Although clock synchronous operation does not require the use of the SSLn_i pin, operation of the module is the same as in SPI operation. In both master mode and slave mode operations, communications can be performed with the same flow as in SPI operation. However, mode fault errors are not detected, because the SSLn_i pin is not used.

Additionally, do not perform operation if clock synchronous operation is enabled when the SPCMD_m.CPHA bit is set to 0 in slave mode (SPCR.MSTR = 0).

36.3.13.1 Master mode operation

(1) Starting serial transfer

When data is written to the SPI data register (SPDR) while the next transfer data is not set in the transmit FIFO, the SPI updates the transmit buffer (SPTX_n, n = 0 to 3) data in SPDR. While the shift register is empty, the SPI copies transmit buffer data to the shift register to start serial transfer. After the SPI copies transmit data to the shift register, it changes the shift register status to full. Upon completion of serial transfer, the SPI changes the shift register status to empty. The shift register status cannot be monitored.

For details about the SPI transfer format, see [section 36.3.5. Transfer Formats](#). In clock synchronous operation, however, the SSLn₀ output signal is not used for communication.

(2) Terminating serial transfer

The SPI terminates the serial transfer after transmitting an RSPCKn edge corresponding to the sampling timing. If the number of data stored in the receive FIFO < the number of FIFO stages, on termination of serial transfer, the SPI copies data from the shift register to the receive buffer of the SPI Data Register (SPDR).

The final sampling timing varies depending on the bit length of transfer data. In master mode, the SPI data length depends on the SPCMDm.SPB[4:0] bits setting. Transfer in clock synchronous operation is conducted without the SSLn0 output signal. For details on the SPI transfer format, see [section 36.3.5. Transfer Formats](#).

(3) Sequence control

The transfer format used in master mode is determined by the SPCR3, SPCMDm, and SPDECR registers. Although the SSLn signals are not output in clock synchronous operation, these settings are valid.

The SPCR3.SPSSLN[2:0] bits determine the sequence configuration for serial transfers that are executed by the SPI in master mode. The following parameters are specified in the SPCMDm register:

- SSLn output signal value
- MSB or LSB first
- Data length
- Some of the bit rate settings
- RSPCKn polarity and phase
- Whether SPDECR.SCKDL is to be referenced
- Whether SPDECR.SLNDL is to be referenced
- Whether SPDECR.SPNDL is to be referenced

SPCR3.SPBR holds some of the bit rate settings such as SPDECR.SCKDL, an SPI clock delay value, SPDECR.SLNDL, an SSL negation delay, and SPDECR.SPNDL, a next-access delay value.

Based on the sequence length that is assigned to SPCR3, the SPI makes up a sequence comprised of a part or all of SPCMDm register. The SPI contains a pointer to the SPCMDm register that makes up the sequence. The value of this pointer can be checked by reading the SPDCR2.SPCP[2:0] bits. When the SPCR.SPE bit is set to 1 and the SPI function is enabled, the SPI loads the pointer to the commands in SPCMD0 register, and incorporates the SPCMD0 register setting into the transfer format at the beginning of serial transfer. The SPI increments the pointer each time the next-access delay period for a data transfer ends. On completion of the serial transfer that corresponds to the final command comprising the sequence, the SPI sets the pointer to the SPCMD0 register, and in this manner the sequence is executed repeatedly.

Figure 36.73 Procedure for determining the form of serial transmission in master mode

In this section, a frame is the combination of the data (SPDR) and the settings (SPCMDm).

Figure 36.74 Conceptual diagram of frames

[Figure 36.75](#) shows the relationship between the command and the transmit and receive buffers in the sequence of operations specified by the settings.

Figure 36.75 Correspondence between SPI Command Register and transmit and receive buffers in sequence operations

(4) Initialization flow

Figure 36.76 shows an example of initialization flow for clock synchronous operation when the SPI is used in master mode. For information on how to set up the ICU, DMAC or DTC, and I/O ports, see the descriptions given in the individual blocks.

Figure 36.76 Example of initialization flow in master mode for clock synchronous operation

(5) Software processing flow

Software processing during clock synchronous master operation is the same as that for SPI master operation. For details, see (9) Software processing flow in [section 36.3.12.1. Master mode operation](#). Mode fault errors do not occur in clock synchronous operation.

36.3.13.2 Slave mode operation

(1) Starting serial transfer

When the SPCR.SPMS bit is 1, the first RSPCKn edge triggers the start of a serial transfer in the SPI, and the SPI drives the MISO_n output signal. The SSL_{n0} input signal is not used in clock synchronous operation. For details on the SPI transfer format, see [section 36.3.5. Transfer Formats](#).

(2) Terminating serial transfer

The SPI terminates the serial transfer after detecting an RSPCKn edge corresponding to the final sampling timing. When the number of data stored in the receive FIFO < the number of FIFO stages, on termination of serial transfer, the SPI copies received data from the shift register to the receive buffer of the SPDR register. On termination of a serial transfer, the SPI changes the status of the shift register to empty regardless of the receive buffer.

The final sampling timing changes depending on the bit length of transfer data. In slave mode, the SPI data length depends on the SPCMD0.SPB[4:0] bits setting. For details on the SPI transfer format, see [section 36.3.5. Transfer Formats](#).

(3) Initialization flow

[Figure 36.77](#) shows an example of initialization flow for clock synchronous operation when the SPI is used in slave mode. For a description of how to set up the ICU, DMAC or DTC, and I/O ports, see the descriptions given in the individual blocks.

Figure 36.77 Example of initialization flow in slave mode for clock synchronous operation

(4) Software processing flow

Software processing during clock synchronous slave operation is the same as that for SPI slave operation. For details, see [\(6\) Software processing flow](#). Mode fault errors do not occur in clock synchronous mode.

36.3.14 Loopback Mode

When 1 is written to the SPCR2.SPLP2 bit or SPCR2.SPLP bit, the SPI shuts off the path between the MISOn pin and the shift register if the SPCR.MSTR bit is 1, or between the MOSIn pin and the shift register if the SPCR.MSTR bit is 0, and connects the input and output paths of the shift register, establishing a loopback mode. The SPI does not shut off the path between the MOSIn pin and the shift register if the SPCR.MSTR bit is 1, or between the MISOn pin and the shift register if the SPCR.MSTR bit is 0. This is called loopback mode. When a serial transfer is executed in loopback mode, the transmit data for the SPI or the reversed transmit data becomes the received data for the SPI.

[Table 36.13](#) lists the relationship between the SPLP2 and SPLP bits and the received data. [Figure 36.78](#) shows the configuration of the shift register I/O paths when the SPI in master mode is set to loopback mode (SPCR2.SPLP2 = 0, SPCR2.SPLP = 1).

Table 36.13 SPLP2 and SPLP bit settings and received data

SPCR2.SPLP2 bit	SPCR2.SPLP bit	Received data
0	0	Input data from the MOSIn pin or MISOn pin
0	1	Inverted transmit data
1	0	Transmit data
1	1	Transmit data

**Figure 36.78** Configuration of shift register I/O paths in loopback mode for master mode

36.3.15 Self-Diagnosis of Parity Bit Function

The parity circuit consists of a parity bit adding unit used for transmit data and an error detecting unit used for received data. To detect defects in the parity bit adding unit and error detecting unit, the parity circuit performs self-diagnosis as shown in [Figure 36.79](#).

Figure 36.79 Self-diagnosis flow for parity circuit

36.3.16 Interrupt Sources

The SPI has the following interrupt sources:

- Receive buffer full
- Transmit buffer empty

- SPI error (mode-fault, underrun, overrun, or parity error)
- SPI idle
- Communication-end

The DMAC or DTC can be activated by the receive buffer full or transmit buffer empty interrupt to perform data transfer.

Because the vector address for the SPIi_SPEI (SPI error interrupt) is allocated to interrupt requests on mode-fault, underrun, overrun, and parity errors, the actual interrupt source must be determined from the flags. Interrupt sources for the SPI are listed in [Table 36.14](#). An interrupt is generated on satisfaction of one of the interrupt conditions in [Table 36.14](#). Clear the receive buffer full and transmit buffer empty sources through a data transfer.

When using the DMAC or DTC to perform data transmission and reception, you must first set up the DMAC or DTC to be in a transfer-enabled status before setting the SPI. For information on setting up the DMAC or DTC, see [section 16, DMA Controller \(DMAC\)](#) and [section 17, Data Transfer Controller \(DTC\)](#).

If the conditions for generating a transmit buffer empty or receive buffer full interrupt occur while the ICU.IELSRn.IR flag is 1, the interrupt is not output as a request for the ICU but is retained internally (the capacity for retention is one request per source). A retained interrupt request is output when the ICU.IELSRn.IR flag becomes 0. A retained interrupt request is automatically discarded when it is output as an actual interrupt request. The interrupt enable bit (the SPCR.SPTIE or SPCR.SPRIE bit) for an internally retained interrupt request can also be set to 0.

Table 36.14 SPI interrupt sources

Interrupt source	Symbol	Interrupt condition	DTC/DMAC activation
Receive buffer full	SPIi_SPRI	The receive buffer becomes full (SPSR.SPRF flag is 1) while the SPCR.SPRIE bit is 1 or The receive data become ready (SPSR.SPDRF flag is 1) while the SPCR.SPDRS bit is 0	Possible
Transmit buffer empty	SPIi_SPTI	The transmit buffer becomes empty (SPSR.SPTEF flag is 1) while the SPCR.SPTIE bit is 1	Possible
SPI error (mode-fault, underrun, overrun, or parity error)	SPIi_SPEI	The SPSR.MODF, OVRF, or PERF flag sets to 1, or the SPSR.SPDRS and SPDRF flag set to 1 while the SPCR.SPEIE bit is 1	Impossible
SPI idle	SPIi_SPII	The SPSR.IDLNF flag sets to 0 while the SPCR.SPIIE bit is 1	Impossible
Communication-end	SPIi_SPCEND	CENDIE = 1 and CENDF = 1	Impossible

36.4 Event Link Controller Event Output

The Event Link Controller (ELC) can produce the following event output signals:

- Receive buffer full event output
- Transmit buffer empty event output
- Mode-fault, underrun, overrun, or parity error event output
- SPI idle event output
- Transmission-completed event output

The event link output signal is output regardless of the interrupt enable bit setting.

36.4.1 Receive Buffer Full Event Output

When the number of data stored in the receive FIFO > the threshold value, or when the number of data stored in the receive FIFO ≤ the threshold value and SPDRES = 0 has elapsed after writing to the receive FIFO, and the SPDRC [7:0] has elapsed outputs an event.

36.4.2 Transmit Buffer Empty Event Output

An event is output when the number of empty transmission FIFO stage > the threshold or when the SPCR.SPE bit changes from 0 to 1.

36.4.3 Mode-Fault, Underrun, Overrun, Parity Error, or received data ready Event Output

This event signal is output when mode-fault, underrun, overrun, or parity error is detected. See [section 36.5.4. Constraints on Mode-Fault, Underrun, Overrun, Parity Error, or Receive Data Ready Event Output](#) if using this event signal.

(1) Mode-fault

[Table 36.15](#) lists the conditions for occurrence of a mode-fault event.

Table 36.15 Conditions for mode-fault occurrence

SPI mode	SPCR.MODFEN bit	SSLn0 pin	Remarks
SPI operation (SPMS = 0) Slave (SPCR.MSTR = 0) Motorola-SPI (SPCR.SPFRF = 0)	1	Not active	Event is output only when the SSLn0 pin is deactivated during transmission
SPI operation (SPMS = 0) Slave (SPCR.MSTR = 0) TI-SSP (SPCR.SPFRF = 1)	1	active	Event is output only when the SSLn0 pin is activated during transmission

(2) Underrun

This event signal is output in response to an underrun when a serial transfer starts while the transmission data is not ready, and the value of the SPCR.MSTR bit is 0 and the SPCR.SPE bit is 1. Under these conditions, the MODF and UDRF flags are set to 1.

(3) Overrun

This event signal is output in response to an overrun when a serial transfer completes while the receive buffer contains unread data and the value of the SPCR.TXMD[1:0] bits are 00b or 10b. Under these conditions, the OVRF flag is set to 1.

(4) Parity error

This event signal is output in response to a parity error detected on completion of a serial transfer while the value of the SPPE bit in SPCR is 1.

(5) Receive Data Ready

When TXMD[1:0] of SPCR = 00b or 10b and SPDRES = 1 as the receive data ready event output condition, the number of data stored in the receive FIFO is received after writing the receive FIFO. An event will be output when the set value of SPDR[7:0] has elapsed while the number is less than the FIFO threshold.

36.4.4 SPI Idle Event Output

(1) In master mode

In Transmit-Receive / Transmit-only master mode, an event is output when the IDLNF flag in SPSR changes from 1 to 0.

The IDLNF flag changes from 1 to 0 only when either of the conditions 1) and 2) below is met.

- The SPE bit in SPCR is cleared to 0 (SPI initialized) during transmission.
- All of the following three conditions are met.
 - The transmit buffer (SPTXn, n = 0 to 3) is empty (next transfer data has not been set).
 - The SPCP [2:0] bits in SPSR are 000b (at the start of sequence control).
 - Operation completed by the next access delay (when the master main state machine transitions to the idle state).

In receive only master mode

Any of the following 2 conditions is met.

- SPE bit of SPCR is 0 (SPI initialization)
- When any of the following is met
 - When RMFM [4:0] = 0x00, after writing 1 to RMEDTG, operation completed by the next access delay (when the master main state machine transitions to the idle state).

- When RMFM [4:0] $\neq$ 0x00, after writing 1 to RMEDTG, operation completed by the next access delay (when the master main state machine transitions to the idle state).
- When RMFM [4:0] $\neq$ 0x00, the SPI internal sequencer transitions to the idle state after operation completed by the next access delay (when the master main state machine transitions to the idle state).

(2) In slave mode

In slave mode, an event is output when the SPCR.SPE bit is set to 0 (SPI is initialized).

36.4.5 Communication End Event Output

In master mode, an event is output when the IDLNF flag (SPI idle flag) changes from 1 to 0. In slave mode, an event occurs with conditions shown in [Table 36.16](#) and [Table 36.17](#)

Table 36.16 Communication End Event Generating Conditions (transmit-receive/transmit slave mode)

	Transmit Buffer Status	Shift Register Status	Others
SPI operation (SPMS = 0, SPFRF = 0)	Empty	Empty	SSLn0 input is negated
SPI operation (SPMS = 0, SPFRF = 1)	Empty	Empty	SSL negation delay completed
Clock synchronous operation (SPMS = 1)	Empty	Empty	The last even edge of RSPCK of last data was detected (CPHA = 1)

Table 36.17 Communication End Event Generating Conditions (receive only slave mode)

	Others
SPI operation (SPMS = 0, SPFRF = 0)	After storing the frames corresponding to the SPFC setting value in the receive buffer, negate SSLn0 input.
SPI operation (SPMS = 0, SPFRF = 1)	After storing the frames corresponding to the SPFC setting value in the receive buffer, SSL negation delay completed
Clock synchronous operation (SPMS = 1)	RSPCK last even edge detection when receiving the last frame for the SPFC set value (CPHA = 1)

Regardless of master mode or slave mode, no event is output when 0 is written to the SPCR.SPE bit during transmission or when the SPCR.SPE bit is cleared due to a mode fault error or an underrun error.

A communication end event is output at the following timing. The communication end event output timing in master operation is omitted because it is output at the same timing as an idle event.

Figure 36.80 Communication End Event Output Timing (Transmit slave mode, Motorola SPI operation)

Figure 36.81 Communication End Event Output Timing (Transmit slave mode, TI-SSP Operation)

Figure 36.82 Communication End Event Output Timing (Transmit slave mode, Clock Synchronous Operation)

Figure 36.83 Communication End Event Output Timing (Receive only slave mode, Motorola SPI operation)

Figure 36.84 Communication End Event Output Timing (Receive only slave mode, TI-SSP Operation)

Figure 36.85 Communication End Event Output Timing (Receive only slave mode, Clock Synchronous Operation)

36.4.6 Synchronization bypass function

SPI has an internal clock (PCLK) and an operation clock (TCLK), and each has its own operation circuit. Therefore, a synchronization circuit is inserted between the signals between different clocks, and a signal delay between different clocks requires a synchronization delay time.

However, the synchronization circuit can be bypassed by the BPEN = 1 of the SPI control register (SPCR) only when the same clock is input as the internal bus clock and the operation clock. In this case, the synchronization delay time is excluded, and responsiveness is improved.

In addition, SPI has a synchronization circuit between the communication clock (RSPCK) and the operation clock (TCLK), but this synchronization circuit cannot be bypassed.

36.5 Usage Notes

36.5.1 Settings for the Module-Stop State

The Module Stop Control Register B (MSTPCRB) can enable or disable the SPI operation. The SPI is initially stopped after reset. Releasing the module-stop state enables access to the registers. For details on the Module Stop Control Register B, see [section 10, Low Power Modes](#).

36.5.2 Constraint on Low-Power Functions

When using the module-stop function and entering a low-power mode other than CPU Sleep mode or CPU Deep Sleep mode, set the SPCR.SPE bit to 0 before completing communication.

36.5.3 Constraints on Starting Transfer

If the ICU.IELSRn.IR flag is 1 when transfer starts, the interrupt request is internally retained, which can lead to unanticipated behavior of the ICU.IELSRn.IR flag.

To prevent this, use the following procedure to clear interrupt requests before enabling operations (by setting the SPCR.SPE bit to 1):

1. Confirm that transfer stopped (the SPCR.SPE bit is 0).
2. Set the associated interrupt enable bit (SPCR.SPTIE bit or SPCR.SPRIE bit) to 0.
3. Read the associated interrupt enable bit (SPCR.SPTIE bit or SPCR.SPRIE bit) and confirm that its value is 0.
4. Set the ICU.IELSRn.IR flag to 0.

36.5.4 Constraints on Mode-Fault, Underrun, Overrun, Parity Error, or Receive Data Ready Event Output

Using the mode-fault, underrun, overrun, parity error, or receive data ready event is prohibited if the SPI is in multi-master mode (when the SPCR.SPMS bit is 0, the SPCR.MSTR bit is 1, and the SPCR.MODFEN bit is 1).

36.5.5 Constraints on the SPSR.SPRF and SPSR.SPTEF Flags

If the polling flags, SPRF and SPTEF, are used, using the interrupts is prohibited, and you must set the SPCR.SPRIE and SPCR.SPTIE bits to 0. Either the interrupts or the flags can be used, but not both.

37. Octal Serial Peripheral Interface (OSPI)

This is the OSPI_B version of the OSPI peripheral module.

OSPI_B is referred to as OSPI in this chapter.

37.1 Overview

The xSPI (eXpanded Serial Peripheral Interface) protocol specifies the interface for Non-Volatile Memory Devices, which provides high data throughput, low signal count, and limited backward compatibility with legacy SPI devices. The electrical interface can deliver up to 200 Mbytes per second raw data throughput. The OSPI is compliant with JEDEC standard JESD251(Profile 1.0 and 2.0), JESD251-1 and JESD252.

JESD251 specifies two interface profiles where profile 1.0 is Octal SPI and profile 2.0 is HyperBus™ (HyperRAM™ and HyperFlash™).

OSPI supports QSPI protocol.

Table 37.1 lists the OSPI specifications, Figure 37.1 shows a block diagram, and Table 37.2 lists the I/O pins.

Table 37.1 OSPI specifications

Item	Description
Protocol	Compliant with the xSPI protocol
Data transmission and reception	Issue the transaction for up to 2 Slave as Master Only one of the memory devices can operate at a time.
Transfer speed	Support the transfer at xSPI200
Mode	- Support Protocol modes below 1/4/8pin with SDR/DDR (1S-1S-1S, 4S-4D-4D, 8D-8D-8D) 2/4pin with SDR (1S-2S-2S, 2S-2S-2S, 1S-4S-4S, 4S-4S-4S) - Configurable address length - Configurable initial access latency cycle - Support XiP mode
OSPI function	- Support Write Data Mask - Support In-band Reset - Memory-mapping - Support up to 256 MB address space each CS 1 control channels per unit for the bus masters More details, see section 14, Buses. - Prefetch function for burst-read with low latency - Outstanding buffer for burst-write with high throughput - Manual command - Configurable up to 4 commands - Status Register Polling function - Input Strobe port timing shift
Decryption function	Decryption on the fly is available for memory map read
Interrupt source	Error interrupt Completion interrupt
Module-stop function	Module-stop state can be set to reduce power consumption
TrustZone Filter	Security attribution can be set for IO register area External address space is defined as Non-secure

Figure 37.1 Block diagram

Table 37.2 OSPI I/O pins

Pin name	I/O	Function
OM_SCLK	Output	Clock Positive
OM_SCLKN	Output	Clock Negative
OM_CS0	Output	Chip Select for slave0
OM_CS1	Output	Chip Select for slave1
OM_DQS	I/O	Read Data Strobe / Write Data Mask
OM_SIO0	I/O	Data 0 input/output
OM_SIO1	I/O	Data 1 input/output
OM_SIO2	I/O	Data 2 input/output
OM_SIO3	I/O	Data 3 input/output
OM_SIO4	I/O	Data 4 input/output
OM_SIO5	I/O	Data 5 input/output
OM_SIO6	I/O	Data 6 input/output
OM_SIO7	I/O	Data 7 input/output
OM_RESET	Output	Master reset status for slave0,1
OM_RSTO1	Input	Slave reset status for slave1
OM_ECSINT1	Input	Interrupt for slave1 / Error Correction Status for slave1
OM_WP1	Output	Write Protect for slave1

Note: For OM_SIO7-0, OM_SCLK, OM_SCKN and OM_DQS pins, $36\Omega \pm 5\%$ resistor need to be put on the board to comply with JESD251 I/O driver definition. It is recommended for the operation with proper signal quality.

37.2 Register Descriptions

37.2.1 OSPI Configuration Registers

These registers configure xSPI Master function. These registers should be configured in the initialization phase before issuing xSPI transaction.

37.2.1.1 WRAPCFG : OSPI Wrapper Configuration Register

Base address: OSPI0_B = 0x4026_8000
OSPI0_B_NS = 0x5026_8000

Offset address: 0x000

Bit position:	31	28	24	20	16	12	8	4	0
Bit field:	—	—	—	DSSFTCS1[4:0]	—	—	—	DSSFTCS0[4:0]	—
Value after reset:	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	—	These bits are read as 0. The write value should be 0.	R/W
12:8	DSSFTCS0[4:0]	OM_DQS shift for slave0 This field configures the number of delay cell for a OM_DQS port. It is used to adjust the OM_DQS sampling timing. When automatic calibration is enabled, it could be updated automatically. In this case, it shall not be written by user. 0x00: No shift 0x01: Add a delay of 1 cell ⋮ 0x1E: Add a delay of 30 cells 0x1F: Add a delay of 31 cells	R/W
23:13	—	These bits are read as 0. The write value should be 0.	R/W
28:24	DSSFTCS1[4:0]	OM_DQS shift for slave1 The function is same as one of slave0.	R/W
31:29	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

This register has functions to configure xSPI Master function.

37.2.1.2 COMCFG : OSPI Common Configuration Register

Base address: OSPI0_B = 0x4026_8000
OSPI0_B_NS = 0x5026_8000

Offset address: 0x004

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	OENEGEX	OEASTEX
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	—	These bits are read as 0. The write value should be 0.	R/W
16	OEASTEX	Output Enable Asserting extension This bit extends 1 cycle output enable of OM_SIO7-0 and OM_DQS during output enable asserting. When set to 1, OM_CS _n (n = 0, 1) asserting should be extended (LIOCFCGS _n .CSASTEX = 1 (n = 0, 1)). This bit shall not be used in case of no latency cycle. Because OSPI output data could be conflicted with OSPI input data. 0: No extend 1 cycle Output enable 1: Extend 1 cycle Output enable	R/W

Bit	Symbol	Function	R/W
17	OENEGEX	Output Enable Negating extension This bit extends 1 cycle output enable of OM_SIO7-0 and OM_DQS during output enable negating. This bit should not be used in case of no latency cycle. Because OSPI output data could be conflicted with OSPI input data. 0: No extend 1 cycle Output enable 1: Extend 1 cycle Output enable	R/W
31:18	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

This register has functions to configure xSPI Master function.

37.2.1.3 BMCFGCH0 : OSPI Bridge Map Configuration Register ch0

Base address: OSPI0_B = 0x4026_8000
OSPI0_B_NS = 0x5026_8000

Offset address: 0x008 + 0x004

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	CMBTIM[7:0]								—	—	—	—	—	—	—	PREEN
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	MWRSIZE[7:0]								MWR COMB	—	—	—	—	—	—	WRMD
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	WRMD	System bus Write Response mode This bit selects the timing of System bus write response in memory-mapping mode. When set to 1, it returns the response after transmitting a frame on xSPI bus. When enabled this mode, Memory Write Combination mode must be disabled. 0: Return response after storing to Internal Write Buffer 1: Return response after issuing write transaction to xSPI bus	R/W
6:1	—	These bits are read as 0. The write value should be 0.	R/W
7	MWRCOMB	Memory Write Combination mode This bit selects to combine the OSPI data in write access of memory-mapping mode. When set to 0, OSPI data size depends on system bus's burst type and size. When this field is set to "1", the data size depends on MWRSIZE[7:0] field.*1 When set to 1, any write transaction could be held in this xSPI master temporarily. 0: Disable combination mode 1: Enable combination mode	R/W
15:8	MWRSIZE[7:0]	Memory Write Size These bits select the size to combine incremental address in memory-mapping mode. It transmits an xSPI frame with the data combined up to the configured size while the address is incremental. When detected non-incremental address or a read transaction before reaching to the target size, it transmits the pending data into xSPI bus. 0x00: Combine incremental address up to 4 bytes 0x01: Combine incremental address up to 8 bytes ⋮ 0x0E: Combine incremental address up to 60 bytes 0x0F: Combine incremental address up to 64 bytes 0xFF: Combine incremental address up to 2 bytes Others: Setting prohibited	R/W
16	PREEN	Prefetch enable This bit enables prefetch function for read transaction in memory-mapping mode. It could reduce the latency for read transaction with incremental address. 0: Disable prefetch function 1: Enable prefetch function	R/W

Bit	Symbol	Function	R/W
23:17	—	These bits are read as 0. The write value should be 0.	R/W
31:24	CMBTIM[7:0]	Combination timer This field specifies expiration period of combination timer. This timer is counted by PCLKA. 0x00 means disabling the combination timer. When the timer is expired, the data in the combination buffer is pushed to memory device.	R/W

Note: S-TYPE-3, P-TYPE-3

Note 1. Writing to OSPI memory space other than 64 bit is prohibited during combination mode.

This register has functions to configure xSPI Master function.

37.2.1.4 CMCFG0CSn : OSPI Command Map Configuration Register 0 CSn (n = 0, 1)

Base address: OSPI0_B = 0x4026_8000
OSPI0_B_NS = 0x5026_8000

Offset address: 0x010 + 0x010 × n

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	ADDRPCD[7:0]								ADDRPEN[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	ARYA MD	WPBS TMD	ADDSize[1:0]	FFMT[1:0]		
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
1:0	FFMT[1:0]	Frame format These bits configure xSPI frame format in memory-mapping mode. Please see Table 37.7 for detail. 0 0: Normal format: Command 1 byte, Address ADDSIZE, Data up to system bus transaction. 0 1: 8D-8D-8D profile 1.0 format: Command 2 bytes, Address ADDSIZE, Data up to system bus transaction 1 0: 8D-8D-8D profile 2.0 Command Modifier format: Command & Modifier 6 bytes, Data up to system bus transaction 1 1: 8D-8D-8D profile 2.0 Commands with Extended Command Modifier format: Command & Modifier 6 bytes, Data up to system bus transaction	R/W
3:2	ADDSize[1:0]	Address size These bits configure the number of address byte in memory-mapping mode. In case of 8D-8D-8D profile 2.0, it should be configured to 4 bytes. 0 0: 1 byte (256-byte address space) 0 1: 2 bytes (64 KB address space) 1 0: 3 bytes (16 MB address space) 1 1: 4 bytes (4 GB address space)	R/W
4	WPBSTMD	Wrapping burst mode When this field is set to 1, the wrapping boundary between system bus access and xSPI memory shall be matched. 0: Separate xSPI transfer at the wrapping address boundary 1: Not separate xSPI transfer at the wrapping address boundary	R/W
5	ARYAMD	Array address mode When this field is set to 1, address for memory is mapped as {A[25:10], A[9:4], 6{RSV}, A[3:0]} where A[25:0] is normal address, and RSV is reserved value(0b). This field is effective only when FFMT=1d. 0: Normal address mode 1: Array address mode	R/W
15:6	—	These bits are read as 0. The write value should be 0.	R/W

Bit	Symbol	Function	R/W
23:16	ADDRPEN[7:0]	Address Replace Enable These bits select the bits to replace for MSByte of System bus address in memory-mapping mode. 0: No replacement (xSPI frame address field is same as System bus address) 1: Replacement	R/W
31:24	ADDRPCD[7:0]	Address Replace Code These bits configure the code to replace the MSByte of System bus address in memory-mapping mode. It replaces the corresponding bits when Address Replace Enable bit is set to 1.	R/W

Note: S-TYPE-3, P-TYPE-3

This register has functions to configure xSPI Master function.

Bit	Symbol	Function	R/W
9:0	PRTMD[9:0]	Protocol mode These bits configure the protocol mode and the pin to sample data inputs. In case of using not SPI clock but Data strobe for sampling in SDR mode, it is required to set PRTMD[9] to 1. 0x000: 1S-1S-1S 0x3B2: 4S-4D-4D 0x3FF: 8D-8D-8D 0x048: 1S-2S-2S 0x049: 2S-2S-2S 0x090: 1S-4S-4S 0x092: 4S-4S-4S Others: Setting prohibited	R/W

Bit	Symbol	Function	R/W																				
10	LATEMD	Latency mode This bit selects the behavior of initial access latency phase for both direct-manual mode and memory-mapping mode. When set to 0, the latency cycle is equal to each configured cycle from transmitting address field. When set to 1, the latency cycle is incremented from the last byte-pair of Address field and is extended 2 times of each configured cycle depending on OM_DQS port. It is used only for profile 2.0 frame format of 8D-8D-8D protocol mode with 6 bytes command/address field. Please refer to xSPI protocol for detail. <table border="1"> <thead> <tr> <th>Value</th><th>Function</th><th>Frame format</th><th>Usage</th></tr> </thead> <tbody> <tr> <td>0</td><td>Configurable latency</td><td>profile 2.0</td><td>The configurable latency cycle should be set as minus 1.</td></tr> <tr> <td></td><td></td><td>Others</td><td>Latency cycle increments after address field.</td></tr> <tr> <td>1</td><td>Variable latency</td><td>profile 2.0</td><td>Latency cycle increments from address [23:16]. 0	Configurable latency	profile 2.0	The configurable latency cycle should be set as minus 1.																				
		Others	Latency cycle increments after address field.																				
1	Variable latency	profile 2.0	Latency cycle increments from address [23:16]. And it should not be set to 1.																				
		Others	Not support																				
11	WRMSKMD	Write mask mode This bit selects to use OM_DQS port as write data mask. It could be useful for write access of odd byte. It is used only for 8D-8D-8D protocol mode. 0: Write mask disable 1: Write mask enable	R/W																				
15:12	—	These bits are read as 0. The write value should be 0.	R/W																				
19:16	CSMIN[3:0]	CS minimum idle term This bit configures the minimum cycle between xSPI frames. 0x0: 1 cycle 0x1: 2 cycles ⋮ 0x7: 8 cycles (default) ⋮ 0xE: 15 cycles 0xF: 16 cycles Others: Setting prohibited	R/W																				
20	CSASTEX	CS asserting extension This bit extends 1 cycle chip select pins when asserting. 0: No extension 1: Extend 1 cycle	R/W																				
21	CSNEGEX	CS negating extension This bit extends 1 cycle chip select pins when negating. 0: No extension 1: Extend 1 cycle	R/W																				
22	SDRDRV	SDR driving timing This bit configures the timing of data output in SDR. This bit should not be set to 1 in case of no latency cycle. Because OSPI output data could be conflicted with OSPI input data. 0: Drive at 1/2 cycle before CK rising-edge 1: Drive at CK rising-edge	R/W																				
23	SDRSMPMD	SDR Sampling mode This bit selects the edge of sampling in SDR. In DDR, regardless of this setting, it samples OM_SIO_n (n = 0 to 7) ports with both edges of OM_DQS. When set to 1, it samples at rising-edge before falling-edge. 0: Samples data input at falling-edge 1: Samples data input at rising-edge	R/W																				

Bit	Symbol	Function	R/W
27:24	SDRSMPST[3:0]	SDR Sampling window shift These bits shift the timing of CK sampling in SDR. In case of using OM_DQS in SDR, there is no influence on the behavior. In case of DDR or using OM_DQS in SDR, it should be set to 0. 0x0: Sample without delay 0x1: Sample at 1 cycle delay ⋮ 0x6: Sample at 6 cycle delay 0x7: Sample at 7 cycle delay Others: Setting prohibited	R/W
31:28	DDRSMPST[3:0]	DDR sampling window extend These bits configure the cycle of extending the sampling window in DDR. In DDR, the input data is sampled during the expected cycle soon after latency cycle. The input data out of range is ignored. It can be configured depending on OM_DQS propagation delay. 0x0: Expand no cycle 0x1: Expand 1 cycle ⋮ 0x6: Expand 6 cycles 0x7: Expand 7 cycles Others: Setting prohibited	R/W

Note: S-TYPE-3, P-TYPE-3

This register has functions to configure xSPI Master function.

37.2.2 OSPI Control Registers

These registers control xSPI Master function.

37.2.2.1 BMCTL0 : OSPI Bridge Map Control Register 0

Base address: OSPI0_B = 0x4026_8000
OSPI0_B_NS = 0x5026_8000

Offset address: 0x060

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	CH0CS1ACC [1:0]	CH0CS0ACC [1:0]	CH0CS0ACC [1:0]	CH0CS0ACC [1:0]
Value after reset:	0	0	0	0	0	0	0	0	1	1	1	1	1	1	1	1

Bit	Symbol	Function	R/W
1:0	CH0CS0ACC[1:0]	System bus ch0 to slave0 memory area access enable This field enables the access from ch0 to CS0 memory. 0 0: Read/Write disable 0 1: Read enable, Write disable 1 0: Read disable, Write enable 1 1: Read/Write enable	R/W
3:2	CH0CS1ACC[1:0]	System bus ch0 to slave1 memory area access enable This field enables the access from ch0 to CS1 memory. 0 0: Read/Write disable 0 1: Read enable, Write disable 1 0: Read disable, Write enable 1 1: Read/Write enable	R/W
7:4	—	These bits are read as 1. The write value should be 1.	R/W
31:8	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

This register has functions to control xSPI Master function.

This register shall be configured in the initialization phase. When setting is needed to be changed after beginning xSPI transaction, please stop all communication, see [section 37.3.7.2. Flow of Communication Stop](#) before changing the value of BMCTL0.

37.2.2.2 BMCTL1 : OSPI Bridge Map Control Register 1

Base address: OSPI0_B = 0x4026_8000
OSPI0_B_NS = 0x5026_8000

Offset address: 0x064

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	PBUF CLRC H0	—	MWRP USHC H0	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	—	The write value should be 0.	W
8	MWRPUSHCH0	Memory Write Data Push for ch0 This field requests to push the pending data in combination mode.*1 0: No command 1: Push request	W
9	—	The write value should be 0.	W
10	PBUFCLRCH0	Prefetch Buffer clear for ch0 This field requests to clear the prefetch buffer when the prefetch function is enabled.*1 It should not be set during memory access (COMSTT.MEMACCCH0 = 1). 0: No command 1: Clear request	W
31:11	—	The write value should be 0.	W

Note: S-TYPE-3, P-TYPE-3

Note 1. Prefetch/Combination behavior is not defined when cycle base race condition between asserting these bits and system bus access is occurred.

This register has functions to control xSPI Master function.

37.2.2.3 CMCTLCH0 : OSPI Command Map Control register ch0

Base address: OSPI0_B = 0x4026_8000
OSPI0_B_NS = 0x5026_8000

Offset address: 0x0068 + 0x004

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	XIPEN
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	XIPEXCODE[7:0]								XIPENCODE[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	XIPENCODE[7:0]	XiP mode enter code These bits configure the code to enter XiP mode in memory-mapping mode.	R/W
15:8	XIPEXCODE[7:0]	XiP mode exit code These bits configure the code to exit XiP mode in memory-mapping mode.	R/W
16	XIPEN	XiP mode enable This bit enables XiP mode in memory-mapping mode. When set to 1, XiP enter code is inserted in the latency field, and the command field in next transaction is omitted. When set to 0, XiP exit code is inserted in the latency field. And it is set to 0 automatically when transmitting XiP disable pattern. It should not be used for 8D-8D-8D protocol mode profile 2.0 frame format. 0: Disable XiP mode 1: Enable XiP mode	R/W
31:17	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

This register has functions to control xSPI Master function.

37.2.2.4 CDCTL0 : OSPI Command Manual Control Register 0

Base address: OSPI0_B = 0x4026_8000
OSPI0_B_NS = 0x5026_8000

Offset address: 0x070

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	PERREP[3:0]				—	—	—	PERITV[4:0]				
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	TRNUM[1:0]	CSSEL	—	PERMD	TRREQ	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	TRREQ	Transaction request This bit requests to issue the transaction of manual-command. When set to 1, it starts the transaction. It is cleared to 0 when the transaction completed. The transaction is canceled by clearing to 0 while the transaction is ongoing. 0: No transaction 1: Request transaction	R/W
1	PERMD	Periodic mode This bit enables the periodic transaction mode. When set to 1, it repeats a transaction periodically and compares the read value with the expected value. It alternates the status polling operation for external memory. 0: Direct manual-command mode 1: Periodic manual-command mode	R/W
2	—	This bit is read as 0. The write value should be 0.	R/W
3	CSSEL	Chip select This bit selects a target memory to issue manual-command. 0: CS0 1: CS1	R/W
5:4	TRNUM[1:0]	Transaction number These bits configure the number of transactions in normal manual-command mode. In periodic manual-command, regardless of this setting, the read data of last command is compared. 0 0: Issue 1 command (using command buffer 0) 0 1: Issue 2 commands (using command buffer 0-1) 1 0: Issue 3 commands (using command buffer 0-2) 1 1: Issue 4 commands (using command buffer 0-3)	R/W

Bit	Symbol	Function	R/W
15:6	—	These bits are read as 0. The write value should be 0.	R/W
20:16	PERITV[4:0]	Periodic transaction interval These bits configure the interval of transaction in periodic manual-command mode. Too short interval compared with CPU bus cycle could result in no store into command buffer0. The interval should be longer than 4 times of CPU bus cycle. 0x00: 2 (= 2 ¹) cycles 0x01: 4 (= 2 ²) cycles : 0x1E: 2,147,483,648 (= 2 ³¹) cycles 0x1F: 4,294,967,296 (= 2 ³²) cycles	R/W
23:21	—	These bits are read as 0. The write value should be 0.	R/W
27:24	PERREP[3:0]	Periodic transaction repeat These bits configure the number of transaction repetitions in periodic manual-command mode. 0x0: 1 (= 2 ⁰) time 0x1: 2 (= 2 ¹) times : 0xE: 16384 (= 2 ¹⁴) times 0xF: 32768 (= 2 ¹⁵) times	R/W
31:28	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

This register has functions to control xSPI Master function.

37.2.2.5 CDCTL1 : OSPI Command Manual Control Register 1

Base address: OSPI0_B = 0x4026_8000
OSPI0_B_NS = 0x5026_8000

Offset address: 0x074

Bit position: 31

0

Bit field:

PEREXP[31:0]

Value after reset: 0

Bit	Symbol	Function	R/W
31:0	PEREXP[31:0]	Periodic transaction expected value These bits configure the expected value to compare with the read value in periodic manual-command mode. For example, in case of comparing 1 byte, the lower byte should be configured.	R/W

Note: S-TYPE-3, P-TYPE-3

This register has functions to control xSPI Master function.

37.2.2.6 CDCTL2 : OSPI Command Manual Control Register 2

Base address: OSPI0_B = 0x4026_8000
OSPI0_B_NS = 0x5026_8000

Offset address: 0x078

Bit position: 31

0

Bit field:

PERMSK[31:0]

Value after reset: 0

Bit	Symbol	Function	R/W
31:0	PERMSK[31:0]	Periodic transaction masked value These bits configure the masked value for the expected value in periodic manual-command mode. When set 1 to any bit, the corresponding bit configured as expected value (CDCTL1.PEREXP[31:0]) is ignored. In 8D-8D-8D, the data bytes are transferred only in byte pairs on xSPI bus. It means the dummy read data could be stored. It should be masked for unused bits. For example, in case of read lower 1 byte, it should be configured to 0xFFFFFFFF00.	R/W

Note: S-TYPE-3, P-TYPE-3

This register has functions to control xSPI Master function.

37.2.2.7 CDTBUFn : OSPI Command Manual Type Buf n (n = 0 to 3)

Base address: OSPI0_B = 0x4026_8000
OSPI0_B_NS = 0x5026_8000

Offset address: 0x080 + 0x010 × n

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	CMD[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	TRTY PE	—	LATE[4:0]					DATASIZE[3:0]				ADDSize[2:0]			CMDSize[1:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
1:0	CMDSize[1:0]	Command Size These bits configure the size of command field. In case of 8D-8D-8D, it should be fixed to 10b. It should not be configured both command size and address size to zero. 0 0: 0 bytes (No command phase) 0 1: 1 byte 1 0: 2 bytes Others: Setting prohibited	R/W
4:2	ADDSize[2:0]	Address size These bits configure the size of address field. 0 0 0: 0 bytes (No address phase) 0 0 1: 1 byte 0 1 0: 2 bytes 0 1 1: 3 bytes 1 0 0: 4 bytes Others: Setting prohibited	R/W
8:5	DATASize[3:0]	Write/Read Data Size These bits configure the size of data field. In 8D-8D-8D, the data bytes are transferred only in byte pairs on xSPI bus. For example, even if configuring 1 byte for read, 2 bytes data is received. The last byte should be ignored. The 0 bytes must not configured for read transaction. 0x0: 0 bytes (No data phase) 0x1: 1 byte ⋮ 0x7: 7 bytes 0x8: 8 bytes Others: Setting prohibited	R/W

Bit	Symbol	Function	R/W
13:9	LATE[4:0]	Latency cycle These bits configure the latency cycle in manual-command mode. 0x0: No latency 0x1: 1 cycle : 0x1E: 30 cycles 0x1F: 31 cycles	R/W
14	—	This bit is read as 0. The write value should be 0.	R/W
15	TRTYPE	Transaction Type This bit selects the type of transaction. 0: Read transaction (Readout data from slave device) 1: Not read transaction	R/W
31:16	CMD[15:0]	Command (1-2 bytes) These bits configure the command field in manual-command mode. The number of bytes configured in Command Size bit is transferred. 1S-1S-1S, 4S-4D-4D: CMD[15:8] is command field, CMD[7:0] is not used. 8D-8D-8D profile 1.0: CMD[15:8] is command field, CMD[7:0] is extension field. 8D-8D-8D profile 2.0: CMD[15:0] is upper 2 bytes of command & modifier field. (bit 47-32 in xSPI protocol)	R/W

Note: S-TYPE-3, P-TYPE-3

This register has functions to control xSPI Master function.

37.2.2.8 CDABUF_n : OSPI Command Manual Address Buf _n (n = 0 to 3)

Base address: OSPI0_B = 0x4026_8000
OSPI0_B_NS = 0x5026_8000

Offset address: 0x084 + 0x10 × n

Bit position: 31

0

Bit field:

ADD[31:0]

Value after reset: 0

Bit	Symbol	Function	R/W
31:0	ADD[31:0]	Address These bits configure the address field in manual-command mode. 1S-1S-1S, 4S-4D-4D, 8D-8D-8D profile 1.0: It is address field. 8D-8D-8D profile 2.0: It is lower 4 bytes of command & modifier field. (bit 31-0 in xSPI protocol)	R/W

Note: S-TYPE-3, P-TYPE-3

This register has functions to control xSPI Master function.

37.2.2.9 CDD0BUF_n : OSPI Command Manual Data 0 Buf _n (n = 0 to 3)

Base address: OSPI0_B = 0x4026_8000
OSPI0_B_NS = 0x5026_8000

Offset address: 0x088 + 0x10 × n

Bit position: 31

0

Bit field:

DATA[31:0]

Value after reset: 0

Bit	Symbol	Function	R/W
31:0	DATA[31:0]	Write/Read Data These bits configure the data field in manual-command mode. In case of write transaction, the write data should be configured. In case of read transaction, the read data is stored.	R/W

Note: S-TYPE-3, P-TYPE-3

This register has functions to control xSPI Master function.

37.2.2.10 CDD1BUF_n : OSPI Command Manual Data 1 Buf _n (n = 0 to 3)

Base address: OSPI0_B = 0x4026_8000
OSPI0_B_NS = 0x5026_8000

Offset address: 0x08C + 0x10 × n

Bit position: 31

0

Bit field:

DATA[31:0]

Value after reset: 0

Bit	Symbol	Function	R/W
31:0	DATA[31:0]	Write/Read Data These bits configure the data field in manual-command mode. In case of write transaction, the write data should be configured. In case of read transaction, the read data is stored.	R/W

Note: S-TYPE-3, P-TYPE-3

This register has functions to control xSPI Master function.

37.2.2.11 LPCTL0 : OSPI Link Pattern Control Register 0

Base address: OSPI0_B = 0x4026_8000
OSPI0_B_NS = 0x5026_8000

Offset address: 0x100

Bit position: 31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16

Bit field:

XD2V AL	—	—	XD2LEN[4:0]				XD1V AL	—	—	XD1LEN[4:0]			
------------	---	---	-------------	--	--	--	------------	---	---	-------------	--	--	--

Value after reset: 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

Bit position: 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

Bit field:

—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
---	---	---	---	---	---	---	---	---	---	---	---	---	---	---	---

Value after reset: 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

Bit	Symbol	Function	R/W
0	PATREQ	Pattern request This bit requests to issue the pattern. When set to 1, it starts the pattern. It is cleared to 0 when the pattern completed. 0: No request XiP Disable pattern 1: Request XiP Disable pattern	R/W
2:1	—	These bits are read as 0. The write value should be 0.	R/W
3	CSSEL	Chip select This bit selects a target memory to issue a pattern. 0: slave0 (CS0) 1: slave1 (CS1)	R/W

Bit	Symbol	Function	R/W
5:4	XDPIN[1:0]	XiP Disable pattern pin These bits select the data output pins to transmit XiP Disable pattern. 0 0: 1 pin 0 1: 2 pins 1 0: 4 pins 1 1: 8 pins	R/W
15:6	—	These bits are read as 0. The write value should be 0.	R/W
20:16	XD1LEN[4:0]	XiP Disable pattern 1st phase length These bits select the length of 1st phase in XiP disable pattern. The pattern with zero-length both 1st phase and 2nd phase should not be configured. 0x0: 0 cycles 0x1: 1 cycle ⋮ 0x1E: 30 cycles 0x1F: 31 cycles	R/W
22:21	—	These bits are read as 0. The write value should be 0.	R/W
23	XD1VAL	XiP Disable pattern 1st phase value This bit selects the value of 1st phase in XiP disable pattern. 0: Low drive 1: High drive	R/W
28:24	XD2LEN[4:0]	XiP Disable pattern 2nd phase length These bits select the length of 2nd phase in XiP disable pattern. 0x00: 0 cycles 0x01: 1 cycle ⋮ 0x1E: 30 cycles 0x1F: 31 cycles	R/W
30:29	—	These bits are read as 0. The write value should be 0.	R/W
31	XD2VAL	XiP Disable pattern 2nd phase value This bit selects the value of 2nd phase in XiP disable pattern. 0: Low drive 1: High drive	R/W

Note: S-TYPE-3, P-TYPE-3

This register has functions to control xSPI Master function.

37.2.2.12 LPCTL1 : OSPI Link Pattern Control Register 1

Base address: OSPI0_B = 0x4026_8000
OSPI0_B_NS = 0x5026_8000

Offset address: 0x104

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	RSTSU[2:0]			—	RSTWID[2:0]			—	—	RSTREP[1:0]		CSSE L	—	PATREQ[1:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
1:0	PATREQ[1:0]	Pattern request These bits request to issue the pattern. When set to 01b or 10b, it starts the pattern. It is cleared to 00b when the pattern completed. 0 0: No request 0 1: Request Reset pattern 1 0: Request CS only pattern 1 1: Setting prohibited	R/W
2	—	This bit is read as 0. The write value should be 0.	R/W
3	CSSEL	Chip select This bit selects a target memory to issue a pattern. 0: slave0 (CS0) 1: slave1 (CS1)	R/W
5:4	RSTREP[1:0]	Reset pattern repeat These bits select the repeating time to toggle CS from LOW to HIGH. 0 0: 4 times (Specified on Reset Signaling Protocol) 0 1: 5 times 1 0: 6 times 1 1: 7 times	R/W
7:6	—	These bits are read as 0. The write value should be 0.	R/W
10:8	RSTWID[2:0]	Reset pattern width These bits configure the width of cycle in reset pattern and CS only pattern. It toggles CS with the configured cycle. 0 0 0: 2 (= 2 ¹) cycles 0 0 1: 4 (= 2 ²) cycles ⋮ 1 1 0: 128 (= 2 ⁷) cycles 1 1 1: 256 (= 2 ⁸) cycles	R/W
11	—	This bit is read as 0. The write value should be 0.	R/W
14:12	RSTSU[2:0]	Reset pattern data output setup time These bits configure the number of setup cycle for data output based on the edge of CS in reset pattern. It needs enough setup time because xSPI slave samples any data at the rising edge of CS. This cycle of setup time should be less than the cycle of reset pattern width (RSTWID[2:0]). 0 0 0: 1 cycle 0 0 1: 2 cycles ⋮ 1 1 0: 7 cycles 1 1 1: 8 cycles	R/W
31:15	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

This register has functions to control xSPI Master function.

37.2.2.13 LIOCTL : OSPI Link I/O Control Register

Base address: OSPI0_B = 0x4026_8000
OSPI0_B_NS = 0x5026_8000

Offset address: 0x108

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	RSTC S0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	WPCS 1	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1

Bit	Symbol	Function	R/W
0	—	This bit is read as 1. The write value should be 1.	R/W
1	WPCS1	WP drive for slave1 This bit controls the value of OM_WP1 port. It can be useful only for xSPI slave with write protect port. 0: Drive Low level 1: Drive High level	R/W
15:2	—	These bits are read as 0. The write value should be 0.	R/W
16	RSTCS0	Reset drive This bit controls the value of OM_RESET port. It could be useful only for xSPI slave with reset port. 0: Drive Low level 1: Drive High level	R/W
17	—	This bit is read as 1. The write value should be 1.	R/W
31:18	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

This register has functions to control xSPI Master function.

37.2.2.14 CCCTL0CSn : OSPI Command Calibration Control Register 0 CSn (n = 0, 1)

Base address: OSPI0_B = 0x4026_8000
OSPI0_B_NS = 0x5026_8000

Offset address: 0x130 + 0x020 × n

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	CASFTEND[4:0]				—	—	—	CASFTSTA[4:0]					
Value after reset:	0	0	0	1	1	1	1	1	0	0	0	0	0	0	0	0
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	CAITV[4:0]				—	—	—	—	—	—	—	CANO WR	CAEN
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	CAEN	Automatic Calibration Enable This bit enables the automatic calibration. When set to 1, it transmits the calibration sequence periodically and adjusts the value of phase shift. When set to 0 during the calibration sequence, it stops after completed ongoing calibration sequence, and then this bit is cleared. 0: Disable automatic calibration 1: Enable automatic calibration	R/W
1	CANOWR	Calibration no write mode This bit selects to omit write command in calibration sequence. It can be used for any slave device with fixed calibration pattern data. 0: Calibration sequence with write command 1: Calibration sequence without write command	R/W
7:2	—	These bits are read as 0. The write value should be 0.	R/W
12:8	CAITV[4:0]	Calibration interval These bits configure the interval between calibration patterns. 0x00: 2 (= 2 ¹) cycle wait 0x01: 4 (= 2 ²) cycle wait ⋮ 0x1E: 2,147,483,648 (= 2 ³¹) cycle wait 0x1F: 4,294,967,296 (= 2 ³²) cycle wait	R/W
15:13	—	These bits are read as 0. The write value should be 0.	R/W

Bit	Symbol	Function	R/W
20:16	CASFTSTA[4:0]	Calibration OM_DQS shift start value These bits configure the start value of OM_DQS shift.	R/W
23:21	—	These bits are read as 0. The write value should be 0.	R/W
28:24	CASFTEND[4:0]	Calibration OM_DQS shift end value These bits configure the end value of OM_DQS shift. It should be equal or more than the start value (CASFTSTA[4:0]).	R/W
31:29	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

This register has functions to control xSPI Master function.

37.2.2.15 CCCTL1CSn : OSPI Command Calibration Control Register 1 CSn (n = 0, 1)

Base address: OSPI0_B = 0x4026_8000
OSPI0_B_NS = 0x5026_8000

Offset address: 0x134 + 0x020 × n

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	CARDLATE[4:0]				—	—	—	CAWLRLATE[4:0]					
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	CADATASIZE[3:0]				CAADDSIZE[2:0]		CACMDSIZE[1:0]		
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
1:0	CACMDSIZE[1:0]	Command Size These bits configure the size of command field. In case of 8D-8D-8D, it should be fixed to 10b. It should not be configured both command size and address size to zero. 0 0: 0 bytes (No command phase) 0 1: 1 byte 1 0: 2 bytes 1 1: Setting prohibited	R/W
4:2	CAADDSIZE[2:0]	Address size These bits configure the size of address field. 0 0 0: 0 bytes (No address phase) 0 0 1: 1 byte 0 1 0: 2 bytes 0 1 1: 3 bytes 1 0 0: 4 bytes Others: Setting prohibited	R/W
8:5	CADATASIZE[3:0]	Write/Read Data Size These bits configure the size of data field. In 8D-8D-8D, it should be configured with even byte. 0x0: 1 byte 0x1: 2 bytes ⋮ 0xE: 15 bytes 0xF: 16 bytes	R/W
15:9	—	These bits are read as 0. The write value should be 0.	R/W

Bit	Symbol	Function	R/W
20:16	CAWRLATE[4:0]	Write Latency cycle These bits configure the latency cycle in calibration frame. 0x00: No latency 0x01: 1 cycle ⋮ 0x1E: 30 cycles 0x1F: 31 cycles	R/W
23:21	—	These bits are read as 0. The write value should be 0.	R/W
28:24	CARDLATE[4:0]	Read Latency cycle These bits configure the latency cycle in calibration frame. 0x00: No latency 0x01: 1 cycle ⋮ 0x1E: 30 cycles 0x1F: 31 cycles	R/W
31:29	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

This register has functions to control xSPI Master function. It should be updated while Automatic Calibration Enable is disabled.

37.2.2.16 CCCTL2CSn : OSPI Command Calibration Control Register 2 CSn (n = 0, 1)

Base address: OSPI0_B = 0x4026_8000
OSPI0_B_NS = 0x5026_8000

Offset address: 0x138 + 0x020 × n

Bit position:	31	16	15	0
Bit field:	CARDCMD[15:0]		CAWRCMD[15:0]	

Value after reset: 0

Bit	Symbol	Function	R/W
15:0	CAWRCMD[15:0]	Calibration pattern write command These bits configure the calibration pattern write command.	R/W
31:16	CARDCMD[15:0]	Calibration pattern read command These bits configure the calibration pattern read command.	R/W

Note: S-TYPE-3, P-TYPE-3

This register has functions to control xSPI Master function. It should be updated while Automatic Calibration Enable is disabled.

37.2.2.17 CCCTL3CSn : OSPI Command Calibration Control Register 3 CSn (n = 0, 1)

Base address: OSPI0_B = 0x4026_8000
OSPI0_B_NS = 0x5026_8000

Offset address: 0x13C + 0x020 × n

Bit position:	31	0
Bit field:	CAADD[31:0]	

Value after reset: 0

Bit	Symbol	Function	R/W
31:0	CAADD[31:0]	Calibration pattern address These bits configure the calibration pattern address.	R/W

Note: S-TYPE-3, P-TYPE-3

This register has functions to control xSPI Master function. It should be updated while Automatic Calibration Enable is disabled.

37.2.2.18 CCCTL4CSn : OSPI Command Calibration Control Register 4 CSn (n = 0, 1)

Base address: OSPI0_B = 0x4026_8000
OSPI0_B_NS = 0x5026_8000

Offset address: 0x140 + 0x020 × n

Bit position: 31

0

Bit field:

CADATA[31:0]

Value after reset: 0

Bit	Symbol	Function	R/W
31:0	CADATA[31:0]	Calibration pattern data These bits configure the calibration pattern data.	R/W

Note: S-TYPE-3, P-TYPE-3

This register has functions to control xSPI Master function. It should be updated while Automatic Calibration Enable is disabled.

37.2.2.19 CCCTL5CSn : OSPI Command Calibration Control Register 5 CSn (n = 0, 1)

Base address: OSPI0_B = 0x4026_8000
OSPI0_B_NS = 0x5026_8000

Offset address: 0x144 + 0x020 × n

Bit position: 31

0

Bit field:

CADATA[31:0]

Value after reset: 0

Bit	Symbol	Function	R/W
31:0	CADATA[31:0]	Calibration pattern data These bits configure the calibration pattern data.	R/W

Note: S-TYPE-3, P-TYPE-3

This register has functions to control xSPI Master function. It should be updated while Automatic Calibration Enable is disabled.

37.2.2.20 CCCTL6CSn : OSPI Command Calibration Control Register 6 CSn (n = 0, 1)

Base address: OSPI0_B = 0x4026_8000
OSPI0_B_NS = 0x5026_8000

Offset address: 0x148 + 0x020 × n

Bit position: 31

0

Bit field:

CADATA[31:0]

Value after reset: 0

Bit	Symbol	Function	R/W
31:0	CADATA[31:0]	Calibration pattern data These bits configure the calibration pattern data.	R/W

Note: S-TYPE-3, P-TYPE-3

This register has functions to control xSPI Master function. It should be updated while Automatic Calibration Enable is disabled.

37.2.2.21 CCCTL7CSn : OSPI Command Calibration Control Register 7 CSn (n = 0, 1)

Base address: OSPI0_B = 0x4026_8000
OSPI0_B_NS = 0x5026_8000

Offset address: 0x14C + 0x020 × n

Bit position: 31

0

Bit field:

CADATA[31:0]

Value after reset: 0

Bit	Symbol	Function	R/W
31:0	CADATA[31:0]	Calibration pattern data These bits configure the calibration pattern data.	R/W

Note: S-TYPE-3, P-TYPE-3

This register has functions to control xSPI Master function. It should be updated while Automatic Calibration Enable is disabled.

37.2.3 OSPI Status Registers

These registers monitor the status of xSPI Master.

37.2.3.1 COMSTT : OSPI Common Status Register

Base address: OSPI0_B = 0x4026_8000
OSPI0_B_NS = 0x5026_8000

Value after reset: 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

Bit	Symbol	Function	R/W
0	CMDCMP	Command Completed This bit is set to 1 when completed the requested manual-command. In direct manual-command, it means all transactions completed. In periodic manual-command, it means the read data matches with the expected data. 0: No detection 1: Detection	R
1	PATCMP	Pattern Completed This bit is set to 1 when completed the requested pattern. 0: No detection 1: Detection	R
2	—	This bit is read as 0.	R
3	PERTO	Periodic transaction timeout This bit is set to 1 when the read value does not match with the expected value in periodic manual-command mode. 0: No detection 1: Detection	R
4	DSTOCS0	OM_DQS timeout for slave0 This bit is set to 1 when lost OM_DQS in read transaction with using OM_DQS. It means not receiving the data during expected read phase. In this case, xSPI master stops the read transaction and the following transaction. This error may issue error response to system bus. 0: No detection 1: Detection	R
5	DSTOCS1	OM_DQS timeout for slave1 This function is same as DSTOCS0. 0: No detection 1: Detection	R
8:6	—	These bits are read as 0.	R
9	ECSCS1	ECC error detection for slave1 This bit is set to 1 when detected the falling edge on OM_ECSINT1 port. It can be useful only for xSPI slave with ECC detection function. 0: No detection 1: Detection	R
12:10	—	These bits are read as 0.	R
13	INTCS1	Interrupt detection for slave1 This bit is set to 1 when detected the falling edge on OM_ECSINT1 port. It can be useful only for xSPI slave with interrupt function. 0: No detection 1: Detection	R
19:14	—	These bits are read as 0.	R
20	BUSERRCH0	System bus error for ch0 This bit is set to 1 when an error response occurs on system bus channel0.	R
27:21	—	These bits are read as 0.	R
28	CAFAILCS0	Calibration failed for slave0 This bit is set to 1 when failed calibration. 0: No detection 1: Detection	R
29	CAFAILCS1	Calibration failed for slave1 This function is same as CAFAILCS0. 0: No detection 1: Detection	R
30	CASUCCS0	Calibration success for slave0 This bit is set to 1 when success calibration. 0: No detection 1: Detection	R

Bit	Symbol	Function	R/W
31	CASUCCS1	Calibration success for slave1 This function is same as CASUCCS0. 0: No detection 1: Detection	R

Note: S-TYPE-3, P-TYPE-3

This register indicates the status of interrupt. The bits in this register are cleared to 0 when writing 1 on the corresponding bit of INTC register.

37.2.4.2 INTC : OSPI Interrupt Clear Register

Base address: OSPI0_B = 0x4026_8000
OSPI0_B_NS = 0x5026_8000

Offset address: 0x194

Bit	Symbol	Function	R/W
0	CMDCMPE	Command Completed interrupt enable 0: Disabled 1: Enabled	R/W
1	PATCMPE	Pattern Completed interrupt enable 0: Disabled 1: Enabled	R/W
2	—	This bit is read as 0. The write value should be 0.	R/W
3	PERTOE	Periodic transaction timeout interrupt enable 0: Disabled 1: Enabled	R/W
4	DSTOCS0E	OM_DQS timeout for slave0 interrupt enable 0: Disabled 1: Enabled	R/W
5	DSTOCS1E	OM_DQS timeout for slave1 interrupt enable 0: Disabled 1: Enabled	R/W
8:6	—	These bits are read as 0. The write value should be 0.	R/W
9	ECSCS1E	ECC error detection for slave1 interrupt enable 0: Disabled 1: Enabled	R/W
12:10	—	These bits are read as 0. The write value should be 0.	R/W

Bit	Symbol	Function	R/W
13	INTCS1E	Interrupt detection for slave1 interrupt enable 0: Disabled 1: Enabled	R/W
19:14	—	These bits are read as 0. The write value should be 0.	R/W
20	BUSERRCH0E	System bus error for ch0 interrupt enable 0: Disabled 1: Enabled	R/W
27:21	—	These bits are read as 0. The write value should be 0.	R/W
28	CAFAILCS0E	Calibration failed for slave0 interrupt enable 0: Disabled 1: Enabled	R/W
29	CAFAILCS1E	Calibration failed for slave1 interrupt enable 0: Disabled 1: Enabled	R/W
30	CASUCCS0E	Calibration success for slave0 interrupt enable 0: Disabled 1: Enabled	R/W
31	CASUCCS1E	Calibration success for slave1 interrupt enable 0: Disabled 1: Enabled	R/W

Note: S-TYPE-3, P-TYPE-3

This register enables the interrupt.

37.3 Operation

xSPI Master interface has the functions to issue the transaction for external memory with xSPI Slave interface. It allows to write to registers in external memory or read from it.

This xSPI Master mainly has two modes to issue the transaction. One is a manual-command mode; Software configures all fields of xSPI frame and starts the transaction by software request. The other is a memory-mapping mode; it automatically converts system bus for pre-configured memory area into xSPI transaction. It enables to access from system bus to external memory area outside of chip via xSPI bus.

This section describes the xSPI bus operation, the direct control of xSPI frame (manual-command), the control of memory access (memory-mapping), the error operation, and the flow to operation.

37.3.1 xSPI Bus

This section describes the xSPI bus operation.

Figure 37.2 shows an example of connections between OSPI and memory devices.

In this case, OM_CS0 should be connected to the RAM device and OM_CS1 should be connected to the Flash device.

Pull-up resistors should be specified according to the instructions for each device.

Figure 37.2 Example of Connection between this and memory devices

37.3.1.1 Supported Protocol Mode

This xSPI Master supports various protocol modes. It is configured by Protocol mode bits (LIOCFGCSn.PRTMD[9:0]). [Table 37.3](#) shows the summary of protocol modes.

Table 37.3 Supported protocol mode (1 of 2)

Protocol mode	Function	PRTMD[9:0]	Note
1S-1S-1S	Command, Address and Data field are transferred at SDR with using 1 data input pin and 1 data output pin. Read data is sampled with CK.	0x000	Specified by xSPI protocol
4S-4D-4D	Command field is transferred at SDR with using 4 data pins. Address and Data fields are transferred at DDR with using 4 data pins. Read data is sampled with OM_DQS.	0x3B2	Specified by xSPI protocol
8D-8D-8D	Command, Address and Data fields are transferred at DDR with using 8 data pins. Read data is sampled with OM_DQS.	0x3FF	Specified by xSPI protocol
1S-2S-2S	Command field is transferred at SDR with using 1 data pin. Address and Data fields are transferred at SDR with using 2 data pins. Read data is sampled with CK.	0x048	—

Table 37.3 Supported protocol mode (2 of 2)

Protocol mode	Function	PRTMD[9:0]	Note
2S-2S-2S	Command, Address and Data fields are transferred at SDR with using 2 data pins. Read data is sampled with CK.	0x049	—
1S-4S-4S	Command field is transferred at SDR with using 1 data pin. Address and Data fields are transferred at SDR with using 4 data pins. Read data is sampled with CK.	0x090	—
4S-4S-4S	Command, Address, and Data fields are transferred at SDR with using 4 data pins. Read data is sampled with CK.	0x092	—

Note: In case of XiP mode enable, XiP code is inserted in Latency field. It is valid only for memory-mapping mode.

The bytes of Command and Address fields are transferred in highest order to lowest order sequence. The sequential bytes of Data field are transferred in lowest address to highest address order. In case of using multiple pins, the least significant bit of each byte is placed on OM_SIO0 with each higher order bit on the successively higher numbered OM_SIO_n (n = 1 to 7) signals.

Figure 37.3 shows timing-chart for 1S-1S-1S protocol mode. The OM_SIO0 signal is used for output data and the OM_SIO1 signal is used for input data.

Figure 37.3 1S-1S-1S timing-chart

Figure 37.4 shows timing-chart for 1S-2S-2S protocol mode.

Figure 37.4 1S-2S-2S timing-chart

Figure 37.5 shows timing-chart for 4S-4D-4D protocol mode.

Figure 37.5 4S-4D-4D timing-chart

Figure 37.6 shows timing-chart for 8D-8D-8D profile 1.0 protocol mode. In 8D-8D-8D, the data is always transmitted with byte-pair. In case each field is odd byte, last one byte is padded with invalid data.

Figure 37.6 8D-8D-8D profile 1.0 timing-chart

Figure 37.7 shows timing-chart for 8D-8D-8D profile 2.0 protocol mode. In 8D-8D-8D, the data is always transmitted with byte-pair. In case each field is odd byte, last one byte is padded with invalid data.

Figure 37.7 8D-8D-8D profile 2.0 timing-chart

37.3.1.2 xSPI Frame Interval

The interval between xSPI frames is configured with CS minimum idle term bits (LIOCFCGSn.CSMIN[3:0]). It depends on the specification of xSPI slave device.

37.3.1.3 OSPI Signals Timing Control

This xSPI Master supports both SDR and DDR. It is possible to sample input data with Data-Strobe (*OM_DQS*) signal at SDR. For various modes and easy implementation, this xSPI Master could adjust the timing to drive/sample xSPI interface signals statically. Table 37.4 shows the summary of xSPI Interface signal timing control.

Table 37.4 Summary of OSPI signals timing control (1 of 2)

Signal	Mode	Default operation	Timing control (n = 0, 1)
OM_CS0, OM_CS1 drive	—	Asserting 1 cycle before the rising-edge of first OM_SCLK	1 cycle extension for asserting with LIOCFCGSn.CSASTEX bit
		Negating 1.5 cycle after the falling-edge of last OM_SCLK	1 cycle extension for negating with LIOCFCGSn.CSNEGEX bit
OM_SCLK drive	SDR without OM_DQS	Reference point	—
	SDR with OM_DQS		
	DDR with OM_DQS	Reference point	—

Table 37.4 Summary of OSPI signals timing control (2 of 2)

Signal	Mode	Default operation	Timing control (n = 0, 1)
OM_SIO _n (n = 0 to 7) output drive	SDR without OM_DQS	Falling edge of clk_spi (Internal Clock)	0 or 0.5 cycle shift with LIOCFGCSn.SDRDRV bit
	SDR with OM_DQS		
	DDR with OM_DQS	Both edges of clk_spi (Internal Clock)	—
OM_SIO _n (n = 0 to 7) input sample	SDR without OM_DQS	Falling edge of OM_SCLK on expected data size	0 to 7 cycle shift (1 cycle unit) with LIOCFGCSn.SDRSMPSFT[3:0] bits 0 or 0.5 cycle shift with LIOCFGCSn.SDRSMPMD bit
	SDR with OM_DQS	Falling edge of OM_DQS signal on expected data size	Sample at rising edge with LIOCFGCSn.SDRSMPMD bit 0 to 1 cycle phase shift with WRAPCFG.DSSFTCSn[4:0] bits 0 to 7 cycle extension with LIOCFGCSn.DDRSMPEX[3:0] bits
	DDR with OM_DQS	Both edges of OM_DQS signal on expected data size	0 to 1 cycle phase shift with WRAPCFG.DSSFTCSn[4:0] bits 0 to 7 cycle extension with LIOCFGCSn.DDRSMPEX[3:0] bits

Note: In DDR on xSPI protocol, OM_DQS should be aligned for center of data. It means to shift the phase by 0.25 cycle (90 degrees). This xSPI master supports to adjust this phase depending on the usage conditions.

Figure 37.8 shows the default operation and timing control for SDR without OM_DQS.

Figure 37.8 Timing control for SDR without OM_DQS

Figure 37.9 shows the default operation and timing control for SDR with OM_DQS.

Figure 37.9 Timing control for SDR with OM_DQS

Figure 37.10 shows the default operation and timing control for DDR with OM_DQS.

Figure 37.10 Timing control for DDR with OM_DQS

37.3.1.4 Automatic calibration

This xSPI master supports the function to adjust OM_DQS shift value (WRAPCFG.DSSFTCSn (n = 0, 1)) automatically. When this function is enabled (CCCTL0CSn.CAEN = 1), this xSPI master transmits the calibration sequence periodically and adjusts the value of phase shift.

When all read compare is mismatched in read transaction during the calibration sequence, the calibration fail bit (INTS.CAFAILCSn = 1 (n = 0, 1)) is asserted and OM_DQS shift value is not updated. When at least one read compare is matched, the calibration success bit (INTS.CASUCCSn = 1 (n = 0, 1)) is asserted and OM_DQS shift value is updated. The result of each OM_DQS shift value is monitored by Calibration Status register (CASTTCSn). Figure 37.11 shows automatic calibration.

Figure 37.11 Automatic calibration

37.3.2 Manual-command

This section describes the manual-command mode. The manual-command has two functional modes: direct mode and periodic mode.

37.3.2.1 Direct Mode

This mode sequentially can issue up to four xSPI transactions configured and requested by Software. A series of transaction can be issued by a transaction request (CDCTL0.TRREQ = 1 with PERMD = 0). The number of transactions (CDCTL0.TRNUM[1:0]) can be configured up to 4. It can be used to change the mode or read the status of xSPI slave device.

Table 37.5 shows the configured register bits for direct manual-command. The operating flow is illustrated in Figure 37.25.

Table 37.5 Manual-command configuration for direct mode

Transaction	Transaction type	Command	Command size	Address	Address size	Data (x = 0, 1)	Data size	Latency cycle
1st Transaction	CDTBUF0. TRTYPE	CDTBUF0. CMD[15:0]	CDTBUF0. CMDSIZE [1:0]	CDABUF0. ADD[31:0]	CDTBUF0. ADDSIZE [2:0]	CDDxBUF0. DATA[31:0]	CDTBUF0. DATASIZE [3:0]	CDTBUF0. LATE[4:0]
2nd Transaction	CDTBUF1. TRTYPE	CDTBUF1. CMD[15:0]	CDTBUF1. CMDSIZE [1:0]	CDABUF1. ADD[31:0]	CDTBUF1. ADDSIZE [2:0]	CDDxBUF1. DATA[31:0]	CDTBUF1. DATASIZE [3:0]	CDTBUF1. LATE[4:0]
3rd Transaction	CDTBUF2. TRTYPE	CDTBUF2. CMD[15:0]	CDTBUF2. CMDSIZE [1:0]	CDABUF2. ADD[31:0]	CDTBUF2. ADDSIZE [2:0]	CDDxBUF2. DATA[31:0]	CDTBUF2. DATASIZE [3:0]	CDTBUF2. LATE[4:0]
4th Transaction	CDTBUF3. TRTYPE	CDTBUF3. CMD[15:0]	CDTBUF3. CMDSIZE [1:0]	CDABUF3. ADD[31:0]	CDTBUF3. ADDSIZE [2:0]	CDDxBUF3. DATA[31:0]	CDTBUF3. DATASIZE [3:0]	CDTBUF3. LATE[4:0]

37.3.2.2 Periodic Mode

This mode periodically issues an xSPI read transaction configured and requested by Software. And it can compare the read value up to 4 bytes with expected value. The transaction is issued by a transaction request (CDCTL0.TRREQ = 1 with PERMD = 1). It can be used to alternate the status polling operation of xSPI slave device.

The periodic term is configured in Periodic transaction interval bits (CDCTL0.PERITV[4:0]). The expected value is configured in Periodic transaction expected and masked value bits (CDCTL1.PEREXP[31:0] and CDCTL2.PERMSK[31:0]). Table 37.6 shows the configured register bits for periodic manual-command. The operating flow is illustrated in Figure 37.26.

Table 37.6 Manual-command configuration for periodic mode

Transaction	Transaction type	Command	Command size	Address	Address size	Data (x = 0, 1)	Data size	Latency cycle
Read Transaction	CDTBUF0. TRTYPE	CDTBUF0. CMD[15:0]	CDTBUF0. CMSIZE [1:0]	CDABUF0. ADD[31:0]	CDTBUF0. ADDSIZE [2:0]	CDDxBUF0. DATA[31:0]	CDTBUF0. DATASIZE [3:0]	CDTBUF0. LATE[4:0]

37.3.3 Memory-mapping

This section describes the memory-mapping mode. This mode automatically converts system bus access for pre-configured memory area into xSPI transaction.

37.3.3.1 Configuration

In this operation, the payload of address and data field are delivered from system bus signals. The information of command field and size are delivered from the configured register bits. [Table 37.7](#) shows the register bits configured for memory-mapping.

Table 37.7 Memory-mapping configuration for memory area access (n = 0, 1)

System bus Transaction	Format Change mode	Command	Command size	Address	Address size	Data	Data size	Latency cycle
Write for slave n memory area	Normal	CMCFG2CSn. WRCMD[15:8]	1 byte	SAWADDR[x:0]	CMCFG0C Sn. ADDSIZE [1:0]	SWDATA	Up to SAWLEN and SAWSIZE	CMCFG2CSn. WRLATE[4:0]
	8D-8D-8D profile 1.0	CMCFG2CSn. WRCMD[15:0]	2 bytes					
	8D-8D-8D profile 2.0 Command Modifier	CMCFG2CSn. WRCMD[15:8]	1 byte	{SAWADDR[27:4], 0000000000000b, SAWADDR[3:1]}	5 bytes			
	8D-8D-8D profile 2.0 Extended Command Modifier	CMCFG2CSn. WRCMD[15:13]	3 bits	{0b, SAWADDR [31:4], 0000000000000b, SAWADDR[3:1]}	45 bits			
Read for slave n memory area	Normal	CMCFG1CSn. RDCMD[15:8]	1 byte	SARADDR[x:0]	CMCFG0C Sn. ADDSIZE [1:0]	SRDATA	Up to SARLEN and SARSIZE	CMCFG1CSn. RDLATE[4:0]
	8D-8D-8D profile 1.0	CMCFG1CSn. RDCMD[15:0]	2 bytes					
	8D-8D-8D profile 2.0 Command Modifier	CMCFG1CSn. RDCMD[15:8]	1 byte	{SARADDR[27:4], 0000000000000b, SARADDR[3:1]}	5 bytes			
	8D-8D-8D profile 2.0 Extended Command Modifier	CMCFG1CSn. RDCMD[15:13]	3 bits	{0b, SARADDR [31:4], 0000000000000b, SARADDR[3:1]}	45 bits			

Note: The MSByte of Address can be replaced with Address Replace Enable and Code bits (CMCFG0CSn.ADDRPEN[7:0] / ADDRPCD[7:0]).

37.3.3.2 Write Access Operation

At accepting write access for memory area from system bus, this xSPI Master stores all payload data in internal bridge buffer and then issues a write transaction into xSPI slave. [Figure 37.12](#) shows the operation summary.

Figure 37.12 Write access for memory area

The operation of xSPI bus changes depending on system bus's burst type. When the burst type is single type or incremental type, one system bus transaction triggers for one xSPI frame. When the burst type is wrap type and the CMCFG0CSn.WPBSTMD is 0, one system bus transaction triggers two xSPI frames. [Figure 37.13](#) shows the relationship between AXI and xSPI frames.

Figure 37.13 xSPI frame format in write access (Normal format)

37.3.3.3 Combination Function

At the system bus write access for memory area, this xSPI master has the function to combine the write data for high throughput on xSPI bus. When this function is enabled (BMCFGCHn.MWRCOMB = 1), this xSPI master transmits a xSPI frame with the selected size while the sequential address is incremental^{*1}. When one of the below conditions is detected, even though not reaching to the target size (BMCFGCHn.MWRSIZE[7:0]), this xSPI master transmits the pending data into xSPI bus.

- Non-incremental address is detected.
- Different burst type is detected.

- Read transaction is detected.
- Access for different slave is detected.
- Memory Write Data Push bit (BMCTL1.MWRPUSHCHn (n = 0)) is set.

This function could be useful for any slave device to request a chunk of data at a time. In the case, system bus master shall continue to provide the fixed data size with incremental address. e.g. there is any device to request to write in page unit.

Figure 37.14 shows the operation when enable the combination function.

Figure 37.14 Combination function

Note 1. The access which comply all below condition is considered as incremental address.

- Transaction type is INCR.
- The access's start address is continuous to the previous last write address.
 - The access's start position of WSTRB is treated as start address.
 - Previous access's last WSTRB is treated last write address.

Figure 37.15 shows data combined example with AXI access.

Figure 37.15 Data combined example with AXI access

37.3.3.4 Read Access Operation

At the read access for memory area, soon after detected the read access, this xSPI Master issues a read transaction into xSPI slave. Figure 37.16 shows the operation summary.

Figure 37.16 Read access for memory area

The operation of xSPI bus changes depending on burst type. When the type is single or increment type, one system bus's read transaction triggers one xSPI frame. When the type is wrap type and the CMCFG0CSn.WPBSTMD is 0, one system bus read transactions triggers two xSPI frames. Figure 37.17 shows the relationship between AXI and xSPI frames.

Figure 37.17 xSPI frame format in read access (Normal format)

37.3.3.5 Prefetch Function

At the read access for memory area from system bus, this xSPI Master has the function to prefetch the read data for reducing the latency. When enabled this function (BMCFGCHn.PREEN = 1), this xSPI Master continues to read the

incremental address and store the read data from xSPI slave in internal prefetch buffer. And this xSPI master searches in prefetch buffer for the following read access from system bus. If found the target read data in prefetch buffer, this xSPI Master returns the data from prefetch buffer. If not found, this xSPI Master clears prefetch buffer and newly issues a read transaction into xSPI slave. This function is effective in application such as the consecutive read addresses are close. But it is not effective in application such as the consecutive read addresses are not incremental because xSPI read frame for prefetch uses xSPI bus. Figure 37.18 shows the operation summary.

Figure 37.18 Read access for memory area with prefetch enabled

Note: When enabled this prefetch function, Bus Master could read from not a slave device but the internal prefetch buffer. When accessed to the same address from multiple Bus Masters, this xSPI Master does not guarantee to read the latest data. If Bus Master wish to read the latest data from a slave device, it should read after cleared the prefetch buffer (BMCTL1.PBUFCLRCHn ($n = 0$)).

Note: Prefetch buffer is implemented as FIFO-based, and when read access is issued, the data before the access address is discarded from the buffer. And when next access is issued to the region which is discarded at previous access, this module issues the xSPI read access again to fill the prefetch buffer.

Note: OSPI has the 1line buffer which keeps the last 8Byte read data from prefetch buffer. When read access is issued to the same address to the data in 1line buffer, OSPI returns read data from 1line buffer.

37.3.3.6 XiP Mode

Some slave devices have a mode (XiP mode) in which the command phase is not required for lower latency. While in this mode, the xSPI master skips sending the command and the slave device implicitly performs the command that was executed in the previous transaction. When enabled XiP mode bit (CMCTLCHn.XIPEN = 1), this xSPI master inserts XiP enter code (CMCTLCHn.XIPEXCODE[7:0]) in latency field. When disabled XiP mode bit (CMCTLCHn.XIPEN = 0), this xSPI master inserts XiP exit code (CMCTLCHn.XIPEXCODE[7:0]) in latency field. This function is available only for memory-mapping mode.

And when this xSPI master transmits XiP disable pattern, this master clears XiP mode bit and disables XiP mode configured for both channels. Note that it is not possible to disable XiP mode for only one channel by transmitting XiP disable pattern.

Note: When enough latency cycle does not exist for XiP code, this xSPI Master could not insert XiP code.

Note: XiP mode could be used only for unidirectional access to a slave. The write transaction and read transaction should be separated.

Note: The XiP exit code is inserted once when disabled. More details, See Figure 37.30.

37.3.4 Pattern Control

This xSPI Master has the function to transmit 3 type of patterns which is not xSPI frame format. The pattern is triggered by setting trigger bit (LPCTL0-1.PATREQ).

37.3.4.1 XiP Disable Pattern

XiP Disable pattern transmits any pattern with the configured length and value (LPCTL0.XD1LEN[4:0] / XD1VAL / XD2LEN[4:0] / XD2VAL). It uses OM_SCLK, OM_SIO7-0 signals. The number of output pin can be configured by XiP Disable pattern pin bits (LPCTL0.XDPIN[1:0]). It may be used to disable XiP mode for legacy SPI. Figure 37.19 shows the timing-chart.

Figure 37.19 XiP Disable pattern

37.3.4.2 Reset Pattern

Reset pattern transmits the pattern specified in Serial Flash Reset Signaling Protocol. Figure 37.20 shows the timing chart.

CS Low/High width is configured with Reset Pattern Length bits (LPCTL1.RSTWID[2:0]). xSPI slave will sample the data input at the rising edge of CS. Setup time for data output is configured with Reset pattern data output setup time bits (LPCTL1.RSTSU[2:0]). The setup time should be less than Reset pattern width always.

Figure 37.20 Reset pattern

Note: In the protocol, CS Low/High width is defined as minimum 500 ns and Setup time is defined as minimum 6 ns.

37.3.4.3 CS Only Pattern

CS Only pattern activates CS port with the configured length bits (LPCTL1.RSTWID[2:0]). It may be used to resume from Deep Power Down state. Figure 37.21 shows the timing-chart.

**Figure 37.21 CS Only pattern**

37.3.5 Integrity Checking

This xSPI Master can detect some errors. [Table 37.8](#) shows the error list and the detail behavior.

Table 37.8 Error list (n = 0, 1)

Error type	Event	Flag bit	Note (action)
Calibration failed	When the read data did not match the expected value during automatic calibration.	INTS.CAFAILCSn	It results in writing unexpected data to xSPI slave.
System bus error	When an error response occurred on AXI slave interface for memory-mapping.	INTS.BUSERRCHn	This xSPI master shall be reset for fatal error.
ECC error detection	When detected the falling edge on OM_ECSINT1 port. It can be useful only for xSPI slave with ECC detection function.	INTS.ECSCS1	Only notify the error event of xSPI slave.
OM_DQS timeout	When OM_DQS does not toggle in read transaction with using OM_DQS.	INTS.DSTOCSn	If this error occurs during calibration, clear the interrupt status bit. Other than above, both xSPI master and xSPI slave should be reset for fatal error.
Periodic transaction timeout	When the read value does not match with the expected value in periodic manual-command mode.	INTS.PERTO	Depending on the status of function.

37.3.6 Interrupts

This xSPI Master has an interrupt port.

It can monitor with Interrupt Status Register (INTS). In case of initialization phase, it can be programmable with Interrupt Enable register (INTE). [Table 37.9](#) shows OSPI interrupt sources, and [Table 37.10](#) shows the related register bit.

Note: Interrupt pulse port signal is not asserted when the corresponding bit of INTE is set after the interrupt event is detected.

Table 37.9 OSPI interrupt sources

Name	Interrupt sources	DMAC activation
OSPI0_ERR	Error	Not possible
OSPI0_CMP	Complete	Not possible

Table 37.10 Interrupt register bit

Flag bit	Enable bit	Clear bit	Interrupt sources
CASUCCS1	CASUCCS1E	CASUCCS1C	OSPI0_CMP
CASUCCS0	CASUCCS0E	CASUCCS0C	
CAFAILCS1	CAFAILCS1E	CAFAILCS1C	OSPI0_ERR
CAFAILCS0	CAFAILCS0E	CAFAILCS0C	
BUSERRCH0	BUSERRCH0E	BUSERRCH0C	OSPI0_ERR
INTCS1	INTCS1E	INTCS1C	OSPI0_ERR
ECSCS1	ECSCS1E	ECSCS1C	OSPI0_ERR
DSTOCS1	DSTOCS1E	DSTOCS1C	OSPI0_ERR
DSTOCS0	DSTOCS0E	DSTOCS0C	
PERTO	PERTOE	PERTOC	OSPI0_ERR
PATCMP	PATCMPE	PATCMPC	OSPI0_CMP
CMDCMP	CMDCMPE	CMDCMPC	OSPI0_CMP

37.3.7 Flows of Operations

37.3.7.1 Flow of Configuration

Figure 37.22 shows flow of configuration.

**Figure 37.22** Flow of configuration

37.3.7.2 Flow of Communication Stop

Figure 37.23 shows flow of communication stop.

Figure 37.23 Flow of communication stop

Note: In case of re-config of any configuration register, all communication with xSPI slave shall be stopped surely to avoid race condition between register setting and memory access. It means that the automatic calibration is disabled, and there is no pending manual-command and memory-mapping access.

37.3.7.3 Flow of Automatic Calibration

Figure 37.24 shows flow of automatic calibration.

Figure 37.31 shows example flow of read while write.

Figure 37.31 Flow of read while write

37.4 Usage Notes

37.4.1 Constraint on Memory Access

The memory access has the following constraints:

- Not using prefetch function if application access to the last 128 byte area

37.4.2 Constraint on Burst Length

AXI bus master must have a Burst Length of 16 or less.

37.4.3 Memory Write Combination Mode

When BMCFGCHn.MWRComb is 1, memory write combination mode is enabled. However, combination does not work if the bus master is CPU, and OSPI data is under 32bit. [Table 37.11](#) shows the possibility of data write for each bus master.

Table 37.11 Data write possibility for each bus master

Bus Master	Combination Enable	Combination Disable
CPU under 64 bit Access	Not possible	Possible
CPU 64 bit Access	Possible	Possible
DMAC/DTC	Possible	Possible
EDMAC	Possible	Possible
CEU	Possible	Possible

37.4.4 Module-stop function

OSPI operation can be disabled or enabled using Module Stop Control Register B (MSTPCRB). The OSPI module is initially stopped after reset. Releasing the module-stop state enables access to the registers. For details, see [section 10, Low Power Modes](#).

37.4.5 Restriction in 8D-8D-8D profile 1.0 format

"When read or write access to the Octal Serial Peripheral Interface (OSPI) is performed from the following bus masters with 8-bit wide, access to odd addresses is prohibited as it will not be worked correctly. See [Table 37.12](#) for the applicable conditions and their workarounds for each bus master"

Table 37.12 Workaround for the restriction in 8D-8D-8D profile 1.0 format

Bus master		Conditions that require workaround	Workaround
CPU	Normal memory	Debugger is connected	Access only even addresses.
	Device memory	Always	Access only even addresses.
DMAC/DTC	DMAC	DMTMD.SZ[1:0] = 00b	Access only even addresses.
	DTC	MRA.SZ[1:0] = 00b	Access only even addresses.

37.4.6 Byte data order in 8pin-DDR mode

In 8pin-DDR mode, OSPI read and write data in the order of byte0 at rising edge and byte1 at falling edge.

Some memory devices read and write in the swapped order in 8pin-DDR mode. For these devices, if 8pin-DDR read the data which is written in other than 8pin-DDR mode, this data should be written in swapped order.

38. Decryption On The Fly (DOTF)

38.1 Overview

DOTF has a function to decode read data of the AXI bus using AES core.

[Table 38.1](#) lists the DOTF specifications and for a system using DOTF, see [section 37.1. Overview](#).

Table 38.1 DOTF Specification

Item	Description
Clock Source	Register clock : PCLKB AES core clock : PCLKA
AES core function	- Utilize for on-the-fly decryption of encrypted software stored in external memory. - Block size: 128-bit - Key size: 128-bit, 192-bit, 256-bit - Support the following block cipher mode. - Counter (CTR) mode following NIST SP800-38A - Support side channel countermeasure function. - Supports self-test function. - Counter[127:0] = {IV[127:28], Address[31:4]}, where Address is the memory mapped address of the encrypted data, aligned to the AES block size of 128 bits (16 bytes). The IV shall be chosen according to the recommendations provided in appendix B of SP800-38A. See section 37, Octal Serial Peripheral Interface (OSPI) and section 4.1. Address Space for details. See NIST SP800-38A for details of AES counter mode operation.
Tamper Resistance	Countermeasures available for side-channel attacks, including SPA/DPA and timing attacks
Module-stop function	Module-stop state can be set to reduce power consumption. same as OSPI module stop
TrustZone Filter	Security and Privilege attribution can be set for each channel. same as TZF of OSPI

38.2 Block Diagram

The block diagram of DOTF is shown in [Figure 38.1](#). See [Figure 37.1](#) for a diagram including the OSPI.

Figure 38.1 Block diagram

38.3 Register Descriptions

DOTF allows the entire area to be an accessible area, but the area where decryption processing is performed can be specified as the entire area or one contiguous area. The region can be specified by setting the start and end addresses to the CONVAREAST and CONAREAED registers, respectively.

Figure 38.2 Image of decryption area setting

38.3.1 CONVAREAST : DOTF Conversion Area Start Address Register

Base address: DOTF0 = 0x4026_8800
DOTF0_NS = 0x5026_8800

Offset address: 0x00

Value after reset: 0 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1

Bit	Symbol	Function	R/W
11:0	—	These bits are read as 1.	R/W
31:12	CONVAREAST [31:12]	The first address of the decryption processing area. The actual address is CONVAREAST [31:12] × 0x1000.	R/W

Note: S-TYPE-3, P-TYPE-3

Specify the first address of the decryption processing area. Set before the AXI transfer request and do not make any further changes. Setting CONVAREAST[31:12] > CONVAREAED[31:12] is prohibited.

38.3.2 CONVAREAD : DOTF Conversion Area End Address Register

Base address: DOTF0 = 0x4026_8800
DOTF0_NS = 0x5026_8800

Offset address: 0x04

Value after reset: 0

Bit	Symbol	Function	R/W
11:0	—	These bits are read as 0.	R/W
31:12	CONVAREAED [31:12]	The end address of the decryption processing area. The actual address is (CONVAREAED [31:12] + 1) × 0x1000 - 1.	R/W

Note: S-TYPE-3, P-TYPE-3

Note: Setting CONVAREAST[31:12] > CONVAREAED[31:12] is prohibited.

Specify the tail address of the decryption processing area. Set before the AXI transfer request and do not make any further changes. Setting CONVAREAST[31:12] > CONVAREAED[31:12] is prohibited.

38.4 Operation

DOTF has one AXI Read Slave Interface and one AXI Read Master Interface.

An AXI transfer request received on the AXI Slave Address channel is issued to the AXI Master's Read Address channel, and the Slave data is received from the Master's AXI Read data channel and sent to the AXI Slave Read data channel.

At this time, the necessity of decryption is determined by the requested address area, and the decrypted data is transmitted through AES core if necessary. When decryption is not required, the received response is sent without conversion.

38.5 System flow

The initialization flow after HW reset is shown in [Figure 38.3](#).

Figure 38.3 Initialization flow

38.6 Usage notes

38.6.1 Module-stop function

DOTF operation can be disabled or enabled using Module Stop Control Register B (MSTPCRB). The DOTF module is initially stopped after reset. Releasing the module-stop state enables access to the registers. For details, see [section 10, Low Power Modes](#).

39. Serial Sound Interface Enhanced (SSIE)

39.1 Overview

The Serial Sound Interface Enhanced (SSIE) can transmit and receive audio data to and from various devices that support any of audio data formats, such as I²S, monaural, and TDM.

Table 39.1 lists the SSIE specifications, Figure 39.3, Figure 39.4 and Figure 39.5 show a block diagram of SSIE, and Table 39.4 lists the I/O pins.

Table 39.1 SSIE specifications

Item		Description
Number of channels		Two channels, SSIE0 and SSIE1
Communication mode		- Master/slave - Transmission/reception (SSIE0:full duplex communication, SSIE1:half-duplex communication)
Communication format		- I²S format - Monaural format - TDM format
Serial data		- MSB first - Data can be left-justified or right-justified. - Data delay (1 clock cycle) or no delay selectable for the period from SSILRCKn/SSIFS_n (n = 0, 1) to SSITXD0/SSIRXD0/SSIDATA1 - System word length: 8, 16, 24, 32, 48, 64, 128, or 256 bits - Data word length: 8, 16, 18, 20, 22, 24, or 32 bits - Padding polarity: Low or high
Bit clock (SSIBCK _n (n = 0, 1))	In master mode	- Two clock sources available (AUDIO_CLK/GPT output (GTIOC2A)) - Clock source division ratio: 1/1, 1/2, 1/4, 1/6, 1/8, 1/12, 1/16, 1/24, 1/32, 1/48, 1/64, 1/96, and 1/128. - Supply/stop is selectable while communication is halted.
	In master/slave mode	Polarity (rising edge or falling edge) selectable
LR clock/frame synchronization (SSILRCK _n /SSIFS _n (n = 0, 1))	In master mode	- Polarity (low level or high level) selectable - Supply/stop is selectable while communication is halted.
Transmit data (SSITXD0/SSIDATA1) and receive data (SSIRXD0/SSIDATA1)	Transmission	Muting method (transmission of transmit FIFO data or transmission of data fixed to 0) selectable
FIFO	Capacity	Transmit FIFO/receive FIFO: 4 bytes × 32 stages
	Data alignment	Data alignment method (left-justification or right-justification) selectable for the data transfer between FIFO and shift register
Interrupt	Interrupt output	- Communication error/idle mode - Receive data full - Transmit data empty
Low power consumption function		Whether to supply the audio clock selectable in master mode
Module stop function		Module stop state can be set for each channels to reduce power consumption.
TrustZone Filter		Security and Privilege attribution can be set for each channels.

The following table lists and defines the terms used for the communication formats SSIE can use:

Table 39.2 Definition of terms (1 of 2)

Term	Definition
Start trigger	First edge of the signal on the SSILRCK _n /SSIFS _n (n = 0, 1) pin when the signal is set to the value specified in LRCKP to enable communication

Table 39.2 Definition of terms (2 of 2)

Term	Definition
Frame boundary	Point where SSIE starts transferring the first data of a frame or the point where SSIE ends transferring the last data of the frame
Frame word number	Number of sound channels per frame
System word length	Number of bits per channel
Data word length	Number of significant bits per channel
Control bits for communication formats	- SSICR register: FRM, DWL, SWL, LRCKP, SPDP, SDTA, PDTA, and DEL bits - SSIFCR register: BSW bit - SSIOFR register: OMOD bit - SSISCR register: TDES[4:0] and RDFS[4:0] bits

**Figure 39.1** Definition of communication format

Figure 39.2 and Figure 39.3 shows a block diagram of SSIE.

Figure 39.2 SSIE block diagram (SSIE0)

Figure 39.3 SSIE block diagram (SSIE1)

Figure 39.4 shows the clock configuration of SSIE.

Figure 39.4 SSIE clock configuration

The AUDIO_CLK can be input according to the security attribution of Port and SSIE and SSICR.CKS bit setting as shown in the [Table 39.3](#).

Table 39.3 The input condition of AUDIO_CLK by the security setting

PORT Security Attribution (PmSAR (m = 0 - 9, A, B))	SSIE0 Security Attribution (PSARm (B - E))	SSIE0's SSICR.CKS	SSIE1 Security Attribution (PSARm (B - E))	SSIE1's SSICR.CKS	AUDIO_CLK pin input
0 (secure)	0 (secure)	0 (AUDIO_CLK)	Don't care		AUDIO_CLK input enable
	Don't care		0 (secure)	0 (AUDIO_CLK)	
1 (non-secure)	1 (non-secure)	Don't care	0 (secure)	1 (GTIOC2A)	
			1 (non-secure)	Don't care	
	0 (secure)	1 (GTIOC2A)	1 (non-secure)	Don't care	
	1 (non-secure)	Don't care			
other than above					AUDIO_CLK input disable

[Table 39.4](#) lists the I/O pins.

Table 39.4 SSIE I/O pins

Channel	Pin name	I/O	Function
Common	SSIBCKn	Input	Serial bit clock pins
	AUDIO_CLK	Input	External clock pin for audio (input oversampling clock)
	SSILRCKn/SSIFSn	Output	LR clock/frame synchronization pins
SSIE0	SSIRXD0	Input	Serial data input pin
	SSITXD0	Output	Serial data output pin
SSIE1	SSIDATA1	I/O	Serial data input/output pin

Note: $n = 0, 1$

39.2 Register Descriptions

39.2.1 SSICR : Control Register

Base address: $SSIE_n = 0x4025_D000 + 0x0100 \times n$ ($n = 0, 1$)
 $SSIE_NS = 0x5025_D000 + 0x0100 \times n$ ($n = 0, 1$)

Offset address: 0x00

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	CKS	TUIEN	TOIEN	RUIEN	ROIEN	IIEN	—	FRM[1:0]	DWL[2:0]			SWL[2:0]			
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	MST	BCKP	LRCK P	SPDP	SDTA	PDTA	DEL	CKDV[3:0]				MUEN	—	TEN	REN
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	REN	Reception Enable*2 0: Disables reception 1: Enables reception (starts reception)	R/W
1	TEN	Transmission Enable*2 0: Disables transmission 1: Enables transmission (starts transmission)	R/W
2	—	This bit is read as 0. The write value should be 0.	R/W
3	MUEN	Mute Enable 0: Disables muting on the next frame boundary 1: Enables muting on the next frame boundary	R/W
7:4	CKDV[3:0]	Selects Bit Clock Division Ratio*1 0x0: AUDIO_MCK 0x1: AUDIO_MCK/2 0x2: AUDIO_MCK/4 0x3: AUDIO_MCK/8 0x4: AUDIO_MCK/16 0x5: AUDIO_MCK/32 0x6: AUDIO_MCK/64 0x7: AUDIO_MCK/128 0x8: AUDIO_MCK/6 0x9: AUDIO_MCK/12 0xA: AUDIO_MCK/24 0xB: AUDIO_MCK/48 0xC: AUDIO_MCK/96 Others: Setting prohibited	R/W
8	DEL	Selects Serial Data Delay*1 In the monaural format, this bit controls the waveform of SSILRCKn/SSIFS _n ($n = 0, 1$). For details, see section 39.3.2. Monaural Format . 0: Delay of 1 cycle of SSIBCK _n ($n = 0, 1$) between SSILRCKn/SSIFS _n ($n = 0, 1$) and SSITXD0/SSIRXD0/SSIDATA1 1: No delay between SSILRCKn/SSIFS _n ($n = 0, 1$) and SSITXD0/SSIRXD0/SSIDATA1	R/W
9	PDTA	Selects Placement Data Alignment*1 0: Left-justifies placement data (SSIFTDR, SSIFRDR) 1: Right-justifies placement data (SSIFTDR, SSIFRDR)	R/W
10	SDTA	Selects Serial Data Alignment*1 0: Transmits and receives serial data first and then padding bits 1: Transmit and receives padding bits first and then serial data	R/W

Bit	Symbol	Function	R/W																				
11	SPDP	Selects Serial Padding Polarity ^{*1} 0: Padding data is at a low level 1: Padding data is at a high level	R/W																				
12	LRCKP	Selects the Initial Value and Polarity of LR Clock/Frame Synchronization Signal ^{*1} 0: The initial value is at a high level. The start trigger for a frame is synchronized with a falling edge of SSILRCKn/SSIFS _n (n = 0, 1). 1: The initial value is at a low level. The start trigger for a frame is synchronized with a rising edge of SSILRCKn/SSIFS _n (n = 0, 1).	R/W																				
13	BCKP	Selects Bit Clock Polarity ^{*1} 0: SSILRCKn/SSIFS _n (n = 0, 1) and SSITXD0/SSIRXD0/SSIDATA1 change at a falling edge (SSILRCKn/SSIFS _n (n = 0, 1) and SSIRXD0/SSIDATA1 are sampled at a rising edge of SSIBCKn (n = 0, 1)). 1: SSILRCKn/SSIFS _n (n = 0, 1) and SSITXD0/SSIRXD0/SSIDATA1 change at a rising edge (SSILRCKn/SSIFS _n (n = 0, 1) and SSIRXD0/SSIDATA1 are sampled at a falling edge of SSIBCKn (n = 0, 1)).	R/W																				
14	MST	Master Enable ^{*1} 0: Slave-mode communication 1: Master-mode communication	R/W																				
15	—	This bit is read as 0. The write value should be 0.	R/W

28	TOIEN	Transmit Overflow Interrupt Output Enable 0: Disables transmit overflow interrupt output 1: Enables transmit overflow interrupt output	R/W
29	TUIEN	Transmit Underflow Interrupt Output Enable 0: Disables transmit underflow interrupt output 1: Enables transmit underflow interrupt output	R/W
30	CKS	Selects an Audio Clock for Master-mode Communication*1 0: Selects the AUDIO_CLK input 1: Selects the GTIOC2A (GPT output)	R/W
31	—	This bit is read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

Note 1. Writing to these bits while SSIE is in a communication state (SSISR.IIRQ = 0) is prohibited. If the value of these bits is changed by rewriting, subsequent operation is unpredictable.

Note 2. If the TEN bit or REN bit is rewritten, make sure that the SSISR.IIRQ bit is in the desired status. If the value of the TEN or REN bit is changed by rewriting, subsequent operation is unpredictable. For example, when transmission or reception is enabled, check that SSISR.IIRQ is 0; when transmission or reception is disabled, check that SSISR.IIRQ is 1.

With this register, select an audio clock, control interrupt requests, select data formats, and set an operation mode.

TEN and REN bits (Transmission and Reception Enable)

The TEN and REN bits enable/disable transmission and reception. When 1 is written to one of these bits, the corresponding communication operation starts in synchronization with a start trigger by the SSILRCKn/SSIFS_n (n = 0, 1) signal. For details, see [section 39.6.2. Transmission](#) to [section 39.6.4. Transmission and Reception](#). When 0 is written to this bit, the current communication operation stops at the next frame boundary. To use SSIE for both transmission and reception, always write 1 to these bits together. When stopping the communication using SSIE, always disable both transmission and reception (write 0 to the TEN and REN bits).

If you want to stop SSIE before a frame boundary is reached, perform a software reset procedure.

MUEN bit (Mute Enable)

The MUEN bit sets/clears the mute function for the data output from the SSITXD0/SSIDATA1 pin. When this bit is set to 1 in the middle of a frame, the SSITXD0/SSIDATA1 output changes to 0 at the next frame boundary. When this bit is set to 0 in the middle of a frame, the SSITXD0/SSIDATA1 output changes to the data of transmit FIFO data register at the next frame boundary. Note that this bit controls data only. Status flags and interrupt signals are normally generated.

Changing the value of this bit must be performed only after setting the communication format to be used.

Figure 39.5 Transmit data with the mute function set

CKDV[3:0] bits (Selects Bit Clock Division Ratio)

The CKDV[3:0] bits set the division ratio of the bit clock based on AUDIO_MCK in master-mode communication (MST=1). In slave-mode communication (MST=0), setting of these bits are invalid.

Writing to this bit must be performed when the supply of AUDIO_MCK is stopped. For details about the timing, see the detailed description of the AUCKE bit in [section 39.2.3. SSIFCR : FIFO Control Register](#).

Figure 39.6 Sampling frequencies in master-mode communication

DEL bit (Selects Serial Data Delay)

The DEL bit sets whether or not there will be a delay between SSILRCKn/SSIFSn ($n = 0, 1$) and SSITXD0/SSIRXD0/SSIDATA1.

For the I²S or TDM format, set the DEL bit to 0. When the monaural format is used, setting of this bit changes the high period width of SSILRCKn/SSIFSn ($n = 0, 1$). For details, see [section 39.3.2. Monaural Format](#). When using a compatible communication format, specify a setting of this bit that enables communication.

Figure 39.7 Setting of delay in serial data

PDTA bit (Selects Placement Data Alignment)

The PDTA bit sets how to align placement data. With the setting of data word length as 32 bits (SSICR.DWL[2:0] = 110b), this bit is invalid.

At transmission, see [Figure 39.8](#).

First transmission data			Second transmission data			Third transmission data			Fourth transmission data			
DWL[2:0]	SSIFTDR						Transmission shift register					
	PDTA = 0 (left-justify)			PDTA = 1 (right-justify)

111 (Setting prohibited)			

Figure 39.9 Alignment of placement data at reception

SDТА bit (Selects Serial Data Delay)

The SDТА bit sets how to align serial data and padding bits. For communication without padding bits, this bit is invalid.

Figure 39.10 Alignment setting of serial data with padding bits

SPDP bit (Selects Serial Padding Polarity)

The SPDP bit sets polarity of padding bits.

Figure 39.11 Padding bit polarity

LRCKP bit (Selects the Initial Value and Polarity of LR Clock/Frame Synchronization Signal)

The LRCKP bit sets the initial value and polarity of SSILRCKn/SSIFS_n ($n = 0, 1$). Set this bit according to the communication format to be used in SSIE. See [Table 39.5](#) Initial output value and polarity of SSILRCKn/SSIFS_n ($n = 0, 1$) pin. For the slave-mode communication (MST = 0), only the start trigger is used.

Writing to these bits must be performed when the LR clock supply to the SSILRCKn/SSIFS_n ($n = 0, 1$) pin is stopped. For details about the output of LR clock, see the detailed description of the LRCONT bit in [section 39.2.7. SSIOFR : Audio Format Register](#).

Table 39.5 Initial output value and polarity of SSILRCKn/SSIFS_n ($n = 0, 1$) pin

Communication Format	Expected Initial State	Setting Value of LRCKP
I ² S	High	0
Monaural	Low	1
TDM	Low	1

Note: When the format to be used is compatible with the I²S, monaural, or TDM format, specify settings to enable communication with the respective formats.

**Figure 39.12 LR clock/frame synchronization polarity setting****BCKP bit (Selects Bit Clock Polarity)**

The BCKP bit sets the bit clock polarity.

Writing to this bit must be performed when the supply of AUDIO_MCK is stopped. For details about the timing, see the detailed description of the AUCKE bit in [section 39.2.3. SSIFCR : FIFO Control Register](#).

Table 39.6 Bit clock polarity

Communication	Master/Slave	Timing	BCKP = 0	BCKP = 1
Reception	Slave	At SSILRCKn/SSIFS _n (n = 0, 1) sampling	SSIBCK _n (n = 0, 1) rising edge	SSIBCK _n (n = 0, 1) falling edge
	Master/slave	At SSIRXD0/SSIDATA1 sampling	SSIBCK _n (n = 0, 1) rising edge	SSIBCK _n (n = 0, 1) falling edge
Transmission	Master	At change of SSILRCKn/SSIFS _n (n = 0, 1) output	SSIBCK _n (n = 0, 1) falling edge	SSIBCK _n (n = 0, 1) rising edge
	Master/slave	At change of SSITXD0/SSIDATA1 output	SSIBCK _n (n = 0, 1) falling edge	SSIBCK _n (n = 0, 1) rising edge

MST bit (Master Enable)

The MST bit sets master-/slave-mode communication.

Writing to this bit must be performed when the supply of AUDIO_MCK is stopped. For details about the timing, see the detailed description of the AUCKE bit in [section 39.2.3. SSIFCR : FIFO Control Register](#).

SWL[2:0] bits (Selects System Word Length)

The SWL[2:0] bits set the number of bits in one system word. Padding bits are sent and received in relation with one data word set with DWL[2:0]. See [Table 39.13](#) for details.

Writing to these bits must be performed when the LR clock supply to the SSILRCKn/SSIFS_n (n = 0, 1) pin is stopped. For details about the output of LR clock, see the detailed description of the LRCONT bit in [section 39.2.7. SSIOFR : Audio Format Register](#).

DWL[2:0] bits (Selects Data Word Length)

The DWL[2:0] bits set the number of bits in one data word. The data word length (number of bits per data word) must not exceed the system word length (number of bits per system word). For details, see [Table 39.13](#).

FRM[1:0] bits (Selects Frame Word Number)

The FRM[1:0] bits set the frame word number in individual communication formats.

Writing to these bits must be performed when the LR clock supply to the SSILRCKn/SSIFS_n (n = 0, 1) pin is stopped. For details about the output of LR clock, see the detailed description of the LRCONT bit in [section 39.2.7. SSIOFR : Audio Format Register](#).

**Figure 39.13 Frame word number****IEN bit (Idle Mode Interrupt Output Enable)**

The IEN bit enables/disables output of idle mode interrupts. By enabling this bit (set it to 1), an interrupt is output at a rising edge of SSISR.IIRQ = 1. An interrupt is also output when this bit is changed from 0 to 1 while SSISR.IIRQ = 1.

ROIEN bit (Receive Overflow Interrupt Output Enable)

The ROIEN bit enables/disables output of receive overflow interrupts. By enabling this bit (set it to 1), an interrupt is output at a rising edge of SSISR.ROIRQ = 1. An interrupt is also output when this bit is changed from 0 to 1 while SSISR.ROIRQ = 1.

RUIEN bit (Receive Underflow Interrupt Output Enable)

The RUIEN bit enables/disables output of receive underflow interrupts. By enabling this bit (set it to 1), an interrupt is output at a rising edge of SSISR.RUIRQ = 1. An interrupt is also output when this bit is changed from 0 to 1 while SSISR.RUIRQ = 1.

TOIEN bit (Transmit Overflow Interrupt Output Enable)

The TOIEN bit enables/disables output of transmit overflow interrupts. By enabling this bit (set it to 1), an interrupt is output at a rising edge of SSISR.TOIRQ = 1. An interrupt is also output when this bit is changed from 0 to 1 while SSISR.TOIRQ = 1.

TUIEN bit (Transmit Underflow Interrupt Output Enable)

The TUIEN bit enables/disables output of transmit underflow interrupts. By enabling this bit (set it to 1), an interrupt is output at a rising edge of SSISR.TUIRQ = 1. An interrupt is also output when this bit is changed from 0 to 1 while SSISR.TUIRQ = 1.

CKS bit (Selects an Audio Clock for Master-mode Communication)

The CKS bit sets the audio clock in master-mode communication (MST = 1). In slave-mode communication (MST = 0), setting of this bit is invalid.

Writing to this bit must be performed when the supply of AUDIO_MCK is stopped. For details about the timing, see the detailed description of the AUCKE bit in [section 39.2.3. SSIFCR : FIFO Control Register](#).

39.2.2 SSISR : Status Register

Base address: SSIE_n = 0x4025_D000 + 0x0100 × n (n = 0, 1)
SSIE_n_NS = 0x5025_D000 + 0x0100 × n (n = 0, 1)

Offset address: 0x04

31:30	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

This register is configured with status flags that indicate SSIE operational state.

IIRQ flag (Idle Mode Status Flag)

The IIRQ flag is a status flag that indicates the idle state. It indicates whether SSIE is in the idle state or communication state.

For details, see [Figure 39.14](#) and [Figure 39.15](#).

Figure 39.14 IIRQ setting timing (transmission)

- Transmitter (dedicated to transmission)

[Clearing condition]

While transmission was enabled (SSICR.TEN = 1 and SSICR.REN = 0), the transmit data for a transmission frame was written to the SSIFTDR register, and a start trigger was generated by the SSILRCKn/SSIFS_n (n = 0, 1) signal.

[Clearing timing]

1 SSIBCK_n (n = 0, 1) cycle + 2 PCLKB cycles after generation of the start trigger that is the clearing condition.

[Setting condition]

While transmission and reception were disabled (SSICR.TEN = 0 and SSICR.REN = 0), transmission of one frame was complete.

[Setting timing]

Two PCLKB cycles after the end of transmission (at a frame boundary) that is the setting condition.

Figure 39.15 IIRQ setting timing (reception)

- Receiver (dedicated to reception)

[Clearing condition]

While reception was enabled (SSICR.TEN = 0 and SSICR.REN = 1, a start trigger was generated by the SSILRCKn/SSIFSs (n = 0, 1) signal.

[Clearing timing]

1 SSIBCKn (n = 0, 1) cycle + 2 PCLKB cycles after generation of the start trigger that is the clearing condition.

[Setting condition]

While transmission and reception were disabled (SSICR.TEN = 0 and SSICR.REN = 0), reception of one frame was complete.

[Setting timing]

Two PCLKB cycles after the end of reception (at a frame boundary) that is the setting condition.

- Transceiver (transmission and reception)

[Clearing condition]

While transmission and reception were enabled (SSICR.TEN = 1 and SSICR.REN = 1), the transmit data for a transmission frame was written to the SSIFTDR register, and a start trigger is generated by the SSILRCKn/SSIFSs (n = 0, 1) signal.

[Clearing timing]

1 SSIBCKn (n = 0, 1) cycle + 2 PCLKB cycles after generation of the start trigger that is the clearing condition.

[Setting condition]

While transmission and reception were disabled (SSICR.TEN = 0 and SSICR.REN = 0), transmission of one frame was complete.

[Setting timing]

Two PCLKB cycles after the end of transmission (at a frame boundary) that is the setting condition.

ROIRQ flag (Receive Overflow Error Status Flag)

The ROIRQ flag is a status flag that indicates a receive overflow error. This flag is set by automatic determination but it must be cleared by register access. This flag indicates that received data is supplied at a higher rate than requested. Data is not transferred from the receive shift register to SSIFRDR where a receive overflow error is generated. For the procedure to recover from the overflow error, see [section 39.6.6. Error Handling](#). This flag is not cleared by a receive FIFO data register reset (SSIFCR.RFRST).

[Priority order for setting and clearing]

Setting is prioritized.*1

[Clearing condition]

When either of the following operations is done:

1. Writing 0 to this bit after reading 1 from this bit*2
2. Enabling communication (changing SSICR.REN from 0 to 1).

[Clearing timing]

Clearing timing corresponding to the above clearing condition:

1. When 0 is written to this bit after reading 1 from this bit (same as the timing in [Figure 39.19](#))
2. One PCLKB cycle after writing 1 to SSICR.REN.*3

[Setting condition]

At completion of receiving new data while SSIFRDR is full.

[Setting timing]

Three cycles of PCLKB after reception is completed.

Note 1. This bit is cleared by a software reset (SSIFCR.SSIRST = 1). The software reset has priority over all the clearing conditions described above.

Note 2. After reading 1 from this bit, this bit is cleared when one of the following three conditions is met:

- A software reset (SSIFCR.SSIRST = 1) is done.
- After 1 has been read, writing of 0 is complete.
- One PCLKB cycle passes after 1 has been written to SSICR.REN.

Note 3. After communication is enabled (by changing the value of SSICR.REN bit from 0 to 1), the reception error flags (RUIRQ and ROIRQ in the SSISR register) are cleared. If, however, the SSISR register is read continuously, the cleared status of the reception error flags might be unable to be read.

Figure 39.16 ROIRQ setting timing

RUIRQ flag (Receive Underflow Error Status Flag)

The RUIRQ flag is a status flag that indicates a receive underflow error. This flag is set by automatic determination but it must be cleared by register access. This flag indicates that SSIFRDR is read while it is empty. Data read from SSIFRDR where a receive underflow error is generated is invalid. See [section 39.6.6. Error Handling](#) for the error recovery procedure. This flag is not cleared by a receive FIFO data register reset (SSIFCR.RFRST). Note, however, that this flag is not set even if the SSIFRDR register is read while the receive FIFO data register is reset (by setting SSIFCR.RFRST to 1).

[Priority order for setting and clearing]

Setting is prioritized.*1

[Clearing condition]

When either of the following operations is done:

1. Writing 0 to this bit after reading 1 from this bit*2
2. Enabling communication (changing SSICR.REN from 0 to 1).

[Clearing timing]

Clearing timing corresponding to the above clearing condition

1. When 0 is written to this bit after reading 1 from this bit (same as the timing in [Figure 39.19](#))
2. One PCLKB cycle after writing 1 to SSICR.REN.*3

[Setting condition]

Reading from SSIFRDR while it is empty.

[Setting timing]

At completion of reading from SSIFRDR. See [Figure 39.17](#).

- Note 1. This bit is cleared by a software reset (SSIFCR.SSIRST = 1). The software reset has priority over all the clearing conditions described above.
- Note 2. After reading 1 from this bit, this bit is cleared when one of the following three conditions is met:
- A software reset (SSIFCR.SSIRST = 1) is done.
 - After 1 has been read, writing of 0 is complete.
 - One PCLKB cycle passes after 1 has been written to SSICR.REN.
- Note 3. After communication is enabled (by changing the value of SSICR.REN bit from 0 to 1), the reception error flags (RUIRQ and ROIRQ in the SSISR register) are cleared. If, however, the SSISR register is read continuously, the cleared status of the reception error flags might be unable to be read.

Figure 39.17 RUIRQ setting timing

TOIRQ flag (Transmit Overflow Error Status Flag)

The TOIRQ flag is a status flag that indicates a transmit overflow error. This flag is set by automatic determination but it must be cleared by register access. This flag indicates that an attempt has been made to write data to the SSIFTDR register when the register is full of data. The data writing that causes a transmit overflow is ignored. For the procedure to recover from the overflow error, see [section 39.6.6. Error Handling](#). This flag is not cleared by a transmit FIFO data register reset (SSIFCR.TFRST).

[Priority order for setting and clearing]

Setting is prioritized.*1

[Clearing condition]

When either of the following operations is done:

1. Writing 0 to this bit after reading 1 from this bit*2
2. Enabling communication (changing SSICR.TEN from 0 to 1).

[Clearing timing]

Clearing timing corresponding to the above clearing condition

1. When 0 is written to this bit after reading 1 from this bit (same as the timing in [Figure 39.19](#))
2. One PCLKB cycle after writing 1 to SSICR.TEN.*³

[Setting condition]

An attempt was made to write data to the SSIFTDR register when the register is full of data.

[Setting timing]

At completion of writing to SSIFTDR. For details, see [Figure 39.18](#).

Note 1. This bit is cleared by a software reset (SSIFCR.SSIRST = 1). The software reset has priority over all the clearing conditions described above.

Note 2. After reading 1 from this bit, this bit is cleared when one of the following three conditions is met:

- A software reset (SSIFCR.SSIRST = 1) is done.
- After 1 has been read, writing of 0 is complete.
- One PCLKB cycle passes after 1 has been written to SSICR.TEN.

Note 3. After communication is enabled (by changing the value of SSICR.TEN bit from 0 to 1), the transmission error flags (TOIRQ and TUIRQ in the SSISR register) are cleared. If, however, the SSISR register is read continuously, the cleared status of the transmission error flags might be unable to be read.

Figure 39.18 TOIRQ setting timing

TUIRQ flag (Transmit Underflow Error Status flag)

The TUIRQ flag is a status flag that indicates a transmit underflow error. This flag is set by automatic determination but it must be cleared by register access. This flag indicates that writing the serial data required for a frame to SSIFTDR did not catch up with transmission of the frame. Even if this flag is cleared after it has been set, the SSITXD0/SSIDATA1 output remains to be 0. To output the data written to the transmit FIFO data register (SSIFTDR) to the SSITXD0/SSIDATA1 pin, follow the communication stop procedure in [Figure 39.56](#) and error-handling procedure in [Figure 39.57](#). For the procedure to recover from an error, see [section 39.6.6. Error Handling](#). This flag is not cleared by a reset of transmit FIFO data register (by the SSIFCR.TFRST signal).

[Priority order for setting and clearing]

Setting is prioritized.*1

[Clearing condition]

When either of the following operations is done:

1. Writing 0 to this bit after reading 1 from this bit^{*2}
2. Enabling communication (changing SSICR.TEN from 0 to 1).

[Clearing timing]

Clearing timing corresponding to the above clearing condition

1. When 0 is written to this bit after reading 1 from this bit
2. One PCLKB cycle after writing 1 to SSICR.TEN.^{*3}

Figure 39.19 TUIRQ clearing timing

- Note 1. This bit is cleared by a software reset (SSIFCR.SSIRST = 1). The software reset has priority over all the clearing conditions described above.
- Note 2. After reading 1 from this bit, this bit is cleared when one of the following three conditions is met:
- A software reset (SSIFCR.SSIRST = 1) is done.
 - After 1 has been read, writing of 0 is complete.
 - One PCLKB cycle passes after 1 has been written to SSICR.TEN.
- Note 3. After communication is enabled (by changing the value of SSICR.TEN bit from 0 to 1), the transmission error flags (TOIRQ and TUIRQ in the SSISR register) are cleared. If, however, the SSISR register is read continuously, the cleared status of the transmission error flags might be unable to be read.

[Setting condition]

When communication continues over a frame boundary, the transmit data required for the next frame has not been written to SSIFTDR. For details, see [Figure 39.20](#) and [Figure 39.21](#).

[Setting timing]

Three PCLKB cycles after the frame boundary. For details, see [Figure 39.20](#).

Figure 39.20 TUIRQ setting timing (when communication continues)

Figure 39.21 TUIRQ setting timing (when communication stops)

39.2.3 SSIFCR : FIFO Control Register

Base address: SSIE_n = 0x4025_D000 + 0x0100 × n (n = 0, 1)
 SSIE_n_NS = 0x5025_D000 + 0x0100 × n (n = 0, 1)

Offset address: 0x10

11	BSW	Byte Swap Enable* ¹ 0: Disables byte swap 1: Enables byte swap	R/W
15:12	—	These bits are read as 0. The write value should be 0.	R/W
16	SSIRST	Software Reset 0: Clears a software reset condition 1: Sets a software reset condition	R/W
30:17	—	These bits are read as 0. The write value should be 0.	R/W
31	AUCKE	AUDIO_MCK Enable in Mastermode Communication* ¹ 0: Disables supply of AUDIO_MCK 1: Enables supply of AUDIO_MCK	R/W

Note: S-TYPE-3, P-TYPE-3

Note 1. Writing to these bits while SSIE is in a communication state (SSISR.IIRQ = 0) is prohibited. If the value of these bits is changed by rewriting, subsequent operation is unpredictable.

This register sets a software reset, byte swap, and enable/disable of interrupt requests.

RFRST bit (Receive FIFO Data Register Reset)

The RFRST bit sets a software reset of the receive FIFO data register (SSIFRDR). Writing 1 to this bit initializes the internal state related to SSIFRDR. The register bits subject to the software reset triggered by this bit are indicated by shading in [Table 39.7](#). Because this bit is not automatically cleared after it has been set, write 0 to this bit to release the register bits from the software reset. After writing 0 to this bit, be sure to check that this bit is 0 before starting the next procedural step.

This bit is subject to the software reset by the SSIRST bit. Because the software reset by the SSIRST bit has priority over the reset by this bit, setting this bit is ignored when the SSIRST bit is set.

TFRST bit (Transmit FIFO Data Register Reset)

The TFRST bit sets a software reset of the transmit FIFO data register (SSIFTDR). Writing 1 to this bit initializes the internal state related to SSIFTDR. The register bits subject to the software reset triggered by this bit are indicated by shading in [Table 39.8](#). Because this bit is not automatically cleared after it has been set, write 0 to this bit to release the register bits from the software reset. After writing 0 to this bit, be sure to check that this bit is 0 before starting the next procedural step.

This bit is subject to the software reset by the SSIRST bit. Because the software reset by the SSIRST bit has priority over the reset by this bit, setting this bit is ignored when the SSIRST bit is set.

RIE bit (Receive Data Full Interrupt Output Enable)

The RIE bit enables/disables output of receive data full interrupts. Use a receive data full interrupt as an interrupt to trigger data reading from the receive FIFO data register. Write 1 to this bit after specifying the setting condition for receive data full interrupt (by using the SSISCR.RDFS bit). [Figure 39.22](#) shows the timing of generating the receive data full interrupt.

**Figure 39.22 Timing of receive data full interrupt****TIE bit (Transmit Data Empty Interrupt Output Enable)**

The TIE bit enables/disables output of transmit data empty interrupts. Use a transmit data empty interrupt as an interrupt to trigger data writing to the transmit FIFO data register. Write 1 to this bit after specifying the setting condition for transmit data empty interrupt (by using the SSISCR.TDES bit). [Figure 39.23](#) shows the timing of generating the transmit data empty interrupt.

Figure 39.23 Timing of transmit data empty interrupt

BSW bit (Byte Swap Enable)

The BSW bit enables/disables byte swap of register access for the transmit FIFO data register (SSIFTDR) and the receive FIFO data register (SSIFRDR). This bit is valid only with 16-bit access or 32-bit access to SSIFTDR and SSIFRDR. For details, see [Figure 39.24](#).

Figure 39.24 Operation example of byte swap

SSIRST bit (Software Reset)

The SSIRST bit sets a software reset of SSIE. Writing 1 to this bit initializes the internal state of SSIE. The register bits subject to the software reset triggered by this bit are indicated by shading in [Table 39.9](#). Because this bit is not automatically

cleared after it has been set, write 0 to this bit to release the register bits from the software reset. After writing 0 to this bit, be sure to check that this bit is 0 before starting the next procedural step.

To stop communication of SSIE immediately, after turning off the peripheral functions, write 1 to this bit. Initialization by a software reset is performed without any relation with the bit clock.

Table 39.9 Bits subject to software reset by the SSIRST bit

AUCKE bit (AUDIO_MCK Enable in Mastermode Communication)

The AUCKE bit enables/disables supply to AUDIO_MCK while in master-mode communication (MST = 1).

Changing the value of this bit must be performed only after specifying the settings related to AUDIO_MCK (by using the CKS, MST, BCKP, and CKDV bits in the SSICR register).

Figure 39.25 Stop/resume of AUDIO_MCK

Note: In slave-mode communication (SSICR.MST = 0), SSIE needs supply of SSIBCKn (n = 0, 1). To stop BCK on the master side, make sure that SSIE is in the idle state (SSISR.IIRQ = 1). If BCK is stopped before SSIE becomes idle, take the procedure to start communication in [Figure 39.52](#) or wait for an idle state by taking the procedure to resume communication in [Figure 39.58](#).

In master-mode communication (SSICR.MST = 1), SSIE operates with the audio clock (AUDIO_MCK). To stop SSIE completely, make sure that SSIE is in the idle state (SSISR.IIRQ = 1) and then write 0 to SSIFCR.AUCKE. If 0 is written to SSIFCR.AUCKE before SSIE becomes idle, take the procedure to start communication in [Figure 39.52](#).

[Figure 39.26](#) and [Figure 39.27](#) show the timings of signal operation in the period from setting this bit to 1 to the output to the SSIBCKn (n = 0, 1) pin.

Figure 39.26 Timing diagram for the operation from system reset to start of master-mode communication

Figure 39.27 Timing diagram for the operation from stop of communication to start of master-mode communication

Note: If the supply of AUDIO_MCK stops, the value of the SSIBCKn (n = 0, 1) pin is held. Therefore, the SSIBCKn (n = 0, 1) signal might stop in the H (high level) state.

39.2.4 SSIFSR : FIFO Status Register

Base address: SSIE_n = 0x4025_D000 + 0x0100 × n (n = 0, 1)
 SSIE_n_NS = 0x5025_D000 + 0x0100 × n (n = 0, 1)

Offset address: 0x14

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	TDC[5:0]					—	—	—	—	—	—	—	—	TDE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	RDC[5:0]					—	—	—	—	—	—	—	—	RDF
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	RDF	Receive Data Full Flag 0: The size of received data in SSIFRDR is not more than the value of SSISCR.RDFS. 1: The size of received data in SSIFRDR is not less than the value of SSISCR.RDFS plus one.	R/W
7:1	—	These bits are read as 0. The write value should be 0.	R/W
13:8	RDC[5:0]	Receive Data Count Number of valid data stored in the receive FIFO data register	R

Bit	Symbol	Function	R/W
16	TDE	Transmit Data Empty Flag 0: The free space of SSIFTDR is not more than the value of SSISCR.TDES. 1: The free space of SSIFTDR is not less than the value of SSISCR.TDES plus one.	R/W
23:17	—	These bits are read as 0. The write value should be 0.	R/W
29:24	TDC[5:0]	Transmit Data Count Number of valid data stored in the transmit FIFO data register	R
31:30	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

This register is configured with status flags that indicate the status of the transmit FIFO data register and the receive FIFO data register.

RDF flag (Receive Data Full Flag)

The RDF flag indicates that the receive FIFO data register (SSIFRDR) has unread received data not less than the amount set with the SSISCR.RDFS bits plus one. This flag is set by automatic determination but it must be cleared by register access.

[Priority order for setting and clearing]

Clearing is prioritized.

[Clearing condition]

Either of the following two:^{*1}

1. Writing 0 to this bit after reading 1 from this bit (CPU operation)^{*2}
2. Last access (DTC/DMAC operation) to read data from SSIFRDR by an interrupt routine using the DTC and DMAC.

[Clearing timing]

Clearing timing corresponding to the above clearing condition

1. When 0 is written to this bit after reading 1 from this bit (same as the timing in [Figure 39.19](#))
2. After the PCLKB cycle in which the last access instruction is issued to read data from SSIFRDR by an interrupt routine using the DTC and DMAC.

[Setting condition]

SSIFRDR has free space not less than the amount set with the SSISCR.RDFS bits plus one.

[Setting timing]

At completion of transfer from the shift register that results in SSIFRDR having data not less than the amount set with the SSISCR.RDFS bits plus one.

Note 1. These bits are cleared by a software reset (SSIFCR.SSIRST = 1) and receive FIFO data register reset (SSIFCR.RFRST = 1). Reset conditions available for these bits are the software reset and receive FIFO data register reset as well as the clearing conditions described above.

Note 2. After reading 1 from this bit, this bit is cleared when one of the following four conditions is met:

- A software reset is done (SSIFCR.SSIRST = 1).
- A receive FIFO data register reset is done (SSIFCR.RFRST = 1).
- After 1 has been read, writing of 0 is complete.
- Last access is performed to read data from SSIFRDR by an interrupt routine using the DTC and DMAC.

Figure 39.28 Timing diagram for setting and clearing RDF

RDC[5:0] bits (Receive Data Count)

The RDC[5:0] bits indicate the number of valid data that are stored in the receive FIFO data register (SSIFRDR). With these bits as 0x00, there is no received data. With 0x20, the register is filled with received data and there is no free space.

TDE flag (Transmit Data Empty Flag)

The TDE flag indicates that the transmit FIFO data register (SSIFTDR) has free space not less than the amount set with the SSISCR.TDES bits plus one. This flag is set by automatic determination but it must be cleared by register access.

[Priority order for setting and clearing]

Clearing is prioritized.*1

[Clearing condition]

Either of the following two:

1. Writing 0 to this bit after reading 1 from this bit (CPU operation)*2
2. Last access (DTC/DMAC operation) to write data to SSIFTDR by an interrupt routine using the DTC and DMAC.

[Clearing timing]

Clearing timing corresponding to the above clearing condition

1. When 0 is written to this bit after reading 1 from this bit (same as the timing in [Figure 39.19](#))
2. Last access (DTC/DMAC operation) to write data to SSIFTDR by an interrupt routine using the DTC and DMAC.

[Setting condition]

SSIFTDR has free space not less than the amount set with the SSISCR.TDES bits plus one.

[Setting timing]

While operating on PCLKB, SSIFTDR is found to have free space not less than “size set in the SSISCR.TDES bits + 1.”

Note 1. This bit is cleared by a software reset (SSIFCR.SSIRST = 1) and transmit FIFO data register reset (SSIFCR.TFRST = 1). The software reset and transmit FIFO data register reset have priority over all the clearing conditions described above.

Note 2. After reading 1 from this bit, this bit is cleared when one of the following four conditions is met:

- A software reset is done (SSIFCR.SSIRST = 1).
- A transmit FIFO data register reset is done (SSIFCR.TFRST = 1).
- After 1 has been read, writing of 0 is complete.
- Last access is performed to write data to SSIFTDR by an interrupt routine using the DTC and DMAC.

Figure 39.29 Timing diagram for setting and clearing TDE

TDC[5:0] bits (Transmit Data Count)

The TDC[5:0] bits indicate the number of valid data that are stored in the transmit FIFO data register (SSIFTDR). With these bits as 0x00, there is no data to be transmitted. With 0x20, there is no space to write data.

39.2.5 SSIFTDR : Transmit FIFO Data Register

Base address: SSIE_n = 0x4025_D000 + 0x0100 × n (n = 0, 1)
SSIE_n_NS = 0x5025_D000 + 0x0100 × n (n = 0, 1)

Bit field:	—	—	—	—	—	—	BCKA STP	LRCK NT	—	—	—	—	—	—	—	OMOD[1:0]
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
1:0	OMOD[1:0]	Audio Format Select ^{*3 *4} 0 0: I ² S format 0 1: TDM format 1 0: Monaural format 1 1: Setting prohibited	R/W
7:2	—	These bits are read as 0. The write value should be 0.	R/W
8	LRCONT	Whether to Enable LRCK/FS Continuation ^{*1 *2} 0: Disables LRCK/FS continuation 1: Enables LRCK/FS continuation	R/W
9	BCKASTP	Whether to Enable Stopping BCK Output When SSIE is in Idle Status ^{*1 *2} 0: Always outputs BCK to the SSIBCK _n (n = 0, 1) pin 1: Automatically controls output of BCK to the SSIBCK _n (n = 0, 1) pin	R/W
31:10	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

Note 1. This bit is valid only in master-mode communication (SSICR.MST = 1). The setting is invalid in slave-mode communication (SSICR.MST = 0).

Note 2. The BCKASTP and LRCONT bits must not be set to 1 together.

Note 3. While SSIE is communicating (SSISR.IIRQ = 0), writing to these bits is prohibited. If the value of these bits is changed by writing, subsequent operation is unpredictable.

Note 4. If the communication format of other-party device is compatible with a communication format of SSIE, specify and use the communication format that enables communication with the other-party device.

This register is used to set an audio format (which involves the settings of communication format, LR clock/frame synchronization continuation mode, and BCK output stop).

OMOD[1:0] bits (Audio Format Select)

The OMOD[1:0] bits set an audio format. Writing to these bits must be performed when the LR clock supply to the SSILRCK_n/SSIFS_n (n = 0, 1) pin is stopped. For details about the output of LR clock, see the detailed description of the LRCONT bit in [section 39.2.7. SSIOFR : Audio Format Register](#).

LRCONT bit (Whether to Enable LRCK/FS Continuation)

The LRCONT bit enables or disables the output from SSILRCK_n/SSIFS_n (n = 0, 1) pin when the communication mode is master-mode communication (SSICR.MST = 1) and SSIE is in the idle state (SSISR.IIRQ = 1).

Even in the idle state, a signal can output from the SSILRCK_n/SSIFS_n (n = 0, 1) pin when this bit is set to 1 (to enable LR clock/frame synchronization continuation) in master mode (SSICR.MST = 1).

Figure 39.33 Example of LR clock/frame synchronization continuation operation

BCKASTP bit (Whether to Enable Stopping BCK Output When SSIE is in Idle Status)

The BCKASTP bit turns on or off the function to output BCK to the SSIBCKn (n = 0, 1) pin according to the communication shown in [Figure 39.34](#) and [Figure 39.35](#) in master-mode communication (SSICR.MST = 1).

Changing the value of this bit must be performed only after setting the communication format to be used.

This bit must be used in the following way:

Write 0 to the BCKASTP bit, and then start communication. During the communication, write 1 to the BCKASTP bit. By this operation, the bit clock output to the SSIBCKn (n = 0, 1) pin stops automatically when the communication stops. To resume the communication, set SSIE to the idle state (SSICR.IIRQ = 1), enable the supply of AUDIO_MCK (SSIFCR.AUCKE = 1), and then write 0 to the BCKASTP bit.

When the communication mode is master-mode communication (SSICR.MST = 1) and SSIE is in the idle state (SSICR.IIRQ = 1):

Table 39.11 BCKASTP bit status and SSIBCKn (n = 0, 1) pin output

BCKASTP Bit	SSIBCKn (n = 0, 1) Pin Output Status
0	Output
1	Stopped

Note: The BCKASTP bit cannot be used when the other-party device (which is a slave) requires the clock output from the SSIBCKn (n = 0, 1) pin before and during communication. In such a case, use the BCKASTP bit to stop the clock only after communication. For the timing of enabling the clock stop function, see [Figure 39.34](#).

Figure 39.34 Example operation of the BCKASTP bit (idle state)

When the communication mode is master-mode communication (SSICR.MST = 1) and the BCK output stop function is enabled (BCKASTP = 1):

Details of the BCK output to the SSIBCKn (n = 0, 1) pin are as follows:

Output start timing: BCK is output in appropriate timing so that a valid edge is generated when the LR clock/frame synchronization signal shifts to a valid value.

Output stop timing: 1 to 1.5 clock cycles after a frame boundary.

For details about the timings, see the timing diagram in [Figure 39.35](#).

Figure 39.35 Example operation of the BCKASTP bit (communication operation with BCKASTP = 1)

39.2.8 SSICR : Status Control Register

Base address: SSIE_n = 0x4025_D000 + 0x0100 × n (n = 0, 1)
 SSIE_n_NS = 0x5025_D000 + 0x0100 × n (n = 0, 1)

Offset address: 0x24

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
4:0	RDFS[4:0]	RDF Setting Condition Select* ¹ 0x00: SSIFRDR has one stage or more data size. 0x01: SSIFRDR has two stages or more data size. ⋮ 0x1E: SSIFRDR has thirty-one stages or more data size. 0x1F: SSIFRDR has thirty-two stages or more data size.	R/W
7:5	—	These bits are read as 0. The write value should be 0.	R/W
12:8	TDES[4:0]	TDE Setting Condition Select* ¹ 0x00: SSIFTDR has one stage or more free space. 0x01: SSIFTDR has two stages or more free space. ⋮ 0x1E: SSIFTDR has thirty-one stages or more free space. 0x1F: SSIFTDR has thirty-two stages or more free space.	R/W
31:13	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

Note 1. Writing to these bits while SSIE is in a communication state (SSISR.IIRQ = 0) is prohibited. If written, the operation performed immediately after writing is not guaranteed.

RDFS[4:0] bits (RDF Setting Condition Select)

The RDFS[4:0] bits set the setting condition of the receive data full flag (RDF).

TDES[4:0] bits (TDE Setting Condition Select)

The TDES[4:0] bits set the setting condition of the transmit data empty flag (TDE).

39.3 Communication Formats

SSIE supports three communication formats. Table 39.12 shows supported communication formats.

Table 39.12 Supported communication formats

Communication Format	SSIOFR.OMOD[1:0]
I ² S format	00
TDM format	01
Monaural format	10

The following describes the serial data structure shared by communication formats. A serial data structure is defined by the system word length (set in SSICR.SWL[2:0]) and the data word length (set in SSICR.DWL[2:0]). If the data word length is shorter than the system word length, padding bits are transferred in the serial data. For details, see Figure 39.36.

Figure 39.36 Example of padding bit transfer (I²S format: system word length > data word length)

Table 39.13 lists the number of padding bits to be transferred with each combination of system word length (SSICR.SWL[2:0]) and data word length (SSICR.DWL[2:0]). “-” indicates that the setting is prohibited.

Table 39.13 Number of padding bits

	SSICR.DWL[2:0]	000b	001b	010b	011b	100b	101b	110b	111b
SSICR.SWL[2:0]	System Word Length	8	16	18	20	22	24	32	Setting prohibited
000b	8	0	—	—	—	—	—	—	—
001b	16	8	0	—	—	—	—	—	—
010b	24	16	8	6	4	2	0	—	—

100b	48	40	32	30	28	26	24	16	—
101b	64	56	48	46	44	42	40	32	—
110b	128	120	112	110	108	106	104	96	—
111b	256	248	240	238	236	234	232	224	—

39.3.1 I²S Format

The I²S format is a communication format used for connection with I²S-compatible serial devices. With this format setting (SSIOFR.OMOD[1:0] = 00b), one frame is configured with two system words, one for the channel L and the other for channel R. The SSILRCKn/SSIFS_n (n = 0, 1) signals are at a low level for the channel L and at a high level for the channel R. Set the polarity of the signals with the SSICR.LRCKP bit. [Figure 39.37](#) shows the I²S format without padding. See [Figure 39.36](#) for the format with padding.

**Figure 39.37** I²S format (without padding: system word length = data word length)

For the state of external pins when SSIE is in the idle state, see [section 39.5.1. Idle State](#).

Note: SSIE has the SSILRCKn/SSIFS_n (n = 0, 1) pin, which indicates the synchronization of communication. When SSIE is in slave mode (SSICR.MST = 0), the communication format SSIE uses must match that of the other-party device to communicate. SSIE uses the signal input by the SSILRCKn/SSIFS_n (n = 0, 1) pin only as a trigger to start communication.

39.3.2 Monaural Format

The monaural format is a communication format used for connection with monaural-compatible serial devices. When the monaural format is specified (SSIOFR.OMOD[1:0] = 10b) for use, one frame consists of one system word. Also, a rising edge of the SSILRCKn/SSIFS_n (n = 0, 1) signal indicates a communication start trigger. [Figure 39.38](#) and [Figure 39.39](#) respectively show the monaural formats without and with padding.

Figure 39.38 Short frame in monaural format (without padding: system word length = data word length)

Figure 39.39 Short frame in monaural format (with padding: system word length > data word length)

The monaural formats supported by SSIE consist of short frames and long frames. See [section 39.3.2.1. Short frame](#) and [section 39.3.2.2. Long frame](#) for the difference between these two frames.

For the state of external pins state when SSIE is in the idle state, see [section 39.5.1. Idle State](#).

Note: SSIE has the SSILRCKn/SSIFSnn ($n = 0, 1$) pin, which indicates the synchronization of communication. When SSIE is in slave mode (SSICR.MST = 0), the communication format SSIE uses must match that of the other-party device to communicate. SSIE uses the signal input by the SSILRCKn/SSIFSnn ($n = 0, 1$) pin only as a trigger to start communication.

39.3.2.1 Short frame

When a short frame is used (SSICR.DEL = 0), the SSILRCKn/SSIFSnn ($n = 0, 1$) signal indicating the start of serial data is set to high level only for 1 cycle of SSIBCKn ($n = 0, 1$). Data transfer starts at the falling edge of the signal.

39.3.2.2 Long frame

When a long frame is used (SSICR.DEL = 1), the SSILRCKn/SSIFSnn ($n = 0, 1$) signal indicating the start of serial data is set to high level only for 2 cycles of SSIBCKn ($n = 0, 1$). See [Figure 39.40](#). Data transfer starts at the rising edge of the signal.

System word length: 8 bits (SSICR.SWL[2:0] = 000b),
 Data word length: 8 bits (SSICR.DWL[2:0] = 000b),
 Number of frame words: One word (SSICR.FRM[1:0] = 00b)
 Delay of transfer data: No delay (SSICR.DEL = 1)
 BCK polarity: Rising edge (BCKP = 1)
 Other control bits of communication format are at their initial values.

Figure 39.40 Long frame in monaural format (without padding)

39.3.3 TDM Format

The TDM format is a communication format used for connection with TDM-compatible multi-channel devices. With this format setting (SSIOFR.OMOD[1:0] = 01b), one frame is configured with four to eight system words set with the SSICR.FRM[1:0] bits. With this format, the SSILRCK_n/SSIFS_n (n = 0, 1) signal is at a high level for the first one system word and at a low level for the rest. The pulse generated on the SSILRCK_n/SSIFS_n (n = 0, 1) signal is defined as the SYNC pulse and its rising edge means a start of one frame. [Figure 39.41](#) and [Figure 39.42](#) respectively show the TDM formats without and with padding.

System word length: 8 bits (SSICR.SWL[2:0] = 000b), Data word length: 8 bits (SSICR.DWL[2:0] = 000b),
 Number of frame words: Four words (SSICR.FRM[1:0] = 01b)
 Other control bits of communication format are at their initial values.

Figure 39.41 TDM format (without padding: system word length = data word length)

System word length: 16 bits (SSICR.SWL[2:0] = 001b), Data word length: 8 bits (SSICR.DWL[2:0] = 000b), Number of frame words: Four words (SSICR.FRM[1:0] = 01b)
 Other control bits of communication format are at their initial values.

Figure 39.42 TDM format (with padding: system word length > data word length)

For the state of external pins when SSIE is in the idle state, see [section 39.5.1. Idle State](#).

Note: SSIE has the SSILRCKn/SSIFS_n ($n = 0, 1$) pin, which indicates the synchronization of communication. When SSIE is in slave mode (SSICR.MST = 0), the communication format SSIE uses must match that of the other-party device to communicate. SSIE uses the signal input by the SSILRCKn/SSIFS_n ($n = 0, 1$) pin only as a trigger to start communication.

39.4 Communication Modes

SSIE supports the following communication modes. Table 39.15 lists the control bits that are not available with each communication mode. See section 39.4.1. [Slave-mode Communication](#) to section 39.4.5. [Transmission and Reception](#) for details of these communication modes.

Table 39.14 Communication modes

Communication Mode	SSICR.MST Bit	SSICR.REN Bit	SSICR.TEN Bit
Slave-mode transmission	0	0	1
Slave-mode reception	0	1	0
Slave-mode transmission and reception	0	1	1
Master-mode transmission	1	0	1
Master-mode reception	1	1	0
Master-mode transmission and reception	1	1	1

Table 39.15 Control bits that cannot be used in each communication mode

Control Bit	Slave-mode Reception	Slave-mode Transmission	Slave-mode Transmission and Reception	Master-mode Reception	Master-mode Transmission	Master-mode Transmission and Reception
SSICR.CKS	Invalid	Invalid	Invalid	Available	Available	Available
SSICR.CKDV	Invalid	Invalid	Invalid	Available	Available	Available
SSICR.MUEN	Invalid	Available	Available	Invalid	Available	Available
SSICR.TEN	Invalid	Available	Available	Invalid	Available	Available
SSICR.REN	Available	Invalid	Available	Available	Invalid	Available
SSIFCR.AUCKEN	Invalid	Invalid	Invalid	Available	Available	Available
SSIFCR.TIE	Invalid	Available	Available	Invalid	Available	Available
SSIFCR.RIE	Available	Invalid	Available	Available	Invalid	Available
SSIFCR.TFRST	Invalid	Available	Available	Invalid	Available	Available
SSIFCR.RFRST	Available	Invalid	Available	Available	Invalid	Available
SSIOFR.BCKASTP	Invalid	Invalid	Invalid	Available	Available	Available
SSIOFR.LRCONT	Invalid	Invalid	Invalid	Available	Available	Available
SSIOFR.OMOD	Available	Available	Available	Available	Available	Available
SSISCR.TDES	Invalid	Available	Available	Invalid	Available	Available
SSISCR.RDFS	Available	Invalid	Available	Available	Invalid	Available

“Invalid” means it has no effect on operation. Writing is possible.

39.4.1 Slave-mode Communication

SSIE operates in slave mode with SSICR.MST = 0. The SSIBCK_n ($n = 0, 1$) and SSILRCK_n/SSIFS_n ($n = 0, 1$) signals to be used for serial-data communication must be supplied from an external device. If these signals do not match the communication format set for SSIE, operation is not guaranteed.

39.4.2 Master-mode Communication

SSIE operates in master mode with SSICR.MST = 1. The SSIBCK_n (n = 0, 1) and SSILRCK_n/SSIFS_n (n = 0, 1) signals to be used for serial data communication must be internally generated from the audio clock. These signals use the format according to the setting of SSIE. If the communication format the slave device uses does not match the communication format set for SSIE, the operation is unpredictable.

39.4.3 Transmission

SSIE transmits serial data to the other-party device when the SSICR.TEN bit is 1 and the SSICR.REN bit is 0. If the communication format the other-party device uses does not match the communication format set for SSIE, the operation is unpredictable.

39.4.4 Reception

SSIE receives serial data from the other-party device when the SSICR.TEN bit is 0 and the SSICR.REN bit is 1. If the communication format the other-party device uses does not match the communication format set for SSIE, the operation is unpredictable.

39.4.5 Transmission and Reception

SSIE transmits and receives serial data to and from the other-party device when the SSICR.TEN bit is 1 and the SSICR.REN bit is 1. If the communication format the other-party device uses does not match the communication format set for SSIE, the operation is unpredictable.

39.5 Operation

SSIE has the following two main operation states [Figure 39.43](#) shows SSIE state transition.

- Idle state (SSISR.IIRQ = 1)
- Communication state (SSISR.IIRQ = 0).

Figure 39.43 SSIE state transition

Note: See [section 39.6.1. Start Communication](#) for details of the idle state.

See [section 39.6.2. Transmission](#) for details of the communication state.

39.5.1 Idle State

In this state, communication of SSIE is halted. If, however, the SSICR.MST bit is 1, output of the BCK and LR clock/frame synchronization signals to external pins can be controlled according to the settings of SSIOFR.BCKASTP and SSIOFR.LRCONT bits. This function is common to all formats. For details, see [Table 39.16](#).

Table 39.16 Output from external pins in the idle state (1 of 2)

SSICR.MST	SSIOFR.BCKASTP	SSIOFR.LRCONT	Output from Pins		
			SSIBCK _n (n = 0, 1)	SSILRCK _n /SSIFS _n (n = 0, 1)	SSITXD0/SSIDATA1
0	—	—	Stop	Stop	Stop

Table 39.16 Output from external pins in the idle state (2 of 2)

SSICR.MST	SSIOFR.BCKASTP	SSIOFR.LRCONT	Output from Pins		
			SSIBCKn (n = 0, 1)	SSILRCKn/SSIFS _n (n = 0, 1)	SSITXD0/SSIDATA1
1	0	0	Supply	Stop	Stop
1	0	1	Supply	Supply	Stop
1	1	0	Stop	Stop	Stop
1	1	1	Stop	Supply	Stop

**Figure 39.44 Example of disabling LR clock/frame synchronization continuation by SSIOFR.LRCONT**

Note: To stop the output to the SSILRCKn/SSIFS_n (n = 0, 1) pin with SSIOFR.LRCONT when SSIE is in the idle state in master-mode communication (SSICR.MST = 1), note the following: The output stops when the value of the SSIOFR.LRCONT bit is changed from 1 to 0. Make sure that the other-party device is not affected.

Figure 39.45 Example of stopping SSIBCKn (n = 0, 1) with SSIOFR.BCKASTP

Note: To stop the output to the SSIBCKn (n = 0, 1) pin with SSIOFR.BCKASTP in master-mode communication (SSICR.MST = 1) and while SSIE is in the idle state, note the following: The output stops when the value of the SSIOFR.BCKASTP bit is changed from 0 to 1. So, make sure that the other-party device is not affected.

39.5.2 Communication States

In this state, SSIE is during communication. [Figure 39.46](#) shows transitions of communication states and [Table 39.17](#) lists the conditions for transition. If the transition condition is not satisfied, the state does not transit.

Figure 39.46 Communication state transition

Table 39.17 Condition for communication state transition

Condition Number	Condition for Transition
1	Writing SSICR.TEN = 1 or SSICR.REN = 1 while SSICR.SDTA = 0 or in the setting without padding bits.
2	Writing SSICR.TEN = 1 or SSICR.REN = 1 while SSICR.SDTA = 1 and in the setting with padding bits.
3	The following three conditions are all met: - SSICR.TEN = 1 or SSICR.REN = 1 - In the setting with padding bits - The last bit of the data words has been transferred.
4	Both the following two conditions are met: - SSICR.SDTA = 1 or without padding bits - While SSICR.TEN = 0 and SSICR.REN = 0, the last bit of the data words in a frame has been transferred.
5	Transfer of the last padding bit is completed while SSICR.TEN = 1 or SSICR.REN = 1
6	Both the following two conditions are met: - SSICR.SDTA = 0 and with padding bits - While SSICR.TEN = 0 and SSICR.REN = 0, the last padding bit has been transferred.

See [Table 39.13](#) for the setting with/without padding bits.

39.5.2.1 Data Communication State

In this state, SSIE is during communication. Data of the data word length set with the SSICR.DWL[2:0] bits is transmitted, received, or transmitted and received.

- State Transition in the Setting without Padding Bits

During communication (SSISR.IIRQ = 0), SSIE is during data communication for all the time. By disabling transmission and reception (SSICR.TEN = 0, SSICR.REN = 0), SSIE transits to the idle state. For details, see [Figure 39.47](#) and [Figure 39.48](#).

Figure 39.47 Continuation of the data communication

Figure 39.48 Halt from the data communication (without padding bits)

- State Transition in the Setting with Padding Bits

When SSIE ends transfer of the last bit of a data word during communication (SSISR.IIRQ = 0), SSIE transitions from the data communication state to the padding communication state in [Figure 39.49](#). Except in the status with SSICR.SDTA = 1 and transmission and reception disabled (SSICR.TEN = 0 and SSICR.REN = 0), SSIE transitions from the data communication state to the idle state when it stops communication in [Figure 39.50](#).

Figure 39.49 Transition from data communication to padding communication

Figure 39.50 Halt from data communication (with padding bits)

39.5.2.2 Padding Communication

In this state, SSIE is during communication. The padding bits set with the SSICR.SWL[2:0] bits and SSICR.DWL[2:0] bits are transmitted, received, or transmitted and received.

- State Transition in the Setting with Padding Bits

When SSIE ends transfer of the last padding bit during communication (SSISR.IIRQ = 0), SSIE transitions to the data communication state in [Figure 39.49](#). If SSIE is in the status with SSICR.SDTA = 0 and transmission and reception disabled (SSICR.TEN = 0 and SSICR.REN = 0), SSIE transitions from the padding communication state to the idle state when it stops communication in [Figure 39.51](#).

Figure 39.51 Halt from the padding communication

39.6 Communication Operation

Figure 39.52 shows the communication flow of SSIE.

Figure 39.52 SSIE communication operation

The procedure of each operation is described from [section 39.6.1. Start Communication](#) to [section 39.6.7. Resume Communication](#).

39.6.1 Start Communication

This section describes how to start communication of SSIE. [Figure 39.53](#) shows the procedure to start communication. Be sure to follow the procedure. See [section 39.6.2. Transmission](#) for transmission operation and [section 39.6.3. Reception](#) for reception operation.

Figure 39.53 Procedure to start communication (CPU operation procedure)

SSIE can perform continuous communication based on interrupts by the DTC/DMAC. For transmission, write 1 to SSIFCR.TIE, SSICR.TUIEN, and SSICR.TOIEN. For reception, write 1 to SSIFCR.RIE, SSICR.RUIEN, and SSICR.ROIEN.

39.6.2 Transmission

The transmission procedure in [Figure 39.54](#) must be followed throughout a transmission operation.

After transmission is enabled (SSICR.TEN = 1 and SSICR.REN = 0), SSIE starts transmission when a start trigger is generated by SSILRCKn/SSIFS_n (n = 0, 1) with the serial data for at least a frame contained in the transmit FIFO data register (SSIFTDR). SSIE outputs a transmit data empty interrupt to the DTC/DMAC according to the TDE setting condition (SSISCR.TDES) and the status of transmit data empty interrupt enable (SSIFCR.TIE) bit specified in the communication start procedure. This interrupt requests writing to the transmit FIFO data register (SSIFTDR). In the communication start procedure, specify writing to the transmit FIFO data register (SSIFTDR) as the DTC/DMAC operation in response to the transmit data empty interrupt. With this setting, SSIE can continuously transmit data not through the CPU. The transmit data empty interrupt is generated when the free space size of transmit FIFO data register reaches the value set in SSISCR.TDES. The number of times of writing must be specified in accordance with the free space size of the transmit FIFO data register indicated by the transmit data empty interrupt. If an error occurs, perform the error-handling procedure as instructed in the communication stop procedure.

Figure 39.54 Transmission procedure

Note: The communication flow defined in SSIE uses the DTC/DMAC. If you do not use the DTC/DMAC, perform polling of the value 1 of SSIFSR.TDE to write data to SSIFTDR. The number of times of writing data to SSIFTDR by detecting the value 1 of SSIFSR.TDE must be in accordance with the free space size of the transmit FIFO data register specified by SSISCR.TDES. After as much transmit data as the free space size is written to SSIFTDR, the SSIFSR.TDE flag must be cleared. Continuous transmission is enabled by repeating data writing. If the SSIFSR.TDE flag is not cleared, the flag is not cleared automatically.

39.6.3 Reception

The reception procedure in [Figure 39.55](#) must be followed throughout a reception operation.

After reception is enabled (SSICR.TEN = 0 and SSICR.REN = 1), SSIE starts reception when a start trigger is generated by SSILRCKn/SSIFS_n (n = 0, 1). SSIE outputs a receive data full interrupt to the DTC/DMAC according to the RDF setting condition (SSISCR.RDFS) and the status of receive data full interrupt enable (SSIFCR.RIE) bit specified in the communication start procedure. This interrupt requests data reading from the receive FIFO data register (SSIFRDR). In the communication start procedure, specify reading from the receive FIFO data register (SSIFRDR) as the DTC/DMAC operation in response to the receive data full interrupt. With this setting, SSIE can continuously read data not through the CPU. The receive data full interrupt is generated when data as much as the capacity of receive FIFO data register has been stored. The number of times of reading must be specified in accordance with the data size of the receive FIFO data register

indicated by the receive data full interrupt. If an error occurs, perform the error-handling procedure as instructed in the communication stop procedure.

Figure 39.55 Reception procedure

Note: The communication flow defined in SSIE uses the DTC/DMAC. If you do not use the DTC/DMAC, perform polling of the value 1 of SSIFSR.RDF to read data from SSIFRDR. The number of times of reading data from SSIFRDR by detecting the value 1 of SSIFSR.RDF must be in accordance with the receive data storage capacity of the receive FIFO data register specified by SSISCR.RDFS. After received data is read from SSIFRDR, the SSIFSR.RDF flag must be cleared. Continuous reception is enabled by repeating data reading. If the SSIFSR.RDF flag is not cleared, the flag is not cleared automatically.

39.6.4 Transmission and Reception

After transmission and reception are enabled (SSICR.TEN = 1 and SSICR.REN = 1), SSIE starts transmission and reception when a start trigger is generated by SSILRCKn/SSIFS_n (n = 0, 1) with the serial data for at least a frame contained in the transmit FIFO data register (SSIFTDR). SSIE can continuously transmit and receive data by performing the procedures described in [section 39.6.2. Transmission](#) and [section 39.6.3. Reception](#), respectively. For how to stop transmission and reception, see [section 39.6.5. Halt Communication](#).

39.6.5 Halt Communication

This section describes how to halt communication of SSIE. [Figure 39.56](#) shows the procedure to halt communication. Be sure to follow the procedure.

Figure 39.56 Procedure to halt communication (CPU operation procedure)

To halt the communication of SSIE, supply of the following clocks are required until the SSISR.IIRQ bit indicates an idle state.

- Input clock from the SSIBCK_n (n = 0, 1) pin when SSICR.MST = 0
- AUDIO_MCK when SSICR.MST = 1

To resume communication of SSIE in the previous setting, see [section 39.6.7. Resume Communication](#).

Note: When communication of SSIE is halted according to the procedure to halt communication in [Figure 39.56](#), resume communication according to the procedure to resume communication in [Figure 39.58](#).

39.6.6 Error Handling

SSIE has the following four errors.

- Transmit underflow error
- Transmit overflow error
- Receive underflow error

- Receive overflow error.

When an underflow error or overflow error is generated, SSIE need to be restarted. Follow the procedure to halt communication in [Figure 39.56](#) and error-handling procedure in [Figure 39.57](#).

Figure 39.57 Error-handling procedure

Four error operations are described as follows. When the interrupt output enable bit of the SSICR register is enabled and error flags are set, an error interrupt is generated. See [section 39.2.2. SSISR : Status Register](#) for the setting conditions of error flags.

(1) Transmit Underflow Error

If a transmit underflow error occurs, review the number of times of writing data to the transmit FIFO data register (SSIFTDR) in response to a transmit data empty interrupt. After a transmit underflow error occurs, SSIE outputs 0s as data. To normally output the serial data written to the transmit FIFO data register (SSIFTDR) to the SSITXD0/SSIDATA1 pin, follow the procedure to halt communication in [Figure 39.56](#) and error-handling procedure in [Figure 39.57](#). After this error occurs, serial data is consumed as usual. If you resume communication, write the serial data from the beginning.

(2) Transmit Overflow Error

If a transmit overflow error occurs, review the number of times of writing data to the transmit FIFO data register (SSIFTDR) in response to transmit data empty interrupts. The serial data written to the transmit FIFO data register (SSIFTDR) that caused the transmit overflow error becomes invalid. This error can occur regardless of whether a transmission operation is being done. To recover from the error, follow the procedure to halt communication in [Figure 39.56](#) and error-handling procedure in [Figure 39.57](#). When you resume communication, deal with the invalid serial data appropriately.

(3) Receive Underflow Error

If a receive underflow error occurs, review the number of times of reading data from the receive FIFO data register (SSIFRDR) in response to receive data full interrupts. The values read from the receive FIFO data register (SSIFRDR) that caused the receive underflow error are undefined. This error can occur regardless of whether a reception operation is being done. To recover from the error, follow the procedure to halt communication in [Figure 39.56](#) and error-handling procedure in [Figure 39.57](#).

(4) Receive Overflow Error

If a receive overflow error occurs, review the number of times of reading data from the receive FIFO data register (SSIFRDR) in response to receive data full interrupts. The receive data that caused the receive overflow error cannot be stored in the receive FIFO data register (SSIFRDR). To recover from the error, follow the procedure to halt communication in [Figure 39.56](#) and error-handling procedure in [Figure 39.57](#).

39.6.7 Resume Communication

When you resume the communication using SSIE, follow the communication resume procedure in [Figure 39.58](#). The communication resume procedure is designed on the assumption that you resume the communication stopped by the

communication stop procedure without changing any settings. If you want to change clock and slave/master settings, use and follow the communication start procedure in [Figure 39.53](#). For details about the transmission operation and reception operation after starting communication, see [section 39.6.2. Transmission](#) and [section 39.6.3. Reception](#), respectively.

Figure 39.58 Procedure to resume communication (CPU operation procedure)

39.7 Interrupts

[Table 39.18](#) lists the interrupt sources. Set enable/disable of interrupt output of each source with the TUIEN, TOIEN, RUIEN, ROIEN, and IIEEN bits in the SSICR register and the TIE and RIE bits in the SSIFCR register.

Table 39.18 SSIE interrupt sources

Channel	Interrupt source	Description	Interrupt flag	DMAC/DTC activation
SSIE0	SSIE0_SSIF	- Transmit underflow interrupt - Transmit overflow interrupt - Receive underflow interrupt - Receive overflow interrupt - Idle interrupt	SSISR.TUIRQ SSISR.TOIRQ SSISR.RUIRQ SSISR.ROIRQ SSISR.IIRQ	Not possible
	SSIE0_SSIRXI	Receive data full interrupt	SSIFSR.RDF	Possible
	SSIE0_SSITXI	Transmit data empty interrupt	SSIFSR.TDE	Possible
SSIE1	SSIE1_SSIF	- Transmit underflow interrupt - Transmit overflow interrupt - Receive underflow interrupt - Receive overflow interrupt - Idle interrupt	SSISR.TUIRQ SSISR.TOIRQ SSISR.RUIRQ SSISR.ROIRQ SSISR.IIRQ	Not possible
	SSIE1_SSIRT	- Receive data full interrupt - Transmit data empty interrupt	SSIFSR.RDF SSIFSR.TDE	Possible

39.7.1 SSIE_n_SSIF Interrupt (n = 0, 1)

This interrupt source combines five interrupts. Enable output of necessary interrupts before using SSIE. The five interrupts are operated by using the flags assigned to individual interrupts and interrupt output enable bits. To clear an interrupt, set the interrupt enable to 0 or clear the interrupt flag to 0.

**Figure 39.59 Timing Diagram of the common interrupt source, SSIE_n_SSIF**

- Transmit underflow interrupt

As the transmit underflow interrupt, SSISR.TUIRQ is output while SSICR.TUIEN = 1. When you use SSIE for transmission, enable the output of this interrupt (SSICR.TUIEN = 1). If this interrupt occurs, follow instructions in the procedure to halt communication in [Figure 39.56](#) and error-handling procedure in [Figure 39.57](#).

- Transmit overflow interrupt

As the transmit overflow interrupt, SSISR.TOIRQ is output while SSICR.TOIEN = 1. When you use SSIE for transmission, enable the output of this interrupt (SSICR.TOIEN = 1). If this interrupt occurs, follow instructions in the procedure to halt communication in [Figure 39.56](#) and error-handling procedure in [Figure 39.57](#).

- Receive underflow interrupt

As the receive underflow interrupt, SSISR.RUIRQ is output while SSICR.RUIEN = 1. When you use SSIE for reception, enable the output of this interrupt (SSICR.RUIEN = 1). If this interrupt occurs, follow instructions in the procedure to halt communication in [Figure 39.56](#) and error-handling procedure in [Figure 39.57](#).

- Receive overflow interrupt

As the receive overflow interrupt, SSISR.ROIRQ is output while SSICR.ROIEN = 1. When you use SSIE for reception, enable the output of this interrupt (SSICR.ROIEN = 1). If this interrupt occurs, follow instructions in the procedure to halt communication in [Figure 39.56](#) and error-handling procedure in [Figure 39.57](#).

- Idle mode interrupt

As the idle mode interrupt, SSISR.IIRQ is output while SSICR.IIEN = 1. This interrupt is used to make sure that communication has stopped fully.

39.7.2 SSIE0_SSITXI Interrupt [Full-duplex communication]

The transmit data empty interrupt is a pulse interrupt that is output when the following condition is met:

- SSIFCR.TIE = 1 and SSIFSR.TDE = 1
 SSIE operation: When the value of SSIFSR.TDE changes from 0 to 1 while the value of SSIFCR.TIE is 1
 CPU instruction: When the value of SSIFCR.TIE changes from 0 to 1 while the value of SSIFSR.TDE is 1

This interrupt is subject to the interrupt suppression function. If an interrupt condition for this interrupt occurs when the DTC/DMAC is busy (when the DTC/DMAC cannot accept interrupts), the interrupt suppression function holds the output of this interrupt. The held interrupt will be output after the DTC/DMAC is enabled to accept interrupts. For details, see [Figure 39.60](#).

Figure 39.60 SSIE1_SSITXI interrupt timing diagram

39.7.3 SSIE0_SSIRXI Interrupt [Full-duplex communication]

The receive data full interrupt is a pulse interrupt that is output when the following condition is met:

- SSIFCR.RIE = 1 and SSIFSR.RDF = 1.
 SSIE operation: When the value of SSIFSR.RDF changes from 0 to 1 while the value of SSIFCR.RIE is 1
 CPU instruction: When the value of SSIFCR.RIE changes from 0 to 1 while the value of SSIFSR.RDF is 1

This interrupt is subject to the interrupt suppression function. If an interrupt condition for this interrupt occurs when the DTC/DMAC is busy (when the DTC/DMAC cannot accept interrupts), the interrupt suppression function holds the output of this interrupt. The held interrupt will be output after the DTC/DMAC is enabled to accept interrupts. The behavior of this interrupt is the same as the behavior shown in [Figure 39.60](#).

39.7.4 SSIE1_SSIRT Interrupt [Half-duplex communication]

This interrupt is output by two sources, transmit data empty interrupt and receive data full interrupt. When this interrupt is generated, read the interrupt flag and specify the interrupt source.

This interrupt is subject to the interrupt suppression function. If an interrupt condition for this interrupt occurs when the DTC/DMAC is busy (when the DTC/DMAC cannot accept interrupts), the interrupt suppression function holds the output of this interrupt. The held interrupt will be output after the DTC/DMAC is enabled to accept interrupts. For details, see [Figure 39.61](#).

Figure 39.61 SSIE1_SSIRT interrupt timing diagram

39.8 Software Resets

SSIE has three software reset bits to reset its states.

- SSIE software reset (SSIFCR.SSIRST)
- Transmit FIFO data register reset (SSIFCR.TFRST)
- Receive FIFO data register reset (SSIFCR.RFRST).

This section describes the procedures for the three types of software resets.

39.8.1 Software Reset Procedure

(1) SSIE Software Reset

For the SSIE software reset bit (SSIFCR.SSIRST), follow the procedure shown in [Figure 39.62](#). After a reset, the same setting is applied when it is resumed. To change the settings of clocks and slave/master mode, follow the procedure to start communication in [Figure 39.53](#). See [section 39.6.2. Transmission](#) and [section 39.6.3. Reception](#) respectively for transmission and reception after communication is resumed.

Figure 39.62 Software reset procedure (CPU operation procedure)

(2) Transmit FIFO data register reset

To perform a transmit FIFO data register reset, follow instructions in the procedure to start communication in [Figure 39.53](#) and procedure to resume communication in [Figure 39.58](#).

(3) Receive FIFO data register reset

To perform a receive FIFO data register reset, follow instructions in the procedure to start communication in [Figure 39.53](#) and procedure to resume communication in [Figure 39.58](#).

39.9 Usage Notes

39.9.1 Notes for Slave-mode Communication

39.9.1.1 SSIBCK_n (n = 0, 1) control

In slave-mode communication (SSICR.MST = 0), SSIE needs supply of SSIBCK_n (n = 0, 1). To stop BCK on the master side, make sure that SSIE is in the idle state (SSISR.IIRQ = 1). If BCK is stopped before SSIE becomes idle, take the procedure to start communication in [Figure 39.53](#) or wait for an idle state by taking the procedure to resume communication in [Figure 39.58](#).

39.9.1.2 SSILRCKn/SSIFS_n (n = 0, 1) pin

SSIE has the SSILRCK_n/SSIFS_n (n = 0, 1) pin, which indicates the synchronization of communication. When SSIE is in slave mode (SSICR.MST = 0), the communication format SSIE uses must match that of the other-party device to communicate. SSIE uses the signal input by the SSILRCK_n/SSIFS_n (n = 0, 1) pin only as a trigger to start communication.

39.9.2 Notes for Master-mode Communication

39.9.2.1 AUCKE control

In master-mode communication (SSICR.MST = 1), SSIE operates with the audio clock (AUDIO_MCK). To stop SSIE completely, make sure that SSIE is in the idle state (SSISR.IIRQ = 1) and then write 0 to SSIFCR.AUCKE.

39.9.2.2 LRCONT control

To stop the output to the SSILRCK_n/SSIFS_n (n = 0, 1) pin with SSIOFR.LRCONT when SSIE is in the idle state in master-mode communication (SSICR.MST = 1), note the following: The output stops when the value of the SSIOFR.LRCONT bit is changed from 1 to 0. Make sure that the other-party device is not affected. For details, see [Figure 39.44](#).

39.9.2.3 BCKASTP control

To stop the output to the SSIBCK_n (n = 0, 1) pin with SSIOFR.BCKASTP in master-mode communication (SSICR.MST = 1) and while SSIE is in the idle state, note the following: The output stops when the value of the SSIOFR.BCKASTP bit is changed from 0 to 1. So, make sure that the other-party device is not affected. For details, see [Figure 39.45](#).

The BCKASTP bit cannot be used when the other-party device (which is a slave) requires the clock output from the SSIBCK_n (n = 0, 1) pin before and during communication.

39.9.3 Notes for Communication Flow

39.9.3.1 When an error interrupt is generated

SSIE has the following four errors.

- Transmit underflow error
- Transmit overflow error
- Receive underflow error
- Receive overflow error

When an underflow error or overflow error is generated, SSIE need to be restarted. Follow the procedure to halt communication in [Figure 39.56](#) and error-handling procedure in [Figure 39.57](#).

(1) Transmit Underflow Error

If a transmit underflow error occurs, review the number of times of writing data to the transmit FIFO data register (SSIFTDR) in response to a transmit data empty interrupt. After a transmit underflow error occurs, SSIE outputs 0s as data. To normally output the serial data written to the transmit FIFO data register (SSIFTDR) to the SSITXD0/SSIDATA1 pin, follow the procedure to halt communication in [Figure 39.56](#) and error-handling procedure in [Figure 39.57](#). After this error occurs, serial data is consumed as usual. If you resume communication, write the serial data from the beginning.

(2) Transmit Overflow Error

If a transmit overflow error occurs, review the number of times of writing data to the Transmit FIFO Data Register (SSIFTDR) in response to transmit data empty interrupts. The serial data written to the Transmit FIFO Data Register (SSIFTDR) that caused the transmit overflow error becomes invalid. This error can occur regardless of whether a transmission operation is being done. To recover from the error, follow the procedure to halt communication in [Figure 39.56](#) and error-handling procedure in [Figure 39.57](#). When you resume communication, deal with the invalid serial data appropriately.

(3) Receive Underflow Error

If a receive underflow error occurs, review the number of times of reading data from the receive FIFO data register (SSIFRDR) in response to receive data full interrupts. The values read from the receive FIFO data register (SSIFRDR) that caused the receive underflow error are undefined. This error can occur regardless of whether a reception operation is being done. To recover from the error, follow the procedure to halt communication in [Figure 39.56](#) and error-handling procedure in [Figure 39.57](#).

(4) Receive Overflow Error

If a receive overflow error occurs, review the number of times of reading data from the receive FIFO data register (SSIFRDR) in response to receive data full interrupts. The receive data that caused the receive overflow error cannot be stored in the receive FIFO data register (SSIFRDR). To recover from the error, follow the procedure to halt communication in [Figure 39.56](#) and error-handling procedure in [Figure 39.57](#).

39.9.3.2 Transmit data empty interrupt

The communication flow defined in SSIE uses the DTC/DMAC. If you do not use the DTC/DMAC, perform polling of the value 1 of SSIFSR.TDE to write data to SSIFTDR. The number of times of writing data to SSIFTDR by detecting the value 1 of SSIFSR.TDE must be in accordance with the free space size of the transmit FIFO data register specified by SSISCR.TDES. After as much transmit data as the free space size is written to SSIFTDR, the SSIFSR.TDE flag must be cleared. Continuous transmission is enabled by repeating data writing. If the SSIFSR.TDE flag is not cleared, the flag is not cleared automatically.

39.9.3.3 Receive data full interrupt

The communication flow defined in SSIE uses the DTC/DMAC. If you do not use the DTC/DMAC, perform polling of the value 1 of SSIFSR.RDF to read data from SSIFRDR. The number of times of reading data from SSIFRDR by detecting the value 1 of SSIFSR.RDF must be in accordance with the receive data storage capacity of the receive FIFO data register specified by SSISCR.RDFS. After received data is read from SSIFRDR, the SSIFSR.RDF flag must be cleared. Continuous reception is enabled by repeating data reading. If the SSIFSR.RDF flag is not cleared, the flag is not cleared automatically.

39.9.3.4 Switching transfer modes

1. For state transition from transmission, reception, and transmission and reception, disable transmission and reception (SSICR.TEN = 0, SSICR.REN = 0).
2. Confirm it is in the idle state (SSISR.IIRQ = 1).
3. In the idle state, set the SSICR.TEN bit or the SSICR.REN bit again and resume transfer.

39.9.3.5 Resume communication after halting SSIE

When communication of SSIE is halted according to the procedure to halt communication in [Figure 39.56](#), resume communication according to the procedure to resume communication in [Figure 39.58](#).

39.9.4 Write Access Restriction

39.9.4.1 SSICR register

If the TEN bit or REN bit is rewritten, make sure that the SSISR.IIRQ bit is in the desired status. If the value of the TEN or REN bit is changed by rewriting, subsequent operation is unpredictable. For example, when transmission or reception is enabled, check that SSISR.IIRQ is 0; when transmission or reception is disabled, check that SSISR.IIRQ is 1.

(1) TEN Bit and REN Bit

These bits enable/disable transmission and reception. When 1 is written to one of these bits, the corresponding communication operation starts in synchronization with a start trigger by the SSILRCKn/SSIFS_n (n = 0, 1) signal. For details, see [section 39.6.2. Transmission](#), [section 39.6.3. Reception](#), and [section 39.6.4. Transmission and Reception](#). When 0 is written to this bit, the current communication operation stops at the next frame boundary. To use SSIE for both transmission and reception, always write 1 to these bits together. When stopping the communication using SSIE, always disable both transmission and reception (write 0 to the TEN and REN bits).

39.9.4.2 SSISR register

(1) Clearing TUIRQ and TOIRQ

After communication is enabled (by changing the value of SSICR.TEN bit from 0 to 1), the transmission error flags (TOIRQ and TUIRQ in the SSISR register) are cleared. If, however, the SSISR register is read continuously, the cleared status of the transmission error flags might be unable to be read.

(2) Clearing RUIRQ and ROIRQ

After communication is enabled (by changing the value of SSICR.REN bit from 0 to 1), the reception error flags (RUIRQ and ROIRQ in the SSISR register) are cleared. If, however, the SSISR register is read continuously, the cleared status of the reception error flags might be unable to be read.

39.9.4.3 Communication state

Writing to the bits with orange-shaded area in [Table 39.19](#) is prohibited. If written, the operation performed immediately after writing is not guaranteed.

Table 39.19 Bits protected from writing during communication

Symbol	Address (BASE+)		+0								+1							
			31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

39.9.5 Module-stop function

SSIE operation can be disabled or enabled using Module Stop Control Register C (MSTPCRC). The SSIE module is initially stopped after reset. Releasing the module-stop state enables access to the registers. For details, see [section 10, Low Power Modes](#).

40. SD/MMC Host Interface (SDHI)

40.1 Overview

The Secure Digital Host Interface (SDHI) and MultiMediaCard (MMC) Interface provide the functionality required to connect a variety of external memory cards with the MCU. The SDHI supports both 1- and 4-bit buses for connecting different memory cards that support SD, SDHC, and SDXC formats. When developing host devices that are compliant with the SD Specifications, you must comply with the SD Host/Ancillary Product License Agreement (SD HALA).

The MMC interface supports 1-bit, 4-bit, and 8-bit MMC buses that provide eMMC 4.51 (JEDEC Standard JESD 84- B451) device access. This interface also provides backward compatibility and supports for high-speed SDR transfer modes.

Table 40.1 lists the SD/MMC Host Interface specifications and Figure 40.1 shows a block diagram.

Table 40.1 SD/MMC Host Interface specifications

Interface	Parameter	Specifications
SD	SD bus interface	- Compatible with SD memory card and SDIO card - Transfer bus mode selectable from 4-bit wide bus mode or 1-bit default bus mode - Compatible with SD, SDHC, and SDXC formats
	Transfer modes	Default Speed mode, High Speed mode, SDR12 or SDR25
SD and MMC shared	SDHI clock frequency	The SDHI clock is generated by dividing PCLKB by 2^n ($n = 0$ to 9)
	Error check functions	CRC7 (command/response), CRC16 (transfer data)
	Interrupt sources	Card access interrupt (SDHI_MMChn_ACCS), SDIO access interrupt (SDHI_MMChn_SDIO), Card detection interrupt (SDHI_MMChn_CARD) ($n = 0, 1$)
	DMA transfer sources	DMAC and DTC triggerable by the DMA transfer requests (SDHI_MMChn_ODMSDBREQ ($n = 0, 1$)) interrupt SD buffer is read and write accessible using the DMAC
	Other functions	- Card detect function - Write protect support
MMC	MMC bus interface	Transfer bus mode selectable from 1-bit, 4-bit, or 8-bit
	Transfer modes	Backward compatible mode or high-speed SDR mode selectable
	Other functions	e.MMC device access supported
Module-stop function	Module-stop state can be set for each channel to reduce power consumption.	
TrustZone Filter	Security and Privilege attribution can be set for each channel.	

Figure 40.1 SD/MMC Host Interface block diagram

Table 40.2 SDHI I/O pins (n = 0, 1)

Channel	Pin name	I/O	Description
Ch n	SDnCLK	Output	SDHI clock
	SDnCMD	I/O	Command output, response input
	SDnDAT0	I/O	Data 0 (DAT0)
	SDnDAT1	I/O	Data 1 (DAT1), SDIO interrupt
	SDnDAT2	I/O	Data 2 (DAT2), SDIO Read wait
	SDnDAT3	I/O	Data 3 (DAT3), SD Card detect
	SDnDAT4	I/O	MMC Data 4 (DAT4)
	SDnDAT5	I/O	MMC Data 5 (DAT5)
	SDnDAT6	I/O	MMC Data 6 (DAT6)
	SDnDAT7	I/O	MMC Data 7 (DAT7)
	SDnCD	Input	SD card detection
	SDnWP	Input	SD card write protection

40.2 Register Descriptions

40.2.1 SD_CMD : Command Type Register

Base address: SDHIn = 0x4025_2000 + 0x0400 × n (n = 0, 1)
SDHIn_NS = 0x5025_2000 + 0x0400 × n (n = 0, 1)

Offset address: 0x000

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	CMD12AT[1:0]		TRST P	CMDR W	CMDT P	RSPTP[2:0]			ACMD[1:0]		CMDIDX[5:0]					
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
5:0	CMDIDX[5:0]	Command Index Field Value Select These bits configure the command index field value. The examples shown include the bit values for the ACMD[1:0] bits. 0x06: CMD6 0x12: CMD18 0x4D: ACMD13	R/W
7:6	ACMD[1:0]	Command Type Select 0 0: CMD 0 1: ACMD Others: Setting prohibited	R/W
10:8	RSPTP[2:0]	Response Type Select*1 0 0 0: Normal mode Depending on the command, the response type and transfer method are selected in the ACMD[1:0] and CMDIDX[5:0] bits. At this time, the values for bits 15 to 11 in this register are invalid. 0 1 1: Extended mode and no response 1 0 0: Extended mode and R1, R5, R6, or R7 response 1 0 1: Extended mode and R1b response 1 1 0: Extended mode and R2 response 1 1 1: Extended mode and R3 or R4 response Others: Setting prohibited	R/W

Bit	Symbol	Function	R/W
11	CMDTP	Data Transfer Select ^{*2} 0: Do not include data transfer (bc, bcr, or ac) in command 1: Include data transfer (adtc) in command	R/W
12	CMDRW	Data Transfer Direction Select ^{*3} 0: Write (SD/MMC Host Interface → SD card/MMC) 1: Read (SD/MMC Host Interface ← SD card/MMC)	R/W
13	TRSTP	Block Transfer Select ^{*3} 0: Single block transfer 1: Multiple blocks transfer	R/W
15:14	CMD12AT[1:0]	CMD12 Automatic Issue Select ^{*4} 0 0: Automatically issue CMD12 during multiblock transfer 0 1: Do not automatically issue CMD12 during multiblock transfer Others: Setting prohibited	R/W
31:16	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

Note 1. Some commands cannot be used in normal mode.

Note 2. The CMDTP bit is only valid when the RSPTP[2:0] bits are 011b, 100b, 101b, 110b, or 111b.

Note 3. Bits CMDRW and TRSTP are only valid when the RSPTP[2:0] bits are 011b, 100b, 101b, 110b, or 111b, and the CMDTP bit is 1.

Note 4. The CMD12AT[1:0] bits are only valid when the RSPTP[2:0] bits are 011b, 100b, 101b, 110b, or 111b, and the TRSTP bit is 1.

The command type and response type are set in the SD_CMD register. The command type and transfer mode must be set when the RSPTP[2:0] bits are 011b, 100b, 101b, 110b, or 111b. The sequence starts when a value is written to this register. See [Table 40.8](#) and [Table 40.9](#) for setting examples. Do not write to the SD_CMD register when the SD_INFO2.CBSY flag is 1.

40.2.2 SD_ARG : SD Command Argument Register

Base address: SDHIn = 0x4025_2000 + 0x0400 × n (n = 0, 1)
SDHIn_NS = 0x5025_2000 + 0x0400 × n (n = 0, 1)

Offset address: 0x008

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:																
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:																
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	—	These bits specify command format[39:8] (argument).	R/W

Note: S-TYPE-3, P-TYPE-3

The SD_ARG register is used for setting the argument field value. Set the SD_ARG register before setting the SD_CMD register. The argument field value of the automatically issued CMD12 is 0x0000_0000 regardless of the SD_ARG register value.

40.2.3 SD_ARG1 : SD Command Argument Register 1

Base address: SDHIn = $0x4025_2000 + 0x0400 \times n$ ($n = 0, 1$)
 SDHIn_NS = $0x5025_2000 + 0x0400 \times n$ ($n = 0, 1$)

Offset address: 0x00C

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:																
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	—	These bits specify command format[39:24] (argument).	R/W
31:16	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

The SD_ARG1 register is used for setting the argument field value. Set the SD_ARG1 register before setting the SD_CMD register. The argument field value of the automatically issued CMD12 is 0x0000_0000 regardless of the SD_ARG1 register value.

40.2.4 SD_STOP : Data Stop Register

Base address: SDHIn = $0x4025_2000 + 0x0400 \times n$ ($n = 0, 1$)
 SDHIn_NS = $0x5025_2000 + 0x0400 \times n$ ($n = 0, 1$)

Offset address: 0x010

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	SEC	—	—	—	—	—	—	—	STP
Value after reset:	0	0	0	0	0	0	0	0 ^{*1}	0	0	0	0	0	0	0	0 ^{*1}

Bit	Symbol	Function	R/W
0	STP	Transfer Stop Data transfer stops when this bit is set to 1.	R/W
7:1	—	These bits are read as 0. The write value should be 0.	R/W
8	SEC	Block Count Register Value Select ^{*2} 0: Disable SD_SECCNT register value 1: Enable SD_SECCNT register value	R/W
31:9	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

Note 1. The value is initialized by a reset and also on reset triggered by the SOFT_RST.SDRST flag.

Note 2. Do not rewrite this bit when the SD_INFO2.CBSY flag is 1.

The SD_STOP register stops data transfer. During a multiblock transfer sequence, the SD_SECCNT register value (number of blocks to be transferred) can be set to valid or invalid by setting the SD_STOP register.

STP bit (Transfer Stop)

When the STP bit is set to 1 during multiple block transfer, CMD12 is issued to halt the transfer through the SDHI. However, if a command sequence is halted because of a communications error or timeout, CMD12 is not issued. Although continued buffer access is possible even after STP is set to 1, the buffer access error bit (ILR or ILW) in SD_INFO2 is set accordingly.

When STP is set to 1 during transfer for single block write, the access end flag sets when SD_BUF becomes empty, and CMD12 is not issued. If SD_BUF does contain data, the access end flag sets on completion of reception of the busy state without CMD12 being issued.

When STP is set to 1 during transfer for single block read, the access end flag sets immediately after the STP bit is set, and CMD12 is not issued.

When STP is set to 1 during reception of the busy state after an R1b response, the access end flag sets on completion of reception of the busy state without CMD12 being issued.

When STP is set to 1 after a command sequence is completed, CMD12 is not issued and the access end flag does not set.

Set STP to 1 after the response end flag sets.

Set STP to 0 after the access end flag sets.

SEC bit (Block Count Register Value Select)

When SD_CMD is set in the following section to start the command sequence while the SEC bit is set to 1, CMD12 is automatically issued to stop multiblock transfer with the number of blocks set in SD_SECCNT.

CMD18 or CMD25 in normal mode (SD_CMD[10:8] = 000b)

SD_CMD[15:13] = 001b in extended mode (CMD12 is automatically issued, multiple block transfer)

When the command sequence is halted because of a communications error or timeout, CMD12 is not automatically issued.

40.2.5 SD_SECCNT : Block Count Register

Base address: SDHIn = 0x4025_2000 + 0x0400 × n (n = 0, 1)
SDHIn_NS = 0x5025_2000 + 0x0400 × n (n = 0, 1)

Offset address: 0x014

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:																
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:																
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	—	These bits set the number of blocks to be transferred.	R/W

Note: S-TYPE-3, P-TYPE-3

When performing a multiblock transfer, SD_SECCNT is a read/write register used to set the number of blocks to be transferred. For example, when the register value is 0x0000_0001, 1 block is transferred. When the register value is 0x0000_FFFF, 65,535 blocks are transferred and when the register value is 0xFFFF_FFFF, 4,294,967,295 blocks are transferred. Do not set this register to 0x0000_0000. Do not rewrite the SD_SECCNT register when the SD_INFO2.CBSY flag is 1.

40.2.6 SD_RSPi : SD Card Response Register i (i = 10, 32, 54)

Base address: SDHIn = 0x4025_2000 + 0x0400 × n (n = 0, 1)
SDHIn_NS = 0x5025_2000 + 0x0400 × n (n = 0, 1)

Offset address: 0x018 (SD_RSP10)
0x020 (SD_RSP32)
0x028 (SD_RSP54)

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:																
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:																
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	—	These bits store the response from the SD card/MMC.	R

Note: S-TYPE-3, P-TYPE-3

40.2.7 SD_RSPj : SD Card Response Register j (j = 1, 3, 5)

Base address: SDHIn = 0x4025_2000 + 0x0400 × n (n = 0, 1)
SDHIn_NS = 0x5025_2000 + 0x0400 × n (n = 0, 1)

Offset address: 0x01C (SD_RSP1)
0x024 (SD_RSP3)
0x02C (SD_RSP5)

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:																
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	—	These bits store the response from the SD card/MMC.	R
31:16	—	These bits are read as 0.	R

Note: S-TYPE-3, P-TYPE-3

40.2.8 SD_RSP76 : SD Card Response Register 76

Base address: SDHIn = $0x4025_2000 + 0x0400 \times n$ ($n = 0, 1$)
 SDHIn_NS = $0x5025_2000 + 0x0400 \times n$ ($n = 0, 1$)

Offset address: 0x030

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	SD_RSP76[23:16]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	SD_RSP76[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
23:0	SD_RSP76[23:0]	These bits store the response from the SD card/MMC.	R
31:24	—	These bits are read as 0.	R

Note: S-TYPE-3, P-TYPE-3

40.2.9 SD_RSP7 : SD Card Response Register 7

Base address: SDHIn = $0x4025_2000 + 0x0400 \times n$ ($n = 0, 1$)
 SDHIn_NS = $0x5025_2000 + 0x0400 \times n$ ($n = 0, 1$)

Offset address: 0x034

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	SD_RSP7[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	SD_RSP7[7:0]	These bits store the response from the SD card/MMC.	R
31:8	—	These bits are read as 0.	R

Note: S-TYPE-3, P-TYPE-3

SD_RSP10, SD_RSP32, SD_RSP54, SD_RSP1, SD_RSP3, SD_RSP5, SD_RSP76, and SD_RSP7 are read-only registers that store the response from the SD card/MMC. Depending on the type of response from the SD card/MMC, the SD/MMC Host Interface divides and stores the response among the four registers.

Table 40.3 lists the correspondence between the response type and its storage destination.

Table 40.3 Correspondence between response type and storage destination (1 of 2)

Response type	SD_RSP10 register	SD_RSP32 register	SD_RSP54 register	SD_RSP1 register	SD_RSP3 register	SD_RSP5 register	SD_RSP76 register	SD_RSP7 register
R1	[39:8]	—	[39:8]*1	—	—	—	—	—
R1b	[39:8]	—	[39:8]*1	—	—	—	—	—
R2	[39:8]	[71:40]	[103:72]	—	—	—	[127:104]	—
R3	[39:8]	—	—	—	—	—	—	—
R4	[39:8]	—	—	—	—	—	—	—

Table 40.3 Correspondence between response type and storage destination (2 of 2)

Response type	SD_RSP10 register	SD_RSP32 register	SD_RSP54 register	SD_RSP1 register	SD_RSP3 register	SD_RSP5 register	SD_RSP76 register	SD_RSP7 register
R5	[39:8]	—	—	—	—	—	—	—
R6	[39:8]	—	—	—	—	—	—	—
R7	[39:8]	—	—	—	—	—	—	—

Note 1. The responses for CMD18 and CMD25 are stored in registers SD_RSP10 and SD_RSP54. Therefore, even if the SD_RSP10 register is overwritten with the response for the automatically issued CMD12, the response for CMD18 or CMD25 can be confirmed by reading the SD_RSP54 register.

40.2.10 SD_INFO1 : SD Card Interrupt Flag Register 1

Base address: SDHIn = 0x4025_2000 + 0x0400 × n (n = 0, 1)
SDHIn_NS = 0x5025_2000 + 0x0400 × n (n = 0, 1)

Offset address: 0x038

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	SDD3 MON	SDD3I N	SDD3 RM	SDWP MON	—	SDCD MON	SDCDI N	SDCD RM	ACEN D	—	RSPE ND
Value after reset:	0	0	0	0	0	x	0	0	x	0	x	0	0	0 ^{*1}	0	0 ^{*1}

Bit	Symbol	Function	R/W
0	RSPEND	Response End Detection Flag 0: Response end not detected 1: Response end detected	R/(W) ^{*2}
1	—	This bit is read as 0. The write value should be 0.	R/W
2	ACEND	Access End Detection Flag 0: Access end not detected 1: Access end detected	R/(W) ^{*2}
3	SDCDRM	SDnCD Removal Flag 0: SD card/MMC removal not detected by the SDnCD pin 1: SD card/MMC removal detected by the SDnCD pin	R/(W) ^{*2}
4	SDCDIN	SDnCD Insertion Flag 0: SD card/MMC insertion not detected by the SDnCD pin 1: SD card/MMC insertion detected by the SDnCD pin	R/(W) ^{*2}
5	SDCDMON	SDnCD Pin Monitor Flag 0: SDnCD pin level is high ^{*3} 1: SDnCD pin level is low ^{*3}	R
6	—	This bit is read as 0. The write value should be 0.	R/W
7	SDWPMON	SDnWP Pin Monitor Flag 0: SDnWP pin level is high 1: SDnWP pin level is low	R
8	SDD3RM	SDnDAT3 Removal Flag 0: SD card/MMC removal not detected by the SDnDAT3 pin 1: SD card/MMC removal detected by the SDnDAT3 pin	R/(W) ^{*2}
9	SDD3IN	SDnDAT3 Insertion Flag 0: SD card/MMC insertion not detected by the SDnDAT3 pin 1: SD card/MMC insertion detected by the SDnDAT3 pin	R/(W) ^{*2}
10	SDD3MON	SDnDAT3 Pin Monitor Flag 0: SDnDAT3 pin level is low 1: SDnDAT3 pin level is high	R

Bit	Symbol	Function	R/W
31:11	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

Note 1. The value is initialized by a reset and also on reset triggered by the `SOFT_RST.SDRST` flag.

Note 2. The flag does not change even if set to 1. Writing 0 changes the flag value to 0.

Note 3. The flag changes when the pin level continues for the period set in the `SD_OPTION.CTOP[3:0]` bits or longer.

The `SD_INFO1` register indicates the detection of a response end or access end for a command sequence. The `SD_INFO1` register also indicates the detection SD card/MMC insertion/removal and the write protection status.

During a multiblock transfer sequence, if `CMD12` or `CMD52` (SDIO abort) is issued, the `ACEND` flag sets to 1, but the `RSPEND` flag remains set to 0.

If the command sequence is stopped because of a communication error or timeout, the `ACEND` flag or `RSPEND` flag sets to 1.

After a reset is canceled, the `SDD3MON` bit, `SDD3IN` flag, and `SDD3RM` flag values are changed in accordance with the status of the `SDnDAT3` ($n = 0, 1$) pin, and their values are changed when data is being transferred in wide bus mode. These 3 bits are used only for SD card. Set flags to be cleared to 0. Set flags that are not being cleared to 1.

RSPEND flag (Response End Detection Flag)

The `RSPEND` flag indicates that a response end was detected.

[Setting conditions]

- When reception of the response is completed
- When transmission of a command without response is completed
- When reception of the busy state after `R1b` response is completed
- When reception of the response to `CMD52` that was issued by setting the `C52PUB` bit to 1 is completed for transfer of multiple block read
- When reception of the response to `CMD52` that was issued by setting the `C52PUB` bit to 1 is completed for transfer of multiple block write
- This bit is set when a command sequence is halted because of a communications error or timeout.

[Clearing conditions]

- When 0 is written to `RSPEND`
- When a command without data is issued.

Note: When a command is issued in absence of data transfer, the `RSPEND` flag becomes 1 after the command sequence ends.

ACEND flag (Access End Detection Flag)

The `ACEND` flag indicates that an access end was detected.

[Setting conditions]

- When read access to the buffer is completed for transfer of single block read
- When read access to the buffer for the last block of data is completed for transfer of multiple block read
- When read access to the buffer and reception of the response to `CMD12` are completed for transfer of multiple block read with automatic issuing of `CMD12`
- When reception of the busy state after reception of the CRC status is completed for transfer of single block write
- When reception of the busy state after reception of the CRC status of the last block of data is completed for transfer of multiple block write
- When reception of the response busy state for `CMD12` is completed for transfer of multiple block write with automatic issuing of `CMD12`
- When reception of the response to `CMD12` that was issued by setting the `STP` bit to 1 is completed for transfer of multiple block read

- When reception of the response busy state for CMD12 that was issued by setting the STP bit to 1 is completed for transfer of multiple block write
- When reception of the response to CMD52 that was issued by setting the IOABT bit to 1 is completed for transfer of multiple block read
- When reception of the response to CMD52 that was issued by setting the IOABT bit to 1 is completed for transfer of multiple block write
- This bit is set when a command sequence is halted because of a communications error or timeout.

[Clearing conditions]

- When 0 is written to ACEND
- When the access end bit is set to 1.

Note: The ACEND flag becomes 1 after the command sequence ends.

SDCDRM flag (SDnCD Removal Flag)

The SDCDRM flag indicates that SDnCD was removed.

[Setting condition]

- After a change in SDnCD from 0 to 1, Mcycle elapsed with SDnCD held at 1.

[Clearing conditions]

- When 0 is written to SDCDRM.

Note: Mcycle is set in bits [3:0] in SD_OPTION.

SDCDIN flag (SDnCD Insertion Flag)

The SDCDIN flag indicates that SDnCD was inserted.

[Setting condition]

- After a change in SDnCD from 1 to 0, Mcycle elapsed with SDnCD held at 0.

[Clearing conditions]

- When 0 is written to SDCDIN.

Note: Mcycle is set in bits [3:0] in SD_OPTION.

SDD3RM flag (SDnDAT3 Removal Flag)

The SDD3RM flag indicates that SDnDAT3 was removed.

[Setting condition]

- After a change in SDnDAT3 from 1 to 0, two cycles of PCLKB elapsed with SDnDAT3 held at 0.

[Clearing condition]

- When 0 is written to SDD3RM.

SDD3IN flag (SDnDAT3 Insertion Flag)

The SDD3IN flag indicates that SDnDAT3 was inserted.

[Setting condition]

- After a change in SDnDAT3 from 0 to 1, two cycles of PCLKB elapsed with SDnDAT3 held at 1.

[Clearing condition]

- When 0 is written to SDD3IN.

40.2.11 SD_INFO2 : SD Card Interrupt Flag Register 2

Base address: SDHIn = 0x4025_2000 + 0x0400 × n (n = 0, 1)
SDHIn_NS = 0x5025_2000 + 0x0400 × n (n = 0, 1)

Offset address: 0x03C

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	ILA	CBSY	SD_CLK_CTRLLEN	—	—	—	BWE	BRE	SDD0MON	RSPTO	ILR	ILW	DTO	ENDE	CRCE	CMDE
Value after reset:	0 ^{*1}	0 ^{*1}	1 ^{*1}	0	x	0	0 ^{*1}	0 ^{*1}	x	0 ^{*1}	0 ^{*1}	0 ^{*1}	0 ^{*1}	0 ^{*1}	0 ^{*1}	0 ^{*1}

Bit	Symbol	Function	R/W
0	CMDE	Command Error Detection Flag 0: Command error not detected 1: Command error detected	R/W ^{*2}
1	CRCE	CRC Error Detection Flag 0: CRC error not detected 1: CRC error detected	R/W ^{*2}
2	ENDE	End Bit Error Detection Flag 0: End bit error not detected 1: End bit error detected	R/W ^{*2}
3	DTO	Data Timeout Detection Flag 0: Data timeout not detected 1: Data timeout detected	R/W ^{*2}
4	ILW	SD_BUF0 Illegal Write Access Detection Flag 0: Illegal write access to the SD_BUF0 register not detected 1: Illegal write access to the SD_BUF0 register detected	R/W ^{*2}
5	ILR	SD_BUF0 Illegal Read Access Detection Flag 0: Illegal read access to the SD_BUF0 register not detected 1: Illegal read access to the SD_BUF0 register detected	R/W ^{*2}
6	RSPTO	Response Timeout Detection Flag 0: Response timeout not detected 1: Response timeout detected	R/W ^{*2}
7	SDD0MON	SDnDAT0 Pin Status Flag 0: SDnDAT0 pin is low 1: SDnDAT0 pin is high	R
8	BRE	SD_BUF0 Read Enable Flag 0: Disable read access to the SD_BUF0 register 1: Enable read access to the SD_BUF0 register	R/W ^{*2}
9	BWE	SD_BUF0 Write Enable Flag 0: Disable write access to the SD_BUF0 register 1: Enable write access to the SD_BUF0 register	R/W ^{*2}
10	—	This bit is read as 0. The write value should be 0.	R/W
11	—	The read value is undefined. The write value should be 1.	R/W
12	—	This bit is read as 0. The write value should be 0.	R/W
13	SD_CLK_CTRLLEN	SD_CLK_CTRL Write Enable Flag 0: SD/MMC bus (CMD and DAT lines) is busy, so write access to the SD_CLK_CTRL.CLKEN and CLKSEL[7:0] bits is disabled 1: SD/MMC bus (CMD and DAT lines) is not busy, so write access to the SD_CLK_CTRL.CLKEN and CLKSEL[7:0] bits is enabled	R

Bit	Symbol	Function	R/W
14	CBSY	Command Sequence Status Flag 0: Command sequence complete 1: Command sequence in progress (busy)	R
15	ILA	Illegal Access Error Detection Flag 0: Illegal access error not detected 1: Illegal access error detected	R/W ²
31:16	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

Note 1. The value is initialized by a reset and also on reset triggered by the `SOFT_RST.SDRST` flag.

Note 2. The flag does not change even if set to 1. Writing 0 changes the flag value to 0.

The `SD_INFO2` register indicates the status of the SD buffer and the status of the SD card/MMC. Set flags to be cleared to 0. Set flags that are not being cleared to 1.

CMDE flag (Command Error Detection Flag)

The CMDE flag indicates that a command error was detected. The command sequence stops when a command error occurs. When the `SDIO_MODE.C52PUB` bit is set to 1 and `CMD52` is automatically issued, if a communication error or response timeout occurs, the command sequence is not completed. Perform the error processing shown in [section 40.3.12. IO_RW_EXTENDED Command \(SD: CMD53/Multiple Block Read\)](#) or [section 40.3.13. IO_RW_EXTENDED Command \(SD: CMD53/Multiple Block Write\)](#), and complete the command sequence.

[Setting conditions]

- The command index of the transmitted command differs from the command index of the received response.
- The command index of a command issued within a command sequence differs from the command index of the received response.

[Clearing condition]

- When 0 is written to CMDE.

CRCE flag (CRC Error Detection Flag)

The CRCE flag indicates that a CRC error was detected. The command sequence stops when a CRC error occurs. When the `SDIO_MODE.C52PUB` bit is set to 1 and `CMD52` is automatically issued, if a communication error or response timeout occurs, the command sequence is not completed. Perform the error processing shown in [section 40.3.12. IO_RW_EXTENDED Command \(SD: CMD53/Multiple Block Read\)](#) or [section 40.3.13. IO_RW_EXTENDED Command \(SD: CMD53/Multiple Block Write\)](#), and complete the command sequence.

[Setting conditions]

- When an error occurs in the CRC status.
- When a CRC error occurs in the read data.
- When a CRC error occurs in the response.
- A CRC error in the response to a command issued within a command sequence.

[Clearing condition]

- When 0 is written to CRCE.

ENDE flag (End Bit Error Detection Flag)

The ENDE flag indicates that an end bit error was detected. The command sequence is stopped when an end bit error occurs. When the `SDIO_MODE.C52PUB` bit is set to 1 and `CMD52` is automatically issued, if a communication error or response timeout occurs, the command sequence is not completed. Perform the error processing shown in [section 40.3.12. IO_RW_EXTENDED Command \(SD: CMD53/Multiple Block Read\)](#) or [section 40.3.13. IO_RW_EXTENDED Command \(SD: CMD53/Multiple Block Write\)](#), and complete the command sequence.

[Setting conditions]

- When an error occurs in the response length (and the end bit is not detected).
- When an error occurs in the read data length (and the end bit is not detected among the valid bits).

- When an error occurs in the CRC status length (and the end bit is not detected).
- An error in the length of a response to a command issued within a command sequence, for example when the end bit is not detected.

[Clearing condition]

- When 0 is written to ENDE.

DTO flag (Data Timeout Detection Flag)

The DTO flag indicates that a data timeout was detected. The command sequence stops when a data timeout occurs.

[Setting conditions]

- After R1b response, the busy state (SDnDAT0 = 0) continues for longer than Ncycle.
- After CRC status, the busy state (SDnDAT0 = 0) continues for longer than Ncycle.
- After write data, the CRC status is not received though Ncycle has elapsed.
- After read command, read data is not received though a time longer than Ncycle has elapsed.
- After CMD12 is issued within a command sequence, the busy state (SDnDAT0 = 0) for longer than Ncycle continues.
- After the reception of read data, read data for the next block are not received though a time longer than Ncycle has elapsed.
- After release of the read wait state, read data for the next block are not received though a time longer than Ncycle has elapsed.

Note: Ncycle is set in bits [7:4] in SD_OPTION.

[Clearing condition]

- When 0 is written to DTO.

ILW flag (SD_BUF0 Illegal Write Access Detection Flag)

The ILW flag indicates that an SD_BUF0 illegal write access was detected.

[Setting conditions]

- When data is written to SD_BUF0 while it is not in the data read/write command state.
- When data is written to SD_BUF0 while SD_BUF is full.
- When data is written to SD_BUF0 while an error occurs in the CRC status or CRC status length.
- When data is written to SD_BUF0 while a busy state after the CRC status continues for longer than Ncycle.

Note: Ncycle is set in bits [7:4] in SD_OPTION.

[Clearing condition]

- When 0 is written to ILW.

ILR flag (SD_BUF0 Illegal Read Access Detection Flag)

The ILR flag indicates that an SD_BUF0 illegal read access was detected.

[Setting conditions]

- When SD_BUF is empty while SD_BUF0 is read.
- When data with a CRC error or END error is read from SD_BUF0.

[Clearing condition]

- When 0 is written to ILR.

RSPTO flag (Response Timeout Detection Flag)

The RSPTO flag indicates that a response timeout was detected. The command sequence is stopped when a response timeout occurs. When the SDIOMD.C52PUB bit is set to 1 and CMD52 is automatically issued, if a communication error

or response timeout occurs, the command sequence is not completed. Perform the error processing shown in [section 40.3.12. IO_RW_EXTENDED Command \(SD: CMD53/Multiple Block Read\)](#) or [section 40.3.13. IO_RW_EXTENDED Command \(SD: CMD53/Multiple Block Write\)](#), and complete the command sequence.

[Setting condition]

- When a response is not received though a time longer than 640 cycles of SD/MMC clock has elapsed (including a response to a command issued within a command sequence).

[Clearing condition]

- When 0 is written to RSPTO.

SDD0MON flag (SDnDAT0 Pin Status Flag)

The SDD0MON flag indicates the status of the SDnDAT0 pin. If the data timeout (DTO) is set but the response timeout (RSPTO) is not set after the Erase command is issued, the end of the Erase sequence (SDD0MON = 1) is confirmed by polling DAT0.

If a communication error or timeout occurs during a write sequence, the DAT0 bit might retain the value 0.

While the SD/MMC clock is stopped, the DAT0 bit retains the value before the clock is stopped.

BRE flag (SD_BUF0 Read Enable Flag)

The BRE flag indicates that SD_BUF0 is enabled for reading.

[Setting conditions]

- When data set in SD_SIZE is stored in SD_BUF0 at single block transfer.
- When data set in SD_SIZE is stored in either bank 1 or bank 2 of SD_BUF0 at multiple block transfer.

[Clearing conditions]

- When 0 is written to BRE
- Reading of a block of data from SD_BUF0 by DMA transfer

When data is read from SD_BUF0 by the CPU, clear BRE then read the amount of data specified in SD_SIZE.

Even if a CRC error or an END error occurs while block data is read, data is stored in SD_BUF0 and BRE is set.

BWE flag (SD_BUF0 Write Enable Flag)

The BWE flag indicates that SD_BUF0 is enabled for writing.

[Setting conditions]

- When SD_BUF0 is empty at single block transfer.
- When either bank 1 or bank 2 of SD_BUF0 is empty at multiple block transfer.

[Clearing conditions]

- When 0 is written to BWE.
- Writing of a block of data to SD_BUF0 by DMA transfer.

When data is written to SD_BUF0 by the CPU, clear BWE and then write the amount of data specified in SD_SIZE.

SD_CLK_CTRLLEN flag (SD_CLK_CTRL Write Enable Flag)

When a command sequence is started by writing to SD_CMD, the CBSY bit is set to 1 and, at the same time, the SD_CLK_CTRLLEN bit is set to 0. The SD_CLK_CTRLLEN bit is set to 1 after 8 cycles of SDCLK have elapsed after the CBSY bit clears to 0 on completion of the command sequence.

ILA flag (Illegal Access Error Detection Flag)

The ILA flag indicates that an illegal access error was detected.

[Setting conditions]

- Writing of data to SD_CMD within a command sequence (CBSY = 1).

- When SD_CMD[11] = 1 (command with data transfer) and SD_CMD[7:0] = 0000 1100b (CMD12) are set in SD_CMD.

[Clearing condition]

- When 0 is written to ILA.

40.2.12 SD_INFO1_MASK : SD INFO1 Interrupt Mask Register

Base address: SDHIn = 0x4025_2000 + 0x0400 × n (n = 0, 1)
SDHIn_NS = 0x5025_2000 + 0x0400 × n (n = 0, 1)

Offset address: 0x040

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

6	RSPTOM	Response Timeout Interrupt Request Mask 0: Do not mask response timeout interrupt request 1: Mask response timeout interrupt request	R/W
7	—	This bit is read as 0. The write value should be 0.	R/W
8	BREM*1	BRE Interrupt Request Mask 0: Do not mask read enable interrupt request for the SD buffer 1: Mask read enable interrupt request for the SD buffer	R/W
9	BWEM*1	BWE Interrupt Request Mask 0: Do not mask write enable interrupt request for the SD_BUF0 register 1: Mask write enable interrupt request for the SD_BUF0 register	R/W
10	—	This bit is read as 0. The write value should be 0.	R/W
11	—	This bit is read as 1. The write value should be 1.	R/W
14:12	—	These bits are read as 0. The write value should be 0.	R/W
15	ILAM	Illegal Access Error Interrupt Request Mask 0: Do not mask illegal access error interrupt request 1: Mask illegal access error interrupt request	R/W
31:16	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

Note 1. When the SD_INFO2_MASK.BWEM bit is 0 or the SD_INFO2_MASK.BREM bit is 0, set the SD_DMAEN.DMAEN bit to 0. When the SD_DMAEN.DMAEN bit is 1, set the SD_INFO2_MASK.BWEM bit to 1 and the SD_INFO2_MASK.BREM bit to 1.

The SD_INFO2_MASK register enables or disables interrupt requests from the status flags in the SD_INFO2 register. See [Table 40.5](#) for details on the relationship between the status flags and the requested interrupt source.

40.2.14 SD_CLK_CTRL : SD Clock Control Register

Base address: SDHIn = 0x4025_2000 + 0x0400 × n (n = 0, 1)
SDHIn_NS = 0x5025_2000 + 0x0400 × n (n = 0, 1)

Offset address: 0x048

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	CLKC TRLE N	CLKE N	CLKSEL[7:0]							
Value after reset:	0	0	0	0	0	0	0	0 ¹	0	0	1	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	CLKSEL[7:0]	SDHI Clock Frequency Select ^{*2} 0xFF: PCLKB 0x00: PCLKB/2 0x01: PCLKB/4 0x02: PCLKB/8 0x04: PCLKB/16 0x08: PCLKB/32 0x10: PCLKB/64 0x20: PCLKB/128 0x40: PCLKB/256 0x80: PCLKB/512 Others: Setting prohibited	R/W
8	CLKEN	SD/MMC Clock Output Control ^{*2} 0: Disable SD/MMC clock output (fix SDnCLK signal low) 1: Enable SD/MMC clock output	R/W
9	CLKCTRLN	SD/MMC Clock Output Automatic Control Select 0: Disable automatic control of SD/MMC clock output 1: Enable automatic control of SD/MMC clock output	R/W
31:10	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

Note 1. The value is initialized by a reset and also on reset triggered by the SOFT_RST.SDRST flag.

Note 2. Bits CLKSEL[7:0] and CLKEN cannot be write accessed when the SD_INFO2.SD_CLK_CTRLN flag is 0.

The SD_CLK_CTRL register controls the SD/MMC clock frequency settings and output. Set the CLKEN bit to 1 before writing to the SD_CMD register to start a command sequence. Do not write to the SD_CLK_CTRL register when the SD_INFO2.SD_CLK_CTRLN flag is 0.

CLKCTRLN bit (SD/MMC Clock Output Automatic Control Select)

The CLKCTRLN bit enables or disables the automatic control function for SD/MMC clock output, which causes the SD/MMC clock to output only within a command sequence.

The timing with which SD/MMC clock output starts and stops is as follows:

- SD/MMC clock output starts after writing to SD_CMD
- SD/MMC clock output stops when 8 cycles of SD/MMC clock have elapsed after the end of the command sequence.

In addition, SD/MMC clock is fixed to 0 while SCLKEN of SD_CLK_CTRL is 0, regardless of the value of this bit.

40.2.15 SD_SIZE : Transfer Data Length Register

Base address: SDHIn = 0x4025_2000 + 0x0400 × n (n = 0, 1)
SDHIn_NS = 0x5025_2000 + 0x0400 × n (n = 0, 1)

Offset address: 0x04C

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	LEN[9:0]									
Value after reset:	0	0	0	0	0	0	1	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
9:0	LEN[9:0]	Transfer Data Size Setting These bits specify the transfer data size.*1	R/W
31:10	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

Note 1. Do not rewrite these bits when the SD_INFO2.CBSY flag is 1.

The SD_SIZE register sets the transfer data size.

LEN[9:0] bits (Transfer Data Size Setting)

When using single block transfer, the transfer data size can be set in the LEN[9:0] bits from 1 byte to 512 bytes. When CMD12 is automatically issued during a multiblock transfer sequence (CMD18 and CMD25), the transfer data size can only be set to 512 bytes. When CMD12 is not automatically issued during a multiblock transfer sequence, the transfer data size can be set to 32, 64, 128, 256, or 512 bytes. However, a 32, 64, 128, or 256 bytes multiblock read transfer can only be performed during an SDIO multiblock transfer (CMD53). Do not set these bits to 0 when using a command that includes data transfer.

40.2.16 SD_OPTION : SD Card Access Control Option Register

Base address: SDHIn = 0x4025_2000 + 0x0400 × n (n = 0, 1)
SDHIn_NS = 0x5025_2000 + 0x0400 × n (n = 0, 1)

Offset address: 0x050

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	WIDT H	—	WIDT H8	—	—	—	—	TOUT MASK	TOP[3:0]				CTOP[3:0]			
Value after reset:	0*1	1	0*1	0	0	0	0	0*1	1*1	1*1	1*1	0*1	1*1	1*1	1*1	0*1

Do not set 8-bit width.	WIDTH	WIDTH8	Bus Width	0	1	8-bit width	0	0	4-bit width	1	0	1-bit width	1	1	1-bit width	R/W
WIDTH	WIDTH8	Bus Width																
0	1	8-bit width																
0	0	4-bit width																
1	0	1-bit width																
1	1	1-bit width																
31:16	—	These bits are read as 0. The write value should be 0.	R/W															

Note: S-TYPE-3, P-TYPE-3

Note 1. The value is initialized by a reset and also on reset triggered by the SOFT_RST.SDRST flag.

Note 2. Do not rewrite these bits when the SD_INFO2.CBSY flag is 1.

The SD bus width and timeout counter are set in the SD_OPTION register.

40.2.17 SD_ERR_STS1 : SD Error Status Register 1

Base address: SDHIn = 0x4025_2000 + 0x0400 × n (n = 0, 1)
SDHIn_NS = 0x5025_2000 + 0x0400 × n (n = 0, 1)

Offset address: 0x058

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Value after reset:	0	0 ^{*1}	1 ^{*1}	0 ^{*1}	0 ^{*1}	0 ^{*1}	0 ^{*1}	0 ^{*1}	0	0	0 ^{*1}	0 ^{*1}	0 ^{*1}	0 ^{*1}	0 ^{*1}	0 ^{*1}

Bit	Symbol	Function	R/W
0	CMDE0	Command Error Flag 0 0: No error exists in command index field value of a command ^{*2} response 1: Error exists in command index field value of a command ^{*2} response	R
1	CMDE1	Command Error Flag 1 0: No error exists in command index field value of a command ^{*3} response 1: Error exists in command index field value of a command ^{*3} response (with SD_CMD.CMDIDX[5:0] setting, an error that occurs with CMD12 issue is indicated in the CMDE0 flag)	R
2	RSPLNE0	Response Length Error Flag 0 0: No error exists in command ^{*2} response length 1: Error exists in command ^{*2} response length	R
3	RSPLNE1	Response Length Error Flag 1 0: No error exists in command ^{*3} response length 1: Error exists in command ^{*3} response length (with SD_CMD.CMDIDX[5:0] setting, an error that occurs with CMD12 issue is indicated in the RSPLNE0 flag)	R
4	RDLENE	Read Data Length Error Flag 0: No read data length error occurred 1: Read data length error occurred	R
5	CRCLNE	CRC Status Token Length Error Flag 0: No CRC status token length error occurred 1: CRC status token length error occurred	R
7:6	—	These bits are read as 0.	R
8	RSPCRCE0	Response CRC Error Flag 0 0: No CRC error detected in command ^{*2} response 1: CRC error detected in command ^{*2} response	R
9	RSPCRCE1	Response CRC Error Flag 1 0: No CRC error detected in command ^{*3} response (with SD_CMD.CMDIDX[5:0] setting, an error that occurs with CMD12 issue is indicated in the RSPCRCE0 flag) 1: CRC error detected in command ^{*3} response	R
10	RDCRCE	Read Data CRC Error Flag 0: No CRC error detected in read data 1: CRC error detected in read data	R
11	CRCTKE	CRC Status Token Error Flag 0: No error detected in CRC status token 1: Error detected in CRC status token	R

Bit	Symbol	Function	R/W
14:12	CRCTK[2:0]	CRC Status Token These bits store the CRC status token value (normal value is 010b).	R
31:15	—	These bits are read as 0.	R

Note: S-TYPE-3, P-TYPE-3

Note 1. The value is initialized by a reset and also on reset triggered by the `SOFT_RST.SDRST` flag.

Note 2. CMD other than CMD12 when automatic issuing is enabled for multiple block transfer by the setting in `SD_CMD`, CMD12 when the STP bit in `SD_STOP` is set to 1, or CMD52 when the C52PUB or IOABT bit in `SDIO_MODE` is set to 1.

Note 3. CMD12 when automatic issuing is enabled for multiple block transfer by the setting in `SD_CMD`, CMD12 when the STP bit in `SD_STOP` is set to 1, or CMD52 when the C52PUB or IOABT bit in `SDIO_MODE` is set to 1.

The `SD_ERR_STS1` register indicates the CRC status token, CRC error, end bit error, and command error.

40.2.18 SD_ERR_STS2 : SD Error Status Register 2

Base address: `SDHIn = 0x4025_2000 + 0x0400 × n (n = 0, 1)`
`SDHIn_NS = 0x5025_2000 + 0x0400 × n (n = 0, 1)`

Offset address: 0x05C

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	CRCB SYTO	CRCT O	RDTO	BSYT O1	BSYT O0	RSPT O1	RSPT O0
Value after reset:	0	0	0	0	0	0	0	0	0	0 ^{*1}	0 ^{*1}	0 ^{*1}	0 ^{*1}	0 ^{*1}	0 ^{*1}	0 ^{*1}

Bit	Symbol	Function	R/W
0	RSPTO0	Response Timeout Flag 0 0: After command ^{*2} was issued, response was received in less than 640 cycles of the SD/MMC clock 1: After command ^{*2} was issued, response was not received in 640 or more cycles of the SD/MMC clock	R
1	RSPTO1	Response Timeout Flag 1 0: After command ^{*3} was issued, response was received in less than 640 cycles of the SD/MMC clock 1: After command ^{*3} was issued, response was not received after 640 or more cycles of the SD/MMC clock (with <code>SD_CMD.CMDIDX[5:0]</code> setting, an error that occurs with CMD12 issue is indicated in the RSPTO0 flag)	R
2	BSYTO0	Busy Timeout Flag 0 0: After R1b response was received, SD/MMC was released from the busy state during the specified period ^{*4} 1: After R1b response was received, SD/MMC was in the busy state after the specified period ^{*4} elapsed	R
3	BSYTO1	Busy Timeout Flag 1 0: After CMD12 was automatically issued, SD/MMC was released from the busy state during the specified period ^{*4} 1: After CMD12 was automatically issued, SD/MMC was in the busy state after the specified period ^{*4} elapsed (with <code>SD_CMD.CMDIDX[5:0]</code> setting, an error that occurs with CMD12 issue is indicated in the BSYTO0 flag)	R
4	RDTO	Read Data Timeout Flag When a read command is issued, this flag sets to 1 when read data is not received after the specified period ^{*4} elapses. When read data is received, this flag sets to 1 when the next block of read data is not received after the specified period ^{*4} elapses. When the SD/MMC exits the read wait state, this flag sets to 1 when the next block of read data is not received after the specified period ^{*4} elapses.	R

Bit	Symbol	Function	R/W
5	CRCTO	CRC Status Token Timeout Flag 0: After CRC data was written to the SD card/MMC, a CRC status token was received during the specified period* ⁴ 1: After CRC data was written to the SD card/MMC, a CRC status token was not received after the specified period* ⁴ elapsed	R
6	CRCBSYTO	CRC Status Token Busy Timeout Flag 0: After a CRC status token was received, the SD/MMC was released from the busy state during the specified period* ⁴ 1: After a CRC status token was received, the SD/MMC was in the busy state after the specified period* ⁴ elapsed	R
31:7	—	These bits are read as 0.	R

Note: S-TYPE-3, P-TYPE-3

Note 1. The value is initialized by a reset and also on reset triggered by the SOFT_RST.SDRST flag.

Note 2. CMD other than CMD12 when automatic issuing is enabled for multiple block transfer by the setting in SD_CMD, CMD12 when the STP bit in SD_STOP is set to 1, or CMD52 when the C52PUB or IOABT bit in SDIO_MODE is set to 1.

Note 3. CMD12 when automatic issuing is enabled for multiple block transfer by the setting in SD_CMD, CMD12 when the STP bit in SD_STOP is set to 1, or CMD52 when the C52PUB or IOABT bit in SDIO_MODE is set to 1.

Note 4. Set the SD_OPTION.TOP[3:0] bits to select the number of *n* cycles.

The SD_ERR_STS2 register indicates the timeout status.

40.2.19 SD_BUF0 : SD Buffer Register

Base address: SDHIn = 0x4025_2000 + 0x0400 × *n* (*n* = 0, 1)
SDHIn_NS = 0x5025_2000 + 0x0400 × *n* (*n* = 0, 1)

Offset address: 0x060

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:																
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:																
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x

Bit	Symbol	Function	R/W
31:0	n/a	When writing to the SD card, the write data is written to this register. When reading from the SD card, the read data is read from this register.	R/W

This register is internally connected to two 512-byte buffers.

If both buffers are not empty when executing multiple block read, the SD card/MMC clock is stopped to suspend receiving data. When one of the buffers is empty, the SD card/MMC clock is supplied to resume receiving data.

40.2.20 SDIO_MODE : SDIO Mode Control Register

Base address: SDHIn = 0x4025_2000 + 0x0400 × n (n = 0, 1)
SDHIn_NS = 0x5025_2000 + 0x0400 × n (n = 0, 1)

Offset address: 0x068

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	C52P UB	IOABT	—	—	—	—	—	RWRE Q	—	INTEN
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	INTEN	SDIO Interrupt Acceptance Enable*1 0: Disable SDIO interrupt acceptance 1: Enable SDIO interrupt acceptance	R/W
1	—	This bit is read as 0. The write value should be 0.	R/W
2	RWREQ	Read Wait Request 0: Allow SD/MMC to exit read wait state 1: Request for SD/MMC to enter read wait state	R/W
7:3	—	These bits are read as 0. The write value should be 0.	R/W
8	IOABT	SDIO Abort If this bit is set to 1 during multiblock transfer triggered by CMD53, CMD52 is immediately issued, and the command sequence is aborted.	R/W
9	C52PUB	SDIO None Abort If this bit is set to 1 during multiblock transfer triggered by CMD53, CMD52 is issued after the transfer process is complete, and the command sequence is completed.	R/W
31:10	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

Note 1. Do not rewrite this bit when the SD_INFO2.CBSY flag is 1.

The SDIO_MODE register controls reception of the SDIO interrupt, CMD52 issuance during multiblock transfer, and read wait request. Do not set bits C52PUB and IOABT to 1 at the same time.

RWREQ bit (Read Wait Request)

When RWREQ is set to 1 in the CMD53 (multiple block) read sequence, the block transfer enters the read wait state between blocks.

[Read wait state releasing]

- The read wait state is released, when RWREQ is cleared to 0 in the read wait state.
- When IOABT is set to 1 in the read wait state, RWREQ is automatically cleared to 0 after CMD52 is issued, and then the read wait state is released.
- When C52PUB and RWREQ are set to 1 simultaneously in the CMD53 (multiple block) read sequence, the read wait state is not automatically released. Therefore, after the CMD52 response is received, clear RWREQ. You must set RWREQ and C52PUB simultaneously.

When RWREQ is set to 1 while the last block in the CMD53 (multiple block) read sequence is transferred, the read wait state is not entered and RWREQ is automatically cleared to 0 by setting access end. Set RWREQ to 1 after the response end flag sets.

IOABT bit (SDIO Abort)

When the IOABT bit is set to 1 in a CMD53 (multiple block) sequence, the CMD53 sequence is halted and CMD52 is issued. However, if a command sequence is halted because of a communication error or timeout, CMD52 is not issued.

Although continued buffer access is possible even after IOABT is set to 1, the buffer access error bit (ILR or ILW) in SD_INFO2 is set accordingly. Set SD_ARG before setting IOABT to 1.

When IOABT is set to 1 during transfer for a single block write, the access end flag sets when SD_BUF0 becomes empty, and CMD52 is not issued. If SD_BUF0 contains data, the access end flag sets on completion of reception of the busy state without CMD52 being issued.

When IOABT is set to 1 during transfer for single block read, the access end flag sets immediately after IOABT is set, and CMD52 is not issued.

When IOABT is set to 1 during reception of the busy state after an R1b response, the access end flag sets on completion of reception of the busy state without CMD52 being issued.

When IOABT is set to 1 after a command sequence is completed, CMD52 is not issued and the access end flag does not set.

Set IOABT to 1 after the response end flag sets.

Set IOABT to 0 after the access end flag sets.

C52PUB bit (SDIO None Abort)

When the C52PUB bit is set to 1 in the CMD53 (multiple block) write sequence, CMD52 is automatically issued between blocks if SD_BUF0 becomes empty. C52PUB is automatically cleared to 0 after reception of the response to CMD52 is completed. Additionally, if C52PUB is set to 1 while the last block is being transferred, CMD52 is not issued. In this case, C52PUB is automatically cleared to 0 after the access end flag sets to 1.

When C52PUB and RWREQ are set to 1 in the CMD53 (multiple block) read sequence, the block transfer enters the read wait state between blocks and CMD52 is automatically issued. C52PUB is automatically cleared to 0 after reception of the response to CMD52 is completed. Additionally, if C52PUB is set to 1 while the last block is being transferred, CMD52 is not issued. In this case, C52PUB is automatically cleared to 0 after the access end flag sets to 1.

If C52PUB is set to 1 in the CMD53 (multiple block) read sequence, you must set RWREQ to 1 in addition to C52PUB.

Set SD_ARG before setting C52PUB to 1.

Set C52PUB to 1 after the response end flag sets.

40.2.21 SDIO_INFO1 : SDIO Interrupt Flag Register

Base address: SDHIn = 0x4025_2000 + 0x0400 × n (n = 0, 1)
SDHIn_NS = 0x5025_2000 + 0x0400 × n (n = 0, 1)

Offset address: 0x06C

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	EXWT	EXPUB52	—	—	—	—	—	—	—	—	—	—	—	—	—	IOIRQ
Value after reset:	0 ^{*1}	0 ^{*1}	0	0	0	0	0	0	0	0	0	0	0	x	x	0 ^{*1}

Bit	Symbol	Function	R/W
0	IOIRQ	SDIO Interrupt Status Flag 0: No SDIO interrupt detected 1: SDIO interrupt detected	R/(W) ^{*2}
2:1	—	The read values are undefined. The write value should be 1.	R/W
13:3	—	These bits are read as 0. The write value should be 0.	R/W
14	EXPUB52	EXPUB52 Status Flag Indicates the status of the EXPUB52.	R/(W) ^{*2}
15	EXWT	EXWT Status Flag Indicates the status of the EXWT.	R/(W) ^{*2}

Bit	Symbol	Function	R/W
31:16	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

Note 1. The value is initialized by a reset and also on reset triggered by the `SOFT_RST.SDRST` flag.

Note 2. Only 0 can be written to clear the bit.

The `SDIO_INFO1` register indicates the status of the SDIO card access. Set flags to be cleared to 0. Set flags that are not being cleared to 1.

IOIRQ flag (SDIO Interrupt Status Flag)

The IOIRQ flag indicates that an SDIO interrupt occurred.

[Setting condition]

- When SDIO interrupt from an SDIO card is received while `INTEN` in `SDIO_MODE` is set to 1.

[Clearing condition]

- When 0 is written to IOIRQ.*¹

Note 1. Before clearing this bit, access the SDIO card to negate the SDIO interrupt signal from the SDIO card. If the interrupt signal is not negated, this bit can be set again.

EXPUB52 flag (EXPUB52 Status Flag)

The EXPUB52 flag indicates the EXPUB52 status.

[Setting conditions]

- While the last block in the CMD53 (multiple block) sequence is transferred, `C52PUB` in `SDIO_MODE` is set to 1.
- While `C52PUB` is set to 1 in the CMD53 (multiple block) write sequence, the last block is transferred.

[Clearing condition]

- When 0 is written to EXPUB52.

EXWT flag (EXWT Status Flag)

The EXWT flag indicates the EXWT status.

[Setting condition]

- While the last block in the CMD53 (multiple block) read sequence is transferred, `RWREQ` in `SDIO_MODE` is set to 1.

[Clearing condition]

- When 0 is written to EXWT.

40.2.22 SDIO_INFO1_MASK : SDIO INFO1 Interrupt Mask Register

Base address: $\text{SDHIn} = 0x4025_2000 + 0x0400 \times n$ ($n = 0, 1$)
 $\text{SDHIn_NS} = 0x5025_2000 + 0x0400 \times n$ ($n = 0, 1$)

Offset address: 0x070

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	EXWT M	EXPU B52M	—	—	—	—	—	—	—	—	—	—	—	—	—	IOIRQ M
Value after reset:	1	1	0	0	0	0	0	0	0	0	0	0	0	1	1	1

Bit	Symbol	Function	R/W
0	IOIRQM	IOIRQ Interrupt Mask Control 0: Do not mask IOIRQ interrupts 1: Mask IOIRQ interrupts	R/W
2:1	—	These bits are read as 1. The write value should be 1.	R/W
13:3	—	These bits are read as 0. The write value should be 0.	R/W
14	EXPUB52M	EXPUB52 Interrupt Request Mask Control 0: Do not mask EXPUB52 interrupt requests 1: Mask EXPUB52 interrupt requests	R/W
15	EXWTM	EXWT Interrupt Request Mask Control 0: Do not mask EXWT interrupt requests 1: Mask EXWT interrupt requests	R/W
31:16	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

The SDIO_INFO1_MASK register enables or disables interrupt requests from the status flags in the SDIO_INFO1 register. See [Table 40.5](#) for details on the relationship between the status flags and the requested interrupt source.

40.2.23 SD_DMAEN : DMA Mode Enable Register

Base address: SDHIn = 0x4025_2000 + 0x0400 × n (n = 0, 1)
SDHIn_NS = 0x5025_2000 + 0x0400 × n (n = 0, 1)

Offset address: 0x1B0

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	DMAEN	—
Value after reset:	0	0	0	1	0	0	0	0	0	0	0	1	0	0	0	0

Bit	Symbol	Function	R/W
0	—	This bit is read as 0. The write value should be 0.	R/W
1	DMAEN	DMA Transfer Enable ^{*1 *2} 0: Disable use of DMA transfer to access SD_BUF0 register 1: Enable use of DMA transfer to access SD_BUF0 register	R/W
3:2	—	These bits are read as 0. The write value should be 0.	R/W
4	—	This bit is read as 1. The write value should be 1.	R/W
11:5	—	These bits are read as 0. The write value should be 0.	R/W
12	—	This bit is read as 1. The write value should be 1.	R/W
31:13	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

Note 1. Do not rewrite this bit when the SD_INFO2.CBSY bit is 1.

Note 2. When the SD_INFO2_MASK.BWEM bit is 0 or the SD_INFO2_MASK.BREM bit is 0, set the SD_DMAEN.DMAEN bit to 0. When the SD_DMAEN.DMAEN bit is 1, set the SD_INFO2_MASK.BWEM bit to 1 and the SD_INFO2_MASK.BREM bit to 1.

The SD_DMAEN register enables or disables DMA transfers.

DMAEN bit (DMA Transfer Enable)

When using DMA transfer to access the SD buffer, set the DMAEN bit to 1 before setting the SD_CMD register.

40.2.24 SOFT_RST : Software Reset Register

Base address: SDHIn = $0x4025_2000 + 0x0400 \times n$ ($n = 0, 1$)
 SDHIn_NS = $0x5025_2000 + 0x0400 \times n$ ($n = 0, 1$)

Offset address: 0x1C0

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	SDRST
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1	1

Bit	Symbol	Function	R/W
0	SDRST	Software Reset Control 0: Reset SD/MMC Host Interface software 1: Cancel reset of SD/MMC Host Interface software	R/W
2:1	—	These bits are read as 1. The write value should be 1.	R/W
31:3	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

Table 40.4 lists the bits and flags initialized by SD/MMC Host Interface software reset.

Table 40.4 Bits and flags initialized by SD/MMC Host Interface software reset

Register	Bit/flag
SD_STOP	SEC, STP
SD_INFO1	RSPEND, ACEND
SD_INFO2	CMDE, CRCE, ENDE, DTO, ILW, ILR, RSPTO, BRE, BWE, SD_CLK_CTRLLEN, CBSY, ILA
SD_CLK_CTRL	CLKEN
SD_OPTION	CTOP[3:0], TOP[3:0], TOUTMASK, WIDTH8, WIDTH
SD_ERR_STS1	CMDE0, CMDE1, RSPLNE0, RSPLNE1, RDLENE, CRCLNE, RSPCRCE0, RSPCRCE1, RDCRCE, CRCTKE, CRCTK[2:0]
SD_ERR_STS2	RSPTO0, RSPTO1, BSYTO0, BSYTO1, RDTO, CRCTO, CRCBSYTO
SDIO_INFO1	IOIRQ, EXPUB52, EXWT
SDIF_MODE	NOCHKCR

40.2.25 SDIF_MODE : SD Interface Mode Setting Register

Base address: SDHIn = $0x4025_2000 + 0x0400 \times n$ ($n = 0, 1$)
 SDHIn_NS = $0x5025_2000 + 0x0400 \times n$ ($n = 0, 1$)

Offset address: 0x1CC

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	NOCHKCR	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0 ^{*1}	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	—	These bits are read as 0. The write value should be 0.	R/W
8	NOCHKCR	CRC Check Mask CRC check mask bit for MMC test commands. Set when CRC16 or CRC status value check is not executed. 0: Enable CRC check 1: Disable CRC Check (ignore CRC16 valued when reading and ignore CRC status value when writing)	R/W
31:9	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

Note 1. The value is initialized by a reset and also on reset triggered by the SOFT_RST.SDRST flag.

NOCHKCR bit (CRC Check Mask)

The NOCHKCR bit is used for MMC test commands. This bit is set when CRC16 or CRC status value check is not executed.

40.2.26 EXT_SWAP : Swap Control Register

Base address: SDHIn = 0x4025_2000 + 0x0400 × n (n = 0, 1)
SDHIn_NS = 0x5025_2000 + 0x0400 × n (n = 0, 1)

Offset address: 0x1E0

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	BRSW P	BWS WP	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
5:0	—	These bits are read as 0. The write value should be 0.	R/W
6	BWSWP	SD_BUF0 Swap Write*1 0: Normal write operation 1: Swap the byte endian order before writing to SD_BUF0 register	R/W
7	BRSWP	SD_BUF0 Swap Read*1 0: Normal read operation 1: Swap the byte endian order before reading SD_BUF0 register	R/W
31:8	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

Note 1. Do not rewrite this bit when the SD_INFO2.CBSY flag is 1.

The EXT_SWAP register selects whether or not the byte endian order is swapped when accessing the SD_BUF0 register. See [section 40.3.1. SD/MMC Interface](#) for details on the differences in accessing the SD_BUF0 register based on the EXT_SWAP register value.

40.3 Operation

40.3.1 SD/MMC Interface

When data is read from the SD card/MMC, the process is as follows:

1. The SD/MMC Host Interface receives data from the SD card/MMC through the SDnDAT signal (see [Figure 40.2](#) and [Figure 40.3](#)).
2. The received data is stored in SD_BUF of the MMC Host Interface (see [Figure 40.4](#)).

3. The data stored in SD_BUF is read from SD_BUF0 (see [Figure 40.5](#)).

When data is written to the SD card/MMC, the specified procedure is reversed.

When accessing SD_BUF0, pay attention to the transfer order in SDnDAT and the store order in SD_BUF. If required, you can change the byte endian of the data read from or written to SD_BUF0 using the SDSWAP register. See [Figure 40.6](#).

Figure 40.2 SDnDAT in 1-bit width mode

Figure 40.3 SDnDAT in 4-bit width mode

Figure 40.4 SDnDAT in 8-bit width mode

Figure 40.5 SD_BUF store data

- 32-bit access, in the case where the data in SD_BUF0 are read without the bytes being swapped (EXT_SWAP: BRSWAP = 0)

- 32-bit access, in the case where the data in SD_BUF0 are read with the bytes being swapped (EXT_SWAP: BRSWAP = 1)

Figure 40.6 Read from SD_BUF0

40.3.2 Card Detect/Write Protect

40.3.2.1 Card detect

The SD/MMC Host Interface has two types of card detect functions.

(1) Card detect with SDnCD (n = 0, 1)

Figure 40.7 shows the timing for card detect using SDnCD. SDnCD is connected to the card socket and pulled up on the host device. The resistance of the pull-up resistor is determined by the specification of the SD/MMC host device.

(2) Card insertion

SDnCD is pulled down when a card is inserted. At this point, if SDnCD is pulled down for the Mcycle period (set in SD_OPTION), SDCDIN in SD_INFO1 is set to 1. It is cleared by writing 0.

(3) Card removal

SDnCD is pulled up when a card is removed. At this point, if SDnCD is pulled up for the Mcycle period (set in SD_OPTION), SDCDRM in SD_INFO1 is set to 1. It is cleared by writing 0.

Figure 40.7 Example of card detect with SDnCD

(4) SD card detect with SDnDAT3 (n = 0, 1)

Figure 40.8 shows the timing when the SD card is detected with SDnDAT3. In addition, SDnDAT3 is pulled down by the host device, and the resistance value for pulling down is determined by the specification of the SD host device.

(5) Card insertion

When an SD card is inserted, SDnDAT3 is pulled up and SDD3IN in SD_INFO1 is set to 1. It is cleared by writing 0.

(6) Card removal

When an SD card is removed, SDnDAT3 is pulled down and SDD3RM in SD_INFO1 is set to 1. It is cleared by writing 0.

Figure 40.8 SD card detect with SDnDAT3

40.3.2.2 Write protect

The SD/MMC Host Interface has two types of write protect functions.

(1) Write protect with SDnWP (n = 0, 1)

SDnWP is connected to the card socket and pulled up or pulled down by the card insertion. The selection of pulling up or pulling down and the resistance value is determined by the specification of the SD host device. When the SDnWP state is reflected to SDWPMON in SD_INFO1, the write protect state is set after the SD card is inserted.

(2) Write protect with command

The internal write protection of the card and the lock/unlock operation of the card are realized by the command.

40.3.3 Interrupt Request and DMA Transfer Request

40.3.3.1 Interrupts

Table 40.5 lists the SDHI interrupt sources. The SDHI requests an interrupt when:

- The status flags in registers SD_INFO1, SD_INFO2, and SDIO_INFO1 set to 1.
- The associated bits in the SD_INFO1_MASK, SD_INFO2_MASK, and SDIO_INFO1_MASK registers are 0.

When clearing the status flags in registers SD_INFO1, SD_INFO2, and SDIO_INFO1, write 0 to the status flags to be cleared and write 1 to the status flags that are not being cleared.

Table 40.5 Interrupt sources

Interrupt sources	Status flag register		Interrupt mask register		Interrupt name
	Register symbol	Bit symbol	Register symbol	Bit symbol	Channel n (n = 0, 1)
Card Access Interrupt (CACI)	SD_INFO1	ACEND	SD_INFO1_MASK	ACENDM	SDHI_MMChn_ACCS
		RSPEND		RSPENDM	
	SD_INFO2	ILA	SD_INFO2_MASK	ILAM	
		BWE		BWEM	
		BRE		BREM	
		RSPTO		RSPTOM	
		ILR		ILRM	
		ILW		ILWM	
		DTO		DTOM	
		ENDE		ENDEM	
		CRCE		CRCEM	
		CMDE		CMDEM	
SDIO Access Interrupt (SDACI)	SDIO_INFO1	EXWT	SDIO_INFO1_MASK	EXWTM	SDHI_MMChn_SDIO
		EXPUB52		EXPUB52M	
		IOIRQ		IOIRQM	
Card Detect Interrupt (CDETI)	SD_INFO1	SDD3IN	SD_INFO1_MASK	SDD3INM	SDHI_MMChn_CARD
		SDD3RM		SDD3RMM	
		SDCDIN		SDCDINM	
		SDCDRM		SDCDRMM	

40.3.3.2 DMA transfer requests (SDHI_MMChn_ODMSDBREQ, n = 0, 1)

The SD/MMC Host Interface has two types of DMA transfer requests.

(1) SD_BUF write DMA transfer request

- When the BWE bit in SD_INFO2 is set to 1 while the DMAEN bit in SD_DMAEN is set to 1, the SD_BUF write DMA transfer request is asserted.
- The SD_BUF write DMA transfer request is negated when the last data in one block (based on the transfer data size set in SD_SIZE) is transferred. The SD_BUF write DMA transfer request is also negated by clearing the SDRST bit in SOFT_RST to 0 or setting the STP bit in SD_STOP to 1. However, if a communications error or timeout occurs at the DMA transfer, the SD_BUF write DMA transfer request is not negated.
- The BWE bit in SD_INFO2 is cleared after transfer of the last data in one block following a request for writing to SD_BUF by DMA transfer.
- The number of DMA transfers must be $n \times$ one block. (n = integer, one block = the transfer data size set in SD_SIZE)
- When the IOABT bit in SDIO_MODE is set to 1, the SD_BUF write DMA transfer request is negated.
- The DMA transfer request is also negated by clearing the DMAEN bit to 0. However, the DMA transfer request is asserted again when the DMAEN bit is set to 1 before writing to SD_CMD.
- Because the BWE bit in SD_INFO2 is not cleared in response to setting the STP/IOABT bit, or to a communications error or timeout, clear the bit to 0 before issuing the next command. The next request to write to SD_BUF by DMA transfer is not issued while the BWE bit is set.

(2) SD_BUF read DMA transfer request

- When the BRE bit in SD_INFO2 is set to 1 while the DMAEN bit in the SD_DMAEN register is set to 1, the SD_BUF read DMA transfer request is asserted.

- The SD_BUF read DMA transfer request is negated when the last data in one block (based on the transfer data size set in SD_SIZE) is transferred. The SD_BUF read DMA transfer request is also negated by clearing the SDRST bit in SOFT_RST to 0 or setting the STP bit in SD_STOP to 1. However, if a communications error or timeout occurs at the DMA transfer, the SD_BUF read DMA transfer request is not negated.
- The BRE bit in SD_INFO2 is cleared after transfer of the last data in one block following a request to write to SD_BUF by DMA transfer.
- The number of DMA transfers must be $n \times$ one block. (n = integer, one block = the transfer data size set in SD_SIZE)
- When the IOABT bit in SDIO_MODE is set to 1, the SD_BUF read DMA transfer request is negated.
- The DMA transfer request is also negated by clearing the DMAEN bit to 0. However, the DMA transfer request is asserted again when the DMAEN bit is set to 1 before writing to SD_CMD.
- Because the BRE bit in SD_INFO2 is not cleared in response to setting the STP/IOABT bit or in response to a communications error or timeout, clear the bit to 0 before issuing the next command. The next request to write to SD_BUF by DMA transfer is not issued while the BRE bit is set.

40.3.4 Communication Errors and Timeouts

When a communication error or timeout error occurs, depending on the type of error, the associated status flag in the SD_INFO2 register sets to 1. Also, depending on the source of the error, the associated flag in the SD_ERR_STS1 or SD_ERR_STS2 register sets to 1.

The status flags in registers SD_ERR_STS1 and SD_ERR_STS2 clear to 0 by writing to the SD_CMD register, or by setting the SOFT_RST.SDRST bit to 0.

Table 40.6 Communication errors

Communication error	Interrupt flag register		Error status register		This occurs when...
	Register symbol	Bit symbol	Register symbol	Bit symbol	
End bit error	SD_INFO2	ENDE	SD_ERR_STS1	CRCLENE	The CRC status token length is in error
				RDLENE	The read data length is in error
				RSPLENE1	The response length is in error ^{*1}
				RSPLENE0	The response length is in error ^{*2}
CRC error		CRCE		CRCTKE	The CRC status token is in error
				RDCRCE	There is a CRC error in the read data
				RSPCRCE1	There is a CRC error in the response ^{*1}
				RSPCRCE0	There is a CRC error in the response ^{*2}
Command error		CMDE		CMDE1	The command index field value for the transmitted command and received response do not match ^{*1}
				CMDE0	The command index field value for the transmitted command and received response do not match ^{*2}

Note 1. CMD12 when automatic issuing is enabled for multiple block transfer by the setting in SD_CMD, CMD12 when the STP bit in SD_STOP is set to 1, or CMD52 when the C52PUB or IOABT bit in SDIO_MODE is set to 1.

Note 2. CMD other than CMD12 when automatic issuing is enabled for multiple block transfer by the setting in SD_CMD, CMD12 when the STP bit in SD_STOP is set to 1, or CMD52 when the C52PUB or IOABT bit in SDIO_MODE is set to 1.

Table 40.7 Timeouts

	Interrupt flag register		Error status register			
Timeout	Register symbol	Bit symbol	Register symbol	Bit symbol	This occurs when...	
Response timeout	SD_INFO2	RSPTO	SD_ERR_STS2	RSPTO1	A response is not received even after a minimum of 640 SDHI clock cycles elapse ^{*1}	
				RSPTO0	A response is not received even after a minimum of 640 SDHI clock cycles elapse ^{*2}	
Data timeout (excluding response timeout)		DTO		CRCBSYTO	After the CRC status token is received, the SDHI is busy for at least the period set ^{*3}	
				CRCTO	After the write data is transmitted, the CRC status token is not received even after at least the period set ^{*3} elapses	
					RDTO	After the read command is issued, the read data is not received even after at least the period set ^{*3} elapses
						After the read data is received, the next block read data is not received even after at least the period set ^{*3} elapses
					After the SDHI exits the read wait state, the next block read data is not received even after at least the period set ^{*3} elapses	
		BSYTO1		After CMD12 is issued during the command sequence, the SDHI is busy for at least the period set ^{*3}		
		BSYTO0		After the R1b response is received, the SDHI is busy for at least the period set ^{*3} (a command other than CMD12 is issued during the command sequence)		

Note 1. CMD12 when automatic issuing is enabled for multiple block transfer by the setting in SD_CMD, CMD12 when the STP bit in SD_STOP is set to 1, or CMD52 when the C52PUB or IOABT bit in SDIO_MODE is set to 1.

Note 2. CMD other than CMD12 when automatic issuing is enabled for multiple block transfer by the setting in SD_CMD, CMD12 when the STP bit in SD_STOP bit is set to 1, or CMD52 when the C52PUB or IOABT bit in SDIO_MODE is set to 1.

Note 3. The period is set in the SD_OPTION.TOP[3:0] bits.

40.3.5 Command without Data Transfer (SD/MMC)

The following legend is used for description of register read/write.

W (register name, value): Write to register

R (register name): Read from register

Figure 40.9 and Figure 40.10 show example flows.

Figure 40.9 Example flow of command without response or data

Figure 40.10 Example flow of command without data

40.3.5.1 Operation for command without data transfer

The operation is described in the following section.

(1) Command without response and data

- a. Flag register clear
First, clear the bits in the flag register. (SD_INFO1 and SD_INFO2)
- b. Control register set
Set the SD/MMC clock and interrupt masking. (SD_CLK_CTRL, SD_INFO1_MASK, and SD_INFO2_MASK)
- c. Command issue
Set CMD argument in SD_ARG and write to SD_CMD.

Accordingly, CMD is issued, and the operation is started.

d. Flag clear

When transmission of a command is completed, RSPEND (response end) in SD_INFO1 is set to 1 to generate an interrupt. Clear RSPEND to 0.

(2) Command without data

a. Flag register clear

First, clear the bits in the flag register. (SD_INFO1 and SD_INFO2)

b. Control register set

Set the SD/MMC clock and interrupt masking. (SD_CLK_CTRL, SD_INFO1_MASK, and SD_INFO2_MASK)

c. Command issue

Set CMD argument in SD_ARG and write to the SD_CMD.
Accordingly, CMD is issued, and the operation is started.

d. Flag clear

When a response is received, RSPEND (response end) in SD_INFO1 is set to 1 to generate an interrupt. Clear RSPEND to 0.

e. Read a response from SD_RSP10. Additionally, perform error processing (clear the interrupt flag register) if a communication error or timeout occurs.

40.3.6 Single Block Read (SD/MMC)

Figure 40.11 shows an example flow of a single block read operation.

Figure 40.11 Example flow of single block read operation

40.3.6.1 Single block read operation

The operation of the single block read is described as follows:

- Flag register clear**
First, clear the bits in the flag register (SD_INFO1 and SD_INFO2).
- Control register set**
Set the SD/MMC clock, transfer data size, interrupt mask (SD_CLK_CTRL, SD_SIZE, SD_INFO1_MASK, and SD_INFO2_MASK).
- Command issue (CMD17)**
Set CMD17 argument in SD_ARG and write 0x0000_0011 to SD_CMD. CMD17 is issued and the single block read operation is started.
- Response check**
On receiving the response, RSPEND (response end) in SD_INFO1 is set to 1 to generate an interrupt. Clear RSPEND to 0 and read the response from SD_RSP10. If the result of response decoding is an error, the command sequence can be halted by setting the STP bit in SD_STP or the IOABT bit in SDIO_MODE to 1. In addition, this causes CMD12 and CMD52 to not be issued. If the ACEND bit (access end) in SD_INFO1 is set, halting the command sequence also leads to the generation of an interrupt.
- Data receive from SD card/MMC and data read**

Write 0x0000_0319 to SD_INFO1_MASK to enable the access end interrupt. In addition, write 0x0000_0A00 to SD_INFO2_MASK to enable the BRE interrupt. When the data received from the SD card/MMC is completed, the BRE bit in SD_INFO2 is set to 1 to generate an interrupt. Clear the BRE bit to 0 and read the amount of data specified in SD_SIZE from SD_BUF0.

A communication error or timeout might be generated if data is being received while reading of SD_BUF0 is in progress.

f. Operation complete

When the data read from SD_BUF0 is completed, ACEND (access end) in SD_INFO1 is set to 1 to generate an interrupt. Clear ACEND to 0 to end the single block read operation.

Additionally, perform error processing (clear the interrupt flag register) if a communication error or timeout occurs.

40.3.7 Single Block Write (SD/MMC)

Figure 40.12 shows an example flow of a single block write operation.

Figure 40.12 Example of single block write operation

40.3.7.1 Single block write operation

The operation of the single block write is described as follows:

- Flag register clear
First, clear the bits in the flag register (SD_INFO1 and SD_INFO2).
- Control register set

Set the SD/MMC clock, transfer data size, interrupt mask (SD_CLK_CTRL, SD_SIZE, SD_INFO1_MASK, and SD_INFO2_MASK).

c. Command issue (CMD24)

Set CMD24 argument in SD_ARG and write 0x0000_0018 to SD_CMD. CMD24 is issued and the single block write operation is started.

d. Response check

On receiving the response, RSPEND (response end) in SD_INFO1 is set to 1 to generate an interrupt. Clear RSPEND to 0 and read the response from SD_RSP10. If the result of response decoding is an error, the command sequence can be halted by setting the STP bit in SD_STP or the IOABT bit in SDIO_MODE to 1. In addition, this causes CMD12 and CMD52 to not be issued. If the ACEND bit (access end) in SD_INFO is set, halting the command sequence also leads to the generation of an interrupt.

e. Data write and data transmit to SD card/MMC

Write 0x0000_0319 to SD_INFO1_MASK to enable the access end interrupt. In addition, write 0x0000_0900 to SD_INFO2_MASK to enable the BWE interrupt. When SD_BUF0 is ready for the data to be written, the BWE bit in SD_INFO2 is set to 1 to generate an interrupt. Clear the BWE bit to 0 and write the amount of data specified in SD_SIZE to SD_BUF0. When the data write to SD_BUF0 is completed, data is transmitted to the SD card. Then, the CRC status and busy state are received from the SD card/MMC.

However, a communications error or timeout might be generated if data is being transmitted after writing to SD_BUF0.

f. Operation complete

When the CRC status and busy state are received from the SD card/MMC, ACEND (access end) in SD_INFO1 is set to 1 to generate an interrupt. Clear the ACEND bit to 0 to end the single block write operation.

In addition, perform error processing (clear the interrupt flag register) if a communication error or timeout occurs.

40.3.8 Multiple Block Read (SD/MMC)

Figure 40.13 shows an example flow of a multiple block read operation.

Figure 40.13 Example of multiple block read operation

40.3.8.1 Multiple block read operation

The operation of the multiple block read is described as follows:

- Flag register clear**
First, clear the bits in the flag register (SD_INFO1 and SD_INFO2).
- Control register set**
Set the SD/MMC clock, transfer data size, interrupt mask (SD_CLK_CTRL, SD_SIZE, SD_INFO1_MASK, and SD_INFO2_MASK).
Set SEC in SD_STOP to 1, and set the number of transfer blocks in SD_SECCNT.
- Command issue (CMD18)**
Set CMD18 argument in SD_ARG and write 0x0000_0012 to SD_CMD. CMD18 is issued and the multiple block read operation is started.
- Response check**
On receiving the response, RSPEND (response end) in SD_INFO1 is set to 1 to generate an interrupt. Clear RSPEND to 0 and read the response from SD_RSP54. If the result of response decoding is an error, the command sequence can be

halted by setting the STP bit in SD_STP to 1. Setting the STP bit to 1 also causes CMD12 to be issued and the response received. If the command sequence is halted because the access end interrupt is enabled, an interrupt is generated when the ACEND bit (access end) bit in SD_INFO1 sets to 1 on completion of response reception. Clear the ACEND bit to 0 and read the response.

e. Data receive from SD card/MMC and data read

Write 0x0000_0319 to SD_INFO1_MASK to enable the access end interrupt. In addition, write 0x0000_0A00 to SD_INFO2_MASK to enable the BRE interrupt. When one-block data received from the SD card/MMC is completed, the BRE bit in SD_INFO2 is set to 1 to generate an interrupt. Clear the BRE bit to 0 and read the amount of data specified in SD_SIZE from SD_BUF0. Doing this repeats transfer of the number of blocks set in SD_SECCNT. However, a communication error or timeout might be generated if data is being received while reading of SD_BUF0 is in progress. CMD12 is automatically issued to stop multiblock transfer with the number of blocks that is set to SD_SECCNT and the response is received. At this point, CMD12 argument is automatically set to 0x0000_0000.

f. Operation complete

When all-block data read and the CMD12 response received are completed, ACEND (access end) in SD_INFO1 is set to 1 to generate an interrupt. Clear ACEND to 0 to read the response. This is the end of multiple block read operation. In addition, perform error processing (clear the interrupt flag register) if a communication error or timeout occurs.

40.3.9 Multiple Block Write (SD/MMC Using Internal Timer)

Figure 40.14 shows an example flow of a multiple block write using internal timer.

Figure 40.14 Example of multiple block write operation using internal timer

40.3.9.1 Multiple block write operation using internal timer

The operation of the multiple block write is described as follows:

- Flag register clear**
First, clear the bits in the flag register (SD_INFO1 and SD_INFO2).
- Control register set**
Set the SD/MMC clock, transfer data size, interrupt mask (SD_CLK_CTRL, SD_SIZE, SD_INFO1_MASK, and SD_INFO2_MASK).
Set the SEC bit in SD_STOP to 1, and set the number of transfer blocks in SD_SECCNT.
- Command issue (CMD25)**
Set CMD25 argument in SD_ARG and write 0x0000_0019 to SD_CMD. CMD25 is issued and the multiple block write operation is started.
- Response check**
On receiving the response, the RSPEND bit (response end) in SD_INFO1 is set to 1 to generate an interrupt.

Clear the RSPEND bit to 0 and read the response from SD_RSP54. If the result of response decoding is an error, the command sequence can be halted by setting the STP bit in SD_STP to 1. Setting the STP bit to 1 also causes CMD12 to be issued and the response received. If the command sequence is halted because the access end interrupt is enabled, an interrupt is generated by when the ACEND bit (access end) bit in SD_INFO1 sets to 1 on completion of response reception. Clear the ACEND bit to 0 and read the response.

e. Data write and data transmit to SD card/MMC

Write 0x0000_0319 to SD_INFO1_MASK to enable the access end interrupt. In addition, write 0x0000_0900 to SD_INFO2_MASK to enable the BWE interrupt. When SD_BUF0 is ready for the data to be written, the BWE bit in the SD_INFO2 register is set to 1 to generate an interrupt. Clear the BWE bit to 0 and write the amount of data specified in SD_SIZE to SD_BUF0. When the data write to SD_BUF0 is completed, data is transmitted to the SD card/MMC. The CRC status and busy state are received from the SD card/MMC. This repeats transfer of the number of blocks set in SD_SECCNT. However, a communication error or timeout might be generated if data is being received while writing to SD_BUF0 is in progress. CMD12 is automatically issued to stop multiblock transfer with the number of blocks which is set to SD_SECCNT and the response is received. At this point, CMD12 argument is automatically set to 0x0000_0000.

f. Operation complete

When all-block data transmit and the CRC status receive are completed, the ACEND bit (access end) in SD_INFO1 is set to 1 to generate an interrupt. Clear the ACEND bit to 0 to read the response. This is the end of multiple block write operation. Additionally, perform error processing (clear the interrupt flag register) if a communications error or timeout occurs.

40.3.10 Multiple Block Write (MMC using external timer)

Figure 40.15 shows an example flow of a multiple block write using an external timer.

Figure 40.15 Example of multiple block write operation using external timer

40.3.10.1 Multiple block write operation using external timer

The operation of the multiple block write is described as follows:

- Flag register clear**
First, clear the bits in the flag register (SD_INFO1 and SD_INFO2).
- Control register set**
Set the MMC clock, transfer data size, interrupt mask (SD_CLK_CTRL, SD_SIZE, SD_INFO1_MASK, and SD_INFO2_MASK).
Set the SEC bit in SD_STOP to 1, and set the number of transfer blocks in SD_SECCNT.
- Command issue (CMD54)**
Set CMD54 Argument in SD_ARG and write 0x0000_6C36 to SD_CMD. CMD54 is issued and the multiple block write operation is started.
- Response check**
On receiving the response, the RSPEND bit (response end) in SD_INFO1 is set to 1 to generate an interrupt. Clear the RSPEND bit to 0 and read the response from SD_RSP54. If the result of response decoding is an error, the command sequence can be halted by setting the STP bit in SD_STP to 1. Setting the STP bit to 1 also causes CMD12 to be issued

and the response received. If the command sequence is halted because the access end interrupt is enabled, an interrupt is generated by when the ACEND bit (access end) bit in SD_INFO1 sets to 1 on completion of response reception. Clear the ACEND bit to 0 and read the response.

e. Data write and data transmit to MMC

Write 0x0000_0319 to SD_INFO1_MASK to enable the access end interrupt, write 0x0000_0900 to SD_INFO2_MASK to enable the BWE interrupt and set 1 to TOUTMASK of SD_OPTION to inactivate timeout. In addition, start external timer. When SD_BUF0 is ready for the data to be written, the BWE bit in the SD_INFO2 register is set to 1 to generate an interrupt. Clear the BWE bit to 0 and write the amount of data specified in SD_SIZE to SD_BUF0. When the data write to SD_BUF0 is completed, data is transmitted to the MMC. The CRC status and busy state are received from the MMC. Doing this repeats transfer of the number of blocks set in SD_SECCNT. However, a communication error or timeout might be generated if data is being received while writing to SD_BUF0 is in progress.

f. Operation complete

When all-block data transmit and the CRC status receive are completed, the ACEND bit (access end) in SD_INFO1 is set to 1 to generate an interrupt. Clear the ACEND bit to 0 to read the response. This is the end of multiple block write operation. Additionally, perform error processing (clear the interrupt flag register) if a communications error or timeout occurs when receiving response. Execute software reset if a timeout by external timer occurs when transmitting data.

40.3.11 IO_RW_DIRECT Command (SD: CMD52)

Figure 40.16 shows an example flow of an IO_DIRECT command (CMD52) operation.

40.4 Usage Notes

40.4.1 SD_BUF Illegal Write Access (SD/MMC)

When writing data to SD_BUF0 after the single block write or multi block write command is issued, the data of the size specified in SD_SIZE must be written.

If the data exceeds the size specified in SD_SIZE is written, the ERR4 bit in SD_INFO2 is set to 1. In addition, the data written to SD_BUF0 might not be transmitted and the SD_CLK_CTRLLEN bit in SD_INFO2 is held at the value of 0. If this occurs, clearing the SDRST bit in SOFT_RST to 0 and then restoring its value to 1 clears the SD_CLK_CTRLLEN bit to 1.

However, this does not apply to the single byte or three bytes when the SD_SIZE setting is odd, or to the fraction of bytes when the SD_SIZE setting is even (the 2 bytes that are not in a 4-byte unit), because the portion of dummy data writing is regarded as excess data and ignored.

40.4.2 Block Number Constraint for Multiple Block Read (SD)

When performing a multiple block read of one or two blocks, depending on the timing with which the SD card response register is read, the response value might not be read properly. To prevent this, do one of the following:

1. When receiving one or two blocks of data, use single block reading.
2. Read the response to CMD18 from SD_RSP54.

40.4.2.1 Mechanism of incorrect reading

Figure 40.25 shows the processing flows of the SDHI (hardware) operation and software operation when a multiple block read is performed on two blocks. As shown in the incorrect operation in Figure 40.25, when an interrupt is generated on reception of the CMD18 response and the timing with which the SD card response register (SD_RSP10) is read by the interrupt is delayed, the data during the CMD12 response reception or the CMD12 response might be read. This problem does not occur for multiple block reads of three or more blocks, because CMD12 is not issued until the block of data is read. The problem also does not occur for multiple block writes, because the CMD25 response is read before the block of data is sent.

Figure 40.25 Multiple block read operation flow chart (two blocks)

40.4.3 Automatic Control of SD/MMC Clock Output (SD/MMC)

In the SD Card/MMC standard, 74 cycles of SD/MMC clock must be output before initialization of the card. For this reason, use automatic control of SD/MMC clock output after 74 cycles of SD/MMC clock are output. In addition, if

automatic control of SD/MMC clock output was in use, SD/MMC clock output is stopped on completion of the sequence for a communications error or timeout. When state transitions within the SD card/MMC are necessary after completion of the sequence, release automatic control of SD/MMC clock output and restart supply of the SD/MMC clock to the SD card/MMC.

40.4.4 Control of the C52PUB Setting for Multiple Block Write (SD)

If the C52PUB bit in SDIO_MODE is set to 1 during a sequence of multiple block write because of CMD53, CMD52 is not issued until SD_BUF becomes empty. For this reason, set the C52PUB bit after suspending writing to SD_BUF by using one of the following procedures, as appropriate:

(a) When DMA transfer is not in use

1. Before setting the C52PUB bit, suspend writing to SD_BUF by making the setting in SD_INFO2 to disable BWE interrupts.
2. Set the C52PUB bit in SDIO_MODE to 1 (so that CMD52 is issued when SD_BUF becomes empty).
3. After the RSPEND interrupt processing in SD_INFO1 because the issuing of CMD52 is completed, restart writing to SD_BUF by making the setting in SD_INFO2 to enable BWE interrupts.

(b) When DMA transfer is in use

1. Every time DMA transfer of the value set in SD_SIZE $\times$ n blocks (where n = 1, 2,...) proceeds, suspend writing to SD_BUF by DMA transfer before the C52PUB bit is set.
2. Set the C52PUB bit in SDIO_MODE to 1 (so that CMD52 is issued when SD_BUF becomes empty).
3. After the RSPEND interrupt processing in SD_INFO1 because the issuing of CMD52 is completed, restart writing to SD_BUF by DMA transfer.

40.4.5 Notes on SD_CLK_CTRL Register Settings (SD/MMC)

When the SD_CLK_CTRLLEN bit in SD_INFO2 is 0, SD_CLK_CTRL cannot be written to. Before writing to SD_CLK_CTRL, you must check that the SD_CLK_CTRLLEN bit in SD_INFO2 is 1.

40.4.6 Specification Limitations

1. The Suspend/Resume operation of the SDIO is not supported.
2. The SPI bus is not supported. (SD/MMC)
3. The shared bus and 8-bit SD bus of the embedded SDIO are not supported.
4. Stream transfer of MMC is not supported.
5. High Priority Interrupt (HPI) of MMC is not supported.
6. Boot Operation/Alternative Boot Operation of MMC is not supported.
7. Open-ended multiple block transfer of MMC is not supported.

40.4.7 STP Bit Setting during Multiple Block Read (SD/MMC)

During execution of multiple block read with automatic CMD12 execution by setting the SEC bit in SD_STOP to 1, even if the STP bit in SD_STOP is set to 1 to forcibly stop the execution, the command sequence might not stop depending on the timing of setting the STP bit.

To avoid this, when setting the STP bit in SD_STOP to 1 during multiple block transfer, clear the SEC bit in SD_STOP to 0 at the same time. (Even when the SD_CLK_CTRLLEN bit in SD_INFO2 is 0, change the SEC bit from 1 to 0.)

When the command sequence does not stop because the SEC bit was not cleared to 0, the command sequence can be stopped by clearing the SDRST bit in SOFT_RST to 0.

When forcibly terminating the CMD53 multiple block transfer through the IOABT bit in SDIO_MODE, you must leave the SEC bit in SD_STOP as 1.

40.4.8 Register Setting Notes

1. All registers in [section 40.2. Register Descriptions](#) are accessed in 32-bit access-only.
2. When setting registers, set them after the I/O Port Register setting.

40.4.9 Module-stop function

SDHI operation can be disabled or enabled using Module Stop Control Register C (MSTPCRC). The SDHI module is initially stopped after reset. Releasing the module-stop state enables access to the registers. For details, see [section 10, Low Power Modes](#).

41. Cyclic Redundancy Check (CRC)

41.1 Overview

The Cyclic Redundancy Check (CRC) calculator generates CRC codes to detect errors in the data. The bit order of CRC calculation results can be switched for LSB-first or MSB-first communication. Additionally, various CRC-generation polynomials are available. The snoop function allows monitoring reads from and writes to specific addresses. This function is useful in applications that require CRC code to be generated automatically in certain events, such as monitoring writes to the serial transmit buffer and reads from the serial receive buffer.

Table 41.1 lists the CRC calculator specifications and Figure 41.1 shows a block diagram.

Table 41.1 CRC calculator specifications

Item	Description	
Data size	8-bit	32-bit
Data for CRC calculation ^{*1}	CRC code generated for data in 8n-bit units (where n is a natural number)	CRC code generated for data in 32n-bit units (where n is a natural number)
CRC processor unit	Operation executed on 8 bits in parallel	Operation executed on 32 bits in parallel
CRC generating polynomial	One of three generating polynomials that is selectable: [8-bit CRC] $X^8 + X^2 + X + 1$ (CRC-8) [16-bit CRC] $X^{16} + X^{15} + X^2 + 1$ (CRC-16) $X^{16} + X^{12} + X^5 + 1$ (CRC-CCITT)	One of two generating polynomials that is selectable: [32-bit CRC] $X^{32} + X^{26} + X^{23} + X^{22} + X^{16} + X^{12} + X^{11} + X^{10} + X^8 + X^7 + X^5 + X^4 + X^2 + X + 1$ (CRC-32) $X^{32} + X^{28} + X^{27} + X^{26} + X^{25} + X^{23} + X^{22} + X^{20} + X^{19} + X^{18} + X^{14} + X^{13} + X^{11} + X^{10} + X^9 + X^8 + X^6 + 1$ (CRC-32C)
CRC calculation switching	The bit order of CRC calculation results can be switched for LSB-first or MSB-first communication	
Module-stop function	Module-stop state can be set to reduce power consumption	
CRC snoop	Monitor reads from and writes to a certain register address	
TrustZone Filter	Security and Privilege attribution can be set	

Note 1. This function cannot divide data used in CRC calculations. Write data in 8-bit or 32-bit units.

Figure 41.1 CRC calculator block diagram

41.2 Register Descriptions

41.2.1 CRCCR0 : CRC Control Register 0

Base address: CRC = 0x4031_0000
CRC_NS = 0x5031_0000

Offset address: 0x00

Bit position:	7	6	5	4	3	2	1	0
Bit field:	DORCLR	LMS	—	—	—	GPS[2:0]		

Value after reset: 0 0 0 0 0 0 0 0

Bit	Symbol	Function	R/W
2:0	GPS[2:0]	CRC Generating Polynomial Switching 0 0 1: 8-bit CRC-8 ($X^8 + X^2 + X + 1$) 0 1 0: 16-bit CRC-16 ($X^{16} + X^{15} + X^2 + 1$) 0 1 1: 16-bit CRC-CCITT ($X^{16} + X^{12} + X^5 + 1$) 1 0 0: 32-bit CRC-32 ($X^{32} + X^{26} + X^{23} + X^{22} + X^{16} + X^{12} + X^{11} + X^{10} + X^8 + X^7 + X^5 + X^4 + X^2 + X + 1$) 1 0 1: 32-bit CRC-32C ($X^{32} + X^{28} + X^{27} + X^{26} + X^{25} + X^{23} + X^{22} + X^{20} + X^{19} + X^{18} + X^{14} + X^{13} + X^{11} + X^{10} + X^9 + X^8 + X^6 + 1$) Others: No calculation is executed	R/W
5:3	—	These bits are read as 0. The write value should be 0.	R/W
6	LMS	CRC Calculation Switching 0: Generate CRC code for LSB-first communication 1: Generate CRC code for MSB-first communication	R/W
7	DORCLR	CRCDOR/CRCDOR_HA/CRCDOR_BY Register Clear 0: No effect 1: Clear the CRCDOR/CRCDOR_HA/CRCDOR_BY register	W

Note: S-TYPE3, P-TYPE3

GPS[2:0] bits (CRC Generating Polynomial Switching)

The GPS[2:0] bits select the CRC generating polynomial.

LMS bit (CRC Calculation Switching)

The LMS bit selects the bit order of generated CRC code. Transmit the lower byte of the CRC code first for LSB-first communication and the upper byte first for MSB-first communication. For details on transmitting and receiving CRC code, see [section 41.3. Operation](#).

DORCLR bit (CRCDOR/CRCDOR_HA/CRCDOR_BY Register Clear)

Write 1 to the DORCLR bit to set the CRCDOR/CRCDOR_HA/CRCDOR_BY register to 0x00000000. This bit is read as 0. Only 1 can be written to it.

41.2.2 CRCCR1 : CRC Control Register 1

Base address: CRC = 0x4031_0000
CRC_NS = 0x5031_0000

Offset address: 0x01

Bit position:	7	6	5	4	3	2	1	0
Bit field:	CRCS EN	CRCS WR	—	—	—	—	—	—

Value after reset: 0 0 0 0 0 0 0 0

Bit	Symbol	Function	R/W
5:0	—	These bits are read as 0. The write value should be 0.	R/W
6	CRCSWR	Snoop-On-Write/Read Switch 0: Snoop-on-read 1: Snoop-on-write	R/W
7	CRCSEN	Snoop Enable 0: Disabled 1: Enabled	R/W

Note: S-TYPE3, P-TYPE3

CRCSWR bit (Snoop-On-Write/Read Switch)

The CRCSWR bit selects the direction of access in the CRC snoop function.

When this bit is set to 0 (initial value), the CRC snoop operation to read a specific register is enabled. Similarly, when this bit is set to 1, the CRC snoop operation to write a specific register is enabled.

CRCSEN bit (Snoop Enable)

When the CRCSEN bit is set to 1, the CRC snoop operation is enabled. When this bit is set to 0, the CRC snoop operation is disabled.

41.2.3 CRCDIR/CRCDIR_BY : CRC Data Input Register

Base address: CRC = 0x4031_0000
CRC_NS = 0x5031_0000

Offset address: 0x04

Bit position: 31 0

Bit field:

Value after reset: 0

Bit	Symbol	Function	R/W
31:0	n/a	CRC input data The CRCDIR register is a 32-bit read/write register to write data for CRC-32 or CRC-32C calculation. The CRCDIR_BY (CRCDIR[31:24]) is an 8-bit read/write register to write data for CRC-8, CRC-16, or CRC-CCITT calculation.	R/W

Note: S-TYPE3, P-TYPE3

41.2.4 CRCDOR/CRCDOR_HA/CRCDOR_BY : CRC Data Output Register

Base address: CRC = 0x4031_0000
CRC_NS = 0x5031_0000

Offset address: 0x08

Bit position: 31 0

Bit field:

Value after reset: *1

Bit	Symbol	Function	R/W
31:0	n/a	CRC output data The CRCDOR register is a 32-bit read/write register for CRC-32 or CRC-32C calculation. The CRCDOR_HA (CRCDOR[31:16]) register is a 16-bit read/write register for CRC-16 or CRC-CCITT calculation. The CRCDOR_BY (CRCDOR[31:24]) register is an 8-bit read/write register for CRC-8 calculation. Rewrite the CRCDOR/CRCDOR_HA/CRCDOR_BY register to perform the calculations using a value other than the initial value. Data written to the CRCDIR/CRCDIR_BY register is CRC calculated and the result is stored in the CRCDOR/CRCDOR_HA/CRCDOR_BY register. If the CRC code is calculated following the transferred data and the result is 0x00000000, there is no CRC error.	R/W

Note: S-TYPE3, P-TYPE3

Note 1. If FSBL is executed in reset, then value after reset is 1, if FSBL is skipped in reset, then values after reset is 0.

41.2.5 CRCSAR : Snoop Address Register

Base address: CRC = 0x4031_0000
CRC_NS = 0x5031_0000

Offset address: 0x0C

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	CRCSA[13:0]													
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
13:0	CRCSA[13:0]	Register Snoop Address These bits store the TDR or RDR address in the SCI module to snoop	R/W
15:14	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE3, P-TYPE3

CRCSA[13:0] bits (Register Snoop Address)

The CRCSA[13:0] bits specify the lower address 14 bits of the register monitored by the CRC snoop operation.

Only the following addresses can be used for the CRCSA[13:0] bits:

[secure region address]

- 0x4035_8004: SCI0.TDR, 0x4035_8000: SCI0.RDR
- 0x4035_8104: SCI1.TDR, 0x4035_8100: SCI1.RDR
- 0x4035_8204: SCI2.TDR, 0x4035_8200: SCI2.RDR
- 0x4035_8304: SCI3.TDR, 0x4035_8300: SCI3.RDR
- 0x4035_8404: SCI4.TDR, 0x4035_8400: SCI4.RDR
- 0x4035_8904: SCI9.TDR, 0x4035_8900: SCI9.RDR

[non-secure region address]

- 0x5035_8004: SCI0.TDR, 0x5035_8000: SCI0.RDR
- 0x5035_8104: SCI1.TDR, 0x5035_8100: SCI1.RDR
- 0x5035_8204: SCI2.TDR, 0x5035_8200: SCI2.RDR
- 0x5035_8304: SCI3.TDR, 0x5035_8300: SCI3.RDR
- 0x5035_8404: SCI4.TDR, 0x5035_8400: SCI4.RDR
- 0x5035_8904: SCI9.TDR, 0x5035_8900: SCI9.RDR

41.3 Operation

41.3.1 Basic Operation

The CRC calculator generates CRC codes for use in LSB-first or MSB-first transfer.

The following examples show CRC code generation for input data (0xF0) using the 16-bit CRC-CCITT generating polynomial ($X^{16} + X^{12} + X^5 + 1$). In these examples, the value of the CRC Data Output Register (CRCDOR_HA) is cleared before CRC calculation.

When an 8-bit CRC (with the polynomial $X^8 + X^2 + X + 1$) is in use, the valid bits of the CRC code are obtained in CRCDOR_BY. When a 32-bit CRC is in use, the valid bits of the CRC code are obtained in CRCDOR.

Figure 41.2 and Figure 41.3 show the LSB-first and MSB-first data transmission examples respectively. Figure 41.4 and Figure 41.5 show the LSB-first and MSB-first data reception examples.

Figure 41.2 LSB-first data transmission

1. Write 0xC3 to CRC Control Register 0 (CRCCR0)

2. Write 0xF0 to the CRC Data Input Register (CRCDIR_BY)

3. Read the calculation result in the CRC Data Output Register (CRCDOR_HA)
CRC code = 0xEF1F

4. 8-bit serial transmission (MSB-first)

Figure 41.3 MSB-first data transmission

1. 8-bit serial reception (LSB-first)

2. Write 0x83 to the CRC Control Register 0 (CRCCR0)

3. Write 0xF0 to the CRC Data Input Register (CRCDIR_BY)

4. Write 0x8F to the CRC Data Input Register (CRCDIR_BY)

5. Write 0xF7 to the CRC Data Input Register (CRCDIR_BY)

6. Read the calculation result in the CRC Data Output Register (CRCDOR_HA)

CRC code = 0x0000 → no error

Figure 41.4 LSB-first data reception

Figure 41.5 MSB-first data reception

41.3.2 CRC Snoop Function

The CRC snoop function monitors reads from and writes to a specific register and performs CRC calculation on the monitored data automatically. Because the CRC snoop function recognizes writes to and reads from a specific register address as a trigger to automatically perform CRC calculation, there is no need to write data to the CRCDIR register. All I/O register specified in the [section 41.2.5. CRCSAR : Snoop Address Register](#) are subject to the CRC snoop. The CRC snoop is useful in monitoring writes to the SCIn.TDR (n = 0 to 4, 9) register, and reads from the SCIn.RDR (n = 0 to 4, 9) register.

To use this function, write the lower address 14 bits of a specific register to bits CRCSA13 to CRCSA0 in the CRCSAR register, and set CRCSEN bit in the CRCCR1 register to 1. Then, set the CRCSWR bit in the CRCCR1 register to 1 to enable snooping on writes to the target register, or set the CRCSWR bit in the CRCCR1 register to 0 to enable snooping on reads from the target register. It is possible that access to a target I/O register may be executed before the CRCSWR bit write completed. In this case, the data is not stored in the CRCDIR register. To avoid this issue, before accessing I/O register, read back the CRCSWR bit that was written to confirm that the write completed.

When both the CRCSEN and CRCSWR bits are set to 1, and data is written to a target register in a bus master module such as the CPU, DMAC, and DTC, the CRC calculator stores the data in the CRCDIR register and performs CRC calculation. Similarly, when the CRCSEN bit is set to 1, CRCSWR bit to 0, and data is read from a target register in a bus master

module such as the CPU, DMAC, and DTC, the CRC calculator stores the data in the CRCDIR register and performs CRC calculations.

When the CRC code is generated by using CRC-8, CRC-16, and CRC-CCITT generating polynomial, the target register is accessed in 1 byte (8 bits). RDR_BY and TDR_LL should be used to access RDR and TDR. Similarly, when the CRC code is generated by using CRC-32 and CRC-32C generating polynomial, the target register is accessed in words (32 bits). Note that for RDR and TDR, CRC codes are generated that contain data other than RDAT and TDAT.

When CRC is marked as secure by PSARC.PSARC1 bit, the CRC snoop function is available for secure access to the specified I/O registers. When CRC is marked as non-secure by PSARC.PSARC1 bit, the CRC snoop function is available for non-secure access to the specified I/O registers.

41.4 Usage Notes

41.4.1 Settings for the Module-Stop State

The Module Stop Control Register C (MSTPCRC) can enable or disable CRC calculator operation. The CRC calculator is initially stopped after a reset. Releasing the module-stop state enables access to the registers. For details, see [section 10, Low Power Modes](#).

41.4.2 Note on Transmission

The transmission sequence for the CRC code differs based on whether the transmission is LSB-first or MSB-first. [Figure 41.6](#) shows an LSB-first and MSB-first data transmission.

When transmitting 32-bit data (for operation executed on 8 bits in parallel)

1. CRC code

After specifying the method for generation calculation, write data to CRCDIR in order of (1), (2), (3), and (4).

2. Transmit data

(i) When transmission is LSB-first

(ii) When transmission is MSB-first

Figure 41.6 LSB-first and MSB-first data transmission

42. Boundary Scan

42.1 Overview

The boundary scan function provides a serial I/O interface based on the JTAG (Joint Test Action Group), IEEE Std.1149.1, and IEEE Standard Test Access Port and Boundary Scan Architecture. [Table 42.1](#) lists the boundary scan specifications, [Figure 42.1](#) shows a block diagram, and [Table 42.2](#) lists the I/O pins.

Table 42.1 Boundary scan specifications

Parameter	Specifications
Execution condition	Boundary scan must be executed when the RES pin is driven low.
Test modes	• BYPASS mode • EXTEST mode • SAMPLE/PRELOAD mode • CLAMP mode • HIGHZ mode • IDCODE mode

Figure 42.1 Boundary scan function block diagram

Table 42.2 Boundary scan I/O pins

Pin name	I/O	Description
TCK	Input	Test clock input pin Clock signal for boundary scan. The input clock duty cycle is 50% when the boundary scan function is used.
TMS	Input	Test mode select pin
TDI	Input	Test data input pin
TDO	Output	Test data output pin

Note: This device does not support the TRST pin for the JTAG interface.

42.2 Register Descriptions

[Table 42.3](#) lists the boundary scan registers.

Table 42.3 Boundary scan registers

Register name	Symbol	Value after reset
Instruction Register	JTIR	0xE
ID Code Register	JTIDR	0x0841_9447
Bypass Register	JTBPR	Undefined
Boundary Scan Register	JTBSR	Undefined

Usage notes for the boundary scan registers:

- Instructions can be input to the Instruction Register (JTIR) through the TDI pin by serial transfer.
- The Bypass Register (JTBPR), which is a 1-bit register, is connected between the TDI and TDO pins in BYPASS mode.
- The Boundary Scan Register (JTBSR), which is configured according to the BSDL description, is connected between the TDI and TDO pins when test data is being shifted in.

Table 42.4 shows the availability of serial transfer for the registers.

Table 42.4 Serial transfer for registers

Register name	Serial input	Serial output
Instruction Register (JTIR)	Available	Available
ID Code Register (JTIDR)	Available	Available
Bypass Register (JTBPR)	Available	Available
Boundary Scan Register (JTBSR)	Available	Available

42.2.1 JTIR : Instruction Register

Bit	Symbol	Function	R/W	
3:0	TS[3:0]	Test Bit Set The command configuration for these bits	—	
		TS[3:0]		Instruction
		0x0		EXTEST
		0x1		SAMPLE/PRELOAD
		0x3		IDCODE (Renesas code)
		0x5		CLAMP
		0x6		HIGHZ
		0xF		BYPASS
		Others		Reserved

JTAG instructions can be transferred to the JTIR register by serial input from the TDI pin. The JTIR register is initialized when a power-on reset occurs, or when the TAP controller is in the Test-Logic-Reset state.

42.2.2 JTIDR : ID Code Register

Bit	Symbol	Function	R/W
31:0	DID[31:0]	Device ID These bits store the fixed value that indicates the device IDCODE (0x0841_9447).	—

The JTIDR register data is output from the TDO pin when the IDCODE instruction is executed. After a reset release, the DID[31:0] of JTIDR changes into the Arm® debug code. See the *Arm® CoreSight™ SoC-400 Technical Reference Manual* (ARM DDI 0480F).

42.2.3 JTBPR : Bypass Register

The JTBPR register is a 1-bit register and is connected between the TDI and TDO pins when the JTIR register is set to BYPASS mode. The JTBPR register cannot be read from or written to by the CPU.

42.2.4 JTBSR : Boundary Scan Register

The JTBSR register is a shift register for controlling the external input and output pins of this device, and is distributed across the pads. To apply the JTBSR register in boundary-scan testing, issue the EXTEST, SAMPLE/PRELOAD, CLAMP and HIGHZ instructions. The BSDL file describes the associations between the JTBSR register bits and the pins of this device. The value after reset is undefined.

42.3 Operation

During a reset, the JTAG ports, TCK, TMS, TDI and TDO are assigned as default pin functions. The TCK, TMS and TDI pins are pulled up by the pull-up resistors. Boundary scan testing can be executed after the setup time elapses when POR is negated and RES is driven low.

42.3.1 TAP Controller

Figure 42.2 shows the state transition diagram of the TAP controller. All transitions are controlled by the TMS signal.

Figure 42.2 State transition diagram of TAP controller

42.3.2 Commands

(1) BYPASS

The BYPASS instruction drives the Bypass Register (JTBPB). This instruction shortens the shift path, facilitating the transfer of serial data to other LSIs on a printed circuit board at higher speeds. While this instruction is being executed, the test circuit has no effect on the system circuits.

The JTBPB register is connected between the TDI and TDO pins. Bypass operation is initiated from the Shift-DR operation. The TDO is low in the first clock cycle in the Shift-DR state. In the subsequent clock cycles, values input to the TDI pin are output from the TDO pin.

(2) EXTEST

The EXTEST instruction is used to test external circuits when this device is installed on the printed circuit board. If this instruction is executed, output pins are used to output test data (specified in the SAMPLE/PRELOAD instruction) from the Boundary Scan Register (JTBSR) to the other devices, and input pins are used to input the test result.

(3) SAMPLE/PRELOAD

The SAMPLE/PRELOAD instruction is used to input data from the internal circuits of this device to the JTBSR register, output data from the scan path, and reload the data to the scan path. While this instruction is executed, input signals are directly input to this device and output signals are also directly output to the external circuits. This device system circuit is not affected by this instruction.

In SAMPLE operation, the JTBSR register latches a snapshot of the data transferred from the input pins to the internal circuit or data transferred from the internal circuit to the output pins. The latched data is read from the scan path. The JTBSR register latches the data snapshot on the rising edge of the TCK pin in the Capture-DR state. The data snapshot is only transferred from the internal circuit to the output pins during a reset.

In PRELOAD operation, the initial value is written from the scan path to the parallel output latch of the JTBSR register prior to the EXTEST instruction execution. If EXTEST is executed without executing this PRELOAD operation, undefined values are output from the beginning to the end (transfer to the output latch) of the EXTEST sequence. (In the EXTEST instruction, output parallel latches are always output to the output pins.)

(4) IDCODE

When the IDCODE instruction is selected, the ID Code Register (JTIDR) value is output to the TDO pin in the Shift-DR state of the TAP controller. In this case, the JTIDR register value is output LSB-first. During this instruction execution, the test circuit does not affect the system circuit.

(5) CLAMP

When the CLAMP instruction is selected, output pins output the JTBSR register value that was specified in the SAMPLE/PRELOAD instruction in advance. While the CLAMP instruction is selected, the status of the JTBSR register is maintained regardless of the TAP controller state.

The JTBPR register is connected between the TDI and TDO pins, leading to the same operation as when the BYPASS instruction is selected.

(6) HIGHZ

When the HIGHZ instruction is selected, all output pins enter high-impedance state. While the HIGHZ instruction is selected, the JTBSR register is maintained regardless of the state of the TAP controller.

The JTBPR register is connected between the TDI and TDO pins, leading to the same operation as when the BYPASS instruction is selected.

42.4 Usage Notes

The boundary scan function is subject to the following constraints:

- The boundary scan must be executed when the RES pin is driven low
- Serial data input/output is in LSB order, as shown in [Figure 42.3](#)

Figure 42.3 Serial data input/output

The following pins cannot be boundary-scanned:

- Power supply pins (VCC, VCC2, VCC_DCDC, VCL, VSS, VSS_DCDC, VBATT, AVCC0, AVSS0, VCC_USB, VSS_USB, VSS1_USBHS, VSS2_USBHS)
- Analog reference pins (VREFH0, VREFL0, VREFH, VREFL)
- Clock pins (EXTAL, XTAL, XCIN, and XCOU)
- Reset pin (RES)
- USBHS-dedicated pins (USBHS_DP, USBHS_DM)
- USBFS pin (USB_DP, USB_DM)
- The boundary-scan pins (TCK, TMS, TDI, and TDO).
- The switching regulator pin (VLO)

43. Security Features

43.1 Features

- Armv8-M TrustZone Technology
 - Implementation Defined Attribution Unit (IDAU) is implemented
 - Security Attribution Unit (SAU) is implemented
 - 8 regions
 - Master Security Attribution Unit (MSAU) is implemented (IDAU for master other than CPU)
 - Code flash
 - Up to 2 regions (secure/non-secure) in linear mode
 - Up to 4 regions (2 secure regions/2 non-secure regions) in dual mode
 - Data flash
 - Up to 2 regions (secure/non-secure)
 - SRAM
 - Up to 2 regions (secure/non-secure) per SRAM
 - Standby SRAM
 - Up to 2 regions (secure/non-secure)
 - VBATT backup registers
 - Up to 2 regions (secure/non-secure)
 - Peripheral
 - Security attributes can be set individually for each unit/channel
 - CSC^{*1}
 - CSC region is defined as non-secure
 - SDRAM^{*1}
 - SDRAM region is defined as non-secure
 - OSPI^{*1}
 - OSPI region is defined as non-secure
- Privileged control
 - Access permissions for memory except Standby SRAM and VBATT backup register are controlled by MPU managed by the privileged code
 - Privilege attributes of Standby SRAM and VBATT backup register are controlled by the registers of each controller
 - Individual privileged or Unprivileged attribution for each peripheral.
- Device lifecycle management
- Three debug levels
 - AL2: Non-secure and secure debug functions are enabled and accessible from the debugger
 - AL1: Only non-secure debug functions is enabled, and the debugger can access only defined non-secure debug accessible regions
 - AL0: No debug functions are available.
- Key injection
- Secure factory programming
 - Supports image programming in ciphertext format in an untrusted factory
- Secure boot

- Verify the integrity and authenticity of image to be programmed
- Verify the integrity and authenticity of the executable image by the immutable (ROM) First Stage Bootloader (FSBL) prior to executing the image.
- Cryptographic accelerator
 - See [section 44, Renesas Secure IP \(RSIP-E51A\)](#).
- Secure pin multiplexing
 - All I/O port pins can be configured individually as secure or non-secure
 - Peripheral pin function is valid when the security attribute of peripheral and I/O port match. See [section 19, I/O Ports](#).

Note 1. There is no TrustZone filter in the external RAM and external device area. Therefore, even if these regions are marked as secure in the SAU settings, non-secure masters except the CPU can access them.

43.2 Tamper Detection

The device is provided with I/O ports capable of detecting an external tamper attempt. In the case of a tamper event:

- Timestamping
The RTC can take a timestamp to log the event, and an interrupt can be generated. See [section 24, Realtime Clock \(RTC\)](#).
- VBATT backup registers
VBATT backup registers are zeroized (set to zero) following detection of a tamper event. See [section 11, Battery Backup Function](#).

43.3 Arm Security Features

43.3.1 Arm TrustZone Technology

Arm TrustZone technology divides the system and the application into secure and non-secure domains. A secure application can issue both secure and non-secure transactions, but a non-secure application can only issue non-secure transactions. Secure transactions can only access secure memory and resources, and non-secure transactions can only access non-secure memory and resources. Secure transactions can be issued only using secure region addresses and non-secure transactions can be issued only using non-secure region addresses. [Figure 43.1](#) shows the security attributes of transactions that can be issued by each master.

Figure 43.1 Transactions that can be issued by each master

For more details, see the *Arm® v8-M Architecture Reference Manual* and *Arm® Platform Security Architecture Trusted Base System Architecture for Arm®v8-M 1.0*.

43.3.2 Privileged Control

Systems and applications are divided into privileged and unprivileged domains. The CPU can limit or exclude access to some resources by executing code in privileged or unprivileged mode. Privileged mode can access both privileged and unprivileged domains, but unprivileged mode can access only the unprivileged domain.

For more details, see the *Arm® v8-M Architecture Reference Manual* and *Arm® Platform Security Architecture Trusted Base System Architecture for Arm®v8-M 1.0*.

43.3.3 Security Attribution

The TrustZone for Armv8.1-M implementation consists of the Security Attribution Unit (SAU) and Implementation Defined Attribution Unit (IDAU). The 4GB memory space is partitioned into Secure (S) and Non-secure (NS) memory regions. The Secure memory space is further divided into two types, Non-secure Callable (NSC) and Secure.

- Note:
- S = Secure addresses are used for memory and peripherals that are only accessible by secure software or secure masters.
 - NSC = A special type of secure location. This type of memory is the only type in which an Armv8.1-M processor permits to hold a Secure Gateway (SG) instruction that enables software to transition from Non-secure to Secure state.
 - NS = Non-secure addresses are used for memory and peripherals accessible by all software running on the device.

43.3.3.1 Implementation Defined Attribution Unit (IDAU)

The IDAU defines the code, SRAM and peripheral region into the secure alias region and the non-secure alias region by the address bit [28]. The secure code region and secure SRAM region are assigned the NSC security attributes. The security map defined by IDAU is fixed in hardware and cannot be changed by software.

43.3.3.2 Master Security Attribution Unit (MSAU)

MSAU is IDAU that defines system-specific security address map for masters other than CPU. The MSAU defines secure and non-secure alias regions but does not define the Non-secure Callable (NSC) and region number. Masters other than the CPU can issue a security transaction using the secure alias address defined by MSAU. However, non-secure masters are prohibited from issuing secure transactions using an address in the secure alias region. Figure 43.2 shows the defined security map of IDAU and MSAU. The security map defined by MSAU is fixed in hardware and cannot be changed by software.

Figure 43.2 IDAU and MSAU defined security map

43.3.3.3 Secure Attribution Unit (SAU)

The SAU is a programmable unit that determines the security of an address. The SAU is programmable in the Secure state and has a programmers' model similar to the MPU. If an address maps to regions defined by both IDAU and SAU, the region of the highest security level is selected. Secure master can issue secure and non-secure transactions using the address of each security alias region. Non-secure master cannot issue secure transactions using the address of the secure alias region. Figure 43.3 shows the final determination of the address map security level.

Figure 43.3 Final determination of address map security level

When using TrustZone to perform secure and non-secure region separation, SAU MUST be set according to the following.

The regions set as NS attribute in IDAU MUST be set to NS in the SAU as well. The regions set to NS attribute in IDAU are:

0x1000_0000 to 0x1FFF_FFFF (SAU Region 1 in [Figure 43.4](#))

0x3000_0000 to 0x3FFF_FFFF (SAU Region 3 in [Figure 43.4](#))

0x5000_0000 to 0xDFFF_FFFF (SAU Region 3 in [Figure 43.4](#))

At least one NSC region MUST be created within any region defined as NSC by the IDAU. The regions set to NSC attribute by the IDAU are:

0x0000_0000 to 0x0FFF_FFFF (SAU Region 0 in [Figure 43.4](#))

0x2000_0000 to 0x2FFF_FFFF (SAU Region 2 in [Figure 43.4](#))

If you do not wish to define any isolation by means of using TrustZone, do not change SAU_CTRL.ALLNS = 0 and SAU_CTRL.ENABLE = 0 (initial value).

Figure 43.4 SAU settings and resulting security attributes

43.3.3.4 Region Number

The SAU and IDAU also define region numbers for each of the memory regions and security attributes. This region number is used by software to determine if a contiguous range of memory shares common security attributes. Figure 43.5 shows the defined region number of IDAU.

Address	Address map	Security Attribution partition	Region number
0xFFFF_FFFF	Vendor SYS	Exempt	0
0xE000_0000	PPB		
0xC000_0000	External Device	NS	6
0xA000_0000			
0x8000_0000	External RAM		
0x6000_0000			
	Peripheral	NS	5
0x4000_0000		S	
	SRAM	NS	4
0x2000_0000		NSC	3
	Code	NS	2
0x0000_0000		NSC	1

Figure 43.5 IDAU defined region numbers

43.3.3.5 Memory Security Attribution of TrustZone filter

The memories are divided into S and NS regions. The memory security attribution of code flash and data flash is stored into nonvolatile memory by a boot firmware command when the device lifecycle is in the OEM state and the authentication level is AL2. These memory security attributions are applied before application execution. They cannot be updated by the application but are readable using dedicated registers. The memory security attributions of SRAM, standby SRAM, and VBATT backup registers are set by a dedicated security attribution register writable only by secure access.

The code flash can be divided in up to two regions in linear mode and four regions in dual mode. The partitioning is the same between bank0 and bank1 in the dual mode. The data flash can be divided in up to two regions. SRAM, standby SRAM, and VBATT backup registers can be divided in up to two regions. [Figure 43.6](#) shows the memory mapping. [Table 43.1](#) shows size of the memory region and [Table 43.2](#) shows access permission of the memory region.

It is prohibited to place Secure or Non-secure Callable regions in a block swappable area in linear mode because the secure application would be placed in the non-secure region after block swapping.

Bank swapping by the Non-secure user may change the code in the Secure or Non-secure callable areas. The following is recommended to prevent this.

- Set BANKSEL_SEL.BANKSWP[2:0] = 000b to disable the bank swapping for Non-secure users.
- Make the code in Secure or Non-secure callable areas for both banks the same when allow Non-secure user to swap banks.

See [section 43.8. Field Updating in Dual Mode](#).

Figure 43.6 Memory mapping

Table 43.1 Size of memory region (1 of 2)

Memory region		Start address	Size
Linear mode	Code flash secure	0x0200_0000	CFS2 size (32 KB)
	Code flash non-secure	0x1200_0000 + CFS2 size (32 KB)	Code flash size - CFS2 size (32 KB)
Dual mode	Code flash bank0 secure	0x0200_0000	CFS2 size (32 KB)
	Code flash bank0 non-secure	0x1200_0000 + CFS2 size (32 KB)	Code flash size/2 - CFS2 size (32 KB)
	Code flash bank1 secure	0x0220_0000	CFS2 size (32 KB)
	Code flash bank1 non-secure	0x1220_0000 + CFS2 size (32 KB)	Code flash size/2 - CFS2 size (32 KB)
Data flash secure		0x2700_0000	DFS size (1 KB)
Data flash non-secure		0x3700_0000 + DFS size (1 KB)	Data flash size - DFS size (1 KB)
SRAM0 secure		0x2200_0000	BA (8 KB)
SRAM0 non-secure		0x3200_0000 + BA (8 KB)	SRAM0 size - BA (8 KB)
SRAM1 secure		0x2206_0000	BA (8 KB)
SRAM1 non-secure		0x3206_0000 + BA (8 KB)	SRAM1 size - BA (8 KB)
Standby SRAM secure		0x2600_0000	BA (128 bytes)
Standby SRAM non-secure		0x3600_0000 + BA (128 bytes)	Standby SRAM size - BA (128 bytes)
VBATT backup register secure		0x4001_ED00	BA (32 bytes)

Table 43.1 Size of memory region (2 of 2)

Memory region	Start address	Size
VBATT backup register non-secure	0x5001_ED00 + BA (32 bytes)	Backup register size - BA (32 bytes)

Note: The number in parentheses indicates the smallest unit that can be set by the user.

Note: BA is the setting value of the security attribution boundary address register for each memory region.

Table 43.2 Access permission of the memory region

Memory region	Secure transaction	Non-secure transaction
Each memory region configured as S or NSC	Allowed	Write ignored/Read ignored TrustZone access error is generated
Each memory region configured as NS	Write ignored/Read ignored TrustZone access error is generated	Allowed

43.3.3.6 Peripheral Security Attribution of TrustZone filter

Each peripheral can be configured as secure or non-secure and privileged or unprivileged.

Peripherals are divided into two types.

Type1 peripherals has one security and privilege attribution. Access to all registers is controlled by one security and privilege attribution. Type1 peripheral security and privilege attribution is set to the PSARx (x = B to E) and the PPARx (x = B to E) register by the secure and privileged application.

Type2 peripheral has the security attribution for each register or for each bit and access to each register or bit field is controlled according to these security attributions. Type2 peripheral security attribution is set to the Security Attribution register in each module by the secure application. For details on the Security Attribution register, see each section.

Table 43.3 shows the classification of peripheral type.

Table 43.3 Classification of peripheral type

Type1	Type2
SCI, SPI, OSPI, DOTF, ETHERC, EDMAC, USBHS, USBFS, IIC, I3C, RSIP-E51A, CANFD, CEU, DOC, SDHI, SSIE, CRC, CAC, ACPHPS, TSN, ADC12, DAC12, POEG, AGT, GPT, ULPT, RTC, IWD, and WDT	System control (Resets, PVD, Clock Generation Circuit, Low Power Modes, Battery Backup Function), Flash memory controller, Flash cache, SRAM controller, CPU cache, DMAC, DTC, ICU, MPU, BUS, Security setting, ELC, and I/O ports

Table 43.4 shows the access permission of type1 peripherals. The access permission of type2 peripherals is different by peripherals. Each register description of type2 peripherals includes the note of S-TYPE and P-TYPE indicating the specification of the access permission. For details on S-TYPE and P-TYPE, see [section Appendix 4, Note for Register R/W](#).

Table 43.4 Access permission of type1 peripherals

	Secure and Privileged access	Secure and Unprivileged access	Non-secure and Privileged access	Non-secure and Unprivileged access
Peripheral configured as Secure and Privileged	Allowed	Write ignored/Read ignored TrustZone Access error is generated	Write ignored/Read ignored TrustZone Access error is generated	Write ignored/Read ignored TrustZone Access error is generated
Peripheral configured as Secure and Unprivileged	Allowed	Allowed	Write ignored/Read ignored TrustZone Access error is generated	Write ignored/Read ignored TrustZone Access error is generated
Peripheral configured as Non-secure and Privileged	Write ignored/Read ignored TrustZone Access error is generated	Write ignored/Read ignored TrustZone Access error is generated	Allowed	Write ignored/Read ignored TrustZone Access error is generated
Peripheral configured as Non-secure and Unprivileged	Write ignored/Read ignored TrustZone Access error is generated	Write ignored/Read ignored TrustZone Access error is generated	Allowed	Allowed

43.3.4 TrustZone Access Error

Table 43.5 shows the behavior when TrustZone access error occurs. The behavior varies depending on the master or the slave area to be accessed.

Table 43.5 Behavior of TrustZone access error

DAP	CPU	DMAC/DTC	EDMAC	CEU
Only error response is returned^{*1}	- IDAU/SAU detects SecureFault exception - TrustZone filter detects BusFault exception - Can issue a reset^{*2}	- Stop transfer - Issue NMI or reset^{*2} - Generate interrupt (DMA0_TRANSERR)	- Issue NMI or reset^{*2} - Generate interrupt (ETHER_EINT0)^{*3}	Issue NMI or reset^{*2}

Note: This behavior is not applicable for bufferable write access. For more information on when a bufferable write access error is detected, see [section 14.7.2. Operations When a Bus Error Occurs](#).

Note 1. When a TrustZone access error occurs by a debugger access, exception, NMI, or reset does not occur. Only the error response is returned.

Note 2. The operation after error detection is selected by the BUSOAD.SRERRROAD bit.

Note 3. Address Error flag in EESR.ADE bit is set. The interrupt occurs when it is enabled in EESIPR.ADEIP bit.

43.4 Device Lifecycle Management

Device Lifecycle Management (DLM) identifies the current development/production/deployment phase of the device and controls the capabilities of the debug function, the serial programming interface, and Renesas test mode. [Figure 43.7](#) shows the available device lifecycle states and [Table 43.6](#) shows the lifecycle state definitions and capabilities in each state.

**Figure 43.7 Device lifecycle states****Table 43.6 Lifecycle state definition and capabilities in each state (1 of 2)**

Lifecycle	Definition	Protection level	Debug function	Serial programming	Renesas test mode
CM	"Chip Manufacturing"	PL2	Available in the secure and non-secure debug	Available Cannot access code/data flash area	Not available
OEM	"Original Equipment Manufacturer" The device is owned by the customer.	PL2 or PL1 or PL0	Depend on the authentication level		Not available
LCK_BOOT	"LoCKed BOOT interface" The debug interface and the serial programming interface are permanently disabled.	PL0	Not available	Not available	Not available
RMA_REQ	"Return Material Authorization REQUEST" Request for RMA. The customer must send the device to Renesas in this state.	PL0	Not available	Available Cannot access code/data flash area	Not available
RMA_ACK	"Return Material Authorization ACKnowledged" Failure analysis in Renesas	PL2	Available in the secure and non-secure debug	Available Cannot access code/data flash area	Available

Table 43.6 Lifecycle state definition and capabilities in each state (2 of 2)

Lifecycle	Definition	Protection level	Debug function	Serial programming	Renesas test mode
RMA_RET	"Return Material Authorization RETurn" The device is back to the customer. The device does not boot.	PL0	Not available	Not available	Not available

Note: The customer receives the device in either CM or OEM state (Protection level: PL2).

43.4.1 Changing the Lifecycle State

Use the boot firmware commands to change the device lifecycle state. These commands are available via the boot firmware's UART and USB interfaces, plus SWD/JTAG. See the boot firmware application note for details of the command. The lifecycle state cannot be updated by an application, but the current lifecycle state can be read through the dedicated registers.

As shown in [Figure 43.7](#), each transition is one-way and the state cannot be regressed.

Transition from OEM to RMA_REQ requires key authentication using the RMA_KEY which must have been previously injected by the customer. The key length of the RMA_KEY is 128 bits. Inject the RMA_KEY as shown in [section 43.5. Secure Key Injection](#). RMA_KEY can be injected in AL2.

The key authentication uses a challenge and response authentication or authentication using the MCU's unique ID. The response (challenge and response authentication) or the authentication code (using the MCU's unique ID) can be calculated as follows:

Response = AES-128 CMAC (RMA_KEY, 128-bit challenge)

Authentication code = AES-128 CMAC (RMA_KEY, 128-bit MCU unique ID)

The contents of the flash memory except permanently locked blocks or registers are erased when transitioning to RMA_REQ. The contents of the permanently locked blocks or registers can be read by Renesas at failure analysis. A flash block can permanently locked by setting the PBPS/PBPS_SEC and BPS_SEL registers to permanently disable programming and erasure of the block. The SAS register can be permanently locked by the FSPR bit, permanently disabling programming and erasure of the register. Transition to RMA_REQ is not possible if the AL2_KEY is disabled. The MCU does not respond after changing the device lifecycle state to RMA_REQ. To continue to use boot firmware commands, you must enter boot mode again after a reset. See the boot firmware application note for details.

Transition from OEM to LCK_BOOT is possible unless that transition has been explicitly disabled. Use the parameter setting command in AL2 or AL1 to prohibit the transition to LCK_BOOT. The LCK_BOOT transition prohibition is a permanent setting and cannot be undone. The debug interface and serial programming interface are permanently disabled in LCK_BOOT.

Note: For proper DLM state management, it is required to issue an initial DLM state transition command to OEM in case of receiving in CM state.

43.4.2 Protection and Authentication Level

The protection level (PL) and the authentication level (AL) determine the availability of the debug function and the serial programming interface. PL and AL are fixed except in the OEM state. For PL and for AL, three levels can be set for each in the OEM state. AL indicates a temporary authentication status and is initialized to PL after an MCU power-on reset. Both PL and AL can be changed only by the boot firmware and cannot be changed by the application. [Figure 43.8](#) shows the available Protection Level and Authentication Level states and transitions. [Table 43.7](#) shows the availability of the debug function and the serial programming interface in each level.

**Figure 43.8 PL and AL states and transitions****Table 43.7 Availability of the debug function and the serial programming interface in each authentication level**

AL	Debug function	Serial programming interface
AL2	Non-secure and Secure debug functions are enabled and accessible from the debugger	All functions are available
AL1	Only non-secure debug function is enabled, and debugger can access only defined non-secure debug accessible regions	Available but cannot program, erase, or read secure code or data flash area
AL0	No debug functions are available	Available but cannot access code or data flash area

Use the boot firmware commands to change PL and AL. See the boot firmware application note for details of the command.

Changing to a lower PL can be done with no restriction. Changing to a higher PL requires that the MCU be at that AL or higher. For example, when the current AL is AL1, changing to PL1 is possible but changing to PL2 is impossible. PL can be reset by the Initialize command unless the command itself is disabled. The Initialize command will set the PL to PL2 and the content in the flash memory will be erased. If there are any permanently locked blocks or registers, the Initialize command does not execute. In other words, when all the bits of the PBPS and PBPS_SEC registers are 1 and the FSPR bit is 1, the Initialize command is executable. The Initialize command can be disabled permanently in all AL states by the parameter setting command to prevent users from erasing the contents of flash memory. The Initialize command is disabled also when AL2_KEY is disabled. The MCU does not respond after executing the Initialize command. To continue to use the boot firmware commands, enter boot mode again after a reset. See the boot firmware application note for details.

Changing to a lower AL can be done without authentication. Changing to a higher AL requires key authentication using AL2_KEY or AL1_KEY, as appropriate. These keys are 128-bit keys. Injection of AL2_KEY or AL1_KEY is performed as shown in [section 43.5. Secure Key Injection](#). AL2_KEY can be injected in AL2, AL1_KEY can be injected in AL2 or AL1. The key authentication uses a challenge and response authentication. The response can be calculated as follows:

Response = AES-128 CMAC (KEY, 128 bits challenge)

AL2_KEY can be disabled permanently in AL2 by parameter setting command. AL1_KEY can be disabled permanently in AL2 or AL1 by parameter setting command.

43.4.3 Serial Programming

Whether a serial programmer can be connected and the range of flash memory that can be accessed depends on the device lifecycle state and AL as shown in [Table 43.6](#) and [Table 43.7](#). In addition, the accepted serial programming commands differ depending on the device lifecycle state and AL. See the boot firmware application note for details of the commands.

43.4.4 Device Lifecycle State and PL Change Example

The following section describes a typical device lifecycle state and PL change example.

- Secure developer
 - Change the device lifecycle state from CM to OEM using the boot firmware command
 - Set the memory security attribution of the code flash and data flash using the boot firmware command
 - Program and debug the secure application. Debug is possible if the lifecycle is CM, but it is not possible to set the memory security attribution in CM state. If the memory security attribution is not set, all area of the code flash and data flash is secure. Inject application AES, RSA, ECC, HMAC keys listed in [Table 43.8](#) (if required)
 - If the AL2_KEY and RMA_KEY are required, inject them using the boot firmware commands.
 - Prepare the MCU for the Non-secure developer
 - If the Non-secure Developer will not be permitted to use the Initialize command, disable it using the boot firmware command.
 - If the AL2_KEY will not be used and the Non-secure Developer will not be permitted to use the Initialize function, disable the AL2_KEY using the boot firmware command.
 - Change the PL from PL2 to PL1 using the boot firmware command
- Non-secure developer
 - Program and debug the non-secure application. Inject application AES, RSA, ECC, HMAC keys listed in [Table 43.8](#) (if required)
 - If the AL1_KEY is required, inject it using the boot firmware command.
 - Prepare the MCU for end-product deployment
 - Disable the Initialize command using the boot firmware command (if required)
 - If the AL1_KEY will not be used, disable the AL1_KEY using the boot firmware command.
 - Change the PL from PL1 to PL0 using the boot firmware command

43.4.5 Failure Analysis

If the customer requests failure analysis by Renesas, it is necessary to send the device after changing the device lifecycle state to RMA_REQ. If the device lifecycle state is not RMA_REQ, Renesas cannot perform the failure analysis. After failure analysis, Renesas changes the lifecycle to RMA_RET and returns the device to the customer.

Note: RMA_KEY is required to change the device lifecycle state to RMA_REQ or the MCU's Unique ID must be used as part of an authentication code. See [section 43.4.1. Changing the Lifecycle State](#) for details.

43.5 Secure Key Injection

To inject a user key into the MCU, perform the following steps.

Renesas provides the Security Key Management Tool, available on the Renesas web site, to assist with key injection preparation.

1. Create a 256-bit installation key.
This key is called the User Factory Programming Key (UFPK) and is used to wrap a user key
2. Get the wrapped version (W-UFPK) of the UFPK through the Renesas Key Wrapping Service.
3. Wrap the user key using the UFPK.
4. Send the W-UFPK and the wrapped user key to the MCU using a boot firmware interface.
The user key is unwrapped, wrapped with the MCU's hardware unique key, and stored in nonvolatile memory. DLM keys are stored in unmapped flash. Application keys are stored at the address specified with the key injection command.

[Figure 43.9](#) shows an example of key injection and [Table 43.8](#) shows the keys that can be injected.

**Figure 43.9** Key injection

Table 43.8 Keys that can be injected

DLM transition	AL transition	AES	RSA	ECC	HMAC	EdDSA	Secure boot	Other
RMA_KEY	AL2_KEY, AL1_KEY	AES-128, AES-192, AES-256, AES- XTS-128, AES- XTS-256	RSA-1024, RSA-2048, RSA-3072, RSA-4096 (Public and Private) RSA-2048 Public Key for TLS	secp192r1, secp224r1, secp256r1, secp384r1, secp521r1, Brainpool P256r1, Brainpool P384r1, Brainpool P512r1, Koblitz secp256k1 (Public and Private)	HMAC- SHA224, HMAC- SHA256, HMAC- SHA384, HMAC- SHA512, HMAC- SHA512/224, HMAC- SHA512/256	Ed25519 (Public and Private)	OEM_ROOT _PK	Key-Update Key

43.6 Secure Factory Programming

In addition to secure key injection support for injecting user keys (DLM, debug authentication, application, and secure boot keys), the MCU supports the programming of a firmware image in ciphertext format to prevent assets from being leaked during production programming. This enables secure factory programming in a non-secure environment. Secure factory programming is supported by boot firmware. The maximum capacity that can be programmed with the secure factory programming is almost 16 MB. See the security key management tool user's manual or the boot firmware application note for details of the capacity limitation. [Figure 43.10](#) shows an example of secure factory programming of an encrypted firmware image. The customer wraps the Image Encryption Key with the UFPK and encrypts the image with the Image Encryption Key using AES128-CCM. When the customer sends the W-UFPK, the wrapped Image Encryption Key, and encrypted image to the MCU through the serial programming interface, the MCU decrypts and programs the firmware image.

To further support secure factory programming in a non-secure environment, the DLM state, Protection Level, and Authentication Keys can all be set via a single boot firmware command. Points to note about this boot firmware command include:

- Encrypted firmware programming can be performed only when the MCU is in the OEM state.
- This command will change the Protection Level of the MCU. The initial PL must be PL2. The final PL must be PL0.
- If the DLM state will remain in the OEM state, AL2 key must be injected. Do not inject AL1 key.
- The MCU can be transitioned to the LCK_BOOT state. In this case, AL keys cannot be injected.
- AL2 key must be wrapped with the same UFPK as the Image Encryption Key.
- This command will erase all code and data flash area except option-setting memory before programming encrypted firmware image. If there are any permanently locked blocks, this command can not be executed.
- Prohibit to execute this command if the current register setting or write value to the registers related to startup area selection and startup bank selection are other than the following.
 - SAS.BTFLG = 1b
 - BANKSEL.BANKSWP[2:0] = 111b
 - BANKSEL_SEC.BANKSWP[2:0] = 111b
- All option-setting memory values must be included in the encrypted firmware image, including those not changed from their default values. However, if the following areas are write-protected, the write data in these areas should not be included in the image. If included, this command will terminate with an error.
 - SAS register
 - Lockable Area 0 to 2 in the data flash option setting memory

Figure 43.10 Secure factory encrypted image programming

43.7 Secure Boot

Secure boot verifies the integrity and authenticity of an OEM boot loader (called OEM_BL) starting at the beginning of application executable memory.

The OEM_BL is verified when it is initially programmed and prior to execution.

OEM_BL is verified when it is programmed using the boot firmware. Two certificates are used for validation. One is the key certificate, which is used to certify the OEM_BL verification key (called the OEM_BL_PK, the public part of the OEM_BL verification key pair). The key certificate is signed by the secret part of OEM_BL verification root key pair (called OEM_ROOT_SK). The public part of OEM_BL verification root key pair (called OEM_ROOT_PK) is registered with the MCU as the root of trust key using secure key injection as described in [section 43.5. Secure Key Injection](#). The OEM_ROOT_SK and OEM_ROOT_PK are a 256-bit ECC (secp256r1 curve) key pair. The SHA2-256 hash of the OEM_ROOT_PK is stored during the secure key injection process.

The other certificate for validation during programming is the code certificate, which is used to certify the OEM_BL. The code certificate is signed by the secret part of OEM_BL verification key pair (called OEM_BL_SK). After successful validation of the OEM_BL, the HMAC value of OEM_BL and the code certificate (called OEM_BL_digest) is generated and programmed to flash. HMAC SHA2-256 is used to generate the HMAC value. A derived key from the HUK is used as the HMAC key, so the HMAC value is unique in each MCU.

In single-chip mode, the immutable first stage boot loader (called FSBL) in ROM is executed after reset when the FSBL is enabled in the FSBLCTRL0 register. When secure boot is selected in FSBLCTRL1 register, the FSBL generates the HMAC value of the OEM_BL and the code certificate, and compares it to the expected HMAC value. When the HMAC value is the same, the FSBL jumps to the OEM_BL. When CRC boot is selected in the FSBLCTRL1 register, the FSBL calculates the CRC of the OEM_BL and compares it to the expected CRC value, which is located in the code certificate. If the CRC values match, the FSBL jumps to the OEM_BL.

The Code certificate must be programmed into flash, and its location in flash must be programmed into the SACC0 register or SACC1 register. The SACC0 register specifies the start address of the code certificate when BANKSWP[2:0] = 111b in dual mode or when BTFLG = 1 in linear mode. The SACC1 register specifies the start address of the code certificate when BANKSWP[2:0] = 000b in dual mode or when BTFLG = 0 in linear mode.

When measurement reporting is enabled in the FSBLCTRL1 register, the FSBL stores the measurement report to the SRAM address specified by the SAMR register.

FSBL execution can be skipped after a software reset or deep software standby reset, as configured by the FSBLCTRL0 register.

If the generated HMAC or CRC value is different from the expected value, the high level is output to the port set by the FSBLCTRL2 register and the MCU goes to CPU Sleep mode.

Programming the hash of OEM_ROOT_PK and FSBL related registers can be permanently locked. It is strongly recommended to lock these items during production programming.

TLV length		4	Length in bytes of TLV field
TLV ECCPUBKEY	Type & Length	4	Set to 0x01088010
	Value	64	ECC P-256 OEM_BL_PK
TLV EXPECTED_CRC	Type & Length	4	Set to 0x40000001
	Value	4	CRC32 of OEM_BL

Table 43.10 Detail of code certificate (2 of 2)

Field		Size [byte]	Description
TLV SIGNER_ID	Type & Length	4	Set to 0x10144008
	Value	32	SHA2-256 hash value of OEM_BL_PK
TLV EXPECTED_SIG	Type & Length	4	Set to 0x25088410
	Value	64	Signature of [Code Certificate OEM_BL], signed by the OEM_BL_SK When generating the signature, enter the code certificate and OEM_BL in the hash function in this order.

Table 43.11 Detail of OEM_BL_digest

Field		Size [byte]	Description
TLV EXPECTED_MAC	Type & Length	4	Fixed value 0x30184008
	Value	32	Unique OEM_BL_digest in each MCU

Note: OEM_BL_digest should be programmed in the area contiguous with the code certificate.

**Figure 43.14 Format and location of the measurement report**

OEM_BL can be updated by application code. In this case, the application code must validate the updated bootloader, generate the OEM_BL_digest, and store it immediately after the new code certificate, as per the flow described by [Figure 43.11](#). [Figure 43.15](#) and [Figure 43.16](#) show the OEM_BL update flow in dual mode or linear mode. When using linear mode, if the total size of OEM_BL, code certificate, and OEM_BL_digest is larger than the startup area size of 8 KB, you cannot use this update flow. It is recommended to use dual mode.

The implementation of the OEM_BL is user defined and application specific. However, it is recommended to implement status flags such as Update Complete Flag (UCF) and Increment Complete Flag (ICF) in the user lockable area of the data flash option-setting memory as a countermeasure against update errors due to unexpected power failure. If an update error occurs, it can be recovered as shown in the following figures. If an update error occurs, the current OEM_BL is executed after FSBL execution. Note that the update error determination program is required for both the current OEM_BL and the new OEM_BL.

Figure 43.15 OEM_BL update flow in dual mode

Figure 43.16 OEM_BL update flow in linear mode

43.8 Field Updating in Dual Mode

Be careful when performing in-field firmware update to keep the contents of secure (S or NSC) or Non-secure (NS) regions after bank swapping in the dual mode. [Figure 43.17](#) and [Figure 43.18](#) show the performing in-field update of information flow of secure or non-secure regions in the dual mode.

[Figure 43.17](#) and [Figure 43.18](#) show updating the Secure and the Non-secure regions respectively when operating in dual bank mode. Initially, BANK0 contains Version 1 of the firmware, and BANK1 is blank. As shown in [Figure 43.17](#), to update the S or NSC firmware to Version 2, first copy the Version 1 NS firmware in BANK0 to BANK1, update the S or NSC to Version 2, and then execute the bank swap.

As shown in [Figure 43.18](#), to update the NS firmware to Version 2, first copy the Version 1 S and NSC firmware from BANK0 to BANK1. Note that this process must be done by a secure service. After that, non-secure users should update the NS firmware to Version 2 and execute the bank swap.

Figure 43.17 Field updating flow of secure or non-secure callable regions

Figure 43.18 Field updating flow of non-secure region

43.9 Register Description

43.9.1 PSARB : Peripheral Security Attribution Register B

Base address: PSCU = 0x4020_4000
PSCU_NS = 0x5020_4000

Offset address: 0x04

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	PSAR B31	PSAR B30	PSAR B29	PSAR B28	PSAR B27	—	—	—	—	PSAR B22	—	—	PSAR B19	PSAR B18	—	PSAR B16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	PSAR B15	—	—	PSAR B12	PSAR B11	—	PSAR B9	PSAR B8	—	—	—	PSAR B4	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
3:0	—	These bits are read as 0. The write value should be 0.	R/W
4	PSARB4	I3C Bus Interface Security Attribution Target module: I3C and the MSTPCRB.MSTPB4 bit 0: Secure 1: Non-secure	R/W
7:5	—	These bits are read as 0. The write value should be 0.	R/W
8	PSARB8	I2C Bus Interface 1 Security Attribution Target module: IIC1 and the MSTPCRB.MSTPB8 bit 0: Secure 1: Non-secure	R/W
9	PSARB9	I2C Bus Interface 0 Security Attribution Target module: IIC0 and the MSTPCRB.MSTPB9 bit 0: Secure 1: Non-secure	R/W
10	—	This bit is read as 0. The write value should be 0.	R/W
11	PSARB11	Universal Serial Bus 2.0 FS Interface 0 Security Attribution Target module: USBFS0 and the MSTPCRB.MSTPB11 bit 0: Secure 1: Non-secure	R/W
12	PSARB12	Universal Serial Bus 2.0 HS Interface Security Attribution Target module: USBHS and the MSTPCRB.MSTPB12 bit 0: Secure 1: Non-secure	R/W
14:13	—	These bits are read as 0. The write value should be 0.	R/W
15	PSARB15	ETHERC/EDMAC Controller Security Attribution Target module: ETHERC/EDMAC, the MSTPCRB.MSTPB15 bit, and the PFENET.PHYMODE0 bit 0: Secure 1: Non-secure	R/W
16	PSARB16	Octa Memory Controller Security Attribution Target module: OSPI (+DOTF) and the MSTPCRB.MSTPB16 bit 0: Secure 1: Non-secure	R/W
17	—	This bit is read as 0. The write value should be 0.	R/W
18	PSARB18	Serial Peripheral Interface 1 Security Attribution Target module: RSPI1 and the MSTPCRB.MSTPB18 bit 0: Secure 1: Non-secure	R/W

Bit	Symbol	Function	R/W
19	PSARB19	Serial Peripheral Interface 0 Security Attribution Target module: RSPI0 and the MSTPCRB.MSTPB19 bit 0: Secure 1: Non-secure	R/W
21:20	—	These bits are read as 0. The write value should be 0.	R/W
22	PSARB22	Serial Communication Interface 9 Security Attribution Target module: SCI9 and the MSTPCRB.MSTPB22 bit 0: Secure 1: Non-secure	R/W
26:23	—	These bits are read as 0. The write value should be 0.	R/W
27	PSARB27	Serial Communication Interface 4 Security Attribution Target module: SCI4 and the MSTPCRB.MSTPB27 bit 0: Secure 1: Non-secure	R/W
28	PSARB28	Serial Communication Interface 3 Security Attribution Target module: SCI3 and the MSTPCRB.MSTPB28 bit 0: Secure 1: Non-secure	R/W
29	PSARB29	Serial Communication Interface 2 Security Attribution Target module: SCI2 and the MSTPCRB.MSTPB29 bit 0: Secure 1: Non-secure	R/W
30	PSARB30	Serial Communication Interface 1 Security Attribution Target module: SCI1 and the MSTPCRB.MSTPB30 bit 0: Secure 1: Non-secure	R/W
31	PSARB31	Serial Communication Interface 0 Security Attribution Target module: SCI0 and the MSTPCRB.MSTPB31 bit 0: Secure 1: Non-secure	R/W

Note: S-TYPE-1, P-TYPE-1.

The PSARB register specifies the security attribution for each module and the corresponding bit in Module Stop Control Register.

43.9.2 PSARC : Peripheral Security Attribution Register C

Base address: PSCU = 0x4020_4000
PSCU_NS = 0x5020_4000

Offset address: 0x08

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	PSAR C31	—	—	—	PSAR C27	PSAR C26	—	—	—	—	—	—	—	—	—	PSAR C16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	PSAR C13	PSAR C12	PSAR C11	—	—	PSAR C8	PSAR C7	—	—	—	—	—	PSAR C1	PSAR C0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	PSARC0	Clock Frequency Accuracy Measurement Circuit Security Attribution register specifies the security attribution for each module and the corresponding bit in Module Stop Control Register. Target module: CAC and the MSTPCRC.MSTPC0 bit 0: Secure 1: Non-secure	R/W

Bit	Symbol	Function	R/W
1	PSARC1	Cyclic Redundancy Check Calculator Security Attribution Target module: CRC and the MSTPCRC.MSTPC1 bit 0: Secure 1: Non-secure	R/W
6:2	—	These bits are read as 0. The write value should be 0.	R/W
7	PSARC7	Serial Sound Interface Enhanced (channel 1) Security Attribution Target module: SSIE1 and the MSTPCRC.MSTPC7 bit 0: Secure 1: Non-secure	R/W
8	PSARC8	Serial Sound Interface Enhanced (channel 0) Security Attribution Target module: SSIE0 and the MSTPCRC.MSTPC8 bit 0: Secure 1: Non-secure	R/W
10:9	—	These bits are read as 0. The write value should be 0.	R/W
11	PSARC11	Secure Digital Host IF 1 Security Attribution Target module: SDHI1 and the MSTPCRC.MSTPC11 bit 0: Secure 1: Non-secure	R/W
12	PSARC12	Secure Digital Host IF 0 Security Attribution Target module: SDHI0 and the MSTPCRC.MSTPC12 bit 0: Secure 1: Non-secure	R/W
13	PSARC13	Data Operation Circuit Security Attribution Target module: DOC and the MSTPCRC.MSTPC13 bit 0: Secure 1: Non-secure	R/W
15:14	—	These bits are read as 0. The write value should be 0.	R/W
16	PSARC16	CEU Security Attribution Target module: CEU and the MSTPCRC.MSTPC16 bit 0: Secure 1: Non-secure	R/W
25:17	—	These bits are read as 0. The write value should be 0.	R/W
26	PSARC26	Controller Area Network with Flexible Data-Rate 1 Security Attribution Target module: CANFD1 and the MSTPCRC.MSTPC26 bit 0: Secure 1: Non-secure	R/W
27	PSARC27	Controller Area Network with Flexible Data-Rate 0 Security Attribution Target module: CANFD0 and the MSTPCRC.MSTPC27 bit 0: Secure 1: Non-secure	R/W
30:28	—	These bits are read as 0. The write value should be 0.	R/W
31	PSARC31	RSIP-E51A Security Attribution Target module:RSIP-E51A and the MSTPCRC.MSTPC31 bit 0: Secure 1: Non-secure	R/W

Note: S-TYPE-1, P-TYPE-1.

The PSARC register specifies the security attribution for each module and the corresponding bit in Module Stop Control Register.

43.9.3 PSARD : Peripheral Security Attribution Register D

Base address: PSCU = 0x4020_4000
PSCU_NS = 0x5020_4000

Offset address: 0x0C

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	PSAR D28	PSAR D27	—	—	—	—	PSAR D22	—	PSAR D20	—	—	—	PSAR D16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	PSAR D15	PSAR D14	PSAR D13	PSAR D12	PSAR D11	—	—	—	—	—	PSAR D5	PSAR D4	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
3:0	—	These bits are read as 0. The write value should be 0.	R/W
4	PSARD4	Low Power Asynchronous General Purpose Timer 1 Security Attribution Target module: AGT1 and the MSTPCRD.MSTPD4 bit 0: Secure 1: Non-secure	R/W
5	PSARD5	Low Power Asynchronous General Purpose Timer 0 Security Attribution Target module: AGT0 and the MSTPCRD.MSTPD5 bit 0: Secure 1: Non-secure	R/W
10:6	—	These bits are read as 0. The write value should be 0.	R/W
11	PSARD11	Port Output Enable for GPT Group 3 Security Attribution Target module: POEG Group D and the MSTPCRD.MSTPD11 bit 0: Secure 1: Non-secure	R/W
12	PSARD12	Port Output Enable for GPT Group 2 Security Attribution Target module: POEG Group C and the MSTPCRD.MSTPD12 bit 0: Secure 1: Non-secure	R/W
13	PSARD13	Port Output Enable for GPT Group 1 Security Attribution Target module: POEG Group B and the MSTPCRD.MSTPD13 bit 0: Secure 1: Non-secure	R/W
14	PSARD14	Port Output Enable for GPT Group 0 Security Attribution Target module: POEG Group A and the MSTPCRD.MSTPD14 bit 0: Secure 1: Non-secure	R/W
15	PSARD15	12-Bit A/D 1 Converter Security Attribution Target module: ADC12_1 and the MSTPCRD.MSTPD15 bit 0: Secure 1: Non-secure	R/W
16	PSARD16	12-Bit A/D 0 Converter Security Attribution Target module: ADC12_0 and the MSTPCRD.MSTPD16 bit 0: Secure 1: Non-secure	R/W
19:17	—	These bits are read as 0. The write value should be 0.	R/W
20	PSARD20	12-Bit D/A Converter Security Attribution Target module: DAC12 and the MSTPCRD.MSTPD20 bit 0: Secure 1: Non-secure	R/W
21	—	This bit is read as 0. The write value should be 0.	R/W

Bit	Symbol	Function	R/W
22	PSARD22	Temperature Sensor Security Attribution Target module: TSN and the MSTPCRD.MSTPD22 bit 0: Secure 1: Non-secure	R/W
26:23	—	These bits are read as 0. The write value should be 0.	R/W
27	PSARD27	High Speed Analog Comparator 1 Security Attribution Target module: ACMPHS1 and the MSTPCRD.MSTPD27 bit 0: Secure 1: Non-secure	R/W
28	PSARD28	High Speed Analog Comparator 0 Security Attribution Target module: ACMPHS0 and the MSTPCRD.MSTPD28 bit 0: Secure 1: Non-secure	R/W
31:29	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-1, P-TYPE-1.

The PSARD register specifies the security attribution for each module and the corresponding bit in Module Stop Control Register.

43.9.4 PSARE : Peripheral Security Attribution Register E

Base address: PSCU = 0x4020_4000
PSCU_NS = 0x5020_4000

Offset address: 0x10

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	PSAR E31	PSAR E30	PSAR E29	PSAR E28	PSAR E27	PSAR E26	PSAR E25	PSAR E24	PSAR E23	PSAR E22	PSAR E21	PSAR E20	PSAR E19	PSAR E18	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	PSAR E9	PSAR E8	—	—	—	—	PSAR E3	PSAR E2	PSAR E1	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	—	This bit is read as 0. The write value should be 0.	R/W
1	PSARE1	WDT Security Attribution Target module: WDT 0: Secure 1: Non-secure	R/W
2	PSARE2	IWDT Security Attribution Target module: IWDT 0: Secure 1: Non-secure	R/W
3	PSARE3	Real Time Clock Security Attribution Target module: RTC 0: Secure 1: Non-secure	R/W
7:4	—	These bits are read as 0. The write value should be 0.	R/W
8	PSARE8	ULPT1 Security Attribution Target module: ULPT1 and the MSTPCRE.MSTPE8 bit 0: Secure 1: Non-secure	R/W

Bit	Symbol	Function	R/W
9	PSARE9	ULPT0 Security Attribution Target module: ULPT0 and the MSTPCRE.MSTPE9 bit 0: Secure 1: Non-secure	R/W
17:10	—	These bits are read as 0. The write value should be 0.	R/W
18	PSARE18	General PWM Timer Channel 13 Security Attribution Target module: GPT13 and the MSTPCRE.MSTPE18 bit 0: Secure 1: Non-secure	R/W
19	PSARE19	General PWM Timer Channel 12 Security Attribution Target module: GPT12 and the MSTPCRE.MSTPE19 bit 0: Secure 1: Non-secure	R/W
20	PSARE20	General PWM Timer Channel 11 Security Attribution Target module: GPT11 and the MSTPCRE.MSTPE20 bit 0: Secure 1: Non-secure	R/W
21	PSARE21	General PWM Timer Channel 10 Security Attribution Target module: GPT10 and the MSTPCRE.MSTPE21 bit 0: Secure 1: Non-secure	R/W
22	PSARE22	General PWM Timer Channel 9 Security Attribution Target module: GPT9 and the MSTPCRE.MSTPE22 bit 0: Secure 1: Non-secure	R/W
23	PSARE23	General PWM Timer Channel 8 Security Attribution Target module: GPT8 and the MSTPCRE.MSTPE23 bit 0: Secure 1: Non-secure	R/W
24	PSARE24	General PWM Timer Channel 7 Security Attribution Target module: GPT7 and the MSTPCRE.MSTPE24 bit 0: Secure 1: Non-secure	R/W
25	PSARE25	General PWM Timer Channel 6 Security Attribution Target module: GPT6 and the MSTPCRE.MSTPE25 bit 0: Secure 1: Non-secure	R/W
26	PSARE26	General PWM Timer Channel 5 Security Attribution Target module: GPT5 and the MSTPCRE.MSTPE26 bit 0: Secure 1: Non-secure	R/W
27	PSARE27	General PWM Timer Channel 4 Security Attribution Target module: GPT4 and the MSTPCRE.MSTPE27 bit 0: Secure 1: Non-secure	R/W
28	PSARE28	General PWM Timer Channel 3 Security Attribution Target module: GPT3 and the MSTPCRE.MSTPE28 bit 0: Secure 1: Non-secure	R/W
29	PSARE29	General PWM Timer Channel 2 Security Attribution Target module: GPT2 and the MSTPCRE.MSTPE29 bit 0: Secure 1: Non-secure	R/W
30	PSARE30	General PWM Timer Channel 1 Security Attribution Target module: GPT1 and the MSTPCRE.MSTPE30 bit 0: Secure 1: Non-secure	R/W

Bit	Symbol	Function	R/W
31	PSARE31	General PWM Timer Channel 0 Security Attribution Target module: GPT0, GPT_OPS and the MSTPCRE.MSTPE31 bit 0: Secure 1: Non-secure	R/W

Note: S-TYPE-1, P-TYPE-1.

The PSARE register specifies the security attribution for each module and the corresponding bit in Module Stop Control Register.

43.9.5 MSSAR : Module Stop Security Attribution Register

Base address: PSCU = 0x4020_4000
PSCU_NS = 0x5020_4000

Offset address: 0x14

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	MSSA R31	—	—	—	—	—	—	—	—	MSSA R22	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	MSSA R15	—	—	—	—	—	—	—	—	—	—	—	—	—	MSSA R1	MSSA R0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	MSSAR0	SRAM0 Clock Stop Security Attribution Target module: the MSTPCRA.MSTPA0 bit 0: Secure 1: Non-secure	R/W
1	MSSAR1	SRAM1 Clock Stop Security Attribution Target module: the MSTPCRA.MSTPA1 bit 0: Secure 1: Non-secure	R/W
14:2	—	These bits are read as 0. The write value should be 0.	R/W
15	MSSAR15	Standby RAM Clock Stop Security Attribution Target module: the MSTPCRA.MSTPA15 bit 0: Secure 1: Non-secure	R/W
21:16	—	These bits are read as 0. The write value should be 0.	R/W
22	MSSAR22	DMAC/DTC Clock Stop Security Attribution Target module: the MSTPCRA.MSTPA22 bit 0: Secure 1: Non-secure	R/W
30:23	—	These bits are read as 0. The write value should be 0.	R/W
31	MSSAR31	ELC Clock Stop Security Attribution Target module: the MSTPCRC.MSTPC14 bit 0: Secure 1: Non-secure	R/W

Note: S-TYPE-1, P-TYPE-1.

The MSSAR register specifies the security attribution for the corresponding bit in Module Stop Control Register.

43.9.6 PPARB : Peripheral Privilege Attribution Register B

Base address: PSCU = 0x4020_4000
PSCU_NS = 0x5020_4000

Offset address: 0x1C

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	PPAR B31	PPAR B30	PPAR B29	PPAR B28	PPAR B27	—	—	—	—	PPAR B22	—	—	PPAR B19	PPAR B18	—	PPAR B16
Value after reset:	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	PPAR B15	—	—	PPAR B12	PPAR B11	—	PPAR B9	PPAR B8	—	—	—	PPAR B4	—	—	—	—
Value after reset:	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

Bit	Symbol	Function	R/W
3:0	—	These bits are read as 1. The write value should be 1.	R/W
4	PPARB4	I3C Bus Interface Privilege Attribution Target module: I3C and the MSTPCRB.MSTPB4 bit 0: Privileged 1: UnPrivileged	R/W
7:5	—	These bits are read as 1. The write value should be 1.	R/W
8	PPARB8	I2C Bus Interface 1 Privilege Attribution Target module: IIC1 and the MSTPCRB.MSTPB8 bit 0: Privileged 1: UnPrivileged	R/W
9	PPARB9	I2C Bus Interface 0 Privilege Attribution Target module: IIC0 and the MSTPCRB.MSTPB9 bit 0: Privileged 1: UnPrivileged	R/W
10	—	This bit is read as 1. The write value should be 1.	R/W
11	PPARB11	Universal Serial Bus 2.0 FS Interface 0 Privilege Attribution Target module: USBFS0 and the MSTPCRB.MSTPB11 bit 0: Privileged 1: UnPrivileged	R/W
12	PPARB12	Universal Serial Bus 2.0 HS Interface 0 Privilege Attribution Target module: USBHS and the MSTPCRB.MSTPB12 bit 0: Privileged 1: UnPrivileged	R/W
14:13	—	These bits are read as 1. The write value should be 1.	R/W
15	PPARB15	ETHERC/EDMAC Controller Privilege Attribution Target module: ETHERC/EDMAC, the MSTPCRB.MSTPB15 bit, and the PFENET.PHYMODE0 bit 0: Privileged 1: UnPrivileged	R/W
16	PPARB16	Octa Memory Controller Privilege Attribution Target module: OSPI (+DOTF) and the MSTPCRB.MSTPB16 bit 0: Privileged 1: UnPrivileged	R/W
17	—	This bit is read as 1. The write value should be 1.	R/W
18	PPARB18	Serial Peripheral Interface 1 Privilege Attribution Target module: RSPI1 and the MSTPCRB.MSTPB18 bit 0: Privileged 1: UnPrivileged	R/W

Bit	Symbol	Function	R/W
19	PPARB19	Serial Peripheral Interface 0 Privilege Attribution Target module: RSPI0 and the MSTPCRB.MSTPB19 bit 0: Privileged 1: UnPrivileged	R/W
21:20	—	These bits are read as 1. The write value should be 1.	R/W
22	PPARB22	Serial Communication Interface 9 Privilege Attribution Target module: SCI9 and the MSTPCRB.MSTPB22 bit 0: Privileged 1: UnPrivileged	R/W
26:23	—	These bits are read as 1. The write value should be 1.	R/W
27	PPARB27	Serial Communication Interface 4 Privilege Attribution Target module: SCI4 and the MSTPCRB.MSTPB27 bit 0: Privileged 1: UnPrivileged	R/W
28	PPARB28	Serial Communication Interface 3 Privilege Attribution Target module: SCI3 and the MSTPCRB.MSTPB28 bit 0: Privileged 1: UnPrivileged	R/W
29	PPARB29	Serial Communication Interface 2 Privilege Attribution Target module: SCI2 and the MSTPCRB.MSTPB29 bit 0: Privileged 1: UnPrivileged	R/W
30	PPARB30	Serial Communication Interface 1 Privilege Attribution Target module: SCI1 and the MSTPCRB.MSTPB30 bit 0: Privileged 1: UnPrivileged	R/W
31	PPARB31	Serial Communication Interface 0 Privilege Attribution Target module: SCI0 and the MSTPCRB.MSTPB31 bit 0: Privileged 1: UnPrivileged	R/W

Note: S-TYPE-2, P-TYPE-1.

The PPARB register specifies the privilege attribution for each module and the corresponding bit in Module Stop Control Register.

43.9.7 PPARC : Peripheral Privilege Attribution Register C

Base address: PSCU = 0x4020_4000
PSCU_NS = 0x5020_4000

Offset address: 0x20

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

1	PPARE1	WDT Privilege Attribution Target module: WDT 0: Privileged 1: UnPrivileged	R/W
2	PPARE2	IWDT Privilege Attribution Target module: IWDT 0: Privileged 1: UnPrivileged	R/W
3	PPARE3	Real Time Clock Privilege Attribution Target module: RTC 0: Privileged 1: UnPrivileged	R/W
7:4	—	These bits are read as 1. The write value should be 1.	R/W
8	PPARE8	ULPT1 Privilege Attribution Target module: ULPT1 and the MSTPCRE.MSTPE8 bit 0: Privileged 1: UnPrivileged	R/W

Bit	Symbol	Function	R/W
9	PPARE9	ULPT0 Privilege Attribution Target module: ULPT0 and the MSTPCRE.MSTPE9 bit 0: Privileged 1: UnPrivileged	R/W
17:10	—	These bits are read as 1. The write value should be 1.	R/W
18	PPARE18	General PWM Timer Channel 13 Privilege Attribution Target module: : GPT13 and the MSTPCRE.MSTPE18 bit 0: Privileged 1: UnPrivileged	R/W
19	PPARE19	General PWM Timer Channel 12 Privilege Attribution Target module: : GPT12 and the MSTPCRE.MSTPE19 bit 0: Privileged 1: UnPrivileged	R/W
20	PPARE20	General PWM Timer Channel 11 Privilege Attribution Target module: : GPT11 and the MSTPCRE.MSTPE20 bit 0: Privileged 1: UnPrivileged	R/W
21	PPARE21	General PWM Timer Channel 10 Privilege Attribution Target module: : GPT10 and the MSTPCRE.MSTPE21 bit 0: Privileged 1: UnPrivileged	R/W
22	PPARE22	General PWM Timer Channel 9 Privilege Attribution Target module: : GPT9 and the MSTPCRE.MSTPE22 bit 0: Privileged 1: UnPrivileged	R/W
23	PPARE23	General PWM Timer Channel 8 Privilege Attribution Target module: : GPT8 and the MSTPCRE.MSTPE23 bit 0: Privileged 1: UnPrivileged	R/W
24	PPARE24	General PWM Timer Channel 7 Privilege Attribution Target module: : GPT7 and the MSTPCRE.MSTPE24 bit 0: Privileged 1: UnPrivileged	R/W
25	PPARE25	General PWM Timer Channel 6 Privilege Attribution Target module: : GPT6 and the MSTPCRE.MSTPE25 bit 0: Privileged 1: UnPrivileged	R/W
26	PPARE26	General PWM Timer Channel 5 Privilege Attribution Target module: : GPT5 and the MSTPCRE.MSTPE26 bit 0: Privileged 1: UnPrivileged	R/W
27	PPARE27	General PWM Timer Channel 4 Privilege Attribution Target module: : GPT4 and the MSTPCRE.MSTPE27 bit 0: Privileged 1: UnPrivileged	R/W
28	PPARE28	General PWM Timer Channel 3 Privilege Attribution Target module: : GPT3 and the MSTPCRE.MSTPE28 bit 0: Privileged 1: UnPrivileged	R/W
29	PPARE29	General PWM Timer Channel 2 Privilege Attribution Target module: : GPT2 and the MSTPCRE.MSTPE29 bit 0: Privileged 1: UnPrivileged	R/W
30	PPARE30	General PWM Timer Channel 1 Privilege Attribution Target module: : GPT1 and the MSTPCRE.MSTPE30 bit 0: Privileged 1: UnPrivileged	R/W

The PPARE register specifies the privilege attribution for each module and the corresponding bit in Module Stop Control Register.

43.9.10 MSPAR : Module Stop Privilege Attribution Register

Base address: PSCU = 0x4020_4000
PSCU_NS = 0x5020_4000

Offset address: 0x2C

[illegible]

Bit	Symbol	Function	R/W
30:0	—	These bits are read as 1. The write value should be 1.	R/W
31	MSPAR31	ELC Clock Stop Privilege Attribution Target module: the MSTPCRC.MSTPC14 bit 0: Privileged 1: UnPrivileged	R/W

Note: S-TYPE-2, P-TYPE-1.

The MSPAR register specifies the privilege attribution for the corresponding bit in the Module Stop Control Register.

43.9.11 CFSAMONA : Code Flash Security Attribution Monitor Register A

Base address: PSCU = 0x4020_4000
PSCU NS = 0x5020 4000

Offset address: 0x30

[illegible]

Note 1. The value in a blank product is 0x1FF. It is set to the value written by your application.

Bit	Symbol	Function	R/W
14:0	—	These bits are read as 0.	R
23:15	CFS2[8:0]	Code Flash Secure Area Indicate the area of secure region for code flash.	R
31:24	—	These bits are read as 0.	R

Note: S-TYPE-5, P-TYPE-5.

Base address: PSCU = 0x4020_4000
PSCU_NS = 0x5020_4000

Offset address: 0x34

[illegible]

Note 1. The value in a blank product is 0x3F. It is set to the value written by your application.

Bit	Symbol	Function	R/W
9:0	—	These bits are read as 0.	R
15:10	DFS[5:0]	Data Flash Secure Area Indicate the area of secure region for data flash.	R
31:16	—	These bits are read as 0.	R

Note: S-TYPE-5, P-TYPE-5.

Base address: PSCU = 0x4020_4000
PSCU_NS = 0x5020_4000

Offset address: 0x38

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	DLMMON[3:0]			
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	*1	*1	*1	*1

Note 1. The value in a blank product is 0001b. These bits depend on DLM status.

Bit	Symbol	Function	R/W
3:0	DLMMON[3:0]	Device Lifecycle Management State Monitor Indicate DLM status value. 0x0: Reserved 0x1: CM 0x2: Reserved 0x3: Reserved 0x4: OEM 0x5: Reserved 0x6: LCK_BOOT 0x7: RMA_REQ 0x8: RMA_ACK 0x9: RMA_RET Others: Reserved	R
31:4	—	These bits are read as 0.	R

Note: S-TYPE-5, P-TYPE-5.

43.9.14 MSAOAD : Master Security Attribution Operation After Detection Register

Base address: BUS = 0x4000_3000

Offset address: 0x1010

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	KEY[7:0]								—	—	—	—	—	—	—	OAD
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	OAD	Operation after detection 0: NMI 1: Reset	R/W
7:1	—	These bits are read as 0. The write value should be 0.	R/W
15:8	KEY[7:0]	Key Code These bits enable or disable writing of the OAD bit.	W

Note: S-TYPE-6, P-TYPE-2.

OAD bit (Operation after detection)

The OAD bit specifies operation when the access violation is detected. When OAD = 0, error response is returned and NMI is generated. When OAD = 1, reset request is generated. When writing to the OAD bit, write 0xA5 simultaneously to the KEY[7:0] bits using halfword access.

KEY[7:0] bits (Key Code)

The KEY[7:0] bits enable or disable writing to the OAD bit. When writing to the OAD bit, write 0xA5 simultaneously to the KEY[7:0] bits. If this value is not written to the KEY[7:0] bits, the OAD bit is not updated.

43.9.15 MSAPT : Master Security Attribution Protect Register

Base address: BUS = 0x4000_3000

Offset address: 0x1014

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	KEY[7:0]								—	—	—	—	—	—	—	PROTECT
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	PROTECT	Protection of register 0: MSAOAD register writing is possible. 1: MSAOAD register writing is protected. Read is possible.	R/W
7:1	—	These bits are read as 0. The write value should be 0.	R/W
15:8	KEY[7:0]	Key Code These bits enable or disable writing of the PROTECT bit.	W

Note: S-TYPE-6, P-TYPE-2.

PROTECT bit (Protection of register)

The PROTECT bit enables or disables writes to the associated registers to be protected.

MSAPT.PROTECT controls the MSAOAD register.

When the PROTECT bit is set simultaneously, write 0xA5 to the KEY[7:0] bits using half word access.

KEY[7:0] bits (Key Code)

The KEY[7:0] bits enable or disable writing to the PROTECT bit. When writing to the PROTECT bit, write 0xA5 simultaneously to the KEY[7:0] bits. If this value is not written to the KEY[7:0] bits, the PROTECT bit is not updated.

43.10 Usage Note

43.10.1 Security or Privilege Bit Write Timing

When writing a security or privilege attribution bit, confirm that the write is complete by reading the security or privilege register until it matches the value written. The protection is not effective until the write to the security or privilege register is complete.

43.10.2 Note on Security and Privilege Attribute Bit Setting

After the reset is released, the program executes in the Secure Privileged state. Before changing the state, configure the security and privilege attributes for memory and peripheral.

Set these attributes before using the relevant resources, and do not modify them subsequently. For memory security and privilege attributes, configure the attributes for the relevant addresses before access.

44. Renesas Secure IP (RSIP-E51A)

44.1 Overview

This security engine consists of an isolated subsystem comprising an access management circuit, storage area, encryption/decryption circuit, and random number generation circuit. In combination with the RSIP library, the security engine can prevent eavesdropping (to maintain confidentiality), falsification of information (to ensure integrity), and impersonation (to verify authenticity).

Because key information required for encryption and decryption is stored only in the security engine and all accesses from the outside can be blocked, the security engine enables building a more robust security system.

Table 44.1 lists the security engine specifications. Figure 44.1 shows the security engine block diagram.

Table 44.1 Security engine specifications (1 of 2)

Parameter	Specifications
Access control	Access management circuit In case of irregular access to the security engine due to a tampered program or CPU runaway, this circuit blocks all subsequent accesses and stops data output from the security engine
Symmetric cryptography	AES: Compliant with NIST FIPS PUB 197 - Key length: 128, 192, or 256 bits - Data block size: 128 bits - AES supports following block cipher mode ECB, CBC, CTR: Compliant with NIST SP 800-38A CCM: Compliant with NIST SP 800-38C GCM: Compliant with NIST SP 800-38D XTS: Compliant with IEEE 1619-2007 - AES supports following authentication algorithm CMAC: Compliant with NIST SP 800-38B GMAC: Compliant with NIST SP 800-38D - AES does not support the KEY size of 192-bit in CCM, GCM, XTS, CMAC and GMAC.
Random number generation	128-bit true random number generation circuit
Asymmetric cryptography	RSA - Maximum number of operable bits: 4224 bits - Supported key sizes: 1024-bit, 2048-bit, 3072-bit, and 4096-bit - Signature generation, signature verification, public-key encryption, private-key decryption ECC - Maximum number of operable bits: 576 bits - Support for curve - NIST P-192, P-224, P-256, P-384 and P-521 - Brainpool P256r1, P384r1, and P512r1 - Ed25519 - secp256k1 - Signature generation, signature verification, key generation
Message digest computation	HASH - Block size: 512-bit(SHA-224, SHA-256) 1024-bit(SHA-512/224, SHA-512/256, SHA-384, SHA-512) - Key size: 512-bit or less - HASH supports following secure hash algorithms SHA-224, SHA-256, SHA-512/224, SHA-512/256, SHA-384 and SHA-512: Compliant with FIPS PUB 180-4 - HASH supports following message authentication algorithm HMAC: Compliant with FIPS PUB 198

Table 44.1 Security engine specifications (2 of 2)

Parameter	Specifications
Hardware Unique Key	• A read-only, 256-bit Hardware Unique Key (HUK) is exclusively accessible by the security engine access management circuit through a dedicated bus. • Key derivation functions (KDFs) combine the Hardware Unique Key with the key generation information. The derived keys implement the key wrapping for user key secure storage. • The HUK uniqueness prevents the illicit cloning and copying of keys to another MCU of the MCU group. • The HUK itself is stored in wrapped (encrypted, non-plain) format in an isolated memory area. Therefore, it is protected from illicit access and copy.
Application Key Management	• Wrapped keys are only valid within the security engine.
Unique ID	• A read-only, 128-bit ID unique to an MCU (Unique ID) is accessible from the access management circuit. • Key derivation functions (KDFs) combine the Unique ID with the key generation information. Such derived keys are used to unwrap the HUK within the security engine boundary.
OEM boot loader version	• The security engine outputs OEM boot loader version (OEM BL Ver.). • Flash sequencer supports Anti-Rollback Counter Protection using the OEM boot loader version, which is protected by the security engine.
Decryption-on-the-fly	The security engine outputs the key data of the decryption-on-the-fly IP (DOTF) through a dedicated bus
Tamper Resistance	Countermeasures available for side-channel attacks, including SPA/DPA and timing attacks.
Module-stop function	Module-stop state can be set to reduce power consumption
TrustZone Filter	Security and Privilege attribution can be set

Figure 44.1 Security engine block diagram

44.2 Operation

44.2.1 Symmetric cryptography

Figure 44.2 shows conceptual block diagram of the symmetric cryptography installed in the security engine.

The symmetric cryptography uses the input key information and converts the plaintext data to ciphertext or ciphertext data to plaintext through the hardware.

The encryption/decryption process can be completed without exposing the key data and the process's intermediate data outside of the security engine. This process is performed by the encryption/decryption circuit and storage area of the security engine internally.

Figure 44.2 Conceptual diagram of the symmetric cryptography

44.2.2 Asymmetric Cryptography

Figure 44.3 shows conceptual block diagram of the asymmetric cryptography installed in the security engine.

The asymmetric cryptography uses the input key information and converts the plaintext data to ciphertext or ciphertext data to plaintext or generates/verifies the signature.

The encryption/decryption or signature generation/verification process can be completed without exposing the key data and the process's intermediate data outside of the security engine. This process is performed by the cryptographic circuit and storage area of the security engine internally.

Figure 44.3 Conceptual diagram of the asymmetric cryptography

44.2.3 Hash generator

Figure 44.4 shows conceptual block diagram of the hash generator installed in the security engine.

The hash generator generates uses the input key information (if required for the hash calculation) and generates the message digest or tag.

The calculation process can be completed without exposing any key data and the process's intermediate data outside of the security engine. This process is performed by the hash circuit and storage area of the security engine internally.

Figure 44.4 Conceptual diagram of the hash generator

44.2.4 Encryption and Decryption

Follow the procedure below to encrypt and decrypt the data:

1. Input the key information to the security engine.
2. Input the target data to the security engine. Plaintext data is converted to ciphertext and ciphertext data to plaintext.
3. Read the converted data.

The encryption/decryption circuit has input and output buffers, and can perform encryption/decryption in parallel with data input/output. Figure 44.5 shows the encryption engine timing.

Figure 44.5 Encryption and decryption timing (AES)

44.3 Usage Notes

44.3.1 Software Standby Mode

When Software Standby mode is entered while the security engine is in process, proper processing cannot be resumed after cancelling Software Standby mode. Software Standby mode should therefore be entered while the security engine is not running.

44.3.2 Module-Stop Function Setting

The security engine operation can be disabled or enabled using Module Stop Control Register C (MSTPCRC). The security engine module is initially stopped after reset. Releasing the module-stop state enables access to the registers.

44.3.3 SPA/DPA Protections

SPA/DPA protections can optionally be enabled for encryption/decryption processing.

44.3.4 Restrictions on Open process

While open process of security engine's API (R_RSIP_Open) is running, the following restrictions is applied.

- Available CPU frequency is up to 240MHz
- Do not change frequency of CPUCLK, ICLK and PCLKn (n = A to E)
- Do not change MSTPCRn registers (n = A to E)
- Do not transition to CPU Sleep mode, CPU Deep Sleep mode, Software Standby mode and Deep Software Standby mode 1/2/3."

45. 12-Bit A/D Converter (ADC12)

45.1 Overview

The MCU includes 12-bit successive approximation A/D converter (ADC12) units. In unit 0, up to 12 analog input channels are selectable. In unit 1, up to 13 analog input channels, temperature sensor output, internal reference voltage, VBATT 1/3 voltage monitor output can be selected for conversion in respective units.

The A/D conversion accuracy is selectable from 12-bit, 10-bit, 8-bit conversion, making it possible to optimize the trade-off between speed and resolution in generating a digital value.

The ADC12 supports the following operating modes:

- Single scan mode to convert analog inputs of selected channels in ascending order of channel number
- Continuous scan mode to convert analog inputs of selected channels continuously in ascending order of channel number
- Group scan mode to divide analog inputs of channels into two groups (group A and B) and convert the analog inputs of selected channels for each group in ascending order of channel number.

In group scan mode, select two groups (group A and B). You can individually select the scan start conditions for each group (group A, B) and start scanning of each group at different times. In addition, when group A priority control operation is set, the ADC12 accepts group A scan start during group B A/D conversion, suspending group B conversion. This allows you to assign higher priority to A/D conversion start for group A.

In double trigger mode, the analog input of a selected channel is converted in single scan mode or group scan mode (group A), and data converted by the first and second A/D conversion start triggers are stored in different registers, providing duplexing of A/D converted data.

Self-diagnosis is performed once at the beginning of each scan, and one of the three reference voltage values generated in ADC12 is A/D converted.

The temperature sensor output and the internal reference voltage is selectable at the same time as the analog input of the channel. First A/D conversion is performed for the analog input of the channel, next the temperature sensor output and then for the internal reference voltage.

The ADC12 also provides a compare function (window A and window B). The compare function specifies the upper reference value for window A and lower reference value for window B, and outputs an interrupt when the A/D converted value of the selected channel meets the comparison conditions.

The A/D data storage buffer is a ring buffer consisting of 16 buffers to sequentially store A/D converted data.

[Table 45.1](#) lists the ADC12 specifications and [Table 45.2](#) lists the functions. [Figure 45.1](#) shows a block diagram of ADC12 and [Table 45.3](#) lists the I/O pins.

Table 45.1 ADC12 specifications (1 of 3)

Parameter	Specifications
Number of units	Two units
Input channels	Up to 25 channels (AN000 to AN002, AN004 to AN008, AN016 to AN019, AN100 to AN102, AN104 to AN106, AN116 to AN122)
Analog function	Temperature sensor output, internal reference voltage, VBATT 1/3 voltage monitor output
Conversion method	Successive approximation method
Resolution	12-bit, 10-bit, 8-bit
Conversion time	0.4 μ s/channel (when 12-bit A/D conversion clock PCLKC (ADCLK) is operating at 60 MHz)
A/D conversion clock	Peripheral module clock PCLKA and A/D conversion clock PCLKC (ADCLK) can be set with the following division ratios: PCLKA to PCLKC (ADCLK) frequency ratio = 1:1, 2:1, 4:1, 8:1, 1:2, 1:4

Table 45.1 ADC12 specifications (2 of 3)

Parameter	Specifications
Data registers ^{*1}	• 25 registers for analog input • One register for A/D-converted data duplication in double trigger mode • Two registers for A/D-converted data duplication during extended operation in double trigger mode • One register for temperature sensor output • One register for internal reference voltage • One register for VBATT 1/3 voltage monitor output • One register for self-diagnosis • A/D conversion results are stored in A/D data registers • 12-bit, 10-bit, 8-bit accuracy for A/D conversion results • A/D-converted value addition mode, in which the sum of all A/D-converted results is stored in the A/D data registers as a value with the conversion accuracy bit count + extended bits • Double-trigger mode (selectable in single scan and group scan modes): – The first unit of A/D-converted analog input data on one selected channel is stored in the data register for the channel, and the second unit is stored in the duplication register. • Extended operation in double trigger mode (available for specific triggers): – A/D-converted analog input data on one selected channel is stored in the duplication register provided for the associated trigger.
Operating modes	• Single scan mode: – A/D conversion is performed only once on the analog inputs of arbitrarily selected channels, on the temperature sensor output, on the internal reference voltage. • Continuous scan mode: A/D conversion is performed repeatedly on the analog inputs of the selected channels on the temperature sensor output, and on the internal reference voltage. • Group scan mode: – Analog inputs of selected channels, the temperature sensor output, and the internal reference voltage are divided into groups A and B. Then A/D conversion of the analog inputs selected on a group basis is performed once. – The scan start conditions can be independently selected for group A, B, allowing A/D conversion of group A, B to be started independently. • Group scan mode (when group priority operation is selected): – If a priority group trigger is input during scanning of a lower-priority group, the scanning of the lower-priority group is stopped and then scanning of the priority group is started. The order of priority is group A > group B. – It is possible to select whether to restart scanning (rescan) of the lower-priority group upon completion of the priority group scan. It is also possible to specify rescanning to be started from the first channel of the selected channels or from the channel for which A/D conversion has not been completed.
Conditions for A/D conversion start	• Software trigger • Synchronous triggers from the Event Link Controller (ELC) and GPT • Asynchronous triggering by the external trigger pins, ADTRG0 (unit 0) and ADTRG1 (unit 1)
Functions	• Dedicated sample-and-hold function with optional constant sampling and 3 channels in unit 0 • Variable sampling state count • Self-diagnosis of A/D converter • Selectable A/D-converted value addition mode or average mode • Analog input disconnection detection function (discharge and precharge functions) • Double-trigger mode (duplication of A/D conversion data) • Automatic clear function for A/D data registers • Digital comparison of values in the comparison register and data register, and comparison between values in the data registers • Ring buffer

Table 45.1 ADC12 specifications (3 of 3)

Parameter	Specifications
Interrupt sources	- In single scan mode (double trigger deselected), an A/D scan end interrupt request (ADC12i_ADI (i = 0, 1)) and ELC event signal (ADC12i_ADI (i = 0, 1)) can be generated on completion of single scan. - A compare interrupt request (ADC12i_CMPAI (i = 0, 1)/ADC12i_CMPBI (i = 0, 1)) can be generated in response to a match with a digital comparison condition. - A window compare ELC event signal (ADC12i_WCMPI (i = 0, 1)) can be generated in response to a match with a digital comparison condition. - A window compare ELC event signal (ADC12i_WCMPUM (i = 0, 1)) can be generated in response to a mismatch with a digital comparison condition. - In single scan mode (double trigger selected), an A/D scan end interrupt request (ADC12i_ADI (i = 0, 1)) and ELC event signal (ADC12i_ADI (i = 0, 1)) is generated on completion of two scans. - In continuous scan mode, an A/D scan end interrupt request (ADC12i_ADI (i = 0, 1)) and ELC event signal (ADC12i_ADI (i = 0, 1)) is generated on completion of all the selected channel scans. - In group scan mode (double trigger deselected), an A/D scan end interrupt request (ADC12i_ADI (i = 0, 1)) and ELC event signal (ADC12i_ADI (i = 0, 1)) is generated on completion of group A scan, and an A/D scan end interrupt request for group B (ADC12i_GBADI (i = 0, 1)) can be generated on completion of group B scan. - In group scan mode (double trigger selected), an A/D scan end interrupt request (ADC12i_ADI (i = 0, 1)) and ELC event signal (ADC12i_ADI (i = 0, 1)) is generated on completion of two group A scans, and an A/D scan end interrupt request for group B (ADC12i_GBADI (i = 0, 1)) can be generated on completion of group B scan. - ADC12i_ADI (i = 0, 1), ADC12i_GBADI (i = 0, 1), ADC12i_WCMPI (i = 0, 1), and ADC12i_WCMPUM (i = 0, 1) can activate the Data Transfer Controller (DTC).
ELC interface	- An event is generated upon completion of group A scan in group-scan mode. - An event is generated upon completion of group B scan in group-scan mode. - An event is generated when all scans complete. - Scan can be started by a trigger from the ELC. - An event is generated according to conditions of the compare function window in single-scan mode.
Reference voltage	- Unit 0: VREFH0 is the analog reference voltage. VREFL0 is the analog reference ground. - Unit 1: VREFH is the analog reference voltage. VREFL is the analog reference ground.
Analog channel input SA judgement function	Input channels of analog can be valid only when the security attribution of ADC12n (n = 0, 1) match the security attribution of PORT (PmSAR). When the security attribution of ADC12n (n = 0, 1) does not match the PORT security attribution, the conversion result of ADC input channel will be unexpected. Internal reference voltage, Temperature sensor output and VBATT 1/3 voltage monitor output have no Security Attribution judgement function.
Module-stop function	Module-stop state can be set to for each units reduce power consumption.*2
TrustZone Filter	Security and Privilege attribution can be set for each unit

Note 1. Changing the A/D conversion accuracy also changes the A/D conversion time. For details, see [section 45.3.6. Analog Input Sampling and Scan Conversion Time](#).

Note 2. For details, see [section 10, Low Power Modes](#).

Table 45.2 ADC12 functions (1 of 2)

Parameter	Function		
Analog input channel	AN000 to AN002, AN004 to AN008, AN016 to AN019 (unit 0), AN100 to AN102, AN104 to AN106, AN116 to AN122 (unit 1) Internal reference voltage Temperature sensor output VBATT 1/3 voltage monitor output		
Conditions for A/D conversion starts	Software	Software trigger	Enabled
	Asynchronous trigger (external trigger)	Trigger input pin	ADTRGn (n = 0, 1)
	Synchronous trigger (trigger from ELC)	ELC trigger	ELC_AD00 (unit 0) and ELC_AD10 (unit 1), ELC_AD01 (unit 0) and ELC_AD11 (unit 1)
		GPT trigger	GTCIADAm, GTCIADBm (unit 0) (m = 0 to 3) GTCIADAn, GTCIADBn (unit 1) (n = 4 to 7)

Figure 45.2 **ADC12 block diagram (unit 1)**

Table 45.3 lists the ADC12 I/O pins.

Table 45.3 ADC12 I/O pins (unit 0)

Pin name	I/O	Function
AVCC0	Input	Analog block power supply pin (Connect to VCC when ADC12/DAC12 is not used.)
AVSS0	Input	Analog block power supply ground pin (Connect to VSS when ADC12/DAC12 is not used.)
VREFH0	Input	Analog reference voltage supply pin
VREFL0	Input	Analog reference ground pin
AN000 to AN002, AN004 to AN008, AN016 to AN019	Input	Analog input pins 0 to 2, 4 to 8, 16 to 19
ADTRG0	Input	External trigger input pin for starting A/D conversion

Table 45.4 ADC12 I/O pins (unit 1)

Pin name	I/O	Function
AVCC0	Input	Analog block power supply pin (Connect to VCC when ADC12/DAC12 is not used.)
AVSS0	Input	Analog block power supply ground pin (Connect to VSS when ADC12/DAC12 is not used.)
VREFH	Input	Analog reference voltage supply pin
VREFL	Input	Analog reference ground pin
AN100 to AN102, AN104 to AN106, AN116 to AN122	Input	Analog input pins 0 to 2, 4 to 6, 16 to 22
ADTRG1	Input	External trigger input pin for starting A/D conversion

45.2 Register Descriptions

45.2.1 ADDRn : A/D Data Registers n

Base address: $ADC12m = 0x4033_2000 + 0x0200 \times m$ ($m = 0, 1$)
 $ADC12m_NS = 0x5033_2000 + 0x0200 \times m$ ($m = 0, 1$)

Offset address: $0x020 + 0x2 \times n$ ($n = 0$ to $8, 16$ to $19, m = 0$)
 $0x020 + 0x2 \times n$ ($n = 0$ to $6, 16$ to $22, m = 1$)

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	ADDR [15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	ADDR [15:0]	Converted Value 15 to 0 Functions vary depending on the selected mode and accuracy. See Table 45.5 and Table 45.6 .	R

Note: S-TYPE-3, P-TYPE-3

ADDRn registers are 16-bit read-only registers to store A/D conversion results.

The following conditions determine the formats for data in the A/D data registers:

- Setting of the A/D Data Register Format Select bit (ADCER.ADRFMT) (flush-left or flush-right)
- The setting in the A/D Conversion Accuracy Select bits (ADCER.ADPRC[1:0]) (12-bit, 10-bit, 8-bit is selectable.)
- Setting of the Addition/Average Count Select bits (ADADC.ADC[2:0]) (1, 2, 3, 4, or 16 times)
- Setting of the Average Mode Enable bit (ADADC.AVEE) (addition or average).

This section describes the data formats for these conditions in different modes.

(1) When A/D-converted value addition/average mode is not selected

[Table 45.5](#) shows the example of bit assignment for 12-bit accuracy.

Table 45.5 Example of bit assignment for 12-bit accuracy

Accuracy	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Right-justified data with 12-bit accuracy	These bits are read as 0.				Converted Value 11 to 0: 12-bit A/D-converted value											
Left-justified data with 12-bit accuracy	Converted Value 11 to 0: 12-bit A/D-converted value												These bits are read as 0.			

(2) When A/D-converted value average mode is selected

A/D-converted value average mode can be selected when 2 or 4 times is specified in the A/D-converted value addition mode. When A/D converted value average mode is selected, these registers indicate the mean of A/D-converted values on a specific channel. The value is stored in the A/D data register based on the setting of the A/D Data Register Format Select bit in the same way as for normal A/D conversion.

(3) When A/D-converted value addition mode is selected

For 12-bit, 10-bit, 8-bit accuracy, 1, 2, 3, or 4 times can be selected in the A/D-converted value addition mode. A/D conversion results are stored in the A/D data register as a 2-bit-extended value of the specified conversion accuracy.

For 12-bit accuracy, 16 times can also be selected in the A/D-converted value addition mode. In A/D-converted value addition mode, these registers indicate the value that is obtained by adding A/D-converted values on a specific channel. A/D conversion results are stored in the A/D data register as a 4-bit-extended value of the specified conversion accuracy.

When A/D-converted value addition mode is selected, the value is stored in the A/D data register based on the settings of the A/D Data Register Format Select bits.

Table 45.6 shows example of the bit assignment for 12-bit accuracy.

Table 45.6 Example of bit assignment for 12-bit accuracy when A/D-converted value addition mode is selected

Accuracy		b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Right-justified data with 12-bit accuracy	When 16 conversion times is specified	Added Value 15 to 0: 16-bit sum of A/D conversion results															
	When 1, 2, 3, or 4 conversion times is specified	These bits are read as 0.		Added Value 13 to 0: 14-bit sum of A/D conversion results													
Left-justified data with 12-bit accuracy	When 1, 2, 3, or 4 conversion times is specified	Added Value 15 to 0: 16-bit sum of A/D conversion results															
	When 16 conversion times is specified	Added Value 13 to 0: 14-bit sum of A/D conversion results														These bits are read as 0.	

45.2.2 ADDBLDR : A/D Data Duplexing Register

Base address: $\text{ADC12m} = 0x4033_2000 + 0x0200 \times m$ ($m = 0, 1$)
 $\text{ADC12m_NS} = 0x5033_2000 + 0x0200 \times m$ ($m = 0, 1$)

Offset address: 0x018

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	ADDBLDR [15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	ADDBLDR [15:0]	Converted Value 15 to 0 Functions vary depending on the selected mode and accuracy. See Table 45.7 and Table 45.8 .	R

Note: S-TYPE-3, P-TYPE-3

ADDBLDR register is a 16-bit read-only register to store A/D conversion results in response to a second trigger in double-trigger mode.

The following conditions determine the formats for data in the A/D data registers:

- Setting of the A/D Data Register Format Select bit (ADCER.ADRFMT) (flush-left or flush-right)
- The setting in the A/D Conversion Accuracy Select bits (ADCER.ADPRC[1:0]) (12-bit, 10-bit, 8-bit is selectable.)
- Setting of the Addition/Average Count Select bits (ADADC.ADC[2:0]) (1, 2, 3, 4, or 16 times)
- Setting of the Average Mode Enable bit (ADADC.AVEE) (addition or average).

This section describes the data formats for these conditions in different modes.

(1) When A/D-converted value addition/average mode is not selected

Table 45.7 shows the example of bit assignment for 12-bit accuracy.

Table 45.7 Example of bit assignment for 12-bit accuracy

Accuracy	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Right-justified data with 12-bit accuracy	These bits are read as 0.				Converted Value 11 to 0: 12-bit A/D-converted value											
Left-justified data with 12-bit accuracy	Converted Value 11 to 0: 12-bit A/D-converted value												These bits are read as 0.			

(2) When A/D-converted value average mode is selected

A/D-converted value average mode can be selected when 2 or 4 times is specified in the A/D-converted value addition mode. When A/D converted value average mode is selected, this register indicates the mean of A/D-converted values on a specific channel. The value is stored in the A/D data register based on the setting of the A/D Data Register Format Select bit in the same way as for normal A/D conversion.

(3) When A/D-converted value addition mode is selected

For 12-bit, 10-bit, 8-bit accuracy, 1, 2, 3, or 4 times can be selected in the A/D-converted value addition mode. A/D conversion results are stored in the A/D data register as a 2-bit-extended value of the specified conversion accuracy.

For 12-bit accuracy, 16 times can also be selected in the A/D-converted value addition mode. In A/D-converted value addition mode, this register indicates the value that is obtained by adding A/D-converted values on a specific channel. A/D conversion results are stored in the A/D data register as a 4-bit-extended value of the specified conversion accuracy.

When A/D-converted value addition mode is selected, the value is stored in the A/D data register based on the settings of the A/D Data Register Format Select bits.

Table 45.8 shows example of the bit assignment for 12-bit accuracy.

Table 45.8 Example of bit assignment for 12-bit accuracy when A/D-converted value addition mode is selected

Accuracy		b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Right-justified data with 12-bit accuracy	When 16 conversion times is specified	Added Value 15 to 0: 16-bit sum of A/D conversion results															
	When 1, 2, 3, or 4 conversion times is specified	These bits are read as 0.		Added Value 13 to 0: 14-bit sum of A/D conversion results													
Left-justified data with 12-bit accuracy	When 1, 2, 3, or 4 conversion times is specified	Added Value 15 to 0: 16-bit sum of A/D conversion results															
	When 16 conversion times is specified	Added Value 13 to 0: 14-bit sum of A/D conversion results														These bits are read as 0.	

45.2.3 ADDBLDRn : A/D Data Duplexing Register n (n = A, B)

Base address: ADC12m = 0x4033_2000 + 0x0200 × m (m = 0, 1)
ADC12m_NS = 0x5033_2000 + 0x0200 × m (m = 0, 1)

Offset address: 0x084 (n = A)
0x086 (n = B)

Bit position: 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

Bit field: ADDBLDR [15:0]

Value after reset: 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

Bit	Symbol	Function	R/W
15:0	ADDBLDR [15:0]	Converted Value 15 to 0 Functions vary depending on the selected mode and accuracy. See Table 45.9 and Table 45.10.	R

Note: S-TYPE-3, P-TYPE-3

ADDBLDRn registers are 16-bit read-only registers to store A/D conversion results in response to respective triggers during extended operation in double-trigger mode.

The following conditions determine the formats for data in the A/D data registers:

- Setting of the A/D Data Register Format Select bit (ADCER.ADRFMT) (flush-left or flush-right)
- The setting in the A/D Conversion Accuracy Select bits (ADCER.ADPRC[1:0]) (12-bit, 10-bit, 8-bit is selectable.)

- Setting of the Addition/Average Count Select bits (ADADC.ADC[2:0]) (1, 2, 3, 4, or 16 times)
- Setting of the Average Mode Enable bit (ADADC.AVEE) (addition or average).

This section describes the data formats for these conditions in different modes.

(1) When A/D-converted value addition/average mode is not selected

Table 45.9 shows the example of bit assignment for 12-bit accuracy.

Table 45.9 Example of bit assignment for 12-bit accuracy

Accuracy	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Right-justified data with 12-bit accuracy	These bits are read as 0.				Converted Value 11 to 0: 12-bit A/D-converted value											
Left-justified data with 12-bit accuracy	Converted Value 11 to 0: 12-bit A/D-converted value												These bits are read as 0.			

(2) When A/D-converted value average mode is selected

A/D-converted value average mode can be selected when 2 or 4 times is specified in the A/D-converted value addition mode. When A/D converted value average mode is selected, these registers indicate the mean of A/D-converted values on a specific channel. The value is stored in the A/D data register based on the setting of the A/D Data Register Format Select bit in the same way as for normal A/D conversion.

(3) When A/D-converted value addition mode is selected

For 12-bit, 10-bit, 8-bit accuracy, 1, 2, 3, or 4 times can be selected in the A/D-converted value addition mode. A/D conversion results are stored in the A/D data register as a 2-bit-extended value of the specified conversion accuracy.

For 12-bit accuracy, 16 times can also be selected in the A/D-converted value addition mode. In A/D-converted value addition mode, these registers indicate the value that is obtained by adding A/D-converted values on a specific channel. A/D conversion results are stored in the A/D data register as a 4-bit-extended value of the specified conversion accuracy.

When A/D-converted value addition mode is selected, the value is stored in the A/D data register based on the settings of the A/D Data Register Format Select bits.

Table 45.10 shows example of the bit assignment for 12-bit accuracy.

Table 45.10 Example of bit assignment for 12-bit accuracy when A/D-converted value addition mode is selected

Accuracy		b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Right-justified data with 12-bit accuracy	When 16 conversion times is specified	Added Value 15 to 0: 16-bit sum of A/D conversion results															
	When 1, 2, 3, or 4 conversion times is specified	These bits are read as 0.		Added Value 13 to 0: 14-bit sum of A/D conversion results													
Left-justified data with 12-bit accuracy	When 1, 2, 3, or 4 conversion times is specified	Added Value 15 to 0: 16-bit sum of A/D conversion results															
	When 16 conversion times is specified	Added Value 13 to 0: 14-bit sum of A/D conversion results														These bits are read as 0.	

45.2.4 ADTSDR : A/D Temperature Sensor Data Register

Base address: $ADC12m = 0x4033_2000 + 0x0200 \times m$ ($m = 0, 1$)
 $ADC12m_NS = 0x5033_2000 + 0x0200 \times m$ ($m = 0, 1$)

Offset address: 0x01A

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	ADTSDR [15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	ADTSDR [15:0]	Converted Value 15 to 0 Functions vary depending on the selected mode and accuracy. See Table 45.11 and Table 45.12 .	R

Note: S-TYPE-3, P-TYPE-3

ADTSDR register is a 16-bit read-only register to store A/D conversion result of the temperature sensor output.

The following conditions determine the formats for data in the A/D data registers:

- Setting of the A/D Data Register Format Select bit (ADCER.ADRFMT) (flush-left or flush-right)
- The setting in the A/D Conversion Accuracy Select bits (ADCER.ADPRC[1:0]) (12-bit, 10-bit, 8-bit is selectable.)
- Setting of the Addition/Average Count Select bits (ADADC.ADC[2:0]) (1, 2, 3, 4, or 16 times)
- Setting of the Average Mode Enable bit (ADADC.AVEE) (addition or average).

This section describes the data formats for these conditions in different modes.

(1) When A/D-converted value addition/average mode is not selected

[Table 45.11](#) shows the example of bit assignment for 12-bit accuracy.

Table 45.11 Example of bit assignment for 12-bit accuracy

Accuracy	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Right-justified data with 12-bit accuracy	These bits are read as 0.				Converted Value 11 to 0: 12-bit A/D-converted value											
Left-justified data with 12-bit accuracy	Converted Value 11 to 0: 12-bit A/D-converted value												These bits are read as 0.			

(2) When A/D-converted value average mode is selected

A/D-converted value average mode can be selected when 2 or 4 times is specified in the A/D-converted value addition mode. When A/D converted value average mode is selected, this register indicates the mean of A/D-converted values on a specific channel. The value is stored in the A/D data register based on the setting of the A/D Data Register Format Select bit in the same way as for normal A/D conversion.

(3) When A/D-converted value addition mode is selected

For 12-bit, 10-bit, 8-bit accuracy, 1, 2, 3, or 4 times can be selected in the A/D-converted value addition mode. A/D conversion results are stored in the A/D data register as a 2-bit-extended value of the specified conversion accuracy.

For 12-bit accuracy, 16 times can also be selected in the A/D-converted value addition mode. In A/D-converted value addition mode, this register indicates the value that is obtained by adding A/D-converted values on a specific channel. A/D conversion results are stored in the A/D data register as a 4-bit-extended value of the specified conversion accuracy.

When A/D-converted value addition mode is selected, the value is stored in the A/D data register based on the settings of the A/D Data Register Format Select bits.

[Table 45.12](#) shows example of the bit assignment for 12-bit accuracy.

Table 45.12 Example of bit assignment for 12-bit accuracy when A/D-converted value addition mode is selected

Accuracy		b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Right-justified data with 12-bit accuracy	When 16 conversion times is specified	Added Value 15 to 0: 16-bit sum of A/D conversion results															
	When 1, 2, 3, or 4 conversion times is specified	These bits are read as 0.		Added Value 13 to 0: 14-bit sum of A/D conversion results													
Left-justified data with 12-bit accuracy	When 1, 2, 3, or 4 conversion times is specified	Added Value 15 to 0: 16-bit sum of A/D conversion results															
	When 16 conversion times is specified	Added Value 13 to 0: 14-bit sum of A/D conversion results														These bits are read as 0.	

45.2.5 ADOCDR : A/D Internal Reference Voltage Data Register

Base address: $ADC12m = 0x4033_2000 + 0x0200 \times m$ ($m = 0, 1$)
 $ADC12m_NS = 0x5033_2000 + 0x0200 \times m$ ($m = 0, 1$)

Offset address: 0x01C

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	ADOCDR [15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	ADOCDR [15:0]	Converted Value 15 to 0 Functions vary depending on the selected mode and accuracy. See Table 45.13 and Table 45.14 .	R

Note: S-TYPE-3, P-TYPE-3

ADOCDR register is a 16-bit read-only register to store A/D conversion result of the internal reference voltage.

The following conditions determine the formats for data in the A/D data registers:

- Setting of the A/D Data Register Format Select bit (ADCER.ADRFMT) (flush-left or flush-right)
- The setting in the A/D Conversion Accuracy Select bits (ADCER.ADPRC[1:0]) (12-bit, 10-bit, 8-bit is selectable.)
- Setting of the Addition/Average Count Select bits (ADADC.ADC[2:0]) (1, 2, 3, 4, or 16 times)
- Setting of the Average Mode Enable bit (ADADC.AVEE) (addition or average).

This section describes the data formats for these conditions in different modes.

(1) When A/D-converted value addition/average mode is not selected

[Table 45.13](#) shows the example of bit assignment for 12-bit accuracy.

Table 45.13 Example of bit assignment for 12-bit accuracy

Accuracy	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Right-justified data with 12-bit accuracy	These bits are read as 0.				Converted Value 11 to 0: 12-bit A/D-converted value											
Left-justified data with 12-bit accuracy	Converted Value 11 to 0: 12-bit A/D-converted value												These bits are read as 0.			

(2) When A/D-converted value average mode is selected

A/D-converted value average mode can be selected when 2 or 4 times is specified in the A/D-converted value addition mode. When A/D converted value average mode is selected, this register indicates the mean of A/D-converted values on a

specific channel. The value is stored in the A/D data register based on the setting of the A/D Data Register Format Select bit in the same way as for normal A/D conversion.

(3) When A/D-converted value addition mode is selected

For 12-bit, 10-bit, 8-bit accuracy, 1, 2, 3, or 4 times can be selected in the A/D-converted value addition mode. A/D conversion results are stored in the A/D data register as a 2-bit-extended value of the specified conversion accuracy.

For 12-bit accuracy, 16 times can also be selected in the A/D-converted value addition mode. In A/D-converted value addition mode, this register indicates the value that is obtained by adding A/D-converted values on a specific channel. A/D conversion results are stored in the A/D data register as a 4-bit-extended value of the specified conversion accuracy.

When A/D-converted value addition mode is selected, the value is stored in the A/D data register based on the settings of the A/D Data Register Format Select bits.

Table 45.14 shows example of the bit assignment for 12-bit accuracy.

Table 45.14 Example of bit assignment for 12-bit accuracy when A/D-converted value addition mode is selected

Accuracy		b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Right-justified data with 12-bit accuracy	When 16 conversion times is specified	Added Value 15 to 0: 16-bit sum of A/D conversion results															
	When 1, 2, 3, or 4 conversion times is specified	These bits are read as 0.		Added Value 13 to 0: 14-bit sum of A/D conversion results													
Left-justified data with 12-bit accuracy	When 1, 2, 3, or 4 conversion times is specified	Added Value 15 to 0: 16-bit sum of A/D conversion results															
	When 16 conversion times is specified	Added Value 13 to 0: 14-bit sum of A/D conversion results														These bits are read as 0.	

45.2.6 ADVMDR : A/D VBATT Monitor Data Register

Base address: $\text{ADC12m} = 0x4033_2000 + 0x0200 \times m$ ($m = 0, 1$)
 $\text{ADC12m_NS} = 0x5033_2000 + 0x0200 \times m$ ($m = 0, 1$)

Offset address: 0x026

Bit position: 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

Bit field: ADDR [15:0]

Value after reset: 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

Bit	Symbol	Function	R/W
15:0	ADDR[15:0]	Converted Value 15 to 0 Functions vary depending on the selected mode and accuracy. See Table 45.15 and Table 45.16	R

Note: S-TYPE-3, P-TYPE-3

ADVMDR register is a 16-bit read-only register to store A/D conversion result of the VBATT 1/3 voltage. For VBATT 1/3 voltage measurement, VBATTMNSLR.VBTMNSLR need to be set. For more information, see [section 11, Battery Backup Function](#). ADVMDR register is an alias for the ADDR3 register.

The following conditions determine the formats for data in the A/D data registers:

- Setting of the A/D Data Register Format Select bit (ADCER.ADRFMT) (flush-left or flush-right)
- The setting in the A/D Conversion Accuracy Select bits (ADCER.ADPRC[1:0]) (12-bit, 10-bit, 8-bit is selectable.)
- Setting of the Addition/Average Count Select bits (ADADC.ADC[2:0]) (1, 2, 3, 4, or 16 times)
- Setting of the Average Mode Enable bit (ADADC.AVEE) (addition or average).

This section describes the data formats for these conditions in different modes.

(1) When A/D-converted value addition/average mode is not selected

Table 45.15 shows the example of bit assignment for 12-bit accuracy.

Table 45.15 Example of bit assignment for 12-bit accuracy

Accuracy	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Right-justified data with 12-bit accuracy	These bits are read as 0.				Converted Value 11 to 0: 12-bit A/D-converted value											
Left-justified data with 12-bit accuracy	Converted Value 11 to 0: 12-bit A/D-converted value												These bits are read as 0.			

(2) When A/D-converted value average mode is selected

A/D-converted value average mode can be selected when 2 or 4 times is specified in the A/D-converted value addition mode. When A/D converted value average mode is selected, this register indicates the mean of A/D-converted values on a specific channel. The value is stored in the A/D data register based on the setting of the A/D Data Register Format Select bit in the same way as for normal A/D conversion.

(3) When A/D-converted value addition mode is selected

For 12-bit, 10-bit, 8-bit accuracy, 1, 2, 3, or 4 times can be selected in the A/D-converted value addition mode. A/D conversion results are stored in the A/D data register as a 2-bit-extended value of the specified conversion accuracy.

For 12-bit accuracy, 16 times can also be selected in the A/D-converted value addition mode. In A/D-converted value addition mode, this register indicates the value that is obtained by adding A/D-converted values on a specific channel. A/D conversion results are stored in the A/D data register as a 4-bit-extended value of the specified conversion accuracy.

When A/D-converted value addition mode is selected, the value is stored in the A/D data register based on the settings of the A/D Data Register Format Select bits.

Table 45.16 shows example of the bit assignment for 12-bit accuracy.

Table 45.16 Example of bit assignment for 12-bit accuracy when A/D-converted value addition mode is selected

Accuracy		b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Right-justified data with 12-bit accuracy	When 16 conversion times is specified	Added Value 15 to 0: 16-bit sum of A/D conversion results															
	When 1, 2, 3, or 4 conversion times is specified	These bits are read as 0.		Added Value 13 to 0: 14-bit sum of A/D conversion results													
Left-justified data with 12-bit accuracy	When 1, 2, 3, or 4 conversion times is specified	Added Value 15 to 0: 16-bit sum of A/D conversion results															
	When 16 conversion times is specified	Added Value 13 to 0: 14-bit sum of A/D conversion results														These bits are read as 0.	

45.2.7 ADRD : A/D Self-Diagnosis Data Register

Base address: $ADC12m = 0x4033_2000 + 0x0200 \times m$ ($m = 0, 1$)
 $ADC12m_NS = 0x5033_2000 + 0x0200 \times m$ ($m = 0, 1$)

Offset address: 0x01E

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	DIAGST[1:0]		—	—	AD[11:0]											
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
11:0	AD[11:0]	Converted Value 11 to 0 12-bit A/D-converted value	R
13:12	—	These bits are read as 0.	R
15:14	DIAGST[1:0]	Self-Diagnosis Status For details on self-diagnosis, see section 45.2.16. ADCER : A/D Control Extended Register . 0 0: Self-diagnosis not executed after power-on. 0 1: Self-diagnosis was executed using the 0 V voltage. 1 0: Self-diagnosis was executed using the reference voltage ^{*1} × 1/2. 1 1: Self-diagnosis was executed using the reference voltage ^{*1} .	R

Note: S-TYPE-3, P-TYPE-3

Note: The example of the bit assignment for the right-justified data with 12-bit accuracy is indicated.

Note 1. The reference voltage refers to VREFH0 for unit 0 and to VREFH for unit 1.

ADRD is a 16-bit read-only register that holds the A/D conversion results based on the self-diagnosis of the ADC12. In addition to the AD[11:0] bits indicating the A/D-converted value, it includes the Self-Diagnosis Status bit (DIAGST[1:0]).

The settings of the A/D data register format and the A/D conversion accuracy determines the formats for data in this register.

The A/D-converted value addition and average modes cannot be applied to the A/D self-diagnosis function. For details on self-diagnosis, see [section 45.2.16. ADCER : A/D Control Extended Register](#).

This section describes the data formats for each condition. The register diagram and the register bit table shown in this section indicate example of the bit assignment for the left and right-justified data with 12-bit accuracy.

Table 45.17 Bit assignment for each right-justified accuracy

Accuracy	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Right-justified data with 12-bit accuracy	DIAGST[1:0]	—	—	—	AD[11:0]	—	—	—	—	—	—	—	—	—	—	—

Table 45.18 Bit assignment for each left-justified accuracy

Accuracy	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Left-justified data with 12-bit accuracy	AD[11:0]	—	—	—	—	—	—	—	—	—	—	—	—	—	DIAGST[1:0]	—

45.2.8 ADCSR : A/D Control Register

Base address: ADC12m = 0x4033_2000 + 0x0200 × m (m = 0, 1)
ADC12m_NS = 0x5033_2000 + 0x0200 × m (m = 0, 1)

Offset address: 0x000

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	ADST	ADCS[1:0]	—	—	—	TRGE	EXTRG	DBLE	GBADIE	—	—	—	—	—	—	DBLANS[4:0]

Value after reset: 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

Bit	Symbol	Function	R/W
4:0	DBLANS[4:0]	Double Trigger Channel Select These bits select one analog input channel for double-trigger operation. The setting is only valid in double-trigger mode.	R/W
5	—	This bit is read as 0. The write value should be 0.	R/W
6	GBADIE	Group B Scan End Interrupt and ELC Event Enable Group B scan only works in group scan mode. 0: Disable ADC12i_GBADI (i = 0, 1) interrupt generation on group B scan completion. 1: Enable ADC12i_GBADI (i = 0, 1) interrupt generation on group B scan completion.	R/W

Bit	Symbol	Function	R/W
7	DBLE	Double Trigger Mode Select 0: Deselect double-trigger mode. 1: Select double-trigger mode.	R/W
8	EXTRG	Trigger Select* ¹ 0: Start A/D conversion by the synchronous trigger (GPT, ELC). 1: Start A/D conversion by the asynchronous trigger (ADTRGn* ²).	R/W
9	TRGE	Trigger Start Enable 0: Disable A/D conversion to be started by the synchronous or asynchronous trigger 1: Enable A/D conversion to be started by the synchronous or asynchronous trigger	R/W
12:10	—	These bits are read as 0. The write value should be 0.	R/W
14:13	ADCS[1:0]	Scan Mode Select 0 0: Single scan mode 0 1: Group scan mode 1 0: Continuous scan mode 1 1: Setting prohibited	R/W
15	ADST	A/D Conversion Start 0: Stop A/D conversion process. 1: Start A/D conversion process.	R/W

Note: S-TYPE-3, P-TYPE-3

Note 1. To start A/D conversion using an external pin (asynchronous trigger):

After a high-level signal is input to the external pin (ADTRGn), write 1 to both the TRGE and EXTRG bits in the ADCSR register and drive the ADTRGn pin low. With these settings, the scan conversion process starts on detection of the falling edge of ADTRGn. The pulse width of the low-level input must be at least PCLKA 1.5 clock cycles.

Note 2. n = 0 (unit 0), 1 (unit 1)

The ADCSR register sets double-trigger mode and A/D conversion start trigger, enables or disables scan end interrupt, selects the scan mode, and starts or stops A/D conversion.

DBLANS[4:0] bits (Double Trigger Channel Select)

The DBLANS[4:0] bits select one channel for A/D conversion data duplication in double-trigger mode. This can be selected by setting the binary value of the channel number to be duplicated. The A/D conversion results of the analog input of the channel selected in the DBLANS[4:0] bits are stored in A/D Data Register y when conversion is started by the first trigger, and stored in the A/D Data Duplexing Register when conversion is started by the second trigger.

In double-trigger mode, the channels selected in the ADANSA0 and ADANSA1 registers, are invalid, and the channel selected in the DBLANS[4:0] bits is A/D converted instead.

When double-trigger mode is used in group scan mode, double-trigger control is only applied to group A and not to group B.

Also, in double trigger mode, the analog inputs of multiple channels, temperature sensor outputs, or internal reference voltage cannot be selected for group A, but can be selected for groups B.

Only set the DBLANS[4:0] bits when the ADST bit is 0. Do not set the DBLANS[4:0] bits at the same time that you write 1 to the ADST bit.

To enter A/D-converted value addition/average mode when in double-trigger mode, set the same channel in the ADADS0 and ADADS1 registers as the channel selected in the DBLANS[4:0] bits.

A/D-converted data from the self-diagnosis function, temperature sensor output and internal reference voltage cannot be used in double-trigger mode.

GBADIE bit (Group B Scan End Interrupt and ELC Event Enable)

The GBADIE bit enables or disables group B scan end interrupt (ADC12i_GBADI (i = 0, 1)) in group scan mode.

DBLE bit (Double Trigger Mode Select)

The DBLE bit selects or deselects double-trigger mode. Double-trigger mode can only be operated by the synchronous trigger (GPT, ELC) selected in the ADSTRGR.TRSA[5:0] bits.

Double-trigger operation is as follows:

1. The ADC12i_ADI (i = 0, 1) interrupt is not output on completion of the first conversion but on completion of the second conversion.
2. The A/D conversion results from the duplication channel (selected in DBLANS[4:0]) started by the first trigger are stored in A/D Data Register y and those started by the second trigger are stored in the A/D Data Duplexing Register.

When the DBLE bit is set (double-trigger mode is selected), the channels specified in the ADANSA0 and ADANSA1 registers are invalid. Double-trigger mode is deselected by setting DBLE to 0. Setting DBLE to 1 again enables the same double-trigger operation described in 1. and 2. for first time scanning with the first trigger.

Do not select double-trigger mode in continuous scan mode. When using double trigger mode in group scan mode, A/D conversion of the temperature sensor output and internal reference voltage should not be selected for group A. Software triggering cannot be used in double-trigger mode. Always set the ADST bit to 0 before setting the DBLE bit. Do not set the DBLE bit at that same time as writing 1 to the ADST bit.

EXTRG bit (Trigger Select)

The EXTRG bit selects the synchronous or asynchronous trigger as the trigger for starting A/D conversion.

In group scan mode, the setting of this bit takes effect on the trigger selected for group A. For group B, A/D conversion is started by the selected synchronous trigger regardless of this bit setting.

TRGE bit (Trigger Start Enable)

The TRGE bit enables or disables A/D conversion by the synchronous and asynchronous triggers. In group scan mode, set this bit to 1.

ADCS[1:0] bits (Scan Mode Select)

The ADCS[1:0] bits select the scan mode.

In single scan mode, A/D conversion is performed for the analog inputs of the channels selected in the ADANSA0 and ADANSA1 registers, in ascending order of channel number. When 1 cycle of A/D conversion completes for all the selected channels, the scan conversion stops.

In continuous scan mode, when the ADCSR.ADST bit is 1, A/D conversion is performed for the analog inputs of the channels selected with the ADANSA0 and ADANSA1 registers, in ascending order of channel number. When 1 cycle of A/D conversion completes for all the selected channels, A/D conversion repeats from the first channel. If the ADCSR.ADST bit is set to 0 during continuous scan, A/D conversion stops even if scanning is in progress.

In group scan mode:

- Group A scanning is started by the synchronous trigger (GPT, ELC) selected in the TRSA[5:0] bits in the ADSTRGR register. A/D conversion is performed on group A analog inputs of the channels selected in the ADANSA0 and ADANSA1 registers, in ascending order of channel number. When 1 cycle of A/D conversion completes for all the selected channels, A/D conversion stops.
- Group B scanning is started by the synchronous trigger (GPT, ELC) selected in the ADSTRGR.TRSB[5:0] bits. A/D conversion is performed on group B analog inputs of the channels selected in the ADANSB0 and ADANSB1 registers, in ascending order of channel number. When 1 cycle of A/D conversion completes for all the selected channels, A/D conversion stops.

If the conversion processes in group A and group B occur at the same time, those conversions cannot be controlled separately. In this case, set group A Priority Control Setting bit (ADGSPCR.PGS) in the A/D Group Scan Priority Control Register (ADGSPCR) to 1 to assign a priority to group A conversion.

In group scan mode, select different channels and triggers for group A and group B.

Only set the ADCS[1:0] bits when the ADST bit is 0. Do not set the ADCS[1:0] bits at the same time that you write 1 to the ADST bit.

Table 45.19 Selectable targets for A/D conversion depending on scan and double-trigger mode settings

Scan mode setting	Double-trigger mode setting	Targets for A/D conversion				
		Self-diagnosis	Analog input (group A)	Analog input (group B)	Temperature sensor output	Internal reference voltage
Single scan	DBLE = 0	✓	✓	—	✓	✓
	DBLE = 1	—	✓ (1 ch only)	—	—	—
Continuous scan	DBLE = 0	✓	✓	—	✓	✓
	DBLE = 1	—	—	—	—	—
Group scan	DBLE = 0	✓	✓	✓	✓	✓
	DBLE = 1	—	✓ (1 ch only)	✓	✓	✓

Note: ✓: Selectable, —: Not selectable

ADST bit (A/D Conversion Start)

The ADST bit starts or stops the A/D conversion process. Before the ADST bit is set to 1, set the A/D conversion clock, the conversion mode, and the conversion target analog input.

[Setting conditions]

- 1 is written.
- The synchronous trigger (GPT, ELC) selected in the ADSTRGR.TRSA[5:0] bits is detected when ADCSR.EXTRG is 0 and ADCSR.TRGE is 1.
- The synchronous trigger (GPT, ELC) selected in the ADSTRGR.TRSB[5:0] bits is detected when ADCSR.TRGE is set to 1 in group scan mode.
- The asynchronous trigger is detected when the ADCSR.TRGE and ADCSR.EXTRG bits are set to 1 and the ADSTRGR.TRSA[5:0] bits are set to 0x00.
- When group priority operation mode is enabled (ADCSR.ADCS[1:0] = 01b and ADGSPCR.PGS = 1), the ADGSPCR.GBRP bit is set to 1, and each time A/D conversion on the group with the lowest priority is started.

[Clearing conditions]

- 0 is written.
- The A/D conversion of all the selected channels, the temperature sensor output the internal reference voltage completes in single scan mode.
- Group A scan completes in group scan mode.
- Group B scan completes in group scan mode.
- When group priority operation mode is enabled (ADCSR.ADCS[1:0] = 01b and ADGSPCR.PGS = 1), the ADGSPCR.GBRSCN bit is set to 1, and A/D conversion on the group with the lowest priority started by trigger completes.

Note: When group priority operation mode is enabled (ADCSR.ADCS[1:0] = 01b and ADGSPCR.PGS = 1), do not set the ADST bit to 1.

Note: When group priority operation mode is enabled (ADCSR.ADCS[1:0] = 01b and ADGSPCR.PGS = 1), do not set the ADST bit to 0. When forcing A/D conversion to terminate, follow the procedure for clearing the ADST bit.

45.2.9 ADANSA0 : A/D Channel Select Register A0

Base address: $ADC12m = 0x4033_2000 + 0x0200 \times m$ ($m = 0, 1$)
 $ADC12m_NS = 0x5033_2000 + 0x0200 \times m$ ($m = 0, 1$)

Offset address: 0x004

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	ANSA15	ANSA14	ANSA13	ANSA12	ANSA11	ANSA10	ANSA09	ANSA08	ANSA07	ANSA06	ANSA05	ANSA04	ANSA03	ANSA02	ANSA01	ANSA00
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	ANSA15 to ANSA00 ^{*1}	A/D Conversion Channels Select Bit 15 (ANSA15) is associated with ANm15 and bit 0 (ANSA00) is associated with ANm00. 0: Do not select associated input channel. 1: Select associated input channel.	R/W

Note: S-TYPE-3, P-TYPE-3

Note: Bits associated with non-existent pins are reserved. This bit is read as 0. The write value should be 0.

Note 1. 00 to 08 (unit 0), 00 to 06 (unit 1) is available.

ADANSA0 register selects analog input channels for A/D conversion. In group scan mode, this register selects group A channels.

Only set the ADANSA0 register when the ADCSR.ADST bit is 0.

ANSAn bits (A/D Conversion Channels Select)

The ADANSA0 register selects any combination of analog input channels for A/D conversion. The channels and the number of channels can be arbitrarily set.

In double trigger mode, the channels selected in the ADANSA0 register are invalid, and the channel selected in the ADCSR.DBLANS[4:0] bits is selected in group A instead.

When group scan mode is selected, do not select the channels specified in A/D Channel Select Register B0 (ADANSB0) and A/D Channel Select Register B1 (ADANSB1).

VBATT 1/3 voltage monitor output correspond to ADC120.ADANSA0.ANSA03 or ADC121.ADANSA0.ANSA03 bit.

Security attribution function between ADC12n ($n = 0, 1$) and PORT. Detail conversion result please see [section 45.3.12. Security Attribution between ADCn \(\$n = 0, 1\$ \) and PORT \(PmSAR \(\$m = 0\$ to 9, A, B\)\)](#).

45.2.10 ADANSA1 : A/D Channel Select Register A1

Base address: $ADC12m = 0x4033_2000 + 0x0200 \times m$ ($m = 0, 1$)
 $ADC12m_NS = 0x5033_2000 + 0x0200 \times m$ ($m = 0, 1$)

Offset address: 0x006

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Bit	Symbol	Function	R/W
15:0	ADS15 to ADS00*1	A/D-Converted Value Addition/Average Channel Select Bit 15 (ADS15) is associated with ANm15 and bit 0 (ADS00) is associated with ANm00. 0: Do not select associated input channel. 1: Select associated input channel.	R/W

Note: S-TYPE-3, P-TYPE-3

Note: Bits associated with non-existent pins are reserved. This bit is read as 0. The write value should be 0.

Note 1. 00 to 08 (unit 0), 00 to 06 (unit 1) is available.

ADSn bits (A/D-Converted Value Addition/Average Channel Select)

The ADSn bits determine which A/D-converted channels are subject to A/D-converted value addition/averaging. When an ADSn bit associated with a channel selected for A/D conversion is set to 1, A/D conversion of the analog input of the respective channel is performed successively 1, 2, 3, 4, or 16 times, as specified in the ADC[2:0] bits in the ADADC register.

When the ADADC.AVEE bit is 0, the value obtained by addition is stored in the A/D data register. When the ADADC.AVEE bit is 1, the mean value of the results obtained by addition is stored in the A/D data register.

The ADSn bits apply only to channels that are selected for A/D conversion in:

- The ANSAn bits in the ADANSA0 register or the DBLANS[4:0] bits in the ADCSR register
- The ANSBn bits in the ADANSB0 register

For channels on which the A/D conversion is performed and for which addition/average mode is not selected, a normal 1-time conversion is executed, and the conversion result is stored in the A/D data register.

Only set ADADS0 register bits when the ADCSR.ADST bit is 0.

Figure 45.3 shows a scanning operation sequence in which the ADADS0 register bits (channel c and g) are set to 1. In this figure:

- Addition mode is selected (ADADC.AVEE = 0)
- The number of conversions is set to 4 (ADADC.ADC[1:0] = 11b)
- The analog input channels (a to h) are selected by ADANSA0 register in continuous scan mode (ADCSR.ADCS[1:0] = 10b).

The conversion process begins with analog input A (channel a). The analog input C (channel c) conversion is performed successively 4 times and the added value is returned to A/D Data Register c (ADDRc). Next, the analog input D (channel d) conversion process is started. The analog input G (channel g) is performed successively 4 times and the added value is returned to A/D Data Register g (ADDRg). After conversion of analog input H (channel h), the conversion operation repeats in the same sequence starting with analog input A (channel a).

Figure 45.3 Scan conversion sequence with ADADC.ADC[2:0] = 011b, set 1 for analog inputs C and G by ADADS0/1

45.2.14 ADADS1 : A/D-Converted Value Addition/Average Channel Select Register 1

Base address: $ADC12m = 0x4033_2000 + 0x0200 \times m$ ($m = 0, 1$)
 $ADC12m_NS = 0x5033_2000 + 0x0200 \times m$ ($m = 0, 1$)

Offset address: 0x00A

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	ADS31	ADS30	ADS29	ADS28	ADS27	ADS26	ADS25	ADS24	ADS23	ADS22	ADS21	ADS20	ADS19	ADS18	ADS17	ADS16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	ADS31 to ADS16*1	A/D-Converted Value Addition/Average Channel Select Bit 15 (ADS31) is associated with ANm31 and bit 0 (ADS16) is associated with ANm16. 0: Do not select associated input channel. 1: Select associated input channel.	R/W

Note: S-TYPE-3, P-TYPE-3

Note: Bits associated with non-existent pins are reserved. This bit is read as 0. The write value should be 0.

Note 1. 16 to 19 (unit 0), 16 to 22 (unit 1) is available.

ADSn bits (A/D-Converted Value Addition/Average Channel Select)

The ADSn bits determine which A/D-converted channels are subject to A/D-converted value addition/averaging. When an ADSn bit associated with a channel selected for A/D conversion is set to 1, A/D conversion of the analog input of the respective channel is performed successively 1, 2, 3, 4, or 16 times, as specified in the ADC[2:0] bits in the ADADC register.

When the ADADC.AVEE bit is 0, the value obtained by addition is stored in the A/D data register. When the ADADC.AVEE bit is 1, the mean value of the results obtained by addition is stored in the A/D data register.

The ADSn bits apply only to channels that are selected for A/D conversion in:

- The ANSAn bits in the ADANSA1 register or the DBLANS[4:0] bits in the ADCSR register
- The ANSBn bits in the ADANSB1 register.

For channels on which the A/D conversion is performed and for which addition/average mode is not selected, a normal 1-time conversion is executed, and the conversion result is stored in the A/D data register.

Only set ADADS1 register when the ADCSR.ADST bit is 0.

45.2.15 ADADC : A/D-Converted Value Addition/Average Count Select Register

Base address: ADC12m = 0x4033_2000 + 0x0200 × m (m = 0, 1)
ADC12m_NS = 0x5033_2000 + 0x0200 × m (m = 0, 1)

Offset address: 0x00C

Bit position:	7	6	5	4	3	2	1	0
Bit field:	AVEE	—	—	—	—	ADC[2:0]		
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
2:0	ADC[2:0]	Addition/Average Count Select 0 0 0: 1-time conversion (no addition, same as normal conversion) 0 0 1: 2-time conversion (1 addition) 0 1 0: 3-time conversion (2 additions) 0 1 1: 4-time conversion (3 additions) 1 0 1: 16-time conversion (15 additions) Others: Setting prohibited	R/W
6:3	—	These bits are read as 0. The write value should be 0.	R/W
7	AVEE	Average Mode Select 0: Enable addition mode 1: Enable average mode	R/W

Note: S-TYPE-3, P-TYPE-3

ADADC sets the addition or average mode and addition count for A/D conversion. [Table 45.20](#) lists the settable combinations of ADADC register.

Table 45.20 Settable combinations of ADADC register

Mode select	Resolution	Conversion time				
		1-time	2-time	3-time	4-time	16-time
Addition mode (AVEE = 0)	8-bit	✓	✓	✓	✓	—
	10-bit	✓	✓	✓	✓	—
	12-bit	✓	✓	✓	✓	✓
Average mode (AVEE = 1)	8, 10, 12 bits	—	✓	—	✓	—

Note: ✓: Selectable, —: Not selectable

ADC[2:0] bits (Addition/Average Count Select)

The ADC[2:0] bits set the addition count in all channels for which A/D conversion and addition/average mode are selected, including the channel selected in double trigger mode with the ADCSR.DBLANS[4:0] bits. The count also applies to A/D conversion of the temperature sensor output and the internal reference voltage.

When self-diagnosis is executed (ADCER.DIAGM = 1), do not set the ADC[2:0] bits to any value other than 000b.

AVEE bit (Average Mode Select)

The AVEE bit selects addition or average mode in all channels for which A/D conversion and addition/average mode are selected, including the channels selected in double-trigger mode in the ADCSR.DBLANS[4:0] bits, temperature sensor output, internal reference voltage.

45.2.16 ADCER : A/D Control Extended Register

Base address: ADC12m = 0x4033_2000 + 0x0200 × m (m = 0, 1)
 ADC12m_NS = 0x5033_2000 + 0x0200 × m (m = 0, 1)

Offset address: 0x00E

Bit position: 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

7:6	—	These bits are read as 0. The write value should be 0.	R/W
9:8	DIAGVAL[1:0]	Self-Diagnosis Conversion Voltage Select 0 0: Setting prohibited when self-diagnosis is enabled 0 1: 0 volts 1 0: Reference voltage ^{*1} × 1/2 1 1: Reference voltage ^{*1}	R/W
10	DIAGLD	Self-Diagnosis Mode Select 0: Select rotation mode for self-diagnosis voltage 1: Select mixed mode for self-diagnosis voltage	R/W

Bit	Symbol	Function	R/W
11	DIAGM	Self-Diagnosis Enable 0: Disable ADC12 self-diagnosis 1: Enable ADC12 self-diagnosis	R/W
14:12	—	These bits are read as 0. The write value should be 0.	R/W
15	ADRFMT	A/D Data Register Format Select 0: Select right-justified for the A/D data register format 1: Select left-justified for the A/D data register format	R/W

Note: S-TYPE-3, P-TYPE-3

Note 1. The reference voltage refers to VREFH0 for unit 0 and to VREFH for unit 1.

ADPRC[1:0] bit (A/D Conversion Accuracy Specify)

The ADPRC[1:0] bits set the A/D conversion accuracy. Changing the A/D conversion accuracy also changes the bit width of valid data stored in the result register and the A/D conversion time. For details, see [section 45.3.6. Analog Input Sampling and Scan Conversion Time](#). Only set the ADPRC[1:0] bits while the ADCSR.ADST bit is 0.

ACE bit (A/D Data Register Automatic Clearing Enable)

The ACE bit enables or disables automatic clearing (all 0) of the ADDRy, ADDR, ADDBLDR, ADDBLDRA, ADDBLDRB, ADTSDR, ADOCDR or ADVMDR register after any of these registers is read by the CPU or DTC. Automatic clearing of the A/D data registers enables detection of failures that are not updated in the A/D data registers. For details, see [section 45.3.7. Usage Example of A/D Data Register Automatic Clearing Function](#).

DIAGVAL[1:0] bits (Self-Diagnosis Conversion Voltage Select)

The DIAGVAL[1:0] bits select the voltage value used in self-diagnosis fixed voltage mode. For details, see the DIAGLD bit description.

Do not execute self-diagnosis by setting the DIAGLD bit to 1 when the DIAGVAL[1:0] bits are set to 00b.

DIAGLD bit (Self-Diagnosis Mode Select)

The DIAGLD bit selects whether the three voltage values are rotated, or the fixed voltage is used in self-diagnosis.

Setting the DIAGLD bit to 0 selects conversion of the voltages in rotation mode, where 0 V, the reference voltage $\times 1/2$, and the reference voltage are converted, in that order. After reset and when self-diagnosis voltage rotation mode is selected, self-diagnosis is executed from 0 V. The self-diagnosis voltage value does not return to 0 V when scan conversion completes. When scan conversion is restarted, rotation starts at the voltage value following the previous value.

Setting the DIAGLD bit to 1 selects fixed voltage, in which the fixed voltage specified in the ADCER.DIAGVAL[1:0] bits is converted. If fixed mode is switched to rotation mode, rotation starts at the fixed voltage value.

Only set the DIAGLD bit when the ADCSR.ADST bit is 0.

DIAGM bit (Self-Diagnosis Enable)

The DIAGM bit enables or disables self-diagnosis.

Self-diagnosis is used to detect a failure of the ADC12. In self-diagnosis mode, one of the three voltage values (0 V, the reference voltage $\times 1/2$, or the reference voltage) is converted. When conversion completes, information on the converted voltage and the conversion result is stored into the A/D Self-Diagnosis Data Register (ADDRD). The ADDRD register can be read to determine whether the conversion result falls within the normal or abnormal range.

Self-diagnosis is executed once at the beginning of each scan, and one of the three voltages is converted. In double trigger mode (ADCSR.DBLE = 1), self-diagnosis (DIAGM = 0) is deselected. When self-diagnosis is selected in group scan mode, self-diagnosis is executed separately for group A and group B.

Only set the DIAGM bit when the ADCSR.ADST bit is 0.

ADRFMT bit (A/D Data Register Format Select)

The ADRFMT bit specifies flush-right or flush-left for data to be stored in the ADDRy, ADDBLDR, ADDBLDRA, ADDBLDRB, ADTSDR, ADOCDR, ADVMDR, ADCMPDR0/1, ADWINLLB, ADWINULB, or ADDRD register.

Only set the ADRFMT bit when the ADCSR.ADST bit is 0.

45.2.17 ADSTRGR : A/D Conversion Start Trigger Select Register

Base address: $ADC12m = 0x4033_2000 + 0x0200 \times m$ ($m = 0, 1$)
 $ADC12m_NS = 0x5033_2000 + 0x0200 \times m$ ($m = 0, 1$)

Offset address: 0x010

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	TRSA[5:0]						—	—	TRSB[5:0]					
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
5:0	TRSB[5:0]	A/D Conversion Start Trigger Select for Group B Select the A/D conversion start trigger for group B in group scan mode.	R/W
7:6	—	These bits are read as 0. The write value should be 0.	R/W
13:8	TRSA[5:0]	A/D Conversion Start Trigger Select Select the A/D conversion start trigger in single scan mode and continuous scan mode. In group scan mode, the A/D conversion start trigger for group A is selected.	R/W
15:14	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

TRSB[5:0] bits (A/D Conversion Start Trigger Select for Group B)

The TRSB[5:0] bits select the trigger to start scanning of the analog input selected in group B. The TRSB[5:0] bits must only be set in group scan mode and are not used in any other scan mode. For the scan conversion start trigger for group B, setting a software trigger or an asynchronous trigger is prohibited. In group scan mode, set the TRSB[5:0] bits to a value other than 0x00 and set the ADCSR.TRGE bit to 1.

When group A is given priority in group scan mode, setting the ADGSPCR.GBRP bit to 1 allows group B to continuously operate in single scan mode. When setting the ADGSPCR.GBRP bit to 1, set the TRSB[5:0] bits to 0x3F. The issuance period for a conversion trigger must be more than or equal to the actual scan conversion time (t_{SCAN}). If the issuance period is less than t_{SCAN} , A/D conversion by the trigger might have no effect.

When the GPT module is selected as an A/D conversion start trigger, a delay for synchronization processing occurs. For details, see [section 45.3.6. Analog Input Sampling and Scan Conversion Time](#).

[Table 45.21](#) lists the A/D conversion startup sources selected in the TRSB[5:0] bits.

Table 45.21 Selection of A/D conversion start sources in the TRSB[5:0] bits (1 of 2)

TRSA[5:0] bits (A/D Conversion Start Trigger Select)

The TRSA[5:0] bits select the trigger to start A/D conversion in single scan mode and continuous scan mode, or the trigger to start scanning of group A analog inputs in group scan mode. When scanning is executed in group scan mode or double trigger mode, software trigger or asynchronous trigger is prohibited.

- When using a synchronous trigger (GPT, ELC), set the TRGE bit in the ADCSR register to 1 and set the EXTRG bit in the ADCSR register to 0.
- When using the asynchronous trigger (ADTRGn (n = 0, 1), set the TRGE bit in the ADCSR register to 1 and set the EXTRG bit in the ADCSR register to 1.
- Software trigger (ADCSR.ADST) is enabled regardless of the settings of the ADCSR.TRGE bit, the ADCSR.EXTRG bit, or the TRSA[5:0] bits.

The issuance period for a conversion trigger must be more than or equal to the actual scan conversion time (tSCAN). If the issuance period is less than tSCAN, A/D conversion by a trigger might have no effect.

When the GPT module is selected as an A/D conversion start trigger, a delay for synchronization processing occurs. For details, see [section 45.3.6. Analog Input Sampling and Scan Conversion Time](#).

[Table 45.22](#) lists the A/D conversion start sources selected in the TRSA[5:0] bits.

Table 45.22 Selection of A/D activation sources in the TRSA[5:0] bits (1 of 2)

11	OCSB	Internal Reference Voltage A/D Conversion Select for Group B 0: Disable A/D conversion of internal reference voltage 1: Enable A/D conversion of internal reference voltage	R/W
15:12	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

TSSAD bit (Temperature Sensor Output A/D-Converted Value Addition/Average Mode Select)

When the TSSAD bit is set to 1, A/D conversion of the temperature sensor output is selected and performed successively the number of times specified in the ADC[2:0] bits in ADADC. When the ADADC.AVEE bit is 0, the value obtained by addition (integration) is returned to the A/D Temperature Sensor Data Register (ADTSDR). When the ADADC.AVEE bit is 1, the mean value is returned to ADTSDR.

Only set the TSSAD bit while the ADCSR.ADST bit is 0.

OCSAD bit (Internal Reference Voltage A/D-Converted Value Addition/Average Mode Select)

When the OCSAD bit is set to 1, A/D conversion of the internal reference voltage is selected and performed successively the number of times specified in the ADC[2:0] bits in ADADC. When the ADADC.AVEE bit is 0, the value obtained by addition (integration) is returned to the A/D Internal Reference Voltage Data Register (ADOCDR). When the ADADC.AVEE bit is 1, the mean value is returned to ADOCDR.

Only set the OCSAD bit while the ADCSR.ADST bit is 0.

TSSA bit (Temperature Sensor Output A/D Conversion Select)

The TSSA bit selects A/D conversion of the temperature sensor output for group A in single scan mode, continuous scan mode, or group scan mode. When A/D conversion of the temperature sensor output is selected and performed, set the ADCSR.DBLE bit to 0.

Only set the TSSA bit while the ADCSR.ADST bit is 0.

OCSA bit (Internal Reference Voltage A/D Conversion Select)

The OCSA bit selects A/D conversion of the internal reference voltage for group A in single scan mode, continuous scan mode, or group scan mode. When A/D conversion of the internal reference voltage is selected and performed, set the ADCSR.DBLE bit to 0.

Only set the OCSA bit while the ADCSR.ADST bit is 0. In addition, wait for 400 ns or more after the OCSA bit is set to 1 before starting A/D conversion.

TSSB bit (Temperature Sensor Output A/D Conversion Select for Group B)

The TSSB bit selects A/D conversion of the temperature sensor output for group B in group scan mode. Only set the TSSB bit while the ADCSR.ADST bit is 0. Do not set the TSSB bit to 1 while the TSSA bit is 1.

OCSB bit (Internal Reference Voltage A/D Conversion Select for Group B)

The OCSB bit selects A/D conversion of the internal reference voltage for group B in group scan mode. Only set the OCSB bit while the ADCSR.ADST bit is 0. Do not set the OCSB bit to 1 while the OCSA bit is 1. Moreover, start the A/D conversion after waiting for 400 ns or more after the OCSB bit is set to 1.

45.2.19 ADSSTRn/ADSSTRL/ADSSTRT/ADSSTRO/ADSSTRV: A/D Sampling State Register (n = 0 to 8)

Base address: $ADC12m = 0x4033_2000 + 0x0200 \times m$ ($m = 0, 1$)
 $ADC12m_NS = 0x5033_2000 + 0x0200 \times m$ ($m = 0, 1$)

Offset address: $0x0E0 + 0x1 \times n$ ($n = 0$ to 8 , $m = 0$)
 $0x0E0 + 0x1 \times n$ ($n = 0$ to 6 , $m = 1$)
 $0x0DD$ (ADSSTRL)
 $0x0DE$ (ADSSTRT)
 $0x0DF$ (ADSSTRO)
 $0x0E3$ (ADSSTRV)

Bit position: 7 6 5 4 3 2 1 0

Bit field: SST[7:0]

Value after reset: 0 0 0 0 1 0 1 1

Bit	Symbol	Function	R/W
7:0	SST[7:0]	Sampling Time Setting These bits set the sampling time in the range from 5 to 255 states.	R/W

Note: S-TYPE-3, P-TYPE-3

The ADSSTRn register sets the sampling time for analog input.

The sampling time can be adjusted if the impedance of the analog input signal source is too high to secure sufficient sampling time, or if the ADCLK clock is slow. The set value indicates the time for one ADCLK cycle, and the required sampling time is specified by the voltage conditions. For details, see [section 55.5. ADC12 Characteristics](#).

ADSSTRV register is an alias for the ADSSTR3 register.

The lower limit of the sampling time setting depends on the frequency ratio:

- If the frequency ratio of PCLKA to PCLKC (ADCLK) = 1:1, 2:1, 4:1, or 8:1 the sampling time must be set to a value of more than 5 states
- If the frequency ratio of PCLKA to PCLKC (ADCLK) = 1:2 or 1:4, the sampling time must be set to a value of more than 6 states.

[Table 45.23](#) shows the relationship between the A/D Sampling State Register and the associated channels. For details, see [section 45.3.6. Analog Input Sampling and Scan Conversion Time](#).

Only set the SST[7:0] bits when the ADCSR.ADST bit is 0.

Table 45.23 Relationship between A/D sampling state register and associated channels

Bit name	Associated channels
ADSSTRn.SST[7:0] bits ($n = 0$ to 8 (unit 0), 0 to 6 (unit 1))* ¹	AN000 to AN008, AN100 to AN106
ADSSTRL.SST[7:0] bits	AN016 to AN019, AN116 to AN122
ADSSTRT.SST[7:0] bits	Temperature sensor output
ADSSTRO.SST[7:0] bits	Internal reference voltage
ADSSTRV.SST[7:0] bits	VBATT 1/3 voltage monitor output* ²

Note 1. When the self-diagnosis function is selected, the sampling time set in the ADSSTR0.SST[7:0] bits is applied.

Note 2. For the stabilization time, see [section 11, Battery Backup Function](#).

45.2.20 ADShCR : A/D Sample and Hold Circuit Control Register

Base address: $ADC12m = 0x4033_2000 + 0x0200 \times m$ ($m = 0$)
 $ADC12m_NS = 0x5033_2000 + 0x0200 \times m$ ($m = 0$)

Offset address: 0x066

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	SHANS[2:0]			SSTSH[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	1	1	0	0	0

Bit	Symbol	Function	R/W
7:0	SSTSH[7:0]	Channel-Dedicated Sample-and-Hold Circuit Sampling Time Setting Sampling time (4 to 255 states).	R/W
10:8	SHANS[2:0]	Channel-Dedicated Sample-and-Hold Circuit Bypass Select Select whether to use or bypass channel-dedicated sample-and-hold circuits for AN000 to AN002 (unit 0). 0: Bypass the circuits 1: Use the circuits	R/W
15:11	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

SSTSH[7:0] bits (Channel-Dedicated Sample-and-Hold Circuit Sampling Time Setting)

The SSTSH[7:0] bits set the sampling time for the channel-dedicated sample-and-hold circuits. If one state is 1 ADCLK (A/D conversion clock) cycle and the ADCLK clock is 60 MHz, one state is 16.7 ns. The initial value is 24 states. The sampling time can be adjusted if the impedance of the analog input signal source is too high to secure sufficient sampling time, or if the ADCLK clock is slow.

Only set the SSTSH[7:0] bits while the ADCSR.ADST bit is 0. The sampling time must be set to a value that is 4 states or more and 255 or less.

SHANS[2:0] bits (Channel-Dedicated Sample-and-Hold Circuit Bypass Select)

The SHANS[2:0] bits select whether to use or bypass the channel-dedicated sample-and-hold circuits for AN000 to AN002 (unit 0). In unit 0, the SHANS[0] bit is associated with AN000, the SHANS[1] bit with AN001, and the SHANS[2] bit with AN002.

If any channel from among AN000 to AN002 (unit 0) is selected for group B while operation is in group scan mode under group A priority control, use this setting to bypass the dedicated sample-and-hold circuit of the channel.

Only set the SHANS[2:0] bits while the ADCSR.ADST bit is 0 and the ADShMSR.SHMD bit is 0.

45.2.21 ADShMSR : A/D Sample and Hold Operation Mode Selection Register

Base address: $ADC12m = 0x4033_2000 + 0x0200 \times m$ ($m = 0$)
 $ADC12m_NS = 0x5033_2000 + 0x0200 \times m$ ($m = 0$)

Offset address: 0x07C

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	SHMD
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	SHMD	Sampling Operation Selection 0: Sampling Operation Selection 1: Enable continuous sampling function	R/W
7:1	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

SHMD bit (Sampling Operation Selection)

Setting SHMD to 1 enables the constant sampling function of the channel-dedicated sample-and-hold selected in the ADSHCR.SHANS[2:0] bits. Only set the SHMD bit while the ADCSR.ADST bit is 0.

When the sampling function is enabled, the sample-and-hold circuit operates sampling while the ADC12 is not operating, and it operates holding while the ADC12 is operating.

Note: The ADCSR.ADST bit must become 1 after a time of 400 ns or more elapses after the SHMD bit is set to 1 (when the permissible signal source impedance is 1 kΩ). The sampling period of the sample-and-hold circuit must be 400 ns or more (when the permissible signal source impedance is 1 kΩ).

45.2.22 ADDISCR : A/D Disconnection Detection Control Register

Base address: $\text{ADC12m} = 0x4033_2000 + 0x0200 \times m$ ($m = 0, 1$)
 $\text{ADC12m_NS} = 0x5033_2000 + 0x0200 \times m$ ($m = 0, 1$)

Offset address: 0x07A

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	PCHG	ADNDIS[3:0]			
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
3:0	ADNDIS[3:0]	Disconnection Detection Assist Setting 0x0: The disconnection detection assist function is disabled 0x1: Setting prohibited Others: The number of states for the discharge or precharge period.	R/W
4	PCHG	Precharge/discharge select 0: Discharge 1: Precharge	R/W
7:5	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

The ADDISCR register selects either precharge or discharge, and the period of precharge or discharge for the A/D disconnection detection assist function. Only set the ADDISCR register when the ADCSR.ADST bit is 0. When the temperature sensor output or internal reference voltage is converted, the A/D converter executes discharge automatically.

Disable the disconnection detection assist function if any of the following functions are used:

- The temperature sensor
- The internal reference voltage
- A/D self-diagnosis
- VBATT 1/3 voltage monitor

ADNDIS[3:0] bits (Disconnection Detection Assist Setting)

The ADNDIS[3:0] bits specify the period of precharge or discharge. When ADNDIS[3:0] = 0000b, the disconnection detection assist function is disabled. Setting the ADNDIS[3:0] bits to 0001b is prohibited. Except when ADNDIS[3:0] = 0000b or 0001b, the specified value indicates the number of states for the period of precharge or discharge. When the ADNDIS[3:0] bits are set to any values other than 0000b or 0001b, the disconnection detection assistance function is enabled. The ADNDIS[4:0] should be set while the ADCSR.ADST bit is 0. When the ADNDIS[3:0] bits are set to any values other than 0000b, and the disconnection detection assistance is enabled, the disconnection detection assistance for the channel-dedicated sample-and-hold circuit used for analog inputs are also enabled. When the temperature sensor output or internal reference voltage is converted or self-diagnosis is used, the disconnection detection assistance cannot be used. In that case, the ADNDIS[3:0] bits should be set to 0000b.

PCHG bit (Precharge/discharge select)

The PCHG bit selects either precharge or discharge.

45.2.23 ADGSPCR : A/D Group Scan Priority Control Register

Base address: $ADC12m = 0x4033_2000 + 0x0200 \times m$ ($m = 0, 1$)
 $ADC12m_NS = 0x5033_2000 + 0x0200 \times m$ ($m = 0, 1$)

Offset address: 0x080

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	GBRP	LGRRS	—	—	—	—	—	—	—	—	—	—	—	—	GBRSCN	PGS
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	PGS	Group Priority Operation Setting* ¹ 0: Operate without group priority control. 1: Operate with group priority control.	R/W
1	GBRSCN	Lower-Priority Group Restart Setting (enabled only when PGS = 1 and reserved when PGS = 0.) 0: Disable rescanning of the group that was stopped in group priority operation 1: Enable rescanning of the group that was stopped in group priority operation.	R/W
13:2	—	These bits are read as 0. The write value should be 0.	R/W
14	LGRRS	Restart Channel Select Enabled only when PGS = 1 and GBRSCN = 1. 0: Start rescanning from the first channel for scanning 1: Start rescanning from the channel for which A/D conversion is not completed.	R/W
15	GBRP	Single Scan Continuous Start* ² (enabled only when PGS = 1 and reserved when PGS = 0.) 0: Single scan is not continuously activated. 1: Single scan for the group with the lower-priority is continuously activated.	R/W

Note: S-TYPE-3, P-TYPE-3

Note 1. The ADCSR.ADCS[1:0] bits must be set to 01b (group scan mode) before setting PGS to 1. Operation is not guaranteed if these bits are set to any other value.

Note 2. When the GBRP bit is set to 1, single scan is performed continuously for the group with the lower-priority regardless of the setting in the GBRSCN bit.

PGS bit (Group Priority Operation Setting)

The PGS bit controls group priority operation in group scan mode. Set the PGS bit to 1 to enable group priority operation.

The ADCSR.ADCS[1:0] bits must be set to 01b (group scan mode) before setting the PGS bit to 1. Operation is not guaranteed if the bits are set to any other value.

When the PGS bit is set to 0, a clear operation must be performed by software as described in [section 45.6.3. Constraints on Stopping A/D Conversion](#). When the PGS bit is set to 1, use the settings described in [section 45.3.4.3. Group Priority Operation](#).

GBRSCN bit (Lower-Priority Group Restart Setting)

The GBRSCN bit controls the restarting of scan operation in group priority operation.

When the GBRSCN bit is set to 1, if the scan operation of a lower-priority group is stopped by a trigger input of a priority group, the lower-priority group scanning is restarted on completion of the priority group scanning. If a trigger of a lower-priority group is input during scanning of the priority group, the lower-priority group scanning is started on completion of the priority group scanning.

When the GBRSCN bit is set to 0, triggers input during scanning are ignored. Set the GBRSCN bit while the ADCSR.ADST bit is 0.

LGRRS bit (Restart Channel Select)

This bit sets the channel from which rescanning is to be started in group priority operation. The setting of the LGRRS bit is valid when the PGS and GBRSCN bits are 1.

If the LGRRS bit is 0, scanning of a lower-priority group that was stopped in group priority operation is restarted from the first channel after scanning of the priority group completes.

If the LGRRS bit is 1, scanning of a lower-priority group that was stopped in group priority operation is restarted (upon completion of scanning of the priority group) from the channel for which A/D conversion is not complete. If A/D conversion of the addition setting channel was not completed the specified number of times when scanning stopped, A/D conversion of the addition setting channel is performed again the specified number of times when scanning restarts.

Set the LGRRS bit while the ADCSR.ADST bit is 0.

GBRP bit (Single Scan Continuous Start)

The GBRP bit is set when a single scan operation is to be performed continuously on the group with the lower-priority.

Setting the GBRP bit to 1 starts a single scan of the group with the lower-priority. On completion of the scan, another single scan of the group with the lower-priority is started automatically. If scanning has been stopped during group priority operation, single scan of the group with the lower-priority is automatically restarted on completion of the A/D conversion of the priority group.

Before setting the GBRP bit to 1, disable input of a trigger for the lower-priority group. If the GBRP bit is set to 1, rescanning is performed only on the group with the lower-priority even if the GBRSCN bit is set to 0.

45.2.24 ADCMPCR : A/D Compare Function Control Register

Base address: ADC12m = 0x4033_2000 + 0x0200 × m (m = 0, 1)
ADC12m_NS = 0x5033_2000 + 0x0200 × m (m = 0, 1)

Offset address: 0x090

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	CMPAIE	WCMP E	CMPBIE	—	CMPAE	—	CMPBE	—	—	—	—	—	—	—	—	CMPAB[1:0]
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
1:0	CMPAB[1:0]	Window A/B Composite Conditions Setting These bits are valid when both window A and window B are enabled (CMPAE = 1 and CMPBE = 1). 0 0: Output ADC12i_WCMPM (i = 0, 1) when window A OR window B comparison conditions are met. Otherwise, output ADC12i_WCMPUM (i = 0, 1). 0 1: Output ADC12i_WCMPM (i = 0, 1) when window A EXOR window B comparison conditions are met. Otherwise, output ADC12i_WCMPUM (i = 0, 1). 1 0: Output ADC12i_WCMPM (i = 0, 1) when window A AND window B comparison conditions are met. Otherwise, output ADC12i_WCMPUM (i = 0, 1). 1 1: Setting prohibited.	R/W
8:2	—	These bits are read as 0. The write value should be 0.	R/W
9	CMPBE	Compare Window B Operation Enable 0: Disable compare window B operation. Disable ADC12i_WCMPM (i = 0, 1) and ADC12i_WCMPUM (i = 0, 1) outputs regardless of the value of CMPAE.*1 1: Enable compare window B operation.	R/W
10	—	This bit is read as 0. The write value should be 0.	R/W
11	CMPAE	Compare Window A Operation Enable 0: Disable compare window A operation. Disable ADC12i_WCMPM (i = 0, 1) and ADC12i_WCMPUM (i = 0, 1) outputs regardless of the value of CMPBE.*1 1: Enable compare window A operation.	R/W
12	—	This bit is read as 0. The write value should be 0.	R/W
13	CMPBIE	Compare B Interrupt Enable 0: Disable ADC12i_CMPBI (i = 0, 1) interrupt when comparison conditions (window B) are met. 1: Enable ADC12i_CMPBI (i = 0, 1) interrupt when comparison conditions (window B) are met.	R/W

Bit	Symbol	Function	R/W
14	WCMPE	Window Function Setting 0: Disable window function Window A and window B operate as a comparator to compare the single value on the lower side with the A/D conversion result. 1: Enable window function Window A and window B operate as a comparator to compare the two values on the upper and lower sides with the A/D conversion result.	R/W
15	CMPAIE	Compare A Interrupt Enable 0: Disable ADC12i_CMPAI (i = 0, 1) interrupt when comparison conditions (window A) are met. 1: Enable ADC12i_CMPAI (i = 0, 1) interrupt when comparison conditions (window A) are met.	R/W

Note: S-TYPE-3, P-TYPE-3

Note 1. For event output when using only Window A or Window B with the Compare function, see [section 45.3.5.2. Event Output of Compare Function](#).

CMPAB[1:0] bits (Window A/B Composite Conditions Setting)

The CMPAB[1:0] bits are valid when both window A and window B are enabled (CMPAE = 1 and CMPBE = 1) in single scan mode. These bits specify the compare function match/mismatch event output conditions and monitoring conditions of ADWINMON.MONCOMB. Only set the CMPAB[1:0] bits while the ADCSR.ADST bit is 0.

CMPBE bit (Compare Window B Operation Enable)

The CMPBE bit enables or disables the compare window B operation. Set the CMPBE bit while the ADCSR.ADST bit is 0.

Set this bit to 0 before setting the following registers:

- A/D Channel Select Registers A0, A1, B0, B1 (ADANSA0, ADANSA1, ADANSB0, ADANSB1)
- OCSB, TSSB, OCSA, or TSSA bits in the A/D Conversion Extended Input Control Register (ADEXICR)
- CMPCHB[5:0] bits in the Window B Channel Select Register (ADCMPBNSR)

CMPAE bit (Compare Window A Operation Enable)

The CMPAE bit enables or disables the compare window A operation. Set the CMPAE bit while the ADCSR.ADST bit is 0.

Set this bit to 0 before setting the following registers:

- A/D Channel Select Registers A0, A1, B0, B1 (ADANSA0, ADANSA1, ADANSB0, ADANSB1)
- OCSB, TSSB, OCSA, or TSSA bits in the A/D Conversion Extended Input Control Register (ADEXICR)
- Window A Channel Select Registers 0 and 1 (ADCMPANSR0 and ADCMPANSR1)
- Window A Extended Input Select Register (ADCMPANSER)

CMPBIE bit (Compare B Interrupt Enable)

The CMPBIE bit enables or disables the ADC12i_CMPBI (i = 0, 1) interrupt output when the comparison conditions (window B) are met.

WCMPE bit (Window Function Setting)

The WCMPE bit enables or disables the window function. Set the WCMPE bit while the ADCSR.ADST bit is 0.

CMPAIE bit (Compare A Interrupt Enable)

The CMPAIE bit enables or disables the ADC12i_CMPAI (i = 0, 1) interrupt output when the comparison conditions (window A) are met.

45.2.25 ADCMPANSR0 : A/D Compare Function Window A Channel Select Register 0

Base address: $ADC12m = 0x4033_2000 + 0x0200 \times m$ ($m = 0, 1$)
 $ADC12m_NS = 0x5033_2000 + 0x0200 \times m$ ($m = 0, 1$)

Offset address: 0x094

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	CMPCHA15	CMPCHA14	CMPCHA13	CMPCHA12	CMPCHA11	CMPCHA10	CMPCHA09	CMPCHA08	CMPCHA07	CMPCHA06	CMPCHA05	CMPCHA04	CMPCHA03	CMPCHA02	CMPCHA01	CMPCHA00
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	CMPCHA15 to CMPCHA00*1	Compare Window A Channel Select Bit 15 (CMPCHA15) is associated with ANm15 and bit 0 (CMPCHA00) is associated with ANm00. 0: Disable compare function for associated input channel 1: Enable compare function for associated input channel	R/W

Note: S-TYPE-3, P-TYPE-3

Note: Bits associated with non-existent pins are reserved. This bit is read as 0. The write value should be 0.

Note 1. 00 to 08 (unit 0), 00 to 06 (unit 1) is available.

CMPCHAN bits (Compare Window A Channel Select)

The compare function is enabled by writing 1 to the CMPCHAN bits with the same number as the A/D conversion channel selected in the ADANSA0.ANSAn bits and the ADANSB0.ANSBn bits.

Set the CMPCHAN bits while the ADCSR.ADST bit is 0.

45.2.26 ADCMPANSR1 : A/D Compare Function Window A Channel Select Register 1

Base address: $ADC12m = 0x4033_2000 + 0x0200 \times m$ ($m = 0, 1$)
 $ADC12m_NS = 0x5033_2000 + 0x0200 \times m$ ($m = 0, 1$)

Value after reset: 0 0 0 0 0 0 0 0

Bit	Symbol	Function	R/W
0	CMPTSA	Temperature Sensor Output Compare Select 0: Exclude the temperature sensor output from the compare Window A target range. 1: Include the temperature sensor output in the compare Window A target range.	R/W
1	CMPOCA	Internal Reference Voltage Compare Select 0: Exclude the internal reference voltage from the compare Window A target range. 1: Include the internal reference voltage in the compare Window A target range.	R/W
7:2	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

CMPTSA bit (Temperature Sensor Output Compare Select)

The compare Window A function is enabled by setting the CMPTSA bit to 1 while the ADEXICR.TSSA bit or the ADEXICR.TSSB bit is 1. Set the CMPTSA bit while the ADCSR.ADST bit is 0.

CMPOCA bit (Internal Reference Voltage Compare Select)

The compare window A function is enabled by setting the CMPOCA bit to 1 when the ADEXICR.OCSA and ADEXICR.OCSE bit is 1. Set the CMPOCA bit when the ADCSR.ADST bit is 0.

45.2.28 ADCMPLR0 : A/D Compare Function Window A Comparison Condition Setting Register 0

Base address: $ADC12m = 0x4033_2000 + 0x0200 \times m$ ($m = 0, 1$)
 $ADC12m_NS = 0x5033_2000 + 0x0200 \times m$ ($m = 0, 1$)

Bit	Symbol	Function	R/W
7:2	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

CMPLTSA bit (Compare Window A Temperature Sensor Output Comparison Condition Select)

The CMPLTSA bit specifies comparison conditions when the temperature sensor output is the target for the Window A comparison condition. When the temperature sensor output comparison result meets the set condition, the ADCMPSER.CMPSTTSA flag sets to 1 and a compare interrupt (ADC12i_CMPAI (i = 0, 1)) is generated.

CMPLOCA bit (Compare Window A Internal Reference Voltage Comparison Condition Select)

The CMPLOCA bit specifies comparison conditions when the internal reference voltage is the target for the Window A comparison condition. When the internal reference voltage comparison result meets the set condition, the ADCMPSER.CMPSTOCA flag sets to 1 and a compare interrupt (ADC12i_CMPAI (i = 0, 1)) is generated.

45.2.31 ADCMPDRn : A/D Compare Function Window A Lower-Side/Upper-Side Level Setting Register (n = 0, 1)

Base address: $ADC12m = 0x4033_2000 + 0x0200 \times m$ (m = 0, 1)
 $ADC12m_NS = 0x5033_2000 + 0x0200 \times m$ (m = 0, 1)

Offset address: $0x09C + (0x2 \times n)$

Bit position: 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

Bit field:

Value after reset: 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

Note: S-TYPE-3, P-TYPE-3

The ADCMPDRy (y = 0, 1) register specifies the reference data when the compare window A function is used. ADCMPDR0 sets the lower reference for window A, and ADCMPDR1 sets the upper reference for window A.

ADCMPDRy are read/write registers.

ADCMPDRy are writable even during A/D conversion. The reference data can be dynamically changed by rewriting register values during A/D conversion^{*1}.

Set these registers so that the upper reference is not less than the lower reference ($ADCMPDR1 \geq ADCMPDR0$).

ADCMPDR1 are not used when the window function is disabled.

Note 1. The lower and the upper references are changed when each register is written. For example, when the upper reference value is changed and the lower reference value is being changed, the MCU compares the upper reference (after rewrite), and the lower reference (before rewrite) with the A/D conversion result. See [Figure 45.5](#). If the comparison during the rewriting of these two references is erroneous, then rewrite these reference values when both ADCSR.ADST and the target Compare Window Operation Enable bit (ADCMPCR.CMPAE or ADCMPCR.CMPBE) are 0.

Figure 45.5 Comparison between upper and lower references before and after a rewrite

The ADCMPDRy registers use different formats depending on the following conditions:

- The value of A/D Data Register Format Select bit (flush-right or flush-left)
- The value of the A/D Conversion Accuracy Select bit (12-bit, 10-bit, 8-bit)
- The value of A/D-Converted Value Addition/Average Channel Select bits (A/D-converted value addition mode selected or not selected).

The data formats for each condition are shown as follows:

1. When A/D-converted value addition mode is not selected
 - Flush-right data with 12-bit accuracy — Lower 12 bits ([11:0]) are valid
 - Flush-right data with 10-bit accuracy — Lower 10 bits ([9:0]) are valid
 - Flush-right data with 8-bit accuracy — Lower 8 bits ([7:0]) are valid
 - Flush-left data with 12-bit accuracy — Upper 12 bits ([15:4]) are valid
 - Flush-left data with 10-bit accuracy — Upper 10 bits ([15:6]) are valid
 - Flush-left data with 8-bit accuracy — Upper 8 bits ([15:8]) are valid
2. When A/D-converted value addition mode is selected
 - Flush-right data with 12-bit accuracy — Lower 14 bits ([13:0]) are valid
 - Flush-right data with 10-bit accuracy — Lower 12 bits ([11:0]) are valid
 - Flush-right data with 8-bit accuracy — Lower 10 bits ([9:0]) are valid
 - Flush-left data with 12-bit accuracy — Upper 14 bits ([15:2]) are valid
 - Flush-left data with 10-bit accuracy — Upper 12 bits ([15:4]) are valid
 - Flush-left data with 8-bit accuracy — Upper 10 bits ([15:6]) are valid

45.2.32 ADWINnLB : A/D Compare Function Window B Lower-Side/Upper-Side Level Setting Register (n = L, U)

Base address: $ADC12m = 0x4033_2000 + 0x0200 \times m$ ($m = 0, 1$)
 $ADC12m_NS = 0x5033_2000 + 0x0200 \times m$ ($m = 0, 1$)

Offset address: $0x0A8$ ($n = L$)
 $0x0AA$ ($n = U$)

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:																
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Note: S-TYPE-3, P-TYPE-3

The ADWINULB and ADWINLLB registers specify the reference data when the compare window B function is used. ADWINLLB sets the lower reference for window B, and ADWINULB sets the upper reference for window B.

ADWINnLB are read/write registers.

ADWINnLB are writable even during A/D conversion. The reference data can be dynamically changed by rewriting register values during A/D conversion^{*1}.

Set these registers so that the upper reference is not less than the lower reference ($ADWINULB \geq ADWINLLB$). ADWINULB are not used when the window function is disabled.

Note 1. The lower and the upper references are changed when each register is written. For example, when the upper reference value is changed and the lower reference value is being changed, the MCU compares the upper reference (after rewrite), and the lower reference (before rewrite) with the A/D conversion result. See [Figure 45.6](#). If the comparison during the rewriting of these two references is erroneous, then rewrite these reference values when both ADCSR.ADST and the target Compare Window Operation Enable bit (ADCMPCR.CMPAE or ADCMPCR.CMPBE) are 0.

Figure 45.6 Comparison between upper and lower references before and after a rewrite

The ADWINnLB registers use different formats depending on the following conditions:

- The value of A/D Data Register Format Select bit (flush-right or flush-left)
- The value of the A/D Conversion Accuracy Select bit (12-bit, 10-bit, 8-bit)
- The value of A/D-Converted Value Addition/Average Channel Select bits (A/D-converted value addition mode selected or not selected).

The data formats for each condition are shown as follows:

1. When A/D-converted value addition mode is not selected
 - Flush-right data with 12-bit accuracy — Lower 12 bits ([11:0]) are valid
 - Flush-right data with 10-bit accuracy — Lower 10 bits ([9:0]) are valid
 - Flush-right data with 8-bit accuracy — Lower 8 bits ([7:0]) are valid
 - Flush-left data with 12-bit accuracy — Upper 12 bits ([15:4]) are valid
 - Flush-left data with 10-bit accuracy — Upper 10 bits ([15:6]) are valid
 - Flush-left data with 8-bit accuracy — Upper 8 bits ([15:8]) are valid
2. When A/D-converted value addition mode is selected
 - Flush-right data with 12-bit accuracy — Lower 14 bits ([13:0]) are valid
 - Flush-right data with 10-bit accuracy — Lower 12 bits ([11:0]) are valid
 - Flush-right data with 8-bit accuracy — Lower 10 bits ([9:0]) are valid
 - Flush-left data with 12-bit accuracy — Upper 14 bits ([15:2]) are valid
 - Flush-left data with 10-bit accuracy — Upper 12 bits ([15:4]) are valid
 - Flush-left data with 8-bit accuracy — Upper 10 bits ([15:6]) are valid

45.2.33 ADCMPSTR0 : A/D Compare Function Window A Channel Status Register 0

Base address: $ADC12m = 0x4033_2000 + 0x0200 \times m$ ($m = 0, 1$)
 $ADC12m_NS = 0x5033_2000 + 0x0200 \times m$ ($m = 0, 1$)

Offset address: 0x0A0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	CMPS TCHA 15	CMPS TCHA 14	CMPS TCHA 13	CMPS TCHA 12	CMPS TCHA 11	CMPS TCHA 10	CMPS TCHA 09	CMPS TCHA 08	CMPS TCHA 07	CMPS TCHA 06	CMPS TCHA 05	CMPS TCHA 04	CMPS TCHA 03	CMPS TCHA 02	CMPS TCHA 01	CMPS TCHA 00
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	CMPSTCHA15 to CMPSTCHA00 ^{*1}	Compare Window A Flag When Window A operation is enabled (ADCMPCR.CMPAE = 1b), these bits indicate the comparison result of channels to which Window A comparison conditions are applied. Bit 15 (CMPSTCHA15) is associated with ANm15 and bit 0 (CMPSTCHA00) is associated with ANm00. 0: Comparison conditions are not met. 1: Comparison conditions are met.	R/W

Note: S-TYPE-3, P-TYPE-3

Note: Bits associated with non-existent pins are reserved. This bit is read as 0. The write value should be 0.

Note 1. 00 to 08 (unit 0), 00 to 06 (unit 1) is available.

CMPSTCHAN flags (Compare Window A Flag)

The CMPSTCHAN flags indicate the comparison results for channels to which Window A comparison conditions are applied. When a comparison condition set in ADCMPLR0.CMPLCHA is met at the end of A/D conversion, the associated CMPSTCHAN flag sets to 1. When the ADCMPCR.CMPAIE bit is 1, a compare interrupt request (ADC12i_CMPAI ($i = 0, 1$)) is generated when this flag sets to 1.

Writing 1 to the CMPSTCHAN flags is invalid.

[Setting condition]

- The condition set in ADCMPLR0.CMPLCHA is met when ADCMPCR.CMPAE = 1.

[Clearing condition]

- Writing 0 after reading 1.

45.2.34 ADCMPSR1 : A/D Compare Function Window A Channel Status Register1

Base address: $ADC12m = 0x4033_2000 + 0x0200 \times m$ ($m = 0, 1$)

Bit	Symbol	Function	R/W
15:0	CMPSTCHA31 to CMPSTCHA16*1	Compare Window A Flag When Window A operation is enabled (ADCMPCR.CMPAE = 1), these bits indicate the comparison result of channels to which Window A comparison conditions are applied. Bit 15 (CMPSTCHA31) is associated with ANm31 and bit 0 (CMPSTCHA16) is associated with ANm16. 0: Comparison conditions are not met. 1: Comparison conditions are met.	R/W

Note: S-TYPE-3, P-TYPE-3

Note: Bits associated with non-existent pins are reserved. This bit is read as 0. The write value should be 0.

Note 1. 16 to 19 (unit 0), 16 to 22 (unit 1) is available.

CMPSTCHAN flags (Compare Window A Flag)

The CMPSTCHAN flags indicate the comparison results for channels to which Window A comparison conditions are applied. When the comparison condition set in ADCMPLR1.CMPLCHA is met at the end of A/D conversion, the associated CMPSTCHAN flag sets to 1. When the ADCMPCR.CMPAIE bit is 1, a compare interrupt request (ADC12i_CMPAI ($i = 0, 1$)) is generated when this flag sets to 1.

Writing 1 to the CMPSTCHAN flags is invalid.

[Setting condition]

- The condition set in ADCMPLR1.CMPLCHA is met when ADCMPCR.CMPAE = 1.

[Clearing condition]

- Writing 0 after reading 1.

45.2.35 ADCMPSER : A/D Compare Function Window A Extended Input Channel Status Register

Base address: $ADC12m = 0x4033_2000 + 0x0200 \times m$ ($m = 0, 1$)
 $ADC12m_NS = 0x5033_2000 + 0x0200 \times m$ ($m = 0, 1$)

Offset address: 0x0A4

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	CMPS TOCA	CMPS TTSA
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	CMPSTTSA	Compare Window A Temperature Sensor Output Compare Flag When Window A operation is enabled (ADCMPCR.CMPAE = 1), this bit indicates the temperature sensor output comparison result. 0: Comparison conditions are not met. 1: Comparison conditions are met.	R/W

Bit	Symbol	Function	R/W
1	CMPSTOCA	Compare Window A Internal Reference Voltage Compare Flag When Window A operation is enabled (ADCMPCR.CMPAE = 1), this bit indicates the internal reference voltage comparison result. 0: Comparison conditions are not met. 1: Comparison conditions are met.	R/W
7:2	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

The ADCMPSEER register stores compare results of compare function window A.

CMPSTTSA flag (Compare Window A Temperature Sensor Output Compare Flag)

The CMPSTTSA flag indicates the temperature sensor output comparison result. When the comparison condition set in ADCMPLEER.CMPLTSA is met at the end of A/D conversion, this flag sets to 1. When the ADCMPCR.CMPAIE bit is 1, a compare interrupt request (ADC12i_CMPAI (i = 0, 1)) is generated when this flag sets to 1.

Writing 1 to the CMPSTTSA flag is invalid.

[Setting condition]

- The condition set in ADCMPLEER.CMPLTSA is met when ADCMPCR.CMPAE = 1.

[Clearing condition]

- Writing 0 after reading 1.

CMPSTOCA flag (Compare Window A Internal Reference Voltage Compare Flag)

The CMPSTOCA flag indicates the internal reference voltage comparison result. When the comparison condition set in ADCMPLEER.CMPLOCA is met at the end of A/D conversion, this flag sets to 1. When the ADCMPCR.CMPAIE bit is 1, a compare interrupt request (ADC12i_CMPAI (i = 0, 1)) is generated when this flag sets to 1.

Writing 1 to the CMPSTOCA flag is invalid.

[Setting condition]

- The condition set in ADCMPLEER.CMPLOCA is met when ADCMPCR.CMPAE = 1.

[Clearing condition]

- Writing 0 after reading 1.

45.2.36 ADCMPBNSR : A/D Compare Function Window B Channel Select Register

Base address: ADC12m = 0x4033_2000 + 0x0200 × m (m = 0, 1)
ADC12m_NS = 0x5033_2000 + 0x0200 × m (m = 0, 1)

Offset address: 0x0A6

		7		CMPLB	Compare Window B Comparison Condition Setting This bit sets comparison conditions for channels for Window B. The comparison conditions are shown in Figure 45.7 . 0: When window function is disabled (ADCMPCR.WCMPE = 0): ADWINLLB value > A/D-converted value When window function is enabled (ADCMPCR.WCMPE = 1): A/D-converted value < ADWINLLB value, or ADWINULB value < A/D-converted value 1: When window function is disabled (ADCMPCR.WCMPE = 0): ADWINLLB value < A/D-converted value When window function is enabled (ADCMPCR.WCMPE = 1): ADWINLLB value < A/D-converted value < ADWINULB value	R/W																																																																	

Note: S-TYPE-3, P-TYPE-3

CMPCHB[5:0] bits (Compare Window B Channel Select)

The CMPCHB[5:0] bits specify the channels to be compared with the compare Window B conditions from AN000 to AN002, AN004 to AN008, AN016 to AN019, AN100 to AN102, AN104 to AN106, AN116 to AN122, the temperature sensor, the internal reference voltage and the VBATT 1/3 voltage monitor output. The compare Window B function is enabled by specifying the hexadecimal number of the A/D conversion channel selected in the ADANSA0, ADANSA1, ADANSB0, ADANSB1 registers.

Set the CMPCHB[5:0] bits while the ADCSR.ADST bit is 0.

CMPLB bit (Compare Window B Comparison Condition Setting)

The CMPLB bit specifies the comparison conditions for channels for Window B. When the comparison result of an analog input meets the set condition, the associated ADCMPBSR.CMPSTB flag sets to 1 and a compare interrupt request (ADC12i_CMPBI (i = 0, 1)) is generated.

Compare conditions when the window function is disabled			
CMPLB = 0		CMPLB = 1	
ADWINLLB value $\leq$ A/D converted value	Not met	ADWINLLB value $<$ A/D converted value	Met
ADWINLLB value $>$ A/D converted value	Met	ADWINLLB value $\geq$ A/D converted value	Not met
Compare conditions when the window function is enabled			
CMPLB = 0			
A/D converted value $>$ ADWINULB value		Met	
ADWINLLB value $\leq$ A/D converted value $\leq$ ADWINULB value		Not met	
A/D converted value $<$ ADWINLLB value		Met	
CMPLB = 1			
A/D converted value $\geq$ ADWINULB value		Not met	
ADWINLLB value $<$ A/D converted value $<$ ADWINULB value		Met	
A/D converted value $\leq$ ADWINLLB value		Not met	

Figure 45.7 Explanation of compare conditions for compare function Window B

45.2.37 ADCMPBSR : A/D Compare Function Window B Status Register

Base address: $\text{ADC12m} = 0x4033_2000 + 0x0200 \times m$ (m = 0, 1)
 $\text{ADC12m_NS} = 0x5033_2000 + 0x0200 \times m$ (m = 0, 1)

Offset address: 0x0AC

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	CMPS TB
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	CMPSTB	Compare Window B Flag When Window B operation is enabled (ADCMPCR.CMPBE = 1), this bit indicates the comparison result of channels to which Window B comparison conditions are applied, temperature sensor output, internal reference voltage. 0: Comparison conditions are not met. 1: Comparison conditions are met.	R/W
7:1	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

CMPSTB flag (Compare Window B Flag)

The CMPSTB flag indicates the comparison result of channels to which Window B comparison conditions are applied, the temperature sensor output, internal reference voltage. When the comparison condition set in ADCMPBNSR.CMPLB is met at the end of A/D conversion, this flag sets to 1. When the ADCMPCR.CMPBIE bit is 1, a compare interrupt request (ADC12i_CMPBI (i = 0, 1)) is generated when this flag sets to 1.

Writing 1 to the CMPSTB flag is invalid.

[Setting condition]

- The condition set in ADCMPBNSR.CMPLB is met when ADCMPCR.CMPBE = 1.

[Clearing condition]

- Writing 0 after reading 1.

45.2.38 ADWINMON : A/D Compare Function Window A/B Status Monitor Register

Base address: $ADC12m = 0x4033_2000 + 0x0200 \times m$ (m = 0, 1)
 $ADC12m_NS = 0x5033_2000 + 0x0200 \times m$ (m = 0, 1)

Offset address: 0x08C

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	MONC MPB	MONC MPA	—	—	—	MONC OMB
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	MONCOMB	Combination Result Monitor This bit indicates the combination result. This bit is valid when both Window A and Window B operations are enabled. 0: Window A/B composite conditions are not met. 1: Window A/B composite conditions are met.	R
3:1	—	These bits are read as 0.	R
4	MONCMPA	Comparison Result Monitor A 0: Window A comparison conditions are not met. 1: Window A comparison conditions are met.	R
5	MONCMPB	Comparison Result Monitor B 0: Window B comparison conditions are not met. 1: Window B comparison conditions are met.	R
7:6	—	These bits are read as 0.	R

Note: S-TYPE-3, P-TYPE-3

MONCOMB bit (Combination Result Monitor)

The read-only MONCOMB bit indicates the combined result of comparison condition results A and B based on the combination condition set in the ADCMPCR.CMPAB[1:0] bits.

[Setting condition]

- The combined result meets the combination condition set in the ADCMPCR.CMPAB[1:0] bits when ADCMPCR.CMPAE = 1 and ADCMPCR.CMPBE = 1.

[Clearing conditions]

- The combined result does not meet the combination condition set in the ADCMPCR.CMPAB[1:0] bits.
- ADCMPCR.CMPAE = 0 or ADCMPCR.CMPBE = 0.

MONCMPA bit (Comparison Result Monitor A)

The read-only MONCMPA bit is read as 1 when the A/D-converted value of the Window A target channel meets the condition set in ADCMPLR0/ADCMPLR1 and ADCMPLER. Otherwise, it is read as 0.

[Setting condition]

- The A/D-converted value meets the condition set in the ADCMPLR0/ADCMPLR1 and ADCMPLER registers when ADCMPCR.CMPAE = 1.

[Clearing conditions]

- The A/D-converted value does not meet the condition set in the ADCMPLR0/ADCMPLR1 and ADCMPLER registers when ADCMPCR.CMPAE = 1.
- ADCMPCR.CMPAE = 0 (automatically cleared when the ADCMPCR.CMPAE value changes from 1 to 0).

MONCMPB bit (Comparison Result Monitor B)

The read-only MONCMPB bit is read as 1 when the A/D-converted value of the Window B target channel meets the condition set in the ADCMPBNSR.CMPLB bit. Otherwise, it is read as 0.

[Setting condition]

- The A/D-converted value meets the condition set in ADCMPBNSR.CMPLB when ADCMPCR.CMPBE = 1.

[Clearing conditions]

- The A/D-converted value does not meet the condition set in ADCMPBNSR.CMPLB when ADCMPCR.CMPBE = 1.
- ADCMPCR.CMPBE = 0 (automatically cleared when the ADCMPCR.CMPBE value changes from 1 to 0).

45.2.39 ADBUFEN : A/D Data Buffer Enable Register

Base address: ADC12m = 0x4033_2000 + 0x0200 × m (m = 0, 1)
ADC12m_NS = 0x5033_2000 + 0x0200 × m (m = 0, 1)

Offset address: 0x0D0

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	BUFEN
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	BUFEN	Data Buffer Enable 0: The data buffer is not used. 1: The data buffer is used.	R/W
7:1	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

The ADBUFEN register sets whether to enable the data buffer.

BUFEN bit (Data Buffer Enable)

This bit enables the use of the data buffer.

When BUFEN = 1b, A/D conversion result (addition result) other than self-diagnosis result is stored in ADBUFn.

Disable the data storage operation (BUFEN = 0b) before reading ADBUFPTR.

Do not use the data buffer for data duplexing, or group scan.

45.2.40 ADBUFPTR : A/D Data Buffer Pointer Register

Base address: $ADC12m = 0x4033_2000 + 0x0200 \times m$ ($m = 0, 1$)
 $ADC12m_NS = 0x5033_2000 + 0x0200 \times m$ ($m = 0, 1$)

Offset address: 0x0D2

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	PTROVF	BUFPtr[3:0]			
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
3:0	BUFPtr[3:0]	Data Buffer Pointer These bits indicate the number of data buffer to which the next A/D converted data is transferred.	R/W
4	PTROVF	Pointer Overflow Flag 0: The data buffer pointer has not overflowed. 1: The data buffer pointer has overflowed.	R/W
7:5	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

ADBUFPtr is a register that indicates the data buffer pointer and overflow status.

BUFPtr[3:0] bit (Data Buffer Pointer)

These bits indicate the number of data buffer to which the next A/D converted data is transferred.

When data has been transferred to data buffer 15, the pointer value becomes 0000b and the PTROVF bit is set to 1.

When the next data has been transferred, the data in data buffer 0 is overwritten.

Writing 0x00 to this register clears the value of these bits. Writing a value other than 0x00 is disabled.

PTROVF bit (Pointer Overflow Flag)

This bit indicates whether the data buffer pointer has overflowed. This bit is set to 1 when the pointer value becomes 0000b (overflow).

Writing 0x00 to this register clears this bit value. Writing a value other than 0x00 is disabled.

45.2.41 ADBUFn : A/D Data Buffer Registers n ($n = 0$ to 15)

Base address: $ADC12m = 0x4033_2000 + 0x0200 \times m$ ($m = 0, 1$)
 $ADC12m_NS = 0x5033_2000 + 0x0200 \times m$ ($m = 0, 1$)

Offset address: $0x0B0 + 0x2 \times n$ ($n = 0$ to 15)

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	ADBUF[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	ADBUF[15:0]	Converted Value 15 to 0 Functions vary depending on the selected mode and accuracy. See Table 45.24 and Table 45.25 .	R

Note: S-TYPE-3, P-TYPE-3

ADBUF n registers are 16-bit read-only registers that sequentially store all A/D conversion results. The automatic clear function is not applied to these registers.

ADBUF n settings are the same as the A/D data register format settings.

The following conditions determine the formats for data in the ADBUF n registers:

- Setting of the Register Format Select bit (ADCER.ADRFMT) (flush-left or flush-right)
- Setting of the Addition/Average Count Select bits (ADADC.ADC[2:0]) (1, 2, 3, 4, or 16 times)
- Setting of the Average Mode Enable bit (ADADC.AVEE) (addition or average).

This section describes the data formats for these conditions in different modes.

(1) When A/D-converted value addition/average mode is not selected

Table 45.24 shows the bit assignment for each accuracy.

Table 45.24 Bit assignment for each accuracy

Accuracy	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Right-justified data with 12-bit accuracy	These bits are read as 0.				Converted Value 11 to 0: 12-bit A/D-converted value											
Left-justified data with 12-bit accuracy	Converted Value 11 to 0: 12-bit A/D-converted value												These bits are read as 0.			

(2) When A/D-converted value average mode is selected

A/D-converted value average mode can be selected when 2 or 4 times is specified in the A/D-converted value addition mode. When A/D converted value average mode is selected, These registers indicate the mean of A/D-converted values on a specific channel. The value is stored in the A/D data register based on the setting of the A/D Data Register Format Select bit in the same way as for normal A/D conversion.

(3) When A/D-converted value addition mode is selected

For 12-bit, 10-bit, 8-bit accuracy, 1, 2, 3, or 4 times can be selected in the A/D-converted value addition mode. A/D conversion results are stored in the A/D data register as a 2-bit-extended value of the specified conversion accuracy.

For 12-bit accuracy, 16 times can also be selected in the A/D-converted value addition mode. In A/D-converted value addition mode, these registers indicate the value that is obtained by adding A/D-converted values on a specific channel. A/D conversion results are stored in the A/D data register as a 4-bit-extended value of the specified conversion accuracy.

When A/D-converted value addition mode is selected, the value is stored in the A/D data register based on the settings of the A/D Data Register Format Select bits.

Table 45.25 shows the bit assignment for each accuracy.

Table 45.25 Bit assignment for each accuracy when A/D-converted value addition mode is selected

Accuracy		b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Right-justified data with 12-bit accuracy	When 16 conversion times is specified	Added Value 15 to 0: 16-bit sum of A/D conversion results															
	When 1, 2, 3, or 4 conversion times is specified	These bits are read as 0.		Added Value 13 to 0: 14-bit sum of A/D conversion results													
Left-justified data with 12-bit accuracy	When 1, 2, 3, or 4 conversion times is specified	Added Value 15 to 0: 16-bit sum of A/D conversion results															
	When 16 conversion times is specified	Added Value 13 to 0: 14-bit sum of A/D conversion results														These bits are read as 0.	

45.3 Operation

45.3.1 Scanning Operation

In scanning, A/D conversion is performed sequentially on the analog inputs of the specified channels.

Scan conversion is performed in any of the three operating modes:

- Single scan mode
- Continuous scan mode
- Group scan mode

In single scan mode, one or more specified channels are scanned once. In continuous scan mode, one or more specified channels are scanned repeatedly until software sets the ADCSR.ADST bit to 0. In group scan mode, the selected channels in group A, B are scanned once after scan starts in response to the respective synchronous trigger.

In single scan mode and continuous scan mode, A/D conversion is performed for the ANn channels selected in the ADANSA0 and ADANSA1 registers, starting from the channel with the smallest number n. In group scan mode, A/D conversion is performed for the ANn channels in group A selected in the ADANSA0 and ADANSA1 registers, and for the ANn channels in group B selected in the ADANSB0 and ADANSB1 registers, starting from the channel with the smallest number n.

When self-diagnosis is selected, it is executed once at the beginning of each scan and one of the three reference voltages is converted.

The temperature sensor output and internal reference voltage can be selected at the same time as the analog input of the channels, and A/D conversion is performed on the analog input of channels, temperature sensor output, and internal reference voltage, in that order.

Double trigger mode can be used with single scan mode or group scan mode. With double trigger mode enabled (ADCSR.DBLE = 1), A/D conversion data of a channel selected in the ADCSR.DBLANS[4:0] bits is duplicated only if the conversion is started by the synchronous trigger (GPT, ELC) selected in the ADSTRGR.TRSA[5:0] bits. In group scan mode, only group A can use double trigger mode.

In the extended operation of double trigger mode, the A/D conversion operation is generated from the synchronous trigger combination selected in the ADSTRGR.TRSA[5:0] bits. In addition to normal double trigger mode operation, A/D conversion data with odd number trigger (ELC_AD00 (unit 0), ELC_AD10 (unit 1), GTCIADAn (Unit0) and GTCIADAm (Unit1) (n = 0 to 3, m = 4 to 7)) is stored in A/D Data Duplexing Register A (ADDBLDRA), and A/D conversion data with even number trigger (ELC_AD01 (unit 0), ELC_AD11 (unit1), GTCIADBn (Unit0) and GTCIADBm (Unit1) (n = 0 to 3, m = 4 to 7)) is stored in A/D Data Duplexing Register B (ADDBLDRB). In the extended operation of double trigger mode, when one of the trigger combinations occurs at the same time, the data duplexing register settings for the specified triggers do not work, and A/D conversion data is stored in A/D Data Duplexing Register B (ADDBLDRB).

The ADC12 ignores a synchronous trigger that occurs during the A/D conversion started by another synchronous trigger.

When any of the channels AN000 to AN002 (unit 0) are set as a channel-dedicated sample-and-hold circuit in the SHANS[2:0] bits in ADSHCR, the target analog input specified is sampled and held before the first A/D conversion of each scan.

45.3.2 Single Scan Mode

45.3.2.1 Basic Operation (Without Channel-Dedicated Sample-and-Hold Circuits)

In basic operation of single scan mode, A/D conversion is performed once on the analog input of the specified channels as follows:

1. When the ADCSR.ADST bit is set to 1 (A/D conversion start) by a software trigger, a synchronous trigger input (GPT, ELC), or an asynchronous trigger input, A/D conversion is performed for the ANn channels selected in the ADANSA0 and ADANSA1 registers, starting from the channel with the smallest number n.
2. Each time A/D conversion of a single channel is completed, the A/D conversion result is stored in the associated A/D data register (ADDRy).
3. When A/D conversion of all the selected channels is completed, an ADC12i_ADI (i = 0, 1) interrupt request is generated.
4. The ADST bit remains 1 (A/D conversion start) during A/D conversion and is automatically set to 0 when A/D conversion of all the selected channels is completed. The ADC12 then enters a wait state.

Figure 45.8 Example basic operation in single scan mode when the analog inputs (channel x to z) are selected

45.3.2.2 Basic Operation (With Channel-Dedicated Sample-and-Hold Circuits and Continuous Sampling Disabled)

When the channel-dedicated sample-and-hold circuit is used, sample-and-hold operation is first performed, and then A/D conversion is performed on the analog input of all the specified channels once. The channels whose dedicated sample-and-hold circuit is to be used can be selected in the SHANS[2:0] bits in ADSHCR.

The operation is as follows:

1. Analog input sampling of all channels whose dedicated sample-and-hold circuit is to be used starts when the ADCSR.ADST bit is set to 1 (A/D conversion start) by a software trigger, synchronous trigger input (GPT, ELC), or asynchronous trigger input.
2. After the sample-and-hold operation, A/D conversion is performed on the ANn channels selected in the ADANSA0 and ADANSA1 registers, starting from the channel with the smallest number n.
3. Each time A/D conversion of a single channel completes, the A/D conversion result is stored in the associated A/D data register (ADDRy).
4. When A/D conversion of all the selected channels completes, an ADC12i_ADI ($i = 0$) interrupt request is generated (no register setting).
5. The ADST bit remains 1 (A/D conversion start) during A/D conversion, and is automatically cleared to 0 when A/D conversion of all the selected channels completes. Then, the ADC12 enters a wait state.

Figure 45.9 Example operation in single scan mode when the channel-dedicated sample-and-hold circuits are used and AN000 to AN002 are selected

45.3.2.3 Basic Operation (With Channel-Dedicated Sample-and-Hold Circuits and Continuous Sampling Enabled)

When a channel-dedicated sample-and-hold circuit is used while continuous sampling is enabled, sample-and-hold operations are performed first, followed by A/D conversion on the analog inputs on all selected channels, once. The ADSHCR.SHANS[2:0] bits specify the channels for which the channel-dedicated sample-and-hold circuits are to be used.

The operation is as follows:

1. When the ADSHMSR.SHMD bit is set to 1, the sample-and-hold circuits selected in the ADSHCR.SHANS[2:0] bits start continuous sampling.
2. Analog input holding starts for all the channels for which the channel-dedicated sample-and-hold circuits are to be used when the ADCSR.ADST bit is set to 1 (A/D conversion start) by a software trigger, input of a synchronous trigger signal (GPT, ELC), or input of an asynchronous trigger.
3. After the stabilization time of the sample-and-hold circuits elapses, A/D conversion is performed on the AN_n channels selected in the ADANSA0 and ADANSA1 registers, starting from the channel with the smallest number *n*.
4. Each time A/D conversion of a single channel completes, the A/D conversion result is stored in the associated A/D data register (ADDR_y), and the sample-and-hold circuit restarts continuous sampling.
5. When A/D conversion of all the selected channels completes, an ADC12_i_ADI (*i* = 0) interrupt request is generated (no register setting).
6. The ADCSR.ADST bit remains 1 (A/D conversion start) during A/D conversion, and is automatically cleared to 0 when A/D conversion of all the selected channels completes. Then, the ADC12 enters a wait state. If this is followed by single scanning, set the continuous sampling time for the sample-and-hold circuits to at least 400 ns (when the permissible signal source impedance is 1 kΩ).
7. When the ADSHMSR.SHMD bit is set to 0, the sample-and-hold circuits stop.

Figure 45.10 Example operation in single scan mode when channel-dedicated sample-and-hold circuits are used, AN000 to AN002 are selected, and continuous sampling is enabled

45.3.2.4 Channel Selection and Self-Diagnosis (Without Channel-Dedicated Sample-and-Hold Circuits)

When channels and self-diagnosis are selected, A/D conversion is first performed for the reference voltage VREFH0, VREFH ($\times 0$, $\times 1/2$, or $\times 1$), then A/D conversion is performed once on the analog input of the selected channels as follows:

1. A/D conversion for self-diagnosis is first started when the ADCSR.ADST bit is set to 1 (A/D conversion start) by a software trigger input, a synchronous trigger input (GPT, ELC), or an asynchronous trigger input.
2. When A/D conversion for self-diagnosis is completed, the A/D conversion result is stored in the A/D Self-Diagnosis Data Register (ADDRD). A/D conversion is then performed for the ANn channels selected in the ADANSA0 and ADANSA1 registers, starting from the channel with the smallest number n.
3. Each time A/D conversion of a single channel is completed, the A/D conversion result is stored in the associated A/D data register (ADDRy).
4. When A/D conversion of all the selected channels is completed, an ADC12i_ADI (i = 0, 1) interrupt request is generated.
5. The ADCSR.ADST bit remains 1 (A/D conversion start) during A/D conversion and is automatically set to 0 when A/D conversion of all the selected channels is completed. The ADC12 then enters a wait state.

Figure 45.11 Example basic operation in single scan mode when the analog inputs (channel x and y) are selected with self-diagnosis

45.3.2.5 Channel Selection and Self-Diagnosis (With Channel-Dedicated Sample-and-Hold Circuits and Continuous Sampling Disabled)

When channels and self-diagnosis are selected and a channel-dedicated sample-and-hold circuit is used while continuous sampling is disabled, the sample-and-hold operation is performed first, and then A/D conversion is performed once for the reference voltage VREFH0 (unit 0) ($\times 0$, $\times 1/2$, or $\times 1$) supplied to the ADC12. After that, A/D conversion is performed only once on the analog input of the selected channels.

The operation is as follows:

1. Analog input sampling starts for all channels whose dedicated sample-and-hold circuit is to be used when the ADCSR.ADST bit is set to 1 (A/D conversion start) by a software trigger, synchronous trigger input (GPT, ELC), or asynchronous trigger input.
2. After the sample-and-hold operation, A/D conversion for self-diagnosis starts.
3. When A/D conversion for self-diagnosis completes, the A/D conversion result is stored in the A/D Self-Diagnosis Data Register (ADRD). A/D conversion is then performed for the ANn channels selected in the ADANSA0 and ADANSA1 registers, starting from the channel with the smallest number n.
4. Each time A/D conversion of a single channel completes, the A/D conversion result is stored in the associated A/D Data Register y (ADDRy).
5. When A/D conversion of all the selected channels completes, an ADC12i_ADI ($i = 0$) interrupt request is generated (no register setting).
6. The ADST bit remains 1 (A/D conversion start) during A/D conversion, and is automatically cleared to 0 when A/D conversion of all the selected channels completes. Then, the ADC12 enters a wait state.

Figure 45.12 Example operation in single scan mode when channel-dedicated sample-and-hold circuits are used, AN000 and AN002 are selected with self-diagnosis, and continuous sampling is disabled

45.3.2.6 Channel Selection and Self-Diagnosis (With Channel-Dedicated Sample-and-Hold Circuits and Continuous Sampling Enabled)

When channels and self-diagnosis are selected and a channel-dedicated sample-and-hold circuit is used while continuous sampling is enabled, sample-and-hold operations are performed first, followed by A/D conversion of the reference voltage VREFH0 (unit 0) supplied to the ADC12. After that, A/D conversion is performed only once on the analog input of the selected channels.

The operation is as follows:

1. When the ADSHMSR.SHMD bit is set to 1, the sample-and-hold circuits selected in the ADSHCR.SHANS[2:0] bits start continuous sampling.
2. Analog input holding starts for all the channels for which the channel-dedicated sample-and-hold circuits are to be used when the ADCSR.ADST bit is set to 1 (A/D conversion start) by a software trigger, input of a synchronous trigger signal (GPT, ELC), or input of an asynchronous trigger. Set the ADCSR.ADST bit to 1 after at least 400 ns (when the permissible signal source impedance is 1 kΩ) elapse after the ADSHMSR.SHMD bit is set to 1.
3. After the stabilization time of the sample-and-hold circuits elapse, A/D conversion for self-diagnosis starts.
4. When A/D conversion for self-diagnosis completes, the A/D conversion result is stored in the A/D Self-Diagnosis Data Register (ADRD). A/D conversion is then performed for the ANn channels selected in the ADANSA0 and ADANSA1 registers, starting from the channel with the smallest number n.
5. Each time A/D conversion of a single channel completes, the A/D conversion result is stored in the associated A/D Data Register y (ADDRy), and the sample-and-hold circuit restarts continuous sampling.
6. When A/D conversion of all the selected channels completes, an ADC12i_ADI (i = 0) interrupt request is generated (no register setting).
7. The ADCSR.ADST bit remains 1 (A/D conversion start) during A/D conversion, and is automatically cleared to 0 when A/D conversion of all the selected channels completes. Then, the ADC12 enters a wait state. If this is followed by single scanning, set the continuous sampling time for the sample-and-hold circuits to at least 400 ns (when the permissible signal source impedance is 1 kΩ).
8. When the ADSHMSR.SHMD bit is set to 0, the sample-and-hold circuits stop.

Figure 45.13 Example operation in single scan mode when channel-dedicated sample-and-hold circuits are used, AN000 to AN002 are selected with self-diagnosis, and continuous sampling is enabled

45.3.2.7 A/D Conversion of Temperature Sensor Output or Internal Reference Voltage

When the channels and temperature sensor output or internal reference voltage are selected at the same time, A/D conversion is performed first on the analog input of the selected channels, and once on the temperature sensor output or internal reference voltage. When both temperature sensor output and internal reference voltage are selected, A/D conversion of the temperature sensor output and internal reference voltage is performed, in that order. With the channels deselected, selecting only the temperature sensor output or internal reference voltage is also possible.

The operation is as follows:

1. When a software trigger, synchronous trigger (GPT, ELC), or asynchronous trigger sets the ADCSR.ADST bit to 1 (A/D conversion start), A/D conversion is performed for the ANn channels selected in the ADANSA0 and ADANSA1 registers, starting from the channel with the smallest number n.
2. On completion of A/D conversion on the channels, the result is stored in the associated A/D Data Register y (ADDRy), and then A/D conversion of the temperature sensor output starts.
3. On completion of A/D conversion of the temperature sensor output, the result is stored in the associated A/D Temperature Sensor Data Register (ADTSDR), and then A/D conversion of the internal reference voltage starts.
4. On completion of A/D conversion of the internal reference voltage, the result is stored in the associated A/D Internal Reference Voltage Data Register (ADOCDR), and an ADC12i_ADI (i = 0, 1) interrupt request is generated (no register setting).
5. The ADCSR.ADST bit remains 1 (A/D conversion start) during A/D conversion, and is automatically cleared to 0 on completion of A/D conversion. Then, the ADC12 enters a wait state.

Figure 45.14 Example basic operation in single scan mode when AN000 and temperature sensor output or internal reference voltage are selected

45.3.2.8 A/D Conversion in Double-Trigger Mode

When double trigger mode is selected in single scan mode, two rounds of single scan operation started by a synchronous trigger (GPT, ELC) are performed in sequence.

Deselect self-diagnosis and set the temperature sensor output A/D conversion select bit (ADEXICR.TSSA and ADEXICR.TSSB) and the internal reference voltage A/D conversion select bit (ADEXICR.OCSA and ADEXICR.OCSB) to 0.

Duplication of A/D conversion data is enabled by setting the channel numbers to be duplicated in the ADCSR.DBLANS[4:0] bits and setting the ADCSR.DBLE bit to 1. When the ADCSR.DBLE bit is set to 1, channel selection using the ADANSA0 and ADANSA1 registers is invalid.

In double trigger mode, select a synchronous trigger (GPT, ELC) with the ADSTRGR.TRSA[5:0] bits. Additionally, set the ADCSR.EXTRG bit to 0 and the ADCSR.TRGE bit to 1. Do not use a software trigger.

The operation is as follows:

1. When the ADCSR.ADST bit is set to 1 (A/D conversion start) by a synchronous trigger input (GPT, ELC), A/D conversion starts on the single channel selected in the ADCSR.DBLANS[4:0] bits.
2. Each time A/D conversion of a single channel is completed, the A/D conversion result is stored in the associated A/D Data Register y (ADDRy).
3. The ADCSR.ADST bit is automatically set to 0 and the ADC12 enters a wait state. An ADC12i_ADI (i = 0, 1) interrupt request is not generated.
4. When the ADCSR.ADST bit is set to 1 (A/D conversion start) by the second trigger input, A/D conversion starts on the single channel selected in the ADCSR.DBLANS[4:0] bits.
5. When A/D conversion is completed, the result is stored in the A/D Data Duplexing Register (ADDBLDR), which is exclusively used in double-trigger mode.
6. An ADC12i_ADI (i = 0, 1) interrupt request is generated.
7. The ADCSR.ADST bit remains 1 (A/D conversion start) during A/D conversion and is automatically set to 0 when A/D conversion is completed. Then the ADC12 enters a wait state.

Figure 45.15 Example operation in single scan mode when double-trigger mode is selected and the analog input (channel x) is duplicated

45.3.2.9 Extended Operations when Double-Trigger Mode is Selected

When double trigger mode is selected in single scan mode, and a synchronous trigger (ELC_AD00 (unit 0) and ELC_AD10 (unit 1)/ELC_AD01 (unit 0) and ELC_AD11 (unit 1), GTCIADA0 (unit 0) and GTCIADA4 (unit 1) / GTCIADB0 (Unit0) and GTCIADB4 (unit 1), GTCIADA1 (unit 0) and GTCIADA5 (unit 1) / GTCIADB1 (Unit0) and GTCIADB5 (unit 1), GTCIADA2 (unit 0) and GTCIADA6 (unit 1) / GTCIADB2 (Unit0) and GTCIADB6 (unit 1) or GTCIADA3 (unit 0) and GTCIADA7 (unit 1) / GTCIADB3 (Unit0) and GTCIADB7 (unit 1)) is selected as the trigger for the start of A/D conversion, two rounds of single scan operation are performed.

Deselect self-diagnosis and set the temperature sensor output A/D conversion select bit (ADEXICR.TSSA and ADEXICR.TSSB), and the internal reference voltage A/D conversion select bit (ADEXICR.OCOSA and ADEXICR.OCOSB) to 0.

Duplication of A/D conversion data is enabled by setting the channel number to be duplicated to the ADCSR.DBLANS[4:0] bits and setting the ADCSR.DBLE bit to 1. When the ADCSR.DBLE bit is set to 1, channel selection using the ADANSA0 and ADANSA1 registers is invalid.

In extended double trigger mode, select a synchronous trigger combination by setting the ADSTRGR.TRSA[5:0] bits to 0x0B, set the ADCSR.EXTRG bit to 0, and set the ADCSR.TRGE bit to 1. Do not use a software trigger.

The operation is as follows:

1. When the ADCSR.ADST bit is set to 1 (A/D conversion start) by a synchronous trigger input, A/D conversion starts on the single channel selected in the ADCSR.DBLANS[4:0] bits.
2. When A/D conversion completes, the A/D conversion result is stored in the associated A/D Data Register (ADDR_y) and in A/D Data Duplexing Register A (ADDBLDR A) or A/D Data Duplexing Register B (ADDBLDR B) when the ELC_ADi0 or ELC_ADi1 trigger is input respectively (i = 0, 1).
3. The ADCSR.ADST bit is automatically set to 0 and the ADC12 enters a wait state. An ADC12i_ADI (i = 0, 1) interrupt request is not generated.
4. When the ADCSR.ADST bit is set to 1 (A/D conversion start) by the second trigger (ELC_AD00 (unit 0) and ELC_AD10 (unit 1)/ELC_AD01 (unit 0) and ELC_AD11 (unit 1)), A/D conversion starts on the single channel selected in the ADCSR.DBLANS[4:0] bits.
5. When A/D conversion completes, the A/D conversion result is stored in the A/D Data Duplexing Register (ADDBLDR) and in A/D Data Duplexing Register A (ADDBLDR A) or A/D Data Duplexing Register B (ADDBLDR B) when the ELC_ADi0 or ELC_ADi1 trigger is input respectively (i = 0, 1).
6. An ADC12i_ADI (i = 0, 1) interrupt request is generated.

7. The ADCSR.ADST bit remains 1 (A/D conversion start) during A/D conversion and is automatically set to 0 when A/D conversion completes. The ADC12 then enters a wait state.

Figure 45.16 Example extended operation in double trigger mode with duplication selected for the analog input (channel x) and ELC_AD00 (unit 0) and ELC_AD10 (unit 1)/ELC_AD01 (unit 0) and ELC_AD11 (unit 1)

45.3.3 Continuous Scan Mode

45.3.3.1 Basic Operation (Without Channel-Dedicated Sample-and-Hold Circuits)

In continuous scan mode, A/D conversion is performed repeatedly on the analog input of the specified channels.

The operation is as follows:

1. When the ADCSR.ADST bit is set to 1 (A/D conversion start) by a software trigger, a synchronous trigger input (GPT, ELC), or an asynchronous trigger input, A/D conversion is performed for ANn channels selected in the ADANSA0 and ADANSA1 registers, starting from the channel with the smallest number n.
2. Each time A/D conversion of a single channel is completed, the A/D conversion result is stored in the associated A/D Data Register (ADDRy).
3. When A/D conversion of all the selected channels is completed, an ADC12i_ADI (i = 0, 1) interrupt request is generated. The ADC12 sequentially starts A/D conversion for the ANn channels selected in the ADANSA0 and ADANSA1 registers, starting from the channel with the smallest number n.
4. The ADCSR.ADST bit is not automatically cleared, and steps 2. and 3. are repeated as long as ADCSR.ADST remains 1 (A/D conversion start). When the ADCSR.ADST bit is set to 0 (A/D conversion stop), A/D conversion stops and the ADC12 enters a wait state.
5. When the ADCSR.ADST bit is later set to 1 (A/D conversion start), A/D conversion starts again for the ANn channels selected in the ADANSA0 and ADANSA1 registers, starting from the channel with the smallest number n.

Figure 45.17 Example basic operation in continuous scan mode when the analog inputs (channel x to z) are selected

45.3.3.2 Basic Operation (With Channel-Dedicated Sample-and-Hold Circuits and Continuous Sampling Disabled)

When the channel-dedicated sample-and-hold circuit is used with the continuous sampling disabled, sample-and-hold operation is performed first, and then A/D conversion is repeated on the analog input of all the specified channels. The channels whose dedicated sample-and-hold circuit is to be used can be selected in the SHANS[2:0] bits in ADSHCR.

The operation is as follows:

1. Analog input sampling starts for all channels whose dedicated sample-and-hold circuit is to be used when the ADCSR.ADST bit is set to 1 (A/D conversion start) by a software trigger, synchronous trigger input (GPT, ELC), or asynchronous trigger input.
2. After the sample-and-hold operation, A/D conversion is performed for the ANn channels selected in the ADANSA0 and ADANSA1 registers, starting from the channel with the smallest number n.
3. Each time A/D conversion of a single channel completes, the A/D conversion result is stored in the associated A/D Data Register y (ADDRy).
4. When A/D conversion of all the selected channels completes, an ADC12i_ADI (i = 0) interrupt request is generated (no register setting). At the same time, analog input sampling starts for all channels whose dedicated sample-and-hold circuit is to be used.
5. The ADST bit is not automatically cleared, and steps 2 to 4 are repeated as long as the bit remains 1. When the ADST bit is set to 0 (A/D conversion stop), A/D conversion stops and the ADC12 enters a wait state.
6. When the ADST bit is then set to 1 (A/D conversion start), analog input sampling starts again for all the channels whose dedicated sample-and-hold circuit is to be used.

Figure 45.18 Example operation in continuous scan mode when channel-dedicated sample-and-hold circuits are used and AN000 and AN001 are selected

45.3.3.3 Basic Operation (With Channel-Dedicated Sample-and-Hold Circuits and Continuous Sampling Enabled)

When a channel-dedicated sample-and-hold circuit is used while continuous sampling is enabled, sample-and-hold operations are performed first, after which the analog inputs on all the selected channels are A/D-converted as described in this section. The channels for which the channel-dedicated sample-and-hold circuits are to be used can be selected in the ADSHCR.SHANS[2:0] bits.

The operation is as follows:

1. When the ADSHMSR.SHMD bit is set to 1, the sample-and-hold circuits selected in the ADSHCR.SHANS[2:0] bits start continuous sampling.
2. Analog input holding starts for all channels for which the channel-dedicated sample-and-hold circuits are to be used when the ADCSR.ADST bit is set to 1 (A/D conversion start) by a software trigger, input of a synchronous trigger signal (GPT, ELC), or input of an asynchronous trigger. Set the ADCSR.ADST bit to 1 after at least 400 ns (when the permissible signal source impedance is 1 k Ω) elapse after the ADSHMSR.SHMD bit is set to 1.
3. After the stabilization time of the sample-and-hold circuits elapses, A/D conversion is performed for the ANn channels selected in the ADANSA0 and ADANSA1 registers, starting from the channel with the smallest number n.
4. Each time A/D conversion of a single channel completes, the A/D conversion result is stored in the associated A/D Data Register y (ADDRy), and the sample-and-hold circuit restarts continuous sampling.
5. When A/D conversion of all the selected channels completes, an ADC12i_ADI (i = 0) interrupt request is generated (no register setting). Also, analog input holding starts for all channels for which the channel-dedicated sample-and-hold circuits are to be used.
6. The ADCSR.ADST bit is not automatically cleared, and steps 3 to 5 are repeated as long as the bit remains 1. When the ADCSR.ADST bit is set to 0 (A/D conversion stop), A/D conversion stops and the ADC12 enters a wait state.
7. When the ADSHMSR.SHMD bit is set to 0, the sample-and-hold circuits stop.
8. When the ADSHMSR.SHMD bit is then set to 1, the sample-and-hold circuits selected in the ADSHCR.SHANS[2:0] bits start continuous sampling.
9. When the ADCSR.ADST bit is then set to 1 (A/D conversion start), analog input holding starts for all channels for which the channel-dedicated sample-and-hold circuits are to be used.

Note: If continuous scanning is performed when only those channels with the sample-and-hold circuits are selected, time for continuous sampling cannot be secured in the second and subsequent continuous scans. When continuous sampling by the channel-dedicated sample-and-hold circuits is enabled for continuous scanning, select one or more channels among AN003 to AN008 and AN016 to AN019, temperature sensor output, internal reference voltage and VBATT 1/3 voltage monitor output for unit 0, and AN100 to AN106 and AN116 to AN122, temperature sensor output,

internal reference voltage and VBATT 1/3 voltage monitor output for unit 1, and set the continuous sampling time for the sample-and-hold circuits to at least 400 ns (when the permissible signal source impedance is 1 kΩ).

Figure 45.19 Example operation in continuous scan mode when channel-dedicated sample-and-hold circuits are used, AN000, AN001, and AN004 are selected, and continuous sampling is enabled

45.3.3.4 Channel Selection and Self-Diagnosis (Without Channel-Dedicated Sample-and-Hold Circuits)

When channels and self-diagnosis are selected at the same time, A/D conversion is first performed for the reference voltage VREFH0, VREFH ($\times 0$, $\times 1/2$, or $\times 1$) supplied to the ADC12, and A/D conversion is performed on the analog input of the selected channels. This sequence is repeated as described in the section that follows.

The operation is as follows:

1. A/D conversion for self-diagnosis is first started when the ADCSR.ADST bit is set to 1 (A/D conversion start) by a software trigger input, a synchronous trigger input (GPT, ELC), or an asynchronous trigger input.
2. When A/D conversion for self-diagnosis is completed, the A/D conversion result is stored in the A/D Self-Diagnosis Data Register (ADDR). A/D conversion is then performed for the ANn channels selected in the ADANSA0 and ADANSA1 registers, starting from the channel with the smallest number n.
3. Each time A/D conversion of a single channel is completed, the A/D conversion result is stored in the corresponding A/D Data Register (ADDRy).
4. When A/D conversion of all the selected channels is completed, an ADC12i_ADI (i = 0, 1) interrupt request is generated. At the same time, the ADC12 starts A/D conversion for self-diagnosis and then on the ANn channels selected in the ADANSA0 and ADANSA1 registers, starting from the channel with the smallest number n.
5. The ADCSR.ADST bit is not automatically cleared, and steps 2. to 4. are repeated as long as the ADCSR.ADST bit remains 1. When the ADST bit is set to 0 (A/D conversion stop), A/D conversion stops and the ADC12 enters a wait state.
6. When the ADST bit is later set to 1 (A/D conversion start), the A/D conversion for self-diagnosis is started again.

Figure 45.20 Example basic operation in continuous scan mode when the analog inputs (channel x and y) are selected with self-diagnosis

45.3.3.5 Channel Selection and Self-Diagnosis (With Channel-Dedicated Sample-and-Hold Circuits and Continuous Sampling Disabled)

When the channels and self-diagnosis are selected and a channel-dedicated sample-and-hold circuit is used while continuous sampling is disabled, sample-and-hold operation is performed first, and then A/D conversion is performed for the reference voltage VREFH0 (unit 0) (×0, ×1/2, or ×1) supplied to the ADC12, and then A/D conversion is performed on the analog input of the selected channels, and this sequence is repeated.

The operation is as follows:

1. Analog input sampling starts for all channels whose dedicated sample-and-hold circuit is to be used when the ADCSR.ADST bit is set to 1 (A/D conversion start) by a software trigger, synchronous trigger input (GPT, ELC), or asynchronous trigger input.
2. After the sample-and-hold operation, A/D conversion for self-diagnosis starts.
3. When A/D conversion for self-diagnosis completes, the A/D conversion result is stored in the A/D Self-Diagnosis Data Register (ADRD). A/D conversion is then performed for the ANn channels selected in the ADANSA0 and ADANSA1 registers, starting from the channel with the smallest number n.
4. Each time A/D conversion of a single channel completes, the A/D conversion result is stored in the associated A/D data register (ADDRy).
5. When A/D conversion of all the selected channels completes, an ADC12i_ADI (i = 0) interrupt request is generated (no register setting). At the same time, analog input sampling starts for all channels whose dedicated sample-and-hold circuit is to be used.
6. The ADST bit is not automatically cleared, and steps 2 to 5 are repeated as long as the bit remains 1. When the ADST bit is set to 0 (A/D conversion stop), A/D conversion stops and the ADC12 enters a wait state.
7. When the ADST bit is then set to 1 (A/D conversion start), analog input sampling starts again for all the channels whose dedicated sample-and-hold circuits are to be used.

Figure 45.21 Example operation in continuous scan mode when channel-dedicated sample-and-hold circuits are used and AN000 and AN001 are selected with self-diagnosis

45.3.3.6 Channel Selection and Self-Diagnosis (With Channel-Dedicated Sample-and-Hold Circuits and Continuous Sampling Enabled)

When channels and self-diagnosis are selected and a channel-dedicated sample-and-hold circuit is used while continuous sampling is enabled, the sample-and-hold operation is performed first, and followed by A/D conversion of the reference voltage VREFH0 (unit 0) ($\times 0$, $\times 1/2$, or $\times 1$) supplied to the ADC12. After that, A/D conversion is performed on the analog input of the selected channels, and this sequence is repeated.

The operation is as follows:

1. When the ADSHMSR.SHMD bit is set to 1, the sample-and-hold circuits selected in the ADSHCR.SHANS[2:0] bits start continuous sampling.
2. Analog input holding starts for all channels for which the channel-dedicated sample-and-hold circuits are to be used when the ADCSR.ADST bit is set to 1 (A/D conversion start) by a software trigger, input of a synchronous trigger signal (GPT, ELC), or input of an asynchronous trigger. Set the ADCSR.ADST bit to 1 after at least 400 ns (when the permissible signal source impedance is 1 k Ω) elapse after the ADSHMSR.SHMD bit is set to 1.
3. After the stabilization time of the sample-and-hold circuits elapses, A/D conversion for self-diagnosis starts.
4. When A/D conversion for self-diagnosis completes, the A/D conversion result is stored in the A/D Self-Diagnosis Data Register (ADDRD). A/D conversion is then performed for the ANn channels selected in the ADANSA0 and ADANSA1 registers, starting from the channel with the smallest number n.
5. Each time A/D conversion of a single channel completes, the A/D conversion result is stored in the associated A/D Data Register y (ADDRy), and the sample-and-hold circuit restarts continuous sampling.
6. When A/D conversion of all the selected channels completes, an ADC12i_ADI (i = 0) interrupt request is generated (no register setting). Also, analog input holding starts for all channels for which the channel-dedicated sample-and-hold circuits are to be used.
7. The ADCSR.ADST bit is not automatically cleared, and steps 3 to 6 are repeated as long as the bit remains 1. When the ADCSR.ADST bit is set to 0 (A/D conversion stop), A/D conversion stops and the ADC12 enters a wait state.
8. When the ADSHMSR.SHMD bit is set to 0, the sample-and-hold circuits stop.
9. When the ADSHMSR.SHMD bit is then set to 1, the sample-and-hold circuits selected in the ADSHCR.SHANS[2:0] bits start continuous sampling.
10. When the ADCSR.ADST bit is then set to 1 (A/D conversion start), analog input holding starts for all channels for which the channel-dedicated sample-and-hold circuits are to be used.

Note: If continuous scanning is performed when only those channels with the sample-and-hold circuits are selected, time for continuous sampling cannot be secured in the second and subsequent continuous scans. When continuous sampling by the channel-dedicated sample-and-hold circuits is enabled for continuous scanning, select one or more

channels among AN003 to AN008 and AN016 to AN019, temperature sensor output, internal reference voltage and VBATT 1/3 voltage monitor output for unit 0, and AN100 to AN106 and AN116 to AN122, temperature sensor output, internal reference voltage and VBATT 1/3 voltage monitor output for unit 1, and set the continuous sampling time for the sample-and-hold circuits to at least 400 ns (when the permissible signal source impedance is 1 kΩ).

Figure 45.22 Example operation in continuous scan mode when channel-dedicated sample-and-hold circuits are used, AN000, AN001, and AN004 are selected with self-diagnosis, and continuous sampling is enabled

45.3.3.7 A/D Conversion of Temperature Sensor Output or Internal Reference Voltage

When the channels and temperature sensor output or internal reference voltage are selected at the same time, A/D conversion is first performed on the analog input of the selected channels, and then the A/D conversion of the temperature sensor output or internal reference voltage is repeated. When both the temperature sensor output and internal reference voltage are selected, A/D conversion of the temperature sensor output and internal reference voltage is performed, in that order.

With the channels deselected, selecting only the temperature sensor output or internal reference voltage is also possible.

The operation is as follows:

1. When a software trigger, synchronous trigger (GPT, ELC), or asynchronous trigger sets the ADCSR.ADST bit to 1 (A/D conversion start), A/D conversion is performed for the ANn channels selected in the ADANSA0 and ADANSA1 registers, starting from the channel with the smallest number n.
2. On completion of A/D conversion on the channels, the result is stored in the associated A/D Data Register y (ADDRy), and then A/D conversion of temperature sensor output starts.
3. On completion of A/D conversion of the temperature sensor output, the result is stored in the associated A/D Temperature Sensor Data Register (ADTSDR), and then A/D conversion of the internal reference voltage starts.
4. On completion of A/D conversion of the internal reference voltage, the result is stored in the associated A/D Internal Reference Voltage Data Register (ADOCDR), and an ADC12i_ADI (i = 0, 1) interrupt request is generated. In addition, the ADC12 continuously starts A/D conversion for the ANn channels selected in the ADANSA0 and ADANSA1 registers, starting from the channel with the lowest number n.
5. The ADCSR.ADST bit is not cleared automatically, and steps 2 to 4 are repeated as long as this bit remains set to 1. When the ADCSR.ADST bit is set to 0 (A/D conversion stop), A/D conversion stops and the ADC12 enters a wait state.
6. When the ADCSR.ADST bit is then set to 1 (A/D conversion start), A/D conversion starts again for the ANn channels selected in the ADANSA0 and ADANSA1 registers, starting from the channel with the lowest number n.

Figure 45.23 Example basic operation in continuous scan mode when AN000 and temperature sensor output or internal reference voltage are selected

45.3.4 Group Scan Mode

45.3.4.1 Basic Operation

In group scan mode, A/D conversion is performed once on the analog input of all the specified channels in group A and B after scanning is started by a synchronous trigger (GPT, ELC). The scan operation of each group is similar to the scan operation in single scan mode.

The synchronous triggers can be selected in the ADSTRGR.TRSA[5:0] bits for group A and in the ADSTRGR.TRSB[5:0] bits for group B. Use different triggers for group A and B to prevent simultaneous A/D conversion of the two groups. Do not use a software trigger.

The group A channels to be A/D-converted are selected using the ADANSA0 and ADANSA1 registers and the ADEXICR.TSSA and OCSA bits. The group B channels to be A/D-converted are selected using the ADANSB0 and ADANSB1 registers and the ADEXICR.TSSB and OCSB bits. Group A and B cannot use the same channels.

When self-diagnosis is selected in group scan mode, self-diagnosis is separately executed for Group A and B.

The following sequence describes operation in group scan mode using a synchronous trigger from the ELC. In this example, the ELC_AD00 (unit 0) and ELC_AD10 (unit 1) trigger from the ELC is used to start conversion of group A and the ELC_AD01 (unit 0) and ELC_AD11 (unit 1) trigger from the ELC is used to start conversion of group B. In addition, ELC_AD00 (unit 0) and ELC_AD10 (unit 1) and ELC_AD01 (unit 0) and ELC_AD11 (unit 1) are selected for the GPT event in the associated ELC.ELSRn registers.

The operation is as follows:

1. Scanning of group A is started by ELC_AD00 (unit 0) and ELC_AD10 (unit 1).
2. When group A scanning completes, an ADC12i_ADI (i = 0, 1) interrupt is generated (no register setting).
3. Scanning of group B is started by ELC_AD01 (unit 0) and ELC_AD11 (unit 1).
4. When group B scanning completes, an ADC12i_GBADI (i = 0, 1) interrupt is generated if the ADCSR.GBADIE bit is 1 (ADC12i_GBADI (i = 0, 1) interrupt when scanning completion is enabled).

Figure 45.24 Example basic operation in group scan mode when synchronous triggers from the ELC are used

45.3.4.2 A/D Conversion in Double-Trigger Mode

When double trigger mode is selected in group scan mode, two rounds of single scan operation started by a synchronous trigger (GPT, ELC) are performed as a sequence for group A. For group B, single scan operation started by a synchronous trigger (GPT, ELC) is performed once.

In group scan mode, the synchronous trigger can be selected in the ADSTRGR.TRSA[5:0] bits for group A and in the ADSTRGR.TRSB[5:0] bits for group B. Use different triggers for group A, B to prevent simultaneous A/D conversion of the two groups. Do not use a software trigger or an asynchronous trigger.

When an ELC_AD00 (unit 0) and ELC_AD10 (unit 1)/ELC_AD01 (unit 0) and ELC_AD11 (unit 1) is selected as group A synchronous triggers by setting the ADSTRGR.TRSA[5:0] bits to 0x0B, operation proceeds in extended double trigger mode.

The group A channel to be A/D-converted is selected using the DBLANS[4:0] bits in the ADCSR register, while the group B channels to be A/D-converted are selected using the ADANSB0 and ADANSB1 registers. Group A, B cannot use the same channels.

When double-trigger mode is selected in group scan mode, set the A/D conversion select bits for both the temperature sensor output (ADEXICR.TSSA) and the internal reference voltage (ADEXICR.OCSA) to 0 (deselected).

Self-diagnosis cannot be selected when double trigger mode is selected in group scan mode.

Duplication of A/D conversion data is enabled by setting the channel numbers to be duplicated in the ADCSR.DBLANS[4:0] bits and setting the ADCSR.DBLE bit to 1.

The following sequence describes operation in group scan mode with double trigger mode selected and using a synchronous trigger from the ELC. In this example, the ELC_AD00 (unit 0) and ELC_AD10 (unit 1) trigger is used to start conversion of group A and the ELC_AD01 (unit 0) and ELC_AD11 (unit 1) trigger is used to start conversion of group B. In addition, ELC_AD00 (unit 0) and ELC_AD10 (unit 1) and ELC_AD01 (unit 0) and ELC_AD11 (unit 1) are selected for the GPT event in the associated ELC.ELSRn registers.

The operation is as follows:

1. Scanning of group B is started by the ELC_AD00 (unit 0) and ELC_AD10 (unit 1) trigger from the ELC.

- When group B scanning completes, an ADC12i_GBADI ($i = 0, 1$) interrupt is generated if the GBADIE bit in ADCSR is 1 (ADC12i_GBADI ($i = 0, 1$) interrupt when scanning completion is enabled).
- The first scan of group A is started by the first ELC_AD01 (unit 0) and ELC_AD11 (unit 1) trigger.
- When the first scan of group A completes, the conversion result is stored in the associated A/D Data Register y (ADDRy). An ADC12i_ADI ($i = 0, 1$) interrupt request is not generated.
- The second scan of group A is started by the second ELC_AD01 (unit 0) and ELC_AD11 (unit 1) trigger.
- When the second scan of group A completes, the conversion result is stored in ADDBLDR. An ADC12i_ADI ($i = 0, 1$) interrupt is generated.

Figure 45.25 Example basic operation in group scan mode with double-trigger mode when synchronous triggers from the ELC are used

45.3.4.3 Group Priority Operation

Group priority operation is performed by setting the ADGSPCR.PGS bit to 1 in group-scan mode. The priority of groups is group A > group B.

When setting the PGS bit in the ADGSPCR register to 1, follow the procedure described in [Figure 45.26](#). If the procedure is not followed, A/D conversion operation and stored data are not guaranteed.

As the basic operation in group-scan mode, a trigger input generated during A/D conversion of group A, B is ignored, and the A/D conversion operation of each group is similar to the operation in single-scan mode.

In group priority operation, if a trigger for a priority group is input during scanning of a lower-priority group, A/D conversion for the lower-priority group is stopped and A/D conversion for the priority group is performed.

If the setting of the ADGSPCR.GBRSCN bit is 0, the lower-priority group enters a wait state when A/D conversion for the priority group completes. A trigger input of the lower-priority group generated during A/D conversion is ignored.

If the setting of the ADGSPCR.GBRSCN bit is 1, A/D conversion for the lower-priority group automatically restarts upon completion of A/D conversion for the priority group. A trigger input of the lower-priority group generated during A/D conversion on the priority group takes effect, and A/D conversion for the lower-priority group is automatically performed upon completion of A/D conversion on the priority group.

If the ADGSPCR.GBRSCN bit is 1 and the ADGSPCR.LGRRS bit is 0, A/D conversion for the lower-priority group is restarted from the first channel. If the setting of the ADGSPCR.LGRRS bit is 1, A/D conversion for the lower-priority group is restarted from the channel for which the conversion stopped. However, if the self-diagnosis function is used, the A/D conversion is restarted from the channel for which the conversion stopped after self-diagnosis completed.

Table 45.26 summarizes operations in response to the input of a trigger during A/D conversion with the settings of the ADGSPCR.GBRSCN bit.

If the setting of the ADGSPCR.GBRP bit is 1, A/D conversion operation for the lowest-priority group is to continuously perform single scans.

For the trigger settings in group-scan mode, select a synchronous trigger for group A by using the ADSTRGR.TRSA[5:0] bits, a synchronous trigger for group B by using the ADSTRGR.TRSB[5:0] bits. Each trigger must be different from each other. Set the ADSTRGR.TRSB[5:0] bits to 0x3F when setting the ADGSPCR.GBRP bit to 1.

The channels to be scanned must be selected in the registers shown in [section 45.3.4. Group Scan Mode](#).

Figure 45.26 Flowchart for ADGSPCR.PGS bit setting

Table 45.26 Control of A/D conversion operations according to ADGSPCR.GBRSCN bit setting

A/D conversion operation	Trigger input	ADGSPCR.GBRSCN = 0	ADGSPCR.GBRSCN = 1
When A/D conversion for group A is in progress	Input of trigger for group A	Trigger input is ineffective.	Trigger input is ineffective.
	Input of trigger for group B	Trigger input is ineffective.	A/D conversion for group B is performed after A/D conversion for group A completes.
When A/D conversion for group B is in progress	Input of trigger for group A	A/D conversion for group B is discontinued and A/D conversion for group A starts.	- A/D conversion for group B is discontinued and A/D conversion for group A starts. - A/D conversion for group B starts after A/D conversion for group A completes.
	Input of trigger for group B	Trigger input is ineffective.	Trigger input is ineffective.

To use group priority operation mode, select the operation mode to be implemented and set the registers according to the following table.

Table 45.27 Group priority operation setting and operation mode for two groups (ADGSPCR.PGS = 1)

ADGSPCR			Operation category
GBRSCN	LGRRS	GBRP	
0	x	0	Group priority operation for two groups (groups A and B) When a trigger of group A is input, A/D conversion for group B is terminated (and will not be restarted).
1	0	0	Group priority operation for two groups (groups A and B) After A/D conversion for group B stopped, when A/D conversion for group A completes, A/D conversion for the group B channels selected in the ADANSB0 and ADANSB1 registers restarts according to the conversion order of smaller channel number.
1	1	0	Group priority operation for two groups (groups A and B) After A/D conversion for group B stopped, when A/D conversion for group A completes, A/D conversion for the group B channels selected in the ADANSB0/1 register restarts according to the conversion order of smaller channel number, beginning from the channel for which A/D conversion stopped.*1
x	0	1	Group priority operation for two groups (groups A and B) Single scanning for group B is continuously performed without a start trigger input. After A/D conversion for group B stopped, when A/D conversion for group A completes, single scanning for the channels selected in the ADANSB0/1 register restarts according to the conversion order of smaller channel number.
1	1	1	Group priority operation for two groups (groups A and B) Single scanning for group B is continuously performed without a start trigger input. After A/D conversion for group B stopped, when A/D conversion for group A completes, single scanning for the channels selected in the ADANSB0/1 register restarts according to the conversion order of smaller channel number, beginning from the channel for which A/D conversion stopped.*1

Note: x: Don't care.

Note 1. When the self-diagnosis function is enabled (ADCER.DIAGM = 1), A/D conversion for the channel that has been stopped is started after self-diagnosis is performed.

(1) Group priority operation for two groups (when ADGSPCR.PGS = 1)

Operation examples 1-1 to 1-3 show group priority operations in group-scan mode (when ADGSPCR.GBRSCN = 1, ADGSPCR.GBRP = 0, and ADGSPCR.LGRRS = 0).

Operation example 1-1: "Group A trigger input during group B scan" when rescanning is enabled

- When input of a trigger for group B sets the ADCSR.ADST bit to 1 (starting A/D conversion), A/D conversion for the analog input channels selected in the ADANSB0 and ADANSB1 registers starts according to the conversion order from the channel with the smallest number n.
- On completion of A/D conversion for each channel in group B, the result is stored in the corresponding A/D Data Register y (ADDRy).
- When a trigger for group A is input during A/D conversion for group B, A/D conversion for group B stops while the ADCSR.ADST bit remains 1. Then A/D conversion for the group A analog input channels selected in the ADANSA0

and ADANSA1 registers starts according to the conversion order from the channel with the smallest number n. If A/D conversion stops before it is completed, the conversion result is not stored in the A/D Data Register y (ADDRy).

4. On completion of A/D conversion on the channels, the result is stored in the corresponding A/D Data Register y (ADDRy).
5. An ADC120_ADI interrupt request is generated.
6. If the setting of the ADGSPCR.GBRSCN bit is 1 (enabling rescanning of the group that was stopped in group priority operation), A/D conversion for the group B analog input channels selected in the ADANSB0 and ADANSB1 registers restarts according to the conversion order from the channel with the smallest number n while the ADCSR.ADST remains 1.
7. On completion of A/D conversion on the channels, the result is stored in the corresponding A/D Data Register y (ADDRy).
8. If the setting of the ADCSR.GBADIE bit is 1 (enabling interrupt generation on completion of group B scan), a group B scan end interrupt request is generated.
9. When A/D conversion for all the channels completes, the ADCSR.ADST bit is automatically cleared and the A/D converter enters a wait state.

Figure 45.27 Example of group priority operation 1-1: Group A trigger input during group B scanning when rescanning is enabled (when ADGSPCR.GBRSCN = 1, ADGSPCR.GBRP = 0, and ADGSPCR.LGRRS = 0)

Operation example 1-2: “Group A trigger input during rescanning of group B” when rescanning is enabled

Figure 45.28 shows the operation when a group A trigger is input during rescanning operation for group B.

Even during rescanning operation, when a trigger for group A is input, A/D conversion on group B stops and A/D conversion for group A starts. A/D conversion for group B starts after A/D conversion for group A completes.

Operations for setting the ADCSR.ADST bit, storing the A/D conversion result in the corresponding A/D Data Register y (ADDRy), and generating interrupt requests are the same as those in operation example 1-1.

Figure 45.28 Example of group priority operation 1-2: Group A trigger input during rescanning of group B when rescanning is enabled (when ADGSPCR.GBRSCN = 1, ADGSPCR.GBRP = 0, and ADGSPCR.LGRRS = 0)

Operation example 1-3: “Group B trigger input during group A scan” when rescanning is enabled

The following describes the operation when the setting of the ADGSPCR.GBRSCN bit is 1 (enabling rescanning of the group that was stopped in group priority operation) and a trigger for group B is input during scanning operation for group A. If the setting of the ADGSPCR.GBRSCN bit is 0, any trigger for group B that is input during scanning operation for group A is invalid.

- When input of a trigger for group A sets the ADCSR.ADST bit to 1 (starting A/D conversion), A/D conversion for the group A analog input channels selected in the ADANSA0 and ADANSA1 registers starts according to the conversion order from the channel with the smallest number n.
- When a trigger for group B is input during A/D conversion for group A, group B is ready for A/D conversion.
- On completion of A/D conversion for each channel in group A, the result is stored in the corresponding A/D Data Register y (ADDRy).
- An ADC120_ADI interrupt request is generated.
- When A/D conversion for group A completes, while the ADCSR.ADST bit remains 1, A/D conversion for the group B analog input channels selected in the ADANSB0 and ADANSB1 registers starts according to the conversion order from the channel with the smallest number n.
As with the case of operation example 1-1, if a trigger for group A is input during A/D conversion for group B, A/D conversion for group A starts. Then A/D conversion for group B starts upon completion of A/D conversion for group A.
- On completion of A/D conversion of a single channel, the result is stored in the corresponding A/D Data Register y (ADDRy).
- Upon completion of A/D conversion for group B, a group B scan end interrupt request is generated if the setting of the ADCSR.GBADIE bit is 1 (enabling interrupt generation on completion of group B scan).
- When A/D conversion for all the channels completes, the ADCSR.ADST bit is automatically cleared and the A/D converter enters a wait state.

Note: w, x, y, and z ($x < y < z$) are the selected channel numbers by ADANSA0/1 or ADANSB0/1.

Note 1. ADC12i_ADI ($i = 0, 1$)

Note 2. ADC12i_GBADI ($i = 0, 1$)

Figure 45.29 Example of group priority operation 1-3: Group B trigger input during group A scan when rescanning is enabled (when ADGSPCR.GBRSCN = 1, ADGSPCR.GBRP = 0, and ADGSPCR.LGRRS = 0)

Operation example 1-4 shows the group priority operation in group-scan mode (when ADGSPCR.GBRSCN = 0, ADGSPCR.GBRP = 0, and ADGSPCR.LGRRS = 0).

Operation example 1-4: “Group A trigger input during group B scan” when rescanning is disabled

- When input of a trigger for group B sets the ADCSR.ADST bit to 1 (starting A/D conversion), A/D conversion for the analog input channels selected in the ADANSB0 and ADANSB1 registers starts according to the conversion order from the channel with the smallest number n.
- On completion of A/D conversion for each channel in group B, the result is stored in the corresponding A/D Data Register y (ADDRy).
- When a trigger for group A is input during A/D conversion for group B, A/D conversion for group B stops while the ADCSR.ADST bit remains 1, and then A/D conversion for the group A analog input channels selected in the ADANSA0 and ADANSA1 registers starts according to the conversion order from the channel with the smallest number n. If A/D conversion stops before it is completed, the conversion result is not stored in the A/D Data Register y (ADDRy).
- On completion of A/D conversion of a single channel, the result is stored in the corresponding A/D Data Register y (ADDRy).
- On completion of A/D conversion for group A, an ADC120_ADI interrupt request is generated.
- When A/D conversion for group A completes, the ADCSR.ADST bit is automatically cleared and the A/D converter enters a wait state. A/D conversion for group B is not performed until a trigger for group B is input the next time.

Figure 45.30 Group priority operation example 1-4: “Group A trigger is input during group B scan” when rescanning is disabled (when ADGSPCR.GBRSCN = 0, ADGSPCR.GBRP = 0, and ADGSPCR.LGRRS = 0)

Operation example 1-5 shows the group priority operation in group-scan mode (when ADGSPCR.GBRP = 1, and ADGSPCR.LGRRS = 0).

Operation example 1-5: Continuously activating single-scan operation for group B

1. When ADGSPCR.GBRP = 1 is set, the ADCSR.ADST bit is set to 1 (starting A/D conversion) and A/D conversion for the analog input channels selected in the ADANSB0 and ADANSB1 registers starts according to the conversion order from the channel with the smallest number n.
2. On completion of A/D conversion for each channel in group B, the result is stored in the corresponding A/D Data Register y (ADDRy).
3. When a trigger for group A is input during A/D conversion for group B, A/D conversion for group B stops while the ADCSR.ADST bit remains 1, and then A/D conversion for group A analog input channels selected in the ADANSA0 and ADANSA1 registers starts according to the conversion order from the channel with the smallest number n. If A/D conversion stops before it is completed, the conversion result is not stored in the A/D Data Register y (ADDRy).
4. On completion of A/D conversion of a single channel, the result is stored in the corresponding A/D Data Register y (ADDRy).
5. On completion of A/D conversion for group A, an ADC120_ADI interrupt request is generated.
6. If ADGSPCR.GBRP = 1 is set (performing single scan continuously), A/D conversion for the group B analog input channels selected in the ADANSB0 and ADANSB1 registers restarts according to the conversion order from the channel with the smallest number n while the ADCSR.ADST remains 1 (starting A/D conversion).
7. On completion of A/D conversion of a single channel, the result is stored in the corresponding A/D Data Register y (ADDRy).

8. If the setting of the ADCSR.GBADIE bit is 1 (enabling interrupt generation on completion of group B scan), a group B scan end interrupt request is generated.
9. If ADGSPCR.GBRP = 1 is set (performing single scan continuously), A/D conversion for the group B analog input channels selected in the ADANSB0 and ADANSB1 registers restarts according to the conversion order from the channel with the smallest number n while the ADCSR.ADST remains 1 (starting A/D conversion).

Steps 6 to 9 are repeated as long as the ADGSPCR.GBRP bit remains 1. Do not clear the ADCSR.ADST bit as long as the ADGSPCR.GBRP bit is 1. To forcibly stop A/D conversion while ADGSPCR.GBRP = 1, follow the procedure shown in Figure 45.43.

Figure 45.31 Group priority operation example 1-5: Continuously activating single scan for group B (when ADGSPCR.GBRP = 1, ADGSPCR.LGRRS = 0)

Note: To continuously activate single-scan operation for group B, disable group B trigger input.

45.3.5 Compare Function for Windows A and B

45.3.5.1 Compare Function Windows A and B

The compare function compares a reference value with the A/D conversion result. The reference value can be set for Window A and Window B independently. When the compare function is in use, the self-diagnosis function and double trigger mode cannot be used. The main differences between Window A and Window B are their different interrupt output signals and the constraint on Window B of only one selectable channel.

This section provides an example operation that combines continuous scan mode and the compare function.

The operation is as follows:

1. When the ADCSR.ADST bit is set to 1 (A/D conversion start) by software, a synchronous trigger (GPT, ELC) or an asynchronous trigger, A/D conversion starts in the order of the selected channels, temperature sensor, and internal reference voltage.
2. On completion of A/D conversion, the A/D conversion result is stored in the associated A/D Data Register y (ADDRy, ADTSDR, or ADOCDR). When ADCMPCR.CMPAE = 1, if bits in the ADCMPANSRy register or the ADCMPANSER register are set for Window A, the A/D conversion result is compared with the set ADCMPDR0/1 register value. When ADCMPCR.CMPBE = 1, if bits in the ADCMPBNSR register are set for Window B, the A/D conversion result is compared with the ADWINULB/ADWINLLB register setting.

3. As a result of the comparison, when Window A meets the condition set in ADCMPLR0/1 or ADCMPLER, the Compare Window A Flag (ADCMPSTR0.CMPSTCHAn, ADCMPSTR1.CMPSTCHAn, ADCMPSTR.CMPSTTSA or ADCMPSTR.CMPSTOCA) sets 1. At this time, if the ADCMPSTR.CMPAIE bit is 1, an ADC12i_CMPAI ($i = 0, 1$) interrupt request is generated. In the same way, when Window B meets the condition set in ADCMPBNSR.CMPLB, the Compare Window B Flag (ADCMPBNSR.CMPSTB) sets to 1. At this time, if the ADCMPSTR.CMPBIE bit is 1, an ADC12i_CMPBI ($i = 0, 1$) interrupt request is generated.
4. On completion of all selected A/D conversions and comparisons, scan restarts.
5. After the ADC12i_CMPAI ($i = 0, 1$) and ADC12i_CMPBI ($i = 0, 1$) interrupts are accepted, the ADCSR.ADST bit is set to 0 (A/D conversion stop) and processing is performed for channels for which the compare flag is set to 1.
6. When all compare flags of Window A are cleared, the ADC12i_CMPAI ($i = 0, 1$) interrupt request is canceled. In the same way, when all compare flags of Window B are cleared, the ADC12i_CMPBI ($i = 0, 1$) interrupt request is reset. To perform comparison again, restart the A/D conversion.

Figure 45.32 Example of compare function operation, when the analog inputs (channel w to z) are compared

45.3.5.2 Event Output of Compare Function

The event output of the compare function specifies the upper-side reference value and the lower-side reference value for window A and window B, respectively. The output compares the A/D converted value of the selected channel with the upper and lower side reference value and outputs events (ADC12i_WCMPLM ($i = 0, 1$)/ADC12i_WCMPUM ($i = 0, 1$)) based on event conditions (A OR B, A AND B, A XOR B) and comparison result of window A and window B.

If more than one channel is selected for window A, and even when one channel in window A meets the comparison condition, the comparison result of window A is met. When using this function, perform A/D conversion in single scan mode.

Any channels from analog input, internal reference voltage, temperature sensor output and VBATT 1/3 voltage monitor output are selectable for window A.

One channel from analog input, internal reference voltage, temperature sensor output and VBATT 1/3 voltage monitor output is selectable for window B.

The following sequence is an example of how to set up and use the event output of the compare function:

1. Confirm that the value in the ADCSR.ADCS bits is 00b (single scan mode).
2. Select the channel for window A in the ADCMPANSR0/1 and ADCMPANSER registers. Set the window comparison conditions in the ADCMPLR0/1 and ADCMPLER registers. Set the upper-side and lower-side reference values in the ADCMPDR0/1 registers.
3. Select the channel and comparison conditions for Window B in the ADCMPBNSR register, and set the upper and lower reference values in the ADWINULB and ADWINLLB registers.
4. Set the composite conditions for window A/B, window A/B operation enable, and interrupt output enable in the ADCMPCR register.

Figure 45.33 Setting example when using the event output of the compare function

For event output usage when using only window A for the compare function, note the following:

- Enable both Window A and Window B (ADCMPCR.CMPAE = 1, ADCMPCR.CMPBE = 1)
- Set the compound condition of Window A and Window B to “OR condition” (ADCMPCR.CMPAB[1:0] = 00b)
- Set the compared channel of Window B to “No selection” (ADCMPSNR.CMPCHB[5:0] = 0x3F)
- Set the compare condition of Window B to “0 < results < 0 always means mismatch”. (ADCMPCR.WCMPE = 1, ADWINLLB[15:0] = ADWINULB[15:0] = 0x0000, and ADCMPBNSR.CMPLB = 1)

Figure 45.34 shows the event output operation example of compare function.

A scan end event (ADC12i_ADI (i = 0, 1)) is output with the same timing as single scan completion. A match or mismatch event (ADC12i_WCMPM (i = 0, 1)/ADC12i_WCMPUM (i = 0, 1)) is output with 1 PCLKA cycle delay depending on the ADCMPCR.CMPAB[1:0] settings.

Note: The match and mismatch events are exclusive, so both events are never output simultaneously.

Figure 45.34 Example operation of the compare function event output, when the analog inputs (channel x and y) are compared

Note: Event output of compare function outputs match/mismatch from the comparison results of Window A and Window B, based on the ADCMPCR.CMPAB[1:0] settings.

Note: The comparison result of Window A is the logical addition of the comparison results of the comparison target channels of Window A. The comparison results of Window A and Window B are updated by each A/D conversion, and are kept even when single scan ends. Set ADCMPCR.CMPAE and ADCMPCR.CMPBE to 0 to clear the comparison results to 0.

45.3.5.3 Restrictions on Compare Function

The following constraints apply for the compare function:

- The compare function cannot be used together with the self-diagnosis function or double-trigger mode. The compare function is not available for ADDR, ADDBLDR, ADDBLDRA, and ADDBLDRB.
- Specify single scan mode when using match/mismatch event outputs.
- When the temperature sensor output, internal reference voltage is selected for Window A, Window B operations are prohibited.
- When the temperature sensor output, internal reference voltage is selected for Window B, Window A operations are prohibited.
- Setting the same channel for Window A and Window B is prohibited.
- Specify single scan mode when using the buffer function. It is prohibited to use double trigger mode together.
- Set the reference voltage values so that the upper-side reference voltage value is equal to or larger than the lower-side reference voltage value.

45.3.6 Analog Input Sampling and Scan Conversion Time

Scan conversion can be activated either by a software trigger, a synchronous trigger (GPT, ELC), or an asynchronous trigger (ADTRGn (n = 0, 1)). After the start-of-scanning-delay time (t_D) has elapsed, processing by the channel-dedicated sample-and-hold circuits, processing for disconnection detection assistance, and processing of conversion for self-diagnosis all proceed, followed by processing for A/D conversion.

Figure 45.35 shows the scan conversion timing, in which scan conversion is activated by a software trigger or a synchronous trigger (GPT, ELC). Figure 45.36 shows the scan conversion timing, in which scan conversion is activated by an asynchronous trigger (ADTRGn (n = 0, 1)). The scan conversion time (t_{SCAN}) includes the start-of-scanning-delay time (t_D), channel-dedicated sample-and-hold circuit processing time (t_{SPLSH})^{*1}, disconnection detection assistance processing time (t_{DIS})^{*2}, self-diagnosis A/D conversion processing time (t_{DIAG} and t_{DSD})^{*3}, A/D conversion processing time (t_{CONV} and t_{DSD}), channel-dedicated sample-and-hold circuit end time (t_{SHED})^{*4} and end-of-scanning-delay time (t_{ED}).

The A/D conversion processing time (t_{CONV}) consists of input sampling time (t_{SPL}) and time for conversion by successive approximation (t_{SAM}). The sampling time (t_{SPL}) is used to charge sample-and-hold circuits in the A/D converter. If there is not sufficient sampling time due to the high impedance of an analog input signal source, or if the A/D conversion clock (ADCLK) is slow, sampling time can be adjusted using the ADSSTRn register.

The time for conversion by successive approximation (t_{SAM}) is the following:

- 13 ADCLK states with 12-bit accuracy selected.
- 11 ADCLK states with 10-bit accuracy selected.
- 9 ADCLK states with 8-bit accuracy selected.

Table 45.28 shows the time for conversion by successive approximation (t_{SAM}).

The scan conversion time (t_{SCAN}) in single scan mode for which the number of selected channels is n can be determined as follows:

$$t_{SCAN} = t_D + t_{SPLSH} + (t_{DIS} \times n) + t_{DIAG} + t_{ED} + (t_{CONV} \times n) + t_{ED}^{*5}$$

The scan conversion time for the first cycle in continuous scan mode is t_{SCAN} for single scan minus t_{ED} . The scan conversion time for the second and subsequent cycles in continuous scan mode is fixed in the following:

$$t_{SPLSH} + (t_{DIS} \times n) + t_{DIAG} + t_{DSD} + t_{SHED} + (t_{CONV} \times n) + t_{SHED}^{*5}$$

Note 1. When no channel-dedicated sample-and-hold circuits are used, $t_{SPLSH} = 0$.

Note 2. When disconnection detection assistance is not selected, $t_{DIS} = 0$.

Note 3. When the self-diagnosis function is not used, $t_{DIAG} = 0$, $t_{DSD} = 0$.

Note 4. When no channel-dedicated sample-and-hold circuits are used, $t_{SHED} = 0$, assuming continuous scan mode is active. In single scan mode and group scan mode, t_{SHED} is included in the end-of-scanning-delay (t_{ED}).

Note 5. When input sampling times (t_{SPL}) of all selected channels are the same, this element equals $t_{CONV} \times n$. If each channel has a different sampling time, this element equals that of t_{SPL} and t_{SAM} set to each selected channel.

Table 45.28 shows the times for conversion during scanning.

Table 45.28 Conversion times during scanning (in numbers of cycles of ADCLK and PCLKA)

Item			Symbol		Type/Conditions			Unit
					Synchronous trigger ^{*4}	Asynchronous trigger	Software trigger	
Scan start processing time ^{*1 *2}	A/D conversion on group A under group A priority control.	Group B is to be stopped (Group A is activated after group B is stopped by of an A/D conversion source from group A).	t _D	3 PCLKA + 6 ADCLK 5 PCLKA + 3 ADCLK ^{*5}	—	—	Cycles	
		Group B is not to be stopped (activation by an A/D conversion source from group A).		2 PCLKA + 4 ADCLK	—	—		
	A/D conversion when self-diagnosis is enabled.	A/D conversion for self-diagnosis is to be started.		2 PCLKA + 6 ADCLK	4 PCLKA + 6 ADCLK	6 ADCLK		
	All other	2 PCLKA + 4 ADCLK		2 PCLKA + 4 ADCLK	4 ADCLK			
Channel-dedicated sample-and-hold processing time ^{*1}	Sampling time		t _{SPLSH}	t _{SH}	Without continuous sampling: setting in ADSHCR.SSTSH[7:0] (initial value = 0x18 × ADCLK) With continuous sampling: 0			
	Wait time between sampling and A/D Conversion			t _W	12 ADCLK			
Disconnection detection assistance processing time			t _{DIS}		Setting in ADNDIS[3:0] (initial value = 0x0) × ADCLK			
Self-diagnosis conversion processing time ^{*1}	Sampling time		t _{DIAG}	t _{SPL}	Setting in ADSSTR00 (initial value = 0x0B) × ADCLK ^{*3}	—	—	
	Time for conversion by successive approximation	12-bit conversion accuracy		t _{SAM}	15 ADCLK	—	—	
		10-bit conversion accuracy			13 ADCLK	—	—	
		8-bit conversion accuracy			11 ADCLK	—	—	
	Wait time between self-diagnosis conversion end and analog channel sampling start.			t _{DED}	2 ADCLK			
	Wait time between last channel conversion end and self-diagnosis sampling start in continuous scan mode.		t _{DSD}		2 ADCLK			
A/D conversion processing time ^{*1}	Sampling time		t _{CONV}	t _{SPL}	Setting in ADSSTRn (n = 0 to 8 (unit 0), 0 to 6 (unit 1), L, T, O, V) (initial value = 0x0B) × ADCLK + 0.5 ADCLK			
	Time for conversion by successive approximation	12-bit conversion accuracy		t _{SAM}	13 ADCLK			
		10-bit conversion accuracy			11 ADCLK			
		8-bit conversion accuracy			9 ADCLK			
Channel-dedicated sample-and-hold end processing time			t _{SHED}		2 ADCLK			
Scan end processing time ^{*1}			t _{ED}		1 PCLKA + 3 ADCLK 2 PCLKA + 3 ADCLK ^{*5}			

Note 1. See [Figure 45.35](#) and [Figure 45.36](#) for an illustration of times t_D , t_{SPLSH} , t_{DIAG} , t_{CONV} , and t_{ED} .

Note 2. This is the maximum time required from software writing or trigger input to A/D conversion start.

Note 3. The sampling time setting must satisfy the electrical characteristics.

Note 4. This does not include the time consumed in the path from timer output to trigger input.

Note 5. If ADCLK is faster than PCLKA (PCLKA to ADCLK frequency ratio = 1:2 or 1:4), the scan end processing time changes.

Figure 45.35 Scan conversion timing when activated by software or a synchronous trigger input (GPT, ELC)

Figure 45.36 Scan conversion timing when activated by an asynchronous trigger input (ADTRGn (n = 0, 1))

45.3.6.1 Timing of Suspension and Starting of Scanning in Operation under Group Priority Control

The timings for suspension and starting of scanning in operation under group priority control that must be considered are listed below.

1. The timing for suspending a scan of a group with a lower-priority and the timing for starting a scan of a group with a higher-priority.
2. The time at which scanning by the group with a lower-priority is resumed on completion of scanning by the higher-priority group when the trigger for scanning by the lower-priority group is accepted during scanning by the higher-priority group.
3. The timing for performing sequential single scans by a lower-priority group.

Figure 1.37 shows the timing diagram of each of the above cases.

Figure 45.37 Timing diagram of suspension and starting of scanning in operation under group priority control

45.3.7 Usage Example of A/D Data Register Automatic Clearing Function

Setting the ADCER.ACE bit to 1 automatically clears the A/D data registers (ADDRy, ADDR, ADDBLDR, ADDBLDRA, ADDBLDRB, ADTSDR, ADOCDR, ADVMDR) to 0x0000 when the A/D data registers are read by the CPU or DTC or DMAC.

This function enables detection of update failures of the A/D data registers (ADDRy, ADDR, ADDBLDR, ADDBLDRA, ADDBLDRB, ADTSDR, ADOCDR, ADVMDR). This section describes examples in which the function to automatically clear the ADDRy register is enabled and disabled.

- If the ADCER.ACE bit is 0 (automatic clearing is disabled) and for some reason, if the A/D conversion result (0x0222) is not written to the ADDRy register, the ADDRy value retains the old data (0x0111). In addition, if this ADDRy value is read into a general-purpose register using an A/D scan end interrupt, the old data (0x0111) can be saved in the general-purpose register. When checking whether there is an update failure, it is necessary to frequently save the old data in SRAM or in a general-purpose register.
- If the ADCER.ACE bit is 1 (automatic clearing is enabled), when ADDRy = 0x0111 is read by the CPU or DTC or DMAC, ADDRy is automatically set to 0x0000. Next, if the A/D conversion result of 0x0222 cannot be transferred to ADDRy for some reason, the cleared data (0x0000) remains as the ADDRy value. If this ADDRy value is read into a general-purpose register using an A/D scan end interrupt, 0x0000 is saved in the general-purpose register. Occurrence of an ADDRy update failure can be determined by checking that the read data value is 0x0000.

45.3.8 A/D-Converted Value Addition/Average Mode

A/D-converted value addition/average mode can be used when A/D conversion of the analog input of the selected channels, the temperature sensor output, the internal reference voltage and VBATT 1/3 voltage monitor output is selected.

In A/D-converted value addition mode, the same channel is A/D-converted 1, 2, 3, 4, or 16 consecutive times, and the sum of the converted values is stored in the data register. The conversion count of the addition function can be set to 16 only when 12-bit accuracy is selected. In A/D-converted value average mode, the same channel is A/D-converted 2 or 4 consecutive times, and the mean of the converted values is stored in the data register. The use of the average of these results can improve the accuracy of A/D conversion, depending on the types of noise components that are present. This function, however, cannot always guarantee an improvement in A/D conversion accuracy.

The A/D-converted value addition/average function can be used when A/D conversion of the analog inputs of the selected channels or A/D conversion of the temperature sensor output or A/D conversion of the internal reference voltage or A/D conversion of the VBATT 1/3 voltage monitor output is selected. The A/D-converted value addition/average function can also be used for channels for which the double-trigger function is selected.

The addition function for self-diagnosis is not provided.

45.3.9 Disconnection Detection Assist Function

The ADC12 incorporates a function to fix the charge for sampling capacitance to the specified state (VREFH0 or VREFL0 for unit 0, VREFH or VREFL for unit 1) before the start of A/D conversion. This function enables disconnection detection in wiring of analog inputs.

When using the disconnection detection assist function for the channel-dedicated sample-and-hold circuit, set the ADHMSR.SHMD bit to 0 (select disable continuous sampling function).

Figure 45.38 shows the A/D conversion operation when the disconnection detection assist function is used. Figure 45.39 shows an example of disconnection detection when precharge is selected. Figure 45.40 shows an example of disconnection detection when discharge is selected.

Note 1. 0 to 15 cycles of ADCLK

Figure 45.38 Operation of A/D conversion when disconnection detection assist function is used

Note 1. The converted result should be used after it is fully evaluated because the result data when disconnection occurs varies depending on the external circuit.

Figure 45.39 Example of disconnection detection when precharge is selected

Figure 45.40 Example of disconnection detection when discharge is selected

45.3.10 Starting A/D Conversion with an Asynchronous Trigger

A/D conversion can be started by the input of an asynchronous trigger. To start A/D conversion by an asynchronous trigger, set the pin function in the PmnPFS register, set the A/D Conversion Start Trigger Select bits (ADSTRGR.TRSA[5:0]) to 0x00, then input a high-level signal to the asynchronous trigger (ADTRGn (n = 0, 1) pin). Finally, set both the ADCSR.TRGE and ADCSR.EXTRG bits to 1. Figure 45.41 shows timing of the asynchronous trigger input.

An asynchronous trigger cannot be selected in the A/D conversion start trigger for group B used in group scan mode. For details on setting the pin function, see [section 19, I/O Ports](#).

Figure 45.41 Asynchronous trigger input timing

45.3.11 Starting A/D Conversion with a Synchronous Trigger from a Peripheral Module

A/D conversion can be started by a synchronous trigger (GPT, ELC). To do this, set the ADCSR.TRGE bit to 1 and the ADCSR.EXTRG bit to 0, and select the relevant sources in the ADSTRGR.TRSA[5:0] bits and ADSTRGR.TRSB[5:0] bits.

45.3.12 Security Attribution between ADCn (n = 0, 1) and PORT (PmSAR (m = 0 to 9, A, B))

Only when the security attribution of ADC12n (n = 0, 1) match the security attribution of PORT (PmSAR), the correspond analog input channel can be set for ADC conversion. Otherwise the conversion result is unexpected.

Table 45.29 shows the condition of ADC for each Security Attribution setting.

Table 45.29 Analog input pin conditions by security settings

Security Attribution setting*1		ADC input channel select	
ADC12n (n = 0, 1) security setting PSARD	PORT security setting PmSAR	ADANSA0/ADANSA1 ADANSB0/ADANSB1	Setting Combination result
0 (Secure)	0 (Secure)	1 (channel correspond bit)	Input Valid
1 (Non-secure)	1 (Non-secure)	1 (channel correspond bit)	Input Valid
1 (Non-secure)	0 (Secure)	1 (channel correspond bit)	Input invalid and the conversion result is unexpected
0 (Secure)	1 (Non-secure)	1 (channel correspond bit)	Input invalid and the conversion result is unexpected

Note 1. VBATT 1/3 voltage monitor output do not have the Security Attribution judgement function.

45.3.13 Using Data Buffers

A ring buffer function consisting of 16 A/D data buffers is available. This function sequentially stores A/D conversion results other than self-diagnosis result (including addition/average results) in data buffers (ADBUF_n, n = 0 to 15).

Each conversion result is stored at the timing when the A/D conversion result is stored in the data register, and most recent 16 conversion result data are retained.

The figure-below shows the schematic of data buffers, pointer, and overflow flag operations. When the BUFEN bit is set to 1, the A/D conversion result is transferred at each end of A/D conversion. The pointer indicates the number of data buffer to which the next transferred data is to be written. When data is written to up to buffer 15, the pointer is reset to 0000b and the overflow flag is set to 1. Subsequently transferred data overwrites the previously written data.

The overflow flag is reset to the initial value by writing 0x00 to the ADBUFPTR register.

Figure 45.42 Data Buffers, Pointer, and Overflow Flag Operations

45.4 Interrupt Sources and DTC, DMAC Transfer Requests

45.4.1 Interrupt Requests

The ADC12 can send scan end interrupt requests ADC12i_ADI (i = 0, 1) and ADC12i_GBADI (i = 0, 1) to the CPU. The ADC12 also generates the ADC12i_CMPAI (i = 0, 1)/ADC12i_CMPBI (i = 0, 1) interrupt for the CPU in response to matches with a condition for comparison.

An ADC12i_ADI (i = 0, 1) interrupt is always generated. An ADC12i_GBADI (i = 0, 1) interrupt can be generated by setting the ADCSR.GBADIE bit to 1. Similarly, ADC12i_CMPAI (i = 0, 1) and ADC12i_CMPBI (i = 0, 1) interrupts can be generated by setting the ADCMPCR.CMPAIE and ADCMPCR.CMPBIE bit to 1.

In addition, the DTC or DMAC can be started when an ADC12i_ADI (i = 0, 1) or an ADC12i_GBADI (i = 0, 1) interrupt is generated. Using an ADC12i_ADI (i = 0, 1) or ADC12i_GBADI (i = 0, 1) interrupt to activate the DTC or DMAC to read the converted data enables continuous conversion without a burden on software.

Table 45.30 describes the interrupt sources and ELC events available for the ADC12.

Table 45.30 The interrupt source and ELC event of ADC12 (1 of 2)

Operation			Interrupt request or ELC event	Interrupt request	DTC or DMAC activation	ELC event request	Function
Scan mode	Double trigger mode	Compare function Window A/B					
Single scan mode	Deselected	Deselected	ADC12i_ADI (i = 0, 1)	✓	✓	✓	ADC12i_ADI (i = 0, 1) generated at the end of single scan
		Selected	ADC12i_ADI (i = 0, 1)	✓	✓	✓	ADC12i_ADI (i = 0, 1) generated at the end of single scan
			ADC12i_CMPAI (i = 0, 1)	✓	—	—	ADC12i_CMPAI (i = 0, 1) generated on a match comparison condition of Window A
			ADC12i_CMPBI (i = 0, 1)	✓	—	—	ADC12i_CMPBI (i = 0, 1) generated on a match comparison condition of Window B
			ADC12i_WCMPPM (i = 0, 1)	—	✓	✓	ADC12i_WCMPPM (i = 0, 1) generated on a match condition of the Window A/B compare function
			ADC12i_WCMPUM (i = 0, 1)	—	✓	✓	ADC12i_WCMPUM (i = 0, 1) generated on a mismatch condition of the Window A/B compare function
	Selected	Deselected	ADC12i_ADI (i = 0, 1)	✓	✓	✓	ADC12i_ADI (i = 0, 1) generated at the end of scans in the even numbered times
Continuous scan mode	Deselected	Deselected	ADC12i_ADI (i = 0, 1)	✓	✓	✓	ADC12i_ADI (i = 0, 1) generated at the end of scan of all selected channels
		Selected	ADC12i_CMPAI (i = 0, 1)	✓	—	—	ADC12i_CMPAI (i = 0, 1) generated on a match comparison condition of Window A
			ADC12i_CMPBI (i = 0, 1)	✓	—	—	ADC12i_CMPBI (i = 0, 1) generated on a match comparison condition of Window B

Table 45.30 The interrupt source and ELC event of ADC12 (2 of 2)

Operation			Interrupt request or ELC event	Interrupt request	DTC or DMAC activation	ELC event request	Function
Scan mode	Double trigger mode	Compare function Window A/B					
Group scan mode	Deselected	Deselected	ADC12i_ADI (i = 0, 1)	✓	✓	✓	ADC12i_ADI (i = 0, 1) generated at the end of group A scan
			ADC12i_GBADI (i = 0, 1)	✓	✓	—	ADC12i_GBADI (i = 0, 1) dedicated to group B generated at the end of group B scan
		Selected	ADC12i_ADI (i = 0, 1)	✓	✓	✓	ADC12i_ADI (i = 0, 1) generated at the end of group A scan
			ADC12i_GBADI (i = 0, 1)	✓	✓	—	ADC12i_GBADI (i = 0, 1) dedicated to group B generated at the end of group B scan
			ADC12i_CMPAI (i = 0, 1)	✓	—	—	ADC12i_CMPAI (i = 0, 1) generated on a match comparison condition of Window A
			ADC12i_CMPBI (i = 0, 1)	✓	—	—	ADC12i_CMPBI (i = 0, 1) generated on a match comparison condition of Window B
	Selected	Deselected	ADC12i_ADI (i = 0, 1)	✓	✓	✓	ADC12i_ADI (i = 0, 1) generated at the end of group A scans in the even-numbered times
			ADC12i_GBADI (i = 0, 1)	✓	✓	—	ADC12i_GBADI (i = 0, 1) dedicated to group B generated at the end of group B scan

Note: ✓ available
—: unavailable

For details on DTC settings, see [section 17, Data Transfer Controller \(DTC\)](#).

45.5 Event Link Function

45.5.1 Event Output to the ELC

The ELC uses the ADC12i_ADI (i = 0, 1) interrupt request signal as an event signal ADC12i_ADI (i = 0, 1), enabling link operation for the preset module. The ADC12i_GBADI (i = 0, 1) interrupt and ADC12i_CMPAI (i = 0, 1)/ADC12i_CMPBI (i = 0, 1) interrupts cannot be used as an event signal. For details, see [Table 45.30](#).

An event signal can be output regardless of the settings of the corresponding interrupt request enable bits. For the scan end event (ADC12i_ADI (i = 0, 1)), a high-level pulse for one PCLKA cycle is output at the same output timing as the interrupt output (ADC12i_ADI (i = 0, 1)) shown in [Table 45.30](#). For a compare function match (ADC12i_WCMPM (i = 0, 1)) and mismatch event (ADC12i_WCMPUM (i = 0, 1)) to the ELC, a high-level pulse for one PCLKA cycle is output at the timing delayed by one cycle (PCLKA) from the interrupt output (ADC12i_ADI (i = 0, 1)) shown in [Table 45.30](#).

To use compare function match (ADC12i_WCMPM (i = 0, 1)) or mismatch event (ADC12i_WCMPUM (i = 0, 1)) to the ELC, specify single-scan mode.

45.5.2 ADC12 Operation through an Event from the ELC

The ADC12 can start A/D conversion by the preset event specified in the ELSRn settings for the ELC as follows:

- Select the ELC_AD00 (unit 0) signal in the ELC.ELSR8 register
- Select the ELC_AD01 (unit 0) signal in the ELC.ELSR9 register

- Select the ELC_AD10 (unit 1) signal in the ELC.ELSR10 register
- Select the ELC_AD11 (unit 1) signal in the ELC.ELSR11 register.

If an ELC event occurs during A/D conversion, the event is disabled.

45.6 Usage Notes

45.6.1 Constraints on Setting the Registers

Set each register while the ADCSR.ADST bit is 0.

45.6.2 Constraints on Reading the Data Registers

The following registers must be read in halfword units:

- A/D Data Registers
- A/D Data Duplexing Register
- A/D Data Duplexing Register A
- A/D Data Duplexing Register B
- A/D Temperature Sensor Data Register
- A/D Internal Reference Voltage Register
- A/D VBATT monitor Data Register
- A/D Self-Diagnosis Data Register
- A/D Data Buffer Registers n (N = 0 to 15)

If a register is read twice in byte units, that is, the upper byte and lower byte are read separately, the A/D-converted value read initially might disagree with the A/D-converted value read subsequently. To prevent this, never read the data registers in byte units.

45.6.3 Constraints on Stopping A/D Conversion

(1) A/D Conversion Stop Procedure

To stop A/D conversion when an asynchronous trigger or a synchronous trigger is selected as the condition for starting A/D conversion, follow the procedure shown in [Figure 45.43](#).

Figure 45.43 Procedures for clearing the ADCSR.ADST bit by software

To specify the following settings after performing the clear operation by software, provide a wait period for at least two ADCLK cycles.

- Enabling scan end interrupts
- Enabling scan end events for the event link controller
- Starting A/D conversion by software
- Enabling trigger input

(2) Notes on Modes and Status Bits

If necessary, individually initialize or set again the voltage status for self-diagnosis, the judgment of the even number or odd number specified for double-trigger mode, and the monitor flags of the compare function.

- To set again the voltage status for self-diagnosis, set the ADCER.DIAGLD bit to 1 and then set a desired value in the ADCER.DIAGVAL[1:0] bits.
- If the setting of the ADCSR.DBLE bit is changed from 0 to 1, the double-trigger mode operation starts from the first scanning.
- To initialize the monitor flags of the compare function (MONCMPA, MONCMPB, and MONCOMB), set the ADCMPCR.CMPAE and ADCMPCR.CMPBE bits to 0.
- To initialize the data storage buffer pointer, set the ADBUFPTR register to 0x00.
- To initialize the continuous sampling function (ADSHMSR.SHMD = 1), set ADCSHMSR.SHMD to 0. To use the continuous sampling function again after initialization, set ADCSHMSR.SHMD to 1 after waiting for 1 cycle of ADCLK or longer.

45.6.4 A/D Conversion Restart and Termination Timing

A maximum of 6 ADCLK cycles is required for the idle analog unit of the ADC12 to restart on setting the ADCSR.ADST bit to 1. A maximum of 2 ADCLK cycles is required for the operating analog unit of the ADC12 to terminate on setting the ADCSR.ADST bit to 0. A maximum of 1 PCLKA + 1 ADCLK cycles is required for the operating analog unit of the ADC12 to terminate on setting the ADCSR.ADST bit to 0 when PCLKA to ADCLK frequency ratio is 1:2 or 1:4.

45.6.5 Constraints on Scan End Interrupt Handling

When scanning the same analog input twice using any trigger, the first A/D-converted data is overwritten with the second A/D-converted data. This occurs when the CPU does not complete the reading of the A/D-converted data by the time the A/D conversion of the first analog input for the second scan ends after the first scan end interrupt is generated.

45.6.6 Settings for the Module-Stop Function

The Module Stop Control Register can enable or disable ADC12 operation. The ADC12 is initially stopped after a reset. The registers become accessible on release from the module-stop state. After release from the module-stop state, wait for at least 1 μ s before starting A/D conversion. For details, see [section 10, Low Power Modes](#).

45.6.7 Notes on Entering the Low-Power States

Before entering the module-stop state or Software Standby mode, be sure to stop A/D conversion. Set the ADCSR.ADST bit to 0 and secure certain period until the analog unit of the ADC12 stops. Follow the procedure shown in [Figure 45.43](#) to clear the ADCSR.ADST bit with software. Then, wait for 2 clock cycles of ADCLK before entering the module-stop state or Software Standby mode.

45.6.8 Notes on Canceling Software Standby Mode

After software standby mode is canceled, wait at least 1 μ s after the stabilization time for the oscillator elapses and before starting A/D conversion. For details, see [section 10, Low Power Modes](#).

45.6.9 Error in Absolute Accuracy When Disconnection Detection Assistance Is in Use

Using disconnection detection assistance leads to an error in absolute accuracy of the ADC12. This error arises because an erroneous voltage is input to the analog input pins due to the resistive voltage division between the pull-up or pull-down resistor (R_p) and the resistance of the signal source (R_s). This error in absolute accuracy is calculated from the following formula:

$$\text{Maximum error in absolute accuracy (LSB)} = (2^{\text{Resolution}} - 1) \times R_s / (R_s + R_p)$$

Only use disconnection detection assistance after thorough evaluation.

45.6.10 Constraints on Operating Modes and Status Bits

Initialize or set again individually, if necessary, the voltage values in self-diagnosis, the value of the first scan or second scan in double trigger mode, the data buffer pointer, and status monitor in the compare function.

- Select the voltage values in self-diagnosis (ADCER.DIAGVAL[1:0]) after setting ADCER.DIAGLD to 1.
- Double-trigger mode operates as the first scan after setting ADCSR.DBLE from 0 to 1.
- The status monitor bits (MONCMPA, MONCMPB, MONCOMB) in the compare function are initialized after setting ADCMPCR.CMPAE and ADCMPCR.CMPBE to 0.

45.6.11 Notes on Board Design

The board should be designed so that digital circuits and analog circuits are separated from each other as far as possible. In addition, digital circuit signal lines and analog circuit signal lines should not intersect or be placed near each other. If these rules are not followed, noise can occur on analog signals and A/D conversion accuracy is affected. The analog input pins, reference power supply pin (VREFH0, VREFH), reference ground pin (VREFL0, VREFL), and analog power supply (AVCC0) should be separated from digital circuits using the analog ground (AVSS0). The analog ground (AVSS0) should be connected to a stable digital ground (VSS) on the board (single-point ground plane connection).

45.6.12 Constraints on Noise Prevention

To prevent the analog input pins from being destroyed by abnormal voltage such as excessive surge, insert a capacitor between AVCC0 and AVSS0 and between VREFH0 and VREFL0 and between VREFH and VREFL. Additionally, connect a protection circuit to protect the analog input pins as shown in [Figure 45.44](#).

Figure 45.44 Example protection circuit for analog inputs

45.6.13 Port Settings When Using the ADC12 Input

When using the high-precision channels, do not use PORT0 as digital output ports. Renesas recommends that you do not use the digital output that is also used as the AD analog input if normal-precision channel is used. If the digital output that is also used as the AD analog input is used for output signals, perform A/D conversion several times, eliminate the maximum and minimum values, and obtain the average of the other results.

45.6.14 Relationship between ADC12 Units 0 and 1 and the ACPHPS

For the A/D conversion targets in [Table 45.31](#), unit 0 and 1 cannot perform A/D conversion at the same time.

Table 45.31 A/D conversion targets that are mutually exclusive with each other

A/D conversion target	
Unit 0	Unit 1
Temperature sensor	
Internal reference voltage	
VBATT 1/3 voltage monitor output	
AN016	AN116
AN017	AN117
AN018	AN118
AN019	AN119

The A/D conversion targets in [Table 45.32](#) should not be selected as ACPHPS input during A/D conversion, because these pins are multiplexed with the ADC12 and ACPHPS.

Table 45.32 A/D conversion targets that are mutually exclusive with ACPHPS

A/D conversion target		
Unit 0	Unit 1	ACPHPS
AN000	-	ACPHPS0.IVCMP2
AN002	-	ACPHPS0.IVCMP3
AN005	-	ACPHPS0.IVCMP0
AN007/DA0	-	ACPHPS0.IVREF3
AN016	AN116	ACPHPS1.IVCMP0
Internal reference voltage	-	ACPHPS0.IVREF2
-	AN100	ACPHPS1.IVCMP2
-	AN101	ACPHPS1.IVREF0
-	AN102	ACPHPS1.IVCMP3
-	AN104	ACPHPS1.IVREF1
-	AN105/DA1	ACPHPS1.IVCMP1
-	Internal reference voltage	ACPHPS1.IVREF2

45.6.15 Calculation for Sampling Time

The sampling time can be easily estimated by the following figure and formula. This is the time to reach the voltage within 1/4 LSB.

$$t_{SPL} = (R_{EXT} + R_{AD}) \times (C_{EXT} + C_{AD}) \times \ln(C_{AD} / (C_{EXT} + C_{AD}) \times 2^{N+2})$$

R_{EXT} shows external signal source impedance

C_{EXT} shows external capacitance (pin capacitance*1 + PCB parasitic capacitance)

$N = 12, 10$ or 8 (conversion resolution)

$C_{AD} = 5$ pF (internal capacitance)

$R_{AD} = 1.0$ k Ω (internal resistance, case of high-speed channels)

$R_{AD} = 2.0$ k Ω (internal resistance, case of normal-speed channels)

Note 1. Typical value of analog input pin is 5 pF

For example, if R_{EXT} is 1 k Ω , C_{EXT} is 10 pF and N is 12 bits, t_{SPL} of high-speed channel is 258 ns.

This formula simplifies the general use case. This formula is not guaranteed and should be used only for estimation.

Figure 45.45 Sample and hold circuit simplified diagram

45.6.16 Notes on simultaneous operation with other modules

The following combinations may degrade the ADC accuracy depending on the specific timing of operation.

1. AN000 without channel-dedicated sample-and-hold and AN104 mutually.
2. AN007 and AN105 mutually.
3. Normal-precision channel of unit 0 and 1 mutually when these pins are adjacent or one pin apart.
4. AN000 to AN002 using channel-dedicated sample-and-hold when ADC unit 1, DAC12 or ACMPHS is operated.
5. High-precision channels of ADC unit1 when AN000 to AN002 using channel-dedicated sample-and-hold are operated.
6. AN019 when DAC12 or ACMPHS is operated.
7. AN119 to AN122 when DAC12 is operated in DCDC mode.
8. All channels of ADC unit 1 when ACMPHS is operated.
9. All channels of ADC unit 1 when DAC12 is operated.

To mitigate deterioration, it is recommended to take following measures.

- Performing A/D conversion with average mode.
- For even better results, performing A/D conversion several times, eliminate the maximum and minimum values, and obtain the average of the other results. (For the condition No.4, only performing average mode may not be effective depending on the noise. Eliminating the maximum and minimum is recommended.)
- For the condition No.9, using DA AD synchronous conversion set by DAADSCR.DAADST and DAADUSR.AMADSEL1 bits of DAC12.

Depending on the environment, ADC accuracy may be deteriorated even under conditions not listed here.

46. 12-Bit D/A Converter (DAC12)

46.1 Overview

The MCU provides a 12-bit D/A Converter (DAC12) with an output amplifier. [Table 46.1](#) lists the DAC12 specifications, [Figure 46.1](#) shows a block diagram, and [Table 46.2](#) lists the I/O pins.

Table 46.1 DAC12 specifications

Parameter	Specifications
Resolution	12 bits
Output channels	2 channels
Interference reduction between analog modules	Methods provided to minimize interference between D/A and A/D conversion: - D/A converted data update timing is controlled by the synchronous D/A conversion enable input signal from the ADC12 (unit 1) - Degradation of A/D conversion accuracy caused by interference is reduced by controlling the DAC12 inrush current generation timing with the enable signal.
Module-stop function	Module-stop state can be set to reduce power consumption
Event link function (input)	The DA0 and DA1 conversion can be started on input of an event signal
D/A output amplifier control function	Controls whether the output amplifier (for both amplifier-through and amplifier-bias controls) is used
Destination of D/A output control function	Controls whether the output to the external pin or to the internal modules (ACMPHS) is used
TrustZone Filter	Security and Privilege attribution can be set

Figure 46.1 DAC12 block diagram

[Table 46.2](#) lists the pin configuration of the DAC12.

Table 46.2 DAC12 I/O pins (1 of 2)

Pin name	I/O	Function
AVCC0	Input	- Analog power and analog reference top voltage supply pin for TSN, ADC12, and DAC12. - Connect to VCC when these modules are not used.
AVSS0	Input	- Analog ground and analog reference ground supply pin for TSN, ADC12, and DAC12. - Connect to VSS when these modules are not used.
VREFH	Input	Analog reference top voltage supply pin for the ADC12 (unit 1) and the DAC12

Table 46.2 DAC12 I/O pins (2 of 2)

Pin name	I/O	Function
VREFL	Input	Analog reference ground pin for the ADC12 (unit 1) and the DAC12
DA0	Output	Channel 0 output pin for the analog signals processed by the DAC12
DA1	Output	Channel 1 output pin for the analog signals processed by the DAC12

46.2 Register Descriptions

46.2.1 DADRn : D/A Data Register n (n = 0, 1)

Base address: DAC12 = 0x4033_3000
DAC12_NS = 0x5033_3000

Offset address: 0x00 + 0x02 × n

Bit position: 15 0

Bit field:

Value after reset: 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

Note: S-TYPE-3, P-TYPE-3

DADRn register is 16-bit read/write registers that store data for D/A conversion. When an analog output is enabled, the values in DADRn are converted and output to the analog output pins.

12-bit data can be formatted as left- or right-justified in the DADPR.DPSEL bit setting. In right-justified format (DADPR.DPSEL = 0), the lower 12 bits, [11:0], are valid. In left-justified format (DADPR.DPSEL = 1), the upper 12 bits, [15:4], are valid.

46.2.2 DACR : D/A Control Register

Base address: DAC12 = 0x4033_3000
DAC12_NS = 0x5033_3000

Offset address: 0x04

Bit position: 7 6 5 4 3 2 1 0

Bit field:

DAOE1	DAOE0	DAE	—	—	—	—	—
-------	-------	-----	---	---	---	---	---

Value after reset: 0 0 0 1 1 1 1 1

Bit	Symbol	Function	R/W
4:0	—	These bits are read as 1. The write value should be 1.	R/W
5	DAE*1	D/A Enable 0: Control D/A conversion of channels 0 and 1 individually 1: Control D/A conversion of channels 0 and 1 collectively	R/W
6	DAOE0	D/A Output Enable 0 0: Disable D/A conversion and analog output of channel 0 (DA0) 1: Enable D/A conversion and analog output of channel 0 (DA0)	R/W
7	DAOE1	D/A Output Enable 1 0: Disable D/A conversion and analog output of channel 1 (DA1) 1: Enable D/A conversion and analog output of channel 1 (DA1)	R/W

Note: S-TYPE-3, P-TYPE-3

Note 1. This bit controls D/A conversion and analog output in combination with the DAOEi bit (i = 0, 1), which controls the output of the conversion results. For details, see [Table 46.3](#).

Table 46.3 D/A conversion controls

DAE	DAOE1	DAOE0	Description
0	0	0	Disable D/A conversion and analog output pins (DA0, DA1)* ¹
		1	• Enable D/A conversion of channel 0 and disable D/A conversion of channel 1 • Enable analog output of channel 0 (DA0) and disable analog output of channel 1 (DA1)*¹
	1	0	• Disable D/A conversion of channel 0 and enable D/A conversion of channel 1 • Disable analog output of channel 0 (DA0)*¹ and enable analog output of channel 1 (DA1)
		1	• Enable D/A conversion of channels 0 and 1 • Enable analog output of channels 0 and 1 (DA0, DA1)
1	x	x	• Enable D/A conversion of channels 0 and 1 • Collective enable analog output of channels 0 and 1 (DA0, DA1)

Note: x: Don't care

Note 1. When analog output is disabled, the analog output signal is placed in the Hi-Z state.

Only set this register while the ADC12 is halted when the DAADSCR.DAADST bit is 1 (interference reduction between D/A and A/D conversion is enabled). Only set DACR while the ADCSR.ADST bit is 0 and after selecting the software trigger, for the ADC12 trigger to securely stop the ADC12. This MCU only supports ADC12 (unit 1).

DAE bit (D/A Enable)

The DAE bit controls D/A conversion, amplifier operation, and analog output in combination with the DAOEi bit (i = 0, 1), the DAAMPCR.DAAMPi bit (i = 0, 1) and the DAASWCR.DAASWi bit (i = 0, 1). See [Table 46.4](#).

When interference reduction between D/A and A/D conversions is enabled (DAADSCR.DAADST = 1), set the ADCSR.ADST bit of the ADC12 (unit 1) to 0. Then, select the software trigger for the ADC12 (unit 1) trigger to securely stop the ADC12 (unit 1).

DAOEi bit (D/A Output Enable i)

The DAOEi bit (i = 0, 1) controls D/A conversion, amplifier operation, and analog output in combination with the DAE bit, DAAMPCR.DAAMPi bit (i = 0, 1) and the DAASWCR.DAASWi bit (i = 0, 1). See [Table 46.4](#).

When both the DAOEi bit (i = 0, 1) and DAE bit are 0, D/A conversion of channel i (i = 0, 1) is not processed, and no conversion result is output.

When interference reduction between D/A and A/D conversions is enabled (DAADSCR.DAADST = 1), set the DAOEi bit while the ADCSR.ADST bit of the ADC12 (unit 1) is set to 0. Then, select the software trigger for the ADC12 (unit 1) trigger to securely stop the ADC12 (unit 1).

The event link function can be used to set the DAOEi bit to 1. The DAOE0 bit is set to 1 when the event specified in the ELSR12 register of the ELC (ELC_DA0 event) occurs, and output of the D/A conversion results starts. The DAOE1 bit is set to 1 when the event specified in the ELSR13 register of the ELC (ELC_DA1 event) occurs, and output of the D/A conversion results starts.

Table 46.4 D/A conversion and analog output control

DACR		DAAMPCR	DAASWCR	Channel i operation	Amplifier operation of channel i	Analog external output of channel i* ¹	Analog internal output of channel i* ²
DAE	DAOEi	DAAMPi	DAASWi				
0	0	x	x	Stop	Stop	Hi-Z	Hi-Z
0	1	0	0	Run	Stop	Amplifier-through	Hi-Z
0	1	0	1	Run	Stop	Hi-Z	Amplifier-through
0	1	1	0	Run	Run	Amplifier output	Hi-Z
0	1	1	1	Run	Run	Hi-Z	Hi-Z
1	x	0	0	Run	Stop	Amplifier-through	Hi-Z
1	x	0	1	Run	Stop	Hi-Z	Amplifier-through
1	x	1	0	Run	Run	Amplifier output	Hi-Z
1	x	1	1	Run	Run	Hi-Z	Hi-Z

Note: x : Don't care

Note 1. output to pin

Note 2. output to ACMPHS

46.2.3 DADPR : DADRn Format Select Register

Base address: DAC12 = 0x4033_3000
DAC12_NS = 0x5033_3000

Offset address: 0x05

Bit position:	7	6	5	4	3	2	1	0
Bit field:	DPSEL	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
6:0	—	These bits are read as 0. The write value should be 0.	R/W
7	DPSEL	DADRn Format Select 0: Right-justified format 1: Left-justified format	R/W

Note: S-TYPE-3, P-TYPE-3

46.2.4 DAADSCR : D/A A/D Synchronous Start Control Register

Base address: DAC12 = 0x4033_3000
DAC12_NS = 0x5033_3000

Offset address: 0x06

Bit position:	7	6	5	4	3	2	1	0
Bit field:	DAADST	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
6:0	—	These bits are read as 0. The write value should be 0.	R/W
7	DAADST	D/A A/D Synchronous Conversion 0: Do not synchronize DAC12 with ADC12 (unit 1) operation (disable interference reduction between D/A and A/D conversion). 1: Synchronize DAC12 with ADC12 (unit 1) operation (enable interference reduction between D/A and A/D conversion).	R/W

Note: S-TYPE-3, P-TYPE-3

To minimize interference between D/A and A/D conversion, the DAADSCR register enables synchronization of the start timing of D/A conversion with the ADC12 synchronous D/A conversion enable input signal.

Only set this register while the ADC12 (unit 1) is halted, that is, while the ADCSR.ADST bit is 0 after selecting the software trigger as the ADC12 (unit 1) trigger.

Select unit 1 as the target ADC12 unit before setting the DAADST bit to 1. Set DAADUSR.AMAADSEL1 bit to 1 to select unit 1. This MCU only supports ADC12 unit 1.

DAADST bit (D/A A/D Synchronous Conversion)

Setting the DAADST bit to 0 allows the DADRn register value to be converted into analog data at any time. Setting the DAADST bit to 1 allows synchronization of D/A conversion with the synchronous D/A conversion enable input signal from the ADC12 (unit 1). With this bit set, D/A conversion does not start until the ADC12 (unit 1) completes A/D conversion, even when the DADRn register is changed.

Set this bit while the ADCSR.ADST bit is set to 0. Then, select the software trigger for the ADC12 (unit 1) trigger to securely stop the ADC12 (unit 1). Set the DAADUSR.AMAADSEL1 bit to 1 before setting the DAADST bit to 1.

The event link function cannot be used when the DAADST bit is set to 1. Stop the event link function by setting the ELSR12 and ELSR13 registers of the ELC. The setting of the DAADST bit is shared by channels 0 and 1 of the DAC12.

46.2.5 DAAMPCR : D/A Output Amplifier Control Register

Base address: DAC12 = 0x4033_3000
DAC12_NS = 0x5033_3000

Offset address: 0x08

Bit position:	7	6	5	4	3	2	1	0
Bit field:	DAAM P1	DAAM P0	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
5:0	—	These bits are read as 0. The write value should be 0.	R/W
6	DAAMP0	Amplifier Control 0 0: Do not use channel 0 output amplifier 1: Use channel 0 output amplifier	R/W
7	DAAMP1	Amplifier Control 1 0: Do not use channel 1 output amplifier 1: Use channel 1 output amplifier	R/W

Note: S-TYPE-3, P-TYPE-3

The DAAMPCR register selects D/A output with or without using the amplifier.

DAAMP0 bit (Amplifier Control 0)

When the DAAMP0 bit is 0, analog values are output for D/A output of channel 0 without using the amplifier. When the DAAMP0 bit is 1, analog values are output for D/A output of channel 0 through the amplifier.

When both the DACR.DAE and DACR.DAOE0 bits are 0, the amplifier is not used regardless of the setting of the DAAMP0 bit. See [Table 46.4](#) for details.

DAAMP1 bit (Amplifier Control 1)

When the DAAMP1 bit is 0, analog values are output for D/A output of channel 1 without using the amplifier. When the DAAMP1 bit is 1, analog values are output for D/A output of channel 1 through the amplifier.

When both the DACR.DAE and DACR.DAOE1 bits are 0, the amplifier is not used regardless of the setting of the DAAMP1 bit. See [Table 46.4](#) for details.

46.2.6 DAASWCR : D/A Amplifier Stabilization Wait Control Register

Base address: DAC12 = 0x4033_3000
DAC12_NS = 0x5033_3000

Offset address: 0x1C

Bit position:	7	6	5	4	3	2	1	0
Bit field:	DAAS W1	DAAS W0	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
5:0	—	These bits are read as 0. The write value should be 0.	R/W
6	DAASW0	D/A Amplifier Stabilization Wait 0 and D/A internal output control 0: For output to external pin: Amplifier stabilization wait off (output) for channel 0 For output to internal module: Disable output for channel 0 1: For output to external pin: Amplifier stabilization wait on (high-Z) for channel 0 For output to internal module: Enable output for channel 0	R/W

Bit	Symbol	Function	R/W
7	DAASW1	D/A Amplifier Stabilization Wait 1 and D/A internal output control 0: For output to external pin: Amplifier stabilization wait off (output) for channel 1 For output to internal module: Disable output for channel 1 1: For output to external pin: Amplifier stabilization wait on (high-Z) for channel 1 For output to internal module: Enable output for channel 1	R/W

Note: S-TYPE-3, P-TYPE-3

The DAASWCR register controls D/A output with the output amplifier or D/A output for internal modules. This register is used in the initialization procedure to wait for stabilization of the D/A output amplifier. Each bit in DAASWCR should be set to 1 when both the DACR.DAE bit and the DACR.DAOE_i (i = 0, 1) bit are 0. See [section 46.7.5. Initialization Procedure with the Output Amplifier](#).

DAASW0 bit (D/A Amplifier Stabilization Wait 0)

Set the DAASW0 bit to 1 in the initialization procedure to wait for the stabilization of the D/A channel 0 output amplifier. When DAASW0 is set to 1, D/A conversion operates, but the conversion result of D/A is not output from channel 0 to the DA0 pin. When the DAASW0 bit is 0, the stabilization wait time stops, and the D/A conversion result of channel 0 is output through the output amplifier to the DA0 pin. When the amplifier is not used (DAAMPCR.DAAMP0 bit is 0) and DAASW0 is set to 1, D/A conversion result of channel 0 is output to the internal modules.

DAASW1 bit (D/A Amplifier Stabilization Wait 1)

Set the DAASW1 bit to 1 in the initialization procedure to wait for the stabilization of the D/A channel 1 output amplifier. When DAASW1 is set to 1, D/A conversion operates, but the conversion result of D/A is not output from channel 1 to the DA1 pin. When the DAASW1 bit is 0, the stabilization wait time stops, and the D/A conversion result of channel 1 is output through the output amplifier to the DA1 pin. When the amplifier is not used (DAAMPCR.DAAMP1 bit is 0) and DAASW1 is set to 1, D/A conversion result of channel 1 is output to the internal modules.

46.2.7 DAADUSR : D/A A/D Synchronous Unit Select Register

Base address: DAC12 = 0x4033_3000
DAC12_NS = 0x5033_3000

Offset address: 0x10C0

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	AMAD SEL1	—

Value after reset: 0 0 0 0 0 0 0 0

Bit	Symbol	Function	R/W
0	—	This bit is read as 0. The write value should be 0.	R/W
1	AMADSEL1	A/D Unit 1 Select 0: Do not select unit 1 1: Select unit 1	R/W
7:2	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

The DAADUSR register selects the target ADC12 unit for D/A and A/D synchronous conversions. Set the AMADSEL1 bit to 1 to select unit 1 as the target synchronous unit for the MCU. When setting the DAADSCR.DAADST bit to 1 for synchronous conversions, select the target unit in this register in advance.

Only set the DAADUSR register while the ADCSR.ADST bit of the ADC12 is set to 0 and the DAADSCR.DAADST bit is set to 0.

46.3 Operation

The DAC12 includes D/A conversion circuits for two channels, each of which can operate independently. When the DAOEn bit (n = 0, 1) in DACR is set to 1, DAC12 is enabled and the conversion result is output.

This following example shows D/A conversion on channel 0. [Figure 46.2](#) shows the timing of this operation.

To process D/A conversion on channel 0:

1. Set the data for D/A conversion in the DADR0 register and the data format in the DADPR.DPSEL bit.
2. Set the DACR.DAOE0 bit to 1 to start D/A conversion. The conversion result is output from the analog output pin DA0 after the conversion time $t_{\text{D CONV}}$ elapses. The conversion result continues to be output until DADR0 is written to again or the DAOE0 bit is set to 0. The output value (reference) is expressed by the following formula:

$$\frac{\text{Setting in DADR0}}{4096} \times \text{VREFH}$$

3. To start conversion again, write another value to DADR0. The conversion result is output after the conversion time $t_{\text{D CONV}}$ elapses.

When the DAADSCR.DAADST bit is 1 (interference reduction between D/A and A/D conversion is enabled), a maximum of one A/D conversion time is required for D/A conversion to start. When ADCLK is faster than the peripheral clock, a longer time might be required.

4. To disable analog output, set the DAOE0 bit to 0.

Figure 46.2 Example of DAC12 operation

46.3.1 Reducing Interference between D/A and A/D Conversion

When D/A conversion starts, the DAC12 generates inrush current. Because the DAC12 and ADC12 (unit 1) share the same analog power supply, the generated inrush current can interfere with ADC12 (unit 1) operation.

While the DAADSCR.DAADST bit is 1, D/A conversion does not start immediately on updating the DADRm register. Instead:

- If the DADRm register data is modified while the ADC12 is halted, D/A conversion starts in 1 PCLKA cycle.
- If the DADRm register data is modified while the ADC12 is performing a 12-bit A/D conversion, D/A conversion starts on A/D conversion completion. Therefore, it takes up to one A/D conversion time period for the DADRm register data update to be reflected as the D/A conversion circuit output. Until the D/A conversion completes, the DADRm register value does not correspond to the analog output value.

When the DAADSCR.DAADST bit is 1, it is not possible to check through software whether the DADRm register value was D/A-converted.

The following sequence provides an example of channel 0 D/A conversion, in which the DAC12 is synchronized with the ADC12 (unit 1). [Figure 46.3](#) shows the timing of this operation.

To perform D/A conversion on channel 0 in synchronization with the ADC12 (unit 1):

1. Confirm that the ADC12 (unit 1) is halted and set the DAADUSR.AMADSEL1 bit to 1.

2. Confirm that the ADC12 (unit 1) is halted and set the DAADSCR.DAADST bit to 1.
3. Confirm that the ADC12 (unit 1) is halted and set the DACR.DAOE0 bit to 1.
4. Set the DADR0 register. If ADCLK is faster than the peripheral clock, D/A conversion might be delayed for longer than one A/D conversion time.
 - If the ADC12 (unit 1) is halted (ADCSR.ADST = 0) when the DADR0 register is modified, D/A conversion starts in 1 PCLKA cycle.
 - If the 12-bit A/D conversion is in progress (ADCSR.ADST = 1) when the DADR0 register is modified, D/A conversion starts on A/D conversion completion. If the DADR0 register is modified twice during A/D conversion, the first update might not be converted.

Figure 46.3 Example conversion when DAC12 is synchronized with ADC12 (unit 1)

When ADCLK is faster than PCLKA, the DAC12 might not be able to capture the synchronous D/A conversion enable input signal from the ADC12 (unit 1) during the 1 ADCLK cycle that is output between A/D conversion 1 and A/D conversion 2, as shown in Figure 46.4. In this case, post-D/A conversion value A is continuously output as the DA0 signal.

Figure 46.4 Example when the DAC12 cannot capture the synchronous D/A conversion enable input signal from the ADC12 (unit 1)

46.4 Event Link Operation Setting Procedure

This section describes the procedures used in event link operation.

46.4.1 DA0 Event Link Operation Setting Procedure

To set up DA0 event link operation:

1. Set the DADPR.DPSEL bit and the data for D/A conversion in the DADR0 register.
2. Set the ELC_DA0 event signal to be linked to each peripheral module in the ELSR12 register.
3. Set the ELCR.ELCON bit to 1. This enables event link operation for all modules with the event link function selected.
4. Set the event output source module to activate the event link. After the event is output from the module, the DACR.DAOE0 bit becomes 1, and D/A conversion starts on channel 0.
5. Set the ELSR12 register to 0x0000 to stop event link operation of DAC12 channel 0. All event link operation is stopped when the ELCR.ELCON bit is set to 0.

46.4.2 DA1 Event Link Operation Setting Procedure

To set up DA1 event link operation:

1. Set the DADPR.DPSEL bit and set the data for D/A conversion in the DADR1 register.
2. Set the ELC_DA1 event signal to be linked to each peripheral module in the ELSR13 register.
3. Set the ELCR.ELCON bit to 1. This enables the event link operation for all modules with the event link function selected.
4. Set the event output source module to activate the event link. After the event is output from the module, the DACR.DAOE1 bit becomes 1, and D/A conversion starts on channel 1.
5. Set the ELSR13 register to 0x0000 to stop event link operation on DAC12 channel 1. All event link operation is stopped when the ELCR.ELCON bit is set to 0.

46.5 Analog Output Control by Security Attribution

Analog output to DA0/DA1 pin is controlled by the security attribution of Port and DAC12 as shown in [Table 46.5](#).

Analog output to ACPHPS is not controlled by the security attribution.

Table 46.5 Analog output control by security attribution

Security Attribution			Analog Output	
DAC12 (PSARD)	P014 (PmSAR (m = 0~9, A, B))	P015 (PmSAR (m = 0~9, A, B))	P014 pin output	P015 pin output
0 (secure)	1 (non-secure)	1 (non-secure)	enable	enable
0 (secure)	1 (non-secure)	0 (secure)	enable	enable
0 (secure)	0 (secure)	1 (non-secure)	enable	enable
0 (secure)	0 (secure)	0 (secure)	enable	enable
1 (non-secure)	1 (non-secure)	1 (non-secure)	enable	enable
1 (non-secure)	1 (non-secure)	0 (secure)	enable	disable
1 (non-secure)	0 (secure)	1 (non-secure)	disable	enable
1 (non-secure)	0 (secure)	0 (secure)	disable	disable

46.6 Usage Notes on Event Link Operation

- When the event link function is used, do not use the amplifier output function.
- When the event link function is used, set the DACR.DAE bit to 0.
- When the event specified for the ELC_DA0 event signal is generated while a write to the DACR.DAOE0 bit is performed, the write cycle is stopped, and the generated event takes precedence in setting the bit to 1.
- When the event specified for the ELC_DA1 event signal is generated while a write to the DACR.DAOE1 bit is performed, the write cycle is stopped, and the generated event takes precedence in setting the bit to 1.
- Use of the event link function is prohibited when the DAADSCR.DAADST bit is set to 1 to reduce interference between D/A and A/D conversions.

46.7 Usage Notes

46.7.1 Settings for the Module-Stop Function

DAC12 operation can be disabled or enabled using the Module Stop Control Register. The DAC12 is initially stopped after reset. Releasing the module-stop state enables access to the registers. For details, see [section 10, Low Power Modes](#).

46.7.2 DAC12 Operation in the Module-Stop State

When the MCU enters the module-stop state with D/A conversion enabled, the D/A outputs are retained, and the analog power supply current is the same as during D/A conversion. If the analog power supply current must be reduced in the module-stop state, disable D/A conversion by setting the DACR.DAOE1, DAOE0, and DAE bits to 0.

46.7.3 DAC12 Operation in Software Standby Mode

When the MCU enters Software Standby mode with D/A conversion enabled, the D/A outputs are retained, and the analog power supply current is the same as during D/A conversion. If the analog power supply current must be reduced in Software Standby mode, disable D/A conversion by setting the DACR.DAOE1, DAOE0, and DAE bits to 0.

46.7.4 Constraint on Entering Deep Software Standby Mode

When the MCU enters Deep Software Standby mode with D/A conversion enabled, the outputs of the DAC12 are placed in a high impedance state.

46.7.5 Initialization Procedure with the Output Amplifier

Use the following initialization procedures with the output amplifier. The example shows the case for channel 0.

To initialize the DAC12 with the output amplifier:

1. Write 0x0000 to the DADR0 register.
2. Set the DAASWCR.DAASW0 bit to 1.
3. Set the DAAMPCR.DAAMP0 bit to 1.
4. Set the DACR.DAE bit or the DACR.DAOE0 bit to 1 to start operation of the amplifier.
5. Clear the DAASWCR.DAASW0 bit to 0 after waiting for the duration of D/A conversion time $t_{\text{D CONV}}$.
6. Write the value to be converted in the DADR0 register.

Figure 46.5 Example of the initial flow with the output amplifier in DAC12

While the amplifier is running, clearing the DACR.DAE and DACR.DAOE0 bits to 0 allows the amplifier to stop operation. To use the amplifier again, repeat steps 1 to 6.

46.7.6 Initialization Procedure of the Output to internal modules

Use the following initialization procedures for the output to internal modules.

The example shows the case for channel 0.

1. Set the DAASWCR.DAASW0 bit to 1.
2. Set the DACR.DAE bit or the DACR.DAOE0 bit to 1.
3. Write the value to be converted in the DADR0 register.

When you stop output of the DAC12, set DAASWCR.DAASWi to 0 after setting DACR.DAE to 0 or DACR.DAOEi to 0.

46.7.7 Constraint on Usage When Interference Reduction between D/A and A/D Conversion Is Enabled

When the DAADSCR.DAADST bit is 1, enabling interference reduction between D/A and A/D conversion, do not place the ADC12 in the module-stop state. Doing so can halt D/A conversion in addition to A/D conversion.

47. Temperature Sensor (TSN)

47.1 Overview

The on-chip Temperature Sensor (TSN) determines and monitors the die temperature for reliable operation of the device. The sensor outputs a voltage directly proportional to the die temperature, and the relationship between the die temperature and the output voltage is fairly linear. The output voltage is provided to the ADC12 for conversion and can be further used by the end application.

Table 47.1 lists the TSN specifications, and Figure 47.1 shows a block diagram.

Table 47.1 TSN specifications

Item	Description
Temperature sensor voltage output	Temperature sensor outputs a voltage to the 12-bit A/D converter
Module-stop function	Module-stop state can be set to reduce power consumption
Temperature sensor calibration data	Reference data measured for each chip at factory shipment is stored in a register
TrustZone Filter	Security and Privilege attribution can be set

Figure 47.1 TSN block diagram

47.2 Register Descriptions

47.2.1 TSCR : Temperature Sensor Control Register

Base address: TSN = 0x4023_5000
TSN_NS = 0x5023_5000

Offset address: 0x00

Bit position:	7	6	5	4	3	2	1	0
Bit field:	TSEN	—	—	TSOE	—	—	—	—

Value after reset: 0 0 0 0 0 0 0 0

Bit	Symbol	Function	R/W
3:0	—	These bits are read as 0. The write value should be 0.	R/W
4	TSOE	Temperature Sensor Output Enable 0: Disable output from the temperature sensor to the ADC12 1: Enable output from the temperature sensor to the ADC12	R/W
6:5	—	These bits are read as 0. The write value should be 0.	R/W
7	TSEN	Temperature Sensor Enable 0: Stop the temperature sensor 1: Start the temperature sensor.	R/W

Note: S-TYPE3, P-TYPE3

The TSCR is a register which controls the temperature sensor. The timing constraints shown in [Figure 47.3](#) apply to the settings of the TSCR register.

TSOE bit (Temperature Sensor Output Enable)

The TSOE bit enables or disables the temperature sensor output to ADC12.

TSEN bit (Temperature Sensor Enable)

The TSEN bit starts or stops the temperature sensor.

47.2.2 TSCDR : Temperature Sensor Calibration Data Register

Base address: TSD = 0x4011_B000
TSD_NS = 0x5011_B000

Offset Address: 0x017C

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

Value after reset: 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	TSCDR[15:0]															

Value after reset: Chip-specific value

Bit	Symbol	Function	R/W
15:0	TSCDR[15:0]	Temperature Sensor Calibration Data Chip-specific value	R
31:16	—	These bits are read as 0.	R

Note: S-TYPE5, P-TYPE5

The TSCDR register stores temperature sensor calibration data measured for each chip at factory shipment.

Temperature sensor calibration data is the output voltage of the temperature sensor under the conditions $T_j = 125^{\circ}\text{C}$ and $\text{AVCC0} = \text{VREFH0} = 3.3 \text{ V}$ converted to a digital value by the 12-bit A/D converter.

The TSCDR register is a read-only 32-bit register. Read from this register in 32-bit units.

Temperature sensor calibration data is stored in the lower 12 bits of the TSCDR register.

47.3 Using the Temperature Sensor

The temperature sensor outputs a voltage that varies with the temperature. This voltage is converted to a digital value by the 12-bit A/D converter. To obtain the die temperature, convert this value into the temperature.

47.3.1 Preparation for Using the Temperature Sensor

The ambient temperature (T) is proportional to the temperature sensor voltage output (V_s), so ambient temperature is calculated with the following formula:

$$T = (V_s - V_1) / \text{slope} + T_1$$

- T: Ambient temperature of MCU as calculation result ($^{\circ}\text{C}$)
- V_s : Voltage output by the temperature sensor on temperature measurement (V)
- T_1 : Temperature experimentally measured at one point ($^{\circ}\text{C}$)
- V_1 : Voltage output by the temperature sensor on measurement of T_1 (V)
- T_2 : Temperature experimentally measured at a second point ($^{\circ}\text{C}$)
- V_2 : Voltage output by the temperature sensor on measurement of T_2 (V)
- Slope: Temperature gradient of the temperature sensor ($\text{V} / ^{\circ}\text{C}$), $\text{slope} = (V_2 - V_1) / (T_2 - T_1)$

Characteristics vary between sensors, so Renesas recommends measuring two different sample temperatures as follows:

1. Use the 12-bit A/D converter to measure the voltage V_1 output by the temperature sensor at temperature T_1 .
2. Again use the 12-bit A/D converter to measure the voltage V_2 output by the temperature sensor at a different temperature T_2 .
3. Obtain the temperature gradient ($\text{slope} = (V_2 - V_1) / (T_2 - T_1)$) from these results.
4. Subsequently, obtain temperatures by substituting the slope into the formula for the temperature characteristic ($T = (V_s - V_1) / \text{slope} + T_1$).

In order to make the temperature T_a and T_j as close as possible, perform the measurement with the power consumption of the MCU as low as possible.

If you are using the temperature gradient given in [section 55, Electrical Characteristics](#), use the A/D converter to measure the voltage V_1 output by the temperature sensor at temperature T_1 , then calculate the temperature characteristic using the following formula:

$$T = (V_s - V_1) / \text{slope} + T_1$$

Note: This method produces less accurate temperatures than measurement at two points.

In this MCU, the TSCDR register stores the temperature value (CAL125) of the temperature sensor measured under the condition $T_a = T_j = 125^{\circ}\text{C}$ and $\text{AVCC0} = \text{VREFH0} = 3.3 \text{ V}$. If you use this value as the sample measurement result at the first point, you can omit the preparation before using the temperature sensor.

V_1 is calculated from CAL125:

$$V_1 = 3.3 \times \text{CAL125} / 4096 \text{ [V]} \text{ (In case of 12 bit accuracy)}$$

Using this value, the measured temperature can be calculated according to the following formula:

$$T = (V_s - V_1) / \text{slope} + 125 \text{ [}^{\circ}\text{C]} \text{]}$$

- T: Ambient temperature of MCU as calculation result ($^{\circ}\text{C}$)
- V_s : Voltage output by the temperature sensor when the temperature is measured (V)
- V_1 : Voltage output by the temperature sensor when $T_a = T_j = 125^{\circ}\text{C}$ and $\text{AVCC0} = \text{VREFH0} = 3.3 \text{ V}$ (V)

- Slope: Temperature gradient of the temperature sensor^{*1} / 1000 (V/°C)

Note 1. See [section 55, Electrical Characteristics](#)

47.3.2 Procedures for Using the Temperature Sensor

[Figure 47.2](#) shows the procedure for using the TSN.

For details, see [section 45, 12-Bit A/D Converter \(ADC12\)](#).

Note 1. This setting is not required if addition/average mode is not set.

Note 2. The ADADC.ADC[2:0] setting is limited to some values in additions/average mode. For details on the available ADADC.ADC[2:0] settings in additions/average mode, see [section 45, 12-Bit A/D Converter \(ADC12\)](#).

Note 3. Set the sampling time to more than the value described in [section 55, Electrical Characteristics](#).

Figure 47.2 Procedure example for using the TSN

[Figure 47.3](#) shows the timing from the start of temperature sensor operation until the completion of A/D conversion when the ADC12 is in single scan mode (the conversion target is the temperature sensor output only). The times shown in the figure are described in [Table 47.2](#)

Figure 47.3 Timing from start of temperature sensor operation until completion of A/D conversion

Table 47.2 Time until completion of A/D conversion after start of temperature sensor operation

Parameter	Symbol	Time
Wait time for temperature sensor reference voltage stabilization	t_{TSTBL}	30 μ s (min)
Wait time for temperature sensor output stabilization	t_{OSTBL}	0 μ s (min)
A/D converter input sampling time	t_{SPL}	ADSSTRn setting $\times$ ADCLK period
A/D conversion time	t_{SAM}	See the table in section 45.3.6. Analog Input Sampling and Scan Conversion Time .
Scan conversion end delay	t_{ED}	

47.4 Usage Notes

47.4.1 Settings for the Module-Stop Function

TSN operation can be disabled or enabled using the associated bit in Module Stop Control Register D (MSTPCRD). The TSN is initially stopped after reset. Releasing the module-stop state enables access to the registers. For details, see [section 10, Low Power Modes](#).

47.4.2 Settings for the Software Standby Mode

Before entering Software Standby Mode, set TSCR.TSOE bit to 0 after stopping A/D conversion, then set TSCR.TSEN bit to 0 to stop the TSN.

48. High-Speed Analog Comparator (ACMPHS)

48.1 Overview

The High-Speed Analog Comparator (ACMPHS) can be used to compare an analog input voltage with a reference voltage and to provide a digital output based on the result of conversion. Both the analog input voltage and the reference voltage can be provided to the ACMPHS from internal sources (D/A converter output or internal reference voltage) and an external source. Such flexibility is useful in applications that require go/no-go comparisons to be performed between analog signals without necessarily requiring A/D conversion.

[Table 48.1](#) lists the ACMPHS specifications, [Figure 48.1](#) shows a block diagram, and [Table 48.2](#) shows the input source configurations.

Table 48.1 ACMPHS specifications

Parameter	Specifications
Number of channels	2 channels: ACMPHSn (n = 0, 1)
Analog input voltage	- Output from internal D/A converter - Input from an external source (compatible with internal A/D converter input pin (one selectable))
Reference voltage	- Internal reference voltage (Vref) - Output from internal D/A converter - Input from an external source (compatible with internal A/D converter input pin (one selectable))
ACMPHS output	- Comparison result output to terminal PIN - Generation of ELC event output - Monitor output from register - Generation of interrupt request output
Interrupt request signal	- Interrupt request generated on valid edge detection from comparison result (when CMPCTL.CSTEN = 0^{*1}) - Selectable to rising edge, falling edge, or both edges (when CMPCTL.CSTEN = 0^{*1}) - Rising edge only (when CMPCTL.CSTEN = 1^{*1})
Digital filter function	- Selectable to one of three sampling frequencies - Not using the filter function is selectable
Module-stop function	Module-stop state can be set for each groups to reduce power consumption.
TrustZone Filter	Security and Privilege attribution can be set for each group

Note 1. Interrupt request signal selection restriction detail refers to [section 48.5. ACMPHS Interrupts](#) and [section 48.6. ACMPHS Output to the Event Link Controller \(ELC\)](#).

Figure 48.1 ACMPHS block diagram

Table 48.2 Input source configuration of the ACMPHS

Comparator	Reference voltage input source				Analog voltage input source				Output pin
	IVREF3	IVREF2	IVREF1	IVREF0	IVCMP3	IVCMP2	IVCMP1	IVCMP0	
ACMPHS0	DA0 ^{*3}	Vref ^{*1}	AN104	AN101	AN002	AN000	DA1 ^{*4}	AN005	VCOUT ^{*2}
ACMPHS1	DA0 ^{*3}	Vref ^{*1}	AN104	AN101	AN102	AN100	DA1 ^{*4}	AN016/ AN116	

Note 1. Internal voltage reference.

Note 2. ACMPHS0 to ACMPHS1 compare outputs are bundled with the VCOUT pin.

Note 3. When D/A converter 0 output is not used, the signal can be used as AN007 analog input.

Note 4. When D/A converter 1 output is not used, the signal can be used as AN105 analog input.

48.2 Register Descriptions

48.2.1 CMPCTL : Comparator Control Register

Base address: ACMPHSn = 0x4023_6000 + 0x0100 × n (n = 0, 1)

ACMPHSn_NS = 0x5023_6000 + 0x0100 × n (n = 0, 1)

Offset address: 0x000

Bit position:	7	6	5	4	3	2	1	0
Bit field:	HCMP ON	CDFS[1:0]		CEG[1:0]		CSTE N	COE	CINV

Value after reset: 0 0 0 0 0 0 0 0 0

Bit	Symbol	Function	R/W
0	CINV	Comparator Output Polarity Selection* ¹ * ² 0: Do not invert comparator output 1: Invert comparator output	R/W
1	COE	Comparator Output Enable 0: Disable comparator output (output signal is low level) 1: Enable comparator output	R/W
2	CSTEN	Interrupt Select* ³ 0: Output through the edge selector 1: Output directly	R/W
4:3	CEG[1:0]	Selection of Valid Edge (Edge Selector) 0 0: Do not detect edge 0 1: Detect rising edge 1 0: Detect falling edge 1 1: Detect both edges	R/W
6:5	CDFS[1:0]	Noise Filter Selection * ¹ * ² * ³ * ⁴ 0 0: Do not use noise filter 0 1: Use noise filter sampling frequency of PCLKB/2 ³ 1 0: Use noise filter sampling frequency of PCLKB/2 ⁴ 1 1: Use noise filter sampling frequency of PCLKB/2 ⁵	R/W
7	HCOMPON	Comparator Operation Control* ⁵ 0: Stop operation (comparator outputs a low-level signal) 1: Enable operation (enables input to the comparator pins)	R/W

Note: S-TYPE-3, P-TYPE-3

Note 1. Disable the ACMPHS output (COE = 0) before changing the CDFS[1:0] and CINV bits.

Note 2. If the CDFS[1:0] and CINV bits are changed, an ACMPHS interrupt request and an ELC event might be generated. Before changing these bits, set the ELSRn register to 0 (the ACMPHS output is not linked). After changing these bits, clear the IR flag in the IELSRn register to 0 to clear the interrupt status.

Note 3. Set the CSTEN bit to 1 and the CDFS[1:0] bits to 00b if the ACMPHS interrupt causes release of Software Standby mode. CSTEN is supported only by the ACMPHS0. ACMPHS1.CMPCTL.CSTEN must be set to 0.

Note 4. If the CDFS[1:0] bits are changed from 00b (noise filter not used) to a value other than 00b (noise filter used), perform sampling four times and update the filter output, and then use the ACMPHS interrupt request or the ELC event.

Note 5. A stabilization wait time is required to permit ACMPHS operation after enabling it (HCOMPON = 1). The operation stabilization wait time for ACMPHS modules 0 to 1 is 300 ns.

Note: Set this register before setting registers in the POEG when using comparator output as a POEG source.

The CMPCTL register controls the ACMPHS operation, enables or disables the ACMPHS output, selects the noise filter, selects the valid edge of the interrupt signal, and selects the interrupt.

48.2.2 CMPSEL0 : Comparator Input Select Register

Base address: ACMPHSn = 0x4023_6000 + 0x0100 × n (n = 0, 1)
ACMPHSn_NS = 0x5023_6000 + 0x0100 × n (n = 0, 1)

Offset address: 0x004

Bit position: 7 6 5 4 3 2 1 0

Bit field:	—	—	—	—	CMPSEL[3:0]		
------------	---	---	---	---	-------------	--	--

Value after reset: 0 0 0 0 0 0 0 0

Bit	Symbol	Function	R/W
3:0	CMPSEL[3:0]	Comparator Input Selection* ¹ * ² * ³ 0x00: Do not input 0x01: Select IVCMP0 0x02: Select IVCMP1 0x04: Select IVCMP2 0x08: Select IVCMP3 Others: Setting prohibited	R/W

Bit	Symbol	Function	R/W
7:4	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

Note 1. Use the following procedure to change the CMPSEL[3:0] bits. Writing a value other than 0x00 while the value of the CMPSEL0 register is not 0x00 is invalid. Writing 1 to two or more bits is also invalid. In both cases, the previous value is retained.

To change the CMPSEL[3:0] bits:

1. Set the CMPCTL.COE bit to 0.
2. Set the CMPSEL0 register to 0x00.
3. Set a new value in the CMPSEL[3:0] bits, with 1 set in only one of the bits.
4. Wait for the input switching stabilization wait time (200 ns).
5. Set the CMPCTL.COE bit to 1.
6. Clear the IR flag in the IELSRn register to clear the interrupt status.

Note 2. For details, see [Table 48.2](#).

Note 3. If ACMPHSn level detection signal is used as a POEG source, write access to these bits after the setting of any register in the POEG may generate a POEG source.

48.2.3 CMPSEL1 : Comparator Reference Voltage Select Register

Base address: ACMPHSn = 0x4023_6000 + 0x0100 × n (n = 0, 1)
ACMPHSn_NS = 0x5023_6000 + 0x0100 × n (n = 0, 1)

Offset address: 0x008

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	CRVS[3:0]			
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
3:0	CRVS[3:0]	Reference Voltage Selection*1*2*3*4 0x00: Do not input 0x01: Select IVREF0 0x02: Select IVREF1 0x04: Select IVREF2 0x08: Select IVREF3 Others: Setting prohibited	R/W
7:4	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

Note 1. Use the following procedure to change the CRVS[3:0] bits. Writing a value other than 0x00 while the value of the CMPSEL1 register is not 0x00 is invalid. Writing 1 to two or more bits is also invalid. In both cases, the previous value is retained.

To change the CRVS[3:0] bits:

1. Set the CMPCTL.COE bit to 0.
2. Set the CMPSEL1 register to 0x00.
3. Set a new value to the CRVS[3:0] bits, with 1 set in only one of the bits.
4. Wait for the input switching stabilization wait time (200 ns).
5. Set the CMPCTL.COE bit to 1.
6. Clear the IR flag in the IELSRn register to clear the interrupt status.

Note 2. For details, see [Table 48.2](#).

Note 3. When the on-chip D/A converter output voltage is used, set the D/A converter to generate comparator C reference voltage before enabling comparator operation (CMPCTL.HCMPON bit = 1). For details on setting the D/A converter, see [section 46, 12-Bit D/A Converter \(DAC12\)](#).

Note 4. If ACMPHSn level detection signal is used as a POEG source, write access to these bits after the setting of any register in the POEG may generate a POEG source.

48.2.4 CMPMON : Comparator Output Monitor Register

Base address: $ACMPHSn = 0x4023_6000 + 0x0100 \times n$ ($n = 0, 1$)
 $ACMPHSn_NS = 0x5023_6000 + 0x0100 \times n$ ($n = 0, 1$)

Offset address: 0x00C

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	COMP MON
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	COMPON	Comparator Output Monitor*1 0: Comparator output is low 1: Comparator output is high	R
7:1	—	These bits are read as 0. The write value should be 0.	R

Note: S-TYPE-3, P-TYPE-3

Note 1. When ACMPHS operation is enabled (CMPCTL.HCMPON = 1 and CMPCTL.COE = 1) but the noise filter is not in use (CDFS[1:0] = 00b), design the software so that the COMPON bit is read twice and the values are only used after the two consecutive values match.

48.2.5 CPIOC : Comparator Output Control Register

Base address: $ACMPHSn = 0x4023_6000 + 0x0100 \times n$ ($n = 0, 1$)
 $ACMPHSn_NS = 0x5023_6000 + 0x0100 \times n$ ($n = 0, 1$)

Offset address: 0x010

Bit position:	7	6	5	4	3	2	1	0
Bit field:	VREF EN	—	—	—	—	—	—	CPOE
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	CPOE	External Pin Output Enable Comparison result by the comparator is output to an external pin. 0: Output to the comparator external pin is disabled (the output signal is fixed to low) 1: Output to the comparator external pin is enabled	R/W
6:1	—	These bits are read as 0. The write value should be 0.	R/W
7	VREFEN	Internal Vref Enable*1 0: Disable internal Vref 1: Enable internal Vref	R/W

Note: S-TYPE-3, P-TYPE-3

Note 1. For ACMPHS modules 0 to 1, VREFEN exists only in ACMPHS0.CPIOC. When using the internal Vref in ACMPHS0 to ACMPHS1, set the VREFEN bit in ACMPHS0.CPIOC to 1. Bit [7] in ACMPHS1.CPIOC should be 0 regardless of whether or not the internal Vref is used.

48.2.6 CPINTCTL : Comparator Interrupt Control Register

Base address: $ACMPHSn = 0x4023_6000 + 0x0100 \times n$ ($n = 0, 1$)
 $ACMPHSn_NS = 0x5023_6000 + 0x0100 \times n$ ($n = 0, 1$)

Offset address: 0x040

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	MSKE
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	MSKE	Comparator Interrupt Periodic Mask Enable 0: Disable interrupt masking (Default) 1: Enable interrupt masking by GPT output signal selected by CPMSKCTL.MSKSEL [2:0]	R/W
7:1	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

This register controls the interrupt to ICU/ELC, while the event to POEG (Port Output Enable) is not controlled by this register.

48.2.7 CPMSKCTL : Comparator Interrupt Mask Control Register

Base address: $ACMPHSn = 0x4023_6000 + 0x0100 \times n$ ($n = 0, 1$)
 $ACMPHSn_NS = 0x5023_6000 + 0x0100 \times n$ ($n = 0, 1$)

Offset address: 0x044

Bit position: 7 6 5 4 3 2 1 0

Bit field:	—	—	—	—	—	—	MSKSEL[2:0]
------------	---	---	---	---	---	---	-------------

Value after reset: 0 0 0 0 0 0 0 0

Bit	Symbol	Function	R/W
2:0	MSKSEL[2:0]	Comparator Interrupt Periodic Mask Selection 0 0 0: Enable interrupt masking by GTIOC0A output signal 0 0 1: Enable interrupt masking by GTIOC1A output signal 0 1 0: Enable interrupt masking by GTIOC2A output signal 0 1 1: Enable interrupt masking by GTIOC3A output signal 1 0 0: Enable interrupt masking by GTIOC4A output signal 1 0 1: Enable interrupt masking by GTIOC5A output signal 1 1 0: Enable interrupt masking by GTIOC6A output signal 1 1 1: Enable interrupt masking by GTIOC7A output signal	R/W
7:3	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

This register controls the interrupt to ICU/ELC, while the event to POEG (Port Output Enable) is not controlled by this register.

48.3 Operation

The ACMPHS compares a reference voltage to an analog input voltage. Operation is not guaranteed when the values of registers are changed during ACMPHS operation. Table 48.3 shows the procedures for setting the registers associated with ACMPHS.

Table 48.3 Procedure for setting registers associated with ACMPHSn ($n = 0, 1$) (1 of 2)

Step	Register	Bit	Setting
1	Associated MSTPCRD register	MSTPD28 to MSTPD27	0: Input clock supply.
2	Associated pin function control register (PFS)	ASEL	1: Select the function of pins IVREF and IVCMP.
3	ACMPHSn.CPIOC	VREFEN	1: When using the internal Vref.
4	Associated D/A convertor		When using the D/A convertor, select in the register.
5	CMPSEL0, CMPSEL1	CMPSEL[3:0] CRVS[3:0]	Select the ACMPHSn input, with 1 set in only one of the bits.
6	CMPCTL	CDFS[1:0], CEG[1:0], and CINV	Set up ACMPHSn control.
		HCMPON	1: Enable ACMPHSn operation.
7	CPMSKCTL	MSKSEL[2:0]	Select the interrupt mask source signal (from GPT)

Table 48.3 Procedure for setting registers associated with ACMPHSn (n = 0, 1) (2 of 2)

Step	Register	Bit	Setting
8	CPINTCTL	MSKE	1: Enable interrupt mask function if need
9	Waiting for the ACMPHS stabilization time (minimum 300 ns).		
10	CMPCTL	COE	1: Enable ACMPHSn output.
11	CPIOC	CPOE	Set the VCOUT output
	Associated pin function control register (PFS)	PSEL, PMR	Select the VCOUT port function.
12	IELSRn	IR, IELS[8:0]	When using an interrupt, select the interrupt status flag and the ICU event link.* ¹
13	ELSRn	ELS[8:0]	When using an ELC, select the event link* ² .
14	Operation started		
15	CMPCTL	COE	0: When changing IVREF or IVCMP, to disable ACMPHSn output.
16	CMPSEL1	CRVS[3:0]	Change the CMPSEL1 bits as follows: 1. Set bits CMPSEL1 to 0000 0000b. 2. Set a new value to the CMPSEL1 bits, with 1 set in only one of the bits.
	CMPSEL0	CMPSEL[3:0]	Change the CMPSEL0 bits as follows: 1. Set bits CMPSEL0 to 0000 0000b. 2. Set a new value to the CMPSEL0 bits, with 1 set in only one of the bits.
17	Waiting for the ACMPHS switching stabilization time (minimum 200 ns).		
18	CMPCTL	COE	1: Enable ACMPHSn output.
19	Operation restarted		

Note 1. After ACMPHSn is set, an unnecessary interrupt might occur until operation becomes stable, so initialize the interrupt flag.

Note 2. After ACMPHSn is set, an unnecessary interrupt might occur until operation becomes stable, so initialize the event link select.

Figure 48.2 and Figure 48.3 show an example of ACMPHS operation. The VCOUT output becomes 1 when the analog input voltage is higher than the ACMPHS reference input voltage, and the VCOUT output becomes 0 when the analog input voltage is lower than the reference voltage. When the ACMPHS output changes, an interrupt request and an ELC event are output.

Figure 48.2 ACMPHS operation example (interrupt mask function invalid)

Figure 48.2 applies when $CPOE = 1$ (pin output enabled), $CDFS[1:0] = 00b$ (filter not used), and $CEG[1:0] = 11b$ (both-edge detection selected). When $CINV = 0$, $CEG[1:0] = 01b$ (rising-edge detection selected for non-inversion output signal from the ACMPHS), the IELSR.IR flag changes as shown by (A) only. When $CINV = 0$, $CEG[1:0] = 10b$ (falling-edge detection selected for non-inversion output signal from the ACMPHS), the IR flag changes as shown by (B) only. When $CPOE = 1$, VCOUNT directly outputs.

Figure 48.3 ACMPHS operation example (interrupt mask function valid)

Figure 48.3 applies when $CPOE = 1$ (pin output enabled), $CDFS[1:0] = 00b$ (filter not used), $CEG[1:0] = 11b$ (both-edge detection selected). When $CINV = 0$, $CEG[1:0] = 01b$ (rising-edge detection selected for non-inversion output signal from

the ACMPHS), the IELSR.IR flag changes as shown by (A) only. When CINV = 0, CEG[1:0] = 10b (falling-edge detection selected for non-inversion output signal from the ACMPHS), the IR flag changes as shown by (B) only.

When MSKE = 1 and MSKSEL[2:0] = 000b, the interrupt signal output to ICU is masked by GTIOC0A when GTIOC0A = low level as shown by (C), while it passes through when GTIOC0A = high level.

When CPOE = 1, VCOOUT directly outputs, regardless of the MSKE setting.

48.4 Noise Filter

The ACMPHS contains a noise filter. The sampling clock can be selected in the CMPCTL.CDFS[1:0] bits. The comparator output signal is sampled every sampling clock, and if the same value is sampled three times, the noise filter output at the next sampling clock cycle is used as the ACMPHS output.

Figure 48.4 shows the configuration of the noise filter and edge detector, and Figure 48.5 shows an example of noise filter and interrupt operation.

Figure 48.4 Noise filter and edge detection configuration

Figure 48.5 Noise filter and interrupt operation example

The operation example in Figure 48.5 applies when the CMPCTL.CDFS[1:0] bits are 01b, 10b, or 11b (noise filter used).

48.5 ACMPHS Interrupts

The ACMPHS generates two interrupt requests from sources ACMPHSn (n = 0, 1). To use an ACMPHS interrupt, select it in the IELSR register in the Interrupt Controller Unit (ICU). Select the interrupt request in the CMPCTL.CSTEN bit either through the edge selector, or not.

Interrupt event to ICU/ELC can be masked by GPT output (GTIOCnA (n = 0 to 7)), it's controlled by CPINTCTL.MSKE bit and CPMSKCTL.MSKSEL[2:0] bits. Detail refer to Figure 48.3.

Event to POEG can't be masked by GPT output (GTIOCnA (n = 0 to 7)), it's not controlled by CPINTCTL.MSKE bit and CPMSKCTL.MSKSEL[2:0] bits.

When using the ACMPHS interrupt through the edge selector, set at least one of the CMPCTL.CEG[1:0] bits to 1 (to a value other than 00b for no edge selection). Set the CMPCTL.CSTEN bit to 0 (output through the edge selector) in Normal mode, CPU Sleep mode, and CPU Deep Sleep mode.

To use the ACMPHS interrupt in Software Standby mode, set the CMPCTL.CSTEN bit to 1 (direct output), set the CMPCTL.CDFS[1:0] bit to 00b (digital noise filter not used), and set CMPCTL.CINV as follows:

- When detecting compare result 0 to 1, set CMPCTL.CINV to 0 (comparator output not inverted)
- When detecting compare result 1 to 0, set CMPCTL.CINV to 1 (comparator output inverted).

An ACMPHS0 interrupt request can be used to release Software Standby mode. ACMPHS1 cannot be used.

ACMPHS0/ACMPHS1 both can not be used in Deep Software Standby mode.

For details on the register settings related to ACMPHS interrupt requests, see [section 48.2.1. CMPCTL : Comparator Control Register](#), [section 48.2.6. CPINTCTL : Comparator Interrupt Control Register](#) and [section 48.2.7. CPMSKCTL : Comparator Interrupt Mask Control Register](#).

48.6 ACMPHS Output to the Event Link Controller (ELC)

The ELC uses the ACMPHS interrupt request signal as an ELC event signal, enabling link operation for the preset module. To use the ACMPHS ELC event, select them in the ELSR register in the ELC. When using the ELC event request, set the CMPCTL.CSTEN bit to 0 (output through the edge selector). Also set at least one of the CMPCTL.CEG[1:0] bits to 1 (to a value other than 00b for no edge selection).

Interrupt event to ELC can be masked by GPT output (GTIOCnA (n = 0 to 7)), it's controlled by CPINTCTL.MSKE bit and CPMSKCTL.MSKSEL[2:0] bits.

48.7 ACMPHS Pin Output

The comparison result from the ACMPHS can be output to external pins. Use the CMPCTL.CINV and CPIOC.CPOE bits to set the output polarity (non-inverted or inverted output) and enable or disable output. To output the ACMPHS comparison result to the VCOUNT output pin, set the associated port mn pin function control register (PmnPFS) in the I/O register.

Only when the security attribution of Port and ACMPHS match, the ACMPHS comparison result is output to the VCOUNT pin as shown in the [Table 48.4](#).

Table 48.4 The output condition of VCOUNT pin by the security setting

PORT Security Attribution (PmSAR (m = 0 to 9, A, B))	ACMPHS0 Security Attribution PSARD	ACMPHS1 Security Attribution PSARD	VCOUNT pin output
0 (secure)	0 (secure)	0 (secure)	both ACMPHS0/1 output enable
1 (non-secure)	0 (secure)	0 (secure)	both ACMPHS0/1 output disable
0 (secure)	0 (secure)	1 (non-secure)	ACMPHS0_VCOUNT output enable ACMPHS1_VCOUNT output disable
1 (non-secure)	0 (secure)	1 (non-secure)	ACMPHS0_VCOUNT output disable ACMPHS1_VCOUNT output enable
0 (secure)	1 (non-secure)	0 (secure)	ACMPHS0_VCOUNT output disable ACMPHS1_VCOUNT output enable
1 (non-secure)	1 (non-secure)	0 (secure)	ACMPHS0_VCOUNT output enable ACMPHS1_VCOUNT output disable
0 (secure)	1 (non-secure)	1 (non-secure)	both ACMPHS0/1 output disable
1 (non-secure)	1 (non-secure)	1 (non-secure)	both ACMPHS0/1 output enable

48.8 Usage Notes

48.8.1 Settings for the Module-Stop Function

ACMPHS operation can be disabled or enabled using the Module Stop Control Register. The ACMPHS is initially stopped after reset. Releasing the module-stop state enables access to the registers. For details, see [section 10, Low Power Modes](#).

48.8.2 Settings for the DAC12

ACMPHS is connected to the internal module output of the D/A converter. For details, see [section 46, 12-Bit D/A Converter \(DAC12\)](#).

48.8.3 Relationship with the ADC12

Constraints apply on the simultaneous use of ACMPHS analog input and ADC12 analog input. For details, see [section 45.6.14. Relationship between ADC12 Units 0 and 1 and the ACMPHS](#).

48.8.4 ACMPHS Operation in Module-Stop State

When the module-stop state is entered while ACMPHS is operating, analog circuits in the ACMPHS are not stopped and the analog power supply current is the same as that when ACMPHS is being used. If the analog power supply current needs to be reduced in the module-stop state, set the CMPCTL.HCMPON bit to 0 to stop the ACMPHS.

48.8.5 ACMPHS Operation in Software Standby Mode

When Software Standby mode is entered while ACMPHS is operating, analog circuits in the ACMPHS are not stopped and the analog power supply current is the same as that when ACMPHS is being used. If the analog power supply current needs to be reduced in Software Standby mode, set the CMPCTL.HCMPON bit to 0 to stop the ACMPHS.

48.8.6 Setting the D/A Converter for Generating Reference Voltage

Set the D/A converter to generate reference voltage and wait for the D/A converter output settling time before enabling the comparator. Similarly, before making any changes to the settings of the D/A converter, stop the comparator temporarily. After the changes are made, wait for the D/A converter output settling time before enabling the comparator.

49. Data Operation Circuit (DOC)

This is the DOC_B version of the DOC peripheral module.

DOC_B is referred to as DOC in this chapter.

49.1 Overview

The data operation circuit (DOC) is used to compare, add, and subtract 16 or 32-bit data. An interrupt can be generated when the following conditions apply.

- When the 16 or 32-bit compared values match the detection condition
- When the result of 16 or 32-bit data addition overflows
- When the result of 16 or 32-bit data subtraction underflows

Table 49.1 lists the data operation circuit specifications and Figure 49.1 shows a block diagram of the data operation circuit.

Table 49.1 DOC specifications

Item	Description
Data operation function	• 16 or 32-bit data comparison, comparison to detect data above or below thresholds, and window comparison • 16 or 32-bit data addition, and subtraction
Module-stop function	The module-stop state can be set to reduce power consumption.
Interrupts	• The compared values match the detection condition • The result of data addition is greater than 0xFFFF (DOCR.DOBW = 0) or 0xFFFF_FFFF (DOCR.DOBW = 1) • The result of data subtraction is less than 0x0000 (DOCR.DOBW = 0) or 0x0000_0000 (DOCR.DOBW = 1)
Event link function (output)	• The result of data comparison is consistent with detection condition • The result of data addition is greater than 0xFFFF (DOCR.DOBW = 0) or 0xFFFF_FFFF (DOCR.DOBW = 1) • The result of data subtraction is less than 0x0000 (DOCR.DOBW = 0) or 0x0000_0000 (DOCR.DOBW = 1)
TrustZone Filter	Security and Privilege attribution can be set

Figure 49.1 DOC block diagram

49.2 DOC Register Descriptions

49.2.1 DOCR : DOC Control Register

Base address: DOC_B = 0x4031_1000
DOC_B_NS = 0x5031_1000

Offset address: 0x00

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	DCSEL[2:0]			DOBW	—	OMS[1:0]	

Value after reset: 0 0 0 0 0 0 0 0

Bit	Symbol	Function	R/W
1:0	OMS[1:0]	Operating Mode Select 0 0: Data comparison mode 0 1: Data addition mode 1 0: Data subtraction mode 1 1: Setting prohibited	R/W
2	—	This bit is read as 0. The write value should be 0.	R/W
3	DOBW	Data Operation Bit Width Select 0: 16-bit 1: 32-bit	R/W
6:4	DCSEL[2:0] ^{*1}	Detection Condition Select 0 0 0: Mismatch (DODSR0 ≠ DODIR) 0 0 1: Match (DODSR0 = DODIR) 0 1 0: Lower (DODSR0 > DODIR) 0 1 1: Upper (DODSR0 < DODIR) 1 0 0: Inside window (DODSR0 < DODIR < DODSR1) 1 0 1: Outside window (DODIR < DODSR0, DODSR1 < DODIR) Others: Setting prohibited	R/W

Bit	Symbol	Function	R/W
7	—	This bit is read as 0. The write value should be 0.	R/W

Note: S-TYPE3, P-TYPE3

Note 1. Valid only when data comparison mode is selected.

The DOCR is a register which can set the operation mode of data operation circuit and interrupt enable/disable.

OMS[1:0] bits (Operating Mode Select)

These bits select the operating mode of the data operation circuit.

DOBW bit (Data Operation Bit Width Select)

This bit selects the bit width of data operation.

DCSEL[2:0] bits (Detection Condition Select)

These bits are valid only when data comparison mode is selected.

These bits select the condition for detection in data comparison mode.

49.2.2 DOSR : DOC Flag Status Register

Base address: DOC_B = 0x4031_1000
DOC_B_NS = 0x5031_1000

Offset address: 0x04

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	DOPCF

Value after reset: 0 0 0 0 0 0 0 0 0

Bit	Symbol	Function	R/W
0	DOPCF	Data Operation Circuit Flag Indicates the result of an operation.	R
7:1	—	These bits are read as 0.	R

Note: S-TYPE3, P-TYPE3

The DOSR register indicates the status of the data operation.

DOPCF flag (Data Operation Circuit Flag)

[Setting conditions]

- DOCR.OMS[1:0] bits = 00b (Data comparison mode): The compared value matches the detection condition selected by DOCR.DCSEL[2:0] bits
- DOCR.OMS[1:0] bits = 01b (Data addition mode): The result of data addition is greater than 0xFFFF (DOCR.DOBW = 0) or 0xFFFF_FFFF (DOCR.DOBW = 1)
- DOCR.OMS[1:0] bits = 10b (Data subtraction mode): The result of data subtraction is less than 0x0000 (DOCR.DOBW = 0) or 0x0000_0000 (DOCR.DOBW = 1)

[Clearing condition]

- Writing 1 to the DOSCR.DOPCFCL bit

Base address: DOC_B = 0x4031_1000
DOC_B_NS = 0x5031_1000

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	DOPC FCL
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	DOPCFCL	DOPCF Clear 0: Maintains the DOPCF flag state. 1: Clears the DOPCF flag.	W
7:1	—	The write value should be 0.	W

The DOSCR is a register which can clear the status of data operation. This register is read as 0x00.

Setting this bit to 1 clears the DOPCF flag.

Base address: DOC_B = 0x4031_1000
DOC_B_NS = 0x5031_1000

[illegible]

Bit	Symbol	Function	R/W
31:0	n/a	It stores data used in the operations. Access the DODIR with the bit width of data operation selected by the DOCR.DOBW bit.	R/W

49.2.5 DODSR0 : DOC Data Setting Register 0

Base address: DOC_B = 0x4031_1000
DOC_B_NS = 0x5031_1000

[illegible]

Bit	Symbol	Function	R/W
31:0	n/a	Access the DODSR0 with the bit width of data operation selected by the DOCR.DOBW bit. This register stores data for use as a reference in data comparison mode. When selecting window comparison (DOCR.DCSEL[2:0] = 100b, 101b), set a value less than DODSR1 (DODSR1 > DODSR0). This register also stores the results of operations in data addition and data subtraction modes.	R/W

R01UH0994EJ0140 Rev.1.40
Jul 24, 2026

49.2.6 DODSR1 : DOC Data Setting Register 1

Base address: DOC_B = 0x4031_1000
DOC_B_NS = 0x5031_1000

Offset address: 0x14

Bit position: 31

0

Bit field:

Value after reset: 0

Bit	Symbol	Function	R/W
31:0	n/a	Access the DODSR1 with the bit width of data operation selected by the DOCR.DOBW bit. This register stores data for use as a reference in data comparison mode. When selecting window comparison (DOCR.DCSEL[2:0] = 100b, 101b), set a value greater than DODSR0 (DODSR1 > DODSR0). This register is only used for window comparisons.	R/W

Note: S-TYPE3, P-TYPE3

49.3 Operation

49.3.1 Data Comparison Mode

Figure 49.2 to Figure 49.7 shows an example of the steps involved in data comparison mode operation by the data operation circuit.

The following is an example of operation when the bit width of data operation is 32-bit.

1. Writing 00b to the DOCR.OMS[1:0] bits selects data comparison mode, and setting the DOCR.DCSEL[2:0] to selects detection condition.
2. The 32-bit reference data is set in DODSR0 and DODSR1.*1
3. 32-bit data for comparison is written to DODIR.
4. If a value written to DODIR match the detection condition set by DOCR.DCSEL[2:0], the DOCR.DOPCF flag is set to 1 and an ELC event and a data operation circuit interrupt are generated.

Note: The comparison operation is executed only by writing to the DODIR

Note 1. The DODSR1 register setting is required only when window comparison is selected. Set a value greater than DODSR0 (DODSR1 > DODSR0).

Figure 49.2 Example of Operation in Data Comparison Mode (Detection condition: Mismatch)

Figure 49.3 Example of Operation in Data Comparison Mode (Detection condition: Match)

Figure 49.4 Example of Operation in Data Comparison Mode (Detection condition: Lower)

Figure 49.5 Example of Operation in Data Comparison Mode (Detection condition: Upper)

Figure 49.6 Example of Operation in Data Comparison Mode (Detection condition: Inside window)

Figure 49.7 Example of Operation in Data Comparison Mode (Detection condition: Outside window)

49.3.2 Data Addition Mode

Figure 49.8 shows an example of the steps involved in data addition mode ^{*1} operation by the data operation circuit.

The following is an example of operation when the bit width of data operation is 32-bit.

1. Writing 01b to the DOCR.OMS[1:0] bits selects data addition mode.
2. 32-bit data is set in the DODSR0 register as the initial value.
3. 32-bit data to be added is written to DODIR. The result of the operation is stored in DODSR0.
4. Writing of 32-bit data continues until all data for addition have been written to DODIR.
5. If the result of an operation is greater than 0xFFFF_FFFF, the DOSR.DOPCF flag is set to 1 and an ELC event and a data operation circuit interrupt are generated.

Note 1. Addition is executed only by writing to the DODIR.

Figure 49.8 Example of Operation in Data Addition Mode

49.3.3 Data Subtraction Mode

Figure 49.9 shows an example of the steps involved in data subtraction mode ^{*1} operation by the data operation circuit.

The following is an example of operation when the bit width of data operation is 32-bit.

1. Writing 10b to the DOCR.OMS[1:0] bits selects data subtraction mode.
2. 32-bit data is set in the DODSR0 register as the initial value.
3. 32-bit data to be subtracted is written to DODIR. The result of the operation is stored in DODSR0.
4. Writing of 32-bit data continues until all data for subtraction have been written to DODIR.
5. If the result of an operation is less than 0x0000_0000, the DOSR.DOPCF flag is set to 1 and an ELC event and a data operation circuit interrupt are generated.

Note 1. Subtraction is executed only by writing to the DODIR.

Figure 49.9 Example of Operation in Data Subtraction Mode

49.4 Interrupt Source

The data operation circuit generates the data operation circuit interrupt (DOC_DOPCI) as an interrupt request. When an interrupt source is generated, the data operation circuit flag corresponding to the interrupt is set to 1, and then interrupt request signal is generated. Table 49.2 describes the interrupt request.

Table 49.2 Interrupt request from DOC

Interrupt request	Status flag	Interrupt source
DOC interrupt	DOPCF	- The compared values match the detection condition. - The result of data addition is greater than 0xFFFF (DOCR.DOBW = 0) or 0xFFFF_FFFF (DOCR.DOBW = 1). - The result of data subtraction is less than 0x0000 (DOCR.DOBW = 0) or 0x0000_0000 (DOCR.DOBW = 1).

49.5 Event Link Output

The DOC outputs event signals for the event link controller (ELC) under the following conditions, and these can be used to initiate operations by other modules selected in advance.

- The compared values match the detection condition
- The data addition result is greater than 0xFFFF (DOCR.DOBW = 0) or 0xFFFF_FFFF (DOCR.DOBW = 1)
- The data subtraction result is less than 0x0000 (DOCR.DOBW = 0) or 0x0000_0000 (DOCR.DOBW = 1)

49.6 Interrupt Handling and Event Linking

The DOC has a bit to enable or disable interrupts. An interrupt request signal is output for the CPU when an interrupt source is generated while the corresponding enable bit is enabled.

In contrast, an event link output signal is sent to other modules as an event signal via the ELC when an interrupt source is generated, regardless of the setting of the corresponding interrupt enable bit.

49.7 Usage Notes

49.7.1 Settings for the Module-Stop State

The module Stop Control Register C (MSTPCRC) can enable or disable DOC operation. The DOC is initially stopped after reset. Releasing the module-stop state enables access to the registers. For details, see [section 10, Low Power Modes](#).

50. SRAM

50.1 Overview

The MCU provides an on-chip, high-density SRAM module with either parity-bit checking or Error Correction Code (ECC). SRAM0 is ECC. SRAM1 is Parity check.

Table 50.1 lists the SRAM specifications.

Table 50.1 SRAM specifications

Parameter	SRAM0	SRAM1
SRAM capacity	384 KB	512 KB
SRAM address	0x2200_0000 to 0x2205_FFFF (Secure alias), 0x3200_0000 to 0x3205_FFFF (Non-secure alias)	0x2206_0000 to 0x220D_FFFF (Secure alias), 0x3206_0000 to 0x320D_FFFF (Non-secure alias)
Access	Wait states are inserted into the read cycle by default. If the ICLK frequency is higher than 120 MHz, a wait state is required. If the ICLK frequency is 120 MHz or less, a wait state is not required.	
Data retention function	Not available in Deep Software Standby mode	
Module-stop function	Module-stop state can be set to reduce power consumption	
Error checking	SEC-DED (Single-Error Correction and Double-Error Detection Code)	Even-parity (Data: 8 bits, Parity: 1 bit)
Security	TrustZone Filter is integrated for memory access and SFR access. Access to the memory space is controlled by setting the memory Security Attribution (SA). And access to I/O space (SFR) space is controlled by setting the register SA. See section 50.3.6. TrustZone Filter function .	

50.2 Register Descriptions

50.2.1 SRAMSABARn : SRAM Security Attribute Boundary Address Register (n = 0, 1)

Base address: CPSCU = 0x4000_8000
CPSCU_NS = 0x5000_8000

Offset address: 0x400 + 0x04 × n

Bit position: 31

0

Bit field:

n/a

Value after reset: 0 0 0 0 0 0 0 0 0 0 0 0 0 0 1 1 1 1 1 1 1 1 0 0 0 0 0 0 0 0 0 0 0 0 0 0

Bit	Symbol	Function	R/W
31:0	n/a	Boundary address between Secure and Non-secure. (Start address of Non-secure region)	R/W

Note: S-TYPE-1, P-TYPE-1

Note: This register is write-protected by PRCCR_S.PRC4 register.

SRAMSABARn specifies the boundary address between the Secure and Non-secure regions of each SRAM. Write the absolute address to the SRAMSABARn. When writing to SRAMSABARn, writing from b31 to b21 is ignored and the value written from b12 to b0 should be 0.

The region lower than the boundary address is marked as Secure, and higher than or equal to the boundary address is marked as Non-secure.

The boundary address is as follows.

0x2200_0000 + SRAMSABARn (Secure alias)

0x3200_0000 + SRAMSABARn (Non-secure alias)

For SRAMSABAR0

When the boundary address is 0x00000000, whole SRAM0 is marked as Non-secure.

When the boundary address is 0x00060000 or large, whole SRAM0 is marked as Secure.

For SRAMSABAR1

When the boundary address is 0x00060000 or less, whole SRAM1 is marked as Non-secure.

When the boundary address is 0x000E0000 or large, whole SRAM1 is marked as Secure.

50.2.2 SRAMSAR : SRAM Security Attribution Register

Base address: CPSCU = 0x4000_8000
CPSCU_NS = 0x5000_8000

Offset address: 0x10

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	SRAM WTSA	STBR AMSA	—	—	—	—	—	SRAM SA1	SRAM SA0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	SRAMSA0	SRAM0 Register Security Attribution 0: Secure 1: Non-secure	R/W
1	SRAMSA1	SRAM1 Register Security Attribution 0: Secure 1: Non-secure	R/W
6:2	—	These bits are read as 0. The write value should be 0.	R/W
7	STBRAMSA	Standby SRAM Register Security Attribution 0: Secure 1: Non-secure	R/W
8	SRAMWTSA	SRAMWTSC Security Attribution 0: Secure 1: Non-secure	R/W
31:9	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-1, P-TYPE-1

Note: Only Secure access can write to this register. Both Secure access and Non-secure read access are allowed but Non-secure write access is not allowed and TrustZone access error is not generated.

Note: This register is write-protected by PRCR_S.PRC4 register.

SRAMSA0 bit (SRAM0 Register Security Attribution)

The SRAMSA0 bit specifies security attributes of SRAMCR0, SRAMECCRG0, SRAMESCLR.CLR00, and SRAMESCLR.CLR01.

SRAMSA1 bit (SRAM1 Register Security Attribution)

The SRAMSA1 bit specifies security attributes of SRAMCR1 and SRAMESCLR.CLR1.

STBRAMSA bit (Standby SRAM Register Security Attribution)

The STBRAMSA bit specifies security attributes of STBRAMCR and SRAMESCLR.CLR5.

SRAMWTSA bit (SRAMWTSC Security Attribution)

The SRAMWTSA bit specifies security attributes of SRAMWTSC.

50.2.3 SRAMPRCR_S : SRAM Protection Control Register for Secure

Base address: SRAM = 0x4000_2000

Offset address: 0x00

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	KW[7:0]								—	—	—	—	—	—	—	PR
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	PR	Register Write Control 0: Writing to registers are disabled 1: Writing to registers are enabled	R/W
7:1	—	These bits are read as 0. The write value should be 0.	R/W
15:8	KW[7:0]	Write Key Code Key code protection to the PR bit	R/W

Note: S-TYPE-6, P-TYPE-2

Note: It is necessary to write by half word access.

Byte write access is prohibited. When byte write access is executed, operation is not guaranteed.

PR bit (Register Write Control)

The PR bit controls the write mode of the SRAMWTSC, SRAMCR0, SRAMCR1, SRAMECCRGNO, and STBRAMCR registers that are marked as Secure by SRAMSAR register. When this bit is set to 1, writing to the SRAMWTSC, SRAMCR0, SRAMCR1, SRAMECCRGNO, and STBRAMCR marked as Secure is enabled.

While writing to this register it is necessary to write 0xA5 to the KW[7:0] bits simultaneously.

KW[7:0] bits (Write Key Code)

The KW[7:0] bits enable or disable writing to the PR bit. When you write to the PR bit, write 0xA5 to the KW[7:0] bits simultaneously. When a value other than 0xA5 is written to KW[7:0], the PR bit is not updated. The KW[7:0] bits are always read as 0x00.

50.2.4 SRAMPRCR_NS : SRAM Protection Control Register for Non-secure

Base address: SRAM_NS = 0x5000_2000

Offset address: 0x04

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	KW[7:0]								—	—	—	—	—	—	—	PR
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	PR	Register Write Control 0: Writing to registers are disabled 1: Writing to registers are enabled	R/W
7:1	—	These bits are read as 0. The write value should be 0.	R/W
15:8	KW[7:0]	Write Key Code Key code protection to the PR bit	R/W

Note: S-TYPE-7, P-TYPE-2

Note: It is necessary to write by half word access.

Byte write access is prohibited. When byte write access is executed, operation is not guaranteed.

PR bit (Register Write Control)

The PR bit controls the write mode of the SRAMWTSC, SRAMCR0, SRAMCR1, SRAMECCRG0, and STBRAMCR registers that are marked as Non-secure by SRAMSAR register. When this bit is set to 1, writing to the SRAMWTSC, SRAMCR0, SRAMCR1, SRAMECCRG0, and STBRAMCR marked as Non-secure is enabled.

While writing to this register it is necessary to write 0xA5 to the KW[7:0] bits simultaneously.

KW[7:0] bits (Write Key Code)

The KW[7:0] bits enable or disable writing to the PR bit. When you write to the PR bit, write 0xA5 to the KW[7:0] bits simultaneously. When a value other than 0xA5 is written to KW[7:0], the PR bit is not updated. The KW[7:0] bits are always read as 0x00.

50.2.5 SRAMWTSC : SRAM Wait State Control Register

Base address: SRAM = 0x4000_2000
SRAM_NS = 0x5000_2000

Offset address: 0x08

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	WTEN
Value after reset:	0	0	0	0	0	0	0	1

Bit	Symbol	Function	R/W
0	WTEN	SRAM Wait Enable 0: No wait 1: Add wait state in read access cycle to SRAMs	R/W
7:1	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3 (SRAMSAR.SRAMWTSA), P-TYPE-2

This register can be written only when the PR bit in the SRAMPRCR_S or SRAMPRCR_NS register is 1.

WTEN bit (SRAM Wait Enable)

The WTEN bit sets the wait cycle insertion to the access cycle of SRAM. When 1 is set to the WTEN bit, 1 wait cycle is inserted to the read access cycle of SRAM. Also when the WTEN bit is 1, the access to the same region^{*1} and the same mat^{*2} is continuous and 1 wait cycle is inserted to the second access cycle. When the access frequency is more than 120 MHz, it is necessary to set 1 wait cycle to the WTEN bit.

Note 1. The region of SRAM is divided into 128 KB units.

Note 2. The mat is divided into 0x0 to 0x7 and 0x8 to 0xF in the lower 4 bits of the address.

For example, the same region and the same mat is 6 areas of SRAM0, and 8 areas of SRAM1 in the figure below. If 1 area is accessed continuously, 1 wait cycle is inserted. If ECC function is enabled or bypass is enabled, ECC region is accessed, and so if access to the same mat continues, 1 wait cycle is inserted.

Figure 50.1 Mat configuration of each SRAM

50.2.6 SRAMCR0 : SRAM Control Register 0

Base address: SRAM = 0x4000_2000
 SRAM_NS = 0x5000_2000

Offset address: 0x10

Bit position:	7	6	5	4	3	2	1	0
Bit field:	TSTB YP	—	—	E1STS EN	ECCMOD[1:0]	—	—	OAD

Value after reset: 0 0 0 0 0 0 0 0

Bit	Symbol	Function	R/W
0	OAD	Operation after Detection for ECC Error Detection 0: Non-maskable interrupt 1: Reset.	R/W
1	—	This bit is read as 0. The write value should be 0.	R/W
3:2	ECCMOD[1:0]	ECC Operating Mode Select 0 0: Disable ECC function 0 1: Setting prohibited 1 0: Enable ECC function without error checking 1 1: Enable ECC function with error checking	R/W
4	E1STSEN	ECC 1-Bit Error Information Update Enable 0: Disable updating of 1-bit ECC error information 1: Enable updating of 1-bit ECC error information	R/W
6:5	—	These bits are read as 0. The write value should be 0.	R/W

Bit	Symbol	Function	R/W
7	TSTBYP	ECC Bypass Select 0: Disable ECC bypass 1: Enable ECC bypass	R/W

Note: S-TYPE-3 (SRAMSAR.SRAMSA0), P-TYPE-2

This register can be written only when the PR bit in the SRAMPRCR_S or SRAMPRCR_NS register is 1.

Do not write to this register while access to SRAM is in progress. See [section 50.4.2. Note of write to SRAMCR0, SRAMCR1 and SRAMECCRGNO registers](#) for writing to this register.

OAD bit (Operation after Detection for ECC Error Detection)

The OAD bit selects a reset or non-maskable interrupt when an ECC error is detected.

ECCMOD[1:0] bits (ECC Operating Mode Select)

The ECCMOD[1:0] bits set the access mode to the ECC area.

E1STSEN bit (ECC 1-Bit Error Information Update Enable)

The E1STSEN bit enables or disables updating of the ECC 1-bit error status bit in the SRAMESR in response to a 1-bit error. This bit also functions as an interrupt or a reset mask.

TSTBYP bit (ECC Bypass Select)

The TSTBYP bit enables direct access to ECC code by bypassing the ECC function. The ECC Bypass function is used along with setting the ECCMOD[1:0] bits in the same register as 00b. The ECC must be accessed the same address. The ECC code is assigned to the lower 8 bits. When writing the ECC code, the bits above the ECC bits are ignored. When reading the ECC code, the bits above the ECC bits are undefined.

For details of ECC test, see [section 50.3.4. ECC Decoder Testing](#).

50.2.7 SRAMCR1 : SRAM Control Register 1

Base address: SRAM = 0x4000_2000
SRAM_NS = 0x5000_2000

Offset address: 0x14

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	OAD

Value after reset: 0 0 0 0 0 0 0 0

Bit	Symbol	Function	R/W
0	OAD	Operation after Detection for Parity Error Detection 0: Non-maskable interrupt 1: Reset.	R/W
7:1	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3 (SRAMSAR.SRAMSA1), P-TYPE-2

This register can be written only when the PR bit in the SRAMPRCR_S or SRAMPRCR_NS register is 1.

Do not write to this register while access to SRAM is in progress. See [section 50.4.2. Note of write to SRAMCR0, SRAMCR1 and SRAMECCRGNO registers](#) for writing to this register.

OAD bit (Operation after Detection for Parity Error Detection)

The OAD bit selects a reset or non-maskable interrupt when a parity error is detected.

50.2.8 SRAMECCRG0 : SRAM0 ECC Region Control Register

Base address: SRAM = 0x4000_2000
SRAM_NS = 0x5000_2000

Offset address: 0x30

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	ECCRG0[1:0]	
Value after reset:	1	1	1	1	1	1	1	1

Bit	Symbol	Function	R/W
1:0	ECCRG0[1:0]	ECC Region Control ECC region selection 0 0: No ECC Region 0 1: 0x2200_0000 – 0x2201_FFFF / 0x3200_0000 – 0x3201_FFFF (128 KB) 1 0: 0x2200_0000 – 0x2203_FFFF / 0x3200_0000 – 0x3203_FFFF (256 KB) 1 1: 0x2200_0000 – 0x2205_FFFF / 0x3200_0000 – 0x3205_FFFF (384 KB) The ECC area selected by this register can be controlled by SRAMCR0.	R/W
7:2	—	These bits are read as 1. The write value should be 1.	R/W

Note: S-TYPE-3 (SRAMSAR.SRAMSA0), P-TYPE-2

This register can be written only when the PR bit in the SRAMPRCR_S or SRAMPRCR_NS register is 1.

Do not write to this register while access to SRAM is in progress. See [section 50.4.2. Note of write to SRAMCR0, SRAMCR1 and SRAMECCRG0 registers](#) for writing to this register.

ECCRG0[1:0] bits (ECC Region Control)

The ECCRG0[1:0] bits select ECC area in SRAM0.

50.2.9 SRAMESR : SRAM Error Status Register

Base address: SRAM = 0x4000_2000
SRAM_NS = 0x5000_2000

Offset address: 0x40

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	ERRS	—	—	—	—	—	—	—	—	—	—	—	ERR1	ERR0 1	ERR0 0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	ERR00	SRAM0 1-bit ECC Error Status 0: 1-bit ECC error has not occurred. 1: 1-bit ECC error has occurred.	R
1	ERR01	SRAM0 2-bit ECC Error Status 0: 2-bit ECC error has not occurred. 1: 2-bit ECC error has occurred.	R
2	ERR1	SRAM1 Parity Error Status 0: Parity error has not occurred. 1: Parity error has occurred.	R
13:3	—	These bits are read as 0.	R
14	ERRS	Standby SRAM Parity Error status 0: Parity error has not occurred. 1: Parity error has occurred.	R
15	—	This bit is read as 0.	R

Note: S-TYPE-5, P-TYPE-2

This register is cleared by the corresponding bit in the SRAMESCLR register or resets other than Bus Error Reset and Memory Error Reset. If error and clear occur at the same time, clear has priority. Also updating register stops during accessing from debugger.

ERR00 bit (SRAM0 1-bit ECC Error Status)

The ERR00 bit shows whether there is a 1-bit ECC error in SRAM0.

When ECC operations are enabled, error correction is selected and updating of the 1-bit error information is enabled. The ERR00 bit is set to 1 if there is a 1-bit error.

When the ERR00 bit is set to 1, a reset or non-maskable interrupt request is generated according to the SRAMCR0.OAD.

ERR01 bit (SRAM0 2-bit ECC Error Status)

The ERR01 bit shows whether there is a 2-bit ECC error in SRAM0.

When ECC operations are enabled, error correction is selected. The ERR01 bit is set to 1 if there is a 2-bit error.

When the ERR01 bit is set to 1, a reset or non-maskable interrupt request is generated according to the SRAMCR0.OAD.

ERR1 bit (SRAM1 Parity Error Status)

The ERR1 bit shows whether there is a parity error or not in the SRAM1.

The ERR1 bit is set if a parity error is detected.

When the ERR1 bit is set to 1, a reset or non-maskable interrupt request is generated according to the SRAMCR1.OAD.

ERRS bit (Standby SRAM Parity Error status)

The ERRS bit shows whether there is a parity error or not in the Standby SRAM.

The ERRS bit is set to 1 if there is an error.

When the ERRS bit is set to 1, a reset or non-maskable interrupt request is generated according to the STBRAMCR.OAD.

50.2.10 SRAMESCLR : SRAM Error Status Clear Register

Base address: SRAM = 0x4000_2000
SRAM_NS = 0x5000_2000

Offset address: 0x48

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	CLRS	—	—	—	—	—	—	—	—	—	—	—	CLR1	CLR01	CLR00
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	CLR00	SRAM0 1-bit ECC Error Status Clear Writing to the CLR00 clears SRAMESR.ERR00. 1: Clear 1-bit ECC error. Read value is always 0.	R/W ^{*1}
1	CLR01	SRAM0 2-bit ECC Error Status Clear Writing to the CLR01 clears SRAMESR.ERR01. 1: Clear 2-bit ECC error. Read value is always 0.	R/W ^{*1}
2	CLR1	SRAM1 Parity Error Status Clear Writing to the CLR1 clears SRAMESR.ERR1. 1: Clear Parity error. Read value is always 0.	R/W ^{*1}
13:3	—	These bits are read as 0. The write value should be 0.	R/W
14	CLRS	Standby SRAM Parity Error Status Clear Writing to the CLRS clears SRAMESR. ERRS. 1: Clear Parity error. Read value is always 0.	R/W ^{*1}

Bit	Symbol	Function	R/W
15	—	This bit is read as 0. The write value should be 0.	R/W

Note: S-TYPE-4 (SRAMSAR.SRAMSAn, STBRAMSA), P-TYPE-2

Note 1. For each bit, only 1 can be written to clear the error status.

CLR00 bit (SRAM0 1-bit ECC Error Status Clear)

The CLR00 bit can clear the SRAM0 1-bit ECC error status bit in the SRAMESR. If error and clear occur at the same time, clear has priority.

The SRAMESR.ERR00 bit can be cleared when writing 1 to CLR00.

CLR01 bit (SRAM0 2-bit ECC Error Status Clear)

The CLR01 bit can clear the SRAM0 2-bit ECC error status bit in the SRAMESR. If error and clear occur at the same time, clear has priority.

The SRAMESR.ERR01 bit can be cleared when writing 1 to CLR01.

CLR1 bit (SRAM1 Parity Error Status Clear)

The CLR1 bit can clear the SRAM1 parity error status bit in the SRAMESR. If error and clear occur at the same time, clear has priority.

The SRAMESR.ERR1 bit can be cleared when writing 1 to CLR1.

CLRS bits (Standby SRAM Parity Error Status Clear)

The CLRS bits can clear the Standby SRAM Parity error bit in the SRAMESR. If error and clear occur at the same time, clear has priority.

The SRAMESR.ERRS bit can be cleared when writing 1 to CLRS.

50.2.11 SRAMEAR_n : SRAM Error Address Register (n = 0 to 2)

Base address: SRAM = 0x4000_2000
SRAM_NS = 0x5000_2000

Offset address: 0x50 + 0x04 × n

Bit position: 31

0

Bit field:

Value after reset: 0

Bit	Symbol	Function	R/W
31:0	n/a	When an SRAM error occurs, it stores an error address.	R

Note: S-TYPE-5, P-TYPE-2

This register is cleared by the corresponding bit in the SRAMESCLR register or resets other than Bus Error Reset and Memory Error Reset. If error and clear occur at the same time, clear has priority. Also updating register stops during accessing from debugger.

The error address is as follows.

0x2200_0000 + SRAMEAR_n (Secure alias)

0x3200_0000 + SRAMEAR_n (Non-secure alias)

For SRAMEAR0

This register stores the error address where 1-bit ECC error is detected. These bits hold the error address that occurred first. These bits are cleared by clearing 1-bit ECC error from SRAMESCLR.

For SRAMEAR1

This register stores the error address where 2-bit ECC error is detected. These bits hold the error address that occurred first. These bits are cleared by clearing 2-bit ECC error from SRAMESCLR.

For SRAMEAR2

This register stores the error address where parity error is detected. These bits hold the error address that occurred first. These bits are cleared by clearing parity error from SRAMESCLR.

50.3 Operation

50.3.1 Module Stop Function

Power consumption can be reduced by setting module stop control register A (MSTPCRA) to stop supply of the clock signal to SRAM.

SRAMn (n = 0, 1) is controlled by MSTPAn (n = 0, 1) bit in MSTPCRA register and, in the case of 1, SRAMn becomes the clock stop state.

The SRAM is thus placed in the module-stop state by stopping supply of the clock signals. The SRAM operates after a reset.

SRAM is not accessible if it is in the module-stop state. A transition to the module-stop state should not be made while access to SRAM is in progress.

Access to the SRAM in the module-stop state is prohibited. If access is attempted, correct operation is not guaranteed.

For details on the MSTPCRA register, see [section 10, Low Power Modes](#).

50.3.2 Correction of ECC errors

Enabling and disabling of ECC error correction can be selected through the setting by ECCMOD[1:0] bits of SRAMCR0 register. In the initial state, ECC error correction is disabled. The ECC check type is SEC-DED (Single-Error Correction and Double-Error Detection Code).

When ECC function is enabled, 8-bit check bits are appended to 64-bit data for writing. For reading, 72-bit (data: 64 bits, check bits: 8 bits) data is read out from the SRAM (ECC area).

When ECC function and error checking are enabled, error correction is done if a 1-bit error occurs and the ERR00 bit in the SRAMESR register is set to 1 if the E1STSEN bit in the SRAMCR0 register is 1. If a 2-bit error occurs, error detection is done and the ERR01 bit in the SRAMESR register is set to 1, though error correction is not performed.

When ECC function is enabled and the error checking is disable, error correction is done if a 1-bit error occurs but ERR00 bit in the SRAMESR register is not updated although E1STSEN bit in the SRAMCR0 register is 1. If a 2-bit error occurs, this error is detected but the ERR01 bit in the SRAMESR register is not updated, and error correction is not performed.

When ECC function is disable, neither error correction nor error detection is done although 1-bit or 2-bit error occur.

So ERR00 and ERR01 bits are not updated.

When updating all the data after the occurrence of an error, the only support of 64 bit data writing.

Since the SRAM data is undefined after power on and release from Deep Software Standby mode, accessing the SRAM when ECC function is enabled and error checking is selected causes an ECC error to occur. Therefore, before using ECC function, initial writing with 64-bit data size, or initial writing with ECC function is enabled and the error checking is disabled, to the area to be used in the SRAM should be done.

When a read access is executed in a row after a write access, read access may be executed with priority. Therefore, during initialization, please do not perform the read access in a row after the write access.

50.3.3 ECC Error Interrupt Function

When ECC function is enabled, error checking is possible in the SRAM0. In the case of a 2-bit error, the ERR01 bit in the SRAMESR register set to 1. In the case of a 1-bit error, the ERR00 bit in the SRAMESR register set to 1 when SRAMCR0.E1STSEN bit is 1.

When the ECC 1-bit error is to be masked, it is necessary to set the SRAMCR0.E1STSEN bit to 0 to disable updating of the ERR00 bit to 1. An ECC error will not be generated while ECC function is disabled or when ECC function is enabled but error checking is not selected using the SRAMCR0.ECCMOD[1:0] bits.

ECC error may result in non-maskable interrupt or reset. When the OAD bit in the SRAMCR0 register is 1, ECC error is outputted to the Reset function. When it is 0, ECC Error interrupt is outputted to the ICU as a non-maskable interrupt.

ECC Error interrupt occurs when one flag in the SRAMESR register is set. ECC Error interrupt continues to occur until the SRAMESR register flag is cleared.

50.3.4 ECC Decoder Testing

ECC decoder testing should be done in the following order.

1. Executes the DMB instruction.
2. Write 0xA501 to the SRAMPRCR_S or SRAMPRCR_NS and enable writes to the SRAM-related registers.
3. Write 0x08 to the SRAMCR0 and enable the ECC function without error checking and disable the ECC bypass.
4. Executes the DMB instruction.
5. Write 8-bytes data to the target address. The 8-bits ECC code is automatically updated.
6. Executes the DMB instruction.
7. Write 0x80 to the SRAMCR0 and enable the ECC bypass.
8. Executes the DMB instruction.
9. Read target address to get 8-bits-ECC code.
10. To generate 1-bit/2-bit ECC error, reverse 1-bit/2-bit of the data read in the previous process and write the data back to the target address.
11. Executes the DMB instruction.
12. Write 0x1C to the SRAMCR0, disable the ECC bypass and enable the updating of 1-bit ECC error information and enable the ECC function with error checking.
13. Executes the DMB instruction.
14. Read the target address.
15. Executes the DMB instruction.
16. Confirm the generation of the ECC error by the SRAMESR.

50.3.5 Parity Calculation Function

The IEC60730 standard requires the checking of SRAM data. When data is written, a parity bit is added to every 8-bit data in the SRAM, and when data is read, the parity is checked. When a parity error occurs, a parity-error notification is generated. This function can also be used to trigger a reset.

The parity-error notification can be specified as a non-maskable interrupt or a reset in the OAD bit of the SRAMCR1 register. When the OAD bit is set to 1, a parity error is output to the reset function. When the OAD bit is set to 0, a parity error is output to the ICU as a non-maskable interrupt.

Parity Error often occurs due to noise. It is possible to confirm whether the parity error is caused by noise or destruction of data by following the parity operation flowchart. [Figure 50.2](#) and [Figure 50.3](#) shows flowcharts of SRAM parity check operation.

When a read access is executed in a row after a write access, read access is executed with priority. Therefore, during initialization, do not perform the read access in a row after the write access.

Figure 50.2 Flow of SRAM parity check when SRAM parity reset is enabled

Figure 50.3 Flow of SRAM parity check when SRAM parity interrupt is enabled

50.3.6 TrustZone Filter function

50.3.6.1 TrustZone Filter for SRAM Registers

SRAM registers can be protected with a Security Attribution (SA) from Non-secure or Secure transaction. When SA indicates that SRAM registers are Secure status, Non-secure transaction cannot access them because TrustZone Filter detects an error and protects the access. When SA indicates that SRAM registers are Non-secure status, Secure transaction cannot access them because Trust Zone Filter detects an error and protects the access. SA for SRAM registers is just one to be used commonly among SRAM registers.

In the case of a failed access due to TrustZone error, error response is generated.

Table 50.2 Register protection (1 of 2)

SA	Transaction	Write access	Read access
Secure	Secure	Permitted	Permitted
	Non-secure	Protected (TrustZone Filter error)	Protected (TrustZone Filter error)

Table 50.2 Register protection (2 of 2)

SA	Transaction	Write access	Read access
Non-secure	Secure	Protected (TrustZone Filter error)	Protected (TrustZone Filter error)
	Non-secure	Permitted	Permitted

50.3.6.2 TrustZone Filter for SRAM Memory Regions

SRAM0, SRAM1 regions can be divided into Secure and Non-secure independently. The access permissions for these regions are as below.

Table 50.3 Memory protection

SA	Transaction	Write access	Read access
Secure	Secure	Permitted	Permit
	Non-secure	Protected (TrustZone Filter error)	Protected (TrustZone Filter error)
Non-secure	Secure	Protected (TrustZone Filter error)	Protected (TrustZone Filter error)
	Non-secure	Permitted	Permitted

TrustZone filter error for SRAM memory generates an error notification.

50.3.7 Interrupt Source

The SRAM interrupt source includes an ECC error, Parity error and TrustZone filter error. ECC error and Parity error can choose non-maskable interrupt or reset by SRAMCR0.OAD or SRAMCR1.OAD bit. The SRAM interrupt occurs when one error status in the SRAMESR register is set to 1, the SRAM interrupt continues to occur until the SRAMESR register flag is cleared. When Common memory error occur (NMISR.CMST = 1 or RSTSR1.CMSR = 1), please read SRAMESR and check SRAM interrupt source. When the access from debugger, the error is detected and corrected, but no error flag is set, reset and non-maskable interrupt are maskable. For details on the debug mode, see [section 2, CPU](#).

Table 50.4 SRAM Interrupt Source

Name	Interrupt Source	DTC Activation	DMAC Activation
ECCERR	ECC error (SRAMs with ECC)	Not possible	Not possible
PARITYERR	Parity error (SRAMs with parity)	Not possible	Not possible
TZFLT	TrustZone filter error	Not possible	Not possible

50.3.8 Wait state

When ICLK frequencies is higher than 120 MHz, do not set 0x00 in wait enable bit for the SRAMWTSC register, in order to insert a wait cycle. When the wait is not inserted, the operation is not guaranteed.

Depending on the operating frequency of ICLK, the WAIT setting for SRAM access has the following conditions.

[ICLK frequency]:

- $240\text{ MHz} \geq \text{ICLK} > 120\text{ MHz} = 1\text{ wait}$
- $120\text{ MHz} \geq \text{ICLK} = \text{No-wait}$

50.4 Usage Note

50.4.1 Instruction fetch from SRAM area

When using SRAM to operate a program, initialize the SRAM area so that the CPU can correctly prefetch data. A parity or ECC error might occur if the CPU prefetches from an area that is not initialized. Initialize the additional 12-byte area from the end address of the program with the 8-byte boundary. Renesas recommends using the NOP instruction for data initialization.

50.4.2 Note of write to SRAMCR0, SRAMCR1 and SRAMECCRG0 registers

This chapter provides examples of how to configure SRAMCR0, SRAMCR1 and SRAMECCRG0.

All of the followings have to be satisfied:

1. CPU does not execute program stored in SRAM
2. All bus masters other than CPU does not access SRAM
3. SRAMCR0, SRAMCR1 and SRAMECCRG0 are Device-nGnRnE set by MPU
4. SRAMCR0, SRAMCR1 and SRAMECCRG0 have to be configured with the following procedure:
 1. DMB instruction
 2. Write to SRAMCR0, SRAMCR1 and SRAMECCRG0 registers
 3. DMB instruction

50.4.3 Notes on Using Error Checking of SRAM

Data in SRAM are undefined when the power is turned on. Therefore, parity check errors or ECC errors occur if the data are read before initialization. The SRAM are read in 8-byte (64-bit) units. Initialize them on 8-byte boundaries.

51. Standby SRAM

51.1 Overview

An on-chip SRAM is provided to retain data in Deep Software Standby mode. [Table 51.1](#) lists the Standby SRAM specifications.

Table 51.1 Standby SRAM specifications

Item	Description
SRAM capacity	1 KB
SRAM address	0x2600_0000 to 0x2600_03FF (Secure alias), 0x3600_0000 to 0x3600_03FF (Non-secure alias)
Access	Wait states are inserted into the access cycle by default. If the ICLK frequency is higher than 120 MHz, a wait state is required. If the ICLK frequency is 120 MHz or less, a wait state is not required.
Data retention function	Data can be retained in Deep Software Standby mode 1. In Deep Software Standby mode 2 and 3, data cannot be retained. See section 51.3.1. Data Retention for details.
parity	Even parity (data: 8 bits, parity: 1 bit)
Module-stop function	Module-stop state can be set to reduce power consumption. See section 51.3.2. Module-stop Function for details.
Security	Permits the read and write operations to Standby RAM following TrustZone Filter function. See section 51.3.4. TrustZone Filter function for details.

51.2 Register Descriptions

51.2.1 STBRAMSABAR : Standby SRAM Security Attribute Boundary Address Register

Base address: CPSCU = 0x4000_8000
CPSCU_NS = 0x5000_8000

Offset address: 0x420

Bit position: 31

0

Bit field:

Value after reset: 0 1 1 1 1 1 1 1 1 0 0 0 0 0 0 0

Bit	Symbol	Function	R/W
31:0	n/a	Boundary address between Secure and Non-secure.	R/W

Note: S-TYPE-1, P-TYPE-1

Note: This register is write-protected by PRCR_S.PRC4 register.

STBRAMSABAR specifies the boundary address between the Secure and Non-secure regions of Standby SRAM. Write the absolute address to the STBRAMSABAR. When writing to STBRAMSABAR, writing from b31 to b15 is ignored and the value written from b6 to b0 should be 0.

The region lower than the boundary address is marked as Secure, and higher than or equal to the boundary address is marked as Non-secure. Therefore, when the boundary address is 0x00000000, whole Standby SRAM is marked as Non-secure, and when the boundary address is 0x00000400 or large, whole Standby SRAM is marked as Secure.

The boundary address is as follow.

- 0x2600_0000 + STBRAMSABAR (Secure alias)
- 0x3600_0000 + STBRAMSABAR (Non-secure alias)

51.2.2 STBRAMPABAR_NS : Standby SRAM Privilege Attribute Boundary Address Register for Non-secure

Base address: CPSCU_NS = 0x5000_8000

Offset address: 0x490

Bit position: 31

0

Bit field:

n/a

Value after reset: 0

Bit	Symbol	Function	R/W
31:0	n/a	Boundary address between Privileged and Unprivileged.	R/W

Note: S-TYPE-7, P-TYPE-2

Note: This register is write-protected by PRCR_NS.PRC4 register.

STBRAMPABAR_NS specifies the boundary address between the Privileged and Unprivileged regions of Standby SRAM Non-secure regions set by STBRAMSABAR. Write the absolute address to the STBRAMPABAR_NS. When writing to STBRAMPABAR_NS, writing from b31 to b15 is ignored and the value written from b6 to b0 should be 0.

The region lower than the boundary address is marked as Privileged, and higher than or equal to the boundary address is marked as Unprivileged. Therefore, when the boundary address is 0x00000000, or less than or equal to start address of Standby SRAM Non-secure regions set by STBRAMSABAR, whole Standby SRAM is marked as Unprivileged, and when the boundary address is 0x00000400 or large, or higher than or equal to end address of Standby SRAM Non-secure regions set by STBRAMSABAR, whole Standby SRAM is marked as Privileged.

The boundary address is as follow.

- 0x3600_0000 + STBRAMPABAR_NS (Non-secure alias)

51.2.3 STBRAMPABAR_S : Standby SRAM Privilege Attribute Boundary Address Register for Secure

Base address: CPSCU = 0x4000_8000

Offset address: 0x494

Bit position: 31

0

Bit field:

n/a

Value after reset: 0

Bit	Symbol	Function	R/W
31:0	n/a	Boundary address between Privileged and Unprivileged.	R/W

Note: S-TYPE-6, P-TYPE-2

Note: This register is write-protected by PRCR_S.PRC4 register.

STBRAMPABAR_S specifies the boundary address between the Privileged and Unprivileged regions of Standby SRAM Secure regions set by STBRAMSABAR. Write the absolute address to the STBRAMPABAR_S. When writing to STBRAMPABAR_S, writing from b31 to b15 is ignored and the value written from b6 to b0 should be 0.

The region lower than the boundary address is marked as Privileged, and higher than or equal to the boundary address is marked as Unprivileged. Therefore, when the boundary address is 0x00000000, or less than or equal to start address of Standby SRAM Secure regions set by STBRAMSABAR, whole Standby SRAM is marked as Unprivileged, and when the boundary address is 0x00000400 or large, or higher than or equal to end address of Standby SRAM Secure regions set by STBRAMSABAR, whole Standby SRAM is marked as Privileged.

The boundary address is as follow.

- 0x2600_0000 + STBRAMPABAR_S (Secure alias)

51.2.4 STBRAMCR : Standby SRAM Control Register

Base address: SRAM = 0x4000_2000
SRAM_NS = 0x5000_2000

Offset address: 0x110

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	OAD

Value after reset: 0 0 0 0 0 0 0 0 0

Bit	Symbol	Function	R/W
0	OAD	Operation after detection 0: Non-maskable interrupt. 1: Reset.	R/W
7:1	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3 (SRAMSAR.STBRAMSA), P-TYPE-2

This register can be written only when the PR bit in the SRAMPRCR_S or SRAMPRCR_NS register is 1.

Do not write to this register while access to Standby SRAM is in progress.

OAD bit (Operation after detection)

This bit is specified to generate either reset or non-maskable interrupt when parity error is detected.

51.2.5 STBRAMEAR : Standby SRAM Error Address Register

Base address: SRAM = 0x4000_2000
SRAM_NS = 0x5000_2000

Offset address: 0x150

Bit position:	31	0
Bit field:	n/a	

Value after reset: 0

Bit	Symbol	Function	R/W
31:0	n/a	When an SRAM error occurs, it stores an error address.	R

Note: S-TYPE-5, P-TYPE-2

This register is cleared by the corresponding bit in SRAMESCLR register, or resets other than Bus Error Reset and Memory Error Reset. If error and clear occur at the same time, clear has priority. Also during accessing from debugger it is to stop updating register.

The error address is as follow.

- 0x2600_0000 + STBRAMEAR (Secure alias)
- 0x3600_0000 + STBRAMEAR (Non-secure alias)

This register stores the error address where parity error is detected. These bits hold the error address that occurred first. These bits are cleared by clearing parity error from SRAMESCLR.

51.3 Operation

51.3.1 Data Retention

The power supply to the Standby SRAM in Deep Software Standby mode is enabled by the DPSBYCR.SRKEEP bit. If the DPSBYCR.SRKEEP bit are set to 1b, data in the Standby SRAM is retained in Deep Software Standby mode 1. For details on the DPSBYCR.SRKEEP bit, see [section 10, Low Power Modes](#).

51.3.2 Module-stop Function

Power consumption can be reduced by setting module stop control register A (MSTPCRA) to stop supply of the clock signal to SRAM.

If the Standby SRAM bit in MSTPCRA is set to 1, supply of the clock signal to the Standby SRAM is stopped.

The Standby SRAM is thus placed in the module-stop state by stopping supply of the clock signals. The Standby SRAM operates after a reset.

The Standby SRAM is not accessible if it is in the module-stop state. A transition to the module-stop state should not be made while access to the standby SRAM is in progress.

Access to the Standby SRAM in the module-stop state is prohibited. If access is attempted, correct operation is not guaranteed.

For details on the MSTPCRA register, see [section 10, Low Power Modes](#).

51.3.3 Parity Calculation Function

The IEC60730 standard requires the checking of STBRAMCR data. When data is written, a parity bit is added to every 8-bit data in the Standby SRAM which has 32-bit data width, and when data is read, the parity is checked. When a parity error occurs, a parity error notification is generated. This function can also be used to trigger a reset.

The parity-error notification can be specified as a non-maskable interrupt or a reset in the OAD bit of the STBRAMCR register. When the OAD bit is set to 1, a parity error is output to the reset function. When the OAD bit is set to 0, a parity error is output to the ICU as a non-maskable interrupt.

Parity errors often occur because of noise. To confirm whether the cause of the parity error is noise or corruption, follow the parity check flows shown in [Figure 51.1](#) and [Figure 51.2](#).

When a read access is executed in a row after a write access, read access is executed with priority. Therefore, during initialization, do not perform the read access in a row after the write access.

Figure 51.1 Flow of Standby SRAM parity check when SRAM parity reset is enabled

Figure 51.2 Flow of Standby SRAM parity check when SRAM parity interrupt is enabled

51.3.4 TrustZone Filter function

51.3.4.1 TrustZone Filter for Standby SRAM registers

Standby SRAM registers can be protected with a Security Attribution (SA) from Non-secure or Secure transaction. When SA indicates that Standby SRAM registers are Secure status, Non-secure transaction can not access them because TrustZone Filter detects finds an error and protects the access. When SA indicates that SRAM registers are Non-secure status, Secure transaction can not access them because Trust Zone Filter detects finds an error and protects the access. SA for Standby SRAM registers is just one to be used commonly among Standby SRAM registers.

In the case of a failed access due to TrustZone error, error response is generated.

Table 51.2 Standby SRAM register protection

SA	Transaction	Write access	Read access
Secure	Secure	Permitted	Permitted
	Non-secure	Protected (TrustZone Filter error)	Protected (TrustZone Filter error)
Non-secure	Secure	Protected (TrustZone Filter error)	Protected (TrustZone Filter error)
	Non-secure	Permitted	Permitted

51.3.4.2 TrustZone Filter for Standby SRAM memory regions

Standby SRAM regions can be divided into Secure and Non-secure. The access permissions for these regions are as below.

Table 51.3 Standby SRAM memory protection by Security Attribution

SA	Transaction	Write access	Read access
Secure	Secure	Permitted	Permitted
	Non-secure	Protected (TrustZone Filter error)	Protected (TrustZone Filter error)
Non-secure	Secure	Protected (TrustZone Filter error)	Protected (TrustZone Filter error)
	Non-secure	Permitted	Permitted

Standby SRAM regions can be divided into Privileged and Unprivileged. The access permissions for these regions are as below.

Table 51.4 Standby SRAM memory protection by Privilege Attribution

PA	Transaction	Write access	Read access
Privileged	Privileged	Permitted	Permitted
	Unprivileged	Protected (TrustZone Filter error)	Protected (TrustZone Filter error)
Unprivileged	Privileged	Permitted	Permitted
	Unprivileged	Permitted	Permitted

TrustZone Filter error for Standby SRAM memory generates an error notification.

For details, see [section 43, Security Features](#).

51.3.5 Interrupt Source

The Standby SRAM interrupt source includes a Parity error and TrustZone filter error.

Parity error can choose non-maskable interrupt or reset by STBRAMCR.OAD bit.

The Standby SRAM interrupt occurs when the SRAMESR.ERRS is set to 1. the Standby SRAM interrupt continues to occur until the SRAMESR.ERRS is cleared.

When Common memory error occur(NMISR.CMST=1 or RSTSR1.CMSR=1), please read SRAMESR and check SRAM interrupt source. When the access from debugger, no error flag is set, reset and non-maskable interrupt are maskable.

For more detail on the debug mode, see [section 2, CPU](#).

Table 51.5 Standby SRAM Interrupt Source

Name	Interrupt Source	DTC Activation	DMAC Activation
PARITYERR	Parity error	Not possible	Not possible
TZFLT	TrustZone filter error	Not possible	Not possible

51.3.6 Wait state

When ICLK frequencies is higher than 120 MHz, do not set 0x00 in wait enable bit for the SRAMWTSC register, in order to insert a wait cycle. When the wait is not inserted, the operation is not guaranteed.

Depending on the operating frequency of ICLK, the WAIT setting for Standby SRAM access has the following conditions.

[ICLK frequency]:

- $240\text{ MHz} \geq \text{ICLK} > 120\text{ MHz} = 1\text{ wait}$
- $120\text{ MHz} \geq \text{ICLK} = \text{No-wait}$

51.4 Usage Notes

51.4.1 Instruction Fetch from the Standby SRAM Area

When using Standby SRAM to operate a program, initialize the Standby SRAM area so that the CPU can correctly prefetch data. A parity error might occur if the CPU prefetches from an area that is not initialized. Initialize the additional 12-byte area from the end address of the program with the 4-byte boundary. Renesas recommends using the NOP instruction for data initialization.

51.4.2 Notes on Self-Diagnosis of the Standby SRAM

A write buffer is mounted for the Standby Standby SRAM. When the same address is read after a write operation, data in the write buffer, rather than in the memory cell of the Standby SRAM may be read. When the Standby SRAM is self-diagnosed, confirm that the data have been written by following the procedure below so that data will not be read from the write buffer.

1. Write data to the address targeted for diagnosis.
2. Write data to an address which is at least 4 addresses away from the that in step1.
3. Read the data from the address in step1.

52. Flash Memory

This MCU incorporates code flash memory, data flash memory, and option-setting memory. The code flash memory stores instructions and operands, and the data flash memory stores data. For option-setting memory, see [section 6, Option-Setting Memory](#).

52.1 Overview

[Table 52.1](#) lists the specifications of the flash memory, and [Figure 52.1](#) is block diagrams of the flash memory related modules.

The I/O pins used in boot mode, see [Table 52.37](#).

The FCU (flash control unit) controls programming and erasure of the flash memory. The FACL (flash application command interface) controls the FCU according to the specified FACL commands.

Regarding the configuration of the code flash memory, see [Figure 52.2](#) to [Figure 52.3](#), and for the configuration of the data flash memory, see [Figure 52.4](#).

Table 52.1 Specifications of flash memory (1 of 2)

Item	Code flash memory	Data flash memory
Memory capacity	User area: 2 Mbytes max	Data area: 12 Kbytes
Value after erasure	0xFF	Undefined
Programming/erasing method	- Programming and erasing the code flash memory and data flash memory, and programming the option-setting memory are handled by the FACL commands specified in the FACL command issuing area (Secure: 0x4010_0000, Non-secure: 0x5010_0000) (self-programming). - Programming/erasure through transfer by a serial-programmer via a serial interface (serial programming)	
Protection	Protects against erroneous rewriting of the flash memory	
Dual bank function	The dual-bank structure makes a safe update possible in cases where programming is suspended. - Linear mode: the code flash memory is used as one area. - Dual mode: the code flash memory is divided into two areas.	Not available
Block swap function	The block swap structure makes a safe update for a part of Non-secure application possible in case where programming is suspended.	Not available
Background operations (BGOs)	- The code flash memory can be read while the code flash memory is being programmed or erased. - The data flash memory can be read while the code flash memory is being programmed or erased. - The code flash memory can be read while the data flash memory is being programmed or erased.	
Units of programming and erasure	- Units of programming for the user area: 128 bytes - Units of erasure for the user area: Block units	- Unit of programming for the data area: 4/8/16 bytes - Unit of erasure for the data area: 64/128/256 bytes
Other functions	Interrupts can be accepted during self-programming. In the initial settings of this MCU, an expansion area of the option-setting memory can be set.	
On-board programming (four types)	Programming/erasure in boot mode (for the SCI interface) - The asynchronous serial interface (SCI9) is used. - The transfer rate is adjusted automatically. Programming/erasure in boot mode (for the USB interface) - USBFS is used. - Dedicated hardware is not required, so direct connection to a PC is possible. Programming/erasure in On-chip debug mode - JTAG or SWD interface is used Programming and erasure by self-programming - This allows code flash memory programming/erasure without resetting the system.	

Table 52.1 Specifications of flash memory (2 of 2)

Item	Code flash memory	Data flash memory
Unique ID	A 16-byte ID code provided for each MCU	
FACI command	Program : 128 bytes Block erase: 1 block (8 KB or 32 KB) P/E suspend P/E resume Forced Stop Status Clear Configuration set (16 bytes)	Program: 4/8/16 bytes Block Erase: 1 block (64 bytes) Multi Block Erase: 64/128/256 bytes P/E suspend P/E resume Forced Stop Blank Check: 4 bytes to data flash memory capacity Status Clear Configuration set (4/16 Bytes) Increment Counter: 1bit Refresh Counter Read Counter: 8 Bytes
Security function	Protects against illicit tampering with or reading out of data in flash memory Startup area select setting protection • BTFLG and FSUACR registers are protected by the FSPR bit. Permanent block protect setting protection • Code flash memory is permanently protected from programming/erasure operation by the permanent block protect function. Flash memory protection for TrustZone • Protection for flash memory area (P/E) • Protection for flash memory area (read) • Protection for register • Protection during FACI command operation. • Code flash P/E mode entry protection • Data flash configuration area protection • Anti-rollback Counter	
Safety function	Software protection • FACI command protection by FENTRYR register. • Flash memory is protected by FWEPROR register • The user area is protected by the block protect setting Error protection • Error is detected when unintended commands or prohibited settings occur. The FACI command is not accepted after an error detection. Boot area protection • The start-up area select function allows customer to safely update the boot firmware. The size of the start-up area is 8 KB.	
Interrupt request	• FRDYI (flash sequencer ready (processing end)) : Enabled by FRDYIE bit. • FIFERR (flash sequencer error) : Enabled by CFAEIE/CMDLKIE/DFAEIE bits	
Address conversion	Start-up area select function is supported in linear mode Dual mode and Linear mode • Bank swap function is supported in dual mode • Block swap function is supported in linear mode	

Figure 52.1 shows how modules related to flash memory can be configured. The flash sequencer is configured with the FCU and FACI. The FCU executes basic control for rewriting of the flash memory. The FACI receives FACI commands using peripheral bus, and controls FCU operations accordingly.

In response to a reset, the FACI transfers data from the flash memory to the option byte storage registers.

Figure 52.1 Block diagram of flash memory-related modules

52.2 Structure of Memory

Figure 52.2 shows the memory map of code flash memory in linear mode. Figure 52.3 shows the memory map of code flash memory in dual mode. This MCU can use the code flash memory as 2 bank areas by using the dual bank function. This dual-bank structure allows a safe update of a program while a user program is running.

The user area of the code flash memory in this MCU is divided into 8 KB and 32 KB blocks, which serve as the units of erasure.

Figure 52.2 Map of the Code Flash Memory in Linear Mode

Table 52.2 Read and programming/erasure address by product for the code flash memory in Linear Mode

Product	Address	Number of blocks
2 MB product	Secure alias : 0x0200_0000 to 0x021F_7FFF Non-secure alias : 0x1200_0000 to 0x121F_7FFF	0 to 68
1 MB product	Secure alias : 0x0200_0000 to 0x020F_FFFF Non-secure alias : 0x1200_0000 to 0x120F_FFFF	0 to 37

Figure 52.3 Map of the Code Flash Memory in Dual Mode

Table 52.3 Read and programming/erasure address by product for the code flash memory in Dual Mode

Product	Address	Number of blocks
2 MB product, lower side bank	Secure alias : 0x0200_0000 to 0x020F_7FFF Non-secure alias : 0x1200_0000 to 0x120F_7FFF	0 to 36
2 MB product, upper side bank	Secure alias : 0x0220_0000 to 0x022F_7FFF Non-secure alias : 0x1220_0000 to 0x122F_7FFF	70 to 106
1 MB product, lower side bank	Secure alias : 0x0200_0000 to 0x0207_FFFF Non-secure alias : 0x1200_0000 to 0x1207_FFFF	0 to 21
1 MB product, upper side bank	Secure alias : 0x0220_0000 to 0x0227_FFFF Non-secure alias : 0x1220_0000 to 0x1227_FFFF	70 to 91

The data area of the data flash memory in this MCU is divided into 64 byte blocks, with each being a unit for erasure.

Figure 52.4 shows the mapping of the data flash memory.

Figure 52.4 Map of the Data Flash Memory

52.3 Address Space

Using the hardware interface with flash memory requires access to all registers of the hardware, which is for issuing FACI commands. [Table 52.4](#) provides information about the hardware interface.

Table 52.4 Information on the hardware interface area

Area	Address	Capacity
Area containing various registers of the hardware	See section 52.4. Register Descriptions .	See section 52.4. Register Descriptions .
FACI command-issuing area	Secure alias : 0x4010_0000 Non-secure alias : 0x5010_0000	4 bytes

For the address information of the flash memory, see [Figure 52.2](#).

52.4 Register Descriptions

52.4.1 FCACHEE : Flash Cache Enable Register

Base address: FCACHE = 0x4001_C100
FCACHE_NS = 0x5001_C100

Offset address: 0x000

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	FCACHEEN
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	FCACHEEN	Flash Cache Enable 0: FCACHE is disabled 1: FCACHE is enabled	R/W
15:1	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-2

Note: Associated SA: FSAR register. See [section 52.4.4. FSAR : Flash Security Attribution Register](#).

FCACHEEN bit (Flash Cache Enable)

FCACHEE.FCACHEEN bit enable and disables the function of Flash Cache of FCACHE1, FCACHE2 and FLPF.

FCACHEE.FCACHEEN bit does not influence for FCACHEIV.FCACHEIV.

When FCACHE is enabled, it works for accesses marked as cacheable.

It is prohibited to disable FCACHE after enabling.

52.4.2 FCACHEIV : Flash Cache Invalidate Register

Base address: FCACHE = 0x4001_C100
FCACHE_NS = 0x5001_C100

Offset address: 0x004

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	FCACHEIV
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	FCACHEIV	Flash Cache Invalidate 0: Read: Do not invalidate. Write: The setting is ignored. 1: Invalidate FCACHE is invalidated.	R/W
15:1	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-5, P-TYPE-2

This register is not controlled by any security attribute register.

FCACHEIV bit (Flash Cache Invalidate)

When 1 is written to FCACHEIV.FCACHEIV bit, the Flash cache data of FCACHE1, FCACHE2 and FLPF is invalidated.

Invalidate FCACHE with keeping FCACHE enabled after programming or erasing the code flash or the option setting memory.

52.4.3 FLWT : Flash Wait Cycle Register

Base address: FCACHE = 0x4001_C100
FCACHE_NS = 0x5001_C100

Offset address: 0x01C

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	FLWT[2:0]		
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
2:0	FLWT[2:0]	Flash Wait Cycle 0 0 0: 0 wait (ICLK ≤ 48 MHz) 0 0 1: 1 wait (48 MHz < ICLK ≤ 96 MHz) 0 1 0: 2 wait (96 MHz < ICLK ≤ 144 MHz) 0 1 1: 3 wait (144 MHz < ICLK ≤ 192 MHz) 1 0 0: 4 wait (192 MHz < ICLK ≤ 240 MHz) Others: Setting prohibited	R/W
7:3	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-2

Note: Associated SA: FSAR register. See [section 52.4.4. FSAR : Flash Security Attribution Register](#).

FLWT[2:0] bits (Flash Wait Cycle)

The Flash Wait Cycle Register (FLWT) sets the access wait count for the flash memory.

For faster clock frequencies, set FLWT.FLWT before changing the clock frequency. For slower clock frequencies, set FLWT.FLWT after changing the clock frequency.

For information on the frequency setting, see [section 8, Clock Generation Circuit](#).

52.4.4 FSAR : Flash Security Attribution Register

Base address: FCACHE = 0x4001_C100
FCACHE_NS = 0x5001_C100

Offset address: 0x040

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	FACIC MRSA	FACIC MISA	FCKM HZSA	—	—	—	—	—	—	FCAC HESA	FLWT SA
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	FLWTSA	FLWT Security Attribution Target register : FLWT 0: Secure 1: Non-secure	R/W
1	FCACHESA	FCACHEEN Security Attribution Target register : FCACHEEN 0: Secure 1: Non-secure	R/W
7:2	—	These bits are read as 0. The write value should be 0.	R/W
8	FCKMHZSA	FCKMHZ Security Attribution Target register : FCKMHZ 0: Secure 1: Non-secure	R/W
9	FACICMISA	FACI command Issuing Security Attribution Target area : Flash access area 0: Secure 1: Non-secure	R/W
10	FACICMRSA	FACI command Registers Security Attribution Target registers : FASTAT, FAEINT, FRDYIE, FSADDR, FEADDR, FBPROT1, FSTATR, FENTRYR, FSUINITR, FCMDR, FBCCNT, FBCSTAT, FPSADDR, FSUASMON, FCPSR, FPCKAR, FWEPROR 0: Secure 1: Non-secure	R/W
15:11	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-1, P-TYPE-1

Note: Set the PRCR.PRC4 bit to 1 (write enabled) before rewriting this register.

FLWTSA bit (FLWT Security Attribution)

This bit sets the security attribute of FLWT.

FCACHESA bit (FCACHEEN Security Attribution)

This bit sets the security attribute of FCACHEEN.

FCKMHZSA bit (FCKMHZ Security Attribution)

This bit sets the security attribute of Flash access area.

FACICMISA bit (FACI command Issuing Security Attribution)

This bit sets the security attribute of Flash access area.

FACICMRSA bit (FACI command Registers Security Attribution)

This bit sets the security attribute of FACI command security registers.

52.4.5 UIDRn : Unique ID Registers n (n = 0 to 3)

Address: 0x0300_8190 + n × 4 (Secure)
0x1300_8190 + n × 4 (Non-secure)

Bit	Symbol	Function	R/W
31:0	UID	Unique ID	R

Note: S-TYPE-5, P-TYPE-5

The UIDRn is a read-only register that stores a 16-byte ID code (unique ID) for identifying the individual MCU. The UIDRn register should be read in 32-bit units. When reading by the signature request command of the serial programming interface, the data is read in order from the data with the large address. That is, the data in 0x0300_819F is read first, and in 0x0300_8190 is read last.

52.4.6 PNRn : Part Numbering Register n (n = 0 to 3)

Address: 0x0300_80F0 + n × 4 (Secure)
0x1300_80F0 + n × 4 (Non-secure)

Bit	Symbol	Function	R/W
31:0	PNR	Part Number	R

Note: S-TYPE-5, P-TYPE-5

The PNRn is a read-only register that stores a 16-byte part numbering. The PNRn register should be read in 32-bit units. Each byte corresponds to the ASCII code representation of the product part number as detailed in [Table 1.13](#). The first character ("R", 0x52 in ASCII code) of the part number is stored in the byte with the smallest address (0x0300_80F0). When reading by the signature request command of the serial programming interface, the data is read in order from the data with the small address. That is, the data in 0x0300_80F0 is read first, and in 0x0300_80FF is read last.

52.4.7 MCUVER : MCU Version Register

Address: 0x0300_81B0 (Secure)
0x1300_81B0 (Non-secure)

Bit	Symbol	Function	R/W
7:0	MCUVE	MCU Version	R

Note: S-TYPE-5, P-TYPE-5

The MCUVER is a read-only register that stores a MCU version. The MCUVER register should be read in 8-bit units.

52.4.8 FWEPROR : Flash P/E Protect Register

Base address: SYSC = 0x4001_E000
SYSC_NS = 0x5001_E000

Offset address: 0xA54

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	FLWE[1:0]	
Value after reset:	0	0	0	0	0	0	1	0

Bit	Symbol	Function	R/W
1:0	FLWE[1:0]	Flash Programming and Erasure 0 0: Prohibits Program, Block Erase, Multi Block Erase, Blank Check, and Configuration set command processing. 0 1: Permits Program, Block Erase, Multi Block Erase, Blank Check, and Configuration set command processing. 1 0: Prohibits Program, Block Erase, Multi Block Erase, Blank Check, and Configuration set command processing. 1 1: Prohibits Program, Block Erase, Multi Block Erase, Blank Check, and Configuration set command processing.	R/W
7:2	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-2

It is possible that Program, Block Erase, Multi Block Erase, Blank Check, and Configuration set command processing are prohibited by software.

The FWEPROR register is initialized by a reset from the following:

- All reset source except for VBATT_POR reset
- Transition to Deep Software Standby mode
- Transition to Software Standby mode.

FLWE[1:0] bits (Flash Programming and Erasure)

The FLWE[1:0] bits are used to set the flash P/E protection. The value after reset is 10b.

If these bits are set to other than 01b that does not allow programming and erasure of the flash memory, the following commands cannot be executed. Issuing any of the following commands leads to setting of the FLWEERR bit in the FSTATR register to 1.

Program / Block Erase / Multi Block Erase / Blank Check / Configuration set command

52.4.9 FASTAT : Flash Access Status Register

Base address: FACL = 0x4011_E000
FACL_NS = 0x5011_E000

Offset address: 0x10

Bit position:	7	6	5	4	3	2	1	0
Bit field:	CFAE	—	—	CMDL K	DFAE	—	—	—
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
2:0	—	These bits are read as 0. The write value should be 0.	R/W
3	DFAE	Data Flash Memory Access Violation Flag 0: No data flash memory access violation has occurred 1: A data flash memory access violation has occurred.	R/W ¹

Bit	Symbol	Function	R/W
4	CMDLK	Command Lock Flag 0: The flash sequencer is not in the command-locked state 1: The flash sequencer is in the command-locked state.	R
6:5	—	These bits are read as 0. The write value should be 0.	R/W
7	CFAE	Code Flash Memory Access Violation Flag 0: No code flash memory access violation has occurred 1: A code flash memory access violation has occurred.	R/W ^{*1}

Note: S-TYPE-3, P-TYPE-2

Note: Associated SA: FSAR register. See [section 52.4.4. FSAR : Flash Security Attribution Register](#)

Note 1. Only 0 can be written to clear the flag after 1 is read.

The FASTAT register indicates whether a code flash or data flash memory access violation has occurred. If any of the CFAE, CMDLK, and DFAE bits is set to 1, the flash sequencer enters the command-locked state (see [section 52.11.2. Error Protection](#)). To release it from the command-locked state, issue a status clear command or Forced Stop command to the flash sequencer.

DFAE bit (Data Flash Memory Access Violation Flag)

The DFAE bit indicates whether a data flash memory access violation occurred. When this bit is set to 1, the ILGLERR bit in the FSTATR register is set to 1, placing the flash sequencer in the command-locked state.

[Setting conditions]

FACI commands issued in the data flash P/E mode are as follows:

- The setting of the FSADDR or FEADDR register is the reserved portion of the data area
- The Configuration set command is issued while the setting of the FSADDR register is out of 0x2703_0050 to 0x2703_03FF.
- FACI command is issued to data flash memory with the wrong security attribution.

[Clearing conditions]

- When this bit is written as 0 after it is set to 1
- When the flash sequencer starts to process the Status Clear or Forced Stop command.

CMDLK bit (Command Lock Flag)

The CMDLK bit indicates that the flash sequencer is in the command-locked state.

[Setting conditions]

- The flash sequencer detects an error and enters the command-locked state.

[Clearing conditions]

- When the flash sequencer starts to process the Status Clear or Forced Stop command.

CFAE bit (Code Flash Memory Access Violation Flag)

The CFAE bit indicates whether a code flash memory access violation has occurred. When this bit is set to 1, the ILGLERR bit in the FSTATR register is set to 1, placing the flash sequencer in the command-locked state.

[Setting conditions]

FACI commands issued in the code flash P/E mode are as follows:

- The setting of the FSADDR register is the reserved portion of the user area
- The Configuration set command is issued while the setting of the FSADDR register is from 0x0200_A100 to 0x0200_A2F0 in self-programming mode
- FACI command is issued to code flash memory with the wrong security attribution.

[Clearing conditions]

- When this bit is written as 0 after it is set to 1

- When the flash sequencer starts to process the Status Clear or Forced Stop command.

52.4.10 FAEINT : Flash Access Error Interrupt Enable Register

Base address: FACL = 0x4011_E000
FACL_NS = 0x5011_E000

Offset address: 0x14

Bit position:	7	6	5	4	3	2	1	0
Bit field:	CFAEIE	—	—	CMDLKIE	DFAEIE	—	—	—
Value after reset:	1	0	0	1	1	0	0	0

Bit	Symbol	Function	R/W
2:0	—	These bits are read as 0. The write value should be 0.	R/W
3	DFAEIE	Data Flash Memory Access Violation Interrupt Enable 0: Generation of an FIFERR interrupt request is disabled when FASTAT.DFAE is set to 1 1: Generation of an FIFERR interrupt request is enabled when FASTAT.DFAE is set to 1.	R/W
4	CMDLKIE	Command Lock Interrupt Enable 0: Generation of an FIFERR interrupt request is disabled when FASTAT.CMDLK is set to 1 1: Generation of an FIFERR interrupt request is enabled when FASTAT.CMDLK is set to 1.	R/W
6:5	—	These bits are read as 0. The write value should be 0.	R/W
7	CFAEIE	Code Flash Memory Access Violation Interrupt Enable 0: Generation of an FIFERR interrupt request is disabled when FASTAT.CFAE is set to 1 1: Generation of an FIFERR interrupt request is enabled when FASTAT.CFAE is set to 1.	R/W

Note: S-TYPE-3, P-TYPE-2

Note: Associated SA: FSAR register. See [section 52.4.4. FSAR : Flash Security Attribution Register](#).

The FAEINT register enables or disables generation of a flash access error (FIFERR) interrupt request.

DFAEIE bit (Data Flash Memory Access Violation Interrupt Enable)

The DFAEIE bit enables or disables generation of an FIFERR interrupt request when a data flash memory access violation occurs, setting the DFAE bit in the FASTAT register to 1.

CMDLKIE bit (Command Lock Interrupt Enable)

The CMDLKIE bit enables or disables generation of an FIFERR interrupt request when the flash sequencer enters the command-locked state, setting the CMDLK bit in the FASTAT register to 1.

CFAEIE bit (Code Flash Memory Access Violation Interrupt Enable)

The CFAEIE bit enables or disables generation of an FIFERR interrupt request when a code flash memory access violation occurs, setting the CFAE bit in the FASTAT register to 1.

52.4.11 FRDYIE : Flash Ready Interrupt Enable Register

Base address: FACL = 0x4011_E000
FACL_NS = 0x5011_E000

Offset address: 0x18

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	FRDYIE
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	FRDYIE	Flash Ready Interrupt Enable 0: Generation of an FRDY interrupt request is disabled 1: Generation of an FRDY interrupt request is enabled.	R/W
7:1	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-2

Note: Associated SA: FSAR register. See [section 52.4.4. FSAR : Flash Security Attribution Register](#)

The FRDYIE register enables or disables generation of a flash ready (FRDY) interrupt request.

FRDYIE bit (Flash Ready Interrupt Enable)

The FRDYIE bit enables or disables generation of an FRDY interrupt request when the FRDY bit in the FSTATR register is changed from 0 to 1 on completion of processing by the flash sequencer of the Program, Block Erase, Multi Block Erase, Blank Check, and Configuration set command.

52.4.12 FSADDR : FACL Command Start Address Register

Base address: FACL = 0x4011_E000
FACL_NS = 0x5011_E000

Offset address: 0x30

Bit position: 31

0

Bit field:

FSADDR[31:0]

Value after reset: 0

Bit	Symbol	Function	R/W
31:0	FSADDR[31:0]	Start Address for FACL Command Processing	R/W*1

Note: S-TYPE-3, P-TYPE-2

Note: Associated SA: FSAR register. See [section 52.4.4. FSAR : Flash Security Attribution Register](#)

Note 1. These bits can be written when the FRDY bit in the FSTATR register is 1. Writing to these bits are ignored when the FRDY bit is 0.
Note that b0 and b1 are read-only.

Table 52.5 FACL command address boundary

Command	Address Boundary
Program (code flash memory)	128 byte
Program (data flash memory)	4, 8, 16 byte
Block Erase (code flash memory)	8 KB or 32 KB
Block Erase (data flash memory)	64 byte
Multi Block Erase (data flash memory)	64 byte
Blank Check (data flash memory)	4 byte
For code flash configuration set	16 byte
For data flash configuration set	4, 16 byte

The FSADDR register specifies the address where the target area for command processing starts when the FACL command for Program, Block Erase, Multi Block Erase, Blank Check, or Configuration set is issued.

The FSADDR value is initialized when the SUINIT bit in the FSUINITR register is set to 1. It is also initialized by a reset.

FSADDR[31:0] bits (Start Address for FACL Command Processing)

The FSADDR[31:0] bits specify the start address for FACL command processing. Bits [31:29] and [27:24] are ignored in FACL command processing for the code flash memory. Bits [31:29] and [27:13] are ignored in FACL command processing for the data flash memory. Bit [28] is used the security alias for flash sequencer command. When bit [28] is "0", flash sequencer can update secure region with secure access. When bit [28] is "1", flash sequencer can update non-security region with secure and non-secure access. Bits associated with the address bits of lower order than the address boundary listed in [Table 52.5](#) are also ignored.

For information on the addresses of the code flash memory and the data flash memory, see [section 52.2. Structure of Memory](#).

For information on the addresses of the configuration setting, see [section 52.9.3.15. Configuration Set Command](#).

52.4.13 FEADDR : FACL Command End Address Register

Base address: FACL = 0x4011_E000
FACL_NS = 0x5011_E000

Offset address: 0x34

Bit position: 31

0

Bit field:

FEADDR[31:0]

Value after reset: 0

Bit	Symbol	Function	R/W
31:0	FEADDR[31:0]	End Address for FACL Command Processing	R/W ^{*1}

Note: S-TYPE-3, P-TYPE-2

Note: Associated SA: FSAR register. See [section 52.4.4. FSAR : Flash Security Attribution Register](#)

Note 1. These bits can be written when the FRDY bit in the FSTATR register is 1. Writing to these bits are ignored when the FRDY bit is 0. Note that bit [0] and bit [1] are read-only.

The FEADDR register specifies the end address of the target area for Multi Block Erase and Blank Check command processing. When incremental mode is selected as the addressing mode for Blank Checking (when FBCCNT.BCDIR = 0), the address specified in the FSADDR register should be equal to or smaller than the address in the FEADDR register. Conversely, the address in the FSADDR register should be equal to or larger than the address in the FEADDR register when decremental mode is selected as the addressing mode for Blank Check (i.e. when FBCCNT.BCDIR = 1). If the BCDIR, FSADDR, and FEADDR bit settings are inconsistent with the specified rules, the flash sequencer enters the command-locked state (see [section 52.11.2. Error Protection](#)).

The FEADDR value is initialized when the SUINIT bit in the FSUINITR register is set to 1. It is also initialized by a reset.

FEADDR[31:0] bits (End Address for FACL Command Processing)

The FEADDR[31:0] bits specify the end address for Multi Block Erase and Blank Check command processing. In command processing, bits 31 to 17 and any bits that do not reach the address boundaries listed in the [section 52.4.12. FSADDR : FACL Command Start Address Register](#) are ignored.

For information on the addresses of the flash memory, see [section 52.2. Structure of Memory](#).

52.4.14 FMEPROT : Flash P/E Mode Entry Protection Register

Base address: FACL = 0x4011_E000

Offset address: 0x44

Bit position: 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

Bit field:

KEY[7:0]

Value after reset: 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 x 1

Bit	Symbol	Function	R/W
0	CEPROT	Code Flash P/E Mode Entry Protection 0: FENTRYC bit is not protected 1: FENTRYC bit is protected.	R/W ^{*1 *2 *4}
1	—	The read value is undefined. The write value should be 0.	R/W
7:2	—	These bits are read as 0. The write value should be 0.	R/W
15:8	KEY[7:0]	Key Code	W ^{*3}

Note: S-TYPE-6, P-TYPE-2

Note 1. Writing to this bit is only possible when the FRDY bit in the FSTATR register is 1. Writing to this bit while the FRDY bit = 0 is ignored.

Note 2. Writing to this bit is only possible when 16 bits are written and the value written to the KEY bits is 0xD9.

Note 3. Written values are not retained by these bits (always read as 0x00).

Note 4. Only Secure access can write to this register. Both Secure access and Non-secure read access are allowed. Non-secure write access is denied, but TrustZone access error is not generated.

CEPROT bit (Code Flash P/E Mode Entry Protection)

The CEPROT bit specifies the protection setting of the FRNTRYC bit in the FENTRYR register.

[Setting condition]

- 1 being written to the CEPROT bit while writing to FMEPROT is enabled.

[Clearing condition]

- 0 being written to the CEPROT bit while writing to FMEPROT is enabled.

52.4.15 FCNTSELR : Flash Counter Select Register

Base address: FACL = 0x4011_E000

Offset address: 0x048

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	CNTSEL[2:0]		
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
2:0	CNTSEL[2:0]	Counter Select 0 0 0: Anti-rollback counter is not selected 0 0 1: ARC_SEC is selected. Counter size is 64 bits. 0 1 0: ARC_OEMBL is selected. Counter size is 64 bits. 0 1 1: Anti-rollback counter is not selected. 1 x x: ARC_NSEC is selected. Counter configuration is 64 or 256 bits. See , Table 52.6 Table 52.7 and Table 52.8 in details counter select condition. Others: Setting prohibited	R/W
7:3	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-6, P-TYPE-2

Note: If the security attribution is configured as Secure:

- Secure access and Non-secure read access are allowed
- Non-secure write access is ignored, and TrustZone access error is not generated.

If the security attribution is configured as Non-secure:

- Secure and Non-secure access are allowed.

CNTSEL[2:0] bits (Counter Select)

FCNTSELR specifies 3 types of anti-rollback counter (ARC_SEC, ARC_NSEC, or ARC_OEMBL) in "Increment Counter", "Refresh Counter", or "Read Counter" command.

FCNTSELR value is initialized when SUINIT bit in FSUINTR is set to "1"

Note: This bit can be written when the FRDY bit in the FSTATR register is 1. Writing to this bit is ignored when the FRDY bit is 0.

Before using the ARC_NSEC counter, it is necessary to set whether the counter is to be used with 4line x 64 bits or 1line x 256 bits using the Data Flash configuration set command. The bits to be set are CNF_ARCNS0 and CNF_ARCNS1. If the CNF_ARCNS1 bit is set to 1, the ARC_NSEC counter cannot be used. Once the counter type is decided, it cannot be changed.

Table 52.6 Select condition of ARC_NSEC (64 bits) in Increment/Refresh/Read Counter Command

FCNTSEL _R [2:0]	Target Counter	Counter Configuration
100	ARC_NSEC[63:0]	Counter number is 4. Counter size is 64bit.
101	ARC_NSEC[127:64]	
110	ARC_NSEC[191:128]	
111	ARC_NSEC[255:192]	

Table 52.7 Select condition of ARC_NSEC (256 bits) in Increment/Refresh Counter Command

FCNTSEL _R [2:0]	Target Counter	Counter Configuration
100	ARC_NSEC[255:0]	Counter number is 1. Counter size is 256bit.
101		
110		
111		

Table 52.8 Select condition of ARC_NSEC (256 bits) in Read Counter Command

FCNTSEL _R [2:0]	Target Counter	Counter Configuration
100	ARC_NSEC[63:0]	Counter number is 1. Counter size is 256bit.
101	ARC_NSEC[127:64]	
110	ARC_NSEC[191:128]	
111	ARC_NSEC[255:192]	

52.4.16 FCNTDATAR_n : Flash Counter Data Register n (n = 0, 1)

Base address: FACL = 0x4011_E000

Offset address: 0x04C + 0x004 × n (n = 0, 1)

Bit position: 31

0

Bit field:

CNTRDAT

Value after reset:

Unique value for each chip

Bit	Symbol	Function	R/W
31:0	CNTRDAT	Counter Read Data Reading data of 32 bits (LSB side of counter values) is output to FCNTDATAR0. Reading data of 32 bits (MSB side of counter values) is output to FCNTDATAR1.	R

Note: S-TYPE-6, P-TYPE-2

FCNTDATAR0 and FCNTDATAR1 indicate anti-rollback counter values (64 bits) that read by "Read Counter" command.

CNTRDAT bit (Counter Read Data)

[Setting condition]

- FACL has accepted "Read Counter" command.

[Clearing condition]

- FACL has accepted flash sequencer command except for "Read Counter" command.
- Flash sequencer enters "Command Lock" state

52.4.17 FBPROT0 : Flash Block Protection Register

Base address: FACL = 0x4011_E000
FACL_NS = 0x5011_E000

Offset address: 0x78

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	KEY[7:0]								—	—	—	—	—	—	—	BPCN 0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	BPCN0	Block Protection for Non-secure Cancel 0: Block protection is enabled 1: Block protection is disabled.	R/W*1 *2
7:1	—	These bits are read as 0. The write value should be 0.	R/W
15:8	KEY[7:0]	Key Code	W*3

Note: S-TYPE-3, P-TYPE-2

Note: Associated SA: FSAR register. See [section 52.4.4. FSAR : Flash Security Attribution Register](#)

Note 1. This bit can be written when the FRDY bit in the FSTATR register is 1. Writing to this bit is ignored when the FRDY bit is 0.

Note 2. Writing to this bit is only possible when 16 bits are written and the value written to the KEY[7:0] bits is 0x78.

Note 3. Written values are not retained by these bits (always read as 0x00).

The FBPROT0 register is used to disable the block protect function for Non-secure. When the block protect setting is locked by the permanent block setting, it cannot be disabled by this register.

The FBPROT0 value is initialized when the SUINIT bit in the FSUINITR is set to 1, because the FENTRYR value is initialized to 0x0000. It is also initialized by a reset.

BPCN0 bit (Block Protection for Non-secure Cancel)

The BPCN0 bit disables the block protect setting for Non-secure function.

[Setting condition]

- When the write-enabling conditions are satisfied and the FENTRYR is not 0x0000, write 1 to this bit.

[Clearing conditions]

- 8 bits being written to FBPROT0 while the FRDY bit is 1.
- A value other than 0x78 specified in the KEY bits and 16 bits are written to FBPROT0 while the FRDY bit is 1.
- 0 being written to the BPCN0 bit while writing to FBPROT0 is enabled.
- The FENTRYR register value is 0x0000.

52.4.18 FBPROT1 : Flash Block Protection for Secure Register

Base address: FACL = 0x4011_E000

Offset address: 0x7C

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	KEY[7:0]								—	—	—	—	—	—	—	BPCN 1
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	BPCN1	Block Protection for Secure Cancel 0: Block protection is enabled 1: Block protection is disabled.	R/W*1 *2
7:1	—	These bits are read as 0. The write value should be 0.	R/W

Bit	Symbol	Function	R/W
15:8	KEY[7:0]	Key Code	W ³

Note: S-TYPE-6, P-TYPE-2

Note: Associated SA: FSAR register. See [section 52.4.4. FSAR : Flash Security Attribution Register](#)

Note 1. Writing to this bit is only possible when the FRDY bit in the FSTATR register is 1. Writing to this bit while FRDY bit = 0 is ignored.

Note 2. Writing to this bit is only possible when 16 bits are written and the value written to the KEY[7:0] bits is 0xB1.

Note 3. Written values are not retained by these bits (always read as 0x00).

The FBPROT1 register is used to disable the block protect function for Secure developer. When the block protect setting is locked by the permanent block setting, it cannot be disabled by this register.

The FBPROT1 value is initialized when the SUNIT bit in the FSUNITR is set to 1, because the FENTRYR value is initialized to 0x0000. It is also initialized by a reset.

BPCN1 bit (Block Protection for Secure Cancel)

The BPCN1 bit disables the block protect setting for Secure function.

[Setting condition]

- When the write-enabling conditions are satisfied and the FENTRYR is not 0x0000, write 1 to BPCN1.

[Clearing conditions]

- 8 bits being written to FBPROT1 while the FRDY bit is 1.
- A value other than 0xB1 specified in the KEY bits and 16 bits are written to FBPROT1 while the FRDY bit is 1.
- 0 being written to the BPCN1 bit while writing to FBPROT1 is enabled.
- The FENTRYR register value is 0x0000.

52.4.19 FSTATR : Flash Status Register

Base address: FACL = 0x4011_E000
FACL_NS = 0x5011_E000

Offset address: 0x80

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	ILGCO MERR	FESE TERR	SECE RR	OTER R	TZFE RR	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	FRDY	ILGLE RR	ERSE RR	PRGE RR	SUSR DY	DBFU LL	ERSS PD	PRGS PD	—	FLWE ERR	—	—	—	—	—	—
Value after reset:	1	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
5:0	—	These bits are read as 0.	R
6	FLWEERR	Flash Write/Erase Protect Error Flag 0: An error has not occurred 1: An error has occurred.	R
7	—	This bit is read as 0.	R
8	PRGSPD	Programming Suspend Status Flag 0: The flash sequencer is not in the programming suspension processing state or programming suspended state 1: The flash sequencer is in the programming suspension processing state or programming suspended state.	R
9	ERSSPD	Erase Suspend Status Flag 0: The flash sequencer is not in the erasure suspension processing state or the erasure suspended state 1: The flash sequencer is in the erasure suspension processing state or the erasure suspended state.	R

Bit	Symbol	Function	R/W
10	DBFULL	Data Buffer Full Flag 0: The data buffer is empty 1: The data buffer is full.	R
11	SUSRDY	Suspend Ready Flag 0: The flash sequencer cannot receive P/E suspend commands 1: The flash sequencer can receive P/E suspend commands.	R
12	PRGERR	Programming Error Flag 0: Programming has completed successfully 1: An error has occurred during programming.	R
13	ERSERR	Erase Error Flag 0: Erasure has completed successfully 1: An error has occurred during erasure.	R
14	ILGLERR	Illegal Command Error Flag 0: The flash sequencer has not detected an illegal FACI command or illegal flash memory access 1: The flash sequencer has detected an illegal FACI command or illegal flash memory access.	R
15	FRDY	Flash Ready Flag 0: Program, Block Erase, Multi Block Erase, P/E suspend, P/E resume, Forced Stop, Blank Check, Configuration set, Increment counter, Refresh counter, or Read counter command processing is in progress. 1: None of the above is in progress.	R
18:16	—	These bits are read as 0.	R
19	TZFERR	TrustZone Filter Error 0: A TrustZone filter error has not been detected. 1: A TrustZone filter error has been detected.	R
20	OTERR	Other Error 0: An error has not been detected. 1: An error has been detected.	R
21	SECERR	Security Error 0: A write protection error against MSUASMON.FSPR bit has not been detected. 1: A write protection error against MSUASMON.FSPR bit has been detected.	R
22	FESETERR	FENTRY Setting Error 0: A setting error in the FENTRYR register has not been detected. 1: A setting error in the FENTRYR register has been detected.	R
23	ILGCOMERR	Illegal Command Error 0: An illegal FACI command error has not been detected. 1: An illegal FACI command error has been detected.	R
31:24	—	These bits are read as 0.	R

Note: S-TYPE-3, P-TYPE-2

Note: Associated SA: FSAR register. See [section 52.4.4. FSAR : Flash Security Attribution Register](#)

The FSTATR register indicates the state of the flash sequencer.

FLWEERR flag (Flash Write/Erase Protect Error Flag)

The FLWEERR flag indicates a violation of the flash memory overwrite protection setting in the FWEPROR register. When this flag is 1, the flash sequencer is in the command-locked state.

[Setting condition]

- An error has occurred.

[Clearing condition]

- The flash sequencer starts processing the Forced Stop command.

PRGSPD flag (Programming Suspend Status Flag)

The PRGSPD flag indicates that the flash sequencer is in the programming suspension processing state or programming suspended state.

[Setting condition]

- The flash sequencer starts processing in response to the programming suspend command.

[Clearing conditions]

- Reception of the P/E resume command by the flash sequencer (after write access to the FACI command-issuing area is complete)
- The flash sequencer starts processing the Forced Stop command.

ERSSPD flag (Erasure Suspend Status Flag)

The ERSSPD flag indicates that the flash sequencer is in the erasure suspension processing state or erasure suspended state.

[Setting condition]

- The flash sequencer starts processing in response to an erasure suspend command.

[Clearing condition]

- Reception of the P/E resume command by the flash sequencer (after write access to the FACI command-issuing area is complete)
- The flash sequencer starts processing of the Forced Stop command.

DBFULL flag (Data Buffer Full Flag)

The DBFULL flag indicates the state of the data buffer when the program command is issued. The flash sequencer incorporates a buffer for write data (data buffer). When data for writing to the flash memory are written to the FACI command-issuing area while the data buffer is full, the flash sequencer inserts a wait cycle in the peripheral bus.

[Setting condition]

- The data buffer becomes full while program commands are issued.

[Clearing condition]

- The data buffer becomes empty.

SUSRDY flag (Suspend Ready Flag)

The SUSRDY flag indicates whether the flash sequencer can receive a P/E suspend command.

[Setting condition]

- After starting programming/erasure processing, the flash sequencer enters a state in which P/E suspend commands can be received.

[Clearing conditions]

- Reception of the P/E suspend command or Forced Stop command by the flash sequencer (after write access to the FACI command-issuing area is complete)
- During programming or erasure, the flash sequencer enters the command-locked state
- Programming or erasure has completed.

PRGERR flag (Programming Error Flag)

The PRGERR flag indicates the result of programming of the flash memory. When this flag is 1, the flash sequencer is in the command-locked state.

[Setting condition]

- An error has occurred during programming.

[Clearing condition]

- The flash sequencer starts processing of the Status Clear or Forced Stop command.

ERSERR flag (Erasure Error Flag)

The ERSERR flag indicates the result of erasure of the flash memory. When this flag is 1, the flash sequencer is in the command-locked state.

[Setting condition]

- An error has occurred during erasure.

[Clearing condition]

- The flash sequencer starts processing of the Status Clear or Forced Stop command.

ILGLERR flag (Illegal Command Error Flag)

The ILGLERR flag indicates that the flash sequencer has detected an illegal FACI command or flash memory access. If this flag is 1, the flash sequencer is in the command-locked state.

[Setting conditions]

- See [section 52.11.2. Error Protection](#).

[Clearing condition]

- The flash sequencer starts processing of the Status Clear or Forced Stop command.

FRDY flag (Flash Ready Flag)

The FRDY flag indicates the command processing state of the flash sequencer.

[Setting conditions]

- The flash sequencer completes command processing
- The flash sequencer receives a P/E suspend command and suspends programming of the flash memory
- The flash sequencer received the Forced Stop command and ended command processing.

Note: In the case of program command processing, the FRDY flag might be set to 1 even if the flash sequencer does not complete command processing. For details, see [section 52.9.3.7. Program Command](#).

[Clearing conditions]

- The flash sequencer received an FACI command
- For Program and Configuration setting, the first write access to the FACI command-issuing area
- For other commands, the last write access to the FACI command-issuing area.

TZFERR flag (TrustZone Filter Error)

This flag indicates the TrustZone protection error in the FACI command.

See [Table 52.30](#). When this bit is "1", flash sequencer enters "Command Lock" state.

[Setting conditions]

- An error has been detected.

[Clearing conditions]

- Status Clear or Forced Stop command processing is completed.

OTERR flag (Other Error)

This flag indicates that an FACI command has been issued when the condition of accepting commands is not satisfied.

See [Table 52.30](#). When this flag is 1, the flash sequencer is in the command-lock state.

[Setting condition]

- An error has occurred.

[Clearing condition]

- The status clear or forced stop command processing is complete.

SECERR flag (Security Error)

This flag indicates that write protection by the MSUASMON.FSPR bit is violated.
See [Table 52.30](#). When this flag is 1, the flash sequencer is in the command-lock state.

[Setting condition]

- An error has occurred.

[Clearing condition]

- The status clear or forced stop command processing is complete.

FESETERR flag (FENTRY Setting Error)

This flag indicates that a value of 0xAA81 is written in the FENTRYR register or the value in the FENTRYR register differs when P/E is suspended and resumed.

See [Table 52.30](#). When this flag is 1, the flash sequencer is in the command-lock state.

[Setting condition]

- An error has occurred.

[Clearing condition]

- The status clear or forced stop command processing is complete.

ILGCOMERR flag (Illegal Command Error)

This flag indicates that the flash sequencer has detected an illegal FACL command.

See [Table 52.30](#). When this flag is 1, the flash sequencer is in the command-lock state.

[Setting condition]

- An error has occurred.

[Clearing condition]

- The status clear or forced stop command processing is complete.

52.4.20 FENTRYR : Flash P/E Mode Entry Register

Base address: FACL = 0x4011_E000
FACL_NS = 0x5011_E000

Offset address: 0x84

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	KEY[7:0]							FENT RYD	—	—	—	—	—	—	—	FENT RYC
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	FENTRYC	Code Flash P/E Mode Entry 0: Code flash is in read mode 1: Code flash is in P/E mode.	R/W ^{*1,2}
6:1	—	These bits are read as 0. The write value should be 0.	R/W
7	FENTRYD	Data Flash P/E Mode Entry 0: Data flash is in read mode 1: Data flash is in P/E mode.	R/W ^{*1,2}
15:8	KEY[7:0]	Key Code	W ^{*3}

Note: S-TYPE-3, P-TYPE-2

Note: Associated SA: FSAR register. See [section 52.4.4. FSAR : Flash Security Attribution Register](#)

Note 1. These bits can be written when the FRDY bit in the FSTATR register is 1. Writing to these bits are ignored when the FRDY bit is 0.

Note 2. Writing to these bits is only possible when 16 bits are written and the value written to the KEY[7:0] bits is 0xAA.

Note 3. Written values are not retained by these bits (always read 0x00).

FENTRYR is used to specify code flash P/E mode or data flash P/E mode. To specify the code flash P/E mode or data flash P/E mode so that the flash sequencer can receive FACL commands, set either the FENTRYD or FENTRYC bit to 1 to place the flash sequencer in P/E mode.

FENTRYR is initialized when the SUINIT bit in FSUINITR is set to 1. It is also initialized by a reset.

Note: Writing a value of 0XAA81 to this register causes the ILGLERR bit in the FSTATR register to be set to 1, resulting in the flash sequencer being placed in the command-locked state.

FENTRYC bit (Code Flash P/E Mode Entry)

The FENTRYC bit specifies P/E mode for the code flash memory.

[Setting condition]

- Write 1 to the FENTRYC bit while writing to FENTRYR is enabled and FENTRYR is 0x0000.

[Clearing conditions]

- Write 8 bits to FENTRYR while the FRDY bit is 1
- A value other than 0xAA is specified in the KEY[7:0] bits and 16 bits are written to FENTRYR while the FRDY bit is 1
- Write 0 to the FENTRYC bit while writing to FENTRYR is enabled
- Write to FENTRYR while writing is enabled and its value is other than 0x0000
- The protection of FMEPROT register is enabled.

FENTRYD bit (Data Flash P/E Mode Entry)

The FENTRYD bit specifies P/E mode for the data flash memory.

[Setting condition]

- Write 1 to the FENTRYD bit while writing to FENTRYR is enabled and FENTRYR is 0x0000.

[Clearing conditions]

- Write 8 bits to FENTRYR while the FRDY bit is 1
- Writing of 16 bits to FENTRYR with a value other than 0xAA specified for the KEY[7:0] bits while the FRDY bit is 1
- Write 0 to the FENTRYD bit while writing to FENTRYR is enabled
- Write to FENTRYR while writing is enabled and its value is other than 0x0000.

KEY[7:0] bits (Key Code)

The KEY[7:0] bits control writing permission to the FENTRYD or FENTRYC bits.

52.4.21 FSUINITR : Flash Sequencer Setup Initialization Register

Base address: FACL = 0x4011_E000
FACL_NS = 0x5011_E000

Offset address: 0x8C

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	KEY[7:0]								—	—	—	—	—	—	—	SUINIT
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	SUINIT	Set-Up Initialization 0: The FSADDR, FEADDR, FBPROT0, FBPROT1, FENTRYR, FBCCNT, FCPSR, and FCNTSELR flash sequencer setup registers keep their current values 1: The FSADDR, FEADDR, FBPROT0, FBPROT1, FENTRYR, FBCCNT, FCPSR, and FCNTSELR flash sequencer setup registers are initialized.	R/W ^{*1*2}
7:1	—	These bits are read as 0. The write value should be 0.	R/W

Bit	Symbol	Function	R/W
15:8	KEY[7:0]	Key Code	W*3

Note: S-TYPE-3, P-TYPE-2

Note: Associated SA: FSAR register. See [section 52.4.4. FSAR : Flash Security Attribution Register](#)

Note 1. This bit can be written when the FRDY bit in the FSTATR register is 1. Writing to this bit is ignored when the FRDY bit is 0.

Note 2. Writing to these bits is only possible when 16 bits are written and the value written to the KEY[7:0] bits is 0x2D.

Note 3. Written values are not retained by these bits (always read 0x00).

FSUINITR is used for initialization of the flash sequencer setup.

SUINIT bit (Set-Up Initialization)

The SUINIT bit initializes the following flash sequencer setup registers:

- FSADDR
- FEADDR
- FBPROT0
- FBPROT1
- FENTRYR
- FBCCNT
- FCPSR
- FCNTSELR

KEY[7:0] bits (Key Code)

The KEY[7:0] bits control writing permission to the SUINIT bit.

52.4.22 FCMDR : FACL Command Register

Base address: FACL = 0x4011_E000
FACL_NS = 0x5011_E000

Offset address: 0xA0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	CMDR[7:0]								PCMDR[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	PCMDR[7:0]	Pre-command Flag The command just before the latest command is stored.	R
15:8	CMDR[7:0]	Command Flag The latest command is stored.	R

Note: S-TYPE-3, P-TYPE-2

Note: Associated SA: FSAR register. See [section 52.4.4. FSAR : Flash Security Attribution Register](#)

FCMDR records the two most recent commands accepted by the flash sequencer.

PCMDR[7:0] bits (Pre-command Flag)

The PCMDR[7:0] bits indicate the command received immediately before the latest command received by the flash sequencer.

CMDR[7:0] bits (Command Flag)

The CMDR[7:0] bits indicate the latest command received by the flash sequencer.

Table 52.9 States of FCMDR after receiving commands

Command	CMDR	PCMDR
Program	0xE8	Previous command
Block erase	0xD0	0x20
Multi block erase	0xD0	0x21
P/E suspend	0xB0	Previous command
P/E resume	0xD0	Previous command
Status Clear	0x50	Previous command
Forced Stop	0xB3	Previous command
Blank Check	0xD0	0x71
Configuration set	0x40	Previous command
Increment Counter	0xD0	0x35
Refresh Counter	0xD0	0x37
Read Counter	0xD0	0x39

52.4.23 FBCCNT : Blank Check Control Register

Base address: FACL = 0x4011_E000
FACL_NS = 0x5011_E000

Offset address: 0xD0

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	BCDIR

Value after reset: 0 0 0 0 0 0 0 0

Bit	Symbol	Function	R/W
0	BCDIR	Blank Check Direction 0: Blank checking is executed from the lower addresses to the higher addresses (incremental mode) 1: Blank checking is executed from the higher addresses to the lower addresses (decremental mode).	R/W
7:1	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-2

Note: Associated SA: FSAR register. See [section 52.4.4. FSAR : Flash Security Attribution Register](#)

FBCCNT specifies the addressing mode in processing the Blank Check command. FBCCNT is initialized when the SUINIT bit in FSUINTR is set to 1. It is also initialized by a reset.

BCDIR bit (Blank Check Direction)

The BCDIR bit specifies the addressing mode for Blank Check.

52.4.24 FBCSTAT : Blank Check Status Register

Base address: FACL = 0x4011_E000
FACL_NS = 0x5011_E000

Offset address: 0xD4

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	BCST

Value after reset: 0 0 0 0 0 0 0 0

Bit	Symbol	Function	R/W
0	BCST	Blank Check Status Flag 0: The target area is in the non-programmed state, that is, the area has been erased but has not yet been reprogrammed 1: The target area has been programmed with 0s or 1s.	R
7:1	—	These bits are read as 0.	R

Note: S-TYPE-3, P-TYPE-2

Note: Associated SA: FSAR register. See [section 52.4.4. FSAR : Flash Security Attribution Register](#)

FBCSTAT stores the results of checking in response to the Blank Check command.

BCST flag (Blank Check Status Flag)

The BCST flag indicates the results of checking in response to the Blank Check command.

52.4.25 FPSADDR : Data Flash Programming Start Address Register

Base address: FACL = 0x4011_E000
FACL_NS = 0x5011_E000

Offset address: 0xD8

Bit position:	31	16	0
Bit field:	— — — — — — — — — — — — — — — —	PSADR[16:0]	
Value after reset:	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0	0

Bit	Symbol	Function	R/W
16:0	PSADR[16:0]	Programmed Area Start Address The address of the first programmed area	R
31:17	—	These bits are read as 0. The write value should be 0.	R

Note: S-TYPE-3, P-TYPE-2

Note: Associated SA: FSAR register. See [section 52.4.4. FSAR : Flash Security Attribution Register](#)

FPSADDR indicates the address of the first programmed area found in processing of the Blank Check command.

PSADR[16:0] bits (Programmed Area Start Address)

The PSADR[16:0] bits indicate the address of the first programmed area found in processing of the Blank Check command. The address is an offset from the address where the data flash memory starts. The setting of these bits is only valid if the BCST bit in the FBCSTAT register is 1 and while the FRDY bit in the FSTATR register is 1. When the BCST bit in the FBCSTAT register is 0, the PSADR[16:0] bits hold the address produced by the previous check.

52.4.26 FSUASMON : Flash Startup Area Select Monitor Register

Base address: FACL = 0x4011_E000
FACL_NS = 0x5011_E000

Offset address: 0xDC

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	BTFL G	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0/1	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	FSPR	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0/1	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
14:0	—	These bits are read as 0. The write value should be 0.	R
15	FSPR	Protection Programming Flag to set Boot Flag and Startup Area Control 0: Protected state 1: Non-protected state.	R
30:16	—	These bits are read as 0. The write value should be 0.	R
31	BTFLG	Flag of Startup Area Select for Boot Swap 0: The startup area is the alternate block (block 1) 1: The startup area is the default block (block 0).	R

Note: S-TYPE-3, P-TYPE-2

Note: Associated SA: FSAR register. See [section 52.4.4. FSAR : Flash Security Attribution Register](#).

FSPR bit (Protection Programming Flag to set Boot Flag and Startup Area Control)

The FSPR bit indicates the protection state against the configuration set command for the BTFLG bit, and FSUACR Register.

In response to a reset or configuration set command, the FSCI transfers data from flash memory to this register.

BTFLG bit (Flag of Startup Area Select for Boot Swap)

The BTFLG bit indicates whether the address of the startup area is exchanged for the boot swap function or not.

In response to a reset or configuration set command, the FSCI transfers data from flash memory to this register.

52.4.27 FCPSR : Flash Sequencer Processing Switching Register

Base address: FSCI = 0x4011_E000
FSCI_NS = 0x5011_E000

Offset address: 0xE0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	ESUS PMD
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	ESUSPMD	Erase Suspend Mode 0: Suspension priority mode 1: Erasure priority mode.	R/W
15:1	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-2

Note: Associated SA: FSAR register. See [section 52.4.4. FSAR : Flash Security Attribution Register](#)

FCPSR selects the erasure suspension mode. FCPSR is initialized when the SUINIT bit in FSUINITR is set to 1. It is also initialized by a reset.

ESUSPMD bit (Erasure Suspend Mode)

The ESUSPMD bit selects the erasure suspension mode when a P/E suspend command is issued while the flash sequencer is executing erasure processing (see [section 52.9.3.10. P/E Suspend Command](#)). This bit should be set before issuing Block Erase or Multi Block Erase command.

52.4.28 FPCKAR : Flash Sequencer Processing Clock Notification Register

Base address: FACL = 0x4011_E000
FACL_NS = 0x5011_E000

Offset address: 0xE4

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	KEY[7:0]								PCKA[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	1	1	1	1	0	0

Bit	Symbol	Function	R/W
7:0	PCKA[7:0]	Flash Sequencer Operating Clock Notification These bits are used to set the operating frequency of the flash sequencer while processing FACL commands.	R/W ^{*1,2}
15:8	KEY[7:0]	Key Code	W ^{*3}

Note: S-TYPE-3, P-TYPE-2

Note: Associated SA: FSAR register. See [section 52.4.4. FSAR : Flash Security Attribution Register](#)

Note 1. This bit can be written when the FRDY bit in the FSTATR register is 1. Writing to this bit is ignored when the FRDY bit is 0.

Note 2. Writing to these bits is only possible when 16 bits are written and the value written to the KEY[7:0] bits is 0x1E.

Note 3. Written values are not retained by these bits (always read 0x00).

FPCKAR specifies the operating frequency of the flash sequencer while processing FACL commands. The highest operating frequency for the given product is set as the initial value.

PCKA[7:0] bits (Flash Sequencer Operating Clock Notification)

The PCKA[7:0] bits specify the operating frequency of the flash sequencer while processing FACL commands. Set the desired frequency for these bits before issuing an FACL command. Specifically, convert the frequency in MHz to a binary number and set it for these bits.

Example:

Frequency is 35.9 MHz (PCKA = 0x24)

Round up the first decimal place of 35.9 MHz to a whole number (= 36) and convert it into a binary number.

If the value set in these bits is smaller than the actual operating frequency of the flash sequencer, the flash memory programming/erasure characteristics cannot be guaranteed. If the value set in these bits is greater than the actual operating frequency of the flash sequencer, the flash memory programming/erasure characteristics can be guaranteed but the FACL command processing time such as the time programming/erasure takes will increase. The minimum FACL command processing time is obtained when the operating frequency of the flash sequencer is the same as the PCKA value.

KEY[7:0] bits (Key Code)

The KEY[7:0] bits control writing permission to the PCKA bit.

52.4.29 FSUACR : Flash Startup Area Control Register

Base address: FACL = 0x4011_E000

Offset address: 0xE8

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	KEY[7:0]								—	—	—	—	—	—	SAS[1:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
1:0	SAS[1:0]	Startup Area Select 0 0: Startup area is selected by BTFLG bit 0 1: Startup area is selected by BTFLG bit 1 0: Startup area is temporarily switched to the default area (block 0) 1 1: Startup area is temporarily switched to the alternate area (block 1).	R/W*1 *3
7:2	—	These bits are read as 0. The write value should be 0.	R/W
15:8	KEY[7:0]	Key Code	W*2

Note: S-TYPE-6, P-TYPE-2

Note 1. Following described the write condition of these bits (these conditions are required at the same time).

1. Access size to this register is 16 bits
2. The value of KEY[7:0] is 0x66
3. The FSPR bit is 1.

Note 2. Written values are not retained by these bits (always read 0x00).

Note 3. Only Secure access can write to this register. Both Secure access and Non-secure read access are allowed. Non-secure write access is denied, but TrustZone access error is not generated.

FSUACR sets the startup area for the boot swap function. Do not use this register in dual mode (the DUALSEL.BANKMD[2:0] bits are 000b). In dual mode, starting up proceeds from startup area 0.

SAS[1:0] bits (Startup Area Select)

The SAS[1:0] bits select the startup area. Three methods are available for changing the startup area.

KEY[7:0] bits (Key Code)

The KEY[7:0] bits control writing permission to the SAS [1:0] bits.

52.4.30 FCKMHZ : Data Flash Access Frequency Register

Base address: FLAD = 0x4011_C000
FLAD_NS = 0x5011_C000

Offset address: 0x40

Bit position: 7 6 5 4 3 2 1 0

Bit field: FCKMHZ[7:0]

Value after reset: 0 0 1 1 1 1 0 0

Bit	Symbol	Function	R/W
7:0	FCKMHZ[7:0]	Data Flash Access Frequency Register These bits optimize the speed of reading the data flash memory.	R/W

Note: S-TYPE-3, P-TYPE-2

Note: If the security attribution is configured as Secure:

- Secure access and Non-secure read access are allowed
- Non-secure write access is ignored, and TrustZone access error is not generated.

If the security attribution is configured as Non-secure:

- Secure and Non-secure access are allowed.

This register optimizes the speed of reading the data flash memory.

Set the frequency of the peripheral module clock (FCLK) of internal peripheral bus which is the clock for access to the data flash memory, in MHz units. For example, 35.9 MHz should be rounded up and set the frequency to 36. Number of cycles required for access to the data flash memory are inserted according to the frequency. When changing the frequency of the FCLK, follow the procedure below to modify the value of the data flash access frequency register (FCKMHZ) in either of the following ways according to whether operation is at a lower frequency before or after the change.

- When changing the speed from low to high: Modify FCKMHZ. After confirming the change by reading FCKMHZ, change the frequency.
- When changing the speed from high to low: Change the frequency. After the frequency is changed, modify FCKMHZ.

52.5 Flash Cache

52.5.1 Feature of flash cache

The FCACHE (Flash Cache) speeds up read access from bus master to the flash memory. The FCACHE includes:

- FCACHE1, for CPU instruction fetches
- FCACHE2, for CPU operand access and access from DMAC/DTC
- FLPF, for the prefetch access in CPU instruction fetches

Table 52.10 Flash Cache 1 (FCACHE1) overview

Item	Description
Cache Target Region	Secure alias : 0x0200_0000 - 0x021F_7FFF Non-secure alias : 0x1200_0000 - 0x121F_7FFF
Target Bus Master	CPU instruction Fetch
Capacity	256 bytes
Associativity	8WAY set associative 128 bits/entry (128 bit aligned data), 2 entries/way
Access Cycle	Cache Hit : 0 wait Cache Miss : wait number of Flash Wait Cycle Register

Table 52.11 Flash Cache 2 (FCACHE2) overview

Item	Description
Cache Target Region	Secure alias : 0x0200_0000 - 0x021F_7FFF Non-secure alias : 0x1200_0000 - 0x121F_7FFF
Target Bus Master	CPU Operand Access and Access from DMAC/DTC
Capacity	16 bytes
Associativity	Full Associative 128 bits/entry (128 bit aligned data), 1 entry
Access Cycle	Cache Hit : 0 wait Cache Miss : wait number of Flash Wait Cycle Register

Table 52.12 Prefetch Buffer (FLPF) overview

Item	Description
Cache Target Region	Secure alias : 0x0200_0000 - 0x021F_7FFF Non-secure alias : 0x1200_0000 - 0x121F_7FFF
Capacity	32 bytes
Associativity	Full Associative 128 bits/entry (128 bit aligned data), 2 entries
Request Address	Next address of previous CPU Instruction
Access Cycle	Cache Hit : 0 wait Cache Miss : wait number of Flash Wait Cycle Register

Figure 52.5 Block diagram of FCACHE

52.6 Operating Modes Associated with Flash Memory

Figure 52.6 is a diagram of the mode transitions associated with the flash memory. For the procedures for setting the modes, see [section 6, Option-Setting Memory](#).

Figure 52.6 Mode Transitions Associated with Flash Memory

The flash memory area where programming and erasure are permitted and the boot program after a reset are different according to each mode. The differences between modes are listed in [Table 52.13](#).

Table 52.13 Differences between Modes

Parameter	Normal operating mode	Serial programming mode (SCI or USB boot mode)	On-chip debug mode (JTAG or SWD boot mode)
Programmable and erasable areas	- Code flash memory - Data flash memory - Option setting memory (programming only)	- Code flash memory - Data flash memory - Option-setting memory (programming only)	- Code flash memory - Data flash memory - Option setting memory (programming only)
Erasure in block units	Possible	Possible	Possible
Boot program at a reset	User area program	Embedded program for serial programming	Depends on debug command

52.7 Overview of Functions

By using a dedicated flash-memory programmer to program the flash memory through a serial interface (serial programming) or JTAG/SWD interface (on-chip debug mode), the device can be rewritten regardless of whether this is before or after it is mounted on the target system.

Furthermore, security functions to prohibit rewriting or reading of the user program written to the flash memory are incorporated, and this can prevent falsification and illicit reading of the programs by third parties.

Programming by the user program (self-programming) is available to suit applications where the application on the target system may require updating after manufacturing or shipment. Protection features for the safe rewriting of the flash memory are also incorporated. Furthermore, interrupt processing during self-programming is supported, so programming can proceed at the same time as processing for external communications, etc., and this is the case in various situations. [Table 52.14](#) lists the overview of the methods of programming and the corresponding operating modes.

Table 52.14 Programming methods

Programming method	Functional overview	Operating mode
Serial programming	A dedicated flash-memory programmer through the SCI or USBFS interface enables on-board programming of the flash memory after the device is mounted on the target system.	Serial programming mode
	A dedicated flash-memory programmer through the SCI or USBFS interface and a dedicated programming adapter board allow off-board programming of the flash memory, for example, programming of the device before it is mounted on the target system.	
Self-programming	A user program written to memory in advance of serial programming execution can also program the flash memory. The background operation capability makes it possible to fetch instructions or otherwise read data from the code flash memory while the data flash memory is programmed. As a result, a program resident in the code flash memory is able to program the data flash memory. For background operations that are not possible, instructions in the code flash memory cannot be fetched and data cannot be accessed while the code flash memory is being programmed by self-programming. In such cases, a program for programming from the internal SRAM or external memory must be transferred in advance and executed.	Normal operating mode
JTAG or SWD programming	A dedicated flash-memory programmer or an on-chip debugger through JTAG or SWD enables on-board programming of the flash memory after the device is mounted on the target system. A dedicated flash-memory programmer or an on-chip debugger through JTAG or SWD and a dedicated programming adapter board allow off-board programming of the flash memory, for example, programming of the device before it is mounted on the target system.	On-chip debug mode

[Table 52.15](#) lists the functions of the flash memory. Serial programmer commands realize each function of serial programming, while reading of the flash memory by an FSCI command or the user program realizes each function of self-programming.

Table 52.15 Basic Functions

Function	Functional overview	Availability	
		Serial programming	Self-programming
Blank check	Checks a specified block to ensure that writing to it has not already proceeded. Results of reading from data flash memory to which nothing is written after erasure are not guaranteed, so use blank checking to confirm that writing to memory has not proceeded after erasure.	Not supported	Supported (data flash programming only)
Block erasure	Erases the memory contents in the specified block	Supported	Supported
Programming	Writes to the specified address	Supported	Supported
CRC	Calculates the CRC in the specified range of the flash memory and transfers it to the flash programmer	Supported	Not supported
Read	Reads data programmed in the flash memory	Supported	Not supported (read by user program is possible)
Start-up program protection functions	Configures the start-up program protection functions	Supported	Supported
Option function selection	Selects the option function, and modifies the initial setting of this MCU	Supported	Supported
Dual bank function	Switches different modes (linear or dual)	Supported	Supported
Block swap function	Setting block swap functions	Supported	Supported
Block protection	Setting block protection	Supported	Supported
Device lifecycle transition	Transitions the device lifecycle	Supported	Not supported
Memory security attribution	Setting the memory security attribution	Supported	Not supported
Key	Injects key	Supported	Supported (except the key related to device lifecycle transition)
All erasure	Erase the flash memory to the state after shipment	Supported	Not supported

The flash memory supports various security functions.

Table 52.16 lists the security functions supported by the flash memory.

Table 52.16 Lists of Security Functions

Function	Description
Security flag for Start-up area select	Start-up area selection can be protected by setting of security flag (FSPR).
Permanently block protection	Programming or erasure of each block of code flash memory can be protected permanently.
Protection for TrustZone	Programming or erasure area, readable area, register access, and FACI command operation are protected by ARM TrustZone security.
Data flash configuration area protection	When target area of configuration set command includes protection area by lock bit, flash sequencer detects an error and enters command lock state.
Anti-rollback Counter	Anti-rollback counter used only by Secure applications for firmware updates.
Programming or erasure mode protection	Only Secure developer can enter the programming or erasure mode for code flash.

52.8 Operating Modes of the Flash Sequencer

The flash sequencer has three operating modes as shown in Figure 52.7. Transitions between modes are initiated by changing the value of the FENTRYR register.

When the value of the FENTRYR register is 0x0000, the flash sequencer is in read mode. In this mode, it does not receive FACI commands. The code flash memory and data flash memory are both readable.

When the value of the FENTRYR register is 0x0001, the flash sequencer is in code flash P/E mode where the code flash memory can be programmed or erased by FACI commands. In this mode, the data flash memory is readable. In addition, the code flash memory is not readable if background operation (BGO) is disabled. If BGO is enabled, the code flash memory

that is not selected by FSADDR register is readable when the FRDY bit in the FSTATR register is 0. As for the condition for enabling BGO, see [section 52.15.2. Background Operation](#).

When the value of the FENTRYR register is 0x0080, the flash sequencer is in data flash P/E mode where the data flash memory can be programmed or erased by FACI commands. In this mode, the data flash memory is not readable. However, the code flash memory is readable.

Figure 52.7 Modes of the flash sequencer

52.9 FACI Commands

52.9.1 List of FACI Commands

The FACI controls the FCU according to the specified FACI commands.

This section describes information about the FACI commands and [Table 52.17](#) lists the FACI commands.

Table 52.17 FACI commands (1 of 2)

FACI command	Function
Program	Programs the user area and data area. Units of programming are 128 bytes for the user area and 4, 8, or 16 bytes for the data area.
Block erase	Erases user area and data area. The erase unit is 8 KB or 32 KB for user area, and 64 bytes for data flash.
Multi block erase	Erases data area. The erase unit is 64, 128, 256 bytes for data flash.
P/E suspend	Suspends programming or erasure processing.
P/E resume	Resumes suspended programming or erasure processing.
Status clear	Initializes the ILGLERR, ERSERR, PRGERR, ILGCOMERR, FESETERR, SECERR, and OTERR bits in the FSTATR register and the CMDLK, CFAE, OTERR and TZFERR bits in the FASTAT register, and the flash sequencer released from command-locked state.

Table 52.17 FACI commands (2 of 2)

FACI command	Function
Forced stop	Forcibly stops processing of FACI commands and initializes the FSTATR and FASTAT registers.
Blank check	Checks if data areas are blank. Units of Blank Check: 4 bytes to data flash memory capacity (specified in 4-byte units).
Configuration set	Sets the option-setting memory. Units of setting: 16 bytes (Code flash memory) 4/16 bytes (Data flash memory)
Increment Counter (Secure access only)	Increments Anti-rollback counter value . The target of counter is selected by FCNTSELR register. Update data unit is 1bit.
Refresh Counter recovery flow (Secure access only)	This is used to anti-rollback counter recovery flow. The target of counter is selected by FCNTSELR register. This command can refresh anti-rollback counter area without increasing counter value.
Read Counter (Secure access only)	Read Anti-rollback counter value. The target of counter is selected by FCNTSELR register. Reading data is output to FCNTDatar0 and FCNTDatar1 registers. Read unit is 64bit.

The FACI commands are issued by writing to the FACI command-issuing area (see [Table 52.4](#)). When write access as shown in [Table 52.18](#) proceeds in the specified state, the flash sequencer executes the processing associated with the given command (see [section 52.9.2. Relationship between the Flash Sequencer State and FACI Commands](#)).

Table 52.18 FACI command formats (1 of 2)

FACI commands	Number of write access	Write data to the FACI command-issuing area			
		1st access	2nd access	3rd to (N+2)th access	(N+3)th access
Program (user area) N = 64	67	0xE8	0x40 (=N)	WD1 to WD64	0xD0
Program (data area) 4-byte programming: N = 2 8-byte programming: N = 4 16-byte programming: N = 8	N+3	0xE8	0x02 (=N) 0x04 (=N) 0x08 (=N)	WD1 to WDN	0xD0
Block Erase (user area 8K/32K Bytes)	2	0x20	0xD0	—	—
Block Erase (data area 64 bytes)	2	0x20	0xD0	—	—
Multi block erase (data area 64/128/256 bytes)	2	0x21	0xD0	—	—
P/E suspend	1	0xB0	—	—	—
P/E resume	1	0xD0	—	—	—
Status Clear	1	0x50	—	—	—
Forced Stop	1	0xB3	—	—	—
Blank Check	2	0x71	0xD0	—	—
Configuration set (Code flash memory) N = 8	11	0x40	0x08 (=N)	WD1 to WD8	0xD0
Configuration set (Data flash memory) N = 2 (4 Bytes) N = 8 (16 Bytes)	N+3	0x40	0x02 (=N) 0x08 (=N)	WD1 to WDN	0xD0
Increment Counter	2	0x35	0xD0	—	—

Table 52.18 FACI command formats (2 of 2)

FACI commands	Number of write access	Write data to the FACI command-issuing area			
		1st access	2nd access	3rd to (N+2)th access	(N+3)th access
Refresh Counter	2	0x37	0xD0	—	—
Read Counter	2	0x39	0xD0	—	—

Note: WDN (N = 1, 2, ...): Nth 16-bit data to be programmed.

The flash sequencer clears the FSTATR.FRDY bit to 0 at the start of a command processing other than the Status Clear command, and sets this bit to 1 on completion.

If the FRDYIE.FRDYIE bit setting is 1, a flash ready (FRDY) interrupt is generated when the FSTATR.FRDY bit is set to 1.

52.9.2 Relationship between the Flash Sequencer State and FACI Commands

The FACI commands are accepted according to the mode/state of the flash sequencer. FACI commands should be issued after transitioning of the flash sequencer to the code flash P/E mode or data flash P/E mode and after checking the state of the flash sequencer.

Use the FSTATR and FASTAT registers to check the state of the flash sequencer. In addition, the occurrence of errors in general can be checked by reading the CMDLK bit in the FASTAT register. The value of the CMDLK bit is the logical OR of the following bits in the FSTATR register:

- ILGLERR
- ILGCOMERR
- FESETERR
- SECERR
- OTERR
- TZFERR
- ERSERR
- PRGERR
- FLWEERR.

Table 52.19 lists the available FACI commands in each operating mode.

Table 52.19 Operating mode and available FACI commands

Operating mode	FENTRYR	Available FACI commands
Read mode	0x0000	None
Code flash P/E mode	0x0001	Program Block erase P/E suspend P/E resume Status Clear Forced Stop Configuration set
Data flash P/E mode	0x0080	Program Block erase Multi block erase P/E suspend P/E resume Status Clear Forced Stop Blank Check Configuration set Increment Counter Refresh Counter Read Counter

Table 52.20 shows the state of the flash sequencer and acceptable FACI commands. An appropriate mode is assumed to have been set before the commands are executed.

Table 52.20 Acceptable FACI commands and state of the flash sequencer

	Program, block erase or multi block erase command processing	Configuration set, configuration clear, increment counter, refresh counter or read counter command processing	Program, block erase or multi block erase command suspension processing	Blank check command processing	Programming suspended	Erase suspended	Programming while erasure is suspended	Command-locked state (FRDY = 1)	Command-locked state (FRDY = 0)	Processing of forced stop command	Other state
FRDY bit	0	0	0	0	1	1	0	1	0	0	1
SUSRDY bit	1	0	0	0	0	0	0	0	0	0	0
ERSSPD bit	0	0	0/1	0/1	0	1	1	0/1	0/1	0	0
PRGSPD bit	0	0	0/1	0/1	1	0	0	0/1	0/1	0	0
CMDLK bit	0	0	0	0	0	0	0	1	1	0	0
Program	X	X ^{*3}	X	X	X	O ^{*2}	X	X	X	X	O
Block erase or multi block erase	X	X ^{*3}	X	X	X	X	X	X	X	X	O
P/E suspend	O	X ^{*3}	X	X	X	X	X	—	X	X	—
P/E resume	X	X ^{*3}	X	X	O	O	X	X	X	X	X
Status clear	X	X ^{*3}	X	X	O	O	X	O	X	X	O
Forced stop	O	O ^{*3}	O	O	O	O	O	O	O	O	O
Blank check	X	X ^{*3}	X	X	O ^{*1}	O ^{*1}	X	X	X	X	O ^{*1}
Configuration set	X	X ^{*3}	X	X	X	X	X	X	X	X	O
Increment Counter	X	X ^{*3}	X	X	X	X	X	X	X	X	O ^{*1}
Refresh Counter	X	X ^{*3}	X	X	X	X	X	X	X	X	O ^{*1}
Read Counter	X	X ^{*3}	X	X	X	X	X	X	X	X	O ^{*1}

Note: O: Acceptable
X: Not acceptable (places the sequencer in the command-locked state)
—: Ignored

Note 1. Only acceptable in data flash P/E mode.

Note 2. Acceptable when programming area is other than erase suspending block.

Note 3. When configuration set is processing and when FSTATR.DBFULL bit is 1, do not issue this command.

52.9.3 Usage of FACI Commands

52.9.3.1 Overview of Command Usage in Code Flash P/E Mode

Figure 52.8 show an overview of FACI command usage in code flash P/E mode. For the available commands in code flash P/E mode, see Table 52.19.

Figure 52.8 Overview of command usage in code flash P/E mode

52.9.3.2 Overview of Command Usage in Data Flash P/E Mode

Figure 52.9 shows an overview of FACL command usage in data flash P/E and Table 52.19 lists the available commands in data flash P/E mode.

Figure 52.9 Overview of command usage in data flash P/E mode

52.9.3.3 Transition to Code Flash P/E Mode

To issue FACL commands for the code flash memory, a transition to code flash P/E mode is required by setting the FENTRYC bit in the FENTRYR register to 1.

[Figure 52.10](#) shows the procedure to transition to code flash P/E mode.

Figure 52.10 Procedure to transition to code flash P/E mode

52.9.3.4 Transition to Data Flash P/E Mode

To issue FACS commands for the data flash memory, a transition to data flash P/E mode is required by setting the FENTRYD bit in the FENTRYR register to 1.

Figure 52.11 shows the procedure to transition to data flash P/E mode.

Figure 52.11 Procedure to transition to data flash P/E mode

52.9.3.5 Transition to Read Mode

To read the flash memory, a transition to read mode is required by setting the FENTRYR register to 0x0000. The transition to read mode should be made after the flash sequencer completes the processing and while operation is not in the command-locked state.

Figure 52.12 shows the procedure to transition to read mode.

Figure 52.12 Procedure to transition to read mode

52.9.3.6 Recovery from the Command-Locked State

When the flash sequencer enters the command-locked state, FACL commands cannot be accepted. To release the sequencer from the command-locked state, use the status clear command, forced stop command, or FASTAT register.

When the command-locked state is detected by checking for an error before issuing the P/E suspend command, the FRDY bit in the FSTATR register might be 0 even though command processing has not completed. If processing is not complete by the maximum programming/erasure time specified in the electrical characteristics, this is a timeout and the flash sequencer must be stopped with the forced stop command.

The FLWEERR bit in the FSTATR register does not change from 1 to 0 with the status clear command. When these bits are set to 1, use the forced stop command to release from the command-locked state. Bits other than FRDY and FLWEERR in FSTATR register that indicate the command-locked state can be changed from 1 to 0 with the status clear or forced stop command.

[Figure 52.13](#) shows the recovery flow from the command-locked state.

Figure 52.13 Recovery flow from the command-locked state

52.9.3.7 Program Command

Program commands are used to write to the user and data areas. Before issuing the FACI program command, set the first address of the target block in the FSADDR register.

Program processing is started by writing the last 16 bits of program data (WD64 for code flash and WD2, WD4, and WD8 for data flash in [Table 52.18](#)) to the FACI command-issuing area before 0xD0, the final value of the FACI command, is written. Therefore, if it takes time from writing the last 16 bits of program data to writing the final FACI command value 0xD0 (for example, due to interrupt processing), the FSTATR.FR DY bit is set to 1 when program processing is completed even if 0xD0 has not been written. In this case, the program processing has been completed, but the FACI command reception has not been completed. If a subsequent FACI command is issued in this state, an illegal command error will occur. To avoid illegal command errors, disable interrupts with processing that issues FACI commands while program commands are issued (from writing 0xE8 to writing 0xD0).

If the target area for program command processing includes an area that is not for writing, write 0xFFFF to the corresponding area. If a program command is issued while the FACI internal data buffer is full, a wait period may occur on

the peripheral bus, which may affect the communication performance of other peripheral modules. To avoid the occurrence of a waiting period, set the DBFULL bit in the FSTATR register to 0 when issuing a FOCI command. Writing to the data area will not cause the data buffer to become full.

[Figure 52.14](#) shows the usage of the program command.

Note 1. Judgment of the timeout is based on 1.1 times the maximum time of programming. See [section 55, Electrical Characteristics](#) about those time

Note 2. 1.4 μ s ($f_{CLK} \geq 20$ MHz)

Figure 52.14 Usage flow of the program command

52.9.3.8 Block Erase Command

The block erase command is used for erasing user area or data area. The erase unit is one block. Before issuing a block erase command, set the first address of the target block to FSADDR register. Writing 0xD0 at the second write access of the FACL command triggers the FACL to start the block erase command processing. Completion of command processing can be confirmed with the FRDY bit of FSTATR register.

Set the FCPSR registers before issuing the block erase command. Additionally, FCPSR must be set when the erasure-suspended mode is to be switched.

Figure 52.15 shows the usage of the block erase command.

Figure 52.15 Usage flow of the block erase command

52.9.3.9 Multi Block Erase Command

The multi block erase command is used for erasing data area. The erase unit is 64, 128, or 256 bytes. Before issuing the multi block erase command, set the start address to FSADDR register and the end address to FEADDR register. Writing 0xD0 at the second write access of the FACL command triggers FACL to start the multi block erase command processing. Completion of command processing can be confirmed with the FRDY bit of FSTATR register.

Set the FCPSR registers before issuing the multi block erase command. Additionally, FCPSR must be set when the erasure-suspended mode is to be switched.

The erase size is specified by both the FSADDR and FEADDR settings. [Table 52.21](#) describes how to set the FSADDR and FEADDR.

Table 52.21 Settings for the erase size

Erase size	FSADDR	FEADDR
64 bytes	FSA0 to FSA5 = 0 (64 byte-boundary)	FSADDR + 0x3C
128 bytes	FSA0 to FSA6 = 0 (128 byte-boundary)	FSADDR + 0x7C
256 bytes	FSA0 to FSA7 = 0 (256 byte-boundary)	FSADDR + 0xFC

Figure 52.16 Usage flow of the multi block command

52.9.3.10 P/E Suspend Command

The P/E suspend command is used to suspend programming/erasure. Before issuing a P/E suspend command, check that the CMDLK bit in the FASTAT register is 0, and that the execution of programming/erasure is performed normally. To confirm that the P/E suspend command can be received, check that the SUSRDY bit in the FSTATR register is 1. After issuing a P/E suspend command, read the CMDLK bit to confirm that no error occurs.

If an error occurs during programming/erasure, the CMDLK bit is set to 1. When programming/erasure processing has finished from the time when the SUSRDY bit is 1 to when the P/E suspend command is received, no error occurs and the

suspended state is not entered (the FRDY bit in the FSTATR register is 1 and the ERSSPD and PRGSPD bits in FSTATR are 0).

When a P/E suspend command is received and the programming/erasure suspend processing finishes normally, the flash sequencer enters the suspended state, the FRDY bit is set to 1, and the ERSSPD or PRGSPD bit is 1. After issuing a P/E suspend command, check that the ERSSPD or PRGSPD bit is 1 and the suspended state is entered, then proceed with the subsequent flow. If a P/E resume command is issued in the subsequent flow even when the suspended state is not entered, an illegal command error occurs and the flash sequencer shifts to the command-locked state (see [section 52.11.2. Error Protection](#)).

If the erasure suspended state is entered, programming to blocks other than an erasure target block can be performed. Additionally, the programming and erasure suspended states can shift to read mode by clearing the FENTRYR register.

[Figure 52.17](#) shows the usage of the P/E suspend command.

Note 1. Judgment of the timeout is based on 1.1 times the maximum time of suspend delay during erasure for both code flash and data flash.

See [section 55, Electrical Characteristics](#).

Note 2. $4.4\mu\text{s}$ ($f_{\text{CLK}} \geq 20\text{MHz}$)

Figure 52.17 Usage flow of the P/E suspend command

(1) Suspension during Programming

When issuing a P/E suspend command during flash memory programming, the flash sequencer suspends programming processing. [Figure 52.18](#) shows the suspend programming operation. When receiving programming-related command, the flash sequencer clears the FRDY bit in the FSTATR register to 0 to start programming. If the flash sequencer enters the

state in which the P/E suspend command can be received after programming starts, it sets the SUSRDY bit in the FSTATR register to 1.

When a P/E suspend command is issued, the flash sequencer receives the command and clears the SUSRDY bit to 0. If the flash sequencer receives a P/E suspend command while a programming pulse is applied, the flash sequencer continues with the pulse. After the specified pulse application time, the flash sequencer finishes pulse application, starts the programming suspend processing, and sets the PRGSPD bit in the FSTATR register to 1.

When a suspended processing finishes, the flash sequencer sets the FRDY bit to 1 to enter the programming suspended state. When receiving a P/E resume command in the programming suspended state, the flash sequencer clears the FRDY and PRGSPD bits to 0 and resumes programming.

Figure 52.18 shows the timing for suspension during programming.

Figure 52.18 Suspension during programming

(2) Suspension during Erasure (Suspension Priority Mode)

The flash sequencer has a suspension priority mode for the suspension of erasure. Figure 52.19 shows the suspend operation of erasure when the erasure suspend mode is set to the suspension priority mode (the ESUSPMD bit in the FCPSR register is 0).

When receiving an erasure-related command, the flash sequencer clears the FRDY bit in the FSTATR register to 0 to start erasure. If the flash sequencer enters the state in which the P/E suspend command can be received after erasure starts, it sets the SUSRDY bit in the FSTATR register to 1.

When a P/E suspend command is issued, the flash sequencer receives the command and clears the SUSRDY bit to 0.

When receiving a suspend command during erasure, the flash sequencer starts the suspend processing and sets the ERSSPD bit in the FSTATR register to 1 even when it is applying an erasure pulse. When the suspended processing finishes, the flash sequencer sets the FRDY bit to 1 to enter the erasure suspended state. When receiving a P/E resume command in the erasure suspended state, the flash sequencer clears the FRDY and ERSSPD bits to 0 and resumes erasure. Operations of the FRDY, SUSRDY, and ERSSPD bits at the suspension and resumption of erasure are the same, regardless of the erasure suspend mode.

The setting of the erasure suspend mode affects the control method of erasure pulses. In suspension priority mode, when receiving a P/E suspend command while erasure pulse A that has not been previously suspended is being applied, the flash sequencer suspends the application of erasure pulse A and enters the erasure suspended state. When receiving a P/E suspend command while reapplying erasure pulse A after erasure is resumed with a P/E resume command, the flash sequencer

continues to apply erasure pulse A. After the specified pulse application time, the flash sequencer finishes erasure pulse application and enters the erasure suspended state.

When the flash sequencer receives a P/E resume command next and erasure pulse B is being applied, the flash sequencer receives a P/E suspend command again, and the application of erasure pulse B is then suspended. In suspension priority mode, delays due to suspension can be minimized because the application of an erasure pulse is suspended once per pulse, and priority is given to the suspend processing.

If the interval of suspension after resume is longer than t_{REST1} (Resume time: priority on suspension, resume after the 1st suspend for the same pulse), suspend delay will be always t_{SED1} (Suspend delay: priority on suspension, the 1st suspend for the same pulse).

If the interval of suspension after resume is shorter than t_{REST1} , suspend delay becomes either t_{SED1} or t_{SED2} (Suspend delay: priority on suspension, the 2nd suspend for the same pulse).

(The value of t_{REST1} / t_{SED1} / t_{SED2} , see [section 55, Electrical Characteristics](#).)

Figure 52.19 Suspension during erasure (suspension priority mode)

(3) Suspension during Erasure (Erasure Priority Mode)

The flash sequencer has an erasure priority mode for the suspension of erasure. [Figure 52.20](#) shows the suspend operation of erasure when the erasure suspend mode is set to the erasure priority mode (the ESUSPMD bit in the FCPSR register is 1). The control method of erasure pulses in erasure priority mode is the same as that of programming pulses for the programming suspend processing.

If the flash sequencer receives a P/E suspend command while an erasure pulse is applied, the flash sequencer continues to apply the pulse. In this mode, the required time for the erasure processing can be reduced compared to the suspension priority mode because the re-application of erasure pulses does not occur when a P/E resume command is issued.

Figure 52.20 Suspension during erasure (erasure priority mode)

52.9.3.11 P/E Resume Command

The P/E resume command is used to resume suspended programming or erasure. If the FENTRYR setting has been modified during suspension, issue a P/E resume command only after resetting FENTRYR to the previous value that was held before the P/E suspend command was issued. [Figure 52.21](#) shows usage of the P/E resume command.

Figure 52.21 Usage flow of the P/E resume command

52.9.3.12 Status Clear Command

The status clear command is used to clear the command-locked state (see [section 52.9.3.6. Recovery from the Command-Locked State](#)).

You can use the status clear command to clear the following bits in the FSTATR register in the command-locked state:

- ILGLERR
- ILGCOMERR
- FESETERR
- SECERR
- OTERR
- ERSERR
- PRGERR
- TZFERR

[Figure 52.22](#) shows usage of the status clear command.

Figure 52.22 Usage flow of the status clear command

52.9.3.13 Forced Stop Command

The forced stop command is used to forcibly end command processing by the flash sequencer. Although this command halts command processing more quickly than the P/E suspension command, values from the programming or erasure that are in progress are not guaranteed. Additionally, resumption of processing is not possible. Processing of programming or erasure that is halted by the forced stop command is also defined as one programming round.

Executing the forced stop command also initializes part of the FACL, the whole FCU, the FSTATR and FASTAT registers. This command can be used in the procedure for recovery from the command-locked state and for processing in response to a timeout of the flash sequencer (see [section 52.9.3.6. Recovery from the Command-Locked State](#)).

[Figure 52.23](#) shows usage of the forced stop command.

Figure 52.23 Usage flow of the forced stop command

(1) Notes on Using the Forced Stop Command during Command Issue

When using the forced stop command at the timeout occurrence by DBFULL bit of the program command, writing in the FACI command-issuing area is sometimes processed as writing in data of the program command. See [Table 52.4](#) in [section 52.3. Address Space](#) for information on the FACI command-issuing area to force a command lock. Then issue a forced stop command with return method from the command lock status (see [Figure 52.14](#)). Locking commands is possible in any case where the unit for reading the FACI command issuing area is 8, 16, or 32 bits.

52.9.3.14 Blank Check Command

The blank check command is used to confirm that an area is in the non-programmed state. Values read from the data flash memory that have been erased but not yet programmed again that is in the non-programmed state, are undefined.

Before issuing the Blank Check command, set addressing mode, start address, and end address of the target area for Blank Check to the FBCCNT, FSADDR, and FEADDR registers. When Blank Check addressing mode is set to decremental mode (i.e. FBCCNT.BCDIR = 1), address specified in FSADDR should be equal to or larger than address in FEADDR.

On the other hand, the address in FSADDR should be equal to or smaller than address in FEADDR when Blank Check addressing mode is set to incremental mode (i.e. FBCCNT.BCDIR = 0).

If the settings of the BCDIR bit, FSADDR, and FEADDR are inconsistent, the flash sequencer enters the command-locked state. The size of the target area for Blank Check is in the range from 4 bytes to the data flash memory capacity and is set in units of 4 bytes.

Write 0x71 and 0xD0 to the FACI command-issuing area to start Blank Check. Completion of processing can be confirmed by the FRDY bit of the FSTATR register. At the end of processing, the result of Blank Check is stored in the BCST bit in the FBCSTAT register. If non-programmed data exists within the target area for Blank Check, flash sequencer stops Blank Check command operation. In this case, address of non-programmed data is indicated to FPSADDR register.

[Figure 52.24](#) shows usage of the blank check command.

Note 1. Judgment of the timeout is based on 1.1 times the maximum time of Blank Checking for the whole target range. See [section 55, Electrical Characteristics](#).

Figure 52.24 Usage flow of the blank check command

52.9.3.15 Configuration Set Command

The Configuration set command is used to set option-setting memory. Before issuing the Configuration set command, set the specified address (shown in [Table 52.22](#)) in the FSADDR register. Writing 0xD0 to the FACL command-issuing area in the final access for issuing the FACL command starts FACL processing of the Configuration set command.

[Figure 52.25](#) shows usage of the configuration set command.

Note 1. Judgment of the timeout is based on 1.1 times the maximum time of programming in option-setting memory. See [section 55, Electrical Characteristics](#).

Figure 52.25 Usage flow of the configuration set command

The correspondence between the possible target data for configuration setting and the address value set in the FSADDR register is shown in Table 52.22. For details, see section 52.4.12. FSADDR : FACS Command Start Address Register.

Table 52.22 Address Used by Configuration Set Command for Secure alias (Code flash memory)

Address	FSADDR Register Value	Setting Data	Operation of additional writing		Timing when the Setting is Enabled
			SAS.FSPR bit is 1	SAS.FSPR bit is 0	
0x0300_A100	0x0300_A100	Option Function Select Register 0 (OFS0)	Writable	Writable	At a reset
0x0300_A104		Option Function Select Register 2 (OFS2)			
0x0300_A110	0x0300_A110	Dual Mode Select Register (DUALSEL)	Writable	Writable	At a reset
0x0300_A134	0x0300_A130	Start-up Area Setting Register (SAS)	Writable	Not writable*1	When a reset or command is executed
0x1300_A180	0x1300_A180	Option Function Select Register 1 (OFS1)	Writable	Writable	At a reset
0x1300_A190	0x1300_A190	Bank Select Register (BANKSEL)	Writable	Writable	At a reset
0x1300_A1C0	0x1300_A1C0	Block Protect Setting Register (BPS)	Writable*2	Writable*2	When a reset or command is executed
0x1300_A1E0	0x1300_A1E0	Permanent Block Protect Setting Register (PBPS)	Writable*3 (from 1 to 0 only)	Writable*3 (from 1 to 0 only)	When a reset or command is executed
0x0300_A200	0x0300_A200	Option Function Select Register 1 Secure (OFS1_SEC)	Writable	Writable	At a reset
0x0300_A210	0x0300_A210	Bank Select Register Secure (BANKSEL_SEC)	Writable	Writable	At a reset
0x0300_A240	0x0300_A240	Block Protect Setting Register Secure (BPS_SEC)	Writable*4	Writable*4	When a reset or command is executed
0x0300_A260	0x0300_A260	Permanent Block Protect Setting Register Secure (PBPS_SEC)	Writable*5 (from 1 to 0 only)	Writable*5 (from 1 to 0 only)	When a reset or command is executed
0x0300_A280	0x0300_A280	Option Function Select Register 1 Select (OFS1_SEL)*6	Writable	Writable	At a reset
0x0300_A290	0x0300_A290	Bank Select Register Select (BANKSEL_SEL)	Writable	Writable	At a reset
0x0300_A2C0	0x0300_A2C0	Block Protect Setting Register Select (BPS_SEL)	Writable*6	Writable*6	At a reset

- Note 1. The SAS.FSPR bit cannot be restored to 1 by using the Configuration set command once it is set to 0. Therefore, setting the start-up area select flags again becomes impossible. (when the Configuration set command is issued to the address of 0x0100A134, the command is locked.) Exercise extra caution when handling the SAS.FSPR bit.
- Note 2. Once PBPS[n] bit is set to 0, the BPS[n] bit cannot be restored to 1 by using the Configuration set command.
- Note 3. Once these bits are set to 0, the bits cannot be restored to 1 by using the Configuration set command. The PBPS[n] bit cannot be set to 0 by using the Configuration set command when the BPS[n] bit is 1.
- Note 4. Once PBPS_SEC[n] bit is set to 0, the BPS_SEC[n] bit cannot be restored to 1 by using the Configuration set command.
- Note 5. Once these bits are set to 0, the bits cannot be restored to 1 by using the Configuration set command. The PBPS_SEC[n] bit cannot be set to 0 by using the Configuration set command when the BPS_SEC[n] bit is 1.
- Note 6. When the Permanent Block Protect bit is enabled, Block protect setting register cannot be written.

Table 52.23 Address Used by Configuration Set Command for Secure alias (Data flash memory) (1 of 2)

Address	FSADDR	Setting Data	Operation of additional writing			Timing when the Setting is Enabled
	Register Value			Lock bit is 1	Lock bit is 0	
0x2703_0080~0x2703_017C	0x2703_0080~0x2703_017C	Lockable Configuration Data Area 0 (LK_CD_A0)	Writable*1	Not Writable*1		At a reset
0x2703_0180~0x2703_027C	0x2703_0180~0x2703_027C	Lockable Configuration Data Area 1 (LK_CD_A1)	Writable*1	Not Writable*1		At a reset
0x2703_0280~0x2703_037C	0x2703_0280~0x2703_037C	Lockable Configuration Data Area 2 (LK_CD_A2)	Writable*1	Not Writable*1		At a reset

Table 52.23 Address Used by Configuration Set Command for Secure alias (Data flash memory) (2 of 2)

Address	FSADDR	Setting Data	Operation of additional writing		Timing when the Setting is Enabled
	Register Value		Lock bit is 1	Lock bit is 0	
0x2703_0380~0x2703_0384	0x2703_0380~0x2703_0384	Configuration Data Lock Bit Area 0 (CD0_LK)	Writable	Writable	When a reset or command is executed
0x2703_0388~0x2703_038C	0x2703_0388~0x2703_038C	Configuration Data Lock Bit Area 1 (CD1_LK)	Writable (from 1 to 0 only)	Writable (from 1 to 0 only)	When a reset or command is executed
0x2703_0390	0x2703_0390	Configuration Data Lock Bit Area 2 (CD2_LK)	Writable (from 1 to 0 only)	Writable (from 1 to 0 only)	When a reset or command is executed
0x2703_03C0	0x2703_03C0	Anti-Rollback Counter Lock Setting (ARCLS)	Writable (from 1 to 0 only)	Writable (from 1 to 0 only)	When a reset or command is executed
0x2703_03C2		Anti-Rollback Counter Configuration Setting for ARC_NSEC (ARCCS)	Writable*2	Writable*2	When a reset or command is executed

Note 1. For details of relation of write-protection area and lock bit, see [section 52.12.4. Data Flash Configuration Area Protection](#).

Note 2. The ARC_NSEC counter selection bit cannot be changed after set to 00b or 01b. When using the ARC_NSEC counter, this counter can be selected either of 4 lines of 64 bits (00b setting) or 1 line of 256 bits (01b setting).

52.9.3.16 Increment Counter Command

The Increment Counter command is used to security function, safety function. "Increment Counter" command is used for updating 3 types of anti-rollback counter (ARC_SEC, ARC_NSEC, and ARC_OEMBL). The counter update is executed increment processing and cannot be decrement processing.

Writing "0xD0" at 2nd write access of flash sequencer command triggers FACL to start "Increment Counter" command processing. Completion of command processing can be confirmed by FRDY bit of FSTATR register.

If "Command Lock" status occurs during command execution, refresh the counter with "Refresh Counter" command after "Command Lock" state is released.

Figure 52.26 Usage of the Increment Counter Command

Anti-rollback counter value is not increased the following conditions by "Increment Counter" command.

- Target counter is protected by ARCSEC_LK, ARCNSEC_LK0~3, or ARCOEMBL_LK.
- The previous command is not "Read Counter" command against ARC_OEMBL when target counter is ARC_OEMBL.
- The anti-rollback counter for OEM_BL cannot be incremented more than OEM_BL version number specified in the image version of the header of the code certificate. After updated the OEM_BL, the anti-rollback counter for OEM_BL cannot be incremented. For details, see [section 43, Security Features](#).
- Target counter value is maximum. (Error does not occur)
- Target counter is ARC_NSEC when CNF_ARCNSEC0~1 is invalid setting.

52.9.3.17 Refresh Counter Command

The Refresh Counter command is used to security function, safety function. "Refresh Counter" command is used for update of anti-rollback counter when power failure is occurred while "Increment Counter" command processing. Counter value is not changed by "Refresh Counter" command.

Writing "0xD0" at 2nd write access of flash sequencer command triggers FACL to start "Increment Counter" command processing. Completion of command processing can be confirmed by FRDY bit of FSTATR register.

If "Command Lock" status occurs during command execution, refresh the counter with "Refresh Counter" command after "Command Lock" state is released.

Figure 52.27 Usage of the Refresh Counter Command

52.9.3.18 Read Counter Command

The Read Counter command is used to security function, safety function. "Read Counter" command is used for reading 3 types of anti-rollback counter (ARC_SEC, ARC_NSEC, and ARC_OEMBL). Flash sequencer automatically judges valid area of anti-rollback counter, reads 64 bits data, and stores to FCNTDATAR0 and FCNTDATAR1 registers.

Writing "0xD0" at 2nd write access of flash sequencer command triggers FACL to start "Read Counter" command processing. Completion of command processing can be confirmed by FRDY bit of FSTATR register.

Figure 52.28 Usage of the Read Counter Command

52.10 Suspend Operation

Reading from the flash memory is not possible during programming or erasure if the conditions for background operation given in [Table 52.39](#) are not satisfied. When a P/E suspend command is issued to suspend the programming or erasure of the flash memory, reading from the flash memory is enabled. Regarding P/E suspend commands, there are one suspend command mode for programming and two suspend command modes for erasure (suspension priority mode and erasure priority mode). To resume suspended programming or erasure, the P/E resume command is available. For details on the suspend operation, see [Figure 52.17](#).

52.11 Protection Function

52.11.1 Software Protection

Software protection disables programming and erasure of the code flash memory through the settings of control registers and block protect setting in the user area. If an attempt is made to issue an FACL command against software protection, the flash sequencer enters the command-locked state.

52.11.1.1 Protection through FWEPROR

Unless the FWEPROR.FLWE[1:0] bits are set to 01b, programming cannot proceed in any mode.

52.11.1.2 Protection by FENTRYR

When the FENTRYR register is set to 0x0000, the flash sequencer enters read mode. In read mode, FACL commands cannot be accepted. If an attempt is made to issue an FACL command in read mode, the flash sequencer enters the command-locked state.

52.11.1.3 Protection by Block Protect Setting

Each block in user area has the block protect setting (BPS or BPS_SEC). When the FBPROT0 or FBPROT1 register is 0x0000 and the block protect bit is 0, issuing the Program or Block Erase command to user area of the code flash causes the command-locked state. To program or erase the block whose block protect bit is 0, set the FBPROT0 or FBPROT1 register to 0x0001.

The block protect setting can be locked by the permanent block protect setting (PBPS or PBPS_SEC). When the permanent block protect setting and the block protect setting are 0, issuing a Program or Block erase command to user area of the code flash causes the flash sequencer to enter the command-locked state regardless of the FBPROT0 and FBPROT1 register settings.

Valid block protect setting (BPS or BPS_SEC) depends on the Block Protect Select bit (BPS_SEL).

See [section 52.12.2. Permanent Block Protect Setting](#) for details of the block protect setting and permanent block protect setting. See [section 52.4.17. FBPROT0 : Flash Block Protection Register](#) and [section 52.4.18. FBPROT1 : Flash Block Protection for Secure Register](#) for more information.

For details of block protect setting (BPS or BPS_SEC) and block protect select (BPS_SEL), see [section 6, Option-Setting Memory](#).

The protected area by the block protect setting is always determined by the address of the FSADDR register setting regardless of the address swapping function setting (the startup area select, the block swap in linear mode, and the startup bank select in dual mode). [Table 52.24](#) to [Table 52.29](#) show the relation of user area and the block protect setting in each function setting.

(1) In case of the linear mode

- BPS[0] to BPS[n] or BPS_SEC[0] to BPS_SEC[n] are assigned to the block of user area (for example, address is 0x00_0000 to the last block address).
- BPS[0]/BPS_SEC[0] and BPS[1]/BPS_SEC[1] are assigned to the block of user area depending on the startup area select setting (SAS.BTFLG bit). (See [section 52.11.3. Start-Up Program Protection](#)).
- The second half of FLI user area is assigned to block protect setting depending on the block swap select setting (BANKSEL.BLOCKSWP[6:0] bits). See [section 52.11.5. Block Swap Function](#).

[Table 52.24](#) shows the block protect setting when the startup area select is disabled (not swapping).

[Table 52.25](#) and later show example of the block protect setting when the address conversion function is used.

Table 52.24 Example of Block Protect setting when SAS.BTFLG is 1

FSADDR[23:0]	Block size	Block protect setting	User area block number	Notes
The last block address	32 KB	BPS[n] or BPS_SEC[n]	Block n	—
⋮	⋮	⋮	⋮	—
0x01_8000 to 0x01_FFFF	32 KB	BPS[9] or BPS_SEC[9]	Block 9	—
0x01_0000 to 0x01_7FFF	32 KB	BPS[8] or BPS_SEC[8]	Block 8	—
0x00_E000 to 0x00_FFFF	8 KB	BPS[7] or BPS_SEC[7]	Block 7	—
0x00_C000 to 0x00_DFFF	8 KB	BPS[6] or BPS_SEC[6]	Block 6	—
⋮	⋮	⋮	⋮	—
0x00_2000 to 0x00_3FFF	8 KB	BPS[1] or BPS_SEC[1]	Block 1	Not swap block 0 and block 1 in this startup area select setting
0x00_0000 to 0x00_1FFF	8 KB	BPS[0] or BPS_SEC[0]	Block 0	Not swap block 0 and block 1 in this startup area select setting

Table 52.25 Example of Block Protect setting when SAS.BTFLG is 0

FSADDR[23:0]	Block size	Block protect setting	User area block number	Notes
The last block address	32 KB	BPS[n] or BPS_SEC[n]	Block n	—
⋮	⋮	⋮	⋮	—
0x01_8000 to 0x01_FFFF	32 KB	BPS[9] or BPS_SEC[9]	Block 9	—

Table 52.27 Example of Block Protect setting when BANKSEL.BLCKSWP is 0 (1 of 2)

FSADDR[23:0]	Block size	Block protect setting	User area block number	Notes
The last block address	32 KB	BPS[n] or BPS_SEC[n]	Block n	—
⋮	⋮	⋮	⋮	—
The updating side address of the block swap target	32 KB	BPS[b] or BPS_SEC[b]	Block a	Swap block a and block b in this block swap select setting
⋮	⋮	⋮	⋮	—
The operating side address of the block swap target	32 KB	BPS[a] or BPS_SEC[a]	Block b	Swap block a and block b in this block swap select setting

Table 52.27 Example of Block Protect setting when BANKSEL.BLCKSWP is 0 (2 of 2)

FSADDR[23:0]	Block size	Block protect setting	User area block number	Notes
⋮	⋮	⋮	⋮	—
0x01_8000 to 0x01_FFFF	32 KB	BPS[9] or BPS_SEC[9]	Block 9	—
0x01_0000 to 0x01_7FFF	32 KB	BPS[8] or BPS_SEC[8]	Block 8	—
0x00_E000 to 0x00_FFFF	8 KB	BPS[7] or BPS_SEC[7]	Block 7	—
0x00_C000 to 0x00_DFFF	8 KB	BPS[6] or BPS_SEC[6]	Block 6	—
⋮	⋮	⋮	⋮	—
0x00_2000 to 0x00_3FFF	8 KB	BPS[1] or BPS_SEC[1]	Block 1	—
0x00_0000 to 0x00_1FFF	8 KB	BPS[0] or BPS_SEC[0]	Block 0	—

(2) In case of the dual mode (DUALSEL.BANKMD[2:0] = 000b)

- BPS[0] to BPS[n] or BPS_SEC[0] to BPS_SEC[n] are assigned the block of bank 0 user area (for example, address is 0x00000000 to the last block address in the lower side bank).
- BPS[70] to BPS[70 + n] or BPS_SEC[70] to BPS_SEC[70 + n] are assigned to the block of bank 1 user area (for example, address is 0x00200000 to the last block address in the upper side bank).

Bank0 is upper side bank (BANKSEL.BANKSWP[2:0] = 000b)

- BPS[0] to BPS[n] or BPS_SEC[0] to BPS_SEC[n] are assigned to the block of bank1 user area (e.g. Address is 0x00_0000 to The last block address in lower side bank).
- BPS[70] to BPS[70+n] or BPS_SEC[70] to BPS_SEC[70+n] are assigned to the block of bank0 user area (e.g. Address is 0x20_0000 to The last block address in upper side bank).

Table 52.28 and Table 52.29 show example of the block protect setting in the dual mode. See [section 52.11.4. Dual Bank Function](#) for details of dual bank function (DUALSEL.BANKMD[2:0] and BANKSEL.BANKSWP[2:0] bits).

Table 52.28 Example of Block Protect setting when BANKSEL.BANKSWP[2:0] is 111b (1 of 2)

FSADDR[23:0]	Block size	Block protect setting	User area block number	Notes
The last block address in upper side bank	32 KB	BPS[70 + n] or BPS_SEC[70 + n]	Block 70 + n	Not swap bank 0 and bank 1 in this startup bank switch setting
⋮	⋮	⋮	⋮	
0x21_8000 to 0x21_FFFF	32 KB	BPS[79] or BPS_SEC[79]	Block 79	
0x21_0000 to 0x21_7FFF	32 KB	BPS[78] or BPS_SEC[78]	Block 78

⋮	⋮	⋮	⋮	
0x00_2000 to 0x00_3FFF	8 KB	BPS[1] or BPS_SEC[1]	Block 71	
0x00_0000 to 0x00_1FFF	8 KB	BPS[0] or BPS_SEC[0]	Block 70	

52.11.2 Error Protection

Error protection detects the issuing of illegal FACL commands, illegal access, and flash sequencer malfunction. FACL command acceptance is disabled (command-locked state) in response to the detection of these errors. The flash memory cannot be programmed or erased while the flash sequencer is in the command-locked state. For release from the command-locked state, issue the Status Clear or Forced Stop command. The Status Clear command can only be used while the FRDY bit in the FSTATR register is 1. The Forced Stop command can be used regardless of the value of the FRDY bit. While the CMDLKIE bit in the FAEINT register is 1, a flash access error (FIFERR) interrupt is generated if the flash sequencer enters the command-locked state (the CMDLK bit in the FSTAT register is set to 1).

If the flash sequencer enters the command-locked state in response to a command other than the P/E suspend command during programming or erasure processing, the flash sequencer continues the processing for programming or erasure. In this

state, the P/E suspend command cannot be used to suspend the processing for programming or erasure. If a command is issued in the command-locked state, the ILGLERR bit becomes 1 and the other bits retain the values set from previous error detection.

Table 52.30 shows the error protection types and status bit values after error detections.

Table 52.30 Error protection type (1 of 3)

Error type	Description	ILGOMERR	FESETERR	SECERR	OTERR	TZFERR	ILGLERR	ERSERR	PRGERR	FLWEERR	CFAE	DFAE
FENTRYR setting error	The value set in FENTRYR is not 0x0000, 0x0001, or 0x0080	0	1	0	0	0	1	0	0	0	0	0
	The FENTRYR setting at suspension is different from that at resumption	0	1	0	0	0	1	0	0	0	0	0
Illegal command error	An undefined size is specified in the first cycle of the command. (not byte-write)	1	0	0	0	0	1	0	0	0	0	0
	An undefined code is written in the first access of the FACL command	1	0	0	0	0	1	0	0	0	0	0
	The value specified in the last access of the multiple-access FACL command is not 0xD0	1	0	0	0	0	1	0	0	0	0	0
	The value (N) specified in the second write access of the FACL command in the program or configuration set command is wrong	1	0	0	0	0	1	0	0	0	0	0
	Blank Check command is issued with inconsistent BCDIR, FSADDR, and FEADDR settings (see section 52.4.13. FEADDR : FACL Command End Address Register)	1	0	0	0	0	1	0	0	0	0	0/1 *1
	A multi block erase command is issued with inconsistent FSADDR and FEADDR settings. - FSADDR > FEADDR - FEADDR is set to reserved area.	1	0	0	0	0	1	0	0	0	0	0/1 *1
	Increment Counter, Refresh Counter, or Read Counter command is issued with inconsistent FCNTSEL[2:0] setting. (Include CNF_ARCNS0,1 setting is the mismatch.)	1	0	0	0	0	1	0	0	0	0	0
	An FACL command not acceptable in each mode is issued (see Table 52.19)	1	0	0	0	0	1	0	0	0	0	0
	An FACL command is issued when command acceptance conditions are not satisfied (see Table 52.20)	0/1	0/1	0/1	0/1	0	1	0/1	0/1	0/1	0/1	0/1
	A program, block erase or multi block erase command is issued against the area protected by the block protect setting (see section 52.11.1.3. Protection by Block Protect Setting)	1	0	0	0	0	1	0	0	0	0	0

Table 52.30 Error protection type (2 of 3)

Error type	Description	ILGOMERR	FESETERR	SECERR	OTERR	TZFERR	ILGLERR	ERSERR	PRGERR	FLWEERR	CFAE	DFAE
Illegal command error	Configuration set command is issued against Data flash configuration area protected by lock bit setting	1	0	0	0	0	1	0	0	0	0	0
	Increment Counter or Refresh Counter command is issued against anti-rollback area protected by lock bit setting	1	0	0	0	0	1	0	0	0	0	0
	A program command is issued against the erase area in erase suspend	1	0	0	0	0	1	0	0	0	0	0
	Increment counter command against ARC_OEMBL is issued when the RSIP-E51A register setting is same or smaller than ARC_OEMBL value. (see section 52.12.5. Anti-Rollback Counter)	1	0	0	0	0	1	0	0	0	0	0
	Increment counter command against ARC_OEMBL is issued when previous command is not read counter command against ARC_OEMBL.	1	0	0	0	0	1	0	0	0	0	0
	A command is issued against flash sequencer command illegal status (see Table 52.17).	0/1	0/1	0/1	0/1	0	1	0/1	0/1	0/1	0/1	0/1
Erase error	An error occurs during erasure	0	0	0	0	0	0	1	0	0	0	0
Programming error	An error occurs during programming	0	0	0	0	0	0	0	1	0	0	0
Code flash memory access violation	An FACL command is issued to the reserved portion of the user area in code flash P/E mode	0	0	0	0	0	1	0	0	0	1	0
	Configuration set command is issued to the reserved configuration area in code flash P/E mode.	0/1	0	0	0	0	1	0	0	0	1	0
	Program, block erase, or configuration set command is issued to TrustZone protection area in code flash P/E mode.	0/1	0	0	0	1	1	0	0	0	1	0
Data flash memory access violation	A program or block erase command is issued to the reserved data area in data flash P/E mode	0	0	0	0	0	1	0	0	0	0	1
	A multi block erase command is issued to the reserved data area in data flash P/E mode. (FSADDR is set to reserved data area).	1	0	0	0	0	1	0	0	0	0	1
	Blank Check command is issued to reserved data area in data flash P/E mode. (FSADDR is set to reserved data area).	1	0	0	0	0	1	0	0	0	0	1
	Configuration set command has been issued to reserved configuration area in data flash P/E mode.	0/1	0	0	0	0	1	0	0	0	0	1
	A program, block erase, multi block erase, blank check, configuration set, increment counter, refresh counter, or read counter command is issued to TrustZone protection area in data flash P/E mode.	0	0	0	0	0	1	0	0	0	0	1

Table 52.30 Error protection type (3 of 3)

Error type	Description	ILGOMERR	FESETERR	SECERR	OTERR	TZFERR	ILGLERR	ERSERR	PRGERR	FLWEERR	CFAE	DFAE
Security error	Configuration set command for the SAS.BTFLG bit setting is issued when the SAS.FSPR bit is 0 (see section 52.9.3.15. Configuration Set Command)	0	0	1	0	0	1	0	0	0	0	0
Others	An FACL command-issuing area is accessed in read mode	0	0	0	1	0	1	0	0	0	0	0
	An FACL command-issuing area is read in code flash P/E mode or data flash P/E mode	0	0	0	1	0	1	0	0	0	0	0
Flash write erase protection error	A flash memory write protection error is detected by the FWEPROR register setting* ² during command processing by the flash sequencer	0	0	0	0	0	0	0/1	0/1	1	0	0

Note 1. DFAE value depends on the FSADDR setting.

Note 2. For details on the FWEPROR register, see [section 52.4.8. FWEPROR : Flash P/E Protect Register](#).

52.11.3 Start-Up Program Protection

Protection of the startup program is for protection of the program to be started after a reset (the startup program). This function provides a way to safely update the startup program when rewriting is suspended during a reset.

The startup area is 8 Kbytes in size and is assigned to the user area in the code flash memory. This function uses the values of the SAS.BTFLG bit and the FSUACR.SAS[1:0] bits to change the area where the startup program is stored in block units (see [Figure 52.29](#) to [Figure 52.32](#)).

In protection of the startup program, the state of the selection of the startup area can be fixed by the FSPR bit. However, the SAS.FSPR bit never be restored to 1 once the flag is set to 0. Exercise extra caution when handling the SAS.FSPR bit.

In addition, this protection cannot be used when dual mode is selected by the bank mode switching function (when the BANKMD[2:0] bits are 000b).

For details of SAS.FSPR bit and DUALSEL.BANKMD[2:0] bits, see [section 6, Option-Setting Memory](#).

Figure 52.29 Concept of Protection of the Startup Program for Secure alias

Figure 52.30 Example 1 of Transitions for Startup Program Protection Settings for Secure alias

Figure 52.31 Example 2 of Transitions for Startup Program Protection Settings for Secure alias

Figure 52.32 Concept of Protection of the Startup Program for Secure alias

52.11.4 Dual Bank Function

This protection uses the functions of bank mode switching and startup bank selection to update a program while a user program is running and to provide a safe method of updating in cases where programming is suspended during a reset.

52.11.4.1 Switching Bank Modes

The bank mode switching function selects either linear mode in which the user area in the code flash memory is used as one area, or dual mode in which the user area is divided into two bank areas. [Figure 52.33](#) shows an example of flow of switching bank modes. A reset after setting the DUALSEL.BANKMD[2:0] bits in the option setting memory determines the mode of the bank mode switching function. Selecting dual mode enables the startup bank selection function.

When dual mode is selected by bank mode switching function (the DUALSEL.BANKMD[2:0] bits are 000b), start-up program protection function cannot be used.

For details of DUALSEL.BANKMD[2:0] bits, see [section 6, Option-Setting Memory](#).

Figure 52.33 Example of Flow of Switching Bank Modes for Secure alias (For Products with 2 Mbytes of Code Flash Memory)

52.11.4.2 Selecting the Startup Bank

Startup bank selection provides a way to safely update the program by selecting a bank area to be started in dual mode (when the DUALSEL.BANKMD[2:0] bits are 000b) when programming is suspended during a reset. [Figure 52.34](#) is a schematic view of startup bank selection and [Table 52.31](#) shows an example of the flow of startup bank selection. A reset after setting the value of the BANKSEL.BANKSWP[2:0] bits in the option-setting memory changes the addresses of banks 0 and 1 and booting up a program proceeds from the updated area. When the address is switched by using startup bank selection, the programming/erase target for the FACL commands is also switched. This function is invalid in linear mode.

For details of DUALSEL.BANKMD[2:0] bits and BANKSEL.BANKSWP[2:0] bits, see [section 6, Option-Setting Memory](#).

Figure 52.34 Example of Startup Bank Selection for Secure alias (For Products with 2 MB of Code Flash Memory)

Table 52.31 Example of Startup Bank Selection Flow for Secure alias (For Products with 2 MB of Code Flash Memory)

No.	Step Name	Description
1	Erase block	Erase blocks to be programmed in the address range from 0x0220_0000 to 0x022F_7FFF
2	Program a new software	Program a new software in the address range from 0x0220_0000 to 0x022F_7FFF
3	Read the value	Read the value of the BANKSEL.BANKSWP [2:0] bits.
4	Write an inverted value	Write an inverted value in the BANKSEL.BANKSWP[2:0] bits*1.
5	Issue a reset	Issue a reset (A reset switches the banks.)

Note 1. Set the inverse of the read value of the BANKSEL.BANKSWP[2:0] bits (000b or 111b).

52.11.5 Block Swap Function

This protection uses the functions of block swap selection to update a program while a user program is running and to provide a safe method of updating in cases where programming is suspended during a reset.

52.11.5.1 Selecting the Block Swap

Block swap selection provides a way to safely update the program when programming is suspended during a reset. [Figure 52.35](#) is a schematic view of block swap selection and [Figure 52.36](#) shows an example of the flow of block swap selection. A reset after setting the value of the BANKSEL.BLCKSWP bit in the option-setting memory changes the addresses of block A and B. When the address is switched, the Programming/erasure target for the FACL commands is also switched.

In addition, this protection cannot be used when dual mode is selected by the bank mode switching function (when the DUALSEL.BANKMD[2:0] bits are 000b).

For details of DUALSEL.BANKMD[2:0] bits and BANKSEL.BLCKSWP bit, see [section 6, Option-Setting Memory](#).

Figure 52.35 Example of Block Swap Selection for Secure alias (For Products with 2 Mbytes of Code Flash Memory)

Figure 52.36 Example of Block Swap Selection Flow for Secure alias (For Products with 2 Mbytes of Code Flash Memory)

52.12 Security Function

The flash sequencer supports the following security functions:

- Security flag for startup area
- Permanent block protect setting
- Flash memory protection for TrustZone
- Code Flash P/E mode Entry Protection
- Data flash configuration area protection
- Anti-rollback Counter

52.12.1 Security Flag for Startup Area Select

The security flag (SAS.FSPR) for the startup area is located in the option-setting memory.

When the SAS.FSPR bit is 0, issuing the configuration set command to change the SAS.BTFLG bit causes the flash sequencer to be in the command-locked state. Also, when the SAS.FSPR bit is 0, it is invalid to write to the Startup Area Select bits SAS[1:0] in the FSUACR register. The SAS.FSPR bit enables protection.

52.12.2 Permanent Block Protect Setting

The permanent block protect setting is the clear protection for the block protection setting. User area cannot be permanently updated by the FACL command when the permanent block protect setting is enabled. See [section 52.11.1.3. Protection by Block Protect Setting](#) for more details.

The block protect setting and the permanent block protect setting have the write/clear protection against the configuration set command. The flash sequencer does not detect an error when the configuration set command is issued to the write/clear protected settings.

Figure 52.37 and Table 52.32 show the write/clear protection against the block protect setting (BPS[n]) and the permanent protect setting (PBPS[n]). Figure 52.38 and Table 52.33 show the write/clear protection against the block protect setting for Secure (BPS_SEC[n]) and permanent protect setting for Secure (PBPS_SEC[n]).

Effective permanent block protect setting (PBPS or PBPS_SEC) depends on block protect select (BPS_SEL). For details of permanent block protect setting (PBPS or PBPS_SEC) and block protect select (BPS_SEL), see section 6, Option-Setting Memory.

Figure 52.37 Status transition of flash sequencer by BPS[n] and PBPS[n]

Table 52.32 Write/clear protection of BPS[n] , PBPS[n] and BPS_SEL[n]

Current state		Updatable state by configuration set command				
BPS[n]	PBPS[n]	BPS[n] = 1	BPS[n] = 0	PBPS[n] = 1	PBPS[n] = 0	BPS_SEL[n] = 1
1	1	✓	✓	✓	X	✓
1	0	—	—	—	—	—
0	1	✓	✓	✓	✓	✓
0	0	X	✓	X	✓	X

Note:

- ✓ indicates updatable by configuration set command.
- X indicates not updatable by configuration set command (error does not occur).
- — indicates not reaching to this state.

Figure 52.38 Status transition of flash sequencer by BPS_SEC[n] and PBPS_SEC[n]

Table 52.33 Write/clear protection of BPS_SEC[n], PBPS_SEC[n] and BPS_SEL[n]

Current state		Updatable state by configuration set command				
BPS_SEC[n]	PBPS_SEC[n]	BPS_SEC[n] = 1	BPS_SEC[n] = 0	PBPS_SEC[n] = 1	PBPS_SEC[n] = 0	BPS_SEL[n] = 0
1	1	✓	✓	✓	X	✓
1	0	—	—	—	—	—
0	1	✓	✓	✓	✓	✓
0	0	X	✓	X	✓	X

Note:

- ✓ indicates updatable by configuration set command.
- X indicates not updatable by configuration set command (error does not occur).
- indicates not reaching to this state.

52.12.3 Flash Memory Protection for TrustZone

Information in this section focuses on the flash sequencer operation.

The flash memory provides the following types of protect function against Non-secure access:

- Protection for flash memory area (P/E)
- Protection for flash memory area (read)
- Protection for registers
- Code flash P/E mode entry protection

52.12.3.1 Protection for Flash Memory Area (P/E)

This function protects the Secure region of the code flash and data flash from FACL commands of Non-secure access. The condition of protection depends on the FACL command, the access attribution, and the memory boundary setting.

For details of Secure region, see [section 43, Security Features](#).

See [Table 52.34](#) for information on protection of the flash memory area (P/E).

Table 52.34 Protection for the flash memory area (P/E) (1 of 2)

FACL command	Target area			Issuing FACL command by Non-secure access	Issuing FACL command by Secure access
Program Block Erase	Code flash memory	User area (Non-secure area)	Secure alias ^{*1}	X	X
			Non-secure alias ^{*2}	✓	✓
		User area (Secure area)	Secure alias ^{*1}	X	✓
			Non-secure alias ^{*2}	X	X
	Data flash memory	Data area (Non-secure area)	Secure ^{*1} alias	X	X
			Non-secure alias ^{*2}	✓	✓
		Data area (Secure area)	Secure alias ^{*1}	X	✓
			Non-secure alias ^{*2}	X	X
Multi Block Erase Blank Check	Data flash memory	Data area (Non-secure area)	Secure alias ^{*3}	X	X
			Non-secure alias ^{*4}	✓	✓
		Data area (Secure area)	Secure alias ^{*3}	X	✓
			Non-secure alias ^{*4}	X	X

Table 52.34 Protection for the flash memory area (P/E) (2 of 2)

FACI command	Target area			Issuing FACI command by Non-secure access	Issuing FACI command by Secure access
Configuration set	Code flash memory	Configuration area (Non-secure area)	Secure alias ^{*1}	X	X
			Non-secure alias ^{*2}	✓	✓
		Configuration area (Secure area)	Secure alias ^{*1}	X	✓
			Non-secure alias ^{*2}	X	X
	Data flash memory	Configuration area (Secure area only)	Secure alias ^{*1}	X	✓
			Non-secure alias ^{*2}	X	X
Increment Counter Refresh Counter Read Counter	Data flash memory	Anti-rollback counter area (Secure area only)	-	X	✓

Note:

- ✓ indicates FACI command operation is not prohibited.
- X indicates FACI command operation is prohibited. Error occurs when the area is selected, and the FACI command is executed.

Note 1. The Secure alias is judged when the address of FSADDR[28] is 0.

Note 2. The Non-secure alias is judged when the address of FSADDR[28] is 1.

Note 3. The Secure alias is judged when the address of FSADDR[28] and FEADDR[28] are 0.

Note 4. The Non-secure alias is judged when the address of FSADDR[28] and FEADDR[28] are 1.

When the target area of FACI command is the user area of code flash, the flash sequencer compares the FSADDR register setting with the memory boundary setting of the code flash and determines whether the target area is in the Secure region.

In linear mode, the memory boundary can be set to 0x0200_0000 to 0x021F_0000 in 32 KB unit.

In dual mode, the memory boundary can be set to 0x0200_0000 to 0x0220_0000 in 32 KB unit. When the memory boundary is set to 0x0220_0000 or greater in the dual mode, the entire user area is defined as the Secure region.

Figure 52.39 shows details of the Secure and Non-secure attribute of user area in the code flash.

**Figure 52.39 Secure and Non-secure region in user area for Secure alias**

When the target area of the issuing FACI command is the data area of data flash, the flash sequencer compares the FSADDR/FEADDR register setting with the memory boundary setting of the data flash and determines whether the target area is in Secure region. The memory boundary can be set to 0x0270_0000 to 0x0270_FC00 in 1 KB unit. Figure 52.40 shows details of the Secure and Non-secure attribute of data area in the data flash.

**Figure 52.40 Secure and Non-secure region in data area for Secure alias**

See [Figure 52.41](#) in the details of Secure and Non-secure region of option-setting memory. The flash sequencer judges that target area is Secure region from the FSADDR register setting.

**Figure 52.41 Secure and Non-secure region in option-setting memory for Secure alias**

52.12.3.2 Protection for Flash Memory Area (Read)

This function protects the Secure region of code flash and data flash from Non-secure bus access.

For details of Secure region, see [section 43, Security Features](#).

52.12.3.3 Protection for Register

The flash sequencer registers have write-access protection against Non-secure access. [Table 52.35](#) shows details of the protected registers of the flash sequencer.

Table 52.35 Protected registers of the flash sequencer for TrustZone

Protection target register	Security attribute setting	Notes
FCKMHZ register	SA register setting (FSAR.FCKMHZSA)	For details of section 52.4.4. FSAR : Flash Security Attribution Register
Flash Access area	SA register setting (FSAR.FACICMISA)	For details of section 52.4.4. FSAR : Flash Security Attribution Register
FACI registers* ¹ and FWEPROR registers	SA register setting (FSAR.FACICMRSA)	For details of section 52.4.4. FSAR : Flash Security Attribution Register
FCTRCNTR, FCTRLSR FCTRADDR, and FCTRSTATR registers	SA register setting (FSAR.FACITRSA)	For details of section 52.4.4. FSAR : Flash Security Attribution Register
FMEPROT, FCNTSELR, FCNTDATAR0 to 1, FBPROT1 and FSUACR registers	Always Secure	—

Note 1. The target FACL registers are FASTAT, FAEINT, FRDYIE, FSADDR, FEADDR, FBPROT0, FSTATR, FENTRYR, FSUINITR, FCMDR, FBCCNT, FBCSTAT, FPSADDR, FSUASMON, FCPSR, and FPCKAR.

52.12.3.4 Code Flash P/E Mode Entry Protection

The flash sequencer has protection function of code flash P/E by the FMEPROT register for the Secure developer. Secure function can prevent disturbance of reading code flash memory by this protection function. See [section 52.4.14. FMEPROT : Flash P/E Mode Entry Protection Register](#).

For applications that do not require Non-secure region programming/erasure other than from Secure function, it is recommended to always disable Non-secure function of code flash programming/erasure by enabling the protection function of FMEPROT register.

For details, see [Figure 52.42](#) of the code flash P/E sequence example by Non-secure function.

Figure 52.42 Code Flash P/E Sequence Example by Non-secure function (Using Secure function for code flash P/E)

52.12.4 Data Flash Configuration Area Protection

Data flash configuration area has 3 types of lockable area (LK_CD_A0, LK_CD_A1, and LK_CD_A2) by lock bit. When target area of "Configuration set" command includes protection area by lock bit, flash sequencer detects an error and enters "Command Lock" state.

LK_CD_A0 and LK_CD_A1 are protected 4 bytes data by 1 lock bit.

LK_CD_A2 are protected 16 bytes data by 1 lock bit, and 32 bytes (0x2703_0360 to 0x2703_037F) in LK_CD_A2 have writing protection that cannot update except for serial programming mode. For details, see [section 52.12.3.1. Protection for Flash Memory Area \(P/E\)](#). See [Table 52.36](#) in detail of protection condition of lockable area in data flash configuration area.

Table 52.36 Protection Condition of Lockable area in Data Flash Configuration Area for Secure alias

Lockable Area		Protection Size	Lock Bit	Remarks
Area Name	address			
LK_CD_A0	0x2703_0080 to 0x2703_0083	4 bytes	CD0_LK0	In the case of the 16-byte Configuration set command, data cannot be updated if any of the lock bits corresponding to the update address is 0.
	0x2703_0084 to 0x2703_0087	4 bytes	CD0_LK1	
	:	:	:	
	0x2703_0170 to 0x2703_0173	4 bytes	CD0_LK60	
	0x2703_0174 to 0x2703_0177	4 bytes	CD0_LK61	
	0x2703_0178 to 0x2703_017B	4 bytes	CD0_LK62	
	0x2703_017C to 0x2703_017F	4 bytes	CD0_LK63	
LK_CD_A1	0x2703_0180 to 0x2703_0183	4 bytes	CD1_LK0	
	0x2703_0184 to 0x2703_0187	4 bytes	CD1_LK1	
	:	:	:	
	0x2703_0270 to 0x2703_0273	4 bytes	CD1_LK60	
	0x2703_0274 to 0x2703_0277	4 bytes	CD1_LK61	
	0x2703_0278 to 0x2703_027B	4 bytes	CD1_LK62	
	0x2703_027C to 0x2703_027F	4 bytes	CD1_LK63	
LK_CD_A2	0x2703_0280 to 0x2703_028F	16 bytes	CD2_LK0	
	0x2703_0290 to 0x2703_029F	16 bytes	CD2_LK1	
	:	:	:	
	0x2703_0340 to 0x2703_034F	16 bytes	CD2_LK12	
	0x2703_0350 to 0x2703_035F	16 bytes	CD2_LK13	
	0x2703_0360 to 0x2703_036F	16 bytes	CD2_LK14	This lockable area and lock bit cannot be updated except for serial programming mode.
	0x2703_0370 to 0x2703_037F	16 bytes	CD2_LK15	

52.12.5 Anti-Rollback Counter

See [section 6.2.21. ARCLS : Anti-Rollback Counter Lock Setting](#) to [section 6.2.25. ARC_OEMBLn : Anti-Rollback Counter for OEMBL \(n = 0, 1\)](#) for Anti-rollback counter related Option flash memory.

Anti-rollback counter cannot be decremented and is used in the firmware update. Only Secure applications are available. Anti-rollback counter shifts one bit to the left with the increment counter command from the initial value of 0. The least

significant bit (bit 0) is set to 1. When anti-rollback counter is maximum value, flash sequencer does not change counter by Increment Counter command (does not occur error).

There are three commands that control the counters. For details, see [section 52.9.3.16. Increment Counter Command](#), [section 52.9.3.17. Refresh Counter Command](#), and [section 52.9.3.18. Read Counter Command](#).

[Figure 52.43](#) shows anti-rollback counter increment image when increment counter command is issued.

Figure 52.43 Increment image of anti-rollback counter

Anti-rollback counter has 3 types of counters (ARC_SEC, ARC_NSEC, and ARC_OEMBL) and lock bit (ARCSEC_LK, ARCNSEC_LK0 to 3, ARCOEMBL_LK) for protection each counter.

ARC_NSEC can be configured as 1×256 or 4×64 bits by configuration area setting (CNF_ARCNS0 and CNF_ARCNS1) and cannot be updated in invalid setting.

ARC_OEMBL is used in conjunction with the Secure Boot security feature when updating the OEM boot loader. For details, see [section 43.7. Secure Boot](#). ARC_OEMBL is protected by RSIP-E51A. It can only be incremented when version of the OEMBL update (validated using the RSIP OEMBL integrity check procedure) is higher than the current value stored in FCNTDATAR0 and FCNTDATAR1 registers by the read counter command. For details on RSIP-E51A see [section 44, Renesas Secure IP \(RSIP-E51A\)](#).

52.12.5.1 Anti-Rollback Counter Recovery Flow

[Figure 52.44](#), [Figure 52.45](#) and [Figure 52.46-4](#) shows the recovery flow in the case of OEM_BL anti-rollback counter. The recovery flow for rest anti-rollback counter should be considered necessary processing to depend on customer's application by Secure software developer. As an example, the flow in dual mode is shown. In linear mode, the same operation can be performed using start-up area select, but application size that be managed by anti-rollback counter should be limited to 8 KB.

Example Operation: Update from Bank0 selected in Dual mode**Notation**

UCF: Update Complete Flag set/clear by Secure software.
 ICF: Increment Complete Flag set/clear by Secure software.
 Set status: Indicate that update processing is completed.
 Clear status: Indicate that the update processing is not completed.

User area bank0 (Valid)	OEM_BL/v0 etc.
User area bank1 (Invalid)	
Data Flash Config. Area	UCF/set
	ICF/set
Code Flash Config. Area	Bank0 select
Anti-rollback counter	Counter/v0

Step 0 Status before update

OEM_BL is before version update in bank0.

User area bank0 (Valid)	OEM_BL/v0 etc.
User area bank1 (Invalid)	OEM_BL/v1 etc.
Data Flash Config. Area	UCF/clear
	ICF/clear
Code Flash Config. Area	Bank0 select
Anti-rollback counter	Counter/v0

Step 1 Write new OEM_BL, Clear UCF and ICF

UCF and ICF are cleared by configuration set command.
 Next, new OEM_BL etc. is written to invalid user area by program/erase command.

How to select recovery flow:

It can check that power failure is occurred by below status.

- UCF is clear status.
- Counter value is old version.

Recovery flow:

It should resume from step1.

Figure 52.44 Recovery flow of OEM_BL update in Dual mode at power failure (1/3)

Example Operation: Update from Bank0 selected in Dual mode

Notation

UCF: Update Complete Flag set/clear by Secure software.
 ICF: Increment Complete Flag set/clear by Secure software.
 Set status: Indicate that update processing is completed.
 Clear status: Indicate that the update processing is not completed.

User area bank0 (Valid)	OEM_BL/v0 etc.
User area bank1 (Invalid)	OEM_BL/v1 etc.
Data Flash Config. Area	UCF/set
	ICF/clear
Code Flash Config. Area	Bank0 select
Anti-rollback counter	Counter/v0

Step 2 Set UCF

UCF is set by configuration set command.

How to select recovery flow:

Same as step1.

Recovery flow:

Same as step1.

User area bank0 (Valid)	OEM_BL/v0 etc.
User area bank1 (Invalid)	OEM_BL/v1 etc.
Data Flash Config. Area	UCF/set
	ICF/set
Code Flash Config. Area	Bank0 select
Anti-rollback counter	Counter/v1

Step 3 Update counter version, Set ICF

OEM_BL version counter is update by increment counter command. Next, ICF is set by configuration set command.

How to select recovery flow(a):

It can check that power failure is occurred by below status.

- UCF is set status.
- ICF is clear status.
- Counter value is old version.

Recovery flow(a):

It should issue refresh counter command. Next, after clearing UCF, it should resume from step1.

How to select recovery flow(b):

It can check that power failure is occurred by below status.

- UCF is set status.
- ICF is clear status.
- Counter value is new version.

Recovery flow(b):

It should issue refresh counter command and set ICF. Next, it should resume from step4.

User area bank0 (Valid)	OEM_BL/v0 etc.
User area bank1 (Invalid)	OEM_BL/v1 etc.
Data Flash Config. Area	UCF/clear
	ICF/clear
Code Flash Config. Area	Bank1 select
Anti-rollback counter	Counter/v1

Step 4 Update bank selection

BANKSWP[2:0] bits are changed to bank1 selection by configuration set command.

How to select recovery flow:

It can check that power failure is occurred by below status.

- UCF is set status.
- ICF is set status.
- Counter value is new version.
- BANKSWP[2:0] bits are bank0 selection.

Recovery flow:

It should resume from step4.

Figure 52.45 Recovery flow of OEM_BL update in Dual mode at power failure (2/3)

Example Operation: Update from Bank0 selected in Dual mode

Notation

UCF: Update Complete Flag set/clear by Secure software.
 ICF: Increment Complete Flag set/clear by Secure software.
 Set status: Indicate that update processing is completed.
 Clear status: Indicate that the update processing is not completed.

User area bank0 (Invalid)	OEM_BL/v0 etc.
User area bank1 (valid)	OEM_BL/v1 etc.
Data Flash Config. Area	UCF/set
	ICF/clear
Code Flash Config. Area	Bank1 select
Anti-rollback counter	Counter/v1

Step 5 Switch valid user area

Bank1 is changed to valid area after system reset.
 New OEM_BL should check that update processing is completed successfully by checking UCF, ICF, and anti-rollback counter

Figure 52.46 Recovery flow of OEM_BL update in Dual mode at power failure (3/3)

52.13 Boot Mode

There are two serial programming modes; the boot mode (for the SCI interface) with SCI9 and the boot mode (for the USB interface) with USBFS. [Table 52.37](#) lists the I/O pins used in boot mode. [Table 52.38](#) lists the available communication interface used in the boot mode.

Table 52.37 I/O Pins Used in Boot Mode

Pin Name	I/O	Mode to be Used	Use
MD	Input	Boot mode (for the SCI interface) Boot mode (for the USB interface) Boot mode (for the JTAG interface) Boot mode (for the SWD interface)	Selection of operating mode
P208/RXD9	Input	Boot mode (for the SCI interface)	For host communication (to receive data through SCI)
P209/TXD9	Output		For host communication (to transmit data through SCI)
USB_DP, USB_DM	I/O	Boot mode (for the USB interface)	Data input/output of USB
USB_VBUS	Input		Detection of connection and disconnection of USB cables
P211/TCK	Input	Boot mode (for the JTAG interface)	Clock pin of JTAG
P210/TMS	Input		Mode Select pin of JTAG
P208/TDI	Input		Data In pin of JTAG
P209/TDO	Output		Data Out pin of JTAG
P211/SWCLK	Input	Boot mode (for the SWD interface)	Clock pin of SWD
P210/SWDIO	I/O		Data In-Out pin of SWD

Table 52.38 Available Communication Interface Used in Boot Mode (1 of 2)

Main clock oscillator or external clock is connected	Yes	No	No
Sub clock oscillator is connected ^{*1}	Yes or No	Yes	No
Available interface	JTAG, SWD, SCI or USB	JTAG, SWD, SCI or USB	JTAG, SWD or SCI

Table 52.38 Available Communication Interface Used in Boot Mode (2 of 2)

Tool connection time*2	Up to 1 second	Up to 2 seconds	Up to 3 seconds
------------------------	----------------	-----------------	-----------------

Note 1. The drive capability of the sub clock oscillator is set to standard by SOMCR.SODRV bit. Note that if you use the crystal corresponding the low drive capability on your board, the crystal may not oscillate in the boot mode.

Note 2. See the boot firmware manual for the detail connection time.

52.13.1 Boot Mode (for the SCI Interface)

In boot mode (for the SCI interface), the host sends control commands and data for programming, and the flash memory is programmed or erased accordingly. An on-chip SCI handles transfer between the host and this MCU in asynchronous mode. Tools for transmission of control commands and the data for programming must be prepared in the host.

When this MCU is activated in boot mode (for the SCI interface), the program on the dedicated area the MCU is executed. The boot program automatically adjusts the bit rate of the SCI and controls programming/erasure by receiving control commands from the host.

Figure 52.47 shows the system configuration for operations in boot mode (for the SCI interface).

**Figure 52.47 System Configuration for Operations in Boot Mode (for the SCI Interface)**

52.13.2 Boot Mode (for the USB Interface)

In boot mode (with the USB interface), the flash memory can be programmed or erased by sending control commands and program data from the host. An on-chip USB is used for communications between the host and this MCU. The host requires tools for sending control commands and data for programming. Figure 52.48 shows the configuration of a system for use in boot mode (for the USB interface). The USB cable must be connected on reset release.

Figure 52.48 System Configuration in Boot Mode (for the USB Interface)

52.14 Using the Serial Programmer for Rewriting

A serial programmer can be used to rewrite flash memory in boot mode.

(1) Serial Programming

This MCU is mounted on the system board at the time of serial programming. Providing a connector to the board enables rewriting of this MCU by the serial programmer to proceed.

52.14.1 Environments for Serial Programming

The recommended environments for rewriting the flash memory of the MCU with data are described below.

Figure 52.49 Environments for Rewriting the Flash Memory

52.15 Programming through Self-Programming

52.15.1 Overview

This MCU supports programming of the flash memory by the user program itself. The FACL commands can be used with user programs for writing to the flash memory. This allows upgrading of user programs and rewriting of constant data fields.

The program for rewriting must be transferred to the internal RAM or external memory in advance when the BGO is not available or when rewriting the option-setting memory.

Figure 52.50 Schematic View of Self-Programming

For comprehensive information on the self-programming, see [section 52.9. FACI Commands](#).

52.15.2 Background Operation

The background operation (BGO) can be used to execute the flash rewrite routine on the code flash memory when the data flash memory or other area of code flash memory is rewritten.

Background operations can be used when the combination of the flash memory for rewriting and the flash memory for reading is any of those listed below.

Table 52.39 Conditions under which Background Operation is Usable (1 of 2)

		Range for rewriting	Range for reading
Common to linear and dual modes		Code flash memory	Data flash memory
		Data flash memory	Code flash memory
Linear mode	Products with 2 Mbytes of code flash memory	First half (1 Mbytes) of the code flash memory addresses Secure alias: 0x0200_0000 to 0x020F_FFFF Non-secure alias: 0x1200_0000 to 0x120F_FFFF	Second half (1 Mbytes) of the code flash memory addresses Secure alias: 0x0210_0000 to 0x021F_7FFF Non-secure alias: 0x1210_0000 to 0x121F_7FFF
		Second half (1 Mbytes) of the code flash memory addresses Secure alias: 0x0210_0000 to 0x021F_7FFF Non-secure alias: 0x1210_0000 to 0x121F_7FFF	First half (1 Mbytes) of the code flash memory addresses Secure alias: 0x0200_0000 to 0x020F_FFFF Non-secure alias: 0x1200_0000 to 0x120F_FFFF
	Products with 1 Mbytes of code flash memory	First half (0.5 Mbytes) of the code flash memory addresses Secure alias: 0x0200_0000 to 0x0207_FFFF Non-secure alias: 0x1200_0000 to 0x1207_FFFF	Second half (0.5 Mbytes) of the code flash memory addresses Secure alias: 0x0208_0000 to 0x020F_FFFF Non-secure alias: 0x1208_0000 to 0x120F_FFFF
		Second half (0.5 Mbytes) of the code flash memory addresses Secure alias: 0x0208_0000 to 0x020F_FFFF Non-secure alias: 0x1208_0000 to 0x120F_FFFF	First half (0.5 Mbytes) of the code flash memory addresses Secure alias: 0x0200_0000 to 0x0207_FFFF Non-secure alias: 0x1200_0000 to 0x1207_FFFF

Table 52.39 Conditions under which Background Operation is Usable (2 of 2)

		Range for rewriting	Range for reading
Dual mode	When the BANKSEL_SEC.BANKSWP [2:0] or BANKSEL.BANKSWP[2:0] bits are 111b	Bank 1 area of the code flash memory	Bank 0 area of the code flash memory
	When the BANKSEL_SEC.BANKSWP [2:0] or BANKSEL.BANKSWP[2:0] bits are 000b	Bank 0 area of the code flash memory	Bank 1 area of the code flash memory

52.16 Reading Flash Memory

52.16.1 Reading Code Flash Memory

Special settings are not required to read code flash memory after release from the reset state. Data can simply be read out through access to addresses in the code flash memory.

When reading code flash memory that has been erased but not yet been programming again (i.e. that is in the non-programmed state), all bits are read as 1.

52.16.2 Reading Data Flash Memory

Special settings are not required to read data flash memory after release from the reset state. Data can simply be read out through access to addresses in the data flash memory.

Values read from data flash memory that has been erased but not yet been programming again (i.e. that is in the non-programmed state) are undefined. Use blank checking when you need to confirm that an area is in the non-programmed state.

52.17 Usage Notes

(1) Reading Area Where Programming/Erase was Interrupted and Area Targeted for Suspension

The data stored in the area where programming or erase has been suspended or the area where programming or erase has been suspended by using the suspend command are undefined. To avoid faulty operation caused by reading undefined data, take care not to fetch instructions or read data from areas where programming or erase was suspended and where programming or erase was suspended by using the suspend command.

(2) Suspension During Programming/Erase

When processing of programming/erase is stopped by issuing the P/E suspend command, the programming/erase processing can be resumed by issuing the P/E resume command. If the flash sequencer enters the command-locked state for any reason and issues the forced stop command after the suspended processing is normally completed and the ERSSPD flag or PRGSPD flag is set to 1, the suspended processing cannot be resumed. In addition, the values in the area where the processing was suspended are not guaranteed. Erase that area

(3) Prohibition of Additional Programming

Programming a given area of the code flash memory or data flash memory twice is not possible. To program the code flash memory or data flash memory where has been programmed, erase the target area. Programming can be added to the option-setting memory.

(4) Resets During Programming/Erase, or Blank Checking

In the case of a reset due to the signal on the RES pin during programming/erase, or blank checking of the flash memory, wait for at least t_{RESW} (see [section 55, Electrical Characteristics](#)) of the reset input period once the operating voltage is within the range stipulated in the electrical characteristics, then release the device from the reset state.

(5) Allocation of Vectors for Interrupts and Other Exceptions During Programming/Erase

Generation of an interrupt or other exception during programming/erase may lead to fetching of the vector from the code flash memory. Under conditions where BGO cannot be used, set the address of the vector to an address that is not in the code flash memory. Alternatively, make sure that no handling of interrupts or exceptions proceeds during programming/erase.

(6) Items Prohibited During Programming/Erase, or Blank Checking

High voltage is applied to the flash memory during programming/erase, or blank checking. To prevent damage to the flash memory, do not perform the following operations.

- Have the operating voltage from the power supply go beyond the permitted range.
- Change the FWEPROR.FLWE[1:0]bits.
- Change the OPCCR.OPCM[2:0] bits.
- Change the SCKDIVCR.FCK[2:0]bits.
- Change the SCKSCR.CKSEL[2:0]bits.
- Transition to the software standby mode, or Deep Software Standby mode.

(7) Programming/Erase in Low-Speed Modes

Do not programming/erase the flash memory when low-speed mode is selected with the operating power control register (OPCCR).

(8) Setting dual bank mode and programming in Boot Mode

The initial mode of the MCU shipped from Renesas is linear mode. In customer's factory when programming dual bank mode and customer's applications on MCU set in linear mode, it is recommended that only area1 in [Figure 52.51](#) is programmed in boot mode and area2 is kept blank. After reset, MCU starts in dual mode and the application is in bank0. Use self-programming when programming area2 for updating in the field. See [section 43.8. Field Updating in Dual Mode](#) for details

Figure 52.51 Programming the application for the dual mode in the linear mode

(9) Emulator Connection

Renesas provides the emulator which supports both debugging using SWD or JTAG communication and serial programming using SCI communication.

[Table 52.40](#) shows the pinout of 10 pin or 20 pin socket pinouts when using this emulator. The pinout of SWD and JTAG is ARM standard, and MD, TXD, RXD pins are added for the serial programming using SCI communication.

Table 52.40 Pin assign for emulator (1 of 2)

Pin No.	SWD	JTAG	Serial Programming using SCI
1	VCC	VCC	VCC
2	P210/SWDIO	P210/TMS	NC
4	P211/SWCLK	P211/TCK	P201/MD

Table 52.40 Pin assign for emulator (2 of 2)

Pin No.	SWD	JTAG	Serial Programming using SCI
6	P209/SWO	P209/TDO	P209/TXD9
8	P208	P208/TDI	P208/RXD9
9	GNDdetect	GNDdetect	GNDdetect
10	nRESET	nRESET	nRESET
12	P308/TCLK	P308/TCLK	NC
14	P307/TDATA[0]	P307/TDATA[0]	NC
16	P306/TDATA[1]	P306/TDATA[1]	NC
18	P305/TDATA[2]	P305/TDATA[2]	NC
20	P304/TDATA[3]	P304/TDATA[3]	NC

7	NC	NC	NC
11, 13	NC	NC	NC

53. Capture Engine Unit (CEU)

53.1 Overview

The Capture Engine Unit (CEU) is a capture module that fetches image data externally input and transfers it to the memory. The CEU is connected to the system bus via bus bridge modules.

Lists the features of CEU as follows.

(1) Image data fetch

- Captures an image output from an external module and writes YCbCr data to the memory with it separated into Y data and CbCr data.
- Fetches image data other than YCbCr data, for example, JPEG data, RGB565, from an externally connected module, such as a camera, and sequentially writes the image data to the memory.
- Fetches an interlace source image in both-field units or one-field units and writes it to the memory. In both-field capture, an image can be stored in the memory as a frame image.

(2) Filter processing

- Performs scale-down and removal of high-frequency components (only in the horizontal direction) for an image using internal filters. Note that the scaled-down image must not exceed VGA. The filter processing can be applied to only YCbCr input data.

(3) Format conversion

- Converts image data input in the YCbCr422 format into the YCbCr420 format and writes it to the memory. Note that the conversion algorithm is simple thinning in which the chrominance component (CbCr) of the even-numbered lines is thinned.

The functional overview of the CEU is shown in [Table 53.1](#) and the main functions and their details are shown in [Table 53.2](#).

Table 53.1 Functional overview of CEU (1 of 2)

Classification	Item	Function	Description	Note
Connectable camera	Size ^{*1}	5 megapixels	2,560 pixels × 1,920 lines	Image capture mode or data synchronous fetch mode Horizontal : 8-pixel units Vertical : 4-line units Data enable fetch mode 32-byte units The range of the image size that can be input is as follows. Horizontal: 2,560 pixels to 128 pixels Vertical: 1,920 lines to 96 lines
		3 megapixels	2,048 pixels × 1,536 lines	
		2 megapixels	1,632 pixels × 1,224 lines	
		UXGA	1,600 pixels × 1,200 lines

		Binary data	Specified amount to be fetched on edges of the sync signal	Written sequentially
			Data is fetched with the horizontal sync signal as an enable signal	
	Horizontal and vertical sync signal polarities	Arbitrary	High-active and low-active	
	Capture start location	Arbitrary	Can be specified in camera input clock units	Horizontal: 1-cycle units Vertical: 1-HD (horizontal sync signal) units
	Number of captured pixels	Arbitrary	Can be specified in 8-pixel units horizontally and in 4-line units vertically	
	Interlace	Both-field capture	Stored as a field image	Capture: 2-VD (vertical sync signal) units
			Stored as a frame image	
		One-field capture	Top field or bottom field can be specified	Capture: 1-VD units
Memory write	Output format	YCbCr422 YCbCr420	YCbCr420 is realized by simple thinning	

Table 53.1 Functional overview of CEU (2 of 2)

Classification	Item	Function	Description	Note
Filter function	No scaling or scale-down	Scale-down of captured display	Desired scaling factor from 1/16 to 1 (scaled-down display must not exceed VGA)	
	Low-pass filter		Removal of high-frequency components	Only in the horizontal direction
Module-stop function	Module-stop state can be set to reduce power consumption.			
TrustZone Filter	Security and Privilege attribution can be set.			

Note 1. The range of the image size that can be input depends on the AC characteristics and the frame rate of the connected device, and the transfer speed to the destination RAM.

Table 53.2 Main functions of CEU and their details

Main function	Detailed description
Image data fetch	- Captures an image output from an external module and writes YCbCr data to the memory with it separated into Y data and CbCr data. - Fetches image data other than YCbCr data, e.g. JPEG data, from an externally connected module, such as a camera, and sequentially writes the image data to the memory. - Fetches an interlace source image in both-field units or one-field units and writes it to the memory. In both-field capture, an image can be stored in the memory as a frame image.
Filter processing	Performs scale-down and removal of high-frequency components (only in the horizontal direction) for an image using internal filters. Note that the scaled-down image must not exceed VGA. The filter processing can be applied to only YCbCr input data.
Format conversion	Converts image data input in the YCbCr422 format into the YCbCr420 format and writes it to the memory. Note that the conversion algorithm is simple thinning in which the chrominance component (CbCr) of the even-numbered lines is thinned.

Figure 53.1 shows a block diagram of the CEU.

**Figure 53.1 Block diagram of CEU**

The pin configuration of the CEU is shown in Table 53.3.

Table 53.3 Pin configuration of CEU (1 of 2)

Pin name	Function	I/O	Description
VIO_D15 to VIO_D0 ^{*1}	CEU data bus	Input	Camera image data input to the CEU
VIO_CLK	CEU clock	Input	Camera clock input to the CEU
VIO_VD	CEU vertical sync	Input	Camera vertical sync signal input to the CEU

Table 53.3 Pin configuration of CEU (2 of 2)

Pin name	Function	I/O	Description
VIO_HD	CEU horizontal sync	Input	Camera horizontal sync signal input to the CEU
VIO_FLD*2	Field signal	Input	Field identification signal to the CEU

Note 1. When the distinction according to the bus width for the data bus is not needed, VIO_D is used in this manual. Otherwise, VIO_D15 to VIO_D0 are used.

Note 2. The VIO_FLD pin is valid only in interlace input mode (CAIFR.IFS=1).

53.2 Register Descriptions

The register configuration of the CEU is shown in [Table 53.4](#).

Most CEU registers have a 2-plane configuration (plane A and plane B). The CEU switches the planes when using these 2-plane registers. A mirror address, which is an address that can always access the register on the unused plane, is provided for each 2-plane register. [Figure 53.2](#) shows the timing to switch the register planes. The CEU switches the register planes at the same time a VD interrupt is asserted.

In the following register descriptions, "during operation" indicates the period that begins when the CEU is activated by the CE bit in the capture start register (CAPSR) and ends when a capture end interrupt (CPE) of the capture event flag clear register (CETCR) occurs. In the read-only bits in each register, the write value should always be 0. If a value other than 0 is written to any of these bits, correct operation cannot be guaranteed.

Table 53.4 Register configuration of CEU (1 of 2)

Register name	Abbr.	R/W	Addresses			Access size
			Address (Plane A)	Address (Plane B)	Mirror Address

CEU Bufferable Write Enable Register	CBWER	R/W	0x4034_80A0	—	—	32

Note: The address shown in this table are Secure region. The address corresponding to the Non-secure region is when b28 of address is set to 1.

Note 1. After changing the setting of a register (CAMCR or CMCYR) that is determined by the external module characteristics, do not start capture until at least 10 external input clock cycles have elapsed.

**Figure 53.2 Register plane switching timing (VD polarity is high-active in data enable fetch mode)**

53.2.1 CAPSR : Capture Start Register

Base address: CEU = 0x4034_8000
CEU_NS = 0x5034_8000

Offset address: 0x0000

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	CPKIL
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	CE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	CE	Capture enable • Single-capture This bit reserves capturing of the next frame. When 1 is written to this bit, the capture of one frame starts from the next VD input, and stops when the one-frame capture end interrupt (CPE bit in CETCR) is asserted (Figure 53.7). To perform capture again, write 1 to this bit. After the VD or HD polarity is changed, do not write 1 to this bit until the next VD interrupt is asserted. • Continuous capture When this bit is set to 1 while the CTNCP bit in CAPCR is set to 1, continuous capture starts from the next frame (Figure 53.8). Note that this bit is not cleared to 0 but remains as 1. To stop capturing, clear this bit to 0; capturing stops after the current frame is completed. Continuous capture operations are possible in only image capture mode. The start address of the memory to which the captured data is written to must be set for each frame. 0: Stops capturing 1: Starts capturing	R/W
15:1	—	These bits are read as 0. The write value should be 0.	R/W
16	CPKIL	Software reset of capturing Write 1 to this bit to perform a software reset of capturing. At a software reset, capturing ends immediately without completing capture operation until the end of a frame. Clear the CE bit to 0 when writing 1 to this bit. Processing of the capture software reset is indicated by this bit being set to 1. When CPKIL = 1, do not start capturing since reset processing is in progress. When restarting capture operations, after referring to the CPTON bit in CSTSR to ensure that the CEU is halted (in the idle state), wait until this bit is cleared to 0. The timing of restarting capture operations is shown in Figure 53.6. When a software reset is generated by this bit, a capture end interrupt (CPE bit in CETCR) may be output immediately after the software reset. However, such kind of interrupt should be ignored. Also, even if the capture end interrupt is not output, the interrupt source (CPE bit) must be cleared before capturing of the next frame. 0: Normal state 1: Software reset of capturing	R/W
31:17	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

CAPSR captures data input to the CEU from an external module.

When both the VD (vertical sync signal) and HD (horizontal sync signal) polarities are high-active, one frame is defined as a period from a VD rising edge to the next VD rising edge, and one line as a period from an HD rising edge to the next HD rising edge. Figure 53.3 shows the timing of one frame (when both the VD and HD polarities are high-active).

Figure 53.3 Frame timing

When both the VD and HD polarities are high-active, similar to one frame, one field is defined as follows:

- Period from a VD rising edge to the next VD rising edge
- One line is a period from an HD rising edge to the next HD rising edge

The field identification signal FLD should be fixed for at least 1-HD period from a VD input. [Figure 53.4](#) shows the timing of one field (when both the VD and HD polarities are high-active).

Figure 53.4 One field timing

In data enable fetch, one frame is defined as a period from a VD rising edge to the VD falling edge. With the HD as an enable signal (positive polarity), data of a cycle in which the HD is asserted is fetched while the VD is high. [Figure 53.5](#) shows the timing of one frame for data enable fetch.

Figure 53.5 Frame timing (data enable fetch)

Figure 53.6 Timing of software reset and restart of capturing

Figure 53.7 Timing of modifying CE bit and register setting in one frame capture

53.2.2 CAPCR : Capture Control Register

Base address: CEU = 0x4034_8000
CEU_NS = 0x5034_8000

Offset address: 0x0004

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	FDRP[7:0]								—	—	MTCM[1:0]	—	—	—	—	CTNCP
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	—	These bits are read as 0. The write value should be 0.	R/W
16	CTNCP	Continuous capture When capturing is started with this bit set to 1, capturing continues until the CE bit in CAPSR is cleared to 0 or a software reset is initiated by the CPKIL bit in CAPSR (see Figure 53.8). Continuous capture must be set before capturing is started. This bit is modified only after 0 is written to the CE bit to stop capturing. If this bit is modified during capturing, correct operation cannot be guaranteed. In data fetch mode, clear this bit to 0. 0: One-frame capture when CAPSR.CE = 1 1: Continuous capture until CAPSR.CE = 0	R/W
19:17	—	These bits are read as 0. The write value should be 0.	R/W
21:20	MTCM[1:0]	Specify the unit for transferring data to a bus bridge module. The efficiency of writing image data can be improved by continuously accessing the addresses. To improve the write efficiency, set these bits to 11. The setting of these bits appear to be unchanged from the outside. 0 0: Image capture: Y data and C data are transferred in 32-byte units Data fetch: Data is transferred in 32-byte units 0 1: Image capture: Y data and C data are transferred in 64-byte units Data fetch: Data is transferred in 64-byte 1 0: Image capture: Y data and C data are transferred in 128-byte units Data fetch: Data is transferred in 128-byte 1 1: Image capture: Y data and C data are transferred in 256-byte units Data fetch: Data is transferred in 256-byte	R/W
23:22	—	These bits are read as 0. The write value should be 0.	R/W
31:24	FDRP[7:0]	Set the frame drop interval in continuous-frame capture. When these bits are cleared to 0, frame drop is not performed, and all frames are captured. Figure 53.9 shows the value set in these bits and the timing of captured frames. The frame drop interval unit differs according to the capture setting. Table 53.5 shows the relationship between the capture setting and frame drop interval unit. The image of the frame drop timing for each capture setting when these bits are set to 2 is shown in Figure 53.10. In both-field capture, capturing is performed continuously for 2-VD periods, regardless of whether the second field is the top field or bottom field. In addition, in both-field capture, the frame drop counter is incremented when the first field has been identified as the top field or bottom field, regardless of whether the second field is the top field or bottom field. When 0 is written to the CE bit in CAPSR, capturing terminates after the current frame has been captured for a capture frame. However, for a drop frame, capturing is forcibly terminated in the CEU so no capture end interrupt (CPE bit in CETCR) is output. While CAPSR.CE = 1, do not change the setting of these bits. Note: Do not change the setting of these bits during continuous capture operations. To change the setting of these bits, stop continuous capture (CAPSR.CE = 0), clear the CTNCP bit (continuous capture) in CAPCR to 0, and then restart continuous capture. Continuous capture is performed during the period of CAPSR.CE = 1 shown in Figure 53.9.	R/W

Note: S-TYPE-3, P-TYPE-3

CAPCR sets continuous-frame capture and the frame drop intervals.

Do not modify this register during operation. If this register is modified during operation, correct operation cannot be guaranteed. In addition, the IGRW bit (interrupt source) in CETCR is set to 1.

Figure 53.9 Setting of FDRP bits and frame drop timing

Table 53.5 Relationship between capture setting and frame drop interval unit

Input Mode	Captured Image	First Captured Image	Frame Drop Interval Unit	Capture Setting
Progressive	Frame	Frame immediately after capture start	Frame	A
Interlace	Both-field (2-VD capture)	Field immediately after capture start	2 fields (first capture field count)	B
				C
		Top field	2 fields (top-field count)	D
		Bottom field	2 fields (bottom-field count)	E
	One-field (1-VD capture)	Field immediately after capture start	First capture field	F
				G
		Top field	Top field	H
		Bottom field	Bottom field	I

Bit field:	—	—	—	DTIF	—	—	DTARY[1:0]	—	—	—	JPG[1:0]	—	—	—	VDPO L	HDPO L
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	HDPOL	Sets the polarity for detection of the horizontal sync signal (HD) input from an external module. Figure 53.16 shows the relationship between the HD and HD interrupt when high-active is selected. Since an HD interrupt may occur when this bit value is modified, the HD bit in CETCR must always be cleared to 0 when this bit value is changed. In data enable fetch mode, set this bit to 0. 0: Horizontal sync signal (HD) from an external module is detected as high active 1: Horizontal sync signal (HD) from an external module is detected as low active	R/W
1	VDPOL	Sets the polarity for detection of the vertical sync signal (VD) input from an external module. Figure 53.14 and Figure 53.15 show the relationship between the VD, HD and VD interrupt when high-active is selected. Since a VD interrupt may occur when this bit value is modified, the VD bit in CETCR must always be cleared to 0 when this bit value is changed. In data enable fetch mode, this bit is not used and the sense for detection is always active high. 0: Vertical sync signal (VD) from an external module is detected as high active 1: Vertical sync signal (VD) from an external module is detected as low active	R/W
3:2	—	These bits are read as 0. The write value should be 0.	R/W

Bit	Symbol	Function	R/W
5:4	JPG[1:0]	These bits select the fetched data type. 0 0: Image capture mode (input data are separated into the luminance component data (Y) and the chrominance component data (CbCr) for output to the memory) 0 1: Data synchronous fetch mode (specified size of input data are output to the specified memory addresses in order of input and in synchronization with the sync signal) 1 0: Data enable fetch mode (input data are fetched with HD as an enable signal and output to the specified addresses in memory in order of input) 1 1: Setting prohibited	R/W
7:6	—	These bits are read as 0. The write value should be 0.	R/W
9:8	DTARY[1:0]	Set the input order of the luminance component and chrominance component. The order in which Y and CbCr are input from an external module differs among modules. The CEU supports the input orders shown in Figure 53.12 . Set the corresponding value in these bits. In data fetch mode, set these bits to 00. 0 0: 8-bit interface: Image input data is fetched in the order of Cb ₀ , Y ₀ , Cr ₀ , and Y ₁ 16-bit interface: Image input data is fetched in the order of {Cb ₀ , Y ₀ } and {Cr ₀ , Y ₁ } 0 1: 8-bit interface: Image input data is fetched in the order of Cr ₀ , Y ₀ , Cb ₀ , and Y ₁ 16-bit interface: Image input data is fetched in the order of {Cr ₀ , Y ₀ } and {Cb ₀ , Y ₁ } 1 0: 8-bit interface: Image input data is fetched in the order of Y ₀ , Cb ₀ , Y ₁ , and Cr ₀ 16-bit interface: Image input data is fetched in the order of {Y ₀ , Cb ₀ } and {Y ₁ , Cr ₀ } 1 1: 8-bit interface: Image input data is fetched in the order of Y ₀ , Cr ₀ , Y ₁ , and Cb ₀ 16-bit interface: Image input data is fetched in the order of {Y ₀ , Cr ₀ } and {Y ₁ , Cb ₀ }	R/W
11:10	—	These bits are read as 0. The write value should be 0.	R/W
12	DTIF	Sets the digital image input pins from which data is to be captured. 0: Data input to 8-bit digital image input pins is captured 1: Data input to 16-bit digital image input pins is captured	R/W
15:13	—	These bits are read as 0. The write value should be 0.	R/W
16	FLDPOL	Sets the polarity of the field identification signal (FLD) from an external module. 0: When the FLD signal is high-active, the field is detected as the top field and when low-active, the field is detected as the bottom field. 1: When the FLD signal is low-active, the field is detected as the top field and when high-active, the field is detected as the bottom field.	R/W
23:17	—	These bits are read as 0. The write value should be 0.	R/W
24	DSEL	Sets the edge for fetching the image data (D15 to D0) from an external module. 0: D15 to D0 are fetched at the rising edge of the camera clock. 1: D15 to D0 are fetched at the falling edge of the camera clock.	R/W
25	FLDSEL	Sets the edge for capturing FLD from an external module. 0: FLD is captured at the rising edge of the camera clock. 1: FLD is captured at the falling edge of the camera clock.	R/W
26	HDSEL	Sets the edge for capturing HD from an external module. 0: HD is captured at the rising edge of the camera clock. 1: HD is captured at the falling edge of the camera clock.	R/W
27	VDSEL	Sets the edge for capturing VD from an external module. 0: VD is captured at the rising edge of the camera clock. 1: VD is captured at the falling edge of the camera clock.	R/W
31:28	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

CAMCR sets the capture interface.

The following items are set by CAMCR.

- Selection between the rising edge or falling edge of the camera clock for signal capture or data fetch operation
- Selection between image capture operation or data fetch operation
- Polarities of the vertical and horizontal sync signals
- Input order of image data components (Y, Cb, and Cr) (only for image capture mode)
- Selection of digital image input pins (8 bits or 16 bits)

- Polarity of the field identification signal

CAMCR must be set according to the module connected. In data fetch mode, set the DTARY bits to 0. Do not modify this register during operation. If this register is modified during operation, correct operation cannot be guaranteed. In addition, the IGRW bit (interrupt source) in CETCR is set to 1.

Note: After changing the setting of this register, do not start capture until at least 10 external input clock cycles have elapsed.

Figure 53.11 Input order of image data

The JPG bit in CAMCR selects whether digital image data is fetched or data such as JPEG is fetched. In addition, when data such as JPEG is fetched, select whether the specified amount of data is continuously fetched in synchronization with the sync signal or data is fetched while the horizontal sync signal is enabled.

In data enable fetch mode, one frame is defined as a period from the rising edge to the falling edge of the vertical sync signal (VD) for data fetching. The horizontal sync signal (HD) is enabled only when the VD is high and treated as an enable signal. Data input in the cycle in which the HD is asserted (high) is fetched and output to the memory continuously.

This module starts fetching data at the rising edge of the VD and stops fetching data at the falling edge of the VD in data enable fetch mode. Thus, if the VD remains high and does not go low, end processing does not start. In addition, if the VD remains high and the HD also remains asserted, data continues to be fetched.

Figure 53.12 and Figure 53.13 show the interface timing in data enable fetch mode.

Figure 53.12 Data enable fetch timing (HD asserted (high) while VD is high)

Figure 53.13 Data enable fetch timing (HD asserted (high) when VD is not high)

In data enable fetch mode, this module generates a VD interrupt in response to detection of the active level of VD. In image capture mode and data synchronous fetch mode, this module generates a VD interrupt in response to the first detection of the active level of HD following detection of the active level of VD. Note that, when VD and HD are asserted and detected at the same time, this module generates a VD interrupt at that time.

Figure 53.14 to Figure 53.16 show the relationships between the VIO_VD signal and the VD interrupt, the VIO_VD and VIO_HD signals and the VD interrupt, and the VIO_HD signal and the HD interrupt.

Figure 53.14 Relationship between VIO_VD and VD interrupt when VD is high-active (in data enable fetch mode)

Figure 53.15 Relationship between the VIO_VD and VIO_HD signals and the VD Interrupt when VD and HD are high-active (in Image capture mode or data synchronous fetch mode)

Figure 53.16 Relationship between VIO_HD and HD interrupt when HD is high-active

53.2.4 CMCYR : Capture Interface Cycle Register

Base address: CEU = 0x4034_8000
CEU_NS = 0x5034_8000

Offset address: 0x000C

Bit	Symbol	Function	R/W
13:0	HCYL[13:0]	Horizontal Cycle Count of External Module These bits set the number of HD cycles of an external module. The interrupt source bit IGHS in CETCR is set to 1 when the actual number of HD cycles input from the external module differs from this setting. Set these bits for detecting an illegal HD. When these bits are all cleared to 0, the interrupt source bit IGHS in CETCR is not set to 1. Though the interrupt source bit IGHS in CETCR may be set to 1 after the HDPOL bit (HD polarity) in CAMCR is changed, this interrupt should be ignored.	R/W
15:14	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

Do not modify this register during operation. If this register is modified during operation, correct operation cannot be guaranteed. In addition, the IGRW bit (interrupt source) in CETCR is set to 1.

Set 0 in all bits of this register, during data enable fetch mode.

53.2.5 CAMOR, CAMOR x : Capture Interface Offset Register (x = B, M)

Offset address: 0x0010 (CAMOR)
0x1010 (CAMOR_B)
0x2010 (CAMOR_M)

Note: S-TYPE-3, P-TYPE-3

CAMOR sets the location to start capturing when capturing images.

Since the number of HD (horizontal sync signal) inputs from a VD (vertical sync signal) input to the start of a valid image period, and the number of clock cycles from an HD input to the start of a valid image period differ among external modules, these must be set in CAMOR. By setting a value greater than the valid image area, part of the image can be clipped for capture. In data synchronous fetch mode, the setting of this register becomes the number of cycles (HD count) up to the start of a valid data period.

This register is not used, during data enable fetch mode.

Figure 53.17 Vertical offset

Figure 53.18 Timing when VD is data enable signal

Figure 53.19 Horizontal offset

Figure 53.20 Timing when HD is data enable signal (8-bit interface)

53.2.6 CAPWR, CAPWR_x : Capture Interface Width Register (x = B, M)

Base address: CEU = 0x4034_8000
CEU_NS = 0x5034_8000

Offset address: 0x0014 (CAPWR)
0x1014 (CAPWR_B)
0x2014 (CAPWR_M)

Bit	Symbol	Function	R/W
12:0	HWDTH[12:0]	Specify the horizontal capture period. Specify the number of cycles to be captured from the location specified by the HOFST bits. Figure 53.22 shows the timing when the horizontal blanking period is 0. The CEU captures for only the number of cycles specified by these bits in the horizontal direction. Make a similar setting for data synchronous fetch. The maximum value to be set is as follows: 8-bit interface Image capture (16-cycle units) : 5,120 cycles (2,560 pixels) Data synchronous fetch (8-cycle units) : 2,560 cycles (2,560 bytes) 16-bit interface Image capture (8-cycle units) : 2,560 cycles (2,560 pixels) Data synchronous fetch (4-cycle units) : 1,280 cycles (2,560 bytes) The lower 2 bits should be written 0. Note: In data synchronous fetch mode, set CFSZR and CDWDR according to the values set in this register. For details, see the descriptions on CFSZR and CDWDR.	R/W
15:13	—	These bits are read as 0. The write value should be 0.	R/W
27:16	VWDTH[11:0]	Specify the vertical capture period (4-HD units). Specify the number of lines (HD count) to be captured from the location specified by the VOFST bits in CAMOR. Figure 53.21 shows the timing when the vertical blanking period is 0. The CEU captures only the number of lines (HD count) specified by these bits in the vertical direction. Make a setting in the same way to obtain data synchronization. The maximum value to be set is 1,920 HD (5 megapixels). The value of writing are ignored on the lower 2 bits, so write 0 to the lower 2 bits.	R/W
31:28	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

CAPWR sets the fetch (capture) cycle width when capturing images.

The cycle width unit differs according to the interface and the data type to be captured. For each setting unit, see [Table 53.6](#).

This register is not used, during data enable fetch mode.

Table 53.6 Unit for setting fetch (capture) cycle width

Interface	Vertical Direction		Horizontal Direction	
	Image Capture	Data Synchronous Fetch	Image Capture	Data Synchronous Fetch
8-bit interface	4 HD	4 HD	16 cycles	8 cycles
16-bit interface	4 HD	4 HD	8 cycles	4 cycles

Figure 53.21 Vertical capture timing

Figure 53.22 Horizontal capture timing (image capture with 8-bit interface)

53.2.7 CAIFR : Capture Interface Input Format Register

Base address: CEU = 0x4034_8000
CEU_NS = 0x5034_8000

Offset address: 0x0018

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	IFS	—	—	—	CIM	—	—	—	FCI[1:0]
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
1:0	FCI[1:0]	Set the timing to start capturing. The timing to start capturing is set by specifying the image to be captured first. Set these bits to 00 when the input mode is progressive. 0 0: Capture starts from the VD input immediately after the CEU activation regardless of it being a top or bottom field 0 1: After the CEU activation, input of a top-field image is waited, and then capture starts from the top field 1 0: After the CEU activation, input of a bottom-field image is waited, and then capture starts from the bottom field 1 1: Setting prohibited	R/W
3:2	—	These bits are read as 0. The write value should be 0.	R/W

Bit	Symbol	Function	R/W
4	CIM	Sets the images to be captured. Clear this bit to 0 when the input mode for image capture is progressive (frame image) or when the input mode for image capture is interlace for continuous capture of both the top and bottom fields. Set this bit to 1 when the input mode for image capture is interlace for capture of only a one-field image. 0: Capture of frame image (1 VD) or both-field image (2 VD) 1: Capture of one-field image (1 VD)	R/W
7:5	—	These bits are read as 0. The write value should be 0.	R/W
8	IFS	Sets the input mode for capturing images. 0: Progressive 1: Interlace	R/W
31:9	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

CAIFR sets the input mode (progressive or interlace) for capturing images, the images to be captured (frame, both-field, or one-field), the image from which capturing starts (top field or bottom field), etc. CAIFR is not used in data fetch mode.

Do not modify this register during operation. If this register is modified during operation, correct operation cannot be guaranteed. In addition, the IGRW bit (interrupt source) in CETCR is set to 1.

The items set by CAIFR are listed in [Table 53.7](#).

Table 53.7 CAIFR Setting Items

Input Mode	IFS Bit	Captured Image	CIM Bit	Image to Start Capture	FCI Bits
Progressive	0	Frame	0	Frame immediately after activation	00
Interlace	1	Both-field (2-VD capture)	0	Field immediately after activation	00
				Top field	01
				Bottom field	10
				Setting prohibited	11
		One-field (1-VD capture)	1	Field immediately after activation	00
				Top field	01
				Bottom field	10
				Setting prohibited	11

In frame image capture and one-field image capture, a one-frame capture end interrupt occurs when capture for 1 VD finishes. In both-field image capture, a one-field capture end interrupt occurs when capture for 1 VD finishes and a one-frame capture end interrupt occurs when capture for 2 VD finishes. At this time, a one-field capture end interrupt occurs simultaneously with a one-frame capture end interrupt. [Figure 53.23](#) shows the timing of a one-frame capture end interrupt and one-field capture end interrupt in both-field image capture.

Figure 53.23 One-frame capture end interrupt and one-field capture end interrupt in both-field image capture

A captured frame image or captured one-field image is stored in the memory from the addresses set in CDAYR and CDACR (Figure 53.24). Captured both-field images are stored in different memory areas depending on whether it is a top-field or bottom-field image. A top-field image is stored in the memory from the addresses set in CDAYR and CDACR whereas a bottom-field image is stored in the memory from the addresses set in CDBYR and CDBCR (Figure 53.25).

Figure 53.24 Image of storing captured frame image or captured one-field image in memory

Figure 53.25 Image of storing captured both-field images in memory

If the FCI bits are set to 00b for continuous capture in interlace input mode, images are continuously captured for 2 VD with the first captured field as the reference in both-field image capture (Figure 53.26). In one-field image capture, only the first captured field is continuously captured for 1 VD (Figure 53.27).

Figure 53.26 Continuous both-field capture in interlace mode (Image Immediately after Activation is Top Field (FCI[1:0] = 00b))

Figure 53.27 Continuous one-field capture in interlace mode (Image Immediately after Activation is Top Field (FCI[1:0] = 00b))

(1) Storage of Interlace Input as Frame Image

The CEU can store an interlace source image in the memory as a frame image. To store an interlace source image as a frame image, make the following register settings:

Input mode: Interlace (IFS = 1)

Capture image: Both-field (CIM = 0)

Image to start capture: Any setting other than the prohibited setting (FCI[1:0] = as desired)

Figure 53.28 shows a memory image of capturing both fields of an interlace input and storing it as a frame image in the memory. Set the start addresses of the memory destination for the captured top-field image in CDAYR and CDACR, and the start addresses of the memory destination for the captured bottom-field image in CDBYR and CDBCR. When storing an interlace image as a frame image in the memory, set the horizontal image size of the memory area in CDWDR with the top-field image and bottom-field image placed next to each other as shown in Figure 53.28. In addition, set the number of captured lines of the field image in the VWDTH bits in CAPWR.

A memory image of folding the horizontal image size of the memory area in Figure 53.28 at CDWDR/2 is shown in Figure 53.29. Setting the registers to form the image in Figure 53.28 enables an interlace image to be stored as a frame image in the memory as shown in Figure 53.29.

Figure 53.28 Image of storing captured both-fields of interlace input in memory

Figure 53.29 Image of storing Interlace input as frame image in memory

53.2.8 CRCNTR : CEU Register Control Register

Base address: CEU = 0x4034_8000
CEU_NS = 0x5034_8000

Offset address: 0x0028

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	RVS	—	—	RS	RC
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	RC	Specifies switching of the register plane used by the CEU in synchronization with VD. If the register plane is not switched, the register plane specified by the RS bit is used. 0: Uses the specified register plane in synchronization with VD 1: Switches the register plane in synchronization with VD	R/W
1	RS	Specifies which register plane is used by the CEU in synchronization with VD. The setting of this bit is valid only when RC = 0. 0: Uses plane A of the register 1: Uses plane B of the register	R/W
3:2	—	These bits are read as 0. The write value should be 0.	R/W
4	RVS	Sets the timing to switch the register plane in both-field capture. The setting of this bit is valid only when RC = 1 in both-field capture. 0: Switches the register plane every 2 VD 1: Switches the register plane every 1 VD	R/W
31:5	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

CRCNTR controls switching of the planes of registers with a 2-plane configuration.

Figure 53.30 Timing for register plane switching when RVS = 0

Figure 53.31 Timing for register plane switching when RVS = 1

53.2.9 CRCMPR : CEU Register Forcible Control Register

Base address: CEU = 0x4034_8000
CEU_NS = 0x5034_8000

Offset address: 0x002C

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	RA
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	RA	Indicates the register plane currently specified. This register value automatically changes in synchronization with VD for starting capture. To start capture with plane A of the register when a setting to switch the register plane in synchronization with VD has been made (CRCNTR.RC = 1), specify plane B of the register using this bit. 0: Specifies plane A of the register 1: Specifies plane B of the register	R/W
31:1	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

CRCMPR forcibly controls switching of the planes of registers with a 2-plane configuration. Setting this register enables direct control of register plane switching.

Do not modify this register during operation. If this register is modified during operation, correct operation cannot be guaranteed. In addition, the IGRW bit (interrupt source) in CETCR is set to 1.

53.2.10 CFLCR, CFLCR_x : Capture Filter Control Register (x = B, M)

Base address: CEU = 0x4034_8000
CEU_NS = 0x5034_8000

Offset address: 0x0030 (CFLCR)
0x1030 (CFLCR_B)
0x2030 (CFLCR_M)

Bit position:	31	28	27											16	15												12	11																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																						
---------------	----	----	----	--	--	--	--	--	--	--	--	--	--	----	----	--	--	--	--	--	--	--	--	--	--	--	----	----	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--

Bit	Symbol	Function	R/W
11:0	HFRAC[11:0]	Fraction Part of Horizontal Scale-Down Factor The specifiable range is 0x000 to 0xFF8. The fraction of the scale-down factor that cannot be set with only the HMANT bits must be specified with these bits. The value of writing are ignored on the lower 3 bits, so write 0 to the lower 3 bits.	R/W
15:12	HMANT[3:0]	Mantissa Part of Horizontal Scale-Down Factor The specifiable range is 0x0 to 0xF. When 0x0 is set for the HMANT bits and 0x000 is set for the HFRAC bits, the scale-down filter is not used.	R/W
27:16	VFRAC[11:0]	Fraction Part of Vertical Scale-Down Factor The specifiable range is 0x000 to 0xFF8. The fraction of the scale-down factor that cannot be set with only the VMANT bits must be set with these bits. The value of writing are ignored on the lower 3 bits, so write 0 to the lower 3 bits.	R/W
31:28	VMANT[3:0]	Mantissa Part of Vertical Scale-Down Factor The specifiable range is 0x0 to 0xF. When 0x0 is set for the VMANT bits and 0x000 is set for the VFRAC bits, the scale-down filter is not used.	R/W

Note: S-TYPE-3, P-TYPE-3

CFLCR sets the scale-down factor for the filter to scale images down.

The CEU has an image scale-down filter which can be used to scale down the captured images before storing them in the memory. Set CFLCR to 0 when not performing scale-down (same size output). If a value other than 0 is set in CFLCR, scale-down is performed. In data fetch mode, set CFLCR to 0.

When handling an interlace source image as a frame image, set CFLCR to 0 not to use the filter.

An image scale-down filter is installed in the CEU, and the captured images can be scaled down and stored in the memory.

Figure 53.32 Scale-down of captured image

The formulas for obtaining the MANT (VMANT or HMANT) and FRAC (VFRAC or HFRAC) values from the input pixel count and output pixel count of the filter are shown below. Set the MANT and FRAC bits in order to obtain the desired output pixel count from the number of pixels input to the CEU.

First, calculate preliminary MANT and FRAC values. The parameters needed for calculation are defined as follows:

$$\alpha = \text{MANT} \times 4096 + \text{FRAC} \quad \dots \text{Formula 1}$$

$$\text{SCL (scaling factor)} = \frac{4096}{\alpha} \quad \dots \text{Formula 2}$$

Assuming an operator $\lfloor x \rfloor$ which discards fractions of an integer x , the MANT and FRAC values can be temporarily set as follows, according to formula 1 and formula 2.

$$\text{MANT} = \left\lfloor \frac{1}{\text{SCL}} \right\rfloor, \text{FRAC} = \left\lfloor 512 \times \left(\frac{1}{\text{SCL}} - \text{MANT} \right) \right\rfloor \times 8$$

Here, the scaled-down filter output size (SIZE_D) can be calculated using the input image size S_{in} (8-bit interface: half of the CAPWR setting, 16-bit interface: CAPWR setting) in the following formula.

$$\text{SIZE}_D = \left\lfloor 1 + \left(\left\lfloor \frac{1}{2} + \frac{S_{in}-1}{\text{MANT}_{pre}} \right\rfloor - 1 \right) \times \frac{\text{MANT}_{pre} \times 4096}{\alpha} \right\rfloor \quad \dots \text{Formula 3}$$

$$\begin{cases} \text{MANT}_{pre} = 1 \rightarrow (0 \leq \text{MANT} < 2) \\ \text{MANT}_{pre} = 2 \rightarrow (2 \leq \text{MANT} < 4) \\ \text{MANT}_{pre} = 4 \rightarrow (4 \leq \text{MANT} < 8) \\ \text{MANT}_{pre} = 8 \rightarrow (8 \leq \text{MANT}) \end{cases}$$

The number of output pixels can be obtained by substituting the temporarily calculated MANT, FRAC, and input image size into these formulas. If the calculated number of output pixels is smaller than the number of output pixels used to obtain the preliminary MANT and FRAC values, recalculate with a smaller FRAC (α) value, and set the MANT and FRAC values in this register so that a pixel value greater than the desired number of output pixels can be obtained.

Example: Scale down 640 pixels to 480 pixels

$\text{SCL} = 480/640 = 3/4$, and the preliminary settings of $\text{MANT} = 1$, $\text{MANT}_{pre} = 1$, and $\text{FRAC} = 0x550$ are made. Substituting these in the following formula results in an output pixel count of 479.

$$\text{SIZE}_D = \left\lfloor 1 + \left(\left\lfloor \frac{1}{2} + \frac{S_{in}-1}{\text{MANT}_{pre}} \right\rfloor - 1 \right) \times \frac{\text{MANT}_{pre} \times 4096}{\alpha} \right\rfloor \quad \dots \text{Formula 3}$$

Since this output pixel count is smaller than the desired output pixel count of 480, the formula is recalculated with a FRAC value of $0x548$, a value eight less than the previous time. The obtained result of output pixel count = 480 is equal to the desired output pixel count of 480, so this register is set as $\text{MANT} = 1$ and $\text{FRAC} = 0x548$.

Table 53.8 Setting examples for each scale-down filter factor

Scale-down factor	FRAC		MANT	Input pixel count	Output pixel count	Clipping size (CFSZR)
	Decimal	Hexadecimal				
7/8	576	0x240	1	640	560	560
3/4	1352	0x548	1	640	480	480
5/8	2448	0x990	1	640	400	400
1/2	0	0x0	2	640	320	320
3/8	2728	0xAA8	2	640	240	240
1/3	0.0	0x0	3	640	213	212
1/4	0.0	0x0	4	640	160	160
1/5	0.0	0x0	5	640	128	128
1/6	0.0	0x0	6	640	107	104
1/7	0.0	0x0	7	640	91	88
1/8	0.0	0x0	8	640	80	80
1/16	4088	0xFF8	15	640	40	40

Note: This scale-down filter uses a VGA-size line memory for scale-down. Therefore, when an image larger than the VGA size is input for scale-down, settings must be made so that the output image size is equal to or larger than the SubQCIF size and equal to or smaller than the VGA size. When an image is not scaled down (same size output), this restriction does not apply.

53.2.11 CFSZR, CFSZR_x : Capture Filter Size Clip Register (x = B, M)

Base address: CEU = 0x4034_8000
CEU_NS = 0x5034_8000

Offset address: 0x0034 (CFSZR)
0x1034 (CFSZR_B)
0x2034 (CFSZR_M)

Bit	Symbol	Function	R/W
11:0	HFCLP[11:0]	Specify the horizontal clipping value of the filter output size (8-pixel units). The lower 3 bits should be written 0.	R/W
15:12	—	These bits are read as 0. The write value should be 0.	R/W
27:16	VFCLP[11:0]	Specify the vertical clipping value of the filter output size (4-pixel units). The value of writing are ignored on the lower 2 bits, so write 0 to the lower 2 bits.	R/W
31:28	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

CFSZR sets the clipping size for fine adjustment of the image size output from the filter, and must be set in combination with CFLCR. When clipping the output size of the filter, set the clipping size as a number of pixels, and the setting unit should be four pixels. CFSZR must be set even when scale-down is not performed (same size output).

This register is not used, during data enable fetch mode.

In data synchronous fetch mode, set CFSZR according to the setting of CAPWR.

The scale-down filter in the CEU may output an odd number of pixels or lines depending on the settings. To adjust the output size of the filter, the CEU clips the destination image by using the number of pixels specified in CFSZR, as shown in [Figure 53.33](#). The clipping size must be specified vertically in 4-pixel units and horizontally in 8-pixel units.

Figure 53.33 Clipping of image output from filter

The pixels to be clipped are counted from the top-left corner of a display. The pixels located to the right of the specified number of pixels or below the specified number of lines are discarded by the clipping function. If the number of pixels specified in CFSZR is larger than that output from the filter, correct operation cannot be guaranteed. To avoid this, the clipping size specified in CFSZR must be equal to or smaller than the number of pixels output from the filter.

Note: In data synchronous fetch mode, the following settings are required. Data cannot be fetched correctly unless the following settings are made.

- 8-bit interface:
 $VFCLP = CAPWR.VWDTH$
 $HFCLP = CAPWR.HWDTH/2$
- 16-bit interface:
 $VFCLP = CAPWR.VWDTH$
 $HFCLP = CAPWR.HWDTH$

53.2.12 CDWDR, CDWDR_x : Capture Destination Width Register (x = B, M)

Base address: CEU = 0x4034_8000
 CEU_NS = 0x5034_8000

Offset address: 0x0038 (CDWDR)
 0x1038 (CDWDR_B)
 0x2038 (CDWDR_M)

Value after reset: 0

Bit	Symbol	Function	R/W
12:0	CHDW[12:0]	Specify the horizontal image size in the memory area where the captured image is to be stored (8-byte units). The image data captured by the CEU is stored in the memory. In data synchronous fetch mode, set as follows: 8-bit interface: CHDW = CAPWR.HWDTH 16-bit interface: CHDW = CAPWR.HWDTH × 2 The lower 3 bits should be written 0.	R/W
31:13	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

CDWDR sets the horizontal image size in the memory area where the captured image is to be output in 8-byte units (8-pixel units).

In data synchronous fetch mode, set CDWDR according to the setting of CAPWR.

This register is not used, during data enable fetch mode.

53.2.13 CDAYR, CDAYR_x : Capture Data Address Y Register (x = B, M)

Base address: CEU = 0x4034_8000
CEU_NS = 0x5034_8000

Offset address: 0x003C (CDAYR)
0x103C (CDAYR_B)
0x203C (CDAYR_M)

Bit position: 31

0

Bit field:

CAYR[31:0]

Value after reset: 0

Bit	Symbol	Function	R/W
31:0	CAYR[31:0]	Capture Data Address Y - Frame image capture: These bits set the address for storing the luminance component data of the captured data (8-pixel units). - One-field image capture: These bits set the address for storing the luminance component data of the captured data (8-pixel units). - Both-field image capture: These bits set the address for storing the luminance component data of the captured top-field data (8-pixel units). - Data fetch: These bits set the address for storing data (8-byte units). - Data enable fetch bundle write: These bits set the address for storing data (32-byte units). The lower 3 bits should be written 0.	R/W

Note: S-TYPE-3, P-TYPE-3

CDAYR specifies the address where the luminance component of the captured data is to be stored in frame image capture or one-field image capture, the address where the luminance component of the captured top field is to be stored in both-field image capture, and the address where the fetched data is to be stored in data fetch. The CEU separates the captured image data into the luminance component data (Y) and the chrominance component data (C), and stores them in the memory via the bus. In frame image capture or one-field image capture, set the start address of the memory area where the luminance component of the captured data is to be stored by CDAYR. In both-field image capture, set the start address of the memory area where the luminance component of the captured top-field image is to be stored by CDAYR. In data fetch, set the start address of the memory area where data is to be stored by CDAYR.

Because the address must be specified in 32 bits, the address set by CDAYR must be in longword units.

Set the address of the starting point of the memory area where the fetched data is to be stored in this register, as shown in [Figure 53.34](#).

- Frame image capture: Set the address of the starting point of the memory area where the luminance component of the captured image is to be stored.
- One-field image capture: Set the address of the starting point of the memory area where the luminance component of the captured image is to be stored.

- Both-field image capture: Set the address of the starting point of the memory area where the luminance component of the captured top-field image is to be stored.
- Data fetch: Set the address of the starting point of the memory area where the fetched data is to be stored. In data fetch mode, the data is simply stuffed in order from the start address so the end address becomes as follows:
End address = CDAYR + number of fetched bytes
- Data enable fetch bundle write: Set the address in 32-byte units.

Figure 53.34 Relationship between captured image and luminance component memory area

53.2.14 CDACR, CDACR_x : Capture Data Address C Register (x = B, M)

Base address: CEU = 0x4034_8000
CEU_NS = 0x5034_8000

Offset address: 0x0040 (CDACR)
0x1040 (CDACR_B)
0x2040 (CDACR_M)

Bit position: 31

0

Bit field:

CACR[31:0]

Value after reset: 0

Bit	Symbol	Function	R/W
31:0	CACR[31:0]	Capture Data Address C • Frame image capture: These bits set the address for storing the chrominance component data of the captured data (8-pixel units). • One-field image capture: These bits set the address for storing the chrominance component data of the captured data (8-pixel units). • Both-field image capture: These bits set the address for storing the chrominance component data of the captured top-field data (8-pixel units). The lower 3 bits should be written 0.	R/W

Note: S-TYPE-3, P-TYPE-3

CDACR specifies the address where the chrominance component of the captured data is to be stored in frame image capture or one-field image capture, and the address where the chrominance component of the captured top field is to be stored in both-field image capture. The CEU separates the captured image data into the luminance component data (Y) and the chrominance component data (C), and stores them in the memory via the bus. In frame image capture or one-field image capture, set the start address of the memory area where the chrominance component of the captured data is to be stored by

CDACR. In both-field image capture, set the start address of the memory area where the chrominance component of the captured top-field image is to be stored by CDACR. CDACR is not used in data fetch.

Because the address must be specified in 32 bits, the address set by CDACR must be in longword units.

Set the address of the starting point of the memory area where the chrominance component of the captured image is to be stored in this register, as shown in Figure 53.35. The chrominance component has an output data format like that in Figure 53.36, and is saved in the memory in this format.

- Frame image capture: Set the address of the starting point of the memory area where the chrominance component of the captured image is to be stored.
- One-field image capture: Set the address of the starting point of the memory area where the chrominance component of the captured image is to be stored.
- Both-field image capture: Set the address of the starting point of the memory area where the chrominance component of the captured top-field image is to be stored.

Figure 53.35 Relationship between captured image and chrominance component memory area

Figure 53.36 Image of storing chrominance components in memory

53.2.15 CDBYR, CDBYR_x : Capture Data Bottom-Field Address Y Register (x = B, M)

Base address: CEU = 0x4034_8000
CEU_NS = 0x5034_8000

Offset address: 0x0044 (CDBYR)
0x1044 (CDBYR_B)
0x2044 (CDBYR_M)

Bit position: 31

0

Bit field:

CBYR[31:0]

Value after reset: 0

Bit	Symbol	Function	R/W
31:0	CBYR[31:0]	Set the address for storing the luminance component data of the captured bottom-field data (8-pixel units). The lower 3 bits should be written 0.	R/W

Note: S-TYPE-3, P-TYPE-3

CDBYR specifies the address where the luminance component of the captured bottom-field data is to be stored in both-field image capture. The CEU separates the captured image data into the luminance component data (Y) and the chrominance component data (C), and stores them in the memory via the bus. Set the start address of the memory area where the luminance component of the captured bottom-field image is to be stored by CDBYR. CDBYR is not used in frame image capture, one-field image capture, or data fetch.

Because the address must be specified in 32 bits, the address set by CDBYR must be in longword units.

Set the address of the starting point of the memory area where the luminance component of the captured bottom-field image is to be stored in this register, as shown in Figure 53.37.

Figure 53.37 Relationship between captured bottom-field image and luminance component memory area

53.2.16 CDBCR, CDBCR_x : Capture Data Bottom-Field Address C Register (x = B, M)

Base address: CEU = 0x4034_8000
CEU_NS = 0x5034_8000

Offset address: 0x0048 (CDBCR)
0x1048 (CDBCR_B)
0x2048 (CDBCR_M)

Bit position: 31

0

Bit field:

CBCR[31:0]

Value after reset: 0

Bit	Symbol	Function	R/W
31:0	CBCR[31:0]	Set the address for storing the chrominance component data of the captured bottom-field data (8-pixel units). The lower 3 bits should be written 0.	R/W

Note: S-TYPE-3, P-TYPE-3

CDBCR specifies the address where the chrominance component of the captured bottom-field data is to be stored in both-field image capture. The CEU separates the captured image data into the luminance component data (Y) and the chrominance component data (C), and stores them in the memory via the bus. Set the start address of the memory area where the chrominance component of the captured bottom-field image is to be stored by CDBCR. CDBCR is not used in frame image capture, one-field image capture, or data fetch.

Because the address must be specified in 32 bits, the address set by CDBCR must be in longword units.

Set the address of the starting point of the memory area where the chrominance component of the captured bottom-field image is to be stored in this register, as shown in Figure 53.38. The chrominance component has an output data format like that in Figure 53.39, and is saved in the memory in this format.

Figure 53.38 Relationship between captured bottom-field image and chrominance component memory area

Figure 53.39 Image of storing chrominance components in memory

53.2.17 CBDSR, CBDSR_x : Capture Bundle Destination Size Register (x = B, M)

Base address: CEU = 0x4034_8000
CEU_NS = 0x5034_8000

Offset address: 0x004C (CBDSR)
0x104C (CBDSR_B)
0x204C (CBDSR_M)

Bit	Symbol	Function	R/W
22:0	CBVS[22:0]	Select the number of lines or number of bytes for output to the memory in a bundle write. Image capture and data synchronous fetch: Number of lines for output to the memory in a bundle write. Unit: 8 lines, min.: 8 lines, max.: 1,920 lines (0x780) Data enable fetch: Number of bytes for output to the memory in a bundle write. Unit: 32 bytes, min.: 512 bytes, max.: 6291456 bytes (0x600000) The value of writing are ignored on the lower 3 bits, so write 0 to the lower 3 bits.	R/W
31:23	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

CBDSR sets the size of output to memory in a bundle write. The number of output lines should be specified for image capture or data synchronous fetch. The number of bytes should be specified for data enable fetch.

(a) Image capture and data synchronous fetch

Set the number of lines of captured data to be written to the memory by a bundle write as a multiple of eight. This register is valid only when CDOCR.CBE = 1. When CDOCR.CBE = 1 and this register cleared to 0, this module operates with the number of lines of captured data to be written to the memory as eight. The maximum number of lines that can be set is 1,920 (0x780). Only bits CBVS[11:3] are valid.

Figure 53.40 Image of storing captured image in memory by bundle write

(b) Data enable fetch

Set the number of bytes of captured data to be written to the memory by a bundle write as a multiple of 32. This register is valid only when CDOCR.CBE = 1. The minimum settable size is 512 bytes. When a number smaller than 512 bytes is specified, operation is not guaranteed.

53.2.18 CFWCR : Firewall Operation Control Register

Base address: CEU = 0x4034_8000
CEU NS = 0x5034_8000

Offset address: 0x005C

Bit position: 31

5

Q

Bit field:

FWV[26:0]

A/E

Value after reset: 0 1 0 0 0 0 0 0 0 0

Bit	Symbol	Function	R/W
0	FWE	Firewall Operation With the setting of FWE = 1, when a write address exceeds the value set with FWV, the address is retained and an interrupt source FWF is set. After this, the address is not incremented and data is overwritten on the upper limit address. 0: Firewall is not activated. 1: Firewall is activated.	R/W
4:1	—	These bits are read as 0. The write value should be 0.	R/W
31:5	FWV[26:0]	Specify the upper limit of a write address. Specify the upper 27 bits of the 32-bit address. The upper limit of an address is $FWV[26:0] \ll 5 + 0x1F$.	R/W

Note: S-TYPE-3, P-TYPE-3

CFWCR specifies the upper limit of a write address in data enable fetch. When the VD input from an external module does not go low and end notification is not given, this register can prevent writing to memory from being out of control.

This register is enabled only in data enable fetch.

53.2.19 CLFCR, CLFCR_x : Capture Low-Pass Filter Control Register (x = B, M)

Base address: CEU = 0x4034_8000
CEU_NS = 0x5034_8000

Offset address: 0x0060 (CLFCR)
0x1060 (CLFCR_B)
0x2060 (CLFCR_M)

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	LPF
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	LPF	Enables or disables operation of the low-pass filter. The low-pass filter removes high-frequency components from the destination image in the horizontal direction. Clear this bit to 0 in data fetch mode. 0: Low-pass filter not used 1: Low-pass filter used (only in the horizontal direction)	R/W
31:1	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

CLFCR specifies whether or not to operate the low-pass filter. In data fetch mode, clear the LPF bit to 0.

The characteristic of the low-pass filter installed in the CEU causes the phase location of the image processed by the low-pass filter to be shifted right by one pixel compared to the raw image.

53.2.20 CDOCR, CDOCR_x : Capture Data Output Control Register (x = B, M)

Base address: CEU = 0x4034_8000
CEU_NS = 0x5034_8000

Offset address: 0x0064 (CDOCR)
0x1064 (CDOCR_B)
0x2064 (CDOCR_M)

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	CBE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	CDS	—	COLS	COWS	COBS
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	COBS	Controls swapping in 8-bit units for data output from the CEU. 0: Data is not swapped in 8-bit units 1: Data is swapped in 8-bit units	R/W
1	COWS	Controls swapping in 16-bit units for data output from the CEU. 0: Data is not swapped in 16-bit units 1: Data is swapped in 16-bit units	R/W
2	COLS	Controls swapping in 32-bit units for data output from the CEU. 0: Data is not swapped in 32-bit units 1: Data is swapped in 32-bit units	R/W

Bit	Symbol	Function	R/W
3	—	This bit is read as 0. The write value should be 0.	R/W
4	CDS	Sets the image format when outputting the image data captured in the YCbCr422 format to the memory. When 0 is written to this bit, only the luminance component (Y) is output and no chrominance components (Cb and Cr) are output for the odd-numbered lines. With an interlace source image, similarly only the luminance component (Y) is output and no chrominance components (Cb and Cr) are output for the odd-numbered lines of the field. In data fetch mode, set this bit to 1. 0: Converts the YCbCr422 format to the YCbCr420 format before outputting data to the memory 1: Outputs data in the YCbCr422 format to the memory without conversion	R/W
15:5	—	These bits are read as 0. The write value should be 0.	R/W
16	CBE	Controls the number of lines of captured data to be written to the memory. - Image capture This bit controls the number of lines of captured data to be written to the memory. When bundle write is set by this register, captured data is written in line units specified by CBDSR to the addresses specified by CDAYR and CDACR, and CDAYR2 and CDACR2 (CDBYR and CDBCR, and CDBYR2 and CDBCR2 for the bottom field in both-field capture) alternately (Figure 53.41). When captured data has been written for the number of lines set by CBDSR, a write end interrupt corresponding to each address setting register occurs. However, after write for one-frame (one-field) capture ends, a bundle write end interrupt does not occur even when bundle write has finished. - Data synchronous fetch This bit controls the number of lines of captured data to be written to the memory. When bundle write is set by this register, captured data is written in line units specified by CBDSR to the addresses specified by CDAYR and CDAYR2 alternately. When captured data has been written for the number of lines set by CBDSR, a write end interrupt corresponding to each address setting register occurs. However, after write for one-frame capture ends, a bundle write end interrupt does not occur even when bundle write has finished. - Data enable fetch This bit controls the number of bytes of captured data to be written to the memory. When bundle write is set by this register, captured data is written in byte units specified by CBDSR to the addresses specified by CDAYR and CDAYR2 alternately. When captured data has been written for the number of bytes set by CBDSR, a write end interrupt corresponding to each address setting register occurs. Also, only in data enable fetch, a bundle write end interrupt occurs when bundle write has finished after write for one-frame capture ends. Table 53.9 shows the correspondence between address setting registers and write end interrupt sources. Figure 53.42 shows the timing of write end interrupts in image capture and data synchronous fetch. Figure 53.43 shows the timing of write end interrupts in data enable fetch. 0: Normal write 1: Bundle write	R/W
31:17	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

CDOCR sets the format for outputting captured data to the memory. In data fetch mode, set the CDS bit to 1.

Figure 53.41 Image of bundle write to memory

Table 53.9 Correspondence between address setting registers and write end interrupt sources

Address setting registers	Bundle write end interrupt source
CDAYR, CDACR	CPBE1 bit in CETCR
CDAYR2, CDACR2	CPBE2 bit in CETCR
CDBYR, CDBCR	CPBE3 bit in CETCR
CDBYR2, CDBCR2	CPBE4 bit in CETCR

Figure 53.42 Timing of write end interrupts (Image capture, data synchronous fetch)

Figure 53.43 Timing of write end interrupts (data enable fetch)

For data output from the CEU, the COLS, COWS, and COBS bits control swapping in 32-bit, 16-bit, and 8-bit units, respectively. Set these bits when data is misaligned because of a difference in endian. The data swapping bits are shown below. These bits can be set similarly in data fetch mode.

Data can be swapped in 8-bit, 16-bit, 32-bit units, or in 32 bits, 16 bits and 8 bits, as shown in [Figure 53.44](#). To enable data swapping, set the corresponding control bit to 1.

Figure 53.44 Data swapping by data aligner

53.2.21 CEIER : Capture Event Interrupt Enable Register

Base address: CEU = 0x4034_8000
CEU_NS = 0x5034_8000

Offset address: 0x0070

31:26	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

CEIER enables or disables interrupts of the event flag register that generates CEU interrupts.

53.2.22 CETCR : Capture Event Flag Clear Register

Base address: CEU = 0x4034_8000
CEU_NS = 0x5034_8000

Offset address: 0x0074

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	NVD	NHD	FWF	—	—	VBP	—	IGVS	IGHS	CDTO F
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	CPBE 4	CPBE 3	CPBE 2	CPBE 1	—	—	VD	HD	—	—	—	IGRW	—	—	CFE	CPE
Value after reset:	0	0	0	0	0	0	x	x	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	CPE	An interrupt indicating that capturing of one frame from an external module has finished. This interrupt is output when the last captured data has been transferred and the end notification received, regardless of the next VD input. This interrupt indicates that capturing of one frame has finished. This bit is set to 1 when the image of the size set in CAPWR is captured and the last data transfer to the bus finished (see Figure 53.46).	R/W
1	CFE	An interrupt indicating that capturing of one field from an external module has finished. This interrupt is output when the last captured data has been transferred and the end notification received, regardless of the next VD input (see Figure 53.45). This interrupt occurs only in both-field capture mode.	R/W
3:2	—	These bits are read as 0. The write value should be 0.	R/W
4	IGRW	An interrupt indicating that during capturing, access was attempted to a register to which writing during operation is prohibited. Among the CEU registers, writing during capturing is prohibited for some registers. Table 53.10 shows which registers can/cannot be written to during capturing. This bit is set to 1 when a register to which writing during capturing is prohibited has been written to.	R/W
7:5	—	These bits are read as 0. The write value should be 0.	R/W

Bit	Symbol	Function	R/W
8	HD	An interrupt indicating that HD (horizontal sync signal) was input from an external module. This bit is set to 1 when an HD input from an external module is detected. Immediately after the HDPOL bit in CAMCR is modified, a pseudo HD is input and this bit is set to 1. The HD interrupt after the HDPOL bit is modified should be ignored.	R/W
9	VD	An interrupt indicating that VD (vertical sync signal) was input from an external module. In data enable fetch mode, this bit is set to 1 when a VD input from an external module is detected. In image capture mode and data synchronous fetch mode, this module generates a VD interrupt in response to the first detection of the active level of HD following detection of the active level of VD from an external module. Note that, when VD and HD are asserted and detected at the same time, this module generates a VD interrupt at that time. Immediately after the VDPOL bit in CAMCR is modified, a pseudo VD is input and this bit is set to 1. The VD interrupt after the VDPOL bit is modified should be ignored.	R/W
11:10	—	These bits are read as 0. The write value should be 0.	R/W
12	CPBE1	An interrupt indicating that writing to CDAYR and CDACR in a bundle write has finished. This interrupt is output when the last captured data has been transferred and the end notification received, regardless of the next HD input. This bit is set to 1 when data for the number of lines (number of bytes in data enable fetch) set in CBDSR has been captured and the last data transfer to the bus has completed. However, in image capture or data synchronous fetch, this interrupt does not occur when the last captured data in a bundle write is the last captured data of a frame (field).	R/W
13	CPBE2	An interrupt indicating that writing to CDAYR2 and CDACR2 in a bundle write has finished. This interrupt is output when the last captured data has been transferred and the end notification received, regardless of the next HD input. This bit is set to 1 when data for the number of lines (number of bytes in data enable fetch) set in CBDSR has been captured and the last data transfer to the bus has completed. However, in image capture or data synchronous fetch, this interrupt does not occur when the last captured data in a bundle write is the last captured data of a frame (field).	R/W
14	CPBE3	An interrupt indicating that writing to CDBYR and CDBCR in a bundle write has finished. This interrupt is output when the last captured data has been transferred and the end notification received, regardless of the next HD input. This bit is set to 1 when data for the number of lines set in CBDSR has been captured and the last data transfer to the bus has completed. However, this interrupt does not occur when the last captured data in a bundle write is the last captured data of a frame (field).	R/W
15	CPBE4	An interrupt indicating that writing to CDBYR2 and CDBCR2 in a bundle write has finished. This interrupt is output when the last captured data has been transferred and the end notification received, regardless of the next HD input. This bit is set to 1 when data for the number of lines set in CBDSR has been captured and the last data transfer to the bus has completed. However, this interrupt does not occur when the last captured data in a bundle write is the last captured data of a frame (field).	R/W
16	CDTOF	An interrupt indicating that data overflowed in the CRAM of the write buffer. Since data is input at realtime from an external module in capture operations, the frame image is overwritten unless the captured data is transferred from the CEU internal buffer to the memory at a certain or higher transfer rate. This bit is set to 1 when writing the data in the CRAM of the CEU internal write buffer to the bus is not performed within time and data has overflowed.	R/W
17	IGHS	An interrupt generated when the number of HD cycles set in CMCYR differ from the number of HD cycles input from an external module. This bit is set to 1 when there is an illegal HD input from an external module. This bit is set to 1 when the number of clock cycles for the HD input to the CEU differs from the value set in the HCYL bits in CMCYR. Note however that when the HCYL bits are cleared to 0, this interrupt does not occur.	R/W
18	IGVS	An interrupt generated when the number of VD cycles set in CMCYR differ from the number of VD cycles input from an external module. This bit is set to 1 when there is an illegal VD input from an external module. This bit is set to 1 when the number of HD cycles for the VD input to the CEU differs from the value set in the VCYL bits in CMCYR. Note however that when the VCYL bits are cleared to 0, this interrupt does not occur.	R/W
19	—	This bit is read as 0. The write value should be 0.	R/W

Bit	Symbol	Function	R/W
20	VBP	An interrupt indicating that VD has been input while the CEU holds data (insufficient vertical-sync front porch). The conditions for a VBP interrupt to occur are as follows: - Condition 1 VD is input when there is captured data within the CEU - Condition 2 The last transfer data cannot be internally detected due to a write buffer overflow or an illegal HD so that the end timing is unclear until the next VD (By generating a VBP interrupt at the VD input timing, capture fail can be announced.) When a VBP interrupt occurs, a capture end interrupt (CPE bit in CETCR) does not occur and the image of that frame is not captured correctly. Though a capture end interrupt (CPE bit) will occur on rare occasions, it should be ignored in this case. Capturing cannot be performed until the next VD (even if the CE bit (capture reservation signal) in CAPSR is 1, capturing does not start). In the case of condition 2, instead of waiting for a VBP interrupt to occur, execute a software reset (CPKIL bit in CAPSR) to stop capturing and then restart capturing. In this case, since capture operation is terminated without waiting for the next VD, a VBP interrupt does not occur and capturing can be performed from the next VD.	R/W
22:21	—	These bits are read as 0. The write value should be 0.	R/W
23	FWF	The interrupt is generated when data is written to the address that exceeds the value specified with CFWCR.FMV. This bit is set to 1 when data is written to the address that exceeds the value specified with CFWCR.FMV while CFWCR.FWE = 1.	R/W
24	NHD	An interrupt indicating that no HD was input. The timing for a non-HD interrupt to occur differs depending on the bit width of the digital image input pins. 8-bit digital image input pins: Occurs when the 11-bit internal counter that is incremented every eight cycles becomes full. Accordingly, this bit is set to 1 when no HD has been input for at least 16,376 cycles since the last HD was input. 16-bit digital image input pins: Occurs when the 12-bit internal counter that is incremented every four cycles becomes full. Accordingly, this bit is set to 1 when no HD has been input for at least 16,380 cycles since the last HD was input. When connecting a camera whose HD is fixed low when VD is low, this bit may be set to 1. Ignore this interrupt during data enable fetch.	R/W
25	NVD	An interrupt indicating that no VD was input. A non-VD interrupt occurs when the 14-bit internal counter becomes full. Accordingly, this bit is set to 1 when no VD has been input for at least 16,383 lines since the last VD was input.	R/W
31:26	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

CETCR notifies the CPU of the source of an interrupt that is generated in the CEU. The flags of CETCR can be used as interrupt signals. When the corresponding interrupt is enabled, an interrupt (CEU_CEUI) is generated. To clear the interrupt, clear the bit corresponding to the interrupt source to 0. After several cycles have passed after modifying the bit, the interrupt is cleared.

To clear the bit corresponding to the interrupt source to be cleared to 0 and retain that state, write 1 to that bit. For example, to clear only the CPE bit to 0, write 0xFFFFF0FE to CETCR.

In CETCR, only bits to which 0 is written are cleared. Bits to which 1 is written retain their current values. To clear an interrupt source, write 0 only to the bit corresponding to the interrupt source to be cleared, and 1 to the other bits.

Note: Since the CETCR value becomes undefined in the following cases, clear all bits in CETCR to 0.

- VD and HD bits immediately after system reset or Software Standby mode is entered.
- VD and HD bits after the polarities of the capture interface sync signals are changed.

53.2.23 CSTSR : Capture Status Register

Base address: CEU = 0x4034_8000
CEU_NS = 0x5034_8000

Offset address: 0x007C

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	CRST	—	—	—	—	—	—	—	CPFLD
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	CPTON
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	CPTON	Indicates that the CEU is operating. This bit retains 1 during the period that starts from the internal VD at capture start and ends when a one-frame capture end interrupt occurs. Figure 53.47 shows the CEU operating period.	R
15:1	—	These bits are read as 0.	R
16	CPFLD	Indicates which field is being captured. 0: Bottom field is being captured 1: Top field is being captured	R
23:17	—	These bits are read as 0.	R
24	CRST	Indicates which register plane is currently used. 0: Plane A of the register is being used 1: Plane B of the register is being used	R
31:25	—	These bits are read as 0.	R

Note: S-TYPE-3, P-TYPE-3

CSTSR indicates the internal status of the CEU. CSTSR differs from CETCR in that no interrupt is generated for the events indicated in CSTSR.

The CEU operating/halt state can be confirmed using CSTSR. To confirm the halt state of the CEU, make sure that the status bit (bit 0) indicating that the CEU is operating is cleared to 0 for sure.

Figure 53.47 Operating status during capturing

53.2.24 CDSSR : Capture Data Size Register

Base address: CEU = 0x4034_8000
CEU_NS = 0x5034_8000

Offset address: 0x0084

Bit position: 31

0

Bit field:

CDSS[31:0]

Value after reset: 0

Bit	Symbol	Function	R/W
31:0	CDSS[31:0]	Indicate the size of data written to the memory in data enable fetch. In a bundle write, size of data written to the selected address at the end of one-frame capture is indicated. In a bundle write, as soon as the number of bytes specified by CBDSR is transferred to the bus, address to which data is written is switched. Therefore, if one-frame capture is completed at the same time as a bundle write is completed, this register indicates 0x00000000. Figure 53.48 and Figure 53.49 show the overall timing of the CDSSR operation in a bundle write.	R

Note: S-TYPE-3, P-TYPE-3

CDSSR indicates the size of data written to the memory in data enable fetch. As this register indicates a correct value at the end of capture, confirm this register when capture is completed.

Figure 53.48 Overall timing of CDSSR operation in bundle write (when bundle write end and capture end coincide)

Figure 53.49 Overall timing of CDSSR operation in bundle write (when bundle write end and capture end do not coincide)

53.2.25 CDAYR2, CDAYR2_x : Capture Data Address Y Register 2 (x = B, M)

Base address: CEU = 0x4034_8000
CEU_NS = 0x5034_8000

Offset address: 0x0090 (CDAYR2)
0x1090 (CDAYR2_B)
0x2090 (CDAYR2_M)

Bit position: 31

0

Bit field:

CAYR2[31:0]

Value after reset: 0

Bit	Symbol	Function	R/W
31:0	CAYR2[31:0]	Capture Data Address Y Frame image capture: These bits set the address for storing the luminance component data of the captured data (8-pixel units). - One-field image capture: These bits set the address for storing the luminance component data of the captured data (8-pixel units). - Both-field image capture: These bits set the address for storing the luminance component data of the captured top-field data (8-pixel units). - Data synchronous fetch: These bits set the address for storing data (8-byte units). - Data enable fetch: These bits set the address for storing data (32-byte units). The lower 3 bits should be written 0.	R/W

Note: S-TYPE-3, P-TYPE-3

CDAYR2 specifies the address for the luminance component used in a bundle write and the address for data storage in a bundle write in data fetch. CDAYR2 is used only in a bundle write.

CDAYR2 specifies the address where the luminance component of the captured data is to be stored in frame image capture or one-field image capture, the address where the luminance component of the captured top field is to be stored in both-field image capture, and the address where data is to be stored in data fetch. The CEU separates the captured image data into the luminance component data (Y) and the chrominance component data (C), and stores them in the memory via the bus. In frame image capture or one-field image capture, set the start address of the memory area where the luminance component of the captured data is to be stored by CDAYR2. In both-field image capture, set the start address of the memory area where the luminance component of the captured top-field image is to be stored by CDAYR2. In data fetch, set the start address of the memory area to be used for data storage.

The address specified by this register must be in 32-bit units.

Set the address of the starting point of the memory area where the luminance component of the captured image is to be stored in this register, as shown in [Figure 53.50](#).

- Frame image capture: Set the address of the starting point of the memory area where the luminance component of the captured image is to be stored.
- One-field image capture: Set the address of the starting point of the memory area where the luminance component of the captured image is to be stored.
- Both-field image capture: Set the address of the starting point of the memory area where the luminance component of the captured top-field image is to be stored.
- Data synchronous fetch: Set the address of the starting point of the memory area where the captured data is to be stored.
- Data enable fetch: Set the address of the starting point of the memory area where the captured data is to be stored in 32-byte units.

Figure 53.50 Relationship between captured image and luminance component memory area

53.2.26 CDACR2, CDACR2_x : Capture Data Address C Register 2 (x = B, M)

Base address: CEU = 0x4034_8000
CEU_NS = 0x5034_8000

Offset address: 0x0094 (CDACR2)
0x1094 (CDACR2_B)
0x2094 (CDACR2_M)

Bit position: 31

0

Bit field:

CACR2[31:0]

Value after reset: 0

Bit	Symbol	Function	R/W
31:0	CACR2[31:0]	Capture Data Address C - Frame image capture: These bits set the address for storing the chrominance component data of the captured data (8-pixel units). - One-field image capture: These bits set the address for storing the chrominance component data of the captured data (8-pixel units). - Both-field image capture: These bits set the address for storing the chrominance component data of the captured top-field data (8-pixel units). The lower 3 bits should be written 0.	R/W

Note: S-TYPE-3, P-TYPE-3

CDACR2 specifies the address for the chrominance component used in a bundle write. CDACR2 is used only in a bundle write.

CDACR2 specifies the address where the chrominance component of the captured data is to be stored in frame image capture or one-field image capture, and the address where the chrominance component of the captured top field is to be stored in both-field image capture. The CEU separates the captured image data into the luminance component data (Y) and the chrominance component data (C), and stores them in the memory via the bus. In frame image capture or one-field image capture, set the start address of the memory area where the chrominance component of the captured data is to be stored by CDACR2. In both-field image capture, set the start address of the memory area where the chrominance component of the captured top-field image is to be stored by CDACR2. CDACR2 is not used in data fetch.

The address specified by this register must be in 32-bit units.

In this register, set the address of the starting point of the memory area where the captured data is to be stored in a bundle write, as shown in [Figure 53.51](#).

- Frame image capture: Set the address of the starting point of the memory area where the chrominance component of the captured image is to be stored.
- One-field image capture: Set the address of the starting point of the memory area where the chrominance component of the captured image is to be stored.
- Both-field image capture: Set the address of the starting point of the memory area where the chrominance component of the captured top-field image is to be stored.

The chrominance component has an output data format as shown in [Figure 53.52](#), and is saved in the memory in this format.

Figure 53.51 Relationship between captured image and chrominance component memory area

Figure 53.52 Image of storing chrominance components in memory

53.2.27 CDBYR2, CDBYR2_x : Capture Data Bottom-Field Address Y Register 2 (x = B, M)

Base address: CEU = 0x4034_8000
CEU_NS = 0x5034_8000

Offset address: 0x0098 (CDBYR2)
0x1098 (CDBYR2_B)
0x2098 (CDBYR2_M)

Bit position: 31

0

Bit field:

CBYR2[31:0]

Value after reset: 0

Bit	Symbol	Function	R/W
31:0	CBYR2[31:0]	Set the address for storing the luminance component data of the captured bottom-field data (8-pixel units). The lower 3 bits should be written 0.	R/W

Note: S-TYPE-3, P-TYPE-3

CDBYR2 specifies the address for the luminance component of the bottom field used in a bundle write. CDBYR2 is used only in a bundle write.

CDBYR2 specifies the address where the luminance component of the captured bottom-field data is to be stored in both-field image capture. The CEU separates the captured image data into the luminance component data (Y) and the chrominance component data (C), and stores them in the memory via the bus. Set the start address of the memory area where the luminance component of the bottom-field image captured in both-field image capture is to be stored by CDBYR2. CDBYR2 is not used in frame image capture, one-field image capture, or data fetch.

The address specified by this register must be in 32-bit units.

In this register, set the address of the starting point of the memory area where the luminance component of the captured bottom-field image is to be stored in a bundle write, as shown in [Figure 53.53](#).

Figure 53.53 Relationship between captured bottom-field image and luminance component memory area

53.2.28 CDBCR2, CDBCR2_x : Capture Data Bottom-Field Address C Register 2 (x = B, M)

Base address: CEU = 0x4034_8000
CEU_NS = 0x5034_8000

Offset address: 0x009C (CDBCR2)
0x109C (CDBCR2_B)
0x209C (CDBCR2_M)

Bit position: 31

0

Bit field:

CBCR2[31:0]

Value after reset: 0

Bit	Symbol	Function	R/W
31:0	CBCR2[31:0]	Set the address for storing the chrominance component data of the captured bottom-field data (8-pixel units). The lower 3 bits should be written 0.	R/W

Note: S-TYPE-3, P-TYPE-3

CDBCR2 specifies the address for the chrominance component of the bottom field used in a bundle write. CDBCR2 is used only in a bundle write.

CDBCR2 specifies the address where the chrominance component of the captured bottom-field data is to be stored in both-field image capture. The CEU separates the captured image data into the luminance component data (Y) and the chrominance component data (C), and stores them in the memory via the bus. Set the start address of the memory area where the chrominance component of the bottom-field image captured in both-field image capture is to be stored by CDBCR2. CDBCR2 is not used in frame image capture, one-field image capture, or data fetch.

The address specified by this register must be in 32-bit units.

In this register, set the address of the starting point of the memory area where the chrominance component of the captured bottom-field image is to be stored in a bundle write, as shown in [Figure 53.54](#). The chrominance component has an output data format as shown in [Figure 53.55](#), and is saved in the memory in this format.

Figure 53.54 Relationship between captured bottom-field image and chrominance component memory area

53.3.2 Conditions for Connection to an External Module

(1) Clock Frequency

The external input clock (VIO_CLK) should have a frequency at most the same as the CEU operating clock (PCLKA) frequency, with jitter on both sides included.

$$PCLKA \geq VIO_CLK$$

(2) Blanking Period

The period from the last valid pixel in each line to the next horizontal sync signal HD must be at least 20 cycles.

(3) Fixed Period of Field Identification Signal

The field identification signal FLD should be fixed for at least 1-HD period since a VD input

53.3.3 Restrictions on Input/Output Functions

Table 53.11 lists the restrictions regarding the CEU input/output functions.

Table 53.11 Restrictions on CEU Input/Output Functions

Item	Restrictions
External module interface	The operating clock of the external module (VIO_CLK) should always have a frequency at most the same as that of the CEU operating (PCLKA), with jitter on both sides included.
	Selecting the interface, or modifying the frequency of the external module operating clock or HD/VD polarity must be done when capture operations are halted for sure.
	The capture horizontal size in image capture must be specified as follows: 8-bit interface: 16-cycle units 16-bit interface: 8-cycle units
	The capture horizontal size in data fetch must be specified as follows: 8-bit interface: 8-cycle units 16-bit interface: 4-cycle units
	The capture vertical size must be specified in 4-line units.
	The maximum number of cycles in the horizontal sync signal period should be 16,375 cycles of external input clock for 8-bit digital image input pins, or 16,379 cycles of external input clock for 16-bit digital image input pins.
	The maximum number of lines (HD count) in the vertical sync signal should be 16,382 lines.
	The minimum number of captured pixels should be sub-QCIF (128 × 96).
	The maximum number of captured pixels should be 5 megapixels (2,560 × 1,920).
	The capture size in data enable fetch must be controlled by VD and HD in 4-byte units. The range of the capture size in data enable fetch that can be input is as follows. Maximum: 6 MB (2,048 × 1,536 × 2) Minimum: 16 bytes
Memory output	The output address must be specified in 32-bit units.
	The horizontal size of the destination image (memory) must be specified in 8-pixel units.
	The number of horizontal output pixels (= horizontal clipping size) must be specified in 8-pixel units.
	The number of vertical output lines (HD) (= vertical clipping size) must be specified in 4-line (HD) units.
	In data enable fetch bundle write, the output address must be specified in 32-byte units.
Internal processing	The filter clipping size must be specified as a value equal to or lower than the actual output size of the filter.

54. Internal Voltage Regulator

54.1 Overview

The MCU supports two power supply providing for core voltage (VDD):

- Switching regulator (DCDC)
- External power supply from external power device (External VDD)

Table 54.1 shows the specifications of Internal voltage regulator.

DCDC or External VDD is selected with the OFS setting.

- When OFS2.DCDCEN is 1, DCDC is selected (DCDC mode)
- When OFS2.DCDCEN is 0, External VDD is selected (External VDD mode)

Table 54.1 Power supply selection

OFS setting (OFS2.DCDCEN)	Power mode
1	DCDC mode
0	External VDD mode

54.2 Operation

54.2.1 DCDC mode

Table 54.2 lists the DCDC mode pin settings, and Figure 54.1 shows the DCDC mode settings.

In DCDC mode, VDD is supplied from VCL through VLO output and an external inductor and capacitor.

Table 54.2 DCDC mode pin settings

Pins	Setting descriptions
All VCC and VCC2 pins	• Connect each pin to the system power supply. • Connect each pin to VSS through a 0.1 μF multilayer ceramic capacitor. Place the capacitor close to the pin.
VCC_DCDC pins	• Connect the pin to the system power supply. • Connect the pin to VSS_DCDC through a 22 μF and 0.1-μF multilayer ceramic capacitor in parallel. Place the capacitor close to the pin.
VCL pins	• Connect each pin to VSS through a 0.22 μF multilayer ceramic capacitor. Place the capacitor close to the pin. • Connect each pin to an external inductor and capacitor. Place the inductor and capacitor close to the pin.(see Figure 54.1.)
All VLO pins	Connect each pin to an external inductor and capacitor. Place the 2.2- μ H inductor and 47 μ F capacitor close to the pin. This capacitor must be grounded to VSS_DCDC

Figure 54.1 DCDC mode setting

54.2.2 External VDD mode

Table 54.3 lists the external VDD mode pin settings, and Figure 54.2 shows the external VDD mode settings.

VDD is supplied from VCL pins.

Note: Low-speed mode, Software Standby mode, Deep Software Standby mode 1, 2, 3 and Battery Backup Function are not supported in this mode.

Table 54.3 Setting Descriptions for external VDD mode

Pins	Setting descriptions
All VCC and VCC2 pins	- Connect each pin to the system power supply device for VCC. - Connect each pin to VSS through a 0.1 µF multilayer ceramic capacitor. Place the capacitor close to the pin.
VCC_DCDC pins	Connect the pin to VSS_DCDC through 0.1 µF multilayer ceramic capacitor. Place the capacitor close to the pin.
VCL pins	- Connect each pin to the system power supply device for VDD. - Connect each pin to VSS through a 0.22 µF multilayer ceramic capacitor. Place the capacitor close to the pin.
All VLO pins	Keep pin open

Figure 54.2 External VDD mode setting

In order to startup the device properly, use either of following procedure.

- VCL voltage must be raised 500 μs after VCC voltage is raised to minimum VCC voltage.
- Raise VCC voltage with RES pin is low, and release RES pin after 200 μs when VCL voltage is raised.

Figure 54.3 Power-up sequence of external VDD mode without using RES pin

Figure 54.4 Power-up sequence of external VDD mode with using RES pin

54.3 Usage Notes

In DCDC mode, to minimize power loss and maximize efficiency, Renesas recommends using a 2.2-μH inductor with a DC resistance of 100 mΩ or less. Short VCC and VCC_DCDC.

In external VDD mode, the voltage of VDD should always be below the voltage of VCC including the power-on and power-off sequence. Refer to the chapter of electrical characteristics for more information.

55. Electrical Characteristics

Unless otherwise specified, minimum and maximum values are guaranteed by either design simulation, characterization results or test in production.

Supported peripheral functions and pins differ from one product name to another.

Unless otherwise specified, the electrical characteristics of the MCU are defined under the following conditions:

- $VCC = VCC_DCDC = VCC_USB = VBATT = 1.68$ to 3.6 V
- $VCC2 = 1.65$ to 3.6 V
- $AVCC0 = 1.65$ to 3.6 V
- $VCC_USBHS = AVCC_USBHS = 3.0$ to 3.6 V
- $VREFH0 = 2.7$ V to $AVCC0$
- $VREFH = 1.65$ V to $AVCC0$
- $VSS = VSS_DCDC = AVSS0 = VREFL0 / VREFL = VSS_USB = VSS1_USBHS = VSS2_USBHS = 0$ V
- VCC voltage is lower than 2.7 V : $LVOCR.LVO0E = 1$, otherwise $LVOCR.LVO0E = 0$
- VCC2 voltage is lower than 2.7 V : $LVOCR.LVO1E = 1$, otherwise $LVOCR.LVO1E = 0$
- $T_j = T_{opj}$

When not specified otherwise, typical values are measured at room temperature of 25 °C and $VCC = VCC_DCDC = VCC_USB = VBATT = VCC_USBHS = AVCC_USBHS = AVCC0 = VREFH0 = VREFH = 3.3$ V.

Figure 55.1 shows the timing conditions.

Figure 55.1 Input or output timing measurement conditions

The recommended measurement conditions for the timing specification of each peripheral provided are for the best peripheral operation. Make sure to adjust the driving abilities of each pin to meet your conditions.

55.1 Absolute Maximum Ratings

Table 55.1 Absolute maximum ratings (1 of 2)

Parameter	Symbol	Value	Unit
Power supply voltage	$VCC, VCC2, VCC_DCDC, VCC_USB^{*2}$	-0.3 to +4.0	V
External power supply voltage	VCL	-0.3 to +1.6	V

Table 55.1 Absolute maximum ratings (2 of 2)

Parameter	Symbol	Value	Unit
VBATT power supply voltage	VBATT	−0.3 to +4.0	V
Input voltage (except for 5 V-tolerant ports*1)	V _{in}	−0.3 to VCC + 0.3 or −0.3 to VCC2 + 0.3	V
Input voltage (5 V-tolerant ports*1)	V _{in}	−0.3 to + VCC + 4.0 (max. 5.8)	V
Reference power supply voltage	VREFH/VREFH0	−0.3 to AVCC0 + 0.3	V
USBHS power supply voltage	VCC_USBHS	−0.3 to +4.0	V
USBHS analog power supply voltage	AVCC_USBHS	−0.3 to +4.0	V
Analog power supply voltage	AVCC0	−0.3 to +4.0	V
Analog input voltage	V _{AN}	−0.3 to AVCC0 + 0.3	V
Operating junction temperature*3 *4	T _{opj}	−40 to +125	°C
Storage temperature	T _{stg}	−55 to +125	°C

Note 1. Ports P205, P206, P402 to P404, P406 to P415, P511, P512, P709 to P715 and PB01 are 5 V tolerant.

Note 2. Connect VCC_DCDC and VCC_USB to VCC.

Note 3. See [section 55.2.1. Tj/Ta Definition](#).

Note 4. Contact a Renesas Electronics sales office for information on derating operation when Tj = +105°C to +125°C. Derating is the systematic reduction of load for improved reliability.

Caution: Permanent damage to the MCU might result if absolute maximum ratings are exceeded.

Table 55.2 Recommended operating conditions

Parameter	Symbol		Min	Typ	Max	Unit
Power supply voltages	VCC, VCC_DCDC	Other than the following	1.68	—	3.60	V
		When ETHERC/IIC Fast-mode+ is used	2.70	—	3.60	V
		When USB/SDRAM is used	3.00	—	3.60	V
	VCC2		1.65	—	3.60	V
	VCL	When external VDD is used*2	1.20	—	1.25	V
		When DCDC is used (High-speed mode)	—	1.21	—	V
		When DCDC is used (Low-speed mode or Software Standby mode)	—	1.18	—	V
	VSS, VSS_DCDC		—	0	—	V
USB power supply voltages	VCC_USB, VCC_USBHS, AVCC_USBHS		—	VCC	—	V
	VSS_USB, VSS1_USBHS, VSS2_USBHS		—	0	—	V
VBATT power supply voltage	VBATT		1.62	—	3.60	V
Analog power supply voltages	AVCC0*1	When ADC is not used	1.65	—	3.60	V
		When ADC is used	2.70	—	3.60	V
	AVSS0		—	0	—	V

Note 1. When the A/D converter, the D/A converter and the High-Speed Analog Comparator are not in use, do not leave the AVCC0, VREFH/VREFH0, AVSS0, and VREFL/VREFL0 pins open. Connect the AVCC0 and VREFH/VREFH0 pins to VCC, and the AVSS0 and VREFL/VREFL0 pins to VSS, respectively.

Note 2. VCL voltage must never be higher than VCC voltage.

55.2 DC Characteristics

55.2.1 Tj/Ta Definition

Table 55.3 DC characteristics

Parameter	Symbol	Typ	Max	Unit	Test conditions
Permissible operating junction temperature	T_j	—	125	°C	High-speed mode Low-speed mode

Note: Make sure that $T_j = T_a + \theta_{ja} \times \text{total power consumption (W)}$, where total power consumption = $(V_{CC} - V_{OH}) \times \Sigma I_{OH} + V_{OL} \times \Sigma I_{OL} + (I_{CCmax} + I_{CC_DCDCmax}) \times V_{CC}$.

Note: Minimum Ambient Temperature(T_a) is -40°C

55.2.2 I/O V_{IH} , V_{IL} Table 55.4 I/O V_{IH} , V_{IL} except for Schmitt trigger input pins

Parameter		VCC/VCC2/ AVCC0	Symbol	Min	Typ	Max	Unit
Peripheral function pins	EXTAL (external clock input), WAIT, SPI* ¹ (except RSPCK)	1.68 V or above	V_{IH}	$VCC \times 0.8$	—	—	V

				I_{OL}	—	—	8.0	mA
		High drive ^{*3}	—	I_{OH}	—	—	-32	mA
				I_{OL}	—	—	32.0	mA
Permissible output current (max value of total of all pins)	Maximum of all output pins	VCC I/O	1.68 V or above	$\Sigma I_{OH} \text{ (max)}$	—	—	-80	mA
		VCC2 I/O	1.65 V or above		—	—	-80	
		AVCC0 I/O	1.65 V or above		—	—	-33	
		VCC and VCC2 I/O	1.65 V or above	$\Sigma I_{OL} \text{ (max)}$	—	—	80	mA
		AVCC0 I/O	1.65 V or above		—	—	33	

Note 1. This is the value when low driving ability is selected in the Port Drive Capability bit in the PmnPFS register. The selected driving ability except for P400 and P401 is retained in Deep Software Standby mode.

Note 2. This is the value when middle driving ability is selected in the Port Drive Capability bit in the PmnPFS register. The selected driving ability except for P400 and P401 is retained in Deep Software Standby mode.

Note 3. This is the value when high driving ability is selected in the Port Drive Capability bit in the PmnPFS register. The selected driving ability except for P400 and P401 is retained in Deep Software Standby mode.

Note 4. This is the value when high-speed high driving ability is selected in the Port Drive Capability in the PmnPFS register. The selected driving ability is retained in Deep Software Standby mode.

Note 5. Except for P200, which is an input port.

Caution: To protect the reliability of the MCU, the output current values should not exceed the values in this table. The average output current indicates the average value of current measured during 100 μ s.

55.2.4 I/O V_{OH} , V_{OL} , and Other CharacteristicsTable 55.7 I/O V_{OH} , V_{OL} , and other characteristics (1 of 3)

Note 1. Supply current values are with all output pins unloaded and all input pull-up MOSs in the off state.

Note 2. Measured with clocks supplied to the peripheral functions and peripherals being operated. This does not include the BGO operation.

Note 3. I_{DD} depends on f (CPUCLK and ICLK) as follows.

I_{DD} Max. (105 °C) = 0.68 × fCPUCLK + 0.41 × fICLK + 175 (unit : mA, fCPUCLK and fICLK are MHz)

I_{DD} Max. (125 °C) = 0.68 × fCPUCLK + 0.41 × fICLK + 253 (unit : mA, fCPUCLK and fICLK are MHz)

Note 4. Do not actual consumption current during operation exceed the current value described here in VCC_DCDC < 2.5 V.

Note 5. Typical DCDC efficiency is applied.

Table 55.9 Current of high-speed mode, maximum condition (MVE and peripheral operation) (External VDD mode)

Parameter	CPUCLK Frequency	Symbol	Typ	Max		Unit	Test conditions

Note 1. Supply current values are with all output pins unloaded and all input pull-up MOSs in the off state.

Note 2. Supply of the clock signal to peripherals is stopped in this state. This does not include the BGO operation.

Note 3. I_{DD} depends on f (CPUCLK and ICLK) as follows.

I_{DD} Max. (105 °C) = 0.68 × fCPUCLK + 0.17 × fCLK + 175 (unit : mA, fCPUCLK and fCLK are MHz)

I_{DD} Max. (125 °C) = 0.68 × fCPUCLK + 0.17 × fCLK + 253 (unit : mA, fCPUCLK and fCLK are MHz)

Note 4. Typical DCDC efficiency is applied.

Note 5. Same frequency condition is applied as in the maximum condition.

Table 55.13 Current of high-speed mode, maximum data processing (MVE operation), peripheral clock OFF (External VDD mode)

Parameter		Symbol	Typ	Max		Unit	Test conditions
				105 °C	125 °C		
Supply current ^{*1*2}	CPUCLK = 480 MHz	I _{DD} ^{*3}	342	536	—	mA	^{*4}
	CPUCLK = 400 MHz	I _{DD} ^{*3}	289	478	560		
	CPUCLK = 360 MHz	I _{DD} ^{*3}	261	445	528		
	CPUCLK = 240 MHz	I _{DD} ^{*3}	194	373	457		

Note 1. Supply current values are with all output pins unloaded and all input pull-up MOSs in the off state.

Note 2. Supply of the clock signal to peripherals is stopped in this state. This does not include the BGO operation.

Note 3. I_{DD} depends on f (CPUCLK and ICLK) as follows.

$I_{DD} \text{ Max. (105 °C)} = 0.68 \times f_{CPUCLK} + 0.17 \times f_{ICLK} + 175$ (unit : mA, fCPUCLK and fICLK are MHz)

$I_{DD} \text{ Max. (125 °C)} = 0.68 \times f_{CPUCLK} + 0.17 \times f_{ICLK} + 253$ (unit : mA, fCPUCLK and fICLK are MHz)

Note 4. Same frequency condition is applied as in the maximum condition.

Table 55.14 Current of high-speed mode, CPU Sleep mode (DCDC mode and External VDD mode)

Parameter		Symbol	Typ	Max		Unit	Test conditions
				105 °C	125 °C		
Supply current*1*3*4	CPUCLK = 240 MHz	I_{DD}^{*2}	29	216	310	mA	—

Note 1. Supply current values are with all output pins unloaded and all input pull-up MOSs in the off state.

Note 2. I_{DD} depends on f (CPUCLK and ICLK) as follows.

$I_{DD} \text{ Typ. (25 °C)} = 0.063 \times f_{CPUCLK} + 0.13 \times f_{ICLK} + 17.6$ (unit : mA, fCPUCLK and fICLK are MHz)

$I_{DD} \text{ Max. (105 °C)} = 0.063 \times f_{CPUCLK} + 0.13 \times f_{ICLK} + 175$ (unit : mA, fCPUCLK and fICLK are MHz)

$I_{DD} \text{ Max. (125 °C)} = 0.063 \times f_{CPUCLK} + 0.13 \times f_{ICLK} + 253$ (unit : mA, fCPUCLK and fICLK are MHz)

Note 3. Supply of the clock signal to peripherals is stopped in this state. This does not include the BGO operation.

Note 4. ICLK, FCLK, BCLK, PCLKA, PCLKB, PCLKC, PCLKD and PCLKE are set to divided by 64.

Table 55.15 Current of high-speed mode, CPU Deep Sleep mode (DCDC mode and External VDD mode)

Parameter		Symbol	Typ	Max		Unit	Test conditions
				105 °C	125 °C		
Supply current*1*3*4	CPUCLK = 240 MHz	I_{DD}^{*2}	12	85	112	mA	—

Note 1. Supply current values are with all output pins unloaded and all input pull-up MOSs in the off state.

Note 2. I_{DD} depends on f (ICLK) as follows.

$I_{DD} \text{ Typ. (25 °C)} = 0.13 \times f_{ICLK} + 5$ (unit : mA, fCPUCLK and fICLK are MHz)

$I_{DD} \text{ Max. (105 °C)} = 0.13 \times f_{ICLK} + 69$ (unit : mA, fCPUCLK and fICLK are MHz)

$I_{DD} \text{ Max. (125 °C)} = 0.13 \times f_{ICLK} + 97$ (unit : mA, fCPUCLK and fICLK are MHz)

Note 3. Supply of the clock signal to peripherals is stopped in this state. This does not include the BGO operation.

Note 4. ICLK, FCLK, BCLK, PCLKA, PCLKB, PCLKC, PCLKD and PCLKE are set to divided by 64.

Table 55.16 Increase during BGO operation (DCDC mode and External VDD mode)

Parameter		Symbol	Typ	Max		Unit	Test conditions
				105 °C	125 °C		
Supply current*1	Data flash P/E	I_{CC}	6	—	—	mA	—
	Code flash P/E		8	—	—		

Note 1. Supply current values are with all output pins unloaded and all input pull-up MOSs in the off state.

Table 55.17 Current of Low-speed mode (DCDC mode)

Parameter	Symbol	Typ	Max		Unit	Test conditions
			105 °C	125 °C		
Supply current*1*2*3	I_{DD}	14.5	—	—	mA	CPUCLK = ICLK = 1 MHz

Note 1. Supply current values are with all output pins unloaded and all input pull-up MOSs in the off state.

Note 2. Supply of the clock signal to peripherals is stopped in this state. This does not include the BGO operation.

Note 3. FCLK, BCLK, PCLKA, PCLKB, PCLKC, PCLKD and PCLKE are set to divided by 64 (15.6 kHz).

Table 55.18 Standby current (DCDC mode)

Parameter				Symbol	Typ	Max 125 °C	Unit	Test conditions	
Supply current*1	Software Standby mode*2			I _{CC}	0.02	0.94	mA	—	
				Data of SRAM and TCM is retained	I _{CC_DCDC}	0.88		28.29	VCC_DCDC = 3.3 V PDRAMSCR0.RKEEPn = 1 (n = 0 to 6) PDRAMSCR1.RKEEP0 = 1
				Data of SRAM and TCM is not retained	I _{CC_DCDC}	0.83		26.64	VCC_DCDC = 3.3 V PDRAMSCR0.RKEEPn = 0 (n = 0 to 6) PDRAMSCR1.RKEEP0 = 0
	Deep Software Standby mode 1			I _{CC}	5.21	148	μA	—	
				I _{CC_DCDC}	0.57	5.50		—	
	Increase when the function is activated	Data of Standby SRAM is retained	I _{CC}	0.12	2.60	—			
		PVD0, PVD1,PVD2 or Battery power supply switch		See Table 55.20		—			
		When the LOCO is in use		3.10	—	—

		Standby mode (direct power down)	USBHS	I _{CC} USBSBY	0.5	3.00	μA	VCC_USBHS = AVCC_USBHS

Note 1. Supply current values are with all output pins unloaded and all input pull-up MOSs in the off state.

Note 2. When the MCU is in Software Standby mode or the MSTPCRD.MSTPD16 (12-Bit A/D Converter 0 Module Stop bit) and MSTPCRD.MSTPD15 (12-bit A/D converter 1 module stop bit) are in the module-stop state.

Figure 55.3 Temperature dependency in Software Standby mode (I_{CC}) (reference data)

Figure 55.4 Temperature dependency in Software Standby mode (I_{CC_DcDc}) (reference data)

Figure 55.5 Temperature dependency in Deep Software Standby mode 1 (reference data)

Figure 55.6 Temperature dependency in Deep Software Standby mode 2 (reference data)

Figure 55.7 Temperature dependency in Deep Software Standby mode 3 (reference data)

Figure 55.8 Software Standby current per SRAM state (reference data)

The more practical I_{CC_DCDC} value can be obtained with the following formula.

$$I_{CC_DCDC} = I_{DD} \times (V_{CL} \div V_{CC}) \div \text{efficiency}$$

Where: VCL and VCC are the voltage of VCL pin and VCC pin respectively, and efficiency is shown in the following figures.

Figure 55.9 Typical DCDC efficiency (%) vs load current (A) in High-speed mode, Tj = 25 °C

Figure 55.10 Typical DCDC efficiency (%) vs load current (A) in High-speed mode, Tj = 125 °C

Figure 55.11 Typical DCDC efficiency (%) vs load current (A) in Low-speed mode and Software Standby mode, $T_j = 25\text{ °C}$

Figure 55.12 Typical DCDC efficiency (%) vs load current (A) in Low-speed mode and Software Standby mode, $T_j = 125\text{ °C}$

Note: DCDC efficiency is obtained based on the VCC_DCDC current.

55.2.6 VCC Rise and Fall Gradient and Ripple Frequency

Table 55.24 VCC rise and fall gradient characteristics at power on/off

Parameter		Symbol	Min	Typ	Max	Unit	Test conditions
VCC rising gradient at power on ^{*1}		SrVCC	0.0084	—	20	ms/V	—
VCC falling gradient at power off	VBATT function is disabled ^{*1}	SfVCC1	0.0084	—	—	ms/V	—
	VBATT function is enabled	SfVCC2	1.0000	—	—	—	—

Note 1. In case the VCC voltage crosses V_{POR1} .

Table 55.25 VCC ripple frequency and gradient characteristics during operation

The ripple voltage must meet the allowable ripple frequency $f_r(VCC)$ within the range between the VCC upper limit (3.6 V) and lower limit (1.68 V). When the VCC change exceeds $VCC \pm 10\%$, the allowable voltage change rising and falling gradient $dt/dVCC$ must be met.

Parameter	Symbol	Min	Typ	Max	Unit	Test conditions
Allowable ripple frequency	$f_r(VCC)$	—	—	10.0	kHz	Figure 55.13 $V_r(VCC) \leq VCC \times 0.2$
		—	—	1.0	MHz	Figure 55.13 $V_r(VCC) \leq VCC \times 0.08$
		—	—	10.0	MHz	Figure 55.13 $V_r(VCC) \leq VCC \times 0.06$
Allowable voltage change rising and falling gradient	$dt/dVCC^{*1}$	1.0	—	—	ms/V	When VCC change exceeds $VCC \pm 10\%$

Note 1. In case the VCC voltage does not cross V_{POR1} .

Figure 55.13 Ripple waveform

Figure 55.14 VCC rising and falling waveform

55.2.7 Thermal Characteristics

Maximum value of junction temperature (T_j) must not exceed the value of [section 55.2.1. \$T_j/T_a\$ Definition.](#)

T_j is calculated by either of the following equations.

- $T_j = T_a + \theta_{ja} \times \text{Total power consumption}$
- $T_j = T_t + \Psi_{jt} \times \text{Total power consumption}$
 - T_j : Junction Temperature ($^{\circ}\text{C}$)
 - T_a : Ambient Temperature ($^{\circ}\text{C}$)
 - T_t : Top Center Case Temperature ($^{\circ}\text{C}$)
 - θ_{ja} : Thermal Resistance of “Junction”-to-“Ambient” ($^{\circ}\text{C}/\text{W}$)
 - Ψ_{jt} : Thermal Resistance of “Junction”-to-“Top Center Case” ($^{\circ}\text{C}/\text{W}$)
- Total power consumption = Voltage $\times$ (Leakage current + Dynamic current)
- Leakage current of IO = $\Sigma (I_{OL} \times V_{OL}) / \text{Voltage} + \Sigma (|I_{OH}| \times |V_{CC} - V_{OH}|) / \text{Voltage}$
- Dynamic current of IO = $\Sigma \text{IO} (C_{in} + C_{load}) \times \text{IO switching frequency} \times \text{Voltage}$
 - C_{in} : Input capacitance
 - C_{load} : Output capacitance

Regarding θ_{ja} and Ψ_{jt} , see [Table 55.26](#).

Table 55.26 Thermal Resistance

Parameter	Package	Symbol	Value*1	Unit	Test conditions
Thermal Resistance	100-pin LQFP (PLQP0100KP-A)	θ_{ja}	32.9	°C/W	JESD 51-2 and 51-7 compliant
	144-pin LQFP (PLQP0144KA-B)		31.7		
	176-pin LQFP (PLQP0176KJ-A)		32.0		
	169-pin BGA (PLBG0169KD-A)		20.5		JESD 51-2 and 51-9 compliant
	224-pin BGA (PLBG0224GD-A)		21.5		
	100-pin LQFP (PLQP0100KP-A)	Ψ_{jt}	0.42	°C/W	JESD 51-2 and 51-7 compliant
	144-pin LQFP (PLQP0144KA-B)		0.40		
	176-pin LQFP (PLQP0176KJ-A)		0.42		
	169-pin BGA (PLBG0169KD-A)		0.23		JESD 51-2 and 51-9 compliant
	224-pin BGA (PLBG0224GD-A)		0.24		

Note 1. The values are reference values when the 4-layer board is used. Thermal resistance depends on the number of layers or size of the board. For details, see the JEDEC standards.

55.2.7.1 Calculation guide of maximum current

Table 55.27 Power consumption of each unit (1 of 2)

Dynamic current/ Leakage current	MCU Domain	Category	Item	Symbol	Frequency [MHz]	Current [uA/MHz]	Current*1 [mA]	Condition

							120	—	72.9	—	

Note 1. Regulator and Leak are Internal voltage regulator's current and MCU's leakage current.

It is selected according to the temperature of T_j.

Note 2. To determine the current consumption per channel or unit, divide Current [mA] by the number of channels, groups or units.

Table 55.28 Outline of operation for each unit

Peripheral	Outline of operation
RTC	RTC is operating with LOCO.
GPT	Operating modes is set to saw-wave PWM mode.
POEG	Only clear module stop bit.
AGT	AGT is operating with PCLKB.
ULPT	ULPT is operating with LOCO.
WDT	WDT is operating with PCLKB.
IWDT	IWDT is operating with IWDTCLK.
ETHERC	Operation modes is set to full-duplex mode. ETHERC is operating using Reduced Media Independent Interface (RMII).
USBFS	Transfer types is set to bulk transfer. USBFS is operating using Full-speed transfer (12 Mbps).
USBHS	Transfer types is set to bulk transfer. USBHS is operating using High-speed transfer.
SCI	SCI is transmitting data in clock synchronous mode.
IIC	Communication format is set to I2C-bus format. IIC is transmitting data in master mode.
I3C	Communication format is set to I3C SDR format. I3C is transmitting data in master mode (12.5MHz).
CANFD	CANFD is transmitting and receiving data in self-test mode 1.
SPI	SPI mode is set to SPI operation (4-wire method). SPI master/slave mode is set to master mode. SPI is transmitting 32-bit width data.
OSPI	OSPI is issuing memory write command to HyperRAM.
SSIE	Communication mode is set to Master. System word length is set to 32 bits. Data word length is set to 20 bits. SSIE is transmitting data using I2S format.
SDHI	Transfer bus mode is set to 8-bit wide bus mode. SDHI is issuing CMD24 (single-block write).
ADC	Resolution is set to 12-bit accuracy. Data registers is set to A/D-converted value addition mode. ADC12 is converting the analog input in continuous scan mode.
DAC12	DAC12 is outputting the conversion result while updating the value of data register.
TSN	TSN is operating.
ACMPHS	ACMPHS is operating.
CEU	CEU is capturing data and transferring to the SRAM.
ELC	Only clear module stop bit.
RSIP-E51A	RSIP is doing self-test operation.
DOTF	DOTF is doing decryption with AES.
CRC	CRC is generating CRC code using 32-bit CRC32-C polynomial.
DOC	DOC is operating in data comparison mode.
CAC	Measurement target clocks is set to PCLKB. Measurement reference clocks is set to PCLKB. CAC is measuring the clock frequency accuracy.
DMAC	Bit length of transfer data is set to 32 bits. Transfer mode is set to block transfer mode. DMAC is transferring data from SRAM0 to SRAM0.
DTC	Bit length of transfer data is set to 32 bits. Transfer mode is set to block transfer mode. DTC is transferring data from SRAM0 to SRAM0.

55.2.7.2 Example of Tj calculation

Assumption :

- Package 224-pin BGA : $\theta_{ja} = 21.5 \text{ }^{\circ}\text{C/W}$
- $T_a = 80 \text{ }^{\circ}\text{C}$
- $I_{CC} + I_{CC_DCDC} = 240 \text{ mA}$

- $V_{CC} = 3.5 \text{ V}$ ($V_{CC} = V_{CC2} = AV_{CC0} = AV_{CC_USBHS} = V_{CC_USB} = V_{CC_USBHS}$)
- $I_{OH} = 1 \text{ mA}$, $V_{OH} = V_{CC} - 0.5 \text{ V}$, 12 Outputs
- $I_{OL} = 20 \text{ mA}$, $V_{OL} = 1.0 \text{ V}$, 8 Outputs
- $I_{OL} = 1 \text{ mA}$, $V_{OL} = 0.5 \text{ V}$, 12 Outputs
- $C_{in} = 8 \text{ pF}$, 32 pins, Input frequency = 10 MHz
- $C_{load} = 30 \text{ pF}$, 32 pins, Output frequency = 10 MHz

Static current of IO = $\Sigma (V_{OL} \times I_{OL}) / \text{Voltage} + \Sigma ((V_{CC} - V_{OH}) \times I_{OH}) / \text{Voltage}$

$$= (20 \text{ mA} \times 1 \text{ V}) \times 8 / 3.5 \text{ V} + (1 \text{ mA} \times 0.5 \text{ V}) \times 12 / 3.5 \text{ V} + ((V_{CC} - (V_{CC} - 0.5 \text{ V})) \times 1 \text{ mA}) \times 12 / 3.5 \text{ V}$$

$$= 45.7 \text{ mA} + 1.71 \text{ mA} + 1.71 \text{ mA}$$

$$= 49.1 \text{ mA}$$

Dynamic current of IO = $\Sigma IO (C_{in} + C_{load}) \times \text{IO switching frequency} \times \text{Voltage}$

$$= ((8 \text{ pF} \times 32) \times 10 \text{ MHz} + (30 \text{ pF} \times 32) \times 10 \text{ MHz}) \times 3.5 \text{ V}$$

$$= 42.6 \text{ mA}$$

Total power consumption = $\text{Voltage} \times (\text{Static current} + \text{Dynamic current})$

$$= (240 \text{ mA} \times 3.5 \text{ V}) + (49.1 \text{ mA} + 42.6 \text{ mA}) \times 3.5 \text{ V}$$

$$= 1161 \text{ mW (1.161 W)}$$

$T_j = T_a + \theta_{ja} \times \text{Total power consumption}$

$$= 80 \text{ }^\circ\text{C} + 21.5 \text{ }^\circ\text{C/W} \times 1.161 \text{ W}$$

$$= 105.0 \text{ }^\circ\text{C}$$

55.3 AC Characteristics

55.3.1 Frequency

Table 55.29 Operation frequency value in high-speed mode (1 of 2)

Parameter			Symbol	Min	Typ	Max	Unit
Operation frequency	CPU clock (CPUCLK)* ²	DCDC, 224-pin BGA package, T _j ≤ 105°C* ⁴	f	—	—	480	MHz

		External VDD, 176-pin and 144-pin LQFP package, T _j ≤ 125°C		—	—	400	
		DCDC, 100-pin LQFP package, T _j ≤ 105°C* ⁴		—	—	360	
		DCDC, 100-pin LQFP package, T _j ≤ 125°C* ⁴		—	—	240	
		External VDD, 100-pin LQFP package, T _j ≤ 105°C		—	—	360	
		External VDD, 100-pin LQFP package, T _j ≤ 125°C		—	—	240	
		System clock (ICLK)* ²		—	—	240	
	Peripheral module clock (PCLKA)* ²			—	—	120	
	Peripheral module clock (PCLKB)* ²			—	—	60	
	Peripheral module clock (PCLKC)* ²			—* ³	—	60	
	Peripheral module clock (PCLKD)* ²			—	—	120	
	Peripheral module clock (PCLKE)* ²			—	—	240	
	Flash interface clock (FCLK)* ²			—* ¹	—	60	
	External bus clock (BCLK)* ²	VCC ≥ 2.7 V		—	—	120	
		VCC ≥ 1.68 V		—	—	60	
	EBCLK pin output	VCC ≥ 2.7 V		—	—	60	
		VCC ≥ 1.68 V		—	—	30	
	SDCLK pin output	VCC ≥ 3.0 V		—	—	120	

Table 55.29 Operation frequency value in high-speed mode (2 of 2)

Parameter	Symbol	Min	Typ	Max	Unit
Operation frequency	SCI clock (SCICLK)	f	—	120	MHz
	SPI clock (SPICLK)	—	—	120	
	Octal SPI clock (OCTACLK)	—	—	200	
	CANFD core clock (CANFDCLK)	—	—	80	
	USB clock (USBCLK)	—	—	48	
	USB clock (USB60CLK)	—	—	60	
	I3C clock (I3CCLK)	—	—	200	

Note 1. FCLK must run at a frequency of at least 4 MHz when programming or erasing the flash memory.

Note 2. See [section 8, Clock Generation Circuit](#) for the relationship between the CPUCLK, ICLK, PCLKA, PCLKB, PCLKC, PCLKD, PCLKE, FCLK, and BCLK frequencies.

Note 3. When the ADC12 is used, the PCLKC frequency must be at least 1 MHz.

Note 4. When DCDC is used with VCC_DCDC < 2.5V, I_{DD} current must be less than the value specified in operating current.

Please see [Table 55.8](#).

Table 55.30 Operation frequency value in low-speed mode

Parameter			Symbol	Min	Typ	Max	Unit
Operation frequency	CPU clock (CPUCLK)* ²		f	—	—	1	MHz
	System clock (ICLK)* ²			—	—	1	
	Peripheral module clock (PCLKA)* ²			—	—	1	
	Peripheral module clock (PCLKB)* ²			—	—	1	
	Peripheral module clock (PCLKC)* ²			—* ³	—	1	
	Peripheral module clock (PCLKD)* ²			—	—	1	
	Peripheral module clock (PCLKE)* ²			—	—	1	
	Flash interface clock (FCLK) * ²			—* ¹	—	1	
	External bus clock (BCLK)* ²			—	—	1	
	EBCLK pin output			—	—	1	
	SDCLK pin output	VCC ≥ 3.0 V		—	—	1	
	SCI clock (SCICLK)			—	—	1	
	SPI clock (SPICLK)			—	—	1	
	Octal SPI clock (OCTACLK)			—	—	1	
	CANFD core clock (CANFDCLK)			—	—	1	
	USB clock (USBCLK)			—	—	1	
	USB clock (USB60CLK)			—	—	1	
	I3C clock (I3CCLK)			—	—	1	

Note 1. Programming or erasing the flash memory is disabled in low-speed mode.

Note 2. See [section 8, Clock Generation Circuit](#) for the relationship between the CPUCLK, ICLK, PCLKA, PCLKB, PCLKC, PCLKD, PCLKE, FCLK, and BCLK frequencies.

Note 3. When the ADC12 is used, the PCLKC frequency must be at least 1 MHz.

55.3.2 Clock Timing

Table 55.31 Clock timing except for sub-clock oscillator (1 of 2)

Parameter		Symbol	Min	Typ	Max	Unit	Test conditions
EBCLK pin output cycle time	VCC = 2.70 V or above	t _{Bcyc}	16.6	—	—	ns	Figure 55.15
	VCC = 1.68 V or above		33.3	—	—		
EBCLK pin output high pulse width	VCC = 2.70 V or above	t _{CH}	3.3	—	—	ns	
	VCC = 1.68 V or above		9.6	—	—		
EBCLK pin output low pulse width	VCC = 2.70 V or above	t _{CL}	3.3	—	—	ns	
	VCC = 1.68 V or above		9.6	—	—		
EBCLK pin output rise time	VCC = 2.70 V or above	t _{Cr}	—	—	5.0	ns	
	VCC = 1.68 V or above		—	—	7.0		
EBCLK pin output fall time	VCC = 2.70 V or above	t _{Cf}	—	—	5.0	ns	
	VCC = 1.68 V or above		—	—	7.0		
SDCLK pin output cycle time		t _{SDcyc}	8.33	—	—	ns

		f_{HOCO32}	31.42	32.00	32.58		
		f_{HOCO48}	47.14	48.00	48.86		
	With FLL	f_{HOCO16}	15.960	16.000	16.040		$-40 \leq T_j \leq 125\text{ }^{\circ}\text{C}$ Sub-clock frequency accuracy is ± 50 ppm.
		f_{HOCO18}	17.955	18.000	18.045		
		f_{HOCO20}	19.950	20.000	20.050		
		f_{HOCO32}	31.920	32.000	32.080		
		f_{HOCO48}	47.880	48.000	48.120		
HOCO clock oscillation stabilization wait time ^{*2}		t_{HOCOWT}	—	—	64.7	μs	—
HOCO stop width time		$t_{HOCOSTP}$	1	—	—	μs	Figure 55.21
HOCO period jitter		Jitter	-3	—	3	%	—
FLL stabilization wait time		t_{FLLWT}	—	—	1.8	ms	—
PLL1/PLL2 VCO frequency		f_{VCO}	640	—	1440.0	MHz	—
PLL1/PLL2 Output frequency for output clock P		t_{PLL}	40	—	480	MHz	—
PLL1/PLL2 Output frequency for output clock Q, R		t_{PLL}	71	—	480	MHz	—
PLL1/PLL2 clock oscillation stabilization wait time		t_{PLLWT}	—	—	40	μs	Figure 55.19
PLL1/PLL2 period jitter		—	—	± 70	—	ps	—
PLL1/PLL2 long term jitter		—	—	± 300	—	ps	Term: 1 μs , 10 μs

Note 1. When setting up the main clock oscillator, ask the oscillator manufacturer for an oscillation evaluation, and use the results as the recommended oscillation stabilization time. Set the MOSCWTCR register to a value equal to or greater than the recommended value.

After changing the setting in the MOSCCR.MOSTP bit to start main clock operation, read the OSCSF.MOSCSF flag to confirm that it is 1, and then start using the main clock oscillator.

Note 2. This is the time from release from reset state until the HOCO oscillation frequency (f_{HOCO}) reaches the range for guaranteed operation.

Table 55.32 Clock timing for the sub-clock oscillator

Parameter	Symbol	Min	Typ	Max	Unit	Test conditions
Sub-clock frequency	f_{SUB}	—	32.768	—	kHz	—
Sub-clock oscillation stabilization wait time	$t_{SUBOSCWT}$	—	—	— ^{*1}	s	Figure 55.20

Note 1. When setting up the sub-clock oscillator, ask the oscillator manufacturer for an oscillation evaluation and use the results as the recommended oscillation stabilization time.

After changing the setting in the SOSCCR.SOSTP bit to start sub-clock operation, only start using the sub-clock oscillator after the sub-clock oscillation stabilization time elapses with an adequate margin. A value that is two times the value shown is recommended.

Table 55.34 Timing of recovery from low power modes (2 of 2)

Parameter			Fast return function* ⁹	Symbol	Min	Typ	Max	Unit	Test conditions
Recovery time from Deep Software Standby mode	Deep Software Standby mode 1	Any of PVD0(OFS1(_SEC).PV DLPSEL=1), PVD1, PVD2, or Battery power supply switch is enabled	Standard	t _{DSBY}	—	0.68	1.20	ms	Figure 55.25
			Fast		—	0.29	0.62	ms	
		All of PVD0(OFS1(_SEC).PV DLPSEL=1), PVD1, PVD2, and Battery power supply switch are disabled	Standard			0.73	1.30		
			Fast			0.33	0.71		
	Deep Software Standby mode 2	DPSWCR.WSTS = 0x0B	Standard		—	0.73	1.10	ms	
			Fast		—	0.33	0.50	ms	
		DPSWCR.WSTS = 0x9A	Standard		—	1.60	2.00	ms	
			Fast		—	1.20	1.50	ms	
	Deep Software Standby mode 3			Standard	—	2.10	3.50	ms	
				Fast	—	1.70	2.90	ms	
Wait time after cancellation of Deep Software Standby mode			—	t _{DSBYWT}	47.7	—	64.6	μs	

Note 1. When the frequency of the crystal is 48 MHz (Main Clock Oscillator Wait Control Register (MOSCWTCR) is set to 0x05) and the greatest value of the internal clock division setting is 1.

Note 2. When the frequency of PLL1P is 480 MHz (Main Clock Oscillator Wait Control Register (MOSCWTCR) is set to 0x05) and the greatest value of the internal clock division setting is 8.

Note 3. When the frequency of the external clock is 48 MHz (Main Clock Oscillator Wait Control Register (MOSCWTCR) is set to 0x00) and the greatest value of the internal clock division setting is 1.

Note 4. When the frequency of PLL1P is 480 MHz (Main Clock Oscillator Wait Control Register (MOSCWTCR) is set to 0x00) and the greatest value of the internal clock division setting is 8.

Note 5. The Sub-clock oscillator frequency is 32.768 kHz and the greatest value of the internal clock division setting is 1.

Note 6. The HOCO frequency is 20 MHz and the greatest value of the internal clock division setting is 1.

Note 7. The PLL frequency is 480 MHz and the greatest value of the internal clock division setting is 8.

Note 8. The MOCO frequency is 8 MHz and the greatest value of the internal clock division setting is 1.

Note 9. For details, see SSCR1.SS1FR, DPSBYCR.DCSSMODE bits in the [section 10, Low Power Modes](#).

Note 10. The recovery time can be calculated with the equation of $t_{Common} + \max(t_{OSCSTB}, t_{PG1}, t_{PGCK}) + \max(t_{PG2}, t_{LPW})$. And they can be determined with the following values and equations. For n, the greatest value is selected from among the internal clock(CPUCLK, ICLK, PCLKm, FCLK, BCLK and EBCLK) division settings (m = A to E).
 t_{OSCSTB} in the table below means the time when each oscillator is active. When multiple oscillators are active, t_{OSCSTB} is determined by the longest t_{OSCSTB} among the active oscillators.

Note 11. The ICLK frequency is 240 MHz. This recovery time corresponds to t_{PG2} .

Table 55.35 Each element of recovery time

Wakeu p time	Oscillat ion keep	Fast return function	Typ							Max					Unit
			t _{Commo n}	t _{OSCSTB *1}	t _{PG1}	t _{PGCK}	t _{PG2}	t _{LPW}	t _{Commo n}	t _{OSCSTB *1}	t _{PG1}	t _{PGCK}	t _{PG2}	t _{LPW}	
t _{SBYMC}	MOSC disabled	Enabled	52.667 + 4/ f _{ICLK}	t _{MAINOSC WT}	75.5	2.1 + 10.5/ f _{MOCO} + 10/ f _{ICLK} 2.5n/ f _{MOCO} + 2.5/ f _{SRC CLK} + 2/ f _{ICLK}	1449/ f _{MOCO} + 10/ f _{ICLK}	10 + 2/ f _{ICLK} + 2n/ f _{MAIN}	82.369 + 4/ f _{ICLK}	t _{MAINOSC WT} + 11/0.236	88.8	2.5 + 10.5/ f _{MOCO} + 2.5n/ f _{MOCO} + 2.5/ f _{SRC CLK} + 2/ f _{ICLK}	1449/ f _{MOCO} + 10/ f _{ICLK}	10 + 2/ f _{ICLK} + 2n/ f _{MAIN}	μs

55.3.6 Bus Timing

Table 55.37 Bus timing (1 of 2)

Condition 1: When using the CS area controller (CSC).

VCC = VCC_DCDC = VCC_USB = VBATT = 1.68 V to 3.6 V, VCC2 = 1.65 V to 3.6 V

BCLK = 8 to 120 MHz, EBCLK = 8 to 60 MHz (When VCC = VCC_USB = VBATT = 2.70 to 3.6 V)

BCLK = 8 to 60 MHz, EBCLK = 8 to 30 MHz (When VCC = VCC_USB = VBATT = 1.68 to 3.6 V)

Output load conditions: VOH = VCC × 0.5, VOL = VCC × 0.5, C = 30 pF

EBCLK: High drive output is selected in the port drive capability bit in the PmnPFS register.

Others: Middle drive output is selected in the port drive capability bit in the PmnPFS register.

Condition 2: When using the SDRAM area controller (SDRAMC).

BCLK = SDCLK = 8 to 120 MHz

VCC = VCC2 = VCC_DCDC = VCC_USB = VBATT = 3.0 to 3.6 V

Output load conditions: VOH = VCC × 0.5, VOL = VCC × 0.5, C = 15 pF

SDCLK: High-speed high drive output is selected in the port drive capability bit in the PmnPFS register.

Others: High drive output is selected in the port drive capability bit in the PmnPFS register.

Condition 3: When using the SDRAM area controller (SDRAMC) and CS area controller (CSC) simultaneously.

BCLK = SDCLK = 8 to 60 MHz

VCC = VCC2 = VCC_DCDC = VCC_USB = VBATT = 3.0 to 3.6 V

Output load conditions: VOH = VCC × 0.5, VOL = VCC × 0.5, C = 15 pF

EBCLK/SDCLK: High drive output is selected in the port drive capability bit in the PmnPFS register.

Others: Middle drive output is selected in the port drive capability bit in the PmnPFS register.

Parameter		Symbol	Min	Max	Unit	Test conditions
Address delay	2.70V or above	t_{AD}	1.0	12.5	ns	Figure 55.28 to Figure 55.34

55.3.12 IIC Timing

Table 55.46 IIC timing (1) (1 of 2)

(1) Conditions: Middle drive output is selected when VCC is 2.70 V or above, High drive output is selected when VCC is 1.68 to 1.95 V in the port drive capability bit in the PmnPFS register for the following pins: SDA0_B, SCL0_B, SDA1_B, SCL1_B

(2) The following pins do not require setting: SCL0_A, SDA0_A, SCL1_A, SDA1_A

(3) Use pins that have a letter appended to their names, for instance “_A” or “_B”, to indicate group membership.
For the IIC interface, the AC portion of the electrical characteristics is measured for each group.

Parameter		Symbol	VCC	Min	Max	Unit	Test conditions
IIC (Standard mode, SMBus) ICFER.FMPE = 0 when VCC is 2.70 V or above, ICFER.FMPE = 1 when VCC is 1.68 to 1.95 V	SCL input cycle time	t _{SCL}	2.70 V or above	6 (12) × t _{IICcyc} + 1300	—	ns	Figure 55.71
			1.68 to 1.95 V				
	SCL input high pulse width	t _{SCLH}	2.70 V or above	3 (6) × t _{IICcyc} + 300	—	ns	
			1.68 to 1.95 V				
	SCL input low pulse width	t _{SCLL}	2.70 V or above	3 (6) × t _{IICcyc} + 300	—	ns	
			1.68 to 1.95 V				
	SCL, SDA rise time	t _{Sr}	2.70 V or above	—	1000	ns	
			1.68 to 1.95 V				
	SCL, SDA fall time	t _{Sf}	2.70 V or above	—	300	ns	
			1.68 to 1.95 V				
	SCL, SDA input spike pulse removal time	t _{SP}	2.70 V or above	0	1 (4) × t _{IICcyc}	ns	
			1.68 to 1.95 V				
	SDA input bus free time when wakeup function is disabled	t _{BUF}	2.70 V or above	3 (6) × t _{IICcyc} + 300	—	ns	
			1.68 to 1.95 V				
	SDA input bus free time when wakeup function is enabled	t _{BUF}	2.70 V or above	3 (6) × t _{IICcyc} + 4 × t _{Pcyc} + 300	—	ns	
			1.68 to 1.95 V				
	START condition input hold time when wakeup function is disabled	t _{STAH}	2.70 V or above	t _{IICcyc} + 300	—	ns	
			1.68 to 1.95 V				
	START condition input hold time when wakeup function is enabled	t _{STAH}	2.70 V or above	1 (5) × t _{IICcyc} + t _{Pcyc} + 300	—	ns	
			1.68 to 1.95 V				
Repeated START condition input setup time	t _{STAS}	2.70 V or above	1000	—	ns		
		1.68 to 1.95 V					
STOP condition input setup time	t _{STOS}	2.70 V or above	1000	—	ns		
		1.68 to 1.95 V					
Data input setup time	t _{SDAS}	2.70 V or above	t _{IICcyc} + 50	—	ns		
		1.68 to 1.95 V					
Data input hold time	t _{SDAH}	2.70 V or above	0	—	ns		
		1.68 to 1.95 V					
SCL, SDA capacitive load	C _b	2.70 V or above	—	400	pF		
		1.68 to 1.95 V					

Table 55.46 IIC timing (1) (2 of 2)

(1) Conditions: Middle drive output is selected when VCC is 2.70 V or above, High drive output is selected when VCC is 1.68 to 1.95 V in the port drive capability bit in the PmnPFS register for the following pins: SDA0_B, SCL0_B, SDA1_B, SCL1_B

(2) The following pins do not require setting: SCL0_A, SDA0_A, SCL1_A, SDA1_A

(3) Use pins that have a letter appended to their names, for instance "_A" or "_B", to indicate group membership.

For the IIC interface, the AC portion of the electrical characteristics is measured for each group.

Parameter	Symbol	VCC	Min	Max	Unit	Test conditions
IIC (Fast mode) ICFER.FMPE = 0 when VCC is 2.70 V or above, ICFER.FMPE = 1 when VCC is 1.68 to 1.95 V	SCL input cycle time	t_{SCL}	2.70 V or above 1.68 to 1.95 V	$6 (12) \times t_{IICcyc} + 600$	—	ns
	SCL input high pulse width	t_{SCLH}	2.70 V or above 1.68 to 1.95 V	$3 (6) \times t_{IICcyc} + 300$	—	ns
	SCL input low pulse width	t_{SCLL}	2.70 V or above 1.68 to 1.95 V	$3 (6) \times t_{IICcyc} + 300$	—	ns
	SCL, SDA rise time	t_{Sr}	2.70 V or above 1.68 to 1.95 V	20	300	ns
	SCL, SDA fall time	t_{Sf}	2.70 V or above 1.68 to 1.95 V	$20 \times (\text{external pullup voltage}/5.5 \text{ V})^{*1}$	300	ns
	SCL, SDA input spike pulse removal time	t_{SP}	2.70 V or above 1.68 to 1.95 V	0	$1 (4) \times t_{IICcyc}$	ns
	SDA input bus free time when wakeup function is disabled	t_{BUF}	2.70 V or above 1.68 to 1.95 V	$3 (6) \times t_{IICcyc} + 300$	—	ns
	SDA input bus free time when wakeup function is enabled	t_{BUF}	2.70 V or above 1.68 to 1.95 V	$3 (6) \times t_{IICcyc} + 4 \times t_{Pcyc} + 300$	—	ns
	START condition input hold time when wakeup function is disabled	t_{STAH}	2.70 V or above 1.68 to 1.95 V	$t_{IICcyc} + 300$	—	ns
	START condition input hold time when wakeup function is enabled	t_{STAH}	2.70 V or above 1.68 to 1.95 V	$1 (5) \times t_{IICcyc} + t_{Pcyc} + 300$	—	ns
	Repeated START condition input setup time	t_{STAS}	2.70 V or above 1.68 to 1.95 V	300	—	ns
	STOP condition input setup time	t_{STOS}	2.70 V or above 1.68 to 1.95 V	300	—	ns
	Data input setup time	t_{SDAS}	2.70 V or above 1.68 to 1.95 V	$t_{IICcyc} + 50$	—	ns
	Data input hold time	t_{SDAH}	2.70 V or above 1.68 to 1.95 V	0	—	ns
	SCL, SDA capacitive load	C_b	2.70 V or above 1.68 to 1.95 V	—	400	pF

Note: t_{IICcyc} : IIC internal reference clock (IIC ϕ) cycle, t_{Pcyc} : PCLKB cycle.

Note: Values in parentheses apply when ICMR3.NF[1:0] is set to 11b while the digital filter is enabled with ICFER.NFE set to 1.

Note: Must use pins that have a letter appended to their name, for instance "_A", "_B", to indicate group membership. For the IIC interface, the AC portion of the electrical characteristics is measured for each group.

Note 1. Only supported for SCL0_A, SDA0_A, SCL1_A, and SDA1_A.

Table 55.47 IIC timing (2)

Setting of the SCL0_A, SDA0_A, SCL1_A, SDA1_A pins are not required with the port drive capability bit in the PmnPFS register.

Parameter		Symbol	VCC	Min	Max	Unit	Test conditions
IIC (Fast-mode+) ICFER.FMPE = 1	SCL input cycle time	t_{SCL}	2.70 V or above	$6 (12) \times t_{IICcyc} + 240$	—	ns	Figure 55.71
	SCL input high pulse width	t_{SCLH}	2.70 V or above	$3 (6) \times t_{IICcyc} + 120$	—	ns	
	SCL input low pulse width	t_{SCLL}	2.70 V or above	$3 (6) \times t_{IICcyc} + 120$	—	ns	
	SCL, SDA rise time	t_{Sr}	2.70 V or above	—	120	ns	
	SCL, SDA fall time	t_{Sf}	2.70 V or above	$20 \times (\text{external pullup voltage} / 5.5V)$	120	ns	
	SCL, SDA input spike pulse removal time	t_{SP}	2.70 V or above	0	$1 (4) \times t_{IICcyc}$	ns	
	SDA input bus free time when wakeup function is disabled	t_{BUF}	2.70 V or above	$3 (6) \times t_{IICcyc} + 120$	—	ns	
	SDA input bus free time when wakeup function is enabled	t_{BUF}	2.70 V or above	$3 (6) \times t_{IICcyc} + 4 \times t_{Pcyc} + 120$	—	ns	
	Start condition input hold time when wakeup function is disabled	t_{STAH}	2.70 V or above	$t_{IICcyc} + 120$	—	ns	
	START condition input hold time when wakeup function is enabled	t_{STAH}	2.70 V or above	$1 (5) \times t_{IICcyc} + t_{Pcyc} + 120$	—	ns	
	Restart condition input setup time	t_{STAS}	2.70 V or above	120	—	ns	
	Stop condition input setup time	t_{STOS}	2.70 V or above	120	—	ns	
	Data input setup time	t_{SDAS}	2.70 V or above	$t_{IICcyc} + 30$	—	ns	
	Data input hold time	t_{SDAH}	2.70 V or above	0	—	ns	
	SCL, SDA capacitive load	C_b^{*1}	2.70 V or above	—	550	pF	

Note: t_{IICcyc} : IIC internal reference clock (IIC ϕ) cycle, t_{Pcyc} : PCLKB cycle.

Note: Values in parentheses apply when ICMR3.NF[1:0] is set to 11b while the digital filter is enabled with ICFER.NFE set to 1.

Note 1. C_b indicates the total capacity of the bus line.

Figure 55.71 I²C bus interface input/output timing

55.3.13 I3C Timing

Table 55.48 IIC timing(1)-1

Setting of the I3C_SCL0, I3C_SDA0 pins are not required with the Port Drive Capability bit in the PmnPFS register.

Parameter		Symbol	VCC	Min	Max	Unit
IIC (Standard mode, SMBus) BFCTL.FMPE = 0	SCL input cycle time	t_{SCL}	2.70 V or above, 1.68 to 1.95 V	$10 (18) \times t_{I3C_{Cyc}} + 1300$	—	ns
	SCL input high pulse width	t_{SCLH}	2.70 V or above, 1.68 to 1.95 V	$5 (9) \times t_{I3C_{Cyc}} + 300$	—	ns
	SCL input low pulse width	t_{SCLL}	2.70 V or above, 1.68 to 1.95 V	$5 (9) \times t_{I3C_{Cyc}} + 300$	—	ns
	SCL, SDA rise time	t_{Sr}	2.70 V or above, 1.68 to 1.95 V	—	1000	ns
	SCL, SDA fall time	t_{Sf}	2.70 V or above, 1.68 to 1.95 V	—	300	ns
	SCL, SDA input spike pulse removal time	t_{SP}	2.70 V or above, 1.68 to 1.95 V	0	$1 (4) \times t_{I3C_{Cyc}}$	ns
	SDA input bus free time when wakeup function is disabled	t_{BUF}	2.70 V or above, 1.68 to 1.95 V	$5(9) \times t_{I3C_{Cyc}} + 300$	—	ns
	SDA input bus free time when wakeup function is enabled	t_{BUF}	2.70 V or above, 1.68 to 1.95 V	$5(9) \times t_{I3C_{Cyc}} + 4 \times t_{T_{Cyc}} + 300$	—	ns
	START condition input hold time when wakeup function is disabled	t_{STAH}	2.70 V or above, 1.68 to 1.95 V	$t_{I3C_{Cyc}} + 300$	—	ns
	START condition input hold time when wakeup function is enabled	t_{STAH}	2.70 V or above, 1.68 to 1.95 V	$1(5) \times t_{I3C_{Cyc}} + t_{T_{Cyc}} + 300$	—	ns
	Repeated START condition input setup time	t_{STAS}	2.70 V or above, 1.68 to 1.95 V	1000	—	ns
	STOP condition input setup time	t_{STOS}	2.70 V or above, 1.68 to 1.95 V	1000	—	ns
	Data input setup time	t_{SDAS}	2.70 V or above, 1.68 to 1.95 V	$t_{I3C_{Cyc}} + 50$	—	ns
	Data input hold time	t_{SDAH}	2.70 V or above, 1.68 to 1.95 V	0	—	ns
	SCL, SDA capacitive load	C_b^{*1}	2.70 V or above, 1.68 to 1.95 V	—	400	pF

Note: $t_{I3C_{Cyc}}$: I3C internal reference clock (I3C ϕ) cycle, $t_{T_{Cyc}}$: TCLK cycle.

Note: Values in parentheses apply when INCTL.DNFS[3:0] is set to 0011b while the digital filter is enabled with INCTL.DNFE set to 1.

Note 1. C_b indicates the total capacity of the bus line.

Table 55.49 IIC timing(1)-2

Setting of the I3C_SCL0, I3C_SDA0 pins are not required with the Port Drive Capability bit in the PmnPFS register.

Parameter		Symbol	VCC	Min	Max	Unit
IIC (Fast-mode)	SCL input cycle time	t_{SCL}	2.70 V or above, 1.68 to 1.95 V	$10 (18) \times t_{I3CCyc} + 600$	—	ns

	Clock Before STOP (P) Condition	t_{CBP}	3.00 V or above	$t_{\text{CASmin}} / 2$	—	seconds Figure 55.77
			1.68 to 1.95 V	$t_{\text{CASmin}} / 2$	—	
	Current Master to Secondary Master Overlap time during handoff	$t_{\text{MMOverlap}}$	3.00 V or above	$t_{\text{DIG_OD_Lmin}}$	—	ns Figure 55.83
			1.68 to 1.95 V	$t_{\text{DIG_OD_Lmin}}$	—	
	Bus Available Condition	t_{AVAL}^{*7}	3.00 V or above	1	—	μ s —
			1.68 to 1.95 V	1	—	
	Bus Idle Condition	t_{IDLE}	3.00 V or above	1	—	ms —
			1.68 to 1.95 V	1	—	
	Time Internal Where New Master Not Driving SDA Low	t_{MMLock}	3.00 V or above	t_{AVALmin}	—	μ s Figure 55.83
			1.68 to 1.95 V	t_{AVALmin}	—	

Note 1. This is approximately equal to $t_{\text{LOWmin}} + t_{\text{DS_ODmin}} + t_{\text{rDA_ODtyp}} + t_{\text{SU_ODmin}}$.

Note 2. The Master may use a shorter Low period if it knows that this is safe, i.e., that SDA is already above VIH.

Note 3. Based on t_{SPIKE} , rise and fall times, and interconnect.Note 4. This maximum High period may be exceeded when the signals can be safely seen by Legacy I²C Devices, and/or in consideration of the interconnect (e.g., a short Bus).

As a product specification, if this Max value cannot be guaranteed, change this Max value and specify that it cannot be used in the Mixed Bus.

Note 5. On a Legacy Bus where I²C Devices need to see Start

Note 6. Slaves that do not support the optional ENTASx CCCs shall use the t_{CAS} Max value shown for ENTAS3

Note 7. On a Mixed Bus with Fm Legacy I²C Devices, t_{AVAIL} is 300 ns shorter than the Fm Bus Free Condition time (t_{BUF})

Table 55.53 I3C timing (Push-Pull Timing Parameters for SDR and HDR-DDR Modes)

Setting of the I3C_SCL0, I3C_SDA0 pins are not required with the Port Drive Capability bit in the PmnPFS register.

Parameter		Symbol	VCC	Min	Max	Unit	Test conditions
I3C Push-Pull Timing Parameters for SDR and HDR-DDR Modes	SCL Clock Frequency	f _{SCL} ^{*1}	3.00 V or above	0.01	12.5	MHz	—
			1.68 to 1.95 V	0.01	12.5

			1.68 to 1.95 V	—	12		
	SCL Clock Rise Time	t _{CR}	3.00 V or above	—	150 × 1 / f _{SCL} (capped at 60)	ns	Figure 55.74
			1.68 to 1.95 V	—	150 × 1 / f _{SCL} (capped at 60)		
	SCL Clock Fall Time	t _{CF}	3.00 V or above	—	150 × 1 / f _{SCL} (capped at 60)	ns	Figure 55.74
			1.68 to 1.95 V	—	150 × 1 / f _{SCL} (capped at 60)		
	SDA Signal Data Hold in Push-Pull Mode	Master	t _{HD_PP} ^{*4*5}	3.00 V or above	t _{CR} + 3 and t _{CF} + 3	—	Figure 55.78
				1.68 to 1.95 V	t _{CR} + 3 and t _{CF} + 3	—	
		Slave	t _{HD_PP} ^{*5}	3.00 V or above	0	—	Figure 55.78
				1.68 to 1.95 V	0	—	
	SDA Signal Data Setup in Push-Pull Mode	t _{SU_PP}	3.00 V or above	12	N/A	ns	Figure 55.80
			1.68 to 1.95 V	18	N/A		
	Clock After Repeated START (Sr)	t _{CASr}	3.00 V or above	t _{CASmin}	N/A	ns	Figure 55.82
			1.68 to 1.95 V	t _{CASmin}	N/A		
	Clock Before Repeated START (Sr)	t _{CBSr}	3.00 V or above	t _{CASmin} / 2	N/A	ns	Figure 55.82
			1.68 to 1.95 V	t _{CASmin} / 2	N/A		
	Capacitive Load per Bus Line (SDA/SCL)	C _b	3.00 V or above	—	50	pF	—
			1.68 to 1.95 V	—	50		

Note 1. $f_{SCL} = 1 / (t_{DIG_L} + t_{DIG_H})$

Note 2. t_{DIG_L} and t_{DIG_H} are the clock Low and High periods as seen at the receiver end of the I3C Bus using V_{IL} and V_{IH} .

Note 3. When communicating with an I3C Device on a mixed Bus, the $t_{DIG_H_MIXED}$ period must be constrained in order to make sure that I²C Devices do not interpret I3C signaling as valid I²C signaling.

Note 4. As both edges are used, the hold time needs to be satisfied for the respective edges; i.e., $t_{CF} + 3$ for falling edge clocks, and $t_{CR} + 3$ for rising edge clocks.

Note 5. In SDR Mode the Hold time parameter is referred to as t_{HD_SDR} , and in DDR Mode it is referred to as t_{HD_DDR} .

Table 55.54 I3C timing (Push-Pull Timing Parameters for HDR-TSP and HDR-TSL Modes)

Setting of the I3C_SCL0, I3C_SDA0 pins are not required with the Port Drive Capability bit in the PmnPFS register.

Parameter	Symbol	VCC	Min	Max	Unit	Test conditions
I3C Push-Pull Timing Parameters for HDR-TSP and HDR-TSL Modes	Edge-to-Edge Period	$t_{EDGE}^{*1 *2}$	3.00 V or above	t_{DIG_H}	—	Figure 55.74
			1.68 to 1.95 V	t_{DIG_H}	—	
	Allowed Difference Between Signals for 'Simultaneous' Change	t_{SKEW}	3.00 V or above	—	10	
			1.68 to 1.95 V	—	10	
	Stable Condition Between Symbols	t_{EYE}	3.00 V or above	12	—	
			1.68 to 1.95 V	12	—	
	Time Between Successive Symbols	t_{SYMBOL}	3.00 V or above	t_{EDGE} Min	—	
			1.68 to 1.95 V	t_{EDGE} Min	—	
	Symbol Clock	t_{CLOCK}	3.00 V or above	$1 / f_{SCL}$ (Max)	—	
			1.68 to 1.95 V	$1 / f_{SCL}$ (Max)	—	

Note 1. Edges occur at the rate of $1 / (t_{EDGE} \times 2)$

Note 2. In a Mixed Bus, HDR-TSL shall respect the maximum $t_{DIG_H_MIXED}$ shown in Figure 55.77.

55.3.14 SSIE Timing

Table 55.55 SSIE timing (1 of 2)

(1) High drive output is selected with the Port Drive Capability bit in the PmnPFS register.

(2) Use pins that have a letter appended to their names, for instance “_A”, “_B” or “_C” to indicate group membership. For the SSIE interface, the AC portion of the electrical characteristics is measured for each group.

Parameter			Symbol	VCC	Min.	Max.	Unit	Comments
SSIBCK	Cycle	Master	t_o	2.70V or above	80	—	ns	Figure 55.85
				1.68V or above	80	—		
		Slave	t_i	2.70V or above	80	—	ns	
				1.68V or above	80	—		
	High level/ low level	Master	t_{HC}/t_{LC}	2.70V or above	0.35	—	t_o	
				1.68V or above	0.35	—		
		Slave		2.70V or above	0.35	—	t_i	
				1.68V or above	0.35	—		
	Rising time/ falling time	Master	t_{RC}/t_{FC}	2.70V or above	—	0.15	t_o / t_i	
				1.68V or above	—	0.15		
		Slave		2.70V or above	—	0.15	t_o / t_i	
				1.68V or above	—	0.15		

Table 55.55 SSIE timing (2 of 2)

(1) High drive output is selected with the Port Drive Capability bit in the PmnPFS register.

(2) Use pins that have a letter appended to their names, for instance “_A”, “_B” or “_C” to indicate group membership. For the SSIE interface, the AC portion of the electrical characteristics is measured for each group.

Parameter			Symbol	VCC	Min.	Max.	Unit	Comments
SSILRCK0/ SSIFS0, SSITXD0, SSIRXD0	Input set up time	Master	t _{SR}	2.70V or above	12	—	ns	Figure 55.87, Figure 55.88
				1.68V or above	20	—		
		Slave		2.70V or above	12	—	ns	
				1.68V or above	12	—		
	Input hold time	Master	t _{HR}	2.70V or above	8	—	ns	
				1.68V or above	8	—		
		Slave		2.70V or above	15	—	ns	
				1.68V or above	15	—		
	Output delay time	Master	t _{DTR}	2.70V or above	-10	5	ns	
				1.68V or above	-10	7		
		Slave		2.70V or above	0	20	ns	
				1.68V or above	0	25		
	Output delay time from SSILRCK/ SSIFS change	Slave	t _{DTRW}	2.70V or above	—	20	ns	Figure 55.89
				1.68V or above	—	25		
GTIOC2A, AUDIO_CLK	Cycle		t _{EXcyc}	2.70V or above	20	—	ns	Figure 55.86 ^{*1}
				1.68V or above	40	—		
	High level/ low level		t _{EXL} /t _{EXH}	2.70V or above	0.4	—	t _{EXcyc}	
				1.68V or above	0.4	—		
	Rising time/ falling time		t _{EXr} /t _{EXf}	2.70V or above	—	0.1 ^{*2}	t _{EXcyc}	
				1.68V or above	—	0.1 ^{*2}		

Note 1. For slave-mode transmission, SSIE has a path, through which the signal input from the SSILRCK/SSIFS pin is used to generate transmit data, and the transmit data is logically output to the SSITXD0 or SSIDATA1 pin.

Note 2. 1μs at the longest

55.3.15 SD/MMC Host Interface Timing

Table 55.56 SD/MMC Host Interface signal timing

Conditions: High drive output is selected in the Port Drive Capability bit in the PmnPFS register.

High-speed high drive output is selected in specific condition, please see note 1.

Clock duty ratio is 50%.

Parameter	Symbol	VCC/VCC2	Min	Max	Unit	Test conditions
SDnCLK clock cycle	tSDCYC	2.70V or above	20	—	ns	Figure 55.90
		1.70 to 1.95V*1	20	—		
		1.70 to 1.95V	40	—		
SDnCLK clock high pulse width	tSDWH	2.70V or above	6.5	—	ns	
		1.70 to 1.95V*1	6.5	—		
		1.70 to 1.95V	13.0	—		
SDnCLK clock low pulse width	tSDWL	2.70V or above	6.5	—	ns	
		1.70 to 1.95V*1	6.5	—		
		1.70 to 1.95V	13.0	—		
SDnCLK clock rise time	tSDLH	2.70V or above	—	3.0	ns	
		1.70 to 1.95V*1	—	4.0		
		1.70 to 1.95V	—	8.0		
SDnCLK clock fall time	tSDHL	2.70V or above	—	3.0	ns	
		1.70 to 1.95V*1	—	4.0		
		1.70 to 1.95V	—	8.0		
SDnCMD/SDnDATm output data delay	tSDODLY	2.70V or above	−7.0	4.0	ns	
		1.70 to 1.95V*1	−7.0	7.0		
		1.70 to 1.95V	−15.0	15.0		
SDnCMD/SDnDATm input data setup	tSDIS	2.70V or above	4.5	—	ns	
		1.70 to 1.95V*1	4.5	—		
		1.70 to 1.95V	20.0	—		
SDnCMD/SDnDATm input data hold	tSDIH	2.70V or above	1.5	—	ns	
		1.70 to 1.95V	1.5	—		

Note: Must use pins that have a letter appended to their name, for instance “_A”, “_B”, to indicate group membership. For the SD/MMC Host interface, the AC portion of the electrical characteristics is measured for each group.

Note: If SD1DAT4_A~SD1DAT7_A are used, characteristics above is guaranteed only when VCC = VCC2.

Note 1. Only supported for Ch0 group B ("SD0*_B") and Ch1 group A ("SD1*_A")

High-speed high drive output is selected in the port drive capability bit in the PmnPFS register for the following pins:
SD0CLK_B, SD1CLK_A

Figure 55.90 SD/MMC Host Interface signal timing

55.3.16 ETHERC Timing

Table 55.57 ETHERC timing

Conditions: ETHERC (RMII): Middle drive output is selected in the Port Drive Capability bit in the PmnPFS register for the following pins: ET0_MDC, ET0_MDIO.

For other pins, high drive output is selected in the Port Drive Capability bit in the PmnPFS register.

ETHERC (MII): Middle drive output is selected in the Port Drive Capability bit in the PmnPFS register.

Parameter	Symbol	VCC	Min	Max	Unit	Test conditions
ETHERC (RMII)	REF50CK0 cycle time	2.70V or above	20	—	ns	Figure 55.91 to Figure 55.94
	REF50CK0 frequency, typical 50 MHz		—	50 + 100 ppm	MHz	
	REF50CK0 duty		35	65	%	
	REF50CK0 rise/fall time		0.5	3.5	ns

Figure 55.116 Illustration of ADC12 characteristic terms

Absolute accuracy

Absolute accuracy is the difference between output code based on the theoretical A/D conversion characteristics, and the actual A/D conversion result. When measuring absolute accuracy, the voltage at the midpoint of the width of the analog input voltage (1-LSB width), which can meet the expectation of outputting an equal code based on the theoretical A/D conversion characteristics, is used as an analog input voltage. For example, if 12-bit resolution is used and the reference voltage $V_{REFH0} = 3.072$ V, then the 1-LSB width becomes 0.75 mV, and 0 mV, 0.75 mV, and 1.5 mV are used as the analog input voltages. If the analog input voltage is 6 mV, an absolute accuracy of ± 5 LSB means that the actual A/D conversion result is in the range of 0x003 to 0x00D, though an output code of 0x008 can be expected from the theoretical A/D conversion characteristics.

Integral nonlinearity error (INL)

Integral nonlinearity error is the maximum deviation between the ideal line when the measured offset and full-scale errors are zeroed, and the actual output code.

Differential nonlinearity error (DNL)

Differential nonlinearity error is the difference between the 1-LSB width based on the ideal A/D conversion characteristics and the width of the actual output code.

Offset error

Offset error is the difference between the transition point of the ideal first output code and the actual first output code.

Full-scale error

Full-scale error is the difference between the transition point of the ideal last output code and the actual last output code.

Time delay in assertion of the reset signal for the backup domain*3	t _p (PDRL)	—	—	2000	μs	
Time delay in negation of the reset signal for the backup domain	t _p (PDRH)	—	—	3000		
VBATT monitor operation stabilization time (after VBATTMNSLR.VBTMNSL is changed to 1)	t _{MONWT}	—	—	4.2	μs	—
VBATT voltage monitor level	V _{MONBATT}	—	VBATT / 3	—	V	—
VBATT current increase (when VBATTMNSLR.VBTMNSL is 1 compared to the case that VBATTMNSLR.VBTMNSL is 0)	I _{VBATTSELB}	—	1.50	2.35	μA	—
VCC current increase (when VBATTMNSLR.VBTMNSL is 1 compared to the case that VBATTMNSLR.VBTMNSL is 0)	I _{VBATTSELC}	—	330	577	μA	—

Note 1. The VCC-off period for starting power supply switching indicates the period in which VCC is below the minimum value of the voltage level for switching to battery backup (V_{DETBATT}).

In addition, this period indicates the time t_{VOFFP} when VCC is below the minimum value of voltage detection levels V_{POR1}.

Note 2. Stable time when VBTBPCR2.VDETLVL is changed or VBTBPCR1.BPWSWSTP is changed from 1 to 0.

Note 3. When the VBATT_R recovers within this period, the backup domain reset signal may not be generated.

First suspend delay during erasure in suspend priority mode		t_{SESD1}	—	—	216	—	—	120	μs	
Second suspend delay during erasure in suspend priority mode		t_{SESD2}	—	—	1.7	—	—	1.7	ms	
Suspend delay during erasure in erasure priority mode		t_{SEED}	—	—	1.7	—	—	1.7	ms	
First erasing resume time during erasure in suspend priority mode ^{*5}		t_{REST1}	—	—	1.7	—	—	1.7	ms	
Second erasing resume time during erasure in suspend priority mode		t_{REST2}	—	—	144	—	—	80	μs	
Erasing resume time during erasure in erasure priority mode		t_{REET}	—	—	144	—	—	80	μs	
Forced stop command		t_{FD}	—	—	32	—	—	20	μs	
Data hold time ^{*2}		t_{DRP}	10 ^{*2} *3	—	—	10 ^{*2} *3	—	—	Years	Tj = +125°C
			20 ^{*2} *3	—	—	20 ^{*2} *3	—	—		Tj = +105°C
			30 ^{*2} *3	—	—	30 ^{*2} *3	—	—		Tj = +85°C

Note 1. This is the minimum number of times to guarantee all the characteristics after reprogramming. The guaranteed range is from 1 to the minimum value.

Note 2. This indicates the minimum value of the characteristic when reprogramming is performed within the specified range.

Note 3. This result is obtained from reliability testing.

Note 4. The reprogram/erase cycle is the number of erasures for each block. When the reprogram/erase cycle is n times (n = 10,000), erasing can be performed n times for each block. For example, when 128-byte programming is performed 64 times for different addresses in 8-KB blocks, and then the entire block is erased, the reprogram/erase cycle is counted as one. However, programming the same address several times as one erasure is not enabled. Overwriting is prohibited.

Note 5. Time for resumption includes time for reapplying the erasing pulse (up to one full pulse) that was cut off at the time of suspension.

Note 6. The reference value at VCC = 3.3V and room temperature.

Figure 55.123 Suspension and forced stop timing for flash memory programming and erasure

55.12.2 Data Flash Memory Characteristics

Table 55.79 Data flash memory characteristics (1 of 2)

Conditions: Program or erase: FCLK = 4 to 60 MHz

Command time for increment counter and refresh counter	t _{IRCT}	—	11.9	81	—	6.3	42	ms	
Command time for read counter	t _{RCT}	—	—	25	—	—	5	μs	
Update Cycles (total of increment and refreshing)	N _{cupc}	125000 ^{*1}	—	—	125000 ^{*1}	—	—	Times	

Table 55.82 Anti-rollback counter characteristics (2 of 2)

Conditions: Program: FCLK = 4 to 60 MHz

Read: FCLK ≤ 60 MHz

Parameter	Symbol	FCLK = 4 MHz			20 MHz ≤ FCLK ≤ 60 MHz			Unit	Test conditions
		Min	Typ ^{*4}	Max	Min	Typ ^{*4}	Max		
Data hold time ^{*2}	t _{DRP}	10 ^{*2 *3}	—	—	10 ^{*2 *3}	—	—	Years	T _j = +125°C
		20 ^{*2 *3}	—	—	20 ^{*2 *3}	—	—		T _j = +105°C
		30 ^{*2 *3}	—	—	30 ^{*2 *3}	—	—		T _j = +85°C

Note 1. This is the minimum number of times to guarantee all the characteristics after reprogramming. The guaranteed range is from 1 to the minimum value.

Note 2. This indicates the minimum value of the characteristic when reprogramming is performed within the specified range.

Note 3. This result is obtained from reliability testing.

Note 4. The reference value at VCC = 3.3 V and room temperature.

55.13 Boundary Scan

Others	—	Hi-Z	Keep-O		Keep		Hi-Z	Keep

Note: Hi-Z: High-impedance

Keep-O: Output pins retain their previous values. Input pins go to high-impedance.

Keep-I: Pin states are retained same as during periods in Normal mode.

Keep: Pin states are retained same as during periods in Software Standby mode.

Note 1. Retains the I/O port state until the DPSBYCR.IOKEEP bit is cleared to 0.

Note 2. Input is enabled if the pin is specified as the Software Standby canceling source while it is used as an external interrupt pin.

Note 3. Input is enabled if the pin is specified as the Deep Software Standby canceling source.

Note 4. Input is enabled while the pin is used as an input pin.

Note 5. For host operation, set the USBHS.SYSCFG.DRPD bit to 1 to enable the USBHS_DP and USBHS_DM pull-down resistors.

For device operation, set the USBHS.SYSCFG.DPRPU bit to 1 to enable the DP pull-up resistor.

Note 6. Depending on the operation before the transition to Software Standby Mode, either High-level or Low-level is output. See [section 14.9.1. BC0 pin when in Software Standby Mode \(SSTBY\) and SBYCR.OPE=1](#).

Appendix 2. Package Dimensions

Information on the latest version of the package dimensions or mountings is displayed in “Packages” on the Renesas Electronics Corporation website.

Flash Cache	FCACHE	0x4001_C100	FCACHE_NS	0x5001_C100
Data Flash	FLAD	0x4011_C000	FLAD_NS	0x5011_C000
Flash Application Command Interface	FACI	0x4011_E000	FACI_NS	0x5011_E000
Data Flash Security Setting	FDFS	0x2703_0000	—	—

Note: Name = Peripheral name
Description = Peripheral functionality
Base address = Lowest reserved address or address used by the peripheral

3.2 Access Cycles

This section provides access cycle information for the I/O registers described in this manual.

- Registers are grouped by associated module.

- The number of access cycles indicates the number of cycles based on the specified reference clock.
- In the internal I/O area, reserved addresses that are not allocated to registers must not be accessed, otherwise operations cannot be guaranteed.
- The number of I/O access cycles depends on bus cycles of the internal peripheral bus, divided clock synchronization cycles, and wait cycles of each module. Divided clock synchronization cycles differ depending on the frequency ratio between ICLK and PCLK.
- When the frequency of ICLK is equal to that of PCLK, the number of divided clock synchronization cycles is always constant.
- When the frequency of ICLK is greater than that of PCLK, at least 1 PCLK cycle is added to the number of divided clock synchronization cycles.
- The number of write access cycles indicates the number of cycles obtained by non-bufferable write access.

Note: This applies to the number of cycles when access from the CPU does not conflict with the instruction fetching to the external memory or bus access from other bus masters such as DTC or DMAC.

Table A3.2 Access cycles (1 of 3)

Peripheral base address symbol	Address*1		Number of access cycles					
			ICLK = PCLK		ICLK > PCLK*2		Cycle Unit	Related function
	From	To	Read	Write	Read	Write		
RMPU, SRAM, BUS, ICU_COMMON, CPSCU, DMAC0n, DMA0, DTC0, ICU, CPU_CTRL	0x4000_0000	0x4001_CFFF	3	2	3	2	ICLK	Renesas Memory Protection Unit, SRAM Control, BUS Control, Common Interrupt Controller, CPU System Security Control Unit, Direct memory access controller 0 n, DMAC Module Activation 0, Data Transfer Controller 0, Interrupt Controller, CPU Control Registers
CPU_OCD	0x4001_1004	0x4001_1FFF	7	2	7	2	ICLK	On-Chip Debug
CPU_DBG, FCACHE	0x4000_B000	0x4001_CFFF	3	2	3	2	ICLK	Debug Function, Flash Cache
SYSC	0x4001_E000	0x4001_E9FF	4	3	2 to 4	1 to 3	PCLK B	System Control
SYSC	0x4001_EA00	0x4001_ED7F	7	6	5 to 7	4 to 6	PCLK B	System Control
TSD	0x4011_B17C	0x4011_B17C	4	3	4	3	ICLK	Temperature Sensor Data
ELC, RTC	0x4020_1000	0x4020_21FF	4	3	2 to 4	1 to 3	PCLK B	Event Link Controller, Realtime Clock
IWDT	0x4020_2200	0x4020_22FF	4	65	2 to 4	63 to 65	PCLK B	Independent Watchdog Timer
CAC, WDT0, MSTP, PSCU, POEG	0x4020_2400	0x4021_2FFF	4	3	2 to 4	1 to 3	PCLK B	Clock Frequency Accuracy Measurement Circuit, Watchdog Timer 0, Module Stop Control, Peripheral Security Control Unit, Port Outupt Enable Module for GPT
ULPTn	0x4022_0000	0x4022_01FF	6	65	4 to 6	63 to 65	PCLK B	Ultra-Low Power Timer n
AGTn	0x4022_1000	0x4022_11FF	6	3	4 to 6	1 to 3	PCLK B	Low Power Asynchronous General purpose Timer n
TSN	0x4023_5000	0x4023_5FFF	4	3	2 to 4	1 to 3	PCLK B	Temperature Sensor
ACMPHSn	0x4023_6000	0x4023_61FF	3	3	1 to 3	1 to 3	PCLK B	High-Speed Analog Comparator n
USBFS	0x4025_0000	0x4025_03FF	5	4	3 to 5	2 to 4	PCLK B	USB 2.0 FS Module
USBFS	0x4025_0400	0x4025_04FF	4	65	2 to 4	63 to 65	PCLK B	USB 2.0 FS Module
SDHIn, SSIE n, IICn, OSPI0, DOTF0	0x4025_2000	0x4026_88FF	4	3	2 to 4	1 to 3	PCLK B	SD Host Interface n, Serial Sound Interface Enhanced n, Inter-Integretad Circuit n, Octal Serial Peripheral Interface 0, Decryption On-The-Fly 0

Table A3.2 Access cycles (2 of 3)

Peripheral base address symbol	Address*1		Number of access cycles					
			ICLK = PCLK		ICLK > PCLK*2		Cycle Unit	Related function
	From	To	Read	Write	Read	Write		
CRC, DOC	0x4031_0000	0x4031_1FFF	4	3	2 to 4	1 to 3	PCLK A	CRC Calculator, Data Operation Circuit
GPT32n, GPT16n, GPT_OPS	0x4032_2000	0x4032_3FFF	7	4	5 to 7	2 to 4	PCLK A	General PWM 32-Bit Timer n, General PWM 16-Bit Timer n, Output Phase Switching Controller
ADC12n, DAC12n	0x4033_2000	0x4034_6FFF	4	3	2 to 4	1 to 3	PCLK A	12-bit A/D Converter n, 12-bit D/A Converter n
CEU	0x4034_8000	0x4034_FFFF	7	5	5 to 7	3 to 5	PCLK A	Capture Engine Unit
USBHS*3	0x4035_1000	0x4035_115F	BWAIT + 4	BWAIT + 3	(BWAIT+ 2) to (BWAIT+ 4)	(BWAIT +1) to (BWAIT + 3)	PCLK A	USB 2.0 High-Speed Module
USBHS*3	0x4035_1160	0x4035_1167	BWAIT + 4	130	(BWAIT+ 2) to (BWAIT+ 4)	128 to 130	PCLK A	USB 2.0 High-Speed Module
USBHS	0x4035_1168	0x4035_116F	8	130	6 to 8	128 to 130	PCLK A	USB 2.0 High-Speed Module
EDMAC0	0x4035_4000	0x4035_40FF	5	4	3 to 5	2 to 4	PCLK A	DMA Controller for the Ethernet Controller Channel 0
ETHERC0	0x4035_4100	0x4035_43FF	14	13	12 to 14	11 to 13	PCLK A	Ethernet Controller Channel 0
SCIn, SPIn, I3C	0x4035_8000	0x4035_FFFF	4	3	2 to 4	1 to 3	PCLK A	Serial Communication Interface n, Serial Peripheral Interface n, I3C Bus Interface
ECCMBn	0x4036_F200	0x4036_F3FF	5	4	3 to 5	2 to 4	PCLK A	Error correction circuit for MBRAMn
CANFDn	0x4038_0000	0x4038_3FFF	4	3	2 to 4	1 to 3	PCLK A	CANFD Module n
PORTn	0x4040_0000	0x4040_01FF	4	2	4	2	ICLK	Port n Control Registers
PFS	0x4040_0800	0x4040_0FFF	8	2	8	2	ICLK	Pmn Pin Function Control Register
RSIP-E51A	—	—	1 to 3	2	1 to 3	1 to 2	PCLK A	Renesas Security IP

Table A3.2 Access cycles (3 of 3)

Peripheral base address symbol	Address* ¹		Number of access cycles					
			ICLK = FCLK		ICLK > FCLK* ²		Cycle Unit	Related function
	From	To	Read	Write	Read	Write		
FLAD, FACI	0x4011_C040	0x4011_EFFF	4	3	4	3	FCLK	Data Flash, Flash Application Command Interface

Note 1. This table only shows secure address. Access cycle of the non-secure address is the same as its secure address.

Note 2. If the number of PCLK or FCLK cycles is non-integer (for example 1.5), the minimum value is without the decimal point, and the maximum value is rounded up to the decimal point. For example, 1.5 to 2.5 is 1 to 3.

Note 3. BWAIT is the number of waits (not cycles) described in the USBHS.BUSWAIT register.

Appendix 4. Note for Register R/W

- A secure bus master issues a "secure access" using an address marked as secure by IDAU/SAU or MSAU.
- A secure bus master issues a "non-secure access" using an address marked as non-secure by IDAU/SAU or MSAU.
- A non-secure bus master issues a "non-secure access" using an address marked as non-secure by IDAU/SAU or MSAU.

Table A4.1 Type of Register Notes (S-TYPE)

TYPE	UM Description
S-TYPE-1	Only Secure access can write to this register. Read access is always allowed. Non-secure write access is ignored, but TrustZone access error is not generated.
S-TYPE-2	Read access is always allowed If the security attribution is configured as Secure, • Secure write access is allowed. • Non-secure write access is ignored, but TrustZone access error is not generated.
	If the security attribution is configured as Non-secure, • Secure write access is ignored, but TrustZone access error is not generated. • Non-secure access is allowed.
S-TYPE-3	If the security attribution is configured as Secure, • Secure access is allowed. • Non-secure write access is ignored and Non-secure read access is read as 0, TrustZone access error is generated
	If the security attribution is configured as Non-secure, • Secure write access is ignored and Secure read access is read as 0, TrustZone access error is generated. • Non-secure access is allowed
S-TYPE-4	If the security attribution is configured as Secure, • Secure access is allowed • Non-secure write access is ignored and Non-secure read access is read as 0, but TrustZone access error is not generated.
	If the security attribution is configured as Non-secure, • Secure write access is ignored and Secure read access is read as 0, but TrustZone access error is not generated. • Non-secure access is allowed.
S-TYPE-5	Access is always allowed.
S-TYPE-6	Secure access is allowed. Non-secure write access is ignored, and Non-secure read access is read as 0, TrustZone access error is generated.
S-TYPE-7	Secure write access is ignored, and Secure read access is read as 0, TrustZone access error is generated. Non-secure access is allowed.

Note: A non-secure bus master does NOT issue any access using an address marked as secure by IDAU/SAU or MSAU.

Table A4.2 Type of Register Notes (P-TYPE)

TYPE	UM Description
P-TYPE-1	Privileged write access is allowed. Read access is always allowed. Unprivileged write access is ignored, but TrustZone access error is not generated.
P-TYPE-2	Privileged access is allowed. Unprivileged write access is ignored, and Unprivileged read access is read as 0, TrustZone access error is generated.
P-TYPE-3	If the privilege attribution is configured as Privileged, • Privileged access is allowed. • Unprivileged write access is ignored and Unprivileged read access is read as 0, TrustZone access error is generated.
	If the privilege attribution is configured as Unprivilege, • Privileged access and Unprivileged access are allowed.
P-TYPE-4	If the privilege attribution is configured as Privileged, • Privileged access is allowed. • Unprivileged write access is ignored and Unprivileged read access is read as 0, TrustZone access error is not generated.
	If the privilege attribution is configured as Unprivilege, • Privileged access and Unprivileged access are allowed.
P-TYPE-5	Access is always allowed.

Appendix 5. Peripheral Variant

[Table A5.1](#) shows the correspondence between the module name used in this manual and the Peripheral Variant.

Table A5.1 Module name vs Peripheral Variant

Module name	Peripheral variant
SCI	SCI_B
SPI	SPI_B
OSPI	OSPI_B
DOC	DOC_B

Revision History

Revision 1.10 — October 24, 2023

First edition, issued

Revision 1.20 — November 22, 2024

1. Overview:

- Updated Table 1.8 Communication interfaces.
- Updated Table 1.14 Function Comparison.

2. CPU:

- Updated Table 2.9 CPU peripherals.

4. Address Space:

- Updated Note 1 in Figure 4.1 Memory map example of 2 MB flash product.

5. Resets:

- Updated Table 5.3 Module-related registers initialized by each reset source.

6. Option-Setting Memory:

- Updated 6.2.5 OFS1, OFS1_SEC : Option Function Select Register 1 for Non-secure and Secure.
- Updated 6.2.10 PBPS, PBPS_SEC : Permanent Block Protect Setting Register.
- Updated 6.2.20 CFGD2LOCK : Configuration Data 2 Lock Bit.
- Deleted 6.5 References.

8. Clock Generation Circuit:

- Updated Table 8.1 Clock generation circuit specifications for the clock sources.
- Updated 8.2.1 CGFSAR : Clock Generation Function Security Attribute Register.
- Updated 8.2.6 PLLCCR : PLL Clock Control Register.
- Updated 8.2.9 PLL2CCR : PLL2 Clock Control Register.
- Updated 8.2.13 MOSCCR : Main Clock Oscillator Control Register.
- Updated 8.2.16 HOCOCR : High-Speed On-Chip Oscillator Control Register.
- Added 8.2.17 HOCOCR2 : High-Speed On-Chip Oscillator Control Register2.
- Updated 8.2.20 FLLCR2 : FLL Control Register2.
- Updated 8.2.50 TRCKCR : Trace Clock Control Register.
- Added Note 1 to the following sections:
 - 8.10.1 CPU Clock (CPUCLK)
 - 8.10.2 System Clock (ICLK)
 - 8.10.4 Peripheral Module Clock (PCLKA, PCLKB, PCLKC, PCLKD, PCLKE)
 - 8.10.5 FlashIF Clock (FCLK)
 - 8.10.6 External Bus Clock (BCLK, EBCLK)
 - 8.10.7 SDRAM Clock (SDCLK)
 - 8.10.9 SCI Clock (SCICLK)
 - 8.10.10 SPI Clock (SPICLK)
 - 8.10.11 Octal-SPI clock (OCTACLK, OCTADIVCLK)
 - 8.10.12 CANFD Core clock (CANFDCLK)
 - 8.10.13 USB Clock (USBCLK)
 - 8.10.14 USB Clock (USB60CLK)
 - 8.10.16 I3C Clock (I3CCLK)
 - 8.10.24 External Pin Output Clock (CLKOUT)
- Updated Table 8.14 Example of the HOCO initial setting procedure after reset release / after Deep Software Standby cancellation (OFS1(_SEC).HOCOEN = 1, without FLL).
- Updated Table 8.15 Example of the HOCO setting procedure with FLL function after reset release / after Deep Software Standby cancellation (OFS1(_SEC).HOCOEN = 1).

10. Low Power Modes:

- Updated 10.2.3 RSCSAR : RAM Standby Control Security Attribution Register.
- Updated 10.2.11 PDRAMSCR0 : SRAM Power Domain Standby Control Register 0.

11. Battery Backup Function:

- Updated 11.2.12 VBTBPCR2 : VBATT Battery Power Supply Control Register 2.

12. Register Write Protection:

- Updated Table 12.1 Association between the bits in the PRCR register and registers to be protected.

13. Interrupt Controller Unit:

- Updated Table 13.4 Event table.

Revision 1.20 — November 22, 2024**14. Buses:**

- Updated Figure 14.1 System bus connection.
- Updated Table 14.2 System bus access path.
- Updated 14.3.8 CSnMOD : CSn Mode Register (n = 0 to 7).
- Updated 14.3.10 CSnWCR2 : CSn Wait Control Register 2 (n = 0 to 7).
- Updated 14.7.2 Operations When a Bus Error Occurs.
- Updated Table 14.47 Conditions leading to illegal address access errors.

16. DMA Controller:

- Updated 16.2.2 DMACCHPAR : DMA channel Privilege Attribution Register.
- Updated Figure 16.19 Example of use case: from unaligned ring buffer to single ring buffer.
- Updated 16.3.13 Channel Security.

17. Data Transfer Controller:

- Updated 17.8.1 Interrupt Request of Transfer End.

20. Port Output Enable for GPT:

- Updated 20.3.1.1 Digital Filter.
- Updated 20.5 External Trigger Output to the GPT.

21. General PWM Timer:

- Updated the base address in the following sections:
 - 21.2.22 GTADTRk : A/D Conversion Start Request Timing Register k (k = A, B)
 - 21.2.23 GTADTBRk : A/D Conversion Start Request Timing Buffer Register k (k = A, B)
 - 21.2.24 GTADTDBRk : A/D Conversion Start Request Timing Double-Buffer Register k (k = A, B)
- Updated 21.2.28 GTICLF : General PWM Timer Inter Channel Logical Operation Function Setting Register.

22. Low Power Asynchronous General Purpose Timer:

- Updated Figure 22.9 Operation example 2 in event counter mode.

23. Ultra-Low-Power Timer:

- Updated 23.4.7 Standby mode.
- Updated 23.5.9 Restrictions on Event Counting during Deep Software Standby Mode 1.

25. Watchdog Timer:

- Updated 25.3.3 Refresh Operation.

26. Independent Watchdog Timer:

- Updated Figure 26.6 IWDTCR refresh operation waveforms (IWDTCR.CKS[3:0] = 0000b, IWDTCR.TOPS[1:0] = 11b).
- Updated Figure 26.8 Processing for reading IWDTCR counter value when IWDTCR.CKS[3:0] = 0000b and IWDTCR.TOPS[1:0] = 11b.
- Updated Figure 26.9 Processing for reading IWDTCR counter value when IWDTCR.CKS[3:0] = 0010b and IWDTCR.TOPS[1:0] = 11b.

28. Ethernet DMA Controller:

- Updated 28.5.1 Settings for the Module-Stop Function.

29. USB 2.0 Full-Speed Module:

- Updated 29.2.31 PIPESEL : Pipe Window Select Register.
- Updated 29.2.34 PIPEPERI : Pipe Cycle Control Register.
- Updated 29.3.3.1 BRDY interrupt.
- Updated 29.3.5 FIFO Buffer.

30. USB 2.0 High-Speed Module:

- Updated 30.2.38 PIPEnCTR : Pipe n Control Register (n = 1 to 9).

31. Serial Communications Interface:

- Updated 31.2.11 FCR : FIFO Control Register.
- Updated 31.3.6 Address Match (Receive Data Match Detection) Function.
- Updated 31.3.8 Serial Data Transmission in Asynchronous Mode.
- Updated 31.3.9 Serial Data Reception in Asynchronous Mode.
- Updated 31.5.3 Initialization of the SCI in Manchester Mode.
- Updated Table 31.44 SCI interrupt sources with FIFO selected.

32. I²C Bus Interface:

- Updated Precautions on the use of the wakeup function in 32.8 Wakeup Function.

33. I³C Bus Interface:

- Updated 33.2.64 SDATBASn : Slave Device Address Table Basic Register n (n = 0 to 2).

34. CAN-FD:

- Updated 34.2.56 CFDGLOCKK : Global Lock Key Register.
- Updated 34.6.2.1 FIFO Buffers Configuration.
- Updated 34.9.2.1 RAM Test Mode.
- Added 34.10 RAM Area Configuration, 34.10.1 Examples, 34.10.2 OTB Area, 34.10.3 RAM Initialization Cycle.
- Updated Table 34.30 RAM initialization cycle.

Revision 1.20 — November 22, 2024**36. Serial Peripheral Interface:**

- Updated 36.2.10 SPTFSR : SPI Transfer FIFO Status Register.

37. Octal Serial Peripheral Interface:

- Updated 37.1 Overview.
- Updated 37.2.2.1 BMCTL0 : OSPI Bridge Map Control Register 0.
- Updated 37.2.3.1 COMSTT : OSPI Common Status Register.
- Added 37.3.7.9 Flow of Read While Write.
- Updated Table 37.11 Data write possibility for each bus master.
- Added 37.3.8.6 Byte data order in 8pin-DDR mode.

38. Decryption On The Fly:

- Updated Table 38.1 DOTF Specification.

39. Serial Sound Interface Enhanced:

- Updated 39.2.1 SSICR : Control Register.
- Updated Table 39.7 Bits subject to software reset by the RFRST bit.
- Updated Table 39.8 Bits subject to software reset by the TFRST bit.
- Updated Table 39.9 Bits subject to software reset by the SSIRST bit.
- Updated Figure 39.25 Stop/resume of AUDIO_MCK.
- Updated 39.2.4 SSIFSR : FIFO Status Register.
- Updated Figure 39.31 Configuration of the transmit FIFO data register and transmit shift register, and FIFO operation example.
- Updated Figure 39.32 Configuration of the receive FIFO data register and receive shift register, and FIFO operation example.
- Updated 39.7.1 SSIEEn_SSIF Interrupt (n = 0, 1).
- Updated Table 39.19 Bits protected from writing during communication.

43. Security Features:

- Updated 43.3.3.5 Memory Security Attribution of TrustZone filter.
- Updated 43.6 Secure Factory Programming.

45. 12-Bit A/D Converter:

- Updated 45.2.9 ADANSA0 : A/D Channel Select Register A0.
- Updated 45.2.11 ADANSB0 : A/D Channel Select Register B0.
- Updated 45.3.6 Analog Input Sampling and Scan Conversion Time.
- Updated 45.6.13 Port Settings When Using the ADC12 Input.

52. Flash Memory:

- Updated the base address in the following sections:
 - 52.4.5 UIDRn : Unique ID Registers n (n = 0 to 3)
 - 52.4.6 PNRn : Part Numbering Register n (n = 0 to 3)
 - 52.4.7 MCUVER : MCU Version Register
- Updated 52.5.1 Feature of flash cache.
- Updated Table 52.17 FACL commands.
- Updated Table 52.23 Address Used by Configuration Set Command for Secure alias (Data flash memory).
- Updated Figure 52.36 Example of Block Swap Selection Flow for Secure alias (For Products with 2 Mbytes of Code Flash Memory).
- Updated Table 52.36 Protection Condition of Lockable area in Data Flash Configuration Area for Secure alias.
- Updated 52.12.5 Anti-Rollback Counter.

55. Electrical Characteristics:

- Updated Table 55.8 Current of high-speed mode, maximum condition (MVE and peripheral operation) (DCDC mode).
- Updated Table 55.9 Current of high-speed mode, maximum condition (MVE and peripheral operation) (External VDD mode).
- Updated Table 55.10 Current of high-speed mode, maximum data processing (MVE operation), peripheral clock ON (DCDC mode).
- Updated Table 55.11 Current of high-speed mode, maximum data processing (MVE operation), peripheral clock ON (External VDD mode).
- Updated Table 55.12 Current of high-speed mode, maximum data processing (MVE operation), peripheral clock OFF (DCDC mode).
- Updated Table 55.13 Current of high-speed mode, maximum data processing (MVE operation), peripheral clock OFF (External VDD mode).
- Updated Table 55.27 Power consumption of each unit.
- Updated Figure 55.67 SDR transmit/receive timing (1S-1S-1S, 1S-2S-2S, 2S-2S-2S, 1S-4S-4S, 4S-4S-4S).
- Updated Table 55.59 CANFD interface timing.

Appendix 5. Peripheral Variant:

- Added Appendix 5. Peripheral Variant.

Revision 1.30 — December 19, 2025**1. Overview:**

- Updated Figure 1.2 Part numbering scheme.
- Updated Table 1.14 Function Comparison.
- Updated Table 1.16 Pin list.

2. CPU:

- Updated Table 2.5 Initial vector table base address.

Revision 1.30 — December 19, 2025**6. Option-Setting Memory:**

- Updated 6.2.5 OFS1, OFS1_SEC : Option Function Select Register 1 for Non-secure and Secure.
- Updated 6.2.6 OFS1_SEL : Option Function Select Register 1 for Security Attribution.
- Updated 6.2.16 SAMR : Start Address of Measurement Report.
- Added 6.4.4 Notes on FSBL execution.

8. Clock Generation Circuit:

- Updated 8.2.31 LOCOUTCR : LOCO User Trimming Control Register.
- Updated 8.2.32 MOCOUTCR : MOCO User Trimming Control Register.
- Updated 8.2.34 MOSCSCR : Main Clock Oscillator Standby Control Register.
- Updated 8.2.35 HOCOSCR : High-Speed On-Chip Oscillator Standby Control Register.
- Updated 8.2.36 USBCKDIVCR : USB Clock Division Control Register.
- Updated 8.2.37 OCTACKDIVCR : Octal-SPI Clock Division Control Register.
- Updated 8.2.38 CANFDCKDIVCR : CANFD Core Clock Division Control Register.
- Updated 8.2.39 USB60CKDIVCR : USB60 clock Division control register.
- Updated 8.2.40 I3CCKDIVCR : I3C clock Division control register.
- Updated 8.2.41 USBCKCR : USB Clock Control Register.
- Updated 8.2.42 OCTACKCR : Octal-SPI Clock Control Register.
- Updated 8.2.43 CANFDCKCR : CANFD Core Clock Control Register.
- Updated 8.2.44 USB60CKCR : USB60 Clock Control Register.
- Updated 8.2.45 I3CCKCR : I3C clock control register.
- Updated 8.2.46 SCICKDIVCR : SCI clock Division control register.
- Updated 8.2.47 SPICKDIVCR : SPI clock Division control register.
- Updated 8.2.48 SCICKCR : SCI clock control register.
- Updated 8.2.49 SPICKCR : SPI clock control register.
- Updated 8.10.1 CPU Clock (CPUCLK).
- Updated 8.10.2 System Clock (ICLK)
- Updated 8.10.4 Peripheral Module Clock (PCLKA, PCLKB, PCLKC, PCLKD, PCLKE).
- Updated 8.10.5 FlashIF Clock (FCLK).
- Updated 8.10.6 External Bus Clock (BCLK, EBCLK).
- Updated 8.10.7 SDRAM Clock (SDCLK).
- Updated 8.10.9 SCI Clock (SCICLK).
- Updated 8.10.10 SPI Clock (SPICLK).
- Updated 8.10.11 Octal-SPI clock (OCTACLK, OCTADIVCLK).
- Updated 8.10.12 CANFD Core clock (CANFDCLK).
- Updated 8.10.13 USB Clock (USBCLK).
- Updated 8.10.14 USB Clock (USB60CLK).
- Updated 8.10.16 I3C Clock (I3CCLK).
- Added 8.12.6 Notes on MOSCSCR.MOSCSOKP.

10. Low Power Modes:

- Updated Table 10.2 Operating state of processor low power mode.
- Updated Table 10.3 Operating state of each low power mode.
- Updated Figure 10.1 Mode Transitions.
- Updated 10.2.5 MSTPCRB : Module Stop Control Register B.
- Updated 10.2.6 MSTPCRC : Module Stop Control Register C.
- Updated 10.2.9 SBYCR : Standby Control Register.
- Updated Figure 10.8 Additional flow for the canceling software standby mode.
- Added 10.7.11 Interruption During Transition to Low Power Modes.

11. Battery Backup Function:

- Updated 11.3.7.3 Not using the power supply switch flow example.

14. Buses:

- Updated Table 14.9 Bus priorities with fixed-priority arbitration (ARBS = 0).
- Updated Table 14.10 Bus priorities with round-robin arbitration (ARBS = 1).
- Updated 14.3.31 BUSnERRCLR : BUS Error Clear Register (n = 1 to 5, 10).
- Updated Table 14.38 SDRAM connection example (512-Mb × 2, with 16-bit bus).
- Updated Table 14.40 SDRAM connection example (128-Mb × 2, with 16-bit bus).
- Updated Table 14.41 SDRAM connection example with 512-Mb × 2 and 8-bit bus.

Revision 1.30 — December 19, 2025**19. I/O Ports:**

- Updated Table 19.7 Register settings for input/output pin function (PORT1).
- Updated Table 19.8 Register settings for input/output pin function (PORT2).
- Updated Table 19.9 Register settings for input/output pin function (PORT3).
- Updated Table 19.10 Register settings for input/output pin function (PORT4).
- Updated Table 19.12 Register settings for input/output pin function (PORT6).
- Updated Table 19.13 Register settings for input/output pin function (PORT7).
- Updated Table 19.14 Register settings for input/output pin function (PORT8).
- Updated Table 19.15 Register settings for input/output pin function (PORT9).
- Updated Table 19.16 Register settings for input/output pin function (PORTA).
- Updated Table 19.17 Register settings for input/output pin function (PORTB).

21. General PWM Timer:

- Updated 21.2.12 GTCR : General PWM Timer Control Register.
- Updated 21.4.1 Interrupt Sources.
- Updated Figure 21.71 Example of A/D Conversion Start Request Timing Operation.

22. Low Power Asynchronous General Purpose Timer:

- Updated Table 22.1 AGT specifications.
- Updated Table 22.9 Usable settings in Software Standby mode (AGT0).
- Updated Table 22.10 Usable settings in Software Standby mode (AGT1).

23. Ultra-Low-Power Timer (ULPT):

- Updated Table 23.1 ULPT specifications.

25. Watchdog Timer:

- Updated Figure 25.1 WDT block diagram.

26. Independent Watchdog Timer:

- Updated Figure 26.1 IWDTCR block diagram.
- Updated 26.2.2 IWDTCR : IWDTCR Control Register.
- Updated Figure 26.2 RPSS[1:0] and RPES[1:0] bits settings and refresh-permitted and refresh-prohibited periods.

28. Ethernet DMA Controller:

- Updated 28.2.17 RPADIR : Receive Data Padding Insert Register.

29. USB 2.0 Full-Speed Module:

- Updated 29.2.31 PIPESEL : Pipe Window Select Register.

30. USB 2.0 High-Speed Module:

- Updated Table 30.1 USBHS specifications.
- Updated 30.2.5 DVSTCTR0 : Device State Control Register 0.
- Updated 30.2.8 CFIFOSEL : CFIFO Port Selection Register.
- Updated 30.2.9 DnFIFOSEL : DnFIFO Port Selection Register (n = 0, 1).
- Updated 30.2.30 DCP_CFG : DCP Configuration Register.
- Updated 30.2.31 DCP_MAXP : DCP Maximum Packet Size Register.
- Updated 30.2.33 PIPESEL : Pipe Window Select Register.
- Updated 30.2.34 PIPE_CFG : Pipe Configuration Register.
- Updated 30.2.36 PIPE_MAXP : Pipe Maximum Packet Size Register.
- Updated 30.2.37 PIPE_PERI : Pipe Cycle Control Register.
- Updated 30.2.38 PIPE_nCTR : Pipe n Control Register (n = 1 to 9).
- Updated 30.2.42 LPCTRL : Low Power Control Register.
- Updated 30.3.8.5 Allocating the FIFO buffer.
- Updated Figure 30.27 Example OTG connection in a self-powered system.

32. I²C Bus Interface:

- Updated 32.3.6 Slave Receive Operation.

33. I³C Bus Interface:

- Updated 33.2.1 PRTS : Protocol Selection Register.
- Updated Figure 33.140 Example of I²C initialization flowchart (single buffer transfer).
- Updated Figure 33.141 Example of each initialization flowchart for I³C master mode and slave mode.
- Added 33.7.4 Notes on Rewriting PRTS.PRTMD Bit.

34. CAN-FD:

- Updated Table 34.1 CANFD module specifications.
- Updated Table 34.2 Clock restriction.

36. Serial Peripheral Interface:

- Updated 36.3.12.1 Master mode operation.
- Updated Figure 36.69 Transmission flow in slave mode.

Revision 1.30 — December 19, 2025**37. Octal Serial Peripheral Interface:**

- Updated Table 37.1 OSPI specifications.
- Updated 37.2.1.3 BMCFGCH0 : OSPI Bridge Map Configuration Register ch0.
- Updated 37.2.2.3 CMCTLCH0 : OSPI Command Map Control register ch0.
- Updated Figure 37.12 Write access for memory area.
- Updated Figure 37.16 Read access for memory area.
- Updated Figure 37.18 Read access for memory area with prefetch enabled.
- Updated Table 37.8 Error list (n = 0, 1).
- Updated 37.4.1 Constraint on Memory Access.

38. Decryption On The Fly:

- Updated 38.3.2 CONVAREAD : DOTF Conversion Area End Address Register.

41. Cyclic Redundancy Check:

- Updated 41.2.4 CRCDOR/CRCDOR_HA/CRCDOR_BY : CRC Data Output Register.

43. Security Features:

- Updated 43.3.3.6 Peripheral Security Attribution of TrustZone filter.
- Updated Table 43.4 Access permission of type1 peripherals.
- Updated Table 43.6 Lifecycle state definition and capabilities in each state.
- Updated 43.4.1 Changing the Lifecycle State.
- Updated 43.6 Secure Factory Programming.
- Updated Figure 43.14 Format and location of the measurement report.

45. 12-Bit A/D Converter:

- Updated Table 45.4 ADC12 I/O pins (unit 1).
- Updated 45.3.3.6 Channel Selection and Self-Diagnosis (With Channel-Dedicated Sample-and- Hold Circuits and Continuous Sampling Enabled).
- Updated Table 45.28 Conversion times during scanning (in numbers of cycles of ADCLK and PCLKA).

46. 12-Bit D/A Converter:

- Updated Table 46.2 DAC12 I/O pins.
- Updated 46.2.2 DACR : D/A Control Register.

52. Flash Memory:

- Updated Table 52.11 Flash Cache 2 (FCACHE2) overview.
- Updated Figure 52.27 Usage of the Refresh Counter Command.

55. Electrical Characteristics:

- Updated Table 55.6 I/O I_{OH} , I_{OL} .
- Updated Table 55.56 SD/MMC Host Interface signal timing.
- Updated Figure 55.109 Test circuit in low-speed mode.
- Updated Figure 55.111 Test circuit in full-speed mode.
- Added Table 55.71 A/D input voltage range for each input channel.
- Updated Table 55.75 Battery backup function characteristics.

Appendix 4. Note for Register R/W:

- Updated Table A4.1 Type of Register Notes(S-TYPE).
- Updated Table A4.2 Type of Register Notes(P-TYPE).

Appendix 5. Peripheral Variant:

- Updated Table A5.1 Module name vs Peripheral Variant.

Revision 1.40 — July 24, 2026**Features:**

- Updated Operating Junction Temperature and Packages.

1. Overview:

- Updated 1.3 Part Numbering.
- Updated Table 1.14 Function Comparison.
- Added Figure 1.4 Pin assignment for BGA 169-pin.
- Updated Table 1.16 Pin list.

8. Clock Generation Circuit:

- Updated Figure 8.14 Additional flow of system clock setting when PLL is used for the system clock source and CPUCLK to be faster frequency and Figure 8.15 Additional flow of system clock setting when PLL is used for the system clock source and CPUCLK to be slower frequency.

10. Low Power Modes:

- Updated Table 10.2 Operating state of processor low power mode.

13. Interrupt Controller Unit:

- Updated 13.2.14 IELSRn : ICU Event Link Setting Register n (n = 0 to 95).

Revision 1.40 — July 24, 2026**14. Buses:**

- Updated Table 14.10 Bus priorities with round-robin arbitration (ARBS = 1).

17. Data Transfer Controller:

- Updated 17.2.3 MRB : DTC Mode Register B.

18. Event Link Controller (ELC):

- Updated Table 18.3 Association between event signal names set in .ELS[8:0] bits and signal numbers.

19. I/O Ports:

- Updated Table 19.1 I/O port specifications.
- Updated 19.6 Peripheral Select Settings for Each Product.
- Updated Table 19.10 Register settings for input/output pin function (PORT4).

21. General PWM Timer (GPT):

- Updated 21.2.7 GTCSR : General PWM Timer Clear Source Select Register.
- Updated 21.2.9 GTDNSR : General PWM Timer Down Count Source Select Register.

24. Realtime Clock:

- Updated 24.2.27 RTCCRN : Time Capture Control Register n (n = 0 to 2).

25. Watchdog Timer:

- Updated 25.2.3 WDTSR : WDT Status Register.

26. Independent Watchdog Timer:

- Updated Table 26.1 IWDTC specifications.
- Updated 26.2.2 IWDTCR : IWDTC Control Register and 26.2.3 IWDTSR : IWDTC Status Register.
- Updated Figure 26.3 Operation example in register start mode.
- Updated 26.3.3 Refresh operation.
- Added 26.5 Usage Notes.

27. Ethernet MAC Controller:

- Updated 27.2.14 BCRR : Broadcast Frame Receive Count Setting Register.

29. USB 2.0 Full-Speed Module:

- Updated 29.2.36 PIPEnCTR : PIPEn Control Registers (n = 6 to 9).

31. Serial Communications Interface:

- Updated Figure 31.107 Example of Start Frame Reception Flowchart.
- Updated 31.12.2 Interrupts in Asynchronous, Manchester, Clock Synchronous, and Simple SPI Modes.

34. CAN-FD:

- Updated 34.2.43 CFDTMIEC : TX Message Buffer Interrupt Enable Configuration Register.
- Updated 34.2.61.2 CFDRMBPb[0] : RX Message Buffer Component b (b = 0 to 15).

36. Serial Peripheral Interface:

- Updated Table 36.3 Usage of SSL delay control between transfer frames (Master mode).
- Updated Figure 36.66 Software Processing Flowchart in Master Mode (Reception-only).
- Updated Figure 36.76 Example of initialization flow in master mode for clock synchronous operation.

38. Decryption On The Fly:

- Updated 38.3.1 CONVAREAST : DOTF Conversion Area Start Address Register.

39. Serial Sound Interface Enhanced:

- Updated Table 39.4 SSIE I/O pins.
- Updated 39.7.3 SSIE0_SSIRXI Interrupt [Full-duplex communication].

43. Security Features:

- Updated Table 43.8 Keys that can be injected.
- Added 43.10.2 Note on Security and Privilege Attribute Bit Setting

45. 12-Bit A/D Converter:

- Updated Table 45.1 ADC12 specifications.
- Updated 45.2.24 ADCMPCR : A/D Compare Function Control Register.

48. High-Speed Analog Comparator:

- Updated Figure 48.1 ACMPHS block diagram.
- Updated Table 48.3 Procedure for setting registers associated with ACMPHSn (n = 0, 1).

52. Flash Memory:

- Updated 52.4.4 FSAR : Flash Security Attribution Register.
- Updated 52.4.21 FSUINTR : Flash Sequencer Setup Initialization Register.
- Updated 52.12.5 Anti-Rollback Counter.

Revision 1.40 — July 24, 2026**55. Electrical Characteristics:**

- Updated Table 55.26 Thermal Resistance.
- Updated Table 55.29 Operation frequency value in high-speed mode.
- Updated Table 55.55 SSIE timing.

Appendix 2. Package Dimensions:

- Added Figure A2.5 BGA 169-pin.
