPE bit is 1, triggering a parity error, and satisfy one of following.

- The SPCR.TXMD bit = 0. (transmit-receive master mode or transmit-receive slave mode or receive only slave mode)
- The SPCR.MSTR bit = 0, and the SPCR3.ETXMD bit = 1. (receive only slave mode)

[Clearing condition]

- When SPSR is read while this flag is 1, and then 0 is written to this flag.

### UDRF flag (Underrun Error Flag)

The UDRF flag indicates the occurrence of an underrun error.

[Setting condition]

- When the serial transfer begins with the SPCR.MSTR bit is set to 0 (slave mode), the SPCR3.ETXMD bit = 0 (transmit-receive slave mode or transmit slave mode) the SPCR.SPE bit is set to 1, and the transmission data not prepared, triggering an underrun error.

[Clearing condition]

- When SPSR is read while this flag is 1, and then 0 is written to this flag.

### SPTEF flag (SPI Transmit Buffer Empty Flag)

The SPTEF flag indicates the status of the transmit buffer for the SPI Data Register (SPDR/SPDR_HA).

[Setting conditions]

- When condition 1. or 2. is satisfied.
  1. The SPCR.SPE bit is 0, indicating that the SPI is initialized.
  2. Transmit data (the frame size specified by the SPDCR.SPFC[1:0]) is transferred from the transmit buffer to the shift register.

[Clearing condition]

- When data written to SPDR/SPDR_HA/SPDR_BY equals the number of frames set in the SPFC[1:0] bits in the SPI Data Control Register (SPDCR).

Data can only be written to SPDR/SPDR_HA/SPDR_BY when the SPTEF flag is 1. If data is written to the transmit buffer of SPDR/SPDR_HA when the SPTEF flag is 0, data in the transmit buffer is not updated.

### CENDF flag (Communication End Flag)

This flag indicates communication end status of SPI. It turns 1 at communication end, and turns 0 at starting next communication.

[Setting condition]

Master mode

The following 3 conditions are met.

- The transmit buffer(SPTX) is empty. (There is no next transmission data.)
- The SPSSR.SPCP[2:0] are 000b. (It means the head of the sequential control.)
- The state of SPI internal sequencer transferred to the idle state. (It means the next access delay has been completed.)

Transmit-receive / transmit only slave mode in SPI serial communication (4-wire: the SPCR.SPMS bit is 0)

The following 3 conditions are met.

- The transmit buffer(SPTX) is empty. (There is no next transmission data.)
- The transmission shift register is empty. (It means SPI does not do serial transfer.)
- SSL0 was negated.

Transmit-receive / transmit only slave mode in clock synchronous (3-wire: the SPCR.SPMS bit is 1)

The following 3 conditions are met.

- The transmit buffer(SPTX) is empty. (There is no next transmission data.)

- The transmission shift register is empty. (It means SPI does not do serial transfer.)
- The last even edge of RSPCK of the last data was detected. (When the SPCMD.CPHA bit is “1”.)

Receive only slave mode in SPI serial communication (4-wire: the SPCR.SPMS bit is 0)

The following condition is met.

- SSL0 was negated after the last data was written in the received buffer.

Receive only slave mode in clock synchronous (3-wire: the SPCR.SPMS bit is 1)

The following condition is met.

- The last even edge of RSPCK of the last data was detected. (When the SPCMD.CPHA bit is 1.)

[Clearing condition]

Master mode

Satisfy one of following.

- The next transmit data was written to the transmit buffer (SPTX).
- The CENDF flag was written 0 after reading the SPSR when the CENDF flag was 1

Transmit-receive / transmit only slave mode

Satisfy one of following.

- The next transmit data was written to the transmit buffer(SPTX).
- The CENDF flag was written 0 after reading the SPSR when the CENDF flag was 1.

Receive only slave mode in SPI serial communication (4-wire: the SPCR.SPMS bit is 0)

Satisfy one of following.

- SSL0 assertion of next data was detected.
- The CENDF flag was written 0 after reading the SPSR when the CENDF flag was 1.

Receive only slave mode in clock synchronous (3-wire: the SPCR.SPMS bit is 1)

Satisfy one of following.

- The first edge of RSPCK of the next data was detected.
- The CENDF flag was written 0 after reading the SPSR when the CENDF flag was 1.

### SPRF flag (SPI Receive Buffer Full Flag)

The SPRF flag indicates the status of the receive buffer for the SPI Data Register (SPDR/SPDR_HA).

[Setting condition]

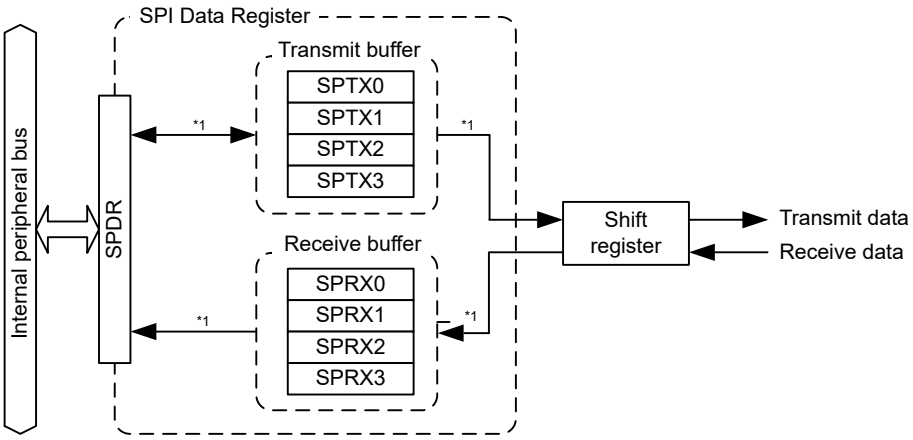
- Received data with the frame size specified by the SPDCR.SPFC[1:0] bits have been transferred to the SPDR from the shift register while the SPRF flag is 0. And satisfy one of following. However, the SPRF flag does not change from 0 to 1 while the OVRF flag = 1.
  - The SPCR.TXMD bit is 0 (transmit-receive master mode, transmit-receive slave mode, or receive only slave mode)
  - The SPCR.MSTR bit is 0 and the SPCR3.ETXMD bit is 1 (receive only slave mode)

[Clearing condition]

- When received data is read from the SPDR/SPDR_HA.

## 33.2.5 SPDR/SPDR_HA/SPDR_BY : SPI Data Register

Base address: SPI0 = 0x4011_A000



Offset address: 0x04

| Bit position: | 31 | | | | | | | | | | | | | | | | | | | | | | | | | | | | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 31:0 | n/a | SPI Data | R/W |

SPDR/SPDR_HA/SPDR_BY is the interface with the buffers that hold data for transmission and reception by the SPI. When accessing this register in words (the SPDCR.SPLW bit is 1), access SPDR. When accessing it in halfwords (the SPLW bit is 0), access SPDR_HA. When accessing it in byte (the SPDCR.SPBYT bit is 1), access SPDR_BY.

The transmit buffer (SPTX) and receive buffer (SPRX) are independent but are both mapped to SPDR/SPDR_HA. Figure 33.2 shows the configuration of the SPDR/SPDR_HA register.

Note: SPDR = SPDR/SPDR_HA/SPDR_BY
Note 1. The destination buffer and stage for access is automatically switched by the hardware.

**Figure 33.2 Configuration of SPDR/SPDR_HA/SPDR_BY**

The transmit and receive buffers each have four stages. The eight stages of the buffer are all mapped to the single address of SPDR/SPDR_HA/SPDR_BY.

Data written to SPDR/SPDR_HA/SPDR_BY is written to a transmit-buffer stage (SPTXn) (n = 0 to 3), and then transmitted from the buffer. The receive buffer holds received data on completion of reception. The receive buffer is not updated if an overrun is generated.

Additionally, if the data length is not 32 bits, bits not referred to in SPTXn (n = 0 to 3) are stored in the associated bits in SPRXn (n = 0 to 3). For example, if the data length is 9 bits, the received data is stored in the SPRXn[8:0] bits, and the SPTXn[31:9] bits are stored in the SPRXn[31:9] bits.

### (1) Bus interface

SPDR/SPDR_HA/SPDR_BY is an interface with 32-bit wide transmit and receive buffers, each of which has one stages, for a total of 32 bytes. The 32 bytes are mapped to the 4-byte address space for SPDR/SPDR_HA/SPDR_BY. Additionally, the unit of access for SPDR/SPDR_HA/SPDR_BY is selected by the SPI Word Access/Halfword Access Specification bit in

the SPI Data Control Register (SPDCR.SPLW). SPDR can also be accessed with the access size specified by the SPI Byte Access bit in the SPI Data Control Register (SPDCR.SPBYT).

Flush the transmission data at the LSB end of the register, and store the received data at the LSB end.

The following sections describe the operations involved in writing to and reading from SPDR/SPDR_HA/SPDR_BY.

### Writing

Data written to SPDR/SPDR_HA/SPDR_BY is written to a transmit buffer (SPTXn). This is not affected by the value of the SPDCR.SPRDTD bit, unlike when reading from SPDR/SPDR_HA/SPDR_BY. The transmit buffer includes a transmit buffer write pointer that is automatically updated to reference the next stage each time data is written to SPDR/SPDR_HA/SPDR_BY.

Figure 33.3 shows the configuration of the bus interface with the transmit buffer when writing to SPDR/SPDR_HA/SPDR_BY.

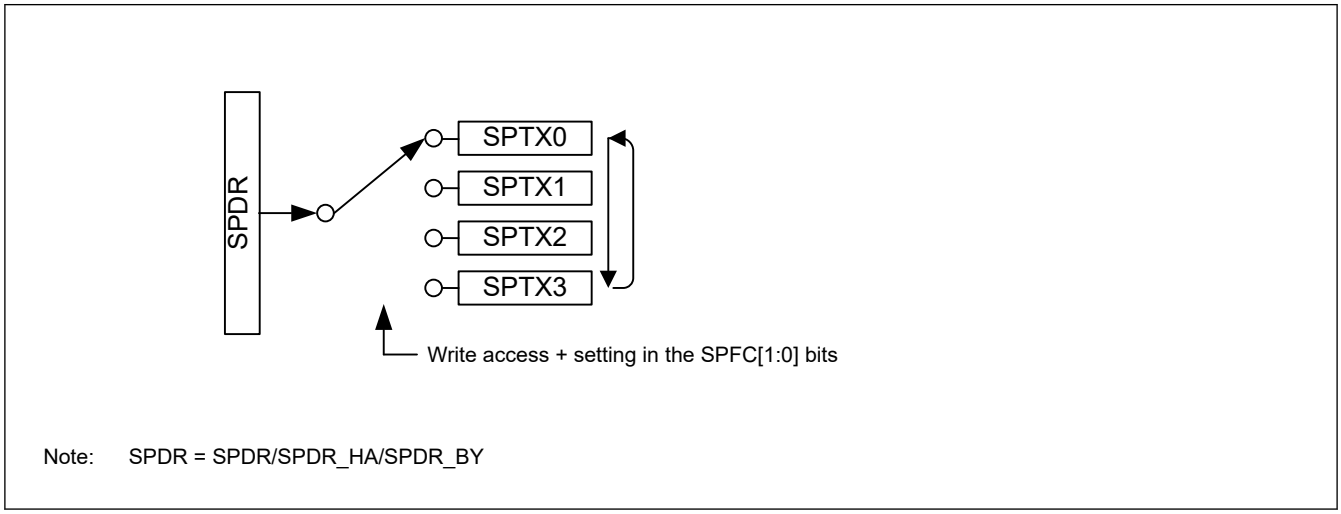


**Figure 33.3 Configuration of SPDR/SPDR_HA/SPDR_BY for write access**

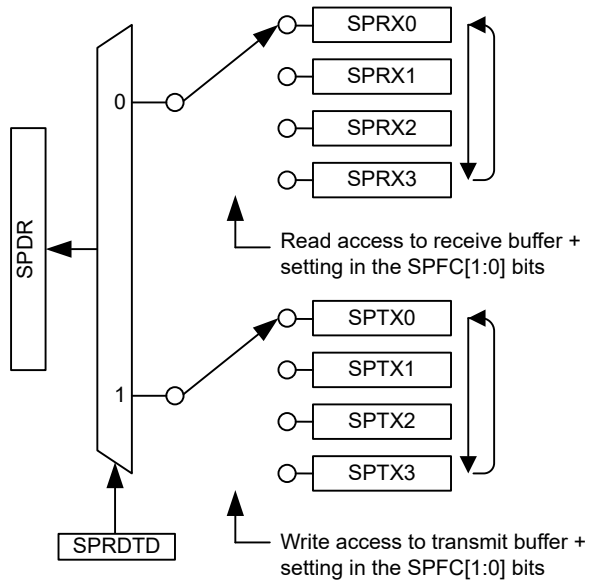
The sequence for switching the transmit buffer write pointer differs with the setting of the number of frames specification bits in the SPI Data Control Register (SPDCR.SPFC[1:0]). The relationship of the SPFC[1:0] setting and the sequence of pointer switching from SPTX0 to SPTX3 is as follows:

- When SPFC[1:0] = 00b: SPTX0 → SPTX0 → SPTX0 → …
- When SPFC[1:0] = 01b: SPTX0 → SPTX1 → SPTX0 → SPTX1 → …
- When SPFC[1:0] = 10b: SPTX0 → SPTX1 → SPTX2 → SPTX0 → SPTX1 → …
- When SPFC[1:0] = 11b: SPTX0 → SPTX1 → SPTX2 → SPTX3 → SPTX0 → SPTX1 → …



When 1 is written to the SPI Function Enable bit in the SPI Control Register (SPCR.SPE) while the bit is 0, SPTX0 is the destination for the next write.

When writing to the transmit buffer (SPTXn) after generating the transmit buffer empty interrupt (when SPSR.SPTEF is 1), write the number of frames set in SPFC[1:0] in the SPI Data Control Register (SPDCR). Even when the specified number of frames is written to the transmit buffer (SPTXn), the value of the buffer is not updated after completion of the writing and before generation of the next transmit buffer empty interrupt (when SPTEF is 0).

### Reading

SPDR/SPDR_HA/SPDR_BY can be accessed to read the value of a receive buffer (SPRXn) or a transmit buffer (SPTXn). The setting in the SPI Receive/Transmit Data Select bit in the SPI Data Control Register (SPDCR.SPRDTD) selects whether reading is of the receive or transmit buffer. The sequence of reading the SPDR/SPDR_HA/SPDR_BY register is controlled by the independent receive buffer and transmit buffer read pointers.

Figure 33.4 shows the configuration of the bus interface with the receive and transmit buffers for reading from SPDR/SPDR_HA/SPDR_BY.

Note: SPDR = SPDR/SPDR_HA/SPDR_BY

**Figure 33.4 Configuration of SPDR/SPDR_HA/SPDR_BY for read access**

Reading the receive buffer switches the receive buffer read pointer to the next buffer automatically. The switching sequence for the receive buffer read pointer is the same as that for the transmit buffer write pointer. However, when 1 is written to the SPI Function Enable bit in the SPI Control Register (SPCR.SPE) while the value of the bit is 1, SPRX0 is referenced by the buffer read pointer for the next read.

The transmit buffer read pointer is updated when writing to SPDR/SPDR_HA/SPDR_BY, but not updated when reading from the transmit buffer. When reading from the transmit buffer, the value most recently written to SPDR/SPDR_HA/SPDR_BY is read.

After a transmit buffer empty interrupt is generated, reading from the transmit buffer returns all 0s after the completion of writing the number of frames of data specified in the SPDCR.SPFC[1:0] bits, until the next buffer empty interrupt is generated (when SPTEF is 0).

## 33.2.6 SPSCR : SPI Sequence Control Register

Base address: SPI0 = 0x4011_A000

Offset address: 0x08

| Bit position: | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | — | — | SPSLN[2:0] | | |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 2:0 | SPSLN[2:0] | SPI Sequence Length Specification<br>The sequence length that is set in these bits determines the order in which the SPCMD0 to SPCMD07 registers are referenced. The setting defines the relationship between the sequence length and the SPCMD0 to SPCMD7 registers referenced by the SPI. In slave mode, the SPI references SPCMD0.<br>0 0 0: Sequence Length is 1 (Referenced SPCMDn, n = 0→0→…)<br>0 0 1: Sequence Length is 2 (Referenced SPCMDn, n = 0→1→0→…)<br>0 1 0: Sequence Length is 3 (Referenced SPCMDn, n = 0→1→2→0→…)<br>0 1 1: Sequence Length is 4 (Referenced SPCMDn, n = 0→1→2→3→0→…)<br>1 0 0: Sequence Length is 5 (Referenced SPCMDn, n = 0→1→2→3→4→0→…)<br>1 0 1: Sequence Length is 6 (Referenced SPCMDn, n = 0→1→2→3→4→5→0→…)<br>1 1 0: Sequence Length is 7 (Referenced SPCMDn, n = 0→1→2→3→4→5→6→0→…)<br>1 1 1: Sequence Length is 8 (Referenced SPCMDn, n = 0→1→2→3→4→5→6→7→0→…) | R/W |
| 7:3 | — | These bits are read as 0. The write value should be 0. | R/W |

SPSCR specifies the sequence length when the SPI operates in master mode. Before changing the SPSLN[2:0] bits while both the SPCR.MSTR and SPCR.SPE bits are 1, check that the SPSR.IDLNF flag is 0.

### SPSLN[2:0] bits (SPI Sequence Length Specification)

The SPSLN[2:0] bits specify the sequence length when the SPI in master mode performs sequential operations. The SPI in master mode changes the SPCMD0 to SPCMD7 registers to be referenced, and the order in which they are referenced is based on this sequence length setting. In slave mode, SPCMD0 is referenced.

## 33.2.7 SPSSR : SPI Sequence Status Register

Base address: SPI0 = 0x4011_A000

Offset address: 0x09

| Bit position: | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|
| Bit field: | — | SPECM[2:0] | | | — | SPCP[2:0] | | |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

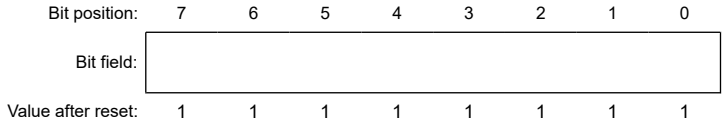
| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 2:0 | SPCP[2:0] | SPI Command Pointer<br>0 0 0: SPCMD0<br>0 0 1: SPCMD1<br>0 1 0: SPCMD2<br>0 1 1: SPCMD3<br>1 0 0: SPCMD4<br>1 0 1: SPCMD5<br>1 1 0: SPCMD6<br>1 1 1: SPCMD7 | R |
| 3 | — | This bit is read as 0. | R |
| 6:4 | SPECM[2:0] | SPI Error Command<br>0 0 0: SPCMD0<br>0 0 1: SPCMD1<br>0 1 0: SPCMD2<br>0 1 1: SPCMD3<br>1 0 0: SPCMD4<br>1 0 1: SPCMD5<br>1 1 0: SPCMD6<br>1 1 1: SPCMD7 | R |
| 7 | — | This bit is read as 0. | R |

SPSSR indicates the sequence control status when the SPI operates in master mode. Any writes to SPSSR are ignored.

### SPCP[2:0] bits (SPI Command Pointer)

The SPCP[2:0] bits indicate the SPCMDm register that is referenced to by the pointer during sequence control by the SPI. For the SPI sequence control, see section 33.3.12.1. Master mode operation.

### SPECM[2:0] bits (SPI Error Command)



The SPECM[2:0] bits indicate the SPCMDm register that is specified in the SPCP[2:0] bits when an error is detected during sequence control by the SPI. The SPI updates the SPECM[2:0] bits only when an error is detected. If both the SPSR.OVRF and SPSR.MODF flags are 0 and there is no error, the values of the SPECM[2:0] bits have no meaning.

For the SPI error detection function, see section 33.3.10. Error Detection. For the SPI sequence control, see section 33.3.12.1. Master mode operation.

## 33.2.8 SPBR : SPI Bit Rate Register

Base address: SPI0 = 0x4011_A000

Offset address: 0x0A

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 7:0 | n/a | Bit rate | R/W |

SPBR sets the bit rate in master mode.

When the SPI is in slave mode, the bit rate depends on the bit rate of the input clock, regardless of the settings in SPBR and the SPCMDm.BRDV[1:0] bits (bit rate division setting). Use bit rates that satisfy the electrical characteristics of the device.

The bit rate is determined by combinations of the SPBR and SPCMDm.BRDV[1:0] settings in the SPI Command Register. The equation for calculating the bit rate is given as follows:

$$\text{Bit rate} = \frac{f(\text{PCLK})}{2 \times (n+1) \times 2^{N}}$$

(PCLK = PCLKA)

In the equation, n denotes an SPBR setting (0, 1, 2, …, 255), and N denotes a BRDV[1:0] setting (0, 1, 2, 3).

Table 33.3 lists examples of the relationship between the SPBR settings, the BRDV[1:0] settings, and bit rates.

**Table 33.3 Relationship between SPBR settings, BRDV[1:0] settings, and bit rates**

| SPBR(n) | BRDV[1:0] bits (N) | Division ratio | Bit rate |
|---|---|---|---|
| | | | PCLKA = 32 MHz |
| 0 | 0 | 2 | 16.0 Mbps |
| 1 | 0 | 4 | 8.00 Mbps |
| 2 | 0 | 6 | 5.33 Mbps |
| 3 | 0 | 8 | 4.00 Mbps |
| 4 | 0 | 10 | 3.20 Mbps |
| 5 | 0 | 12 | 2.67 Mbps |
| 5 | 1 | 24 | 1.33 Mbps |
| 5 | 2 | 48 | 667 kbps |
| 5 | 3 | 96 | 333 kbps |
| 255 | 3 | 4096 | 7.81 kbps |

## 33.2.9 SPDCR : SPI Data Control Register

Base address: SPI0 = 0x4011_A000

Offset address: 0x0B

| Bit position: | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|
| Bit field: | — | SPBYT | SPLW | SPRDTD | — | — | SPFC[1:0] | |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 1:0 | SPFC[1:0] | Number of Frames Specification<br>0 0: 1 frame<br>0 1: 2 frames<br>1 0: 3 frames<br>1 1: 4 frames | R/W |
| 3:2 | — | These bits are read as 0. The write value should be 0. | R/W |
| 4 | SPRDTD | SPI Receive/Transmit Data Select<br>0: Read SPDR/SPDR_HA values from receive buffer<br>1: Read SPDR/SPDR_HA values from transmit buffer, but only if the transmit buffer is empty | R/W |
| 5 | SPLW | SPI Word Access/Halfword Access Specification<br>0: Set SPDR_HA to valid for halfword access<br>1: Set SPDR to valid for word access | R/W |
| 6 | SPBYT | SPI Byte Access Specification<br>0: SPDR/SPDR_HA is accessed in halfword or word (SPLW is valid)<br>1: SPDR_BY is accessed in byte (SPLW is invalid) | R/W |
| 7 | — | This bit is read as 0. The write value should be 0. | R/W |

The SPI Data Control Register (SPDCR) is used to read the number of frames that can be stored in the SPDR register, read the SPDR register, and to set the access width for the SPDR register to word access, halfword access, or byte access. Up to four frames can be transmitted or received in one round of transmission or reception. The amount of data in each transfer is controlled by the combination of the SPCMDm.SPB[3:0] bits, the SPSCR.SPSLN[2:0] bits, and the SPFC[1:0] bits.

When changing the SPFC[1:0] bits while the SPCR.SPE bit is 1, check that the SPSR.IDLNF flag is 0.

### SPFC[1:0] bits (Number of Frames Specification)

The SPFC[1:0] bits specify the number of frames that can be stored in SPDR/SPDR_HA per transfer activation. Up to four frames can be transmitted or received in one round of transmission or reception.

When the number of transmission data frames specified in the SPFC[1:0] bits is written to the SPDR/SPDR_HA register, SPI clears the SPSR.SPTEF flag to 0 and begins transmitting. After that, when the number of transmission data frames specified in the SPFC[1:0] bits is transmitted to the shift register, the SPI generates the transmit buffer empty interrupt (SPSR.SPTEF sets to 1).

When the number of data frames specified in the SPFC[1:0] bits is received, the SPI generates the receive buffer full interrupt (SPSR.SPRF sets to 1).

**Table 33.4 Settable combinations of the SPSLN[2:0] and SPFC[1:0] bits (1 of 2)**

| Setting | SPSLN[2:0] | SPFC[1:0] | Number of frames in a single sequence | Number of frames at which transmission or receive buffer is filled |
|---|---|---|---|---|
| 1-1 | 000b | 00b | 1 | 1 |
| 1-2 | 000b | 01b | 2 | 2 |
| 1-3 | 000b | 10b | 3 | 3 |
| 1-4 | 000b | 11b | 4 | 4 |
| 2-1 | 001b | 01b | 2 | 2 |

**Table 33.4 Settable combinations of the SPSLN[2:0] and SPFC[1:0] bits (2 of 2)**

| Setting | SPSLN[2:0] | SPFC[1:0] | Number of frames in a single sequence | Number of frames at which transmission or receive buffer is filled |
|---|---|---|---|---|
| 2-2 | 001b | 11b | 4 | 4 |
| 3 | 010b | 10b | 3 | 3 |
| 4 | 011b | 11b | 4 | 4 |
| 5 | 100b | 00b | 5 | 1 |
| 6 | 101b | 00b | 6 | 1 |
| 7 | 110b | 00b | 7 | 1 |
| 8 | 111b | 00b | 8 | 1 |

### SPRDTD bit (SPI Receive/Transmit Data Select)

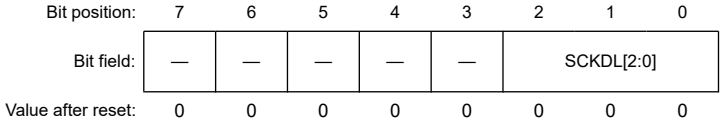
The SPRDTD bit selects whether the SPDR/SPDR_HA reads values from the receive buffer or from the transmit buffer. If reading is from the transmit buffer, the last value written to SPDR/SPDR_HA register is read. Read the transmit buffer after an SPI transmit buffer empty interrupt is generated until data of frames specified by SPFC[1:0] has been written (while the SPSR.SPTEF flag is 1).

For details, see section 33.2.5. SPDR/SPDR_HA/SPDR_BY : SPI Data Register.

### SPLW bit (SPI Word Access/Halfword Access Specification)

The SPLW bit specifies the access width for SPDR. Access to SPDR_HA in halfwords is valid when the SPLW bit is 0 and access to SPDR in words is valid when the SPLW bit is 1. Also, when this bit is 0, set the SPI data length setting bits, SPCMDm.SPB[3:0], from 8 to 16 bits. Do not perform any operations when a data length of 20, 24, or 32 bits is specified.

### SPBYT bit (SPI Byte Access Specification)



The SPBYT bit is used to set the data width of access to the SPI Data Register (SPDR). When SPBYT = 0, use word or half word access to SPDR/SPDR_HA. When SPBYT = 1 (in that case, SPLW is invalid), use byte access to SPDR_BY.

When SPBYT = 1, set the SPI data length bits (SPB[3:0]) in the SPI Command Register m (SPCMDm) to 8 bits. If SPB[3:0] are set to 9 to 16, 20, 24, or 32 bit, subsequent operation is not guaranteed.

## 33.2.10 SPCKD : SPI Clock Delay Register

Base address: SPI0 = 0x4011_A000

Offset address: 0x0C

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 2:0 | SCKDL[2:0] | RSPCK Delay Setting<br>0 0 0: 1 RSPCK<br>0 0 1: 2 RSPCK<br>0 1 0: 3 RSPCK<br>0 1 1: 4 RSPCK<br>1 0 0: 5 RSPCK<br>1 0 1: 6 RSPCK<br>1 1 0: 7 RSPCK<br>1 1 1: 8 RSPCK | R/W |
| 7:3 | — | These bits are read as 0. The write value should be 0. | R/W |

SPCKD specifies the RSPCK delay, the period from the beginning of SSLni signal assertion to RSPCK oscillation, when the SPCMDm.SCKDEN bit is 1.

### SCKDL[2:0] bits (RSPCK Delay Setting)

The SCKDL[2:0] bits specify an RSPCK delay value when the SPCMDm.SCKDEN bit is 1. When using the SPI in slave mode, set the SCKDL[2:0] bits to 000b.

## 33.2.11 SSLND : SPI Slave Select Negation Delay Register

Base address: SPI0 = 0x4011_A000

Offset address: 0x0D

| Bit position: | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | — | — | SLNDL[2:0] | | |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 2:0 | SLNDL[2:0] | SSL Negation Delay Setting<br>0 0 0: 1 RSPCK<br>0 0 1: 2 RSPCK<br>0 1 0: 3 RSPCK<br>0 1 1: 4 RSPCK<br>1 0 0: 5 RSPCK<br>1 0 1: 6 RSPCK<br>1 1 0: 7 RSPCK<br>1 1 1: 8 RSPCK | R/W |
| 7:3 | — | These bits are read as 0. The write value should be 0. | R/W |

SSLND specifies the SSL negation delay, the period from the transmission of a final RSPCK edge to the negation of the SSLni signal during a serial transfer by the SPI in master mode. If the contents of SSLND are changed while both the SPCR.MSTR and SPCR.SPE bits are 1, do not perform subsequent operations.

### SLNDL[2:0] bits (SSL Negation Delay Setting)

The SLNDL[2:0] bits specify an SSL negation delay value when the SLNDEN bit in SPCMDn is 1 and the SPI is in master mode. When using the SPI in slave mode, set the SLNDL[2:0] bits to 000b.

## 33.2.12 SPND : SPI Next-Access Delay Register

Base address: SPI0 = 0x4011_A000

Offset address: 0x0E

| Bit position: | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | — | — | SPNDL[2:0] | | |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 2:0 | SPNDL[2:0] | SPI Next-Access Delay Setting<br>0 0 0: 1 RSPCK + 2 PCLKA<br>0 0 1: 2 RSPCK + 2 PCLKA<br>0 1 0: 3 RSPCK + 2 PCLKA<br>0 1 1: 4 RSPCK + 2 PCLKA<br>1 0 0: 5 RSPCK + 2 PCLKA<br>1 0 1: 6 RSPCK + 2 PCLKA<br>1 1 0: 7 RSPCK + 2 PCLKA<br>1 1 1: 8 RSPCK + 2 PCLKA | R/W |
| 7:3 | — | These bits are read as 0. The write value should be 0. | R/W |

SPND specifies the next-access delay, the non-active period of the SSLni signal after termination of a serial transfer, when the SPCMDm.SPNDEN bit is 1.

### SPNDL[2:0] bits (SPI Next-Access Delay Setting)

The SPNDL[2:0] bits specify a next-access delay when the SPCMDm.SPNDEN bit is 1. When using the SPI in slave mode, set the SPNDL[2:0] bits to 000b.

## 33.2.13 SPCR2 : SPI Control Register 2

Base address: SPI0 = 0x4011_A000

Offset address: 0x0F

| Bit position: | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | SCKASE | PTE | SPIIE | SPOE | SPPE |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 0 | SPPE | Parity Enable<br>0: Do not add parity bit to transmit data and do not check parity bit of receive data<br>1: When SPCR.TXMD = 0: Add parity bit to transmit data and check parity bit of receive data<br>When SPCR.TXMD = 1: Add parity bit to transmit data but do not check parity bit of receive data | R/W |
| 1 | SPOE | Parity Mode<br>0: Select even parity for transmission and reception<br>1: Select odd parity for transmission and reception | R/W |
| 2 | SPIIE | SPI Idle Interrupt Enable<br>0: Disable idle interrupt requests<br>1: Enable idle interrupt requests | R/W |
| 3 | PTE | Parity Self-Testing<br>0: Disable self-diagnosis function of the parity circuit<br>1: Enable self-diagnosis function of the parity circuit | R/W |
| 4 | SCKASE | RSPCK Auto-Stop Function Enable<br>0: Disable RSPCK auto-stop function<br>1: Enable RSPCK auto-stop function | R/W |
| 7:5 | — | These bits are read as 0. The write value should be 0. | R/W |

### SPPE bit (Parity Enable)

The SPPE bit enables or disables the parity function.

When the SPCR.TXMD bit is 0 and this bit is 1, the parity bit is added to transmit data and parity checking is performed for receive data.

When the SPCR.TXMD bit is 1 and this bit is 1, the parity bit is added to transmit data, but parity checking is not performed for receive data.

### SPOE bit (Parity Mode)

The SPOE bit specifies odd or even parity.

When even parity is set, parity bit addition is performed so that the total number of bits whose value is 1 in the transmit or receive character plus the parity bit is even. Similarly, when odd parity is set, parity bit addition is performed so that the total number of bits whose value is 1 in the transmit or receive character plus the parity bit is odd.

The SPOE bit is only valid when the SPPE bit is 1.

### SPIIE bit (SPI Idle Interrupt Enable)

The SPIIE bit enables or disables the generation of SPI idle interrupt requests when an idle state is detected in the SPI and the SPSR.IDLNF flag clears is set to 0.

### PTE bit (Parity Self-Testing)

The PTE bit enables self-diagnosis of the parity circuit to check whether the parity function is operating correctly.

### SCKASE bit (RSPCK Auto-Stop Function Enable)

The SCKASE bit enables or disables the RSPCK auto-stop function. When this function is enabled, the RSPCK clock is stopped before an overrun error occurs, when data is received in master mode. For details, see section 33.3.10.1. Overrun errors.

## 33.2.14 SPCMDm : SPI Command Register m (m = 0 to 7)

Base address: SPI0 = 0x4011_A000

Offset address: 0x10 + 0x02 × m

| Bit position: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | SCKDEN | SLNDEN | SPNDEN | LSBF | SPB[3:0] | | | | SSLKP | SSLA[2:0] | | | BRDV[1:0] | | CPOL | CPHA |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 1 | 1 | 1 | 0 | 0 | 0 | 0 | 1 | 1 | 0 | 1 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 0 | CPHA | RSPCK Phase Setting<br>0: Select data sampling on leading edge, data change on trailing edge<br>1: Select data change on leading edge, data sampling on trailing edge | R/W |
| 1 | CPOL | RSPCK Polarity Setting<br>0: Set RSPCK low during idle<br>1: Set RSPCK high during idle | R/W |
| 3:2 | BRDV[1:0] | Bit Rate Division Setting<br>0 0: Base bit rate<br>0 1: Base bit rate divided by 2<br>1 0: Base bit rate divided by 4<br>1 1: Base bit rate divided by 8 | R/W |
| 6:4 | SSLA[2:0] | SSL Signal Assertion Setting<br>0 0 0: SSL0<br>0 0 1: SSL1<br>0 1 0: SSL2<br>0 1 1: SSL3<br>Others: Setting prohibited | R/W |
| 7 | SSLKP | SSL Signal Level Keeping<br>0: Negate all SSL signals on completion of transfer<br>1: Keep SSL signal level from the end of transfer until the beginning of the next access | R/W |
| 11:8 | SPB[3:0] | SPI Data Length Setting<br>0x0: 20 bits<br>0x1: 24 bits<br>0x2: 32 bits<br>0x3: 32 bits<br>0x8: 9 bits<br>0x9: 10 bits<br>0xA: 11 bits<br>0xB: 12 bits<br>0xC: 13 bits<br>0xD: 14 bits<br>0xE: 15 bits<br>0xF: 16 bits<br>Others: 8 bits | R/W |
| 12 | LSBF | SPI LSB First<br>0: MSB-first<br>1: LSB-first | R/W |
| 13 | SPNDEN | SPI Next-Access Delay Enable<br>0: Select next-access delay of 1 RSPCK + 2 PCLKA<br>1: Select next-access delay equal to the setting in the SPI Next-Access Delay Register (SPND) | R/W |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 14 | SLNDEN | SSL Negation Delay Setting Enable<br>0: Select SSL negation delay of 1 RSPCK<br>1: Select SSL negation delay equal to the setting in the SPI Slave Select Negation Delay Register (SSLND) | R/W |
| 15 | SCKDEN | RSPCK Delay Setting Enable<br>0: Select RSPCK delay of 1 RSPCK<br>1: Select RSPCK delay equal to the setting in the SPI Clock Delay Register (SPCKD) | R/W |

The SPCMDm registers specify the transfer format for the SPI in master mode. Each channel has eight SPCMDm (m = 0 to 7). Some of the bits in the SPCMD0 registers are used to set the transfer mode for the SPI in slave mode. The SPI in master mode sequentially references the SPCMDm registers based on the settings in the SPSCR.SPSLN[2:0] bits and executes the serial transfer that is set in the referenced SPCMDm registers.

Set the SPCMDm registers while the transmit buffer is empty (SPSR.SPTEF is 1 and data for the next transfer is not set) and before the setting of the data to be transmitted when that SPCMDm registers are referenced.

The SPCMDm registers referenced by the SPI in master mode can be checked by means of the SPSSR.SPCP[2:0] bits.

#### CPHA bit (RSPCK Phase Setting)

The CPHA bit selects the RSPCK phase of the SPI in master or slave mode. Data communications between SPI modules require the same RSPCK phase setting between the modules.

#### CPOL bit (RSPCK Polarity Setting)

The CPOL bit selects the RSPCK polarity of the SPI in master or slave mode. Data communications between SPI modules require the same RSPCK polarity setting between the modules.

#### BRDV[1:0] bits (Bit Rate Division Setting)

The BRDV[1:0] bits determine the bit rate in combination with the settings in the SPBR register. (see section 33.2.8. SPBR : SPI Bit Rate Register). The SPBR settings determine the base bit rate. The BRDV[1:0] setting selects the bit rate obtained by dividing the base bit rate by 1, 2, 4, or 8. Different BRDV[1:0] bit settings can be specified in the SPCMD0 register. This enables execution of serial transfers at different bit rates for each command.

#### SSLA[2:0] bits (SSL Signal Assertion Setting)

The SSLA[2:0] bits control the SSLni signal assertion when the SPI performs serial transfers in master mode. When an SSLni signal is asserted, its polarity is determined by the value set in the associated SSLP. When the SSLA[2:0] bits are set to 000b in multi-master mode, serial transfers are performed with all the SSL signals in the negated state (as the SSLn0 pin acts as input).

When using the SPI in slave mode, set the SSLA[2:0] bits to 000b.

#### SSLKP bit (SSL Signal Level Keeping)

When the SPI in master mode performs a serial transfer, the SSLKP bit specifies whether the SSLni signal level for the current command is to be kept or negated between the SSL negation associated with the current command and the SSL assertion associated with the next command. Setting the SSLKP bit to 1 enables a burst transfer. For details, see section 33.3.12.1. Master mode operation. When using the SPI in slave mode, set the SSLKP bit to 0.

#### SPB[3:0] bits (SPI Data Length Setting)

The SPB[3:0] bits specify the transfer data length for the SPI in master or slave mode.

#### LSBF bit (SPI LSB First)

The LSBF bit specifies the data format of the SPI in master or slave mode to MSB-first or LSB-first.

#### SPNDEN bit (SPI Next-Access Delay Enable)

The SPNDEN bit specifies the next-access delay, the period from the time the SPI in master mode terminates a serial transfer and sets the SSLni signal inactive until the SPI enables the SSLni signal assertion for the next access. If the SPNDEN bit is 0, the SPI sets the next-access delay to 1 RSPCK + 2 PCLKA. If the SPNDEN bit is 1, the SPI inserts a next-access delay according to the SPND setting.

When using the SPI in slave mode, set the SPNDEN bit to 0.

### SLNDEN bit (SSL Negation Delay Setting Enable)

The SLNDEN bit specifies the SSL negation delay, the period from the time the SPI in master mode stops RSPCK oscillation until the SPI sets the SSLni signal to inactive. If the SLNDEN bit is 0, the SPI sets the SSL negation delay to 1 RSPCK. If the SLNDEN bit is 1, the SPI negates the SSL signal at the SSL negation delay according to the SSLND setting.

When using the SPI in slave mode, set the SLNDEN bit to 0.

### SCKDEN bit (RSPCK Delay Setting Enable)

The SCKDEN bit specifies the SPI clock delay, the period from the point when the SPI in master mode asserts the SSLni signal until the RSPCK starts oscillation. If the SCKDEN bit is 0, the SPI sets the RSPCK delay to 1 RSPCK. If the SCKDEN bit is 1, the SPI starts the oscillation of RSPCK at an RSPCK delay according to the SPCKD setting.

When using the SPI in slave mode, set the SCKDEN bit to 0.

## 33.2.15 SPDCR2 : SPI Data Control Register 2

Base address: SPI0 = 0x4011_A000

Offset address: 0x20

| Bit position: | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | — | — | — | SINV | BYSW |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 0 | BYSW | Byte Swap Operating Mode Select<br>0: Byte Swap OFF<br>1: Byte Swap ON | R/W |
| 1 | SINV | Serial Data Invert Bit<br>0: Not invert serial data<br>1: Invert serial data | R/W |
| 7:2 | — | These bits are read as 0. The write value should be 0. | R/W |

SPI Data Control Register 2 (SPDCR2) is the setting register, that is to swap a transmit/receive data in byte units and to invert serial data. If these bits are modified while the SPI in slave mode is enabled (SPCR.SPE = 1), subsequent operation is not guaranteed.

### BYSW bit (Byte Swap Operating Mode Select)

It is a setting bit, that is to swap a transmit/receive data in byte units. When byte access is valid (SPDCR.SPBYT = 1), byte swap is invalid. When byte swap is valid, parity function must be invalid (SPCR2.SPPE bit = 0). Setting change of BYSW bit must be SPCR.SPE bit = 0.

A data after byte swap is different by a data length (setting of SPCMD.SPB[3:0]).

When byte swap, A data length (setting of SPB[3:0]) must be set to 32 bit or 16bit. Other case of data length (that is 8 to 15, 20, 24 bit length), byte swap is not guaranteed. Before swap and after swap are shown below (length data (32 bit/16 bit)).

- Length data 32 bits (SPB[3:0] = 0010b or 0011b)

  Before swap: [31:24] [23:16] [15:8] [7:0]

  After swap: [7:0] [15:8] [23:16] [31:24]
- Length data 16 bit (SPB[3:0] = 1111b)

  Before swap: [31:24] [23:16]

  After swap: [23:16] [31:24]

When byte access mode (SPDCR.SPBT = 1), byte swap setting is invalid.

When byte swap is valid, set parity function to invalid (SPCR2.SPPE = 0). When the parity function set to valid, the behavior is not guaranteed.

### SINV bit (Serial Data Invert Bit)

This bit is used to invert transmit data and receive data.

When the SINV bit is set to 1, transmit buffer (SPTX) data is inverted to invert transmit data and receive data, and then the inverted data is stored in the receive buffer (SPRX). The parity bit is the value corresponding to the inverted transmission/reception data.

## 33.2.16 SPCR3 : SPI Control Register 3

Base address: SPI0 = 0x4011_A000

Offset address: 0x21

| Bit position: | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | CENDIE | — | — | BFDS | ETXMD |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 0 | ETXMD | Extended Communication Mode Select<br>0: Full-duplex synchronous or transmit-only serial communications. [the SPCR.TXMD bit is enabled]<br>1: Receive-only serial communications in slave mode (SPCR.MSTR bit = 0). [the SPCR.TXMD bit is disabled]<br>Setting is prohibited in master mode (SPCR.MSTR bit = 1). | R/W |
| 1 | BFDS | Between Burst Transfer Frames Delay Select<br>0: Delay (RSPCK delay, SSL negation delay and next-access delay) between frames is inserted in burst transfer.<br>1: Delay between frames is not inserted in burst transfer. | R/W |
| 3:2 | — | These bits are read as 0. The write value should be 0. | R/W |
| 4 | CENDIE | SPI Communication End Interrupt Enable<br>0: Communication end interrupt request is disabled.<br>1: Communication end interrupt request is enabled. | R/W |
| 7:5 | — | These bits are read as 0. The write value should be 0. | R/W |

SPI control register 3 (SPCR3) is control register for operation mode. If you change the value of ETXMD and BFDS when the SPCR.SPE bit is 1, the SPI operation does not guarantee.

### ETXMD bit (Extended Communication Mode Select)

This bit is valid on slave mode only (the SPCR.MSTR bit is 0). This bit select receive only operation. When the ETXMD bit is 1 on slave mode, the communication is only received not transmit (see section 33.3.6. Data Transfer Modes). When the ETXMD is 1, transmit data empty interrupt can not be used.

The communication state by each mode (master mode, slave mode) is shown as below. It is controlled by the ETXMD bit, the SPCR.MSTR bit and the TXMD bit.

**Table 33.5 SPI communication state (master/slave mode)**

| SPCR.MSTR bit | SPCR3.ETXMD bit | SPCR.TXMD bit | Communication state |
|---|---|---|---|
| 1 | 0 | 0 | Transmit-receive master mode |
| 1 | 0 | 1 | Transmit master mode |
| 0 | 0 | 0 | Transmit-receive slave mode (default) |
| 0 | 0 | 1 | Transmit slave mode |
| 0 | 1 | — | Receive slave mode |

### BFDS bit (Between Burst Transfer Frames Delay Select)

This bit controls whether insert the delay time between the burst transfer frames.

This bit is valid when the SPCMD.SSLKP bit is 1 in master mode (the SPCR.MSTR bit is 1).

This bit should be set to 0 in slave mode. The usage of SSL delay control between transfer frames is shown as below. For details, see (4) Burst transfers.

**Table 33.6 Usage of SSL delay control between transfer frames (Master mode)**

| Transmit | | SPCMD.SSLKP bit | SPCR3.BFDS bit | SSL delay control register*1 (RSPCK clock delay, SSL negation delay, next access delay) |
|---|---|---|---|---|
| Non-burst transmit | | 0 | 0 | Any given value. You can control each delay value according to setting for RSPCK clock delay, SSL negation delay and next access delay. |
| Burst transmit with delay between frames | From the 1st frame to the last previous frame | 1 | 0 | |
| | The last frame | 0 | 0 | |
| Burst transmit with no delay between frames | From the 1st frame to the last previous frame | 1 | 1 | Any given value. But delay is inserted only below.<br>• RSPCK clock delay of the 1st frame<br>• SSL negation delay and next access delay of the last frame |
| | The last frame | 0 | 1 | |

Note 1. Whether the setting value of following bits are valid or not depends on the setting value of the SPCMD.SPNDEN bit (see section 33.2.14. SPCMDm : SPI Command Register m (m = 0 to 7)).
The SPCKD.SCKDL[2:0] bits: RSPCK delay
The SSLND.SLNDL[2:0] bits: SSL negate delay
The SPND.SPNDL[2:0] bits: Next access delay

### CENDIE bit (SPI Communication End Interrupt Enable)

This bit controls generation of a communication end interrupt request.

## 33.3 Operation

In this section, the serial transfer period refers to the period from the beginning of driving valid data to the fetching of the final valid data.

### 33.3.1 Overview of SPI Operation

The SPI is capable of synchronous serial transfers in the following modes:

- Slave mode (SPI operation)
- Single master mode (SPI operation)
- Multi-master mode (SPI operation)
- Slave mode (clock synchronous operation)
- Master mode (clock synchronous operation)

The SPI mode can be selected by using the MSTR, MODFEN, and SPMS bits in SPCR. Table 33.7 lists the relationship between SPI modes and SPCR settings, and a description of each mode.

**Table 33.7 Relationship between SPCR settings and SPI modes (1 of 2)**

| Mode | Slave (SPI operation) | Single-master (SPI operation) | Multi-master (SPI operation) | Slave (clock synchronous operation) | Master (clock synchronous operation) |
|---|---|---|---|---|---|
| MSTR bit setting | 0 | 1 | 1 | 0 | 1 |
| MODFEN bit setting | 0 or 1 | 0 | 1 | 0 | 0 |
| SPMS bit setting | 0 | 0 | 0 | 1 | 1 |
| RSPCKn pins | Input | Output | Output/Hi-Z | Input | Output |
| MOSIn pin | Input | Output | Output/Hi-Z | Input | Output |
| MISOn pin | Output/Hi-Z | Input | Input | Output | Input |

**Table 33.7 Relationship between SPCR settings and SPI modes (2 of 2)**

| Mode | Slave (SPI operation) | Single-master (SPI operation) | Multi-master (SPI operation) | Slave (clock synchronous operation) | Master (clock synchronous operation) |
|---|---|---|---|---|---|
| SSLn0 pins | Input | Output | Input | Hi-Z*1 | Hi-Z*1 |
| SSLn1 to SSLn3 pins | Hi-Z*1 | Output | Output/Hi-Z | Hi-Z*1 | Hi-Z*1 |
| SSL polarity change function | Supported | Supported | Supported | — | — |
| Max transfer rate | PCLKA/4 | PCLKA/2 | PCLKA/2 | PCLKA/4 | PCLKA/2 |
| Clock source | RSPCK input | On-chip baud rate generator | On-chip baud rate generator | RSPCK input | On-chip baud rate generator |
| Clock polarity | Two | | | | |
| Clock phase | Two | Two | Two | One (CPHA = 1) | Two |
| First transfer bit | MSB/LSB | | | | |
| Transfer data length | 8 to 16, 20, 24, 32 bits | | | | |
| Burst transfer | Possible (CPHA = 1) | Possible (CPHA = 0, 1) | Possible (CPHA = 0, 1) | — | — |
| RSPCK delay control | Not supported | Supported | Supported | Not supported | Supported |
| SSL negation delay control | Not supported | Supported | Supported | Not supported | Supported |
| Next-access delay control | Not supported | Supported | Supported | Not supported | Supported |
| Transfer trigger | SSL input active or RSPCK oscillation | Write to transmit buffer on generation of transmit buffer empty interrupt request (SPTEF = 1) | Write to transmit buffer on generation of transmit buffer empty interrupt request (SPTEF = 1) | RSPCK oscillation | Write to transmit buffer on generation of transmit buffer empty interrupt request (SPTEF = 1) |
| Sequence control | Not supported | Supported | Supported | Not supported | Supported |
| Transmit buffer empty detection | Supported*5 | | | | |
| Receive buffer full detection | Supported*2 | | | | |
| Overrun error detection | Supported*2 | Supported*2*4 | Supported*2*4 | Supported*2 | Supported*2 |
| Parity error detection | Supported*3*2 | | | | |
| Mode fault error detection | Supported (MODFEN = 1) | Not supported | Supported | Not supported | Not supported |
| Underrun error detection | Supported*5 | Not supported | Not supported | Supported*5 | Not supported |

Note 1. This function is not supported in this mode.
Note 2. When the SPCR.TXMD bit is 1, detection of receiver buffer full, overrun error, and parity error are not performed.
Note 3. When the SPCR2.SPPE bit is 0, parity error detection is not performed.
Note 4. When the SPCR2.SCKASE bit is 1, overrun error detection does not proceed.
Note 5. When SPI is receive only slave mode, none of transmit buffer empty and underrun error is detected.

## 33.3.2 Controlling the SPI Pins

Based on the settings of the MSTR, MODFEN, and SPMS bits in SPCR and the PmnPFS.NCODR bit for I/O Ports, the SPI can switch pin states. Table 33.8 lists the relationship between pin states and bit settings. Setting the PmnPFS.NCODR bit for an I/O port to 0 selects the CMOS output. Setting it to 1 selects the open-drain output. The I/O port settings must follow this relationship.

**Table 33.8 Relationship between pin states and bit settings**

| Mode | Pin | Pin state*2 | |
|---|---|---|---|
| | | PmnPFS.NCODR bit for I/O ports = 0 | PmnPFS.NCODR bit for I/O ports = 1 |
| Single-master mode (SPI operation) (MSTR = 1, MODFEN = 0, SPMS = 0) | RSPCKn | CMOS output | Open-drain output |
| | SSLn0 to SSLn3 | CMOS output | Open-drain output |
| | MOSIn | CMOS output | Open-drain output |
| | MISOn | Input | Input |
| Multi-master mode (SPI operation) (MSTR = 1, MODFEN = 1, SPMS = 0) | RSPCKn*3 | CMOS output/Hi-Z | Open-drain output/Hi-Z |
| | SSLn0 | Input | Input |
| | SSLn1 to SSLn3*3 | CMOS output/Hi-Z | Open-drain output/Hi-Z |
| | MOSIn*3 | CMOS output/Hi-Z | Open-drain output/Hi-Z |
| | MISOn | Input | Input |
| Slave mode (SPI operation) (MSTR = 0, SPMS = 0) | RSPCKn | Input | Input |
| | SSLn0 | Input | Input |
| | SSLn1 to SSLn3*5 | Hi-Z*1 | Hi-Z*1 |
| | MOSIn | Input | Input |
| | MISOn*4 | CMOS output/Hi-Z | Open-drain output/Hi-Z |
| Master mode (clock synchronous operation) (MSTR = 1, MODFEN = 0, SPMS = 1) | RSPCKn | CMOS output | Open-drain output |
| | SSLn0 to SSLn3*5 | Hi-Z*1 | Hi-Z*1 |
| | MOSIn | CMOS output | Open-drain output |
| | MISOn | Input | Input |
| Slave mode (clock synchronous operation) (MSTR = 0, SPMS = 1) | RSPCKn | Input | Input |
| | SSLn0 to SSLn3*5 | Hi-Z*1 | Hi-Z*1 |
| | MOSIn | Input | Input |
| | MISOn | CMOS output | Open-drain output |

Note 1. This function is not supported in this mode.
Note 2. SPI settings are not reflected in multiplexed pins for which the SPI function is not selected.
Note 3. When SSLn0 is at the active level, the pin state is Hi-Z. Whether or not the input signal is at the active level determines the setting of the SSLP.SSL0P bit.
Note 4. When SSLn0 is at the non-active level or the SPCR.SPE bit is 0, the pin state is Hi-Z. Whether or not the input signal is at the active level determines the setting of the SSLP.SSL0P bit.
Note 5. These pins are available for use as I/O port pins.

The SPI in single-master mode (SPI operation) or multi-master mode (SPI operation) determines the MOSI signal values during the SSL negation period (including the SSL retention period during a burst transfer) based on the MOIFE and MOIFV bit settings in SPPCR, as listed in Table 33.9.

**Table 33.9 MOSI signal value determination during SSL negation**

| MOIFE bit | MOIFV bit | MOSIn signal value during SSL negation |
|---|---|---|
| 0 | 0, 1 | Final data from previous transfer |
| 1 | 0 | Low |
| 1 | 1 | High |

## 33.3.3 SPI System Configuration Examples

### 33.3.3.1 Single-master/single-slave with the MCU as a master

Figure 33.5 shows a single-master/single-slave SPI system configuration example where the MCU is used as a master. In the single-master/single-slave configuration, the SSLni outputs of the MCU (master) are not used. The SSL input of the SPI slave is fixed to the low level, and the SPI slave is maintained in the selected state.*1

Note 1. In the transfer format configured when the SPCMDm.CPHA bit is 0, the SSL signal for some slave devices cannot be fixed to an active level. In this case, always connect the SSLni output of the MCU to the SSL input of the slave device.

The MCU (master) drives the RSPCKn and MOSIn signals. The SPI slave drives the MISO signal.

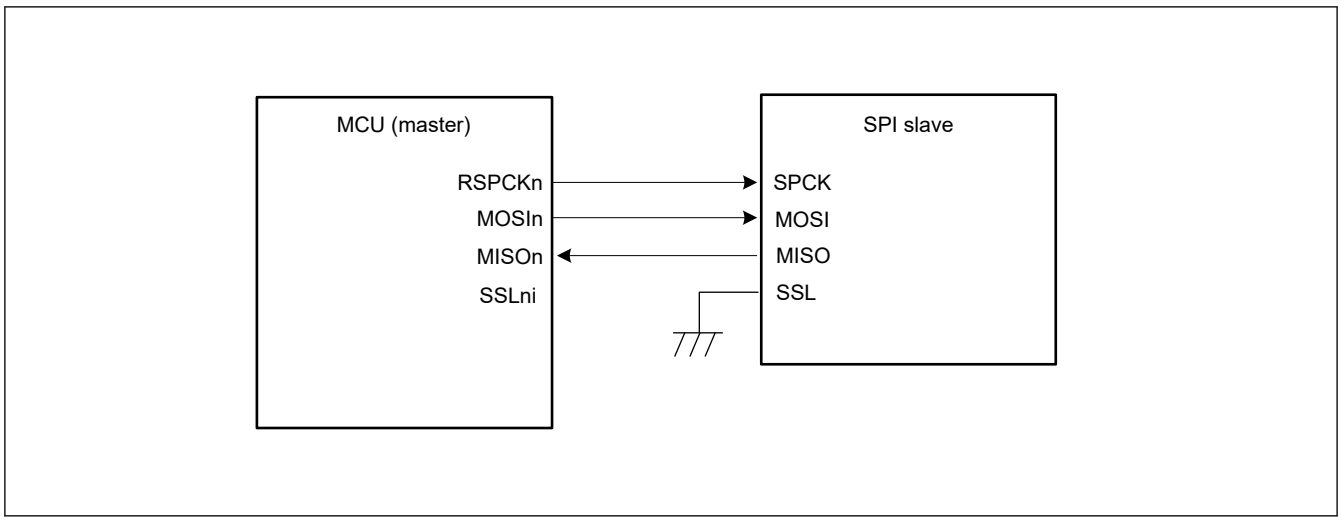


**Figure 33.5 Single-master/single-slave configuration example with the MCU as a master**

### 33.3.3.2 Single-master/single-slave with the MCU as a slave

Figure 33.6 shows a single-master/single-slave SPI system configuration example where the MCU is used as a slave. When the MCU operates as a slave, the SSLn0 pin is used as SSL input. The SPI master drives the RSPCK and MOSI signals. The MCU (slave) drives the MISOn signal.*1

Note 1. When SSLn0 is at a non-active level, the pin state is Hi-Z.

In the single-slave configuration when the SPCMDm.CPHA bit is set to 1, the SSLn0 input of the MCU (slave) is fixed to the low level and the MCU (slave) is maintained in the selected state. This enables serial transfer execution (Figure 33.7). However, the communication end interrupt does not output when SSL0 input is fixed as Figure 33.7.

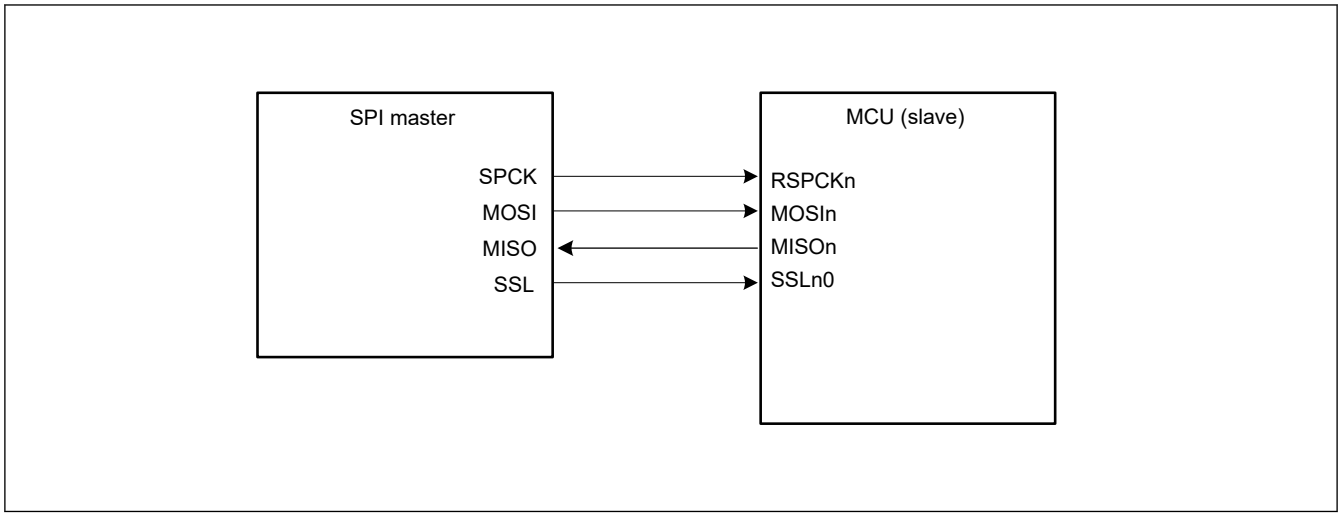

**Figure 33.6 Single-master/single-slave configuration example with the MCU as a slave and CPHA = 0**

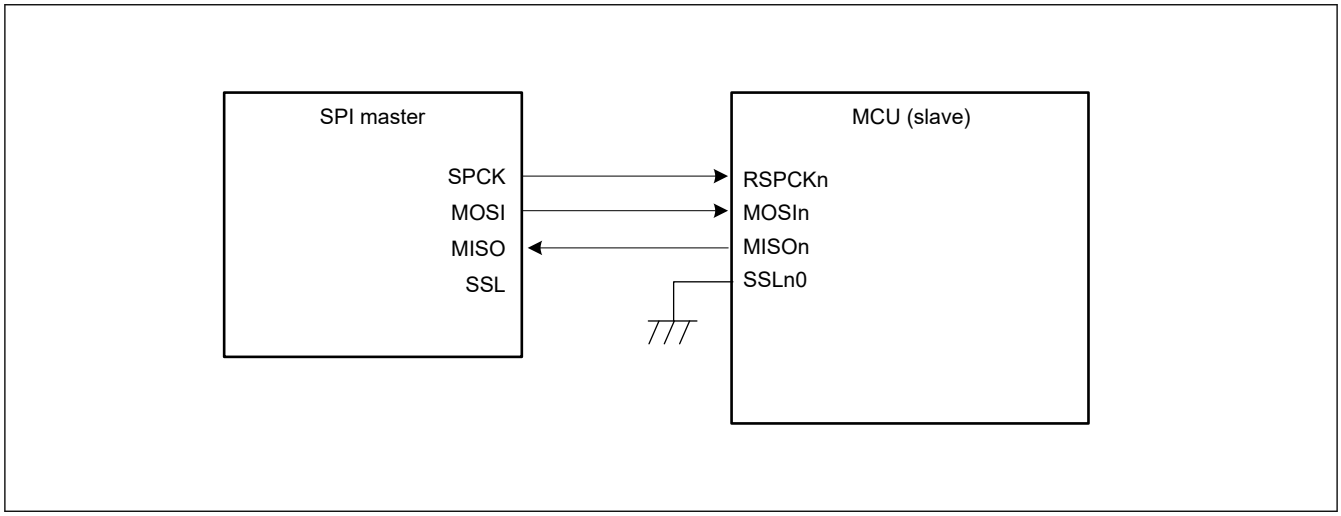

**Figure 33.7 Single-master/single-slave configuration example with the MCU as a slave and CPHA = 1**

### 33.3.3.3 Single-master/multi-slave with the MCU as a master

Figure 33.8 shows a single-master/multi-slave SPI system configuration example where the MCU is used as a master. In this example, the SPI system includes the MCU (master) and four slaves (SPI slave 0 to SPI slave 3).

The RSPCKn and MOSIn outputs of the MCU (master) are connected to the RSPCK and MOSI inputs of SPI slaves 0 to 3. The MISO outputs of SPI slaves 0 to 3 are all connected to the MISOn input of the MCU (master). The SSLn0 to SSLn3 outputs of the MCU (master) are connected to the SSL inputs of SPI slaves 0 to 3, respectively.

The MCU (master) drives the RSPCKn, MOSIn, and SSLn0 to SSLn3 signals. Out of the SPI slaves 0 to 3, the slave that receives low-level input into the SSL input drives the MISO signal.

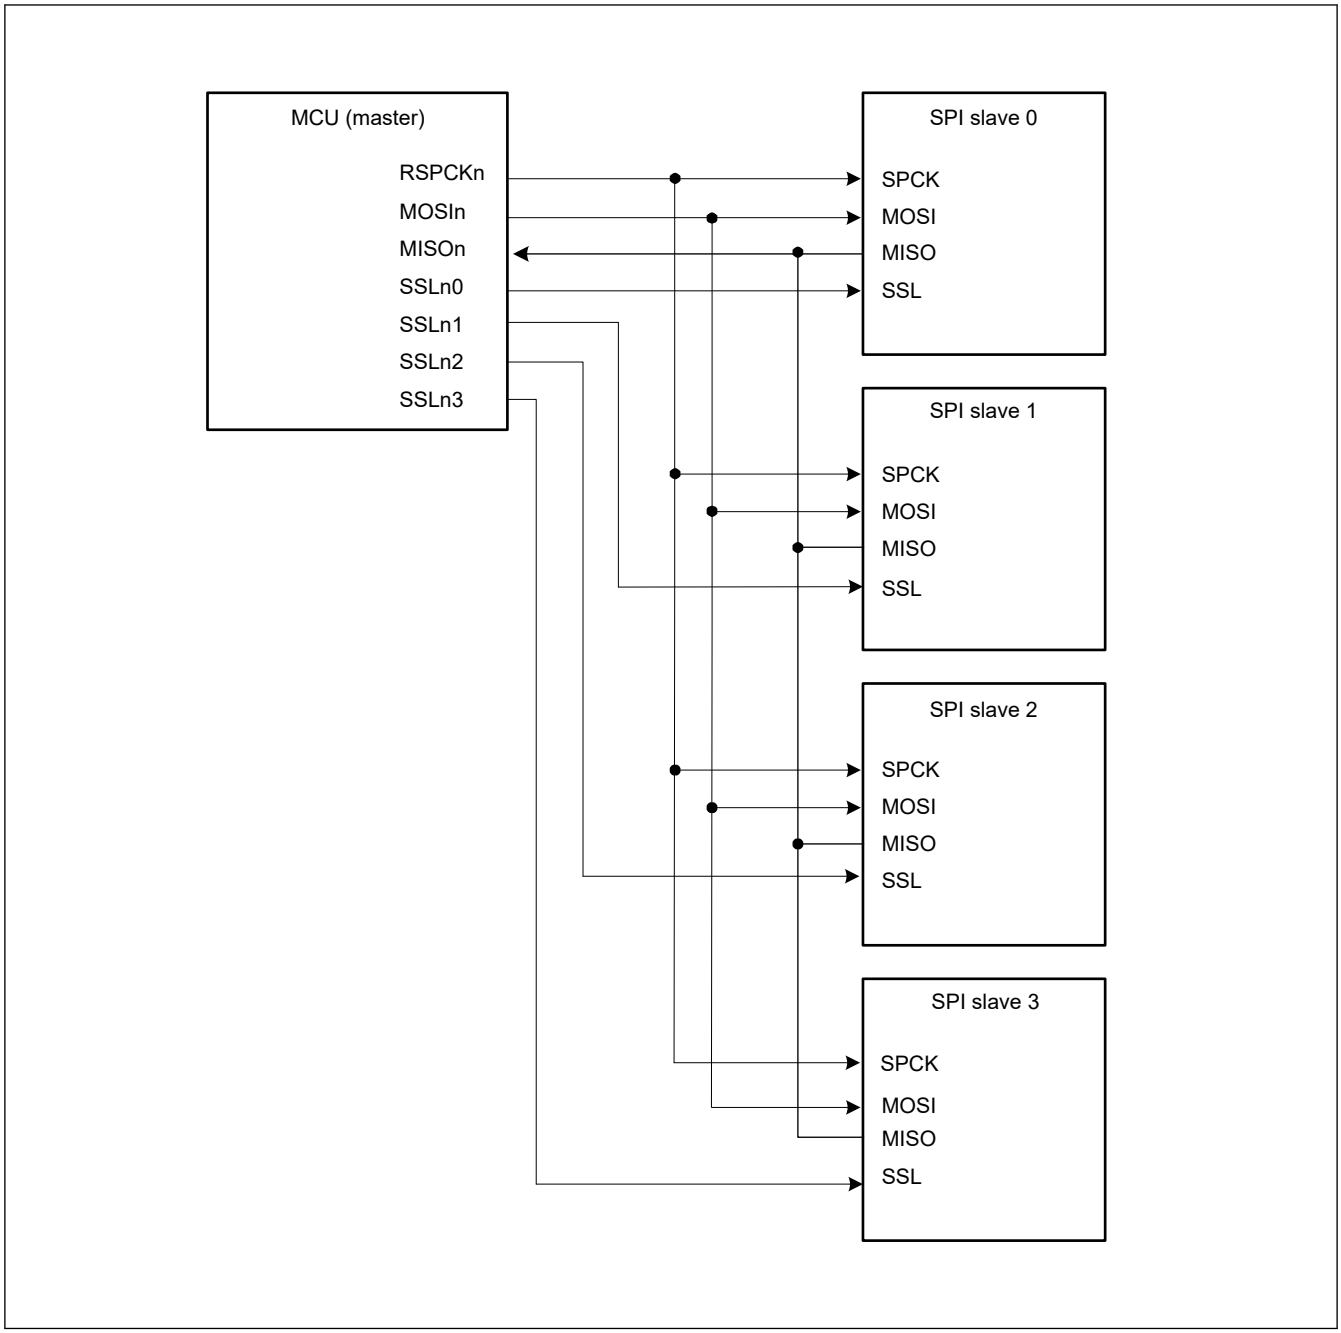

**Figure 33.8 Single-master/multi-slave configuration example with the MCU as a master**

### 33.3.3.4 Single-master/Multi-slave With the MCU as a Slave

Figure 33.9 shows a single-master/multi-slave SPI system configuration example where the MCU is used as a slave. In this example, the SPI system includes an SPI master and two MCUs (slaves X and Y).

The SPCK and MOSI outputs of the SPI master are connected to the RSPCKn and MOSIn inputs of the MCUs (slaves X and Y). The MISOn outputs of the MCUs (slaves X and Y) are all connected to the MISO input of the SPI master. The SSLX and SSLY outputs of the SPI master are connected to the SSLn0 inputs of the MCUs (slaves X and Y, respectively).

The SPI master drives the SPCK, MOSI, SSLX, and SSLY signals. Of the MCUs (slaves X and Y), the slave that receives low-level input into the SSLn0 input drives the MISOn signal.

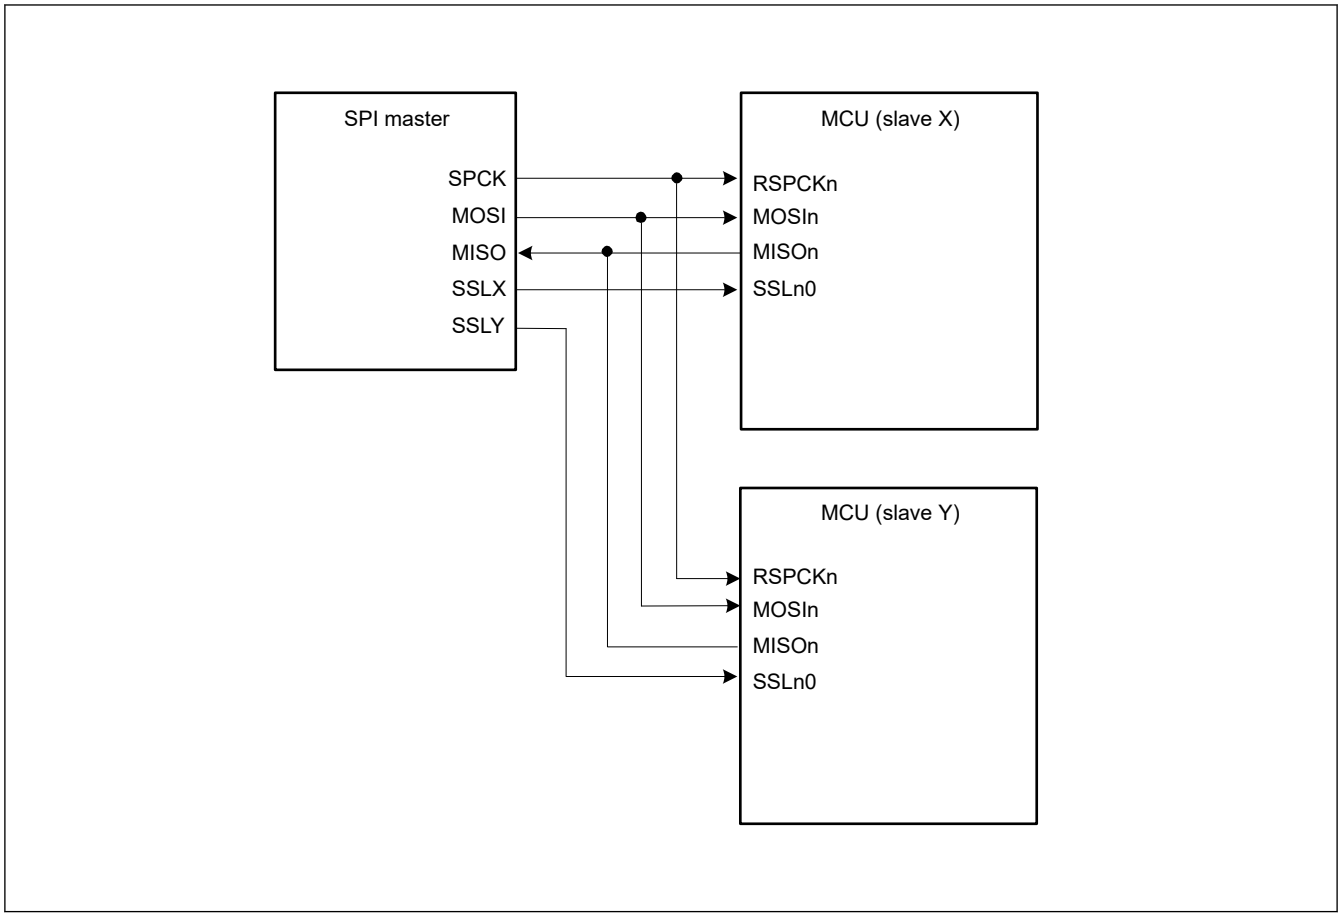

**Figure 33.9 Single-master/multi-slave configuration example with the MCU as a slave**

### 33.3.3.5 Multi-master/multi-slave with the MCU as a master

Figure 33.10 shows a multi-master/multi-slave SPI system configuration example where the MCU is used as a master. In this example, the SPI system includes two MCUs (masters X and Y) and two SPI slaves (SPI slaves 1 and 2).

The RSPCKn and MOSIn outputs of the MCUs (masters X and Y) are connected to the RSPCK and MOSI inputs of SPI slaves 1 and 2. The MISO outputs of SPI slaves 1 and 2 are connected to the MISOn inputs of the MCUs (masters X and Y). Any generic port Y output from the MCU (master X) is connected to the SSLn0 input of the MCU (master Y). Any generic port X output of the MCU (master Y) is connected to the SSLn0 input of the MCU (master X). The SSLn1 and SSLn2 outputs of the MCUs (masters X and Y) are connected to the SSL inputs of the SPI slaves 1 and 2. In this configuration example, because the system can be comprised solely of SSLn0 input, and SSLn1 and SSLn2 outputs for slave connections, the SSLn3 output of the MCU is not required.

The MCU drives the RSPCKn, MOSIn, SSLn1, and SSLn2 signals when the SSLn0 input level is high. When the SSLn0 input level is low, the MCU detects a mode fault error, sets RSPCKn, MOSIn, SSLn1, and SSLn2 to Hi-Z, and releases the SPI bus directly to the other master. Of the SPI slaves 1 and 2, the slave that receives low-level input into the SSL input drives the MISO signal.

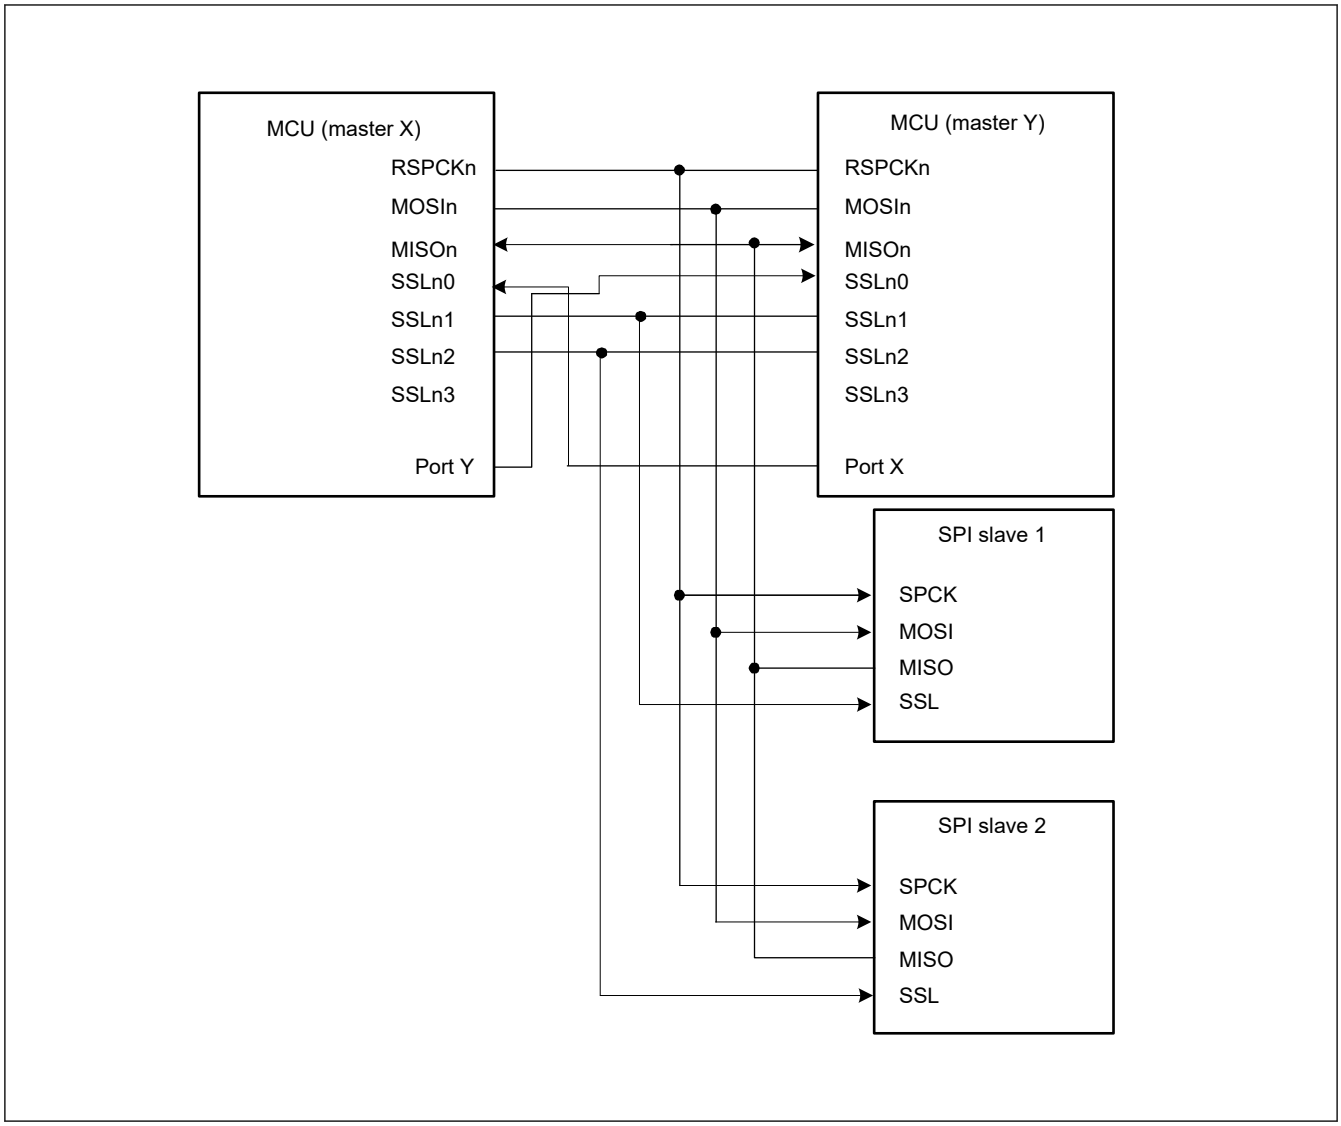

**Figure 33.10 Multi-master/multi-slave configuration example with the MCU as a master**

### 33.3.3.6 Master and slave in clock synchronous mode with the MCU configured as a master

Figure 33.11 shows a master and slave in clock synchronous mode configuration example where the MCU is used as a master. In this configuration, SSLni of the MCU (master) are not used.

The MCU (master) drives the RSPCKn and MOSIn signals. The SPI slave drives the MISO signal.

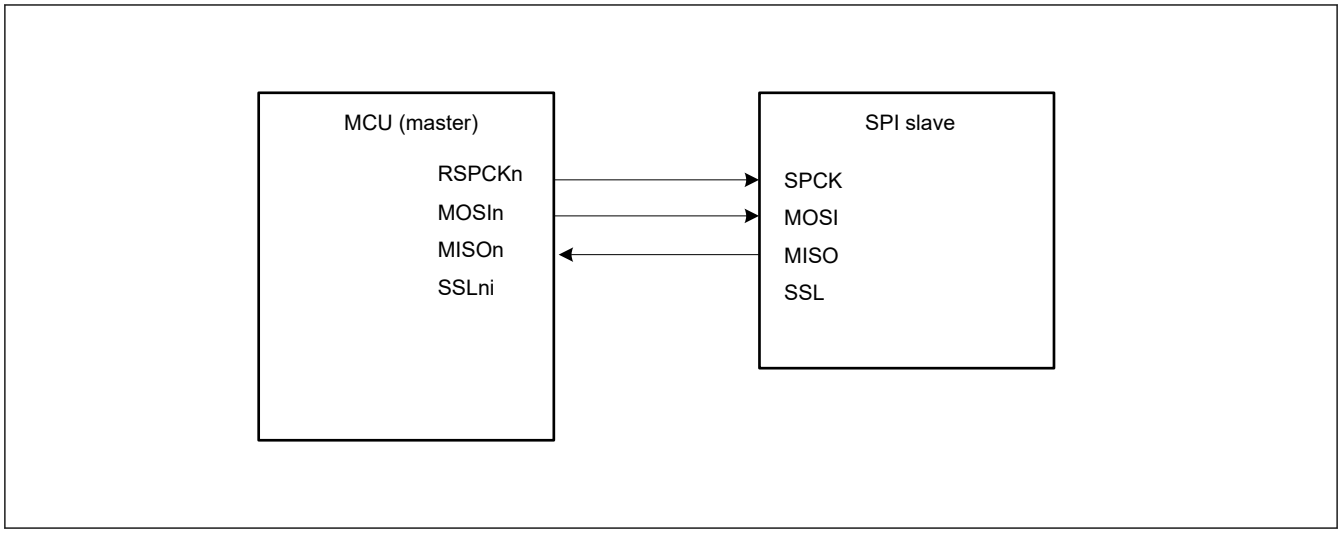

**Figure 33.11 Clock synchronous master/slave configuration example with the MCU as a master**

### 33.3.3.7 Master and slave in clock synchronous mode with the MCU as a slave

Figure 33.12 shows a master and slave in clock synchronous mode configuration example where the MCU is used as a slave. When the MCU operates as a slave (clock synchronous operation), the MCU (slave) drives the MISOn signal and the SPI master drives the SPCK and MOSI signals. In addition, SSLn0 to SSLn3 of the MCU (slave) are not used.

The MCU (slave) can only execute serial transfers in the single-slave configuration when the SPCMDm.CPHA bit is set to 1.

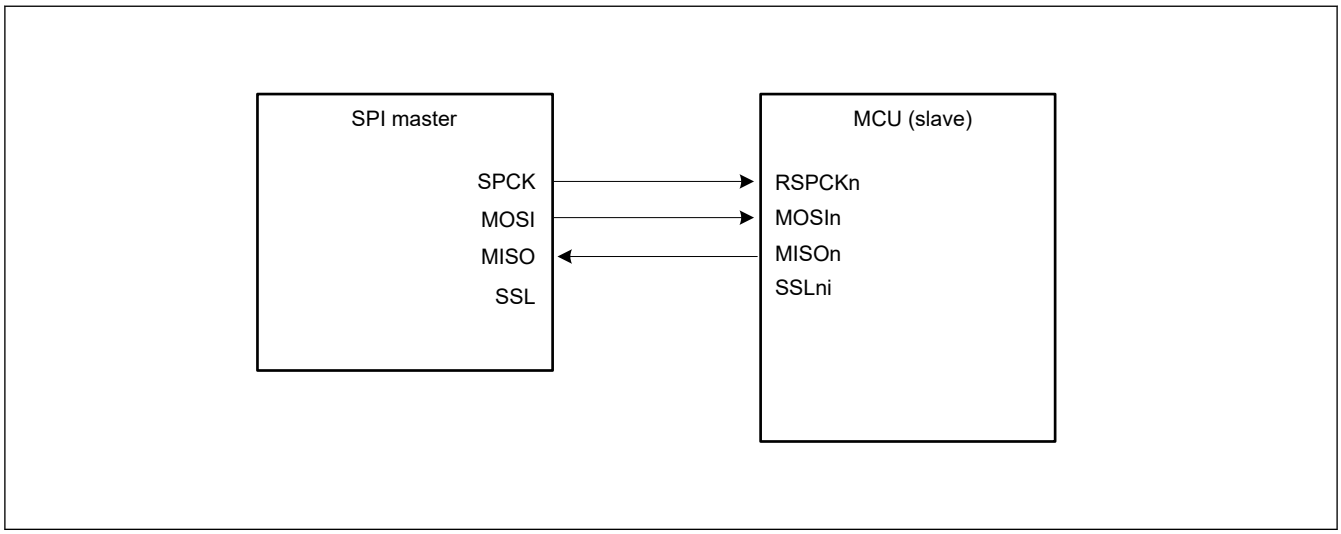

**Figure 33.12 Clock synchronous master/slave configuration example with the MCU as a slave and CPHA = 1**

## 33.3.4 Data Formats

The data format of the SPI depends on the settings in SPI Command Register m (SPCMDm) and the parity enable bit in SPI Control Register 2 (SPCR2.SPPE). Regardless of whether the MSB or LSB is first, the SPI treats the range from the LSB bit in the SPI Data Register (SPDR/SPDR_HA) to the bit associated with the selected data length, as transfer data.

This section shows the format of one frame of data before or after transfer.

#### Data format with parity disabled

When parity is disabled, transmission or reception of data proceeds with the length in bits selected in the SPI data length setting in SPI Command Register m (SPCMDm.SPB[3:0]).

**Data format with parity enabled**

When parity is enabled, transmission or reception of data proceeds with the length in bits selected in the SPI data length setting in SPI Command Register m (SPCMDm.SPB[3:0]). In this case, however, the last bit is a parity bit.

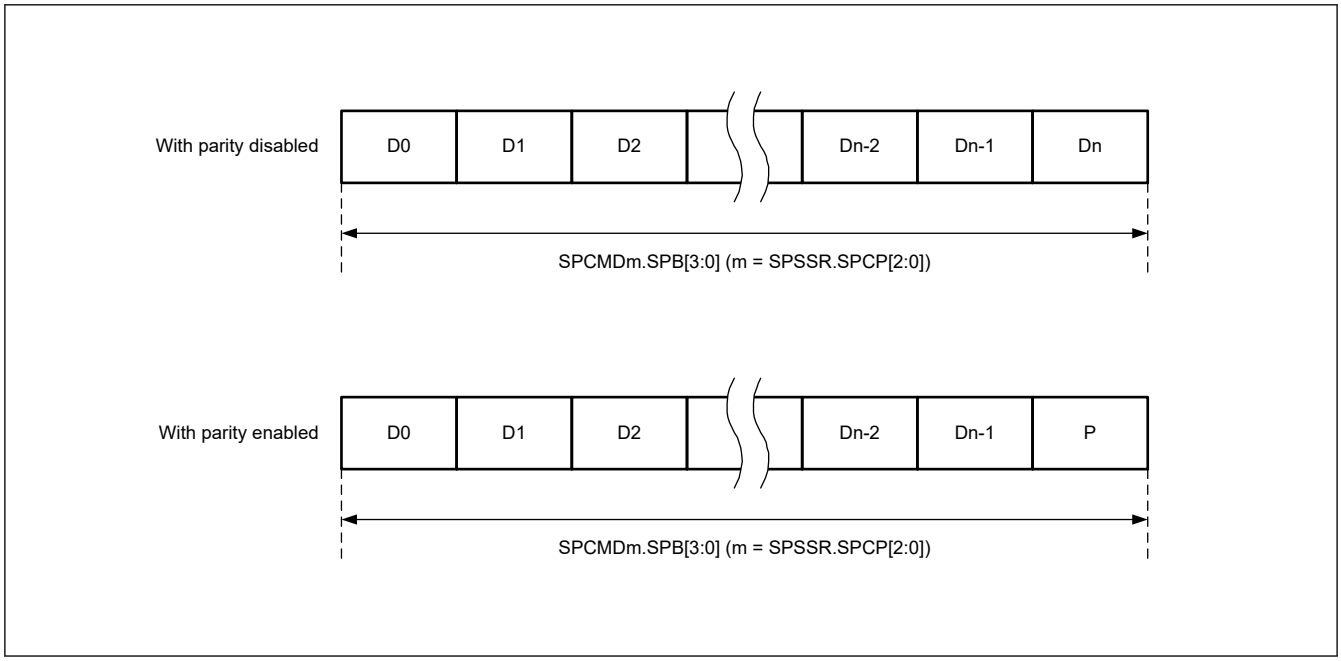

**Figure 33.13 Data format with parity disabled and enabled**

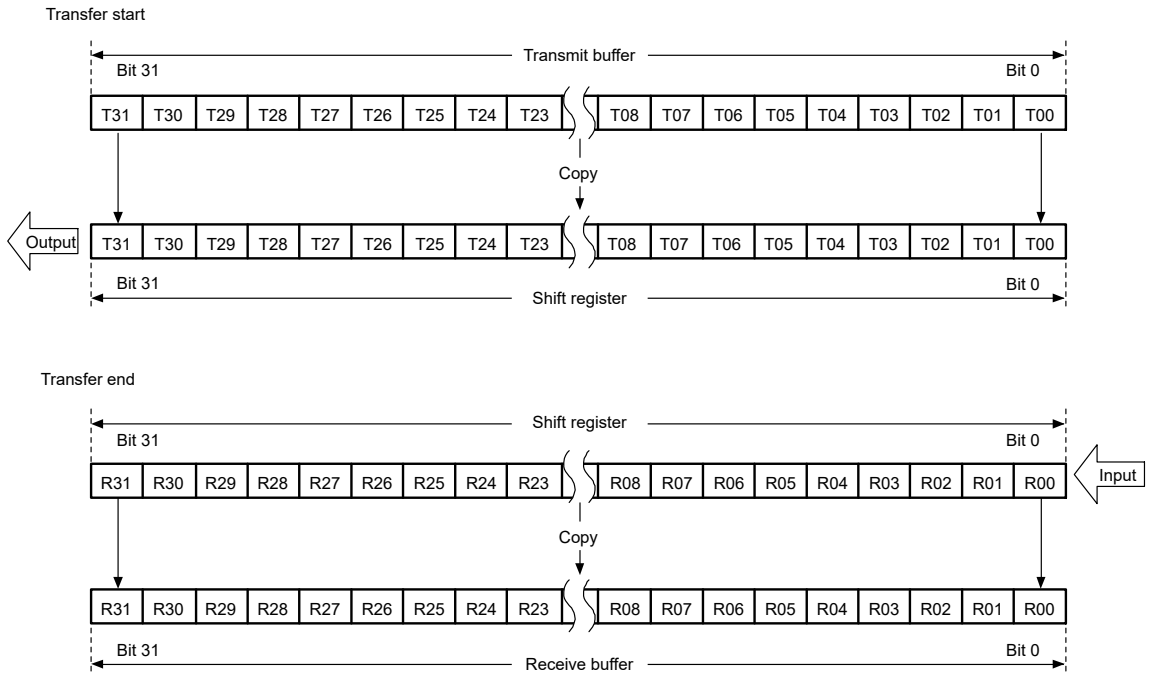
### 33.3.4.1 Operation when parity is disabled (SPCR2.SPPE = 0)



When parity is disabled, data for transmission is copied to the shift register with no pre-processing. This section describes the connection between the SPI Data Register (SPDR/SPDR_HA) and the shift register in terms of the combination of MSB- or LSB-first order and data length.

#### (1) MSB-first transfer with 32-bit data

Figure 33.14 shows the operation of the SPI Data Register (SPDR) and the shift register in a transfer with parity disabled, an SPI data length of 32 bits, and MSB-first selected.

In transmission, bits T31 to T00 from the current stage of the transmit buffer are copied to the shift register. Data for transmission is shifted out from the shift register from T31 to T30, and continuing to T00.

In reception, received data is shifted in bit-by-bit through bit[0] of the shift register. When the R31 to R00 bits are collected after input of the required number of RSPCK cycles, the value in the shift register is copied to the receive buffer.

Note: Output = MOSI (master)/MISO (slave), input = MISO (master)/MOSI (slave)

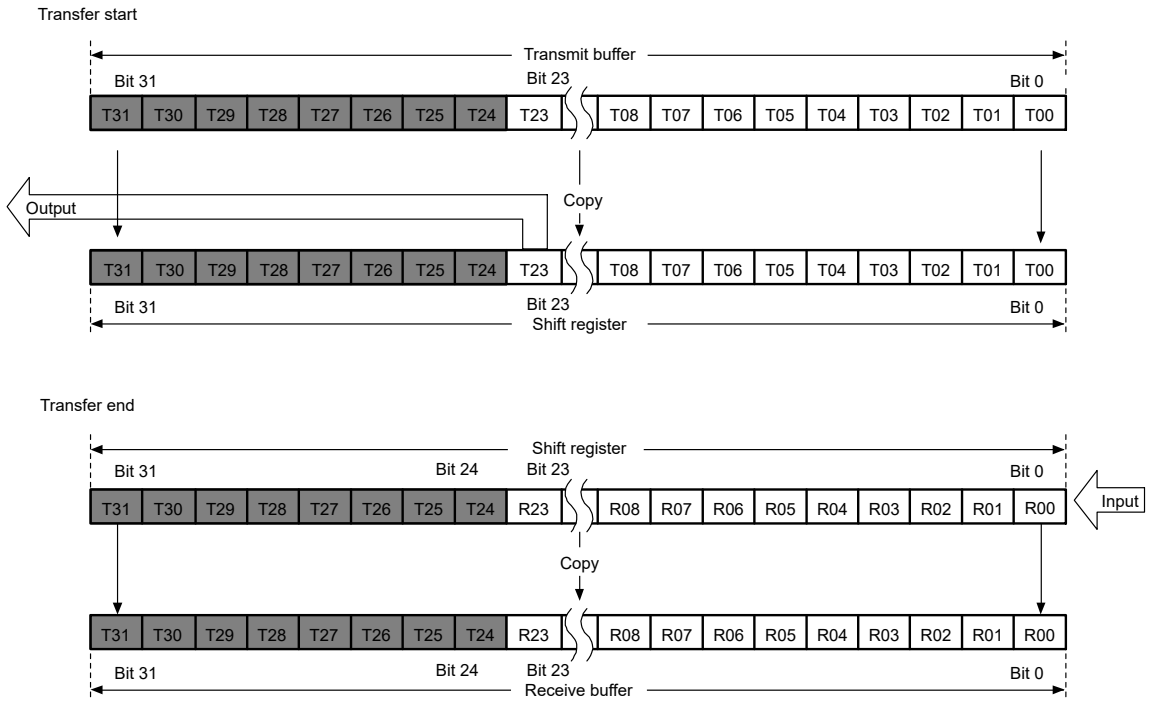


**Figure 33.14 MSB-first transfer with 32-bit data and parity disabled**

## (2) MSB-first transfer with 24-bit data

Figure 33.15 shows the operation of the SPI Data Register (SPDR) and the shift register in a transfer with parity disabled, an SPI data length of 24 bits for an example that is not 32 bits, and MSB-first selected.

In transmission, the lower 24 bits (T23 to T00) from the current stage of the transmit buffer are copied to the shift register. Data for transmission is shifted out from the shift register from T23 to T22, and continuing to T00.

In reception, received data is shifted in bit-by-bit through bit[0] of the shift register. When the R23 to R00 bits are collected after input of the required number of RSPCK cycles, the value in the shift register is copied to the receive buffer. The upper 8 bits of the transmit buffer are stored in the upper 8 bits of the receive buffer in case of transmit-receive operation. Writing 0 to bits T31 to T24 during transmission leads to 0 being inserted in the upper 8 bits of the receive buffer. On the other hand, the upper 8-bits of the receive buffer is written 0 in case of receive only operation.

Note: Output = MOSI (master)/MISO (slave), input = MISO (master)/MOSI (slave)

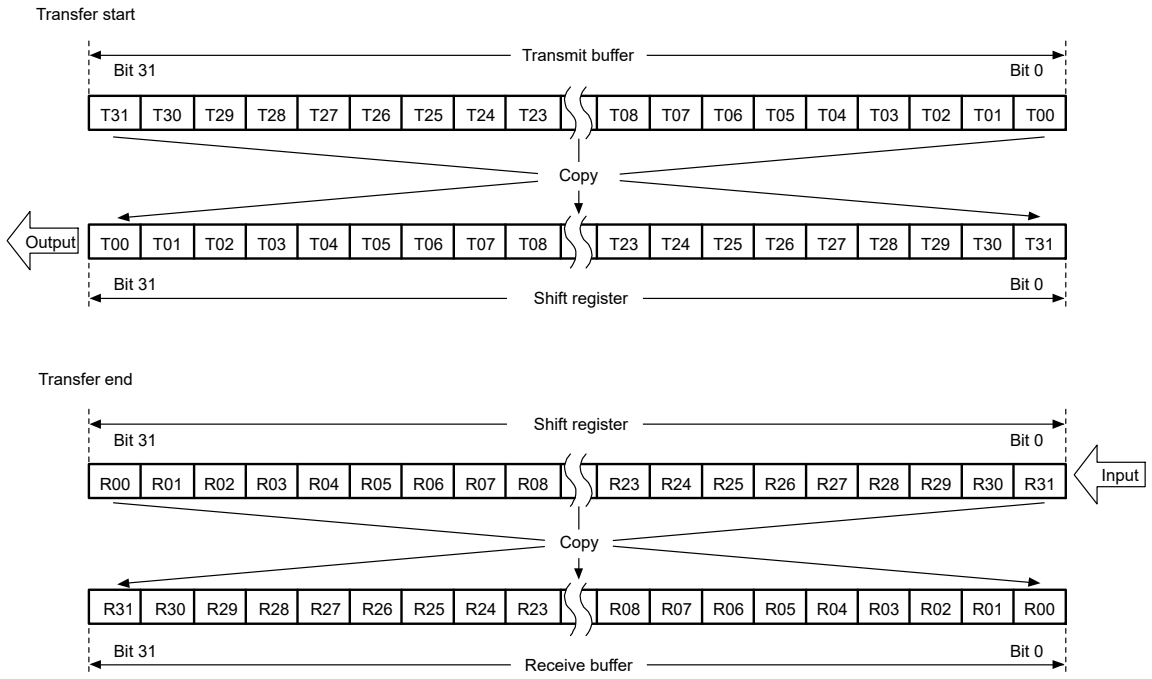

**Figure 33.15 MSB-first transfer with 24-bit data and parity disabled**

### (3) LSB-first transfer with 32-bit data

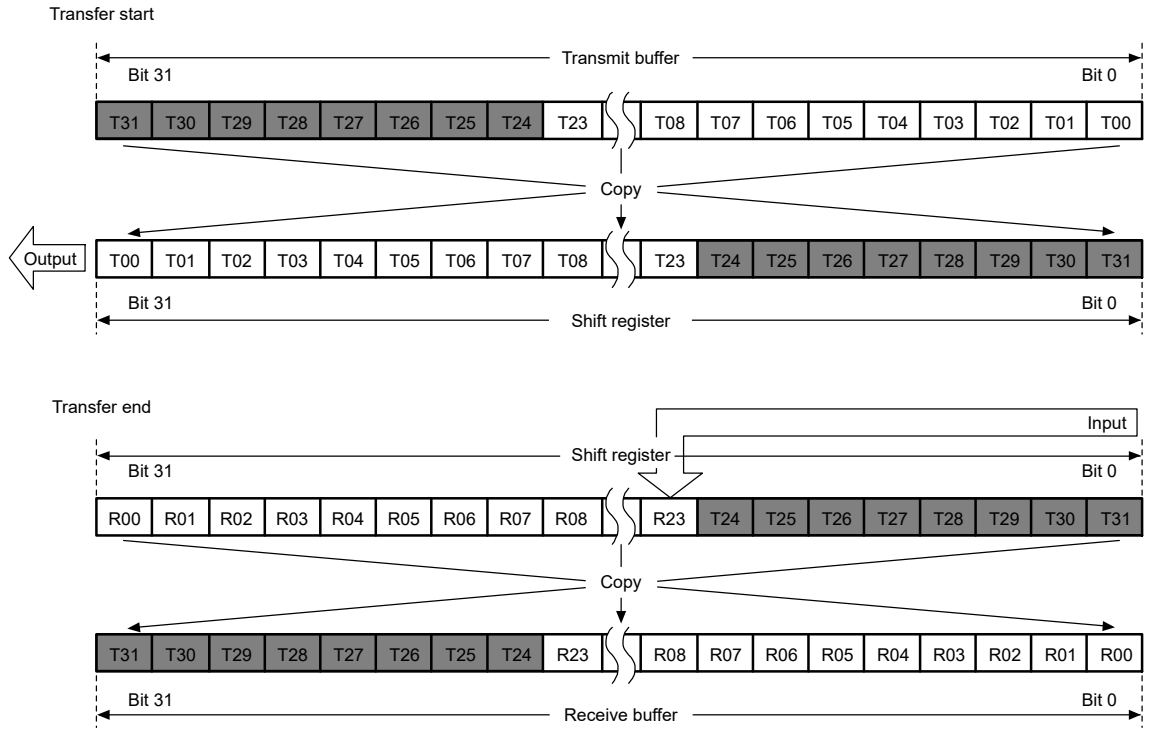
Figure 33.16 shows the operation of the SPI Data Register (SPDR) and the shift register in a transfer with parity disabled, an SPI data length of 32 bits, and LSB-first selected.

In transmission, bits T31 to T00 from the current stage of the transmit buffer are reordered bit-by-bit to obtain the order T00 to T31 for copying to the shift register. Data for transmission is shifted out from the shift register in order from T00 to T01, and continuing to T31.

In reception, received data is shifted in bit-by-bit through bit[0] of the shift register. When the R00 to R31 bits are collected after input of the required number of RSPCK cycles, the value in the shift register is copied to the receive buffer.

Note: Output = MOSI (master)/MISO (slave), input = MISO (master)/MOSI (slave)

**Figure 33.16 LSB-first transfer with 32-bit data and parity disabled**



## (4) LSB-first transfer with 24-bit data

Figure 33.17 shows the operation of the SPI Data Register (SPDR) and the shift register in transfers with parity disabled, an SPI data length of 24 bits for an example that is not 32, and LSB-first selected.

In transmission, the lower 24 bits (T23 to T00) from the current stage of the transmit buffer are reordered bit-by-bit to obtain the order T00 to T23 for copying to the shift register. Data for transmission is shifted out from the shift register from T00 to T01, and continuing to T23.

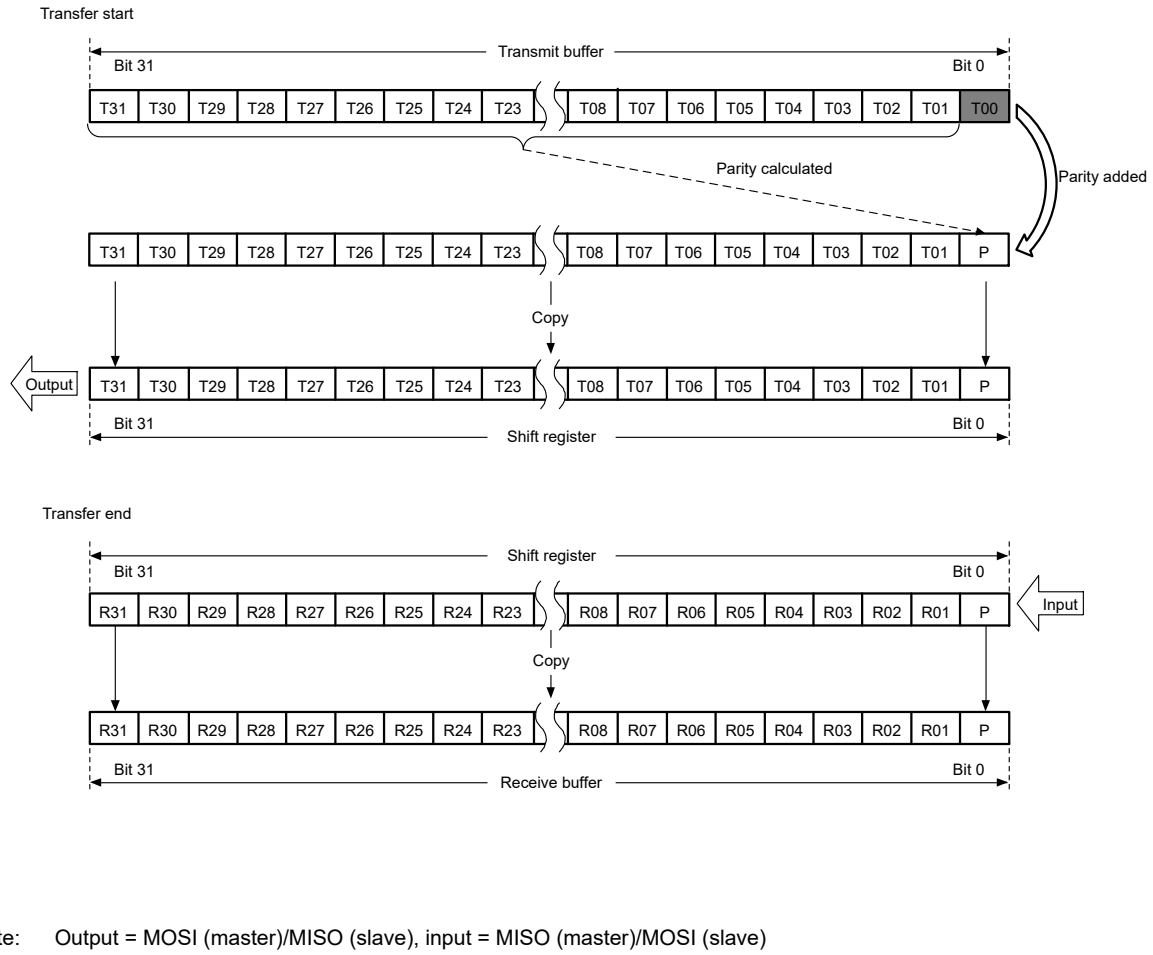
In reception, received data is shifted in bit-by-bit through bit[8] of the shift register. When the R00 to R23 bits are collected after input of the required number of RSPCK cycles, the value in the shift register is copied to the receive buffer.

The upper 8 bits of the transmit buffer are stored in the upper 8 bits of the receive buffer in case of transmit-receive operation. Writing 0 to T31 to T24 during transmission leads to 0 being inserted in the upper 8 bits of the receive buffer. On the other hand, the upper 8-bits of the receive buffer is written 0 in case of receive only operation.

Note: Output = MOSI (master)/MISO (slave), input = MISO (master)/MOSI (slave)

**Figure 33.17 LSB-first transfer with 24-bit data and parity disabled**

### 33.3.4.2 Operation when parity is enabled (SPCR2.SPPE = 1)



When parity is enabled, the lowest-order bit of the data for transmission becomes a parity bit. Hardware calculates the value of the parity bit.

#### (1) MSB-first transfer with 32-bit data

Figure 33.18 shows the operation of the SPI Data Register (SPDR) and the shift register in a transfer with parity enabled, an SPI data length of 32 bits, and MSB-first selected.

In transmission, the value of the parity bit (P) is calculated from bits T31 to T01. This replaces the final bit, T00, and the whole value is copied to the shift register. Data is transmitted in the order T31, T30, …, T01, and P.

In reception, received data is shifted in bit-by-bit through bit[0] of the shift register. When the R31 to P bits are collected after input of the required number of RSPCK cycles, the value in the shift register is copied to the receive buffer. On copying of data to the shift register, the data from R31 to P is checked for parity.

Note: Output = MOSI (master)/MISO (slave), input = MISO (master)/MOSI (slave)

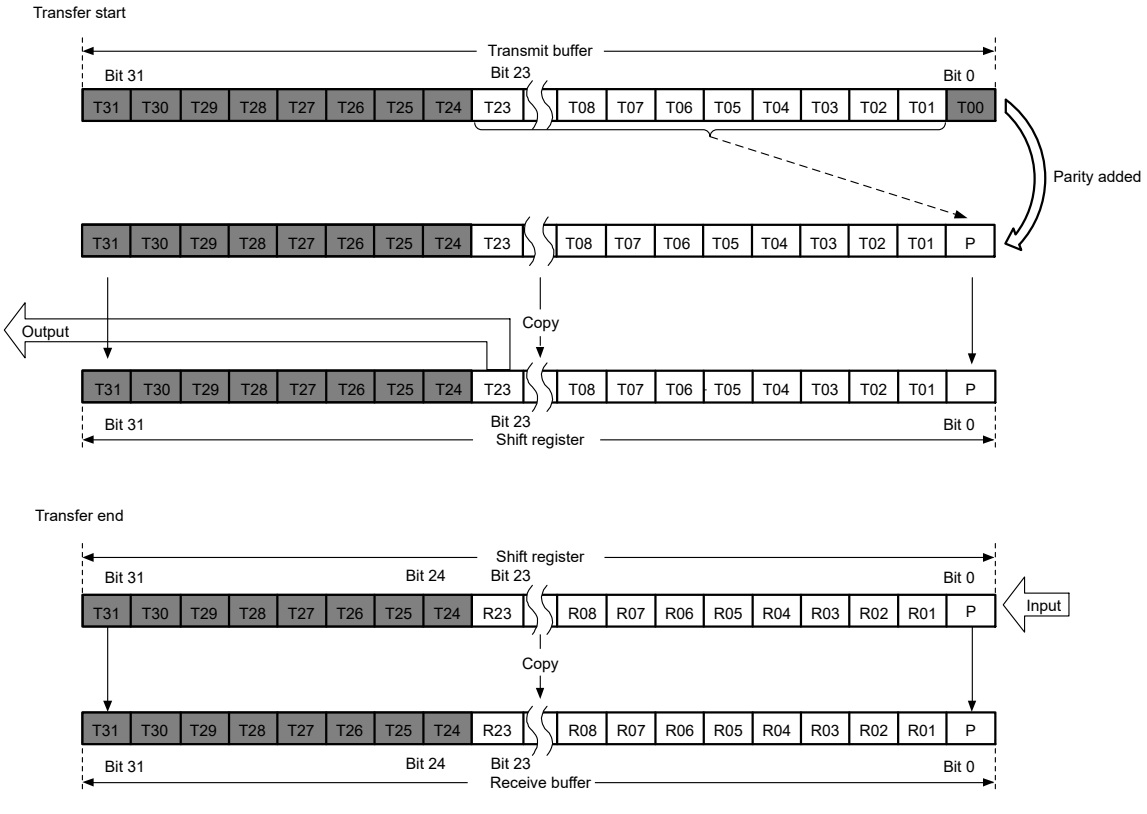


**Figure 33.18 MSB-first transfer with 32-bit data and parity enabled**

## (2) MSB-first transfer with 24-bit data

Figure 33.19 shows the operation of the SPI Data Register (SPDR) and the shift register in a transfer with parity enabled, an SPI data length of 24 bits, and MSB-first selected.

In transmission, the value of the parity bit (P) is calculated from bits T23 to T01. This replaces the final bit, T00, and the whole value is copied to the shift register. Data is transmitted in the order T23, T22, …, T01, and P.

In reception, received data is shifted in bit-by-bit through bit[0] of the shift register. When the R23 to P bits are collected after input of the required number of RSPCK cycles, the value in the shift register is copied to the receive buffer. On copying of data to the shift register, the data from R23 to P is checked for parity. The upper 8 bits of the transmit buffer is stored in the upper 8 bits of the receive buffer in case of transmit-receive operation. Writing 0 to T31 to T24 during transmission leads to 0 being inserted in the upper 8 bits of the receive buffer. On the other hand, the upper 8-bits of the receive buffer is written 0 in case of receive only operation.

Note: Output = MOSI (master)/MISO (slave), input = MISO (master)/MOSI (slave)

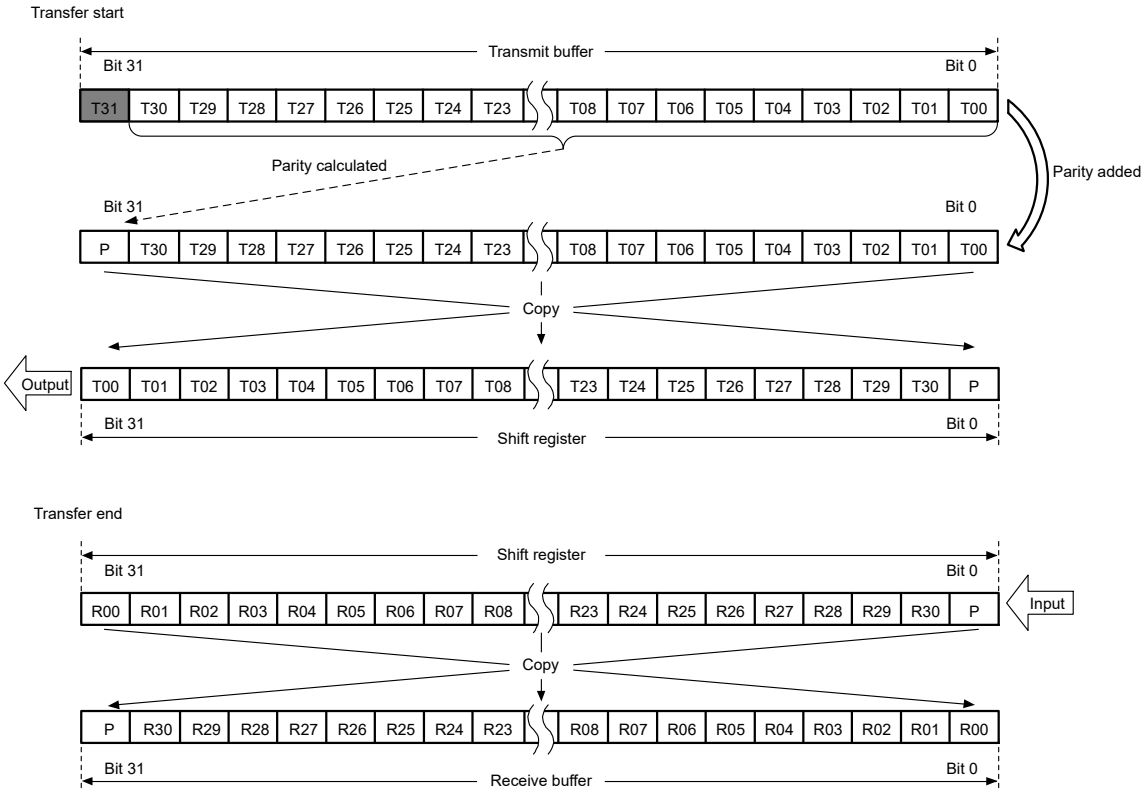

**Figure 33.19 MSB-first transfer with 24-bit data and parity enabled**

## (3) LSB-first transfer with 32-bit data

Figure 33.20 shows the operation of the SPI Data Register (SPDR) and the shift register in a transfer with parity enabled, an SPI data length of 32 bits, and LSB-first selected.

In transmission, the value of the parity bit (P) is calculated from bits T30 to T00. This replaces the final bit, T31, and the whole value is copied to the shift register. Data is transmitted in the order T00, T01, …, T30, and P.

In reception, received data is shifted in bit-by-bit through bit[0] of the shift register. When the R00 to P bits are collected after input of the required number of RSPCK cycles, the value in the shift register is copied to the receive buffer. On copying of data to the shift register, the data from R00 to P is checked for parity.

Note: Output = MOSI (master)/MISO (slave), input = MISO (master)/MOSI (slave)

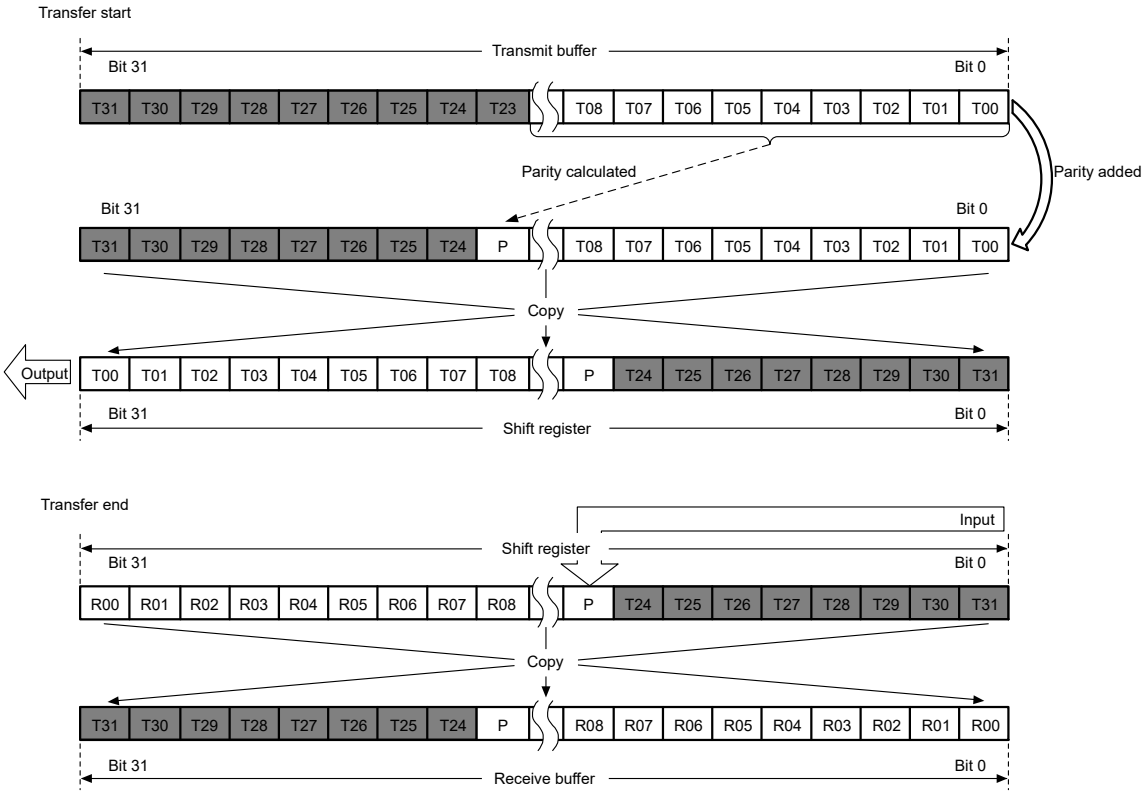

**Figure 33.20 LSB-first transfer with 32-bit data and parity enabled**

## (4) LSB-first transfer with 24-bit data

Figure 33.21 shows the operation of the SPI Data Register (SPDR) and the shift register in a transfer with parity enabled, an SPI data length of 24 bits, and LSB-first selected.

In transmission, the value of the parity bit (P) is calculated from bits T22 to T00. This replaces the final bit, T23, and the whole value is copied to the shift register. Data is transmitted in the order T00, T01, …, T22, and P.

In reception, received data is shifted in bit-by-bit through bit[8] of the shift register. When the R00 to P bits are collected after input of the required number of RSPCK cycles, the value in the shift register is copied to the receive buffer. On copying of data to the shift register, the data from R00 to P is checked for parity. The upper 8 bits of the transmit buffer is stored in the upper 8 bits of the receive buffer in case of transmit-receive operation. Writing 0 to T31 to T24 during transmission leads to 0 being inserted in the upper 8 bits of the receive buffer. On the other hand, the upper 8-bits of the receive buffer is written 0 in case of receive only operation.

Note: Output = MOSI (master)/MISO (slave), input = MISO (master)/MOSI (slave)

**Figure 33.21 LSB-first transfer with 24-bit data and parity enabled**

### 33.3.4.3 Byte Swap Transmission

#### (1) MSB-first transfer. (When the byte swap is disabled.)

Data (Byte0 [T31 to T24] to Byte3 [T07 to T00]) in the transmit buffer are copied to the shift register.

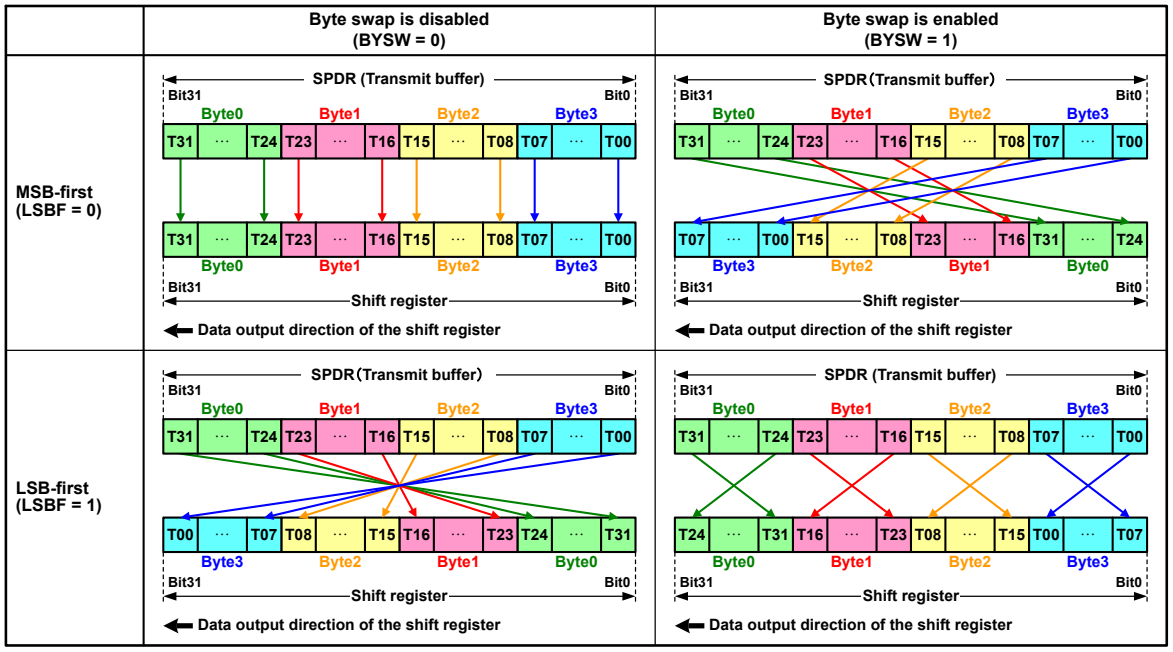
Bit values in the shift register are shifted and transmitted in the order of T31 → T30 → … → T00 as transmit data.

#### (2) MSB-first transfer. (When the byte swap is enabled.)

Byte values of the transmit buffer (Byte0 [T31 to T24] to Byte3 [T07 to T00]) are reversed in byte units and are copied to the shift register in the order of Byte3 [T07 to T00] to Byte0 [T31 to T24].

Bit values in the shift register are shifted and transmitted in the order of T07 → T06 → … → T00 → T15 → T14 → … → T08 → T23 → T22 → … → T16 → T31 → T30 → … → T24 as transmit data.

#### (3) LSB-first transfer. (When the byte swap is disabled.)



Bit values of the transmit buffer (Byte0 [T31 to T24] to Byte3 [T07 to T00]) are reversed in bit units and are copied to the shift register in the order of Byte3 [T00 to T07] to Byte0 [T24 to T31].

Bit values in the shift register are shifted and transmitted in the order of T00 → T01 → … → T31 as transmit data.

#### (4) LSB-first transfer. (When the byte swap is enabled.)

Bit values of each byte of the transmit buffer (Byte0 [T31 to T24] to Byte3 [T07 to T00]) are reversed in bit units and are copied to the shift register in the order of Byte0 [T24 to T31] to Byte3 [T00 to T07].

Bit values in the shift register are shifted and transmitted in the order of T24 → T25 → … → T31 → T16 → T17 → … → T23 → T08 → T09 → … → T15 → T00 → T01 → … → T07 as transmit data.

Note: 1. When using the byte swap, set 16 bits or 32 bits to the data length (SPCMD.SPB[3:0] setting). If setting for other length (8 to 15, 20, 24 bits), the behavior is not guaranteed.
2. When the byte swap is valid, set the parity function as invalid (SPCR2.SPPE bit = 0). If setting the parity function as valid (SPPE bit = 1), the behavior is not guaranteed.
3. Set the SPDCR2.BYSW bit, when the SPCR.SPE bit is 0. If rewriting the BYSW bit, when the SPE bit is 1, the after behavior is not guaranteed.

**Figure 33.22 Byte swap with MSB/LSB transfer**

### 33.3.4.4 Byte Swap Reception

#### (1) MSB-first transfer (when the byte swap is disabled)

The first received data (R31) is stored in bit 0 of the shift register, and received data is shifted in the order of R31 → R30 → … → R00.

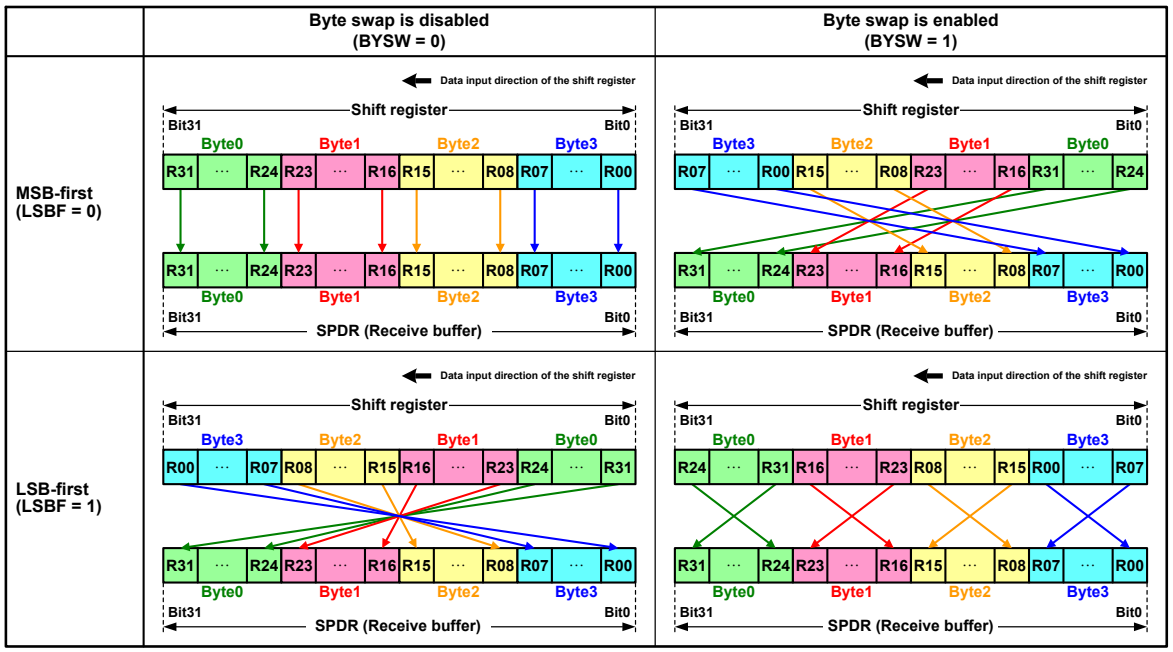
When necessary RSPCK cycles are input and data is stored from Byte0 [R31 to R24] to Byte3 [R07 to R00], the shift register value is copied to the receive buffer.

#### (2) MSB-first transfer (when the byte swap is enabled)

The first received data (R07) is stored in bit 0 of the shift register, and received data is shifted in the order of R07 → R06 → … → R00 → R15 → R14 → … → R08 → R23 → R22 → … → R16 → R31 → R30 → … → R24.

When necessary RSPCK cycles are input and data is stored from Byte3 [R07 to R00] to Byte0 [R31 to R24], byte values in the shift register are reversed in byte units and are copied to the receive buffer in the order of Byte0 [R31 to R24] to Byte3 [R07 to R00].

#### (3) LSB-first transfer (when the byte swap is disabled)



The first received data (R00) is stored in bit 0 of the shift register, and received data is shifted in the order of R00 → R01 → … → R31.

When necessary RSPCK cycles are input and data is stored from Byte3 [R00 to R07] to Byte0 [R24 to R31], bit values in the shift register are reversed in bit units and are copied to the receive buffer in the order of Byte0 [R31 to R24] to Byte3 [R07 to R00].

### (4) LSB-first transfer (when the byte swap is enabled)

The first received data (R24) is stored in bit 0 of the shift register, and received data is shifted in the order of R24 → R25 → … → R31 → R16 → R17 → … → R23 → R08 → R09 → … → R15 → R00 → R01 → … → R07.

When necessary RSPCK cycles are input and data is stored from Byte0 [R24 to R31] to Byte3 [R00 to R07], bit values of each byte in the shift register are reversed in bit units and are copied to the receive buffer in the order of Byte0 [R31 to R24] to Byte3 [R07 to R00].

Note: 1. When using the byte swap, set 16 bits or 32 bits to the data length (SPCMD.SPB[3:0] setting). If setting for other length (8 to 15, 20, 24 bits), the behavior is not guaranteed.
2. When the byte swap is valid, set the parity function as invalid (SPCR2.SPPE bit = 0). If setting the parity function as valid (SPPE bit = 1), the behavior is not guaranteed.
3. Set the SPDCR2.BYSW bit when the SPCR.SPE bit is 0. If rewriting the BYSW bit when the SPE bit is 1, the after behavior is not guaranteed.

**Figure 33.23 Byte swap with MSB/LSB transfer**

## 33.3.5 Transfer Formats

### 33.3.5.1 When CPHA = 0

Figure 33.24 shows an example transfer format for the serial transfer of 8-bit data when the SPCMDm.CPHA bit is 0. Do not perform clock synchronous operation (SPCR.SPMS = 1) when the SPI operates in slave mode (SPCR.MSTR = 0) and the CPHA bit is 0. In Figure 33.24, RSPCKn (CPOL = 0) indicates the RSPCKn signal waveform when the SPCMDm.CPOL bit is 0, and RSPCKn (CPOL = 1) indicates the RSPCKn signal waveform when the CPOL bit is 1. The sampling timing represents the timing at which the SPI fetches serial transfer data into the shift register. The I/O directions of the signals depend on the SPI settings. For details, see section 33.3.2. Controlling the SPI Pins.

When the SPCMDm.CPHA bit is 0, the driving of valid data to the MOSIn and MISOn signals begins at an SSLni signal assertion. The first RSPCKn signal change that occurs after the SSLni signal assertion becomes the first transfer data fetch. After this, data is sampled every 1 RSPCKn cycle. The change timing for MOSIn and MISOn signals is 1/2 RSPCK cycles after the transfer data fetch timing. The CPOL bit setting does not affect the RSPCK signal operation timing as it only affects the signal polarity.

t1 denotes the RSPCK delay, the period from an SSLni signal assertion to RSPCKn oscillation. t2 denotes the SSL negation delay, the period from the termination of RSPCKn oscillation to an SSLni signal negation. t3 denotes the next-access delay,

the period in which SSLni signal assertion is suppressed for the next transfer after the end of serial transfer. t1, t2, and t3 are controlled by a master device running on the SPI system. For a description of t1, t2, and t3 when the SPI is in master mode, see section 33.3.12.1. Master mode operation.

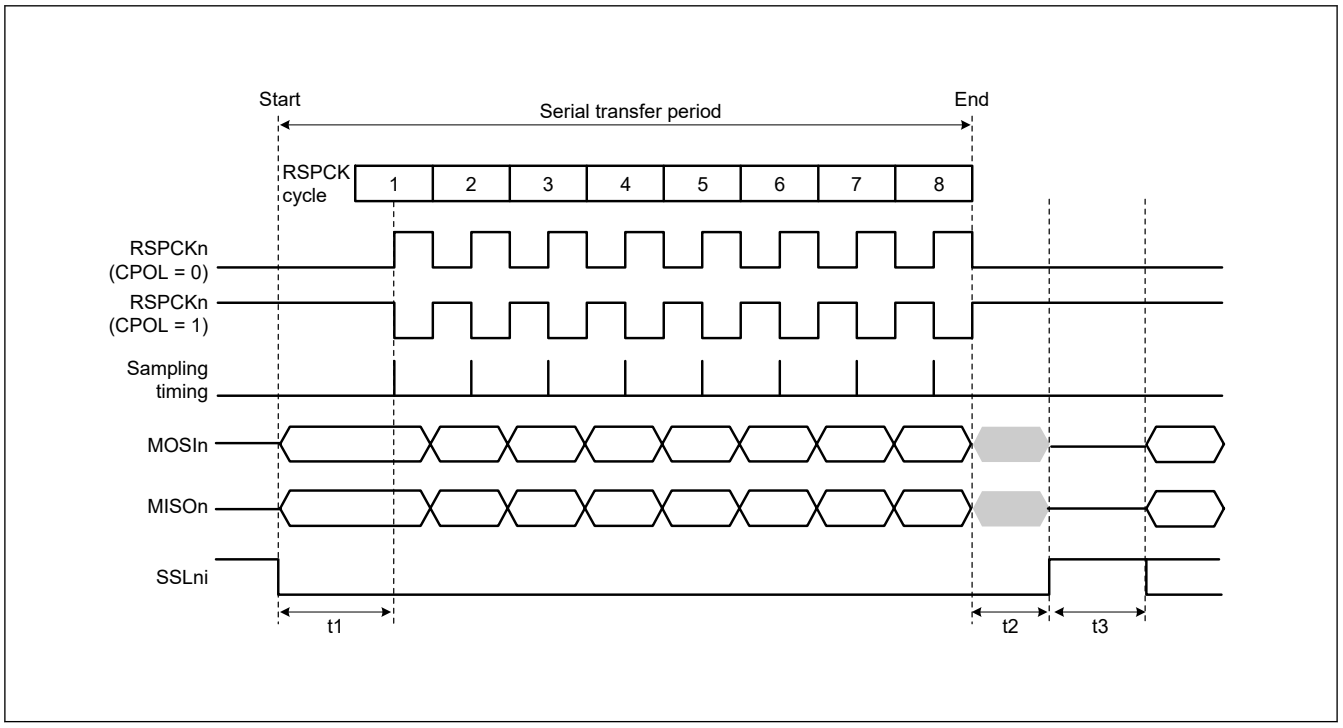


**Figure 33.24 SPI transfer format when CPHA = 0**

### 33.3.5.2 When CPHA = 1

Figure 33.25 shows an example transfer format for the serial transfer of 8-bit data when the SPCMDm.CPHA bit is 1. However, when the SPCR.SPMS bit is 1, the SSLni signals are not used, and only the three signals RSPCKn, MOSIn, and MISOn handle communications. In Figure 33.25, RSPCK (CPOL = 0) indicates the RSPCKn signal waveform when the SPCMDm.CPOL bit is 0 and RSPCK (CPOL = 1) indicates the RSPCKn signal waveform when the CPOL bit is 1. The sampling timing represents the timing at which the SPI fetches serial transfer data into the shift register. The I/O directions of the signals depend on the SPI mode (master or slave mode). For details, see section 33.3.2. Controlling the SPI Pins.

When the SPCMDm.CPHA bit is 1, the driving of invalid data to the MISOn signal begins at an SSLni signal assertion. The output of valid data to the MOSIn and MISOn signals begins at the first RSPCKn signal change that occurs after the SSLni signal assertion. After this, data is updated every 1 RSPCK cycle. The transfer data fetch timing is 1/2 RSPCK cycles after the data update timing. The SPCMDm.CPOL bit setting does not affect the RSPCKn signal operation timing. It only affects the signal polarity.

t1, t2, and t3 are the same as those when CPHA = 0. For a description of t1, t2, and t3 when the SPI of the MCU is in master mode, see section 33.3.12.1. Master mode operation.

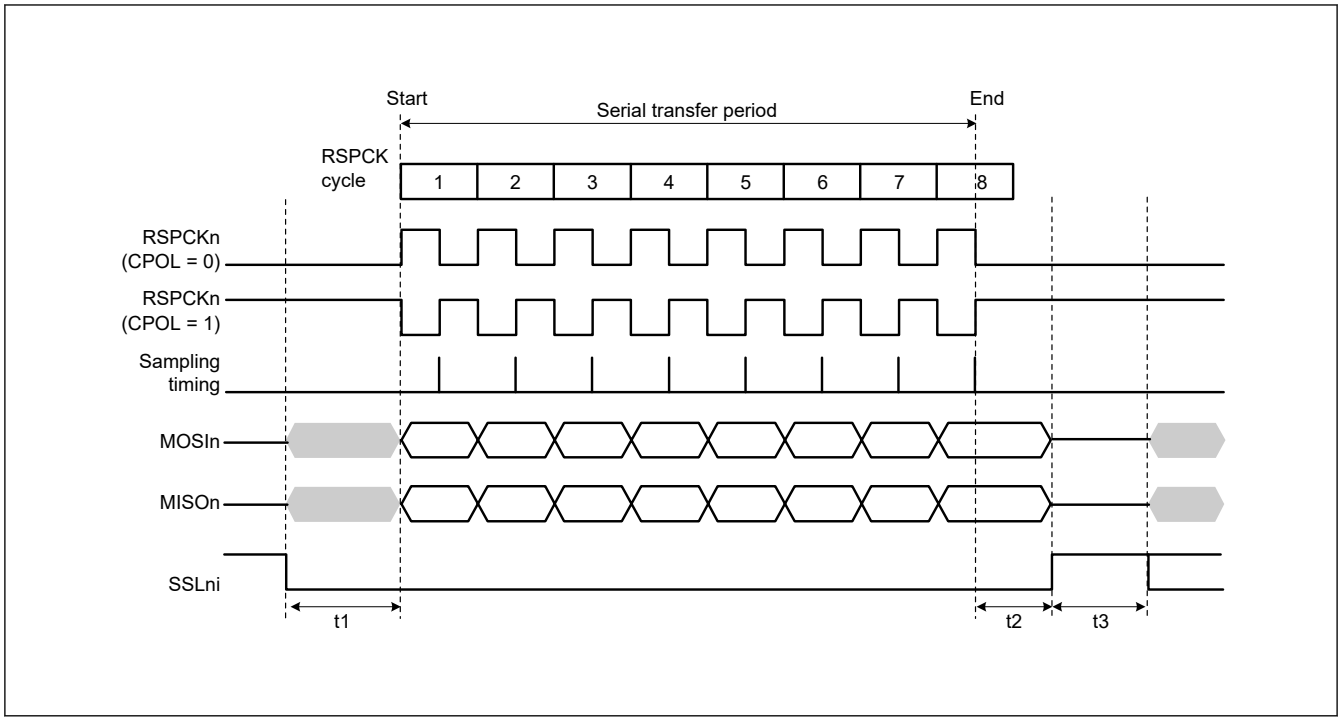

**Figure 33.25 SPI transfer format when CPHA = 1**

## 33.3.6 Data Transfer Modes

Full-duplex synchronous serial communications or transmit operations can only be selected in the Communications Operating Mode Select bit (SPCR.TXMD) when the extended communication mode select bit (ETXMD) in the SPI control register 3 (SPCR3) is 0. The SPI operation is receive only in slave mode (SPCR.MSTR = 0) when the SPCR3.ETXMD bit is 1, because SPCR.TXMD bit does not affect the SPI operation. The register accesses shown in Figure 33.26, Figure 33.27, and Figure 33.28 indicate the condition of access to the SPDR/SPDR_HA register, where W denotes a write cycle.

### 33.3.6.1 Full-duplex synchronous serial communications (SPCR3.ETXMD = 0, SPCR.TXMD = 0)

Figure 33.26 shows an example of operation when the extended communication mode select bit (ETXMD) in the SPI control register 3 (SPCR3) is set to 0 and the Communications Operating Mode Select bit (SPCR.TXMD) is set to 0. In this example, the SPI performs an 8-bit serial transfer when SPDCR.SPFC[1:0] bits are 00b, the SPCMDm.CPHA bit is 1, and the SPCMDm.CPOL bit is 0. The numbers given for RSPCKn in the waveform represent the number of RSPCK cycles, such as the number of transferred bits.

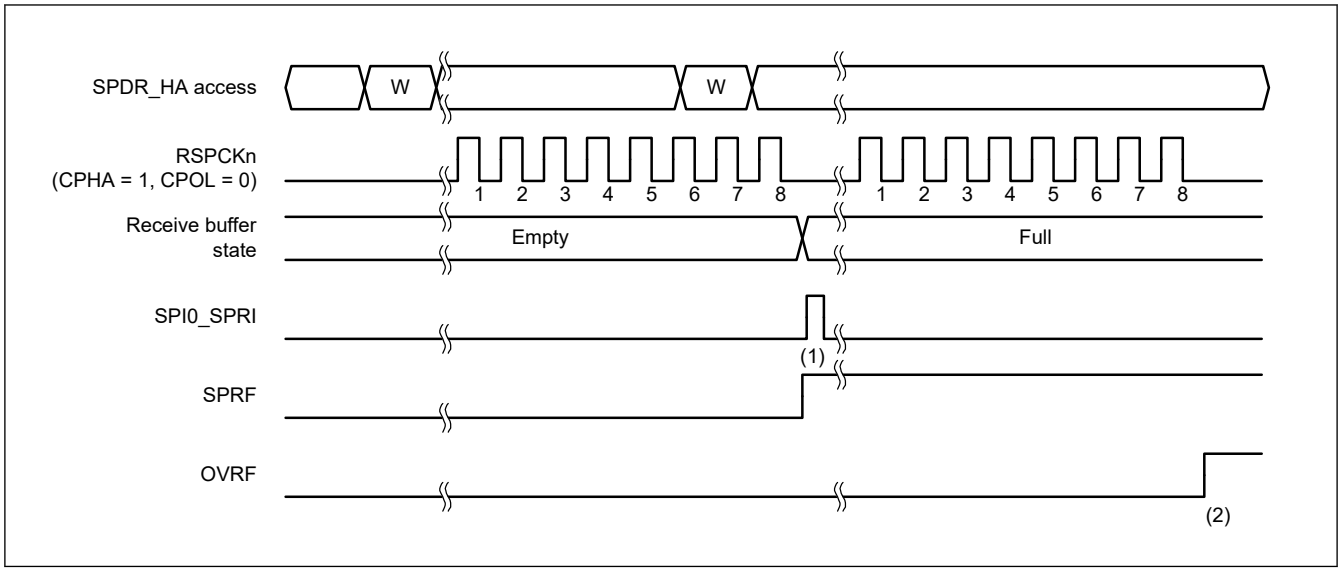

**Figure 33.26 Operation example when SPCR3.ETXMD = 0 and SPCR.TXMD = 0**

The operation of the flags at timings (1) and (2) in Figure 33.26 is as follows:

1. When a serial transfer ends with the receive buffer of SPDR_HA empty, the SPI generates a receive buffer full interrupt request (SPI0_SPRI), the SPI sets the SPSR.SPRF flag to 1, and copies the received data in the shift register to the receive buffer.
2. When a serial transfer ends with the receive buffer of SPDR_HA holding data that was received in the previous serial transfer, the SPI sets the SPSR.OVRF flag to 1, and discards the received data in the shift register. For details about the operation of the SPSR.OVRF flag, see section 33.3.10.1. Overrun errors.

### 33.3.6.2 Transmit-Only Serial Communications (SPCR3.ETXMD = 0, SPCR.TXMD = 1)

Figure 33.27 shows an example of operation when the extended communication mode select bit (ETXMD) in the SPI control register 3 (SPCR3) is set to 0 and the Communications Operating Mode Select bit (SPCR.TXMD) is set to 1. In this example, the SPI performs an 8-bit serial transfer when SPDCR.SPFC[1:0] bits are 00b, the SPCMDm.CPHA bit is 1, and the SPCMDm.CPOL bit is 0. The numbers given for RSPCKn in the waveform represent the number of RSPCK cycles, such as the number of transferred bits.

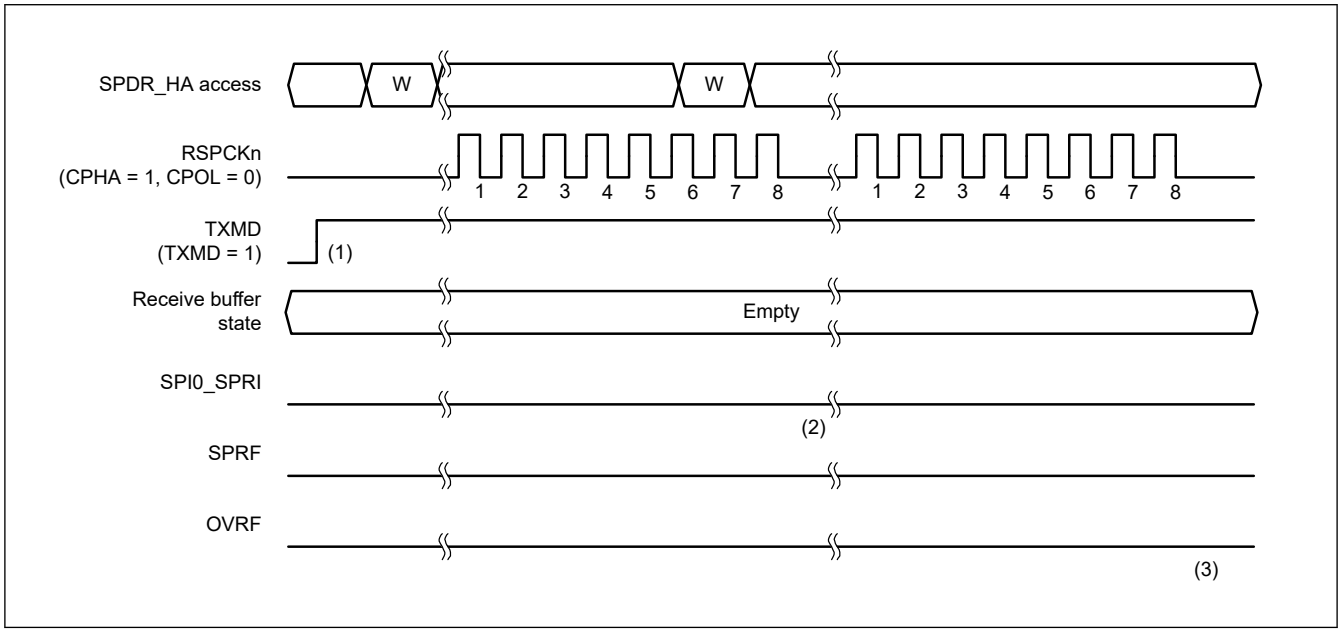

**Figure 33.27 Operation example when SPCR3.ETXMD = 0 and SPCR.TXMD = 1**

The operation of the flags at timings (1) to (3) in Figure 33.27 is as follows:

1. Make sure there is no data left in the receive buffer (the SPSR.SPRF flag is 0) and the SPSR.OVRF flag is 0 before entering transmit-only mode (SPCR3.ETXMD = 0, SPCR.TXMD = 1).
2. When a serial transfer ends with the receive buffer of SPDR_HA empty, if the transmit-only mode is selected (SPCR3.ETXMD = 0, SPCR.TXMD = 1), the SPSR.SPRF flag retains the value of 0, and the SPI does not copy the data in the shift register to the receive buffer.
3. Because the receive buffer of SPDR_HA does not hold data that was received in the previous serial transfer, even when a serial transfer ends, the SPSR.OVRF flag retains the value of 0, and the data in the shift register is not copied to the receive buffer.

In transmit-only mode (SPCR3.ETXMD = 0, SPCR.TXMD = 1), the SPI transmits data but does not receive data. Therefore, the SPSR.SPRF and SPSR.OVRF flags remain 0 at timings (1) to (3).

### 33.3.6.3 Receive-Only Serial Communication (MSTR = 0, ETXMD = 1)

Figure 33.28 shows an example of operation when the SPI master/slave mode select bit (MSTR) in the SPI control register (SPCR) is set to 0 and the extended communication mode select bit (ETXMD) in the SPI control register 3 (SPCR3) is set to 1. In the example in Figure 33.28, the SPI performs 8-bit data serial transfer with the settings of SPFC[1:0] in the SPI data control register (SPDCR) = 00b, CPHA in the SPI command register (SPCMD) = 1, and CPOL in SPCMD = 0. Numbers under the RSPCK waveform show the number of RSPCK cycles (number of transfer bits).

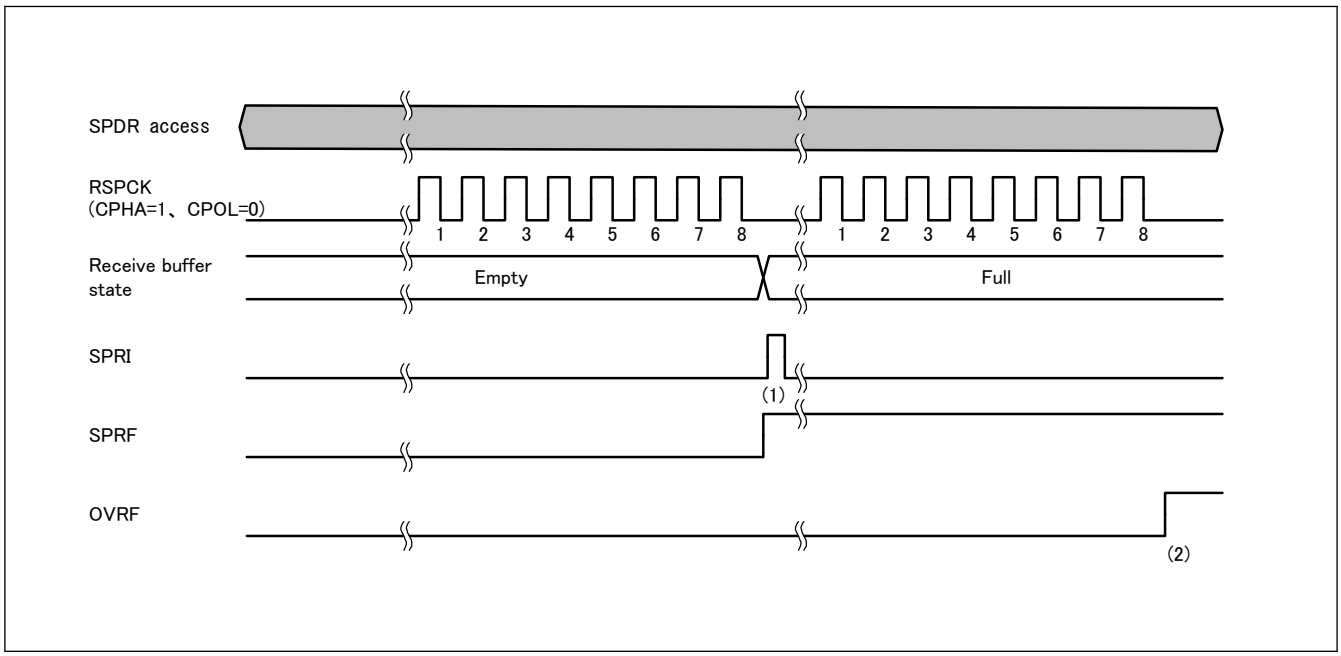

**Figure 33.28 Example of Operation when MSTR = 0 and ETXMD = 1**

The following describes operation of flags at timings (1) and (2) in the figure above.

(1) When serial transfer ends while the SPDR's receive buffer is empty, the SPI generates a receive buffer full interrupt request SPRI (setting the SPSR.SPRF flag to 1) and copies the received data in the shift register to the receive buffer

(2) When serial transfer ends while previously received data is remaining in the SPDR's receive buffer, the SPI sets the OVRF flag in the SPI status register (SPSR) to 1 and discards the received data in the shift register.

## 33.3.7 Transmit Buffer Empty and Receive Buffer Full Interrupts

Figure 33.29 and Figure 33.30 show examples of operation of the transmit buffer empty interrupt (SPI0_SPTI) and the receive buffer full interrupt (SPI0_SPRI). The SPDR_HA register accesses shown in these figures indicate the conditions of access to the register, where W denotes a write cycle and R a read cycle. In Figure 33.29, the SPI performs an 8-bit serial transfer when SPCR.TXMD bit is 0, the SPDCR.SPFC[1:0] bits are 00b, the SPCMDm.CPHA bit is 0, and the SPCMDm.CPOL bit is 0. In Figure 33.30, the SPI performs an 8-bit serial transfer when SPCR.TXMD bit is 0, the SPDCR.SPFC[1:0] bits are 00b, the SPCMDm.CPHA bit is 1, and the SPCMDm.CPOL bit is 0. The numbers given for RSPCKn in the waveform represent the number of RSPCK cycles, such as the number of transferred bits.

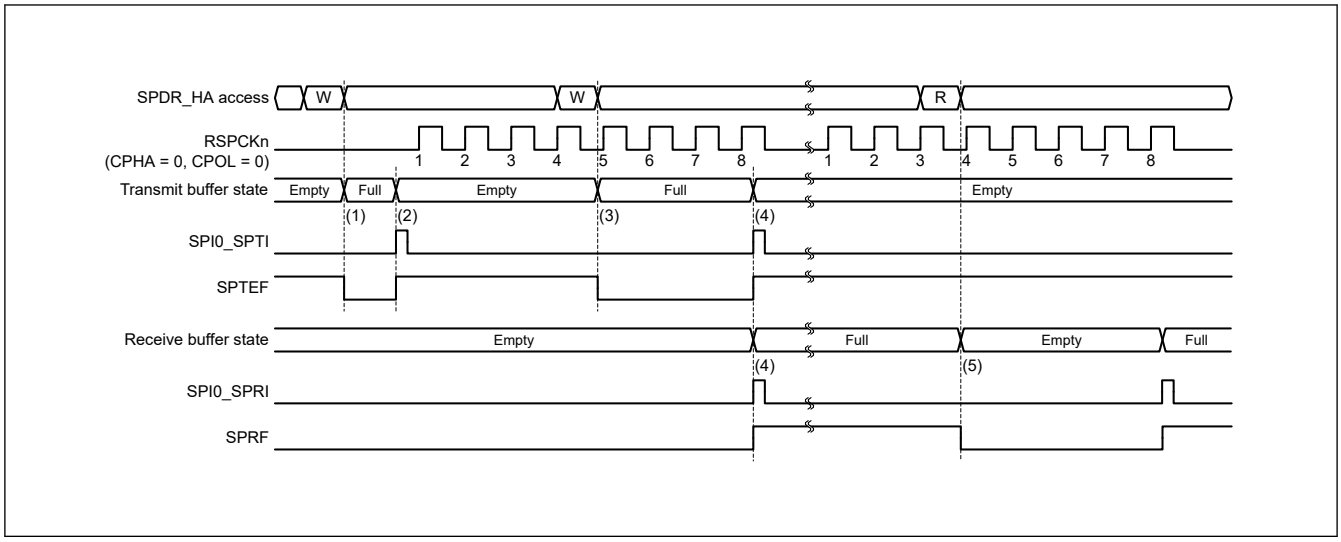

**Figure 33.29 Operation example of the SPI0_SPTI and SPI0_SPRI interrupts when CPHA = 0 and CPOL = 0 in master mode**

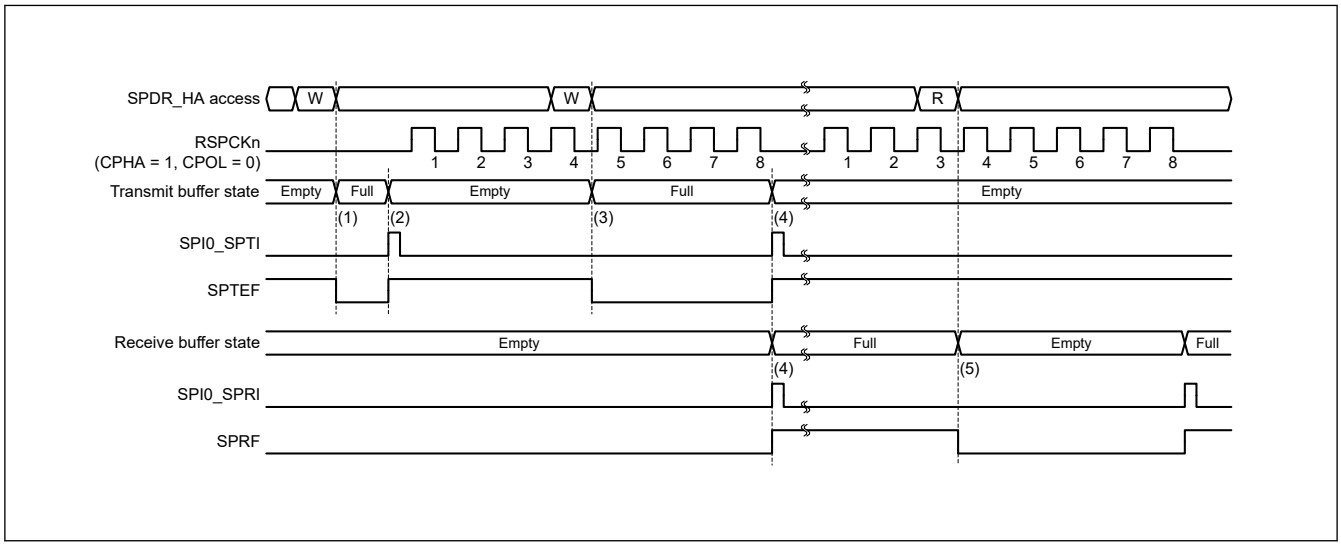

**Figure 33.30 Operation example of the SPI0_SPTI and SPI0_SPRI interrupts when CPHA = 1 and CPOL = 0 in master mode**

The operation of the SPI at timings (1) to (5) in Figure 33.29 and Figure 33.30 is as follows:

1. When transmit data is written to SPDR_HA with the transmit buffer of SPDR_HA is empty and data for the next transfer is not set, the SPI writes data to the transmit buffer and clears the SPSR.SPTEF flag to 0.
2. If the shift register is empty, the SPI copies the data in the transmit buffer to the shift register, generates a transmit buffer empty interrupt request (SPI0_SPTI), and sets the SPSR.SPTEF flag to 1. How a serial transfer is started depends on the SPI mode. For details, see section 33.3. Operation, and section 33.3.13. Clock Synchronous Operation.
3. When transmit data is written to SPDR_HA either by the transmit buffer empty interrupt routine, or by the processing of the transmit buffer empty using the SPTEF flag, the SPI writes data to the transmit buffer and clears the SPTEF flag to 0. Because the data being transferred serially is stored in the shift register, the SPI does not copy the data in the transmit buffer to the shift register.
4. When the serial transfer ends with the receive buffer of SPDR_HA empty, the SPI copies the receive data in the shift register to the receive buffer, generates a receive buffer full interrupt request (SPI0_SPRI), and sets the SPRF flag to 1. Because the shift register becomes empty on completion of the serial transfer, if the transmit buffer is full before the serial transfer ended, the SPI sets the SPTEF flag to 1 and copies data in the transmit buffer to the shift register. Even when received data is not copied from the shift register to the receive buffer in an overrun error status, on completion of the serial transfer, the SPI determines that the shift register is empty, so data transfer from the transmit buffer to the shift register is enabled.

5. When SPDR_HA is read either by the receive buffer full interrupt routine or processing of the receive buffer full interrupt using the SPRF flag, the receive data can be read.

If SPDR_HA is written to when the transmit buffer holds data that is not yet transmitted (the SPTEF flag is 0), the SPI does not update data in the transmit buffer. When writing to SPDR_HA, always use either a transmit buffer empty interrupt request or processing of the transmit buffer empty interrupt using the SPTEF flag. To use a transmit buffer empty interrupt, set the SPTIE bit in SPCR to 1. If the SPI function is disabled (the SPCR.SPE bit is 0), set the SPTIE bit to 0.

When serial transfer ends and the receive buffer is full (the SPRF flag is 1), the SPI does not copy data from the shift register to the receive buffer, and it detects an overrun error (see section 33.3.10. Error Detection). To prevent a receive data overrun error, read the received data using a receive buffer full interrupt request before the next serial transfer ends. To use an SPI receive buffer full interrupt, set the SPCR.SPRIE bit to 1.

Transmission and reception interrupts or the associated IELSRn.IR flags (where n is the interrupt vector number) in the ICU can be used to confirm the states of the transmit and receive buffers.

Similarly, the SPTEF and SPRF flags can be used to confirm the states of the transmit and receive buffers. See section 12, Interrupt Controller Unit (ICU) for the interrupt vector numbers.

## 33.3.8 Idle Interrupt

When the SPCP[2:0] of the SPI Status Register (SPSR) becomes 000b (start of sequence control), the IDLNF flag in the SPI Status Register (SPSR) is set to 1 and an idle interrupt request is made during master mode operation. An interrupt request is also made by clearing the SPCR.SPE bit to 0.

[In master mode]

Figure 33.31 shows an example of idle interrupt operation during normal operation.

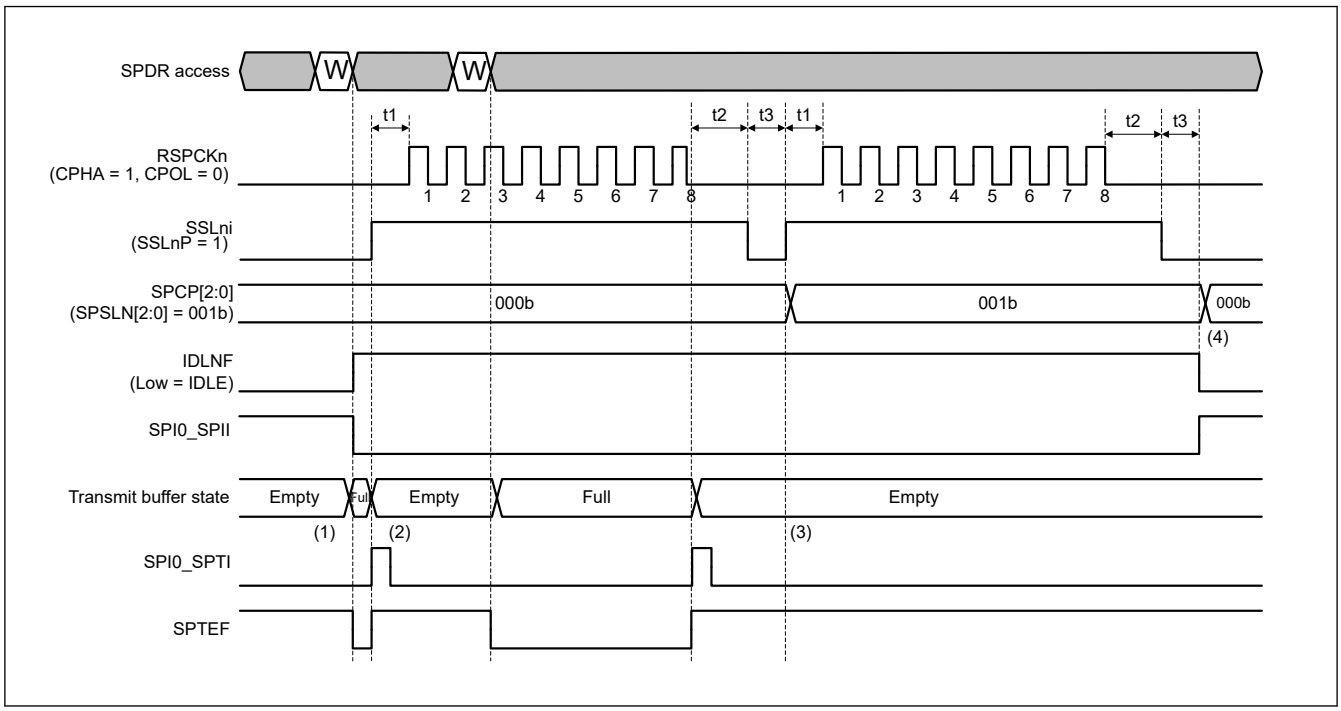

**Figure 33.31 Example of idle interrupt operation (master mode)**

1. At the start of transmission, if the next transfer data is not set in the transmission buffer, the IDLNF flag is 0 (IDLE). Writing transmit data sets the IDLNF flag to 1 (BUSY). When the SPIIE bit in the SPI Control Register 2 (SPCR2) is set to 1 before transmit data is written, interrupt processing is required before transmission start. For this reason, set the SPIIE bit to 0 before starting transmission.
2. After transmission has started, the IDLNF flag remains 1 (BUSY) regardless of the transmit buffer state.
3. The SPCP[2:0] bits change the command to the next command at the end of t3 cycle. When the next command is not 000b, the IDLNF flag remains unchanged even when the next transmit data has not been written.

4. The IDLNF flag is cleared to 0 (IDLE) at the end of t3 cycle because the next command is 000b and the next transmit data is not present. When the SPIIE bit is 1, an SPI0_SPII interrupt is output.

[In slave mode]

An idle interrupt during slave mode operation depends only on the set SPCR.SPE bit value.

Figure 33.32 shows an example of idle interrupt operation during slave mode operation.

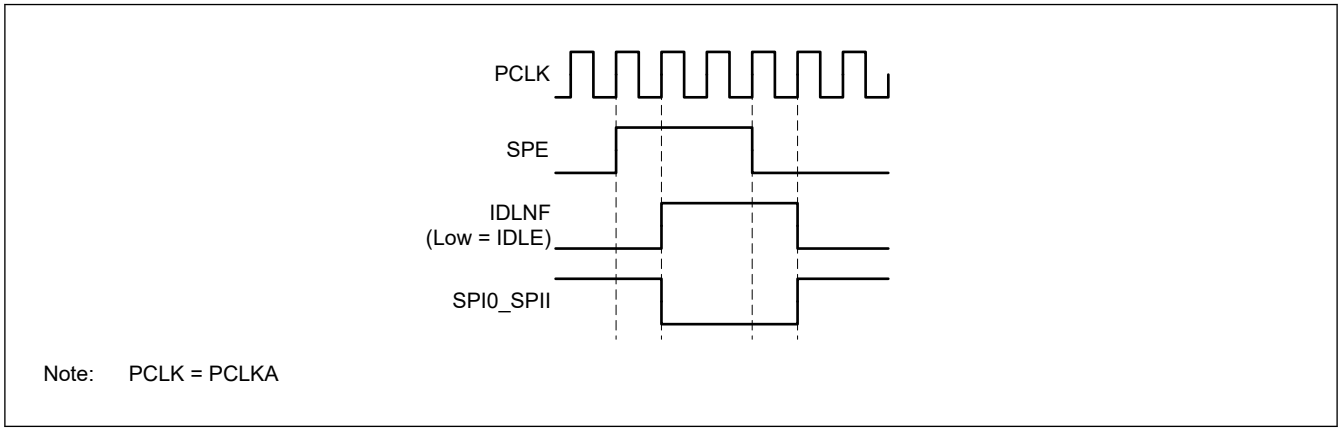

**Figure 33.32 Example of idle interrupt operation (slave mode)**

## 33.3.9 Communication End Interrupt

### 33.3.9.1 Transmit-Receive/Transmit in Master Mode

The communication end interrupt (SPCI) is made and the CENDF flag is set to 1, when following conditions are satisfied in transmit-receive master mode and transmit master mode. The set timing of the CENDF flag is same as IDLNF flag. The communication end interrupt (SPCI) is one PCLKA width and low active.

- When the value of the SPSSR.SPCP[2:0] bits are same as the SPSCR.SPSLN[2:0] bits.
- When there is no next transmission data.

The CENDF flag will not be cleared even if the SPCR.SPE bit is cleared after CENDF = 1. The CENDF flag will be cleared in one of following two conditions.

- When the next transmission data is written to the transmit buffer (SPTX).
- The CENDF flag was written 0 after reading the SPSR when the CENDF flag was 1.

Figure 33.33 shows an example of communication end interrupt operation during transmit-receive/transmit master mode.

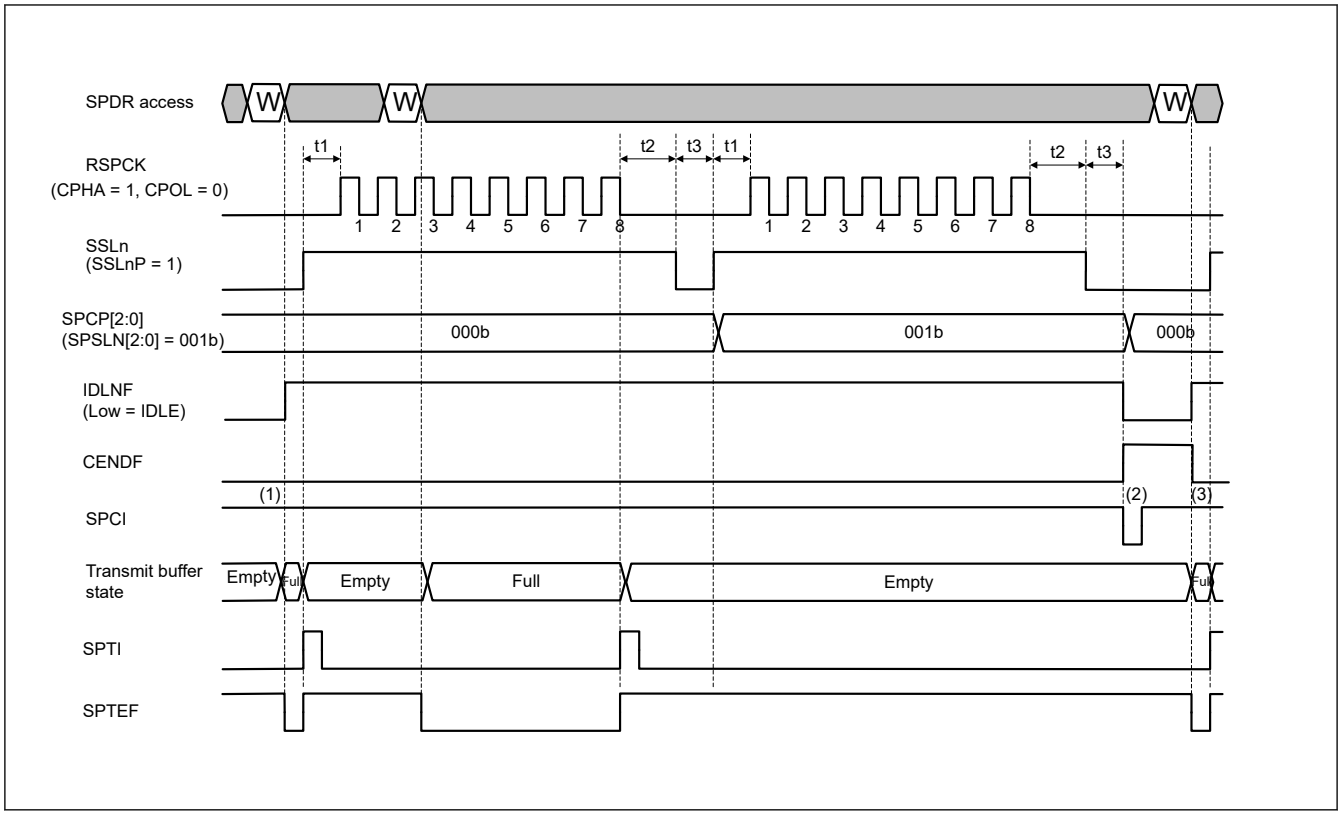

**Figure 33.33 Example of Communication End Interrupt Operation (Transmit-Receive/Transmit Master mode)**

1. The CNEDF flag is 0 and the level of SPCI is 1 before communication start, and these have kept during communication.
2. The CENDF flag will be 1 (Communication End) at the end of t3 cycle, because the next command is 000b and there is no next transmit data, and then the SPCI interrupt output when the CENDIE bit is 1.
3. The CENDF flag is cleared when the next transmission data is written to the transmit buffer (SPTX). Or the CENDF flag is cleared if the CENDF flag was written 0 after reading the SPCR when the CENDF flag was 1.

In slave mode operation, the output timing of the communication end interrupt is deferent due to the value of the SPCR.SPMS bit (SPI mode select bit), and the clear timing of the communication end interrupt is deferent due to the communication mode (transmit-receive or transmit-only or receive-only).

### 33.3.9.2 Transmit-Receive/Transmit in Slave Mode on SPI Operation (4-wire)

The communication end interrupt (SPCI) is made and the CENDF flag is set to 1, when both SPTX buffer and transmit shift buffer are empty in transmit-receive/transmit slave mode on SPI Operation (4-wire). The set timing of the CENDF flag is same as SSL0 negate timing. The communication end interrupt (SPCI) is one PCLKA width and low active.

The CENDF flag will not be cleared even if the SPCR.SPE bit is cleared after CENDF = 1. The CENDF flag will be cleared in one of following two conditions.

- When the next transmission data is written to the transmit buffer (SPTX).
- The CENDF flag was written 0 after reading the SPSR when the CENDF flag was 1.

Figure 33.34 shows an example of communication end interrupt operation during transmit-receive/transmit slave mode on SPI operation.

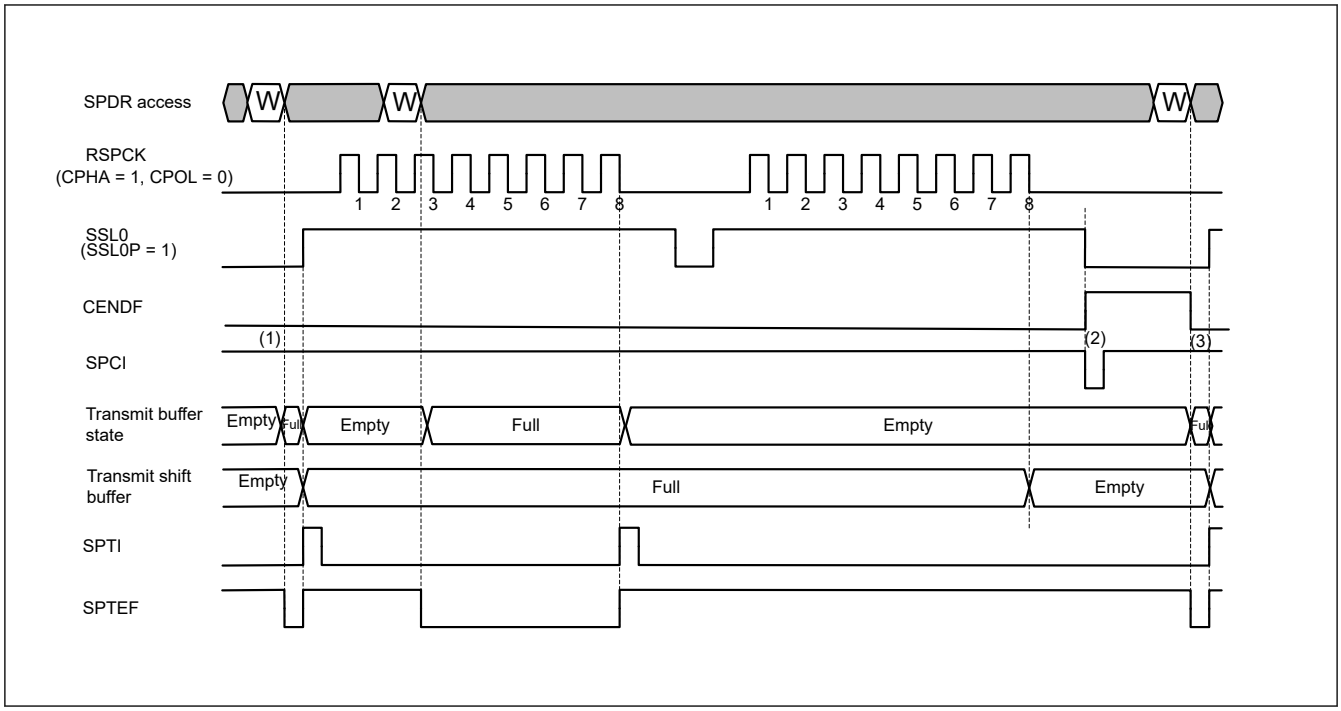

**Figure 33.34 Example of Communication End Interrupt Operation (Transmit-Receive/Transmit Slave mode on SPI Operation)**

1. The CNEDF flag is 0 and the level of SPCI is 1 before communication start, and these have kept during communication.
2. The CENDF flag will be 1 (Communication End) at the timing of SSL0 negate, when both SPTX buffer and transmit shift buffer are empty, and then the SPCI interrupt output when the CENDIE bit is 1.
3. The CENDF flag is cleared when the next transmission data is written to the transmit buffer (SPTX). Or the CENDF flag is cleared if the CENDF flag was written 0 after reading the SPCR when the CENDF flag was 1.

### 33.3.9.3 Receive Only in Slave Mode on SPI Operation (4-wire)

The communication end interrupt (SPCI) is made and the CENDF flag is set to 1 at the SSL0 negate timing in receive only slave mode on SPI operation (4-wire). The number of transmission frame is set by the SPDCR.SPFC[1:0]. Then the SSL0 is negated at the last frame transmission end. The communication end interrupt (SPCI) is one PCLKA width and low active.

The CENDF flag will not be cleared even if the SPCR.SPE bit is cleared after CENDF = 1. The CENDF flag will be cleared in one of following two conditions.

- The SSL0 assert timing of next transmission.
- The CENDF flag was written 0 after reading the SPSR when the CENDF flag was 1.

Figure 33.35 shows an example of communication end interrupt operation during receive only slave mode on SPI operation (4-wire).

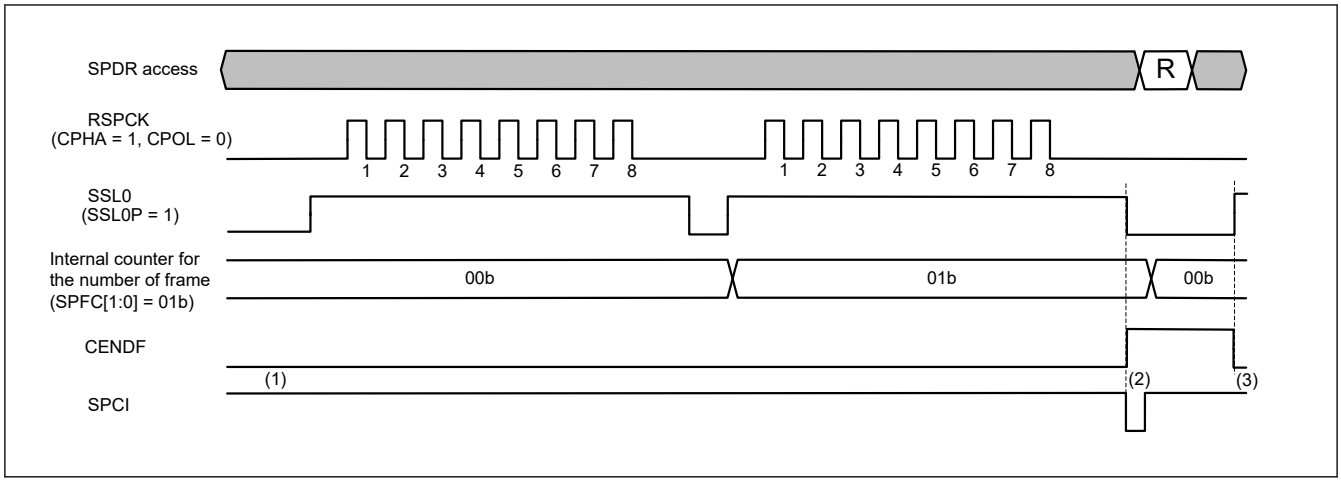

**Figure 33.35 Example of Communication End Interrupt Operation (Receive only Slave mode on SPI Operation)**

1. The CNEDF flag is 0 and the level of SPCI is 1 before communication start, and these have kept during communication.
2. The CENDF flag will be 1 (Communication End) at the timing of SSL0 negate, when the last frame transmission ends, and then the SPCI interrupt output when the CENDIE bit is 1.
3. The CENDF flag is cleared at the SSL0 assert when the next transmission start. Or the CENDF flag is cleared if the CENDF flag was written 0 after reading the SPCR when the CENDF flag was 1.

### 33.3.9.4 Transmit-Receive/Transmit in Slave Mode on Clock Synchronous Operation (3-wire)

The communication end interrupt (SPCI) is made and the CENDF flag is set to 1 when both SPTX buffer and transmit shift register are empty in transmit-receive/transmit slave mode on clock synchronous operation (3-wire). The set timing of CENDF flag is same as the last data sampling of the RSPCK (the last odd edge of RSPCK when the SPCMD0.CPHA bit is 0, the last even edge of RSPCK when the SPCMD0.CPHA bit is 1). The communication end interrupt (SPCI) is one PCLKA width and low active.

The CENDF flag will not be cleared even if the SPCR.SPE bit is cleared after CENDF = 1. The CENDF flag will be cleared in one of following two conditions.

- The SSL0 assert timing of next transmission.
- The CENDF flag was written 0 after reading the SPSR when the CENDF flag was 1.

Figure 33.36 shows an example of communication end interrupt operation during transmig-receive/transmit slave mode on clock synchronous operation (3-wire).

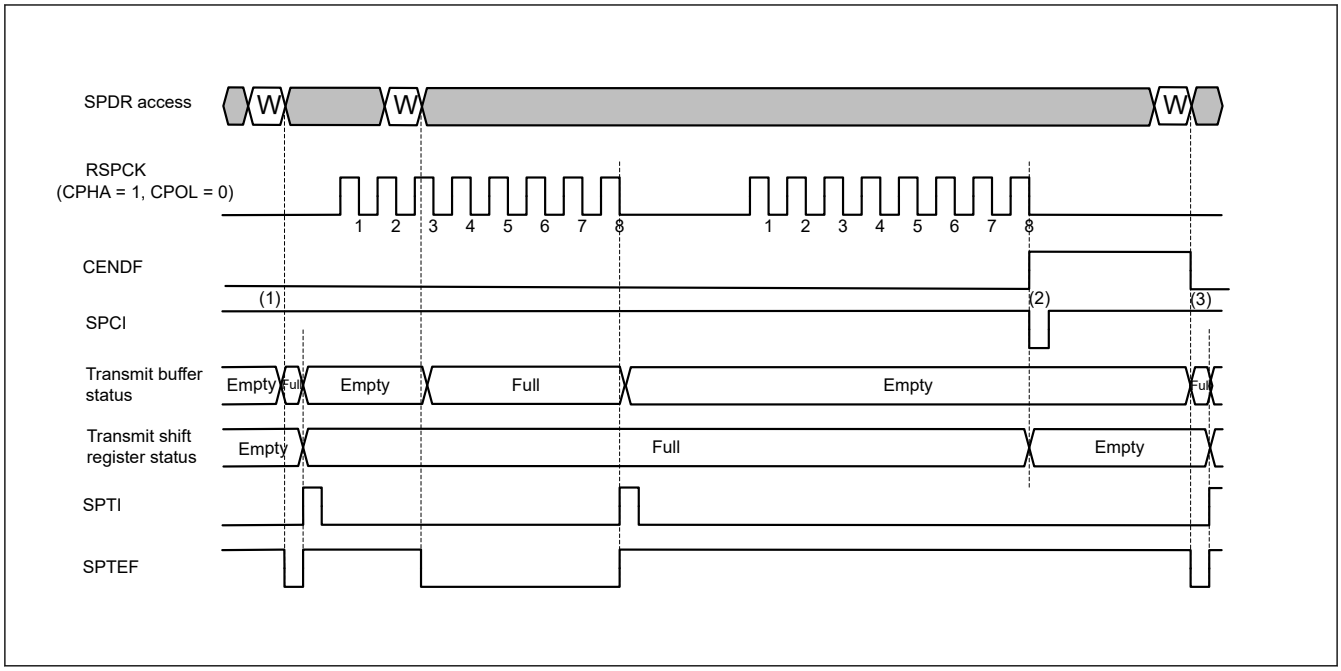

**Figure 33.36 Example of Communication End Interrupt Operation (Transmit-Receive/Transmit Slave mode on Clock Synchronous Operation)**

1. The CNEDF flag is 0 and the level of SPCI is 1 before communication start, and these have kept during communication.
2. The CENDF flag will be 1 (Communication End) at the last data sampling timing of RSPCK, when both SPTX buffer and transmit shift buffer are empty, and then the SPCI interrupt output when the CENDIE bit is 1.
3. The CENDF flag is cleared when the next transmission data is written to the transmit buffer (SPTX). Or the CENDF flag is cleared if the CENDF flag was written 0 after reading the SPCR when the CENDF flag was 1.

### 33.3.9.5 Receive Only in Slave Mode on Clock Synchronous Operation (3-wire)

The communication end interrupt (SPCI) is made and the CENDF flag is set to 1 at the last data sampling of the last transmission frame in receive only slave mode on clock synchronous operation (3-wire). The sampling timing is the last odd edge of RSPCK when the SPCMD0.CPHA bit is 0, the last even edge of RSPCK when the SPCMD0.CPHA bit is 1. The number of transmission frame is set by the SPDCR.SPFC[1:0]. The communication end interrupt (SPCI) is one PCLKA width and low active.

The CENDF flag will not be cleared even if the SPCR.SPE bit is cleared after CENDF = 1. The CENDF flag will be cleared in one of following two conditions.

- The first edge of RSPCK for next transmission.
- The CENDF flag was written 0 after reading the SPSR when the CENDF flag was 1.

Figure 33.37 shows an example of communication end interrupt operation during receive only slave mode on clock synchronous operation.

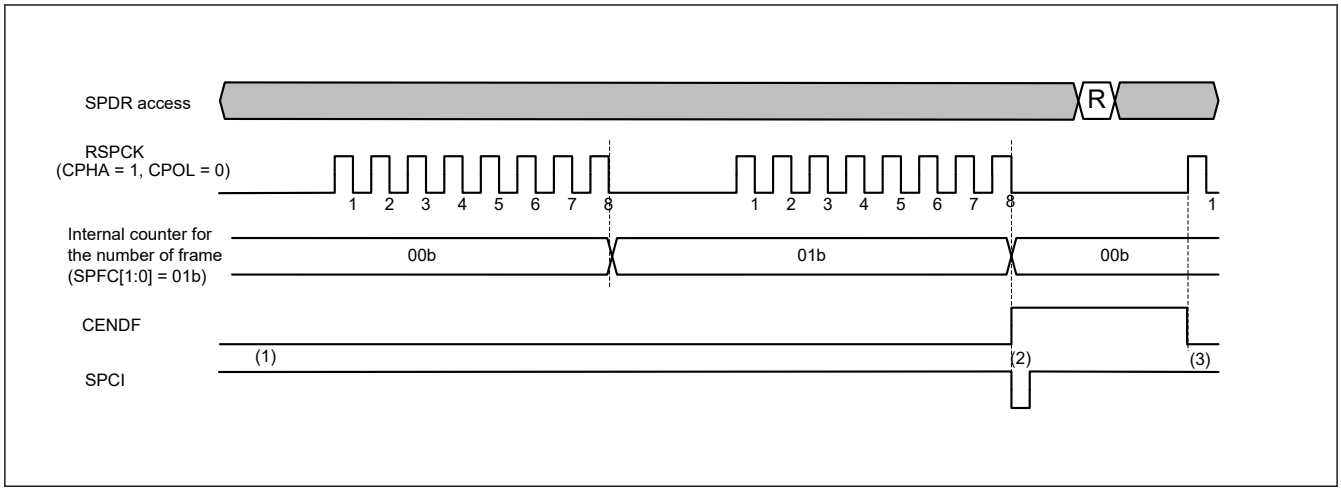

**Figure 33.37 Example of Communication End Interrupt Operation (Receive-only Slave mode on Clock Synchronous Operation)**

1. The CNEDF flag is 0 and the level of SPCI is 1 before communication start, and these have kept during communication.
2. The CENDF flag will be 1 (Communication End) at the last data sampling timing of RSPCK, when the last frame transmission end. The number of transmission frame is set by the SPDCR.SPFC[1:0]. And then the SPCI interrupt output when the CENDIE bit is 1.
3. The CENDF flag is cleared at the first edge of RSPCK for the next transmission. Or the CENDF flag is cleared if the CENDF flag was written 0 after reading the SPCR when the CENDF flag was 1.

### 33.3.9.6 Common Operation

In this chapter, the operation common to each mode / area option communication in section 33.3.9.1. Transmit-Receive/ Transmit in Master Mode to section 33.3.9.5. Receive Only in Slave Mode on Clock Synchronous Operation (3-wire) is explained. When the enable of SPI communication end interrupt (CENDIE) is 0, at the time of communication completion, a flag of communication end (CENDF) is set and an event of communication end (sp_elccend) is output, but no interrupt is output. However, if the enable of communication end interrupt (CENDIE) is set to 1 before clearing the flag of communication end (CENDF) while the enable of SPI function (SPE) is 1, the communication end interrupt is output.

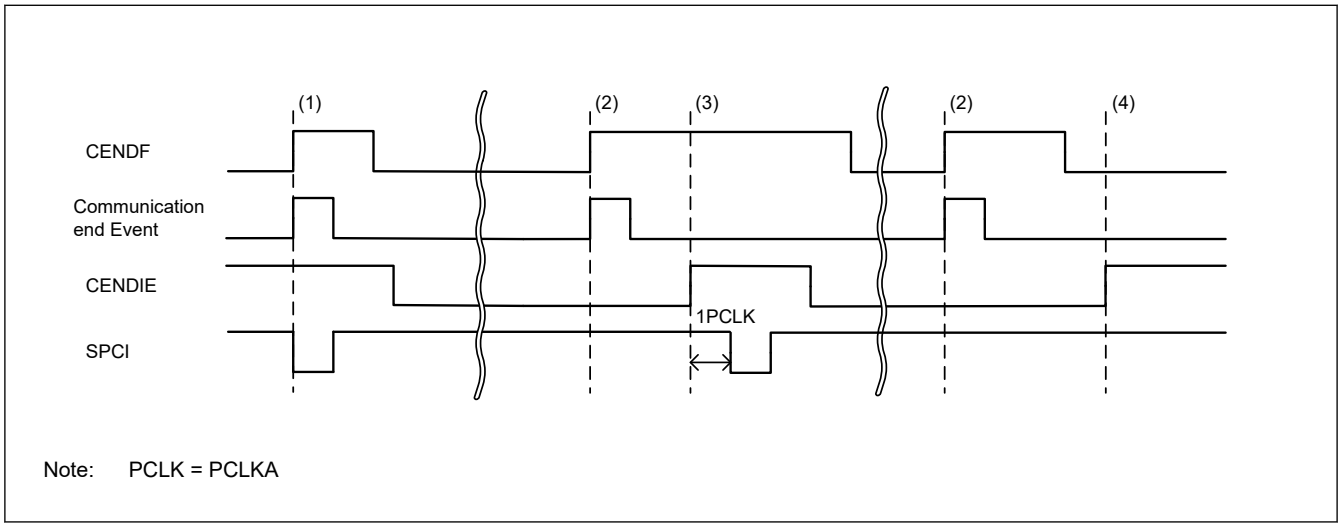

**Figure 33.38 Example of Communication End Interrupt Operation (Enable control)**

1. When the enable of SPI communication end interrupt (CENDIE) is 1, at the time of communication completion, the following three are the same timing.
   - A flag of communication end (CENDF)
   - An event of communication end (sp_elccend)
   - The communication end interrupt

2. When the enable of SPI communication end interrupt (CENDIE) is 0, at the time of communication completion, the following two are the same timing, but no interrupt.
   - A flag of communication end (CENDF)
   - An event of communication end (sp_elccend)
3. After (2), if the enable of communication end interrupt (CENDIE) is set when the enable of SPI function (SPE) and the flag of communication end (CENDF) are 1, the communication end interrupt is output after 1 PCLKA.
4. After (2), even if the enable of communication end interrupt (CENDIE) is set when the enable of SPI function (SPE) or the flag of communication end (CENDF) is 0, the communication end interrupt is not output.

### 33.3.10 Error Detection

In normal SPI serial transfers, data written to the transmit buffer of SPDR/SPDR_HA is transmitted, and received data can be read from the receive buffer of SPDR/SPDR_HA. If access is made to SPDR/SPDR_HA, an abnormal transfer might occur, depending on the status of the transmit or receive buffer or the status of the SPI at the beginning or end of serial transfer.

If an abnormal transfer occurs, the SPI detects the event as an underrun error, overrun error, parity error, or mode fault error. Table 33.10 lists the relationship between non-normal transfer operations and the SPI error detection function.

**Table 33.10 Relationship between non-normal transfer operations and SPI error detection**

| Operation | Occurrence condition | SPI operation | Error detection |
|---|---|---|---|
| 1 | SPDR/SPDR_HA is written when the transmit buffer is full. | • The contents of the transmit buffer are kept<br>• Write data is missing | None |
| 2 | SPDR/SPDR_HA is read when the receive buffer is empty. | The contents of the receive buffer and previously received data are output. | None |
| 3 | Serial transfer is started in slave mode when the SPI is not able to transmit data. | • Serial transfer is suspended<br>• Transmit or receive data is missing<br>• Driving of the MISOn output signal is stopped<br>• SPI function is disabled | Underrun error |
| 4 | Serial transfer terminates when the receive buffer is full. | • Keeps the contents of the receive buffer<br>• Missing receive data | Overrun error |
| 5 | An incorrect parity bit is received during full-duplex synchronous serial communication with the parity function enabled in following mode:<br>• Transmit-receive master mode<br>• Transmit-receive slave mode<br>• Receive-only slave mode | The parity error flag is asserted | Parity error |
| 6 | The SSLn0 input signal is asserted when the serial transfer is idle in multi-master mode. | • Driving of the RSPCKn, MOSIn, SSLn1 to SSLn3 output signals is stopped<br>• SPI function is disabled | Mode fault error |
| 7 | The SSLn0 input signal is asserted during serial transfer in multi-master mode. | • Serial transfer is suspended<br>• Transmit or receive data is missing<br>• Driving of the RSPCKn, MOSIn, SSLn1 to SSLn3 output signals is stopped<br>• SPI function is disabled | Mode fault error |
| 8 | The SSLn0 input signal is negated during serial transfer in slave mode. | • Serial transfer is suspended<br>• Transmit or receive data is missing<br>• Driving of the MISOn output signal is stopped<br>• SPI function is disabled | Mode fault error |

In operation 1 described in Table 33.10, the SPI does not detect an error. To prevent data omission during writes to SPDR/SPDR_HA, the writes to SPDR/SPDR_HA must be executed using a transmit buffer empty interrupt request (when the SPSR.SPTEF flag is 1).

Similarly, the SPI does not detect an error in operation 2. To prevent extraneous data from being read, SPDR/SPDR_HA read must be executed with an SPI receive buffer full interrupt request (when the SPSR.SPRF flag is 1).

For information on the other errors, see the following sections:

- Underrun error, indicated in operation 3, see section 33.3.10.4. Underrun errors
- Overrun error, indicated in operation 4, see section 33.3.10.1. Overrun errors
- Parity error, indicated in operation 5, see section 33.3.10.2. Parity errors
- Mode fault error, indicated in operations 6 to 8, see section 33.3.10.3. Mode fault errors
- For the transmit and receive interrupts, see section 33.3.7. Transmit Buffer Empty and Receive Buffer Full Interrupts.

### 33.3.10.1 Overrun errors

If a serial transfer ends when the receive buffer of SPDR/SPDR_HA is full, the SPI detects an overrun error and sets the SPSR.OVRF flag to 1. When the OVRF flag is 1, the SPI does not copy data from the shift register to the receive buffer, so the data prior to the error occurrence is retained in the receive buffer. To set the OVRF flag to 0, write 0 to the OVRF flag after the CPU reads SPSR with the OVRF flag set to 1.

Figure 33.39 shows an example of operation of the OVRF and SPRF flags. The SPSR and SPDR_HA accesses shown in Figure 33.39 indicate the condition of accesses to the SPSR and SPDR_HA register, where W denotes a write cycle, and R a read cycle. In this example, the SPI performs an 8-bit serial transfer when SPCMDm.CPHA bit is 1 and the SPCMDm.CPOL bit is 0. The numbers given for RSPCKn in the waveform represent the number of RSPCK cycles, such as the number of transferred bits.

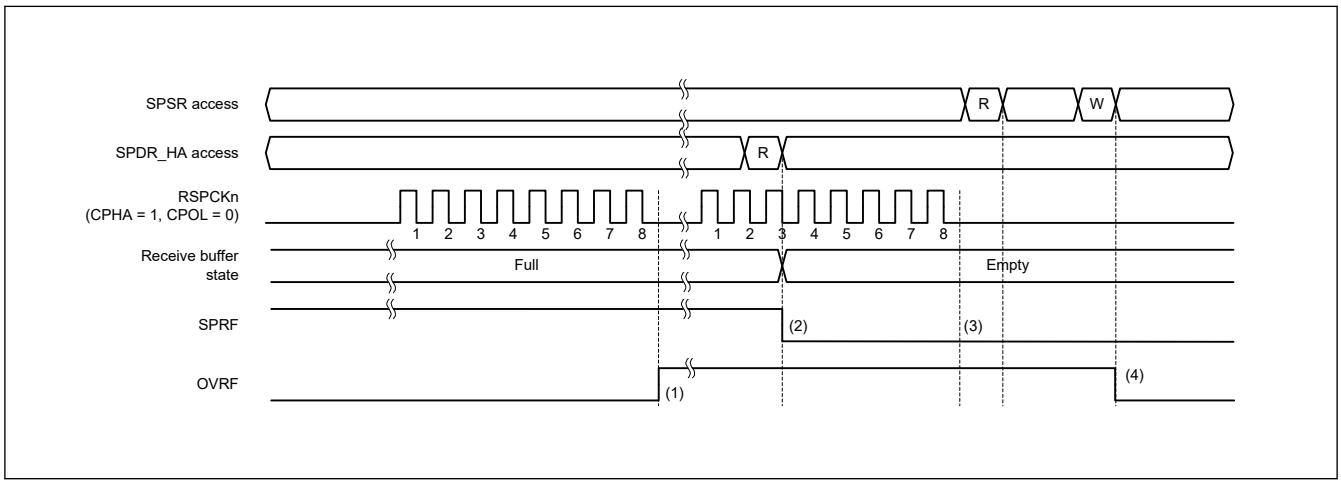

**Figure 33.39 Operation example of the OVRF and SPRF flags**

The operation of the flags at timings (1) to (4) in Figure 33.39 is as follows:

1. If a serial transfer terminates with the SPRF flag set to 1 (receive buffer full), the SPI detects an overrun error, and sets the OVRF flag to 1. The SPI does not copy the data in the shift register to the receive buffer. Even when the SPPE bit is 1, parity errors are not detected.
2. When SPDR/SPDR_HA is read, the SPI outputs the data in the receive buffer. The SPRF flag is then set to 0. The receive buffer becoming empty does not set the OVRF flag to 0.
3. If the serial transfer ends with the OVRF flag set to 1 (overrun error occurred), the SPI does not copy data in the shift register to the receive buffer (the SPRF flag does not set to 1). A receive buffer full interrupt is not generated. Even when the SPPE bit is 1, parity errors are not detected. In an overrun error state when the SPI does not copy the received data from the shift register to the receive buffer, on termination of the serial transfer, the SPI determines that the shift register is empty. This enables data transfer from the transmit buffer to the shift register.
4. If 0 is written to the OVRF flag after SPSR is read when the OVRF flag is 1, the OVRF flag clears is set to 0.

The occurrence of an overrun can be checked either by reading SPSR or by using an SPI error interrupt and reading SPSR. When executing a serial transfer, you must ensure that overrun errors are detected early, for example by reading SPSR immediately after SPDR/SPDR_HA/SPDR_BY is read.

If an overrun error occurs and the OVRF flag sets to 1, normal reception operations cannot be performed until the OVRF flag is set to 0.

When the RSPCK auto-stop function is enabled (SPCR2.SCKASE = 1) in master mode, an overrun error does not occur. Figure 33.40 and Figure 33.41 show the clock stop waveform when a serial transfer continues while the receive buffer is full in master mode.

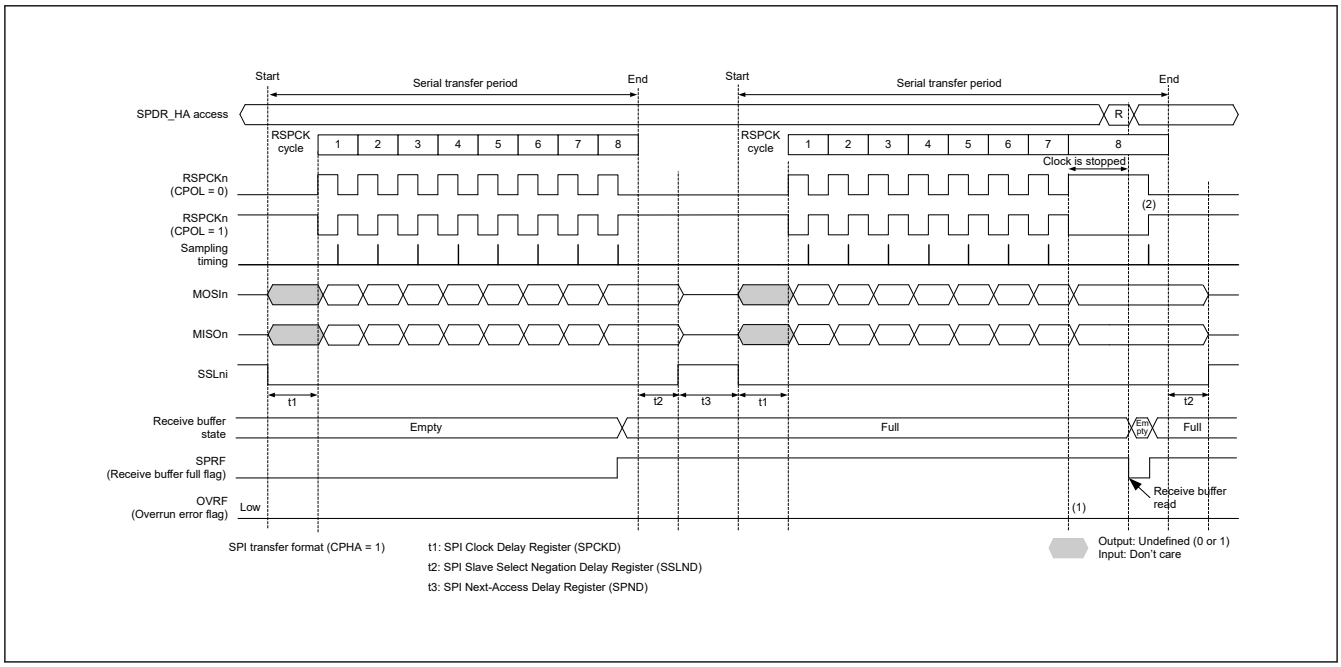

**Figure 33.40 Clock stop waveform when serial transfer continues while receive buffer is full in master mode (CPHA = 1)**

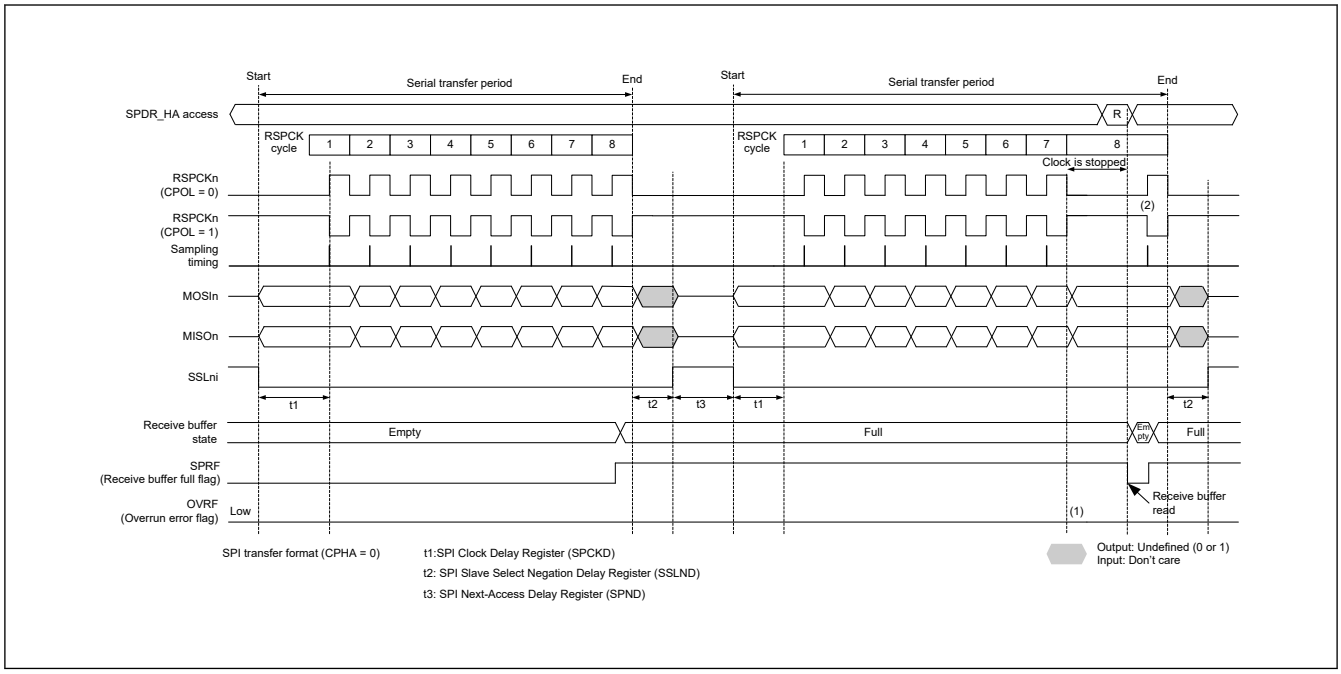

**Figure 33.41 Clock stop waveform when serial transfer continues while receive buffer is full in master mode (CPHA = 0)**

The operation of the flags at timings (1) and (2) in Figure 33.40 and Figure 33.41 is as follows:

1. When the receive buffer is full, an overrun error does not occur because the RSPCK clock is stopped.
2. If SPDR/SPDR_HA is read while the clock is stopped, data in the receive buffer can be read. The RSPCK clock restarts after reading the receive buffer (after the SPSR.SPRF flag is set to 0).

Overrun error does not occur when RSPCK automatic stop function is enabled for transfer with no delay of between frames during burst transfer in master mode. Figure 33.42 and Figure 33.43 show the clock stop waveform, when there is no delay between frames at burst transfer and the serial transfer continues in the reception buffer full state.

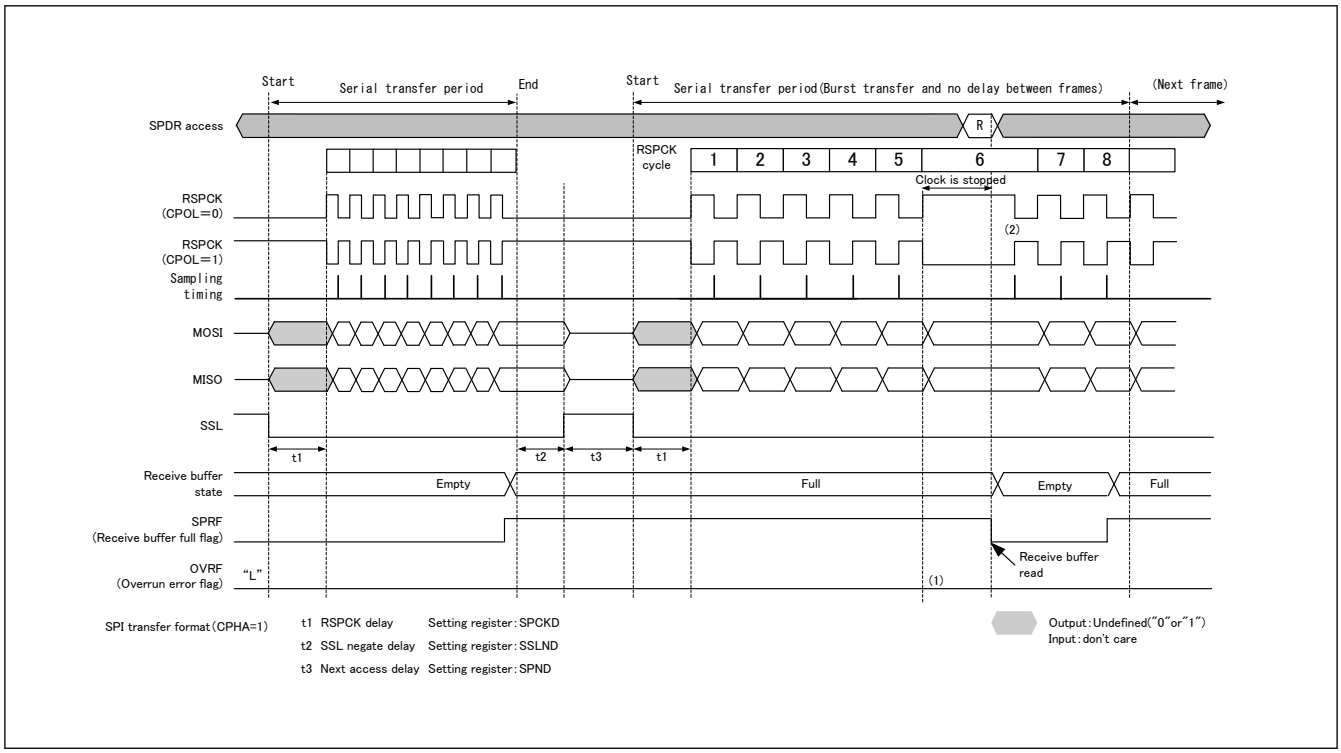

**Figure 33.42 Clock stop waveform when serial transfer continues in the receive buffer full in master mode (at burst transfer and no delay between frames CPHA = 1)**

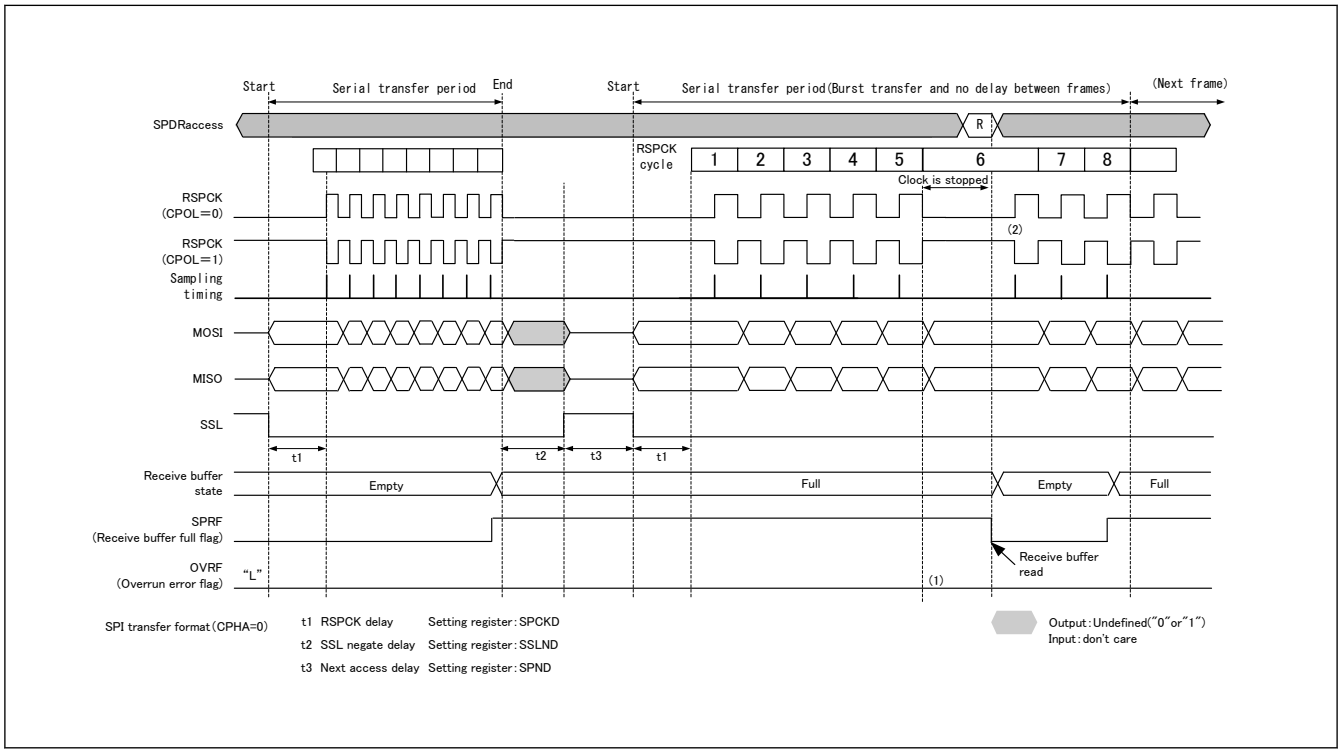

**Figure 33.43 Clock stop waveform when serial transfer continues in the receive buffer full in master mode (at burst transfer and no delay between frames CPHA = 0)**

The following describes operation of flags at timings (1) and (2) in the figure above.

1. While the receive buffer is full, the RSPCK clock is deactivated and no overrun error occurs.
2. Receive buffer data can be read by reading SPDR during clock stop. After the receive buffer data has been read (after the SPSR.SPRF flag has been cleared to 0), the RSPCK clock restarts.

### 33.3.10.2 Parity errors

When full-duplex synchronous serial communications is performed with the SPCR.TXMD bit set to 0 and the SPCR2.SPPE bit set to 1, when serial transfer ends, the SPI checks whether there are parity errors. On detecting a parity error in the received data, the SPI sets the SPSR.PERF flag to 1. Because the SPI does not copy data in the shift register to the receive buffer when the SPSR.OVRF flag is set to 1, parity error detection is not performed for the received data. To set the PERF flag to 0, write 0 to the PERF flag after the SPSR register is read with the PERF flag set to 1.

Figure 33.44 shows an example of operation of the OVRF and PERF flags. The SPSR access shown in Figure 33.44 indicates the condition of access to the register, where W denotes a write cycle, and R a read cycle. In this example, full-duplex serial communication is performed while the SPCR2.SPPE bit is 1. The SPI performs an 8-bit serial transfer when SPCMDm.CPHA bit is 1 and the SPCMDm.CPOL bit is 0. The numbers given for RSPCKn in the waveform represent the number of RSPCK cycles, such as the number of transferred bits.

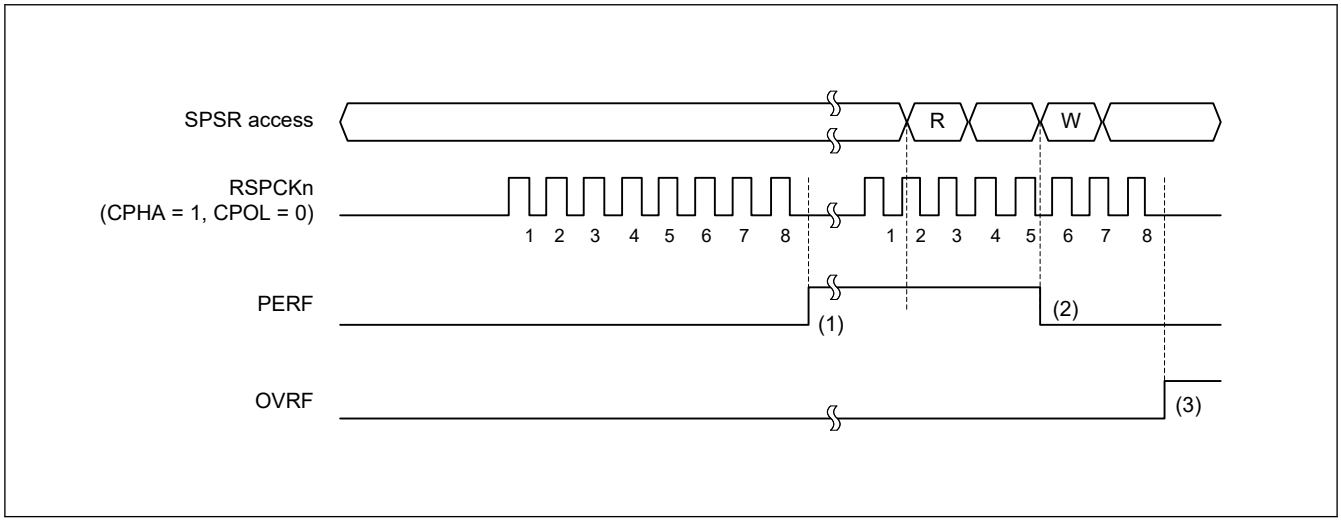

**Figure 33.44 Operation example of the OVRF and PERF flags**

The operation of the flags at timings (1) to (3) in Figure 33.44 is as follows:

1. If a serial transfer terminates with the SPI not detecting an overrun error, the SPI copies the data in the shift register to the receive buffer. The SPI checks the received data at this time and sets the PERF flag to 1 if a parity error is detected.
2. If 0 is written to the PERF flag after the SPSR register is read when the PERF flag is 1, the PERF flag is set to 0.
3. When the SPI detects an overrun error and serial transfer is terminated, the data in the shift register is not copied to the receive buffer. The SPI does not perform parity error detection at this time.

Parity errors can be checked for by either reading the SPSR register or using an SPI error interrupt and reading the SPSR register. When executing a serial transfer, such checks are required to ensure early detection of parity errors. When the SPI is used in master mode, the pointer value to the SPCMDm register at the occurrence of the error can be checked by reading the SPSSR.SPECM[2:0] bits (Only SPI0).

### 33.3.10.3 Mode fault errors

The SPI operates in multi-master mode when the SPCR.MSTR bit is 1, the SPCR.SPMS bit is 0, and the SPCR.MODFEN bit is 1. If the active level is input for the SSLn0 input signal of the SPI in multi-master mode, the SPI detects a mode fault error regardless of the status of the serial transfer, and sets the SPSR.MODF flag to 1. On detecting the mode fault error, the SPI copies the value of the pointer to SPCMDm to the SPDCR.SPFC[1:0] bits. The active level of the SSLn0 signal is determined by the SSLP.SSL0P bit.

When the MSTR bit is 0, the SPI operates in slave mode. The SPI detects a mode fault error if the MODFEN bit of the SPI in slave mode is 1, and the SPMS bit is 0, and if the SSLn0 input signal is negated during the serial transfer period (from the time the driving of valid data is started to the time the final valid data is fetched).

On detecting a mode fault error, the SPI stops the driving of the output signals and clears the SPCR.SPE bit to 0 (see section 33.3.11. Initializing the SPI). For multi-master configuration, detection of a mode fault error is used to stop the driving of output signals and the SPI function, which allows the master to be released.

The occurrence of a mode fault error can be checked either by reading SPSR or by using an SPI error interrupt and reading SPSR. Detecting mode-fault errors without using the SPI error interrupt requires polling of SPSR. When using the SPI in master mode, the value of the pointer to the SPCMDm register at the occurrence of the error can be checked by reading the SPSSR.SPECM[2:0] bits.

When the MODF flag is 1, writing 1 to the SPE bit is ignored by the SPI. To enable the SPI function after the detection of a mode fault error, the MODF flag must be set to 0.

#### 33.3.10.4 Underrun errors

While the SPI is operating in slave mode (SPCR.MSTR bit = 0) and the Extended Communication Mode Select bit (ETXMD) in the SPI Control Register 3 (SPCR3) is set to 0, if serial transfer is started before transmit data output is ready with the SPCR.SPE bit set to 1 (SPI function enabled), the SPI detects an underrun error and sets the SPSR.MODF and SPSR.UDRF flags to 1.

On detecting an underrun error, the SPI stops the driving of output signals and clears the SPCR.SPE bit to 0 (see section 33.3.11. Initializing the SPI).

The occurrence of underrun errors can be checked either by reading SPSR or by using an SPI error interrupt and reading SPSR. Detecting underrun errors without using the SPI error interrupt requires polling of SPSR.

When the MODF flag is 1, writing 1 to the SPE bit is ignored by the SPI. To enable the SPI function after the detection of an underrun error, the MODF flag must be set to 0.

### 33.3.11 Initializing the SPI

If 0 is written to the SPCR.SPE bit or if the SPI sets the SPE bit to 0 because it detected a mode fault error or an underrun error, the SPI disables the SPI function and initializes some of the module functions. When a system reset is generated, the SPI initializes all the module functions. This section describes initialization by clearing of the SPCR.SPE bit and by a system reset.

#### 33.3.11.1 Initialization by clearing of the SPCR.SPE bit

When the SPCR.SPE bit is set to 0, the SPI initializes by:

- Suspending any serial transfer that is being executed
- Stopping the driving of output signals (Hi-Z) in slave mode
- Initializing the internal state of the SPI
- Initializing the transmit buffer of the SPI (the SPSR.SPTEF flag sets to 1)

Initialization by clearing of the SPE bit does not initialize the control bits of the SPI. For this reason, the SPI can be started in the same transfer mode in use prior to initialization when the SPE bit is set to 1 again.

The SPSR.CENDF, SPSR.SPRF, SPSR.OVRF, SPSR.MODF, SPSR.PERF, and SPSR.UDRF flags are not initialized, and the value of the SPI Sequence Status Register (SPSSR) is not initialized. Therefore, even after the SPI is initialized, data from the receive buffer can be read to check the communication completion status and the error status during an SPI transfer.

The transmit buffer is initialized to an empty state (the SPSR.SPTEF flag sets to 1). Therefore, if the SPCR.SPTIE bit is set to 1 after SPI initialization, a transmit buffer empty interrupt is generated. To disable any transmit buffer empty interrupts when the SPI is initialized, write 0 to the SPTIE bit simultaneously while writing 0 to the SPE bit.

#### 33.3.11.2 Initialization by System Reset

A system reset completely initializes the SPI by initializing all SPI control bits, status bits, and data registers, in addition to meeting the requirements described in section 33.3.11.1. Initialization by clearing of the SPCR.SPE bit.

## 33.3.12 SPI Operation

### 33.3.12.1 Master mode operation

The only difference between single- and multi-master mode operation is the use of mode fault error detection (see section 33.3.10. Error Detection). In single-master mode, the SPI does not detect mode fault errors whereas in multi-master mode, it does. This section explains operations that are common to both modes.

#### (1) Starting a serial transfer

The SPI updates the data in the transmit buffer (SPTX) when data is written to the SPI Data Register (SPDR/SPDR_HA) with the SPI transmit buffer empty, data for the next transfer is not set, and the SPSR.SPTEF flag is 0. When the shift register is empty after the number of frames set in the SPDCR.SPFC[1:0] bits are written to the SPDR/SPDR_HA/SPDR_BY, the SPI copies data from the transmit buffer to the shift register and starts serial transfer. On copying transmit data to the shift register, the SPI changes the status of the shift register to full. On termination of the serial transfer, it changes the status of the shift register to empty. The status of the shift register cannot be referenced.

The polarity of the SSLni output pins depends on the SSLP register settings. For details on the SPI transfer format, see section 33.3.5. Transfer Formats.

#### (2) Terminating a serial transfer

Regardless of the SPCMDm.CPHA bit setting, the SPI terminates the serial transfer after transmitting an RSPCKn edge associated with the final sampling timing. If free space is available in the receive buffer (SPRX) (the SPSR.SPRF flag is 0), on termination of the serial transfer, the SPI copies data from the shift register to the receive buffer of the SPDR/SPDR_HA register.

The final sampling timing varies depending on the bit length of transfer data. In master mode, the SPI data length depends on the SPCMDm.SPB[3:0] bit settings. The polarity of the SSLni output pin depends on the SSLP register settings. For details on the SPI transfer format, see section 33.3.5. Transfer Formats.

#### (3) Sequence control

The transfer format used in master mode is determined by the SPSCR, SPCMDm, SPBR, SPCKD, SSLND, and SPND registers.

The SPSCR register determines the sequence configuration for serial transfers that are executed by the SPI in master mode. The following items are set in the SPCMDm register:

- SSLni pin output signal value
- MSB- or LSB-first
- Data length
- Some of the bit rate settings
- RSPCK polarity and phase
- Whether SPCKD is to be referenced
- Whether SSLND is to be referenced
- Whether SPND is to be referenced

SPBR holds some of the bit rate settings, including SPCKD (SPI clock delay), SSLND (SSL negation delay), and SPND (next-access delay).

Based on the sequence length assigned in SPSCR, the SPI makes up a sequence comprised of a part or all of the SPCMDm register. The SPI contains a pointer to the SPCMDm register that makes up the sequence. The value of this pointer can be checked by reading the SPSSR.SPCP[2:0] bits. When the SPCR.SPE bit is set to 1 and the SPI function is enabled, the SPI loads the pointer to the commands in SPCMD0, and incorporates the SPCMD0 settings into the transfer format at the beginning of serial transfer. The SPI increments the pointer each time the next-access delay period for a data transfer ends. On completion of the serial transfer that corresponds to the final command in the sequence, the SPI sets the pointer to SPCMD0, and in this way the sequence is executed repeatedly.

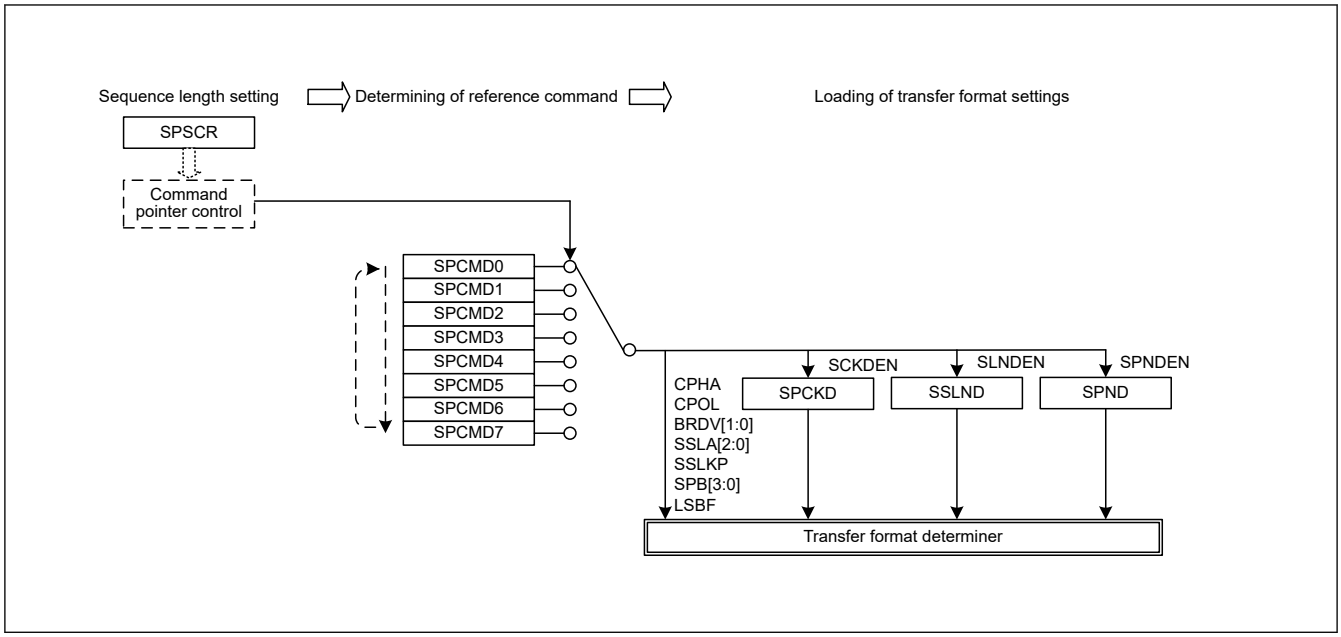

**Figure 33.45 Procedure for determining the form of a serial transfer in master mode**

In this section, a frame is the combination of the data in SPDR/SPDR_HA and the settings in SPCMDm.

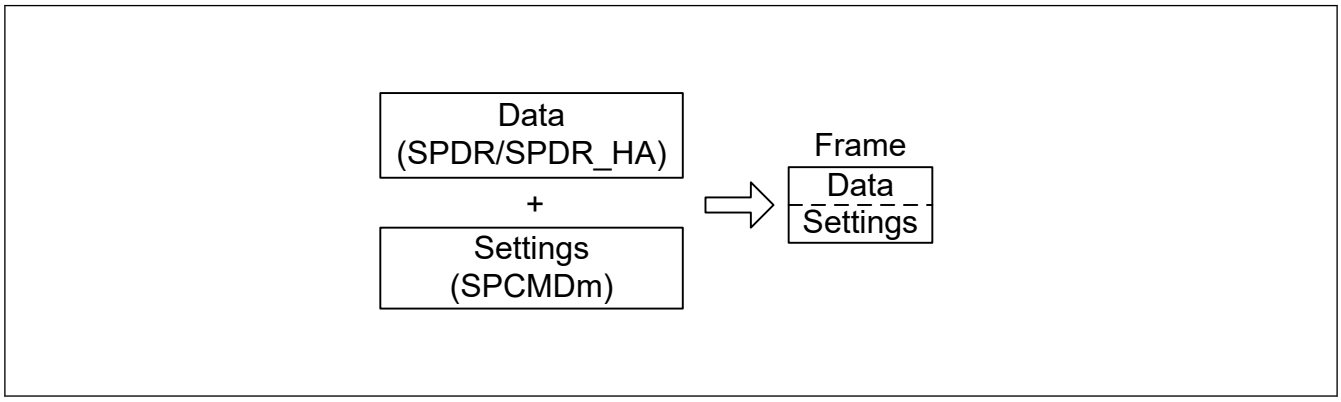

**Figure 33.46 Conceptual diagram of frames**

Figure 33.47 shows the correspondence between the commands and the transmit and receive buffers in the sequence of operations specified by the settings in Table 33.4.

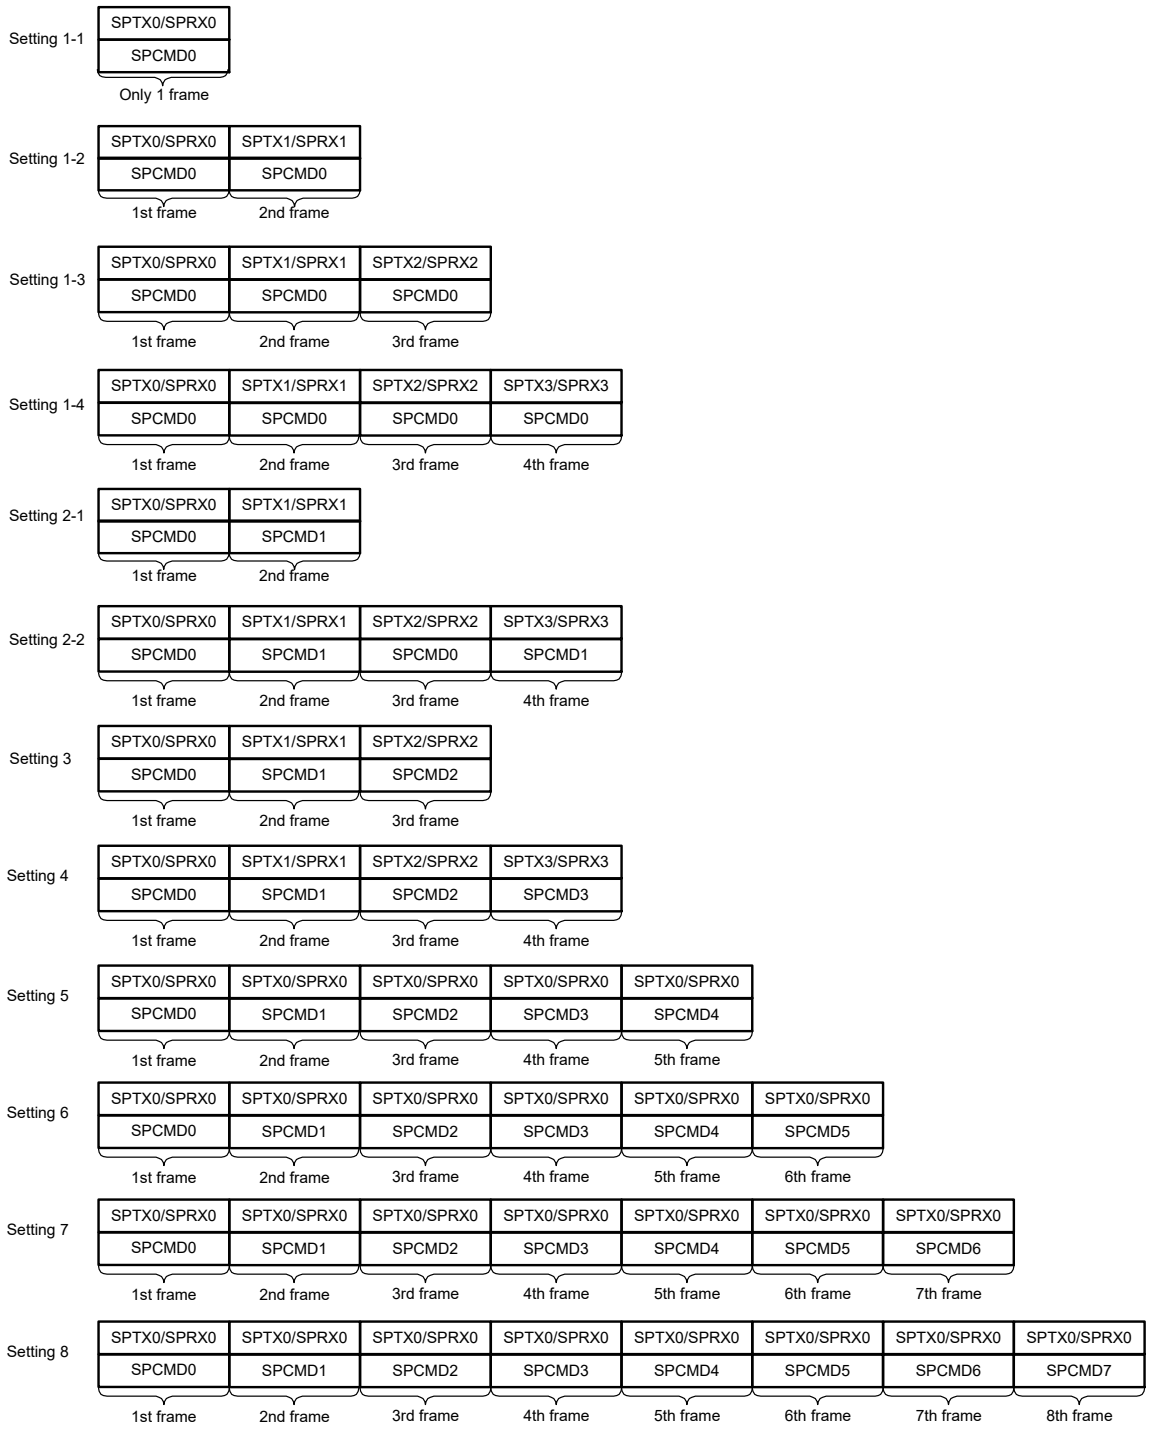

**Figure 33.47 Correspondence between SPI Command Register and transmit and receive buffers in sequence operations**

## (4) Burst transfers

If the SPCMDm.SSLKP bit that the SPI references during the current serial transfer is 1, the SPI maintains the SSLni signal level during the serial transfer until the beginning of the SSLni signal assertion for the next serial transfer. If the SSLni signal level for the next serial transfer is the same as the SSLni signal level for the current serial transfer, the SPI can execute continuous serial transfers while keeping the SSLni signal assertion status (burst transfer).

- When Between Burst Transfer Frames Delay Select bit (BFDS) of SPI control register 3 (SPCR3) is 0.

Figure 33.48 shows an example of an SSLni signal operation for a burst transfer that is implemented using the SPCMD0 and SPCMD1 register settings. This section describes SPI operations (1) to (8) shown in Figure 33.48.

Note: The polarity of the SSLni output signal depends on the SSLP register settings.

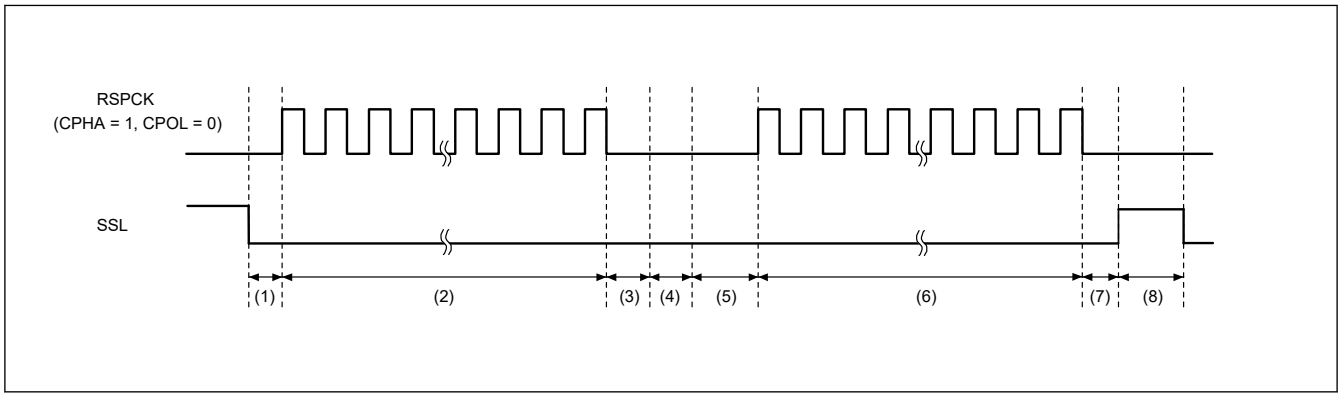

**Figure 33.48 Example of burst transfer operation using the SSLKP bit (BFDS = 0)**

The SPI operation at times (1) to (8) in the figure is as follows:

1. Based on the SPCMD0 settings, the SPI asserts the SSLni signal and inserts RSPCK delays.
2. The SPI executes serial transfers in accordance with the SPCMD0 settings.
3. The SPI inserts an SSL negation delay.
4. Because the SPCMD0.SSLKP bit is 1, the SPI keeps the SSLni signal value specified in SPCMD0. This period is sustained at a minimum for a period equal to the next-access delay in SPCMD0. If the shift register is empty after the passage of the minimum period, this period is sustained until the transmit data is stored in the shift register for the next transfer.
5. Based on the SPCMD1 settings, the SPI asserts the SSLni signal and inserts RSPCK delays.
6. The SPI executes serial transfers in accordance with the SPCMD1 settings.
7. Insert SSL negate delay.
8. Because the SPCMD1.SSLKP bit is 0, the SPI negates the SSLni signal. In addition, a next-access delay is inserted in accordance with SPCMD1.

If the SSLni signal output settings in the SPCMDm register where 1 is assigned to the SSLKP bit are different from the SSLni signal output settings in the SPCMDm register to be used in the next transfer, the SPI switches the SSLni signal status to SSLni signal assertion as shown in (5) in Figure 33.48. This corresponds to the command for the next transfer.

Note: If such an SSLni signal switching occurs, the slaves that drive the MISOn signal compete, and collision of signal levels might occur.

The SPI in master mode references the SSLni signal operation within the module when the SSLKP bit is not used. When the SPCMDm.CPHA bit is 0, the SPI can accurately start serial transfers by using the SSLni signal assertion for the next transfer that is detected internally.

- When Between Burst Transfer Frames Delay Select bit (BFDS) of SPI control register 3 (SPCR3) is 1.

Figure 33.49 shows an example of SSL signal operation when burst transfer is achieved by using the settings of SPCMD0 and SPCMD1. The following describes SPI operations of (1) to (6) shown in Figure 33.49. The SSL output signal polarity depends on the set SPI slave select polarity register (SSLP) value.

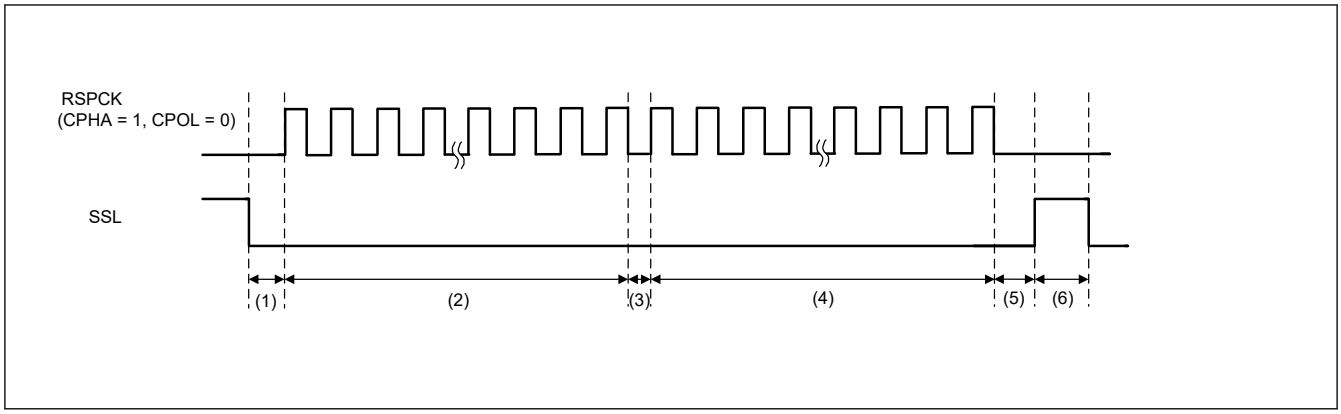

**Figure 33.49 Example of Burst Transfer Operation Using SSLKP Bit (BFDS = 1)**

1. Assert the SSL signal and insert an RSPCK delay according to SPCMD0. The RSPCK delay is inserted only the first frame of burst transmission.
2. Perform serial transfer according to SPCMD0. Wait last clock until the next transmit data is stored in the shift register, if the shift register is empty during RSPCK negate period between frames.
3. The value of SSL signal according to SPCMD0 was hold, because the SPCMD0.SSLKP bit is 1. RSPCK negate period between frames is 0.5RSPCK, if the shift register is not empty.
4. Perform serial transfer according to SPCMD1.
5. Insert SSL negate delay for the last frame.
6. The SSL signal is negated because the SSLKP bit in SPCMD1 is 0. Furthermore, the next-access delay is inserted according to SPCMD1.

### (5) RSPCK delay (t1)

The RSPCK delay value of the SPI in master mode depends on the SPCMDm.SCKDEN bit setting and the SPCKD.SCKDL[2:0] bits setting. The SPI determines the SPCMDm register to be referenced during a serial transfer by pointer control, and determines an RSPCK delay using the SPCMDm.SCKDEN bit and SPCKD.SCKDL[2:0] bits, as listed in Table 33.11. For a definition of RSPCK delay, see section 33.3.5. Transfer Formats.

RSPCK delay insert to only the first frame of burst transmission, when transmit without “Between Burst Transfer Frames Delay”. (The SPCMD.SSLKP bit is 1 and the SPCR3.BFDS bit is 1.)

**Table 33.11 Relationship between the SPCMDm.SCKDEN bit, SPCKD.SCKDL[2:0] bits, and RSPCK delay**

| SPCMDm.SCKDEN bit | SPCKD.SCKDL[2:0] bits | RSPCK delay |
|---|---|---|
| 0 | 000b to 111b | 1 RSPCK |
| 1 | 000b | 1 RSPCK |
| | 001b | 2 RSPCK |
| | 010b | 3 RSPCK |
| | 011b | 4 RSPCK |
| | 100b | 5 RSPCK |
| | 101b | 6 RSPCK |
| | 110b | 7 RSPCK |
| | 111b | 8 RSPCK |

### (6) SSL negation delay (t2)

The SSL negation delay value of the SPI in master mode depends on the SPCMDm.SLNDEN bit setting and the SSLND.SLNDL[2:0] bits setting. The SPI determines the SPCMDm register to be referenced by pointer control during a serial transfer, and determines an SSL negation delay using the SPCMDm.SLNDEN bit and SSLND.SLNDL[2:0] bits, as listed in Table 33.12. For a definition of SSL negation delay, see section 33.3.5. Transfer Formats.

An SSL negation delay is inserted to only the last frame of the burst transmission, that is, transmit without “between burst transfer frames delay”. (SPCMD.SSLKP bit is 1 and SPCR3.BFDS bit is 1).

**Table 33.12 Relationship between the SPCMDm.SLNDEN bit, SSLND.SLNDL[2:0] bits, and SSL negation delay**

| SPCMDm.SLNDEN bit | SSLND.SLNDL[2:0] bits | SSL negation delay |
|---|---|---|
| 0 | 000b to 111b | 1 RSPCK |
| 1 | 000b | 1 RSPCK |
| | 001b | 2 RSPCK |
| | 010b | 3 RSPCK |
| | 011b | 4 RSPCK |
| | 100b | 5 RSPCK |
| | 101b | 6 RSPCK |
| | 110b | 7 RSPCK |
| | 111b | 8 RSPCK |

### (7) Next-access delay (t3)

The next-access delay value of the SPI in master mode depends on the SPCMDm.SPNDEN bit setting and the SPND.SPNDL[2:0] bits setting. The SPI determines the SPCMDm register to be referenced during serial transfer by pointer control, and then determines a next-access delay during serial transfer using the SPCMDm.SPNDEN bit and SPND.SPNDL[2:0] bits, as listed in Table 33.13. For a definition of next-access delay, see section 33.3.5. Transfer Formats.

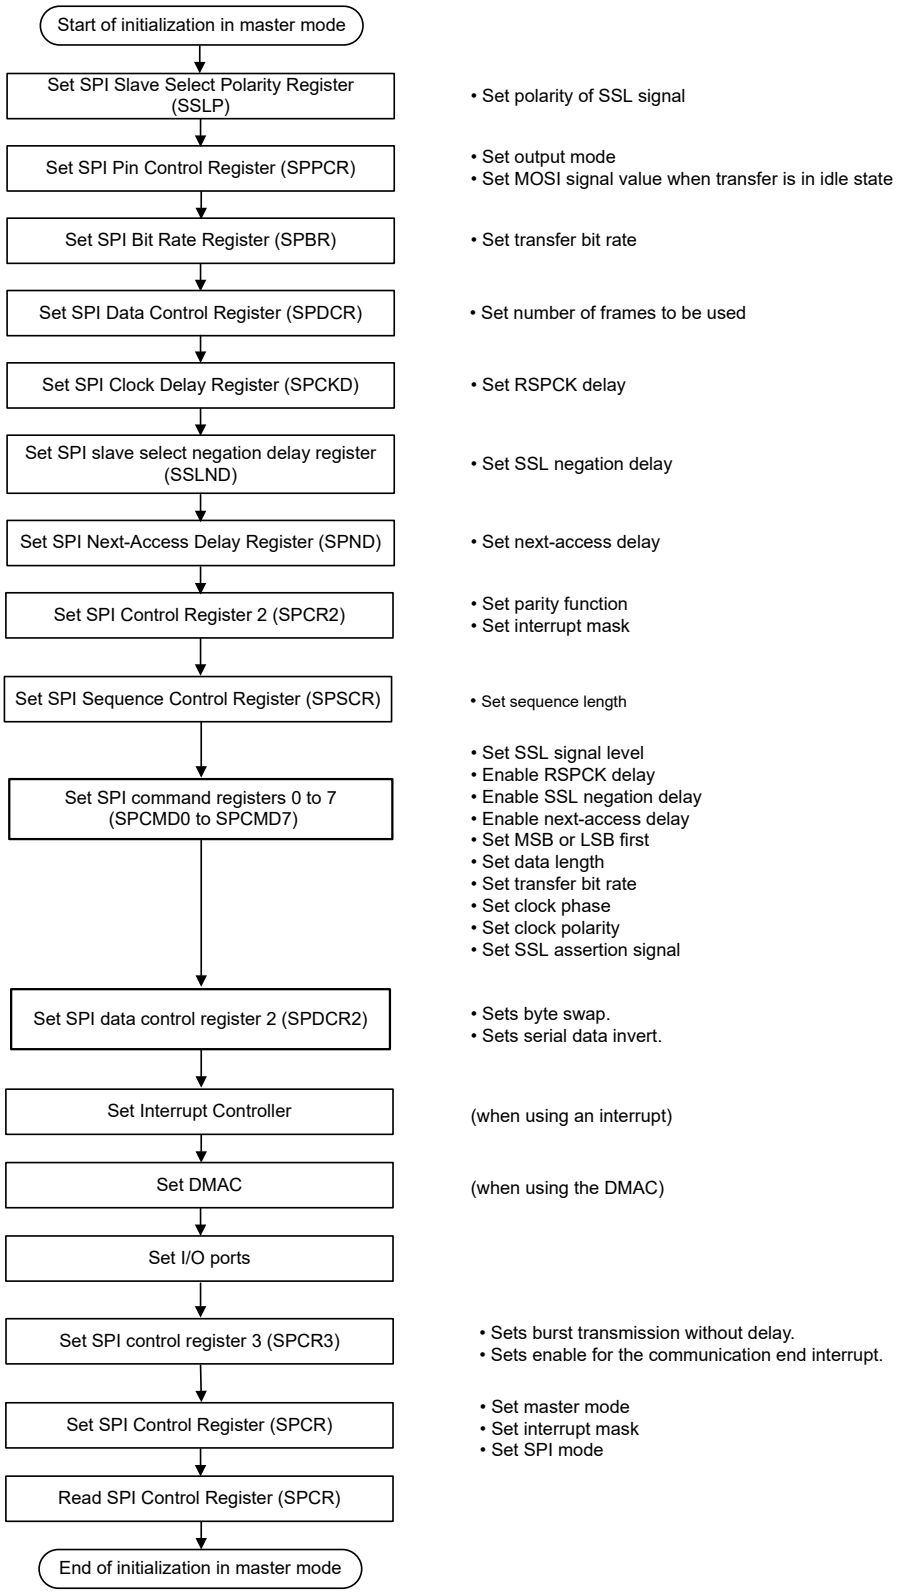
A next-Access delay is inserted to only the last frame of the burst transmission, that is, transmit without “between burst transfer frames delay”. (SPCMD.SSLKP bit is 1 and SPCR3.BFDS bit is 1).

**Table 33.13 Relationship between the SPCMDm.SPNDEN bit, SPND.SPNDL[2:0] bits, and next-access delay**

| SPCMDm.SPNDEN bit | SPND.SPNDL[2:0] bits | Next-access delay |
|---|---|---|
| 0 | 000b to 111b | 1 RSPCK + 2 PCLKA |
| 1 | 000b | 1 RSPCK + 2 PCLKA |
| | 001b | 2 RSPCK + 2 PCLKA |
| | 010b | 3 RSPCK + 2 PCLKA |
| | 011b | 4 RSPCK + 2 PCLKA |
| | 100b | 5 RSPCK + 2 PCLKA |
| | 101b | 6 RSPCK + 2 PCLKA |
| | 110b | 7 RSPCK + 2 PCLKA |
| | 111b | 8 RSPCK + 2 PCLKA |

### (8) Initialization flow

Figure 33.50 shows an example of SPI initialization flow when the SPI is in master mode. For information on how to set up the Interrupt Controller Unit (ICU), DMAC and I/O ports, see the descriptions given in the individual blocks.



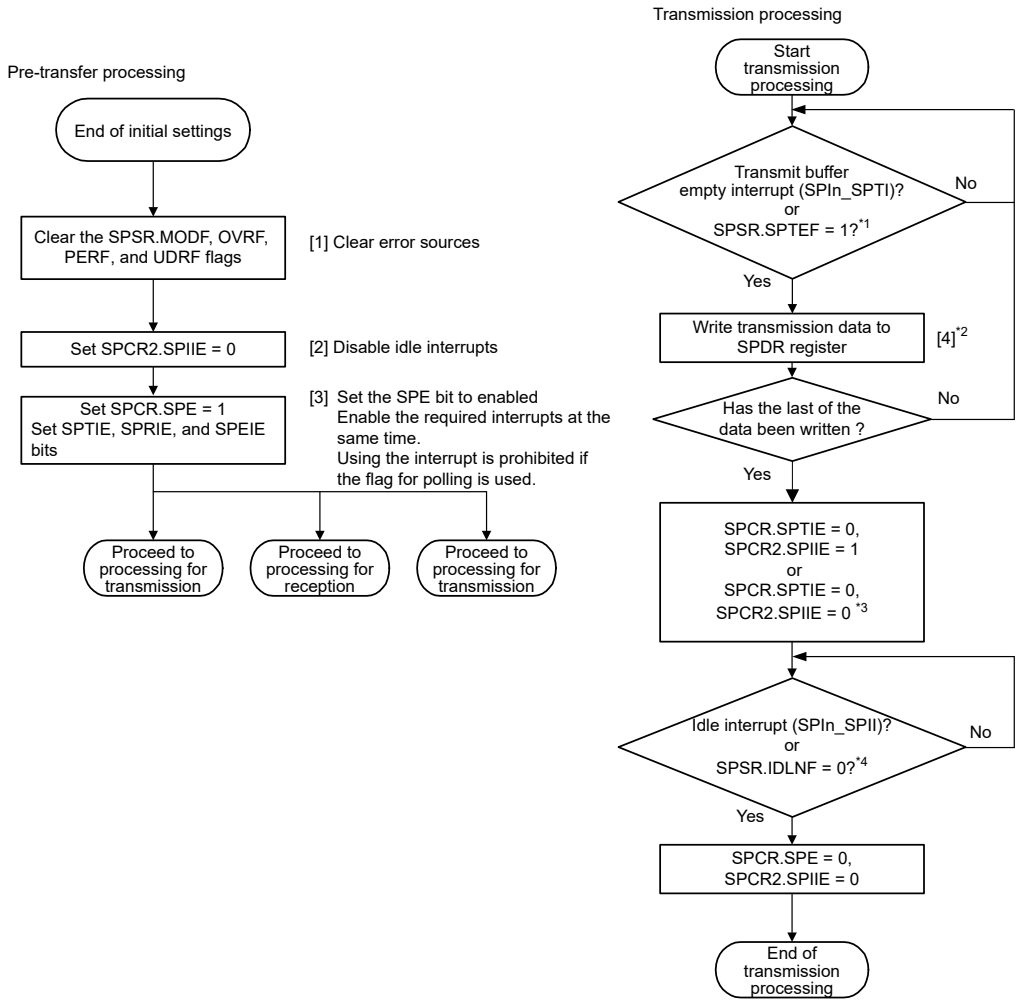


**Figure 33.50 Example of initialization flow in master mode for SPI operation**

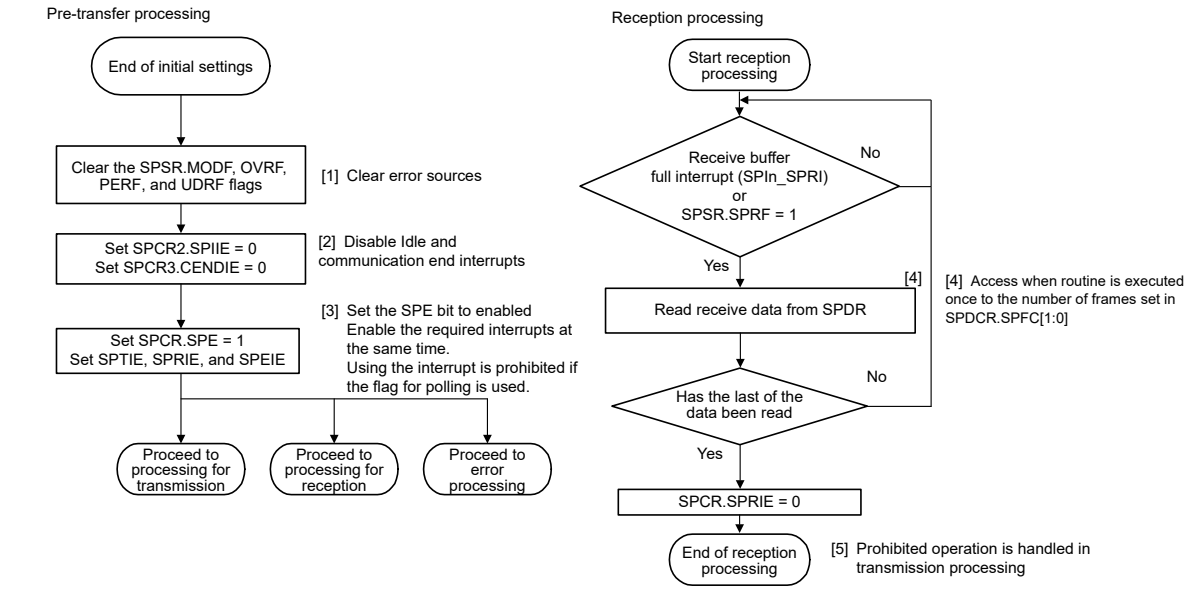
## (9) Software processing flow

Figure 33.51 to Figure 33.53 show examples of the software processing flow.

### Transmit processing flow

When transmitting data, with the SPI0_SPII interrupt enabled, the CPU is notified of the completion of data transmission after the last data write for transmission.



Note 1. Before writing data for transmission to SPDR/SPDR_HA/SPDR_BY, check that the transmit buffer is empty by reading the SPSR.SPTEF flag, if the flag for polling is used.
Note 2. SPDR = SPDR/SPDR_HA/SPDR_BY
Access when interrupt handling routine is executed once to the number of frames set in SPDCR.SPFC[1:0] bits.
Note 3. Setting SPCR2.SPIIE and SPCR3.CENDIE to 0 is prohibited if the flag for polling is used.
Note 4. Wait more than 1 PCLKA, after writing data for transmission to SPDR register, and before starting to poll SPSR.IDLNF flag or SPSR.CENDF, if the flag for polling is used.

**Figure 33.51 Transmission flow in master mode**

### Receive processing flow

The SPI has receive only operation in slave mode.

Note 1. SPDR = SPDR/SPDR_HA/SPDR_BY

**Figure 33.52 Reception flow in master mode**

### Error processing flow

The SPI detects the following errors:

- Mode fault error
- Underrun error
- Overrun error
- Parity error

When a mode fault error is generated, the SPCR.SPE bit is automatically cleared, stopping operations for transmission and reception. For errors from other sources, the SPCR.SPE bit is not cleared and operations for transmission and reception continue. Therefore, Renesas recommends clearing the SPCR.SPE bit to stop operations for errors other than mode fault errors. Not doing so leads to updating of the SPSSR.SPECM[2:0] bits.

When an error is detected using an interrupt, clear the ICU.IELSRn.IR flag in the error processing routine. If this is not done, the ICU.IELSRn.IR flag might continue to indicate the SPI0_SPTI or SPI0_SPRI interrupt request. If the SPI0_SPRI interrupt request is indicated, read the receive buffer and initialize the sequencer in the SPI.

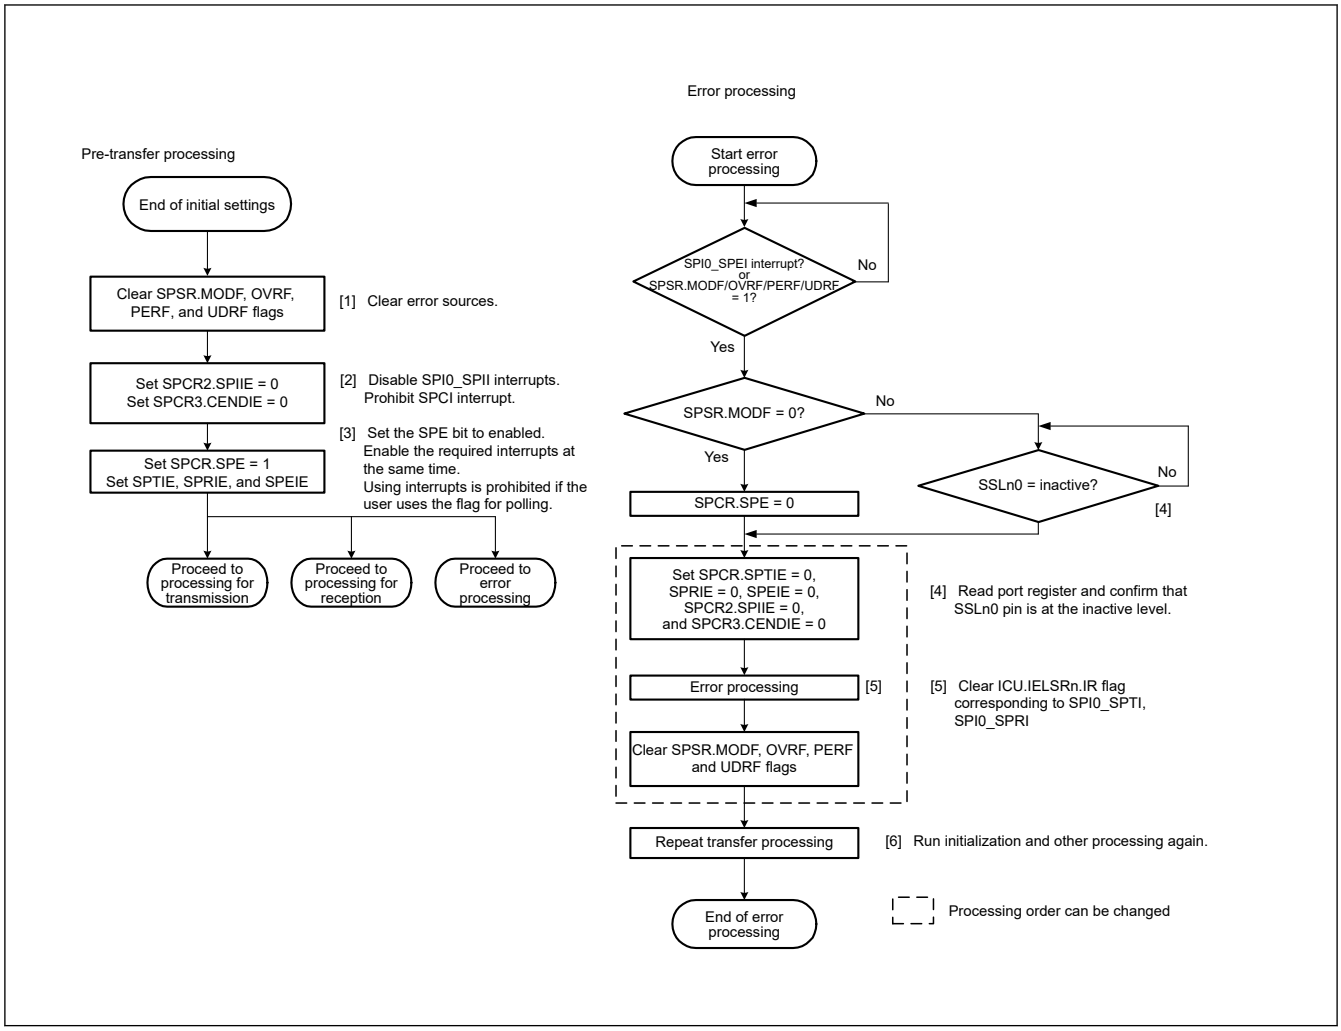


**Figure 33.53 Error processing flow in master mode**

## 33.3.12.2 Slave mode operation

### (1) Starting a serial transfer

When the SPCMD0.CPHA bit is 0, if the SPI detects an SSLn0 input signal assertion, it must drive valid data to the MISOn output signal. For this reason, when the CPHA bit is 0, the assertion of the SSLn0 input signal triggers the start of a serial transfer.

When the CPHA bit is 1, if the SPI detects the first RSPCKn edge in an SSLn0 signal asserted condition, it must drive valid data to the MISOn output signal. For this reason, when the CPHA bit is 1, the first RSPCKn edge in an SSLn0 signal asserted condition triggers the start of a serial transfer.

Regardless of the CPHA bit setting, the SPI drives the MISOn output signal on SSLn0 signal assertion. The data that is output by the SPI is either valid or invalid, depending on the CPHA bit setting.

For details on the SPI transfer format, see section 33.3.5. Transfer Formats. The polarity of the SSLn0 input signal depends on the SSLP.SSL0P setting.

### (2) Terminating a serial transfer

Regardless of the SPCMD0.CPHA bit setting, the SPI terminates the serial transfer after detecting an RSPCKn edge corresponding to the final sampling timing. When free space is available in the receive buffer (the SPSR.SPRF flag is 0), on termination of serial transfer, the SPI copies received data from the shift register to the receive buffer of the SPDR/SPDR_HA register. On termination of a serial transfer, the SPI changes the status of the shift register to empty, regardless of the receive buffer state. A mode fault error occurs if the SPI detects an SSLn0 input signal negation from the beginning of serial transfer to the end of serial transfer (see section 33.3.10. Error Detection).

The final sampling timing changes depending on the bit length of transfer data. In slave mode, the SPI data length is determined by the SPCMD0.SPB[3:0] bits setting. The polarity of the SSLn0 input signal is determined by the SSLP.SSL0P bit setting. For details on the SPI transfer format, see section 33.3.5. Transfer Formats.

### (3) Notes on single-slave operations

If the SPCMD0.CPHA bit is 0, the SPI starts serial transfers when it detects the assertion edge for an SSLn0 input signal. In the configuration shown in Figure 33.7, if the SPI is used in single-slave mode, the SSLn0 signal is fixed at an active state. Therefore, when the CPHA bit is set to 0, the SPI cannot correctly start a serial transfer. For the SPI to correctly execute transmit and receive operations in slave mode when the SSLn0 input signal is fixed at an active state, the CPHA bit must be set to 1. Do not fix the SSLn0 input signal if there is a requirement for setting the CPHA bit to 0.

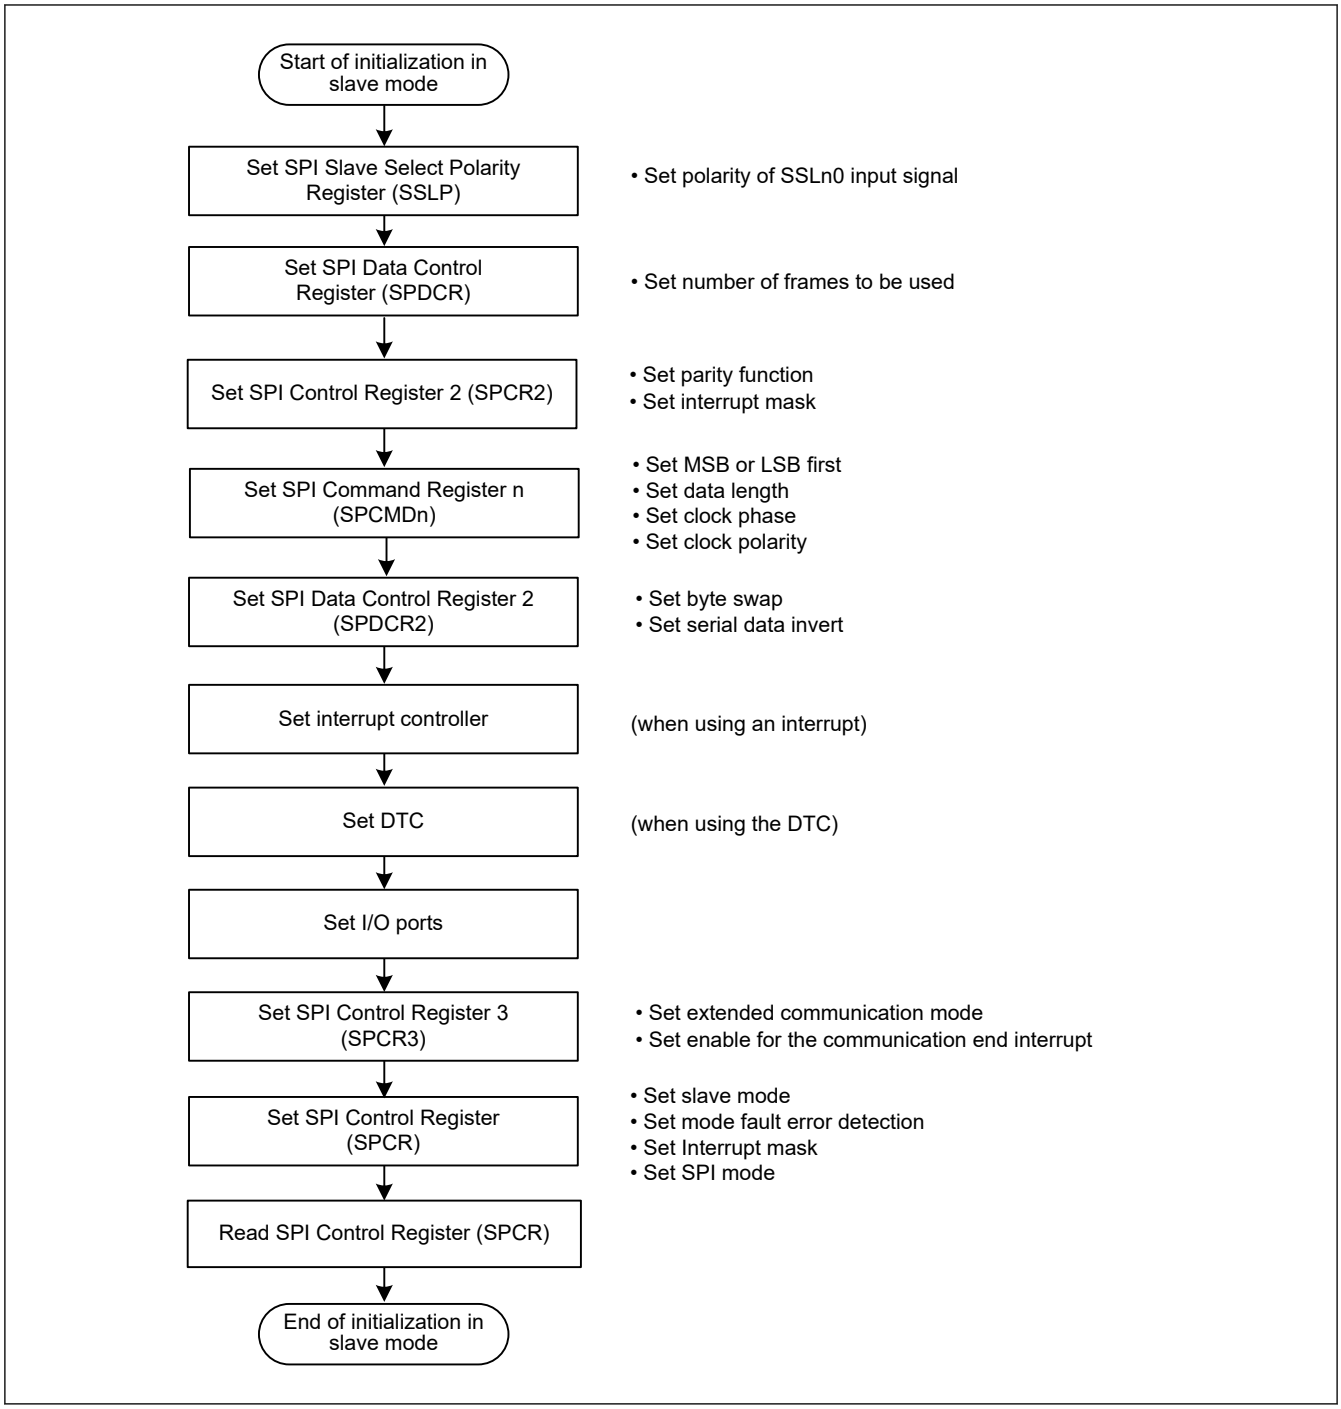
### (4) Burst transfer

If the SPCMD0.CPHA bit is 1, continuous serial transfer (burst transfer) can be executed while retaining the assertion state for the SSLn0 input signal. When the CPHA bit is 1, the serial transfer period is the period from the first RSPCKn edge to the sampling timing for the reception of the final bit in an SSLn0 signal active state. Even when the SSLn0 input signal remains at the active level, the SPI can accommodate burst transfers, because it can detect the start of an access.

When the CPHA bit is 0, the second and subsequent serial transfers during burst transfer cannot be executed correctly.

### (5) Initialization flow

Figure 33.54 shows an example of initialization flow for SPI operation when the SPI is in slave mode. For a description of how to set up the ICU, DTC, and I/O ports, see the descriptions given in the individual blocks.



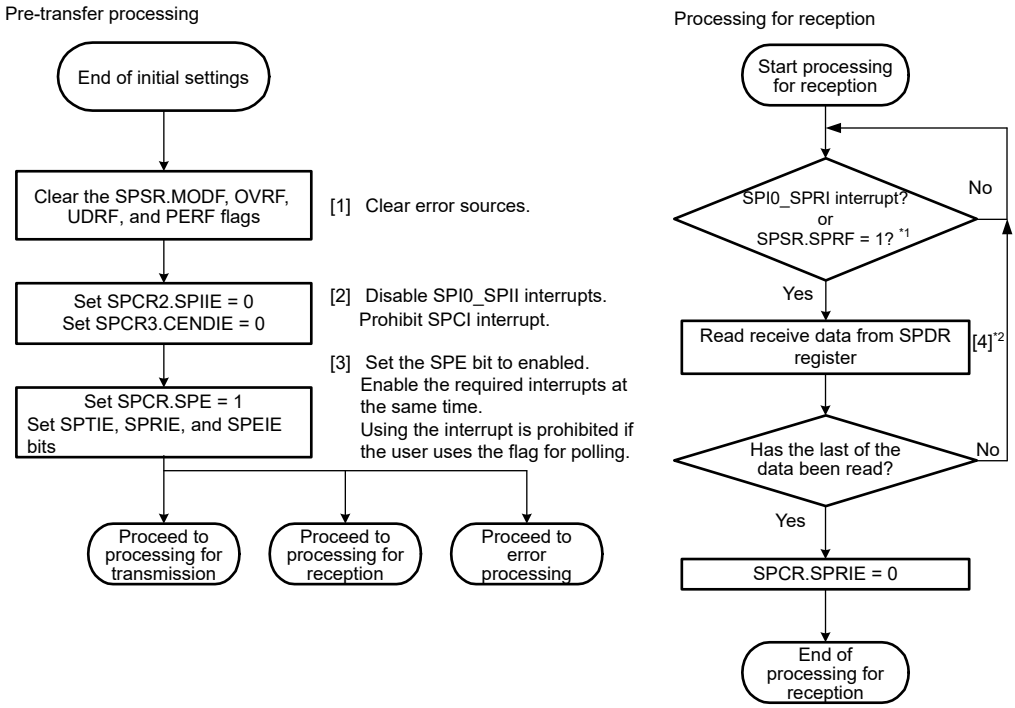


**Figure 33.54 Example initialization flow in slave mode for SPI operation**

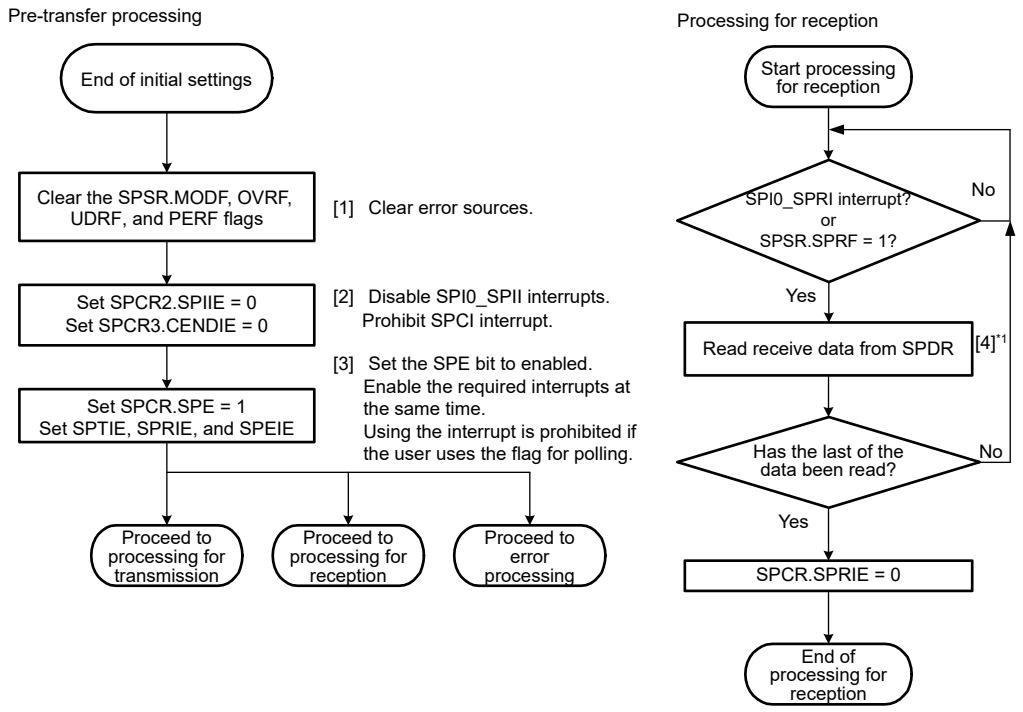
### (6) Software processing flow

Figure 33.55 to Figure 33.57 show examples of the flow of software processing.

### Transmit processing flow



Note 1. Before writing data for transmission to SPDR register, check the transmit buffer empty interrupt by reading SPSR.SPTEF flag, if the flag for polling is used.
Note 2. SPDR = SPDR/SPDR_HA/SPDR_BY
Access when interrupt handling routine is executed once to the number of frames set in SPDCR.SPFC[1:0] bits.

**Figure 33.55 Transmission flow in slave mode**

### Receive processing flow

The SPI does not handle receive-only operation, so processing for transmission is required.

Note 1. Before writing data for transmission to the SPDR register, check that the transmit buffer is empty by reading the SPSR.SPTEF flag, if the flag for polling is used.
Note 2. SPDR = SPDR/SPDR_HA/SPDR_BY
Access when interrupt handling routine is executed once to the number of frames set in SPDCR.SPFC[1:0] bits.

**Figure 33.56 Reception flow in slave mode**

### Error processing flow

In slave mode operation, even when a mode fault error is generated, the SPSR.MODF flag can be cleared regardless of the state of the SSLn0 pin.

When an error is detected by using an interrupt, clear the ICU.IELSRn.IR flag in the error processing routine. If this is not done, the ICU.IELSRn.IR flag might continue to indicate the SPI0_SPTI or SPI0_SPRI interrupt request. If the SPI0_SPRI interrupt request is indicated, read the receive buffer and initialize the sequencer in the SPI.

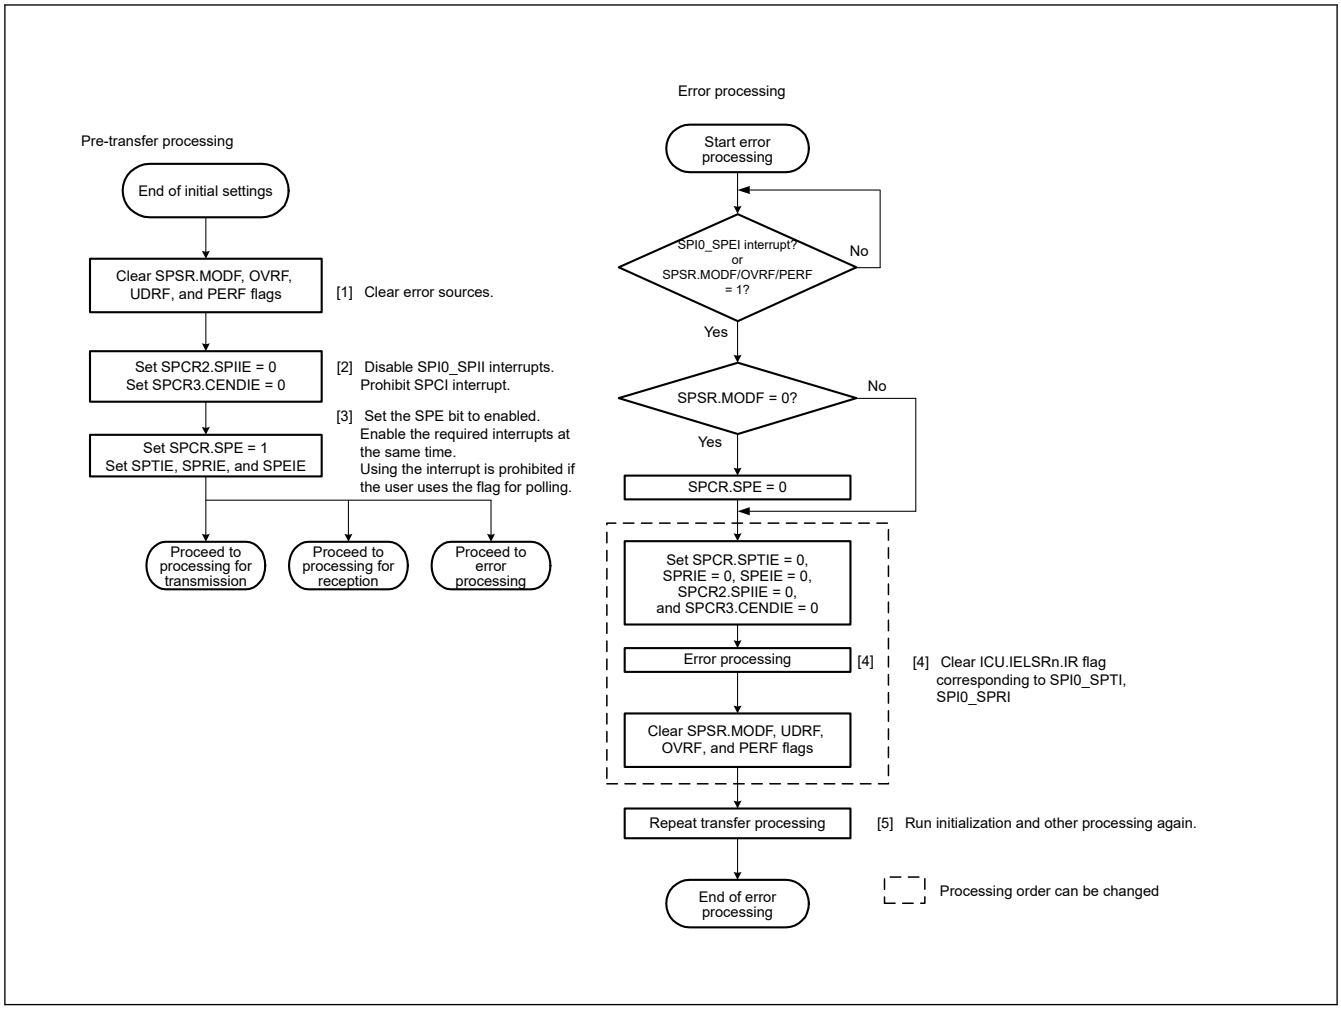


**Figure 33.57 Error processing flow for slave mode**

## 33.3.13 Clock Synchronous Operation

Setting the SPCR.SPMS bit to 1 selects clock synchronous operation of the SPI. In clock synchronous operation, the SSLni pin is not used, and the RSPCKn, MOSIn, and MISOn pins handle communications. All SSLni pins are available as I/O port pins.

Although clock synchronous operation does not require the use of the SSLni pin, operation of the module is the same as in SPI operation. In both master mode and slave mode operations, communications can be performed with the same flow as in SPI operation. However, mode fault errors are not detected, because the SSLni pin is not used.

Additionally, do not perform operation if clock synchronous operation is enabled when the SPCMDm.CPHA bit is set to 0 in slave mode (SPCR.MSTR = 0).

### 33.3.13.1 Master mode operation

#### (1) Starting serial transfer

The SPI updates the data in the transmit buffer (SPTX) of SPDR/SPDR_HA when data is written to the SPDR/SPDR_HA register with the transmit buffer empty, the data for the next transfer not set and the SPSR.SPTEF flag is 1. When the shift register is empty after the number of frames set in the SPDCR.SPFC[1:0] bits are written to the SPDR/SPDR_HA, the SPI copies data from the transmit buffer to the shift register and starts serial transmission. On copying transmit data to the shift register, the SPI changes the status of the shift register to full, and on termination of serial transfer, it changes the status of the shift register to empty. The status of the shift register cannot be referenced.

Transfer in clock synchronous operation is conducted without the SSLn0 output signal. For details on the SPI transfer format, see section 33.3.5. Transfer Formats.

### (2) Terminating serial transfer

The SPI terminates the serial transfer after transmitting an RSPCKn edge corresponding to the sampling timing. If free space is available in the receive buffer (the SPSR.SPRF flag is 0), on termination of serial transfer, the SPI copies data from the shift register to the receive buffer of the SPI Data Register (SPDR/SPDR_HA).

The final sampling timing varies depending on the bit length of transfer data. In master mode, the SPI data length depends on the SPCMDm.SPB[3:0] bits setting. Transfer in clock synchronous operation is conducted without the SSLn0 output signal. For details on the SPI transfer format, see section 33.3.5. Transfer Formats.

### (3) Sequence control

The transfer format used in master mode is determined by the SPSCR, SPCMDm, SPBR, SPCKD, SSLND, and SPND registers. Although the SSLni signals are not output in clock synchronous operation, these settings are valid.

The SPSCR register determines the sequence configuration for serial transfers that are executed by the SPI in master mode. The following parameters are specified in the SPCMDm register:

- SSLni output signal value
- MSB or LSB first
- Data length
- Some of the bit rate settings
- RSPCKn polarity and phase
- Whether SPCKD is to be referenced
- Whether SSLND is to be referenced
- Whether SPND is to be referenced

SPBR holds some of the bit rate settings such as SPCKD, an SPI clock delay value, SSLND, an SSL negation delay, and SPND, a next-access delay value.

Based on the sequence length that is assigned to SPSCR, the SPI makes up a sequence comprised of a part or all of SPCMDm register. The SPI contains a pointer to the SPCMDm register that makes up the sequence. The value of this pointer can be checked by reading the SPSSR.SPCP[2:0] bits. When the SPCR.SPE bit is set to 1 and the SPI function is enabled, the SPI loads the pointer to the commands in SPCMD0 register, and incorporates the SPCMD0 register setting into the transfer format at the beginning of serial transfer. The SPI increments the pointer each time the next-access delay period for a data transfer ends. On completion of the serial transfer that corresponds to the final command comprising the sequence, the SPI sets the pointer to the SPCMD0 register, and in this manner the sequence is executed repeatedly.

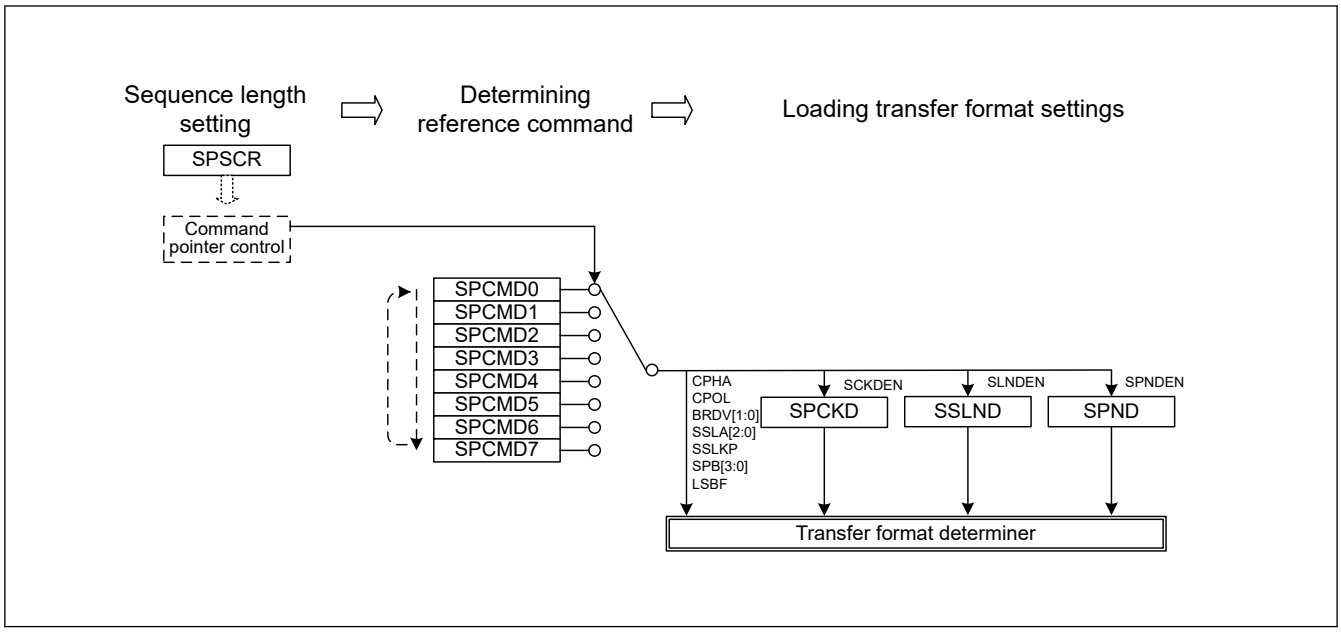

**Figure 33.58 Procedure for determining the form of serial transmission in master mode**

In this section, a frame is the combination of the data (SPDR/SPDR_HA) and the settings (SPCMDm).

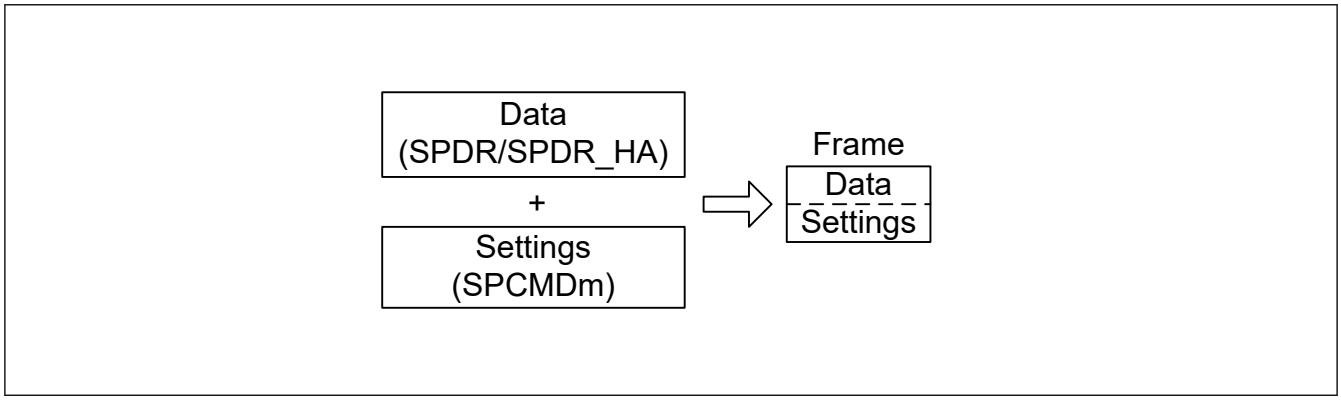

**Figure 33.59 Conceptual diagram of frames**

Figure 33.60 shows the relationship between the command and the transmit and receive buffers in the sequence of operations specified by the settings in Table 33.4.

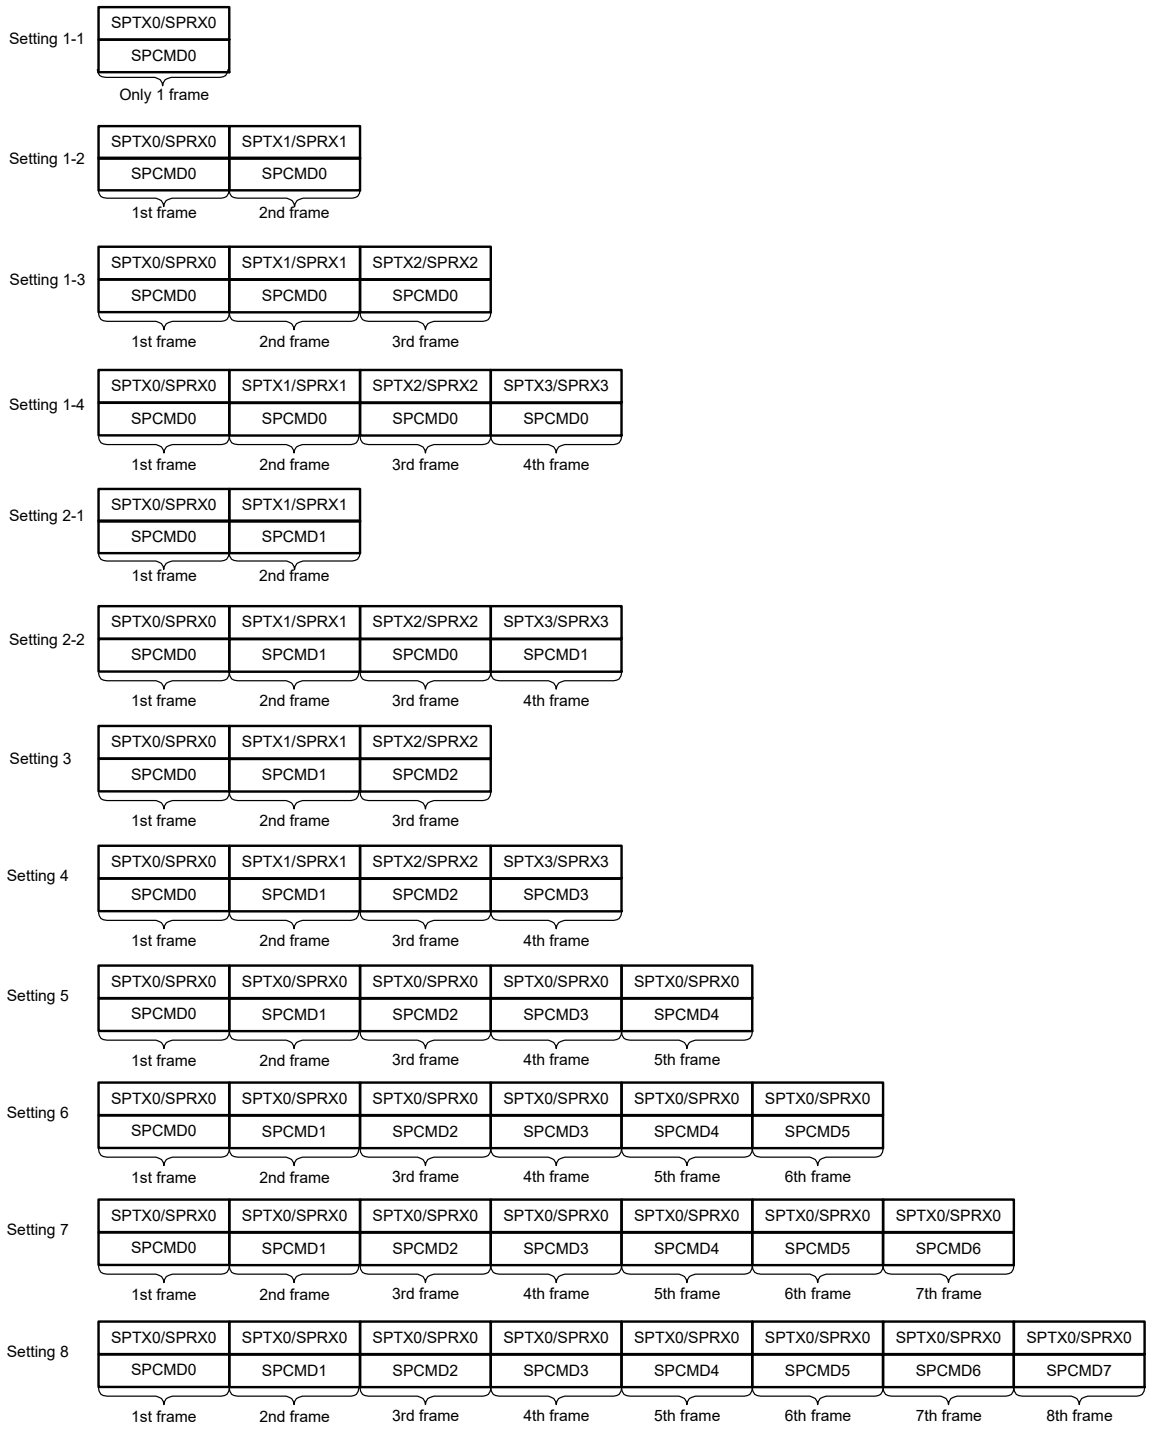

**Figure 33.60 Correspondence between SPI Command Register and transmit and receive buffers in sequence operations**

## (4) Initialization flow

Figure 33.61 shows an example of initialization flow for clock synchronous operation when the SPI is used in master mode. For information on how to set up the ICU, DMAC or DTC, and I/O ports, see the descriptions given in the individual blocks.

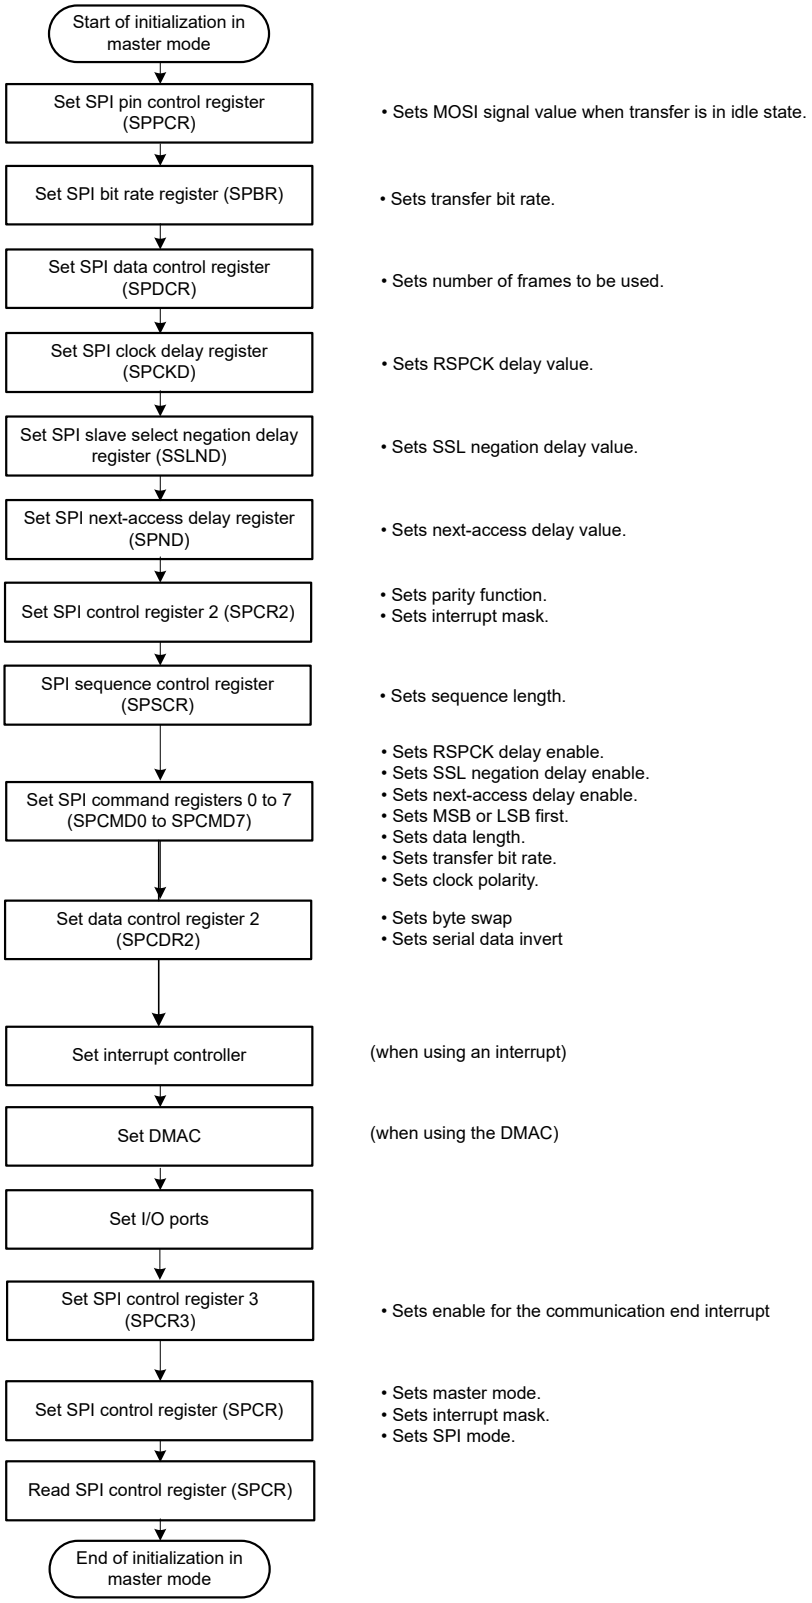

**Figure 33.61 Example of initialization flow in master mode for clock synchronous operation**

#### (5) Software processing flow

Software processing during clock synchronous master operation is the same as that for SPI master operation. For details, see (9) Software processing flow in section 33.3.12.1. Master mode operation. Mode fault errors do not occur in clock synchronous operation.

### 33.3.13.2 Slave mode operation

#### (1) Starting serial transfer

When the SPCR.SPMS bit is 1, the first RSPCKn edge triggers the start of a serial transfer in the SPI, and the SPI drives the MISOn output signal. The SSL0 input signal is not used in clock synchronous operation. For details on the SPI transfer format, see section 33.3.5. Transfer Formats.

#### (2) Terminating serial transfer

The SPI terminates the serial transfer after detecting an RSPCKn edge corresponding to the final sampling timing. When free space is available in the receive buffer (the SPSR.SPRF flag is 0), on termination of serial transfer, the SPI copies received data from the shift register to the receive buffer of the SPDR/SPDR_HA register. On termination of a serial transfer, the SPI changes the status of the shift register to empty regardless of the receive buffer.

The final sampling timing changes depending on the bit length of transfer data. In slave mode, the SPI data length depends on the SPCMD0.SPB[3:0] bits setting. For details on the SPI transfer format, see section 33.3.5. Transfer Formats.

#### (3) Initialization flow

Figure 33.62 shows an example of initialization flow for clock synchronous operation when the SPI is used in slave mode. For a description of how to set up the ICU, DTC, and I/O ports, see the descriptions given in the individual blocks.

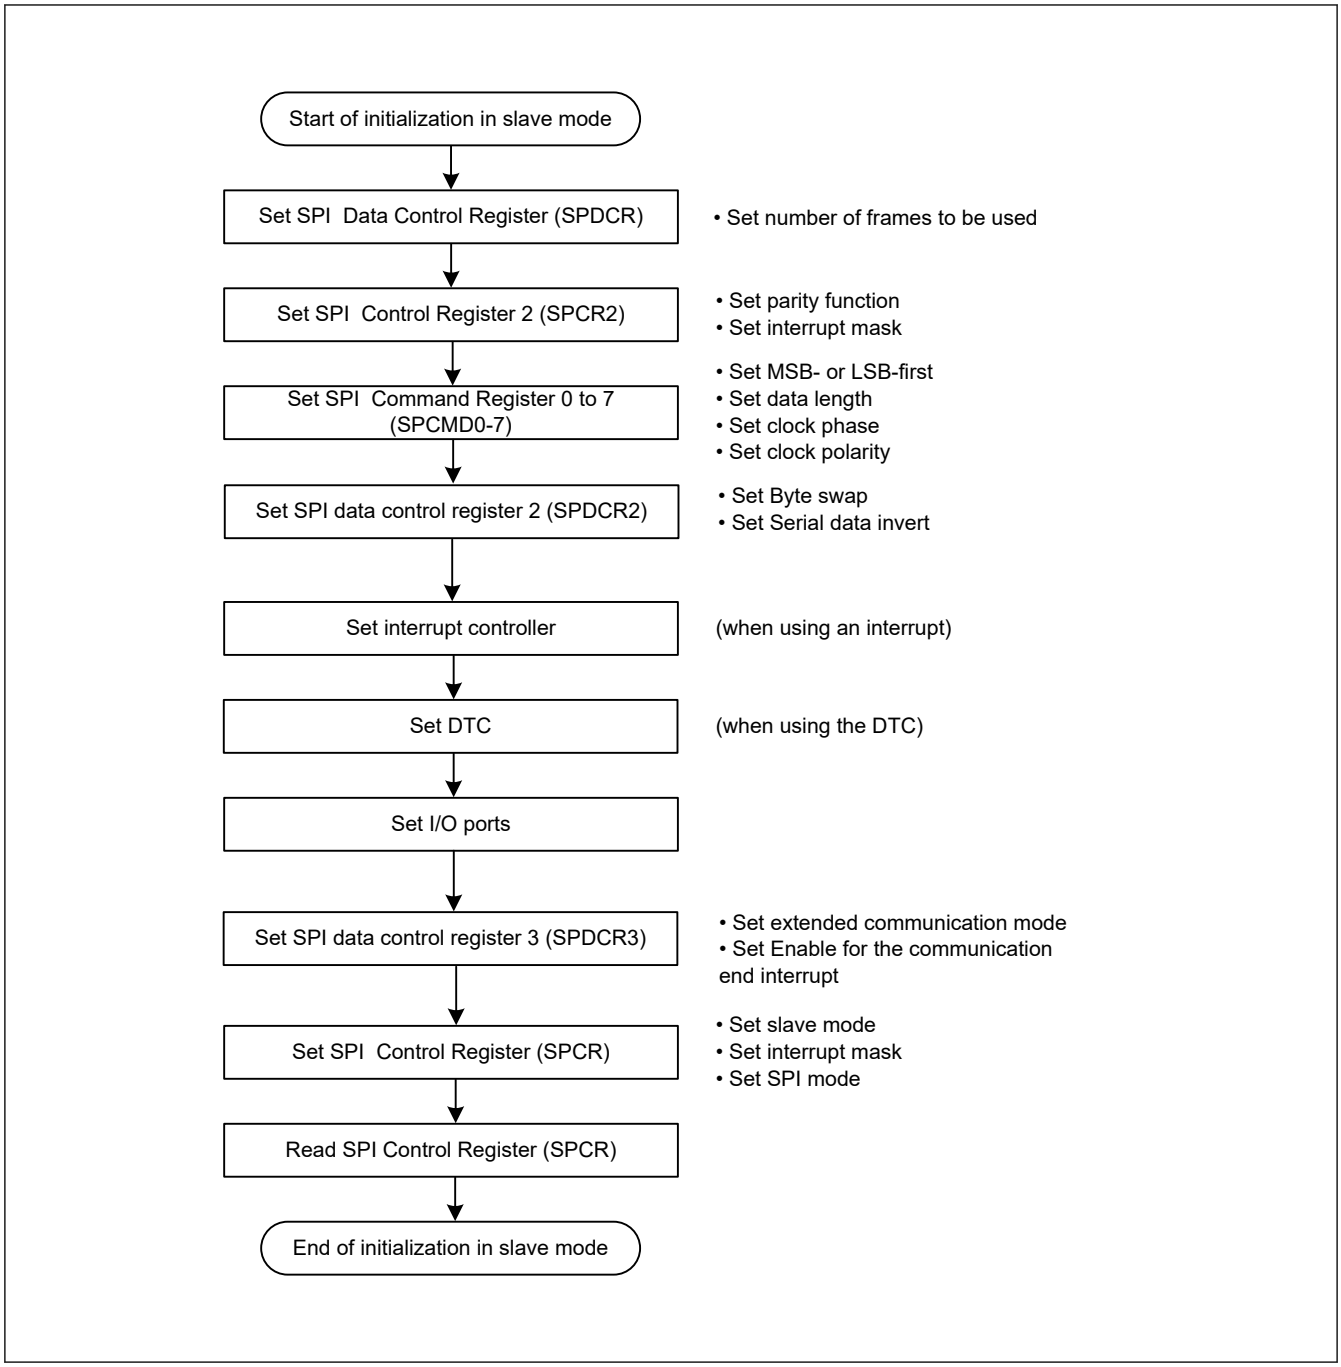

**Figure 33.62 Example of initialization flow in slave mode for clock synchronous operation**

### (4) Software processing flow

Software processing during clock synchronous slave operation is the same as that for SPI slave operation. For details, see (6) Software processing flow. Mode fault errors do not occur in clock synchronous mode.

## 33.3.14 Loopback Mode

When 1 is written to the SPPCR.SPLP2 bit or SPPCR.SPLP bit, the SPI shuts off the path between the MISOn pin and the shift register if the SPCR.MSTR bit is 1, or between the MOSIn pin and the shift register if the SPCR.MSTR bit is 0, and connects the input and output paths of the shift register, establishing a loopback mode. The SPI does not shut off the path between the MOSIn pin and the shift register if the SPCR.MSTR bit is 1, or between the MISOn pin and the shift register if the SPCR.MSTR bit is 0. This is called loopback mode. When a serial transfer is executed in loopback mode, the transmit data for the SPI or the reversed transmit data becomes the received data for the SPI.

Table 33.14 lists the relationship between the SPLP2 and SPLP bits and the received data. Figure 33.63 shows the configuration of the shift register I/O paths when the SPI in master mode is set to loopback mode (SPPCR.SPLP2 = 0, SPPCR.SPLP = 1).

**Table 33.14 SPLP2 and SPLP bit settings and received data**

| SPPCR.SPLP2 bit | SPPCR.SPLP bit | Received data |
|---|---|---|
| 0 | 0 | Input data from the MOSIn pin or MISOn pin |
| 0 | 1 | Inverted transmit data |
| 1 | 0 | Transmit data |
| 1 | 1 | Transmit data |

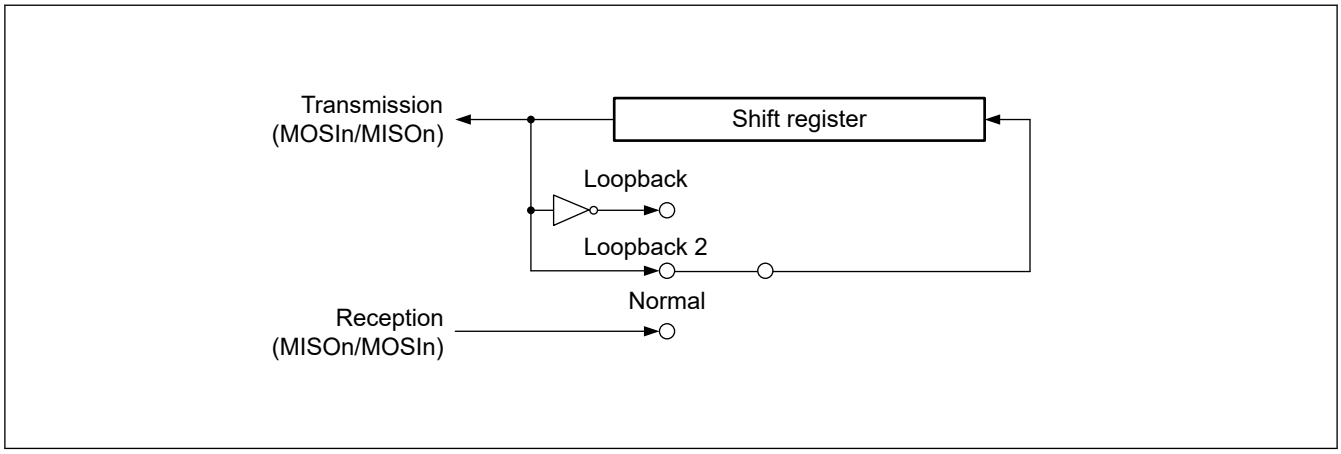

**Figure 33.63 Configuration of shift register I/O paths in loopback mode for master mode**

## 33.3.15 Self-Diagnosis of Parity Bit Function

The parity circuit consists of a parity bit adding unit used for transmit data and an error detecting unit used for received data. To detect defects in the parity bit adding unit and error detecting unit, the parity circuit performs self-diagnosis as shown in Figure 33.64.

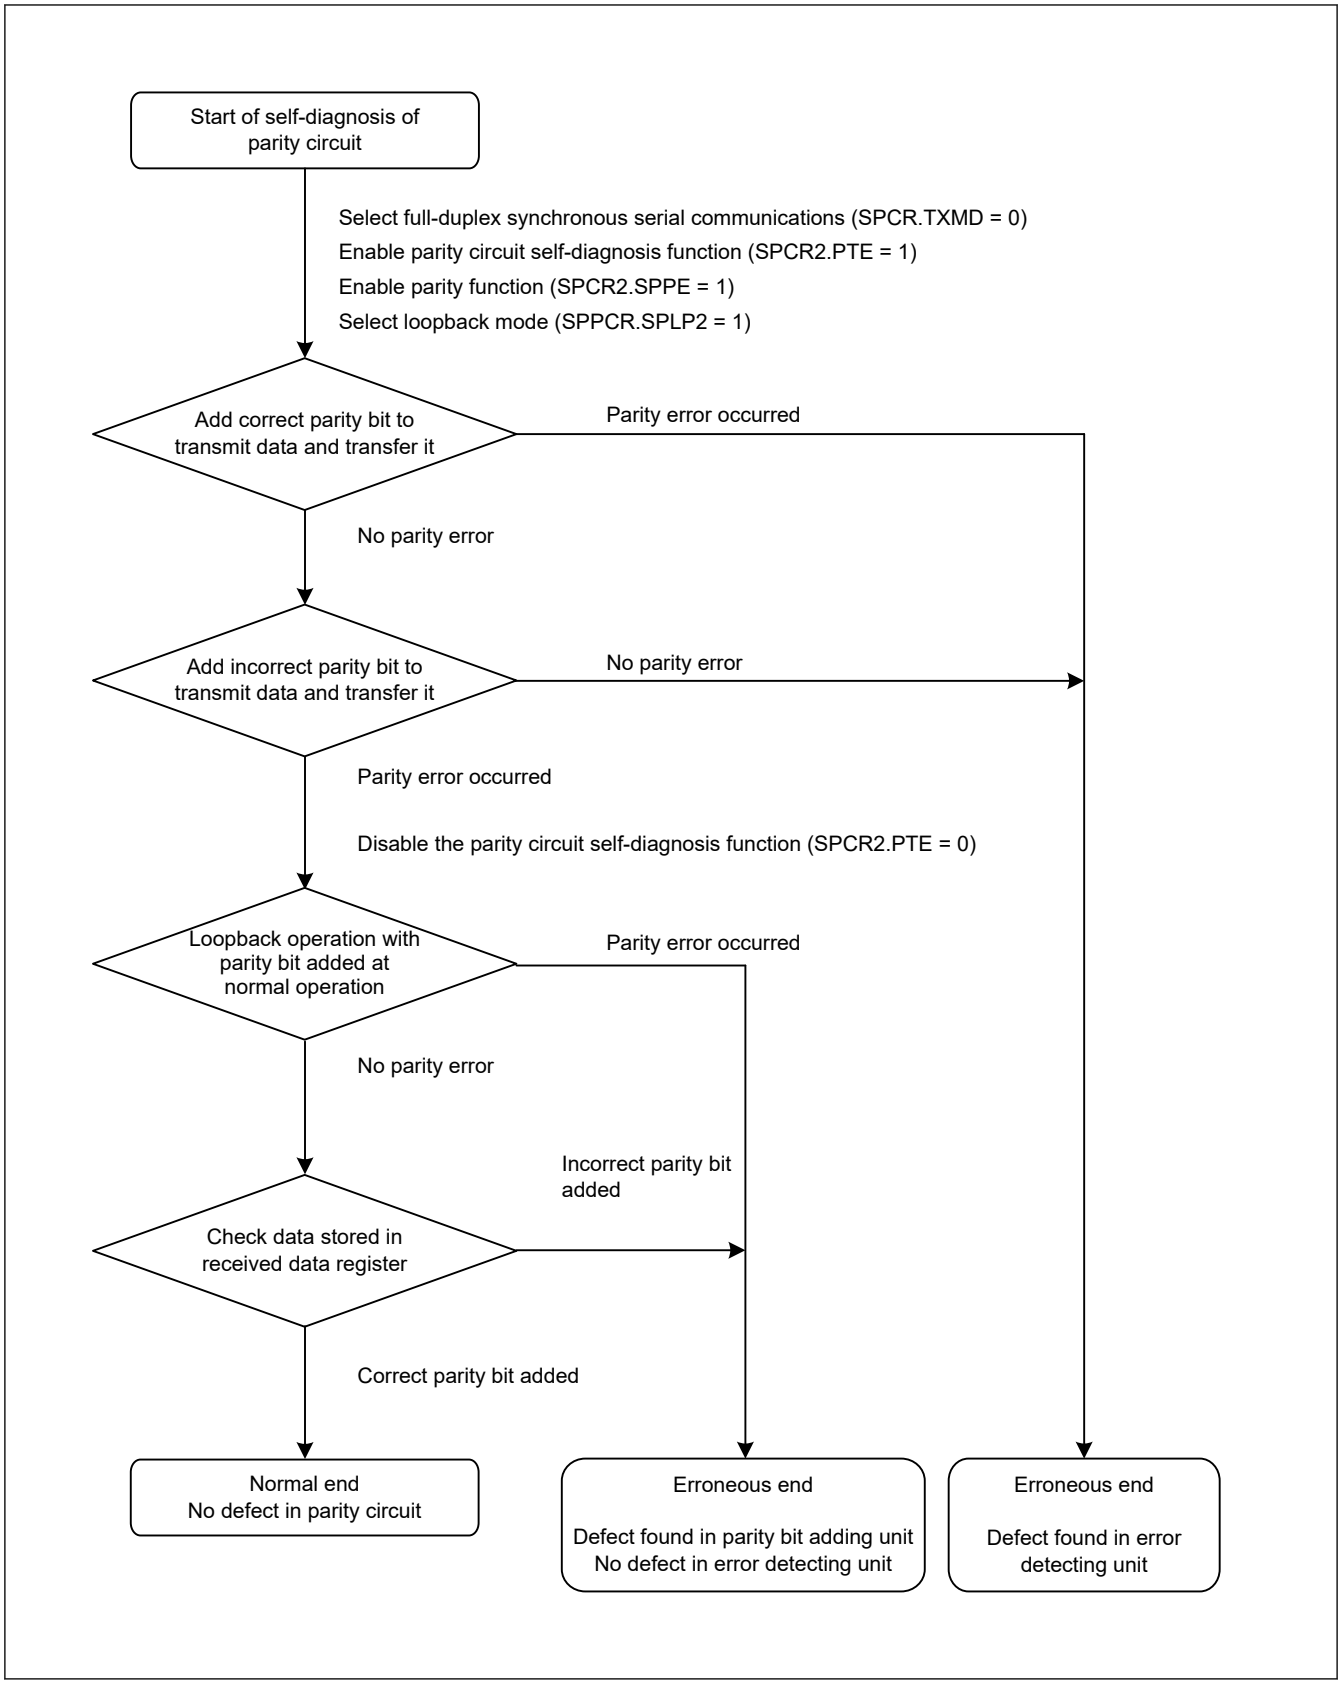

**Figure 33.64 Self-diagnosis flow for parity circuit**

## 33.3.16 Interrupt Sources

The SPI has the following interrupt sources:

- Receive buffer full
- Transmit buffer empty
- SPI error (mode-fault, underrun, overrun, or parity error)
- SPI idle
- Communication-end

The DMAC or DTC can be activated by the receive buffer full or transmit buffer empty interrupt to perform data transfer.

Because the vector address for the SPI0_SPEI (SPI error interrupt) is allocated to interrupt requests on mode-fault, underrun, overrun, and parity errors, the actual interrupt source must be determined from the flags. Interrupt sources for the SPI are listed in Table 33.15. An interrupt is generated on satisfaction of one of the interrupt conditions in Table 33.15. Clear the receive buffer full and transmit buffer empty sources through a data transfer.

When using the DMAC or DTC to perform data transmission and reception, you must first set up the DMAC or DTC to be in a transfer-enabled status before setting the SPI. For information on setting up the DMAC or DTC, see section 15, DMA Controller (DMAC) and section 16, Data Transfer Controller (DTC).

If the conditions for generating a transmit buffer empty or receive buffer full interrupt occur while the ICU.IELSRn.IR flag is 1, the interrupt is not output as a request for the ICU but is retained internally (the capacity for retention is one request per source). A retained interrupt request is output when the ICU.IELSRn.IR flag becomes 0. A retained interrupt request is automatically discarded when it is output as an actual interrupt request. The interrupt enable bit (the SPCR.SPTIE or SPCR.SPRIE bit) for an internally retained interrupt request can also be set to 0.

**Table 33.15 SPI interrupt sources**

| Interrupt source | Symbol | Interrupt condition | DTC/DMAC activation |
|---|---|---|---|
| Receive buffer full | SPI0_SPRI | The receive buffer becomes full (SPSR.SPRF flag is 1) while the SPCR.SPRIE bit is 1 | Possible |
| Transmit buffer empty | SPI0_SPTI | The transmit buffer becomes empty (SPSR.SPTEF flag is 1) while the SPCR.SPTIE bit is 1 | Possible |
| SPI error (mode-fault, underrun, overrun, or parity error) | SPI0_SPEI | The SPSR.MODF, OVRF, UDRF or PERF flag sets to 1 while the SPCR.SPEIE bit is 1 | Impossible |
| SPI idle | SPI0_SPII | The SPSR.IDLNF flag sets to 0 while the SPCR2.SPIIE bit is 1 | Impossible |
| Communication-end | SPI0_SPCI | CENDIE = 1 and CENDF = 1 | Impossible |

## 33.4 Event Link Controller Event Output

The Event Link Controller (ELC) can produce the following event output signals:

- Receive buffer full event output
- Transmit buffer empty event output
- Mode-fault, underrun, overrun, or parity error event output
- SPI idle event output
- Transmission-completed event output

The event link output signal is output regardless of the interrupt enable bit setting.

### 33.4.1 Receive Buffer Full Event Output

This event signal is output when received data is transferred from the shift register to the SPDR/SPDR_HA on completion of serial transfer.

### 33.4.2 Transmit Buffer Empty Event Output

This event signal is output when data for transmission is transferred from the transmit buffer to the shift register and when the value of the SPE bit changes from 0 to 1.

### 33.4.3 Mode-Fault, Underrun, Overrun, or Parity Error Event Output

This event signal is output when mode-fault, underrun, overrun, or parity error is detected. See section 33.5.4. Constraints on Mode-Fault, Underrun, Overrun, or Parity Error Event Output if using this event signal.

#### (1) Mode-fault

Table 33.16 lists the conditions for occurrence of a mode-fault event.

**Table 33.16 Conditions for mode-fault occurrence**

| SPI mode | SPCR.MODFEN bit | SSLn0 pin | Remarks |
|---|---|---|---|
| SPI operation (SPMS = 0)<br>Slave (SPCR.MSTR = 0) | 1 | Not active | Event is output only when the SSLn0 pin is deactivated during transmission |

#### (2) Underrun

This event signal is output in response to an underrun when a serial transfer starts while the transmission data is not ready, and the value of the SPCR.MSTR bit is 0 and the SPCR.SPE bit is 1. Under these conditions, the MODF and UDRF flags are set to 1.

#### (3) Overrun

This event signal is output in response to an overrun when a serial transfer completes while the receive buffer contains unread data and the value of the SPCR.TXMD bit is 0. Under these conditions, the OVRF flag is set to 1.

#### (4) Parity error

This event signal is output in response to a parity error detected on completion of a serial transfer while the value of the TXMD bit in SPCR is 0 and the value of the SPPE bit in SPCR2 is 1.

### 33.4.4 SPI Idle Event Output

#### (1) In master mode

In master mode, an event is output when the condition for setting the IDLNF flag (SPI idle flag) to 0 is satisfied.

#### (2) In slave mode

In slave mode, an event is output when the SPCR.SPE bit is set to 0 (SPI is initialized).

### 33.4.5 Communication End Event Output

In master mode, an event is output when the IDLNF flag (SPI idle flag) changes from 1 to 0. In slave mode, an event occurs with conditions shown in Table 33.17 and Table 33.18

**Table 33.17 Communication End Event Generating Conditions (transmit-receive/transmit slave mode)**

| | Transmit Buffer Status | Shift Register Status | Others |
|---|---|---|---|
| SPI operation (SPMS = 0) | Empty | Empty | SSL0 input is negated |
| Clock synchronous operation (SPMS = 1) | Empty | Empty | The last even edge of RSPCK of last data was detected (CPHA = 1) |

**Table 33.18 Communication End Event Generating Conditions (receive only slave mode)**

| | Others |
|---|---|
| SPI operation (SPMS = 0) | SSL0 input is negated |
| Clock synchronous operation (SPMS = 1) | The last even edge of RSPCK of last data was detected (CPHA = 1) |

Regardless of master mode or slave mode, no event is output when 0 is written to the SPCR.SPE bit during transmission or when the SPCR.SPE bit is cleared due to a mode fault error or an underrun error.

A communication end event is output at the following timing. The communication end event output timing in master operation is omitted because it is output at the same timing as an idle event.

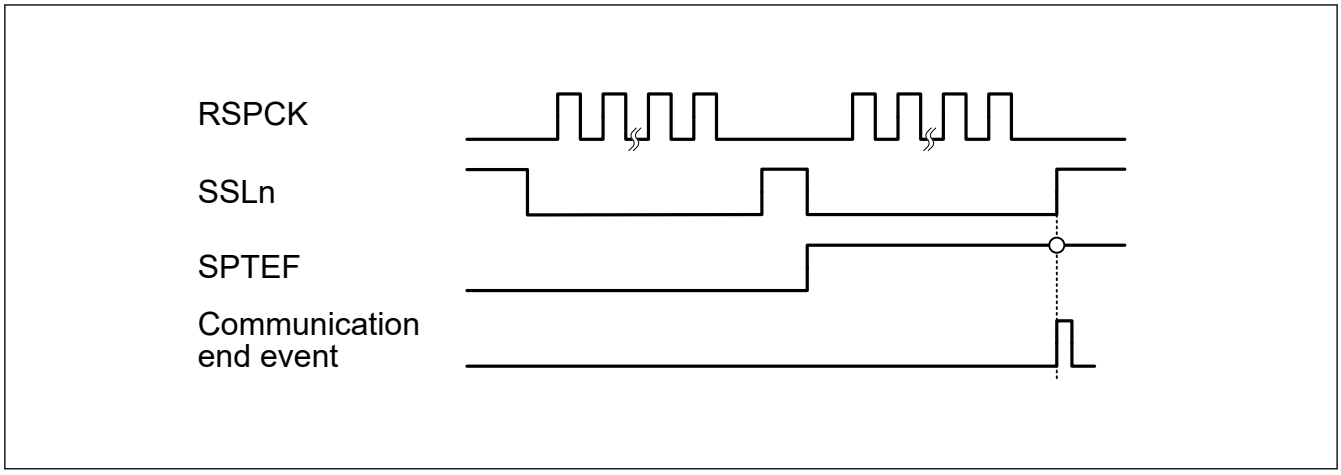

**Figure 33.65 Communication End Event Output Timing (Transmit slave mode, SPI Operation)**

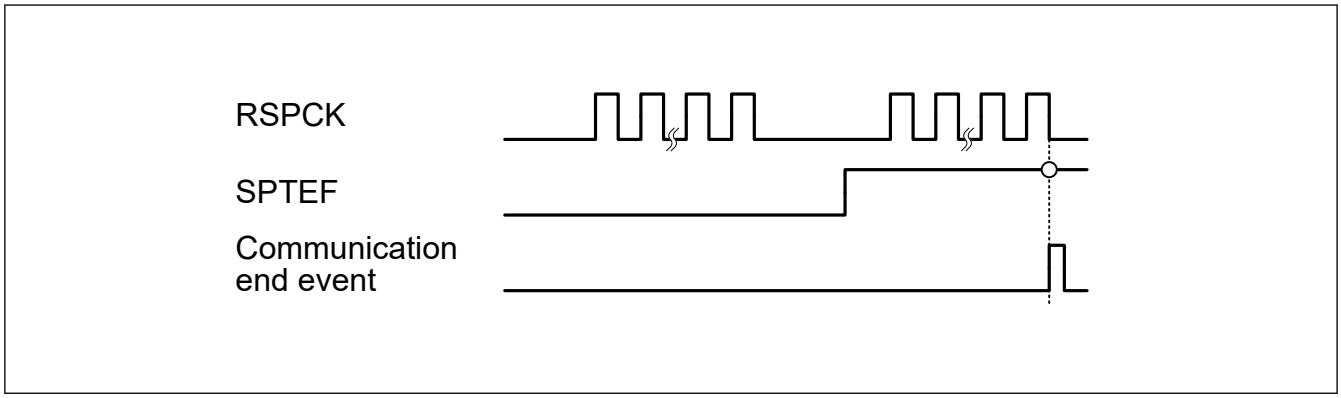

**Figure 33.66 Communication End Event Output Timing (Transmit slave mode, Clock Synchronous Operation)**

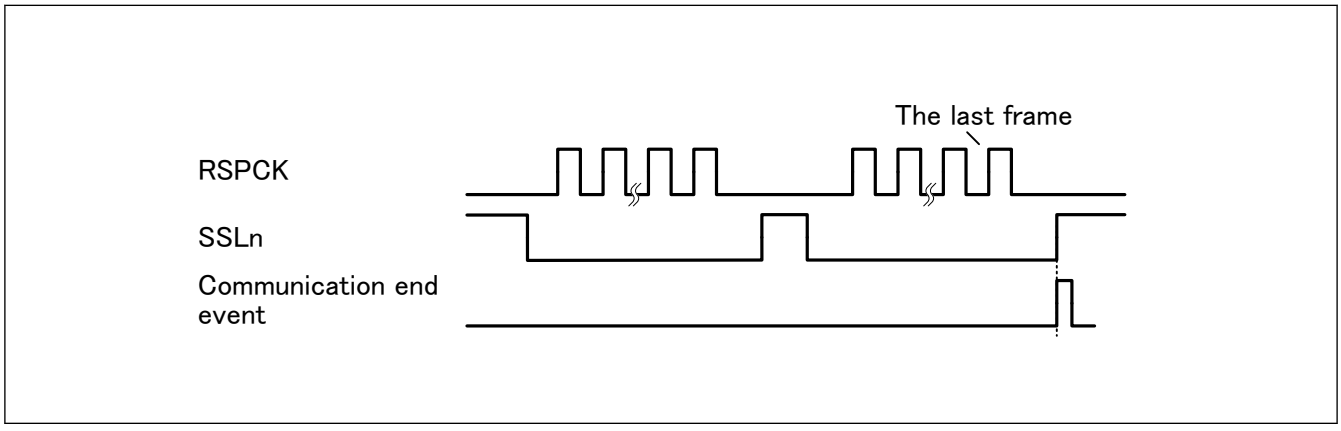

**Figure 33.67 Communication End Event Output Timing (Receive only slave mode, SPI Operation)**

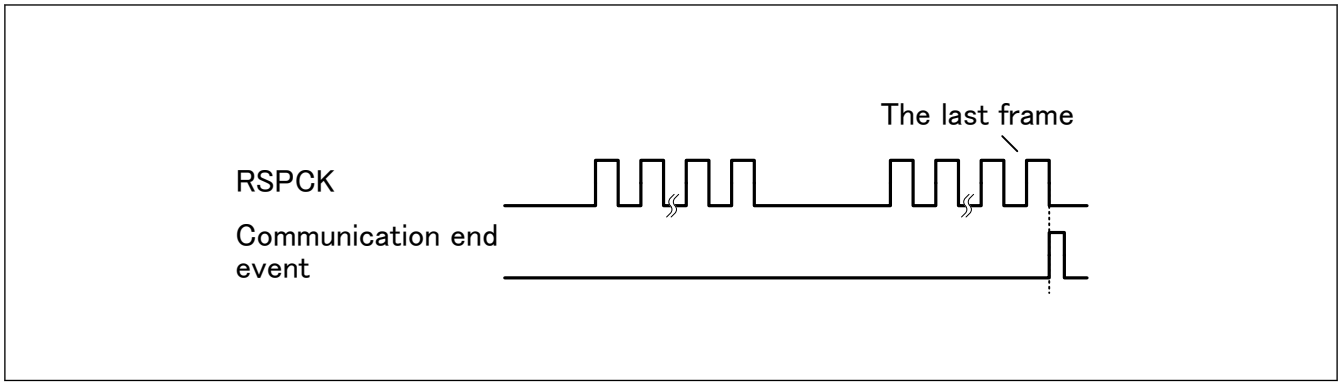

**Figure 33.68 Communication End Event Output Timing (Receive only slave mode, Clock Synchronous Operation)**

## 33.5 Usage Notes

### 33.5.1 Settings for the Module-stop State

The Module Stop Control Register B (MSTPCRB) can enable or disable the SPI operation. The SPI is initially stopped after reset. Releasing the module-stop state enables access to the registers. For details on the Module Stop Control Register B, see section 10, Low Power Modes.

### 33.5.2 Constraint on Low-power Functions

When using the module-stop function and entering a low-power mode other than Sleep mode, set the SPCR.SPE bit to 0 before completing communication.

### 33.5.3 Constraints on Starting Transfer

If the ICU.IELSRn.IR flag is 1 when transfer starts, the interrupt request is internally retained, which can lead to unanticipated behavior of the ICU.IELSRn.IR flag.

To prevent this, use the following procedure to clear interrupt requests before enabling operations (by setting the SPCR.SPE bit to 1):

1. Confirm that the transfer stopped (the SPCR.SPE bit is 0).
2. Set the associated interrupt enable bit (SPCR.SPTIE bit or SPCR.SPRIE bit) to 0.
3. Read the associated interrupt enable bit (SPCR.SPTIE bit or SPCR.SPRIE bit) and confirm that its value is 0.
4. Set the ICU.IELSRn.IR flag to 0.

### 33.5.4 Constraints on Mode-Fault, Underrun, Overrun, or Parity Error Event Output

Using the mode-fault, underrun, overrun, or parity error event is prohibited if the SPI is in multi-master mode (when the SPCR.SPMS bit is 0, the SPCR.MSTR bit is 1, and the SPCR.MODFEN bit is 1).

### 33.5.5 Constraints on the SPSR.SPRF and SPSR.SPTEF Flags

If the polling flags SPRF and SPTEF are used, using the interrupts is prohibited. Therefore, set the SPCR.SPRIE and SPCR.SPTIE bits to 0. Either the interrupts or the flags can be used, but not both.

# 34. Quad Serial Peripheral Interface (QSPI)

## 34.1 Overview

The QSPI is a memory controller for connecting a serial ROM (nonvolatile memory such as a serial flash memory, serial EEPROM, or serial FeRAM) that has an SPI-compatible interface.

Table 34.1 lists the QSPI specifications, Figure 34.1 shows a block diagram, and Table 34.2 lists the I/O pins.

**Table 34.1 QSPI specifications**

| Parameter | Specifications |
|---|---|
| Number of channels | 1 channel |
| SPI protocols | • Single SPI protocol, extended SPI protocol to achieve full-duplex communications<br>Note: Standard or fast reading can only be used in single SPI operation.<br>Four-wire communications with the serial flash memory by using the QSSL, QSPCLK, QIO0, and QIO1 pins (QIO0, QSSL, and QSPCLK for output, and QIO1 for input)<br>• Dual SPI protocol to achieve half-duplex communications<br>Four-wire communications with the serial flash memory by using the QSSL, QSPCLK, QIO0, and QIO1 pins (QSSL and QSPCLK for output, and QIO0 and QIO1 for input and output)<br>• Quad SPI protocol to achieve half-duplex communications<br>Six-wire communications with the serial flash memory by using the QSSL, QSPCLK, and QIO0 to QIO3 pins (QSSL and QSPCLK for output, and QIO0 to QIO3 for input and output) |
| SPI mode | • SPI mode 0: The QSPCLK signal is driven low when the SPI bus is not active.<br>• SPI mode 3: The QSPCLK signal is driven high when the SPI bus is not active. |
| SPI timing adjustment function | The following settings are possible to suit various types of serial flash memory device:<br>• SPI bus reference cycle (SFMSKC.SFMDV[4:0])<br>• Duty cycle correction (SFMSKC.SFMDTY)<br>• Adjustment of the number of dummy cycles (SFMSDC.SFMDN[3:0])<br>• Minimum width at high level for the QSSL signal (SFMSSC.SFMSW[3:0])<br>• QSSL signal setup time (SFMSSC.SFMSLD)<br>• QSSL signal hold time (SFMSSC.SFMSHD)<br>• Serial data output enable hold time (SFMSMD.SFMOEX) |
| ROM access mode | • Support for Standard Read, Fast Read, Fast Read Dual Output, Fast Read Dual I/O, Fast Read Quad Output, and Fast Read Quad I/O instructions<br>• Substitutable instruction code<br>• Prefetch function (data are sequentially stored in a buffer after one request without waiting for further requests to read the serial flash memory)<br>• Polling processing<br>• SPI bus cycle extension function<br>• XIP mode (allowing skipping of the reception of an instruction code to read the serial flash memory)<br>Note: ROM access mode is only possible with reading . |
| Direct communication mode | Flexible support for a wide variety of serial flash memory instructions and functions through software control, including erase, ID read, and power-down control |
| Interrupt source | Error interrupts |
| Module-stop function | Module-stop state can be set to reduce power consumption. |
| TrustZone Filter | Security attribution is always non-secure |

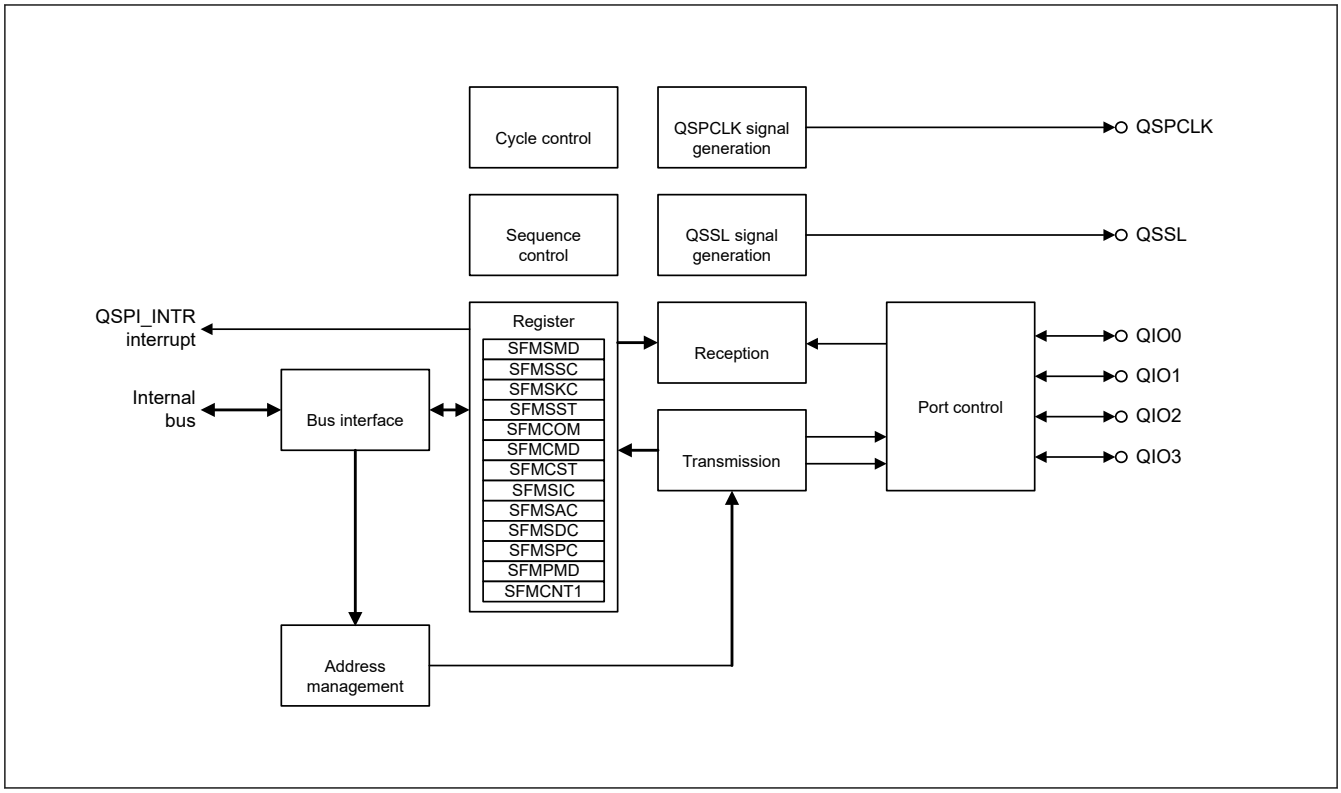

**Figure 34.1 QSPI block diagram**

**Table 34.2 QSPI I/O pins**

| Function | Pin name | I/O | Description |
|---|---|---|---|
| QSPI | QSPCLK | Output | QSPI clock output pin. |
| | QSSL | Output | QSPI slave output pin. |
| | QIO0 to QIO3 | I/O | Data0 to Data3 |

## 34.2 Register Descriptions

### 34.2.1 SFMSMD : Transfer Mode Control Register

Base address: QSPI = 0x6400_0000

Offset address: 0x000

| Bit position: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit position: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |

| 7 | PFOFF | Prefetch function operating state<br>0: Prefetch function operating<br>1: Prefetch function not enabled or not operating | R |
| 31:8 | — | These bits are read as 0. | R |

## 34.2.5 SFMCOM : Communication Port Register

Base address: QSPI = 0x6400_0000

Offset address: 0x010

| Bit position: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit position: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | — | — | — | — | — | SFMD[7:0] | | | | | | | |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | x | x | x | x | x | x | x | x |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 7:0 | SFMD[7:0] | Port for direct communication with the SPI bus<br>Input and output from this port are converted to an SPI bus cycle in direct communications mode (DCOM = 1). Access to this port is ignored in ROM access mode. | R/W |
| 31:8 | — | These bits are read as 0. The write value should be 0. | R/W |

## 34.2.6 SFMCMD : Communication Mode Control Register

Base address: QSPI = 0x6400_0000

Offset address: 0x014

| Bit position: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit position: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | DCOM |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 0 | DCOM | Mode select for communication with the SPI bus<br>0: ROM access mode<br>1: Direct communication mode*1 | R/W |
| 31:1 | — | These bits are read as 0. The write value should be 0. | R/W |

Note 1. SFMCMD.DCOM = 1 must be written when the transaction ends. For details, see section 34.10. Direct Communication Mode.

## 34.2.7 SFMCST : Communication Status Register

Base address: QSPI = 0x6400_0000

Offset address: 0x018

| Bit position: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit position: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | — | — | — | — | — | EROMR | — | — | — | — | — | — | COMBSY |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 0 | COMBSY | SPI bus cycle completion state in direct communication<br>0: No serial transfer being processed<br>1: Serial transfer being processed | R |
| 6:1 | — | These bits are read as 0. The write value should be 0. | R/W |
| 7 | EROMR | ROM access detection status in direct communication mode<br>0: ROM access not detected<br>1: ROM access detected | R/(W)*1 |
| 31:8 | — | These bits are read as 0. The write value should be 0. | R/W |

Note 1. Only 0 can be written to this bit.

## 34.2.8 SFMSIC : Instruction Code Register

Base address: QSPI = 0x6400_0000

Offset address: 0x020

| Bit position: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit position: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | — | — | — | — | — | SFMCIC[7:0] | | | | | | | |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 7:0 | SFMCIC[7:0] | Serial flash instruction code to substitute | R/W |
| 31:8 | — | These bits are read as 0. The write value should be 0. | R/W |

## 34.2.9 SFMSAC : Address Mode Control Register

Base address: QSPI = 0x6400_0000

Offset address: 0x024

| Bit position: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit position: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | — | — | — | — | — | — | — | — | SFM4BC | — | — | SFMAS[1:0] | |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 1 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 1:0 | SFMAS[1:0] | Number of address bytes select for the serial interface<br>0 0: 1 byte<br>0 1: 2 bytes<br>1 0: 3 bytes<br>1 1: 4 bytes | R/W |
| 3:2 | — | These bits are read as 0. The write value should be 0. | R/W |
| 4 | SFM4BC | Selection of instruction code automatically generated when the serial interface address width is 4 bytes<br>0: Do not use 4-byte address read instruction code<br>1: Use 4-byte address read instruction code | R/W |
| 31:5 | — | These bits are read as 0. The write value should be 0. | R/W |

## 34.2.10 SFMSDC : Dummy Cycle Control Register

Base address: QSPI = 0x6400_0000

Offset address: 0x028

| Bit position: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit position: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | SFMXD[7:0] | | | | | | | | SFMX EN | SFMX ST | — | — | SFMDN[3:0] | | | |
| Value after reset: | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 3:0 | SFMDN[3:0] | Number of dummy cycles select for Fast Read instructions<br>0x0: Default dummy cycles for each instruction:<br>- Fast Read Quad I/O: 6 QSPCLK<br>- Fast Read Quad Output: 8 QSPCLK<br>- Fast Read Dual I/O: 4 QSPCLK<br>- Fast Read Dual Output: 8 QSPCLK<br>- Fast Read: 8 QSPCLK<br>0x1: 3 QSPCLK*1<br>0x2: 4 QSPCLK<br>0x3: 5 QSPCLK<br>0x4: 6 QSPCLK<br>0x5: 7 QSPCLK<br>0x6: 8 QSPCLK<br>0x7: 9 QSPCLK<br>0x8: 10 QSPCLK<br>0x9: 11 QSPCLK<br>0xA: 12 QSPCLK<br>0xB: 13 QSPCLK<br>0xC: 14 QSPCLK<br>0xD: 15 QSPCLK<br>0xE: 16 QSPCLK<br>0xF: 17 QSPCLK | R/W |
| 5:4 | — | These bits are read as 0. The write value should be 0. | R/W |
| 6 | SFMXST | XIP mode status<br>0: Normal (non-XIP) mode<br>1: XIP mode | R |
| 7 | SFMXEN | XIP mode permission<br>0: Prohibit XIP mode<br>1: Permit XIP mode | R/W |
| 15:8 | SFMXD[7:0] | Mode data for serial flash (Controls XIP mode.)*2 | R/W |
| 31:16 | — | These bits are read as 0. The write value should be 0. | R/W |

Note 1. To avoid a conflict with the input/output switch of the serial flash memory pin connected to QIO0 pin, select more than four cycles of QSPCLK as the number of dummy cycles for the fast read instruction when the output enable signal is extended by setting the SFMOEX bit in the SFMSMD register to 1.

Note 2. As the mode data for serial flash memory, specify the XIP mode setting data set in actual serial flash memory.

## 34.2.11 SFMSPC : SPI Protocol Control Register

Base address: QSPI = 0x6400_0000

Offset address: 0x030

| Bit position: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit position: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | — | — | — | — | — | — | — | — | SFMSDE | — | — | SFMSPI[1:0] | |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 1 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 1:0 | SFMSPI[1:0] | SPI protocol select*1<br>0 0: Single SPI Protocol, Extended SPI protocol<br>0 1: Dual SPI protocol<br>1 0: Quad SPI protocol<br>1 1: Setting prohibited | R/W |
| 3:2 | — | These bits are read as 0. The write value should be 0. | R/W |
| 4 | SFMSDE | QSPCLK extended selection bit when switching I/O of QIOn pin<br>0: No QSPCLK extension<br>1: QSPCLK expansion when switching I/O direction of QIOn pin | R/W |
| 31:5 | — | These bits are read as 0. The write value should be 0. | R/W |

Note 1. The states of the QIO2 and QIO3 pins change depending on the settings of the SFMSMD.SFMRM[2:0] and SFMSPI[1:0] bits. For details, see section 34.9. QIO2 and QIO3 Pin States.

## 34.2.12 SFMPMD : Port Control Register

Base address: QSPI = 0x6400_0000

Offset address: 0x034

| Bit position: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit position: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | — | — | — | — | — | — | — | — | — | — | SFMWPL | — | — |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 1:0 | — | These bits are read as 0. The write value should be 0. | R/W |
| 2 | SFMWPL | WP pin level specification<br>0: Low level<br>1: High level | R/W |
| 31:3 | — | These bits are read as 0. The write value should be 0. | R/W |

### 34.2.13 SFMCNT1 : External QSPI Address Register

Base address: QSPI = 0x6400_0000

Offset address: 0x804

| Bit position: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | QSPI_EXT[5:0] | | | | | | — | — | — | — | — | — | — | — | — | — |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit position: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 25:0 | — | These bits are read as 0. The write value should be 0. | R/W |
| 31:26 | QSPI_EXT[5:0] | Bank switching address<br>When accessing from 0x60000000 to 0x63FFFFFF, the address bus is set from QSPI_EXT [5:0] to the upper 6 bits of the internal bus address for the address bus.<br>0x00: QSPI bank 00<br>0x01: QSPI bank 01<br>0x02: QSPI bank 02<br>⋮ ⋮<br>0x3C: QSPI bank 60<br>0x3D: QSPI bank 61<br>0x3E: QSPI bank 62<br>0x3F: Setting prohibited | R/W |

## 34.3 Memory Map

### 34.3.1 External Bus Space

The locations of a serial flash memory and control register on the address space are determined by the address range of the area set in the configuration.

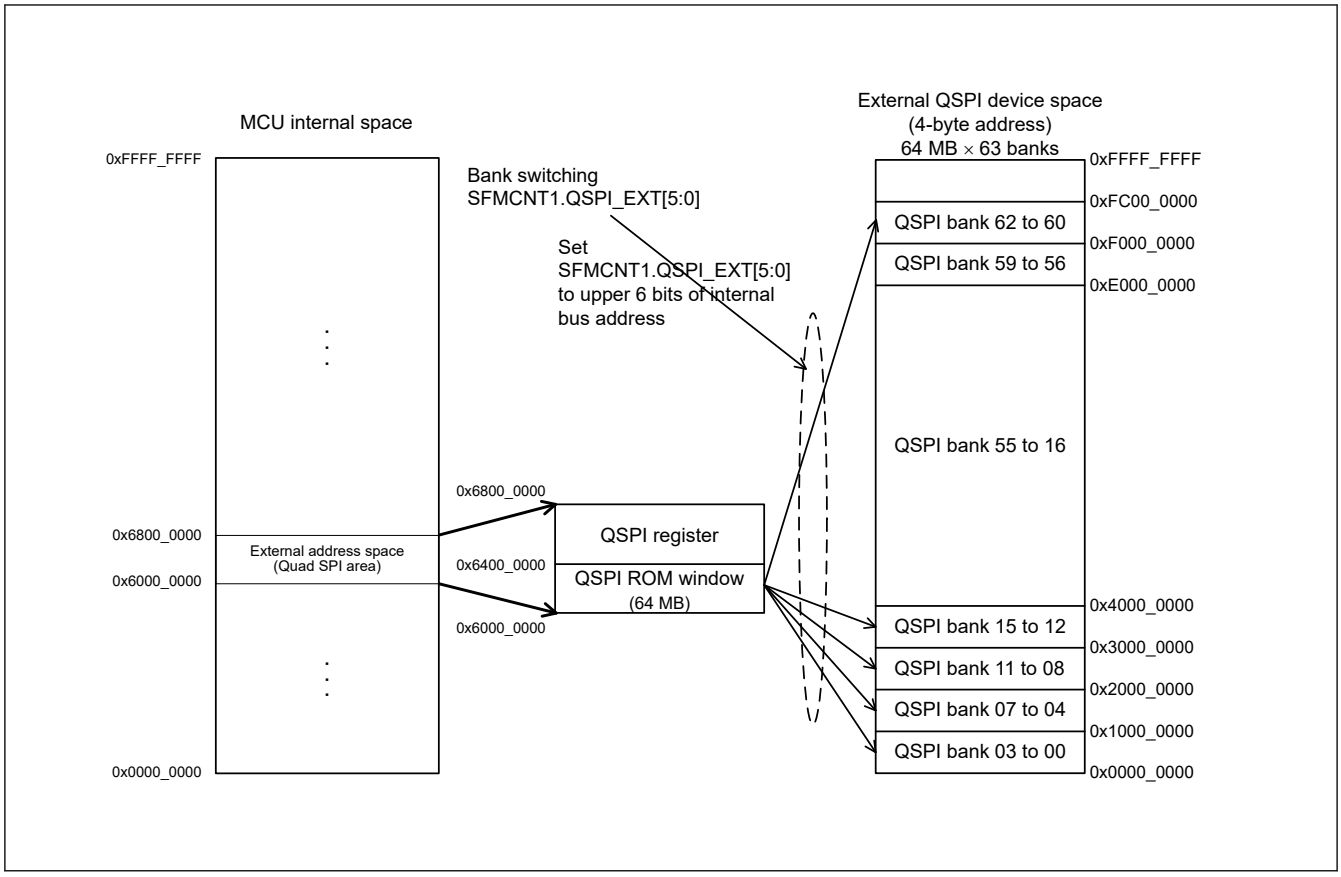

**Figure 34.2 Default area setting and memory map**

## 34.3.2 Address Width of the SPI Space and SPI Bus

The SPI space has a 32-bit address width for referencing the serial flash memory. When the SPI space is accessed for a read, an SPI bus cycle starts automatically, and data read from the serial flash is returned.

The address width of the SPI space is fixed at 32 bits. However, the address width of the SPI bus is selectable to 8, 16, 24, or 32 bits in the SFMAS[1:0] bits in the Address Mode Control Register (SFMSAC) register. If 8, 16, or 24 bits is selected as the address width of the SPI bus, only the lower part of the address used to access the SPI space is posted to the serial flash memory through the SPI bus. As a result, the mirror image of the serial flash corresponding to the address width of the SPI bus repeatedly appears in the SPI space.

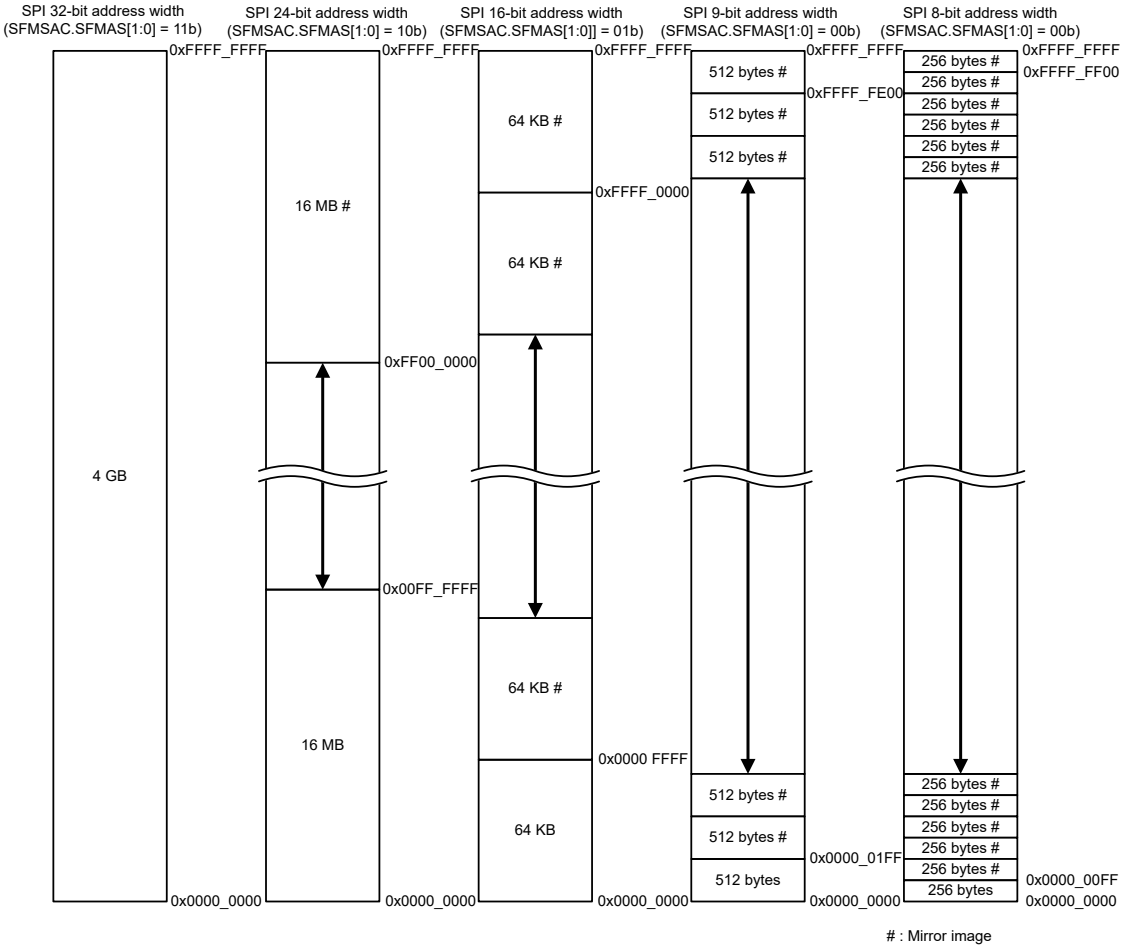

**Figure 34.3 Memory map of SPI space**

Note: The SPI bus address width is selectable to 8, 16, 24, or 32 bits in the SFMAS[1:0] bits in the SFMSAC register (cases 1 to 3 and 5 in the figure correspond to the respective address widths). When an 8-bit address width is selected, the address information of the ninth bit can be embedded in the Read instruction code. The memory map in case 4 in the figure is for the 9-bit address width. For details on the Read instruction, see section 34.6.2. Standard Read Instruction.

## 34.4 SPI Bus

### 34.4.1 SPI Protocol

Single SPI, extended SPI, dual SPI, and quad SPI are supported in addition to the SPI protocol used for serial flash memory connection.

The initial state of the SPI protocol is Single SPI, extended SPI and can be changed with the SFMSPI[1:0] bits in the SPI Protocol Control Register (SFMSPC) register.

The address and data pins used in the Single SPI, extended SPI protocol change depending on the setting of the serial interface read mode select bits SFMRM[2:0] in Transfer Mode Control Register (SFMSMD). Table 34.3 and Table 34.4 list the pins used for instruction code, addresses, and data in each of the SPI protocols.

Note: In read operation, the QSPI outputs additional one clock without accompanying data reception per one SPI bus cycle. For details, see section 34.5.9. Serial Data Receiving Latency.

**Table 34.3 List of SPI Protocols (1)**

| SPI Protocol (SFMSPC.SFMSPI[1:0]) | Single SPI Protocol, Extended SPI Protocol | | | | | |
|---|---|---|---|---|---|---|
| Serial interface read mode select (SFMSMD.SFMRM[2:0]) | Standard read | Fast read | Fast read dual output | Fast read dual I/O | Fast read quad output | Fast read quad I/O |
| All pins used | QSPCLK, QSSL, QIO0, QIO1 | QSPCLK, QSSL, QIO0, QIO1 | QSPCLK, QSSL, QIO0, QIO1 | QSPCLK, QSSL, QIO0, QIO1 | QSPCLK, QSSL, QIO0, QIO1, QIO2, QIO3 | QSPCLK, QSSL, QIO0, QIO1, QIO2, QIO3 |
| Pins used for instruction code | QIO0 | QIO0 | QIO0 | QIO0 | QIO0 | QIO0 |
| Pins used for addresses | QIO0 | QIO0 | QIO0 | QIO0, QIO1 | QIO0 | QIO0, QIO1, QIO2, QIO3 |
| Pins used for data | QIO0/QIO1 | QIO0/QIO1 | QIO0, QIO1 | QIO0, QIO1 | QIO0, QIO1, QIO2, QIO3 | QIO0, QIO1, QIO2, QIO3 |

Note: Single SPI protocol operation is for standard read and fast read. Extended SPI protocol operation is fast read dual output, fast read dual I/O, fast read quad output, and fast read quad I/O.

**Table 34.4 List of SPI Protocols (2)**

| SPI Protocol (SFMSPC.SFMSPI[1:0]) | Dual-SPI Protocol | | Quad-SPI Protocol | |
|---|---|---|---|---|
| Serial interface read mode select (SFMSMD.SFMRM[2:0]) | Fast read dual output | Fast read dual I/O | Fast read quad output | Fast read quad I/O |
| All pins used | QSPCLK, QSSL, QIO0, QIO1 | QSPCLK, QSSL, QIO0, QIO1 | QSPCLK, QSSL, QIO0, QIO1, QIO2, QIO3 | QSPCLK, QSSL, QIO0, QIO1, QIO2, QIO3 |
| Pins used for instruction code | QIO0, QIO1 | QIO0, QIO1 | QIO0, QIO1, QIO2, QIO3 | QIO0, QIO1, QIO2, QIO3 |
| Pins used for addresses | QIO0, QIO1 | QIO0, QIO1 | QIO0, QIO1, QIO2, QIO3 | QIO0, QIO1, QIO2, QIO3 |
| Pins used for data | QIO0, QIO1 | QIO0, QIO1 | QIO0, QIO1, QIO2, QIO3 | QIO0, QIO1, QIO2, QIO3 |

In single SPI protocol and extended SPI protocol, the instruction code is always output from the QIO0 pin. Address and data input/output operations are performed according to the settings in SFMSMD.SFMRM[2:0].

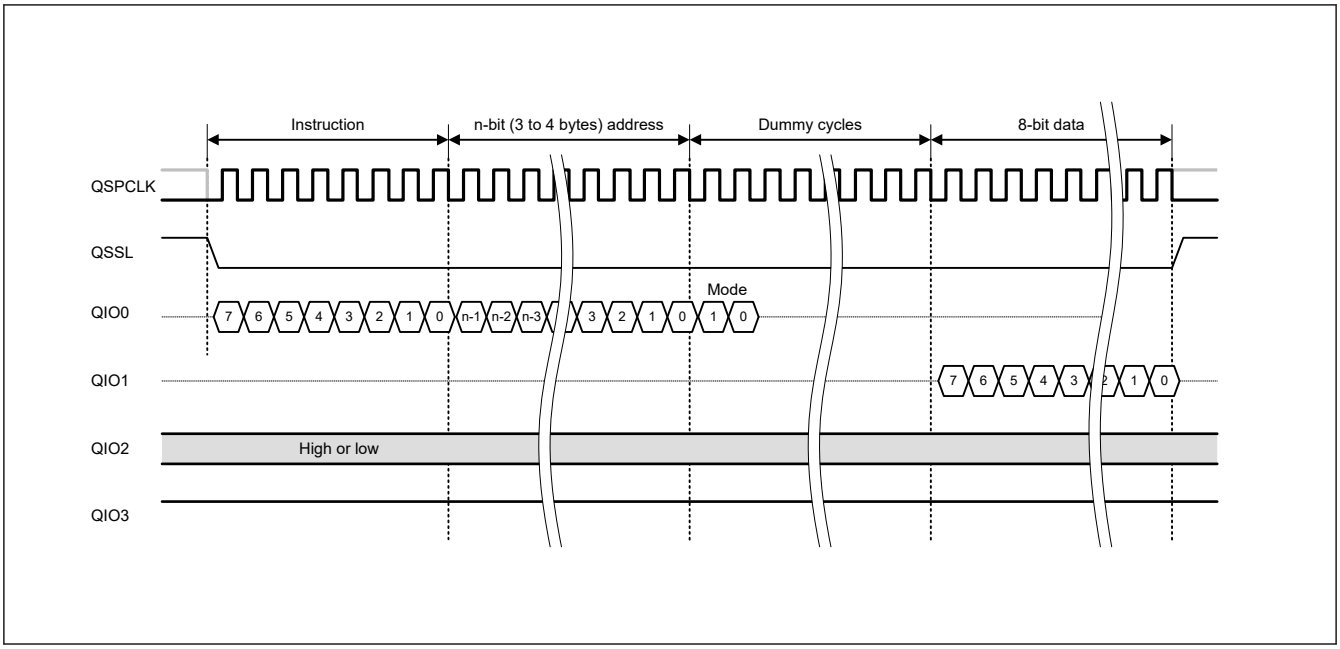

**Figure 34.4 Single SPI Protocol example for Fast Read**

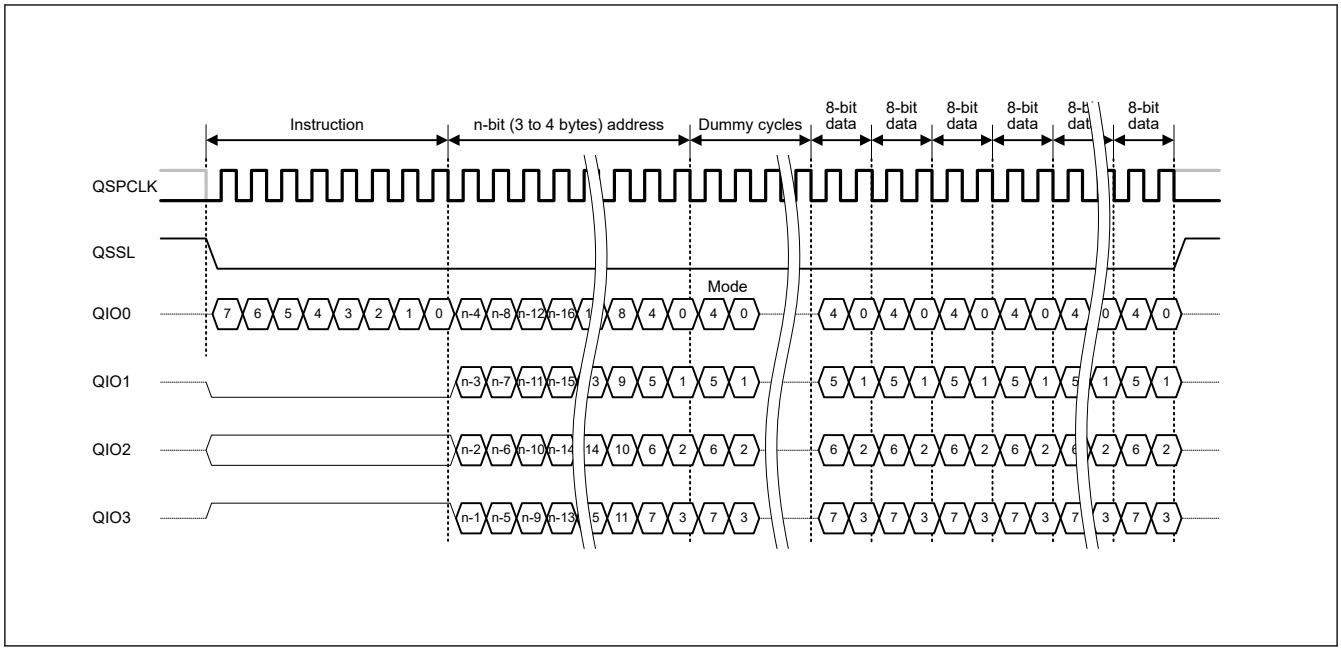

**Figure 34.5 Extended SPI Protocol example for Fast Read Quad I/O**

The Dual SPI protocol performs I/O operation of all signals such as instruction codes, addresses, and data using two pins, QIO0 and QIO1.

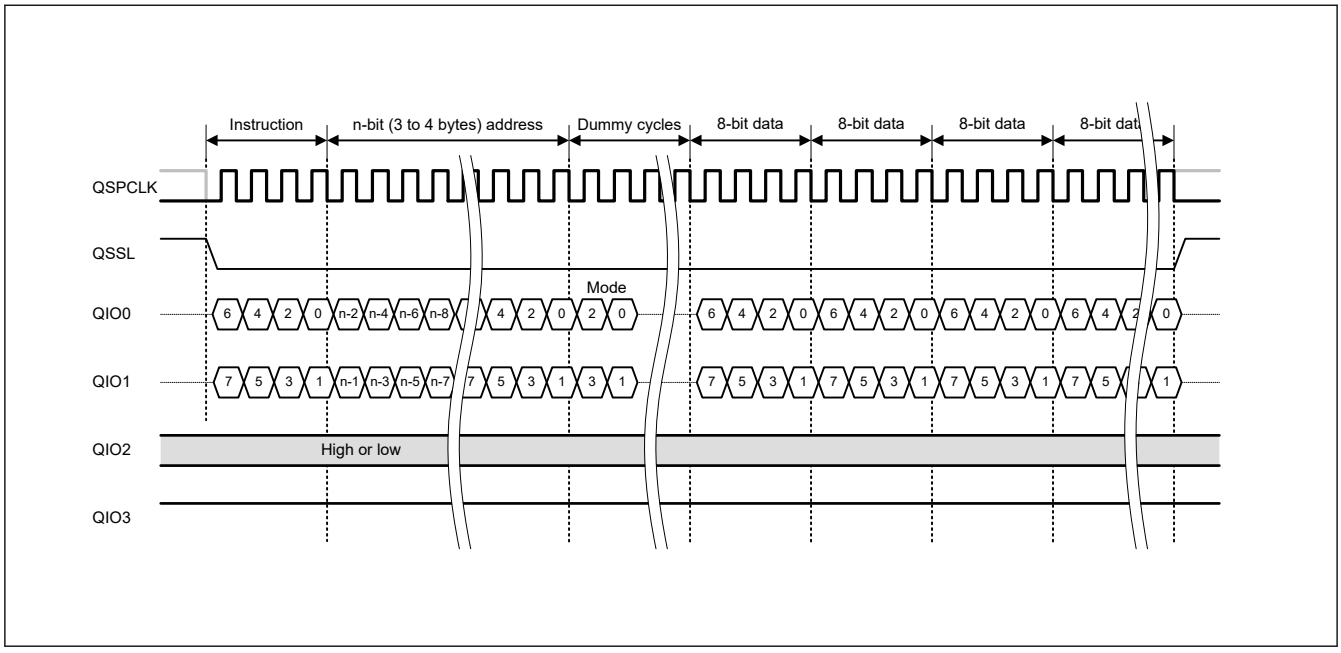

**Figure 34.6 Dual SPI protocol example for Fast Read Dual I/O**

The Quad SPI protocol performs I/O operation of all signals such as instruction codes, addresses, and data using four pins, QIO0, QIO1, QIO2, and QIO3.

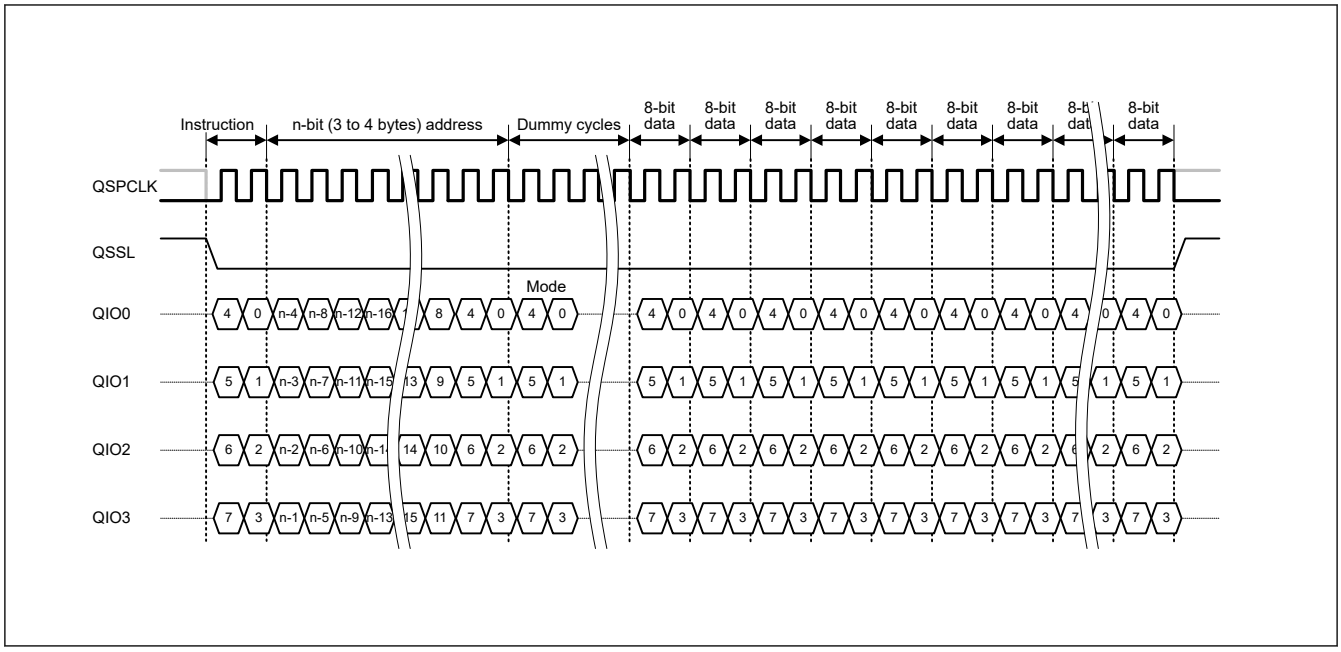

**Figure 34.7 Quad SPI protocol example for Fast Read Quad I/O**

## 34.4.2 SPI Mode

Either SPI mode 0 or SPI mode 3 can be selected as the SPI mode by the SFMSMD.SFMMD3 bit. This can be switched by changing the register setting during operation. The difference between SPI modes 0 and 3 is the state of the QSPCLK signal when it is inactive. The standby level of the QSPCLK signal in SPI mode 0 is low, and high in SPI mode 3.

Serial data is output from the QSPI on a falling edge of the serial clock and is read into the serial flash memory on a rising edge of the serial clock. Serial data is output from the serial flash memory on a falling edge of the serial clock and is read into the QSPI on the next falling edge of the serial clock.

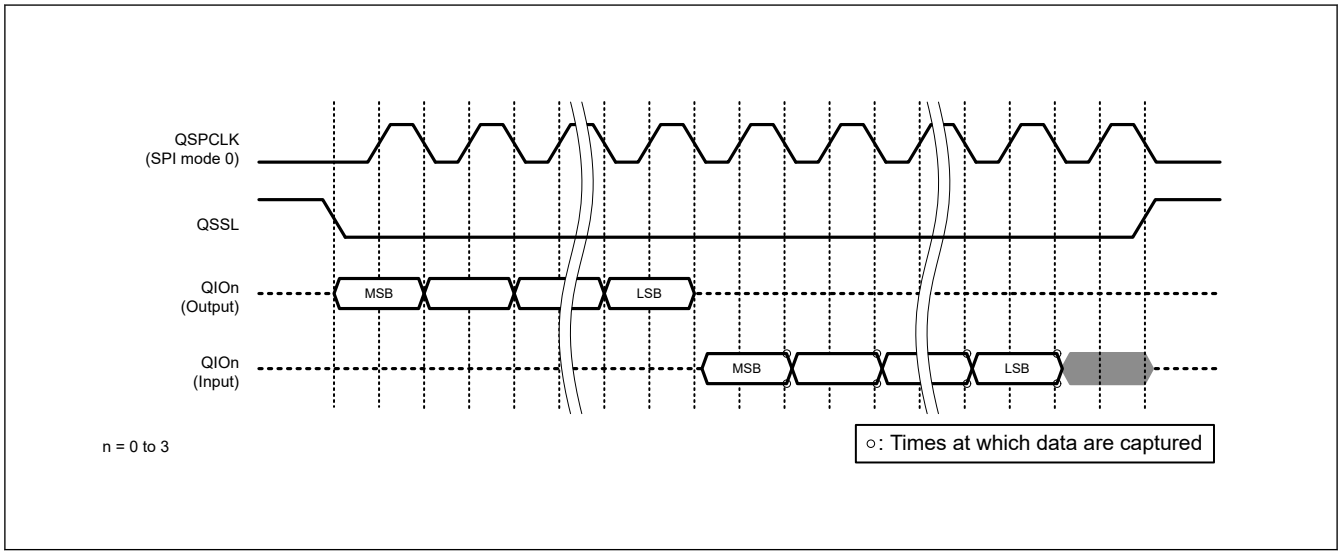

**Figure 34.8 Basic serial interface timing (SPI mode 0)**

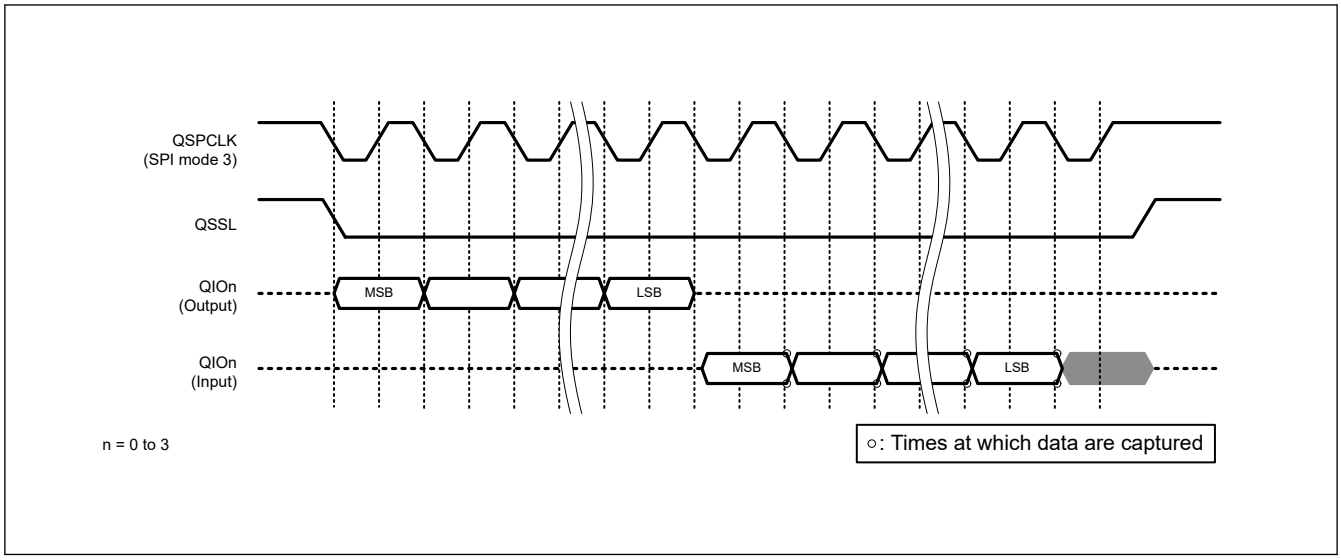

**Figure 34.9 Basic serial interface timing (SPI mode 3)**

## 34.5 SPI Bus Timing Adjustment

The timing of the SPI bus signal can be adjusted in the registers. The configured timing is applied to all SPI bus accesses, for both ROM access and direct communication.

### 34.5.1 SPI Bus Reference Cycles

The SPI bus operates on reference (QSPCLK) cycles obtained by multiplying PCLKA by an integer. The reference cycles are selectable within the range of PCLKA multiplied by 4 to 48 in the SFMDV[4:0] bits in the Clock Control Register (SFMSKC).

**Table 34.5 Relationship among SFMDV[4:0] bits, cycle multiplier, and serial clock frequencies (1 of 2)**

| SFMDV[4:0] | Cycle multiplier | QSPCLK when PCLKA = 80MHz |
|---|---|---|
| 11111b | 48 | 1.67 |
| 11110b | 46 | 1.74 |
| 11101b | 44 | 1.82 |
| 11100b | 42 | 1.90 |
| 11011b | 40 | 2.00 |
| 11010b | 38 | 2.11 |
| 11001b | 36 | 2.22 |
| 11000b | 34 | 2.35 |
| 10111b | 32 | 2.50 |
| 10110b | 30 | 2.67 |

## 34.5.2 QSPCLK Signal Duty Ratio

When the reference clock is configured as PCLKA divided by an odd number without duty ratio correction, the duty ratio of the QSPCLK signal will not be 50%. When the reference clock is PCLKA divided by an odd number, be sure to enable the duty ratio correction function (SFMSKC.SFMDTY = 1).

When the reference clock is PCLKA divided by an even number, the SFMDTY setting in the SFMSKC register is ignored.

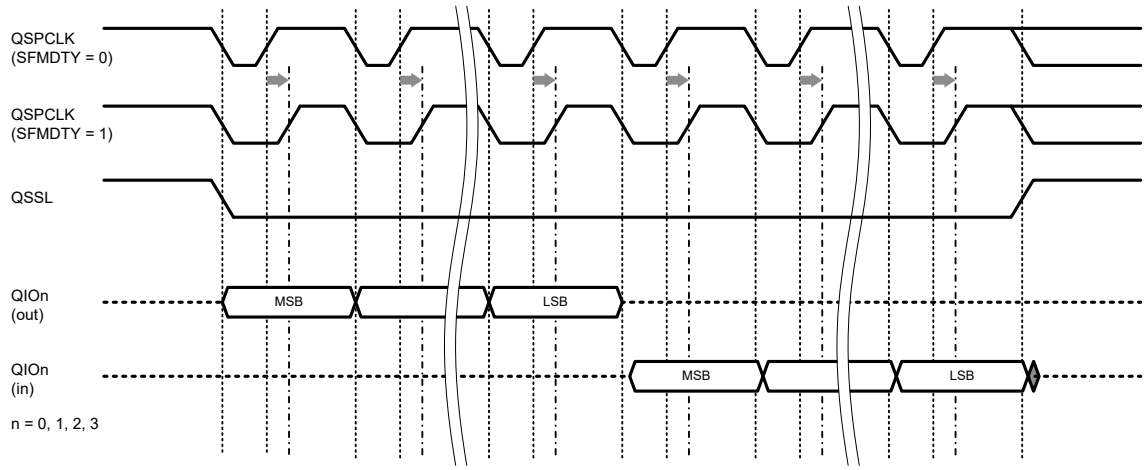

**Figure 34.10 Example correction of the QSPCLK signal duty ratio using the SFMDTY bit, when PCLKA is multiplied by 3**

## 34.5.3 Minimum High-Level Width for the QSSL Signal

Between adjacent SPI bus cycles, the QSSL signal must be held high (inactive) for a sufficient time to satisfy the deselect time required by the serial flash memory. The minimum high-level width of the QSSL output signal is selectable as the reference cycle multiplied by an integer from 1 to 16 in the SFMSW[3:0] bits in the Instruction Code Register (SFMSSC) register.

### 34.5.4 QSSL Signal Setup Time

The QSSL signal setup time that the serial flash memory requires after the QSSL signal is driven active low until the first rising edge of the QSPCLK signal can be configured. The setup time can be selected as 0.5 or 1.5 cycles of QSPCLK in the SFMSLD bit of the SFMSSC register.

Set a value that meets the most constrained timing condition for your application.

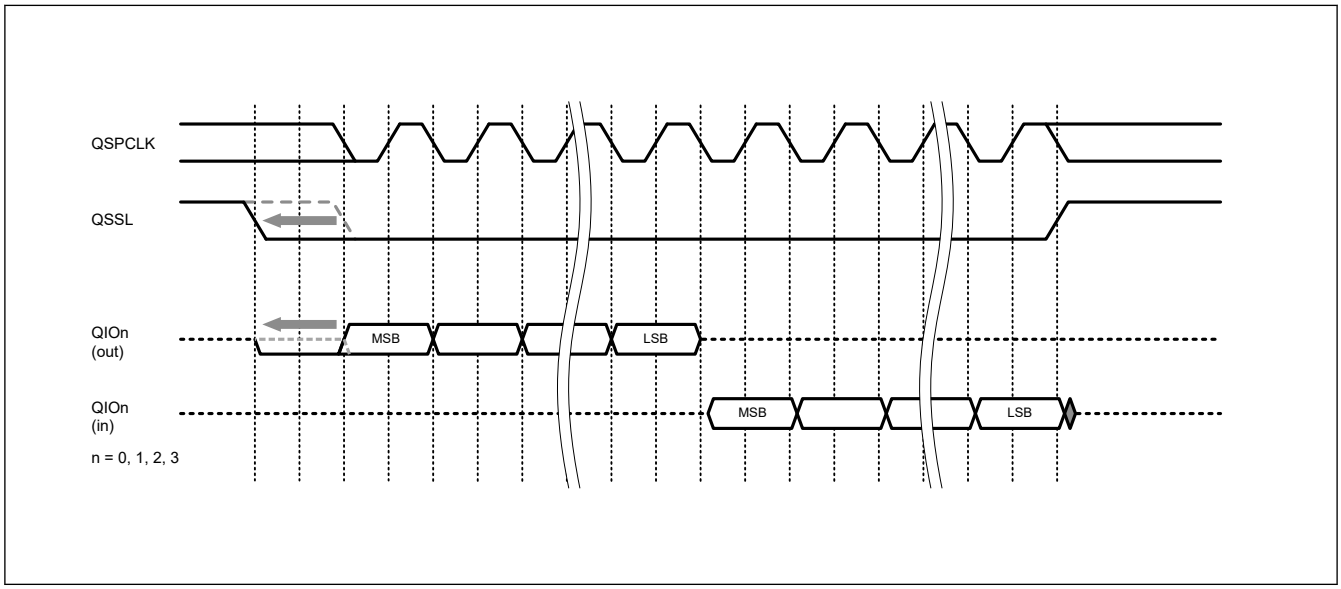

**Figure 34.11 Setup time adjustment for the QSSL signal using the SFMSLD bit**

### 34.5.5 QSSL Signal Hold Time

The QSSL signal hold time that the serial flash memory requires until the QSSL signal is driven high after the last rising edge of the QSPCLK signal can be configured. The hold time can be selected as 0.5 or 1.5 cycles of QSPCLK in the SFMSHD bit of the SFMSSC register.

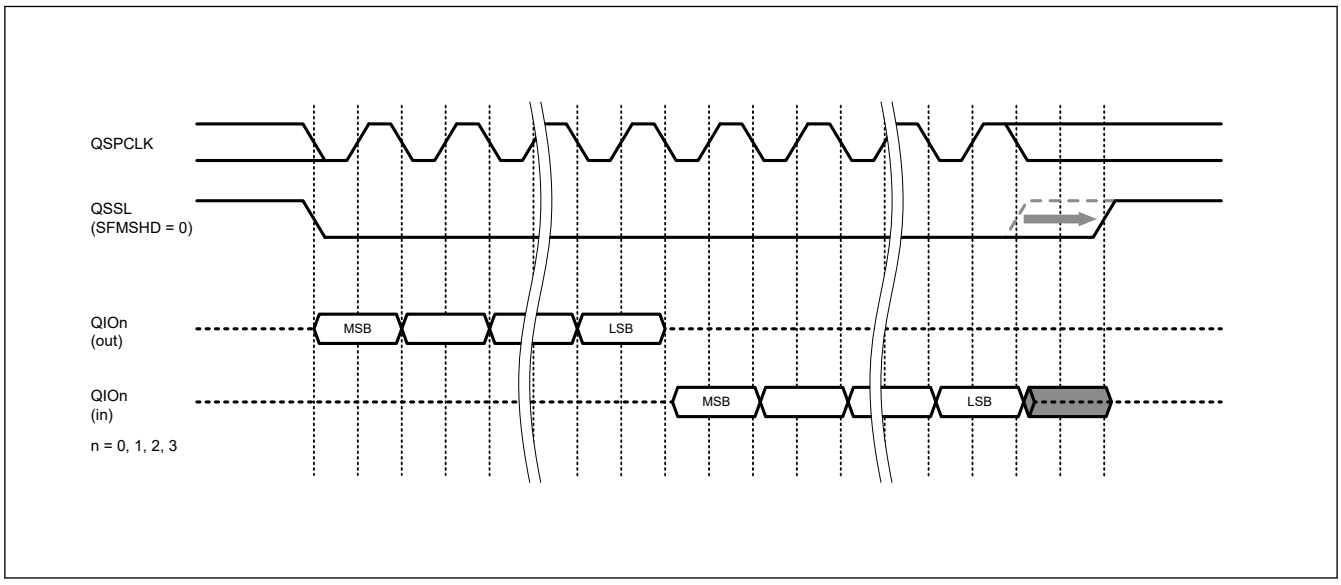

**Figure 34.12 Hold time adjustment for the QSSL signal using the SFMSHD bit**

### 34.5.6 Hold Time of the Serial Data Output Enable

The buffer output enable of the QIO0, QIO1, QIO2, or QIO3 pin can be extended by 1 QSPCLK using the SFMOEX bit in the SFMSMD register.

For a standard read instruction, it is extended immediately after an address code. For other read instructions, it is extended after two cycles of mode data (XIP mode control) of the serial flash memory in dummy cycles.

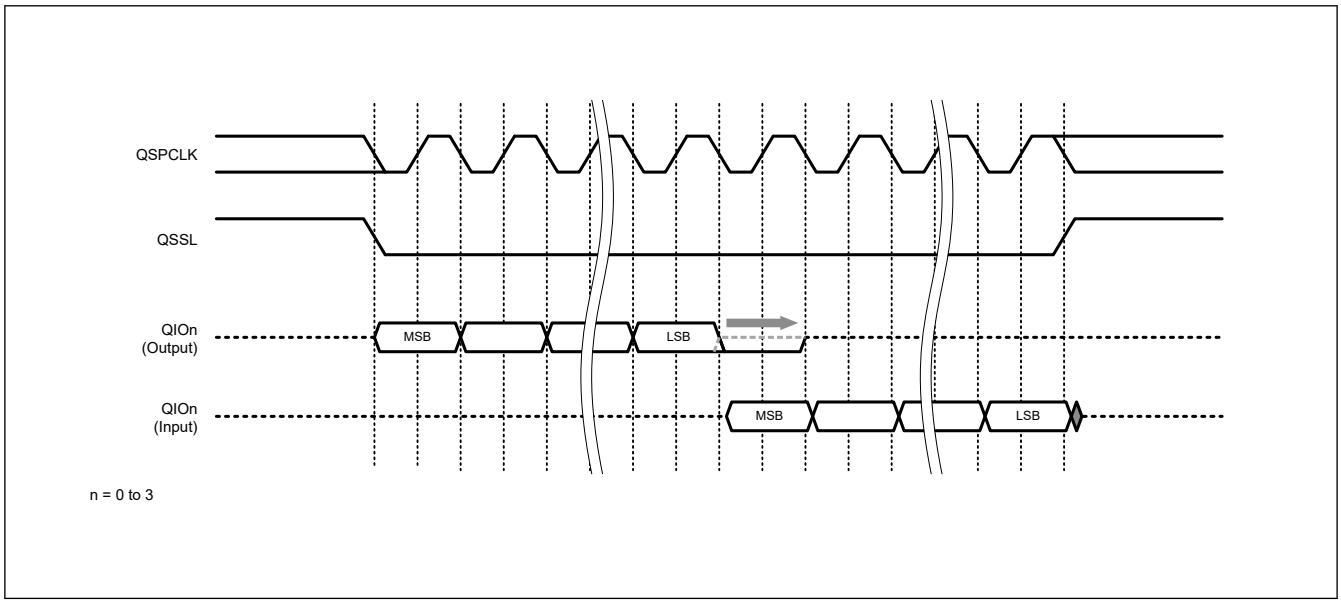

**Figure 34.13 Hold time adjustment for output enable using the SFMOEX bit (Standard Read)**

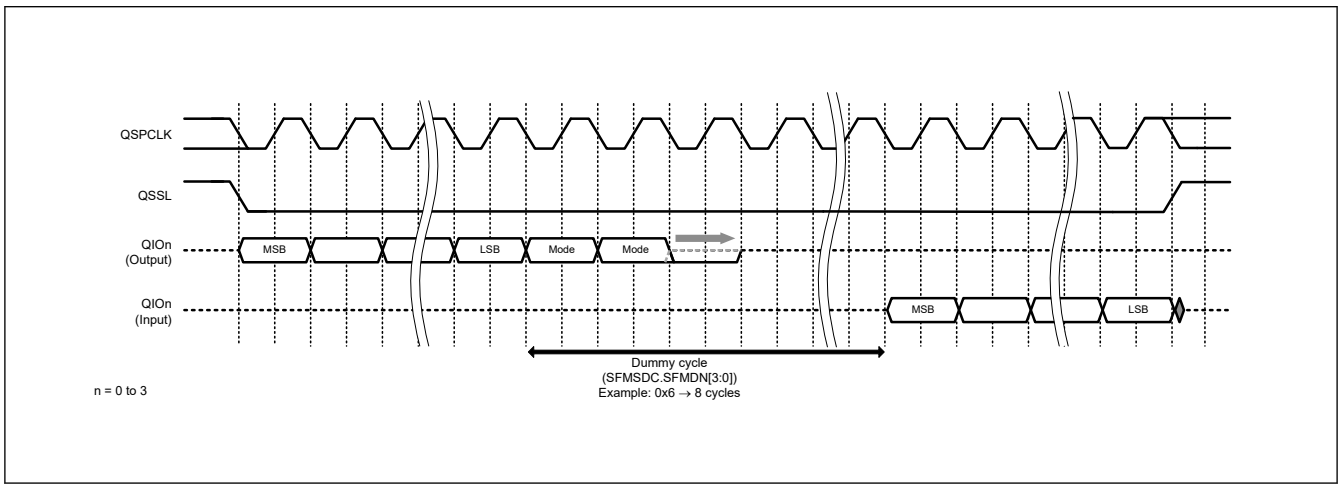

**Figure 34.14 Hold Time Adjustment of Output Enabling Using the SFMOEX Bit (Fast Read)**

### 34.5.7 Setup Time for Serial Data Output

When a command or address is transmitted to the serial flash memory, the setup time begins on serial data output and ends when the QSPCLK signal rises. If this setup time is insufficient, it can be extended by 1 PCLKA using the SFMOSW bit in the SFMSMD register. When SFMOSW is 1, the low-level width of QSPCLK during serial data transmission is extended by 1 PCLKA while data is being output from the QSPI. This function has no effect on serial data reception.

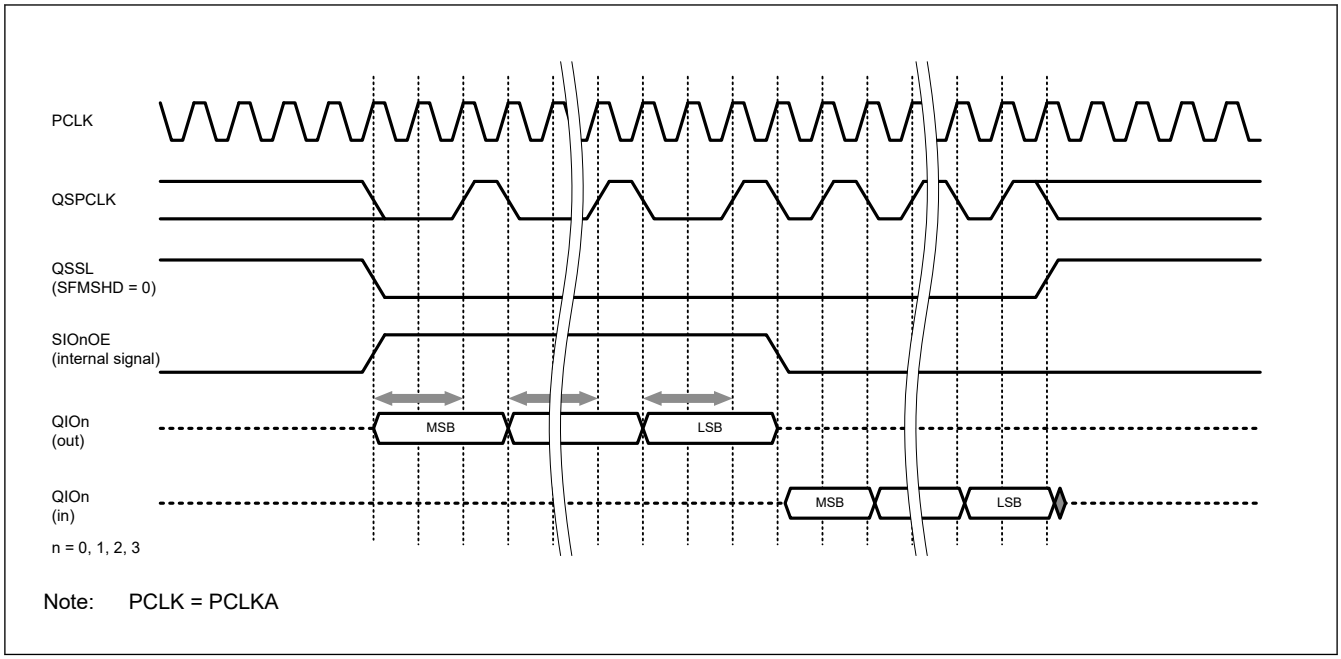

**Figure 34.15 Setup time adjustment for serial data output using the SFMOSW bit**

## 34.5.8 Hold Time for Serial Data Output

When a command or address is transmitted to the serial flash memory, the hold time begins on the rising edge of QSPCLK and ends when the serial data makes another transmission. If this hold time is insufficient, it can be extended by 1 PCLKA using the SFMOHW bit in the SFMSMD register. When SFMOHW is 1, the high-level width of QSPCLK during serial data transmission is extended by 1 PCLKA while data is being output from the QSPI. This function has no effect on serial data reception.

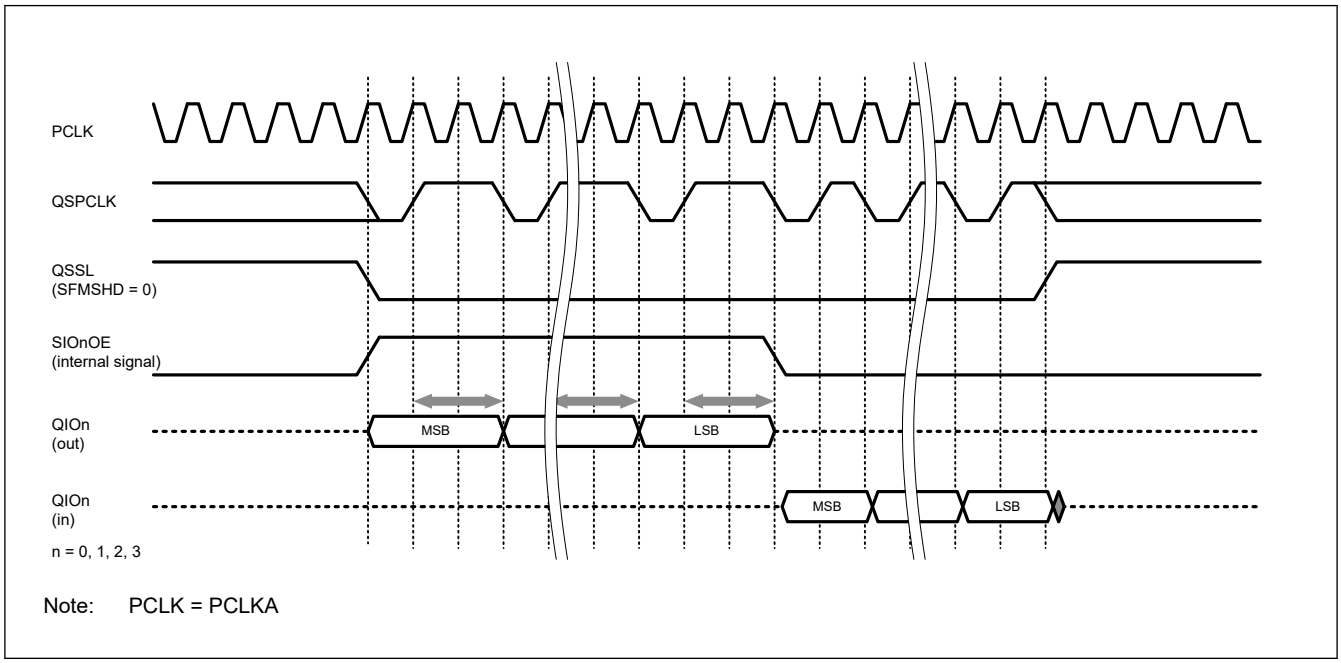

**Figure 34.16 Hold time adjustment for serial data output using the SFMOHW bit**

## 34.5.9 Serial Data Receiving Latency

The serial flash outputs data in synchronization with the falling edge of the QSPCLK signal. The QSPI receives that data in synchronization with the falling edge of the subsequent QSPCLK signal. The delay from when the serial flash starts outputting data until the QSPI receives that data is called the receiving latency. The QSPI adds a latency adjustment cycle

immediately before the first data reception cycle in the SPI bus cycle. From the serial flash side, this is seen as an increase in the number of data reception cycles. This added latency adjustment cycle is not generated in the SPI bus cycle without accompanying data reception.

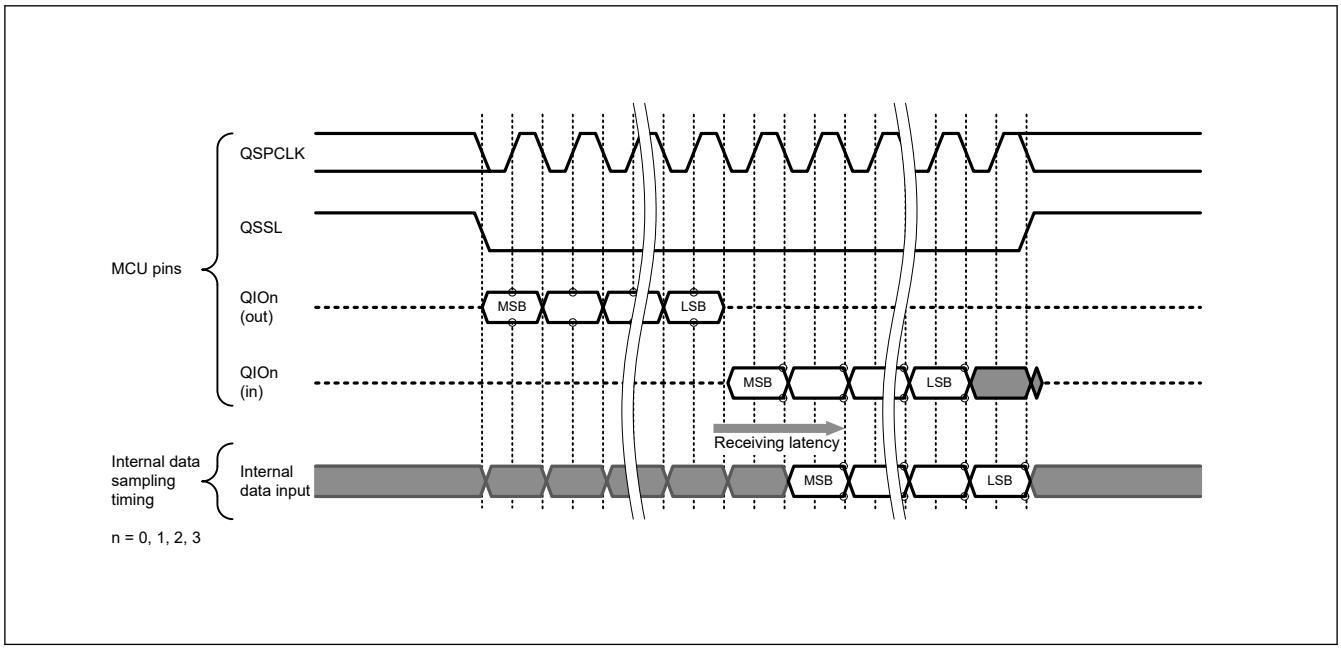

**Figure 34.17 Receiving latency**

## 34.6 SPI Instruction Set Used for Serial Flash Memory Access

### 34.6.1 SPI Instructions That Are Automatically Generated

When the serial flash memory is accessed, an SPI bus cycle using the instructions described in Table 34.6 to Table 34.10 is automatically generated based on the settings in the SFMSAC register and in the SFMSMD register.

**Table 34.6 SPI instructions automatically generated when SFMAS[1:0] = 00b**

| SPI instruction | Instruction code | Address bytes | Dummy cycles | Data bytes | Remarks |
|---|---|---|---|---|---|
| Standard Read | 0x03*1 | 1 | — | 1 to ∞ | SFMRM[2:0] = 000b, A8 = 0 |
| | 0x0B*1 | 1 | — | 1 to ∞ | SFMRM[2:0] = 000b, A8 = 1 |

Note 1. If the SFMSMD.SFMCCE bit is set to 1, the SFMCIC[7:0] bits in the Instruction Code Register (SFMSIC) setting is used as an instruction code.

**Table 34.7 SPI instructions automatically generated when SFMAS[1:0] = 01b**

| SPI instruction | Instruction code | Address bytes | Dummy cycles | Data bytes | Remarks |
|---|---|---|---|---|---|
| Standard Read | 0x03*1 | 2 | — | 1 to ∞ | SFMRM[2:0] = 000b |

Note 1. If the SFMSMD.SFMCCE bit is set to 1, the SFMSIC.SFMCIC[7:0] setting is used as an instruction code.

**Table 34.8 SPI instructions automatically generated when SFMAS[1:0] = 10b (1 of 2)**

| SPI instruction | Instruction code | Address bytes | Dummy cycles | Data bytes | Remarks |
|---|---|---|---|---|---|
| Standard Read | 0x03*1 | 3 | — | 1 to ∞ | SFMRM[2:0] = 000b |
| Fast Read | 0x0B*1 | 3 | 8*2 | 1 to ∞ | Selectable: SFMRM[2:0] = 001b |
| Fast Read Dual Output | 0x3B*1 | 3 | 8*2 | 1 to ∞ | Selectable: SFMRM[2:0] = 010b |
| Fast Read Dual I/O | 0xBB*1 | 3 | 4*2 | 1 to ∞ | Selectable: SFMRM[2:0] = 011b |

**Table 34.8 SPI instructions automatically generated when SFMAS[1:0] = 10b (2 of 2)**

| SPI instruction | Instruction code | Address bytes | Dummy cycles | Data bytes | Remarks |
|---|---|---|---|---|---|
| Fast Read Quad Output | 0x6B*1 | 3 | 8*2 | 1 to ∞ | Selectable: SFMRM[2:0] = 100b |
| Fast Read Quad I/O | 0xEB*1 | 3 | 6*2 | 1 to ∞ | Selectable: SFMRM[2:0] = 101b |

Note 1. If the SFMSMD.SFMCCE bit is set to 1, the SFMSIC.SFMCIC[7:0] setting is used as an instruction code.
Note 2. The number of dummy cycles is configurable by using SFMDN[3:0] bits in the Dummy Cycle Control Register (SFMSDC).

**Table 34.9 SPI instructions automatically generated when SFMAS[1:0] = 11b and SFM4BC = 0**

| SPI instruction | Instruction code | Address bytes | Dummy cycles | Data bytes | Remarks |
|---|---|---|---|---|---|
| Standard Read | 0x03*1 | 4 | — | 1 to ∞ | SFMRM[2:0] = 000b |
| Fast Read | 0x0B*1 | 4 | 8*2 | 1 to ∞ | Selectable: SFMRM[2:0] = 001b |
| Fast Read Dual Output | 0x3B*1 | 4 | 8*2 | 1 to ∞ | Selectable: SFMRM[2:0] = 010b |
| Fast Read Dual I/O | 0xBB*1 | 4 | 4*2 | 1 to ∞ | Selectable: SFMRM[2:0] = 011b |
| Fast Read Quad Output | 0x6B*1 | 4 | 8*2 | 1 to ∞ | Selectable: SFMRM[2:0] = 100b |
| Fast Read Quad I/O | 0xEB*1 | 4 | 6*2 | 1 to ∞ | Selectable: SFMRM[2:0] = 101b |

Note 1. If the SFMSMD.SFMCCE bit is set to 1, the SFMSIC.SFMCIC[7:0] setting is used as an instruction code.
Note 2. The number of dummy cycles is configurable by using the SFMSDC.SFMDN[3:0] bits.

**Table 34.10 SPI instructions automatically generated when SFMAS[1:0] = 11b and SFM4BC = 1**

| SPI instruction | Instruction code | Address bytes | Dummy cycles | Data bytes | Remarks |
|---|---|---|---|---|---|
| Standard Read | 0x13*1 | 4 | — | 1 to ∞ | SFMRM[2:0] = 000b |
| Fast Read | 0x0C*1 | 4 | 8*2 | 1 to ∞ | Selectable: SFMRM[2:0] = 001b |
| Fast Read Dual Output | 0x3C*1 | 4 | 8*2 | 1 to ∞ | Selectable: SFMRM[2:0] = 010b |
| Fast Read Dual I/O | 0xBC*1 | 4 | 4*2 | 1 to ∞ | Selectable: SFMRM[2:0] = 011b |
| Fast Read Quad Output | 0x6C*1 | 4 | 8*2 | 1 to ∞ | Selectable: SFMRM[2:0] = 100b |
| Fast Read Quad I/O | 0xEC*1 | 4 | 6*2 | 1 to ∞ | Selectable: SFMRM[2:0] = 101b |

Note 1. If the SFMSMD.SFMCCE bit is set to 1, the SFMSIC.SFMCIC[7:0] setting is used as an instruction code.
Note 2. The number of dummy cycles is configurable by using the SFMSDC.SFMDN[3:0] bits..

### 34.6.2 Standard Read Instruction

The standard Read instruction is a common read instruction supported by most serial flash memory. When an SPI bus cycle starts, the QSSL signal (serial flash memory select) is asserted, and the instruction code (0x03 or 0x13)*1 is output. Next, an address with a width of 1 to 4 bytes, specified in the SFMAS[1:0] bits in the SFMSAC register, is transmitted. Data is then received.

This standard Read instruction is selected in the initial QSPI settings.

Note 1. Many 4-KB serial flash memory devices have an address field not larger than 1 byte (A7-A0) to minimize the overhead and to receive A8 information from bit 3 of the Read instruction code. To support these devices, the QSPI only outputs A8 (address bit 8) to bit [3] of the standard Read instruction code when an address width of 1 byte is specified (SFMAS[1:0] = 00). This means that 0x0B might be output instead of 0x03 as the standard Read instruction code. This code duplicates the Fast Read instruction code. However, for most of the 2-KB or smaller serial flash memory, with an address width of 1 byte, bit 3 of a command is designed to be excluded from decoding as a don't-care bit, so such a Read instruction code is recognized correctly as the standard Read instruction code. In rare cases, some serial flash memory allow bit 3 to be decoded. When such a serial flash memory is connected, configure your application to avoid access resulting in A8 = 1.

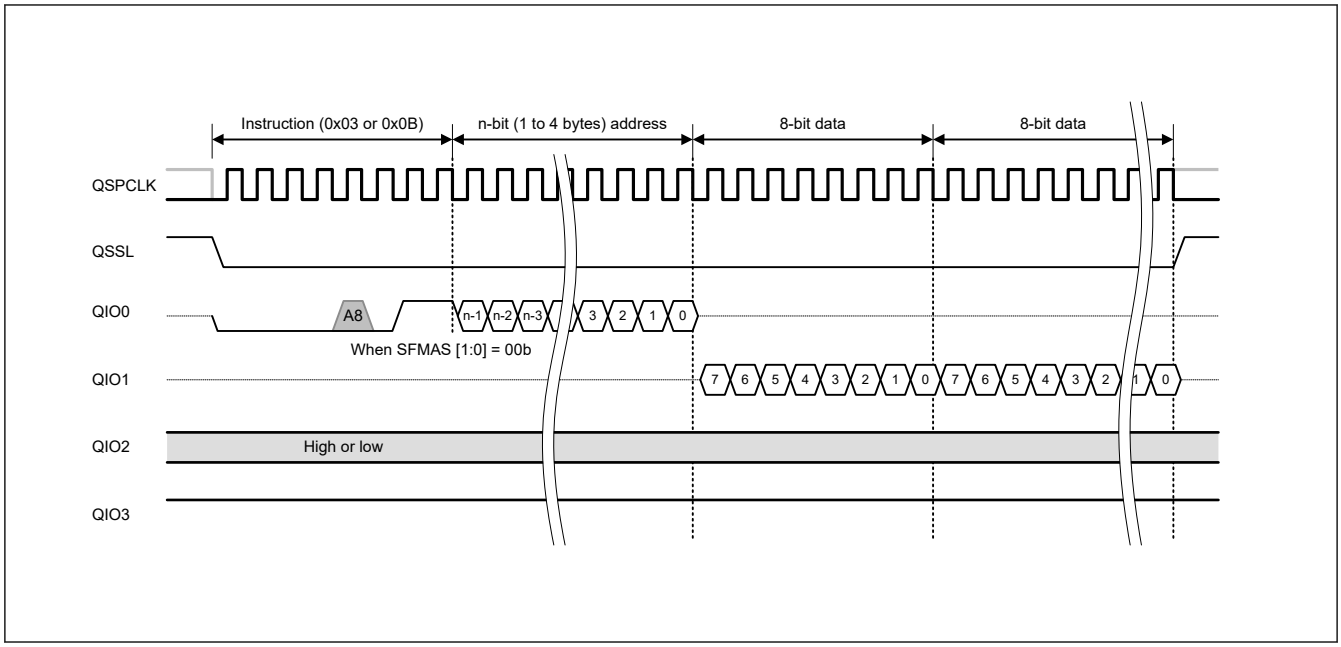

**Figure 34.18 Standard Read bus cycle**

## 34.6.3 Fast Read Instruction

The Fast Read instruction is a read instruction that supports a higher communication clock speed than the standard Read instruction. When an SPI bus cycle starts, the QSSL signal is asserted, and the instruction code (0x0B or 0x0C) is output. Next, an address with a width of 1 to 4 bytes specified by the SFMSAC.SFMAS [1: 0] bits is transmitted, a dummy cycle specified by the SFMSDC register is generated, then the data is received.

The first two dummy cycles are used to select the XIP mode. When the XIP mode is selected, the same instruction used this time is applied to the next SPI bus cycle, and the instruction code is not output the next SPI bus cycle. For details on the XIP mode, see section 34.8. XIP Control.

Switching to the Fast Read instruction is controlled in the SFMSMD register.

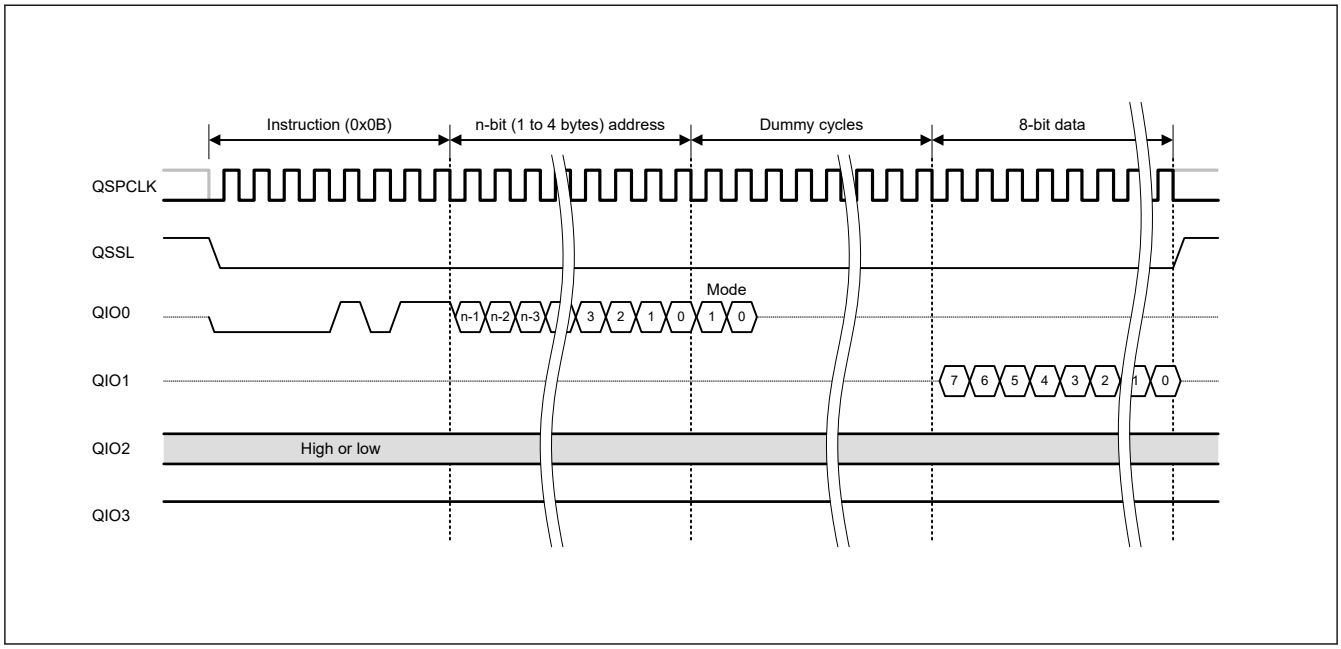

**Figure 34.19 Fast Read bus cycle**

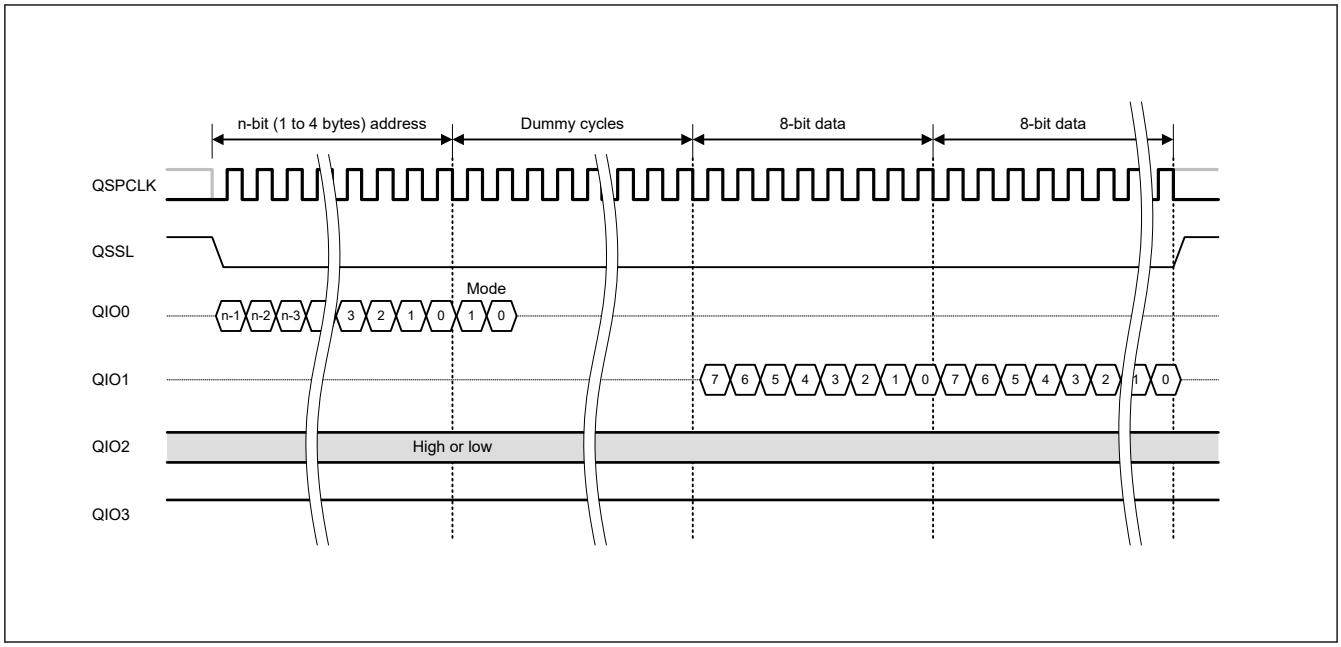

**Figure 34.20 Fast Read bus cycle in XIP mode**

Note: To use the Fast Read instruction, a serial flash memory that supports Fast Read transfers is required.

### 34.6.4 Fast Read Dual Output Instruction

The Fast Read Dual Output instruction is a read instruction that uses two signal lines to receive data. When the SPI bus cycle starts, the QSSL signal is asserted. The instruction code (0x3B or 0x3C) and an address with a width of 1 to 4 bytes, specified by the SFMSAC.SFMAS [1: 0] bits are transmitted from the QIO0 pin in the extended SPI protocol, and transmitted from the QIO0 and QIO1 pins in the Dual-SPI protocol. Next, a certain number of dummy cycles, specified in the SFMSDC register, is generated. Data is then received through the QIO0 and QIO1 pins. Even bit data is received from the QIO0 pin and odd bit data is received from the QIO1 pin.

The first two dummy cycles are used to select the XIP mode. When the XIP mode is selected, the same instruction used this time is applied to the next SPI bus cycle, and the instruction code is not output the next SPI bus cycle. For details on the XIP mode, see section 34.8. XIP Control.

Switching to Fast Read Dual Output is controlled in the SFMSMD register.

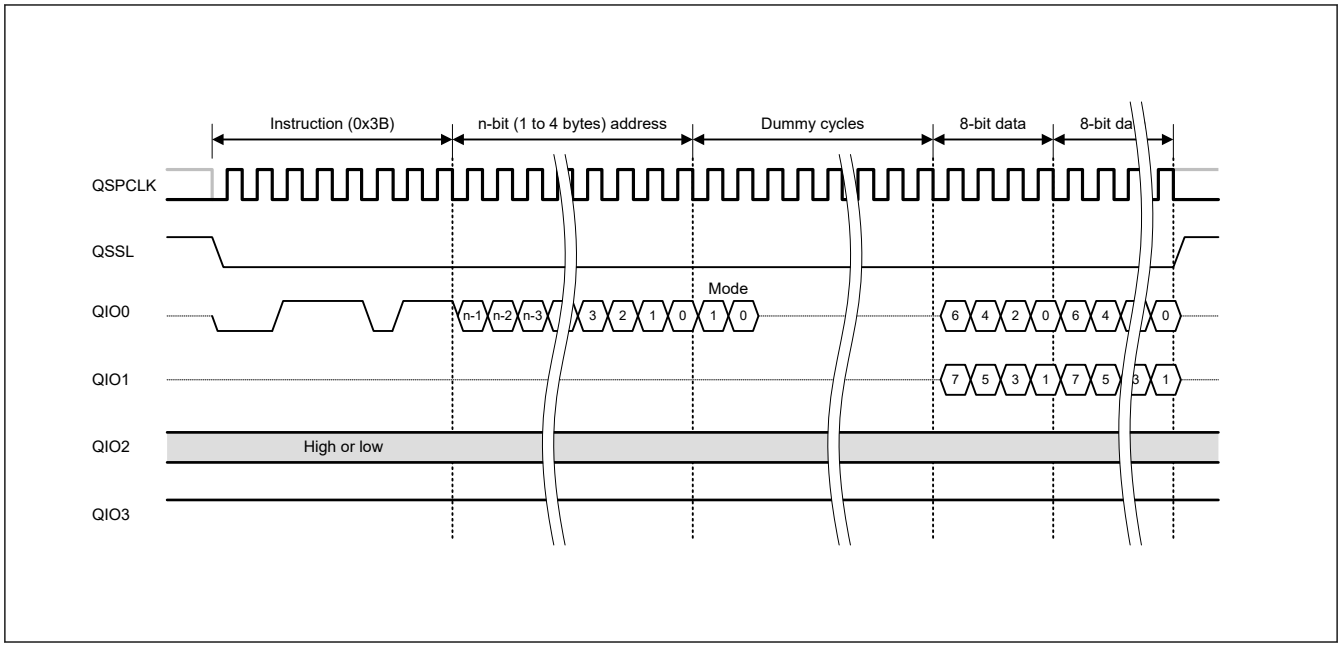

**Figure 34.21 Fast Read Dual Output bus cycle (with extended SPI protocol)**

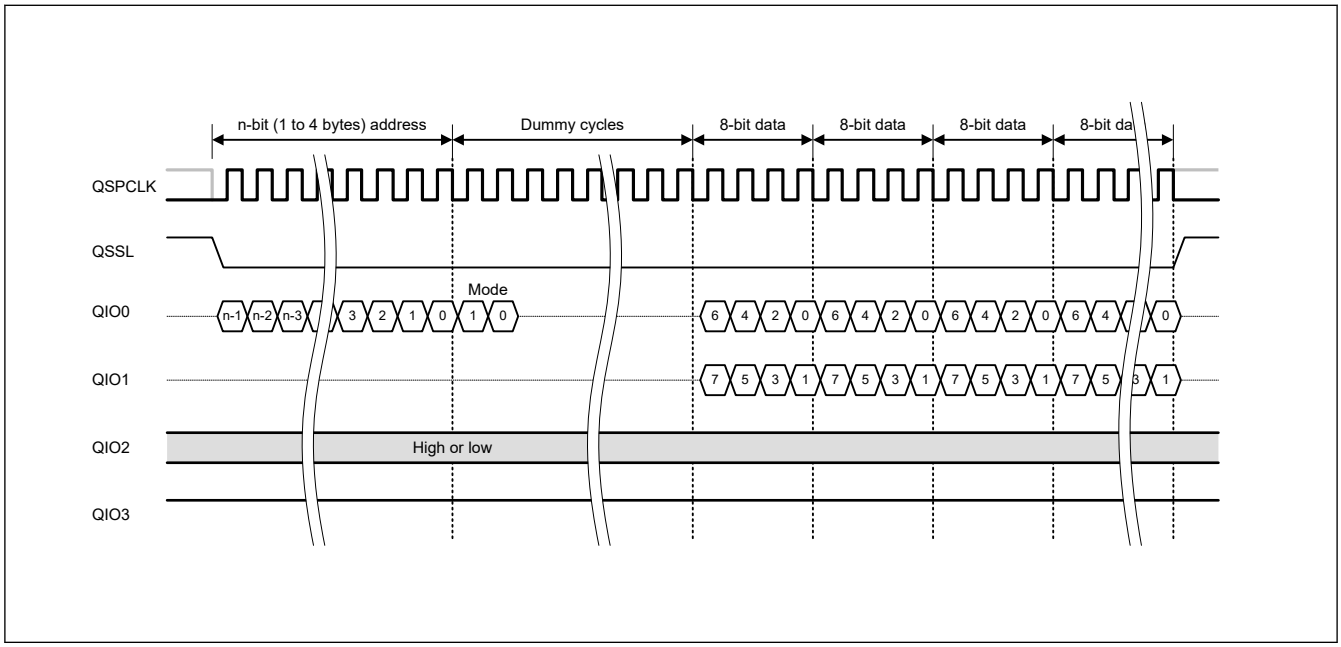

**Figure 34.22 Fast Read Dual Output bus cycle in XIP mode (with extended SPI protocol)**

Note: To use the Fast Read Dual Output instruction, a serial flash memory that supports Fast Read Dual Output transfers is required.

## 34.6.5 Fast Read Dual I/O Instruction

The Fast Read Dual I/O instruction is a read instruction that uses two signal lines to transmit an address and receive data. When the SPI bus cycle starts, the QSSL signal is asserted, and the instruction code (0xBB / 0xBC) is transmitted from QIO0 pin in the extended SPI protocol and from QIO0, and QIO1 pins in the Dual SPI protocol. Next, an address with a width of 1 to 4 bytes, specified in the SFMAS[1:0] bits in the SFMSAC register, is transmitted through the QIO0 and QIO1 pins, and a certain number of dummy cycles, specified in the SFMSDC register, is generated. Data is then is received through the QIO0 and QIO1 pins. Address and dummy cycle transmission and data reception are performed through the QIO0 pin for even bits and through the QIO1 pin for odd bits.

The first two dummy cycles are used to select the XIP mode. When the XIP mode is selected, the same instruction used this time is applied to the next SPI bus cycle, and the instruction code is not output the next SPI bus cycle. For details on the XIP mode, see section 34.8. XIP Control.

Switching to Fast Read Dual I/O is controlled in the SFMSMD register.

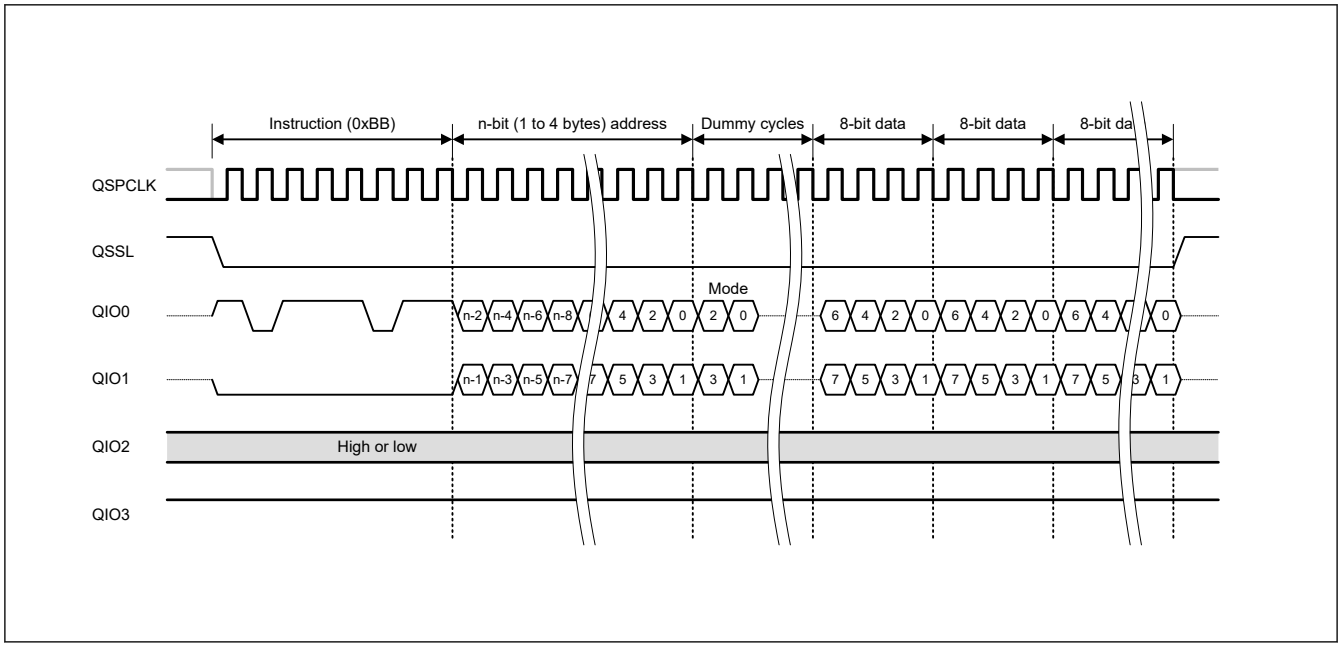

**Figure 34.23 Fast Read Dual I/O bus cycle (with extended SPI protocol)**

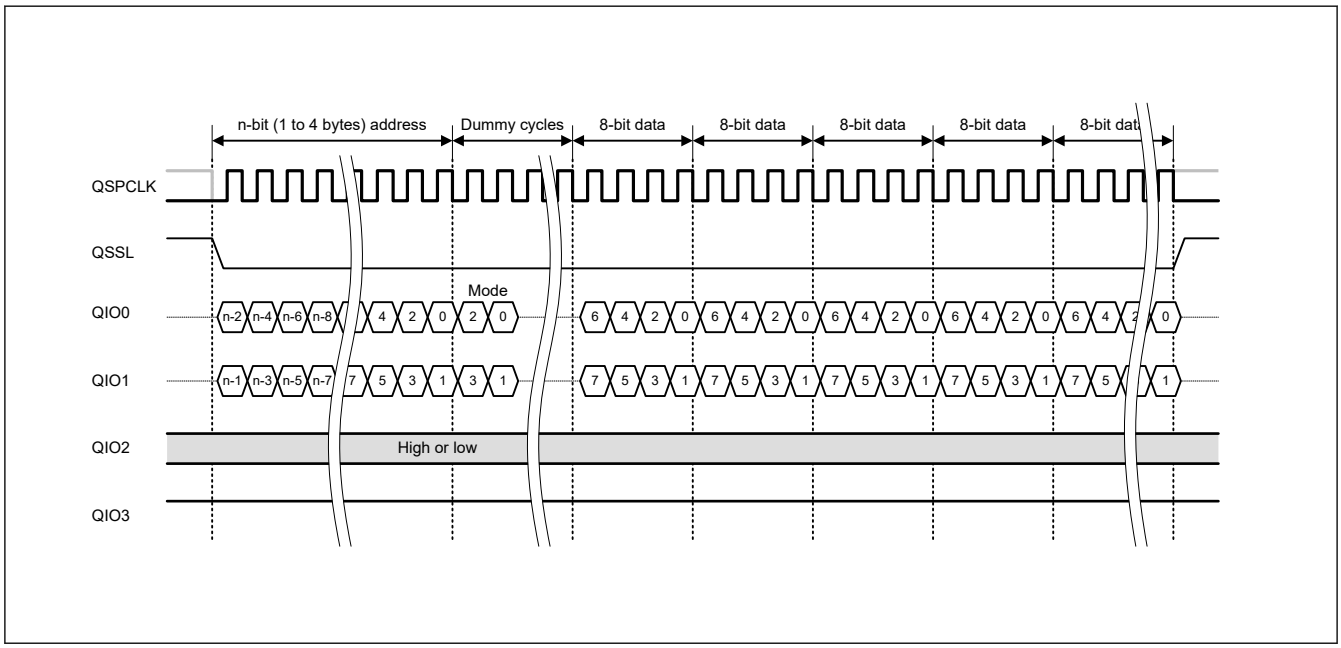

**Figure 34.24 Fast Read Dual I/O bus cycle in XIP mode**

Note: To use the Fast Read Dual I/O instruction, a serial flash memory that supports Fast Read Dual I/O transfers is required.

## 34.6.6 Fast Read Quad Output Instruction

The Fast Read Quad Output instruction is a read instruction that uses four signal lines to receive data. When the SPI bus cycle starts, the QSSL signal is asserted. The instruction code (0x6B or 0x6C) and an address with a width of 1 to 4 bytes, specified in the SFMAS[1:0] bits in the SFMSAC register, are output from the QIO0 pin. Next, a certain number of dummy

cycles, specified in the SFMDN[3:0] bits in the SFMSDC register, are generated. Data is then received through the QIO0, QIO1, QIO2, and QIO3 pins.

The first two dummy cycles are used to select the XIP mode. When the XIP mode is selected, the same instruction used this time is applied to the next SPI bus cycle, and the instruction code is not output the next SPI bus cycle. For details on the XIP mode, see section 34.8. XIP Control.

Switching to Fast Read Quad Output is controlled in the SFMSMD register.

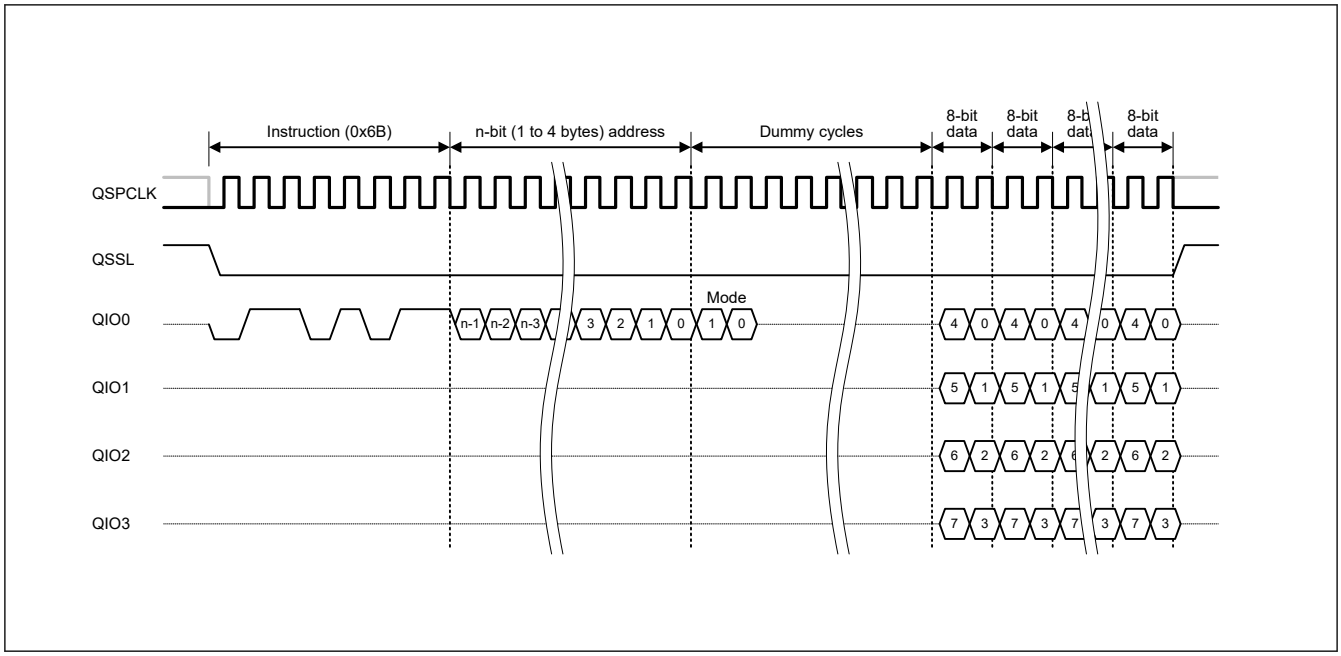

**Figure 34.25 Fast Read Quad Output bus cycle (with extended SPI protocol)**

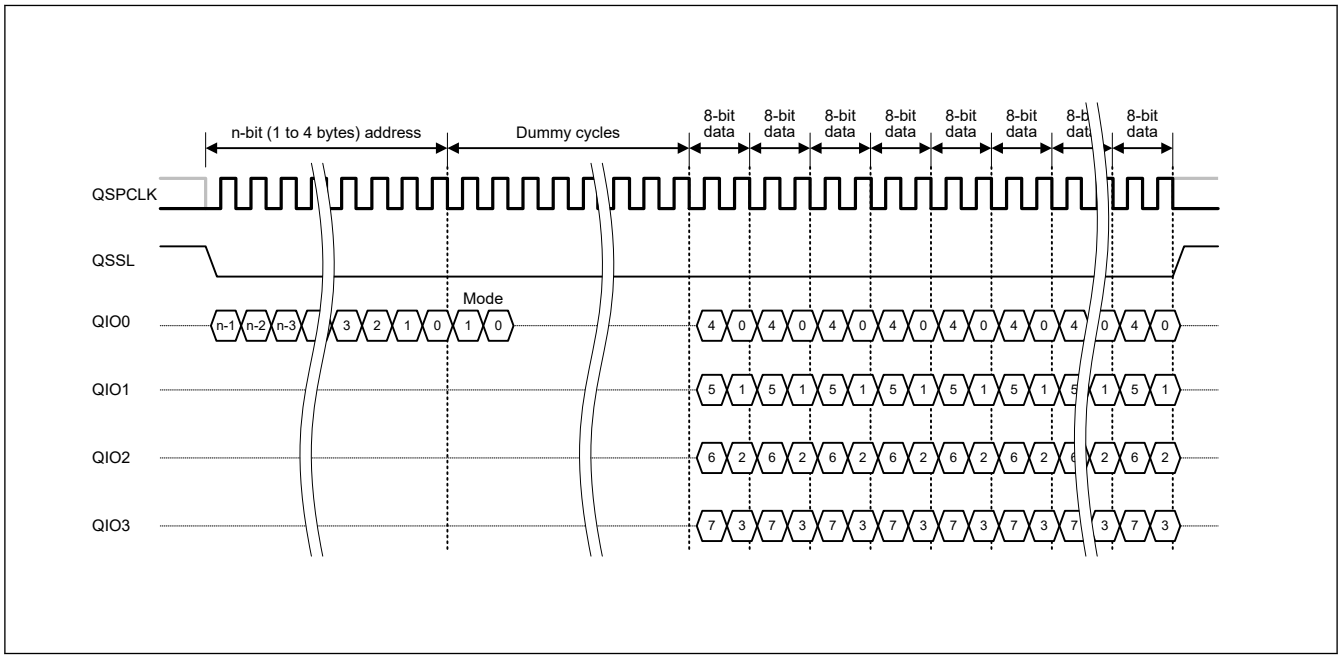

**Figure 34.26 Fast Read Quad Output bus cycle in XIP mode (with extended SPI protocol)**

Note: To use Fast Read Quad Output, a serial flash memory that supports Fast Read Quad Output transfer is required.

## 34.6.7 Fast Read Quad I/O Instruction

The Fast Read Quad I/O instruction is a read instruction that uses four signal lines to transmit an address and receive data. When the SPI bus cycle starts, the QSSL signal is asserted, and the instruction code (0xEB / 0xEC) is transmitted from

QIO0 pin in the extended SPI protocol and from QIO0, QIO1, QIO2, and QIO3 pins in the Quad-SPI protocol. Next, an address with a width of 1 to 4 bytes, specified in the SFMAS[1:0] bits in the SFMSAC register, is transmitted through the QIO0, QIO1, QIO2, and QIO3 pins, and a certain number of dummy cycles, specified in the SFMDN[3:0] bits in the SFMSDC register, is generated. Data is then received through the QIO0, QIO1, QIO2, and QIO3 pins.

The first two dummy cycles are used to select the XIP mode. When the XIP mode is selected, the same instruction used this time is applied to the next SPI bus cycle, and the instruction code is not output the next SPI bus cycle. For details on the XIP mode, see section 34.8. XIP Control.

Switching to Fast Read Quad I/O is controlled in the SFMSMD register.

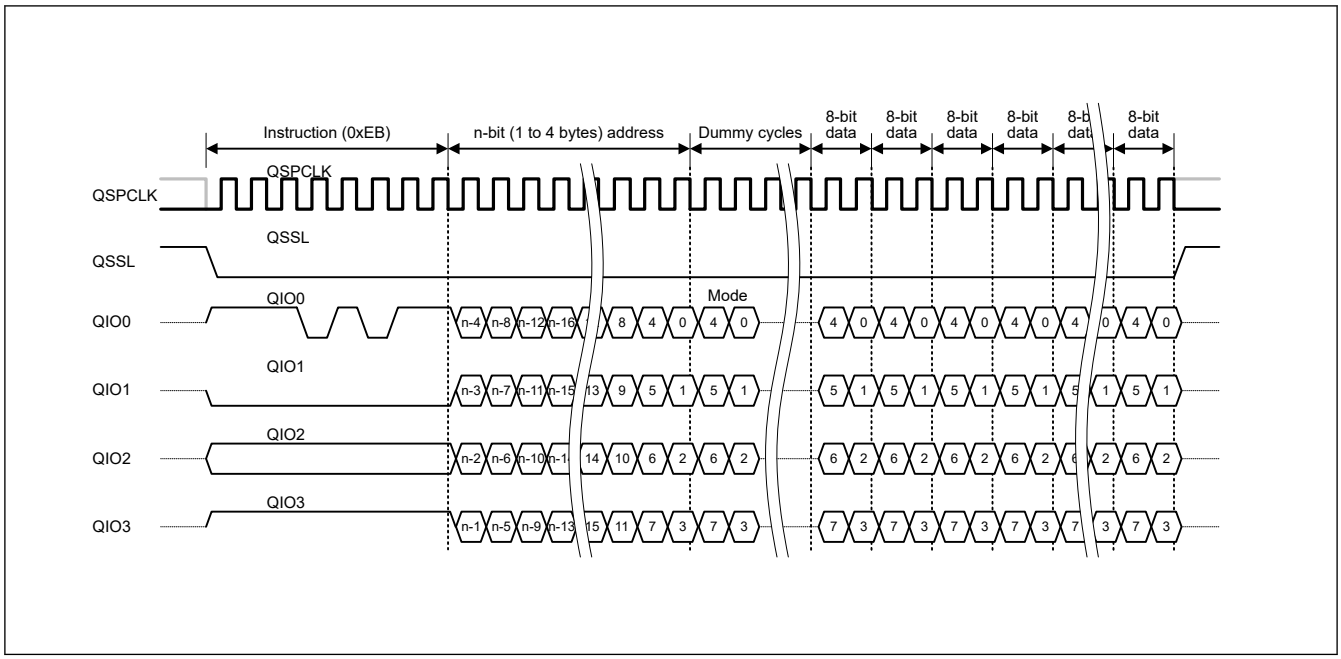

**Figure 34.27 Fast Read Quad I/O bus cycle**

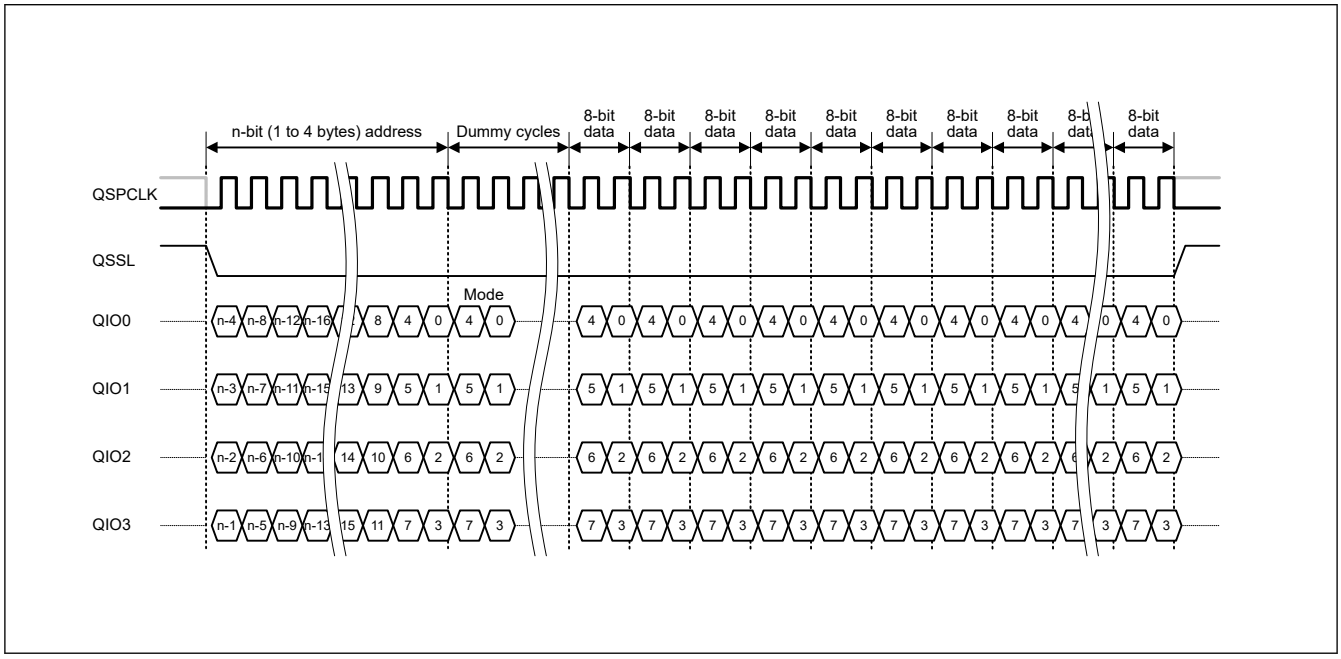

**Figure 34.28 Fast Read Quad I/O bus cycle in XIP mode**

Note: To use the Fast Read Quad I/O instruction, a serial flash memory that supports Fast Read Quad I/O transfers is required.

### 34.6.8 Enter 4-Byte Mode Instruction

The Enter 4-Byte Mode instruction sets the serial flash address width to 4 bytes. When the SPI bus cycle starts, the serial flash select signal is asserted, and the instruction code (0xB7) is output.

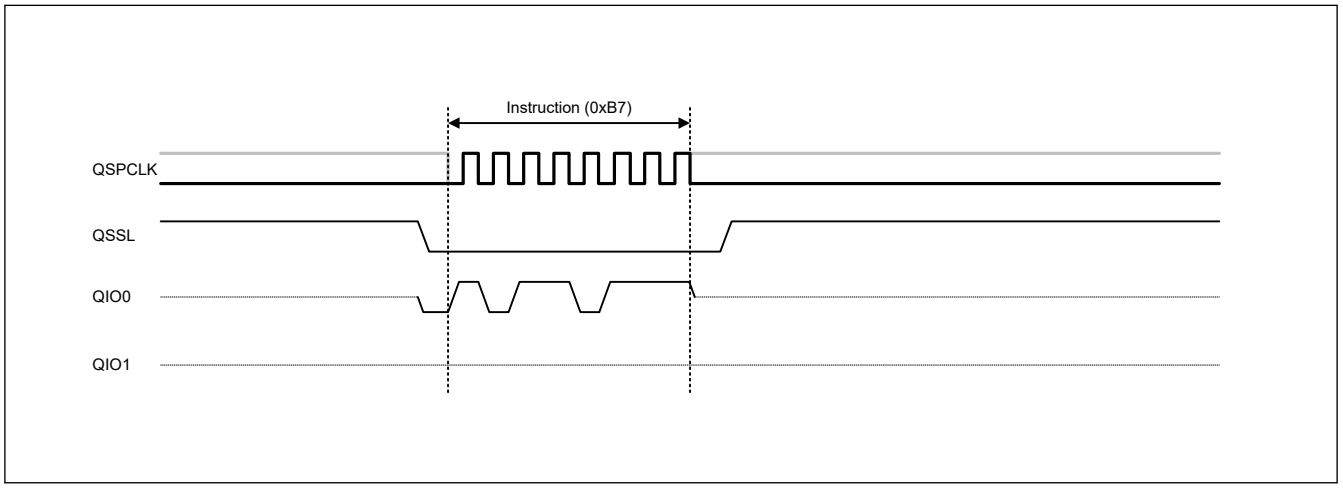

**Figure 34.29 Enter 4-Byte Mode bus cycle**

Note: The Enter 4-Byte Mode instruction is issued regardless of whether the serial flash is in 3- or 4-byte mode.

### 34.6.9 Exit 4-Byte Mode Instruction

The Exit 4-Byte Mode instruction sets the serial flash address width to 3 bytes. When the SPI bus cycle starts, the serial flash select signal is asserted, and the instruction code (0xE9) is output.

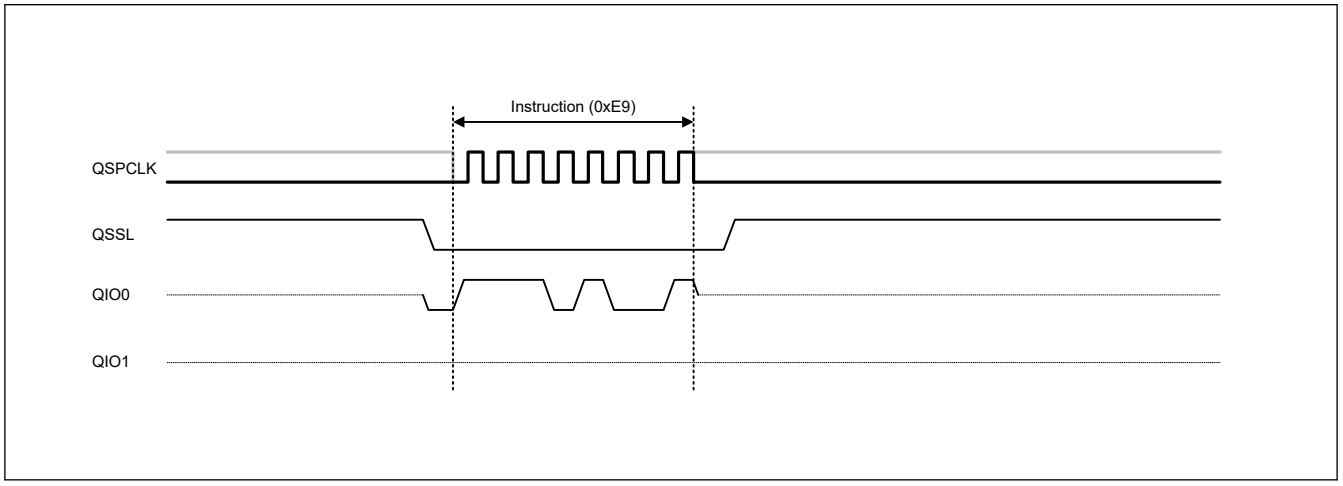

**Figure 34.30 Exit 4-Byte Mode bus cycle**

Note: The Exit 4-Byte Mode instruction is issued regardless of whether the serial flash is in 3- or 4-byte mode.

### 34.6.10 Write Enable Instruction

The Write Enable instruction enables changing of the serial flash address width. When the SPI bus cycle starts, the serial flash select signal is asserted, and the instruction code (0x06) is output.

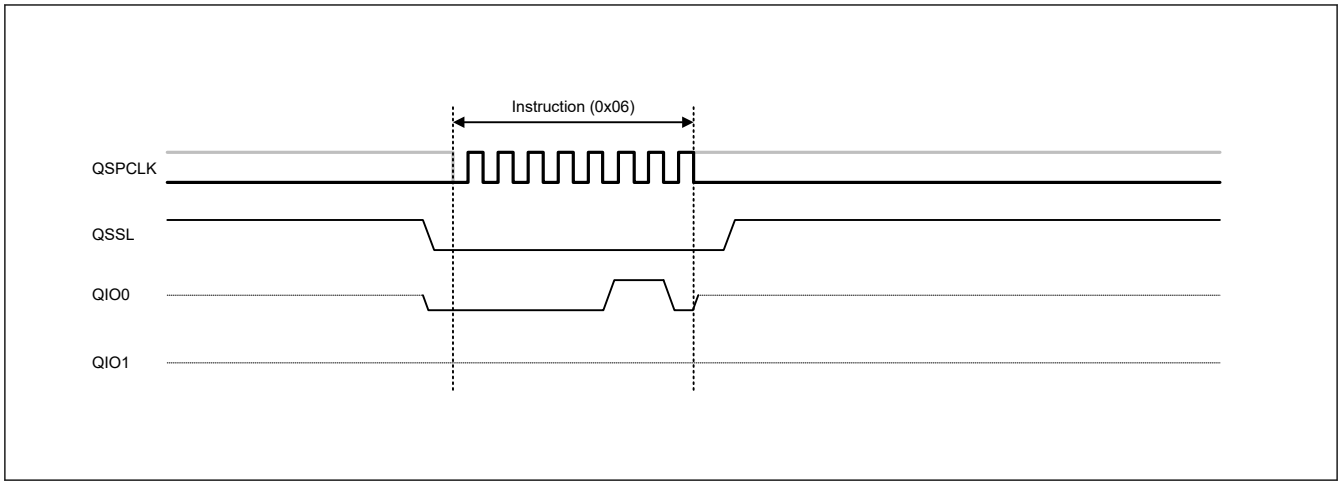

**Figure 34.31 Write Enable bus cycle**

## 34.7 SPI Bus Cycle Arrangement

### 34.7.1 Serial Flash Memory Read Based on Individual Conversion

ROM read bus cycles are individually converted to SPI bus cycles on a one-to-one basis. When a ROM read bus cycle is detected, the QSSL signal is asserted, and an SPI bus cycle starts. When the data receiving is finished from the serial flash memory, the QSSL signal is negated and the SPI bus cycle is complete.

When the next ROM read bus cycle is detected, the QSSL signal set by the SFMSSC.SFMSW[3: 0] bits is asserted again, then the next SPI bus cycle starts.

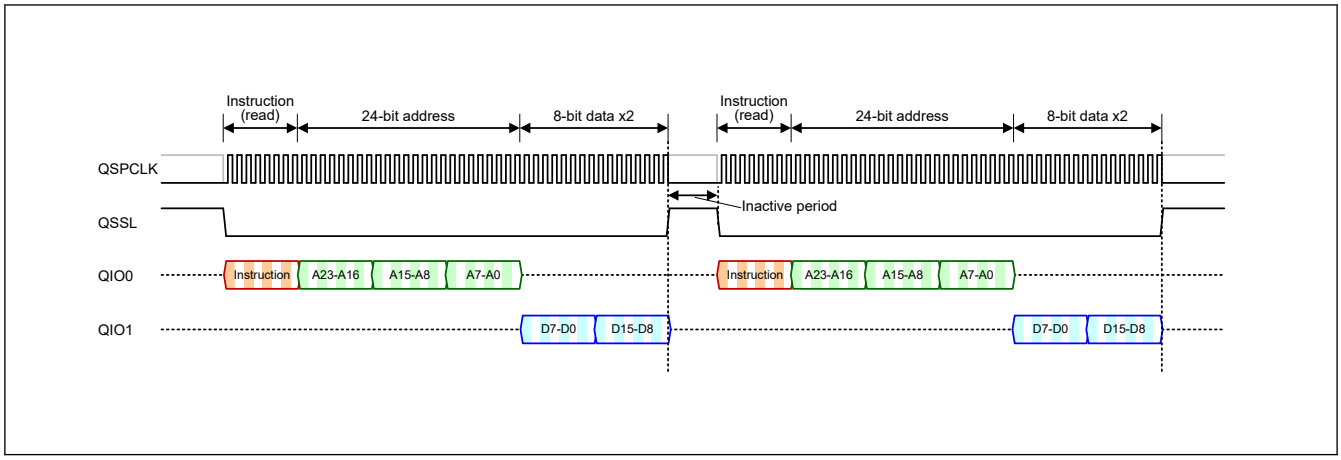

**Figure 34.32 Successive data read operations based on individual conversion**

### 34.7.2 Serial Flash Memory Read Using the Prefetch Function

In operations such as CPU instruction execution and block data transfer, data is often read in ascending order from contiguous addresses. Serial flash memory provides the ability to repeat data reception without reissuing an instruction code and address. To work with this function, the QSPI has a prefetch function for continuous data reception. However, if the CPU issues a flash read request for discontinuous flash addresses, SPI bus cycles are separated from each other, disabling the prefetch function.

To enable the prefetch function of the QSPI, set the SFMPFE bit in the SFMSMD register to 1. When the prefetch function is enabled, data is received continuously and stored in the prefetch buffer of the QSPI, without waiting for another flash read request. When the CPU issues a flash read request, an address check is made. If an address match is confirmed, the data in the buffer is passed to the CPU. If an address mismatch is detected, the data in the buffer is discarded and a new SPI bus cycle is issued.

The buffer for prefetching is 18 bytes long. When this buffer is full, the SPI bus cycle is ended. When the buffer data is read to create free space, a new SPI bus cycle is automatically started to resume prefetching.

The prefetch function allows for efficient transfer operations when data is read in ascending order from contiguous addresses, as in instruction fetch and block data transfer.

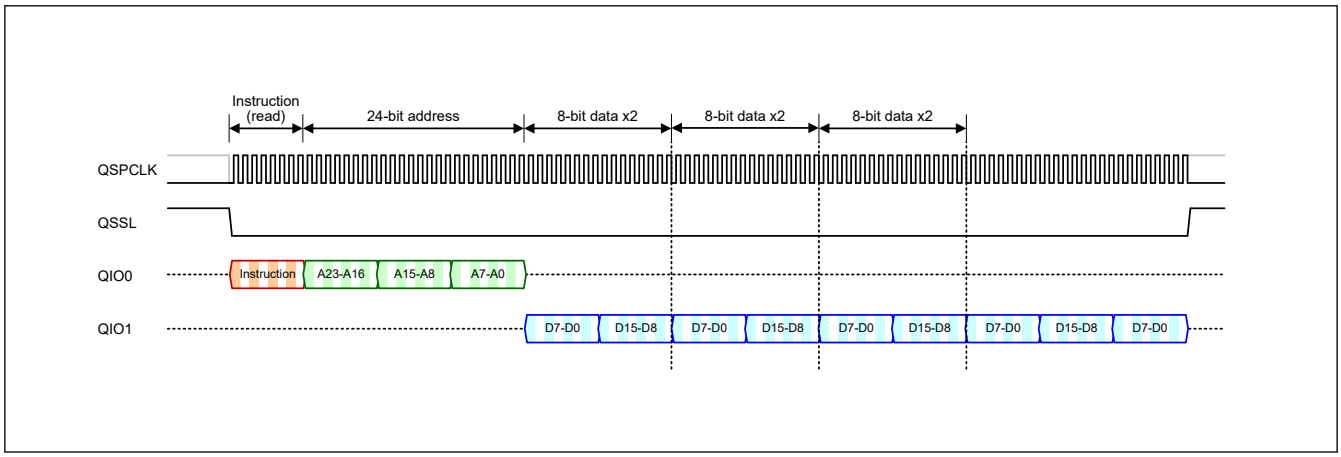

**Figure 34.33 Successive data read operations using the prefetch function**

## 34.7.3 Halt of Prefetching

If a serial flash memory read request for discontinuous addresses is issued when continuous data is being received by the prefetch function, the transfer of continuous data being made is halted and a new SPI bus cycle is started. Usually, such a halt of serial transfer occurs on data reception byte boundaries. However, if the SFMPAE bit in the SFMSMD register is set to 1, the halt can occur on locations other than byte boundaries.

## 34.7.4 Direct Specification of Prefetch Destination

When the prefetch function is enabled (SFMSMD.SFMPFE = 1), when writing to the QSPI window area occurs, after the writing is completed, prefetching starts from the write start address. Writes to serial flash memory cannot be performed.

Combining this function with described in section 34.7.5. Prefetch State Polling, can reduce the load on the internal bus when data is read from a low-speed serial flash memory.

Note: Writing to the QSPI window area with a data size of 2 bytes or more causes a hardfault.

## 34.7.5 Prefetch State Polling

A read by CPU from a low-speed serial flash memory causes the CPU system bus to be occupied until completion of the SPI reception bus cycle. The prefetch state polling function is provided to reduce this load.

The PFOFF bit in the Status Register (SFMSST) register indicates the state of the prefetch function, and the PFCNT[4:0] bits in the SFMSST register indicate the number of data bytes already prefetched. Place the polling program in the SRAM of this device.

```
//
// copy 1K byte (32bit x 256 word) data from serial flash to internal SRAM
//
unsigned long *sptr; // pointer for the serial flash
unsigned long *dptr; // pointer for the destination
int i;

SFMSMD |= 0x0040; // set SFMPFE bit to enable prefetch
*( (volatile unsigned char *) sptr ) = 0; // make the TAG valid to start prefetch

for ( i = 0 ; i < 256 ; i++ ){
while ( ( SFMSST & 0x00FF ) < 0x04 ){}; // waiting for 4-byte data to be received
*(dptr++) = *(sptr++);
}
```

Note: When executing a polling program, place the program outside of the serial flash memory. If the polling program is executed when the program is placed on the serial flash memory, the prefetch target frequently switches to an instruction code. This eliminates the effect of polling, and an infinite loop can result because the prefetch buffer is not filled.

### 34.7.6 SPI Bus Cycle Extension Function

If the SFMSE[1:0] bits in the SFMSMD register are set to a value other than 00b, the QSPI waits for the next flash read. At this time, the QSPCLK signal stops, the QSSL signal is kept active low even after data is obtained from the serial flash memory, and the SPI bus cycle is suspended.

If the address of the next flash read is contiguous in ascending order, the toggling of the QSPCLK signal is restarted to continue reception of subsequent data. If the address of the next flash read is not contiguous in ascending order, the QSSL signal is driven high once to end the SPI bus cycle being suspended. A new SPI bus cycle is then started.

When data is read intermittently from ascending order contiguous addresses, this function enables an efficient transfer operation to be performed by reducing the overhead for instruction code and address transmission.

The SPI bus cycle extension time is selectable in the SFMSE[1:0] bits in the SFMSMD register. When the specified extension time elapses, the QSSL signal returns to the high level to automatically end the SPI bus cycle being suspended. If the SFMSE[1:0] bits are set to 11b, QSSL is extended infinitely. This increases the power consumption of the serial flash memory.

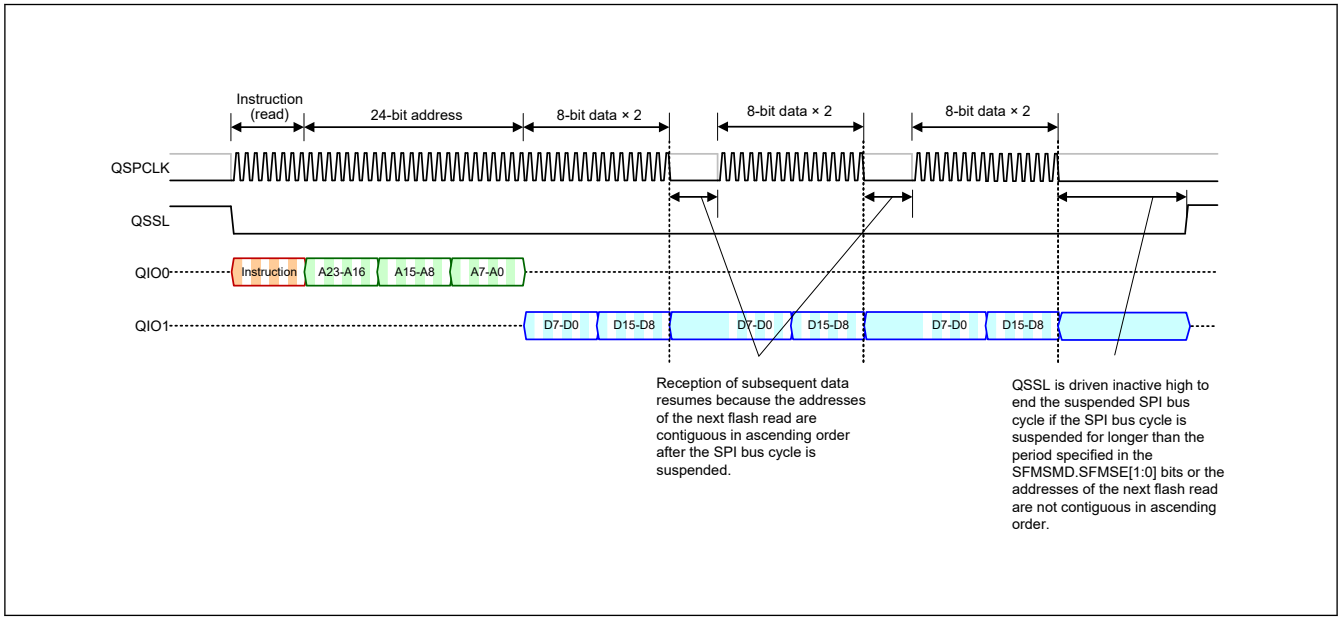

**Figure 34.34 Successive data read operations using the SPI bus cycle extension**

## 34.8 XIP Control

Some serial flash memory devices allow latencies to be reduced by skipping instruction code reception for flash reads. This instruction code skip function is selected in mode data received during the dummy cycle period of the previous serial bus cycle.

In the dummy cycle of the Fast Read instructions, the QSPI controls the XIP mode of the serial flash memory by using the serial data signal to send the mode data set in the SFMXD[7:0] bits in the SFMSDC register during the first 2 cycles, as shown in Figure 34.35.

The mode data to enable the XIP mode differs for each serial flash memory. Accordingly, set the appropriate mode data in the SFMXD[7:0] bits.

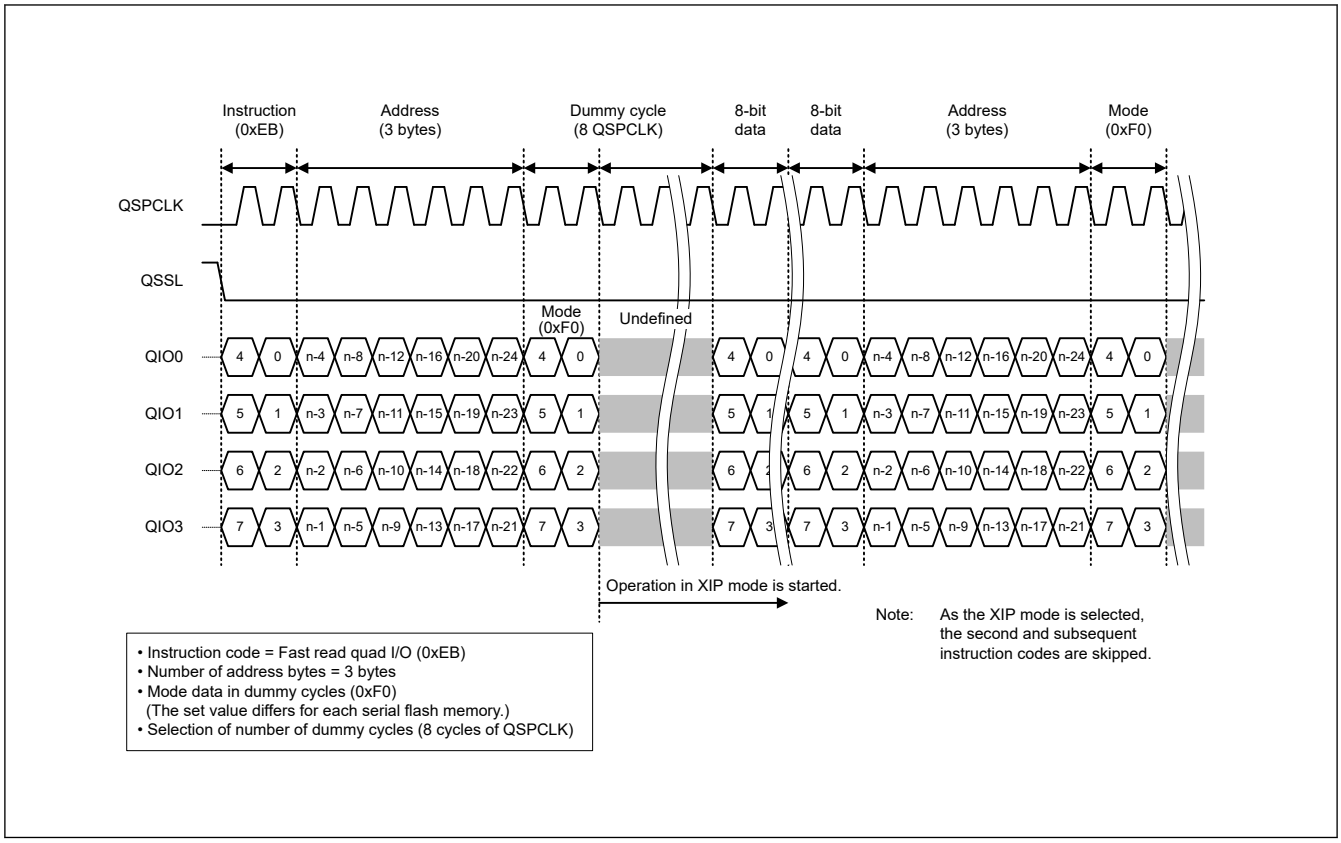

**Figure 34.35 XIP mode control data**

## 34.8.1 Setting XIP Mode

To start XIP mode in serial flash memory, perform the following register settings:

- Set a mode data value in the SFMXD[7:0] bits in the SFMSDC register.*1
- Set the SFMXEN bit in the SFMSDC register to 1.

In the dummy cycle of the first fast read cycle after these registers are set, the mode data value set in the register is transferred. From that point, XIP mode is enabled in the serial flash memory. To confirm the current XIP mode status, read the SFMXST flag in the SFMSDC register.

Note 1. In the SFMXD[7:0] bits in the SFMSDC register, set the mode data that follows the specifications for the actual serial flash memory.

The following figure shows an example of the XIP mode setting procedure.

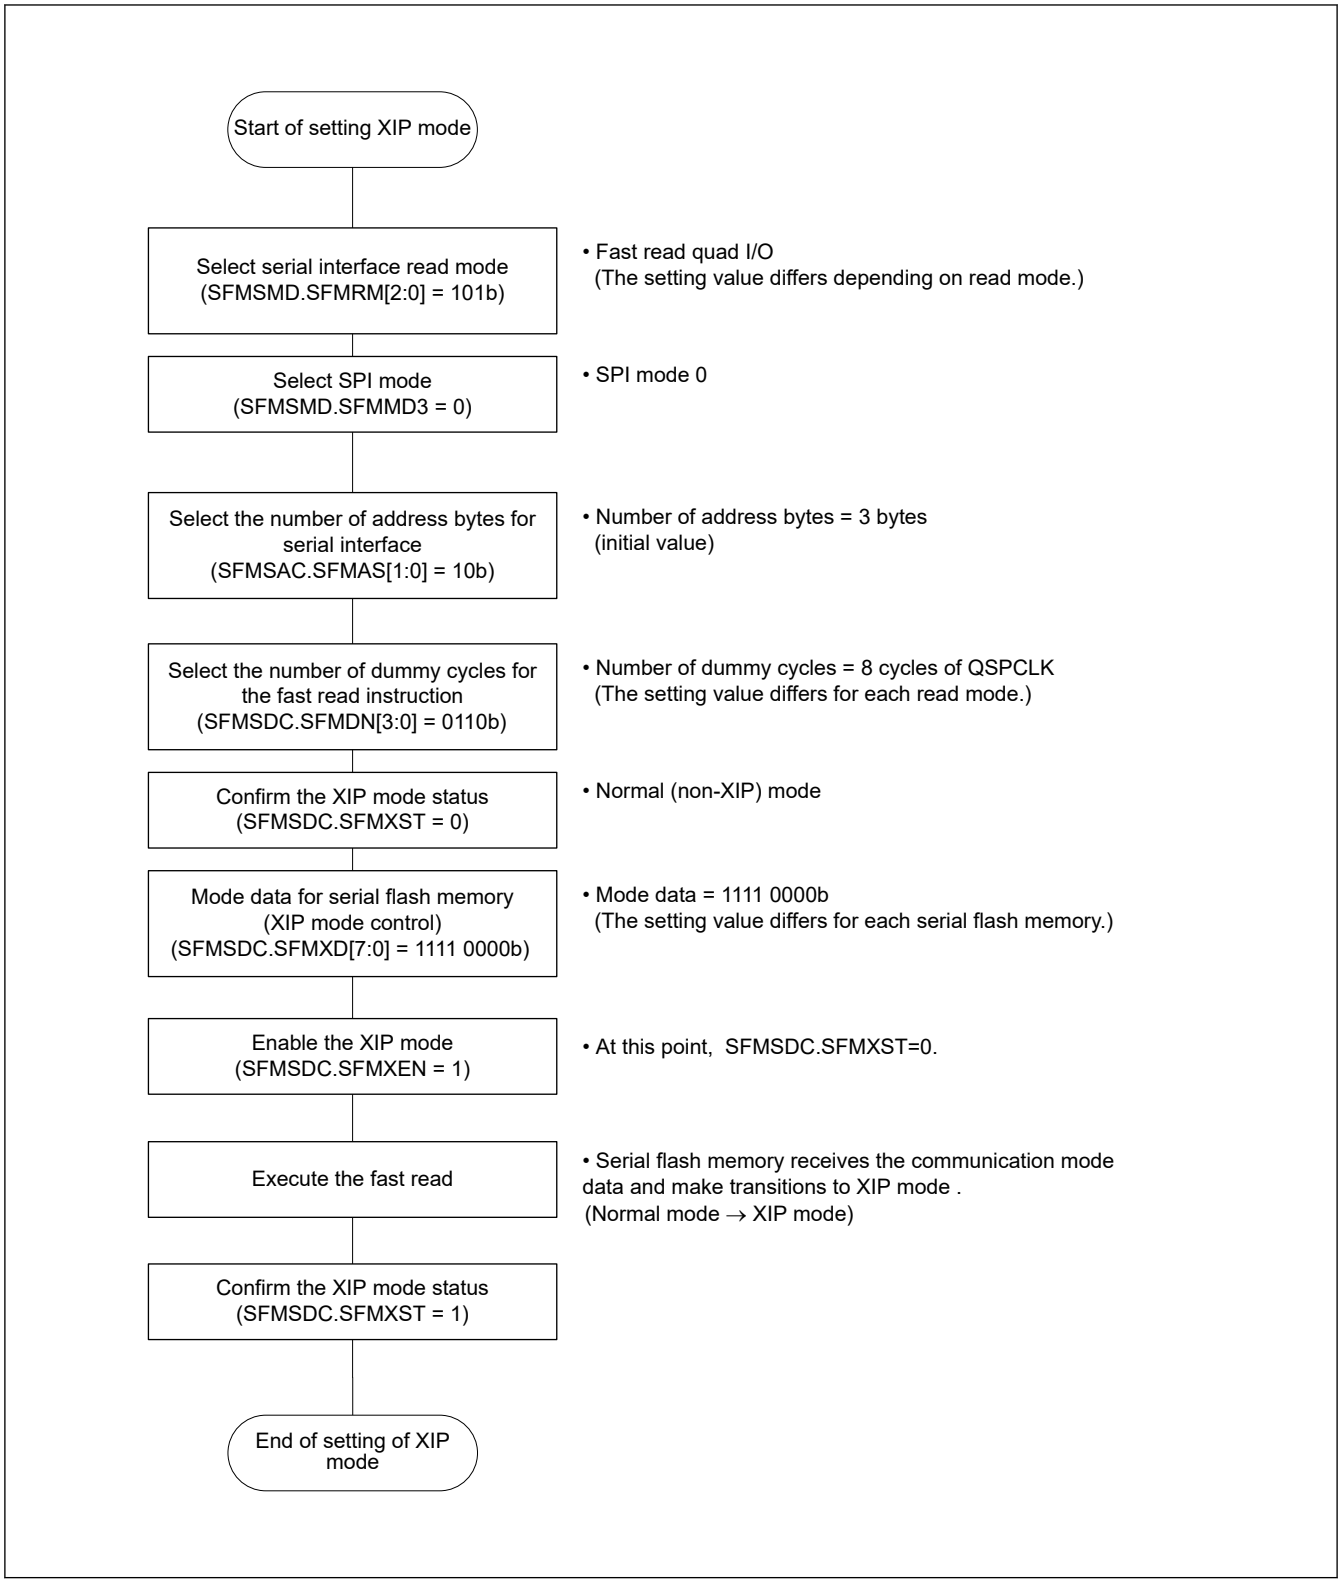

**Figure 34.36 Flowchart of XIP Mode**

## 34.8.2 Releasing the XIP Mode

To release XIP mode in serial flash memory, perform the following register setting:

- Set the mode data value to disable XIP mode in SFMSDC.SFMXD [7: 0] bits*1
- Set the SFMXEN bit in the SFMSDC register to 0.

In the dummy cycle of the first fast read cycle after this register is set, The mode data value that disables the XIP mode set in the register is transferred. From that point, XIP mode is disabled in the serial flash memory. To confirm the current XIP mode status, read the SFMXST flag in the SFMSDC register.

Note 1. Set the mode data in the SFMSDC.SFMXD [7: 0] bits according to the specifications of the serial flash memory.

Figure 34.37 shows an example of the procedure for releasing XIP mode.

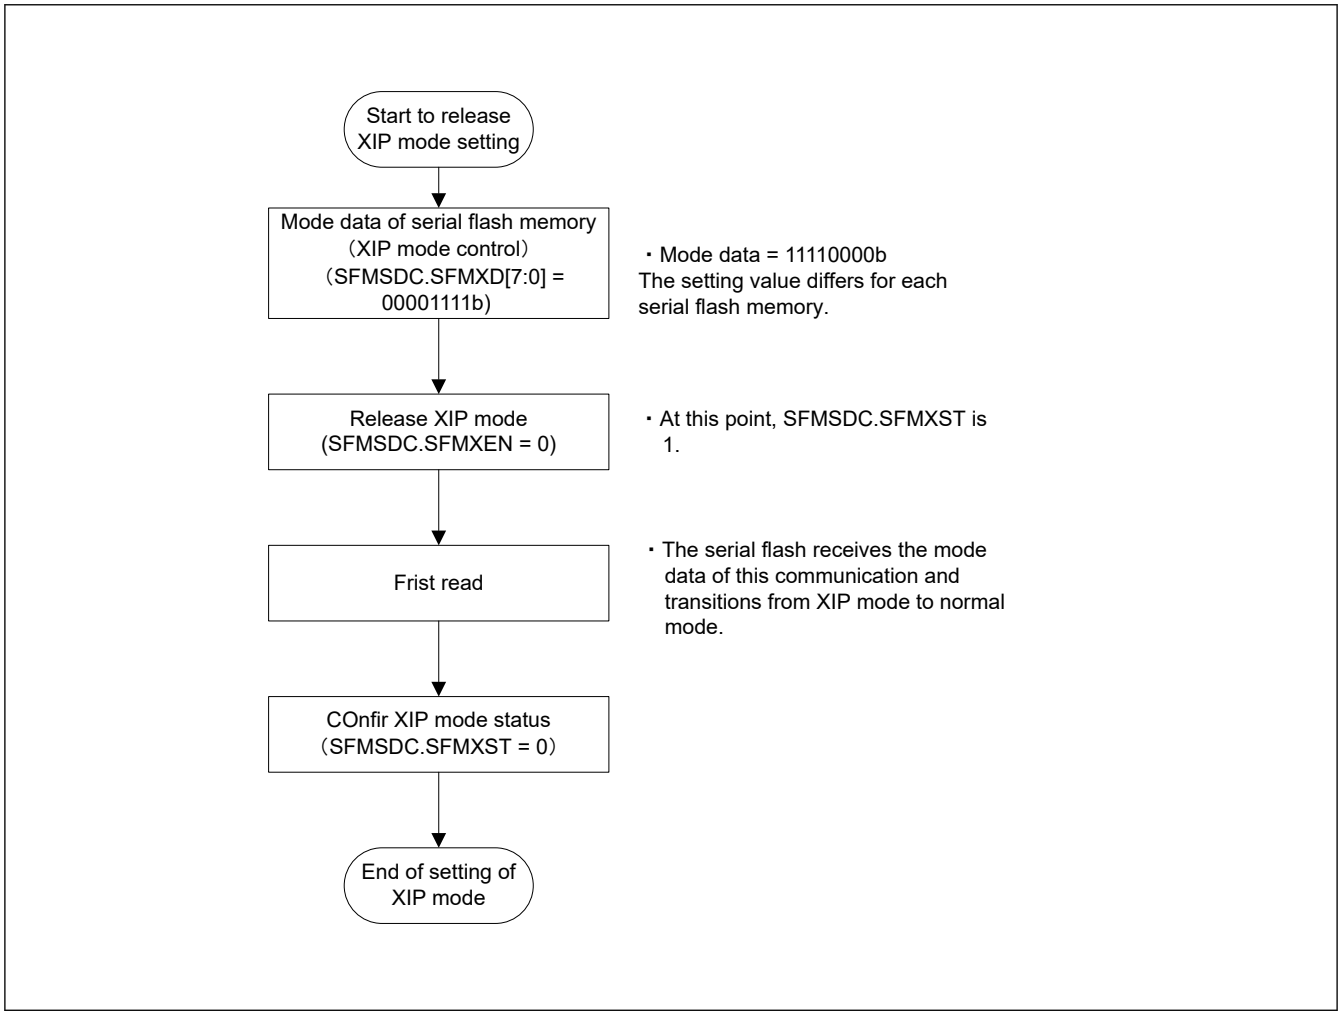

**Figure 34.37 Releasing XIP mode (flowchart)**

## 34.9 QIO2 and QIO3 Pin States

The QIO2 and QIO3 pin states depend on the serial interface read mode specified in the SFMRM[2:0] bits in the SFMSMD register.

**Table 34.11 QIO2 and QIO3 pin states (1 of 2)**

| SFMSMD.SFMRM[2:0] bits | QIO2 pin state*1 | QIO3 pin state*2 | Remarks |
|---|---|---|---|
| 111 | Setting prohibited | | |
| 110 | | | |
| 101 | Input or output as serial data signal (The pin is in the Hi-Z state when it is inactive.) | Input or output as serial data signal (The pin is in the Hi-Z state when it is inactive.) | Fast Read Quad I/O |
| 100 | | | Fast Read Quad Output |

**Table 34.11 QIO2 and QIO3 pin states (2 of 2)**

| SFMSMD.SFMRM[2:0] bits | QIO2 pin state*1 | QIO3 pin state*2 | Remarks |
|---|---|---|---|
| 011 | Output SFMWPL bit variable of the Port Control Register (SFMPMD) (initial value is low level) | Output high level | Fast Read Dual I/O |
| 010 | | | Fast Read Dual Output |
| 001 | | | Fast Read |
| 000 | | | Standard Read (Initial State) |

Note 1. The serial flash memory can also use the QIO2 pin for the write protect (WP) function. The WP function prohibits writes to the status registers. (The function is available in mode other than Quad-SPI mode.)

Note 2. The serial flash memory can also use the QIO3 pin for the HOLD or RESET function.
The hold function places the I/O pin in an inactive state without deselecting the chip. (The function is available in mode other than Quad-SPI mode.)
The reset function resets the serial flash memory. (The function is available when the QSSL pin function is disabled or in a mode in which the QIO3 pin is not used.)

## 34.10 Direct Communication Mode

### 34.10.1 About Direct Communication

The QSPI can read the serial flash memory contents by automatically converting from reading the QSPI window area to SPI bus cycles. However, serial flash memory have many different functions in addition to memory data read, including ID information read, erase, programming, and status information read. There is no standardized instruction set for using these functions, and more functions are being added rapidly by different vendors to different devices. Therefore, to support these functions, the software can create any required SPI bus cycle by communicating directly with serial flash memory.

### 34.10.2 Using Direct Communication Mode

To communicate directly with serial flash memory, transition to direct communication mode by setting the DCOM bit in the Communication Mode Control Register (SFMCMD) register to 1. While direct communications mode is selected, the read operation to the serial flash memory by the QSPI window is invalid.

Note: If the QSPI is set to the XIP mode, you must terminate the XIP mode before starting direct communication mode.

### 34.10.3 Generating the SPI Bus Cycle during Direct Communication

The SPI bus cycle in direct communications starts on the first access to the SFMCOM register, and after a series of input / output operations are executed via the SFMCOM register, the bus cycle ends when 1 is written to the SFMCMD register. At that point, a write to the SFMCOM port is converted to a one-byte transmission to the SPI bus, and a read from the SFMCOM register is converted to a one-byte reception from the SPI bus.

During the period from the first access to the SFMCOM register to the last write operation to the SFMCMD register, the QSSL signal is held active to notify the serial flash memory that a series of SPI bus cycles is in progress.

Note: In direct communication mode, all writes to registers other than SFMCMD and SFMCOM (including SFMSMD, SFMSSC, SFMSKC, SFMSST, SFMCST, SFMSIC, SFMSAC, SFMSDC, SFMSPC, and SFMPMD) are disabled.

Figure 34.38 to Figure 34.40 show direct communication program examples, and Figure 34.41 shows ID read direct communication timing examples.

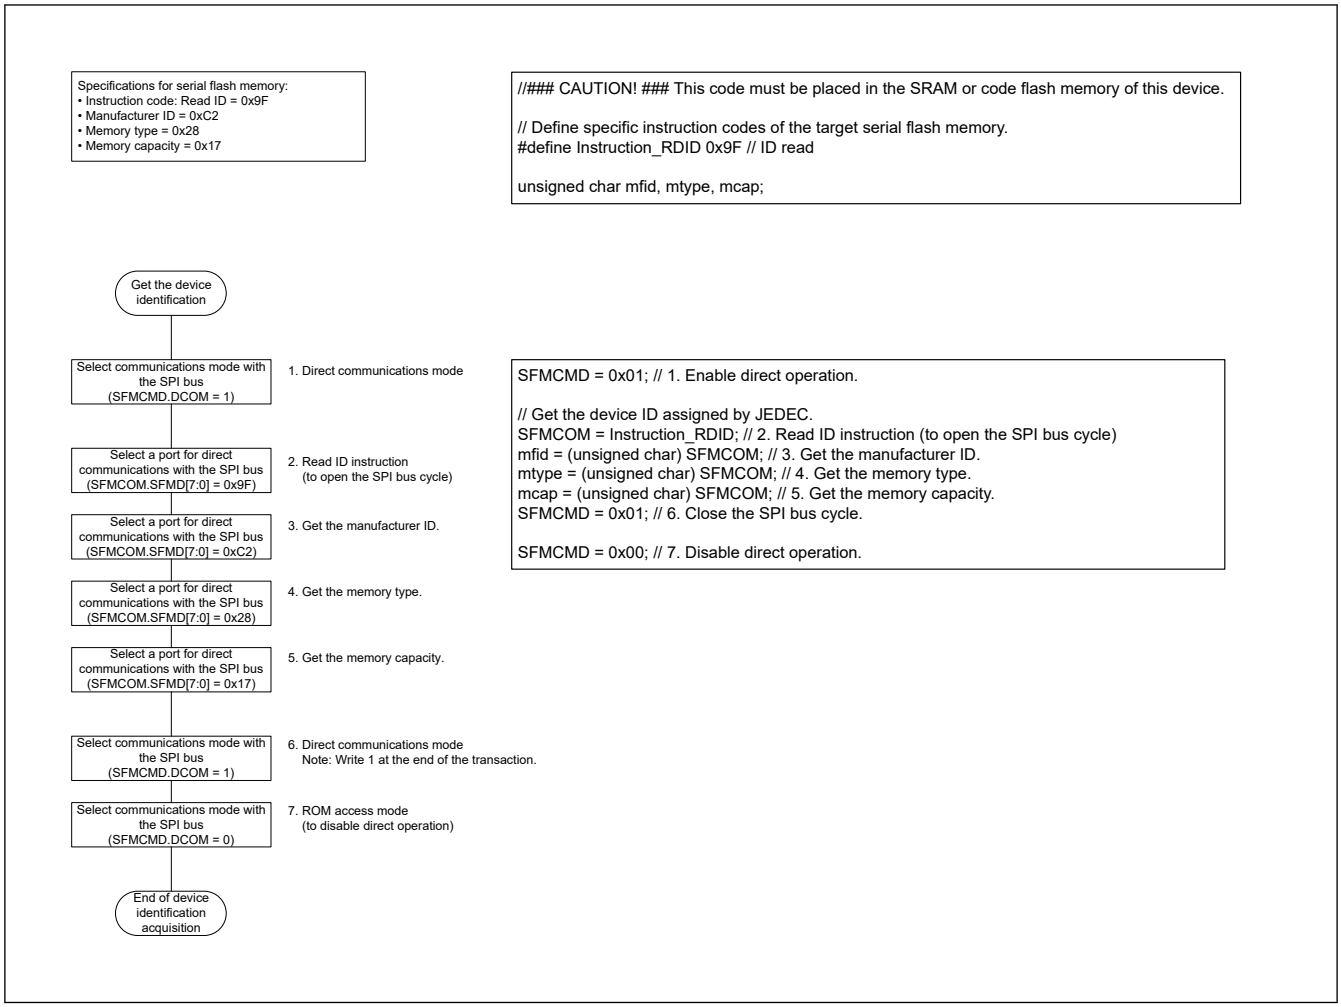

**Figure 34.38 Flowchart of Device ID Acquisition**

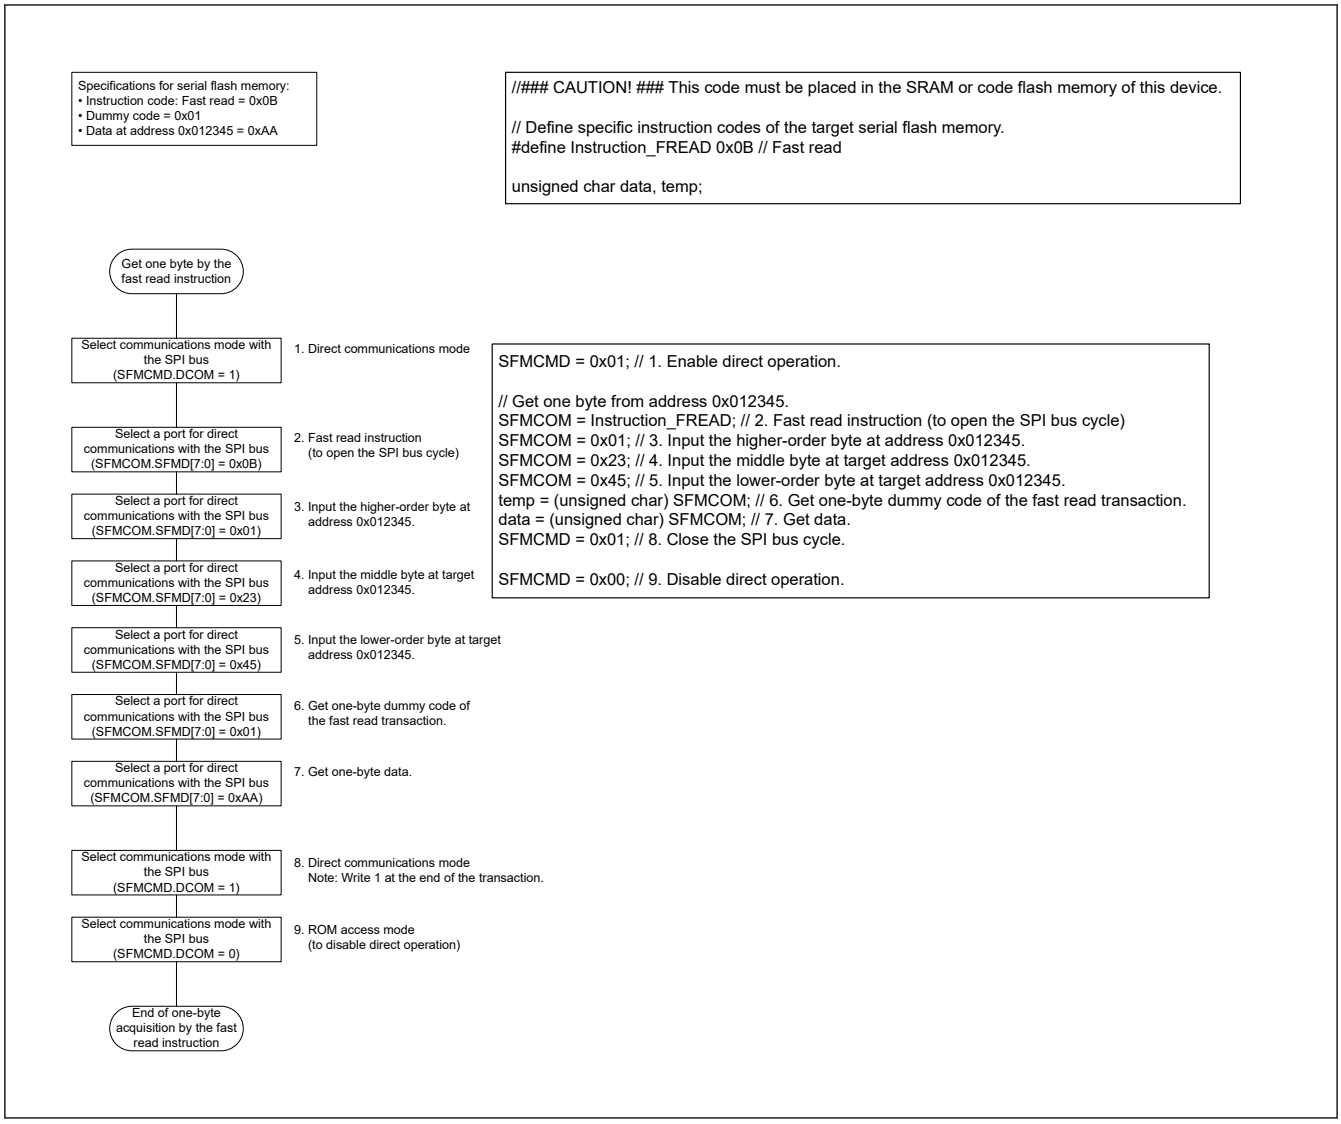

**Figure 34.39 Flowchart of One-byte Acquisition by the Fast Read Instruction**

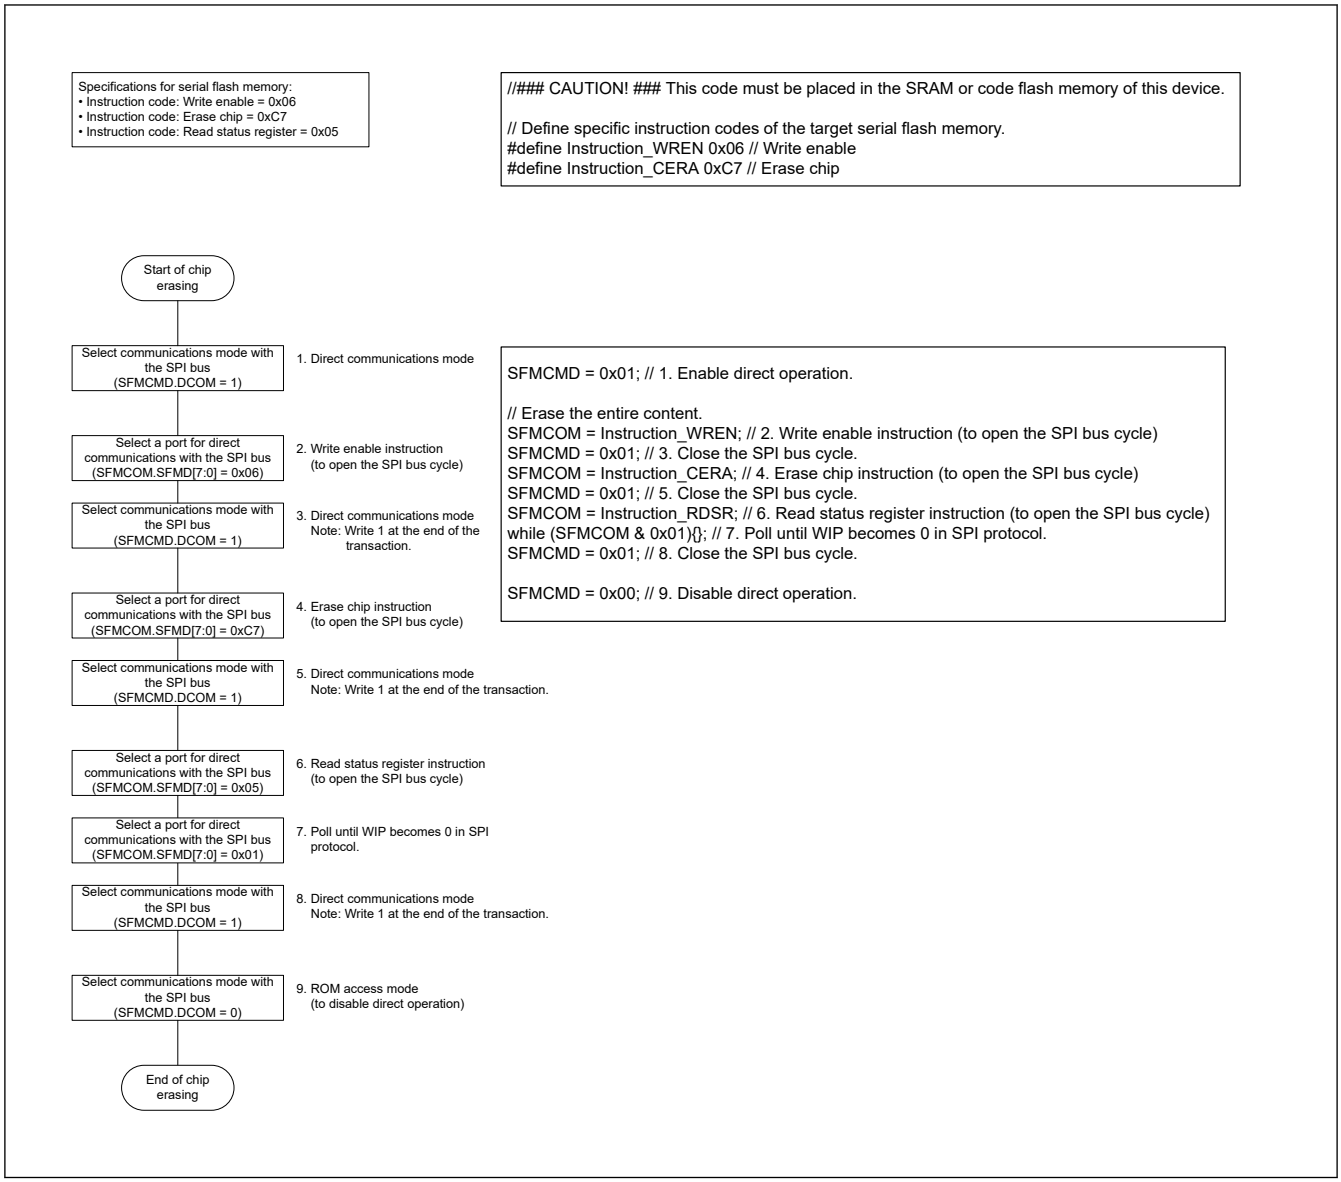

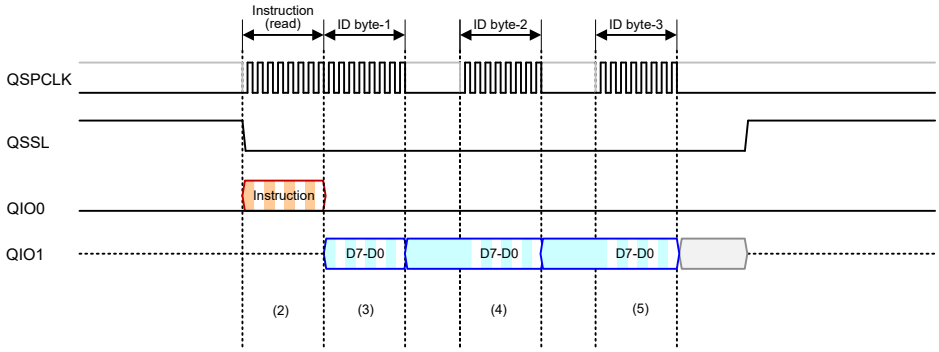

**Figure 34.40 Flowchart of Chip Erasing**

Note: (1) SFMCMD = 0x01; // Enable direct operation. Get the device ID assigned by JEDEC.
(2) SFMCOM = Instruction_RDID; // Read ID instruction (to open the transaction)
(3) mfid = (unsigned char) SFMCOM; // Get the manufacturer ID from ID byte 1.
(4) mtype = (unsigned char) SFMCOM; // Get the memory type from ID byte 2.
(5) mcap = (unsigned char) SFMCOM; // Get the memory capacity from ID byte 3.
(6) SFMCMD = 0x01; // Close the transaction.
(7) SFMCMD = 0x00; // Disable direct operation.

The timings (1), (6) and (7) for enabling or disabling direct communications mode are omitted in the figure.

**Figure 34.41 Example of direct communication timing for ID read**

Note: When the Single SPI Protocol, Extended SPI Protocol is used in direct communication mode, the standard Read or Fast Read instruction must be used to reference the contents of the serial flash memory. The QSPI does not support Fast Read Dual Output, Fast Read Dual I/O, Fast Read Quad Output, or Fast Read Quad I/O transfers in this configuration. When these Fast Read operations are required, use ROM access memory.

## 34.11 Interrupts

When ROM read access is detected in direct communication mode, the SFMCST.EROMR flag is set to 1 and QSPI generates an interrupt request. Interrupt requests are retained until the EROMR flag is cleared by a 0 write. For details, see section 12, Interrupt Controller Unit (ICU).

## 34.12 Usage Note

### 34.12.1 Settings for the Module-Stop Function

QSPI operation can be disabled or enabled using Module Stop Control Register B (MSTPCRB). The QSPI is initially stopped after reset. Releasing the module-stop state enables access to the registers. For details, see section 10, Low Power Modes.

### 34.12.2 Procedure for Changing Settings in Multiple Control Registers

The settings of the QSPI control registers can be modified dynamically during system operation. However, when the settings of multiple control registers are changed sequentially, an SPI bus cycle might occur before all of the registers are updated. The register setting sequence must be designed so that the SPI bus timing specifications are satisfied at all stages of register setting modification.

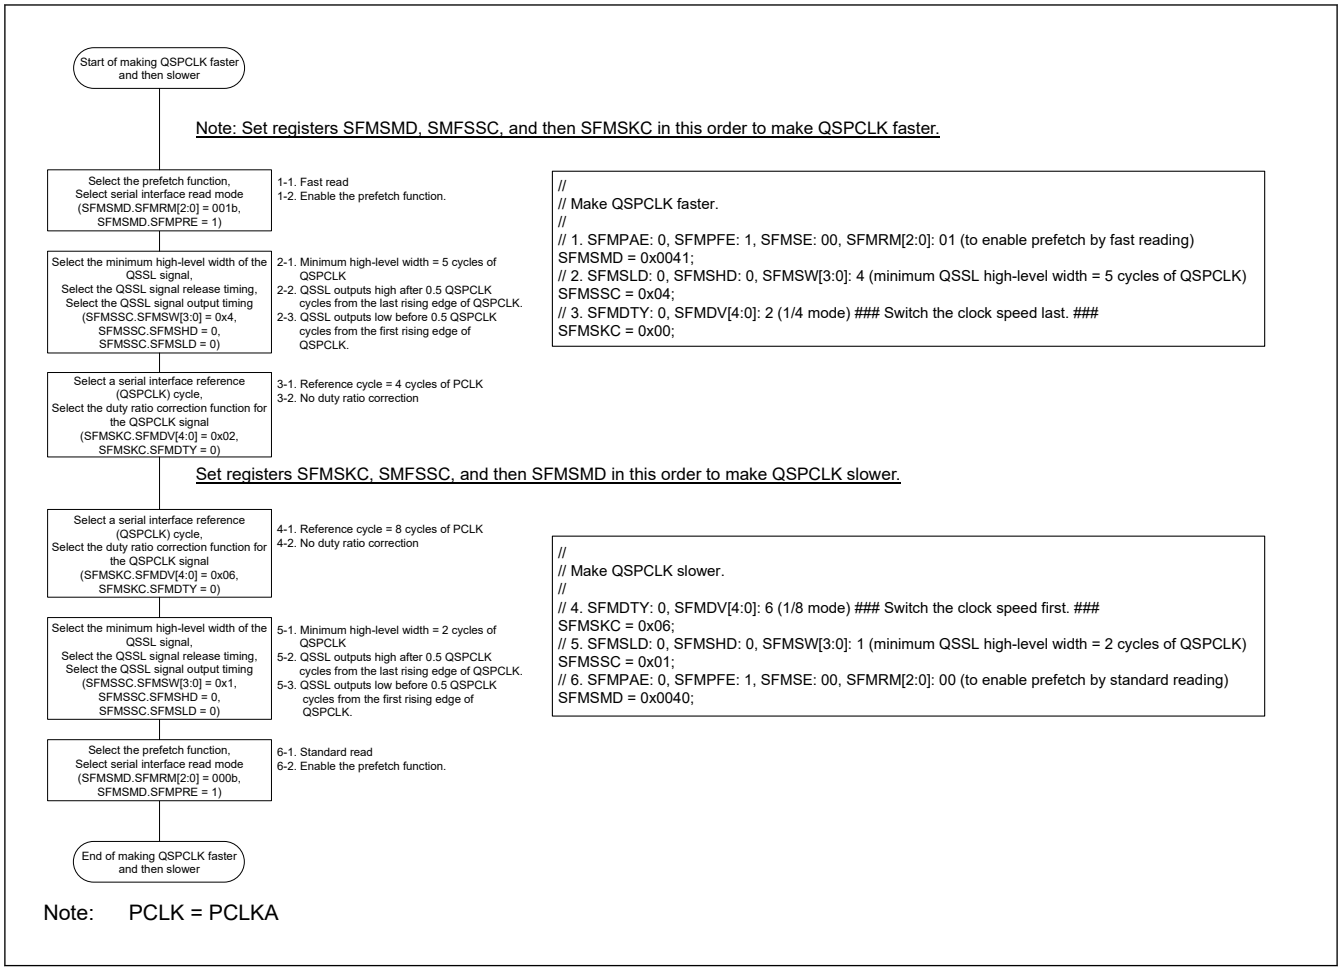

**Figure 34.42 Flowchart of Making QSPCLK Faster and Slower**

# 35. Serial Sound Interface Enhanced (SSIE)

## 35.1 Overview

The Serial Sound Interface Enhanced (SSIE) can transmit and receive audio data to and from various devices that support any of audio data formats, such as $I^2S$, monaural, and TDM.

## 35.2 Features

**Table 35.1 Features of SSIE**

| Item | | Description |
|---|---|---|
| Number of channels | | One channel, SSIE0 |
| Communication mode | | • Master/slave<br>• Transmission/reception (SSIE0 full duplex communication) |
| Communication format | | • $I^2S$ format<br>• Monaural format<br>• TDM format |
| Serial data | | • MSB first<br>• Data can be left-justified or right-justified.<br>• Data delay (1 clock cycle) or no delay selectable for the period from SSILRCK0/ SSIFS0 to SSITXD0/SSIRXD0<br>• System word length: 8, 16, 24, 32, 48, 64, 128, or 256 bits<br>• Data word length: 8, 16, 18, 20, 22, 24, or 32 bits<br>• Padding polarity: Low or high |
| Bit clock (SSIBCK0) | In master mode | • Two clock sources available (AUDIO_CLK/GPT output (GTIOC2A))<br>• Clock source division ratio: 1/1, 1/2, 1/4, 1/6, 1/8, 1/12, 1/16, 1/24, 1/32, 1/48, 1/64, 1/96, and 1/128.<br>• Supply/stop is selectable while communication is halted. |
| | In master/slave mode | • Polarity (rising edge or falling edge) selectable |
| LR clock/frame synchronization (SSILRCK0/ SSIFS0) | In master mode | • Polarity (low level or high level) selectable<br>• Supply/stop is selectable while communication is halted. |
| Transmit data (SSITXD0) and receive data (SSIRXD0) | Transmission | • Muting method (transmission of transmit FIFO data or transmission of data fixed to 0) selectable |
| FIFO | Capacity | • Transmit FIFO/receive FIFO: 4 bytes × 32 stages |
| | Data alignment | • Data alignment method (left-justification or right-justification) selectable for the data transfer between FIFO and shift register |
| Interrupt | Interrupt output | • Communication error/idle mode<br>• Receive data full<br>• Transmit data empty |
| Low power consumption function | | • Whether to supply the audio clock selectable in master mode |
| Module stop function | • Module stop state can be set to reduce power consumption. | |
| TrustZone Filter | • Security attribution can be set. | |

The following table lists and defines the terms used for the communication formats SSIE can use:

**Table 35.2 Definition of terms (1 of 2)**

| Term | Definition |
|---|---|
| Start trigger | First edge of the signal on the SSILRCK0/SSIFS0 pin when the signal is set to the value specified in LRCKP to enable communication |
| Frame boundary | Point where SSIE starts transferring the first data of a frame or the point where SSIE ends transferring the last data of the frame |

**Table 35.2 Definition of terms (2 of 2)**

| Term | Definition |
|---|---|
| Frame word number | Number of sound channels per frame |
| System word length | Number of bits per channel |
| Data word length | Number of significant bits per channel |
| Control bits for communication formats | • SSICR register: FRM, DWL, SWL, LRCKP, SPDP, SDTA, PDTA, and DEL bits<br>• SSIFCR register: BSW bit<br>• SSIOFR register: OMOD bit<br>• SSISCR register: TDES[4:0] and RDFS[4:0] bits |

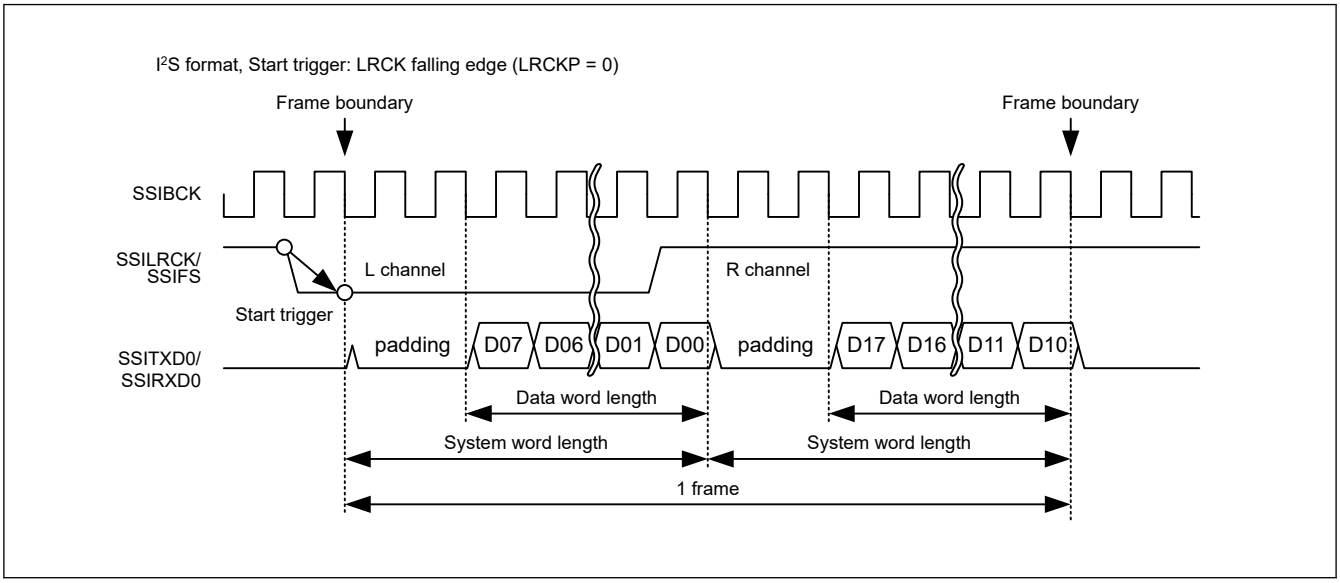

**Figure 35.1 Definition of communication format**

## 35.3 Block Diagram

Figure 35.2 shows a block diagram of SSIE.

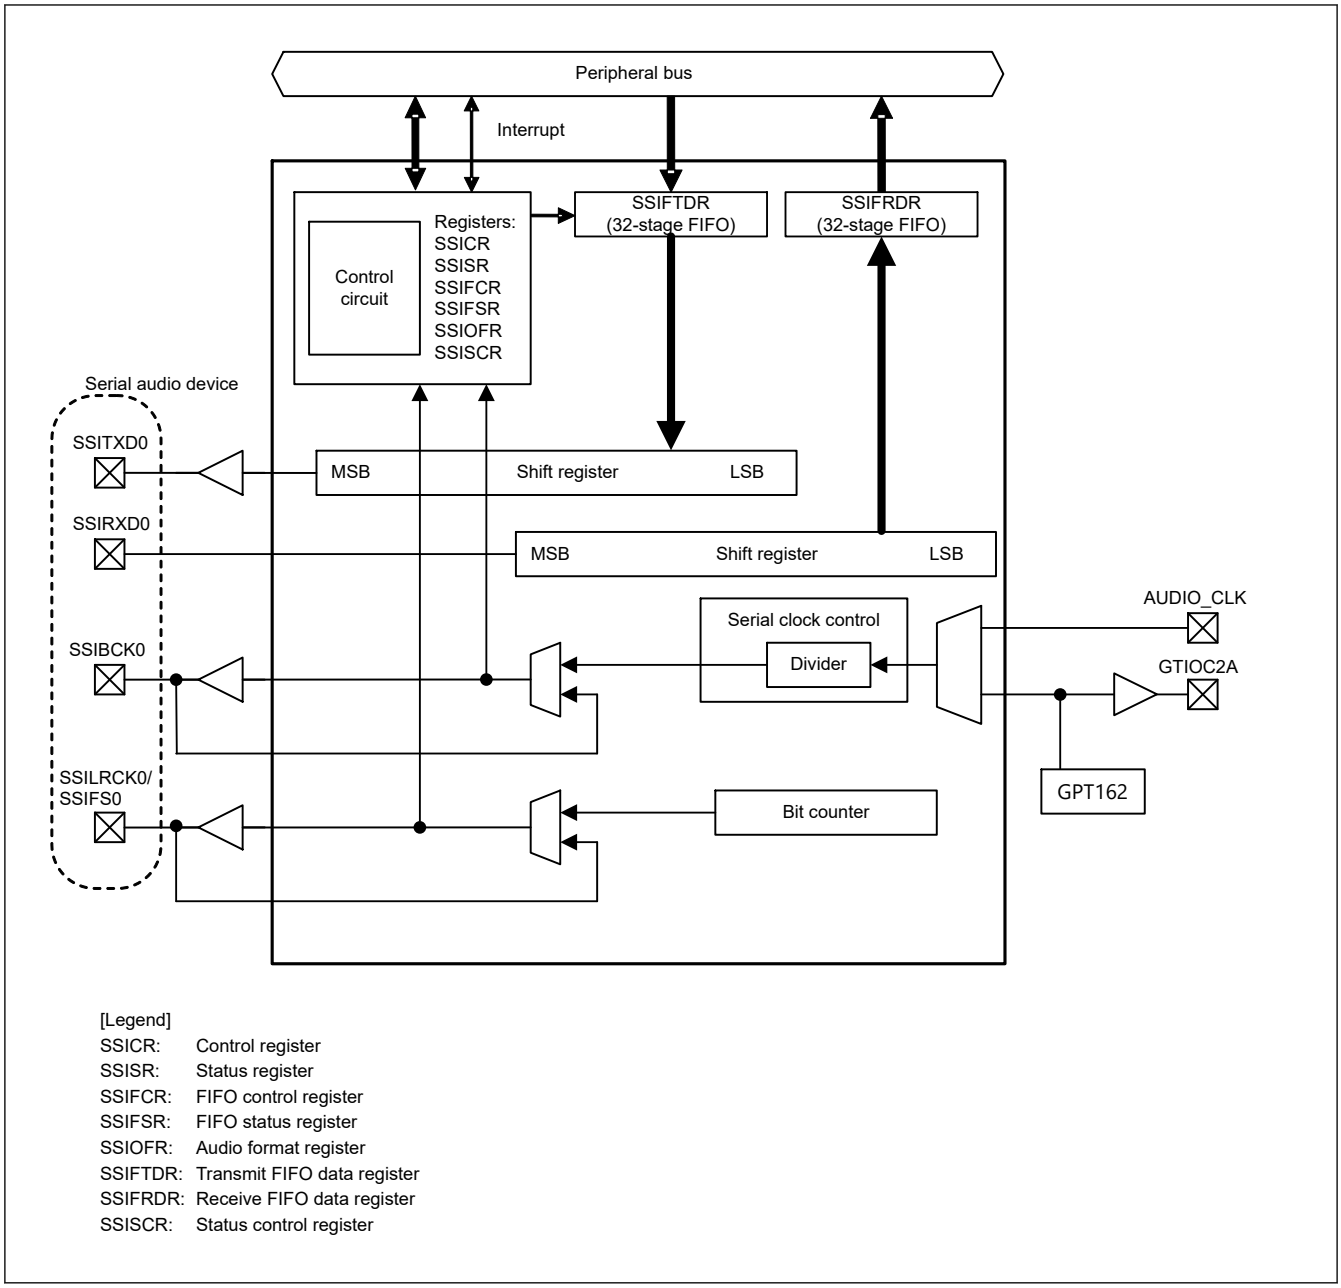

**Figure 35.2 SSIE block diagram**

Figure 35.3 shows the clock configuration of SSIE.

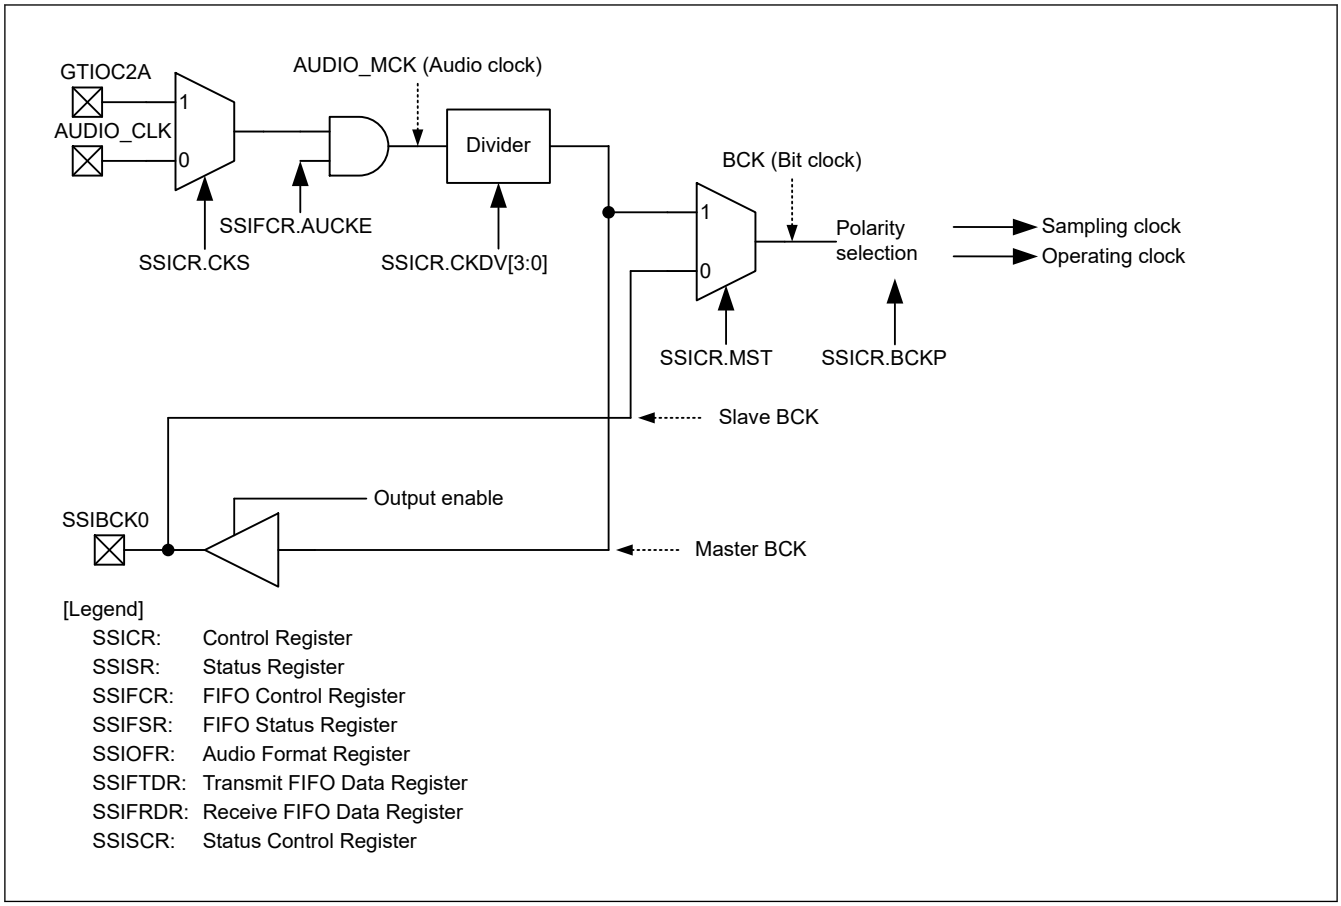

**Figure 35.3 SSIE clock configuration**

## 35.4 Register Descriptions

### 35.4.1 SSICR : Control Register

Base address: SSIE0 = 0x4009_D000

Offset address: 0x00

| Bit position: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

</table>

Note 1. Writing to these bits while SSIE is in a communication state (SSISR.IIRQ = 0) is prohibited. If the value of these bits is changed by rewriting, subsequent operation is unpredictable.

Note 2. If the TEN bit or REN bit is rewritten, make sure that the SSISR.IIRQ bit is in the desired status. If the value of the TEN or REN bit is changed by rewriting, subsequent operation is unpredictable. For example, when transmission or reception is enabled, check that SSISR.IIRQ is 0; when transmission or reception is disabled, check that SSISR.IIRQ is 1.

With this register, select an audio clock, control interrupt requests, select data formats, and set an operation mode.

### TEN and REN bits (Transmission and Reception Enable)

The TEN and REN bits enable/disable transmission and reception. When 1 is written to one of these bits, the corresponding communication operation starts in synchronization with a start trigger by the SSILRCK0/SSIFS0 signal. For details, see section 35.8.2. Transmission to section 35.8.4. Transmission and Reception. When 0 is written to this bit, the current communication operation stops at the next frame boundary. To use SSIE for both transmission and reception, always write 1 to these bits together. When stopping the communication using SSIE, always disable both transmission and reception (write 0 to the TEN and REN bits).

If you want to stop SSIE before a frame boundary is reached, perform a software reset procedure.

### MUEN bit (Mute Enable)

The MUEN bit sets/clears the mute function for the data output from the SSITXD0 pin. When this bit is set to 1 in the middle of a frame, the SSITXD0 output changes to 0 at the next frame boundary. When this bit is set to 0 in the middle of a frame, the SSITXD0 output changes to the data of transmit FIFO data register at the next frame boundary. Note that this bit controls data only. Status flags and interrupt signals are normally generated.

Changing the value of this bit must be performed only after setting the communication format to be used.

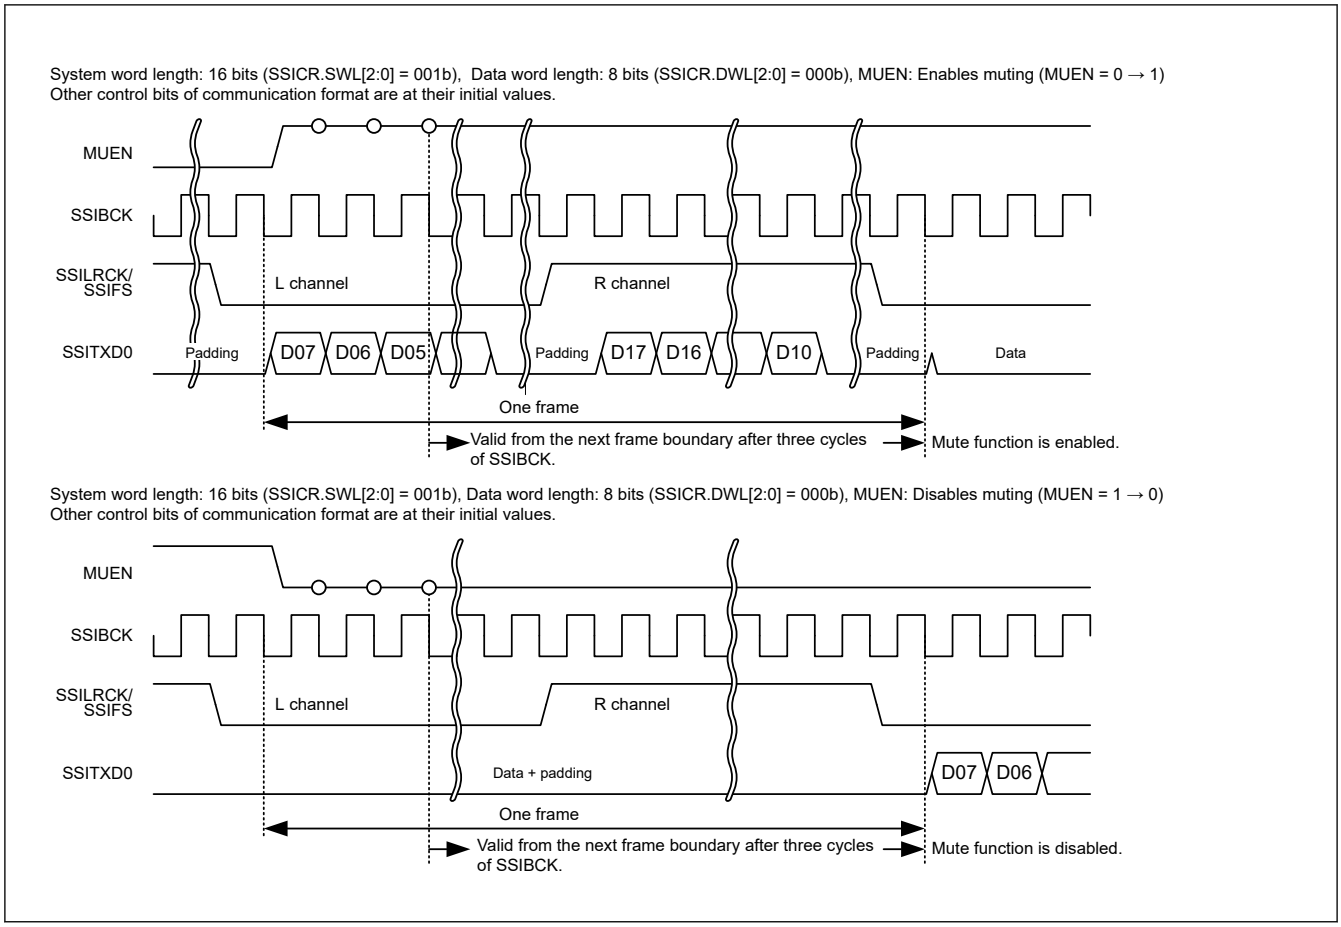

**Figure 35.4 Transmit data with the mute function set**

### CKDV[3:0] bits (Selects Bit Clock Division Ratio)

The CKDV[3:0] bits set the division ratio of the bit clock based on AUDIO_MCK in master-mode communication (MST= 1). In slave-mode communication (MST = 0), setting of these bits are invalid.

Writing to this bit must be performed when the supply of AUDIO_MCK is stopped. For details about the timing, see the detailed description of the AUCKE bit in section 35.4.3. SSIFCR : FIFO Control Register.

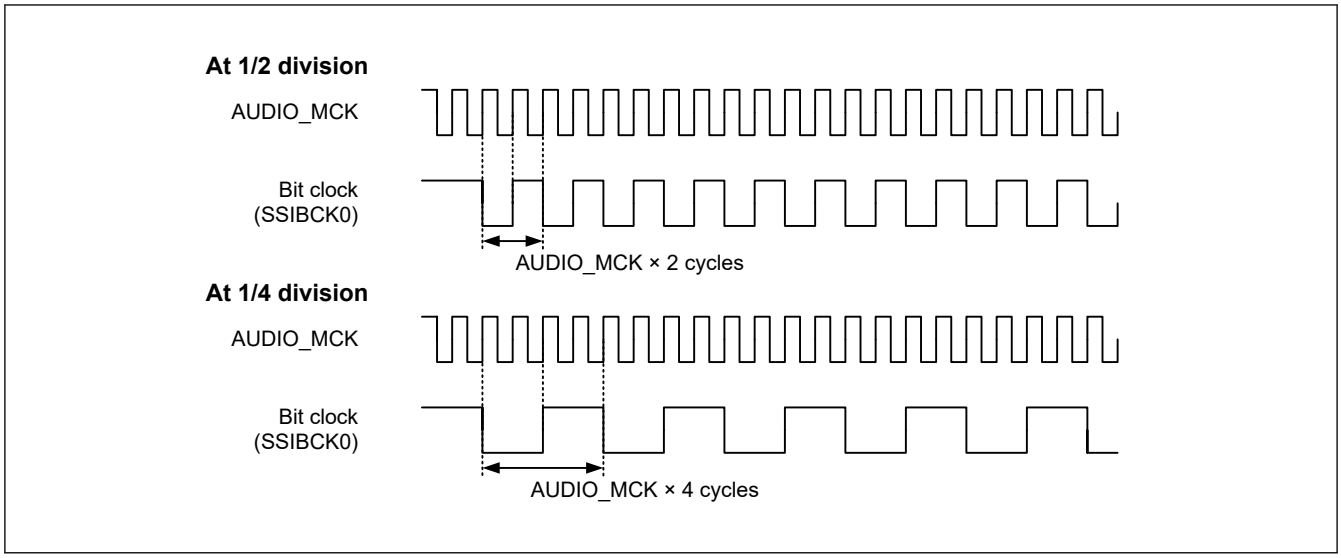

**Figure 35.5 Sampling frequencies in master-mode communication**

### DEL bit (Selects Serial Data Delay)

The DEL bit sets whether or not there will be a delay between SSILRCK0/SSIFS0 and SSITXD0/SSIRXD0.

For the $I^2S$ or TDM format, set the DEL bit to 0. When the monaural format is used, setting of this bit changes the high period width of SSILRCK0/SSIFS0. For details, see section 35.5.2. Monaural Format. When using a compatible communication format, specify a setting of this bit that enables communication.

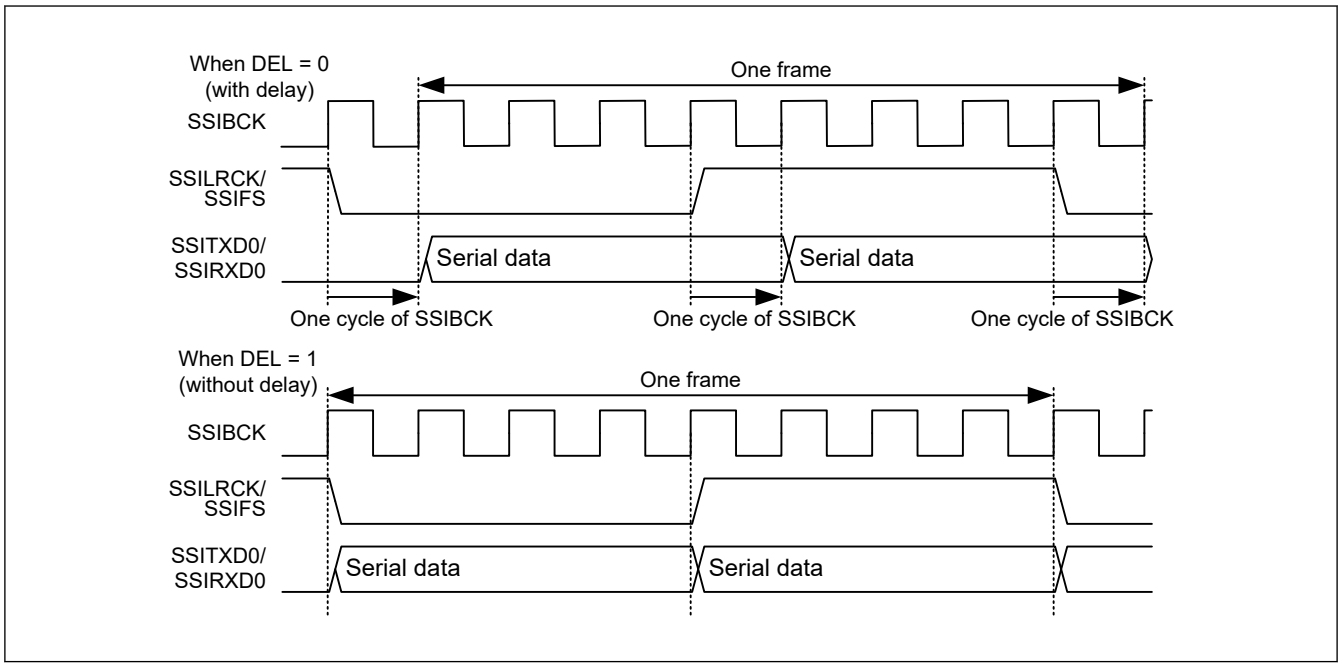

**Figure 35.6 Setting of delay in serial data**

### PDTA bit (Selects Placement Data Alignment)

The PDTA bit sets how to align placement data. With the setting of data word length as 32 bits (SSICR.DWL[2:0] = 110b), this bit is invalid.

At transmission, see Figure 35.7.

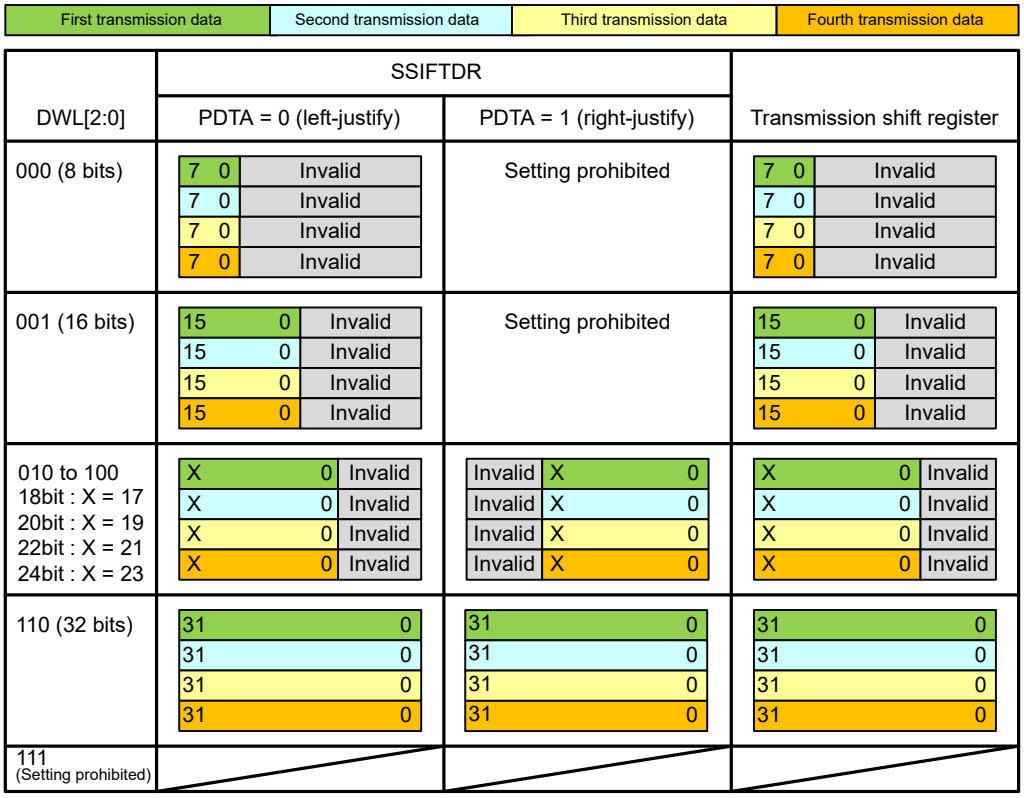

**Figure 35.7 Alignment of placement data at transmission**

At reception, see Figure 35.8.

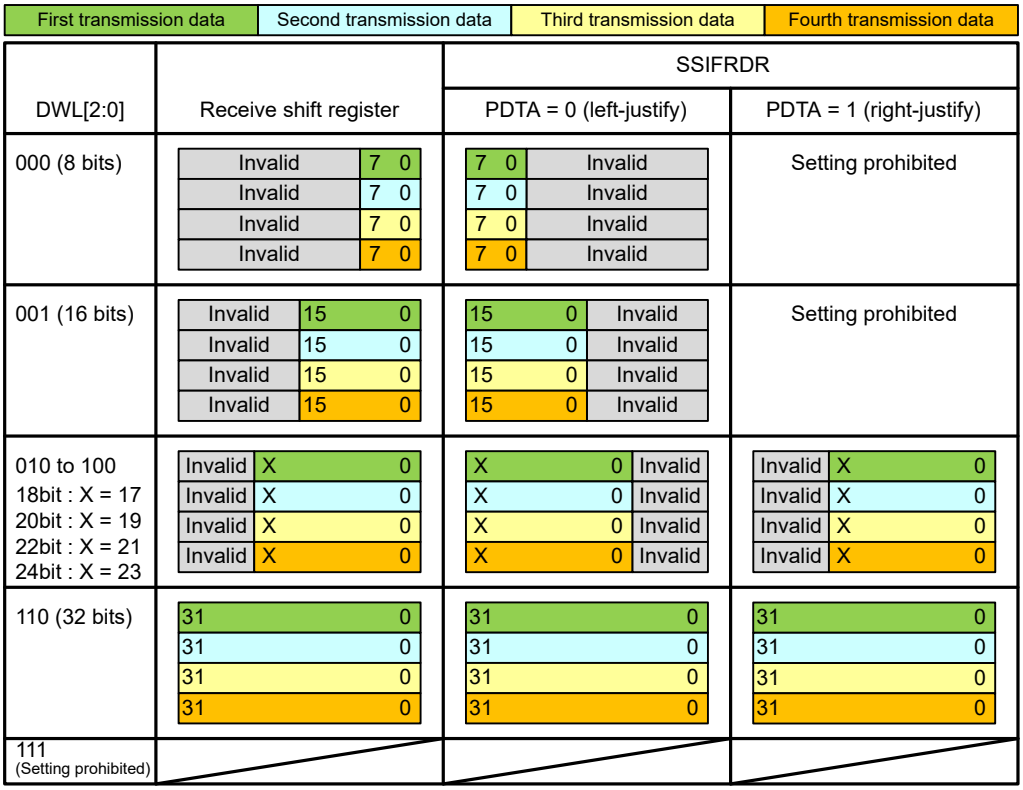

**Figure 35.8 Alignment of placement data at reception**

### SDTA bit (Selects Serial Data Delay)

The SDTA bit sets how to align serial data and padding bits. For communication without padding bits, this bit is invalid.

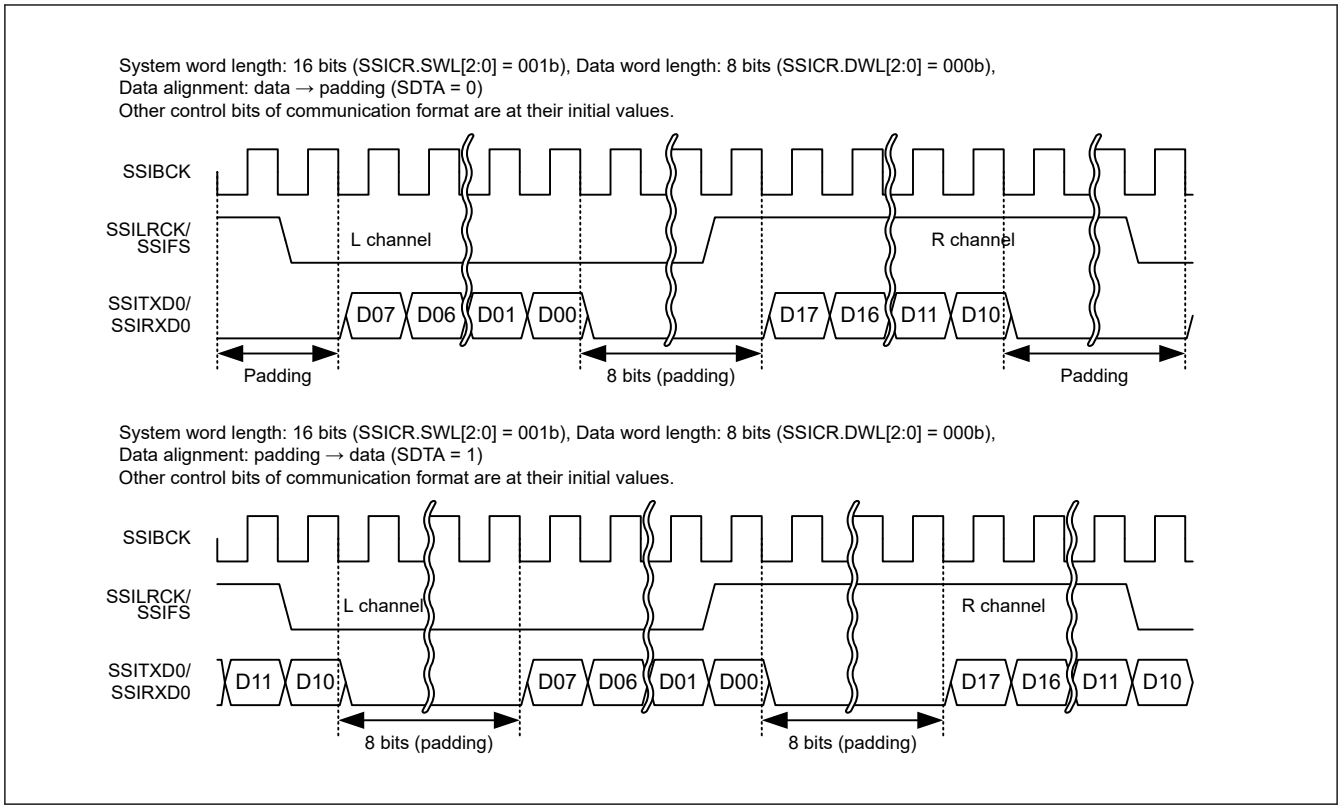

**Figure 35.9 Alignment setting of serial data with padding bits**

### SPDP bit (Selects Serial Padding Polarity)

The SPDP bit sets polarity of padding bits.

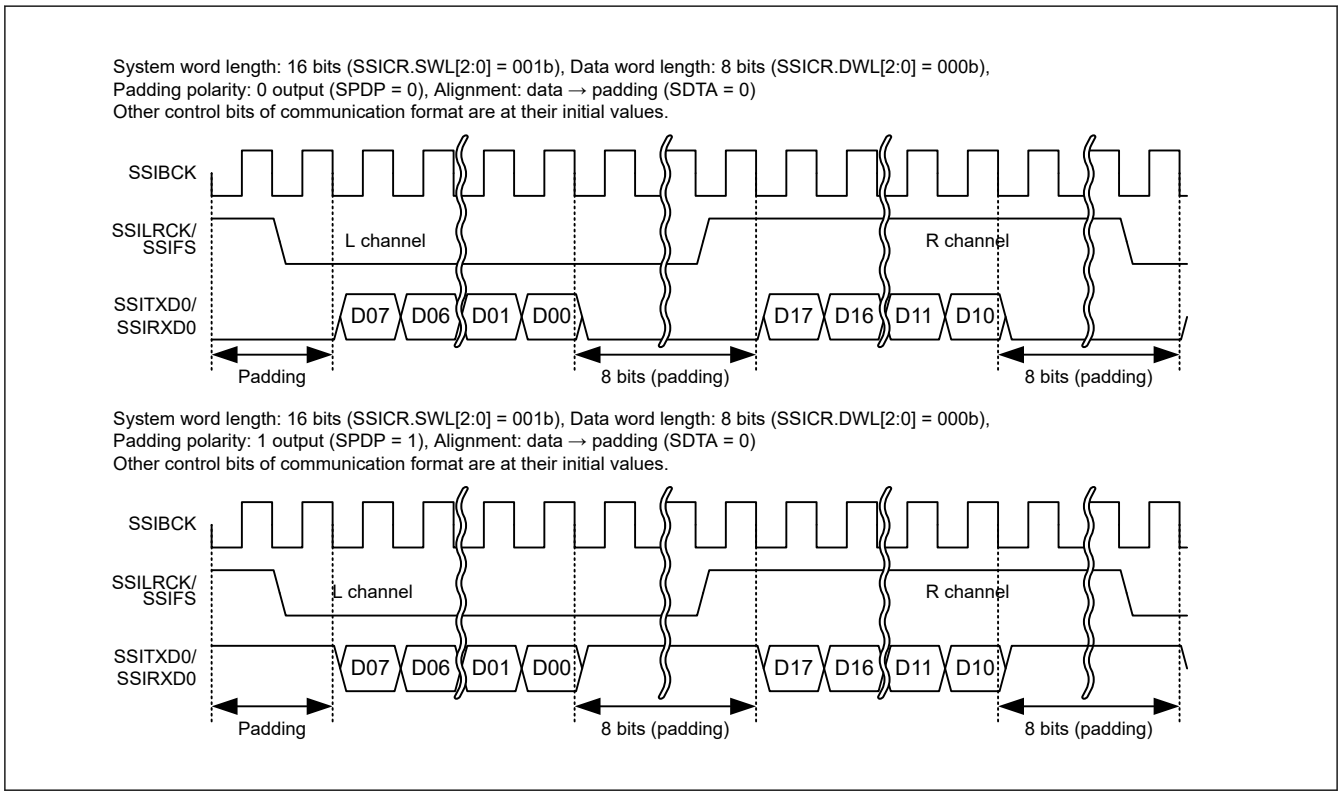

**Figure 35.10 Padding bit polarity**

### LRCKP bit (Selects the Initial Value and Polarity of LR Clock/Frame Synchronization Signal)

The LRCKP bit sets the initial value and polarity of SSILRCK0/SSIFS0. Set this bit according to the communication format to be used in SSIE. See Table 35.3 Initial output value and polarity of SSILRCK0/SSIFS0 pin. For the slave-mode communication (MST = 0), only the start trigger is used.

Writing to these bits must be performed when the LR clock supply to the SSILRCK0/SSIFS0 pin is stopped. For details about the output of LR clock, see the detailed description of the LRCONT bit in section 35.4.7. SSIOFR : Audio Format Register.

**Table 35.3 Initial output value and polarity of SSILRCK0/SSIFS0 pin**

| Communication Format | Expected Initial State | Setting Value of LRCKP |
|---|---|---|
| $I^2S$ | High | 0 |
| Monaural | Low | 1 |
| TDM | Low | 1 |

Note: When the format to be used is compatible with the $I^2S$, monaural, or TDM format, specify settings to enable communication with the respective formats.

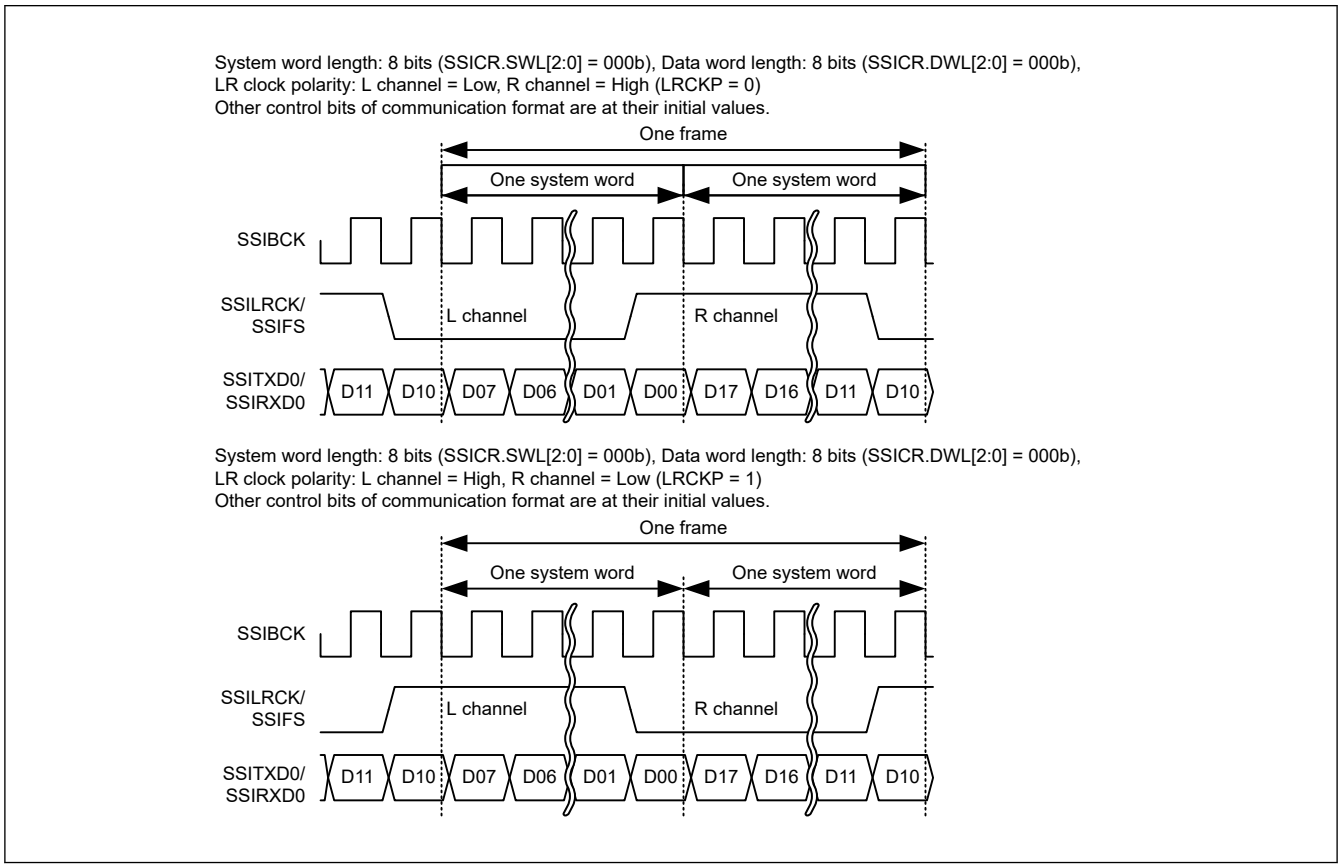

**Figure 35.11 LR clock/frame synchronization polarity setting**

### BCKP bit (Selects Bit Clock Polarity)

The BCKP bit sets the bit clock polarity.

Writing to this bit must be performed when the supply of AUDIO_MCK is stopped. For details about the timing, see the detailed description of the AUCKE bit in section 35.4.3. SSIFCR : FIFO Control Register.

**Table 35.4 Bit clock polarity**

| Communication | Master/Slave | Timing | BCKP = 0 | BCKP = 1 |
|---|---|---|---|---|
| Reception | Slave | At SSILRCK0/SSIFS0 sampling | SSIBCK0 rising edge | SSIBCK0 falling edge |
| | Master/slave | At SSIRXD0 sampling | SSIBCK0 rising edge | SSIBCK0 falling edge |
| Transmission | Master | At change of SSILRCK0/SSIFS0 output | SSIBCK0 falling edge | SSIBCK0 rising edge |
| | Master/slave | At change of SSITXD0 output | SSIBCK0 falling edge | SSIBCK0 rising edge |

### MST bit (Master Enable)

The MST bit sets master-/slave-mode communication.

Writing to this bit must be performed when the supply of AUDIO_MCK is stopped. For details about the timing, see the detailed description of the AUCKE bit in section 35.4.3. SSIFCR : FIFO Control Register.

### SWL[2:0] bits (Selects System Word Length)

The SWL[2:0] bits set the number of bits in one system word. Padding bits are sent and received in relation with one data word set with DWL[2:0]. See Table 35.11 for details.

Writing to these bits must be performed when the LR clock supply to the SSILRCK0/SSIFS0 pin is stopped. For details about the output of LR clock, see the detailed description of the LRCONT bit in section 35.4.7. SSIOFR : Audio Format Register.

### DWL[2:0] bits (Selects Data Word Length)

The DWL[2:0] bits set the number of bits in one data word. The data word length (number of bits per data word) must not exceed the system word length (number of bits per system word). For details, see Table 35.11.

### FRM[1:0] bits (Selects Frame Word Number)

The FRM[1:0] bits set the frame word number in individual communication formats.

Writing to these bits must be performed when the LR clock supply to the SSILRCK0/SSIFS0 pin is stopped. For details about the output of LR clock, see the detailed description of the LRCONT bit in section 35.4.7. SSIOFR : Audio Format Register.

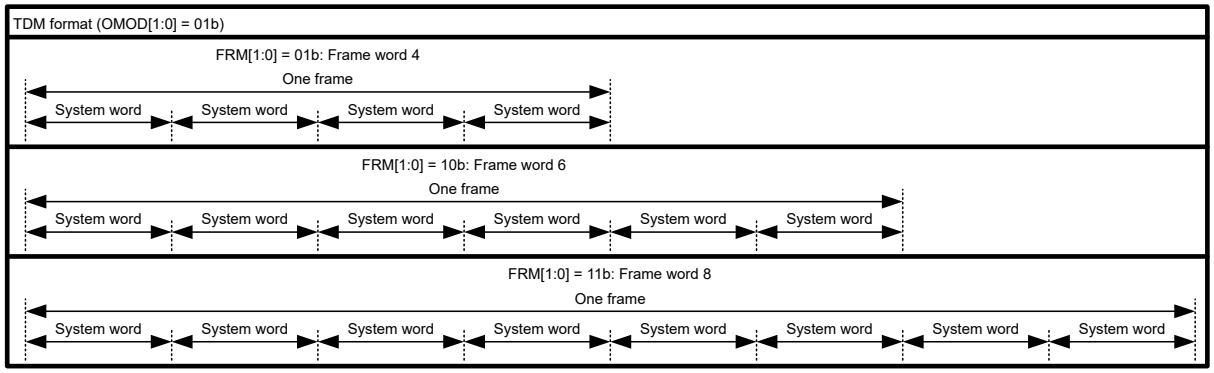

**Figure 35.12 Frame word number**

### IIEN bit (Idle Mode Interrupt Output Enable)

The IIEN bit enables/disables output of idle mode interrupts. By enabling this bit (set it to 1), an interrupt is output at a rising edge of SSISR.IIRQ = 1. An interrupt is also output when this bit is changed from 0 to 1 while SSISR.IIRQ = 1.

### ROIEN bit (Receive Overflow Interrupt Output Enable)

The ROIEN bit enables/disables output of receive overflow interrupts. By enabling this bit (set it to 1), an interrupt is output at a rising edge of SSISR.ROIRQ = 1. An interrupt is also output when this bit is changed from 0 to 1 while SSISR.ROIRQ = 1.

### RUIEN bit (Receive Underflow Interrupt Output Enable)

The RUIEN bit enables/disables output of receive underflow interrupts. By enabling this bit (set it to 1), an interrupt is output at a rising edge of SSISR.RUIRQ = 1. An interrupt is also output when this bit is changed from 0 to 1 while SSISR.RUIRQ = 1.

### TOIEN bit (Transmit Overflow Interrupt Output Enable)

The TOIEN bit enables/disables output of transmit overflow interrupts. By enabling this bit (set it to 1), an interrupt is output at a rising edge of SSISR.TOIRQ = 1. An interrupt is also output when this bit is changed from 0 to 1 while SSISR.TOIRQ = 1.

### TUIEN bit (Transmit Underflow Interrupt Output Enable)

The TUIEN bit enables/disables output of transmit underflow interrupts. By enabling this bit (set it to 1), an interrupt is output at a rising edge of SSISR.TUIRQ = 1. An interrupt is also output when this bit is changed from 0 to 1 while SSISR.TUIRQ = 1.

### CKS bit (Selects an Audio Clock for Master-mode Communication)

The CKS bit sets the audio clock in master-mode communication (MST = 1). In slave-mode communication (MST = 0), setting of this bit is invalid.

Writing to this bit must be performed when the supply of AUDIO_MCK is stopped. For details about the timing, see the detailed description of the AUCKE bit in section 35.4.3. SSIFCR : FIFO Control Register.

## 35.4.2 SSISR : Status Register

Base address: SSIE0 = 0x4009_D000

Offset address: 0x04

| Bit position: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | TUIRQ | TOIRQ | RUIRQ | ROIRQ | IIRQ | — | — | — | — | — | — | — | — | — |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 1 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit position: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 24:0 | — | These bits are read as 0. The write value should be 0. | R/W |
| 25 | IIRQ | Idle Mode Status Flag<br>0: In the communication state<br>1: In the idle state | R |
| 26 | ROIRQ | Receive Overflow Error Status Flag<br>0: No receive overflow error is generated.<br>1: A receive overflow error is generated. | R/W |
| 27 | RUIRQ | Receive Underflow Error Status Flag<br>0: No receive underflow error is generated.<br>1: A receive underflow error is generated. | R/W |
| 28 | TOIRQ | Transmit Overflow Error Status Flag<br>0: No transmit overflow error is generated.<br>1: A transmit overflow error is generated. | R/W |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 29 | TUIRQ | Transmit Underflow Error Status flag<br>0: No transmit underflow error is generated.<br>1: A transmit underflow error is generated. | R/W |
| 31:30 | — | These bits are read as 0. The write value should be 0. | R/W |

This register is configured with status flags that indicate SSIE operational state.

### IIRQ flag (Idle Mode Status Flag)

The IIRQ flag is a status flag that indicates the idle state. It indicates whether SSIE is in the idle state or communication state.

For details, see Figure 35.13 and Figure 35.14.

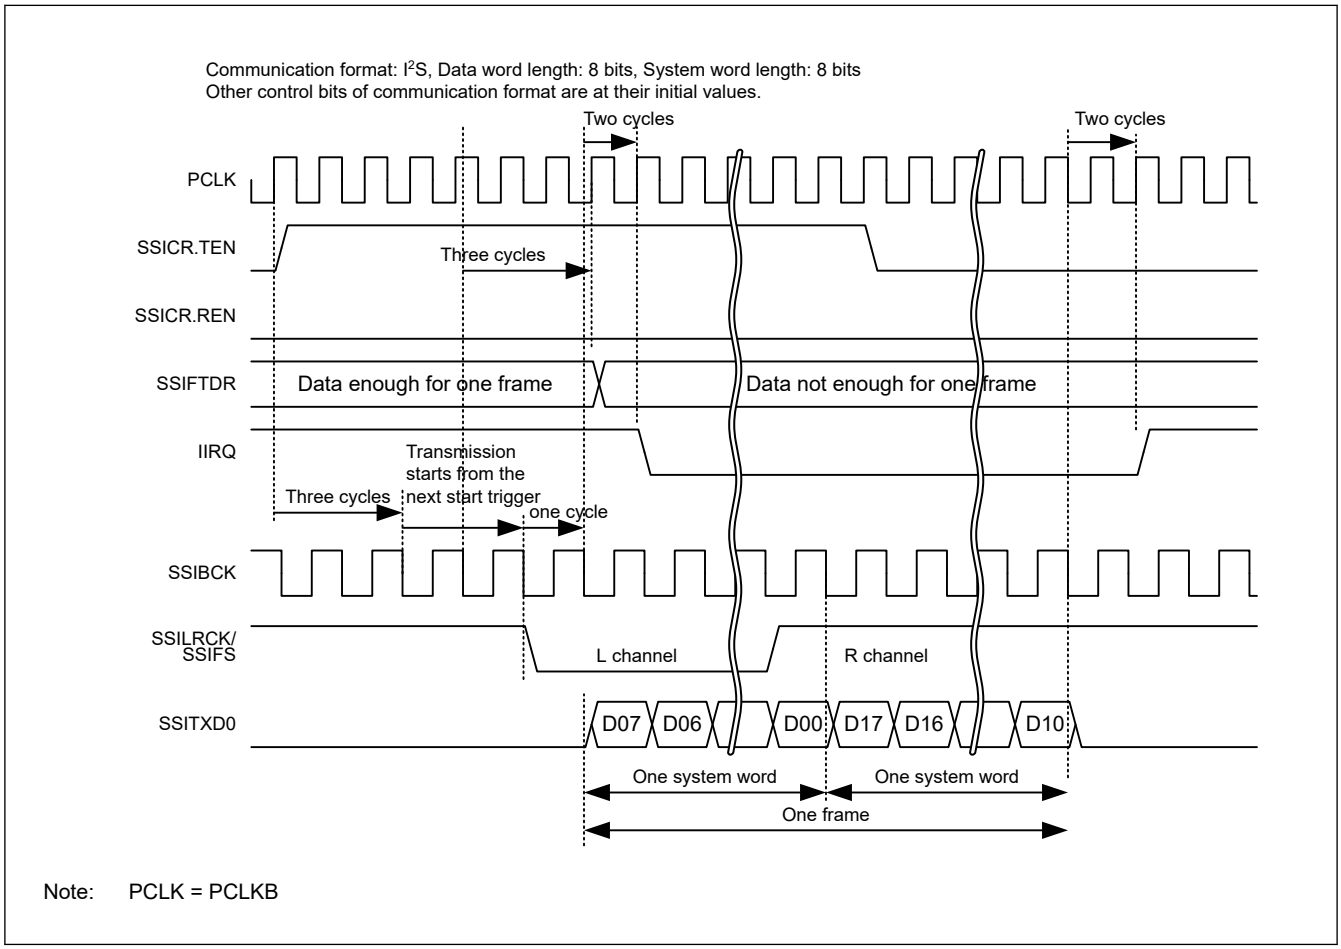

**Figure 35.13 IIRQ setting timing (transmission)**

- Transmitter (dedicated to transmission)

[Clearing condition]

While transmission was enabled (SSICR.TEN = 1 and SSICR.REN = 0), the transmit data for a transmission frame was written to the SSIFTDR register, and a start trigger was generated by the SSILRCK0/SSIFS0 signal.

[Clearing timing]

1 SSIBCK0 cycle + 2 PCLKB cycles after generation of the start trigger that is the clearing condition.

[Setting condition]

While transmission and reception were disabled (SSICR.TEN = 0 and SSICR.REN = 0), transmission of one frame was complete.

[Setting timing]

2 PCLKB cycles after the end of transmission (at a frame boundary) that is the setting condition.

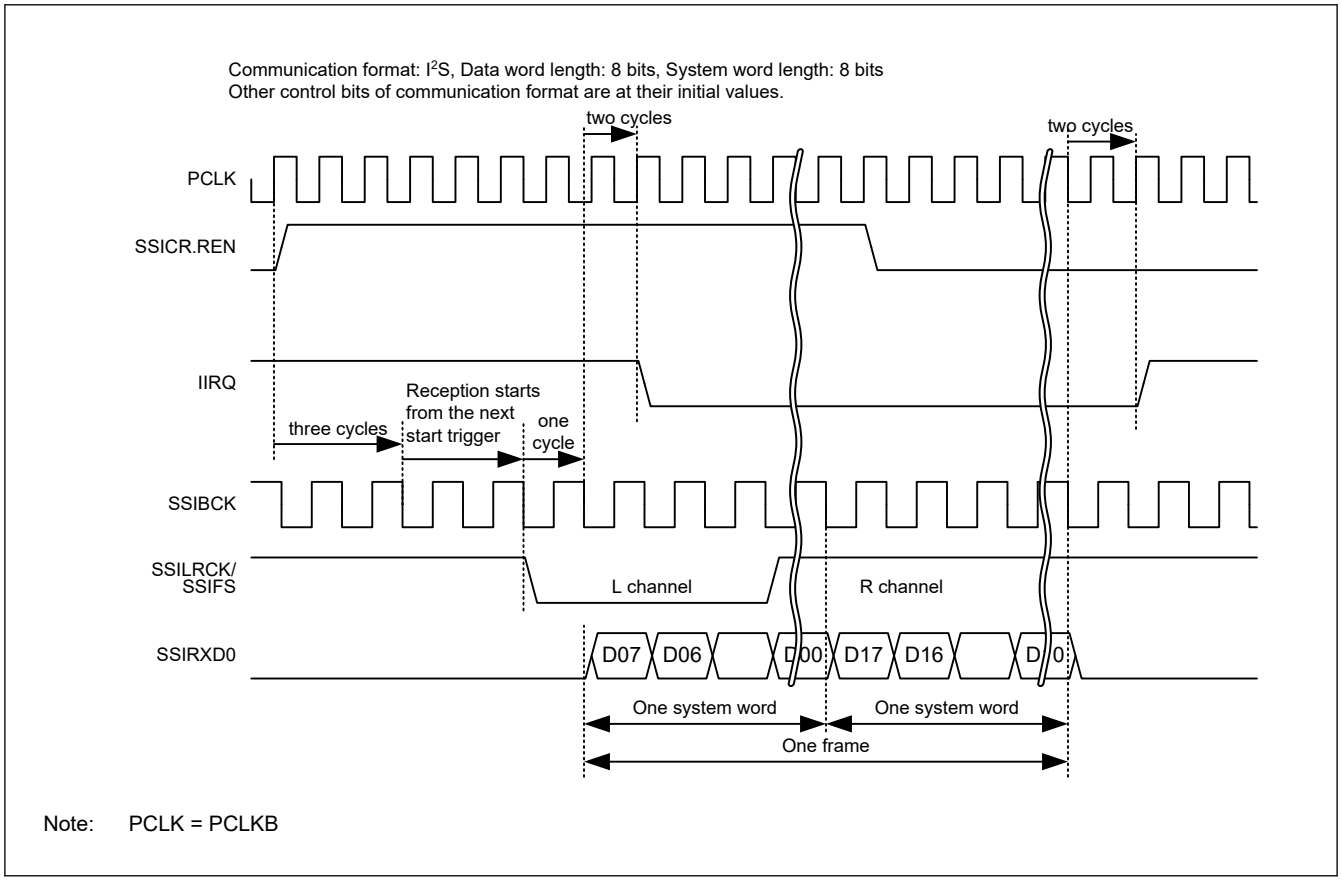

**Figure 35.14 IIRQ setting timing (reception)**

- Receiver (dedicated to reception)

[Clearing condition]

While reception was enabled (SSICR.TEN = 0 and SSICR.REN = 1), a start trigger was generated by the SSILRCK0/ SSIFS0 signal.

[Clearing timing]

1 SSIBCK0 cycle + 2 PCLKB cycles after generation of the start trigger that is the clearing condition.

[Setting condition]

While transmission and reception were disabled (SSICR.TEN = 0 and SSICR.REN = 0), reception of one frame was complete.

[Setting timing]

2 PCLKB cycles after the end of reception (at a frame boundary) that is the setting condition.

- Transceiver (transmission and reception)

[Clearing condition]

While transmission and reception were enabled (SSICR.TEN = 1 and SSICR.REN = 1), the transmit data for a transmission frame was written to the SSIFTDR register, and a start trigger is generated by the SSILRCK0/SSIFS0 signal.

[Clearing timing]

1 SSIBCK0 cycle + 2 PCLKB cycles after generation of the start trigger that is the clearing condition.

[Setting condition]

While transmission and reception were disabled (SSICR.TEN = 0 and SSICR.REN = 0), transmission of one frame was complete.

[Setting timing]

2 PCLKB cycles after the end of transmission (at a frame boundary) that is the setting condition.

### ROIRQ flag (Receive Overflow Error Status Flag)

The ROIRQ flag is a status flag that indicates a receive overflow error. This flags is set by automatic determination but it must be cleared by register access. This flag indicates that received data is supplied at a higher rate than requested. Data is not transferred from the receive shift register to SSIFRDR where a receive overflow error is generated. For the procedure to recover from the overflow error, see section 35.8.6. Error Handling. This flag is not cleared by a receive FIFO data register reset (SSIFCR.RFRST).

[Priority order for setting and clearing]

Setting is prioritized.*1

[Clearing condition]

When either of the following operations is done:

1. Writing 0 to this bit after reading 1 from this bit*2
2. Enabling communication (changing SSICR.REN from 0 to 1).

[Clearing timing]

Clearing timing corresponding to the above clearing condition:

1. When 0 is written to this bit after reading 1 from this bit (same as the timing in Figure 35.18)
2. 1 PCLKB cycle after writing 1 to SSICR.REN.*3

[Setting condition]
At completion of receiving new data while SSIFRDR is full.

[Setting timing]
3 cycles of PCLKB after reception is completed.

Note 1. This bit is cleared by a software reset (SSIFCR.SSIRST = 1). The software reset has priority over all the clearing conditions described above.

Note 2. After reading 1 from this bit, this bit is cleared when one of the following three conditions is met:
- A software reset (SSIFCR.SSIRST = 1) is done.
- After 1 has been read, writing of 0 is complete.
- 1 PCLKB cycle passes after 1 has been written to SSICR.REN.

Note 3. After communication is enabled (by changing the value of SSICR.REN bit from 0 to 1), the reception error flags (RUIRQ and ROIRQ in the SSISR register) are cleared. If, however, the SSISR register is read continuously, the cleared status of the reception error flags might be unable to be read.

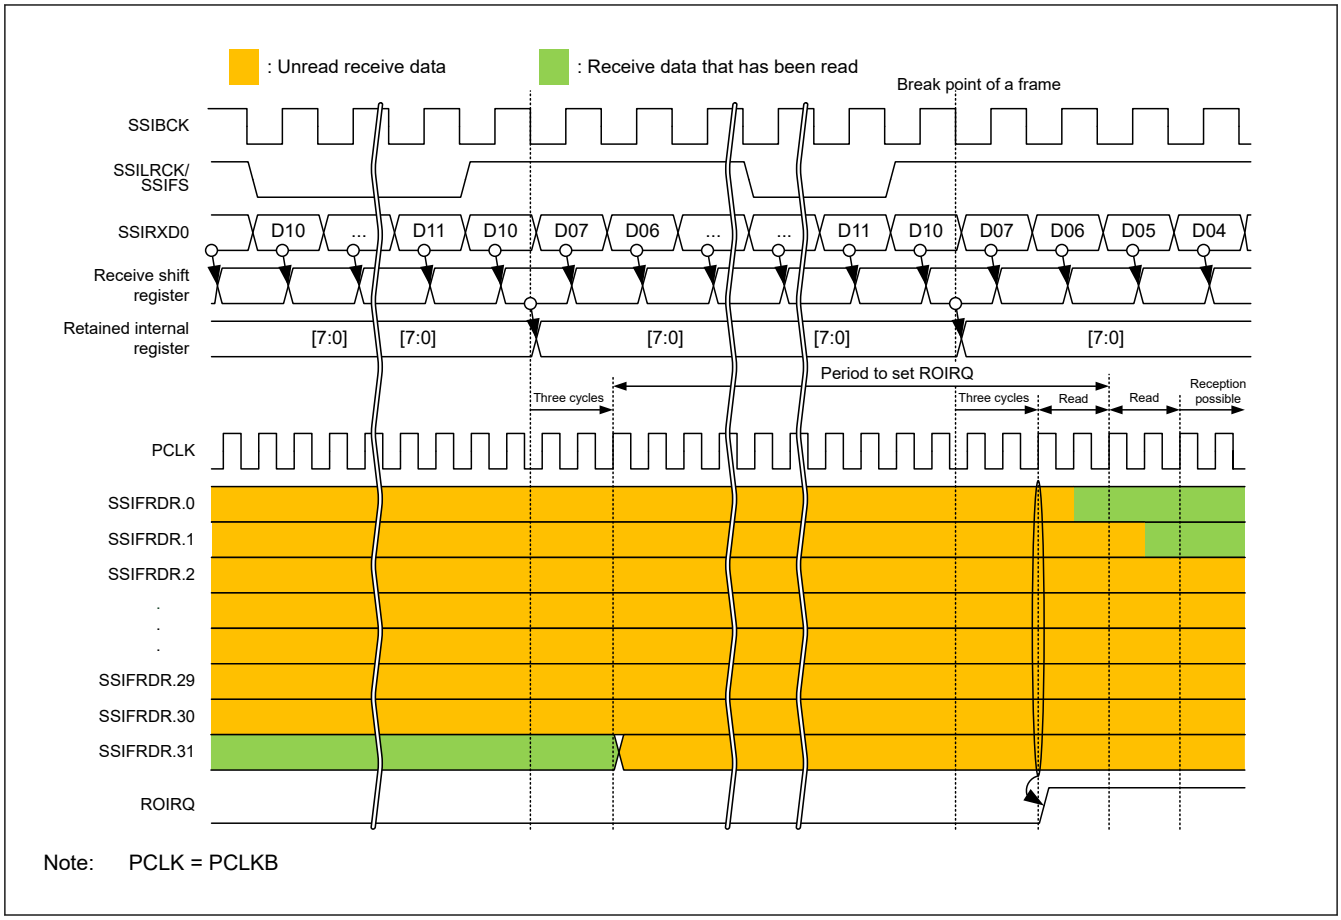

**Figure 35.15 ROIRQ setting timing**

### RUIRQ flag (Receive Underflow Error Status Flag)

The RUIRQ flag is a status flag that indicates a receive underflow error. This flags is set by automatic determination but it must be cleared by register access. This flag indicates that SSIFRDR is read while it is empty. Data read from SSIFRDR where a receive underflow error is generated is invalid. See section 35.8.6. Error Handling for the error recovery procedure. This flag is not cleared by a receive FIFO data register reset (SSIFCR.RFRST). Note, however, that this flag is not set even if the SSIFRDR register is read while the receive FIFO data register is reset (by setting SSIFCR.RFRST to 1).

[Priority order for setting and clearing]

Setting is prioritized.*1

[Clearing condition]

When either of the following operations is done:

1. Writing 0 to this bit after reading 1 from this bit*2
2. Enabling communication (changing SSICR.REN from 0 to 1).

[Clearing timing]
Clearing timing corresponding to the above clearing condition

1. When 0 is written to this bit after reading 1 from this bit (same as the timing in Figure 35.18)
2. 1 PCLKB cycle after writing 1 to SSICR.REN.*3

[Setting condition]

Reading from SSIFRDR while it is empty.

[Setting timing]

At completion of reading from SSIFRDR. See Figure 35.16.

Note 1. This bit is cleared by a software reset (SSIFCR.SSIRST = 1). The software reset has priority over all the clearing conditions described above.

Note 2. After reading 1 from this bit, this bit is cleared when one of the following three conditions is met:

- A software reset (SSIFCR.SSIRST = 1) is done.
- After 1 has been read, writing of 0 is complete.
- 1 PCLKB cycle passes after 1 has been written to SSICR.REN.

Note 3. After communication is enabled (by changing the value of SSICR.REN bit from 0 to 1), the reception error flags (RUIRQ and ROIRQ in the SSISR register) are cleared. If, however, the SSISR register is read continuously, the cleared status of the reception error flags might be unable to be read.

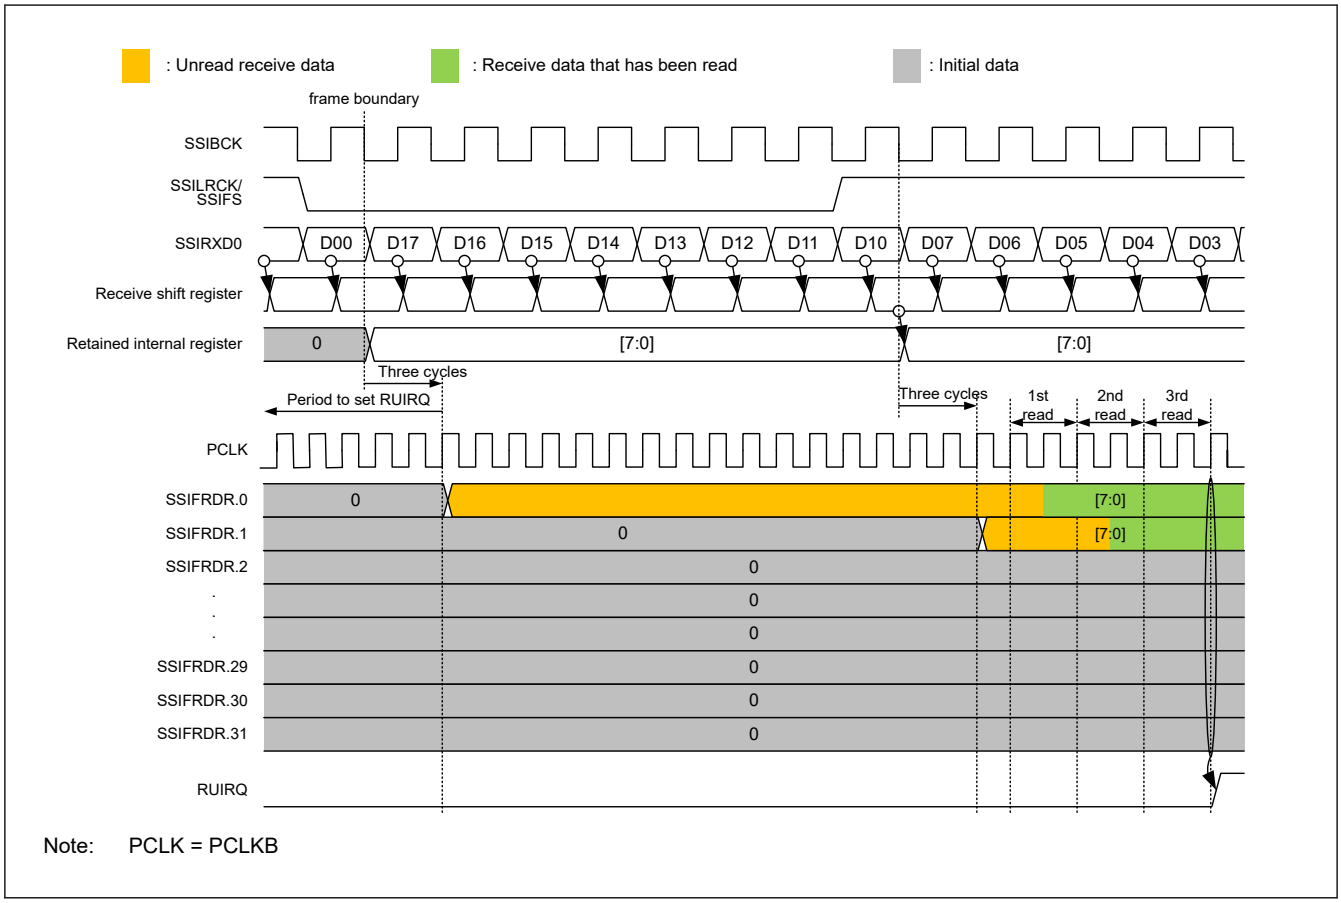

**Figure 35.16 RUIRQ setting timing**

### TOIRQ flag (Transmit Overflow Error Status Flag)

The TOIRQ flag is a status flag that indicates a transmit overflow error. This flag is set by automatic determination but it must be cleared by register access. This flag indicates that an attempt has been made to write data to the SSIFTDR register when the register is full of data. The data writing that causes a transmit overflow is ignored. For the procedure to recover from the overflow error, see section 35.8.6. Error Handling. This flag is not cleared by a transmit FIFO data register reset (SSIFCR.TFRST).

[Priority order for setting and clearing]

Setting is prioritized.*1

[Clearing condition]

When either of the following operations is done:

1. Writing 0 to this bit after reading 1 from this bit*2
2. Enabling communication (changing SSICR.TEN from 0 to 1).

[Clearing timing]

Clearing timing corresponding to the above clearing condition

1. When 0 is written to this bit after reading 1 from this bit (same as the timing in Figure 35.18)
2. 1 PCLKB cycle after writing 1 to SSICR.TEN.*3

[Setting condition]

An attempt was made to write data to the SSIFTDR register when the register is full of data.

[Setting timing]

At completion of writing to SSIFTDR. For details, see Figure 35.17.

Note 1. This bit is cleared by a software reset (SSIFCR.SSIRST = 1). The software reset has priority over all the clearing conditions described above.

Note 2. After reading 1 from this bit, this bit is cleared when one of the following three conditions is met:
- A software reset (SSIFCR.SSIRST = 1) is done.
- After 1 has been read, writing of 0 is complete.
- 1 PCLKB cycle passes after 1 has been written to SSICR.TEN.

Note 3. After communication is enabled (by changing the value of SSICR.TEN bit from 0 to 1), the transmission error flags (TOIRQ and TUIRQ in the SSISR register) are cleared. If, however, the SSISR register is read continuously, the cleared status of the transmission error flags might be unable to be read.

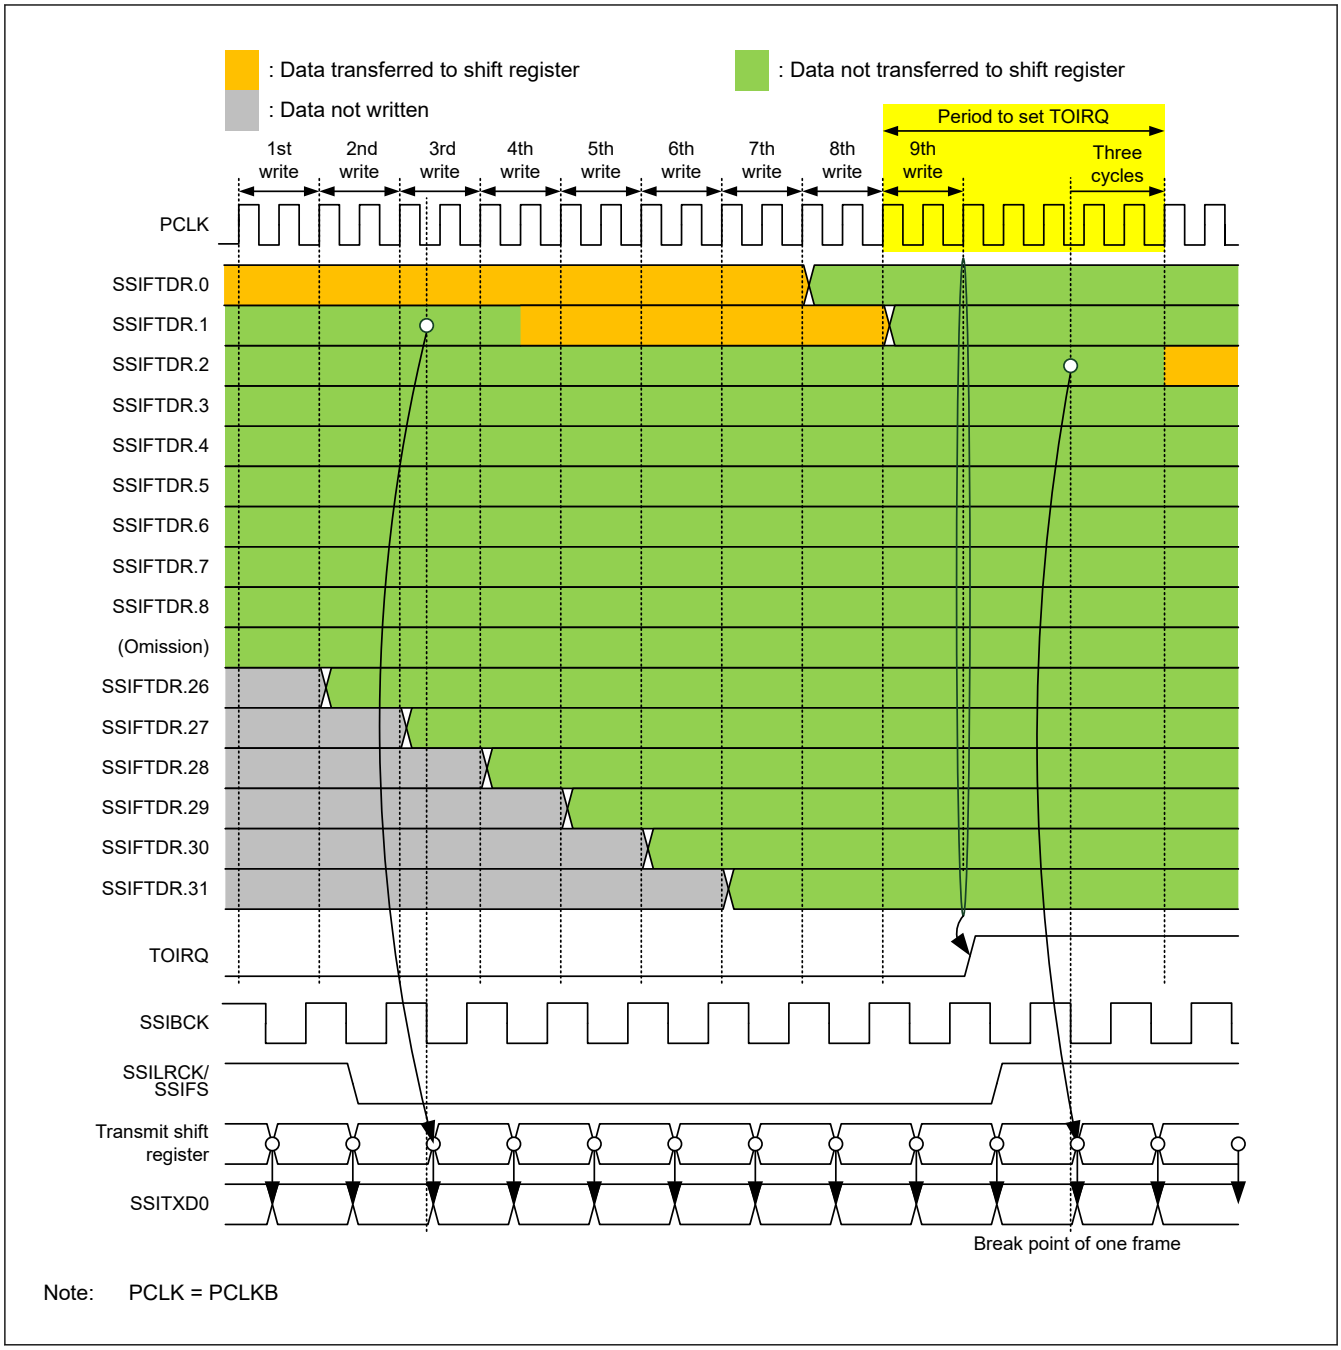

**Figure 35.17 TOIRQ setting timing**

### TUIRQ flag (Transmit Underflow Error Status flag)

The TUIRQ flag is a status flag that indicates a transmit underflow error. This flag is set by automatic determination but it must be cleared by register access. This flag indicates that writing the serial data required for a frame to SSIFTDR did not catch up with transmission of the frame. Even if this flag is cleared after it has been set, the SSITXD0 output remains to be 0. To output the data written to the transmit FIFO data register (SSIFTDR) to the SSITXD0 pin, follow the communication stop procedure in Figure 35.55 and error-handling procedure in Figure 35.56. For the procedure to recover from an error, see section 35.8.6. Error Handling. This flag is not cleared by a reset of transmit FIFO data register (by the SSIFCR.TFRST signal).

[Priority order for setting and clearing]

Setting is prioritized.*1

[Clearing condition]

When either of the following operations is done:

1. Writing 0 to this bit after reading 1 from this bit*2
2. Enabling communication (changing SSICR.TEN from 0 to 1).

[Clearing timing]

Clearing timing corresponding to the above clearing condition

1. When 0 is written to this bit after reading 1 from this bit
2. 1 PCLKB cycle after writing 1 to SSICR.TEN.*3

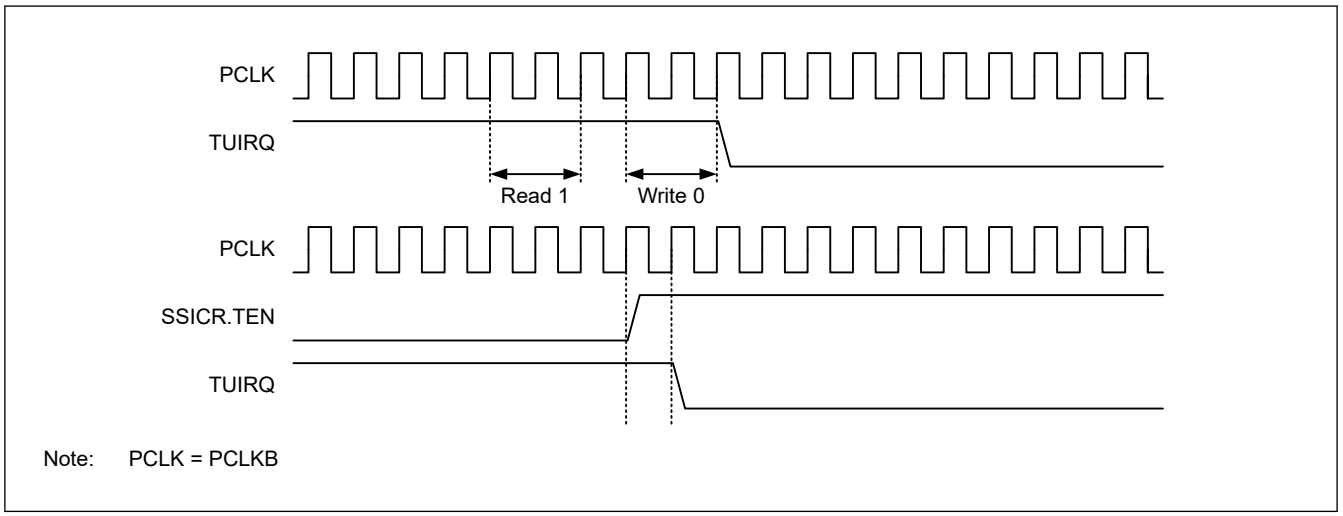

**Figure 35.18 TUIRQ clearing timing**

Note 1. This bit is cleared by a software reset (SSIFCR.SSIRST = 1). The software reset has priority over all the clearing conditions described above.

Note 2. After reading 1 from this bit, this bit is cleared when one of the following three conditions is met:
- A software reset (SSIFCR.SSIRST = 1) is done.
- After 1 has been read, writing of 0 is complete.
- 1 PCLKB cycle passes after 1 has been written to SSICR.TEN.

Note 3. After communication is enabled (by changing the value of SSICR.TEN bit from 0 to 1), the transmission error flags (TOIRQ and TUIRQ in the SSISR register) are cleared. If, however, the SSISR register is read continuously, the cleared status of the transmission error flags might be unable to be read.

[Setting condition]

When communication continues over a frame boundary, the transmit data required for the next frame has not been written to SSIFTDR. For details, see Figure 35.19 and Figure 35.20.

[Setting timing]

3 PCLKB cycles after the frame boundary. For details, see Figure 35.19.

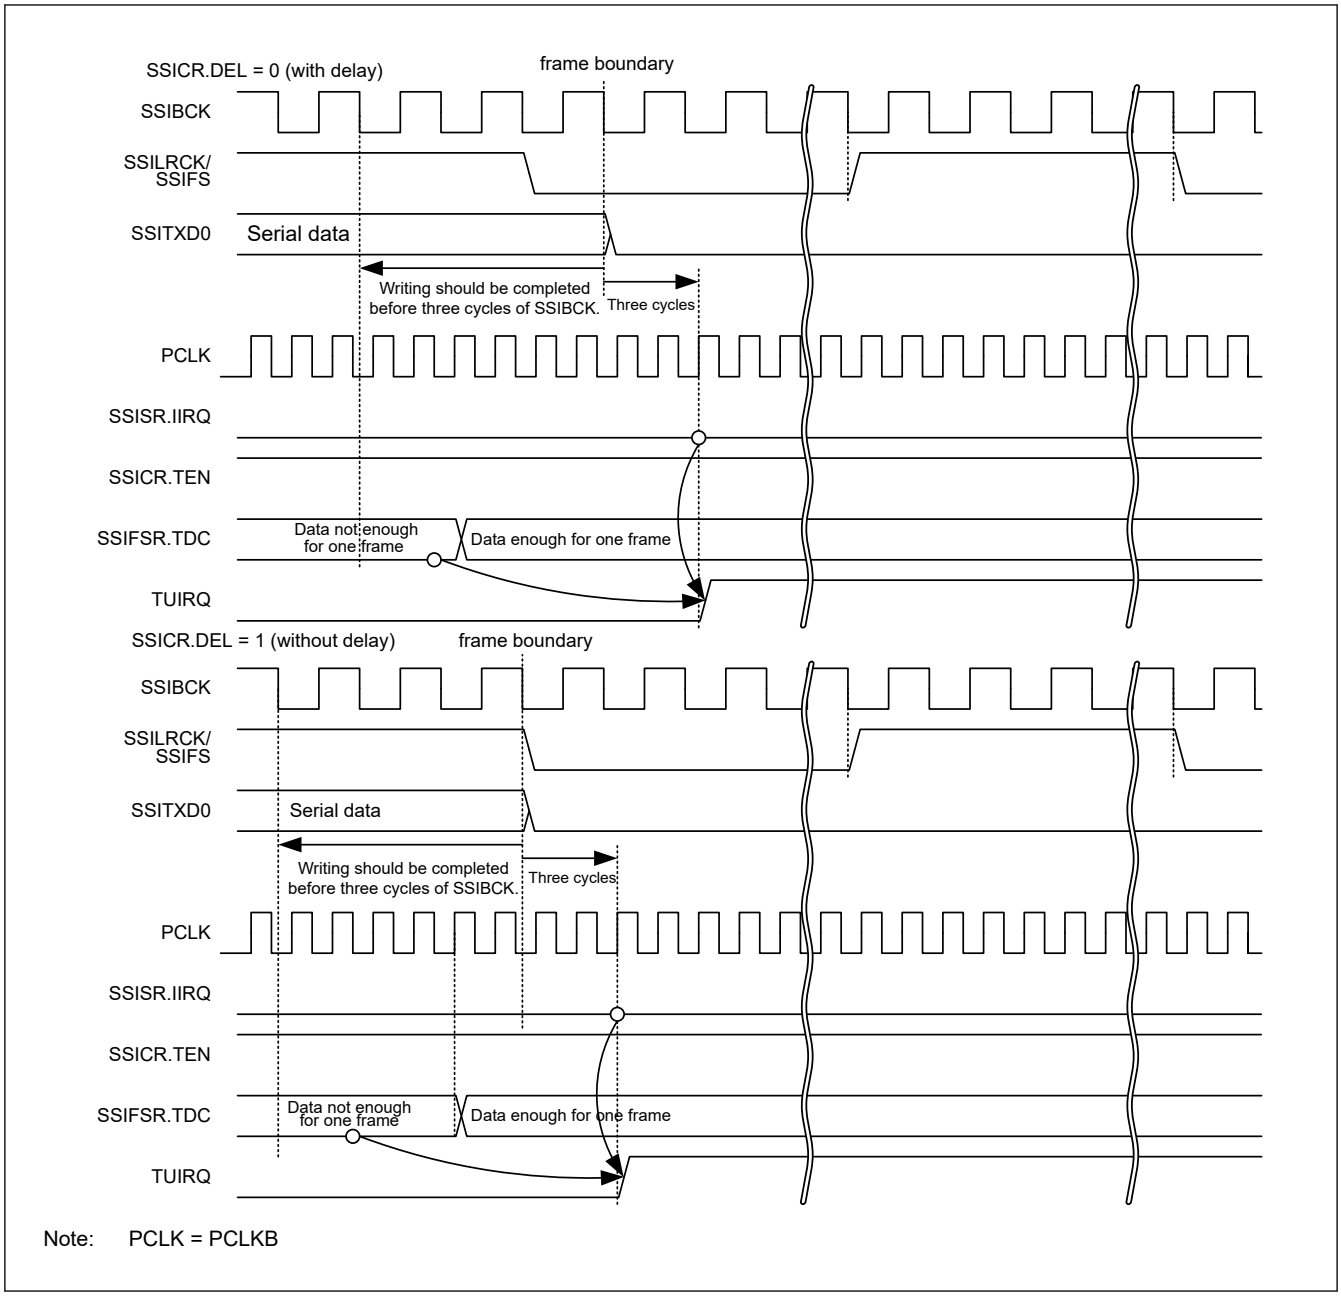

**Figure 35.19 TUIRQ setting timing (when communication continues)**

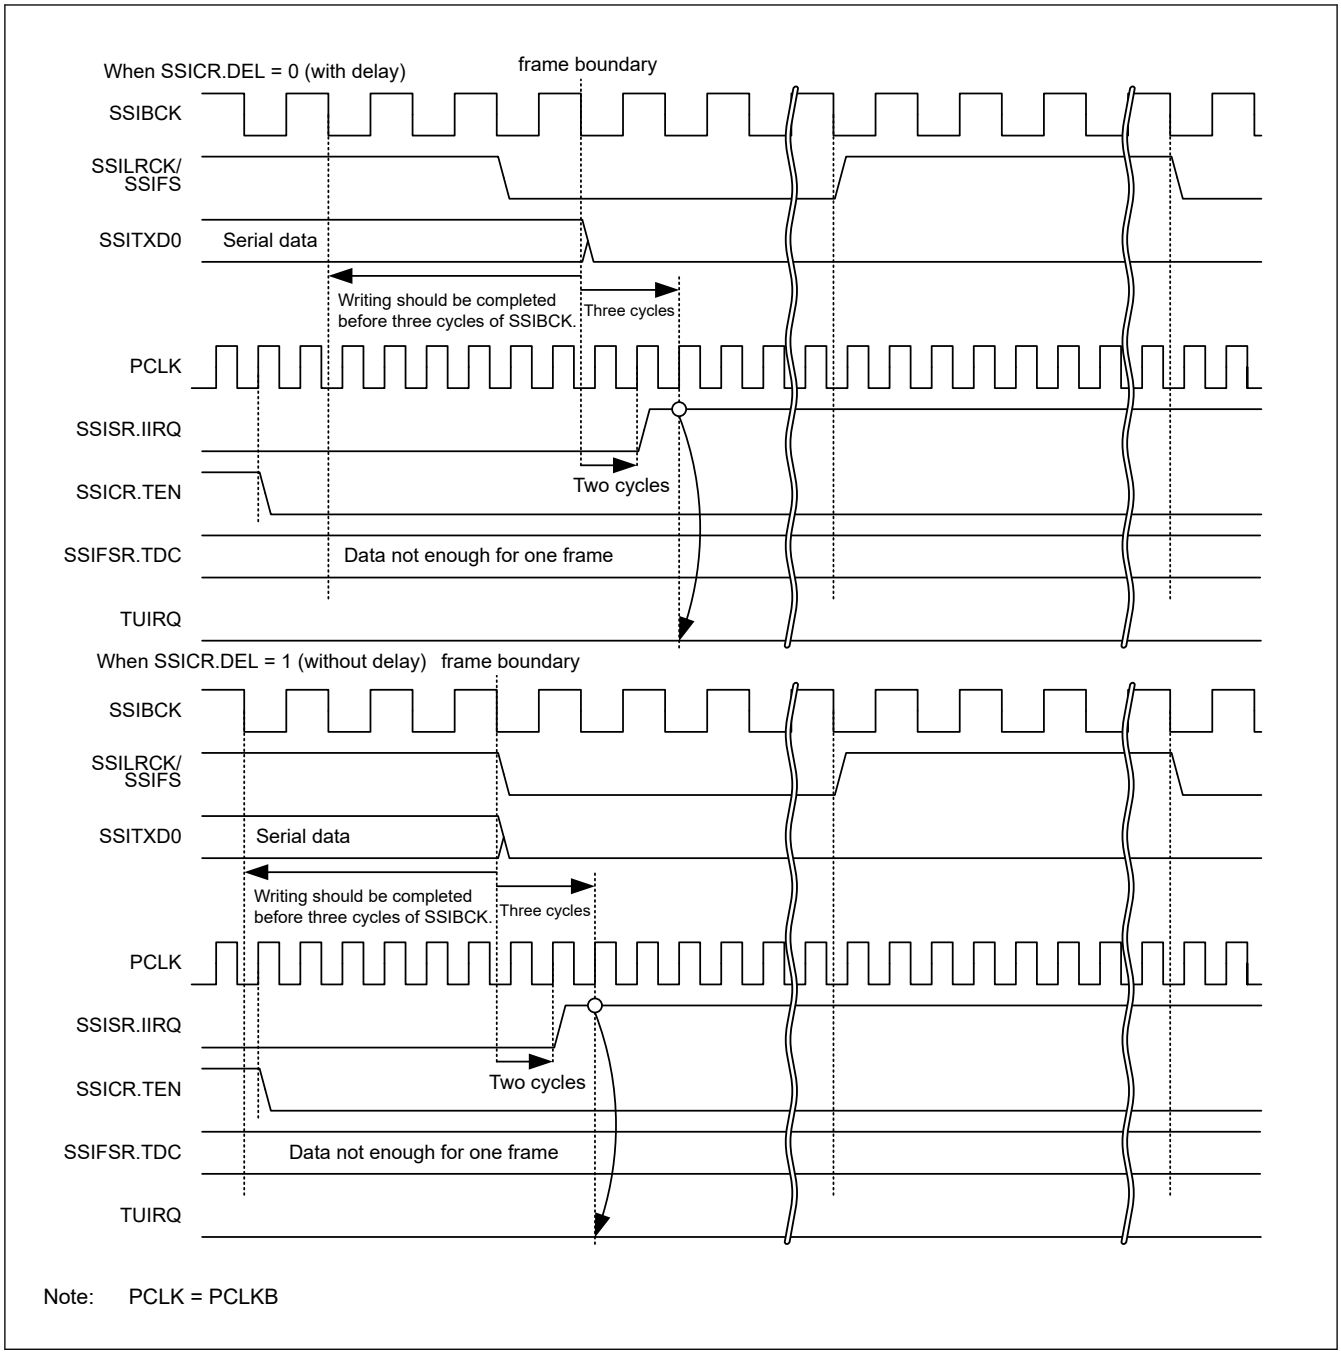

**Figure 35.20 TUIRQ setting timing (when communication stops)**

## 35.4.3 SSIFCR : FIFO Control Register

Base address: SSIE0 = 0x4009_D000

Offset address: 0x10

| Bit position: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | AUCKE | — | — | — | — | — | — | — | — | — | — | — | — | — | — | SSIRST |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit position: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | — | BSW | — | — | — | — | — | — | — | TIE | RIE | TFRST | RFRST |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 0 | RFRST | Receive FIFO Data Register Reset*1<br>0: Clears a receive data FIFO reset condition<br>1: Sets a receive data FIFO reset condition | R/W |
| 1 | TFRST | Transmit FIFO Data Register Reset*1<br>0: Clears a transmit data FIFO reset condition<br>1: Sets a transmit data FIFO reset condition | R/W |
| 2 | RIE | Receive Data Full Interrupt Output Enable<br>0: Disables receive data full interrupts<br>1: Enables receive data full interrupts | R/W |
| 3 | TIE | Transmit Data Empty Interrupt Output Enable<br>0: Disables transmit data empty interrupts<br>1: Enables transmit data empty interrupts | R/W |
| 10:4 | — | These bits are read as 0. The write value should be 0. | R/W |
| 11 | BSW | Byte Swap Enable*1<br>0: Disables byte swap<br>1: Enables byte swap | R/W |
| 15:12 | — | These bits are read as 0. The write value should be 0. | R/W |
| 16 | SSIRST | Software Reset<br>0: Clears a software reset condition<br>1: Sets a software reset condition | R/W |
| 30:17 | — | These bits are read as 0. The write value should be 0. | R/W |
| 31 | AUCKE | AUDIO_MCK Enable in Master-mode Communication*1<br>0: Disables supply of AUDIO_MCK<br>1: Enables supply of AUDIO_MCK | R/W |

Note 1. Writing to these bits while SSIE is in a communication state (SSISR.IIRQ = 0) is prohibited. If the value of these bits is changed by rewriting, subsequent operation is unpredictable.

This register sets a software reset, byte swap, and enable/disable of interrupt requests.

### RFRST bit (Receive FIFO Data Register Reset)

The RFRST bit sets a software reset of the receive FIFO data register (SSIFRDR). Writing 1 to this bit initializes the internal state related to SSIFRDR. The register bits subject to the software reset triggered by this bit are indicated by shading in Table 35.5. Because this bit is not automatically cleared after it has been set, write 0 to this bit to release the register bits from the software reset. After writing 0 to this bit, be sure to check that this bit is 0 before starting the next procedural step.

This bit is subject to the software reset by the SSIRST bit. Because the software reset by the SSIRST bit has priority over the reset by this bit, setting this bit is ignored when the SSIRST bit is set.

**Table 35.5 Bits subject to software reset by the RFRST bit**

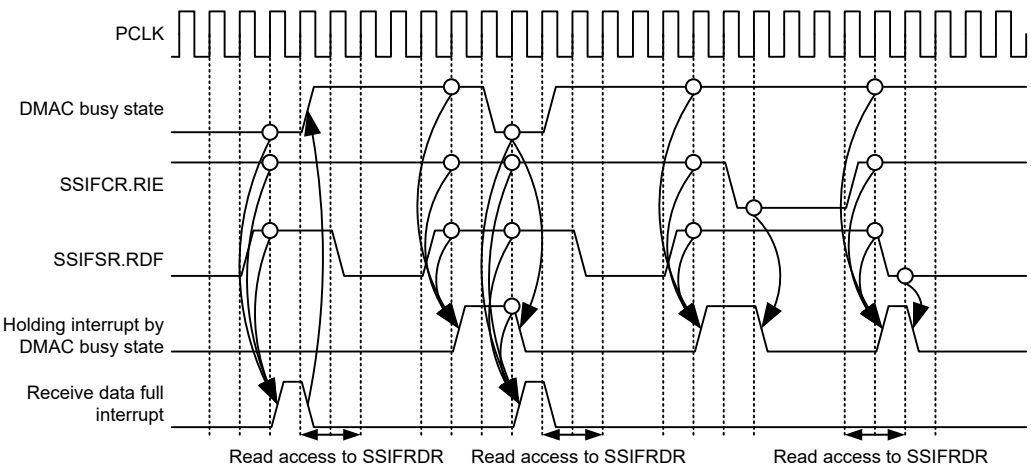
### TFRST bit (Transmit FIFO Data Register Reset)

The TFRST bit sets a software reset of the transmit FIFO data register (SSIFTDR). Writing 1 to this bit initializes the internal state related to SSIFTDR. The register bits subject to the software reset triggered by this bit are indicated by shading in Table 35.6. Because this bit is not automatically cleared after it has been set, write 0 to this bit to release the register bits from the software reset. After writing 0 to this bit, be sure to check that this bit is 0 before starting the next procedural step.

This bit is subject to the software reset by the SSIRST bit. Because the software reset by the SSIRST bit has priority over the reset by this bit, setting this bit is ignored when the SSIRST bit is set.

**Table 35.6 Bits subject to software reset by the TFRST bit (1 of 2)**



| Symbol | Address (BASE+) | | +0 | | | | | | | | +1 | | | | | | | |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | | | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

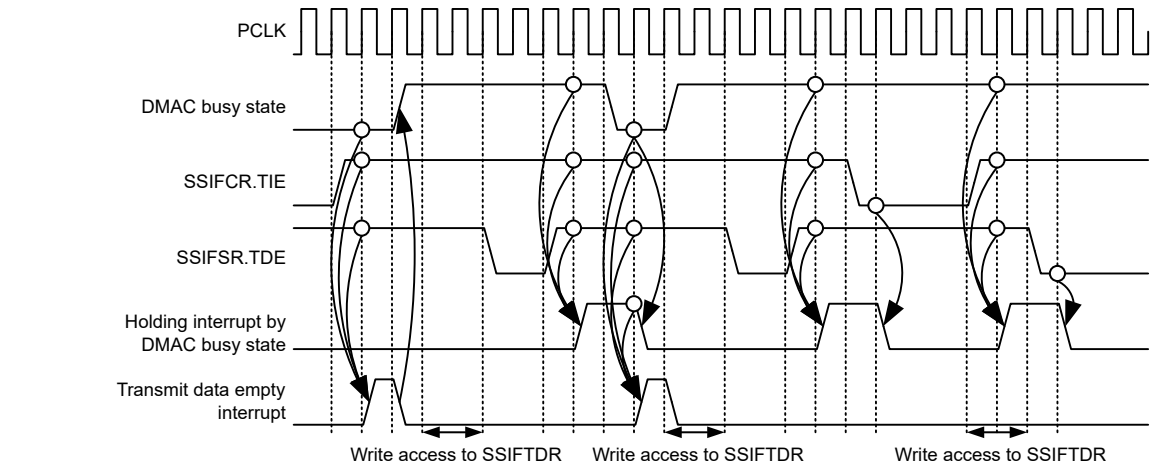
| | | +2 | — | — | — | — | — | — | BCKASTP | LRCONT | — | — | — | — | — | — | OMOD[1:0] | |
| SSISCR | 0x24 | +0 | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — |
| | | +2 | — | — | — | TDES[4:0] | | | | | — | — | — | RDFS[4:0] | | | | |

### RIE bit (Receive Data Full Interrupt Output Enable)

The RIE bit enables/disables output of receive data full interrupts. Use a receive data full interrupt as an interrupt to trigger data reading from the receive FIFO data register. Write 1 to this bit after specifying the setting condition for receive data full interrupt (by using the SSISCR.RDFS bit). Figure 35.21 shows the timing of generating the receive data full interrupt.



Note: PCLK = PCLKB

**Figure 35.21 Timing of receive data full interrupt**

### TIE bit (Transmit Data Empty Interrupt Output Enable)

The TIE bit enables/disables output of transmit data empty interrupts. Use a transmit data empty interrupt as an interrupt to trigger data writing to the transmit FIFO data register. Write 1 to this bit after specifying the setting condition for transmit data empty interrupt (by using the SSISCR.TDES[4:0] bits). Figure 35.22 shows the timing of generating the transmit data empty interrupt.

Note: PCLK = PCLKB

**Figure 35.22 Timing of transmit data empty interrupt**

### BSW bit (Byte Swap Enable)

The BSW bit enables/disables byte swap of register access for the transmit FIFO data register (SSIFTDR) and the receive FIFO data register (SSIFRDR). This bit is valid only with 16-bit access or 32-bit access to SSIFTDR and SSIFRDR. For details, see Figure 35.23.

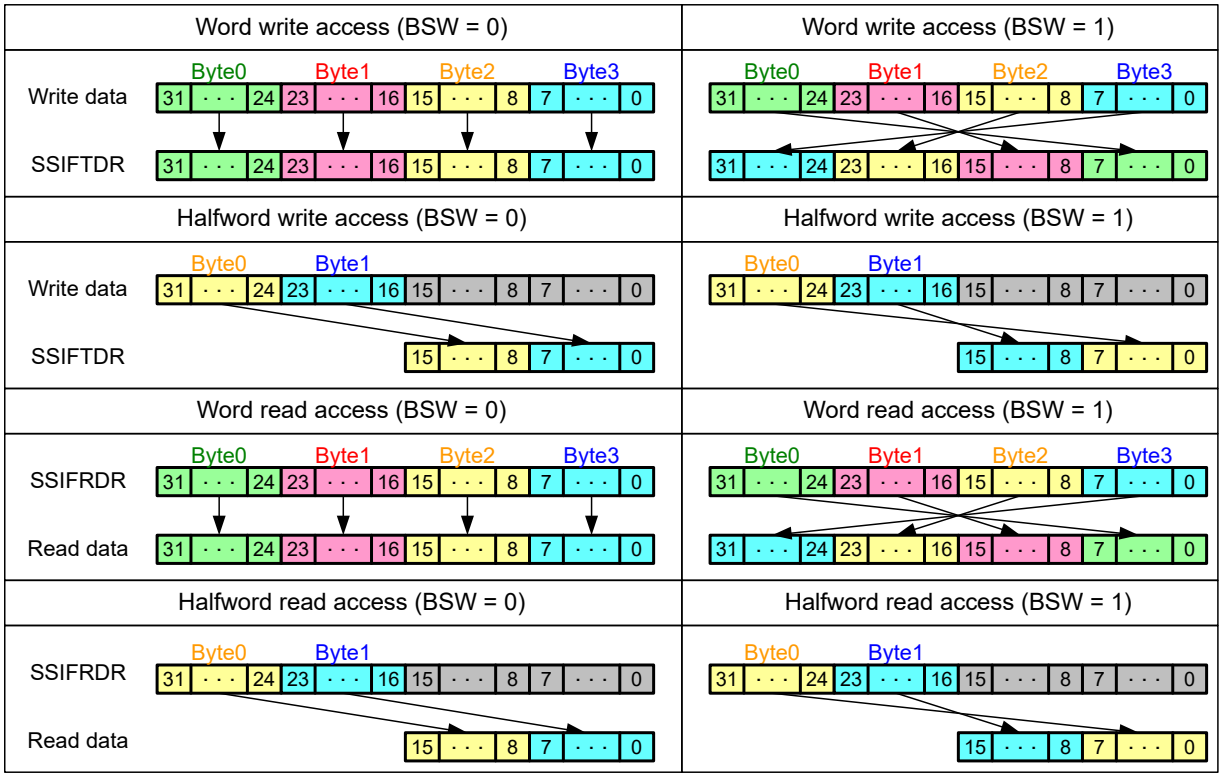


**Figure 35.23 Operation example of byte swap**

### SSIRST bit (Software Reset)

The SSIRST bit sets a software reset of SSIE. Writing 1 to this bit initializes the internal state of SSIE. The register bits subject to the software reset triggered by this bit are indicated by shading in Table 35.7. Because this bit is not automatically

cleared after it has been set, write 0 to this bit to release the register bits from the software reset. After writing 0 to this bit, be sure to check that this bit is 0 before starting the next procedural step.

To stop communication of SSIE immediately, after turning off the peripheral functions, write 1 to this bit. Initialization by a software reset is performed without any relation with the bit clock.

**Table 35.7 Bits subject to software reset by the SSIRST bit**

| Symbol | Address (BASE+) | | +0 | | | | | | | | +1 | | | | | | | |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | | | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

| | | +2 | — | — | — | TDES[4:0] | | | | | — | — | — | RDFS[4:0] | | | | |

### AUCKE bit (AUDIO_MCK Enable in Master-mode Communication)

The AUCKE bit enables/disables supply to AUDIO_MCK while in master-mode communication (MST = 1).

Changing the value of this bit must be performed only after specifying the settings related to AUDIO_MCK (by using the CKS, MST, BCKP, and CKDV bits in the SSICR register).

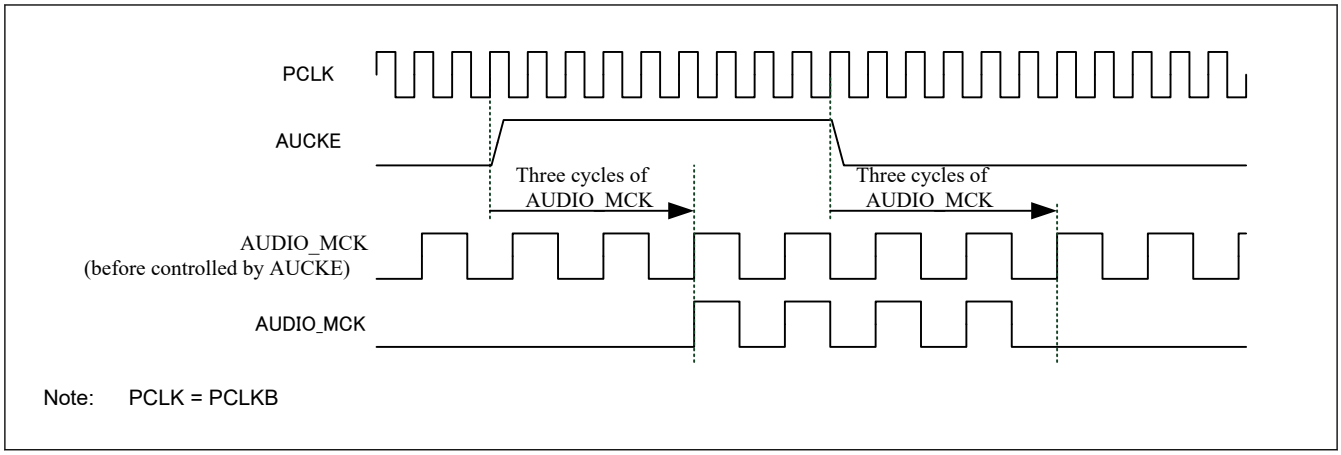

**Figure 35.24 Stop/resume of AUDIO_MCK**

Note: In slave-mode communication (SSICR.MST = 0), SSIE needs supply of SSIBCK0. To stop BCK on the master side, make sure that SSIE is in the idle state (SSISR.IIRQ = 1). If BCK is stopped before SSIE becomes idle, take the procedure to start communication in Figure 35.51 or wait for an idle state by taking the procedure to resume communication in Figure 35.57.

In master-mode communication (SSICR.MST = 1), SSIE operates with the audio clock (AUDIO_MCK). To stop SSIE completely, make sure that SSIE is in the idle state (SSISR.IIRQ = 1) and then write 0 to SSIFCR.AUCKE. If 0 is written to SSIFCR.AUCKE before SSIE becomes idle, take the procedure to start communication in Figure 35.51.

Figure 35.25 and Figure 35.26 show the timings of signal operation in the period from setting this bit to 1 to the output to the SSIBCK0 pin.

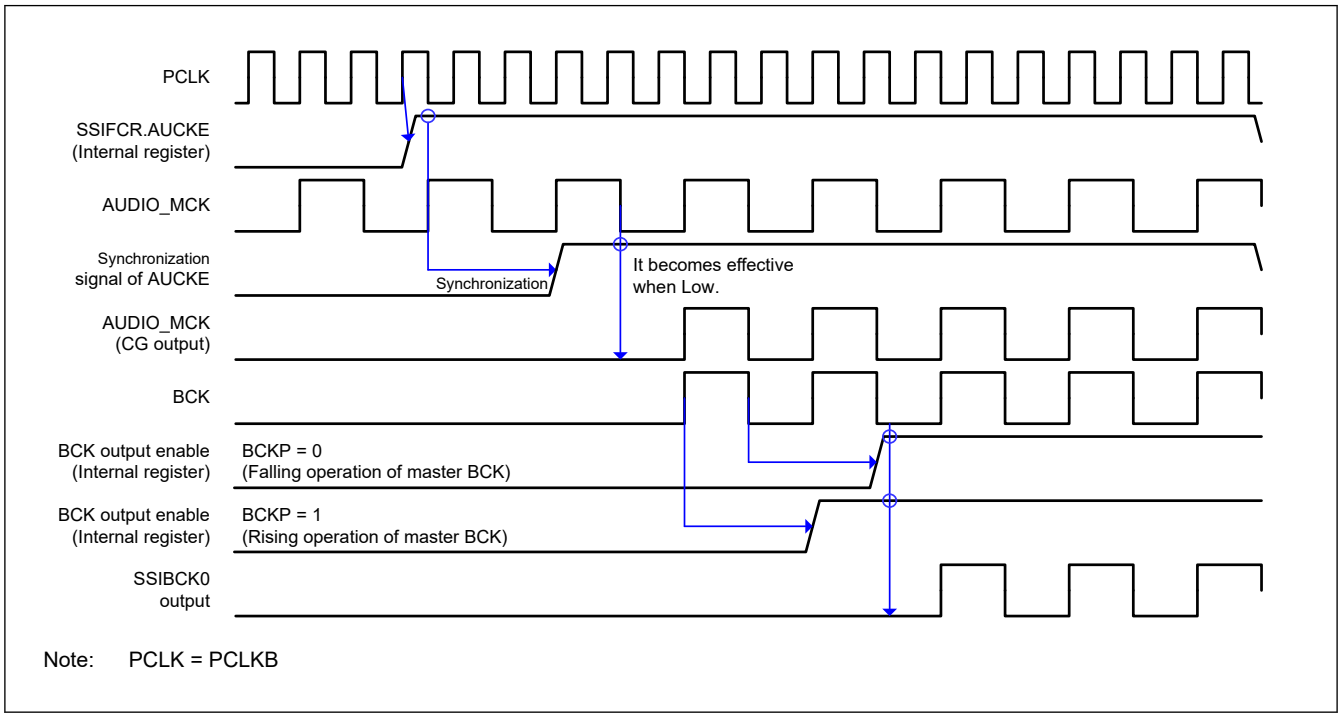

**Figure 35.25 Timing diagram for the operation from system reset to start of master-mode communication**

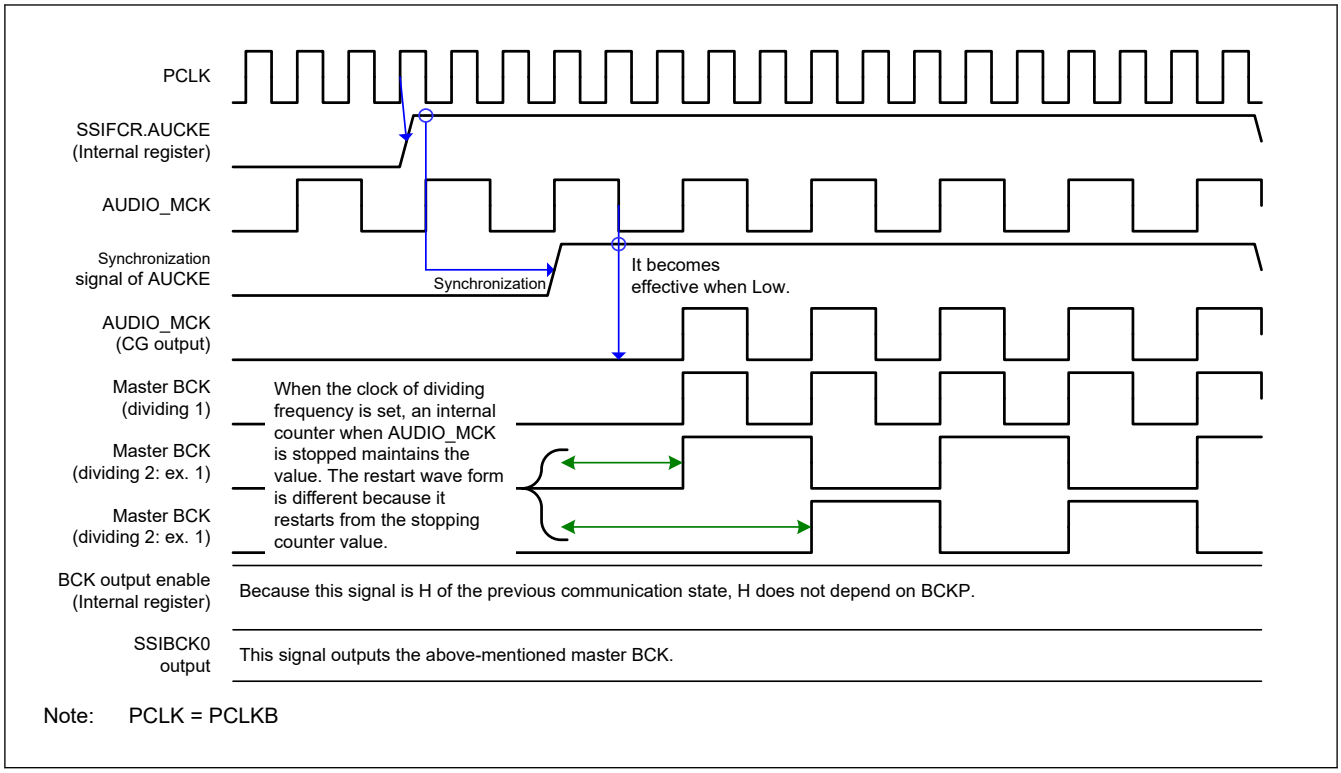

**Figure 35.26 Timing diagram for the operation from stop of communication to start of master-mode communication**

Note: If the supply of AUDIO_MCK stops, the value of the SSIBCK0 pin is held. Therefore, the SSIBCK0 signal might stop in the H (high level) state.

## 35.4.4 SSIFSR : FIFO Status Register

Base address: SSIE0 = 0x4009_D000

Offset address: 0x14

| 29:24 | TDC[5:0] | Transmit Data Count<br>Number of valid data stored in the transmit FIFO data register | R |
| 31:30 | — | These bits are read as 0. The write value should be 0. | R/W |

This register is configured with status flags that indicate the status of the transmit FIFO data register and the receive FIFO data register.

### RDF flag (Receive Data Full Flag)

The RDF flag indicates that the receive FIFO data register (SSIFRDR) has unread received data not less than the amount set with the SSISCR.RDFS bit plus one. This flag is set by automatic determination but it must be cleared by register access.

[Priority order for setting and clearing]

Clearing is prioritized.

[Clearing condition]

Either of the following two:*1

1. Writing 0 to this bit after reading 1 from this bit (CPU operation)*2
2. Last access (DTC/DMAC operation) to read data from SSIFRDR by an interrupt routine using the DTC and DMAC.

[Clearing timing]

Clearing timing corresponding to the above clearing condition

1. When 0 is written to this bit after reading 1 from this bit (same as the timing in Figure 35.18)
2. After the PCLKB cycle in which the last access instruction is issued to read data from SSIFRDR by an interrupt routine using the DTC and DMAC.

[Setting condition]

SSIFRDR has free space not less than the amount set with the SSISCR.RDFS bits plus one.

[Setting timing]

At completion of transfer from the shift register that results in SSIFRDR having data not less than the amount set with the SSISCR.RDFS bits plus one.

Note 1. These bits are cleared by a software reset (SSIFCR.SSIRST = 1) and receive FIFO data register reset (SSIFCR.RFRST = 1). Reset conditions available for these bits are the software reset and receive FIFO data register reset as well as the clearing conditions described above.

Note 2. After reading 1 from this bit, this bit is cleared when one of the following four conditions is met:
- A software reset is done (SSIFCR.SSIRST = 1).
- A receive FIFO data register reset is done (SSIFCR.RFRST = 1).
- After 1 has been read, writing of 0 is complete.
- Last access is performed to read data from SSIFRDR by an interrupt routine using the DTC and DMAC.

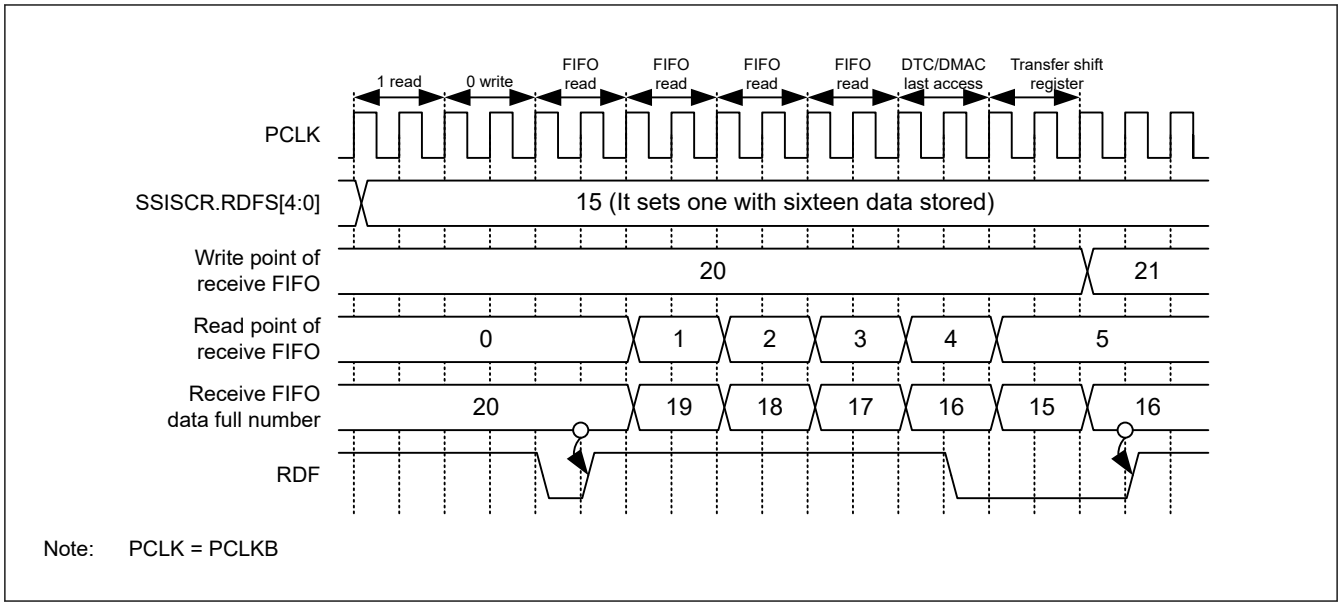

**Figure 35.27 Timing diagram for setting and clearing RDF**

### RDC[5:0] bits (Receive Data Count)

The RDC[5:0] bits indicate the number of valid data that are stored in the receive FIFO data register (SSIFRDR). With these bits as 0x00, there is no received data. With 0x20, the register is filled with received data and there is no free space.

### TDE flag (Transmit Data Empty Flag)

The TDE flag indicates that the transmit FIFO data register (SSIFTDR) has free space not less than the amount set with the SSISCR.TDES bits plus one. This flag is set by automatic determination but it must be cleared by register access.

[Priority order for setting and clearing]

Clearing is prioritized.*1

[Clearing condition]

Either of the following two:

1. Writing 0 to this bit after reading 1 from this bit (CPU operation)*2
2. Last access (DTC/DMAC operation) to write data to SSIFTDR by an interrupt routine using the DTC and DMAC.

[Clearing timing]

Clearing timing corresponding to the above clearing condition

1. When 0 is written to this bit after reading 1 from this bit (same as the timing in Figure 35.18)
2. Last access (DTC/DMAC operation) to write data to SSIFTDR by an interrupt routine using the DTC and DMAC.

[Setting condition]

SSIFTDR has free space not less than the amount set with the SSISCR.TDES bits plus one.

[Setting timing]

While operating on PCLKB, SSIFTDR is found to have free space not less than “size set in the SSISCR.TDES bits + 1.”

Note 1. This bit is cleared by a software reset (SSIFCR.SSIRST = 1) and transmit FIFO data register reset (SSIFCR.TFRST = 1). The software reset and transmit FIFO data register reset have priority over all the clearing conditions described above.

Note 2. After reading 1 from this bit, this bit is cleared when one of the following four conditions is met:
- A software reset is done (SSIFCR.SSIRST = 1).
- A transmit FIFO data register reset is done (SSIFCR.TFRST = 1).
- After 1 has been read, writing of 0 is complete.
- Last access is performed to write data to SSIFTDR by an interrupt routine using the DTC and DMAC.

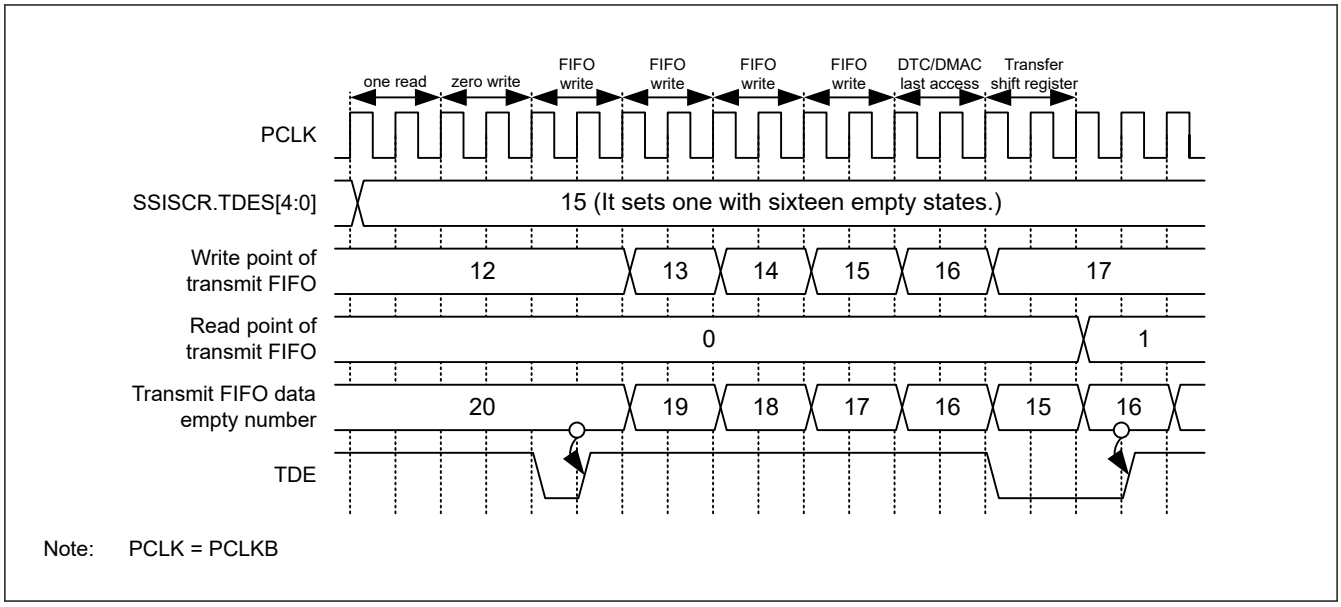

**Figure 35.28 Timing diagram for setting and clearing TDE**

### TDC[5:0] bits (Transmit Data Count)

The TDC[5:0] bits indicate the number of valid data that are stored in the transmit FIFO data register (SSIFTDR). With these bits as 0x00, there is no data to be transmitted. With 0x20, there is no space to write data.

## 35.4.5 SSIFTDR : Transmit FIFO Data Register

Base address: SSIE0 = 0x4009_D000

Offset address: 0x18

| Bit position: | 31 | | | | | | | | | | | | | | | | | | | | | | | | | | | | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | SSIFTDR[31:0] | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 31:0 | SSIFTDR[31:0] | Transmit FIFO Data | W |

This register stores data to be serially transmitted. 0 is returned when this register is read.

When you use this register for transmission, specify data writing to this register as the DTC/DMAC operation that is triggered by a transmit data empty interrupt. Determine the access size to this register according to the data word length to be communicated in Table 35.8.

**Table 35.8 Register access restriction to FIFOs (1 of 2)**

| Access Size | | | | |
|---|---|---|---|---|
| SSICR.DWL[2:0] | Data Word Length | Byte | Halfword | Word |
| 000b | 8 | ✓ | — | — |
| 001b | 16 | — | ✓ | — |
| 010b | 18 | — | — | ✓ |
| 011b | 20 | — | — | ✓ |
| 100b | 22 | — | — | ✓ |
| 101b | 24 | — | — | ✓ |
| 110b | 32 | — | — | ✓ |

**Table 35.8 Register access restriction to FIFOs (2 of 2)**

| Access Size | | | | |
|---|---|---|---|---|
| **SSICR.DWL[2:0]** | **Data Word Length** | **Byte** | **Halfword** | **Word** |
| 111b | Setting prohibited | — | — | — |

Figure 35.29 shows register access to the transmit FIFO data register.

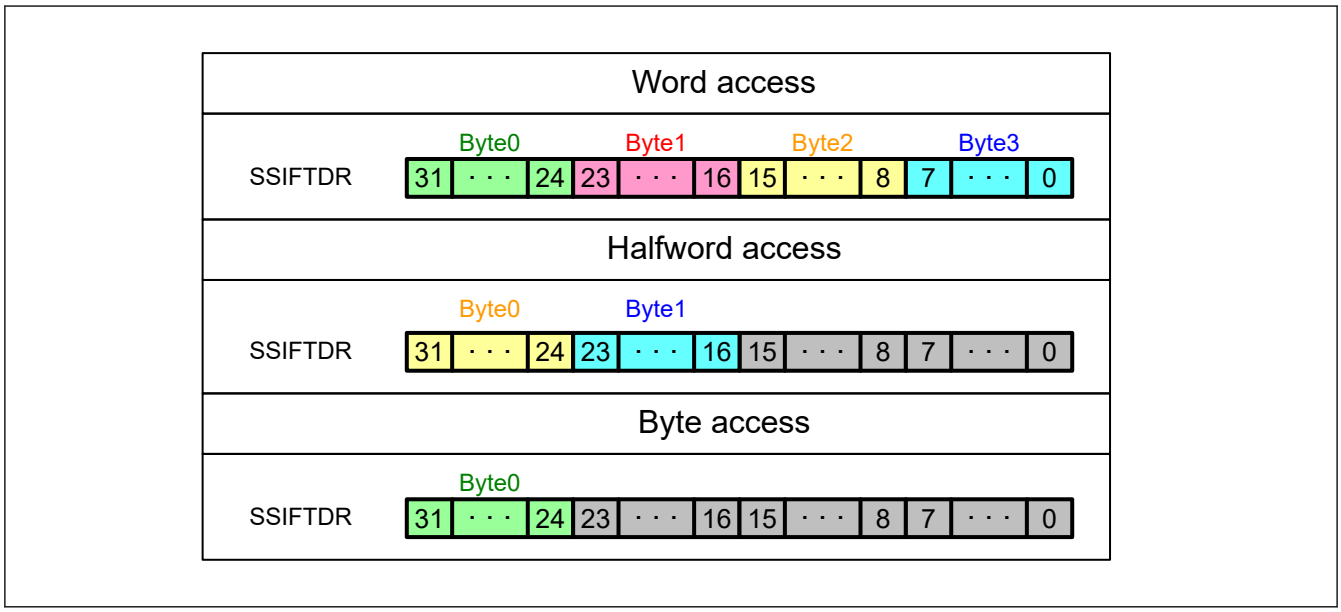

**Figure 35.29 Example of register access to the transmit FIFO data register**

Figure 35.30 shows the configurations and operation examples of the transmit FIFO data register and transmit shift register. The configurations are for storing data to FIFO and not related with communication.

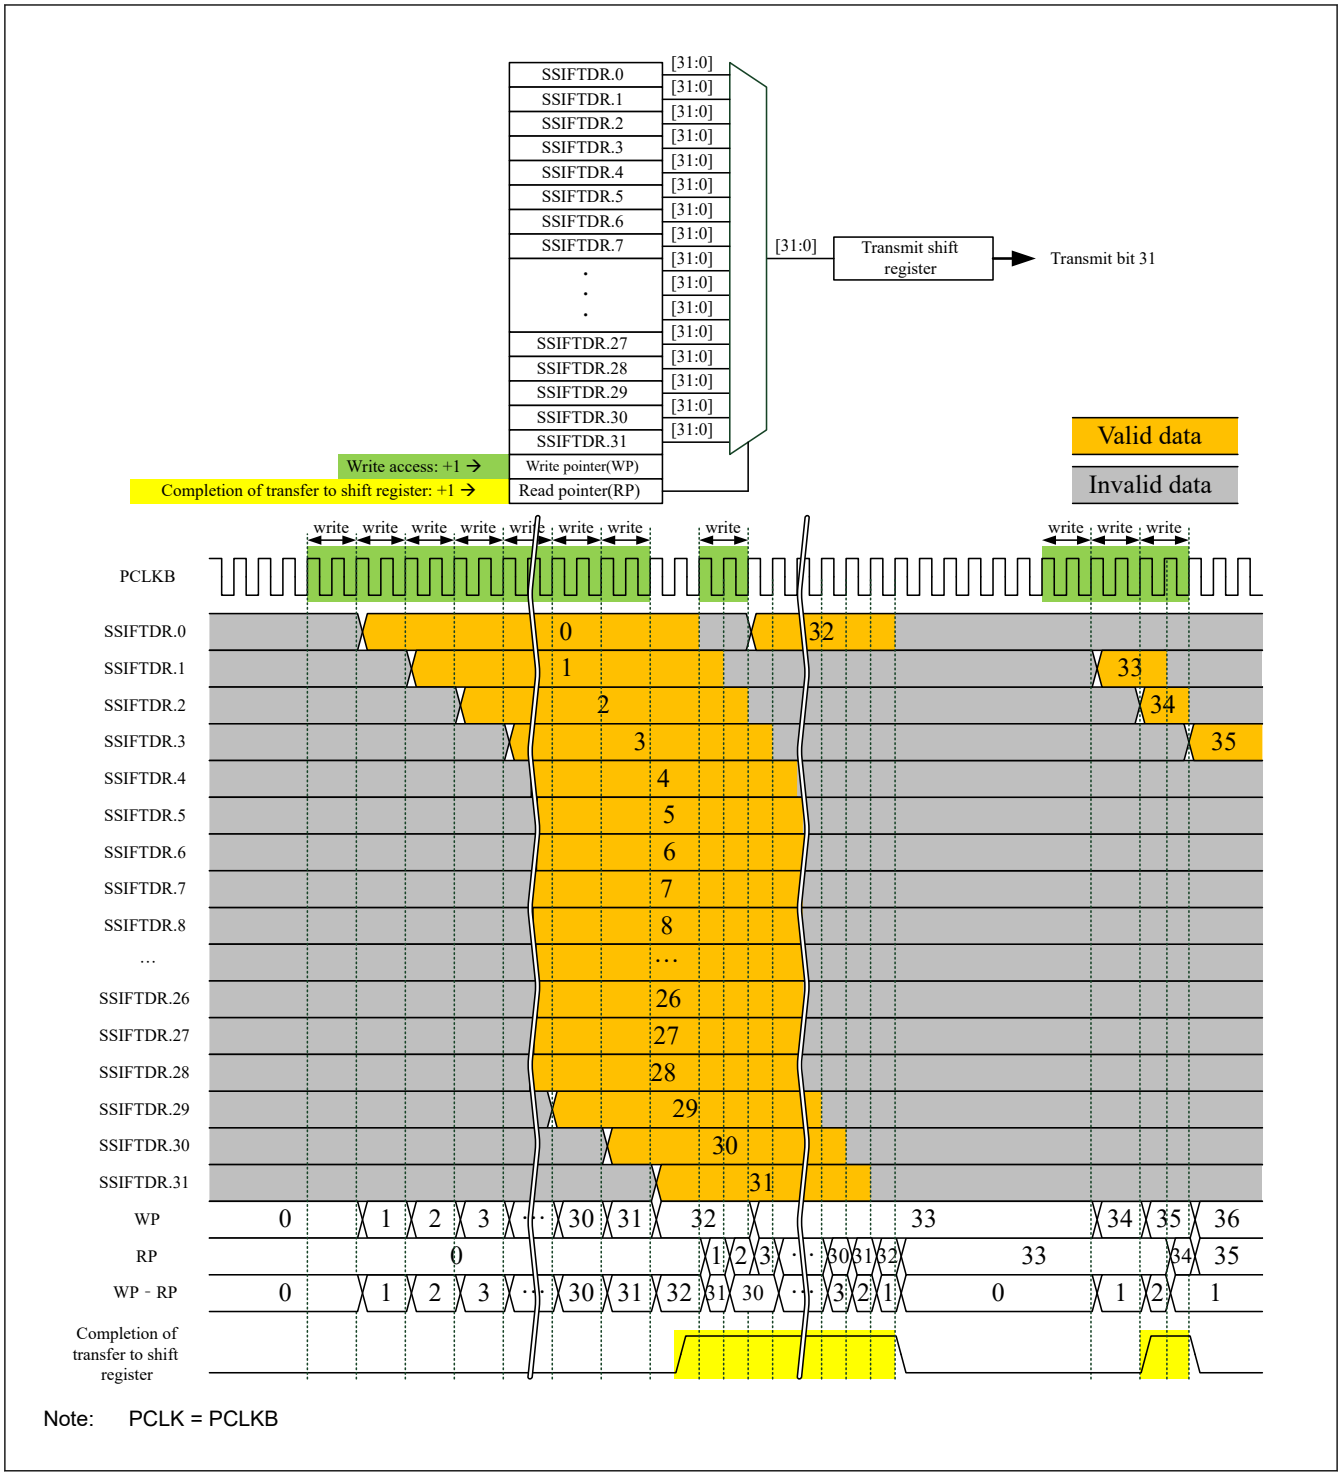

**Figure 35.30 Configuration of the transmit FIFO data register and transmit shift register, and FIFO operation example**

## 35.4.6 SSIFRDR : Receive FIFO Data Register

Base address: SSIE0 = 0x4009_D000

Offset address: 0x1C

| Bit position: | 31 | | | | | | | | | | | | | | | | | | | | | | | | | | | | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | SSIFRDR[31:0] | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 31:0 | SSIFRDR[31:0] | Receive FIFO Data | R |

When you use this register for reception, specify data reading from this register as the DTC/DMAC operation that is triggered by a transmit data empty interrupt. Determine the access size to this register according to the data word length to be communicated in Table 35.8.

Register access to the receive FIFO data register is same as for the transmit FIFO data register.

Figure 35.31 shows the configurations and operation examples of the receive FIFO data register and receive shift register.

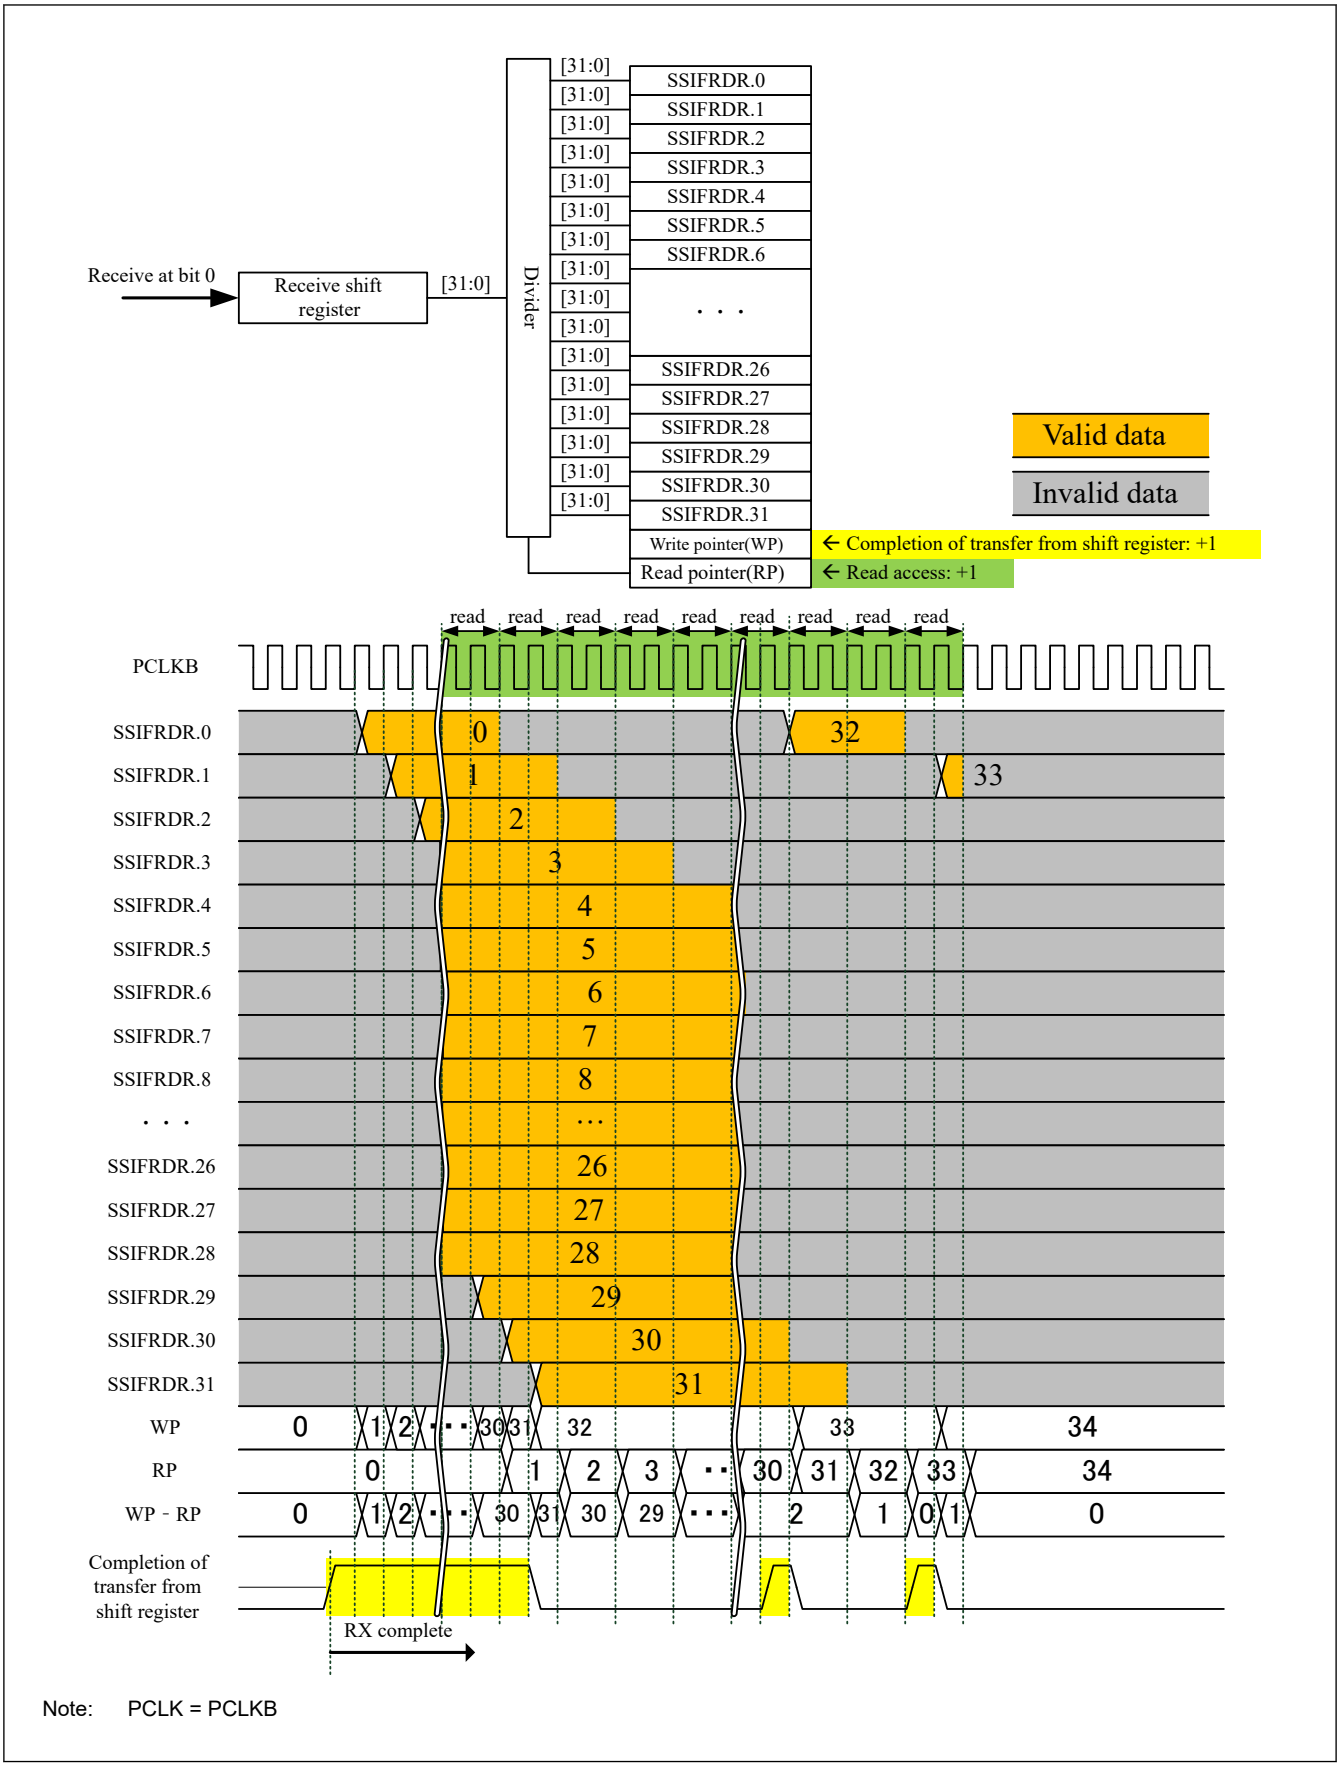

**Figure 35.31 Configuration of the receive FIFO data register and receive shift register, and FIFO operation example**

## 35.4.7 SSIOFR : Audio Format Register

Base address: SSIE0 = 0x4009_D000

Offset address: 0x20

| Bit position: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit position: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | — | — | — | BCKASTP | LRCONT | — | — | — | — | — | — | OMOD[1:0] | |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 1:0 | OMOD[1:0] | Audio Format Select*3 *4<br>0 0: $I^2S$ format<br>0 1: TDM format<br>1 0: Monaural format<br>1 1: Setting prohibited | R/W |
| 7:2 | — | These bits are read as 0. The write value should be 0. | R/W |
| 8 | LRCONT | Whether to Enable LRCK/FS Continuation*1 *2<br>0: Disables LRCK/FS continuation<br>1: Enables LRCK/FS continuation | R/W |
| 9 | BCKASTP | Whether to Enable Stopping BCK Output When SSIE is in Idle Status*1 *2<br>0: Always outputs BCK to the SSIBCK0 pin<br>1: Automatically controls output of BCK to the SSIBCK0 pin | R/W |
| 31:10 | — | These bits are read as 0. The write value should be 0. | R/W |

Note 1. This bit is valid only in master-mode communication (SSICR.MST = 1). The setting is invalid in slave-mode communication (SSICR.MST = 0).

Note 2. The BCKASTP and LRCONT bits must not be set to 1 together.

Note 3. While SSIE is communicating (SSISR.IIRQ = 0), writing to these bits is prohibited. If the value of these bits is changed by writing, subsequent operation is unpredictable.

Note 4. If the communication format of other-party device is compatible with a communication format of SSIE, specify and use the communication format that enables communication with the other-party device.

This register is used to set an audio format (which involves the settings of communication format, LR clock/frame synchronization continuation mode, and BCK output stop).

### OMOD[1:0] bits (Audio Format Select)

The OMOD[1:0] bits set an audio format. Writing to these bits must be performed when the LR clock supply to the SSILRCK0/SSIFS0 pin is stopped. For details about the output of LR clock, see the detailed description of the LRCONT bit in section 35.4.7. SSIOFR : Audio Format Register.

### LRCONT bit (Whether to Enable LRCK/FS Continuation)

The LRCONT bit enables or disables the output from SSILRCK0/SSIFS0 pin when the communication mode is master-mode communication (SSICR.MST = 1) and SSIE is in the idle state (SSISR.IIRQ = 1).

Even in the idle state, a signal can output from the SSILRCK0/SSIFS0 pin when this bit is set to 1 (to enable LR clock/frame synchronization continuation) in master mode (SSICR.MST = 1).

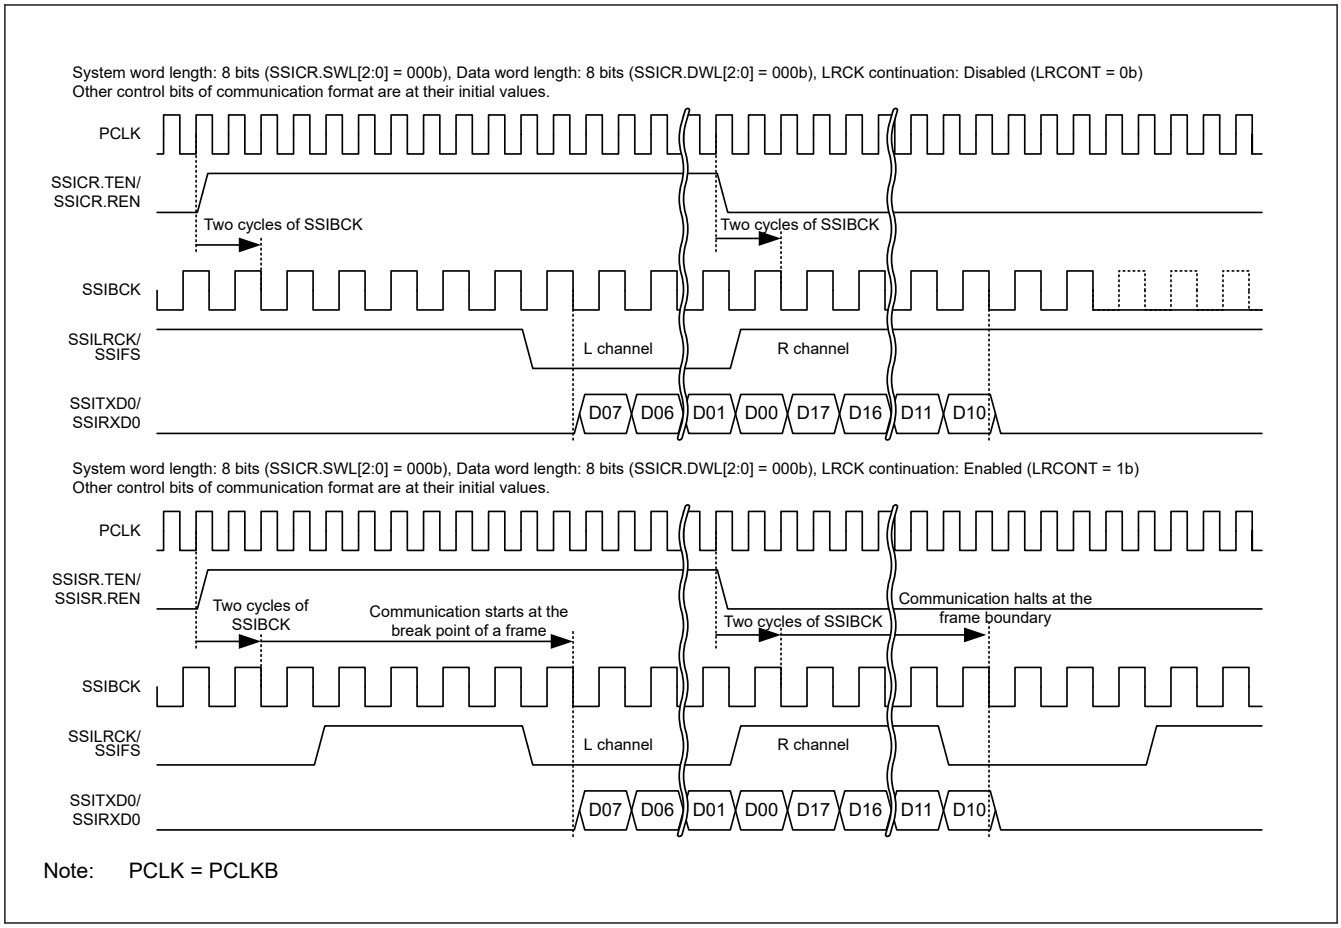

**Figure 35.32 Example of LR clock/frame synchronization continuation operation**

### BCKASTP bit (Whether to Enable Stopping BCK Output When SSIE is in Idle Status)

The BCKASTP bit turns on or off the function to output BCK to the SSIBCK0 pin according to the communication shown in Figure 35.33 and Figure 35.34 in master-mode communication (SSICR.MST = 1).

Changing the value of this bit must be performed only after setting the communication format to be used.

This bit must be used in the following way:

Write 0 to the BCKASTP bit, and then start communication. During the communication, write 1 to the BCKASTP bit. By this operation, the bit clock output to the SSIBCK0 pin stops automatically when the communication stops. To resume the communication, set SSIE to the idle state (SSICR.IIRQ = 1), enable the supply of AUDIO_MCK (SSIFCR.AUCKE = 1), and then write 0 to the BCKASTP bit.

When the communication mode is master-mode communication (SSICR.MST = 1) and SSIE is in the idle state (SSICR.IIRQ = 1):

**Table 35.9 BCKASTP bit status and SSIBCK0 pin output**

| BCKASTP bit | SSIBCK0 pin output status |
|---|---|
| 0 | Output |
| 1 | Stopped |

Note: The BCKASTP bit cannot be used when the other-party device (which is a slave) requires the clock output from the SSIBCK0 pin before and during communication. In such a case, use the BCKASTP bit to stop the clock only after communication. For the timing of enabling the clock stop function, see Figure 35.33.

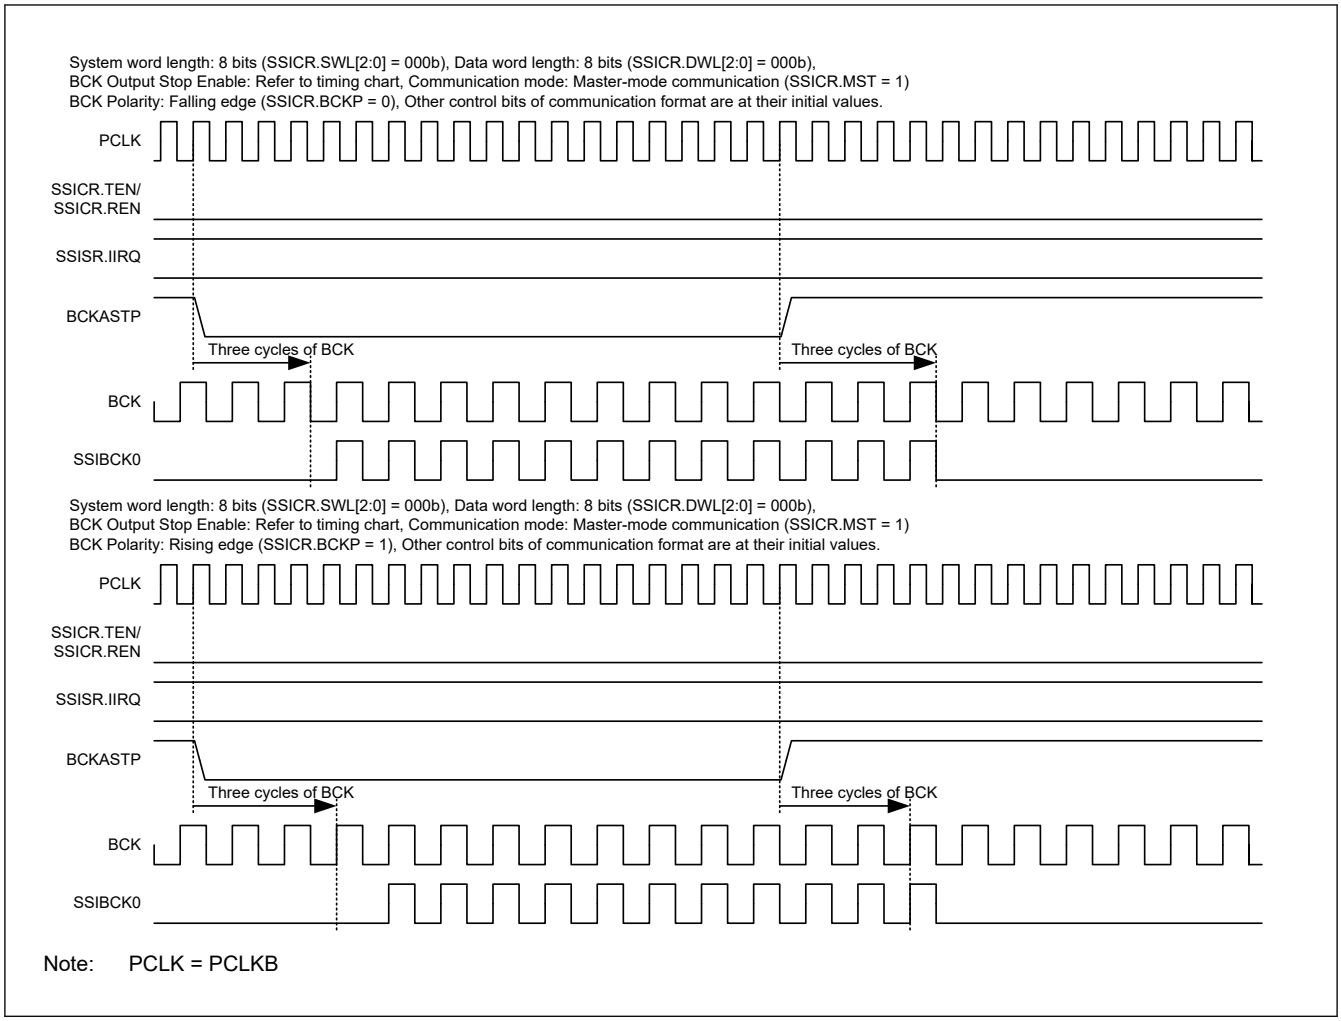

**Figure 35.33 Example operation of the BCKASTP bit (idle state)**

When the communication mode is master-mode communication (SSICR.MST = 1) and the BCK output stop function is enabled (BCKASTP = 1):

Details of the BCK output to the SSIBCK0 pin are as follows:

Output start timing: BCK is output in appropriate timing so that a valid edge is generated when the LR clock/frame synchronization signal shifts to a valid value.

Output stop timing: 1 to 1.5 clock cycles after a frame boundary.

For details about the timings, see the timing diagram in Figure 35.34.

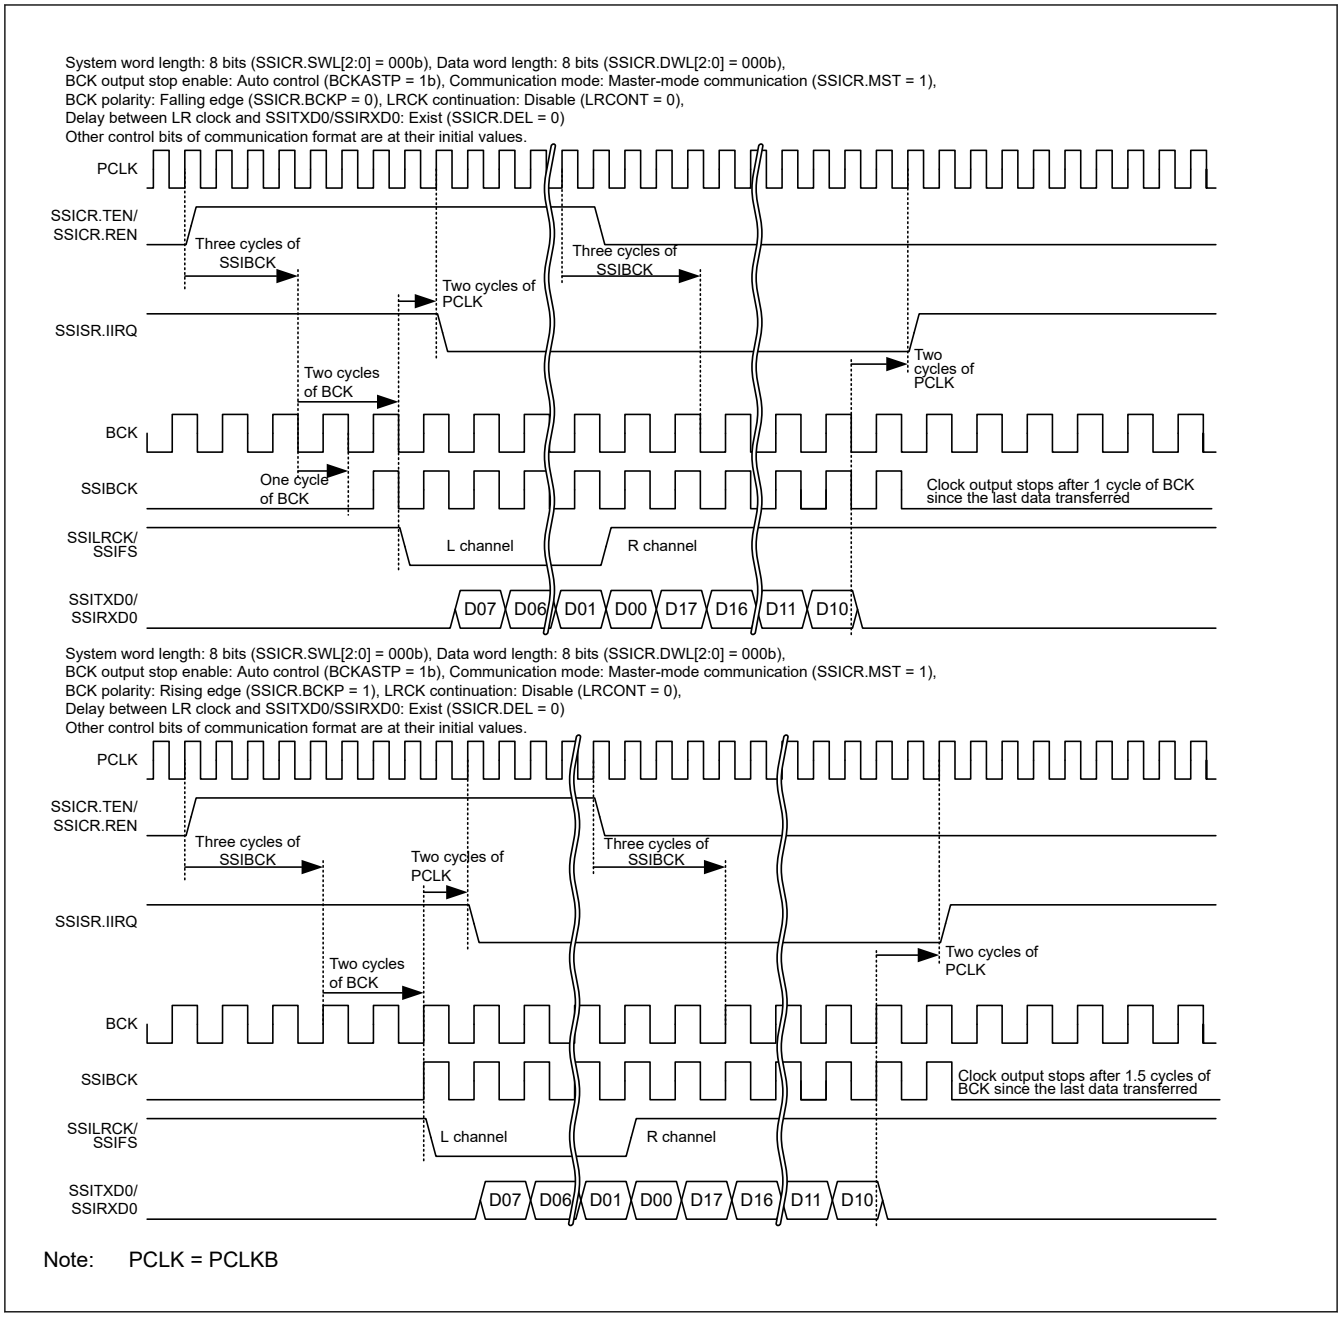

**Figure 35.34 Example operation of the BCKASTP bit (communication operation with BCKASTP = 1)**

## 35.4.8 SSISCR : Status Control Register

Base address: SSIE0 = 0x4009_D000

Offset address: 0x24

| Bit position: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit position: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | TDES[4:0] | | | | | — | — | — | RDFS[4:0] | | | | |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 4:0 | RDFS[4:0] | RDF Setting Condition Select*1<br>0x00: SSIFRDR has one stage or more data size<br>0x01: SSIFRDR has two stages or more data size<br>⋮<br>0x1E: SSIFRDR has 31 stages or more data size<br>0x1F: SSIFRDR has 32 stages or more data size | R/W |
| 7:5 | — | These bits are read as 0. The write value should be 0. | R/W |
| 12:8 | TDES[4:0] | TDE Setting Condition Select*1<br>0x00: SSIFTDR has one stage or more free space<br>0x01: SSIFTDR has two stages or more free space<br>⋮<br>0x1E: SSIFTDR has 31 stages or more free space<br>0x1F: SSIFTDR has 32 stages or more free space | R/W |
| 31:13 | — | These bits are read as 0. The write value should be 0. | R/W |

Note 1. Writing to these bits while SSIE is in a communication state (SSISR.IIRQ = 0) is prohibited. If written, the operation performed immediately after writing is not guaranteed.

### RDFS[4:0] bits (RDF Setting Condition Select)

The RDFS[4:0] bits set the setting condition of the receive data full flag (RDF).

### TDES[4:0] bits (TDE Setting Condition Select)

The TDES[4:0] bits set the setting condition of the transmit data empty flag (TDE).

## 35.5 Communication Formats

SSIE supports three communication formats. Table 35.10 shows supported communication formats.

**Table 35.10 Supported communication formats**

| Communication format | SSIOFR.OMOD[1:0] |
|---|---|
| I²S format | 00 |
| TDM format | 01 |
| Monaural format | 10 |

The following describes the serial data structure shared by communication formats. A serial data structure is defined by the system word length (set in SSICR.SWL[2:0]) and the data word length (set in SSICR.DWL[2:0]). If the data word length is shorter than the system word length, padding bits are transferred in the serial data. For details, see Figure 35.35.

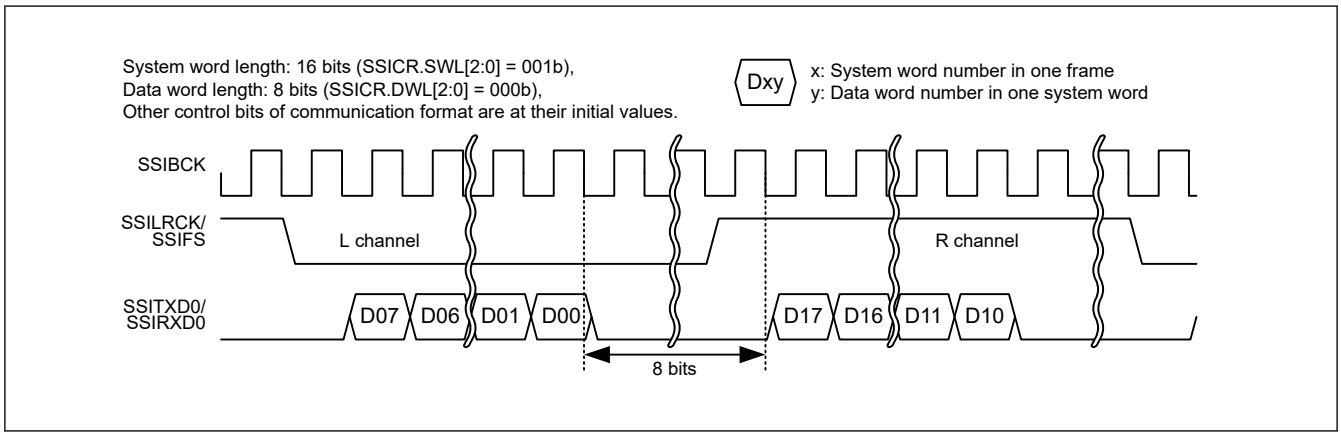

**Figure 35.35 Example of padding bit transfer (I²S format: system word length > data word length)**

Table 35.11 lists the number of padding bits to be transferred with each combination of system word length (SSICR.SWL[2:0]) and data word length (SSICR.DWL[2:0]). "-" indicates that the setting is prohibited.

**Table 35.11 Number of padding bits**

| SSICR.SWL[2:0] | System Word Length | SSICR.DWL[2:0] | | | | | | | |
|---|---|---|---|---|---|---|---|---|---|
| | | 000b | 001b | 010b | 011b | 100b | 101b | 110b | 111b |
| | | 8 | 16 | 18 | 20 | 22 | 24 | 32 | Setting prohibited |
| 000b | 8 | 0 | — | — | — | — | — | — | — |
| 001b | 16 | 8 | 0 | — | — | — | — | — | — |
| 010b | 24 | 16 | 8 | 6 | 4 | 2 | 0 | — | — |
| 011b | 32 | 24 | 16 | 14 | 12 | 10 | 8 | 0 | — |
| 100b | 48 | 40 | 32 | 30 | 28 | 26 | 24 | 16 | — |
| 101b | 64 | 56 | 48 | 46 | 44 | 42 | 40 | 32 | — |
| 110b | 128 | 120 | 112 | 110 | 108 | 106 | 104 | 96 | — |
| 111b | 256 | 248 | 240 | 238 | 236 | 234 | 232 | 224 | — |

## 35.5.1 I²S Format

The I²S format is a communication format used for connection with I²S-compatible serial devices. With this format setting (SSIOFR.OMOD[1:0] = 00b), one frame is configured with two system words, one for the channel L and the other for channel R. The SSILRCK0/SSIFS0 signals are at a low level for the channel L and at a high level for the channel R. Set the polarity of the signals with the SSICR.LRCKP bit. Figure 35.36 shows the I²S format without padding. See Figure 35.35 for the format with padding.

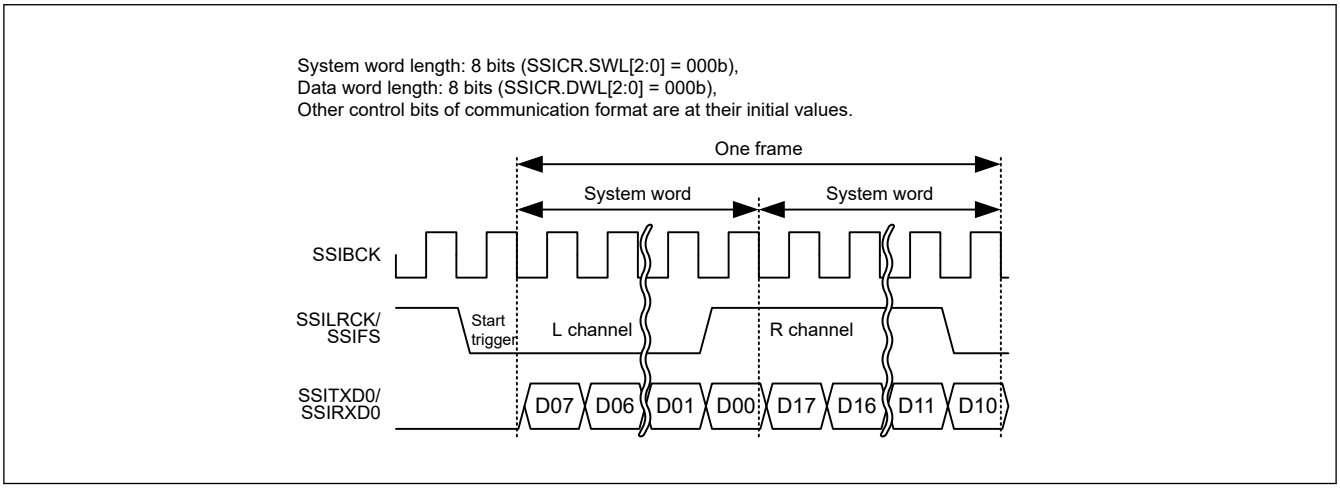

**Figure 35.36 I²S format (without padding: system word length = data word length)**

For the state of external pins when SSIE is in the idle state, see section 35.7.1. Idle State.

Note: SSIE has the SSILRCK0/SSIFS0 pin, which indicates the synchronization of communication. When SSIE is in slave mode (SSICR.MST = 0), the communication format SSIE uses must match that of the other-party device to communicate. SSIE uses the signal input by the SSILRCK0/SSIFS0 pin only as a trigger to start communication.

## 35.5.2 Monaural Format

The monaural format is a communication format used for connection with monaural-compatible serial devices. When the monaural format is specified (SSIOFR.OMOD[1:0] = 10b) for use, one frame consists of one system word. Also, a rising edge of the SSILRCK0/SSIFS0 signal indicates a communication start trigger. Figure 35.37 and Figure 35.38 respectively show the monaural formats without and with padding.

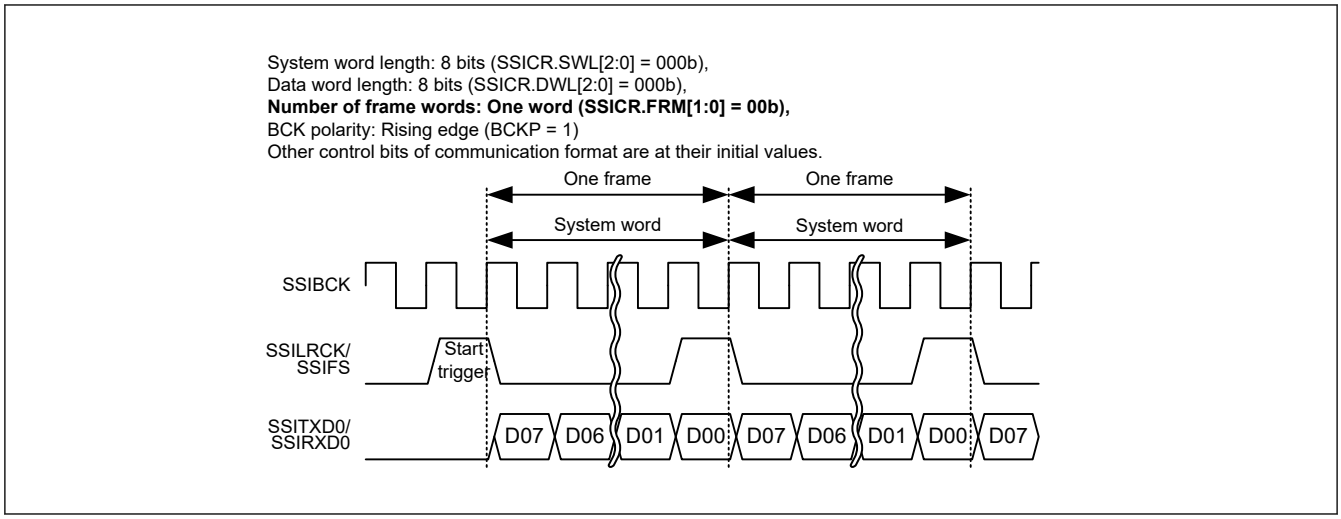

**Figure 35.37 Short frame in monaural format (without padding: system word length = data word length)**

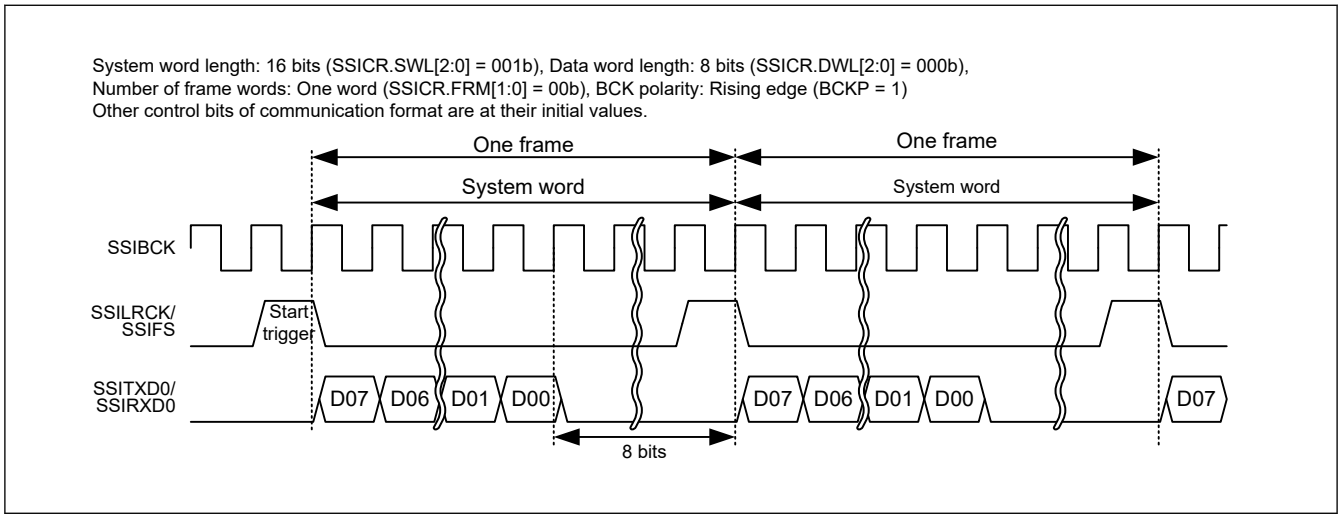

**Figure 35.38 Short frame in monaural format (with padding: system word length > data word length)**

The monaural formats supported by SSIE consist of short frames and long frames. See section 35.5.2.1. Short Frame and section 35.5.2.2. Long Frame for the difference between these two frames.

For the state of external pins state when SSIE is in the idle state, see section 35.7.1. Idle State.

Note: SSIE has the SSILRCK0/SSIFS0 pin, which indicates the synchronization of communication. When SSIE is in slave mode (SSICR.MST = 0), the communication format SSIE uses must match that of the other-party device to communicate. SSIE uses the signal input by the SSILRCK0/SSIFS0 pin only as a trigger to start communication.

### 35.5.2.1 Short Frame

When a short frame is used (SSICR.DEL = 0), the SSILRCK0/SSIFS0 signal indicating the start of serial data is set to high level only for 1 cycle of SSIBCK0. Data transfer starts at the falling edge of the signal.

### 35.5.2.2 Long Frame

When a long frame is used (SSICR.DEL = 1), the SSILRCK0/SSIFS0 signal indicating the start of serial data is set to high level only for 2 cycles of SSIBCK0. See Figure 35.39. Data transfer starts at the rising edge of the signal.

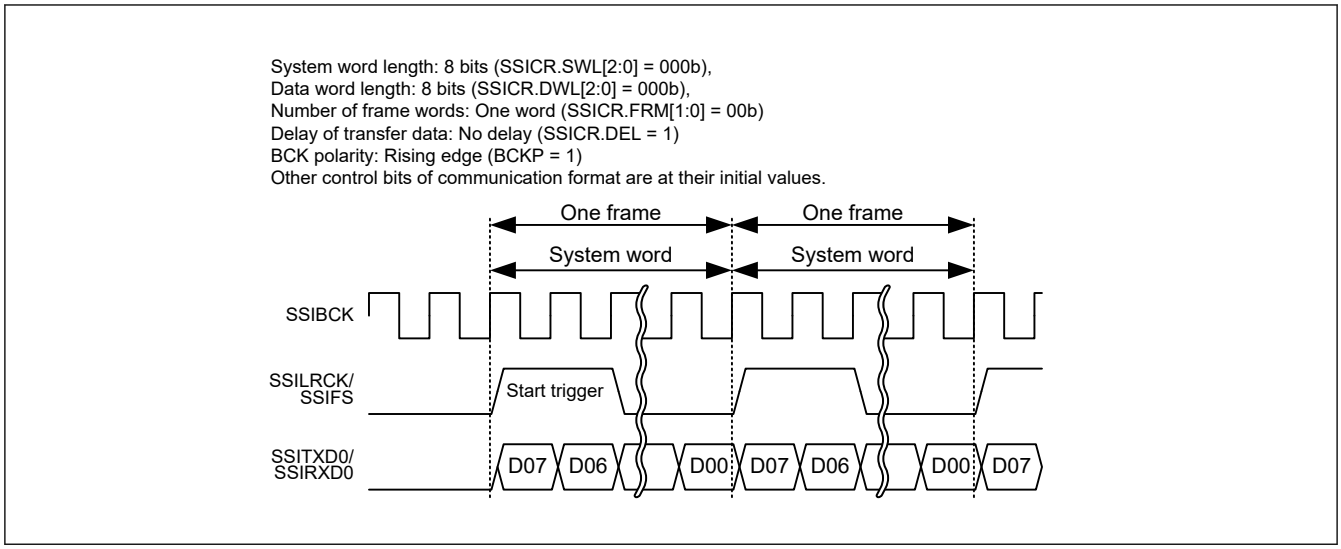

**Figure 35.39 Long frame in monaural format (without padding)**

## 35.5.3 TDM Format

The TDM format is a communication format used for connection with TDM-compatible multi-channel devices. With this format setting (SSIOFR.OMOD[1:0] = 01b), one frame is configured with four to eight system words set with the SSICR.FRM[1:0] bits. With this format, the SSILRCK0/SSIFS0 signal is at a high level for the first one system word and at a low level for the rest. The pulse generated on the SSILRCK0/SSIFS0 signal is defined as the SYNC pulse and its rising edge means a start of one frame. Figure 35.40 and Figure 35.41 respectively show the TDM formats without and with padding.

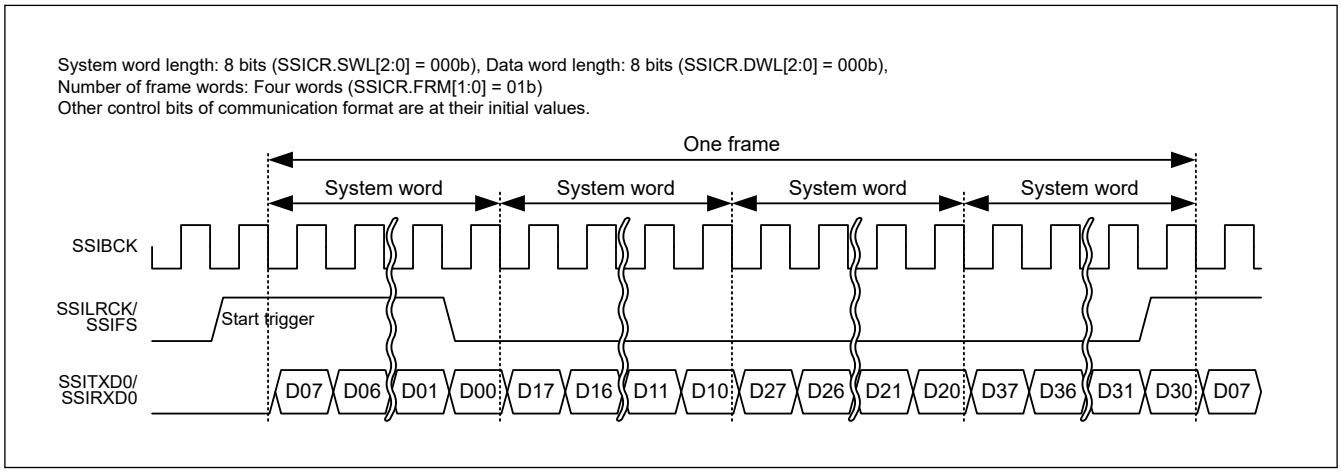

**Figure 35.40 TDM format (without padding: system word length = data word length)**

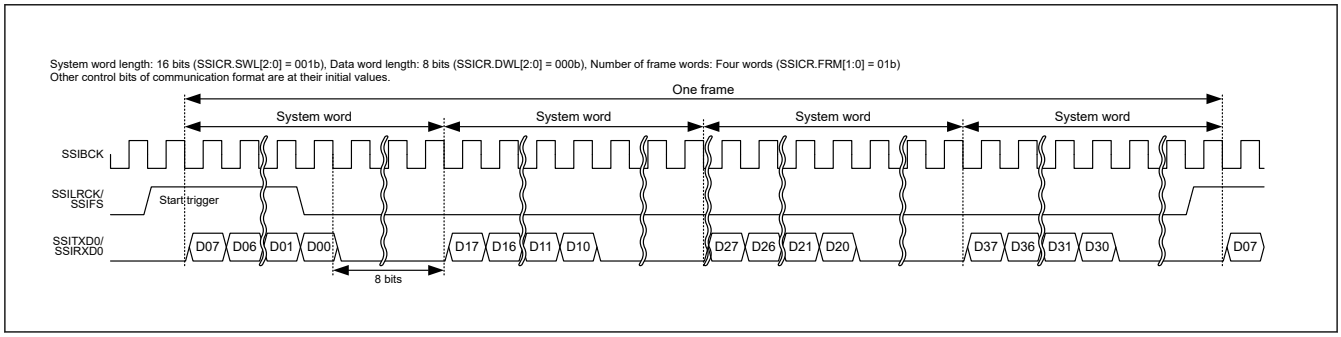

**Figure 35.41 TDM format (with padding: system word length > data word length)**

For the state of external pins when SSIE is in the idle state, see section 35.7.1. Idle State.

Note: SSIE has the SSILRCK0/SSIFS0 pin, which indicates the synchronization of communication. When SSIE is in slave mode (SSICR.MST = 0), the communication format SSIE uses must match that of the other-party device to communicate. SSIE uses the signal input by the SSILRCK0/SSIFS0 pin only as a trigger to start communication.

## 35.6 Communication Modes

SSIE supports the following communication modes. Table 35.13 lists the control bits that are not available with each communication mode. See section 35.6.1. Slave-mode Communication to section 35.6.5. Transmission and Reception for details of these communication modes.

**Table 35.12 Communication modes**

| Communication Mode | SSICR.MST Bit | SSICR.REN Bit | SSICR.TEN Bit |
|---|---|---|---|
| Slave-mode transmission | 0 | 0 | 1 |
| Slave-mode reception | 0 | 1 | 0 |
| Slave-mode transmission and reception | 0 | 1 | 1 |
| Master-mode transmission | 1 | 0 | 1 |
| Master-mode reception | 1 | 1 | 0 |
| Master-mode transmission and reception | 1 | 1 | 1 |

**Table 35.13 Control bits that cannot be used in each communication mode**

| Control Bit | Slave-mode Reception | Slave-mode Transmission | Slave-mode Transmission and Reception | Master-mode Reception | Master-mode Transmission | Master-mode Transmission and Reception |
|---|---|---|---|---|---|---|
| SSICR.CKS | Invalid | Invalid | Invalid | Available | Available | Available |
| SSICR.CKDV | Invalid | Invalid | Invalid | Available | Available | Available |
| SSICR.MUEN | Invalid | Available | Available | Invalid | Available | Available |
| SSICR.TEN | Invalid | Available | Available | Invalid | Available | Available |

| SSIOFR.BCKASTP | Invalid | Invalid | Invalid | Available | Available | Available |
| SSIOFR.LRCONT | Invalid | Invalid | Invalid | Available | Available | Available |
| SSIOFR.OMOD | Available | Available | Available | Available | Available | Available |
| SSISCR.TDES | Invalid | Available | Available | Invalid | Available | Available |
| SSISCR.RDFS | Available | Invalid | Available | Available | Invalid | Available |

“Invalid” means it has no effect on operation. Writing is possible.

### 35.6.1 Slave-mode Communication

SSIE operates in slave mode with SSICR.MST = 0. The SSIBCK0 and SSILRCK0/SSIFS0 signals to be used for serial data communication must be supplied from an external device. If these signals do not match the communication format set for SSIE, operation is not guaranteed.

### 35.6.2 Master-mode Communication

SSIE operates in master mode with SSICR.MST = 1. The SSIBCK0 and SSILRCK0/SSIFS0 signals to be used for serial data communication must be internally generated from the audio clock. These signals use the format according to the setting

of SSIE. If the communication format the slave device uses does not match the communication format set for SSIE, the operation is unpredictable.

### 35.6.3 Transmission

SSIE transmits serial data to the other-party device when the SSICR.TEN bit is 1 and the SSICR.REN bit is 0. If the communication format the other-party device uses does not match the communication format set for SSIE, the operation is unpredictable.

### 35.6.4 Reception

SSIE receives serial data from the other-party device when the SSICR.TEN bit is 0 and the SSICR.REN bit is 1. If the communication format the other-party device uses does not match the communication format set for SSIE, the operation is unpredictable.

### 35.6.5 Transmission and Reception

SSIE transmits and receives serial data to and from the other-party device when the SSICR.TEN bit is 1 and the SSICR.REN bit is 1. If the communication format the other-party device uses does not match the communication format set for SSIE, the operation is unpredictable.

## 35.7 Operation

SSIE has the following two main operation states Figure 35.42 shows SSIE state transition.

- Idle state (SSISR.IIRQ = 1)
- Communication state (SSISR.IIRQ = 0).

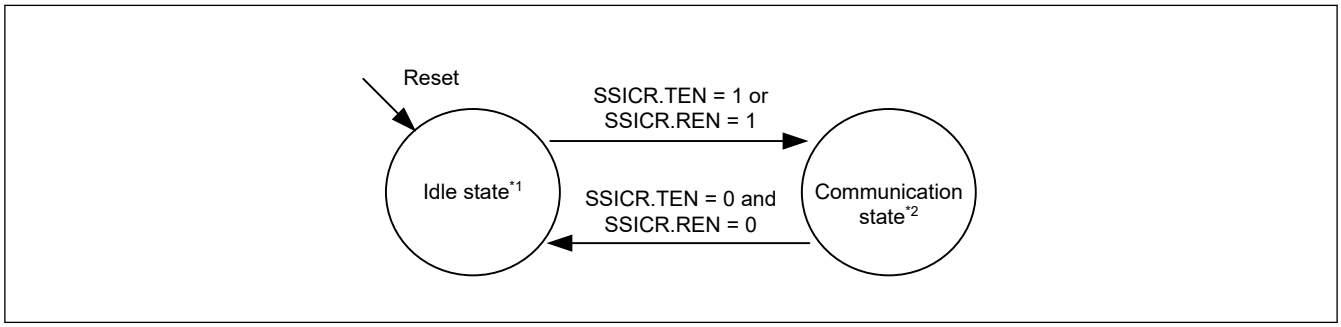

**Figure 35.42 SSIE state transition**

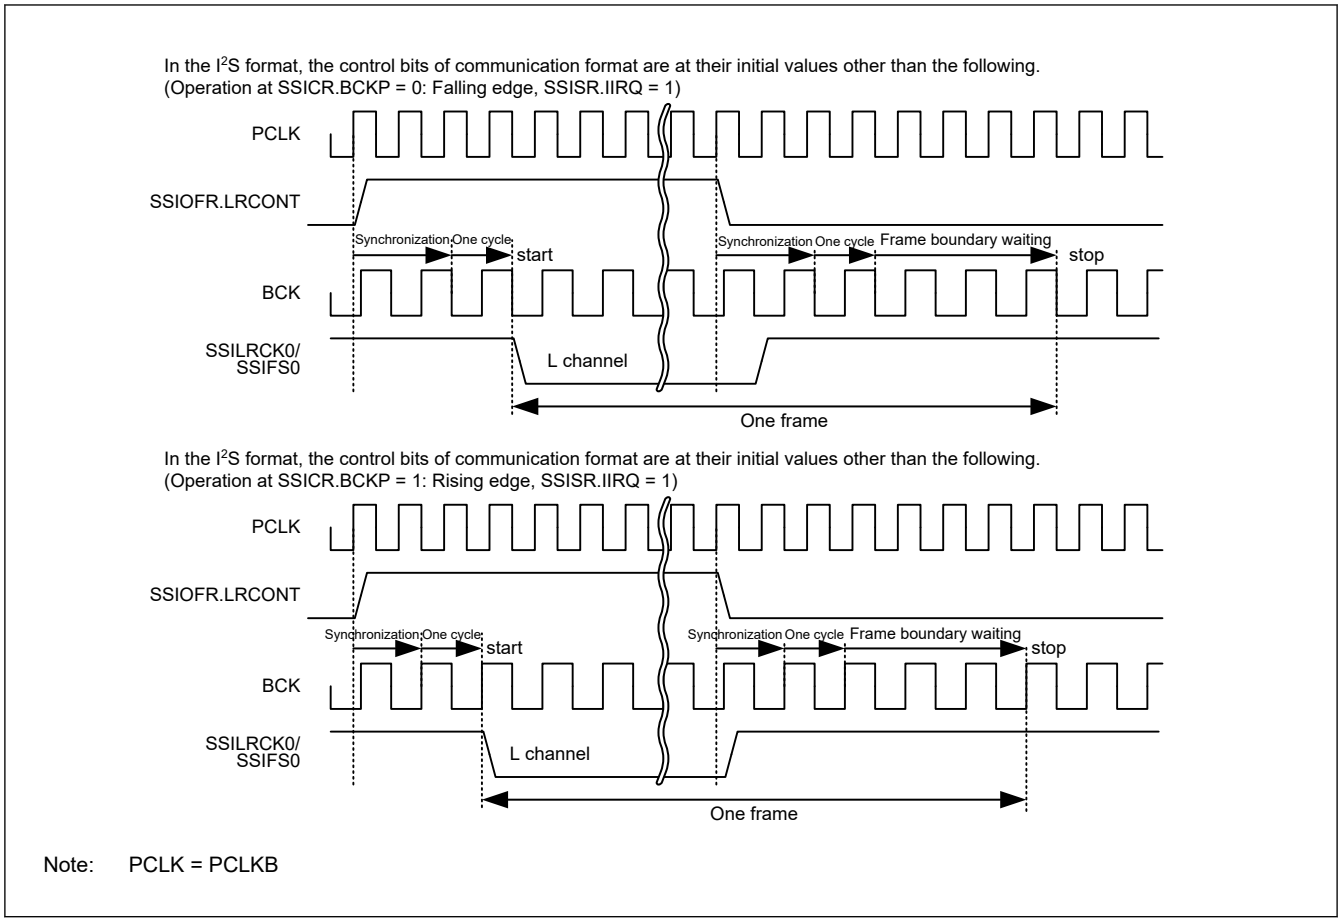
Note: See section 35.8.1. Start Communication for details of the idle state.
See section 35.8.2. Transmission for details of the communication state.

### 35.7.1 Idle State

In this state, communication of SSIE is halted. If, however, the SSICR.MST bit is 1, output of the BCK and LR clock/ frame synchronization signals to external pins can be controlled according to the settings of SSIOFR.BCKASTP and SSIOFR.LRCONT bits. This function is common to all formats. For details, see Table 35.14.

**Table 35.14 Output from external pins in the idle state**

| SSICR.MST | SSIOFR.BCKASTP | SSIOFR.LRCONT | Output from pins | | |
|---|---|---|---|---|---|
| | | | SSIBCK0 | SSILRCK0/SSIFS0 | SSITXD0 |
| 0 | — | — | Stop | Stop | Stop |
| 1 | 0 | 0 | Supply | Stop | Stop |
| 1 | 0 | 1 | Supply | Supply | Stop |
| 1 | 1 | 0 | Stop | Stop | Stop |
| 1 | 1 | 1 | Stop | Supply | Stop |



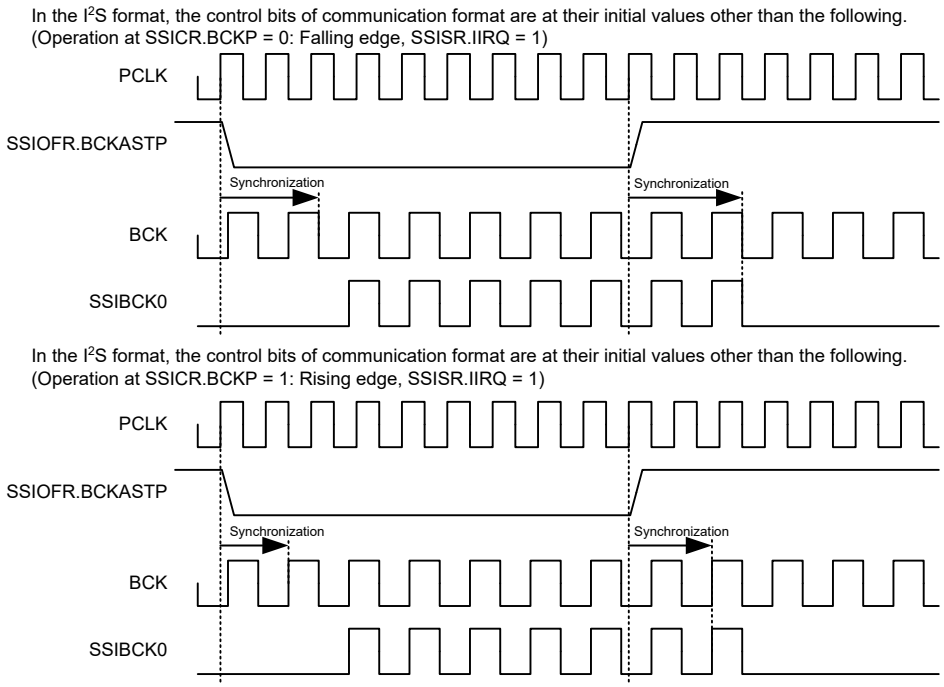


**Figure 35.43 Example of disabling LR clock/frame synchronization continuation by SSIOFR.LRCONT**

Note: To stop the output to the SSILRCK0/SSIFS0 pin with SSIOFR.LRCONT when SSIE is in the idle state in master-mode communication (SSICR.MST = 1), note the following: The output stops when the value of the SSIOFR.LRCONT bit is changed from 1 to 0. Make sure that the other-party device is not affected.

Note: PCLK = PCLKB

**Figure 35.44 Example of stopping SSIBCK0 with SSIOFR.BCKASTP**

Note: To stop the output to the SSIBCK0 pin with SSIOFR.BCKASTP in master-mode communication (SSICR.MST = 1) and while SSIE is in the idle state, note the following: The output stops when the value of the SSIOFR.BCKASTP bit is changed from 0 to 1. So, make sure that the other-party device is not affected.

## 35.7.2 Communication States

In this state, SSIE is during communication. Figure 35.45 shows transitions of communication states and Table 35.15 lists the conditions for transition. If the transition condition is not satisfied, the state does not transit.

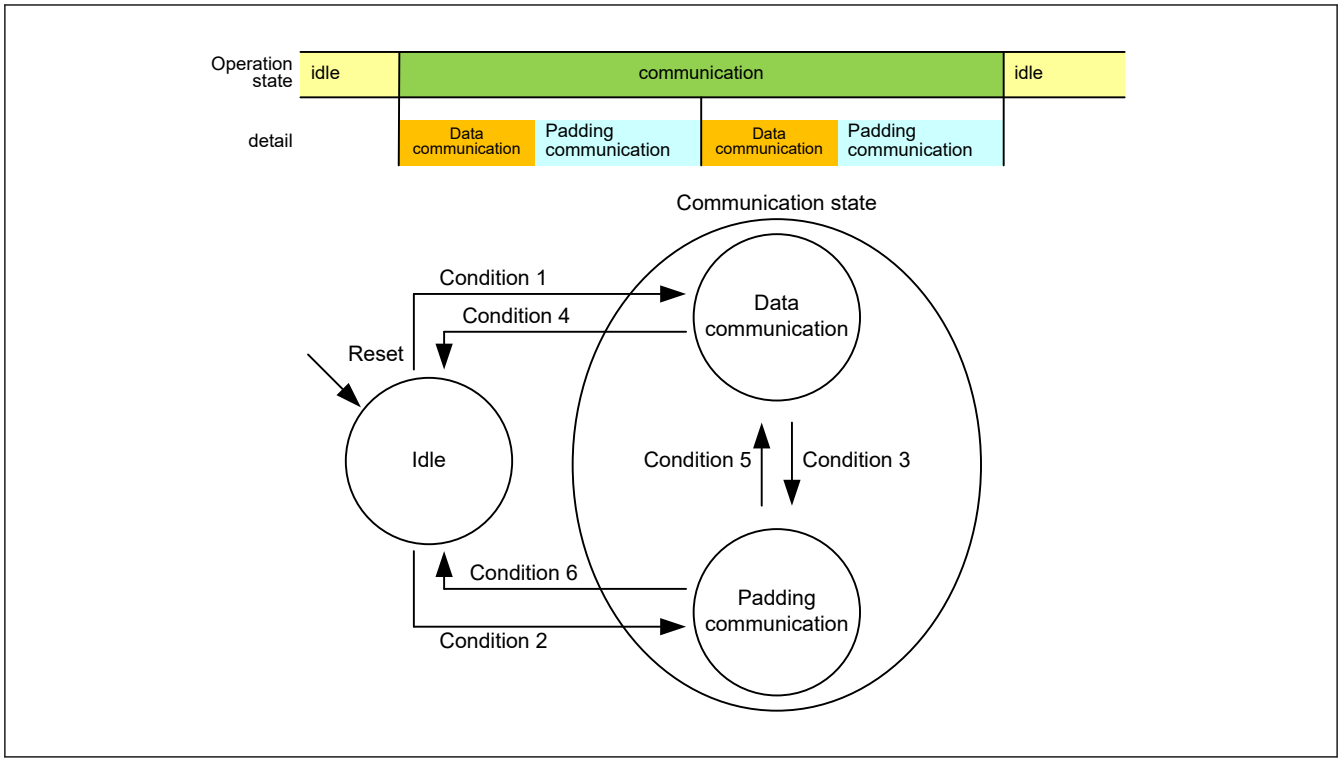

**Figure 35.45 Communication state transition**

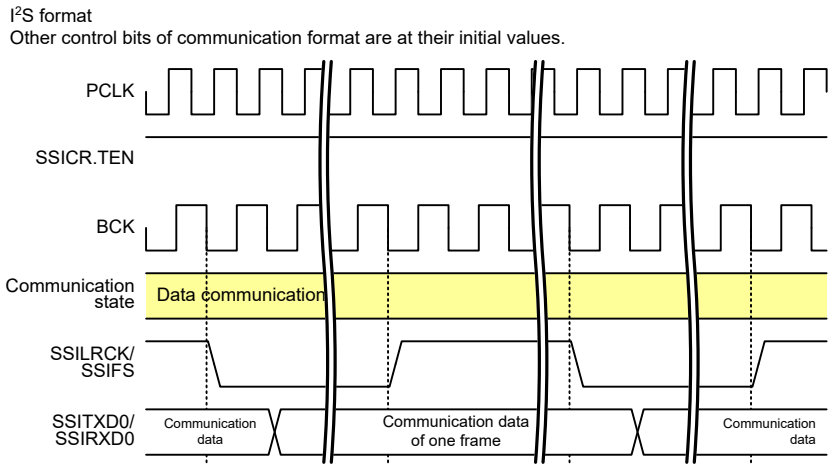
**Table 35.15 Condition for communication state transition**

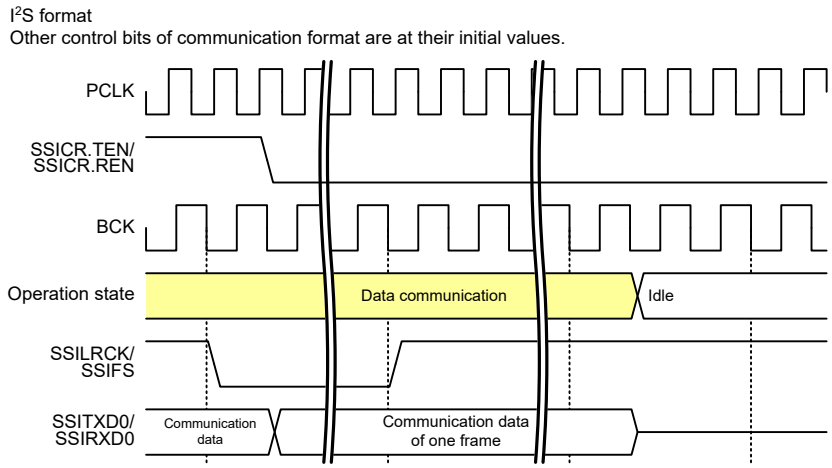
| Condition Number | Condition for Transition |
|---|---|
| 1 | Writing SSICR.TEN = 1 or SSICR.REN = 1 while SSICR.SDTA = 0 or in the setting without padding bits. |
| 2 | Writing SSICR.TEN = 1 or SSICR.REN = 1 while SSICR.SDTA = 1 and in the setting with padding bits. |
| 3 | The following three conditions are all met:<br>● SSICR.TEN = 1 or SSICR.REN = 1<br>● In the setting with padding bits<br>● The last bit of the data words has been transferred. |
| 4 | Both the following two conditions are met:<br>● SSICR.SDTA = 1 or without padding bits<br>● While SSICR.TEN = 0 and SSICR.REN = 0, the last bit of the data words in a frame has been transferred. |
| 5 | Transfer of the last padding bit is completed while SSICR.TEN = 1 or SSICR.REN = 1 |
| 6 | Both the following two conditions are met:<br>● SSICR.SDTA = 0 and with padding bits<br>● While SSICR.TEN = 0 and SSICR.REN = 0, the last padding bit has been transferred. |



See Table 35.11 for the setting with/without padding bits.

### 35.7.2.1 Data Communication State

In this state, SSIE is during communication. Data of the data word length set with the SSICR.DWL[2:0] bits is transmitted, received, or transmitted and received.



- State Transition in the Setting without Padding Bits

During communication (SSISR.IIRQ = 0), SSIE is during data communication for all the time. By disabling transmission and reception (SSICR.TEN = 0, SSICR.REN = 0), SSIE transits to the idle state. For details, see Figure 35.46 and Figure 35.47.

Note: PCLK = PCLKB

**Figure 35.46 Continuation of the data communication**

Note: PCLK = PCLKB

**Figure 35.47 Halt from the data communication (without padding bits)**

- State Transition in the Setting with Padding Bits

When SSIE ends transfer of the last bit of a data word during communication (SSISR.IIRQ = 0), SSIE transitions from the data communication state to the padding communication state in Figure 35.48. Except in the status with SSICR.SDTA = 1 and transmission and reception disabled (SSICR.TEN = 0 and SSICR.REN = 0), SSIE transitions from the data communication state to the idle state when it stops communication in Figure 35.49.

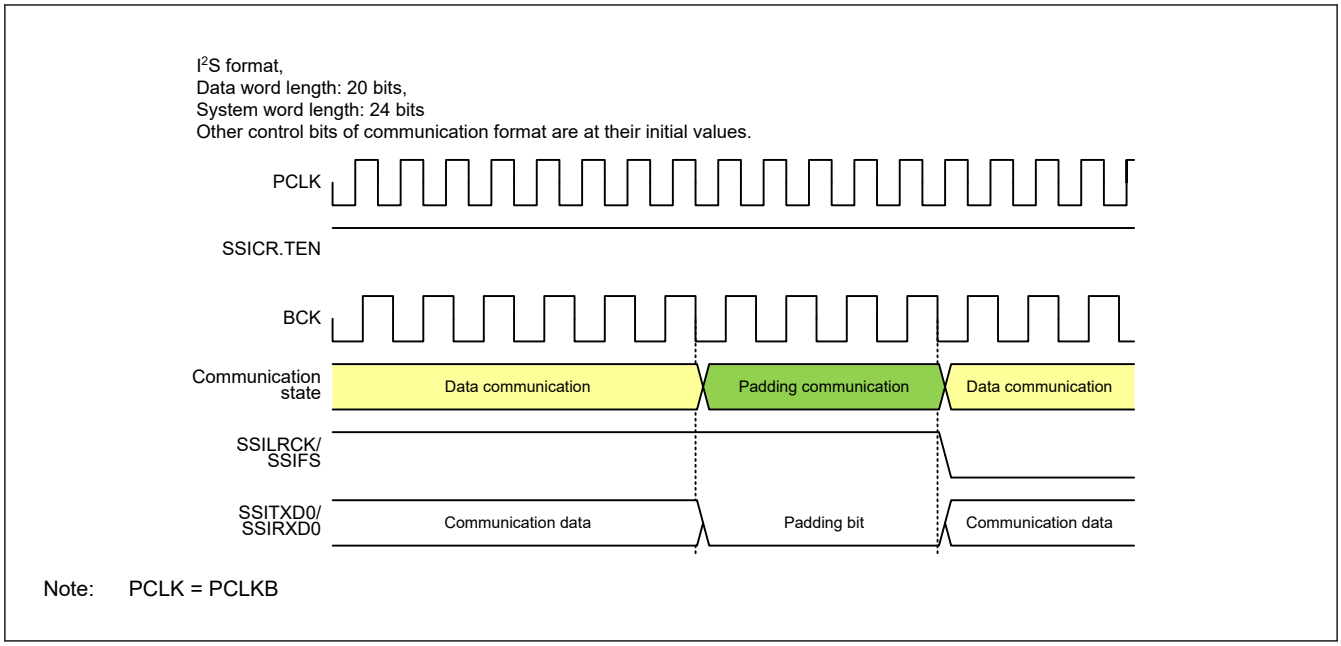


**Figure 35.48 Transition from data communication to padding communication**

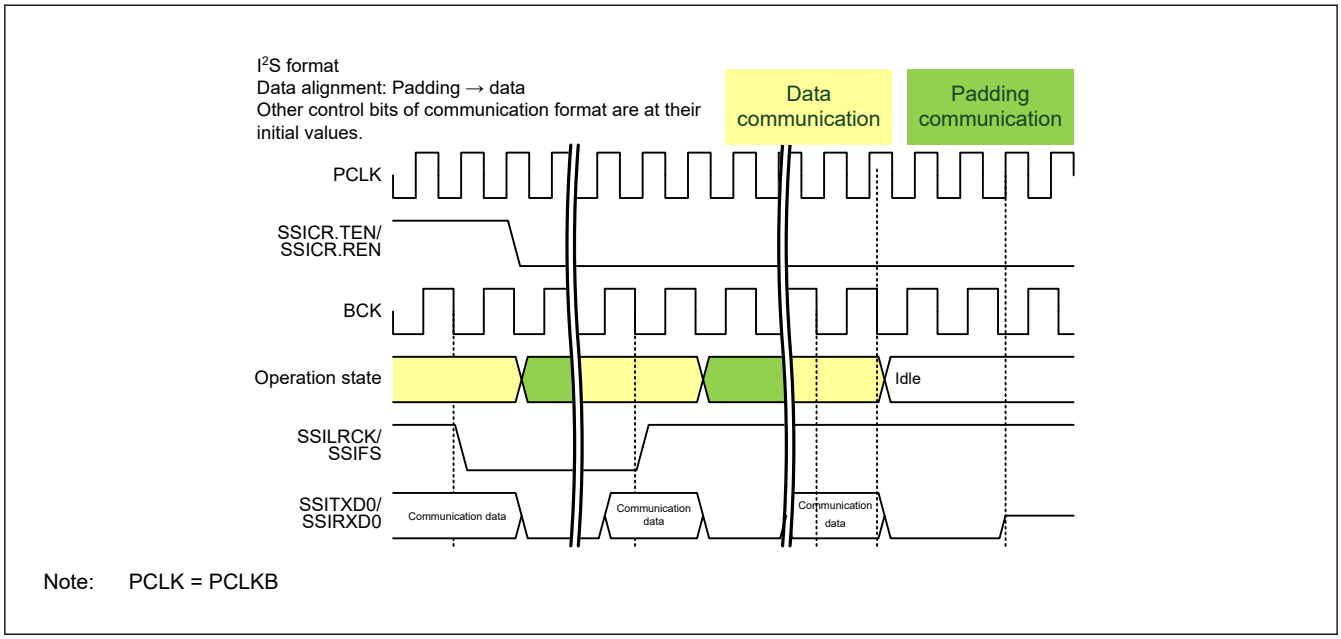

**Figure 35.49 Halt from data communication (with padding bits)**

### 35.7.2.2 Padding Communication State

In this state, SSIE is during communication. The padding bits set with the SSICR.SWL[2:0] bits and SSICR.DWL[2:0] bits are transmitted, received, or transmitted and received.

- State Transition in the Setting with Padding Bits

When SSIE ends transfer of the last padding bit during communication (SSISR.IIRQ = 0), SSIE transitions to the data communication state in Figure 35.48. If SSIE is in the status with SSICR.SDTA = 0 and transmission and reception disabled (SSICR.TEN = 0 and SSICR.REN = 0), SSIE transitions from the padding communication state to the idle state when it stops communication in Figure 35.50.

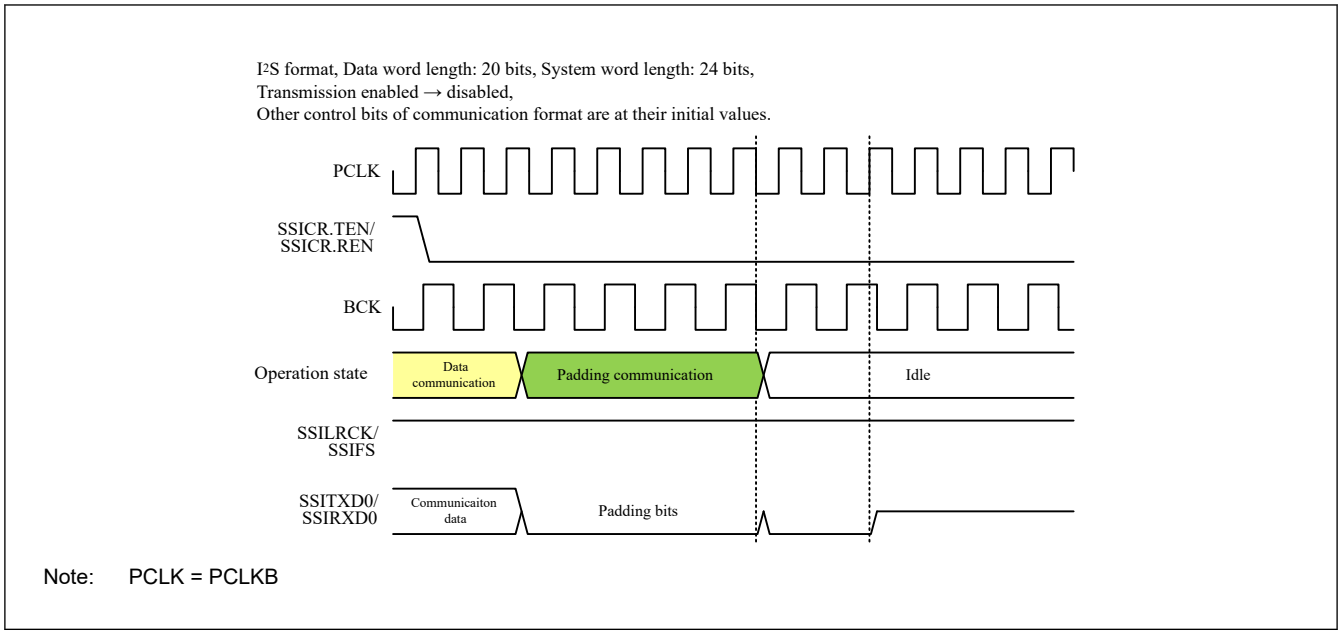

**Figure 35.50 Halt from the padding communication**

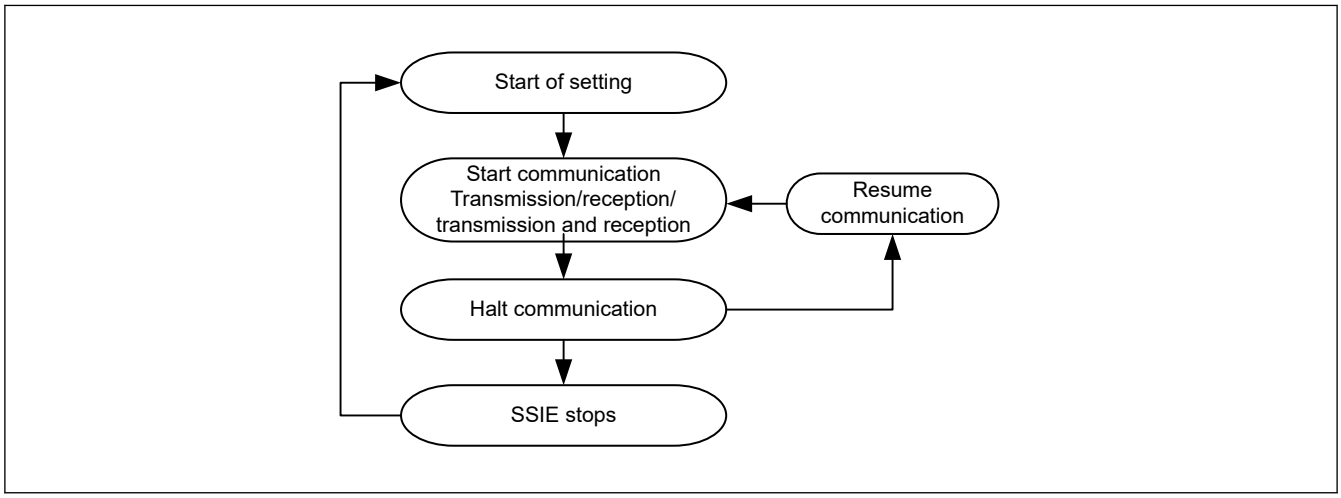
## 35.8 Communication Operation

Figure 35.51 shows the communication flow of SSIE.



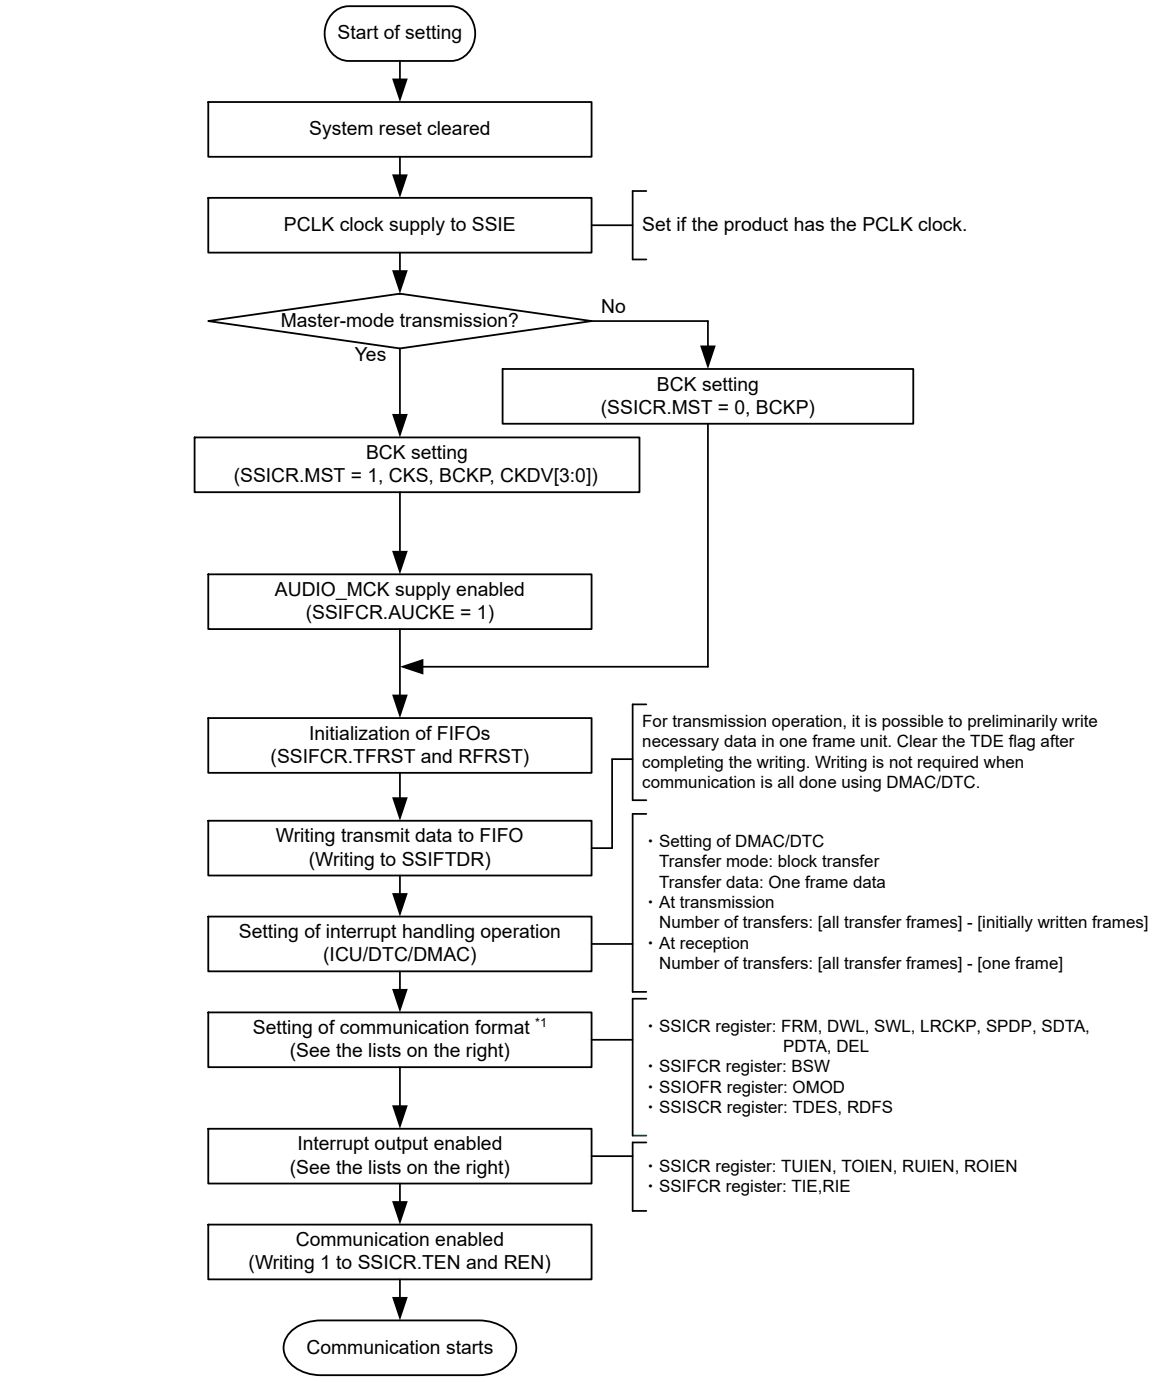


**Figure 35.51 SSIE communication operation**

The procedure of each operation is described from section 35.8.1. Start Communication to section 35.8.7. Resume Communication.

### 35.8.1 Start Communication

This section describes how to start communication of SSIE. Figure 35.52 shows the procedure to start communication. Be sure to follow the procedure. See section 35.8.2. Transmission for transmission operation and section 35.8.3. Reception for reception operation.

Note: PCLK = PCLKB
Note 1. Set SSICR.MUEN, SSIOFR.BCKASTP, and SSIOFR.LRCONT after completing the setting of the communication format.

**Figure 35.52 Procedure to start communication (CPU operation procedure)**

SSIE can perform continuous communication based on interrupts by the DTC/DMAC. For transmission, write 1 to SSIFCR.TIE, SSICR.TUIEN, and SSICR.TOIEN. For reception, write 1 to SSIFCR.RIE, SSICR.RUIEN, and SSICR.ROIEN.

## 35.8.2 Transmission

The transmission procedure in Figure 35.53 must be followed throughout a transmission operation.

After transmission is enabled (SSICR.TEN = 1 and SSICR.REN = 0), SSIE starts transmission when a start trigger is generated by SSILRCK0/SSIFS0 with the serial data for at least a frame contained in the transmit FIFO data register (SSIFTDR). SSIE outputs a transmit data empty interrupt to the DTC/DMAC according to the TDE setting condition (SSISCR.TDES) and the status of transmit data empty interrupt enable (SSIFCR.TIE) bit specified in the communication start procedure. This interrupt requests writing to the transmit FIFO data register (SSIFTDR). In the communication start procedure, specify writing to the transmit FIFO data register (SSIFTDR) as the DTC/DMAC operation in response to the transmit data empty interrupt. With this setting, SSIE can continuously transmit data not through the CPU. The transmit data empty interrupt is generated when the free space size of transmit FIFO data register reaches the value set in SSISCR.TDES. The number of times of writing must be specified in accordance with the free space size of the transmit FIFO data register indicated by the transmit data empty interrupt. If an error occurs, perform the error-handling procedure as instructed in the communication stop procedure.

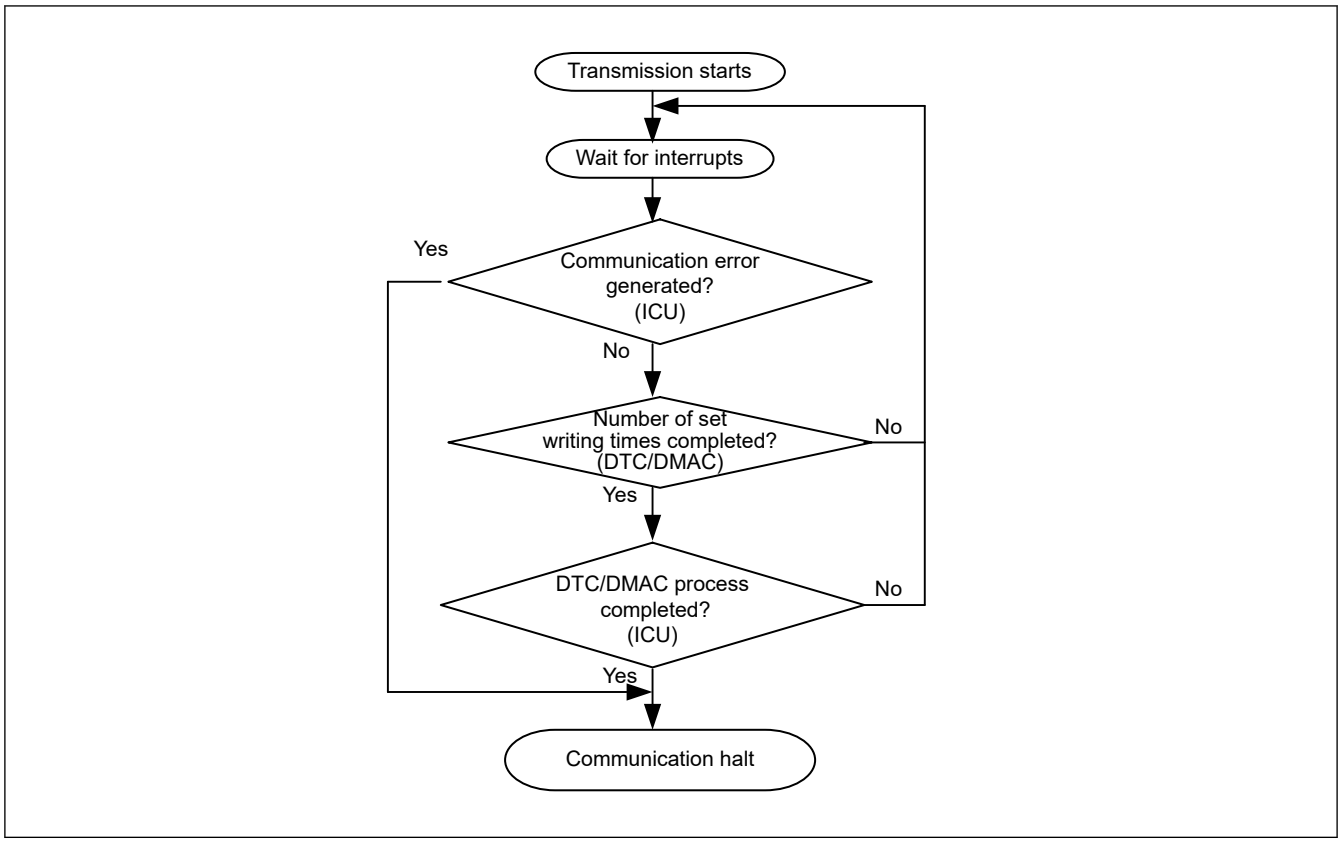

**Figure 35.53 Transmission procedure**

Note: The communication flow defined in SSIE uses the DTC/DMAC. If you do not use the DTC/DMAC, perform polling of the value 1 of SSIFSR.TDE to write data to SSIFTDR. The number of times of writing data to SSIFTDR by detecting the value 1 of SSIFSR.TDE must be in accordance with the free space size of the transmit FIFO data register specified by SSISCR.TDES. After as much transmit data as the free space size is written to SSIFTDR, the SSIFSR.TDE flag must be cleared. Continuous transmission is enabled by repeating data writing. If the SSIFSR.TDE flag is not cleared, the flag is not cleared automatically.

## 35.8.3 Reception

The reception procedure in Figure 35.54 must be followed throughout a reception operation.

After reception is enabled (SSICR.TEN = 0 and SSICR.REN = 1), SSIE starts reception when a start trigger is generated by SSILRCK0/SSIFS0. SSIE outputs a receive data full interrupt to the DTC/DMAC according to the RDF setting condition (SSISCR.RDFS) and the status of receive data full interrupt enable (SSIFCR.RIE) bit specified in the communication start procedure. This interrupt requests data reading from the receive FIFO data register (SSIFRDR). In the communication start procedure, specify reading from the receive FIFO data register (SSIFRDR) as the DTC/DMAC operation in response to the receive data full interrupt. With this setting, SSIE can continuously read data not through the CPU. The receive data full interrupt is generated when data as much as the capacity of receive FIFO data register has been stored. The number of times

of reading must be specified in accordance with the data size of the receive FIFO data register indicated by the receive data full interrupt. If an error occurs, perform the error-handling procedure as instructed in the communication stop procedure.

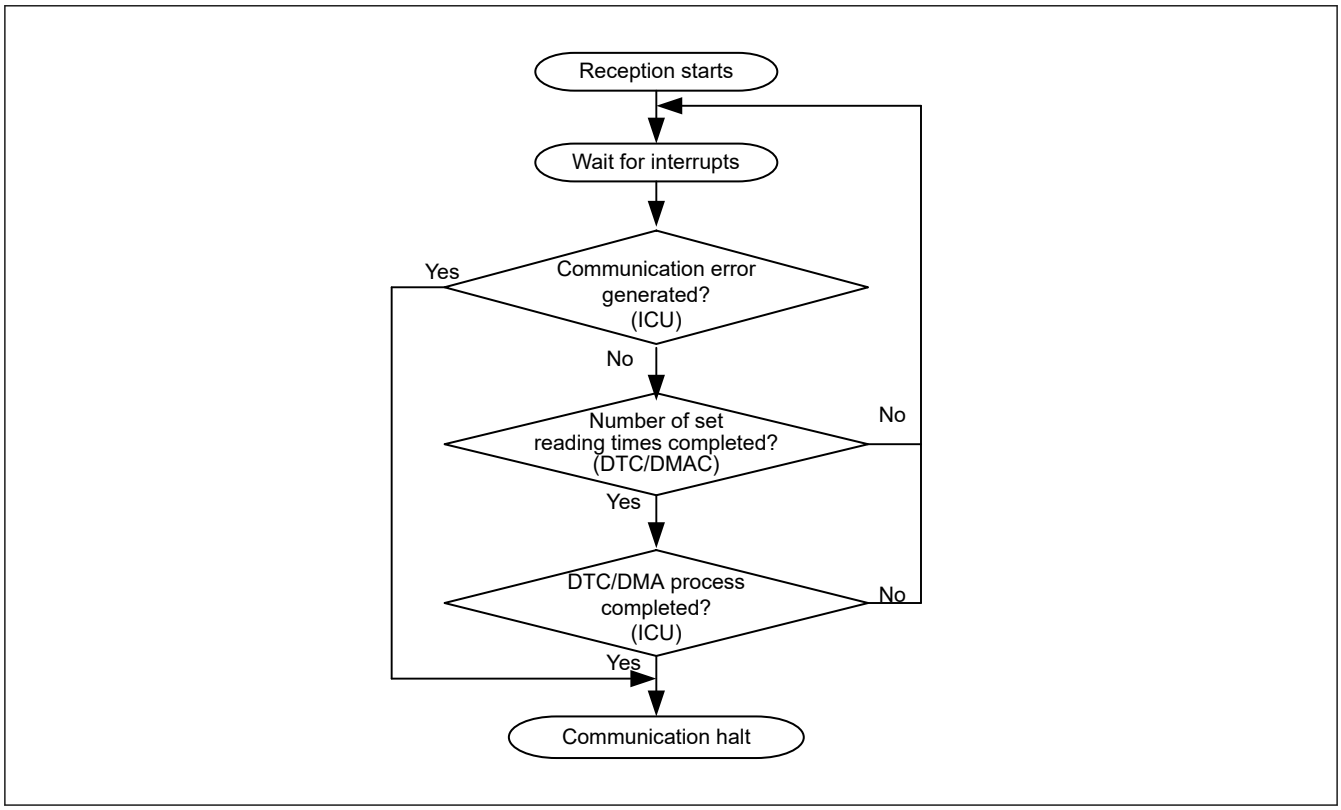

**Figure 35.54 Reception procedure**

Note: The communication flow defined in SSIE uses the DTC/DMAC. If you do not use the DTC/DMAC, perform polling of the value 1 of SSIFSR.RDF to read data from SSIFRDR. The number of times of reading data from SSIFRDR by detecting the value 1 of SSIFSR.RDF must be in accordance with the receive data storage capacity of the receive FIFO data register specified by SSISCR.RDFS. After received data is read from SSIFRDR, the SSIFSR.RDF flag must be cleared. Continuous reception is enabled by repeating data reading. If the SSIFSR.RDF flag is not cleared, the flag is not cleared automatically.

### 35.8.4 Transmission and Reception

After transmission and reception are enabled (SSICR.TEN = 1 and SSICR.REN = 1), SSIE starts transmission and reception when a start trigger is generated by SSILRCK0/SSIFS0 with the serial data for at least a frame contained in the transmit FIFO data register (SSIFTDR). SSIE can continuously transmit and receive data by performing the procedures described in section 35.8.2. Transmission and section 35.8.3. Reception, respectively. For how to stop transmission and reception, see section 35.8.5. Halt Communication.

### 35.8.5 Halt Communication

This section describes how to halt communication of SSIE. Figure 35.55 shows the procedure to halt communication. Be sure to follow the procedure.

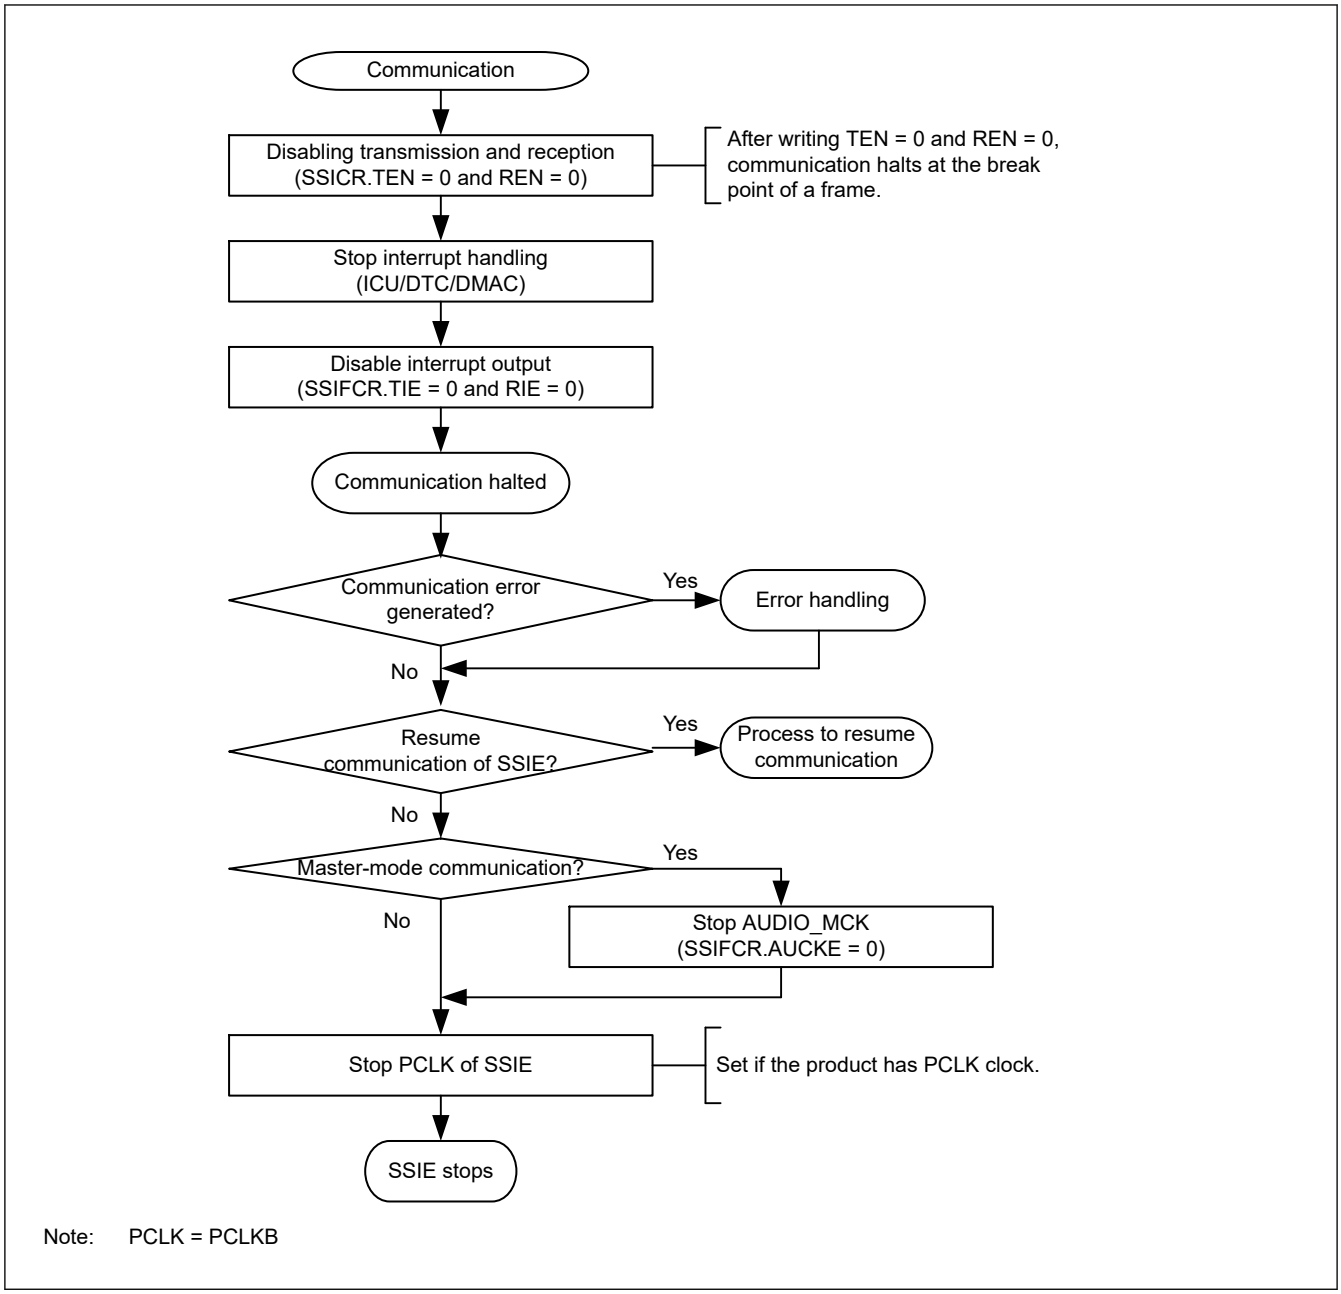

**Figure 35.55 Procedure to halt communication (CPU operation procedure)**

To halt the communication of SSIE, supply of the following clocks are required until the SSISR.IIRQ bit indicates an idle state.

- Input clock from the SSIBCK0 pin when SSICR.MST = 0
- AUDIO_MCK when SSICR.MST = 1
  To resume communication of SSIE in the previous setting, see section 35.8.7. Resume Communication.

Note: When communication of SSIE is halted according to the procedure to halt communication in Figure 35.55, resume communication according to the procedure to resume communication in Figure 35.57.

## 35.8.6 Error Handling

SSIE has the following four errors.

- Transmit underflow error
- Transmit overflow error
- Receive underflow error

- Receive overflow error.

When an underflow error or overflow error is generated, SSIE need to be restarted. Follow the procedure to halt communication in Figure 35.55 and error-handling procedure in Figure 35.56.

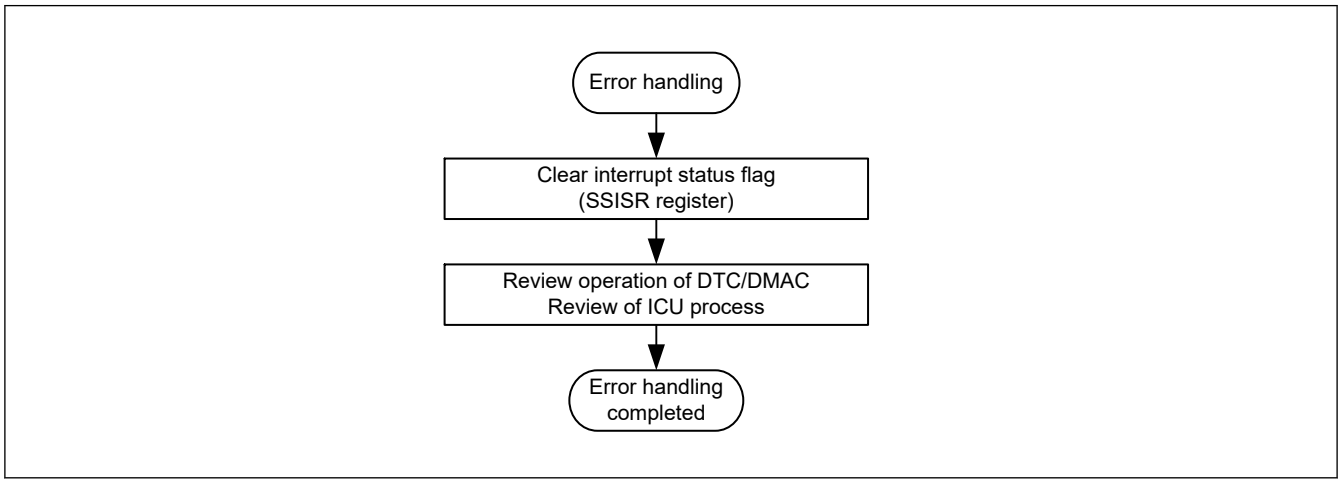

**Figure 35.56 Error-handling procedure**

Four error operations are described as follows. When the interrupt output enable bit of the SSICR register is enabled and error flags are set, an error interrupt is generated. See section 35.4.2. SSISR : Status Register for the setting conditions of error flags.

### (1) Transmit Underflow Error

If a transmit underflow error occurs, review the number of times of writing data to the transmit FIFO data register (SSIFTDR) in response to a transmit data empty interrupt. After a transmit underflow error occurs, SSIE outputs 0s as data. To normally output the serial data written to the transmit FIFO data register (SSIFTDR) to the SSITXD0 pin, follow the procedure to halt communication in Figure 35.55 and error-handling procedure in Figure 35.56. After this error occurs, serial data is consumed as usual. If you resume communication, write the serial data from the beginning.

### (2) Transmit Overflow Error

If a transmit overflow error occurs, review the number of times of writing data to the transmit FIFO data register (SSIFTDR) in response to transmit data empty interrupts. The serial data written to the transmit FIFO data register (SSIFTDR) that caused the transmit overflow error becomes invalid. This error can occur regardless of whether a transmission operation is being done. To recover from the error, follow the procedure to halt communication in Figure 35.55 and error-handling procedure in Figure 35.56. When you resume communication, deal with the invalid serial data appropriately.

### (3) Receive Underflow Error

If a receive underflow error occurs, review the number of times of reading data from the receive FIFO data register (SSIFRDR) in response to receive data full interrupts. The values read from the receive FIFO data register (SSIFRDR) that caused the receive underflow error are undefined. This error can occur regardless of whether a reception operation is being done. To recover from the error, follow the procedure to halt communication in Figure 35.55 and error-handling procedure in Figure 35.56.

### (4) Receive Overflow Error

If a receive overflow error occurs, review the number of times of reading data from the receive FIFO data register (SSIFRDR) in response to receive data full interrupts. The receive data that caused the receive overflow error cannot be stored in the receive FIFO data register (SSIFRDR). To recover from the error, follow the procedure to halt communication in Figure 35.55 and error-handling procedure in Figure 35.56.

## 35.8.7 Resume Communication

When you resume the communication using SSIE, follow the communication resume procedure in Figure 35.57. The communication resume procedure is designed on the assumption that you resume the communication stopped by the

communication stop procedure without changing any settings. If you want to change clock and slave/master settings, use and follow the communication start procedure in Figure 35.52. For details about the transmission operation and reception operation after starting communication, see section 35.8.2. Transmission and section 35.8.3. Reception, respectively.

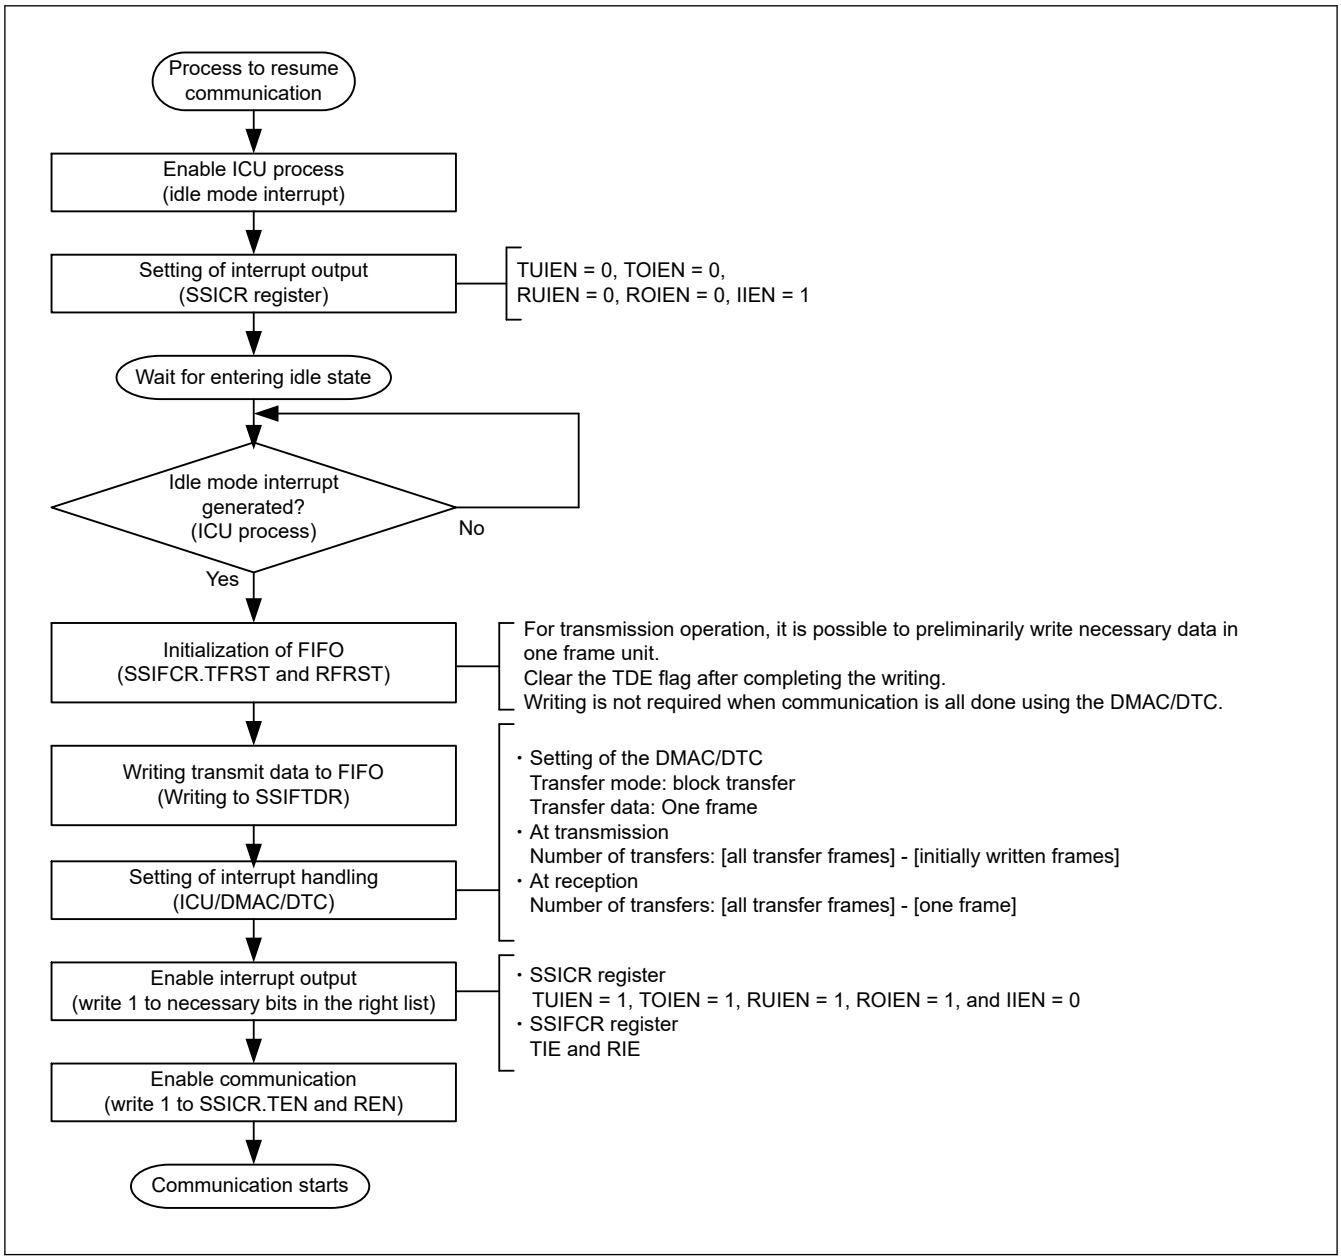

**Figure 35.57 Procedure to resume communication (CPU operation procedure)**

## 35.9 Interrupts

Table 35.16 lists the interrupt sources. Set enable/disable of interrupt output of each source with the TUIEN, TOIEN, RUIEN, ROIEN, and IIEN bits in the SSICR register and the TIE and RIE bits in the SSIFCR register.

**Table 35.16 SSIE interrupt sources**

| Channel | Interrupt source | Description | Interrupt flag | DMAC/DTC activation |
|---|---|---|---|---|
| SSIE0 | SSIE0_SSIF | • Transmit underflow interrupt<br>• Transmit overflow interrupt<br>• Receive underflow interrupt<br>• Receive overflow interrupt<br>• Idle interrupt | SSISR.TUIRQ<br>SSISR.TOIRQ<br>SSISR.RUIRQ<br>SSISR.ROIRQ<br>SSISR.IIRQ | Not possible |
| | SSIE0_SSIRXI | Receive data full interrupt | SSIFSR.RDF | Possible |
| | SSIE0_SSITXI | Transmit data empty interrupt | SSIFSR.TDE | Possible |

## 35.9.1 SSIE0_SSIF Interrupt

This interrupt source combines five interrupts. Enable output of necessary interrupts before using SSIE. The five interrupts are operated by using the flags assigned to individual interrupts and interrupt output enable bits. To clear an interrupt, set the interrupt enable to 0 or clear the interrupt flag to 0.

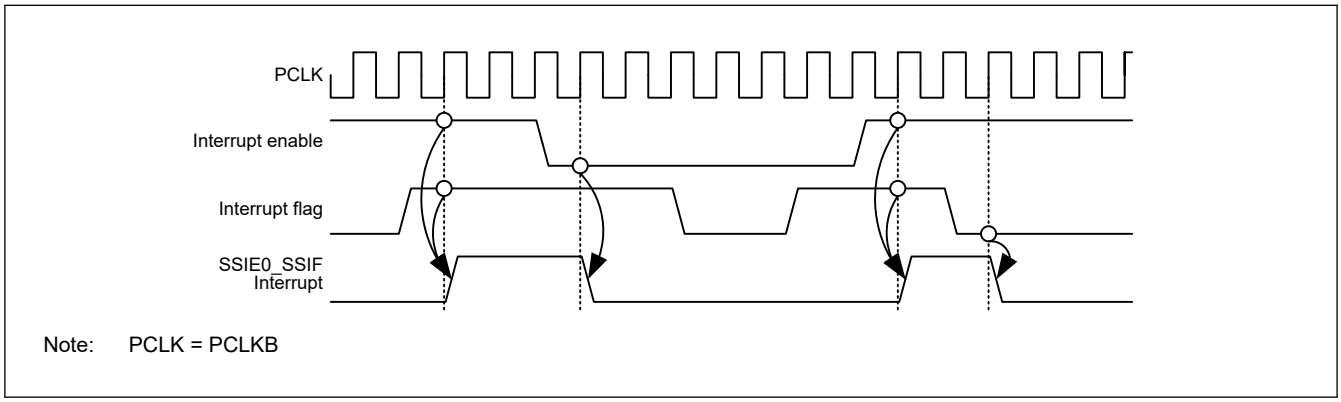

**Figure 35.58 Timing diagram of the common interrupt source, SSIE0_SSIF**

- Transmit underflow interrupt

As the transmit underflow interrupt, SSISR.TUIRQ is output while SSICR.TUIEN = 1. When you use SSIE for transmission, enable the output of this interrupt (SSICR.TUIEN = 1). If this interrupt occurs, follow instructions in the procedure to halt communication in Figure 35.55 and error-handling procedure in Figure 35.56.

- Transmit overflow interrupt

As the transmit overflow interrupt, SSISR.TOIRQ is output while SSICR.TOIEN = 1. When you use SSIE for transmission, enable the output of this interrupt (SSICR.TOIEN = 1). If this interrupt occurs, follow instructions in the procedure to halt communication in Figure 35.55 and error-handling procedure in Figure 35.56.

- Receive underflow interrupt

As the receive underflow interrupt, SSISR.RUIRQ is output while SSICR.RUIEN = 1. When you use SSIE for reception, enable the output of this interrupt (SSICR.RUIEN = 1). If this interrupt occurs, follow instructions in the procedure to halt communication in Figure 35.55 and error-handling procedure in Figure 35.56.

- Receive overflow interrupt

As the receive overflow interrupt, SSISR.ROIRQ is output while SSICR.ROIEN = 1. When you use SSIE for reception, enable the output of this interrupt (SSICR.ROIEN = 1). If this interrupt occurs, follow instructions in the procedure to halt communication in Figure 35.55 and error-handling procedure in Figure 35.56.

- Idle mode interrupt

As the idle mode interrupt, SSISR.IIRQ is output while SSICR.IIEN = 1. This interrupt is used to make sure that communication has stopped fully.

### 35.9.2 SSIE0_SSITXI Interrupt

The transmit data empty interrupt is a pulse interrupt that is output when the following condition is met:

- SSIFCR.TIE = 1 and SSIFSR.TDE = 1
  SSIE operation: When the value of SSIFSR.TDE changes from 0 to 1 while the value of SSIFCR.TIE is 1
  CPU instruction: When the value of SSIFCR.TIE changes from 0 to 1 while the value of SSIFSR.TDE is 1

This interrupt is subject to the interrupt suppression function. If an interrupt condition for this interrupt occurs when the DTC/DMAC is busy (when the DTC/DMAC cannot accept interrupts), the interrupt suppression function holds the output of this interrupt. The held interrupt will be output after the DTC/DMAC is enabled to accept interrupts. For details, see Figure 35.59.

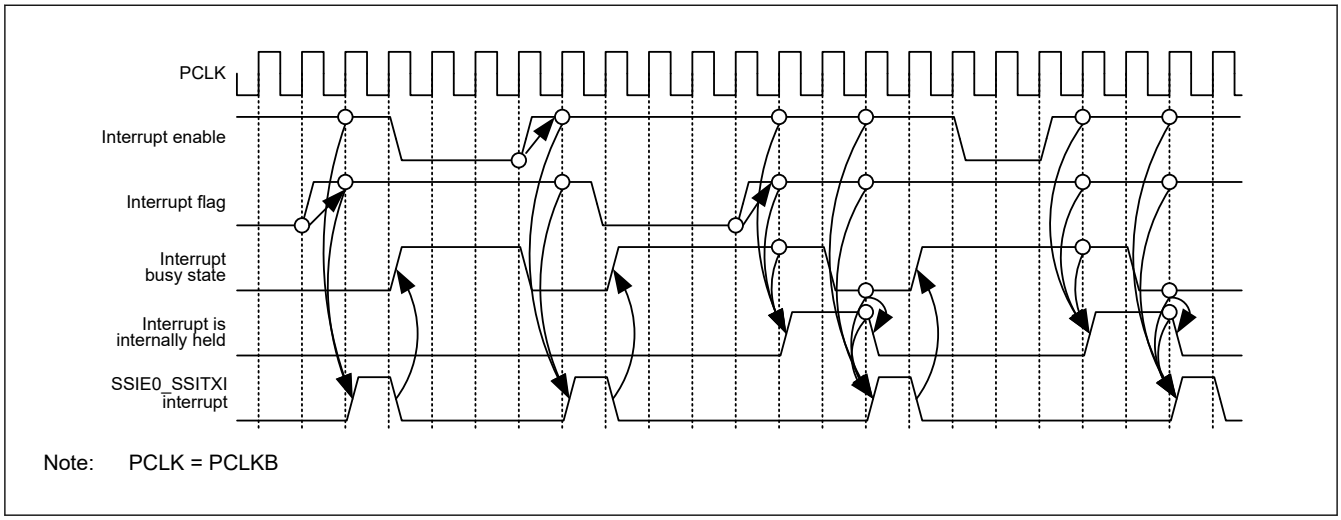

**Figure 35.59 SSIE0_SSITXI interrupt timing diagram**

### 35.9.3 SSIE0_SSIRXI Interrupt

The receive data full interrupt is a pulse interrupt that is output when the following condition is met:

- SSIFCR.RIE = 1 and SSIFSR.RDF = 1.
  SSIE operation: When the value of SSIFSR.RDF changes from 0 to 1 while the value of SSIFCR.RIE is 1
  CPU instruction: When the value of SSIFCR.RIE changes from 0 to 1 while the value of SSIFSR.RDE is 1

This interrupt is subject to the interrupt suppression function. If an interrupt condition for this interrupt occurs when the DTC/DMAC is busy (when the DTC/DMAC cannot accept interrupts), the interrupt suppression function holds the output of this interrupt. The held interrupt will be output after the DTC/DMAC is enabled to accept interrupts. The behavior of this interrupt is the same as the behavior shown in Figure 35.59.

## 35.10 Software Resets

SSIE has three software reset bits to reset its states.

- SSIE software reset (SSIFCR.SSIRST)
- Transmit FIFO data register reset (SSIFCR.TFRST)
- Receive FIFO data register reset (SSIFCR.RFRST).

This section describes the procedures for the three types of software resets.

### 35.10.1 Software Reset Procedure

#### (1) SSIE Software Reset

For the SSIE software reset bit (SSIFCR.SSIRST), follow the procedure shown in Figure 35.60. After a reset, the same setting is applied when it is resumed. To change the settings of clocks and slave/master mode, follow the procedure

to start communication in Figure 35.52. See section 35.8.2. Transmission and section 35.8.3. Reception respectively for transmission and reception after communication is resumed.

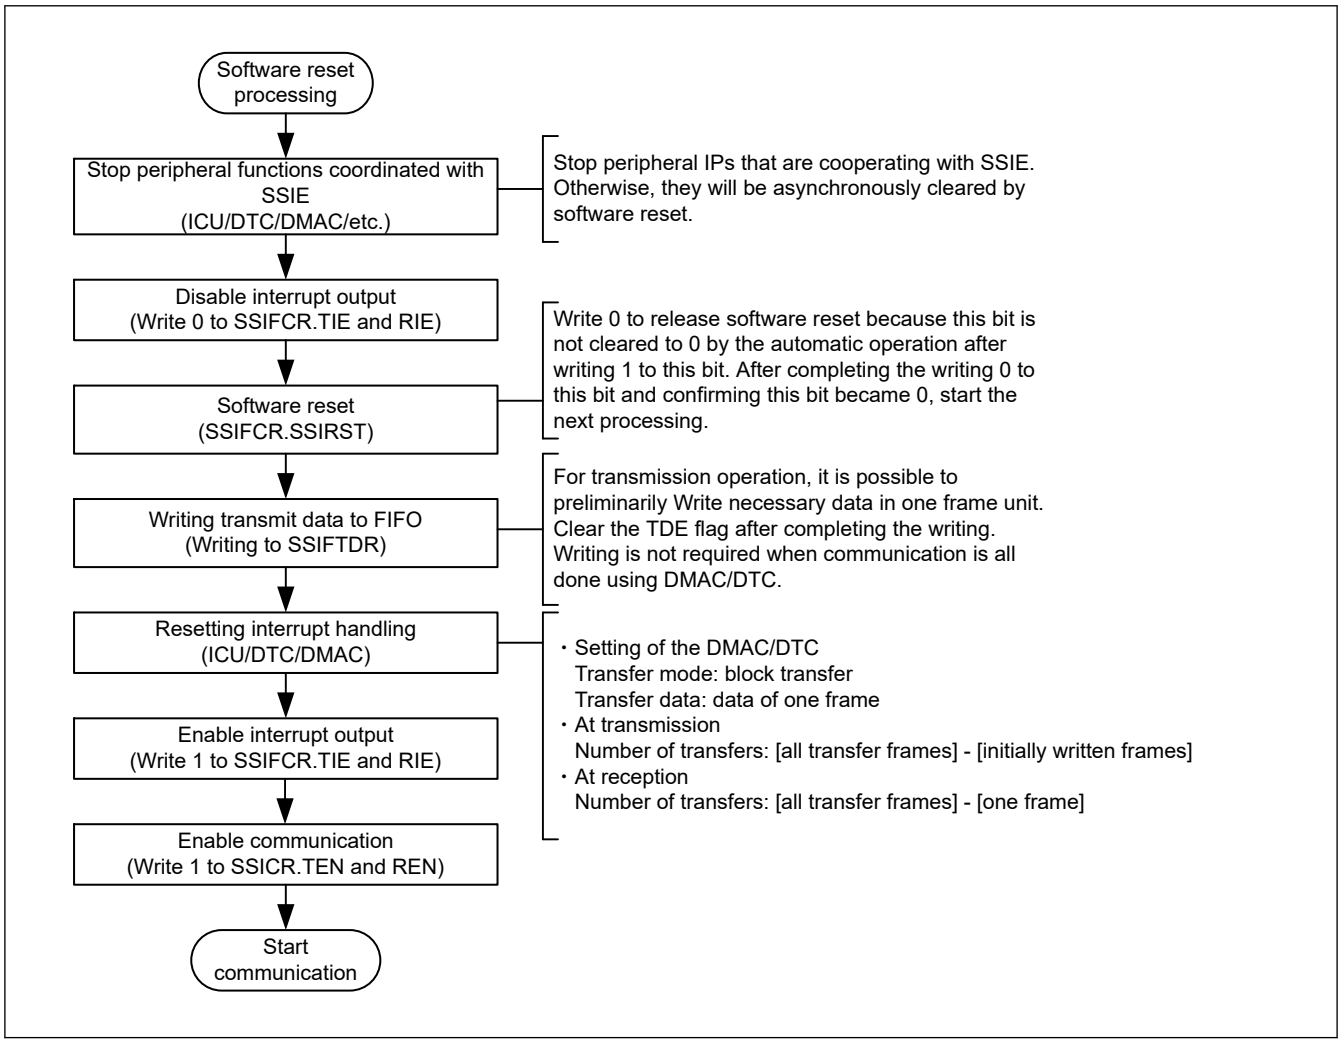

**Figure 35.60 Software reset procedure (CPU operation procedure)**

### (2) Transmit FIFO data register reset

To perform a transmit FIFO data register reset, follow instructions in the procedure to start communication in Figure 35.52 and procedure to resume communication in Figure 35.57.

### (3) Receive FIFO data register reset

To perform a receive FIFO data register reset, follow instructions in the procedure to start communication in Figure 35.52 and procedure to resume communication in Figure 35.57.

## 35.11 Notes

## 35.11.1 Notes for Slave-mode Communication

### 35.11.1.1 SSIBCK0 control

In slave-mode communication (SSICR.MST = 0), SSIE needs supply of SSIBCK0. To stop BCK on the master side, make sure that SSIE is in the idle state (SSISR.IIRQ = 1). If BCK is stopped before SSIE becomes idle, take the procedure to start communication in Figure 35.52 or wait for an idle state by taking the procedure to resume communication in Figure 35.57.

#### 35.11.1.2 SSILRCK0/SSIFS0 pin

SSIE has the SSILRCK0/SSIFS0 pin, which indicates the synchronization of communication. When SSIE is in slave mode (SSICR.MST = 0), the communication format SSIE uses must match that of the other-party device to communicate. SSIE uses the signal input by the SSILRCK0/SSIFS0 pin only as a trigger to start communication.

### 35.11.2 Notes for Master-mode Communication

#### 35.11.2.1 AUCKE control

In master-mode communication (SSICR.MST = 1), SSIE operates with the audio clock (AUDIO_MCK). To stop SSIE completely, make sure that SSIE is in the idle state (SSISR.IIRQ = 1) and then write 0 to SSIFCR.AUCKE.

#### 35.11.2.2 LRCONT control

To stop the output to the SSILRCK0/SSIFS0 pin with SSIOFR.LRCONT when SSIE is in the idle state in master-mode communication (SSICR.MST = 1), note the following: The output stops when the value of the SSIOFR.LRCONT bit is changed from 1 to 0. Make sure that the other-party device is not affected. For details, see Figure 35.43.

#### 35.11.2.3 BCKASTP control

To stop the output to the SSIBCK0 pin with SSIOFR.BCKASTP in master-mode communication (SSICR.MST = 1) and while SSIE is in the idle state, note the following: The output stops when the value of the SSIOFR.BCKASTP bit is changed from 0 to 1. So, make sure that the other-party device is not affected. For details, see Figure 35.44.

The BCKASTP bit cannot be used when the other-party device (which is a slave) requires the clock output from the SSIBCK0 pin before and during communication.

### 35.11.3 Notes for Communication Flow

#### 35.11.3.1 When an error interrupt is generated

SSIE has the following four errors.

- Transmit underflow error
- Transmit overflow error
- Receive underflow error
- Receive overflow error

When an underflow error or overflow error is generated, SSIE need to be restarted. Follow the procedure to halt communication in Figure 35.55 and error-handling procedure in Figure 35.56.

##### (1) Transmit Underflow Error

If a transmit underflow error occurs, review the number of times of writing data to the transmit FIFO data register (SSIFTDR) in response to a transmit data empty interrupt. After a transmit underflow error occurs, SSIE outputs 0s as data. To normally output the serial data written to the transmit FIFO data register (SSIFTDR) to the SSITXD0 pin, follow the procedure to halt communication in Figure 35.55 and error-handling procedure in Figure 35.56. After this error occurs, serial data is consumed as usual. If you resume communication, write the serial data from the beginning.

##### (2) Transmit Overflow Error

If a transmit overflow error occurs, review the number of times of writing data to the Transmit FIFO Data Register (SSIFTDR) in response to transmit data empty interrupts. The serial data written to the Transmit FIFO Data Register (SSIFTDR) that caused the transmit overflow error becomes invalid. This error can occur regardless of whether a transmission operation is being done. To recover from the error, follow the procedure to halt communication in Figure 35.55 and error-handling procedure in Figure 35.56. When you resume communication, deal with the invalid serial data appropriately.

#### (3) Receive Underflow Error

If a receive underflow error occurs, review the number of times of reading data from the receive FIFO data register (SSIFRDR) in response to receive data full interrupts. The values read from the receive FIFO data register (SSIFRDR) that caused the receive underflow error are undefined. This error can occur regardless of whether a reception operation is being done. To recover from the error, follow the procedure to halt communication in Figure 35.55 and error-handling procedure in Figure 35.56.

#### (4) Receive Overflow Error

If a receive overflow error occurs, review the number of times of reading data from the receive FIFO data register (SSIFRDR) in response to receive data full interrupts. The receive data that caused the receive overflow error cannot be stored in the receive FIFO data register (SSIFRDR). To recover from the error, follow the procedure to halt communication in Figure 35.55 and error-handling procedure in Figure 35.56.

### 35.11.3.2 Transmit data empty interrupt

The communication flow defined in SSIE uses the DTC/DMAC. If you do not use the DTC/DMAC, perform polling of the value 1 of SSIFSR.TDE to write data to SSIFTDR. The number of times of writing data to SSIFTDR by detecting the value 1 of SSIFSR.TDE must be in accordance with the free space size of the transmit FIFO data register specified by SSISCR.TDES. After as much transmit data as the free space size is written to SSIFTDR, the SSIFSR.TDE flag must be cleared. Continuous transmission is enabled by repeating data writing. If the SSIFSR.TDE flag is not cleared, the flag is not cleared automatically.

### 35.11.3.3 Receive data full interrupt

The communication flow defined in SSIE uses the DTC/DMAC. If you do not use the DTC/DMAC, perform polling of the value 1 of SSIFSR.RDF to read data from SSIFRDR. The number of times of reading data from SSIFRDR by detecting the value 1 of SSIFSR.RDF must be in accordance with the receive data storage capacity of the receive FIFO data register specified by SSISCR.RDFS. After received data is read from SSIFRDR, the SSIFSR.RDF flag must be cleared. Continuous reception is enabled by repeating data reading. If the SSIFSR.RDF flag is not cleared, the flag is not cleared automatically.

### 35.11.3.4 Switching transfer modes

1. For state transition from transmission, reception, and transmission and reception, disable transmission and reception (SSICR.TEN = 0, SSICR.REN = 0).
2. Confirm it is in the idle state (SSISR.IIRQ = 1).
3. In the idle state, set the SSICR.TEN bit or the SSICR.REN bit again and resume transfer.

### 35.11.3.5 Resume communication after halting SSIE

When communication of SSIE is halted according to the procedure to halt communication in Figure 35.55, resume communication according to the procedure to resume communication in Figure 35.57.

## 35.11.4 Write Access Restriction

### 35.11.4.1 SSICR register

If the TEN bit or REN bit is rewritten, make sure that the SSISR.IIRQ bit is in the desired status. If the value of the TEN or REN bit is changed by rewriting, subsequent operation is unpredictable. For example, when transmission or reception is enabled, check that SSISR.IIRQ is 0; when transmission or reception is disabled, check that SSISR.IIRQ is 1.

#### (1) TEN Bit and REN Bit

These bits enable/disable transmission and reception. When 1 is written to one of these bits, the corresponding communication operation starts in synchronization with a start trigger by the SSILRCK0/SSIFS0 signal. For details, see section 35.8.2. Transmission, section 35.8.3. Reception, and section 35.8.4. Transmission and Reception. When 0 is written to this bit, the current communication operation stops at the next frame boundary. To use SSIE for both transmission and reception, always write 1 to these bits together. When stopping the communication using SSIE, always disable both transmission and reception (write 0 to the TEN and REN bits).

### 35.11.4.2 SSISR register

#### (1) Clearing TUIRQ and TOIRQ

After communication is enabled (by changing the value of SSICR.TEN bit from 0 to 1), the transmission error flags (TOIRQ and TUIRQ in the SSISR register) are cleared. If, however, the SSISR register is read continuously, the cleared status of the transmission error flags might be unable to be read.

#### (2) Clearing RUIRQ and ROIRQ

After communication is enabled (by changing the value of SSICR.REN bit from 0 to 1), the reception error flags (RUIRQ and ROIRQ in the SSISR register) are cleared. If, however, the SSISR register is read continuously, the cleared status of the reception error flags might be unable to be read.

### 35.11.4.3 Communication state

Writing to the bits with orange-shaded area in Table 35.17 is prohibited. If written, the operation performed immediately after writing is not guaranteed.

**Table 35.17 Bits protected from writing during communication**

# 36. Cyclic Redundancy Check (CRC)

## 36.1 Overview

The Cyclic Redundancy Check (CRC) generates CRC codes to detect errors in the data. The bit order of CRC calculation results can be switched for LSB-first or MSB-first communication. Additionally, various CRC-generation polynomials are available.

Table 36.1 lists the CRC calculator specifications and Figure 36.1 shows a block diagram.

**Table 36.1 CRC calculator specifications**

| Item | Description | |
|---|---|---|
| Data size | 8-bit | 32-bit |
| Data for CRC calculation*1 | CRC code generated for data in 8n-bit units (where n is a natural number) | CRC code generated for data in 32n-bit units (where n is a natural number) |
| CRC processor unit | Operation executed on 8 bits in parallel | Operation executed on 32 bits in parallel |
| CRC generating polynomial | One of three generating polynomials that is selectable:<br>[8-bit CRC]<br>• $X^8 + X^2 + X + 1$ (CRC-8)<br>[16-bit CRC]<br>• $X^{16} + X^{15} + X^2 + 1$ (CRC-16)<br>• $X^{16} + X^{12} + X^5 + 1$ (CRC-CCITT). | One of two generating polynomials that is selectable:<br>[32-bit CRC]<br>• $X^{32} + X^{26} + X^{23} + X^{22} + X^{16} + X^{12} + X^{11} + X^{10} + X^8 + X^7 + X^5 + X^4 + X^2 + X + 1$ (CRC-32)<br>• $X^{32} + X^{28} + X^{27} + X^{26} + X^{25} + X^{23} + X^{22} + X^{20} + X^{19} + X^{18} + X^{14} + X^{13} + X^{11} + X^{10} + X^9 + X^8 + X^6 + 1$ (CRC-32C). |
| CRC calculation switching | The bit order of CRC calculation results can be switched for LSB-first or MSB-first communication | |
| Module-stop function | Module-stop state can be set to reduce power consumption | |
| TrustZone Filter | Security attribution can be set | |

Note 1. This function cannot divide data used in CRC calculations. Write data in 8-bit or 32-bit units.

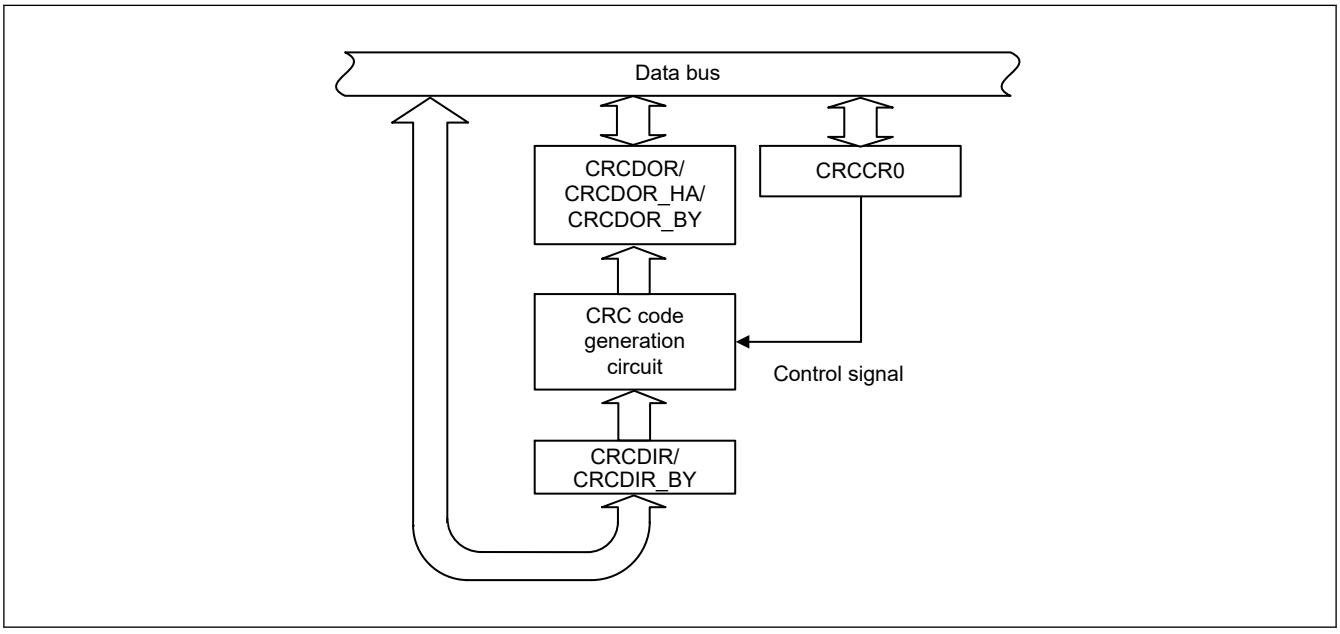

**Figure 36.1 CRC calculator block diagram**

## 36.2 Register Descriptions

### 36.2.1 CRCCR0 : CRC Control Register 0

Base address: CRC = 0x4010_8000

Offset address: 0x00

| Bit position: | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|
| Bit field: | DORCLR | LMS | — | — | — | GPS[2:0] | | |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 2:0 | GPS[2:0] | CRC Generating Polynomial Switching<br>0 0 1: 8-bit CRC-8 ($X^8 + X^2 + X + 1$)<br>0 1 0: 16-bit CRC-16 ($X^{16} + X^{15} + X^2 + 1$)<br>0 1 1: 16-bit CRC-CCITT ($X^{16} + X^{12} + X^5 + 1$)<br>1 0 0: 32-bit CRC-32 ($X^{32} + X^{26} + X^{23} + X^{22} + X^{16} + X^{12} + X^{11} + X^{10} + X^8 + X^7 + X^5 + X^4 + X^2 + X + 1$)<br>1 0 1: 32-bit CRC-32C ($X^{32} + X^{28} + X^{27} + X^{26} + X^{25} + X^{23} + X^{22} + X^{20} + X^{19} + X^{18} + X^{14} + X^{13} + X^{11} + X^{10} + X^9 + X^8 + X^6 + 1$)<br>Others: No calculation is executed | R/W |
| 5:3 | — | These bits are read as 0. The write value should be 0. | R/W |
| 6 | LMS | CRC Calculation Switching<br>0: Generate CRC code for LSB-first communication<br>1: Generate CRC code for MSB-first communication | R/W |
| 7 | DORCLR | CRCDOR/CRCDOR_HA/CRCDOR_BY Register Clear<br>0: No effect<br>1: Clear the CRCDOR/CRCDOR_HA/CRCDOR_BY register | W |

#### GPS[2:0] bits (CRC Generating Polynomial Switching)

The GPS[2:0] bits select the CRC generating polynomial.

#### LMS bit (CRC Calculation Switching)

The LMS bit selects the bit order of generated CRC code. Transmit the lower byte of the CRC code first for LSB-first communication and the upper byte first for MSB-first communication. For details on transmitting and receiving CRC code, see section 36.3. Operation.

#### DORCLR bit (CRCDOR/CRCDOR_HA/CRCDOR_BY Register Clear)

Write 1 to the DORCLR bit to set the CRCDOR/CRCDOR_HA/CRCDOR_BY register to 0x00000000. This bit is read as 0. Only 1 can be written to it.

### 36.2.2 CRCDIR/CRCDIR_BY : CRC Data Input Register

Base address: CRC = 0x4010_8000

Offset address: 0x04

| Bit position: | 31 | 0 |
|---|---|---|
| Bit field: | | |
| Value after reset: | 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 | |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 31:0 | n/a | CRC input data<br>The CRCDIR register is a 32-bit read/write register to write data for CRC-32 or CRC-32C calculation. The CRCDIR_BY (CRCDIR[31:24]) is an 8-bit read/write register to write data for CRC-8, CRC-16, or CRC-CCITT calculation. | R/W |

### 36.2.3 CRCDOR/CRCDOR_HA/CRCDOR_BY : CRC Data Output Register

Base address: CRC = 0x4010_8000

Offset address: 0x08

| Bit position: | 31 | | | | | | | | | | | | | | | | | | | | | | | | | | | | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 31:0 | n/a | CRC output data<br>The CRCDOR register is a 32-bit read/write register for CRC-32 or CRC-32C calculation.<br>The CRCDOR_HA (CRCDOR[31:16]) register is a 16-bit read/write register for CRC-16 or CRC-CCITT calculation.<br>The CRCDOR_BY (CRCDOR[31:24]) register is an 8-bit read/write register for CRC-8 calculation. Because its initial value is 0x00000000, rewrite the CRCDOR/CRCDOR_HA/CRCDOR_BY register to perform the calculations using a value other than the initial value.<br>Data written to the CRCDIR/CRCDIR_BY register is CRC calculated and the result is stored in the CRCDOR/CRCDOR_HA/CRCDOR_BY register. If the CRC code is calculated following the transferred data and the result is 0x00000000, there is no CRC error. | R/W |

## 36.3 Operation

### 36.3.1 Basic Operation

The CRC calculator generates CRC codes for use in LSB-first or MSB-first transfer.

The following examples show CRC code generation for input data (0xF0) using the 16-bit CRC-CCITT generating polynomial ($X^{16} + X^{12} + X^5 + 1$). In these examples, the value of the CRC Data Output Register (CRCDOR_HA) is cleared before CRC calculation.

When an 8-bit CRC (with the polynomial $X^8 + X^2 + X + 1$) is in use, the valid bits of the CRC code are obtained in CRCDOR_BY. When a 32-bit CRC is in use, the valid bits of the CRC code are obtained in CRCDOR.

Figure 36.2 and Figure 36.3 show the LSB-first and MSB-first data transmission examples respectively. Figure 36.4 and Figure 36.5 show the LSB-first and MSB-first data reception examples.

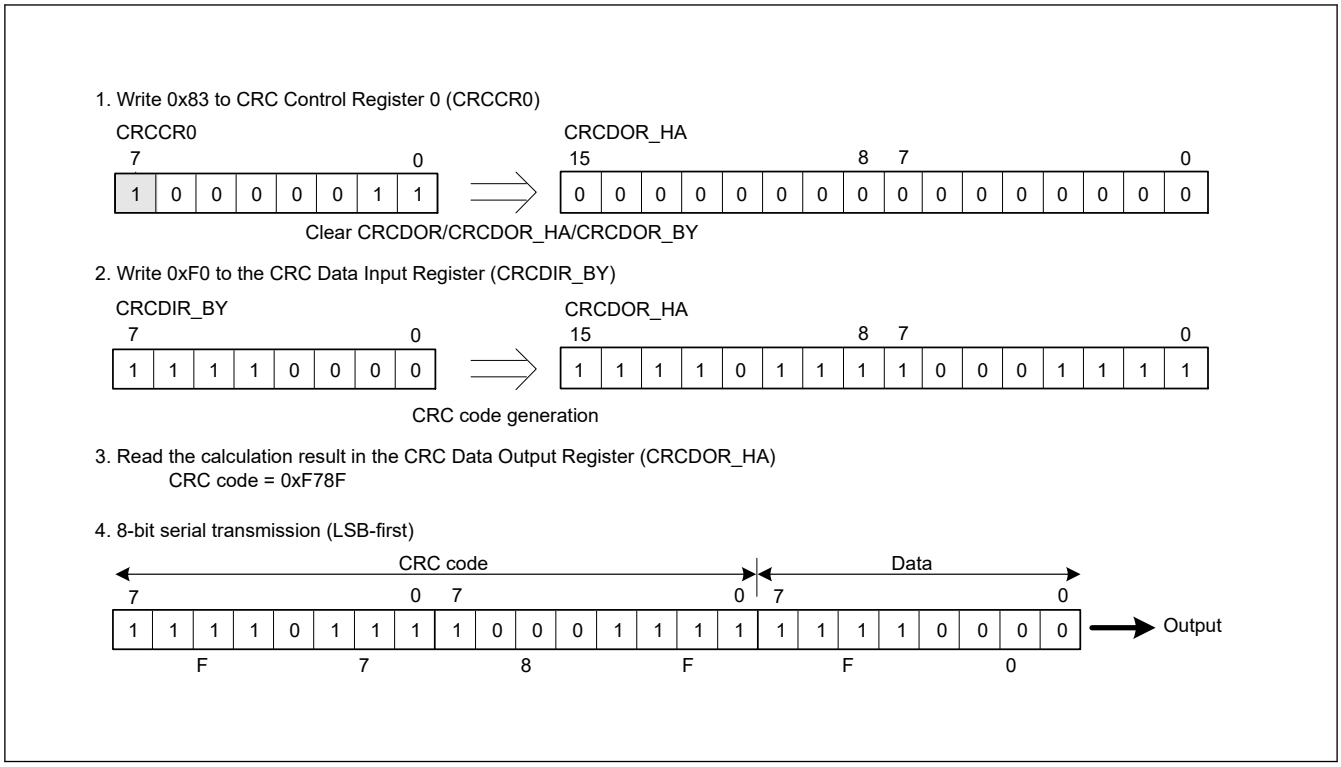

**Figure 36.2 LSB-first data transmission**

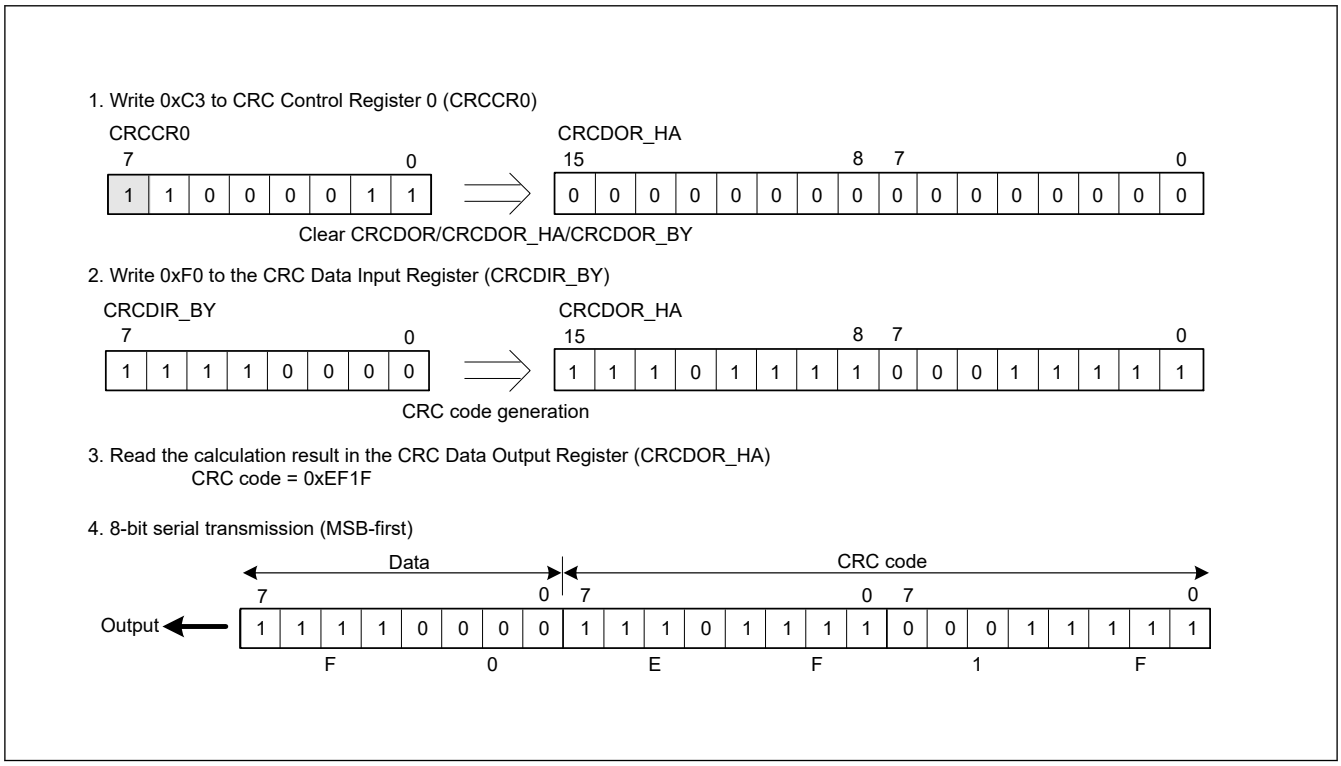

**Figure 36.3 MSB-first data transmission**

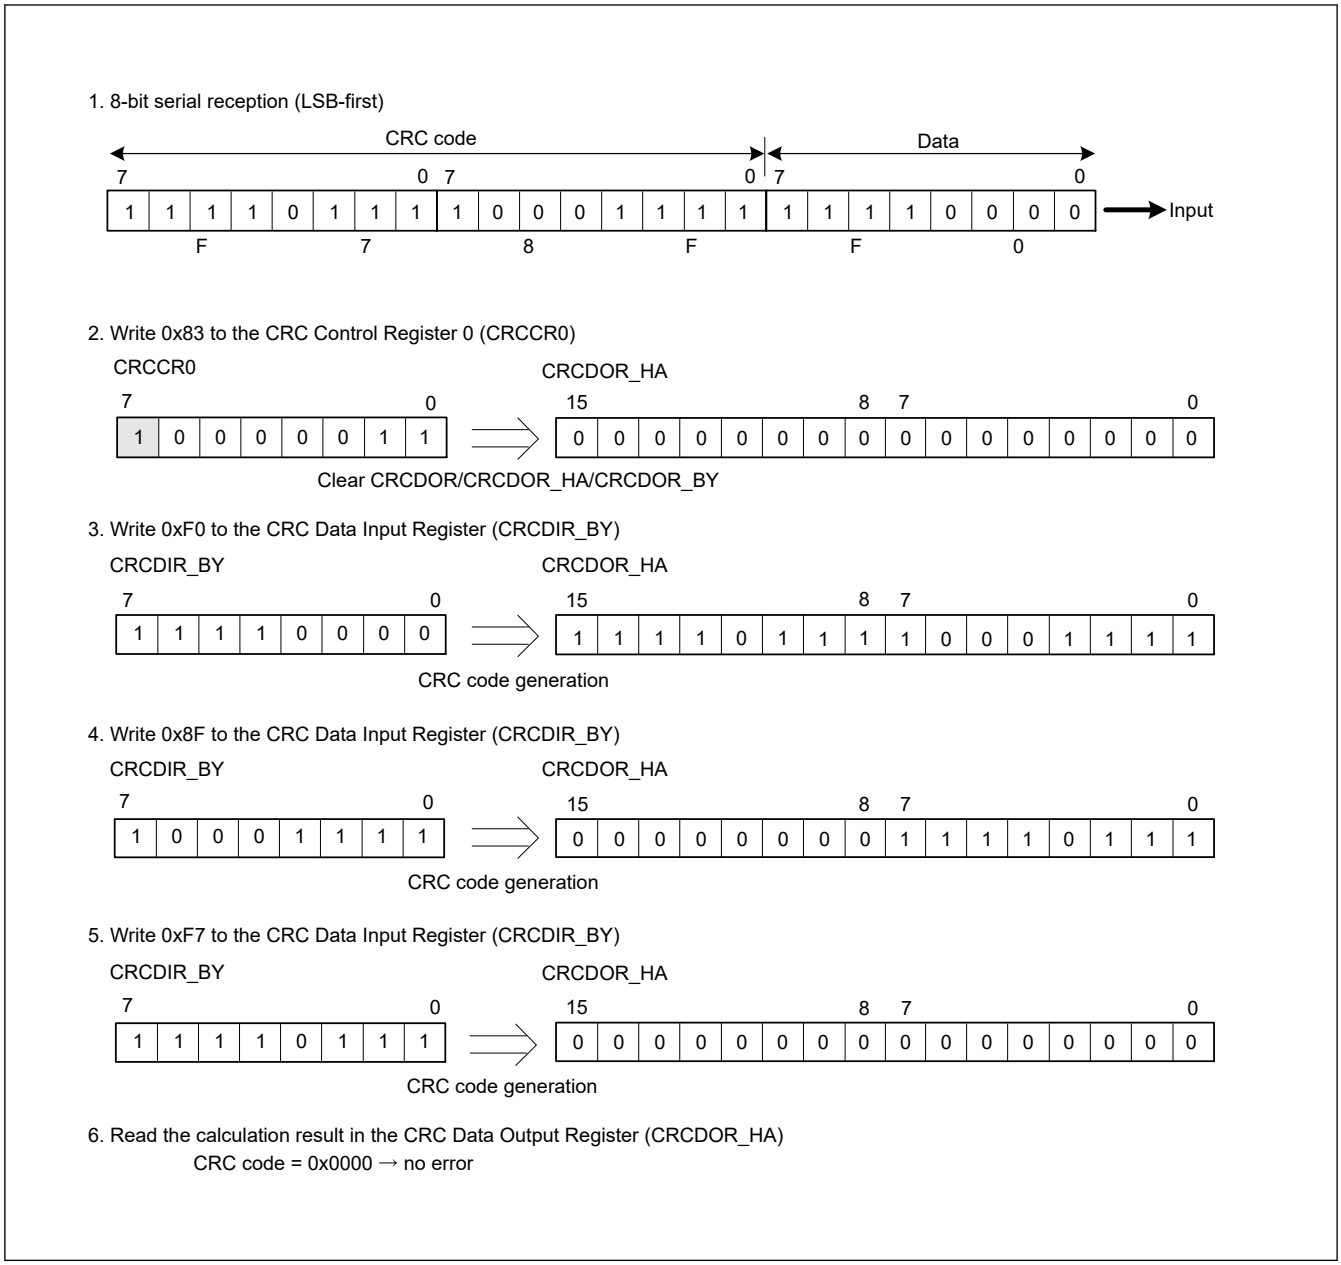

**Figure 36.4 LSB-first data reception**

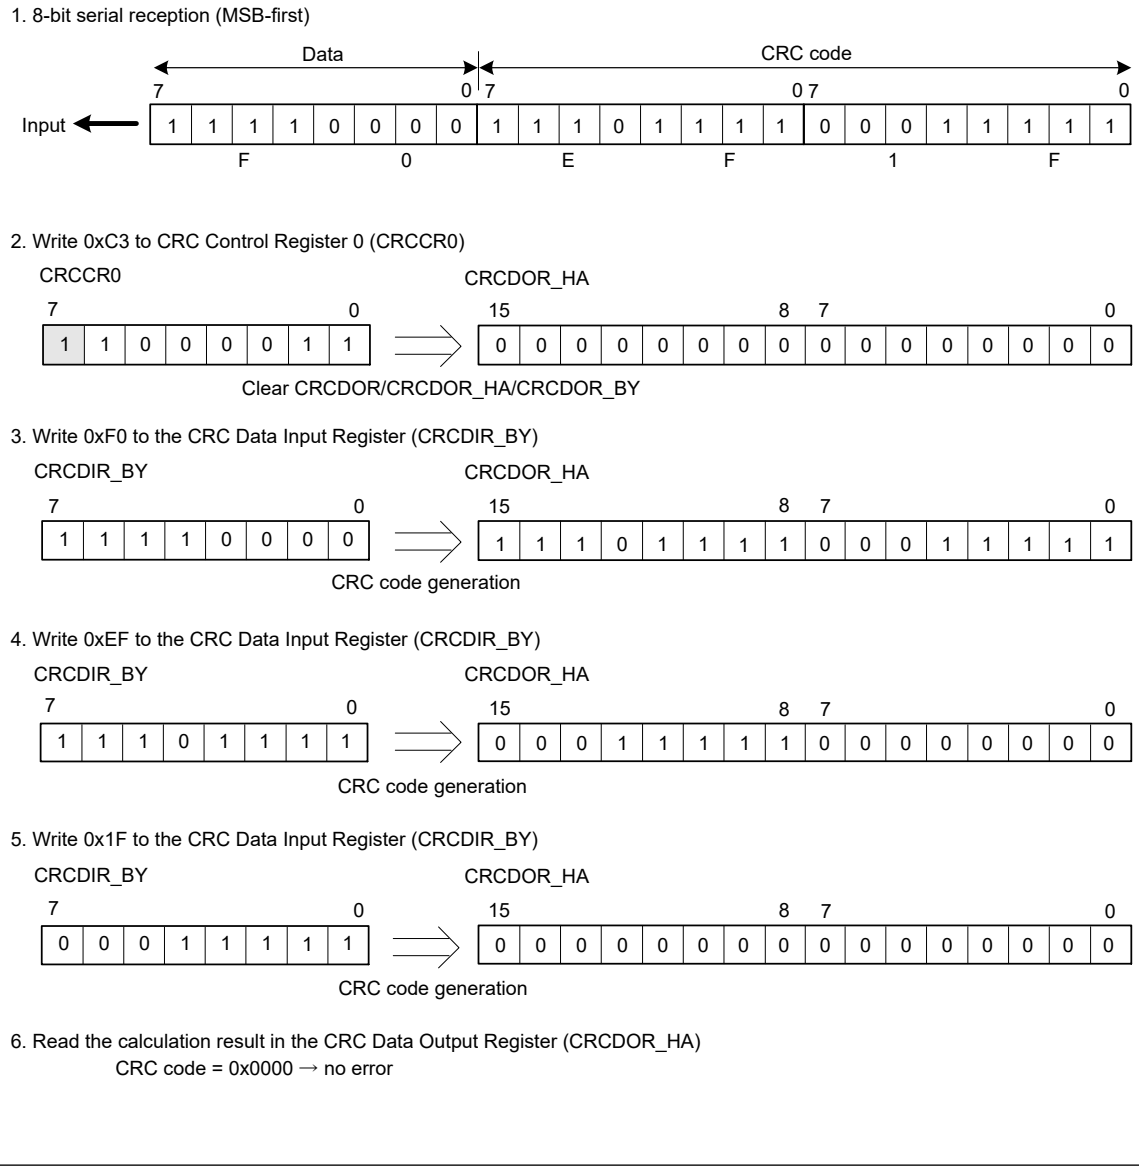

**Figure 36.5 MSB-first data reception**

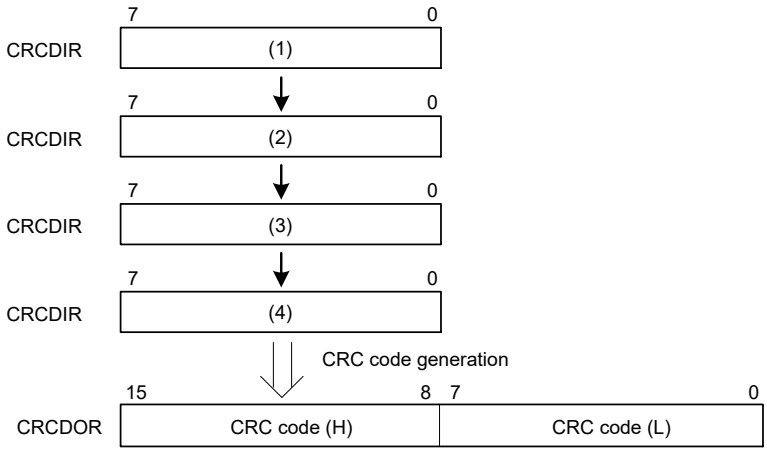
## 36.4 Usage Notes

### 36.4.1 Settings for the Module-Stop State

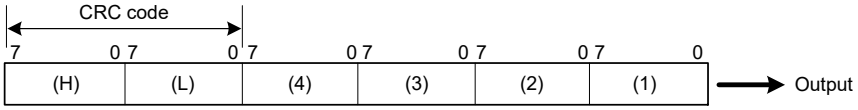
The Module Stop Control Register C (MSTPCRC) can enable or disable CRC calculator operation. The CRC calculator is initially stopped after a reset. Releasing the module-stop state enables access to the registers. For details, see section 10, Low Power Modes.



### 36.4.2 Note on Transmission

The transmission sequence for the CRC code differs based on whether the transmission is LSB-first or MSB-first. Figure 36.6 shows an LSB-first and MSB-first data transmission.

When transmitting 32-bit data (for operation executed on 8 bits in parallel)



1. CRC code

After specifying the method for generation calculation, write data to CRCDIR in order of (1), (2), (3), and (4).

2. Transmit data

(i) When transmission is LSB-first

(ii) When transmission is MSB-first

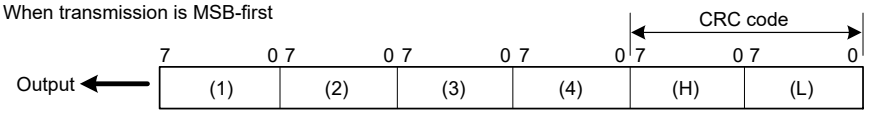


**Figure 36.6 LSB-first and MSB-first data transmission**

# 37. Renesas Secure IP (RSIP-E11A)

## 37.1 Overview

This security engine consists of an isolated subsystem comprising an access management circuit, storage area, encryption/decryption circuit, and random number generation circuit. In combination with the RSIP library, the security engine can prevent eavesdropping (to maintain confidentiality), falsification of information (to ensure integrity), and impersonation (to verify authenticity).

Because key information required for encryption and decryption is stored only in the security engine and all accesses from the outside can be blocked, the security engine enables building a more robust security system.

Table 37.1 lists the security engine specifications. Figure 37.1 shows the security engine block diagram.

**Table 37.1 Security engine specifications (1 of 2)**

| Parameter | Specifications |
|---|---|
| Access control | Access management circuit<br>● In case of irregular access to the security engine due to a tampered program or CPU runaway, this circuit blocks all subsequent accesses and stops data output from the security engine. Interrupt RSIP_TADI is generated in response. |
| Symmetric cryptography | AES: Compliant with NIST FIPS PUB 197<br>● Key length: 128 or 256 bits<br>● Data block size: 128 bits<br>● AES supports following block cipher mode<br>ECB, CBC, CTR: Compliant with NIST SP 800-38A<br>CCM: Compliant with NIST SP 800-38C<br>GCM: Compliant with NIST SP 800-38D<br>● AES supports following authentication algorithm<br>CMAC: Compliant with NIST SP 800-38B<br>GMAC: Compliant with NIST SP 800-38D |
| Random number generation | 128-bit true random number generation circuit |
| Asymmetric cryptography | ECC<br>● Maximum number of operable bits: 256 bits<br>● Support for curve<br>– NIST P-256<br>– Brainpool P256r1<br>– secp256k1<br>● Signature generation, signature verification, key generation |
| Message digest computation | HASH<br>● Block size:<br>512-bit (SHA-224, SHA-256)<br>● Key size: 512-bit or less<br>● HASH supports following secure hash algorithms<br>SHA-224, SHA-256: Compliant with FIPS PUB 180-4<br>● HASH supports following message authentication algorithm<br>HMAC: Compliant with FIPS PUB 198 |
| Hardware Unique Key | ● A read-only, 256-bit Hardware Unique Key (HUK) is exclusively accessible by the security engine access management circuit through a dedicated bus.<br>● Key derivation functions (KDFs) combine the Hardware Unique Key with the key generation information. The derived keys implement the key wrapping for user key secure storage.<br>● The HUK uniqueness prevents the illicit cloning and copying of keys to another MCU of the MCU group.<br>● The HUK itself is stored in wrapped (encrypted, non-plain) format in an isolated memory area. Therefore, it is protected from illicit access and copy. |
| Application Key Management | ● Wrapped keys are only valid within the security engine. |
| Unique ID | ● A read-only, 128-bit ID unique to an MCU (Unique ID) is accessible from the access management circuit.<br>● Key derivation functions (KDFs) combine the Unique ID with the key generation information. Such derived keys are used to unwrap the HUK within the security engine boundary. |

**Table 37.1 Security engine specifications (2 of 2)**

| Parameter | Specifications |
|---|---|
| Tamper Resistance | Countermeasures available for side-channel attacks, including SPA/DPA and timing attacks. |
| Module-stop function | Module-stop state can be set to reduce power consumption |
| TrustZone Filter | Security attribution can be set |

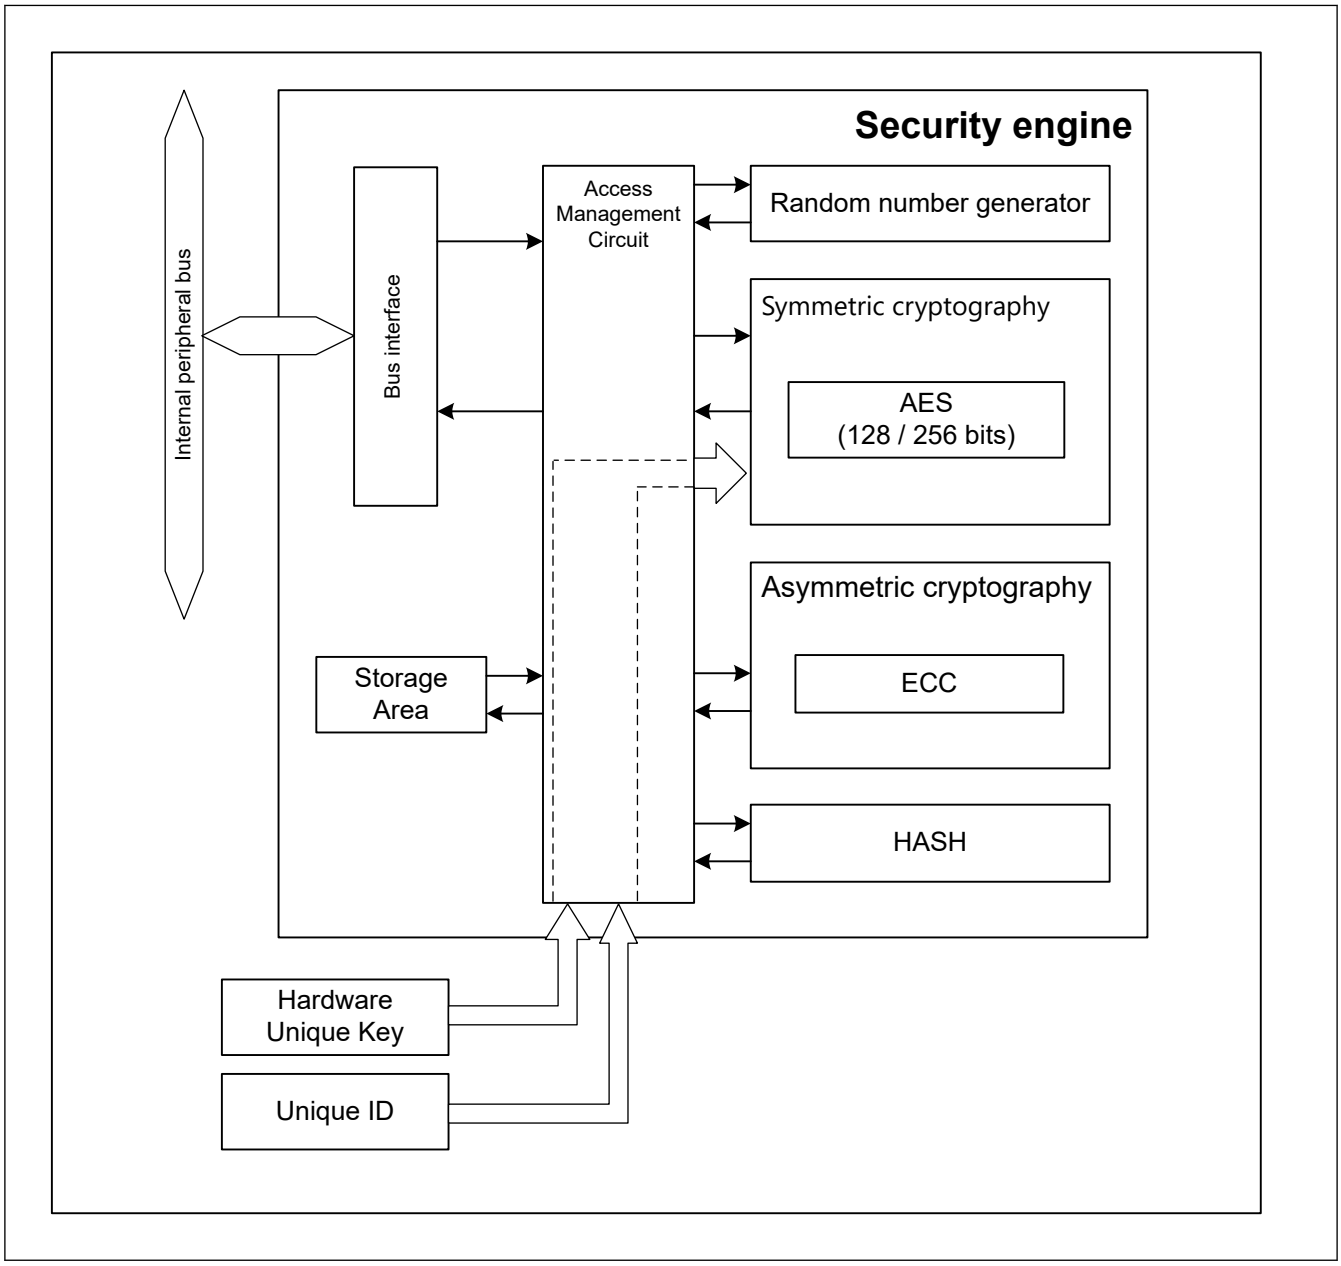

**Figure 37.1 Security engine block diagram**

## 37.2 Operation

### 37.2.1 Symmetric cryptography

Figure 37.2 shows conceptual block diagram of the symmetric cryptography installed in the security engine.

The symmetric cryptography uses the input key information and converts the plaintext data to ciphertext or ciphertext data to plaintext through the hardware.

The encryption/decryption process can be completed without exposing the key data and the process's intermediate data outside of the security engine. This process is performed by the encryption/decryption circuit and storage area of the security engine internally.

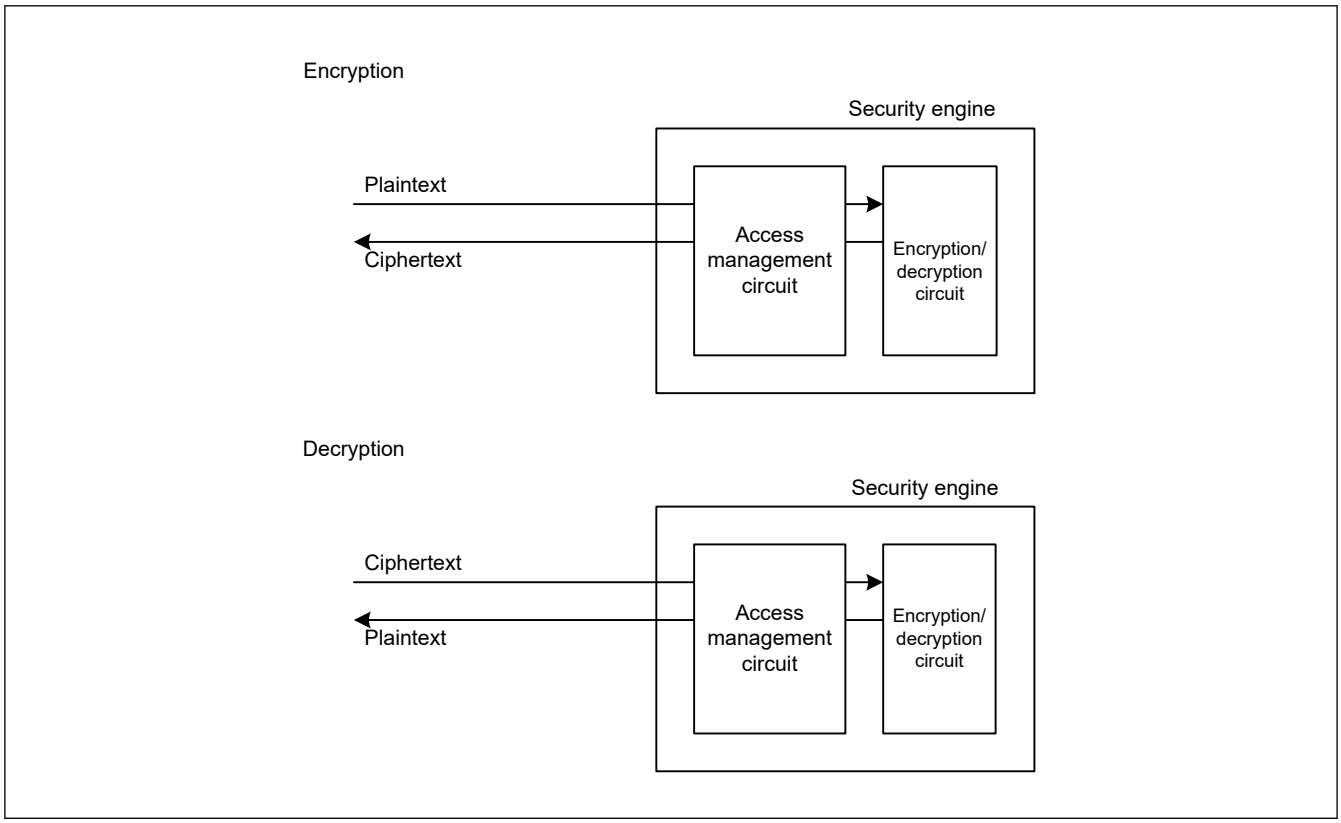

**Figure 37.2 Conceptual diagram of the symmetric cryptography**

## 37.2.2 Asymmetric Cryptography

Figure 37.3 shows conceptual block diagram of the asymmetric cryptography installed in the security engine.

The asymmetric cryptography uses the input key information and converts the plaintext data to ciphertext or ciphertext data to plaintext or generates/verifies the signature.

The encryption/decryption or signature generation/verification process can be completed without exposing the key data and the process's intermediate data outside of the security engine. This process is performed by the cryptographic circuit and storage area of the security engine internally.

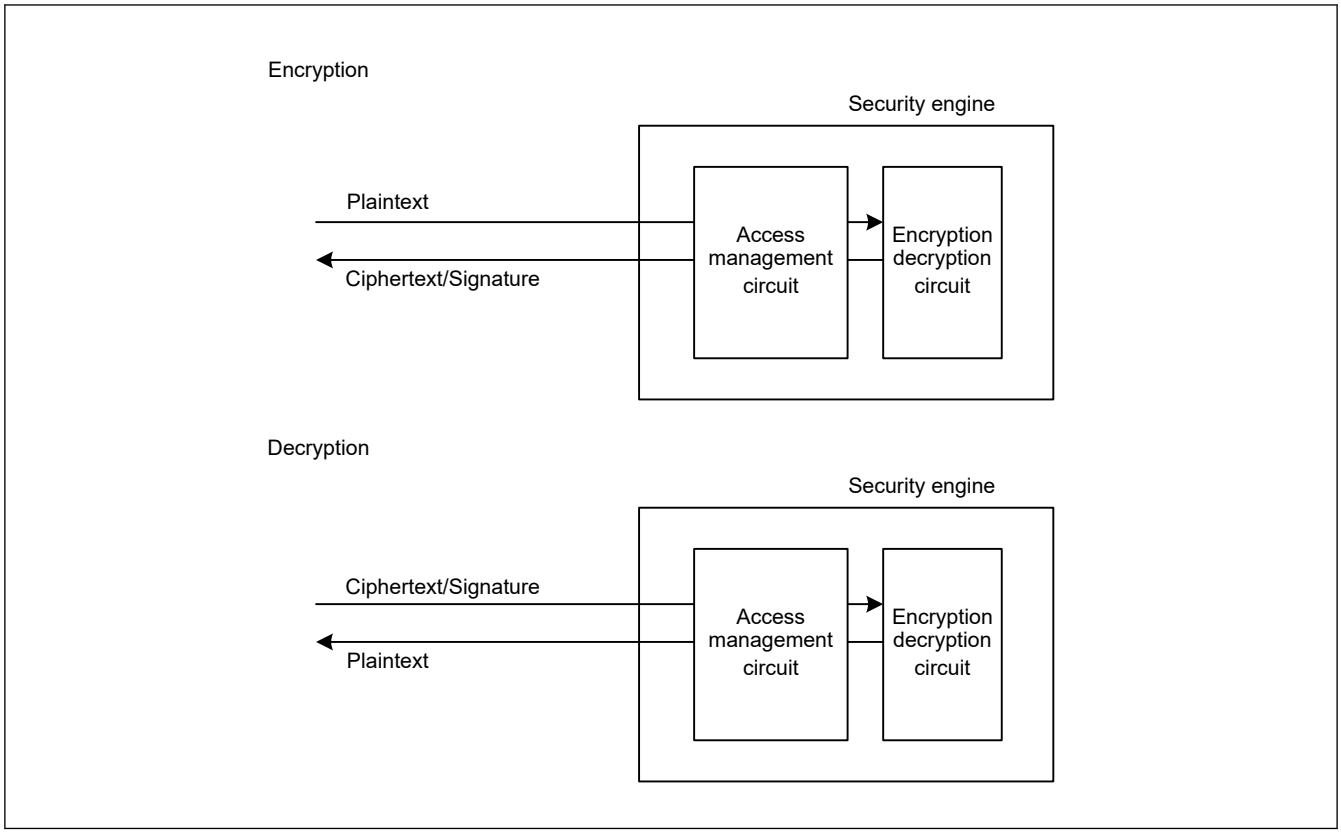

**Figure 37.3 Conceptual diagram of the asymmetric cryptography**

### 37.2.3 Hash generator

Figure 37.4 shows conceptual block diagram of the hash generator installed in the security engine.

The hash generator generates uses the input key information (if required for the hash calculation) and generates the message digest or tag.

The calculation process can be completed without exposing any key data and the process's intermediate data outside of the security engine. This process is performed by the hash circuit and storage area of the security engine internally.

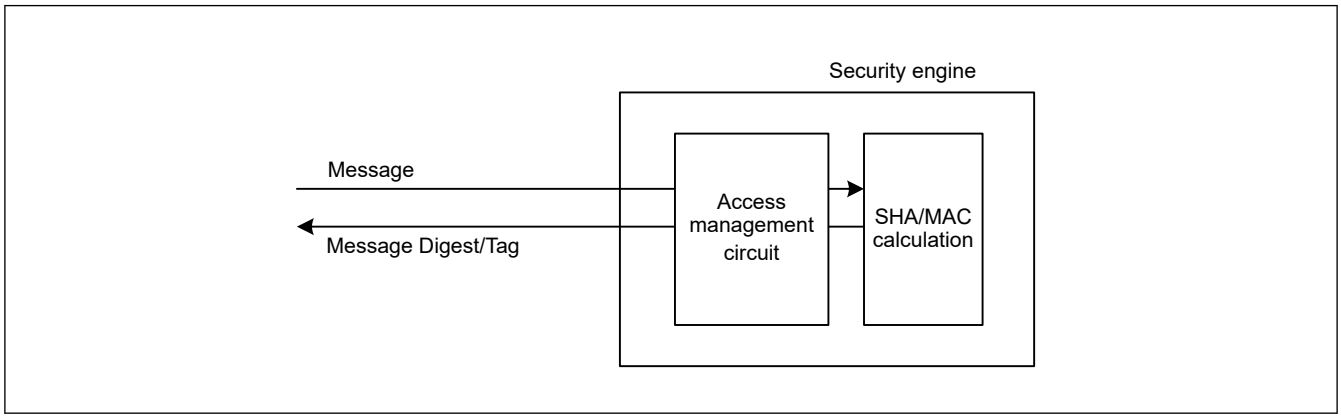

**Figure 37.4 Conceptual diagram of the hash generator**

### 37.2.4 Encryption and Decryption

Follow the procedure below to encrypt and decrypt the data:

1. Input the key information to the security engine.
2. Input the target data to the security engine. Plaintext data is converted to ciphertext and ciphertext data to plaintext.
3. Read the converted data.

The encryption/decryption circuit has input and output buffers, and can perform encryption/decryption in parallel with data input/output. Figure 37.5 shows the encryption engine timing.

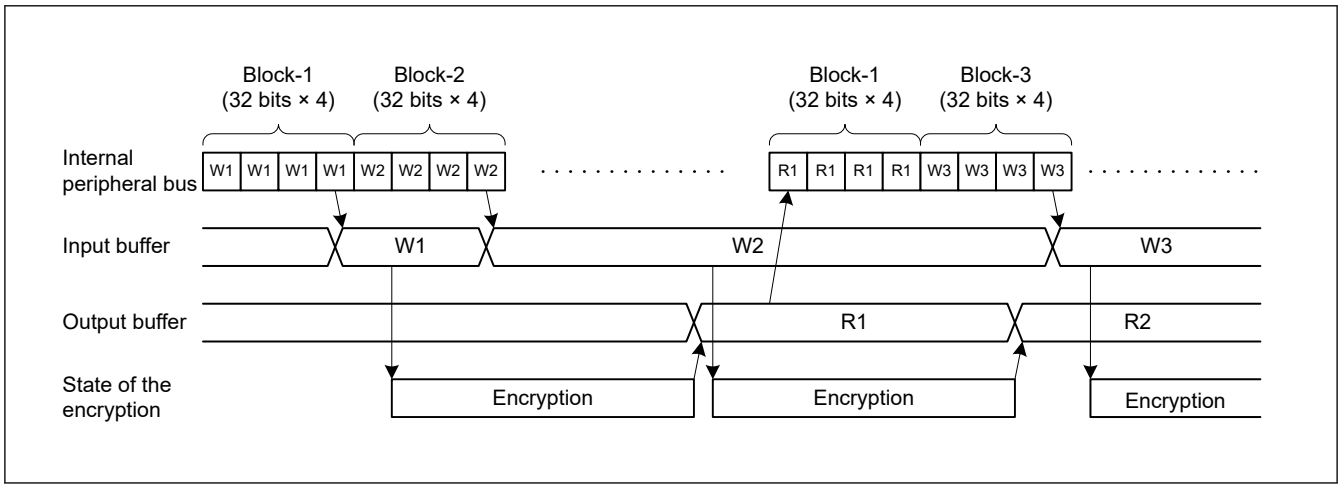

**Figure 37.5 Encryption and decryption timing (AES)**

## 37.3 Usage Notes

### 37.3.1 Software Standby Mode

When Software Standby mode is entered while the security engine is in process, proper processing cannot be resumed after cancelling Software Standby mode. Software Standby mode should therefore be entered while the security engine is not running.

### 37.3.2 Module-Stop Function Setting

The security engine operation can be disabled or enabled using Module Stop Control Register C (MSTPCRC). The security engine module is initially stopped after reset. Releasing the module-stop state enables access to the registers.

### 37.3.3 SPA/DPA Protections

SPA/DPA protections can optionally be enabled for encryption/decryption processing.

### 37.3.4 Restrictions on Open process

While open process of security engine's API (R_RSIP_Open) is running, the following restrictions is applied.

- Available CPU frequency is up to 80 MHz
- Do not change frequency of ICLK and PCLKn (n = A to D)
- Do not change MSTPCRn registers (n = A to E)
- Do not transition to Sleep mode, Software Standby mode, and Snooze mode.

# 38. 12-Bit A/D Converter (ADC12)

## 38.1 Overview

The MCU includes 12-bit successive approximation A/D converter (ADC12) unit. Up to 16 analog input channels, temperature sensor output, internal reference voltage, and CTSU TSCAP voltage can be selected for conversion.

The ADC12 supports the following operating modes:

- Single scan mode to convert analog inputs of selected channels in ascending order of channel number
- Continuous scan mode to convert analog inputs of selected channels continuously in ascending order of channel number
- Group scan mode to divide analog inputs of channels into two groups (group A and B) and convert the analog inputs of selected channels for each group in ascending order of channel number

In group scan mode, select two groups (group A and B). You can individually select the scan start conditions for each group (group A, B) and start scanning of each group at different times. In addition, when group A priority control operation is set, the ADC12 accepts group A scan start during group B A/D conversion, suspending group B conversion. This allows you to assign higher priority to A/D conversion start for group A.

In double trigger mode, the analog input of a selected channel is converted in single scan mode or group scan mode (group A), and data converted by the first and second A/D conversion start triggers are stored in different registers, providing duplexing of A/D converted data.

Self-diagnosis is performed once at the beginning of each scan, and one of the three reference voltage values generated in ADC12 is A/D converted.

The temperature sensor output and the internal reference voltage cannot be selected for conversion simultaneously. Perform A/D conversion independently for the temperature sensor output or the internal reference voltage.

The ADC12 also provides a compare function (window A and window B). The compare function specifies the upper reference value for window A and lower reference value for window B, and outputs an interrupt when the A/D converted value of the selected channel meets the comparison conditions.

The reference power supply pin (VREFH0), the analog block power supply pin (AVCC0), or the internal reference voltage can select as the high-potential reference voltage. The reference power supply ground pin (VREFL0) or the analog block power supply ground pin (AVSS0) can be selected as the low-potential reference voltage. If the internal reference voltage is selected as the high-potential reference voltage, A/D conversion of the temperature sensor or internal reference voltage is prohibited.

Table 38.1 lists the ADC12 specifications and Table 38.2 list the functions. Figure 38.1 shows a block diagram of ADC12 and Table 38.3 lists the I/O pins.

**Table 38.1 ADC12 specifications (1 of 3)**

| Parameter | Specifications |
|---|---|
| Number of units | one unit |
| Input channels | Up to 16 channels (AN000 to AN006, AN017 to AN025) |
| Extended analog function | Temperature sensor output, internal reference voltage, CTSU TSCAP voltage |
| A/D conversion method | Successive approximation method |
| Resolution | 12-bit |
| Conversion time | Normal conversion mode (ADACSR.ADSAC = 0): 0.94 µs/channel (when 12-bit A/D conversion clock PCLKC (ADCLK) operates at 48 MHz)<br>Fast conversion mode (ADACSR.ADSAC = 1): 0.67 µs/channel (when 12-bit A/D conversion clock PCLKC (ADCLK) operates at 48 MHz) |
| A/D conversion clock | Peripheral module clock PCLKA and A/D conversion clock PCLKC (ADCLK) can be set with the following division ratios: PCLKA to PCLKC (ADCLK) frequency ratio = 1:1, 2:1, 4:1, 8:1, 1:2, 1:4 |

**Table 38.1 ADC12 specifications (2 of 3)**

| Parameter | Specifications |
|---|---|
| Data registers*1 | • 16 registers for analog input<br>• One register for A/D-converted data duplication in double trigger mode<br>• Two registers for A/D-converted data duplication during extended operation in double trigger mode<br>• One register for temperature sensor output<br>• One register for internal reference voltage<br>• One register for CTSU TSCAP voltage<br>• One register for self-diagnosis<br>• A/D conversion results are stored in A/D data registers<br>• 12-bit accuracy for A/D conversion results<br>• A/D-converted value addition mode, in which the sum of all A/D-converted results is stored in the A/D data registers as a value with the conversion accuracy bit count + extended bits<br>• Double-trigger mode (selectable in single scan and group scan modes):<br>– The first unit of A/D-converted analog input data on one selected channel is stored in the data register for the channel, and the second unit is stored in the duplication register.<br>• Extended operation in double trigger mode (available for specific triggers):<br>– A/D-converted analog input data on one selected channel is stored in the duplication register provided for the associated trigger. |
| Operating modes*2 | • Single scan mode:<br>– A/D conversion is performed only once on the analog inputs of arbitrarily selected channels, on the temperature sensor output, on the internal reference voltage, and the CTSU TSCAP voltage.<br>• Continuous scan mode:<br>A/D conversion is performed repeatedly on the analog inputs of the selected channels.<br>• Group scan mode:<br>– Analog inputs of selected channels, the temperature sensor output, and the internal reference voltage are divided into groups A and B. Then A/D conversion of the analog inputs selected on a group basis is performed once.<br>– The scan start conditions can be independently selected for group A, B, allowing A/D conversion of group A, B to be started independently.<br>• Group scan mode (when group priority operation is selected):<br>– If a priority group trigger is input during scanning of a lower-priority group, the scanning of the lower-priority group is stopped and then scanning of the priority group is started. The order of priority is group A > group B. |
| Conditions for A/D conversion start | • Software trigger<br>• Synchronous triggers from the Event Link Controller (ELC)<br>• Asynchronous triggering by the external trigger pins, ADTRG0 |
| Functions | • Variable sampling state count<br>• Self-diagnosis of A/D converter<br>• Selectable A/D-converted value addition mode or average mode<br>• Analog input disconnection detection function (discharge and precharge functions)<br>• Double-trigger mode (duplication of A/D conversion data)<br>• Automatic clear function for A/D data registers<br>• Digital comparison of values in the comparison register and data register, and comparison between values in the data registers |
| Interrupt sources | • In single scan mode (double trigger deselected), an A/D scan end interrupt request (ADC120_ADI) and ELC event signal (ADC120_ADI) can be generated on completion of single scan.<br>– A compare interrupt request (ADC120_CMPAI/ADC120_CMPBI) can be generated in response to a match with a digital comparison condition.<br>– A window compare ELC event signal (ADC120_WCMPM) can be generated in response to a match with a digital comparison condition.<br>– A window compare ELC event signal (ADC120_WCMPUM) can be generated in response to a mismatch with a digital comparison condition.<br>• In single scan mode (double trigger selected), an A/D scan end interrupt request (ADC120_ADI) and ELC event signal (ADC120_ADI) is generated on completion of two scans.<br>• In continuous scan mode, an A/D scan end interrupt request (ADC120_ADI) and ELC event signal (ADC120_ADI) is generated on completion of all the selected channel scans.<br>• In group scan mode (double trigger deselected), an A/D scan end interrupt request (ADC120_ADI) and ELC event signal (ADC120_ADI) is generated on completion of group A scan, and an A/D scan end interrupt request for group B (ADC120_GBADI) can be generated on completion of group B scan.<br>• In group scan mode (double trigger selected), an A/D scan end interrupt request (ADC120_ADI) and ELC event signal (ADC120_ADI) is generated on completion of two group A scans, and an A/D scan end interrupt request for group B (ADC120_GBADI) can be generated on completion of group B scan.<br>• ADC120_ADI, ADC120_GBADI, ADC120_WCMPM, and ADC120_WCMPUM can activate the Data Transfer Controller (DTC). |

**Table 38.1 ADC12 specifications (3 of 3)**

| Parameter | Specifications |
|---|---|
| ELC interface | • An event is generated upon completion of group A scan in group-scan mode.<br>• An event is generated upon completion of group B scan in group-scan mode.<br>• An event is generated when all scans complete.<br>• Scan can be started by a trigger from the ELC.<br>• An event is generated according to conditions of the compare function window in single-scan mode. |
| Reference voltage | • VREFH0, AVCC0, or internal reference voltage (external reference voltage or output voltage from reference voltage generation circuit) can be selected as the analog reference voltage.<br>• VREFL0 or AVSS0 can be selected as the analog reference ground. |
| Module-stop function | Module-stop state can be set to reduce power consumption.*3 |
| TrustZone Filter | Security attribution can be set. |

Note 1. Changing the A/D conversion accuracy also changes the A/D conversion time. For details, see section 38.3.6. Analog Input Sampling and Scan Conversion Time.
Note 2. When selecting the temperature sensor output and the internal reference voltage, do not use continuous scan mode or group scan mode.
Note 3. For details, see section 10, Low Power Modes.

**Table 38.2 ADC12 functions**

| Parameter | | | function |
|---|---|---|---|

Table 38.3 lists the ADC12 I/O pins.

**Table 38.3 ADC12 I/O pins**

| Pin name | I/O | Function |
|---|---|---|
| AVCC0 | Input | Analog block power supply pin<br>(Connect to VCC when ADC12/DAC12 is not used.) |
| AVSS0 | Input | Analog block power supply ground pin<br>(Connect to VSS when ADC12/DAC12 is not used.) |
| VREFH0 | Input | Analog reference voltage supply pin |
| VREFL0 | Input | Analog reference ground pin |
| AN000 to AN006, AN017 to AN025 | Input | Analog input pins 0 to 6, 17 to 25 |
| ADTRG0 | Input | External trigger input pin for starting A/D conversion |

## 38.2 Register Descriptions

### 38.2.1 ADDRn : A/D Data Registers n (n = 0 to 6, 17 to 25)

Base address: ADC120 = 0x4017_0000

Offset address: 0x020 + 0x2 × n (n = 0 to 6, 17 to 25)

| Bit position: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | ADDR [15:0] | | | | | | | | | | | | | | | |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 15:0 | ADDR [15:0] | Converted Value 15 to 0<br>Functions vary depending on the selected mode and accuracy. See Table 38.4 and Table 38.5. | R |

ADDRn registers are 16-bit read-only registers to store A/D conversion results.

The following conditions determine the formats for data in the A/D data registers:

- Setting of the A/D Data Register Format Select bit (ADCER.ADRFMT) (flush-left or flush-right)
- Setting of the Addition/Average Count Select bits (ADADC.ADC[2:0]) (1, 2, 3, 4, or 16 times)
- Setting of the Average Mode Enable bit (ADADC.AVEE) (addition or average).

This section describes the data formats for these conditions in different modes.

### (1) When A/D-converted value addition/average mode is not selected

Table 38.4 shows the example of bit assignment for 12-bit accuracy.

**Table 38.4 Example of bit assignment for 12-bit accuracy**

| Accuracy | b15 | b14 | b13 | b12 | b11 | b10 | b9 | b8 | b7 | b6 | b5 | b4 | b3 | b2 | b1 | b0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Right-justified data with 12-bit accuracy | These bits are read as 0. | | | | Converted Value 11 to 0:<br>12-bit A/D-converted value | | | | | | | | | | | |
| Left-justified data with 12-bit accuracy | Converted Value 11 to 0:<br>12-bit A/D-converted value | | | | | | | | | | | | These bits are read as 0. | | | |

### (2) When A/D-converted value average mode is selected

A/D-converted value average mode can be selected when 2 or 4 times is specified in the A/D-converted value addition mode. When A/D converted value average mode is selected, these registers indicate the mean of A/D-converted values on a specific channel. The value is stored in the A/D data register based on the setting of the A/D Data Register Format Select bit in the same way as for normal A/D conversion.

### (3) When A/D-converted value addition mode is selected

For 12-bit accuracy, 1, 2, 3, or 4 times can be selected in the A/D-converted value addition mode. A/D conversion results are stored in the A/D data register as a 2-bit-extended value of the specified conversion accuracy.

For 12-bit accuracy, 16 times can also be selected in the A/D-converted value addition mode. In A/D-converted value addition mode, these registers indicate the value that is obtained by adding A/D-converted values on a specific channel. A/D conversion results are stored in the A/D data register as a 4-bit-extended value of the specified conversion accuracy.

When A/D-converted value addition mode is selected, the value is stored in the A/D data register based on the settings of the A/D Data Register Format Select bits.

Table 38.5 shows example of the bit assignment for 12-bit accuracy.

**Table 38.5 Example of bit assignment for 12-bit accuracy when A/D-converted value addition mode is selected (1 of 2)**

| Accuracy | | b15 | b14 | b13 | b12 | b11 | b10 | b9 | b8 | b7 | b6 | b5 | b4 | b3 | b2 | b1 | b0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Right-justified data with 12-bit accuracy | When 16 conversion times is specified | Added Value 15 to 0:<br>16-bit sum of A/D conversion results | | | | | | | | | | | | | | | |
| | When 1, 2, 3, or 4 conversion times is specified | These bits are read as 0. | Added Value 13 to 0:<br>14-bit sum of A/D conversion results | | | | | | | | | | | | | | |

**Table 38.5 Example of bit assignment for 12-bit accuracy when A/D-converted value addition mode is selected (2 of 2)**

| Accuracy | | b15 | b14 | b13 | b12 | b11 | b10 | b9 | b8 | b7 | b6 | b5 | b4 | b3 | b2 | b1 | b0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Left-justified data with 12-bit accuracy | When 16 conversion times is specified | Added Value 15 to 0:<br>16-bit sum of A/D conversion results | | | | | | | | | | | | | | | |
| | When 1, 2, 3, or 4 conversion times is specified | Added Value 13 to 0:<br>14-bit sum of A/D conversion results | | | | | | | | | | | | | | These bits are read as 0. | |

## 38.2.2 ADDBLDR : A/D Data Duplexing Register

Base address: ADC120 = 0x4017_0000

Offset address: 0x018

| Bit position: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | ADDBLDR [15:0] | | | | | | | | | | | | | | | |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 15:0 | ADDBLDR [15:0] | Converted Value 15 to 0<br>Functions vary depending on the selected mode and accuracy. See Table 38.6 and Table 38.7. | R |

ADDBLDR register is a 16-bit read-only register to store A/D conversion results in response to a second trigger in double-trigger mode.

The following conditions determine the formats for data in the A/D data registers:

- Setting of the A/D Data Register Format Select bit (ADCER.ADRFMT) (flush-left or flush-right)
- Setting of the Addition/Average Count Select bits (ADADC.ADC[2:0]) (1, 2, 3, 4, or 16 times)
- Setting of the Average Mode Enable bit (ADADC.AVEE) (addition or average).

This section describes the data formats for these conditions in different modes.

### (1) When A/D-converted value addition/average mode is not selected

Table 38.6 shows the example of bit assignment for 12-bit accuracy.

**Table 38.6 Example of bit assignment for 12-bit accuracy**

| Accuracy | b15 | b14 | b13 | b12 | b11 | b10 | b9 | b8 | b7 | b6 | b5 | b4 | b3 | b2 | b1 | b0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Right-justified data with 12-bit accuracy | These bits are read as 0. | | | | Converted Value 11 to 0:<br>12-bit A/D-converted value | | | | | | | | | | | |
| Left-justified data with 12-bit accuracy | Converted Value 11 to 0:<br>12-bit A/D-converted value | | | | | | | | | | | | These bits are read as 0. | | | |

### (2) When A/D-converted value average mode is selected

A/D-converted value average mode can be selected when 2 or 4 times is specified in the A/D-converted value addition mode. When A/D converted value average mode is selected, this register indicates the mean of A/D-converted values on a specific channel. The value is stored in the A/D data register based on the setting of the A/D Data Register Format Select bit in the same way as for normal A/D conversion.

### (3) When A/D-converted value addition mode is selected

For 12-bit accuracy, 1, 2, 3, or 4 times can be selected in the A/D-converted value addition mode. A/D conversion results are stored in the A/D data register as a 2-bit-extended value of the specified conversion accuracy.

For 12-bit accuracy, 16 times can also be selected in the A/D-converted value addition mode. In A/D-converted value addition mode, this register indicates the value that is obtained by adding A/D-converted values on a specific channel. A/D conversion results are stored in the A/D data register as a 4-bit-extended value of the specified conversion accuracy.

When A/D-converted value addition mode is selected, the value is stored in the A/D data register based on the settings of the A/D Data Register Format Select bits.

Table 38.7 shows example of the bit assignment for 12-bit accuracy.

**Table 38.7 Example of bit assignment for 12-bit accuracy when A/D-converted value addition mode is selected**

| Accuracy | | b15 | b14 | b13 | b12 | b11 | b10 | b9 | b8 | b7 | b6 | b5 | b4 | b3 | b2 | b1 | b0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Right-justified data with 12-bit accuracy | When 16 conversion times is specified | Added Value 15 to 0: 16-bit sum of A/D conversion results | | | | | | | | | | | | | | | |
| | When 1, 2, 3, or 4 conversion times is specified | These bits are read as 0. | | Added Value 13 to 0: 14-bit sum of A/D conversion results | | | | | | | | | | | | | |
| Left-justified data with 12-bit accuracy | When 16 conversion times is specified | Added Value 15 to 0: 16-bit sum of A/D conversion results | | | | | | | | | | | | | | | |
| | When 1, 2, 3, or 4 conversion times is specified | Added Value 13 to 0: 14-bit sum of A/D conversion results | | | | | | | | | | | | | | These bits are read as 0. | |

## 38.2.3 ADDBLDRn : A/D Data Duplexing Register n (n = A, B)

Base address: ADC120 = 0x4017_0000

Offset address: 0x084 (n = A)
0x086 (n = B)

| Bit position: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | ADDBLDR [15:0] | | | | | | | | | | | | | | | |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 15:0 | ADDBLDR [15:0] | Converted Value 15 to 0<br>Functions vary depending on the selected mode and accuracy. See Table 38.8 and Table 38.9. | R |

ADDBLDRn registers are 16-bit read-only registers to store A/D conversion results in response to respective triggers during extended operation in double-trigger mode.

The following conditions determine the formats for data in the A/D data registers:

- Setting of the A/D Data Register Format Select bit (ADCER.ADRFMT) (flush-left or flush-right)
- Setting of the Addition/Average Count Select bits (ADADC.ADC[2:0]) (1, 2, 3, 4, or 16 times)
- Setting of the Average Mode Enable bit (ADADC.AVEE) (addition or average).

This section describes the data formats for these conditions in different modes.

### (1) When A/D-converted value addition/average mode is not selected

Table 38.8 shows the example of bit assignment for 12-bit accuracy.

**Table 38.8 Example of bit assignment for 12-bit accuracy**

| Accuracy | b15 | b14 | b13 | b12 | b11 | b10 | b9 | b8 | b7 | b6 | b5 | b4 | b3 | b2 | b1 | b0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Right-justified data with 12-bit accuracy | These bits are read as 0. | | | | Converted Value 11 to 0: 12-bit A/D-converted value | | | | | | | | | | | |
| Left-justified data with 12-bit accuracy | Converted Value 11 to 0: 12-bit A/D-converted value | | | | | | | | | | | | These bits are read as 0. | | | |

### (2) When A/D-converted value average mode is selected

A/D-converted value average mode can be selected when 2 or 4 times is specified in the A/D-converted value addition mode. When A/D converted value average mode is selected, these registers indicate the mean of A/D-converted values on a specific channel. The value is stored in the A/D data register based on the setting of the A/D Data Register Format Select bit in the same way as for normal A/D conversion.

### (3) When A/D-converted value addition mode is selected

For 12-bit accuracy, 1, 2, 3, or 4 times can be selected in the A/D-converted value addition mode. A/D conversion results are stored in the A/D data register as a 2-bit-extended value of the specified conversion accuracy.

For 12-bit accuracy, 16 times can also be selected in the A/D-converted value addition mode. In A/D-converted value addition mode, these registers indicate the value that is obtained by adding A/D-converted values on a specific channel. A/D conversion results are stored in the A/D data register as a 4-bit-extended value of the specified conversion accuracy.

When A/D-converted value addition mode is selected, the value is stored in the A/D data register based on the settings of the A/D Data Register Format Select bits.

Table 38.9 shows example of the bit assignment for 12-bit accuracy.

**Table 38.9 Example of bit assignment for 12-bit accuracy when A/D-converted value addition mode is selected**

| Accuracy | | b15 | b14 | b13 | b12 | b11 | b10 | b9 | b8 | b7 | b6 | b5 | b4 | b3 | b2 | b1 | b0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Right-justified data with 12-bit accuracy | When 16 conversion times is specified | Added Value 15 to 0: 16-bit sum of A/D conversion results | | | | | | | | | | | | | | | |
| | When 1, 2, 3, or 4 conversion times is specified | These bits are read as 0. | Added Value 13 to 0: 14-bit sum of A/D conversion results | | | | | | | | | | | | | | |
| Left-justified data with 12-bit accuracy | When 16 conversion times is specified | Added Value 15 to 0: 16-bit sum of A/D conversion results | | | | | | | | | | | | | | | |
| | When 1, 2, 3, or 4 conversion times is specified | Added Value 13 to 0: 14-bit sum of A/D conversion results | | | | | | | | | | | | | | | These bits are read as 0. |

## 38.2.4 ADTSDR : A/D Temperature Sensor Data Register

Base address: ADC120 = 0x4017_0000

Offset address: 0x01A

| Bit position: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | ADTSDR [15:0] | | | | | | | | | | | | | | | |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 15:0 | ADTSDR [15:0] | Converted Value 15 to 0<br>Functions vary depending on the selected mode and accuracy. See Table 38.10 and Table 38.11. | R |

ADTSDR register is a 16-bit read-only register to store A/D conversion result of the temperature sensor output.

The following conditions determine the formats for data in the A/D data registers:

- Setting of the A/D Data Register Format Select bit (ADCER.ADRFMT) (flush-left or flush-right)
- Setting of the Addition/Average Count Select bits (ADADC.ADC[2:0]) (1, 2, 3, 4, or 16 times)
- Setting of the Average Mode Enable bit (ADADC.AVEE) (addition or average).

This section describes the data formats for these conditions in different modes.

### (1) When A/D-converted value addition/average mode is not selected

Table 38.10 shows the example of bit assignment for 12-bit accuracy.

**Table 38.10 Example of bit assignment for 12-bit accuracy**

| Accuracy | b15 | b14 | b13 | b12 | b11 | b10 | b9 | b8 | b7 | b6 | b5 | b4 | b3 | b2 | b1 | b0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Right-justified data with 12-bit accuracy | These bits are read as 0. | | | | Converted Value 11 to 0:<br>12-bit A/D-converted value | | | | | | | | | | | |
| Left-justified data with 12-bit accuracy | Converted Value 11 to 0:<br>12-bit A/D-converted value | | | | | | | | | | | | These bits are read as 0. | | | |

### (2) When A/D-converted value average mode is selected

A/D-converted value average mode can be selected when 2 or 4 times is specified in the A/D-converted value addition mode. When A/D converted value average mode is selected, this register indicates the mean of A/D-converted values on a specific channel. The value is stored in the A/D data register based on the setting of the A/D Data Register Format Select bit in the same way as for normal A/D conversion.

### (3) When A/D-converted value addition mode is selected

For 12-bit accuracy, 1, 2, 3, or 4 times can be selected in the A/D-converted value addition mode. A/D conversion results are stored in the A/D data register as a 2-bit-extended value of the specified conversion accuracy.

For 12-bit accuracy, 16 times can also be selected in the A/D-converted value addition mode. In A/D-converted value addition mode, this register indicates the value that is obtained by adding A/D-converted values on a specific channel. A/D conversion results are stored in the A/D data register as a 4-bit-extended value of the specified conversion accuracy.

When A/D-converted value addition mode is selected, the value is stored in the A/D data register based on the settings of the A/D Data Register Format Select bits.

Table 38.11 shows example of the bit assignment for 12-bit accuracy.

**Table 38.11 Example of bit assignment for 12-bit accuracy when A/D-converted value addition mode is selected**

| Accuracy | | b15 | b14 | b13 | b12 | b11 | b10 | b9 | b8 | b7 | b6 | b5 | b4 | b3 | b2 | b1 | b0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Right-justified data with 12-bit accuracy | When 16 conversion times is specified | Added Value 15 to 0:<br>16-bit sum of A/D conversion results | | | | | | | | | | | | | | | |
| | When 1, 2, 3, or 4 conversion times is specified | These bits are read as 0. | Added Value 13 to 0:<br>14-bit sum of A/D conversion results | | | | | | | | | | | | | | |
| Left-justified data with 12-bit accuracy | When 16 conversion times is specified | Added Value 15 to 0:<br>16-bit sum of A/D conversion results | | | | | | | | | | | | | | | |
| | When 1, 2, 3, or 4 conversion times is specified | Added Value 13 to 0:<br>14-bit sum of A/D conversion results | | | | | | | | | | | | | | These bits are read as 0. | |

## 38.2.5 ADOCDR : A/D Internal Reference Voltage Data Register

Base address: ADC120 = 0x4017_0000

Offset address: 0x01C

| Bit position: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | ADOCDR [15:0] | | | | | | | | | | | | | | | |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 15:0 | ADOCDR [15:0] | Converted Value 15 to 0<br>Functions vary depending on the selected mode and accuracy. See Table 38.12 and Table 38.13. | R |

ADOCDR register is a 16-bit read-only register to store A/D conversion result of the internal reference voltage.

The following conditions determine the formats for data in the A/D data registers:

- Setting of the A/D Data Register Format Select bit (ADCER.ADRFMT) (flush-left or flush-right)
- Setting of the Addition/Average Count Select bits (ADADC.ADC[2:0]) (1, 2, 3, 4, or 16 times)
- Setting of the Average Mode Enable bit (ADADC.AVEE) (addition or average).

This section describes the data formats for these conditions in different modes.

### (1) When A/D-converted value addition/average mode is not selected

Table 38.12 shows the example of bit assignment for 12-bit accuracy.

**Table 38.12 Example of bit assignment for 12-bit accuracy**

| Accuracy | b15 | b14 | b13 | b12 | b11 | b10 | b9 | b8 | b7 | b6 | b5 | b4 | b3 | b2 | b1 | b0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Right-justified data with 12-bit accuracy | These bits are read as 0. | | | | Converted Value 11 to 0:<br>12-bit A/D-converted value | | | | | | | | | | | |
| Left-justified data with 12-bit accuracy | Converted Value 11 to 0:<br>12-bit A/D-converted value | | | | | | | | | | | | These bits are read as 0. | | | |

### (2) When A/D-converted value average mode is selected

A/D-converted value average mode can be selected when 2 or 4 times is specified in the A/D-converted value addition mode. When A/D converted value average mode is selected, this register indicates the mean of A/D-converted values on a specific channel. The value is stored in the A/D data register based on the setting of the A/D Data Register Format Select bit in the same way as for normal A/D conversion.

### (3) When A/D-converted value addition mode is selected

For 12-bit accuracy, 1, 2, 3, or 4 times can be selected in the A/D-converted value addition mode. A/D conversion results are stored in the A/D data register as a 2-bit-extended value of the specified conversion accuracy.

For 12-bit accuracy, 16 times can also be selected in the A/D-converted value addition mode. In A/D-converted value addition mode, this register indicates the value that is obtained by adding A/D-converted values on a specific channel. A/D conversion results are stored in the A/D data register as a 4-bit-extended value of the specified conversion accuracy.

When A/D-converted value addition mode is selected, the value is stored in the A/D data register based on the settings of the A/D Data Register Format Select bits.

Table 38.13 shows example of the bit assignment for 12-bit accuracy.

**Table 38.13 Example of bit assignment for 12-bit accuracy when A/D-converted value addition mode is selected**

| Accuracy | | b15 | b14 | b13 | b12 | b11 | b10 | b9 | b8 | b7 | b6 | b5 | b4 | b3 | b2 | b1 | b0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Right-justified data with 12-bit accuracy | When 16 conversion times is specified | Added Value 15 to 0: 16-bit sum of A/D conversion results | | | | | | | | | | | | | | | |
| | When 1, 2, 3, or 4 conversion times is specified | These bits are read as 0. | | Added Value 13 to 0: 14-bit sum of A/D conversion results | | | | | | | | | | | | | |
| Left-justified data with 12-bit accuracy | When 16 conversion times is specified | Added Value 15 to 0: 16-bit sum of A/D conversion results | | | | | | | | | | | | | | | |
| | When 1, 2, 3, or 4 conversion times is specified | Added Value 13 to 0: 14-bit sum of A/D conversion results | | | | | | | | | | | | | | These bits are read as 0. | |

## 38.2.6 ADCTDR : A/D CTSU TSCAP Voltage Data Register

Base address: ADC120 = 0x4017_0000

Offset address: 0x040

| Bit position: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | ADCTDR[15:0] | | | | | | | | | | | | | | | |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 15:0 | ADCTDR[15:0] | Converted Value 15 to 0<br>Functions vary depending on the selected mode and accuracy. See Table 38.14 and Table 38.15. | R |

ADCTDR register is a 16-bit read-only register to store A/D conversion results of the CTSU TSCAP voltage.

The following conditions determine the formats for data in the A/D data registers:

- Setting of the A/D Data Register Format Select bit (ADCER.ADRFMT) (flush-left or flush-right)
- Setting of the Addition/Average Count Select bits (ADADC.ADC[2:0]) (1, 2, 3, 4, or 16 times)
- Setting of the Average Mode Enable bit (ADADC.AVEE) (addition or average).

This section describes the data formats for these conditions in different modes.

### (1) When A/D-converted value addition/average mode is not selected

Table 38.14 shows the example of bit assignment for 12-bit accuracy.

**Table 38.14 Example of bit assignment for 12-bit accuracy**

| Accuracy | b15 | b14 | b13 | b12 | b11 | b10 | b9 | b8 | b7 | b6 | b5 | b4 | b3 | b2 | b1 | b0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Right-justified data with 12-bit accuracy | These bits are read as 0. | | | | Converted Value 11 to 0: 12-bit A/D-converted value | | | | | | | | | | | |
| Left-justified data with 12-bit accuracy | Converted Value 11 to 0: 12-bit A/D-converted value | | | | | | | | | | | | These bits are read as 0. | | | |

### (2) When A/D-converted value average mode is selected

A/D-converted value average mode can be selected when 2 or 4 times is specified in the A/D-converted value addition mode. When A/D converted value average mode is selected, this register indicates the mean of A/D-converted values on a specific channel. The value is stored in the A/D data register based on the setting of the A/D Data Register Format Select bit in the same way as for normal A/D conversion.

### (3) When A/D-converted value addition mode is selected

For 12-bit accuracy, 1, 2, 3, or 4 times can be selected in the A/D-converted value addition mode. A/D conversion results are stored in the A/D data register as a 2-bit-extended value of the specified conversion accuracy.

For 12-bit accuracy, 16 times can also be selected in the A/D-converted value addition mode. In A/D-converted value addition mode, this register indicates the value that is obtained by adding A/D-converted values on a specific channel. A/D conversion results are stored in the A/D data register as a 4-bit-extended value of the specified conversion accuracy.

When A/D-converted value addition mode is selected, the value is stored in the A/D data register based on the settings of the A/D Data Register Format Select bits.

Table 38.15 shows example of the bit assignment for 12-bit accuracy.

**Table 38.15 Example of bit assignment for 12-bit accuracy when A/D-converted value addition mode is selected**

| Accuracy | | b15 | b14 | b13 | b12 | b11 | b10 | b9 | b8 | b7 | b6 | b5 | b4 | b3 | b2 | b1 | b0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Right-justified data with 12-bit accuracy | When 16 conversion times is specified | Added Value 15 to 0: 16-bit sum of A/D conversion results | | | | | | | | | | | | | | | |
| | When 1, 2, 3, or 4 conversion times is specified | These bits are read as 0. | | Added Value 13 to 0: 14-bit sum of A/D conversion results | | | | | | | | | | | | | |
| Left-justified data with 12-bit accuracy | When 16 conversion times is specified | Added Value 15 to 0: 16-bit sum of A/D conversion results | | | | | | | | | | | | | | | |
| | When 1, 2, 3, or 4 conversion times is specified | Added Value 13 to 0: 14-bit sum of A/D conversion results | | | | | | | | | | | | | | These bits are read as 0. | |

## 38.2.7 ADRD : A/D Self-Diagnosis Data Register

Base address: ADC120 = 0x4017_0000

Offset address: 0x01E

| Bit position: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | DIAGST[1:0] | | — | — | AD[11:0] | | | | | | | | | | | |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 11:0 | AD[11:0] | Converted Value 11 to 0<br>12-bit A/D-converted value | R |
| 13:12 | — | These bits are read as 0. | R |
| 15:14 | DIAGST[1:0] | Self-Diagnosis Status<br>For details on self-diagnosis, see section 38.2.16. ADCER : A/D Control Extended Register.<br>0 0: Self-diagnosis not executed after power-on.<br>0 1: Self-diagnosis was executed using the 0 V voltage.<br>1 0: Self-diagnosis was executed using the reference voltage*1 × 1/2.<br>1 1: Self-diagnosis was executed using the reference voltage *1. | R |

Note: The example of the bit assignment for the right-justified data with 12-bit accuracy is indicated.
Note 1. The reference voltage refers to VREFH0, AVCC0, or internal reference voltage by ADHVREFCNT setting.

ADRD is a 16-bit read-only register that holds the A/D conversion results based on the self-diagnosis of the ADC12. In addition to the AD[11:0] bits indicating the A/D-converted value, it includes the Self-Diagnosis Status bit (DIAGST[1:0]).

The settings of the A/D data register format and the A/D conversion accuracy determines the formats for data in this register.

The A/D-converted value addition and average modes cannot be applied to the A/D self-diagnosis function. For details on self-diagnosis, see section 38.2.16. ADCER : A/D Control Extended Register.

This section describes the data formats for each condition. The register diagram and the register bit table shown in this section indicate example of the bit assignment for the left and right-justified data with 12-bit accuracy.

**Table 38.16 Bit assignment for each right-justified accuracy**

| Accuracy | b15 | b14 | b13 | b12 | b11 | b10 | b9 | b8 | b7 | b6 | b5 | b4 | b3 | b2 | b1 | b0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Right-justified data with 12-bit accuracy | DIAGST[1:0] | | — | | AD[11:0] | | | | | | | | | | | |

**Table 38.17 Bit assignment for each left-justified accuracy**

| Accuracy | b15 | b14 | b13 | b12 | b11 | b10 | b9 | b8 | b7 | b6 | b5 | b4 | b3 | b2 | b1 | b0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Left-justified data with 12-bit accuracy | AD[11:0] | | | | | | | | | | | | — | | DIAGST[1:0] | |

## 38.2.8 ADCSR : A/D Control Register

Base address: ADC120 = 0x4017_0000

Offset address: 0x000

| Bit position: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | ADST | ADCS[1:0] | | — | — | ADHSC | TRGE | EXTRG | DBLE | GBADIE | — | DBLANS[4:0] | | | | |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 4:0 | DBLANS[4:0] | Double Trigger Channel Select<br>These bits select one analog input channel for double-trigger operation. The setting is only valid in double-trigger mode. | R/W |
| 5 | — | This bit is read as 0. The write value should be 0. | R/W |
| 6 | GBADIE | Group B Scan End Interrupt and ELC Event Enable<br>Group B scan only works in group scan mode.<br>0: Disable ADC120_GBADI interrupt generation on group B scan completion.<br>1: Enable ADC120_GBADI interrupt generation on group B scan completion. | R/W |
| 7 | DBLE | Double Trigger Mode Select<br>0: Deselect double-trigger mode.<br>1: Select double-trigger mode. | R/W |
| 8 | EXTRG | Trigger Select*1<br>0: Start A/D conversion by the synchronous trigger (ELC).<br>1: Start A/D conversion by the asynchronous trigger (ADTRG0). | R/W |
| 9 | TRGE | Trigger Start Enable<br>0: Disable A/D conversion to be started by the synchronous or asynchronous trigger<br>1: Enable A/D conversion to be started by the synchronous or asynchronous trigger | R/W |
| 10 | ADHSC | A/D Conversion Mode Select<br>0: High-speed A/D conversion mode<br>1: Low-power A/D conversion mode | R/W |
| 11 | — | These bits are read as 0. The write value should be 0. | R/W |
| 12 | — | These bits are read as 0. The write value should be 0. | R/W |
| 14:13 | ADCS[1:0] | Scan Mode Select<br>0 0: Single scan mode<br>0 1: Group scan mode<br>1 0: Continuous scan mode<br>1 1: Setting prohibited | R/W |
| 15 | ADST | A/D Conversion Start<br>0: Stop A/D conversion process.<br>1: Start A/D conversion process. | R/W |

Note 1. To start A/D conversion using an external pin (asynchronous trigger):
After a high-level signal is input to the external pin (ADTRG0), write 1 to both the TRGE and EXTRG bits in the ADCSR register and drive the ADTRG0 pin low. With these settings, the scan conversion process starts on detection of the falling edge of ADTRG0. The pulse width of the low-level input must be at least PCLKA 1.5 clock cycles.

The ADCSR register sets double-trigger mode and A/D conversion start trigger, enables or disables scan end interrupt, selects the scan mode, and starts or stops A/D conversion.

### DBLANS[4:0] bits (Double Trigger Channel Select)

The DBLANS[4:0] bits select one channel for A/D conversion data duplication in double-trigger mode. This can be selected by setting the binary value of the channel number to be duplicated. The A/D conversion results of the analog input of the channel selected in the DBLANS[4:0] bits are stored in A/D Data Register y when conversion is started by the first trigger, and in the A/D Data Duplexing Register when conversion is started by the second trigger.

In double-trigger mode, the channels selected in the ADANSA0 and ADANSA1 registers, are invalid, and the channel selected in the DBLANS[4:0] bits is A/D converted instead.

When double-trigger mode is used in group scan mode, double-trigger control is only applied to group A and not to group B. Therefore, multiple channel analog input can be selected for group B even in double-trigger mode.

Only set the DBLANS[4:0] bits when the ADST bit is 0. Do not set the DBLANS[4:0] bits at the same time that you write 1 to the ADST bit.

To enter A/D-converted value addition/average mode when in double-trigger mode, select the channel using the DBLANS[4:0] bits in the ADADS0 and ADADS1 registers.

A/D-converted data from the self-diagnosis function temperature sensor output, CTSU TSCAP voltage and internal reference voltage cannot be used in double-trigger mode.

**Table 38.18 Relationship between DBLANS bit Settings and Double-trigger Enabled Channels**

| DBLANS[4:0] | Duplication channel |
|---|---|
| 0x00 | AN000 |
| 0x01 | AN001 |
| 0x02 | AN002 |
| 0x03 | AN003 |
| 0x04 | AN004 |
| 0x05 | AN005 |
| 0x06 | AN006 |
| 0x11 | AN017 |
| 0x12 | AN018 |
| 0x13 | AN019 |
| 0x14 | AN020 |
| 0x15 | AN021 |
| 0x16 | AN022 |
| 0x17 | AN023 |
| 0x18 | AN024 |
| 0x19 | AN025 |

### GBADIE bit (Group B Scan End Interrupt and ELC Event Enable)

The GBADIE bit enables or disables group B scan end interrupt (ADC120_GBADI) in group scan mode.

### DBLE bit (Double Trigger Mode Select)

The DBLE bit selects or deselects double-trigger mode. Double-trigger mode can only be operated by the synchronous trigger (ELC) selected in the ADSTRGR.TRSA[5:0] bits.

Double-trigger operation is as follows:

1. The ADC120_ADI interrupt is not output on completion of the first conversion but on completion of the second conversion.
2. The A/D conversion results from the duplication channel (selected in DBLANS[4:0]) started by the first trigger are stored in A/D Data Register y and those started by the second trigger are stored in the A/D Data Duplexing Register.

When the DBLE bit is set (double-trigger mode is selected), the channels specified in the ADANSA0 and ADANSA1 registers are invalid. Double-trigger mode is deselected by setting DBLE to 0. Setting DBLE to 1 again enables the same double-trigger operation described in 1. and 2. for first time scanning with the first trigger.

Do not select double-trigger mode in continuous scan mode. Software triggering cannot be used in double-trigger mode. Always set the ADST bit to 0 before setting the DBLE bit. Do not set the DBLE bit at that same time as writing 1 to the ADST bit.

#### EXTRG bit (Trigger Select)

The EXTRG bit selects the synchronous or asynchronous trigger as the trigger for starting A/D conversion.

In group scan mode, the setting of this bit takes effect on the trigger selected for group A. For group B, A/D conversion is started by the selected synchronous trigger regardless of this bit setting.

#### TRGE bit (Trigger Start Enable)

The TRGE bit enables or disables A/D conversion by the synchronous and asynchronous triggers. In group scan mode, set this bit to 1.

#### ADHSC bit (A/D Conversion Mode Select)

The ADHSC bit selects either high speed mode or low current mode for A/D conversion. For details on how to rewrite the ADHSC bit, see section 38.8.9. ADHSC Bit Rewriting Procedure.

#### ADCS[1:0] bits (Scan Mode Select)

The ADCS[1:0] bits select the scan mode.

In single scan mode, A/D conversion is performed for the analog inputs of the channels selected in the ADANSA0 and ADANSA1 registers, in ascending order of channel number (CTSU TSCAP voltage can be regarded as AN016). When 1 cycle of A/D conversion completes for all the selected channels, the scan conversion stops.

In continuous scan mode, when the ADCSR.ADST bit is 1, A/D conversion is performed for the analog inputs of the channels selected with the ADANSA0 and ADANSA1 registers , in ascending order of channel number (CTSU TSCAP voltage can be regarded as AN016). When 1 cycle of A/D conversion completes for all the selected channels, A/D conversion repeats from the first channel. If the ADCSR.ADST bit is set to 0 during continuous scan, A/D conversion stops even if scanning is in progress.

In group scan mode:

- Group A scanning is started by the synchronous trigger (ELC) selected in the TRSA[5:0] bits in the ADSTRGR register. A/D conversion is performed on group A analog inputs of the channels selected in the ADANSA0 and ADANSA1 registers, in ascending order of channel number. When 1 cycle of A/D conversion completes for all the selected channels, A/D conversion stops.
- Group B scanning is started by the synchronous trigger (ELC) selected in the ADSTRGR.TRSB[5:0] bits. A/D conversion is performed on group B analog inputs of the channels selected in the ADANSB0 and ADANSB1 registers, in ascending order of channel number. When 1 cycle of A/D conversion completes for all the selected channels, A/D conversion stops.

If the conversion processes in group A and group B occur at the same time, those conversions cannot be controlled separately. In this case, set group A Priority Control Setting bit (ADGSPCR.PGS) in the A/D Group Scan Priority Control Register (ADGSPCR) to 1 to assign a priority to group A conversion.

In group scan mode, select different channels and triggers for group A and group B.

When selecting temperature sensor output or internal reference voltage, select single scan mode, and perform A/D conversion after deselecting all analog input channels in the ADANSA0 and ADANSA1 registers. When A/D conversion of the temperature sensor output or internal reference voltage completes, A/D conversion stops.

Only set the ADCS[1:0] bits when the ADST bit is 0. Do not set the ADCS[1:0] bits at the same time that you write 1 to the ADST bit.

**Table 38.19 Selectable targets for A/D conversion depending on scan and double-trigger mode settings**

| Scan mode setting | Double-trigger mode setting | Targets for A/D conversion | | | | | |
|---|---|---|---|---|---|---|---|
| | | Self-diagnosis | Analog input (group A) | Analog input (group B) | Temperature sensor output | Internal reference voltage | CTSU TSCAP voltage |
| Single scan | DBLE = 0 | ✓ | ✓ | — | ✓ | ✓ | ✓ |
| | DBLE = 1 | — | ✓ (1 ch only) | — | — | — | — |
| Continuous scan | DBLE = 0 | ✓ | ✓ | — | — | — | ✓ |
| | DBLE = 1 | — | — | — | — | — | — |
| Group scan | DBLE = 0 | ✓ | ✓ | ✓ | — | — | — |
| | DBLE = 1 | — | ✓ (1 ch only) | ✓ | — | — | — |

Note: ✓: Selectable, —: Not selectable

### ADST bit (A/D Conversion Start)

The ADST bit starts or stops the A/D conversion process. Before the ADST bit is set to 1, set the A/D conversion clock, the conversion mode, and the conversion target analog input.

[Setting conditions]

- 1 is written.
- The synchronous trigger (ELC) selected in the ADSTRGR.TRSA[5:0] bits is detected when ADCSR.EXTRG is 0 and ADCSR.TRGE is 1.
- The synchronous trigger (ELC) selected in the ADSTRGR.TRSB[5:0] bits is detected when ADCSR.TRGE is set to 1 in group scan mode.
- The asynchronous trigger is detected when the ADCSR.TRGE and ADCSR.EXTRG bits are set to 1 and the ADSTRGR.TRSA[5:0] bits are set to 0x00.
- When group priority operation mode is enabled (ADCSR.ADCS[1:0] = 01b and ADGSPCR.PGS = 1), the ADGSPCR.GBRP bit is set to 1, and each time A/D conversion on the group with the lowest priority is started.

[Clearing conditions]

- 0 is written.
- The A/D conversion of all the selected channels, the temperature sensor output, the internal reference voltage, or the CTSU TSCAP voltage completes in single scan mode.
- Group A scan completes in group scan mode.
- Group B scan completes in group scan mode.
- When group priority operation mode is enabled (ADCSR.ADCS[1:0] = 01b and ADGSPCR.PGS = 1), the ADGSPCR.GBRSCN bit is set to 1, and A/D conversion on the group with the lowest priority started by trigger completes.

Note: When group priority operation mode is enabled (ADCSR.ADCS[1:0] = 01b and ADGSPCR.PGS = 1), do not set the ADST bit to 1.

Note: When group priority operation mode is enabled (ADCSR.ADCS[1:0] = 01b and ADGSPCR.PGS = 1), do not set the ADST bit to 0. When forcing A/D conversion to terminate, follow the procedure for clearing the ADST bit.

## 38.2.9 ADANSA0 : A/D Channel Select Register A0

Base address: ADC120 = 0x4017_0000

Offset address: 0x004

| Bit position: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | ANSA15 | ANSA14 | ANSA13 | ANSA12 | ANSA11 | ANSA10 | ANSA9 | ANSA8 | ANSA7 | ANSA6 | ANSA5 | ANSA4 | ANSA3 | ANSA2 | ANSA1 | ANSA0 |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 15:0 | ANSA15 to ANSA0 | A/D Conversion Channels Select<br>Bit 15 (ANSA15) is associated with AN015 and bit 0 (ANSA0) is associated with AN000.<br>0: Do not select associated input channel.<br>1: Select associated input channel. | R/W |

Note: n = 00 to 06

Note: Bits associated with non-existent pins are reserved. This bit is read as 0. The write value should be 0.

ADANSA0 register selects analog input channels for A/D conversion. In group scan mode, this register selects group A channels.

Only set the ADANSA0 register when the ADCSR.ADST bit is 0.

### ANSAn bits (A/D Conversion Channels Select)

The ADANSA0 register selects any combination of analog input channels for A/D conversion. The channels and the number of channels can be arbitrarily set.

When performing A/D conversion of temperature sensor output or internal reference voltage, set the ADANSA0 register to 0x0000 to deselect all analog input channels.

In double trigger mode, the channels selected in the ADANSA0 register are invalid, and the channel selected in the ADCSR.DBLANS[4:0] bits is selected in group A instead.

When group scan mode is selected, do not select the channels specified in A/D Channel Select Register B0 (ADANSB0) and A/D Channel Select Register B1 (ADANSB1).

## 38.2.10 ADANSA1 : A/D Channel Select Register A1

Base address: ADC120 = 0x4017_0000

Offset address: 0x006

| Bit position: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | ANSA31 | ANSA30 | ANSA29 | ANSA28 | ANSA27 | ANSA26 | ANSA25 | ANSA24 | ANSA23 | ANSA22 | ANSA21 | ANSA20 | ANSA19 | ANSA18 | ANSA17 | ANSA16 |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 15:0 | ANSA31 to ANSA16 | A/D Conversion Channels Select<br>Bit 15 (ANSA31) is associated with AN031 and bit 1 (ANSA17) is associated with AN017.<br>Bit 0 (ANSA16) is associated with CTSU TSCAP<br>0: Do not select associated input channel.<br>1: Select associated input channel. | R/W |

Note: n = 16 to 25

Note: Bits associated with non-existent pins are reserved. This bit is read as 0. The write value should be 0.

ADANSA1 register selects analog input channels for A/D conversion. In group scan mode, this register selects group A channels.

Only set the ADANSA1 register when the ADCSR.ADST bit is 0.

### ANSAn bits (A/D Conversion Channels Select)

The ADANSA1 register selects any combination of analog input channels for A/D conversion. The channels and the number of channels can be arbitrarily set.

When performing A/D conversion of temperature sensor output or internal reference voltage, set the ADANSA1 register to 0x0000 to deselect all analog input channels.

In double trigger mode, the channels selected in the ADANSA1 register are invalid, and the channel selected in the ADCSR.DBLANS[4:0] bits is selected in group A instead.

When group scan mode is selected, do not select the channels specified in A/D Channel Select Register B0 (ADANSB0) and A/D Channel Select Register B1 (ADANSB1).

## 38.2.11 ADANSB0 : A/D Channel Select Register B0

Base address: ADC120 = 0x4017_0000

Offset address: 0x014

| Bit position: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | ANSB 15 | ANSB 14 | ANSB 13 | ANSB 12 | ANSB 11 | ANSB 10 | ANSB 9 | ANSB 8 | ANSB 7 | ANSB 6 | ANSB 5 | ANSB 4 | ANSB 3 | ANSB 2 | ANSB 1 | ANSB 0 |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 15:0 | ANSB15 to ANSB0 | A/D Conversion Channels Select<br>Bit 15 (ANSB15) is associated with AN015 and bit 0 (ANSB0) is associated with AN000.<br>0: Do not select associated input channel.<br>1: Select associated input channel. | R/W |

Note: n = 00 to 06

Note: Bits associated with non-existent pins are reserved. This bit is read as 0. The write value should be 0.

ADANSB0 selects analog input channels for A/D conversion in group B when group scan mode is selected. The ADANSB0 register is not used in any scan mode other than group scan mode.

Only set the ADANSB0 register when the ADCSR.ADST bit is 0.

### ANSBn bits (A/D Conversion Channels Select)

The ADANSB0 register selects any combination of analog input channels in group B for A/D conversion when group scan mode is selected. The ADANSB0 register is used for group scan mode only and not for any other modes.

Do not select channels specified in group A as selected in the ADANSA0 and ADANSA1 registers or the ADCSR.DBLANS[4:0] bits in double-trigger mode.

When performing A/D conversion of temperature sensor output or internal reference voltage, set the ADANSB0 register to 0x0000 to deselect all analog input channels.

## 38.2.12 ADANSB1 : A/D Channel Select Register B1

Base address: ADC120 = 0x4017_0000

Offset address: 0x016

| Bit position: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | ANSB 31 | ANSB 30 | ANSB 29 | ANSB 28 | ANSB 27 | ANSB 26 | ANSB 25 | ANSB 24 | ANSB 23 | ANSB 22 | ANSB 21 | ANSB 20 | ANSB 19 | ANSB 18 | ANSB 17 | ANSB 16 |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 15:0 | ANSB31 to ANSB16 | A/D Conversion Channels Select<br>0: Do not select associated input channel.<br>1: Select associated input channel. | R/W |

Note: n = 16 to 25

Note: Bits associated with non-existent pins are reserved. This bit is read as 0. The write value should be 0.

ADANSB1 selects analog input channels for A/D conversion in group B when group scan mode is selected. The ADANSB1 register is not used in any scan mode other than group scan mode.

Only set the ADANSB1 register when the ADCSR.ADST bit is 0.

### ANSBn bits (A/D Conversion Channels Select)

The ADANSB1 register selects any combination of analog input channels in group B for A/D conversion when group scan mode is selected. The ADANSB1 register is used for group scan mode only and not for any other modes.

Do not select channels specified in group A as selected in the ADANSA0 and ADANSA1 registers or the ADCSR.DBLANS[4:0] bits in double-trigger mode.

When performing A/D conversion of temperature sensor output or internal reference voltage or CTSU TSCAP voltage, set the ADANSB1 register to 0x0000 to deselect all analog input channels.

## 38.2.13 ADADS0 : A/D-Converted Value Addition/Average Channel Select Register 0

Base address: ADC120 = 0x4017_0000

Offset address: 0x008

| Bit position: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | ADS15 | ADS14 | ADS13 | ADS12 | ADS11 | ADS10 | ADS9 | ADS8 | ADS7 | ADS6 | ADS5 | ADS4 | ADS3 | ADS2 | ADS1 | ADS0 |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 15:0 | ADS15 to ADS0 | A/D-Converted Value Addition/Average Channel Select<br>Bit 15 (ADS15) is associated with AN015 and bit 0 (ADS0) is associated with AN000.<br>0: Do not select associated input channel.<br>1: Select associated input channel. | R/W |

Note: n = 00 to 06

Note: Bits associated with non-existent pins are reserved. This bit is read as 0. The write value should be 0.

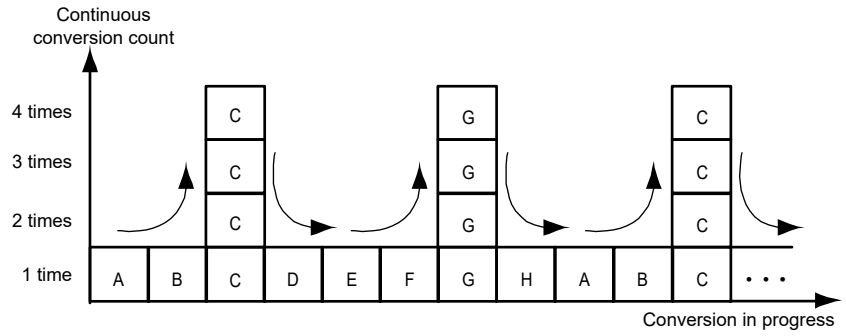
### ADSn bits (A/D-Converted Value Addition/Average Channel Select)

The ADSn bits determine which A/D-converted channels are subject to A/D-converted value addition/averaging. When an ADSn bit associated with a channel selected for A/D conversion is set to 1, A/D conversion of the analog input of the respective channel is performed successively 1, 2, 3, 4, or 16 times, as specified in the ADC[2:0] bits in the ADADC register.

When the ADADC.AVEE bit is 0, the value obtained by addition is stored in the A/D data register. When the ADADC.AVEE bit is 1, the mean value of the results obtained by addition is stored in the A/D data register.

The ADSn bits apply only to channels that are selected for A/D conversion in:

- The ANSAn bits in the ADANSA0 register or the DBLANS[4:0] bits in the ADCSR register
- The ANSBn bits in the ADANSB0 register



For channels on which the A/D conversion is performed and for which addition/average mode is not selected, a normal 1-time conversion is executed, and the conversion result is stored in the A/D data register.

Only set ADADS0 register bits when the ADCSR.ADST bit is 0.

Figure 38.2 shows a scanning operation sequence in which the ADADS0 register bits (channel c and g) are set to 1. In this figure:

- Addition mode is selected (ADADC.AVEE = 0)
- The number of conversions is set to 4 (ADADC.ADC[1:0] = 11b)
- The analog input channels (a to h) are selected by ADANSA0 register in continuous scan mode (ADCSR.ADCS[1:0] = 10b).

The conversion process begins with analog input A (channel a). The analog input C (channel c) conversion is performed successively 4 times and the added value is returned to A/D Data Register c (ADDRc). Next, the analog input D (channel d) conversion process is started. The analog input G (channel g) is performed successively 4 times and the added value is returned to A/D Data Register g (ADDRg). After conversion of analog input H (channel h), the conversion operation repeats in the same sequence starting with analog input A (channel a).

Note: A to H are analog inputs (channel a to h)

**Figure 38.2 Scan conversion sequence with ADADC.ADC[2:0] = 011b, set 1 for analog inputs C and G by ADADS0/1**

## 38.2.14 ADADS1 : A/D-Converted Value Addition/Average Channel Select Register 1

Base address: ADC120 = 0x4017_0000

Offset address: 0x00A

| Bit position: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | ADS31 | ADS30 | ADS29 | ADS28 | ADS27 | ADS26 | ADS25 | ADS24 | ADS23 | ADS22 | ADS21 | ADS20 | ADS19 | ADS18 | ADS17 | ADS16 |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 15:0 | ADS31 to ADS16 | A/D-Converted Value Addition/Average Channel Select<br>Bit 15 (ADS31) is associated with AN031 and bit 1 (ADS17) is associated with AN017. Bit 0 (ADS16) is associated with CTSU TSCAP<br>0: Do not select associated input channel.<br>1: Select associated input channel. | R/W |

Note: n = 16 to 25

Note: Bits associated with non-existent pins are reserved. This bit is read as 0. The write value should be 0.

### ADSn bits (A/D-Converted Value Addition/Average Channel Select)

The ADSn bits determine which A/D-converted channels are subject to A/D-converted value addition/averaging. When an ADSn bit associated with a channel selected for A/D conversion is set to 1, A/D conversion of the analog input of the respective channel is performed successively 1, 2, 3, 4, or 16 times, as specified in the ADC[2:0] bits in the ADADC register.

When the ADADC.AVEE bit is 0, the value obtained by addition is stored in the A/D data register. When the ADADC.AVEE bit is 1, the mean value of the results obtained by addition is stored in the A/D data register.

The ADSn bits apply only to channels that are selected for A/D conversion in:

- The ANSAn bits in the ADANSA1 register or the DBLANS[4:0] bits in the ADCSR register
- The ANSBn bits in the ADANSB1 register.

For channels on which the A/D conversion is performed and for which addition/average mode is not selected, a normal 1-time conversion is executed, and the conversion result is stored in the A/D data register.

Only set ADADS1 register when the ADCSR.ADST bit is 0.

## 38.2.15 ADADC : A/D-Converted Value Addition/Average Count Select Register

Base address: ADC120 = 0x4017_0000

Offset address: 0x00C

| Bit position: | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|
| Bit field: | AVEE | — | — | — | — | ADC[2:0] | | |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 2:0 | ADC[2:0] | Addition/Average Count Select<br>0 0 0: 1-time conversion (no addition, same as normal conversion)<br>0 0 1: 2-time conversion (1 addition)<br>0 1 0: 3-time conversion (2 additions)<br>0 1 1: 4-time conversion (3 additions)<br>1 0 1: 16-time conversion (15 additions)<br>Others: Setting prohibited | R/W |
| 6:3 | — | These bits are read as 0. The write value should be 0. | R/W |
| 7 | AVEE | Average Mode Select<br>0: Enable addition mode<br>1: Enable average mode | R/W |

ADADC sets the addition or average mode and addition count for A/D conversion. Table 38.20 lists the settable combinations of ADADC register.

**Table 38.20 Settable combinations of ADADC register**

| Mode select (AVEE) | Conversion time | | | | |
|---|---|---|---|---|---|
| | 1-time | 2-time | 3-time | 4-time | 16-time |
| Addition mode (AVEE = 0) | ✓ | ✓ | ✓ | ✓ | ✓ |
| Average mode (AVEE = 1) | — | ✓ | — | ✓ | — |

Note: ✓: Selectable, —: Not selectable

### ADC[2:0] bits (Addition/Average Count Select)

The ADC[2:0] bits set the addition count in all channels for which A/D conversion and addition/average mode are selected, including the channel selected in double trigger mode with the ADCSR.DBLANS[4:0] bits. The count also applies to A/D conversion of the temperature sensor output and the internal reference voltage and CTSU TSCAP voltage.
When self-diagnosis is executed (ADCER.DIAGM = 1), do not set the ADC[2:0] bits to any value other than 000b.

### AVEE bit (Average Mode Select)

The AVEE bit selects addition or average mode in all channels for which A/D conversion and addition/average mode are selected, including the channels selected in double-trigger mode in the ADCSR.DBLANS[4:0] bits, temperature sensor output, internal reference voltage, and CTSU TSCAP voltage.

## 38.2.16 ADCER : A/D Control Extended Register

Base address: ADC120 = 0x4017_0000

Offset address: 0x00E

| Bit position: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | ADRFMT | — | — | — | DIAGM | DIAGLD | DIAGVAL[1:0] | | — | — | ACE | — | — | — | — | — |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 4:0 | — | These bits are read as 0. The write value should be 0. | R/W |
| 5 | ACE | A/D Data Register Automatic Clearing Enable<br>0: Disable automatic clearing<br>1: Enable automatic clearing | R/W |
| 7:6 | — | These bits are read as 0. The write value should be 0. | R/W |
| 9:8 | DIAGVAL[1:0] | Self-Diagnosis Conversion Voltage Select<br>0 0: Setting prohibited when self-diagnosis is enabled<br>0 1: 0 volts<br>1 0: Reference voltage*1 × 1/2<br>1 1: Reference voltage*1 | R/W |
| 10 | DIAGLD | Self-Diagnosis Mode Select<br>0: Select rotation mode for self-diagnosis voltage<br>1: Select mixed mode for self-diagnosis voltage | R/W |
| 11 | DIAGM | Self-Diagnosis Enable<br>0: Disable ADC12 self-diagnosis<br>1: Enable ADC12 self-diagnosis | R/W |
| 14:12 | — | These bits are read as 0. The write value should be 0. | R/W |
| 15 | ADRFMT | A/D Data Register Format Select<br>0: Select right-justified for the A/D data register format<br>1: Select left-justified for the A/D data register format | R/W |

Note 1. The reference voltage refers to VREFH0, AVCC0, or internal reference voltage by ADHVREFCNT setting.

### ACE bit (A/D Data Register Automatic Clearing Enable)

The ACE bit enables or disables automatic clearing (all 0) of the ADDRy, ADRD, ADDBLDR, ADDBLDRA, ADDBLDRB, ADTSDR, or ADOCDR register after any of these registers is read by the CPU or DTC. Automatic clearing of the A/D data registers enables detection of failures that are not updated in the A/D data registers. For details, see section 38.3.7. Usage Example of A/D Data Register Automatic Clearing Function.

### DIAGVAL[1:0] bits (Self-Diagnosis Conversion Voltage Select)

The DIAGVAL[1:0] bits select the voltage value used in self-diagnosis fixed voltage mode. For details, see the DIAGLD bit description.

Do not execute self-diagnosis by setting the DIAGLD bit to 1 when the DIAGVAL[1:0] bits are set to 00b.

### DIAGLD bit (Self-Diagnosis Mode Select)

The DIAGLD bit selects whether the three voltage values are rotated, or the fixed voltage is used in self-diagnosis.

Setting the DIAGLD bit to 0 selects conversion of the voltages in rotation mode, where 0 V, the reference voltage × 1/2, and the reference voltage are converted, in that order. After reset and when self-diagnosis voltage rotation mode is selected, self-diagnosis is executed from 0 V. The self-diagnosis voltage value does not return to 0 V when scan conversion completes. When scan conversion is restarted, rotation starts at the voltage value following the previous value.

Setting the DIAGLD bit to 1 selects fixed voltage, in which the fixed voltage specified in the ADCER.DIAGVAL[1:0] bits is converted. If fixed mode is switched to rotation mode, rotation starts at the fixed voltage value.

Only set the DIAGLD bit when the ADCSR.ADST bit is 0.

### DIAGM bit (Self-Diagnosis Enable)

The DIAGM bit enables or disables self-diagnosis.

Self-diagnosis is used to detect a failure of the ADC12. In self-diagnosis mode, one of the three voltage values (0 V, the reference voltage × 1/2, or the reference voltage) is converted. When conversion completes, information on the converted voltage and the conversion result is stored into the A/D Self-Diagnosis Data Register (ADRD). The ADRD register can be read to determine whether the conversion result falls within the normal or abnormal range.

Self-diagnosis is executed once at the beginning of each scan, and one of the three voltages is converted. In double trigger mode (ADCSR.DBLE = 1), self-diagnosis (DIAGM = 0) is deselected. When self-diagnosis is selected in group scan mode, self-diagnosis is executed separately for group A and group B.

Only set the DIAGM bit when the ADCSR.ADST bit is 0.

### ADRFMT bit (A/D Data Register Format Select)

The ADRFMT bit specifies flush-right or flush-left for data to be stored in the ADDRy, ADDBLDR, ADDBLDRA, ADDBLDRB, ADTSDR, ADOCDR, ADCMPDR0/1, ADWINLLB, ADWINULB, or ADRD register.

Only set the ADRFMT bit when the ADCSR.ADST bit is 0.

## 38.2.17 ADSTRGR : A/D Conversion Start Trigger Select Register

Base address: ADC120 = 0x4017_0000

Offset address: 0x010

| Bit position: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | TRSA[5:0] | | | | | | — | — | TRSB[5:0] | | | | | |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 5:0 | TRSB[5:0] | A/D Conversion Start Trigger Select for Group B<br>Select the A/D conversion start trigger for group B in group scan mode. | R/W |
| 7:6 | — | These bits are read as 0. The write value should be 0. | R/W |
| 13:8 | TRSA[5:0] | A/D Conversion Start Trigger Select<br>Select the A/D conversion start trigger in single scan mode and continuous scan mode. In group scan mode, the A/D conversion start trigger for group A is selected. | R/W |
| 15:14 | — | These bits are read as 0. The write value should be 0. | R/W |

### TRSB[5:0] bits (A/D Conversion Start Trigger Select for Group B)

The TRSB[5:0] bits select the trigger to start scanning of the analog input selected in group B. The TRSB[5:0] bits must only be set in group scan mode and are not used in any other scan mode. For the scan conversion start trigger for group B, setting a software trigger or an asynchronous trigger is prohibited. In group scan mode, set the TRSB[5:0] bits to a value other than 0x00 and set the ADCSR.TRGE bit to 1.

When group A is given priority in group scan mode, setting the ADGSPCR.GBRP bit to 1 allows group B to continuously operate in single scan mode. When setting the ADGSPCR.GBRP bit to 1, set the TRSB[5:0] bits to 0x3F. The issuance period for a conversion trigger must be more than or equal to the actual scan conversion time ($t_{SCAN}$). If the issuance period is less than $t_{SCAN}$, A/D conversion by the trigger might have no effect.

When the GPT module is selected as an A/D conversion start trigger, a delay for synchronization processing occurs. For details, see section 38.3.6. Analog Input Sampling and Scan Conversion Time.

Table 38.21 lists the A/D conversion startup sources selected in the TRSB[5:0] bits.

**Table 38.21 Selection of A/D conversion start sources in the TRSB[5:0] bits**

| Source | Remarks | TRSB[5] | TRSB[4] | TRSB[3] | TRSB[2] | TRSB[1] | TRSB[0] |
|---|---|---|---|---|---|---|---|
| Trigger source deselected state | — | 1 | 1 | 1 | 1 | 1 | 1 |
| ELC_AD00 | ELC | 0 | 0 | 1 | 0 | 0 | 1 |
| ELC_AD01 | ELC | 0 | 0 | 1 | 0 | 1 | 0 |
| ELC_AD00, ELC_AD01 | ELC | 0 | 0 | 1 | 0 | 1 | 1 |

### TRSA[5:0] bits (A/D Conversion Start Trigger Select)

The TRSA[5:0] bits select the trigger to start A/D conversion in single scan mode and continuous scan mode, or the trigger to start scanning of group A analog inputs in group scan mode. When scanning is executed in group scan mode or double trigger mode, software trigger or asynchronous trigger is prohibited.

- When using a synchronous trigger (ELC), set the TRGE bit in the ADCSR register to 1 and set the EXTRG bit in the ADCSR register to 0.
- When using the asynchronous trigger (ADTRG0), set the TRGE bit in the ADCSR register to 1 and set the EXTRG bit in the ADCSR register to 1.
- Software trigger (ADCSR.ADST) is enabled regardless of the settings of the ADCSR.TRGE bit, the ADCSR.EXTRG bit, or the TRSA[5:0] bits.

The issuance period for a conversion trigger must be more than or equal to the actual scan conversion time (tSCAN). If the issuance period is less than tSCAN, A/D conversion by a trigger might have no effect.

When the GPT module is selected as an A/D conversion start trigger, a delay for synchronization processing occurs. For details, see section 38.3.6. Analog Input Sampling and Scan Conversion Time.

Table 38.22 lists the A/D conversion start sources selected in the TRSA[5:0] bits.

**Table 38.22 Selection of A/D activation sources in the TRSA[5:0] bits**

| Source | Remarks | TRSA[5] | TRSA[4] | TRSA[3] | TRSA[2] | TRSA[1] | TRSA[0] |
|---|---|---|---|---|---|---|---|
| Trigger source deselected state | — | 1 | 1 | 1 | 1 | 1 | 1 |
| ADTRG0 | Input pin for the trigger | 0 | 0 | 0 | 0 | 0 | 0 |
| ELC_AD00 | ELC | 0 | 0 | 1 | 0 | 0 | 1 |
| ELC_AD01 | ELC | 0 | 0 | 1 | 0 | 1 | 0 |
| ELC_AD00, ELC_AD01 | ELC | 0 | 0 | 1 | 0 | 1 | 1 |

## 38.2.18 ADEXICR : A/D Conversion Extended Input Control Registers

Base address: ADC120 = 0x4017_0000

Offset address: 0x012

| Bit position: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | — | — | — | OCSA | TSSA | — | — | — | — | — | — | OCSAD | TSSAD |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 0 | TSSAD | Temperature Sensor Output A/D-Converted Value Addition/Average Mode Select<br>0: Do not select addition/average mode for temperature sensor output.<br>1: Select addition/average mode for temperature sensor output. | R/W |
| 1 | OCSAD | Internal Reference Voltage A/D-Converted Value Addition/Average Mode Select<br>0: Do not select addition/average mode for internal reference voltage.<br>1: Select addition/average mode for internal reference voltage. | R/W |
| 7:2 | — | These bits are read as 0. The write value should be 0. | R/W |
| 8 | TSSA | Temperature Sensor Output A/D Conversion Select<br>0: Disable A/D conversion of temperature sensor output<br>1: Enable A/D conversion of temperature sensor output | R/W |
| 9 | OCSA | Internal Reference Voltage A/D Conversion Select<br>0: Disable A/D conversion of internal reference voltage<br>1: Enable A/D conversion of internal reference voltage | R/W |
| 15:10 | — | These bits are read as 0. The write value should be 0. | R/W |

### TSSAD bit (Temperature Sensor Output A/D-Converted Value Addition/Average Mode Select)

When the TSSAD bit is set to 1, A/D conversion of the temperature sensor output is selected and performed successively the number of times specified in the ADC[2:0] bits in ADADC. When the ADADC.AVEE bit is 0, the value obtained by addition (integration) is returned to the A/D Temperature Sensor Data Register (ADTSDR). When the ADADC.AVEE bit is 1, the mean value is returned to ADTSDR.

Only set the TSSAD bit while the ADCSR.ADST bit is 0.

### OCSAD bit (Internal Reference Voltage A/D-Converted Value Addition/Average Mode Select)

When the OCSAD bit is set to 1, A/D conversion of the internal reference voltage is selected and performed successively the number of times specified in the ADC[2:0] bits in ADADC. When the ADADC.AVEE bit is 0, the value obtained by addition (integration) is returned to the A/D Internal Reference Voltage Data Register (ADOCDR). When the ADADC.AVEE bit is 1, the mean value is returned to ADOCDR.

Only set the OCSAD bit while the ADCSR.ADST bit is 0.

### TSSA bit (Temperature Sensor Output A/D Conversion Select)

The TSSA bit selects A/D conversion of the temperature sensor output. When executing the A/D conversion of the temperature sensor output:

1. Set all bits in the ADANSA0/1 and ADANSB0/1 registers, the ADCSR.DBLE bit, and the ADEXICR.OCSA bit to 0.
2. Execute the A/D conversion in single scan mode.

Only set the TSSA bit when the ADCSR.ADST bit is 0.

When executing A/D conversion of the temperature sensor output, the ADDISCR register is set to 0x0F and the A/D converter executes discharge (15 ADCLK) before executing sampling. The required sampling time is 5 µs or more.

The A/D converter executes discharge each time A/D conversion is executed on the temperature sensor output.

### OCSA bit (Internal Reference Voltage A/D Conversion Select)

The OCSA bit selects A/D conversion of the internal reference voltage. When executing A/D conversion of the internal reference voltage:

1. Set all bits in the ADANSA0/1 and ADANSB0/1 registers, the ADCSR.DBLE bit, and the ADEXICR.TSSA bits to 0.
2. Execute the A/D conversion in single scan mode.

Only set the OCSA bit when the ADCSR.ADST bit is 0.

When executing A/D conversion of the internal reference voltage, the ADDISCR register are set to 0x0F and the A/D converter executes discharge (15 ADCLK) before executing sampling. The required sampling time is 5 µs or more.

The A/D converter executes discharge each time A/D conversion is executed on the internal reference voltage.

## 38.2.19 ADSSTRn/ADSSTRL/ADSSTRT/ADSSTRO : A/D Sampling State Register (n = 0 to 6)

Base address: ADC120 = 0x4017_0000

Offset address: 0x0E0 + 0x1 × n (n = 0 to 6)
0x0DD (ADSSTRL)
0x0DE (ADSSTRT)
0x0DF (ADSSTRO)

| Bit position: | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|
| Bit field: | SST[7:0] | | | | | | | |
| Value after reset: | 0 | 0 | 0 | 0 | 1 | 1 | 0 | 1 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 7:0 | SST[7:0] | Sampling Time Setting<br>These bits set the sampling time in the range from 5 to 255 states. | R/W |

The ADSSTRn register sets the sampling time for analog input.

The sampling time can be adjusted if the impedance of the analog input signal source is too high to secure sufficient sampling time, or if the ADCLK clock is slow. The set value indicates the time for one ADCLK cycle, and the required sampling time is specified by the voltage conditions. For details, see section 49.5. ADC12 Characteristics.

The lower limit of the sampling time setting depends on the frequency ratio:

- If the frequency ratio of PCLKA to PCLKC (ADCLK) = 1:1, 2:1, 4:1, or 8:1, the sampling time must be set to a value of more than 5 states
- If the frequency ratio of PCLKA to PCLKC (ADCLK) = 1:2 or 1:4, the sampling time must be set to a value of more than 6 states.

Table 38.23 shows the relationship between the A/D Sampling State Register and the associated channels. For details, see section 38.3.6. Analog Input Sampling and Scan Conversion Time.

Only set the SST[7:0] bits when the ADCSR.ADST bit is 0.

**Table 38.23 Relationship between A/D sampling state register and associated channels**

| Bit name | Associated channels |
|---|---|
| ADSSTRn.SST[7:0] bits (n = 0 to 6)*1 | AN0n (n = 00 to 06) |
| ADSSTRL.SST[7:0] bits | AN0n (n = 17 to 25), CTSU_TSCAP |
| ADSSTRT.SST[7:0] bits | Temperature sensor output*2 |
| ADSSTRO.SST[7:0] bits | Internal reference voltage*2 |

Note 1. When the self-diagnosis function is selected, the sampling time set in the ADSSTR0.SST[7:0] bits is applied.
Note 2. When the temperature sensor output or the internal reference voltage is converted, set the sampling time to more than 5 µs.

## 38.2.20 ADDISCR : A/D Disconnection Detection Control Register

Base address: ADC120 = 0x4017_0000

Offset address: 0x07A

| Bit position: | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | PCHG | ADNDIS[3:0] | | | |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 3:0 | ADNDIS[3:0] | Disconnection Detection Assist Setting<br>0x0: The disconnection detection assist function is disabled<br>0x1: Setting prohibited<br>Others: The number of states for the discharge or precharge period. | R/W |
| 4 | PCHG | Precharge/discharge select<br>0: Discharge<br>1: Precharge | R/W |
| 7:5 | — | These bits are read as 0. The write value should be 0. | R/W |

The ADDISCR register selects either precharge or discharge, and the period of precharge or discharge for the A/D disconnection detection assist function. Only set the ADDISCR register when the ADCSR.ADST bit is 0. When the temperature sensor output or internal reference voltage is converted, the A/D converter executes discharge automatically.

This operation is achieved by setting the ADDISCR register to 0x0F (15 ADCLK) when ADEXICR.OCSA or TSSA is set to 1. After executing discharge, the A/D converter executes sampling.

Disable the disconnection detection assist function if any of the following functions are used:

- The temperature sensor
- The internal reference voltage
- A/D self-diagnosis

### ADNDIS[3:0] bits (Disconnection Detection Assist Setting)

The ADNDIS[3:0] bits specify the period of precharge or discharge. When ADNDIS[3:0] = 0000b, the disconnection detection assist function is disabled. Setting the ADNDIS[3:0] bits to 0001b is prohibited. Except when ADNDIS[3:0] = 0000b or 0001b, the specified value indicates the number of states for the period of precharge or discharge. When the ADNDIS[3:0] bits are set to any values other than 0000b or 0001b, the disconnection detection assistance function is enabled.

### PCHG bit (Precharge/discharge select)

The PCHG bit selects either precharge or discharge.

## 38.2.21 ADACSR : A/D Conversion Operation Mode Select Register

Base address: ADC120 = 0x4017_0000

Offset address: 0x07E

| Bit position: | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | — | — | — | ADSAC | — |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 0 | — | This bit is read as 0. The write value should be 0. | R/W |
| 1 | ADSAC | Successive Approximation Control Setting<br>0: Normal conversion mode (default)<br>1: Fast conversion mode | R/W |
| 7:2 | — | These bits are read as 0. The write value should be 0. | R/W |

The ADACSR register selects the A/D conversion operation mode.

### ADSAC bit (Successive Approximation Control Setting)

The ADSAC bit selects either normal conversion mode or fast conversion mode for A/D conversion.

When the ADSAC bit is 0, the ADCLK maximum frequency is 48 MHz. At high-speed A/D conversion mode (ADCSR.ADHSC = 0), the conversion time of successive approximation is 31.5 ADCLK. At Low-Power A/D conversion mode (ADCSR.ADHSC = 1), the conversion time of successive approximation is 40.5 ADCLK.

When the ADSAC bit is 1, the ADCLK maximum frequency is 48 MHz. At high-speed A/D conversion mode (ADCSR.ADHSC = 0), the conversion time of successive approximation is 21.5 ADCLK. At Low-Power A/D conversion mode (ADCSR.ADHSC = 1), the conversion time of successive approximation is 27.5 ADCLK.

For details, see section 38.3.6. Analog Input Sampling and Scan Conversion Time

## 38.2.22 ADGSPCR : A/D Group Scan Priority Control Register

Base address: ADC120 = 0x4017_0000

Offset address: 0x080

| Bit position: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | GBRP | — | — | — | — | — | — | — | — | — | — | — | — | — | GBRSCN | PGS |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 0 | PGS | Group Priority Operation Setting*1<br>0: Operate without group priority control.<br>1: Operate with group priority control. | R/W |
| 1 | GBRSCN | Lower-Priority Group Restart Setting<br>(enabled only when PGS = 1 and reserved when PGS = 0.)<br>0: Disable rescanning of the group that was stopped in group priority operation<br>1: Enable rescanning of the group that was stopped in group priority operation. | R/W |
| 14:2 | — | These bits are read as 0. The write value should be 0. | R/W |
| 15 | GBRP | Single Scan Continuous Start*2<br>(enabled only when PGS = 1 and reserved when PGS = 0.)<br>0: Single scan is not continuously activated.<br>1: Single scan for the group with the lower-priority is continuously activated. | R/W |

Note 1. The ADCSR.ADCS[1:0] bits must be set to 01b (group scan mode) before setting PGS to 1. Operation is not guaranteed if these bits are set to any other value.

Note 2. When the GBRP bit is set to 1, single scan is performed continuously for the group with the lower-priority regardless of the setting in the GBRSCN bit.

### PGS bit (Group Priority Operation Setting)

The PGS bit controls group priority operation in group scan mode. Set the PGS bit to 1 to enable group priority operation.

The ADCSR.ADCS[1:0] bits must be set to 01b (group scan mode) before setting the PGS bit to 1. Operation is not guaranteed if the bits are set to any other value.

When the PGS bit is set to 0, a clear operation must be performed by software as described in section 38.8.3. Constraints on Stopping A/D Conversion. When the PGS bit is set to 1, use the settings described in section 38.3.4.3. Group Priority Operation.

### GBRSCN bit (Lower-Priority Group Restart Setting)

The GBRSCN bit controls the restarting of scan operation in group priority operation.

When the GBRSCN bit is set to 1, if the scan operation of a lower-priority group is stopped by a trigger input of a priority group, the lower-priority group scanning is restarted on completion of the priority group scanning. If a trigger of a lower-priority group is input during scanning of the priority group, the lower-priority group scanning is started on completion of the priority group scanning.

When the GBRSCN bit is set to 0, triggers input during scanning are ignored. Set the GBRSCN bit while the ADCSR.ADST bit is 0.

### GBRP bit (Single Scan Continuous Start)

The GBRP bit is set when a single scan operation is to be performed continuously on the group with the lower-priority.

Setting the GBRP bit to 1 starts a single scan of the group with the lower-priority. On completion of the scan, another single scan of the group with the lower-priority is started automatically. If scanning has been stopped during group priority

operation, single scan of the group with the lower-priority is automatically restarted on completion of the A/D conversion of the priority group.

Before setting the GBRP bit to 1, disable input of a trigger for the lower-priority group. If the GBRP bit is set to 1, rescanning is performed only on the group with the lower-priority even if the GBRSCN bit is set to 0.

## 38.2.23 ADCMPCR : A/D Compare Function Control Register

Base address: ADC120 = 0x4017_0000

Offset address: 0x090

| Bit position: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | CMPAIE | WCMPE | CMPBIE | — | CMPAE | — | CMPBE | — | — | — | — | — | — | — | CMPAB[1:0] | |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 1:0 | CMPAB[1:0] | Window A/B Composite Conditions Setting<br>These bits are valid when both window A and window B are enabled (CMPAE = 1 and CMPBE = 1).<br>0 0: Output ADC120_WCMPM when window A OR window B comparison conditions are met. Otherwise, output ADC120_WCMPUM.<br>0 1: Output ADC120_WCMPM when window A EXOR window B comparison conditions are met. Otherwise, output ADC120_WCMPUM.<br>1 0: Output ADC120_WCMPM when window A AND window B comparison conditions are met. Otherwise, output ADC120_WCMPUM.<br>1 1: Setting prohibited. | R/W |
| 8:2 | — | These bits are read as 0. The write value should be 0. | R/W |
| 9 | CMPBE | Compare Window B Operation Enable<br>0: Disable compare window B operation.<br>Disable ADC120_WCMPM and ADC120_WCMPUM outputs.<br>1: Enable compare window B operation. | R/W |
| 10 | — | This bit is read as 0. The write value should be 0. | R/W |
| 11 | CMPAE | Compare Window A Operation Enable<br>0: Disable compare window A operation.<br>Disable ADC120_WCMPM and ADC120_WCMPUM outputs.<br>1: Enable compare window A operation. | R/W |
| 12 | — | This bit is read as 0. The write value should be 0. | R/W |
| 13 | CMPBIE | Compare B Interrupt Enable<br>0: Disable ADC120_CMPBI interrupt when comparison conditions (window B) are met.<br>1: Enable ADC120_CMPBI interrupt when comparison conditions (window B) are met. | R/W |
| 14 | WCMPE | Window Function Setting<br>0: Disable window function<br>Window A and window B operate as a comparator to compare the single value on the lower side with the A/D conversion result.<br>1: Enable window function<br>Window A and window B operate as a comparator to compare the two values on the upper and lower sides with the A/D conversion result. | R/W |
| 15 | CMPAIE | Compare A Interrupt Enable<br>0: Disable ADC120_CMPAI interrupt when comparison conditions (window A) are met.<br>1: Enable ADC120_CMPAI interrupt when comparison conditions (window A) are met. | R/W |

**CMPAB[1:0] bits (Window A/B Composite Conditions Setting)**

The CMPAB[1:0] bits are valid when both window A and window B are enabled (CMPAE = 1 and CMPBE = 1) in single scan mode. These bits specify the compare function match/mismatch event output conditions and monitoring conditions of ADWINMON.MONCOMB. Only set the CMPAB[1:0] bits while the ADCSR.ADST bit is 0.

### CMPBE bit (Compare Window B Operation Enable)

The CMPBE bit enables or disables the compare window B operation. Set the CMPBE bit while the ADCSR.ADST bit is 0.

Set this bit to 0 before setting the following registers:

- A/D Channel Select Registers A0, A1, B0, B1 (ADANSA0, ADANSA1, ADANSB0, ADANSB1)
- OCSA, or TSSA bits in the A/D Conversion Extended Input Control Register (ADEXICR)
- CMPCHB[5:0] bits in the Window B Channel Select Register (ADCMPBNSR)

### CMPAE bit (Compare Window A Operation Enable)

The CMPAE bit enables or disables the compare window A operation. Set the CMPAE bit while the ADCSR.ADST bit is 0.

Set this bit to 0 before setting the following registers:

- A/D Channel Select Registers A0, A1, B0, B1 (ADANSA0, ADANSA1, ADANSB0, ADANSB1)
- TSSB, OCSA, or TSSA bits in the A/D Conversion Extended Input Control Register (ADEXICR)
- Window A Channel Select Registers 0 and 1 (ADCMPANSR0 and ADCMPANSR1)
- Window A Extended Input Select Register (ADCMPANSER)

### CMPBIE bit (Compare B Interrupt Enable)

The CMPBIE bit enables or disables the ADC120_CMPBI interrupt output when the comparison conditions (window B) are met.

### WCMPE bit (Window Function Setting)

The WCMPE bit enables or disables the window function. Set the WCMPE bit while the ADCSR.ADST bit is 0.

### CMPAIE bit (Compare A Interrupt Enable)

The CMPAIE bit enables or disables the ADC120_CMPAI interrupt output when the comparison conditions (window A) are met.

## 38.2.24 ADCMPANSR0 : A/D Compare Function Window A Channel Select Register 0

Base address: ADC120 = 0x4017_0000

Offset address: 0x094

| Bit position: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | CMPCHA15 | CMPCHA14 | CMPCHA13 | CMPCHA12 | CMPCHA11 | CMPCHA10 | CMPCHA9 | CMPCHA8 | CMPCHA7 | CMPCHA6 | CMPCHA5 | CMPCHA4 | CMPCHA3 | CMPCHA2 | CMPCHA1 | CMPCHA0 |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 15:0 | CMPCHA15 to CMPCHA0 | Compare Window A Channel Select<br>Bit 15 (CMPCHA15) is associated with AN015 and bit 0 (CMPCHA0) is associated with AN000.<br>0: Disable compare function for associated input channel<br>1: Enable compare function for associated input channel | R/W |

Note: n = 00 to 06

Note: Bits associated with non-existent pins are reserved. This bit is read as 0. The write value should be 0.

### CMPCHAn bits (Compare Window A Channel Select)

The compare function is enabled by writing 1 to the CMPCHAn bits with the same number as the A/D conversion channel selected in the ADANSA0.ANSAn bits and the ADANSB0.ANSBn bits.

Set the CMPCHAn bits while the ADCSR.ADST bit is 0.

## 38.2.25 ADCMPANSR1 : A/D Compare Function Window A Channel Select Register 1

Base address: ADC120 = 0x4017_0000

Offset address: 0x096

| Bit position: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | CMPCHA31 | CMPCHA30 | CMPCHA29 | CMPCHA28 | CMPCHA27 | CMPCHA26 | CMPCHA25 | CMPCHA24 | CMPCHA23 | CMPCHA22 | CMPCHA21 | CMPCHA20 | CMPCHA19 | CMPCHA18 | CMPCHA17 | CMPCHA16 |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 15:0 | CMPCHA31 to CMPCHA16 | Compare Window A Channel Select<br><br>Bit 15 (CMPCHA31) is associated with AN031 and bit 1 (CMPCHA17) is associated with AN017. Bit 0 (CMPCHA16) is associated with CTSU TSCAP<br>0: Disable compare function for associated input channel<br>1: Enable compare function for associated input channel | R/W |

Note: n = 16 to 25

Note: Bits associated with non-existent pins are reserved. This bit is read as 0. The write value should be 0.

### CMPCHAn bits (Compare Window A Channel Select)

The compare function is enabled by writing 1 to the CMPCHAn bits with the same number as the A/D conversion channel selected in the ADANSA1.ANSA bits and the ADANSB1.ANSB bits.

Set the CMPCHAn bits while the ADCSR.ADST bit is 0.

## 38.2.26 ADCMPANSER : A/D Compare Function Window A Extended Input Select Register

Base address: ADC120 = 0x4017_0000

Offset address: 0x092

| Bit position: | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | — | — | — | CMPOCA | CMPTSA |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 0 | CMPTSA | Temperature Sensor Output Compare Select<br>0: Exclude the temperature sensor output from the compare Window A target range.<br>1: Include the temperature sensor output in the compare Window A target range. | R/W |
| 1 | CMPOCA | Internal Reference Voltage Compare Select<br>0: Exclude the internal reference voltage from the compare Window A target range.<br>1: Include the internal reference voltage in the compare Window A target range. | R/W |
| 7:2 | — | These bits are read as 0. The write value should be 0. | R/W |

### CMPTSA bit (Temperature Sensor Output Compare Select)

The compare window A function is enabled by setting the CMPTSA bit to 1 when the ADEXICR.TSSA bit is 1. Set the CMPTSA bit when the ADCSR.ADST bit is 0.

### CMPOCA bit (Internal Reference Voltage Compare Select)

The compare window A function is enabled by setting the CMPOCA bit to 1 when the ADEXICR.OCSA bit is 1. Set the CMPOCA bit when the ADCSR.ADST bit is 0.

## 38.2.27 ADCMPLR0 : A/D Compare Function Window A Comparison Condition Setting Register 0

Base address: ADC120 = 0x4017_0000

Offset address: 0x098

| Bit position: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | CMPLCHA15 | CMPLCHA14 | CMPLCHA13 | CMPLCHA12 | CMPLCHA11 | CMPLCHA10 | CMPLCHA9 | CMPLCHA8 | CMPLCHA7 | CMPLCHA6 | CMPLCHA5 | CMPLCHA4 | CMPLCHA3 | CMPLCHA2 | CMPLCHA1 | CMPLCHA0 |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 15:0 | CMPLCHA15 to CMPLCHA0 | Compare Window A Comparison Condition Select<br>These bits set comparison conditions for channels to which Window A comparison conditions are applied.<br>Bit 15 (CMPLCHA15) is associated with AN015 and bit 0 (CMPLCHA0) is associated with AN000.<br>Comparison conditions are shown in Figure 38.3.<br>0: When window function is disabled (ADCMPCR.WCMPE = 0):<br>ADCMPDR0 value > A/D-converted value<br>When window function is enabled (ADCMPCR.WCMPE = 1):<br>A/D-converted value < ADCMPDR0 value,<br>or ADCMPDR1 value < A/D-converted value<br>1: When window function is disabled (ADCMPCR.WCMPE = 0):<br>ADCMPDR0 value < A/D-converted value<br>When window function is enabled (ADCMPCR.WCMPE = 1):<br>ADCMPDR0 value < A/D-converted value < ADCMPDR1 value | R/W |

Note: n = 00 to 06

Note: Bits associated with non-existent pins are reserved. This bit is read as 0. The write value should be 0.

### CMPLCHAn bits (Compare Window A Comparison Condition Select)

The CMPLCHAn bits specify the comparison conditions for channels to which Window A comparison conditions are applied. These bits can be set for each analog input to be compared. When the comparison result of each analog input meets the set condition, the ADCMPSR0.CMPSTCHAn flag sets to 1 and a compare interrupt (ADC120_CMPAI) is generated.

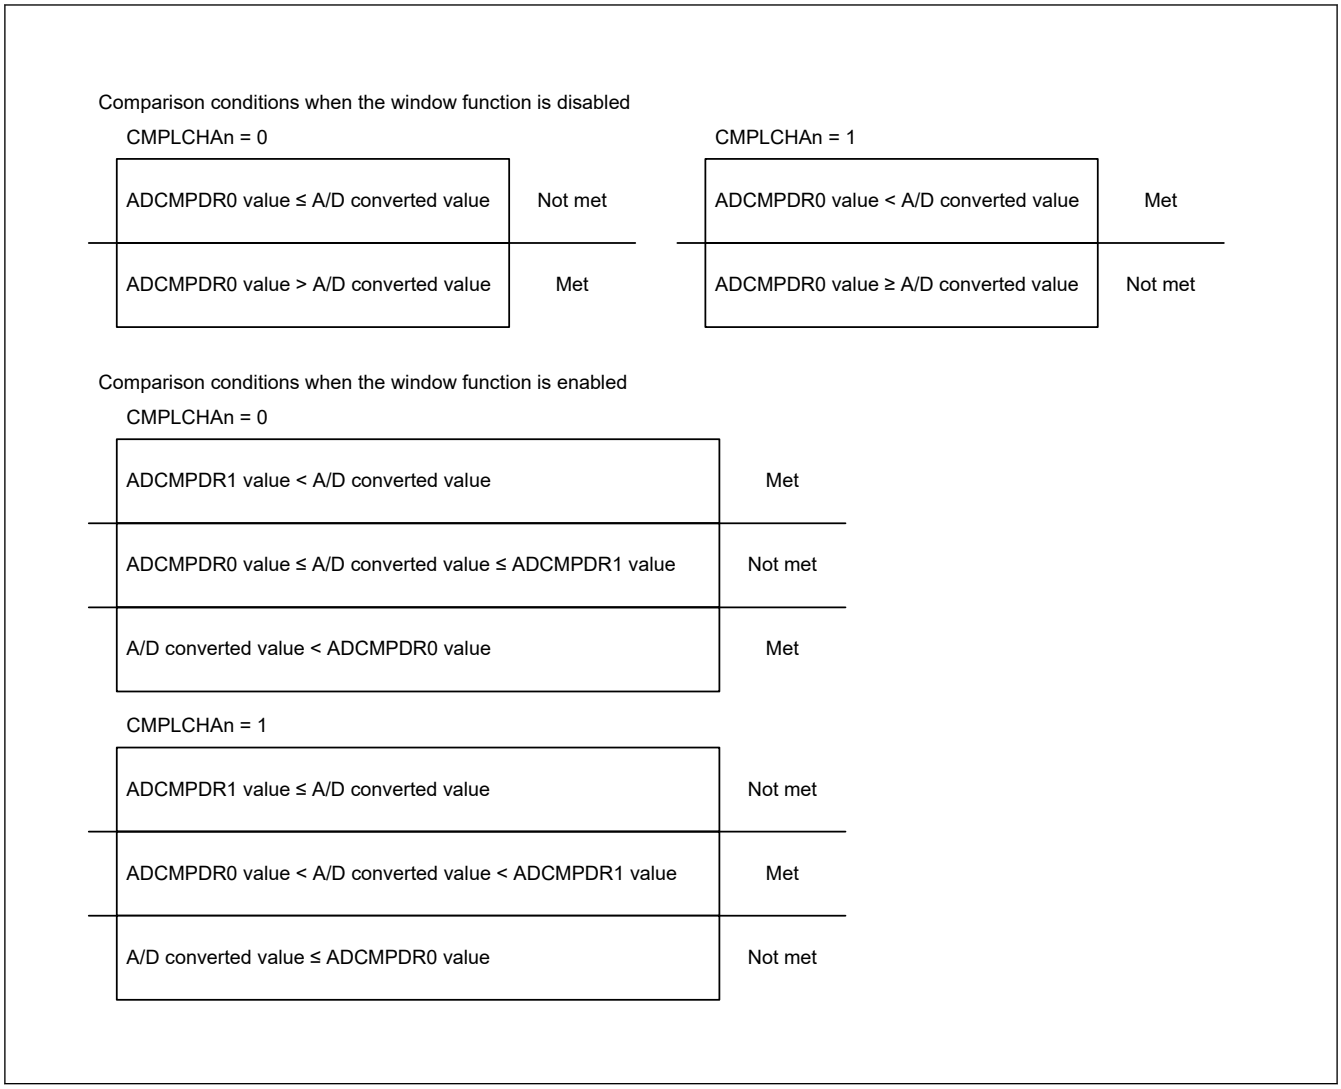


**Figure 38.3 Explanation of comparison conditions for compare function Window A**

## 38.2.28 ADCMPLR1 : A/D Compare Function Window A Comparison Condition Setting Register 1

Base address: ADC120 = 0x4017_0000

Offset address: 0x09A

| Bit position: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | CMPLCHA31 | CMPLCHA30 | CMPLCHA29 | CMPLCHA28 | CMPLCHA27 | CMPLCHA26 | CMPLCHA25 | CMPLCHA24 | CMPLCHA23 | CMPLCHA22 | CMPLCHA21 | CMPLCHA20 | CMPLCHA19 | CMPLCHA18 | CMPLCHA17 | CMPLCHA16 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 15:0 | CMPLCHA31 to CMPLCHA16 | Compare Window A Comparison Condition Select<br>These bits set comparison conditions for channels to which Window A comparison conditions are applied.<br><br>Bit 15 (CMPLCHA31) is associated with AN031 and bit 1 (CMPLCHA17) is associated with AN017. Bit 0 (CMPLCHA16) is associated with CTSU TSCAP<br>Comparison conditions are shown in Figure 38.3.<br>0: When window function is disabled (ADCMPCR.WCMPE = 0):<br>ADCMPDR0 value > A/D-converted value<br>When window function is enabled (ADCMPCR.WCMPE = 1):<br>A/D-converted value < ADCMPDR0 value,<br>or ADCMPDR1 value < A/D-converted value<br>1: When window function is disabled (ADCMPCR.WCMPE = 0):<br>ADCMPDR0 value < A/D-converted value<br>When window function is enabled (ADCMPCR.WCMPE = 1):<br>ADCMPDR0 value < A/D-converted value < ADCMPDR1 value | R/W |

Note: n = 16 to 25
Note: Bits associated with non-existent pins are reserved. This bit is read as 0. The write value should be 0.

### CMPLCHAn bits (Compare Window A Comparison Condition Select)

The CMPLCHAn bits specify the comparison conditions for analog channels to which window A comparison conditions are applied. These bits can be set for each analog input to be compared. When the comparison result of each analog input meets the set condition, the ADCMPSR1.CMPSTCHAn bit is set to 1 and a compare interrupt (ADC120_CMPAI) is generated.

## 38.2.29 ADCMPLER : A/D Compare Function Window A Extended Input Comparison Condition Setting Register

Base address: ADC120 = 0x4017_0000

Offset address: 0x093

| Bit position: | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|

|---|---|---|---|
| 0 | CMPLTSA | Compare Window A Temperature Sensor Output Comparison Condition Select<br>Comparison conditions are shown in Figure 38.3.<br>0: When window function is disabled (ADCMPCR.WCMPE = 0) :<br>ADCMPDR0 value > A/D-converted value, Compare Window A Temperature Sensor Output Comparison Condition Select<br>When window function is enabled (ADCMPCR.WCMPE = 1) :<br>Compare Window A Temperature Sensor Output Comparison, Condition A/D-converted value < ADCMPDR0 value,<br>or A/D-converted value > ADCMPDR1 value<br>1: When window function is disabled (ADCMPCR.WCMPE = 0) :<br>ADCMPDR0 value < A/D-converted value<br>When window function is enabled (ADCMPCR.WCMPE = 1) :<br>ADCMPDR0 value < A/D-converted value < ADCMPDR1 value | R/W |
| 1 | CMPLOCA | Compare Window A Internal Reference Voltage Comparison Condition Select<br>Comparison conditions are shown in Figure 38.3.<br>0: When window function is disabled (ADCMPCR.WCMPE = 0) :<br>ADCMPDR0 value > A/D-converted value<br>When window function is enabled (ADCMPCR.WCMPE = 1):<br>A/D-converted value < ADCMPDR0 value,<br>or A/D-converted value > ADCMPDR1 value<br>1: When window function is disabled (ADCMPCR.WCMPE = 0):<br>ADCMPDR0 value < A/D-converted value<br>When window function is enabled (ADCMPCR.WCMPE = 1):<br>ADCMPDR0 value < A/D-converted value < ADCMPDR1 value | R/W |
| 7:2 | — | These bits are read as 0. The write value should be 0. | R/W |

### CMPLTSA bit (Compare Window A Temperature Sensor Output Comparison Condition Select)

The CMPLTSA bit specifies comparison conditions when the temperature sensor output is the target for the Window A comparison condition. When the temperature sensor output comparison result meets the set condition, the ADCMPSER.CMPSTTSA flag sets to 1 and a compare interrupt (ADC120_CMPAI) is generated.

### CMPLOCA bit (Compare Window A Internal Reference Voltage Comparison Condition Select)

The CMPLOCA bit specifies comparison conditions when the internal reference voltage is the target for the Window A comparison condition. When the internal reference voltage comparison result meets the set condition, the ADCMPSER.CMPSTOCA flag sets to 1 and a compare interrupt (ADC120_CMPAI) is generated.

## 38.2.30 ADCMPDRn : A/D Compare Function Window A Lower-Side/Upper-Side Level Setting Register (n = 0, 1)

Base address: ADC120 = 0x4017_0000

Offset address: 0x09C + (0x2 × n)

| Bit position: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | | | | | | | | | | | | | | | | |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

The ADCMPDRy (y = 0, 1) register specifies the reference data when the compare window A function is used. ADCMPDR0 sets the lower reference for window A, and ADCMPDR1 sets the upper reference for window A.

ADCMPDRy are read/write registers.

ADCMPDRy are writable even during A/D conversion. The reference data can be dynamically changed by rewriting register values during A/D conversion*1.

Set these registers so that the upper reference is not less than the lower reference (ADCMPDR1 ≥ ADCMPDR0). ADCMPDR1 are not used when the window function is disabled.

Note 1. The lower and the upper references are changed when each register is written. For example, when the upper reference value is changed and the lower reference value is being changed, the MCU compares the upper reference (after rewrite), and the lower reference (before rewrite) with the A/D conversion result. See Figure 38.4. If the comparison during the rewriting of these two references is erroneous, then rewrite these reference values when both ADCSR.ADST and the target Compare Window Operation Enable bit (ADCMPCR.CMPAE or ADCMPCR.CMPBE) are 0.

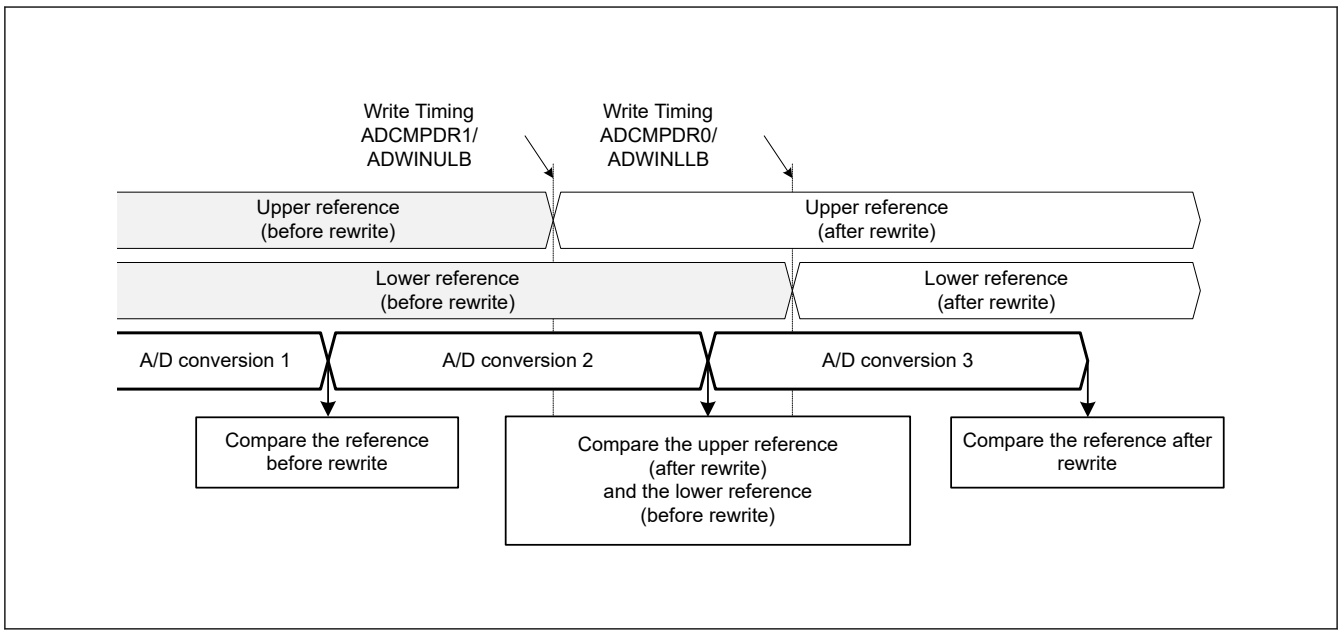

**Figure 38.4 Comparison between upper and lower references before and after a rewrite**

The ADCMPDRy registers use different formats depending on the following conditions:

- The value of A/D Data Register Format Select bit (flush-right or flush-left)
- The value of A/D-Converted Value Addition/Average Channel Select bits (A/D-converted value addition mode selected or not selected).

The data formats for each condition are shown as follows:

1. When A/D-converted value addition mode is not selected
   - Flush-right data with 12-bit accuracy — Lower 12 bits ([11:0]) are valid
   - Flush-left data with 12-bit accuracy — Upper 12 bits ([15:4]) are valid
2. When A/D-converted value addition mode is selected (other than 16-time conversion)
   - Flush-right data with 12-bit accuracy — Lower 14 bits ([13:0]) are valid
   - Flush-left data with 12-bit accuracy — Upper 14 bits ([15:2]) are valid
3. When A/D-converted value addition mode is selected (16-time conversion)
   - All bits ([15:0]) are valid

## 38.2.31 ADWINnLB : A/D Compare Function Window B Lower-Side/Upper-Side Level Setting Register (n = L, U)

Base address: ADC120 = 0x4017_0000

Offset address: 0x0A8 (n = L)
0x0AA (n = U)

| Bit position: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | | | | | | | | | | | | | | | | |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

The ADWINULB and ADWINLLB registers specify the reference data when the compare window B function is used. ADWINLLB sets the lower reference for window B, and ADWINULB sets the upper reference for window B.

ADWINnLB are read/write registers.

ADWINnLB are writable even during A/D conversion. The reference data can be dynamically changed by rewriting register values during A/D conversion*1.

Set these registers so that the upper reference is not less than the lower reference (ADWINULB ≥ ADWINLLB). ADWINULB are not used when the window function is disabled.

Note 1. The lower and the upper references are changed when each register is written. For example, when the upper reference value is changed and the lower reference value is being changed, the MCU compares the upper reference (after rewrite), and the lower reference (before rewrite) with the A/D conversion result. See Figure 38.5. If the comparison during the rewriting of these two references is erroneous, then rewrite these reference values when both ADCSR.ADST and the target Compare Window Operation Enable bit (ADCMPCR.CMPAE or ADCMPCR.CMPBE) are 0.

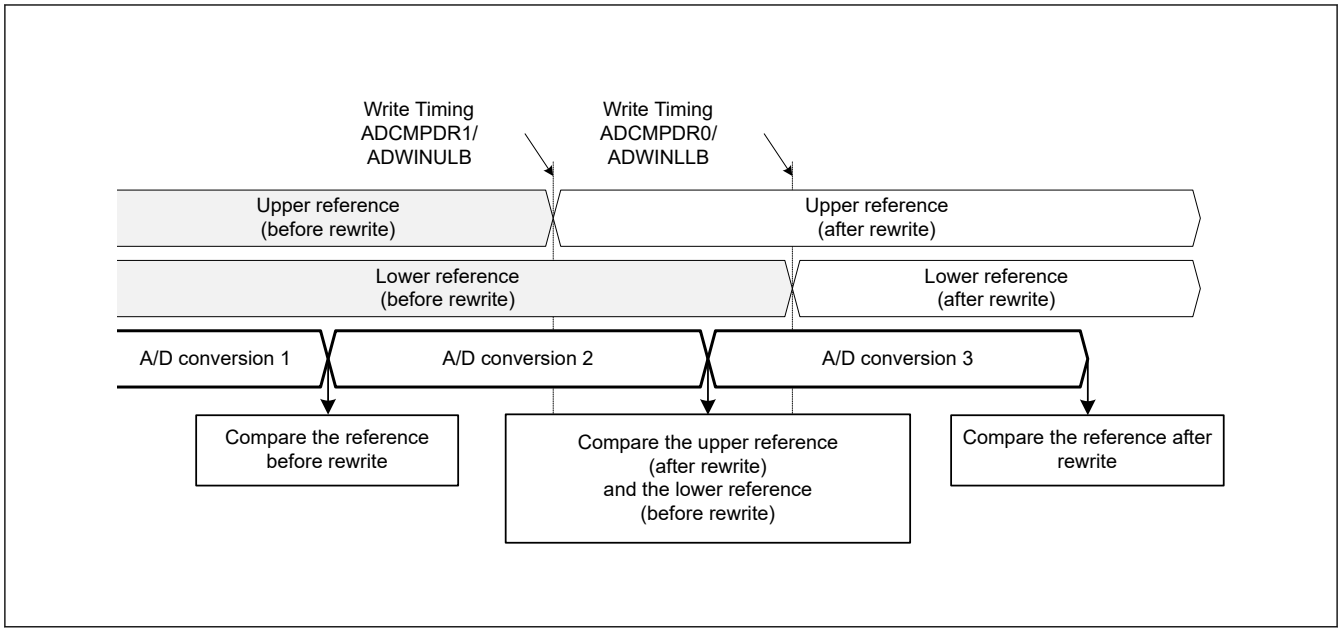

**Figure 38.5 Comparison between upper and lower references before and after a rewrite**

The ADWINnLB registers use different formats depending on the following conditions:

- The value of A/D Data Register Format Select bit (flush-right or flush-left)
- The value of A/D-Converted Value Addition/Average Channel Select bits (A/D-converted value addition mode selected or not selected).

The data formats for each condition are shown as follows:

1. When A/D-converted value addition mode is not selected
   - Flush-right data with 12-bit accuracy — Lower 12 bits ([11:0]) are valid
   - Flush-left data with 12-bit accuracy — Upper 12 bits ([15:4]) are valid
2. When A/D-converted value addition mode is selected (other than 16-time conversion)
   - Flush-right data with 12-bit accuracy — Lower 14 bits ([13:0]) are valid
   - Flush-left data with 12-bit accuracy — Upper 14 bits ([15:2]) are valid
3. When A/D-converted value addition mode is selected (16-time conversion)
   - All bits ([15:0]) are valid

## 38.2.32 ADCMPSR0 : A/D Compare Function Window A Channel Status Register 0

Base address: ADC120 = 0x4017_0000

Offset address: 0x0A0

| Bit position: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | CMPSTCHA15 | CMPSTCHA14 | CMPSTCHA13 | CMPSTCHA12 | CMPSTCHA11 | CMPSTCHA10 | CMPSTCHA9 | CMPSTCHA8 | CMPSTCHA7 | CMPSTCHA6 | CMPSTCHA5 | CMPSTCHA4 | CMPSTCHA3 | CMPSTCHA2 | CMPSTCHA1 | CMPSTCHA0 |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 15:0 | CMPSTCHA15 to CMPSTCHA0 | Compare Window A Flag<br>When Window A operation is enabled (ADCMPCR.CMPAE = 1b), these bits indicate the comparison result of channels to which Window A comparison conditions are applied.<br>Bit 15 (CMPSTCHA15) is associated with AN015 and bit 0 (CMPSTCHA0) is associated with AN000.<br>0: Comparison conditions are not met.<br>1: Comparison conditions are met. | R/W |

Note: n = 00 to 06
Note: Bits associated with non-existent pins are reserved. This bit is read as 0. The write value should be 0.

### CMPSTCHAn flags (Compare Window A Flag)

The CMPSTCHAn flags indicate the comparison results for channels to which Window A comparison conditions are applied. When a comparison condition set in ADCMPLR0.CMPLCHA is met at the end of A/D conversion, the associated CMPSTCHAn flag sets to 1. When the ADCMPCR.CMPAIE bit is 1, a compare interrupt request (ADC120_CMPAI) is generated when this flag sets to 1.

Writing 1 to the CMPSTCHAn flags is invalid.

[Setting condition]

- The condition set in ADCMPLR0.CMPLCHA is met when ADCMPCR.CMPAE = 1.

[Clearing condition]

- Writing 0 after reading 1.

## 38.2.33 ADCMPSR1 : A/D Compare Function Window A Channel Status Register1

Base address: ADC120 = 0x4017_0000

Offset address: 0x0A2

| Bit position: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|

Bit 0 (CMPSTCHA16) is associated with CTSU TSCAP<br>0: Comparison conditions are not met.<br>1: Comparison conditions are met. | R/W |

Note: n = 16 to 25
Note: Bits associated with non-existent pins are reserved. This bit is read as 0. The write value should be 0.

### CMPSTCHAn flags (Compare Window A Flag)

The CMPSTCHAn flags indicate the comparison results for channels to which Window A comparison conditions are applied. When the comparison condition set in ADCMPLR1.CMPLCHA is met at the end of A/D conversion, the associated CMPSTCHAn flag sets to 1. When the ADCMPCR.CMPAIE bit is 1, a compare interrupt request (ADC120_CMPAI) is generated when this flag sets to 1.

Writing 1 to the CMPSTCHAn flags is invalid.

[Setting condition]

- The condition set in ADCMPLR1.CMPLCHA is met when ADCMPCR.CMPAE = 1.

[Clearing condition]

- Writing 0 after reading 1.

## 38.2.34 ADCMPSER : A/D Compare Function Window A Extended Input Channel Status Register

Base address: ADC120 = 0x4017_0000

Offset address: 0x0A4

| Bit position: | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | — | — | — | CMPSTOCA | CMPSTTSA |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 0 | CMPSTTSA | Compare Window A Temperature Sensor Output Compare Flag<br>When Window A operation is enabled (ADCMPCR.CMPAE = 1), this bit indicates the temperature sensor output comparison result.<br>0: Comparison conditions are not met.<br>1: Comparison conditions are met. | R/W |
| 1 | CMPSTOCA | Compare Window A Internal Reference Voltage Compare Flag<br>When Window A operation is enabled (ADCMPCR.CMPAE = 1), this bit indicates the internal reference voltage comparison result.<br>0: Comparison conditions are not met.<br>1: Comparison conditions are met. | R/W |
| 7:2 | — | These bits are read as 0. The write value should be 0. | R/W |

The ADCMPSER register stores compare results of compare function window A.

### CMPSTTSA flag (Compare Window A Temperature Sensor Output Compare Flag)

The CMPSTTSA flag indicates the temperature sensor output comparison result. When the comparison condition set in ADCMPLER.CMPLTSA is met at the end of A/D conversion, this flag sets to 1. When the ADCMPCR.CMPAIE bit is 1, a compare interrupt request (ADC120_CMPAI) is generated when this flag sets to 1.

Writing 1 to the CMPSTTSA flag is invalid.

[Setting condition]

- The condition set in ADCMPLER.CMPLTSA is met when ADCMPCR.CMPAE = 1.

[Clearing condition]

- Writing 0 after reading 1.

### CMPSTOCA flag (Compare Window A Internal Reference Voltage Compare Flag)

The CMPSTOCA flag indicates the internal reference voltage comparison result. When the comparison condition set in ADCMPLER.CMPLOCA is met at the end of A/D conversion, this flag sets to 1. When the ADCMPCR.CMPAIE bit is 1, a compare interrupt request (ADC120_CMPAI) is generated when this flag sets to 1.

Writing 1 to the CMPSTOCA flag is invalid.

[Setting condition]

- The condition set in ADCMPLER.CMPLOCA is met when ADCMPCR.CMPAE = 1.

[Clearing condition]

- Writing 0 after reading 1.

## 38.2.35 ADCMPBNSR : A/D Compare Function Window B Channel Select Register

Base address: ADC120 = 0x4017_0000

Offset address: 0x0A6

| Bit position: | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |

| ⋮ | ⋮ |
| 0x19 | AN025 |
| 0x20 | Temparature sensor |
| 0x21 | Internal reference voltage |
| 0x3F | No selection |
| Others | Setting prohibited |

### CMPCHB[5:0] bits (Compare Window B Channel Select)

The CMPCHB[5:0] bits specify the channels to be compared with the compare Window B conditions from AN000 to AN006, AN017 to AN025, the temperature sensor, the internal reference voltage, and the CTSU TSCAP voltage. The compare Window B function is enabled by specifying the hexadecimal number of the A/D conversion channel selected in the ADANSA0, ADANSA1, ADANSB0, ADANSB1 registers.

Set the CMPCHB[5:0] bits while the ADCSR.ADST bit is 0.

**CMPLB bit (Compare Window B Comparison Condition Setting)**

The CMPLB bit specifies the comparison conditions for channels for Window B. When the comparison result of an analog input meets the set condition, the associated ADCMPBSR.CMPSTB flag sets to 1 and a compare interrupt request (ADC120_CMPBI) is generated.

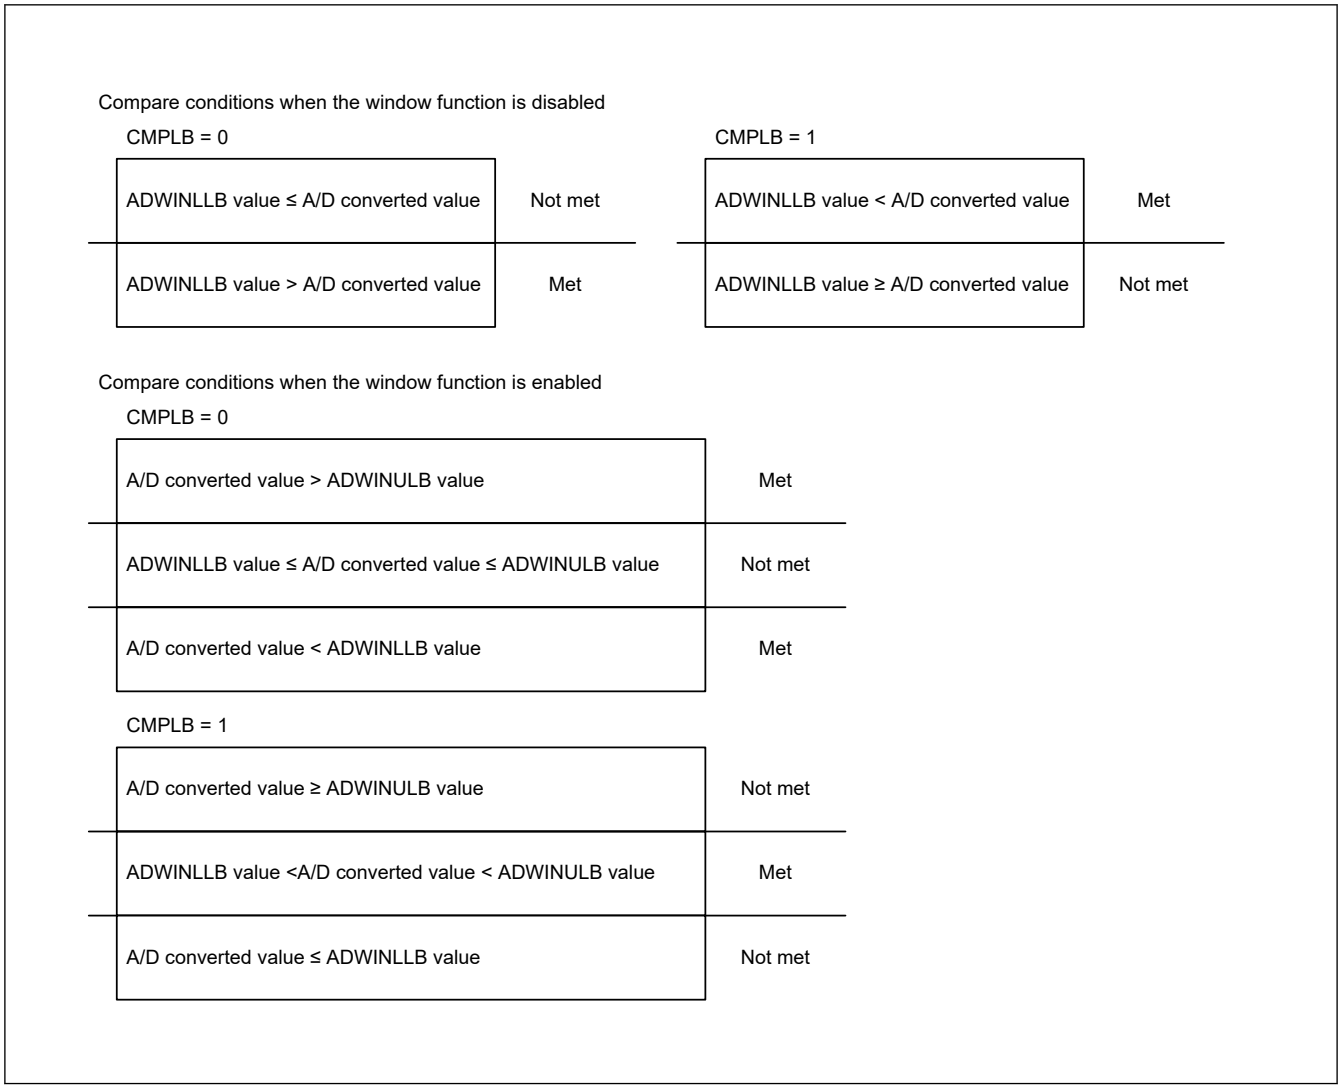

**Figure 38.6 Explanation of compare conditions for compare function Window B**

## 38.2.36 ADCMPBSR : A/D Compare Function Window B Status Register

Base address: ADC120 = 0x4017_0000

Offset address: 0x0AC

| Bit position: | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | — | — | — | — | CMPSTB |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 0 | CMPSTB | Compare Window B Flag<br>When Window B operation is enabled (ADCMPCR.CMPBE = 1), this bit indicates the comparison result of channels to which Window B comparison conditions are applied, temperature sensor output, internal reference voltage, and CTSU TSCAP voltage.<br>0: Comparison conditions are not met.<br>1: Comparison conditions are met. | R/W |
| 7:1 | — | These bits are read as 0. The write value should be 0. | R/W |

### CMPSTB flag (Compare Window B Flag)

The CMPSTB flag indicates the comparison result of channels to which Window B comparison conditions are applied, the temperature sensor output, internal reference voltage, and the CTSU TSCAP voltage. When the comparison condition set in ADCMPBNSR.CMPLB is met at the end of A/D conversion, this flag sets to 1. When the ADCMPCR.CMPBIE bit is 1, a compare interrupt request (ADC120_CMPBI) is generated when this flag sets to 1.

Writing 1 to the CMPSTB flag is invalid.

[Setting condition]

- The condition set in ADCMPBNSR.CMPLB is met when ADCMPCR.CMPBE = 1.

[Clearing condition]

- Writing 0 after reading 1.

## 38.2.37 ADWINMON : A/D Compare Function Window A/B Status Monitor Register

Base address: ADC120 = 0x4017_0000

Offset address: 0x08C

| Bit position: | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | MONCMPB | MONCMPA | — | — | — | MONCOMB |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 0 | MONCOMB | Combination Result Monitor<br>This bit indicates the combination result. This bit is valid when both Window A and Window B operations are enabled.<br>0: Window A/B composite conditions are not met.<br>1: Window A/B composite conditions are met. | R |
| 3:1 | — | These bits are read as 0. | R |
| 4 | MONCMPA | Comparison Result Monitor A<br>0: Window A comparison conditions are not met.<br>1: Window A comparison conditions are met. | R |
| 5 | MONCMPB | Comparison Result Monitor B<br>0: Window B comparison conditions are not met.<br>1: Window B comparison conditions are met. | R |
| 7:6 | — | These bits are read as 0. | R |

### MONCOMB bit (Combination Result Monitor)

The read-only MONCOMB bit indicates the combined result of comparison condition results A and B based on the combination condition set in the ADCMPCR.CMPAB[1:0] bits.

[Setting condition]

- The combined result meets the combination condition set in the ADCMPCR.CMPAB[1:0] bits when ADCMPCR.CMPAE = 1 and ADCMPCR.CMPBE = 1.

[Clearing conditions]

- The combined result does not meet the combination condition set in the ADCMPCR.CMPAB[1:0] bits.
- ADCMPCR.CMPAE = 0 or ADCMPCR.CMPBE = 0.

#### MONCMPA bit (Comparison Result Monitor A)

The read-only MONCMPA bit is read as 1 when the A/D-converted value of the Window A target channel meets the condition set in ADCMPLR0/ADCMPLR1 and ADCMPLER. Otherwise, it is read as 0.

[Setting condition]

- The A/D-converted value meets the condition set in the ADCMPLR0/ADCMPLR1 and ADCMPLER registers when ADCMPCR.CMPAE = 1.

[Clearing conditions]

- The A/D-converted value does not meet the condition set in the ADCMPLR0/ADCMPLR1 and ADCMPLER registers when ADCMPCR.CMPAE = 1.
- ADCMPCR.CMPAE = 0 (automatically cleared when the ADCMPCR.CMPAE value changes from 1 to 0).

#### MONCMPB bit (Comparison Result Monitor B)

The read-only MONCMPB bit is read as 1 when the A/D-converted value of the Window B target channel meets the condition set in the ADCMPBNSR.CMPLB bit. Otherwise, it is read as 0.

[Setting condition]

- The A/D-converted value meets the condition set in ADCMPBNSR.CMPLB when ADCMPCR.CMPBE = 1.

[Clearing conditions]

- The A/D-converted value does not meet the condition set in ADCMPBNSR.CMPLB when ADCMPCR.CMPBE = 1.
- ADCMPCR.CMPBE = 0 (automatically cleared when the ADCMPCR.CMPBE value changes from 1 to 0).

### 38.2.38 ADHVREFCNT : A/D High-Potential/Low-Potential Reference Voltage Control Register

Base address: ADC120 = 0x4017_0000

Offset address: 0x08A

| Bit position: | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|
| Bit field: | ADSLP | — | — | LVSEL | — | — | HVSEL[1:0] | |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 1:0 | HVSEL[1:0] | High-Potential Reference Voltage Select<br>0 0: AVCC0 is selected as the high-potential reference voltage<br>0 1: VREFH0 is selected as the high-potential reference voltage<br>1 0: Internal reference voltage is selected as the high-potential reference voltage<br>1 1: No reference voltage pin is selected (internal node discharge) | R/W |
| 3:2 | — | These bits are read as 0. The write value should be 0. | R/W |
| 4 | LVSEL | Low-Potential Reference Voltage Select<br>0: AVSS0 is selected as the low-potential reference voltage.<br>1: VREFL0 is selected as the low-potential reference voltage. | R/W |
| 6:5 | — | These bits are read as 0. The write value should be 0. | R/W |
| 7 | ADSLP | Sleep<br>0: Normal operation<br>1: Standby state | R/W |

#### HVSEL[1:0] bits (High-Potential Reference Voltage Select)

The HVSEL[1:0] bits specify the high-potential reference voltage as VREFH0, AVCC0, or internal reference voltage.

When setting the register, make sure that HVSEL[1:0] = 11b is set.

Before selecting the internal reference voltage (HVSEL[1:0] = 10b), set HVSEL[1:0] = 11b to discharge the path of the high-potential reference voltage. After the discharge completes, set HVSEL[1:0] = 10b and start the A/D conversion.

When the internal reference voltage is selected as the high-potential reference voltage (HVSEL[1:0] = 10b), A/D conversion is possible for analog channels, and CTSU TSCAP voltage, but A/D conversion of the internal reference voltage and the temperature sensor output is prohibited. When the internal reference voltage is selected as the high-potential reference voltage (HVSEL[1:0] = 10b), can only work in low-current mode (ADCSR.ADHSC = 1).

#### LVSEL bit (Low-Potential Reference Voltage Select)

The LVSEL bit specifies the low-potential reference voltage as AVSS0 or VREFL0.

#### ADSLP bit (Sleep)

The ADSLP bit transitions the A/D converter to the standby state. Set the ADSLP bit to 1 only when modifying the ADCSR.ADHSC bit. In other cases, setting the ADSLP bit to 1 is prohibited.

After the ADSLP bit is set to 1, wait at least 5 µs before setting this bit to 0. Additionally, after the ADSLP bit is set to 0, wait at least 1 µs, then start the A/D conversion.

For the ADHSC bit rewriting procedure, see section 38.8.9. ADHSC Bit Rewriting Procedure.

## 38.3 Operation

### 38.3.1 Scanning Operation

In scanning, A/D conversion is performed sequentially on the analog inputs of the specified channels.

Scan conversion is performed in any of the three operating modes and two conversion modes:

- Single scan mode
- Continuous scan mode
- Group scan mode
- High-speed A/D conversion mode (include fast/normal conversion mode selected by ADACSR.ADSAC)
- Low-power A/D conversion mode (include fast/normal conversion mode selected by ADACSR.ADSAC)

In single scan mode, one or more specified channels are scanned once. In continuous scan mode, one or more specified channels are scanned repeatedly until software sets the ADCSR.ADST bit to 0. The CTSU TSCAP voltage can be regarded as AN016. In group scan mode, the selected channels in group A, B are scanned once after scan starts in response to the respective synchronous trigger.

In single scan mode and continuous scan mode, A/D conversion is performed for the ANn channels selected in the ADANSA0 and ADANSA1 registers, starting from the channel with the smallest number n. CTSU TSCAP voltage can be regarded as AN016. In group scan mode, A/D conversion is performed for the ANn channels in group A selected in the ADANSA0 and ADANSA1 registers, and for the ANn channels in group B selected in the ADANSB0 and ADANSB1 registers, starting from the channel with the smallest number n.

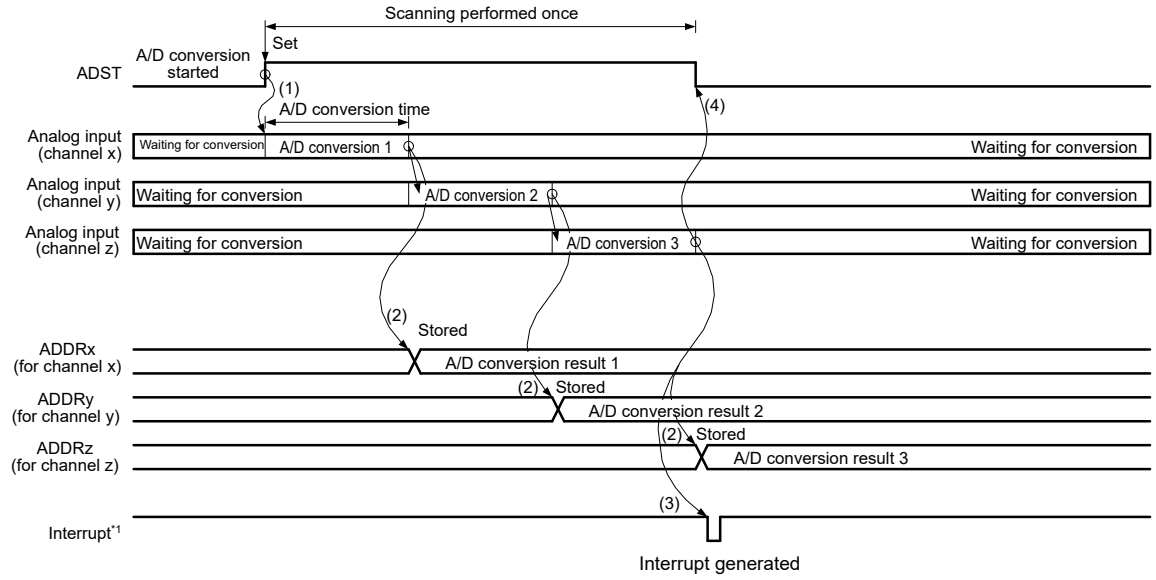
When self-diagnosis is selected, it is executed once at the beginning of each scan and one of the three reference voltages is converted.

It is prohibited to simultaneously select both temperature sensor output and internal reference voltage. If the internal reference voltage is selected as the reference voltage on the high potential side, A/D conversion of the temperature sensor or the internal reference voltage is also prohibited. When temperature sensor output or internal reference voltage is selected for A/D conversion, single scan mode should be used.

Double trigger mode can be used with single scan mode or group scan mode. With double trigger mode enabled (ADCSR.DBLE = 1), A/D conversion data of a channel selected in the ADCSR.DBLANS[4:0] bits is duplicated only if the conversion is started by the synchronous trigger (ELC) selected in the ADSTRGR.TRSA[5:0] bits. In group scan mode, only group A can use double trigger mode.

In the extended operation of double trigger mode, the A/D conversion operation is generated from the synchronous trigger combination selected in the ADSTRGR.TRSA[5:0] bits. In addition to normal double trigger mode operation, A/ D conversion data with odd number trigger (ELC_AD00) is stored in A/D Data Duplexing Register A (ADDBLDRA), and

A/D conversion data with even number trigger (ELC_AD01) is stored in A/D Data Duplexing Register B (ADDBLDRB). In the extended operation of double trigger mode, when one of the trigger combinations occurs at the same time, the data duplexing register settings for the specified triggers do not work, and A/D conversion data is stored in A/D Data Duplexing Register B (ADDBLDRB).



The ADC12 ignores a synchronous trigger that occurs during the A/D conversion started by another synchronous trigger.

## 38.3.2 Single Scan Mode

### 38.3.2.1 Basic Operation

In basic operation of single scan mode, A/D conversion is performed once on the analog input of the specified channels as follows:

1. When the ADCSR.ADST bit is set to 1 (A/D conversion start) by a software trigger, a synchronous trigger input (ELC), or an asynchronous trigger input, A/D conversion is performed for the ANn channels selected in the ADANSA0 and ADANSA1 registers, starting from the channel with the smallest number n. CTSU TSCAP voltage can be regarded as AN016.
2. Each time A/D conversion of a single channel is completed, the A/D conversion result is stored in the associated A/D data register (ADDRy and ADCTDR).
3. When A/D conversion of all the selected channels is completed, an ADC120_ADI interrupt request is generated.
4. The ADST bit remains 1 (A/D conversion start) during A/D conversion and is automatically set to 0 when A/D conversion of all the selected channels is completed. The ADC12 then enters a wait state.

Note: x, y, and z (x < y < z) are the selected channel numbers by ADANSA0/1.
Note 1. ADC120_ADI

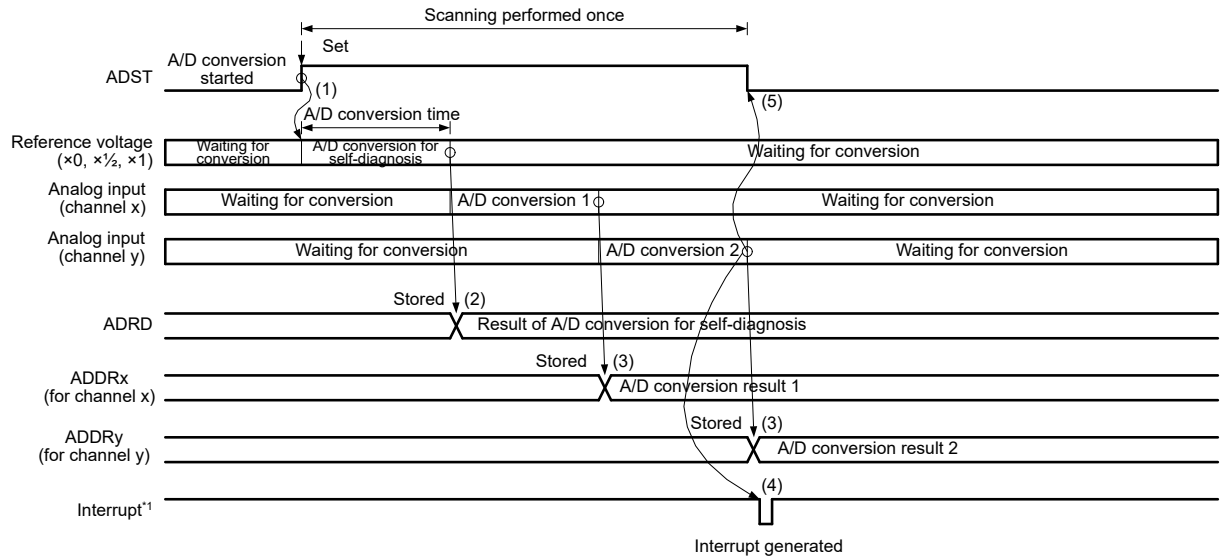


**Figure 38.7 Example basic operation in single scan mode when the analog inputs (channel x to z) are selected**

### 38.3.2.2 Channel Selection and Self-Diagnosis

When channels and self-diagnosis are selected, A/D conversion is first performed for the reference voltage (×0, ×1/2, or ×1), then A/D conversion is performed once on the analog input of the selected channels as follows:

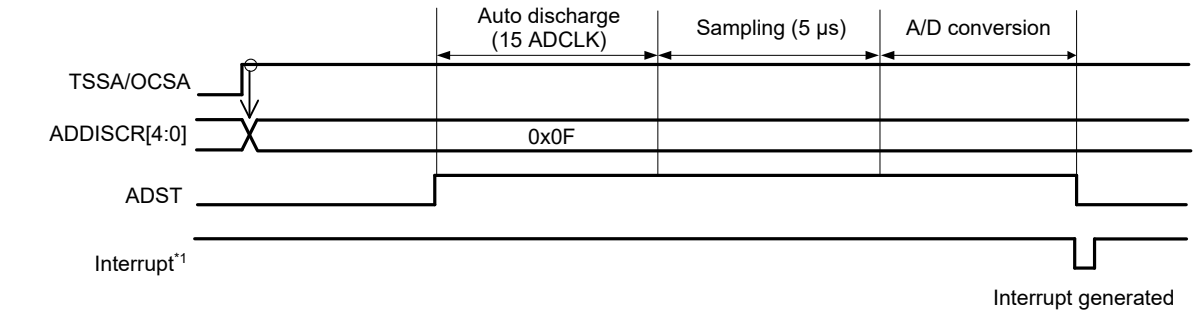
1. A/D conversion for self-diagnosis is first started when the ADCSR.ADST bit is set to 1 (A/D conversion start) by a software trigger input, a synchronous trigger input (ELC), or an asynchronous trigger input.

2. When A/D conversion for self-diagnosis is completed, the A/D conversion result is stored in the A/D Self-Diagnosis Data Register (ADRD). A/D conversion is then performed for the ANn channels selected in the ADANSA0 and ADANSA1 registers, starting from the channel with the smallest number n.
3. Each time A/D conversion of a single channel is completed, the A/D conversion result is stored in the associated A/D data register (ADDRy and ADCTDR).
4. When A/D conversion of all the selected channels is completed, an ADC120_ADI interrupt request is generated.
5. The ADCSR.ADST bit remains 1 (A/D conversion start) during A/D conversion and is automatically set to 0 when A/D conversion of all the selected channels is completed. The ADC12 then enters a wait state.

Note: x and y (x < y) are the selected channel numbers by ADANSA0/1.
Note 1. ADC120_ADI

**Figure 38.8 Example basic operation in single scan mode when the analog inputs (channel x and y) are selected with self- diagnosis**

### 38.3.2.3 A/D Conversion of Temperature Sensor Output or Internal Reference Voltage



A/D conversion is performed on the temperature sensor output or the internal reference voltage in single scan mode as described in this section.

When selecting A/D conversion of the temperature sensor output or the internal reference voltage, deselect all analog input channels and CTSU TSCAP voltage by setting the ADANSA0 and ADANSA1 registers to all 0's and the ADCSR.DBLE bit to 0.

When selecting A/D conversion of temperature sensor output, set the internal reference voltage A/D conversion select bit (ADEXICR.OCSA) to 0 (deselected). When selecting A/D conversion of internal reference voltage, set the temperature sensor output A/D conversion select bit (ADEXICR.TSSA) to 0 (deselected).

The operation is as follows:

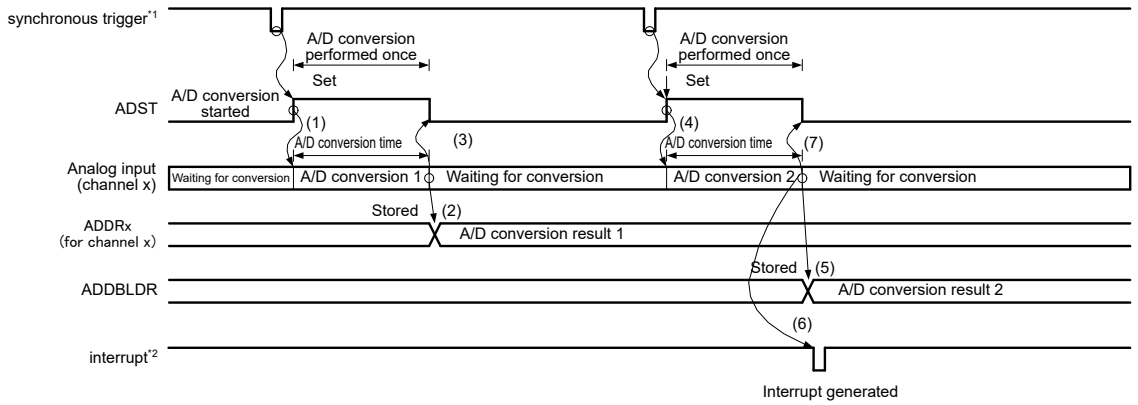
1. Set the sampling time to 5 µs or longer. Take note of the sampling state register settings (ADSSTRT/ADSSTRO) and ADCLK frequency.
2. After switching to A/D conversion of internal reference voltage or temperature sensor output, set the ADST bit to 1 to start conversion.
3. On completion of A/D conversion, the result is stored in the Temperature Sensor Data Register (ADTSDR) or A/D Internal Reference Voltage Data Register (ADOCDR), and an ADC120_ADI interrupt request is generated.
4. The ADST bit remains 1 during A/D conversion and is automatically set to 0 on completion of A/D conversion. The ADC12 then enters a wait state.

Note 1. ADC120_ADI

**Figure 38.9 Example basic operation in single scan mode when temperature sensor output or internal reference voltage is selected**

### 38.3.2.4 A/D Conversion in Double-Trigger Mode

When double trigger mode is selected in single scan mode, two rounds of single scan operation started by a synchronous trigger (ELC) are performed in sequence.



Deselect self-diagnosis and set the temperature sensor output A/D conversion select bit (ADEXICR.TSSA) and the internal reference voltage A/D conversion select bit (ADEXICR.OCSA) to 0.

Duplication of A/D conversion data is enabled by setting the channel numbers to be duplicated in the ADCSR.DBLANS[4:0] bits and setting the ADCSR.DBLE bit to 1. When the ADCSR.DBLE bit is set to 1, channel selection using the ADANSA0 and ADANSA1 registers is invalid.

In double trigger mode, select a synchronous trigger (ELC) with the ADSTRGR.TRSA[5:0] bits. Additionally, set the ADCSR.EXTRG bit to 0 and the ADCSR.TRGE bit to 1. Do not use a software trigger.

The operation is as follows:

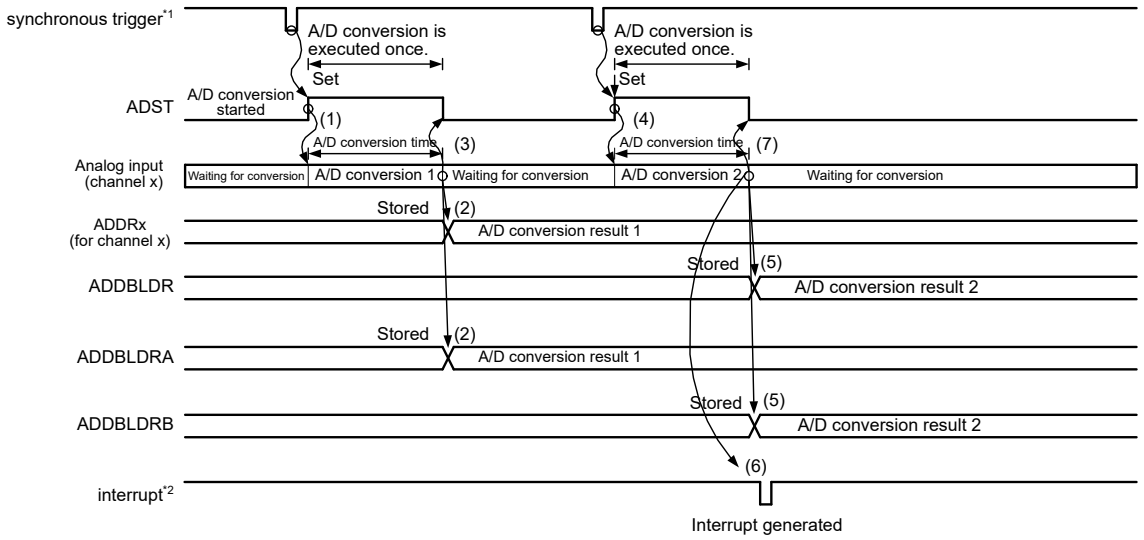
1. When the ADCSR.ADST bit is set to 1 (A/D conversion start) by a synchronous trigger input (ELC), A/D conversion starts on the single channel selected in the ADCSR.DBLANS[4:0] bits.
2. Each time A/D conversion of a single channel is completed, the A/D conversion result is stored in the associated A/D Data Register y (ADDRy).
3. The ADCSR.ADST bit is automatically set to 0 and the ADC12 enters a wait state. An ADC120_ADI interrupt request is not generated.
4. When the ADCSR.ADST bit is set to 1 (A/D conversion start) by the second trigger input, A/D conversion starts on the single channel selected in the ADCSR.DBLANS[4:0] bits.
5. When A/D conversion is completed, the result is stored in the A/D Data Duplexing Register (ADDBLDR), which is exclusively used in double-trigger mode.
6. An ADC120_ADI interrupt request is generated.
7. The ADCSR.ADST bit remains 1 (A/D conversion start) during A/D conversion and is automatically set to 0 when A/D conversion is completed. Then the ADC12 enters a wait state.

Note: x is the selected channel number by ADANSA0/1.
Note 1. ELC_AD00/ELC_AD01
Note 2. ADC120_ADI

**Figure 38.10 Example operation in single scan mode when double-trigger mode is selected and the analog input (channel x) is duplicated**

### 38.3.2.5 Extended Operations When Double-Trigger Mode Is Selected

When double trigger mode is selected in single scan mode, and a synchronous trigger (ELC_AD00/ELC_AD01) is selected as the trigger for the start of A/D conversion, two rounds of single scan operation are performed.



Deselect self-diagnosis and set the temperature sensor output A/D conversion select bit (ADEXICR.TSSA), and the internal reference voltage A/D conversion select bit (ADEXICR.OCSA) to 0.

Duplication of A/D conversion data is enabled by setting the channel number to be duplicated to the ADCSR.DBLANS[4:0] bits and setting the ADCSR.DBLE bit to 1. When the ADCSR.DBLE bit is set to 1, channel selection using the ADANSA0 and ADANSA1 registers is invalid.

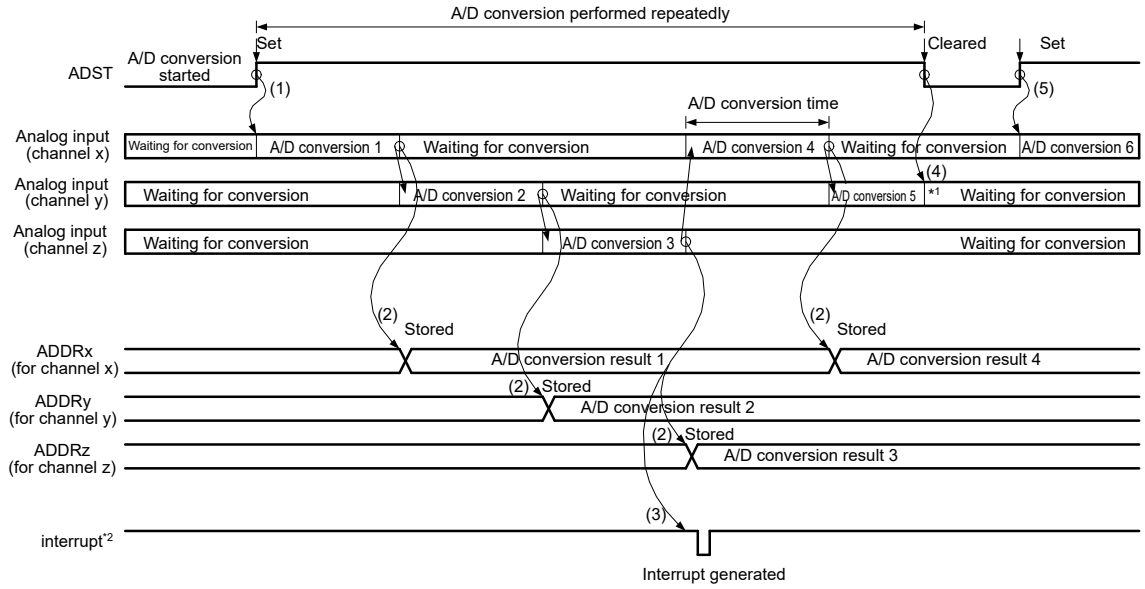
In extended double trigger mode, select a synchronous trigger combination ELC_AD00/ELC_AD01 by setting the ADSTRGR.TRSA[5:0] bits to 0x0B, set the ADCSR.EXTRG bit to 0, and set the ADCSR.TRGE bit to 1. Do not use a software trigger.

The operation is as follows:

1. When the ADCSR.ADST bit is set to 1 (A/D conversion start) by a synchronous trigger input (ELC_AD00/ ELC_AD01), A/D conversion starts on the single channel selected in the ADCSR.DBLANS[4:0] bits.
2. When A/D conversion completes, the A/D conversion result is stored in the associated A/D Data Register (ADDRy) and in A/D Data Duplexing Register A (ADDBLDRA) or A/D Data Duplexing Register B (ADDBLDRB) when the ELC_ADi0 or ELC_ADi1 trigger is input respectively (i = 0).
3. The ADCSR.ADST bit is automatically set to 0 and the ADC12 enters a wait state. An ADC120_ADI interrupt request is not generated.
4. When the ADCSR.ADST bit is set to 1 (A/D conversion start) by the second trigger (ELC_AD00/ELC_AD01), A/ D conversion starts on the single channel selected in the ADCSR.DBLANS[4:0] bits.
5. When A/D conversion completes, the A/D conversion result is stored in the A/D Data Duplexing Register (ADDBLDR) and in A/D Data Duplexing Register A (ADDBLDRA) or A/D Data Duplexing Register B (ADDBLDRB) when the ELC_ADi0 or ELC_ADi1 trigger is input respectively (i = 0).
6. An ADC120_ADI interrupt request is generated.
7. The ADCSR.ADST bit remains 1 (A/D conversion start) during A/D conversion and is automatically set to 0 when A/D conversion completes. The ADC12 then enters a wait state.

Note: x is the selected channel number by ADANSA0/1.
Note 1. ELC_AD00/ELC_AD01
Note 2. ADC120_ADI

**Figure 38.11 Example extended operation in double trigger mode with duplication selected for the analog input (channel x) and ELC_AD00/ELC_AD01**



## 38.3.3 Continuous Scan Mode

### 38.3.3.1 Basic Operation

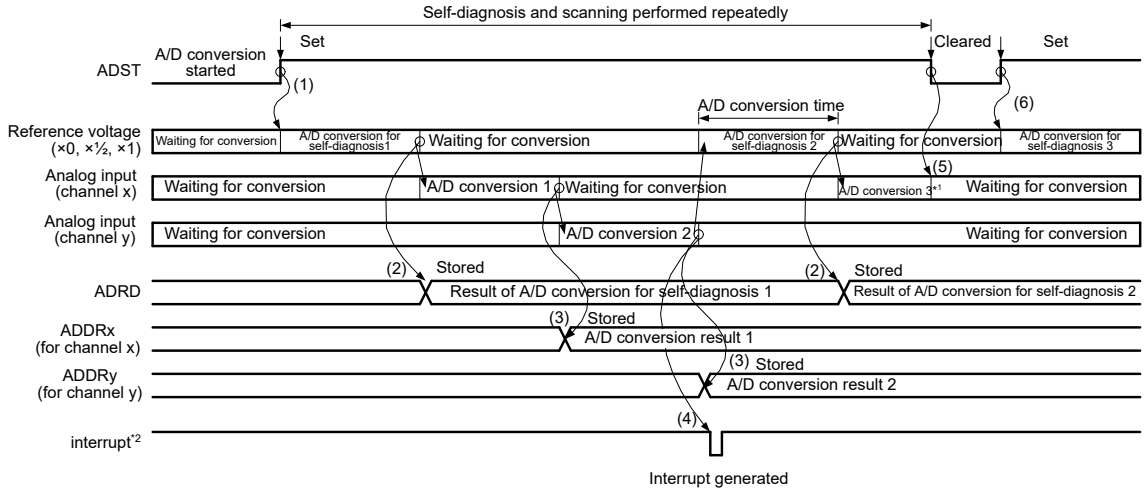
In continuous scan mode, A/D conversion is performed repeatedly on the analog input of the specified channels. In this mode, deselect the temperature sensor output A/D conversion and the internal reference voltage A/D conversion by setting the ADEXICR.TSSA and ADEXICR.OCSA bits to 0.

The operation is as follows:

1. When the ADCSR.ADST bit is set to 1 (A/D conversion start) by a software trigger, a synchronous trigger input (ELC), or an asynchronous trigger input, A/D conversion is performed for ANn channels selected in the ADANSA0 and ADANSA1 registers, starting from the channel with the smallest number n. CTSU TSCAP voltage can be regarded as AN016.
2. Each time A/D conversion of a single channel is completed, the A/D conversion result is stored in the associated A/D Data Register (ADDRy).
3. When A/D conversion of all the selected channels is completed, an ADC120_ADI interrupt request is generated. The ADC12 sequentially starts A/D conversion for the ANn channels selected in the ADANSA0 and ADANSA1 registers, starting from the channel with the smallest number n.
4. The ADCSR.ADST bit is not automatically cleared, and steps 2. and 3. are repeated as long as ADCSR.ADST remains 1 (A/ D conversion start). When the ADCSR.ADST bit is set to 0 (A/D conversion stop), A/D conversion stops and the ADC12 enters a wait state.
5. When the ADCSR.ADST bit is later set to 1 (A/D conversion start), A/D conversion starts again for the ANn channels selected in the ADANSA0 and ADANSA1 registers, starting from the channel with the smallest number n.

Note: x, y, and z (x < y < z) are the selected channel numbers by ADANSA0/1.
Note 1. Data for A/D conversion 5 is ignored.
Note 2. ADC120_ADI

**Figure 38.12 Example basic operation in continuous scan mode when the analog inputs (channel x to z) are selected**



### 38.3.3.2 Channel Selection and Self-Diagnosis

When channels and self-diagnosis are selected at the same time, A/D conversion is first performed for the reference voltage (×0, ×1/2, or ×1) supplied to the ADC12, and A/D conversion is performed on the analog input of the selected channels. This sequence is repeated as described in the section that follows.

In continuous scan mode, deselect the temperature sensor output A/D conversion and the internal reference voltage A/D conversion by setting the ADEXICR.TSSA and ADEXICR.OCSA bits to 0.

The operation is as follows:

1. A/D conversion for self-diagnosis is first started when the ADCSR.ADST bit is set to 1 (A/D conversion start) by a software trigger input, a synchronous trigger input (ELC), or an asynchronous trigger input.
2. When A/D conversion for self-diagnosis is completed, the A/D conversion result is stored in the A/D Self-Diagnosis Data Register (ADRD). A/D conversion is then performed for the ANn channels selected in the ADANSA0 and ADANSA1 registers, starting from the channel with the smallest number n.
3. Each time A/D conversion of a single channel is completed, the A/D conversion result is stored in the corresponding A/D Data Register (ADDRy).
4. When A/D conversion of all the selected channels is completed, an ADC120_ADI interrupt request is generated. At the same time, the ADC12 starts A/D conversion for self-diagnosis and then on the ANn channels selected in the ADANSA0 and ADANSA1 registers, starting from the channel with the smallest number n.
5. The ADCSR.ADST bit is not automatically cleared, and steps 2. to 4. are repeated as long as the ADCSR.ADST bit remains 1. When the ADST bit is set to 0 (A/D conversion stop), A/D conversion stops and the ADC12 enters a wait state.
6. When the ADST bit is later set to 1 (A/D conversion start), the A/D conversion for self-diagnosis is started again.

Note: x and y (x < y) are the selected channel numbers by ADANSA0/1.
Note 1. Data for A/D conversion 3 is ignored.
Note 2. ADC120_ADI

**Figure 38.13 Example basic operation in continuous scan mode when the analog inputs (channel x and y) are selected with self-diagnosis**

## 38.3.4 Group Scan Mode

### 38.3.4.1 Basic Operation

In group scan mode, A/D conversion is performed once on the analog input of all the specified channels in group A and B after scanning is started by a synchronous trigger (ELC). The scan operation of each group is similar to the scan operation in single scan mode.

The synchronous triggers can be selected in the ADSTRGR.TRSA[5:0] bits for group A and in the ADSTRGR.TRSB[5:0] bits for group B. Use different triggers for group A and B to prevent simultaneous A/D conversion of the two groups. Do not use a software trigger.

The group A channels to be A/D-converted are selected using the ADANSA0 and ADANSA1 registers. The group B channels to be A/D-converted are selected using the ADANSB0 and ADANSB1 registers. Group A and B cannot use the same channels.

In group scan mode, deselect the temperature sensor output A/D conversion and the internal reference voltage A/D conversion by setting the ADEXICR.TSSA and (ADEXICR.OCSA) bits to 0. When self-diagnosis is selected in group scan mode, self-diagnosis is separately executed for Group A and B.

The following sequence describes operation in group scan mode using a synchronous trigger from the ELC. In this example, the ELC_AD00 trigger from the ELC is used to start conversion of group A and the ELC_AD01 trigger from the ELC is used to start conversion of group B. In addition, ELC_AD00 and ELC_AD01 are selected for the GPT event in the associated ELC.ELSRn registers.

The operation is as follows:

1. Scanning of group A is started by ELC_AD00.
2. When group A scanning completes, an ADC120_ADI interrupt is generated (no register setting).
3. Scanning of group B is started by ELC_AD01.
4. When group B scanning completes, an ADC120_GBADI interrupt is generated if the ADCSR.GBADIE bit is 1 (ADC120_GBADI interrupt when scanning completion is enabled).

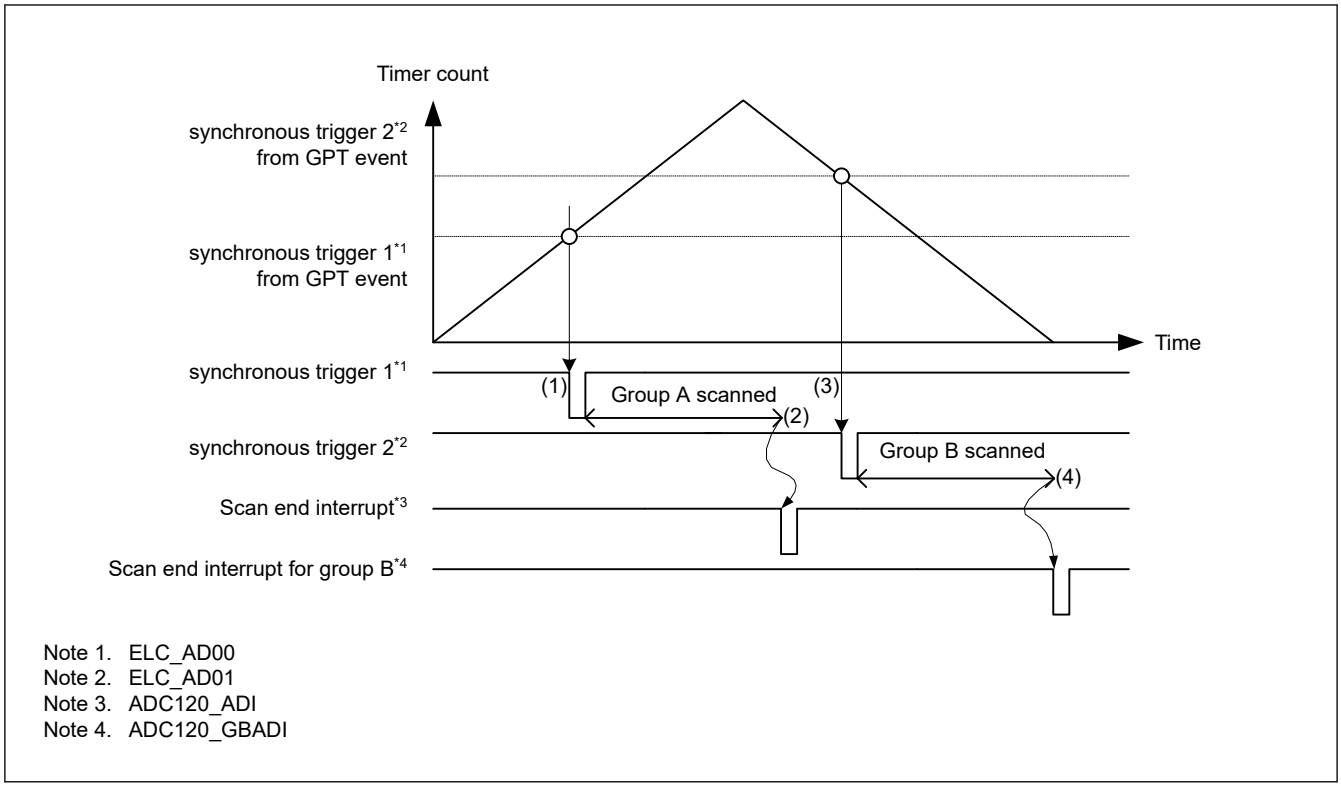


**Figure 38.14 Example basic operation in group scan mode when synchronous triggers from the ELC are used**

### 38.3.4.2 A/D Conversion in Double-Trigger Mode

When double trigger mode is selected in group scan mode, two rounds of single scan operation started by a synchronous trigger (ELC) are performed as a sequence for group A. For group B, single scan operation started by a synchronous trigger (ELC) is performed once.

In group scan mode, the synchronous trigger can be selected in the ADSTRGR.TRSA[5:0] bits for group A and in the ADSTRGR.TRSB[5:0] bits for group B. Use different triggers for groupA, B to prevent simultaneous A/D conversion of the two groups. Do not use a software trigger or an asynchronous trigger.

When an ELC_AD00/ELC_AD01 is selected as group A synchronous triggers by setting the ADSTRGR.TRSA[5:0] bits to 0x0B, operation proceeds in extended double trigger mode.

The group A channel to be A/D-converted is selected using the DBLANS[4:0] bits in the ADCSR register, while the group B channels to be A/D-converted are selected using the ADANSB0 and ADANSB1 registers. Group A, B cannot use the same channels.

In group scan mode, deselect the temperature sensor output A/D conversion and the internal reference voltage A/D conversion by setting the ADEXICR.TSSA and ADEXICR.OCSA bits to 0.

Self-diagnosis cannot be selected when double trigger mode is selected in group scan mode.

Duplication of A/D conversion data is enabled by setting the channel numbers to be duplicated in the ADCSR.DBLANS[4:0] bits and setting the ADCSR.DBLE bit to 1.

The following sequence describes operation in group scan mode with double trigger mode selected and using a synchronous trigger from the ELC. In this example, the ELC_AD00 trigger is used to start conversion of group A and the ELC_AD01 trigger is used to start conversion of group B. In addition, ELC_AD00 and ELC_AD01 are selected for the GPT event in the associated ELC.ELSRn registers.

The operation is as follows:

1. Scanning of group B is started by the ELC_AD00 trigger from the ELC.
2. When group B scanning completes, an ADC120_GBADI interrupt is generated if the GBADIE bit in ADCSR is 1 (ADC120_GBADI interrupt when scanning completion is enabled).
3. The first scan of group A is started by the first ELC_AD01 trigger.

4. When the first scan of group A completes, the conversion result is stored in the associated A/D Data Register y (ADDRy); an ADC120_ADI interrupt request is not generated.
5. The second scan of group A is started by the second ELC_AD01 trigger.
6. When the second scan of group A completes, the conversion result is stored in ADDBLDR. An ADC120_ADI interrupt is generated.

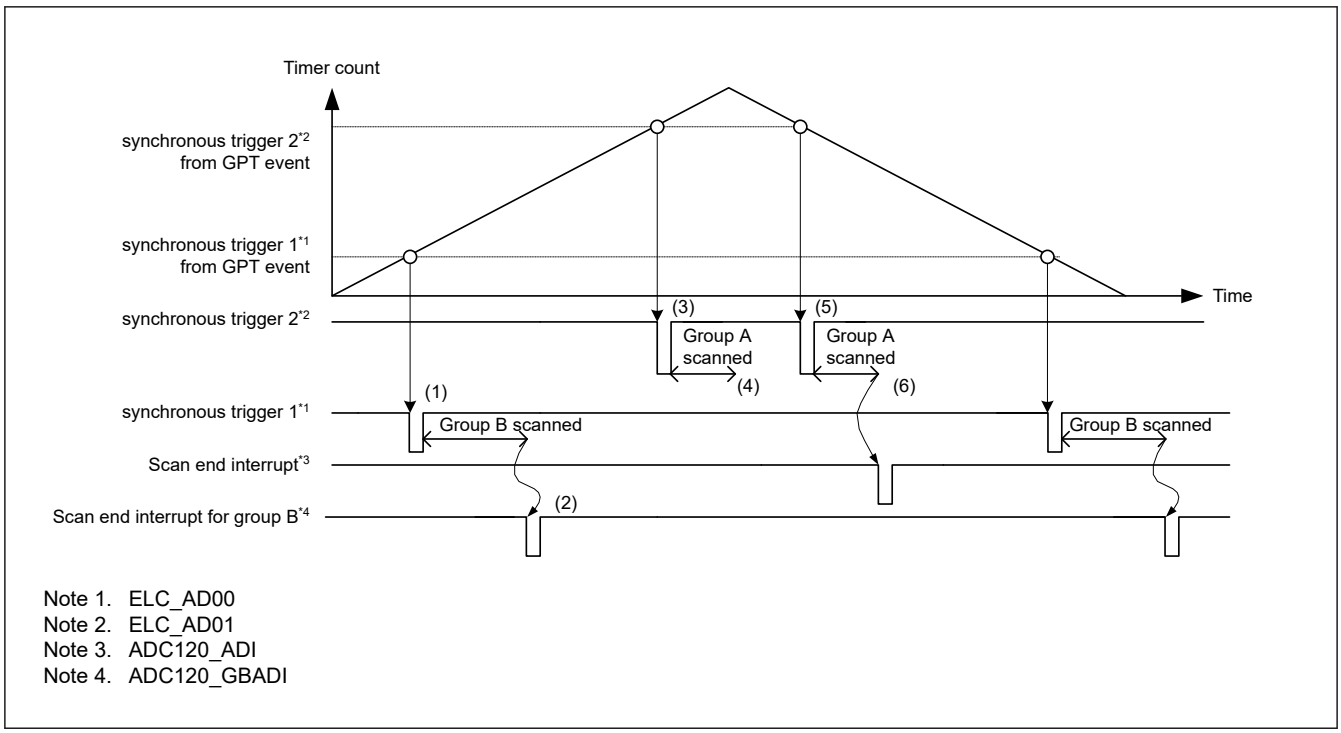

**Figure 38.15 Example basic operation in group scan mode with double-trigger mode when synchronous triggers from the ELC are used**

### 38.3.4.3 Group Priority Operation

Group priority operation is performed by setting the ADGSPCR.PGS bit to 1 in group-scan mode. The priority of groups is group A > group B.

When setting the PGS bit in the ADGSPCR register to 1, follow the procedure described in Figure 38.16. If the procedure is not followed, A/D conversion operation and stored data are not guaranteed.

As the basic operation in group-scan mode, a trigger input generated during A/D conversion of group A, B is ignored, and the A/D conversion operation of each group is similar to the operation in single-scan mode.

In group priority operation, if a trigger for a priority group is input during scanning of a lower-priority group, A/D conversion for the lower-priority group is stopped and A/D conversion for the priority group is performed.

If the setting of the ADGSPCR.GBRSCN bit is 0, the lower-priority group enters a wait state when A/D conversion for the priority group completes. A trigger input of the lower-priority group generated during A/D conversion is ignored.

If the setting of the ADGSPCR.GBRSCN bit is 1, A/D conversion for the lower-priority group automatically restarts upon completion of A/D conversion for the priority group. A trigger input of the lower-priority group generated during A/D conversion on the priority group takes effect, and A/D conversion for the lower-priority group is automatically performed upon completion of A/D conversion on the priority group.

Table 38.24 summarizes operations in response to the input of a trigger during A/D conversion with the settings of the ADGSPCR.GBRSCN bit.

If the setting of the ADGSPCR.GBRP bit is 1, A/D conversion operation for the lowest-priority group is to continuously perform single scans.

For the trigger settings in group-scan mode, select a synchronous trigger for group A by using the ADSTRGR.TRSA[5:0] bits, a synchronous trigger for group B by using the ADSTRGR.TRSB[5:0] bits. Each trigger must be different from each other. Set the ADSTRGR.TRSB[5:0] bits to 0x3F when setting the ADGSPCR.GBRP bit to 1.

The channels to be scanned must be selected in the registers shown in section 38.3.4. Group Scan Mode.

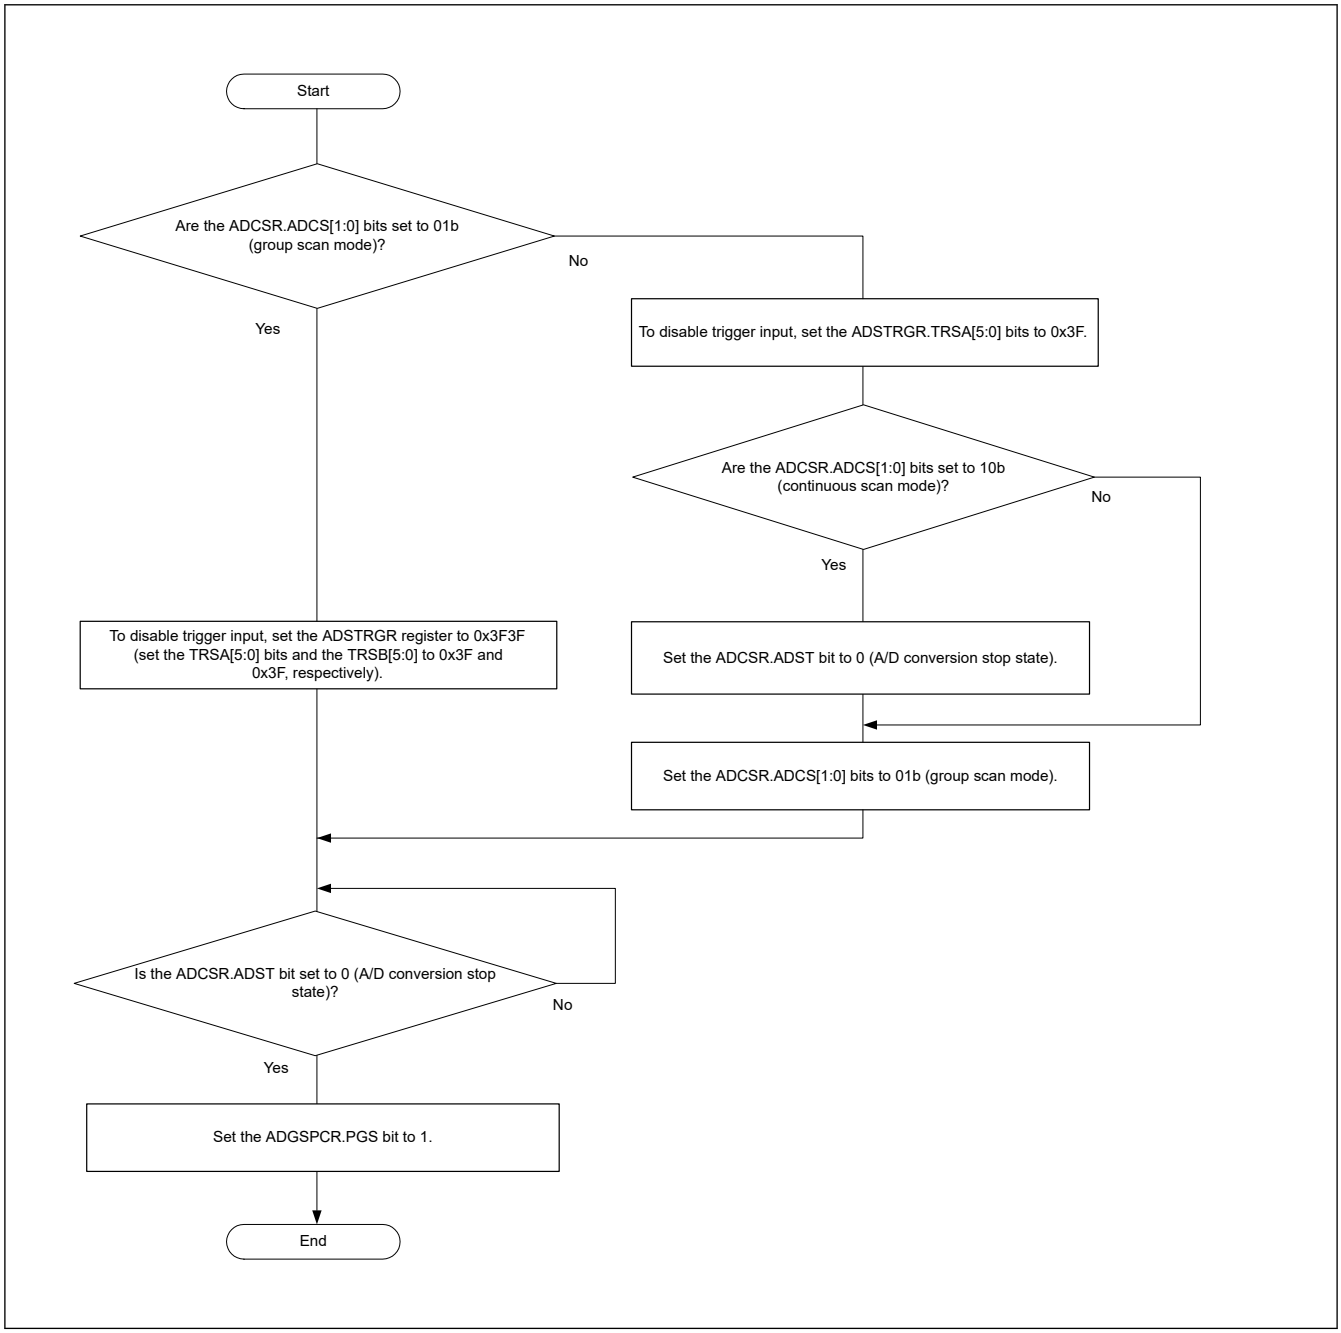

**Figure 38.16 Flowchart for ADGSPCR.PGS bit setting**

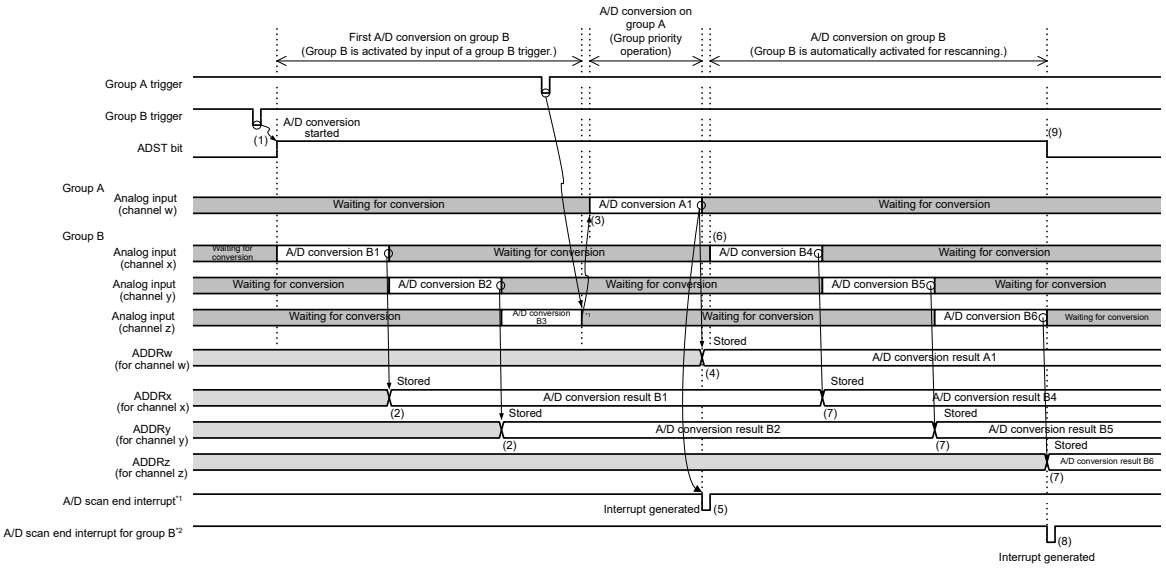
**Table 38.24 Control of A/D conversion operations according to ADGSPCR.GBRSCN bit setting (1 of 2)**

| A/D conversion operation | Trigger input | ADGSPCR.GBRSCN = 0 | ADGSPCR.GBRSCN = 1 |
|---|---|---|---|
| When A/D conversion for group A is in progress | Input of trigger for group A | Trigger input is ineffective. | Trigger input is ineffective. |
| | Input of trigger for group B | Trigger input is ineffective. | A/D conversion for group B is performed after A/D conversion for group A completes. |

**Table 38.24 Control of A/D conversion operations according to ADGSPCR.GBRSCN bit setting (2 of 2)**



| A/D conversion operation | Trigger input | ADGSPCR.GBRSCN = 0 | ADGSPCR.GBRSCN = 1 |
|---|---|---|---|
| When A/D conversion for group B is in progress | Input of trigger for group A | A/D conversion for group B is discontinued and A/D conversion for group A starts. | • A/D conversion for group B is discontinued and A/D conversion for group A starts.<br>• A/D conversion for group B starts after A/D conversion for group A completes. |
| | Input of trigger for group B | Trigger input is ineffective. | Trigger input is ineffective. |

### (1) Group priority operation for two groups (when ADGSPCR.PGS = 1)

Operation examples 1-1 to 1-3 show group priority operations in group-scan mode (when ADGSPCR.GBRSCN = 1, ADGSPCR.GBRP = 0).

#### Operation example 1-1: “Group A trigger input during group B scan” when rescanning is enabled

1. When input of a trigger for group B sets the ADCSR.ADST bit to 1 (starting A/D conversion), A/D conversion for the analog input channels selected in the ADANSB0 and ADANSB1 registers starts according to the conversion order from the channel with the smallest number n.
2. On completion of A/D conversion for each channel in group B, the result is stored in the corresponding A/D Data Register y (ADDRy).
3. When a trigger for group A is input during A/D conversion for group B, A/D conversion for group B stops while the ADCSR.ADST bit remains 1. Then A/D conversion for the group A analog input channels selected in the ADANSA0 and ADANSA1 registers starts according to the conversion order from the channel with the smallest number n. If A/D conversion stops before it is completed, the conversion result is not stored in the A/D Data Register y (ADDRy).
4. On completion of A/D conversion on the channels, the result is stored in the corresponding A/D Data Register y (ADDRy).
5. An ADC120_ADI interrupt request is generated.
6. If the setting of the ADGSPCR.GBRSCN bit is 1 (enabling rescanning of the group that was stopped in group priority operation), A/D conversion for the group B analog input channels selected in the ADANSB0 and ADANSB1 registers restarts according to the conversion order from the channel with the smallest number n while the ADCSR.ADST remains 1.
7. On completion of A/D conversion on the channels, the result is stored in the corresponding A/D Data Register y (ADDRy).
8. If the setting of the ADCSR.GBADIE bit is 1 (enabling interrupt generation on completion of group B scan), a group B scan end interrupt request is generated.
9. When A/D conversion for all the channels completes, the ADCSR.ADST bit is automatically cleared and the A/D converter enters a wait state.

Note: w, x, y, and z (x < y < z) are the selected channel numbers by ADANSA0/1 or ADANSB0/1 .
Note 1. ADC120_ADI
Note 2. ADC120_GBADI

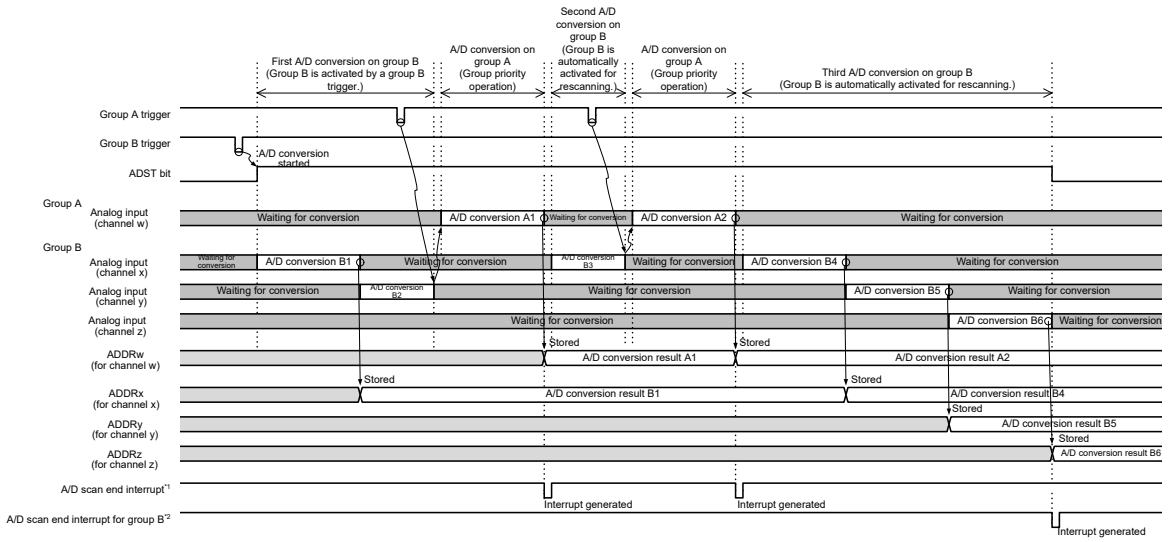


**Figure 38.17 Example of group priority operation 1-1: Group A trigger input during group B scanning when rescanning is enabled (when ADGSPCR.GBRSCN = 1, ADGSPCR.GBRP = 0)**

### Operation example 1-2: “Group A trigger input during rescanning of group B” when rescanning is enabled

Figure 38.18 shows the operation when a group A trigger is input during rescanning operation for group B.

Even during rescanning operation, when a trigger for group A is input, A/D conversion on group B stops and A/D conversion for group A starts. A/D conversion for group B starts after A/D conversion for group A completes.

Operations for setting the ADCSR.ADST bit, storing the A/D conversion result in the corresponding A/D Data Register y (ADDRy), and generating interrupt requests are the same as those in operation example 1-1.

Note: w, x, y, and z (x < y < z) are the selected channel numbers by ADANSA0/1 or ADANSB0/1.
Note 1. ADC120_ADI
Note 2. ADC120_GBADI

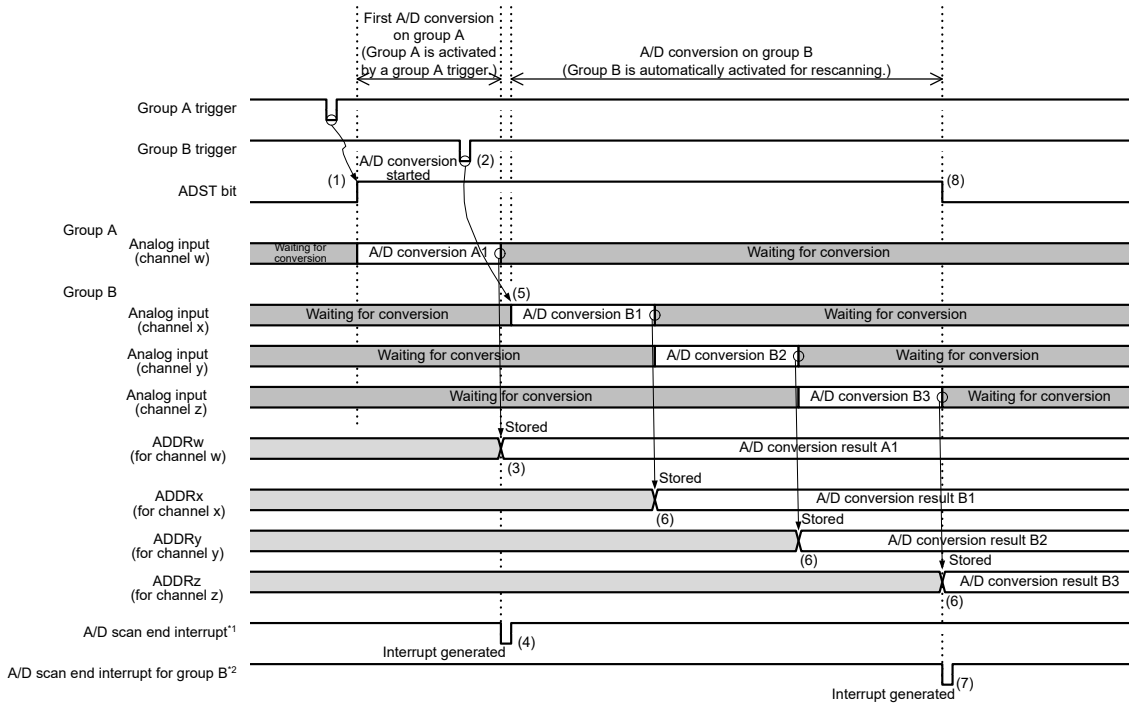

**Figure 38.18 Example of group priority operation 1-2: Group A trigger input during rescanning of group B when rescanning is enabled (when ADGSPCR.GBRSCN = 1, ADGSPCR.GBRP = 0)**

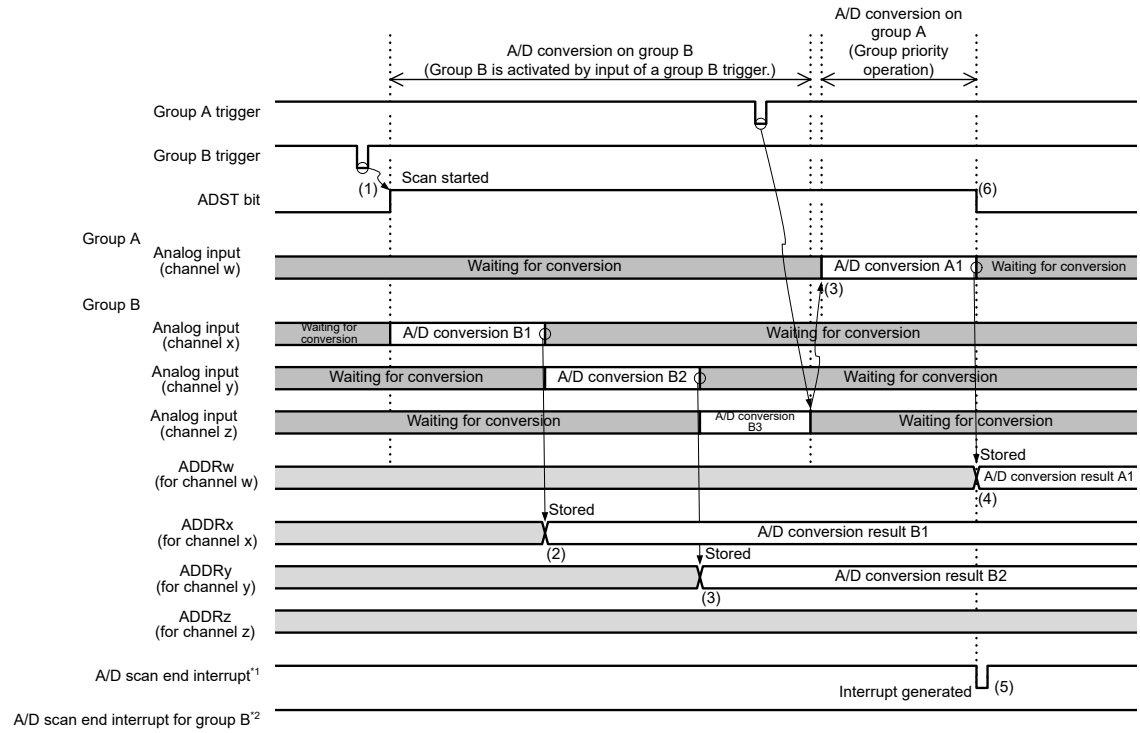
### Operation example 1-3: “Group B trigger input during group A scan” when rescanning is enabled

The following describes the operation when the setting of the ADGSPCR.GBRSCN bit is 1 (enabling rescanning of the group that was stopped in group priority operation) and a trigger for group B is input during scanning operation for group A.

If the setting of the ADGSPCR.GBRSCN bit is 0, any trigger for group B that is input during scanning operation for group A is invalid.

1. When input of a trigger for group A sets the ADCSR.ADST bit to 1 (starting A/D conversion), A/D conversion for the group A analog input channels selected in the ADANSA0 and ADANSA1 registers starts according to the conversion order from the channel with the smallest number n.
2. When a trigger for group B is input during A/D conversion for group A, group B is ready for A/D conversion.
3. On completion of A/D conversion for each channel in group A, the result is stored in the corresponding A/D Data Register y (ADDRy).
4. An ADC120_ADI interrupt request is generated.
5. When A/D conversion for group A completes, while the ADCSR.ADST bit remains 1, A/D conversion for the group B analog input channels selected in the ADANSB0 and ADANSB1 registers starts according to the conversion order from the channel with the smallest number n.
   (As with the case of operation example 1-1, if a trigger for group A is input during A/D conversion for group B, A/D conversion for group A starts. Then A/D conversion for group B starts upon completion of A/D conversion for group A.)
6. On completion of A/D conversion of a single channel, the result is stored in the corresponding A/D Data Register y (ADDRy).
7. Upon completion of A/D conversion for group B, a group B scan end interrupt request is generated if the setting of the ADCSR.GBADIE bit is 1 (enabling interrupt generation on completion of group B scan).
8. When A/D conversion for all the channels completes, the ADCSR.ADST bit is automatically cleared and the A/D converter enters a wait state.



Note: w, x, y, and z (x < y < z) are the selected channel numbers by ADANSA0/1 or ADANSB0/1.
Note 1. ADC120_ADI
Note 2. ADC120_GBADI

**Figure 38.19 Example of group priority operation 1-3: Group B trigger input during group A scan when rescanning is enabled (when ADGSPCR.GBRSCN = 1, ADGSPCR.GBRP = 0)**

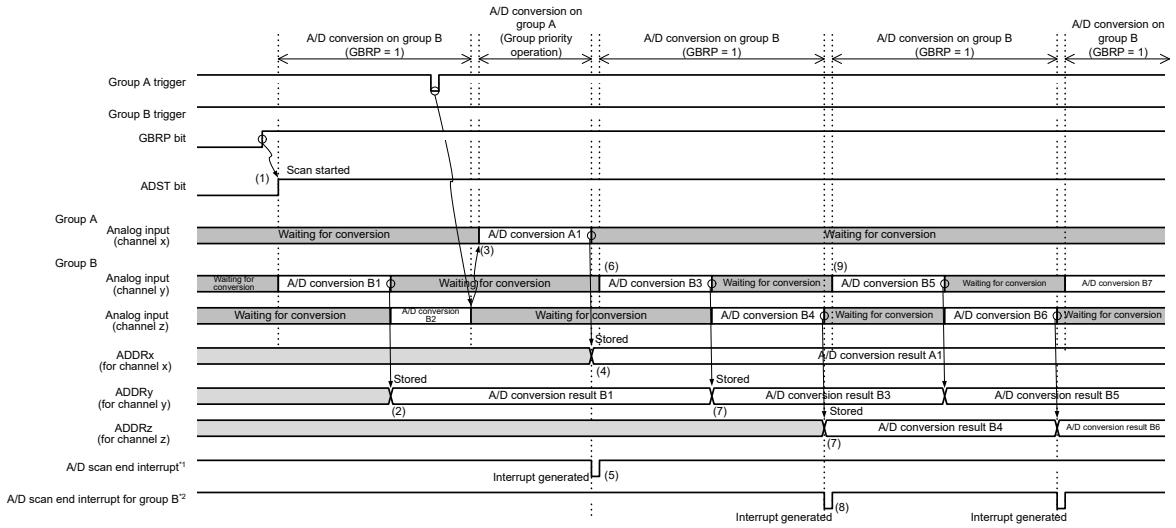
Operation example 1-4 shows the group priority operation in group-scan mode (when ADGSPCR.GBRSCN = 0, ADGSPCR.GBRP = 0).

### Operation example 1-4: “Group A trigger input during group B scan” when rescanning is disabled

1. When input of a trigger for group B sets the ADCSR.ADST bit to 1 (starting A/D conversion), A/D conversion for the analog input channels selected in the ADANSB0 and ADANSB1 registers starts according to the conversion order from the channel with the smallest number n.
2. On completion of A/D conversion for each channel in group B, the result is stored in the corresponding A/D Data Register y (ADDRy).
3. When a trigger for group A is input during A/D conversion for group B, A/D conversion for group B stops while the ADCSR.ADST bit remains 1, and then A/D conversion for the group A analog input channels selected in the ADANSA0 and ADANSA1 registers starts according to the conversion order from the channel with the smallest number n. If A/D conversion stops before it is completed, the conversion result is not stored in the A/D Data Register y (ADDRy).
4. On completion of A/D conversion of a single channel, the result is stored in the corresponding A/D Data Register y (ADDRy).
5. On completion of A/D conversion for group A, an ADC120_ADI interrupt request is generated.
6. When A/D conversion for group A completes, the ADCSR.ADST bit is automatically cleared and the A/D converter enters a wait state. A/D conversion for group B is not performed until a trigger for group B is input the next time.

Note: w, x, y, and z (x < y < z) are the selected channel numbers by ADANSA0/1 or ADANSB0/1.
Note 1. ADC120_ADI
Note 2. ADC120_GBADI

**Figure 38.20 Group priority operation example 1-4: “Group A trigger is input during group B scan” when rescanning is disabled (when ADGSPCR.GBRSCN = 0, ADGSPCR.GBRP = 0)**



Operation example 1-5 shows the group priority operation in group-scan mode (when ADGSPCR.GBRP = 1).

### Operation example 1-5: Continuously activating single-scan operation for group B

1. When ADGSPCR.GBRP = 1 is set, the ADCSR.ADST bit is set to 1 (starting A/D conversion) and A/D conversion for the analog input channels selected in the ADANSB0 and ADANSB1 registers starts according to the conversion order from the channel with the smallest number n.
2. On completion of A/D conversion for each channel in group B, the result is stored in the corresponding A/D Data Register y (ADDRy).
3. When a trigger for group A is input during A/D conversion for group B, A/D conversion for group B stops while the ADCSR.ADST bit remains 1, and then A/D conversion for group A analog input channels selected in the ADANSA0 and ADANSA1 registers starts according to the conversion order from the channel with the smallest number n. If A/D conversion stops before it is completed, the conversion result is not stored in the A/D Data Register y (ADDRy).
4. On completion of A/D conversion of a single channel, the result is stored in the corresponding A/D Data Register y (ADDRy).
5. On completion of A/D conversion for group A, an ADC120_ADI interrupt request is generated.
6. If ADGSPCR.GBRP = 1 is set (performing single scan continuously), A/D conversion for the group B analog input channels selected in the ADANSB0 and ADANSB1 registers restarts according to the conversion order from the channel with the smallest number n while the ADCSR.ADST remains 1 (starting A/D conversion).
7. On completion of A/D conversion of a single channel, the result is stored in the corresponding A/D Data Register y (ADDRy).
8. If the setting of the ADCSR.GBADIE bit is 1 (enabling interrupt generation on completion of group B scan), a group B scan end interrupt request is generated.

9. If ADGSPCR.GBRP = 1 is set (performing single scan continuously), A/D conversion for the group B analog input channels selected in the ADANSB0 and ADANSB1 registers restarts according to the conversion order from the channel with the smallest number n while the ADCSR.ADST remains 1 (starting A/D conversion).

Steps 6 to 9 are repeated as long as the ADGSPCR.GBRP bit remains 1. Do not clear the ADCSR.ADST bit as long as the ADGSPCR.GBRP bit is 1. To forcibly stop A/D conversion while ADGSPCR.GBRP = 1, follow the procedure shown in Figure 38.32.

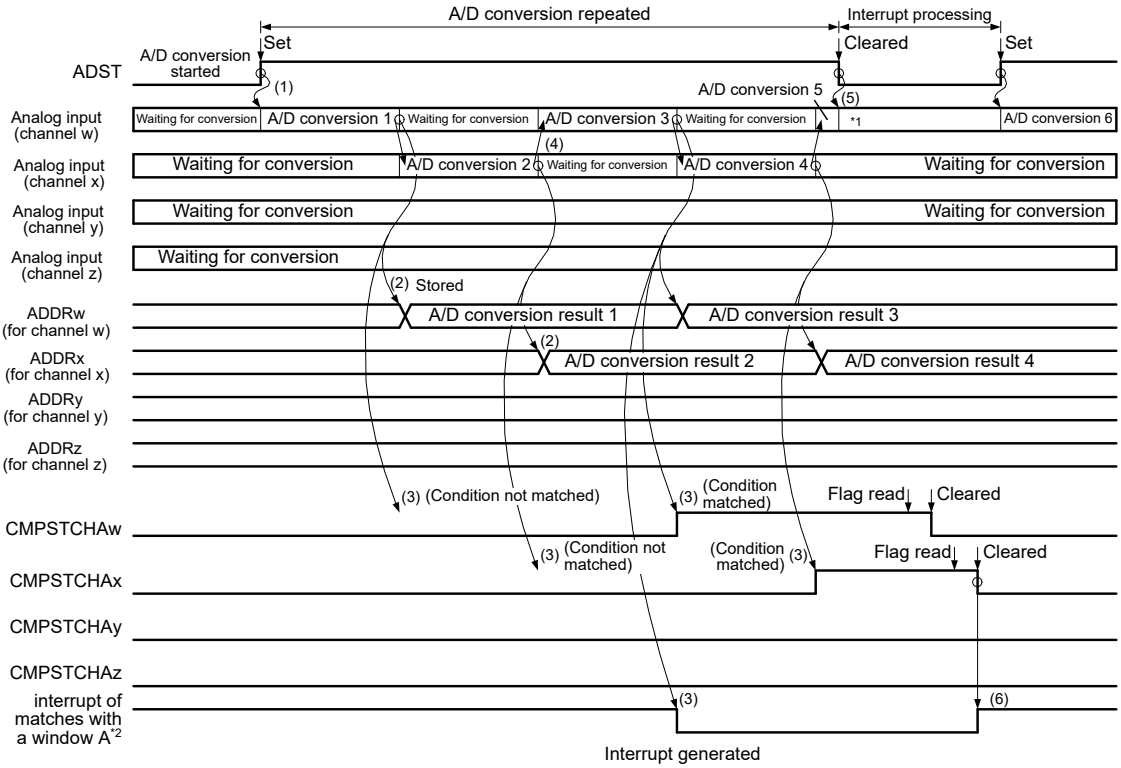
Note: x, y, and z (y < z) are the selected channel numbers by ADANSA0/1 or ADANSB0/1.
Note 1. ADC120_ADI
Note 2. ADC120_GBADI

**Figure 38.21 Group priority operation example 1-5: Continuously activating single scan for group B (when ADGSPCR.GBRP = 1)**

Note: To continuously activate single-scan operation for group B, disable group B trigger input.

## 38.3.5 Compare Function for Windows A and B

### 38.3.5.1 Compare Function Windows A and B



The compare function compares a reference value with the A/D conversion result. The reference value can be set for Window A and Window B independently. When the compare function is in use, the self-diagnosis function and double trigger mode cannot be used. The main differences between Window A and Window B are their different interrupt output signals and the constraint on Window B of only one selectable channel.

This section provides an example operation that combines continuous scan mode and the compare function.

The operation is as follows:

1. When the ADCSR.ADST bit is set to 1 (A/D conversion start) by software, a synchronous trigger (ELC) or an asynchronous trigger, A/D conversion starts of the selected channel. Both temperature sensor and internal reference voltage are not selectable at the same time. Additionally, when the internal reference voltage is selected as the high-potential reference voltage, A/D conversion of the temperature sensor or internal reference voltage is prohibited.
2. On completion of A/D conversion, the A/D conversion result is stored in the associated A/D Data Register y (ADDRy, ADTSDR, or ADOCDR). When ADCMPCR.CMPAE = 1, if bits in the ADCMPANSRy register or the ADCMPANSER register are set for Window A, the A/D conversion result is compared with the set ADCMPDR0/1 register value. When ADCMPCR.CMPBE = 1, if bits in the ADCMPBNSR register are set for Window B, the A/D conversion result is compared with the ADWINULB/ADWINLLB register setting.

3. As a result of the comparison, when Window A meets the condition set in ADCMPLR0/1 or ADCMPLER, the Compare Window A Flag (ADCMPSR0.CMPSTCHAn, ADCMPSR1.CMPSTCHAn, ADCMPSER.CMPSTTSA or ADCMPSER.CMPSTOCA) sets 1. At this time, if the ADCMPCR.CMPAIE bit is 1, an ADC120_CMPAI interrupt request is generated. In the same way, when Window B meets the condition set in ADCMPBNSR.CMPLB, the Compare Window B Flag (ADCMPBSR.CMPSTB) sets to 1. At this time, if the ADCMPCR.CMPBIE bit is 1, an ADC120_CMPBI interrupt request is generated.
4. On completion of all selected A/D conversions and comparisons, scan restarts.
5. After the ADC120_CMPAI and ADC120_CMPBI interrupts are accepted, the ADCSR.ADST bit is set to 0 (A/D conversion stop) and processing is performed for channels for which the compare flag is set to 1.
6. When all compare flags of Window A are cleared, the ADC120_CMPAI interrupt request is canceled. In the same way, when all compare flags of Window B are cleared, the ADC120_CMPBI interrupt request is reset. To perform comparison again, restart the A/D conversion.

Note: w, x, y, and z (w < x < y < z) are the selected channel numbers by ADANSA0/1.
Note 1. Data on conversion is ignored.
Note 2. ADC120_CMPAI

**Figure 38.22 Example of compare function operation, when the analog inputs (channel w to z) are compared**

### 38.3.5.2 Event Output of Compare Function

The event output of the compare function specifies the upper-side reference voltage value and the lower-side reference voltage value for window A and window B, respectively. The output compares the A/D converted value of the selected channel with the upper and lower side reference voltage value and outputs events (ADC120_WCMPM/ ADC120_WCMPUM) based on event conditions (A or B, A and B, A xor B) and comparison result of window A and window B.

If more than one channel is selected for window A, and even when one channel in window A meets the comparison condition, the comparison result of window A is met. When using this function, perform A/D conversion in single scan mode.

Any channels from analog input, internal reference voltage, CTSU TSCAP voltage, and temperature sensor output are selectable for window A. However, neither the internal reference voltage nor the temperature sensor output can be selected together with any other channel. Additionally, if the internal reference voltage is selected as the high-potential reference voltage of the A/D converter, the internal reference voltage or the temperature sensor output cannot be A/D converted.

One channel from analog input, internal reference voltage, CTSU TSCAP voltage, and temperature sensor output is selectable for window B. Additionally, if the internal reference voltage is selected as the high-potential reference voltage, the internal reference voltage or the temperature sensor output cannot be A/D converted.

The following sequence is an example of how to set up and use the event output of the compare function:

1. Confirm that the value in the ADCSR.ADCS bits is 00b (single scan mode).
2. Select the channel for window A in the ADCMPANSR0/1 and ADCMPANSER registers. Set the window comparison conditions in the ADCMPLR0/1 and ADCMPLER registers. Set the upper-side and lower-side reference values in the ADCMPDR0/1 registers.
3. Select the channel and comparison conditions for Window B in the ADCMPBNSR register, and set the upper and lower reference values in the ADWINULB and ADWINLLB registers.
4. Set the composite conditions for window A/B, window A/B operation enable, and interrupt output enable in the ADCMPCR register.

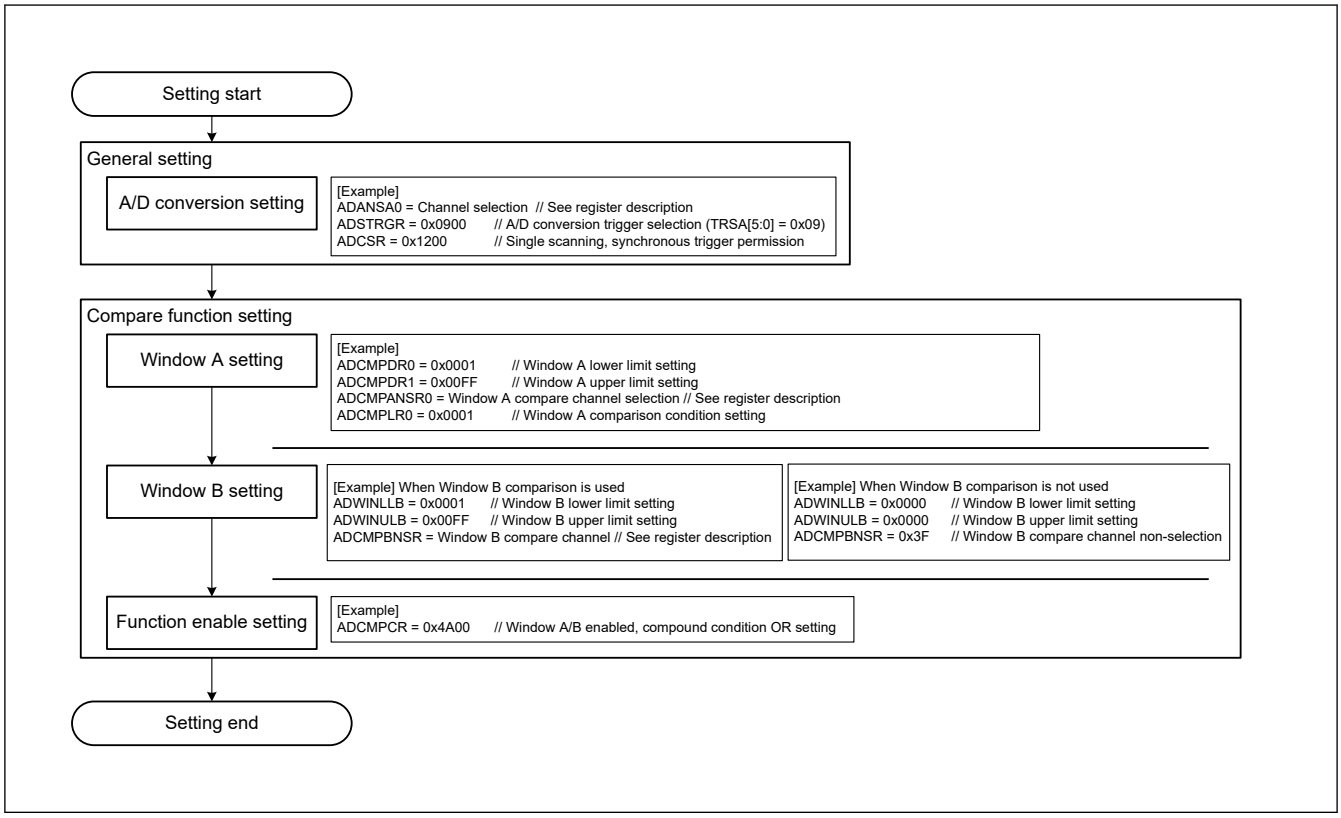


**Figure 38.23 Setting example when using the event output of the compare function**

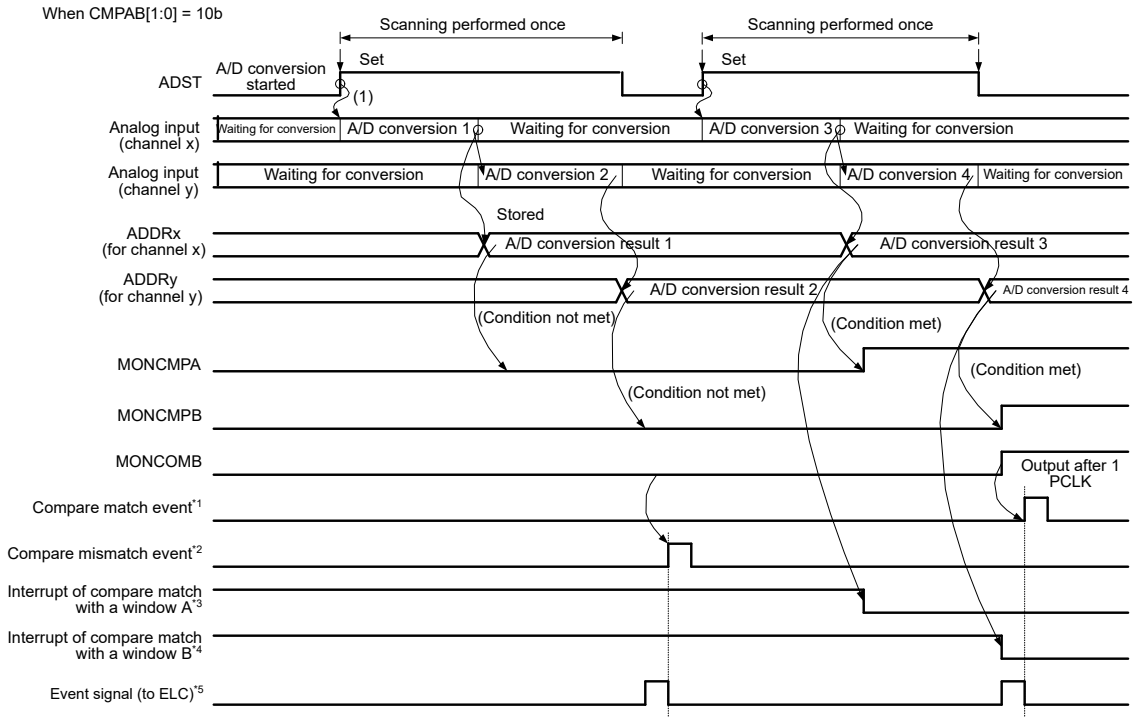

For event output usage when using only window A for the compare function, note the following:

- Enable both Window A and Window B (ADCMPCR.CMPAE = 1, ADCMPCR.CMPBE = 1)
- Set the compound condition of Window A and Window B to “OR condition” (ADCMPCR.CMPAB[1:0] = 00b)
- Set the compared channel of Window B to “No selection” (ADCMPBNSR.CMPCHB[5:0] = 0x3F)
- Set the compare condition of Window B to “0 < results < 0 always means mismatch”. (ADCMPCR.WCMPE = 1, ADWINLLB[15:0] = ADWINULB[15:0] = 0x0000, and ADCMPBNSR.CMPLB = 1)

Figure 38.24 shows the event output operation example of compare function.

A scan end event (ADC120_ADI) is output with the same timing as single scan completion. A match or mismatch event (ADC120_WCMPM/ADC120_WCMPUM) is output with 1 PCLKA cycle delay depending on the ADCMPCR.CMPAB[1:0] settings.

Note: The match and mismatch events are exclusive, so both events are never output simultaneously.

Note: x, and y (x < y) are the selected channel numbers by ADANSA0/1.
Note 1. ADC120_WCMPM
Note 2. ADC120_WCMPUM
Note 3. ADC120_CMPAI
Note 4. ADC120_CMPBI
Note 5. ADC120_ADI

**Figure 38.24 Example operation of the compare function event output, when the analog inputs (channel x and y) are compared**

Note: Event output of compare function outputs match/mismatch from the comparison results of Window A and Window B, based on the ADCMPCR.CMPAB[1:0] settings.

Note: The comparison result of Window A is the logical addition of the comparison results of the comparison target channels of Window A. The comparison results of Window A and Window B are updated by each A/D conversion, and are kept even when single scan ends. Set ADCMPCR.CMPAE and ADCMPCR.CMPBE to 0 to clear the comparison results to 0.

### 38.3.5.3 Restrictions on Compare Function

The following constraints apply for the compare function:

- The compare function cannot be used together with the self-diagnosis function or double-trigger mode. (The compare function is not available for ADRD, ADDBLDR, ADDBLDRA, and ADDBLDRB.)
- Specify single scan mode when using match/mismatch event outputs.
- When the temperature sensor output, internal reference voltage is selected for Window A, Window B operations are prohibited.

- When the temperature sensor output, internal reference voltage is selected for Window B, Window A operations are prohibited.
- Setting the same channel for Window A and Window B is prohibited.
- Set the reference voltage values so that the high-potential reference voltage value is equal to or larger than the low potential reference voltage value.

### 38.3.6 Analog Input Sampling and Scan Conversion Time

Scan conversion can be activated either by a software trigger, a synchronous trigger (ELC), or an asynchronous trigger (ADTRG0). After the start-of-scanning-delay time ($t_D$) has elapsed, processing for disconnection detection assistance, and processing of conversion for self-diagnosis all proceed, followed by processing for A/D conversion.

Figure 38.25 shows the scan conversion timing, in which scan conversion is activated by a software trigger or a synchronous trigger (ELC). Figure 38.26 shows the scan conversion timing, in which scan conversion is activated by an asynchronous trigger (ADTRG0). The scan conversion time ($t_{SCAN}$) includes the start-of-scanning-delay time ($t_D$), disconnection detection assistance processing time ($t_{DIS}$)*1, self-diagnosis A/D conversion processing time ($t_{DIAG}$ and $t_{DSD}$)*2, A/D conversion processing time ($t_{CONV}$), and end-of-scanning-delay time ($t_{ED}$).

The A/D conversion processing time ($t_{CONV}$) consists of input sampling time ($t_{SPL}$) and time for conversion by successive approximation ($t_{SAM}$). The sampling time ($t_{SPL}$) is used to charge sample-and-hold circuits in the A/D converter. If there is not sufficient sampling time due to the high impedance of an analog input signal source, or if the A/ D conversion clock (ADCLK) is slow, sampling time can be adjusted using the ADSSTRn register.

The time for conversion by successive approximation ($t_{SAM}$) is the following

- 31.5 ADCLK states with 12-bit accuracy and high-speed A/D conversion mode (ADCSR.ADHSC = 0) and normal conversion mode (ADACSR.ADSAC = 0) selected.
- 40.5 ADCLK states with 12-bit accuracy and Low-power A/D conversion mode (ADCSR.ADHSC = 1) and normal conversion mode (ADACSR.ADSAC = 0) selected.
- 21.5 ADCLK states with 12-bit accuracy and high-speed A/D conversion mode (ADCSR.ADHSC = 0) and fast conversion mode (ADACSR.ADSAC = 1) selected.
- 27.5 ADCLK states with 12-bit accuracy and Low-power A/D conversion mode (ADCSR.ADHSC = 1) and fast conversion mode (ADACSR.ADSAC = 1) selected.

Table 38.25 shows the time for conversion by successive approximation ($t_{SAM}$).

The scan conversion time ($t_{SCAN}$) in single scan mode for which the number of selected channels is n can be determined as follows:

$$t_{SCAN} = t_D + (t_{DIS} \times n) + t_{DIAG} + t_{ED} + (t_{CONV} \times n)$$ *3

The scan conversion time for the first cycle in continuous scan mode is $t_{SCAN}$ for single scan minus $t_{ED}$ . The scan conversion time for the second and subsequent cycles in continuous scan mode is fixed in the following:

$$(t_{DIS} \times n) + t_{DIAG} + t_{DSD} + (t_{CONV} \times n)$$ *3

Note 1. When disconnection detection assistance is not selected, $t_{DIS}$ = 0.

Only when the temperature sensor or internal reference voltage is A/D-converted, the auto-discharge period of 15 ADCLK states is inserted.

Note 2. When the self-diagnosis function is not used, $t_{DIAG}$ = 0, $t_{DSD}$ = 0.

Note 3. When input sampling times ($t_{SPL}$) of all selected channels are the same, this element equals $t_{CONV}$ × n. If each channel has a different sampling time, this element equals that of $t_{SPL}$ and $t_{SAM}$ set to each selected channel.

Table 38.25 shows the times for conversion during scanning.

**Table 38.25 Conversion times during scanning (in numbers of cycles of ADCLK and PCLKA)**

| Item | | | Symbol | | Type/Conditions: Synchronous trigger*5 | Type/Conditions: Asynchronous trigger | Type/Conditions: Software trigger | Unit |
|---|---|---|---|---|---|---|---|---|
| Scan start delay time*1 *2 | A/D conversion on group A under group A priority control. | Group B is to be stopped (Group A is activated after group B is stopped by of an A/D conversion source from group A). | $t_D$ | | 3 PCLKA + 6 ADCLK<br>5 PCLKA + 3 ADCLK*6 | — | — | Cycles |
| | | Group B is not to be stopped (Activation by an A/D conversion source from group A). | | | 2 PCLKA + 4 ADCLK | — | — | |
| | A/D conversion when self-diagnosis is enabled. | A/D conversion for self-diagnosis is to be started. | | | 2 PCLKA + 4 ADCLK | 4 PCLKA + 6 ADCLK | 6 ADCLK | |
| | All other | | | | 2 PCLKA + 4 ADCLK | 2 PCLKA + 4 ADCLK | 4 ADCLK | |
| Disconnection detection assistance processing time | | | $t_{DIS}$ | | Setting in ADNDIS[3:0] (initial value = 0x00) × ADCLK*3 | | | |
| Self-diagnosis conversion processing time*1 | Sampling time*4 | | $t_{DIAG}$ | $t_{SPL}$ | Setting in ADSSTRn (n = 0 to 14, L, T, O) (initial value = 0x0D) × ADCLK + 0.5 ADCLK | | | |
| | Time for conversion by successive approximation | 12-bit conversion accuracy | | $t_{SAM}$ | 31.5 ADCLK at high-speed A/D conversion mode (ADCSR.ADHSC = 0) and normal conversion mode (ADACSR.ADSAC = 0)<br>40.5 ADCLK at Low-power A/D conversion mode (ADCSR.ADHSC = 1) and normal conversion mode (ADACSR.ADSAC = 0)<br>21.5 ADCLK at high-speed A/D conversion mode (ADCSR.ADHSC = 0) and fast conversion mode (ADACSR.ADSAC = 1)<br>27.5 ADCLK at Low-power A/D conversion mode (ADCSR.ADHSC = 1) and fast conversion mode (ADACSR.ADSAC = 1) | | | |
| | Wait time between self-diagnosis conversion end and analog channel sampling start. | | | $t_{DED}$ | 2 ADCLK | | | |
| | Wait time between last channel conversion end and self-diagnosis sampling start in continuous scan mode. | | | $t_{DSD}$ | 2 ADCLK | | | |
| A/D conversion processing time*1 | Sampling time*4 | | $t_{CONV}$ | $t_{SPL}$ | Setting in ADSSTRn (n = 0 to 14, L, T, O) (initial value = 0x0D) × ADCLK + 0.5 ADCLK | | | |
| | Time for conversion by successive approximation | 12-bit conversion accuracy | | $t_{SAM}$ | 31.5 ADCLK at high-speed A/D conversion mode (ADCSR.ADHSC = 0) and normal conversion mode (ADACSR.ADSAC = 0)<br>40.5 ADCLK at Low-power A/D conversion mode (ADCSR.ADHSC = 1) and normal conversion mode (ADACSR.ADSAC = 0)<br>21.5 ADCLK at high-speed A/D conversion mode (ADCSR.ADHSC = 0) and fast conversion mode (ADACSR.ADSAC = 1)<br>27.5 ADCLK at Low-power A/D conversion mode (ADCSR.ADHSC = 1) and fast conversion mode (ADACSR.ADSAC = 1) | | | |
| Scan end processing time*1 | | | $t_{ED}$ | | 1 PCLKA + 3 ADCLK<br>2 PCLKA + 3 ADCLK*6 | | | |

Note 1. See Figure 38.25 and Figure 38.26 for an illustration of times $t_D$, $t_{DIAG}$, $t_{CONV}$, and $t_{ED}$.
Note 2. This is the maximum time required from software writing or trigger input to A/D conversion start.
Note 3. The value is fixed to 0x0F (15 ADCLK) when the temperature sensor output or internal reference voltage is A/D- converted.
Note 4. The sampling time setting should satisfy the electrical characteristics. For the details, see section 49.5. ADC12 Characteristics.
Note 5. This does not include the time consumed in the path from timer output to trigger input.
Note 6. If ADCLK is faster than PCLKA (PCLKA to ADCLK frequency ratio = 1:2 or 1:4).

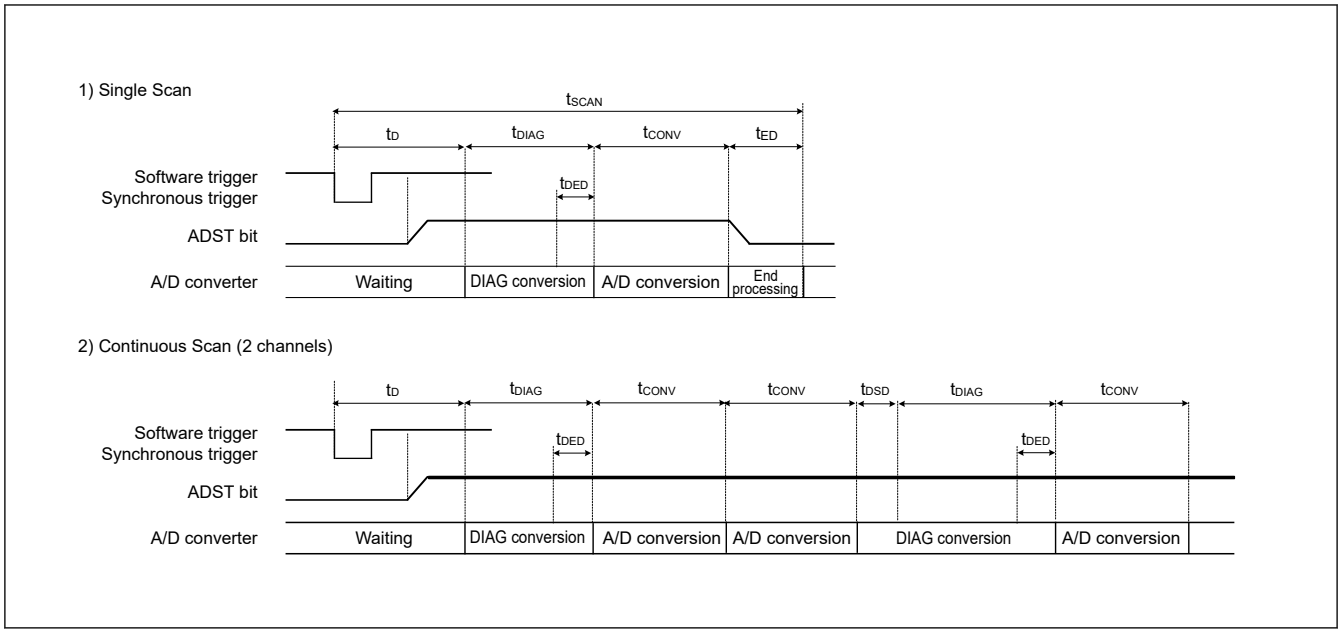

**Figure 38.25 Scan conversion timing when activated by software or a synchronous trigger input (ELC)**

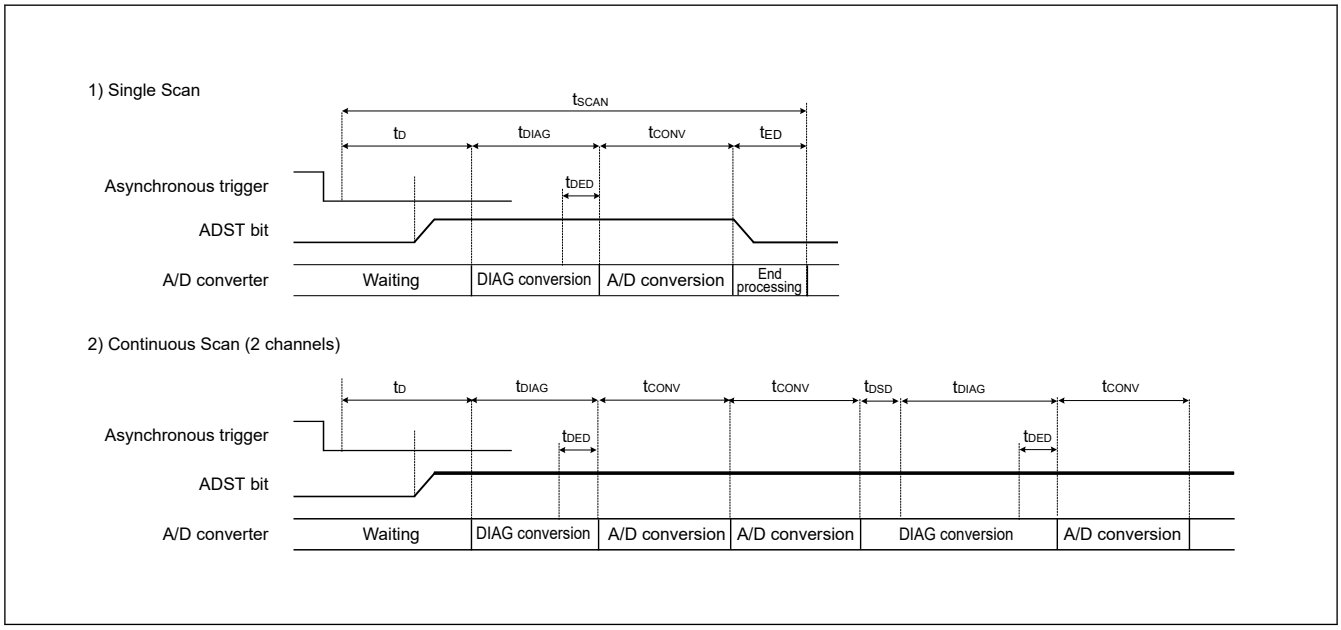

**Figure 38.26 Scan conversion timing when activated by an asynchronous trigger input (ADTRG0)**

## 38.3.7 Usage Example of A/D Data Register Automatic Clearing Function

Setting the ADCER.ACE bit to 1 automatically clears the A/D data registers (ADDRy, ADRD, ADDBLDR, ADDBLDRA, ADDBLDRB, ADTSDR, ADOCDR) to 0x0000 when the A/D data registers are read by the CPU or DTC.

This function enables detection of update failures of the A/D data registers (ADDRy, ADRD, ADDBLDR, ADDBLDRA, ADDBLDRB, ADTSDR, ADOCDR). This section describes examples in which the function to automatically clear the ADDRy register is enabled and disabled.

- If the ADCER.ACE bit is 0 (automatic clearing is disabled) and for some reason, if the A/D conversion result (0x0222) is not written to the ADDRy register, the ADDRy value retains the old data (0x0111). In addition, if this ADDRy value is read into a general-purpose register using an A/D scan end interrupt, the old data (0x0111) can be saved in the general-purpose register. When checking whether there is an update failure, it is necessary to frequently save the old data in SRAM or in a general-purpose register.
- If the ADCER.ACE bit is 1 (automatic clearing is enabled), when ADDRy = 0x0111 is read by the CPU or DTC, ADDRy is automatically set to 0x0000. Next, if the A/D conversion result of 0x0222 cannot be transferred to ADDRy

for some reason, the cleared data (0x0000) remains as the ADDRy value. If this ADDRy value is read into a general-purpose register using an A/D scan end interrupt, 0x0000 is saved in the general-purpose register. Occurrence of an ADDRy update failure can be determined by checking that the read data value is 0x0000.

### 38.3.8 A/D-Converted Value Addition/Average Mode

A/D-converted value addition/average mode can be used when A/D conversion of the analog input of the selected channels, the temperature sensor output, the internal reference voltage, or the CTSU TSCAP voltage is selected.

In A/D-converted value addition mode, the same channel is A/D-converted 1, 2, 3, 4, or 16 consecutive times, and the sum of the converted values is stored in the data register. In A/D-converted value average mode, the same channel is A/D-converted 2 or 4 consecutive times, and the mean of the converted values is stored in the data register. The use of the average of these results can improve the accuracy of A/D conversion, depending on the types of noise components that are present. This function, however, cannot always guarantee an improvement in A/D conversion accuracy.

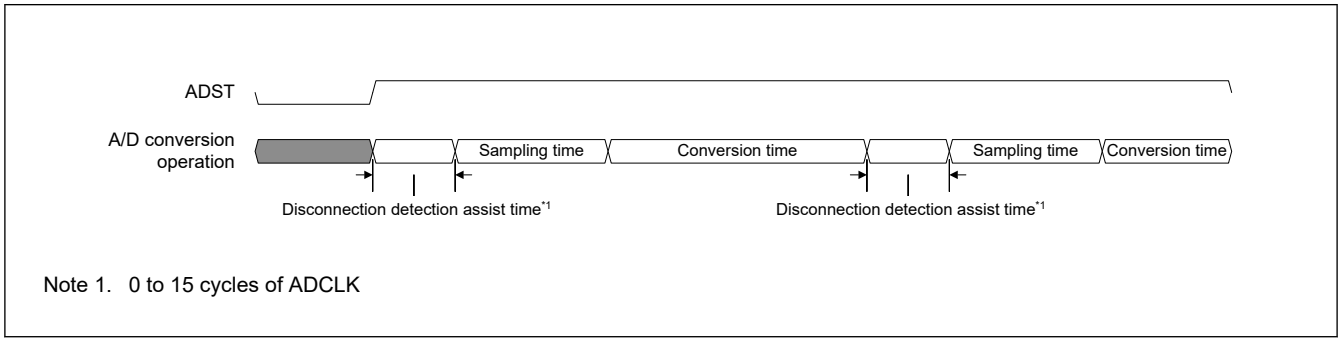
The A/D-converted value addition/average function can be used when A/D conversion of the analog inputs of the selected channels or A/D conversion of the temperature sensor output or A/D conversion of the internal reference voltage is selected. The A/D-converted value addition/average function can also be used for channels for which the double-trigger function is selected.

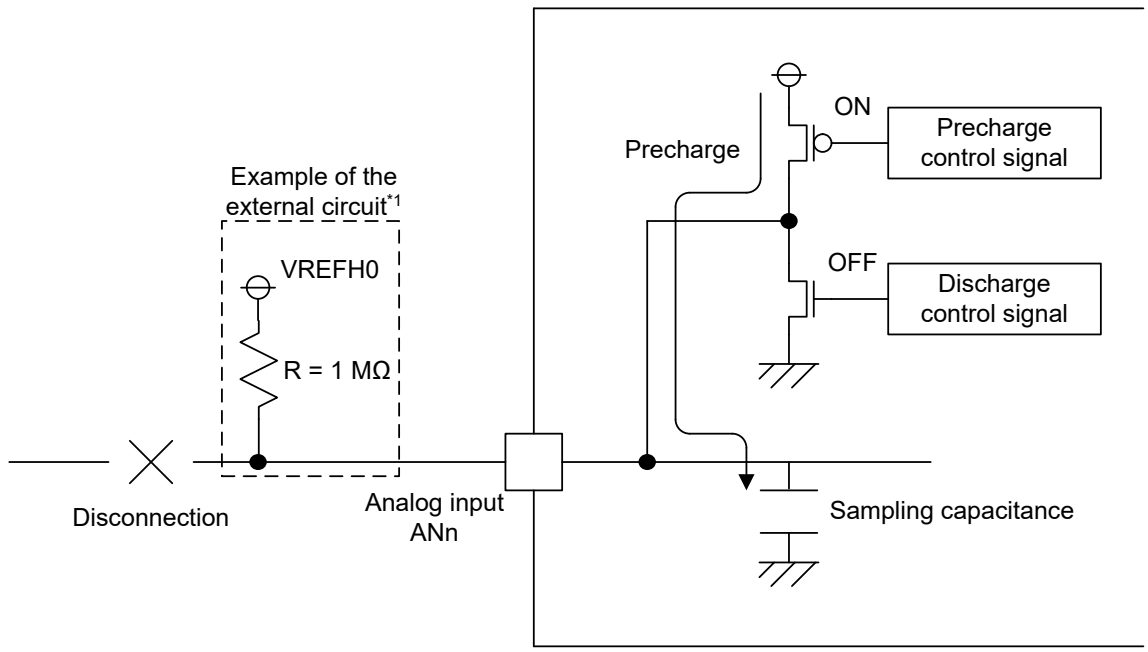
The addition function for self-diagnosis is not provided.

### 38.3.9 Disconnection Detection Assist Function

The ADC12 incorporates a function to fix the charge for sampling capacitance to the specified state VREFH0 or VREFL0 before the start of A/D conversion. This function enables disconnection detection in wiring of analog inputs.

Figure 38.27 shows the A/D conversion operation when the disconnection detection assist function is used. Figure 38.28 shows an example of disconnection detection when precharge is selected. Figure 38.29 shows an example of disconnection detection when discharge is selected.





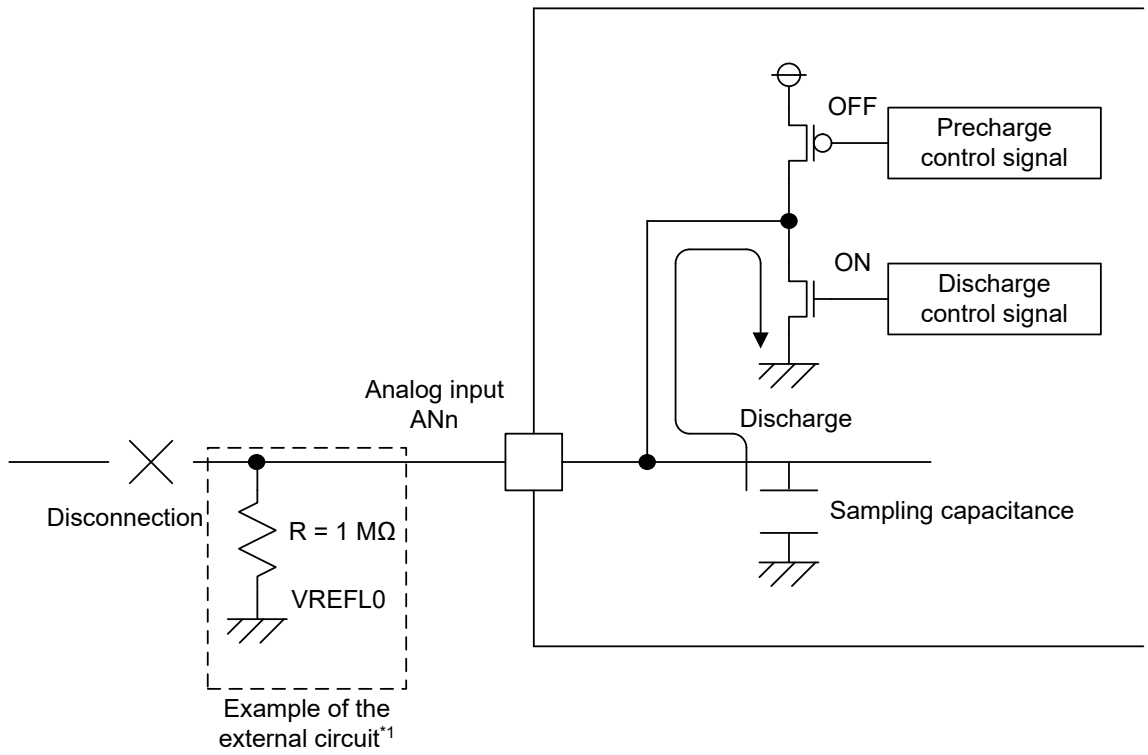


**Figure 38.27 Operation of A/D conversion when disconnection detection assist function is used**

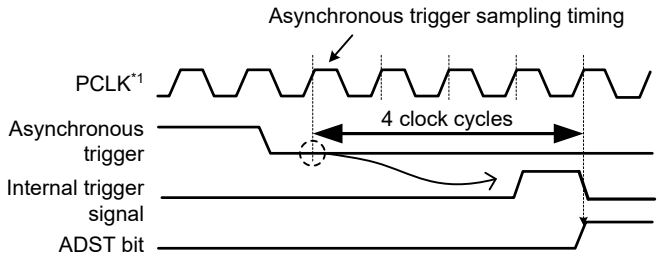
Note 1. The converted result should be used after it is fully evaluated because the result data when disconnection occurs varies depending on the external circuit.

**Figure 38.28 Example of disconnection detection when precharge is selected**



Note 1. The converted result should be used after it is fully evaluated because the result data when disconnection occurs varies depending on the external circuit.

**Figure 38.29 Example of disconnection detection when discharge is selected**

## 38.3.10 Starting A/D Conversion with an Asynchronous Trigger

A/D conversion can be started by the input of an asynchronous trigger. To start A/D conversion by an asynchronous trigger, set the pin function in the PmnPFS register, set the A/D Conversion Start Trigger Select bits (ADSTRGR.TRSA[5:0]) to 0x00, then input a high-level signal to the asynchronous trigger (ADTRG0 pin). Finally, set both the ADCSR.TRGE and ADCSR.EXTRG bits to 1. Figure 38.30 shows timing of the asynchronous trigger input.

An asynchronous trigger cannot be selected in the A/D conversion start trigger for group B used in group scan mode. For details on setting the pin function, see section 18, I/O Ports.

Note 1. PCLKA

**Figure 38.30 Asynchronous trigger input timing**

### 38.3.11 Starting A/D Conversion with a Synchronous Trigger from a Peripheral Module

A/D conversion can be started by a synchronous trigger (ELC). To do this, set the ADCSR.TRGE bit to 1 and the ADCSR.EXTRG bit to 0, and select the relevant sources in the ADSTRGR.TRSA[5:0] bits and ADSTRGR.TRSB[5:0] bits.

## 38.4 Interrupt Sources and DTC Transfer Requests

### 38.4.1 Interrupt Requests

The ADC12 can send scan end interrupt requests ADC120_ADI and ADC120_GBADI to the CPU. The ADC12 also generates the ADC120_CMPAI/ADC120_CMPBI interrupt for the CPU in response to matches with a condition for comparison.

An ADC120_ADI interrupt is always generated. An ADC120_GBADI interrupt can be generated by setting the ADCSR.GBADIE bit to 1. Similarly, ADC120_CMPAI and ADC120_CMPBI interrupts can be generated by setting the ADCMPCR.CMPAIE and ADCMPCR.CMPBIE bit to 1.

In addition, the DTC can be started when an ADC120_ADI or an ADC120_GBADI interrupt is generated. Using an ADC120_ADI or ADC120_GBADI interrupt to activate the DTC to read the converted data enables continuous conversion without a burden on software.

Table 38.26 describes the interrupt sources and ELC events available for the ADC12.

**Table 38.26 The interrupt source and ELC event of ADC12 (1 of 2)**

| Operation | | | Interrupt request or ELC event | Interrupt request | DTC activation | ELC event request | Function |
|---|---|---|---|---|---|---|---|
| Scan mode | Double trigger mode | Compare function Window A/B | | | | | |
| Single scan mode | Deselected | Deselected | ADC120_ADI | ✓ | ✓ | ✓ | ADC120_ADI generated at the end of single scan |
| | | Selected | ADC120_ADI | ✓ | ✓ | ✓ | ADC120_ADI generated at the end of single scan |
| | | | ADC120_CMPAI | ✓ | — | — | ADC120_CMPAI generated on a match comparison condition of Window A |
| | | | ADC120_CMPBI | ✓ | — | — | ADC120_CMPBI generated on a match comparison condition of Window B |
| | | | ADC120_WCMPM | — | ✓ | ✓ | ADC120_WCMPM generated on a match condition of the Window A/B compare function |
| | | | ADC120_WCMPUM | — | ✓ | ✓ | ADC120_WCMPUM generated on a mismatch condition of the Window A/B compare function |
| | Selected | Deselected | ADC120_ADI | ✓ | ✓ | ✓ | ADC120_ADI generated at the end of scans in the even numbered times |
| Continuous scan mode | Deselected | Deselected | ADC120_ADI | ✓ | ✓ | ✓ | ADC120_ADI generated at the end of scan of all selected channels |
| | | Selected | ADC120_CMPAI | ✓ | — | — | ADC120_CMPAI generated on a match comparison condition of Window A |
| | | | ADC120_CMPBI | ✓ | — | — | ADC120_CMPBI generated on a match comparison condition of Window B |

**Table 38.26 The interrupt source and ELC event of ADC12 (2 of 2)**

| Operation | | | Interrupt request or ELC event | Interrupt request | DTC activation | ELC event request | Function |
|---|---|---|---|---|---|---|---|
| Scan mode | Double trigger mode | Compare function Window A/B | | | | | |
| Group scan mode | Deselected | Deselected | ADC120_ADI | ✓ | ✓ | ✓ | ADC120_ADI generated at the end of group A scan |
| | | | ADC120_GBADI | ✓ | ✓ | — | ADC120_GBADI dedicated to group B generated at the end of group B scan |
| | | Selected | ADC120_ADI | ✓ | ✓ | ✓ | ADC120_ADI generated at the end of group A scan |
| | | | ADC120_GBADI | ✓ | ✓ | — | ADC120_GBADI dedicated to group B generated at the end of group B scan |
| | | | ADC120_CMPAI | ✓ | — | — | ADC120_CMPAI generated on a match comparison condition of Window A |
| | | | ADC120_CMPBI | ✓ | — | — | ADC120_CMPBI generated on a match comparison condition of Window B |
| | Selected | Deselected | ADC120_ADI | ✓ | ✓ | ✓ | ADC120_ADI generated at the end of group A scans in the even-numbered times |
| | | | ADC120_GBADI | ✓ | ✓ | — | ADC120_GBADI dedicated to group B generated at the end of group B scan |

Note: ✓ available
—: unavailable

For details on DTC settings, see section 16, Data Transfer Controller (DTC).

## 38.5 Event Link Function

### 38.5.1 Event Output to the ELC

The ELC uses the ADC120_ADI interrupt request signal as an event signal ADC120_ADI, enabling link operation for the preset module. The ADC120_GBADI interrupt and ADC120_CMPAI/ADC120_CMPBI interrupts cannot be used as an event signal. For details, see Table 38.26.

An event signal can be output regardless of the settings of the corresponding interrupt request enable bits. For the scan end event (ADC120_ADI), a high-level pulse for one PCLKA cycle is output at the same output timing as the interrupt output (ADC120_ADI) shown in Table 38.26. For a compare function match (ADC120_WCMPM) and mismatch event (ADC120_WCMPUM) to the ELC, a high-level pulse for one PCLKA cycle is output at the timing delayed by one cycle (PCLKA) from the interrupt output (ADC120_ADI) shown in Table 38.26.

To use compare function match (ADC120_WCMPM) or mismatch event (ADC120_WCMPUM) to the ELC, specify single-scan mode.

### 38.5.2 ADC12 Operation through an Event from the ELC

The ADC12 can start A/D conversion by the preset event specified in the ELSRn settings for the ELC as follows:

- Select the ELC_AD00 signal in the ELC.ELSR8 register
- Select the ELC_AD01 signal in the ELC.ELSR9 register

If an ELC event occurs during A/D conversion, the event is disabled.

## 38.6 Selecting Reference Voltage

The ADC12 can select VREFH0, AVCC0, or internal reference voltage as the high-potential reference voltage and can select VREFL0 or AVSS0 as the low-potential reference voltage. Set these reference voltages before starting A/D conversion. For details on the settings, see section 38.2.38. ADHVREFCNT : A/D High-Potential/Low-Potential Reference Voltage Control Register.

## 38.7 A/D Conversion Procedure When Selecting Internal Reference Voltage as High-Potential Reference Voltage

The following sequence describes the A/D conversion procedure after selecting the internal reference voltage as the high-potential reference voltage. In this case, A/D conversion is possible for channels of analog input, and CTSU TSCAP voltage, however A/D conversion of the internal reference voltage and the temperature sensor output is prohibited.

1. Set ADHVREFCNT.HVSEL[1:0] to 11b to discharge the high-potential reference voltage path in the ADC12.
2. Wait for a 1 µs discharge period in the software.
3. Set ADHVREFCNT.HVSEL[1:0] to 10b to select internal reference voltage as the high-potential reference voltage.*1
4. Wait until the internal reference voltage is stabilized (for 5 µs) in the software, then perform A/D conversion.

Note 1. The ADC12 has a protection function that disables selection of internal reference voltage (ADHVREFCNT.HVSEL[1:0] = 10b) without discharge (ADHVREFCNT.HVSEL[1:0] = 11b) from the selection of VREFH0 (ADHVREFCNT.HVSEL[1:0] = 01b) or AVCC0 (ADHVREFCNT.HVSEL[1:0] = 00b). If the internal reference voltage is selected without discharge, discharge is forcibly set. Select the internal reference voltage again 1 µs later.

Figure 38.31 shows a waveform chart for the procedure to select internal reference voltage as the high-potential reference voltage.

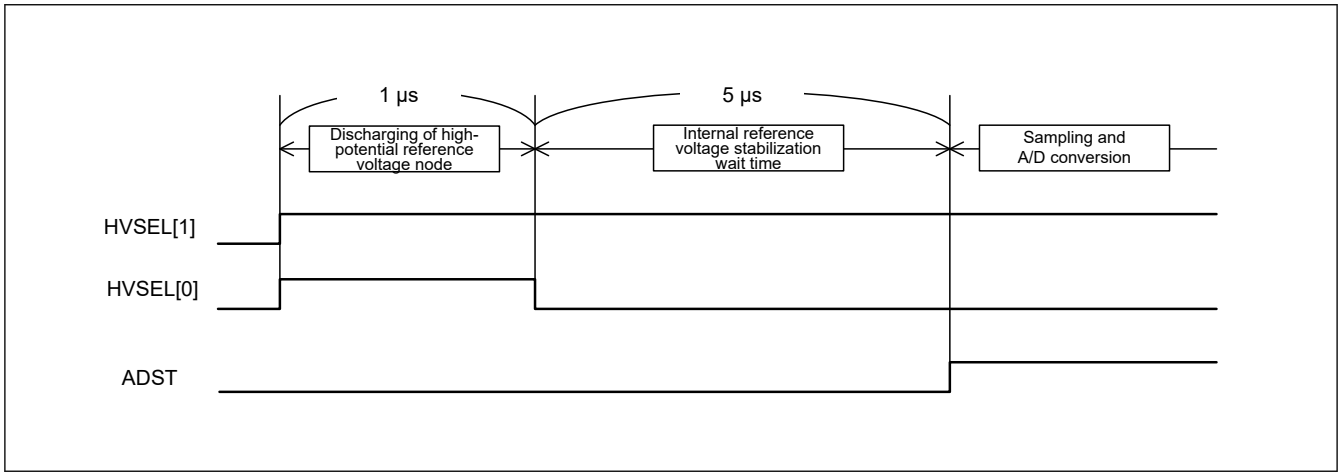


**Figure 38.31 Procedure to select internal reference voltage as high-potential reference voltage**

## 38.8 Usage Notes

### 38.8.1 Constraints on Setting the Registers

Set each register while the ADCSR.ADST bit is 0.

### 38.8.2 Constraints on Reading the Data Registers

The following registers must be read in halfword units:

- A/D Data Registers
- A/D Data Duplexing Register
- A/D Data Duplexing Register A
- A/D Data Duplexing Register B

- A/D Temperature Sensor Data Register
- A/D Internal Reference Voltage Register
- A/D CTSU TSCAP Voltage Data Register
- A/D Self-Diagnosis Data Register

If a register is read twice in byte units, that is, the upper byte and lower byte are read separately, the A/D-converted value read initially might disagree with the A/D-converted value read subsequently. To prevent this, never read the data registers in byte units.

### 38.8.3 Constraints on Stopping A/D Conversion

#### (1) A/D Conversion Stop Procedure

To stop A/D conversion when an asynchronous trigger or a synchronous trigger is selected as the condition for starting A/D conversion, follow the procedure shown in Figure 38.32.

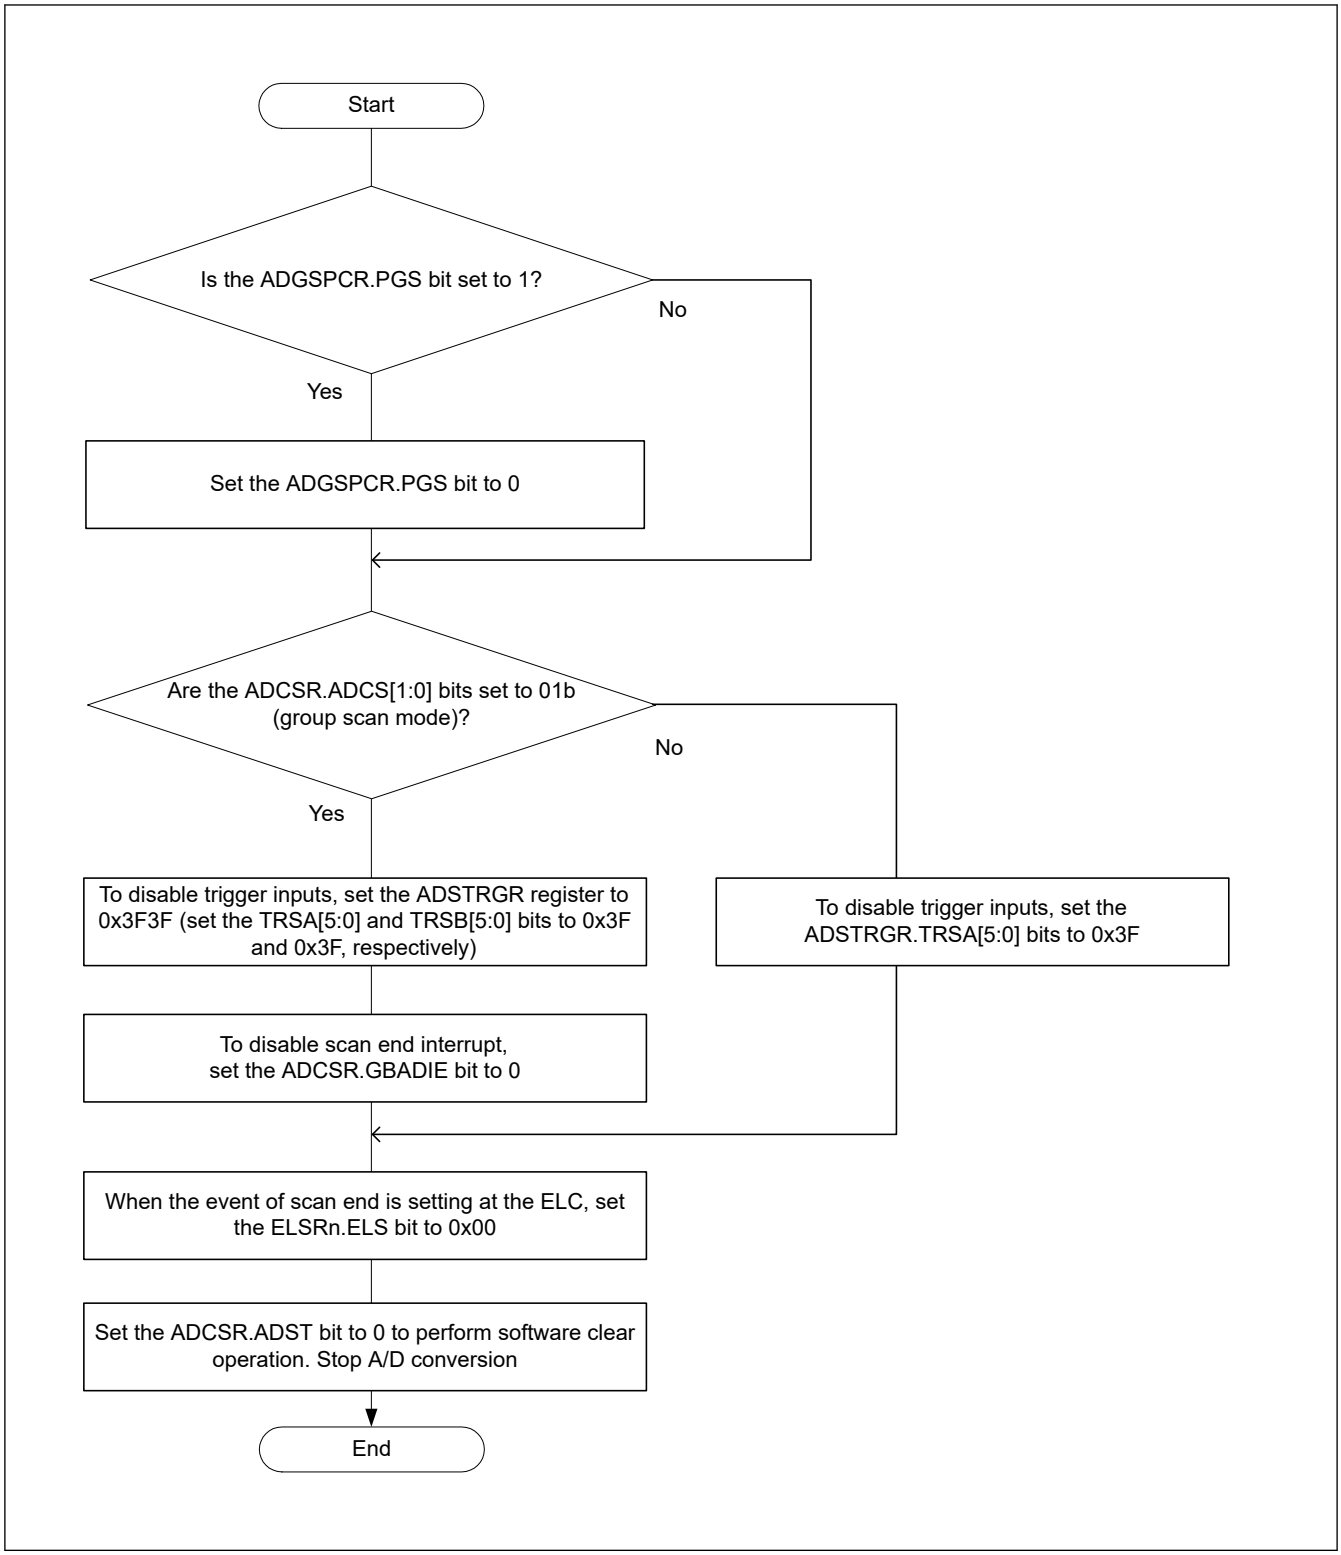

**Figure 38.32 Procedures for clearing the ADCSR.ADST bit by software**

To specify the following settings after performing the clear operation by software, provide a wait period for at least two ADCLK cycles.

- Enabling scan end interrupts
- Enabling scan end events for the event link controller
- Starting A/D conversion by software
- Enabling trigger input

### (2) Notes on Modes and Status Bits

If necessary, individually initialize or set again the voltage status for self-diagnosis, the judgment of the even number or odd number specified for double-trigger mode, and the monitor flags of the compare function.

- To set again the voltage status for self-diagnosis, set the ADCER.DIAGLD bit to 1 and then set a desired value in the ADCER.DIAGVAL[1:0] bits.
- If the setting of the ADCSR.DBLE bit is changed from 0 to 1, the double-trigger mode operation starts from the first scanning.
- To initialize the monitor flags of the compare function (MONCMPA, MONCMPB, and MONCOMB), set the ADCMPCR.CMPAE and ADCMPCR.CMPBE bits to 0.

## 38.8.4 A/D Conversion Restart and Termination Timing

A maximum of 6 ADCLK cycles is required for the idle analog unit of the ADC12 to restart on setting the ADCSR.ADST bit to 1. A maximum of 3 ADCLK cycles is required for the operating analog unit of the ADC12 to terminate on setting the ADCSR.ADST bit to 0.

## 38.8.5 Constraints on Scan End Interrupt Handling

When scanning the same analog input twice using any trigger, the first A/D-converted data is overwritten with the second A/D-converted data. This occurs when the CPU does not complete the reading of the A/D-converted data by the time the A/D conversion of the first analog input for the second scan ends after the first scan end interrupt is generated.

## 38.8.6 Settings for the Module-Stop Function

The Module Stop Control Register can enable or disable ADC12 operation. The ADC12 is initially stopped after a reset. The registers become accessible on release from the module-stop state. After release from the module-stop state, wait for at least 1 µs before starting A/D conversion. For details, see section 10, Low Power Modes.

## 38.8.7 Notes on Entering the Low-Power States

Before entering the module-stop state or Software Standby mode, be sure to stop A/D conversion. Set the ADCSR.ADST bit in ADCSR to 0 and secure certain period until the analog unit of the ADC12 stops. Follow the procedure shown in Figure 38.32 to clear the ADCSR.ADST bit with software. Then, wait for 3 clock cycles of ADCLK before entering the module-stop state or Software Standby mode.

## 38.8.8 Error in Absolute Accuracy When Disconnection Detection Assistance Is in Use

Using disconnection detection assistance leads to an error in absolute accuracy of the ADC12. This error arises because an erroneous voltage is input to the analog input pins due to the resistive voltage division between the pull-up or pull- down resistor (Rp) and the resistance of the signal source (Rs). This error in absolute accuracy is calculated from the following formula:

$$\text{Maximum error in absolute accuracy (LSB)} = \left(2^{\text{Resolution}} - 1\right) \times \text{Rs} / \left(\text{Rs} + \text{Rp}\right)$$

Only use disconnection detection assistance after thorough evaluation.

## 38.8.9 ADHSC Bit Rewriting Procedure

Before changing the A/D Conversion Select bit (ADCSR.ADHSC) from 0 to 1 or from 1 to 0, the ADC12 must be in the standby state. Use the following procedure to modify the ADCSR.ADHSC bit. After the Sleep bit (ADHVREFCNT.ADSLP) is set to 0, wait for at least 1 µs then start the A/D conversion.

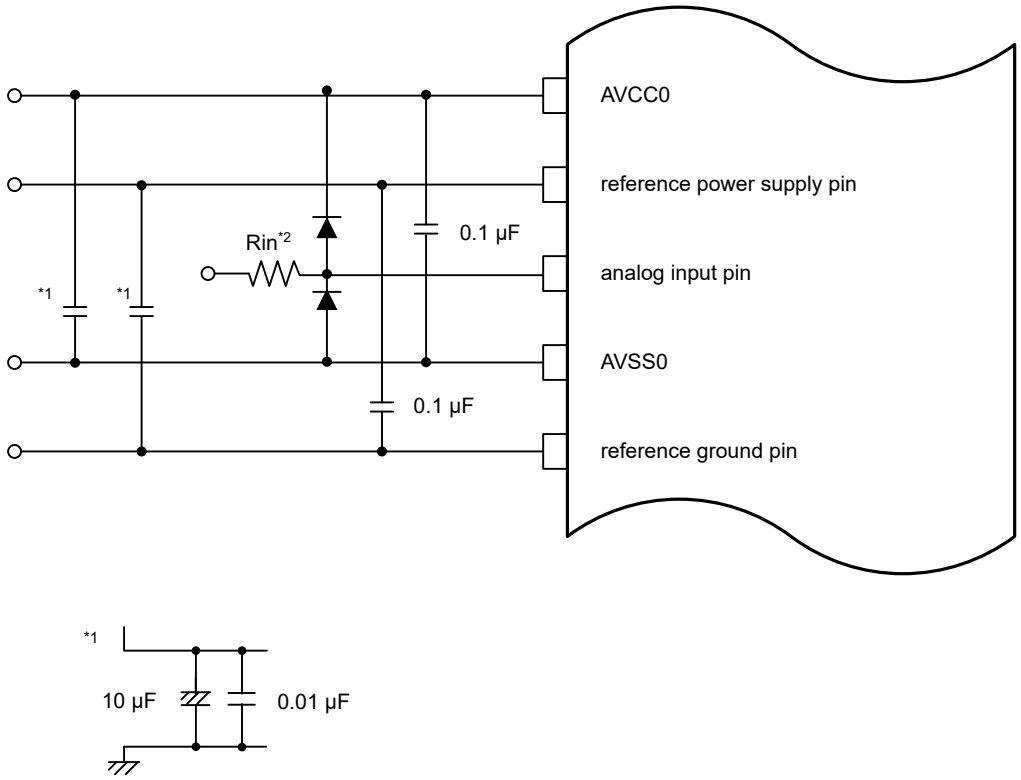
1. Set the Sleep bit (ADHVREFCNT.ADSLP) to 1.
2. Wait for at least 0.2 µs, then modify the A/D Conversion Select bit (ADCSR.ADHSC).
3. Wait for at least 4.8 µs, then set the Sleep bit (ADHVREFCNT.ADSLP) to 0.

Note: Do not set the Sleep bit (ADHVREFCNT.ADSLP) to 1 except when modifying the A/D Conversion Select bit (ADCSR.ADHSC).

Note: Do not reset the Sleep bit when the A/D Conversion Select bit (ADCSR.ADHSC) is 1. After this bit is set to 0 or the operating mode transitions to the module-stop mode, reset the Sleep bit using the ADCSR.ADHSC bit rewriting procedure.

### 38.8.10 Constraints on Operating Modes and Status Bits

Initialize or set again individually, if necessary, the voltage values in self-diagnosis, the value of the first scan or second scan in double trigger mode, the data buffer pointer, and status monitor in the compare function.



- Select the voltage values in self-diagnosis (ADCER.DIAGVAL[1:0]) after setting ADCER.DIAGLD to 1.
- Double-trigger mode operates as the first scan after setting ADCSR.DBLE from 0 to 1.
- The status monitor bits (MONCMPA, MONCMPB, MONCOMB) in the compare function are initialized after setting ADCMPCR.CMPAE and ADCMPCR.CMPBE to 0.

### 38.8.11 Notes on Board Design

The board should be designed so that digital circuits and analog circuits are separated from each other as far as possible. In addition, digital circuit signal lines and analog circuit signal lines should not intersect or be placed near each other. If these rules are not followed, noise can occur on analog signals and A/D conversion accuracy is affected. The analog input pins, CTSU TSCAP pin, reference power supply pin (VREFH0), reference ground pin (VREFL0), and analog power supply (AVCC0) should be separated from digital circuits using the analog ground (AVSS0). The analog ground (AVSS0) should be connected to a stable digital ground (VSS) on the board (single-point ground plane connection).

### 38.8.12 Constraints on Noise Prevention

To prevent the analog input pins from being destroyed by abnormal voltage such as excessive surge, insert a capacitor between AVCC0 and AVSS0 and between VREFH0 and VREFL0. Additionally, connect a protection circuit to protect the analog input pins as shown in Figure 38.33.

Note 1. The values shown here are reference values.
Note 2. Rin: Signal source impedance

**Figure 38.33 Example protection circuit for analog inputs**

## 38.8.13 Port Settings When Using the ADC12 Input

When using the high-precision channels, do not use PORT0 as general I/O and CTSU input pins. Renesas recommends that you do not use the digital output that is also used as the AD analog input if normal-precision channel is used. If the digital output that is also used as the AD analog input is used for output signals, perform A/D conversion several times, eliminate the maximum and minimum values, and obtain the average of the other results.

## 38.8.14 Notes on Canceling Software Standby Mode

After software standby mode is canceled, wait at least 1 µs after the stabilization time for the oscillator elapses and before starting A/D conversion. For details, see section 10, Low Power Modes

# 39. 12-Bit D/A Converter (DAC12)

## 39.1 Overview

The MCU provides a 12-bit D/A Converter (DAC12) with an output amplifier. Table 39.1 lists the DAC12 specifications, Figure 39.1 shows a block diagram, and Table 39.2 lists the I/O pins.

**Table 39.1 DAC12 specifications**

| Parameter | Specifications |
|---|---|
| Resolution | 12 bits |
| Output channels | 1 channel |
| Interference reduction between analog modules | Methods provided to minimize interference between D/A and A/D conversion:<br>• D/A converted data update timing is controlled by the synchronous D/A conversion enable input signal from the ADC12<br>• Degradation of A/D conversion accuracy caused by interference is reduced by controlling the DAC12 inrush current generation timing with the enable signal. |
| Module-stop function | Module-stop state can be set to reduce power consumption |
| Event link function (input) | The DA0 conversion can be started on input of an event signal |
| TrustZone Filter | Security attribution can be set |

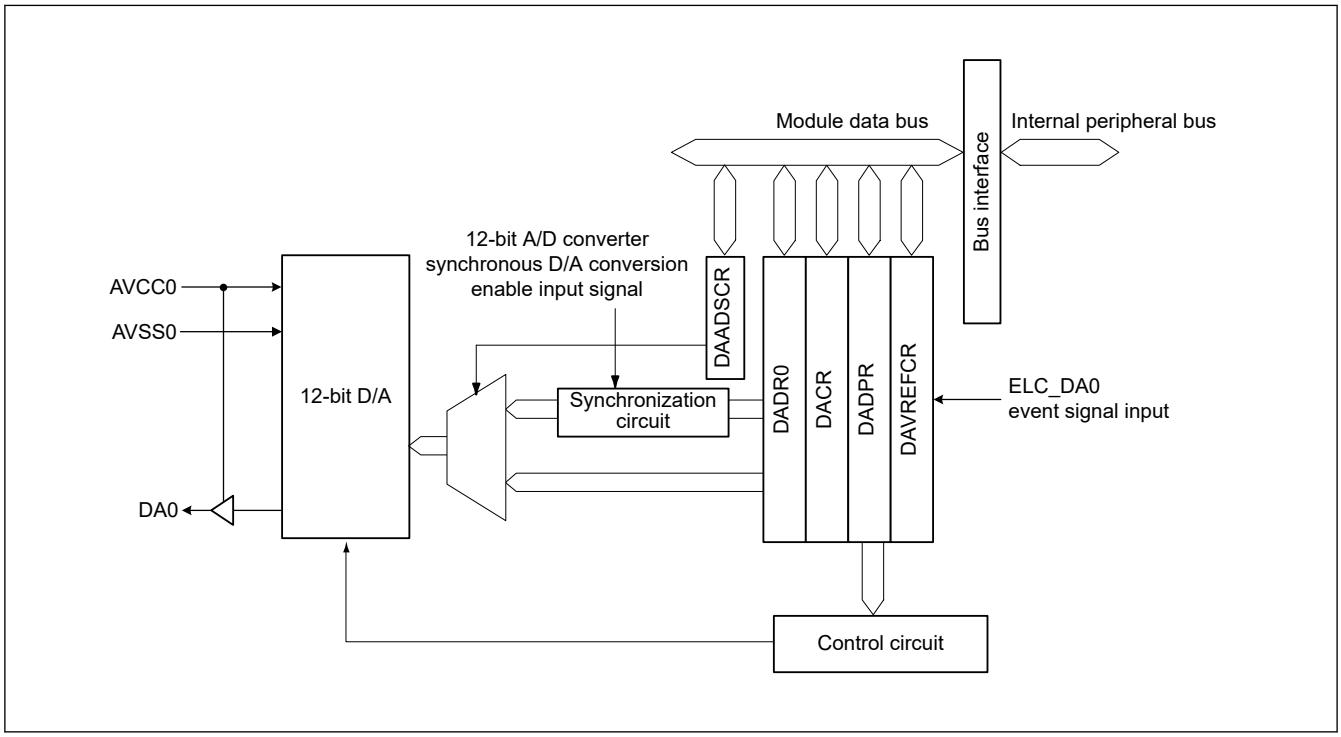


**Figure 39.1 DAC12 block diagram**

Table 39.2 lists the pin configuration of the DAC12.

**Table 39.2 DAC12 I/O pins**

| Pin name | I/O | Function |
|---|---|---|
| AVCC0 | Input | • Analog power and analog reference voltage supply pin for ADC12 and DAC12.<br>• Connect to VCC when these modules are not used. |
| AVSS0 | Input | • Analog ground and analog reference ground supply pin for ADC12 and DAC12.<br>• Connect to VSS when these modules are not used. |
| DA0 | Output | Channel 0 output pin for the analog signals processed by the DAC12 |

## 39.2 Register Descriptions

### 39.2.1 DADR0 : D/A Data Register 0

Base address: DAC12 = 0x4017_1000

Offset address: 0x00

| Bit position: | 15 | | | | | | | | | | | | | | | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | | | | | | | | | | | | | | | | |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

Note: If the security attribution is configured as Secure:
- Secure access and Non-secure read access are allowed
- Non-secure write access is ignored, and TrustZone access error is not generated.

If the security attribution is configured as Non-secure:
- Secure and Non-secure access are allowed.

DADR0 register is 16-bit read/write registers that store data for D/A conversion. When an analog output is enabled, the values in DADR0 are converted and output to the analog output pins.

12-bit data can be formatted as left- or right-justified in the DADPR.DPSEL bit setting. In right-justified format (DADPR.DPSEL = 0), the lower 12 bits, [11:0], are valid. In left-justified format (DADPR.DPSEL = 1), the upper 12 bits, [15:4], are valid.

### 39.2.2 DACR : D/A Control Register

Base address: DAC12 = 0x4017_1000

Offset address: 0x04

| Bit position: | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|
| Bit field: | — | DAOE 0 | — | — | — | — | — | — |
| Value after reset: | 0 | 0 | 0 | 1 | 1 | 1 | 1 | 1 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 4:0 | — | These bits are read as 1. The write value should be 1. | R/W |
| 5 | — | This bit is read as 0. The write value should be 0. | R/W |
| 6 | DAOE0 | D/A Output Enable 0<br>0: Disable analog output of channel 0 (DA0)<br>1: Enable D/A conversion of channel 0 (DA0) | R/W |
| 7 | — | This bit is read as 0. The write value should be 0. | R/W |

Note: If the security attribution is configured as Secure:
- Secure access and Non-secure read access are allowed
- Non-secure write access is ignored, and TrustZone access error is not generated.

If the security attribution is configured as Non-secure:
- Secure and Non-secure access are allowed.

Only set this register while the ADC12 is halted when the DAADSCR.DAADST bit is 1 (interference reduction between D/A and A/D conversion is enabled). Only set DACR while the ADCSR.ADST bit is 0 and after selecting the software trigger, for the ADC12 trigger to securely stop the ADC12.

**DAOE0 bit (D/A Output Enable 0)**

The DAOE0 bit enables D/A conversion and analog output. When interference reduction between D/A and A/D conversions is enabled (DAADSCR.DAADST = 1), only set the DAOE0 bit while the ADC12 is halted (ADCSR.ADST = 0) and software trigger is selected as the ADC12 trigger.

The event link function can be used to set the DAOE0 bit to 1. The DAOE0 bit becomes 1 when the event specified in the ELSR12 register for the ELC_DA0 event occurs.

### 39.2.3 DADPR : DADR0 Format Select Register

Base address: DAC12 = 0x4017_1000

Offset address: 0x05

| Bit position: | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|
| Bit field: | DPSEL | — | — | — | — | — | — | — |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 6:0 | — | These bits are read as 0. The write value should be 0. | R/W |
| 7 | DPSEL | DADR0 Format Select<br>0: Right-justified format<br>1: Left-justified format | R/W |

Note: If the security attribution is configured as Secure:
- Secure access and Non-secure read access are allowed
- Non-secure write access is ignored, and TrustZone access error is not generated.

If the security attribution is configured as Non-secure:
- Secure and Non-secure access are allowed.

### 39.2.4 DAADSCR : D/A A/D Synchronous Start Control Register

Base address: DAC12 = 0x4017_1000

Offset address: 0x06

| Bit position: | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|
| Bit field: | DAADST | — | — | — | — | — | — | — |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 6:0 | — | These bits are read as 0. The write value should be 0. | R/W |
| 7 | DAADST | D/A A/D Synchronous Conversion<br>0: Do not synchronize DAC12 with ADC12 operation (disable interference reduction between D/A and A/D conversion).<br>1: Synchronize DAC12 with ADC12 operation (enable interference reduction between D/A and A/D conversion). | R/W |

Note: If the security attribution is configured as Secure:
- Secure access and Non-secure read access are allowed
- Non-secure write access is ignored, and TrustZone access error is not generated.

If the security attribution is configured as Non-secure:
- Secure and Non-secure access are allowed.

To minimize interference between D/A and A/D conversion, the DAADSCR register enables synchronization of the start timing of D/A conversion with the ADC12 synchronous D/A conversion enable input signal.

Only set this register while the ADC12 is halted, that is, while the ADCSR.ADST bit is 0 after selecting the software trigger as the ADC12 trigger.

#### DAADST bit (D/A A/D Synchronous Conversion)

Setting the DAADST bit to 0 allows the DADR0 register value to be converted into analog data at any time. Setting the DAADST bit to 1 allows synchronization of D/A conversion with the synchronous D/A conversion enable input signal from the ADC12. With this bit set, D/A conversion does not start until the ADC12 completes A/D conversion, even when the DADR0 register is changed.

Set this bit while the ADCSR.ADST bit is set to 0. Then, select the software trigger for the ADC12 trigger to securely stop the ADC12.

The event link function cannot be used when the DAADST bit is set to 1. Stop the event link function by setting the ELSR12 register of the ELC.

### 39.2.5 DAVREFCR : D/A VREF Control Register

Base address: DAC12 = 0x4017_1000

Offset address: 0x07

| Bit position: | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | — | — | — | — | REF |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 0 | REF | D/A Reference Voltage Select<br>0: No reference voltage selected.<br>1: AVCC0/AVSS0 selected. | R/W |
| 7:1 | — | These bits are read as 0. The write value should be 0. | R/W |

Note: If the security attribution is configured as Secure:
- Secure access and Non-secure read access are allowed
- Non-secure write access is ignored, and TrustZone access error is not generated.

If the security attribution is configured as Non-secure:
- Secure and Non-secure access are allowed.

The D/A VREF Control Register (DAVREFCR) selects the reference voltage of the DAC12.

#### REF bit (D/A Reference Voltage Select)

The REF bit selects the reference voltage of DAC12. When changing the value of this bit, write 0 to it in advance. Do not rewrite this register during A/D conversion. If this register is rewritten, the accuracy of A/D conversion is not guaranteed.

## 39.3 Operation

The DAC12 includes D/A conversion circuits for one channel. When the DAOEn bit (n = 0) in DACR is set to 1, DAC12 is enabled and the conversion result is output.

This following example shows D/A conversion on channel 0. Figure 39.2 shows the timing of this operation.

To process D/A conversion on channel 0:

1. Set the data for D/A conversion in the DADR0 register and the data format in the DADPR.DPSEL bit.
2. Set the DACR.DAOE0 bit to 1 to start D/A conversion. The conversion result is output from the analog output pin DA0 after the conversion time $t_{DCONV}$ elapses. The conversion result continues to be output until DADR0 is written to again or the DAOE0 bit is set to 0. The output value (reference) is expressed by the following formula:

$$\frac{\text{Setting in DADR0}}{4096} \times \text{AVCC0}$$

3. To start conversion again, write another value to DADR0. The conversion result is output after the conversion time $t_{DCONV}$ elapses.
   When the DAADSCR.DAADST bit is 1 (interference reduction between D/A and A/D conversion is enabled), a maximum of one A/D conversion time is required for D/A conversion to start. When ADCLK is faster than the peripheral clock, a longer time might be required.
4. To disable analog output, set the DAOE0 bit to 0.

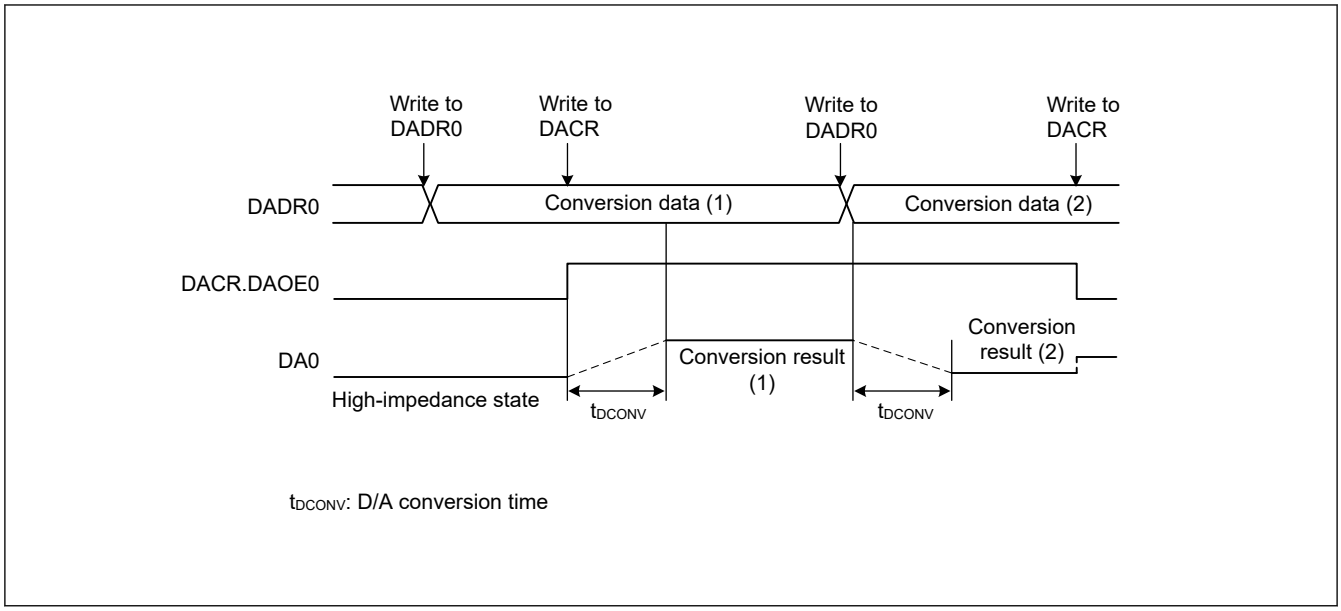

**Figure 39.2 Example of DAC12 operation**

### 39.3.1 Reducing Interference between D/A and A/D Conversion

When D/A conversion starts, the DAC12 generates inrush current. Because the DAC12 and ADC12 share the same analog power supply, the generated inrush current can interfere with ADC12 operation.

While the DAADSCR.DAADST bit is 1, D/A conversion does not start immediately on updating the DADR0 register. Instead:

- If the DADR0 register data is modified while the ADC12 is halted, D/A conversion starts in 1 PCLKA cycle.
- If the DADR0 register data is modified while the ADC12 is performing a 12-bit A/D conversion, D/A conversion starts on A/D conversion completion. Therefore, it takes up to one A/D conversion time period for the DADR0 register data update to be reflected as the D/A conversion circuit output. Until the D/A conversion completes, the DADR0 register value does not correspond to the analog output value.

When the DAADSCR.DAADST bit is 1, it is not possible to check through software whether the DADR0 register value was D/A-converted.

The following sequence provides an example of D/A conversion, in which the DAC12 is synchronized with the ADC12. Figure 39.3 shows the timing of this operation.

To perform D/A conversion in synchronization with the ADC12:

1. Confirm that the ADC12 is halted and set the DAADSCR.DAADST bit to 1.
2. Confirm that the ADC12 is halted and set the DACR.DAOE0 bit to 1.
3. Set the DADR0 register. If ADCLK is faster than the peripheral clock, D/A conversion might be delayed for longer than one A/D conversion time.
   - If the ADC12 is halted (ADCSR.ADST = 0) when the DADR0 register is modified, D/A conversion starts in 1 PCLKA cycle.
   - If the 12-bit A/D conversion is in progress (ADCSR.ADST = 1) when the DADR0 register is modified, D/A conversion starts on A/D conversion completion. If the DADR0 register is modified twice during A/D conversion, the first update might not be converted.

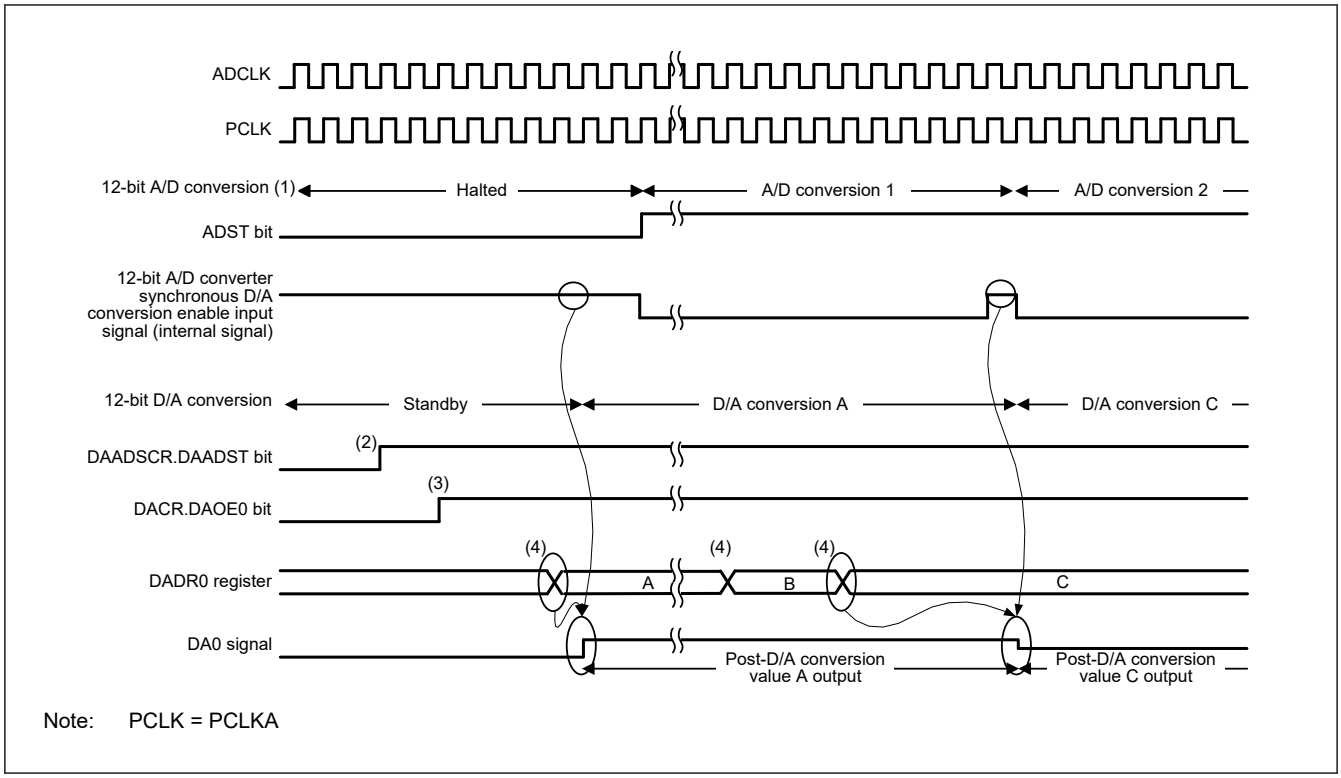

**Figure 39.3 Example conversion when DAC12 is synchronized with ADC12**

When ADCLK is faster than PCLKA, the DAC12 might not be able to capture the synchronous D/A conversion enable input signal from the ADC12 during the 1 ADCLK cycle that is output between A/D conversion 1 and A/D conversion 2, as shown in Figure 39.4. In this case, post-D/A conversion value A is continuously output as the DA0 signal.

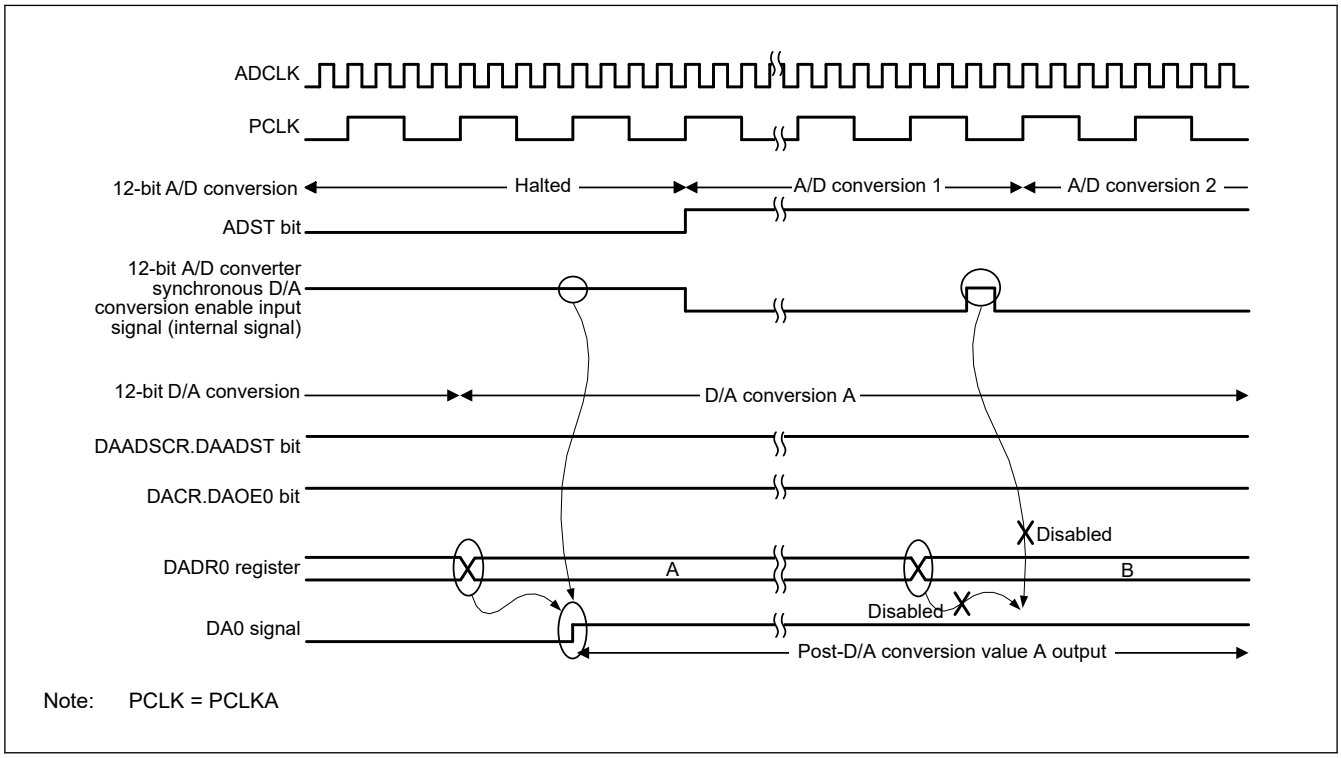

**Figure 39.4 Example when the DAC12 cannot capture the synchronous D/A conversion enable input signal from the ADC12**

## 39.4 Event Link Operation Setting Procedure

This section describes the procedures used in event link operation.

### 39.4.1 DA0 Event Link Operation Setting Procedure

To set up DA0 event link operation:

1. Set the DADPR.DPSEL bit and the data for D/A conversion in the DADR0 register.
2. Set the ELC_DA0 event signal to be linked to each peripheral module in the ELSR12 register.
3. Set the ELCR.ELCON bit to 1. This enables event link operation for all modules with the event link function selected.
4. Set the event output source module to activate the event link. After the event is output from the module, the DACR.DAOE0 bit becomes 1, and D/A conversion starts on channel 0.
5. Set the ELSR12 register to 0x0000 to stop event link operation of DAC12 channel 0. All event link operation is stopped when the ELCR.ELCON bit is set to 0.

## 39.5 Usage Notes on Event Link Operation

- When the event specified for the ELC_DA0 event signal is generated while a write to the DACR.DAOE0 bit is performed, the write cycle is stopped, and the generated event takes precedence in setting the bit to 1.
- Use of the event link function is prohibited when the DAADSCR.DAADST bit is set to 1 to reduce interference between D/A and A/D conversions.

## 39.6 Usage Notes

### 39.6.1 Settings for the Module-Stop Function

DAC12 operation can be disabled or enabled using the Module Stop Control Register. The DAC12 is initially stopped after reset. Releasing the module-stop state enables access to the registers. For details, see section 10, Low Power Modes.

### 39.6.2 DAC12 Operation in the Module-Stop State

When the MCU enters the module-stop state with D/A conversion enabled, the D/A outputs are retained, and the analog power supply current is the same as during D/A conversion. If the analog power supply current must be reduced in the module-stop state, disable D/A conversion by setting the DACR.DAOE0 bit to 0.

### 39.6.3 DAC12 Operation in Software Standby Mode

When the MCU enters Software Standby mode with D/A conversion enabled, the D/A outputs are retained, and the analog power supply current is the same as during D/A conversion. If the analog power supply current must be reduced in Software Standby mode, disable D/A conversion by setting the DACR.DAOE0 bit to 0.

### 39.6.4 Constraint on Usage When Interference Reduction between D/A and A/D Conversion Is Enabled

When the DAADSCR.DAADST bit is 1, enabling interference reduction between D/A and A/D conversion, do not place the ADC12 in the module-stop state. Doing so can halt D/A conversion in addition to A/D conversion.

# 40. Temperature Sensor (TSN)

## 40.1 Overview

The on-chip Temperature Sensor (TSN) determines and monitors the die temperature for reliable operation of the device. The sensor outputs a voltage directly proportional to the die temperature, and the relationship between the die temperature and the output voltage is fairly linear. The output voltage is provided to the ADC12 for conversion and can be further used by the end application.

Table 40.1 lists the TSN specifications, and Figure 40.1 shows a block diagram.

**Table 40.1 TSN specifications**

| Item | Description |
|---|---|
| Temperature sensor voltage output | Temperature sensor outputs a voltage to the 12-bit A/D converter |

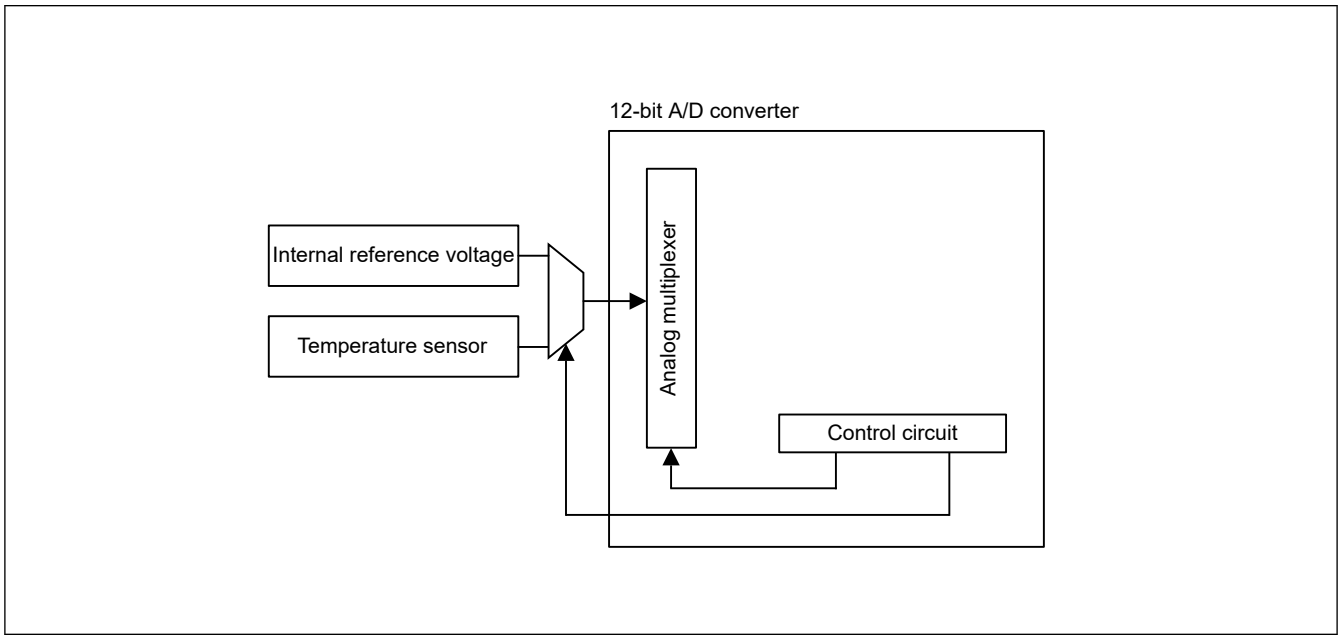

**Figure 40.1 TSN block diagram**

## 40.2 Register Descriptions

### 40.2.1 TSCDR : Temperature Sensor Calibration Data Register

Base address: FLCN = 0x407E_C000

Offset Address: 0x0228

| Bit position: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | | | | | | | | | | | | | | | | |
| Value after reset: | Chip-specific value | | | | | | | | | | | | | | | |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 15:0 | n/a | Temperature Sensor Calibration Data<br>Chip-specific value | R |

The TSCDR register stores temperature sensor calibration data measured for each chip at factory shipment.

Temperature sensor calibration data is the output voltage of the temperature sensor under the conditions Tj = 140°C and AVCC0 = 3.0 V converted to a digital value by the 12-bit A/D converter.

Temperature sensor calibration data is stored in the lower 12 bits of the TSCDR register.

## 40.3 Using the Temperature Sensor

The temperature sensor outputs a voltage that varies with the temperature. This voltage is converted to a digital value by the 12-bit A/D converter. To obtain the die temperature, convert this value into the temperature.

### 40.3.1 Preparation for Using the Temperature Sensor

The ambient temperature (T) is proportional to the temperature sensor voltage output (Vs), so ambient temperature is calculated with the following formula:

T = (Vs - V1) / slope + T1

- T: Ambient temperature of MCU as calculation result (°C)
- Vs: Voltage output by the temperature sensor on temperature measurement (V)
- T1: Temperature experimentally measured at one point (°C)
- V1: Voltage output by the temperature sensor on measurement of T1 (V)
- T2: Temperature experimentally measured at a second point (°C)
- V2: Voltage output by the temperature sensor on measurement of T2 (V)
- Slope: Temperature gradient of the temperature sensor (V / °C), slope = (V2 - V1) / (T2 -T1)

Characteristics vary between sensors, so Renesas recommends measuring two different sample temperatures as follows:

1. Use the 12-bit A/D converter to measure the voltage V1 output by the temperature sensor at temperature T1.
2. Again use the 12-bit A/D converter to measure the voltage V2 output by the temperature sensor at a different temperature T2.
3. Obtain the temperature gradient (slope = (V2 - V1) / (T2 - T1)) from these results.
4. Subsequently, obtain temperatures by substituting the slope into the formula for the temperature characteristic (T = (Vs -V1) / slope + T1).

If you are using the temperature gradient given in section 49, Electrical Characteristics, use the A/D converter to measure the voltage V1 output by the temperature sensor at temperature T1, then calculate the temperature characteristic using the following formula:

T = (Vs - V1) / slope + T1

Note: This method produces less accurate temperatures than measurement at two points.

In this MCU, the TSCDR register stores the temperature value (CAL140) of the temperature sensor measured under the condition Ta = Tj = 140°C and AVCC0 = 3.0 V. If you use this value as the sample measurement result at the first point, you can omit the preparation before using the temperature sensor.

CAL140 = TSCDR register value

V1 is calculated from CAL140:

V1 = 3.0 × CAL140 / 4096 [V] (In case of 12 bit accuracy)

Using this value, the measured temperature can be calculated according to the following formula:

T = (Vs - V1) / slope + 140 [°C]

- T: Ambient temperature of MCU as calculation result (°C)
- Vs: Voltage output by the temperature sensor when the temperature is measured (V)
- V1: Voltage output by the temperature sensor when Ta = Tj = 140°C and AVCC0 = 3.0 V (V)
- Slope: Temperature gradient of the temperature sensor*1 / 1000 (V/°C)

Note 1. See section 49, Electrical Characteristics

Figure 40.2 shows the error in the measured temperature. The variation range is 3σ.

Regarding the characteristics of the 12-bit A/D converter, the typical values are used. See section 49.5. ADC12 Characteristics.

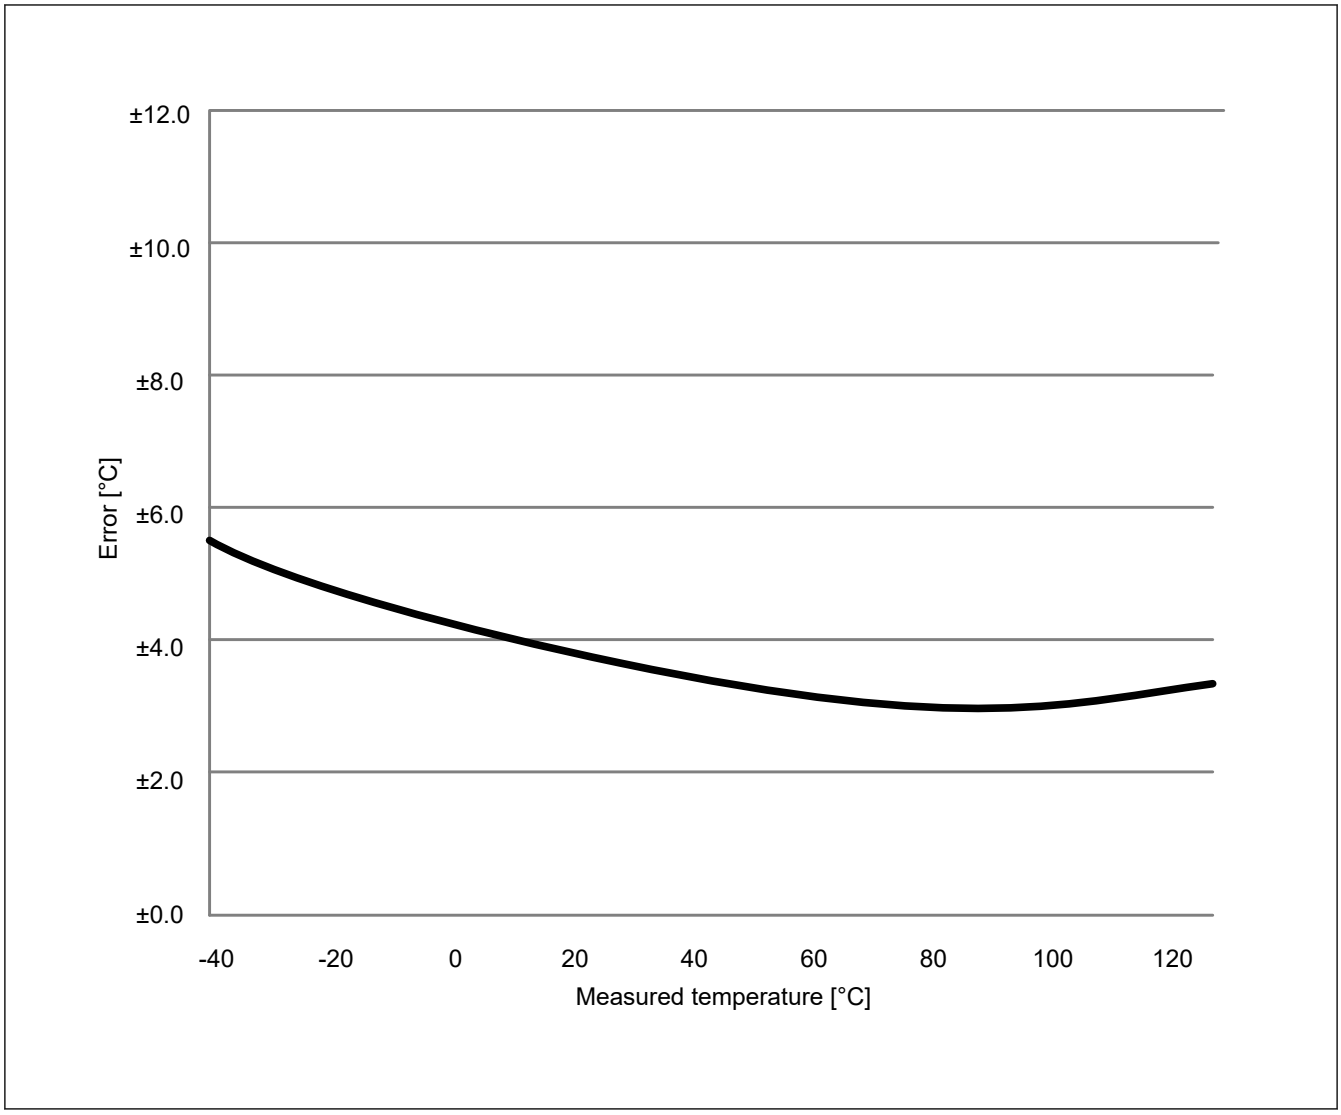

**Figure 40.2 Error in the measured temperature (designed values)**

### 40.3.2 Procedures for Using the Temperature Sensor

For details, see section 38, 12-Bit A/D Converter (ADC12).

# 41. Low Power Analog Comparator (ACMPLP)

## 41.1 Overview

The Low-Power Analog Comparator (ACMPLP) compares a reference input voltage with an analog input voltage. Comparator channels ACMPLP0 and ACMPLP1 are independent of each other.

The comparison result of the reference input voltage and analog input voltage can be read by software. The comparison result can also be output externally. The reference input voltage can be selected from either an input to the CMPREFi (i = 0, 1) pin or from the internal reference voltage (Vref) generated internally in the MCU.

The ACMPLP response speed can be set before starting an operation. Setting high-speed mode decreases the response delay time, but increases current consumption. Setting low-speed mode increases the response delay time, but decreases current consumption.

Table 41.1 lists the features of the ACMPLP, Figure 41.1 shows a block diagram of the ACMPLP when the window function is disabled, and Figure 41.2 shows a block diagram of the ACMPLP when the window function is enabled. Table 41.2 lists the I/O pins of the ACMPLP.

**Table 41.1 ACMPLP features**

| Item | Description |
|---|---|
| Number of channels | 2 channels: ACMPLP0 and ACMPLP1 |
| Analog input voltage | Input from CMPINi (i = 0, 1) pin |
| Reference voltage | • Internal reference voltage (Vref)<br>• Input from CMPREFi (i = 0, 1) pin |
| Comparator output | • Comparison result<br>• Generation of ELC event output<br>• Monitor output from register |

| 4 | C1ENB | ACMPLP1 Operation Enable<br>0: Disable ACMPLP1 operation<br>1: Enable ACMPLP1 operation | R/W |
| 5 | C1WDE | ACMPLP1 Window Function Mode Enable*1 *2<br>0: Disable ACMPLP1 window function mode<br>1: Enable ACMPLP1 window function mode | R/W |
| 6 | C1VRF | ACMPLP1 Reference Voltage Selection<br>0: Select CMPREF1 input as ACMPLP1 reference voltage.<br>1: Select internal reference voltage (Vref) as ACMPLP1 reference voltage.*4 | R/W |
| 7 | C1MON | ACMPLP1 Monitor Flag*3<br>When the window function is disabled:<br>0: CMPIN1 < CMPREF1, CMPIN1 < internal reference voltage, or ACMPLP1 operation disabled.<br>1: CMPIN1 > CMPREF1, or CMPIN1 > internal reference voltage.<br>When the window function is enabled:<br>0: CMPIN1 < VRFL, CMPIN1 > VRFH, or ACMPLP operation disabled.<br>1: VRFL < CMPIN1 < VRFH. | R |

Note 1. Window function mode cannot be set when Low-speed mode is selected (the SPDMD bit in the COMPOCR register is 0).
Note 2. In window function mode, the reference voltage in the comparator is selected regardless of the setting of this bit.
Note 3. The initial value is 0 immediately after a reset is released. However, the value is undefined when C0ENB is set to 0 and C1ENB is set to 0 after operation of the comparator is enabled once.

Note 4. The internal reference voltage (Vref) can be selected as ACMPLP reference voltage only when 2.90 V ≤ VCC ≤ 3.6 V.

## 41.2.2 COMPFIR : ACMPLP Filter Control Register

Base address: ACMPLP = 0x400F_4000

Offset address: 0x01

| Bit position: | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|
| Bit field: | C1EDG | C1EPO | C1FCK[1:0] | | C0EDG | C0EPO | C0FCK[1:0] | |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 1:0 | C0FCK[1:0] | ACMPLP0 Filter Select*1<br>0 0: No Sampling (bypass)<br>0 1: Sampling at PCLKB<br>1 0: Sampling at PCLKB/8<br>1 1: Sampling at PCLKB/32 | R/W |
| 2 | C0EPO | ACMPLP0 Edge Polarity Switching*1<br>0: Interrupt and ELC event request on rising edge<br>1: Interrupt and ELC event request on falling edge | R/W |
| 3 | C0EDG | ACMPLP0 Edge Detection Selection*1<br>0: Interrupt and ELC event request by one-edge detection<br>1: Interrupt and ELC event request by both-edge detection | R/W |
| 5:4 | C1FCK[1:0] | ACMPLP1 Filter Select*1<br>0 0: No Sampling (bypass)<br>0 1: Sampling at PCLKB<br>1 0: Sampling at PCLKB/8<br>1 1: Sampling at PCLKB/32 | R/W |
| 6 | C1EPO | ACMPLP1 Edge Polarity Switching*1<br>0: Interrupt and ELC event request on rising edge<br>1: Interrupt and ELC event request on falling edge | R/W |
| 7 | C1EDG | ACMPLP1 Edge Detection Selection*1<br>0: Interrupt and ELC event request by one-edge detection<br>1: Interrupt and ELC event request by both-edge detection | R/W |

Note 1. If bits CiFCK[1:0], CiEPO, and CiEDG (i = 0, 1) are changed, an ACMPLP interrupt request and an ELC event request can be generated. Change these bits only after setting event link to deselect. Also, be sure to clear the associated interrupt request flag.

## 41.2.3 COMPOCR : ACMPLP Output Control Register

Base address: ACMPLP = 0x400F_4000

Offset address: 0x02

| Bit position: | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|
| Bit field: | SPDMD | C1OP | C1OE | — | — | C0OP | C0OE | — |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 0 | — | This bit is read as 0. The write value should be 0. | R/W |
| 1 | C0OE | ACMPLP0 VCOUT Pin Output Enable*1<br>0: Disabled<br>1: Enabled | R/W |
| 2 | C0OP | ACMPLP0 VCOUT Output Polarity Selection*1<br>0: Non-inverted<br>1: Inverted | R/W |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 4:3 | — | These bits are read as 0. The write value should be 0. | R/W |
| 5 | C1OE | ACMPLP1 VCOUT Pin Output Enable*1<br>0: Disabled<br>1: Enabled | R/W |
| 6 | C1OP | ACMPLP1 VCOUT Output Polarity Selection*1<br>0: Non-inverted<br>1: Inverted | R/W |
| 7 | SPDMD | ACMPLP0/ACMPLP1 Speed Selection*2<br>0: Low-speed mode<br>1: High-speed mode | R/W |

Note 1. ACMPLP0 and ACMPLP1 result outputs are bundled on the VCOUT pin.
Note 2. Set the CiENB bit (i = 0, 1) in the COMPMDR register to 0 before rewriting the SPDMD bit.

## 41.3 Operation

ACMPLP0 and ACMPLP1 operate independently, and their operations are the same. Operation is not guaranteed when the values of their associated registers are changed during comparator operation. Table 41.3 shows the procedure for setting the ACMPLP registers.

**Table 41.3 Procedure for setting the ACMPLP associated registers (i = 0, 1)**

| Step number | Register | Bit | Setting | | |
|---|---|---|---|---|---|
| 1 | MSTPCRD | MSTPD29 | 0: Input clock supply. | | |
| 2 | Corresponding Port mn Pin Function Select Register (PmnPFS) | ASEL | 1: Select the function of pins CMPREFi and CMPINi. | | |
| 3 | COMPOCR | SPDMD | Select the comparator response speed*1<br>0: Low-speed mode<br>1: High-speed mode | | |
| 4 | COMPMDR | CiWDE | 0: Disable window function mode | | 1: Enable window function mode*2 |
| | | CiVRF | 0: Reference = CMPREFi input | 1: Reference = Internal reference voltage | Window comparator operation (reference = VRFL and VRFH*3) |
| | | CiENB | 1: Operation enabled | | |
| 5 | Waiting for the comparator stabilization time $T_{cmp}$ (minimum 100 µs). | | | | |
| 6 | COMPFIR | CiFCK[1:0] | Select whether the digital filter is used or not and the sampling clock. | | |
| | | CiEPO, CiEDG | Select the edge detection condition for an interrupt request (rising edge/ falling edge/both edges). | | |
| 7 | COMPOCR | CiOP, CiOE | Set the VCOUT output (select the polarity and set output enabled or disabled). | | |
| | Corresponding Port mn Pin Function Select Register (PmnPFS) | PSEL, PMR | Select the VCOUT port function. | | |
| 8 | IELSRn | IR, IELS[4:0] | When using an interrupt: select the interrupt status flag, ICU event link select.*3 | | |
| 9 | ELSRn | ELS[7:0] | When using an ELC: Select the Event Link Select.*4 | | |
| 10 | Operation started | | | | |

Note 1. ACMPLP0 and ACMPLP1 cannot be set independently.
Note 2. Can be set in high-speed mode (SPDMD = 1).
Note 3. After the setting of the comparator, a spurious interrupt may occur until operation becomes stable, so initialize the interrupt flag.
Note 4. After the setting of the comparator, a spurious interrupt may occur until operation becomes stable, so initialize the event link select.

Figure 41.3 shows an operating example of the ACMPLPi (i = 0, 1) when the window function is disabled. The reference input voltage (CMPREFi) or internal reference voltage (Vref) and the analog input voltage (CMPINi) are compared. If the analog input voltage is higher than the reference input voltage, the COMPMDR.CiMON bit is set to 1. If the analog input voltage is lower than the reference input voltage, the CiMON bit is set to 0.

ACMPLPi outputs an interrupt to ICU. For details on the interrupt, see section 41.5. ACMPLP Interrupts.

ACMPLPi outputs an event signal to the ELC to activate other modules. For details on the ELC, see section 41.6. ELC Event Output.

Do not change the values of the registers during comparison.

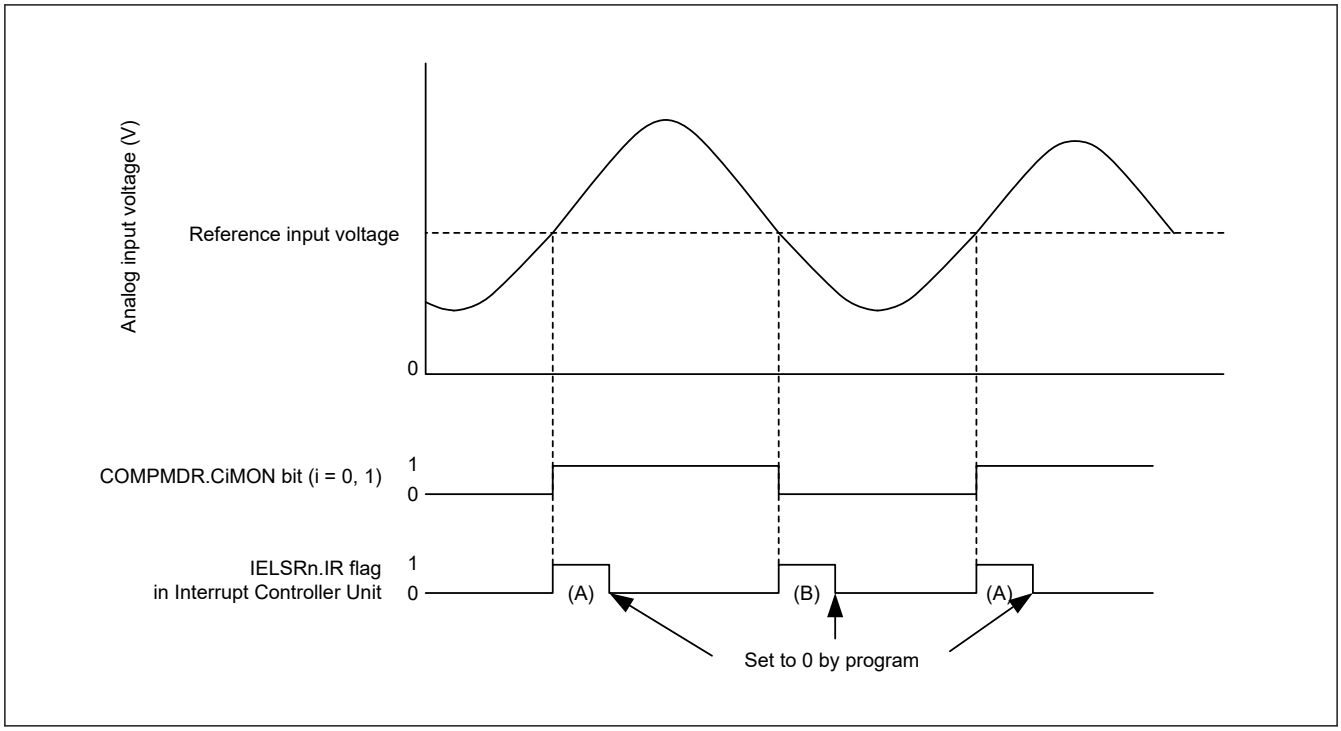

**Figure 41.3 Operating example of ACMPLPi (i = 0, 1) when window function is disabled**

Figure 41.3 applies when the following conditions are met:

- CiFCK[1:0] = 00b (no sampling) and CiEDG = 1 (both edges)
- When CiEDG = 0 and CiEPO = 0 (rising edge), IELSRn.IR changes as shown by (A) only
- When CiEDG = 0 and CiEPO = 1 (falling edge), IELSRn.IR changes as shown by (B) only.

Figure 41.4 shows an operation example of ACMPLPi (i = 0, 1) when the window function is enabled.

The reference voltage (IVREF0/IVREF1) and the analog input voltage are compared. The CiMON bit:

- Is set to 1 when IVREF0 < the analog input voltage < IVREF1
- Is set to 0 when the analog input voltage < IVREF0 or IVREF1 < the analog input voltage.

ACMPLPi outputs an interrupt to ICU. For details on the interrupt, see section 41.5. ACMPLP Interrupts.

ACMPLPi outputs an event signal to the ELC to activate other modules. For details on the ELC, see section 41.6. ELC Event Output.

Do not change the values of the registers during comparison.

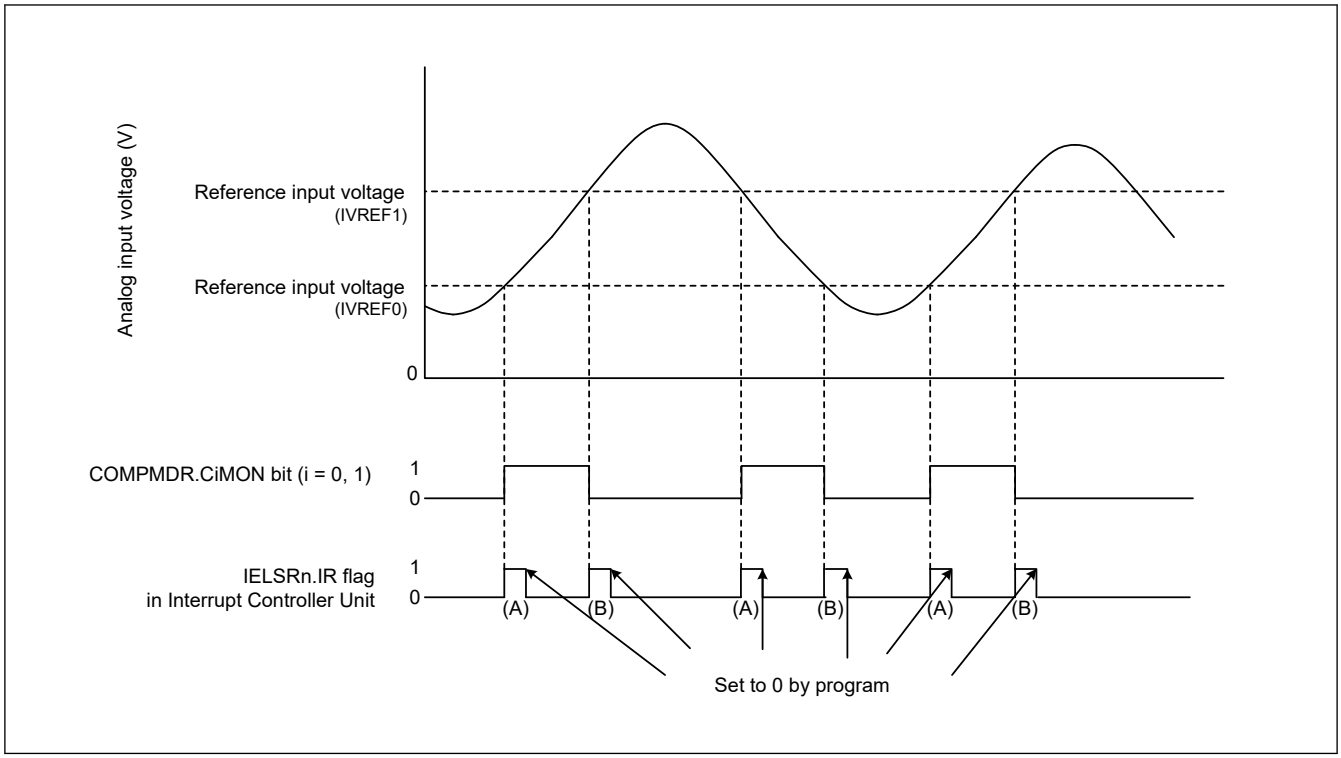

**Figure 41.4 Operating example of ACMPLPi (i = 0, 1) when window function is enabled**

Figure 41.4 applies when the following conditions are met:

- CiFCK[1:0] = 00b (no sampling) and CiEDG = 1 (both edges)
- When CiEDG = 0 and CiEPO = 0 (rising edge), IELSRn.IR changes as shown by (A) only
- When CiEDG = 0 and CiEPO = 1 (falling edge), IELSRn.IR changes as shown by (B) only.

## 41.4 Noise Filter

Figure 41.5 shows the configuration of the ACMPLPi noise filter, and Figure 41.6 shows an operating example of the ACMPLPi noise filter.

The sampling clock can be selected in the COMPFIR.CiFCK[1:0] bits. The ACMPLPi signal (internal signal) output from ACMPLPi is sampled at every sampling clock cycle. When the level matches three times, the corresponding IELSRn.IR bit is set to 1 (interrupt requested) and an ELC event is output.

When using an interrupt in Software Standby mode, set the COMPFIR.CiFCK[1:0] bits to 00b (bypass).

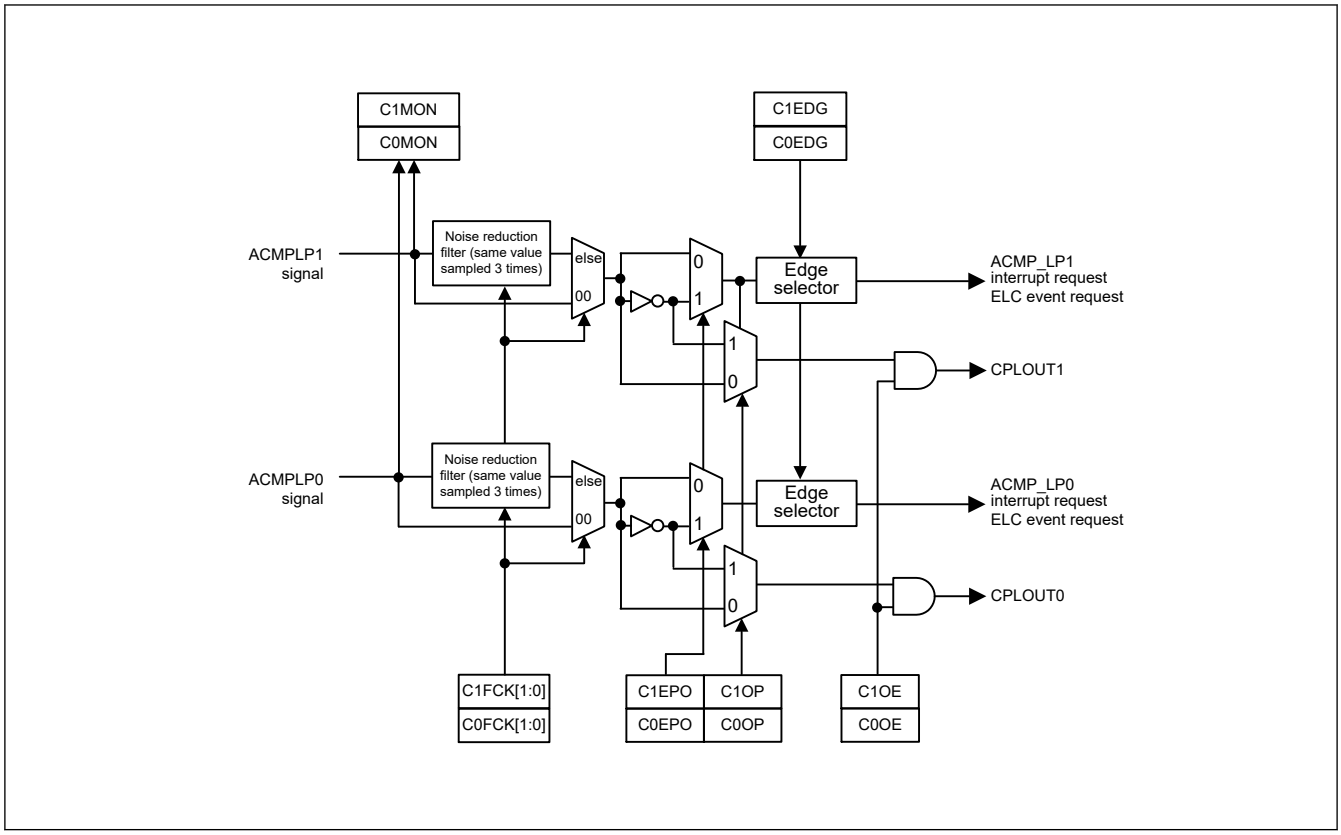

**Figure 41.5 Noise filter and edge detection configuration**

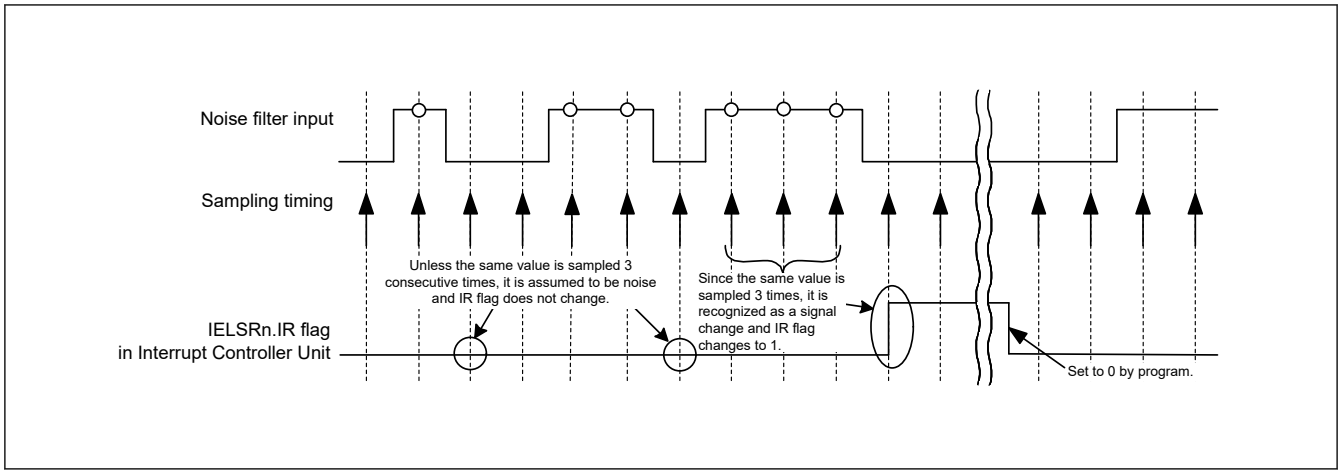

**Figure 41.6 Noise filter and interrupt operation example**

## 41.5 ACMPLP Interrupts

The ACMPLP generates interrupt requests from the ACMPLP0 and ACMPLP1 sources. To use the ACMPLPi (i = 0, 1) interrupt, select it in the IELSRn register in the ICU.

To use the ACMPLPi interrupt, select either single-edge detection or both-edge detection using the COMPFIR.CiEDG bit. When single-edge detection is selected, select the polarity using the CiEPO bit.

The interrupt output can also be passed through the noise filter, which uses one of the three different sampling clocks, as selected in the COMPFIR.CiFCK[1:0] bits. Set the COMPFIR.CiFCK[1:0] bits to 01b, 10b, or 11b to select the respective sampling clock. To use the ACMPLP0 interrupt request to release Software Standby mode or Snooze mode, set COMPFIR.C0FCK[1:0] to 00b (no sampling). The ACMPLP1 interrupt request cannot be used to release Software Standby mode or Snooze mode.

## 41.6 ELC Event Output

The ELC uses the ACMPLP interrupt request signal as an ELC event signal, enabling link operation for the preset module. To use the ELC events of the ACMPLP, select them in the ELSRn register in the ELC. When using ELC event request, set the COMPFIR.CiFCK[1:0] bits to 01b, 10b, or 11b.

## 41.7 Interrupt Handling and ELC Linking

ACMPLPi outputs event signals to the ELC to initiate operations of other modules selected in advance. In the same way as for the interrupt sources, the conditions for generation of the event signals output from ACMPLPi to the ELC can be selected as a single-edge detection or both-edge detection by setting the COMPFIR.CiEDG bit. When the single-edge detection is selected, the polarity can be selected in the CiEPO bit.

## 41.8 Comparator Pin Output

The comparison result from ACMPLPi can be output to external pins. Use the COMPOCR.CiOP and CiOE bits to set the output polarity (non-inverted output or inverted output) and to enable or disable the comparison output.

To output the ACMPLP comparison result to the VCOUT output pin, set the corresponding section 18.2.5. PmnPFS/PmnPFS_HA/PmnPFS_BY : Port mn Pin Function Select Register (m = 0 to 8, n = 00 to 15) in the I/O Ports chapter.

For the register settings and the associated comparator output, see section 41.2.3. COMPOCR : ACMPLP Output Control Register.

## 41.9 Usage Notes

### 41.9.1 Module-Stop Function Settings

The Module Stop Control Register can enable or disable the ACMPLP operation. The ACMPLP is initially stopped after reset. Releasing the module-stop state enables access to the registers. For details, see section 10, Low Power Modes.

# 42. Capacitive Touch Sensing Unit (CTSU)

## 42.1 Overview

The Capacitive Touch Sensing Unit (CTSU) measures the electrostatic capacitance of the sensor. Changes in the electrostatic capacitance are determined by software that enables the CTSU to detect whether a finger is in contact with the sensor. The electrode surface of the sensor is usually enclosed with a dielectric film so that a finger does not come into direct contact with the electrode.

As Figure 42.1 shows, electrostatic capacitance (parasitic capacitance) exists between the electrode and the surrounding conductors. Because the human body is an electrical conductor, when a finger is placed close to the electrode, the value of electrostatic capacitance increases.

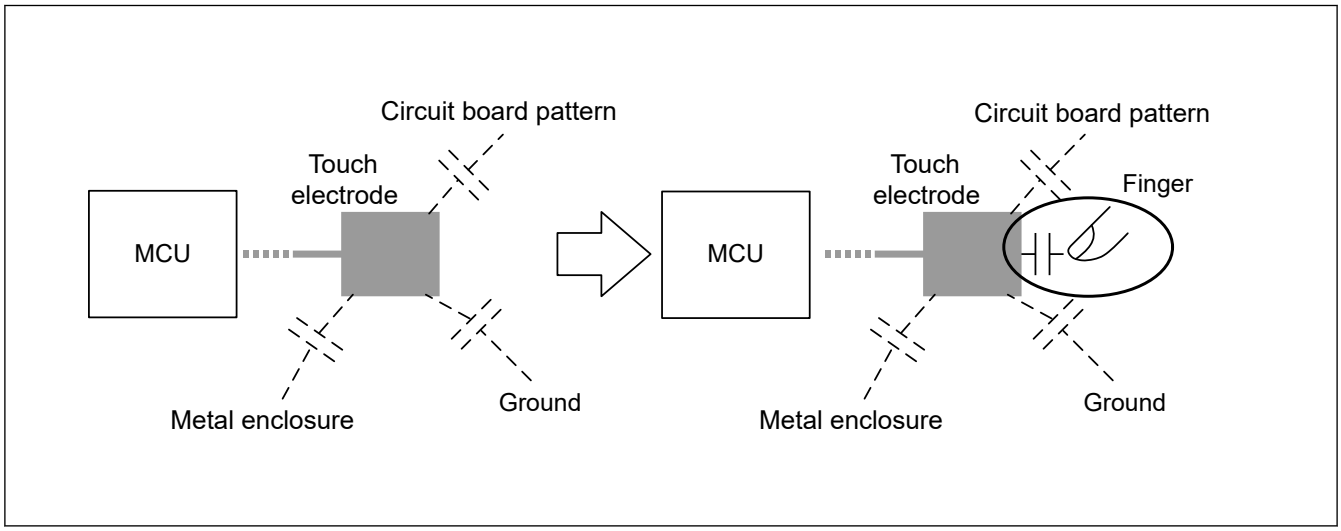

**Figure 42.1 Increased electrostatic capacitance because of the presence of a finger**

Electrostatic capacitance is detected by the self-capacitance and mutual capacitance methods. In the self-capacitance method, the CTSU detects electrostatic capacitance generated between a finger and a single electrode. In the mutual capacitance method, two electrodes are used one as a transmit electrode and the other as a receive electrode, and the CTSU detects the change in the electrostatic capacitance generated between the two when a finger is placed close to them.

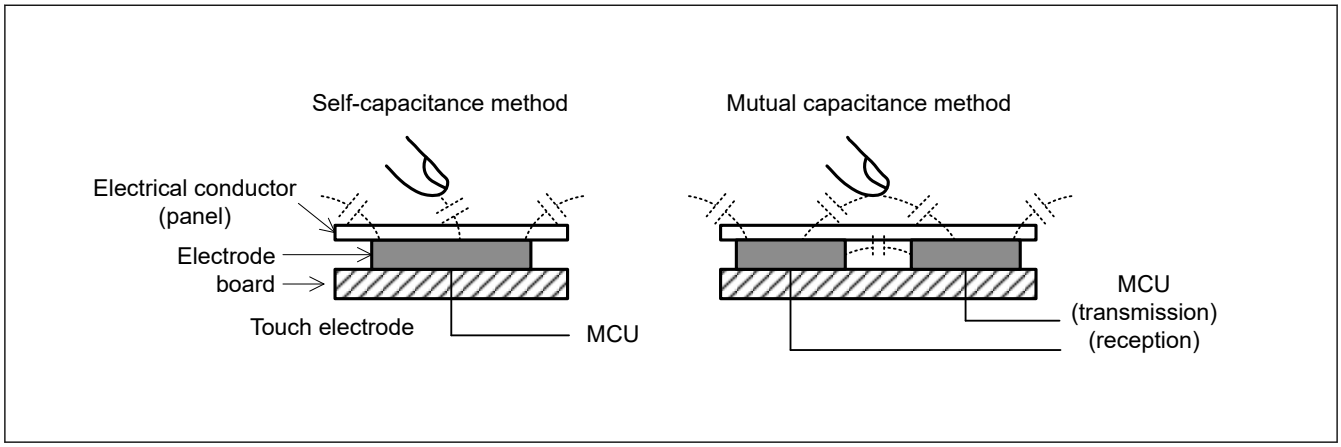

**Figure 42.2 Self-capacitance and mutual capacitance methods**

Electrostatic capacitance is measured by counting a clock signal whose frequency changes according to the amount of charged or discharged current, for a specified period.

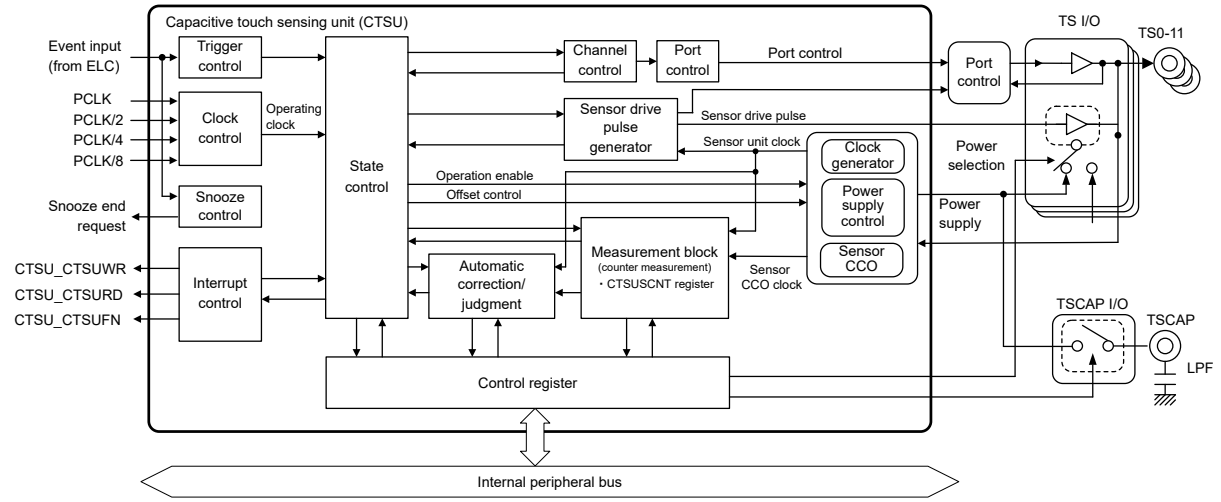

Table 42.1 lists the CTSU specifications and Figure 42.3 shows a block diagram.

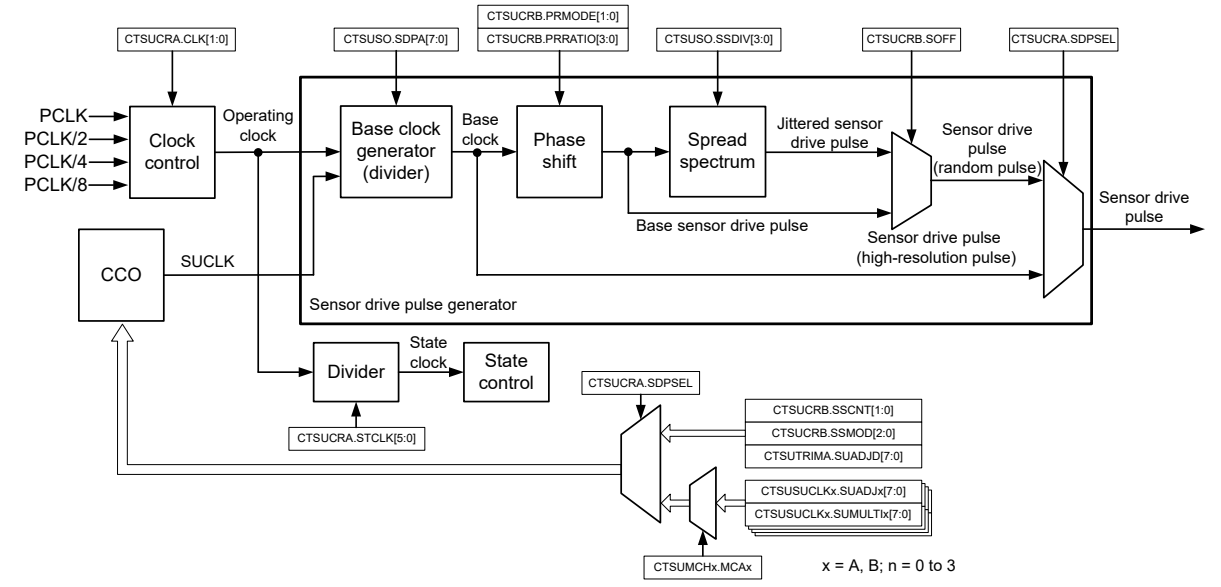
**Table 42.1 CTSU specifications**

| Parameter | | Specifications |
|---|---|---|
| Operating clock | | Selectable from PCLKB (at least 1 MHz), PCLKB/2, PCLKB/4, or PCLKB/8 |
| Pins | Electrostatic capacitance measurement | TS0 to TS11 pins (12 channels) |
| | TSCAP | Low Pass Filter (LPF) connection pin |
| Measurement modes | Self-capacitance measurement mode | The electrostatic capacitance is measured from the current that charges and discharges the capacitance of the electrode. |
| | Mutual capacitance method | The electrostatic capacitance is measured from the current that charges and discharges the capacitance between the transmitting electrode and the receiving electrode |
| | Current measurement mode | Direct measurement of current flowing through a pin |
| Scan mode | Single scan mode | Electrostatic capacitance on a channel is measured |
| | Multi-scan mode | Electrostatic capacitance on multiple channels is measured successively |
| Noise prevention | | • Spread spectrum<br>• Random phase shift<br>• Noise hopping by multiple sensor drive pulses with different frequency |
| Calibration per pin | | • Offset current<br>• Frequency of sensor drive pulse<br>• Measurement time |
| Measurement start conditions | | • Software trigger<br>• External trigger (ELC_CTSU from the Event Link Controller (ELC)) |
| Automatic operation | | • Automatic correction<br>• Automatic judgment |
| Low power operation | | Measurement under Snooze mode is available.<br>• Measurement starts by an external trigger input through ELC<br>• Snooze mode can be ended by non-touch judgment using the automatic judgment function<br>• Snooze mode can be released by the measurement end interrupt |
| Interrupt sources | | • Register setting request (CTSUWR)<br>• Measurement result read request (CTSURD)<br>• Measurement end (CTSUFN) |
| Event link function | | Measurement start trigger input |
| Module-stop function | | The module-stop state can be set to reduce power consumption |
| TrustZone Filter | | Security attribution can be set |



As shown in Figure 42.3, the CTSU consists of the following:

- Status control block
- Trigger control block
- Clock control block
- Channel control block
- Port control block
- Sensor drive pulse generator
- Measurement block
- Interrupt block
- Control registers

Note: PCLK = PCLKB

**Figure 42.3 CTSU block diagram**

Note: PCLK = PCLKB

**Figure 42.4 Generation of sensor drive pulse**

**Table 42.2 CTSU I/O pins**

| Pin name | I/O | Function |
|---|---|---|
| TS0 to TS11 | I/O | Electrostatic capacitive measurement pins (touch pins) |
| TSCAP | — | Secondary power supply for measurement (capacitor) connection pin |

## 42.2 Register Descriptions

### 42.2.1 CTSUCRA/CTSUCRAH/CTSUCRAL/CTSUCR3/CTSUCR2/CTSUCR1/ CTSUCR0 : CTSU Control Register A

Base address: CTSU = 0x400D_0000

Offset address: 0x00 (CTSUCRA/CTSUCRAL/CTSUCR0)
0x01 (CTSUCR1)
0x02 (CTSUCRAH/CTSUCR2)
0x03 (CTSUCR3)

| Bit position: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

| 23 | PCSEL | CTSU Boost Circuit Clock Select<br>0: Sensor drive pulse divided by 2<br>1: STCLK | R/W |
| 29:24 | STCLK[5:0] | CTSU STCLK Select<br>0x00: Operating clock divided by 2<br>0x01: Operating clock divided by 4<br>0x02: Operating clock divided by 6<br>⋮<br>0x3E: Operating clock divided by 126<br>0x3F: Operating clock divided by 128 | R/W |
| 30 | DCMODE | CTSU Current Measurement Mode Select<br>0: Electrostatic capacitance measurement mode<br>1: Current measurement mode | R/W |
| 31 | DCBACK | CTSU Current Measurement Feedback Select<br>0: TSCAP pin is selected<br>1: Measurement pin is selected. It is recommended in the current measurement mode. | R/W |

Note 1. When the CTSU is not used, set this bit to 0.

The CTSU Control Register A (CTSUCRA/CTSUCRAH/CTSUCRAL/CTSUCR3/CTSUCR2/CTSUCR1/CTSUCR0) is a 32-bit, 16-bit, and 8-bit read/write register. The CTSUCRA is accessed in 32-bit units. The CTSUCRAH (bits [31:16] in CTSUCRA) and CTSUCRAL (bits [15:0] in CTSUCRA) are accessed in 16-bit units. The CTSUCR3 (bits [31:24] in

CTSUCRA), CTSUCR2 (bits [23:16] in CTSUCRA), CTSUCR1 (bits [15:8] in CTSUCRA), and CTSUCR0 (bits [7:0] in CTSUCRA) are accessed in 8-bit units.

Only set the bits other than the STRT bit and INIT bit when the STRT bit is 0.

### STRT bit (CTSU Measurement Operation Start)

The STRT bit specifies whether CTSU operation starts or stops. When the CAP bit is 0, measurement is started by writing 1 to the STRT bit, and the STRT bit becomes 0 when measurement is finished. When the STRT bit is 1, the CTSU waits for an external trigger by writing 1 to the STRT bit, and measurement starts on the rising edge of the external trigger. When measurement is finished, the CTSU waits for the next external trigger and operation continues.

Table 42.3 lists the CTSU states.

**Table 42.3 CTSU state**

| STRT bit | CAP bit | CTSU state |
|---|---|---|
| 0 | 0 | Stopped |
| 0 | 1 | Stopped |
| 1 | 0 | Measurement in progress |
| 1 | 1 | Measurement in progress and waiting for an external trigger*1 |

Note 1. The state can be read from the CTSUSR.STC[2:0] flags as follows:

- During measurement: CTSUSR.STC[2:0] flags ≠ 000b
- While waiting for an external trigger: CTSUSR.STC[2:0] flags = 000b
- When the CTSU is not used, set this bit to 0.

If software sets the STRT bit to 1 when the bit is already 1, the write is ignored and operation continues. To force operation to stop through software when the STRT bit is 1, set the STRT bit to 0 and the INIT bit to 1 simultaneously.

### CAP bit (CTSU Measurement Operation Start Trigger Select)

The CAP bit specifies the measurement start condition. For details, see STRT bit (CTSU Measurement Operation Start).

### SNZ bit (CTSU Wait State Power-Saving Enable)

The SNZ bit enables or disables power-saving operation during a wait state. It can also suspend the CTSU analog macro which decreases power consumption during the wait state. In the suspended state, the CTSU power supply is turned off while the external TSCAP is still charged.

Table 42.4 shows the CTSU power supply state control.

**Table 42.4 CTSU power supply state control**

| PON bit | SNZ bit | CAP bit | STRT bit | External trigger | Hard macro (VDC) state |
|---|---|---|---|---|---|
| 0 | 0 | 0 | 0 | — | Stopped |
| 1 | 0 | — | — | — | Operating state |
| 1 | 1 | 0 | 0 | — | Suspended state |
| 1 | 1 | 1 | 1 | No (Waiting) | Suspended state |
| 1 | 1 | 1 | 1 | Yes (Operating) | Operating state |
| 1 | 1 | 0 | 0 | — | S/W Suspended state |
| Other than above | | | | | Setting prohibited |

By enabling the SNOOZE operation and setting the STRT bit to 1, the CPU can transition to STOP mode while waiting for an external trigger. When a falling edge of an external trigger is detected during STOP mode, CTSU issues a clock request to the clock generation block, transitions to the SNOOZE state, and starts measurement. Set the SNZ bit to 0 by software after the completion interrupt. When Sensor Unit clock (SUCLK) is selected for the sensor drive pulse (CTSUCRA.SDPSEL = 1) and the SNOOZE function is used, selection of the sensor drive pulse for the boost clock (CTSUCRA.PCSEL = 0) is prohibited.

#### INIT bit (CTSU Control Block Initialization)

Write 1 to the INIT bit to initialize the internal control registers. To force the current operation to stop, set the STRT bit to 0 and the INIT bit to 1 simultaneously. This stops the operation and initializes the internal control registers.

Do not write 1 to the INIT bit when the STRT bit is 1.

#### PUMPON bit (CTSU Boost Circuit Control)

The PUMPON bit turns on or off the boost circuit.

#### TXVSEL[1:0] bits (CTSU Transmission Power Supply Selection)

In measurement methods other than self-capacitance method, VCC is selected as the power supply for the transmit pins by setting the TXVSEL[1:0] bits to 01b. In self-capacitance method, VCC is selected as the power supply for the transmit pins used as transmit pulse output shield by setting the TXVSEL[1:0] bits to 10b. When the VCC voltage fluctuates greatly due to the switching of the output buffer, switching to the VCL can reduce the effect on the voltage fluctuation.

#### PON bit (CTSU Power On Control)

The PON bit controls the power supply to the CTSU.

#### CSW bit (TSCAP Pin Enable)

The CSW bit controls charging of the LPF capacitor connected to the TSCAP pin by turning the capacitance switch on or off. After the capacitance switch is turned on, wait about 1 ms until the capacitance connected to the TSCAP pin is charged before starting measurement by setting STRT to 1. Before starting measurement, use an I/O port to output low to the TSCAP pin, and discharge the existing LPF capacitance.

Set the PON to 1 only when CSW bit is 1. The CSW bit is set to 1 after the PUMPON bit is set to 1.

#### ATUNE0 bit (CTSU Power Supply Operating Mode Setting)

The ATUNE0 bit sets the power supply operating mode. Set this bit according to the lower limit of VCC to operate the CTSU.

#### ATUNE2 and ATUNE1 bits (CTSU Current Range Adjustment)

The ATUNE2 and ATUNE1 bits set the current range at the time of measurement. In general, setting these bits to 00b is recommended.

#### CLK[1:0] bits (CTSU Operating Clock Select)

The CLK[1:0] bits select the operating clock.

#### MD0 bit (CTSU Measurement Mode Select 0)

The MD0 bit selects the single scan or multi-scan mode. In single scan mode, electrostatic capacitance on a channel is measured. In multi-scan mode, electrostatic capacitance on all channels that are specified as measurement targets by setting the CTSUCHACn registers are measured sequentially in ascending order.

#### MD1 bit (CTSU Measurement Mode Select 1)

The MD1 bit selects the measurement method. If MD1 = 0, a channel is measured once. Set the MD1 bit to 0 when measuring in the self-capacitance method. If MD1 = 1 and the transmit channel is set, a channel is measured twice. In the first measurement, the in-phase pulse is output to the transmit channel and measured. In the second measurement, the reversed-phase pulse is output to the transmit channel and measured. Set the MD1 bit to 1 when measuring in the mutual capacitance method.

#### LOAD[1:0] bits (CTSU Load Control During Measurement)

The LOAD[1:0] bits control the measurement load.

#### POSEL[1:0] bits (CTSU Non-Measured Channel Output Select)

The POSEL[1:0] bits select the CTSU non-measured channel output.

#### SDPSEL bit (CTSU Sensor Drive Pulse Select)

The SDPSEL bit selects the sensor drive pulse.

When SDPSEL = 0, the random pulse mode is selected for sensor drive pulse. PCLKB divided by CTSUCRA.CLK[1:0] and CTSUS0.SDPA[7:0] bits setting (phased-shifted by the random number generated by the CTSUCRB.PRMODE[1:0] and CTSUCRB.PRATTIO[3:0] bits) is selected as the sensor drive pulse. It is also possible to apply jitter by frequency spreading clock.

When SDPSEL = 1, the normal pulse mode using the sensor unit clock is selected. The sensor drive clock is the sensor unit clock divided by the CTSUSO.SDPA[7:0] bits. In addition, it is possible to improve the noise immunity by multiplied clock in the sensor unit and switching the frequency of drive pulse or by using a majority decision processing the frequency measurement results of the clock in the sensor unit.

#### PCSEL bit (CTSU Boost Circuit Clock Select)

The PCSEL bit selects the clock for the boost circuit.

#### STCLK[5:0] bits (CTSU STCLK Select)

STCLK is the reference clock for measurement time. It is generated by dividing PCLKB. The STCLK [5:0] bits set the division value from PCLKB. The division value is determined by the following expression:

Division value = (STCLK[5:0] + 1) × 2

The STCLK frequency should be set to 0.5 MHz (2 µs).

#### DCMODE bit (CTSU Current Measurement Mode Select)

The DCMODE bit selects the capacitance measurement mode by switched-capacitor or the current measurement mode. In the current measurement mode, the switched-capacitor operation turns off and current is measured.

#### DCBACK bit (CTSU Current Measurement Feedback Select)

When DCMODE = 1, the DCBACK bit is enabled. When DCBACK = 1, the voltage of the TS pin is referenced during measurement.

### 42.2.2 CTSUCRB/CTSUCRBH/CTSUCRBL/CTSUDCLKC/CTSUSST/CTSUSDPRS : CTSU Control Register B

Base address: CTSU = 0x400D_0000

Offset address: 0x04 (CTSUCRB/CTSUCRBL/CTSUSDPRS)
0x05 (CTSUSST)
0x06 (CTSUCRBH)

| 31:30 | — | These bits are read as 0. The write value should be 0. | R/W |

Note: The CTSUCRB register should be set when the CTSUCRA.STRT bit is 0.
Note: The PRRATIO[3:0], PRMODE[1:0], and SOFF bits are valid when the CTSUCRA.SDPSEL bit is 0 (random pulse mode).

The CTSU Control Register B (CTSUCRB/CTSUCRBH/CTSUCRBL/CTSUDCLKC/CTSUSST/CTSUSDPRS) is a 32-bit, 16-bit, and 8-bit read/write register.

The CTSUCRB is accessed in 32-bit units. The CTSUCRBH (bits [31:16] in CTSUCRB) and CTSUCRBL (bits [15:0] in CTSUCRB) are accessed in 16-bit units. The CTSUDCLKC (bits [31:24] in CTSUCRB), CTSUSST (bits [15:8] in CTSUCRB), and CTSUSDPRS (bits [7:0] in CTSUCRB) are accessed in 8-bit units.

Only set the CTSUCRB/CTSUCRBH/CTSUCRBL/CTSUDCLKC/CTSUSST/CTSUSDPRS register when the CTSUCRA.STRT bit is 0.

### PRRATIO[3:0] bits (Phase Shift Frequency Setting)

The PRRATIO[3:0] bits are used to determine the measurement time and number of measured pulses. When CTSUCRA.SDPSEL = 0, these bits are enabled.

### PRMODE[1:0] bits (Pseudo-Random Number Generation Cycle Setting)

The PRMODE[1:0] bits select the number of base pulses that occur during measurement. When CTSUCRA.SDPSEL = 0, these bits are enabled.

### SOFF bit (Jitter Injection Off Setting)

The SOFF bit sets the function to reduce high frequency noise using SUCLK as a spread spectrum. This bit is enabled when CTSUCRA.SDPSEL = 0.

### PROFF bit (Pseudo-Random Number Off)

The PROFF bit turns on or off the CTSU random number. Set this bit to 1 to turn random number off. The random number generation outputs 1 or 0 per cycle. Random number generation is 1 bit.

### SST[7:0] bits (Sensor Stabilization Wait Time Setting)

The SST[7:0] bits are used to set the period from the supply of the sensor drive pulse to the stabilization of the voltage at the TSCAP pin.

The voltage at the TSCAP pin is stabilized by supplying a sensor drive pulse. The relationship between the value of these bits and the number of cycles is as follows.

- When the CTSUCRA.SDPSEL bit is 0
  Specify the stabilization wait time based on the number of cycles of the sensor drive pulse synchronized with PCLKB.
  Number of cycles = 2 × (SST[7:0] bit value + 1)
  Set the stabilization wait time within the following range:
  Number of cycles set by SST [7: 0] bits ≥ (PRRATIO[3:0] bits + 1)
- When the CTSUCRA.SDPSEL bit is 1
  Specify the stabilization wait time by the number of STCLK cycles.
  Number of cycles = 1 × (SST[7:0] bit value + 1)

#### SSMOD[2:0] bits (SUCLK Spread-Spectrum Mode Select)

The SSMOD[2:0] bits are used to set the spread-spectrum period of SUCLK oscillator. The oscillation frequency of SUCLK is upspread based on the frequency specified by the CTSUTRIMA.SUADJD[7:0] and SSCNT[1:0] bits.

#### SSCNT[1:0] bits (SUCLK Spread-Spectrum Control)

The SSCNT[1:0] bits adjust the oscillation frequency of the SUCLK oscillator specified by the CTSUTRIMA.SUADJD[7:0] bits.

### 42.2.3 CTSUMCH/CTSUMCHH/CTSUMCHL/CTSUMFAF/CTSUMCH1/CTSUMCH0 : CTSU Measurement Channel Register

Base address: CTSU = 0x400D_0000

Offset address: 0x08 (CTSUMCH/CTSUMCHL/CTSUMCH0)
0x09 (CTSUMCH1)
0x0A (CTSUMCHH/CTSUMFAF)

| Bit position: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

| 7:6 | — | These bits are read as 0. The write value should be 0. | R/W |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 13:8 | MCH1[5:0] | CTSU Measurement Channel 1<br>In single scan mode, these bits set the transmit channel to be measured. Setting undefined pin for these bits is prohibited.<br>In multi-scan modes, these bits indicate the transmit channel that is currently being measured.<br>0x00: TS0<br>0x01: TS1<br>0x02: TS2<br>0x03: TS3<br>0x04: TS4<br>0x05: TS5<br>0x06: TS6<br>0x07: TS7<br>0x08: TS8<br>0x09: TS9<br>0x0A: TS10<br>0x0B: TS11<br>0x3F: Measurement is being stopped. | R/W*1 |
| 15:14 | — | These bits are read as 0. The write value should be 0. | R/W |
| 19:16 | MCA0 to MCA3 | Multiple Clocks Control<br>0: Disable<br>1: Enable | R/W |
| 31:20 | — | These bits are read as 0. The write value should be 0. | R/W |

Note 1. Writing to these bits is enabled only in self-capacitance single scan mode, when CTSUCRA.MD0 bit = 0b.

The CTSU measurement channel register (CTSUMCH/CTSUMCHH/CTSUMCHL/CTSUMFAF/CTSUMCH1/CTSUMCH0) is a 32-bit, 16-bit, and 8-bit read/write register.

The CTSUMCH is accessed in 32-bit units. The CTSUMCHH (bits [31:16] in CTSUMCH) and CTSUMCHL (bits [15:0] in CTSUMCH) are accessed in 16-bit units. The CTSUMFAF (bits [23:16] in CTSUMCH), CTSUMCH1 (bits [15:8] in CTSUMCH), and CTSUMCH0 (bits [7:0] in CTSUMCH) are accessed in 8-bit units.

Only set the CTSUMCH/CTSUMCHH/CTSUMCHL/CTSUMFAF/CTSUMCH1/CTSUMCH0 register when CTSUCR0.STRT bit is 0.

### MCH0[5:0] bits (CTSU Measurement Channel 0)

In self-capacitance single scan mode, the MCH0[5:0] bits set the receive channel to be measured. In this mode, only specify the enabled channels 0x00 to 0x0B and only specify the measure channels that are set by CTSUCHACA and CTSUCHACB registers.

In multi-scan mode, the MCH0[5:0] bits indicate the receive channel that is being measured, and writing to these bits has no effect. However, when CCSUCRA.MD2 is 1, MCH0[5:0] bits become 0x00.

The MCH0[5:0] bits are always 0x3F when measurement is stopped.

### MCH1[5:0] bits (CTSU Measurement Channel 1)

In single scan mode, the MCH1[5:0] bits set the transmit channel to be measured. In this mode, only specify the enabled channels 0x00 to 0x0B and only specify the measure channels that are set by CTSUCHACA and CTSUCHACB registers.

In multi-scan mode, the MCH1[5:0] bits indicate the transmit channel that is being measured, and writing to these bits has no effect.

The MCH1[5:0] bits are always 0x3F when measurement is stopped.

### MCA0 to MCA3 bits (Multiple Clocks Control)

When measuring with multiple SUCLK frequency, the MCA0 to MCA3 bits set the target clock as valid or invalid. If MCA0 to MCA3 bits are set and measurement is started, begin to scan the valid channel from MCA0 in ascending order. After the measurement of one channel is complete, the measurement is carried out at the same channel if there is a next valid clock, and if there is no valid clock, the next channel is measured. The frequency of SUCLK is set in CTSUSUCLKA and CTSUSUCLKB registers. The relationship with MCA0 to MCA3 bits is as follows:

MCA0: The frequency of the SUCLK oscillator is determined by the setting of CTSUSUCLKA.SUMULTI0[7:0] and CTSUSUCLKA.SUADJ0[7:0].

MCA1: The frequency of the SUCLK oscillator is determined by the setting of CTSUSUCLKA.SUMULTI1[7:0] and CTSUSUCLKA.SUADJ1[7:0].

MCA2: The frequency of the SUCLK oscillator is determined by the setting of CTSUSUCLKA.SUMULTI2[7:0] and CTSUSUCLKA.SUADJ2[7:0].

MCA3: The frequency of the SUCLK oscillator is determined by the setting of CTSUSUCLKA.SUMULTI3[7:0] and CTSUSUCLKA.SUADJ3[7:0].

If all the bits from MCA3 to MCA0 are set to disabled, the setting is the same as MCA0 = 1. If multiple clocks are to be enabled, three or all of the bits from MCA3 to MCA0 should be set to 1.

When CTSUCRA.SDPSEL = 1, these bits are enabled. When CTSUCRA.SDPSEL = 0, these bits should be set to 0000b.

## 42.2.4 CTSUCHACA/CTSUCHACAL/CTSUCHAC1/CTSUCHAC0 : CTSU Channel Enable Control Register A

Base address: CTSU = 0x400D_0000

Offset address: 0x0C (CTSUCHACA/CTSUCHACAL/CTSUCHAC0)
0x0D (CTSUCHAC1)

| Bit position: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 11:0 | CHAC00 to CHAC11 | CTSU Channel Enable Control A<br>These bits select whether the associated TS pin is measured.<br>These bits specify the TS0 to TS11 pins.<br>0: Do not measure<br>1: Measure | R/W |
| 31:12 | — | These bits are read as 0. The write value should be 0. | R/W |

The CTSU Channel Enable Control Register A (CTSUCHACA/CTSUCHACAL/CTSUCHAC1/CTSUCHAC0) is a 32-bit, 16-bit, and 8-bit read/write register.

The CTSUCHACA is accessed in 32-bit units. The CTSUCHACAL (bits [15:0] in CTSUCHACA) is accessed in 16-bit units. The CTSUCHAC1 (bits [15:8] in CTSUCHACA) and CTSUCHAC0 (bits [7:0] in CTSUCHACA) are accessed in 8-bit units.

Only set the CTSUCHACA/CTSUCHACAL/CTSUCHAC1/CTSUCHAC0 register when the CTSUCRA.STRT bit is 0.

### CHAC00 to CHAC11 bits (CTSU Channel Enable Control A)

The CHAC00 to CHAC11 bits select the receive and transmit pins whose electrostatic capacitance is to be measured. CHAC00 bit is associated with TS0 and CHAC11 bit is associated with TS11.

## 42.2.5 CTSUCHTRCA/CTSUCHTRCAL/CTSUCHTRC1/CTSUCHTRC0 : CTSU Channel Transmit/Receive Control Register A

Base address: CTSU = 0x400D_0000

Offset address: 0x14 (CTSUCHTRCA/CTSUCHTRCAL/CTSUCHTRC0)
0x15 (CTSUCHTRC1)

| Bit position: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|

| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 11:0 | CHTRC00 to CHTRC11 | CTSU Channel Transmit/Receive Control A<br>These bits control TS0 to TS11 pins reception/transmission.<br>0: Reception<br>1: Transmission | R/W |
| 31:12 | — | These bits are read as 0. The write value should be 0. | R/W |

The CTSU Channel Transmit/Receive Control Register A (CTSUCHTRCA/CTSUCHTRCAL/CTSUCHTRC1/CTSUCHTRC0) is a 32-bit, 16-bit, and 8-bit read/write register.

The CTSUCHTRCA is accessed in 32-bit units. The CTSUCHTRCAL (bits [15:0] in CTSUCHTRCA) is accessed in 16-bit units. The CTSUCHTRC1 (bits [15:8] in CTSUCHTRCA) and CTSUCHTRC0 (bits [7:0] in CTSUCHTRCA) are accessed in 8-bit units.

Only set the CTSUCHTRCA/CTSUCHTRCAL/CTSUCHTRC1/CTSUCHTRC0 register when the CTSUCRA.STRT bit is 0.

### CHTRC00 to CHTRC11 bits (CTSU Channel Transmit/Receive Control A)

The CHTRC00 to CHTRC11 bits assign the associated TS pins to reception or transmission. CHTRC00 bit is associated with TS0 and CHTRC11 bit is associated with TS11.

When CTSUCRA.MD1 = 0, the channel set for transmission can be used as the output of the active shield signal. However, when use as a shield signal output, two or more transmissions setting is prohibited.

## 42.2.6 CTSUSR/CTSUSRH/CTSUSRL/CTSUSR2/CTSUST/CTSUSR0 : CTSU Status Register

Base address: CTSU = 0x400D_0000

Offset address: 0x1C (CTSUSR/CTSUSRL/CTSUSR0)

| 12 | DTSR | CTSU Data Transfer Status Flag<br>This flag indicates whether or not the measurement result stored in the sensor counter was read.<br>0: Read<br>1: Not read | R |
| 13 | SENSOVF | CTSU Sensor Counter Overflow Flag<br>This flag indicates an overflow on the sensor counter.<br>0: No overflow occurred<br>1: Overflow occurred | R/W |
| 14 | SUCKOVF | CTSU SUCLK Counter Overflow Flag<br>This flag indicates an overflow of the SUCLK counter for the drive pulse clock or the frequency spreading clock.<br>0: No overflow occurred<br>1: Overflow occurred | R/W |
| 15 | PS | CTSU Mutual Capacitance Status Flag<br>This flag indicates the measurement status in mutual capacitance mode.<br>0: First measurement<br>1: Second measurement | R |
| 31:16 | — | These bits are read as 0. The write value should be 0. | R/W |

The CTSU Status Register (CTSUSR/CTSUSRH/CTSUSRL/CTSUSR2/CTSUST/CTSUSR0) is a 32-bit, 16-bit, and 8-bit read/write register.

The CTSUSR is accessed in 32-bit units. The CTSUSRH (bits [31:16] in CTSUSR) and CTSUSRL (bits [15:0] in CTSUSR) are accessed in 16-bit units. The CTSUSR2 (bits [23:16] in CTSUSR), CTSUST (bits [15:8] in CTSUSR), and CTSUSR0 (bits [7:0] in CTSUSR) are accessed in 8-bit units.

When using the CTSUCRA.INIT bit to clear an overflow flag, make sure that the CTSUCRA.STRT bit is 0.

### MFC[1:0] bits (CTSU Multi-Clock Counter)

The MFC[1:0] bits indicate the clock being measured while multi-clock measuring (CTSUCRA.FCMODE = 1).

It is valid only when the SDPSEL bit is set to 0.

### ICOMPRST bit (CTSU ICOMP0 and ICOMP1 Flags Reset)

When 1 is written to the ICOMPRST bit, the ICOMP0 and ICOMP1 bits are cleared.

### ICOMP1 bit (CTSU Sense Current Error Monitor)

The ICOMP1 bit specifies that the measurement current is equal to the measurement range set by the ATUNE[1:0] bit. This is set to 1 when the current is excessive.

Adjust the settings to achieve the appropriate range.

When 1 is written to the ICOMPRST or CTSUCRA.PON bit, the ICOMP1 flag is cleared. When the ICOMP1 bit is 1, the sensor counter becomes 0xFFFF.

### ICOMP0 bit (Over-Voltage Detection Flag)

The ICOMP0 bit monitors the TSCAP voltage and is set to 1 if the voltage becomes abnormal.

If the amount of offset current set with the CTSUSO register exceeds the measured current during the capacitance measurement, the TSCAP voltage will be abnormal and the capacitance measurement will not be performed correctly.

If an error occurs in the TSCAP voltage while the correct CTSUSO setting was used for the measurement, a hardware failure such as a wire breakage may be the cause.

### STC[2:0] bits (CTSU Measurement Status Counter)

The STC[2:0] bits indicate the current measurement status.

### DTSR flag (CTSU Data Transfer Status Flag)

The DTSR flag indicates whether the measurement result stored in the sensor counter was read. The flag is set to 1 when measurement completes and 0 when the sensor counter is read by software or the DTC. The flag can also be cleared using the CTSUCRA.INIT bit.

### SENSOVF flag (CTSU Sensor Counter Overflow Flag)

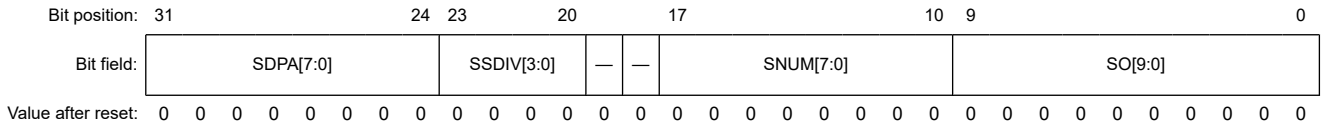
When an overflow occurred in the sensor counter (CTSUSCNT.SENSCNT[15:0]), the SENSOVF bit is set to 1.

When an overflow occurs, the counter value is set to 0xFFFF.

If the SENSOVF bit is set to 1 after the measurement is completed, use the measurement results of each channel to determine which channel the overflow occurred.

This flag is cleared by writing 0 after reading 1 by software. It is also cleared by the CTSUCRA.INIT bit.

### PS flag (CTSU Mutual Capacitance Status Flag)



When the MD1 bit is set to 1, this flag indicates the measurement status and whether the measurement order is first or second in two measurements per channel.

When the MD1 bit is set to 0, this flag is always set to 0.

## 42.2.7 CTSUSO/CTSUSO1/CTSUSO0 : CTSU Sensor Offset Register

Base address: CTSU = 0x400D_0000

Offset address: 0x20 (CTSUSO/CTSUSO0)
0x22 (CTSUSO1)

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 9:0 | SO[9:0] | CTSU Sensor Offset Adjustment<br>Adjusts the CTSU sensor offset current.<br>0x000: Current offset is 0.<br>0x001: Current offset is 1.<br>0x002: Current offset is 2.<br>⋮ ⋮<br>0x3FE: Current offset is 1022.<br>0x3FF: Current offset is 1023 (maximum). | R/W |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 17:10 | SNUM[7:0] | CTSU Measurement Count Setting<br>These bits set the number of measurement repetitions. | R/W |
| 19:18 | — | These bits are read as 0. The write value should be 0. | R/W |
| 23:20 | SSDIV[3:0] | Spread Spectrum Frequency<br>The SSDIV[3:0] bits set the division setting value of the spread spectrum clock based on the division setting of the base clock. It is enabled when CTSUCRA.SDPSEL = 0. | R/W |
| 31:24 | SDPA[7:0] | CTSU Base Clock Setting*1<br>0x00: Operating clock divided by 2 when CTSUCRA.SDPSEL = 0<br>SUCLK divided by 1 when CTSUCRA.SDPSEL = 1<br>0x01: Operating clock divided by 4 when CTSUCRA.SDPSEL = 0<br>SUCLK divided by 2 when CTSUCRA.SDPSEL = 1<br>0x02: Operating clock divided by 6 when CTSUCRA.SDPSEL = 0<br>SUCLK divided by 3 when CTSUCRA.SDPSEL = 1<br>0x03: Operating clock divided by 8 when CTSUCRA.SDPSEL = 0<br>SUCLK divided by 4 when CTSUCRA.SDPSEL = 1<br>⋮<br>0xFE: Operating clock divided by 510 when CTSUCRA.SDPSEL = 0<br>SUCLK divided by 255 when CTSUCRA.SDPSEL = 1<br>0xFF: Operating clock divided by 512 when CTSUCRA.SDPSEL = 0<br>SUCLK divided by 256 when CTSUCRA.SDPSEL = 1 | R/W |

Note 1. When the spread spectrum function is OFF (CTSUCRB.SOFF bit = 1) or in the mutual capacitance method (CTSUCRA.MD1 bit = 1), do not set the SDPA[7:0] bits to 0x00.

The CTSU Sensor Offset Register (CTSUSO/CTSUSO1/CTSUSO0) is a 32-bit and 16-bit read/write register.

The CTSU Sensor Offset Register is accessed in 32-bit units. The CTSUSO1 (bits [31:16] in CTSU Sensor Offset Register) and CTSUSO0 (bits [15:0] in CTSU Sensor Offset Register) are accessed in 16-bit units.

After a CTSU_CTSUWR interrupt occurs, write to the CTSU Sensor Offset Register register. The write to the CTSU Sensor Offset Register register causes a transition to Status 3. Set all of the bits in a single operation when writing to the CTSU Sensor Offset Register.

### SO[9:0] bits (CTSU Sensor Offset Adjustment)

The amount of current changed by touch should be within the range set by the CTSUCRA.ATUNE0 and CTSUCRA.ATUNE0 bits.

### SNUM[7:0] bits (CTSU Measurement Count Setting)

When CTSUCRA.SDPSEL = 0, the SNUM[7:6] bits are set to 00b.

The SNUM[5:0] bits are used in CTSUCRB.PRRATIO[3:0] and repetition of one unit of measurement with a random number period as determined by CTSUCRB.PRMODE[1:0].

The number of repetitions is (SNUM[5:0] bits + 1).

When CTSUCRA.SDPSEL bit is 1, the SNUM[7:0] bits set the time of measurements using the following formula:

Measurement time = (STCLK cycle × 8) × SNUM[7:0] bits + 1)

### SSDIV[3:0] bits (Spread Spectrum Frequency)

In random pulse mode (CTSUCRA.SDPSEL bit = 0), these bits set which clock is used to resample the PCLKB synchronized sensor drive pulse with SUCLK. Set the frequency of the selected clock to be at least four times the frequency of the sensor drive pulse.

### SDPA[7:0] bits (CTSU Base Clock Setting)

When CTSUCRA.SDPSEL = 0, the SDPA[7:0] bits select the base clock used as the source for the sensor drive pulse by dividing the operating clock.

When CTSUCRA.SDPSEL = 1, the SDPA[7:0] bits select the sensor drive pulse by dividing the SUCLK.

## 42.2.8 CTSUSCNT/CTSUSC : CTSU Sensor Counter Register

Base address: CTSU = 0x400D_0000

Offset address: 0x24

| Bit position: | 31 | | | | | | | | | | | | | | | | 16 | 15 | | | | | | | | | | | | | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | SUCKCNT[15:0] | | | | | | | | | | | | | | | | SENSCNT[15:0] | | | | | | | | | | | | | | |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 15:0 | SENSCNT[15:0] | CTSU Sensor Counter<br>These bits indicate the measurement result of the sensor ICO and read 0xFFFF when an overflow occurs. | R |
| 31:16 | SUCKCNT[15:0] | CTSU SUCLK Counter<br>These bits indicate the measurement result of SUCLK clock count results and read 0xFFFF when an overflow occurs. | R |

The CTSU Sensor Counter Register (CTSUSCNT/CTSUSC) is a 32-bit and 16-bit read-only register.

The CTSUSCNT is accessed in 32-bit units. CTSUSC (bits [15:0] in CTSUSCNT) is accessed in 16-bit units.

After a CTSU_CTSURD interrupt is generated, read from the CTSUSCNT/CTSUSC counter.

### SENSCNT[15:0] bits (CTSU Sensor Counter)

The SENSCNT[15:0] bits have the count result of the sensor ICO.

The average oscillation frequency can be calculated and converted to the measured current by dividing the count result by the measurement time.

It can be cleared by writing 1 to the CTSUCRA.INIT bit.

### SUCKCNT[15:0] bits (CTSU SUCLK Counter)

The SUCKCNT[15:0] bits store the SUCLK clock count result.

The average frequency of SUCLK can be calculated by dividing the count result by the measurement time.

It is cleared by writing 1 to the CTSUCRA.INIT bit.

## 42.2.9 CTSUCALIB/CTSUDBGR1/CTSUDBGR0 : CTSU Calibration Register

Base address: CTSU = 0x400D_0000

Offset address: 0x28 (CTSUCALIB/CTSUDBGR0)
0x2A (CTSUDBGR1)

| 26 | SUMSEL | Current Control Oscillator Input Current Matrix Calibration Select<br>0: Capacitance measurement mode<br>1: Current control oscillator input current matrix calibration mode | R/W |
| 27 | SUCARRY | Current Control Oscillator Input Current Adjustment for SUCLK<br>This bit enables all current sources to be turned on for calibration.<br>0: Normal operation<br>1: All current sources can be turned on | R/W |
| 28 | DACCLK | Modulation Clock Select for Offset Current Circuits<br>0: Operating clock selected by CTSUCRA.CLK [1:0]<br>1: SUCLK | R/W |
| 29 | CCOCLK | Modulation Clock Select for Current Controlled Oscillator Input Current of SUCLK<br>0: Operating clock selected by CTSUCRA.CLK [1:0]<br>1: SUCLK | R/W |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 30 | CCOCALIB | Calibration Selection of Current Controlled Oscillator for Measurement<br>0: Capacitance measurement mode<br>1: Oscillator calibration mode | R/W |
| 31 | TXREV | Transmit Pin Inverted Output<br>This bit controls the polarity of the pulse output from the transmission pin.<br>0: Normal<br>1: Invert | R/W |

The CTSU Calibration Register (CTSUCALIB/CTSUDBGR1/CTSUDBGR0) is a 32-bit and 16-bit read/write register.

The CTSUCALIB is accessed in 32-bit units. The CTSUDBGR1 (bits [31:16] in CTSUCALIB) and CTSUDBGR0 (bits [15:0] in CTSUCALIB) are accessed in 16-bit units.

### TSOD bit (All TS Pin Output Control)

The TSOD bit is used to calibrate the CTSU. When measuring the capacitance, set this bit to 0.

When setting this bit to 1, the TS pins are forced to the signal specified by the IOCSEL bit and the IOC bit.

### DRV bit (Power Supply Calibration Select)

DRV bit is used as a calibration for power supply.

### CLKSEL[1:0] bits (Observation Clock Select)

CLKSEL[1:0] bits selects a clock that can be observed on the external pin.

### TSOC bit (Switched Capacitor Operation Calibration Select Bit)

When the TSOC bit is set to 1, the TS terminal switching capacitor operation stops and the CTSU current can be measured. The bit is used for calibration of the current control oscillator based on this current.

### CNTRDSEL bit (Read Count Select of Sensor Counter)

Set the CNTRDSEL bit to 0 to read the sensor counter.

To read the sensor and SUCLK counters twice with 16-bit access, set this bit to 1.

### IOC bit (Transmit Pin Control)

The IOC bit is used to select the level to be output from the TS pin when the TSOD bit and the IOCSEL bit are set to 1 or the CTSUCRA.DCMODE bit is set to 1.

If either the TSOD bit or the IOCSEL bit is 0 and the CTSUCRA.DCMODE bit is 0, the IOC bit is ignored.

### DCOFF bit (Down Converter Control)

The DCOFF bit controls the operation of the voltage down converter to generate TSCAP voltage.

When the DCOFF is set to 0 and PON is set to 1, TSCAP voltage is generated and normal operation is possible.

When the DCOFF is set to 1, voltage down converter is forced to stop and only offset current is output.

### IOCSEL bit (TS Pins Fixed Output Select)

The IOCSEL bit is used for CTSU calibration.

When the CCSUCALIB.TSOD bit is set to 1 and this bit is 0, the TSm that is measured by the CCSUCHACA and CCSUCHACB registers (= 1) and received by the CCSUCHTRCA and CCSUCHACB registers (= 0), the sensor drive pulse is output from the terminal.

When the CCSUCALIB.TSOD bit is set to 1 and this bit is 1, the level specified by the CSUCALIB.IOC bit is output from all TS terminals.

### DACMSEL bit (Current Offset DAC Current Matrix Calibration Select)

When the DACMSEL is set to 1, current offset DAC current matrix calibration mode is on. This is used for calibration.

### DACCARRY bit (Offset Current Adjustment for Calibration)

When the DACCARRY is set to 1, all current sources can be turned on. This is used for calibration.

### SUMSEL bit (Current Control Oscillator Input Current Matrix Calibration Select)

When the SUMSEL is set to 1, current control oscillator input current matrix calibration mode is on. This is used for calibration.

### SUCARRY bit (Current Control Oscillator Input Current Adjustment for SUCLK)

When the SUCARRY is set to 1, all current sources can be turned on. This is used for calibration.

### DACCLK bit (Modulation Clock Select for Offset Current Circuits)

The DACCLK bit selects the modulation clock for the offset current circuit.

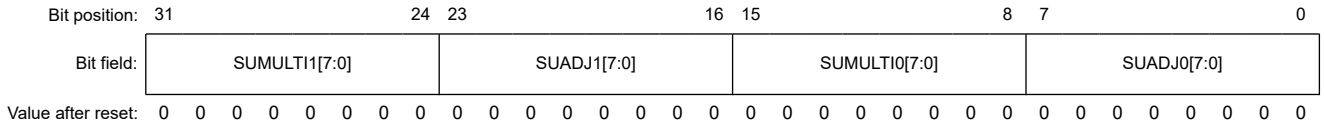
### CCOCLK bit (Modulation Clock Select for Current Controlled Oscillator Input Current of SUCLK)

The CCOCLK bit selects the clock for the CCO modulation circuit.

### CCOCALIB bit (Calibration Selection of Current Controlled Oscillator for Measurement)

When the CCOCALIB is set to 1, the input current of the SUCLK current control oscillator and the measurement current control oscillator are swapped.

The characteristics of the measurement current controlled oscillator can be calibrated by supplying the input current of the SUCLK current controlled oscillator to the measurement current controlled oscillator.



### TXREV bit (Transmit Pin Inverted Output)

When the TXREV is set to 1, the pulse output from the transmit pin can be inverted.

## 42.2.10 CTSUSUCLKA/CTSUSUCLK1/CTSUSUCLK0 : CTSU Sensor Unit Clock Control Register A

Base address: CTSU = 0x400D_0000

Offset address: 0x2C (CTSUSUCLKA/CTSUSUCLK0)
0x2E (CTSUSUCLK1)

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 7:0 | SUADJ0[7:0] | CTSU SUCLK Frequency Adjustment<br>These bits adjust the SUCLK frequency. | R/W |
| 15:8 | SUMULTI0[7:0] | CTSU SUCLK Multiplier Rate Setting<br>These bits set the multiplier rate of SUCLK relative to STCLK.<br>0x00: 1<br>0x01: 2<br>0x02: 3<br>0x03: 4<br>⋮<br>0xFE: 255<br>0xFF: 256 | R/W |
| 23:16 | SUADJ1[7:0] | CTSU SUCLK Frequency Adjustment<br>These bits adjust the SUCLK frequency. | R/W |
| 31:24 | SUMULTI1[7:0] | CTSU SUCLK Multiplier Rate Setting<br>These bits set the multiplier rate of SUCLK relative to STCLK.<br>0x00: 1<br>0x01: 2<br>0x02: 3<br>0x03: 4<br>⋮<br>0xFE: 255<br>0xFF: 256 | R/W |

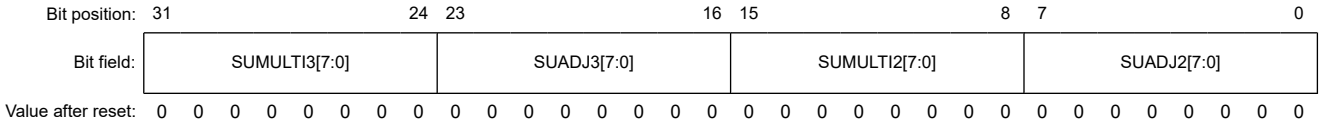
The CTSU Sensor Unit Clock Control Register A (CTSUSUCLKA/CTSUSUCLK1/CTSUSUCLK0) is a 32-bit and 16-bit read/write register.

The CTSUSUCLKA is accessed in 32-bit units. The CTSUSUCLK1 (bits [31:16] in CTSUSUCLKA) and CTSUSUCLK0 (bits [15:0] in CTSUSUCLKA) are accessed in 16-bit units.

#### SUADJ0[7:0] and SUADJ1[7:0] bits (CTSU SUCLK Frequency Adjustment)

The SUADJ0[7:0] and SUADJ1[7:0] bits set the initial value of the SUCLK frequency. The drift is adjusted and the SUADJ0[7:0] and SUADJ1[7:0] bits are updated based on the clock recovery function.

#### SUMULTI0[7:0] and SUMULTI1[7:0] bits (CTSU SUCLK Multiplier Rate Setting)



The SUMULTI0[7:0] and SUMULTI1[7:0] bits set the multiplier rate of SUCLK relative to STCLK. The SUCLK clock frequency should be set in the range of 16 MHz to 40 MHz.

These bits compare the STCLK with the SUCLK divided by the SUMULTI0[7:0] and SUMULTI1[7:0] bits setting, and the SUMULTI0[7:0] and SUMULTI1[7:0] are updated based on comparison result.

## 42.2.11 CTSUSUCLKB/CTSUSUCLK3/CTSUSUCLK2 : CTSU Sensor Unit Clock Control Register B

Base address: CTSU = 0x400D_0000

Offset address: 0x30 (CTSUSUCLKB/CTSUSUCLK2)
0x32 (CTSUSUCLK3)

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 7:0 | SUADJ2[7:0] | CTSU SUCLK Frequency Adjustment<br>These bits adjust the SUCLK frequency. | R/W |
| 15:8 | SUMULTI2[7:0] | CTSU SUCLK Multiplier Rate Setting<br>These bits set the multiplier rate of SUCLK relative to STCLK.<br>0x00: 1<br>0x01: 2<br>0x02: 3<br>0x03: 4<br>⋮<br>0xFE: 255<br>0xFF: 256 | R/W |
| 23:16 | SUADJ3[7:0] | CTSU SUCLK Frequency Adjustment<br>These bits adjust the SUCLK frequency. | R/W |
| 31:24 | SUMULTI3[7:0] | CTSU SUCLK Multiplier Rate Setting<br>These bits set the multiplier rate of SUCLK relative to STCLK.<br>0x00: 1<br>0x01: 2<br>0x02: 3<br>0x03: 4<br>⋮<br>0xFE: 255<br>0xFF: 256 | R/W |

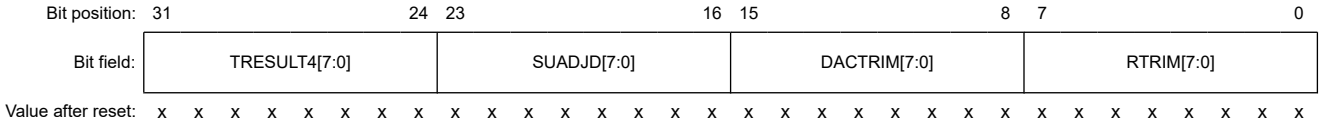
The CTSU Sensor Unit Clock Control Register B (CTSUSUCLKB/CTSUSUCLK3/CTSUSUCLK2) is a 32-bit and 16-bit read/write register.

The CTSUSUCLKB is accessed in 32-bit units. The CTSUSUCLK3 (bits [31:16] in CTSUSUCLKB) and CTSUSUCLK2 (bits [15:0] in CTSUSUCLKB) are accessed in 16-bit units.

### SUADJ2[7:0] and SUADJ3[7:0] bits (CTSU SUCLK Frequency Adjustment)

The SUADJ2[7:0] and SUADJ3[7:0] bits set the initial value of the SUCLK frequency. As the drift is adjusted, the SUADJ2[7:0] and SUADJ1[7:0] bits are updated.

### SUMULTI2[7:0] and SUMULTI3[7:0] bits (CTSU SUCLK Multiplier Rate Setting)



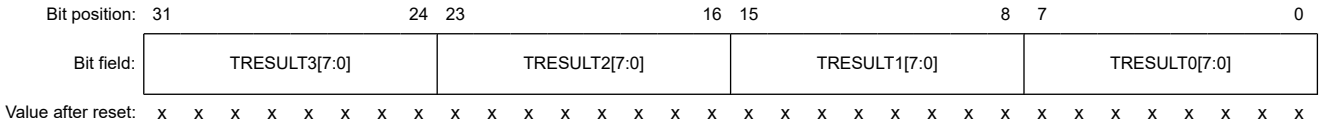
The SUMULTI2[7:0] and SUMULTI3[7:0] bits set the multiplier rate of SUCLK relative to STCLK. The SUCLK clock frequency should be set in the range of 16 MHz to 40 MHz.

These bits compare the STCLK with the SUCLK divided by the SUMULTI2[7:0] and SUMULTI3[7:0] bits setting, and the SUADJx[7:0] bits are updated based on comparison result.

## 42.2.12 CTSUTRIMA : CTSU Trimming Register A

Base address: CIBC = 0x407E_C200

Offset address: 0x01A4



| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 7:0 | RTRIM[7:0] | CTSU Reference Resistance Adjustment<br>The full scale of the offset current at the initial value is set to 160 µA at 25°C. | R/W |
| 15:8 | DACTRIM[7:0] | Linearity Adjustment of Offset Current | R/W |
| 23:16 | SUADJD[7:0] | CTSU SUCLK Frequency Adjustment<br>These bits adjust the SUCLK frequency when the CCSUCRA.SDPSEL bit is 0. | R/W |
| 31:24 | TRESULT4[7:0] | Coefficient of variation for the reference load resistance<br>The coefficient of variation for the 120 kΩ reference load resistance is stored. | R/W |

## 42.2.13 CTSUTRIMB : CTSU Trimming Register B

Base address: CIBC = 0x407E_C200

Offset address: 0x01A8

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 7:0 | TRESULT0[7:0] | The coefficient of variation for the 7.5 kΩ reference load resistance is stored. | R/W |

| 15:10 | — | These bits are read as 0. The write value should be 0. | R/W |
| 19:16 | SCACTB[3:0] | Sensor Counter Automatic Correction Table Number Setting<br>Set the number of the sensor counter automatic correction table to be accessed. The range of values is 0 to 11.<br>When a value is written to the CTSUSCNTACT register, the value of these bits is automatically incremented. | R/W |
| 31:20 | — | These bits are read as 0. The write value should be 0. | R/W |

The CTSU Option Setting Register (CTSUOPT/CTSUOPTH/CTSUOPTL/ACSB/AJ/AC) is a 32-bit, 16-bit, and 8-bit read/write register.

The CTSUOPT is accessed in 32-bit units. The CTSUOPTH (bits [31:16] in CTSUOPT) and CTSUOPTL(bits [15:0] in CTSUOPT) are accessed in 16-bit units. The ACSB (bits [23:16] in CTSUOPT), AJ (bits [15:8] in CTSUOPT), and AC (bits [7:0] in CTSUOPT) are accessed in 8-bit units.

### CCOCFEN bit (CCO Characteristics Correction Function Enable)

When the CCOCFEN bit is set to 1, the measured value is corrected using the sensor counter automatic correction table n (n = 0 to 11). If the corrected result exceeds 0xFFFF, the value of the sensor counter becomes 0xFFFF and the CTSUSR.SCOVF flag becomes 1.

### MCACEFN bit (Multi-clock Correction Function Enable)

The MCACEFN bit enables the multi-clock correction function for multi-clock measurement results. This bit is disabled when CTSUOPT.CCOCFEN = 0.

### MAJIRIMD bit (Majority Mode)

Using multi-clock measurement, the sensor counter value is returned as the result of adding the two nearest neighbor measurement results out of three multi-clock measurement results. In this mode, three multi-clocks must be set. Other multi-clock settings are not supported.

The MAJIRIMD bit must not be set unless CTSUOPT.CCOCFEN = 1 and CTSUOPT.MCACFEN = 1.

### DTCLESS bit (Data Transfer Request Disable)

When the DTCLESS bit is set to 1, the CTSUWR and CTSURD interrupts are not generated. In addition, the state counter transitions from state 2 to state 3 without writing to the CTSUSO register. Set a value in the CTSUSO register before starting measurement. Also, the CTSUSR.DTSR flag does not become 1.

### MTUCFEN bit (Mutual Capacitance Calculation Enable)

When the MTUCFEN bit is set to 1 while the CTSUCRA.MD1 bit is 1 (mutual capacitance method), the second measurement result becomes the difference from the first measurement value. When the first measurement is completed, the CTSUSR.DTSR flag does not become 1 and no CTSURD interrupt is generated. When the second measurement is completed, the DTSR flag becomes 1 and a CTSURD interrupt is generated.

If the result of subtracting the first measurement value from the second measurement value is less than 0x0000, the CTSUSCNT.SENSCNT[15:0] bits become 0x0000. If the first or second measurement value overflows, the CTSUSR.SCOVF flag becomes 1, but the difference is stored in the SENSCNT[15:0] bits.

### AJINTC bit (Automatic Judgment Interrupt Control)

The interrupt can be changed according to the touch judgment result when CTSUCRA.SNZ = 1 and CTSUOPT.AJFEN = 1.

Set this bit to 1 if you want to start the CPU after each decision.

## 42.2.15 CTSUSCNTACT/CTSUSCNTACTH/CTSUSCNTACTL : CTSU Sensor Counter Automatic Correction Table Access Register

Base address: CTSU = 0x400D_0000

Offset address: 0x44 (CTSUSCNTACT/CTSUSCNTACTL)
0x46 (CTSUSCNTACTH)

| Bit position: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | SCNTACCOUNT[15:0] | | | | | | | | | | | | | | | |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| Bit position: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| Bit field: | SCNTACCOEFF[15:0] | | | | | | | | | | | | | | | |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 15:0 | SCNTACCOEFF [15:0] | Sensor Counter Correction Coefficient Setting | R/W |
| 31:16 | SCNTACCOUNT [15:0] | Set the measurement value to be compared. | R/W |

Note: Set this register while the CTSUCRA.STRT bit is 0.

The CTSU Sensor Counter Automatic Correction Table Access Register (CTSUSCNTACT/CTSUSCNTACTL/ CTSUSCNTACTH) is a 32-bit and 16-bit read/write register.

The CTSUSCNTACT is accessed in 32-bit units. The CTSUSCNTACTH (bits [31:16] in CTSUSCNTACT) and CTSUSUCLKL (bits [15:0] in CTSUSCNTACT) are accessed in 16-bit units.

This register is used to access the sensor counter automatic correction table n (n = 0 to 11). The table to be accessed is selected by the CTSUOPT.SCACTB[3:0] bits.

The sensor counter automatic correction tables are used when the CTSUOPT.CCOCFEN bit is 1 (CCO characteristics correction function is enabled).

In the sensor counter automatic correction table n, set the $n^{th}$ measurement value to be compared with measured value and the correction coefficient for the measurement value. The $n^{th}$ measurement value should be larger than the $(n-1)^{th}$ measurement value.

Also, set the $0^{th}$ measurement value to 0x0000 and $11^{th}$ measurement value to 0xFFFF.

Writing to the SCNTACCOUNT[15:0] bits automatically increments the value of the CTSUOPT.SCACTB[3:0] bits to allow access to the next table.

## 42.2.16 CTSUMACT1/CTSUMACT1H/CTSUMACT1L/CTSUMACT2/CTSUMACT2H/ CTSUMACT2L/CTSUMACT3/CTSUMACT3H/CTSUMACT3L : CTSU Multi-Clock Automatic Correction Table Access Register

Base address: CTSU = 0x400D_0000

Offset address: 0x4C (CTSUMACT1/CTSUMACT1L)
0x4E (CTSUMACT1H)
0x50 (CTSUMACT2/CTSUMACT2L)
0x52 (CTSUMACT2H)
0x54 (CTSUMACT3/CTSUMACT3L)
0x56 (CTSUMACT3H)

| Bit position: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 9:0 | SO[9:0] | Sensor offset adjustment bits for multi-clock | R/W |
| 15:10 | — | These bits are read as 0. The write value should be 0. | R/W |
| 31:16 | OFFSETCOEFF [15:0] | Offset coefficient bits for multi-clock | R/W |

The CTSU Multi-Clock Automatic Correction Table Access Register (CTSUMACTn/CTSUMACTnH/CTSUMACTnL) is a 32-bit and 16-bit read/write register.

The CTSUMACTn is accessed in 32-bit units. The CTSUMACTnH (bits [31:16] in CTSUMACTn) and CTSUMACTnL (bits [15:0] in CTSUMACTn) are accessed in 16-bit units.

## 42.2.17 CTSUAJCR/CTSUAJCRH/CTSUAJCRL/AJCR3/AJCR2/AJCR1/AJCR0 : CTSU Automatic Judgment Control Register

Base address: CTSU = 0x400D_0000

Offset address: 0x58 (CTSUAJCR/CTSUAJCRL/AJCR0)
0x59 (AJCR1)
0x5A (CTSUAJCRH/AJCR2)
0x5B (AJCR3)

| Bit position: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 7:0 | TLOT[7:0] | Non-Touch Judgment Criterion Setting | R/W |
| 15:8 | THOT[7:0] | Touch Judgment Criterion Setting | R/W |
| 16 | BLINI | Baseline Initialization<br>0: Perform baseline operations<br>1: Initialize the results of baseline operations*1 | R/W |
| 19:17 | — | These bits are read as 0. The write value should be 0. | R/W |
| 21:20 | JC[1:0] | Judgment Condition Setting*2<br>0 0: Judges as touch when there is one or more touch detections<br>0 1: Judges as touch when there are two or more touch detections<br>1 0: Judges as touch when there are three or more touch detections<br>1 1: Judges as touch only when there are four touch detections | R/W |
| 23:22 | — | These bits are read as 0. The write value should be 0. | R/W |
| 27:24 | AJMMAT[3:0] | Measured Value Moving Average Number Setting | R/W |
| 31:28 | AJBMAT[3:0] | Baseline Average Number Setting | R/W |

Note: Set this register while the CTSUCRA.STRT bit is 0.
Note 1. To initialize the calculation results, it is necessary to perform measurement with this bit set to 1.
Note 2. These bits can only be set when performing multi-clock measurement. Set these bits to 00b when not performing multi-clock measurement or when using the automatic judgment function is enabled (CCSUOPT.AJFEN = 1) in majority mode (CCSUOPT.MAJIRIMD = 1).

### TLOT[7:0] bits (Non-Touch Judgment Criterion Setting)

The TLOT[7:0] bits specify the number of consecutive non-touch detections before a non-touch is reported.

If the set value is m, the CTSUAJRR.TJRn flag becomes 0 when non-touc” is detected m + 1 times in a row.

### THOT[7:0] bits (Touch Judgment Criterion Setting)

The THOT[7:0] bits specify the number of consecutive touch detections before a touch is reported.

If the set value is m, the CTSUAJRR.TJRn flag becomes 1 when touch is detected m + 1 times in a row.

### AJMMAT[3:0] bits (Measured Value Moving Average Number Setting)

The AJMMAT[3:0] bits specify the number of moving averages of the measured value. If the set value is n, the smoothing factor is $1/2^n$. The setting range is 0000b to 1011b.

### AJBMAT[3:0] bits (Baseline Average Number Setting)

The AJBMAT[3:0] bits specify the number of baseline averages. If the set value is n, the number of average is $2^{(n+1)}$. If 0000b is set, the baseline is not updated.

## 42.2.18 CTSUAJTHR/CTSUAJTHRH/CTSUAJTHRL : CTSU Automatic Judgment Control Register

Base address: CTSU = 0x400D_0000

Offset address: 0x5C (CTSUAJTHR/CTSUAJTHRL)
0x5E (CTSUAJTHRH)

| Bit position: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | AJTHH[15:0] | | | | | | | | | | | | | | | |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit position: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | AJTHL[15:0] | | | | | | | | | | | | | | | |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 15:0 | AJTHL[15:0] | Lower Threshold Setting<br>Set the non-touch judgment threshold as a relative value from the baseline. The value is a signed integer between –32768 and 32767. | R/W |
| 31:16 | AJTHH[15:0] | Upper Threshold Setting<br>Set the touch judgment threshold as a relative value from the baseline. The value is a signed integer between –32768 and 32767. | R/W |

Note: Set this register when the measurement state is State 0 or State 2.

The CTSU Automatic Judgment Control Register(CTSUAJTHR/CTSUAJTHRH/CTSUAJTHRL) is a 32-bit and 16-bit read/write register.

The CTSUAJTHR is accessed in 32-bit units. The CTSUAJTHRH (bits [31:16] in CTSUAJTHR) and CTSUAJTHRL (bits [15:0] in CTSUAJTHR) are accessed in 16-bit units.

Set the absolute value of the AJTHH[15:0] bits to be larger than the absolute value of the AJTHL[15:0] bits.

When performing multi-clock measurement (multiple bits of the CTSUMCH.MCAn bits are 1), set threshold values suitable for the frequency of the measurement clock each time a CTSUWR interrupt occurs.

If the value of this register is to be set when a CTSUWR interrupt occurs in multi-scan mode (CTSUCRA.MD0 bit = 1), save the value of this register in RAM when a CTSURD interrupt occurs.

## 42.2.19 CTSUAJMMAR/CTSUAJMMARH/CTSUAJMMARL : CTSU Threshold Register

Base address: CTSU = 0x400D_0000

Offset address: 0x60 (CTSUAJMMAR/CTSUAJMMARL)
0x62 (CTSUAJMMARH)

| Bit position: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | AJMMR[26:0] | | | | | | | | | | | | | | | |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit position: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|

| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 3:0 | AJMMATI[3:0] | Moving Average Count<br>These bits indicate the number of moving averages for the current measurement. Set these bits to 0000b at the first measurement. | R/W |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 4 | — | This bit is read as 0. The write value should be 0. | R/W |
| 31:5 | AJMMR[26:0] | Moving Average Result<br>These bits store the moving average calculation result for the measured value. The value is a fixed-point number with 16 bits for the integer part and 11 bits for the decimal part. | R/W |

Note: Set this register when the measurement state is State 0 or State 2.

The CTSU Threshold Register (CTSUAJMMAR/CTSUAJMMARH/CTSUAJMMARL) is a 32-bit and 16-bit read/write register.

The CTSUAJMMAR is accessed in 32-bit units. The CTSUAJMMARH (bits [31:16] in CTSUAJMMAR) and (bits [15:0] in CTSUAJMMARL) are accessed in 16-bit units.

When performing multi-clock measurement (multiple bits of the CTSUMCH.MCAn bits are 1), save the value of this register in RAM each time a CTSURD interrupt occurs, and write it back when a CTSUWR interrupt for measurement using the same clock occurs.

In multi-scan mode (the CTSUCRA.MD0 bit = 1), save the value of this register in RAM each time a CTSURD interrupt occurs, and write it back when a CTSUWR interrupt occurs when measuring the same channel again.

## 42.2.20 CTSUAJBLACT/CTSUAJBLACTH/CTSUAJBLACTL : CTSU Baseline Average Intermediate Result Register

Base address: CTSU = 0x400D_0000

Offset address: 0x64 (CTSUAJBLACT/CTSUAJBLACTL)
0x66 (CTSUAJBLACTH)

| Bit position: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | AJBLACT[31:0] | | | | | | | | | | | | | | | |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit position: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | AJBLACT[31:0] | | | | | | | | | | | | | | | |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 31:0 | AJBLACT[31:0] | Automatic determination baseline average calculation bits | R/W |

Note: Set this register when the measurement state is State 0 or State 2.

The CTSU Baseline Average Intermediate Result Register (CTSUAJBLACT/CTSUAJBLACTH/CTSUAJBLACTL) is a 32-bit and 16-bit read/write register.

The CTSUAJBLACT is accessed in 32-bit units. The CTSUAJBLACTH (bits [31:16] in CTSUAJBLACT) and CTSUAJBLACTL (bits [15:0] in CTSUAJBLACTR) are accessed in 16-bit units.

This register is used to store intermediate value during the baseline averaging operation. The value is a fixed-point number with 16 bits for the integer part and 16 bits for the decimal part.

When performing multi-clock measurement (multiple bits of the CTSUMCH.MCAn bits are 1), save the value of this register in RAM each time a CTSURD interrupt occurs, and write it back when a CTSUWR interrupt for measurement using the same clock occurs.

In multi-scan mode (the CTSUCRA.MD0 bit = 1), save the value of this register in RAM each time a CTSURD interrupt occurs, and write it back when a CTSUWR interrupt occurs when measuring the same channel again.

## 42.2.21 CTSUAJBLAR/CTSUAJBLARH/CTSUAJBLARL : CTSU Baseline Average Result Register

Base address: CTSU = 0x400D_0000

Offset address: 0x68 (CTSUAJBLAR/CTSUAJBLARL)
0x6A (CTSUAJBLARH)

| Bit position: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|

| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit position: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | AJBLAC[15:0] | | | | | | | | | | | | | | | |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 15:0 | AJBLAC[15:0] | Baseline Average Count<br>These bits indicates the current count value for the baseline average operation. | R/W |
| 31:16 | AJBLAR[15:0] | Baseline Average Result<br>These bits store the baseline average calculation result. | R/W |

Note: Set this register when the measurement state is State 0 or State 2.

The CTSU Baseline Average Result Register (CTSUAJBLAR/CTSUAJBLARH/CTSUAJBLARL) is a 32-bit and 16-bit read/write register.

The CTSUAJBLAR is accessed in 32-bit units. The CTSUAJBLARH (bits [31:16] in CTSUAJBLAR) and CTSUAJBLARL (bits [15:0] in CTSUAJBLAR) are accessed in 16-bit units.

This register is used to store the result of the baseline averaging operation.

When performing multi-clock measurement (multiple bits of the CTSUMCH.MCAn bits are 1), save the value of this register in RAM each time a CTSURD interrupt occurs, and write it back when a CTSUWR interrupt for measurement using the same clock occurs.

In multi-scan mode (the CTSUCRA.MD0 bit = 1), save the value of this register in RAM each time a CTSURD interrupt occurs, and write it back when a CTSUWR interrupt occurs when measuring the same channel again.

## 42.2.22 CTSUAJRR/CTSUAJRRL/CTSUAJRR1/CTSUAJRR0 : CTSU Automatic Judgment Result Register

Base address: CTSU = 0x400D_0000

| 3 | TJR3 | The judgment result when using SUCLK3 is stored.<br>0: Non-touch<br>1: Touch | R/W |
| 4 | FJR | The final judgment result on multi-clock measurement is stored. If multi-clock measurement is not specified, the same value as the TJR0 flag is stored.<br>0: Non-touch<br>1: Touch | R/W |
| 7:5 | — | These bits are read as 0. The write value should be 0. | R/W |
| 15:8 | SJCCR[7:0] | Remaining Number of Consecutive Detections<br>These bits indicate how many more consecutive touch or non-touch detections will invert the value of the TJRn flag. | R/W |
| 31:16 | — | These bits are read as 0. The write value should be 0. | R/W |

Note: Set this register when the measurement state is State 0 or State 2.

The CTSU Automatic Judgment Result Register (CTSUAJRR/CTSUAJRRL/CTSUAJRR1/CTSUAJRR0) is a 32-bit and 16-bit, and 8-bit read/write register.

The CTSUAJRR is accessed in 32-bit units. The CTSUAJRRL(bits [15:0] in CTSUAJRR) is accessed in 16-bit units. The CTSUAJRR1 (bits [15:8] in CTSUAJCR), and CTSUAJRR0 (bits [7:0] in CTSUAJCR) are accessed in 8-bit units.

This register is used to store the touch/non-touch judgment result.

When performing multi-clock measurement (multiple bits of the CTSUMCH.MCAn bits are 1), save the value of this register in RAM each time a CTSURD interrupt occurs, and write it back when a CTSUWR interrupt for measurement using the same clock occurs.

In multi-scan mode (the CTSUCRA.MD0 bit = 1), save the value of this register in RAM each time a CTSURD interrupt occurs, and write it back when a CTSUWR interrupt occurs when measuring the same channel again.

# 43. Data Operation Circuit (DOC)

## 43.1 Overview

The data operation circuit (DOC) is used to compare, add, and subtract 16 or 32-bit data. An interrupt can be generated when the following conditions apply.

- When the 16 or 32-bit compared values match the detection condition
- When the result of 16 or 32-bit data addition overflows
- When the result of 16 or 32-bit data subtraction underflows

Table 43.1 lists the data operation circuit specifications and Figure 43.1 shows a block diagram of the data operation circuit.

**Table 43.1 DOC specifications**

| Item | Description |
|---|---|
| Data operation function | • 16 or 32-bit data comparison, comparison to detect data above or below thresholds, and window comparison<br>• 16 or 32-bit data addition, and subtraction |
| Module-stop function | The module-stop state can be set to reduce power consumption. |
| Interrupts | • The compared values match the detection condition<br>• The result of data addition is greater than 0xFFFF (DOCR.DOBW = 0) or 0xFFFF_FFFF (DOCR.DOBW = 1)<br>• The result of data subtraction is less than 0x0000 (DOCR.DOBW = 0) or 0x0000_0000 (DOCR.DOBW = 1) |
| Event link function (output) | • The result of data comparison is consistent with detection condition<br>• The result of data addition is greater than 0xFFFF (DOCR.DOBW = 0) or 0xFFFF_FFFF (DOCR.DOBW = 1)<br>• The result of data subtraction is less than 0x0000 (DOCR.DOBW = 0) or 0x0000_0000 (DOCR.DOBW = 1) |
| TrustZone Filter | Security attribution can be set |

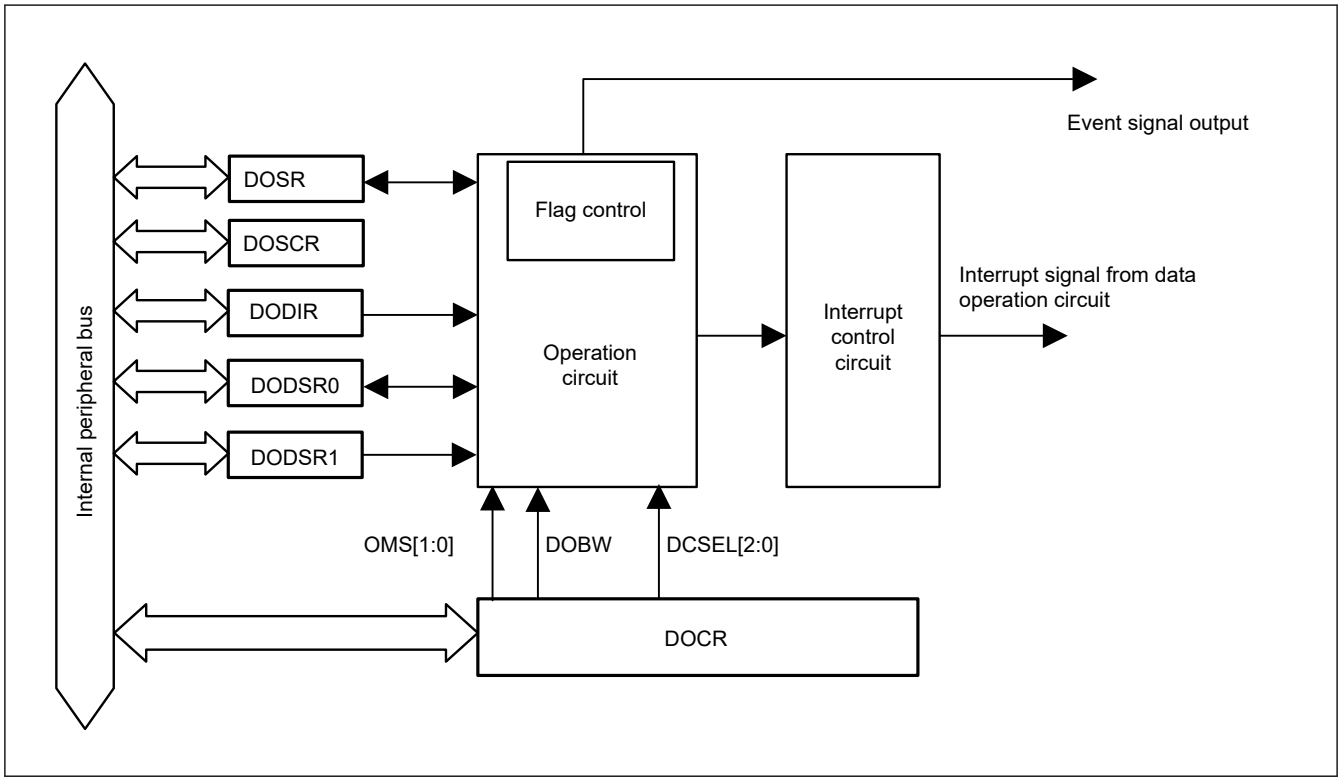

**Figure 43.1 DOC block diagram**

## 43.2 DOC Register Descriptions

### 43.2.1 DOCR : DOC Control Register

Base address: DOC_B = 0x4010_9000

Offset address: 0x00

| Bit position: | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|
| Bit field: | — | DCSEL[2:0] | | | DOBW | — | OMS[1:0] | |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 1:0 | OMS[1:0] | Operating Mode Select<br>0 0: Data comparison mode<br>0 1: Data addition mode<br>1 0: Data subtraction mode<br>1 1: Setting prohibited | R/W |
| 2 | — | This bit is read as 0. The write value should be 0. | R/W |
| 3 | DOBW | Data Operation Bit Width Select<br>0: 16-bit<br>1: 32-bit | R/W |
| 6:4 | DCSEL[2:0]*1 | Detection Condition Select<br>0 0 0: Mismatch (DODSR0 ≠ DODIR)<br>0 0 1: Match (DODSR0 = DODIR)<br>0 1 0: Lower (DODSR0 > DODIR)<br>0 1 1: Upper (DODSR0 < DODIR)<br>1 0 0: Inside window (DODSR0 < DODIR < DODSR1)<br>1 0 1: Outside window (DODIR < DODSR0, DODSR1 < DODIR)<br>Others: Setting prohibited | R/W |
| 7 | — | This bit is read as 0. The write value should be 0. | R/W |

Note: If the security attribution is configured as Secure:
- Secure access and Non-secure read access are allowed
- Non-secure write access is ignored, and TrustZone access error is not generated.

If the security attribution is configured as Non-secure:
- Secure and Non-secure access are allowed.

Note 1. Valid only when data comparison mode is selected.

The DOCR is a register which can set the operation mode of data operation circuit and interrupt enable/disable.

**OMS[1:0] bits (Operating Mode Select)**

These bits select the operating mode of the data operation circuit.

**DOBW bit (Data Operation Bit Width Select)**

This bit selects the bit width of data operation.

**DCSEL[2:0] bits (Detection Condition Select)**

These bits are valid only when data comparison mode is selected.

These bits select the condition for detection in data comparison mode.

## 43.2.2 DOSR : DOC Flag Status Register

Base address: DOC_B = 0x4010_9000

Offset address: 0x04

| Bit position: | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | — | — | — | — | DOPCF |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 0 | DOPCF | Data Operation Circuit Flag<br>Indicates the result of an operation. | R |
| 7:1 | — | These bits are read as 0. | R |

Note: If the security attribution is configured as Secure:
- Secure access and Non-secure read access are allowed
- Non-secure write access is ignored, and TrustZone access error is not generated.

If the security attribution is configured as Non-secure:
- Secure and Non-secure access are allowed.

The DOSR register indicates the status of the data operation.

### DOPCF flag (Data Operation Circuit Flag)

[Setting conditions]

- DOCR.OMS[1:0] bits = 00b (Data comparison mode): The compared value matches the detection condition selected by DOCR.DCSEL[2:0] bits
- DOCR.OMS[1:0] bits = 01b (Data addition mode): The result of data addition is greater than 0xFFFF (DOCR.DOBW = 0) or 0xFFFF_FFFF (DOCR.DOBW = 1)
- DOCR.OMS[1:0] bits = 10b (Data subtraction mode): The result of data subtraction is less than 0x0000 (DOCR.DOBW = 0) or 0x0000_0000 (DOCR.DOBW = 1)

[Clearing condition]

- Writing 1 to the DOSCR.DOPCFCL bit

## 43.2.3 DOSCR : DOC Flag Status Clear Register

Base address: DOC_B = 0x4010_9000

Offset address: 0x08

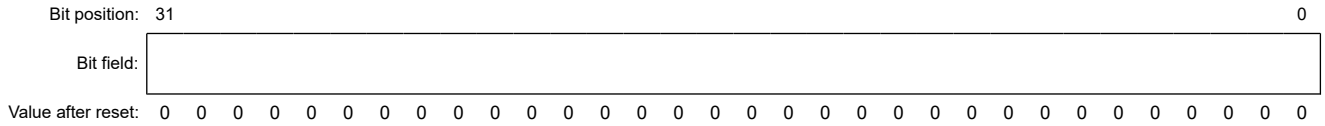
| Bit position: | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | — | — | — | — | DOPCFCL |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 0 | DOPCFCL | DOPCF Clear<br>0: Maintains the DOPCF flag state.<br>1: Clears the DOPCF flag. | W |
| 7:1 | — | The write value should be 0. | W |

Note: If the security attribution is configured as Secure:
- Secure access and Non-secure read access are allowed
- Non-secure write access is ignored, and TrustZone access error is not generated.

If the security attribution is configured as Non-secure:
- Secure and Non-secure access are allowed.

The DOSCR is a register which can clear the status of data operation. This register is read as 0x00.



**DOPCFCL bit (DOPCF Clear)**

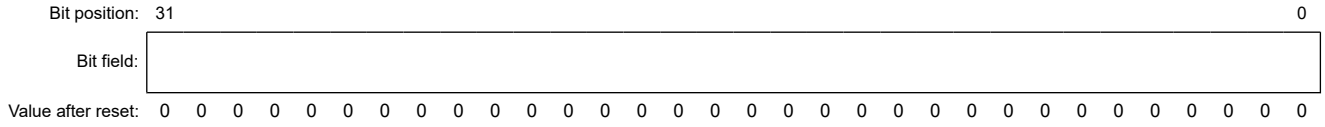
Setting this bit to 1 clears the DOPCF flag.

## 43.2.4 DODIR : DOC Data Input Register

Base address: DOC_B = 0x4010_9000

Offset address: 0x0C

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 31:0 | n/a | It stores data used in the operations.<br>Access the DODIR with the bit width of data operation selected by the DOCR.DOBW bit. | R/W |



Note: If the security attribution is configured as Secure:
- Secure access and Non-secure read access are allowed
- Non-secure write access is ignored, and TrustZone access error is not generated.

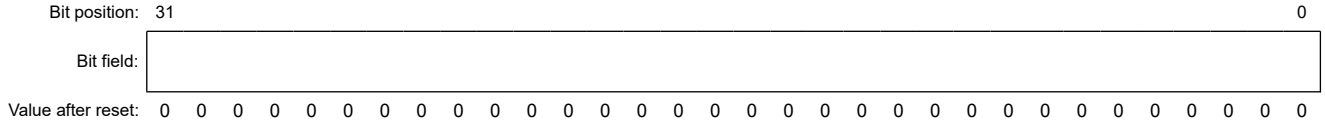
If the security attribution is configured as Non-secure:
- Secure and Non-secure access are allowed.

## 43.2.5 DODSR0 : DOC Data Setting Register 0

Base address: DOC_B = 0x4010_9000

Offset address: 0x10

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 31:0 | n/a | Access the DODSR0 with the bit width of data operation selected by the DOCR.DOBW bit.<br>This register stores data for use as a reference in data comparison mode. When selecting window comparison (DOCR.DCSEL[2:0] = 100b, 101b), set a value less than DODSR1 (DODSR1 > DODSR0).<br>This register also stores the results of operations in data addition and data subtraction modes. | R/W |



Note: If the security attribution is configured as Secure:
- Secure access and Non-secure read access are allowed
- Non-secure write access is ignored, and TrustZone access error is not generated.

If the security attribution is configured as Non-secure:
- Secure and Non-secure access are allowed.

## 43.2.6 DODSR1 : DOC Data Setting Register 1

Base address: DOC_B = 0x4010_9000

Offset address: 0x14

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 31:0 | n/a | Access the DODSR1 with the bit width of data operation selected by the DOCR.DOBW bit. This register stores data for use as a reference in data comparison mode. When selecting window comparison (DOCR.DCSEL[2:0] = 100b, 101b), set a value greater than DODSR0 (DODSR1 > DODSR0). This register is only used for window comparisons. | R/W |

Note: If the security attribution is configured as Secure:
- Secure access and Non-secure read access are allowed
- Non-secure write access is ignored, and TrustZone access error is not generated.

If the security attribution is configured as Non-secure:
- Secure and Non-secure access are allowed.

## 43.3 Operation

### 43.3.1 Data Comparison Mode

Figure 43.2 to Figure 43.7 shows an example of the steps involved in data comparison mode operation by the data operation circuit.

The following is an example of operation when the bit width of data operation is 32-bit.

1. Writing 00b to the DOCR.OMS[1:0] bits selects data comparison mode, and setting the DOCR.DCSEL[2:0] to selects detection condition.
2. The 32-bit reference data is set in DODSR0 and DODSR1.*1
3. 32-bit data for comparison is written to DODIR.
4. If a value written to DODIR match the detection condition set by DOCR.DCSEL[2:0], the DOCR.DOPCF flag is set to 1 and an ELC event and a data operation circuit interrupt are generated.

Note: The comparison operation is executed only by writing to the DODIR

Note 1. The DODSR1 register setting is required only when window comparison is selected. Set a value greater than DODSR0 (DODSR1 > DODSR0).

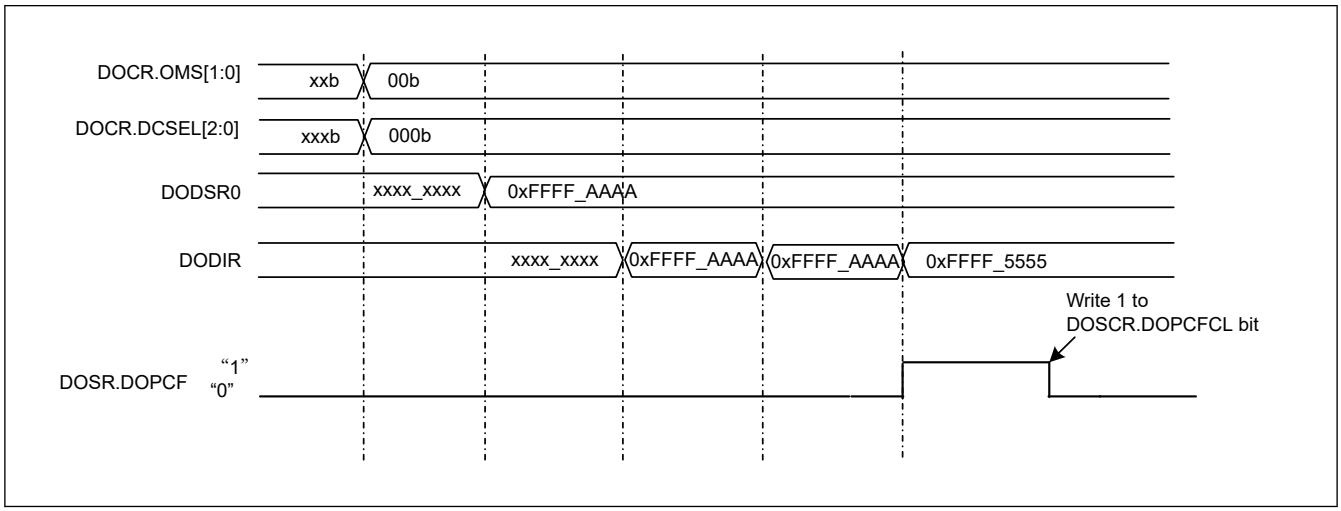


**Figure 43.2 Example of Operation in Data Comparison Mode (Detection condition: Mismatch)**

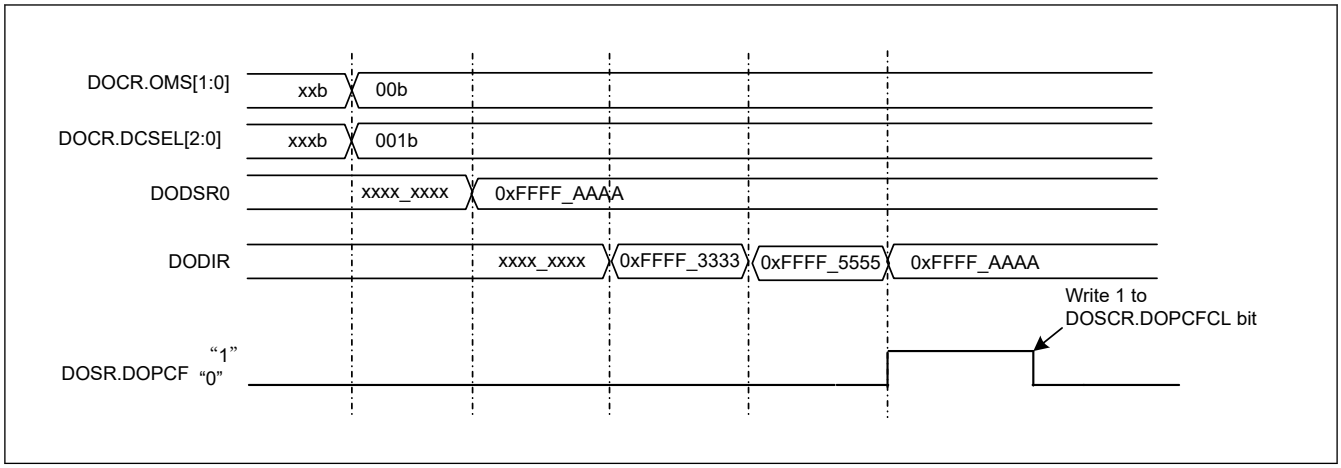

**Figure 43.3 Example of Operation in Data Comparison Mode (Detection condition: Match)**

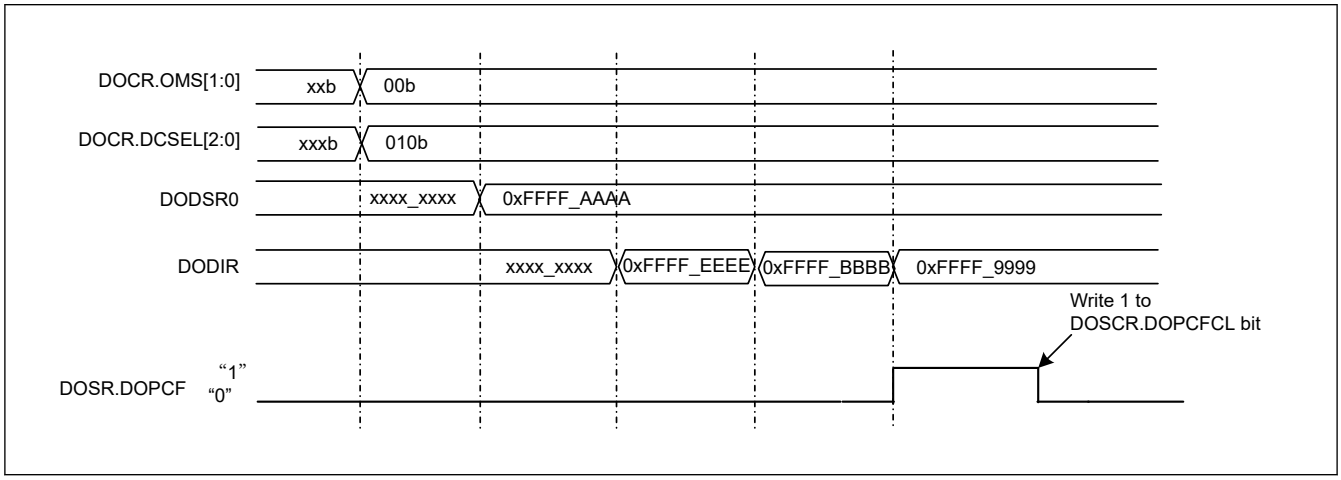

**Figure 43.4 Example of Operation in Data Comparison Mode (Detection condition: Lower)**

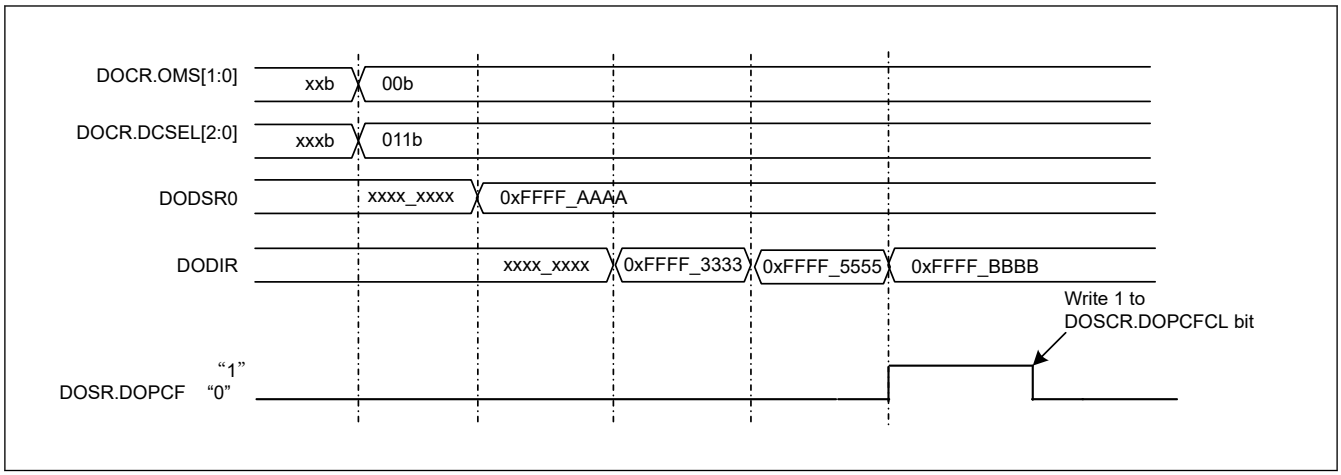

**Figure 43.5 Example of Operation in Data Comparison Mode (Detection condition: Upper)**

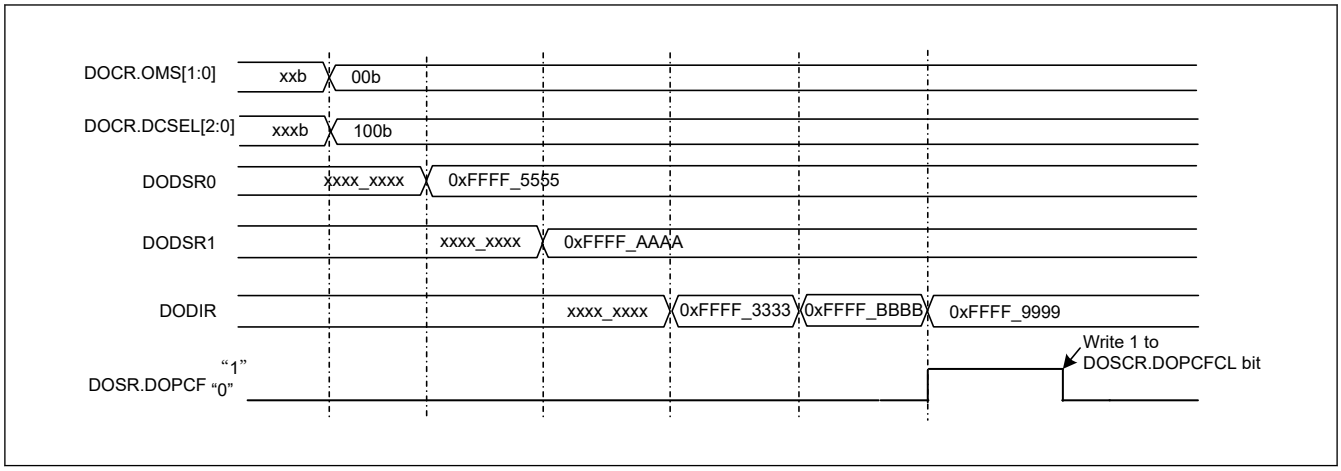

**Figure 43.6 Example of Operation in Data Comparison Mode (Detection condition: Inside window)**

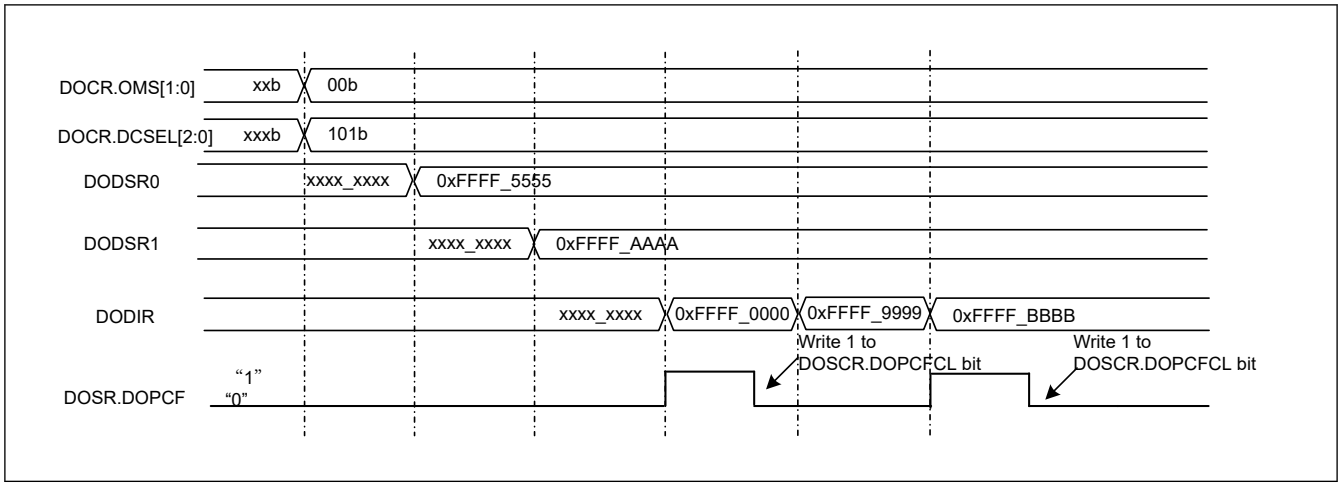

**Figure 43.7 Example of Operation in Data Comparison Mode (Detection condition: Outside window)**

## 43.3.2 Data Addition Mode

Figure 43.8 shows an example of the steps involved in data addition mode [*1] operation by the data operation circuit.

The following is an example of operation when the bit width of data operation is 32-bit.

1. Writing 01b to the DOCR.OMS[1:0] bits selects data addition mode.
2. 32-bit data is set in the DODSR0 register as the initial value.
3. 32-bit data to be added is written to DODIR. The result of the operation is stored in DODSR0.
4. Writing of 32-bit data continues until all data for addition have been written to DODIR.
5. If the result of an operation is greater than 0xFFFF_FFFF, the DOSR.DOPCF flag is set to 1 and an ELC event and a data operation circuit interrupt are generated.

Note 1. Addition is executed only by writing to the DODIR.

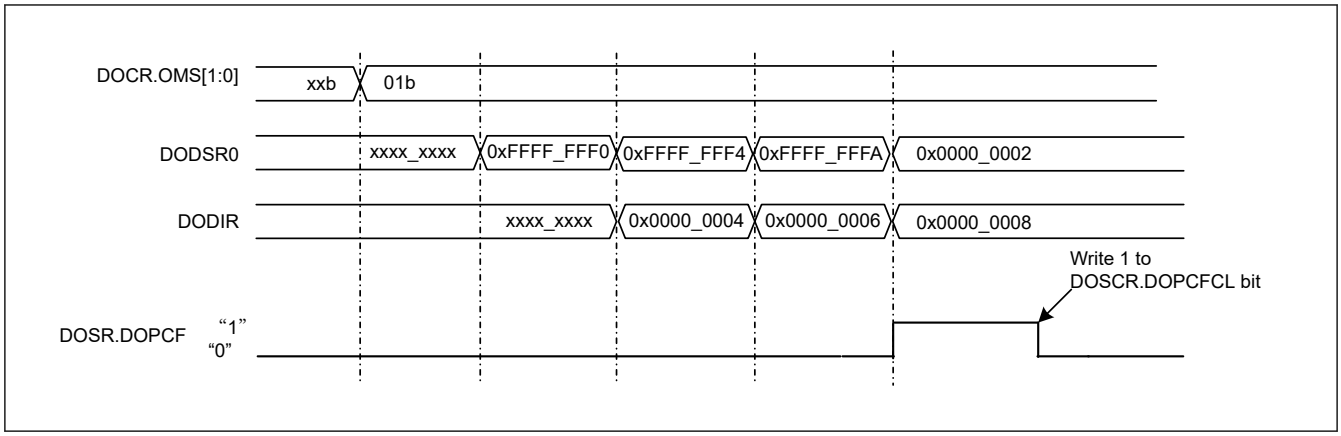

**Figure 43.8 Example of Operation in Data Addition Mode**

### 43.3.3 Data Subtraction Mode

Figure 43.9 shows an example of the steps involved in data subtraction mode *1 operation by the data operation circuit.

The following is an example of operation when the bit width of data operation is 32-bit.

1. Writing 10b to the DOCR.OMS[1:0] bits selects data subtraction mode.
2. 32-bit data is set in the DODSR0 register as the initial value.
3. 32-bit data to be subtracted is written to DODIR. The result of the operation is stored in DODSR0.
4. Writing of 32-bit data continues until all data for subtraction have been written to DODIR.
5. If the result of an operation is less than 0x0000_0000, the DOSR.DOPCF flag is set to 1 and an ELC event and a data operation circuit interrupt are generated.

Note 1. Subtraction is executed only by writing to the DODIR.

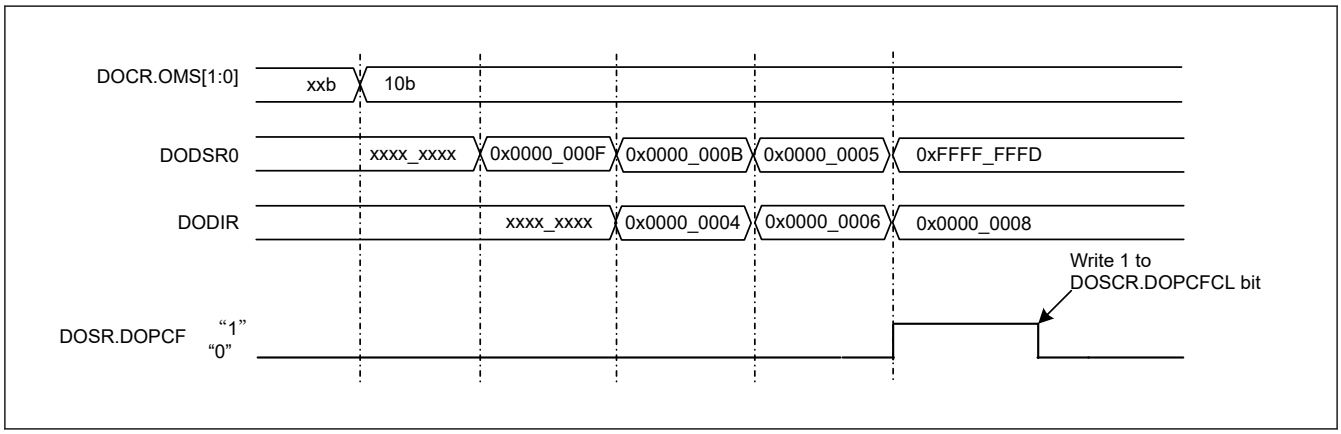

**Figure 43.9 Example of Operation in Data Subtraction Mode**

## 43.4 Interrupt Source

The data operation circuit generates the data operation circuit interrupt (DOC_DOPCI) as an interrupt request. When an interrupt source is generated, the data operation circuit flag corresponding to the interrupt is set to 1, and then interrupt request signal is generated. Table 43.2 describes the interrupt request.

**Table 43.2 Interrupt request from DOC**

| Interrupt request | Status flag | Interrupt source |
|---|---|---|
| DOC interrupt | DOPCF | • The compared values match the detection condition.<br>• The result of data addition is greater than 0xFFFF (DOCR.DOBW = 0) or 0xFFFF_FFFF (DOCR.DOBW = 1).<br>• The result of data subtraction is less than 0x0000 (DOCR.DOBW = 0) or 0x0000_0000 (DOCR.DOBW = 1). |

## 43.5 Event Link Output

The DOC outputs event signals for the event link controller (ELC) under the following conditions, and these can be used to initiate operations by other modules selected in advance.

- The compared values match the detection condition
- The data addition result is greater than 0xFFFF (DOCR.DOBW = 0) or 0xFFFF_FFFF (DOCR.DOBW = 1)
- The data subtraction result is less than 0x0000 (DOCR.DOBW = 0) or 0x0000_0000 (DOCR.DOBW = 1)

## 43.6 Interrupt Handling and Event Linking

The DOC has a bit to enable or disable interrupts. An interrupt request signal is output for the CPU when an interrupt source is generated while the corresponding enable bit is enabled.

In contrast, an event link output signal is sent to other modules as an event signal via the ELC when an interrupt source is generated, regardless of the setting of the corresponding interrupt enable bit.

## 43.7 Usage Notes

### 43.7.1 Settings for the Module-Stop State

The module Stop Control Register C (MSTPCRC) can enable or disable DOC operation. The DOC is initially stopped after reset. Releasing the module-stop state enables access to the registers. For details, see section 10, Low Power Modes.

# 44. SRAM

## 44.1 Overview

The MCU provides an on-chip, high-density SRAM module with either parity-bit checking or Error Correction Code (ECC).The first 32 KB area of the SRAM0 is the ECC. Parity check is performed on the other areas.

Table 44.1 lists the SRAM specifications.

**Table 44.1 SRAM specifications**

| Parameter | Without ECC | With ECC |
|---|---|---|
| SRAM capacity | SRAM0: 32 KB | SRAM0: 32 KB |
| SRAM address | SRAM0: 0x2000_8000 to 0x2000_FFFF | SRAM0: 0x2000_0000 to 0x2000_7FFF |
| Access | Can access with no wait.<br>For details, see section 44.3.8. Number of Access Cycles to SRAM | |
| Module-stop function | Module-stop state can be set to reduce power consumption | |
| Parity | Even parity with 8-bit data and 1-bit parity | No parity |
| Error checking | Even parity (data: 8 bits, parity: 1 bit) | SEC-DED (Single-Error Correction and Double-Error Detection Code) |
| Security | TrustZone Filter is integrated for memory access and SFR access. Access to the memory space is controlled by setting the memory Security Attribution (SA). And, access to I/O space (SFR) space is controlled by setting the register SA. See section 44.3.6. TrustZone Filter Function. | |

## 44.2 Register Descriptions

### 44.2.1 SRAMSAR : SRAM Security Attribution Register

Base address: CPSCU = 0x4000_8000

Offset address: 0x10

| Bit position: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — |
| Value after reset: | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 |

| Bit position: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | — | — | — | — | — | — | — | — | — | — | SRAMSA2 | — | SRAMSA0 |
| Value after reset: | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 0 | SRAMSA0 | Security attributes of registers for SRAM Protection<br>0: Secure<br>1: Non-secure | R/W |
| 1 | — | This bit is read as 1. The write value should be 1. | R/W |
| 2 | SRAMSA2 | Security attributes of registers for ECC Relation<br>0: Secure<br>1: Non-secure | R/W |
| 31:3 | — | These bits are read as 1. The write value should be 1. | R/W |

Note: Only Secure access can write to this register. Both Secure access and Non-secure read access are allowed but Non-secure write access is not allowed and TrustZone access error is not generated.

Note: This register is write-protected by PRCR register.

**SRAMSA0 bit (Security attributes of registers for SRAM Protection)**

Security attributes of registers for SRAM protection. The target registers are as follow:

- PARIOAD
- SRAMPRCR

**SRAMSA2 bit (Security attributes of registers for ECC Relation)**

Security attributes of registers for ECC Relation. The target registers are as follow.

- ECCMODE
- ECC2STS
- ECC1STSEN
- ECC1STS
- ECCPRCR
- ECCPRCR2
- ECCETST
- ECCOAD

## 44.2.2 PARIOAD : SRAM Parity Error Operation After Detection Register

Base address: SRAM = 0x4000_2000

Offset address: 0x00

| Bit position: | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | — | — | — | — | OAD |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 0 | OAD | Operation After Detection<br>0: Non-maskable interrupt<br>1: Reset | R/W |
| 7:1 | — | These bits are read as 0. The write value should be 0. | R/W |

Note: If the security attribution is configured as Secure:
- Secure access and Non-secure read access are allowed
- Non-secure write access is ignored, and TrustZone access error is not generated.

If the security attribution is configured as Non-secure:
- Secure and Non-secure access are allowed.

The PARIOAD register controls the operation on detection of a parity error. The SRAM Protection Register (SRAMPRCR) protects this register against writes. Always set the SRAMPRCR bit in SRAMPRCR to 1 before writing to this bit. Do not write to the PARIOAD register while accessing the SRAM.

**OAD bit (Operation After Detection)**

The OAD bit specifies the generation of either a reset or non-maskable interrupt when a parity error is detected. The OAD bit is commonly used for SRAM0 (without ECC).

## 44.2.3 SRAMPRCR : SRAM Protection Register

Base address: SRAM = 0x4000_2000

Offset address: 0x04

| Bit position: | 7 | | | | | | 1 | 0 |
|---|---|---|---|---|---|---|---|---|
| Bit field: | KW[6:0] | | | | | | | SRAM PRCR |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 0 | SRAMPRCR | Register Write Control<br>0: Disable writes to protected registers<br>1: Enable writes to protected registers | R/W |
| 7:1 | KW[6:0] | Write Key Code<br>These bits enable or disable writes to the SRAMPRCR bit | W |

Note: If the security attribution is configured as Secure:
- Secure access and Non-secure read access are allowed
- Non-secure write access is ignored, and TrustZone access error is not generated.

If the security attribution is configured as Non-secure:
- Secure and Non-secure access are allowed.

### SRAMPRCR bit (Register Write Control)

The SRAMPRCR bit controls the write mode of the PARIOAD register. Setting the bit to 1 enables writes to the PARIOAD register. When you write to this bit, always write 0x78 to KW[6:0] bits simultaneously.

### KW[6:0] bits (Write Key Code)

The KW[6:0] bits enable or disable writes to the SRAMPRCR bit. When you write to the SRAMPRCR bit, always write 0x78 to these bits simultaneously. When a value other than 0x78 is written to KW[6:0], the SRAMPRCR bit is not updated. The KW[6:0] bits are always read as 0x00.

## 44.2.4 ECCMODE : ECC Operating Mode Control Register

Base address: SRAM = 0x4000_2000

Offset address: 0xC0

| Bit position: | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | — | — | — | ECCMOD[1:0] | |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 1:0 | ECCMOD[1:0] | ECC Operating Mode Select<br>0 0: Disable ECC function<br>0 1: Setting prohibited<br>1 0: Enable ECC function without error checking<br>1 1: Enable ECC function with error checking | R/W |
| 7:2 | — | These bits are read as 0. The write value should be 0. | R/W |

Note: If the security attribution is configured as Secure:
- Secure access and Non-secure read access are allowed
- Non-secure write access is ignored, and TrustZone access error is not generated.

If the security attribution is configured as Non-secure:
- Secure and Non-secure access are allowed.

The ECCMODE register specifies the ECC operating mode. The ECC Protection Register (ECCPRCR) protects this register against writes. Before writing to this register, set the ECCPRCR bit in the ECCPRCR register to 1 (write protection disabled). Do not write to the ECCMODE register while accessing the SRAM.

### ECCMOD[1:0] bits (ECC Operating Mode Select)

The ECCMOD[1:0] bits set the access mode to the ECC area in SRAM0.

## 44.2.5 ECC2STS : ECC 2-Bit Error Status Register

Base address: SRAM = 0x4000_2000

Offset address: 0xC1

| Bit position: | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | — | — | — | — | ECC2ERR |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 0 | ECC2ERR | ECC 2-Bit Error Status<br>0: No 2-bit ECC error occurred<br>1: 2-bit ECC error occurred | R/W*1 |
| 7:1 | — | These bits are read as 0. The write value should be 0. | R/W |

Note: If the security attribution is configured as Secure:
- Secure access and Non-secure read access are allowed
- Non-secure write access is ignored, and TrustZone access error is not generated.

If the security attribution is configured as Non-secure:
- Secure and Non-secure access are allowed.

Note 1. Only 0 can be written to clear the bit.

### ECC2ERR bit (ECC 2-Bit Error Status)

The ECC2ERR bit indicates whether a 2-bit ECC error occurred in the ECC area of SRAM0. When a 2-bit error is detected while ECC operations are enabled and error checking is selected, theECC2ERR bit is set to 1. The SRAM error signal is also asserted at this time. The 2-bit ECC error can be cleared by writing 0 to the ECC2ERR bit.

The SRAM error can be specified as a non-maskable interrupt or a reset in the ECCOAD register. Do not access the ECC area in SRAM0 while writing 0 to this register.

## 44.2.6 ECC1STSEN : ECC 1-Bit Error Information Update Enable Register

Base address: SRAM = 0x4000_2000

Offset address: 0xC2

| Bit position: | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | — | — | — | — | E1STSEN |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 0 | E1STSEN | ECC 1-Bit Error Information Update Enable<br>0: Disable updating of 1-bit ECC error information<br>1: Enable updating of 1-bit ECC error information | R/W |
| 7:1 | — | These bits are read as 0. The write value should be 0. | R/W |

Note: If the security attribution is configured as Secure:
- Secure access and Non-secure read access are allowed
- Non-secure write access is ignored, and TrustZone access error is not generated.

If the security attribution is configured as Non-secure:
- Secure and Non-secure access are allowed.

The ECC1STSEN register enables or disables updating of the ECC 1-bit Error Status Register (ECC1STS) in response to a 1-bit error ECC error in the SRAM0 (ECC area).

The ECC Protection Register (ECCPRCR) protects this register against writes. Before writing to this bit, set the ECCPRCR bit in the ECCPRCR register to 1 (write protection disabled).

### E1STSEN bit (ECC 1-Bit Error Information Update Enable)

The E1STSEN bit enables or disables updating of the SRAM (ECC area) 1-Bit Error Status Register (ECC1STS) in response to a 1-bit error in the ECC area of SRAM0. This register also functions as an interrupt or a reset mask.

## 44.2.7 ECC1STS : ECC 1-Bit Error Status Register

Base address: SRAM = 0x4000_2000

Offset address: 0xC3

| Bit position: | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | — | — | — | — | ECC1ERR |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 0 | ECC1ERR | ECC 1-Bit Error Status<br>0: No 1-bit ECC error occurred<br>1: 1-bit ECC error occurred | R/(W)*1 |
| 7:1 | — | These bits are read as 0. The write value should be 0. | R/W |

Note: If the security attribution is configured as Secure:
- Secure access and Non-secure read access are allowed
- Non-secure write access is ignored, and TrustZone access error is not generated.

If the security attribution is configured as Non-secure:
- Secure and Non-secure access are allowed.

Note 1. Only 0 can be written to clear the bit.

### ECC1ERR bit (ECC 1-Bit Error Status)

The ECC1ERR bit indicates whether a 1-bit ECC error occurred in the ECC area of SRAM0. When a 1-bit error is detected while ECC operations are enabled and error checking is selected, theECC1ERR bit is set to 1. The SRAM error signal is also asserted at this time. The 1-bit ECC error can be cleared by writing 0 to the ECC1ERR bit.

The SRAM error can be specified as a non-maskable interrupt or a reset in the ECCOAD register. Do not access the ECC area in SRAM0 while writing 0 to this register.

## 44.2.8 ECCPRCR : ECC Protection Register

Base address: SRAM = 0x4000_2000

Offset address: 0xC4

| Bit position: | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|
| Bit field: | KW[6:0] | | | | | | | ECCPRCR |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 0 | ECCPRCR | Register Write Control<br>0: Disable writes to the protected registers<br>1: Enable writes to the protected registers | R/W |
| 7:1 | KW[6:0] | Write Key Code<br>0x78: Enable write to the ECCPRCR bit<br>Others: Disable write to the ECCPRCR bit | W |

Note: If the security attribution is configured as Secure:
- Secure access and Non-secure read access are allowed
- Non-secure write access is ignored, and TrustZone access error is not generated.

If the security attribution is configured as Non-secure:
- Secure and Non-secure access are allowed.

### ECCPRCR bit (Register Write Control)

The ECCPRCR bit controls the write of the ECCMODE, ECC1STSEN, and ECCOAD registers. When this bit is set to 1, writing to the ECCMODE, ECC1STSEN, and ECCOAD registers is enabled. When writing to this bit, write 0x78 to the KW[6:0] bits at the same time.

### KW[6:0] bits (Write Key Code)

The KW[6:0] bits enable or disable writes to the ECCPRCR bit. When writing toECCPRCR bit, write 0x78 to the KW[6:0] bits at the same time. When a value other than 0x78 is written to theKW[6:0] bits, the ECCPRCR bit is not updated. The KW[6:0] bits are always read as 0x00.

## 44.2.9 ECCPRCR2 : ECC Protection Register 2

Base address: SRAM = 0x4000_2000

Offset address: 0xD0

| Bit position: | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|
| Bit field: | KW2[6:0] | | | | | | | ECCPRCR2 |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 0 | ECCPRCR2 | Register Write Control<br>0: Disable writes to the protected registers<br>1: Enable writes to the protected registers | R/W |
| 7:1 | KW2[6:0] | Write Key Code<br>0x78: Enable write to the ECCPRCR2 bit<br>Others: Disable write to the ECCPRCR2 bit | W |

Note: If the security attribution is configured as Secure:
- Secure access and Non-secure read access are allowed
- Non-secure write access is ignored, and TrustZone access error is not generated.

If the security attribution is configured as Non-secure:
- Secure and Non-secure access are allowed.

### ECCPRCR2 bit (Register Write Control)

The ECCPRCR2 bit controls the write mode of the ECCETST register. When the ECCPRCR2 bit is set to 1, writes to the ECCETST register is enabled. When writing to this bit, write 0x78 to the KW2[6:0] bits at the same time.

### KW2[6:0] bits (Write Key Code)

The KW2[6:0] bits enable or disable writes to the ECCPRCR2 bit. When writing to ECCPRCR2 bit, write 0x78 to the KW2[6:0] bits at the same time. When a value other than 0x78 is written to the KW2[6:0] bits, the ECCPRCR2 bit is not updated. The KW2[6:0] bits are always read as 0x00.

## 44.2.10 ECCETST : ECC Test Control Register

Base address: SRAM = 0x4000_2000

Offset address: 0xD4

| Bit position: | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | — | — | — | — | TSTBYP |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 0 | TSTBYP | ECC Bypass Select<br>0: Disable ECC bypass<br>1: Enable ECC bypass | R/W |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 7:1 | — | These bits are read as 0. The write value should be 0. | R/W |

Note: If the security attribution is configured as Secure:
- Secure access and Non-secure read access are allowed
- Non-secure write access is ignored, and TrustZone access error is not generated.

If the security attribution is configured as Non-secure:
- Secure and Non-secure access are allowed.

The ECC Protection Register 2 (ECCPRCR2) protects this register against writes. Before writing to this bit, set the ECCPRCR2 bit in the ECCPRCR2 register to 1 (write protection disabled). Do not write to the ECCETST register while accessing the SRAM.

#### TSTBYP bit (ECC Bypass Select)

The TSTBYP bit enables direct access to the ECC code by bypassing the ECC function. When the ECC bypass function is used, the ECCMOD[1:0] bits in the ECCMODE register are set to 00b. The ECC must be accessed in 32 bits using the same address for 32-bit data. The ECC code is assigned to the lower 7 bits of the 32-bit data. When writing the ECC code, the upper 25 bits are ignored. When reading the ECC code, the upper 25 bits are undefined.

Note: For details of ECC test, see section 44.3.4. ECC Decoder Testing.

### 44.2.11 ECCOAD : SRAM ECC Error Operation After Detection Register

Base address: SRAM = 0x4000_2000

Offset address: 0xD8

| Bit position: | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | — | — | — | — | OAD |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 0 | OAD | Operation After Detection<br>0: Non-maskable interrupt<br>1: Reset | R/W |
| 7:1 | — | These bits are read as 0. The write value should be 0. | R/W |

Note: If the security attribution is configured as Secure:
- Secure access and Non-secure read access are allowed
- Non-secure write access is ignored, and TrustZone access error is not generated.

If the security attribution is configured as Non-secure:
- Secure and Non-secure access are allowed.

The ECC Protection Register (ECCPRCR) protects this register against writes. Before writing to this bit, set the ECCPRCR bit in the ECCPRCR register to 1 (write protection disabled). Do not write to the ECCOAD register while accessing the SRAM.

#### OAD bit (Operation After Detection)

The OAD bit selects whether to generate a reset or a non-maskable interrupt when an ECC error is detected. The OAD bit in the ECCOAD register is used for SRAM0 (ECC area).

## 44.3 Operation

### 44.3.1 Module Stop Function

Power consumption can be reduced by setting module stop control register A (MSTPCRA) to stop supply of the clock signal to SRAM.

SRAM0 is controlled by SRAM0 bit in MSTPCRA register and, in the case of 1, SRAM0 becomes the clock stop state.

The SRAM is thus placed in the module-stop state by stopping supply of the clock signals. The SRAM operates after a reset.

SRAM is not accessible if it is in the module-stop state. A transition to the module-stop state should not be made while access to SRAM is in progress.

Access to the SRAM in the module-stop state is prohibited. If access is attempted, correct operation is not guaranteed.

For details on the MSTPCRA register, see section 10, Low Power Modes.

### 44.3.2 Correction of ECC Errors

Enabling and disabling of ECC error correction can be selected through ECCMODE register setting. In the initial state, ECC error correction is disabled. The ECC check type is SEC-DED (Single-Error Correction and Double-Error Detection Code).

When ECC function is enabled, 7-bit check bits are appended to 32-bit data for writing. For reading, 39-bit (data: 32 bits, check bits: 7 bits) data is read out from the SRAM (ECC area).

When ECC function is enabled and error checking is selected by setting ECCMOD[1:0] in the ECCMODE register to 11b, error correction is done if a 1-bit error occurs and the ECC1ERR bit in the ECC1STS register is set to 1 if the E1STSEN bit in the ECC1STSEN register is 1. If a 2-bit error occurs, error detection is done and the ECC2ERR bit in the ECC2STS register is set to 1, though error correction is not performed.

When ECC function is enabled and the error checking is disabled, error correction is done if a 1-bit error occurs but ECC1ERR bit in the ECC1STS register is not updated although E1STSEN bit in the ECC1STSEN register is 1. If a 2-bit error occurs, this error is detected but the ECC2ERR bit in the ECC2STS register is not updated, and error correction is not performed.

When ECC function is disable, neither error correction nor error detection is done although 1-bit or 2-bit error occur.

So ECC1ERR bit and ECC2ERR bit are not updated.

There is no way to confirm the location where the error was found. Therefore, when after the occurrence of an error, update all the data.

When updating all the data after the occurrence of an error, the 32-bit data writing is only supported.

Since the SRAM data is undefined after power on accessing the SRAM when ECC function is enabled and error checking is selected causes an ECC error to occur. Therefore, before using ECC function, initial writing with 32-bit data size to the area to be used in the SRAM should be done.

When a read access is executed in a row after a write access, read access is executed with priority. Therefore, during initialization, do not perform the read access in a row after the write access.

### 44.3.3 ECC Error Interrupt Function

When ECC function is enabled and error checking is applied to the SRAM (ECC area), an ECC error occurs when either the ECC2ERR bit in the ECC2STS register or the ECC1ERR bit in the ECC1STS register becomes 1 to indicate that ECC checking revealed a 2-bit error or a 1-bit error, respectively.

An ECC erroris output with a pulse width of ICLK.When the ECC 1-bit error is to be masked, set the ECC1STSEN.E1STSEN bit to 0 to disable updating of the ECC1ERR bit. An ECC error will not be generated while ECC function is disabled or when ECC function is enabled but error checking is not selected.

ECC error can choose non maskable interrupt or reset by ECCOAD register. When set 1 in the OAD bit of the ECCOAD register, ECC error is output to the Reset function. When set 0 in the OAD bit of the ECCOAD register, ECC Error interrupt is output to the ICU as non-maskable interrupt.

### 44.3.4 ECC Decoder Testing

Figure 44.1 shows the ECC decoder testing.

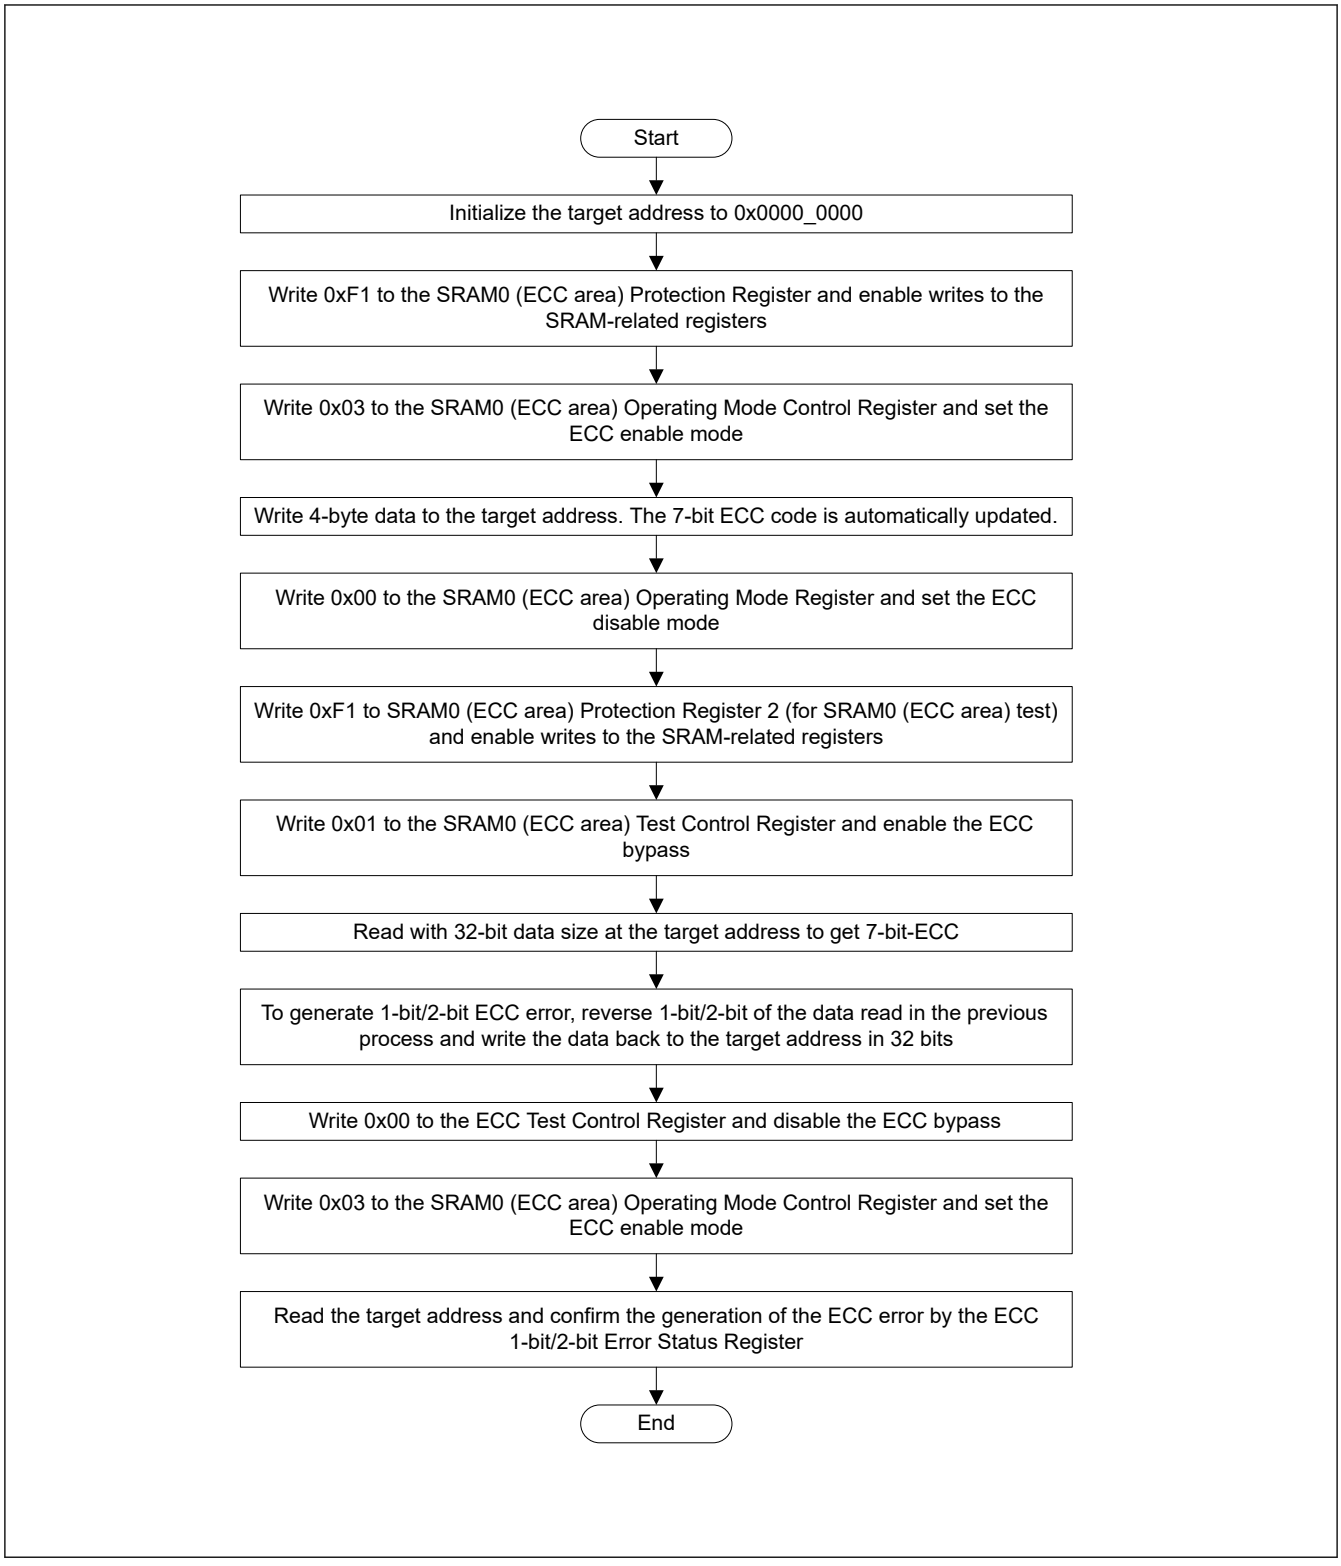

**Figure 44.1 ECC decoder testing**

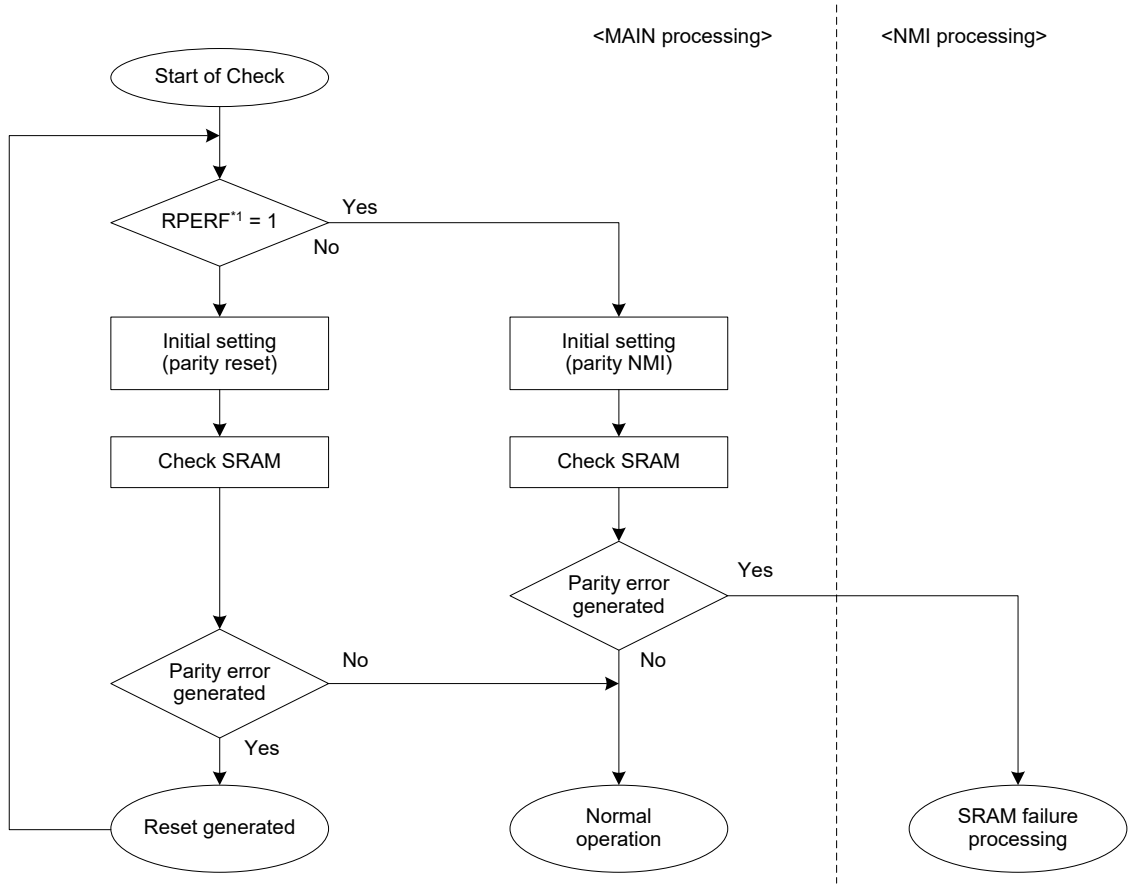
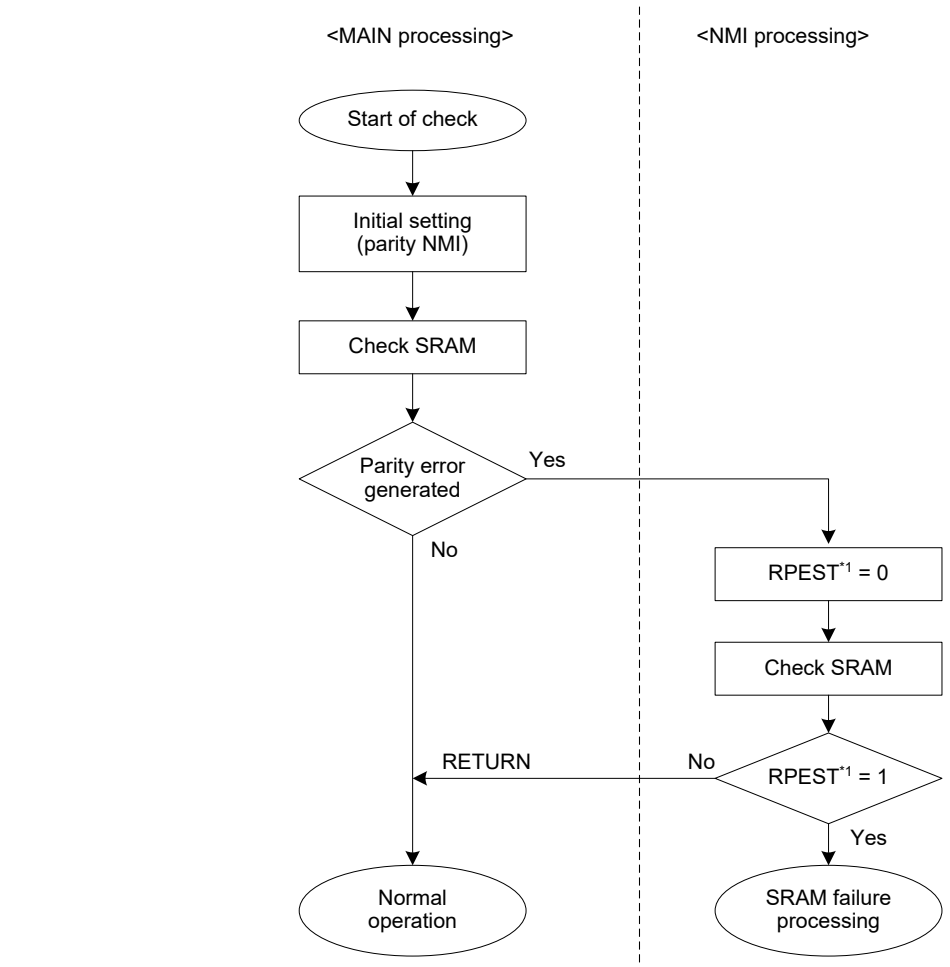


### 44.3.5 Parity Calculation Function

The IEC60730 standard requires the checking of SRAM data. When data is written, a parity bit is added to every 8-bit data in the SRAM which has 32-bit data width, and when data is read, the parity is checked. When a parity error occurs, a parity-error notification is generated. This function can also be used to trigger a reset.

The parity-error notification can be specified as a non-maskable interrupt or a reset in the OAD bit of the PARIOAD register. When the OAD bit is set to 1, a parity error is output to the reset function. When the OAD bit is set to 0, a parity error is output to the ICU as a non-maskable interrupt.



Parity errors can be occasionally caused by noise. To confirm whether the cause of the parity error is noise or corruption, follow the parity check flows shown in Figure 44.2 and Figure 44.3.

When a read access is executed in a row after a write access, read access is executed with priority. Therefore, during initialization, do not perform the read access in a row after the write access.

Note 1. RPERF: SRAM Parity Error Reset Detect Flag (RSTSR1.RPERF bit)

**Figure 44.2 Flow of SRAM parity check when SRAM parity reset is enabled**

Note 1. RPEST: SRAM Parity Error Interrupt Status Flag (NMISR.RPEST bit)

**Figure 44.3 Flow of SRAM parity check when SRAM parity interrupt is enabled**

### 44.3.6 TrustZone Filter Function

There are two types of TrustZone Filter function for SRAM:

- TrustZone Filter for SRAM register protection
- TrustZone Filter for SRAM memory protection

#### 44.3.6.1 TrustZone Filter for SRAM Register Protection

Security attribution (SA) can be used to protect SRAM-related registers from non-secure access. When SA specifies the SRAM-related registers as having secure status, they cannot be overwritten by non-secure access because the TrustZone filter detects this as an error and protects them from the write access. SA for SRAM registers is applied in common to all SRAM registers.

**Table 44.2 Register protection (1 of 2)**

| SA | Access status | Write access | Read access |
|---|---|---|---|
| Secure | Secure | Permit | Permit |
| | Non-secure | TrustZone Filter error Protected | Permit |

**Table 44.2 Register protection (2 of 2)**

| SA | Access status | Write access | Read access |
|---|---|---|---|
| Non-secure | Secure | Permit | Permit |
| | Non-secure | Permit | Permit |

When TrustZone Filter error for SRAM register access occurs, no error notification and no error response occur.

### 44.3.6.2 TrustZone Filter for SRAM Memory Protection

SRAM memory such as SRAM0 includes ECC region and parity can be divided into Secure/Non-secure callable/Non-secure status with Memory Security Attribution (MSA) and can be protected from non-secure access. When MSA indicates that SRAM memory region are of Secure or Non-secure callable status, non-secure access cannot overwrite them.

**Table 44.3 Memory protection**

| SA | Access status | Write access | Read access |
|---|---|---|---|
| Secure/Non-secure callable | Secure | Permit | Permit |
| | Non-secure | TrustZone Filter error<br>• Protected<br>• Error response occurs | TrustZone Filter error<br>• Read data is 0<br>• Error response occurs |
| Non-secure | Secure | Permit | Permit |
| | Non-secure | Permit | Permit |

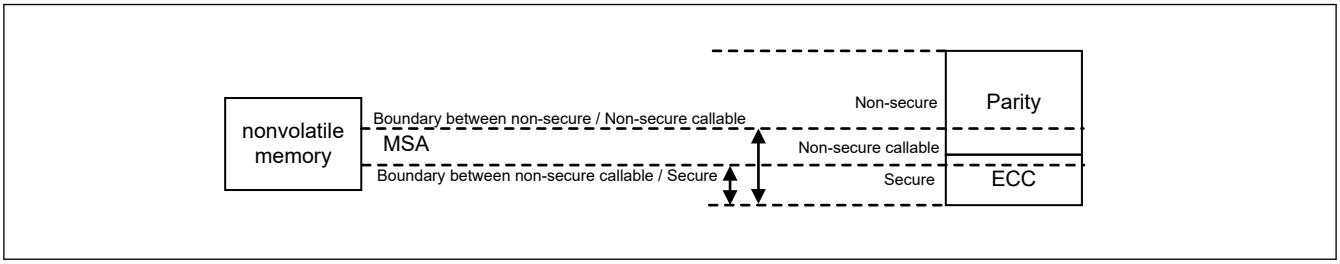


**Figure 44.4 TrustZone Filter for SRAM memory**

When TrustZone Filter error for SRAM memory access occurs, an error notification which becomes reset request or NMI request occurs. See section 48.2. Arm TrustZone Security .

### 44.3.7 Interrupt Source

The SRAM interrupt source includes an ECC error, Parity error and TrustZone filter error. ECC error and Parity error can choose non-maskable interrupt or reset by OAD bit. When the debugger is connected, reset and non-maskable interrupt are maskable. Also, if these masks are set by the debugger, each status register is not set even if an ECC error occurs. For details on the debug mode, see section 2, CPU.

**Table 44.4 SRAM Interrupt Source**

| Name | Interrupt Source | DTC Activation | DMAC Activation |
|---|---|---|---|
| ECCERR | ECC error (ECC operation region in SRAM0) | Not possible | Not possible |
| PARITYERR | Parity error | Not possible | Not possible |
| TZFLT | TrustZone filter error | Not possible | Not possible |

### 44.3.8 Number of Access Cycles to SRAM

When accessing SRAM from the CPU, the access cycle is one cycle if the cache is hit. The number of access cycles differs when the cache is disabled or a miss occurs. Table 44.5 lists the access cycles when the cache is disabled or a cache miss occurs.

**Table 44.5 Access cycles during cache disabled or cache miss**

| Access area | | Read (cycles) | | Write (cycles) | |
|---|---|---|---|---|---|
| | | Word access | Half-word/Byte access | Word access | Half-word/Byte access |
| Cache disabled or non-cacheable in the ECC area | ECCMODE.ECCMOD [1] = 0 (Disable ECC function) | 3 | | 2*1 | |
| | ECCMODE.ECCMOD [1] = 1 (Enable ECC function) | 3 | | 2*1 | 4 |
| Cache disabled or non-cacheable in the Parity area | | 3 | | 2*1 | |
| Cache miss in the cacheable ECC area | ECCMODE.ECCMOD [1] = 0 (Disable ECC function) | 3 | | 1*1 | |
| | ECCMODE.ECCMOD [1] = 1 (Enable ECC function) | 3 | | 1*1 | |
| Cache miss in the cacheable Parity area | | 3 | | 1*1 | |

Note 1. For efficiency of the access, when read access occurs to the same memory after write, memory write by the precedent write command delays it until for the next idle cycle or the next write access. When read continues, it is given priority to read.

# 45. Flash Memory

This MCU incorporates code flash memory, data flash memory, and option-setting memory. The code flash memory stores instructions and operands, and the data flash memory stores data. For option-setting memory, see section 6, Option-Setting Memory.

## 45.1 Overview

Table 45.1 lists the specifications of the flash memory, and Figure 45.1 is block diagrams of the flash memory related modules.

The I/O pins used in boot mode, see Table 45.28.

The FCU (flash control unit) controls programming and erasure of the flash memory. The FACI (flash application command interface) controls the FCU according to the specified FACI commands.

Regarding the configuration of the code flash memory, see Figure 45.2 and Figure 45.3, and for the configuration of the data flash memory, see Figure 45.4. It is necessary to enable HOCO when rewriting the flash memory.

**Table 45.1 Specifications of flash memory (1 of 2)**

| Item | Code flash memory | Data flash memory |
|---|---|---|
| Memory capacity | User area: 512 KB max | Data area: 8 KB |
| Read cycle | See section 45.16.3. Access Cycle | See section 45.16.3. Access Cycle |
| Value after erasure | 0xFF | 0xFF |
| Programming/erasing method | • Programming and erasing the code flash memory and data flash memory, and programming the option-setting memory are handled by the FACI commands specified in the FACI command issuing area (0x407E_0000) (self-programming).<br>• Programming/erasure through transfer by a serial-programmer via a serial interface (serial programming) | |
| Protection | Protects against erroneous rewriting of the flash memory | |
| Dual bank function | The dual-bank structure makes a safe update possible in cases where programming is suspended.<br>• Linear mode: the code flash memory is used as one area.<br>• Dual mode: the code flash memory is divided into two areas. | Not available |
| Block swap function | The block swap structure makes a safe update for a part of non-secure application possible in case where programming is suspended. | Not available |
| Background operations (BGOs) | • The code flash memory can be read while the code flash memory is being programmed or erased.*1<br>• The data flash memory can be read while the code flash memory is being programmed or erased.<br>• The code flash memory can be read while the data flash memory is being programmed or erased. | |
| Units of programming and erasure | • Units of programming for the user area: 8 bytes<br>• Units of erasure for the user area: 2K bytes | • Unit of programming for the data area:1 byte<br>• Unit of erasure for the data area: 256 bytes |
| Other functions | Interrupts can be accepted during self-programming.<br>In the initial settings of this MCU, an expansion area of the option-setting memory can be set. | |

**Table 45.1 Specifications of flash memory (2 of 2)**

| Item | Code flash memory | Data flash memory |
|---|---|---|
| On-board programming (five types) | Programming/erasure in boot mode (for the SCI interface)<br>● The asynchronous serial interface (SCI9) is used.<br>● The transfer rate is adjusted automatically.<br>Programming/erasure in boot mode (for the USB interface)<br>● USBFS is used.<br>● Dedicated hardware is not required, so direct connection to a PC is possible.<br>Programming/erasure in boot mode (for the SWD interface)<br>● SWD interface is used.<br>Programming/erasure in On-chip debug mode<br>● SWD interface is used<br>Programming and erasure by self-programming<br>● This allows code flash memory programming/erasure without resetting the system. | |

| Security function | Protects against illicit tampering with or reading out of data in flash memory<br>Startup area select setting protection<br>● BTFLG and FSUACR registers are protected by the FSPR bit.<br>Permanent block protect setting protection<br>● Code flash memory is permanently protected from programming/erasure operation by the permanent block protect function.<br>Flash memory protection for TrustZone<br>● Protection for flash memory area (P/E)<br>● Protection for flash memory area (read)<br>● Protection for register<br>● Protection during FACI command operation.<br>Code flash P/E mode entry protection | |
| Safety function | Software protection<br>● FACI command protection by FENTRYR register.<br>● Flash memory is protected by FWEPROR register<br>● The user area is protected by the block protect setting<br>Error protection<br>● Error is detected when unintended commands or prohibited settings occur. The FACI command is not accepted after an error detection.<br>Boot area protection<br>● The start-up area select function allows customer to safely update the boot firmware. The size of the start-up area is 8 KB. Boot area is protected from program/erase operation by block protect function. | |
| Interrupt request | ● FRDYI (flash sequencer ready (processing end)) : Enabled by FRDYIE bit.<br>● FIFERR (flash sequencer error) : Enabled by CFAEIE/CMDLKIE/DFAEIE bits | |
| Address conversion | Start-up area select function is supported in linear mode<br>Dual mode and Linear mode<br>● Bank swap function is supported in dual mode<br>● Block swap function is supported in linear mode | |

Note 1. Limitations apply to the combinations of the address ranges for programming/erasure process and reading process: see Table 45.30.

Figure 45.1 shows how modules related to flash memory can be configured. The flash sequencer is configured with the FCU and FACI. The FCU executes basic control for rewriting of the flash memory. The FACI receives FACI commands using peripheral bus, and controls FCU operations accordingly.

In response to a reset, the FACI transfers data from the flash memory to the option byte storage registers.

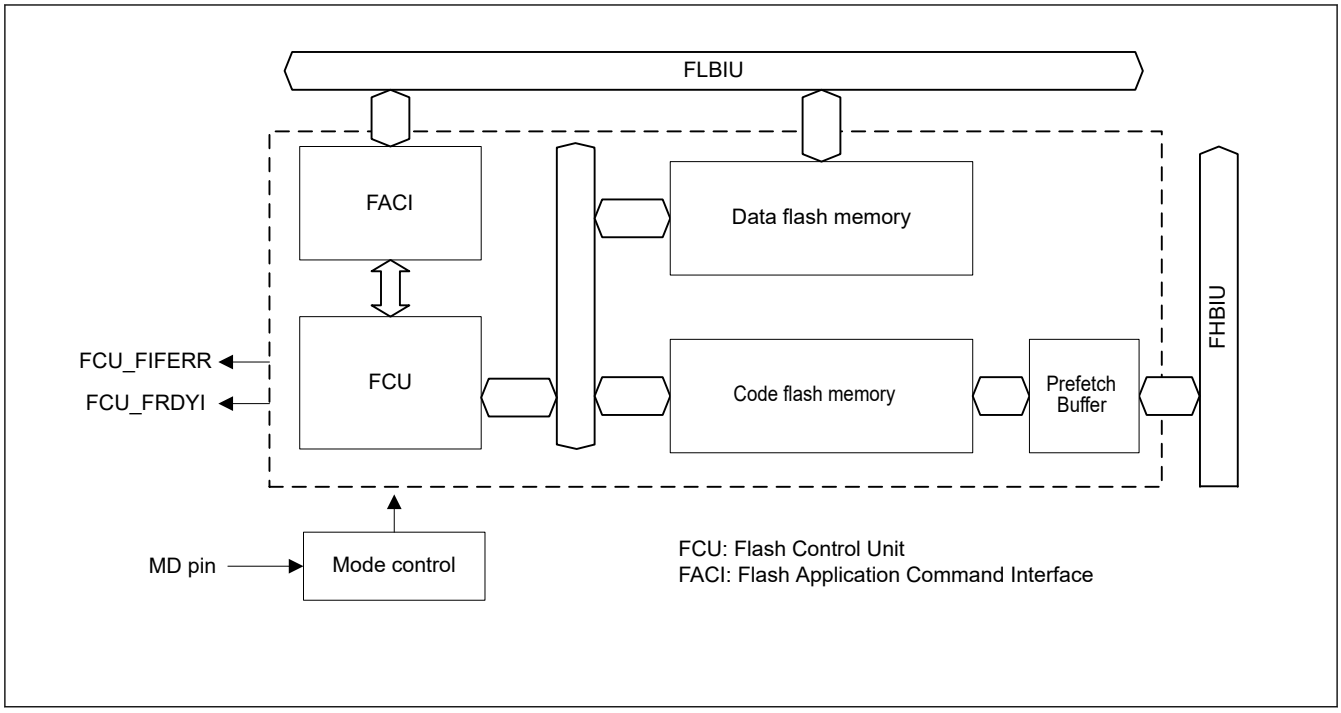

**Figure 45.1 Block diagram of flash memory-related modules**

## 45.2 Structure of Memory

Figure 45.2 shows the memory map of code flash memory in linear mode. Figure 45.3 shows the memory map of code flash memory in dual mode. This MCU can use the code flash memory as 2 bank areas by using the dual bank function. This dual-bank structure allows a safe update of a program while a user program is running.

The user area of the code flash memory in this MCU is divided into 2-Kbyte blocks, which serve as the units of erasure.

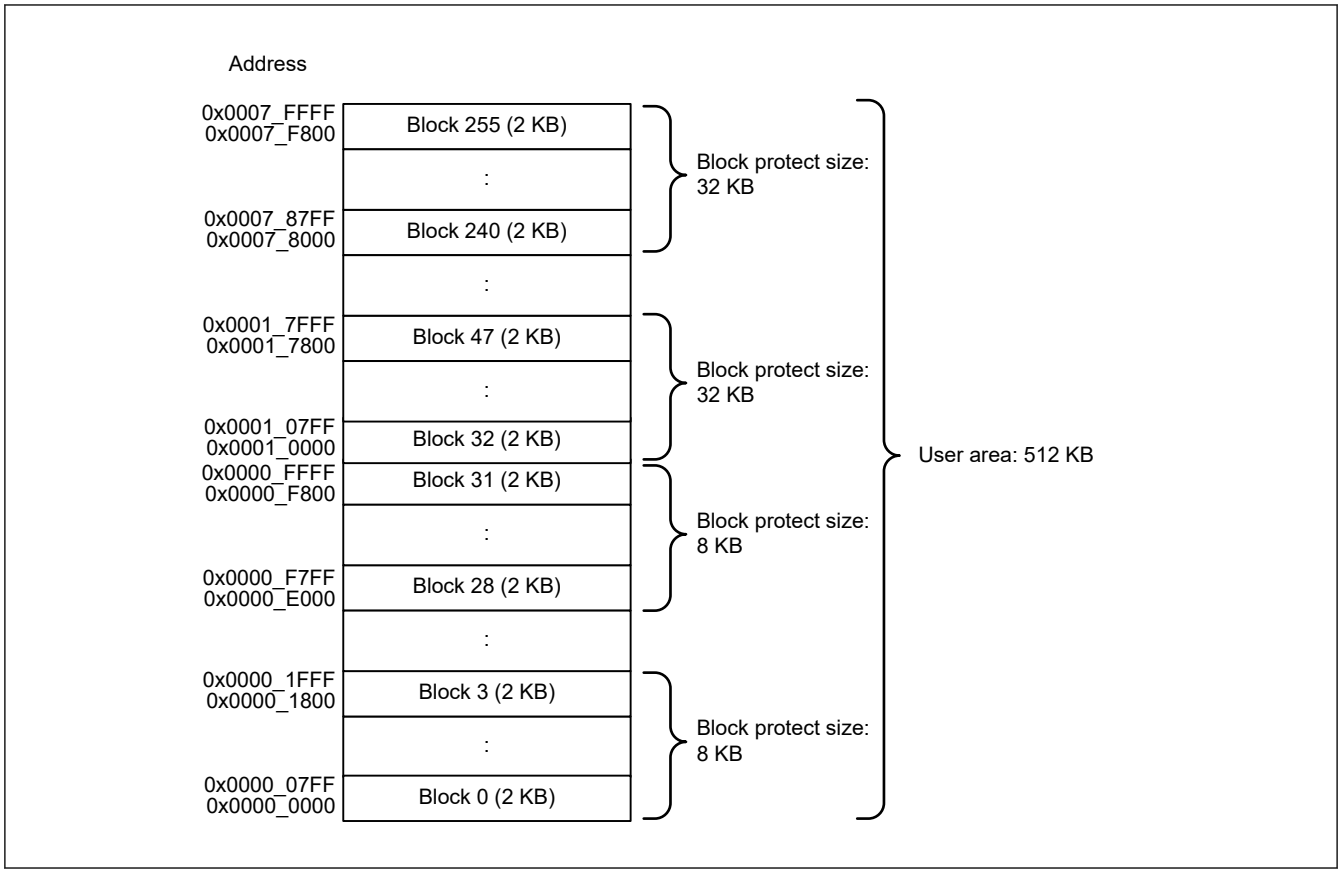

**Figure 45.2 Map of the code flash memory in linear mode**

**Table 45.2 Read and programming/erasure address by product for the code flash memory**

| Product | Address | Number of blocks |
|---|---|---|
| 512 KB product | 0x0000_0000 to 0x0007_FFFF | 0 to 255 |
| 256 KB product | 0x0000_0000 to 0x0003_FFFF | 0 to 127 |

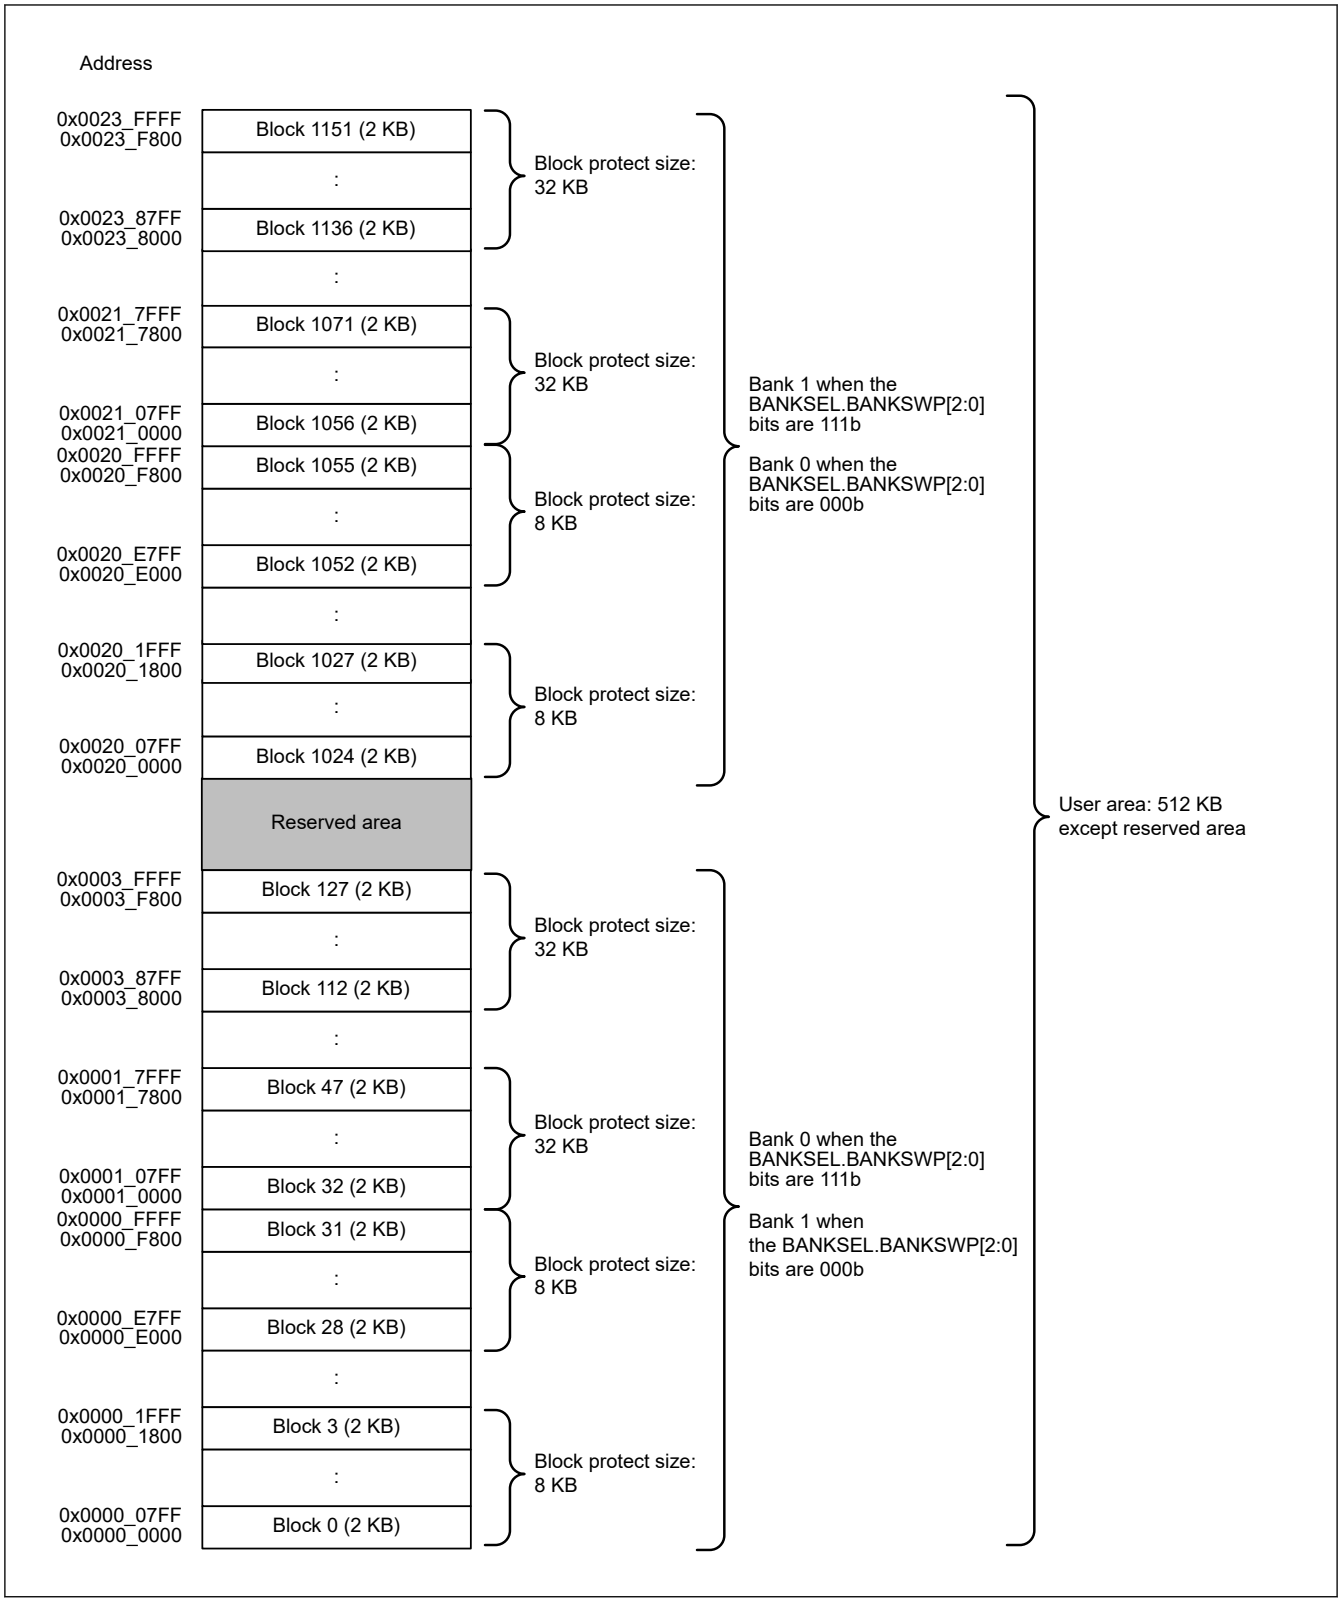

**Figure 45.3 Map of the code flash memory in dual mode**

**Table 45.3 Read and programming/erasure address by product for the code flash memory (1 of 2)**

| Product | Address | Number of blocks |
|---|---|---|
| 512 KB product, lower side bank | 0x0000_0000 to 0x0003_FFFF | 0 to 127 |
| 512 KB product, upper side bank | 0x0020_0000 to 0x0023_FFFF | 1024 to 1151 |

**Table 45.3 Read and programming/erasure address by product for the code flash memory (2 of 2)**

| Product | Address | Number of blocks |
|---|---|---|
| 256 KB product, lower side bank | 0x0000_0000 to 0x0001_FFFF | 0 to 63 |
| 256 KB product, upper side bank | 0x0020_0000 to 0x0021_FFFF | 1024 to 1087 |

The data area of the data flash memory in this MCU is divided into 256-byte blocks, with each being a unit for erasure. Figure 45.4 shows the mapping of the data flash memory.

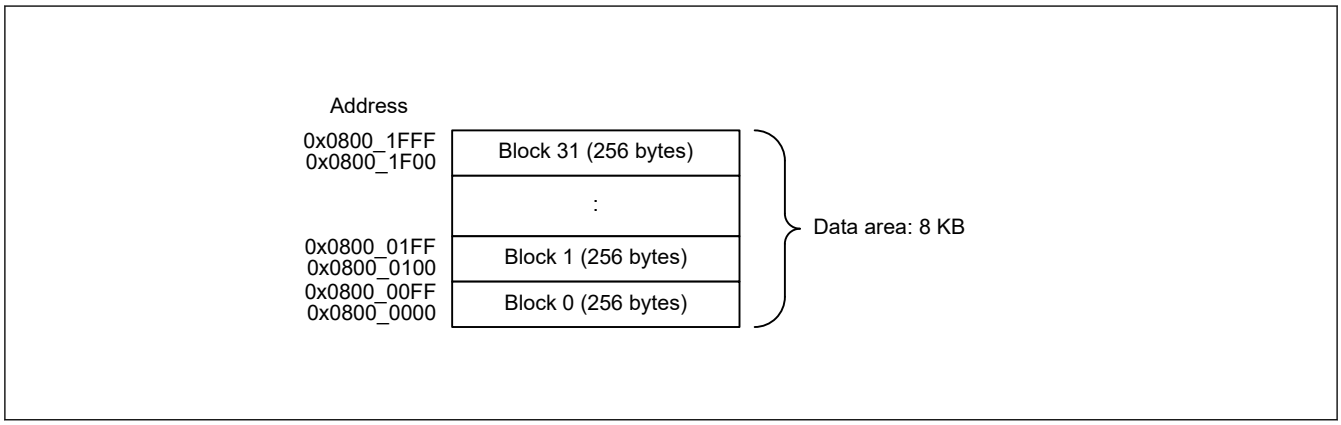

**Figure 45.4 Map of the data flash memory**

## 45.3 Address Space

Using the hardware interface with flash memory requires access to all registers of the hardware, which is for issuing FACI commands. Table 45.4 provides information about the hardware interface.

**Table 45.4 Information on the hardware interface area**

| Area | Address | Capacity |
|---|---|---|
| Area containing various registers of the hardware | See section 45.4. Register Descriptions. | See section 45.4. Register Descriptions. |
| FACI command-issuing area | 0x407E_0000 | 4 bytes |

For the address information of the flash memory, see Figure 45.2.

## 45.4 Register Descriptions

### 45.4.1 DFLCTL : Data Flash Control Register

Base address: FLCN = 0x407E_C000

Offset address: 0x0090

| Bit position: | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | — | — | — | — | DFLEN |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 0 | DFLEN | Data Flash Access Enable*1<br>0: Access to the data flash is disabled<br>1: Access to the data flash is enabled | R/W |
| 7:1 | — | These bits are read as 0. The write value should be 0. | R/W |

Note: If the security attribution is configured as Secure:

- Secure access and Non-secure read access are allowed

- Non-secure write access is ignored, and TrustZone access error is not generated.

If the security attribution is configured as Non-secure:

- Secure and Non-secure access are allowed.

Note 1. It is necessary that DFLCTL.DFLEN bit is set to 1 before issuing the Configuration set command.

The DFLCTL register enables or disables access (reading, programming, and erasing) to the data flash. After setting the DFLCTL.DFLEN bit, Data Flash STOP recovery time ($t_{DSTOP}$) is required before reading the data flash or entering the data flash P/E mode.

## 45.4.2 PFBER : Prefetch Buffer Enable Register

Base address: FLCN = 0x407E_C000

Offset address: 0x3FC8

| Bit position: | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | — | — | — | — | PFBE |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 0 | PFBE | Prefetch Buffer Enable bit<br>0: Prefetch buffer is disabled<br>1: Prefetch buffer is enabled | R/W*1 |
| 7:1 | — | These bits are read as 0. The write value should be 0. | R/W |

Note: If the security attribution is configured as Secure:

- Secure access and Non-secure read access are allowed
- Non-secure write access is ignored, and TrustZone access error is not generated.

If the security attribution is configured as Non-secure:

- Secure and Non-secure access are allowed.

Note 1. The prefetch buffer should be disabled once to initialize the buffer after programming or erasing the code flash memory or after setting the option-setting memory. The setting of PFBE bit from 1b to 0b must be done when the code flash memory is not being read. For example, the software on SRAM that writes PFBE bit and confirms its value changed can avoid PFBE bit changing while the code flash memory read.

## 45.4.3 FSAR : Flash Security Attribution Register

Base address: FCACHE = 0x4001_C100

Offset address: 0x040

| Bit position: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | DFLCTLSA | — | — | — | — | FACICOMRSA | FACICOMISA | — | — | — | — | — | — | — | PFBERSA | FLWTSA |
| Value after reset: | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 0 | FLWTSA | FLWT Security Attribution<br>Target register : MEMWAIT<br>0: Secure<br>1: Non-secure | R/W |
| 1 | PFBERSA | PFBER Security Attribution<br>Target register : PFBER<br>0: Secure<br>1: Non-secure | R/W |
| 8:2 | — | These bits are read as 1. The write value should be 1. | R/W |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 9 | FACICOMISA | FACI Command Issuing Security Attribution<br>Target register : FACI command-issuing area<br>0: Secure<br>1: Non-secure | R/W |
| 10 | FACICOMRSA | FACI Command Registers Security Attribution<br>Target register : FACI registers except read-only registers FMEPROT, FBPROT1, and FSUACR<br>0: Secure<br>1: Non-secure | R/W |
| 14:11 | — | These bits are read as 1. The write value should be 1. | R/W |
| 15 | DFLCTLSA | DFLCTL Security Attribution<br>Target register : DFLCTL<br>0: Secure<br>1: Non-secure | R/W |

Note: Only Secure access can write to this register. Both Secure access and Non-secure read access are allowed but Non-secure write access is not allowed and TrustZone access error is not generated.
Note: This register is write-protected by PRCR register.

Each bit sets the security attribution of each target register.

### 45.4.4 UIDRn : Unique ID Registers n (n = 0 to 3)

Address: 0x0100_8190 + n × 4

| Bit position: | 31 | 0 |
|---|---|---|
| Bit field: | UID | |
| Value after reset: | Unique value for each chip | |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 31:0 | UID | Unique ID | R |

The UIDRn is a read-only register that stores a 16-byte ID code (unique ID) for identifying the individual MCU. The UIDRn register should be read in 32-bit units. When reading by the signature request command of the serial programming interface, the data is read in order from the data with the large address. That is, the data in 0x0100_819F is read first, and in 0x0100_8190 is read last.

### 45.4.5 PNRn : Part Numbering Register n (n = 0 to 3)

Address: 0x0100_80F0 + n × 4

| Bit position: | 31 | 0 |
|---|---|---|
| Bit field: | PNR | |
| Value after reset: | Unique value for each chip | |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 31:0 | PNR | Part Number | R |

The PNRn is a read-only register that stores a 16-byte part numbering. The PNRn register should be read in 32-bit units. Each byte corresponds to the ASCII code representation of the product part number as detailed in Table 1.14. The first character ("R", 0x52 in ASCII code) of the part number is stored in the byte with the smallest address (0x0100_80F0). When reading by the signature request command of the serial programming interface, the data is read in order from the data with the small address. That is, the data in 0x0100_80F0 is read first, and in 0x0100_80FF is read last.

## 45.4.6 MCUVER : MCU Version Register

Address: 0x0100_81B0

| Bit position: | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|
| Bit field: | MCUVE | | | | | | | |
| Value after reset: | Value depend on the chip | | | | | | | |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 7:0 | MCUVE | MCU Version | R |

The MCUVER is a read-only register that stores a MCU version. The MCUVER register should be read in 8-bit units.

## 45.4.7 FASTAT : Flash Access Status Register

Base address: FACI = 0x407F_E000

Offset address: 0x10

| Bit position: | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|
| Bit field: | CFAE | — | — | CMDLK | DFAE | — | — | — |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 2:0 | — | These bits are read as 0. The write value should be 0. | R/W |
| 3 | DFAE | Data Flash Memory Access Violation Flag<br>0: No data flash memory access violation has occurred<br>1: A data flash memory access violation has occurred. | R/W*1 |
| 4 | CMDLK | Command Lock Flag<br>0: The flash sequencer is not in the command-locked state<br>1: The flash sequencer is in the command-locked state. | R |
| 6:5 | — | These bits are read as 0. The write value should be 0. | R/W |
| 7 | CFAE | Code Flash Memory Access Violation Flag<br>0: No code flash memory access violation has occurred<br>1: A code flash memory access violation has occurred. | R/W*1 |

Note: If the security attribution is configured as Secure:
- Secure access and Non-secure read access are allowed
- Non-secure write access is ignored, and TrustZone access error is not generated.

If the security attribution is configured as Non-secure:
- Secure and Non-secure access are allowed.

Note 1. Only 0 can be written to clear the flag after 1 is read.

The FASTAT register indicates whether a code flash or data flash memory access violation has occurred. If any of the CFAE, CMDLK, and DFAE bits is set to 1, the flash sequencer enters the command-locked state (see section 45.11.2. Error Protection). To release it from the command-locked state, issue a status clear command or Forced Stop command to the flash sequencer.

### DFAE bit (Data Flash Memory Access Violation Flag)

The DFAE bit indicates whether a data flash memory access violation occurred. When this bit is set to 1, the ILGLERR bit in the FSTATR register is set to 1, placing the flash sequencer in the command-locked state.

[Setting conditions]

FACI commands issued in the data flash P/E mode are as follows:

- The setting of the FSADDR or FEADDR register is the reserved portion of the data area
- FACI commands of non-secure access are issued while the setting of the FSADDR or FEADDR register is the secure region address.

[Clearing conditions]

- When this bit is written as 0 after it is set to 1
- When the flash sequencer starts to process the Status Clear or Forced Stop command.

### CMDLK bit (Command Lock Flag)

The CMDLK bit indicates that the flash sequencer is in the command-locked state.

[Setting conditions]

- The flash sequencer detects an error and enters the command-locked state.

[Clearing conditions]

- When the flash sequencer starts to process the Status Clear or Forced Stop command.

### CFAE bit (Code Flash Memory Access Violation Flag)

The CFAE bit indicates whether a code flash memory access violation has occurred. When this bit is set to 1, the ILGLERR bit in the FSTATR register is set to 1, placing the flash sequencer in the command-locked state.

[Setting conditions]

FACI commands issued in the code flash P/E mode are as follows:

- The setting of the FSADDR register is the reserved portion of the user area
- The Configuration set command is issued while the setting of the FSADDR register is from 0x0000A100 to 0x0000A2F0 in self-programming mode
- FACI commands of non-secure access are issued while the setting of the FSADDR register is the secure region address.

[Clearing conditions]

- When this bit is written as 0 after it is set to 1
- When the flash sequencer starts to process the Status Clear or Forced Stop command.

## 45.4.8 FAEINT : Flash Access Error Interrupt Enable Register

Base address: FACI = 0x407F_E000

Offset address: 0x14

| Bit position: | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|
| Bit field: | CFAEIE | — | — | CMDLKIE | DFAEIE | — | — | — |
| Value after reset: | 1 | 0 | 0 | 1 | 1 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 2:0 | — | These bits are read as 0. The write value should be 0. | R/W |
| 3 | DFAEIE | Data Flash Memory Access Violation Interrupt Enable<br>0: Generation of an FIFERR interrupt request is disabled when FASTAT.DFAE is set to 1<br>1: Generation of an FIFERR interrupt request is enabled when FASTAT.DFAE is set to 1. | R/W |
| 4 | CMDLKIE | Command Lock Interrupt Enable<br>0: Generation of an FIFERR interrupt request is disabled when FASTAT.CMDLK is set to 1<br>1: Generation of an FIFERR interrupt request is enabled when FASTAT.CMDLK is set to 1. | R/W |
| 6:5 | — | These bits are read as 0. The write value should be 0. | R/W |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 7 | CFAEIE | Code Flash Memory Access Violation Interrupt Enable<br>0: Generation of an FIFERR interrupt request is disabled when FASTAT.CFAE is set to 1<br>1: Generation of an FIFERR interrupt request is enabled when FASTAT.CFAE is set to 1. | R/W |

Note: If the security attribution is configured as Secure:
- Secure access and Non-secure read access are allowed
- Non-secure write access is ignored, and TrustZone access error is not generated.

If the security attribution is configured as Non-secure:
- Secure and Non-secure access are allowed.

The FAEINT register enables or disables generation of a flash access error (FIFERR) interrupt request.

### DFAEIE bit (Data Flash Memory Access Violation Interrupt Enable)

The DFAEIE bit enables or disables generation of an FIFERR interrupt request when a data flash memory access violation occurs, setting the DFAE bit in the FASTAT register to 1.

### CMDLKIE bit (Command Lock Interrupt Enable)

The CMDLKIE bit enables or disables generation of an FIFERR interrupt request when the flash sequencer enters the command-locked state, setting the CMDLK bit in the FASTAT register to 1.

### CFAEIE bit (Code Flash Memory Access Violation Interrupt Enable)

The CFAEIE bit enables or disables generation of an FIFERR interrupt request when a code flash memory access violation occur, setting the CFAE bit in the FASTAT register to 1.

## 45.4.9 FRDYIE : Flash Ready Interrupt Enable Register

Base address: FACI = 0x407F_E000

Offset address: 0x18

| Bit position: | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | — | — | — | — | FRDYIE |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 0 | FRDYIE | Flash Ready Interrupt Enable<br>0: Generation of an FRDY interrupt request is disabled<br>1: Generation of an FRDY interrupt request is enabled. | R/W |
| 7:1 | — | These bits are read as 0. The write value should be 0. | R/W |

Note: If the security attribution is configured as Secure:
- Secure access and Non-secure read access are allowed
- Non-secure write access is ignored, and TrustZone access error is not generated.

If the security attribution is configured as Non-secure:
- Secure and Non-secure access are allowed.

The FRDYIE register enables or disables generation of a flash ready (FRDY) interrupt request.

### FRDYIE bit (Flash Ready Interrupt Enable)

The FRDYIE bit enables or disables generation of an FRDY interrupt request when the FRDY bit in the FSTATR register is changed from 0 to 1 on completion of processing by the flash sequencer of the Program, Block Erase, Chip Erase, Blank Check, and Configuration set command.

## 45.4.10 FSADDR : FACI Command Start Address Register

Base address: FACI = 0x407F_E000

Offset address: 0x30

| Bit position: | 31 | | | | | | | | | | | | | | | | | | | | | | | | | | | | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | FSADDR[31:0] | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 31:0 | FSADDR[31:0] | Start Address for FACI Command Processing | R/W*1 |

Note: If the security attribution is configured as Secure:
- Secure access and Non-secure read access are allowed
- Non-secure write access is ignored, and TrustZone access error is not generated.

If the security attribution is configured as Non-secure:
- Secure and Non-secure access are allowed.

Note 1. These bits can be written when the FRDY bit in the FSTATR register is 1. Writing to these bits are ignored when the FRDY bit is 0. Note that b0 and b1 are read-only.

**Table 45.5 FACI command address boundary**

| Command | Address Boundary |
|---|---|
| Program (code flash memory) | 8 bytes |
| Program (data flash memory) | 1 byte |
| Block Erase (code flash memory) | 2 KB |
| Block Erase (data flash memory) | 256 bytes |
| Chip Erase | One flash memory |
| Blank Check (code flash memory) | 8 bytes |
| Blank Check (data flash memory) | 1 byte |
| Configuration set | 16 bytes |

The FSADDR register specifies the address where the target area for command processing starts when the FACI command for Program, Block Erase, Chip Erase, Blank Check, or Configuration set is issued.

The FSADDR value is initialized when the SUINIT bit in the FSUINITR register is set to 1. It is also initialized by a reset.

### FSADDR[31:0] bits (Start Address for FACI Command Processing)

The FSADDR[31:0] bits specify the start address for FACI command processing. Bits [31:24] are ignored in FACI command processing for the code flash memory. Bits [31:17] are ignored in FACI command processing for the data flash memory. Bits associated with the address bits of lower order than the address boundary listed in Table 45.5 are also ignored.

For information on the addresses of the code flash memory and the data flash memory, see section 45.2. Structure of Memory.

For information on the addresses of the configuration setting, see section 45.9.3.14. Configuration Set Command.

## 45.4.11 FEADDR : FACI Command End Address Register

Base address: FACI = 0x407F_E000

Offset address: 0x34

| Bit position: | 31 | | | | | | | | | | | | | | | | | | | | | | | | | | | | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | FEADDR[31:0] | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 31:0 | FEADDR[31:0] | End Address for FACI Command Processing | R/W*1 |

Note: If the security attribution is configured as Secure:
- Secure access and Non-secure read access are allowed
- Non-secure write access is ignored, and TrustZone access error is not generated.

If the security attribution is configured as Non-secure:
- Secure and Non-secure access are allowed.

Note 1. These bits can be written when the FRDY bit in the FSTATR register is 1. Writing to these bits are ignored when the FRDY bit is 0. Note that bit [0] and bit [1] are read-only.

The FEADDR register specifies the end address of the target area for Chip Erase and Blank Check command processing.

For Chip Erase command, the FEADDR bits should be set to end address of each code flash memory and data flash memory. If the setting of FSADDR is more than FEADDR, the flash sequencer enters the command-locked state.

When incremental mode is selected as the addressing mode for Blank Checking (when FBCCNT.BCDIR = 0), the address specified in the FSADDR register should be equal to or smaller than the address in the FEADDR register. Conversely, the address in the FSADDR register should be equal to or larger than the address in the FEADDR register when decremental mode is selected as the addressing mode for Blank Check (i.e. when FBCCNT.BCDIR = 1). If the BCDIR, FSADDR, and FEADDR bit settings are inconsistent with the specified rules, the flash sequencer enters the command-locked state (see section 45.11.2. Error Protection).

The FEADDR value is initialized when the SUINIT bit in the FSUINITR register is set to 1. It is also initialized by a reset.

### FEADDR[31:0] bits (End Address for FACI Command Processing)

The FEADDR[31:0] bits specify the end address for Chip Erase and Blank Check command processing. Bits [31:24] are ignored in FACI command processing for the code flash memory. Bits [31:17] are ignored in FACI command processing for the data flash memory. Bits corresponding to address bits of lower order than the corresponding boundary listed in the section 45.4.10. FSADDR : FACI Command Start Address Register are ignored.

For information on the addresses of the flash memory, see section 45.2. Structure of Memory.

## 45.4.12 FMEPROT : Flash P/E Mode Entry Protection Register

Base address: FACI = 0x407F_E000

Offset address: 0x44

| Bit position: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | KEY[7:0] | | | | | | | | — | — | — | — | — | — | — | CEPROT |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 1 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 0 | CEPROT | Code Flash P/E Mode Entry Protection<br>0: FENTRYC bit is not protected<br>1: FENTRYC bit is protected. | R/W*1 *2 *4 |
| 7:1 | — | These bits are read as 0. The write value should be 0. | R/W |
| 15:8 | KEY[7:0] | Key Code | W*3 |

Note 1. Writing to this bit is only possible when the FRDY bit in the FSTATR register is 1. Writing to this bit while the FRDY bit = 0 is ignored.
Note 2. Writing to this bit is only possible when 16 bits are written and the value written to the KEY bits is 0xD9.
Note 3. Written values are not retained by these bits (always read as 0x00).
Note 4. Only secure access can write to this register. Both secure access and non-secure read access are allowed. Non-secure write access is denied, but TrustZone access error is not generated.

### CEPROT bit (Code Flash P/E Mode Entry Protection)

The CEPROT bit specifies the protection setting of the FRNTRYC bit in the FENTRYR register.

[Setting condition]

- 1 being written to the CEPROT bit while writing to FMEPROT is enabled.

[Clearing condition]

- 0 being written to the CEPROT bit while writing to FMEPROT is enabled.

## 45.4.13 FBPROT0 : Flash Block Protection Register

Base address: FACI = 0x407F_E000

Offset address: 0x78

| Bit position: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | KEY[7:0] | | | | | | | | — | — | — | — | — | — | — | BPCN0 |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 0 | BPCN0 | Block Protection for Non-secure Cancel<br>0: Block protection is enabled<br>1: Block protection is disabled. | R/W*1 *2*4 |
| 7:1 | — | These bits are read as 0. The write value should be 0. | R/W |
| 15:8 | KEY[7:0] | Key Code | W*3 |

Note 1. This bit can be written when the FRDY bit in the FSTATR register is 1. Writing to this bit is ignored when the FRDY bit is 0.
Note 2. Writing to this bit is only possible when 16 bits are written and the value written to the KEY[7:0] bits is 0x78.
Note 3. Written values are not retained by these bits (always read as 0x00).
Note 4. Only secure access can write to this register. Both secure access and non-secure read access are allowed. Non-secure write access is denied, but TrustZone access error is not generated.

The FBPROT0 register is used to disable the block protect function for non-secure. When the block protect setting is locked by the permanent block setting, it cannot be disabled by this register.

The FBPROT0 value is initialized when the SUINIT bit in the FSUINITR is set to 1, because the FENTRYR value is initialized to 0x0000. It is also initialized by a reset.

### BPCN0 bit (Block Protection for Non-secure Cancel)

The BPCN0 bit disables the block protect setting for non-secure function.

[Setting condition]

- When the write-enabling conditions are satisfied and the FENTRYR is not 0x0000, write 1 to this bit.

[Clearing conditions]

- 8 bits being written to FBPROT0 while the FRDY bit is 1.
- A value other than 0x78 specified in the KEY bits and 16 bits are written to FBPROT0 while the FRDY bit is 1.
- 0 being written to the BPCN0 bit while writing to FBPROT0 is enabled.
- The FENTRYR register value is 0x0000.

## 45.4.14 FBPROT1 : Flash Block Protection for Secure Register

Base address: FACI = 0x407F_E000

Offset address: 0x7C

| Bit position: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | KEY[7:0] | | | | | | | | — | — | — | — | — | — | — | BPCN1 |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 0 | BPCN1 | Block Protection for Secure Cancel<br>0: Block protection is enabled<br>1: Block protection is disabled. | R/W*1 *2 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 7:1 | — | These bits are read as 0. The write value should be 0. | R/W |
| 15:8 | KEY[7:0] | Key Code | W*3 |

Note 1. Writing to this bit is only possible when the FRDY bit in the FSTATR register is 1. Writing to this bit while FRDY bit = 0 is ignored.
Note 2. Writing to this bit is only possible when 16 bits are written and the value written to the KEY[7:0] bits is 0xB1.
Note 3. Written values are not retained by these bits (always read as 0x00).

The FBPROT1 register is used to disable the block protect function for secure developer. When the block protect setting is locked by the permanent block setting, it cannot be disabled by this register.

The FBPROT1 value is initialized when the SUINIT bit in the FSUINITR is set to 1, because the FENTRYR value is initialized to 0x0000. It is also initialized by a reset.

### BPCN1 bit (Block Protection for Secure Cancel)

The BPCN1 bit disables the block protect setting for secure function.

[Setting condition]

- When the write-enabling conditions are satisfied and the FENTRYR is not 0x0000, write 1 to BPCN1.

[Clearing conditions]

- 8 bits being written to FBPROT1 while the FRDY bit is 1.
- A value other than 0xB1 specified in the KEY bits and 16 bits are written to FBPROT1 while the FRDY bit is 1.
- 0 being written to the BPCN1 bit while writing to FBPROT1 is enabled.
- The FENTRYR register value is 0x0000.

## 45.4.15 FSTATR : Flash Status Register

Base address: FACI = 0x407F_E000

Offset address: 0x80

| Bit position: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | — | — | — | — | — | ILGCOMERR | FESETERR | SECERR | OTERR | — | — | — | — |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit position: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | FRDY | ILGLERR | ERSERR | PRGERR | — | — | — | — | — | — | — | — | — | — | — | — |
| Value after reset: | 1 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 11:0 | — | These bits are read as 0. The write value should be 0. | R/W |
| 12 | PRGERR | Programming Error Flag<br>0: Programming has completed successfully<br>1: An error has occurred during programming | R |
| 13 | ERSERR | Erasure Error Flag<br>0: Erasure has completed successfully<br>1: An error has occurred during erasure | R |
| 14 | ILGLERR | Illegal Command Error Flag<br>0: The flash sequencer has not detected an illegal FACI command or illegal flash memory access<br>1: The flash sequencer has detected an illegal FACI command or illegal flash memory access | R |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 15 | FRDY | Flash Ready Flag<br>0: Program, Block Erase, Chip Erase, Forced Stop, Blank Check, or Configuration set command processing is in progress<br>1: None of the above is in progress | R |
| 19:16 | — | These bits are read as 0. The write value should be 0. | R/W |
| 20 | OTERR | Other Error<br>0: A status clear or forced stop command processing is complete<br>1: An error has occurred | R |
| 21 | SECERR | Security Error<br>0: A status clear or forced stop command processing is complete<br>1: An error has occurred | R |
| 22 | FESETERR | FENTRY Setting Error<br>0: A status clear or forced stop command processing is complete<br>1: An error has occurred | R |
| 23 | ILGCOMERR | Illegal Command Error<br>0: A status clear or forced stop command processing is complete<br>1: An error has occurred | R |
| 31:24 | — | These bits are read as 0. The write value should be 0. | R/W |

The FSTATR register indicates the state of the flash sequencer.

### PRGERR flag (Programming Error Flag)

The PRGERR flag indicates the result of programming of the flash memory. When this flag is 1, the flash sequencer is in the command-locked state.

[Setting condition]

- An error has occurred during programming.

[Clearing condition]

- The flash sequencer starts processing of the Status Clear or Forced Stop command.

### ERSERR flag (Erasure Error Flag)

The ERSERR flag indicates the result of erasure of the flash memory. When this flag is 1, the flash sequencer is in the command-locked state.

[Setting condition]

- An error has occurred during erasure.

[Clearing condition]

- The flash sequencer starts processing of the Status Clear or Forced Stop command.

### ILGLERR flag (Illegal Command Error Flag)

The ILGLERR flag indicates that the flash sequencer has detected an illegal FACI command or flash memory access. If this flag is 1, the flash sequencer is in the command-locked state.

[Setting conditions]

- See section 45.11.2. Error Protection.

[Clearing condition]

- The flash sequencer starts processing of the Status Clear or Forced Stop command.

### FRDY flag (Flash Ready Flag)

The FRDY flag indicates the command processing state of the flash sequencer.

[Setting conditions]

- The flash sequencer completes command processing

- The flash sequencer received the Forced Stop command and ended command processing.

[Clearing conditions]

- The flash sequencer received an FACI command
- For Program and Configuration setting, the first write access to the FACI command-issuing area
- For other commands, the last write access to the FACI command-issuing area.

#### OTERR flag (Other Error)

See Table 45.22. When this flag is 1, the flash sequencer is in the command-lock state.

[Setting condition]

- An error has occurred.

[Clearing condition]

- The status clear or forced stop command processing is complete.

#### SECERR flag (Security Error)

See Table 45.22. When this flag is 1, the flash sequencer is in the command-lock state.

[Setting condition]

- An error has occurred.

[Clearing condition]

- The status clear or forced stop command processing is complete.

#### FESETERR flag (FENTRY Setting Error)

See Table 45.22. When this flag is 1, the flash sequencer is in the command-lock state.

[Setting condition]

- An error has occurred.

[Clearing condition]

- The status clear or forced stop command processing is complete.

#### ILGCOMERR flag (Illegal Command Error)

See Table 45.22. When this flag is 1, the flash sequencer is in the command-lock state.

[Setting condition]

- An error has occurred.

[Clearing condition]

- The status clear or forced stop command processing is complete.

### 45.4.16 FENTRYR : Flash P/E Mode Entry Register

Base address: FACI = 0x407F_E000

Offset address: 0x84

| Bit position: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | KEY[7:0] | | | | | | | | FENTRYD | — | — | — | — | — | — | FENTRYC |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 0 | FENTRYC | Code Flash P/E Mode Entry<br>0: Code flash is in read mode<br>1: Code flash is in P/E mode. | R/W*1*2 |
| 6:1 | — | These bits are read as 0. The write value should be 0. | R/W |
| 7 | FENTRYD | Data Flash P/E Mode Entry<br>0: Data flash is in read mode<br>1: Data flash is in P/E mode. | R/W*1*2 |
| 15:8 | KEY[7:0] | Key Code | W*3 |

Note: If the security attribution is configured as Secure:
- Secure access and Non-secure read access are allowed
- Non-secure write access is ignored, and TrustZone access error is not generated.

If the security attribution is configured as Non-secure:
- Secure and Non-secure access are allowed.

Note 1. These bits can be written when the FRDY bit in the FSTATR register is 1. Writing to these bits are ignored when the FRDY bit is 0.
Note 2. Writing to these bits is only possible when 16 bits are written and the value written to the KEY[7:0] bits is 0xAA.
Note 3. Written values are not retained by these bits (always read 0x00).

FENTRYR is used to specify code flash P/E mode or data flash P/E mode. To specify the code flash P/E mode or data flash P/E mode so that the flash sequencer can receive FACI commands, set either the FENTRYD or FENTRYC bit to 1 to place the flash sequencer in P/E mode.

FENTRYR is initialized when the SUINIT bit in FSUINITR is set to 1. It is also initialized by a reset.

Note: Writing a value of 0XAA81 to this register causes the ILGLERR bit in the FSTATR register to be set to 1, resulting in the flash sequencer being placed in the command-locked state.

### FENTRYC bit (Code Flash P/E Mode Entry)

The FENTRYC bit specifies P/E mode for the code flash memory.

[Setting condition]

- Write 1 to the FENTRYC bit while writing to FENTRYR is enabled and FENTRYR is 0x0000.

[Clearing conditions]

- Write 8 bits to FENTRYR while the FRDY bit is 1
- A value other than 0xAA is specified in the KEY[7:0] bits and 16 bits are written to FENTRYR while the FRDY bit is 1
- Write 0 to the FENTRYC bit while writing to FENTRYR is enabled
- Write to FENTRYR while writing is enabled and its value is other than 0x0000
- The protection of FMEPROT register is enabled.

### FENTRYD bit (Data Flash P/E Mode Entry)

The FENTRYD bit specifies P/E mode for the data flash memory.

[Setting condition]

- Write 1 to the FENTRYD bit while writing to FENTRYR is enabled and FENTRYR is 0x0000.

[Clearing conditions]

- Write 8 bits to FENTRYR while the FRDY bit is 1
- Writing of 16 bits to FENTRYR with a value other than 0xAA specified for the KEY[7:0] bits while the FRDY bit is 1
- Write 0 to the FENTRYD bit while writing to FENTRYR is enabled
- Write to FENTRYR while writing is enabled and its value is other than 0x0000.

### KEY[7:0] bits (Key Code)

The KEY[7:0] bits control writing permission to the FENTRYD or FENTRYC bits.

## 45.4.17 FSUINITR : Flash Sequencer Setup Initialization Register

Base address: FACI = 0x407F_E000

Offset address: 0x8C

| Bit position: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | KEY[7:0] | | | | | | | | — | — | — | — | — | — | — | SUINIT |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 0 | SUINIT | Set-Up Initialization<br>0: The FSADDR, FEADDR, FBPROT0, FBPROT1, FENTRYR, and FBCCNT flash sequencer setup registers keep their current values<br>1: The FSADDR, FEADDR, FBPROT0, FBRPOT1, FENTRYR, and FBCCNT flash sequencer setup registers are initialized. | R/W*1*2 |
| 7:1 | — | These bits are read as 0. The write value should be 0. | R/W |
| 15:8 | KEY[7:0] | Key Code | W*3 |

Note: If the security attribution is configured as Secure:
- Secure access and Non-secure read access are allowed
- Non-secure write access is ignored, and TrustZone access error is not generated.

If the security attribution is configured as Non-secure:
- Secure and Non-secure access are allowed.

Note 1. This bit can be written when the FRDY bit in the FSTATR register is 1. Writing to this bit is ignored when the FRDY bit is 0.
Note 2. Writing to these bits is only possible when 16 bits are written and the value written to the KEY[7:0] bits is 0x2D.
Note 3. Written values are not retained by these bits (always read 0x00).

FSUINITR is used for initialization of the flash sequencer setup.

### SUINIT bit (Set-Up Initialization)

The SUINIT bit initializes the following flash sequencer setup registers:

- FSADDR
- FEADDR
- FBPROT0
- FBPROT1
- FENTRYR
- FBCCNT

### KEY[7:0] bits (Key Code)

The KEY[7:0] bits control writing permission to the SUINIT bit.

## 45.4.18 FCMDR : FACI Command Register

Base address: FACI = 0x407F_E000

Offset address: 0xA0

| Bit position: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | CMDR[7:0] | | | | | | | | PCMDR[7:0] | | | | | | | |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 7:0 | PCMDR[7:0] | Pre-command Flag<br>The command just before the latest command is stored. | R |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 15:8 | CMDR[7:0] | Command Flag<br>The latest command is stored. | R |

FCMDR records the two most recent commands accepted by the flash sequencer.

### PCMDR[7:0] bits (Pre-command Flag)

The PCMDR[7:0] bits indicate the command received immediately before the latest command received by the flash sequencer.

### CMDR[7:0] bits (Command Flag)

The CMDR[7:0] bits indicate the latest command received by the flash sequencer.

**Table 45.6 States of FCMDR after receiving commands**

| Command | CMDR | PCMDR |
|---|---|---|
| Program | 0xE8 | Previous command |
| Block erase | 0xD0 | 0x20 |
| Chip erase | 0xD0 | 0x2F |
| Status Clear | 0x50 | Previous command |
| Forced Stop | 0xB3 | Previous command |
| Blank Check | 0xD0 | 0x71 |
| Configuration set | 0x40 | Previous command |

## 45.4.19 FBCCNT : Blank Check Control Register

Base address: FACI = 0x407F_E000

Offset address: 0xD0

| Bit position: | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | — | — | — | — | BCDIR |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 0 | BCDIR | Blank Check Direction<br>0: Blank checking is executed from the lower addresses to the higher addresses (incremental mode)<br>1: Blank checking is executed from the higher addresses to the lower addresses (decremental mode). | R/W |
| 7:1 | — | These bits are read as 0. The write value should be 0. | R/W |

Note: If the security attribution is configured as Secure:
- Secure access and Non-secure read access are allowed
- Non-secure write access is ignored, and TrustZone access error is not generated.

If the security attribution is configured as Non-secure:
- Secure and Non-secure access are allowed.

FBCCNT specifies the addressing mode in processing the Blank Check command. FBCCNT is initialized when the SUINIT bit in FSUINITR is set to 1. It is also initialized by a reset.

### BCDIR bit (Blank Check Direction)

The BCDIR bit specifies the addressing mode for Blank Check.

## 45.4.20 FBCSTAT : Blank Check Status Register

Base address: FACI = 0x407F_E000

Offset address: 0xD4

| Bit position: | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | — | — | — | — | BCST |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 0 | BCST | Blank Check Status Flag<br>0: Blank check passed. The target area is in the non-programmed state, that is, the area has been erased but has not yet been reprogrammed<br>1: Blank check failed. The target area has been programmed. | R |
| 7:1 | — | These bits are read as 0. The write value should be 0. | R/W |

FBCSTAT stores the results of checking in response to the Blank Check command.

### BCST flag (Blank Check Status Flag)

The BCST flag indicates the results of checking in response to the Blank Check command.

## 45.4.21 FBCADDR : Flash Blank Check Address Register

Base address: FACI = 0x407F_E000

Offset address: 0xD8

| Bit position: | 31 | | | | | | | | | | | | | | | | | | | | | | | | | | | | | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | — | — | — | — | — | BCADR[23:0] | | | | | | | | | | | | | | | | | | | | | |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 23:0 | BCADR[23:0] | Blank Check Address<br>The first fail address or the last blank checked address. | R |
| 31:24 | — | These bits are read as 0. The write value should be 0. | R/W |

The FBCADDR register indicates the first fail address (the first address of the programmed area) or the last blank checked address to be found in processing of the Blank Check command.

### BCADR[23:0] bits (Blank Check Address)

The BCADR[23:0] bits indicate the offset address from the address where the code flash memory and data flash memory start. When the BCST bit in FBCSTAT register is 1, the first fail address of Blank the Check command is set. After the Blank Check command is interrupted by a Forced Stop command and when the BCST bit in BCSTAT register is 0, the interrupted address of the Blank Check command is set. In other cases, the BCADR[23:0] bits hold the address produced by the previous check. Bits [23:17] are set to 0 when the Blank Check command to data flash memory is passed or interrupted by a Forced Stop command.

## 45.4.22 FSUASMON : Flash Startup Area Select Monitor Register

Base address: FACI = 0x407F_E000

Offset address: 0xDC

| Bit position: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | BTFLG | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — |
| Value after reset: | 0/1 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit position: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | FSPR | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — |
| Value after reset: | 0/1 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 14:0 | — | These bits are read as 0. The write value should be 0. | R |
| 15 | FSPR | Protection Programming Flag to set Boot Flag, Startup Area Control, and Chip Erase<br>0: Protected state<br>1: Non-protected state | R |
| 30:16 | — | These bits are read as 0. The write value should be 0. | R |
| 31 | BTFLG | Flag of Startup Area Select for Boot Swap<br>0: The startup area is the alternate block (block 1)<br>1: The startup area is the default block (block 0) | R |

### FSPR bit (Protection Programming Flag to set Boot Flag, Startup Area Control, and Chip Erase)

The FSPR bit indicates the protection state against the configuration set command for the BTFLG bit, and FSUACR Register. Also, this bit indicates the protection state against the Chip Erase command execution.

In response to a reset or configuration set command, the FACI transfers data from flash memory to this register.

### BTFLG bit (Flag of Startup Area Select for Boot Swap)

The BTFLG bit indicates whether the address of the startup area is exchanged for the boot swap function or not.

In response to a reset or configuration set command, the FACI transfers data from flash memory to this register.

## 45.4.23 FPCKAR : Flash Sequencer Processing Clock Notification Register

Base address: FACI = 0x407F_E000

Offset address: 0xE4

| Bit position: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | KEY[7:0] | | | | | | | | PCKA[7:0] | | | | | | | |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 1 | 1 | 0 | 0 | 1 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 7:0 | PCKA[7:0] | Flash Sequencer Operating Clock Notification<br>These bits are used to set the operating frequency of the flash sequencer while processing FACI commands. | R/W*1*2 |
| 15:8 | KEY[7:0] | Key Code | W*3 |

Note: If the security attribution is configured as Secure:
- Secure access and Non-secure read access are allowed
- Non-secure write access is ignored, and TrustZone access error is not generated.

If the security attribution is configured as Non-secure:
- Secure and Non-secure access are allowed.

Note 1. This bit can be written when the FRDY bit in the FSTATR register is 1. Writing to this bit is ignored when the FRDY bit is 0.
Note 2. Writing to these bits is only possible when 16 bits are written and the value written to the KEY[7:0] bits is 0x1E.

Note 3. Written values are not retained by these bits (always read 0x00).

FPCKAR specifies the operating frequency of the flash sequencer while processing FACI commands. The highest operating frequency for the given product is set as the initial value.

### PCKA[7:0] bits (Flash Sequencer Operating Clock Notification)

The PCKA[7:0] bits specify the operating frequency of the flash sequencer while processing FACI commands. Set the desired frequency for these bits before issuing an FACI command. Specifically, convert the frequency in MHz to a binary number and set it for these bits.

Example:

Frequency is 35.9 MHz (PCKA = 0x24)

Round up the first decimal place of 35.9 MHz to a whole number (= 36) and convert it into a binary number.

If the value set in these bits is smaller than the actual operating frequency of the flash sequencer, the flash memory programming/erasure characteristics cannot be guaranteed. If the value set in these bits is greater than the actual operating frequency of the flash sequencer, the flash memory programming/erasure characteristics can be guaranteed but the FACI command processing time such as the time programming/erasure takes will increase. The minimum FACI command processing time is obtained when the operating frequency of the flash sequencer is the same as the PCKA value.

### KEY[7:0] bits (Key Code)

The KEY[7:0] bits control writing permission to the PCKA bit.

## 45.4.24 FSUACR : Flash Startup Area Control Register

Base address: FACI = 0x407F_E000

Offset address: 0xE8

| Bit position: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | KEY[7:0] | | | | | | | | — | — | — | — | — | — | SAS[1:0] | |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 1:0 | SAS[1:0] | Startup Area Select<br>0 0: Startup area is selected by BTFLG bit<br>0 1: Startup area is selected by BTFLG bit<br>1 0: Startup area is temporarily switched to the default area (block0 - block3)<br>1 1: Startup area is temporarily switched to the alternate area (block4 - block7). | R/W*1 *3 |
| 7:2 | — | These bits are read as 0. The write value should be 0. | R/W |
| 15:8 | KEY[7:0] | Key Code | W*2 |

Note 1. Following described the write condition of thisese bits (these conditions are required at the same time).
1. Access size to this register is 16 bits
2. The value of KEY[7:0] is 0x66
3. The FSPR bit is 1.

Note 2. Written values are not retained by these bits (always read 0x00).

Note 3. Only secure access can write to this register. Both secure access and non-secure read access are allowed. Non-secure write access is denied, but TrustZone access error is not generated.

FSUACR sets the startup area for the boot swap function. Do not use this register in dual mode (the DUALSEL.BANKMD[2:0] bits are 000b). In dual mode, starting up proceeds from startup area 0.

### SAS[1:0] bits (Startup Area Select)

The SAS[1:0] bits select the startup area. Three methods are available for changing the startup area.

### KEY[7:0] bits (Key Code)

The KEY[7:0] bits control writing permission to the SAS [1:0] bits.

## 45.5 Prefetch Buffer

The prefetch buffer speeds up read access from the bus master (CPU instruction fetch, DMA Controller (DMAC), Data Transfer Controller (DTC)) to the code flash memory. For DMAC and DTC, the read access speed is improved only when the source address update mode is set to increment (DMACn.DMAMD.SM [1:0] =10b, DTC.MRA.SM [1:0] =10b). To enable the prefetch buffer, set the PFBER.PFBE bit to 1b.

## 45.6 Operating Modes Associated with Flash Memory

Figure 45.5 shows the mode transitions associated with flash memory. For the procedures of setting the modes, see section 6, Option-Setting Memory.

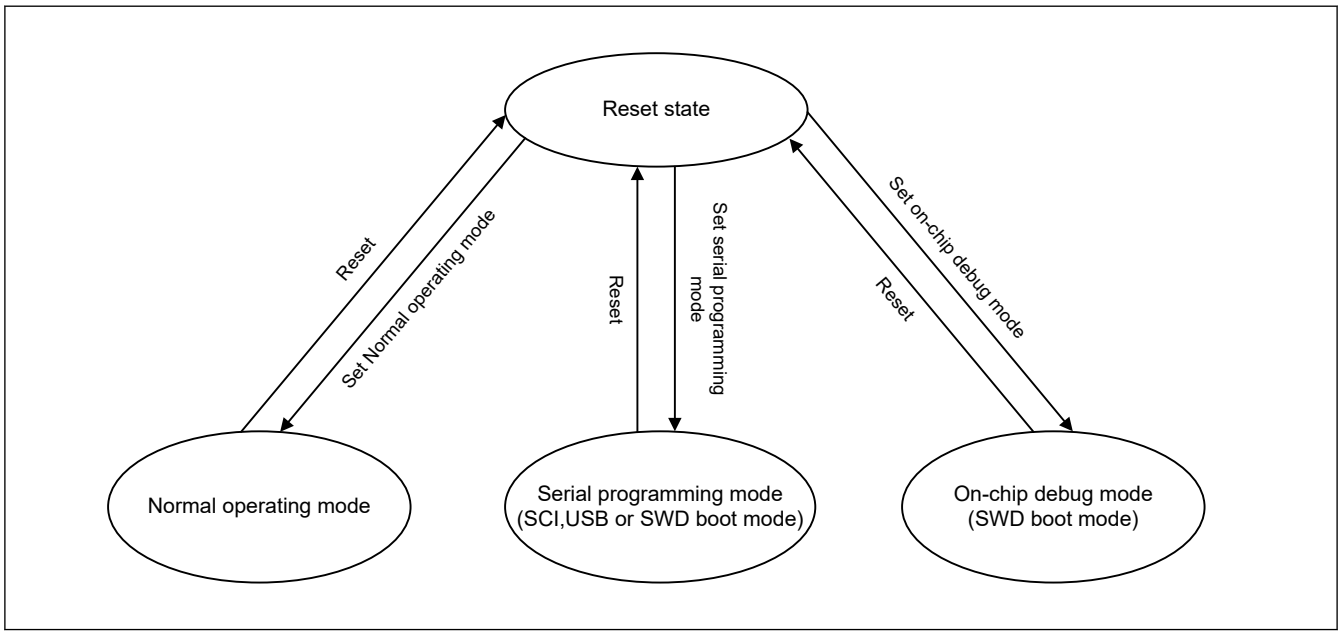

**Figure 45.5 Mode transitions associated with flash memory**

The flash memory area where programming and erasure are permitted and the boot program after a reset are different according to each mode. The differences between modes are listed in Table 45.7.

**Table 45.7 Differences between modes**

| Parameter | Normal operating mode | Serial programming mode (SCI, USB or SWD boot mode) | On-chip debug mode (SWD boot mode) |
|---|---|---|---|
| Programmable and erasable areas | • Code flash memory<br>• Data flash memory<br>• Option setting memory (programming only) | • Code flash memory<br>• Data flash memory<br>• Option-setting memory (programming only) | • Code flash memory<br>• Data flash memory<br>• Option setting memory (programming only) |
| Erasure in block units | Possible | Possible | Possible |
| Boot program at a reset | User area program | Embedded program for serial programming | Depends on debug command |

## 45.7 Overview of Functions

By using a dedicated flash-memory programmer to program the flash memory through a serial interface (serial programming) or SWD interface (on-chip debug mode), the device can be rewritten regardless of whether this is before or after it is mounted on the target system.

Furthermore, security functions to prohibit rewriting or reading of the user program written to the flash memory are incorporated, and this can prevent falsification and illicit reading of the programs by third parties.

Programming by the user program (self-programming) is available to suit applications where the application on the target system may require updating after manufacturing or shipment. Protection features for the safe rewriting of the flash memory are also incorporated. Furthermore, interrupt processing during self-programming is supported, so programming

can proceed at the same time as processing for external communications, etc., and this is the case in various situations. Table 45.8 lists the overview of the methods of programming and the corresponding operating modes.

**Table 45.8 Programming methods**

| Programming method | Functional overview | Operating mode |
|---|---|---|
| Serial programming | A dedicated flash-memory programmer through the SCI, USBFS or SWD interface enables on-board programming of the flash memory after the device is mounted on the target system. | Serial programming mode |
| | A dedicated flash-memory programmer through the SCI, USBFS or SWD interface and a dedicated programming adapter board allow off-board programming of the flash memory, for example, programming of the device before it is mounted on the target system. | |
| Self-programming | A user program written to memory in advance of serial programming execution can also program the flash memory. The background operation capability makes it possible to fetch instructions or otherwise read data from the code flash memory while the data flash memory is programmed. As a result, a program resident in the code flash memory is able to program the data flash memory.<br>For background operations that are not possible, instructions in the code flash memory cannot be fetched and data cannot be accessed while the code flash memory is being programmed by self-programming. In such cases, a program for programming from the internal SRAM or external memory must be transferred in advance and executed. | Normal operating mode |
| SWD programming | A dedicated flash-memory programmer or an on-chip debugger through SWD enables on-board programming of the flash memory after the device is mounted on the target system.<br>A dedicated flash-memory programmer or an on-chip debugger through SWD and a dedicated programming adapter board allow off-board programming of the flash memory, for example, programming of the device before it is mounted on the target system. | On-chip debug mode |

Table 45.9 lists the functions of the flash memory. Serial programmer commands realize each function of serial programming, while reading of the flash memory by an FACI command or the user program realizes each function of self-programming.

**Table 45.9 Basic functions (1 of 2)**

| Function | Functional overview | Availability | |
|---|---|---|---|
| | | Serial programming | Self-programming |
| Blank check | Checks a specified block to ensure that writing to it has not already proceeded. Results of reading from flash memory to which nothing is written after erasure are not guaranteed, so use blank checking to confirm that writing to memory has not proceeded after erasure. | Not supported | Supported |
| Block erasure | Erases the memory contents in the specified block | Supported | Supported |
| Programming | Writes to the specified address | Supported | Supported |
| CRC | Calculates the CRC in the specified range of the flash memory and transfers it to the flash programmer | Supported | Non supported |
| Read | Reads data programmed in the flash memory | Supported | Not supported<br>(read by user program is possible) |
| Start-up program protection functions | Configures the start-up program protection functions | Supported | Supported |
| Option function selection | Selects the option function, and modifies the initial setting of this MCU | Supported | Supported |
| Dual bank function | Switches different modes (linear or dual) | Supported | Supported |
| Block swap function | Setting block swap functions | Supported | Supported |
| Block protection | Setting block protection | Supported | Supported |
| Device lifecycle transition | Transitions the device lifecycle | Supported | Not supported |

**Table 45.9 Basic functions (2 of 2)**

| Function | Functional overview | Availability | |
|---|---|---|---|
| | | Serial programming | Self-programming |
| Memory security attribution | Setting the memory security attribution | Supported | Not supported |
| Key | Injects key | Supported | Supported (except the key related to device lifecycle transition) |
| All erasure | Erase the flash memory to the state after shipment | Supported | Not supported |

The flash memory supports various security functions.

Table 45.10 lists the security functions supported by the flash memory.

**Table 45.10 Lists of Security Functions**

| Function | Description |
|---|---|
| Security flag for Start-up area select | Start-up area selection can be protected by setting of security flag (FSPR). |
| Permanently block protection | Programming or erasure of each block of code flash memory can be protected permanently. |
| Protection for TrustZone | Programming or erasure area, readable area, register access, and FACI command operation are protected by ARM TrustZone security. |
| Programming or erasure mode protection | Only secure developer can enter the programming or erasure mode for code flash. |

## 45.8 Operating Modes of the Flash Sequencer

The flash sequencer has four operating modes as shown in Figure 45.6. Transitions between modes are initiated by changing the value of the DFLCTL and FENTRYR register.

After issuing a reset, the flash sequencer is in data flash access disable mode. In this mode, access to the data flash memory is disabled. When DFLEN bit in DFLCTL register is set to 1, the flash sequencer transits to read mode.

When the value of the FENTRYR register is 0x0000, the flash sequencer is in read mode. In this mode, it does not receive FACI commands. The code flash memory and data flash memory are both readable.

When the value of the FENTRYR register is 0x0001, the flash sequencer is in code flash P/E mode where the code flash memory can be programmed or erased by FACI commands. In this mode, the data flash memory is readable. In addition, the code flash memory is not readable if background operation (BGO) is disabled. If BGO is enabled, the code flash memory that is not selected by FSADDR register is readable when the FRDY bit in the FSTATR register is 0. As for the condition for enabling BGO, see section 45.15.2. Background Operation.

When the value of the FENTRYR register is 0x0080, the flash sequencer is in data flash P/E mode where the data flash memory can be programmed or erased by FACI commands. In this mode, the data flash memory is not readable. However, the code flash memory is readable.

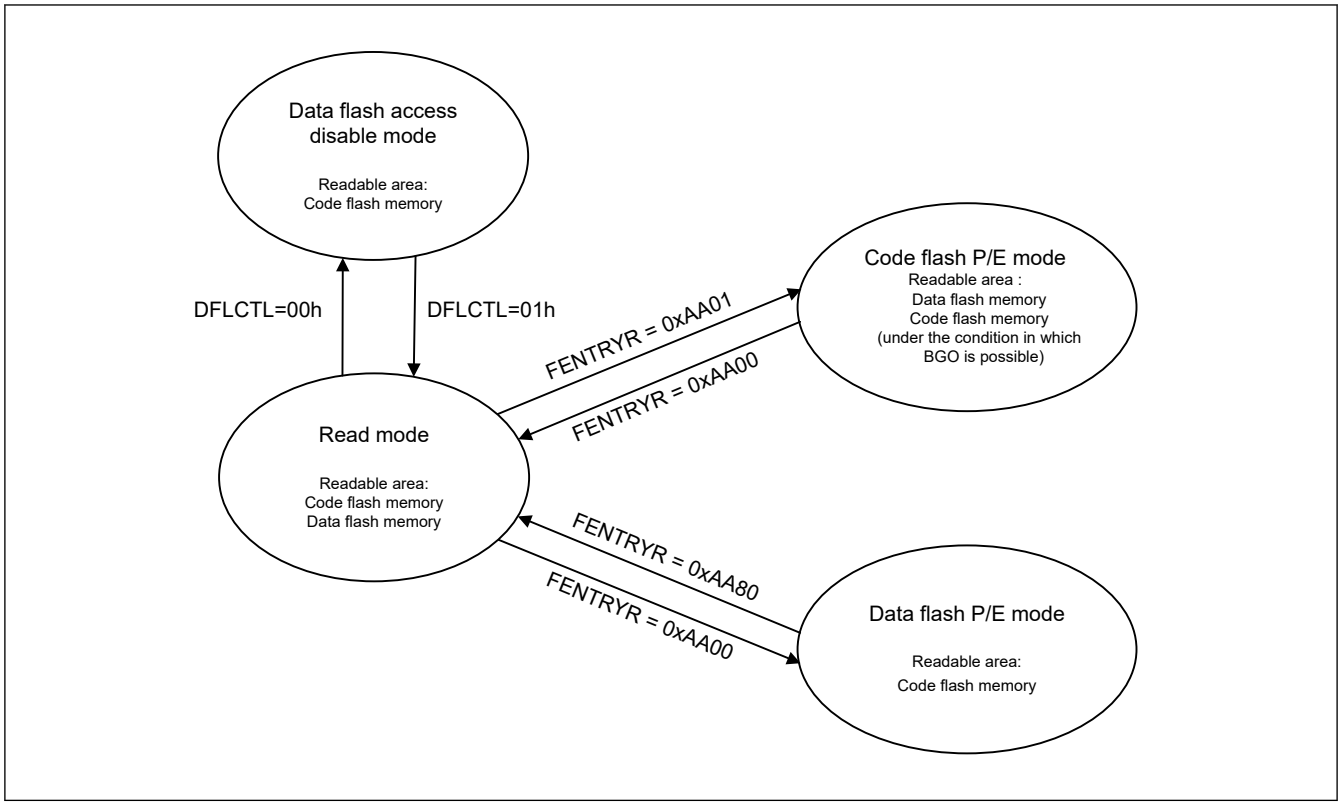

**Figure 45.6 Modes of the flash sequencer**

## 45.9 FACI Commands

### 45.9.1 List of FACI Commands

The FACI controls the FCU according to the specified FACI commands.

This section describes information about the FACI commands and Table 45.11 lists the FACI commands.

**Table 45.11 FACI commands**

| FACI command | Function |
|---|---|
| Program | Programs the user area and data area.<br>Units of programming are 8 bytes for the user area and 1 byte for the data area. |
| Block Erase | Erases user area and data area.<br>The erase unit is 2 KB for user area, and 256 bytes for data flash. |
| Chip Erase | User area and data area can be erased.<br>Erase unit is each macro of code flash and data flash. |
| Status clear | Initializes the ILGLERR, ERSERR, PRGERR, ILGCOMERR, FESETERR, SECERR, and OTERR bits in the FSTATR register and the CMDLK, CFAE, and DFAE bits in the FASTAT register, and the flash sequencer released from command-locked state. |
| Forced stop | Forcibly stops processing of FACI commands and initializes the FSTATR and FASTAT registers. |
| Blank check | Checks if user areas or data areas are blank.<br>Units of Blank Check: 8 bytes to one code flash macro capacity for the user area and 1 byte to data flash macro capacity for data area. |
| Configuration set | Set the security function and safety function.<br>Units of setting: 16 bytes. |

The FACI commands are issued by writing to the FACI command-issuing area (see Table 45.4). When write access as shown in Table 45.12 proceeds in the specified state, the flash sequencer executes the processing associated with the given command (see section 45.9.2. Relationship between the Flash Sequencer State and FACI Commands).

**Table 45.12 FACI command formats**

| FACI commands | Number of write access | Write data to the FACI command-issuing area | | | |
|---|---|---|---|---|---|
| | | 1st access | 2nd access | 3rd to (N + 2)th access | (N + 3)th access |
| Program (user area)<br>N = 4 | 7 | 0xE8 | 0x04 (= N) | WD1 to WD4 | 0xD0 |
| Program (data area)<br>N = 1 | 4 | 0xE8 | 0x01 (= N) | WD1 | 0xD0 |
| Block Erase | 2 | 0x20 | 0xD0 | — | — |
| Chip Erase | 2 | 0x2F | 0xD0 | — | — |
| Status Clear | 1 | 0x50 | — | — | — |
| Forced Stop | 1 | 0xB3 | — | — | — |
| Blank Check | 2 | 0x71 | 0xD0 | — | — |
| Configuration set<br>N = 8 | 11 | 0x40 | 0x08 (= N) | WD1 to WD8 | 0xD0 |

Note: WDN (N = 1, 2, …): Nth 16-bit data to be programmed.

The flash sequencer clears the FSTATR.FRDY bit to 0 at the start of a command processing other than the Status Clear command, and sets this bit to 1 on completion.

If the FRDYIE.FRDYIE bit setting is 1, a flash ready (FRDY) interrupt is generated when the FSTATR.FRDY bit is set to 1.

## 45.9.2 Relationship between the Flash Sequencer State and FACI Commands

The FACI commands are accepted according to the mode/state of the flash sequencer. FACI commands should be issued after transitioning of the flash sequencer to the code flash P/E mode or data flash P/E mode and after checking the state of the flash sequencer.

Use the FSTATR and FASTAT registers to check the state of the flash sequencer. In addition, the occurrence of errors in general can be checked by reading the CMDLK bit in the FASTAT register. The value of the CMDLK bit is the logical OR of the following bits in the FSTATR register:

- ILGLERR
- ILGCOMERR
- FESETERR
- SECERR
- OTERR
- ERSERR
- PRGERR.

Table 45.13 lists the available FACI commands in each operating mode.

**Table 45.13 Operating mode and available FACI commands (1 of 2)**

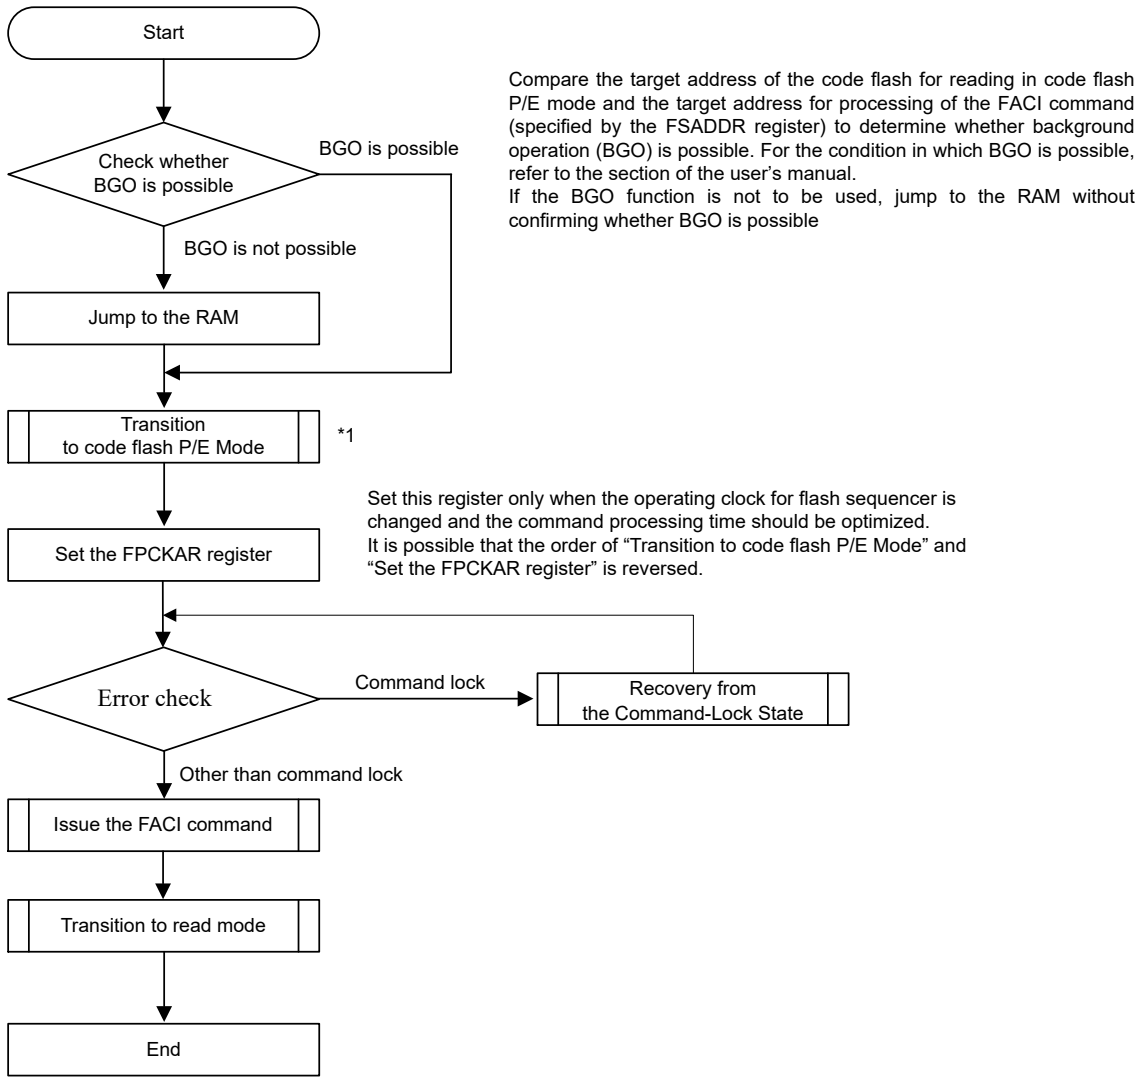
| Operating mode | FENTRYR | Available FACI commands |
|---|---|---|
| Read mode | 0x0000 | None |
| Code flash P/E mode | 0x0001 | Program<br>Block erase<br>Chip Erase<br>Status Clear<br>Forced Stop<br>Blank Check<br>Configuration set |

**Table 45.13 Operating mode and available FACI commands (2 of 2)**

| Operating mode | FENTRYR | Available FACI commands |
|---|---|---|
| Data flash P/E mode | 0x0080 | Program<br>Block erase<br>Chip Erase<br>Status Clear<br>Forced Stop<br>Blank Check |

Table 45.14 shows the state of the flash sequencer and acceptable FACI commands. An appropriate mode is assumed to have been set before the commands are executed.

**Table 45.14 Acceptable FACI commands and state of the flash sequencer**



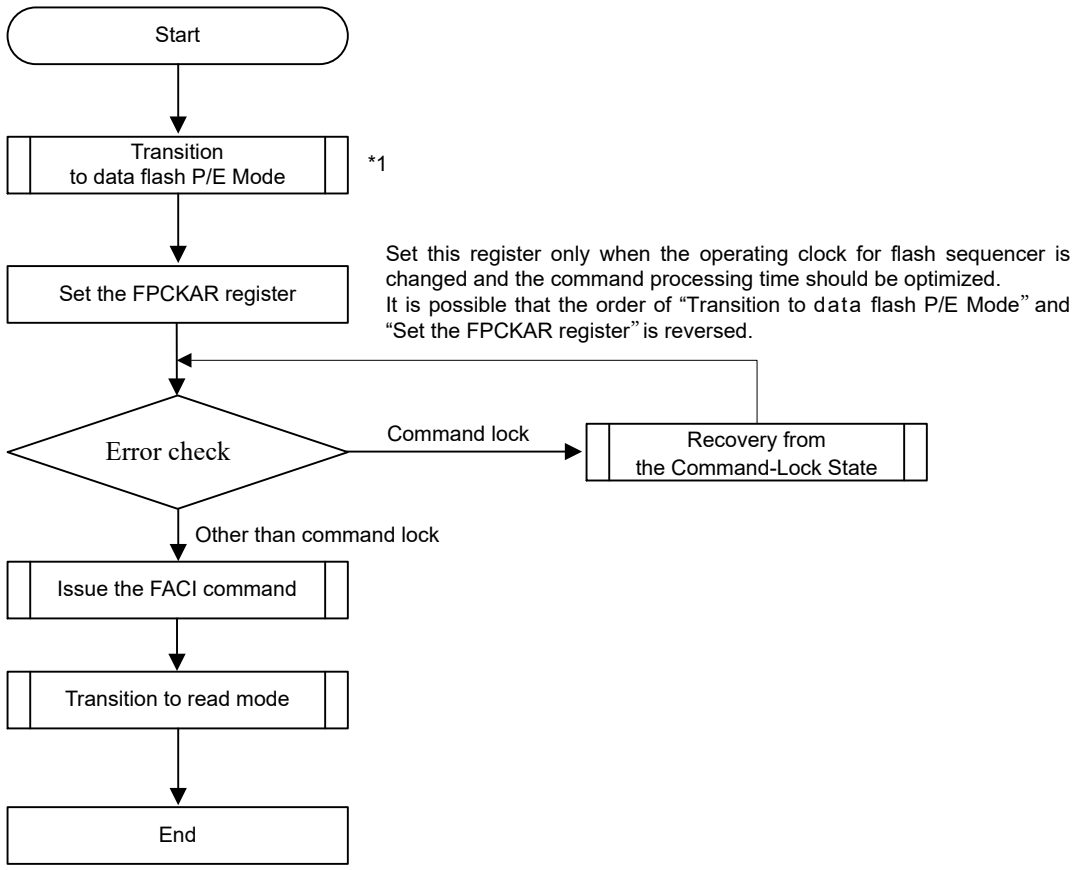
| | Processing of other commands except for Forced Stop | Processing of Forced Stop command | Command-Locked State (FRDY = 1) | Command-Locked State (FRDY = 0) | Other state (include Status Clear command processing) |
|---|---|---|---|---|---|
| FRDY bit | 0 | 0 | 1 | 0 | 1 |
| CMDLK bit | 0 | 0 | 1 | 1 | 0 |
| Program | X | X | X | X | O |
| Block Erase | X | X | X | X | O |
| Chip Erase | X | X | X | X | O |
| Status Clear | X | X | O | X | O |
| Forced Stop | O | O | O | O | O |
| Blank Check | X | X | X | X | O |
| Configuration set | X | X | X | X | O*1 |

Note: O: Acceptable
X: Not acceptable (places the sequencer in the command-locked state)
—: Ignored
Note 1. Only acceptable in code flash P/E mode.

## 45.9.3 Usage of FACI Commands

### 45.9.3.1 Overview of Command Usage in Code Flash P/E Mode

Figure 45.7 show an overview of FACI command usage in code flash P/E mode. For the available commands in code flash P/E mode, see Table 45.13.

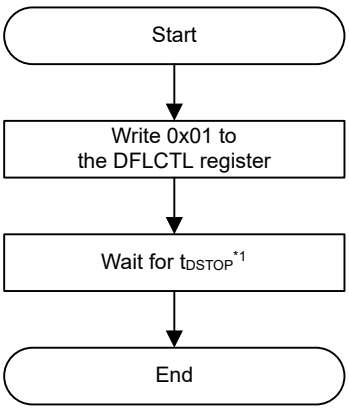


Note 1. See section 45.9.3.4. Transition to Code Flash P/E Mode from Read Mode

**Figure 45.7 Overview of command usage in code flash P/E mode**

### 45.9.3.2 Overview of Command Usage in Data Flash P/E Mode

Figure 45.8 shows an overview of FACI command usage in data flash P/E and Table 45.13 lists the available commands in data flash P/E mode.



Note 1. See section 45.9.3.5. Transition to Data Flash P/E Mode from Read Mode

**Figure 45.8 Overview of command usage in data flash P/E mode**

### 45.9.3.3 Transition to Read Mode from Data Flash Disabled Mode

To read the data flash memory or program/erase the code flash memory or the data flash memory, it is necessary to transit from the data flash disabled mode to read mode. To transition to read mode, set the DFLEN bit in the DFLCTL register to 1. Figure 45.9 shows the procedure for transition to read mode from data flash disabled mode.

Note 1. Stop recovery time (see section 49, Electrical Characteristics).

**Figure 45.9 Procedure for transition to read mode from data flash disabled mode**

### 45.9.3.4 Transition to Code Flash P/E Mode from Read Mode

To issue FACI commands for the code flash memory, a transition to code flash P/E mode is required by setting the FENTRYC bit in the FENTRYR register to 1.

Figure 45.10 shows the procedure to transition to code flash P/E mode.

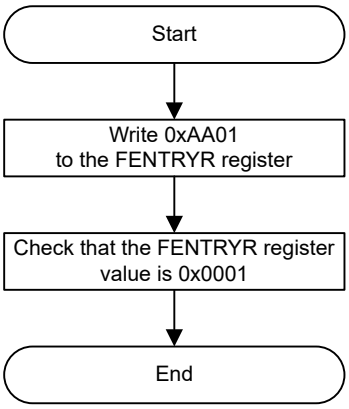


**Figure 45.10 Procedure to transition to code flash P/E mode from read mode**

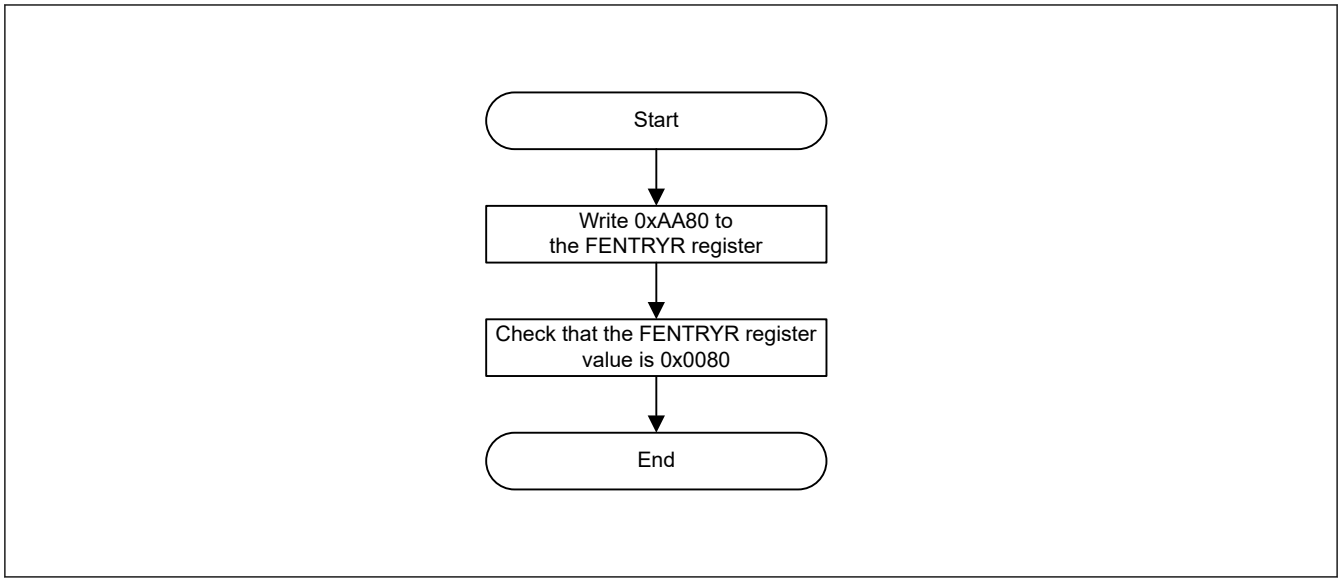
### 45.9.3.5 Transition to Data Flash P/E Mode from Read Mode

To issue FACI commands for the data flash memory, a transition to data flash P/E mode is required by setting the FENTRYD bit in the FENTRYR register to 1.

Figure 45.11 shows the procedure to transition to data flash P/E mode.



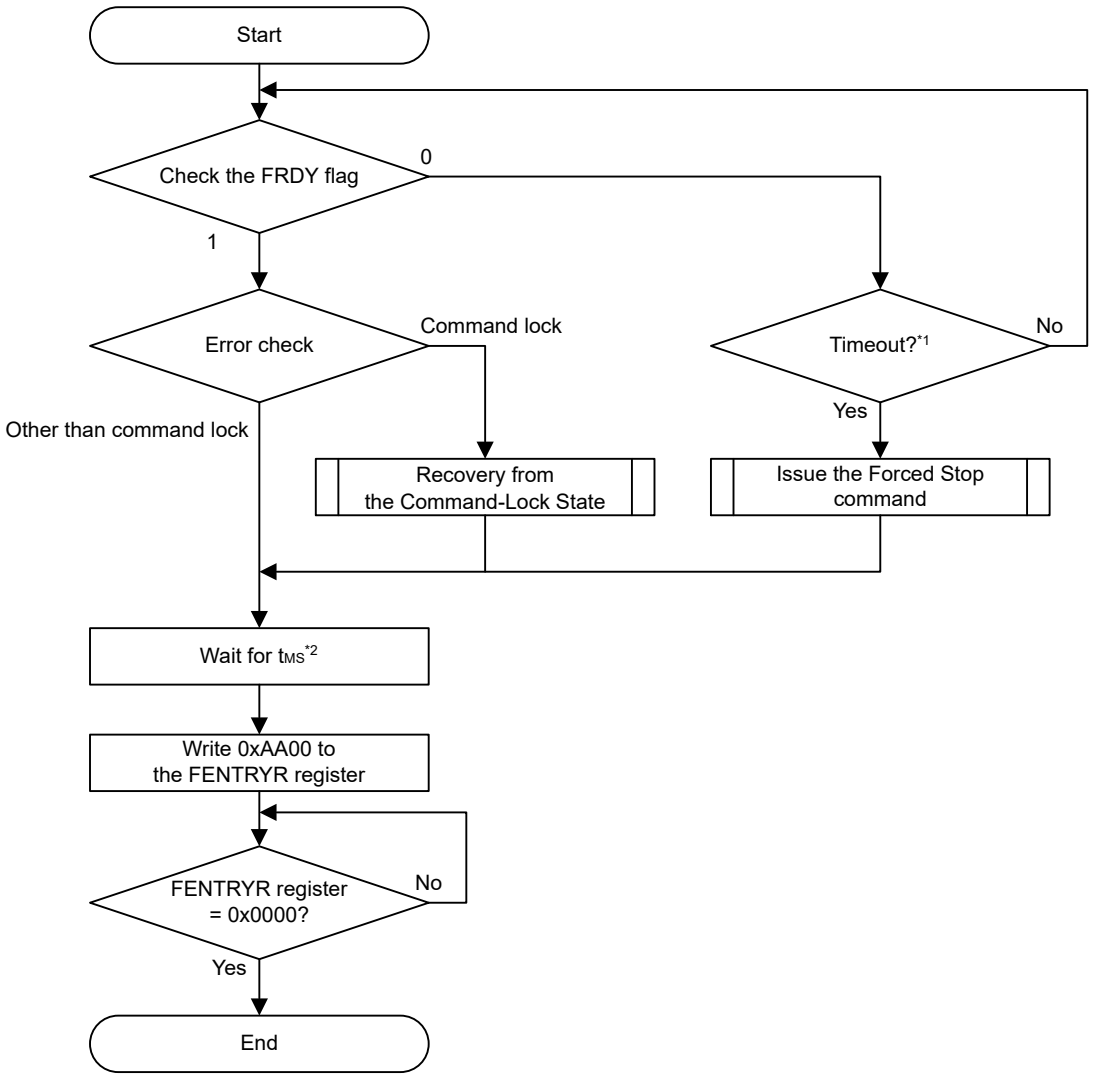


**Figure 45.11 Procedure to transition to data flash P/E mode from read mode**

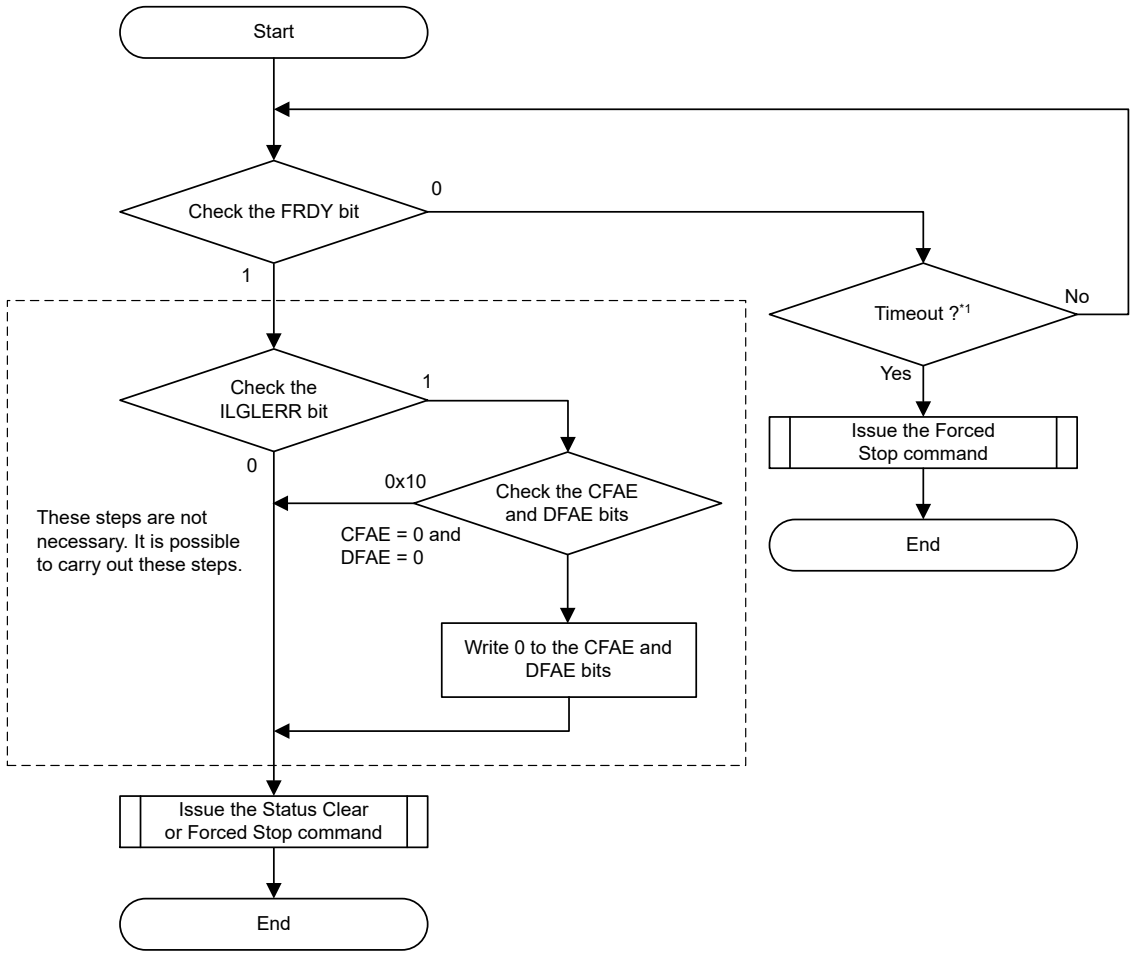
### 45.9.3.6 Transition to Read Mode from Code Flash P/E Mode or Data Flash P/E Mode

To read the flash memory without using the BGO function, a transition to read mode is required by setting the FENTRYR register to 0x0000. The transition to read mode should be made after the flash sequencer completes the processing and while operation is not in the command-locked state.

Figure 45.12 shows the procedure to transition to read mode.

Note 1. Determination of the timeout is based on 1.1 times the maximum time for processing of the FACI command that is in progress (see section 49, Electrical Characteristics)
Note 2. Mode setup time (see section 49, Electrical Characteristics)

**Figure 45.12 Procedure to transition to read mode**



### 45.9.3.7 Recovery from the Command-Locked State

When the flash sequencer enters the command-locked state, FACI commands cannot be accepted. To release the sequencer from the command-locked state, use the Status Clear command, Forced Stop command.

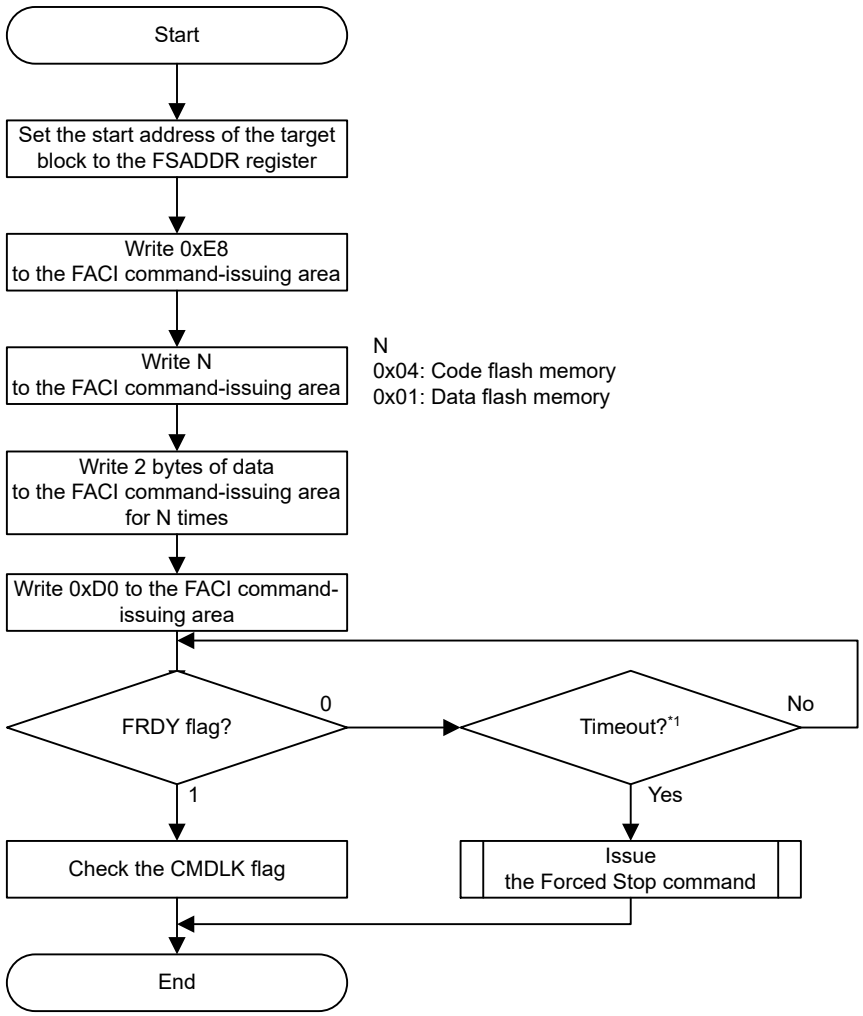
If processing is not completed in time beyond the maximum programming/erasure time specified in the electrical characteristics, this can be considered a timeout, and the flash sequencer should be stopped by the Forced Stop command.

When any one of the ILGLERR, ILGCOMERR, FESETERR, SECERR, OTERR, ERSERR or PRGERR bit in the FSTATR register is set to 1, only a Status Clear or Forced Stop command can change from 1 to 0 to release from the command-locked state.

Figure 45.13 shows the recovery flow from the command-locked state.

Note 1. Determination of the timeout is based on 1.1 times the maximum time for processing of the FACI command that is in progress (see section 49, Electrical Characteristics).

**Figure 45.13 Recovery flow from the command-locked state**



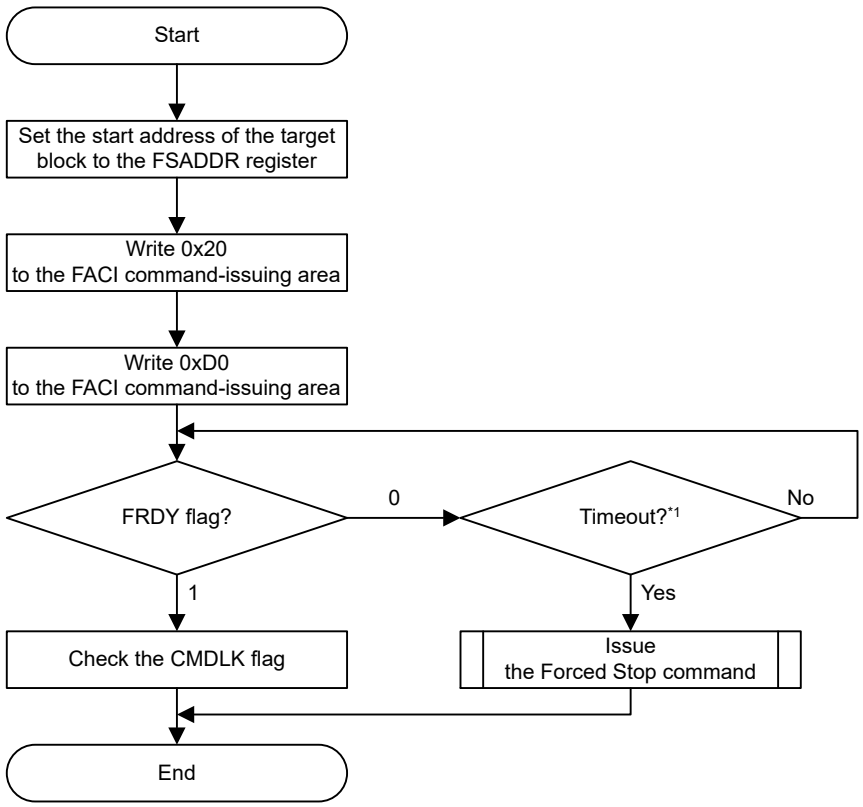
### 45.9.3.8 Program Command

The program command is used for writing to the user area and data area.

Before issuing the program command, set the first address of the target block in the FSADDR register.

Writing D0h to the FACI command-issuing area at the final access of the FACI command-issuing starts the program command processing. If the target area of the program command processing contains area not for writing, write 0xFFFF to the corresponding area.

Figure 45.14 shows the usage of the program command.



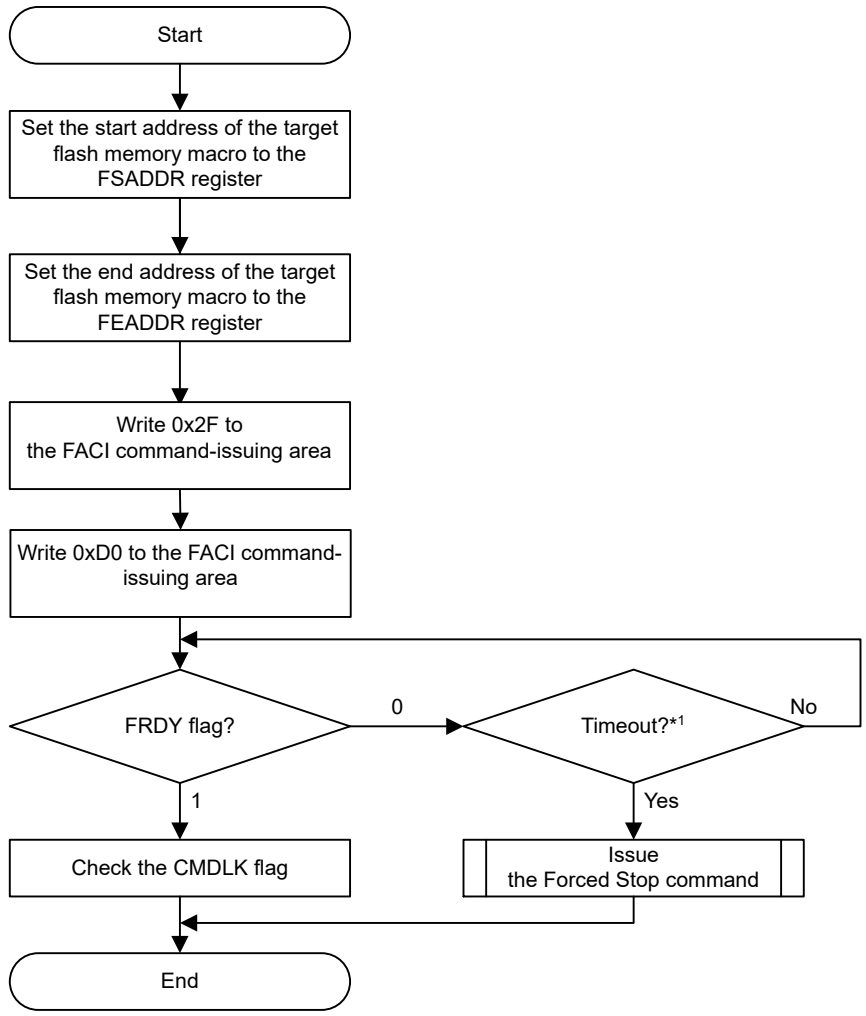
Note 1. Determination of the timeout is based on 1.1 times the maximum time of programming. See section 49, Electrical Characteristics for those time.

**Figure 45.14 Usage flow of the program command**

### 45.9.3.9 Block Erase Command

The Block Erase command is used for erasing user area or data area. The erase unit is one block. Before issuing a Block Erase command, set the first address of the target block to FSADDR register. Writing 0xD0 at the second write access of the FACI command triggers the FACI to start the block erase command processing. Completion of command processing can be confirmed with the FRDY bit of FSTATR register.

Figure 45.15 shows the usage of the Block Erase command.



Note 1. Determination of the timeout is based on 1.1 times the maximum time of erasure.
See section 49, Electrical Characteristics.

**Figure 45.15 Usage flow of the Block Erase command**

### 45.9.3.10 Chip Erase Command

The Chip Erase command is used for erasing user area or data area. The erase unit is one flash memory macro. Before issuing the Chip Erase command, set the start address of one flash memory macro to FSADDR register and the end address of one flash memory macro to FEADDR register. Writing 0xD0 at the second write access of the FACI command triggers FACI to start the Chip Erase command processing. Completion of command processing can be confirmed with the FRDY bit of FSTATR register.

Figure 45.16 shows usage of the Chip Erase command.

Note 1. Determination of the timeout is based on 1.1 times the maximum time of erasure. See section 49, Electrical Characteristics for those time.

**Figure 45.16 Usage flow of the Chip Erase command**

### 45.9.3.11 Status Clear Command

The status clear command is used to clear the command-locked state (see section 45.9.3.7. Recovery from the Command-Locked State).

You can use the status clear command to clear the following bits in the FSTATR register in the command-locked state:

- ILGLERR
- ILGCOMERR
- FESETERR
- SECERR
- OTERR
- ERSERR
- PRGERR

Figure 45.17 shows usage of the status clear command.

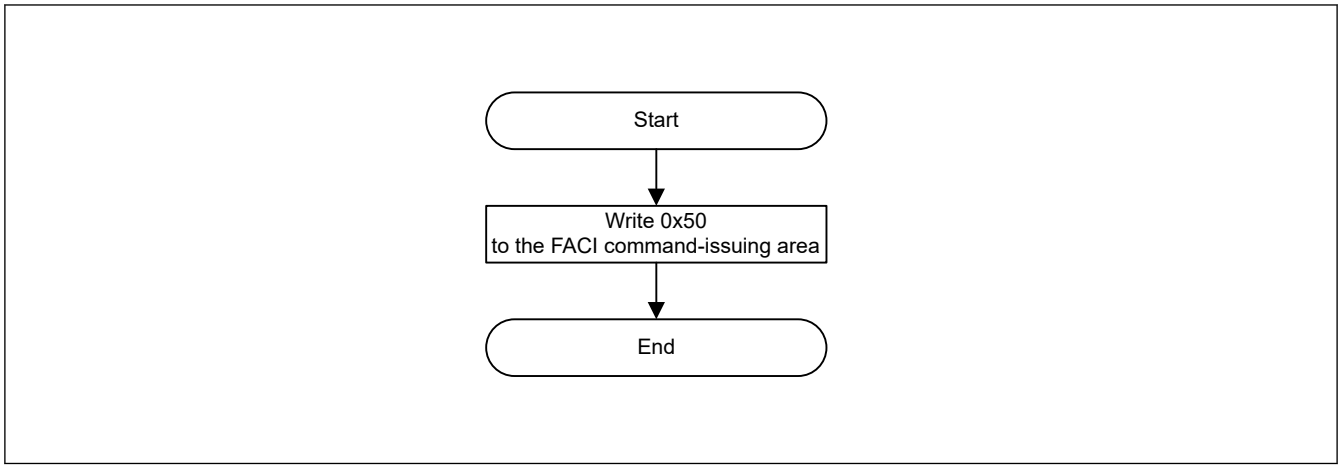


**Figure 45.17 Usage flow of the status clear command**

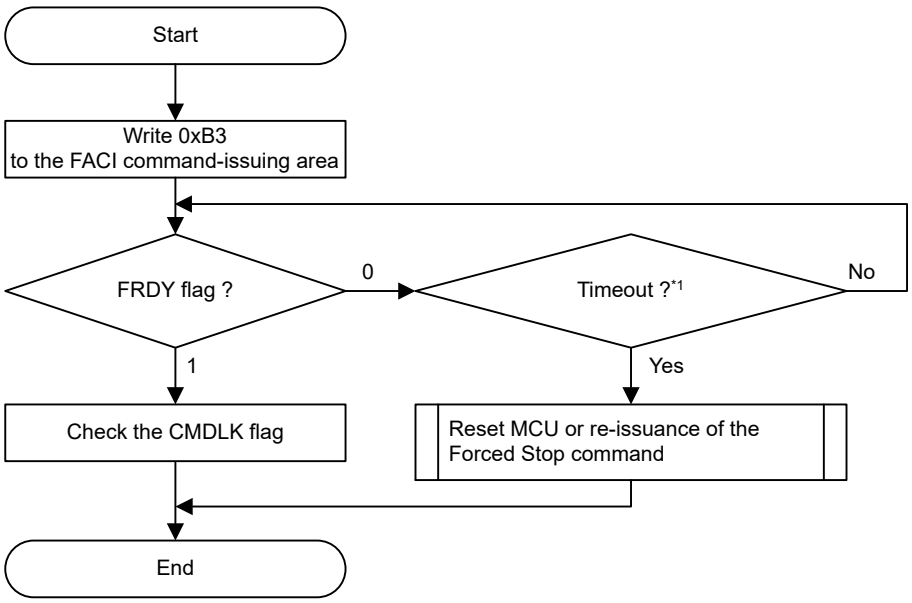


### 45.9.3.12 Forced Stop Command

The Forced Stop command forcibly ends command processing by the flash sequencer. Although this command halts command processing in the shortest latency, values from the programming or erasure that was in progress are not guaranteed. Processing of programming or erasure that was halted by the Forced Stop command is also defined as one from the perspective of programming endurance.

Result of blank checking in FBCSTAT and FBCADDR registers are guaranteed. When there is no error in blank checking, FBCADDR register indicates interrupted blank checking address so that blank check can be restarted from the interrupted address by software copying FBCADDR value to FSADDR.

Executing the Forced Stop command also initializes part of the FACI, the whole FCU, the FSTATR and FASTAT registers. This command can be used in the procedure for recovery from the command-locked state and for processing in response to a timeout of the flash sequencer (see section 45.9.3.7. Recovery from the Command-Locked State).

Figure 45.18 shows usage of the Forced Stop command.

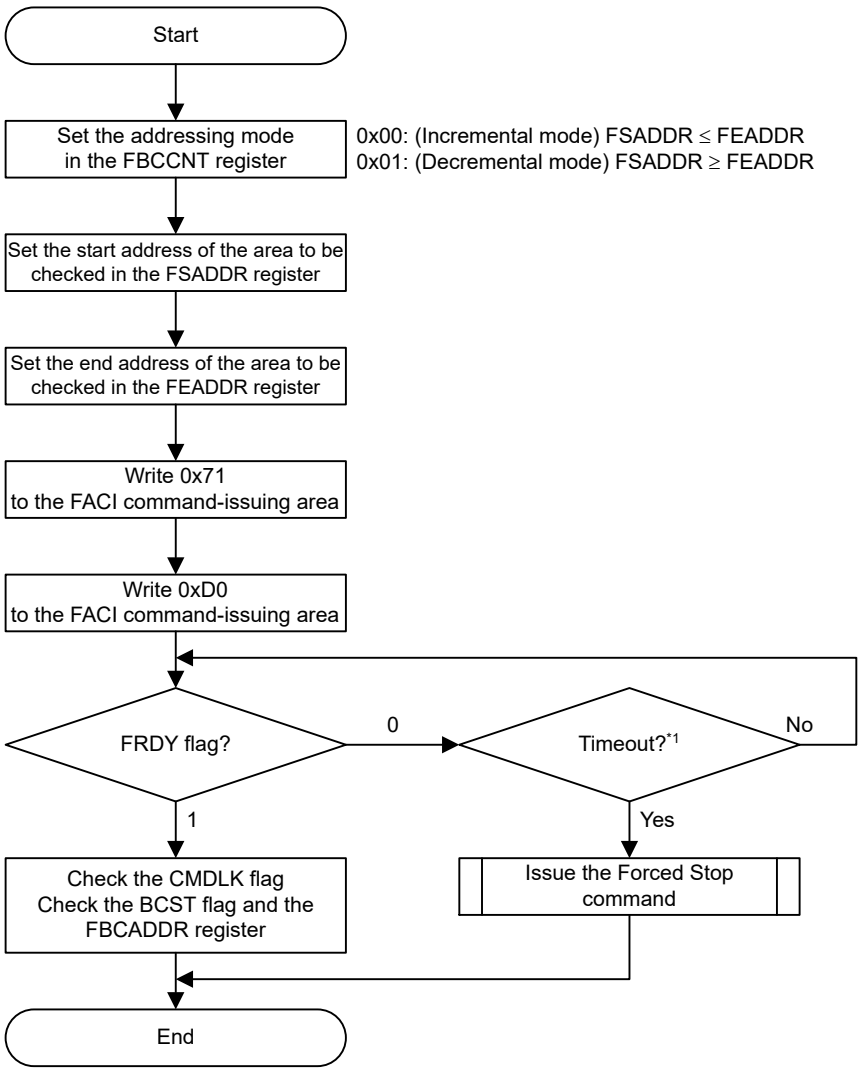
Note 1. Determination of the timeout is based on 1.1 times the maximum time of the Forced Stop command latency ($t_{FD}$). See section 49, Electrical Characteristics.

**Figure 45.18 Usage flow of the Forced Stop command**

### 45.9.3.13 Blank Check Command

The Blank Check command is used to confirm whether user area or data area is erased.

Before issuing the Blank Check command, set addressing mode, start address, and end address of the target area for Blank Check to the FBCCNT, FSADDR, and FEADDR registers. When Blank Check addressing mode is set to decremental mode (FBCCNT.BCDIR = 1), address specified in FSADDR should be equal to or larger than address in FEADDR.



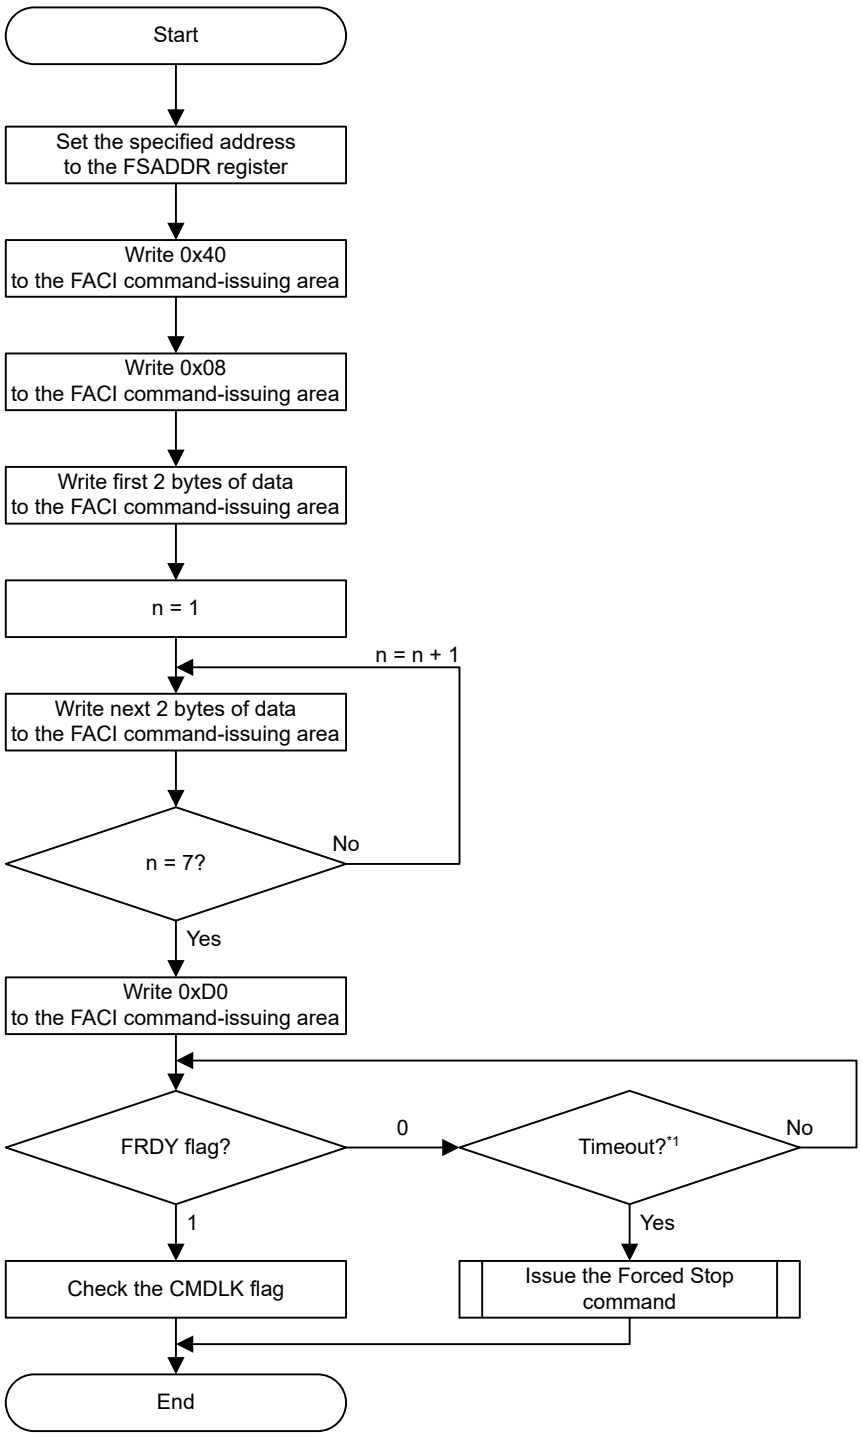
On the other hand, the address in FSADDR should be equal to or smaller than the address in FEADDR when Blank Check addressing mode is set to incremental mode (FBCCNT.BCDIR = 0).

If the settings of the BCDIR bit, FSADDR, and FEADDR are inconsistent, the flash sequencer enters the command-locked state. The size of the user area for Blank Check is in the range from 8 bytes to one code flash memory capacity and is set in units of 8 bytes. The size of data area for Blank Check is in the range from 1 byte to data flash memory capacity and is set in units of 1 byte.

Write 0x71 and 0xD0 to the FACI command-issuing area to start Blank Check. Completion of processing can be confirmed by the FRDY bit of the FSTATR register. At the end of processing, the result of Blank Check is stored in the BCST bit in the FBCSTAT register. If non-blank data exists within the target area for Blank Check, the flash sequencer stops Blank Check command operation. In this case, address of non-blank data is indicated to FBCADDR register.

When BCDIR = 1, FSADDR is set to non-secure area, and FEADDR is set to secure area, the Blank Check command by non-secure access can be executed. If the address of non-blank data in secure area needs to be closed, all secure area should be written.

Figure 45.19 shows usage of the Blank Check command.



Note 1. Determination of the timeout is based on 1.1 times the maximum time of blank checking for the whole target range. See section 49, Electrical Characteristics.

**Figure 45.19 Usage flow of the Blank Check command**

### 45.9.3.14 Configuration Set Command

The Configuration Set command is used to set the security function, safety function and system configuration. Before issuing the Configuration Set command, set the specified address (shown in Table 45.15) in the FSADDR register. Writing 0xD0 to the FACI command-issuing area in the final access for issuing the FACI command starts FACI processing of the Configuration set command.

Figure 45.20 shows usage of the Configuration Set command.

Note 1. Determination of the timeout is based on 1.1 times the maximum time of programming in option-setting memory. See section 49, Electrical Characteristics.

**Figure 45.20 Usage flow of the Configuration Set command**

The correspondence between the possible target data for configuration setting and the address value set in the FSADDR register is shown in Table 45.15. For details, see section 45.4.10. FSADDR : FACI Command Start Address Register.

**Table 45.15 Address used by Configuration Set command**

| Address | FSADDR register value | Setting data | Operation of additional writing | | Timing when the setting is enabled |
|---|---|---|---|---|---|
| | | | SAS.FSPR bit is 1 | SAS.FSPR bit is 0 | |
| 0x0100_A100 | 0x0100_A100 | Option Function Select Register 0 (OFS0) | Writable | Writable | At a reset |
| 0x0100_A110 | 0x0100_A110 | Dual Mode Select Register (DUALSEL) | Writable | Writable | At a reset |
| 0x0100_A134 | 0x0100_A130 | Start-up Area Setting Register (SAS) | Writable | Not writable*1 | When a reset or command is executed |
| 0x0100_A180 | 0x0100_A180 | Option Function Select Register 1 (OFS1) | Writable | Writable | At a reset |
| 0x0100_A190 | 0x0100_A190 | Bank Select Register (BANKSEL) | Writable | Writable | At a reset |
| 0x0100_A1C0 | 0x0100_A1C0 | Block Protect Setting Register (BPS) | Writable*2 | Writable*2 | When a reset or command is executed |
| 0x0100_A1E0 | 0x0100_A1E0 | Permanent Block Protect Setting Register (PBPS) | Writable*3 (from 1 to 0 only) | Writable*3 (from 1 to 0 only) | When a reset or command is executed |
| 0x0100_A200 | 0x0100_A200 | Option Function Select Register 1 Secure (OFS1_SEC) | Writable | Writable | At a reset |
| 0x0100_A210 | 0x0100_A210 | Bank Select Register Secure (BANKSEL_SEC) | Writable | Writable | At a reset |
| 0x0100_A240 | 0x0100_A240 | Block Protect Setting Register Secure (BPS_SEC) | Writable*4 | Writable*4 | When a reset or command is executed |
| 0x0100_A260 | 0x0100_A260 | Permanent Block Protect Setting Register Secure (PBPS_SEC) | Writable*5 (from 1 to 0 only) | Writable*5 (from 1 to 0 only) | When a reset or command is executed |
| 0x0100_A280 | 0x0100_A280 | Option Function Select Register 1 Select (OFS1_SEL) | Writable | Writable | At a reset |
| 0x0100_A290 | 0x0100_A290 | Bank Select Register Select (BANKSEL_SEL) | Writable | Writable | At a reset |
| 0x0100_A2C0 | 0x0100_A2C0 | Block Protect Setting Register Select (BPS_SEL) | Writable | Writable | At a reset |

Note 1. The SAS.FSPR bit cannot be restored to 1 by using the Configuration Set command once it is set to 0. Therefore, setting the startup area select flags again becomes impossible (when the Configuration Set command is issued to the address of 0x0100A134, the command is locked.) Exercise extra caution when handling the SAS.FSPRbit.
Note 2. Once PBPS[n] bit is set to 0, the BPS[n] bit cannot be restored to 1 by using the Configuration Set command.
Note 3. Once these bits are set to 0, the bits cannot be restored to 1 by using the Configuration Set command. The PBPS[n] bit cannot be set to 0 by using the Configuration Set command when the BPS[n] bit is 1.
Note 4. Once PBPS_SEC[n] bit is set to 0, the BPS_SEC[n] bit cannot be restored to 1 by using the Configuration Set command.
Note 5. Once these bits are set to 0, the bits cannot be restored to 1 by using the Configuration Set command. The PBPS_SEC[n] bit cannot be set to 0 by using the Configuration Set command when the BPS_SEC[n] bit is 1.

## 45.10 Suspend Operation

The Forced Stop command forces the Blank Check command or Block Erase command to stop. When a forced stop is executed, the stopped address values are stored in the registers. The command can restart from the stopped address after a reset to the registers for command execution by copying the saved addresses. The Forced Stop command forces the Chip Erase command to stop. Afterwards, the Chip Erase command should be executed again.

## 45.11 Protection Function

### 45.11.1 Software Protection

Software protection disables programming and erasure of the code flash memory through the settings of control registers and block protect setting in the user area. If an attempt is made to issue an FACI command against software protection, the flash sequencer enters the command-locked state.

#### 45.11.1.1 Protection by FENTRYR

When the FENTRYR register is set to 0x0000, the flash sequencer enters read mode. In read mode, FACI commands cannot be accepted. If an attempt is made to issue an FACI command in read mode, the flash sequencer enters the command-locked state.

#### 45.11.1.2 Protection by Block Protect Setting

Each block protect area in user area has the block protect setting (BPS or BPS_SEC). When the FBPROT0 or FBPROT1 register is 0x0000 and the block protect bit is 0, issuing the Program or Block Erase command to user area of the code flash causes the command-locked state. To program or erase the block protect area whose block protect bit is 0, set the FBPROT0 or FBPROT1 register to 0x0001.

The block protect setting can be locked by the permanent block protect setting (PBPS or PBPS_SEC). When the permanent block protect setting and the block protect setting are 0, issuing a Program, Block Erase, or Chip Erase command to user area of the code flash causes the flash sequencer to enter the command-locked state regardless of the FBPROT0 and FBPROT1 register settings.

Valid block protect setting (BPS or BPS_SEC) depends on the Block Protect Select bit (BPS_SEL).

See section 45.12.2. Permanent Block Protect Setting for details of the block protect setting and permanent block protect setting. See section 45.4.13. FBPROT0 : Flash Block Protection Register and section 45.4.14. FBPROT1 : Flash Block Protection for Secure Register for more information.

For details of block protect setting (BPS or BPS_SEC) and block protect select (BPS_SEL), see section 6, Option-Setting Memory.

The protected area by the block protect setting for Program or Block Erase command is always determined by the address of the FSADDR register setting regardless of the address swapping function setting (the startup area select in linear mode, the block swap in linear mode, and the startup bank select in dual mode). Table 45.16 to Table 45.21 show the relation of user area and the block protect setting in each function setting.

##### (1) In case of the linear mode

- BPS[0] to BPS[n] or BPS_SEC[0] to BPS_SEC[n] are assigned to the block of user area (for example, address is 0x00_0000 to the last block address).
- BPS[0]/BPS_SEC[0] and BPS[1]/BPS_SEC[1] are assigned to the block of user area depending on the startup area select setting (SAS.BTFLG bit). (See section 45.11.3. Startup Program Protection).
- The second half of FLI user area is assigned to block protect setting depending on the block swap select setting (BANKSEL.BLCKSWP[2:0] bits). See section 45.11.5. Block Swap Function.

Table 45.16 shows the block protect setting when the startup area select is disabled (not swapping) in linear mode.

Table 45.17 show example of the block protect setting when the address conversion function is used in the linear mode.

**Table 45.16 Example of block protect setting when SAS.BTFLG is 1 (1 of 2)**

| FSADDR[23:0] | Block size | Block protect setting | User area block number | Notes |
|---|---|---|---|---|
| The last block address | 32 KB | BPS[n] or BPS_SEC[n] | Block (16n - 96) to (16n - 81) | — |
| ⋮ | ⋮ | ⋮ | ⋮ | — |
| 0x01_8000 to 0x01_FFFF | 32 KB | BPS[9] or BPS_SEC[9] | Block 48 to 63 | — |
| 0x01_0000 to 0x01_7FFF | 32 KB | BPS[8] or BPS_SEC[8] | Block 32 to 47 | — |
| 0x00_E000 to 0x00_FFFF | 8 KB | BPS[7] or BPS_SEC[7] | Block 28 to 31 | — |
| 0x00_C000 to 0x00_DFFF | 8 KB | BPS[6] or BPS_SEC[6] | Block 24 to 27 | — |
| ⋮ | ⋮ | ⋮ | ⋮ | — |
| 0x00_2000 to 0x00_3FFF | 8 KB | BPS[1] or BPS_SEC[1] | Block 4 to 7 | Not swap block 0 to 3 and block 4 to 7 in this startup area select setting |

**Table 45.16 Example of block protect setting when SAS.BTFLG is 1 (2 of 2)**

| FSADDR[23:0] | Block size | Block protect setting | User area block number | Notes |
|---|---|---|---|---|
| 0x00_0000 to 0x00_1FFF | 8 KB | BPS[0] or BPS_SEC[0] | Block 0 to 3 | Not swap block 0 to 3 and block 4 to 7 in this startup area select setting |

**Table 45.17 Example of block protect setting when SAS.BTFLG is 0**

| FSADDR[23:0] | Block size | Block protect setting | User area block number | Notes |
|---|---|---|---|---|
| The last block address | 32 KB | BPS[n] or BPS_SEC[n] | Block (16n - 96) to (16n - 81) | — |
| ⋮ | ⋮ | ⋮ | ⋮ | — |
| 0x01_8000 to 0x01_FFFF | 32 KB | BPS[9] or BPS_SEC[9] | Block 48 to 63 | — |
| 0x01_0000 to 0x01_7FFF | 32 KB | BPS[8] or BPS_SEC[8] | Block 32 to 47 | — |
| 0x00_E000 to 0x00_FFFF | 8 KB | BPS[7] or BPS_SEC[7] | Block 28 to 31 | — |
| 0x00_C000 to 0x00_DFFF | 8 KB | BPS[6] or BPS_SEC[6] | Block 24 to 27 | — |
| ⋮ | ⋮ | ⋮ | ⋮ | — |
| 0x00_2000 to 0x00_3FFF | 8 KB | BPS[1] or BPS_SEC[1] | Block 0 to 3 | Swap block 0 to 3 and block 4 to 7 in this startup area select setting |
| 0x00_0000 to 0x00_1FFF | 8 KB | BPS[0] or BPS_SEC[0] | Block 4 to 7 | Swap block 0 to 3 and block 4 to 7 in this startup area select setting |

**Table 45.18 Example of block protect setting when BANKSEL.BLCKSWP is 1**

| FSADDR[23:0] | Block size | Block protect setting | User area block number | Notes |
|---|---|---|---|---|
| The last block address | 32 KB | BPS[n] or BPS_SEC[n] | Block (16n - 96) to (16n - 81) | — |
| ⋮ | ⋮ | ⋮ | ⋮ | — |

### (2) In case of the dual mode (DUALSEL.BANKMD[2:0] = 000b)

Bank0 is lower side bank (BANKSEL.BANKSWP[2:0] = 111b).

- BPS[0] to BPS[n] or BPS_SEC[0] to BPS_SEC[n] are assigned the block of bank 0 user area (for example, address is 0x00000000 to the last block address in the lower side bank).
- BPS[70] to BPS[70 + n] or BPS_SEC[70] to BPS_SEC[70 + n] are assigned to the block of bank 1 user area (for example, address is 0x00200000 to the last block address in the upper side bank).

Bank0 is upper side bank (BANKSEL.BANKSWP[2:0] = 000b)

- BPS[0] to BPS[n] or BPS_SEC[0] to BPS_SEC[n] are assigned to the block of bank1 user area (e.g. Address is 0x00_0000 to The last block address in lower side bank).
- BPS[70] to BPS[70+n] or BPS_SEC[70] to BPS_SEC[70+n] are assigned to the block of bank0 user area (e.g. Address is 0x20_0000 to The last block address in upper side bank).

Table 45.20 and Table 45.21 show example of the block protect setting in the dual mode. See section 45.11.4. Dual Bank Function for details of dual bank function (DUALSEL.BANKMD[2:0] and BANKSEL.BANKSWP[2:0] bits).

**Table 45.20 Example of block protect setting when BANKSEL.BANKSWP[2:0] is 111b**

| FSADDR[23:0] | Block size | Block protect setting | User area block number | Notes |
|---|---|---|---|---|
| The last block address in upper side bank | 32 KB | BPS[70 + n] or BPS_SEC[70 + n] | Block (16n + 928) to (16n + 943) | Not swap bank 0 and bank 1 in this startup bank switch setting |
| ⋮ | ⋮ | ⋮ | ⋮ | |

## 45.11.2 Error Protection

Error protection detects the issuing of illegal FACI commands, illegal access, and flash sequencer malfunction. FACI command acceptance is disabled (command-locked state) in response to the detection of these errors. The flash memory cannot be programmed or erased while the flash sequencer is in the command-locked state. For release from the command-locked state, issue the Status Clear or Forced Stop command. The Status Clear command can only be used while the FRDY bit in the FSTATR register is 1. The Forced Stop command can be used regardless of the value of the FRDY bit. While the CMDLKIE bit in the FAEINT register is 1, a flash access error (FIFERR) interrupt is generated if the flash sequencer enters the command-locked state (the CMDLK bit in the FASTAT register is set to 1).

If the flash sequencer enters the command-locked state in response to a command during programming or erasure processing, the flash sequencer continues the processing for programming or erasure. If a command is issued in the command-locked state, the ILGLERR bit becomes 1 and the other bits retain the values set from previous error detection.

Table 45.22 shows the error protection types and status bit values after error detections.

**Table 45.22 Error protection type (1 of 3)**

| Error type | Description | ILGCOMERR | FESETERR | SECERR | OTERR | ILGLERR | ERSERR | PRGERR | CFAE | DFAE |
|---|---|---|---|---|---|---|---|---|---|---|
| FENTRYR setting error | The value set in FENTRYR is not 0x0000, 0x0001, or 0x0080 | 0 | 1 | 0 | 0 | 1 | 0 | 0 | 0 | 0 |

**Table 45.22 Error protection type (2 of 3)**

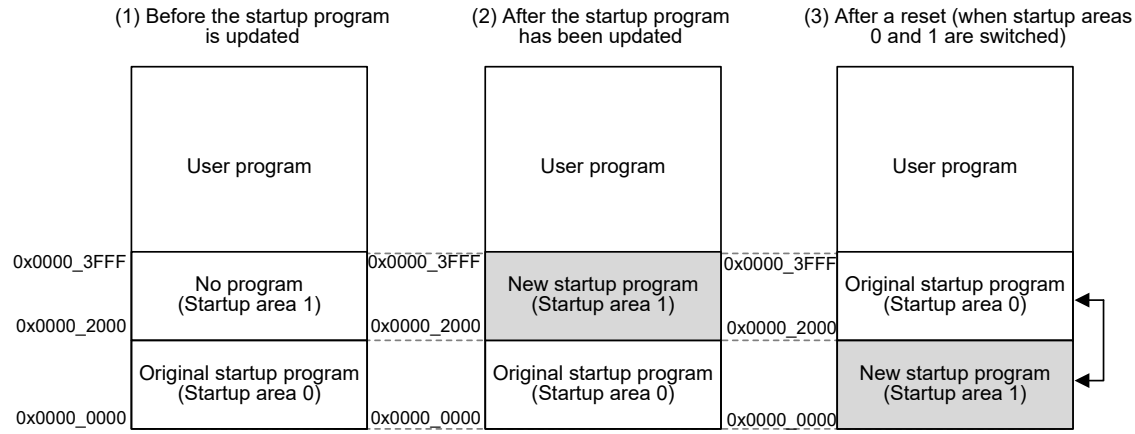
| Error type | Description | ILGCOMERR | FESETERR | SECERR | OTERR | ILGLERR | ERSERR | PRGERR | CFAE | DFAE |
|---|---|---|---|---|---|---|---|---|---|---|
| Illegal command error | An undefined size is specified in the first cycle of the command (not byte-write) | 1 | 0 | 0 | 0 | 1 | 0 | 0 | 0 | 0 |
| | An undefined code is written in the first access of the FACI command | 1 | 0 | 0 | 0 | 1 | 0 | 0 | 0 | 0 |
| | The value specified in the last access of the multiple-access FACI command is not 0xD0 | 1 | 0 | 0 | 0 | 1 | 0 | 0 | 0 | 0 |
| | The value (N) specified in the second write access of the FACI command in the program or configuration set command is wrong | 1 | 0 | 0 | 0 | 1 | 0 | 0 | 0 | 0 |
| | Blank Check command is issued with inconsistent BCDIR, FSADDR, and FEADDR settings (see section 45.4.11. FEADDR : FACI Command End Address Register) | 1 | 0 | 0 | 0 | 1 | 0 | 0 | 0/1*1 | 0/1*1 |
| | A Chip Erase command is issued with inconsistent FSADDR and FEADDR settings.<br>• FSADDR > FEADDR<br>• FEADDR is set to reserved area | 1 | 0 | 0 | 0 | 1 | 0 | 0 | 0/1*1 | 0/1*1 |
| | A FACI command not acceptable in each mode is issued (see Table 45.13) | 1 | 0 | 0 | 0 | 1 | 0 | 0 | 0 | 0 |
| | A FACI command is issued when command acceptance conditions are not satisfied (see Table 45.14) | 0/1 | 0/1 | 0/1 | 0/1 | 1 | 0/1 | 0/1 | 0/1 | 0/1 |
| | A Program or Block Erase command is issued against the area protected by the block protect setting (see section 45.11.1.2. Protection by Block Protect Setting) | 1 | 0 | 0 | 0 | 1 | 0 | 0 | 0 | 0 |
| | A Chip Erase command is issued when any of the user area block is protected by the block protect setting (see section 45.11.1.2. Protection by Block Protect Setting) | 1 | 0 | 0 | 0 | 1 | 0 | 0 | 0 | 0 |
| Erase error | An error occurs during erasure | 0 | 0 | 0 | 0 | 0 | 1 | 0 | 0 | 0 |
| Program error | An error occurs during programming | 0 | 0 | 0 | 0 | 0 | 0 | 1 | 0 | 0 |
| Code flash access error | Program or Block Erase command is issued to the reserved user area in code flash P/E mode (see section 45.4.7. FASTAT : Flash Access Status Register) | 0 | 0 | 0 | 0 | 1 | 0 | 0 | 1 | 0 |
| | Chip Erase or Blank Check command is issued to reserved user area in code flash P/E mode (FSADDR is set to reserved user area) | 1 | 0 | 0 | 0 | 1 | 0 | 0 | 1 | 0 |
| | Configuration set command is issued to reserved configuration area | 0 | 0 | 0 | 0 | 1 | 0 | 0 | 1 | 0 |
| | Configuration Set command of non-secure access is issued to the secure region of configuration area | 0 | 0 | 0 | 0 | 1 | 0 | 0 | 1 | 0 |
| | Program, Block Erase or Blank Check command is issued to the secure region of configuration area | 0/1 | 0 | 0 | 0 | 1 | 0 | 0 | 1 | 0 |

**Table 45.22 Error protection type (3 of 3)**

| Error type | Description | ILGCOMERR | FESETERR | SECERR | OTERR | ILGLERR | ERSERR | PRGERR | CFAE | DFAE |
|---|---|---|---|---|---|---|---|---|---|---|
| Data flash access violation | A Program or Block Erase command is issued to the reserved data area in data flash P/E mode | 0 | 0 | 0 | 0 | 1 | 0 | 0 | 0 | 1 |
| | A Chip Erase or Blank Check command is issued to the reserved data area in data flash P/E mode (FSADDR is set to reserved data area.) | 1 | 0 | 0 | 0 | 1 | 0 | 0 | 0 | 1 |
| | A Program, Block Erase or Blank Check command of non-secure access is issued to the secure region of data area | 0/1 | 0 | 0 | 0 | 1 | 0 | 0 | 0 | 1 |
| Security error | Configuration set command for the SAS.BTFLG bit setting is issued when the SAS.FSPR bit is 0 (see section 45.9.3.14. Configuration Set Command) | 0 | 0 | 1 | 0 | 1 | 0 | 0 | 0 | 0 |
| | A Chip Erase command is issued when the FSPR bit is 0 | 0 | 0 | 1 | 0 | 1 | 0 | 0 | 0 | 0 |
| Others | A FACI command-issuing area is accessed in read mode | 0 | 0 | 0 | 1 | 1 | 0 | 0 | 0 | 0 |
| | An FACI command-issuing area is read in code flash P/E mode or data flash P/E mode | 0 | 0 | 0 | 1 | 1 | 0 | 0 | 0 | 0 |

Note 1. A value depends on the FSADDR setting.

## 45.11.3 Startup Program Protection



Protection of the startup program is for protection of the program to be started after a reset (the startup program). This function provides a way to safely update the startup program when rewriting is suspended during a reset.

The startup area is 8 KB in size and is assigned to the user area in the code flash memory. This function uses the values of the SAS.BTFLG bit and the FSUACR.SAS[1:0] bits to change the area where the startup program is stored in block units (see Figure 45.21 to Figure 45.24).

In protection of the startup program, the state of the selection of the startup area can be fixed by the FSPR bit. However, the SAS.FSPR bit never be restored to 1 once the flag is set to 0. Exercise extra caution when handling the SAS.FSPR bit.

In addition, this protection cannot be used when dual mode is selected by the bank mode switching function (when the BANKMD[2:0] bits are 000b).

For details of SAS.FSPR bit and DUALSEL.BANKMD[2:0] bits, see section 6, Option-Setting Memory.

Note: The addresses are used for reading, programming, and erasure. Startup area 0 is erased when Block Erase command is issued for the address rage from 0x00000000 to 0x00001FFF with allocation shown under 3.

1. Before the startup program is updated
   When the SAS.BTFLG bit is 1 and the FSUACR.SAS[1:0] bits are 0xb, the address range from 0x00002000 to 0x00003FFF is selected as startup area 1 and the address range from 0x00000000 to 0x00001FFF is selected as startup area 0.
2. After the startup program has been updated
   A new startup program can be written to startup area 1. At this time, startup area 0 still contains the previous startup program, so rewriting by starting up from startup area 0 remains possible if rewriting to the startup area 1 fails.
3. After a reset (when startup areas 0 and 1 are switched)
   When rewriting startup area 1 is successfully completed, switch the assignment of startup areas 0 and 1 by rewriting the startup area selection bit (the SAS.BTFLG bit) with Configuration Set command. Afterwards, the program is started up from startup area 1 after a reset.

**Figure 45.21 Concept of protection of the startup program**

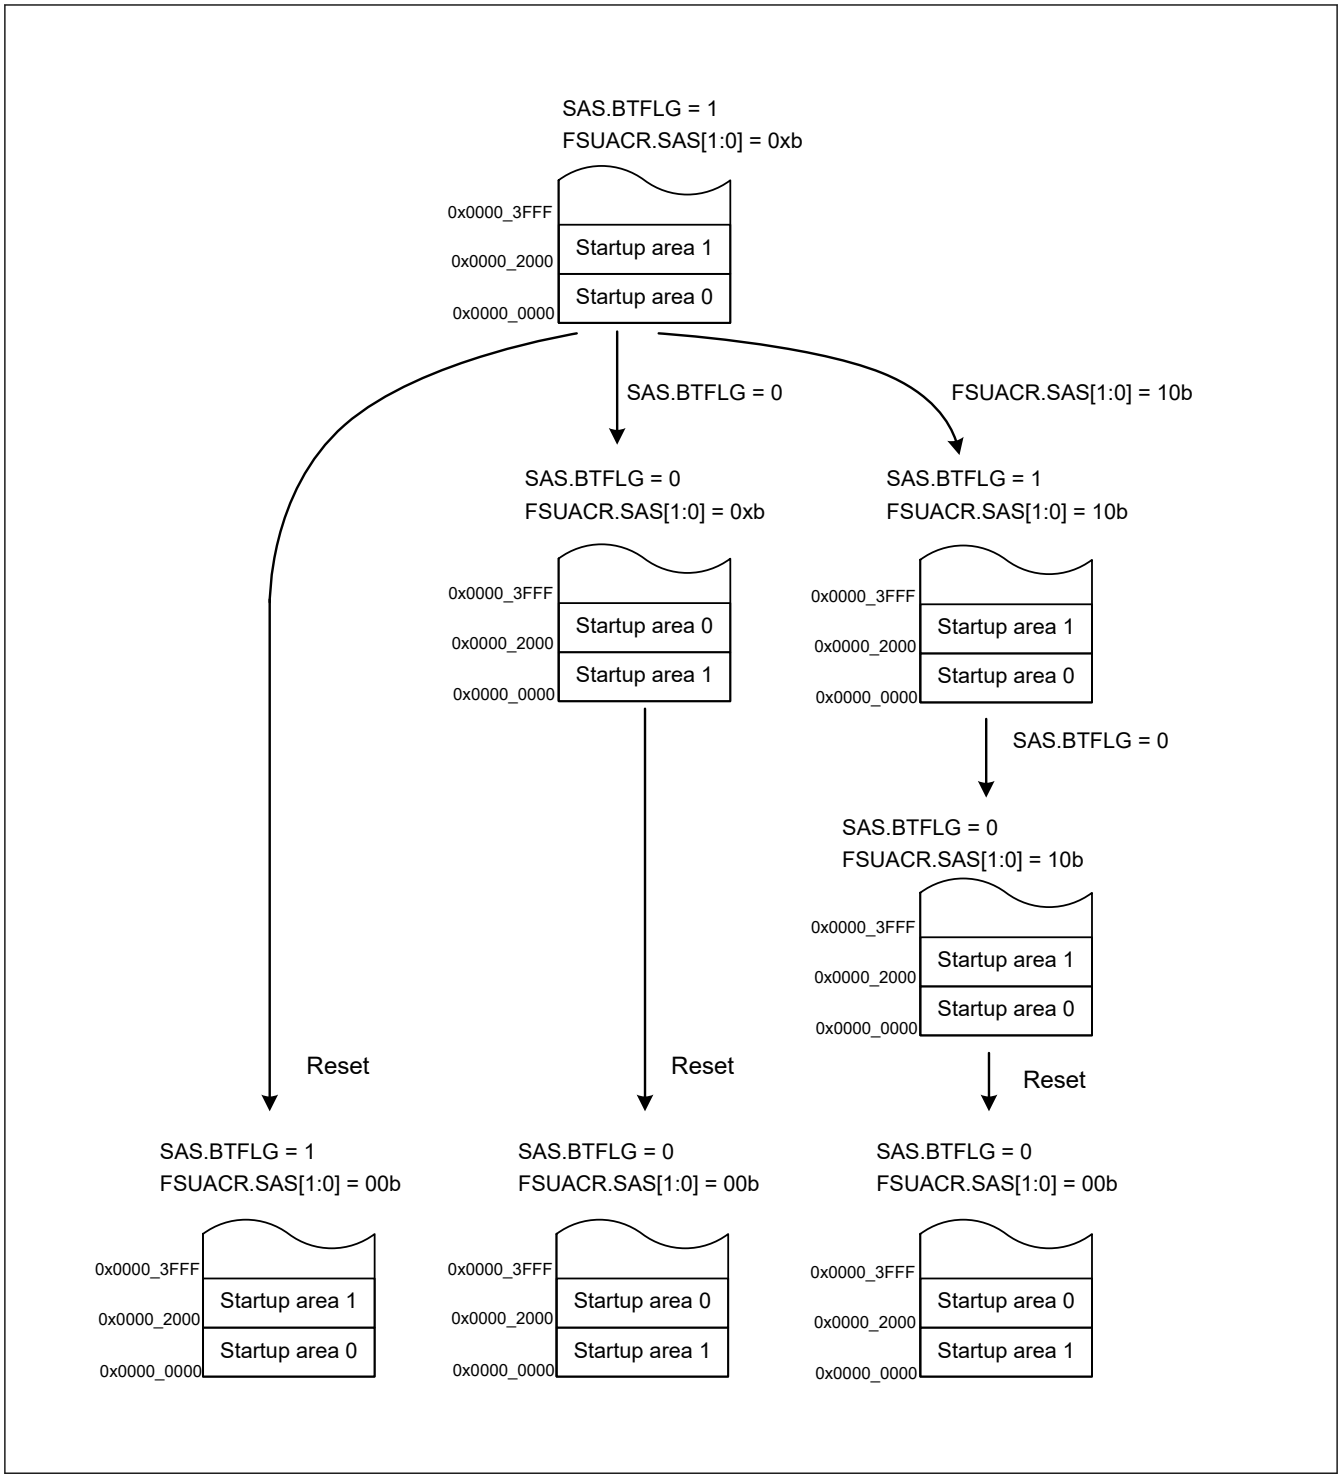


**Figure 45.22 Example 1 of transitions for startup program protection settings**

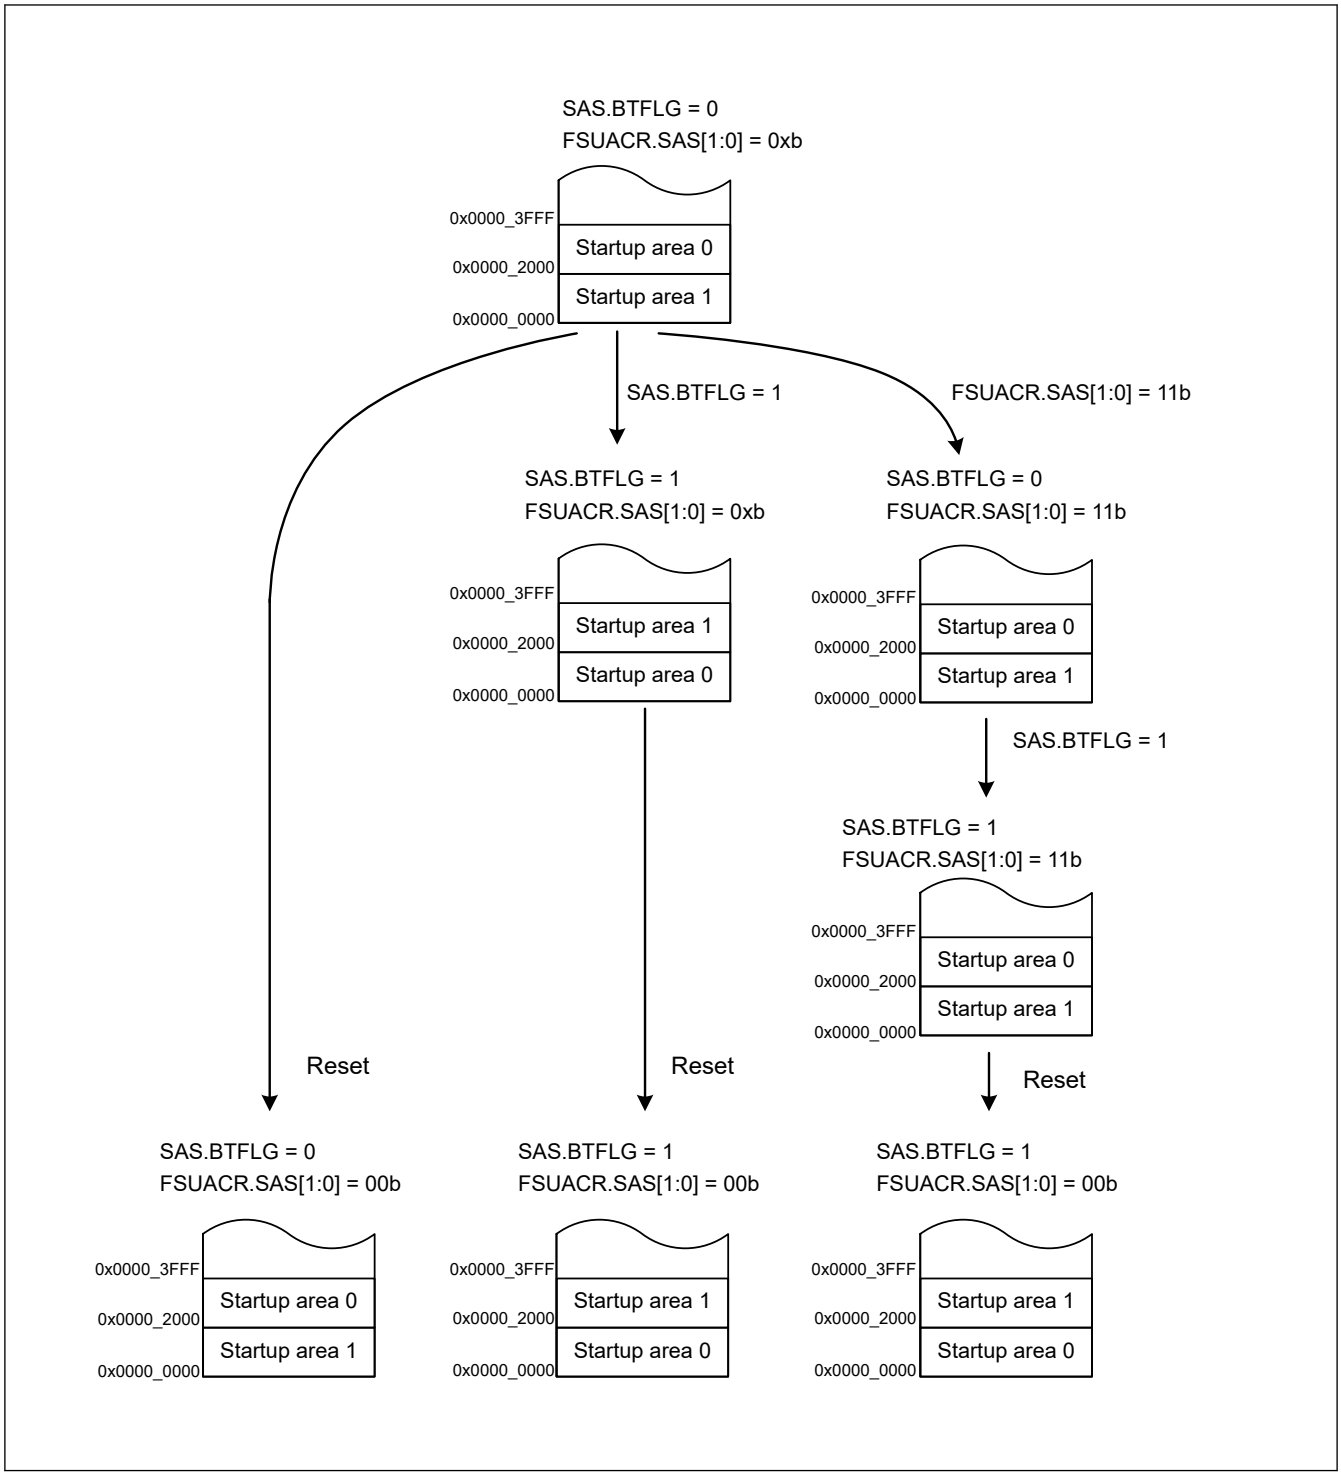

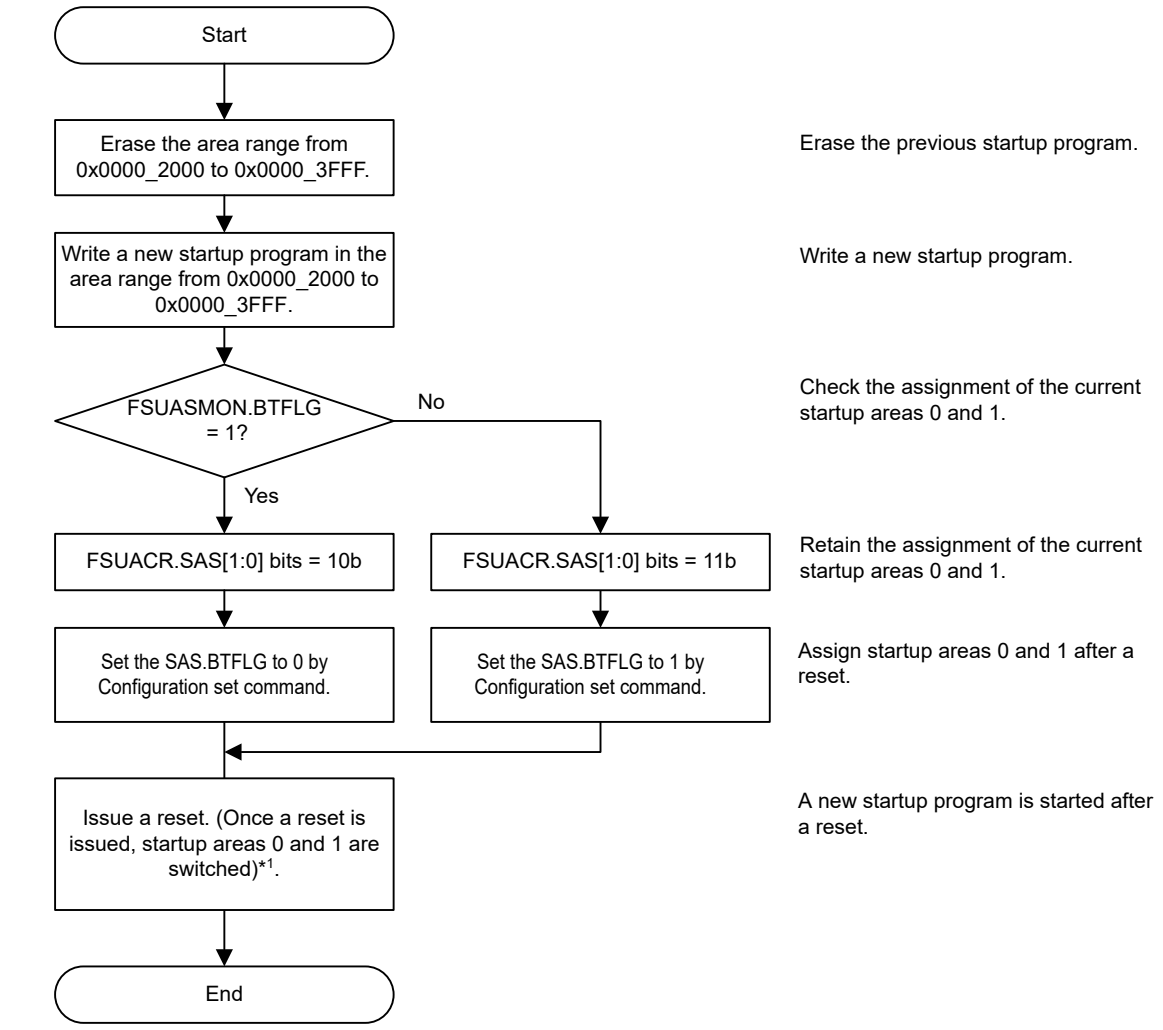

**Figure 45.23 Example 2 of transitions for startup program protection settings**

Note 1. For details, see Figure 45.22 and Figure 45.23.

**Figure 45.24 Concept of protection of the startup program**

## 45.11.4 Dual Bank Function

This protection uses the functions of bank mode switching and startup bank selection to update a program while a user program is running and to provide a safe method of updating in cases where programming is suspended during a reset.

### 45.11.4.1 Switching Bank Modes

The bank mode switching function selects either linear mode in which the user area in the code flash memory is used as one area, or dual mode in which the user area is divided into two bank areas. Figure 45.25 shows an example of flow of switching bank modes. A reset after setting the DUALSEL.BANKMD[2:0] bits in the option setting memory determines the mode of the bank mode switching function. Selecting dual mode enables the startup bank selection function.

When dual mode is selected by bank mode switching function (the DUALSEL.BANKMD[2:0] bits are 000b), startup program protection function cannot be used.

For details of DUALSEL.BANKMD[2:0] bits, see section 6, Option-Setting Memory.

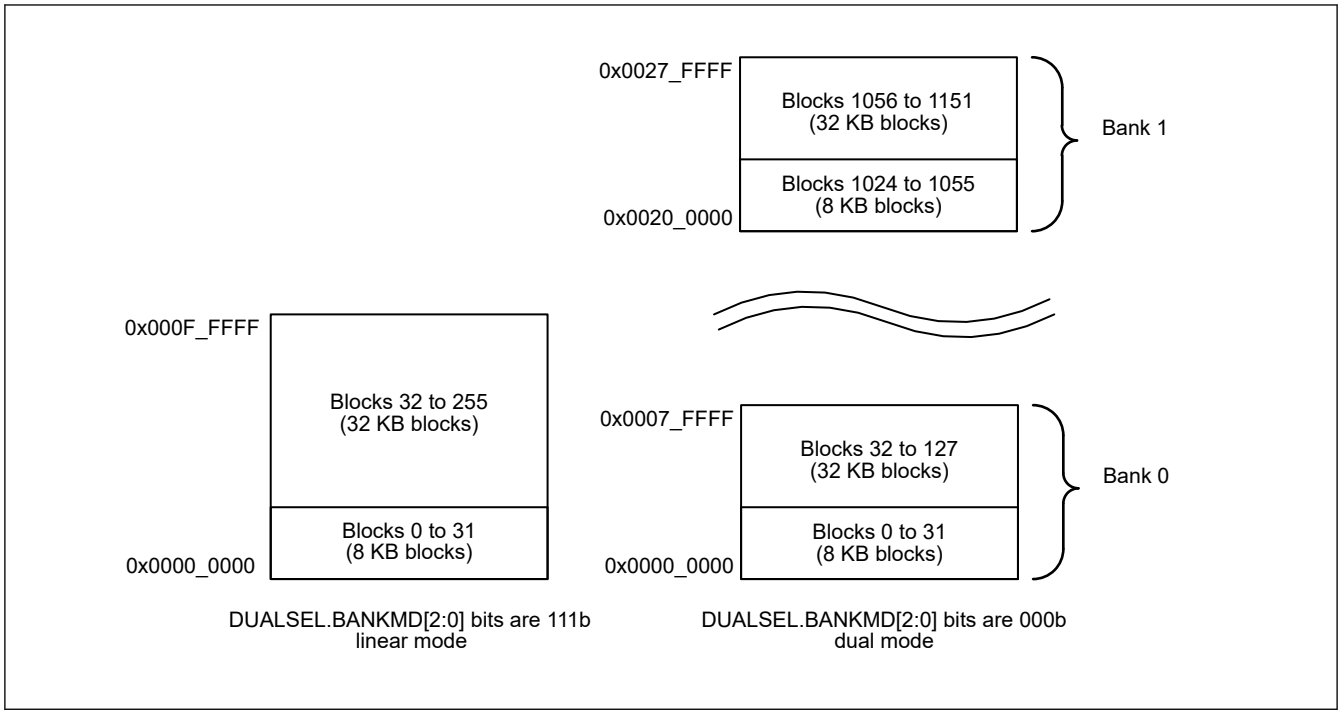

**Figure 45.25 Example of flow for switching bank modes (for products with 1 MB of code flash memory)**

### 45.11.4.2 Selecting the Startup Bank

Startup bank selection provides a way to safely update the program by selecting a bank area to be started in dual mode (when the DUALSEL.BANKMD[2:0] bits are 000b) when programming is suspended during a reset. Figure 45.26 is a schematic view of startup bank selection and Table 45.23 shows an example of the flow of startup bank selection. A reset after setting the value of the BANKSEL.BANKSWP[2:0] bits in the option-setting memory changes the addresses of banks 0 and 1 and booting up a program proceeds from the updated area. When the address is switched by using startup bank selection, the programming/erasure target for the FACI commands is also switched. This function is invalid in linear mode.

For details of DUALSEL.BANKMD[2:0] bits and BANKSEL.BANKSWP[2:0] bits, see section 6, Option-Setting Memory.

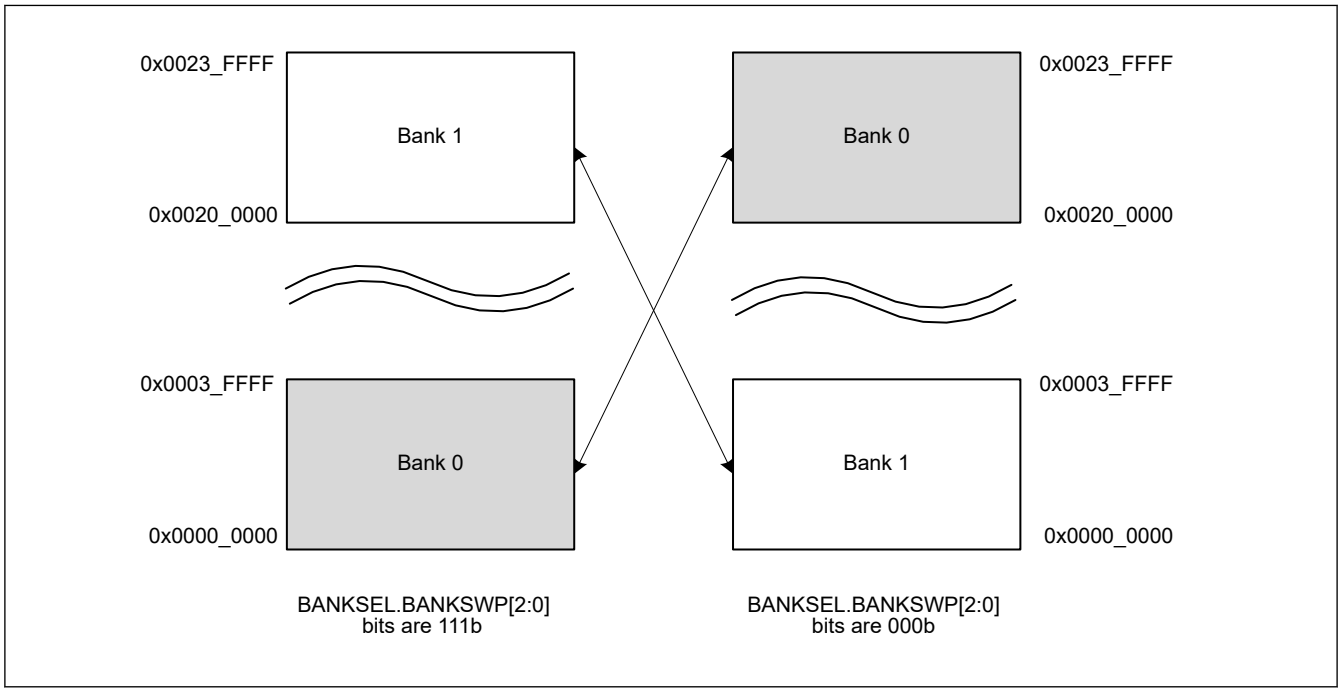

**Figure 45.26 Example of startup bank selection (for products with 512 KB of code flash memory)**

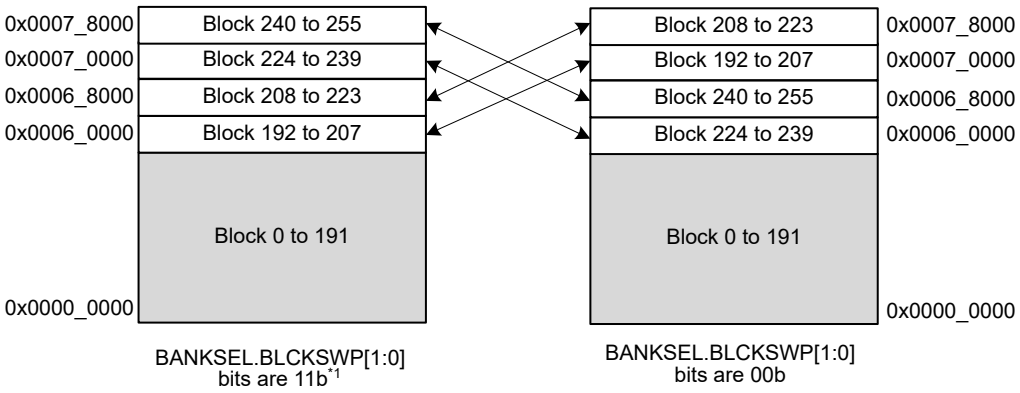
**Table 45.23 Example of startup bank selection flow (for products with 512 KB of code flash memory)**

| No. | Step Name | Description |
|---|---|---|
| 1 | Erase block | Erase blocks to be programed in the address range from 0x0020_0000 to 0x0023_FFFF |
| 2 | Program a new software | Program a new software in the address range from 0x0020_0000 to 0x0023_FFFF |
| 3 | Read the value | Read the value of the BANKSEL.BANKSWP [2:0] bits. |
| 4 | Write an inverted value | Write an inverted value in the BANKSEL.BANKSWP[2:0] bits*1. |
| 5 | Issue a reset | Issue a reset (a reset switches the banks) |

Note 1. Set the inverse of the read value of the BANKSEL.BANKSWP[2:0] bits (000b or 111b).

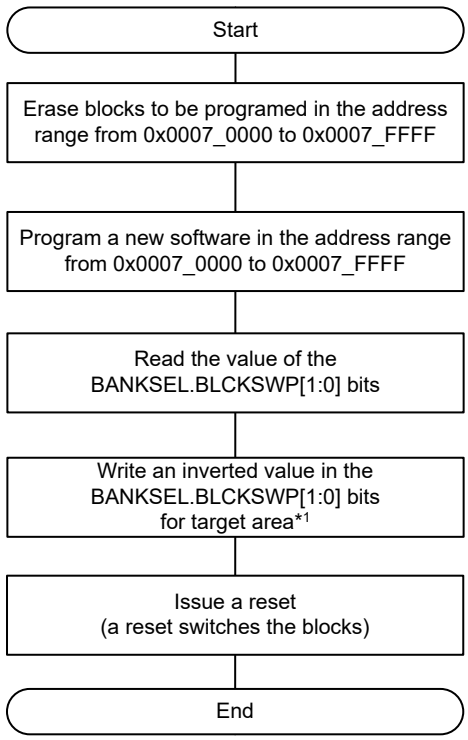
## 45.11.5 Block Swap Function



This protection uses the functions of block swap selection to update a program while a user program is running and to provide a safe method of updating in cases where programming is suspended during a reset.

### 45.11.5.1 Selecting the Block Swap

Block swap selection provides a way to safely update the program when programming is suspended during a reset. Figure 45.27 is a schematic view of block swap selection and Figure 45.28 shows an example of the flow of block swap selection. A reset after setting the value of the BANKSEL.BLCKSWP bit in the option-setting memory changes the addresses of block A and B. When the address is switched, the programming/erasure target for the FACI commands is also switched.



In addition, this protection cannot be used when dual mode is selected by the bank mode switching function (when the DUALSEL.BANKMD[2:0] bits are 000b).

For details of DUALSEL.BANKMD[2:0] bits and BANKSEL.BLCKSWP bit, see section 6, Option-Setting Memory.

Note 1. For products without setting of the option-setting memory, the BANKSEL.BLCKSWP[3:0] bits are 1111b

**Figure 45.27 Example of block swap selection (for products with 512 KB of code flash memory)**

Note 1. When target area is Blocks 192 to 207 and 224 to 239, BANKSEL.BLKSWP[0] bit sets the inverse of the read value.
When target area is Blocks 208 to 223 and 240 to 255, BANKSEL.BLKSWP[1] bit sets the inverse of the read value.

**Figure 45.28 Example of block swap selection flow (for products with 512 KB of code flash memory)**

## 45.12 Security Function

The flash sequencer supports the following security functions:

- Security flag for startup area
- Permanent block protect setting
- Flash memory protection for TrustZone

### 45.12.1 Security Flag for Startup Area Select

The security flag (SAS.FSPR) for the startup area is located in the option-setting memory.

When the SAS.FSPR bit is 0, issuing the configuration set command to change the SAS.BTFLG bit, the Chip Erase command causes the flash sequencer to be in the command-locked state. Also, when the SAS.FSPR bit is 0, it is invalid to write to the Startup Area Select bits SAS[1:0] in the FSUACR register. The SAS.FSPR bit enables protection.

### 45.12.2 Permanent Block Protect Setting

The permanent block protect setting is the clear protection for the block protection setting. User area cannot be permanently updated by the FACI command when the permanent block protect setting is enabled. See section 45.11.1.2. Protection by Block Protect Setting for more details.

The block protect setting and the permanent block protect setting have the write/clear protection against the configuration set command. The flash sequencer does not detect an error when the configuration set command is issued to the write/clear protected settings.

Figure 45.29 and Table 45.24 show the write/clear protection against the block protect setting (BPS[n]) and the permanent protect setting (PBPS[n]). Figure 45.30 and Table 45.25 show the write/clear protection against the block protect setting for secure (BPS_SEC[n]) and permanent protect setting for secure (PBPS_SEC[n]).

Effective permanent block protect setting (PBPS or PBPS_SEC) depends on block protect select (BPS_SEL). For details of permanent block protect setting (PBPS or PBPS_SEC) and block protect select (BPS_SEL), see section 6, Option-Setting Memory.

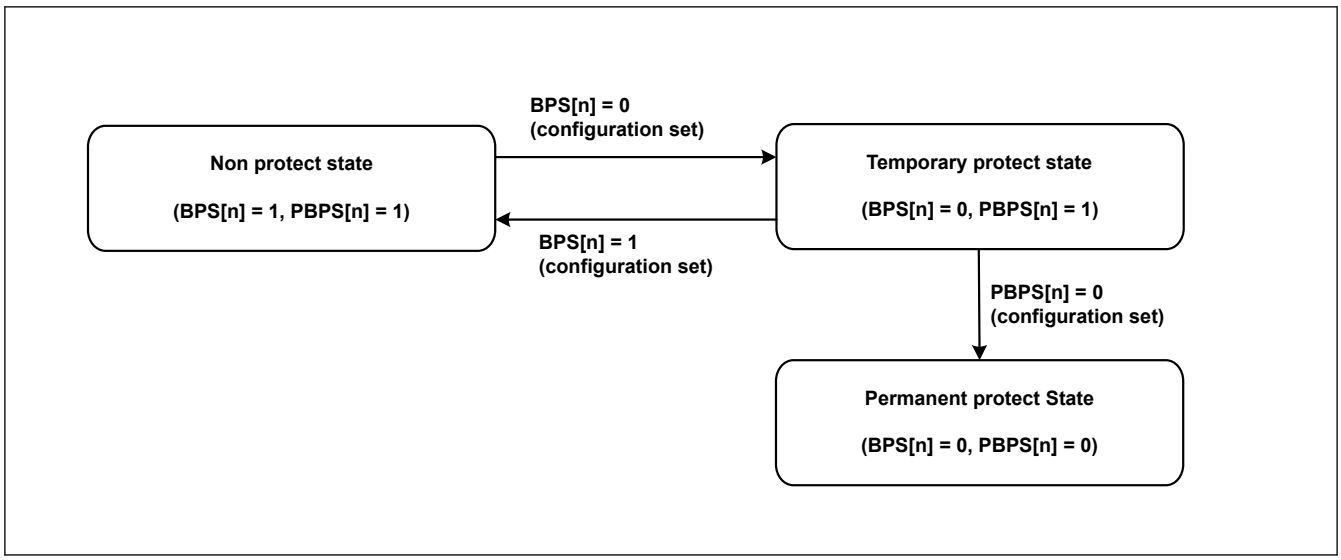


**Figure 45.29 Status transition of flash sequencer by BPS[n] and PBPS[n]**

**Table 45.24 Write/clear protection of BPS[n] and PBPS[n]**

| Current state | | Updatable state by configuration set command | | | |
|---|---|---|---|---|---|
| BPS[n] | PBPS[n] | BPS[n] = 1 | BPS[n] = 0 | PBPS[n] = 1 | PBPS[n] = 0 |
| 1 | 1 | ✓ | ✓ | ✓ | X |
| 1 | 0 | — | — | — | — |
| 0 | 1 | ✓ | ✓ | ✓ | ✓ |
| 0 | 0 | X | ✓ | X | ✓ |

Note:
- ✓ indicates updatable by configuration set command.
- X indicates not updatable by configuration set command (error does not occur).
- — indicates not reaching to this state.

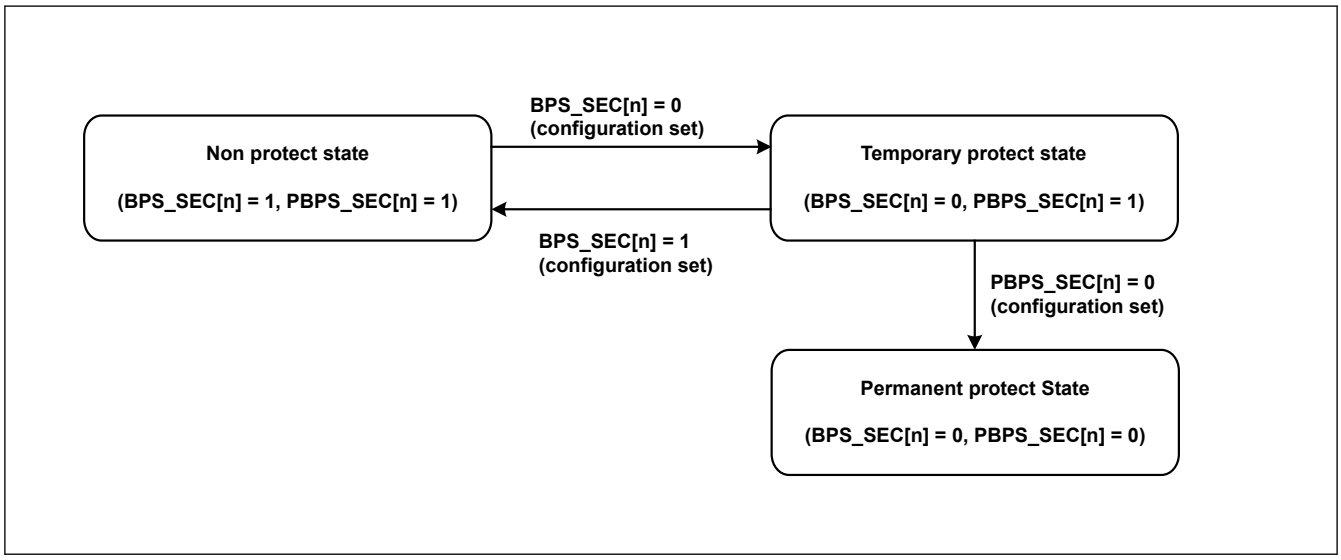

**Figure 45.30 Status transition of flash sequencer by BPS_SEC[n] and PBPS_SEC[n]**

**Table 45.25 Write/clear protection of BPS_SEC[n] and PBPS_SEC[n]**

| Current state | | Updatable state by configuration set command | | | |
|---|---|---|---|---|---|
| BPS_SEC[n] | PBPS_SEC[n] | BPS_SEC[n] = 1 | BPS_SEC[n] = 0 | PBPS_SEC[n] = 1 | PBPS_SEC[n] = 0 |
| 1 | 1 | ✓ | ✓ | ✓ | X |
| 1 | 0 | — | — | — | — |
| 0 | 1 | ✓ | ✓ | ✓ | ✓ |
| 0 | 0 | X | ✓ | X | ✓ |

Note:
- ✓ indicates updatable by configuration set command.
- X indicates not updatable by configuration set command (error does not occur).
- — indicates not reaching to this state.

## 45.12.3 Flash Memory Protection for TrustZone

Information in this section focuses on the flash sequencer operation.

The flash memory provides the following types of protect function against non-secure access:

- Protection for flash memory area (P/E)
- Protection for flash memory area (read)
- Protection for registers
- Code flash P/E mode entry protection

### 45.12.3.1 Protection for Flash Memory Area (P/E)

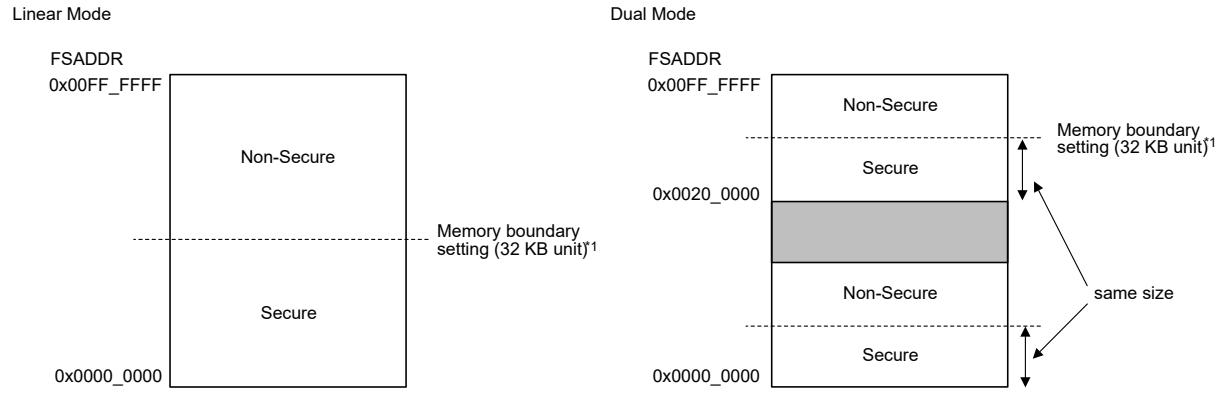
This function protects the secure region of the code flash and data flash from FACI commands of non-secure access (except for Chip Erase command). The condition of protection depends on the FACI command, the access attribution, and the memory boundary setting.

For details of secure region, see section 48, Security Features .

See Table 45.26 for information on protection of the flash memory area (P/E).

**Table 45.26 Protection for the flash memory area (P/E)**

| FACI command | Target area | | Issuing of FACI command by non-secure access | Issuing of FACI command by secure access |
|---|---|---|---|---|
| Program<br>Block Erase<br>Blank Check | Code flash memory | User area (non-secure area) | ✓ | ✓ |
| | | User area (secure area) | X | ✓ |
| | Data flash memory | Data area (non-secure area) | ✓ | ✓ |
| | | Data area (secure area) | X | ✓ |
| Configuration Set | Code flash memory | option-setting memory (non-secure area) | ✓ | ✓ |
| | | option-setting memory (secure area) | X | ✓ |



Note:
- ✓ indicates FACI command operation is not prohibited.
- X indicates FACI command operation is prohibited. Error occurs when the area is selected, and the FACI command is executed.

When the target area of FACI command is the user area of code flash, the flash sequencer compares the FSADDR register setting with the memory boundary setting of the code flash and determines whether the target area is in the secure region.

In linear mode, the memory boundary can be set to 0x0000_0000 to 0x00FF_8000 in 32 KB unit.

In dual mode, the memory boundary can be set to 0x0000_0000 to 0x0020_0000 in 32 KB unit. When the memory boundary is set to 0x0020_0000 or greater in the dual mode, the entire user area is defined as the secure region.

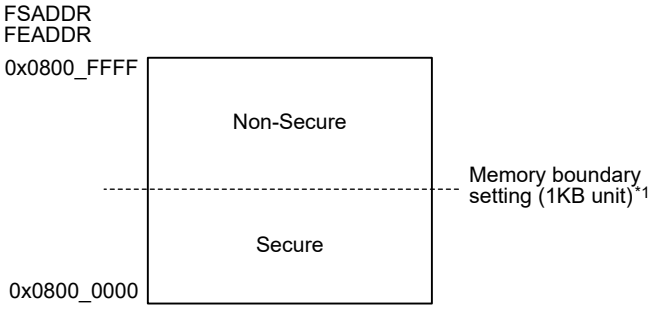


Figure 45.31 shows details of the non-secure/secure attribute of user area in the code flash.

Note 1. Comparing FSADDR with memory boundary setting of user area and judges whether the target area is in secure area.

**Figure 45.31 Secure/non-secure region in user area**

When the target area of the issuing FACI command is the data area of data flash, the flash sequencer compares the FSADDR/FEADDR register setting with the memory boundary setting of the data flash and determines whether the target area is in secure region. The memory boundary can be set to 0x0800_0000 to 0x0800_FC00 in 1 KB unit. Figure 45.32 shows details of the non-secure/secure attribute of data area in the data flash.

Note 1. Compares FSADDR/FEADDR with memory boundary setting of data area and determines whether the target area is in secure area.

**Figure 45.32 Secure/non-secure region in data area**

See Figure 45.33 for details of non-secure/secure region of option-setting memory. The flash sequencer determines that target area is secure region from the FSADDR register setting.

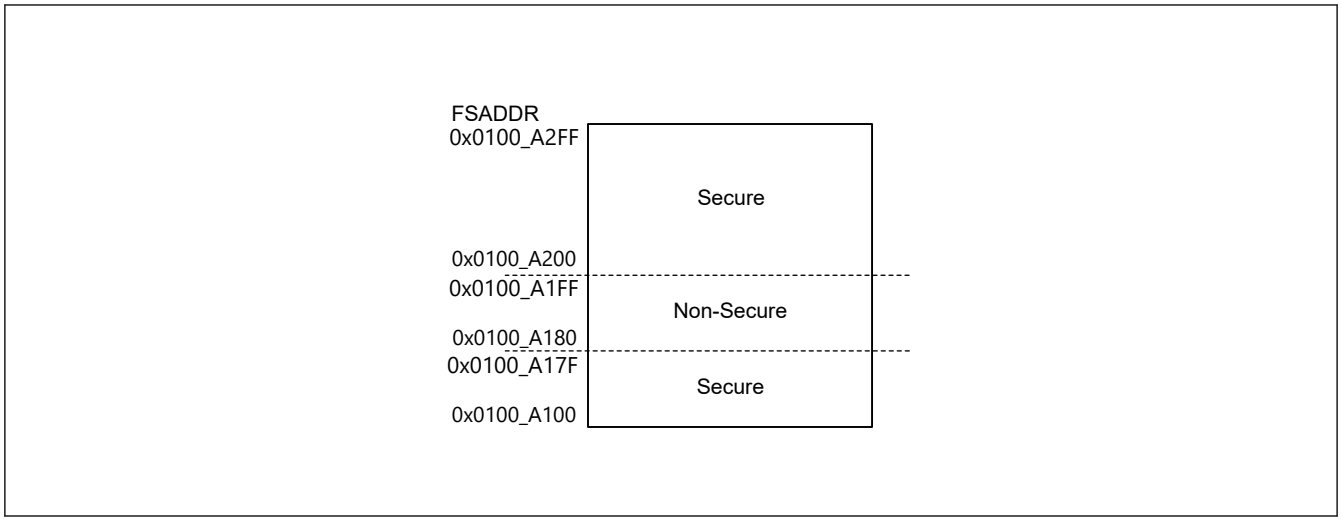

**Figure 45.33 Secure/non-secure region in option-setting memory**

### 45.12.3.2 Protection for Flash Memory Area (Read)

This function protects the secure region of code flash and data flash from non-secure bus access.

For details of secure region, see section 48, Security Features .

### 45.12.3.3 Protection for Register

The flash sequencer registers have write-access protection against non-secure access. Table 45.27 shows details of the protected registers of the flash sequencer.

**Table 45.27 Protected registers of the flash sequencer for TrustZone**

| Protection target register | Security attribute setting | Notes |
|---|---|---|
| FSAR | Always secure | See section 45.4.3. FSAR : Flash Security Attribution Register |
| DFLCTL | SA register setting (FSAR.DFLCTLSA) | See section 45.4.1. DFLCTL : Data Flash Control Register |
| MEMWAIT | SA register setting (FSAR.FLWTSA) | See section 8.2.4. MEMWAIT : Memory Wait Cycle Control Register for Code Flash |
| FLDWAITR | SA register setting (FSAR.FCKMHZSA) | See section 8.2.5. FLDWAITR : Memory Wait Cycle Control Register for Data Flash |
| PFBER | SA register setting (FSAR.PFBERSA) | See section 45.4.2. PFBER : Prefetch Buffer Enable Register |
| FACI registers except the following:<br>• Read-only register<br>• FMEPROT register<br>• FBPROT1 register<br>• FSUACR register | SA register setting (FSAR.FACICOMRSA) | See section 45.4.3. FSAR : Flash Security Attribution Register |
| FMEPROT | Always secure | See section 45.4.12. FMEPROT : Flash P/E Mode Entry Protection Register |
| FBPROT1 | Always secure | See section 45.4.14. FBPROT1 : Flash Block Protection for Secure Register |
| FSUACR | Always secure | See section 45.4.24. FSUACR : Flash Startup Area Control Register |
| FACI command-issuing area | SA register setting (FSAR.FACICOMISA) | See section 45.9.1. List of FACI Commands |

#### 45.12.3.4 Code Flash P/E Mode Entry Protection

The flash sequencer has protection function of code flash P/E by the FMEPROT register for the secure developer. Secure function can prevent disturbance of reading code flash memory by this protection function. See section 45.4.12. FMEPROT : Flash P/E Mode Entry Protection Register.

For applications that do not require non-secure region programming/erasure other than from secure function, it is recommended to always disable non-secure function of code flash programming/erasure by enabling the protection function of FMEPROT register.

For the code flash P/E sequence example by non-secure function, see Figure 45.34.

When the protection of FMEPROT register is enabled, the secure function can set interrupt vector to the code flash, and the non-secure function should call the code flash P/E request. See Figure 45.35 for details of the code flash P/E sequence example by non-secure function.

When the protection of FMEPROT register is disabled, the secure function cannot set interrupt vector to the code flash. See Figure 45.36 for details of the code flash P/E sequence example by the non-secure function.

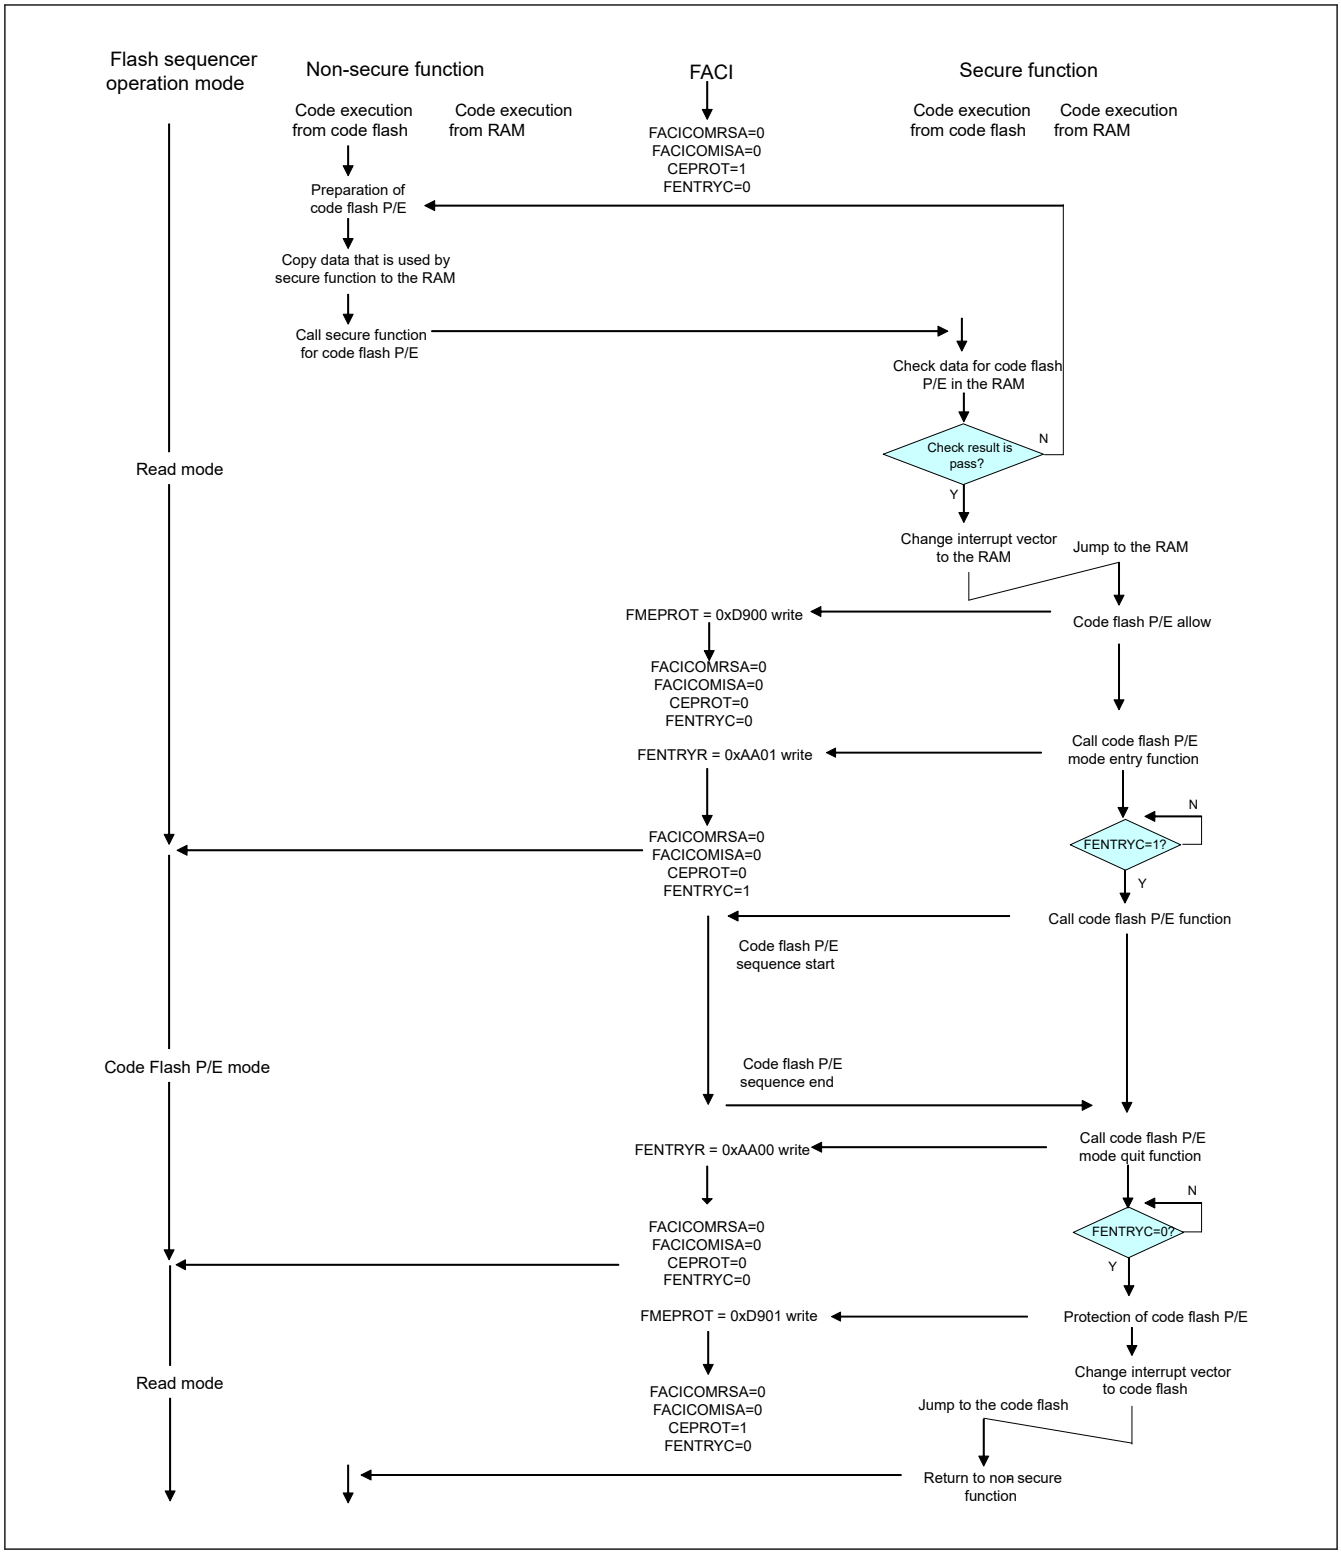

**Figure 45.34 Code flash P/E sequence example by non-secure function (using secure function for code flash P/E)**

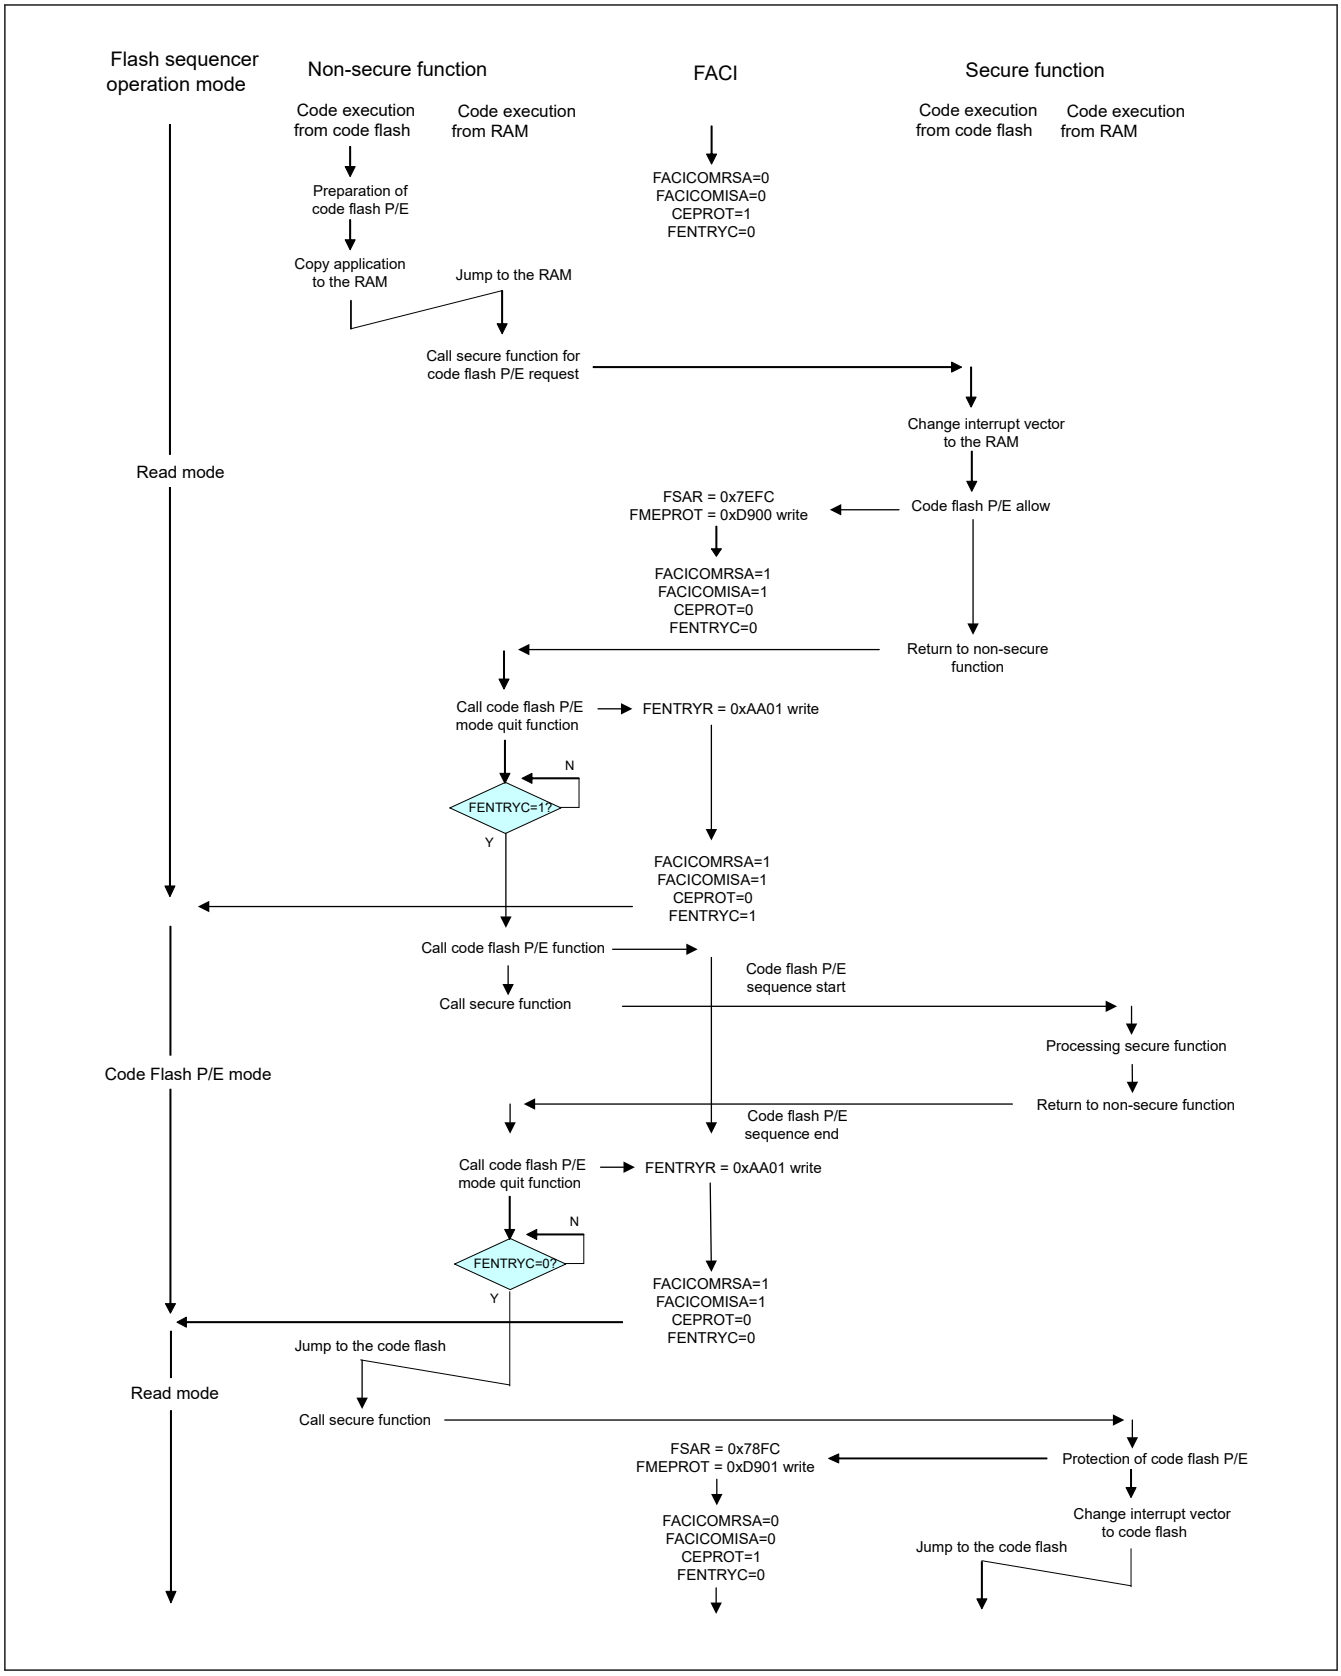

**Figure 45.35 Code flash P/E sequence example by non-secure function (1) (using non-secure function for code flash P/E)**

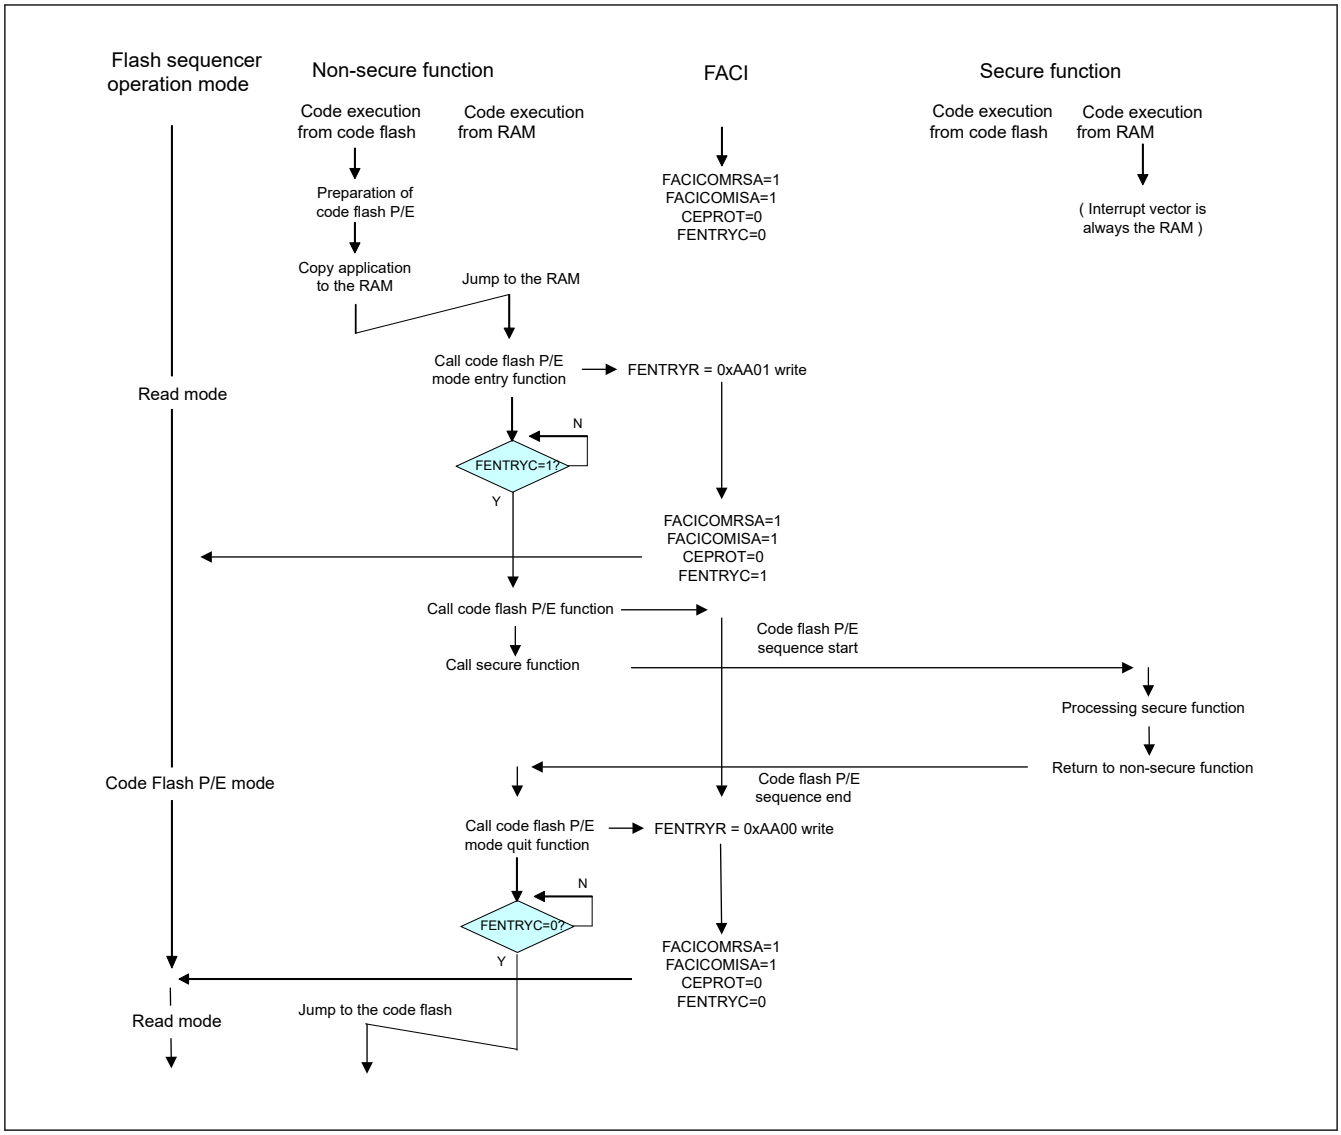

**Figure 45.36 Code flash P/E sequence example by non-secure function (2) (using non-secure function for code flash P/E)**

## 45.13 Boot Mode

There are three serial programming modes:

- Boot mode (for the SCI interface) with SCI9
- Boot mode (for the SWD interface) with on-chip SWD
- Boot mode (for the USB interface) with USBFS.

The available interfaces and connection times to the tool vary depending on the clock source connected to the MCU. Table 45.28 lists the I/O pins used in boot mode. Table 45.29 lists the available communication interface and the connection time depending on the clock sources in the boot mode.

**Table 45.28 I/O pins used in boot mode (1 of 2)**

| Pin name | I/O | Mode to be used | Use |
|---|---|---|---|
| MD | Input | Boot mode (for the SCI interface)<br>Boot mode (for the USB interface)<br>Boot mode (for the SWD interface) | Selection of operating mode |

**Table 45.28 I/O pins used in boot mode (2 of 2)**

| Pin name | I/O | Mode to be used | Use |
|---|---|---|---|
| P110/RXD9 | Input | Boot mode (for the SCI interface) | For host communication (to receive data through SCI) |
| P109/TXD9 | Output | | For host communication (to transmit data through SCI) |
| USB_DP, USB_DM | I/O | Boot mode (for the USB interface) | Data input/output of USB |
| USB_VBUS | Input | | Detection of connection and disconnection of USB cables |
| SWCLK | Input | Boot mode (for the SWD interface) | Serial wire clock pin |
| SWDIO | I/O | | Serial wire data I/O pin |

**Table 45.29 Tool connection time depending on the clock source**

| Main clock oscillator | Sub-clock oscillator | Available interface | Tool connection time*2 |
|---|---|---|---|
| Connected | Don't care | SCI/USB | Up to 1 second |
| Unconnected | Connected*1 | SCI/USB | Up to 2 seconds |
| Unconnected | Unconnected | SCI | Up to 3 seconds |

Note 1. The drive capability of the sub-clock oscillator is set to standard by SOMCR.SODRV bit. Note that if you use the crystal resonator corresponding to the low drive capability on your board, the crystal resonator may not oscillate in the boot mode.
Note 2. Tool connection time means that it takes for communication to be established between MCU and the host. For details, see the boot firmware application note.

## 45.13.1 Boot Mode (for the SCI Interface)

In boot mode (for the SCI interface), the host sends control commands and data for programming, and the flash memory is programmed or erased accordingly. An on-chip SCI handles transfer between the host and this MCU in asynchronous mode. Tools for transmission of control commands and the data for programming must be prepared in the host.

When this MCU is activated in boot mode (for the SCI interface), the program on the dedicated area the MCU is executed. The boot program automatically adjusts the bit rate of the SCI and controls programming/erasure by receiving control commands from the host.

Figure 45.37 shows the system configuration for operations in boot mode (for the SCI interface).

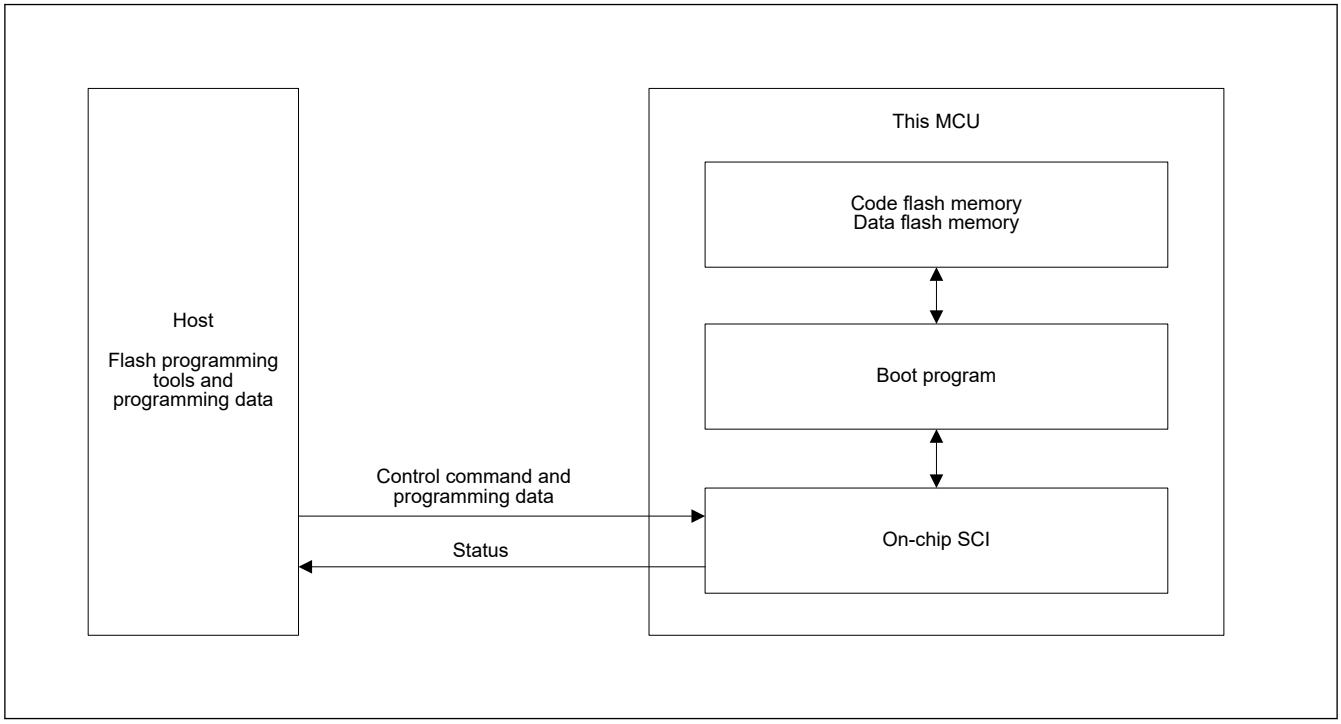

**Figure 45.37 System configuration for operations in boot mode (for the SCI interface)**

## 45.13.2 Boot Mode (for the USB Interface)

In boot mode (with the USB interface), the flash memory can be programmed or erased by sending control commands and program data from the host. An on-chip USB is used for communications between the host and this MCU. The host requires tools for sending control commands and data for programming. Figure 45.38 shows the configuration of a system for use in boot mode (for the USB interface). The USB cable must be connected on reset release.

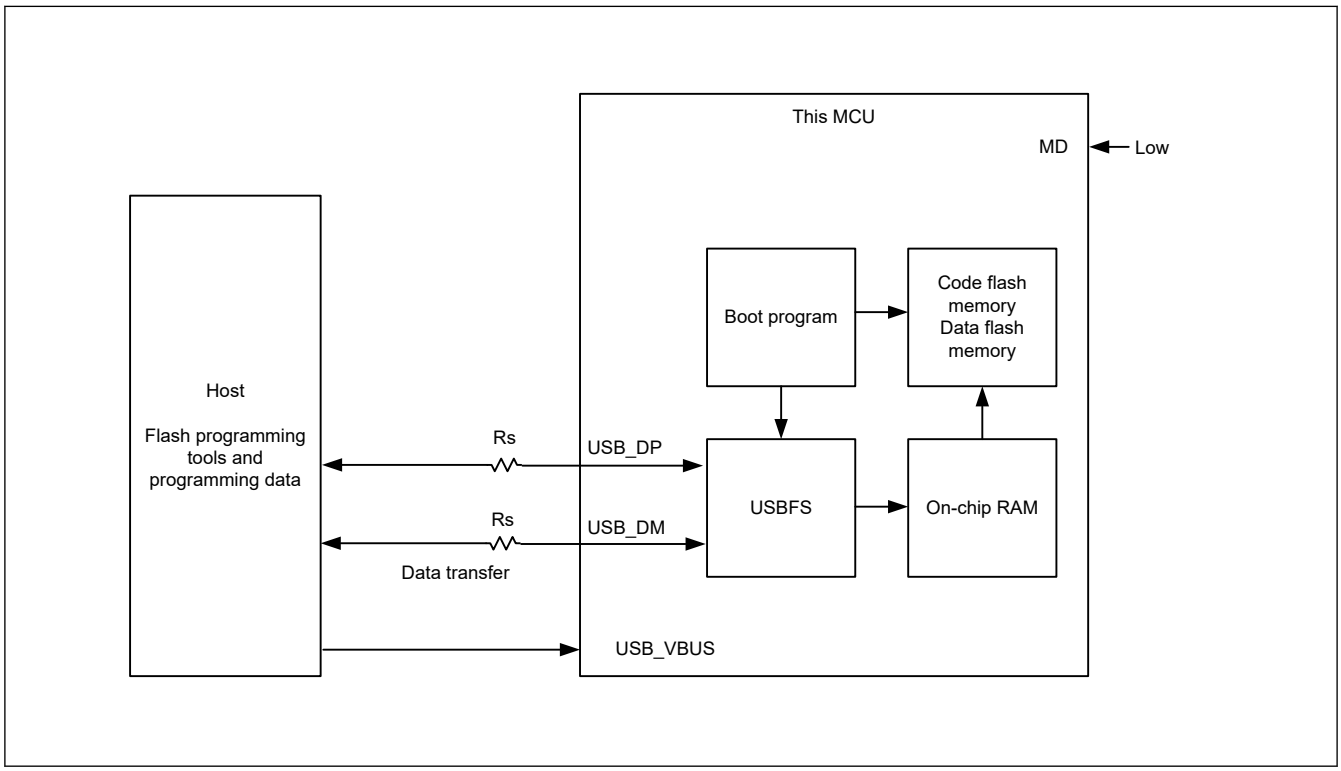

**Figure 45.38 System configuration in boot mode (for the USB interface)**

## 45.13.3 Boot Mode (for the SWD Interface)

In boot mode (with the SWD interface), the flash memory can be programmed or erased by sending control commands and program data from the host. An on-chip SWD is used for communications between the host and this MCU. The host requires tools for sending control commands and data for programming. Figure 45.39 shows the configuration of a system for use in boot mode (with the SWD interface). The SWD interface must be connected on reset release.

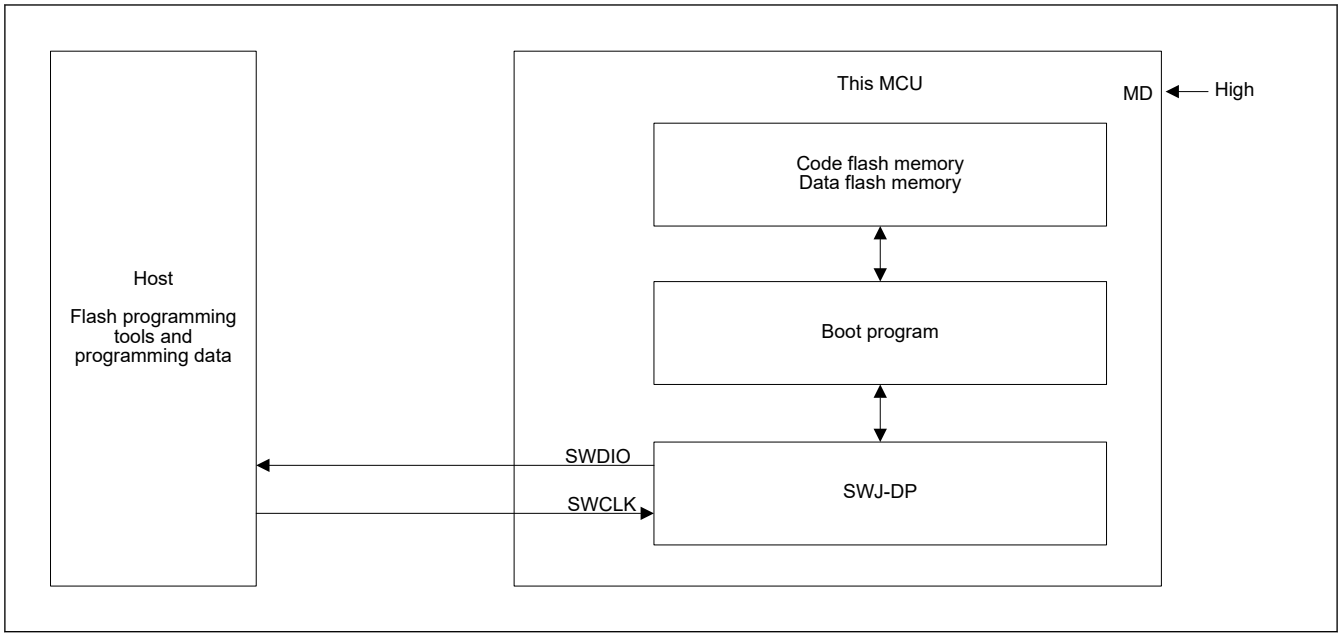

**Figure 45.39 Block diagram of flash memory-related modules**

## 45.14 Using the Serial Programmer for Rewriting

A serial programmer can be used to rewrite flash memory in boot mode.

### (1) Serial Programming

This MCU is mounted on the system board at the time of serial programming. Providing a connector to the board enables rewriting of this MCU by the serial programmer to proceed.

## 45.14.1 Environments for Serial Programming

The recommended environments for rewriting the flash memory of the MCU with data are described below.

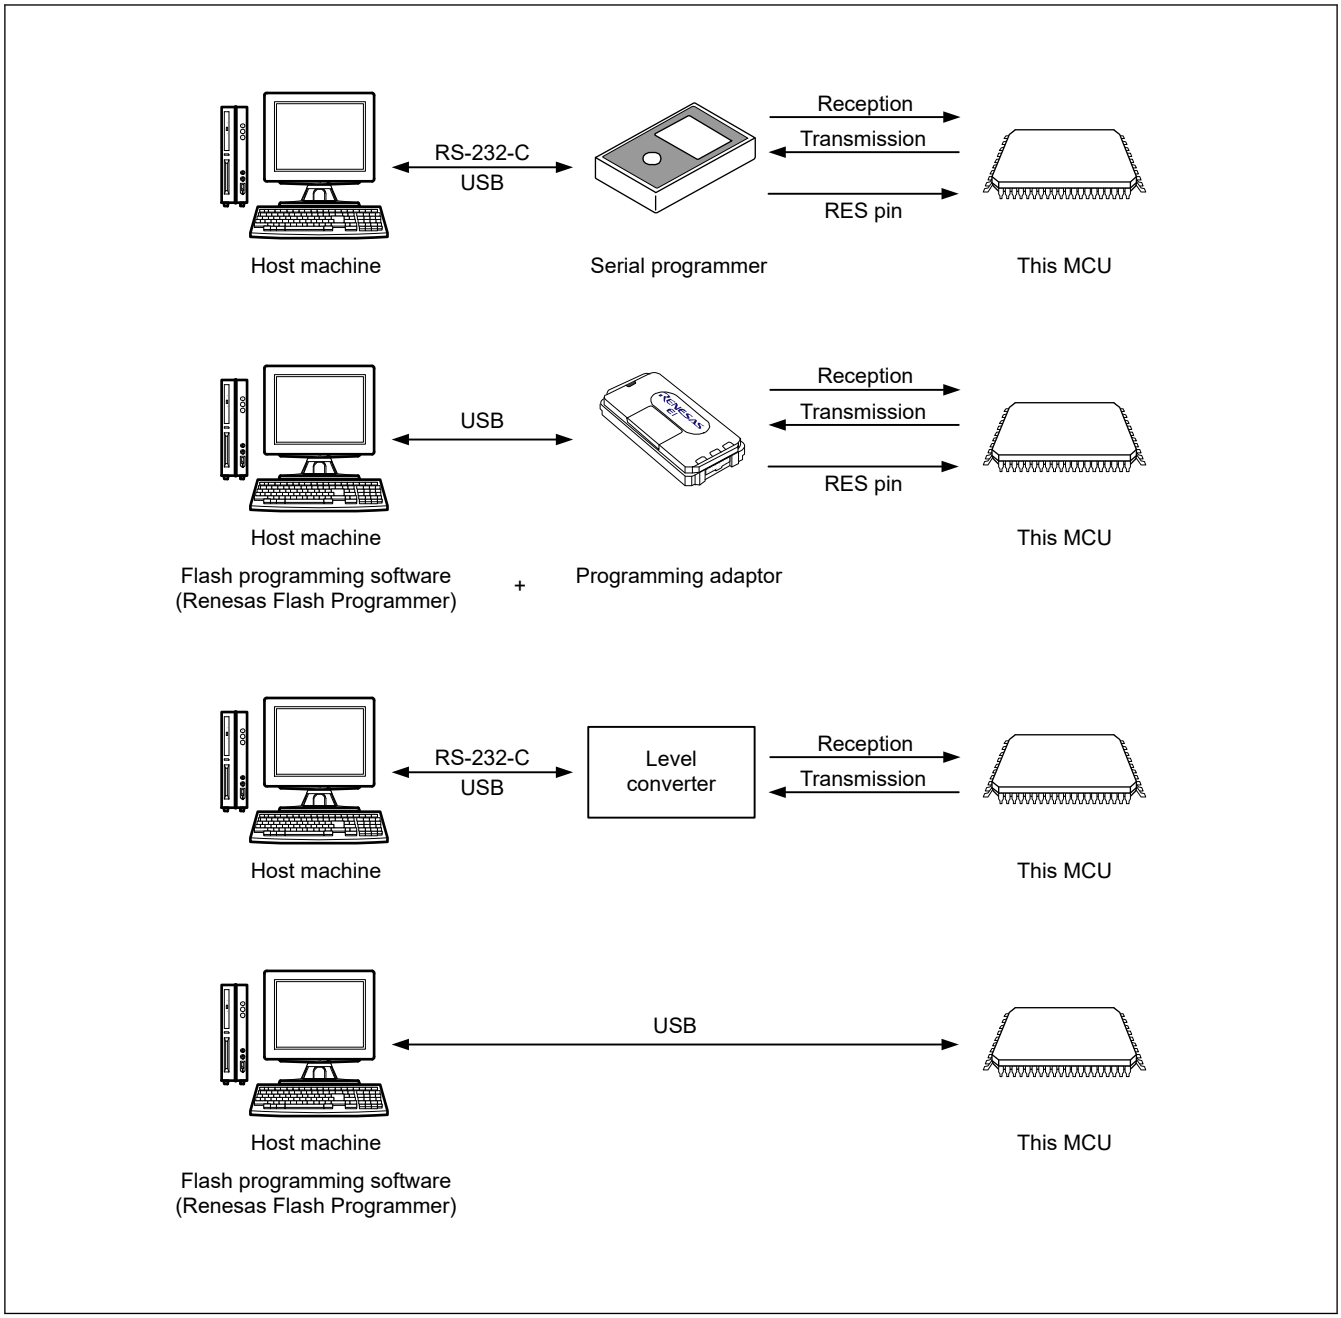

**Figure 45.40 Environments for Rewriting the Flash Memory**

## 45.15 Programming through Self-Programming

### 45.15.1 Overview

This MCU supports programming of the flash memory by the user program itself. The FACI commands can be used with user programs for writing to the flash memory. This allows upgrading of user programs and rewriting of constant data fields.

In self-programming, it is necessary to supply a stable HOCO clock to the flash memory in order to generate the program voltage and erase voltage. Therefore, in case that the HOCO is stopped where another clock source is selected as the system clock, it is necessary to start the HOCO operation and ensure that the oscillation is in a stable state before executing the selfprogramming.

The program for rewriting must be transferred to the internal RAM or external memory in advance when the BGO is not available or when rewriting the option-setting memory.

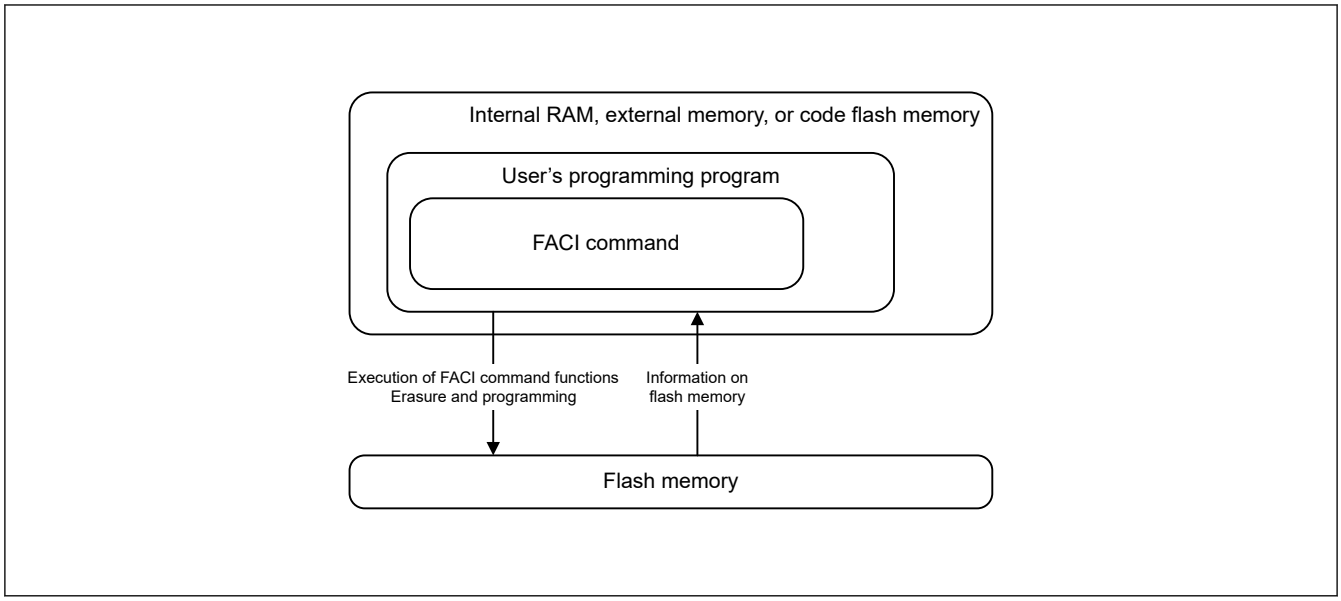

**Figure 45.41 Schematic View of Self-Programming**

For comprehensive information on the self-programming, see section 45.9. FACI Commands.

## 45.15.2 Background Operation

The background operation (BGO) can be used to execute the flash rewrite routine on the code flash memory when the data flash memory or other area of code flash memory is rewritten.

Background operations can be used when the combination of the flash memory for rewriting and the flash memory for reading is any of those listed in Table 45.30.

**Table 45.30 Conditions under which background operation is usable**

| | | Range for rewriting | Range for reading |
|---|---|---|---|
| Common to linear and dual modes | | Code flash memory | Data flash memory |
| | | Data flash memory | Code flash memory |
| Linear mode | Products with 512 KB of code flash memory | First half (256 KB) of the code flash memory (addresses 0x0000_0000 to 0x0003_FFFF) | Second half (256 KB) of the code flash memory (addresses 0x0004_0000 to 0x0007_FFFF) |
| | | Second half (256 KB) of the code flash memory (addresses 0x0004_0000 to 0x0007_FFFF) | First half (256 KB) of the code flash memory (addresses 0x0000_0000 to 0x0003_FFFF) |
| Linear mode | Products with 256 KB of code flash memory | First half (128 KB) of the code flash memory (addresses 0x0000_0000 to 0x0001_FFFF) | Second half (128 KB) of the code flash memory (addresses 0x0002_0000 to 0x0003_FFFF) |
| | | Second half (128 KB) of the code flash memory (addresses 0x0002_0000 to 0x0003_FFFF) | First half (128 KB) of the code flash memory (addresses 0x0000_0000 to 0x0001_FFFF) |
| Dual mode | When the BANKSEL.BANKSWP [2:0] bits are 111b | Bank 1 area of the code flash memory | Bank 0 area of the code flash memory |
| | When the BANKSEL.BANKSWP [2:0] bits are 000b | Bank 0 area of the code flash memory | Bank 1 area of the code flash memory |

## 45.16 Reading Flash Memory

### 45.16.1 Reading Code Flash Memory

Special settings are not required to read code flash memory after release from the reset state. Data can simply be read out through access to addresses in the code flash memory.

When reading code flash memory that has been erased but not yet been programming again (i.e. that is in the non-programmed state), all bits are read as 1.

### 45.16.2 Reading Data Flash Memory

Special settings are not required to read data flash memory in normal mode except when issuing a reset that causes the data flash access disable mode to disable reading. In this case, the application must transfer back to the data flash read mode. Data can simply be read out through access to addresses in the data flash memory.

When reading data flash memory that has been erased but not yet been programming again (that is, in the non-programmed state), all bits are read as 1.

### 45.16.3 Access Cycle

When the CPU cache is hit, access is one cycle.

When the CPU cache is missed while CPU cache operation is enabled, or when CPU cache is disabled, the access cycle is as described in Table 45.31, Table 45.32 and Table 45.33.

**Table 45.31 Code flash memory (CPU access)**

| Prefetch operation | Frequency (MHz) | Read cycle (ICLK) |
|---|---|---|
| Enable and hit | ICLK ≤ 32 | 3 ICLK |
| | 32 < ICLK ≤ 48 | 3 ICLK |
| | 48 < ICLK ≤ 80 | 3 ICLK |
| Disable or miss | ICLK ≤ 32 | 3 ICLK |
| | 32 < ICLK ≤ 48 | 4 ICLK |
| | 48 < ICLK ≤ 80 | Min: 5 ICLK<br>Max: 6 ICLK |

**Table 45.32 Code Flash Memory (DMAC or DTC access)**

| Prefetch operation | Frequency (MHz) | Read cycle (ICLK) |
|---|---|---|
| Enable and hit | ICLK ≤ 32 | 1 ICLK |
| | 32 < ICLK ≤ 48 | 1 ICLK |
| | 48 < ICLK ≤ 80 | 1 ICLK |
| Disable or miss | ICLK ≤ 32 | 1 ICLK |
| | 32 < ICLK ≤ 48 | 2 ICLK |
| | 48 < ICLK ≤ 80 | Min: 3 ICLK<br>Max: 4 ICLK |

**Table 45.33 Data flash memory**

| Frequency (MHz) | Read cycle (ICLK) |
|---|---|
| ICLK ≤ 32 | 7 ICLK |
| 32 < ICLK ≤ 48 | 8 ICLK |
| 48 < ICLK ≤ 80 | Min: 14 ICLK<br>Max: 15 ICLK |

Note: When the read data size is 1 byte.

## 45.17 Usage Notes

### (1) Forced Stop Area of Erasure

Data in areas where a forced stop of an erase operation was performed is undefined. To avoid malfunctions caused by reading undefined data, do not execute commands or read data in the area where a forced stop of an erase operation is performed..

### (2) Erase Suspension by Forced Stop Command

When suspending an operation other than blank check by the Forced Stop command, Resume command is not supported.

### (3) Additional Programming Disabled

The same address cannot be programmed more than once. When programming an area that has been already programmed, erase the area first.

### (4) Resets During Programming/Erasure

In the case of a reset due to the signal on the RES pin during programming/erasure, or blank checking of the flash memory, wait for at least $t_{RESW}$ (see section 49, Electrical Characteristics) of the reset input period once the operating voltage is within the range stipulated in the electrical characteristics, then release the device from the reset state.

### (5) Location of Interrupt Vectors During Programming/Erasure Operation

When an interrupt occurs during a programming/erasure operation, the vector may be fetched from the code flash. To avoid fetching the vector from the code flash, set the destination for fetching interrupt vectors to an area other than the code flash with the interrupt table.

### (6) Programming/Erasure in Low-Speed Operating Mode

Do not program or erase the flash memory when low-speed operating mode is selected with the Operating Power Control Register (OPCCR or SOPCCR) selected.

### (7) Abnormal Termination during Programming/Erasure

When the voltage exceeds the range of the operating voltage during a program/erase operation or when a program/erase operation is not completed successfully due to a reset or prohibited actions described in (8), erase the area again.

### (8) Actions Prohibited during Programming/Erasure

To prevent damage to the flash memory, do not perform the following operations:

- Having the operating voltage from the power supply go beyond the permitted range
- Changing the OPCCR.OPCM[2:0] and SOPCCR.SOPCM bits
- Changing the division ratio of the flash interface clock (FCLK)
- Placing the MCU in Software Standby mode
- Changing the data flash access control setting during a program or erase operation to the data flash memory.

### (9) Setting Dual Bank Mode and Programming in Boot Mode

The initial mode of the MCU shipped from Renesas is linear mode. In customer’s factory when programming dual bank mode and customer's applications on MCU set in linear mode, it is recommended that only area1 in Figure 45.42 is programmed in boot mode and area2 is kept blank. After reset, the MCU starts in dual mode and the application is in bank0. Use self-programming when programming area2 for updating in the field. See section 48.6. Field Updating in Dual Mode for details.

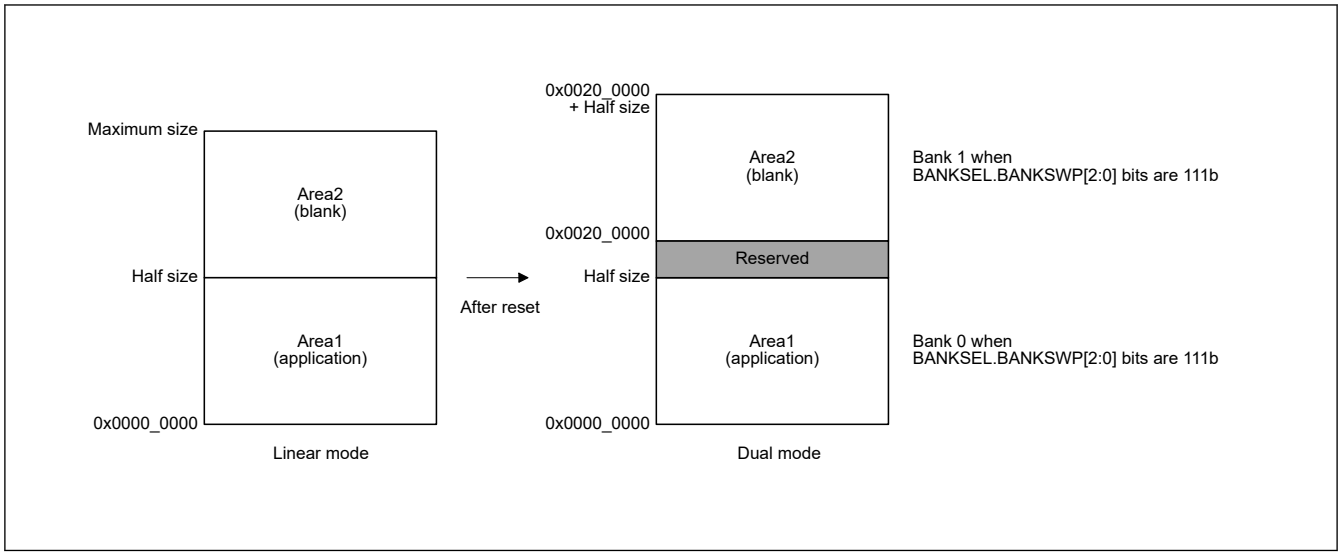

**Figure 45.42 Programming the application for the dual mode in the linear mode**

# 46. Segment LCD Controller (SLCDC)

## 46.1 Overview

The MCU provides a controller for LCD display and display pins. Table 46.1 lists the SLCDC specifications.

**Table 46.1 SLCDC specifications**

| Items | Specifications |
|---|---|
| Features | • Liquid crystal waveform (waveform A or B) selectable<br>• LCD driver voltage generator can switch between internal voltage boosting method, capacitor split method, and external resistance division method<br>• Automatic output of segment and shared signals based on automatic display data register read<br>• Voltage boost circuit reference voltage selectable from 23 steps (contrast adjustment)<br>• LCD blinking and display selectable<br>• VL1 reference mode (1/3 or 1/4 Bias) and VL2 reference mode (1/3 Bias) can be selected at internal voltage boosting method<br>• Conventional VCC reference mode (1/3 Bias) and VL4 reference mode (1/3 Bias) can be selected at capacitor split method |
| Number of pins | For details on the number of pins, see Table 46.2 SLCDC display function pins for 100-pin products |
| Source clocks | • Main clock oscillator (MOSC)<br>• Sub-clock oscillator (SOSC)<br>• Low-speed on-chip oscillator (LOCO)<br>• High-speed on-chip oscillator (HOCO) |
| Module-stop state function | Module-stop state can be set to reduce power consumption |
| TrustZone Filter | Security attribution can be set |

The number of LCD display function pins for the MCU differs depending on the product. Table 46.2 to Table 46.5 show the display function pins for products with different pin counts. Table 46.6 to Table 46.9 show the maximum number of pixels for products with different pin counts. Figure 46.1 shows the SLCDC block diagram.

**Table 46.2 SLCDC display function pins for 100-pin products**

Note 1. ( ) indicates the number of signal output pins when 8-time slice is selected.
Note 2. CAPH and CAPL are capacitor connection pins for the LCD controller/driver.
Note 3. VL1, VL2, VL3, and VL4 are the power supply pins for driving the LCD.

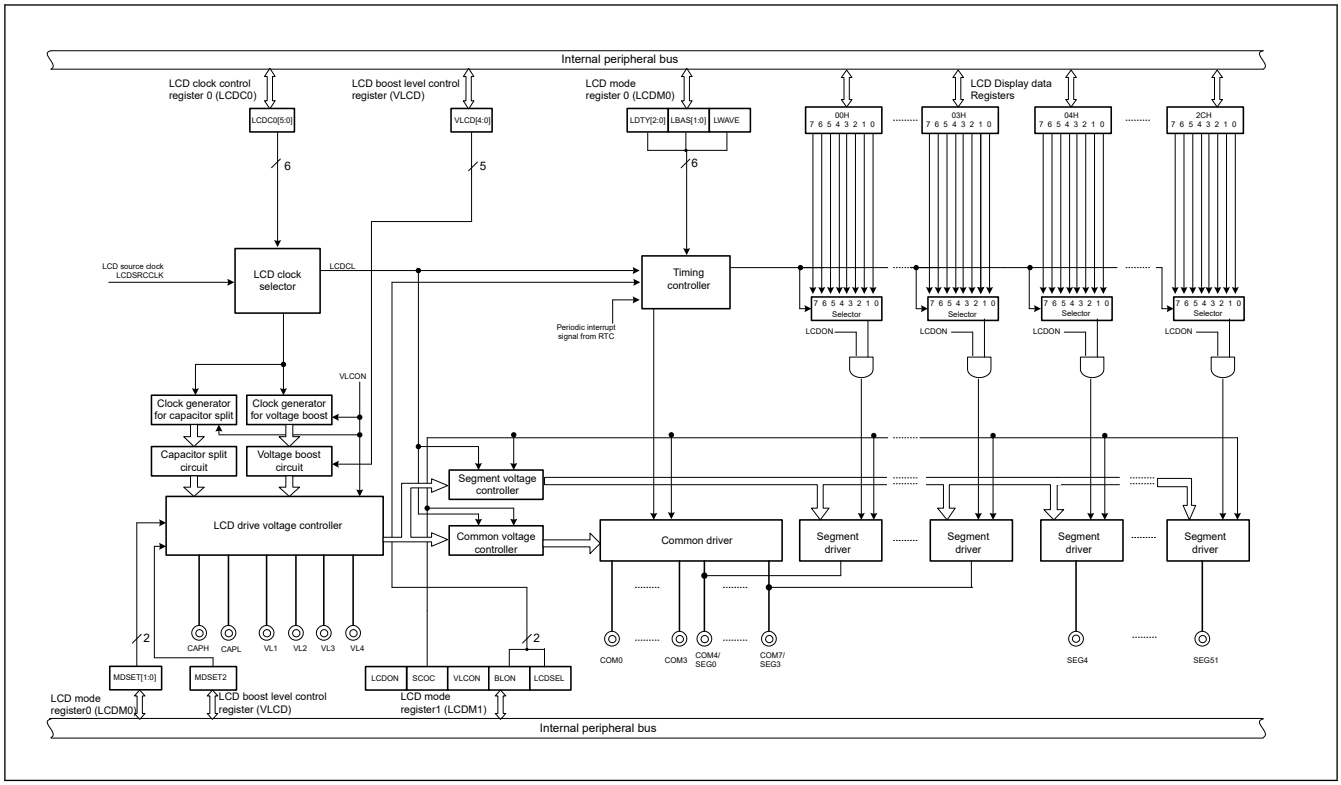

**Figure 46.1 SLCDC block diagram**

## 46.2 Register Descriptions

### 46.2.1 LCDM0 : LCD Mode Register 0

Base address: SLCDC = 0x400D_4000

Offset address: 0x00

| Bit position: | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|
| Bit field: | MDSET[1:0] | | LWAVE | LDTY[2:0] | | | LBAS[1:0] | |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 1:0 | LBAS[1:0] | LCD Display Bias Method Select<br>0 0: 1/2 bias method<br>0 1: 1/3 bias method<br>1 0: 1/4 bias method<br>1 1: Setting prohibited | R/W |
| 4:2 | LDTY[2:0] | Time Slice of LCD Display Select<br>0 0 0: Static<br>0 0 1: 2-time slice<br>0 1 0: 3-time slice<br>0 1 1: 4-time slice<br>1 0 0: 6-time slice<br>1 0 1: 8-time slice<br>Others: Setting prohibited | R/W |
| 5 | LWAVE | LCD Display Waveform Select<br>0: Waveform A<br>1: Waveform B | R/W |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 7:6 | MDSET[1:0] | LCD Drive Voltage Generator Select<br>0 0: External resistance division method<br>0 1: Internal voltage boosting method<br>1 0: Capacitor split method<br>1 1: Setting prohibited | R/W |

Note:
- Do not rewrite the LCDM0 value when the SCOC bit of the LCDM1 register is 1.
- Only combinations of the display waveform, number of time slices, and bias method shown in Table 46.10 are supported. Combinations of settings not shown in Table 46.10 are prohibited.

### LBAS[1:0] bits (LCD Display Bias Method Select)

The LBAS[1:0] bits select the LCD display bias.

When static is selected (LDTY[2:0] = 000b), set the LBAS[1:0] bits to the default value (00b). Otherwise, the operation is not guaranteed.

### LDTY[2:0] bits (Time Slice of LCD Display Select)

The LDTY[2:0] bits select the number of time slice on the LCD display.

### LWAVE bit (LCD Display Waveform Select)

The LWAVE bit selects the waveform A or waveform B for the LCD display.

### MDSET[1:0] bits (LCD Drive Voltage Generator Select)

The MDSET[1:0] bits and the MDSET2 bit of VLCD register select the LCD drive voltage generation method. See Table 46.13 for details.

**Table 46.10 Combinations of display waveform, time slices, bias method, and frame frequency (1 of 2)**

| Display mode | | | Set value | | | | | | Driving voltage generation method | | | | |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | | | | | | | | | | Internal voltage boosting | | Capacitor split | |
| Display waveform | Number of time slices | Bias mode | LWAVE | LDTY[2:0] | | | LBAS[1:0] | | External resistance division | VL1 reference | VL2 reference | VCC reference | VL4 reference |
| Waveform A | 8 | 1/4 | 0 | 1 | 0 | 1 | 1 | 0 | A (24 to 128) | A (24 to 64) | N/A | N/A | N/A |
| Waveform A | 6 | 1/4 | 0 | 1 | 0 | 0 | 1 | 0 | N/A | A (32 to 86) | N/A | N/A | N/A |
| Waveform A | 8 | 1/3 | 0 | 1 | 0 | 1 | 0 | 1 | A (32 to 128) | A (32 to 64) | A (32 to 64) | A (32 to 128) | A (32 to 128) |
| Waveform A | 6 | 1/3 | 0 | 1 | 0 | 0 | 0 | 1 | A (32 to 128) | A (32 to 86) | A (32 to 86) | A (32 to 128) | A (32 to 128) |
| Waveform A | 4 | 1/3 | 0 | 0 | 1 | 1 | 0 | 1 | A (24 to 128) | A (24 to 128) | A (24 to 128) | A (24 to 128) | A (24 to 128) |

## 46.2.2 LCDM1 : LCD Mode Register 1

Base address: SLCDC = 0x400D_4000

Offset address: 0x01

| Bit position: | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|
| Bit field: | LCDON | SCOC | VLCON | BLON | LCDSEL | — | — | LCDVLM |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 0 | LCDVLM | Voltage Boosting Pin Initial Value Switching Control<br>For the condition 2.7 V ≤ VCC ≤ 3.6 V, any value can be set.<br>0: Set when VCC ≥ 2.7 V<br>1: Set when VCC ≤ 3.6 V | R/W |
| 2:1 | — | These bits are read as 0. The write value should be 0. | R/W |
| 3 | LCDSEL | Display Area Data Selection<br>0: Display an A-pattern area data (lower 4 bits of LCD display data register)<br>1: Display a B-pattern area data (higher 4 bits of LCD display data register) | R/W |
| 4 | BLON | Alternately Display A-pattern and B-pattern Area Data (blinking display) Control<br>0: Alternately display A-pattern and B-pattern area data (blinking display) disabled<br>1: Alternately display A-pattern and B-pattern area data (blinking display corresponding to the periodic interrupt (RTC_PRD) timing of the Realtime Clock (RTC)). | R/W |
| 5 | VLCON | Voltage Boost Circuit or Capacitor Split Circuit Operation Enable/Disable<br>0: Disable voltage boost circuit or capacitor split circuit operation<br>1: Enable voltage boost circuit or capacitor split circuit operation | R/W |
| 6 | SCOC | LCD Display Enable/Disable<br>0: Output ground level to segment/common pin<br>1: Display data to segment/common pin | R/W |
| 7 | LCDON | LCD Display Enable/Disable<br>0: Display off<br>1: Display on | R/W |

Note: To use the internal voltage boosting method, specify the reference voltage using the VLCD register (select the internal boosting method by setting VLCD.MDSET2 bit to 0 or 1, the LCDM0.MDSET[1:0] bits to 01b if the default reference voltage is used), wait for the reference voltage setup time (minimum 10 ms), and then set the VLCON bit to 1.

#### LCDVLM bit (Voltage Boosting Pin Initial Value Switching Control)

The LCDVLM bit is used to improve voltage boost efficiency when using the voltage boost circuit by setting the initial VLX pin status. If VCC is 2.7 V or higher when voltage boosting starts, set the LCDVLM bit to 0. If VCC is 3.6 V or lower, set the LCDVLM bit to 1. If VCC is within the range between 2.7 V and 3.6 V, the LCDVLM bit may be set to 0 or 1.

When the external resistance division method is set (VLCD.MDSET2 = 0 or 1, LCDM0.MDSET[1:0] = 00b) or the capacitor split method is set (VLCD.MDSET2 = 0 or 1, LCDM0.MDSET[1:0] = 10b), set the LCDVLM bit to 0.

Do not rewrite the VLCON and LCDVLM bits while SCOC = 1.

#### LCDSEL and BLON bits (Display Area Data Selection and Alternately Display A-pattern and B-pattern Area Data (blinking display) Control )

The LCDSEL and BLON bits can be set to 1 only when 4 or less is selected as the number of time slices for the display mode.

Set the BLON and LCDSEL bits to 0 when 6 or 8 is selected as the number of time slices for the display mode (setting BLON or LCDSEL to 1 is prohibited).

When BLON = 1, setting LCDSEL has no effect.

When LOCO, MOSC or HOCO is selected as the LCD source clock (LCDSRCCLK), be sure to set the BLON bit to 0.

#### VLCON bit (Voltage Boost Circuit or Capacitor Split Circuit Operation Enable/Disable)

When SCOC = 1, rewriting the VLCON bit value is prohibited. Operation is not guaranteed when rewritten. However, it is possible to write the same value.

When the external resistance division mode is selected, setting VLCON to 1 is prohibited.

#### SCOC and LCDON bits (LCD Display Enable/Disable)

The SCOC and LCDON bits control the LCD display enable/disable.

Display is off when common output is the selected signal output. All segment outputs are deselected signal outputs.

Display is on when common and segment outputs are based on the LCD display data.

To reduce power consumption when nothing is to be displayed on the LCD while the voltage boost circuit is in use, set the SCOC and VLCON bits to 0 and set the LCDM0.MDSET[1:0] bits to 00b. When LCDM0.MDSET[1:0] = 01b, the internal reference voltage generator operates and consumes power.

### 46.2.3 LCDC0 : LCD Clock Control Register 0

Base address: SLCDC = 0x400D_4000

Offset address: 0x02

| Bit position: | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | LCDC0[5:0] | | | | | |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 5:0 | LCDC0[5:0] | LCD Clock (LCDCL) Setting<br>0x1: (SOSC)/$2^2$ or (LOCO)/$2^2$<br>0x2: (SOSC)/$2^3$ or (LOCO)/$2^3$<br>0x3: (SOSC)/$2^4$ or (LOCO)/$2^4$<br>0x4: (SOSC)/$2^5$ or (LOCO)/$2^5$<br>0x5: (SOSC)/$2^6$ or (LOCO)/$2^6$<br>0x6: (SOSC)/$2^7$ or (LOCO)/$2^7$<br>0x7: (SOSC)/$2^8$ or (LOCO)/$2^8$<br>0x8: (SOSC)/$2^9$ or (LOCO)/$2^9$<br>0x9: (SOSC)/$2^{10}$ or (LOCO)/$2^{10}$<br>0x11: (MOSC)/$2^8$ or (HOCO)/$2^8$<br>0x12: (MOSC)/$2^9$ or (HOCO)/$2^9$<br>0x13: (MOSC)/$2^{10}$ or (HOCO)/$2^{10}$<br>0x14: (MOSC)/$2^{11}$ or (HOCO)/$2^{11}$<br>0x15: (MOSC)/$2^{12}$ or (HOCO)/$2^{12}$<br>0x16: (MOSC)/$2^{13}$ or (HOCO)/$2^{13}$<br>0x17: (MOSC)/$2^{14}$ or (HOCO)/$2^{14}$<br>0x18: (MOSC)/$2^{15}$ or (HOCO)/$2^{15}$<br>0x19: (MOSC)/$2^{16}$ or (HOCO)/$2^{16}$<br>0x1A: (MOSC)/$2^{17}$ or (HOCO)/$2^{17}$<br>0x1B: (MOSC)/$2^{18}$ or (HOCO)/$2^{18}$<br>0x2B: (MOSC)/$2^{19}$ or (HOCO)/$2^{19}$<br>0x3B: (MOSC)/$2^{20}$ or (HOCO)/$2^{20}$<br>Others: Settings are prohibited | R/W |
| 7:6 | — | These bits are read as 0. The write value should be 0. | R/W |

Note: The LCDSCKSEL[2:0] bits of SLCDSCKCR register select LOCO, SOSC, MOSC or HOCO clock as the LCD clock source (LCDSRCCLK). See section 8.2.22. SLCDSCKCR : Segment LCD Source Clock Control Register for details.

### LCDC0[5:0] bits (LCD Clock (LCDCL) Setting)

Set the frame frequency in a range from 32 Hz to 128 Hz (24 to 128 Hz when the condition is selected, see Table 46.10 for details). Set the LCD clock (LCDCL) to no more than 512 Hz when using the internal voltage boosting method and the capacitor split method.

Do not set LCDC0 when the LCDM1.SCOC bit is 1.

## 46.2.4 VLCD : LCD Boost Level Control Register

| 6:5 | — | These bits are read as 0. The write value should be 0. | R/W |
| 7 | MDSET2 | Reference Voltage Selection<br>0: External resistance division method or VL1 reference mode of internal voltage boosting method or VCC reference mode of capacitor split method<br>1: VL2 reference mode of internal voltage boosting method or VL4 reference mode of capacitor split method | R/W |

### VLCD[4:0] bits (Reference Voltage Select (Contrast Adjustment))

The VLCD[4:0] bit setting is valid only when the voltage boost circuit is operating.

Be sure to change the VLCD value after stopping the operation of the voltage boost circuit (VLCON = 0).

To use the internal voltage boosting method, specify the reference voltage using the VLCD register (select the internal boosting method by setting the VLCD.MDSET2 = 0 or 1, LCDM0.MDSET[1:0] bits to 01b, if the default reference voltage is used), wait for the reference voltage setup time (minimum 10 ms), then set VLCON to 1.

When using the external resistance division method and the capacitor split method, use the default value (04h) for the VLCD resistor.

Combinations of contrast adjustment of VL1 voltage reference is listed in Table 46.11.

Combinations of contrast adjustment of VL2 voltage reference is listed in Table 46.12.

**Table 46.11 List of combinations of contrast adjustment when {MDSET2,MDSET[1:0]} = 001 (VL1 voltage reference)**

| VLCD [4:0] | | | | | VL1 voltage reference | VL4 voltage | |
|---|---|---|---|---|---|---|---|
| | | | | | | 1/3 bias method | 1/4 bias method |
| 0 | 0 | 1 | 0 | 0 | 1.01 V | 3.03 V | 4.04 V |
| 0 | 0 | 1 | 0 | 1 | 1.04 V | 3.12 V | 4.16 V |
| 0 | 0 | 1 | 1 | 0 | 1.07 V | 3.21 V | 4.28 V |
| 0 | 0 | 1 | 1 | 1 | 1.11 V | 3.33 V | 4.44 V |

| 1 | 1 | 0 | 1 | 0 | 3.49 V | 5.24 V |

Note: Other settings are prohibited.

### MDSET2 bit (Reference Voltage Selection)

The MDSET2 bit is used to select the reference voltage generator for the internal voltage boosting method and the capacitor split method. Set MDSET2 to 0 if internal voltage boosting method or capacitor split method is not used. See Table 46.13 for details.

**Table 46.13 LCD drive voltage generation method by setting MDSET2, MDSET[1:0]**

| MDSET2 (VLCD.bit7) | MDSET[1] (LCDM0.bit7) | MDSET[0] (LCDM0.bit6) | Function |
|---|---|---|---|
| 0 | 0 | 0 | External resistance division method |
| 0 | 0 | 1 | VL1 reference mode of internal voltage boosting method |
| 1 | | | VL2 reference mode of internal voltage boosting method |
| 0 | 1 | 0 | VCC reference mode of capacitor split method |
| 1 | | | VL4 reference mode of capacitor split method |

Note: Other settings are prohibited.

## 46.2.5 LCD Display Data Registers

The LCD Display Data registers are mapped as shown in Table 46.14 and Table 46.15. The contents displayed on the LCD can be modified by changing the contents of the LCD Display Data registers. Table 46.14 shows other than 6-time slice and 8-time-slice (static, 2-time slice, 3-time slice, and 4-time slice).

**Table 46.14 Relationship between LCD Display Data register contents and segment/common outputs (1 of 3)**

| Register name | Address | b7 | b6 | b5 | b4 | b3 | b2 | b1 | b0 | 100-pin | 72-pin | 64-pin LQFP | 64-pin BGA |

| SEG51 | 0x400D_4133 | SEG51 | | | | | | | | A | N/A | N/A | N/A |

Note: A: Available
N/A: Not available
All LCD Display Data registers (SEG0 to SEG51) have an initial value of 0x00, and all bits that are read/write.
Note 1. The COM4 to COM7 pins and SEG0 to SEG3 pins are used alternatively. For more information, see section 18, I/O Ports.

When the number of time slices is static, two, three, or four, the lower 4 bits and upper 4 bits of each address of the LCD Display Data register become an A-pattern area and a B-pattern area, respectively.

The association between A-pattern area data and COM signals is as follows:

Bit [0] ↔ COM0, bit [1] ↔ COM1, bit [2] ↔ COM2, and bit [3] ↔ COM3.

The association between B-pattern area data and COM signals is as follows:

Bit [4] ↔ COM0, bit [5] ↔ COM1, bit [6] ↔ COM2, and bit [7] ↔ COM3.

A-pattern area data is displayed on the LCD panel when BLON = LCDSEL = 0 is selected, and B-pattern area data is displayed on the LCD panel when BLON = 0 and LCDSEL = 1 is selected.

## 46.3 Selection of LCD Display Data Register

When the number of time slices is static, two, three, or four, the LCD Display Data register can be selected from the following types, based on the BLON and LCDSEL bit settings:

- Displaying an A-pattern area data (lower 4 bits of LCD Display Data register)
- Displaying a B-pattern area data (upper 4 bits of LCD Display Data register)
- Alternately displaying an A-pattern and B-pattern area data (blinking display associated with the periodic interrupt timing of the Realtime Clock (RTC))

Note: If the normal liquid crystal waveform is displayed when the number of time slices is six or eight, LCD Display Data registers (A-pattern, B-pattern, or blinking display) cannot be selected.

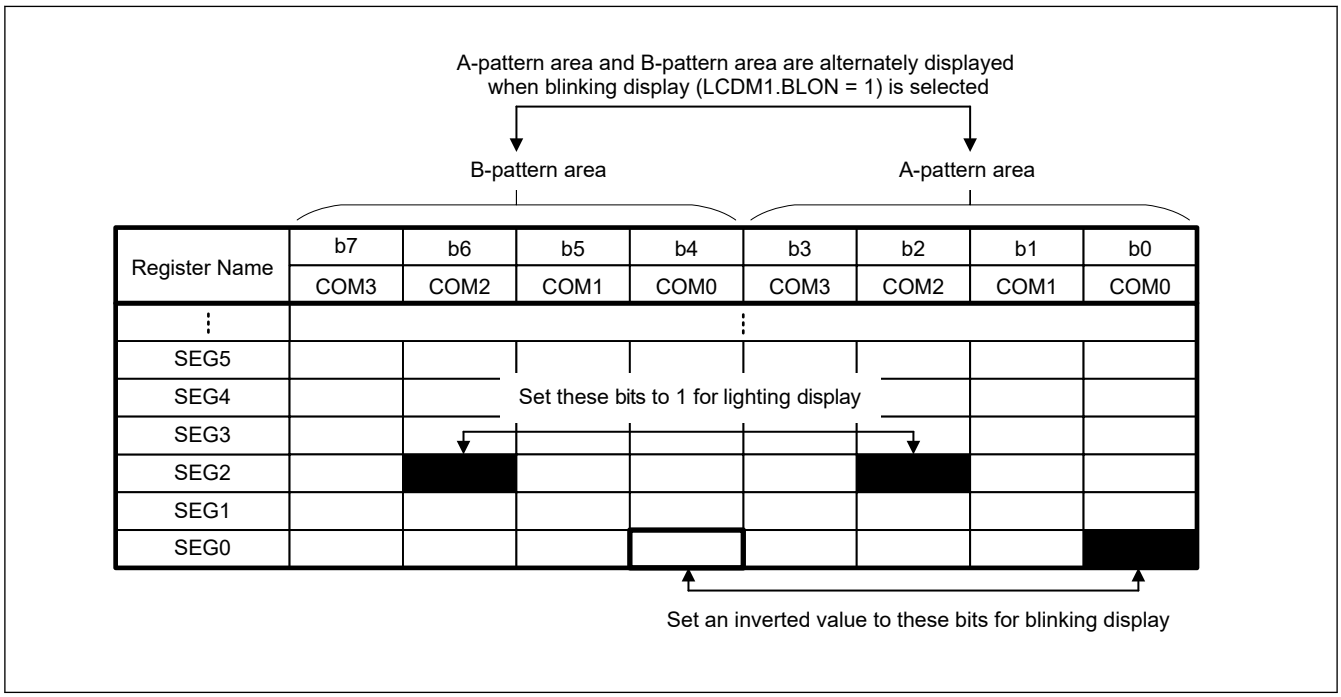

**Figure 46.2 Example for setting LCD Display Data registers when the pattern is changed**

## 46.3.1 A-pattern Area and B-pattern Area Data Display

When both BLON and LCDSEL are 0, A-pattern area (lower 4 bits of the LCD Display Data register) data is output as the LCD Display register.

When BLON is 0 and LCDSEL is 1, B-pattern area (upper 4 bits of the LCD Display Data register) data is output as the LCD Display register.

For details on the display area, see section 46.2.5. LCD Display Data Registers.

## 46.3.2 Blinking Display (Alternately Displaying A-pattern and B-pattern Area Data)

When BLON is set to 1, A-pattern and B-pattern area data are alternately displayed, according to the constant-period interrupt timing of the Realtime Clock (RTC). See section 22, Realtime Clock (RTC) for information about the setting of the RTC constant-period interrupt (0.5 s setting only) timing.

To use the LCD blinking display feature, set inverted values to the B-pattern area bits associated with the A-pattern area bits. For example, set bit [0] of SEG0 register to 1, and set bit [4] of SEG0 register to 0 to use the blinking display. When not using the blinking display feature, set the same values to both the A-pattern and B-pattern area bits. For example, set bit [2] of SEG2 register to 1, and set bit [6] of SEG2 register to 1 for lighting display. For details on the display area, see section 46.2.5. LCD Display Data Registers.

Figure 46.3 and Figure 46.4 show the timing operation of display switching.

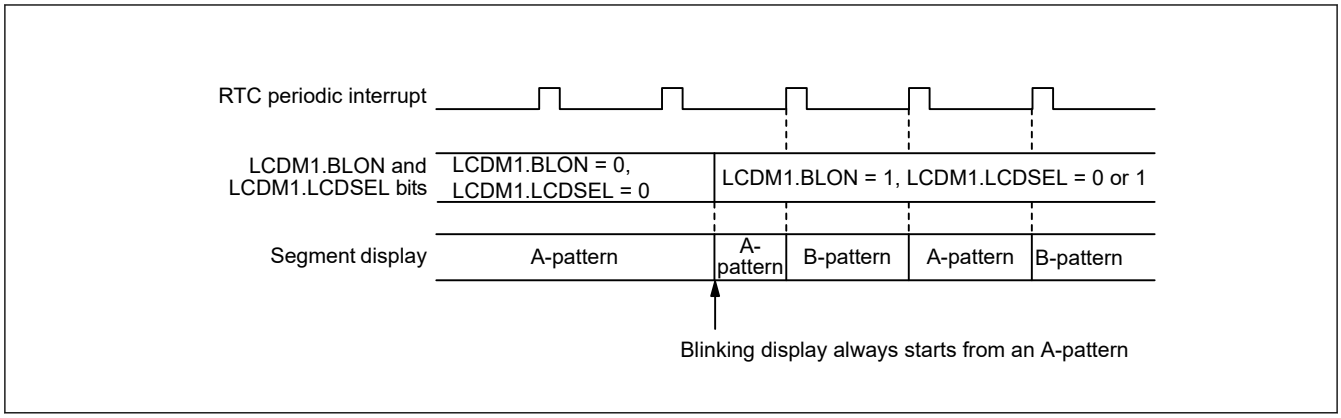

**Figure 46.3 Switching operation from A-pattern display to blinking display**

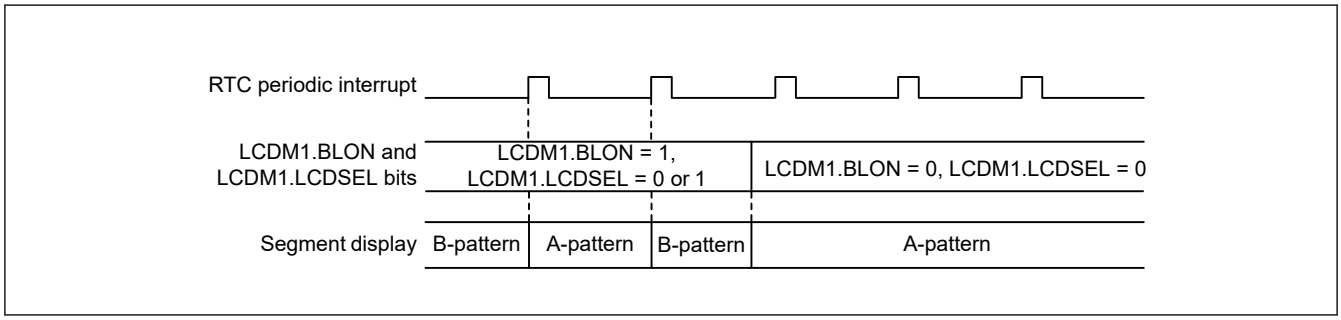

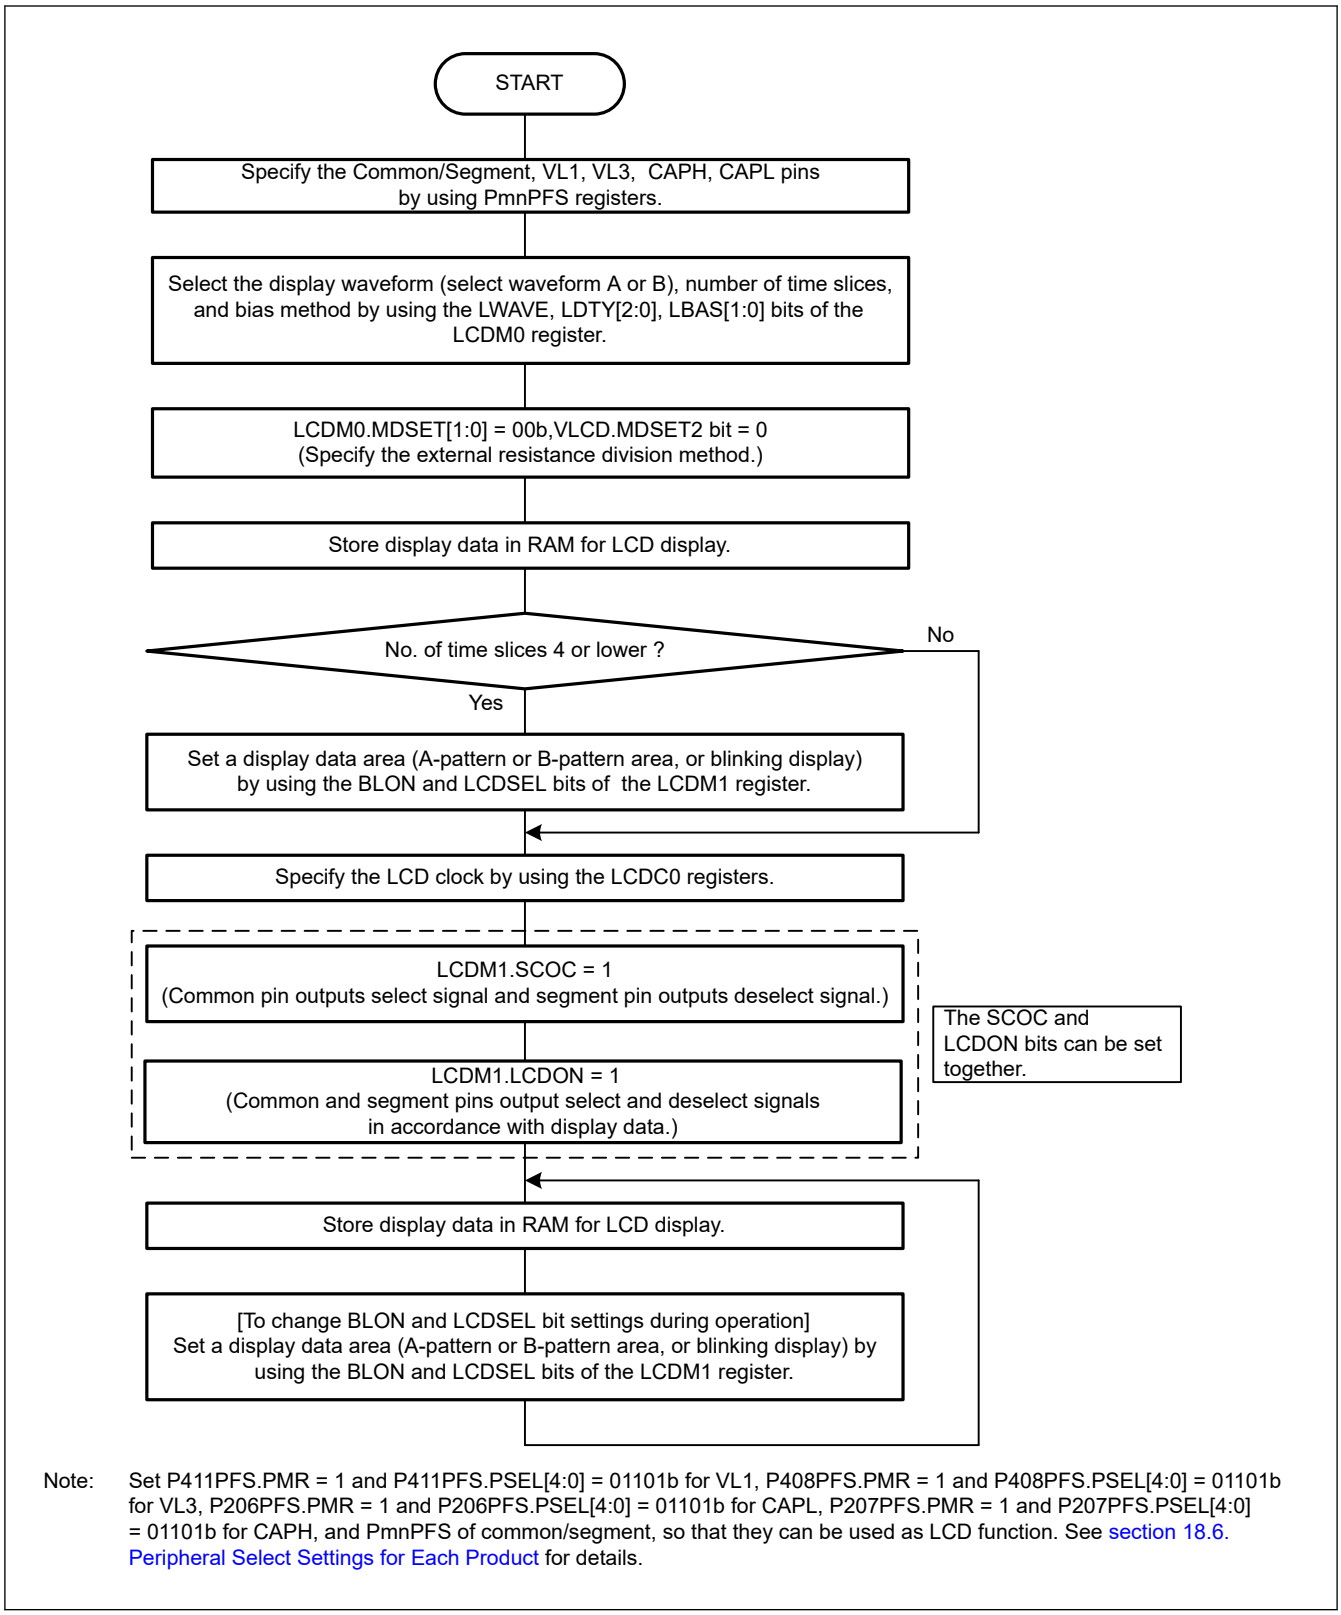

**Figure 46.4 Switching operation from blinking display to A-pattern display**

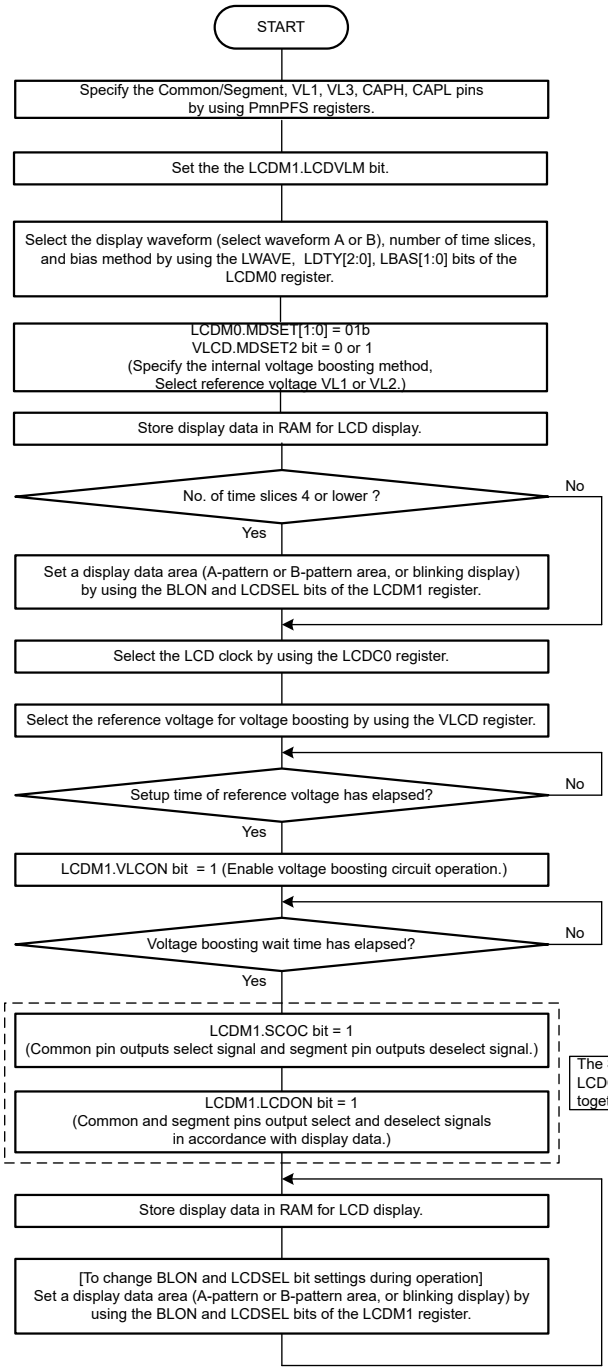
## 46.4 Setting LCD Controller/Driver

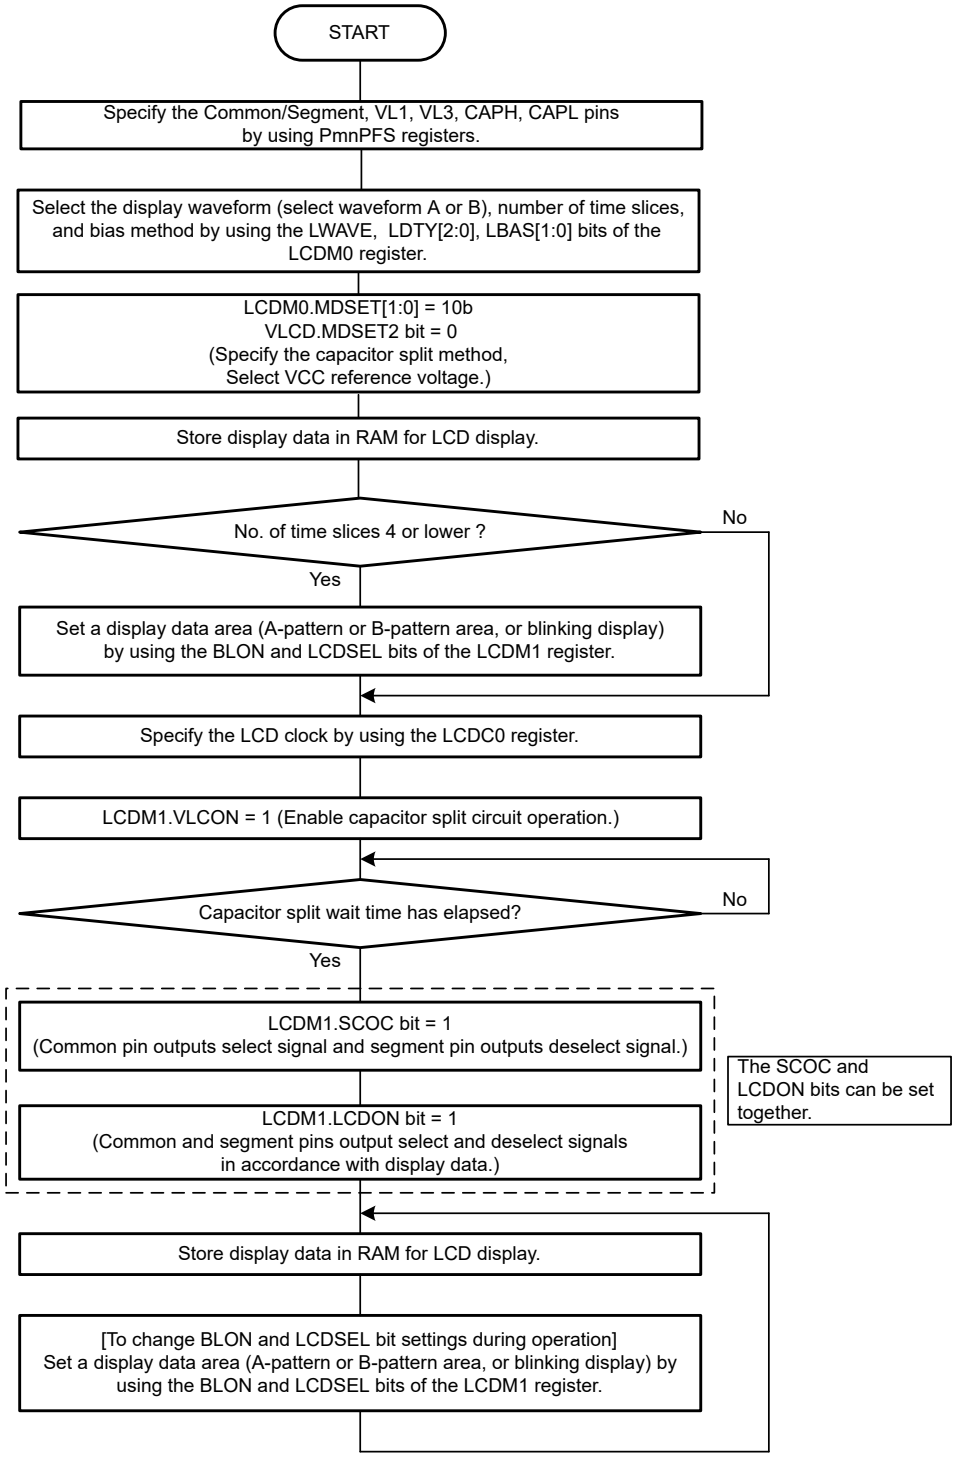
To operate the LCD controller/driver, follow procedures (1) External resistance division method during normal liquid crystal waveform display to (3) Capacitor split method in this section. Otherwise, LCD operation is not guaranteed.



(1) External resistance division method during normal liquid crystal waveform display

Note: Set P411PFS.PMR = 1 and P411PFS.PSEL[4:0] = 01101b for VL1, P408PFS.PMR = 1 and P408PFS.PSEL[4:0] = 01101b for VL3, P206PFS.PMR = 1 and P206PFS.PSEL[4:0] = 01101b for CAPL, P207PFS.PMR = 1 and P207PFS.PSEL[4:0] = 01101b for CAPH, and PmnPFS of common/segment, so that they can be used as LCD function. See section 18.6. Peripheral Select Settings for Each Product for details.

**Figure 46.5 Setting procedure for external resistance division method during normal liquid crystal waveform display**



## (2) Internal voltage boosting method

Note: Set P411PFS.PMR = 1 and P411PFS.PSEL[4:0] = 01101b for VL1, P408PFS.PMR = 1 and P408PFS.PSEL[4:0] = 01101b for VL3, P206PFS.PMR = 1 and P206PFS.PSEL[4:0] = 01101b for CAPL, P207PFS.PMR = 1 and P207PFS.PSEL[4:0] = 01101b for CAPH, and PmnPFS of common/segment, so that they can be used as LCD function. See section 18.6. Peripheral Select Settings for Each Product for details.

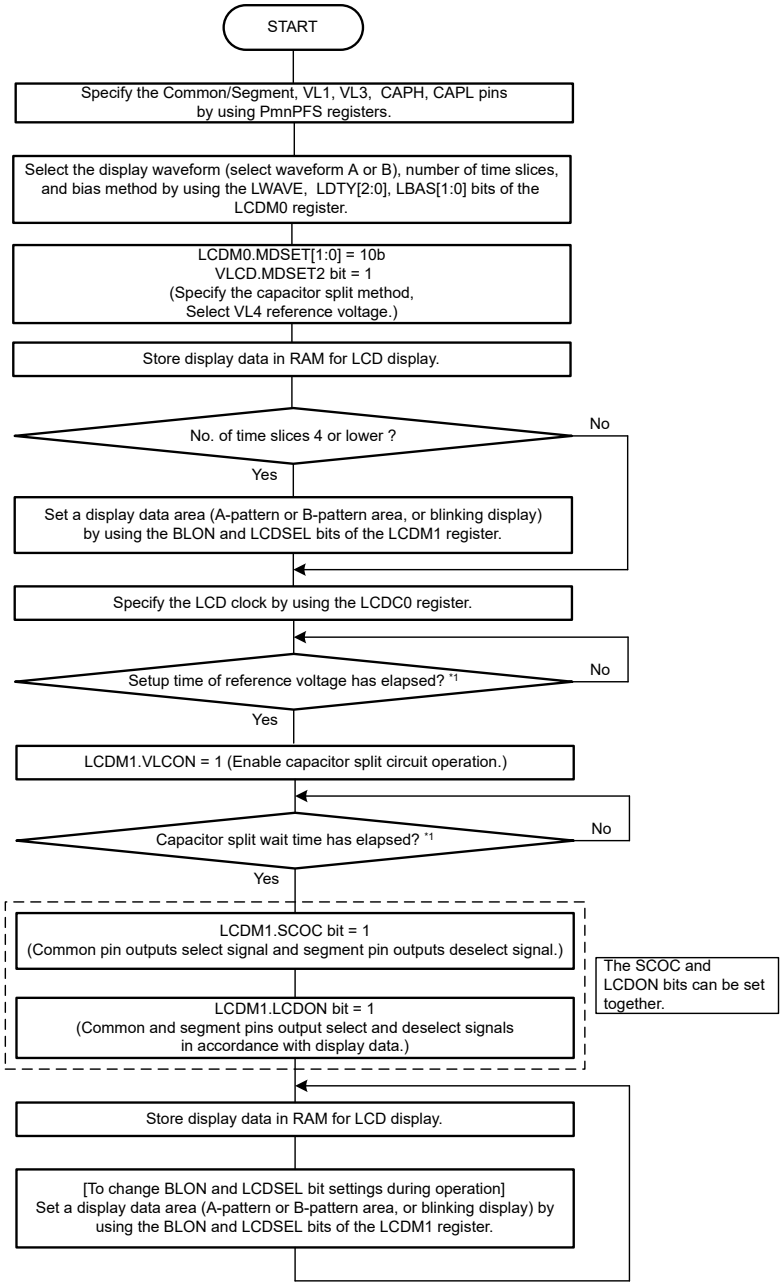


**Figure 46.6 Setting procedure for internal voltage boosting method during normal liquid crystal waveform display**

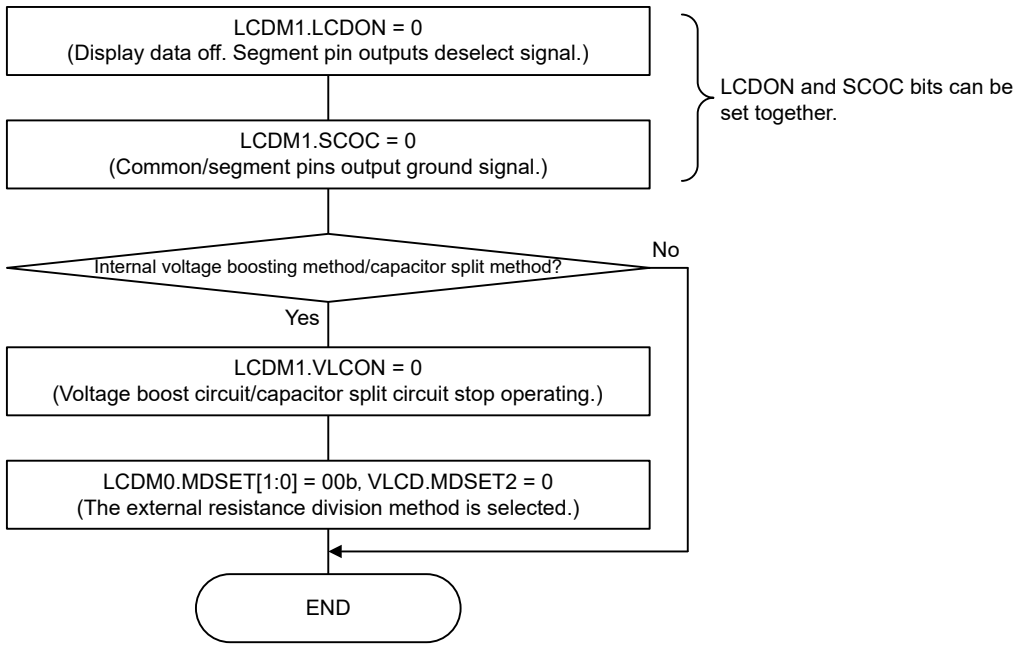
## (3) Capacitor split method

Note: Set P411PFS.PMR = 1 and P411PFS.PSEL[4:0] = 01101b for VL1, P408PFS.PMR = 1 and P408PFS.PSEL[4:0] = 01101b for VL3, P206PFS.PMR = 1 and P206PFS.PSEL[4:0] = 01101b for CAPL, P207PFS.PMR = 1 and P207PFS.PSEL[4:0] = 01101b for CAPH, and PmnPFS of common/segment, so that they can be used as LCD function. See section 18.6. Peripheral Select Settings for Each Product for details.

**Figure 46.7 Setting procedure for VCC reference mode of capacitor split method during normal liquid crystal waveform display**

Note: Set P411PFS.PMR = 1 and P411PFS.PSEL[4:0] = 01101b for VL1, P408PFS.PMR = 1 and P408PFS.PSEL[4:0] = 01101b for VL3, P206PFS.PMR = 1 and P206PFS.PSEL[4:0] = 01101b for CAPL, P207PFS.PMR = 1 and P207PFS.PSEL[4:0] = 01101b for CAPH, and PmnPFS of common/segment, so that they can be used as LCD function. See section 18.6. Peripheral Select Settings for Each Product for details.



Note 1. See section 49.12.5. Capacitor Split Method (VL4 Reference) for the specification of reference voltage setup time ($t_{VL4S}$) and capacitor split wait time ($t_{WAIT}$).

**Figure 46.8 Setting procedure for VL4 reference mode of capacitor split method during normal liquid crystal waveform display**

## 46.5 Operation Stop Procedure

To stop the LCD operation, follow the steps shown in Figure 46.9.

The LCD stops operating when the LCDM1.LDCON and LCDM1.SCOC bits are set to 0.

Note: Stopping the voltage boost or capacitor split circuits is prohibited while the display is on (SCOC and LCDON bits of LCDM1 register = 00b). Otherwise, the operation is not guaranteed. Be sure to turn off the display (SCOC and LCDON bits of LCDM1 register = 00b) before stopping the voltage boost/capacitor split circuits (LCDM1.VLCON = 0).

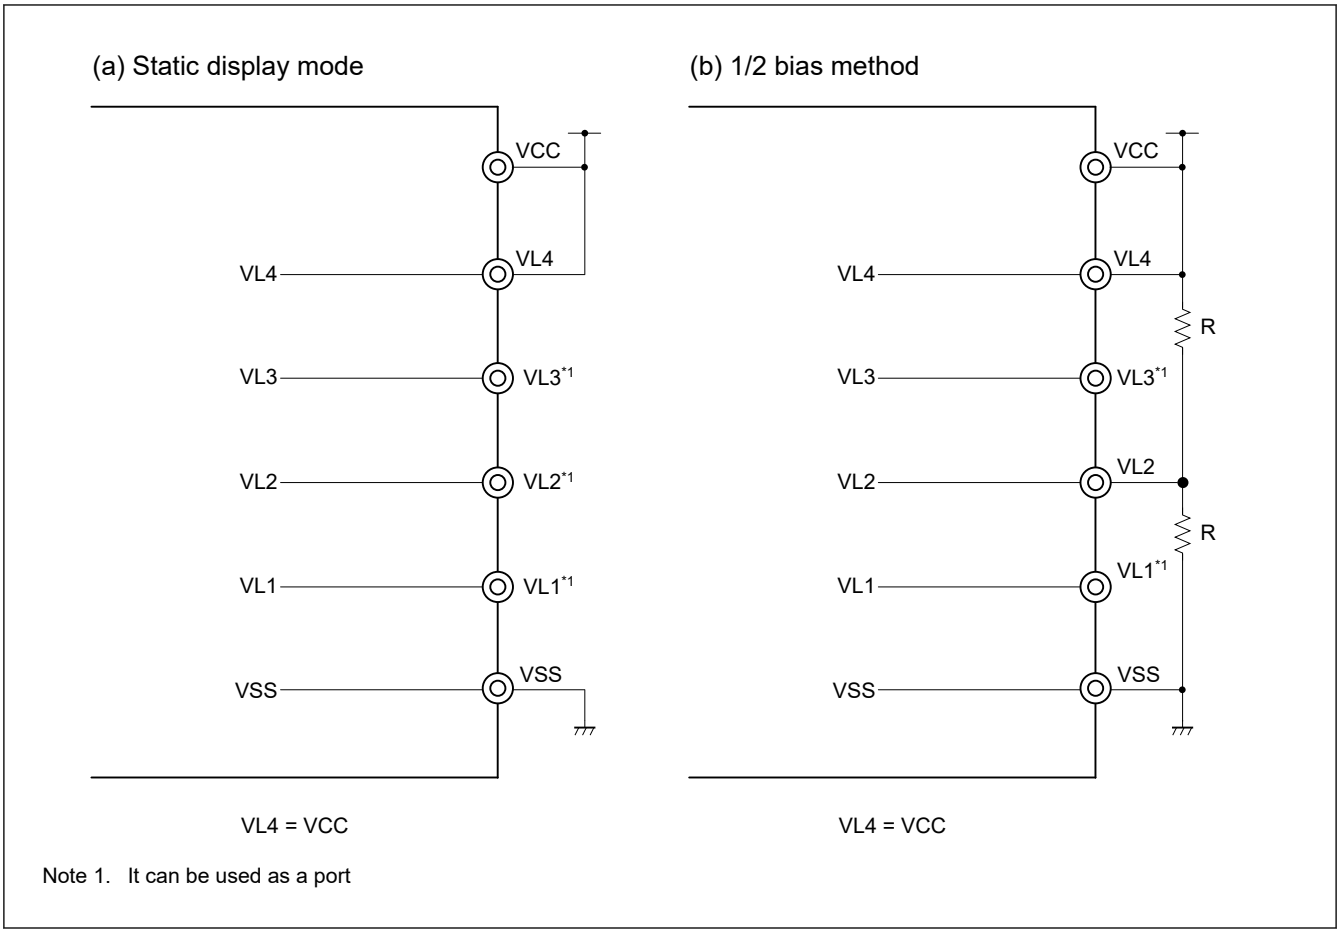


**Figure 46.9 Operation stop procedure during normal liquid crystal waveform (A or B) display**

## 46.6 Supplying LCD Drive Voltages VL1, VL2, VL3, and VL4

The power supply voltages for the LCD driver can be produced through external resistance division method, internal voltage boosting method, or capacitor split method.

### 46.6.1 External Resistance Division Method

Figure 46.10 and Figure 46.11 show examples of the LCD drive power supply connection, associated with each bias method.

Note 1. It can be used as a port

**Figure 46.10 Examples of LCD drive power connections using the external resistance division method (1 of 2)**

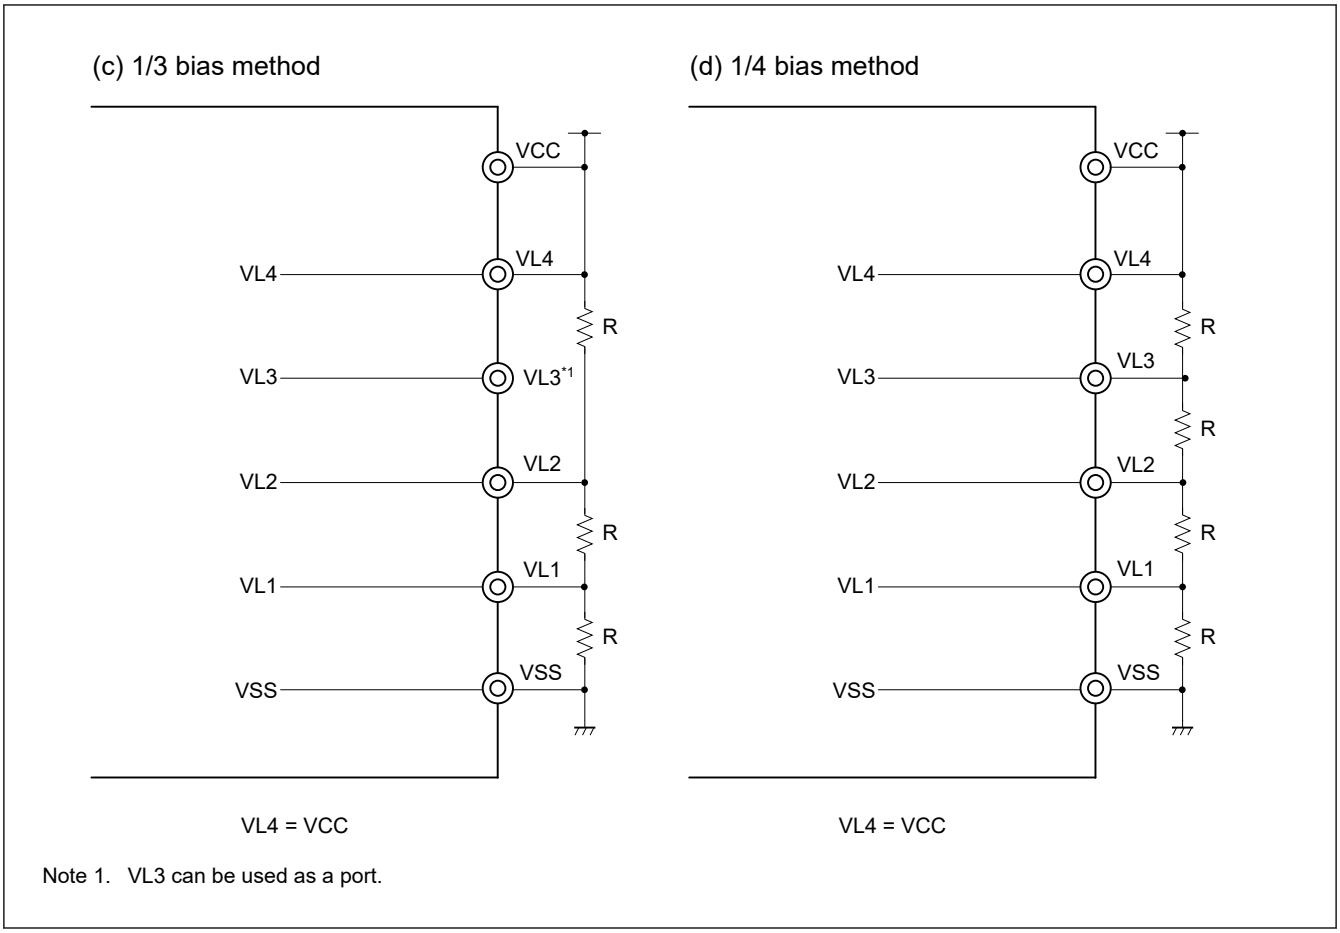

**Figure 46.11 Examples of LCD drive power connections using the external resistance division method (2 of 2)**

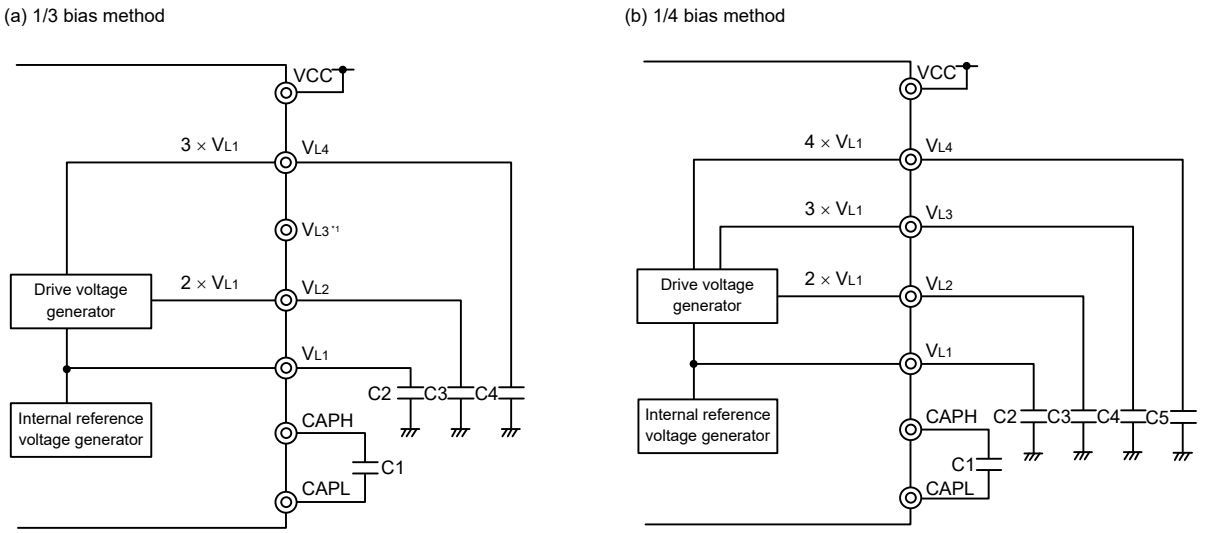
Note: The reference resistance R value for external resistance division is 10 kΩ to 50 kΩ. In addition, to stabilize the voltage at the VL1 to VL4 pins, connect a capacitor between each VL1 to VL4 pin and the GND pin as needed. The reference capacitance is about 0.47 µF, but it depends on the LCD panel used, the number of segment pins, the number of common pins, the frame frequency, and the operating environment. Thoroughly evaluate these values in accordance with your system and adjust the capacitance.



## 46.6.2 Internal Voltage Boosting Method

The MCU contains an internal voltage boost circuit for generating LCD drive power supplies. The internal voltage boost circuit and external capacitors (0.47 µF ± 30%) are used to generate an LCD drive voltage. Only 1/3 bias mode or 1/4 bias mode can be set for VL1 reference mode of internal voltage boosting method. Only 1/3 bias mode can be set for VL2 reference mode of internal voltage boosting method.

The internal voltage boost circuit can supply a constant voltage, regardless of changes in VCC, because it is a power supply separate from the main unit. In addition, the contrast can be adjusted using the LCD Boost Level Control Register (VLCD).

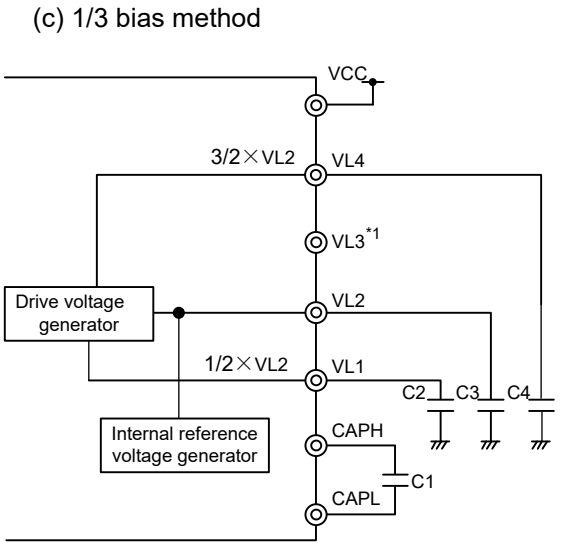


**Table 46.16 LCD drive voltages using the internal voltage boosting method**

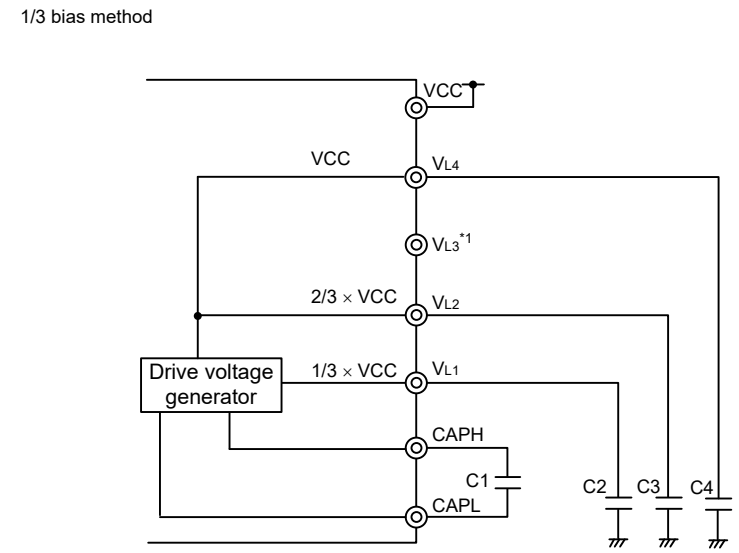
| | 1/3 bias method | | 1/4 bias method |
|---|---|---|---|
| **LCD drive voltage pin** | **VL1 reference** | **VL2 reference** | **VL1 reference** |
| VL4 | 3 × VL1 | 3/2 × VL2 | 4 × VL1 |
| VL3 | — | — | 3 × VL1 |
| VL2 | 2 × VL1 | LCD reference voltage | 2 × VL1 |
| VL1 | LCD reference voltage | 1/2 × VL2 | LCD reference voltage |

Note: Use a capacitor with as little leakage as possible. In addition, make C1 a non-polar capacitor.
Note 1. VL3 can be used as a port.

**Figure 46.12 Examples of LCD drive power connections using VL1 reference mode of internal voltage boosting method**

Note: Use a capacitor with as little leakage as possible. In addition, make C1 a non-polar capacitor.
Note 1. VL3 can be used as a port.

**Figure 46.13 Examples of LCD drive power connections using VL2 reference mode of internal voltage boosting method**



## 46.6.3 Capacitor Split Method

The MCU contains an internal voltage reduction circuit for generating LCD drive power supplies. The internal voltage reduction circuit and external capacitors (0.47 µF ± 30%) are used to generate an LCD drive voltage. Only 1/3 bias mode can be set for VCC reference mode and VL4 reference mode of capacitor split method.

Unlike the external resistance division method, the capacitor split method does not require continuous current flow, and therefore the current consumption can be reduced.

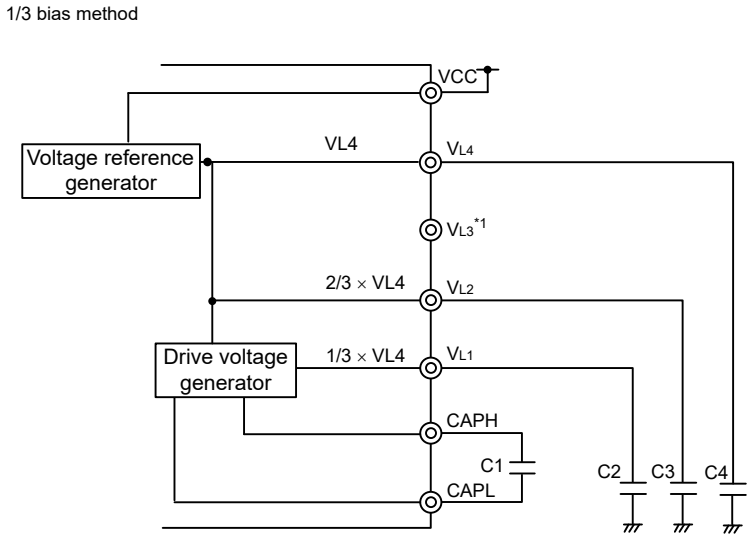


**Table 46.17 LCD drive voltages using capacitor split method**

| | 1/3 bias method | |
|---|---|---|
| **LCD drive voltage pin** | **VCC reference** | **VL4 reference** |
| VL4 | VCC | LCD reference voltage |
| VL3 | — | — |
| VL2 | 2/3 × VL4 | 2/3 × VL4 |
| VL1 | 1/3 × VL4 | 1/3 × VL4 |

Note: Use a capacitor with less leakage current. In addition, make C1 a non-polar capacitor.
Note 1. VL3 can be used as a port.

**Figure 46.14 Examples of LCD drive power connections using VCC reference mode of capacitor split method**

Note: Use a capacitor with less leakage current. In addition, make C1 a non-polar capacitor.
Note 1. VL3 can be used as a port.

**Figure 46.15 Examples of LCD drive power connections using VL4 reference mode of capacitor split method**

## 46.7 Common and Segment Signals

Each pixel of an LCD panel turns on when the potential difference between the corresponding common and segment signals becomes higher than a specific voltage (LCD drive voltage, VLCD). The pixels turn off when the potential difference becomes lower than VLCD.

Applying DC voltage to the common and segment signals of an LCD panel causes deterioration. To avoid this problem, the SLCDC is driven by AC voltage.

### (1) Common signals

Each common signal is selected sequentially according to a specified number of time slices listed in Figure 46.16. In the static display mode, the same signal is output to COM0 to COM3.

In the two-time-slice mode, leave the COM2 and COM3 pins open. In the three-time-slice mode, leave the COM3 pin open.

Use the COM4 to COM7 pins other than in the six-time-slice mode and eight-time-slice mode, and COM6, COM7 pins in the six-time-slice mode as open or segment pins.

| COM Signal Number of Time Slices | COM0 | COM1 | COM2 | COM3 | COM4 | COM5 | COM6 | COM7 |
|---|---|---|---|---|---|---|---|---|
| Static display mode | | | | | *1 | *1 | *1 | *1 |
| Two-time-slice mode | | | Open | Open | *1 | *1 | *1 | *1 |
| Three-time slot mode | | | | Open | *1 | *1 | *1 | *1 |
| Four-time slot mode | | | | | *1 | *1 | *1 | *1 |
| Six-time-slice mode | | | | | | | *1 | *1 |
| Eight-time-slice mode | | | | | | | | |

Note 1. Use the pins as open or segment pins.

**Figure 46.16 COM signals**

### (2) Segment signals

Segment signals are signals that correspond to the LCD Display Data register (see section 46.2.5. LCD Display Data Registers).

When the number of time slices is 8, bit [0] to bit [7] of each Display Data register are read in synchronization with COM0 to COM7, respectively. When the number of time slices is 6, bit [0] to bit [5] of each Display Data register are read in synchronization with COM0 to COM5, respectively. If a bit is 1, it is converted to the select voltage, and if the bit is 0, it is converted to the deselect voltage. The conversion results are output to the segment pins.

When the number of time slices is not 8 or 6, bit [0] to bit [3] of each byte in A-pattern area are read in synchronization with COM0 to COM3, and bit [4] to bit [7] of each byte in B-pattern area are read in synchronization with COM0 to COM3, respectively. If a bit is 1, it is converted to the select voltage, and if the bit is 0, it is converted to the deselect voltage. The conversion results are output to the segment pins.

Check what combination of front-surface electrodes (associated with the segment signals) and rear-surface electrodes (associated with the common signals) forms the display patterns in the LCD Display Data register, then write the bit data associated with the desired display pattern on a one-to-one basis.

### (3) Output waveforms of common and segment signals

The voltages listed in Table 46.18 are output as common and segment signals.

When both common and segment signals are at the select voltage, display on-voltage is ±VLCD. Other combinations of the signals correspond to display off-voltage.

**Table 46.18 LCD drive voltage (static display mode)**

## 46.8 Display Modes

### 46.8.1 Static Display Example

Figure 46.23 shows how a 3-digit LCD panel with the display pattern shown in Figure 46.22 is connected to the segment signals (SEG0 to SEG23) and the common signal (COM0). This example displays “12.3” in the LCD panel. The content of the Display Data register corresponds to this display.

The following description focuses on numeral “2.” displayed in the second digit. To display “2.” in the LCD panel, the select or deselect voltage must be applied to SEG8 to SEG15 pins at the select timing of the common signal COM0. See Figure 46.22 for the relationship between the segment signals and LCD segments.

**Table 46.22 Example of select (1) and deselect (0) data (COM0)**

| Common | Segment | | | | | | | |
|---|---|---|---|---|---|---|---|---|
| | SEG8 | SEG9 | SEG10 | SEG11 | SEG12 | SEG13 | SEG14 | SEG15 |
| COM0 | Select | Deselect | Select | Select | Deselect | Select | Select | Select |

As shown in Table 46.22, bit-0 pattern of the Display Data register must be 10110111b.

Figure 46.24 shows the LCD drive waveforms of SEG11, SEG12, and COM0. When the select voltage is applied to SEG11 at the COM0 timing, an alternating rectangle waveform, +VLCD/-VLCD, is generated to turn on the associated LCD segment.

COM1 to COM3 are supplied with the same waveform as COM0. Therefore, COM0 to COM3 can be connected together to increase the drive capacity.

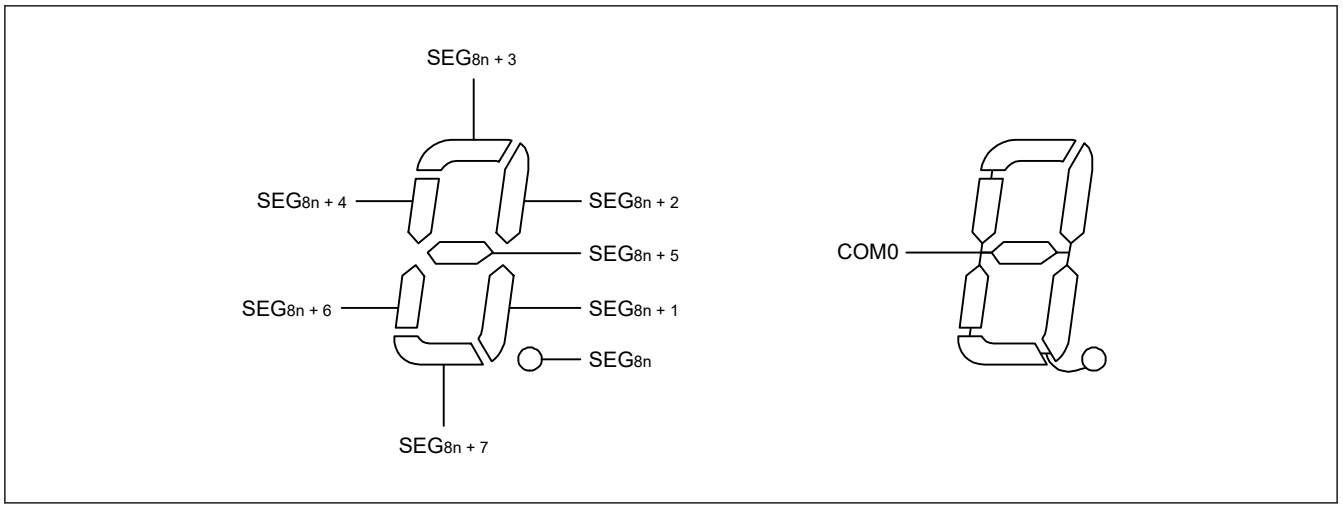

**Figure 46.22 Static LCD display pattern and electrode connections**

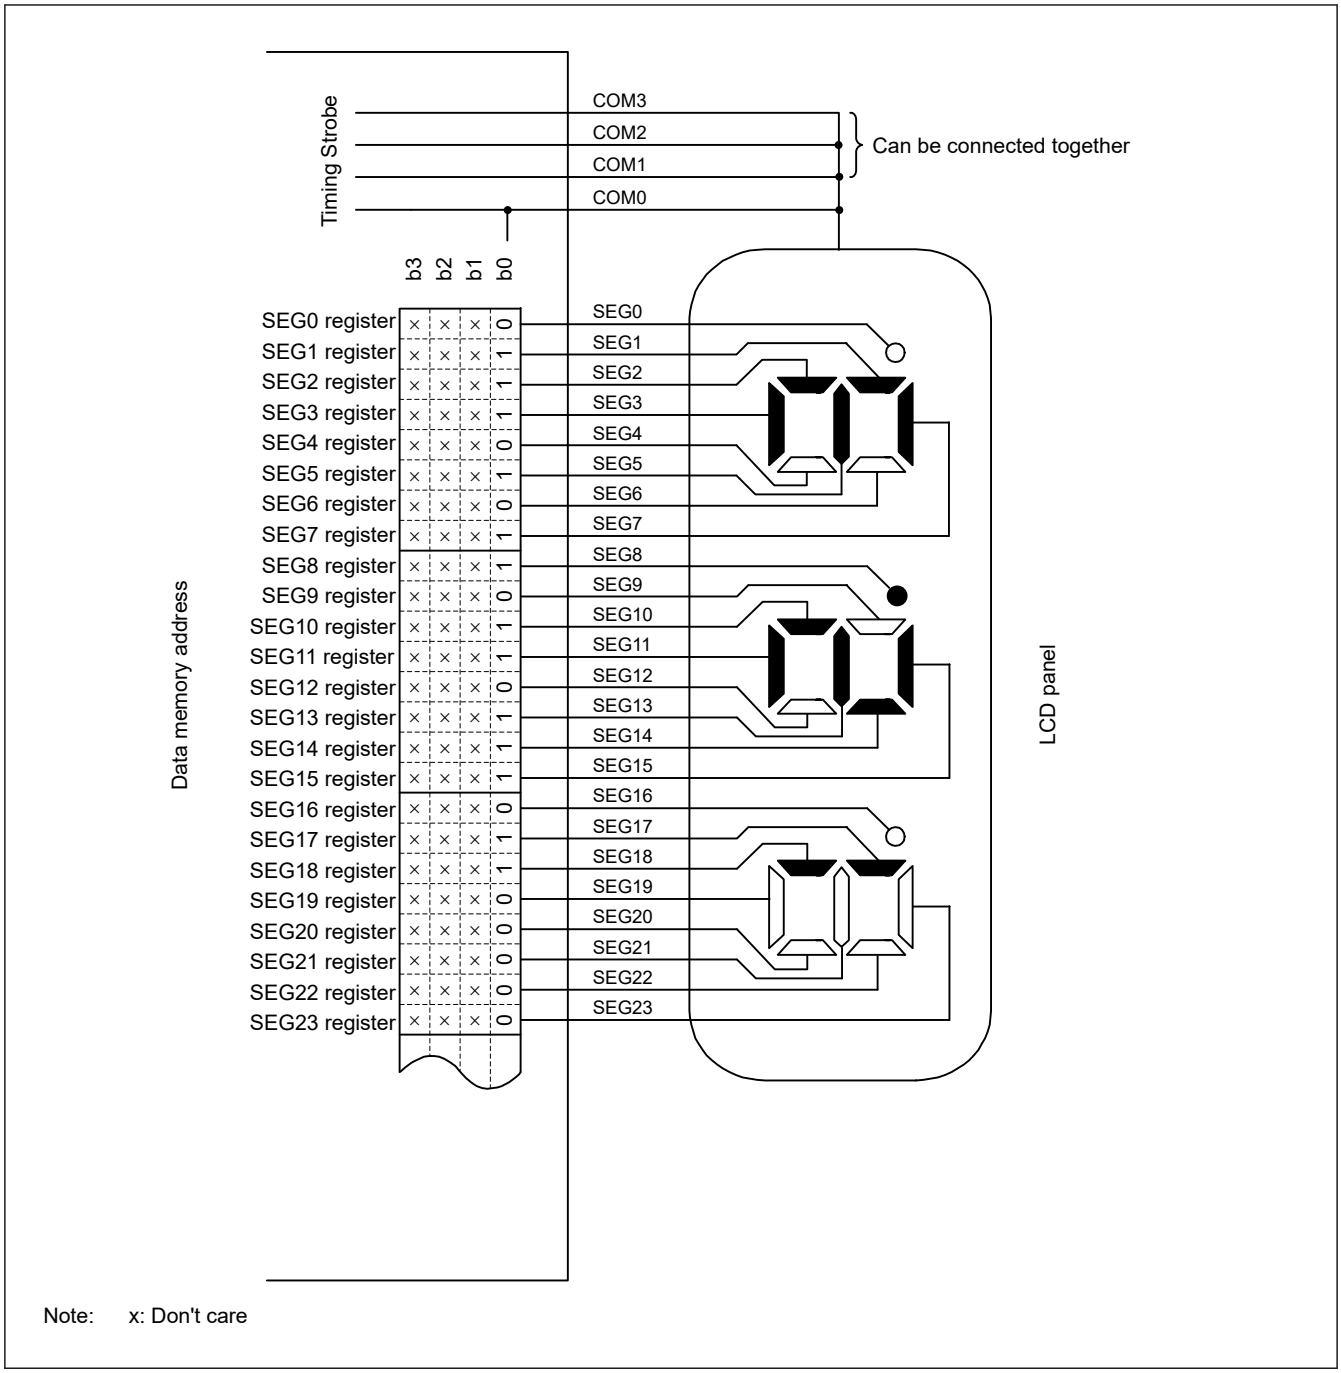

**Figure 46.23 Example of connecting static LCD panel**

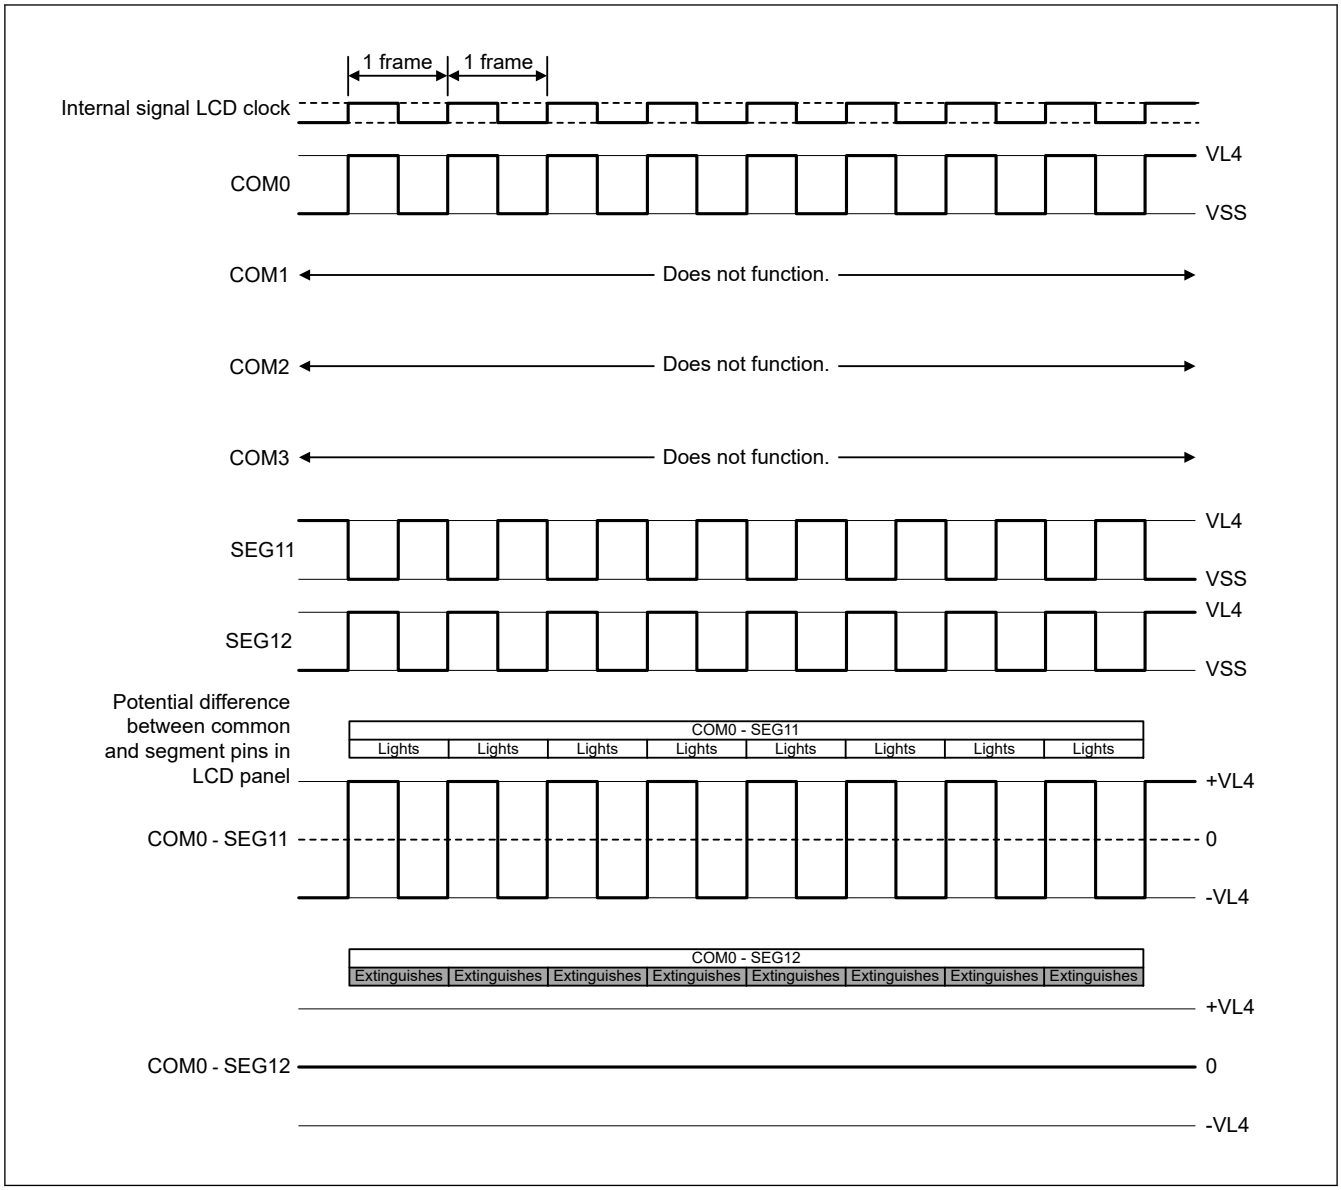

**Figure 46.24 Static LCD drive waveform examples for SEG11, SEG12, and COM0**

## 46.8.2 Two-Time Slice Display Example

Figure 46.26 shows how a 6-digit LCD panel with the display pattern shown in Figure 46.25 is connected to the segment signals (SEG0 to SEG23) and the common signals (COM0 and COM1). This example displays “12345.6” in the LCD panel. The content of the Display Data register corresponds to this display.

The following description is for numeral “3” displayed in the fourth digit. To display “3” in the LCD panel, the select or deselect voltage must be applied to the SEG12 to SEG15 pins at the select timing of the COM0 and COM1 common signals. See Figure 46.25 for the relationship between the segment signals and LCD segments.

**Table 46.23 Example of select (1) and deselect (0) data (COM0 and COM1)**

| Common | Segment | | | |
|---|---|---|---|---|
| | SEG12 | SEG13 | SEG14 | SEG15 |
| COM0 | Select | Select | Deselect | Deselect |
| COM1 | Deselect | Select | Select | Select |

As shown in Table 46.23, the Display Data register location that corresponds to SEG15 must contain xx10b.

Figure 46.27 shows examples of LCD drive waveforms between SEG15 signal and each common signal. When the select voltage is applied to SEG15 at the timing of COM1, an alternating rectangle waveform, +VLCD/−VLCD, is generated to turn on the associated LCD segment.

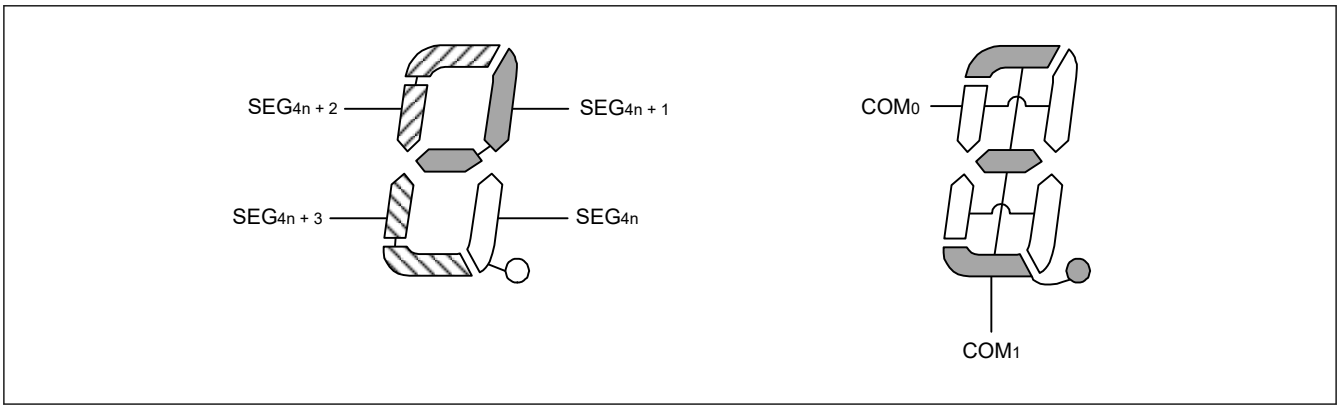

**Figure 46.25 Two-time slice LCD display pattern and electrode connections**

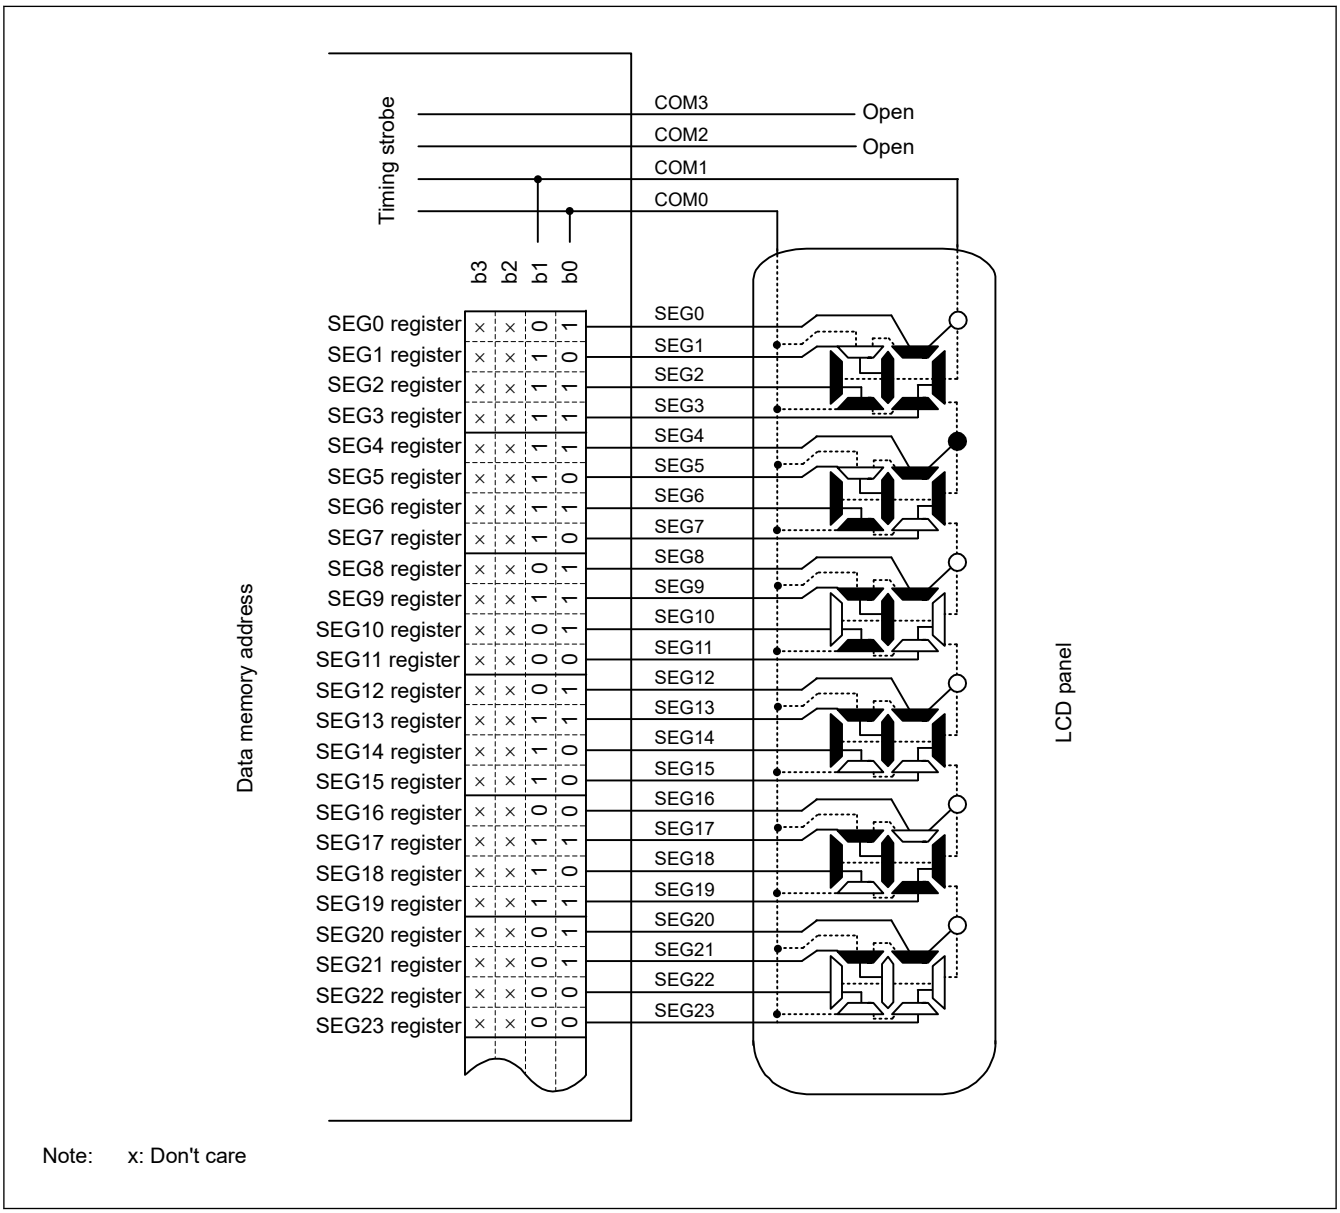

**Figure 46.26 Example of connecting two-time slice LCD panel**

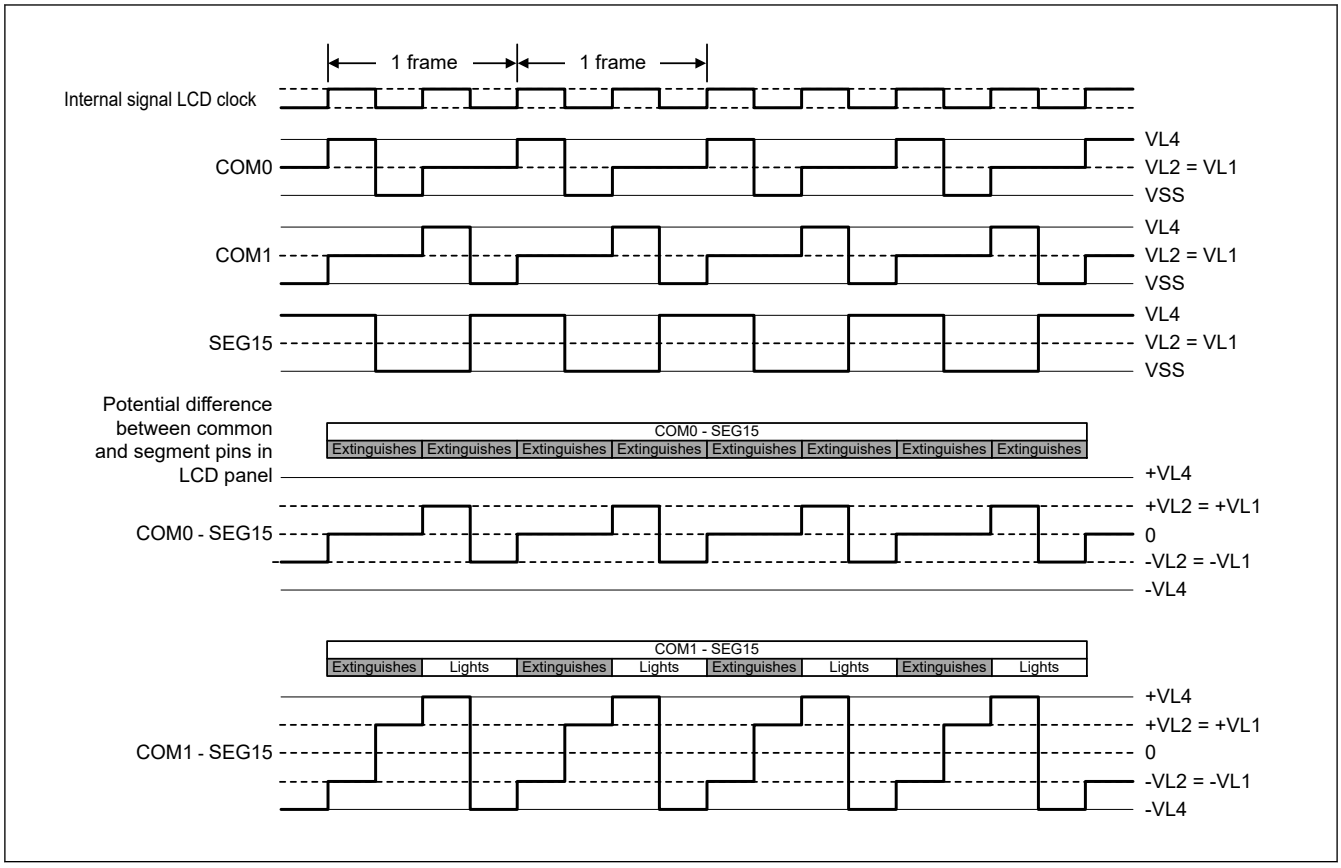

**Figure 46.27 Two-time slice LCD drive waveform examples between SEG15 and each common signal using 1/2 bias method**

## 46.8.3 Three-Time Slice Display Example

Figure 46.29 shows how an 8-digit LCD panel with the display pattern shown in Figure 46.28 is connected to the segment signals (SEG0 to SEG23) and the common signals (COM0 to COM2). This example displays “123456.78” in the LCD panel. The content of the Display Data register corresponds to this display.

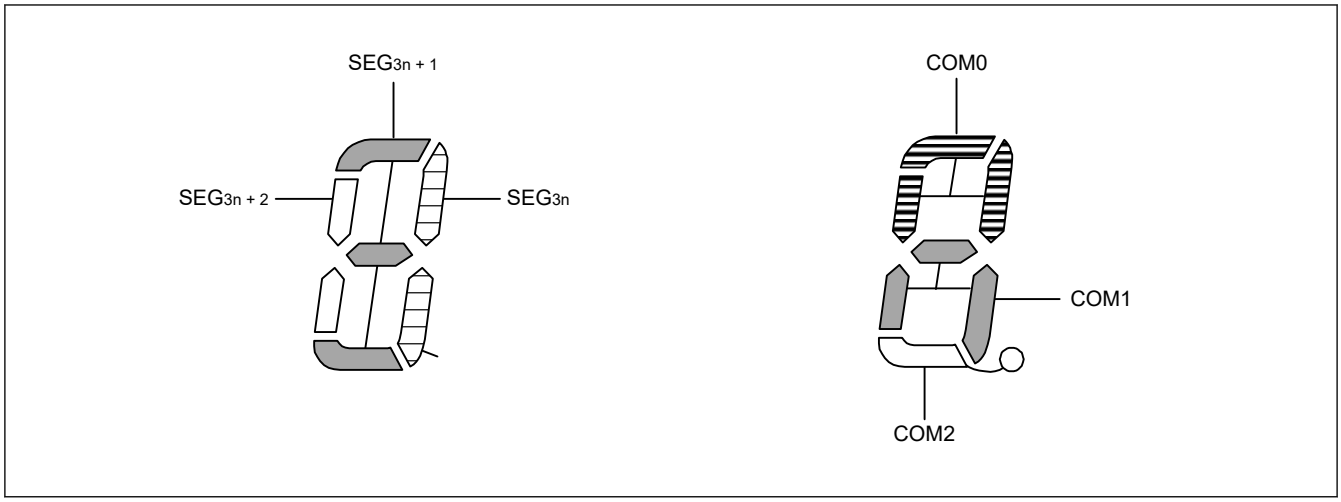
The following description focuses on numeral “6.” displayed in the third digit. To display “6.” in the LCD panel, the select or deselect voltage must be applied to the SEG6 to SEG8 pins at the select timing of COM0 to COM2 common signals. See Figure 46.28 for the relationship between the segment signals and LCD segments.

**Table 46.24 Example of select (1) and deselect (0) data (COM0 to COM2)**

| Common | Segment | | |
|---|---|---|---|
| | SEG6 | SEG7 | SEG8 |
| COM0 | Deselect | Select | Select |
| COM1 | Select | Select | Select |
| COM2 | Select | Select | — |

As shown in Table 46.24, the Display Data register location that corresponds to SEG6 must contain x110b.

Figure 46.30 and Figure 46.31 show examples of LCD drive waveforms between SEG6 signal and each common signal in the 1/2 and 1/3 bias methods, respectively. When the select voltage is applied to SEG6 at the COM1 or COM2 timing, an alternating rectangle waveform, +VLCD/−VLCD, is generated to turn on the associated LCD segment.



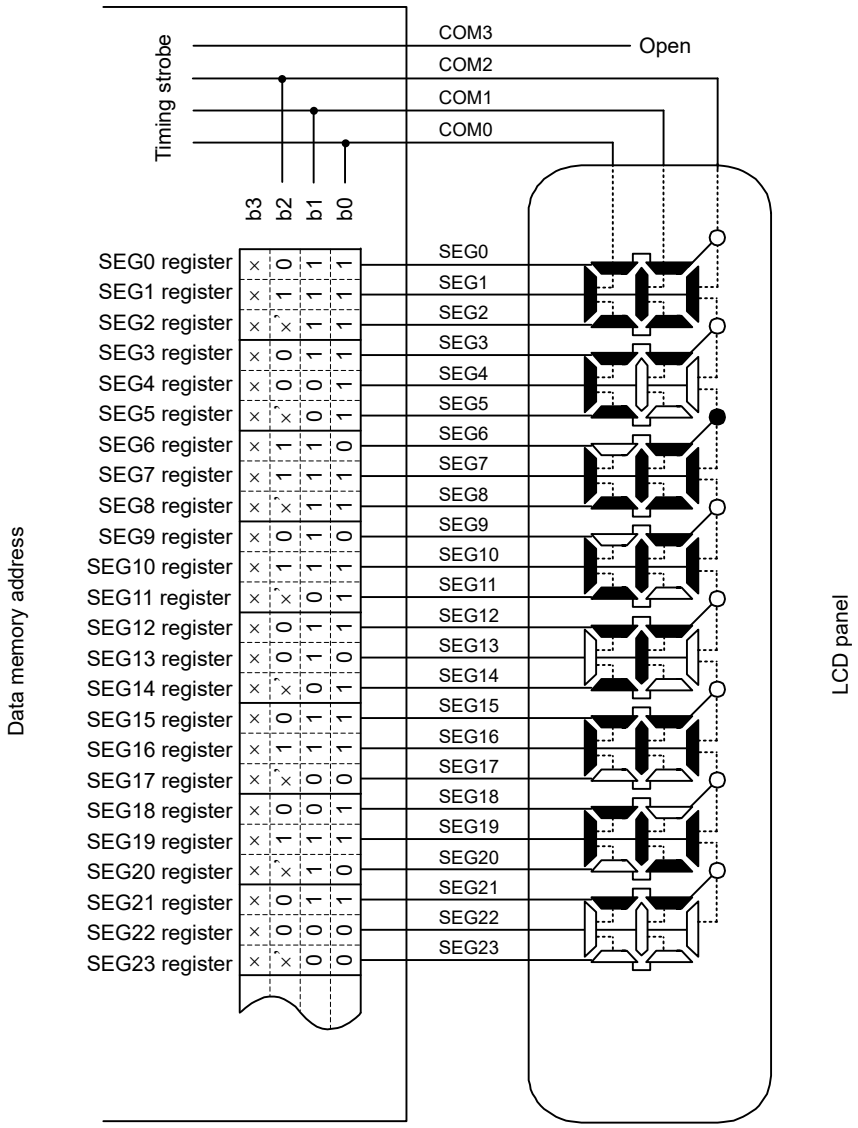


**Figure 46.28 Three-time slice LCD display pattern and electrode connections**

Note: x: Don't care
x': Can be used to store any data because there is no corresponding segment in the LCD panel.

**Figure 46.29 Example of connecting three-time slice LCD panel**

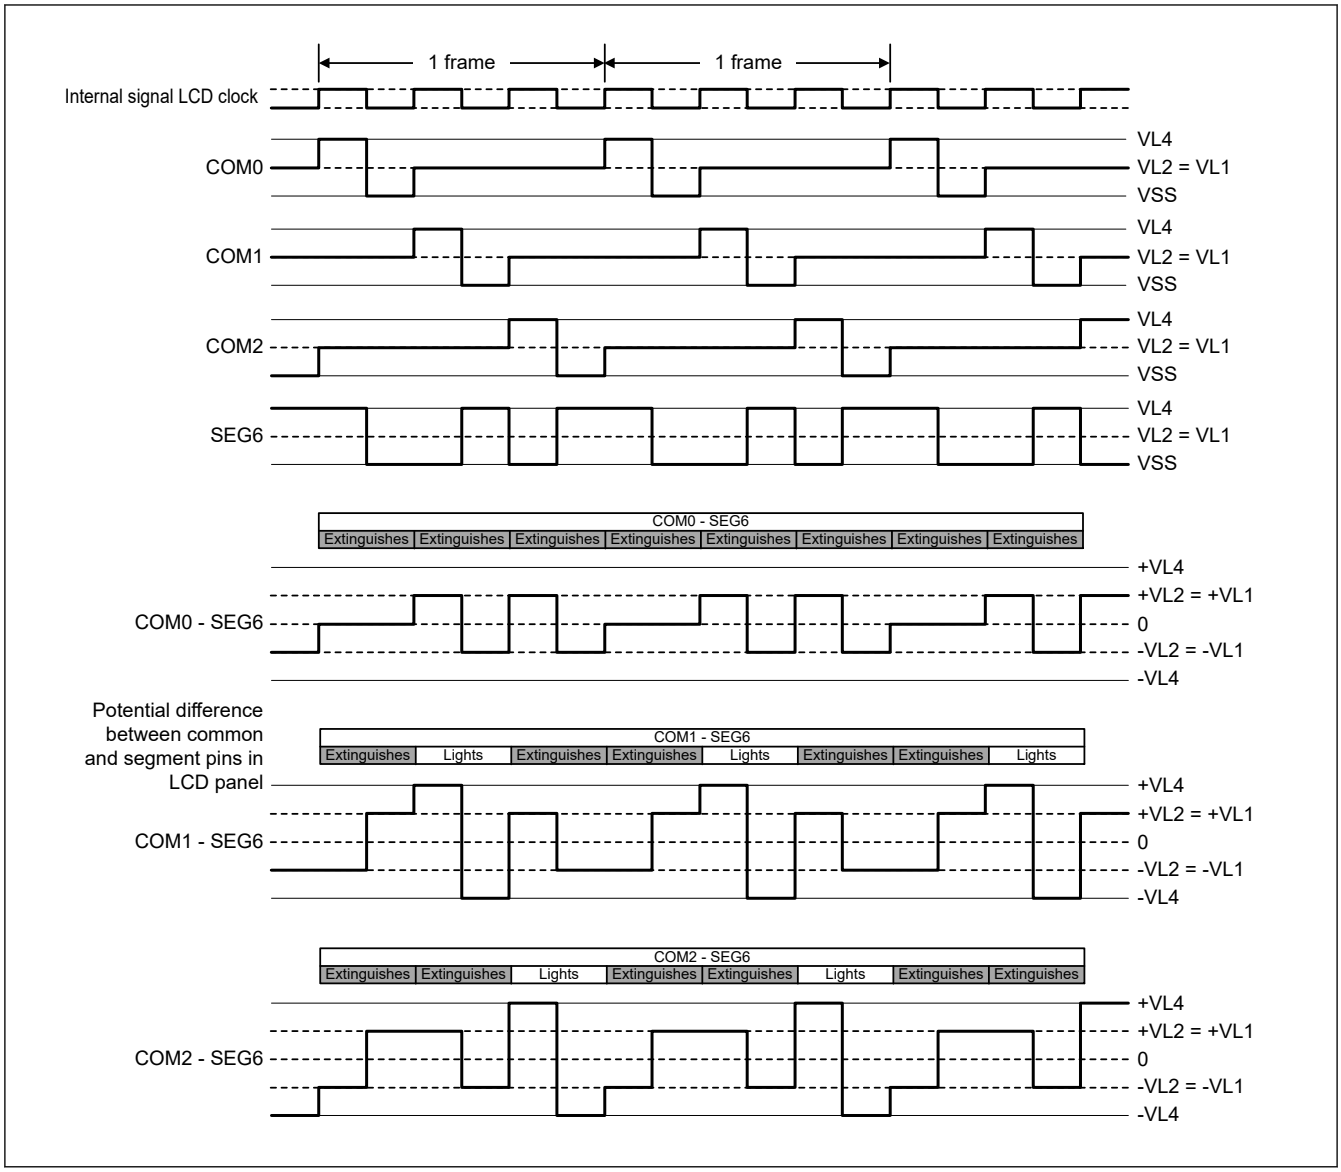

**Figure 46.30 Three-time slice LCD drive waveform examples between SEG6 and each common signal using 1/2 bias method**

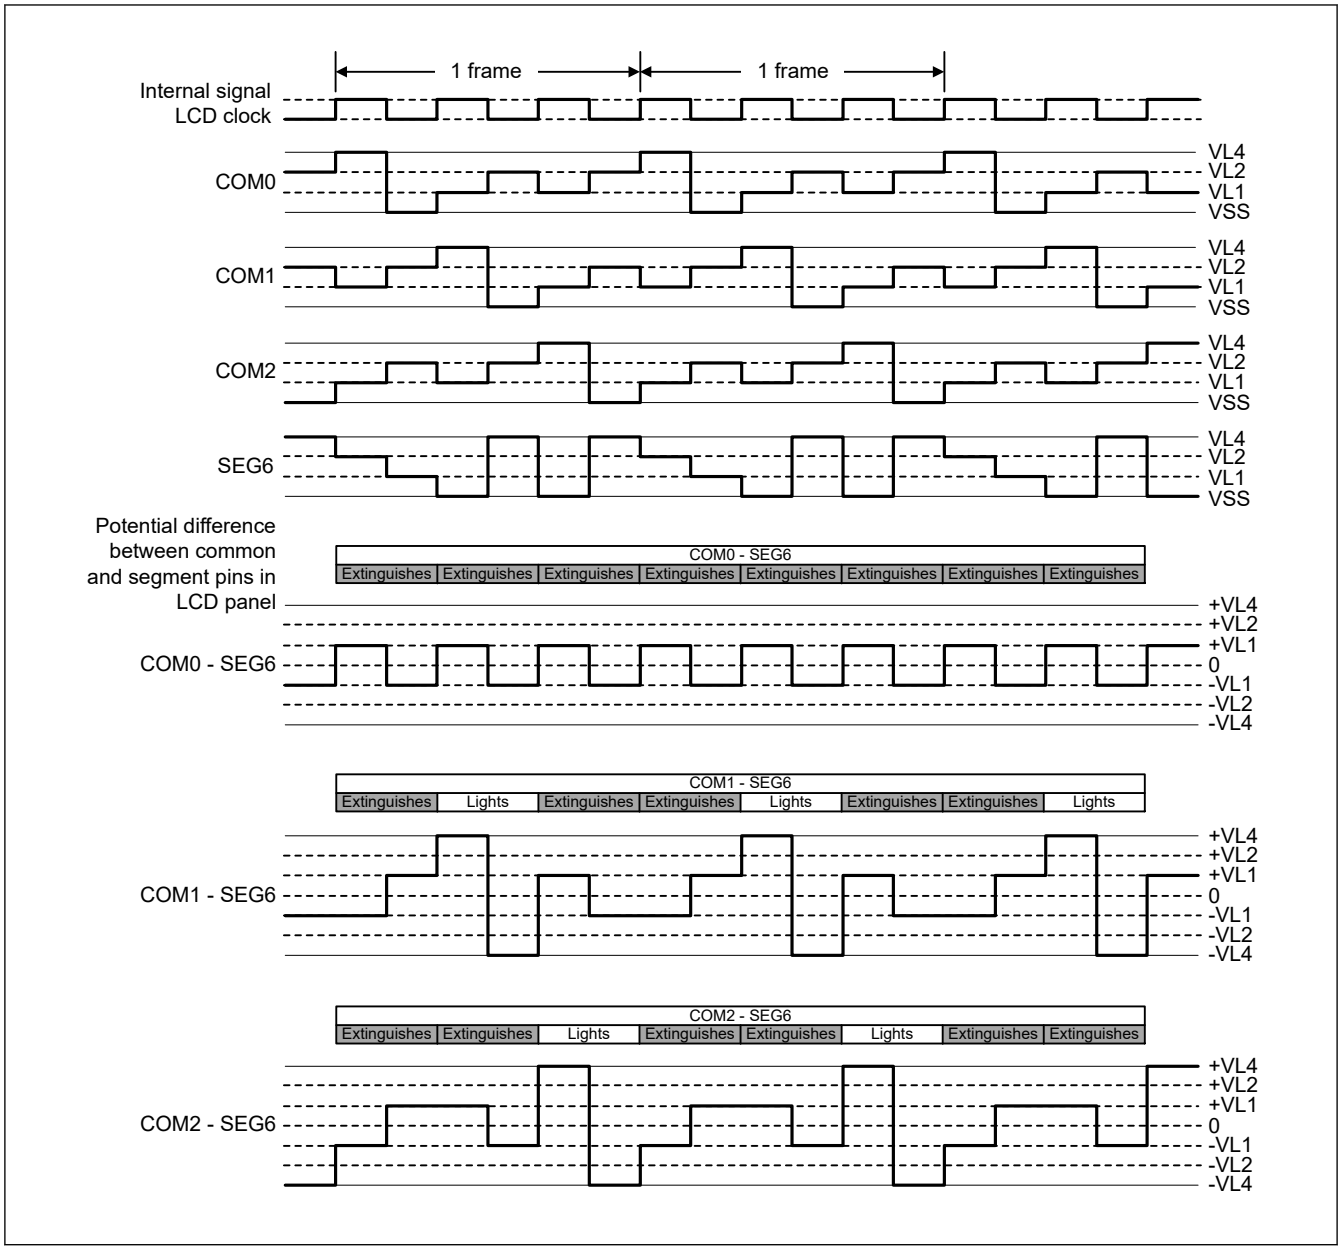

**Figure 46.31 Three-time slice LCD drive waveform examples between SEG6 and each common signal using 1/3 bias method**

## 46.8.4 Four-Time Slice Display Example

Figure 46.33 shows how a 12-digit LCD panel with the display pattern shown in Figure 46.32 is connected to the segment signals (SEG0 to SEG23) and the common signals (COM0 to COM3). This example displays “123456.789012” in the LCD panel. The content of the Display Data register corresponds to this display.

The following description focuses on numeral “6.” displayed in the seventh digit. To display “6.” in the LCD panel, the select or deselect voltage must be applied to the SEG12 and SEG13 pins at the select timing of COM0 to COM3 common signals. See Figure 46.32 for the relationship between the segment signals and LCD segments.

**Table 46.25 Example of select (1) and deselect (0) data (COM0 to COM3) (1 of 2)**

| Common | Segment | |
|---|---|---|
| | SEG12 | SEG13 |
| COM0 | Select | Select |
| COM1 | Deselect | Select |

**Table 46.25 Example of select (1) and deselect (0) data (COM0 to COM3) (2 of 2)**

| Common | Segment | |
|---|---|---|
| | SEG12 | SEG13 |
| COM2 | Select | Select |
| COM3 | Select | Select |

As shown in Table 46.25, the Display Data register location that corresponds to SEG12 must contain 1101b.

Figure 46.34 to Figure 46.35 show examples of LCD drive waveforms between SEG12 signal and each common signal. When the select voltage is applied to SEG12 at the COM0 timing, an alternating rectangle waveform, +VLCD/−VLCD, is generated to turn on the associated LCD segment.

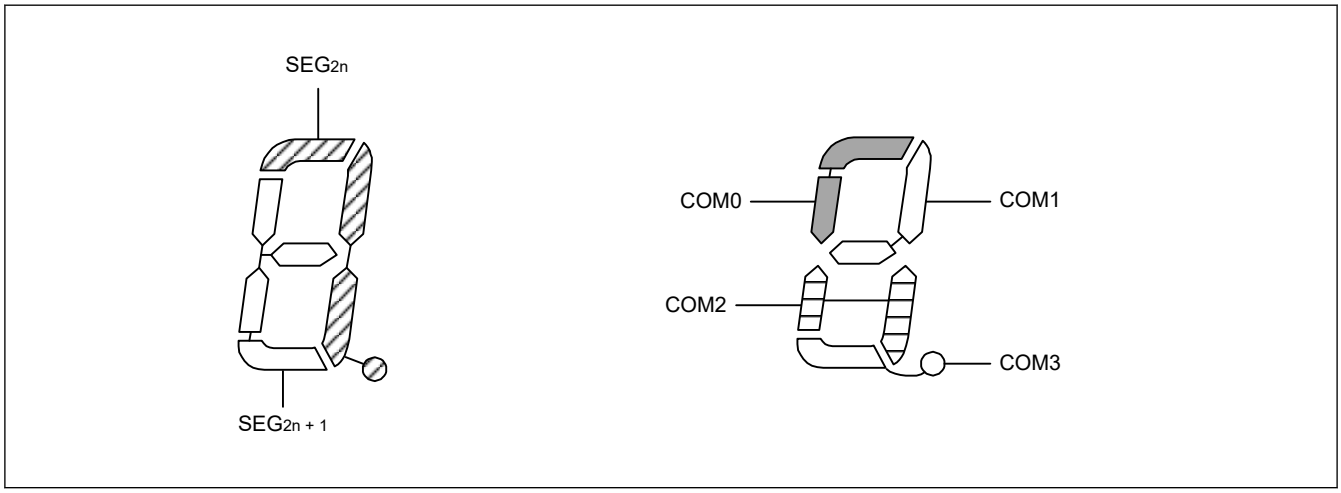

**Figure 46.32 Four-time slice LCD display pattern and electrode connections**

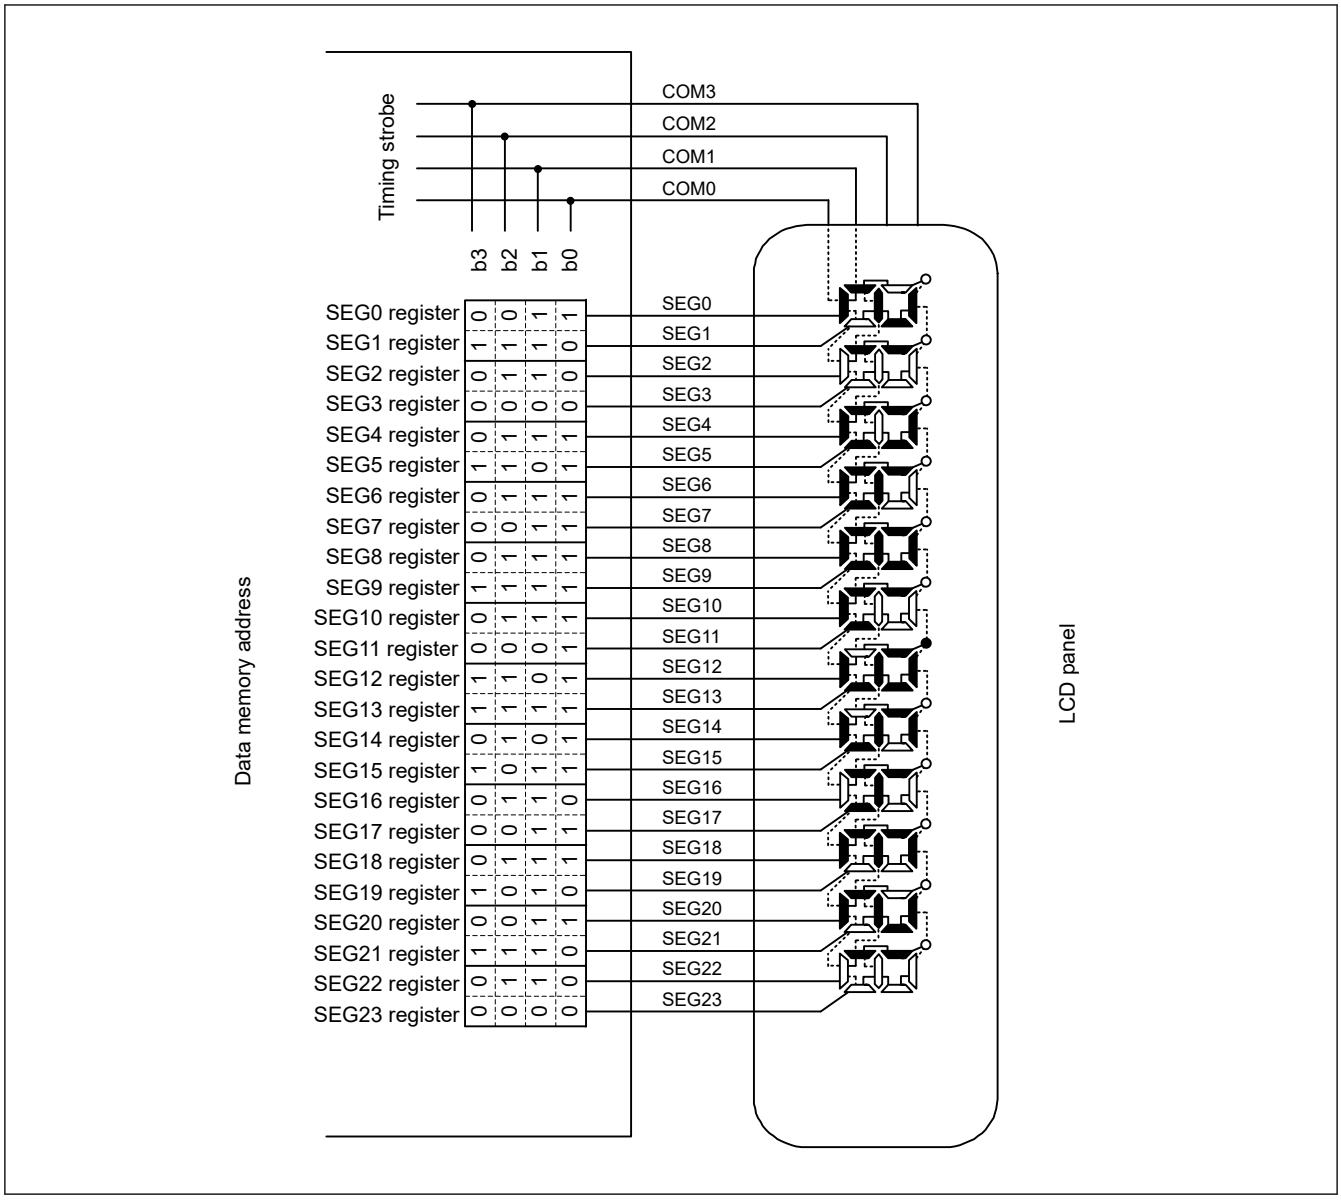

**Figure 46.33 Example of connecting four-time slice LCD panel**

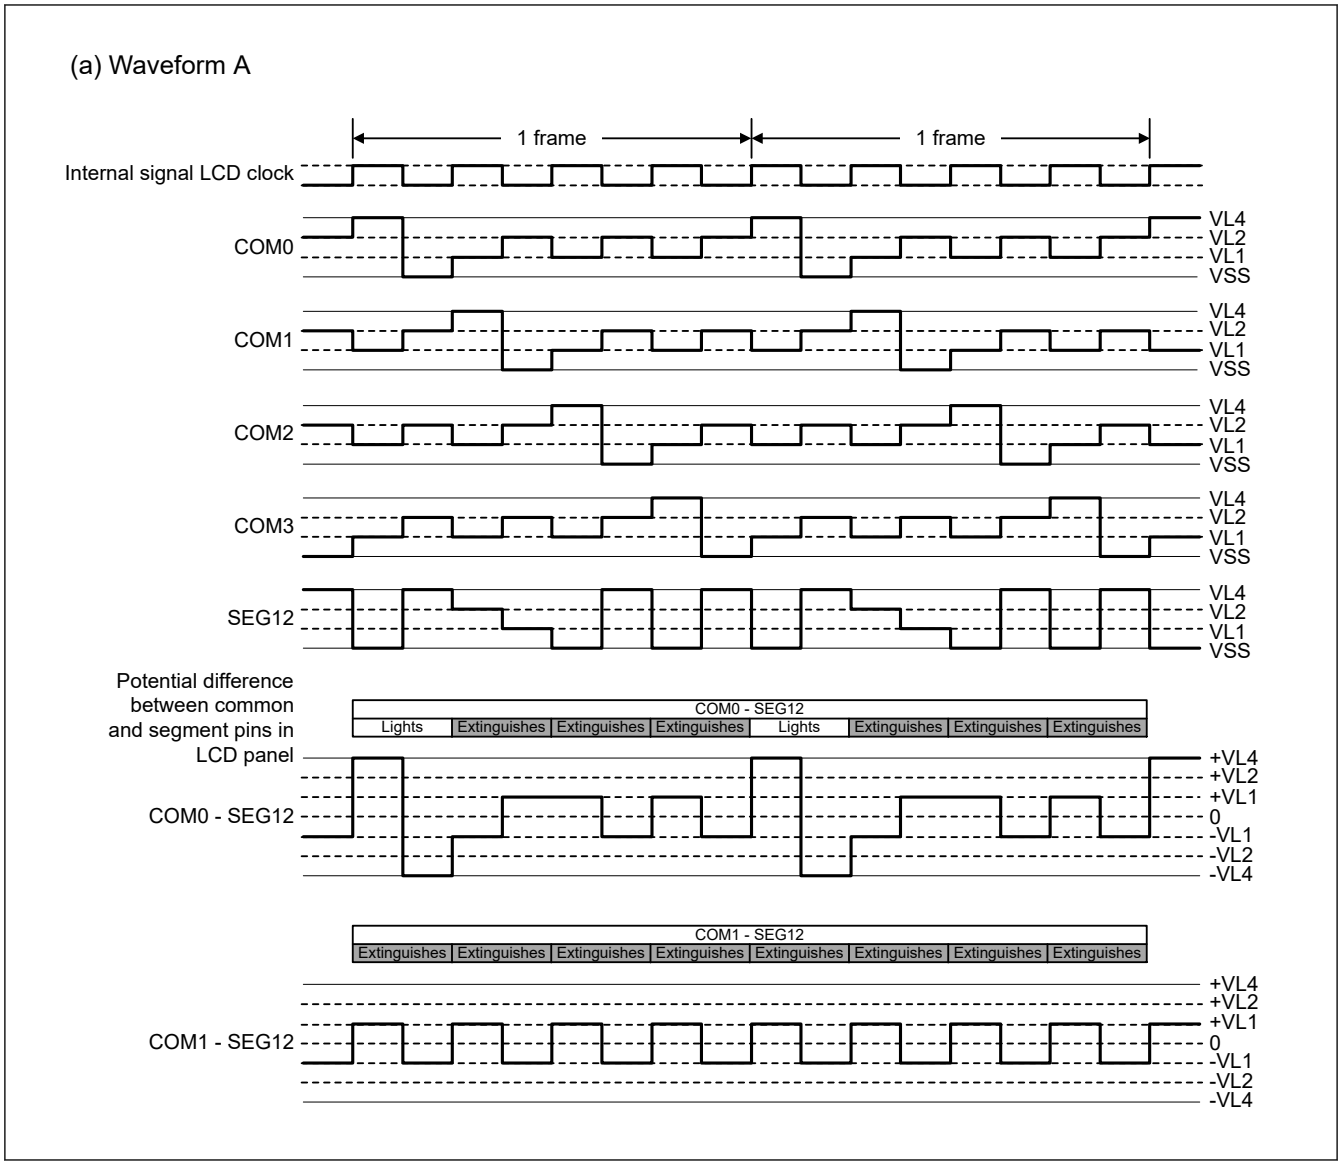

**Figure 46.34 Four-time slice LCD drive waveform examples between SEG12 and each common signal using 1/3 bias method (1 of 2)**

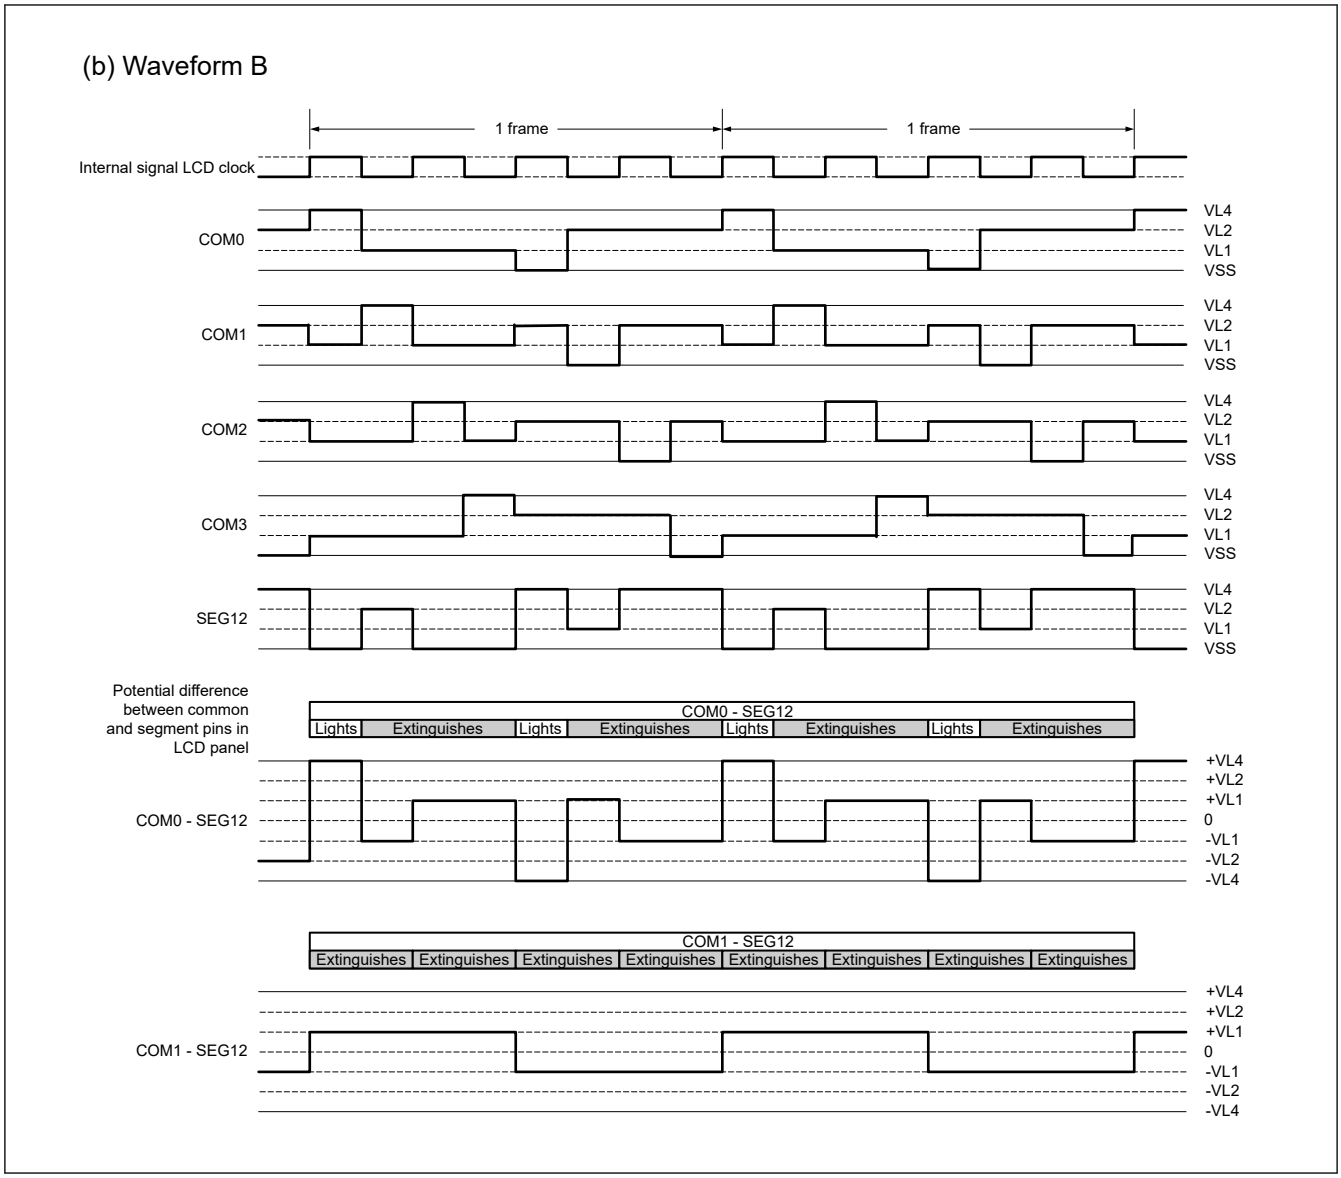

**Figure 46.35 Four-time slice LCD drive waveform examples between SEG12 and each common signal using 1/3 bias method (2 of 2)**

## 46.8.5 Six-Time Slice Display Example

Figure 46.37 shows how a 15 × 6 dot LCD panel with the display pattern shown in Figure 46.36 is connected to the segment signals (SEG2 to SEG16) and the common signals (COM0 to COM5). This example displays “123” in the LCD panel. The contents of the display data register correspond to this display.

The following description is for the numeral “3” displayed in the first digit. To display “3” in the LCD panel, the select or deselect voltage must be applied to the SEG2 to SEG6 pins at the select timing of the common signals COM0 to COM5. See Figure 46.36 for the relationship between the segment signals and LCD segments.

**Table 46.26 Example of select (1) and deselect (0) data (COM0 to COM5) (1 of 2)**

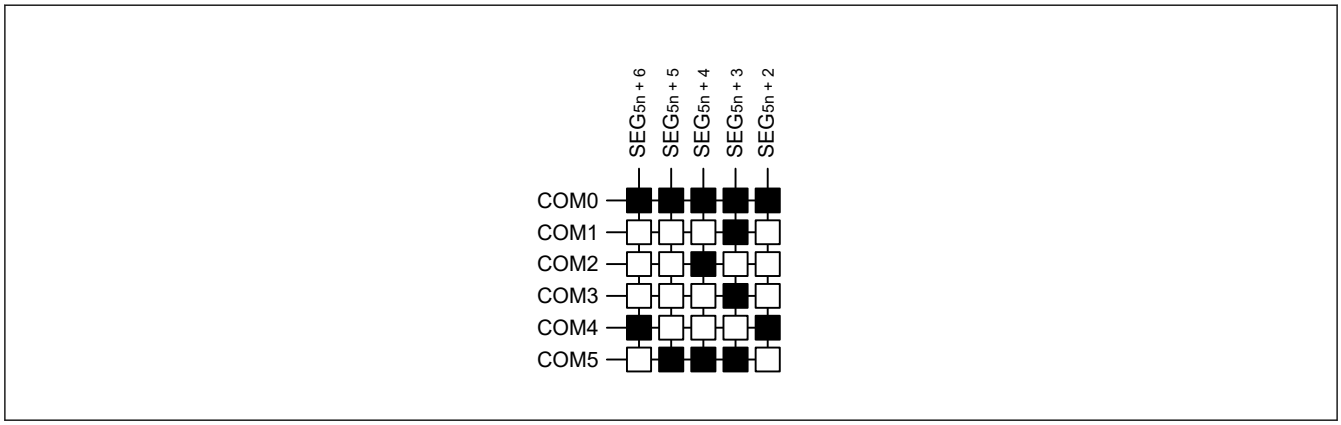
| | Segment | | | | |
|---|---|---|---|---|---|
| **Common** | **SEG2** | **SEG3** | **SEG4** | **SEG5** | **SEG6** |
| COM0 | Select | Select | Select | Select | Select |
| COM1 | Deselect | Select | Deselect | Deselect | Deselect |
| COM2 | Deselect | Deselect | Select | Deselect | Deselect |
| COM3 | Deselect | Select | Deselect | Deselect | Deselect |

**Table 46.26 Example of select (1) and deselect (0) data (COM0 to COM5) (2 of 2)**

| Common | Segment | | | | |
|---|---|---|---|---|---|
| | SEG2 | SEG3 | SEG4 | SEG5 | SEG6 |
| COM4 | Select | Deselect | Deselect | Deselect | Select |
| COM5 | Deselect | Select | Select | Select | Deselect |

As shown in Table 46.26, the Display Data register location that corresponds to SEG2 must contain 010001b.

Figure 46.38 and Figure 46.39 show examples of LCD drive waveforms between SEG2 signal and each common signal. When the select voltage is applied to SEG2 at COM0 timing, a waveform is generated to turn on the associated LCD segment.



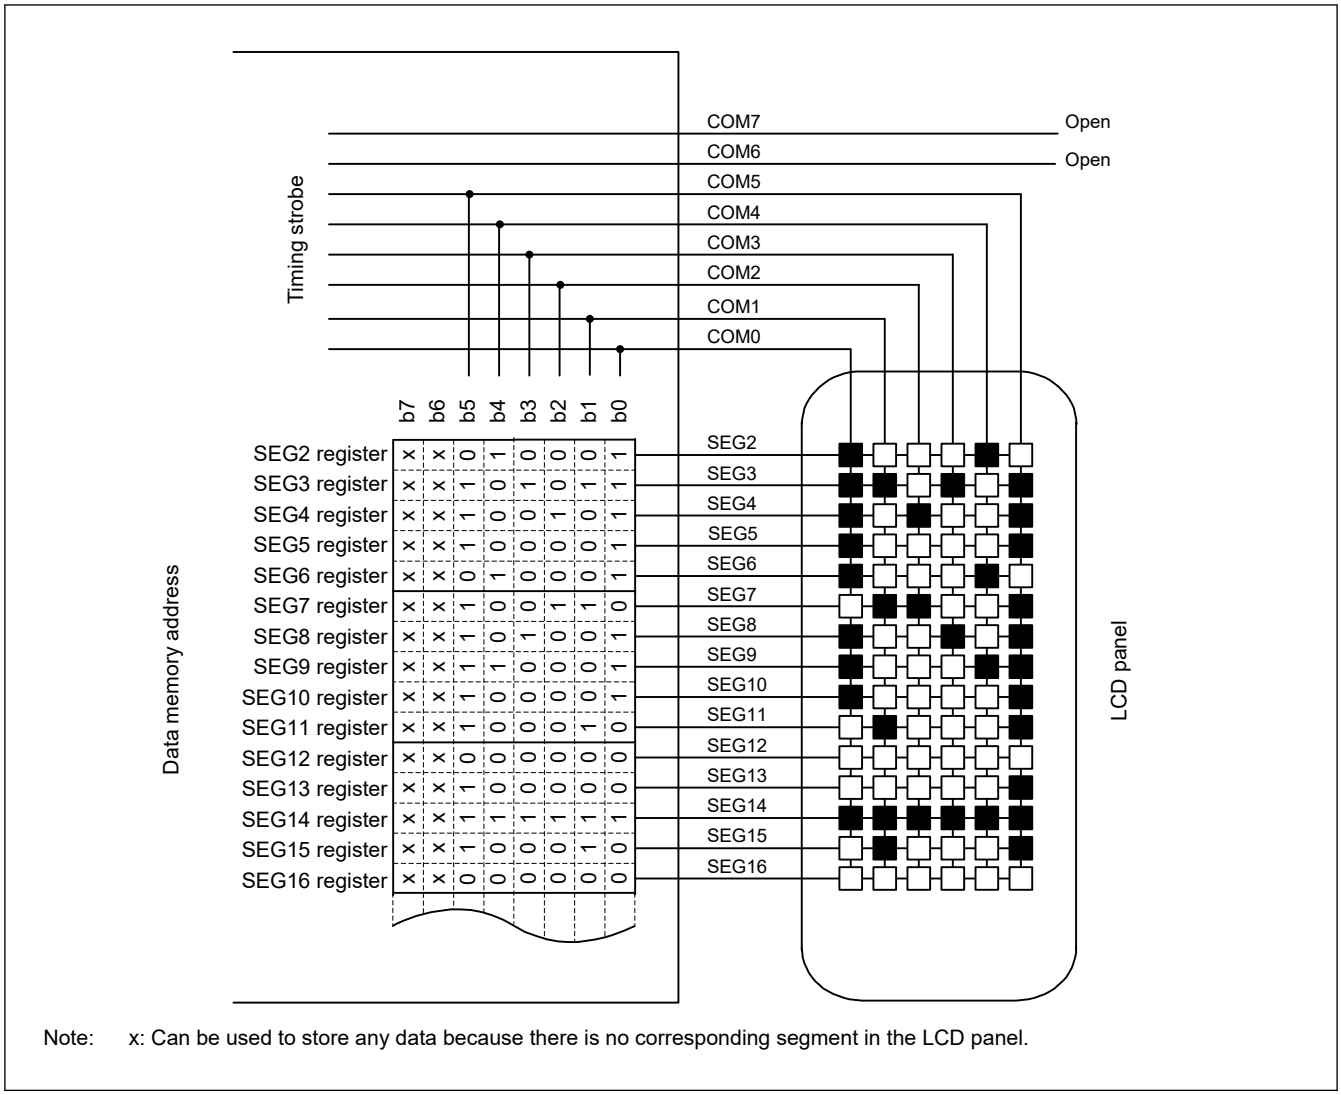


**Figure 46.36 Six-time slice LCD display pattern and electrode connections**

Note: x: Can be used to store any data because there is no corresponding segment in the LCD panel.

**Figure 46.37 Example of connecting six-time slice LCD panel**

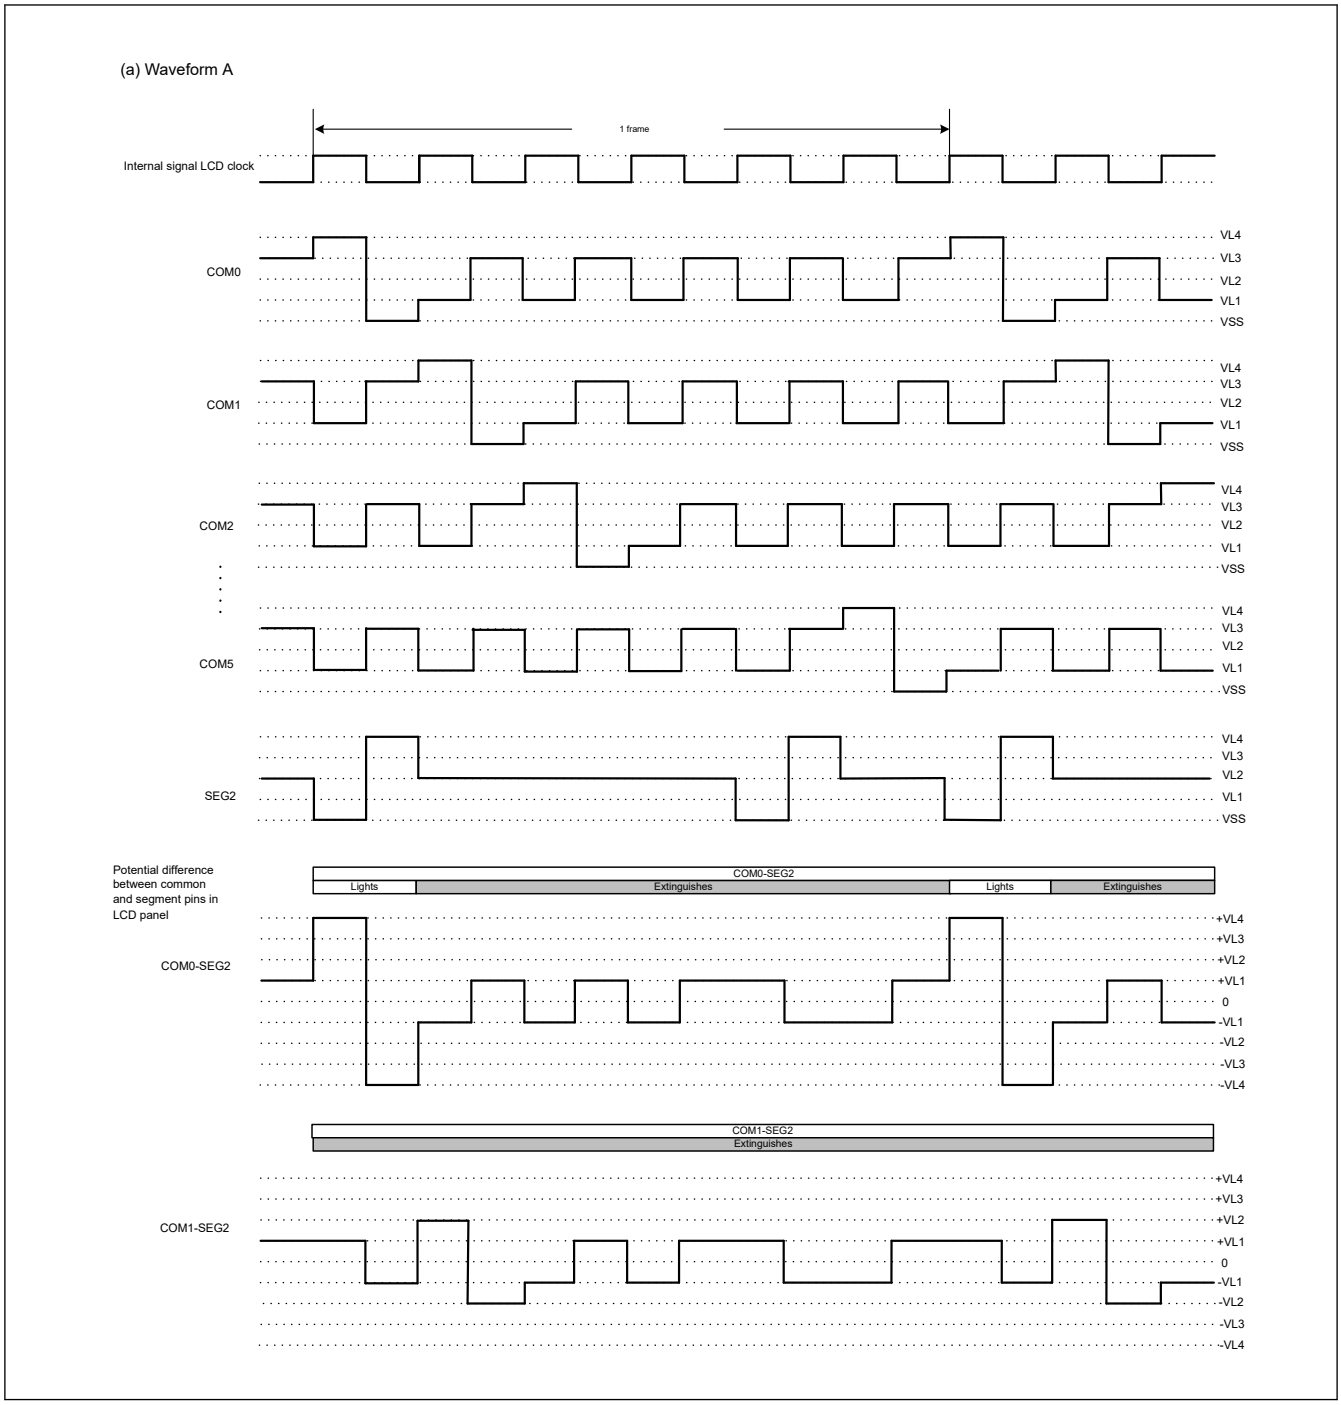

**Figure 46.38 Six-time slice LCD drive waveform examples between SEG2 and each common signal using 1/4 bias method**

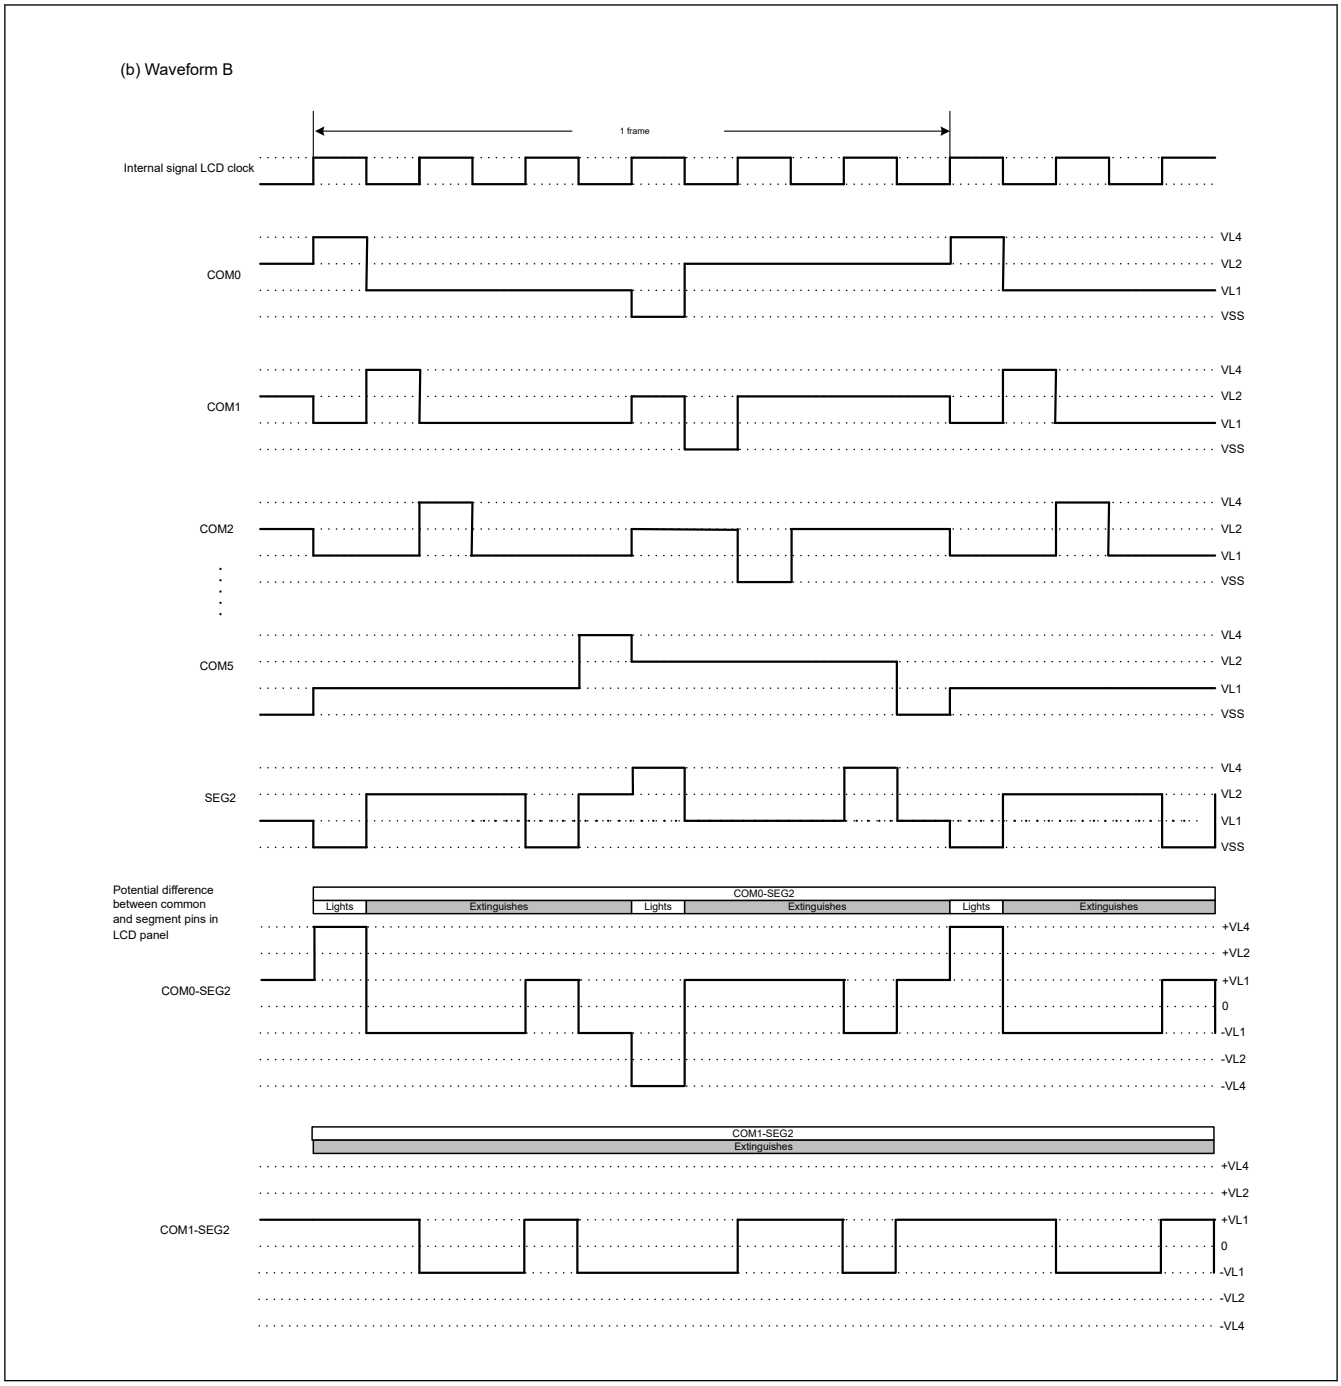

**Figure 46.39 Six-time slice LCD drive waveform examples between SEG2 and each common signal using 1/3 bias method**

## 46.8.6 Eight-Time Slice Display Example

Figure 46.41 shows how a 15 × 8 dot LCD panel with the display pattern shown in Figure 46.40 is connected to the segment signals (SEG4 to SEG18) and the common signals (COM0 to COM7). This example displays “123” in the LCD panel. The content of the Display Data register corresponds to this display.

The following description is for the numeral “3” displayed in the first digit. To display “3” in the LCD panel, the select or deselect voltage must be applied to the SEG4 to SEG8 pins at the select timing of COM0 to COM7 common signals. See Figure 46.40 for the relationship between the segment signals and LCD segments.

**Table 46.27 Example of select (1) and deselect (0) data (COM0 to COM7)**

| | Segment | | | | |
|---|---|---|---|---|---|
| **Common** | **SEG4** | **SEG5** | **SEG6** | **SEG7** | **SEG8** |
| COM0 | Select | Select | Select | Select | Select |
| COM1 | Deselect | Select | Deselect | Deselect | Deselect |
| COM2 | Deselect | Deselect | Select | Deselect | Deselect |
| COM3 | Deselect | Select | Deselect | Deselect | Deselect |
| COM4 | Select | Deselect | Deselect | Deselect | Deselect |
| COM5 | Select | Deselect | Deselect | Deselect | Select |
| COM6 | Deselect | Select | Select | Select | Deselect |
| COM7 | Deselect | Deselect | Deselect | Deselect | Deselect |

As shown in Table 46.27, the Display Data register location that corresponds to SEG4 must contain 00110001b.

Figure 46.42 and Figure 46.43show examples of LCD drive waveforms between SEG4 signal and each common signal. When the select voltage is applied to SEG4 at COM0 timing, a waveform is generated to turn on the associated LCD segment.

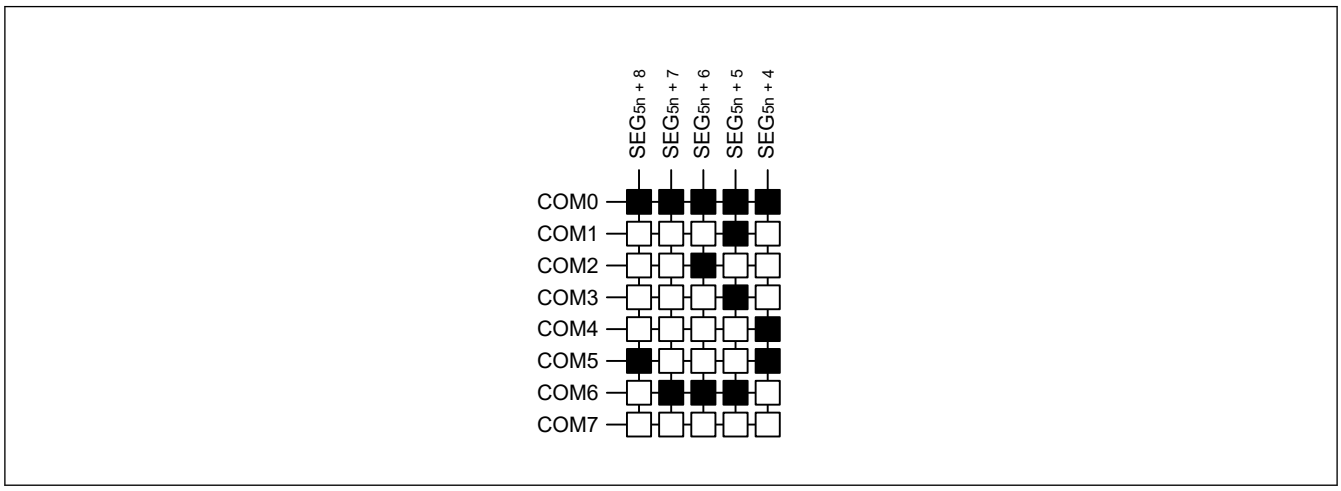

**Figure 46.40 Eight-time slice LCD display pattern and electrode connections**

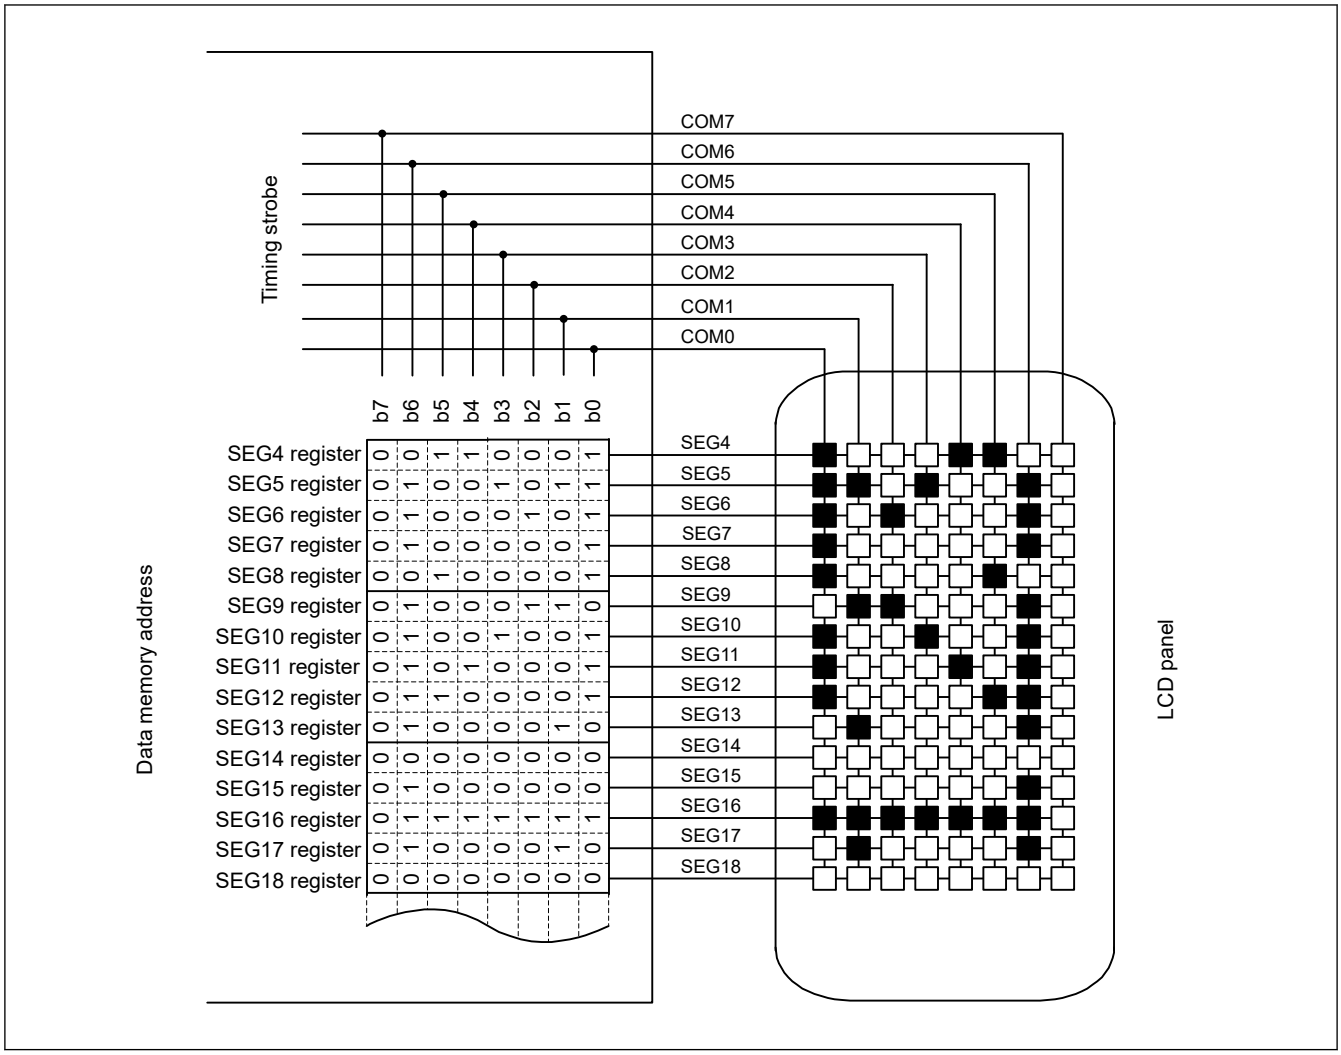

**Figure 46.41 Example of connecting eight-time slice LCD panel**

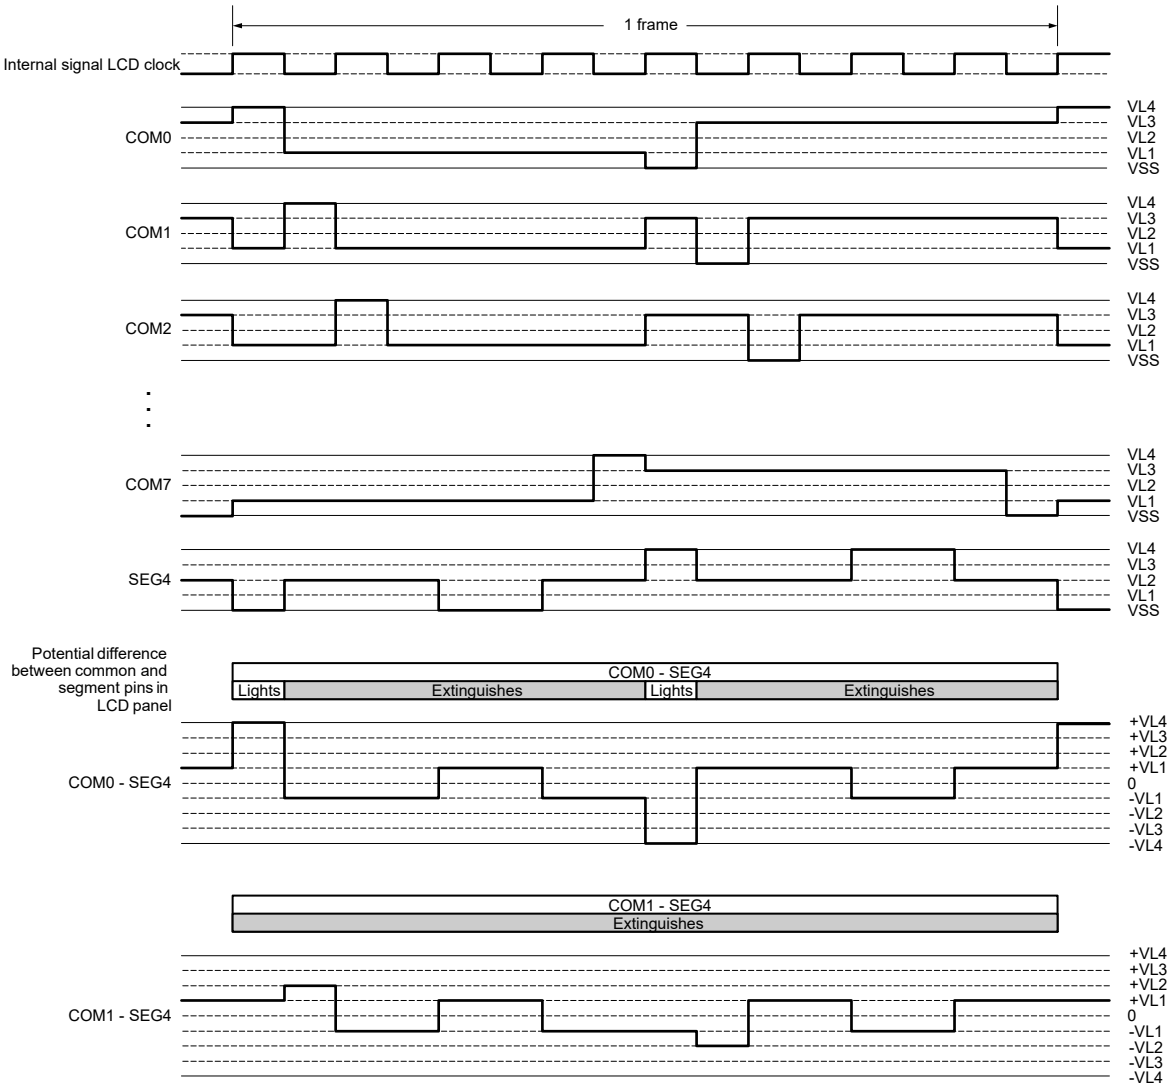

**Figure 46.43 Eight-time slice LCD drive waveform examples between SEG4 and each common signal using 1/4 bias method (2 of 2)**

# 47. Internal Voltage Regulator

## 47.1 Overview

The MCU includes one internal voltage regulator:

- Linear regulator (LDO)

This regulator supplies voltage to all internal circuits and memory except for I/O, analog, and USB domains.

## 47.2 Operation

Table 47.1 lists the LDO pin settings, and Figure 47.1 shows the LDO settings.

**Table 47.1 LDO pin**

| Pins | Setting descriptions |
|---|---|
| ALL VCC | • Connect each pin to the system power supply.<br>• Connect each pin to VSS through a 0.1-µF multilayer ceramic capacitor. Place the capacitor close to the pin. |
| VCL, VCL0 | Connect each pin to VSS through a 4.7-µF multilayer ceramic capacitor. Place the capacitor close to the pin. |

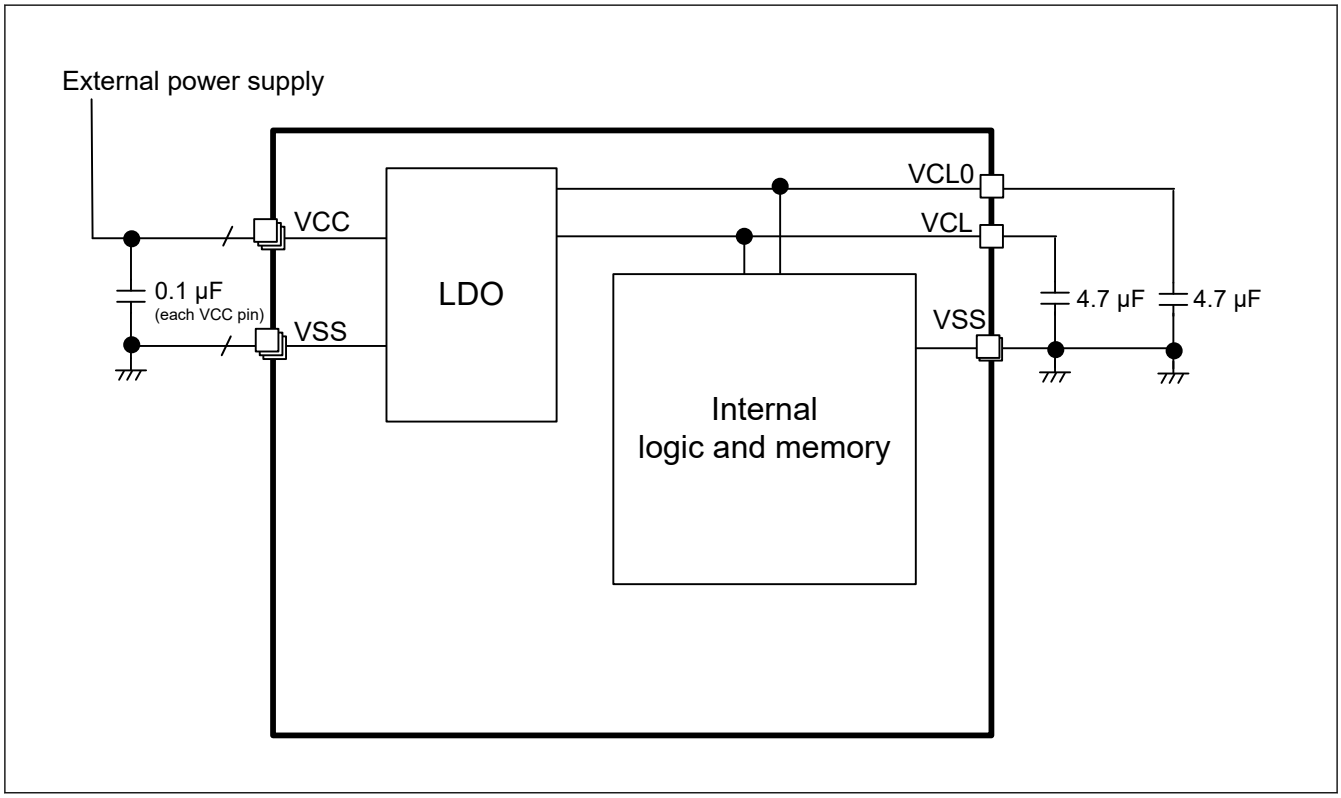

**Figure 47.1 LDO settings**

# 48. Security Features

## 48.1 Overview

- ARMv8-M TrustZone security
  - Eight regions IDAU for memory space
    - Up to three regions for the code flash
    - Up to two regions for the data flash
    - Up to three regions for the SRAM
    - IDAU setting is common for the CPU, DMAC, and DTC
  - SAU is not implemented
  - Individual Secure or Non-secure security attribution for each peripheral
  - Some peripherals support both Secure and Non-secure security attributions
- Device lifecycle management
- Three debug access levels
  - DBG2: The debugger connection is allowed, and no restriction to access memories and peripherals
  - DBG1: The debugger connection is allowed, and restricted to access only non-secure memory regions and peripherals
  - DBG0: The debugger connection is not allowed
- Key injection
- Cryptographic accelerator
  - See section 37, Renesas Secure IP (RSIP-E11A)
- Secure pin multiplexing
  - All I/O port pins can be configured individually as secure or non-secure
  - Pin functions of SCI3, SPI0, IIC0, GPT321 and GPT165 can be configured as secure pin
  - See section 18, I/O Ports

## 48.2 Arm TrustZone Security

### 48.2.1 Arm TrustZone Technology

Arm TrustZone technology divides the system and the application into Secure and Non-secure domains. Secure application can access both Secure and Non-secure memory and resources. Non-secure application can only access Non-secure memory and resources.

The system starts up in Secure state by default. The security state of CPU can be either Secure or Non-secure.

### 48.2.2 Memory Security Attribution

The code flash, the data flash, and the SRAM are divided into Secure (S), Non-secure (NS) and Non-secure callable (NSC) regions. These memory security attributions are set into the nonvolatile memory by the serial programming command when the device lifecycle is SSD state. These memory security attributions are loaded into the IDAU and the memory controller before application execution. These memory security attributions cannot be updated by application but can be through the dedicated registers.

The code flash can be divided in up to three regions in the linear mode and six regions in the dual mode. The area of three regions is the same between bank 0 and bank 1 in the dual mode. The data flash can be divided in up to two regions. The SRAM can be divided in up to three regions. Figure 48.1 shows the memory mapping. Table 48.1 shows the size of memory region.

Note: It is prohibited to place Secure or Non-secure callable regions in a block swappable area in the linear mode because the secure application will be placed in the non-secure region after block swapping.

Note: The contents in Secure or Non-secure callable regions must be the same in both bank 0 and bank 1 in the dual mode. Otherwise, the contents of secure or non-secure regions may not be latest by the field updating of non-secure region. See section 48.6. Field Updating in Dual Mode.

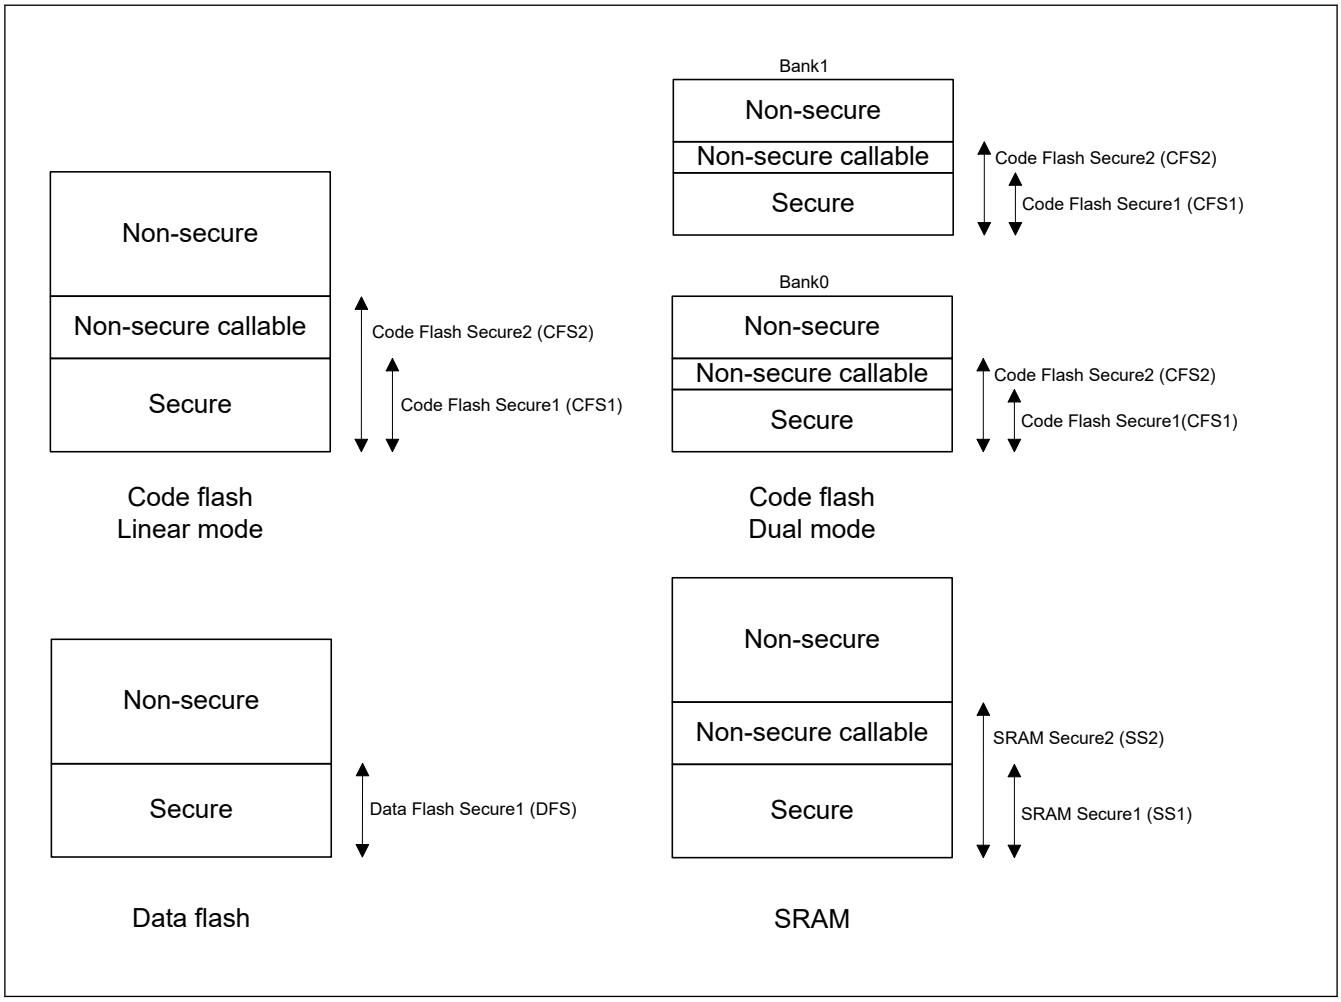

**Figure 48.1 Memory mapping**

**Table 48.1 Memory Region Size (1 of 2)**

| Memory region | | Start address | Size |
|---|---|---|---|
| Linear mode | Code flash secure | 0x0000_0000 | CFS1 × 1 KB |
| | Code flash non-secure callable | CFS1 × 1 KB | CFS2 × 32 KB - CFS1 × 1 KB |
| | Code flash non-secure | CFS2 × 32 KB | Code flash size - CFS2 × 32 KB |
| Dual mode | Code flash bank0 secure | 0x0000_0000 | CFS1 × 1 KB |
| | Code flash bank0 non-secure callable | CFS1 × 1 KB | CFS2 × 32 KB - CFS1 × 1 KB |
| | Code flash bank0 non-secure | CFS2 × 32 KB | Code flash size/2 - CFS2 × 32 KB |
| | Code flash bank1 secure | 0x0020_0000 | CFS1 × 1 KB |
| | Code flash bank1 non-secure callable | 0x0020_0000 + CFS1 × 1 KB | CFS2 × 32 KB - CFS1 × 1 KB |
| | Code flash bank1 non-secure | 0x0020_0000 + CFS2 × 32 KB | Code flash size/2 - CFS2 × 32 KB |
| Data flash secure | | 0x0800_0000 | DFS × 1 KB |
| Data flash non-secure | | 0x0800_0000 + DFS × 1 KB | Data flash size - DFS × 1 KB |
| SRAM secure | | 0x2000_0000 | SS1 × 1 KB |

**Table 48.1 Memory Region Size (2 of 2)**

| Memory region | Start address | Size |
|---|---|---|
| SRAM non-secure callable | 0x2000_0000 + SS1 × 1 KB | SS2 × 8 KB - SS1 × 1 KB |
| SRAM non-secure | 0x2000_0000 + SS2 × 8 KB | SRAM size - SS2 × 8 KB |

Table 48.2 shows the access permission of the memory.

**Table 48.2 Access permissions for memory**

| Memory | Secure access | Non-secure access |
|---|---|---|
| Code flash, data flash, SRAM configured as secure or non-secure callable | Allowed | Write ignored/Read ignored<br>TrustZone access error is generated |
| Code flash, data flash, SRAM configured as non-secure | Allowed | Allowed |

### 48.2.3 Peripheral Security Attribution

Each peripheral can be configured to be secure or non-secure.

Peripherals are divided into two types:

- Type-1 peripherals
- Type-2 peripherals

Type-1 peripherals have the one security attribution. Access to all registers is controlled by one security attribution. Type-1 peripheral security attribution is set to the PSARx (x = B to E) register by the secure application.

Type-2 peripherals have the security attribution for each register or for each bit. Access to each register or bit field is controlled according to these security attributions. Type-2 peripheral security attribution is set to the Security Attribution register in each module by the secure application. For the Security Attribution register, see sections in the User Manual for each peripheral.

Table 48.3 shows the classification of peripheral type.

**Table 48.3 Peripheral type classification**

| Type | Peripherals |
|---|---|
| Type-1 | SCI, SPI, USBFS, CANFD, IIC, RSIP-E11A, DOC, SSIE, CTSU, CRC, CAC, ADC12, DAC12, POEG, AGT, GPT, RTC, IWDT, WDT, UARTA, I3C, IrDA, SLCDC, ACMPLP |
| Type-2 | System control (Resets, LVD, Clock Generation Circuit, Low Power Modes), SRAM controller, DMAC, DTC, ICU, MPU, BUS, Security setting, ELC, I/O ports |
| Always non-secure | QSPI |

Table 48.4 shows the access permission of type-1 peripherals. The access permission of type-2 peripherals is different by peripherals. See the Register Description section of each peripheral.

**Table 48.4 The access permission of type-1 peripherals**

| Permission | Secure access | Non-secure access |
|---|---|---|
| Peripheral configured as secure | Allowed | Write ignored/Read ignored<br>TrustZone access error is generated |
| Peripheral configured as non-secure | Allowed | Allowed |

### 48.2.4 Flash Sequencer Security Attribution

The flash sequencer is used to program or erase the flash.

The flash sequencer has the special security attribution. Table 48.5 shows the access permission of the flash sequencer.

See section 45.12.3. Flash Memory Protection for TrustZone for the details.

**Table 48.5 Access permissions of the flash sequencer**

| | Secure access | Non-secure access |
|---|---|---|
| FACI command issuing area | Allowed | When the FACI command is issued to the secure region of code flash, data flash and option-setting memory:<br>● Issued FACI command is invalid<br>● Flash sequencer error is generated<br>When the FACI command is issued to the non-secure region of code flash, data flash and option-setting memory:<br>● Issued FACI command is valid |
| FSAR, FMEPROT, FBPROT1, FSUACR registers | Allowed | Write ignored/Readable<br>TrustZone access error is not generated |
| DFLCTL, MEMWAIT, PFBER registers, FACI registers except for read-only registers, FMEPROT, FBPROT1, FSUACR registers | Allowed | Configured by Flash Security Attribution register<br>When configured as Secure:<br>● Write ignored/Readable<br>● TrustZone access error is not generated<br>When configured as Non-secure:<br>● Allowed |

## 48.2.5 Address Space Security Attribution

Table 48.6 shows the security attribution of the address space.

**Table 48.6 Address Space Security Attribution**

| Region | Attribution |
|---|---|
| Code flash secure | Secure |
| Code flash non-secure callable | Non-secure callable |
| Code flash non-secure | Non-secure |
| Data flash secure | Secure |
| Data flash non-secure | Non-secure |
| SRAM secure | Secure |
| SRAM non-secure callable | Non-secure callable |
| SRAM non-secure | Non-secure |
| Peripherals | Exempt |
| External address space | Exempt |
| Other area | Exempt |

Note: Exempt: No check will be done. All bus transactions are propagated.

## 48.2.6 TrustZone Access Error

Table 48.7 shows the behavior for TrustZone access error. The behavior varies depending on the master or slave area to be accessed.

**Table 48.7 Behavior of TrustZone access error**

| Area | CPU | DMAC/DTC |
|---|---|---|
| Code flash, data flash, SRAM | Detection of SecureFault exception*2 | ● Transfer does not start<br>● Occurrence of NMI or reset*1<br>● Occurrence of interrupt (DMA_TRANSERR) |
| Other area | ● Detection of BusFault exception*2 *3<br>● Occurrence of NMI or reset*1*2 *3 | ● Stop transfer<br>● Occurrence of NMI or reset *1<br>● Occurrence of interrupt (DMA_TRANSERR) |

Note 1. NMI or reset is selected with TZFOAD.OAD bit.
Note 2. When TrustZone access error occurs by the debugger access, exception, NMI, or reset does not occur. Only error response is returned.
Note 3. These error behaviors do not occur for write access to the PHBIU or PLBIU address space which memory attribute is set to Early Write Acknowledgment by the ARM MPU.

## 48.3 Device Lifecycle Management

Device lifecycle identifies the current phase of the device and controls the capabilities of the debug interface, the serial programming interface and Renesas test mode. Figure 48.2 shows an illustration of the device lifecycle. Table 48.8 shows the lifecycle definition and capability in each lifecycle.

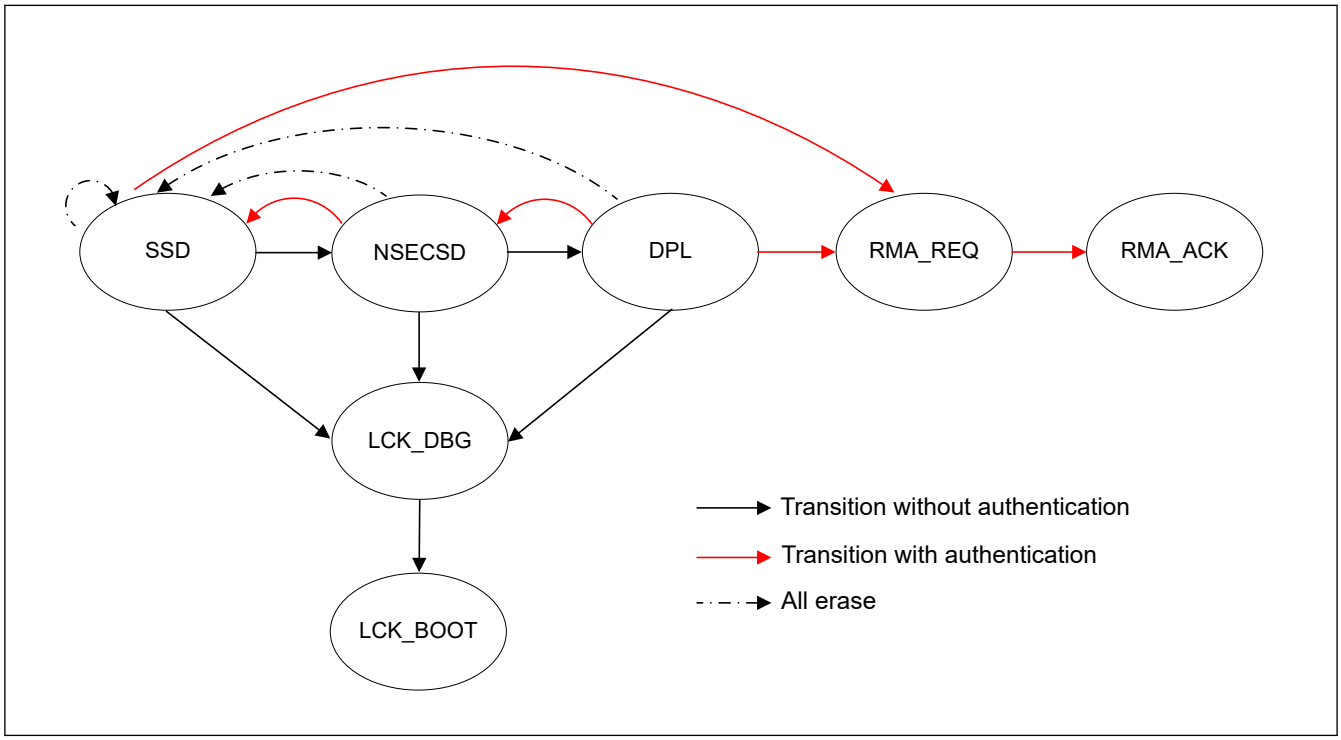

**Figure 48.2 Illustration of the device lifecycle**

**Table 48.8 Lifecycle definition and capability that can be used in each lifecycle (1 of 2)**

| Lifecycle | Definition | Debug level | Serial programming | Renesas test mode |
|---|---|---|---|---|
| SSD | “Secure Software Development”<br>The secure part of application is being developed | DBG2 | Available<br>Can program/erase/read all code/data flash area | Not available |
| NSECSD | “Non-SECure Software Development”<br>The non-secure part of application is being developed | DBG1 | Available<br>Can program/erase/read only non-secure code/data flash area | Not available |
| DPL | “DePLoyed”<br>The device is in-field | DBG0 | Available<br>Cannot access code/data flash area | Not available |

### 48.3.1 Changing the Lifecycle State

Use the serial programming commands to change the device lifecycle state. See the boot firmware application note for the detail of command. The lifecycle cannot be updated by application but can read through the dedicated registers.

As shown in Figure 48.2, there are three types lifecycle transition.

The first one is to change to lower debug access level or restrict the serial programming mode. This change can be done with no restriction.

Note: The debug interface is permanently disabled in LCK_DBG. After changed to LCK_DBG, the debug interface cannot be used forever.

Note: The debug interface and serial programming interface are permanently disabled in LCK_BOOT. After changed to LCK_BOOT, the debug interface and the serial programming interface cannot be used forever.

The second one is to change to higher debug access level or request for RMA. This change needs key authentication. The key length is 128 bits. The secure developer needs to inject two keys when the lifecycle is SSD state. One is “SECDBG_KEY” which is used to authentication to change the lifecycle from NSECSD to SSD. Other one is “RMA_KEY” which is used to authentication to change the lifecycle from SSD or DPL to RMA_REQ. The non-secure developer needs to inject one key when the lifecycle is NSECSD state. This is “NONSECDBG_KEY” which is used to authentication to change the lifecycle from DPL to NSECSD. See section 48.4. Key Injection for the detail of how to inject the key. The key authentication uses a challenge and response authentication or authentication using the unique ID. The authentication using the unique ID is available only transition to RMA_REQ. The following is the process of how to calculate the response, challenge and response authentication, or the authentication code using unique ID.

Response = AES-128 CMAC (RMA_KEY, 128-bit challenge)

Authentication code = AES-128 CMAC (RMA_KEY, 128-bit MCU unique ID)

Note: In case the key is not injected, these lifecycle changes cannot be done.

Note: In the lifecycle transition from NSECSD to SSD or form DPL to NSECSD, the contents on the flash memory are not erased.

Note: MCU does not respond after changing to higher debug access level or RMA_REQ. If you continue to use the serial programming commands, need to re-enter the boot mode after a reset. See the boot firmware application note for the detail.

Note: In the lifecycle transition to RMA_REQ, the contents on the flash memory except permanently locked block or setting or BPS_SEL register are erased. The contents in the permanently locked block or register can be read by Renesas at failure analysis. Permanently locked block means the block which programming and erasure is disabled permanently by PBPS, PBPS_SEC and BPS_SEL register. Permanently locked register means SAS register which programming and erasure is disabled permanently by FSPR bit.

The third one is all erase. This is done by an initialize command unless an initialize command itself is disabled. The lifecycle is back to SSD and the contents on the flash memory is erased. If there is permanently locked block or register, an initialize command does not execute. In case of the all bits of PBPS and PBPS_SEC register are 1 and FSPR bit is1, an initialize command is executable.

Note: The initialize command can be issued by everyone, so contents on the flash memory are easily erased. Developers who do not want this can invalidate the initialize command permanently by parameter setting command.

Note: MCU does not respond after executing the initialize command. If you continue to use the serial programming commands, need to re-enter the boot mode after a reset. See the boot firmware application note for the detail.

Note: Use the serial programming in boot mode (SCI interface) or boot mode (USB interface) to change the device lifecycle state. A serial programming connection is also required even if debugging using SWD communication.

### 48.3.2 Debug Access Level

There are three debug access levels, and the debug access level changes according to the lifecycle state.

- DBG2: The debugger connection is allowed, and no restriction to access memories and peripherals
- DBG1: The debugger connection is allowed, and restricted to access only non-secure memory regions and peripherals
- DBG0: The debugger connection is not allowed

### 48.3.3 Serial Programming

Whether a serial programmer can be connected and the range of flash memory that can be accessed depends on the lifecycle state as shown in Table 48.8. And the accepted serial programming command differs depending on the lifecycle state. See the boot firmware application note for the detail of command.

### 48.3.4 Lifecycle Change Example

The following example shows a typical lifecycle change.

**Secure developer**

- Set the memory security attribution of the code flash, data flash and SRAM by using the serial programming command
- Program the secure application by using the serial programming interface and debug the secure application. If the memory security attribution is not set, all area of the code flash, data flash and SRAM is secure.

Note: Configure the registers listed in Table 48.10 as non-secure only in NSECSD state. See section 48.8.1. Restrictions on setting the security attribution for details.

- Inject “SECDBG_KEY” and “RMA_KEY” by using the serial programming command (if required)
- Inject AES, ECC, HMAC keys listed in Table 48.9 (if required)
- Disable the all erase by using the serial programming command (if required)
- Change the lifecycle from SSD to NSECSD by using the serial programming command

**Non-secure developer**

- Program the non-secure application by using the serial programming interface and debug the non-secure application
- Inject “NONSECDBG_KEY” by using the serial programming command (if required)
- Inject AES, ECC, HMAC keys listed in Table 48.9 (if required)
- Disable the all erase by using the serial programming command (if required)
- Change the lifecycle to DPL by using the serial programming command

### 48.3.5 Failure Analysis

If the customer requests a failure analysis to Renesas, it is necessary to send the device after changing the lifecycle to RMA_REQ. If the lifecycle is not RMA_REQ, Renesas cannot do the failure analysis. Because RMA_REQ is permanent state, it cannot revert to the another state after changing to RMA_REQ. It is assumed to change to SSD or NSECSD and analyze before changing to RMA_REQ.

Devices sent to Renesas will not be returned to customers. The device will be discarded.

Note: As described in section 48.3.1. Changing the Lifecycle State, RMA_KEY is required to change the lifecycle to RMA_REQ. If the customer forgets the RMA_KEY, Renesas cannot do the failure analysis.

## 48.4 Key Injection

There are three steps required to inject a user key into the MCU.

1. Create the 256 bits installation key. This key is called User Factory Programming Key (UFPK) and used to encrypt a user key. Obtain the key of the wrapped version (W-UFPK) through the Renesas Key Wrapping Service.
2. Encrypt the user key using UFPK as the AES key.

3. Send W-UFPK and the encrypted user key to the MCU using serial programming interface. The sent user key is decrypted, wrapped with the hardware unique key, and then stored in the nonvolatile memory.

Figure 48.3 shows an illustration of key injection. Table 48.9 shows the keys that can be injected using serial programming interface.

User key is used for authentication during the lifecycle transition.

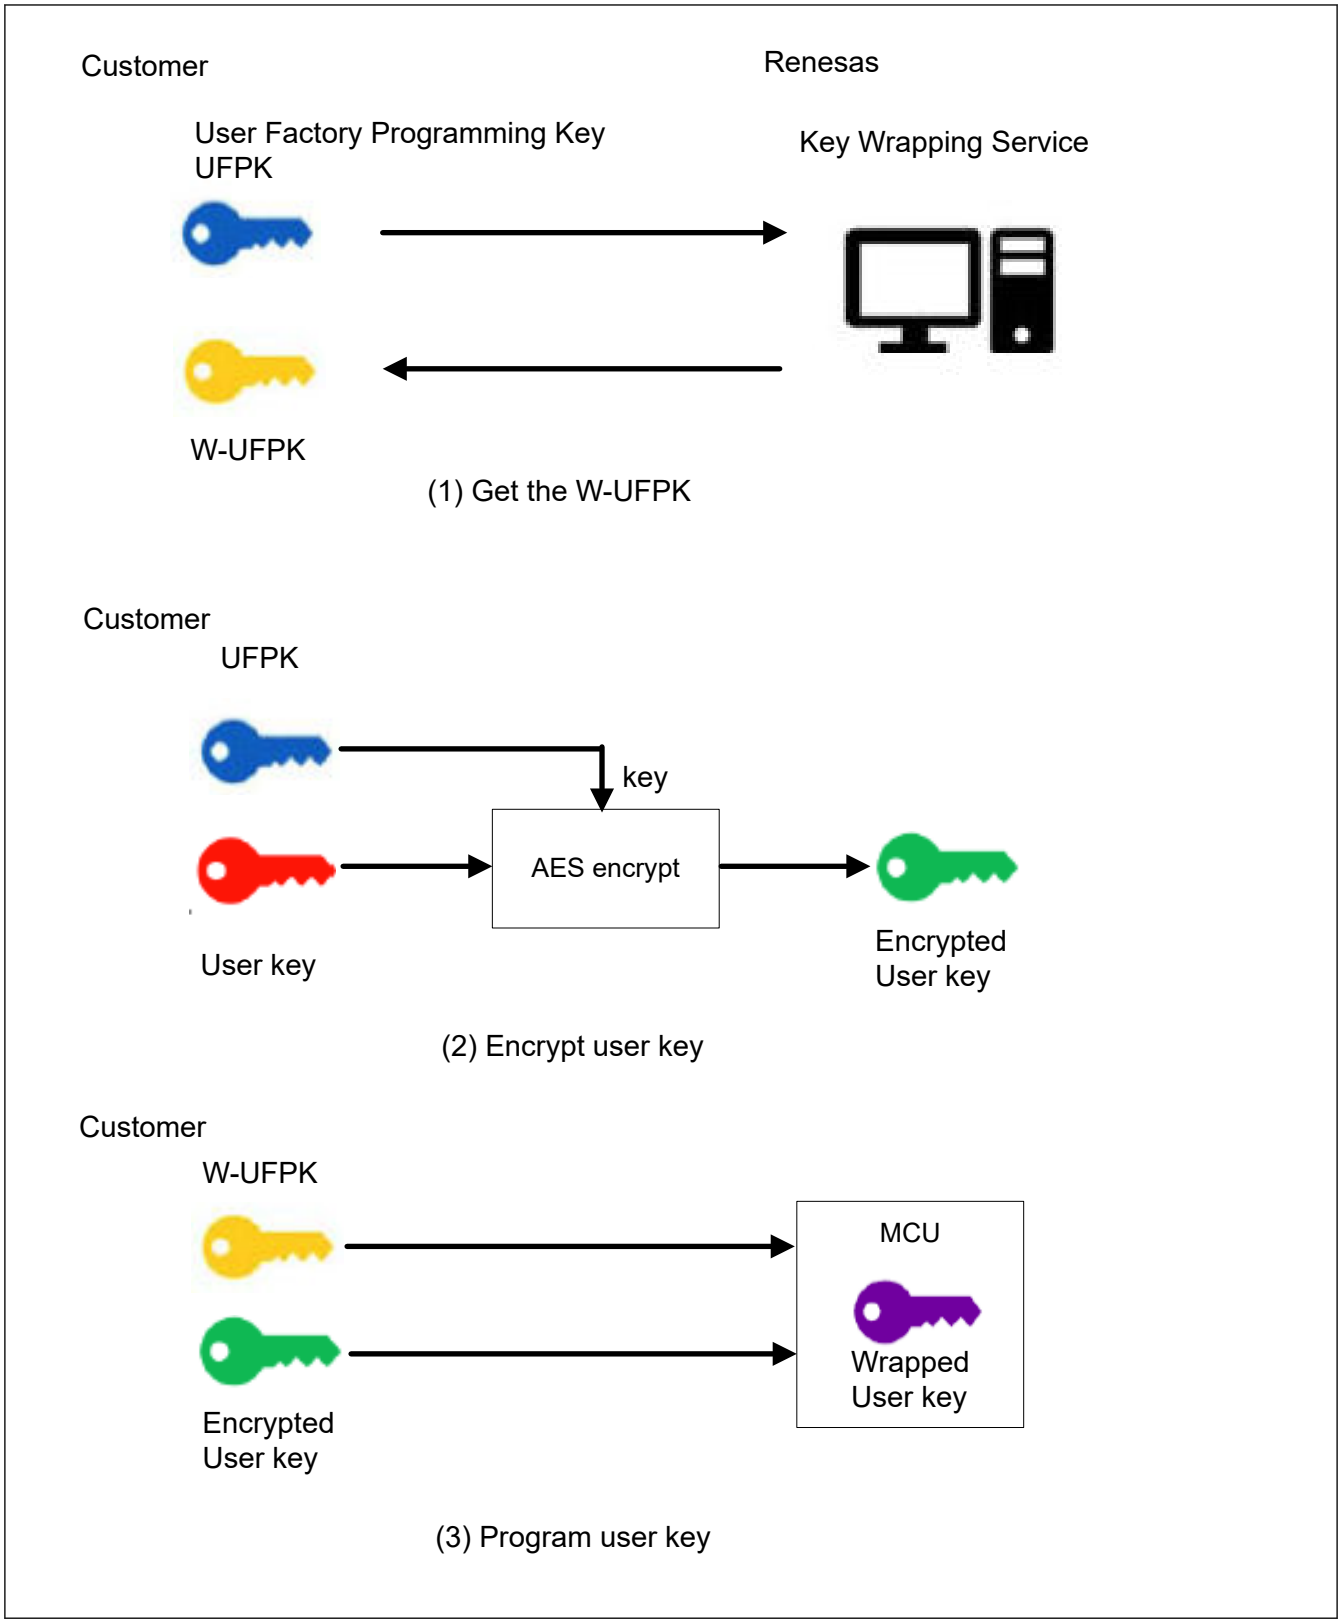

**Figure 48.3 Key injection**

**Table 48.9 The keys that can be injected using serial programming (1 of 2)**

| | |
|---|---|
| **Lifecycle transition** | SECDBG_KEY, NONSECDBG_KEY, RMA_KEY |
| **AES** | AES-128, AES-256 |
| **ECC** | ECC P256 (public and private) |

**Table 48.9 The keys that can be injected using serial programming (2 of 2)**

| | |
|---|---|
| **HMAC** | HMAC-SHA224, HMAC-SHA256 |

## 48.5 Secure Factory Programming

In addition to secure key injection support for injecting user keys (DLM, debug authentication, and application), the MCU supports the programming of a firmware image in ciphertext format to prevent assets from being leaked during production programming. This enables secure factory programming in a non-secure environment. Secure factory programming is supported by the boot firmware. Figure 48.4 shows an example of secure factory programming of an encrypted firmware image. The customer wraps the Image Encryption Key with the UFPK and encrypts the image with the Image Encryption Key using AES128-CCM. When the customer sends the W-UFPK, the wrapped Image Encryption Key, and encrypted image to the MCU through the serial programming interface, the MCU decrypts and programs the firmware image.

To further support secure factory programming in a non-secure environment, the DLM state, and Authentication Keys can all be set via a single boot firmware command. Points to note about this boot firmware command include:

- Encrypted firmware programming can be performed only when the MCU is in the SSD state.
- When transitioning the DLM state to DPL, this command injects both the SECDBG_KEY and NONSECDBG_KEY.
- When transitioning the DLM state to LCK_BOOT, this command does not inject either the SECDBG_KEY or the NONSECDBG_KEY.
- The SECDBG_KEY and NONSECDBG_KEY injected by this command must be wrapped with the same UFPK as the image encryption key.
- This command will set the security attributes of the memory.
- This command will erase all code and data flash area except option-setting memory before programming encrypted firmware image. If there are any permanently locked blocks, this command can not be executed.
- Prohibit to execute this command if the current register setting or write value to the registers related to startup area selection and startup bank selection are other than the following.
  - SAS.BTFLG = 1b
  - BANKSEL.BANKSWP[2:0] = 111b
  - BANKSEL_SEC.BANKSWP[2:0] = 111b
- All option-setting memory values must be included in the encrypted firmware image, including those not changed from their default values. However, if the following areas are write-protected, the write data in these areas should not be included in the image. If included, this command will terminate with an error.
  - SAS register

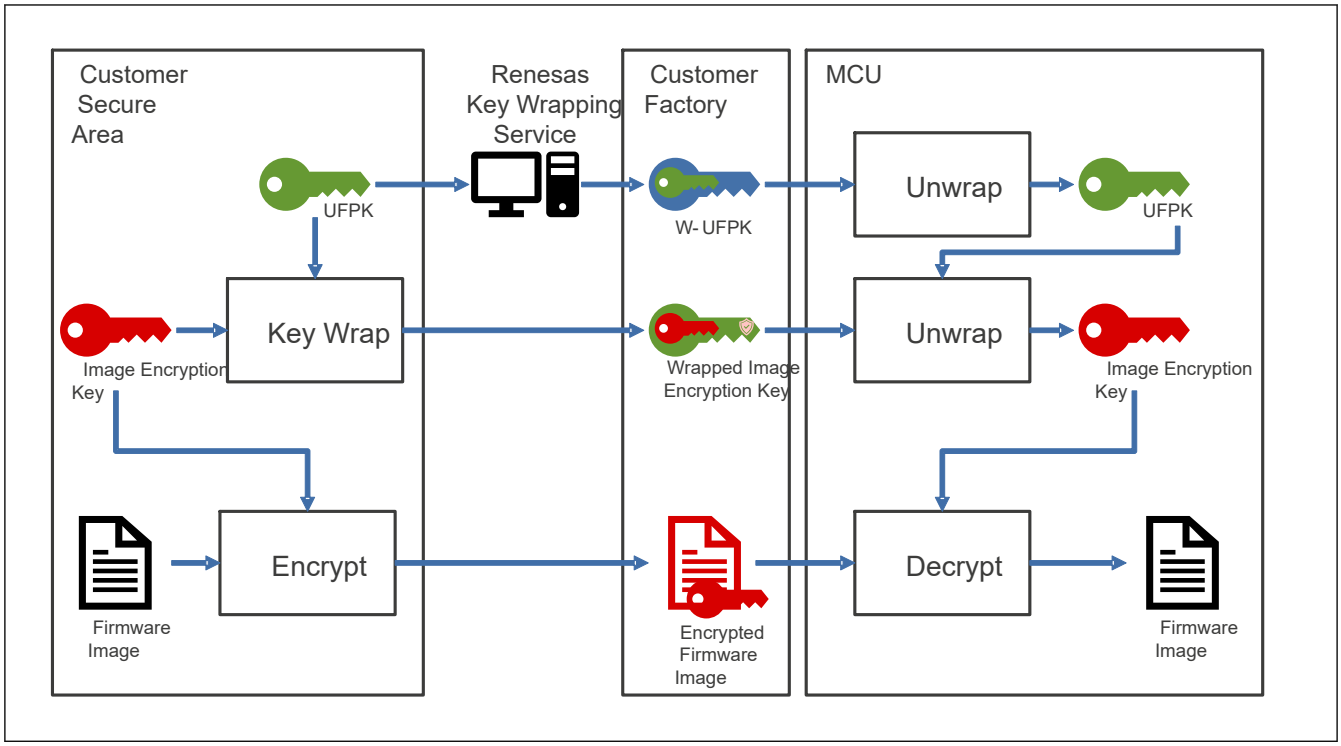

**Figure 48.4 Secure factory encrypted image programming**

## 48.6 Field Updating in Dual Mode

Be careful when performing in-field update of information to keep the contents of secure or non-secure regions after bank swapping in the dual mode. Figure 48.5 and Figure 48.6 shows the performing in-field update of information flow of secure or non-secure regions in the dual mode.

In this example of Figure 48.5, BANK0 is valid, and Version 1 information is stored in NS and S or NSC.

BANK1 is blank. To update the S or NSC information in the field to Version 2, first copy the version 1 information of BANK0 to NS, update the S or NSC to Version 2, and then execute the Bank swap.

In this example of Figure 48.6, BANK0 is valid, and Version 1 information is stored in NS and S or NSC. BANK1 is blank.

To update the NS information in the field and set it to Version 2, First of all, non-secure users should have the Secure user copy the version 1 information of BANK0 to BANK1.

After that, Non-secure user should update NS information to Version 2 and execute BANK swap.

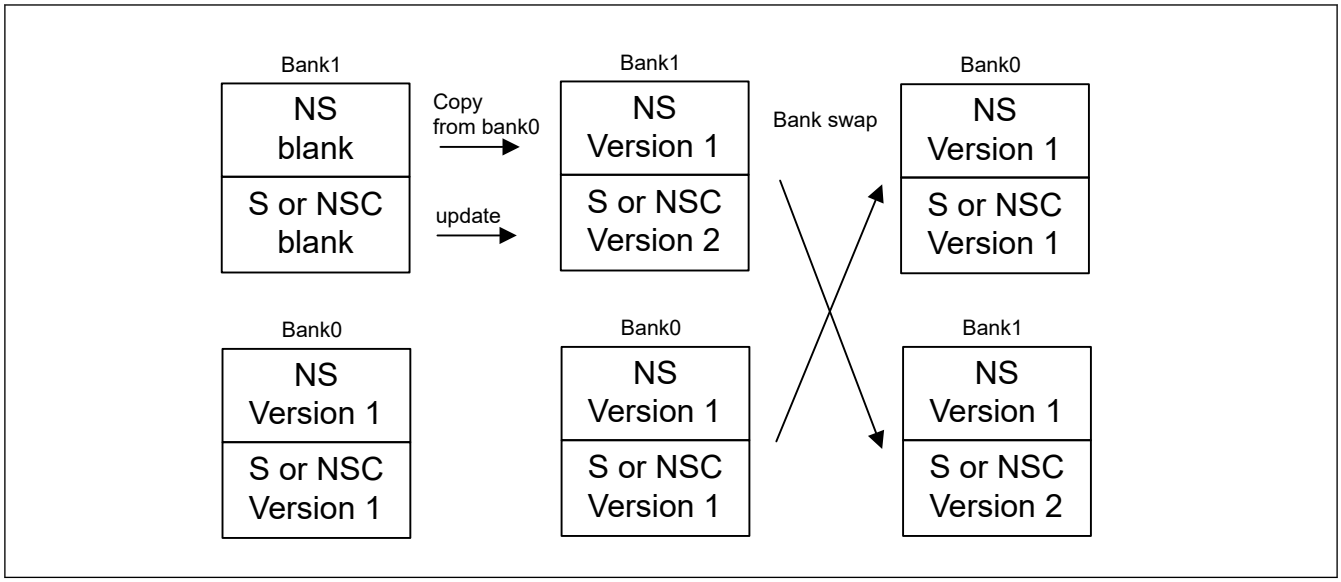

**Figure 48.5 The field updating flow of secure or non-secure callable regions**

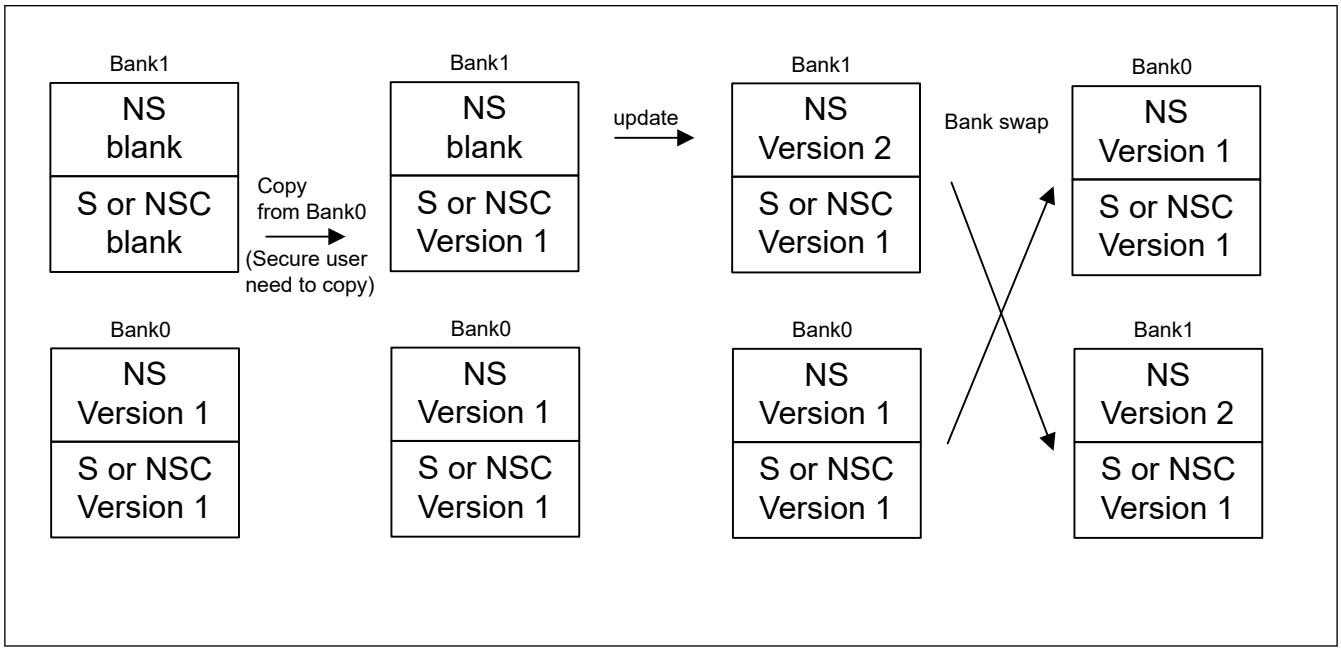

**Figure 48.6 The field updating flow of non-secure region**

## 48.7 Register Description

## 48.7.1 PSARB : Peripheral Security Attribution Register B

Base address: PSCU = 0x400E_0000

Offset address: 0x04

| Bit position: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

| 2 | — | This bit is read as 1. The write value should be 1. | R/W |
| 3 | MSSAR3 | The MSTPCRA.MSTPA0 Bit Security Attribution<br>0: Secure<br>1: Non-secure | R/W |
| 4 | MSSAR4 | The MSTPCRA.MSMSTPA16 Bit Security Attribution<br>0: Secure<br>1: Non-secure | R/W |
| 31:5 | — | These bits are read as 1. The write value should be 1. | R/W |

Note: Only Secure access can write to this register. Both Secure access and Non-secure read access are allowed but Non-secure write access is not allowed and TrustZone access error is not generated.
Note: This register is write-protected by PRCR register.

The MSSAR register specifies the security attribution for the corresponding bit in the Module Stop Control Register.

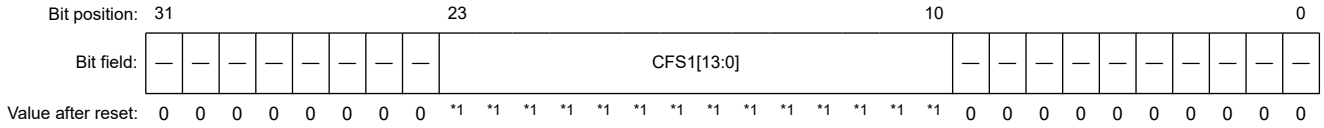
## 48.7.6 CFSAMONA : Code Flash Security Attribution Monitor Register A

Base address: PSCU = 0x400E_0000

Offset address: 0x18

| Bit position: | 31 | | | | | | | | 23 | | | | | | | | 15 | | | | | | | | | | | | | | | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | — | — | — | — | — | CFS2[8:0] | | | | | | | | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | *1 | *1 | *1 | *1 | *1 | *1 | *1 | *1 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 14:0 | — | These bits are read as 0. | R |
| 23:15 | CFS2[8:0] | Code Flash Secure area 2<br>Indicate the total area of secure region and non-secure callable region for code flash. | R |



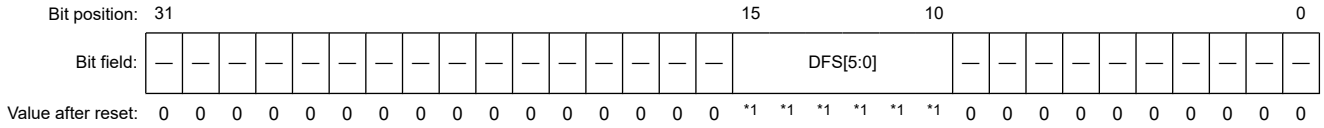
| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 31:24 | — | These bits are read as 0. | R |

Note: The CFSAMONA does not have security attribution.
Note 1. The value in a blank product is 0x1FF. It is set to the value written by your application.

## 48.7.7 CFSAMONB : Code Flash Security Attribution Monitor Register B

Base address: PSCU = 0x400E_0000

Offset address: 0x1C



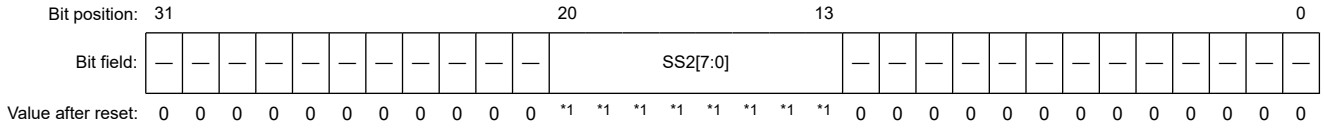
| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 9:0 | — | These bits are read as 0. | R |
| 23:10 | CFS1[13:0] | Code Flash Secure area 1<br>Indicate the area of secure region for code flash. | R |
| 31:24 | — | These bits are read as 0. | R |

Note: The CFSAMONB does not have security attribution.
Note 1. The value in a blank product is 0x3FFF. It is set to the value written by your application.

## 48.7.8 DFSAMON : Data Flash Security Attribution Monitor Register

Base address: PSCU = 0x400E_0000

Offset address: 0x20



| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 9:0 | — | These bits are read as 0. | R |
| 15:10 | DFS[5:0] | Data flash Secure area<br>Indicate the area of Secure region for data flash. | R |
| 31:16 | — | These bits are read as 0. | R |

Note: The DFSAMON does not have security attribution.
Note 1. The value in a blank product is 0x3F. It is set to the value written by your application.

## 48.7.9 SSAMONA : SRAM Security Attribution Monitor Register A

Base address: PSCU = 0x400E_0000

Offset address: 0x24

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 12:0 | — | These bits are read as 0. | R |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 20:13 | SS2[7:0] | SRAM Secure area 2<br>Indicate the total area of Secure region and non-secure callable region for SRAM. | R |
| 31:21 | — | These bits are read as 0. | R |

Note: The SSAMONA does not have security attribution.
Note 1. The value in a blank product is 0xFF. It is set to the value written by your application.

## 48.7.10 SSAMONB : SRAM Security Attribution Monitor Register B

Base address: PSCU = 0x400E_0000

Offset address: 0x28

| Bit position: | 31 | | | | | | | | | | | 20 | | | | | | | | | | 10 | | | | | | | | | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | — | — | — | — | — | — | — | — | SS1[10:0] | | | | | | | | | | — | — | — | — | — | — | — | — | — | — |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | *1 | *1 | *1 | *1 | *1 | *1 | *1 | *1 | *1 | *1 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 9:0 | — | These bits are read as 0. | R |
| 20:10 | SS1[10:0] | SRAM secure area 1<br>Indicate the area of secure region for SRAM. | R |
| 31:21 | — | These bits are read as 0. | R |

Note: The SSAMONB does not have security attribution.
Note 1. The value in a blank product is 0x7FF. It is set to the value written by your application.

## 48.7.11 DLMMON : Device Lifecycle Management State Monitor Register

Base address: PSCU = 0x400E_0000

Offset address: 0x2C

| Bit position: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit position: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | — | — | — | — | — | — | — | — | — | DLMMON[3:0] | | | |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | DLM status value | | | |

| Bit | Symbol | Function | R/W |
|---|---|---|---|

| 31:4 | — | These bits are read as 0. The write value should be 0. | R |

Note: The DLMMON does not have security attribution.

## 48.7.12 TZFSAR : TrustZone Filter Security Attribution Register

Base address: CPSCU = 0x4000_8000

Offset address: 0x180

| Bit position: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — |
| Value after reset: | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 |

| Bit position: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | TZFSA0 |
| Value after reset: | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 0 | TZFSA0 | Security attributes of registers for TrustZone Filter<br>0: Secure<br>1: Non-secure | R/W |
| 31:1 | — | These bits are read as 1. | R |

Note: Only Secure access can write to this register. Both Secure access and Non-secure read access are allowed but Non-secure write access is not allowed and TrustZone access error is not generated.

Note: This register is write-protected by PRCR register.

### TZFSA0 bit (Security attributes of registers for TrustZone Filter)

Security attributes of register for TZFOAD and TZFPT registers.

## 48.7.13 TZFOAD : TrustZone Filter Operation After Detection Register

Base address: TZF = 0x4000_0E00

Offset address: 0x00

| Bit position: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | KEY[7:0] | | | | | | | | — | — | — | — | — | — | — | OAD |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 0 | OAD | Operation after detection<br>0: Non-maskable interrupt<br>1: Reset | R/W |
| 7:1 | — | These bits are read as 0. The write value should be 0. | R/W |
| 15:8 | KEY[7:0] | KeyCode<br>This bit is used to enable or disable writing of the OAD bit. | W |

Note: If the security attribution is configured as Secure:
- Secure access and Non-secure read access are allowed
- Non-secure write access is ignored, and TrustZone access error is not generated.

If the security attribution is configured as Non-secure:
- Secure and Non-secure access are allowed.

### OAD bit (Operation after detection)

The OAD bit is specified to generate either reset or non-maskable interrupt when the access to the protect region is detected by the TrustZone Filter.

When the OAD bit is set, write 0xA5 in the KEY[7:0] bits at the same time.

### KEY[7:0] bits (KeyCode)

The KEY[7:0] bits are used to enable or disable writing of the OAD bit. When writing the OAD bit, write 0xA5 in the KEY[7:0] bits at the same time.

When the KEY[7:0] bits value except 0xA5 is written in, the OAD bit is not updated.

The KEY[7:0] bits are read always as 0x00.

## 48.7.14 TZFPT : TrustZone Filter Protect Register

Base address: TZF = 0x4000_0E00

Offset address: 0x04

| Bit position: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Bit field: | KEY[7:0] | | | | | | | | — | — | — | — | — | — | — | PROTECT |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function | R/W |
|---|---|---|---|
| 0 | PROTECT | Protection of register<br>0: All Bus TrustZone Filter register writing is protected. Read is possible.<br>1: All Bus TrustZone Filter register writing is possible. | R/W |
| 7:1 | — | These bits are read as 0. The write value should be 0. | R/W |
| 15:8 | KEY[7:0] | KeyCode<br>This bit is used to enable or disable writing of the PROTECT bit. | W |

Note: If the security attribution is configured as Secure:
- Secure access and Non-secure read access are allowed
- Non-secure write access is ignored, and TrustZone access error is not generated.

If the security attribution is configured as Non-secure:
- Secure and Non-secure access are allowed.

### PROTECT bit (Protection of register)

The PROTECT bit controls enable or disable writing to the corresponding registers to be protected. TZFOAD register is protected by PROTECT.

When the PROTECT bit is set, write 0xA5 in the KEY[7:0] bits at the same time.

### KEY[7:0] bits (KeyCode)

The KEY[7:0] bits are used to enable or disable writing of the PROTECT bit. When writing the PROTECT bit, write 0xA5 in the KEY[7:0] bits at the same time.

When the KEY[7:0] bits value except 0xA5 is written in, the PROTECT bit is not updated.

The KEY[7:0] bits are read always as 0x00.

# 48.8 Usage Notes

## 48.8.1 Restrictions on setting the security attribution

To set the software breakpoint, the debugger need to re-program the flash. Table 48.10 shows the registers that the debugger sets to re-program the flash. If the security attribution of the register listed in Table 48.10 is configured as secure, the debugger cannot set the software breakpoint in NSECSD state because the debugger cannot change the register setting. Secure developper need to configure the registers listed in Table 48.10 as non-secure only in NSECSD state.

**Table 48.10 The registers that the debugger sets to re-program the flash**

| Function name | Register name |
|---|---|
| Clock Generation Circuit | SCKDIVCR, SCKSCR, PLLCCR, PLLCR, HOCOCR, MOCOCR |
| Low-Power modes | OPCCR, SOPCCR |

### 48.8.2 SAU setting

After reset, all of address space is marked as Secure by SAU default setting. SAU_CTRL register should be set to 0x2 to enable the IDAU security attribution. That is, after setting SAU_CTRL register to 0x2, the address space security attribution becomes as shown in Table 48.6.

# 49. Electrical Characteristics

Unless otherwise specified, minimum and maximum values are guaranteed by either design simulation, characterization results or test in production.

Supported peripheral functions and pins differ from one product name to another.

Unless otherwise specified, the electrical characteristics of the MCU are defined under the following conditions:

$VCC^{*1}$ = AVCC0 = VCC_USB = 1.6 to 3.6 V, VREFH0 = 1.6 V to AVCC0

VSS = AVSS0 = VREFL0 = VSS_USB = 0 V, Ta = $T_{opr}$

Note 1. The typical condition is set to VCC = 3.3 V.

Figure 49.1 shows the timing conditions.

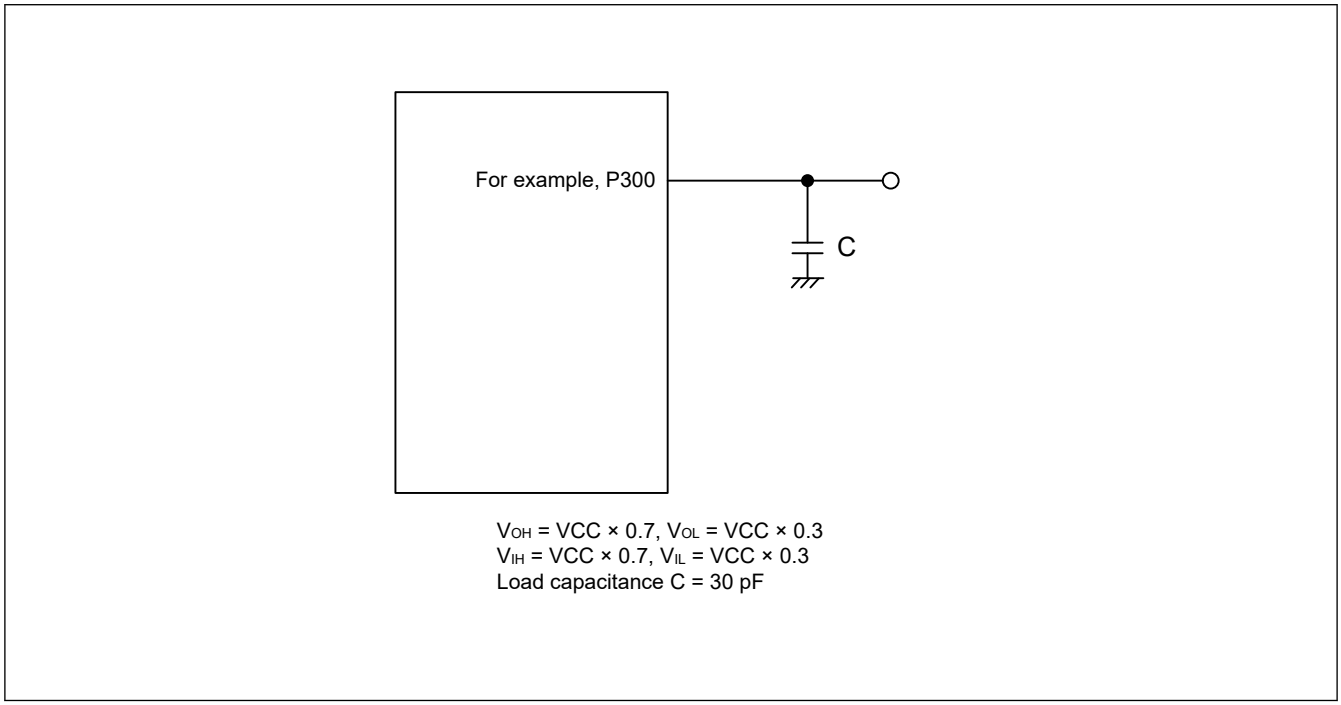

**Figure 49.1 Input or output timing measurement conditions**

The measurement conditions of the timing specifications for each peripheral are recommended for the best peripheral operation. However, make sure to adjust driving abilities for each pin to meet the conditions of your system.

## 49.1 Absolute Maximum Ratings

**Table 49.1 Absolute maximum ratings (1 of 2)**

| Parameter | | Symbol | Value | Unit |
|---|---|---|---|---|
| Power supply voltage | | VCC, VCC_USB*2 | -0.5 to +4.0 | V |
| Input voltage | 5V-tolerant ports*1 | $V_{in}$ | -0.3 to +6.5 | V |
| | P000 to P004, P010, P011 | $V_{in}$ | -0.3 to AVCC0 + 0.3 | V |
| | Others | $V_{in}$ | -0.3 to VCC + 0.3 | V |
| Reference power supply voltage | | VREFH0 | -0.3 to +4.0 | V |
| Analog power supply voltage | | AVCC0*2 | -0.5 to +4.0 | V |
| Analog input voltage | When AN000 to AN006 are used | $V_{AN}$ | -0.3 to AVCC0 + 0.3 | V |
| | When AN017 to AN025 are used | | -0.3 to VCC + 0.3 | V |

**Table 49.1 Absolute maximum ratings (2 of 2)**

| Parameter | | Symbol | Value | Unit |
|---|---|---|---|---|
| LCD voltage | VL1 voltage | $V_{L1}$ | -0.3 to $V_{L4}$ + 0.3*5 | V |
| | VL2 voltage | $V_{L2}$ | -0.3 to $V_{L4}$ + 0.3*5 | V |
| | VL3 voltage | $V_{L3}$ | -0.3 to $V_{L4}$ + 0.3*5 | V |
| | VL4 voltage | $V_{L4}$ | -0.3 to +6.5 | V |
| Operating temperature*3 *4 | | $T_{opr}$ | -40 to +105<br>-40 to +125 | °C |
| Storage temperature | | $T_{stg}$ | -55 to +140 | °C |

Note 1. Ports P301, P302, P400, P401, and P407 are 5V-tolerant.
Do not input signals or an I/O pull-up power supply while the device is not powered. The current injection that results from input of such a signal or I/O pull-up might cause malfunction and the abnormal current that passes in the device at this time might cause degradation of internal elements.
Note 2. Connect AVCC0 and VCC_USB to VCC
Note 3. See section 49.2.1. Tj/Ta Definition.
Note 4. The upper limit of the operating temperature is 105 °C or 125 °C, depending on the product. For details, see section 1.3. Part Numbering.
Note 5. Must be 6.5 V or lower.

**Caution: Permanent damage to the MCU may result if absolute maximum ratings are exceeded.**

**To preclude any malfunctions due to noise interference, insert capacitors with high frequency characteristics between the VCC and VSS pins, between the AVCC0 and AVSS0 pins, and between the VREFH0 and VREFL0 pins when VREFH0 is selected as the high potential reference voltage for the ADC12. Place capacitors of the following value as close as possible to every power supply pin and use the shortest and heaviest possible traces:**

- **VCC and VSS: about 0.1 µF**
- **AVCC0 and AVSS0: about 0.1 µF**
- **VREFH0 and VREFL0: about 0.1 µF**

**Also, connect capacitors as stabilization capacitance.**

**Connect the VCL pin and VCL0 pin to a VSS pin by a 4.7 µF capacitor. Each capacitor must be placed close to the pin.**

**Table 49.2 Recommended operating conditions**

| Parameter | Symbol | | Min | Typ | Max | Unit |
|---|---|---|---|---|---|---|
| Power supply voltages | VCC*1 *2 | When USB is not used | 1.6 | — | 3.6 | V |
| | | When USB is used | 3.0 | — | 3.6 | V |
| | VSS | | — | 0 | — | V |
| USB power supply voltage | VCC_USB | | — | VCC | — | V |
| | VSS_USB | | — | 0 | — | V |
| Analog power supply voltages | AVCC0*1 *2 | | 1.6 | — | 3.6 | V |
| | AVSS0 | | — | 0 | — | V |
| | VREFH0 | When used as ADC12 Reference | 1.6 | — | AVCC0 | V |
| | VREFL0 | | — | 0 | — | V |

Note 1. Use AVCC0 and VCC under the following conditions:
AVCC0 = VCC
Note 2. When powering on the VCC and AVCC0 pins, power them on at the same time or the VCC pin first and then the AVCC0 pins.
When powering off the VCC and AVCC0 pins, power them off at the same time or the AVCC0 pin first and then the VCC pins.

## 49.2 DC Characteristics

## 49.2.1 Tj/Ta Definition

**Table 49.3 DC characteristics**

Conditions: Products with operating temperature (Ta) -40 to +125 °C

| Parameter | Symbol | Typ | Max | Unit | Test conditions |
|---|---|---|---|---|---|
| Permissible junction temperature | Tj | — | 140 | °C | High-speed mode<br>Middle-speed mode<br>Low-speed mode<br>Subosc-speed mode |
| | | | 105*1 | | |

Note: Make sure that Tj = $T_a$ + θja × total power consumption (W), where total power consumption = (VCC - $V_{OH}$) × Σ$I_{OH}$ + $V_{OL}$ × Σ$I_{OL}$ + $I_{CC}$max × VCC.

Note 1. The upper limit of operating temperature is 105 °C or 125 °C, depending on the product. For details, see section 1.3. Part Numbering. If the part number shows the operation temperature at 85 °C, then the maximum value of Tj is 105 °C, otherwise it is 140 °C.

## 49.2.2 I/O $V_{IH}$, $V_{IL}$

**Table 49.4 I/O $V_{IH}$, $V_{IL}$**

Conditions: VCC = AVCC0 = 1.6 to 3.6 V

| Parameter | | Symbol | Min | Typ | Max | Unit | Test Conditions |
|---|---|---|---|---|---|---|---|
| Schmitt trigger input voltage | IIC (SDA0_A, SCL0_A)/I3C (except for SMBus)*1 | $V_{IH}$ | VCC × 0.7 | — | 5.8 | V | — |
| | | $V_{IL}$ | — | — | VCC × 0.3 | | |
| | | $ΔV_T$ | VCC × 0.10 | — | — | | VCC = 2.7 V to 3.6 V |
| | | | VCC × 0.05 | — | — | | VCC = 1.6 V to2.7 V |
| | RES, NMI Other peripheral input pins excluding IIC (SDA0_A, SCL0_A)/I3C | $V_{IH}$ | VCC × 0.8 | — | — | | — |
| | | $V_{IL}$ | — | — | VCC × 0.2 | | |
| | | $ΔV_T$ | VCC × 0.10 | — | — | | VCC = 2.7 V to 3.6 V |
| | | | VCC × 0.05 | — | — | | VCC = 1.6 V to 2.7 V |
| Input voltage except for Schmitt trigger input pin | IIC/I3C (SMBus)*2 | $V_{IH}$ | 2.0 | — | — | | VCC = 1.8 to 3.6 V |
| | | $V_{IL}$ | — | — | 0.5 | | VCC = 1.8 to 3.6 V |
| | 5V-tolerant ports*3 | $V_{IH}$ | VCC × 0.8 | — | 5.8 | | — |
| | | $V_{IL}$ | — | — | VCC × 0.2 | | |
| | P000 to P004, P010, P011 | $V_{IH}$ | AVCC0 × 0.8 | — | — | | |
| | | $V_{IL}$ | — | — | AVCC0 × 0.2 | | |
| | Input port pins except for P000 to P004, P010, P011 | $V_{IH}$ | VCC × 0.8 | — | — | | |
| | | $V_{IL}$ | — | — | VCC × 0.2 | | |

Note 1. SCL0_A, SDA0_A, I3C_SCL, I3C_SDA (total 4 pins)
Note 2. SCL0_A, SDA0_A, SCL0_B, SDA0_B, I3C_SCL, I3C_SDA (total 6 pins)
Note 3. P400, P401, P407, P301, P302 (total 5 pins)

## 49.2.3 I/O $I_{OH}$, $I_{OL}$

**Table 49.5 I/O $I_{OH}$, $I_{OL}$ (1 of 8)**

Conditions: VCC = AVCC0 = 1.6 to 3.6 V

| Parameter | Symbol | Min | Typ | Max | Unit | Test conditions |
|---|---|---|---|---|---|---|
| Permissible output current (average value per pin) | $I_{OH}$ | — | — | −4.0 | mA | |
| | $I_{OL}$ | — | — | 8.0 | mA | |
| Permissible output current (max value per pin) | $I_{OH}$ | — | — | −4.0 | mA | |
| | $I_{OL}$ | — | — | 8.0 | mA | |

**Table 49.5 I/O $I_{OH}$, $I_{OL}$ (2 of 8)**

Conditions: VCC = AVCC0 = 1.6 to 3.6 V

| Parameter | | | Symbol | Min | Typ | Max | Unit | Test conditions |
|---|---|---|---|---|---|---|---|---|
| Permissible output current (max value total pins)*1 | All products | Total of ports P000 to P004, P010, P011 | $\Sigma I_{OH}$ (max) | — | — | −30 | mA | AVCC0 = 2.7 to 3.6 V |
| | | | | — | — | −8 | mA | AVCC0 = 1.8 to 2.7 V |
| | | | | — | — | −4 | mA | AVCC0 = 1.6 to 1.8 V |
| | | | $\Sigma I_{OL}$ (max) | — | — | 50 | mA | AVCC0 = 2.7 to 3.6 V |
| | | | | — | — | 4 | mA | AVCC0 = 1.8 to 2.7 V |
| | | | | — | — | 2 | mA | AVCC0 = 1.6 to 1.8 V |
| | | Total of ports P212, P213 | $\Sigma I_{OH}$ | — | — | −8.0 | mA | VCC = 2.7 to 3.6 V |
| | | | | — | — | −2 | mA | VCC = 1.8 to 2.7 V |
| | | | | — | — | −1 | mA | VCC = 1.6 to 1.8 V |
| | | | $\Sigma I_{OL}$ | — | — | 16.0 | mA | VCC = 2.7 to 3.6 V |
| | | | | — | — | 1.2 | mA | VCC = 1.8 to 2.7 V |
| | | | | — | — | 0.6 | mA | VCC = 1.6 to 1.8 V |
| | 100 pin QFP, 100 pin BGA | Total of ports P400 to P415, P700, P708 | $\Sigma I_{OH}$ (max) | — | — | −30 | mA | VCC = 2.7 to 3.6 V |
| | | | | — | — | −8 | mA | VCC = 1.8 to 2.7 V |
| | | | | — | — | −4 | mA | VCC = 1.6 to 1.8 V |
| | | | $\Sigma I_{OL}$ (max) | — | — | 50 | mA | VCC = 2.7 to 3.6 V |
| | | | | — | — | 4 | mA | VCC = 1.8 to 2.7 V |
| | | | | — | — | 2 | mA | VCC = 1.6 to 1.8 V |

**Table 49.5 I/O $I_{OH}$, $I_{OL}$ (3 of 8)**

Conditions: VCC = AVCC0 = 1.6 to 3.6 V

| Parameter | | | Symbol | Min | Typ | Max | Unit | Test conditions |
|---|---|---|---|---|---|---|---|---|
| Permissible output current (max value total pins)*1 | 100 pin QFP, 100 pin BGA | Total of ports P204 to P211, P814, P815 | $\Sigma I_{OH}$ (max) | — | — | −30 | mA | VCC = 2.7 to 3.6 V |
| | | | | — | — | −8 | mA | VCC = 1.8 to 2.7 V |

| | | | $\Sigma I_{OL}$ (max) | — | — | 50 | mA | VCC = 2.7 to 3.6 V |
| | | | | — | — | 4 | mA | VCC = 1.8 to 2.7 V |
| | | | | — | — | 2 | mA | VCC = 1.6 to 1.8 V |
| | | Total of ports P100 to P103, P500, P506 to P509 | $\Sigma I_{OH}$ (max) | — | — | −30 | mA | VCC = 2.7 to 3.6 V |
| | | | | — | — | −8 | mA | VCC = 1.8 to 2.7 V |
| | | | | — | — | −4 | mA | VCC = 1.6 to 1.8 V |
| | | | $\Sigma I_{OL}$ (max) | — | — | 50 | mA | VCC = 2.7 to 3.6 V |
| | | | | — | — | 4 | mA | VCC = 1.8 to 2.7 V |
| | | | | — | — | 2 | mA | VCC = 1.6 to 1.8 V |
| | | Total of all output pin | $\Sigma I_{OH}$ (max) | — | — | −60 | mA | |
| | | | $\Sigma I_{OL}$ (max) | — | — | 100 | mA | |

Note 1. Specification under conditions where the duty factor ≤ 70%.
The output current value that has changed to the duty factor > 70% the duty ratio can be calculated with the following expression (when changing the duty factor from 70% to n%).
Total output current of pins = ($I_{OH}$ × 0.7)/(n × 0.01)
<Example> Where n = 80% and $I_{OH}$ = −30.0 mA
Total output current of pins = (−30.0 × 0.7)/(80 × 0.01) ≅ −26.2 mA
However, the current that is allowed to flow into one pin does not vary depending on the duty factor.

**Caution: To protect the reliability of the MCU, the output current values should not exceed the values in Table 49.5.**

## 49.2.4 I/O $V_{OH}$, $V_{OL}$, and Other Characteristics

**Table 49.6 I/O $V_{OH}$, $V_{OL}$ (1)**

Conditions: VCC = AVCC0 = 2.7 to 3.6 V

| Parameter | | Symbol | Min | Typ | Max | Unit | Test conditions |
|---|---|---|---|---|---|---|---|
| Output voltage | P400, P401 | $V_{OH}$ | VCC − 0.27 | — | — | V | $I_{OH}$ = −3.0 mA |
| | | | VCC − 0.8 | — | — | | $I_{OH}$ = −4.0 mA |

| | Other input pins | | — | — | 15 | | |

Note 1. P301, P302, P400, P401, and P407 (total 5 pins)

## 49.2.5 Operating and Standby Current

**Table 49.10 High-speed mode current**

| Parameter | | Symbol | Typ | Max | Unit | Test Conditions |
|---|---|---|---|---|---|---|
| Maximum*1 *2 | | ICC*3 | — | 75 | mA | ICLK = 80 MHz<br>PCLKA = 80 MHz<br>PCLKB = 40 MHz<br>PCLKC = 40 MHz<br>PCLKD = 80 MHz<br>FCLK = 40 MHz |
| CoreMark®*4 *5 | | | 20.4 | — | mA | |
| | | | 255 | — | uA/MHz | |
| Normal mode | All peripheral clocks enabled, and cache disable. While (1) code is executing from flash*5 | | 30.7 | — | mA | |
| | | | 384 | — | uA/MHz | |
| | All peripheral clocks disabled, and cache disable. While (1) code is executing from flash*4 *5 | | 13.4 | — | mA | |
| | | | 168 | — | uA/MHz | |
| Sleep mode | All peripheral clocks enabled, and cache disable*5 | | 22.8 | — | mA | |
| | All peripheral clocks disabled, and cache disable.*4 *5 | | 5.63 | — | mA | |
| Increase during BGO operation*6 | | | 2.74 | | mA | |

Note: Supply current values are with all output pins unloaded and all input pull-up MOSs in the off state.
Note: This does not include the BGO operation.
Note 1. Measured with clocks supplied to the peripheral functions.
Note 2. PLL output frequency = 80MHz. The clock source is MOSC.
Note 3. ICC depends on f (ICLK) as follows (reference data).
ICC Max. = 0.80 × f + 9.51 (max. operation)
ICC Typ. = 0.15 × f + 2.37 (normal operation, all peripheral clocks disabled and cache disabled)
ICC Typ. = 0.26 × f + 3.39 (sleep mode, all peripheral clocks enabled and cache disabled)
Note 4. PCLKA, PCLKB, PCLKC, and PCLKD are set to divided by 64 (1.25 MHz).
Note 5. PLL is stopped, and HOCO output frequency = 80 MHz
Note 6. This is the increase for programming or erasure of the flash memory for data storage during program execution.

**Table 49.11 Middle-speed mode current**

| Parameter | | Symbol | Typ | Max | Unit | Test conditions |
|---|---|---|---|---|---|---|
| Normal mode | All peripheral clocks enabled, and cache disable. While (1) code is executing from flash | ICC*1 | 4.38 | — | mA | ICLK = 8 MHz<br>PCLKA = 8 MHz<br>PCLKB = 8 MHz<br>PCLKC = 8 MHz<br>PCLKD = 8 MHz<br>FCLK = 8 MHz |
| | All peripheral clocks disabled, and cache disable. While (1) code is executing from flash*2 | | 1.79 | — | | |
| Sleep mode | All peripheral clocks enabled, and cache disable. | | 3.40 | — | | |
| | All peripheral clocks disabled, and cache disable.*2 | | 0.81 | — | | |
| Increase during BGO operation*3 | | | 2 | | | |

Note: Supply current values are with all output pins unloaded and all input pull-up MOSs in the off state.
Note: This does not include the BGO operation.
Note: The clock source is MOCO.
Note 1. ICC depends on f (ICLK) as follows (reference data).
ICC Typ. = 0.49 × f + 0.48 (normal operation, all peripheral clocks disabled and cache disabled)
Note 2. PCLKA, PCLKB, PCLKC, and PCLKD are set to divided by 64 (125 kHz).
Note 3. This is the increase for programming or erasure of the flash memory for data storage during program execution.

**Table 49.12 Low-speed mode current**

| Parameter | | Symbol | Typ | Max | Unit | Test conditions |
|---|---|---|---|---|---|---|
| Normal mode | All peripheral clocks enabled, and cache disable. While (1) code is executing from flash | ICC*1 | 1.10 | — | mA | ICLK = 1 MHz<br>PCLKA = 1 MHz<br>PCLKB = 1 MHz<br>PCLKC = 1 MHz<br>PCLKD = 1 MHz<br>FCLK = 1 MHz |
| | All peripheral clocks disabled, and cache disable. While (1) code is executing from flash*2 | | 0.33 | — | | |
| Sleep mode | All peripheral clocks enabled, and cache disable. | | 0.94 | — | | |
| | All peripheral clocks disabled, and cache disable.*2 | | 0.22 | — | | |

Note: Supply current values are with all output pins unloaded and all input pull-up MOSs in the off state.
Note: This does not include the BGO operation.
Note: The clock source is MOSC.
Note 1. ICC depends on f (ICLK) as follows (reference data).
ICC Typ. = 0.33 × f + 0.02 (normal operation, all peripheral clocks disabled and cache disabled)
Note 2. PCLKA, PCLKB, PCLKC, and PCLKD are set to divided by 64 (15.625 kHz).

**Table 49.13 Subosc-speed mode current**

| Parameter | | Symbol | Typ | Max | Unit | Test conditions |
|---|---|---|---|---|---|---|
| Normal mode | All peripheral clocks enabled, and cache disable. While (1) code is executing from flash | ICC | 20 | — | µA | ICLK = 32.768 kHz<br>PCLKA = 32.768 kHz<br>PCLKB = 32.768 kHz<br>PCLKC = 32.768 kHz<br>PCLKD = 32.768 kHz<br>FCLK = 32.768 kHz |
| | All peripheral clocks disabled, and cache disable. While (1) code is executing from flash*1 | | 8.73 | — | | |
| Sleep mode | All peripheral clocks enabled, and cache disable. | | 15 | — | | |
| | All peripheral clocks disabled, and cache disable.*1 | | 4.26 | — | | |

Note: Supply current values are with all output pins unloaded and all input pull-up MOSs in the off state.
Note: This does not include the BGO operation.
Note: The clock source is LOCO.
Note 1. PCLKA, PCLKB, PCLKC, and PCLKD are set to divided by 64 (512 Hz).

**Table 49.14 Software Standby mode current**

| Parameter | | Symbol | Typ | Max | Unit | Test conditions |
|---|---|---|---|---|---|---|
| All SRAMs (0x2000_0000 to 0x2000_FFFF) are on | Ta = 25°C | ICC | 1.70 | — | µA | — |
| | Ta = 55°C | | 6.00 | — | | |
| | Ta = 85°C | | 21.40 | — | | |
| | Ta = 105°C | | 50.00 | — | | |
| | Ta = 125°C | | 117.00 | — | | |
| Only 16KB SRAM (0x2000_0000 to 0x2000_3FFF) is on | Ta = 25°C | | 1.65 | — | | |

Note: Supply current values do not include output charge/discharge current from all pins. The values apply when internal pull-up MOS transistors are in the off state. The supply current is total current flowing into VCC.
Note: The IWDT and LVD are not operating.
Note: If you want to operate RTC, please add the value of Table 49.15.

**Table 49.15 Increase current by RTC operation**

| Parameter | | Symbol | Typ | Max | Unit | Test conditions |
|---|---|---|---|---|---|---|
| LOCO*1 | | ICC | 0.47 | — | µA | |
| SOSC*2 (normal mode) | RTC (normal operation mode) | | 0.89 | — | | SOMCR.SODRV[1:0] = 00b RCR4.ROPSEL = 0 |
| | RTC (low-consumption clock mode) | | 0.79 | — | | SOMCR.SODRV[1:0] = 00b RCR4.ROPSEL = 1 |
| SOSC*2 (Low power mode 3) | RTC (normal operation mode) | | 0.27 | — | | SOMCR.SODRV[1:0] = 11b RCR4.ROPSEL = 0 |
| | RTC (low-consumption clock mode) | | 0.11 | — | | SOMCR.SODRV[1:0] = 11b RCR4.ROPSEL = 1 |

Note 1. Includes the low-speed on-chip oscillator current.
Note 2. Includes the sub-clock oscillation circuit current.

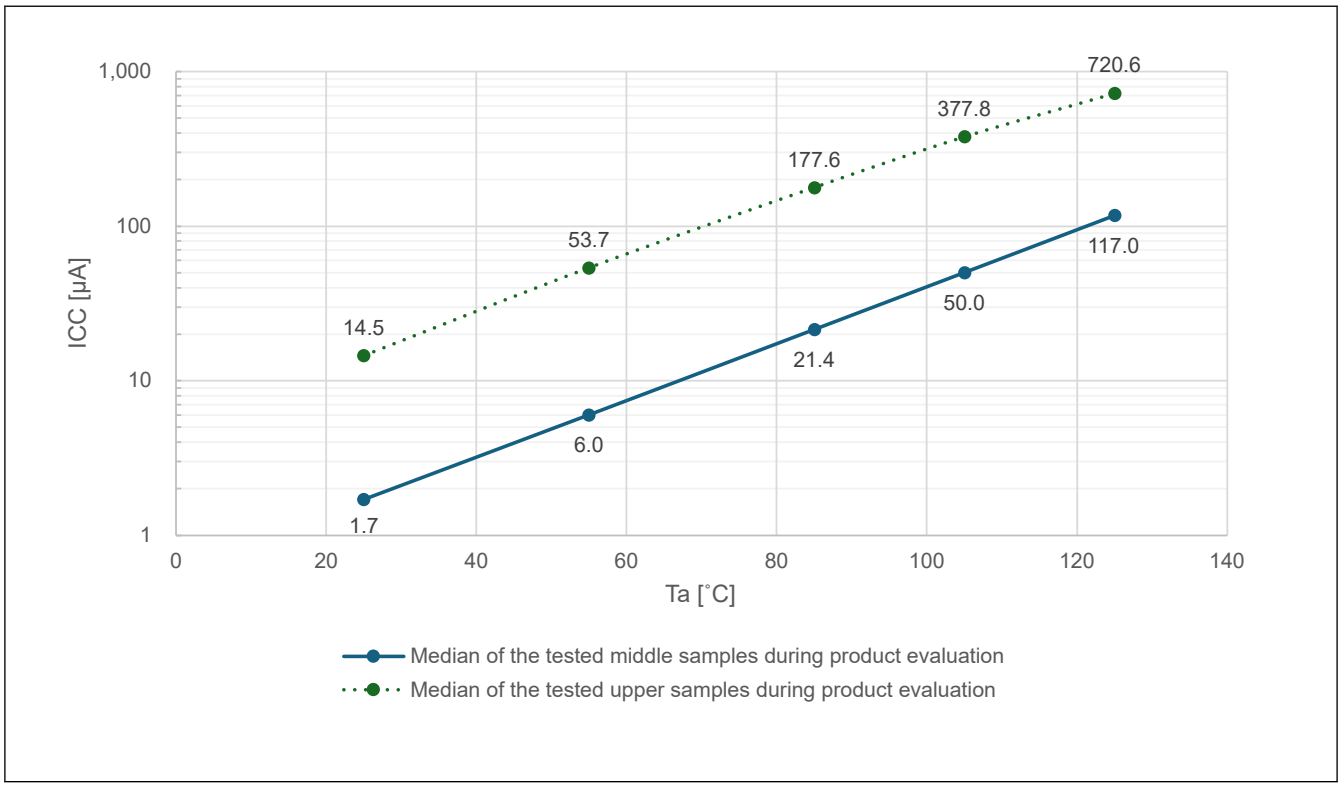
**Table 49.16 Analog current (1 of 2)**

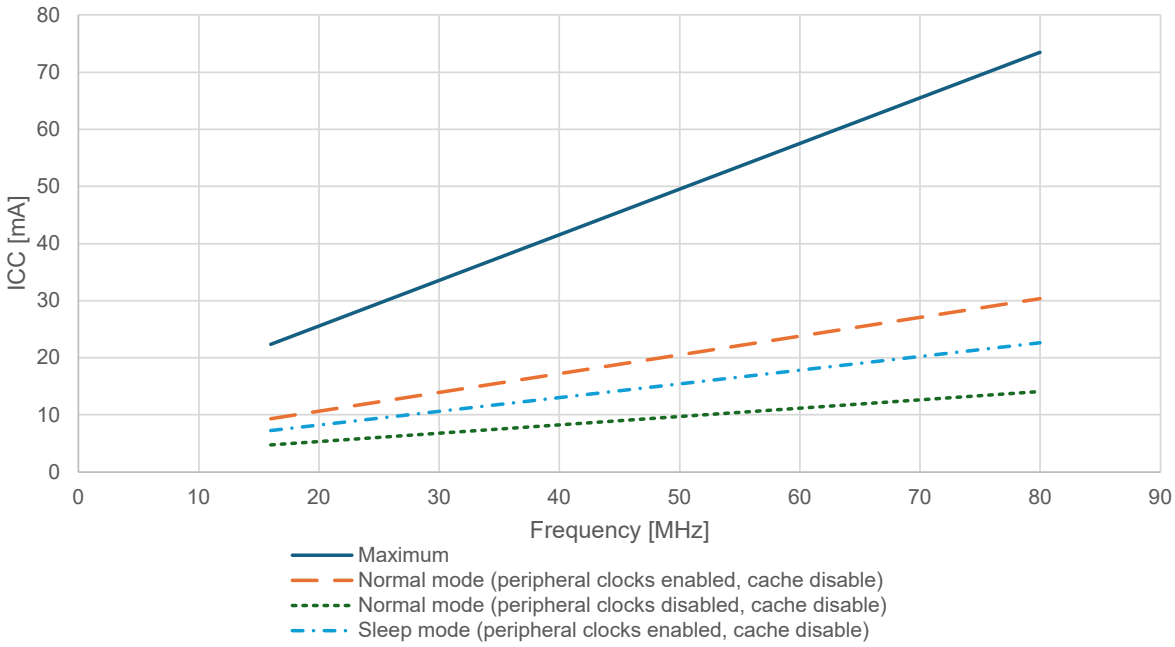
| Parameter | | Symbol | Typ | Max | Unit | Test conditions |
|---|---|---|---|---|---|---|
| Analog power supply current | During 12-bit A/D conversion (at high-speed A/D conversion mode) | $I_{AVCC0}$ | 0.57 | 1 | mA | — |
| | During 12-bit A/D conversion (at low-power A/D conversion mode) | | 0.24 | 0.8 | mA | — |
| | During 12-bit D/A conversion*1 | | 0.45 | 1 | mA | — |
| | Waiting for 12-bit A/D and 12-bit D/A conversion*2 | | — | 4 | µA | — |
| Reference power supply current (VREFH0) | During 12-bit A/D conversion | $I_{REFH0}$ | — | 150 | µA | — |
| | Waiting for 12-bit A/D conversion | | — | 0.5 | µA | — |
| Temperature Sensor (TSN) operating current | | $I_{TSN}$ | 110 | — | µA | — |
| Low-power Analog Comparator (ACMPLP) operating current | Window comparator (high-speed mode) | $I_{ACMPLP}$ | 12.5 | 25 | µA | — |
| | Comparator (high-speed mode) | | 6.7 | 20 | µA | — |
| | Comparator (low-speed mode) | | 1.86 | 6 | µA | — |

**Table 49.16 Analog current (2 of 2)**

| Parameter | | | Symbol | Typ | Max | Unit | Test conditions |
|---|---|---|---|---|---|---|---|
| LCD operating current | External resistance division method*3 | | $I_{LCD}$*4 | 0.04 | — | µA | fLCD = fSUB (32.768 kHz)<br>LCD clock = 128 Hz (LCDC0 = 0x07)<br>1/3 bias four-time-slices<br>VCC = 3.0 V<br>VL4 = 3.0 V |
| | Internal voltage boosting method | VL1 reference VL1AMP enabled (VLCD = 0x04) | | 0.59 | — | µA | |
| | | VL2 reference VL2AMP enabled (VLCD = 0x84) | | 0.48 | — | µA | |
| | Capacitor split method | VCC reference | | 0.3 | — | µA | |
| | | VL4 reference VL4AMP enabled | | 0.47 | — | µA | |
| USBFS operating current | Low speed | Operating | $I_{USBFS}$ | 1.36 | 6 | mA | — |
| | | Standby | | 69 | 200 | µA | — |
| | Full speed | Operating | | 1.68 | 8 | mA | — |
| | | Standby | | 551 | 860 | µA | — |

Note 1. The reference power supply current is included in the power supply current value for D/A conversion.
Note 2. When the MCU is in Software Standby mode or the MSTPCRD.MSTPD16 (ADC120 module-stop bit) is in the module-stop state.
Note 3. Not including the current flowing into the external division resistor when using the external resistance division method.
Note 4. Setting 20 pins as the segment function and blinking all





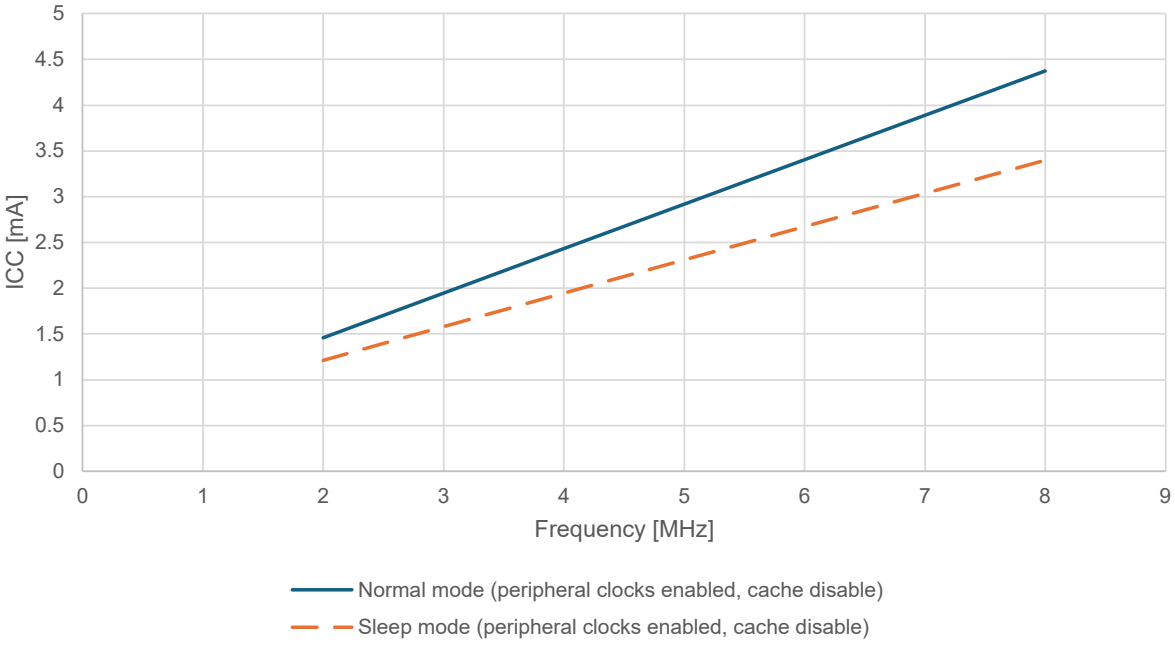


**Figure 49.2 Temperature dependency in Software Standby mode (reference data)**

Note: Average value of the tested middle samples during product evaluation (typical condition).

**Figure 49.3 Frequency dependency in High-speed mode (reference data)**

Note: Average value of the tested middle samples during product evaluation (typical condition).

**Figure 49.4 Frequency dependency in Middle-speed mode (reference data)**

## 49.2.6 VCC Rise and Fall Gradient and Ripple Frequency

**Table 49.17 Rise and fall gradient characteristics**

Conditions: VCC = AVCC0 = 0 to 3.6 V

| Parameter | | Symbol | Min | Typ | Max | Unit | Test conditions |
|---|---|---|---|---|---|---|---|
| Power-on VCC rising gradient | Voltage monitor 0 reset disabled at startup | SrVCC | 0.02 | — | 2 | ms/V | — |
| | Voltage monitor 0 reset enabled at startup*1 *2 | | | | — | | |
| | SCI/USB/SWD boot mode*2 | | | | 2 | | |

Note 1. When OFS1.LVDAS = 0.
Note 2. At boot mode, the reset from voltage monitor 0 is disabled regardless of the value of OFS1.LVDAS bit.

**Table 49.18 Rising and falling gradient and ripple frequency characteristics**

Conditions: VCC = AVCC0 = 1.6 to 3.6 V
The ripple voltage must meet the allowable ripple frequency $f_{r(VCC)}$ within the range between the VCC upper limit (3.6 V) and lower limit (1.6 V).
When the VCC change exceeds VCC ± 10%, the allowable voltage change rising and falling gradient dt/dVCC must be met.

| Parameter | Symbol | Min | Typ | Max | Unit | Test conditions |
|---|---|---|---|---|---|---|
| Allowable ripple frequency | $f_{r(VCC)}$ | — | — | 10 | kHz | Figure 49.5<br>$V_{r\ (VCC)} \leq VCC \times 0.2$ |
| | | — | — | 1 | MHz | Figure 49.5<br>$V_{r\ (VCC)} \leq VCC \times 0.08$ |
| | | — | — | 10 | MHz | Figure 49.5<br>$V_{r\ (VCC)} \leq VCC \times 0.06$ |
| Allowable voltage change rising and falling gradient | dt/dVCC | 1.0 | — | — | ms/V | When VCC change exceeds VCC ± 10% |

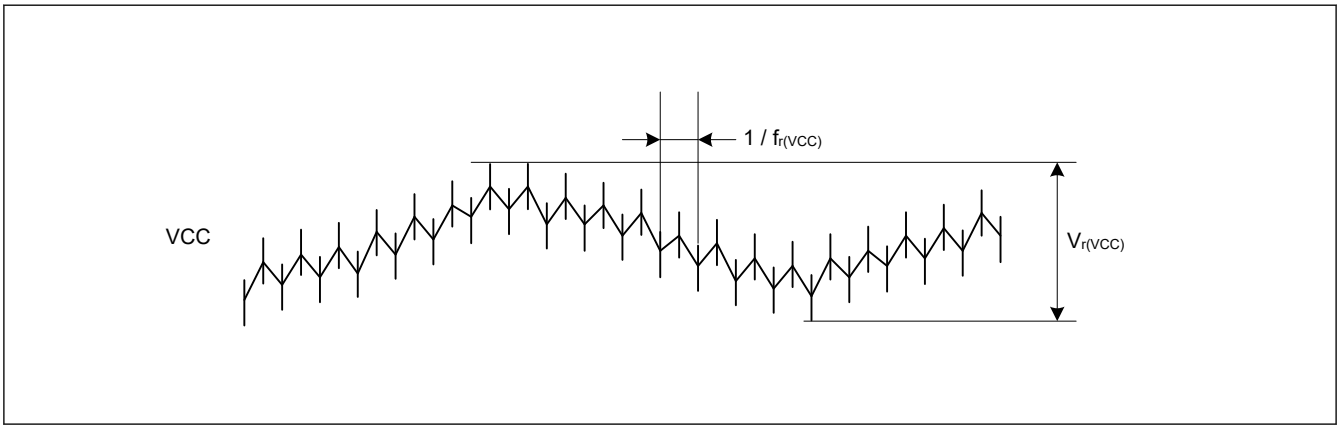

**Figure 49.5 Ripple waveform**

## 49.2.7 Thermal Characteristics

Maximum value of junction temperature (Tj) must not exceed the value of section 49.2.1. Tj/Ta Definition.

Tj is calculated by either of the following equations.

- Tj = Ta + θja × Total power consumption
- Tj = Tt + Ψjt × Total power consumption

  Tj : Junction temperature (°C)

  Ta : Ambient temperature (°C)

  Tt : Top center case temperature (°C)

  θja : Thermal resistance of “Junction”-to-“Ambient” (°C/W)

  Ψjt : Thermal resistance of “Junction”-to-“Top center case” (°C/W)

- Total power consumption = Voltage × (Leakage current + Dynamic current)
- Leakage current of IO = Σ (IOL × VOL) / Voltage + Σ (|IOH| × |VCC – VOH|) / Voltage
- Dynamic current of IO = Σ IO (Cin + Cload) × IO switching frequency × Voltage

  Cin: Input capacitance

  Cload: Output capacitance

Regarding θja and Ψjt, see Table 49.19.

**Table 49.19 Thermal resistance**

| Parameter | Package | Symbol | Value*1 | Unit | Test conditions |
|---|---|---|---|---|---|
| Thermal resistance | 48-pin QFN | θja | 17.7 | °C/W | JESD 51-2 and 51-7 compliant |
| | 48-pin LQFP | | 49.8 | | |
| | 64-pin LQFP | | 42.3 | | |
| | 100-pin LQFP | | 47.1 | | |
| | 48-pin QFN | Ψjt | 0.05 | °C/W | JESD 51-2 and 51-7 compliant |
| | 48-pin LQFP | | 1.21 | | |
| | 64-pin LQFP | | 0.71 | | |
| | 100-pin LQFP | | 0.71 | | |

Note 1. The values are reference values when the 4-layer board is used. Thermal resistance depends on the number of layers or size of the board. For details, see the JEDEC standards.

### 49.2.7.1 Calculation guide of $I_{CC}$max

Table 49.20 shows the power consumption of each unit.

**Table 49.20 Power consumption of each unit (1 of 2)**

| Dynamic current/ Leakage current | MCU Domain | Category | Item | Frequency [MHz] | Current [uA/MHz] | Current*1 [mA] |
|---|---|---|---|---|---|---|
| Leakage current | Analog | LDO and Leak*2 | Ta = 25 °C*3 | — | — | 1.81 |
| | | | Ta = 55 °C*3 | — | — | 1.87 |
| | | | Ta = 75 °C*3 | — | — | 1.96 |
| | | | Ta = 85 °C*3 | — | — | 2.07 |
| | | | Ta = 95 °C*3 | — | — | 2.15 |
| | | | Ta = 105 °C*3 | — | — | 2.34 |
| | | | Ta = 115 °C*3 | — | — | 2.55 |
| | | | Ta = 125 °C*3 | — | — | 2.83 |

**Table 49.20 Power consumption of each unit (2 of 2)**

| Dynamic current/ Leakage current | MCU Domain | Category | Item | Frequency [MHz] | Current [uA/MHz] | Current*1 [mA] |
|---|---|---|---|---|---|---|
| Dynamic current | CPU | Operation with Flash and SRAM | Coremark | 80 | 84.16 | 6.73 |
| | Peripheral Unit | Timer | GPT16 (4ch)*4 | 80 | 19.02 | 1.52 |
| | | | GPT32 (2ch)*4 | 80 | 10.87 | 0.87 |
| | | | POEG (4 Groups)*4 | 40 | 7.45 | 0.30 |
| | | | AGT (2ch)*4 | 40 | 8.08 | 0.32 |
| | | | RTC | 40 | 3.82 | 0.15 |
| | | | WDT | 40 | 2.91 | 0.12 |
| | | | IWDT | 40 | 1.31 | 0.05 |
| | | Communication interfaces | USBFS | 40 | 35.13 | 1.41 |
| | | | SCI (6ch)*4 | 80 | 56.32 | 4.51 |
| | | | Irda*5 | 80 | 10.49 | 0.84 |
| | | | IIC | 40 | 6.33 | 0.25 |
| | | | I3C | 80 | 30.35 | 2.43 |
| | | | CANFD | 40 | 19.97 | 0.80 |
| | | | SPI | 80 | 12.31 | 0.98 |
| | | | QSPI | 80 | 6.35 | 0.51 |
| | | | SSIE | 40 | 8.49 | 0.34 |
| | | | UARTA (2ch)*4 | 40 | 16.70 | 0.67 |
| | | Analog | ACMPLP (2ch)*4 | 40 | 3.41 | 0.14 |
| | | | ADC12 | 80 | 8.01 | 0.64 |
| | | | DAC12 | 80 | 2.02 | 0.16 |
| | | Human machine interfaces | CTSU | 40 | 7.08 | 0.28 |
| | | | SLCDC | 40 | 9.54 | 0.38 |
| | | Event link | ELC | 40 | 5.25 | 0.21 |
| | | Security | RSIP-E04A | 40 | 300.61 | 12.02 |
| | | Data processing | CRC | 80 | 6.17 | 0.49 |
| | | | DOC | 80 | 0.90 | 0.07 |
| | | System | CAC | 40 | 3.24 | 0.13 |
| | | DMA | DMAC (per 1ch) | 80 | 24.96 | 2.00 |
| | | | DTC | 80 | 41.83 | 3.35 |

Note 1. The values are guaranteed by design.
Note 2. LDO and Leak are internal voltage regulator's current and MCU's leakage current. It is selected according to the temperature of Ta.
Note 3. Δ(Tj-Ta) = 20 °C is considered to measure the current.
Note 4. To determine the current consumption per channel, group or unit, divide Current [mA] by the number of channels, groups or units.
Note 5. Includes current for 1 channel of SCI

Table 49.21 shows the outline of operation for each unit.

**Table 49.21 Outline of operation for each unit (1 of 2)**

| Peripheral | Outline of operation |
|---|---|
| GPT | Operating modes is set to saw-wave PWM mode. GPT is operating with PCLKD. |
| POEG | Only clear module stop bit. |
| AGT | AGT is operating with PCLKB. |

**Table 49.21 Outline of operation for each unit (2 of 2)**

| Peripheral | Outline of operation |
|---|---|
| RTC | RTC is operating with LOCO. |
| WDT | WDT is operating with PCLKB. |
| IWDT | IWDT is operating with IWDTCLK. |
| USBFS | Transfer type is set to bulk transfer. USBFS is operating using Full-speed transfer (12 Mbps). |
| SCI | SCI is transmitting data in clock synchronous mode. |
| IrDA | SCI is transmitting data in clock asynchronous mode. IrDA is only clear module stop bit. |
| IIC | Communication format is set to I2C-bus format. IIC is transmitting data in master mode. |
| I3C | Communication format is set to I3C SDR format. I3C is transmitting data in master mode (5 MHz). |
| CANFD | CANFD is transmitting and receiving data in self-test mode 1. |
| SPI | SPI mode is set to SPI operation (4-wire method). SPI master/slave mode is set to master mode. SPI is transmitting 32-bit width data. |
| QSPI | QSPI is issuing Fast Read Quad I/O Instruction. |
| SSIE | Communication mode is set to Master. System word length is set to 32 bits. Data word length is set to 20 bits. SSIE is transmitting data using I2S format. |
| UARTA | UARTA is transmitting 8-bit width data. |
| ACMPLP | ACMPLP is operating. |
| ADC12 | Resolution is set to 12-bit accuracy. Data register is set to A/D-converted value addition mode. ADC12 is converting the analog input in continuous scan mode. |
| DAC12 | DAC12 is outputting the conversion result while updating the value of data register. |
| CTSU | CTSU is operating in self-capacitance single scan mode. |
| SLCDC | SLCDC is operating in A wave, 1/2 bias method, 2-time slice and External resistance division method |
| ELC | Only clear module stop bit. |
| RSIP-E04A | RSIP is doing self-test operation. |
| CRC | CRC is generating CRC code using 32-bit CRC32-C polynomial. |
| DOC | DOC is operating in data comparison mode. |
| CAC | Measurement target clocks is set to PCLKB. Measurement reference clocks is set to PCLKB. CAC is measuring the clock frequency accuracy. |
| DMAC | Bit length of transfer data is set to 32 bits. Transfer mode is set to block transfer mode. DMAC is transferring data from SRAM0 to SRAM0. |
| DTC | Bit length of transfer data is set to 32 bits. Transfer mode is set to block transfer mode. DTC is transferring data from SRAM0 to SRAM0. |

## 49.3 AC Characteristics

## 49.3.1 Frequency

**Table 49.22 Operation frequency in high-speed operating mode**

Conditions: VCC = AVCC0 = 1.6 to 3.6 V

| Parameter | | | Symbol | Min | Typ | Max*5 | Unit |
|---|---|---|---|---|---|---|---|
| Operation frequency | System clock (ICLK)*1 *2 *4 | 1.8 to 3.6 V | f | 0.03277 | — | 80*6 | MHz |
| | | 1.6 to 1.8 V | | 0.03277 | — | 4 | |
| | Peripheral module clock (PCLKA)*4 | 1.8 to 3.6 V | | — | — | 80*6 | |
| | | 1.6 to 1.8 V | | — | — | 4 | |
| | Peripheral module clock (PCLKB)*4 | 1.8 to 3.6 V | | — | — | 40 | |
| | | 1.6 to 1.8 V | | — | — | 4 | |
| | Peripheral module clock (PCLKC)*3 *4 | 1.8 to 3.6 V | | — | — | 48 | |
| | | 1.6 to 1.8 V | | — | — | 4 | |
| | Peripheral module clock (PCLKD)*4 | 1.8 to 3.6 V | | — | — | 80*6 | |
| | | 1.6 to 1.8 V | | — | — | 4 | |
| | Flash IF clock (FCLK)*4 | 1.8V to 3.6V | | — | — | 48 | |
| | | 1.6 to 1.8 V | | — | — | 4 | |

Note: Set LDOCR.CHG0 = 0 when ICLK < 8MHz, and LDOCR.CHG0 = 1 when 8MHz ≤ ICLK.
Note 1. The lower-limit frequency of ICLK is 1 MHz while programming or erasing the flash memory. When using ICLK for programming or erasing the flash memory at below 4 MHz, the frequency can be set to 1 MHz, 2 MHz, or 3 MHz. A non-integer frequency such as 1.5 MHz cannot be set.
Note 2. The frequency accuracy of ICLK must be ± 1.0% during programming or erasing the flash memory. Confirm the frequency accuracy of the clock source.
Note 3. The lower-limit frequency of PCLKD is 1 MHz when the ADC12 is in use.
Note 4. See section 8, Clock Generation Circuit for the relationship of frequencies between ICLK, PCLKA, PCLKB, PCLKC, PCLKD, and FCLK.
Note 5. The maximum value of operation frequency does not include internal oscillator errors. For details on the range for guaranteed operation, see Table 49.26.
Note 6. This is the condition when Tj = 105 °C. Specifications at Tj = 140 °C are 78MHz.

**Table 49.23 Operation frequency in middle-speed mode**

Conditions: VCC = AVCC0 = 1.6 to 3.6 V

| Parameter | | | Symbol | Min | Typ | Max*5 | Unit |
|---|---|---|---|---|---|---|---|
| Operation frequency | System clock (ICLK)*1 *2 *4 | 1.8 to 3.6 V | f | 0.03277 | — | 8 | MHz |
| | | 1.6 to 1.8 V | | 0.03277 | — | 4 | |
| | Peripheral module clock (PCLKA)*4 | 1.8 to 3.6 V | | — | — | 8 | |
| | | 1.6 to 1.8 V | | — | — | 4 | |
| | Peripheral module clock (PCLKB)*4 | 1.8 to 3.6 V | | — | — | 8 | |
| | | 1.6 to 1.8 V | | — | — | 4 | |
| | Peripheral module clock (PCLKC)*3 *4 | 1.8 to 3.6 V | | — | — | 8 | |
| | | 1.6 to 1.8 V | | — | — | 4 | |
| | Peripheral module clock (PCLKD)*4 | 1.8 to 3.6 V | | — | — | 8 | |
| | | 1.6 to 1.8 V | | — | — | 4 | |
| | Flash IF clock (FCLK)*4 | 1.8 to 3.6 V | | — | — | 8 | |
| | | 1.6 to 1.8 V | | — | — | 4 | |

Note 1. The lower-limit frequency of ICLK is 1 MHz while programming or erasing the flash memory. When using ICLK for programming or erasing the flash memory at below 4 MHz, the frequency can be set to 1 MHz, 2 MHz, or 3 MHz. A non-integer frequency such as 1.5 MHz cannot be set.
Note 2. The frequency accuracy of ICLK must be ± 1.0% during programming or erasing the flash memory. Confirm the frequency accuracy of the clock source.
Note 3. The lower-limit frequency of PCLKC is 1 MHz when the ADC12 is in use.
Note 4. See section 8, Clock Generation Circuit for the relationship of frequencies between ICLK, PCLKA, PCLKB, PCLKC, PCLKD, and FCLK.

Note 5. The maximum value of operation frequency does not include internal oscillator errors. For details on the range for guaranteed operation, see Table 49.26.

**Table 49.24 Operation frequency in low-speed mode**

Conditions: VCC = AVCC0 = 1.6 to 3.6 V

| Parameter | | | Symbol | Min | Typ | Max*5 | Unit |
|---|---|---|---|---|---|---|---|
| Operation frequency | System clock (ICLK)*1 *2 *4 | 1.6 to 3.6 V | f | 0.03277 | — | 1 | MHz |
| | Peripheral module clock (PCLKA)*4 | 1.6 to 3.6 V | | — | — | 1 | |
| | Peripheral module clock (PCLKB)*4 | 1.6 to 3.6 V | | — | — | 1 | |
| | Peripheral module clock (PCLKC)*3 *4 | 1.6 to 3.6 V | | — | — | 1 | |
| | Peripheral module clock (PCLKD)*4 | 1.6 to 3.6 V | | — | — | 1 | |
| | FlashIF clock (FCLK)*4 | 1.6 to 3.6 V | | — | — | 1 | |

Note 1. The lower-limit frequency of ICLK is 1 MHz while programming or erasing the flash memory. When using ICLK for programming or erasing the flash memory at below 4 MHz, the frequency can be set to 1 MHz, 2 MHz, or 3 MHz. A non-integer frequency such as 1.5 MHz cannot be set.
Note 2. The frequency accuracy of ICLK must be ± 1.0% during programming or erasing the flash memory. Confirm the frequency accuracy of the clock source.
Note 3. The lower-limit frequency of PCLKC is 1 MHz when the ADC12 is in use.
Note 4. See section 8, Clock Generation Circuit for the relationship of frequencies between ICLK, PCLKA, PCLKB, PCLKC, PCLKD, and FCLK.
Note 5. The maximum value of operation frequency does not include internal oscillator errors. For details on the range for guaranteed operation, see Table 49.26.

**Table 49.25 Operation frequency in Subosc-speed mode**

Conditions: VCC = AVCC0 = 1.6 to 3.6 V

| Parameter | | | Symbol | Min | Typ | Max | Unit |
|---|---|---|---|---|---|---|---|
| Operation frequency | System clock (ICLK)*1 *3 | 1.6 to 3.6 V | f | 27.8528 | 32.768 | 37.6832 | kHz |
| | Peripheral module clock (PCLKA) | 1.6 to 3.6 V | | — | — | 37.6832 | |
| | Peripheral module clock (PCLKB)*3 | 1.6 to 3.6 V | | — | — | 37.6832 | |
| | Peripheral module clock (PCLKC) | 1.6 to 3.6 V | | — | — | 37.6832 | |
| | Peripheral module clock (PCLKD)*2 *3 | 1.6 to 3.6 V | | — | — | 37.6832 | |
| | FlashIF clock (FCLK)*3 | 1.6 to 3.6 V | | — | — | 37.6832 | |

Note 1. Programming and erasing the flash memory is not possible.
Note 2. The ADC12 cannot be used.
Note 3. See section 8, Clock Generation Circuit for the relationship of frequencies between ICLK, PCLKA, PCLKB, PCLKC, PCLKD, and FCLK.

## 49.3.2 Clock Timing

**Table 49.26 Clock timing (1 of 2)**

| Parameter | Symbol | Min | Typ | Max | Unit | Test conditions |
|---|---|---|---|---|---|---|
| EXTAL external clock input cycle time | $t_{Xcyc}$ | 50 | — | — | ns | Figure 49.6 |
| EXTAL external clock input high pulse width | $t_{XH}$ | 20 | — | — | ns | |
| EXTAL external clock input low pulse width | $t_{XL}$ | 20 | — | — | ns | |
| EXTAL external clock rising time | $t_{Xr}$ | — | — | 5 | ns | |
| EXTAL external clock falling time | $t_{Xf}$ | — | — | 5 | ns | |
| EXTAL external clock input wait time*1 | $t_{EXWT}$ | 0.3 | — | — | μs | — |
| EXTAL external clock input frequency | $f_{EXTAL}$ | — | — | 20 | MHz | 1.8 ≤ VCC ≤ 3.6 |
| | | — | — | 4 | | 1.6 ≤ VCC < 1.8 |
| Main clock oscillator oscillation frequency | $f_{MAIN}$ | 1 | — | 20 | MHz | 1.8 ≤ VCC ≤ 3.6 |
| | | 1 | — | 4 | | 1.6 ≤ VCC < 1.8 |

**Table 49.26 Clock timing (2 of 2)**

| Parameter | Symbol | Min | Typ | Max | Unit | Test conditions |
|---|---|---|---|---|---|---|
| LOCO clock oscillation frequency | $f_{LOCO}$ | 27.853 | 32.77 | 37.683 | kHz | — |
| LOCO clock oscillation stabilization time | $t_{LOCO}$ | — | — | 100 | µs | Figure 49.7 |
| IWDT-dedicated clock oscillation frequency | $f_{ILOCO}$ | 12.75 | 15 | 17.25 | kHz | — |
| MOCO clock oscillation frequency | $f_{MOCO}$ | 6.8 | 8 | 9.2 | MHz | — |
| MOCO clock oscillation stabilization time | $t_{MOCO}$ | — | — | 1 | µs | — |
| HOCO clock oscillation frequency | $f_{HOCO24}$ | 23.76 | 24 | 24.24 | MHz | — |
| | $f_{HOCO32}$ | 31.68 | 32 | 32.32 | | — |
| | $f_{HOCO40}$ | 39.6 | 40 | 40.4 | | — |
| | $f_{HOCO48}$ | 47.52 | 48 | 48.48 | | — |
| | $f_{HOCO64}$ | 63.36 | 64 | 64.64 | | — |
| | $f_{HOCO80}$ | 79.2 | 80 | 80.8 | | — |
| HOCO clock oscillation frequency*3 | $f_{HOCOWT}$ | — | 1.9 | — | µs | Figure 49.8 |
| PLL input frequency | $f_{PLLIN}$ | 4 | — | 12.5 | MHz | — |
| PLL clock frequency | $f_{PLL}$ | 24 | — | 80 | MHz | — |
| PLL clock oscillation stabilization time | $f_{PLL}$ | — | — | 70 | µs | Figure 49.9 |
| Sub-clock oscillator oscillation frequency | $f_{SUB}$ | — | 32.77 | — | kHz | — |
| Sub-clock oscillation stabilization time*2 | $t_{SUBOSC}$ | — | 0.5 | — | s | Figure 49.10 |

Note 1. Time until the clock can be used after the Main Clock Oscillator stop bit (MOSCCR.MOSTP) is set to 0 (operating) when the external clock is stable.

Note 2. After changing the setting of the SOSCCR.SOSTP bit to start sub-clock oscillator operation, only start using the sub-clock oscillator after the sub-clock oscillation stabilization wait time elapsed. Use the oscillator wait time value recommended by the oscillator manufacturer.

Note 3. This is the time from release from reset state until the HOCO oscillation frequency ($f_{HOCO}$) reaches the range for guaranteed operation.

## 49.3.3 Reset Timing

**Table 49.27 Reset timing**

| Parameter | | Symbol | Min | Typ | Max | Unit | Test conditions |
|---|---|---|---|---|---|---|---|
| RES pulse width | At power-on | $t_{RESWP}$ | 13 | — | — | ms | Figure 49.11 |
| | Not at power-on | $t_{RESW}$ | 30 | — | — | μs | Figure 49.12 |
| Wait time after RES cancellation (at power-on) | LVD0 enabled*1 | $t_{RESWT}$ | — | 1.0 | — | ms | Figure 49.11 |
| | LVD0 disabled*2 | | — | 0.3 | — | | |
| Wait time after RES cancellation (during powered-on state) | LVD0 enabled*1 | $t_{RESWT2}$ | — | 0.9 | — | ms | Figure 49.12 |
| | LVD0 disabled*2 | | — | 0.2 | — | | |
| Wait time after internal reset cancellation (IWDT reset, WDT reset, RAM parity error reset, RAM ECC error reset, Bus master MPU error reset, TrustZone error reset, Cache parity error reset, Software reset) | LVD0 enabled*1 | $t_{RESWT3}$ | — | 0.9 | — | ms | Figure 49.13 |
| | LVD0 disabled*2 | | — | 0.2 | — | | |

Note 1. When OFS1.LVDAS = 0.
Note 2. When OFS1.LVDAS = 1.

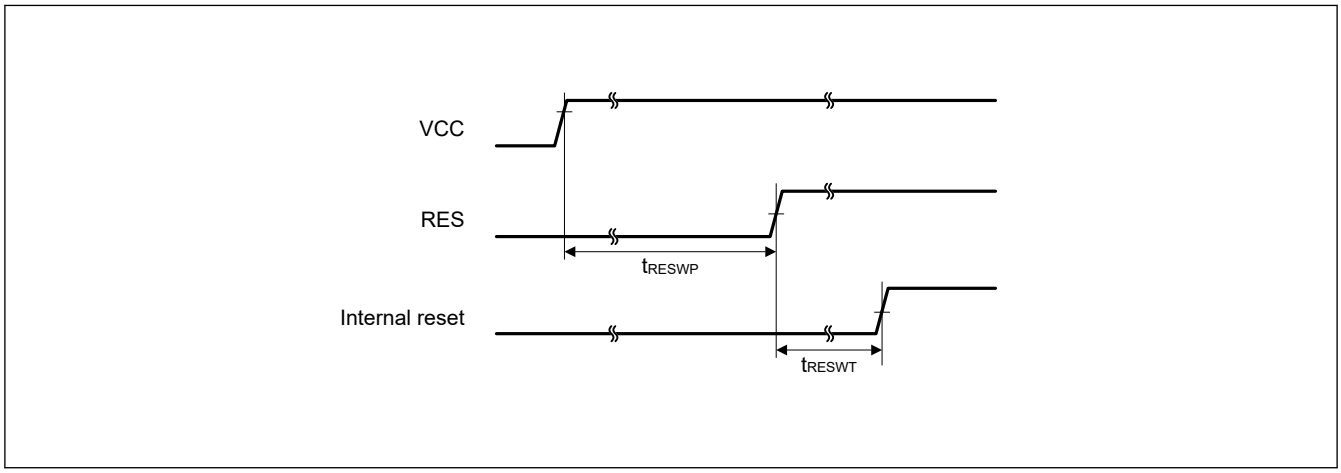

**Figure 49.11 Reset input timing at power-on**

## 49.3.4 Wakeup Time

**Table 49.28 Timing of recovery from low power modes (1)**

| Parameter | | | | Symbol | Min | Typ | Max | Unit | Test conditions |
|---|---|---|---|---|---|---|---|---|---|
| Recovery time from Software Standby mode*1 | High-speed mode | Crystal resonator connected to main clock oscillator | System clock source is main clock oscillator (20 MHz)*2 *4 | $t_{SBYMC}$ | — | 2.1 | 2.7 | ms | Figure 49.14 |
| | | | System clock source is PLL (48 MHz) with Main clock oscillator*2 *5 | $t_{SBYPC}$ | — | 2.1 | 2.8 | ms | |
| | | External clock input to main clock oscillator | System clock source is main clock oscillator (20 MHz)*3 *4 | $t_{SBYEX}$ | — | 8.5 | 11 | µs | |
| | | | System clock source is PLL (48 MHz) with Main clock oscillator*3 *5 | $t_{SBYEX}$ | — | 66 | 85 | µs | |
| | | System clock source is HOCO (HOCO clock is 32 MHz)*6 | | $t_{SBYHO}$ | — | 13.5 | 17.8 | µs | |
| | | System clock source is HOCO (HOCO clock is 48 MHz)*5 | | $t_{SBYHO}$ | — | 13.2 | 17.5 | µs | |
| | | System clock source is MOCO (8 MHz)*7 | | $t_{SBYMO}$ | — | 3.5 | 5.1 | µs | |

Note 1. The division ratio of ICLK, FCLK, and PCLKx is the minimum division ratio within the allowable frequency range. The recovery time is determined by the system clock source.
Note 2. The Main Clock Oscillator Wait Control Register (MOSCWTCR) is set to 0x05.
Note 3. The Main Clock Oscillator Wait Control Register (MOSCWTCR) is set to 0x00.
Note 4. The ICLK is 20 MHz
Note 5. The ICLK is 48 MHz
Note 6. The ICLK is 32 MHz
Note 7. The ICLK is 8 MHz

**Table 49.29 Timing of recovery from low power modes (2)**

| Parameter | | | | Symbol | Min | Typ | Max | Unit | Test conditions |
|---|---|---|---|---|---|---|---|---|---|
| Recovery time from Software Standby mode*1 | Middle speed mode | Crystal resonator connected to main clock oscillator | System clock source is main clock oscillator (20 MHz)*2 *4 | $t_{SBYMC}$ | — | 2.1 | 2.7 | ms | Figure 49.14 |
| | | External clock input to main clock oscillator | System clock source is main clock oscillator (20 MHz)*3 *4<br>VCC = 1.8 V to 3.6 V | $t_{SBYEX}$ | — | 6 | 7.4 | µs | |
| | | | System clock source is main clock oscillator (4 MHz)*3 *5<br>VCC = 1.6 V to 1.8 V | | — | 7.3 | 8.8 | µs | |
| | | System clock source is HOCO (32 MHz) *4 | VCC = 1.8 V to 3.6 V*6 | $t_{SBYHO}$ | — | 10 | 13 | µs | |
| | | | VCC = 1.6 V to 1.8 V*7 | | — | 13 | 16 | | |
| | | System clock source is MOCO (8 MHz) | VCC = 1.8 V to 3.6 V*8 | $t_{SBYMO}$ | — | 3.5 | 5.1 | µs | |
| | | | VCC = 1.6 V to 1.8 V*9 | | — | 6.3 | 8.7 | | |

Note 1. The division ratio of ICLK, FCLK and PCLKx is the minimum division ratio within the allowable frequency range. The recovery time is determined by the system clock source.
Note 2. The Main Clock Oscillator Wait Control Register (MOSCWTCR) is set to 0x05.
Note 3. The Main Clock Oscillator Wait Control Register (MOSCWTCR) is set to 0x00.
Note 4. The ICLK is 5 MHz (20 MHz/4)
Note 5. The ICLK is 4 MHz
Note 6. The ICLK is 8 MHz (32 MHz/4)
Note 7. The ICLK is 4 MHz (32 MHz/8)
Note 8. The ICLK is 8 MHz
Note 9. The ICLK is 4 MHz (8 MHz/2)

**Table 49.30 Timing of recovery from low power modes (3)**

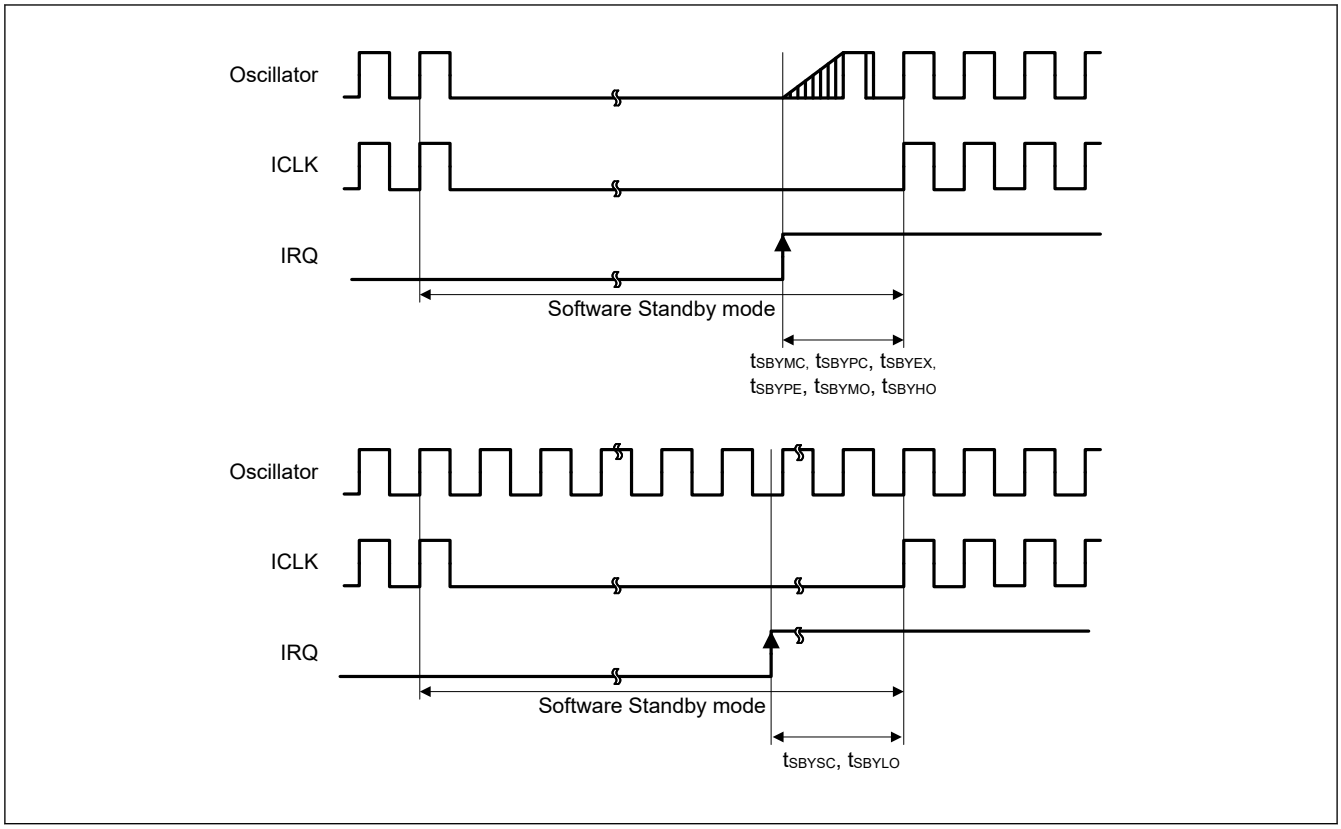
| Parameter | | | | Symbol | Min | Typ | Max | Unit | Test conditions |
|---|---|---|---|---|---|---|---|---|---|
| Recovery time from Software Standby mode*1 | Low speed mode | Crystal resonator connected to main clock oscillator | System clock source is main clock oscillator (20 MHz)*2 *4 | $t_{SBYMC}$ | — | 2.1 | 2.7 | ms | Figure 49.14 |
| | | External clock input to main clock oscillator | System clock source is main clock oscillator (20 MHz)*3 *4 | $t_{SBYEX}$ | — | 41 | 46 | µs | |
| | | System clock source is MOCO (8 MHz)*5 | | $t_{SBYMO}$ | — | 23 | 30 | µs | |

Note 1. The division ratio of ICLK, FCLK and PCLKx is the minimum division ratio within the allowable frequency range. The recovery time is determined by the system clock source.
Note 2. The Main Clock Oscillator Wait Control Register (MOSCWTCR) is set to 0x05.
Note 3. The Main Clock Oscillator Wait Control Register (MOSCWTCR) is set to 0x00.
Note 4. The ICLK is 0.625 MHz (20/32 MHz)
Note 5. The ICLK is 1 MHz (8 MHz/8)

**Table 49.31 Timing of recovery from low power modes (4)**

| Parameter | | | Symbol | Min | Typ | Max | Unit | Test conditions |
|---|---|---|---|---|---|---|---|---|
| Recovery time from Software Standby mode*1 | Subosc-speed mode | System clock source is sub-clock oscillator (32.768 kHz) | $t_{SBYSC}$ | — | 0.8 | 0.9 | ms | Figure 49.14 |
| | | System clock source is LOCO (32.768 kHz) | $t_{SBYLO}$ | — | 0.8 | 1 | ms | |

Note 1. The sub-clock oscillator or LOCO itself continues oscillating in Software Standby mode during Subosc-speed mode.



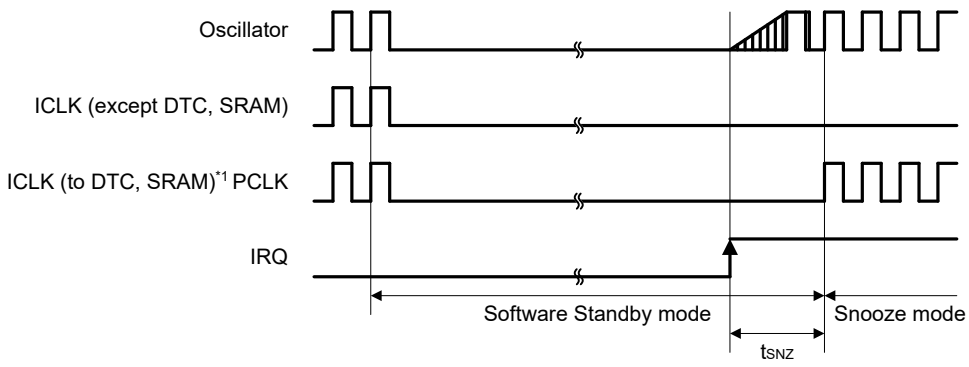


**Figure 49.14 Software Standby mode cancellation timing**

**Table 49.32 Timing of recovery from low power modes (5)**

| Parameter | | Symbol | Min | Typ | Max | Unit | Test conditions |
|---|---|---|---|---|---|---|---|
| Recovery time from Software Standby mode*1 | High-speed mode System clock source is HOCO (32 MHz)*1 | $t_{SNZ}$ | — | 7.4 | 9.3 | µs | Figure 49.15 |
| | Middle-speed mode System clock source is HOCO (24 MHz)*2 VCC = 1.8 V to 3.6 V | $t_{SNZ}$ | — | 8.3 | 10.4 | µs | |
| | Middle-speed mode System clock source is HOCO (24 MHz)*3 VCC = 1.6 V to 1.8 V | $t_{SNZ}$ | — | 9.5 | 11.8 | µs | |
| | Low-speed mode System clock source is MOCO (8 MHz)*4 | $t_{SNZ}$ | — | 11.8 | 15.6 | µs | |

Note 1. The ICLK is 32 MHz
Note 2. The ICLK is 8 MHz (24 MHz/4)
Note 3. The ICLK is 4 MHz (24 MHz/8)
Note 4. The ICLK is 1 MHz (8 MHz/8)

Note 1. When SNZCR.SNZDTCEN bit is set to 1, ICLK is supplied to DTC and SRAM.

**Figure 49.15 Recovery timing from Software Standby mode to Snooze mode**

## 49.3.5 NMI and IRQ Noise Filter

**Table 49.33 NMI and IRQ noise filter**

| Parameter | Symbol | Min | Typ | Max | Unit | Test conditions | |
|---|---|---|---|---|---|---|---|
| NMI pulse width | $t_{NMIW}$ | 200 | — | — | ns | NMI digital filter disabled | $t_{Pcyc} \times 2 \leq 200$ ns |
| | | $t_{Pcyc} \times 2$*1 | — | — | | | $t_{Pcyc} \times 2 > 200$ ns |
| | | 200 | — | — | | NMI digital filter enabled | $t_{NMICK} \times 3 \leq 200$ ns |
| | | $t_{NMICK} \times 3.5$*2 | — | — | | | $t_{NMICK} \times 3 > 200$ ns |
| IRQ pulse width | $t_{IRQW}$ | 200 | — | — | ns | IRQ digital filter disabled | $t_{Pcyc} \times 2 \leq 200$ ns |
| | | $t_{Pcyc} \times 2$*1 | — | — | | | $t_{Pcyc} \times 2 > 200$ ns |
| | | 200 | — | — | | IRQ digital filter enabled | $t_{IRQCK} \times 3 \leq 200$ ns |
| | | $t_{IRQCK} \times 3.5$*3 | — | — | | | $t_{IRQCK} \times 3 > 200$ ns |

Note: 200 ns minimum in Software Standby mode.
Note: If the clock source is being switched it is needed to add 4 clock cycle of switched source.
Note 1. $t_{Pcyc}$ indicates the PCLKB cycle.
Note 2. $t_{NMICK}$ indicates the cycle of the NMI digital filter sampling clock.
Note 3. $t_{IRQCK}$ indicates the cycle of the IRQi digital filter sampling clock (i = 0 to 7).

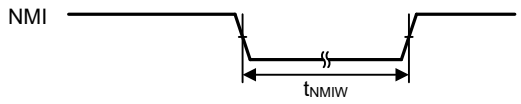

**Figure 49.16 NMI interrupt input timing**

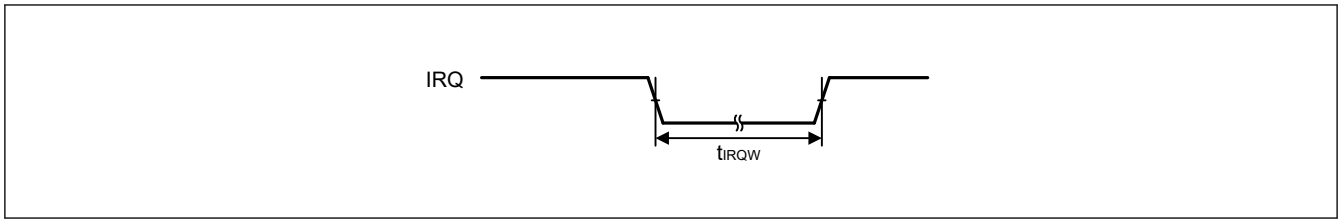

**Figure 49.17 IRQ interrupt input timing**

## 49.3.6 I/O Ports, POEG, GPT, AGT, and ADC12 Trigger Timing

**Table 49.34 I/O Ports, POEG, GPT, AGT, and ADC12 trigger timing**

| Parameter | | | Symbol | Min | Max | Unit | Test conditions |
|---|---|---|---|---|---|---|---|
| I/O Ports | Input data pulse width | 2.7 V ≤ VCC ≤ 3.6 V | $t_{PRW}$ | 2 | — | $t_{Pcyc}$ | Figure 49.18 |
| | | 2.4 V ≤ VCC < 2.7 V | | 3 | | | |
| | | 1.6 V ≤ VCC < 2.4 V | | 4 | | | |
| POEG | POEG input trigger pulse width | | $t_{POEW}$ | 3 | — | $t_{Pcyc}$ | Figure 49.19 |
| GPT | Input capture pulse width | Single edge | $t_{GTICW}$ | 1.5 | — | $t_{PDcyc}$ | Figure 49.20 |
| | | Dual edge | | 2.5 | — | | |
| AGT | AGTIO, AGTEE input cycle | 1.8 V ≤ VCC ≤ 3.6 V | $t_{ACYC}$ *1 | 250 | — | ns | Figure 49.21 |
| | | 1.6 V ≤ VCC < 1.8 V | | 2000 | — | ns | |
| | AGTIO, AGTEE input high-level width, low-level width | 1.8 V ≤ VCC ≤ 3.6 V | $t_{ACKWH}$, $t_{ACKWL}$ | 100 | — | ns | |
| | | 1.6 V ≤ VCC < 1.8 V | | 800 | — | ns | |
| | AGTIO, AGTO, AGTOA, AGTOB output cycle | 2.7 V ≤ VCC ≤ 3.6 V | $t_{ACYC2}$ | 62.5 | — | ns | Figure 49.21 |
| | | 2.4 V ≤ VCC < 2.7 V | | 125 | — | ns | |
| | | 1.8 V ≤ VCC < 2.4 V | | 250 | — | ns | |
| | | 1.6 V ≤ VCC < 1.8 V | | 500 | — | ns | |
| ADC12 | 12-bit A/D converter trigger input pulse width | | $t_{TRGW}$ | 1.5 | — | $t_{Pcyc}$ | Figure 49.22 |

Note 1. Constraints on AGTIO input: $t_{Pcyc}$ × 2 ($t_{Pcyc}$: PCLKB cycle) < $t_{ACYC}$.

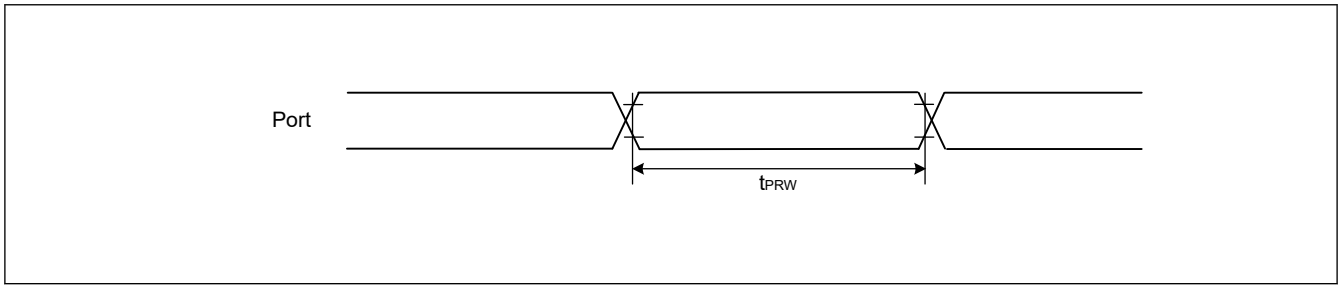

**Figure 49.18 I/O ports input timing**

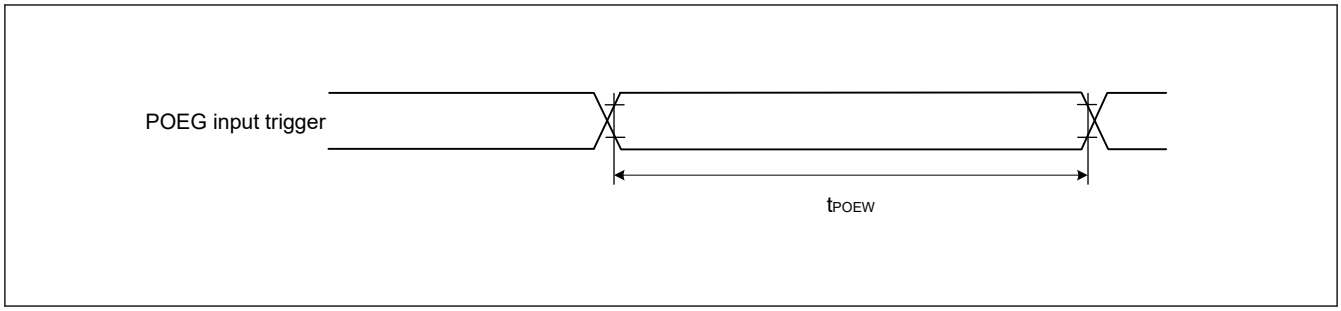

**Figure 49.19 POEG input trigger timing**

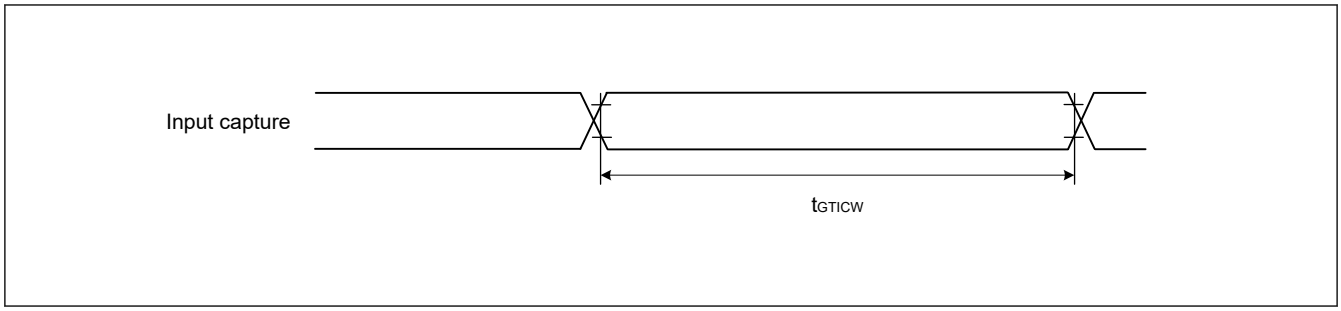

**Figure 49.20 GPT input capture timing**

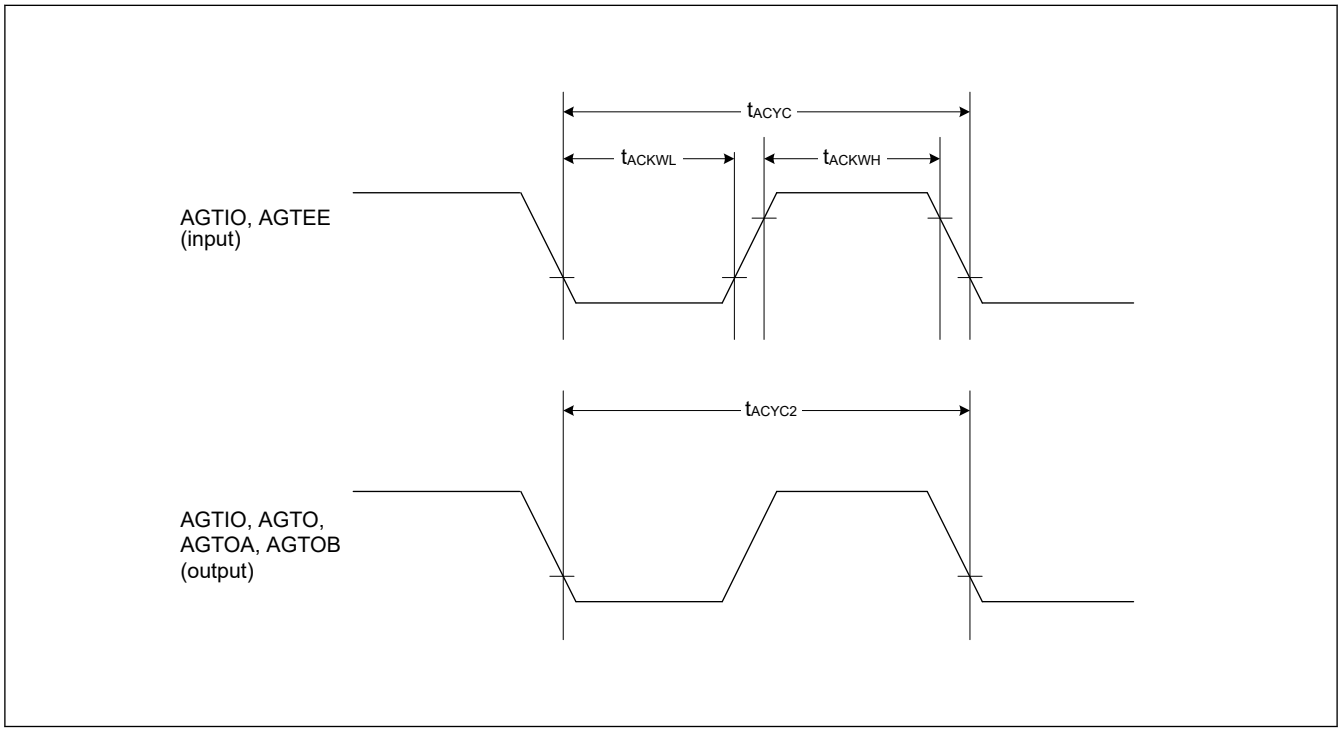

**Figure 49.21 AGT I/O timing**

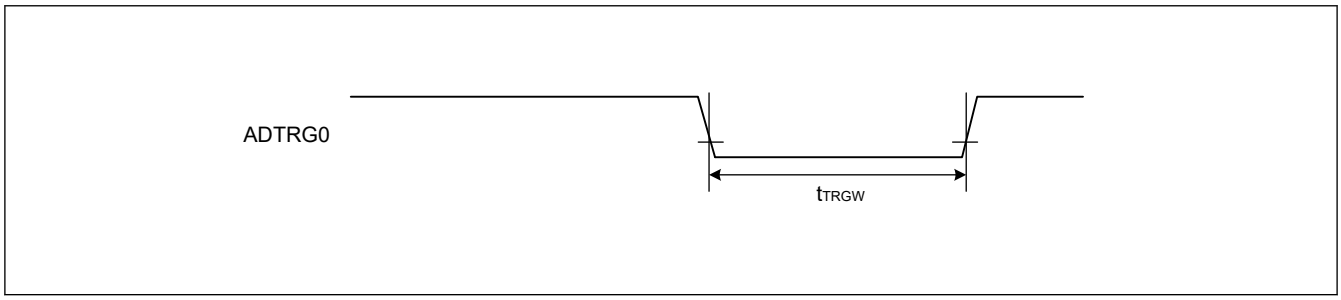

**Figure 49.22 ADC12 trigger input timing**

## 49.3.7 CAC Timing

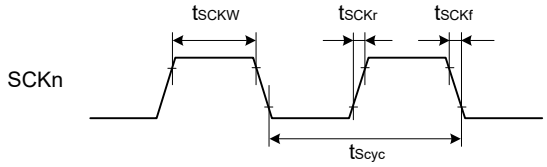
**Table 49.35 CAC timing**

| Parameter | | Symbol | Min | Typ | Max | Unit | Test conditions |
|---|---|---|---|---|---|---|---|
| CACREF input pulse width | $t_{PBcyc} \leq t_{CAC}$ *1 | $t_{CACREF}$ | $4.5 \times t_{CAC} + 3 \times t_{PBcyc}$ | — | — | ns | — |
| | $t_{PBcyc} > t_{CAC}$ *1 | | $5 \times t_{CAC} + 6.5 \times t_{PBcyc}$ | — | — | ns | |

Note: $t_{PBcyc}$: PCLKB cycle.
Note 1. $t_{CAC}$: CAC count clock source cycle.

## 49.3.8 SCI Timing

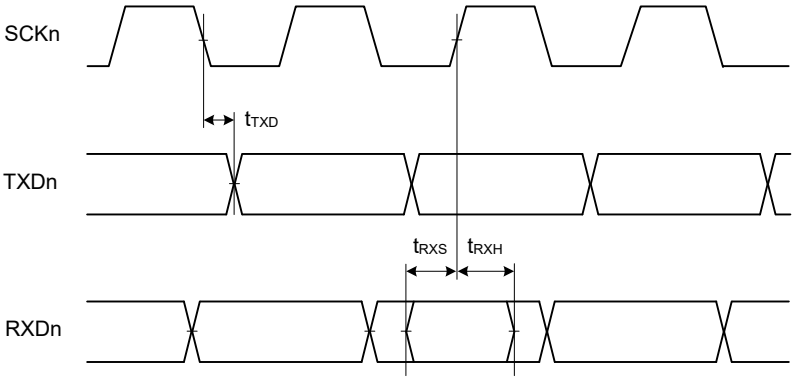
**Table 49.36 SCI timing (1) (1 of 2)**



Conditions: VCC = AVCC0 = 1.6 to 3.6 V

| Parameter | | | | Symbol | Min | Max | Unit | Test conditions |
|---|---|---|---|---|---|---|---|---|
| SCI | Input clock cycle | Asynchronous | 2.7 V ≤ VCC ≤ 3.6 V | $t_{Scyc}$ | 75 | — | ns | Figure 49.23 |
| | | | 2.4 V ≤ VCC < 2.7 V | | 150 | — | | |
| | | | 1.8 V ≤ VCC < 2.4 V | | 300 | — | | |
| | | | 1.6 V ≤ VCC < 1.8 V | | 1000 | — | | |
| | | Clock synchronous | 2.7 V ≤ VCC ≤ 3.6 V | | 100 | — | | |
| | | | 2.4 V ≤ VCC < 2.7 V | | 200 | — | | |
| | | | 1.8 V ≤ VCC < 2.4 V | | 400 | — | | |
| | | | 1.6 V ≤ VCC < 1.8 V | | 1500 | — | | |
| | Input clock pulse width | | | $t_{SCKW}$ | 0.4 | 0.6 | $t_{Scyc}$ | |
| | Input clock rise time | | | $t_{SCKr}$ | — | 10 | ns | |
| | Input clock fall time | | | $t_{SCKf}$ | — | 10 | ns | |
| | Output clock cycle | Asynchronous | 2.7 V ≤ VCC ≤ 3.6 V | $t_{Scyc}$ | 75 (exclude SCI1)<br>100 (SCI1) | — | ns | |
| | | | 2.4 V ≤ VCC < 2.7 V | | 150 (exclude SCI1)<br>200 (SCI1) | — | | |
| | | | 1.8 V ≤ VCC < 2.4 V | | 300 (exclude SCI1)<br>400 (SCI1) | — | | |
| | | | 1.6 V ≤ VCC < 1.8 V | | 1500 (exclude SCI1)<br>2000 (SCI1) | — | | |
| | | Clock synchronous | 1.8 V ≤ VCC ≤ 3.6 V | | 75 | — | | |
| | | | 2.4 V ≤ VCC < 2.7 V | | 150 | — | | |
| | | | 1.8 V ≤ VCC < 2.4 V | | 300 | — | | |
| | | | 1.6 V ≤ VCC < 1.8 V | | 1000 | — | | |
| | Output clock pulse width | | | $t_{SCKW}$ | 0.4 | 0.6 | $t_{Scyc}$ | |
| | Output clock rise time | | 1.8 V ≤ VCC ≤ 3.6 V | $t_{SCKr}$ | — | 7.5 | ns | |
| | | | 1.6 V ≤ VCC < 1.8 V | | — | 30 | | |
| | Output clock fall time | | 1.8 V ≤ VCC ≤ 3.6 V | $t_{SCKf}$ | — | 7.5 | ns | |
| | | | 1.6 V ≤ VCC < 1.8 V | | — | 30 | | |
| | Transmit data delay time (master) | Clock synchronous | 2.7 V ≤ VCC ≤ 3.6 V | $t_{TXD}$ | — | 30 | ns | Figure 49.24 |
| | | | 2.4 V ≤ VCC < 2.7 V | | — | 35 | | |
| | | | 1.8 V ≤ VCC < 2.4 V | | — | 75 | | |
| | | | 1.6 V ≤ VCC < 1.8 V | | — | 125 | | |
| | Transmit data delay time (slave) | Clock synchronous | 1.8 V ≤ VCC ≤ 3.6 V | | — | 40 | ns | |
| | | | 2.4 V ≤ VCC < 2.7 V | | — | 45 | | |
| | | | 1.8 V ≤ VCC < 2.4 V | | — | 70 | | |
| | | | 1.6 V ≤ VCC < 1.8 V | | — | 105 | | |

**Table 49.36 SCI timing (1) (2 of 2)**



Conditions: VCC = AVCC0 = 1.6 to 3.6 V

| Parameter | | | | Symbol | Min | Max | Unit | Test conditions |
|---|---|---|---|---|---|---|---|---|
| SCI | Receive data setup time (master) | Clock synchronous | 1.8 V ≤ VCC ≤ 3.6 V | $t_{RXS}$ | 40 | — | ns | Figure 49.24 |
| | | | 2.4 V ≤ VCC < 2.7 V | | 50 | — | | |
| | | | 1.8 V ≤ VCC < 2.4 V | | 70 | — | | |
| | | | 1.6 V ≤ VCC < 1.8 V | | 110 | — | | |
| | Receive data setup time (slave) | Clock synchronous | 2.4 V ≤ VCC ≤ 3.6 V | | 10 | — | ns | |
| | | | 1.8 V ≤ VCC ≤ 2.4 V | | 15 | — | | |
| | | | 1.6 V ≤ VCC < 1.8 V | | 45 | — | | |
| | Receive data hold time (master) | Clock synchronous | | $t_{RXH}$ | 5 | — | ns | |
| | Receive data hold time (slave) | Clock synchronous | | $t_{RXH}$ | 5 | — | ns | |

**Table 49.38 SCI timing (3)**

Conditions: VCC = AVCC0 = 1.6 to 3.6 V

| Parameter | | Symbol | Min | Max | Unit | Test conditions |
|---|---|---|---|---|---|---|
| Simple IIC (Standard mode) | SDA input rise time | $t_{Sr}$ | — | 1000 | ns | Figure 49.30 |
| | SDA input fall time | $t_{Sf}$ | — | 300 | ns | |
| | SDA input spike pulse removal time | $t_{SP}$ | 0 | 4 × $t_{IICcyc}$ *1 | ns | |
| | Data input setup time | $t_{SDAS}$ | 250 | — | ns | |
| | Data input hold time | $t_{SDAH}$ | 0 | — | ns | |
| | SCL, SDA capacitive load | $C_b$ *2 | — | 400 | pF | |
| Simple IIC (Fast mode) | SDA input rise time | $t_{Sr}$ | — | 300 | ns | Figure 49.30 |
| | SDA input fall time | $t_{Sf}$ | — | 300 | ns | |
| | SDA input spike pulse removal time | $t_{SP}$ | 0 | 4 × $t_{IICcyc}$ *1 | ns | |
| | Data input setup time | $t_{SDAS}$ | 100 | — | ns | |
| | Data input hold time | $t_{SDAH}$ | 0 | — | ns | |
| | SCL, SDA capacitive load | $C_b$ *2 | — | 400 | pF | |

Note 1. $t_{IICcyc}$: Clock cycle selected by the SMR.CKS[1:0] bits.
Note 2. $C_b$ indicates the total capacity of the bus line.

Test conditions:
$V_{IH}$ = VCC × 0.7, $V_{IL}$ = VCC × 0.3
$V_{OL}$ = 0.6 V, $I_{OL}$ = 6 mA

Note: n = 0, 1, 3 to 5, 9
Note 1. S, P, and Sr indicate the following conditions:
S: Start condition
P: Stop condition
Sr: Restart condition

## 49.3.11 IIC Timing

**Table 49.41 IIC timing (1) (1 of 2)**

Conditions: VCC = AVCC0 = 1.8 to 3.6 V

| Parameter | | Symbol | Min*1 | Max*1 | Unit | Test conditions |
|---|---|---|---|---|---|---|
| IIC (standard mode, SMBus) ICFER.FMPE = 0 | SCL input cycle time | $t_{SCL}$ | 6 (12) × $t_{IICcyc}$ + 1300 | — | ns | Figure 49.40 |
| | SCL input high pulse width | $t_{SCLH}$ | 3 (6) × $t_{IICcyc}$ + 300 | — | ns | |
| | SCL input low pulse width | $t_{SCLL}$ | 3 (6) × $t_{IICcyc}$ + 300 | — | ns | |
| | SCL, SDA rise time | $t_{Sr}$ | — | 1000 | ns | |
| | SCL, SDA fall time | $t_{Sf}$ | — | 300 | ns | |
| | SCL, SDA input spike pulse removal time | $t_{SP}$ | 0 | 1 (4) × $t_{IICcyc}$ | ns | |
| | SDA input bus free time when wakeup function is disabled | $t_{BUF}$ | 3 (6) × $t_{IICcyc}$ + 300 | — | ns | |
| | SDA input bus free time when wakeup function is enabled | $t_{BUF}$ | 3 (6) × $t_{IICcyc}$ + 4 × $t_{Pcyc}$ + 300 | — | ns | |
| | START condition input hold time when wakeup function is disabled | $t_{STAH}$ | $t_{IICcyc}$ + 300 | — | ns | |
| | START condition input hold time when wakeup function is enabled | $t_{STAH}$ | 1 (5) × $t_{IICcyc}$ + $t_{Pcyc}$ + 300 | — | ns | |
| | Repeated START condition input setup time | $t_{STAS}$ | 1000 | — | ns | |
| | STOP condition input setup time | $t_{STOS}$ | 1000 | — | ns | |
| | Data input setup time | $t_{SDAS}$ | $t_{IICcyc}$ + 50 | — | ns | |
| | Data input hold time | $t_{SDAH}$ | 0 | — | ns | |
| | SCL, SDA capacitive load | $C_b$*2 | — | 400 | pF | |

**Table 49.41 IIC timing (1) (2 of 2)**

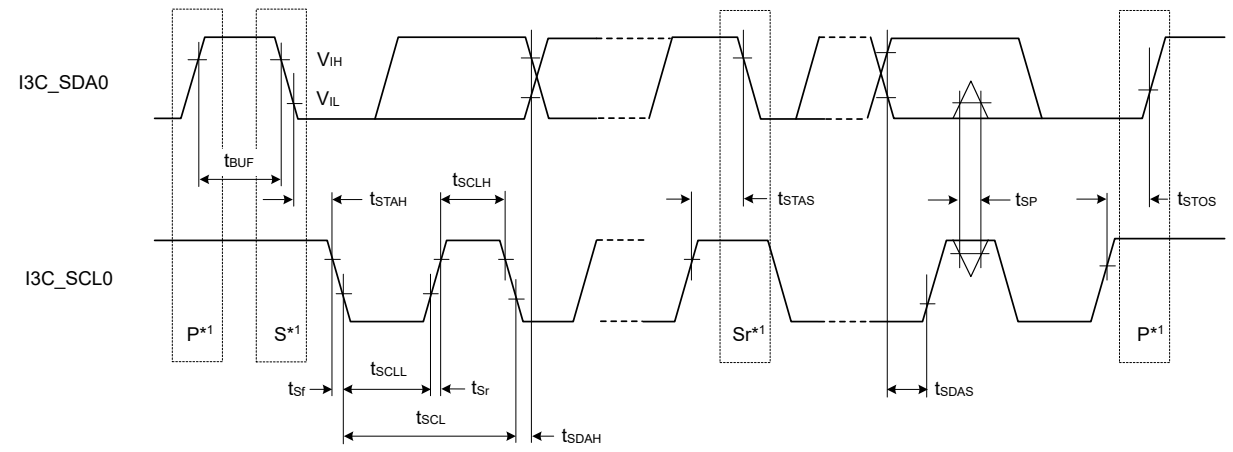
Conditions: VCC = AVCC0 = 1.8 to 3.6 V

| Parameter | | Symbol | Min*1 | Max*1 | Unit | Test conditions |
|---|---|---|---|---|---|---|
| IIC (Fast mode) ICFER.FMPE = 0 | SCL input cycle time | $t_{SCL}$ | 6 (12) × $t_{IICcyc}$ + 600 | — | ns | Figure 49.40 |
| | SCL input high pulse width | $t_{SCLH}$ | 3 (6) × $t_{IICcyc}$ + 300 | — | ns | |
| | SCL input low pulse width | $t_{SCLL}$ | 3 (6) × $t_{IICcyc}$ + 300 | — | ns | |
| | SCL, SDA rise time | $t_{Sr}$ | — | 300 | ns | |
| | SCL, SDA fall time | $t_{Sf}$ | — | 300 | ns | |
| | SCL, SDA input spike pulse removal time | $t_{SP}$ | 0 | 1 (4) × $t_{IICcyc}$ | ns | |
| | SDA input bus free time (When wakeup function is disabled) | $t_{BUF}$ | 3 (6) × $t_{IICcyc}$ + 300 | — | ns | |
| | SDA input bus free time (When wakeup function is enabled) | $t_{BUF}$ | 3 (6) × $t_{IICcyc}$ + 4 × $t_{Pcyc}$+ 300 | — | ns | |
| | START condition input hold time (When wakeup function is disabled) | $t_{STAH}$ | $t_{IICcyc}$ + 300 | — | ns | |
| | START condition input hold time (When wakeup function is enabled) | $t_{STAH}$ | 1 (5) × $t_{IICcyc}$ + $t_{Pcyc}$ + 300 | — | ns | |
| | Repeated START condition input setup time | $t_{STAS}$ | 300 | — | ns | |
| | STOP condition input setup time | $t_{STOS}$ | 300 | — | ns | |
| | Data input setup time | $t_{SDAS}$ | $t_{IICcyc}$ + 50 | — | ns | |
| | Data input hold time | $t_{SDAH}$ | 0 | — | ns | |
| | SCL, SDA capacitive load | $C_b$*2 | — | 400 | pF | |

Note: Use pins that have a letter appended to their names, for instance "_A" or "_B", to indicate group membership. The AC portion of the electrical characteristics is measured for each group.

Note: $t_{IICcyc}$: IIC internal reference clock (IICφ) cycle, $t_{Pcyc}$: PCLKB cycle

Note 1. Values in parentheses apply when ICMR3.NF[1:0] is set to 11b while the digital filter is enabled with ICFER.NFE set to 1.



Note 2. $C_b$ indicates the total capacity of the bus line.

**Table 49.42 IIC timing (2)**

Conditions: VCC = AVCC0 = 2.7 to 3.6 V

| Parameter | | Symbol | Min*1 | Max*1 | Unit | Test conditions |
|---|---|---|---|---|---|---|
| IIC (Fast-mode+) ICFER.FMPE = 1 | SCL input cycle time | $t_{SCL}$ | 6 (12) × $t_{IICcyc}$ + 240 | — | ns | Figure 49.40 |
| | SCL input high pulse width | $t_{SCLH}$ | 3 (6) × $t_{IICcyc}$ + 120 | — | ns | |
| | SCL input low pulse width | $t_{SCLL}$ | 3 (6) × $t_{IICcyc}$ + 120 | — | ns | |
| | SCL, SDA rise time | $t_{Sr}$ | — | 120 | ns | |
| | SCL, SDA fall time | $t_{Sf}$ | — | 120 | ns | |
| | SCL, SDA input spike pulse removal time | $t_{SP}$ | 0 | 1 (4) × $t_{IICcyc}$ | ns | |
| | SDA input bus free time when wakeup function is disabled | $t_{BUF}$ | 3 (6) × $t_{IICcyc}$ + 120 | — | ns | |
| | SDA input bus free time when wakeup function is enabled | $t_{BUF}$ | 3 (6) × $t_{IICcyc}$ + 4 × $t_{Pcyc}$ + 120 | — | ns | |
| | Start condition input hold time when wakeup function is disabled | $t_{STAH}$ | $t_{IICcyc}$ + 120 | — | ns | |
| | START condition input hold time when wakeup function is enabled | $t_{STAH}$ | 1 (5) × $t_{IICcyc}$ + $t_{Pcyc}$ + 120 | — | ns | |
| | Restart condition input setup time | $t_{STAS}$ | 120 | — | ns | |
| | Stop condition input setup time | $t_{STOS}$ | 120 | — | ns | |
| | Data input setup time | $t_{SDAS}$ | $t_{IICcyc}$ + 30 | — | ns | |
| | Data input hold time | $t_{SDAH}$ | 0 | — | ns | |
| | SCL, SDA capacitive load | $C_b$*2 | — | 550 | pF | |

Note: $t_{IICcyc}$: IIC internal reference clock (IICφ) cycle, $t_{Pcyc}$: PCLKB cycle.
Note 1. Values in parentheses apply when ICMR3.NF[1:0] is set to 11b while the digital filter is enabled with ICFER.NFE set to 1.
Note 2. $C_b$ indicates the total capacity of the bus line.

Note: n = 0
Note 1. S, P, and Sr indicate the following conditions:
S: Start condition
P: Stop condition
Sr: Restart condition

**Figure 49.40 I²C bus interface input/output timing**

## 49.3.12 I3C Timing

**Table 49.43 IIC timing(1)**

Conditions: VCC = AVCC0 = 1.8 to 3.6 V

| Parameter | | Symbol | Min*1 | Max*1 | Unit |
|---|---|---|---|---|---|
| IIC (Standard mode, SMBus) BFCTL.FMPE = 0 | SCL input cycle time | $t_{SCL}$ | 10(18) × $t_{I3Ccyc}$ + 1300 | — | ns |

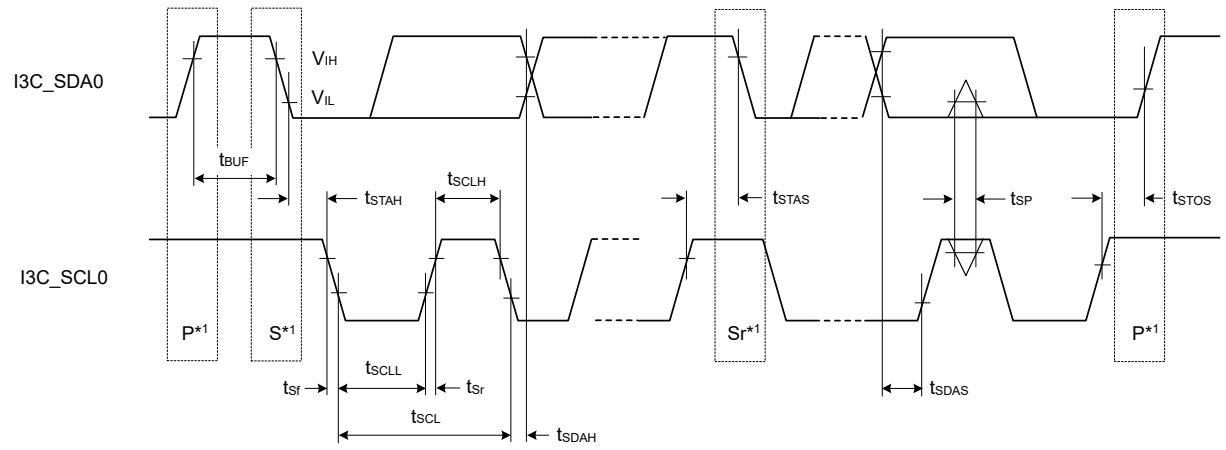
| | SCL, SDA rise time | $t_{Sr}$ | 20 × (external pullup voltage/5.5 V) | 1000 | ns |
| | SCL, SDA fall time | $t_{Sf}$ | 20 × (external pullup voltage/5.5 V) | 300 | ns |
| | SCL, SDA input spike pulse removal time | $t_{SP}$ | 0 | 1(4) × $t_{I3Ccyc}$ | ns |
| | SDA input bus free time when wakeup function is disabled | $t_{BUF}$ | 5(9) × $t_{I3Ccyc}$ + 300 | — | ns |
| | SDA input bus free time when wakeup function is enabled | $t_{BUF}$ | 5(9) × $t_{I3Ccyc}$ + 4 × $t_{Tcyc}$ + 300 | — | ns |
| | START condition input hold time when wakeup function is disabled | $t_{STAH}$ | $t_{I3Ccyc}$ + 300 | — | ns |
| | START condition input hold time when wakeup function is enabled | $t_{STAH}$ | 1(5) × $t_{I3Ccyc}$ + $t_{Tcyc}$ + 300 | — | ns |
| | Repeated START condition input setup time | $t_{STAS}$ | 300 | — | ns |
| | STOP condition input setup time | $t_{STOS}$ | 300 | — | ns |
| | Data input setup time | $t_{SDAS}$ | $t_{I3Ccyc}$ + 50 | — | ns |
| | Data input hold time | $t_{SDAH}$ | 0 | — | ns |
| | SCL, SDA capacitive load | $C_b$*2 | — | 400 | pF |



Note: $t_{I3Ccyc}$: I3C internal reference clock (I3Cφ) cycle, $t_{Tcyc}$: I3CCLK cycle.
Note 1. Values in parentheses apply when INCTL.DNFS[3:0] is set to 0x3 while the digital filter is enabled with INCTL.DNFE set to 1.
Note 2. $C_b$ indicates the total capacity of the bus line.

**Table 49.44 IIC timing (Fast-mode+)**

Conditions: VCC = AVCC0 = 2.7 to 3.6 V

| Parameter | | Symbol | Min*1 | Max*1 | Unit |
|---|---|---|---|---|---|
| IIC (Fast-mode+) BFCTL.FMPE = 1 | SCL input cycle time | $t_{SCL}$ | 10(18) × $t_{I3Ccyc}$ + 240 | — | ns |
| | SCL input high pulse width | $t_{SCLH}$ | 5(9) × $t_{I3Ccyc}$ + 120 | — | ns |
| | SCL input low pulse width | $t_{SCLL}$ | 5(9) × $t_{I3Ccyc}$ + 120 | — | ns |
| | SCL, SDA rise time | $t_{Sr}$ | — | 120 | ns |
| | SCL, SDA fall time | $t_{Sf}$ | — | 120 | ns |
| | SCL, SDA input spike pulse removal time | $t_{SP}$ | 0 | 1(4) × $t_{I3Ccyc}$ | ns |
| | SDA input bus free time when wakeup function is disabled | $t_{BUF}$ | 5(9) × $t_{I3Ccyc}$ + 120 | — | ns |
| | SDA input bus free time when wakeup function is enabled | $t_{BUF}$ | 5(9) × $t_{I3Ccyc}$ + 4 × $t_{Tcyc}$ + 120 | — | ns |
| | START condition input hold time when wakeup function is disabled | $t_{STAH}$ | $t_{I3Ccyc}$ + 120 | — | ns |
| | START condition input hold time when wakeup function is enabled | $t_{STAH}$ | 1(5) × $t_{I3Ccyc}$ + $t_{Tcyc}$ + 120 | — | ns |
| | Restart condition input setup time | $t_{STAS}$ | 120 | — | ns |
| | Stop condition input setup time | $t_{STOS}$ | 120 | — | ns |
| | Data input setup time | $t_{SDAS}$ | $t_{I3Ccyc}$ + 30 | — | ns |
| | Data input hold time | $t_{SDAH}$ | 0 | — | ns |
| | SCL, SDA capacitive load | $C_b$*2 | — | 550 | pF |

Note: $t_{I3Ccyc}$: I3C internal reference clock (I3Cφ) cycle, $t_{Tcyc}$: I3CCLK cycle.
Note 1. Values in parentheses apply when INCTL.DNFS[3:0] is set to 0x3 while the digital filter is enabled with INCTL.DNFE set to 1.
Note 2. $C_b$ indicates the total capacity of the bus line.

Note 1. S, P, and Sr indicate the following conditions:
S: Start condition
P: Stop condition
Sr: Restart condition

**Figure 49.41 $I^2C$ bus interface input/output timing**

**Table 49.45 IIC timing (HS-mode)**

Conditions: VCC = 2.7 to 3.60 V

| Parameter | | | Symbol | Min*1 | Max*1 | Unit |
|---|---|---|---|---|---|---|
| IIC (Hs-mode)<br>BFCTL.HSME = 1 | SCL input cycle time | | $t_{SCL}$ | 55(57) × $t_{I3Ccyc}$ | — | ns |
| | | | | | — | |
| | SCL input high pulse width | $C_b$ = 400 pF | $t_{SCLH}$ | 43(44) × $t_{I3Ccyc}$ | — | ns |
| | | $C_b$ = 100 pF | | 23(24) × $t_{I3Ccyc}$ | — | |
| | SCL input low pulse width | $C_b$ = 400 pF | $t_{SCLL}$ | 64(65) × $t_{I3Ccyc}$ | — | ns |

| | | $C_b$ = 100 pF | | — | 40 | |
| | SDA fall time | $C_b$ = 400 pF | $t_{SfDA}$ | — | 160 | ns |
| | | $C_b$ = 100 pF | | — | 80 | |
| | SCL, SDA input spike pulse removal time | | $t_{SP}$ | 0 | 1(1) × $t_{I3Ccyc}$ | ns |
| | Repeated START condition input setup time | | $t_{STAS}$ | 40 | — | ns |
| | STOP condition input setup time | | $t_{STOS}$ | 40 | — | ns |
| | Data input setup time | | $t_{SDAS}$ | 0 | — | ns |
| | Data input hold time | $C_b$ = 400 pF | $t_{SDAH}$ | 0 | 150 | ns |
| | | $C_b$ = 100 pF | | 0 | 70 | |
| | SCL, SDA capacitive load | | $C_b$*2 | — | 400 | pF |

Note: $t_{I3Ccyc}$: I3C internal reference clock (I3Cφ) cycle.

Note 1. Values in parentheses apply when INCTL.DNFS[3:0] is set to 0x3 while the digital filter is enabled with INCTL.DNFE set to 1.

Note 2. $C_b$ indicates the total capacity of the bus line.

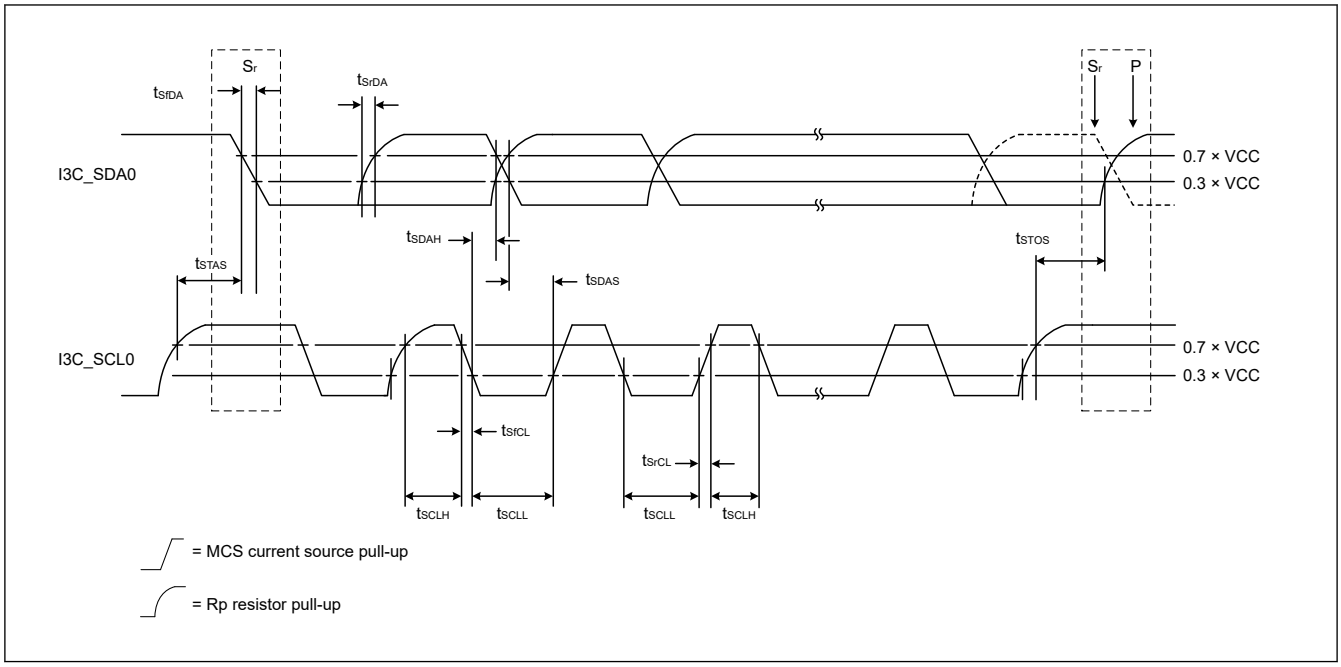

**Figure 49.42 I²C bus interface input/output timing (Hs-mode)**

**Table 49.46 I3C timing (open drain timing parameters)**

Conditions: VCC = 3.0 to 3.60 V

| Parameter | | Symbol | Min | Max | Unit | Test conditions |
|---|---|---|---|---|---|---|
| I3C Open Drain Timing Parameters | SCL Clock Low Period | $t_{LOW_OD}$ *1 *2 | 200 | — | ns | Figure 49.45 |
| | | $t_{DIG_OD_L}$ | $t_{LOW_ODmin} + t_{fDA_ODmin}$ | — | ns | Figure 49.45 |
| | SCL Clock High Period | $t_{HIGH}$ *3 *4 | — | 41 | ns | Figure 49.43 |
| | | $t_{DIG_H}$ | — | $t_{HIGH} + t_{CF}$ | ns | Figure 49.43 |
| | SDA Signal Fall Time | $t_{fDA_OD}$ | $t_{CF}$ | 33 | ns | Figure 49.45 |
| | SDA Data Setup Time Open Drain Mode | $t_{SU_OD}$ *1 | 24 | — | ns | Figure 49.44 |
| | Clock After START (S) Condition | $t_{CAS}$ *5 *6 | 38.4 nano | ENAS0: 1 µ | seconds | Figure 49.45 |
| | | | | ENAS1: 100 µ | | |
| | | | | ENAS2: 2 milli | | |
| | | | | ENAS3: 50 milli | | |
| | Clock Before STOP (P) Condition | $t_{CBP}$ | $t_{CASmin}$ / 2 | — | seconds | Figure 49.46 |
| | Current Master to Secondary Master Overlap time during handoff | $t_{MMOverlap}$ | $t_{DIG_OD_Lmin}$ | — | ns | Figure 49.51 |
| | Bus Available Condition | $t_{AVAL}$ *7 | 1 | — | µs | — |
| | Bus Idle Condition | $t_{IDLE}$ | 1 | — | ms | — |
| | Time Internal Where New Master Not Driving SDA Low | $t_{MMLock}$ | $t_{AVALmin}$ | — | µs | Figure 49.51 |

Note 1. This is approximately equal to $t_{LOWmin} + t_{DS_ODmin} + t_{rDA_ODtyp} + t_{SU_Odmin}$.

Note 2. The Master may use a shorter Low period if it knows that this is safe, i.e., that SDA is already above VIH.

Note 3. Based on $t_{SPIKE}$, rise and fall times, and interconnect

Note 4. This maximum High period may be exceeded when the signals can be safely seen by Legacy I²C Devices, and/or in consideration of the interconnect (e.g., a short Bus).

As a product specification, if this Max value cannot be guaranteed, change this Max value and specify that it cannot be used in the Mixed Bus.

Note 5. On a legacy bus where $I^2C$ devices need to see Start

Note 6. Slaves that do not support the optional ENTASx CCCs shall use the $t_{CAS}$ Max value shown for ENTAS3

Note 7. On a mixed bus with Fm Legacy $I^2C$ Devices, $t_{AVAL}$ is 300 ns shorter than the Fm Bus Free Condition time ($t_{BUF}$)

**Table 49.47 I3C timing (push-pull timing parameters for SDR mode)**

Conditions: VCC = 3.0 to 3.60 V

| Parameter | | | Symbol | Min | Max | Unit |
|---|---|---|---|---|---|---|
| I3C Push-Pull Timing Parameters for SDR and HDR-DDR Modes | SCL Clock Frequency | | $f_{SCL}$ *1 | 0.01 | 6.38 | MHz |
| | SCL Clock Low Period | | $t_{LOW}$ | 71 | — | ns |
| | | | $t_{DIG_L}$ *2 *4 | 79 | — | ns |
| | SCL Clock High Period for Mixed Bus | | $t_{HIGH_MIXED}$ | 60 | — | ns |
| | | | $t_{DIG_H_MIXED}$ *2 *3 | 68 | — | ns |
| | SCL Clock High Period | | $t_{HIGH}$ | 60 | — | ns |
| | | | $t_{DIG_H}$ *2 | 68 | — | ns |
| | Clock in to Data Out for Slave | | $t_{SCO}$ | — | 33 | ns |
| | SCL Clock Rise Time | | $t_{CR}$ | — | 150 × 1 /$f_{SCL}$(capped at 60) | ns |
| | SCL Clock Fall Time | | $t_{CF}$ | — | 150 × 1 /$f_{SCL}$(capped at 60) | µs |
| | SDA Signal Data Hold in Push-Pull Mode | Master | $t_{HD_PP}$ *4 | $t_{CR}$ + 3, $t_{CF}$ +3 | — | — |
| | | Slave | $t_{HD_PP}$ | 0 | — | — |
| | SDA Signal Data Setup in Push-Pull Mode | | $t_{SU_PP}$ | 27 | N/A | ns |
| | Clock After Repeated START (Sr) | | $t_{CASr}$ | $t_{CASmin}$ | N/A | ns |
| | Clock Before Repeated START (Sr) | | $t_{CBSr}$ | $t_{CASmin}$ / 2 | N/A | ns |
| | Capacitive Load per Bus Line (SDA/SCL) | | $C_b$ | — | 50 | pF |

Note 1. $f_{SCL} = 1 / (t_{DIG_L} + t_{DIG_H})$

Note 2. $t_{DIG_L}$ and $t_{DIG_H}$ are the clock Low and High periods as seen at the receiver end of the I3C Bus using $V_{IL}$ and $V_{IH}$.

Note 3. When communicating with an I3C Device on a mixed Bus, the $t_{DIG_H_MIXED}$ period must be constrained in order to make sure that $I^2C$ Devices do not interpret I3C signaling as valid $I^2C$ signaling.

Note 4. As both edges are used, the hold time needs to be satisfied for the respective edges; i.e., $t_{CF}$ + 3 for falling edge clocks, and $t_{CR}$ + 3 for rising edge clocks.

## 49.3.13 SSIE Timing

**Table 49.48 SSIE timing (1 of 2)**

(1) Use pins that have a letter appended to their names, for instance "_A" or "_B" to indicate group membership. For the SSIE interface, the AC portion of the electrical characteristics is measured for each group.

| Parameter | | | | Symbol | Target specification | | Unit | Test conditions |
|---|---|---|---|---|---|---|---|---|
| | | | | | Min | Max | | |
| SSIBCK0 | Cycle | Master | 2.7v ≤ VCC ≤ 3.6 | $t_O$ | 150 | — | ns | Figure 49.52 |
| | | | 2.4 ≤ VCC < 2.7 | | 200 | — | ns | |
| | | | 1.8 ≤ VCC < 2.4 | | 250 | — | ns | |
| | | | 1.6 ≤ VCC < 1.8 | | 1000 | — | ns | |
| | | Slave | 2.7v ≤ VCC ≤ 3.6 | $t_I$ | 150 | — | ns | |
| | | | 2.4 ≤ VCC < 2.7 | | 200 | — | ns | |
| | | | 1.8 ≤ VCC < 2.4 | | 250 | — | ns | |
| | | | 1.6 ≤ VCC < 1.8 | | 1000 | — | ns | |
| | High level/ Low level | Master | | $t_{HC}/t_{LC}$ | 0.35 | — | $t_O$ | |
| | | Slave | | | 0.35 | — | $t_I$ | |
| | Rising time/ falling time | Master | | $t_{RC}/t_{FC}$ | — | 0.15 | $t_O$ / $t_I$ | |
| | | Slave | | | — | 0.15 | $t_O$ / $t_I$ | |

**Table 49.48 SSIE timing (2 of 2)**

(1) Use pins that have a letter appended to their names, for instance "_A" or "_B" to indicate group membership. For the SSIE interface, the AC portion of the electrical characteristics is measured for each group.

| Parameter | | | | Symbol | Target specification | | Unit | Test conditions |
|---|---|---|---|---|---|---|---|---|
| | | | | | Min | Max | | |
| SSILRCK0/ SSIFS0, SSITXD0, SSIRXD0 | Input set up time | Master | 2.7v ≤ VCC ≤ 3.6 | $t_{SR}$ | 30 | — | ns | Figure 49.54, Figure 49.55 |
| | | | 2.4 ≤ VCC < 2.7 | | 30 | — | ns | |
| | | | 1.8 ≤ VCC < 2.4 | | 45 | — | ns | |
| | | | 1.6 ≤ VCC < 1.8 | | 60 | — | ns | |
| | | Slave | 2.7v ≤ VCC ≤ 3.6 | | 10 | — | ns | |
| | | | 1.8 ≤ VCC < 2.7 | | 10 | — | ns | |
| | | | 1.8 ≤ VCC < 2.7 | | 10 | — | ns | |
| | | | 1.6 ≤ VCC < 1.8 | | 10 | — | ns | |
| | Input hold time | Master | | $t_{HR}$ | 10 | — | ns | |
| | | Slave | | | 18 | — | ns | |
| | Output delay time | Master | 2.7v ≤ VCC ≤ 3.6 | $t_{DTR}$ | 0 | 15 | ns | |
| | | | 2.4 ≤ VCC < 2.7 | | 0 | 15 | | |
| | | | 1.8 ≤ VCC < 2.4 | | 0 | 15 | | |
| | | | 1.6 ≤ VCC < 1.8 | | 0 | 15 | | |
| | | Slave | 2.7v ≤ VCC ≤ 3.6 | | 8 | 35 | ns | |
| | | | 2.4 ≤ VCC < 2.7 | | 10 | 40 | | |
| | | | 1.8 ≤ VCC < 2.4 | | 10 | 55 | | |
| | | | 1.6 ≤ VCC < 1.8 | | 10 | 65 | | |
| | Output delay time from SSILRCK0/ SSIFS0 change | Slave | 2.7v ≤ VCC ≤ 3.6 | $t_{DTRW}$ | 10 | 35 | ns | Figure 49.55, Figure 49.56*1 |
| | | | 2.4 ≤ VCC < 2.7 | | 10 | 35 | | |
| | | | 1.8 ≤ VCC < 2.4 | | 10 | 48 | | |
| | | | 1.6 ≤ VCC < 1.8 | | 10 | 60 | | |
| GTIOC2A, AUDIO_CLK | Cycle | | 1.8 ≤ VCC < 3.6 | $t_{EXcyc}$ | 25 | — | ns | Figure 49.53 |
| | | | 1.6 ≤ VCC < 1.8 | | 250 | — | | |
| | High level/ Low level | | | $t_{EXL}/t_{EXH}$ | 0.4 | 0.6 | $t_{EXcyc}$ | |

Note 1. For slave-mode transmission, SSIE has a path, through which the signal input from the SSILRCK0/SSIFS0 pin is used to generate transmit data, and the transmit data is logically output to the SSITXD0 pin.

## 49.3.14 UARTA Timing

**Table 49.49 UARTA interface timing**

| Parameter | Symbol | Min. | Max. | Unit | Test conditions |
|---|---|---|---|---|---|
| Transfer rate | — | 200 | 153600 | bps | — |

## 49.3.15 CANFD Timing

**Table 49.50 CANFD interface timing**

| Parameter | Symbol | CAN | | CANFD | | Unit | Test conditions |
|---|---|---|---|---|---|---|---|
| | | Min | Max | Min | Max | | |
| Internal delay time | $t_{node}$ | — | 100 | — | 75 | ns | Figure 49.57 |

Note: $t_{node} = t_{d(CTX)} + t_{d(CRX)}$

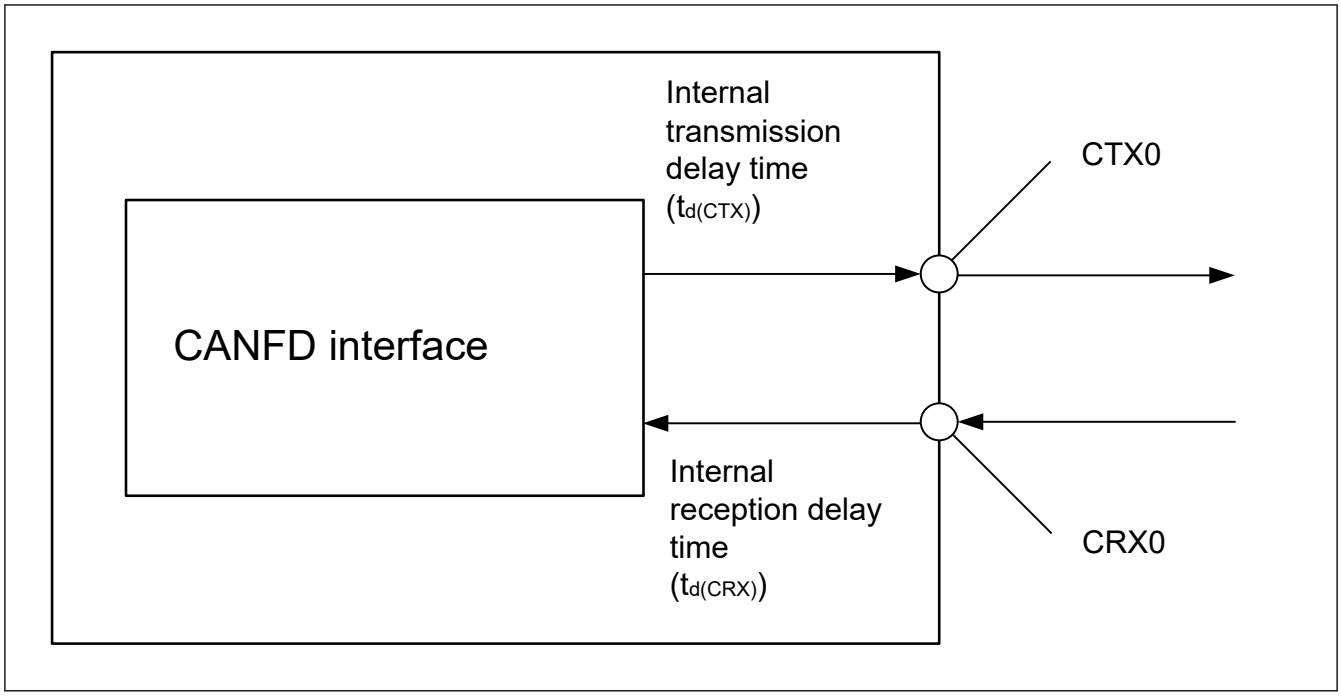

**Figure 49.57 CANFD interface condition**

## 49.4 USB Characteristics

### 49.4.1 USBFS Timing

**Table 49.51 USBFS full-speed characteristics (USB_DP and USB_DM pin characteristics)**

Conditions: VCC = AVCC0 = VCC_USB = 3.0 to 3.6 V, 2.7 ≤ VREFH0/VREFH ≤ AVCC0, USBCLK = 48 MHz

| Parameter | | Symbol | Min | Typ | Max | Unit | Test conditions |
|---|---|---|---|---|---|---|---|
| Input characteristics | Input high voltage | $V_{IH}$ | 2.0 | — | — | V | — |
| | Input low voltage | $V_{IL}$ | — | — | 0.8 | V | — |
| | Differential input sensitivity | $V_{DI}$ | 0.2 | — | — | V | \| USB_DP - USB_DM \| |
| | Differential common-mode range | $V_{CM}$ | 0.8 | — | 2.5 | V | — |
| Output characteristics | Output high voltage | $V_{OH}$ | 2.8 | — | 3.6 | V | $I_{OH}$ = –200 µA |
| | Output low voltage | $V_{OL}$ | 0.0 | — | 0.3 | V | $I_{OL}$ = 2 mA |
| | Cross-over voltage | $V_{CRS}$ | 1.3 | — | 2.0 | V | Figure 49.58 |
| | Rise time | $t_{LR}$ | 4 | — | 20 | ns | |
| | Fall time | $t_{LF}$ | 4 | — | 20 | ns | |
| | Rise/fall time ratio | $t_{LR}$ / $t_{LF}$ | 90 | — | 111.11 | % | $t_{FR}$/ $t_{FF}$ |
| | Output resistance | $Z_{DRV}$ | 28 | — | 44 | Ω | USBFS: Rs = 27 Ω included |
| Pull-up and pull-down characteristics | DM pull-up resistance in device controller mode | $R_{pu}$ | 0.900 | — | 1.575 | kΩ | During idle state |
| | | | 1.425 | — | 3.090 | kΩ | During transmission and reception |
| | USB_DP and USB_DM pull-down resistance in host controller mode | $R_{pd}$ | 14.25 | — | 24.80 | kΩ | — |

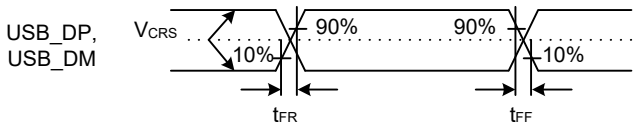

**Figure 49.58 USB_DP and USB_DM output timing in full-speed mode**

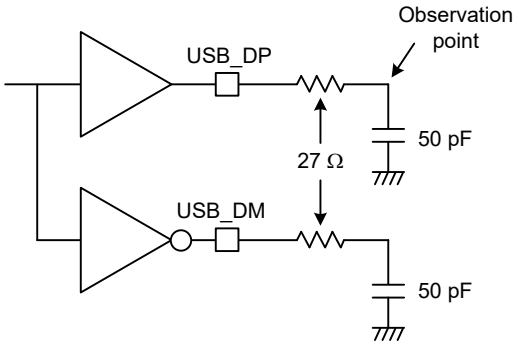

**Figure 49.59 Test circuit in full-speed mode**

## 49.5 ADC12 Characteristics

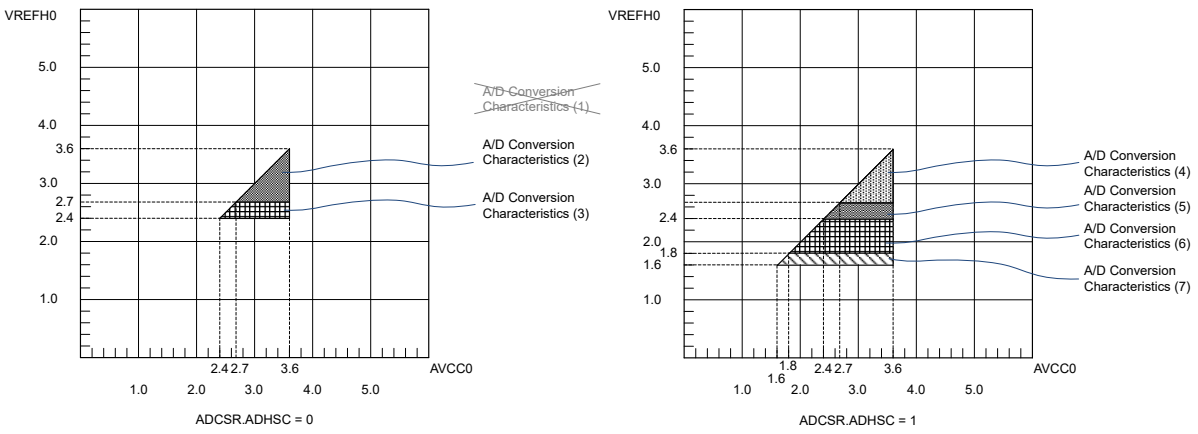

**Figure 49.60 AVCC0 to VREFH0 voltage range**

**Table 49.52 A/D conversion characteristics (1) in high-speed A/D conversion mode (1 of 2)**

Conditions: VCC = AVCC0 = VREFH0 = 2.7 to 3.6 V*5, VSS = AVSS0 = VREFL0 = 0 V
Reference voltage range applied to the VREFH0 and VREFL0.

| Parameter | | Min | Typ | Max | Unit | Test conditions |
|---|---|---|---|---|---|---|
| PCLKC (ADCLK) frequency | | 1 | — | 48 | MHz | — |
| Analog input capacitance*2 | Cs | — | — | 9*3 | pF | High-precision channel |
| | | — | — | 10*3 | pF | Normal-precision channel |
| Analog input resistance | Rs | — | — | 1.9*3 | kΩ | High-precision channel |
| | | — | — | 6.0*3 | kΩ | Normal-precision channel |

**Table 49.52 A/D conversion characteristics (1) in high-speed A/D conversion mode (2 of 2)**

Conditions: VCC = AVCC0 = VREFH0 = 2.7 to 3.6 V[*5], VSS = AVSS0 = VREFL0 = 0 V
Reference voltage range applied to the VREFH0 and VREFL0.

| Parameter | | Min | Typ | Max | Unit | Test conditions |
|---|---|---|---|---|---|---|
| Analog input voltage range | Ain | 0 | — | VREFH0 | V | — |
| Resolution | | — | — | 12 | Bit | — |
| Conversion time[*1] (Operation at PCLKC = 48 MHz) | Permissible signal source impedance Max. = 0.3 kΩ | 0.67 (0.219)[*4] | — | — | µs | High-precision channel<br>ADCSR.ADHSC = 0<br>ADSSTRn.SST[7:0] = 0x0A<br>ADACSR.ADSAC = 1 |
| | | 1.29 (0.844)[*4] | — | — | µs | Normal-precision channel<br>ADCSR.ADHSC = 0<br>ADSSTRn.SST[7:0] = 0x28<br>ADACSR.ADSAC = 1 |
| Offset error | | — | ±1.0 | ±5.5 | LSB | High-precision channel |
| | | | | ±7.0 | LSB | Other than specified |
| Full-scale error | | — | ±1.0 | ±5.5 | LSB | High-precision channel |
| | | | | ±7.0 | LSB | Other than specified |
| Quantization error | | — | ±0.5 | — | LSB | — |
| Absolute accuracy | | — | ±2.5 | ±6.0 | LSB | High-precision channel |
| | | | | ±9.0 | LSB | Other than specified |
| DNL differential nonlinearity error | | — | ±1.0 | — | LSB | — |
| INL integral nonlinearity error | | — | ±1.5 | ±3.0 | LSB | — |

Note: The characteristics apply when no pin functions other than 12-bit A/D converter input are used. Absolute accuracy does not include quantization errors. Offset error, full-scale error, DNL differential nonlinearity error, and INL integral nonlinearity error do not include quantization errors.
Note 1. The conversion time is the sum of the sampling time and the comparison time. The number of sampling states is indicated for the test conditions.
Note 2. Except for I/O input capacitance (Cin), see section 49.2.4. I/O $V_{OH}$, $V_{OL}$, and Other Characteristics.
Note 3. Reference data.
Note 4. ( ) lists sampling time.
Note 5. When VREFH0 < AVCC0, the MAX. values are as follows.
Absolute accuracy/Offset error/Full-scale error:
For voltage difference between AVCC0 and VREFH0, it should be added ±0.75 LSB/V to the Max spec.
INL integral non-linearity error:
For voltage difference between AVCC0 and VREFH0, it should be added ±0.2 LSB/V to the Max spec.

**Table 49.53 A/D conversion characteristics (2) in high-speed A/D conversion mode (1 of 2)**

Conditions: VCC = AVCC0 = VREFH0 = 2.4 to 3.6 V[*5], VSS = AVSS0 = VREFL0 = 0 V
Reference voltage range applied to the VREFH0 and VREFL0.

| Parameter | | Min | | Max | Unit | Test conditions |
|---|---|---|---|---|---|---|
| PCLKC (ADCLK) frequency | | 1 | — | 32 | MHz | — |
| Analog input capacitance[*2] | Cs | — | — | 9[*3] | pF | High-precision channel |
| | | — | — | 10[*3] | pF | Normal-precision channel |

Figure 49.61 shows the equivalent circuit for analog input.

Note: Terminal leakage current is not shown in this figure.

**Figure 49.61 Equivalent circuit for analog input**

**Table 49.58 12-bit A/D converter channel classification**

| Classification | Channel | Conditions | Remarks |
|---|---|---|---|
| High-precision channel | AN000 to AN006 | AVCC0 = 1.6 to 3.6 V | Pins AN000 to AN006 cannot be used as general I/O, when the A/D converter is in use. |
| Normal-precision channel | AN017 to AN025 | | |
| Internal reference voltage input channel | Internal reference voltage | AVCC0 = 1.8 to 3.6 V | — |
| Temperature sensor input channel | Temperature sensor output | AVCC0 = 1.8 to 3.6 V | — |
| Input channel from CTSU | CTSU TSCAP voltage | AVCC0 = 1.6 to 3.6 V | — |

**Table 49.59 A/D internal reference voltage characteristics**

Conditions: VCC = AVCC0 = VREFH0 = 1.8 to 3.6 V*1

| Parameter | Min | Typ | Max | Unit | Test conditions |
|---|---|---|---|---|---|
| Internal reference voltage input channel*2 | 1.42 | 1.48 | 1.54 | V | — |
| PCLKC (ADCLK) frequency*3 | 1 | — | 2 | MHz | — |
| Sampling time*4 | 5.0 | — | — | µs | — |

Note 1. The internal reference voltage cannot be selected for input channels when AVCC0 < 1.8 V.
Note 2. The 12-bit A/D internal reference voltage indicates the voltage when the internal reference voltage is input to the 12-bit A/D converter.
Note 3. When the internal reference voltage is selected as the high-potential reference voltage.
Note 4. When the internal reference voltage is converted.

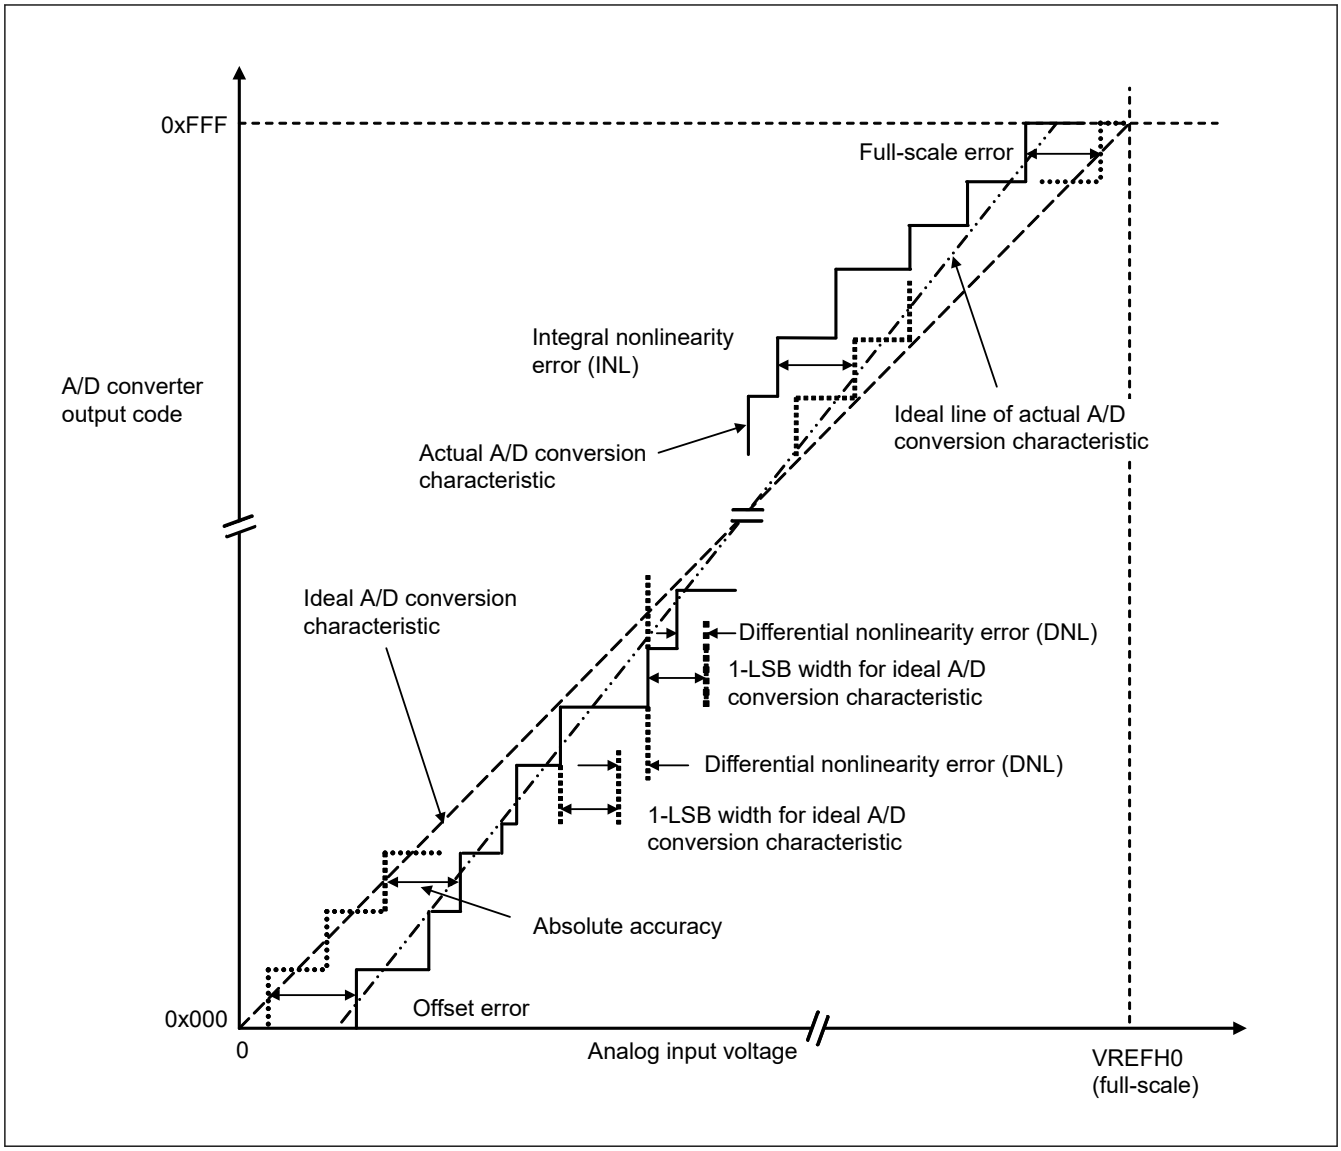

**Figure 49.62 Illustration of 12-bit A/D converter characteristic terms**

### Absolute accuracy

Absolute accuracy is the difference between output code based on the theoretical A/D conversion characteristics, and the actual A/D conversion result. When measuring absolute accuracy, the voltage at the midpoint of the width of the analog input voltage (1-LSB width), which can meet the expectation of outputting an equal code based on the theoretical A/D conversion characteristics, is used as the analog input voltage. For example, if 12-bit resolution is used and the reference voltage VREFH0 = 3.072 V, then 1-LSB width becomes 0.75 mV, and 0 mV, 0.75 mV, and 1.5 mV are used as the analog input voltages. If analog input voltage is 6 mV, an absolute accuracy of ±5 LSB means that the actual A/D conversion result is in the range of 0x003 to 0x00D, though an output code of 0x008 can be expected from the theoretical A/D conversion characteristics.

### Integral nonlinearity error (INL)

Integral nonlinearity error is the maximum deviation between the ideal line when the measured offset and full-scale errors are zeroed, and the actual output code.

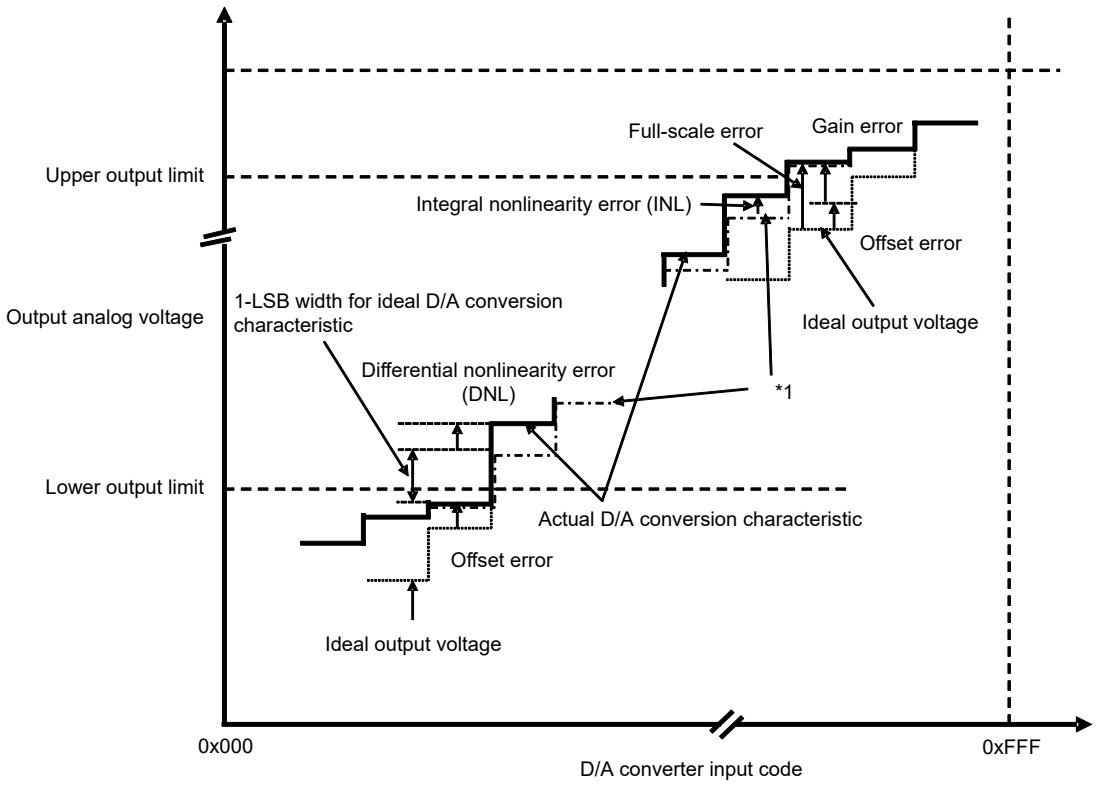
### Differential nonlinearity error (DNL)

Differential nonlinearity error is the difference between 1-LSB width based on the ideal A/D conversion characteristics and the width of the actual output code.

### Offset error

Offset error is the difference between the transition point of the ideal first output code and the actual first output code.

### Full-scale error



Full-scale error is the difference between the transition point of the ideal last output code and the actual last output code.

## 49.6 DAC12 Characteristics

**Table 49.60 12-bit D/A conversion characteristics**

Conditions: VCC = AVCC0 = 1.8 to 3.6 V
Reference voltage = AVCC0 or AVSS0 selected

| Parameter | Min | Typ | Max | Unit | Test conditions |
|---|---|---|---|---|---|
| Resolution | — | — | 12 | bit | — |
| Resistive load | 30 | — | — | kΩ | — |
| Capacitive load | — | — | 50 | pF | — |
| Output voltage range | 0.35 | — | AVCC0-0.47 | V | — |
| DNL differential nonlinearity error | — | ±0.5 | ±2.0 | LSB | — |
| INL integral nonlinearity error | — | ±2.0 | ±8.0 | LSB | — |
| Offset error | — | — | ±30 | mV | — |
| Full-scale error | — | — | ±30 | mV | — |
| Output impedance | — | 5 | — | Ω | — |
| Conversion time | — | — | 30 | μs | — |

Note 1. Ideal D/A conversion output voltage that is adjusted so that offset and full scale errors are zeroed.

**Figure 49.63 Illustration of D/A converter characteristic terms**

### Integral nonlinearity error (INL)

Integral nonlinearity error is the maximum deviation between the ideal output voltage based on the ideal conversion characteristic when the measured offset and full-scale errors are zeroed, and the actual output voltage.

### Differential nonlinearity error (DNL)

Differential nonlinearity error is the difference between 1-LSB voltage width based on the ideal D/A conversion characteristics and the width of the actual output voltage.

### Offset error

Offset error is the difference between the highest actual output voltage that falls below the lower output limit and the ideal output voltage based on the input code.

### Full-scale error

Full-scale error is the difference between the lowest actual output voltage that exceeds the upper output limit and the ideal output voltage based on the input code.

## 49.7 TSN Characteristics

| | When power supply rise | $V_{det2_4}$ | 2.26 | 2.36 | 2.46 | | Figure 49.69 |
| | When power supply fall | | 2.20 | 2.30 | 2.40 | | |
| | When power supply rise | $V_{det2_5}$ | 2.06 | 2.15 | 2.24 | | |
| | When power supply fall | | 2.00 | 2.09 | 2.18 | | |
| | When power supply rise | $V_{det2_6}$ | 1.86 | 1.94 | 2.02 | | |
| | When power supply fall | | 1.80 | 1.88 | 1.96 | | |
| | When power supply rise | $V_{det2_7}$ | 1.66 | 1.73 | 1.80 | | |
| | When power supply fall | | 1.60 | 1.67 | 1.74 | | |

Note: These characteristics apply when noise is not superimposed on the power supply.
Note 1. # in the symbol $V_{det0_\#}$ denotes the value of the OFS1.VDSEL0[1:0] bits.
Note 2. # in the symbol $V_{det1_\#}$ denotes the value of the LVD1CMPCR.LVD1LVL[3:0] bits.
Note 3. # in the symbol $V_{det2_\#}$ denotes the value of the LVD2CMPCR.LVD2LVL[2:0] bits.

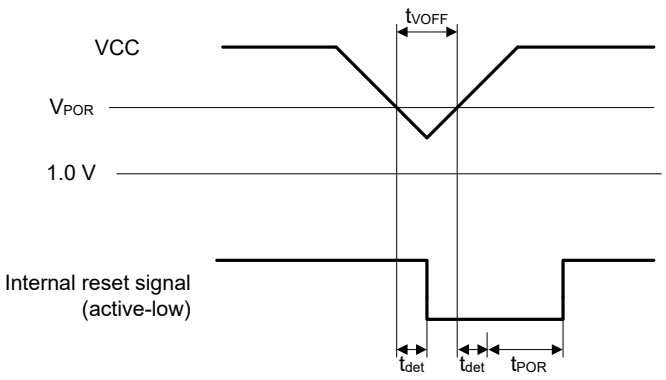
**Table 49.64 Power-on reset circuit and voltage detection circuit characteristics (2) (1 of 2)**

| Parameter | | Symbol | Min | Typ | Max | Unit | Test Conditions |
|---|---|---|---|---|---|---|---|
| Wait time after power-on reset cancellation | LVD0: enable | $t_{POR}$ | — | 4.9 | — | ms | — |
| | LVD0: disable | $t_{POR}$ | — | 4.2 | — | ms | — |
| Wait time after voltage monitor 0, 1, 2 reset cancellation | LVD0: enable*1 | $t_{LVD0,1,2}$ | — | 0.94 | — | ms | — |
| | LVD0: disable*2 | $t_{LVD1,2}$ | — | 0.25 | — | ms | — |
| Power-on reset response delay time*3 | | $t_{det}$ | — | — | 500 | µs | Figure 49.65, Figure 49.66 |
| LVD0 response delay time*3 | | $t_{det}$ | — | — | 500 | µs | Figure 49.67 |
| LVD1 response delay time*3 | | $t_{det}$ | — | — | 600 | µs | Figure 49.68 |
| LVD2 response delay time*3 | | $t_{det}$ | — | — | 600 | µs | Figure 49.69 |
| Minimum VCC down time | POR | $t_{VOFF}$ | 500 | — | — | µs | Figure 49.65 |
| | LVD0 | | 300 | — | — | µs | Figure 49.67 |
| | LVD1 | | 300 | — | — | µs | Figure 49.68 |
| | LVD2 | | 600 | — | — | µs | Figure 49.69 |
| Power-on reset enable time | | $t_{W\ (POR)}$ | 1 | — | — | ms | Figure 49.66, VCC = below 1.0 V |
| LVD1 operation stabilization time (after LVD1 is enabled) | | $T_{d\ (E-A)}$ | — | — | 350 | µs | Figure 49.68 |
| LVD2 operation stabilization time (after LVD2 is enabled) | | $T_{d\ (E-A)}$ | — | — | 600 | µs | Figure 49.69 |
| Hysteresis width (POR) | | $V_{PORH}$ | — | 10 | — | mV | — |

**Table 49.64 Power-on reset circuit and voltage detection circuit characteristics (2) (2 of 2)**

| Parameter | Symbol | Min | Typ | Max | Unit | Test Conditions |
|---|---|---|---|---|---|---|
| Hysteresis width (LVD0, LVD1 and LVD2) | $V_{LVH}$ | — | 60 | — | mV | LVD0 selected |
| | | — | 70 | — | | $V_{det1_0}$ to $V_{det1_5}$ selected |
| | | — | 60 | — | | $V_{det1_6}$ to $V_{det1_7}$ selected |
| | | — | 50 | — | | $V_{det1_8}$ to $V_{det1_B}$ selected |
| | | — | 70 | — | | LVD2 selected |

Note 1. When OFS1.LVDAS = 0.
Note 2. When OFS1.LVDAS = 1.
Note 3. The minimum VCC down time indicates the time when VCC is below the minimum value of voltage detection levels $V_{POR}$, $V_{det0}$, $V_{det1}$, and $V_{det2}$ for the POR/LVD.



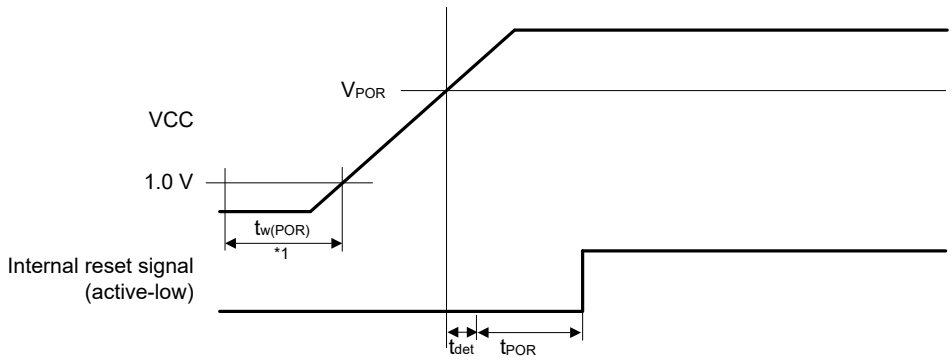


**Figure 49.65 Voltage detection reset timing**

Note 1. $t_{w(POR)}$ is the time required for a power-on reset to be enabled while the external power VCC is being held below the valid voltage (1.0 V).
When VCC turns on, maintain $t_{w(POR)}$ for 1.0 ms or more.

## 49.10 CTSU Characteristics

**Table 49.65 CTSU characteristics**

Conditions: VCC = AVCC0 = 1.8 to 3.6 V

| Parameter | Symbol | Min | Typ | Max | Unit | Test conditions |
|---|---|---|---|---|---|---|
| External capacitance connected to TSCAP pin | $C_{tscap}$ | 9 | 10 | 11 | nF | — |

## 49.11 Comparator Characteristics

**Table 49.66 ACMPLP characteristics (1 of 2)**

Conditions: VCC = AVCC0 = 1.6 to 3.6 V, VSS = AVSS0 = 0 V

| Parameter | | Symbol | Min | Typ | Max | Unit | Test conditions |
|---|---|---|---|---|---|---|---|
| Reference voltage range | | $V_{REF}$ | 0 | — | VCC-1.4 | V | — |
| Input voltage range | | $V_I$ | 0 | — | VCC | V | — |
| Internal reference voltage*1 | | — | 1.34 | 1.44 | 1.54 | V | — |
| Output delay time | High-speed mode | $T_d$ | — | — | 1.2 | µs | VCC = 3.0 V |
| | Low-speed mode | | — | — | 9 | µs | |
| | Window mode | | — | — | 2 | µs | |
| Offset voltage | High-speed mode | — | — | — | 50 | mV | — |
| | Low-speed mode | — | — | — | 40 | mV | — |
| | Window mode | — | — | — | 60 | mV | — |

**Table 49.66 ACMPLP characteristics (2 of 2)**

Conditions: VCC = AVCC0 = 1.6 to 3.6 V, VSS = AVSS0 = 0 V

| Parameter | | Symbol | Min | Typ | Max | Unit | Test conditions |
|---|---|---|---|---|---|---|---|
| Internal reference voltage for window mode | | $V_{RFH}$ | — | 0.76 × VCC | — | V | — |
| | | $V_{RFL}$ | — | 0.24 × VCC | — | V | — |
| Operation stabilization wait time | High-speed mode | $T_{cmp}$ | 100 | — | — | μs | — |
| | Low-speed mode | | 200 | — | — | | |

Note 1. The internal reference voltage can be selected as ACMPLP reference voltage only when 2.94 V ≤ VCC ≤ 3.6 V.

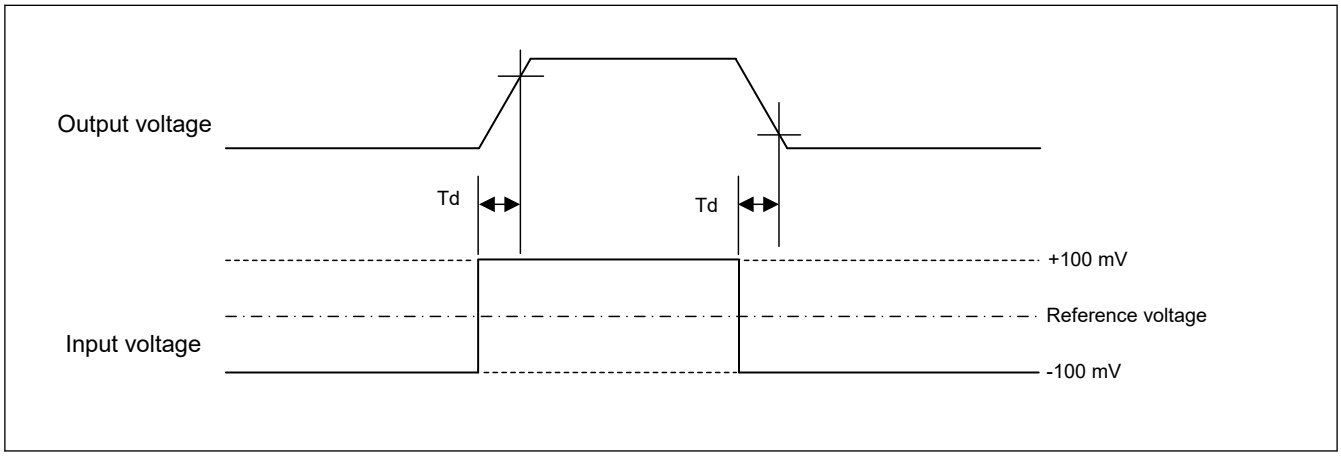

**Figure 49.70 Output delay time**

## 49.12 Segment LCD Controller Characteristics

### 49.12.1 External Resistance Division Method

#### (1) Static display mode

**Table 49.67 External resistance division method LCD characteristics (1)**

Conditions: VL4 (Min) ≤ VCC = AVCC ≤ 3.6 V, VSS = AVSS = 0 V

| Parameter | Symbol | Min | Typ | Max | Unit | Test conditions |
|---|---|---|---|---|---|---|
| LCD drive voltage | $V_{L4}$ | 2.0 | — | VCC | V | — |

#### (2) 1/2 bias method, 1/4 bias method

**Table 49.68 External resistance division method LCD characteristics (2)**

Conditions: VL4 (Min) ≤ VCC = AVCC ≤ 3.6 V, VSS = AVSS = 0 V

| Parameter | Symbol | Min | Typ | Max | Unit | Test conditions |
|---|---|---|---|---|---|---|
| LCD drive voltage | $V_{L4}$ | 2.7 | — | VCC | V | — |

#### (3) 1/3 bias method

**Table 49.69 External resistance division method LCD characteristics (3)**

Conditions: VL4 (Min) ≤ VCC = AVCC ≤ 3.6 V, VSS = AVSS = 0 V

| Parameter | Symbol | Min | Typ | Max | Unit | Test conditions |
|---|---|---|---|---|---|---|
| LCD drive voltage | $V_{L4}$ | 2.5 | — | VCC | V | — |

## 49.12.2 Internal Voltage Boosting Method (VL1 Reference)

### (1) 1/3 bias method

**Table 49.70 Internal voltage boosting method LCD characteristics (1)**

Conditions: VCC = AVCC = 1.8 V to 3.6 V, VSS = AVSS = 0 V

| Parameter | Symbol | Conditions | | Min | Typ | Max | Unit | Test conditions |
|---|---|---|---|---|---|---|---|---|
| LCD output voltage variation range | $V_{L1}$ | C1 to C4[*5] = 0.47 µF | VLCD[*1] = 0x04 | 0.97 | 1.01 | 1.04 | V | — |
| | | | VLCD = 0x05 | 1.00 | 1.04 | 1.08 | V | — |
| | | | VLCD = 0x06 | 1.04 | 1.07 | 1.11 | V | — |

| | | | VLCD = 0x0E | 1.29 | 1.34 | 1.38 | V | — |
| | | | VLCD = 0x0F | 1.33 | 1.37 | 1.42 | V | |
| | | | VLCD = 0x10 | 1.36 | 1.40 | 1.45 | V | — |
| | | | VLCD = 0x11 | 1.39 | 1.44 | 1.49 | V | — |
| | | | VLCD = 0x12 | 1.42 | 1.47 | 1.52 | V | — |
| | | | VLCD = 0x13 | 1.45 | 1.50 | 1.55 | V | — |
| | | | VLCD = 0x14 | 1.49 | 1.54 | 1.59 | V | — |
| | | | VLCD = 0x15 | 1.52 | 1.57 | 1.62 | V | |
| | | | VLCD = 0x16 | 1.55 | 1.60 | 1.66 | V | — |
| | | | VLCD = 0x17 | 1.58 | 1.64 | 1.69 | V | — |
| | | | VLCD = 0x18 | 1.61 | 1.67 | 1.73 | V | — |
| | | | VLCD = 0x19 | 1.65 | 1.70 | 1.76 | V | — |
| | | | VLCD = 0x1A[*4] | 1.68 | 1.74 | 1.79 | V | — |
| Double output voltage | $V_{L2}$ | C1 to C4[*5] = 0.47 µF | | $2 \times V_{L1}$ - 5% | $2 \times V_{L1}$ | $2 \times V_{L1}$ + 5% | V | — |
| Triple output voltage | $V_{L4}$ | C1 to C4[*5] = 0.47 µF | | $3 \times V_{L1}$ - 6% | $3 \times V_{L1}$ | $3 \times V_{L1}$ + 6% | V | — |
| Reference voltage setup time[*2] | $t_{VL1S}$ | — | | 10 | — | — | ms | Figure 49.71 |
| Voltage boost wait time[*3] | $t_{VLWT}$ | — | | 500 | — | — | ms | Figure 49.71 |

Note: 0x0E to 0x1A setting is permitted when using 5V LCD panel, 0x04 to 0x07 setting is permitted when using 3V LCD panel at 1/3 bias.

Note 1. Bit [7] (MDSET[2]) of register VLCD is set to 0 and bits [7:6] (MDSET[1:0]) of register LCDM0 are set to 01 for internal voltage boosting method (VL1 reference), and bits [4:0] (VLCD4-0) of register VLCD are used for voltage variation setting.

Note 2. This is the time required to wait from when the reference voltage is specified by using the VLCD register (or when the internal voltage boosting method is selected (by setting the MDSET[1:0] bits of the LCDM0 register to 01b and MDSET[2] of the register VLCD to 0) if the default value reference voltage is used) until voltage boosting starts (VLCON = 1).

Note 3. This is the wait time from when voltage boosting is started (VLCON = 1) until display is enabled (LCDON = 1).

Note 4. This setting is only available when VCC ≥ VL1.

Note 5. This is a capacitor that is connected between the voltage pins that are used to drive the LCD.

C1: A capacitor connected between CAPH and CAPL

C2: A capacitor connected between VL1 and GND

C3: A capacitor connected between VL2 and GND

C4: A capacitor connected between VL4 and GND

C1 = C2 = C3 = C4 = 0.47 µF ±30%

### (2) 1/4 bias method

**Table 49.71 Internal voltage boosting method LCD characteristics (2)**

Conditions: VCC = AVCC = 1.8 V to 3.6 V, VSS = AVSS = 0 V

| Parameter | Symbol | Conditions | | Min | Typ | Max | Unit | Test conditions |
|---|---|---|---|---|---|---|---|---|
| LCD output voltage variation range | $V_{L1}$ | C1 to C5*1 = 0.47 µF | VLCD*2 = 0x04 | 0.97 | 1.01 | 1.04 | V | — |
| | | | VLCD = 0x05 | 1.00 | 1.04 | 1.08 | V | — |
| | | | VLCD = 0x06 | 1.04 | 1.07 | 1.11 | V | — |
| | | | VLCD = 0x07 | 1.07 | 1.11 | 1.14 | V | — |
| | | | VLCD = 0x08 | 1.10 | 1.14 | 1.18 | V | — |
| | | | VLCD = 0x09 | 1.13 | 1.17 | 1.21 | V | |
| | | | VLCD = 0x0A | 1.16 | 1.21 | 1.25 | V | — |
| | | | VLCD = 0x0B | 1.20 | 1.24 | 1.28 | V | — |
| | | | VLCD = 0x0C | 1.23 | 1.27 | 1.32 | V | — |
| | | | VLCD = 0x0D | 1.26 | 1.31 | 1.35 | V | — |
| Double output voltage | $V_{L2}$ | C1 to C5*1 = 0.47 µF | | 2 × $V_{L1}$ - 5% | 2 × $V_{L1}$ | 2 × $V_{L1}$ + 5% | V | — |
| Triple output voltage | $V_{L3}$ | C1 to C5*1 = 0.47 µF | | 3 × $V_{L1}$ - 6% | 3 × $V_{L1}$ | 3 × $V_{L1}$ + 6% | V | — |
| Quadruple output voltage | $V_{L4}$*5 | C1 to C5*1 = 0.47 µF | | 4 × $V_{L1}$ - 6% | 4 × $V_{L1}$ | 4 × $V_{L1}$ + 6% | V | — |
| Reference voltage setup time*3 | $t_{VL1S}$ | — | | 10 | — | — | ms | Figure 49.71 |
| Voltage boost wait time*4 | $t_{VLWT}$ | — | | 500 | — | — | ms | Figure 49.71 |

Note 1. This is a capacitor that is connected between the voltage pins that are used to drive the LCD.

C1: A capacitor connected between CAPH and CAPL

C2: A capacitor connected between VL1 and GND

C3: A capacitor connected between VL2 and GND

C4: A capacitor connected between VL3 and GND

C5: A capacitor connected between VL4 and GND

C1 = C2 = C3 = C4 = C5 = 0.47 µF ±30%

Note 2. Bit [7] (MDSET[2]) of register VLCD is set to 0 and bits [7:6] (MDSET[1:0]) of register LCDM0 are set to 01 for internal voltage boosting method (VL1 reference), and bits [4:0] (VLCD4-0) of register VLCD are used for voltage variation setting.

Note 3. This is the time required to wait from when the reference voltage is specified by using the VLCD register (or when the internal voltage boosting method is selected (by setting the MDSET[1:0] bits of the LCDM0 register to 01b and MDSET[2] of the register VLCD to 0) if the default value reference voltage is used) until voltage boosting starts (VLCON = 1).

Note 4. This is the wait time from when voltage boosting is started (VLCON = 1) until display is enabled (LCDON = 1).

Note 5. $V_{L4}$ must be 3.6 V or lower.

## 49.12.3 Internal Voltage Boosting Method (VL2 Reference)

### (1) 1/3 bias method

**Table 49.72 Internal voltage boosting method LCD characteristics (3) (1 of 2)**

Conditions: VCC = AVCC = VL2 (Max) + 0.1 to 3.6 V, VSS = AVSS = 0 V

| Parameter | Symbol | Conditions | Min | Typ | Max | Unit | Test conditions |
|---|---|---|---|---|---|---|---|
| Half output voltage | $V_{L1}$ | C1 to C4*1 = 0.47 µF | 1/2 × VL2 - 5% | 1/2 × VL2 | 1/2 × VL2 + 5% | V | — |

**Table 49.72 Internal voltage boosting method LCD characteristics (3) (2 of 2)**

C4: A capacitor connected between VL4 and GND

C1 = C2 = C3 = C4 = 0.47 µF ±30%

Note 3. Bit [7] (MDSET[2]) of register VLCD is set to 1 and bits [7:6] (MDSET[1:0]) of register LCDM0 are set to 10 for capacitor split method (VL4 reference).

## 49.13 Flash Memory Characteristics

### 49.13.1 Code Flash Memory Characteristics

**Table 49.75 Code flash characteristics (1)**

| Parameter | | Symbol | Min | Typ | Max | Unit | Conditions |
|---|---|---|---|---|---|---|---|
| Reprogramming/erasure cycle*1 | | $N_{PEC}$ | 1000 | — | — | Times | — |
| Data hold time | After 1000 times $N_{PEC}$ | $t_{DRP}$ | 20*2 *3 | — | — | Year | $T_a$ = +105 °C |
| | | | 10 | — | — | Year | $T_a$ = +125 °C |

Note 1. The reprogram/erase cycle is the number of erasures for each block. When the reprogram/erase cycle is n times (n = 1,000), erasing can be performed n times for each block. For instance, when 8-byte programming is performed 256 times for different addresses in 2-KB blocks, and then the entire block is erased, the reprogram/erase cycle is counted as one. However, programming the same address for several times as one erasure is not enabled (overwriting is prohibited).

Note 2. Characteristic when using the flash memory programmer and the self-programming library provided by Renesas Electronics.

Note 3. This result is obtained from reliability testing.

**Table 49.76 Code flash characteristics (2)**

High-speed operating mode

Conditions: VCC = AVCC0 = 1.8 to 3.6 V

| Parameter | | Symbol | ICLK = 1 MHz | | | ICLK = 48 MHz | | | Unit |
|---|---|---|---|---|---|---|---|---|---|
| | | | Min | Typ | Max | Min | Typ | Max | |
| Programming time | 8-byte | $t_{P8}$ | — | 128 | 1064 | — | 44.2 | 420 | µs |
| Erasure time | 2-KB | $t_{E2K}$ | — | 14.1 | 390 | — | 5.5 | 214 | ms |
| Blank check time | 8-byte | $t_{BC8}$ | — | — | 67.7 | — | — | 8.6 | µs |
| | 2-KB | $t_{BC2K}$ | — | — | 7538 | — | — | 272 | µs |
| Erase suspended time | | $t_{SED}$ | — | — | 33.4 | — | — | 10.7 | µs |
| Forced stop time | | $t_{FD}$ | — | — | 33.4 | — | — | 10.7 | µs |
| Configuration Set time | | $t_{CFGS}$ | — | 27 | 494 | — | 11 | 255 | ms |
| Flash memory mode transition wait time 1 | | $t_{DIS}$ | 2 | — | — | 2 | — | — | µs |
| Flash memory mode transition wait time 2 | | $t_{MS}$ | 15 | — | — | 15 | — | — | µs |

Note: Does not include the time until each operation of the flash memory is started after instructions are executed by software.

Note: The lower-limit frequency of FCLK is 1 MHz during programming or erasing the flash memory.

Note: The frequency accuracy of FCLK must be ± 1.0% during programming or erasing the flash memory. Confirm the frequency accuracy of the clock source.

**Table 49.77 Code flash characteristics (3) (1 of 2)**

Middle-speed operating mode

Conditions: VCC = AVCC0 = 1.6 to 3.6 V

| Parameter | | Symbol | ICLK = 1 MHz | | | ICLK = 8 MHz*1 | | | Unit |
|---|---|---|---|---|---|---|---|---|---|
| | | | Min | Typ | Max | Min | Typ | Max | |
| Programming time | 8-byte | $t_{P8}$ | — | 128 | 1064 | — | 50.6 | 468 | µs |
| Erasure time | 2-KB | $t_{E2K}$ | — | 14.1 | 390 | — | 6.32 | 231 | ms |
| Blank check time | 8-byte | $t_{BC8}$ | — | — | 67.7 | — | — | 13.3 | µs |
| | 2-KB | $t_{BC2K}$ | — | — | 7538 | — | — | 947 | µs |

**Table 49.77 Code flash characteristics (3) (2 of 2)**

Middle-speed operating mode
Conditions: VCC = AVCC0 = 1.6 to 3.6 V

| Parameter | Symbol | ICLK = 1 MHz | | | ICLK = 8 MHz*1 | | | Unit |
|---|---|---|---|---|---|---|---|---|
| | | Min | Typ | Max | Min | Typ | Max | |
| Erase suspended time | $t_{SED}$ | — | — | 33.4 | — | — | 13.1 | µs |
| Forced stop time | $t_{FD}$ | — | — | 33.4 | — | — | 13.1 | µs |
| Configuration Set time | $t_{CFGS}$ | — | 27 | 494 | — | 12 | 277 | ms |
| Flash memory mode transition wait time 1 | $t_{DIS}$ | 2 | — | — | 2 | — | — | µs |
| Flash memory mode transition wait time 2 | $t_{MS}$ | 15 | — | — | 15 | — | — | µs |

Note: Does not include the time until each operation of the flash memory is started after instructions are executed by software.
Note: The lower-limit frequency of FCLK is 1 MHz during programming or erasing the flash memory.
Note: The frequency accuracy of FCLK must be ± 1.0% during programming or erasing the flash memory. Confirm the frequency accuracy of the clock source.
Note 1. When 1.8 V ≤ VCC = AVCC0 ≤ 3.6 V

**Table 49.78 Code flash characteristics (4)**

Low-speed operating mode
Conditions: VCC = AVCC0 = 1.6 to 3.6 V

| Parameter | | Symbol | ICLK = 1 MHz | | | Unit |
|---|---|---|---|---|---|---|
| | | | Min | Typ | Max | |
| Programming time | 8-byte | $t_{P8}$ | — | 128 | 1064 | µs |
| Erasure time | 2-KB | $t_{E2K}$ | — | 14.1 | 390 | ms |
| Blank check time | 8-byte | $t_{BC8}$ | — | — | 67.7 | µs |
| | 2-KB | $t_{BC2K}$ | — | — | 7538 | µs |
| Erase suspended time | | $t_{SED}$ | — | — | 33.4 | µs |
| Forced stop time | | $t_{FD}$ | — | — | 33.4 | µs |
| Configuration Set time | | $t_{CFGS}$ | — | 27 | 494 | ms |
| Flash memory mode transition wait time 1 | | $t_{DIS}$ | 2 | — | — | µs |
| Flash memory mode transition wait time 2 | | $t_{MS}$ | 15 | — | — | µs |

Note: Does not include the time until each operation of the flash memory is started after instructions are executed by software.
Note: The lower-limit frequency of FCLK is 1 MHz during programming or erasing the flash memory.
Note: The frequency accuracy of FCLK must be ± 1.0% during programming or erasing the flash memory. Confirm the frequency accuracy of the clock source.

## 49.13.2 Data Flash Memory Characteristics

**Table 49.79 Data flash characteristics (1)**

| Parameter | | Symbol | Min | Typ | Max | Unit | Conditions |
|---|---|---|---|---|---|---|---|
| Reprogramming/erasure cycle*1 | | $N_{DPEC}$ | 100000 | 1000000 | — | Times | — |
| Data hold time | After 10000 times of $N_{DPEC}$ | $t_{DDRP}$ | 20*2 *3 | — | — | Year | Ta = +105 °C |
| | | | 10*2 *3 | — | — | | Ta = +125 °C |
| | After 100000 times of $N_{DPEC}$ | | 5*2 *3 | — | — | | Ta = +105 °C |
| | After 1000000 times of $N_{DPEC}$ | | — | 1*2 *3 | — | | Ta = +25 °C |

Note 1. The reprogram/erase cycle is the number of erasure for each block. When the reprogram/erase cycle is n times (n = 100,000), erasing can be performed n times for each block. For instance, when 1-byte programming is performed 256 times for different addresses in 256-byte blocks, and then the entire block is erased, the reprogram/erase cycle is counted as one. However, programming the same address for several times as one erasure is not enabled. (overwriting is prohibited.)
Note 2. Characteristics when using the flash memory programmer and the self-programming library provided by Renesas Electronics.

Note 3. This result is obtained from reliability testing.

**Table 49.80 Data flash characteristics (2)**

High-speed operating mode
Conditions: VCC = AVCC0 = 1.8 to 3.6 V

| Parameter | | Symbol | ICLK = 1 MHz | | | ICLK = 48 MHz | | | Unit |
|---|---|---|---|---|---|---|---|---|---|
| | | | Min | Typ | Max | Min | Typ | Max | |
| Programming time | 1-byte | $t_{DP1}$ | — | 112 | 903 | — | 33.9 | 317 | µs |
| Erasure time | 256-byte | $t_{DE256}$ | — | 14.1 | 390 | — | 5.50 | 214 | ms |
| Blank check time | 1-byte | $t_{DBC1}$ | — | — | 67.7 | — | — | 8.6 | µs |
| | 256-byte | $t_{DBC256}$ | — | — | 7538 | — | — | 272 | µs |
| Suspended time during erasing | | $t_{DSED}$ | — | — | 33.4 | — | — | 10.7 | µs |
| Forced stop time | | $t_{FD}$ | — | — | 33.4 | — | — | 10.7 | µs |
| Data flash STOP recovery time | | $t_{DSTOP}$ | 250 | — | — | 250 | — | — | ns |

Note: Does not include the time until each operation of the flash memory is started after instructions are executed by software.
Note: The lower-limit frequency of FCLK is 1 MHz during programming or erasing the flash memory.
Note: The frequency accuracy of FCLK must be ± 1.0% during programming or erasing the flash memory. Confirm the frequency accuracy of the clock source.

**Table 49.81 Data flash characteristics (3)**

Middle-speed operating mode
Conditions: VCC = AVCC0 = 1.6 to 3.6 V

| Parameter | | Symbol | ICLK = 1 MHz | | | ICLK = 8 MHz*1 | | | Unit |
|---|---|---|---|---|---|---|---|---|---|
| | | | Min | Typ | Max | Min | Typ | Max | |

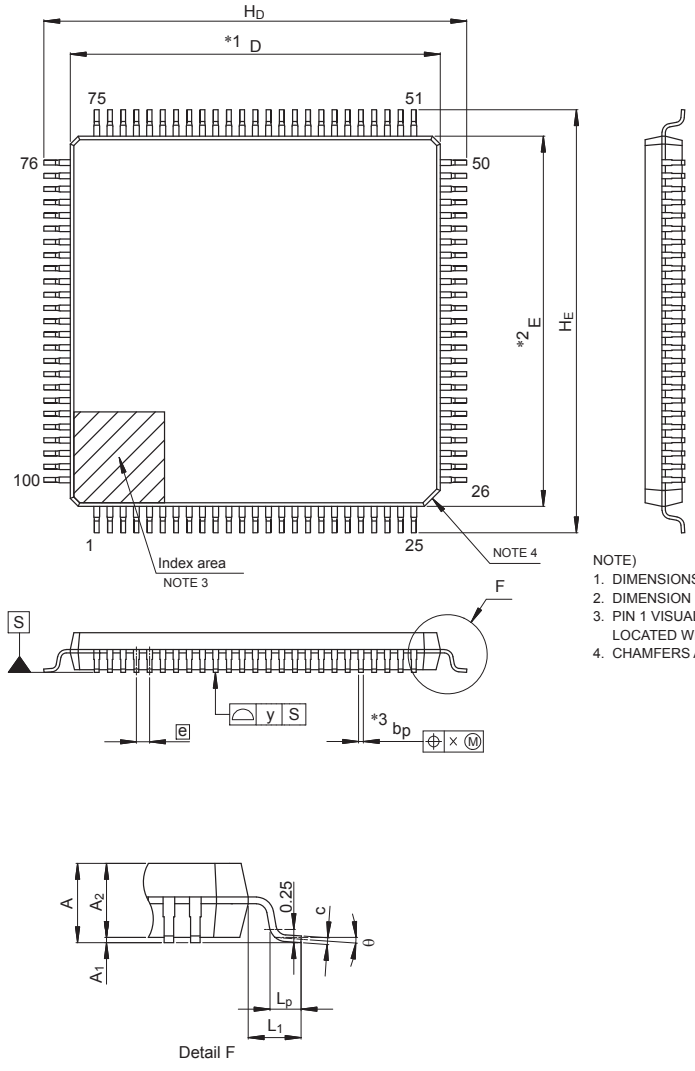
# Appendix 1. Port States in Each Processing Mode

**Table A1.1 Port states in each processing mode**

| Function | Pin function | Reset | Software Standby mode |
|---|---|---|---|
| Mode | MD | Pull-up | Keep-O |
| IRQ | IRQx | Hi-Z | Keep-O*1 |
| AGT | AGTIOn | Hi-Z | AGTIOn input |
| | AGTOn/AGTOAn/AGTOBn | Hi-Z | AGTOn/AGTOAn/AGTOBn output |
| SCI | RXD0 | Hi-Z | Keep-O*1 |
| IIC | SCLn/SDAn | Hi-Z | Keep-O*1 |
| I3C | I3C_SCL0/I3C_SDA0 | Hi-Z | Keep-O*1 |
| UARTA | CLKAn | Hi-Z | CLKAn output |
| | RxDAn | Hi-Z | RxDAn input |
| USBFS | USB_OVRCURx/USB_VBUS | Hi-Z | Keep-O*1 |
| | USB_DP/USB_DM | Hi-Z | Keep-O*2 |
| RTC | RTCICx | Hi-Z | RTCICx input |
| | RTCOUT | Hi-Z | RTCOUT output |
| ACMPLP | CMPINn/CMPREFn | Hi-Z | CMPINn/CMPREFn input |
| | VCOUT | Hi-Z | VCOUT output |
| CLKOUT | CLKOUT | Hi-Z | CLKOUT output |
| DAC | DA0 | Hi-Z | D/A output retained |
| SLCDC | SEGx/COMx | Hi-Z | SEGx/COMx output |
| | VLx/CAPH/CAPL | Hi-Z | VLx/CAPH/CAPL input |
| Others | — | Hi-Z | Keep-O |



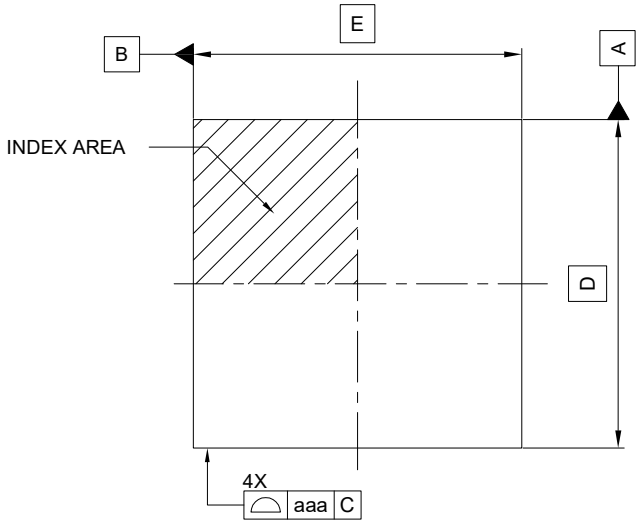
Note: H: High-level
L: Low-level
Hi-Z: High-impedance
Keep-O: Output pins retain their previous values. Input pins go to high-impedance.
Note 1. Input is enabled if the pin is specified as the Software Standby canceling source while it is used as an external interrupt pin.
Note 2. Input is enabled while the pin is used as an input pin.

# Appendix 2. Package Dimensions

Information on the latest version of the package dimensions or mountings is displayed in “Packages” on the Renesas Electronics Corporation website.

| JEITA Package Code | RENESAS Code | Previous Code | MASS (Typ) [g] |
|---|---|---|---|
| P-LFQFP100-14x14-0.50 | PLQP0100KB-B | — | 0.6 |

Unit: mm



NOTE)
1. DIMENSIONS “*1” AND “*2” DO NOT INCLUDE MOLD FLASH.
2. DIMENSION “*3” DOES NOT INCLUDE TRIM OFFSET.
3. PIN 1 VISUAL INDEX FEATURE MAY VARY, BUT MUST BE LOCATED WITHIN THE HATCHED AREA.
4. CHAMFERS AT CORNERS ARE OPTIONAL, SIZE MAY VARY.

| Reference Symbol | Dimensions in millimeters | | |
|---|---|---|---|
| | Min | Nom | Max |

# Appendix 3. I/O Registers

This appendix describes I/O register address and access cycles by function.

## 3.1 Peripheral Base Addresses

This section provides the base addresses for peripherals described in this manual. Table A3.1 shows the name, description, and the base address of each peripheral.

**Table A3.1 Peripheral base address (1 of 2)**

| Name | Description | Base address |
|---|---|---|
| RMPU | Master Memory Protection Unit | 0x4000_0000 |
| TZF | TrustZone Filter | 0x4000_0E00 |
| SRAM | Special Function Register | 0x4000_2000 |

Note: Name = Peripheral name
Description = Peripheral functionality
Base address = Lowest reserved address or address used by the peripheral

## 3.2 Access Cycles

This section provides access cycle information for the I/O registers described in this manual.

- Registers are grouped by associated module.
- The number of access cycles indicates the number of cycles based on the specified reference clock.
- In the internal I/O area, reserved addresses that are not allocated to registers must not be accessed, otherwise operations cannot be guaranteed.
- The number of I/O access cycles depends on bus cycles of the internal peripheral bus, divided clock synchronization cycles, and wait cycles of each module. Divided clock synchronization cycles differ depending on the frequency ratio between ICLK and PCLK.
- When the frequency of ICLK is equal to that of PCLK, the number of divided clock synchronization cycles is always constant.
- When the frequency of ICLK is greater than that of PCLK, at least 1 PCLK cycle is added to the number of divided clock synchronization cycles.
- The number of write access cycles indicates the number of cycles obtained by non-bufferable write access.

Note: This applies to the number of cycles when access from the CPU does not conflict with the instruction fetching to the external memory or bus access from other bus masters such as DTC or DMAC.

**Table A3.2 Access cycles (1 of 3)**

| Peripherals | Address | | Number of access cycles | | | | Cycle Unit | Related function |
|---|---|---|---|---|---|---|---|---|
| | | | ICLK = PCLK | | ICLK > PCLK*1 | | | |
| | From | To | Read | Write | Read | Write | | |
| RMPU, TZF, SRAM, BUS, DMACn, DMA, DTC, ICU | 0x4000_0000 | 0x4000_6FFF | 4 | 3 | 4 | 3 | ICLK | Renesas Memory Protection Unit, TrustZone Filter, SRAM Control, BUS Control, Direct memory access controller n, DMAC Module Activation, DTC Control Register, Interrupt Controller |
| CACHE | 0x4000_7000 | 0x4000_7FFF | 4 | 5 | 4 | 5 | ICLK | CACHE |
| CPSCU, DBG, FCACHE | 0x4000_8000 | 0x4001_CFFF | 4 | 3 | 4 | 3 | ICLK | CPU System Security Control Unit, Debug Function, Flash Security Attribution Control |
| SYSC | 0x4001_E000 | 0x4001_E5FF | 6 | 5 | 6 | 5 | ICLK | System Control |
| PORTn, PFS | 0x4001_F000 | 0x4001_FFFF | 5*2 | 4 | 5*2 | 4 | ICLK | Port n Control Registers, Pmn Pin Function Control Register |
| ELC, RTC, IWDT, WDT, CAC, MSTP, POEG | 0x4008_2000 | 0x4008_AFFF | 5 | 4 | 2 to 5 | 2 to 4 | PCLKB | Event Link Controller, Realtime Clock, Independent Watchdog Timer, Watchdog Timer, Clock Frequency Accuracy Measurement Circuit, Module Stop Control, Port Output Enable Module for GPT |
| USBFS | 0x4009_0000 | 0x4009_0FFF | 6 | 5 | 3 to 6 | 3 to 5 | PCLKB | USB 2.0 FS Module |
| UARTA | 0x4009_7000 | 0x4009_7FFF | 4 | 3 | 1 to 4 | 1 to 3 | PCLKB | Serial Interface UARTA |
| SSIE0, IICn, IIC0WU, CANFD, CTSU | 0x4009_D000 | 0x400D_0FFF | 5 | 4 | 2 to 5 | 2 to 4 | PCLKB | Serial Sound Interface Enhanced, Inter-Integrated Circuit n, Inter-Integrated Circuit 0 Wake-up Unit, CANFD Module, Capacitive Touch Sensing Unit |

**Table A3.2 Access cycles (2 of 3)**

| Peripherals | Address | | Number of access cycles | | | | | |
|---|---|---|---|---|---|---|---|---|
| | | | ICLK = PCLK | | ICLK > PCLK*1 | | Cycle Unit | Related function |
| | From | To | Read | Write | Read | Write | | |

| GPT32n, GPT16n, GPT_OPS | 0x4016_9000 | 0x4016_9FFF | 7 | 4 | 4 to 7 | 2 to 4 | PCLKA | General PWM 32-Bit Timer n, General PWM 16-Bit Timer n, Output Phase Switching Controller |
| ADC120, DAC12 | 0x4017_0000 | 0x4017_1FFF | 5 | 4 | 2 to 5 | 2 to 4 | PCLKA | 12bit A/D Converter 0, 12-bit D/A converter |
| QSPI | 0x6400_0000 | 0x6400_000F | 5 | 14 to *5 | 2 to 5 | 14 to *5 | PCLKA | Quad-SPI |
| QSPI | 0x6400_0010 | 0x6400_0013 | 25 to *5 | 6 to *5 | 25 to *5 | 5 to *5 | PCLKA | Quad-SPI |
| QSPI | 0x6400_0014 | 0x6400_0037 | 5 | 14 to *5 | 2 to 5 | 14 to *5 | PCLKA | Quad-SPI |
| QSPI | 0x6400_0804 | 0x6400_0807 | 4 | 3 | 1 to 4 | 1 to 3 | PCLKA | Quad-SPI |

**Table A3.2 Access cycles (3 of 3)**

| Peripherals | Address | | Number of access cycles | | | | | |
|---|---|---|---|---|---|---|---|---|
| | | | ICLK = FCLK | | ICLK > FCLK*1 | | Cycle Unit | Related function |
| | From | To | Read | Write | Read | Write | | |
| FLCN, FACI | 0x407E_C000 | 0x407F_EFFF | 5 | 4 | 3 to 5 | 2 to 4 | FCLK | Flash I/O Registers, Flash Application Command Interface |

Note 1. If the number of PCLK or FCLK cycles is non-integer (for example 1.5), the minimum value is without the decimal point, and the maximum value is rounded up to the decimal point. For example, 1.5 to 2. 5 is 1 to 3.
Note 2. The access cycles of the PRCNT2 and PFS registers depend on PRWCNTR. For details, see section 18, I/O Ports.
Note 3. When accessing a 16-bit register (FTDRHL, FRDRHL, FCR, FDR, LSR, and CDR), access is 2 cycles more than the value shown in Table A3.2. When accessing an 8-bit register (including FTDRH, FTDRL, FRDRH, and FRDRL), the access cycles are as shown in Table A3.2.
Note 4. When accessing the 32-bit register (SPDR), access is 2 cycles more than the value in Table A3.2. When accessing an 8-bit or 16-bit register (SPDR_HA), the access cycles are as shown in Table A3.2.
Note 5. The access cycles depend on the QSPI bus cycles.

# Appendix 4. Peripheral Variant

Table A4.1 shows the correspondence between the module name used in this manual and the Peripheral Variant.

**Table A4.1 Module name vs Peripheral Variant**

| Module name | Peripheral Variant |
|---|---|
| DOC | DOC_B |
| CTSU | CTSU2SLa |

# Revision History

**Revision 1.10 — January 31, 2025**

First edition, issued

**Revision 1.20 — October 10, 2025**

**Features:**
- Updated product description

**1. Overview:**
- Updated Table 1.14 Product list

**2. CPU:**
- Updated 2.6.5.3 JBMDR : JTAG Boot Mode Entry Register
- Updated 2.6.5.4 JBRDR : JTAG Boot Receive Data Register
- Updated 2.6.5.5 JBTDR : JTAG Boot Transmit Data Register
- Updated 2.6.5.6 JBSTR : JTAG Boot Status Register
- Updated 2.6.5.7 JBICR : JTAG Boot Interrupt Control Register

**5. Resets:**
- Updated Table 5.1 Reset names and sources

**6. Option-Setting Memory:**
- Updated 6.2.4 OFS1, OFS1_SEC : Option Function Select Register 1 for Non-secure and Secure

**8. Clock Generation Circuit:**
- Updated Table 8.2 Clock generation circuit specifications for the internal clocks
- Updated Figure 8.1 Clock generation circuit block diagram
- Updated 8.2.26 HOCOUTCR : HOCO User Trimming Control Register
- Updated 8.2.27 CANFDCKDIVCR : CANFD Clock Division Control Register
- Updated 8.2.28 I3CCKDIVCR : I3C Clock Division Control Register
- Updated 8.2.29 USBCKCR : USB Clock Control Register
- Updated 8.2.30 CANFDCKCR : CANFD Clock Control Register
- Updated 8.2.31 I3CCKCR : I3C Clock Control Register

**21. Low Power Asynchronous General Purpose Timer:**
- Updated Table 21.1 AGT specifications

**22. Realtime Clock:**
- Updated 22.3.8.1 Automatic adjustment

**25. USB 2.0 Full-Speed Module:**
- Added 25.2.37 UCKSEL : USB Clock Selection Register

**29. I3C Bus Interface:**
- Updated Table 29.2 I3C specifications
- Updated 29.2.2 BCTL : Bus Control Register
- Updated 29.2.13 SVCTL : Slave Control Register
- Updated Table 29.4 Requirement and usage of setting in each mode
- Updated 29.2.46 SVST : Slave Status Register
- Updated 29.2.55 SVDVAD0 : Slave Device Address Register 0
- Updated 29.2.66 CGHDRCAP : CCC Get HDR Capability Register
- Updated Table 29.8 I3C transfer
- Updated 29.3.1.1.2 Immediate Transfer Command, 29.3.1.1.3 Regular Transfer Command, and 29.3.1.1.4 Combo Transfer Command
- Updated 29.3.1.4 Receive Status Descriptor
- Updated 29.3.2.1.1 Master Mode Operation and 29.3.2.1.2 Slave Mode Operation
- Updated 29.3.2.3.1 Communication Protocol
- Removed 29.3.2.4.4 HDR-TSP/TSL Error Detection
- Updated 29.3.2.4.7 Abort Operation [I3C mode]
- Updated Figure 29.139 Example of each initialization flowchart for I3C master mode and slave mode
- Updated 29.3.3.3.3 I3C Master Transmission Flow (Normal FIFO Buffer Transfer) and 29.3.3.3.4 I3C Master Reception Flow (Normal FIFO Buffer Transfer)
- Updated 29.3.3.4.3 I3C Slave Transmission Flow (Normal FIFO Buffer Transfer) and 29.3.3.4.4 I3C Slave Reception Flow (Normal FIFO Buffer Transfer)
- Updated Table 29.19 Register states when issuing each condition (1)

**30. Serial Interface UARTA:**
- Updated 30.3.4 Baud Rate Generator

**31. CAN with Flexible Data-rate**
- Updated 31.8.2.5 TX History List

**Revision 1.20 — October 10, 2025**

**33. Serial Peripheral Interface:**
- Updated Figure 33.1 SPI block diagram

**37. Renesas Secure IP:**
- Updated Table 37.1 Security engine specifications

**40. Temperature Sensor:**
- Updated 40.2.1 TSCDR : Temperature Sensor Calibration Data Register

**42. Capacitive Touch Sensing Unit:**
- Updated 42.1 Overview
- Updated 42.2.3 CTSUMCH/CTSUMCHH/CTSUMCHL/CTSUMFAF/CTSUMCH1/CTSUMCH0 : CTSU Measurement Channel Register, 42.2.4 CTSUCHACA/CTSUCHACAL/CTSUCHAC1/CTSUCHAC0 : CTSU Channel Enable Control Register A, and 42.2.5 CTSUCHTRCA/CTSUCHTRCAL/CTSUCHTRC1/CTSUCHTRC0 : CTSU Channel Transmit/Receive Control Register A
- Updated 42.2.17 CTSUAJCR/CTSUAJCRH/CTSUAJCRL/AJCR3/AJCR2/AJCR1/AJCR0 : CTSU Automatic Judgment Control Register

**47. Internal Voltage Regulator:**
- Updated Figure 47.1 LDO settings

**49. Electrical Characteristics:**
- Updated 49. Electrical Characteristics
- Updated Table 49.5 I/O $I_{OH}$, $I_{OL}$
- Updated Table 49.20 Power consumption of each unit
- Updated Table 49.21 Outline of operation for each unit
- Updated Table 49.26 Clock timing
- Updated 49.3.12 I3C Timing
- Updated Table 49.79 Data flash characteristics

**Appendix:**
- Added Figure A2.2 BGA 100-pin
- Added Figure A2.3 WLCSP 72-pin
- Added Figure A2.5 BGA 64-pin
- Updated Table A3.1 Peripheral base address
- Updated Table A3.2 Access cycles

**Revision 1.30 — April 28, 2026**

**1. Overview:**
- Updated 1.3 Part Numbering

**5. Resets:**
- Updated 5.3.4 Independent Watchdog Timer Reset
- Updated 5.3.5 Watchdog Timer Reset
- Updated 5.3.6 Software Reset

**8. Clock Generation Circuit:**
- Updated 8.2.24 LOCOUTCR : LOCO User Trimming Control Register
- Updated 8.2.25 MOCOUTCR : MOCO User Trimming Control Register

**22. Realtime Clock:**
- Updated 22.2.29 RTCCRn : Time Capture Control Register n (n = 0 to 2)

**24. Independent Watchdog Timer (IWDT):**
- Updated 24.3.2 Refresh Operation

**29. I3C Bus Interface (I3C):**
- Updated Table 29.2 I3C specifications

**33. Serial Peripheral Interface (SPI):**
- Updated Figure 33.51 Transmission flow in master mode

**48. Security Features:**
- Updated 48.3.4 Lifecycle Change Example

**49. Electrical Characteristics:**
- Updated Table 49.1 Absolute maximum ratings
- Updated Table 49.72 Internal voltage boosting method LCD characteristics (3)
